**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

Pernicious anemia (PA) is a macrocytic anemia that is caused by vitamin B<sub>12</sub> deficiency, as a result of intrinsic factor deficiency. PA is associated with atrophic body gastritis (ABG), whose diagnosis is based on histological confirmation of gastric body atrophy. Serological markers that suggest oxyntic mucosa damage are increased fasting gastrin and decreased pepsinogen I. Without performing Schilling's test, intrinsic factor deficiency may not be proven, and intrinsic factor and parietal cell antibodies are useful surrogate markers of PA, with 73% sensitivity and 100% specificity. PA is mainly considered a disease of the elderly, but younger patients represent about 15% of patients. PA patients may seek medical advice due to symptoms related to anemia, such as weakness and asthenia. Less commonly, the disease is suspected to be caused by dyspepsia. PA is frequently associated with autoimmune thyroid disease (40%) and other autoimmune disorders, such as diabetes mellitus (10%), as part of the autoimmune polyendocrine syndrome. PA is the end-stage of ABG. Long-standing *Helicobacter pylori* infection probably plays a role in many patients with PA, in whom the active infectious process has been gradually replaced by an autoimmune disease that terminates in a burned-out infection and the irreversible destruction of the gastric

body mucosa. Human leucocyte antigen-DR genotypes suggest a role for genetic susceptibility in PA. PA patients should be managed by cobalamin replacement treatment and monitoring for onset of iron deficiency. Moreover, they should be advised about possible gastrointestinal long-term consequences, such as gastric cancer and carcinoids.

### INTRODUCTION

Pernicious anemia (PA) (also known as Biermer's disease<sup>[1]</sup> and Addisonian anemia<sup>[2]</sup>) is a macrocytic anemia due to vitamin B<sub>12</sub> (cobalamin) deficiency, which, in turn, is the result of deficiency of intrinsic factor, a protein that binds avidly to dietary vitamin B<sub>12</sub> and promotes its transport to the terminal ileum for absorption<sup>[3]</sup>. The deficiency of intrinsic factor is a consequence of the presence of atrophic body gastritis (ABG), which results in the destruction of the oxyntic mucosa, and thus, the loss of parietal cells, which normally produce chlorhydric acid as well as intrinsic factor<sup>[4]</sup>. The term PA is sometimes used as synonym for cobalamin deficiency or for macrocytic anemia, but to avoid ambiguity, PA should be reserved for conditions that result from impaired secretion of intrinsic factor and atrophy of oxyntic mucosa<sup>[5]</sup>. However, differential diagnosis may sometimes be challenging due to the limit of available diagnostic tools.

PA is considered an autoimmune disorder due to the frequent presence of gastric autoantibodies directed against intrinsic factor, as well as against parietal cells. PA is often considered a synonym of autoimmune

gastritis, because PA is thought to be the end stage of an autoimmune process that results in severe damage of the oxyntic gastric mucosa<sup>[6]</sup>. Recent experimental and clinical data strongly suggest an involvement of long-standing *Helicobacter pylori* (*H pylori*) infection in the pathogenesis of ABG and PA, but it is still under debate whether PA may be included among the long-term consequences of *H pylori* gastritis<sup>[7]</sup>.

The present review focuses on novel aspects regarding the pathogenesis, clinical presentation, and diagnosis of PA, as well as the management of PA patients from a gastroenterological point of view.

## PA: AN AUTOIMMUNE DISORDER OR AN INFECTIOUS DISEASE?

PA is the end-stage of ABG and is generally considered an autoimmune disease. The autoimmune origin of PA is based on the presence of parietal cell and/or intrinsic factor autoantibodies, and the frequent association with other autoimmune disorders, such as autoimmune thyroid disease (ATD), type 1 diabetes, and vitiligo<sup>[6,8]</sup>.

ABG associated with PA is often called autoimmune gastritis or type A gastritis, which is defined as a type of chronic atrophic gastritis restricted to the body mucosa, characterized by a severe, diffuse atrophy of the oxyntic glands and hypochlorhydria, and a normal antral mucosa<sup>[4]</sup>. Another classical histological feature of ABG is the absence of *H pylori* on gastric mucosal biopsies<sup>[4]</sup>. It is now accepted that long-standing *H pylori* infection is able to induce atrophy of the gastric mucosa, and *H pylori* is considered the main causative agent of multifocal atrophic gastritis, in which the antrum is almost invariably involved<sup>[9]</sup>. Thus, ABG is generally considered a separate entity from *H pylori*-related atrophic gastritis, mainly because the prevalence of *H pylori* infection in patients with severe ABG and PA has been found to be low<sup>[10,11]</sup>. However, in the past few years, the question has been raised whether *H pylori* may be implicated in the pathogenesis of ABG, and, as a basic mechanism for the induction of gastric autoimmunity by *H pylori* infection, molecular mimicry has been proposed<sup>[7,12,13]</sup>. Molecular mimicry is defined as the possibility that sequence similarities between foreign and self-peptides are sufficient to result in the cross-activation of autoreactive T or B cells by pathogen-derived peptides. It is a phenomenon associated with some pathogens in which the antigens that evoke an immune response have enough similarity to the body's own proteins to cause an autoimmune reaction, such as in rheumatoid arthritis, mediated by cross-reactive T cells and/or circulating antibodies. In fact, gastric H<sup>+</sup>/K<sup>+</sup>-ATPase has been recognized as the major autoantigen in experimental and human ABG<sup>[14-16]</sup>, and autoreactive gastric CD4<sup>+</sup> T cells that recognize H<sup>+</sup>/K<sup>+</sup>-ATPase and *H pylori* antigens have been recently described in ABG<sup>[17,18]</sup>. Thus, PA and ABG seem to be an example of pathogen-induced, organ-specific autoimmunity, in which genetic susceptibility plays an important role in relation to the loss of immu-

nological tolerance<sup>[18]</sup>. In fact, the immunological basis of molecular mimicry lies in the recognition by T-cell antigen receptors of antigenic peptides bound to human leucocyte antigen (HLA) molecules on the surface of antigen-presenting cells, and inappropriate activation of T cells may occur as a result of the upregulation of HLA molecules in genetically susceptible individuals<sup>[19]</sup>. A specific HLA-DR pattern was suggested in PA patients several years ago<sup>[20]</sup>, and more recently, blocking experiments with anti-DR and anti-DQ antibodies have shown that DR antigen probably represents the HLA restriction element in ABG<sup>[17]</sup>. By using a DNA-based, sequence-specific oligonucleotide technology, we observed in our series of PA patients that the genotypes HLA-DRB1\*03 and DRB1\*04, which are known to be associated with other autoimmune disease (such as type 1 diabetes and ATD)<sup>[21]</sup>, were significantly associated with PA, compared to a control group (unpublished data), which supports the idea that genetic susceptibility for autoimmunity may play a role in PA.

Table 1 shows the literature regarding *H pylori* infection and related gastric histological features in some PA patients<sup>[10,22-24]</sup>. The presence of *H pylori* infection was diagnosed by histology in up to 30% (median 11%), but by serology (IgG) in up to 51% (median 20.5%) of PA patients. It is well known that the diagnosis of *H pylori* infection may be difficult in patients with ABG. *H pylori* may disappear over time due to the hostile gastric microenvironment, and past infection may be demonstrated by serological positivity to *H pylori* in a large majority of patients with ABG or PA<sup>[10,25-27]</sup>. A recent study has reported that seropositivity against *H pylori* antigens may be demonstrated in a very high percentage of patients with ABG by using *ad hoc* immunoblotting<sup>[28]</sup>: in this study 47.8% of ABG patients had PA and all but two of them presented with seropositivity against *H pylori* antigens, including CagA and VacA. As far as regards histological features of the gastric body, in the vast majority of PA patients (> 70%) this disorder is associated with severe body atrophy and the presence of intestinal metaplasia. From data reported in Table 1, another interesting observation emerges: irrespective of the presence of *H pylori* infection, in about half of PA patients, the gastric antrum is involved, and about one-third have antral atrophic gastritis, whose presence is strongly related to *H pylori* infection<sup>[9]</sup>. This observation challenges the widely accepted notion that PA occurs exclusively in association with the classical histological feature of corpus-restricted atrophic gastritis. All these data taken together support the idea that long-standing *H pylori* infection probably plays an important role in many genetically susceptible PA patients. In these patients, the active infectious process has been gradually replaced by an autoimmune process directed by autoreactive gastric CD4<sup>+</sup> T cells that recognize H<sup>+</sup>/K<sup>+</sup>-ATPase and *H pylori* antigens, which ends in a burned-out infection and the irreversible destruction of the gastric body mucosa. The failure to demonstrate *H pylori* infection in some of these individuals does not necessarily argue against the role of the bacterium in

Table 1 *H pylori* infection and related gastric histological features in a series of PA patients *n* (%)

<sup>1</sup>Hispanic, *n* = 20; white, *n* = 3; black, *n* = 5. ND: Not done.

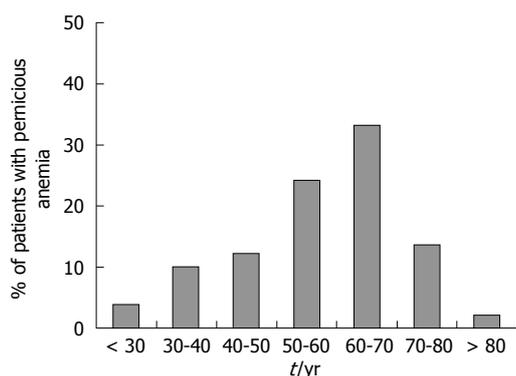

Figure 1 Age cohorts of a series of patients with PA (*n* = 177) consecutively diagnosed between 1992 and 2005 at an academic gastroenterology unit.

these patients, but more likely indicates that a point of no return may be reached beyond which the autoimmune process may no longer require the continued presence of the inducing pathogen<sup>[29]</sup>.

PA is frequently described as a disease of adults > 60 years of age<sup>[8,30,51]</sup>. Among our unpublished series of 177 PA patients, about one half were < 60 years of age; in particular, 4% of patients were < 30 years and 10% were 30-40 years of age (Figure 1). Table 1 shows that the mean age of PA patients in published studies ranges from 59 to 62 years. These data challenge the common notion that PA is an exclusive disease of the elderly, and suggest that, in clinical practice, PA is probably under-diagnosed in elderly and younger patients<sup>[32]</sup>. Stratification by age cohorts (< 20 years to > 60 years) of ABG patients identified by hypergastrinemia and positive parietal cell antibodies has shown a regular and progressive increase in mean corpuscular volume and levels of ferritin and gastrin, and a decrease in vitamin B<sub>12</sub> levels. However, the prevalence of *H pylori* infection has decreased from > 80% at age < 20 years to 12.5% at > 60 years<sup>[32]</sup>. This reminds us that: (1) iron deficiency is a complication of achlorhydria and may precede the development of PA<sup>[4]</sup>; (2) ABG patients frequently present with iron deficiency anemia<sup>[33-35]</sup>; and (3) iron deficiency may be present concomitantly with PA<sup>[36]</sup>. These findings further support the idea that PA seems to be a long-duration disease that is related to *H pylori*, gastric achlorhydria and atrophy, which begins many years before the establishment of clinical vitamin B<sub>12</sub> deficiency.

## CLINICAL PRESENTATION OF PA

The clinical presentation of PA is often insidious for various reasons. The onset and progression of PA are very slow. As a consequence, patients often are not aware of their symptoms related to anemia, because over time they have become used to them. In many such cases, the underlying disease may not be suspected until a complete red blood count has been performed. However, patients with PA may seek medical advice due to non-specific symptoms related to the presence of anemia *per se*, such as weakness, asthenia, decreased mental concentration, headache, and especially, in elderly patients, cardiological symptoms such as palpitations and chest pain<sup>[3,6]</sup>. Less frequently, patients with PA may present only with neurological symptoms, such as paresthesia, unsteady gait, clumsiness, and in some cases, spasticity. Indeed, vitamin B<sub>12</sub> deficiency may cause peripheral neuropathy and lesions in the posterior and lateral columns of the spinal cord (subacute combined degeneration) and in the cerebrum, and these lesions progress from demyelination to axonal degeneration and eventual neuronal death. It is particularly important to recognize these symptoms early, because the neurological lesions may not be reversed after replacement therapy with vitamin B<sub>12</sub><sup>[3,5]</sup>. Finally, the onset of PA may be observed in patients undergoing medical treatment for other autoimmune conditions frequently associated with PA, such as ATD, type 1 diabetes, and vitiligo, as part of the autoimmune polyendocrine syndromes<sup>[37]</sup>.

Although the primary cause of PA is ABG, rarely the disease may result from gastrointestinal tract symptoms. The reason for the apparent paradox may lie in the fact that ABG is associated with hypochlorhydria, and symptoms of the upper gastrointestinal tract are often related to the presence of chlorhydric acid. However, hypochlorhydria itself may cause impaired gastric emptying, which eventually leads to dyspeptic symptoms such as epigastric discomfort, postprandial bloating and fullness, and early satiety<sup>[38]</sup>. In our experience, awareness and concern about upper gastrointestinal or neurological symptoms often are not sufficient to seek medical advice, since patients over time become used to these slowly and insidiously presenting complaints. Only 3% of PA patients presented directly to our gastroenterology unit for long-standing dyspepsia, and only 3% were referred from a neurologist. At the time of diagnosis of

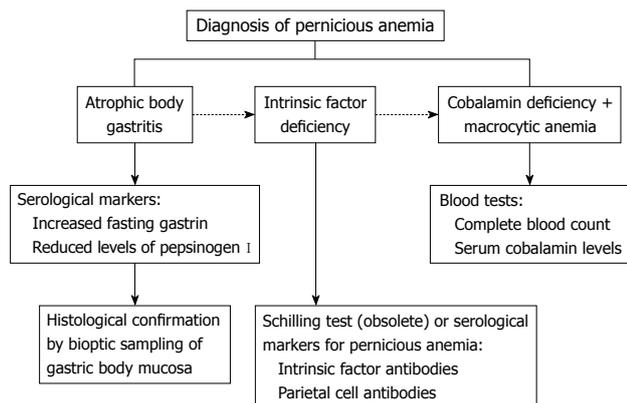

Figure 2 Diagnostic flow-chart for PA.

PA, dyspeptic symptoms were complained of by 28% of patients, and neurological symptoms were present in 19% (unpublished data).

An increased association of PA with other autoimmune diseases, such as type 1 diabetes (3%-4%)<sup>[39]</sup>, vitiligo (2%-8%)<sup>[3]</sup>, and in particular, ATD (3%-32%)<sup>[40]</sup> has been reported. Among our unpublished series of 177 PA patients, 41% had associated ATD and 10% presented with vitiligo or alopecia, which indicates that a subgroup of PA patients can be considered as having a type II autoimmune polyendocrine syndrome. In a recent study, we have observed that ABG and ATD occur in a closely linked fashion, with ATD being present in about 40% of ABG patients<sup>[41]</sup>. These data suggest that, in patients with autoimmune disorders, in particular ATD, a possible association with PA should be suspected and excluded. The diagnosis of concomitant autoimmune thyroiditis and PA may have an important clinical implication, in particular, in those patients who require replacement therapy with thyroxine. Recently, it has been reported that patients with impaired acid secretion may present with thyroxine malabsorption that requires an increased dose of the drug<sup>[42]</sup>, and in patients with PA, associated hypochlorhydria is always present, due to the loss of oxyntic mucosa<sup>[4]</sup>.

Useful information about which patients may have PA can be derived also from epidemiological data. According to the older literature, PA is thought to be particularly common among individuals of Scandinavian, English or Irish ancestry, whereas it appears to be much less common in Caucasians of Italian or Greek origin<sup>[43]</sup>. However, more recently, the disease has been reported in black and Latin American subjects<sup>[30,44]</sup>, and as shown in Table 1, series of PA patients have been diagnosed in the United States, Turkey and Italy, and even in Japan. The reason for the different distribution of PA among different ethnical groups is not known yet, but probably lies in their different genetic background, and in different awareness and diagnostic accuracy for this often overlooked disorder. In the so-called high-risk groups, about nine new cases are detected per 100 000 population per year, and about 0.13% of the population is affected<sup>[31]</sup>. A more recent population survey has reported that 1.9% of persons aged > 60 years have undiagnosed PA<sup>[30]</sup>.

A female preponderance ranging from 1.7 to 2.0:1 has been reported in white subjects<sup>[3]</sup>. This sex distribution has been confirmed in the more recent population survey of persons > 60 years old that was conducted in California, in which the prevalence of PA was 2.7% in women and 1.4% in men<sup>[30]</sup>. However, data reported in Table 1 concerning United States, Japanese, Turkish and Italian PA patients seem not to confirm the female preponderance described in older studies.

## DIAGNOSIS OF PA

PA is defined as the presence of a hemoglobin concentration < 13 g/dL for men and < 12 g/dL for women<sup>[45]</sup>, mean corpuscular volume  $\geq$  100 fL<sup>[5]</sup>, low levels of cobalamin (vitamin B<sub>12</sub>)<sup>[5]</sup>, together with the concomitant presence of ABG and intrinsic factor deficiency (Figure 2). By definition, PA is associated with ABG, and strict diagnostic criteria for ABG are based on the histological confirmation of gastric body mucosal atrophy and enterochromaffin-like (ECL) cell hyperplasia, associated with hypochlorhydria to pentagastrin stimulation<sup>[4]</sup>. Increased levels of fasting gastrin and decreased levels of pepsinogen I are well accepted serological markers<sup>[46,47]</sup>, which suggest the presence of oxyntic mucosa damage, which should be confirmed, however, by appropriate histological sampling of gastric body mucosa to diagnose ABG definitively.

As far as regards gastric mucosa histology, classical findings associated with PA are the presence of corpus-restricted atrophy with a spared antrum, as well as the presence of hyperplasia of ECL cells<sup>[4,6]</sup>. As shown in Table 1, in about 50% of PA patients, antral mucosa is not spared, and in about 27% of PA patients, a concomitant antral atrophic gastritis may be observed. These data strongly suggest that an extension of gastritis to the gastric antrum does not necessarily exclude the diagnosis of PA and the presence of gastric autoimmunity. The determination of ECL cell hyperplasia is helpful in the histological diagnosis of ABG, because the presence of this histological change may be considered an indirect confirmation of the presence of hypochlorhydria. This leads to hypergastrinemia, which in turn, is a trophic factor for ECL cells that leads to their hyperplasia, and eventually, to the development of gastric carcinoids<sup>[48]</sup>.

Intrinsic factor deficiency can be proven by the now obsolete Schilling test. To confirm that the cobalamin deficiency is the result of intestinal malabsorption due to intrinsic factor deficiency, urinary excretion of orally administered vitamin B<sub>12</sub> is low, and is increased by administration of vitamin B<sub>12</sub> and intrinsic factor. Unfortunately, the availability of this test is vanishing due to problems related to its radioactive reagents. Therefore, in clinical practice, the presence of intrinsic factor deficiency may not be proven, and increasing reliance is placed on the detection of intrinsic factor antibodies for the diagnosis of PA, which are viewed as useful markers of this disease<sup>[49]</sup>. Earlier studies have reported positivity for intrinsic factor antibodies in 40%-60% of patients with PA<sup>[50,51]</sup>, which rises to 60%-80% with increasing duration of disease<sup>[52]</sup>.

Table 2 Differential diagnosis of PA: other causes of macrocytic anemia and cobalamin deficiency

Other causes of macrocytic anemia	Other causes of cobalamin deficiency
Folate deficiency due to decreased intake, impaired absorption or increased requirements	Gastric causes of impaired absorption/mal-digestion:
Drugs (e.g. methotrexate, azathioprine, 6-mercaptopurine, acyclovir, 5-fluorouracil, phenobarbital)	Gastrectomy
Accelerated erythropoiesis: hemolytic anemia, response to hemorrhage	Corpus-predominant <i>H pylori</i> gastritis
Liver disease (alcoholic, advanced cirrhosis, poor dietary intake)	Long-term proton pump inhibitor therapy
Hypoplastic anemia, myelodysplastic syndrome	Intestinal causes of impaired absorption:
Chronic obstructive pulmonary disease	Ileal disease or resection
	Blind loop syndrome
	Fish tapeworm
	Severe pancreatic insufficiency
	Decreased intake due to vegetarianism

Recently, we reassessed the diagnostic performance of intrinsic factor and parietal cell antibodies in PA patients by using a novel ELISA<sup>[48]</sup>, which yielded for intrinsic factor antibodies, a sensitivity and specificity of 37% and 100%, respectively, and for parietal cell antibodies, a sensitivity and specificity of 81.5% and 90.3%, respectively. The combined assessment of both autoantibodies significantly increased their diagnostic performance, which yielded 73% sensitivity for PA, while maintaining 100% specificity. Thus, our data show that, by combining the assessment of intrinsic factor and parietal cell autoantibodies, the diagnostic performance of these surrogate markers for PA may be notably improved. Beyond being a specific hallmark of PA, the positivity for intrinsic factor and parietal cell antibodies may be interpreted as an expression of oxyntic mucosal damage, because a positive correlation between the increasing histological score of body mucosa atrophy and the titer of both antibodies can be observed<sup>[27,35]</sup>.

Accurate differential diagnosis of other causes of cobalamin deficiency is mandatory. As shown in Table 2, cobalamin deficiency may result from other causes of impaired absorption in the stomach or intestine, or by decreased intake due to vegetarianism. Among cases of mal-digestion, there are very rare cases related to severe pancreatic insufficiency, but more interesting is the recent evidence of mal-digestion of dietary cobalamin in patients with corpus-predominant *H pylori* gastritis, which leads to impaired acid secretion and consequent increased intragastric pH<sup>[53,54]</sup>. In fact, dietary cobalamin is bound to salivary proteins, which needs to be cleaved in the presence of chlorhydric acid before it can be bound to intrinsic factor and be absorbed in the terminal ileum<sup>[4]</sup>. In these cases of mal-digestion of dietary cobalamin, the Schilling test would be normal, which indicates that cobalamin deficiency is not due to intrinsic factor deficiency. Without performing a Schilling test, it may be challenging to discriminate between the presence of PA and mal-digestion of dietary cobalamin. However, from a practical point of view, the clinical management of these two groups of patients is similar. As observed<sup>[54,55]</sup>, when atrophy of the gastric body mucosa is mild and active *H pylori* infection is present, in patients with mal-digestion of dietary cobalamin, a reversal of body mucosal atrophy, anemia and cobalamin deficiency following eradication treatment may be achieved. An accurate differential diagnosis should be carried out also for macrocytic anemia,

which may underlie other causes such as folate deficiency and myelodysplastic syndrome (Table 2).

In this context, it should be kept in mind that, in order to diagnose vitamin B<sub>12</sub> deficiency, total vitamin B<sub>12</sub> measurement is used cost-effectively as the parameter of choice, but it has limited sensitivity and specificity, especially in persons with vitamin B<sub>12</sub> concentrations in the lower reference range (< 400 pmol/L). As an alternative, modern biomarkers for early diagnosis of vitamin B<sub>12</sub> deficiency, such as holotranscobalamin, also known as active B<sub>12</sub>, and methyl malonic acid as a functional B<sub>12</sub> marker, have been proposed<sup>[56]</sup>. Figure 2 shows a proposed diagnostic work-up when the presence of PA is suspected.

## CLINICAL MANAGEMENT OF PATIENTS WITH PA

The clinical management of patients with PA has two different aspects: firstly, the treatment of cobalamin deficiency and the monitoring of onset of iron deficiency; and secondly, the surveillance of these patients, to detect early the long-term consequences of PA, such as gastric cancer and carcinoids.

### Treatment of cobalamin deficiency and monitoring of iron deficiency

Cobalamin replacement treatment is able to correct the anemia, whereas the neurological complications may be corrected only if the replacement treatment is given soon after their onset. The therapeutic recommendations for PA with regard to dosage and administration of vitamin B<sub>12</sub> substitution treatment are divergent<sup>[57]</sup>. In the United States, patients usually receive vitamin B<sub>12</sub> injections of 1 mg/d in their first week of treatment; in the following month, they receive weekly injections and then monthly injections<sup>[58]</sup>. In Denmark, patients receive injections of 1 mg/wk cyanocobalamin during the first month and every 3 mo subsequently, or 1 mg hydroxycobalamin every other month<sup>[59]</sup>. According to our protocol, a higher dosage of cobalamin is used to prevent early relapse of cobalamin deficiency: firstly patients receive intramuscular injection of 5 mg/d cyanocobalamin for 5 d, which replenishes the cobalamin body stores; then, vitamin B<sub>12</sub> stores are maintained by intramuscular injection of 5 mg cyanocobalamin every 3 mo.

Furthermore, according to our protocol, PA patients are monitored at least yearly by complete blood count, and serum cobalamin and ferritin levels, to monitor the replacement treatment and to detect early the eventual onset of iron deficiency. Also patients with ABG with iron deficiency anemia or without hematological alterations are monitored in the same way, to detect early the eventual onset of cobalamin deficiency. Finally, PA patients are monitored by at least a yearly clinical interview, to verify the onset of new symptoms that are suspicious of long-term consequences of PA, such as dysphagia, epigastric pain, dyspeptic symptoms, loss of body weight, and/or iron-deficiency, which require immediate gastroscopic investigation.

### Long-term consequences of PA

Although PA is substantially a benign disorder for a large number of patients, it is epidemiologically and biologically linked to the development of intestinal-type gastric adenocarcinoma and gastric carcinoid type I<sup>[60,61]</sup>. Hypergastrinemia, secondary to hypochlorhydria in PA patients, is a well-known risk factor for ECL cell hyperplasia and gastric carcinoids<sup>[62,63]</sup>, and it has been reported that one in 25 patients with PA develops gastric carcinoids<sup>[64]</sup>. Moreover, the crucial role of hypochlorhydria, as a consequence of atrophy of the oxyntic mucosa, in the development of gastric cancer, has been highlighted<sup>[65]</sup>. Hypochlorhydria leads to overgrowth of nitrosamine-producing bacteria with potential carcinogen activity<sup>[66]</sup>. Also ascorbic acid, the main redox agent in the gastric juice with protective action against reactive oxygen species, is reduced in the presence of atrophy of the oxyntic mucosa. It has been described previously that the level of ascorbic acid in the gastric juice is reduced in patients with ABG, with an indirect correlation between ascorbic acid level and intragastric pH<sup>[67]</sup>.

In the literature, the annual incidence of gastric cancer in PA patients ranges from 0.1% to 0.5%<sup>[62,64,68]</sup>. A recent follow-up study of patients with ABG has reported an annual incidence risk of 0.14% for developing gastric cancer, during an observation period of 6.7 years<sup>[69]</sup>. To date, the need and cost-effectiveness of endoscopic/histological surveillance in patients with PA have not been established definitively<sup>[4]</sup>. One previous study<sup>[64]</sup> that has considered the relatively benign nature of gastric carcinoids in patients with PA has concluded that follow-up is indicated at 5-year intervals only in patients with ECL hyperplasia. As for gastric cancer, the same authors have concluded that the first gastroscopic follow-up after diagnosis of PA should be performed relatively soon, and that only PA patients with preneoplastic lesions and those with gastrointestinal symptoms should undergo endoscopic surveillance<sup>[64]</sup>. Another study has concluded that follow-up should be performed at 3-year intervals only in PA patients aged < 60 years<sup>[70]</sup>. A more recent study has compared the usefulness of 2- and 4-year follow-up in patients with ABG, and has shown that the first follow-up performed 4 years after the diagnosis seems to be safe and convenient for early detection of potentially neoplastic lesions<sup>[71]</sup>. As a result of the lack

of other prospective data, and considering the risk for developing neoplastic lesions over time in some PA patients, in our unit, PA patients are monitored regularly by gastroscopy with antral and corporal biopsies at 4-year intervals.

## CONCLUSION

PA is an often silent and under-diagnosed autoimmune disease, because its onset and progression are very slow and patients may become used to their complaints. Nevertheless, the clinical consequences of undiagnosed PA may be serious, including gastric neoplastic lesions. Thus, gastroenterologists should increase their awareness of this disorder, whose definite histological diagnosis may be preceded by reliable noninvasive serological screening.

### Abstract

Hepatitis C virus (HCV)-specific CD8<sup>+</sup> T cells play an important role in the resolution of HCV infection. Nevertheless, during chronic hepatitis C these cells lack their effector functions and fail to control the virus. HCV has developed several mechanisms to escape immune control. One of these strategies is the up-regulation of negative co-stimulatory molecules such as programmed death-1 (PD-1). This molecule is up-regulated on intrahepatic and peripheral HCV-specific cytotoxic T cells during acute and chronic phases of the disease, whereas PD-1 expression is low in resolved infection. PD-1 expressing HCV-specific CD8<sup>+</sup> T cells are exhausted with impairment of several effector mechanisms, such as: type-1 cytokine production, expansion ability after antigen encounter and cytotoxic ability. However, PD-1 associated exhaustion can be restored by blocking the interaction between PD-1 and its ligand (PD-L1). After this blockade, HCV-specific

CD8<sup>+</sup> T cells reacquire their functionality. Nevertheless, functional restoration depends on PD-1 expression level. High PD-1-expressing intrahepatic HCV-specific CD8<sup>+</sup> T cells do not restore their effector abilities after PD-1/PD-L1 blockade. The mechanisms by which HCV is able to induce PD-1 up-regulation to escape immune control are unknown. Persistent TCR stimulation by a high level of HCV antigens could favour early PD-1 induction, but the interaction between HCV core protein and gC1q receptor could also participate in this process. The PD-1/PD-L1 pathway modulation could be a therapeutic strategy, in conjunction with the regulation of others co-stimulatory pathways, in order to restore immune response against HCV to succeed in clearing the infection.

### INTRODUCTION

Hepatitis C virus (HCV) is a hepatotropic non-cytopathic positive-strand RNA virus which belongs to the *Flaviviridae* family. HCV infection is a major public problem, affecting more than 200 million people worldwide<sup>[1]</sup>. Only around a quarter of acute HCV infections resolve within a few months, while in the majority of cases the virus establishes a persistent infection, and a significant proportion of cases progress to fibrosis, cirrhosis, liver failure or even hepatocellular carcinoma<sup>[2-4]</sup>. Nowadays standard

anti-HCV therapy resolves about 50% of chronic infections<sup>[5-7]</sup>, therefore new therapeutic strategies should be designed to control this disease. HCV-specific cytotoxic T lymphocytes (CTLs) play a major role in viral control during acute infection<sup>[8]</sup>. Nevertheless, during persistent infection HCV-specific CTL effector functions are significantly impaired, and this situation is a major cause of host inability to eliminate the persistent virus<sup>[9,10]</sup>. Appropriate activation of primed virus-specific CTLs in the infected site depends on the engagement between T cell receptor (TCR) and HLA-I/epitope complex plus interaction among positive co-stimulatory molecules and their ligands<sup>[11,12]</sup>. Virus-specific CTLs, after developing their effector function, express negative co-stimulatory molecules to switch-off their activity. The appropriate virus-specific CTL response development correlates with the adequate balance between positive and negative co-stimulatory signals (Table 1)<sup>[13,14]</sup>. Programmed death-1 (PD-1) is one of the negative co-stimulatory molecules. Engagement of PD-1 and its ligand (PD-L1) delivers a negative signal to the TCR activation pathway, avoiding proliferation, and interleukin (IL)-2 production, which leads to T cell anergy<sup>[15,16]</sup>. Evidence that PD-1 suppresses activation of the immune response comes from studies in which mice deficient in PD-1 developed autoimmune diseases, such as systemic lupus erythematosus, dilated cardiomyopathy, rheumatoid arthritis and type I diabetes mellitus, due to the uncontrolled persistent T cell activation against different epitopes<sup>[17,18]</sup>. The PD-1 induced exhaustion on virus-specific T cells was first described by Barber *et al.*<sup>[19]</sup>, in a murine model of lymphocytic choriomeningitis virus (LCMV) infection. The authors demonstrated that the majority of LCMV-specific CD8<sup>+</sup> T cells were anergic during the chronic phase of infection in association with PD-1 up-regulation. Mice treated with anti-PD-L1 monoclonal antibodies restored the LCMV-specific cytotoxic response and facilitated viral control. These experimental data suggested that the PD-1/PD-L1 pathway could play a major role in the development of persistent infections by non-cytopathic viruses, and different groups started to research the role of this pathway in different chronic viral infections in humans, such as hepatitis B virus (HBV), HCV and human immunodeficiency virus (HIV) infections. Bearing in mind these data, the PD-1/PD-L1 pathway could be an effective escape mechanism and its blockade could be a therapeutic target to reverse T-cell dysfunction. In this editorial, the current state of knowledge about the role of PD-1 expression on specific cytotoxic responses during HCV infection is reviewed.

## STRUCTURE AND EXPRESSION OF PD-1 AND PD-L1

PD-1 is a 55 kDa glycoprotein which belongs to the CD28 immunoglobulin superfamily of transmembrane proteins<sup>[20]</sup>. PD-1 shares a 23% homology with CTLA-4, which is another member of this family, although PD-1 has lost the MYPPPY motif for binding to B7 molecules<sup>[20]</sup>, and the cysteine residue necessary for

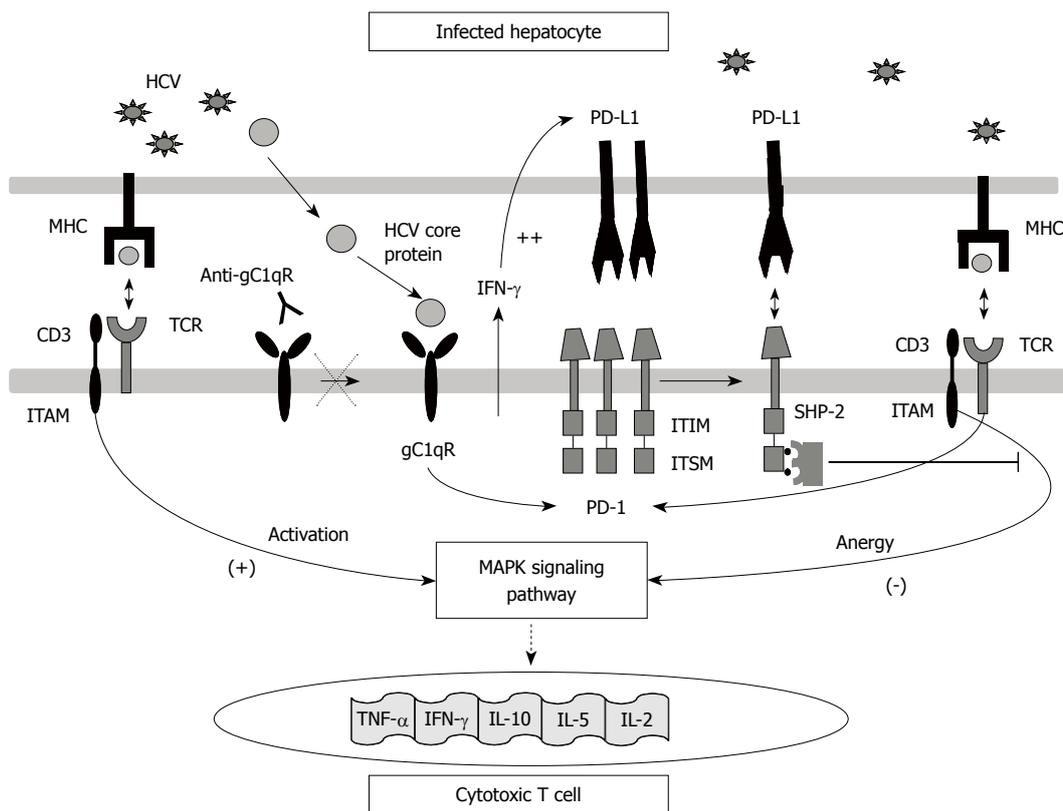

homodimerization<sup>[21]</sup>. PD-1 is expressed on activated T cells, B cells and myeloid cells (Table 1)<sup>[20]</sup>. The PD-1 structure consists of two regions; the extracellular region is formed by a single IgV-like domain and its cytoplasmic region contains an immunoreceptor tyrosine-based inhibitory motif (ITIM) and an immunoreceptor tyrosine-based switch motif (ITSM)<sup>[22,23]</sup>. Following antigen stimulation, PD-1 recruits the protein tyrosine phosphatase src homology 2 domain-containing tyrosine phosphatase 2 (SHP-2) to ITSM but not to the ITIM motif, and subsequently, SHP-2 dephosphorylates effector molecules downstream of the TCR-induced nuclear regulatory pathway<sup>[24,25]</sup>. The direct result of PD-1 mediated inhibition of T cell proliferation is cell cycle arrest in G0/G1 and the inhibition of IL-2 production<sup>[15,16]</sup> (Figure 1). The ligands for PD-1 (PD-L1 and PD-L2) are type I transmembrane proteins with IgV and IgC-like domains in the extracellular region<sup>[26,27]</sup>. PD-L1 is expressed on resting and activated B and T cells, and on non-lymphoid cells such as pancreas, placenta and heart, while PD-L2 is induced on dendritic cells (DC) and macrophages<sup>[26-30]</sup> (Table 1). Interestingly, PD-L1 can be up-regulated on hepatocytes by  $\alpha$ -interferon (IFN) and  $\gamma$ -IFN, and also by activated lymphocytes, and by direct viral infection (perhaps also through IFN pathways)<sup>[31-33]</sup>. PD-1 plays an important physiological role in regulating the cellular immune response, tuning-down the cellular effector functions after T cells have developed their tasks. This physiological function of PD-1 can be damaged by persistent viruses inducing a tolerogenic-like status on specific T cells to avoid immune viral control.

## PD-1 EXPRESSION IN THE LIVER

The liver is characterised by being an immunotolerant organ prepared to deal with intense contact with antigens from the gut, and PD-1/PD-L1 is expressed in resident and infiltrating liver cells to carry out this task<sup>[34]</sup>. The liver is also the primary site for HCV replication and disease pathogenesis<sup>[35]</sup>, and HCV can take advantage of the PD-1/PD-L1 pathway to impair the HCV-specific response reaching the infected liver in order to escape immune control. The liver is exposed to antigens and microbiologically-derived molecules which cause a unique microenvironment that requires liver immunological properties to induce tolerance rather than immunity<sup>[36-38]</sup>. Hepatic tolerance contributes to the common ineffectiveness of immune response against HCV which often results in chronic viral persistence<sup>[39]</sup>. When naive T cells reach the liver from the bloodstream they are activated by resident antigen presenting cells and are prone to become anergic, and this process could take part in the interaction between PD-1 and PD-L1 (Figure 2)<sup>[34,40]</sup>. On the other hand, primed effector HCV-specific T cells, reaching the infected liver, are also conducted through energy by several mechanisms. One of them is PD-1 up-regulation on T cells in the liver<sup>[41,42]</sup>, and the expression of its ligand on resident liver cells, such as hepatocytes, Kupffer cells and sinusoidal endothelial cells (Figure 2)<sup>[31]</sup>. Usually, PD-L1 is constitutively expressed in non-lymphoid tissues such as heart,

Table 1 Summary of CD28 family co-stimulatory and co-inhibitory pathways

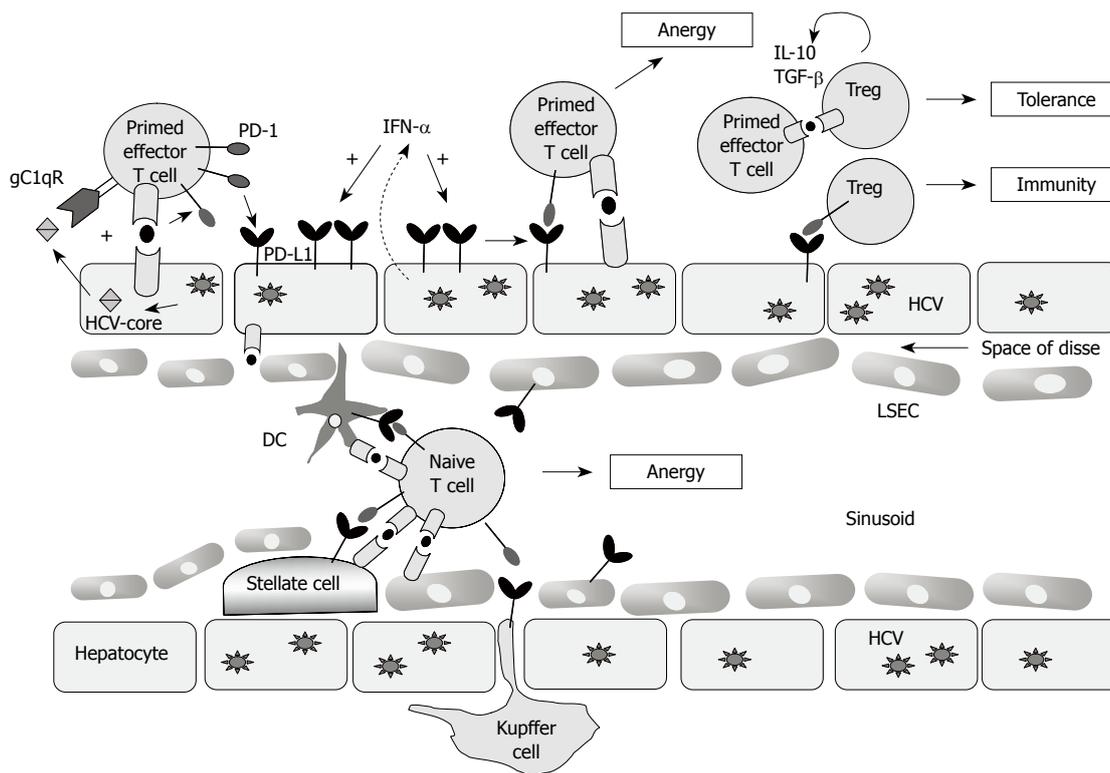

Receptor	Expression	Ligand	Ligand expression	T cell response regulation
CD28	T cells (naive and some memory)	CD80	B, T and DC, macrophages	Positive
PD-1	Activate T cells, B cells, macrophages	PD-L1	B, T and DC, macrophages, non-lymphoid cells	Negative
		PD-L2	(pancreas, placenta, heart)	
CTLA-4	Activate T cells and regulatory T cells	CD80	B, T and DC, macrophages	Negative
		CD86		
BTLA	B and T cells	PD-L2	Macrophages, DC	Negative
		B7-H3	T and B cells, NK	
		B7-H4		
ICOS	T cells (memory and effector)	ICOS-L	B, T cells, macrophages and DC	Positive

**Figure 1 Programmed death-1 (PD-1) structure and interactions.** Interaction between the PD-1 molecule expressed on T cells and its ligand PD-L1 expressed on antigen-presenting cells leads to immunoreceptor tyrosine-based switch motif (ITSM) motif phosphorylation in its cytoplasmic tyrosines which are recognized by src homology 2 domain-containing tyrosine phosphatase 2 (SHP-2). All of these interactions cause T cell anergy due to T cell receptor (TCR)-dependent MAP Kinase-pathway signalling inhibition which avoids interleukin (IL)-2 gene transduction. PD-1 expression is induced by TCR activation but could also be favoured by HCV-core protein through interaction with gC1qR. PD-L1 is up-regulated on antigen presenting cells by the effect of  $\gamma$ -interferon produced during HCV infection by activated lymphocytes.

lung, placenta, kidney, and liver<sup>[43-45]</sup>, but during chronic HCV infection, this molecule is up-regulated on parenchymal liver cells, as previously commented (Figure 3A). The regulation of HCV-specific effector CTLs is also controlled by intrahepatic CD4+CD25+FoxP3+ cells (regulatory T cells, Treg). These cells have an important role in maintaining the balance between tolerance and immunity in HCV infection<sup>[46-48]</sup>. The PD-1/PD-L1 pathway is also important in modulating the regulatory activity of these Treg cells. The PD-1/PD-L1 interaction on intrahepatic Treg suppresses their regulatory activity, favouring CTL response<sup>[49-51]</sup>. Nevertheless, when it is necessary to down-modulate HCV-specific CTL response in order to avoid liver damage, PD-1/PD-L1 engagement is not pro-

duced between Tregs and intrahepatic PD-L1 expressing cells, due to PD-L1 down-regulation on resident liver cells, allowing Tregs to down-modulate HCV-specific CTLs effector functions (Figure 2)<sup>[52]</sup>. The important role of PD-1 in liver pathogenesis during HCV chronic infection is evident, as it is shown by the high PD-1 expression on total intrahepatic T cells<sup>[53-56]</sup>, indicating that some non-specific HCV-dependent stimulus is acting in liver infiltrating T cells to favour PD-1 up-regulation. Previous reports suggest that this factor could be HCV-core protein and this will be discussed later. In addition to this non-specific stimulation on T cells, PD-1 expression is also induced by persistent specific TCR stimulation. PD-1 expression is higher on intrahepatic than in peripheral HCV-specific

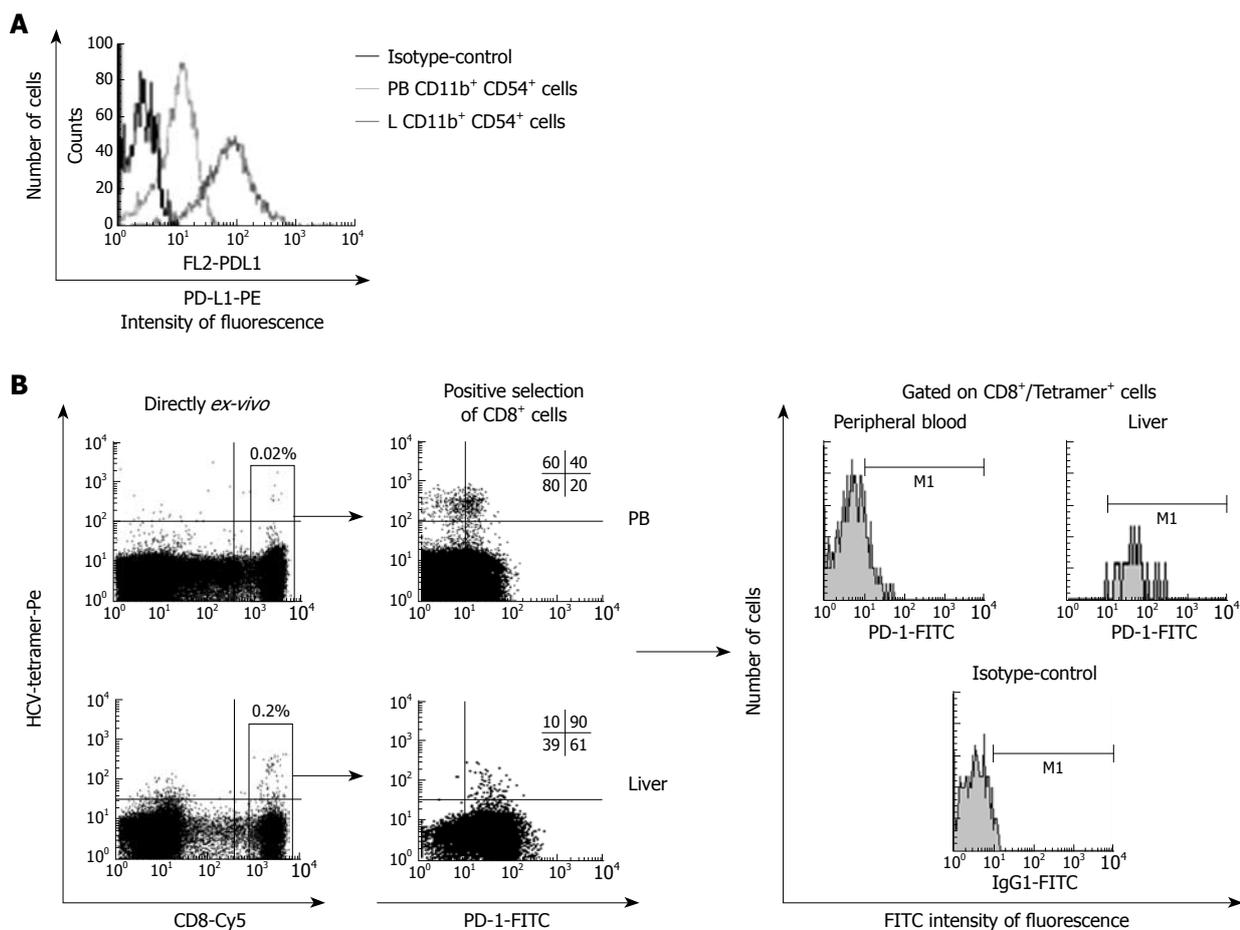

**Figure 2 Liver microenvironment.** Circulating HCV-specific CD8<sup>+</sup> T cells migrating through the hepatic sinusoid interact with resident liver cells [Kupffer cells, dendritic cells (DC), hepatocytes, liver sinusoidal endothelial cells (LSECs), stellate cells] that could act as antigen presenting cells. These cells up-regulate PD-L1 expression during persistent HCV infection and interact with the PD-1 molecule expressed on HCV-specific CD8<sup>+</sup> T cells. This interaction leads to T cell anergy. PD-1 up-regulation is produced by TCR stimulation in addition to the interaction between HCV-core protein and the complement receptor (gC1qR). In this micro-environment the regulatory T cells (Treg) also participate, whose activity is also regulated by the PD-1/PD-L1 pathway.

CD8<sup>+</sup> cells<sup>[41]</sup> (Figure 3B). These data suggest that the intense TCR activation produced in the liver in conjunction with the high level of HCV-core protein leads to the highest PD-1 up-regulation on HCV-specific CD8<sup>+</sup> cells. This high PD-1 up-regulation on intrahepatic specific CD8<sup>+</sup> cells is exquisitely HCV specific, so that PD-1 expression on other virus-specific CD8<sup>+</sup> T cells is not up-regulated during chronic HCV infection<sup>[41]</sup>. Therefore, liver environment conditions produce a huge PD-1 up-regulation on HCV-specific CTLs during persistent infection, and this could impair viral control by the cellular immune response through anergy induction<sup>[41]</sup>.

## DIFFERENTIAL PD-1 EXPRESSION IN ACUTE, CHRONIC AND RESOLVED HEPATITIS C VIRUS INFECTION

During the initial phase of acute infection, HCV-specific CD8<sup>+</sup> T cells are dysfunctional irrespective of the final outcome of the disease, and this impairment persists when infection becomes chronic<sup>[10]</sup>. In contrast, effector and memory CD8<sup>+</sup> T cells generated after acute onset are highly functional in cases of resolving infection<sup>[57,58]</sup>. One of the possible mechanisms responsible for impairment of virus-specific CTL response could be the exhaustion of these cells caused by PD-1 up-regulation. The exhaustion of virus-specific CD8<sup>+</sup> T cells has been observed in

different human infections such as HIV, HBV and HCV infections<sup>[56,59-65]</sup>. In HCV infection, during the early period of primo-infection irrespective of the final outcome, PD-1 is up-regulated on all HCV-specific CD8<sup>+</sup> T cells<sup>[53,66]</sup>. However, after the acute stage of the disease PD-1 expression is modulated depending on the progression. Therefore, during self-limited infection HCV-specific CD8<sup>+</sup> cells down-regulate PD-1 expression, and acquire a CD127<sup>+</sup> phenotype which correlates with appropriate effector functions (Figure 4)<sup>[67]</sup>. CD127 is the IL-7 receptor (IL-7R) which plays an essential role in mature lymphocyte survival through a pathway activated by the interaction with IL-7<sup>[67]</sup>. However, in persistent infection HCV-specific CD8<sup>+</sup> cells remain CD127 negative, and maintain high levels of PD-1 expression<sup>[66,68]</sup> (Figure 4). Therefore, PD-1<sup>+</sup> CD127<sup>-</sup> expressing HCV-specific CD8<sup>+</sup> cells during persistent infection are not only anergic, but also prone to apoptosis after antigen encounter due to the absence of CD127 expression. Furthermore, PD-1 up-regulation on peripheral and intrahepatic HCV-specific CD8<sup>+</sup> cells during the acute and chronic phases of infection is correlated with the apoptosis susceptibility of these cells<sup>[55]</sup>. As a result, the majority of high PD-1 expressing HCV-specific CD8<sup>+</sup> cells could follow an apoptotic process<sup>[69]</sup>, indicating that PD-1 is involved in anergy induction but could also be implicated in specific T cell deletion. Probably, both mechanisms are damaged by HCV infection to escape cellular immune response.

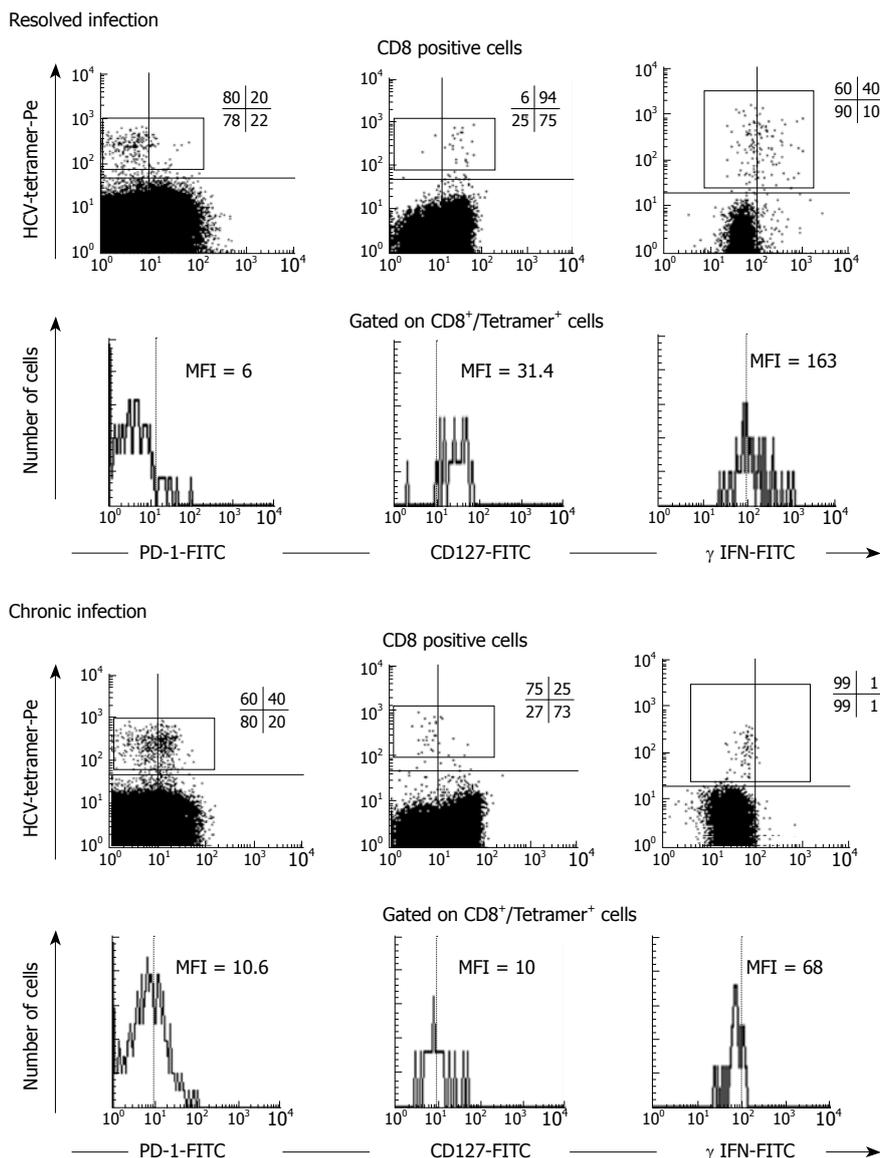

**Figure 3** PD-L1 expression on Kupffer cells and PD-1 expression on HCV-specific CD8<sup>+</sup> T cells. A: PD-L1-FITC FACS<sup>®</sup> histograms gated on CD11b<sup>+</sup> CD54<sup>+</sup> cells from liver (L) and peripheral blood (PB), showing a higher PD-L1 expression on intrahepatic Kupffer cells; B: FACS<sup>®</sup> dot-plots and histograms of peripheral blood and intrahepatic T cells stained with CD8-Cy mAb, HCV-tetramers-PE and PD-1-FITC mAb. Gated Tetramer<sup>+</sup>/CD8<sup>+</sup> cells are presented in the histograms for PD-1-FITC expression. PD-1 is up-regulated on intrahepatic HCV-specific CD8<sup>+</sup> cells.

### CORRELATION BETWEEN PD-1 EXPRESSION AND EFFECTOR FUNCTION IMPAIRMENT ON HCV-SPECIFIC CTLs

Once differential PD-1 expression on HCV-specific CD8<sup>+</sup> T cells between chronic and resolved patients has been described, the next point to address is to analyse whether this difference translates into different quality of HCV-specific CTLs effector functions. Cytotoxic T-cell exhaustion represents a spectrum of effector defects that are correlated with the level of PD-1 expression. Recent reports show that patients with HCV chronic infection, whose CTLs display high PD-1 expression, have impaired CTL capacity to synthesise type-1 cytokines, such as  $\gamma$ -IFN,  $\alpha$ -tumor necrosis factor (TNF) and IL-2, in addition to cytolytic molecules, such as perforin and granzyme B, after direct *ex-vivo* specific *in-vitro* challenge<sup>[41,54]</sup>. One of the variables determining viral control has been suggested to be the ability of virus-specific CD8<sup>+</sup> cells to clonally expand after antigen encounter<sup>[45]</sup>. HCV-specific CD8<sup>+</sup> T cells during persistent infection also displayed impaired proliferation ability after specific stimulation, which correlated with PD-1 expression level<sup>[70,71]</sup>. Because of the role of the

PD-1/PD-L1 pathway in proliferation impairment, subsequent works were aimed at trying to enhance HCV-specific CD8<sup>+</sup> T cell proliferation by modulating this pathway. Blocking the interaction between PD-1 and its ligand increased the proliferation ability of peripheral HCV-specific CD8<sup>+</sup> cells from some chronic HCV patients, characterised by high PD-1 expression, but did not occur in others, suggesting the presence of another anti-proliferative mechanism not yet described<sup>[54,63]</sup>. During HCV-specific CTL exhaustion, not all effector functions are altered at the same time; proliferative potential and IL-2 production are lost at an early phase, whereas cytokine production and cytolytic function are lost later<sup>[72]</sup>. This progressive impairment could be related to the level of PD-1 up-regulation. Interestingly, the exhaustion of CTLs during chronic HCV infection is highly antigen-specific and related to the level of antigenemia, not being present in either CTLs against other specificities or HCV-specific CTLs from patients with resolved infection<sup>[41,66]</sup>. In these two situations PD-1 is not up-regulated on specific CTLs. As commented before, intrahepatic HCV-specific CD8<sup>+</sup> T cells are highly PD-1 positive and they do not expand after antigen encounter and do not produce either  $\gamma$ -IFN or perforin, whereas intrahepatic specific CTLs against other

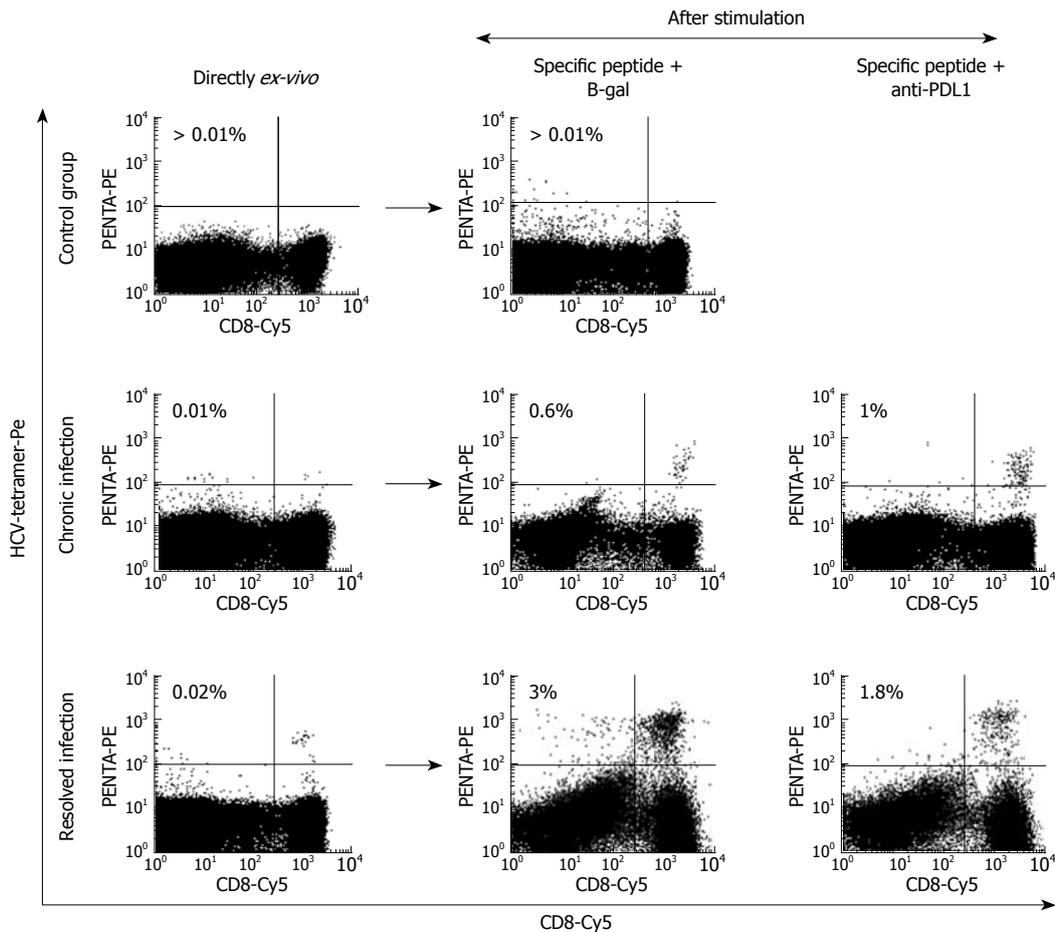

**Figure 4** Direct *ex-vivo* PD-1, CD127 expression and IFN- $\gamma$  production. FACS® dot-plots and histograms of peripheral blood T cells from two representative patients, one with persistent HCV infection and the other with resolved HCV infection. T cells are stained with PD-1-FITC, CD127-FITC,  $\gamma$ -IFN-FITC and CD8-Cy mAbs and HCV-tetramers. In persistent infection, HCV-specific CD8<sup>+</sup> cells maintain a PD-1<sup>+</sup>/CD127<sup>+</sup>/IFN- $\gamma$  phenotype while the resolved infection case displays an opposite phenotype PD-1<sup>-</sup>/CD127<sup>-</sup>/IFN- $\gamma$ <sup>+</sup>.

viruses, such as influenza virus-specific CD8<sup>+</sup> T cells, expand efficiently and present a high level of perforin expression, but interestingly they are PD-1 negative<sup>[41]</sup>. High PD-1 expressing intrahepatic HCV-specific CTLs do not respond to anti-PD-L1 treatment<sup>[41]</sup>. Therefore, when PD-1 expression is extremely up-regulated, treatment with anti-PD-L1 antibodies can not counteract the HCV-specific CTLs exhaustion, induced by the PD-1/PD-L1 pathway.

### HCV-SPECIFIC CTL FUNCTIONAL RESTORATION AFTER PD-1/PD-L1 INTERACTION BLOCKADE

Previous studies developed an LCMV infection animal model, and specific CTL function restoration during persistent infection after treatment with anti-PD-L1 monoclonal antibodies was shown<sup>[19,73]</sup>. This finding could have clinical implications in the treatment of persistent viral infections, as will be discussed later. In HCV infection, the *in-vitro* blockade of the PD-1/

PD-L1 pathway with anti-PDL-1 antibodies increases proliferation capacity after antigen encounter in peripheral PD-1 expressing HCV-specific CTLs from chronic patients (Figure 5). *In-vitro* treatment with anti-PD-L1 antibodies also restored  $\gamma$ -IFN, perforin, CD107a, IL-2 and IL-13 production after antigen specific stimulation<sup>[41,54,74]</sup>. However, this PD-1/PD-L1 pathway blockade is not efficient on intrahepatic HCV-specific CD8<sup>+</sup> T cells, which are characterised by a higher PD-1 expression, as previously discussed. These cells failed to proliferate and produce perforin,  $\gamma$ -IFN and CD107a after specific stimulation in the presence of anti-PD-L1 antibodies<sup>[41]</sup>. All these findings suggest that PD-1 expression level correlates inversely with HCV-specific CD8<sup>+</sup> T cells functional restoration by PD-1/PD-L1 blockade. PD-1/PD-L1 blockade may increase the functionality of peripheral HCV-specific CD8<sup>+</sup> T cells with intermediate PD-1 expression, whereas this blockade did not enhance the effector functions of intrahepatic PD-1<sup>high</sup> expressing HCV-specific CD8<sup>+</sup> T cells. High antigenic stimulation in the liver induces other negative co-stimulatory molecules, such as CTLA-4<sup>[41]</sup>,

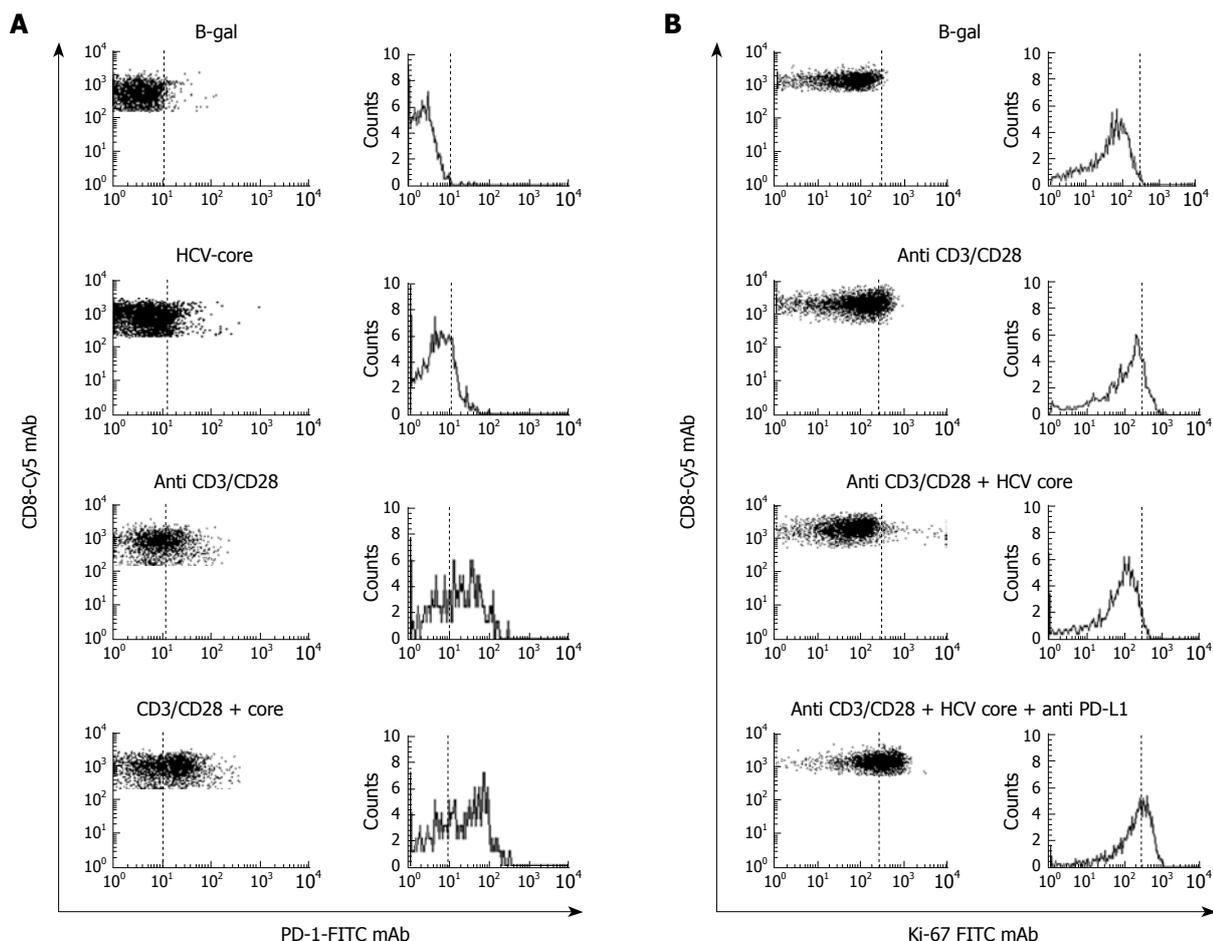

**Figure 5 Proliferation restoration after PD-1 blockade.** FACS® dot-plots of peripheral blood T cells from two representative patients, one with persistent HCV infection and the other with resolved HCV infection, and a control case, after specific stimulation in the presence or absence of anti-PD-L1 mAb. T cells were stimulated for 10 d with the HCV-specific peptide plus IL-2. After stimulation, T cells were stained with CD8-Cy mAbs and HCV-tetramers-PE. PD-1/PD-L1 pathway blockade by anti-PD-L1 antibodies increases the HCV-specific cell proliferation in the chronic patient that had a high level of PD-1 expression.

which could maintain the anergic status, despite blockage of the PD-1/PD-L1 pathway. Therefore, the functional restoration of intrahepatic HCV-specific CTLs could be obtained by the combined blocking of different negative co-stimulatory molecules. In fact, a previous report has shown that combined PD-1 and CTLA-4 blockade induces a restoration of intrahepatic HCV-specific CD8<sup>+</sup> T cell function in chronically HCV infected patients<sup>[75]</sup>. Obviously, the modulation of different co-stimulatory molecules on HCV-specific T cells, such as CD137<sup>[76]</sup>, OX40<sup>[77]</sup> and ICOS<sup>[78]</sup> should be tested in combination with PD-1/PD-L1 blockade in order to restore HCV-specific CTL effector functions<sup>[79,80]</sup>. Nevertheless, blocking the engagement between PD-1 and PD-L1 is not enough in many cases to restore peripheral HCV-specific CTL functionality in chronic patients, even in combination with the blockade of other negative co-stimulatory molecules. It is reasonable to assume that these cells, exposed to high persistent antigenic stimulus, are prone to apoptosis. Previous data on HBV chronic infection showed an up-regulation of the pro-apoptotic molecule Bim on HBV-specific CTLs<sup>[81]</sup>. In this chronic infection, only CD127<sup>+</sup> (IL-7R) cells maintained the ability to expand after antigen encounter. These CD127<sup>+</sup> cells could be protected from apoptosis due

to the antiapoptotic molecule Mcl-1, induced by IL-7. Otherwise, CD127<sup>+</sup> HBV-specific CTLs would die due to apoptosis after antigen encounter, mediated by the Bim pathway. Bearing in mind these data on HBV infection, it is possible that the benefit observed by blocking the PD-1/PD-L1 interaction may occur only in specific T cells protected against apoptosis by CD127 expression. This phenotype is quite rare in patients with long-standing HCV infection, and this could explain why not all PD-1 expressing HCV-specific CTLs respond to anti-PD-L1 treatment. This theoretical scenario should be tested in the near future.

## HCV CORE PROTEIN INDUCES PD-1 UP-REGULATION

The PD-1 up-regulation on intrahepatic total T cells<sup>[53,56]</sup> suggests that something other than TCR stimulation is involved in the PD-1 expression regulation during HCV infection. HCV-core protein binding to the complement receptor gC1q (gC1qR) is responsible for impairing T cell proliferation ability<sup>[82]</sup> through down-regulation of the high affinity IL-2 receptor<sup>[83]</sup>. A recent report suggests that this process could be mediated by PD-1 expression

**Figure 6 PD-1 up-regulation induced by HCV-core protein.** A: FACS® dot-plots and histograms of peripheral blood CD8<sup>+</sup> cells stained with PD-1-FITC and CD8-Cy mAbs from a healthy subject. CD8<sup>+</sup> cells were stimulated with B-galactosidase, HCV-core protein, CD3-CD28 mAb, and HCV-core protein plus CD3-CD28 mAbs. PD-1 expression was highly up-regulated on CD8<sup>+</sup> cells after non-specific stimulation by anti CD3/CD28 mAbs in the presence of HCV core protein; B: FACS® dot-plots and histograms of peripheral blood CD8<sup>+</sup> cells stained with Ki-67 FITC and CD8-Cy mAbs from the same healthy subject to test proliferation ability of CD8<sup>+</sup> cells after incubation with B-galactosidase, CD3-CD28 mAb, HCV-core protein plus CD3-CD28 mAb and HCV-core protein plus CD3-CD28 and anti-PD-L1 mAbs. HCV-core protein decreased the proliferation induced by CD3-CD28 mAb stimulation. This proliferation impairment induced by HCV-core protein was resolved by anti-PD-L1 mAb treatment.

induction<sup>[84]</sup>. In fact, in an intrahepatic HCV-core protein expressing mouse model, liver infiltration by PD-1 expressing cytotoxic T cells unable to clear the virus has been shown. However, the liver from HCV-core non-expressing mice was infiltrated by non-PD-1 expressing specific-CTLs which could control the viral infection<sup>[85]</sup>. These data suggest that HCV-core protein could play a role in early PD-1 induction on T cells, mainly in the liver environment where this protein is richly expressed<sup>[86,87]</sup>. At least *in-vitro*, PD-1 and PD-L1 expression are up-regulated on activated T cells in the presence of HCV-core protein<sup>[84]</sup>. PD-1 up-regulation induced by HCV-core protein translated into impairment of T cell proliferation ability<sup>[84]</sup>. However, this dysfunction could be partially restored by blocking the PD-1/PD-L1 pathway with anti-PD-L1 antibodies (Figures 1 and 6) and by blocking the interaction between HCV-core protein and gC1qR<sup>[84]</sup>. Probably the interaction between HCV-core protein and gC1qR co-operate with the continuous TCR stimulation to produce an early PD-1 up-regulation in order to induce a premature anergy on HCV-specific CTLs as an efficient HCV escape mechanism.

## PD-1/PD-L1 BLOCKADE AS A THERAPUTIC TOOL

As previously commented, a defective virus-specific cytotoxic T cell response is one of the most important causes of host inability to eliminate a persistent viral infection. Several studies have highlighted the role of the PD-1/PD-L1 pathway in the development of anergy on virus-specific CD8<sup>+</sup> T cells, and how PD-1/PD-L1 blockade could enhance virus-specific CD8<sup>+</sup> T cell functionality *in-vitro*<sup>[41,74,88-92]</sup>. Recently, several works have been carried out to analyse whether modulation of the PD-1/PD-L1 pathway could improve T cell response against persistent viral infections either directly, using anti PD-L1 antibodies alone, or in combination with a therapeutic vaccine. Therapeutic vaccine usually fails to induce a vigorous T cell response due to the tolerogenic-like status of HCV-specific T cells<sup>[93,94]</sup>. This scenario could be positive if negative co-stimulatory molecules, such as PD-1, were blocked when the therapeutic vaccine is administered in order to enhance the specific immune response against the supplied epitopes. In the chronic LCMV infection

animal model, the administration of a therapeutic vaccine in combination with PD-1/PD-L1 interaction blockade enhances expansion and improves the function of LC-MV-specific CD8<sup>+</sup> T cells. In addition, this combinatorial therapeutic vaccination accelerates viral control compared with either therapeutic vaccine or PD-1 blockade alone<sup>[95]</sup>. Moreover, the effect of anti-PD-L1 antibodies alone could also be effective in controlling persistent viral infection by restoring specific CTL response. The administration of anti-PD-L1 monoclonal antibodies during simian immunodeficiency virus (SIV) chronic infection in macaques resulted in a rapid expansion and restoration of SIV-specific CD8<sup>+</sup> T cells<sup>[96,97]</sup>. Although these results seem to be quite promising, the blockade of negative costimulatory pathways could lead to the development of autoimmune diseases<sup>[17,18]</sup>, which could prevent the use of this strategy as a therapeutic tool in humans. Therefore, more research is necessary in this field before blockade of the PD-1/PD-L1 pathway is suitable for the treatment of chronic HCV infection.

## CONCLUSION

In summary, the PD-1/PD-L1 pathway displays an important role in the induction of anergy on HCV-specific cytotoxic T cells, and could be important in the development of HCV persistent infection. Blocking the PD-1/PD-L1 interaction, probably in association with the modulation of other co-stimulatory molecules, could be an interesting strategy to restore HCV-specific CTL response in patients unresponsive to standard anti-HCV treatment.

hyperinsulinemia, elevated C-peptide, elevated body mass index, high levels of insulin growth factor-1, low levels of insulin growth factor binding protein-3, high leptin levels and low adiponectin levels are all involved in carcinogenesis. Understanding the pathological mechanism that links metabolic syndrome and its components to carcinogenesis has a major clinical significance and may have profound health benefits on a number of diseases including cancer, which represents a major cause of mortality and morbidity in our societies.

### Abstract

The metabolic syndrome and visceral obesity have an increasing prevalence and incidence in the general population. The actual prevalence of the metabolic syndrome is 24% in US population and between 24.6% and 30.9% in Europe. As demonstrated by many clinical trials (NAHANES III, INTERHART) the metabolic syndrome is associated with an increased risk of both diabetes and cardiovascular disease. In addition to cardiovascular disease, individual components of the metabolic syndrome have been linked to the development of cancer, particularly to colorectal cancer. Colorectal cancer is an important public health problem; in the year 2000 there was an estimated total of 944 717 incident cases of colorectal cancer diagnosed world-wide. This association is sustained by many epidemiological studies. Recent reports suggest that individuals with metabolic syndrome have a higher risk of colon or rectal cancer. Moreover, the clusters of metabolic syndrome components increase the risk of associated cancer. The physiopathological mechanism that links metabolic syndrome and colorectal cancer is mostly related to abdominal obesity and insulin resistance. Population and experimental studies demonstrated that

### INTRODUCTION

The concept of metabolic syndrome has existed for at least 80 years and was first described by Kylin<sup>[1]</sup>, a Swedish physician, as a clustering of hypertension, hyperglycemia and gout, and later on by Vague<sup>[2]</sup> who added to the previous description the presence of abdominal obesity.

While the concept of metabolic syndrome has been accepted for a long time, there was no largely recognized international definition until 1998.

The first proposal came in 1998 from a consultation group for the definition of diabetes for World Health Organisation. This definition was then modified by the European Group for Study of Insulin Resistance in 1999, the National Cholesterol Education Program Adult Treatment Panel III (ATP III) in 2001 and revised in 2005, and the International Diabetes Foundation (IDF) in 2005. These definitions agree on the different components of metabolic syndrome but differ in details (Table 1)<sup>[3]</sup>.

More recently, the use of the term of “metabolic syndrome” has been questioned by the American

Diabetes Association and the European Association for the Study of Diabetes for several reasons: (1) Criteria are ambiguous or incomplete (for example it is unclear if the blood pressure definition is systolic blood pressure  $\geq 130$  mmHg and diastolic  $\geq 85$  mmHg or whether it is either  $\geq 130$  mmHg or  $> 85$  mmHg); (2) The value of including diabetes in the definition is questionable and the role of insulin resistance as unifying etiology is uncertain. Furthermore it is still unclear the extent to which an elevated cardiovascular (CVD) risk is due to insulin resistance itself *vs* isolated hyperinsulinemia; (3) There is no clear basis for including/excluding other CVD risk factors; the CVD risk associated with the syndrome appears to be no greater than the sum of its parts; (4) The treatment of the syndrome is not different from the treatment for each of its components.

A recent review of the ATP III definition broadened the etiological basis of the syndrome from insulin resistance alone to include "obesity and disorders of adipose tissue"<sup>[4]</sup>.

The actual prevalence of obesity is 30.5% and that of associated metabolic syndrome is 24% in the US population<sup>[3,5]</sup>.

In Europe, the age- and sex-adjusted prevalence of metabolic syndrome was 24.6% using the 2005 ATP III definition and 30.9% using the International Diabetes Federation definition, according to the MADRIC study (MADrid Rlsego Cardiovascular Study) performed on 1344 participants<sup>[6]</sup>. In this study, the authors found a good overall agreement between the ATP III and IDF definitions, much closer in women than in men ( $\kappa = 0.92 \pm 0.07$  *vs*  $\kappa = 0.66 \pm 0.06$ ). The prevalence of metabolic syndrome was greater according to the IDF definition than according to ATP III, because the former definition has a lower threshold of abdominal obesity.

A cross-sectional analysis of 10206 participants aged 20-89 years in the Nord-Trøndelag Health Study 1995-97 (HUNT 2) in Norway, found a prevalence of IDF-defined metabolic syndrome of 29.6%, compared to 25.9% using the 2005 ATP III criteria<sup>[7]</sup>.

In a meta-analysis, Cameron *et al*<sup>[8]</sup> found a variable prevalence of metabolic syndrome in urban populations from 8% (India) to 24% (USA) in men, and from 7% (France) to 43% (Iran) in women.

It is well known that the metabolic syndrome is associated with an increased risk of both diabetes and cardiovascular disease.

Many clinical studies outlined the interrelation between the metabolic syndrome and cardiovascular risk<sup>[9]</sup>.

Applying the ATP III criteria to 10537 NHANES III participants resulted in a significant association between the metabolic syndrome with prevalent myocardial infarction and stroke in a multivariate analysis: myocardial infarction [OR: 2.01, 95% confidence intervals (CI): 1.53-2.64], stroke (OR: 2.16, 95% CI: 1.48-3.16), and myocardial infarction/stroke (OR: 2.05, 95% CI: 1.64-2.57)<sup>[10]</sup>.

The INTERHART study performed on 15152 cases and 14820 controls in nearly 52 countries found a significant association between abnormal lipids, smoking,

hypertension, diabetes, abdominal obesity, psychosocial factors, consumption of fruits, vegetables, and alcohol, and regular physical activity and the risk of myocardial infarction. Collectively, these nine risk factors accounted for 90% of the population risks in men and 94% in women<sup>[11]</sup>.

In addition to CVD, individual components of the metabolic syndrome have been linked to the development of cancer<sup>[12]</sup>.

Colorectal cancer is an important health problem since one million new cases are diagnosed world-wide each year with half million related deaths<sup>[13]</sup>. The incidence rate of colon cancer according to Five Continents cancer registries varies from 3% in Africa (Algeria) up to 40% in North America. In Europe the incidence of colon cancer ranges from 12.1% in Belarus up to 30.5% in Italy<sup>[14]</sup>.

There is evidence that body composition and hormonal factors contribute to colorectal cancer etiology. In this paper we will highlight this association supported by epidemiological data and pathophysiological mechanisms arising from prospective human research studies.

## EPIDEMIOLOGY

In an analysis of nearly 58000 individuals who participated in the National Health Interview Survey (2002-2003), Garow *et al*<sup>[15]</sup> identified 1200 individuals with metabolic syndrome, 350 of them being diagnosed with colorectal cancer. After controlling for age, race, gender, obesity, smoking and alcohol use the individuals with metabolic syndrome had a 75% increased risk for colon or rectal cancer.

In a large prospective study of more than 900000 US adults (404576 men and 495477 women) conducted by Calle *et al*<sup>[16]</sup>, there were 57145 deaths from cancer during a follow up period of 16 years. The authors also studied the relationship between the relative risk (RR) of death and body mass index (BMI). For all cancer there was a trend in increasing death rate with BMI. For colorectal cancer the RR of death varied from 1.34 (95% CI: 0.94-1.34) for a BMI of 25-29.9, to 1.90 (95% CI: 1.46-2.47) and 4.52 (95% CI: 2.94-6.94) for an BMI between 30.0-34.9 and 35.0-39.9, respectively<sup>[16]</sup>.

Recent studies also provide information concerning the association between colorectal cancer incidence and the number of metabolic syndrome components, especially BMI, waist circumference (WC), lipid levels, plasma glucose and glycosylated hemoglobin (HbA1c). In an analysis of 14109 participants from the ARIC study (Atherosclerosis Risk in Communities), 194 incident colorectal cancers were identified. In this study baseline metabolic syndrome ( $> 3$  components *vs* 0 components) had a positive association with age-adjusted and gender-adjusted colorectal cancer incidence (RR: 1.49, 95% CI: 1.0-2.4). There was a dose-response association between colorectal cancer incidence and the number of metabolic syndrome components present at baseline ( $P$  for trend = 0.006) after multivariate adjustment<sup>[17]</sup>.

In another study, Trevisan *et al*<sup>[18]</sup>, used information

Table 1 Comparison of definitions of metabolic syndrome

WHO 1999	ATP III 2001	IDF 2005
Diabetes or impaired fasting glycemia or impaired glucose tolerance or insulin resistance Plus 2 or more of the following: Obesity: BMI > 30 or waist-to-hip ratio > 0.9 (male) or 0.85 (female) Dyslipidemia: triglycerides > 150 mg/dL or HDL cholesterol < 35 mg/dL (male) or < 39 mg/dL (female) Hypertension: blood pressure > 140/90 mmHg Microalbuminuria: albumin excretion > 20 µg/min	Three or more of the following: Central obesity: waist circumference > 102 cm (male), > 88 cm (female) Hypertriglyceridemia: triglycerides > 150 mg/dL Low HDL cholesterol: < 40 mg/dL (male), < 50 mg/dL (female) Hypertension: blood pressure > 130/85 mmHg Fasting plasma glucose > 100 mg/dL	Increased waist circumference > 94 cm in men and > 80 cm in women plus any 2 of the following: Hypertriglyceridemia: triglycerides > 150 mg/dL Low HDL cholesterol: < 40 mg/dL (male), < 50 mg/dL (female) Hypertension: blood pressure > 130/85 mmHg Fasting plasma glucose > 100 mg/dL

from the Risk Factors and Life Expectancy study, which pooled data from nine epidemiological studies conducted in Italy between 1978 and 1987, including 21 311 men and 15 991 women. In this study, low high density lipoprotein (HDL) and high triglyceride levels, hypertension and plasma glucose levels were also analyzed as individual components of the metabolic syndrome. For the presence of the cluster of metabolic abnormalities, the calculated hazard ratios and 95% CIs were 2.99 (1.27-7.01) when both sexes were combined. When analyzing the individual components, only glucose level was associated with an increased risk of death from colorectal cancer, and only in men and women combined (RR: 1.8, 95% CI: 1.05-3.09). The results of this study suggest that the effects of the individual components of metabolic syndrome are additive, because the RR of death from colorectal cancer was increased in cluster analysis compared with glucose alone.

The association between plasma glucose levels reflected by HbA1c and the incidence of colorectal cancer was outlined in a prospective analysis from the European Prospective Investigation into Cancer and Nutrition (EPIC) study<sup>[19]</sup>. Among 9605 participants in this study, aged between 45 and 79 years, there were 67 incident colorectal cancers. In this study population, the RR of colorectal cancer for men and women combined was 2.94 (95% CI: 0.80-10.85), age and sex adjusted for an HbA1c  $\geq 7\%$ , compared with RR, 1.13 (95% CI: 0.56-2.30), for HbA1c of 5.0%-5.9%. For the same HbA1c levels of > 7%, the age adjusted RR was higher in men than in women [RR: 4.94 (95% CI: 0.89-27.35) in men, and 1.58 (95% CI: 0.19-13.14) in women]. The association of higher HbA1c levels and increased colorectal cancer risk was also present in the CLUE II cohort<sup>[20]</sup>.

Conversely, to evaluate the association between metabolic syndrome and colorectal cancer, Stocks *et al*<sup>[21]</sup> evaluated the presence of metabolic syndrome components (C-peptide, HbA1c, leptin, adiponectin, BMI, hypertension and fasting glucose) in 306 individuals with known colorectal cancer. The presence of hypertension, obesity and hyperglycemia, correlated with a RR for three *vs* null factors of 2.57 (95% CI: 1.20-5.52, *P* trend = 0.00021).

The relationship between BMI and colon cancer was also studied in the recent EPIC study<sup>[22]</sup>, which was based on 984 cases of colon cancer. A 55% increased

risk of colon cancer was observed between the high and low quintiles of BMI in men, but no significant association was observed in women.

Some recent studies considered anthropometric measures of adipose distribution in addition to BMI in relation to the risk of colon cancer of adenoma. In most of these studies, the association between WC or waist-to-hip ratio and colon cancer risk was stronger than that between BMI and cancer risk. Moore *et al*<sup>[23]</sup>, in a retrospective analysis of 7566 subjects from the Framingham cohort, found 306 cases of incident colorectal cancer. The authors demonstrated a two-fold increased risk of colorectal cancer for a WC of > 99 cm in women and 101 cm in men; the risk increased linearly with increasing WC<sup>[23]</sup>. One Japanese study<sup>[24]</sup> of 51 consecutive patients aged  $\geq 40$  years, suggests that visceral adipose tissue rather than whole body adipose tissue correlates better with the risk of colorectal adenoma. Furthermore, in this study, low adiponectin level is a factor associated with the development of colorectal adenoma. It is known that adiponectin levels decrease in obesity, especially abdominal obesity in association with insulin resistance; thus, the results of this study offer an insight to understanding the relationship of colorectal carcinogenesis with abdominal obesity and insulin resistance which will be discussed later on this paper.

The fact that the metabolic syndrome is a risk factor for both CVD and colorectal cancer raised the question if there is any association between CVD and colorectal cancer. This correlation was found to be positive in several studies. In a pilot study of 63 patients with colorectal cancer, Hamoudi and Dumitrascu demonstrated a statistical association between CVD and colorectal cancer in men<sup>[25]</sup>.

The relationship between individual components of metabolic syndrome and the risk of colorectal cancer was also separately analyzed by several studies. Colangelo *et al*<sup>[26]</sup> found a 35% increased risk of colorectal cancer associated with high blood pressure. The results were confirmed by another study<sup>[17]</sup>. Both studies also underlined that the clustering of metabolic syndrome components significantly increased the risk of associated colorectal cancer.

High circulating triacylglycerols were associated in a large prospective study with a non-significant two-

fold elevation in risk of colorectal cancer in men, but no clear association was observed in women<sup>[17]</sup>. In another prospective study, there was a 40% increased risk of colorectal cancer for men and women in the top quartile of triacylglycerol levels, although this association was not significant<sup>[27]</sup>.

The association between C-peptide levels as a marker of hyperinsulinemia and colorectal cancer risk was also examined by several studies. In a case control study in the Physicians' Health Study, an increased concentration of plasma C-peptide was statistically significantly associated with an increased risk of colorectal cancer in men (RR for the highest *vs* lowest quintile of plasma C-peptide = 2.7, 95% CI: 1.2-6.2, *P* trend = 0.047), after adjusting for age, smoking status, fasting, BMI and alcohol consumption. The results of this study also suggest that elevated insulin production, as reflected by elevated concentrations of plasma C-peptide, may predict the risk of developing colorectal cancer, independently of BMI, factors related to insulin resistance, or levels of insulin growth factor (IGF)-1 and insulin growth factor binding protein (IGFBP)-3<sup>[28]</sup>. The interrelation between a high concentration of plasma C-peptide and colorectal adenoma was also demonstrated in women in a series of 380 patients with a multivariable relative risk (MVRR) top *vs* bottom quartile, 1.63, 95% CI: 1.01-2.66, *P* = 0.01, even after including BMI and physical activity in the statistical model<sup>[29]</sup>.

The findings of all these studies suggest that the clusters of the metabolic syndrome components may be predictors for developing colorectal cancer and for colorectal cancer mortality. The understanding of the underlying physiopathology that links the metabolic syndrome and cancer may play a key role in developing new strategies for prevention and treatment.

## PHYSIOPATHOLOGICAL LINKS BETWEEN METABOLIC SYNDROME AND COLORECTAL CANCER

### **Obesity, insulin resistance and insulin growth factors and binding proteins**

It has been hypothesized that insulin resistance is the most important underlying mechanism of the metabolic syndrome in close relationship to abdominal obesity. Insulin has been shown to affect growth of normal and neoplastic epithelial cells and to have mitogenic actions *in vitro* and in experimental models, either directly or indirectly through IGF-1<sup>[17]</sup>. At high concentrations, insulin can bind to IGF-1 receptors (IGF1Rs) or can act directly to promote IGF-1 biosynthesis, enhancing IGF-1 bioavailability and inhibiting the production of IGFBP-1, IGFBP-2 and IGFBP-3<sup>[30]</sup>.

IGF-1 is an important mitogen required for the progression through the cell cycle and has autocrine, paracrine and endocrine actions on cell proliferation and apoptosis<sup>[31]</sup>, increasing the risk of cellular transformation by enhancing cell turnover. In addition, IGF-1 increases the production of vascular endothelial growth

factor (VEGF), an angiogenic factor that can support cancer growth<sup>[32]</sup>.

It has been shown that normal colorectal epithelia and colon cancer cells have both insulin and IGF1Rs<sup>[17]</sup>. Tissue homeostasis in the normal colonic crypt relies on a balance between proliferation, differentiation and apoptosis, with apoptosis occurring at the top of the colonic crypt as the culmination of a differentiation pathway.

The link between IGF-1 and IGFBP-3 levels and the increased risk of colorectal adenoma and cancer came first to attention in acromegalic patients, characterized by chronically elevated growth hormone (GH) levels. GH excess leads to hepatic and peripheral insulin resistance and thus to hyperinsulinemia, a common feature of acromegaly and metabolic syndrome, that causes IGF-1 hypersecretion and low IGFBP-3 levels<sup>[33]</sup>.

The relationship between IGF-1 and IGFBP-3 levels and colorectal cancer was examined by Giovannucci *et al*<sup>[34]</sup> on 32826 women from Nurses' Health Study. Controlling for IGFBP-3 level, relative to women in the lowest tertile of IGF-1, those in the highest tertile were at elevated risk of intermediate/late-stage colorectal neoplasia adenoma (MVRR: 2.78, 95% CI: 0.76-9.76) and cancer (RR: 2.18, 95% CI: 0.94-5.08). Controlling for IGF-1 level, relative to women in the lowest tertile of IGFBP-3, women in the highest tertile of IGFBP-3 were at lower risk of intermediate/late-stage colorectal adenoma (RR: 0.28, 95% CI: 0.09-0.85) and cancer (RR: 0.28, 95% CI: 0.10-0.83). Neither IGF-1 nor IGFBP-3 had any appreciable relation with early-stage adenoma. These analyses indicate that high levels of circulating IGF-1 and particularly low levels of IGFBP-3 are associated independently with an elevated risk of large or tubulo-villous/villous colorectal adenoma and cancer. These results are concordant with those obtained previously in Physicians' Health Study<sup>[35]</sup>.

The role of IGFBP-3 in colorectal cancer was independently analyzed by Williams *et al*<sup>[36]</sup>. IGFBP-3 has been shown to enhance p53-dependent apoptosis after DNA damage. Therefore, loss of IGFBP-3 could contribute to the development of colonic adenomas that retain wild-type p53 function through suppression of p53-dependent apoptotic signals, allowing aberrant cell survival and tumor formation. Furthermore there is disruption in both adenoma and carcinoma tissue. This pattern is similar to that of TGF- $\beta$  distribution in normal, adenoma and carcinoma tissue<sup>[37]</sup>. Because it is known that TGF- $\beta$  is a potent growth inhibitor for colonic epithelium<sup>[36]</sup>, this similarity suggests that IGFBP-3 may have an important role in the regulation of differentiation and apoptosis in human colonic epithelium<sup>[37]</sup>.

The role of insulin resistance and hyperinsulinemia in colorectal cancer was directly assessed by Schoen *et al*<sup>[27]</sup> in a study performed on 5849 participants in the Cardiovascular Health Study cohort. The authors identified 102 cases of colorectal cancer. Fasting insulin was not related to an increased risk (RR = 1.2), whereas 2 h insulin was related to a significantly increased risk (RR = 2.0).

Giovannucci *et al*<sup>[38]</sup> found that BMI was not significantly

associated with an increased risk of distal colon adenoma irrespective of size, while WC and waist hip ratio were strong risk factors for large distal colon adenomas with diameter  $\geq 1$  cm but were unrelated to small adenomas with diameter  $< 1$  cm. The association of WC with an increased risk of cancer has been reported to be slightly stronger for distal colon cancer.

There are also several studies which determined the relationship between C-peptide (an indicator of insulin production) and the risk of colorectal cancer. As mentioned before, in the Physicians' Health Study, men with C-peptide in the top *vs* the bottom quintile had a 2.7-fold significantly higher risk of colorectal cancer after control for BMI and exercise; this RR increased to 3.4 after the analysis was controlled for indicators of the metabolic syndrome<sup>[28]</sup>. In a prospective study of 14275 women in New York State, a 3-fold higher risk of colorectal cancer was observed in those in the top quartile of C-peptide, and a 4-fold higher risk was observed for colon cancer alone<sup>[39]</sup>.

### **Adipokines and inflammatory cytokines**

Adipose tissue is a complex endocrine organ, responsible for the secretion and synthesis of hormones, cytokines and other signaling proteins, collectively termed as adipokines. Adipokines are a diverse group of signaling molecules that play roles in such processes as appetite and energy balance, inflammation, insulin resistance/sensitivity, angiogenesis, lipid metabolism, cell proliferation and atherosclerosis. Many of these functions are related to either the metabolic syndrome or cancer, and they may serve as a link between these two pathologies<sup>[40]</sup>.

### **Adiponectin**

Adiponectin, a 30-kDa complement C1q-related protein, is a key regulator of insulin sensitivity and inflammation and modulates several physiologic processes, such as metabolism of glucose and fatty acids. In contrast to other adipokines such as leptin, adiponectin circulating levels are decreased in obese individuals and in those with diabetes<sup>[41]</sup>. Decreased plasma adiponectin concentrations are associated with insulin resistance, type 2 diabetes and atherosclerosis. In addition, it was recently shown that adiponectin may play a role in the development and progression of various types of malignancies. Accumulating evidence suggests that adiponectin is an important regulator of cell proliferation. Adiponectin may act either directly on cancer cells or indirectly by regulating whole-body insulin sensitivity<sup>[42]</sup>.

### **Mechanisms that may link adiponectin with carcinogenesis**

In obesity, reduced adiponectin levels lead to the development of insulin resistance and compensatory, chronic hyperinsulinaemia. Increased insulin levels results in increased levels of bioavailable IGF-1. Insulin and IGF-1 signal through the insulin receptors and IGF1R, promote cellular proliferation and inhibit apoptosis in many tissue types up-regulating the secretion of VEGF, contributing thus to carcinogenesis<sup>[39]</sup>. Adiponectin has also

been shown to inhibit both the production of TNF- $\alpha$  in macrophages and its action in endothelial cells, thus promoting carcinogenesis through the altered effect of TNF- $\alpha$  on tumor cell proliferation and angiogenesis<sup>[43]</sup>.

Adiponectin can also protect from carcinogenesis through more direct effects.

Specifically, adiponectin has been found to be an important negative regulator of hematopoiesis and the immune system. Moreover, adiponectin may inhibit activation of nuclear factor- $\kappa$ B (NF- $\kappa$ B), a transcription factor that upregulates VEGF<sup>[44]</sup>.

Several signalling molecules such as 50-AMP-activated protein kinase (AMPK), NF- $\kappa$ B, peroxisome proliferators activated receptor (PPAR)- $\alpha$  and p38 mitogen-activated protein kinase are known to mediate adiponectin-induced metabolic effects. AMPK might inhibit the growth and/or survival of cancer cells<sup>[45]</sup>. Finally, adiponectin may also regulate angiogenesis negatively (independently of AMPK) through induction of apoptosis in vascular endothelial cells by activating the caspase cascade, a group of apoptotic enzymes<sup>[46]</sup>.

The relationship between circulating adiponectin levels and colorectal cancer was demonstrated by several clinical and experimental studies.

Ferroni *et al*<sup>[47]</sup> demonstrated in a study involving 60 patients with non metastatic colorectal cancer that low adiponectin levels are inversely correlated with increases in tumor stage and were independent predictors of recurrent disease. Low adiponectin levels were found in 52% of relapsing patients, compared with 26% of non-relapsing patients<sup>[47]</sup>.

Similar results were obtained by Wei *et al*<sup>[48]</sup> in a prospective case-control study of 18225 men enrolled in the Health Professional Follow-up Study. Over the approximately 8 years of follow-up, the authors noted 25 cases of colorectal cancer in the 3645 men in the highest category of adiponectin compared with 54 cases of colorectal cancer in the 3645 men in the lowest quintile of adiponectin.

### **Leptin**

Leptin is a 16 kDa glycoprotein which is expressed almost exclusively ( $> 95\%$ ) by adipocytes. Initial interest in leptin focused on its role in obesity but recently leptin, has been associated with the inflammatory response, insulin signaling, and carcinogenesis.

Insulin and leptin interact at multiple levels within a complex network of adipose tissue signaling pathways, providing several mechanisms that could link leptin to colon cancer.

Of particular importance for cancer is the influence of leptin on suppressors of cytokine signaling 1 and 3 which in turn limits insulin signaling<sup>[49]</sup>.

Although data directly linking leptin to colon cancer are limited, some studies have shown increased risk of colon and colorectal cancer with high serum leptin levels.

Data from a cohort study in Norway detected an almost 3-fold increased risk of colon cancer among people with high leptin levels, independently of BMI<sup>[50]</sup>.

Another study found that men in the highest tertile of leptin concentrations had a 3.3-fold (95% CI: 1.2-8.7) increased adenoma risk compared with those in the lowest tertile<sup>[51]</sup>. The association between leptin concentration and colorectal cancer was also evaluated in women, in a case-control study conducted in Japan, suggesting that leptin increases substantially the risk of female colorectal cancer, independent of BMI<sup>[52]</sup>.

### **Inflammatory cytokines and colorectal cancer**

Accumulating evidence suggests that systemic inflammation might be a plausible mechanism for colon carcinogenesis. Studies have shown that genetic variations in inflammation-related genes, such as interleukin (IL)-6, IL-8, and IL-10, are associated with susceptibility to colorectal cancer and adenomas.

IL-6 appears to enhance tumorigenesis by a paracrine and autocrine mechanism, to stimulate cell growth and inhibit apoptosis. Also IL-6 concentrations reflected disease status and were commonly associated with metastatic disease<sup>[53]</sup>.

TNF- $\alpha$  activates NF- $\kappa$ B (by phosphorylation of its inhibitor I $\kappa$ B), which increases production of NO, a substrate for reactive oxygen species (ROS) formation, and stimulates other inflammatory cytokines<sup>[54]</sup>. With respect to cancer, ROS can damage DNA by several processes including DNA base modification, deletions, frame shifts, strand breaks, DNA-protein cross-links, and chromosomal rearrangements. DNA damage can occur in genes that are important in cell proliferation (such as ras), or cell survival (such as p53), which can then trigger cancer progression<sup>[55]</sup>.

There are several studies which demonstrated the correlation between high levels of IL-6, TNF- $\alpha$ , C-reactive proteins (CRP) and colorectal carcinogenesis. Moreover, a Greek study demonstrated that high levels of serum IL-6, TNF- $\alpha$  and CRP were correlated with larger tumor size. The relation to tumor size could be related to the fact, that larger tumors may trigger a more potent immunological response manifested by the circulation of proinflammatory cytokines such as TNF- $\alpha$ <sup>[56]</sup>.

### **PPAR- $\gamma$**

PPAR- $\gamma$ , a ligand-activated transcription factor, is a key regulator of adipogenic differentiation and glucose homeostasis. PPAR- $\gamma$  ligands have recently been demonstrated to affect proliferation and differentiation in cancer cell lines. A gradually increasing number of studies demonstrated the association between PPAR- $\gamma$  and colorectal cancer<sup>[57]</sup>.

A recent study demonstrated a positive PPAR- $\gamma$  immunostaining in 48 of 86 cases of colon cancer (56%). No association was found for PPAR- $\gamma$  positivity with different Dukes' stages, histological grade of differentiation, tumor location, presence of lymph node and liver metastasis, venous invasion, or tumor cell proliferating capacity assessed as Ki-67 overexpression. On the contrary, PPAR- $\gamma$  expression was statistically significant correlated with the expression of cell cycle-related molecules<sup>[58]</sup>.

Another recent study demonstrated that PPAR- $\gamma$  agonists have inhibitory effects on the proliferation of colon cancer cell lines associated with G1 cell cycle arrest and invasive activity. The latter effect is demonstrated in certain cell lines through the down-regulation of metalloproteinase-7 synthesis<sup>[59]</sup>.

## **CONCLUSION**

The association between metabolic syndrome and colorectal cancer is now supported by a large number of epidemiological studies<sup>[14,16,17,19,26]</sup>. The components of metabolic syndrome appear to have an additive effect on colon cancer development acting through different pathophysiological pathways. This evidence is based on studies of determinants of the metabolic syndrome (obesity, abdominal distribution of adiposity, physical inactivity), clinical consequences (type 2 diabetes, hypertension) of this syndrome, plasma or serum components of the definition of metabolic syndrome (hypertriglyceridemia, hyperglycemia, low HDL cholesterol), markers of hyperinsulinemia or insulin resistance (insulin, C-peptide), and serum inflammatory cytokines levels in relation to colon cancer or adenoma risk. High insulin and insulin resistance are common features of industrialized societies characterized by a large prevalence of overweight individuals and obesity, a diet rich in energy intake, and a lifestyle characterized by low calorie expenditure. Understanding the pathological mechanism that links metabolic syndrome and its components to carcinogenesis has a very important clinical significance. Controlling even one or two of the components of the metabolic syndrome may result in a longer, healthier and cancer-free life. Public health efforts aimed at reducing lifestyle patterns and dietary habits associated with this imbalance on insulin metabolism may have profound health benefits on a number of diseases including cancer, that represent major causes of mortality and morbidity in our societies.

### Abstract

**AIM:** To investigate EP4-selective agonist effect on indomethacin-induced gastric lesions and on the spontaneous healing of chronic gastric ulcers.

**METHODS:** In a mouse model of gastric bleeding with high dose of indomethacin (20 mg/kg), an EP4-selective agonist was administered orally. Stomach lesions and gastric mucous regeneration were monitored. In a mouse model of chronic gastric ulcer induced by acetic acid, EP4 agonist effect on the healing of chronic gastric ulcer was evaluated in the presence or absence of low dose indomethacin (3 mg/kg). In cultured human gastric mucous cells, EP4 agonist effect on indomethacin-induced apoptosis was assessed by flow cytometry.

**RESULTS:** The EP4-selective agonist reduced high dose indomethacin-induced acute hemorrhagic damage and promoted mucous epithelial regeneration. Low-dose indomethacin aggravated ulcer bleeding and inflammation, and delayed the healing of the established chronic gastric ulcer. The EP4 agonist, when applied locally, not only offset indomethacin-induced gastric bleeding and inflammation, but also accelerated ulcer healing. In the absence of indomethacin, the EP4 agonist even accelerated chronic gastric ulcer healing and suppressed inflammatory cell infiltration in the granulation tissue. *In vitro*, the EP4 agonist protected human gastric mucous cells from indomethacin-induced apoptosis.

**CONCLUSION:** EP4-selective agonist may prevent indomethacin-induced gastric lesions and promote healing of existing and indomethacin-aggravated gastric ulcers, *via* promoting proliferation and survival of mucous epithelial cells.

### INTRODUCTION

Over 300 million patients use non-steroidal anti-inflammatory drugs (NSAIDs) in the world to treat pain, arthritis, fever and other diseases. Nearly 30% of the users suffer from gastric lesions and bleeding. Mechanisms for such actions of NSAIDs seem to be complex and multifactorial, including the inhibition of prostaglandin (PG) synthesis, induction of apoptosis and necrosis of gastric mucosal cells<sup>[1-3]</sup>, neutrophil penetration, dysfunction of microvessels, reduced secretion of bicarbonate and mucus, and increased gastric motility<sup>[4]</sup>.

Proton pump inhibitors (PPIs) have been the mainstay for the treatment of gastric ulcers, primarily due to its abilities to reduce acid secretion<sup>[5]</sup>. An alternative approach is to administer misoprostol, a non-selective prostaglandin E1 (PGE1) analogue. PGE2/E1 has been shown to protect isolated gastric glands from indomethacin, independently of neural, vascular and hormonal factors<sup>[6]</sup>. Misoprostol has successfully prevented NSAID-induced bleeding, perforation or gastric outlet obstruction in patients<sup>[5,7]</sup>, and reversed the negative effects of indomethacin on the maturation of granulation

tissue which PPIs were not able to do<sup>[8]</sup>. Misoprostol, however, produces severe side effects, such as diarrhea, gastrointestinal (GI) cramping pain, nausea, flatulence, dyspepsia, abortion, headache and poor tolerance<sup>[9]</sup>. Among the four PGE2 receptor subtypes (EP1-4), EP4 is constitutively expressed in gastric surface mucous cells, the first layer of lining cells of the stomach mucus<sup>[10-12]</sup>, and its agonists have been shown to inhibit the production of chemokines and cytotoxic cytokines from immune cells<sup>[13,14]</sup>, and to promote epithelial cell survival and growth by activating anti-apoptotic and proliferative cellular signaling pathways<sup>[15,16]</sup>. Previous studies, using a non-selective EP3/EP4 agonist or an EP4 antagonist, imply EP4's role in gastric ulcer healing<sup>[17]</sup>; however, direct evidence of EP4 agonists' role on gastric lesions is still missing. In the present study, we investigated therapeutic potentials of a highly-selective EP4 agonist for treatment of a mouse gastric ulcer model in the presence or absence of indomethacin at various levels.

## MATERIALS AND METHODS

### *The EP4-selective agonist*

Competition binding experiments were performed in a medium containing Hank's balanced salt solution, 20 mmol/L HEPES, pH 7.3, membranes (about 60 µg protein) or  $2 \times 10^5$  cells from HEK 293 cells stably expressing the human EP4 receptor, [<sup>3</sup>H] PGE<sub>2</sub> (10 nmol/L) and various concentrations of test compounds in a total volume of 300 µL, read with LS6500 multi-purpose scintillation counter (Beckman Coulter, CA). cAMP assay was carried out using AlphaScreen cAMP assay kits (PerkinElmer, Boston, MA) following manufacturer's instructions. Intracellular Ca<sup>2+</sup> was monitored using a FLIPR Tetra system and assay kits from Molecular Devices following manufacturer's instructions. All assays were carried out in HEK-293 cells heterologously and stably expressing each of the eight human recombinant prostanoid receptors. For Ca<sup>2+</sup> signals, hEP2, hEP4 and hDP were co-expressed with a chimeric G protein, Gqs, which converts the Gs signal to a Gq Ca<sup>2+</sup> signal, and hEP3 with a chimeric G protein, Gqi. Subtype-selective compounds used here were PGE<sub>2</sub> for EP1, EP2, EP3 and EP4; BW245C for DP; 17-phenyl PGF<sub>2</sub>α for FP, carbacyclin for IP and U-46619 for TP.

The PGE2 analog used in this study bound hEP4 with a Ki of  $6.7 \pm 0.7$  nmol/L, not other prostanoid receptors, and increased cAMP production with an EC<sub>50</sub> of  $0.25 \pm 0.03$  nmol/L. On the other hand, the drug at 10 µmol/L showed no detectable FLIPR signals in HEK 293 cells heterologously expressing hEP1, hFP, hIP and hTP, and also in hEP2 (Gqs), hEP4 (Gqs), hEP3 (Gqi), hDP (Gqs), respectively. This compound is unstable in liver microsomes and thus when locally applied, its systemic exposure was minimal.

### *Cell culture and apoptosis assay*

Human gastric mucosal cells (AGS) were purchased from the American Type Culture Collection (Manassas, VA), and maintained on Ham's F-12 medium (GIBCO-BRL)

with 10% heat-inactivated fetal bovine serum and 1% penicillin/streptomycin. The cells were seeded in 6-well plates at  $1 \times 10^5$  cells/well. After overnight (37°C, 5% CO<sub>2</sub>) culture, the cells were treated with indomethacin at 50, 100, 200 or 400 µmol/L for 24 h, under serum-free conditions, to induce apoptosis as reported elsewhere<sup>[18]</sup>. Cell apoptosis was quantitated with flow cytometry as below. To evaluate EP4 agonist effect on cell survival, 70% confluent cells were treated with the EP4 agonist at 0, 1, 3 or 10 nmol/L, respectively, followed by 400 µmol/L indomethacin 30 min later. Twenty-four hours later, cells were collected and washed in cold PBS, and fixed with cold 70% ethanol added drop by drop while vortex stirring. Following overnight fixation, the cells were stained with propidium iodide (10 µg/mL, Sigma) and RNase A (1 mg/mL, Sigma) for 30 min in the dark. The cells were sorted by flow cytometry using CellQuest software (Becton Dickson, San Diego, CA). The sub-2N population was quantified. The percentage of apoptotic cells was calculated by sub-2N population from each drug treatment minus vehicle treatment<sup>[19]</sup>.

### *Indomethacin-induced gastric damage model*

High dose indomethacin (20 mg/kg in 4% DMSO, corn oil) was orally gavaged to induce gastric damage in C57BL/6 mice (Charles River, Wilmington, MA) at 8 wk old<sup>[20,21]</sup>. Vehicle or the EP4 agonist at 0.1 mg/kg in 0.1 mL 4% DMSO-corn oil was orally gavaged, 24 h and 30 min prior to indomethacin. Gastric lesions were assessed 24 h after indomethacin administration. The stomachs were removed, inflated with 2% formalin, immersed in 2% formalin for 10 min and then opened along the great curvature. The area of hemorrhagic lesions was measured under a dissecting microscope (16 × magnification) with a square grid (× 10), summed per stomach, and used as a lesion score<sup>[20,21]</sup>. The stomachs were then fixed in 10% formalin and sectioned at 5 µm thickness. HE staining was performed as usual. To monitor cell proliferation, BrdU was injected intraperitoneally at 10 mg/mL in 0.1 mL of normal saline, 16 h prior to sacrifice. Paraffin-embedded sections were deparaffinized in xylene and rehydrated in ethanol. Antigen was retrieved with citrate buffer, pH 6.0, boiled for 5 min in a microwave and slowly cooled down at room temperature. Immunofluorescence staining of BrdU was then performed following manufacturer's instructions (Roche-Applied Science, Penzberg, Germany). Briefly, the sections were incubated with sufficient amount of anti-BrdU working solution at 4°C in a humid atmosphere for 24 h; after 3 × washing, anti-mouse-Ig-fluorescein was applied for 30 min at 37°C in a humid atmosphere. DAPI was used to co-stain the slides for 5 min. The slides were covered with antifade mount medium, and evaluated with a fluorescence microscope. Ten views from each section were randomly collected at original magnification, × 200. The percentages of BrdU-positive cells were counted in well-oriented glands of mucous layer.

### *Chronic gastric ulcer model and treatments*

C57BL/6 mice at 3 mo old were shaved in the epigastric region and anesthetized with isoflurane. Following

sterilization with betadine and 70% ethanol, a midline incision was made to expose the stomach. Five microliters of 40% acetic acid was added through a 3 mm curette onto the serosal surface of the anterior wall of the stomach (just proximal to the antral gland area). The curette was placed tightly on the stomach surface to limit the spread of acetic acid. Thirty seconds later, acetic acid was wiped off and the surface was cleaned with normal saline. The abdomen wall was closed by 6-0 silk sutures, and the skin was closed by staples<sup>[22]</sup>. We first performed a study to monitor the dynamic changes of ulcers and animals. The mice lost some weight initially and recovered in 2 d. Their ulcer sizes were peaked at day 3 and then spontaneously healed within 2 wk. Vehicle or the EP4 agonist (0.1 mg/kg per day) and/or indomethacin (3 mg/kg per day) were orally gavaged from day 3 to day 6 in 0.1 mL 4% DMSO-corn oil. Then the animals were assessed on day 7. To study EP4 agonist effect on chronic gastric ulcer healing (without indomethacin), the EP4 agonist (0.1 mg/kg per day) or vehicle were given from day 3 to day 10, and evaluated on days 7 and 11, respectively.

On the day of sacrifice, blood was withdrawn, and hematology analysis was conducted by personnel who did not know the treatments (ADVIA120 Hematology System, Bayer, Tarrytown, NY). The stomachs were inflated with 2% formalin for 10 min and opened along the greater curvature. The stomachs were flattened on 3M paper. The ulcers were photographed under dissection microscopy ( $\times 16$ ) with a hooked camera, and images stored in the computer and analyzed by SPOT software. The stomachs were then fixed in 10% formalin and processed for sectioning. A slice cutting through the biggest diameter of each ulcer was sectioned and stained by HE.

All animal use protocols were approved and performed according to the guidelines of Allergan's animal care and use committee. Data shown are mean  $\pm$  SE. Statistical analysis was conducted by student *t*-test.

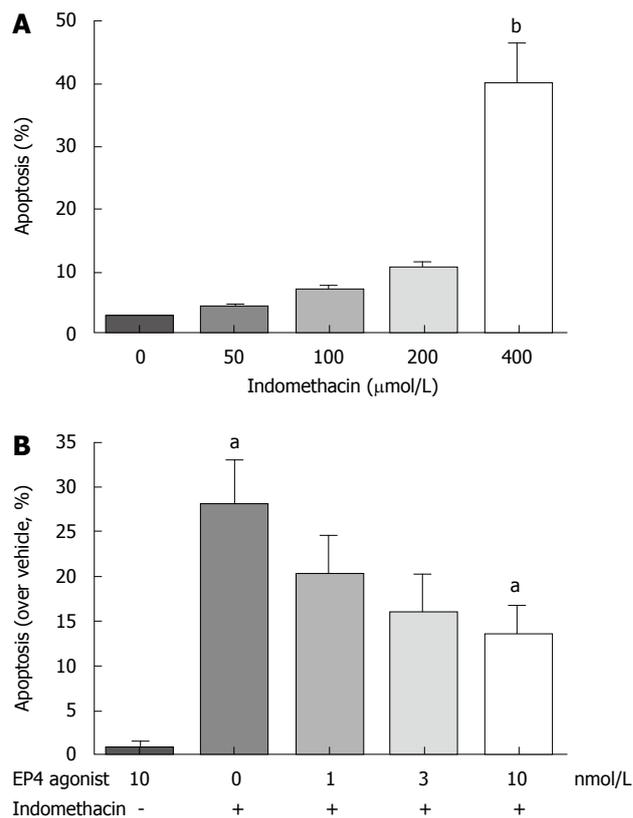

## RESULTS

### EP4 agonist decreased indomethacin-induced apoptosis

Exposure of human gastric mucous epithelial cells (AGS) to indomethacin (0, 50, 100, 200, 400  $\mu\text{mol/L}$ ) for 24 h concentration-dependently induced cell apoptosis as determined using flow cytometry analysis (Figure 1A). Particularly, indomethacin at 400  $\mu\text{mol/L}$  markedly increased apoptosis, nearly 10-fold greater than in the untreated cells, and its activity was significantly reduced upon treatment (30 min before) with a highly-selective and potent EP4 agonist (see materials and methods), in a dose-dependent manner (Figure 1B). The EP4 agonist at the highest dose, 10 nmol/L, significantly decreased indomethacin-induced apoptosis, by more than 50%.

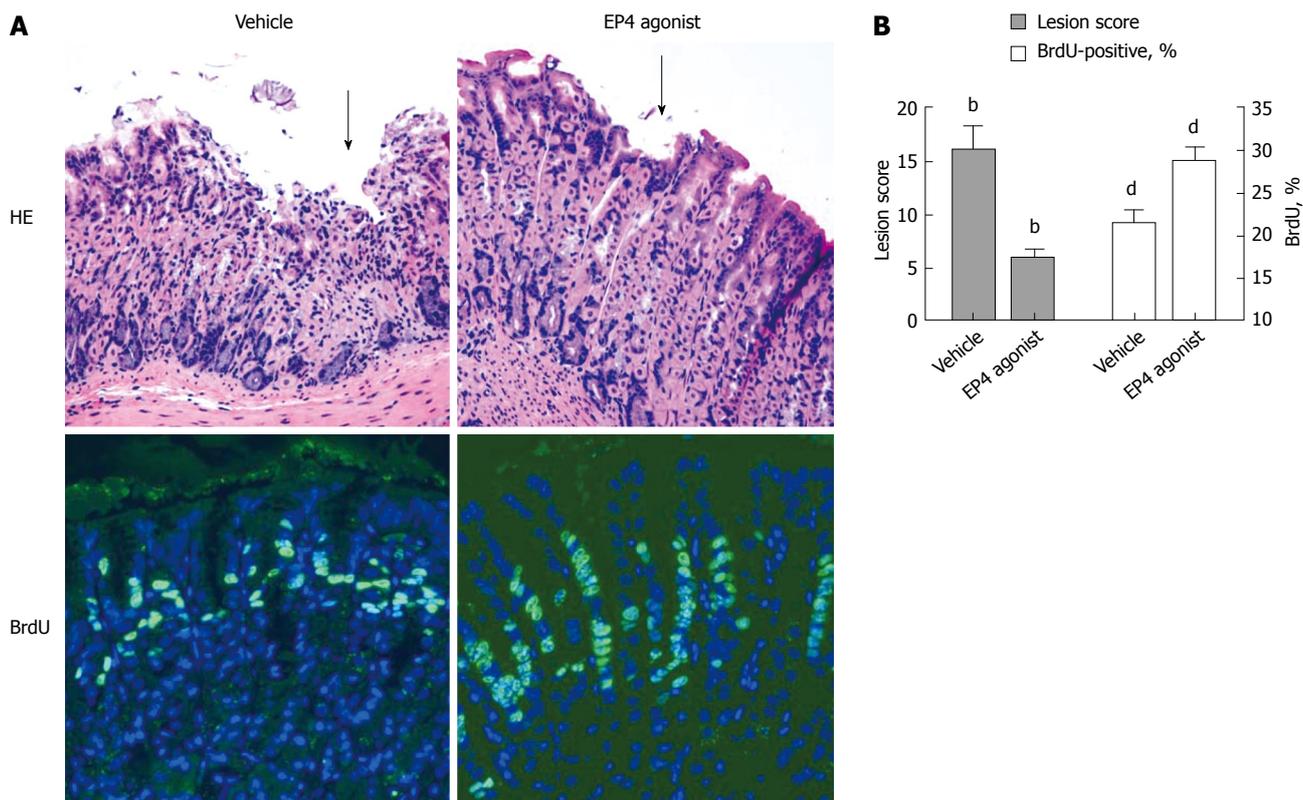

### EP4 agonist alleviated indomethacin-induced acute damage and promoted epithelial regeneration in mice

In rats, apoptosis of mucous epithelial cells contributes to indomethacin-induced lesions in stomachs<sup>[18]</sup>, and

**Figure 1** EP4 agonist effect on indomethacin-induced apoptosis in human gastric mucous epithelial cells (AGS). AGS cells were pre-treated with EP4 agonist for 30 min followed by addition of indomethacin for 24 h and sorted by flow cytometry after PI staining. Sub-2N population was quantified as apoptotic cells. A: indomethacin dose-dependently induced apoptosis, <sup>b</sup> $P < 0.0001$  vs the rest,  $n = 4$ ; B: shown are values minus vehicle controls, <sup>a</sup> $P < 0.005$ ,  $n = 5-9$ ; indomethacin dose was 400  $\mu\text{mol/L}$ .

here we examined whether the EP4 agonist protects the gastric mucus layer from indomethacin. Indomethacin at high dose (20 mg/kg) produced band-shaped hemorrhagic lesions in the mucous layer mostly at the glandular part of the stomachs, occurring 7 h post indomethacin application. Histologically, there was edema and disorganization of the mucous layer, patchy mucous epithelial cell exfoliation, shallow ulcer formation and bleeding with infiltration of inflammatory cells in vehicle treated mice. The mucous layer of EP4-treated mice remained largely intact except for some sparse, focal superficial defects in mucous cells (Figure 2A). Treatment with the EP4 agonist (concentration 0.002%), 24 h and 30 min before indomethacin, significantly reduced gastric lesion scores, from an average of 16 to less than 6 (Figure 2B). BrdU staining-positive cells were largely limited to the isthmus and neck region in the tubular glands of the stomach mucosa layer in vehicle-treated mice (Figure 2A). BrdU-positive cells migrated much higher and lower along the tubular glands in the EP4 agonist-treated mice than vehicle-treated mice (Figure 2A). BrdU-positive cells in mucous layer were on average 29% in EP4 treated mice, and 21% in vehicle treated mice (Figure 2B). Taken together, the EP4 agonist may stimulate proliferation and migration of gastric epithelial progenitors, so as to accelerate mucous repair.

**Figure 2** EP4 agonist effect on indomethacin-induced gastric lesion in mice. EP4 agonist was orally administered 24 h and 30 min prior to indomethacin dosing at 20 mg/kg. The stomachs were assessed for mucus lesions 24 h after indomethacin dosing. A: HE and BrdU immunohistochemistry staining of stomachs ( $\times 200$ ). Superficial mucosal cells had sloughed off gastric mucus with infiltration of inflammatory cells in vehicle-treated group (arrow points to one lesion site). The mucus of EP4 agonist-treated stomachs was almost normal, except for a sparse focal defect of superficial mucous cells without inflammatory cells (arrow points to one lesion site). BrdU labeling showed robust mucous epithelial regeneration and migration in EP4 agonist-treated rats compared with that of vehicle treatment; B: Quantification of gross lesion under dissection microscopy ( $\times 16$ ) and percentage of BrdU-positive cells among mucus cells. Shown are lesion scores,  $^bP < 0.0001$ ,  $n = 10$ ; and BrdU percentage,  $^dP < 0.01$ ,  $n = 10$ , respectively.

### Low dose indomethacin exacerbated chronic gastric ulcers in mice

A chronic gastric ulcer model was established by acetic acid application in mice. Low-dose indomethacin (3 mg/kg per day), which is sufficient to block *de novo* synthesis of PGE<sub>2</sub>, was applied 3 d post ulcer induction. On day 7, the indomethacin treatment increased gross ulcer areas by 76% as compared to vehicle-treated mice ( $P < 0.01$ , Figure 3A). Consistent with exacerbation of gastric ulcer sizes, hematology analysis revealed that indomethacin also worsened blood loss from the ulcers (Figure 3B), and higher lymphocyte surge as compared to untreated controls (Figure 3C). This supports the view that blocking of *de novo* synthesis of PGE<sub>2</sub> delayed spontaneous repair of established gastric ulcer, and exacerbated inflammation and bleeding, which is similar to human gastric ulcer's responses to NSAIDs.

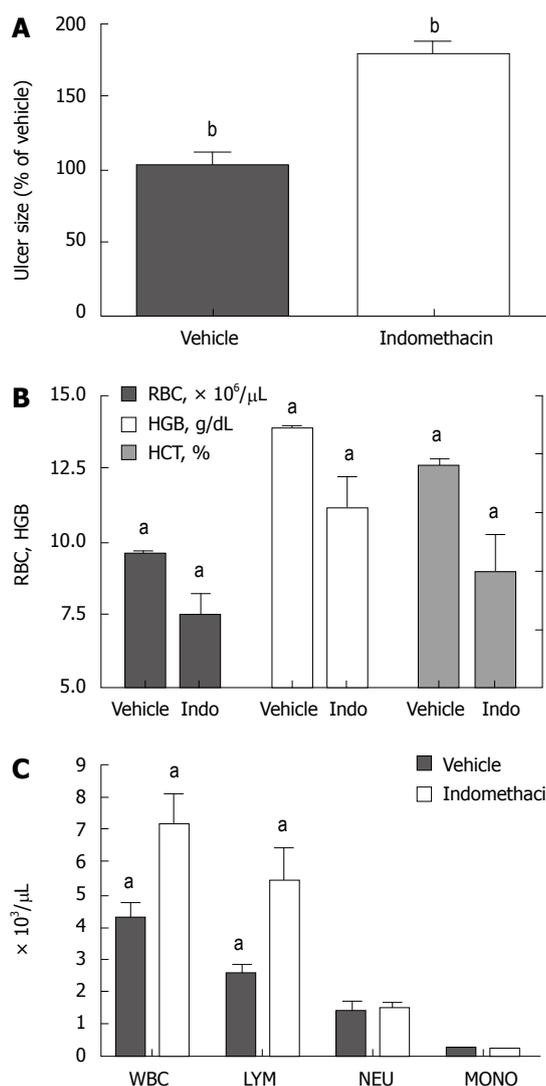

### EP4 agonist ameliorated indomethacin exacerbation on chronic gastric ulcer in mice

We next investigated whether exogenous EP4 agonist is capable of promoting ulcer healing in the presence of indomethacin treatment. Indomethacin (3 mg/kg) with EP4 agonist (0.002% in 0.1 mL) or with vehicle was orally administered to mice with established gastric ulcers from day 3 to day 7. Mice treated with EP4 agonist

had a smaller ulcer size than mice treated with vehicle,  $75.04\% \pm 7.06\%$  and  $100.02\% \pm 9.44\%$ , respectively, on day 7. Hematology analysis showed that EP4 agonist treatment significantly ameliorated loss of red blood cells, hemoglobin and hematocrit (Figure 4A). This may suggest that EP4 agonist-treated mice had either smaller ulcers or more mature granulation tissue than control mice. EP4 agonist leads to gastric mucous vasodilation, not vasoconstriction (mediated by EP3 receptor)<sup>[13]</sup> and mature granulation tissue is more resistant to noxious stimuli. The inflammation at ulcer sites was reflected by white blood cell counts in the peripheral circulation. EP4 agonist treatment decreased white blood cell counts from  $6900/\mu\text{L}$  to  $5600/\mu\text{L}$ , and lymphocyte counts from  $4690/\mu\text{L}$  to  $3330/\mu\text{L}$  ( $P < 0.05$ ) (Figure 4B).

### EP4 agonist accelerated the spontaneous healing of chronic gastric ulcer

We also examined the effects of EP4 agonist alone on gastric ulcer healing. By day 7, treatment with EP4 agonist reduced ulcer area by 40% as compared to that observed with vehicle treated mice (Figure 5A,  $P < 0.005$ ). By day 11, the drug further reduced ulcer size by 70% (Figure 5A). There was much less inflammatory cell infiltration and necrosis tissue in the ulcers of EP4 agonist-treated animals, compared with untreated mice.

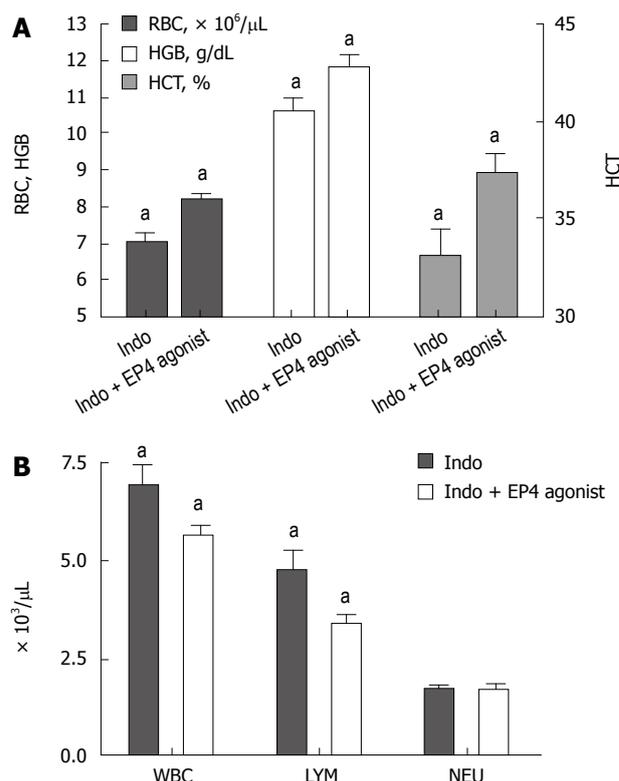

**Figure 3 Low dose indomethacin effect on chronic gastric ulcer of mice.** Chronic gastric ulcers were created by 40% acetic acid as detailed in "Methods". Then the animals were given indomethacin from day 3 to day 6 at 3 mg/kg per day and the ulcers were assessed after blood withdrawal on day 7 post-surgery. A: Ulcer sizes were measured under dissection microscopy with 16 × magnification; <sup>b</sup>*P* = 0.006, *n* = 18; B: Hematology analysis of ulcerated animals on day 7, <sup>a</sup>*P* < 0.05, *n* = 6; RBC: Red blood cell; HGB: Hemoglobin; HCT: Hematocrit; C: Hematology of ulcerated animals on day 7, <sup>a</sup>*P* < 0.05, *n* = 6; WBC: White blood cells; LYM: Lymphocytes; NEU: Neutrophils; MONO: Monocytes.

On sectioning slides, inflammatory cell scores were 1.8 ± 0.2 for the EP4-agonist-treated and 2.7 ± 0.2 for the vehicle-treated mice (*P* < 0.05) (Figure 5B).

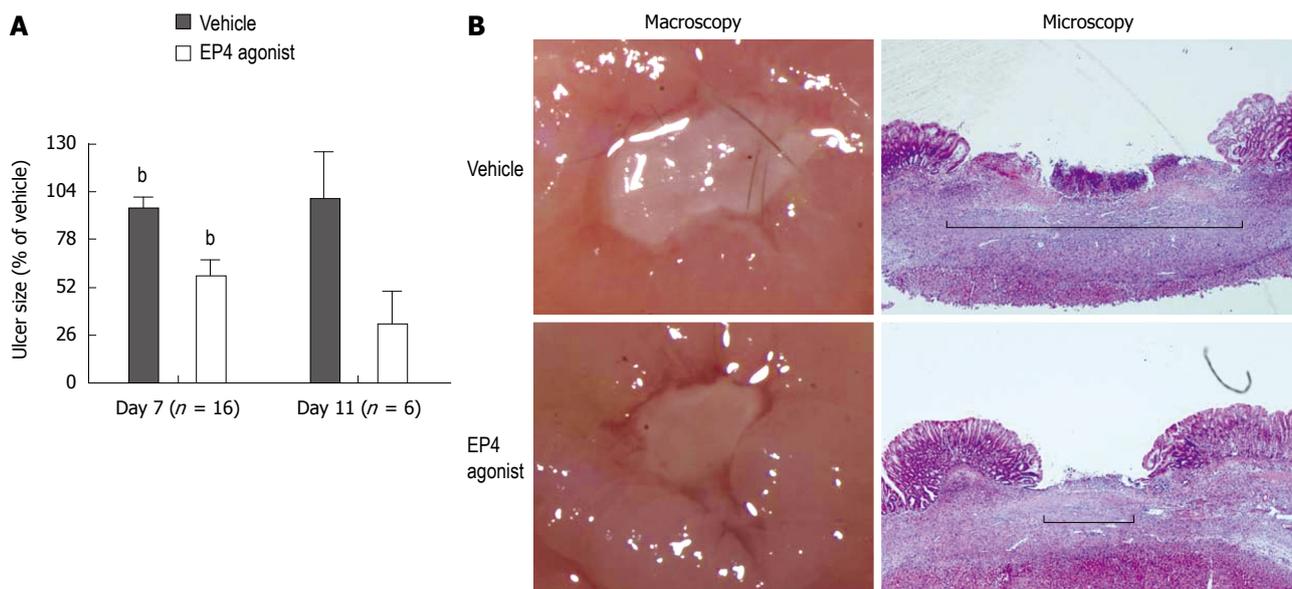

## DISCUSSION

In the present study, we have shown that indomethacin, a prototypic cyclo-oxygenase (COX) inhibitor, at high dose, induced gastric epithelial apoptosis and produced gastric hemorrhagic lesions, and that the EP4-selective agonist we used here reduced such indomethacin-induced gastric injuries. Also, the EP4 agonist ameliorated ulcer bleeding and inflammation exacerbated by indomethacin at a low dose on existing ulcers, and promoted the spontaneous healing of chronic gastric ulcers in the absence of indomethacin.

**Figure 4 EP4 agonist alleviated indomethacin effect on gastric ulcer in mice.** Mice with gastric ulcer were given low-dose indomethacin (3 mg/kg per day) with or without EP4 agonist from day 3 to day 6 post-surgery. The blood was withdrawn on day 7 for hematology analysis. A and B are results of hematology analysis, <sup>a</sup>*P* < 0.05, *n* = 20.

Such indomethacin-induced gastric injuries and PGE2 analogue-induced gastric protection appear to be somewhat similar to their actions observed at cellular level: NSAIDs are known to bring about mitochondrial damage, caspase cleavage, and eventually cell apoptosis in human gastric mucus as well as animal primary gastric epithelial cells<sup>[3,18,23,24]</sup>. PGE2 and its analogs, on the other hand, inhibit indomethacin-induced mitochondrial damage and apoptosis in gastric epithelial cells<sup>[23,25]</sup>, and a PGE1 analog, misoprostol, has been shown to reverse the inhibitory effect of NSAIDs on the regeneration of gastric mucous epithelial cells from human and animals<sup>[26]</sup>. 11-deoxy-PGE1 (EP3/EP4 agonist) reverses indomethacin-induced delay in the healing of chronic gastric ulcers<sup>[17]</sup>. One EP4-selective antagonist shows a deleterious effect on the spontaneous healing of chronic gastric ulcers with simultaneous suppression of vascular endothelial growth factor (VEGF) expression<sup>[17,27]</sup>. So gastric protective effects of PGE2 and its analogs may be partly caused by the activation of EP4, one of its 4 receptor subtypes, which is known to activate Gi- and Gs subtypes of G proteins, and to transduce PI3k/Akt/Erk1/2 and cAMP/PKA signaling<sup>[1,28,29]</sup>. Both pathways mediate pro-survival and proliferation signals in various epithelial cell lines, and are in line with our observation that the EP4 agonist inhibits indomethacin-induced apoptosis in human gastric mucosal cells (AGS), an established model for gastrointestinal effects of COX inhibitors<sup>[30]</sup>, and expressing high levels of EP4

**Figure 5** EP4 agonist promoted gastric ulcer healing in mice. Mice with gastric ulcers were treated with vehicle or EP4 agonist from day 3 to day 10 post-surgery. Gastric ulcers were assessed on day 7 or 11, respectively. A is quantification of ulcer sizes under dissection microscopy with 16 × magnification,  $^bP = 0.003$ ,  $n = 16$ ; B is representative images of gastric ulcers; the macroscopy images are at original magnification, × 16; the microscopy images are at original magnification, × 40 from slide sections.

transcripts (data not shown). Besides cell survival, the stimulation of intracellular cAMP from EP4 activation induces smooth muscle relaxation, and increases mucous blood supply and mucus secretion, which may additionally contribute to lessening indomethacin-induced injuries<sup>[25,31-33]</sup>.

In addition to acute damages produced by high-dose indomethacin, we also observed the chronic deleterious gastric effects of indomethacin at low-dose, which is more relevant to common clinical situations. Consistent with earlier reports<sup>[17,34,35]</sup>, low-dose indomethacin delayed healing of chronic gastric ulcers, exacerbated ulcer bleeding and inflammation, due to the inhibition of COX-2 expression and *de novo* synthesis of PGE<sub>2</sub>, and the inhibition of epithelial cell proliferation at the ulcer edge in both animals and humans. We have shown here that the EP4 agonist reversed such chronic effects induced by indomethacin at low dose.

Interestingly, we also observed here that the EP4 agonist accelerated the healing of chronic gastric ulcers under non-indomethacin challenged conditions. The major part of gastric ulcer healing is the restoration of gastric structure, which depends on the formation of the granulation tissue template made of gastric fibroblast cells and neovasculature. These fibroblasts express EP4 abundantly, and its activation is known to increase the synthesis of basic fibroblast growth factor, hepatocyte growth factor and VEGF<sup>[29,36-38]</sup>. All these factors may accelerate regeneration of fibroblasts and extracellular matrix, thus restoring ulcerated areas, and restituting epithelial cell layers<sup>[17,38]</sup>. Also the EP4 agonist showed anti-inflammatory activities as shown here and reported earlier<sup>[39]</sup>: fewer inflammatory cells in the blood and minimal infiltration in the ulcers from animals treated with the EP4 agonist. This should facilitate the healing process

since the control of inflammation is a pre-requisite to rapid healing<sup>[35]</sup>.

In summary, EP4 agonists may mimic the gastric protective effects of PGE<sub>2</sub> in the presence or absence of NSAIDs, and may show advantages over non-selective analogs such as misoprostol by minimizing adverse effects arising from activating all 4 subtype receptors of PGE<sub>2</sub>.

We are grateful to the excellent assistance from Wu-Xia Fu, Ke-Hui Wang and Margaret A Ramos. We also appreciate the discussion with Professor George Sachs at UCLA.

## COMMENTS

### Background

Non-steroidal anti-inflammatory drugs (NSAIDs) including both cyclooxygenase (COX)-1/2 and COX-2-selective inhibitors, such as indomethacin, ibuprofen and celecoxib, have been prescribed in the world for treatment of pain, arthritis, menstrual symptoms and cancer, to name a few. However, nearly 30% of patients suffer from gastric lesions and bleeding. To mitigate NSAIDs' adverse effects on the stomach, misoprostol, a non-selective PGE<sub>1</sub> analogue, has been prescribed as the first choice for prevention of NSAID-induced injuries in USA, but often induces severe adverse effects. There remain unmet medical needs for drugs with improved therapeutic profiles.

### Research frontiers

PGE<sub>2</sub>/E<sub>1</sub> interacts with 4 subtype receptors, EP<sub>1</sub>, 2, 3 and 4 in mammalian cells. Numerous studies have been performed to understand each subtype receptor's function and mechanism under various physiological and pathological conditions. High subtype receptor-selective ligands have been designed and tested to avoid adverse effects from non-selective drugs, such as misoprostol.

### Innovations and breakthroughs

This study employed a novel, highly selective EP4 agonist, reported direct evidence for its protective activities against NSAIDs in the stomach, and further disclosed that the EP4 agonist may in part function through promoting mucous

epithelial cell survival and regeneration. This is the first study to show that an EP4 agonist may facilitate chronic gastric ulcer healing, although similar activity of EP4 in the stomach has been implicated in several concurrent studies using non-selective EP4 agonists or antagonists.

### Applications

The concept from this paper would facilitate therapeutic developments of EP4-selective agonists for prevention of NSAIDs' adverse effects in the gastrointestinal (GI) tract as well as for monotherapy treatment of gastric ulcers. Further, EP4 agonists may provide gastric protection under conditions such as stress, radio/chemotherapy and other conditions compromising GI activities.

### Terminology

Prostaglandin E2 (PGE2) is synthesized *via* key enzymes COX-1/2, under normal conditions primarily by COX-1 and under pathological conditions by inducible COX-2. PGE2 is a paracrine or autocrine hormone, and is involved in inflammation and pain, and also plays an important role in functional stability of the GI tract.

### Peer review

In this manuscript, the authors investigated the effects of EP4-selective agonist on indomethacin-induced gastric lesions and spontaneous healing of chronic gastric ulcers in mice or cultured human gastric mucous cells. The study was well performed and very interesting.

### Abstract

**AIM:** To evaluate the spatial distribution of cerebral abnormalities in cirrhotic subjects with and without hepatic encephalopathy (HE) found with magnetization transfer imaging (MTI).

**METHODS:** Nineteen cirrhotic patients graded from neurologically normal to HE grade 2 and 18 healthy control subjects underwent magnetic resonance imaging. They gave institutional-review-board-approved written consent. Magnetization transfer ratio (MTR) maps were generated from MTI. We tested for significant differences compared to the control group using statistical non-parametric mapping (SnPM) for a voxel-based evaluation.

**RESULTS:** The MTR of grey and white matter was lower in subjects with more severe HE. Changes were found in patients with cirrhosis without neurological deficits in the basal ganglia and bilateral white matter. The loss in magnetization transfer increased in severity and spatial extent in patients with overt HE. Patients with HE grade 2 showed an MTR decrease in white and grey matter: the maximum loss of magnetization transfer effect was located in the basal ganglia [SnPM (pseudo-) $t = 17.98$ ,  $P = 0.0001$ ].

### INTRODUCTION

Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, which is characterized by sleeping disorders, asterixis, and deficits in motor skills and reaction time. Twenty to eighty percent of patients with cirrhosis suffer from minimal HE (mHE)<sup>[1]</sup>. Five years after the diagnosis of mHE, 26% of patients with liver cirrhosis have episodes of overt HE. This condition is associated with a poor prognosis<sup>[2]</sup>.

Studies using magnetization transfer contrast imaging (MTI) have demonstrated a decrease in the magnetization transfer ratio (MTR) in the brains of cirrhosis patients with mHE and overt HE<sup>[3-10]</sup>. MTR decrease in cirrhosis has been proposed to be an effect of astrocytic water retention<sup>[5-7,9,10]</sup>, demyelination<sup>[5]</sup> and axonal loss<sup>[5]</sup>, in addition to changes in blood flow and energy metabolism<sup>[9]</sup>.

MTI has been used successfully to monitor normalization of cerebral abnormalities in cirrhosis patients following liver transplantation<sup>[8]</sup>, and has been shown to detect increasing abnormalities following induced hyperammonemia<sup>[9]</sup>.

The cited studies evaluated MTR maps using region-of-interest (ROI) based analyses. The MTR of normal appearing white matter<sup>[5-10]</sup> and anatomically defined areas of deep grey matter<sup>[3-5,10]</sup> have been the subject of previous studies on HE. To the best of our knowledge, no systematic evaluation of the spatial distribution of MTR abnormalities in HE has been published so far. The purpose of the present study is to evaluate the spatial distribution of MTI changes caused by central nervous system (CNS) abnormalities in HE.

## MATERIALS AND METHODS

### Subjects

Approval was obtained from the institution's review board. All patients and volunteers gave written informed consent after the neuropsychological tests and magnetic resonance imaging (MRI) had been explained fully. In this prospective study (for details see Table 1), 19 patients (14 male and five female) with non-alcoholic cirrhosis and 18 age-matched controls (eight male and 10 female) were included. Cirrhosis was caused by hepatitis C ( $n = 9$ ), hemochromatosis ( $n = 2$ ), primary chronic cholangitis ( $n = 2$ ), hepatitis B ( $n = 1$ ), Wilson's disease ( $n = 1$ ) and cryptogenic cirrhosis ( $n = 4$ ).

Subjects with a history of drug abuse, including alcohol, and those suffering from neurological or psychiatric diseases were excluded. Also excluded were patients who were taking CNS-relevant medications such as benzodiazepines, benzodiazepine antagonists and antidepressants. Further exclusion criteria were severe diseases such as spontaneous bacterial peritonitis, severe renal failure, uncontrolled diabetes mellitus or coronary heart disease. Since asterixis and hyperreflexia, as well as other more severe neurological conditions such as stupor or somnolence may interfere with safe and artefact-free MRI, patients with higher degrees of HE (grade 3 or 4) who also had these conditions were not considered for investigation. Also, patients needed to cooperate for neuropsychological examination and the patients' willingness represented a limitation in testing subjects with HE grade 3 or 4.

The severity of liver disease was determined according to the Child-Pugh-score<sup>[11]</sup>: patients were graded Child-Pugh A in nine cases, B in five and C in five.

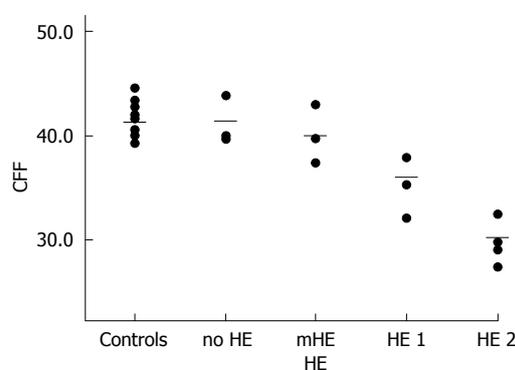

### Neuropsychological examination

Five computerized psychometric neurological tests were performed on each patient. The test battery included the visual pursuit test, motor performance series, Cognitron, Vienna reaction test and Tachistoscopic Traffic Test Mannheim for Screen (TAVTMB) as part of the Vienna Test System (Schuhfried GmbH, Mödling, Austria, 1999). mHE was diagnosed if a patient showed no clinical overt symptoms of HE and performed at  $< 1$  SD below the mean in at least two of the five computer psychometric tests of the test battery. Cirrhosis patients without clinical overt HE who performed at  $< -1$  SD in only one of the tests were graded as having no HE<sup>[12]</sup>. Overt encephalopathy was graded according to the

**Figure 1** CFF of controls and patients. HE grading and CFF (Hz). Circles indicate individuals' CFF, bars represent means of groups (mean CFF of controls: 41.3 Hz; mean CFF of group with no HE: 41.4 Hz; mean CFF of group with mHE: 40.0 Hz; mean CFF of group with HE 1: 36.1 Hz; mean CFF of group with HE 2: 30.2 Hz).

West-Haven criteria<sup>[13]</sup>. Cirrhosis patients were graded as no HE in five cases, mHE in three, HE 1 in six and HE 2 in five cases (Table 1).

In order to assess the severity of HE, the critical flicker frequency (CFF) was introduced in 2002. CFF is used in the evaluation of neurological deficits in low-grade HE and has been shown to respond readily to an improvement or deterioration of neurological symptoms<sup>[12]</sup>.

CFF was determined in each patient using the Schuhfried Test System (Eberhard, G. Schuhfried GmbH, Mödling, Austria, 1994). A flickering light of 650 nm wavelength and 5.3 mcd was used for intrafoveal stimulation, while the flickering frequency decreased at 0.5-0.01 Hz/s. The CFF was defined as the frequency needed to perceive initially the stimulus as non-continuous. The means of eight repeat tests were determined (Figure 1).

### MRI protocol

All scans were acquired on a 1.5-T clinical scanner (Magnetom Vision Plus; Siemens Medical Solutions, Erlangen, Germany) using the standard head coil. MTI was performed with two 2D gradient-echo sequences (TR 700 ms, TE 12 ms, flip angle  $\alpha = 20^\circ$ , one acquisition, 20 slices of 5 mm thickness, 0.5 mm gap), using a matrix

of  $224 \times 256$  pixels with a field of view of  $240 \text{ mm} \times 240 \text{ mm}$ . The first set of images was obtained with no saturation pulse. The latter sequence used a saturation pulse 1.5 kHz below H<sub>2</sub>O frequency, with a bandwidth of 250 Hz, 7.68 ms length and a flip angle of  $500^\circ$ . Additionally, routine examinations including T2- and T1-weighted imaging were performed to exclude patients with asymptomatic infarction or chronic ischemic changes.

### Image processing

For each subject, the MTR was quantified as a percentage of signal loss between the two images according to the following equation:  $\text{MTR} = (S_0 - S_s)/S_0 \times 100\%$ .  $S_0$  is the mean signal intensity of a pixel obtained from the sequence using no saturation pulse, and  $S_s$  is the mean signal intensity with the applied saturation pulse. Gray values in these secondary images represent MTR data, which yielded an MTR map.

Pixels that contained skull and soft tissue in the MTR maps were removed using the MRIcro-Software<sup>[14]</sup>. Images without skull and soft tissue pixels were used, since this has been reported to improve the validity of voxel-based evaluation of brain imaging data<sup>[14]</sup>.

The MTR maps that contained only brain pixels were normalized into a standardized space using statistical parametric mapping (SPM5) software<sup>[15]</sup>. An MTR template was generated to ensure reliable normalization. For this, the images of all individuals were smoothed with a Gaussian kernel of 3 mm full width at half maximum, and normalized to the standard SPM EPI-template (Montreal Neurological Institute). The mean of the 37 normalized images was used as an MTR template for the normalization of each original MTR map. The default spatial normalization settings were applied. A Gaussian kernel of 3 mm full width at half maximum was used for the smoothing of the images.

It has been reported that brain atrophy is present in cirrhosis patients<sup>[16]</sup> and that comparison of atrophied and normal brains may lead to systematic errors<sup>[17]</sup>. To assess, whether atrophy interferes with voxel-based analysis in patients with liver cirrhosis, a test with binary images was performed. Binary images were generated from the normalized images of all patients and controls using MRIcro-Software. Pixels that contained brain were given the value 1. Pixels that contained cerebrospinal fluid (CSF) were set to 0.

### Statistical analysis

Statistical mapping analysis has been applied in functional brain imaging [fMRI or positron emission tomography (PET)]. Recently, the method's successful use has been demonstrated in diffusion-weighted imaging<sup>[18]</sup>, fluid-attenuated inversion-recovery imaging<sup>[19]</sup>, perfusion-weighted imaging<sup>[20]</sup> and MTI<sup>[21]</sup>.

We conducted a voxel-based analysis using the statistical non-parametric mapping (SnPM5b) software<sup>[22]</sup> based on SPM5<sup>[15]</sup>. A non-parametric approach was chosen because uniform variance across the volumes was not given and group size did not permit parametric tests. SnPM uses a permutation approach to account

for the multiple comparison problem in voxel-by-voxel evaluation. It does not make the assumptions derived from random field theory underlying the multiple comparison corrections used in SPM<sup>[22]</sup>.

For all statistical models employed, a threshold of  $P < 0.001$  was used to determine significance. Non-parametric testing was conducted with 10000 random permutations when possible permutations exceeded this number. The anatomical localization of the maximum statistics was determined by co-examination of the SnPM (pseudo-)t map and the customized MTR template. The results are displayed as SnPM (pseudo-)t-map images superimposed on MTR maps of representative subjects.

Based on the hypothesis that cirrhosis patients (no HE, mHE, HE 1 and HE 2) had lower MTR values than controls, two-sample, one-sided permutation tests were conducted. Subject age was included as a confounder in the group comparison tests. Correlation between the MTR maps and CFF was tested. The binary images were tested on the hypothesis of a decreased brain volume in cirrhosis patients compared with controls.

## RESULTS

### MTR group comparisons

Compared with controls, cirrhosis patients without neurological deficits (no HE) displayed significantly decreased MTR values in the basal ganglia and in the hemispheric white matter (Table 2). The maximum statistics were located in the right putamen [(pseudo-)  $t = 4.60$ ,  $P = 0.0004$ ] (Figure 2). Statistics in the left putamen were (pseudo-)  $t = 2.65$ ,  $P = 0.0006$ . In the group with mHE, a significant MTR decrease was found in hemispheric white matter, deep grey matter, brainstem and cerebellum. The cluster exhibiting the maximum statistics was in the right putamen (pseudo-)  $t = 8.57$ ,  $P = 0.0008$ . Contralateral statistics were [(pseudo-)  $t = 5.72$ ,  $P = 0.0004$ ].

The groups with overt HE showed an MTR decrease in the entire brain. In HE 1, the maximum statistics were detected in the left posterior white matter [(pseudo-)  $t = 8.82$ ,  $P = 0.0001$ ]. The statistics of the right posterior white matter were (pseudo-)  $t = 4.70$ ,  $P = 0.0001$ . In HE 2, the maximum statistics were found in the left globus pallidus [(pseudo-)  $t = 17.98$ ,  $P = 0.0001$ ]. The statistics of the right globus pallidus were (pseudo-)  $t = 14.06$ ,  $P = 0.0001$ .

### Binary data comparison

The SnPM results showed significant differences in external and internal CSF space between cirrhosis patients and controls (Figure 3). Spatial extent and maximum (pseudo-)  $t$  was higher in the patients with overt HE.

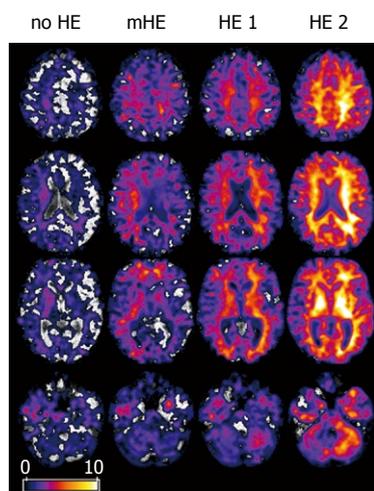

### Correlation of CFF and MTR

In the cirrhosis patients, a positive correlation between CFF and MTR was found in basal ganglia and in supra- and infratentorial white matter (Figures 4 and 5, Table 3). Largest statistics detected in a brain parenchyma cluster

## DISCUSSION

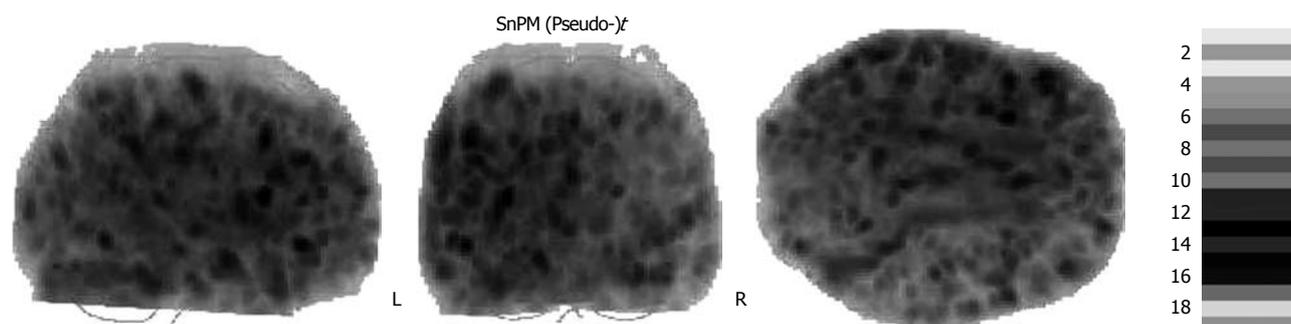

MTI is an application of MRI that is used to assess non-water components in tissue. As opposed to conventional

**Figure 4 (Pseudo-) $t$ -maps ( $P < 0.001$ ).** Areas with a correlation of subjects' CFF and MTR. Axial views superimposed on the MTR map of a representative subject (mHE). Colored areas represent voxels with significant positive correlation between CFF and MTR. The maximum statistics of a brain parenchyma cluster were found in left frontal white matter.

MRI, which is designed to represent different relaxation times in different tissues, MTI uses the exchange of magnetic properties between two brain tissue components: free water and macromolecules. Magnetization transfer takes place with and without physical exchange of protons between these two components. The extent of magnetization transfer is quantified using the ratio between two MR images. One image is acquired without and one with a high-frequency pulse that is designed to saturate the macromolecules. This results in a signal difference between the two images, as a result of the transfer of magnetization from free water protons towards macromolecules. The index derived from the two images can be calculated pixelwise and is rendered as an MTR map<sup>[23]</sup>. Changes in both components can lead to abnormal magnetization transfer. Depletion of macromolecules, a different macromolecule composition, as well as changes in brain water content may influence MTR.

Abnormal magnetization transfer is a known pathological feature in MRI of HE<sup>[24]</sup>. It has been reported to increase with the severity of HE. The present study provides a description of the distribution of these changes. In comparison to former studies that rely on simple ROI type analysis, a voxel-based approach was used to detect the localization of magnetization transfer changes in HE.

**Figure 5 (Pseudo-) $t$  results ( $P < 0.001$ ).** Voxel clusters with a correlation of subjects' CFF and MTR. SnPM glass brain representation of voxel clusters with a positive correlation between CFF and MTR (sagittal, coronal and axial view). A significant correlation was seen in all lobes.

### Spatial distribution of MTR abnormalities

MTR reduction in the brain of patients with cirrhosis involved white and grey matter, the brainstem and the cerebellum. The MTR decrease was more severe in patients with overt HE. The area of significantly reduced MTR was larger in patients with severe HE.

These results go beyond the findings of Iwasa *et al*<sup>[5]</sup>, who have reported decreased MTR values in anatomically defined areas of the brain (globus pallidus, putamen, thalamus, corona radiata and subcortical white matter) in 37 cirrhosis patients with mHE, compared to controls. They also support and exceed the reports of Córdoba *et al*<sup>[6]</sup>, Rovira *et al*<sup>[7]</sup> and Balata *et al*<sup>[9]</sup>, who have described a loss of magnetization transfer effect in frontal and parietal white matter. In patients without overt HE, the maximum statistics were in the right basal ganglia. Patients with HE 2 had a more severe loss of MTR, which was localized bilaterally and symmetrically.

The data suggest that encephalopathy in patients with liver cirrhosis is unlikely to be related to structural damage of a specific area of the brain. In the dysmetabolic situation that accompanies hepatic insufficiency, our data show a diffuse pattern of brain involvement.

Pathological MRI of basal grey matter in HE has been described before the advent of MTI. Hyperintensity in T1-weighted imaging in the globus pallidus of patients with cirrhosis is a frequent finding<sup>[25]</sup>. Basal ganglia hyperintensity has been demonstrated to be reversible after successful liver transplantation<sup>[26]</sup>. Manganese deposition is a suggested condition to shorten T1 in the basal ganglia of cirrhosis patients<sup>[3,27]</sup>, and to be an additive factor to the extrapyramidal symptoms in these patients<sup>[28]</sup>. In the mouse brain, significant shortening of T1 relaxation can be demonstrated after intravenous, intraperitoneal or subcutaneous administration of MnCl<sub>2</sub><sup>[29]</sup>. In a quantitative T1-mapping study of the brains of patients with liver cirrhosis and HE, Shah *et al*<sup>[30]</sup> have

reported T1-shortening for the globus pallidus, caudate nucleus, and posterior limb of the internal capsule. They have discussed manganese deposition as a possible reason for their findings. No significant correlation between HE severity and T1 relaxation time could be found in the putamen, frontal white matter, white matter of the corona radiata, white matter in the occipital lobe, the anterior limb of the internal capsule, visual cortex, thalamus, or frontal cortex<sup>[30]</sup>. Patients with stage 1-2 primary biliary cirrhosis have been shown to exhibit a decrease in pallidal MTR (normalized to putamen), which correlates with blood manganese concentration<sup>[31]</sup>.

In a study of diffusion-weighted imaging, Lodi *et al*<sup>[32]</sup> have reported increased diffusivity in white matter and basal ganglia, which suggests the presence of brain edema in chronic hepatic failure<sup>[32]</sup>. Increased diffusion in mHE and overt HE has been demonstrated to be reversible after successful treatment<sup>[33]</sup>. Both edema and manganese deposition may be explanations for the decrease in magnetization transfer effect.

White matter involvement in HE may be an effect of disturbed blood flow and energy metabolism<sup>[9]</sup>, demyelination<sup>[5]</sup>, axonal loss<sup>[5]</sup>, as well as an effect of astrocytic water retention<sup>[5-7,9,10]</sup>. The loss in magnetization transfer reflected in a decrease in MTR has been proposed to be associated with brain edema in neuropsychiatric systemic lupus erythematosus<sup>[34]</sup>, multiple sclerosis<sup>[35]</sup> and traumatic brain injury<sup>[36]</sup>. In non-cirrhotic patients with portal vein thrombosis, decreased MTR values of normal-appearing white matter have been found, which has been interpreted as an increase in free brain water<sup>[37]</sup>.

The presence of white matter edema in chronic liver dysfunction is supported by the above findings of Lodi *et al*<sup>[32]</sup> and Kale *et al*<sup>[33]</sup>, who reported increased diffusivity in white matter areas and in the basal ganglia.

MR spectroscopy has established the presence of a disturbed metabolic pattern in cirrhosis, which is considered

to represent a state of minimal brain swelling<sup>[26,38,39]</sup>. Reversibility after successful liver transplantation has been suggested to be an indicator of increased free cerebral water rather than structural damage<sup>[8]</sup>.

The maximum statistics in the groups without overt HE were in the right putamen. In patients with HE 1 and HE 2, the highest (pseudo-) *t* was located in the left hemisphere. In each of the four groups, the corresponding contralateral brain area exhibited strongly significant, yet slightly lower statistics. The limited group size and the lack of information about the patients' handedness hinder interpretation of this finding. Unilateral brain involvement is unlikely under dysmetabolic conditions, with clinical symptoms of lack of awareness, constructional apraxia, dyscalculia, personality change and asterixis. A non-focal alteration of the dominant hemisphere might be expected to yield a stronger correlation with neuropsychological test results, than the same alteration of the non-dominant hemisphere. Nevertheless, a structurally higher susceptibility of the dominant hemisphere to metabolic toxins might be worthy of discussion. Further studies will possibly be dedicated to this question.

### MTI and CFF

CFF assesses neurological deficits in cirrhosis as a continuous parameter, rather than offering the six-tier graduation used in the (revised) West-Haven criteria<sup>[40]</sup>. Since the test requires cooperation from the patients, its use in high-grade HE may be hindered. Patients suffering HE grade 3 and 4 were not enrolled in the present study. The CFF has been shown to be reliable in retest evaluation and responds rapidly to neurological deterioration or recovery<sup>[12]</sup>. Both parameters have been shown independently to decrease with increasing severity of HE<sup>[4,7,9,10,12]</sup>.

In an fMRI study, Zafiris *et al*<sup>[41]</sup> have found impaired activation of visual cortex and abnormal neuronal coupling in cirrhosis patients with decreased CFF. Alzheimer-II degeneration of glial Muller cells and mild visual impairment is another proposed mechanism of CFF decrease in HE<sup>[12]</sup>.

A positive correlation was found between CFF and cerebral MTR. Our findings indicate that the MTR of large areas of normal-appearing white matter and deep grey matter correlates with a decrease in CFF in patients with HE.

### Brain atrophy in HE

SnPM group comparison of the binary data sets showed prominent sulci, ventricles and lateral cerebral fissures as morphological correlations of brain atrophy.

In normal aging, a linear decrease in brain volume is known<sup>[42]</sup>. Although there was no significant difference between the mean age of patients ( $61.1 \pm 12.4$  years) and that of the control subjects ( $55.7 \pm 13.8$  years) in the present study, subject age was included in the analysis as a confounding variable. The findings from these images point towards an effect of cirrhosis on brain volume. Brain atrophy has been reported to be present in minimal and overt HE<sup>[27]</sup>, which correlates with poor psychometric performance<sup>[16,43]</sup>.

In voxel-based analysis following normalization, the comparison of normal and atrophied brains may lead to tests, in which voxels with mainly brain parenchyma in controls are tested against voxels that contain predominantly CSF in patients. This may result in non-valid differences. The topic of using the same spatial normalization algorithm for anatomically normal and atrophied brains has been addressed by Ishii *et al*<sup>[17]</sup>. Comparing SPM and NEUROSTAT normalization methods for the analysis of PET images in Alzheimer's disease, the authors have concluded that brains with atrophy tend to show artefacts caused by the anatomical standardization process.

In an MRI and PET study of schizophrenia, SPM results were deemed invalid because of incorrect spatial normalization of atrophied brains. This led to an underestimation of metabolic activity in the caudate nucleus in patients with schizophrenia<sup>[44]</sup>.

The present work shows a correlation between MTR and CFF in intraventricular and superficial voxels. This may be attributed to unreliable normalization of brains with atrophy in the patient group. Evaluating cortical or periventricular MTR values is limited by this effect.

In conclusion, in the brains of patients with non-alcoholic liver cirrhosis, MTR loss is seen. It involves basal ganglia and white matter, even in mild stages of HE. The changes are more severe and spatially more extended in patients with HE. Maximum statistics were found in the basal ganglia in overt HE, compared to healthy controls. The correlation of MTR and CFF is strongest in frontal white matter. Analyses of cerebral MTI of patients with liver cirrhosis might profit from inclusion of both basal ganglia and frontal white matter.

## COMMENTS

### Background

Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis and is associated with poor prognosis. Many studies have shown that magnetization transfer imaging (MTI) of the brain is sensitive to HE and subclinical forms of this condition [minimal HE (mHE)]. Treatment as well as induction of HE has been monitored successfully with MTI. Edema with water accumulation is a possible mechanism for MTI changes. Many brain areas have been investigated with MTI, but no systematic evaluation of the spatial pattern of MTI abnormalities in HE has been published.

### Research frontiers

In the area of brain imaging in liver cirrhosis, the research hotspot is whether magnetic resonance imaging (MRI) can be used to detect HE early and to monitor its treatment. MTI is a MRI technique that is used to assess the interaction of free water protons and macromolecules. MTI is a promising research tool to assess minimal brain edema in HE.

### Innovations and breakthroughs

In the previous application of MTI in HE, alterations have been reported for various brain areas such as the frontal and posterior white matter, basal ganglia and thalamus. More recent studies have demonstrated the sensitivity of MTI in mHE. These studies used simple region-of-interest (ROI) evaluations. The selection of ROIs was based on *a priori* assumptions from reports on white matter MRI anomalies and manganese deposits in the basal ganglia. To the best of the authors' knowledge, no systematic assessment of the distribution of brain MTI changes has been published on which to base the selection of ROIs in the imaging of HE. In the present study, they performed a voxel-based analysis (VBA) of MTI data of patients with HE and showed that abnormal signals were present throughout the brain. No one specific area was present where MTI changes in manifest HE were exclusive.

## Applications

The study results suggest that MTI changes in HE are present throughout the brain. Test results in frontal and posterior white matter, thalamus and basal ganglia were statistically significant in cases with mHE, which might be areas that could be used as ROIs in monitoring HE by means of MTI.

## Terminology

HE is a neurological condition with fatigue, sleeping disorders and motor deficits caused by liver cirrhosis. MTI is an MRI technique that is used to assess the interaction of free water protons and macromolecules, e.g. in mild brain edema. ROI is a means of evaluating MR images of the brain by measuring an image parameter in a defined area. VBA is a statistical evaluation of the entire brain MRI data of a study population.

## Peer review

The manuscript entitled "Voxel-based analyses of magnetization transfer imaging of the brain in hepatic encephalopathy" is an interesting study that aimed to evaluate the spatial distribution of cerebral abnormalities in cirrhosis patients with and without HE found in MTI.

### Abstract

**AIM:** To develop a protocol for direct hepatic lineage differentiation from early developmental progenitors to a population of mature hepatocytes.

**METHODS:** Hepatic progenitor cells and then mature hepatocytes from mouse embryonic stem (ES) cells were obtained in a sequential manner, induced by valproic acid (VPA) and cytokines (hepatocyte growth factor, epidermal growth factor and insulin). Morphological changes of the differentiated cells were examined by phase-contrast microscopy and electron microscopy. Reverse transcription polymerase chain reaction and immunocytochemical analyses were used to evaluate the gene expression profiles of the VPA-induced hepatic progenitors and the hepatic progenitor-derived hepatocytes. Glycogen storage, cytochrome P450 activity, transplantation assay, differentiation of bile duct-like structures and tumorigenic analyses were performed for the functional identification of the differentiated cells. Furthermore, FACS and electron microscopy were used

for the analyses of cell cycle profile and apoptosis in VPA-induced hepatic differentiated cells.

**RESULTS:** Based on the combination of VPA and cytokines, mouse ES cells differentiated into a uniform and homogeneous cell population of hepatic progenitor cells and then matured into functional hepatocytes. The progenitor population shared several characteristics with ES cells and hepatic stem/progenitor cells, and represented a novel progenitor cell between ES and hepatic oval cells in embryonic development. The differentiated hepatocytes from progenitor cells shared typical characteristics with mature hepatocytes, including the patterns of gene expression, immunological markers, *in vitro* hepatocyte functions and *in vivo* capacity to restore acute-damaged liver function. In addition, the differentiation of hepatic progenitor cells from ES cells was accompanied by significant cell cycle arrest and selective survival of differentiating cells towards hepatic lineages.

**CONCLUSION:** Hepatic cells of different developmental stages from early progenitors to matured hepatocytes can be acquired in the appropriate order based on sequential induction with VPA and cytokines.

### INTRODUCTION

Hepatocyte transplantation is an alternative therapy strategy for liver failure or end-stage liver diseases<sup>[1,2]</sup>.

However, the shortage of donor hepatocytes and the difficulties for large scale hepatocyte amplification and function maintenance limit the clinical application of this cell-based therapy<sup>[3]</sup>. Embryonic stem (ES) cells, known for their capacity to proliferate indefinitely and differentiate into almost all types of cells including hepatocytes, have raised the hope of cellular replacement therapy for liver failure. The essential prerequisite for this purpose is to develop well-defined protocols for directing cellular differentiation into hepatic lineage, followed by selective isolation and proliferation *in vitro*. There have been several protocols available up till now for hepatic fate specification from ES cells, for example, the protocols based on spontaneous differentiation, combination of growth factors, co-culture with non-parenchymal liver cells and gene modifications<sup>[4-8]</sup>. However, most of the protocols currently used were devised to induce mature hepatocytes by using embryoid bodies that may result in low yield or purity of functional hepatocytes. Little documentation exists about a strategy for acquiring different developmental hepatic cells, for example, guiding differentiation of ES cells to hepatic progenitors and then to an entire population of mature hepatocytes to meet the requirements of precise study regarding the mechanisms of hepatic differentiation and potential clinical applications. Furthermore, more concise and reproducible methods to acquire abundant hepatic cells still remain to be developed, among which the direct hepatic differentiation from an ES monolayer without using embryoid bodies is most promising<sup>[9]</sup>.

Valproic acid (VPA), a histone deacetylase (HDAC) inhibitor, has been used as a new class of chemotherapeutic drug for cancer clinical purposes and as an inducer for stem cell differentiation<sup>[10-13]</sup>. It has exhibited profound therapeutic activity against hepatocellular carcinoma by inducing apoptosis and cell-cycle arrest<sup>[14-16]</sup>, and dramatic effects on cellular differentiation from stem cells, including cardiomyocyte differentiation from ES cells, neuronal differentiation from neural stem cells, and osteogenic and hepatic differentiation from bone marrow-derived mesenchymal stem cells (MSC)<sup>[17-20]</sup>. In a previous study, we established a method for hepatic differentiation from MSC using VPA, which provided preliminary evidence that VPA could facilitate hepatic differentiation<sup>[21]</sup>. However, little is known about whether VPA can induce the hepatic differentiation of ES cells. Here, we report such research and the development of a protocol for direct hepatic lineage differentiation, from early developmental progenitors to a population of mature hepatocytes, based on sequential induction with VPA and cytokines. Results show that VPA can direct the hepatic specification of ES cells and largely participates in the differentiation of ES cells into hepatic progenitors. Further differentiation of hepatic progenitors into mature hepatocytes requires supplementation with cytokines. The present study may not only be helpful for the clinical application of hepatocyte transplantation, but also provide an *in vitro* research model for the better investigation and understanding of the entire develop-

mental process of hepatocytes, from ES cells to hepatic progenitors, and then to mature hepatocytes. Furthermore, as VPA is an epigenetic modulator, so our results may also be of benefit to the research of mechanisms of epigenetic modifications during liver development.

## MATERIALS AND METHODS

### Reagents

VPA was purchased from Sigma (St Louis, MO); fetal bovine serum (FBS) was purchased from Hyclone (Rockville, MD); murine leukemia inhibitory factor (LIF) was purchased from Chemicon (Temecula, CA); mouse hepatocyte growth factor (mHGF), mouse epidermal growth factor (mEGF), oncostatin M (OSM), Insulin-Transferrin-Selenium (ITS), and collagen I were all from R&D systems (Minneapolis, MN); Matrigel was purchased from BD Biosciences (Palo Alto, CA); sheep anti-ALB antibodies were purchased from Biodesign (Saco, ME); rabbit anti-AFP, mouse anti-CK19 were from Dako (Copenhagen, Denmark); rat anti-OCT-4 was from R&D; mouse anti-SSEA-1 was from Developmental Hybridoma Bank of Iowa University; goat anti-mouse DLK was from Santa Cruz Biotechnology (Santa Cruz, CA, USA); rat anti-A6 was presented by Dr. Valentina Factor of NIH; FITC-conjugated bovine anti-sheep IgG, FITC-conjugated rabbit anti-goat IgG, FITC-conjugated goat anti-rabbit IgG, TRITC-conjugated goat anti-mouse IgG, TRITC-conjugated goat anti-rat IgG were all purchased from Dako; FITC-conjugated goat anti-mouse IgM was from Jackson Immunoresearch Laboratories Inc. All other reagents were from Sigma (St. Louis, MO).

### Culture of mouse ES cells

Mouse ES D3 cells, provided by the Cell Biology Institute of the Chinese Academy of Sciences, were cultured on mitomycin C inactivated MEF feeder layers in high-glucose DMEM supplemented with 15% FBS, 2 mmol/L L-Glu, 0.1 mmol/L N-ME, 1% NEAA and 10 ng/mL murine LIF as described previously<sup>[22]</sup>. Briefly, MEF feeder cells were isolated from ICR mice at embryo day 13.5 and cultured at 37°C and 5% CO<sub>2</sub>. At approximately 80% confluence, the feeder cells were incubated with 10 µg/mL mitomycin C for 4 h and washed three times with PBS. Then the cells were replated at  $8 \times 10^4$  cells/cm<sup>2</sup> on to tissue culture flasks. After allowed for attachment overnight, the ES cells were seeded.

### Differentiation of hepatic cells from mouse ES cells

A protocol was designed to obtain the hepatic progenitor cells and then mature hepatocytes from mouse ES cells in a sequential manner (Figure 1). For differentiation of hepatic progenitor cells, ES cells were cultured in DME medium as described above with the exception of the withdrawal of feeder layer and LIF, and treated with 1 mmol/L VPA for 4-6 d, then the VPA was removed and recombinant mouse HGF 10 ng/mL was added for

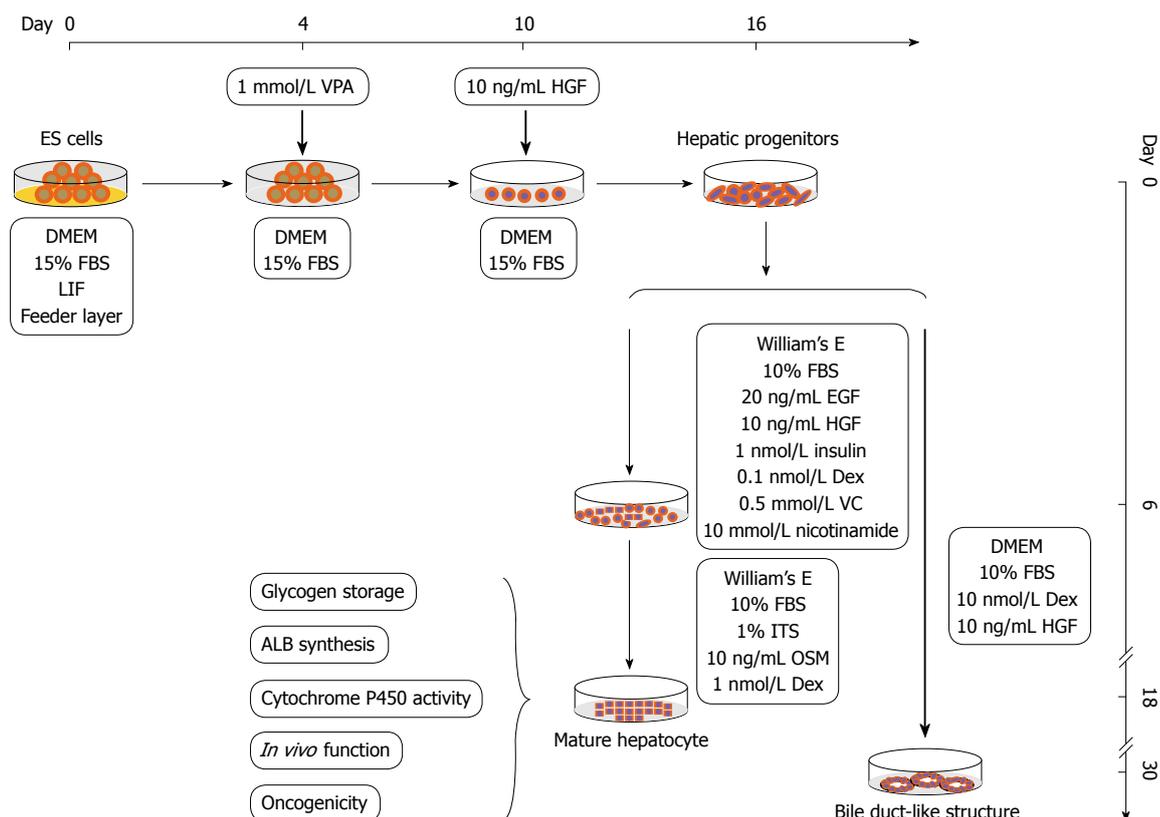

Figure 1 Schematic presentation of the protocol.

another 6-12 d until the hepatic progenitor cells became confluent. For differentiation of hepatocytes from hepatic progenitor cells, the progenitor cells were cultured in a William's E medium supplemented with 20 ng/mL mEGF, 10 ng/mL mHGF,  $10^{-6}$  mol/L insulin,  $10^{-7}$  mol/L Dex, 0.5 mmol/L ascorbic acid diphosphate, 10 mmol/L nicotinamide and 10% FBS (maturation medium I) for 6 d, and then replaced with another William's E medium containing 1% ITS, 10 ng/mL OSM and  $10^{-6}$  mol/L Dex (maturation medium II) for another 6-12 d.

#### Molecular and structural identification of the differentiated cells

**Gene expression analyses:** Total RNA was extracted from the ES cells, hepatic progenitor cells, mature hepatocytes and adult mouse liver using Nucleospin RNA Kits (BD Biosciences, Palo Alto, CA). RNA samples were digested with DNase I for 15 min at room temperature. cDNAs were synthesized from 1  $\mu$ g total RNA with a superscript III first-strand synthesis kit (Invitrogen, Carlsbad, CA) according to the manufacturer's instructions, and amplified with the following program: initial denaturation at 95°C for 5 min followed by 30-40 cycles of 94°C for 30 s, 50-56°C for 30 s, 72°C for 30 s and final extension at 72°C for 10 min. The amplified products were analyzed by electrophoresis on 1.5% agarose gel and stained with ethidium bromide. All the primers used are listed in Table 1.

**Immunocytochemical analyses:** Cells were fixed using 4% paraformaldehyde (PFA) followed by ice-cooled

methanol, and incubated with primary antibodies overnight at 4°C after blocking with 5% normal goat serum. For the application of SSEA-1 antigen, the cells were fixed with PFA only. Following washing with PBS three times, the cells were incubated with fluorescence-conjugated secondary antibodies, and examined under a Carl Zeiss confocal laser-scanning microscope.

**Electron microscopy:** Cells were fixed in 2.5% glutaraldehyde in 0.1 mmol/L phosphate buffer saline (pH 7.4) at 4°C for 24 h, post-fixed in 1% OsO<sub>4</sub> for 1 h, and embedded in Epon 812. They were cut into 30-40 nm sections for ultrastructural evaluation using a Philips TECNAL-10 transmission electron microscope.

#### Functional identification of the differentiated cells

**Glycogen storage:** At the final stage of differentiation, the cells were assessed by periodic acid-Schiff reaction for glycogen storage as previously described<sup>[23]</sup>. Briefly, cells were fixed in Carnoy's solution, oxidized in 1% periodic acid, treated with Schiff's reagent and examined under a Nikon microscope.

**Cytochrome P450 activity:** Cytochrome P450 activity was examined by ethoxyresorufin O-dealkylase assay. Briefly, cells were maintained under the same conditions in the presence or absence of 5  $\mu$ mol/L phenobarbital for 24 h followed by treatment with 5  $\mu$ mol/L ethoxyresorufin for 2-3 h, and then observed under Carl Zeiss confocal laser-scanning microscope at 355 nm excitation and 581 nm emission.

AFP:  $\alpha$ -fetoprotein; HNF: Hepatocyte nuclear factor; TTR: Transthyretin; DPPIV: Cytokeratin 18; ALB: Albumin; OCT4: Octamer-4; AAT:  $\alpha$ -1-antitrypsin; Dlk:  $\Delta$ -like (Pref-1, preadipocyte factor-1); G6p: Glucose-6-phosphatase; TAT: Tyrosine aminotransferase; TDO: Tryptophan 2,3-dioxygenase; BG: Biliary glycoprotein; GGT:  $\gamma$ -glutamyl transpeptidase.

**Transplantation assay:** To evaluate the *in vivo* function of differentiated hepatocytes, a transplantation assay was performed in CCl<sub>4</sub>-intoxicated mice as previously described<sup>[24]</sup>. Five ICR mice were injected intraperitoneally with 10% CCl<sub>4</sub> in olive oil (1 mL/kg body weight). After 6 h, mice underwent intrasplenic transplantation of differentiated hepatocytes at  $1 \times 10^6$  cells ( $0.1 \text{ mL}$  of  $1 \times 10^7$  cells/mL) per mouse. The injection site was ligated to prevent cell leakage and bleeding. Mice were then sacrificed 24 h after transplantation, and sera were collected separately. Liver function was assessed by measuring the total bilirubin (T-Bil), ALT, AST and urea levels. Ten CCl<sub>4</sub>-intoxicated and untreated mice were used as controls.

**Differentiation of bile duct-like structures:** To evaluate the differentiation potential of progenitors into cholangiocytes, a spontaneous and directed bile duct-like structural differentiation assay was designed. For spontaneous differentiation, the progenitors were inoculated into the collagen I coated 96-well plate, and cultured with William's E medium supplemented with  $10^{-6}$  mol/L Dex, 10 ng/mL mHGF for 20-40 d until the special bile duct-like structures appeared. For directed differentiation,

the progenitors were seeded on a layer of Matrigel basement membrane matrix and cultured in the medium supplemented with 100 ng/mL mHGF and 50 ng/mL mEGF until the bile duct-like structures formed. Media were changed every 3 d.

**Tumorigenic analyses:** Undifferentiated ES cells and the hepatic progenitor cells were collected and suspended in DMEM medium ( $1 \times 10^7$  cells/mL). A 0.2 mL aliquot was injected subcutaneously into the backs of Balb/C nude mice. Each experimental group contained three animals. The animals were kept under a controlled lighting schedule with a 12-h dark period. Food and water were available *ad libitum*. All animals received humane care in compliance with institutional guidelines. Mice were sacrificed 6-8 wk after transplantation, the tumors and tumor-like tissues were fixed with formalin. After additional fixation in 4% paraformaldehyde for 2 h at 4°C, tissues were embedded in paraffin. Sections were stained with hematoxylin and eosin, and then microscopically observed.

#### Cell cycle and apoptosis analyses

Flow cytometry was performed to measure cell cycle distribution and apoptosis of VPA-treated cells. The measurements were made with a Becton Dickinson FACS Calibur machine, adapted for excitation with a 488 nm argon laser, and 582/42 nm band-pass filter for detecting propidium iodide emission.

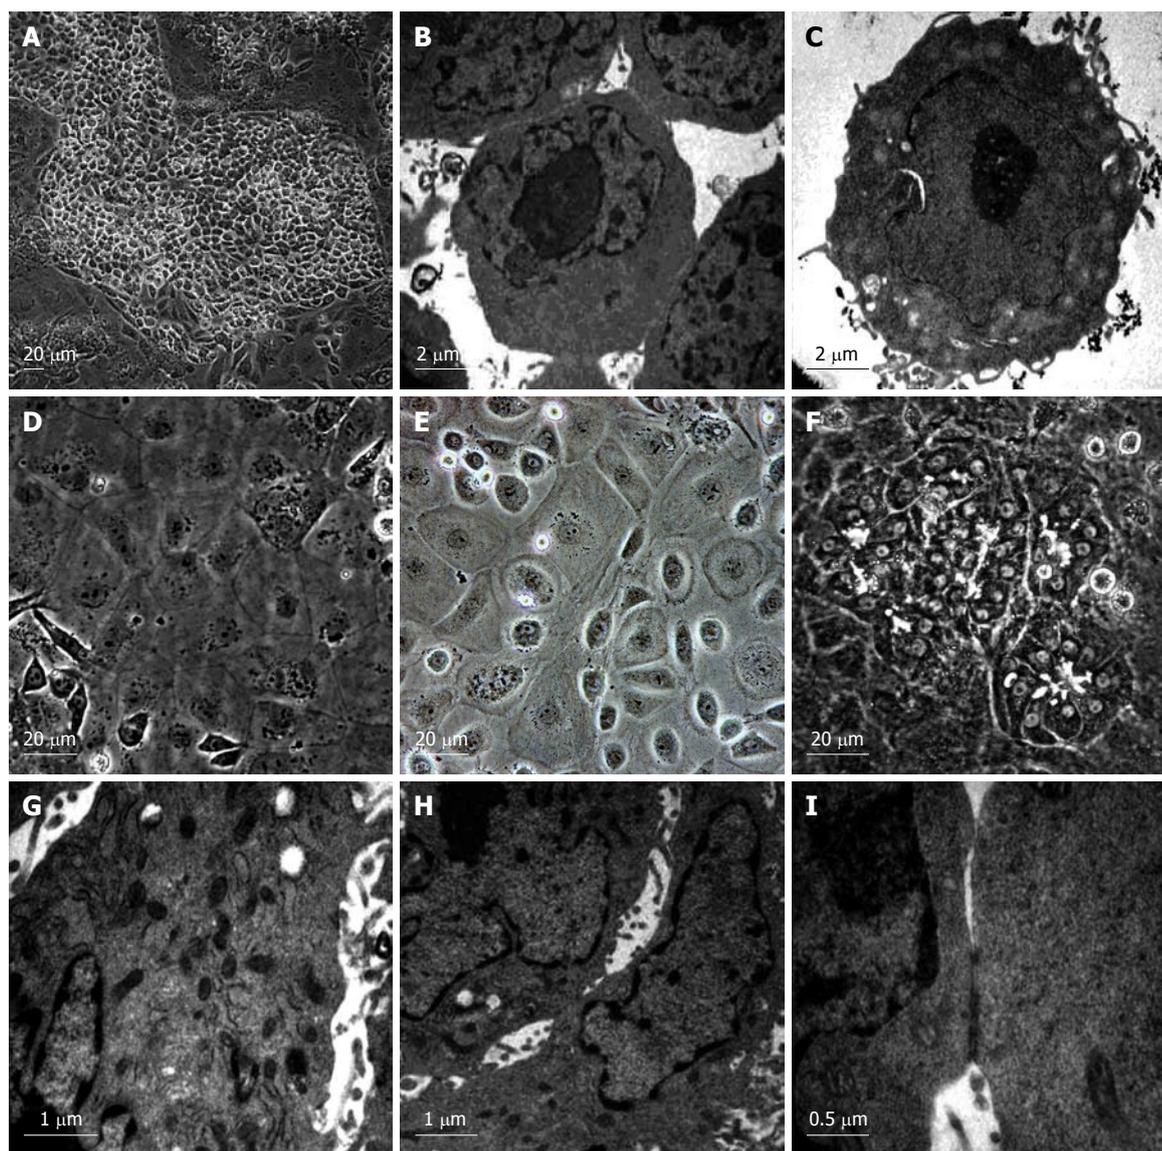

#### Statistical analysis

The data are presented as mean  $\pm$  SD. Statistical tests for the significance of differences between control and transplanted mice were performed by way of Student's *t* test.  $P < 0.05$  was considered as statistically significant.

## RESULTS

### Differentiation of hepatic progenitors from mouse ES cells induced by VPA

To examine whether VPA has an effect on hepatic fate differentiation from mouse ES cells, the ES cultures were subjected to VPA (1 mmol/L) after withdrawing feeder layers and LIF. After treatment for 4-6 d, a small round-shaped progenitor-like population appeared. These cells were then treated with recombinant mouse HGF (10 ng/mL) which allowed the promotion of cellular proliferation. After another 6-12 d, this progenitor-like population underwent rapid growth, and finally proliferated into confluence. The acquired progenitor-like cells exhibited 8-10  $\mu\text{m}$  in diameter, scant cytoplasm and a high nuclear to cytoplasmic ratio (Figure 2A), and resembled the blast-like oval cells proliferating during severe liver injury or the hepatoblasts found in fetal liver. Electron microscopic observation showed that the progenitor-like cells had abundant cell surface microvilli and shared scanty organelles except for a few mitochondria as in ES cells (Figure 2B and C). Noticeably, it was found that few mature functional hepatocytes

**Figure 2 Morphological observation of the differentiated cells.** A: Morphology of hepatic progenitor cells induced by VPA; B: Electron microscopic observation of the undifferentiated ES cells (control); C: Electron microscopic observation of the hepatic progenitor cells differentiated from ES cells; D, E: Morphological observation of typical hepatocytes differentiated from hepatic progenitor cells with flattened and cuboidal morphology, and acquired abundant granules in the cytoplasm; F: Morphological observation of another kind of hepatocyte-like cells differentiated from hepatic progenitor cells with rising and piled morphology, dark cytoplasm and light nuclei, and bile canaliculi-like structures found between these cells; G: Electron microscopic observation of the differentiated hepatocytes with abundant mitochondria in their cytoplasm; H: Electron microscopic observation of the bile canaliculi between adjacent cells as mentioned above (Figure 1F); I: The bile canaliculi between adjacent cells sealed with tight junctions.

could be acquired by treating the ES cells with VPA independently, and further differentiation into mature hepatocytes needed the combination of various cytokines, which indicated that VPA probably participates mainly in the regulation of early hepatic differentiation.

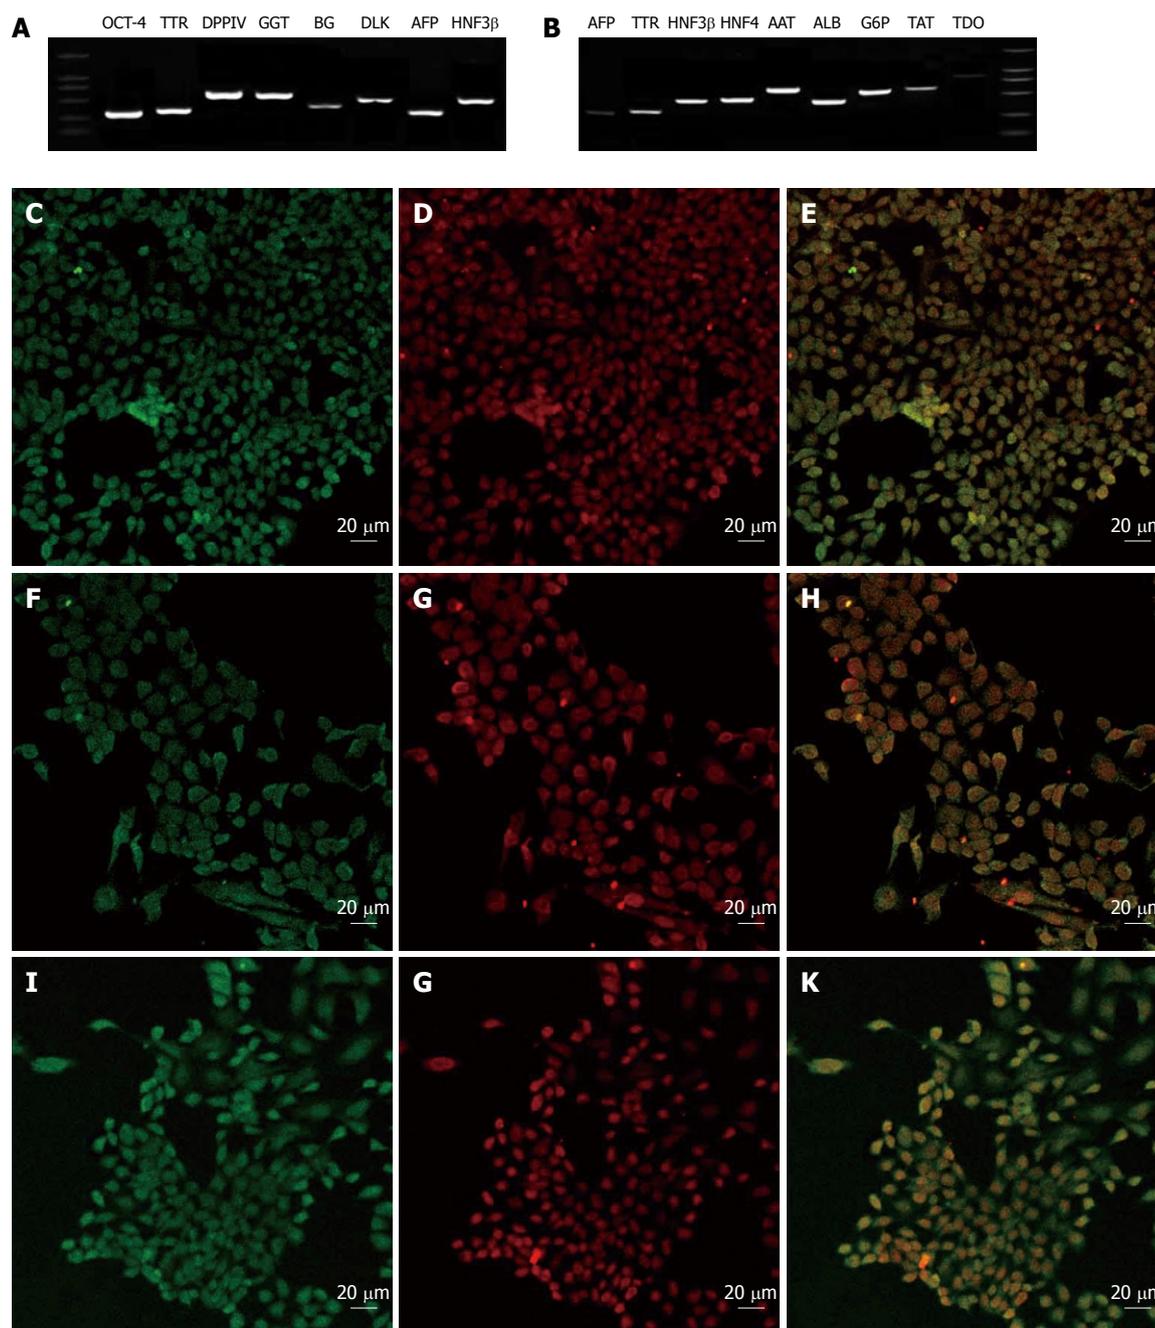

#### **Differentiation of hepatocytes from progenitors**

For maturation of functional hepatocytes from hepatic progenitors, the progenitor cells were further cultured in William's E medium (containing 10% FBS) supplemented with cytokines (EGF, HGF and insulin) and chemical inducers (Dex, ascorbic acid diphosphate and nicotinamide) for 6 d. Then, the cells were cultured in another medium containing ITS, OSM and Dex. After 6-12 d, two kinds of hepatocyte-like cells appeared. One exhibited typical hepatocyte features with a diameter of 20-40  $\mu\text{m}$ ,

flattened and cuboidal morphology, and had acquired abundant granules in the cytoplasm (Figure 2D and E). The other displayed a rising/piled morphology with dark cytoplasm and light nuclei, and bile canaliculi-like structures were often found between these cells (Figure 2F). Ultrastructural analyses revealed that both kinds of hepatocyte-like cells contained numerous mitochondria and endoplasmic reticulum (Figure 2G). Bile canaliculi were also observed between adjacent cells and sealed with tight junctions (Figure 2H and I). These results showed that functional hepatocytes could be acquired from VPA-induced progenitors under sequential induction combinations.

#### **Molecular identification of the hepatic lineage cells**

To evaluate the characterization of the VPA-induced hepatic progenitors and the hepatic progenitor-derived

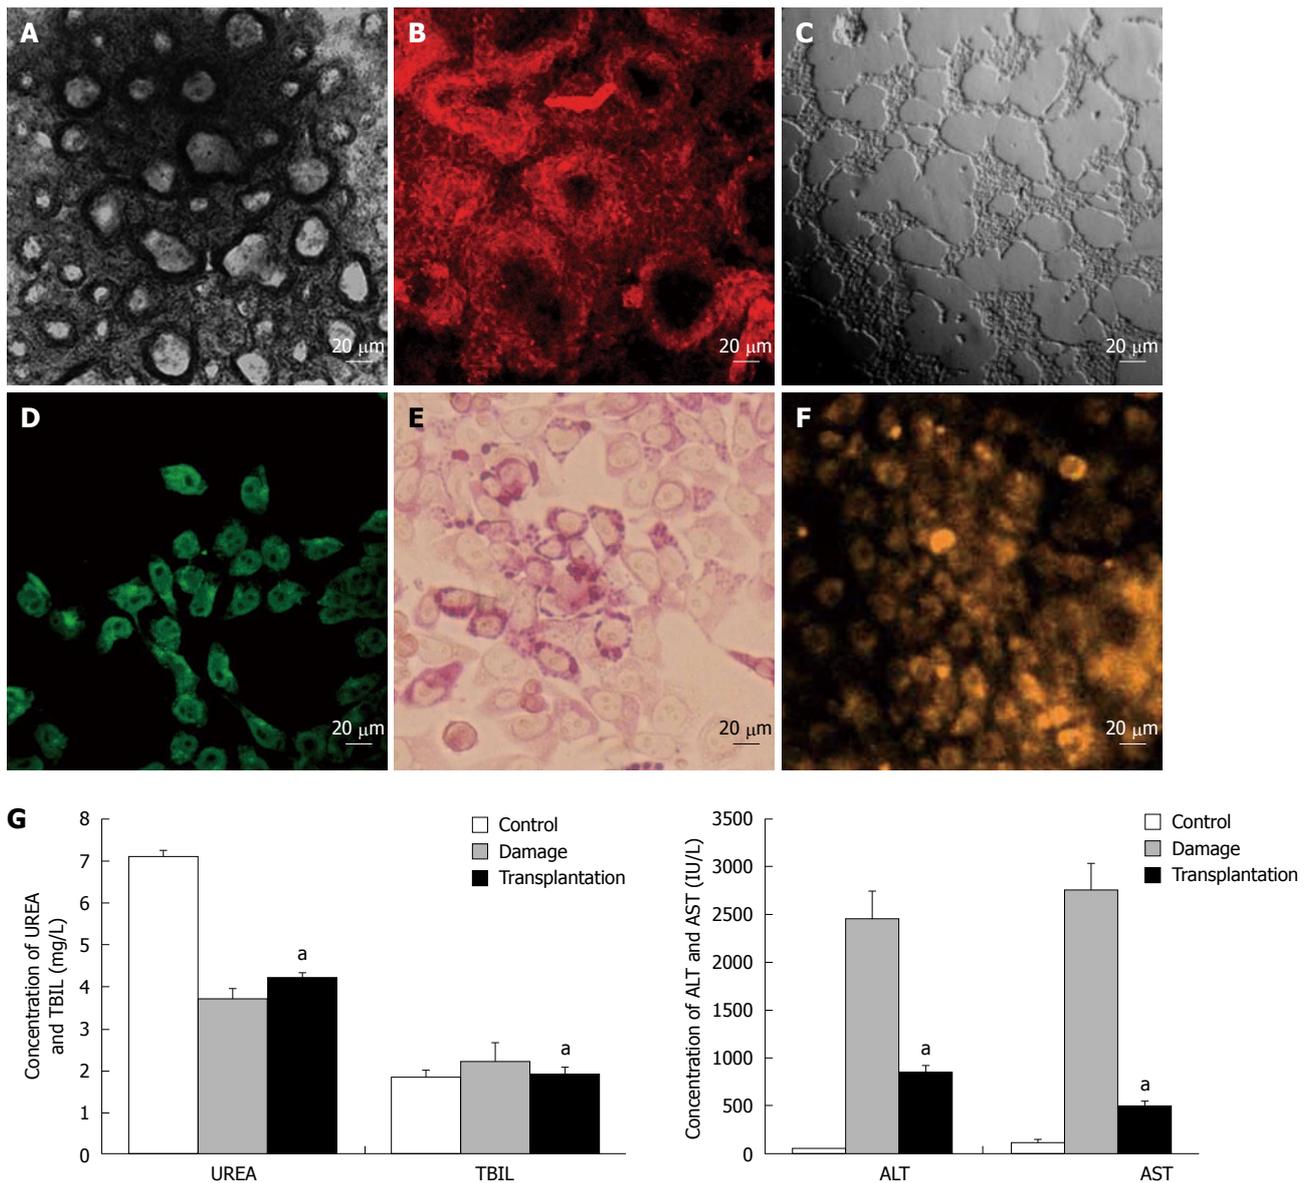

**Figure 3** Gene expression analysis of VPA-induced hepatic lineage cells by RT-PCR and immunofluorescence staining. A: RT-PCR showed hepatic progenitor cells after the treatment with valproic acid expressing most typical markers of hepatic/hepatic stem cells; B: The hepatic progenitor-derived hepatocytes expressing typical markers of mature liver cells; C-E: Immunofluorescent images of AFP (C) and OCT-4 (D) staining in VPA-induced hepatic progenitor cells (E is the merged image of C and D); F-H: Immunofluorescent images of AFP (F) and CK19 (G) staining in VPA-induced hepatic progenitor cells (H is the merged image of F and G); I-K: Immunofluorescent images of AFP (I) and DLK (J) staining in VPA-induced hepatic progenitor cells (K is the merged image of I and J).

hepatocytes, a number of gene expression profiles were examined at mRNA and/or protein levels. The results showed that the undifferentiated ES cells expressed SSEA-1 and OCT-4, but no hepatic markers (data not shown). However, the progenitor cells expressed most typical markers of hepatic/hepatic stem cells, such as AFP, TTR, DPPIV, GGT, BG, HNF3 $\beta$ , CK19 and Dlk (Figure 3), but did not express the ES marker SSEA-1 or mature hepatocyte marker ALB (data not shown). Interestingly, the progenitor cells expressed the ES cell marker OCT-4, which suggested that the VPA-induced

hepatic progenitor cells may share partial properties of ES cells (Figure 3A and D). Accordingly, the hepatic progenitor-derived hepatocytes expressed typical markers of mature liver cells, including ALB, AAT, HNF4, G6p, TAT, AFP, TTR, HNF3 $\beta$  and TDO (Figure 3B).

#### **Functional characterization of the hepatic lineage cells**

For functional evaluation of the progenitor cells, the *in vitro* bi-differentiation potential of the progenitors into bile duct-like structures and mature hepatocytes was determined. The results showed that bile duct-like structures

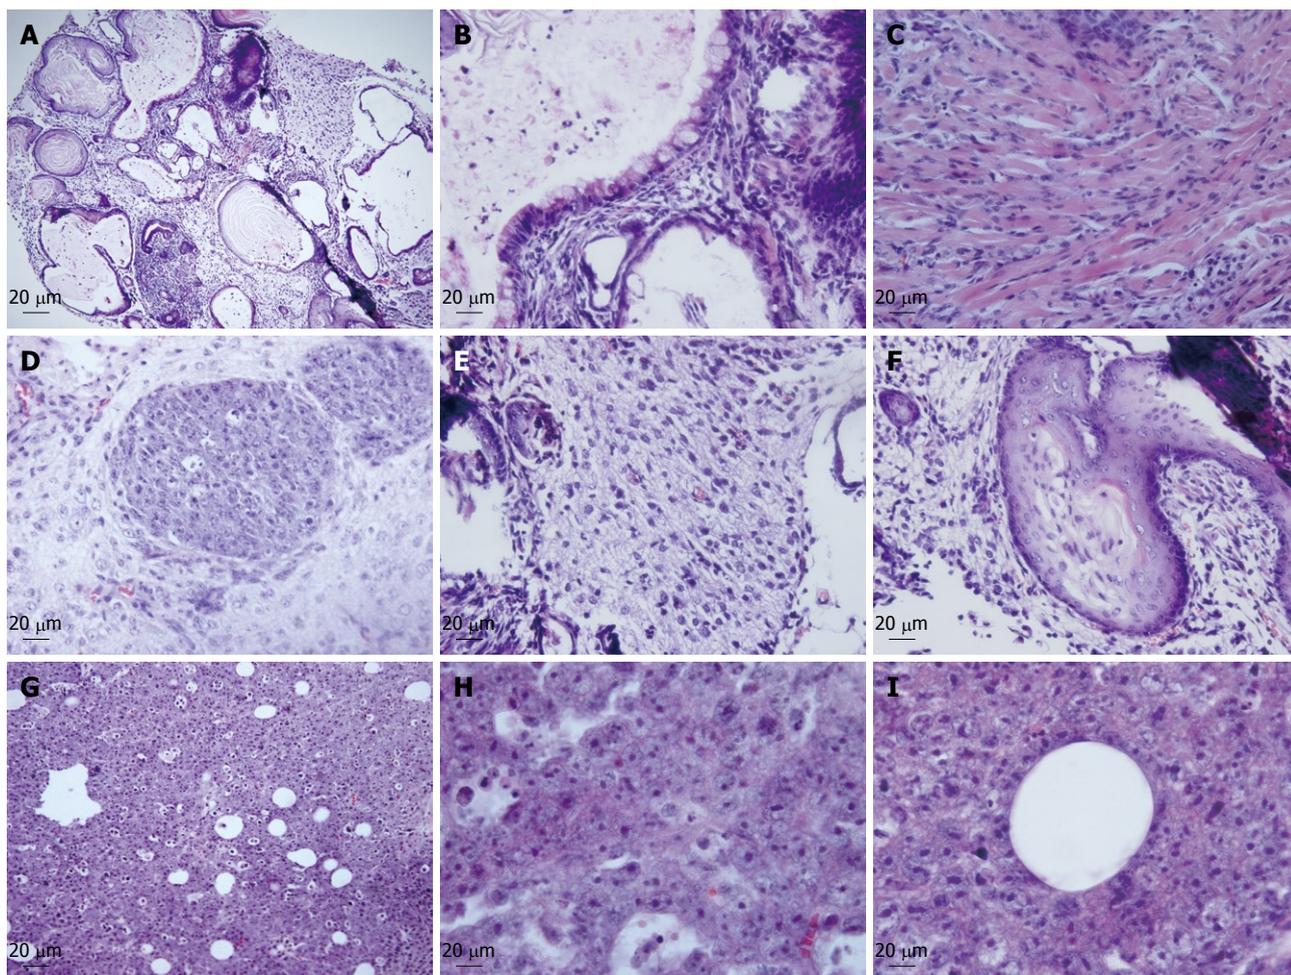

**Figure 4 Functional characterization of the hepatic lineage cells.** A: Bile duct-like structures formed from the VPA-induced hepatic progenitor cells cultured on collagen I coated dishes; B: Bile duct-like structures were stained CK19 positive; C: Bile duct-like structures formed from the VPA-induced hepatic progenitor cells cultured on Matrigel basement membrane matrix; D-F: Differentiated hepatocytes from hepatic progenitor cells could synthesize albumin (D), store glycogen (E) and possessed cytochrome P450 activity (F) after induction for 2-3 wk; G: When ES-HPCs derived hepatocytes were transplanted 6 h after liver intoxication, serum total bilirubin (TBIL), serum ammonia (UREA), AST and ALT levels were significantly improved towards normal at 1 d after the transplantation. <sup>a</sup> $P < 0.05$ .

could be formed from the progenitor cells in two ways. In the first way, the progenitor cells were cultured on collagen I coated dishes in the medium supplemented with  $10^{-6}$  mol/L Dex and 10 ng/mL mHGF for about 30 d until the foci of small dark cells appeared, and these foci became organized and developed as doughnut-like structures identical to bile duct units (Figure 4A). In the second way, the progenitor cells were seeded on a layer of Matrigel basement membrane matrix and cultured in the medium supplemented with 100 ng/mL mHGF and 50 ng/mL mEGF as previously described. Many well-defined duct-like structures comprised of neatly aligned cells were found throughout the dish 1-2 d after inoculation, which developed into spherical 3-dimensional structures consisting of tightly packed columnar epithelium along with a central lumen when further maintained

for another 15 d (Figure 4C). Immunofluorescence analysis demonstrated that the structures were CK19-positive (Figure 4B) and AFP-negative (data not shown), which are typical hallmarks seen in the bile duct.

Accordingly, typical hepatocytes could also be attained from the progenitors as mentioned above. Functional characterization analyses showed that the differentiated hepatocytes could synthesize albumin (Figure 4D), store glycogen (Figure 4E) and possessed cytochrome P450 activity (Figure 4F) after differentiation for 2-3 wk. Furthermore, an *in vivo* transplantation assay of hepatocytes in acute-injured liver was performed. The results showed that when the differentiated hepatocytes were transplanted 6 h after liver intoxication, serum T-Bil, serum ammonia, AST and ALT levels were significantly ( $P < 0.05$ ) improved towards normal levels compared to con-

**Figure 5** *In vivo* multi-differentiation potential and tumorigenic analyses. A-F: The teratomas derived from ES cells were composed of a variety of types of differentiated cells from all three primary germ layers including secretory glands (B), muscle (C), epithelium (D), neuroectodermal cells (E) and cartilage (F); G-I: The tumor-like bumps derived from ES-HPCs contained only epithelial (H) and mesenchymal-like cells, and duct-like structures (I) surrounded by several epithelial cells were also observed.

trol mice without hepatocyte transplantation (Figure 4G), suggesting that the hepatocytes functioned normally *in vivo* and their transplantation improved the liver function of CCl<sub>4</sub>-treated mice.

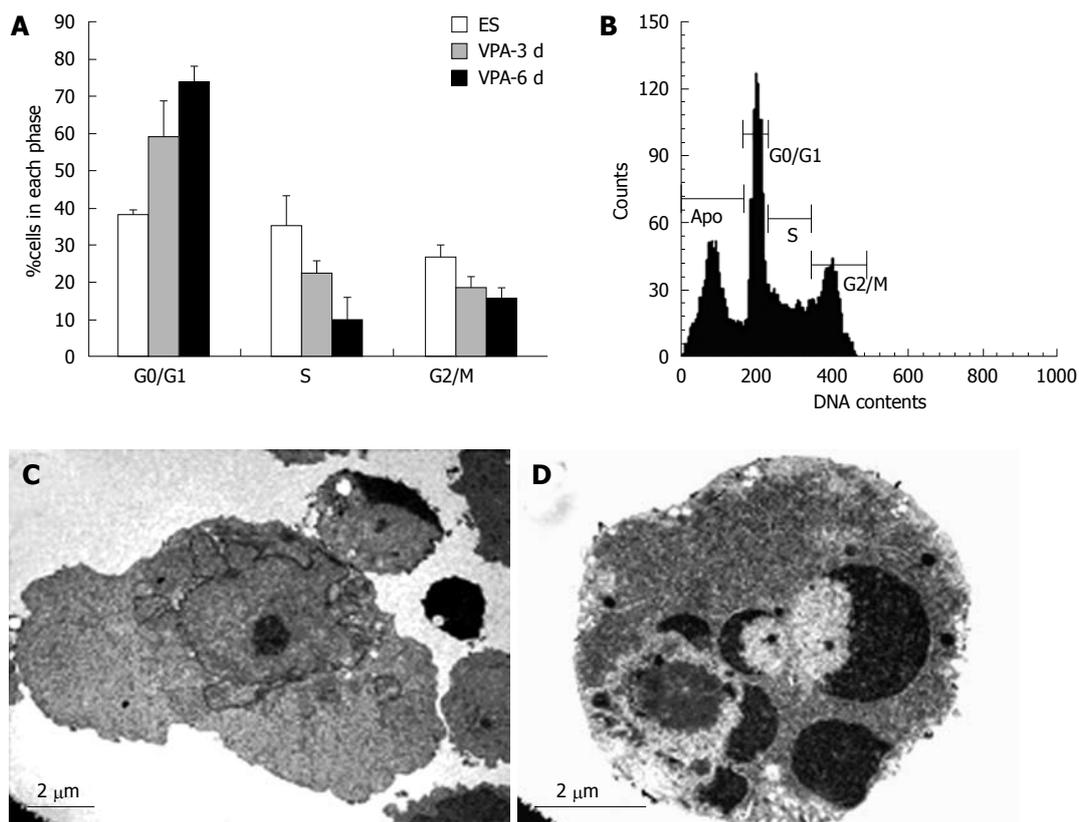

#### **Tumorigenic and *in vivo* differentiation potential analyses**

To evaluate the *in vivo* oncogenicity and differentiation potential of the progenitor cells, we introduced these cells and undifferentiated mES cells (as control) into Balb/c nude mice. Two weeks post-inoculation, the mice implanted with ES cells developed apparent teratomas at the injection site, while the mice with progenitor cells developed tumor-like bumps about 3-4 wk later. After the development of 6-8 wk, the teratomas and tumor-like bumps were fixed and examined with HE staining. The teratomas derived from ES cells were composed of a variety of types of differentiated cells from all three primary germ layers including neuroectodermal cells, adipocytes, muscle and epithelium (Figure 5A-F). However, the tumor-like bumps derived from the progenitor cells contained only epithelial and mesenchymal-like cells, and duct-like structures surrounded by epithelial cells were also observed (Figure 5G-I). The results further confirmed that

the progenitor cells have *in vivo* differentiation potential into hepatic lineages, and indicated the difference in *in vivo* potential between the undifferentiated ES cells and hepatic progenitor cells.

#### **Cell cycle and apoptosis analyses of VPA-induced hepatic differentiation**

To evaluate whether VPA had an effect on cell cycle profile, ES cells were exposed to 1 mmol/L VPA for 0, 3, 6 d and cell cycle analyses were performed with FACS. Results indicated that exposure to VPA decreased the proportion of cells in S phase and increased the G<sub>0</sub>/G<sub>1</sub> phase proportion. Approximately 75% of the cells were arrested in the G<sub>0</sub>/G<sub>1</sub> phase and only 10% of the cells were in the S phase after 6 d of treatment with VPA, whereas over 37% of control ES cells were in the S phase (Figure 6A). These data indicated that VPA could reduce the proliferation of ES cells and cause the inhibition of G<sub>1</sub>-S transition. In addition, DNA content analysis of the cells treated with VPA for 3 d showed that about 28% of the cells adopted apoptotic features (Figure 6B). Furthermore, the ultrastructural observations also showed that a considerable number of cells presented typical

**Figure 6** VPA-induced cell cycle arrest and apoptosis during hepatic differentiation. A: Cell cycle analysis revealed that exposure to VPA decreased the proportion of cells in S phase and increased the proportion of cells in the G0/G1 phase. Approximately 75% of the cells were arrested in the G0/G1 phase and only 10% of the cells in the S phase after 6 d of treatment with 1 mmol/L VPA, whereas greater than 37% of control ES cells were in the S phase; B: The analysis of apoptosis proportions during 3 d of treatment with VPA; C, D: Ultrastructural observations showed that some cells presented typical apoptotic morphology when treated with VPA for more than 5 d.

apoptotic morphology after being treated with VPA for more than 5 d (Figure 6C and D).

## DISCUSSION

To develop well-defined *in vitro* protocols for directing cellular differentiation into hepatic lineage has become critical for better investigating the mechanisms of hepatocyte differentiation, and for providing seed cells for hepatic tissue engineering as well as for clinical purposes. Most of the protocols currently developed to induce the hepatic differentiation from ES cells were devised by using embryoid bodies. However, several disadvantages may exist in this method. For example, it is time-consuming to prepare the embryoid bodies, and hepatic differentiation through embryoid bodies may result in low yield and purity of functional hepatocytes. Therefore, direct hepatic fate differentiation from an ES monolayer without using embryoid bodies is a most promising concept. A previous study has demonstrated that hepatocyte-like cells could be directly induced from human ES cells by using a combination of cytokines, providing preliminary evidence of the possibilities for this method<sup>[25]</sup>. However, the direct hepatic differentiation of ES cells still remains a challenge and needs to be further developed. In the present study, we report a novel strategy for the direct hepatic fate differentiation

of ES cells, which allows hepatic differentiation from progenitor cells to functional hepatocytes, based on a combination of VPA and cytokines. The results show this strategy has obvious advantages, such as being easy to operate, well reproducible and capable of acquirement of abundant and uniform progenitor cells and mature hepatocytes, the latter of which are suitable for the large-scale requirements of cell replacement therapy. Noticeably, following this strategy, we can harvest progenitor cells and mature hepatocytes in a sequential order. Thus, it may provide an *in vitro* research model which could meet the requirement of precise study regarding the mechanisms of hepatic differentiation at different developmental stages.

In addition, histone acetylation is considered to be one of the most important epigenetic regulation processes involved in gene expression, which is largely controlled by HDAC inhibitors including VPA. The observation that VPA could induce hepatic progenitor differentiation from ES cells suggested that epigenetic regulation mediated by histone acetylation might play an important role in early hepatic development. Therefore, the VPA-induced hepatic differentiation may also provide a model for the study of early hepatic developmental events, such as the relationship between the initiation of hepatic differentiation and epigenetic modification.

By FACS and ultrastructural analysis, it was found

that treatment of ES cells with VPA significantly reduced the proportion of the cells in the S phase and promoted the accumulation in the G0/G1 phase, which was accompanied by cellular apoptosis. This finding suggests that cell cycle arrest and apoptosis are involved in the VPA-induced hepatic specification. Further study is needed to elucidate the exact molecular and cellular mechanisms underlying the VPA-induced hepatic cell fate determination from ES cells.

Several lines demonstrated that the VPA-induced progenitor cells possessed some distinctive characteristics distinguished from ES cells or traditionally identified hepatoblasts or hepatic oval cells. For example, the progenitor cells exhibited typical epithelial morphology when cultured in a collagen coated dish, while ES cells formed multilayer compact colonies. There were many condensed-stained heterochromatin areas in the nucleus of ES cells, while the progenitor cells were almost all euchromatic. Also, the results of an *in vivo* differentiation assay revealed that ES cells formed typical teratomas containing the structures of three primary germ layers, while the progenitor cells formed tumor-like bumps containing only epithelial and mesenchymal cells. Moreover, the acquired progenitor cells expressed a number of typical markers of hepatoblasts or oval cells, such as AFP, TTR, Foxa2, DPPIV, GGT and BG. Importantly, Dlk, a marker of hepatic stem cells (hepatoblasts or hepatic oval cells) recently reported<sup>[26-28]</sup>, was also expressed by the progenitor cells. However, investigation of the hepatic oval cell marker, A6, was negative<sup>[29,30]</sup>. In addition, the progenitor cells expressed OCT-4, a marker of multi-lineage stem/progenitor cells<sup>[31-33]</sup>. These data indicated that the acquired progenitor cells may represent a novel subset at a developmental stage between ES cells and the known hepatic stem/progenitor cells, suggesting that a novel progenitor population was involved in the VPA-induced hepatic differentiation. This finding will be of benefit for understanding more about the early differentiation of hepatocytes.

Importantly, mouse is an often-used model species for human disease, so the investigation of hepatic differentiation of mouse ES cells will be of benefit for the better understanding of mechanisms underlying human hepatic differentiation and the development involved. Our results also support the establishment of new strategies to acquire human hepatic progenitor cells as well as hepatocytes, which will be helpful for the solution of obtaining cell sources for clinical cytotherapy.

## COMMENTS

### Background

Embryonic stem (ES) cells, known for their capacity to proliferate indefinitely and differentiate into almost all types of cells including hepatocytes, have raised the hope of cellular replacement therapy for liver failure. There have been several protocols available for hepatic fate specification from ES cells, however, most of the protocols currently used result in low yield or purity of functional hepatocytes. Valproic acid (VPA), a histone deacetylase (HDAC) inhibitor, has been demonstrated to facilitate the hepatic differentiation of mesenchymal stem cells. However, little is known about whether VPA could induce the hepatic differentiation of ES cells.

### Research frontiers

The research hotspot is to develop well-defined protocols for directing cellular differentiation into hepatic lineage, followed by selective isolation and proliferation *in vitro*.

### Innovations and breakthroughs

In the present study, the authors report a novel strategy for the direct hepatic fate differentiation of ES cells, which allows the hepatic differentiation from progenitor cells to functional hepatocytes, based on using a combination of VPA and cytokines. The results show that this strategy has obvious advantages, such as being easy to operate, well reproducible and capable of acquirement of abundant and uniform progenitor cells and mature hepatocytes, the latter of which are suitable for the large-scale requirements of cell replacement therapy. Noticeably, following this strategy, they can harvest progenitor cells and mature hepatocytes in a sequential order. Thus, it may provide an *in vitro* research model which could meet the requirements of precise study regarding the mechanisms of hepatic differentiation at different developmental stages. In addition, the observation that VPA could induce hepatic progenitor differentiation from ES cells suggested that epigenetic regulation mediated by histone acetylation might play an important role in early hepatic development. Therefore, the VPA-induced hepatic differentiation may also provide a model for the study of early hepatic developmental events, such as the relationship between the initiation of hepatic differentiation and epigenetic modification.

### Applications

The present study may not only be helpful for the clinical application of hepatocyte transplantation, but also provide an *in vitro* research model for the better investigation and understanding of the entire developmental process of hepatocytes, from ES cells to hepatic progenitors, and then to a population of mature hepatocytes.

### Terminology

VPA, a HDAC inhibitor, has been used as a new class of chemotherapeutic drug for cancer clinical purposes and as an inducer for stem cell differentiation.

### Peer review

This is an important area for research to find new sources of hepatocytes for future clinical application. The authors have performed a good study.

and rapid eye movement sleep (REM sleep) in most of the 11 wk. SWS I showed no significant variations. During the final weeks, a significant increase in REM sleep frequency was also observed. Histological analyses of the livers showed unequivocal signs of cirrhosis.

**CONCLUSION:** These data suggest that hepatic failure produced by CCl<sub>4</sub> administration is capable of modifying the sleep pattern even after only a few doses.

### Abstract

**AIM:** To analyze the polygraphic sleep patterns during cirrhosis progression in a rat model by repeated CCl<sub>4</sub> administration.

**METHODS:** Male Wistar rats received three weekly injections of CCl<sub>4</sub> for 11 wk, and were analyzed before and during the induction of cirrhosis. Rats were implanted with electrodes to record their sleep patterns. Polygraph recordings were made weekly over 11 wk for 8 h, during the light period. After a basal recording, rats received three weekly injections of CCl<sub>4</sub>. Histological confirmation of cirrhosis was performed after 11 wk.

**RESULTS:** The results showed a progressive decrease in total wake time that reached statistical significance from the second week of treatment. In addition, there was an increase in total time of slow wave sleep (SWS) II

### INTRODUCTION

The sleep-wakefulness cycle is an important circadian rhythm in mammals and is characterized by a reduction in the level of consciousness and by specific metabolic activities. Sleep is controlled by multiple areas of the brain and by several chemical factors, and can be readily modified by different activities, drugs, and pathological process, such as exercise, stress, alcoholism, depression, and metabolic diseases<sup>[1]</sup>.

Cirrhosis, on the other hand, is an irreversible dysfunction of the liver characterized by damage of the parenchyma, alteration of the reticular structure and the connective tissue that sustains the lobules and sinusoids<sup>[2]</sup>. Cirrhosis can progress to hepatic encephalopathy

and to coma<sup>[3]</sup>, but even before these advanced stages, functional alterations of several brain nuclei have been detected during early stages by magnetic transfer ratio, a magnetic resonance imaging technique<sup>[4]</sup>. Cirrhosis could also impact pulmonary function and might be involved in the development of obstructive sleep apnea syndrome (OSAS) in patients with ascitis; however, the early stages have not been associated with OSAS<sup>[5]</sup>. In the advanced stages, cirrhotic patients show an increased frequency of moderate obstructive sleep apnea<sup>[6]</sup>. In addition, cirrhotic patients with metabolic alterations frequently show abnormalities in electroencephalographic recordings<sup>[7]</sup>. Furthermore, patients with severe cirrhosis show a significant increase in power potency associated with the theta frequency and a decrease associated with the  $\alpha$  frequency in the electroencephalogram (EEG)<sup>[8,9]</sup>. Recently, Mostacci *et al.*<sup>[10]</sup> reported significant sleep alterations in 178 patients with cirrhosis when compared to normal control subjects using questionnaires: the basic Nordic sleep and the Epworth Sleepiness Scale. They reported that patients with cirrhosis complained of more daytime sleepiness, because they had fragmented nocturnal sleep caused by frequent nocturnal waking and had difficulties for falling asleep.

Through questionnaires of quality of life, sleep disturbances have been recognized as one of the early signs in patients with cirrhosis and hepatic encephalopathy<sup>[11]</sup>. Sleep disturbances in cirrhosis has not been correlated with clinical parameters or with cognitive impairment. Cirrhotic subjects with unsatisfactory sleep show higher scores for depression and anxiety, raising the possibility that the effects of these chronic emotional alterations might underlie the pathogenesis of sleep disturbances. Moreover, cirrhotic patients show reduced sleep time, increased latencies to sleep and frequent waking. These alterations are not due to previously prescribed medications, but are related to abnormalities of the circadian system<sup>[12]</sup>.

From this evidence we can conclude that hepatic cirrhosis causes a series of cerebral changes, which could modify several behaviors, such as sleep. Alterations of the sleep pattern as hepatic disease develops have not been reported. In addition, chronic administration of CCl<sub>4</sub> in rats induces reactive free radicals that attack membrane components, culminating in cell death<sup>[13]</sup> and promoting fibrosis<sup>[14]</sup>. This is a reliable procedure to induce experimental hepatic cirrhosis. The aim of this study was to analyze the sleep pattern in rats chronically treated with CCl<sub>4</sub> as hepatic damage progresses.

## MATERIALS AND METHODS

### Animals

Ten adult male Wistar rats (250-280 g) were used in this study. The animals were housed in a temperature-controlled room (22°C) and under a 12:12 normal light-dark cycle (light ON at 08:00 am). They were kept in individual clear polycarbonate cages with food and water available *ad libitum*. The experiments were performed following the guidelines of the National Institutes of

Health Guide for Care and Use of Laboratory Animals (Publication No. 85-23, revised 1985).

### Sleep recording

Under deep general anesthesia induced with a cocktail (ketamine: 3.75 mg/100 g, xylazine: 0.19 mg/100 g, and acepromazine: 0.038 mg/100 g ip), rats were chronically implanted with a standard set of electrodes for sleep recording. Two stainless steel screw electrodes were implanted in the frontal and parietal cortex for the EEG and flexible wires were inserted in the neck muscles to record an electromyogram.

### CCl<sub>4</sub> treatment

One week after surgery, and after 3 d of habituation to the recording conditions, rats ( $n = 10$ ) polygraph recordings were made to obtain their basal sleep parameters. Thereafter, animals received an intraperitoneal (ip) injection, three times a week, containing different dilutions of CCl<sub>4</sub> and mineral oil, always in a total volume of 0.25 mL. Treatment lasted for 11 wk under the following pattern of administration: in the first week the animals received a solution with one part of CCl<sub>4</sub> and six parts of mineral oil (1:6). In the second week, the proportion of the solution changed to 1:5. In the third week the proportion of the solution was 1:4. From week four to week eleven the proportion of the solution was 1:3.

### Polygraph recordings

Polygraph recordings of the rats were obtained for 8 h within the light period, once every week, with the Nihon-Kohden model polygraph. Thus, sleep recordings were done before treatment and after every three injections. In addition to the polygraph recordings, rat behavior was observed during the recording period. The polygraph recordings were scored visually according to standard criteria<sup>[15]</sup>. The frequency and the duration of wakefulness, slow wave sleep (SWS) I, SWS II, and rapid eye movement (REM) sleep were quantified.

### Histological liver slices

Half of the animals died during the treatment (Initial  $n = 10$ ; final  $n = 5$ ). After sleep recordings, animals were killed by an overdose of pentobarbital and their livers were removed for histological examination. Liver slices were stained with hematoxylin-eosin and their morphological characteristics were determined.

### Statistical analysis

All data were expressed as mean  $\pm$  SD and analyzed by SPSS 11.0 software. Data were analyzed using an ANOVA for repeated measurements, followed by Fisher post hoc comparisons to detect significant differences between groups.  $P < 0.05$  was considered statistically significant.

## RESULTS

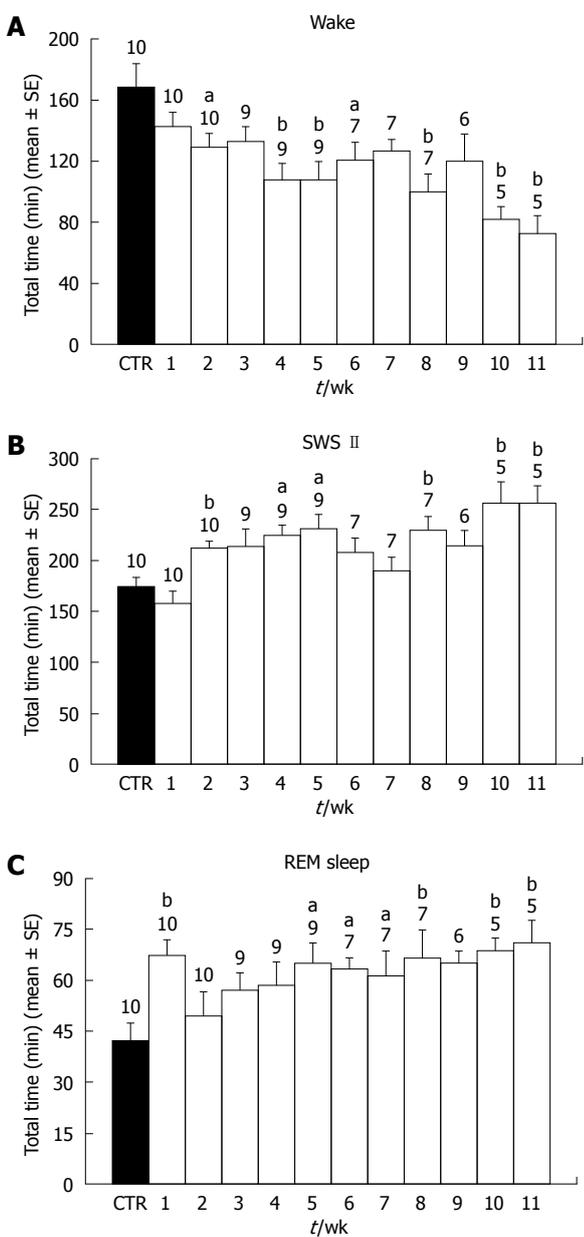

### Sleep pattern

Treatment with CCl<sub>4</sub> induced behavioral changes in all

**Table 1** CCl<sub>4</sub> effect on sleep architecture for 11 wk of treatment (min) (mean ± SE)

<sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 vs control. Repeated measure ANOVA.

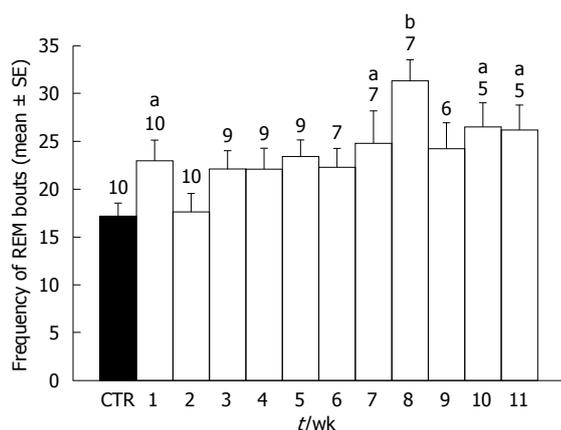

**Figure 1** Percentage of Wakefulness (A), SWS II (B), and REM sleep (C) in weekly 8 h sleep recordings during treatment with CCl<sub>4</sub>. Numbers at the top of the bars express the number of subjects. <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01 vs control. Repeated measurements were analyzed by ANOVA.

rats, characterized mainly by a progressive decrease in locomotion. During the final 2 wk, four out of the five surviving animals showed ascitis. Five of the animals died before the end of the 11-wk period, so the size of the group decreased as the treatment progressed. Concerning sleep, CCl<sub>4</sub> administration elicited a decrease of wake time throughout the 11 wk of treatment. The decrease was observed from the first week of treatment but only reached statistical significance from the second week. This decrease in wake time grew larger as the treatment progressed, and during weeks 10 and 11, wake time was less than 50% of pretreatment values (Figure 1A). Concerning SWS I, no significant modifications were observed. However, SWS II time showed a significant increase from the second week of treatment. The increase remained constant with only small variations during the 11 wk. Only during weeks six and seven did the increase did not reach statistical significance (Figure 1B). REM sleep showed a significant increase in the first week of treatment (Figure 1C). However, REM sleep duration returned to control levels during the second and third weeks of treatment and thereafter, there was a significant increase that lasted until week eleven. The increase of REM sleep time was due mainly to the duration of each period, because no significant increases in REM sleep frequency were observed during most of the weeks. Only during weeks eight, ten, and eleven were there significant increases in REM sleep frequency (Figure 2).

Table 1 summarizes the data obtained concerning all the parameters recorded during pretreatment and during the 11 wk of recording.

**Histological liver slices**

Histological examination revealed the effects of chronic CCl<sub>4</sub> treatment on liver parenchyma. Figure 3 shows a sample of a liver treated with CCl<sub>4</sub>. A normal liver can be observed in Figure 3A. In Figure 3B, the effects of CCl<sub>4</sub> treatment for 11 wk on liver histological features are shown. Clear indications of cirrhosis were observed (fibrosis, lipidic vacuoles, pycnotic nuclei, and necrosis).

**Figure 2** Frequency of REM sleep bouts observed in weekly eight-hour sleep recordings during treatment with CCl<sub>4</sub>. Numbers at the top of the bars express the number of subjects. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control. Repeated measurements were analyzed by ANOVA.

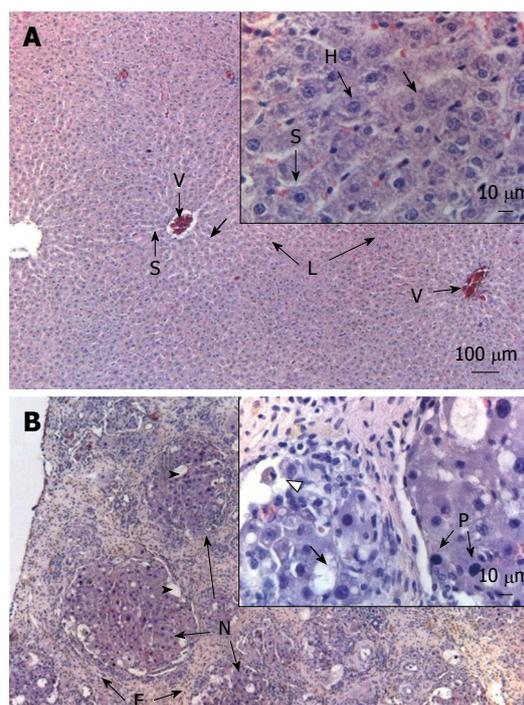

## DISCUSSION

The present results indicate that sleep-wake patterns changed as experimental cirrhosis progressed. REM sleep showed an acute response to the first administrations of CCl<sub>4</sub>. Wake and SWS II time were significantly modified after 2 wk of CCl<sub>4</sub> treatment, and these effects showed a steady and slight increase during the following weeks. These results are consistent with previous reports showing that cirrhotic patients display a reduction in  $\alpha$  activity and an increase in theta and delta activity<sup>[8]</sup>.

Indirect tests, such as actigraphic recordings and questionnaires on sleep, have suggested that cirrhotic patients suffer from unsatisfactory sleep, mainly due to the reduction in the quality of sleep, produced by several awakenings throughout the night<sup>[12]</sup>. However, Steindl *et al.*<sup>[16]</sup> did not find differences in polysomnographic recordings of cirrhotic patients compared to matched healthy controls. However, sleep diaries of these patients indicated more frequent nocturnal awakenings and daytime naps. Moreover, these researchers measured the levels of melatonin and found a significant increase during daytime, when melatonin is normally absent<sup>[16]</sup>. Recently, Velissaris *et al.*<sup>[17]</sup> corroborated these results; they showed that melatonin circadian patterns were altered in cirrhosis patients without clinical encephalopathy. This disruption might reflect changes in the output of the circadian pacemaker located in the suprachiasmatic nucleus of the hypothalamus. It is possible that some of the metabolic disturbances generated by cirrhosis might also alter the function of this biological clock.

On the other hand, several diseases of sleep have been reported, such as the OSAS. OSAS is a frequent disease that has been extensively studied. In patients with advanced liver cirrhosis, OSAS has been reported to be associated with changes in autonomic nervous activities<sup>[18]</sup>.

Recent molecular studies have shown an increased expression of genes associated with monoamine oxidase (MAO-A isoform) and nitric oxide synthase (nNOS isoform) in the brain of cirrhotic patients<sup>[3]</sup>. Moreover, oligodendroglial nodules have been observed in the white

**Figure 3** Effects of repeated administration of CCl<sub>4</sub> on liver morphology in rats after 11 wk of CCl<sub>4</sub> treatment. A: Normal aspect of an untreated liver. In a stain with HE, the typical sinusoidal (S) organization can be observed with lobules (L) surrounding the vessels (V). In a higher magnification, a normal hepatocyte (H) can be distinguished; B: The effects of CCl<sub>4</sub>. A fibrotic process (F) is evident, with hepatocytes grouped in nodules (N) containing vacuoles. In a higher magnification, the bold arrow indicates hepatocytes with lipidic vacuoles can be observed as well as cells with pycnotic nucleus (P) or in necrosis (triangle).

matter associated with CCl<sub>4</sub>-induced liver failure<sup>[19,20]</sup>. In addition, in rats submitted to portacaval anastomosis and in patients with cirrhosis, alterations of the circadian system have been noticed, especially in the rhythm of circadian locomotor activity and in the rhythm of pineal melatonin release<sup>[1,21,22]</sup>. All of these data can account for sleep effects observed in the present study.

Likewise, it has been shown that the activity of the EEG can be modified by several substances, such as ammonium, a potent neurotoxic produced by cirrhotic patients<sup>[3,11,23,24]</sup>. This increase of ammonium affects the homeostasis levels of neurotransmitters and neuropeptides in plasma and in the brain. Thus, the levels of dopamine, acetylcholine, glutamate, nitric oxide, and GABA are modified<sup>[24-26]</sup>. It is possible that, in the present study, the animals treated with CCl<sub>4</sub> have several neurochemical alterations that could modify the levels of different neurotransmitters. These changes, in addition to the alterations in the biological clock, can produce disturbances in some nuclei involved in the regulation of sleep. Further research is needed to elucidate the precise mechanisms of the observed changes.

## ACKNOWLEDGMENTS

The authors express their gratitude to Edith Monroy for her expert review of the language of the manuscript and Dr. Manuel Castillo-Rivera for statistical support.

**COMMENTS****Background**

Sleep disturbances have been described in patients with advanced cirrhosis. However, the development and mechanisms of these alterations are not known. In this study, the sleep pattern of rats submitted to experimental cirrhosis was analyzed as liver damage progressed. The results showed an early decrease of wake time and sustained increases of slow wave sleep (SWS) and later, of REM sleep. This data suggest that sleep alterations could be the warning signs of liver disease.

**Research frontiers**

This study adds information on the relationship between liver function and cerebral function. The mechanisms through which this reciprocal relationship works remain to be elucidated.

**Innovations and breakthroughs**

The animal model of liver cirrhosis induced by chronic administration of CCL<sub>4</sub> is a suitable model to analyze the relationship between liver failure and brain function disturbances.

**Applications**

This study highlights the need for gastroenterologists to pay attention to sleep disturbances as early signs of liver failure.

**Terminology**

SWS and rapid eye movement sleep and the two major sleep stages in most animal species.

**Peer review**

The content of the article will be interesting not only for the gastroenterologists, but also for other specialists. Further investigations of mechanisms of sleep alterations might yield potentially efficacious approaches to its clinical management.

results and amylase level in the placebo groups were similar to those in the AP group. White blood cell count and TNF- $\alpha$  concentration was nearly the same in the CAPE and placebo groups.

**CONCLUSION:** CAPE may be useful agent in treatment of AP but more experimental and clinical studies are needed to support our observation of beneficial effects of CAPE before clinical usage of this agent.

### Abstract

**AIM:** To evaluate the therapeutic role of caffeic acid phenethyl ester (CAPE) in a rat model of cerulein-induced acute pancreatitis (AP).

**METHODS:** Seventy male Wistar albino rats were divided into seven groups. Acute edematous pancreatitis was induced by subcutaneous cerulein injection (20  $\mu$ g/kg) four times at 1-h intervals. CAPE (30 mg/kg) was given by subcutaneous injection at the beginning (CAPE 1 group) and 12 h after the last cerulein injection (CAPE 2 group). Serum amylase, lipase, white blood cell count, and tumor necrosis factor (TNF)- $\alpha$  levels were measured, and pancreatic histopathology was assessed.

**RESULTS:** In the AP group, amylase and lipase levels were found to be elevated and the histopathological evaluation showed massive edema and inflammation of the pancreas, with less fatty necrosis when compared with sham and control groups. Amylase and lipase levels and edema formation decreased significantly in the CAPE therapy groups ( $P < 0001$ ); especially in the CAPE 2 group, edema was improved nearly completely ( $P = 0001$ ). Inflammation and fatty necrosis were partially recovered by CAPE treatment. The pathological

Therapeutic effect of caffeic acid phenethyl ester on cerulein-induced acute pancreatitis. *World J Gastroenterol* 2009; 15(41): 5181-5185 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5181.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5181>

### INTRODUCTION

Acute pancreatitis (AP) is a process of acute inflammation in the pancreas, with variable involvement of regional tissues or organ systems. In most patients, acute necrotizing pancreatitis leads to remote organ failure, sepsis and a high death rate<sup>[1]</sup>. Pathophysiology of AP is poorly understood, but interleukin (IL)-1, IL-6 and tumor necrosis factor (TNF)- $\alpha$  as pro-inflammatory cytokines, oxidative stress and microvascular ischemia are important factors<sup>[2-4]</sup>. In recent years, pathogenesis-oriented treatments of AP have gained importance. Therefore, new experimental studies have focused on pathophysiological mechanisms such as oxidative stress and inflammatory cytokines<sup>[5,6]</sup>. Propolis is a natural substance that is produced by honeybees from the gum of

various plants. It contains several chemical compounds such as polyphenolic compounds like flavonoids, cinnamic acid derivatives, various steroids, and amino acids<sup>[7,8]</sup>. Caffeic acid phenethyl ester (CAPE) is also a phenolic compound and an active substrate of propolis. Several investigators have shown that CAPE has anti-inflammatory activity by inhibiting the release of arachidonic acid from cell membranes, and suppressing cyclooxygenase (COX)-1 and COX-2 enzyme activity<sup>[9]</sup>, antioxidant activity by lipoxygenase inhibition<sup>[10,11]</sup>, and anti-proliferative, antimutagenic and antitumoral effects by inducing apoptosis in tumor cell lines<sup>[12]</sup>. In addition, CAPE is a potent and specific inhibitor of nuclear factor (NF)- $\kappa$ B and inhibits the activation of NF- $\kappa$ B that is induced by TNF- $\alpha$  and other inflammatory agents<sup>[13]</sup>.

The aim of this study was to investigate the therapeutic efficacy of CAPE in the cerulein-induced acute edematous pancreatitis in rats.

## MATERIALS AND METHODS

### Animals

Seventy male Wistar albino rats, weighing 250-320 g were used from the Physiology Laboratory of Gaziantep University Medical School. The animals were housed under a 12-h light-dark cycle at a temperature of 24°C. Food was withdrawn 12 h before the experiment. All experiments were performed in accordance with the recommendations of the national guidelines for the care and handling of laboratory animals, and followed a protocol approved by the local animal ethics committee.

### Experimental design

Acute edematous pancreatitis was induced by subcutaneous cerulein (Sigma, St Louis, MO, USA) injection (20 g/kg) four times at 1-h intervals<sup>[14]</sup>. Seventy male rats were divided into seven groups of 10.

Group 1 (sham): nothing was applied to the sham group. Group 2 (control): 1 mL saline was given by subcutaneous injecting four times at 1-h intervals, but no medication was applied. Animals were killed 12 h after the last injection. Group 3 (AP group): AP was induced by subcutaneous cerulein injection (20 g/kg dissolved in 1 mL saline) four times at 1-h intervals, but no medication was applied. Animals were killed 12 h after the last injection. Group 4 (CAPE 1) 30 mg/kg CAPE (Sigma) was given by subcutaneous injection at the beginning of the procedure, and at the same time, AP was induced by subcutaneous cerulein injection as described before. Group 5 (CAPE 2): AP was induced in the same way as described above, and CAPE (30 mg/kg) was given at 12 h after the last cerulein injection. Animals were killed 6 h after the CAPE injection. Group 6 (placebo 1): AP was induced by subcutaneous cerulein injection (20  $\mu$ g/kg) four times at 1-h intervals, and 1 mL saline was given at the beginning of the studies. Animals were killed 12 h after the last injection. Group 7 (placebo 2): AP was induced in the same way as described above, and 1 mL saline was given at 12 h after the last cerulein injection. Animals were killed 6 h after the saline injection.

Table 1 Pathological grading system in experimental AP

Edema	0	No edema
	1	Interlobular edema
	2	Moderate interlobular edema + intra-acinar edema
	3	Severe interlobular and intra-acinar edema
Inflammatory infiltration	0	No infiltration
	1	Intravascular margination of granulocytes
	2	Granulocytes present in the perivascular tissue
	3	Diffuse infiltration of entire pancreatic gland
Fat necrosis	0	No necrosis
	1	1-4 necrotic cells (each microscopic area)
	2	5-10 necrotic cells
	3	11-16 necrotic cells

### Assays of treatment efficacy

Under ketamine anesthesia, midline laparotomy was performed on all rats, except Groups 5 and 7, at 15 h (12 h after the last cerulein or saline injection). Groups 5 and 7 were killed 6 h after CAPE injection (Group 5) or saline injection (Group 7). Shortly after the blood specimens were taken from the inferior vena cava, the whole pancreas was extracted quickly and the animals were sacrificed. Blood samples were centrifuged at 3000 rpm for 10 min and the plasma was stored at -70°C until assayed. White blood cell count, amylase, lipase and TNF- $\alpha$  concentrations were measured. Plasma TNF- $\alpha$  concentration was measured by immunoassay kit (Rat TNF- $\alpha$  immunoassay; R&D Systems Inc., Minneapolis, MN, USA), plasma amylase and lipase were measured by commercially available kits from Roche Diagnostics (Mannheim, Germany), using an enzymatic photometric method based on cleavage of the substrate ethylidene-4-nitrophenyl maltoheptaose. Results are expressed as U/L.

### Histopathological scoring

Histopathological evaluation of the pancreas was made in order to understand the extent of the injury. Pancreatic tissue was fixed in formaldehyde solution and embedded in paraffin. Sections were stained with hematoxylin and eosin and were evaluated by light microscopy by two experienced pathologists who were blinded to the experimental treatment groups, according to the Schoenberg grading system<sup>[15]</sup> (Table 1). The tissues were scored using a scale for edema, neutrophil infiltration and fatty necrosis.

### Statistical analysis

Results were given as mean  $\pm$  SD. Comparisons between and among the groups were made using non-parametric test (Mann-Whitney *U* test) and one-way ANOVA. Data were evaluated statistically using SPSS for Windows version 10.0 (Chicago, IL, USA). *P* < 0.05 was taken as significant.

## RESULTS

### Serum amylase, lipase and TNF- $\alpha$ levels

Serum biochemical analysis of amylase, lipase and TNF- $\alpha$  levels and pathological examination results are shown in Table 2. Serum amylase and lipase levels were significantly increased in the cerulein-induced AP group

Table 2 Biochemical, values and pathological scores in cerulein-induced AP (mean  $\pm$  SD)

Groups	TNF- $\alpha$ (pg/mL)	Amylase (U/L)	Lipase (U/L)	White blood cells	Edema	Leukocytic infiltration	Total pathological score	Fat necrosis

<sup>b</sup> $P < 0.001$  vs group 1 and 2; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.001$  vs group 3.

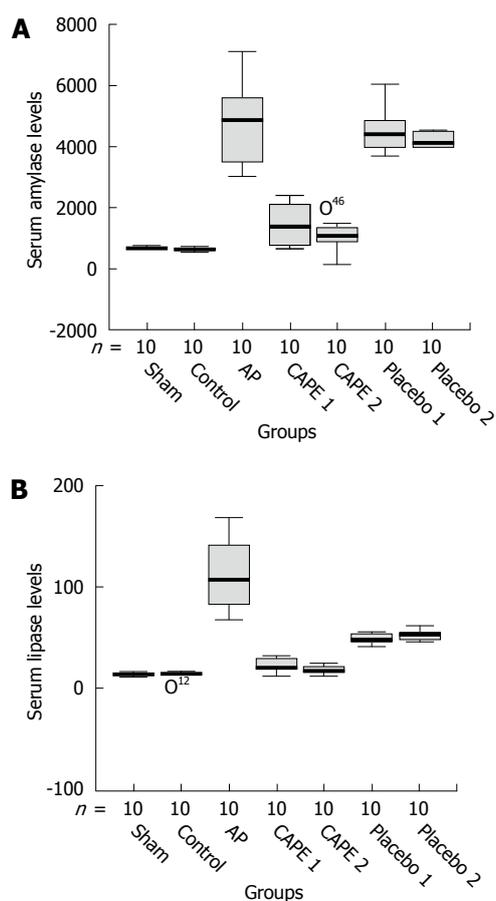

Figure 1 Serum amylase (A) and lipase (B) levels in the experimental groups.

when compared to the control and sham groups ( $P < 0.001$ ). Amylase and lipase levels decreased significantly in the CAPE treatment groups ( $P < 0.001$ ) but the levels were higher than those of the control and sham groups. The levels of amylase and lipase in the placebo groups were similar to those in the AP group (Figure 1A and B). There were no statistically significant differences in serum TNF- $\alpha$  and white blood cell count between the study groups ( $P > 0.05$ , Table 2).

### Pathological examination

In the AP group, histopathological evaluation showed massive edema and inflammation of the pancreas, with less fatty necrosis when compared with the control and sham groups. CAPE treatment significantly decreased edema

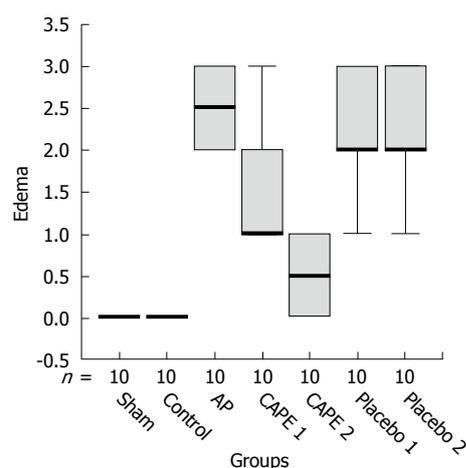

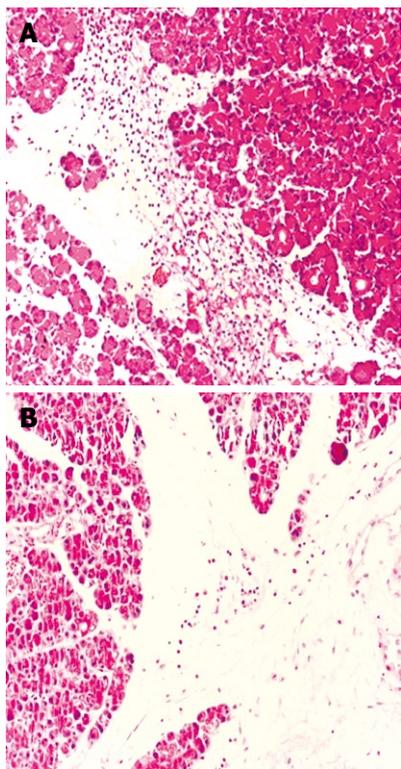

Figure 2 Edema scores in experimental AP groups.

formation, and the most striking finding was that edema was improved nearly completely in the CAPE 2 group ( $P = 0.001$ , Figure 2). Polymorphonuclear leukocytic infiltration was increased in the AP groups ( $P < 0.05$ , Figure 3A). In the therapy groups, inflammation was partially recovered. In the AP groups, fatty necrosis score was  $0.30 \pm 0.48$ . We observed grade 1 fatty necrosis in only three rats in the AP groups. Fatty necrosis was ameliorated in the CAPE treatment groups but this improvement was not statistically significant ( $P > 0.05$ ). The pathological results of the placebo groups were similar to those in the AP groups. After CAPE treatment, the total pathological mean score was decreased significantly ( $P < 0.05$ ) after CAPE treatment (Figure 3B).

## DISCUSSION

Current therapeutic methods are usually insufficient for the treatment of severe AP, despite the development of new diagnostic and therapeutic procedures. Therefore, recently, several experimental studies have focused on the pathogenesis of AP. Several mechanisms, such as oxidative stress, COX-2 and inflammatory cytokines play an important role in the pathogenesis of the disease<sup>[2-4,16]</sup>. CAPE is a phenolic antioxidant, which is an active component of propolis. Previous investigators have demonstrated that CAPE has anti-inflammatory, antioxidant, anti-proliferative and antitumoral effects *in vitro* and *in vivo*<sup>[12]</sup>. In the light of previous findings,

**Figure 3** Histopathological features of cerulein induced AP group and after CAPE therapy. A: Severe edema and leukocytic infiltration of pancreas after cerulein-induced AP (HE,  $\times 200$ ); B: Decreased infiltration in pancreatic tissue after CAPE therapy (HE,  $\times 200$ ).

we investigated the therapeutic role of CAPE as a new agent for the treatment of AP.

TNF- $\alpha$  is a cytokine that plays a central role in the pathogenesis of the disease<sup>[2]</sup>. TNF receptor antagonist observed a reduction in the severity and mortality of experimental pancreatitis<sup>[17]</sup>. Plasma half-life of TNF- $\alpha$  is very short (14-18 min)<sup>[18]</sup>, therefore, we studied TNF- $\alpha$  serum levels in rats, despite this kind of measurement being difficult. We obtained serum at 15 h, and that is probably why the results were low in all groups.

Norman *et al*<sup>[19]</sup> have shown marked amelioration of pancreatic tissue damage and decreased serum amylase and lipase levels after treatment with IL-1 antagonist. Oxidative stress plays an important role in the pathophysiology of AP. For this reason, several studies have reported the therapeutic effect of antioxidant agents. A previous study has disclosed that various antioxidant agents improve pancreatic edema in cerulein-induced pancreatitis, however antioxidants showed no improvement in a sodium-taurocholate model of pancreatitis in rats<sup>[20]</sup>. On the contrary, one recent study in a sodium-taurocholate model of pancreatitis in rats has shown that serum amylase and lipase, edema, leukocytic infiltration, parenchymal necrosis and hemorrhage were significantly decreased by N-acetylcysteine (NAC) treatment. In addition, in the NAC-treated rats, while serum nitrite/nitrate levels were significantly increased, serum concentration of the lipid peroxidation product was significantly decreased. The beneficial effect of NAC may result from its antioxidant activity and the production of and/or inhibition of degradation of nitric oxide<sup>[5]</sup>. In a similar

study, Vaquero *et al*<sup>[21]</sup> have demonstrated that treatment with NAC reduces neutrophil infiltration and mRNA expression for IL-6, cytokines and inducible nitric oxide synthase in pancreatic tissue, by inhibition of NF- $\kappa$ B activity. In conclusion, NF- $\kappa$ B is a key regulator cytokine in induction and oxidative stress in AP. In experimental pancreatitis, the beneficial effect of antioxidants can be explained by inhibition of NF- $\kappa$ B activation. CAPE is a specific and potent inhibitor of NF- $\kappa$ B and causes inhibition of pro-inflammatory cytokine production<sup>[13]</sup>. Likewise, Fitzpatrick *et al*<sup>[22]</sup> have shown that CAPE (30 mg/kg) treatment significantly inhibits NF- $\kappa$ B, and colonic cytokines (TNF- $\alpha$  and IL-1 $\beta$ ) are reduced in experimental colitis in rats.

AP is associated with induction of COX-2 expression. In cerulein-induced pancreatitis, Ethridge *et al*<sup>[16]</sup> have found that COX-2 gene expression is increased in pancreatic tissue. Although serum amylase and lipase are not reduced, the severity of pancreatic necrosis and leukocytic inflammation are significantly decreased by treatment with NS-398 (a COX-2 inhibitor). It has been demonstrated that COX-2 gene expression, activity of COX-1 and COX-2 enzymes, and release of arachidonic acid from cell membranes are inhibited by CAPE<sup>[9]</sup>. In light of this, we investigated the beneficial efficacy of CAPE (which is an antioxidant and anti-inflammatory agent) on the experimental model of cerulein-induced acute edematous pancreatitis in rats. As far as we know, there are no published data on the treatment effect of CAPE in experimental pancreatitis models. In the present study, we showed that CAPE ameliorated the harmful effects in a rat model of cerulein-induced pancreatitis. Serum amylase and lipase levels were decreased by CAPE treatment. In addition, CAPE treatment significantly reduced edema and total pathological mean score. Inflammation and fatty necrosis score were improved but the improvement was not statistically significantly.

There are several models of experimental pancreatitis, such as the cerulein-induced and sodium-taurocholate models. Pancreatic injury is evenly distributed throughout the pancreas in the cerulein-induced models. The reason why we chose the cerulein-induced AP model was that this form of pancreatitis is very similar to that in humans and it occurs within a short time<sup>[23]</sup>. This model is used widely to study potential agents for the treatment of AP<sup>[24]</sup>. In this model, pancreatic inflammation reaches the most severe stage at 12 h, which is why we ended the first part of the study at 12 h after cerulein injection<sup>[25]</sup>. Secondly, we formed a CAPE 2 group to study the effect of CAPE on the most severe stage of pancreatitis at 12 h. Here, our concern was to study the efficacy of the treatment in severe pancreatitis, especially in the full-blown situation. In fact, patients with AP often attend the hospital at an advanced stage, even sometimes with systemic complications.

In conclusion, in the cerulein-induced model of experimental AP, an improvement in the biochemical and histopathological findings were observed in the CAPE treatment groups. CAPE decreased pancreatic tissue injury and this supports the hypothesis that antioxidant

and anti-inflammatory treatment is effective in AP. It is important that CAPE was effective in the CAPE 2 group when AP had already occurred. This will enlighten the following phase 3 and phase 4 studies. Another important step will be to study the efficacy of CAPE in experimental necrotizing pancreatitis. Nevertheless, more experimental and clinical studies are needed to support our observation of the beneficial effects of CAPE before clinical usage of this agent.

## COMMENTS

### Background

Pathophysiology of acute pancreatitis (AP) is poorly understood. Therefore, new experimental therapeutic studies have focused on the pathophysiological mechanisms. The present experimental study investigated the therapeutic role of caffeic acid phenethyl ester (CAPE) as a new agent for the treatment of AP.

### Research frontiers

CAPE is a specific and potent inhibitor of nuclear factor (NF)- $\kappa$ B and causes inhibition of pro-inflammatory cytokine production. CAPE (30 mg/kg) treatment significantly inhibited NF- $\kappa$ B, and colonic cytokines tumor necrosis factor- $\alpha$  and interleukin-1 $\beta$  were reduced in experimental colitis in rats.

### Innovations and breakthroughs

There are no published data on the treatment effect of CAPE in experimental pancreatitis models. In the cerulein-induced model of experimental AP, improvement in biochemical and histopathological findings was observed in the CAPE treatment groups.

### Applications

CAPE may be a useful agent in the treatment of AP but more experimental and clinical studies are needed to support our observation of its beneficial effects.

### Terminology

CAPE is a phenolic compound and an active substrate of propolis. CAPE has anti-inflammatory, antioxidant, anti-proliferative and antitumoral effects *in vitro* and *in vivo*.

### Peer review

This work provides experimental evidence for a protective function of CAPE in a rat model of acute pancreatitis. The study is generally well-designed and controlled. The results show that administration of CAPE reduces serum amylase and lipase levels in cerulein-treated rats and improves pathological scores in pancreatic tissue specimens.

examinations, in addition to insertion to the cecum and withdrawal times.

**RESULTS:** Examination times did not differ, however, VAS scores in the CO<sub>2</sub> group were significantly better than in the air group ( $P < 0.001$ , two-way ANOVA) from immediately after the procedure and up to 2 h later. There were no significant differences between either insufflation method in the EC group ( $P = 0.29$ ), however, VAS scores for CO<sub>2</sub> insufflation were significantly better than air insufflation in the LEC group ( $P = 0.023$ ) immediately after colonoscopies and up to 4 h afterwards.

**CONCLUSION:** CO<sub>2</sub> insufflation reduced patient pain after colonoscopy in potentially difficult cases when performed by LECs.

### Abstract

**AIM:** To clarify the effectiveness of CO<sub>2</sub> insufflation in potentially difficult colonoscopy cases, particularly in relation to the experience level of colonoscopists.

**METHODS:** One hundred twenty potentially difficult cases were included in this study, which involved females with a low body mass index and patients with earlier abdominal and/or pelvic open surgery or previously diagnosed left-side colon diverticulosis. Patients receiving colonoscopy examinations without sedation using a pediatric variable-stiffness colonoscope were divided into two groups based on either CO<sub>2</sub> or standard air insufflation. Both insufflation procedures were also evaluated according to the experience level of the respective colonoscopists who were divided into an experienced colonoscopist (EC) group and a less experienced colonoscopist (LEC) group. Study measurements included a 100-mm visual analogue scale (VAS) for patient pain during and after colonoscopy

### INTRODUCTION

Colonoscopy has a high profile because of its increasingly important role in successfully preventing, detecting and treating colorectal cancer<sup>[1,2]</sup>, however, some patients experience considerable abdominal pain and discomfort when the procedure is performed using air insufflation. In particular, the so-called “difficult colonoscopy” cases<sup>[3-6]</sup>, which involve female patients with a relatively

low body mass index (BMI), patients with a history of abdominal and/or pelvic open surgery and male patients with diverticulosis, often require prolonged insertion to the cecum, thus this procedure can cause increased abdominal pain and discomfort for such patients.

Factors accounting for longer examination times and increased abdominal pain and discomfort can be derived from both a patient's condition and the examining colonoscopist's skill and experience<sup>[7-9]</sup>. Novice and even moderately skilled colonoscopists must improve their technical abilities by gaining experience in successfully handling difficult colonoscopies to become qualified experts, as a suitably high-level colonoscopy training environment has not been established as yet<sup>[10,11]</sup>.

CO<sub>2</sub> insufflation has been reported to reduce patient abdominal pain and discomfort during and after colonoscopies<sup>[12-15]</sup>. Although the safety and efficacy of CO<sub>2</sub> insufflation during colonoscopies have been assessed in earlier studies, air insufflation is still the standard method due to a lack of suitable equipment and inadequate information as to when and on whom CO<sub>2</sub> insufflation should be used during colonoscopy examinations.

We decided to conduct a prospective randomized controlled trial to test the hypothesis that CO<sub>2</sub> insufflation reduces patient abdominal pain and discomfort during and after colonoscopy examinations in potentially difficult cases.

## MATERIALS AND METHODS

### Study protocol

Consecutive patients considered potentially difficult cases for colonoscopic intubation were included in this prospective randomized controlled trial which took place between September 2006 and October 2007. The aim of this study was to clarify the effectiveness of CO<sub>2</sub> insufflation during colonoscopy examinations, with the primary objectives of assessing both patient tolerance and the safety of CO<sub>2</sub> insufflation in these potentially difficult cases. A secondary objective was to clarify any differences between the two insufflation methods in relation to the experience level of the participating colonoscopists. This study was approved by the Ethics Committee at Okayama University Hospital.

### Patients

Patients considered potentially difficult colonoscopy cases, based on published information and clinical experience, were selected, and included females with a relatively low BMI (BMI < 22), patients with a history of abdominal and/or pelvic open surgery, with the exception of low risk procedures for adhesions such as appendectomy or hernia repair, and male patients with previously diagnosed left-side diverticulosis<sup>[3-6]</sup>.

The indications for colonoscopy examination were the standard clinical criteria: colorectal cancer screening, surveillance for polyps, a positive fecal occult blood test, abdominal symptoms or anemia. Exclusion factors included severe heart or lung disease, a prior colorectal

resection, inflammatory bowel disease, severe hematochezia and repeat colonoscopy for therapeutic procedures including polypectomy.

Written informed consent was obtained from each patient and enrolled patients were randomly divided into two groups for colonoscopy examinations using either CO<sub>2</sub> or standard air insufflation. Group allocation for both patients and colonoscopists was performed by specially assigned nurses using standard randomization lists which contained consecutive patient numbers. Each number was linked to one of the two study groups for allocation purposes. These lists were not accessible by the participating colonoscopists.

### Colonoscopy using CO<sub>2</sub> insufflation

Patients underwent bowel preparation with sodium picosulfate the day before their examinations and two liters of polyethylene glycol solution-containing lavage the morning of their colonoscopies. Scopolamine butylbromide (20 mg) was administered intramuscularly to suppress bowel movement, while patients with cardiac disease or benign prostatic hypertrophy received glucagon (1 IU) intramuscularly. Patients were not sedated, although midazolam (2-3 mg, iv) was administered based on the examining colonoscopist's judgment or when requested by the patient due to abdominal pain or distension. Examinations were performed using a pediatric variable-stiffness colonoscope (PVSC) with a distal tip diameter of 11.3 mm (PCF-Q260AI, Olympus Co, Tokyo, Japan).

Procedures were randomly performed by eight colonoscopists who had earlier been divided into two groups according to their colonoscopy experience: four highly experienced colonoscopists (EC) group each of whom had been in colonoscopy practice for over 10 years (TU, JK, KT and SH), and four less experienced colonoscopists (LEC) group with 5-7 years of colonoscopy practice during which each had performed 900-1500 colonoscopies (MK, SI, KH and HF).

If an examining colonoscopist from the LEC group failed to pass through the sigmoid-descending colon junction within 15 min or a patient complained of severe pain, a colonoscopist from the EC group replaced the initial examiner before midazolam was administered and continued insertion to the cecum. When such a case involved a colonoscopist from the EC group as the initial examiner, a more experienced member of the EC group would continue the procedure. After reaching the cecum, the initial examiner proceeded with withdrawal of the colonoscope.

A "complete colonoscopy" was defined as successful insertion to the cecum bottom or terminal ileum. Insertion to the cecum and withdrawal time was recorded for every colonoscopy.

### CO<sub>2</sub> insufflation and monitoring system

CO<sub>2</sub> was administered using a commercial CO<sub>2</sub> regulator (Gas Regulator, Crown, Model FR-IIS-P; Yutaka Engineering, Tokyo, Japan) connected to a CO<sub>2</sub> bottle.

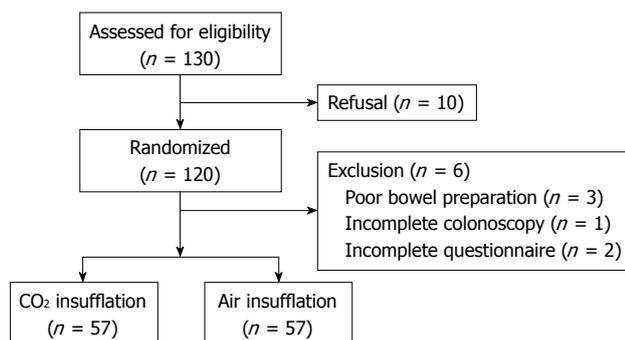

Figure 1 Patient flow chart.

The regulator delivered CO<sub>2</sub> at the rate of 2 L/min. CO<sub>2</sub> and air insufflations were used in a blind fashion both to patients and colonoscopists with full-day colonoscopy sessions randomly assigned CO<sub>2</sub> or air insufflation to avoid unblinding caused by set-up changes between patients.

CO<sub>2</sub> partial pressure was continuously measured using a transcutaneous CO<sub>2</sub> monitoring system (TOSCA 500; Radiometer Basel AG, Switzerland). Processed transcutaneous CO<sub>2</sub> readings (PtcCO<sub>2</sub>) correlate closely with directly obtained arterial blood gas results<sup>[16,17]</sup>. Sensors were attached to a patient's ear lobe with a monitor-specific clip. A colonoscopy assistant recorded readings and an independent observer monitored gas readings to avoid potential serious side effects. CO<sub>2</sub> insufflation was stopped immediately if PtcCO<sub>2</sub> registered > 60 mmHg during any colonoscopy examination.

### Pain and discomfort measurement

A 100-mm visual analogue scale (VAS) consisting of a horizontal line 100 mm in length was used for measuring patient abdominal pain and discomfort (0 mm = painless, 100 mm = extremely painful)<sup>[18]</sup>. Patients recorded the pain level experienced upon reaching the cecum bottom, immediately following their examinations and 30 min, 1, 2, 4 and 6 h afterwards. The VAS score was the distance measured to the nearest millimeter from the left end of the line to the point of the patient's mark.

Another member of the medical staff, who did not know how the procedures were performed, interviewed the patients 30 min after completion of their colonoscopies. A questionnaire was then given to the patients to take home to complete as instructed at intervals of 1, 2, 4 and 6 h and the completed forms were then mailed to the hospital the following day. The completed questionnaires were subsequently mailed to our medical office. No follow-up phone calls were made as 98% of all questionnaires were promptly returned.

### Statistical analysis

A preliminary pilot study was conducted to estimate the SD in pain measurements. With an assumed SD of 19 mm, the study sample size was calculated at 110 patients in order to have an 80% power with two-sided  $\alpha$  levels of 0.05 to detect any differences in VAS scores between

the two insufflation groups ( $\geq 10$  mm was considered clinically important).

The outcomes for our secondary objective to clarify any differences between the two insufflation methods in relation to the experience level of participating colonoscopists were analyzed on an intention-to-treat basis, given the fact that a number of the initial examining colonoscopists were replaced during the insertion phase of the procedure. Statistical comparisons were made using chi-square and Fisher's exact tests. ANOVA was used for repeated measures statistical analysis of pain. Some variables were not distributed normally, thus the Wilcoxon rank sum test was applied for supplementary analysis to compare groups at each measurement point. Statistical analyses were performed using Prism version 5.0 (GraphPad Software, San Diego, CA, USA) and JMP version 6.3 (SAS Institute, Cary, NC, USA). A *P* value < 0.05 was considered significant.

## RESULTS

### Baseline characteristics

A total of 130 patients were asked to participate and 120 consenting patients were randomized into two groups prior to their colonoscopy examinations (Figure 1). Three poor bowel preparation patients were not included and one (0.85%, 1/117) incomplete intubation patient in the air insufflation group with a history of abdominal and pelvic open surgery, whose examination was performed by an EC, was not submitted for consideration. Completed questionnaires were received from 98% of the 116 remaining patients, thus a final total of 114 patients (68% female/32% male) were analyzed in this study. Exactly half or 57 patients were examined using CO<sub>2</sub> insufflation and the other 57 patients were examined with air insufflation. There were no significant differences in baseline patient characteristics including eligibility criteria for potentially difficult cases between the two groups (Table 1).

### Outcome measures comparing CO<sub>2</sub> and air insufflation groups

There were no significant differences in procedure times including intubation, withdrawal and total time between the two groups (Table 2). Midazolam was administered to two patients (4%) in each group. There were no instances of PtcCO<sub>2</sub> > 60 mmHg in the CO<sub>2</sub> insufflation patients or any procedure-related complications in either group.

Figure 2 shows the mean VAS scores during and after colonoscopy examinations. VAS scores in the CO<sub>2</sub> insufflation group were significantly better than those in the air insufflation group (*P* < 0.001, ANOVA for repeated measures). The overall mean difference was 5.3 mm (95% CI: 3.5-7.1, *P* < 0.001). Comparison by nonparametric analysis at each measurement point produced results favoring CO<sub>2</sub> insufflation immediately following the examinations and up to 2 h afterwards. The maximum mean difference of 9.2 mm (95% CI: 0.4-18.0, *P* = 0.0049) was recorded 30 min after the examinations.

	CO <sub>2</sub> group (n = 57)	Air group (n = 57)	P value
Median age, yr (IQR)	65 (59-73)	62 (47-71)	0.107
Females	39 (68)	38 (67)	1.00
Eligibility criteria for difficult cases <sup>1</sup>			
Females with relatively low BMI (< 22)	35 (61)	36 (63)	0.133
Previous abdominal and/or pelvic open surgery	41 (72)	37 (65)	0.546
Males with previously diagnosed left-side diverticulosis	6 (11)	2 (4)	0.271
One or more previous colonoscopies	16 (28)	15 (26)	1.00

<sup>1</sup>Some patients had more than one difficult case factor. IQR: Interquartile range; BMI: Body mass index.

	CO <sub>2</sub> group (n = 57)	Air group (n = 57)	P value
Patients receiving antispasmodic drug (%)	54 (95)	56 (98)	0.616
Median total procedure time, min (IQR)	22.5 (17.9-29.6)	22.3 (16.3-43.9)	0.734
Insertion to cecum	10.3 (6.5-16.6)	9.6 (5.8-16.2)	0.601
Withdrawal	11.9 (10.1-13.6)	12.0 (9.8-14.2)	0.986

	EC group (n = 53)	LEC group (n = 61)	P value
Median total procedure time, min (IQR)	19.5 (15.3-25.8)	23.8 (19.2-34.5)	0.005
Insertion to cecum	7.7 (5.1-13.2)	12.5 (7.0-18.9)	0.036
Withdrawal	10.9 (10.0-13.0)	12.5 (10.2-15.1)	0.003
Examiner replaced during intubation	1	5	0.213

EC: Experienced colonoscopist; LEC: Less experienced colonoscopist.

### Subgroup analysis

Based on the subgroup analysis relative to experience level of the participating colonoscopists, we evaluated 53 patients (46%) in the EC group and 61 patients (54%) in the LEC group. There were no significant differences in eligibility criteria for potentially difficult cases between the two groups, however, the EC group achieved insertion to the cecum significantly faster, while withdrawal and total procedure times were also significantly shorter than those in the LEC group (Table 3). The number of replacements by another colonoscopist was larger in the LEC group (5) than in the EC group (1), however, there was no significant difference between the two groups.

Figure 3 shows the mean VAS scores for 27 CO<sub>2</sub> insufflation patients and 26 air insufflation patients during and following colonoscopy examinations performed by the EC group. There were no significant differences in the mean VAS scores between the two patient groups

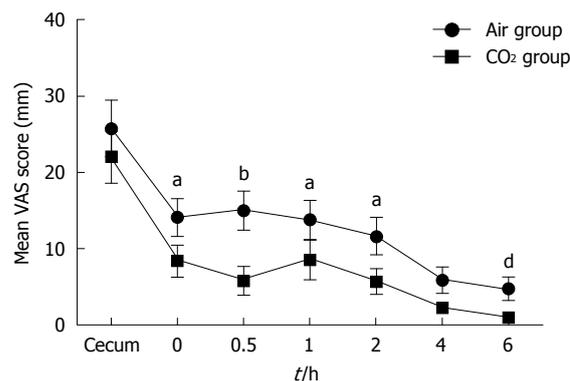

Figure 2 Mean VAS scores at corresponding measurement points during and after colonoscopy examinations in CO<sub>2</sub> and air insufflation groups. VAS scores for CO<sub>2</sub> insufflation were significantly better than those for air insufflation (<sup>a</sup>*P* < 0.001, ANOVA for repeated measures). <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs the CO<sub>2</sub> group at each measurement point by Wilcoxon rank sum test. VAS: Visual analogue scale.

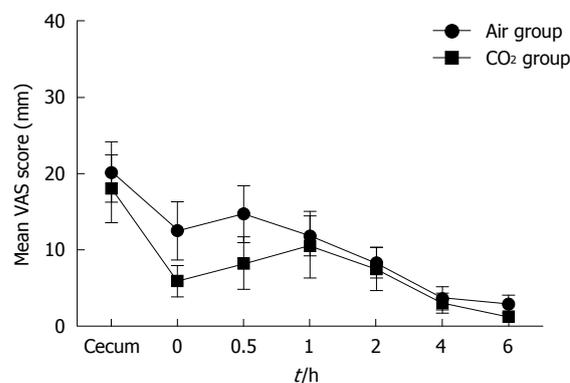

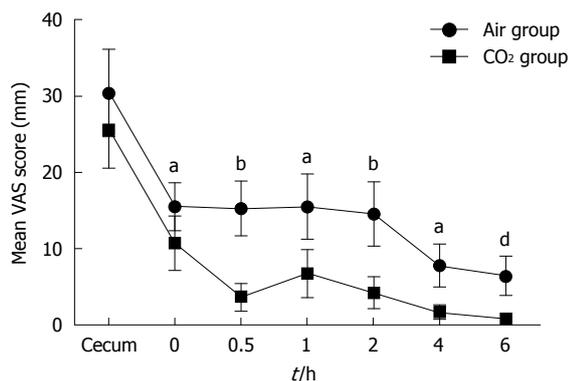

Figure 3 Mean VAS scores at corresponding measurement points during and after colonoscopy examinations for experienced colonoscopists (EC group) in CO<sub>2</sub> and air insufflation groups. There were no significant differences in VAS scores between the two insufflation groups for EC group (*P* = 0.29, ANOVA for repeated measures).

(*P* = 0.29, ANOVA for repeated measures). A comparison of the two patient groups at each measurement point also revealed no significant differences. The maximum mean difference of 6.5 mm (95% CI: -3.7-16.6, *P* = 0.207) occurred 30 min after the examinations.

In the LEC group, 30 CO<sub>2</sub> insufflation patients were evaluated along with 31 air insufflation patients. The mean VAS scores in the CO<sub>2</sub> insufflation group were significantly better than those in the air insufflation group (*P* = 0.023, ANOVA for repeated measures) (Figure 4). The overall mean difference was 7.5 mm (95% CI: 4.9-10.0, *P* < 0.001). A comparison of the two groups by nonparametric analysis at each measurement point produced results favoring CO<sub>2</sub> insufflation from immediately after the examinations up to 4 h later with the maximum mean difference of 11.6 mm (95% CI: 3.4-19.8, *P* = 0.006) occurring 30 min after the examinations.

## DISCUSSION

The increase in patient abdominal pain and discomfort

**Figure 4** Mean VAS scores at corresponding measurement points during and after colonoscopy examinations for less experienced colonoscopists (LEC group) in CO<sub>2</sub> and air insufflation groups. VAS scores for CO<sub>2</sub> insufflation were significantly better compared to air insufflation for LEC group (<sup>d</sup> $P = 0.023$ , ANOVA for repeated measures). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the CO<sub>2</sub> group at each measurement point by Wilcoxon rank sum test.

often encountered in difficult colonoscopy examination cases is a concern that needs to be satisfactorily resolved by colonoscopists. In this study, we successfully demonstrated the clinical effectiveness of CO<sub>2</sub> insufflation in potentially difficult colonoscopy examination cases. We also clarified the efficacy of CO<sub>2</sub> insufflation for LECs compared to highly ECs.

CO<sub>2</sub> with its characteristic rapid rate of absorption into surrounding tissue has been reported to be more suitable than atmospheric air in various clinical settings<sup>[12-15]</sup>. In fact, several randomized trials have shown that CO<sub>2</sub> insufflation reduced post-colonoscopy abdominal pain and discomfort compared to conventional air insufflation in ambulatory settings. Bretthauer *et al*<sup>[15]</sup> demonstrated that CO<sub>2</sub> insufflation was not only effective, but also safe during colonoscopies in patients receiving conscious sedation. Saito *et al*<sup>[19]</sup> introduced the use of CO<sub>2</sub> insufflation during lengthier colorectal endoscopic submucosal dissections in patients receiving conscious sedation. Their results demonstrated the effectiveness and safety of CO<sub>2</sub> insufflation as well as a resultant reduction in total dosage of midazolam. CO<sub>2</sub> insufflation has also been applied in endoscopic retrograde cholangiopancreatography (ERCP)<sup>[20]</sup> and endoscopic dilatation therapy using a double balloon endoscope<sup>[21]</sup>. There have been few detailed investigative reports on the use of CO<sub>2</sub> insufflation during difficult colonoscopy cases. In addition, the effect of the relative experience of colonoscopists using CO<sub>2</sub> insufflation has not been previously analyzed.

This study validated our theory that CO<sub>2</sub> insufflation is more effective than air insufflation in potentially difficult colonoscopy cases with the comparative difference for the two procedures being particularly discernable between LECs and ECs. Colonoscopy is a technically demanding procedure requiring considerable instruction and on-the-job experience for optimal performance. A suitable training program and sufficient opportunities to improve practical skills in a clinical setting are essential for beginners as well as colonoscopists with a moderate degree of experience<sup>[10,11,22]</sup>.

Difficult colonoscopy examinations performed by LECs require additional time as do ERCP and therapeutic endoscopic procedures, and can cause patient abdominal pain and discomfort both during the procedure and afterwards. The results of our study demonstrated a difference not only in intubation times, but also in withdrawal and overall examination times according to the experience of the participating colonoscopists. Avoiding prolonged insufflation especially during insertion, however, might have led to similar results in the LEC group concerning the clinical effectiveness of CO<sub>2</sub> in reducing patient pain and discomfort.

Lee *et al*<sup>[8]</sup> recommended that trainees perform over 150 examinations in a colonoscopy training program to be technically competent for diagnostic colonoscopy. Our results revealed significant differences in examination times and patient abdominal pain and discomfort after colonoscopy between the EC and LEC groups. The four colonoscopists in the LEC group had each performed a minimum of 900 colonoscopies, thus the question arises as to whether a minimum of 150 cases referred to in the report by Lee above, is sufficient for conducting examinations in potentially difficult colonoscopy cases.

A recent study in Ontario, Canada analyzed factors associated with incomplete colonoscopies based on the following settings: an academic hospital, a community hospital and private medical offices. The incomplete colonoscopy rate was highest in private offices with an odds ratio increase of more than three-fold<sup>[3]</sup>, thus introducing CO<sub>2</sub> insufflation may be particularly useful in reducing patient complaints in non-hospital environments. We refrained from using novice colonoscopists in this study because of the formidable nature of potentially difficult colonoscopy cases. Such novices should only conduct difficult colonoscopies after gaining the necessary experience performing routine colonoscopy examinations.

A number of techniques and devices have reportedly been effective in reducing patient abdominal pain and discomfort during difficult colonoscopies, improving the rate of successful insertion to the cecum, shortening insertion time to the cecum and reducing the dosage of sedatives<sup>[23]</sup> including the use of a pediatric colonoscope<sup>[24]</sup>, variable stiffness colonoscope<sup>[25]</sup>, gastroscope<sup>[26]</sup>, double balloon endoscope<sup>[27]</sup> and hood attached to the top of the colonoscope<sup>[28]</sup>. A PVSC featuring both variable stiffness on demand and a thin diameter was used in our trial. Previously, this instrument was shown not to be superior to adult or standard pediatric colonoscopes<sup>[29-32]</sup>. However, there have been reports that use of the PVSC made it possible to complete colonoscopies that would have been much more difficult or impossible to perform using an adult colonoscope, including patients who had undergone hysterectomies<sup>[31]</sup> and patients with diverticular disease and severe stenosis<sup>[32]</sup>.

There was only one case (0.85%) of incomplete insertion to the cecum in our study and just four (3.5%) patients required sedation. Complete screening colonoscopy without sedation or with on-demand sedation in

academic medical centers has been reported to be in the 88%-99% range<sup>[33-36]</sup>, with the optimum intubation rate obtained using a PVSC. In this study, the PVSC more than likely contributed to the impressive successful intubation rates and reduction in pain during insertion to the cecum achieved in both groups, as well as the favorable intubation times for each group. In several studies performed by ECs at academic medical centers, insertion to the cecum times varied between 7-13 min for colonoscopies performed without sedation or with on-demand sedation<sup>[33-36]</sup>. Our median intubation times of 7.7 and 12.5 min for ECs and LECs, respectively, were in line with these earlier reports.

In conclusion, we clearly demonstrated the clinical effectiveness of CO<sub>2</sub> insufflation in potentially difficult colonoscopy examination cases performed without sedation. We also successfully clarified the efficacy of CO<sub>2</sub> insufflation for LECs.

## COMMENTS

### Background

Colonoscopy is the preferred method for preventing, detecting and treating colorectal cancer, however, prolonged cecal intubation can cause increased patient abdominal pain and discomfort especially in difficult cases, such as female patients with a relatively low body mass index, patients with a history of abdominal and/or pelvic open surgery and male patients with diverticulosis. CO<sub>2</sub> with its rapid rate of absorption has been reported to be more suitable than atmospheric air as an insufflation agent in various clinical settings, although air insufflation is still the standard method due to a lack of suitable equipment and inadequate information as to when and on whom CO<sub>2</sub> insufflation should be used during colonoscopy examinations.

### Research frontiers

This prospective randomized controlled study was conducted to clarify the effectiveness of CO<sub>2</sub> insufflation in potentially difficult cases, particularly in relation to colonoscopist experience level.

### Innovations and breakthroughs

The clinical effectiveness of CO<sub>2</sub> insufflation was clearly demonstrated in potentially difficult colonoscopy examination cases performed without sedation. The procedure that was followed also clarified the efficacy of CO<sub>2</sub> insufflation for less experienced colonoscopists (LEC) particularly in comparison to more experienced colonoscopists.

### Applications

The use of CO<sub>2</sub> insufflation can be incorporated into existing and future colonoscopy training programs in order to further improve the technical skills of colonoscopists.

### Peer review

The authors successfully demonstrated that CO<sub>2</sub> insufflation with its rapid rate of CO<sub>2</sub> absorption and improved efficacy reduced patient pain in potentially difficult cases particularly when colonoscopy examinations were performed by LECs.

### Abstract

**AIM:** To elucidate the possible crosstalk between angiogenesis, cytokeratin-18 (CK-18), and insulin resistance (IR) especially in patients with non-alcoholic steatohepatitis (NASH).

**METHODS:** Twenty-eight patients with NASH and 11 with simple fatty liver disease (FL) were enrolled in this study and underwent clinicopathological examination. The measures of angiogenesis, CK-18, and IR employed were CD34-immunopositive vessels, CK-18-immunopositive cells, and homeostasis model assessment of IR (HOMA-IR), respectively. The correlations of these factors with NASH were elucidated.

**RESULTS:** Significant development of hepatic neovascularization was observed only in NASH, whereas almost no neovascularization could be observed in FL and healthy liver. The degree of angiogenesis was almost parallel to liver fibrosis development, and both parameters were positively correlated. Similarly, CK-18

expression and HOMA-R were significantly increased in NASH as compared with FL and healthy liver. Furthermore, CK-18 and HOMA-IR were also positively correlated with the degree of neovascularization.

**CONCLUSION:** These results indicate that the crosstalk between angiogenesis, CK-18, and IR may play an important role in the onset and progression of NASH.

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) ranges from simple steatosis to cirrhosis. Fatty liver (FL) has been recognized as a benign and non-progressive condition<sup>[1,2]</sup>. However, non-alcoholic steatohepatitis (NASH) is now widely known as a liver disease which may progress to liver cirrhosis and finally hepatocellular carcinoma (HCC). Fibrosis development is only seen in NASH but not in simple FL. The pathogenesis of NASH is not well understood, but it is unlikely that one of the recognized mechanisms explains all pathogenic processes of NASH. Thereby, NASH may develop as a consequence of a multifactorial process<sup>[2]</sup>.

Angiogenesis i.e. formation of new vessels by sprouting from the pre-existing vasculature, is of central importance for embryonic development and organogenesis. Abnormally pathological angiogenesis is observed in rheumatoid arthritis, psoriasis, diabetic retinopathy, tumor growth, and even in fibrogenesis<sup>[3]</sup>. Although previous studies conducted to determine the molecular process associated with fibrosis and angiogenesis were performed independently, recent studies have revealed that both biological phenomena developed synergistically<sup>[4]</sup>. It was shown that neovascularization significantly increased during the development of liver fibrosis both in human and animal experimental studies<sup>[5,6]</sup>. In the NASH experimental model, we previously demonstrated that angiogenesis plays an important role in the progression of NASH<sup>[7]</sup>. We also reported that neovascularization developed in patients with NASH whereas no marked augmentation was observed in FL or the healthy liver<sup>[8]</sup>.

Recent studies have suggested that increased hepatocyte apoptosis has an important role in progression from simple FL to NASH, and correlates with disease severity and hepatic fibrosis<sup>[9,10]</sup>. During apoptosis, some intracellular proteins are cleaved by caspase. A neoepitope in cytokeratin-18 (CK-18), the major intermediate filament protein in the liver, becomes available at an early caspase cleavage event during apoptosis and is not detectable in the viable or necrotic cells<sup>[11]</sup>. It has been reported that CK-18 fragments were markedly elevated in NAFLD patients as compared with healthy controls, and that the plasma levels of CK-18 correlated with the expression levels in the liver. A significant increase in CK-18 expression could be observed in patients with NASH as compared with the simple FL patients, and the expression level of CK-18 correlated with the presence of fibrosis<sup>[10]</sup>. The same group recently conducted a multicenter validation study which yielded similar results, and CK-18 was identified as an independent predictor of NASH<sup>[12]</sup>.

NASH is well known as a liver disease that frequently complicates insulin resistance (IR) status<sup>[13]</sup>. Current evidence points to IR and subsequent hyperinsulinemia as the key pathogenic factors in NAFLD and progression from simple FL to NASH<sup>[13]</sup>. It has been reported that IR accelerated the progression in a NASH animal model, and that an insulin-sensitizing agent could reverse the underlying pathogenesis involved through improvement in IR<sup>[14]</sup>. We also have demonstrated that IR itself significantly promoted liver fibrosis development in diabetic rats<sup>[15]</sup>. Several studies have shown that insulin-sensitizing agents improved the metabolic and histologic parameters, most notably liver injury and fibrosis, not only in experimental models, but also in patients with NASH<sup>[16,17]</sup>. Collectively, these findings indicate that neovascularization, CK-18 expression, and IR status play pivotal roles in the progression of NASH. We previously demonstrated that angiogenesis and IR play important roles in animal NASH models<sup>[7,15]</sup>. However, no study has been conducted as yet to examine the interaction among these parameters in NASH using human cases.

In the current study, we elucidated the possible

correlation between angiogenesis, CK-18, and IR especially in fibrosis development, which is one of the specific characteristic features of NASH compared with simple FL.

## MATERIALS AND METHODS

### *Patients and methods*

We recruited a total of 39 patients with NAFLD between 2001 and 2007 at Nara Medical University, and three healthy volunteers were enrolled as a control group. Twenty-eight patients with NASH (17 males and 11 females) and 11 patients with simple FL (seven males and four females), diagnosed by histological examination, were enrolled in this study. First, all patients were re-evaluated clinically for evidence of diseases including diabetes mellitus and hypertension. Alcohol-induced hepatitis was excluded according to each patient's self-report and was confirmed by the family. The height and weight were measured, and the body mass index (BMI) was calculated. Hepatitis B virus surface antigen and hepatitis C virus antibody were negative in all patients. The standard liver function tests were performed for all patients. The fasting blood levels of glucose and insulin were assessed, and the homeostasis model assessment parameter of IR (HOMA-IR) was calculated. The serum fibrosis markers, namely, hyaluronic acid, type IV collagen 7S (7S-collagen), and amino-terminal peptide of type-III pro-collagen, were measured by latex agglutination, enzyme immunoassay, and radioimmunoassay, respectively, using routine laboratory methods. The serum levels of leptin and adiponectin were measured by ELISA kit (R&D systems, Tokyo, Japan) according to the manufacturer's instructions as described previously<sup>[18,19]</sup>.

### *Histology and immunohistochemistry*

Liver biopsies obtained for diagnostic purposes were histologically examined. The liver biopsy specimens exceeded 1.5-2 cm in length and 1.4 cm in width, and contained more than five portal areas in each sample that was sufficient to perform the immunohistochemical analysis. In all samples, serial sections were used for analysis. The first section was routinely stained with hematoxylin and eosin for histological examination. Another section was stained with Sirius Red to detect fibrosis development. The fibrosis stages was scored in an F0 to F4 scale, where F0 means absence of fibrosis; F1, portal fibrosis with few septa; F2, few septa; F3, abundant septa with cirrhosis; F4, cirrhosis, as described elsewhere<sup>[20]</sup>. Regarding the 28 patients with NASH, 10 had low-grade fibrosis (F0 and F1), and 18 had high-grade fibrosis (F2 to F4). For determination of neovascularization, we employed immunohistochemical detection of CD34, which is widely used as a marker of neovascularization, using paraffin-embedded sections as described previously<sup>[21]</sup>. We also performed immunohistochemical staining of CK-18 in the liver. Liver tissue samples were fixed in 4% formaldehyde solution and embedded in paraffin. Then, 5  $\mu$ m tissue sections were incubated in 0.1% hydrogen peroxide in 70%

**Table 1** Characteristic features of patients with FL and NASH (mean  $\pm$  SD)

	NASH (n = 28)	FL (n = 11)	P-value
Age (yr)	45.4 $\pm$ 14.7	43.6 $\pm$ 14.1	0.587

FL: Fatty liver; NASH: Non-alcoholic steatohepatitis; M: Male; F: Female.

methanol for 30 min to inhibit the endogenous peroxidase activity. Microwave antigen retrieval was performed at 500 W for 15 min with pH 9 antigen retrieval solution (Nichirei Bioscience Inc., Tokyo, Japan). Then, 10% fetal bovine serum with 0.3% Triton X was used to prevent nonspecific staining. The slides were subsequently incubated overnight at 4°C in humidified chambers with primary rabbit polyclonal anti-CD34 antibody at a dilution of 1:100 and primary rabbit polyclonal anti-CK-18 antibody (DAKO, Kyoto, Japan) at a dilution of 1:100. The sections were rinsed three times in a phosphate-buffered solution and further incubated with a biotinylated secondary antibody for 30 min at room temperature. Antigen-antibody complexes were detected by the avidin-biotin-peroxidase method, using diaminobenzidine as a chromogenic substrate (DAKO, Carpinteria, CA, USA). Finally, the slides were counter-stained with hematoxylin and then examined microscopically. Immunopositive quantitation of CD34 and Sirius Red-positive liver fibrosis areas were evaluated with Adobe Photoshop software and NIH image software as described previously<sup>[22]</sup>. The intensity of CK-18 staining was scored from 0 to 4 as previously described<sup>[8]</sup> with minor modification; 0: no staining; 1: mild (punctured labeling); 2: mild to moderate (dense labeling in a few lesions); 3: moderate; 4: strong (dense and homogeneous labeling in large areas).

### Statistical analysis

All data are expressed as mean  $\pm$  SD. The statistical analysis was performed using the  $\chi^2$  test for independence,

**Figure 1** Representative microphotographs of CD34-positive neovessels and cytokeratin-18 (CK-18)-positive cells in the liver of patients. A: Marked CD34-positive immunopositive vessels could be found in NASH along with liver fibrosis development; B: The immunopositivity of CK-18 was mainly observed in the hepatocytes. The arrows indicate CD34 and CK-18-immunopositivity in A and B, respectively. The original magnification was  $\times$  100.

the two-tailed Student's *t*-test, and simple regression analysis. Correlation between two parameters was tested by the Spearman rank correlation matrix.

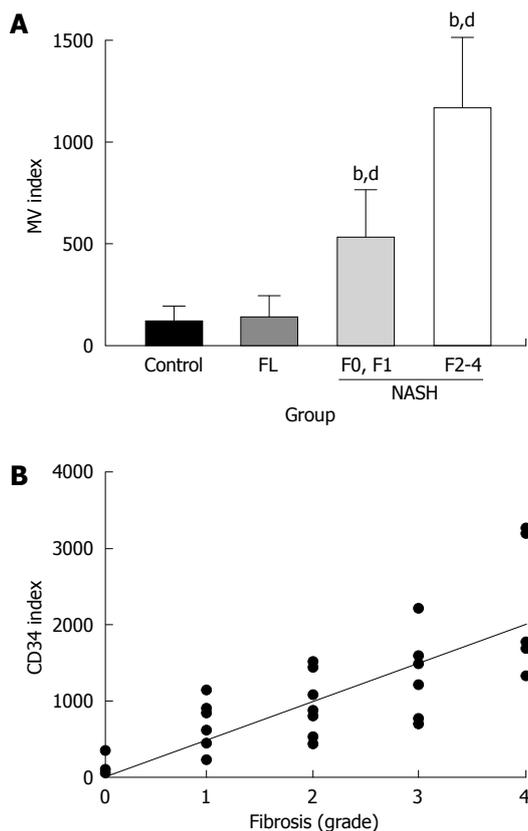

## RESULTS

### Clinical features

The clinical features of both groups are shown in Table 1. Most of the clinical features in the FL and NASH patients were not significantly different except BMI, HOMA-IR, serum aspartate aminotransferase (AST), hyaluronic acid, leptin, and adiponectin. The NASH patients had significantly higher BMI (28.8  $\pm$  4.33 *vs* 25.6  $\pm$  1.20), HOMA-IR (5.79  $\pm$  4.15 *vs* 2.26  $\pm$  0.96), AST (59.4  $\pm$  27.0 *vs* 37.5  $\pm$  10.0), hyaluronic acid (62.0  $\pm$  58.6 *vs* 15.0  $\pm$  9.06), and leptin (7.79  $\pm$  4.47 *vs* 2.58  $\pm$  0.43), than the FL patients. On the other hand, significantly lower serum adiponectin levels were observed in the NASH patients compared with the FL patients (5.31  $\pm$  1.70 *vs* 8.25  $\pm$  0.95).

### Neovascularization

The typical features of CD34-immunopositive neovessels in the liver are shown in Figure 1A. Apparent CD34-positive vessels could be observed neither in the liver of the healthy subjects nor in the FL patients, whereas marked immunopositive vessels could be observed in NASH livers along with the development of liver fibrosis. In the liver of low-grade fibrosis, neovascularization could

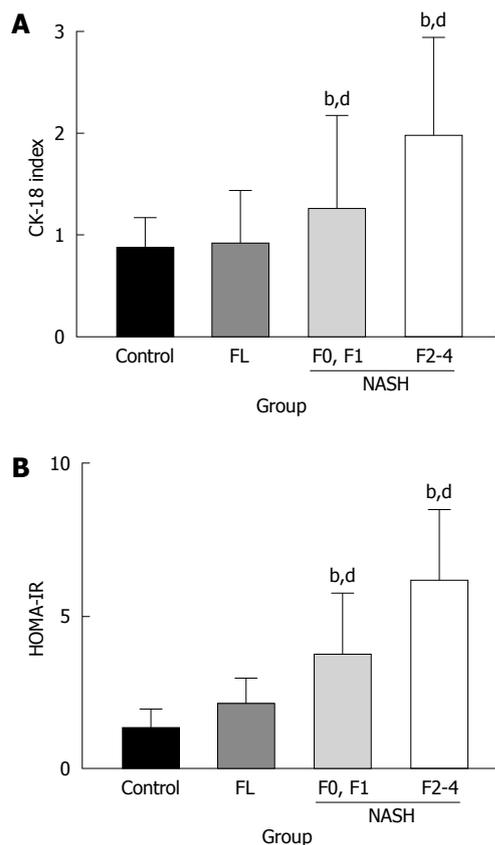

**Figure 2 Semi-quantitative analysis of CD34 and possible correlation with liver fibrosis development.** A: Semi-quantitative analysis of the CD34-positive neovessels in the liver in non-alcoholic fatty liver disease (NAFLD). There was no difference between the control healthy liver and simple FL. In NASH, a marked augmentation of neovascularization was found in the liver of NASH as compared with FL. The magnitude of neovascularization in high-grade (F2 to F4) liver fibrosis was more than in low-grade (F0, F1) fibrosis. The proportional increase in neovascularization was almost parallel to the development of liver fibrosis. <sup>b</sup> $P < 0.01$  vs control group; <sup>d</sup> $P < 0.01$  vs low-grade fibrosis with NASH group. The number of patients in each group was as follows: Control ( $n = 3$ ), FL ( $n = 11$ ), low-grade fibrosis (F0 and F1:  $n = 10$ ), and high-grade fibrosis (F2 to F4:  $n = 18$ ). MV: Microvessel density; B: The relationship between the development of CD-34-positive vessels and fibrosis grade in NAFLD. The degree of angiogenesis correlated with the development of fibrosis. The equation was  $y = 509.82x - 6.7958$ . The correlation coefficient was 0.6288.

be observed around the central vein (zone III). These neovessels progressed to the portal area (zone I) and were also observed along the fibrotic septa in high-grade fibrosis. We next performed a semi-quantitative analysis of the CD34-positive neovessels in conjunction with liver fibrosis development. There was no difference between the normal control liver and the FL (Figure 2A), which conformed with the immunohistochemical features. In NASH, a marked augmentation of neovascularization was found in the liver of NASH cases as compared with the FL. The magnitude of neovascularization in high-grade (F2 to F4) liver fibrosis was more than in low-grade (F0, F1) fibrosis. The increase in neovascularization was almost parallel to the development of liver fibrosis. As shown in Figure 2B, the degree of CD34-positive vessels positively correlated with fibrosis development ( $r^2 = 0.6288$ ).

#### CK-18 and IR

We next examined CK-18 expression in the liver. The

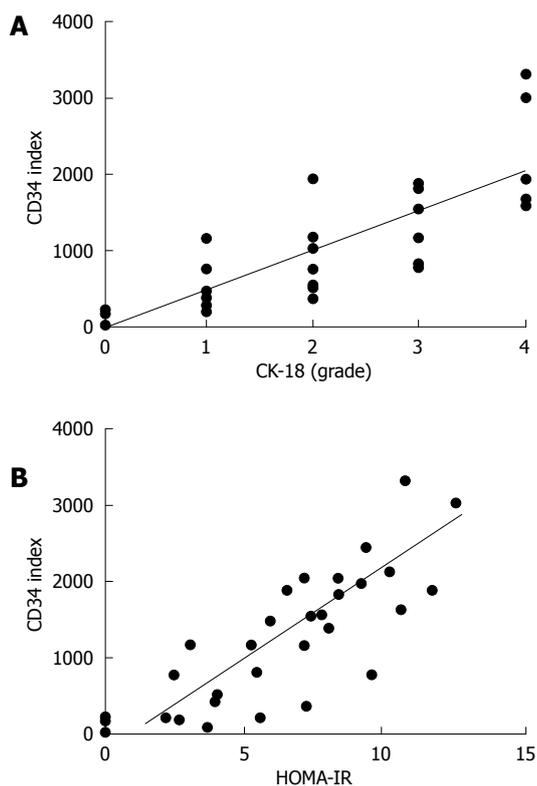

**Figure 3 Semi-quantitative analysis of the CK-18-positive cells in the liver (A) and HOMA-IR (B) in NAFLD.** Similar to the CD34-positive neovascularization, there was no difference between the control healthy liver and FL. In NASH, a marked augmentation of CK-18 (A) and HOMA-IR (B) was found in the liver of NASH as compared with FL. The magnitude of neovascularization in high-grade (F2 to F4) liver fibrosis was more than in low-grade (F0, F1) fibrosis. The number of patients in each group was as follows; C ( $n = 3$ ), FL ( $n = 11$ ), low-grade fibrosis (F0 and F1:  $n = 10$ ), and high-grade fibrosis (F2 to F4:  $n = 18$ ). <sup>b</sup> $P < 0.01$  vs control group; <sup>d</sup> $P < 0.01$  vs low-grade fibrosis with NASH group.

immunopositivity of CK-18 was mainly observed in the hepatocytes (Figure 1B). Similar to CD34, CK-18 expression was significantly increased in the NASH patients as compared with simple FL and healthy liver. Staining of CK-18 was barely visible in the healthy liver and FL, whereas most NASH cases showed positive staining. Among the NASH patients, those with high-grade fibrosis had greater hepatic expression of CK-18 than those with low-grade fibrosis (Figure 3A). We observed that the magnitude of CK-18 expression positively correlated with CD34-positive neovascularization ( $r^2 = 0.6512$ , Figure 4A). We also examined the possible role of IR in progression of NASH, and observed that HOMA-IR was significantly higher in NASH patients than in simple FL and healthy liver. The HOMA-IR also increased with the progression of NASH, and there was a positive correlation between HOMA-IR and hepatic neovascularization (Figure 3B and Figure 4B, respectively).

## DISCUSSION

Recent studies have revealed that angiogenesis plays an important role in many pathological events, including

**Figure 4** The relationship between angiogenesis, CK-18-positive vessels (A), and HOMA-IR (B). The degree of angiogenesis correlated with the CK-18-positive cells (A) and HOMA-IR (B). A: The magnitude of expression of CK-18 correlated positively with CD34-positive neovascularization. The equation was  $y = 500.63x + 4.6606$ . The correlation coefficient was 0.6512; B: Similarly, there was a positive correlation between HOMA-IR and hepatic neovascularization. The equation was  $y = 233.75x - 339.39$ . The correlation coefficient was 0.6184.

liver fibrosis development. Although previous studies conducted to determine the molecular processes associated with fibrosis and angiogenesis were performed independently, recent studies have revealed that both biological phenomena emerged concomitantly<sup>[4]</sup>. Angiogenesis in the liver is characterized by capillarization of the sinusoids<sup>[3]</sup>. It has been shown that capillarization and phenotypic changes of the hepatic sinusoidal endothelial cells (ECs) occur during liver fibrosis development<sup>[23]</sup>. It has been reported that CD34 is not expressed by healthy ECs, but when ECs alter their phenotype, they can express CD34<sup>[24]</sup>. Much attention is focused on a possible association with chronic liver diseases<sup>[25]</sup>. A recent study on chronic hepatitis C (CHC) has shown that the number of CD34-positive new vessels was significantly increased and positively correlated with the fibrosis stage<sup>[26]</sup>. As well as CHC, in the current study we found a significant development of hepatic CD34-positive neovascularization in NASH, whereas almost no development could be observed in FL. The degree of angiogenesis was almost parallel to the development of liver fibrosis in NASH. These results are consistent with our previous experimental finding that angiogenesis increased stepwise during hepatic fibrosis development in several fibrosis models, including the rodent dietary NASH model<sup>[5,7]</sup>. We also observed that HOMA-IR was significantly higher in NASH along with liver

fibrosis development, and that it positively correlated with the development of neovascularization. We previously reported that the IR status, i.e. co-existence of high glucose and insulin, itself significantly promoted liver fibrosis development in rats along with augmentation of neovascularization. Furthermore, high glucose and insulin stimulated *in vitro* neovascularization, and the combination treatment with glucose and insulin significantly promoted the effect as compared with either agent alone<sup>[15]</sup>. Collectively, it is likely that IR-mediated neovascularization is involved in the development and progression of NASH.

Because NAFLD is a common manifestation of metabolic syndromes, various adipocytokines are involved in the progression of NASH<sup>[27,28]</sup>. Among them, adiponectin and leptin are well known to be involved in the pathogenesis of NASH<sup>[27,29,30]</sup>. Adiponectin administration alleviates NAFLD progression in mice, and liver fibrosis is accelerated in adiponectin knockout mice, indicating the protective effect of adiponectin against liver fibrosis development in NASH<sup>[31]</sup>. In the NASH patients, the circulating adiponectin is reportedly decreased<sup>[30]</sup>, and we also observed that the serum level of adiponectin in NASH decreased significantly more than in FL. On the other hand, recent reports have revealed that leptin exerts pro-fibrogenic activity. Hepatic fibrogenesis is impaired in leptin- and leptin receptor-deficient animals<sup>[29,32]</sup>. Leptin also enhances proliferation of activated hepatic stellate cells (HSCs), which play a central role in the development of liver fibrosis<sup>[33]</sup>. In addition to these direct effects on HSC, recent studies have revealed that leptin possesses angiogenic activity<sup>[7,34]</sup>. We previously reported that leptin exerted a potent angiogenic effect, and that leptin-mediated neovascularization played an important role in the development of liver fibrosis in the rat NASH model<sup>[7]</sup>. In the current study, the serum leptin level was significantly higher in NASH than in FL. However, we only measured the serum level of leptin in the current study. The role of leptin in fibrosis development in NASH is still controversial. It has been reported that local leptin plays a more important role than serum leptin in the progression of NASH<sup>[35]</sup>. Further studies are required to elucidate the local leptin and leptin receptor interaction with *in situ* hybridization in the future.

As well as neovascularization, we observed that the hepatocyte apoptosis marker, CK-18, was also significantly increased in NASH as compared with simple FL. This finding was consistent with recent reports suggesting that the CK-18 expression can detect the presence of NASH<sup>[10,12,36]</sup>. Uncontrolled hepatocyte apoptosis proved to be an important event triggering liver fibrogenesis<sup>[9]</sup>. We also observed that the expression of CK-18 was increased along with liver fibrosis development in NASH. Moreover, there was a positive correlation between the CK-18 expression and hepatic neovascularization. These results suggested that there was some crosstalk between CK-18 and angiogenesis in the liver of NASH. As well as being a marker of apoptosis, CK-18 has been found to enhance the migratory and invasive potential of tumor cells<sup>[37]</sup>. Furthermore, it has been reported

that CK-18 expression was significantly higher in HCC than in CHC<sup>[38]</sup>. We previously reported that hepatic neovascularization increased in a stepwise manner during hepatocarcinogenesis, and the increase in angiogenesis was mainly observed in the glutathione-S-transferase placental form (GST-P)-positive pre-neoplastic lesions as compared with the adjacent tissues<sup>[39,40]</sup>. A recent report has shown that CK-18 expression also significantly increased in GST-P-positive lesions<sup>[41]</sup>. These results indicate that, as well as being a marker of apoptosis, CK-18 may have a direct association with hepatic neovascularization.

It is important to elucidate whether the correlation among these factors is a cause or consequence of NASH. However, in this study, we could not identify what factors were the causes or consequences in the progression of NASH. Although the respective factors interact with each other, further sequential studies are required in the future to determine what factors developed prior to other factors during the progression of NASH. Also, the number of patients was not high enough in the current study. We are acquiring a larger number of patients' files and when the sample of patients with NASH and simple FL is adequate, we will perform an advanced analysis of the current parameters.

In conclusion, we have shown that only the liver of NASH cases had marked neovascularization whereas simple FL and healthy livers did not. The hepatic neovascularization was proportional to the increase in grade of liver fibrosis. CK-18 expression and HOMA-IR were also significantly increased in NASH as compared with FL and healthy liver. Furthermore, CK-18 and HOMA-IR also positively correlated with the degree of neovascularization. These results indicate that the crosstalk between angiogenesis, CK-18, and IR may play an important role in the onset and progression of NASH.

## COMMENTS

### Background

It has been reported that angiogenesis, cytokeratin-18 (CK-18), and insulin resistance (IR) play important roles in the development of non-alcoholic steatohepatitis (NASH). The aim of the current study was to elucidate the possible crosstalk between angiogenesis, CK-18, and IR especially in patients with NASH.

### Research frontiers

Significant development of hepatic neovascularization was observed only in NASH, and the degree of angiogenesis was almost parallel to liver fibrosis development. Similarly, CK-18 expression and IR were significantly increased in NASH. Furthermore, CK-18 and IR also positively correlated with the degree of neovascularization.

### Innovations and breakthroughs

Only NASH was associated with marked neovascularization, which was proportional to the increase in grade of liver fibrosis. Moreover, the degree of neovascularization positively correlated with CK-18 and IR in NASH. These results emphasize the new findings that the crosstalk between angiogenesis, CK-18, and IR plays an important role in the onset and progression of NASH.

### Applications

The novel findings may lead to a new alternative therapy for NASH in the near future.

### Peer review

The manuscript is well written and the conclusions are appropriate for the results.

### Abstract

**AIM:** To examine the protective effect of green tea extract (GT) on hepatic fibrosis *in vitro* and *in vivo* in dimethylnitrosamine (DMN)-induced rats.

**METHODS:** HSC-T6, a rat hepatic stellate cell line, was used as an *in vitro* assay system. Cell proliferation, collagen content, and type 1 collagen expression were examined in activated HSC-T6 cells. Collagen was determined by estimating the hydroxyproline content. In rats with DMN-induced hepatic fibrosis, serum aspartate aminotransferase and alanine aminotransferase concentrations, liver hydroxyproline and lipid peroxides were determined. Pathologic changes were examined by hematoxylin & eosin staining.

**RESULTS:** GT administration prevented the development of hepatic fibrosis in the rat model of DMN-induced liver fibrosis. These results were confirmed both by liver histology and by quantitative measurement of hepatic hydroxyproline content, a marker of liver collagen deposition. Accordingly, inhibition of proliferation, reduced collagen deposition, and type 1 collagen expression were observed in activated HSC-T6 cells following GT treatment. These results imply that GT reduced the proliferation of activated HSC and down regulated the collagen content and expression of collagen type 1, thereby ameliorating hepatic fibrosis.

**CONCLUSION:** This study demonstrates that green

### INTRODUCTION

Hepatic fibrosis is a consequence of severe liver damage and occurs in many forms of chronic liver damage, including virus infection, autoimmune liver diseases and sustained alcohol abuse<sup>[1]</sup>. Hepatic stellate cells (HSC) are recognized as the primary cellular source of matrix components in chronic liver diseases, and therefore play a critical role in the development and maintenance of liver fibrosis<sup>[2]</sup>. The key cellular and molecular events involved in the pathogenesis of liver fibrosis include activation of HSC to a myofibroblast-like phenotype, production of excess matrix proteins, and increased cell proliferation<sup>[2]</sup>. Overproduction of extracellular matrix (ECM) components, particularly collagen, is a characteristic of activated HSC, and activation and proliferation of HSC have been implicated in the pathogenesis of liver fibrosis<sup>[3]</sup>. Therefore, suppression of HSC activation has been proposed as a therapeutic target against hepatic fibrosis<sup>[4]</sup>.

Acetaldehyde, a highly reactive compound produced by alcohol metabolism, stimulates the deposition of ECM proteins. Acetaldehyde also stimulates type 1 collagen synthesis and gene transcription in cultured rat and human HSC<sup>[5]</sup> and in human liver fibroblasts<sup>[6]</sup>.

Several studies have shown that lipid peroxidation stimulates collagen production in fibroblasts and HSC<sup>[7]</sup>, and plays an important role in the development of liver

fibrosis. Lipid peroxidation has been shown to stimulate the expression of collagen gene transcripts<sup>[8]</sup>. It has recently been shown that stellate cells are activated by free radicals as well as by malondialdehyde (MDA), a product of lipid peroxidation<sup>[9]</sup>. In addition, stellate cell activation by type 1 collagen has been shown to be blocked by antioxidants<sup>[9]</sup>, suggesting that lipid peroxidation may play a role in hepatofibrogenesis.

Green tea, which is a widely consumed drink, has received much attention due to its beneficial biological effects. Polyphenols, often collectively referred to as catechins, account for up to 30% of the dry weight and serve as a major effective component of green tea. The effects of green tea have been widely studied and antioxidative, antiallergic, antimutagenic/anticarcinogenic, and antibacterial effects have been documented<sup>[10-12]</sup>. It has been shown that an aqueous extract of polyphenols from green tea (*Camellia sinensis*) reduces liver fibrosis in rats induced by bile duct ligation, and epigallocatechin gallate (EGCG), the major component in green tea, was implicated as the main active ingredient<sup>[13]</sup>. EGCG has been reported to suppress cell proliferation and collagen production in HSC<sup>[14]</sup>. In addition, the hepatoprotective effects of green tea against carbon tetrachloride, cholestasis and alcohol induced liver fibrosis were reported in many studies<sup>[13,15,16]</sup>. However, the hepatoprotective effect of green tea in dimethylnitrosamine (DMN)-induced models has not been studied. The DMN-induced liver fibrosis model can reproduce most of the features observed during human liver fibrosis<sup>[17]</sup>. Furthermore, this model has other advantages such as progressive and remarkable pathological alterations, a high fibrosis reproduction rate, and a low mortality rate in experimental animals<sup>[18]</sup>. This model is also stable even after termination of DMN administration and is a reliable tool for screening antifibrotic agents<sup>[19]</sup>. Therefore, the aim of the present study was to examine the protective effect of green tea extract (GT) on hepatic fibrosis in a rat HSC line and in a rat model of DMN-induced hepatic fibrosis.

## MATERIALS AND METHODS

### Preparation of GT

Green tea, cultivated from Cheju island, Korea, was extracted with 80% methanol and freeze-dried.

### In vitro experiment

**Cell culture:** HSC-T6 cells, an immortalized rat HSC line, were cultured in Dulbecco's minimal essential medium (DMEM, Gibco, Grand Island, NY, USA) supplemented with 10% FBS (Gibco) and 0.5% antibiotics. Cultures were placed in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C, and the medium was changed twice a week. Acetaldehyde (175 μmol/L) was added to induce collagen type 1 and morphological features of activated stellate cell.

**Cell viability:** HSC-T6 cells were seeded into 96-well plates at a density of  $1.5 \times 10^4$  cells/well until 50% confluence. Cells treated with GT (10, 50, 100 μg/mL)

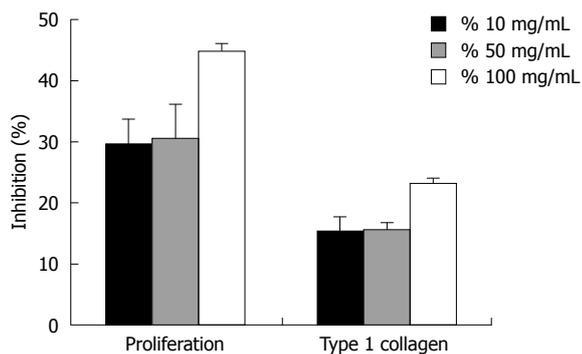

for 48 h were incubated with MTT (1 mg/mL) in a medium for 3 h at 37°C. The supernatant was removed and 100 μL of DMSO was added to each well to dissolve the formazan product. Absorbance at 570 nm was measured using a microplate reader.

**Hydroxyproline content:** Collagen was determined by estimating the hydroxyproline content, an amino acid characteristic of collagen. HSC-T6 cells were lysed after treatment with GT (100 μg/mL) for 24 h. The lysates were hydrolyzed in 6 mol/L HCl for 16 h at 110°C and evaporated to dryness to remove the acid. The residue, dissolved in distilled water, was mixed with 50% isopropanol and chloramine-T solution and left for 10 min at room temperature. Finally, p-dimethylaminobenzaldehyde in 60% perchloric acid was added and heated to 60°C for 25 min. The absorbance was measured at 558 nm.

**Expression of collagen type 1:** The expression of collagen type 1 was observed by ELISA. HSC-T6 cells, seeded on 24-well plates at a density of  $1.5 \times 10^5$  and cultured until 90% confluency, were treated with serum-free DMEM with or without 175 μmol/L acetaldehyde. Ascorbic acid (50 μg/L), and 3-aminopropionitrile fumarate (100 μg/L) were also added to increase the collagen proline hydroxylation and to prevent collagen cross-linking. After 24 h of treatment with GT (100 μg/L), aliquots of medium were transferred into immunowell plates, and glutaraldehyde (0.01%) was added and incubated at room temperature for 1 h. Collagen type 1 antibody (1:4000, Abcam Co., Cambridge, UK) was added and further incubated for 2 h at 37°C. The antigen-coated plates were blocked with casein and incubated with the secondary antibody (1:8000) linked to peroxidase, and subsequently re-incubated with substrate (TMB 10 mg/mL, 3% H<sub>2</sub>O<sub>2</sub>, 50 mmol/L sodium acetate buffer, pH 5.1) for 15 min. The enzymatic reaction was stopped by adding 1 mol/L H<sub>2</sub>SO<sub>4</sub>, and the absorbance at 450 nm was measured with a microplate reader.

### In vivo experiment

**Animals and treatments:** Male albino rats (235-250 g) were purchased from Samtako (Kyunggi-do, Korea) and housed in controlled temperature and relative humidity, and a 12 h light/dark cycle. All experiments were performed according to National guidelines for the use of animals in biomedical research. The rats were randomly assigned to four groups of eight rats each: the normal control group without any treatment (NC), the hepatic fibrosis control group (FC), and hepatic fibrosis with 100 mg/kg GT treated group (FG). Hepatic fibrosis was induced by intraperitoneal injections of 10 mg/kg dimethylnitrosamine (DMN, Sigma, St. Louis, USA) for 3 consecutive days each week over a period of 4 wk. Normal saline was given to NC rats. GT was administered in drinking water which was calculated according to the amount of water consumed the previous day. At the end of the 4 wk experimental period, all rats were killed under ether anesthesia. Blood was obtained from the

**Figure 1** Inhibitory effects of green tea on HSC-T6 cell proliferation and type 1 collagen expression. Green tea suppressed HSC-T6 cell proliferation and type 1 collagen expression in a dose-dependent manner. Data are expressed as mean  $\pm$  SD.

inferior vena cava, and the liver was excised. The liver was immediately frozen for biochemical measurements or fixed in formalin for histochemical examination.

**Hepatotoxicity and lipid peroxidation:** Hepatotoxicity was assessed by quantifying the activities of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) using a spectrophotometric diagnostic kit (Youngdong Pharmaceutical Co., Korea). Lipid peroxidation in the liver and serum were determined by measuring the levels of MDA, an end product of lipid metabolism. For the serum sample, 3 mol/L sulfuric acid and 100 g/L phosphotungstic acid were added and incubated at room temperature for 10 min, and then centrifuged. For the liver sample, homogenates of liver in potassium phosphate buffer were prepared. MDA contents in the serum and liver samples were determined using a colorimetric reaction with thiobarbituric acid.

**Hepatic hydroxyproline content:** A portion of liver tissue (200 mg) was homogenized in 10 volumes of 0.5 mol/L potassium phosphate (KP) buffer and hydroxyproline content was measured as described above.

**Histology of liver:** Liver tissues were fixed in 10% neutral buffered formalin, dehydrated with 50%-100% ethanol, and embedded in paraffin. Five micrometer sections were cut and stained with hematoxylin-eosin.

### Statistical analysis

All data were analyzed and expressed as mean  $\pm$  SD. Comparisons were performed by Student's *t*-test to detect differences between the groups. A level of  $P < 0.05$  was considered statistically significant.

## RESULTS

### Effects on cell proliferation and collagen production

The anti-proliferative activity in HSC-T6 cells was determined by cell viability using the MTT assay. As shown in Figure 1, HSC-T6 cell proliferation was dose-dependently inhibited by GT. GT at 10, 50 and 100  $\mu$ g/mL caused

**Table 1** Relative organ weights and serum enzyme levels in rats with DMN-induced hepatic fibrosis ( $n = 10$ ) (mean  $\pm$  SD)

Group	NC	FC	FG
Liver index	3.1 $\pm$ 0.2	2.9 $\pm$ 0.2	2.8 $\pm$ 0.3
Spleen index	0.2 $\pm$ 0.03 <sup>a</sup>	0.7 $\pm$ 0.1 <sup>c</sup>	0.4 $\pm$ 0.1
ALT (IU/mL)	254.2 $\pm$ 26.3 <sup>a</sup>	572.4 $\pm$ 83.9 <sup>c</sup>	312.8 $\pm$ 29.3
AST (IU/mL)	88.2 $\pm$ 12.1 <sup>a</sup>	451.2 $\pm$ 23.1 <sup>c</sup>	224.4 $\pm$ 24.4

NC: Normal control group; FC: Hepatic fibrosis control group; FG: Hepatic fibrosis with green tea extract (100 mg/kg) treated group. Liver index: Liver weight/body weight  $\times$  100; Spleen index: Spleen weight/body weight  $\times$  100; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase. <sup>a</sup> $P < 0.05$  vs FG; <sup>c</sup> $P < 0.05$  vs FG.

dose-dependent inhibition of HSC-T6 cell proliferation by 29.5%  $\pm$  4.2%, 30.6%  $\pm$  5.6%, and 44.8%  $\pm$  1.2 %, respectively ( $P < 0.05$ , Figure 1). The antiproliferative effects were not related to the nonspecific cytotoxic effects of green tea because cells showed normal morphology (data not shown).

To assess the effect of GT on ECM production, hydroxyproline content and type 1 collagen expression, assessed by ELISA, were examined in activated HSC-T6 cells. Serum-starved HSC-T6 cells were cultured with acetaldehyde and GT treatment for 24 h. Treatment with 100  $\mu$ g/mL GT significantly reduced cell hydroxyproline content by 23.0%  $\pm$  2.1% compared to the control group. Furthermore, the expression of type 1 collagen was up-regulated by acetaldehyde stimulation, and GT markedly reduced collagen type 1 expression in a dose-dependent manner. Acetaldehyde at a concentration of 175  $\mu$ mol/L induced collagen type 1 expression by 17.4%  $\pm$  0.1%, and 10, 50 and 100 mg/mL GT reduced collagen type 1 expression by 15.2%  $\pm$  2.2%, 15.5%  $\pm$  1.3%, and 23.0%  $\pm$  1.1%, respectively (Figure 1).

### Effects on organ weights

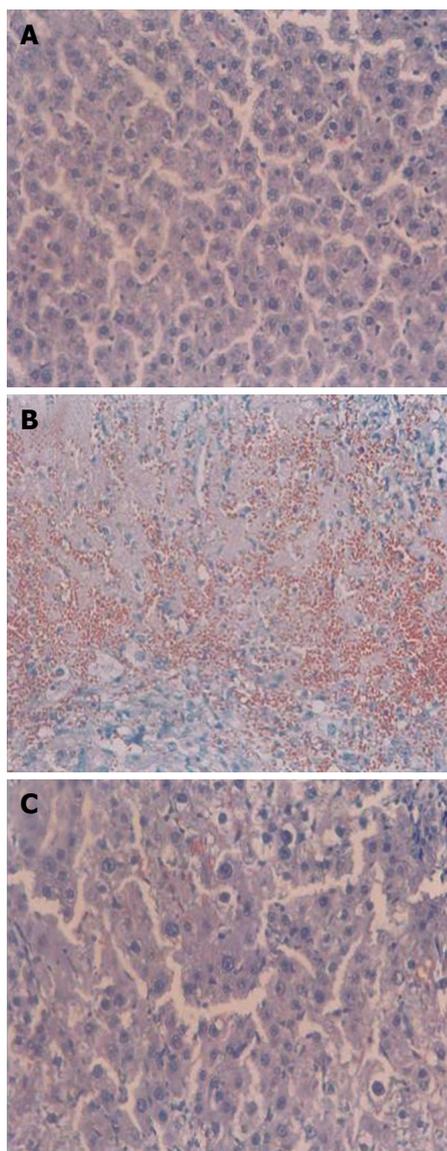

As shown in Table 1, the liver index, which is the percent of liver weight at final body weight, was not significantly different among the experimental groups. In contrast, relative spleen weight was increased 3.5-fold by DMN treatment, and GT administration restored the relative spleen weight ( $P < 0.05$ ).

### Serum biochemical analysis

AST and ALT concentrations in serum were used as biochemical markers to evaluate hepatic injury. ALT is a cytosolic enzyme, primarily present in the liver. An increase in plasma ALT indicates liver damage more specifically than AST. AST, which is a mitochondrial enzyme present in large quantities in the heart, liver, skeletal muscle, and kidney, in part indicates liver injury. Serum activities of ALT and AST were markedly increased with DMN treatment and GT supplementation attenuated the elevation of AST and ALT activities (Table 1).

### Histology and fibrosis marker

Liver fibrosis was evaluated by hematoxylin & eosin staining. The control group showed normal architecture

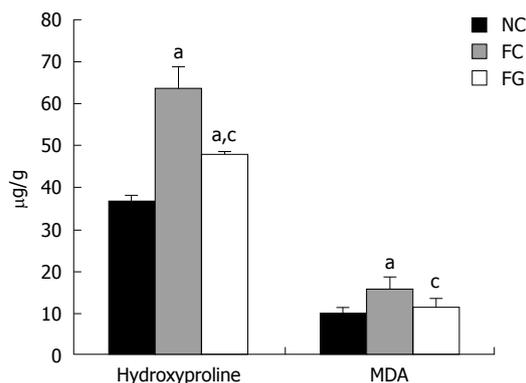

**Figure 2** Effects of green tea extract on liver tissue morphology in DMN-induced fibrosis model. Representative pictures of hematoxylin and eosin-stained sections of liver tissue from normal control rat (A), DMN-treated control (B), DMN-treated + green tea extract (100 mg/kg) group (C). Original magnification,  $\times 200$ .

(Figure 2A), whereas the DMN-treated group exhibited necrosis, congestion, hemorrhage, and destruction of the lobular architecture (Figure 2B). Red blood cells from blood vessels were found in liver tissue due to the collapse of the matrix structure. GT administration exhibited notable recovery effects (Figure 2C).

#### Hydroxyproline and lipid peroxide content in liver

The histological findings were corroborated by biochemical parameters of liver tissue collagen content determined by hydroxyproline, and lipid peroxide determined by MDA.

Hydroxyproline, a product of collagen metabolism, is an amino acid characteristic of collagen. The total collagen present in liver was, therefore, determined by estimating the hydroxyproline content. As shown in Figure 3, hydroxyproline content was significantly in-

**Figure 3** Effects of green tea on hydroxyproline and lipid peroxide (MDA) levels in DMN-treated rat liver. Data are expressed as mean  $\pm$  SD. MDA: Malondialdehyde. <sup>a</sup> $P < 0.05$  vs normal control (NC), <sup>c</sup> $P < 0.05$  vs fibrosis control (FC).

creased following DMN treatment (FC), indicating that the liver fibrosis model was successfully established. GT administration (FG, 100 mg/kg) restored the hydroxyproline content in fibrotic liver. Lipid peroxides, measured in terms of the formation of MDA, were significantly increased in DMN-induced rat liver. GT administration significantly reduced the lipid peroxide level.

## DISCUSSION

Hepatic fibrosis is characterized by an abnormal accumulation of ECM proteins, particularly collagen<sup>[3,4]</sup>. When hepatic fibrosis occurs, collagen proliferation, mainly collagen type 1 and 3, accounts for 50% of the total protein in fibrotic liver<sup>[20]</sup>, and collagens are the main components of ECM. Therefore, collagen type 1 is an important parameter reflecting the metabolism of collagen in liver. The main collagen producing cells in the liver are HSC, which proliferate and undergo a process of activation during the development of fibrosis resulting in increased capacity for collagen synthesis<sup>[21]</sup>. Changes in hydroxyproline content in the liver are considered an index for collagen metabolism and provide valuable information on the biochemical and pathological states of liver fibrosis. The present study demonstrated that consumption of GT prevented the development of hepatic fibrosis in a rat model of DMN-induced liver fibrosis. The results were confirmed both by liver histology and by quantitative measurement of hepatic hydroxyproline content, a marker of collagen deposition in liver.

Accordingly, inhibition of proliferation, reduced collagen content, and type 1 collagen expression were observed in activated HSC-T6 cells following GT treatment. Activated HSC are the main source of ECM when liver fibrosis occurs<sup>[22]</sup>. Therefore, these results imply that GT inhibit the proliferation of activated HSC and down regulate the collagen content and expression of collagen type 1, thereby inhibiting hepatic fibrosis. The results of the present study are consistent with previous observations showing that EGCG, the major component in green

tea, suppresses collagen production<sup>[23]</sup>, and proliferation<sup>[24]</sup> in HSC.

Oxidative stress resulting from the increased production of reactive oxygen species and lipid peroxides is suggested to be associated with the proliferation and activation of stellate cells either directly or through paracrine stimulation of neighboring cells including injured hepatocytes<sup>[25]</sup>. Furthermore, oxidative stress has been shown to modulate collagen gene expression<sup>[7]</sup>. Therefore, a number of studies have focused on the pathogenetic significance of oxidative stress in liver injury, as well as on the therapeutic intervention of this process with antioxidant and metabolic scavengers. GT administration resulted in a reduction of lipid peroxide in HSC-T6 cells and DMN-treated fibrotic liver. Chen *et al*<sup>[26]</sup> have also shown that a single-dose of EGCG improved hepatic injury in rats induced by CCl<sub>4</sub> administration through the inhibition of lipid peroxidation.

In conclusion, this study demonstrates that green tea administration can effectively improve liver fibrosis caused by DMN as shown by reduced levels of collagen, lipid peroxidation, HSC proliferation, and type 1 collagen expression in the liver. Therefore, green tea may protect liver cells and reduce the deposition of collagen fibers in the liver. Green tea provides a safe and effective strategy for improving hepatic fibrosis.

## COMMENTS

### Background

Hepatic stellate cells (HSC) are recognized as the primary cellular source of matrix components in chronic liver diseases, and therefore play a critical role in the development and maintenance of liver fibrosis. Overproduction of extracellular matrix components, particularly collagen, is a characteristic of activated HSC, and activation and proliferation of HSC have been implicated in the pathogenesis of liver fibrosis.

### Research frontiers

Hepatoprotective effects of green tea against carbon tetrachloride, cholestasis and alcohol induced liver fibrosis were reported in many studies. However, the hepatoprotective effect of green tea in dimethylnitrosamine (DMN)-induced models has not been studied.

### Innovations and breakthroughs

The present study demonstrates that consumption of green tea prevents the development of hepatic fibrosis in a rat model of DMN-induced liver fibrosis. These results were confirmed both by liver histology and by quantitative measurement of hepatic hydroxyproline content, a marker of collagen deposition in the liver. Accordingly, inhibition of proliferation, reduced collagen content, and type 1 collagen expression were observed in activated HSC cells following green tea treatment.

### Applications

This study demonstrates that green tea may protect liver cells and reduces the deposition of collagen fibers in the liver. Green tea provides a safe and effective strategy for improving hepatic fibrosis.

### Terminology

HSC are the main collagen producing cells in the liver, which proliferate and undergo a process of activation during the development of fibrosis resulting in an increased capacity for collagen synthesis.

### Peer review

This study examined the protective effect of green tea extract on hepatic fibrosis in a HSC line and in a rat model of DMN-induced liver fibrosis. Green tea administration prevents the development of hepatic fibrosis in the rat model of liver fibrosis. Furthermore, inhibition of proliferation, reduced collagen deposition, and type 1 collagen expression were observed in activated HSC cells following green tea treatment. The results imply that green tea may protect

liver cells and reduce the deposition of collagen fibers in the liver. Green tea provides a safe and effective strategy for improving hepatic fibrosis.

### Abstract

**AIM:** To identify factors that were related to the short term effectiveness of percutaneous transhepatic biliary drainage in cholangiocarcinoma patients and to evaluate the impact of palliative drainage on their survival.

**METHODS:** Seventy-four patients with hilar cholangiocarcinoma who underwent percutaneous biliary drainage were enrolled in the study. The demographic and laboratory data as well as the imaging characteristics were retrospectively analyzed to correlate with the bile output and reduction rate of serum bilirubin 1 wk after drainage.

**RESULTS:** Patients with more bile duct visualized on percutaneous transhepatic cholangiography or absence of multiple liver metastases on imaging studies had more bile output after biliary drainage [odds ratio (OR): 8.471,  $P = 0.010$  and OR: 1.959,  $P = 0.022$ , respectively]. Patients with prolonged prothrombin time had a slow decrease in serum bilirubin (OR: 0.437,  $P = 0.005$ ). The median survival time was not significantly different in patients with low or high bile output (75 d vs 125 d,  $P = 0.573$ ) or in patients with slow or rapid reduction of serum bilirubin (88 d vs 94 d,  $P = 0.576$ ).

**CONCLUSION:** The short term effectiveness of per-

### INTRODUCTION

Cholangiocarcinoma is the second most common primary liver cancer, after hepatocellular carcinoma and the incidence is increasing<sup>[1,2]</sup>. Hilar cholangiocarcinoma with the tumor involving the biliary confluence or the right or left intrahepatic ducts is most common and accounts for 40%-60% of all cholangiocarcinomas<sup>[3]</sup>. About 80% of patients with hilar cholangiocarcinoma are unsuitable for curative surgical resection due to severe comorbidity for major surgery, metastases or advanced loco-regional disease<sup>[4]</sup>. Percutaneous or endoscopic biliary drainage is usually performed as a palliative treatment to relieve these patients from jaundice, pain, and cholangitis<sup>[5]</sup>.

A fluent bile output after percutaneous transhepatic biliary drainage (PTBD) reduces the biliary pressure and therefore, alleviates the cholangitis and pain of patients. The reduction of serum bilirubin is usually the hallmark of successful biliary drainage. Nonetheless, despite the drainage catheter being correctly positioned in the bile duct, there are still some patients who have scanty bile output and persistent elevation of serum bilirubin<sup>[6]</sup>. We retrospectively analyzed the clinical and imaging characteristics of these patients in an attempt to identify the factors related to bile output and reduction of serum bilirubin after PTBD. In addition, we also compared

the survival of patients with different bile output and reduction rates of bilirubin after PTBD to investigate if the short term effectiveness of biliary drainage had any impact on the long term survival.

## MATERIALS AND METHODS

### Patients

From January 1998 to June 2007, 74 consecutive patients with hilar cholangiocarcinoma who underwent PTBD in our hospital, a tertiary transferring center, were enrolled. The diagnosis of cholangiocarcinoma was confirmed either by pathologic diagnosis ( $n = 39$ ) or by imaging studies plus clinical follow-up which illustrated further tumor progression ( $n = 35$ ). These patients included 39 males and 35 females with a mean age of  $66.1 \pm 12.8$  and  $66.5 \pm 12.5$  years, respectively. All of the patients, irrespective of future treatment modality, underwent PTBD due to the presence of jaundice and a dilated biliary system and were further observed for at least 1 wk to evaluate the effectiveness of PTBD. Of them, 54 patients were unsuitable for surgical intervention on the basis of their comorbidity and/or tumor extent and were enrolled for survival analysis.

### Clinical characteristics

The medical records of each patient were retrospectively reviewed. Data collected from all patients on the day of, or 1 d before, biliary drainage included the initial serum levels of albumin, bilirubin, alanine aminotransferase (ALT), alkaline phosphatase and prothrombin time. The average daily bile output and the serum total bilirubin level 1 wk after drainage were recorded for the evaluation of drainage effectiveness. The overall survival time of patients who did not undergo surgical resection was also checked.

### Imaging characteristics analysis

Percutaneous transhepatic cholangiography (PTC), contrast enhanced computed tomography (CT) and/or magnetic resonance (MR) imaging were reviewed for imaging characteristics analysis. The liver tumors were classified as type I, II, IIIa, IIIb, and IV according to the system of Bismuth *et al.*<sup>71</sup>. The maximal diameter of the tumors was estimated on CT or MR imaging either by direct measurement of the tumor size if its margin could be clearly defined or indirect measurement of the distance between dilated ducts if the tumor was difficult to visualize. The maximal diameter of the intrahepatic duct punctured for biliary drainage was measured on CT, MR, or PTC imaging. The number of visualized intrahepatic bile ducts (first branches of right and left intrahepatic ducts) was counted later on a follow-up PTC as it may depend on the injection pressure of contrast and the radiologist usually injected less contrast media to avoid risk of cholangitis when performing PTBD. A follow-up PTC taken several days after the biliary drainage, although it may still have some limitation, should carry a lower risk of cholangitis and allow more contrast injection. In addition, CT or MR

imaging was checked for multiple liver metastases, locoregional lymphadenopathy and peritoneal involvement.

### Percutaneous transhepatic biliary drainage procedure

Before PTBD, the bleeding profile was checked and treated if abnormal, and antibiotic therapy was commenced. If CT or MR images showed dilated ducts were confined to a single lobe, PTBD was performed *via* that lobe. If the ducts of both lobes were dilated, our radiologists preferred to approach from the left side unless it was atrophied due to tumor invasion of the ipsilateral portal vein. The duct selected for drainage depended on the decision of the radiologist, who selected the most feasible duct to approach. PTBD was performed as a standard procedure. In brief, the biliary system was punctured and a guide wire (0.035 inch) was introduced into the bile duct. Through the guide wire, the puncture tract was dilated using a bougie, followed by the insertion of an 8-French pigtail catheter.

### The effectiveness of biliary drainage

The average daily bile output during the first week after PTBD was calculated. The reduction rate of serum bilirubin was calculated by dividing the reduction of total bilirubin level after 1 wk of drainage by the original level. For differentiating the effectiveness of biliary drainage, an average bile output of more or less than 300 mL/d and a reduction rate of serum bilirubin of higher or lower than 20% (i.e. the integer of median value of patient distribution) were chosen to further divide patients into two groups with similar sample size.

### Statistical analysis

Except for patient survival which was presented as median survival days, all the other data were expressed as mean  $\pm$  SD. The differences in demographic, biochemical, and imaging characteristics between patient groups were compared by Independent-Samples *t* test or  $\chi^2$  test as appropriate. Variables that achieved statistical significance ( $P < 0.05$ ) or were close to significance ( $P < 0.1$ ) in the univariate analysis were subsequently included in a multivariate analysis using a stepwise forward logistic regression. The survival of patients with different effectiveness of biliary drainage was compared by using the log-rank test. The statistical calculations were computed using the SPSS 12.0 program for Windows (SPSS Inc., Chicago, IL, US).

## RESULTS

### Events associated with the biliary drainage

There was no procedure associated mortality or significant morbidity, except two cases of transient hemobilia and two cases of cholangitis. Most of our patients who did not undergo surgical intervention were maintained on PTBD and only 12 (16.2%) of them were switched to external-internal biliary drainage. The drainage was further revised if the initial PTBD drainage had unsatisfactory function during the follow up. Of the 26 patients

**Table 1** The clinical characteristics of patients with high and low bile output (mean  $\pm$  SD)

	Bile output		P-value <sup>1</sup>
	> 300 mL (n = 33)	< 300 mL (n = 41)	
Age (yr)	64.5 $\pm$ 10.3	67.7 $\pm$ 14.2	0.25
Sex (male:female)	20:13	19:22	0.35
Biochemical data			
Albumin (g/dL)	3.4 $\pm$ 0.6	3.0 $\pm$ 0.5	0.01
Total bilirubin (mg/dL)	12.2 $\pm$ 7.4	12.0 $\pm$ 8.5	0.92
ALT (U/L)	132.5 $\pm$ 184.5	142.6 $\pm$ 115.2	0.77
Prolonged prothrombin time (s)	1.0 $\pm$ 1.1	1.2 $\pm$ 1.3	0.42
Bilirubin reduction rate (%)	22.5 $\pm$ 41.2	13.6 $\pm$ 29.7	0.31
Alkaline phosphatase (U/L)	463.9 $\pm$ 301.8	552.9 $\pm$ 373.8	0.297
Imaging characteristics			
Visualized bile ducts on PTC	2.7 $\pm$ 1.2	1.7 $\pm$ 1.0	0.001 <sup>2</sup>
Tumor size (cm)	5.3 $\pm$ 2.9	4.6 $\pm$ 2.5	0.31
Diameter of bile duct (mm)	10.5 $\pm$ 6.1	11.1 $\pm$ 5.9	0.65
Approach side (right:left)	9:24	10:31	0.79
Bismuth type I / II / IIIa / IIIb/IV <sup>3</sup>	8/6/5/3/7	2/6/11/11/5	0.03
Lymphadenopathy	10	9	0.59
Liver metastasis	4	14	0.03 <sup>2</sup>
Peritoneal involvement	7	8	1.00

<sup>1</sup>By Independent-Samples *T* test and  $\chi^2$  test as appropriate; <sup>2</sup>Only the absence of multiple liver metastases and more intrahepatic bile ducts visualized on PTC were statistically significant in multivariate analysis; <sup>3</sup>Eleven patients with ambiguous imaging that cannot be confidently classified were not included for analysis. PTC: Percutaneous transhepatic cholangiography.

who underwent palliative treatment only and survived longer than 90 d, 20 patients (77%) received at least one drainage revision.

### Bile output after drainage

There were 33 patients with and 41 patients without an average bile output of more than 300 mL/d. As shown in Table 1, among the biochemical data, only a higher serum albumin concentration was associated with higher bile output in patients undergoing PTBD. Higher bile output was, however, not associated with a more rapid reduction of serum bilirubin as it was not significantly different between both groups. Patients who had fewer intrahepatic bile ducts shown on PTC, hence a more advanced Bismuth classification, or multiple liver metastases had lower bile output after biliary drainage. The size of tumor, the diameter of bile duct, the approach side of PTBD, and the presence of lymphadenopathy or peritoneum involvement were all unrelated to the amount of bile output.

In multivariate analysis, the absence of liver metastases and a greater number of intrahepatic bile ducts visualized on PTC were still significantly associated with a higher bile output. The odds ratios (ORs) were 8.471, (95% CI: 1.675-42.835,  $P = 0.010$ ) for negative metastasis and 1.959, (95% CI: 1.103-3.481,  $P = 0.022$ ) for more intrahepatic bile ducts on PTC.

### Reduction rate of serum bilirubin after drainage

Of the 70 patients available for analysis of bilirubin

**Table 2** Clinical characteristics between the patients who had rapid and slow bilirubin reduction rates after drainage (mean  $\pm$  SD)

	Reduction		P-value <sup>1</sup>
	> 20% (n = 37)	< 20% (n = 33)	
Age (yr)	67.6 $\pm$ 12.5	65.4 $\pm$ 12.3	0.515
Sex (male:female)	19:18	18:15	1.000
Biochemical data			
Albumin (g/dL)	3.4 $\pm$ 0.5	3.0 $\pm$ 0.6	0.016
Total bilirubin (mg/dL)	10.6 $\pm$ 5.9	15.0 $\pm$ 5.1	0.022
ALT (U/L)	172.3 $\pm$ 190.2	102.1 $\pm$ 70.0	0.048
Prolonged prothrombin time (s)	0.7 $\pm$ 0.7	1.7 $\pm$ 1.4	0.001 <sup>2</sup>
Alkaline phosphatase (U/L)	499.5 $\pm$ 268.6	543.8 $\pm$ 428.8	0.630
Imaging characteristics			
Visualized bile ducts on PTC	2.2 $\pm$ 1.2	2.1 $\pm$ 1.2	0.815
Tumor size (cm)	4.9 $\pm$ 2.6	4.9 $\pm$ 3.0	0.968
Diameter of bile duct (mm)	11.0 $\pm$ 5.9	10.4 $\pm$ 5.9	0.670
Approach side (right:left)	10:27	8:25	1.000
Bismuth type I / II / IIIa / IIIb/IV <sup>3</sup>	5/7/10/5/6	5/5/6/9/5	0.657
Lymphadenopathy	11	7	0.583
Liver metastasis	12	5	0.159
Peritoneal involvement	10	5	0.379

<sup>1</sup>Abbreviations as in Table 1; <sup>2</sup>In multivariate analysis, only the prothrombin time was significantly associated with bilirubin reduction; <sup>3</sup>Abbreviations as in Table 1.

reduction (four patients did not have a serum bilirubin check 1 wk after drainage), 37 patients had a bilirubin reduction of more than 20% after 1 wk of drainage and 33 patients did not. The reduction rate of bilirubin was significantly more rapid in patients who had a less prolonged prothrombin time or a better serum biochemical profile including higher serum albumin, lower serum bilirubin or ALT (Table 2). None of the imaging characteristics such as tumor size, Bismuth classification, liver metastasis and lymphadenopathy had an impact on the rate of serum bilirubin reduction after biliary drainage.

In multivariate analysis, only prolonged prothrombin time was significantly associated with a slower reduction rate of serum bilirubin. The OR was 0.437 (95% CI: 0.245-0.780,  $P = 0.005$ ), compared to those with normal prothrombin time.

### Short term effectiveness of biliary drainage and patients' survival

Most of the patients who were unsuitable for surgical resection died of cholangitis and/or liver failure. Only one patient was still alive at the time of analysis. The median survival time of these patients was 94 d. Although 12 patients received additional drainage due to scanty biliary output or persistent hyperbilirubinemia, the median survival of patients with bilateral biliary drainage was similar to that of patients who received only unilateral drainage (66 d vs 94 d,  $P = 0.358$ ). In addition to biliary drainage, 10 of the 54 patients who had unresectable tumors also underwent external beam radiation therapy. The median survival was, however, not significantly longer

in these patients (103 d) than in those who received drainage only (88 d,  $P = 0.493$ ). These patients were therefore, combined for survival analysis.

The serum bilirubin reduction rate, whether it was more rapid or slower than 20% did not affect the median survival time of patients (94 d *vs* 88 d,  $P = 0.576$ ). The median survival time was also similar between patients with a bile output less than 300 mL (75 d) and those with a bile output more than 300 mL (125 d,  $P = 0.573$ ).

## DISCUSSION

As shown in our previous and current studies, bile output was not correlated with the reduction rate of bilirubin<sup>[8]</sup>. Both liver cells and ductular cells contribute to the formation of bile<sup>[9]</sup>. Biliary obstruction results in proliferation of bile ducts and ductules. The increased amount of bile after relief of obstruction can be caused by excretion of water and electrolytes from the proliferated biliary epithelial cells (i.e. the secretin choleresis)<sup>[9]</sup>. Nevertheless, the reduction of serum bilirubin is dependent on bilirubin excretion by liver cells which can be impaired as a result of cholestasis<sup>[10]</sup>. Prolonged biliary obstruction in these patients results in bile duct proliferation and hepatocyte damage, which explains the discrepancy between bile output and bilirubin reduction rate. A high bile output is therefore, not associated with a rapid reduction in serum bilirubin if most of the bile comes from the bile ducts rather than liver cells.

Cholangiocarcinoma with more advanced Bismuth classification implies a complicated biliary obstruction and is frequently found to have fewer intrahepatic bile ducts depicted on PTC<sup>[7]</sup>. Liver metastases also cause biliary obstruction by compressing the bile ducts externally. The presence of multi-site biliary obstruction, either caused by intra-luminal obstruction or external compression of the tumor, leads to fewer sources of bile flowing into the drained bile duct and was therefore, associated with less bile output after PTBD in our observations.

Accumulation of bile salts within the liver can cause necrosis and apoptosis of liver cells<sup>[10-13]</sup>. The liver may need more time to recover in cases with long lasting biliary obstruction. Prolonged prothrombin time in cholangiocarcinoma patients can be due to either vitamin K deficiency or impaired liver synthesis of coagulation factors, both sequelae of prolonged cholestasis. Weston reported that patients with prolonged prothrombin time took longer for bilirubin reduction after endoscopic biliary stenting<sup>[14]</sup>. Similarly, patients with a prolonged prothrombin time in our study also had a slow reduction of serum bilirubin.

Surgical resection is the standard treatment for intrahepatic cholangiocarcinoma<sup>[15]</sup>. Patients unsuitable for surgical resection live a significantly shorter time than those undergo curative tumor resection. Previous reports indicate that the method of drainage has no impact on patient survival<sup>[4]</sup>. Our data further showed that patient's survival was not related to the bile output

or the rate of bilirubin reduction after biliary drainage. This may be because even though the drainage provides good short term success in palliating symptoms, it is however associated with significant morbidity in the long term follow up including catheter clogging, catheter dislodgement, cholangitis, and liver failure<sup>[16]</sup>. As seen in our study, most of the patients who survived more than 90 d received multiple drainage revisions and as a consequence of tumor progression, most of them still died of cholangitis and liver failure. Therefore, the short term effectiveness of PTBD adds little benefit to survival unless other effective methods such as photodynamic therapy are available to retard the tumor progress and keep the biliary systems patent<sup>[17,18]</sup>.

In conclusion, our study identified factors that were related to the short term effectiveness of PTBD in patients with hilar cholangiocarcinoma. After biliary drainage, patients may have less bile output in the presence of multiple sites of biliary obstruction, and slower reduction of serum bilirubin if the prothrombin time is prolonged. A higher bile output was not associated with a more rapid bilirubin reduction. Although we only observed the drainage effect at 1 wk which may not reflect the ultimate result of drainage, we did find that a short term relief of biliary obstruction by PTBD was not associated with a better survival in patients with unresectable cancer.

## COMMENTS

### Background

Biliary drainage is performed as a palliative treatment of hilar cholangiocarcinoma. The reduction of serum bilirubin is usually the hallmark of successful biliary drainage. However, some patients may have persistent jaundice or scanty bile output after biliary drainage.

### Research frontiers

This paper analyzed factors relating to bile output and reduction of serum bilirubin after percutaneous biliary drainage. Furthermore, the impact of short term effectiveness of biliary drainage on long term survival was investigated.

### Innovations and breakthroughs

After percutaneous biliary drainage, high bile output was not associated with a rapid reduction of serum bilirubin. The bilirubin reduction was related to patient's prothrombin time and the bile output, to the extent of tumor involvement. Neither the amount of bile output nor the rate of bilirubin reduction had an impact on survival.

### Applications

The effectiveness of percutaneous biliary drainage can be properly estimated before the procedure. Patient should be observed for daily bile output as well as the reduction of serum bilirubin. An initially well functioning biliary drainage does not link to a longer survival of patients and further efforts to maintain biliary patency are required.

### Peer review

Chen *et al* found that the short term effectiveness of percutaneous biliary drainage was related to patient's prothrombin time or the extent of tumor involvement, but it had no impact on survival. The paper is informative.

### Abstract

**AIM:** To investigate the effect and mechanism of electro-acupuncture (EA) at ST25 and ST37 on irritable bowel syndrome (IBS) of rats.

**METHODS:** A total of 21 male Sprague-Dawley rats were randomly divided into normal group, model group and EA group. A rat model of IBS was established by constraining the limbs and distending the colorectum of rats. Rats in EA group received bilateral EA at ST25 and ST37 with a sparse and intense waveform at a frequency of 2/50 Hz for 15 min, once a day for 7 d as a course. Rats in normal and model groups were stimulated by distending colorectum (CR). An abdominal withdrawal reflex (AWR) scoring system was used to evaluate improvements in visceral hypersensitivity. Toluidine blue-improved method, immunohistochemistry and radioimmunoassay were used to observe mucosal mast cells (MC), changes of substance P (SP) and substance P receptor (SPR) in colon and change of corticotropin-releasing hormone (CRH) in hypothalamus.

**RESULTS:** The threshold of visceral sense was significantly lower in model group than in normal group,

and significantly higher in EA group than in model group. The number of mucosal MC was greater in model group than in normal group and significantly smaller in EA group than in model group. The CRH level in hypothalamus of rats was significantly higher in model group than in normal group, which was remarkably decreased after electro-acupuncture treatment. The SP and SPR expression in colon of rats in model group was decreased after electro-acupuncture treatment.

**CONCLUSION:** EA at ST25 and ST37 can decrease the number of mucosal MC and down-regulate the expression of CRH in hypothalamus, and the expression of SP and SPR in colon of rats with IBS.

### INTRODUCTION

Irritable bowel syndrome (IBS) is a common bowel disorder characterized by recurrent abdominal pain or discomfort associated with altered bowel habits in the absence of structural pathology<sup>[1]</sup>. Since IBS is diagnosed based on its symptoms and its pathophysiology is unclear, its treatment outcome remains unsatisfactory<sup>[2,3]</sup>. Our previous study showed that electro-acupuncture (EA) is effective against IBS<sup>[4]</sup>. However, its mechanism of action needs to be further studied.

IBS patients often describe a correlation between

stressful life events and the onset or exacerbation of their gastrointestinal symptoms, and seem more susceptible to stressful events in daily life<sup>[5]</sup>. The central nervous system response to stressful events modulates the autonomic nervous system outflow and activates the hypothalamic-pituitary-adrenal axis<sup>[6]</sup>. Dysfunction of these systems has been proposed to be an etiological factor for IBS<sup>[7,8]</sup>. It has been reported that there is a difference in hormone level involving stress response between IBS patients and healthy subjects<sup>[8]</sup>. Central release of corticotropin-releasing hormone (CRH) plays an important role in the stress response<sup>[9]</sup>, inducing a higher adrenocorticotropic hormone (ACTH) level and a more profound enhancement of colonic motility in IBS patients than in healthy controls<sup>[10]</sup>. It has been shown that CRH increases rectal sensitivity<sup>[11]</sup>. Thus, alterations in neuroendocrine response to stress may be of importance in the pathophysiology of IBS<sup>[12]</sup>.

Visceral hypersensitivity is highly prevalent in IBS patients, and activation of intestinal mast cells (MC) may play a role in visceral hypersensitivity because they are in close proximity to gastrointestinal mucosal sensory nerve terminals containing neuropeptides, and a bidirectional pathway connecting the central nervous system, gut and MC have been demonstrated. MC at the ileocecal junction may be a mediator of the gut and nervous system in IBS<sup>[13]</sup> and substance P (SP) is a gastrointestinal peptide hormone. Both of them reside in the gastrointestinal tract and central nervous system. SP is also an interactive signaling molecule between the nervous and immune systems<sup>[14]</sup> and can modulate the function of intestinal mucosal MC by regulating neurosecretion and paracrine secretion.

This study was to explore the effect of EA at ST25 and ST37 on IBS by observing the MC count, the CRH level in hypothalamus, and the expression of SP and SPR in colon of rats.

## MATERIALS AND METHODS

### Animals

Twenty-one male Sprague-Dawley rats (SPF class), weighing 185-215 g, were supplied by Experimental Animal Center of Shanghai University of TCM, and randomly divided into normal group, model group and EA group according to their weights, 7 in each group. All rats were housed at a constant temperature and a humidity environment with free access to food and water. All studies were performed in accordance with the proposals of the Committee for Research and Ethical Issues of the International Association and approved by the Committee on the Use of Human and Animal Subjects in Teaching and Research, Shanghai University of TCM.

### Establishment of rat model of IBS

An experimental rat model of IBS was established as previously described<sup>[15,16]</sup>. On the second day after the rats were fasted, experiment was begun. Rats in the

Table 1 AWR<sup>[14]</sup> scoring criteria

Score 0	No behavioral response to CRD
Score 1	Immobile during distension of CR and occasional clicking the head at onset of the stimulus
Score 2	A mild contraction of abdominal muscles, but no lifting of abdomen off the platform
Score 3	A strong contraction of abdominal muscles and lifting of abdomen off the platform, no lifting of pelvic structure off the platform
Score 4	Arching body and lifting of pelvic structure and scrotum

AWR: Abdominal withdrawal reflex; CRD: Colorectal distension; CR: Colorectum.

normal group were given grabbing around the anus, while rats in the other two groups were stimulated by distending colorectum (CR). Limbs of the rats were fixed with medical adhesive tapes to limit their movements. The fixed rats could crawl without using their rear limbs. CR was distended before the limbs of rats were constrained and after the medical adhesive tapes were removed. The finger of a disposable rubber glove was tightly fixed onto the end of a polyethylene tube with 4 holes (0.5 cm apart) using medical silk thread as a 4 cm-long balloon. The other end of the tube was connected to a 10 cm-long rubber tube with a tri-channel valve connected to a syringe and sphygmomanometer. Vaseline was smeared on surface of the balloon which was slowly inserted into 5 cm of the rat anus along the physical curve of CR. The fixed time was 2 h each day, and CR was distended for 3 min, once every other day for 8 d. The whole modeling time was 15 d.

### Treatment

Rats in the EA group were treated with EA at bilateral ST 25 and ST 37, once a day for 7 d as a course. Needles were pricked 0.3 cm in depth with a dense-sparse waveform at a frequency of 2/50 Hz and retained for 15 min. Rats in the normal and model groups received no EA treatment.

### Contraction reaction in rat abnormal scoring test

The abdominal withdrawal reflex (AWR) scoring criteria<sup>[14]</sup> are shown in Table 1. Rats in the model group were fasted in afternoon of the previous day. Vaseline was smeared on surface of the balloon which was slowly inserted into 5 cm of the rat anus according to the physical curve of CR and retained for 5 min. The test was begun when the rats became adapted.

After air was added into the balloon with a syringe, the rat rectum was stimulated and different degrees of contraction reaction were observed. The pressure (mmHg) during behavior response scored as 1, 2, 3, and 4 was recorded and expressed as the threshold of sensitivity. Each score was tested three times, and each rat was tested by two persons not participating in this research. Means were calculated (6 values in total). Three-minute intervals were set between each two tests for the full adaptation of rats.

Table 2 Threshold pressure of rat contraction reaction in different groups ( $n = 7$ ) (mean  $\pm$  SD)

Group	Threshold pressure (mmHg)			
	Score 1	Score 2	Score 3	Score 4
Normal group	23.38 $\pm$ 3.15	41.26 $\pm$ 3.58	68.00 $\pm$ 8.97	86.35 $\pm$ 10.01
Model group	15.50 $\pm$ 3.25 <sup>b</sup>	23.76 $\pm$ 3.91 <sup>b</sup>	37.43 $\pm$ 6.75 <sup>b</sup>	57.95 $\pm$ 5.45 <sup>b</sup>
EA group	21.81 $\pm$ 1.93 <sup>d</sup>	34.02 $\pm$ 3.87 <sup>b,d</sup>	50.50 $\pm$ 7.28 <sup>b,d</sup>	63.23 $\pm$ 6.24 <sup>b,d</sup>

<sup>b</sup> $P < 0.01$  vs normal group; <sup>d</sup> $P < 0.01$  vs model group.

Table 3 Corticotropin-releasing hormone level in hypothalamus of rats and MC count in colonic membrane of rats in different groups ( $n = 7$ ) (mean  $\pm$  SD)

Group	CRH level (pg/mg)	MC count in each visual field
Normal group	42.68 $\pm$ 4.39	2.19 $\pm$ 0.31
Model group	66.63 $\pm$ 18.19 <sup>a</sup>	10.0 $\pm$ 1.21 <sup>a</sup>
EA group	42.81 $\pm$ 7.44 <sup>c</sup>	4.81 $\pm$ 0.63 <sup>a,c</sup>

<sup>a</sup> $P < 0.05$  vs normal group; <sup>c</sup> $P < 0.05$  vs model group. EA: Electro-acupuncture; MC: Mast cells.

### Observation using toluidine blue-improved method

Samples were taken from the descending colon (5 cm above anus) and cecum, cleaned with normal saline, fixed with 10% formalin, dehydrated, paraffin-embedded, cut into sections and stained with toluidine blue-improved (TBI) method, deparaffinized and rehydrated, dipped in toluidine blue for 30 min. Two or three drops of glacial acetic acid were added into the samples until the presence of pretty clear nuclei and granulation. The samples were dried with cold air, cleaned in xylene, mounted onto Permount or Histoclad, and observed under a microscope (Olympus-BH2,  $\times 100$  and  $\times 400$ ). Three high-power fields ( $\times 400$ ) were randomly selected and the number of MC was counted and expressed as mean.

### Radioimmunoassay for CRH

**Sample preparation:** All rats were killed by dislocating cervical vertebra, with their brain taken out and hypothalamus isolated in ice bath. The hypothalamus was rinsed with 0.9% sodium chloride and restored in a liquid nitrogen container. The hypothalamus was taken out from the liquid nitrogen container, weighed and labeled. One milliliter 1 mol/L glacial acetic acid was added and homogenized for 100 min, then 0.8 mL 1 mol/L NaOH was added and centrifuged for 20 min at 4000 r/min. The supernatant was stored at  $-20^{\circ}\text{C}$  for radioimmunoassay. The sample (50  $\mu\text{L}$ ) was incubated for 24 h at  $4^{\circ}\text{C}$ . Then, 500  $\mu\text{L}$  separating-medium was added into each tube, incubated at room temperature for 45 min, centrifuged for 20 min at 4000 r/min. The supernatant was aspirated and the results were calculated.

**Immunohistochemistry for SP/SPR:** Sample sections were deparaffinized in xylene for 10 min, and dehydrated in 95%, 90%, 70% ethanol for 2 min. Primary antibody was bound to the specific rabbit anti-rat antigen diluted

at 1:150, at  $4^{\circ}\text{C}$  for 18 h. The samples stained with the envision immunohistochemistry method served as a positive control, while PBS-alternated primary antibody served as a negative control. Brown and dark brown granulation was observed with a background of purple blue. The positive expressing areas of SP and SPR under three fields were averaged.

### Statistical analysis

Experimental data were expressed as mean  $\pm$  SD. Statistical analyses were performed using SPSS 13.0 (SPSS Inc. Wacker Drive, Chicago, Illinois). Differences in mean were compared by one way ANOVA.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Contraction reaction in rat abnormal scoring test

The threshold pressure was remarkably lower in model group than in normal group, and obviously higher in EA group than in model group ( $P < 0.01$ , Table 2).

### Effect of EA on CRH in hypothalamus of rats

The CRH level was significantly higher in hypothalamus of rats in model group than in normal group ( $P < 0.05$ ), which was significantly decreased after EA treatment ( $P < 0.05$ ). No significant difference was found in CRH level between normal and EA groups (Table 3).

### MC in rat colonic membrane

The number of MC was greater in model group than in normal group ( $P < 0.05$ , Table 3) and smaller in EA group than in model group ( $P < 0.05$ ). The plasma of MC was stained purple, while nuclei were stained dark blue, scattered in mucous and submucous layers, or gathered into groups or lined up. The cells were round, oval, shuttle-like, and arose in shape. Small cells had little plasma and were clear in shape, while big cells had more plasma and were unclear in shape.

### SP and SPR expression in colon tissue of rats

The expression level of SP and SPR was higher in model group than in normal group ( $P < 0.05$ ), which was decreased after EA treatment ( $P < 0.05$ , Table 4, Figure 1).

## DISCUSSION

IBS is a prevalent functional gastrointestinal (GI) disorder

Table 4 SP and SPR expression in colonic membrane of rats in different groups ( $n = 7$ ) (mean  $\pm$  SD)

Group	SP expression		SPR expression	
	Optical density	Expressing area ( $\mu\text{m}^2$ )	Optical density	Expressing area ( $\mu\text{m}^2$ )
Normal group	14.21 $\pm$ 0.64	1772.77 $\pm$ 176.34	14.86 $\pm$ 0.48	362.65 $\pm$ 41.96
Model group	18.21 $\pm$ 1.07 <sup>a</sup>	3157.31 $\pm$ 304.95 <sup>a</sup>	16.36 $\pm$ 1.14 <sup>a</sup>	532.83 $\pm$ 105.60 <sup>a</sup>
EA group	16.29 $\pm$ 0.95 <sup>a,c</sup>	2020.09 $\pm$ 116.31 <sup>a,c</sup>	13.71 $\pm$ 0.70 <sup>a,c</sup>	340.02 $\pm$ 29.61 <sup>c</sup>

<sup>a</sup> $P < 0.05$  vs normal group; <sup>c</sup> $P < 0.05$  vs model group. SP: Substance P; SPR: Substance P receptor.

characterized by chronic or recurrent abdominal pain or discomfort associated with altered bowel habits<sup>[6]</sup>.

IBS is presumed to be a disorder of the brain-gut link<sup>[17]</sup>. Psychological stress induces colonic segmental contractions which are exaggerated in IBS patients<sup>[18,19]</sup>. Stress can alter GI function. However, the mechanism underlying stress-induced intestinal response is still unclear. Epidemiological data show that psychological stress is one of the most important etiological factors for IBS. Mental stress is one of the factors for the in-

duction or aggravation of the symptoms of IBS<sup>[20]</sup>. Visceral hypersensitivity and dysregulation of central pain perception in the brain-gut axis play a pivotal role in the pathophysiology of IBS.

The central nervous system response to stress modulates the autonomic nervous system outflow and activates the hypothalamic-pituitary-adrenal axis<sup>[6]</sup>. Dysfunction of these systems has been proposed to be an etiological factor for IBS<sup>[7,8]</sup>. In addition, CRH, which plays an important role in the stress response<sup>[9]</sup>, induces

a higher adrenocorticotrophic hormone (ACTH) level and a more profound enhancement of colonic motility in IBS patients than in healthy controls<sup>[10]</sup>. It has been shown that CRH increases rectal sensitivity<sup>[11]</sup>. Thus, alterations in neuroendocrine response to stress may be of importance in the pathophysiology of IBS<sup>[12]</sup>.

It was reported that CRH injected into the intracerebral ventricle of rats exerts a stimulatory effect on colonic motor function by inducing spike burst activities in the proximal colon, accelerating transit, and inducing defecation<sup>[21-23]</sup>. Use of nonselective CRH1 (NBI-359565) receptor antagonists showed that colonic motor function induced by CRH is delayed in rats, suggesting that central CRH combined with CRH1 receptor can regulate the colon function<sup>[23]</sup>. In the study by Fukudo *et al.*<sup>[10]</sup>, the descending colon motility induced by CRH was greater in IBS patients than in healthy subjects, CRH produced duodenal phase III motor activities in 80% of healthy subjects and duodenal dysmotility in 40% of IBS patients, the time of abdominal symptoms evoked by CRH was significantly longer in IBS patients than in healthy subjects, the plasma ACTH level induced by CRH was significantly higher in IBS patients than in healthy subjects, indicating that human intestinal motility is probably modulated by exogenous CRH. The brain-gut in IBS patients may have an exaggerated response to CRH. Intravenous injection of CRH can promote the viscera sensibility in rats, which can be inhibited by CRH1 receptor antagonists<sup>[23]</sup>. This study showed that the CRH expression level in hypothalamus of rats was significantly higher in model group than in normal group ( $P < 0.05$ ), which was remarkably decreased ( $P < 0.05$ ) after EA treatment. No distinct difference in CRH expression was found between normal and EA groups, suggesting that EA therapy can inhibit the expression of CRH in hypothalamus of rats.

Recently, the role of probiotics in intestinal ecosystems has received great attention because of their beneficial effects on human and animal gut health<sup>[24]</sup>. It has been shown that probiotics can improve inflammation in some IBS patients and alleviate IBS symptoms such as pain<sup>[25]</sup>. It has been demonstrated in animal studies that neonatal intervention with probiotics can protect against short and long term consequences of impaired intestinal barrier function and gut-associated immune dysfunction induced by neonatal stress, reduce elevated corticosterone levels in pups with early psychological trauma (maternal deprivation), suggesting that normalization of HPA-axis activity is mediated by the effect of probiotics on gut function<sup>[26-30]</sup>. Further study is needed to explore the relation between acupuncture and probiotics used in treatment of IBS.

The pathological mechanism of IBS is not clear, but it is believed to be associated with alterations in mentality, GI motility, and visceral sensitivity, *etc.* Recently, researchers have suggested the role of inflammatory cells in the pathogenesis of IBS<sup>[31]</sup>. Mucosal MC are located throughout the gut in close proximity to enteric nerves, and secrete numerous inflammatory substances including

histamine, cytokines, proteases, and eicosanoids that are known to sensitize visceral sensory nerve fibers. That is why some researchers have become interested in them.

SP is closely related with the pathological change in IBS, which plays a role in stress, intestinal infection, and visceral hypersensitivity in the development of IBS<sup>[31,32]</sup>. Meanwhile, SP is a gastrointestinal peptide hormone existing in the central nervous system and gastrointestinal tract, and a signaling molecule connecting the nervous system to the immune system. Wang *et al.*<sup>[33]</sup> reported that the expression of SP and c-fos protein in the enteric and central nervous systems of the rat model of constipation-predominant IBS is abnormal, suggesting that abnormal changes in SP may be involved in the pathogenesis of IBS, and SP containing the neural pathway may be one of the neural pathways that play an important role in the regulation of gastrointestinal function.

SP in the intestinal tract is mainly produced by nerve terminal and endocrine cells such as MC. SP in combination with its receptor exerts its effect on the homologous effector cells of stomach and intestine, leading to complicated physiologic functions such as gastrointestinal motility, sensibility, secretion and absorption. In the enteric nervous system, SP, as an enteric nervous system of neurotransmitters, can increase gastrointestinal motility, promote contraction of alimentary tract smooth muscle, reinforce colon progradation, and stimulate water and electrolyte secretion in small intestine and colon. Some researchers believe that mucosal MC can restore the function and paresthesia of intestinal tract, while others hold that there is an amplifying ring among SP, MC and sensory neurofibra. Releasing of neuropeptides from sensory nerve ending, such as SP, has a direct effect on target organs. SP in combination with its special receptor on the surface of mucosal MC can activate and degranulate MC, releasing histamine and influencing sensorineural function, which promotes SP and local blood vessels to release nerve growth factor. In this study, the increased expression of SP was closely related with the number of MC in lamina propria of rats with IBS. It was reported that MC are associated with neurofibra by membrane-membrane touch<sup>[34]</sup>. The number of MC and degranulated MC is greater in IBS patients than in healthy subjects and the activated MC are adjacent to the inner-intestinal neuroplexus<sup>[13,35]</sup>. Our previous study showed that MC in colonic mucosa and c-fos positive cells are significantly increased, EA at ST-25 and Tegaserod injected into stomach can inhibit the proliferation and activation of MC in the colon, and regulate the secretion of SP, SPR, VIP, and VIPR, but the effect of EA is obviously better than that of Tegaserod<sup>[36]</sup>. In this study, the number of MC, the optical density and positive expressing areas of SP, SPR were greater in rats with IBS than in normal rats, indicating that MC, SP and SPR are closely related with the development of IBS ( $P < 0.05$ ). However, MC, SP and SPR were decreased after EA treatment ( $P < 0.05$ ), suggesting that EA at ST25 and ST37 can effectively

adjust the dysfunction of MC and down-regulate the expression of SP and SPR.

In conclusion, dysfunction of the central and enteric nervous systems leads to IBS. EA at ST25 and ST37 can decrease the number of MC, the expression of SP and SPR in colon, and the CRH level in hypothalamus of rats.

## COMMENTS

### Background

Irritable bowel syndrome (IBS) is a common disorder in clinical practice, but its pathophysiology has not been completely elucidated, which makes its treatment difficult. The authors' previous study showed that the general therapeutic rate of electro-acupuncture (EA) at ST-25 for IBS is 84.90%. However, the regulatory effect of EA on IBS is still unknown.

### Research frontiers

More and more data show that IBS is closely related with the brain-gut axis, which has becoming a hot spot of study.

### Innovations and breakthroughs

The results of the authors' study have proved that EA at ST25 and ST37 is effective against IBS. EA at ST25 and ST37 exerts its effect on IBS by decreasing the number of mucosal mast cells and down-regulating the expression of substance P, substance P receptor in colon and corticotropin-releasing hormone in hypothalamus of rats.

### Applications

The experimental and clinical data can be used in further study on EA in treatment of IBS.

### Peer review

This study is interesting. Its findings are useful for the treatment of IBS.

### Abstract

The term biloma describes an encapsulated collection of bile within the abdomen, usually secondary to bile duct disruption. The commonest causes reported in the literature are iatrogenic (secondary to hepatobiliary surgery), trauma or complications due to choledocholithiasis. A few cases have been reported as complications of cholangiocarcinoma or acute cholecystitis. We report the case of a 64-year-old man initially diagnosed with a non-obstructive malignancy of the pancreas, who developed a spontaneous intrahepatic biloma 8 mo later. This was identified following a 1-wk history of fever, rigors and icterus. The biloma was identified on computed tomography and subsequently drained under ultrasound guidance. Forty-eight hours later, a stent was inserted endoscopically into his common bile duct and he made an uneventful in-hospital recovery. We believe this is the first documented case of spontaneous intrahepatic biloma to occur secondary to pancreatic malignancy.

### INTRODUCTION

In 1979, Gould and Patel<sup>[1]</sup> described the case of a 32-year-old man who was found to have a large encapsulated collection of bile outside the biliary tree, secondary to a tear in the right hepatic duct. This followed a traumatic insult to the upper abdomen. The patient proceeded to have this collection drained and a T-tube was inserted to permit bile drainage. Since the initial description, there have been a few documented cases of spontaneous biloma formation, usually in the context of choledocholithiasis. The current case is sufficiently exceptional with regard to location, etiology and mode of presentation to merit a report.

### CASE REPORT

A 64-year-old man was referred to the gastroenterology clinic by his general practitioner (GP) with constant upper abdominal pain that was worse after eating. In addition, the patient had been suffering from alternating constipation and loose stools. He denied the passage of blood in his motions or any weight loss.

A full blood count revealed normocytic anemia (hemoglobin 123 g/L; mean corpuscular volume: 88.4 fL). Renal and liver function tests were normal. Given the features on presentation, a colonoscopy was suggested, however, he was reluctant to go ahead with the procedure. As an alternative, a computed tomography (CT) pneumocolon was arranged.

Although no significant polyps or other colonic abnormalities were seen, there was an irregular 3 cm × 4.5 cm mass arising from the neck/body of the pancreas, with multiple lymph nodes in the peripancreatic region. Further assessment with a dual-phase CT scan of the pancreas was performed (Figure 1). As a result of encasement

**Figure 1** CT pneumocolon, which suggested the presence of advanced pancreatic malignancy.

**Figure 2** Large intrahepatic cystic lesion with bile duct compression caused by enlargement of the pancreatic neoplasm.

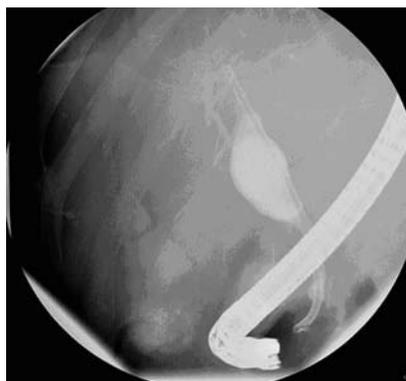

of the superior mesenteric artery and portal veins, the tumor was deemed inoperable. An ultrasound-guided biopsy of the lesion was undertaken, and histology confirmed adenocarcinoma of the pancreas.

The patient went on to complete three courses of gemcitabine chemotherapy but further staging CT demonstrated slowly progressive disease over a 3-mo period.

Six months later, the patient was referred by his GP to the on-call medical team with a week-long history of nausea, anorexia and new-onset jaundice. Upon examination, he was tender in the epigastrium and right upper quadrant, with no overt peritonism. His blood tests were as follows: bilirubin, 164  $\mu\text{mol/L}$ ; alanine aminotransferase, 84 IU/L; alkaline phosphatase, 5567 IU/L; albumin, 35 g/L; C-reactive protein (CRP), > 160 mg/L; prothrombin time, 16.3 s; and white blood cell count,  $12.9 \times 10^9/\text{L}$ .

Repeat CT of the pancreas was undertaken, which demonstrated a dilated common bile duct (CBD) with external compression from enlargement of the pancreatic tumor, and a large, intrahepatic cystic lesion that measured 12 cm  $\times$  9 cm, adjacent to the gallbladder (Figure 2).

Ultrasound-guided drainage was performed and yielded frank bile in keeping with an intrahepatic biloma. Microbiological analysis of the fluid did not reveal the presence of any pathogenic organisms. Endoscopic retrograde cholangiopancreatography (ERCP) demonstrated

**Figure 3** ERCP demonstrating a smooth stricture in the distal CBD, with dilated common hepatic ducts above. Contrast material was seen to flow within the biloma collection, which implied communication with the intrahepatic ducts.

a smooth stricture of the distal CBD and a dilated common hepatic duct above. Contrast material was seen to be flowing into the biloma, which implied a connection with the intrahepatic ducts (Figure 3). The stricture was stented and drainage from the biloma ceased within 48 h following insertion.

## DISCUSSION

The first reported case of a biloma was reported by Gould and Patel in 1979<sup>[1]</sup>. They reported extrahepatic bile leakage post trauma to the right upper quadrant of the abdomen. The bile accumulated in an encapsulated form. Although originally described as a bilious collection outside the liver, the term biloma has been extended to include any such lesion that may be intrahepatic but anatomically outside the biliary tree<sup>[2]</sup>. The majority of bilomas are iatrogenic and follow transhepatic cholangiography, liver biopsy, ERCP or cholecystectomy. Biloma also has been recognized to arise following external trauma<sup>[3]</sup>. Spontaneous biloma is exceedingly rare, and the majority occur secondary to choledocholithiasis or cholangiocarcinoma<sup>[4]</sup>. Rarer causes have been reported in the context of sickle cell disease<sup>[5]</sup> or as a complication of hepatic infarction and abscess formation. To the best of our knowledge, biloma that occurs secondary to primary pancreatic malignancy has not been reported previously in the literature.

As diagnostic techniques continue to evolve, an increasing number of cases have been identified, but the exact mechanism behind spontaneous biloma formation is still unknown. Postulated pathogenic mechanisms are Sphincter of Oddi spasm, CBD tumor or calculus obstruction that results in increased intraductal pressure, bile duct necrosis and rupture of the bile duct. As a result of the relatively slow onset of ductal obstruction that occurs in the context of a pancreatic neoplasm, such an acute elevation in biliary pressure is unusual (cf. impacted CBD stone). The size and location of biloma is influenced by the cause of rupture, location and size of bile leak, and rate of absorption by the peritoneum.

Most bilomas are secondary to CBD rather than hepatic duct perforation<sup>[6]</sup>.

There is no difference in the incidence between males and females, but the condition is found more often in the sixth to seventh decades of life. The age predominance may reflect that of the underlying etiological factor rather than that of developing the complication. Presentation is nonspecific, with abdominal pain, usually in the right upper quadrant (although a few reported cases of bile migration to the left subphrenic space have been documented, which has given rise to a predominance of pain on the left side). Fever may be accompanied by jaundice and abdominal distension. Extreme cases that result in bilious ascites also have been reported<sup>[7]</sup>. In our case, there was no history of recent hepatobiliary intervention (pancreatic biopsy had been performed 6 mo prior to presentation, but no evidence of biloma was seen on interval scanning). There were complaints of fever, rigors, anorexia and scleral icterus. Blood tests may show neutrophil leukocytosis, elevated CRP and obstructive liver function tests. Blood cultures may show Gram-negative bacteremia. Biloma can be picked up on ultrasound, CT or magnetic resonance imaging. Despite advancing imaging modalities, biloma may be difficult to differentiate from large cystic metastasis, seroma, angioma or lymphocele. Ultrasound becomes useful in this situation, with a definitive diagnosis being made following radiologically guided aspiration. Once fluid is obtained, microbiological testing is mandatory to exclude the presence of coexisting infection. ERCP is particularly useful in diagnosing an active leak; this may also allow therapeutic intervention<sup>[8]</sup>. Precise location of the biloma allows for percutaneous drainage, which negates the need for surgical intervention. Endoscopic intervention includes sphincterotomy with stone extraction, if appropriate, to lower biliary pressure. Placement of a stent in more distal lesions is an option, as this reduces

the pressure gradient into the duodenum and facilitates forward flow of bile. This also relieves obstruction from lesions that narrow the biliary tree. In our case, the latter approach was used to overcome the obstruction caused by the large pancreatic tumor.

Surgical management remains contentious but can be useful in cases of ongoing leakage despite endoscopic therapy. The goals are to halt abdominal contamination from bile by means of peritoneal drainage, surgical closure of active leaks, and T-tube drainage<sup>[7,9]</sup>.

### Abstract

The major papilla of Vater is usually located in the second portion of the duodenum, to the posterior medial wall. Sometimes the mouth of the biliary duct is located in other areas. Drainage of the common bile duct into the pylorus is extremely rare. A 73-year old man, with a history of duodenal ulcer, was admitted to hospital with the diagnosis of cholangitis. Dilatation of the extrahepatic biliary duct was observed by abdominal ultrasonography, and endoscopic retrograde cholangiopancreatography (ERCP) was performed. No area suggesting the presence of the papilla of Vater was found within the second duodenal portion. Finally the major papilla was located in the theoretical pyloric duct. Cholangiography was performed and choledocholithiasis was found in the biliary tree. The patient underwent dilatation of the papilla with a balloon tyre and removal of a 7 mm stone using a Dormia basket, which solved the problem without further complications. This anomaly increased the difficulty of performing therapeutic interventions during ERCP. This alteration in anatomy may increase the risk of complications during papillotomy, with a theoretically higher risk of perforation. Dilatation using a balloon was the chosen therapeutic technique both in our case and in the literature, due to its low rate of complications.

### INTRODUCTION

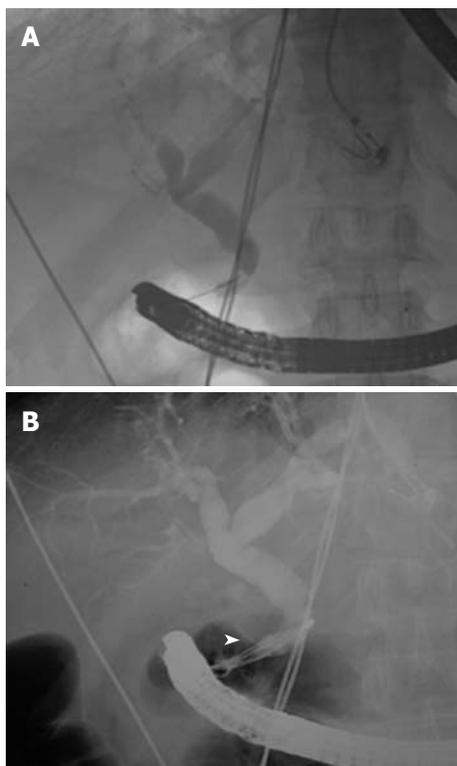

The major papilla of Vater is usually located in the second portion of the duodenum, to the posterior medial wall. Both the common bile duct and the main pancreatic duct empty into it. Sometimes the mouth of the biliary duct is located in other areas along the duodenum, mainly within the third or the fourth portion<sup>[1-3]</sup>, although it has also been found with a much lower frequency in the duodenal bulb<sup>[4-6]</sup>. In such cases it is common to find a previous duodenal ulcerous pathology<sup>[7]</sup>. Very rarely has the papilla been found in the stomach<sup>[8-10]</sup>, although the frequent use of endoscopic retrograde cholangiopancreatography (ERCP) has increased its recognition. In the literature we found a case in the 1930's describing common bile duct drainage into the pylorus<sup>[2]</sup>, and another more recent case of drainage into the duodenal wall adjacent to the pylorus<sup>[11]</sup>, however, no more cases have been published. We describe a case in which the mouth of the biliary duct was found in the pyloric channel.

### CASE REPORT

A 73-year-old patient, with a history of digestive bleeding secondary to duodenal ulcer 10 years previously, presented to hospital due to high temperature and pain in the right hypochondrium. His C-reactive protein level was 190 mg/dL, alanine-aminotransferase 40 IU/L, leucocytes 15 500/mm<sup>3</sup> and total bilirubin 2.62 mg/dL. Abdominal ultrasonography showed dilatation of the extrahepatic biliary duct, with no lithiasis. After the diagnosis of cholangitis with increased bilirubin and dilatation of the biliary duct was made, ERCP was performed. No area suggesting the presence of the papilla of Vater was found within the second duodenal portion. Finally the major papilla was located in the theoretical pyloric duct (Figure 1), since the patient showed a duodenal bulb which was deformed and post-ulcerous, having disappeared almost completely. The papilla did not show clear anatomical signs which made it inadvisable to perform a papillotomy. Cholangiography was carried out and choledocholithiasis

**Figure 1** Endoscopic retrograde cholangiopancreatography. A: View of the papilla located in the pylorus (arrow head); B: Piping of the papilla.

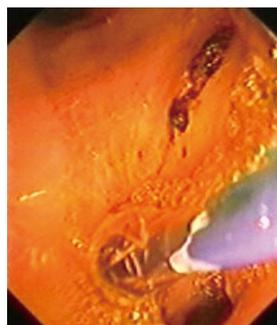

**Figure 2** Cholangiography. A: Common bile duct ending in a hook shape, common in proximal drainage of the papilla; B: Removal of choledocholithiasis with Dormia basket (arrow head).

was found in the biliary tree (Figure 2A). The patient underwent dilatation of the papilla with a balloon tyre and removal of a 7 mm stone using a Dormia basket, which solved the problem without further complications (Figures 2B and 3).

## DISCUSSION

The papilla of Vater is a bulge in the duodenal mucosa into which both the common bile duct and the Wirsung empty, sometimes shaping into a Y, or they can be separated by a mucosa layer making them independent. The most common location of the papilla of Vater is within the posterior medial wall of the second portion of the duodenum. The frequent use of ERCP has allowed better observation of papillae in an ectopic location.

**Figure 3** Endoscopic retrograde cholangiopancreatography. Balloon dilatation of the ectopic papilla.

Although the diagnosis of ectopic papillae have been described by other types of radiological studies such as computed tomography<sup>[4]</sup>, X-ray of the esophagus-gastrointestinal tract<sup>[12]</sup>, intraoperative cholangiography<sup>[11]</sup> and echoendoscopy<sup>[5]</sup>, most ectopic papillae are identified by ERCP. An ectopic location distal to the second duodenal portion, within the third and fourth duodenal portions, has been described frequently, and has a frequency rate of 5.6% to 23%<sup>[13]</sup>. Ectopic papillae are much less frequent in a proximal location, and a few cases have been located in the gastric, pylorus and duodenal bulb areas<sup>[14]</sup>. Filippini in 1931 described the first case of papilla located in the pylorus<sup>[2]</sup>, although Quintana and Labat<sup>[2]</sup> mentioned 3 cases of dual drainage in the duodenum and pylorus. Another recent case has been described where the papilla was located in the posterior duodenal wall below the pylorus<sup>[11]</sup>. In our subject the papilla was located in the pylorus, with a duodenal bulb which was deformed due to previous ulcerous pathology.

A theory on the origin of ectopic papillae has been suggested which describes their occurrence during embryonic formation. The liver originates in the hepatic diverticulum, which is divided into the hepatic pars and the cystic pars during embryogenesis. The hepatic pars then develops into both the liver and the hepatic ducts, while the cystic pars develops into the gall-bladder and the cystic duct. The common bile duct originates in the hepatic antrum, which is the common area of the hepatic diverticulum. Boyden<sup>[15]</sup> claimed that an earlier subdivision of the hepatic diverticulum could cause the common bile duct to empty into different locations other than the usual location.

Ectopic papillae located in the bulb may be secondary to an ulcerous duodenal pathology, which could cause, due to contiguity, anomalous drainage in the duodenum<sup>[11]</sup>. In our patient the location of the papilla in the pyloric channel might be related to the patient's previous ulcerous duodenal pathology. Nevertheless, since we did not find signs of the papilla in the second duodenal portion, his condition was probably due to a congenital malformation with biliary and pancreatic drainage in the posterior pyloric area, which could have caused the later development of a duodenal ulcer. In our subject we observed the diagnosis requirements for an ectopic papilla as described by Lee *et al*<sup>[14]</sup>, for a location in the bulb which were: (1) an orifice was observed in the bulb by duodenoscopy or upper endoscopy, and the bile duct and/or the pancreatic duct were directly visualized radiographically, when contrast

was injected *via* this opening; (2) there was direct drainage of the common bile duct into the duodenal bulb without evidence of any other drainage into the duodenum on cholangiography; and (3) there was no evidence of a papilla-like structure in the second or third duodenal portion on duodenoscopic examination. Fistula secondary to ulcer disease or choledocholithiasis, spontaneous or iatrogenic surgical fistula, and surgical choledochenteric diversion should be included in the differential diagnosis<sup>[8]</sup>.

The clinical importance of the ectopic location of the papilla means that there is a tendency for the development of choledocholithiasis through anomalous bile drainage, due to the lack of a sphincter mechanism. Likewise, it can also lead to mucosal damage in the area, with swelling and ulcer formation, due to the action of biliary pancreatic secretion<sup>[14]</sup>. The clinical symptoms may include recurrent abdominal pain, which could explain the high percentage of patients undergoing cholecystectomy described in some series<sup>[13]</sup>. The absence of a sphincter would allow passage of the gastroduodenal contents into the main bile duct, possibly causing cholangitis in association with biliary obstruction<sup>[7,13,14]</sup>. In a recent study by Disibeyaz *et al*<sup>[13]</sup> on 39 patients where the papilla was located in the bulb, they detected episodic abdominal pain in 95% of patients and cholangitis in 59% of patients. The predominance of male sex and an association with ulcerous duodenal pathology in 61.5% of the patients should be emphasized. In our case, the patient had a history of duodenal ulcer and was admitted to hospital suffering from cholangitis, which led us to think that this patient had a papilla in an ectopic location when we failed to find it in its usual location, making it necessary to check both the duodenal bulb and the stomach.

This anomaly increased the difficulty of performing therapeutic interventions during ERCP. This alteration in anatomy, when there are no clear anatomic signs, may increase the risk of complications during papillotomy, with a theoretically higher risk of perforation, as has been described in the literature<sup>[13]</sup>. Balloon dilatation may be the chosen technique for these patients when there is a biliary obstruction. Its effectiveness has recently been suggested, especially when gallstones need to be removed, without relevant complications<sup>[13]</sup>. Stent installation may be necessary when balloon dilatation is unsuccessful and the patient has comorbidities which make surgery inadvisable. The surgical option should only be taken in these cases when endoscopic treatment is not effective.

In conclusion, ectopic location of the papilla is a rare finding, however, the frequent use of ERCP may increase the number of cases diagnosed. Although a distal location is found most frequently, a proximal location must be taken into account, especially in patients with a history of recurrent abdominal pain, cholangitis, ulcerous duodenal pathology and biliary obstruction in whom the papilla cannot be found in its usual location during ERCP.

Although further studies are necessary, balloon dilatation was the chosen therapeutic technique both in our case and in the literature, due to its low rate of complications. Technical difficulty and a higher probability of perforation when performing a papillotomy, due to the lack of anatomic reference, make its use inadvisable.

### INTRODUCTION

Intussusception, defined as the telescoping of a segment of the gastrointestinal tract into an adjacent one, is extremely rare in the stomach, but more common in the small intestine, ileocecal junction and colon. It is the leading cause of intestinal mechanical obstruction and the second most common surgical emergency in children<sup>[1]</sup>. However, it is rather infrequent in adults, accounting for 0.1% of all surgical admissions and 1%-5% of mechanical bowel obstructions<sup>[2]</sup>. In these cases, it is frequently related to malignancy.

Gastrointestinal stromal tumors (GISTs) are a subset of mesenchymal tumors of varying differentiation. They are rare clinical entities, constitute less than 3% of all gastrointestinal malignant neoplasms and represent only 20% of small-bowel malignant neoplasms (excluding lymphoma)<sup>[3]</sup>. With the improvement on immunohistochemical staining techniques and ultrastructural evaluation, GISTs are recognized as a distinct group of mesenchymal tumors now<sup>[4]</sup>.

In the current report, we present a case of a 45-year-old man with Crohn's disease complaining of intermittent vague abdominal pain for a period of 4 mo. Enteroclysis, computer tomography (CT) and magnetic resonance imaging (MRI) abdominal scans showed small bowel intussusception, a diagnosis which was confirmed after surgical exploration of the abdomen where a tumor causing a jejunoileal intussusception was identified. Pathological examination of the surgical specimen revealed a gastrointestinal stromal tumor as well as inflammation and aphthous ulcerations, which were characteristic of Crohn's disease involving small bowel. Coexistence of these clinical entities resulting in intussusception has never been reported in the literature.

### Abstract

We report a case of jejunoileal intussusception in a 42-year-old patient with Crohn's disease caused by a gastrointestinal stromal tumor. The patient complained of vague diffuse abdominal pain for a period of 4 mo. Intussusception was suspected at computer tomography and magnetic resonance imaging scans. Segmental resection of the small intestine was performed. Pathological examination of the surgical specimen revealed a gastrointestinal stromal tumor as well as aphthous ulcerations and areas of inflammation, which were characteristic of Crohn's disease. This is the first report of small bowel intussusception due to a gastrointestinal stromal tumor coexisting with Crohn's disease.

## CASE REPORT

A 45-year-old man with symptoms of bowel obstruction was admitted to the surgical department of our hospital in April, 2008. He complained of diffuse blunt abdominal pain preceded by two episodes of vomiting and obstipation. The patient reported similar attacks of milder episodes, consisting of intermittent abdominal pain and bloating for the past 4 mo. He was diagnosed as Crohn's disease following gastroenterological evaluation with colonoscopy and terminal ileum biopsies at sites of ileitis 1 year ago on the grounds of chronic diarrhea, cramp abdominal pain attacks and mild anemia. The patient did not receive any regular medication. Physical examination showed mild abdominal distention with slight tenderness and hypoactive bowel sounds. No mass was palpated and rectal examination did not reveal any blood or malignancy. Routine laboratory tests and chest films were normal. However, abdominal plain radiographs showed some small bowel air-fluid levels. The patient underwent a CT scan with *po* and intravenous contrast of 5-mm thick slice, which showed thickening of the distal ileum wall and an intraluminal mass resulting in partial obstruction of the small intestine. Sagittal fast spin echo (FSE) T2, FSE T2 with fat suppression and axial FSE T1 with 5-mm thick slice abdominal MRI (Figure 1) fortified the suspicion of intussusception since it showed a pathognomonic bowel within bowel configuration. In order to secure the diagnosis, an enteroclysis was performed, which showed a jejunoileal stricture caused by invagination of the jejunum into the ileum and proximal to the stenosis bowel dilatation (Figure 2).

Taking into account the high possibility of a malignant mass causing bowel intussusception in an adult patient, laparoscopic approach was not considered in this case, in order to achieve the best possible oncologic clearance at the surgical intervention that followed. So, the patient underwent a laparotomy which identified a jejunoileal intussusception (Figure 3). An approximately 20-cm partial small bowel resection including wide margins and a wedge resection of the respective mesentery up to the beginning of the feeding vessels were performed. The bowel lumen was longitudinally opened immediately following removal of the specimen and an exophytic round-shaped mass of smooth circumference approximately 6 cm in maximum diameter, which was hard at palpation, was easily appreciated. Pathological examination of the surgical specimen proved the lesion to be a stromal tumor with an immunohistochemical profile of c-kit (+), S-100 (-), SMA (-), desmin (-), EMA (-), CD34 (-), AE1/AE3 CK8.18 (-), NSE (-), and synaptophysin (-). The tumor was invading the muscularis propria layer at the point of the intussusception (Figure 4A and B). No lymph node infiltration was identified. Microscopic examination of the remaining specimen disclosed findings consistent with Crohn's disease. The lesion contained aphthous ulcerations and showed severe polymorphonuclear and lymphocytic infiltration as well as eosinophils and intraluminal abscesses.

Figure 1 Abdominal MRI scan (Sagittal fast spin echo T2) revealing the jejunoileal intussusception.

Figure 2 Enteroclysis showing jejunoileal stricture caused by invagination of the jejunum into the ileum and proximal to the stenosis bowel dilatation.

The continuity of the small bowel was restored with a side-to-side entero-enteral anastomosis. The patient, discharged on the 7th postoperative day, following an uncomplicated recovery, was subjected to follow-up with clinical examinations and CT scans at 6-mo intervals and had no clinical or radiologic recurrence at the time when we wrote this paper.

## DISCUSSION

Tumors of the small intestine are rare and usually benign. The majority of them are leiomyomas, but adenocarcinomas and GISTs, although uncommon, may also appear. Conventional histologic methods could not produce correct diagnoses and most tumors referred to as leiomyomas and leiomyosarcomas in the older medical literature are actually GISTs. On the basis of immunohistochemical and ultrastructural studies, GISTs are mesenchymal tumors of the gastrointestinal tract that may show myogenic and/or neurogenic characteristics<sup>[5]</sup>, and are usually asymptomatic, but they have been reported to present with bleeding, obstruction or perforation in some cases<sup>[6]</sup>.

Intussusception is the invagination of one bowel loop and its mesentery into the bowel lumen distal to it. It occurs when a proximal segment of intestine (intussusceptum) telescopes into the intestinal segment distal to it (intussuscipiens), and is the second most common complication when tumors locate in the ileum<sup>[7]</sup>. Invaginations of the lumen may also cause gastrointestinal

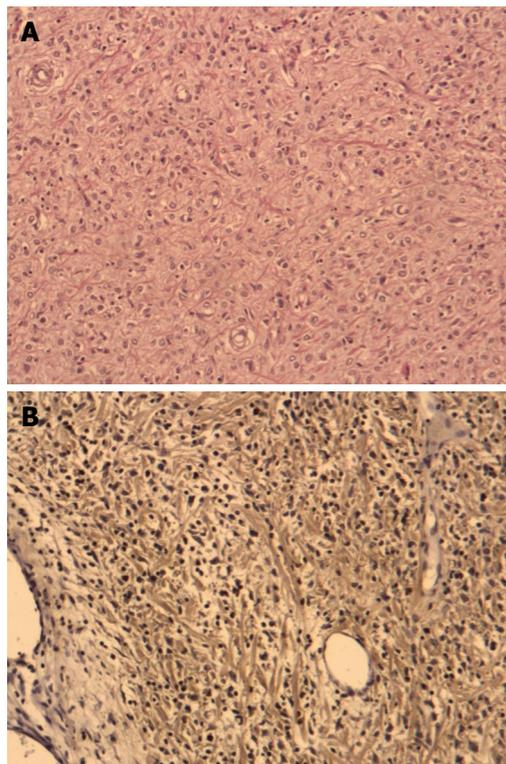

**Figure 3** Intraoperative appearance of the jejunoleal intussusception.

bleeding or necrosis of the tumor. Usually patients have slightly enlarging tumors with no rapid onset. Their complaints are usually non specific and it is finally risky to miss the diagnosis. Our patient experienced vague abdominal pain for a period of 4 mo which led him to undergo a colonoscopy that came up normal.

Intussusception is correctly diagnosed preoperatively in only one-third of cases<sup>[7]</sup>. An accurate diagnosis of intussusception should include a good and specific medical history, a thorough physical examination, radiography, CT, MRI and enteroclysis or even an endoscopic ultrasound or capsule endoscopy. Ultrasound is useful in confirming obstruction and may sometimes identify the cause<sup>[8]</sup>. However, it is highly operator-dependent. Taking into account the rarity of such findings, it requires an experienced radiologist. In our case, ultrasound was not diagnostic of intussusception. It has been recently reported that CT and MRI offer great help in establishing the preoperative diagnosis of intussusception<sup>[9]</sup>. On CT, one can diagnose a bowel intussusception within its configuration, thickening of the wall and compressed mesenteric fat and vessels<sup>[9]</sup>. Although not routinely reported in such cases, an abdominal MRI, like in our report, can aid to establish the preoperative diagnostic suspicion of intussusception.

In contrast to childhood where intussusception is idiopathic in 90% of cases and the basic underlying cause of intussusception is the hypertrophy of Payer's patches activity, adult intussusception has a definable pathologic lesion in over 90% of cases, with neoplasms considered to be the cause in 65% of them<sup>[10]</sup>. Any intraluminal lesion, especially polyps, which irritates and alters normal peristaltic activity, is able to trigger an intraluminal invagination finally causing an intussusception. Subsequent peristaltic bowel activity produces an area of sequence constriction and relaxation, thus telescoping the leading point through the distal bowel lumen<sup>[11]</sup>. The malignancy is more likely to be located in the colon rather than in the small bowel. Less common etiologies of intussusception in adults include postoperative factors (adhesions, suture lines, *etc.*), polyps, Meckel's disease, sprue, cecal duplication and intramural hematoma<sup>[1]</sup>. The presentation of adult intussusception is usually subacute or chronic<sup>[2]</sup>. The most common symptoms are crampy abdominal pain, nausea, vomiting, abdominal distention

**Figure 4** Histological examination (A) (HE,  $\times 100$ ) and c-kit immunohistochemical positive staining (B) (HE,  $\times 40$ ) of the gastrointestinal stromal tumor.

or tenderness. Only up to 20% of all cases present with complete bowel obstruction and acute onset<sup>[10]</sup>. Moreover, it has been reported that a palpable mass is present in 7%-42% of the cases<sup>[11]</sup>.

In the literature, five cases of small bowel intussusception from a stromal tumor in adults have been described<sup>[5,6,10,12,13]</sup>. The most recent one was an intraluminal leiomyoma of the small intestine in a 72-year-old female patient, which resulted in invagination and partial obstruction of the jejunum<sup>[12]</sup>. Another recent report presented a case of a 60-year-old woman with a jejunoleal intussusception due to a myxoid stromal tumor<sup>[10]</sup>. Others described a GIST as the cause of intussusception in a 32-year-old man and emphasized the role of ultrasound in preoperative diagnosis of the disease<sup>[13]</sup>. In an older report<sup>[5]</sup>, a case of a 42-year-old patient with intussusception of the lower jejunum was presented and the patient was admitted with progressive anemia, massive melena and lower abdominal pain. Finally, a malignant GIST of the small intestine causing small bowel obstruction due to ileal invagination has also been described<sup>[6]</sup>.

Coincidence of Crohn's disease and gastrointestinal stromal tumor is extremely rare and only two cases have been reported to date<sup>[14,15]</sup>. The first one described a polypoid tumor within Meckel's diverticulum in an 81-year-old male patient with Crohn's disease and the tumor was immunohistochemically proved to be a GIST<sup>[14]</sup>. The second report presented a 51-year-old patient with a high risk GIST of the terminal ileum within an area of Crohn's ileitis<sup>[15]</sup>.

Conclusively, in the present report we describe a case of a 42-year-old man with no significant medical history other than a 4-mo intermittent dull abdominal pain who presented with symptoms of acute bowel obstruction. Laparotomy revealed a jejunoileal intussusception and histological examination of the surgical specimen indicated a GIST tumor causing the intussusception as well as patchy areas of inflammation and erosions similar to those identified in Crohn's disease. Coexistence of these pathologically distinct and extremely rare entities has not been reported and represents a unique finding.

### Abstract

Intrahepatic cholangiocarcinoma (ICC) is a relatively rare and highly fatal neoplasm that arises from the biliary epithelium. Prognosis is generally poor and survival is limited to a few months. Here we present a case of advanced ICC successfully treated by chemosensitivity test-guided systemic chemotherapy combining S-1 and cisplatin (CDDP). A 65-year-old woman with a liver tumor was referred to our hospital on November 21, 2007. Abdominal ultrasonography and computed tomography (CT) showed low-density masses of 50 and 15 mm in diameter, respectively in segment VIII of the liver and in the enlarged lymph node in the para-aorta. Ultrasonography-guided fine needle biopsy diagnosed the tumors as ICC. Since the patient was inoperable for lymph node metastasis, she underwent systemic chemotherapy with gemcitabine. Six months after initiation of chemotherapy, CT revealed ICC progression in the liver and pleural dissemination with pleural effusion. The patient was admitted to our hospital for anticancer drug sensitivity testing on June 9, 2008. Based on the sensitivity test results, we elected to administer systemic chemotherapy combining S-1 and CDDP. Two months into the second chemotherapy treatment, CT revealed a reduction of the tumors in the liver and lymph node and a decrease in pleural effusion.

After eight cycles of the second chemotherapy, 17 mo after ICC diagnosis, she is alive and well with no sign of recurrence. We conclude that chemosensitivity testing may effectively determine the appropriate chemotherapy regimen for advanced ICC.

A case of advanced intrahepatic cholangiocarcinoma successfully treated with chemosensitivity test-guided systemic chemotherapy. *World J Gastroenterol* 2009; 15(41): 5228-5231 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5228.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5228>

### INTRODUCTION

Intrahepatic cholangiocarcinoma (ICC) is a relatively rare and highly fatal neoplasm that arises from the biliary epithelium. Radical surgery is currently the optimal therapy for ICC with curative potential. However, most patients present with advanced disease at the time of diagnosis. Prognosis in these patients is poor and survival is limited to a few months<sup>[1]</sup>.

Biliary tract carcinoma (BTC) has traditionally been divided into cancers of the gallbladder, the extrahepatic bile ducts, ampulla of Vater, whereas ICC has been classified as liver cancer. Lately, however the term BTC has been used to include the gallbladder, the extrahepatic bile ducts, ICC and the ampulla of Vater.

Chemotherapy has been performed in cases of unresectable advanced ICC and postoperative recurrence of ICC. However, a standard chemotherapeutic regimen has not yet been established for ICC. There are phase II

trials that support the following combinations: gemcitabine/cisplatin (CDDP), gemcitabine/oxaliplatin, gemcitabine/capecitabine, and 5-fluorouracil in unresectable or metastatic ICC<sup>[2]</sup>.

Chemosensitivity testing using surgical material is an established method to evaluate tumor response prior to chemotherapy<sup>[3-5]</sup>. Sensitivity, specificity and accuracy of chemosensitivity testing were reportedly 82.7%, 70.7% and 73.6%, respectively<sup>[6]</sup>. Several methods are established to measure cancer cell viability<sup>[7]</sup>. Recently, chemosensitivity testing for gastric cancer treatment has been approved in Japan. However, it has seldom been performed for ICC, since ICC occurs more rarely than other gastrointestinal malignancies. The adenosine triphosphate (ATP) assay is a highly sensitive and precise method for measuring cell viability, and only a few dozen cells are necessary for the ATP assay<sup>[8,9]</sup>. Very few reports of chemosensitivity testing used surgical material from ICC. This is the first report concerning chemosensitivity testing using the ATP assay for patients with unresectable ICC. We present a case of advanced ICC successfully treated by chemosensitivity test-guided systemic chemotherapy combining S-1 and CDDP.

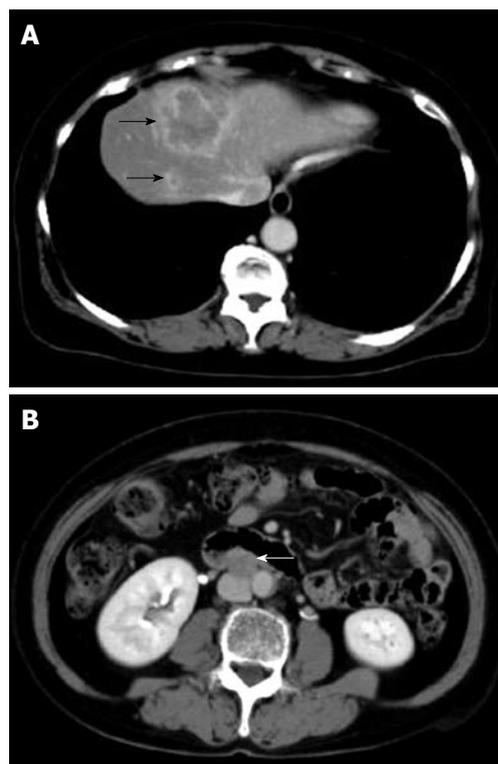

## CASE REPORT

A 65-year-old woman was examined in a follow-up visit at a local hospital for fatty liver 1 year post-diagnosis on October 30, 2007. Although she exhibited no symptoms, abdominal ultrasonography revealed tumors in the liver, and she was referred to our hospital on November 21, 2007. Her past medical and family histories were not remarkable. She did not consume alcohol. On admission, her conjunctivae were not jaundiced, and heart and respiratory sounds were normal. The liver, spleen and tumor were not palpable.

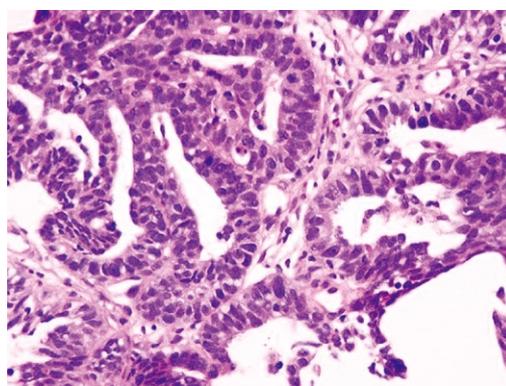

Laboratory findings on admission were as follows: aspartate aminotransferase 24 IU/L (normal, 13-33 IU/L), alanine aminotransferase 39 IU/L (normal, 6-27 IU/L),  $\gamma$ -glutamyl transpeptidase 26 IU/L (normal, 10-47 IU/L) and alkaline phosphatase 240 IU/L (normal, 115-359 IU/L). Assays for hepatitis B surface antigen and hepatitis C virus antibody were negative. All tumor markers tested showed normal values: specifically, 1.8 ng/mL for CEA (criterion, < 5.0), 5.8 U/mL for CA 19-9 (criterion, < 37), 6.2 ng/mL for AFP (criterion, < 10.0), 10 mAU/mL for PIVKALII (criterion, < 40).

Abdominal ultrasound and computed tomography (CT) scan with contrast enhancement revealed a low-density mass, measuring 50 and 15 mm in diameter, in segment VIII of the liver. The tumor did not show enhancement during the arterial phase but did show peripheral rim enhancement during the portal phase. The CT scan also revealed an enlarged lymph node in the para-aorta (Figure 1). The portal vein was intact until the third branch. Chest X-ray and a CT scan revealed no pleural metastasis.

Ultrasonography-guided fine needle biopsy was performed at the main tumor of the liver on November 22, 2007. Microscopic examinations showed tubular adenocarcinoma (Figure 2). Gastroendoscopy and colonoscopy did not show any other malignancy. Subsequently, the tumor was diagnosed as ICC with intrahepatic metastasis and

**Figure 1** Computed tomography (CT) of the tumor on first admission. CT shows a low-density lesion with rim enhancement in segment VIII of the liver (black arrows) (A) and enlarged lymph node in the para-aorta (white arrow) (B).

**Figure 2** Hematoxylin-eosin staining. Cuboidal cancer cells with chromatin-rich nuclei had proliferated invasively, forming indistinct glandular structures.

lymph node metastasis. Since the patient was inoperable for lymph nodes metastasis, she underwent systemic chemotherapy with gemcitabine (800 mg/m<sup>2</sup>, 30 min iv infusion), which was administered on days 1, 8 and 15, and repeated every 4 wk. Six months after initiation of chemotherapy, CT revealed ICC progression in the liver and pleural dissemination with pleural effusion (Figures 3 and 4). The patient was admitted to our hospital for anticancer drug sensitivity testing on June 9, 2008. Cultures and ATP assays were performed as described previously<sup>[5]</sup>. Cell viability was evaluated by measuring the intracellular ATP level using bioluminescence as described by Kangas *et al*<sup>[10]</sup>. Based on the sensitivity test results, we elected to administer systemic chemotherapy combining S-1 and CDDP (S-1 80 mg/m<sup>2</sup> per day orally administered for 3 wk,

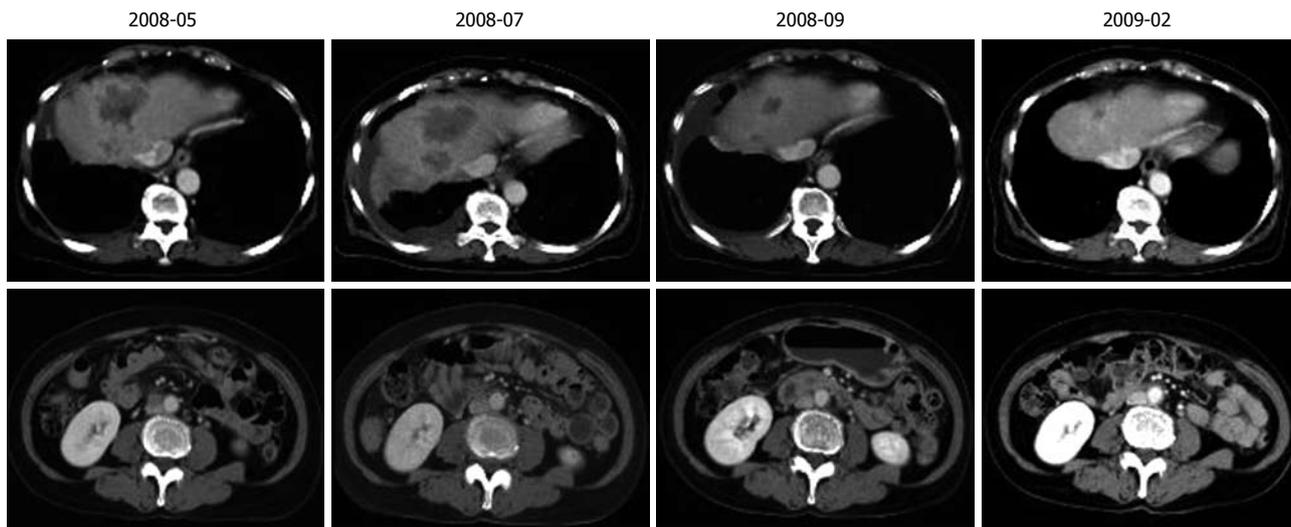

Figure 3 Reduction in tumors in the liver and lymph node following chemotherapy.

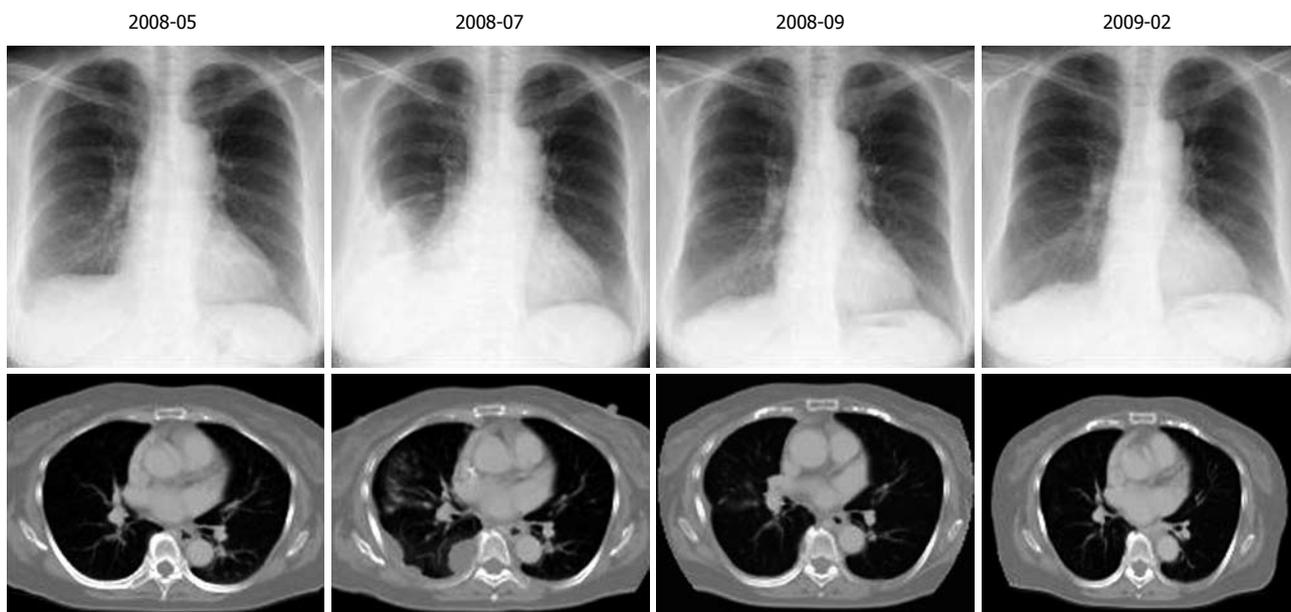

Figure 4 Decreased pleural metastases following chemotherapy.

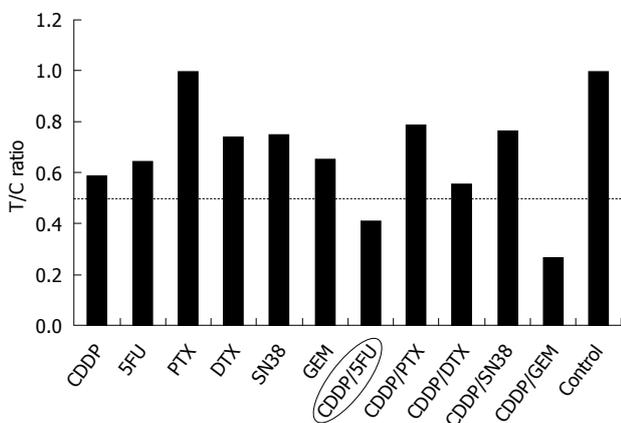

Figure 5 Cell viability evaluated by measuring the intracellular ATP level using bioluminescence. The T/C (treated/control) ratio, or the ratio of ATP quantity of a tumor sample treated with anticancer drugs to that of the control, was used as the index of chemosensitivity.

CDDP 60 mg/m<sup>2</sup> iv infusion administered on day 8, and repeated every 5 wk) (Figure 5). She had symptoms of cough in July 2008. Two months into the second chemotherapy treatment, she had no symptoms and CT revealed a reduction in the tumors of the liver and lymph node and a decrease in pleural effusion (Figures 3 and 4). Side effects and complications of chemotherapy were tolerable, and she experienced only grade-1 nausea. CDDP added to S-1 might worsen nausea. After eight cycles of the second chemotherapy regime, 17 mo after ICC diagnosis, she is alive and well with no sign of recurrence.

## DISCUSSION

Although radical surgery is considered the most effective therapy for ICC, only 20% of patients present with resectable disease<sup>[11]</sup>. Without surgery, ICC is a rapidly fatal disease with a 5-year survival rate of less than 5%<sup>[12]</sup>, while

in curative resections the 5-year survival rate approaches 20%-35% in cases with negative surgical margins<sup>[13]</sup>. In the present case, to our surprise, the patient with unresectable ICC survived more than 17 mo with chemotherapy. The role of systemic chemotherapy in unresectable ICC is undefined. Although chemotherapy has been reported to be more beneficial than the best supportive care<sup>[14]</sup>, no standard chemotherapy regimen has yet been identified. Most promising approaches involve the use of single agents such as gemcitabine, which has been shown to be an effective therapy for BTC in phase II trials<sup>[15,16]</sup>. Response rates for gemcitabine ranged from 8% to 36% and overall survival times from 6.3 to 16 mo. S-1 is a novel oral fluoropyrimidine agent, which contains tegafur, gimeracil and oteracil potassium. Gimeracil is a competitive inhibitor of dihydropyrimidine dehydrogenase and achieves higher concentrations of 5-fluorouracil in plasma and tumor tissues<sup>[17]</sup>. Fluoropyrimidines have known synergistic effects with CDDP<sup>[18]</sup>, and combinations of S-1 and CDDP are reportedly effective therapies for patients with advanced BTC in phase II trials<sup>[19]</sup>. In the present case, we selected gemcitabine as first line chemotherapy, because gemcitabine has been extensively evaluated in patients with metastatic BTC.

Chemosensitivity testing using surgical material is an established method for evaluation of tumor response prior to chemotherapy. Several methods have been established for measurement of cancer cell viability. However, it has seldom been performed in ICC, since ICC occurs more rarely than gastrointestinal malignancies and the prognosis of ICC is poor. There have been few reports of chemosensitivity testing using surgical material for ICC without the ATP assay<sup>[20-22]</sup>. The ATP assay is a highly sensitive and precise method used to measure cell viability. The ATP assay has been shown to be a good predictor of response to chemotherapy in other tissue types, such as breast cancer, ovarian cancer, colorectal adenocarcinoma, melanoma and lung cancer. The assay predicts that anticancer drugs with a lower treated/control (T/C) ratio (< 0.6) are more sensitive. In the present case, based on the results of chemosensitivity testing, we selected systemic chemotherapy combining S-1 and CDDP. Ultimately, *in vitro* ATP chemosensitivity testing was useful. Since 5-fluorouracil has considerable toxic effects and entails the inconvenience of continuous iv infusions, we selected S-1 as an alternative to 5-fluorouracil. Although the T/C ratio combining gemcitabine and CDDP was more sensitive than that combining S-1 and CDDP, we did not select the former combination since gemcitabine administration on its own did not halt disease progression.

### Abstract

Spontaneous or traumatic intramural bleeding of the esophagus, which is often associated with overlying mucosal dissection, constitutes a rare spectrum of esophageal injury called dissecting intramural hematoma of the esophagus (DIHE). Chest pain, swallowing difficulty, and minor hematemesis are common, which resolve spontaneously in most cases. This case report describes a patient with spontaneous DIHE with recurrent massive bleeding which required critical management and highlights a potential role for therapeutic angiography as an alternative to surgery.

dissecting intramural hematoma of the esophagus: Treatment with therapeutic angiography. *World J Gastroenterol* 2009; 15(41): 5232-5235 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5232.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5232>

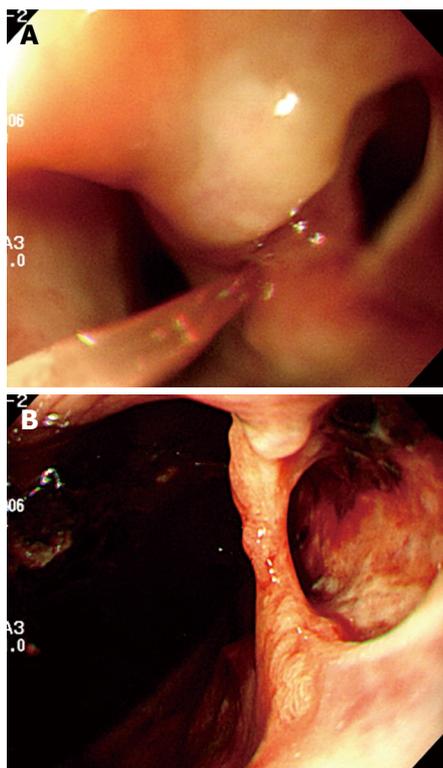

### INTRODUCTION

Dissecting intramural hematoma of the esophagus (DIHE) is a rare but well-known esophageal injury<sup>[1,2]</sup>. It is characterized by a concentric or eccentric intramural hematoma associated with dissection of the esophageal wall<sup>[2]</sup>. Forceful vomiting, mechanical insult, and underlying coagulopathy are common causes. It can also occur spontaneously without any evident cause<sup>[3]</sup>. DIHE is considered a benign disease. The hemorrhage from DIHE does not have clinically significant consequences, although in rare cases massive bleeding with hypovolemic shock can occur. We report a case of DIHE presenting as recurrent massive intraluminal bleeding that was treated by transarterial embolization.

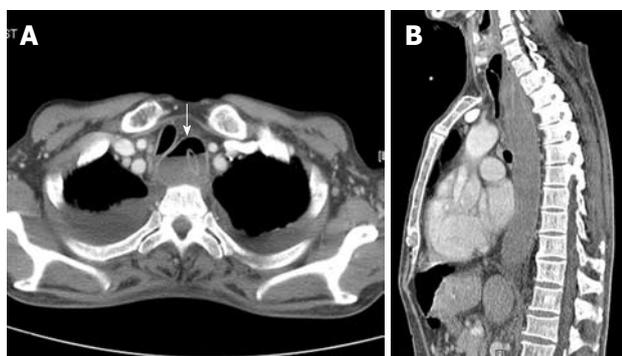

### CASE REPORT

A 57-year-old man visited the emergency room complaining of a sore throat and difficulty swallowing for 5 d. He had a history of alcoholic liver cirrhosis (Child-Pugh class B), but he continued drinking. Laryngoscopy and cervical computed tomography (CT) revealed severe laryngopharyngitis. Upper gastrointestinal endoscopy showed marked laryngeal edema and a small ulceration in the upper esophageal sphincter. There was no intraluminal mass, except for small varices in the distal esophagus. The gastric mucosa was moderately congested. The patient denied any history of cervical trauma or instrumentation. He was treated medically with antibiotics, and his initial symptoms subsided within 5 d.

One week later, the patient complained that he regurgitated blood from the throat. He continued to spit up small volumes of fresh blood repeatedly. His hemoglobin dropped from 13.9 to 6.5 g/dL, and 4 U of packed red cells were transfused. Emergency endoscopy revealed a small opening in the cervical esophagus and

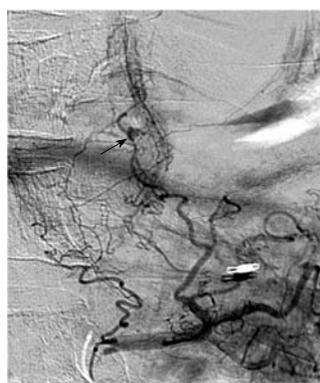

**Figure 1 Endoscopic view.** A: A small opening in the cervical esophagus; B: Mucosal bridging with a large mucosal defect in the esophagogastric junction.

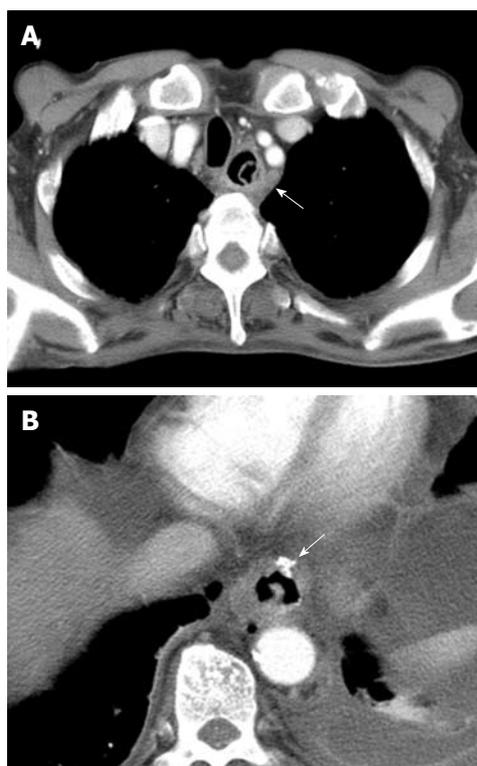

**Figure 2 Chest CT images.** A: The transverse view of the proximal esophagus shows a concentric intramural hematoma and mucosal dissection with an air-fluid level in the false lumen (arrow). mucosal bridging with a large mucosal defect around the esophagogastric junction (Figure 1). Active bleeding was detected from a vessel exposed on the ulcer base in the cardia. After hemostasis with endoscopic clipping, his vital signs and hemoglobin stabilized. Chest CT performed because of the esophageal lesions revealed dissection of the wall and a large circumferential intramural hematoma in the esophagus (Figure 2). Based on the endoscopy and chest CT findings, DIHE with cardiac ulcer bleeding was diagnosed. The patient was treated conservatively without oral intake.

Eight days later, the hematemesis recurred. Conservative treatment with massive transfusion of packed red cells and fresh frozen plasma was ineffective. Endoscopy

**Figure 3 Celiac angiography** showing a hyperstaining pseudoaneurysmal lesion (arrow) in an esophageal branch of the left gastric artery. The branch was embolized using glue and lipiodol.

showed no bleeding at the previously treated site. However, continuous oozing of blood from the distal esophagus was observed. His vital signs were unstable.

Since surgery was very risky due to underlying liver cirrhosis, less invasive celiac angiography was performed for hemostasis. A small hyperstaining pseudoaneurysmal lesion was observed at an esophageal branch of the left gastric artery (Figure 3). The branch was embolized using glue and lipiodol. After the procedure, the patient's vital signs and hemoglobin stabilized. However, he experienced a few bouts of minor hematemesis 10 d later. Transarterial embolization using glue and coils was reattempted, and no further bleeding occurred. Follow-up chest CT 4 wk later showed a resolving hematoma and double lumens separated by the dissected mucosa. The embolization site was seen as focal lipiodol uptake in the distal esophagus (Figure 4). Endoscopic examination

was declined. Supportive care with parenteral nutrition was maintained. The patient was discharged without complications after 6 wk.

## DISCUSSION

The esophagus is susceptible to various extrinsic injuries (from ingested foods, instruments, and bougienage) or intrinsic sheering forces induced by retching, vomiting, or coughing. DIHE lies in the spectrum of esophageal injuries between a mucosal tear (Mallory-Weiss syndrome) and a transmural laceration (Boerhaave's syndrome)<sup>[2,4]</sup>. Although these syndromes are usually associated with severe vomiting, DIHE is not always caused by emesis<sup>[4]</sup>. One out of five patients reports no history of trauma. However, an underlying coagulopathy is found in many patients with so-called spontaneous DIHE<sup>[1]</sup>. Portal hypertension and endoscopic variceal sclerotherapy are also associated with DIHE in cirrhotic patients<sup>[5]</sup>. Although the direct cause was not clear in this present case, the cervical esophageal ulcer and underlying portal hypertension may have been precipitating factors.

Acute chest pain is a common presenting symptom and should be differentiated from acute myocardial infarction and aortic dissection<sup>[6]</sup>. Hematemesis and difficulty swallowing may ensue, and these are helpful for differentiating from other critical diseases. The typical triad of DIHE (chest pain, dysphagia, and hematemesis) is evident only in one third of cases<sup>[1]</sup>. Therefore, the rarity of DIHE and atypical symptoms can delay correct diagnosis. In our case, repeated hematemesis with hypovolemia was the only clinical feature.

DIHE is generally benign. Most patients recover fully with conservative management<sup>[1]</sup>. Esophageal obstruction and major bleeding constitute two major complications of DIHE. Esophageal obstruction by the hematoma may cause or aggravate difficulty swallowing. Successful endoscopic decompression or surgical treatment have been reported in such cases<sup>[7,8]</sup>.

A major intraluminal hemorrhage seems to be caused by overlying mucosal rupture and evacuation of

the hematoma, however, the exact mechanism remains unclear. Although half of patients are reported to experience hematemesis, the volume of bleeding is usually small, and major bleeding with hypovolemic shock is uncommon.

We reviewed 119 patients who were presented in 87 English-language reports since 1968. Major bleeding was defined as more than 500 mL hematemesis with hypovolemic shock or bleeding that required transfusion of at least 4 U. Eleven cases (9.2%), including the present case, were collected and summarized in Table 1<sup>[9-18]</sup>. Seven cases were elderly patients (five females and two males). The bleeding was attributed to anticoagulation therapy in three cases<sup>[10,11,18]</sup>. The majority were treated conservatively. However, this type of treatment was not always effective. An elderly patient who was treated conservatively died after 5 d<sup>[10]</sup>. Two patients were treated with surgery<sup>[13,16]</sup>; one of them had a 5-cm longitudinal tear with a pulsatile bleeding vessel between 25 and 30 cm from the alveolar ridge on endoscopy, and the active arterial bleeder was identified and treated with an emergency thoracotomy<sup>[13]</sup>. In our case, angiography located and treated the bleeding site at an esophageal branch of the left gastric artery. Extensive DIHE and major bleeding might be caused by a small bleeding artery. In this situation, therapeutic angiography may be effective.

Therapeutic angiography has been used to control major non-variceal gastrointestinal bleeding and has been reported to be safe, effective, and durable<sup>[19]</sup>. It is usually considered when endoscopic therapy has failed or when emergency surgery carries a high risk of mortality. It has also been effective in the hemostasis of uncontrolled Mallory-Weiss syndrome<sup>[20]</sup> and in the treatment of a giant gastric intramural hematoma<sup>[21]</sup>.

In conclusion, massive intraluminal bleeding can be a complication of DIHE. Although most bleeding in DIHE can be managed medically, prompt, appropriate treatment should be attempted in hemodynamically unstable patients. In such cases, therapeutic angiography may be a useful treatment alternative to surgery.

### Abstract

Giant esophageal inflammatory fibrous polyp (especially > 17 cm in size) is seen rarely. Endoscopic removal has been reported rarely because the procedure is technically demanding and the hemostasis is difficult to ascertain. Here, we describe a case of a giant upper esophageal inflammatory fibrous polyp that was resected successfully by endoscopy.

### INTRODUCTION

Giant esophageal inflammatory fibrous polyp (especially > 17 cm in size) is seen rarely<sup>[1]</sup>. Surgical excision is usually advised<sup>[2-5]</sup>. Endoscopic removal has been reported rarely<sup>[6]</sup> because the procedure is technically demanding and hemostasis is difficult to ascertain. Here, we described a giant upper esophageal inflammatory fibrous polyp that was resected successfully by endoscopy.

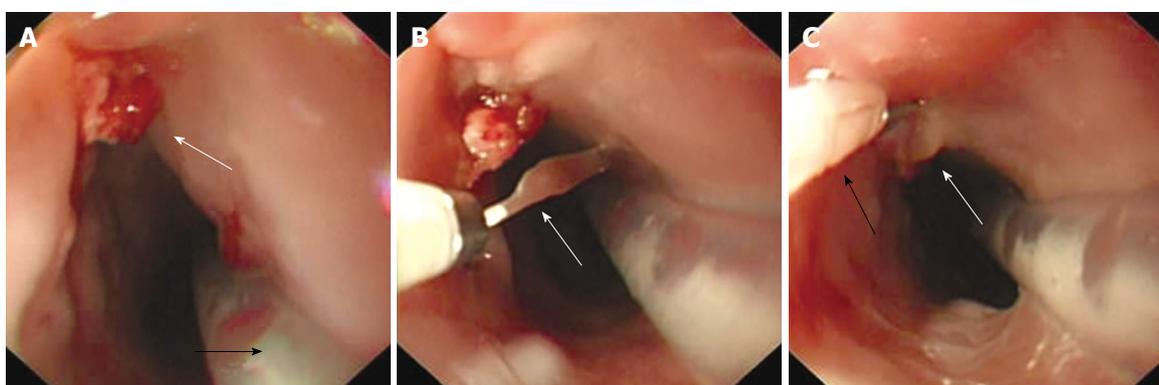

### CASE REPORT

A 50-year-old man presented to our hospital with a 6-mo history of progressive difficulty in swallowing, initially, solid and then liquid food for the past 2 mo. Physical examination and blood tests, including coagulation parameters, were normal. Barium swallow revealed a 17-cm polypoid filling defect inside the esophagus that moved with deglutition (Figure 1). Contrast thoracic computed tomography (CT) revealed a localized isodense upper esophageal lesion, which was free from the lower part of the esophagus. The esophageal wall was intact and there was no evidence of infiltration into adjacent organs or any mediastinal lymphadenopathy. Gastroscopy showed a giant polyp with smooth overlying mucosa, extending from 18 to 35 cm (measured from the incisors), and endoscopic ultrasonography (EUS) revealed well-distributed, low-echo-level lesions at the root of the polyp, excluding echoless lumen-like structures (no large blood vessels inside the lesions) (Figure 1). Therefore, the esophageal polyp was a benign lesion. Endoscopic removal of the polyp with an electro-surgical snare was attempted, using the ICC 200 (ERBE, Tubingen, Germany). The procedure was performed under general anesthesia with elective intubation and airway protection. Equipment for hemostasis, including hemoclips, Coagrasper, injection needle and adrenaline for injection was prepared before the procedure.

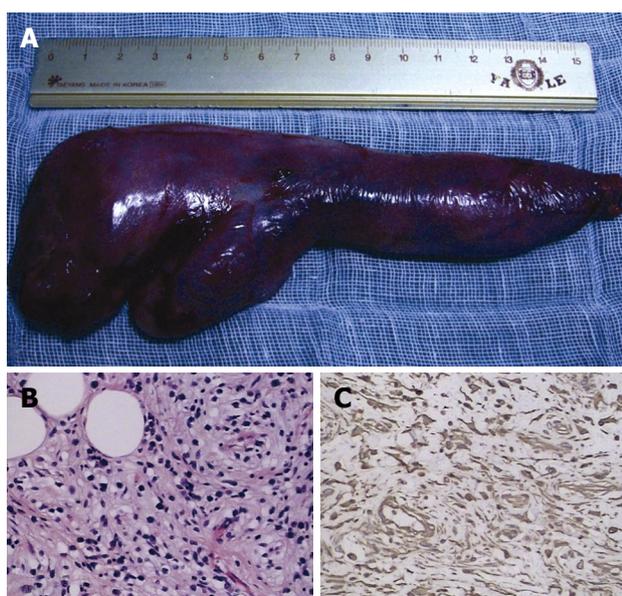

Firstly, we inserted a detachable loop of appropriate stiffness and size through the biopsy channel. Then, the detachable loop was placed from the base to the neck of the esophageal polyp. The loop was closed gradually and the polyp was lifted away from the esophageal wall. Polypectomy was performed and air was inflated to distend the esophagus. The setting of the electro-surgical units was as follows: COAG mode (effect 350 W) was first applied for 2 s, so that the small blood vessels over

**Figure 1 Imaging of esophageal polyp.** A: Barium swallow showed a giant esophageal polyp (arrow), which was free from the middle and lower esophageal wall; B: Gastroscopy showed the polyp with smooth overlying mucosa (at 18 cm from the incisors); C: EUS revealed well-distributed, low-echo-level lesions at root of the polyp (white arrows), excluding echoless lumen-like structures.

**Figure 2 Esophageal polyp removal.** A: Residual polyp (white arrow) after polypectomy at the left wall of the esophagus (18 cm from incisor). A nasogastric tube (black arrow) used for suction (size 16 Fr) was placed over the right wall of the esophagus; B: Hemoclips (white arrow) were applied to the residual polyp; C: After application of the hemoclips (black arrow) to the residual polyp (white arrow).

**Figure 3 Polypectomy specimen and its pathology.** A: The resected esophageal lesion measured 17 cm in length, and the neck, body and tail of the lesion measured 1, 3 and 5 cm, respectively; B: HE staining (original magnification,  $\times 200$ ) showed the presence of lots of fibroblasts, with some acidophilic cells, plasma cells and adipose cells; C: Immunostaining (original magnification,  $\times 200$ ) for vimentin showed strong staining of the cells.

the mucosa were coagulated. Then, we employed the endo-cut mode (effect 380 W) to CUT. Near the end of polypectomy, COAG mode was resumed to minimize bleeding from the central blood vessel. Adequate air insufflation and distension of the esophagus minimized the risk of burning and esophageal perforation. Only minor bleeding was noted at the polypectomy site. The hemostasis was achieved securely with 1:10 000 adrenaline injection and application of two hemoclips over the polypectomy site (Figure 2).

In addition, a 16-Fr nasogastric tube was placed to remove all the blood and gastric fluid during the procedure (Figure 2). If the esophageal polyp failed to be removed or there was any complication, an on-site thoracic surgeon assessed the patient urgently for operation.

The resected esophageal polyp specimen (Figure 3) was retrieved with the snare and sent to the pathology laboratory for pathological examination. Hematoxylin and eosin (HE) staining of the removed esophageal specimen showed the presence of lots of fibroblasts, with some adipocytes, plasma cells and acidophilic cells (Figure 3). Immunostaining revealed CD 117 (-), CD 34 (-), S-100 (-), desmin (-), actin (-), cytokeratin (-), HMB45 (-) and vimentin (+) (Figure 3). The histological diagnosis was

inflammatory fibrous polyp. The patient remained well and was discharged 1 wk after the procedure. Follow-up gastroscopy 4 wk later was normal.

## DISCUSSION

Inflammatory fibrous polyp, also known as inflammatory pseudotumor, is a benign intraluminal tumor that consists of a mixture of inflamed fibrous, granulation tissue and lipomatous elements, which is covered by normal squamous epithelium<sup>[7]</sup>. Giant esophageal inflammatory fibrous polyp (especially > 17 cm in size) is seen rarely<sup>[1,8]</sup>. The presenting symptoms of dysphagia and sensation of a mass in esophageal inflammatory fibrous polyp are the same as in other esophageal tumors (such as leiomyoma and gastrointestinal stromal tumor), unless there is development of regurgitation of the polyp through the mouth or asphyxiation<sup>[9]</sup>. Some cases may stay asymptomatic or with heartburn for a long time<sup>[10,11]</sup>. Inflammatory fibroid polyps should be considered in the differential diagnosis of submucosal and polypoid esophageal masses, although distinctive radiographic features are not found<sup>[12]</sup>. Usually, the diagnosis is made by imaging or endoscopic studies. Barium-enhanced contrast of the esophagus usually shows a sausage-shaped mass with multiple filling defects, which originates in the cervical esophagus and extends to the lower esophagus<sup>[10]</sup>. Endoscopy usually shows an intraluminal mass that is mobile and covered with normal mucosa. Careful examination of the upper esophageal sphincter may reveal the stalk of the pedunculated mass. It is not difficult to distinguish esophageal inflammatory fibrous polyp from leiomyoma, which is usually relatively flat, and non-pedunculated intramural lesions in the middle and lower third of the esophagus<sup>[13]</sup>. EUS has been reported as a method to demonstrate the submucosal origin of anal polyps<sup>[14,15]</sup>.

As a result of its special origin, there may be uncontrollable bleeding during endoscopic resection. Endoscopic removal of giant upper esophageal lesions requires thorough assessment before the procedure. Therefore, multiple modalities (barium, CT, EUS and gastroscopy) are important to delineate the nature and origin of the lesion. EUS provides information on the diameter of the polyp as well as its vascularity and insertion point<sup>[6]</sup>. Special precautions during hemostasis and elective airway protection are necessary to prevent bleeding and aspiration. The placement of the nasogastric tube, adequate insufflation and distension of the esophagus can minimize the risk of burning and esophageal perforation. The site of snare polypectomy should be kept away from the base of stalk to prevent esophageal perforation. Advances in the techniques of endoscopic treatment and the improvement

of endoscopic accessories make endoscopic removal of giant esophageal polyps feasible. Post-polypectomy hemostasis can be achieved with adrenaline injection and hemoclips. If hemostasis fails, one can use Coagrasper to coagulate even a small area of bleeding.

In conclusion, with thorough assessment with multiple imaging modalities, and the availability of good endoscopic accessories, giant upper esophageal inflammatory fibrous polyp can be resected by endoscopy safely and successfully.

### Abstract

Only a few cases of pedunculated hepatocellular carcinoma (P-HCC) have been reported in the literature. The common sites of extrahepatic metastases in patients with HCC are the lungs, regional lymph nodes, kidney, bone marrow and adrenals. Metastasis to spleen is mostly *via* hematogenous metastasis, direct metastasis to spleen was very rare. We report a case of P-HCC presenting as a left upper abdominal lesions which involved the spleen that was actually a P-HCC with splenic metastasis. This case is unique as P-HCC directly involved the spleen which is not *via* hematogenous metastasis.

### INTRODUCTION

The pedunculated hepatocellular carcinoma (P-HCC) which protrudes from its pedicel or presents as epibiotic mass almost making no invasion into the liver, is a rare exception to the gross type<sup>[1,2]</sup>. To date, only a few cases have been reported<sup>[2-4]</sup>. The common sites of extrahepatic metastases in patients with hepatocellular carcinoma (HCC) are the lungs, regional lymph nodes, kidney, bone marrow and adrenals, which is *via* hematogenous metastasis. The P-HCC directly invading the spleen not *via* hematogenous metastasis is extremely rare. In this report, we describe a case of P-HCC which directly involved the spleen.

### CASE REPORT

A 68-year-old man with HBV-related cirrhosis was admitted to our hospital because of left flank pain and loss of weight for a forty-day duration. A mass lesion could be touched in left upper abdomen. AFP level was 166.02 ng/mL, CA125, CA199 and CEA were negative. HBVDNA level was  $1.51 \times 10^4$  copies/mL. Sonographic and CT scan showed a 17 cm  $\times$  14 cm  $\times$  10 cm tumor between left hepatic lobe and spleen, which also involved the upper pole of spleen and almost made no invasion into the liver (Figure 1). Celiac and hepatic arteriography displayed mass lesions taking blood from left hepatic artery, splenic artery and left inferior phrenic artery, and transarterial chemoembolization was performed (Figure 2). Image-guided biopsy of tumor was consistent with HCC.

At operation, mild cirrhosis was found in the liver, a large tumor lied in the left upper abdomen between left hepatic lobe and spleen. The upper pole of spleen was involved, almost making no invasion into the liver, gastrointestinal and pancreas (Figure 3). He underwent spleen, tumor and partial left hepatic lobe resection in January 2008. The loss of blood was 1000 mL in total. HCC and splenic metastasis were confirmed by pathological examination (Figure 4). The postoperative clinical course was uneventful, with a negative follow-up for clinical and radiological investigation at 17 mo after surgery.

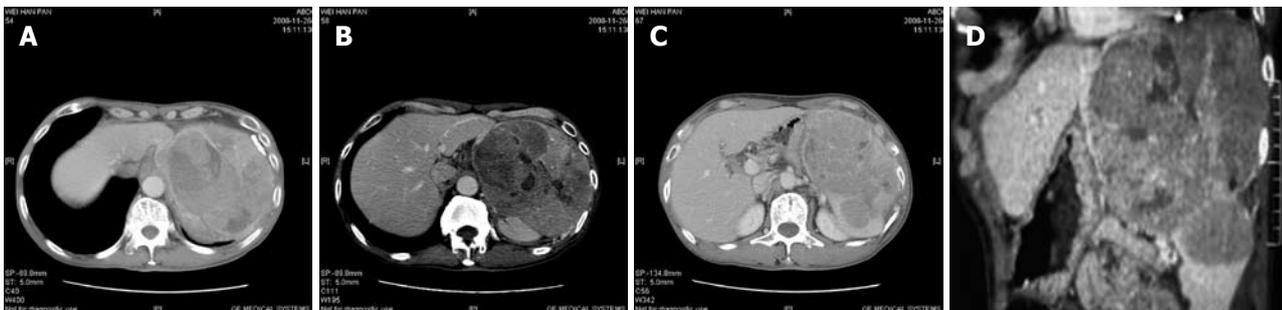

### DISCUSSION

The P-HCC has been reported to occur in 0.24%-3.0% of all HCC patients<sup>[5]</sup>. Hematogenous metastasis to spleen

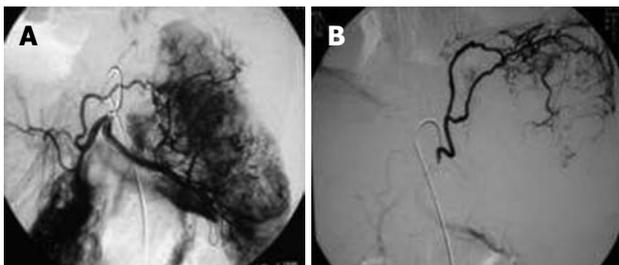

**Table 1** Previous cases reported in literature with HCC and splenic metastasis

HCC: Hepatocellular carcinoma; H: Hematogenous metastasis; LUQ: Left upper quadrant.

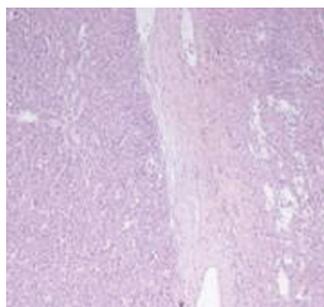

**Figure 1** CT scan in abdomen showing a mass tumor between left hepatic lobe and spleen directly involving the upper pole of spleen and almost making no invasion into the liver (A-D).

**Figure 2** Celiac and hepatic arteriography confirmed the mass lesions taking blood from left hepatic artery and splenic artery (A) and inferior phrenic artery (B).

**Figure 3** Postoperative photography showing the lesions directly involving the upper pole of spleen.

**Figure 4** Histopathology showing the splenic metastasis of hepatocellular carcinoma (HE, × 40).

is very rare with a reported prevalence of 0.7%-0.8% in HCC patients<sup>[6,7]</sup>, but it is probably more common than direct metastasis.

Preoperative differential diagnosis between metastatic or primary splenic tumors is difficult. High levels of AFP (> 1210 ng/mL) may contribute to the diagnosis of P-HCC. With improvement in diagnostics such as angiography and CT scan, the preoperative diagnosis is feasible in patients with negative or mild increase of AFP level. In this patient, selective celiac arteriography showed a tumor fed by hepatic artery, splenic artery and left inferior phrenic artery, from which we can judge the blood

supply and diagnose the tumor. Image-guided biopsy of tumor was utilized to confirm the presence of HCC when the imaging study could not draw a conclusion.

The intrahepatic metastasis from HCC occurs mostly commonly *via* the portal vein, which is followed by hematogenous metastasis to the lungs and bone, lymph node metastasis, direct metastasis and peritoneal metastasis. Previous cases in the literature with HCC and splenic metastasis are summarized in Table 1<sup>[6-17]</sup>. Metastasis to spleen occurred hematogenously in previous cases. In the present case, the splenic metastasis occurred directly. The cumulative survival rates of extrahepatic metastasis of HCC were very poor. Such lesions in the case may not represent remote metastases, but they are actually HCC with extended invasion to the spleen. Whether splenic metastasis happens directly or hematogenously should be distinctive and the resection of P-HCC and splenic metastasis can be curative in the former. The distinction between the two is important, as it affects the stage, prognosis and management of the patient. Although the long-term outcome of resection for such splenic metastasis is unknown, direct splenic metastasis of P-HCC can be easily controlled to obtain gross disease clearance and may achieve better long-term survival.

In conclusion, splenic metastases of P-HCC are difficult to distinguish from primary splenic tumors, even with modern imaging studies. The treatment involves resection and surgical exploration, whenever possible.

### Abstract

The term "hemangioma" refers to the common tumor of infancy that exhibits rapid postnatal growth and slow regression during childhood. It may cause confusion with venous malformations that are often incorrectly called "cavernous hemangioma". Venous malformations comprise abnormally formed channels that are lined by quiescent endothelium. Accurate diagnosis is required for selecting the appropriate treatment.

### TO THE EDITOR

With regard to the article entitled "Large cavernous hemangioma in the cecum treated by laparoscopic ileocecal resection" by Huh *et al*<sup>[1]</sup> published recently on the *World Journal of Gastroenterology*, there are some pertinent considerations. In 1982, Mulliken and Glowacki<sup>[2]</sup> classified vascular lesions into vascular tumors (infantile hemangioma, rapidly involuting congenital hemangioma, non-involuting congenital hemangioma, kaposiform

hemangioendothelioma and tufted angioma) and vascular malformations (arteriovenous malformation, venous malformation, lymphatic malformation, lymphatic-venous malformation, and capillary malformation). In 1996, the International Society for the Study of Vascular Anomalies approved this classification system to establish a common language for the many different medical specialists who are involved in the management of these lesions. A great variety of vascular anomalies is incorrectly referred to as "hemangiomas" in the medical literature and a significant number of patients receive ineffective and potentially harmful treatment based on misclassification. Hemangiomas are usually not present at birth; they proliferate during the first year of life; and then they involute. They are composed of proliferating endothelial cells. Venous malformations consist of dysplastic vessels and are present on a lifelong basis. Unlike hemangiomas, there is no proliferation phase. They seem to grow because the vessels progressively dilate and they do not present a regression phase<sup>[3]</sup>. Histological findings in venous malformations consist of large, dilated, blood-filled vessels lined by flattened endothelium as reported in the article.

After close examination of the reported case of "cavernous hemangioma", we support the diagnosis of venous malformation in the cecum. Colonic venous malformations are often mistaken for tumors because of a similar presentation (from a vague blue patch to a soft blue mass as described in the article) and improper nomenclature. The term "cavernous hemangioma" is frequently used to name a venous malformation. These lesions may cause chronic and acute gastrointestinal hemorrhage.

Sclerotherapy of venous malformations is an effective treatment and seems to be the best therapeutic option, although the surgical resection is preferred for venous malformations localized in the colon in case of bleeding. Although these vascular malformations generally are incompletely resectable because of diffuse pelvic and mesenteric involvement, the goal is to abate bleeding by excluding the lesion from the gastrointestinal lumen. The minimally invasive surgical procedure performed by the authors of this article seems to be appropriate since the venous malformation was removed from the lumen. Other procedures like colectomy with mucosectomy and endorectal pull-through should be considered for diffuse venous malformations of the colorectum<sup>[4]</sup>.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Articles: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

The family of mammalian chitinases includes members both with and without glycohydrolase enzymatic activity against chitin, a polymer of N-acetylglucosamine. Chitin is the structural component of fungi, crustaceans, insects and parasitic nematodes, but is completely absent in mammals. Exposure to antigens containing chitin- or chitin-like structures sometimes induces strong T helper type-I responses in mammals, which may be associated with the induction of mammalian chitinases. Chitinase 3-like-1 (CHI3L1), a member of the mammalian chitinase family, is induced specifically during the course of inflammation in such disorders as inflammatory bowel disease, hepatitis and asthma. In addition, CHI3L1 is expressed and secreted by several types of solid tumors including glioblastoma, colon cancer, breast cancer and malignant melanoma. Although the exact function of CHI3L1 in inflammation and cancer is still largely unknown, CHI3L1 plays a pivotal role in exacerbating the inflammatory processes and in promoting angiogenesis and remodeling of the extracellular matrix. CHI3L1 may be highly involved in the chronic engagement of inflammation which potentiates development of epithelial tumorigenesis

### INTRODUCTION

Chitin, the linear polymer of  $\beta$ -1,4-linked N-acetylglucosamine (GlcNAc), is a structural component of the cell walls and coatings of many organisms, and represents the second most abundant polysaccharide in nature after cellulose. Chitin efficiently protects crustaceans, insects, parasites, fungi, and other pathogens from the harsh adverse effects of their environments and/or hosts<sup>[1]</sup>. Although chitin has not been found in mammals, several mammalian proteins with homology to fungal, bacterial, or plant chitinases have been identified<sup>[2-6]</sup>. Chitotriosidase (CHIT1), and acidic mammalian chitinase (AMCase) are the only 2 of these proteins demonstrating chitinolytic (glycohydrolase) activity, while none of the other mammalian chitinases show enzymatic activity despite the retention and conservation of the substrate-binding cleft of the chitinases<sup>[7-9]</sup>. Therefore, the latter chitinases are called chitinase-like-lectins (Chi-lectins). Only recently, our group and others have identified the important biological roles of mammalian chitinases in chronic inflammatory conditions including inflammatory bowel disease (IBD), type 2 diabetes, proliferative dermatitis and allergic bronchial asthma<sup>[10-16]</sup>. One mammalian chitinase, chitinase

3-like-1 (CHI3L1, also known as YKL-40 or HC-gp39) is overexpressed in many pathological conditions including fibroblastic change in liver cirrhosis, increased deposition of connective tissue components and hyperplastic synovium in rheumatoid arthritis, and increased cellular infiltration as well as epithelial proliferation in chronic colitis. CHI3L1 is difficult to detect in the body of normal individuals and the biological role of CHI3L1 in embryonic development or distribution of this molecule in normal tissues is still largely unclear. Interestingly, significantly high amounts of CHI3L1 are detected in the involuting mammary gland upon cessation of lactation<sup>[2]</sup>, however the exact biological role of CHI3L1 in this process has not yet been elucidated. CHI3L1 can also directly regulate the critical processes of adhesion and migration in vascular smooth muscle cells *in vitro*<sup>[17]</sup>. In addition many groups have reported that CHI3L1 is expressed on many different types of human solid cancers<sup>[3,10,18,19]</sup>. Surprisingly, CHI3L1 seems to be a useful “prognosticator”, or indicator of prognosis, and may also be a potential “tumor marker” in screening and monitoring of cancer patients<sup>[20-23]</sup>. In this review article, we will discuss the potentially important biological functions of mammalian chitinases, in particular CHI3L1, during the development of chronic inflammation and the subsequent inflammation-mediated oncogenic processes in epithelial cells.

## INFLAMMATORY DISORDERS MEDIATED BY MAMMALIAN CHITINASES

Chitin, a polymer of GlcNAc, is produced copiously by a wide variety of organisms such as crustaceans (e.g. shrimp and crab), insects, fungi, amphibians, parasitic nematodes, and other marine organisms<sup>[24,25]</sup>. However, chitin is completely absent in mammals including humans and mice<sup>[26]</sup>. Therefore, it was believed for a long time that mammals were not capable of producing chitinolytic endoglucosaminases in the body, but Hollak *et al*<sup>[27]</sup> first discovered CHIT1, a functional and structural homolog to the chitinases of other species, in serum samples of Gaucher disease patients. Gaucher disease is a genetic disorder causing a lack of the lysosomal enzyme glucocerebrosidase and is characterized by accumulation of macrophage-like Gaucher cells which have glycosphingolipids in cytosolic compartments<sup>[28]</sup>. The serum level of CHIT1 is upregulated approximately 1000-fold in patients with Gaucher disease as compared to normal individuals and the enzyme shows glycohydrolase activity against chitin and other chitin-like substances (e.g. *p*-nitrophenyl chitooligosaccharides)<sup>[29]</sup>. Subsequent studies revealed that the increased CHIT1 activity in Gaucher disease patients is associated with aberrant macrophage activation<sup>[28]</sup>, and the activity can be used as a marker of disease severity and therapeutic response in Gaucher disease<sup>[30]</sup>. Boot *et al*<sup>[31]</sup> reported that approximately 6% of various ethnic groups have a homozygous mutant allele of 24 bp duplication of the CHIT1 gene, resulting in a

complete lack of CHIT1 enzymatic activity. Increased rates of nematode infection seemed to be associated with the mutation<sup>[32]</sup>. The CHIT1 cDNA was cloned by Boot *et al*<sup>[33]</sup> revealing that this molecule has a strong sequential homology to other chitinases belonging to the family 18 of glycosyl hydrolases. CHIT1 contains a complete chitin-binding domain in the C-terminus region that connects with the catalytic groove by a hinge region<sup>[34]</sup>. The chitin-binding domain of CHIT1 efficiently binds with chitin polymers as shown by structural analysis<sup>[35]</sup>. Under inflammatory conditions, CHIT1 expression of pathogenic macrophages is significantly upregulated in the inflamed tissues<sup>[29]</sup>. In addition to CHIT1, there is another mammalian chitinase, AMCase, which shows high structural homology with CHIT1, has an optimal enzymatic activity at around pH2 and exhibits glycohydrolase enzymatic activity. Full-length cDNA of mouse and human AMCase was first cloned in 2001<sup>[36]</sup>, but an exciting biological role of AMCase was revealed by Zhu *et al*<sup>[14]</sup> only recently: the group noticed a formation of crystals in lung tissues of mice with an asthma-like disease model and identified that the crystals were mammalian chitinase<sup>[37]</sup>. The same group further identified that overproduction of AMCase is highly dependent on a Th2 cytokine IL-13, which further induces production of IP-10 [interferon (IFN)-inducible protein-10] and ITAC (IFN-inducible T cell alpha chemoattractant)<sup>[14]</sup>. The production of AMCase was significantly upregulated in the epithelial cells and tissue macrophages of patients with asthma, but the expression at messenger RNA level was undetectable from patients without lung disease<sup>[14,37]</sup>. Interestingly, anti-AMCase specific antibody as well as pan-chitinase inhibitor allosamidin efficiently ameliorate airway hyperresponsiveness and inflammatory cell infiltrations in the lung of aeroallergen-challenged mice<sup>[14]</sup>, suggesting that AMCase would be an attractive therapeutic target in allergic asthma. A common genetic variant within exon 4 of AMCase from A to G at position 47 (termed A47G) and another variant K17R showed significant association with pediatric asthma. These genetic results support strongly that AMCase is associated with the development of asthma. Recently, Elias's group found that not only AMCase but also CHI3L1 levels in serum as well as lung tissue were significantly elevated in 3 cohorts of patient (at Yale University, University of Paris, and University of Wisconsin) with asthma<sup>[15]</sup>. Expression levels of CHI3L1 in the serum and lungs closely correlated with the severity of asthma, suggesting that the CHI3L1 molecule plays both a primary and a secondary role in asthma patients<sup>[15]</sup>. In addition, another group also identified that a promoter single nucleotide polymorphism (C131G) in CHI3L1 was strongly associated with elevated serum levels of CHI3L1, pulmonary function, asthma, and bronchial hyperresponsiveness<sup>[38]</sup>. From those results, it appears mammalian chitinases are somehow associated with the development of inflammatory conditions in mucosal tissues. The association between the mammalian chitinases and inflammatory disorders is summarized in Table 1.

Table 1 Mammalian chitinases in inflammatory disorders

Location	Disorders	Chitinase type	Ref.
Airway	Bacteremia with <i>S. pneumoniae</i>	CHI3L1	[91,92]
	Bronchial asthma	CHI3L1,	[14,38]
		AMCase, Ym1	
	COPD	CHI3L1	[93]
	Cystic fibrosis	AMCase, CHIT1	[94]
	Rhinosinusitis	AMCase	[95]
Blood	Sarcoidosis	CHIT1	[96,97]
	Bacterial septicemia	CHI3L1	[98]
Brain	Encephalitis	CHI3L1	[99,100]
	Meningitis	CHI3L1	[99]
Disc/Joint	Intervertebral disc degeneration	CHI3L1	[101]
	Juvenile idiopathic arthritis	CHIT1	[102]
	Osteoarthritis, RA	CHI3L1	[103,104]
Eye	Conjunctivitis	AMCase	[105,106]
		CHI3L1, CHIT1	[107,108]
GI tract	Helicobacter gastritis	CHI3L1	[10,109]
	Inflammatory bowel disease	CHI3L1	[10,109]
Heart	Acute myocardial infarction	CHI3L3, CHI3L1	[110,111,112]
	Coronary artery disease	CHIT1	[113]
Liver	Chronic hepatitis C, LC	CHI3L1	[114, 115]
	Fatty liver disease	CHIT1	[116,117]
	Hepatic fibrosis	CHI3L1	[118]
Oral cavity	Periodontitis	Chitinase	[119,120]
Systemic	Gaucher disease	CHIT1	[27]
	Systemic sclerosis	CHI3L1	[121,122]

COPD: Chronic obstructive pulmonary disease; LC: Liver cirrhosis; RA: Rheumatoid arthritis; CHI3L1: Chitinase 3-like-1; AMCase: Acidic mammalian chitinase; CHIT1: Chitotriosidase; Ym1: Chitinase-like lectin.

## ROLE OF CHI3L1 IN THE PATHOGENESIS OF CHRONIC INFLAMMATION

Although CHI3L1 was first identified in 1993<sup>[3]</sup>, its biological function has been largely undetermined. CHI3L1 possesses a functional carbohydrate-binding motif which allows binding with a polymer or oligomer of GlcNAc, but CHI3L1 lacks enzymatic activity entirely. The lack of enzymatic activity in CHI3L1 can be explained by the substitution of leucine for an essential glutamic acid residue within the active site of CHI3L1<sup>[59]</sup>. Therefore, chitinases without enzymatic activity (including CHI3L1) act as chi-lectin<sup>[40]</sup> because of the presence of a preserved carbohydrate-binding motif. Recently, Recklies *et al*<sup>[39]</sup> reported that CHI3L1 promotes the growth of human synovial cells and fibroblasts, raising the possibility that this protein plays a role in the pathological conditions leading to arthritis and tissue fibrosis. Of note, increased circulating levels of CHI3L1 have been reported in the serum of patients with several inflammatory conditions including IBD [Crohn's disease (CD) and ulcerative colitis (UC)]<sup>[41]</sup>, asthma<sup>[15,38]</sup> and liver cirrhosis<sup>[42]</sup>. Serum CHI3L1 is rarely detectable in healthy individuals<sup>[41]</sup>, and therefore CHI3L1 has recently been proposed as a useful marker for indicating inflammatory activity and poor clinical prognosis for IBD<sup>[41]</sup>. A soluble form of CHI3L1 seems to be secreted by a wide variety of mammalian cells *in vitro*, including activated neutrophils, granulocytes, differentiated macrophages and colonic epithelial cells (CECs)<sup>[10,19,43]</sup>. CHI3L1 is strongly expressed by macrophages in the synovial membrane of patients with rheumatoid arthritis (RA) and a polarized IFN $\gamma$ -

mediated proinflammatory Th1-type immune response has been observed in half the patients with RA. In contrast, peripheral mononuclear cells from healthy individuals strongly react against the CHI3L1 antigen and eventually produce a regulatory cytokine IL-10<sup>[44]</sup>. These results strongly suggest that CHI3L1-mediated immune responses in RA patients are somehow shifted from an IL-10 dominated immunoregulatory response to an IFN $\gamma$ -dominated proinflammatory phenotype<sup>[44]</sup>. In addition, serum levels of CHI3L1 are positively correlated with the severity of arthritis<sup>[45]</sup>. Interestingly, peripheral blood T cells from RA patients proliferate in response to RA-associated DR4 (DRB1\*0401) peptide which contains a potential self-reactive motif preserved within human CHI3L1<sup>[46]</sup>. In fact, the specific motif within CHI3L1 is responsible for the development and relapse of joint inflammation seen in Balb/c mice, suggesting that CHI3L1 is able to serve as an auto-antigen for arthritis in mice as well as humans<sup>[46]</sup>. Intranasal as well as oral auto-antigen administration is one of the most effective strategies for inducing immuno-tolerance<sup>[47,48]</sup>. Indeed, several groups have tried to administer CHI3L1 intranasally in animal models of arthritis<sup>[49,50]</sup> as well as RA patients with moderate disease activity<sup>[51]</sup>, and the protein administration effectively suppresses the disease activity by downregulating the Th1-type immune response without showing any adverse effects. Therefore, CHI3L1 seems to be the cross-tolerance inducing protein in chronic arthritis which effectively downregulates the pathogenic immune responses. It is possible that nasal administration of CHI3L1 represents an attractive approach for suppressing the clinical manifestation of chronic types of inflammation as well as autoimmune diseases.

Our group recently identified that CHI3L1 plays a unique role during the development of intestinal inflammation: the molecule is induced in both colonic lamina propria macrophages and CECs during the course of intestinal inflammation in experimental colitis models as well as in patients with IBD<sup>[10]</sup>. Gentamicin protection assays using intracellular bacteria, including *Salmonella typhimurium* and adherent invasive *Escherichia coli* show that CHI3L1 is required for the enhancement of adhesion and invasion of these bacteria on/into CECs and acts as a pathogenic mediator in acute colitis. It has been suggested that a genetic defect against intracellular bacterial infection is strongly associated with the development of CD, and an increased prevalence of intracellular bacteria in the ileal biopsies and surgical specimens of CD patients has been reported previously<sup>[52,53]</sup>. We also identified that the CHI3L1 molecule particularly enhances the adhesion of chitin-binding protein-expressing bacteria to CECs through the conserved amino-acid residues<sup>[11]</sup>. Therefore, overexpression of CHI3L1 may be strongly associated with the intracellular bacterial adhesion and invasion on/into CECs in CD patients, who presumably have mutations in the susceptibility genes of CD including NOD2 (CARD 15), IL-23R, ATG16L1 and XBP-1<sup>[54]</sup>. In contrast, in an aseptic condition such as bronchial asthma, epithelium-expressing CHI3L1 seems to play a regulatory role by rescuing Th2-type immune responses<sup>[16]</sup>. Further

study will be required to fully prove the exact role of epithelium-expressing CHI3L1 in inflammatory conditions.

## EXPRESSION OF CHI3L1 IN VARIOUS SOLID TUMORS

The biological function of CHI3L1 is still unclear, but it has been strongly hypothesized that CHI3L1 plays a pivotal role as a growth stimulating factor for solid tumors or has a suppressive/protective effect in the apoptotic processes of cancer cells<sup>[18]</sup> and inflammatory cells<sup>[16]</sup>. Based on an amino acid database search at the National Center for Biotechnology Information, CHI3L1 is expressed in a wide variety of human solid tumors as summarized in Table 2. In addition, elevated levels of CHI3L1 in serum and/or plasma have been detected in patients with different types of solid tumors (Table 2). Therefore, it is reasonable to predict that the serum level of CHI3L1 can be a reliable marker of progression of certain kinds of tumors and of a “bad prognosis” in patients with certain types of malignant tumors<sup>[18]</sup>.

Many clinical laboratories have reported that CHI3L1 could be used as a novel tumor marker for ovarian cancer<sup>[55,56]</sup>, small cell lung cancer<sup>[22]</sup>, metastatic breast cancer<sup>[57]</sup>, and metastatic prostate cancer<sup>[23]</sup>. In addition, several groups have reported that CHI3L1 is one of the most significant prognosis markers for cervical adenocarcinoma<sup>[58]</sup>, recurrent breast cancer<sup>[4]</sup> and metastatic breast cancer<sup>[21]</sup>, as well as advanced stages of breast cancer<sup>[59]</sup>. Interestingly, the CHI3L1 serum level could be a useful and sensitive biomarker for recurrence in locally advanced breast carcinoma<sup>[59]</sup>, ovarian carcinoma<sup>[60]</sup>, endometrial cancer<sup>[61]</sup>, squamous cell carcinoma of the head and neck<sup>[62]</sup>, metastatic prostate cancer or melanoma<sup>[63,64]</sup>, Hodgkin's lymphoma<sup>[65]</sup> and colon cancer<sup>[20]</sup>. Based on extensive research by Johansen and colleagues, CHI3L1 may be used as a novel and sensitive predictor of any cancer<sup>[66,67]</sup>. They categorized patients into 5 distinct levels according to the amount of plasma CHI3L1 detected by ELISA, and found that participants with the highest level of plasma CHI3L1 had a median survival rate of only 1 year after the cancer diagnosis<sup>[66]</sup>. In contrast, the patients with the lowest level of plasma CHI3L1 had a survival rate of more than 4 years. Although the variation of CHI3L1 serum levels in healthy subjects in this study was relatively small, subsequent measurements would be required to determine cancer risk since the serum level of CHI3L1 could also be elevated in patients with other inflammatory diseases or autoimmune disorders<sup>[68]</sup>. From the results, it has been highly predicted that serum CHI3L1 levels seem to be a potential and promising biomarker for malignant tumors.

The expression of CHI3L1 is relatively restricted to a limited number of cell types: it is totally absent in monocytes<sup>[69]</sup> and marginally expressed in monocyte-derived dendritic cells<sup>[70]</sup>, but is strongly induced during the late stages of human macrophage differentiation<sup>[43]</sup>. Rehli *et al*<sup>[43]</sup> clearly demonstrated that promoter

Table 2 Expression of CHI3L1 in solid tumors

Solid tumors	Location	Ref.
Glioma, Oligodendroglioma, glioblastoma	Brain	[74,123-132]
Squamous cell carcinoma of the head and neck	Head and neck	[18,22,62]
Lung cancer (small cell carcinoma)	Lung	[133,134]
Breast cancer	Breast	[4,8,21,55,57,62,67,68,75,132-141]
Colorectal cancer	Colon	[20,132]
Kidney tumor	Kidney	[132,142,143]

elements (in particular, the proximal -377 base pairs of the CHI3L1 promoter region) control the expression of CHI3L1 in the macrophage used. CHI3L1 is also expressed in neutrophils<sup>[71]</sup>, chondrocytes<sup>[3]</sup>, fibroblast-like synoviocytes<sup>[72]</sup>, vascular smooth muscle cells<sup>[5]</sup>, vascular endothelial cells<sup>[73]</sup>, ductal epithelial cells<sup>[67]</sup>, hepatic stellate cells<sup>[18]</sup>, and colonic epithelial cells<sup>[10]</sup>. In physiological concentrations CHI3L1 tends to promote proliferation of these cell types. CHI3L1 is a transmembrane protein whose extracellular domain can undergo cleavage<sup>[39]</sup>. The cleaved components bind to putative receptor(s) on the cell surface or soluble receptor(s), but these receptors have not been identified yet<sup>[18,40]</sup>. Some reports suggest that CHI3L1 can play an important role in tumor invasion. Nigro *et al*<sup>[74]</sup> showed that immortalized human astrocytes stably transfected with CHI3L1 increased invasion across a chemotactic gradient *in vitro*. Roslind *et al*<sup>[75]</sup> demonstrated that metastatic tumor cells in blood vessels, lymph nodes and skin displayed the same pattern of CHI3L1 as primary breast cancer cells by immunohistochemical analysis: normal epithelial cells display the widespread strong dot-like staining in the whole cytoplasm, while the dot-like staining is localized in the restricted area of cytoplasm in malignant tumor cells. Indeed, CHI3L1 is strongly expressed in the invasive front of lobular carcinoma which is adjacent to normal epithelial cells. These studies suggest that CHI3L1 may assist the migration of malignant cells and support metastasis of cancer cells by promoting the malignant transformation of adjacent normal epithelial cells.

## A POSSIBLE BIOLOGICAL ROLE OF CHI3L1 IN ONCOGENIC PROGRAMMING PROCESS

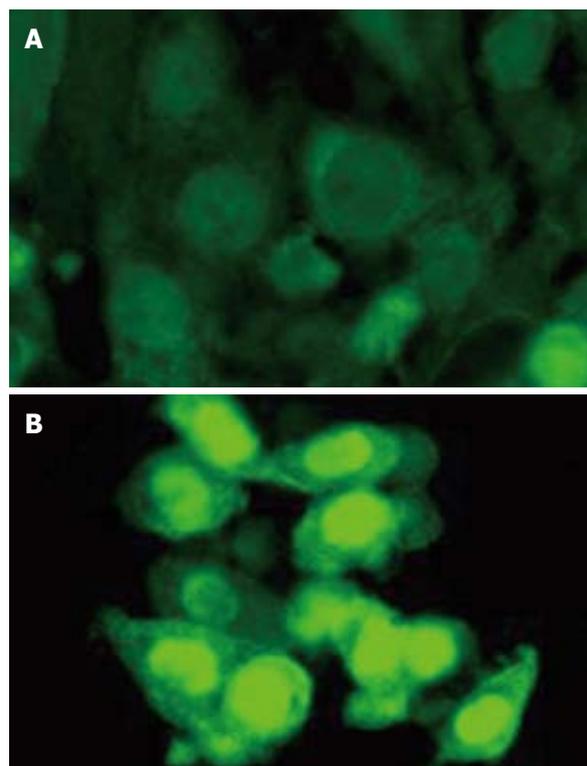

It has been predicted that CHI3L1 can have a growth

**Table 3** Inflammation-associated carcinogenic change

Inflammatory disorder	Carcinogenic formation	Ref.
Human papillomavirus infection	Cervical carcinoma	[149-152]
Crohn's disease, ulcerative colitis	Colorectal carcinoma	[153-159]

stimulating effect since a family of CHI3L molecules in the fruit fly *Drosophila melanogaster* regulates the growth of imaginal disc cells<sup>[76]</sup>. Two of the major biological functions of CHI3L1 are a growth stimulating effect on connective tissue cells<sup>[39,72]</sup> and a potent migration enhancing effect for endothelial cells<sup>[73]</sup>. CHI3L1 also stimulates angiogenesis and reorganization of vascular endothelial cells<sup>[73]</sup>. Insulin-like growth factor-1 is a well-characterized growth factor in connective tissue cells, and works synergistically with CHI3L1 to enhance the response of human synovial cells isolated from patients with osteoarthritis<sup>[39]</sup>. In addition, CHI3L1 strongly promotes the activation of 2 major signaling pathways associated with mitogenesis and cell survival: MAPK (mitogen-activated protein kinase) pathways and PI-3K (phosphoinositide 3-kinase)-mediated pathways in fibroblast cells. The putative cell surface receptor and/or adaptive molecule for CHI3L1 are still unidentified, but the purified human CHI3L1 molecule efficiently leads to phosphorylation of MAPK p42/p44 in human synovial cells, fibroblasts, articular chondrocytes<sup>[39]</sup> and human colonic epithelial cells (Mizoguchi E, unpublished observation) in a dose-dependent manner. It has been suggested that guanine nucleotide-binding protein (G-protein)-regulated MAPK networks are involved in the action of most non-nuclear oncogenes and subsequent carcinogenesis and tumor progression<sup>[77]</sup>. The networks are involved in the activation of MAPK p42/p44 which may enhance the carcinogenic change of epithelial cells during upregulated CHI3L1 expression under inflammatory conditions.

It is believed that IBD is a risk factor of cancer development based on the severity of the disease course. As previously reported, serum CHI3L1 concentration is elevated in patients with IBD<sup>[41]</sup> and primary colorectal cancer<sup>[20]</sup>. People with CD have a 5.6-fold increased risk of developing colon cancer<sup>[78]</sup>; therefore screening for colon cancer by colonoscopy is strongly recommended for patients who have had CD for several years<sup>[79]</sup>. Inflammation was recently recognized as an important

**Figure 1** Activation of  $\beta$ -catenin in colonic epithelial cells by purified Chitinase 3-like-1 (CHI3L1). SW480 human colon cancer cells were cultured without (A) or with purified human CHI3L1 protein (50 ng/mL) for 24 h (B), and cells were stained with mouse anti-human  $\beta$ -catenin monoclonal antibody followed by FITC-horse anti-mouse IgG staining. Purified CHI3L1 significantly stimulates the nuclear translocation of  $\beta$ -catenin in SW480 cells. Original magnification, objective 40  $\times$ .

factor in the pathogenesis of malignant tumors<sup>[80]</sup> and we summarize some examples of inflammation-mediated carcinogenesis in Table 3. Of interest, most of the diseases listed in Table 3 express CHI3L1 during the course of inflammation and the subsequent tumorigenesis. CHI3L1 protects cancer cells from undergoing apoptosis and also has an effect on extracellular tissue remodeling by binding specifically with collagen types I, II, and III<sup>[81]</sup>. Therefore, CHI3L1 is strongly associated with cell survival and cell migration during the drastic tissue remodeling processes by interacting with extracellular matrix components<sup>[39,40]</sup>.

The canonical (Wnt/ $\beta$ -catenin) pathway is known to play a crucial role in UC-related tumor progression<sup>[82]</sup>. Recently, our group identified that the SW480 human colon cancer cell line shows significantly upregulated expression and trans-nuclear translocation of  $\beta$ -catenin after extensive stimulation with low dose (50 ng/mL) purified CHI3L1 protein (Qidel, San Diego, CA) (Figure 1). This result strongly suggests that CHI3L1 may have a direct but not a secondary role for inflammation-associated tumorigenesis by continuously activating the Wnt/ $\beta$ -catenin canonical signaling pathway in CECs. As previously demonstrated, CHI3L1 expression is enhanced by proinflammatory cytokine interleukin-6<sup>[10,83]</sup>, which also has a critical tumor-promoting effect during early colitis-associated cancer tumorigenesis<sup>[84]</sup>. It has been proven that

activation of gp130/STAT3 transcription factor regulates cell cycle progression as well as survival of enterocytes during chronic colitis-associated tumor promotion<sup>[85-88]</sup>. Therefore, the blocking of interleukin-6 mediated CHI3L1 expression by anti-CHI3L1 specific antibody or pan-family 18 chitinase inhibitors including allosamidin and methylxanthine derivatives (e.g. theophylline, caffeine, and pentoxifylline)<sup>[14,89,90]</sup> would be a useful strategy in preventing both chronic mucosal inflammation and the subsequent inflammation-associated carcinogenic change in epithelial cells. In summary, CHI3L1 could be a useful and attractive target for potential anti-cancer therapies, in particular against highly invasive and metastatic solid tumors.

## CONCLUSION

Mammalian chitinases, including CHI3L1 and AMCCase, actively participate in the pathogenesis of acute and chronic inflammation and presumably the following inflammation-associated tumorigenesis. Further understanding of the biological and physiological functions of mammalian chitinases would be very important to develop novel anti-inflammatory as well as anti-cancer therapies for several inflammatory disorders and inflammation-associated cancers in the near future.

## ACKNOWLEDGMENTS

The authors are grateful to Dr. Atsushi Mizoguchi, Dr. Hirotohi Kikuchi, Dr. Mayumi Kawada and Dr. Chun-Chuan Chen for their helpful discussions. We would like to thank Mr. Terry D Lott and Mr. Jiang Zhang for their excellent assistance in preparing this manuscript. Segawa M is a recipient of a Student Research Fellowship Award from the Crohn's and Colitis Foundation of America Inc.

### Abstract

The incidence of acute pancreatitis, an inflammation of the pancreas, is increasing worldwide. Pancreatic injury is mild in 80%-90% of patients who recover without complications. The remaining patients may develop a severe disease with local complications such as acinar cell necrosis, abscess and remote organ injury including lung injury. The early prediction of the severity of the disease is an important goal for physicians in management of patients with acute pancreatitis in order to optimize the therapy and to prevent organ dysfunction and local complications. For that purpose, multiple clinical scale scores have been applied to patients with acute pancreatitis. Recently, a new problem has emerged: the increased severity of the disease in obese patients. However, the mechanisms by which obesity increases the severity of acute pancreatitis are unclear. Several hypotheses have been suggested: (1) obese patients have an increased inflammation within the pancreas; (2) obese patients have an increased accumulation of fat within and around the pancreas where necrosis is often located; (3) increase in both peri- and intra-pancreatic fat and inflammatory cells explain the high incidence of pancreatic inflammation and necrosis in obese patients; (4) hepatic dysfunction associated with obesity might enhance the systemic inflammatory response by altering the detoxification of inflammatory mediators; and (5) ventilation/perfusion

mismatch leading to hypoxia associated with a low pancreatic flow might reduce the pancreatic oxygenation and further enhance pancreatic injury. Recent experimental investigations also show an increased mortality and morbidity in obese rodents with acute pancreatitis and the implication of the adipokines leptin and adiponectin. Such models are important to investigate whether the inflammatory response of the disease is enhanced by obesity. It is exciting to speculate that manipulation of the adipokine milieu has the potential to influence the severity of acute pancreatitis.

### INTRODUCTION

The incidence of acute pancreatitis is increasing worldwide<sup>[1]</sup>. Most episodes of acute pancreatitis are mild and self-limiting, requiring only a short hospitalization<sup>[2]</sup>. However, 10% of the patients (with a significant proportion of obese patients) develop a severe disease with local and extra-pancreatic complications characterized by early development and persistence of hypovolemia and multiple organ dysfunction<sup>[3,4]</sup>. Following the initial pancreatic edema, necrosis is the most severe local complication. The patchy areas of nonviable parenchyma are initially sterile but may be infected by bacteria originated mostly from the gut whose permeability increases during the disease. The most important extra-pancreatic complication is lung injury with a high incidence in severe

pancreatitis, ranging from 15% to 55 %<sup>[5]</sup>. The severity of pulmonary complications varies greatly from mild hypoxemia without clinical or radiological abnormalities to severe acute respiratory distress syndrome. Two peaks of pulmonary complications were observed during the early phase of severe acute pancreatitis, the first peak being described upon admission with new radiological abnormalities by day 5<sup>[6]</sup>. Hepatic injury is mild in acute pancreatitis but may participate in the propagation of inflammation from pancreas to other organs, mostly lungs<sup>[7,8]</sup>.

### **INCREASED SEVERITY OF ACUTE PANCREATITIS IN OBESE PATIENTS**

Several clinical investigations showed that obesity increases the severity of the disease by favoring local complications within the pancreas and injuries in remote organs as well as by increasing the mortality rate<sup>[9-13]</sup>. Obesity increases the incidence of early shock, renal and pulmonary failure<sup>[14]</sup> and extends the hospital stay<sup>[15]</sup>. However, other studies have questioned such findings<sup>[11,16,17]</sup>.

The mechanisms by which obesity increases the severity of acute pancreatitis is unclear, but one hypothesis might be that obese patients have an increased inflammatory response within the pancreas<sup>[11,18]</sup>. In the study by Sempere *et al*<sup>[12]</sup>, among 85 consecutive patients with acute pancreatitis, 74% had a mild disease while the remaining patients were severely ill. Serum concentrations of interleukin-1 $\alpha$  (IL-1 $\alpha$ ), IL-1 receptor antagonist (IL-1-ra), IL-6, IL-8, IL-10 and IL-12p70 were significantly increased in patients with acute pancreatitis as compared with volunteers, and the concentrations were significantly higher in obese patients. One explanation is that obesity per se induces a chronic inflammatory state<sup>[11,19]</sup>. A second hypothesis is that obese patients have an increased accumulation of fat within and around the pancreas where necrosis is often located. The risk of pancreatic infection and inflammation would be proportional to the increased amount of peri-pancreatic fat. Accordingly, patients with intra-pancreatic fat are more prone to develop local complications following pancreatic surgery<sup>[11,20]</sup>. Interestingly, cytokine expression in fat tissue is higher in obese than in lean subjects<sup>[21]</sup>. In obese patients, the cytokine expression is also higher in visceral than in subcutaneous fat, cytokines being produced mainly by macrophages located in the stromal-vascular fraction of fat tissues<sup>[21]</sup>. Thus, increase in both peri- and intra-pancreatic fat and presence of inflammatory cells in adipose tissues might explain the high incidence of pancreatic inflammation and necrosis in obese patients. Weight loss improves the inflammatory profile of fat tissue with an increased expression of anti-inflammatory factors such as IL-10 and IL-1-ra<sup>[21]</sup>. Similarly, in inflammatory bowel diseases, visceral fat is also a source of inflammatory signals<sup>[22,23]</sup>. A third hypothesis is that pancreatic microcirculation is lower in obese than in non-obese patients, which increases the risk of

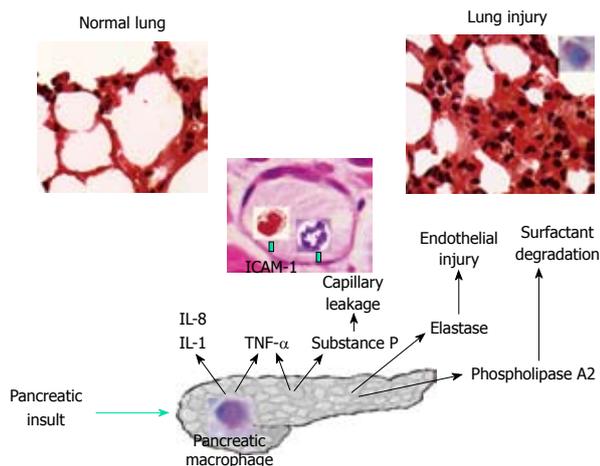

ischemic injury and subsequent local infections. Moreover, obese patients might be immunodeficient, a condition that increases the risk of local infections<sup>[24]</sup>. Finally, because obesity restricts the movement of the chest wall and diaphragm, inspiratory capacity of obese patients is reduced. Ventilation/perfusion mismatch may lead to hypoxemia that, in conjunction with low blood flow, further decreases tissue oxygenation to the pancreas.

### **BRIEF OVERVIEW OF THE PATHOPHYSIOLOGY OF ACUTE PANCREATITIS**

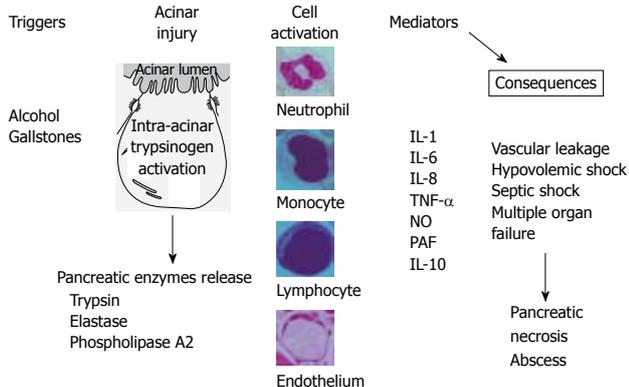

Although controversial, most observers believe that acute pancreatitis is caused by the dysregulated activation of trypsin within pancreatic acinar cells. Enzyme activation within the pancreas leads to autodigestion of the gland followed by local inflammation. The main factors that trigger the acute disease are pancreatic hyperstimulation (mainly observed in experimental models), gallstones and alcohol abuse in humans. Acute pancreatitis occurs when intracellular protective mechanisms designed to prevent trypsinogen activation or reduce trypsin activity are decreased or overwhelmed. Following the activation of trypsinogen into active trypsin within acinar cells, numerous enzymes such as elastase and phospholipase A2, as well as complement and kinin systems, are activated<sup>[25]</sup> (Figures 1 and 2). Additionally, inflammation is initiated with local production of mediators such as tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), IL-1 and IL-8 from neutrophils, macrophages and lymphocytes<sup>[26,27]</sup>. In addition to these events, activation of endothelial cells permits the transendothelial migration of leukocytes that release other harmful mediators<sup>[28]</sup>. Thus, regardless of the initial trigger of the disease, the severity of pancreatic damage is related to the injury of acinar cells and to the activation of inflammatory and endothelial cells. Local complications such as acinar cell necrosis may develop and injury in remote organs (lungs) results from the release of numerous mediators from the pancreas or extrapancreatic organs (Figure 1).

### **EXPERIMENTAL PANCREATITIS, OBESITY, ADIPONECTINS AND INFLAMMATION**

Fat tissues are likely to contribute to the increased inflammation in obese rodents. Thus, adipokines secreted by adipocytes are potent regulators of the inflammatory response, leptin being considered as a pro-inflammatory adipokine, while adiponectin functions as an anti-inflammatory mediator (Table 1). Adipose tissues also produce cytokines that participate in the inflammatory response of obesity and organ dysfunction. Thus, pancreatic necrosis following intrapancreatic duct injection of taurocholic acid (TA) was similar in obese *fa/fa* rats and lean

**Figure 1** Overview of the major events occurring in experimental acute pancreatitis and pancreatitis-associated lung injury. Inflammatory cells adhere to the endothelial walls via the expression of the intercellular molecules (ICAM-1) and translate the local inflammation to remote organs.

**Figure 2** Mediators involved in the pathogenesis of acute pancreatitis. After the acinar cell injury occurs, inflammatory cells will synthesize and release proinflammatory cytokines and chemokines that induce systemic effects (vascular leakage, etc.). All these consequences will finally dictate the occurrence of pancreatic necrosis and abscess.

*fa/+* rats, but the survival was lower in obese rats<sup>[29]</sup>. The pancreatic expression of TNF- $\alpha$  and IL-6 was higher in obese than in lean rats while IL-10 expression was lower<sup>[30]</sup>. TNF- $\alpha$  expression was also higher in liver and lungs from obese rats. Moreover, obese rats with acute pancreatitis had steatohepatitis while livers in lean rats with acute pancreatitis were normal. Thus, dysregulation between inflammatory and anti-inflammatory mediators in obese rats is an important issue to explain the increased severity of the disease. These investigators also determined whether high-fat feeding vs. normal diet may influence the severity of a “two-hit” injury (TA-induced pancreatitis followed by intraperitoneal injection of endotoxin 3 h later)<sup>[31]</sup>. Endotoxin administration lowers the survival rate of lean rats by increasing peripancreatic fat necrosis and systemic inflammatory response while chronic high fat diet does not aggravate pancreatic injury induced by TA plus endotoxin<sup>[31]</sup>.

Obese *fa/fa* rats have a mutation with dysfunction of the leptin receptor and develops obesity by week 5<sup>[32]</sup>. Littermates *fa/+* rats are used as controls. By week 14,

**Table 1** Severity of acute pancreatitis and adipokines

Adipocytokine	Effects	Final effect
Leptin	↑ TNF- $\alpha$ ↑ Chemotaxis ↑ Neutrophil activation ↑ IL-6 ↑ T-cell proliferation	Pro-inflammatory
Adiponectin	↓ Endothelial cell adhesion ↓ TNF- $\alpha$ ↓ IL-6 ↓ Phagocytosis ↑ IL-10 ↑ IL-1RA	Anti-inflammatory

Adiponectin may be considered as an anti-inflammatory compound whereas leptin acts as a proinflammatory mediator. Both adipokines may influence the severity of pancreatitis.

body weight doubles in *fa/fa* rats. Restricted feeding does not modify the occurrence of obesity. The obesity is associated with an increase in the number and size of adipocytes. These rats have hyperlipidemia and hypercholesterolemia. The pancreas weight is similar in *fa/fa* and *fa/+* rats but, according to the increased body weight of *fa/fa* rats, the ratio between pancreas and body weight is lower in *fa/fa* rats<sup>[33]</sup>. Of note, amylase content is lower in *fa/fa* than *fa/+* rats and treatment with ciglitazone that increases the insulin sensitivity partially prevents this low pancreatic amylase content<sup>[34]</sup>. Administration of cholecystokinin (CCK) is known to decrease food intake but the obese rats have a higher threshold than lean rats for this effect<sup>[35]</sup>. Moreover, the exocrine response to cerulein and carbamylcholine is decreased in acini isolated from *fa/fa* rats while the response to secretin or vasoactive intestinal peptide is identical<sup>[36,37]</sup>. When CCK is incubated in isolated acini, less amylase is secreted in *fa/fa* rats than in lean rats<sup>[37]</sup>. In *fa/fa* and *fa/+* rats, the expression of CCK<sub>A</sub> and CCK<sub>B</sub> receptors is unknown. To overcome the absence of effects on the receptor, circulating leptin expression is increased. Leptin mRNA is detected in adipose tissue but not in pancreas, lungs, or liver<sup>[38]</sup>. The expression of leptin decreases gradually from epididymal to retroperitoneal, subcutaneous, and interscapular brown adipose tissue. In isolated adipocytes, leptin mRNA expression is also significantly higher in *fa/fa* than in control rats. Finally, TNF- $\alpha$  protein expression in adipose (perirenal and epididymal) tissues is similar in both strains<sup>[33]</sup>.

The severity of acute pancreatitis has been investigated in other experimental models of obesity, such as *ob/ob* and *db/db* mice. Both mice are congenitally obese but manifest this phenotype via different mechanisms. *Ob/ob* mice have a spontaneous mutation of the *ob* (leptin) gene and produce no leptin while *db/db* mice have a spontaneous mutation of the leptin receptor and have increased circulating concentrations of leptin. *Ob/ob* mice may reach three times the normal weight of wild-type mice. Obesity is characterized by an increase in the number and size of adipocytes. Although hyperphagia contributes to obesity, excess of weight is also

observed with a restrictive diet sufficient for lean mice. Interestingly, *ob/ob* mice have impaired pulmonary bacterial clearance of *Streptococcus pneumoniae* and increased pulmonary concentrations of cytokines<sup>[39]</sup>. *Ob/ob* mice are less hyperglycemic than *db/db* mice. Moreover, in pancreas from *ob/ob* mice, content of triglycerides, free fatty acids, cholesterol and total fat is higher than in lean mice<sup>[40]</sup>. Serum concentrations of IL-1 and TNF- $\alpha$  are also increased.

In a model of acute pancreatitis induced by two injections of IL-12 plus IL-18, all *ob/ob* mice died within 48 h while all wild-type mice survived<sup>[41]</sup>. To differentiate the contribution of obesity or leptin deficiency to the severity of the disease, a group of *ob/ob* mice had leptin replacement therapy (obesity with normal leptin). Interestingly, this group had severe acute pancreatitis, suggesting that obesity *per se* and not leptin deficiency was responsible for the severe acute pancreatitis. Moreover, the authors generated "slim" *ob/ob* mice that had a less severe acute pancreatitis, reinforcing the finding that obesity rather than leptin deficiency was responsible for the severity of acute pancreatitis. In another study, three experimental groups received injections of cerulein: C57BL/6J (lean), *ob/ob* (obese mice with leptin deficiency), and *db/db* (obese mice with leptin receptor deficiency and increased circulating leptin) mice<sup>[42]</sup>. Both *ob/ob* and *db/db* mice developed a significantly more severe disease than wild-type lean mice associated with an increase in pancreatic inflammatory cytokines. Finally, in patients matched for body mass index, the circulating leptin did not correlate with the severity of the disease<sup>[43]</sup>. These studies confirmed the feeling that leptin production does not relate to the severity of acute pancreatitis.

However, the role of leptin in acute pancreatitis remains puzzling (Table 1). In pancreatitis induced by cerulein injections in lean rats, serum leptin concentrations increased by 12 h and remained high for 36 h<sup>[44]</sup>. When a more severe disease was induced (arginine model), leptin concentrations were high at 12 and 24 h but were similar at 48 h in both experimental models. Thus, in lean rodents, the serum concentrations of leptin increase in acute pancreatitis but no relationship is found between severity of the disease and circulating leptin concentrations. To further investigate the role of leptin in the severity of the disease, rats with acute pancreatitis were treated with leptin (10  $\mu\text{g}/\text{kg}$  ip) after the last cerulein injection<sup>[45]</sup>. Leptin treatment increased the survival rate over 48 h and this beneficial effect was associated with a reduced serum expression of TNF- $\alpha$ , IL-1, MIP, sICAM and lung nitric oxide. Pancreatic and pulmonary CD40 expression was significantly reduced by leptin as was pancreatic and pulmonary injuries at histological examinations<sup>[45]</sup>.

The anti-inflammatory adipokine adiponectin has also been investigated in experimental pancreatitis. Adiponectin is decreased in obesity and inversely mirrors the severity of experimental pancreatitis<sup>[46]</sup>. Adiponectin acts through the receptors AdipoR1 and AdipoR2. Both receptors are expressed in rodent pancreas but AdipoR1

expression is significantly decreased in the pancreas of *ob/ob* and *db/db* mice as compared with wild-type lean mice<sup>[46]</sup>. To investigate the role of adiponectin in the severity of acute pancreatitis, adiponectin knockout (APN-KO) and wild type mice were injected with a low dose of cerulein two weeks after normal or high-fat-diet<sup>[47]</sup>. Whereas APN-KO mice fed a high-fat-diet treated with cerulein developed pancreatic damage and inflammation, wild-type mice did not. Finally, adenovirus-mediated over-expression of adiponectin attenuates the severity of acute pancreatitis in APN-KO mice<sup>[47]</sup>. All these data clearly demonstrate that adiponectin plays a protective role in the cerulein model of acute pancreatitis.

## INTERACTION OF CHOLECYTOKININ, DIGESTIVE PROENZYMES AND LEPTIN

Confusion on the protective or deleterious role of leptin in acute experimental pancreatitis may also rise from the fact that a crosstalk between CCK and leptin pathways is observed in acinar cells. CCK is produced in endocrine cells present in the mucosa of the small intestine following the ingestion of proteins and fat. CCK stimulates the contraction of gallbladder and relaxes the sphincter of Oddi (facilitating bile secretion into the intestine) and stimulates pancreatic secretion by acinar cells either by a direct effect or through acetylcholine released by the vagus nerve that possesses receptors for CCK. CCK is also a proliferative hormone for the pancreas and by delaying gastric emptying induces satiety. Leptin, produced and secreted from white adipocytes, regulates food intake and energy consumption<sup>[48]</sup>. Intravenous administration of leptin diminishes the postprandial pancreatic secretions<sup>[49]</sup>. Administration of leptin does not affect the volume of bile and pancreatic juice while the protein and trypsin output is reduced<sup>[49]</sup>. The effect of leptin becomes stronger when protein and trypsin secretions are stimulated by CCK. In contrast, leptin does not affect basal and CCK-8-stimulated amylase release in pancreatic acini, suggesting that leptin does not act directly on pancreatic acinar cells but inhibits the secretion of pancreatic enzymes through CCK-vagal-dependent mechanism<sup>[49]</sup>. In contrast to the intravenous administration, intraduodenal leptin administration to fasted rats increases pancreatic protein and amylase secretions, this effect being related to the stimulation of CCK release through activation of duodeno-pancreatic reflexes<sup>[50]</sup>.

Otsuka Long-Evans Tokushima Fatty (OLETF) rats are spontaneously diabetic rats with polyuria, polydipsia, hyperglycemia, mild obesity and diabetes<sup>[51]</sup>. These rats do not express the CCK-A receptor mRNA in pancreas. This lack of CCK-A receptors results in a reduced ability to produce nutrient-induced satiety signals which leads to increase in meal size, overall hyperphagia and obesity. Administration of increasing doses of CCK8 induced a biphasic dose-response curve of pancreatic juice and protein secretion in control Long-Evans Tokushima Otsuka (LETO) rats whereas the OLETF rats did not respond to CCK-8<sup>[52]</sup>. Cerulein injections induce acute

pancreatitis in LETO rats but did not increase serum amylase or lipase activities in OLETF rats.

Finally, the rat pancreatic acinar tumor (AR42J) cell lines do express the leptin receptor<sup>[53]</sup>. The binding of leptin is specific to the leptin receptor and does not cross-react with CCK pathway. Leptin does not modify basal amylase release but inhibits amylase release stimulated by CCK. Leptin alone has no effect on intracellular Ca<sup>2+</sup> mobilization but pre-treatment with leptin enhances the Ca<sup>2+</sup> response to CCK. Thus, AR42J cells express a functional leptin receptor that modulates the action of CCK on Ca<sup>2+</sup> mobilization and amylase release<sup>[53]</sup>. Relationship between enzyme release from acinar cells and signals of satiety such as leptin in lean and obese rodents are complex and further investigations are needed.

## CONCLUSION

The prevalence of obesity has increased worldwide. Despite numerous clinical investigations, the precise mechanisms involved in the pathogenesis of acute pancreatitis remain elusive, and currently no specific medical therapy is available beyond general support. Investigating the mechanisms, by which acute pancreatitis develops from novel angles such as obesity, offers potentially new observations that may ultimately lead to the development of useful treatment. It is exciting to speculate that manipulation of the adipokine milieu has the potential to influence the severity of acute pancreatitis. Thus, investigations along these lines are warranted.

pattern compared to white light. The mucosal surface was best assessed using filter 4. However, the views obtained were not rated significantly better than those observed with white light. The "gold standard", indigo carmine (IC) dye, was found to be superior to both white light and filter 4. Filter 6 (RGB wavelengths of 580, 520, and 460 nm, respectively) allowed for exploration of the IC-stained mucosa. When assessing mucosal polyps, both FICE with magnification, and magnification following dye spraying were superior to the same techniques without magnification and to white light imaging. In the presence of suboptimal bowel preparation, observation with the FICE mode was possible, and endoscopists considered it to be superior to observation with white light.

**CONCLUSION:** FICE-filter 4 with magnification improves the image quality of the colonic vascular patterns obtained with WLE.

### Abstract

**AIM:** To validate high definition endoscopes with Fujinon intelligent chromoendoscopy (FICE) in colonoscopy.

**METHODS:** The image quality of normal white light endoscopy (WLE), that of the 10 available FICE filters and that of a gold standard (0.2% indigo carmine dye) were compared.

**RESULTS:** FICE-filter 4 [red, green, and blue (RGB) wavelengths of 520, 500, and 405 nm, respectively] provided the best images for evaluating the vascular

### INTRODUCTION

Chromoendoscopy has been proven to be a valuable tool for the study of colorectal neoplasia. Indigo carmine (IC) can be used with conventional endoscopy<sup>[1]</sup> or with magnifying colonoscopy<sup>[2-5]</sup>.

Endoscopy manufacturers have developed artificial image enhancements, including "virtual chromoendoscopy", as a quicker and less messy alternative to dye spraying.

The Olympus narrow band imaging (NBI) system employs a narrow band light to increase the contrast. This has been shown to enhance the views, and it provides similar diagnostic accuracy to chromoendoscopy<sup>[4-6]</sup>. Computed virtual chromoendoscopy (Fujinon intelligent chromoendoscopy, FICE) was subsequently developed<sup>[7]</sup>; with this technique, the wavelength does not change. Instead, the endoscopy processor reconstructs the image and displays what the mucosa would look like if illuminated using a certain wavelength. FICE has 10 pre-programmed settings, some of which have been tested in the upper gastrointestinal tract<sup>[7]</sup> and in Barrett's mucosa<sup>[8]</sup>. In a third preliminary study, we used one of the FICE settings to compare detection of colonic polyps with white light endoscopy (WLE)<sup>[9]</sup>. However, this study did not compare the views obtained using different FICE settings and did not comment on the capabilities in the presence of suboptimal bowel cleansing or after the application of indigo carmine dye. Our study aimed to: (1) systematically compare the 10 pre-set FICE settings with normal white light and indigo carmine dye in terms of their ability to enhance views of normal mucosa and polyps, (2) assess FICE in the presence of suboptimal bowel preparation, (3) determine whether poor bowel preparation markedly degrades the capabilities of "virtual chromoendoscopy" systems<sup>[10]</sup>.

## MATERIALS AND METHODS

High definition magnification colonoscopes (EC-590ZW/M), and the Fujinon EPX-4400 medical video endoscope system were used in the study.

### *The quality of mucosal and vascular pattern views*

In study one, 560 areas of normal colonic mucosa in 10 patients were observed in real time by two experienced endoscopists (Parra-Blanco A and González N), who assessed the quality of mucosal and vascular pattern views. The views were obtained with white light, 0.5% indigo carmine dye, and the different FICE settings (Table 1) both with and without magnification ( $\times 100$ ). The quality of the mucosal views was scored according to the following scale: 0 (poor), 1 (fair), 2 (good), and 3 (excellent). Each endoscopist was blinded to the other endoscopist's assessments.

### *Diagnostic accuracy*

In study two, 114 pictures were taken of 19 mucosal polyps (14 tubular adenomas, 4 hyperplastic polyps, and 1 normal mucosa). The pictures were obtained with white light, 0.5% indigo carmine (IC) dye, and the highest rated FICE settings according to study one (FICE setting 4), both with and without magnification ( $\times 100$ ). Polyp size and shape were estimated by comparison with closed biopsy forceps (Radial Jaw 3, Boston Scientific Corporation). The mean size of the polyps was 2.8 mm (range 1-5 mm). Figure 1 illustrates the sequence of images corresponding to one of the cases.

A panel of 5 fully trained endoscopists was asked to classify each lesion into one of the following categories: benign (for types I and II crypt patterns), neoplastic (types III and IV crypts), and invasive (type V pattern)<sup>[11]</sup>. For the

**Table 1** Spectral specification of each FICE filter estimation set with assignments to the color channels

FICE: Fujinon intelligent chromoendoscopy.

assessment of the capillary pattern, Sano's classification was used<sup>[10]</sup>. The panel members were asked to grade the degree of certainty in the prediction according to the following scale: (1) very uncertain, (2) uncertain, (3) reasonably certain, (4) absolutely certain.

### *The feasibility of FICE colonoscopy in the presence of suboptimal bowel preparation*

In study three, the feasibility of FICE colonoscopy in the presence of suboptimal bowel preparation was evaluated. Images from 17 colonic areas with small or moderate amounts of liquid or solid stools were recorded, both with the conventional view and with FICE setting 4. The panel of endoscopists rated: (a) the image quality of FICE setting 4 as superior, equal, or inferior to that of WLE; (b) the ability of FICE-4 to trace the fecal contents as compared to WLE (superior, equal, or inferior).

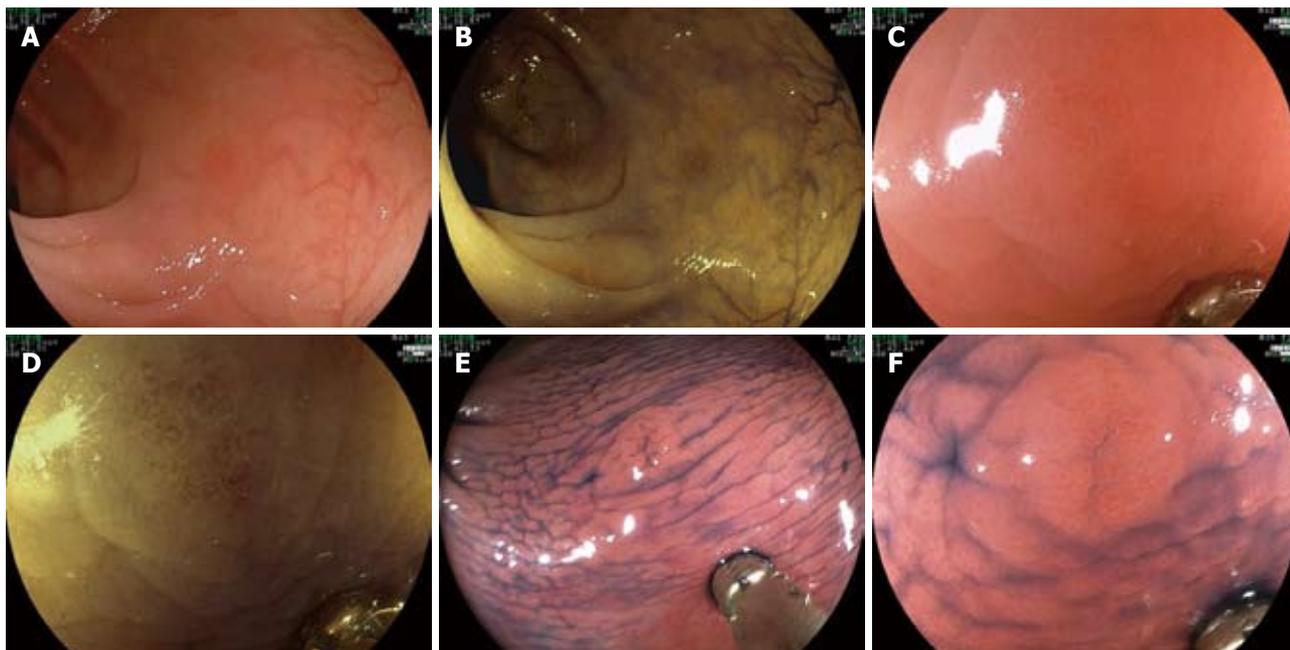

### *The ability of FICE to trace the polyp margin and recognize the irregularities of the polyp surface*

In study four, the ability to trace the polyp margin and recognize the irregularities of the polyp surface was compared between FICE setting 4, conventional endoscopy, and IC. Ninety images corresponding to 15 polyps were obtained and presented to the panel. The panel rated the ability of FICE to trace the margin and surface as superior, equal, or inferior to that of the other techniques.

### *The feasibility of FICE colonoscopy in IC-stained mucosa*

In study five, the feasibility of FICE colonoscopy in IC-stained mucosa was tested. In a preliminary phase, both endoscopists participating in study one had determined that colonoscopy with FICE setting 6 was the most adequate to observe the IC-stained mucosa, with a global image quality that was at least as good as with WLE. Then, 48 images corresponding to 12 polyps were taken, including views with IC and with IC plus FICE setting 6. The members of the panel were asked to rate the ability of FICE-6 plus IC to trace the margin and surface of the polyps as superior, equal, or inferior to the performance of IC.

The study was approved by the Research Ethics Committee of Hospital Universitario de Canarias, and a signed informed consent document was obtained from all participating patients.

**Figure 1** Presentation of a sequence of images for the different diagnostic modalities corresponding to a case included in study two (histopathological diagnosis: tubular adenoma with mild dysplasia). A: Circumscribed erythema with loss of vascular pattern, which can be difficult to detect; B: Observation with Fujinon intelligent chromoendoscopy (FICE) 4. Note that the innominate grooves can be seen in the normal surrounding mucosa; C: Observation under 0.5% indigo carmine (IC), which reveals a 0-II c depressed lesion 3 mm in size; D: High magnification view, showing vascular pattern type Sano II; E: Same magnification image observed under FICE 4, which provides enhanced vascular contrast; F: Under 0.5% IC plus magnification, the depression and the vascular patterns are evident.

### Statistical analysis

No sample sizes were calculated, as this was a pilot study, and no data were available when the study was performed regarding colonoscopy with FICE.

Categorical variables are expressed with frequencies and percentages. Proportions were compared using the  $\chi^2$  test or Fisher's exact test whenever required. Means were compared with the unpaired Student's *t* test, and means and standard deviations (SD) are reported.

For the same endoscopist, comparisons between techniques on quality of the images were carried out using the Wilcoxon test.

Calculated  $P < 0.05$  values were considered to indicate statistical significance.

## RESULTS

### Normal mucosa and vascular pattern

The assessment of FICE settings is shown in Figure 2. In evaluating the normal mucosa, only filter 4 was scored by both assessors as superior to conventional WLE (Table 2). The gold standard for mucosal observation, indigo carmine, was regarded as far superior to any FICE setting according to all assessors. In fact, the normal colonic innominate grooves could only be seen with the aid of dye spraying.

In evaluating the vascular pattern, FICE setting 4 (corresponding to RGB wavelengths 520, 500, and 405 nm, respectively) and FICE setting 2 were found to provide the best image quality. When mucosal and vascular pattern ratings were taken together, FICE setting 4 was considered the best by both assessors.

### Endoscopic diagnosis

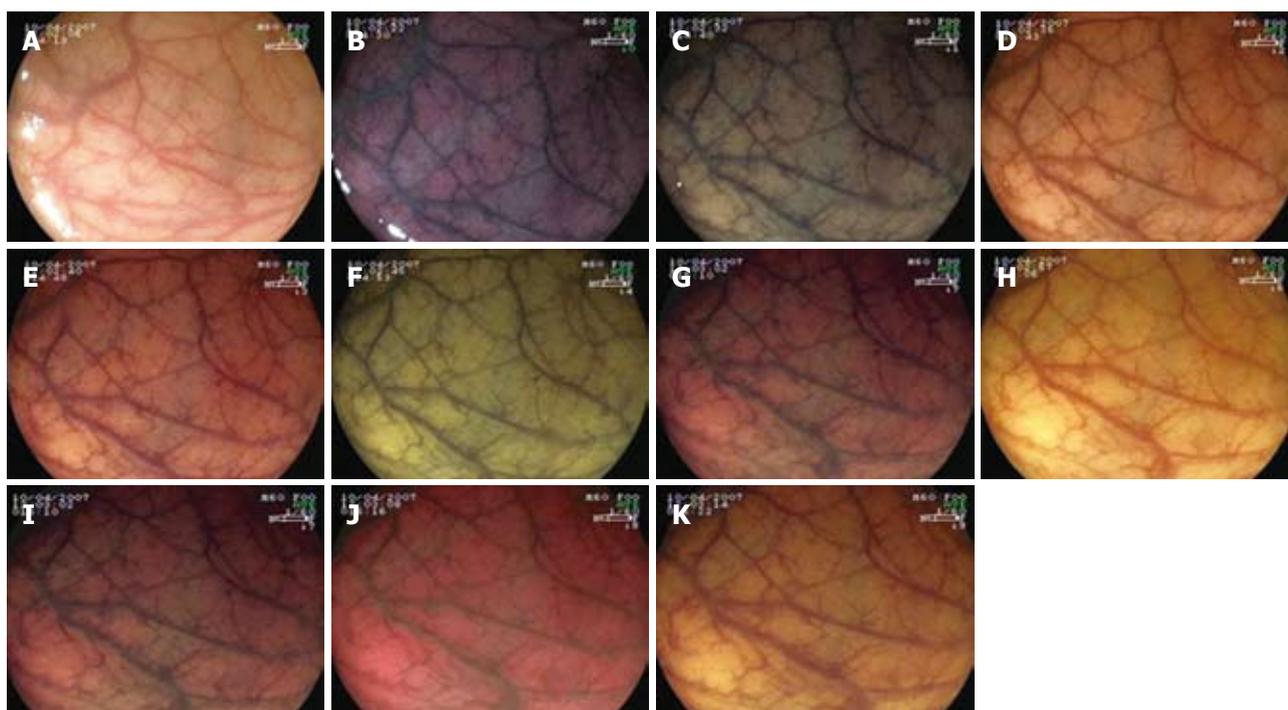

Study two (Figure 1): The histological predictions for the five participants are indicated in Table 3. In general, the diagnostic accuracy was related to the level of experience of the endoscopists in the panel. IC plus magnification, FICE setting 4 plus magnification, and IC without magnification were the most accurate techniques. The following differences among the techniques were statistically significant (Table 3): Conventional *vs* IC-Magnification:  $P = 0.002$ ; Conventional-Magnification *vs* FICE-Magnification:  $P = 0.02$ ; Conventional *vs* IC:  $P = 0.02$ ; Conventional *vs* IC-M:  $P = 0.001$ ; FICE *vs* FICE-Magnification:  $P = 0.048$ ; FICE *vs* IC:  $P = 0.048$ ; FICE *vs* IC-Magnification:  $P = 0.004$ .

The following differences among endoscopists were statistically significant (Table 3): Endoscopist 2 *vs* 4:  $P = 0.003$ ; Endoscopist 2 *vs* 5:  $P = 0.006$ ; Endoscopist 3 *vs* 4:  $P < 0.001$ ; Endoscopist 3 *vs* 5:  $P = 0.002$ .

The endoscopists' level of confidence in the endoscopic diagnosis was increased with these techniques compared to making the diagnosis with white light only (Figure 3).

### FICE and mucosa, polyps

In study three, FICE was particularly useful in evaluating the mucosa in the presence of suboptimal bowel preparation, and the panel found that in that situation, the view was generally better with FICE setting 4 than with WLE (Table 4). Small solid feces showed up as a vivid yellow color and transparent liquid as a darker yellow color; its distinction from colonic mucosa could be clearly seen (Figure 4).

In study four, FICE setting 4 was found to be better than conventional endoscopy for tracing the margin of the polyps and observing the surface irregularities, and IC was found to

be better than FICE setting 4 (Tables 5 and 6, Figure 5).

In study five, when the polyps were observed under IC plus FICE setting 6, the view was not considered inferior

**Table 4** Evaluation of image quality of FICE-4 as compared to conventional WLE in the presence of remaining liquid or solid fecal content

to that of IC alone (Table 7, Figure 6). Therefore, it can be concluded that colonoscopy with FICE setting 6 in the IC-stained mucosa is feasible.

## DISCUSSION

Virtual chromoendoscopy has been developed by endoscope manufacturers to reduce the need for dye spraying. FICE comes with 10 pre-installed settings, which have not previously been evaluated and compared to normal dye spraying techniques and WLE.

In our study, setting 4 was found to be best when assessing mucosal and vascular architecture. Teixeira *et al*<sup>[12]</sup> have reported on the effectiveness of FICE with magnification endoscopes in the differential diagnosis of neoplastic and non-neoplastic lesions. The FICE setting employed was R 500 nm, G 520 nm, and B 405 nm, as we felt that it provided the best imaging of the capillary vessels, after having compared multiple filter settings. However, those comparisons were not probably performed in a structured fashion, as no specific data about the comparisons is available in the study.

We described the settings as provided by the manufacturer. Because it is possible to personalize the filter settings and rename them, care should be taken not to misinterpret the filters used in different studies. Paradoxically, we found that the FICE settings that most closely correlated with the Olympus NBI mode provided the worst mucosal views. NBI and FICE are indeed different technologies, and the results obtained with one of them cannot be extrapolated to the other.

FICE was generally better at assessing vascular architecture than the mucosal surface. Moreover, indigo carmine dye spraying was significantly superior to any

FICE setting. In particular, the innominate grooves, important features when recognizing flat lesions, were perfectly outlined by indigo carmine dye.

Magnification appears to be as effective with FICE as with IC, whereas IC would be superior to FICE in the absence of magnification. Because this is a pilot study, these results should be confirmed in larger studies. The endoscopists participating in image interpretation were far more familiar with IC than with FICE. A learning curve in diagnostic interpretation of FICE may exist. Another possible explanation for the superiority of IC over FICE in our study could be that the former seems to provide a better mucosal contrast, and in the absence of magnification, this might lead to significant differences. In the only study available regarding FICE for the diagnosis of colonic polyps, Pohl *et al*<sup>[9]</sup> also found that IC and FICE were superior to WLE both with and without magnification. However, no difference was found when IC and FICE were compared. Because the mean size of polyps in their study was 7 mm, and lesions up to 20 mm in size were included, their results cannot be directly compared to those from our study, as our polyps were significantly smaller. Although they performed a sub-analysis on the subgroup of lesions  $\leq$  5 mm in size, no information was provided about possible differences between IC and FICE. Moreover, images were evaluated for diagnostic performance by one single endoscopist, whereas five endoscopists were involved in our study.

The diagnostic accuracy with the different techniques in our study was lower than in some other series<sup>[2,5,13-16]</sup>. Possible explanations for such differences are that some series included larger polyps, which are probably easier to diagnose<sup>[5,13-15]</sup>, or that diagnosis was estimated with a live video-endoscopy image and not with stored

<sup>1</sup>P values are comparing the observed proportion of better with respect to 50%.

pictures<sup>[2,13]</sup>, which could enable a more exact diagnosis. Some series used absorptive stains, which can be more accurate<sup>[13,14]</sup>. Moreover, endoscopists with varying degrees of experience in magnifying colonoscopy participated in our study, and there were significant differences in diagnostic accuracy among them. In a recent study, East *et al*<sup>[16]</sup> reported a diagnostic accuracy of 69%-72% for magnification with methylene blue and 72%-84% for magnification plus NBI, which is similar to our findings. Further larger studies should compare FICE with IC without magnification in order to ascertain possible differences between the techniques.

The perceived degree of certainty in the diagnosis given with the different techniques applied was also evaluated. We believe that this issue deserves consideration when test performance is evaluated, as it could have an influence on the therapeutic strategy chosen by the endoscopist. We found that IC (with and without magnification) and FICE plus magnification - the techniques with a higher diagnostic accuracy - were associated with a greater perception of accurate diagnosis, and in fact they were more accurate.

Virtual chromoendoscopy techniques are expected to increase mucosal contrast. In fact, they should probably do so if they are to replace endoscopic stains. In our study, FICE was superior in highlighting the contour of lesions compared with WLE. However, IC remains the gold standard as it was found to be superior to FICE. Machida *et al*<sup>[4]</sup> came to a similar conclusion when comparing NBI with dye staining. One very important issue that will have to be explored in future studies is whether FICE or NBI can aid in the recognition of depressed lesions (Paris type 0-IIc). These lesions are

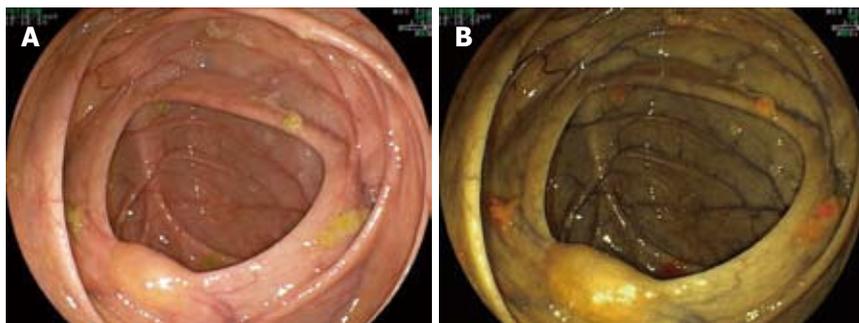

**Figure 3 Degree of certainty in the endoscopic diagnosis for all participating endoscopists with the six diagnostic modalities employed, when endoscopic images were sequentially shown for each case (mean ± SD). frequently small but frequently harbour high grade dysplasia or early invasive cancer<sup>[11,17]</sup>.

Adequate bowel cleansing is a prerequisite for the application of chromoendoscopy, as the mixture of stains and remaining fecal content worsens endoscopic observation<sup>[18]</sup>. It appears important to determine whether FICE can be applied when there is some fecal content remaining, because in most colonoscopies, at least some liquid material persists. when the NBI technology is used, suboptimal bowel preparation appears to negatively affect the endoscopic view. According to our initial impression and the endoscopists' subjective opinion measured in the study, FICE setting 4 was better than WLE for adequately observing the colonic mucosa when bowel content was present and for localizing and individualizing small fecal particles. Liquid and especially small fecal particles showed up as a vivid yellow color. This property of FICE might be useful to differentiate more accurately between small polyps and feces, allowing for targeted washing when small particles are detected.

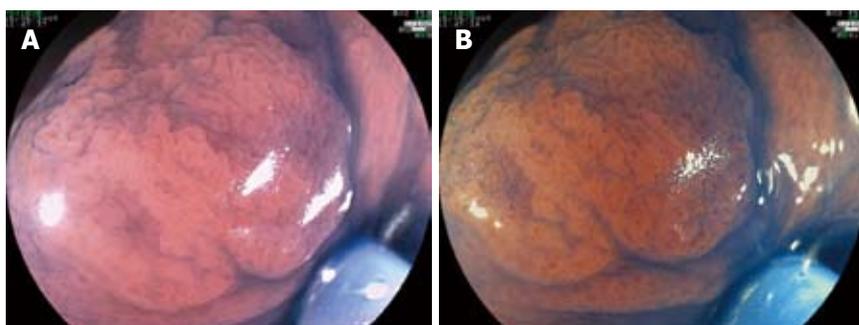

Finally, it is important to know the effect of IC on FICE observation. It is possible that both techniques could be applied in combination for certain indications, as FICE allows for better observation of the vascular

**Figure 4** Observation of the colonic mucosa in the presence of remaining stool particles. A: Plain endoscopy; B: FICE 4.

**Figure 5** Sequence of images shown for the evaluation of mucosal contrast, in a 0-II a flat elevated lesion, 3 mm in maximum diameter (histopathological diagnosis: tubular adenoma with mild dysplasia). **Figure 6** A flat elevated tubular adenoma, shown for the evaluation of FICE 6 plus IC. A: 0.5% IC plus magnification; B: 0.5% IC plus magnification plus FICE 6.

pattern and IC more clearly highlights the lesion edge and surface shape. FICE 6 did not interfere with endoscopic observation. The effect of IC on NBI observation has not been described, but in our experience, the endoscopic view is worsened, resulting in a greenish color.

It is noteworthy that in all cases, FICE was applied with magnifying high definition endoscopes (1 300 000 pixels). When we tried conventional endoscopes (resolution 410 000 pixels), we felt that the image quality was greatly worsened when any FICE filter was applied. Therefore, the results of our study apply only to high resolution endoscopes.

Our study has several limitations: first, the determination of the image quality provided by the different filters is unavoidably a subjective issue. However, we used a scale, a method similar to that used in previous studies<sup>[4]</sup>, and each endoscopist was blinded to the assessments of the other endoscopists. Moreover, although filter 4 had the highest scores, other filters also seemed to provide clear endoscopic images, but they were not evaluated in the current study. The effect of these filters in the colon could represent a field of future research. A second limitation is that our pilot study on polyps only included small

lesions, and none of the lesions was invasive; therefore, the usefulness of FICE for the prediction of invasiveness was not assessed. Finally, one investigator selected the endoscopic images and also participated in the prediction of histopathological diagnosis. However, he was unaware of the diagnosis, and in fact, he did not review any of the histopathological reports for any endoscopic procedure during the study period. When this investigator's assessments were excluded, there were no changes in the statistical results for the diagnostic accuracy of the techniques.

In conclusion, FICE setting 4 seems to be the most suitable for the observation of the colonic mucosa with high definition endoscopes. Its performance in the diagnosis of small polyps appears similar to IC when magnification is applied; however, in our pilot study, IC was superior to FICE in the absence of magnification. FICE seems to depict the polyp shape better than WLE but less clearly than IC. The presence of small amounts of liquid or solid feces or IC does not appear to interfere with endoscopic observation when FICE is applied. This is an initial description, and future studies should clarify the role of FICE in colonoscopic diagnosis.

## ACKNOWLEDGMENTS

We thank Ms. Dolores Gil, Ms. Manuela Ortiz and Ms. Marta Rodríguez Plaza for their invaluable help with the endoscopic procedures and Ms. Rosemary Curran for reviewing the English style.

## COMMENTS

### Background

Fujinon intelligent chromoendoscopy (FICE) provides virtual chromoendoscopy, without the need for endoscopic stains. However, knowledge about the most adequate FICE settings in colonoscopy, and how it compares with conventional chromoendoscopy is still limited.

### Research frontiers

Many issues regarding colonoscopic imaging with FICE have to be explored, including comparison with other virtual chromoendoscopy technologies, traditional chromoendoscopy with stains, and even the influence of the quality of colonic cleansing.

### Innovations and breakthroughs

In this study a structured methodology was applied in order to determine which one among the multiple FICE-filters available provides a better observation of the vascular and mucosal patterns. After the most adequate filter was selected, it was applied for the examination of colonic polyps. In previous studies such a methodology to choose the best FICE-filter was not applied or described in detail. Additionally, in this study certain features of FICE imaging are explored, such as the possibility of applying it to observe indigo carmine-stained mucosa, or whether the existence of fecal contents has an influence on FICE imaging.

### Applications

Our results suggest that FICE is adequate for the observation of the vascular pattern, that indigo carmine is better for examining the fine mucosal surface and the margin and shape of the lesion, and that endoscopic stains (like indigo carmine) can be applied in combination with FICE-6. As opposed to narrow band imaging, indigo carmine or colonic fecal contents do not seem to interfere with FICE imaging. In fact, FICE-4 could clarify whether small mucosal irregularities are really mucosal lesions or adherent particles, and this could have an application in screening colonoscopy.

### Terminology

Virtual chromoendoscopy: The contrast of mucosal and vascular patterns is enhanced without the need of any endoscopic stain, by just pressing a button in the endoscope. FICE: Virtual chromoendoscopy is obtained by means of spectral estimation technology, i.e. computerized image reconstruction by the endoscopic processor. FICE filters or settings: there are 10 pre-programmed filters which are switched on the keyboard, each of which has different settings for estimated R, G, and B wavelengths.

### Peer review

This is a prospective study to validate high definition endoscopes with FICE in colonoscopy. This paper is quite interesting.

### Abstract

**AIM:** To assess the risk of biliary and pancreatic cancers in a large cohort of patients with type 2 diabetes mellitus (DM).

**METHODS:** Eligibility for this study included patients with type 2 DM (ICD-9 code 250.0) who were discharged from Department of Veteran Affairs hospitals between 1990 and 2000. Non-matched control patients without DM were selected from the same patient treatment files during the same period. Demographic information included age, sex and race. Secondary diagnoses included known risk factors based on their ICD-9 codes. By multivariate logistic regression, the occurrence of biliary and pancreatic cancer was compared between case subjects with DM and controls without DM.

**RESULTS:** A total of 1172496 case and control subjects were analyzed. The mean age for study and control subjects was  $65.8 \pm 11.3$  and  $64.8 \pm 12.6$  years, respectively. The frequency of pancreatic cancer in subjects with DM was increased (0.9%) in comparison to control subjects (0.3%) with an OR of 3.22 (95% CI: 3.03-3.42). The incidence of gallbladder and

extrahepatic biliary cancers was increased by twofold in diabetic patients when compared to controls. The OR and 95% CI were 2.20 (1.56-3.00) and 2.10 (1.61-2.53), respectively.

**CONCLUSION:** Our study demonstrated that patients with DM have a threefold increased risk for developing pancreatic cancer and a twofold risk for developing biliary cancer.

Diabetes mellitus as a risk factor for gastrointestinal cancer among American veterans. *World J Gastroenterol* 2009; 15(42): 5274-5278 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5274.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5274>

### INTRODUCTION

The prevalence of type 2 diabetes mellitus (DM) is rapidly growing globally and has become a major public health problem that is approaching epidemic proportions worldwide<sup>[1,2]</sup>. Even though cardiovascular complications are a major cause of morbidity and mortality in patients with diabetes, this disease has also been associated with several cancers, most notably of the liver, endometrium, kidney, and pancreas<sup>[3-5]</sup>.

To the best of our knowledge, the relationship of DM with gallbladder and extrahepatic biliary cancers has not been reported clearly in the literature. There has also been previous discussion over the role of diabetes in the development of pancreatic cancer; and there are recent studies that have suggested an elevated risk of pancreatic cancer in patients with DM<sup>[6-8]</sup>.

Although clinical conditions associated with high levels of insulin, such as acromegaly, are related to an increased risk of colon cancer, esophageal and gastric cancer, the relationship between type 2 DM and these gastrointestinal cancers has not been well established in large studies<sup>[9,10]</sup>.

It is of great significance to investigate the relationship between type 2 DM and gastrointestinal malignancies from an epidemiological standpoint, to determine preventive measures and implement screening strategies. Distinct from most previous studies that have involved either a limited sample size or a specified cancer site, we conducted a comprehensive assessment of the risk of gastrointestinal malignancies in a large cohort of patients with DM.

## MATERIALS AND METHODS

### Data collection and data sources

The Austin Automation Center has maintained the Patient Treatment File (PTF) since July 1969. The PTF documents inpatient treatment from all Veterans Health Administration (VHA) hospitals, extended care discharges and non-VHA hospital discharges at the Veterans Administration (VA) expense. The PTF contains demographic characteristics of patients and discharge diagnoses. Since 1984, a primary diagnosis and up to nine secondary diagnoses have been recorded according to ICD9-CM<sup>[11]</sup>.

### Identification of cases and controls

Cases were defined as patients who were diagnosed with type 2 DM. Cases with ICD9-CM code 250.0 were identified from the PTF from 1990 to 2000<sup>[11]</sup>. The date of a patient's first appearance in the PTF with type 2 DM was considered the date of diagnosis. Non-matched control patients without DM were selected from the same PTF during the same time period. Controls were gathered with a 3:1 ratio in proportion to cases. A method of random selection without replacement was used to ensure that no individual control subject was selected more than once.

### Calculation of comorbidity index

A comorbidity index was calculated for cases and controls. An adaptation of the Charlson Comorbidity Index as applied to administrative databases was employed<sup>[12,13]</sup>.

### Collected information and extraction of secondary diagnoses

Demographic information consisting of age, sex and ethnicity was obtained from the computerized records for cases and controls at the time of selection. Individual social security numbers were used to search the inpatient files from 1990 to 2000 for the following malignancies: gallbladder cancer (156.0), biliary cancers (156.1, 156.8 and 156.9), and pancreatic cancer (157.0, 157.1, 157.2, 157.3, 157.8 and 157.9)<sup>[11]</sup>. To ensure an appropriate temporal relationship between diabetes and these selected malignancies, cases were excluded if diabetes was not diagnosed at least 3 years prior to the diagnosis of the selected malignancy.

We searched the inpatient files for secondary diagnoses of potential risk factors for biliary and pancreatic cancer which included the following: cholelithiasis (574.0, 574.01, 574.10, 564.11, 574.20, 574.21, 574.60, 574.61, 474.70, 574.71, 574.80, 574.81, 574.90 and 574.91); choledocholithiasis (574.30, 574.31, 574.40, 574.41, 574.50 and 574.51); cholecystitis (575.0, 575.10, 575.11 and 575.12); other gallbladder diseases (575.2, 575.3, 575.4, 575.5, 575.6, 575.8, 575.9, 576.2, 576.3, 576.4, 576.8 and 576.9); sclerosing cholangitis (576.1), pancreatitis (577.0, 577.1 and 577.2); other pancreatic diseases (251.8, 251.0, 577.8, 577.9, 579.4 and 251.9); smoking or history of smoking (305.1, 989.84, E869.4 and V15.82); obesity (278.00 and 278.01); and hypercholesterolemia (272.0)<sup>[11]</sup>.

### Statistical analysis

Statistical analysis was performed using SAS/STAT Software (SAS Institute, Cary, NC, USA)<sup>[14]</sup>.  $P < 0.05$  was interpreted as being indicative of statistical significance. Continuous variables were analyzed by unpaired  $t$  tests. Binary variables were analyzed using the  $\chi^2$  and Fisher's exact tests. Quantitative variables were expressed as means  $\pm$  SD. In the multivariable analysis, a logistic regression model was used to assess the occurrence of gallbladder, biliary and pancreatic cancers using age, ethnicity, and potential risk factors as predictor variables, while controlling for differences in comorbid conditions. OR and 95% CI were used to indicate the strength of influence.

## RESULTS

We evaluated 278 761 patients with DM and 836 283 control patients hospitalized between 1990 and 2000. Case and control groups were well matched according to their demographic information. The mean age for case and control subjects was  $65.8 \pm 11.3$  and  $64.8 \pm 12.6$  years, respectively ( $P = \text{NS}$ ). There was a preponderance of male subjects in case and control groups (97.8% and 97.4%, respectively). Also, in the DM group, 66.3% were Caucasian compared to 68.3% in the control group (Table 1). As expected, there was a greater proportion of obesity among patients with DM compared to controls. Also, smokers were seen in 5.8% of the DM group compared to 6.8% in the control group.

Table 1 shows the distribution of pancreatic, gallbladder, and extrahepatic biliary cancers in case and control groups. The frequency of gallbladder cancer was 0.03% among patients with diabetes and there were no patients detected with gallbladder cancer in the control group. Extrahepatic biliary cancer was also five times more common in patients with diabetes when compared to control patients, 0.1% *vs* 0.02%, respectively. Pancreatic cancer in subjects with diabetes (0.9%) was three times more common when compared to control subjects (0.3%).

The occurrence of other biliary and pancreatic disorders is also depicted in Table 1 in both groups, as some of these disorders are potential risk factors for biliary or pancreatic cancer. Cholelithiasis was observed more commonly in DM patients (4.5%) in comparison to controls (2.8%). In addition, cholecystitis, sclerosing cholangitis and other

**Table 1** Demographics and predictive factors in diabetes mellitus (DM) patients and controls (%)

Variable	Diabetes (n = 278 761)	Controls (n = 836 283)	P value
Age ± SD (yr)	65.8 ± 11.3	64.8 ± 12.7	NS
Male sex	97.8	97.4	< 0.001
Caucasian	65.3	68.3	< 0.001
Obesity	15.7	7.5	< 0.001
Smoking	5.8	6.8	< 0.001

Pancreatic cancer	0.9	0.3	< 0.001
Pancreatitis	5.1	2.7	< 0.001
Cholelithiasis	4.5	2.8	< 0.001
Choledocholithiasis	0.8	0.5	< 0.001
Cholecystitis	0.9	0.5	< 0.001
Sclerosing cholangitis	0.4	0.2	< 0.001
Other biliary diseases	1.2	0.6	< 0.001
Other pancreatic disease	1.7	0.3	< 0.001

**Table 3** Pancreatic diseases associated with DM: univariate and multivariate analysis

Variables	Unadjusted OR (95% CI)	P value	Adjusted OR (95% CI)	P value
Age > 50 yr	1.51 (1.49-1.54)	< 0.001	1.51 (1.53-1.57)	< 0.001
Male sex	1.18 (1.14-1.22)	< 0.001	1.09 (1.06-1.22)	< 0.001
Caucasian	0.86 (0.85-0.87)	NS	0.91 (0.90-0.92)	NS
Smoking	1.16 (1.14-1.19)	< 0.001	0.99 (0.95-1.02)	NS
Obesity	2.30 (1.70-3.10)	< 0.001	2.68 (2.62-2.75)	< 0.001
Pancreatic cancer	2.48 (2.26-2.72)	< 0.001	3.22 (3.03-3.42)	< 0.001
Cholelithiasis	1.66 (1.62-1.70)	< 0.001	1.94 (1.89-1.98)	< 0.001
Choledocholithiasis	1.52 (1.44-1.62)	< 0.001	1.82 (1.72-1.93)	< 0.001
Pancreatitis	1.98 (1.94-2.03)	< 0.001	2.30 (2.25-2.36)	< 0.001
Other pancreatic disorders	5.16 (4.88-5.45)	< 0.001	6.15 (5.82-6.50)	< 0.001

biliary diseases occurred more commonly in diabetic patients. Furthermore, other pancreatic diseases were significantly higher in patients with diabetes when compared to controls (1.7% vs 0.3%, respectively).

Table 2 illustrates our first model of multivariate logistic regression, which analyzed gallbladder and extrahepatic biliary cancer in relation to DM. The presence of gallstone disease, smoking, and obesity were controlled for in both groups before the ORs were calculated. We found that gallbladder and extrahepatic biliary cancer was significantly and independently associated with DM with an OR and 95% CI of 2.20 (1.56-3.00) and 2.10 (1.61-2.53), respectively. Included in Table 2 are the associations between diabetes and other biliary diseases, which were accounted for to eliminate potential confounding factors. The presence of DM was found to be associated with cholelithiasis and other biliary disorders. (OR, 1.81; 95% CI, 1.77-1.85 and OR, 2.10; 95% CI, 1.86-2.36, respectively).

Table 3 demonstrates our second model of multivariate analysis, which examined the association between diabetes and the incidence of pancreatic cancer. The results were obtained after controlling for recognized risk factors, such as smoking, obesity, pancreatitis, and other pancreatic disorders. After all case and control patients

**Table 2** Gallbladder diseases associated with DM: univariate and multivariate analysis

Variables	Unadjusted OR (95% CI)	P value	Adjusted OR (95% CI)	P value
Age > 50 yr	1.51 (1.49-1.54)	< 0.001	1.56 (1.54-1.58)	< 0.001

Other biliary diseases	1.99 (1.90-2.09)	< 0.001	2.10 (1.86-2.36)	< 0.001

were considered, a significant relationship between diabetes and pancreatic cancer was established (OR, 3.22; 95% CI, 3.03-3.42). Diabetes was also associated with pancreatitis and other pancreatic disorders with an OR of 2.30 (95% CI, 2.25-2.36) and 6.15 (95% CI, 5.82-6.50).

## DISCUSSION

Type 2 DM is one of the most common and challenging problems faced today because of the many complications that result from this disease. Approximately 140 million people worldwide currently have diabetes, and this number is projected to reach up to 300 million by the year 2025<sup>[15]</sup>. The massive prevalence of this disease may now be unmasking additional, yet to be discovered, complications such as pancreatic and biliary cancer. A recent study has revealed a relationship between increasing fasting serum glucose and the incidence of gastrointestinal malignancies in Korean men and women<sup>[16]</sup>.

Pancreatic cancer is the fifth leading cause of cancer-related mortality in the United States<sup>[17,18]</sup>. The incidence of pancreatic cancer is higher among men and African Americans<sup>[18,19]</sup>. Previous studies have documented risk factors for the development of pancreatic cancer<sup>[6-8]</sup>. The most well-established risk factors for pancreatic cancer are smoking, genetic predisposition, chronic pancreatitis, and DM. A recent study has shown an increase in the incidence of pancreatic cancer among overweight patients, and that moderate exercise is associated with a lower incidence of pancreatic cancer<sup>[20]</sup>.

The linkage between pancreatic cancer and diabetes is well recognized. However, it has been debatable whether diabetes is a risk factor for, or a consequence of, pancreatic cancer. Earlier studies could not address this question adequately because the presence of type 2 diabetes has not been documented before the onset of disease. A more recent meta-analysis has shown that a history of diabetes for  $\geq 5$  years increases the incidence of pancreatic cancer by twofold<sup>[21]</sup>. In a hospital based case-control study, Bonelli *et al*<sup>[22]</sup> have demonstrated that the risk of pancreatic cancer was increased by 6.2-fold in patients with diabetes, which necessitated insulin therapy

for > 5 years. Our study supported these findings by showing that the occurrence of pancreatic cancer was increased by threefold in DM patients when compared to controls.

Primary carcinoma of the gallbladder is the fifth most common malignancy of the gastrointestinal tract in the United States. Approximately 5000-6000 adults are diagnosed annually, and most will die within 1 year of diagnosis<sup>[23,24]</sup>. Although the etiology of primary gallbladder carcinoma is not well understood, several factors have been postulated to place patients at a greater risk. These risk factors include gallstone disease, obesity, female sex, tobacco use, and an anomalous pancreaticobiliary ductal union<sup>[24,25]</sup>. Perhaps no risk factor has been attributed to gallbladder cancer more than gallstone disease, but the relationship between diabetes and gallbladder cancer has not been established conclusively. However, there has been one previous population-based study that showed an excess risk for all biliary cancers in patients with diabetes<sup>[5]</sup>.

This is one of the first studies to demonstrate a clear association of diabetes with gallbladder and extrahepatic biliary cancer. In our study, patients with diabetes had a twofold increased risk of having gallbladder or extrahepatic biliary cancer after controlling for known risk factors.

Our understanding of DM has changed dramatically over the past few years. Initially thought of as a disease secondary to a lack of insulin production, type 2 DM is now recognized as an ailment of insulin resistance and resultant hyperinsulinemia. First-line therapy now specifically targets insulin-mediated glucose utilization in the liver and peripheral tissue<sup>[26,27]</sup>. The over-production of both insulin and insulin-like growth factors (IGFs) has been postulated to increase carcinogenesis and may have played an essential role in the development and progression of pancreatic and biliary cancer in our patients with diabetes<sup>[28]</sup>. It would be of great interest to see whether there is a trend towards a greater risk for pancreatic and gallbladder cancer among diabetics with an increasing degree of hyperinsulinemia.

Evidence from animal and human studies has suggested that abnormal glucose metabolism plays an important role in pancreatic carcinogenesis<sup>[29,30]</sup>. Recent evidence supports the suggestion that insulin and IGF-1 act through a tyrosine kinase growth factor cascade in enhancing tumor cell proliferation.

Another contributor to this problem might be the rising prevalence in all age groups of the metabolic syndrome, specifically insulin resistance, in the United States<sup>[31]</sup>. The metabolic syndrome is associated with a chronic inflammatory state with accompanying cytokine abnormalities, which could also contribute to tumor progression. Furthermore, diabetic patients are at a higher risk for developing gallstones, which have also been recognized as a risk factor for the development of gallbladder and other biliary cancers<sup>[32]</sup>.

The strength of our study was that it encompassed a large patient population, dramatically more than any other study that has examined this association. This

approach allowed for a large sample of diabetics in the VA population, thereby increasing the overall power of the study.

The weakness of our study was that the population we studied was restricted to the VA population and therefore was composed mainly of men. Obtaining a larger female sample could have been helpful in allowing us to observe any differences in the associations according to sex. Other limitations to our study were the potential for misclassification bias (errors in cancer diagnosis ICD9-CM code classification) and cancers diagnosed post mortem. However, given the large size of our patient population, the significance of misclassification and post mortem cancer diagnosis were thought to be inconsequential toward the overall study results. Also, because of our current dearth of knowledge regarding the development of biliary and pancreatic malignancies, our results might have been affected by unknown confounding factors. However, our study did address the known risk factors for these malignancies and controlled for these so that they would not affect our overall results.

In summary, we found that type 2 DM was associated with an increased risk of gallbladder, biliary and pancreatic cancer, independent of other known risk factors such as cholelithiasis, pancreatitis, obesity and smoking. This information should further heighten our awareness of the many complications associated with insulin resistance and modify the intensity of our approach to these patients. This could warrant a keener eye by the primary care physician for any abnormalities in his or her diabetic patients, which indicate the possibility of cardiovascular, renal and ophthalmic complications, as well as the rare but foreseeable possibility of a fatal pancreaticobiliary malignancy.

## COMMENTS

### **Background**

The prevalence of type 2 diabetes mellitus (DM) is growing globally and has become a major public health problem that is approaching epidemic proportions worldwide. This disease has been associated with several cancers, most notably of the liver, endometrium, kidney and pancreas. To the best of our knowledge, the relationship of DM with gallbladder and extrahepatic biliary cancers has not been reported clearly in the literature.

### **Research frontiers**

It is of great significance to investigate the relationship between type 2 DM and gastrointestinal malignancies from an epidemiological standpoint, to determine preventive measures and implement screening strategies.

### **Innovations and breakthroughs**

Distinct from most previous studies that have involved a limited sample size or a specified cancer site, we conducted a comprehensive assessment of the risk of gallbladder, biliary and pancreatic malignancies in a large cohort of patients with DM.

### **Applications**

Type 2 DM poses an increased risk of gallbladder, biliary and pancreatic cancer, independent of other known risk factors such as cholelithiasis, pancreatitis, obesity and smoking. This information heightens awareness of the many complications associated with insulin resistance and should modify the intensity of our approach to these patients. This warrants a keener eye by primary care physicians for any abnormalities in their diabetic patients, which indicate the possibility of cardiovascular, renal and ophthalmic complications, as well as the rare but foreseeable possibility of a fatal pancreaticobiliary malignancy.

### **Terminology**

Type 2 DM is associated with an increase in the occurrence of gallbladder,

biliary and pancreatic cancer among American veterans, independent of other known risk factors.

### Peer review

The study deals with an interesting epidemiological analysis of the question if DM is a risk factor for several gastrointestinal cancers. It reports associations between type 2 DM and incidence of certain cancers.

analysis, tumor resection, CCI score, and serum CA 19-9 levels correlated significantly with outcome. In the multivariate analysis, only resection (HR 0.10; 95% CI, 0.02-0.51,  $P = 0.005$ ) and a CCI score  $\geq 2$  (HR 3.36; 95% CI, 1.0-10.9,  $P = 0.045$ ) were found to independently predict survival.

**CONCLUSION:** Tumor resection and comorbidity emerged as significant prognostic variables in extrahepatic cholangiocarcinoma. Comorbidity evaluation instruments should be applied in the clinical management of such patients.

### Abstract

**AIM:** To study the outcome and prognostic factors in a series of patients with extrahepatic cholangiocarcinoma and determine the impact of comorbidity on survival.

**METHODS:** A retrospective analysis of 68 patients with extrahepatic cholangiocarcinoma (perihilar,  $n = 37$ ; distal,  $n = 31$ ) seen at a single tertiary-care institution during the period 1999-2003 was performed. Data on presentation, management, and outcome were assessed by chart review. Pathologic confirmation was obtained in 37 cases (54.4%). Comorbidity was evaluated by using the Charlson comorbidity index (CCI).

**RESULTS:** Mean age at diagnosis was  $73.4 \pm 11.5$  years. Jaundice was the most common symptom presented (86.8%). Median CCI score was 1 (range, 0 to 4). Nineteen patients (27.9%) underwent tumor resection. Palliative biliary drainage was performed in 39 patients (57.4%), and 6 patients (8.8%) received only best supportive care. Tumor-free margin status (R0) was achieved in 15 cases (78.9% of resection group). Baseline serum carbohydrate antigen 19-9 (CA 19-9) level was revealed to be an independent predictor of surgical treatment ( $P = 0.026$ ). Overall median survival was  $3.1 \pm 0.9$  mo, with 1- and 2-year survival rates of 21% and 7%, respectively. In the univariate

### INTRODUCTION

Cholangiocarcinoma is a relatively uncommon malignant tumor arising in the intrahepatic or extrahepatic biliary ducts. It accounts for about 3% of all gastrointestinal cancers globally and constitutes the second most common primary hepatic malignant disease, with approximately 5000 new cases being diagnosed annually in the United States<sup>[1]</sup>. Although the entire biliary tree is potentially at risk, the perihilar region is the most frequently involved site, accounting for about 60% of all tumors<sup>[1]</sup>. However, it has been suggested that the incidence of intrahepatic forms of the disease is currently increasing in the US and the United Kingdom<sup>[2]</sup>. Cholangiocarcinoma has been characterized as a slow-growing and late metastasizing tumor, tending to spread longitudinally along the bile ducts with neural, perineural, and subepithelial extensions.

Because of the late presentation of symptoms, tumors are usually diagnosed in their later stages, and thus most therapeutic approaches are not curative<sup>[1]</sup>. The prognosis for patients with unresectable disease is dismal, with the reported median survival time less than 1 year from diagnosis<sup>[3]</sup>.

In developed countries, the peak age at diagnosis of cholangiocarcinoma has shifted from the sixth decade of life during the 1970s, toward the seventh decade and older nowadays. According to Patel, the median age at the time of death in individuals with intrahepatic cholangiocarcinoma - based on US vital-statistics data referring to the period between 1973 and 1997 - was 71 years for males and 74 years for females<sup>[2]</sup>. Recent works from various European institutions have reported a median age at diagnosis of 64 to 75 years<sup>[4-7]</sup>. Due to the increased ageing of the Western population, there is an emerging need to develop a means to characterize the "functional age" of older patients in order to optimize therapeutic strategies for cancer and design new multi-disciplinary approaches. Multiple studies have demonstrated that the amount of comorbidity (defined as the presence of diseases or disorders which exist before cancer diagnosis and are not treatment-related adverse effects) significantly impacts on various prognostic outcomes in oncologic patients, such as functional status<sup>[8]</sup>, healthcare resources use<sup>[9]</sup>, therapeutic decision-making<sup>[10]</sup>, and overall survival<sup>[11]</sup>. The Charlson comorbidity index (CCI) was originally developed by Mary Charlson and colleagues in 1987 from the study of 1-year all-cause mortality in a cohort of more than 500 patients admitted to a medical unit of a teaching hospital<sup>[12]</sup>. This index has been validated in predicting mortality risk associated with a wide range of medical conditions, and constitutes one of the most commonly used comorbidity indices to date. Correlations between the severity of comorbid conditions, assessed by means of the CCI, and diverse outcomes have been observed in patients with colorectal<sup>[13]</sup>, head and neck<sup>[14]</sup>, non-small cell lung<sup>[15]</sup>, bladder<sup>[10]</sup>, clear cell renal<sup>[16]</sup>, and ovarian cancer<sup>[17]</sup>. Some reports indicate that the impact of comorbidity on survival may vary among populations with different cancers. To the best of our knowledge, no previous studies have focused on the role of age and comorbidity, quantified using the CCI, on treatment decisions and clinical outcomes for patients with biliary tract malignancies. Thus, we conducted a single-center analysis of consecutive Spanish patients with extrahepatic cholangiocarcinoma to investigate the impact of these variables on the choice of therapeutic approach and patients' overall survival.

## MATERIALS AND METHODS

The tumor registry of the University Hospital "12 de Octubre" compiles data on all new cancer cases in Health Area 11 of the Community of Madrid (Central Spain), with 593931 inhabitants in 2007. We carried out a retrospective analysis of all the patients with extrahepatic cholangiocarcinoma (code C24.0 according to the 2nd edition of the International Classification of

Diseases for Oncology) consecutively diagnosed at our institution between January 1, 1999 and December 31, 2003. Full clinical documentation was available for 68 subjects; they were then included in the study. Diagnosis of cholangiocarcinoma was based on clinical, imaging, cytologic or histopathologic findings. All patients underwent ultrasound examination of the liver and gallbladder as the first diagnostic imaging approach. Further procedures included triple phase helical computed tomography in 60 patients (88.2%), cholangio-magnetic resonance imaging in 14 patients (20.6%), and cholangiography by means of either the percutaneous transhepatic (PTC) or endoscopic retrograde approach (ERCP) in 39 (57.4%) and 32 (47.1%) patients, respectively. Pathologic confirmation was established in 37 cases (54.4%), a proportion in accordance with previously published series<sup>[4,6,18,19]</sup>, and was based on either histologic or cytologic samples (24 and 13 cases, respectively).

Demographic data, predisposing factors, clinical manifestations at admission, laboratory and imaging findings, pathology reports, therapeutic approaches, and all-cause mortality were assessed by review of medical records. Additional variables such as length of hospital stay or presence of perioperative complications were specifically recorded in patients who underwent surgical resection as the first-line treatment. Extrahepatic cholangiocarcinomas were classified as perihilar (those involving or requiring resection of the hepatic duct bifurcation) or distal types (those involving the distal extrahepatic, or intrapancreatic portion of the bile duct and potentially amenable to pancreatoduodenectomy). The American Joint Committee on Cancer (AJCC) 2003 criteria were used for TNM (Tumor, Node, Metastases) staging of the tumor<sup>[20]</sup>. Perihilar tumors were classified according to the modified Bismuth-Corlette classification<sup>[21]</sup>. CCI scores were calculated by the method previously reported by Charlson *et al*<sup>[12]</sup>, in which each specific comorbid condition is weighted and scored (Table 1). These scores were determined by one of the authors (Fernández-Ruiz M) who was blinded to survival status.

The primary endpoint of the study was overall survival, defined as the interval (in months) between tumor diagnosis and death or completion of the follow-up period (December 31, 2004). Patients lost during this period were recorded as of the last known contact in our institution. Quantitative data are shown as mean  $\pm$  SD, or median  $\pm$  range or 95% confidence interval (95% CI), as appropriate. Qualitative variables are expressed as absolute and relative frequencies. Nominal variables were compared by the  $\chi^2$  test or Fisher's exact test. Two-tailed Student's *t* test (or *U* Mann-Whitney test when the assumption of normality did not hold) were applied for continuous variables. We used logistic regression analysis in order to identify factors predictive of tumor resectability. Survival curves were estimated by the Kaplan-Meier product-limit method, and differences between groups were compared with the log-rank test (univariate analysis). Multivariate analysis was based on the stepwise forward Cox proportional hazards model, using survival as the dependent variable and those factors demonstrating statistical significance

**Table 1 The Charlson comorbidity index (CCI)<sup>1,2</sup>**

Weight <sup>1</sup>	Comorbid condition
1	Myocardial infarction Congestive heart failure Peripheral vascular disease Cerebrovascular disease (except hemiplegia) Dementia Chronic obstructive pulmonary disease Connective tissue disease Peptic ulcer disease Mild liver disease
2	Diabetes (without complications) Hemiplegia Moderate or severe renal disease Diabetes with end-organ damage (retinopathy, neuropathy, etc) Any second solid tumor (nonmetastatic), leukemia or lymphoma
3	Moderate or severe liver disease
6	Metastatic solid tumor AIDS

<sup>1</sup>Optionally, the age index leads to adding 1 point for each decade over 40 years.

in the univariate analysis as covariates. To assess the role of CCI as a predictor of mortality, survival analysis was carried out with the cohort divided into 2 groups based on its median value (CCI score equal or lower than 1, or greater than 1). We also dichotomized other continuous variables by using their mean or median values, except for total bilirubin (cut-off value at 10 mg/dL) and hemoglobin (cut-off value at 12 g/dL). Differences were considered significant at *P* < 0.05. All statistical analysis was performed using the software package SPSS, version 12.0 (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Patients' characteristics

A total of 68 consecutive patients diagnosed with extrahepatic cholangiocarcinoma during the study period were analyzed. Their baseline characteristics stratified by primary tumor location are summarized in Table 2. There were 34 males and 34 females, with a mean age at diagnosis of 73.4 ± 11.5 years (range, 42 to 96 years). Forty-seven patients were older than 70 (69.1%) years. Regarding the risk factors for the development of cholangiocarcinoma, only 1 patient from the cohort had a previous diagnosis of primary sclerosing cholangitis (PSC). A history of underlying chronic liver disease was recognized in 5 cases (7.4%): hepatitis B and C infection (2 patients each), and chronic alcoholism (1 patient). Five patients (7.4%) had previously undergone cholecystectomy. No cases of Caroli's disease, choledochal cyst, hepatolithiasis, or exposure to chemical agents were found. A family history of malignancy was reported in 5 patients (7.4%). Major clinical symptoms at admission were jaundice (86.8%), abdominal pain (36.7%), and weight loss (27.9%). Age and sex distribution, predisposing factors, clinical manifestations, and duration of symptoms were similar between patients with perihilar and distal lesions. The serum lactate dehydrogenase level in patients with distal cholangiocarcinoma (169 ± 54 IU/L) was lower than that in patients with perihilar tumors (269 ±

<sup>a</sup>Data available for 29 patients; <sup>b</sup>*P* = 0.005; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; CA 19-9: Carbohydrate antigen 19-9; γ-GT: γ-glutamyltranspeptidase; LDH: Lactate dehydrogenase.

180 IU/L, *P* = 0.005), while there was a nearly significant difference in serum carbohydrate antigen 19-9 (CA 19-9) levels at diagnosis (87.6 IU/L *vs* 989 IU/L, respectively, *P* = 0.057). Other hematologic and liver function tests were similar in both groups.

The median CCI score was 1 (range, 0 to 4). Thirty-one patients (45.6%) had no comorbidities (CCI score of 0), 18 (26.5%) had a modest comorbidity level (CCI score of 1), and 19 (27.9%) had a high comorbidity level (CCI score ≥ 2). The most common comorbid conditions encountered were hypertension (44%), diabetes mellitus (17.6%), chronic obstructive pulmonary disease (16%), coronary heart disease (11.7%), and cerebrovascular disease (8.8%). A history of previous malignancy was identified in 4 patients (5.8%).

### Treatment approaches

After initial assessment, 23 patients (33.8%) were considered to have potentially resectable disease and underwent laparotomy with curative intent. At exploration, 4 patients had findings (locally advanced tumor) that precluded resection. Surgical therapy in the remaining 19 patients (27.9%) consisted of partial duodenopancreatectomy with radical lymphadenectomy in 13 cases, excision of the extrahepatic biliary tree in 4 cases, and extrahepatic duct resection associated with left hemihepatectomy in 2 cases. Median hospital stay was 30 d (range, 15 to 66 d). Major postoperative complications occurred in 14 patients (60.8% of the surgical group) and included sepsis (4 cases), surgical wound infection (3 cases), digestive tract bleeding

Table 3 Analysis of predictive variables for resectable tumor

Variable	Univariate			Multivariate		
	OR	95% CI	P	OR	95% CI	P
Age $\geq$ 73 yr	0.24	0.0-0.7	0.012	-		
Distal location	5.27	1.6-17.1	0.004	-		
CEA $\geq$ 5 IU/L	0.09	0.0-0.6	0.013	-		
CA 19-9 $\geq$ 270 IU/L	0.05	0.0-0.5	0.003	0.07	0.0-0.7	0.026

CEA: Carcinoembryonic antigen; OR: Odds ratio.

(3 cases), and death within 30 d after procedure (3 cases). Primary tumor location, age, and baseline serum levels of carcinoembryonic antigen (CEA) and CA 19-9 were identified as predictive variables for resectable disease, whereas CCI scores did not differ significantly between patients who had surgery and those who did not (Table 3). In logistic regression multivariate analysis, only serum CA 19-9 levels  $\geq$  270 IU/L predicted unresectability (OR, 0.07; 95% CI, 0.0-0.7;  $P = 0.026$ ).

Palliative biliary drainage was performed in 39 subjects (57.4%) with non-resectable tumors. Thirteen patients (19.1%) underwent endoscopic biliary stenting by ERCP, whereas percutaneous approach by PTC was required in 26 patients (38.2%), associated with stent placement in 14 cases. Chemo- or brachy-radiotherapy were employed as adjuvant treatment in 3 and 7 subjects, respectively. Finally, 6 patients (8.8%) received only best supportive care.

### Macroscopic and microscopic appearance

TNM staging distribution by primary location is presented in Table 4. The majority of tumors were pathologically classified as T3 (36.7%) and metastatic spread was identified in 13.2% of patients. According to the Bismuth-Corlette classification of perihilar cholangiocarcinomas, 6 out of the 37 patients with such tumors were diagnosed as stage I, 8 as stage II, 5 as stage IIIa, 7 as stage IIIb, and 7 as stage IV. Four patients remained unclassified. Of the 19 patients who underwent resection, 15 (78.9%) had negative histologic margins (R0 resection), whereas in 3 cases (15.8%) the margins were microscopically involved with the tumor (R1 resection).

### Survival analysis

Median follow-up time for the entire cohort was 2.7 mo (range, 0.07 to 49.4 mo). Five patients (7.4%) were lost to follow-up. At the end of observation, 60 of 68 patients (88.2%) had died, with an overall median survival of 3.1 mo (95% CI, 1.4-4.8). Survival rates at 1, 2, and 3 years were 21%, 7%, and 2% respectively. Tumor progression (27.9%), infection (13.2%), liver failure (8.8%), and bleeding (4.4%) were the most frequently recorded causes of death. The clinical, tumor-related, and treatment-related variables evaluated by univariate and multivariate analysis to determine their impact on outcome are presented in Table 5. For the univariate log-rank analysis, surgical resection, lower comorbidity index (CCI score  $<$  2), and lower serum CA 19-9 levels ( $<$  270 IU/L) correlated significantly with better survival. who underwent resection had a longer median survival than those who did not undergo such treatment ( $8.7 \pm 5.7$  mo *vs*  $2.3 \pm 0.4$  mo,  $P = 0.015$ ) (Figure 1A). Regarding the presence and number of comorbid conditions, the median survival in patients with a CCI score of 0 or 1 was longer than that in patients with a higher score ( $4.7 \pm 0.8$  mo *vs*  $1.4 \pm 0.5$  mo,  $P = 0.017$ ) (Figure 1B). This difference remained significant in the subgroup of patients who did not undergo surgical resection ( $3.6 \pm 1.0$  mo *vs*  $1.1 \pm 0.5$  mo,  $P = 0.001$ ). Within the resection group, median survival in patients with a CCI score of 0 or 1 ( $17.7 \pm 7.9$  mo) was also longer than that in patients with a score  $\geq 2$  ( $8.3 \pm 7.5$  mo), although the difference did not achieve statistical significance ( $P = 0.25$ ). On Cox multivariate analysis, the performance of surgical resection [Hazard Ratio (HR) 0.10; 95% CI, 0.02-0.51,  $P = 0.005$ ] and the number of comorbid conditions (HR 3.36; 95% CI, 1.0-10.9,  $P = 0.045$ ) emerged as independent predictors of survival (Table 5).

## DISCUSSION

Our study is a retrospective analysis of the clinical and evolutive characteristics of a consecutive series of Spanish patients diagnosed with extrahepatic cholangiocarcinoma. The results of the study are in addition to the limited works published to date in our country regarding this condition<sup>[22-24]</sup>. We have demonstrated that the presence and number of comorbid conditions, as assessed by the CCI, act as independent factors of unfavorable prognosis. Patients with higher associated comorbidity (CCI score  $\geq 2$ ) had significantly shorter median survival than those with a lower burden of comorbidity (CCI score  $<$  2). This difference was upheld specifically in patients not subject to surgery. To the best of our knowledge, our work is the very first study to demonstrate the impact of comorbidity - as assessed by the CCI criteria - on the survival of patients with malignancies of the biliary tract, and is in accordance with previous studies focused on other solid-organ malignancies<sup>[10,13-17]</sup>.

Extrahepatic cholangiocarcinoma is a rare condition in the Western world. In a study performed in Spain between

<sup>1</sup>Data available for 29 patients; <sup>2</sup>Data available for 66 patients; <sup>3</sup>Denotes chemotherapy or brachy-radiotherapy in patients not receiving surgical resection; HR: Hazard ratio; CCI: Charlson comorbidity index.

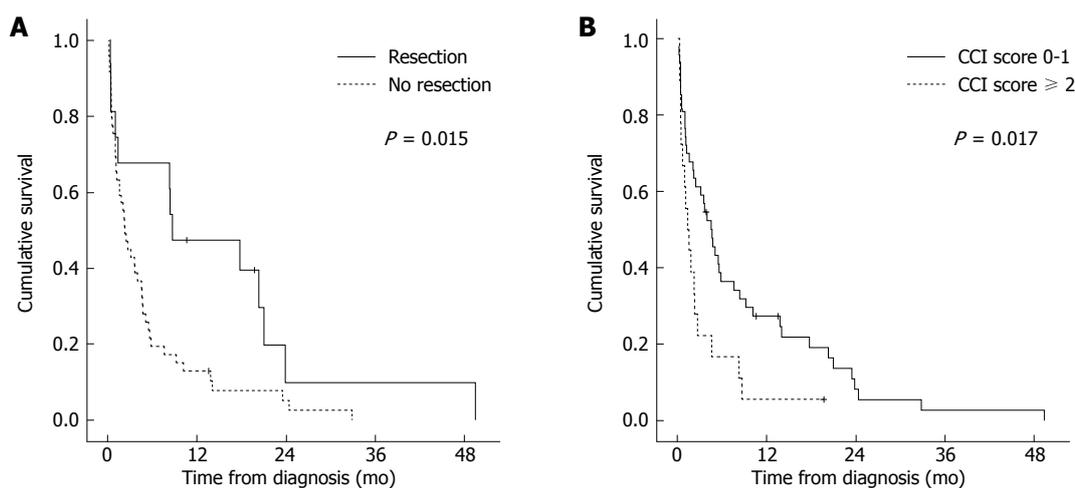

Figure 1 Kaplan-Meier survival curves stratified by treatment approach (log-rank test) (A) and Charlson comorbidity index (CCI) score (log-rank test) (B).

1994 and 1996, Mena *et al.*<sup>[22]</sup> estimated its incidence as 3.23 new cases per 100 000 inhabitants per year. A more recent work, based on data from the nationwide Danish Cancer Registry, revealed a reduced progression of incidence from 1978 (1.05 cases per 100 000 inhabitants per year) up to 2002 (0.74 cases per 100 000 inhabitants per year)<sup>[25]</sup>. In contrast, the incidence and mortality of intrahepatic

forms of the disease seem to have experienced a sustained increase in the last few decades<sup>[1,2]</sup>. The cause of this rise is unknown and does not appear to be explained simply by improvements in diagnosis or changes in coding practice. PSC remains the most common predisposing condition in the development of cholangiocarcinoma in Western countries<sup>[1]</sup>. Cirrhosis of any cause and,

more specifically, hepatitis B and C virus infection, have recently been linked to this type of cancer<sup>[2]</sup>. In our study, only a reduced percentage of patients were associated with some of these risk factors, including 1 case of PSC. These circumstances are common in the literature<sup>[5-7,18]</sup> and appears to suggest the concurrence of other etiopathogenic mechanisms yet to be clarified. Our experience confirms the poor prognosis associated with extrahepatic cholangiocarcinoma, with a median survival of 3.1 mo and a 3-year survival probability of 2%, slightly lower than that described in previous studies with similar clinical and epidemiologic characteristics<sup>[6,7,24]</sup>. The mean age at diagnosis of the patients analyzed in this study (73.4 years) was higher than that reported by other authors (64 years in the study by Figueras *et al*<sup>[23]</sup>, 67 years in the study by Weber *et al*<sup>[5]</sup>) and may have conditioned the reduced rate of resectability obtained in our series (27.9%). Distal tumor location was associated with a higher probability of receiving surgical resection in the univariate analysis, a finding previously reported in the literature<sup>[19,26,27]</sup>. Determination at diagnosis of serum CA 19-9 levels  $\geq$  270 IU/L emerged in the logistic regression multivariate analysis as the only factor independently predictive of unresectability (OR, 0.07; 95% CI, 0.0-0.7). Gerhardt *et al*<sup>[6]</sup> revealed that initial levels of this tumor marker in patients with perihilar cholangiocarcinoma subject to resection were significantly lower in comparison to those affected by unresectable disease. Kau *et al*<sup>[28]</sup> reported similar findings in subjects with periampullar carcinoma. As suggested by these authors, the presence of high serum levels of CA 19-9 probably reflects a greater tumor mass. Consequently, the univariate analysis of survival in our study showed worse prognosis in patients with higher serum levels of CA 19-9 at the time of diagnosis ( $\geq$  270 IU/L), while this difference did not remain significant in the Cox multivariate model.

As early as 1964, Feinstein highlighted the role of comorbidity when explaining the difference between estimated survival according to the TNM system in patients with lung cancer and that observed in clinical practice<sup>[29]</sup>. Since then, various comorbidity scales have been designed; the CCI, the Kaplan-Feinstein Index (KFI), the Cumulative Illness Rating Scale (CIRS), and the Index of Co-Existent Disease (ICED) feature among the most widely used, although no single index has yet emerged as clearly superior to the others<sup>[11]</sup>. The majority of these scales were not designed specifically for subjects with neoplastic disease; as commented, the CCI was developed to analyze 1-year mortality on the basis of data from an internal medicine inpatient department<sup>[12]</sup>. The KFI was created by these authors in 1974 from a cohort of diabetic subjects<sup>[11]</sup>. Only in the last few years have some specific instruments been developed and validated for oncologic patients. The National Institute on Aging (NIA) and National Cancer Institute (NCI) Comorbidity Index<sup>[30]</sup> and the Adult Comorbidity Evaluation-27 (ACE-27)<sup>[31]</sup> are probably the most notable. The latter was developed by Piccirillo *et al*<sup>[31]</sup> and modifications as well as additions of comorbid ailments have been carried out on the KFI, which is currently available online ([\[bidity.wustl.edu\]\(http://cancercomorbidity.wustl.edu\)\). This index has demonstrated its usefulness when analyzing the influence of comorbidity on the prognosis of adult patients with carcinoma of unknown primary site \(CUP\)<sup>\[32\]</sup>, resected colon cancer<sup>\[33\]</sup>, or recently diagnosed head and neck cancer<sup>\[34\]</sup>. However, in spite of the progress made in the last few decades on the design and perfection of new scales, the CCI remains one of the most popular and extensively validated comorbidity instruments. Since its original formulation by Charlson \*et al\*<sup>\[12\]</sup> the CCI has exhibited good prognostic value for predicting cancer patient survival in numerous retrospective studies<sup>\[10,13-17\]</sup>. Reviews of the CCI suggest it has good reliability, excellent correlation with mortality and progression-free survival outcomes, and is easily modified, particularly to account for the effect of age<sup>\[11\]</sup>. Versions of the index adapted to databases \*via\* the International Classification of Diseases \(ICD\)-9 or based on the evaluation of self-reported comorbidities have been also developed. One of its limitations when applied to oncologic patients is characterized by the exclusion of certain comorbidities, such as nonmalignant hematopoietic disorders \(i.e. anemia\) or polyneuropathy<sup>\[10,11\]</sup>.](http://cancercomor-</a></p></div><div data-bbox=)

Not surprisingly, comorbidity has a greater impact on biologically indolent cancers (e.g. prostate or breast), rather than aggressive tumors<sup>[31]</sup>. Chronic conditions, such as those included in the CCI, exert their influence on survival at mid-term and long-term follow-up, losing part of its relevance in the presence of aggressive entities. Although malignancies of the biliary tract are supposed to be relatively slow-growing<sup>[4]</sup>, the late diagnosis at advanced stages of the disease determines its poor prognosis as we reproduced in our series (median survival of 3.1 mo). Consequently, it would be reasonable to suppose that the burden of comorbidity should exert a minor influence on prognosis in patients with extrahepatic cholangiocarcinoma. In support of this hypothesis, tumor progression was the most frequently recorded cause of death in our study (27.9%), ahead of others more directly related to associated comorbidities (e.g. infection or liver failure). Nonetheless, our findings clearly reveal that patients with a higher comorbidity level (CCI score  $\geq$  2) presented significantly lower survival in comparison to the remainder of the cohort, and that this effect was independent of other prognostic variables. The literature contains some equivalent examples in relation to other tumors with aggressive biological behaviour and poor outcome. Seve *et al*<sup>[32]</sup> demonstrated in a cohort of 389 patients with CUP and a median survival of just 12 wk, that the number of comorbid conditions (as assessed by the ACE-27) entailed a worse prognosis, specifically in subjects with impaired functional class. Firat *et al*<sup>[35]</sup> found that comorbidity (evaluated by the CIRS and CCI) was an important prognostic factor in stage III non-small cell lung cancer and concluded that comorbidity should be taken into account even in advanced-stage disease. Similar findings have been reported in ovarian cancer patients with regional spread (FIGO stage II and III) or distant metastases (FIGO stage IV)<sup>[17]</sup>. It has been hypothesized that the type of comorbidities and cancer may interact on a physiologic

level resulting in increased aggressiveness and metastatic potential<sup>[36]</sup>. Another plausible explanation may be related to the nature of therapeutic management. Older and sicker patients are often excluded from prospective clinical trials and are not usually eligible for aggressive cancer therapies, such as duodenopancreatectomy or resection of the biliary tree<sup>[10]</sup>. However, we have not been able to demonstrate the presence of differences in the CCI scores between surgical and nonsurgical groups. The impact of comorbidity on patient survival in our series is also upheld after specific analysis according to the type of treatment, while that difference did not attain statistical significance in subjects who underwent surgical resection (17.7 mo vs 8.3 mo in patients with CCI score < 2 or  $\geq$  2, respectively;  $P = 0.25$ ).

There are a number of limitations in our single-center study to be considered. The retrospective design hinders identification and control of variables with a potential influence on survival, such as performance status or conditions not included in the CCI. We had no control over the quality of the medical records reviewed. The reduced size of the sample analysed, in particular among subjects undergoing surgical resection ( $n = 19$ ), could have hindered demonstration of significant differences in the survival of this subgroup according to their level of comorbidity. Therefore, we cannot generalize the validity of our results on other cohorts of younger patients subject to a higher proportion of surgical procedures. As we previously pointed out, the CCI presents some drawbacks in the evaluation and quantification of comorbidity in individuals with malignant diseases, in comparison with other more recent and specific indices<sup>[30,31]</sup>. Nonetheless, its broad dissemination and simple application guarantee the usefulness of the CCI both in clinical practice and in the context of retrospective studies. As highlighted by Extermann, this index exhibits excellent test-retest reliability, that ranged from 0.86 among a cohort of elderly cancer subjects to 0.92 in surgical patients; its inter-rater reliability is also acceptable, attaining 0.945 in some series<sup>[11]</sup>. A recent study which compared its capacity for prognostic prediction in patients undergoing resection of colorectal carcinoma with that of other recently developed instruments (ACE-27 and NIA/NCI) has concluded the existence of close similarities between them<sup>[33]</sup>.

In conclusion, we have demonstrated that comorbidity exerts an adverse impact on survival in patients diagnosed with extrahepatic cholangiocarcinoma, even after multivariate adjustment for other well-known prognostic factors such as age at diagnosis, primary tumor location, lymph node status, metastatic spread, or nature of the therapeutic approach. With this aim in mind, the CCI constitutes an easy and intuitive instrument in daily clinical practice. In our experience, patients with a CCI score  $\geq$  2 had higher all-cause mortality compared to patients with a CCI score < 2. These data suggest that comorbidity evaluation should be added to the decision-making process in patients with extrahepatic cholangiocarcinoma in order to improve therapy selection and prognostic estimation. However, further prospective studies should be conducted to specifically examine the relationship between comor-

bidity and treatment outcomes such as mid-term efficacy and incidence of postoperative complications.

## COMMENTS

### Background

Cholangiocarcinoma is a relatively uncommon malignant tumor that is associated with a poor prognosis. Many studies have reported that the presence of comorbidity influences various prognostic outcomes in cancer patients, including treatment decision-making and survival.

### Research frontiers

A correlation between the severity of comorbid conditions, as assessed by the Charlson comorbidity index (CCI), and overall survival has been described in patients with various solid-organ malignancies, such as colorectal, head and neck, bladder, clear cell renal, or ovarian cancer.

### Innovations and breakthroughs

The number of comorbid conditions has an adverse impact on survival in patients diagnosed with extrahepatic cholangiocarcinoma, even after multivariate adjustment for other established prognostic factors such as age, tumor location, or type of treatment. Patients with a CCI score  $\geq$  2 had higher all-cause mortality compared to patients with a CCI score < 2. No previous studies have focused on the role of comorbidity on treatment decisions and clinical outcomes for patients with this disease.

### Applications

The study results suggest that comorbidity evaluation should be routinely added to the decision-making process in subjects with extrahepatic cholangiocarcinoma with the aim of improving their treatment selection criteria and survival estimation.

### Terminology

Comorbidity in cancer patients may be defined as the presence of diseases or disorders which exist before cancer diagnosis and are not treatment-related adverse effects. The CCI, in which each specific comorbid condition is weighted and scored, was originally developed from the study of 1-year all-cause mortality in a cohort of patients admitted to the medical unit of a teaching hospital.

### Peer review

This paper is a retrospective research about the impact of comorbidity on extrahepatic cholangiocarcinoma. We are sure that this kind of research is fairly important in the clinical treatment of biliary tract malignancies. Although the data was accurate and stated in detail, this research included a relatively small size of sample, so it can not get more significant results and weakened the conclusion. Anyway, this paper gave us some new information about the prognostic of biliary tract malignancies.

### Abstract

**AIM:** To assess the mucosa-associated bacterial microflora and mucus layer in adolescents with inflammatory bowel disease (IBD).

**METHODS:** Sixty-one adolescents (mean age 15 years, SD  $\pm$  4.13) were included in the study. Intestinal biopsies from inflamed and non-inflamed mucosa of IBD patients and from controls with functional abdominal pain were cultured under aerobic and anaerobic conditions. The number of microbes belonging to the same group was calculated per weight of collected tissue. The mucus thickness in frozen samples was measured under a fluorescent microscope.

**RESULTS:** The ratios of different bacterial groups in inflamed and non-inflamed mucosa of IBD patients and controls were specific for particular diseases. *Streptococcus spp.* were predominant in the inflamed mucosa of Crohn's disease (CD) patients (80% of all bacteria), and *Lactobacillus spp.* were predominant in ulcerative colitis patients (90%). The differences were statistically significant ( $P = 0.01-0.001$ ). Lower number of bifidobacteria was observed in the whole IBD group. A relation was also found between clinical and endoscopic severity and decreased numbers of *Lactobacillus* and, to a lesser extent, of *Streptococcus* in biopsies from CD patients. The mucus layer in the inflamed sites was significantly thinner as compared to controls ( $P = 0.0033$ ) and to non-inflamed areas in IBD patients ( $P = 0.031$ ).

**CONCLUSION:** The significantly thinner mucosa of IBD patients showed a predominance of some aerobes specific for particular diseases, their numbers decreased in relation to higher clinical and endoscopic activity of the disease.

### INTRODUCTION

The term inflammatory bowel disease (IBD), used to describe the chronic intestinal processes, includes ulcerative colitis (UC) and Crohn's disease (CD). Despite very

extensive studies, the pathogenesis of IBD still remains unclear. Genetic, environmental and immunological factors seem to play a substantial role<sup>[1]</sup>. However, an increasing number of both clinical and laboratory studies support the idea of the leading role of bacterial microflora in the onset and persistence of inflammation<sup>[2]</sup>. It is well known that the anatomic sites with the highest concentration of luminal bacteria are most often involved in the inflammatory process<sup>[3]</sup>. Gjaffer *et al*<sup>[4]</sup> showed in 1991 that intestinal flora of patients with active CD is different from that of quiescent patients, UC subjects and controls with functional abdominal pain. Patients with Crohn's disease presented with elevated numbers of aerobic bacteria, mainly *Escherichia coli*, and some anaerobic bacteria. There was also evidence of decreased numbers of *Bifidobacteria*. The results of research based on animal models support the importance of luminal bacteria in experimental colitis. Transgenic mice kept under germ free conditions did not develop inflammation until bacteria were introduced<sup>[5]</sup>. In recent years, the results of several reviews on gut microflora and IBD have suggested that inflammation may be due to a shift in the balance of healthy flora, which leads to dysregulation of the microflora and triggers or maintains the inflammation<sup>[6,7]</sup>. Moreover, it is also known, that microbes which were in close contact with the epithelium were different from those found in stools, and probably more important in the process of gut inflammation<sup>[8]</sup>.

There is very little information about the specificity of the gut microbiota in adolescents with IBD. Up to now, only one study in the literature by Conte *et al*<sup>[9]</sup> where both culture and PCR amplification methods were used, found higher numbers of mucosa-associated bacteria in biopsies from IBD children in comparison to controls. On the other hand, the occurrence of strict anaerobes including *Bacteroides* was low in specimens from patients with CD, UC and indeterminate colitis.

It has also been demonstrated that mucus which is an integral part of the mucosal barrier may play an important role in hindering penetration of the mucosa by luminal bacteria and their products thus preventing the inflammatory process. A study by Pullan *et al*<sup>[10]</sup> showed that a reduction of mucus layer thickness in adult IBD patients caused increased exposure of the microbes to the gut immune system, which in turn sustained the inflammation.

Both mucus and mucosa-associated bacterial microflora form a specific environment in the gut and its disruption may play a crucial role in the development of IBD, promoting specific bacterial colonization and immunological response.

Assessment of the multiple interactions among bacterial microflora and mucus in the very early stage of IBD, seen in newly diagnosed disease, is essential for a better understanding of disease pathogenesis and may help in suggesting therapeutic options such as the use of specific probiotics or antimicrobial treatment.

The aim of our study was to assess mucosa-associated bacterial microflora and mucus layer thickness in relation

to the inflammatory process in adolescents with IBD in comparison to controls.

## MATERIALS AND METHODS

### Ethics

The trial was approved by the Jagiellonian University Bioethical Committee and informed consent was obtained from all patients' legal guardians and/or patients over 16 years of age enrolled in the study.

### Patients

Sixty-one adolescents (25 boys and 36 girls, age:  $15 \pm 4.13$  years) were enrolled in the study from January 2004 to October 2006. There were 12 patients with UC (5 boys and 7 girls, age:  $14.74 \pm 2.9$  years), 22 with CD (9 boys and 13 girls, age:  $16.22 \pm 3.8$  years) and 3 with indeterminate colitis (IC) (1 boy and 2 girls, age:  $15.01 \pm 7.9$  years) in the study group and 24 control subjects (10 boys, 14 girls, age:  $14.13 \pm 4.4$  years) who underwent colonoscopy because of chronic abdominal pain, which was finally diagnosed as functional abdominal pain, without any organic abnormalities. The mean duration of symptoms in the UC group was  $96.5 \pm 75.1$  d,  $153 \pm 146.7$  d in the CD group and  $40.5 \pm 27.6$  d in the IC group. IC patients were not considered for further analysis as a separate group due to the small number of subjects. Patients with UC were younger at disease onset ( $11.64 \pm 4.44$  years) than those with CD ( $13.67 \pm 3.28$  years). Nutritional status of the patients assessed according to the Cole index was comparable in both groups (UC group - 84.57, CD - 82.89). Abdominal pain as the main complaint was more frequent in the group with CD (85.7%) than UC (81.1%), whereas bloody diarrhea and sideropenic anemia were more frequent in UC (81.2% and 36.4%, respectively) than CD patients (40.9% and 19.1%, respectively). Only 9% of UC patients presented with fever at disease onset, as compared to 27.2% of CD patients.

The diagnosis of CD or UC was based on endoscopic, histopathological, immunological and radiological criteria. Disease activity was assessed according to the Pediatric Crohn's Disease Activity Index (PCDAI) for CD patients and the modified Trulove-Witts score for UC patients<sup>[11]</sup>. Depending on the score value the patients were classified into three subgroups of disease activity: mild, moderate and severe. The majority of patients in both groups were classified as having mild (UC - 4 and CD - 8) to moderate (UC - 8 and CD - 12) stages of clinical activity. Only 2 patients with CD (and none with UC) were classified as having severe clinical activity. For the evaluation of endoscopic changes we used Roth's score<sup>[12]</sup>. Seven UC patients showed severe endoscopic activity compared to 6 patients with CD. A minority of patients in the UC group showed mild (2 children) to moderate (3 patients) endoscopic activity, as compared to the CD group (7 and 6 patients, respectively). Histology was assessed blindly by an independent histopathologist. All patients with IBD were in the active phase of the disease.

The use of antibiotics 30 d prior to enrolment,

infectious diarrhea, malabsorption, immunodeficiencies and intestinal enteropathies were the exclusion criteria.

### Sampling of mucosa

All subjects underwent the same type of preparation prior to colonoscopy, with oral sodium phosphate at a dose of 0.6-0.8 mL/kg (up to 45 mL) and bowel cleansing, consisting of 4 saline enemas. During colonoscopy, patients received intravenous sedation or general anesthesia, as required. Biopsy samples from IBD patients were obtained from both, the inflamed and the non-inflamed colonic mucosa. Four biopsy specimens were taken from both sites: two for culture, and one each for standard histopathological assessment and mucus thickness measurement. In the control group, the biopsy samples were taken from a normal sigmoid colon for the same assessments. The biopsy samples were transferred directly into Schaedler Anaerobic Broth (SAB) medium (Difco, BD, Franklin Lakes, USA) with 10% of glycerol. The samples were immediately snap frozen on dry ice and kept at -80°C or on dry ice until analysis. All procedures were performed as fast as possible, using sterile instruments and ensuring the integrity of the intestinal tissue. The codes of the biopsy samples were blinded before performing microbiological analysis.

### Bacteriology

The frozen samples were thawed, weighed, homogenized in 1 mL of SAB and quantitatively analyzed for the main bacterial constituents by cultures on differential media in aerobic and anaerobic conditions<sup>[9]</sup>. All these manipulations were done aseptically in an anaerobic chamber (MACS - MG 500 Work Station, DW Scientific, Shipley, UK) in N<sub>2</sub> (85%) + H<sub>2</sub> (10%) + CO<sub>2</sub> (5%) atmosphere. Homogenized samples were serially diluted with SAB and 100 µL aliquots plated on the following media: McConkey Agar (Oxoid, Basingstoke, UK) for *Enterobacteriaceae*, Columbia Blood Agar (Difco) with 5% sheep blood for streptococci, Enterococcosel Agar (BBL, BD, Franklin Lakes, USA) for enterococci, MRS agar (Oxoid) for lactobacilli and other lactic acid bacteria (LAB), BL agar for bifidobacteria<sup>[13]</sup>, and Wilkins-Chalgren Agar Base with supplements for *Bacteroides*.

The dilutions were then spread over the plate surface using a glass rod and the plates were then incubated aerobically at 37°C for 24 h, except for the cultures for anaerobic bacteria, which were kept in the anaerobic chamber for up to 4 d depending on the type of medium. The morphology of the grown colonies was analyzed under magnifying glass and several colony picks of each morphological type were subcultured on appropriate aerobic and anaerobic media and Gram-stained. After further incubation and culture purity checks, phenotypic identification was performed using commercial identification systems (API 20E, API20A, APIStaph, APIStrept, bioMerieux, Marcy l'Etoile, France; BBL Crystal ID System, BD, Franklin Lakes, USA).

### Measurement of the mucus layer thickness

The frozen biopsy samples, collected as described

above, were cut into 5 µm sections, thawed and fixed to microscopic slides and stained with fluorescein labeled *Maackia amurensis* lectin MAA lectin (EY Labs, San Mateo, USA) which binds to 2-3 linked sialic acid<sup>[14]</sup>. Briefly, the lectin solution (20 µg/mL in 0.05% sodium azide solution in a buffer supplied by the producer) was applied in a 50 µL volume to each slide and incubated under cover in a dark moist chamber at room temperature for 0.5 h. Then the unbound lectin was washed out with the buffer and the slides were counterstained with DAPI (Sigma, St. Louis, USA), washed again and dried. The mucus thickness was measured under a fluorescent microscope (Olympus BX51) with 100 × magnification.

### Statistical analysis

Comparisons were made using the Student's *t* test for variables with a normal distribution and  $\chi^2$  test. For comparison of bacterial populations and ratios of particular bacterial groups the likelihood ratio was used. The Wilcoxon test and Wilcoxon signed-rank test for matching pairs were used to compare mucus thickness. These statistical methods were chosen because data distribution was significantly different from normal distribution. All analyses were conducted using SAS 9.1 package and SAS Enterprise Guide 3.0 (SAS Institute, USA). Data are expressed as mean ± SD.

## RESULTS

All biopsy specimens from IBD patients and controls showed the presence of all groups of bacteria in the cultures although of different populations. The total number of mucosa-associated bacteria was higher in IBD patients compared to the controls with functional abdominal pain, however, the differences were statistically significant only in the UC group. Because of high diversities among the isolated bacteria and their numbers, the ratios of bacterial groups present were calculated as pooled numbers of bacteria weighted by the number of patients in the groups (Table 1).

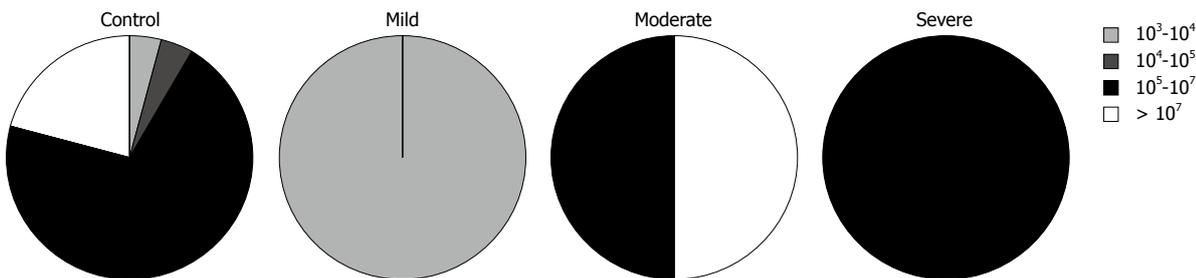

The ratios of different bacterial groups cultured from biopsies obtained both from inflamed and non-inflamed sites in IBD patients were different in samples taken from children with specific diseases. The differences were statistically significant ( $\chi^2$  test,  $P < 0.0001$ ). *Streptococci* were the predominant group of bacteria in inflamed mucosa of CD patients. About 80% of all microbiota cultured from the tissue belonged to these genera. On the other hand, patients with UC showed predominance of *Lactobacillus* (90%) in inflamed sites (Table 1). Both CD and UC patients showed a significant reduction in the ratios for anaerobes such as *Bifidobacterium* in samples taken from inflamed compared to non-inflamed mucosa. Considering the ratios of bacteria found in non-inflamed mucosa of IBD patients as compared with those found in controls, it appeared that bifidobacteria were the predominant group in all these sites (Table 1).

We also looked at the relationship between the total numbers of bacteria and disease activity, measured using PCDAI for CD patients and the modified Trulove-Witts

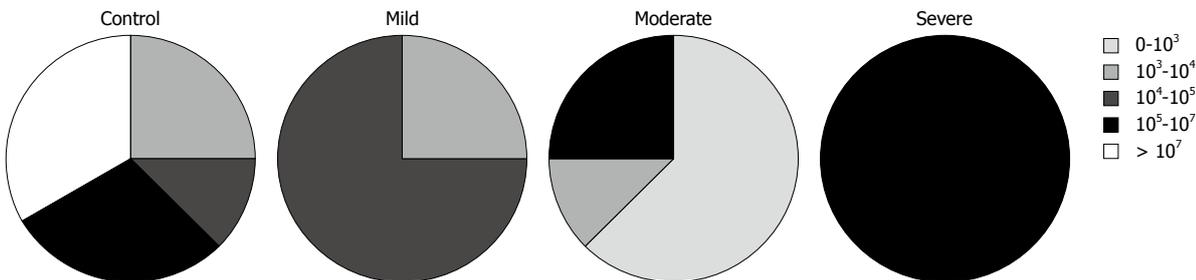

**Table 1** Median number of isolated bacteria per gram in different groups from inflamed and non inflamed tissue taken from children with CD, UC and from the control group

Bacterial groups (taxons)	Children with UC (n = 12)		Children with CD (n = 22)		Children in control group (n = 24)
	Inflamed site	Non-inflamed	Inflamed site	Non-inflamed	
<i>Enterobacteriaceae</i>	$4.92 \times 10^5$	$5.55 \times 10^6$	$2.17 \times 10^7$	$9.71 \times 10^6$	$1.94 \times 10^7$
<i>Enterococcus</i>	$1.80 \times 10^6$	$1.27 \times 10^6$	$1.36 \times 10^6$	$1.43 \times 10^6$	$6.82 \times 10^5$
<i>Streptococcus</i>	$6.83 \times 10^5$	$1.07 \times 10^6$	$1.29 \times 10^{6b}$	$1.33 \times 10^6$	$5.39 \times 10^6$
<i>Lactobacillus</i>	$9.28 \times 10^{7a}$	$7.30 \times 10^6$	$3.37 \times 10^6$	$7.76 \times 10^6$	$1.01 \times 10^7$

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 differences between inflamed site and the control group; CD: Crohn’s disease; UC: Ulcerative colitis.

**Figure 1** Relationships between endoscopic activity and total numbers of bacteria cultured from biopsies of UC patients and the control group. Likelihood ratio = 9.535, *P* = 0.0490. UC: Ulcerative colitis.

**Figure 2** Relationships between disease activity and numbers of *Lactobacillus* group of bacteria cultured from biopsies of CD patients and the control group. Likelihood ratio = 13.209, *P* = 0.0398. CD: Crohn’s disease.

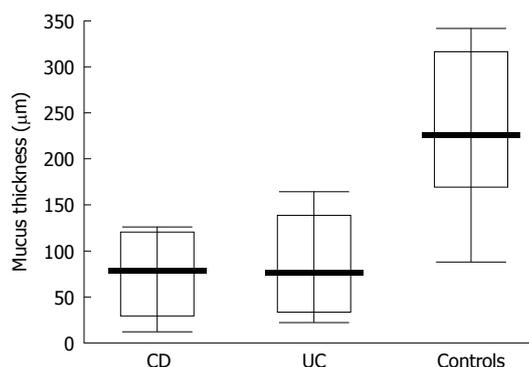

score for UC in addition to the Roth’s endoscopic scoring index. To express these relationships we adopted the five interval scale of bacterial populations from Swidsinski *et al*<sup>[5]</sup>: 0-10<sup>3</sup> cfu/g, 10<sup>3</sup>-10<sup>4</sup> cfu/g, 10<sup>4</sup>-10<sup>5</sup> cfu/g, 10<sup>5</sup>-10<sup>7</sup> cfu/g, and > 10<sup>7</sup> cfu/g.

The total numbers of cultured bacteria found in biopsies from inflamed mucosa of UC patients was increased with severity of the disease estimated by endoscopic activity (Figure 1). This relationship was statistically significant (likelihood ratio = 9.535, *P* = 0.0490). In relation to specific groups of bacteria, this analysis showed that the number of lactobacilli, which was the predominant group in the samples from inflamed mucosa of patients with UC, was lower in samples taken from patients with severe endoscopic activity. This was, however, not statistically significant (likelihood ratio = 6.959, *P* = 0.1381).

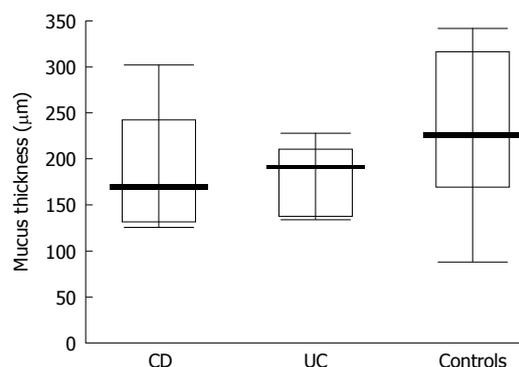

There was no relationship between the total numbers of bacteria in samples from inflamed sites and severity of the disease in CD patients. In relation to various groups of bacteria, the analysis showed that numbers

of lactobacilli were lower in samples with higher clinical activity (likelihood ratio = 13.209, *P* = 0.0328, Figure 2). The same tendency, although less significant, was observed for numbers of streptococci in samples from CD patients (likelihood ratio = 13.889, *P* = 0.0847).

When studying the thickness of the mucus layer in biopsies taken from inflamed sites of the gut in adolescents with IBD, it appeared thinner when compared to the controls (CD-74 ± 40 μm; UC-83.35 ± 49.93 μm; controls- 218 ± 81.07 μm) and these differences were statistically significant (*P* = 0.0047 and *P* = 0.0093, respectively) (Figure 3). Also, the matching pair test analysis showed a statistically significant thinner mucus layer in inflamed as compared to non-inflamed sites in the same IBD patients (*Z* = 10.50, *P* = 0.031). Focusing on specific IBD groups and comparing inflamed to non-inflamed sites, the difference was significant in CD (*P* = 0.0109), but not in UC patients (*P* = 0.0662). On the other hand, there was no difference between the CD and control group (*P* = 0.7003) and the UC and control

**Figure 3** The average thickness of the mucus layer in biopsy samples obtained from inflamed areas in CD ( $H = 8.0$ ,  $P = 0.0047$ ) and UC ( $H = 6.76$ ,  $P = 0.0093$ ) patients and controls. The horizontal line represents median value with 25% and 75% quartile.

**Figure 4** The average thickness of the mucus layer in biopsy samples obtained from non-inflamed areas in CD ( $H = 0.1481$ ,  $P = 0.7003$ ) and UC ( $H = 0.987$ ,  $P = 0.3137$ ) patients and controls. The horizontal line represents median value with 25% and 75% quartile.

group ( $P = 0.3137$ ) (Figure 4) when comparing the thickness of the mucus layer in biopsies from non-inflamed areas in IBD patients to those of the control group.

When trying to assess the histopathological activity and goblet cell depletion according to the scoring index proposed by Kudo *et al.*<sup>[16]</sup>, we found no statistically significant differences between thinner and thicker mucus layer sites both in the UC and CD groups. However, histopathological activity and goblet cell depletion was more severe in the UC group (77% and 61.5%, respectively) than in the CD group (59.1% and 32%, respectively).

Considering the numbers of bacteria contained in the biopsy samples, their ratios and the mucus thickness no relationship was found between age, gender and disease status of the patients.

## DISCUSSION

It is well known that bacterial microflora in the human gastrointestinal tract play an important role in maintaining human health and may also contribute to the pathogenesis of IBD<sup>[17]</sup>. The data from animal models of IBD suggest that intestinal inflammation is dependent on the presence of intestinal microflora, although no specific pathogen has been identified and confirmed to be responsible for this process. Some studies performed on adult patients showed a strong correlation between disease activity and increased numbers of bacteria attached to the mucosa<sup>[18,19]</sup>. Although in our study we did not observe a significant increase in microflora contained in the biopsy samples in IBD adolescents in relation to controls, we did find a higher number of bacteria in biopsies taken from UC patients, particularly in those with the most advanced stage of changes as estimated at endoscopy. Increasing disease activity was inversely related to the numbers of lactobacilli in samples from CD (but not from UC patients) and to a minor degree to *Streptococcus*.

In various studies carried out on adult IBD patients, it is possible to find conflicting results relating to the numbers of specific groups or genera of bacteria with respect to inflammation. Some authors reported increased numbers of aerobic Gram-negative rods (*E. coli*), while others found increased numbers of non-spore forming

anaerobes (*Proteobacteria* and *Bacteroides*) and decreased numbers of spore-forming anaerobes like *Clostridium*<sup>[20-24]</sup>. There are also papers in which the authors found no differences between the bacterial flora in inflamed and non-inflamed tissue in the same patient<sup>[25,26]</sup>. On the contrary, Sepehri *et al.*<sup>[27]</sup> using a PCR method showed significant differences in bacterial flora between the inflamed and non-inflamed mucosa, and an increase in microbial diversity in controls and the non-inflamed tissue from adult IBD patients.

We found differences in microflora composition between endoscopically inflamed and non-inflamed mucosal sites in newly diagnosed IBD adolescents which were specific for each form of the disease. In the controls and in the endoscopically non-inflamed mucosa of IBD children there were high numbers of bifidobacteria compared with decreased populations of these bacteria in inflamed sites of IBD patients. Thus, our observations are in concordance with the earlier findings of Seksik *et al.*<sup>[28]</sup> who also showed decreased numbers of *Bifidobacterium* and *Enterobacteriaceae* in adult patients with active and inactive CD. Our CD and UC patients also had decreased numbers of *Bifidobacterium* in inflamed mucosal sites compared with controls. It should also be noted that the numbers of lactobacilli, known for their protective effect in IBD, were lower in samples from CD adolescents with severe inflammation in our study<sup>[29]</sup>. Seksik *et al.*<sup>[28]</sup> showed that the numbers of *Lactobacillus* strains were low in active and inactive CD adult patients.

Conte *et al.*<sup>[9]</sup> recently reported the first, to our knowledge, study on gut-associated bacterial microflora in children with IBD. They found higher numbers of aerobic and facultative anaerobic bacteria in biopsy specimens from IBD children in comparison to controls, but lower numbers of *Bacteroides* in CD patients.

It should be noted that more than 50% of intestinal bacteria are not cultivable and this may represent a limitation of the study. Furthermore, molecular analytical methods have utility in discriminating between bowel microbiota of altered compositions and could be used in future studies in children. These techniques enable characterization as well as quantification of the microbiota; composition of the microbiota may be identified with

clone libraries, fingerprinting techniques may be used to analyze microbial community structure and dot blot hybridization or fluorescent *in situ* hybridization (FISH) may be used to analyze a multitude of given taxa<sup>[30-32]</sup>. In our previous pilot study (results not included here) we used FISH to analyze colonic microflora in children with IBD, however, this approach was limited by low sensitivity of the method.

Considering the conflicting results on microflora in IBD presented in the literature one should remember that the patient populations as well as stages of the illness in various studies were different. Other factors that could strongly affect the results and cause obvious discrepancies were: different sites from which the biopsies were taken, the cleaning procedures and microbiological methods used to identify the microflora. Moreover, it is possible that gut bacterial flora in children is generally less stable than in adults. All these factors could be responsible for the observed variations.

We have carried out our investigation using samples of tissue and feces which were stored at -80°C during transport from the ward to the laboratory. According to Achá *et al*<sup>[33]</sup> and Dan *et al*<sup>[34]</sup>, freezing does not influence viability of fecal samples.

Colonic mucus is an adherent, water insoluble gel that has several functions, including protection of the epithelium from mechanical trauma, toxins, allergens and from microbial invasion<sup>[35]</sup>. Thus, the mucus layer plays a protective role in the intestinal mucosa<sup>[36,37]</sup>. The gut mucus lubricates the passage of food and protects the epithelial cells from direct contact with bacterial flora. The mucus consists of glycoproteins called mucins, which are encoded by many *MUC* genes - to date more than 20 types of *MUC* genes have been described<sup>[38]</sup>. Thickness of the mucus layer is related to the dynamic equilibrium between mucus secretion and its subsequent removal into the lumen. In UC, the absence of an adherent layer in some areas may be a result of inadequate secretion or excessive removal. The findings of various studies on mucus synthesis in colitis have suggested that the epithelial layer remains intact in the presence of mild to moderate inflammation. In the presence of severe inflammation or inactivity, however, it tends to be lower than normal<sup>[10]</sup>.

In our study we have shown that the thickness of the mucus layer lining the intestinal lumen of adolescents with IBD is about three times thinner in both CD and UC patients compared with the control group. A similar relationship was observed in biopsies taken from inflamed and non-inflamed mucosa in the same IBD patients and these differences were statistically significant. In addition, we have demonstrated that mucus layer thickness measured in tissue samples taken from normal sites in patients with IBD was only slightly thinner than that in the control group and the difference was not statistically significant.

At present, there is no data in the literature on the mucus layer in children and adolescents with CD. There is also no clear explanation of observed differences, however, the results of the latest studies are in accordance

with our findings. The course of CD and localization of inflammatory lesions in childhood may be quite different from than in adults. The majority of CD adolescents (63.6%) in our study had colon involvement on endoscopic assessment, similar to UC which may have influenced the observed mucus layer depletion in this group of patients. Moreover, Gersemann *et al*<sup>[39]</sup> using a real-time PCR method in adult IBD patients, showed that goblet cells were diminished in the intestinal biopsies of both UC and CD patients, however, in the CD group enhanced differentiation was found.

In addition, using immunostaining Ardesjö *et al*<sup>[40]</sup> reported the presence of immunoreactive agents in the serum of IBD patients, which reacted with goblet cells in the intestine.

A reduction in mucus layer thickness leads to bacteria from the intestinal lumen having closer contact with the intestinal epithelium, also causing a different selection of microorganisms, which may induce an inflammatory process in the bowel<sup>[10]</sup>. In adult patients suffering from IBD, the numbers of bacterial cells adhering to the intestinal mucus layer are much higher as compared to controls without IBD, and this dependence is proportional to the severity of the clinical course<sup>[19,21]</sup>. Whether this is a result or cause of bowel inflammation still remains unclear, however, the protective property of the mucosa is significantly weakened by this process.

In summary, our results showed that non-inflamed mucosa in both IBD patients and controls was covered with a thick mucus layer with the attached microflora showing a predominance of *Bifidobacterium*. In contrast, in inflamed sites there was a reduction in mucus layer thickness with the prevalence of specific bacterial groups which were different for CD and UC: *Streptococcus* in CD and *Lactobacillus* in UC. However, numbers of these bacteria decreased proportionally with the intensity of inflammation. Thus, our results also support the idea of a disruption of the balance between the different protective and harmful intestinal bacteria in the gastrointestinal tract. These results also provide evidence which suggest that the therapeutic use of probiotics, especially those containing *Bifidobacterium* and *Lactobacillus* may have some positive effects in patients with IBD.

## COMMENTS

### Background

The pathogenesis of inflammatory bowel disease (IBD) still remains unclear. Genetic, environmental and immunological factors seem to play a substantial role. However, an increasing number of both clinical and laboratory studies support the idea of the leading role of bacterial microflora in the onset and persistence of inflammation. It is well known, that the anatomic sites with the highest concentrations of luminal bacteria are most often involved in the inflammatory process. The intestinal flora of patients with active Crohn's disease (CD) is different from that of quiescent subjects, ulcerative colitis (UC) patients and healthy controls. Transgenic mice kept under germ-free conditions did not develop inflammation until bacteria were introduced. In recent years several studies on gut microflora have suggested that inflammation may be due to a shift in the balance of healthy flora, which leads to dysbiosis and triggers or maintains inflammation.

### Research frontiers

The multiple interactions among bacterial microflora, mucus and host immunity

in the children's mucosa play a crucial role in IBD pathogenesis. We suggest that the local mucus layer in the intestine, especially in childhood, determines bacterial colonization and metabolism. The aim of our study was to assess mucosa-associated bacterial microflora and mucus layer thickness in relation to the inflammatory process in adolescents with newly diagnosed IBD in comparison to controls.

### Innovations and breakthroughs

Up to now, this is the second study focused on the mucosa-associated bacterial microflora in children with IBD, used both culture and a PCR amplification method, and found significant differences between CD and UC children. The authors went a step further and assessed both the mucosa-associated bacterial microflora and intestinal mucosa.

### Applications

Assessment of the multiple interactions among bacterial microflora and mucus in the very early stage of IBD, seen in newly diagnosed disease, is essential for a better understanding of disease pathogenesis and may help in suggesting therapeutic options such as the use of specific probiotics or antimicrobial treatment.

### Terminology

Mucosa-associated bacterial microflora consists of bacteria that are located very close to the mucus layer. This layer forms a specific environment in the gut and its disruption may play a crucial role in the development of IBD, promoting specific bacterial colonization and immunological response. The colonic mucus layer is an adherent, water insoluble gel that has several functions, including protection of the epithelium from mechanical trauma, toxins, allergens and from microbial invasion. The mucus consists of glycoproteins called mucins, which are encoded by many *MUC* genes - to date more than 20 types of *MUC* genes have been described. Thickness of the mucus layer is related to the dynamic equilibrium between mucus secretion and its subsequent removal into the lumen.

### Peer review

The authors demonstrated changes of mucosa-associated microbiota in adolescents with IBD, using classical culture techniques. They also showed depletion of the mucus layer in IBD patients. This paper is well documented.

### Abstract

**AIM:** To evaluate gastrointestinal (GI) symptoms and breath hydrogen responses to oral fructose-sorbitol (F-S) and glucose challenges in eating disorder (ED) patients.

**METHODS:** GI symptoms and hydrogen breath concentration were monitored in 26 female ED inpatients for 3 h, following ingestion of 50 g glucose on one day, and 25 g fructose/5 g sorbitol on the next day, after an overnight fast on each occasion. Responses to F-S were compared to those of 20 asymptomatic healthy females.

**RESULTS:** F-S provoked GI symptoms in 15 ED patients and one healthy control ( $P < 0.05$  ED vs control). Only one ED patient displayed symptom provocation to glucose ( $P < 0.01$  vs F-S response). A greater symptom response was observed in ED patients with a body mass index (BMI)  $\leq 17.5$  kg/m<sup>2</sup> compared to those with a BMI  $> 17.5$  kg/m<sup>2</sup> ( $P < 0.01$ ). There were no differences in psychological scores, prevalence of functional GI disorders or breath hydrogen responses between patients with and without an F-S response.

**CONCLUSION:** F-S, but not glucose, provokes GI symptoms in ED patients, predominantly those with low BMI. These findings are important in the dietary management of ED patients.

### INTRODUCTION

A high prevalence of gastrointestinal (GI) symptoms, fulfilling criteria for functional GI disorders (FGID), is present in patients with eating disorders (ED), with more than half of a large sample of ED inpatients meeting the symptom criteria for irritable bowel syndrome (IBS)<sup>[1]</sup>. In addition to the distress caused by these chronic or recurrent GI symptoms, such symptoms may potentially interfere with the nutritional rehabilitation of ED patients.

Ingestion of fructose-sorbitol (F-S) is an established means of GI symptom provocation in IBS patients<sup>[2,3]</sup>. It remains controversial whether such symptom provocation is related to hydrogen production in the colon as a result of incomplete small bowel absorption. Because both fruit and sorbitol-containing "diet" products are frequently consumed by ED patients<sup>[4]</sup>, we hypothesized that ingestion of both these substances together may be an important factor in the genesis of the GI symptoms in ED patients. Furthermore, we hypothesized that certain characteristics associated with ED, such as body weight, and behavioral and psychological features, could influence the responses to F-S symptom provocation.

The specific aims of this study were therefore: (1) to determine the prevalence of F-S symptom provocation in female ED patients when compared to healthy female subjects; (2) to determine the specificity of any positive symptom response to F-S by evaluating whether, in ED patients, symptom provocation is greater after F-S

ingestion than after glucose ingestion, a substance not recognized to provoke GI symptoms; (3) to examine the relationships between body mass index (BMI), menstrual status, behavioral and psychological characteristics, type of ED and the F-S symptom responses; (4) to determine if symptom provocation is related to the presence of symptoms compatible with IBS, or to the number of FGIDs present in an ED patient; and (5) to determine whether F-S symptom provocation in ED patients, if present, is related to incomplete small bowel absorption of F-S detected by breath hydrogen testing.

## MATERIALS AND METHODS

### Subjects

Twenty-six consecutive female ED inpatients ( $23 \pm 7$  years, BMI  $18.6 \pm 3.6$  kg/m<sup>2</sup>) from the Eating Disorder Unit at the Northside Clinic, Sydney, Australia, participated in the study. Inclusion criteria were eating disorder diagnosis<sup>[5]</sup> confirmed by a specialist psychiatrist and a specialist psychologist, minimum age 16 years, and no known organic GI or other systemic disease. The study was conducted 2 wk after admission to hospital. ED assessment included current BMI, menstrual status, and ED behaviors (self-induced vomiting, laxative abuse, binge eating). Ten patients had a diagnosis of anorexia nervosa, 5 bulimia nervosa, and 11 eating disorder not otherwise specified (EDNOS: 6 purging type and 5 restricting type). Twenty asymptomatic, normal weight, healthy women ( $31 \pm 9$  years) who underwent F-S provocation breath testing in our laboratory using the same protocol as the ED patients formed a control group. Informed consent was obtained from all subjects, and the study was approved by the Ethics Committee of the Northside Clinic.

### GI symptom, psychological and behavioral assessment

The following self-report questionnaires were administered to the ED patients: the Rome II modular questionnaire<sup>[6]</sup>, the Beck Depression Inventory (BDI)<sup>[7]</sup>, the Eating Attitudes Test (EAT)<sup>[8]</sup>, the Eysenck Personality Questionnaire - neuroticism (EPQ)<sup>[9]</sup>, the Spielberger State-Trait Anxiety Inventory (STAI)<sup>[10]</sup>, the Brief Symptom Inventory - somatization (BSI)<sup>[11]</sup>, and the Quality of Life Eating Disorder Scale (QOL ED)<sup>[12]</sup> of the computerized Eating and Exercise Examination<sup>[13]</sup>.

### Experimental protocol

On the evening prior to the test day, subjects ate a carbohydrate-free dinner, and then fasted from midnight until the end of testing the following day. Immediately prior to testing the subjects brushed their teeth, and subjects were not allowed to eat, drink, or smoke cigarettes during the testing<sup>[3]</sup>.

In the ED patients, substrate testing took place on 2 consecutive days. On the first day patients underwent a challenge with a glucose solution and on the second day with an F-S solution. Three baseline breath hydrogen samples were obtained on each day. Patients then ingested 50 g glucose dissolved in 250 mL water (2200 mOsm/L), or an F-S mixture of 25 g fructose and 5 g sorbitol

dissolved in 250 mL water (1680 mOsm/L)<sup>[3,14]</sup>. Breath samples were obtained at 10 min intervals for a 3 h period, and the hydrogen concentration (ppm) of each sample was determined<sup>[3]</sup> on a portable instrument (Gastrolyser II, Bedford Pty Ltd., UK). The instrument was calibrated with research grade hydrogen, as per the manufacturer's recommendations. Patients were blind to the order of substrate challenge, and were not aware of the hydrogen concentrations obtained.

### Symptom assessment during provocative testing

A standard proforma assessment of GI symptoms was completed before, and at 1, 2, and 3 h following ingestion of the test solutions<sup>[3]</sup>. The symptoms rated were: abdominal pain, abdominal discomfort, abdominal bloating, abdominal distension, belching, nausea, loose or increased frequency of bowel motions, sensation of fullness, borborygmi, and flatulence. These symptoms were each rated on a score of 0 to 3, as follows: absent (score 0); mild (score 1); moderate (score 2); or severe (score 3).

### Statistical analysis

An hourly symptom score was determined by summing the individual symptom scores (corrected for baseline) for each symptom at hour 1, hour 2 and hour 3. A total symptom score was obtained by summing the 3-hourly symptom scores. A symptom response was defined as a total symptom score of 5 or greater; this measure was used to relate symptom provocation to BMI, behavioral characteristics and psychological measures, type of ED and presence of FGIDs. A BMI  $\leq 17.5$  kg/m<sup>2</sup> was used to determine 2 categories of ED patients<sup>[5]</sup>. The total number of FGIDs was determined for each ED patient. A breath hydrogen level  $\geq 20$  ppm above baseline was used as a cut-off value to categorize each subject as either a "malabsorber", or an "absorber" (i.e. no breath hydrogen response)<sup>[3]</sup>. Mouth-to-cecum transit time was defined as the time between ingestion of the solution and an increase in breath hydrogen of 10 ppm in 3 consecutive samples<sup>[15]</sup>. Peak hydrogen level was taken as the maximum hydrogen value recorded during the 3-h test period. To test for differences between groups, the Chi square with Fisher's Exact test for low cell numbers, ANOVA, and the Student's *t*-test were used where appropriate. Unless otherwise noted, results are presented as frequencies or mean  $\pm$  SD, and *P* values  $< 0.05$  are considered significant.

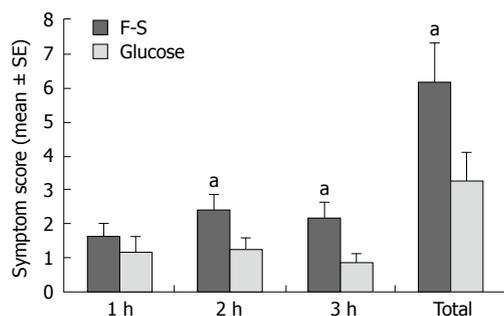

## RESULTS

### F-S symptom provocation in ED patients and controls

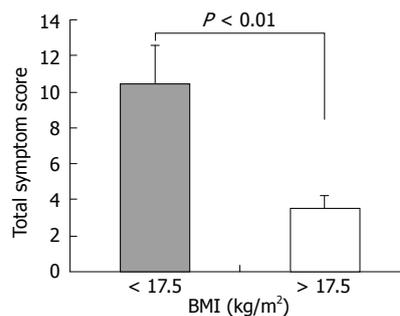

Fifteen (58%) ED patients compared to one (5%) control subject reported one or more individual symptoms at 3 h after F-S provocation (*P*  $< 0.05$ ).

### F-S vs glucose symptom provocation in ED patients

Hourly and total symptom scores following F-S and glucose ingestion are shown in Figure 1. There was a significantly greater symptom score following F-S than

**Figure 1** Hourly and total symptom scores in eating disorder patients following ingestion of 25 g fructose-5 g sorbitol (F-S) and 50 g glucose (<sup>a</sup>*P* < 0.05 vs glucose).

**Figure 2** Total symptom scores (mean ± SE) in eating disorder patients following ingestion of 25 g fructose-5 g sorbitol, grouped according to body mass index (BMI).

**Table 1** Type of eating disorder and ED behaviors in patients according to symptom response to fructose-sorbitol

	No symptom response ( <i>n</i> = 12)	Symptom response ( <i>n</i> = 14)
Type of eating disorder	f (%)	f (%)
Anorexia nervosa	2 (17)	8 (57)
Bulimia nervosa	4 (33)	1 (7)
EDNOS	6 (50)	5 (36)
Eating disorder behaviors		
Self-induced vomiting	7 (58)	6 (43)
Laxative abuse	1 (8)	1 (7)
Binge eating	7 (58)	2 (14) <sup>1</sup>

ED: Eating disorder; EDNOS: Eating disorder not otherwise specified; f: Frequency; <sup>1</sup> $\chi^2 > 5.54$ , *df* = 1, *P* < 0.05 (Fisher's exact test).

there was following glucose at both 2 and 3 h. Fourteen (55%) patients exhibited a symptom response to F-S, while only one (4%) patient exhibited a symptom response to glucose (*P* < 0.01).

**F-S symptom provocation and ED characteristics**

Total symptom score for patients with a BMI ≤ 17.5 kg/m<sup>2</sup> was significantly higher than that of patients with a BMI >17.5 (Figure 2). Excluding 7 patients who were taking oral contraception, 7 (64%) of the 11 patients with a symptom response were suffering from oligo- or secondary amenorrhoea, compared with 2 (25%) of the 8 patients with no symptom response; this difference did not reach statistical significance.

There was no significant difference in type of ED diagnosis in patients with and without an F-S symptom response (Table 1), although 80% of anorexia nervosa patients showed a symptom response. There was a significant difference in binge eating behavior between patients with and without an F-S symptom response (Table 1). There were no differences in psychological or QOL ED scores between ED patients with and without an F-S symptom response (Table 2).

**F-S symptom provocation and FGID**

Sixteen patients fulfilled the criteria for IBS, while 8 patients had 3 or more FGID diagnoses. There was no significant difference in the prevalence of IBS or in the proportion of patients with 3 or more FGIDs, in ED

**Table 2** Psychological characteristics and QOL ED in ED patients according to symptom response to fructose-sorbitol (mean ± SD)

	No symptom response ( <i>n</i> = 12)	Symptom response ( <i>n</i> = 14)
Eating attitudes test	62 ± 26	67 ± 19
BSI somatization	14.0 ± 8.1	13.6 ± 7.1
BDI depression	30.4 ± 12.6	30.8 ± 7.0
STAI trait anxiety	63.6 ± 9.7	61.0 ± 7.2
STAI state anxiety	60.1 ± 9.4	63.3 ± 10.2
EPQ neuroticism	19.3 ± 2.5	20.6 ± 2.5
QOL ED global	17.0 ± 3.2	14.7 ± 2.4
QOL ED psychological	3.3 ± 1.1	3.2 ± 1.3

patients with (73%, 36% respectively) and without (80%, 40%) an F-S symptom response.

**F-S breath hydrogen response in ED patients and controls**

Thirteen (50%) ED patients and 14 (70%) control subjects malabsorbed F-S; this difference was not significant. There were no significant differences in the peak hydrogen levels between ED “malabsorbers” and control subject “malabsorbers” (71 ± 31 ppm *vs* 48 ± 30 ppm). In ED patients, there were no significant differences in total symptom scores between F-S “malabsorbers” (8 ± 7) and “absorbers” (5 ± 3). When the ED “malabsorbers” were compared with the ED “absorbers” there were no significant differences in the prevalence of IBS (85% *vs* 63%), or the number of ED patients with ≥ 3 FGIDs (46% *vs* 25%). The mouth-to-cecum transit time for ED “malabsorbers” was significantly longer (106 ± 35 min) than for control subject “malabsorbers” (54 ± 25 min, *P* < 0.001).

**DISCUSSION**

This study is the first to examine the GI symptom responses to F-S ingestion in patients with eating disorders. The key findings are that F-S provoked symptoms in more than half of female ED patients.

This is a significantly greater proportion than that found in healthy individuals. Moreover, the response was specific for F-S ingestion. Additionally, there was a greater symptom response in patients at lower BMI values; consistent with this finding, symptom provocation was more common in anorexia nervosa patients. Symptom provocation was not related to the patients' psychological characteristics, to the presence of chronic digestive tract symptoms such as IBS, or to the presence of a positive breath hydrogen response to F-S.

These findings are clinically relevant to the day-to-day management of ED patients. Eating disorder patients preferentially select low energy foods, including fruit and diet drinks<sup>[4]</sup>. Fructose, a monosaccharide, is found naturally in fruit, including apples, grapes and stone fruit<sup>[16]</sup>. Sorbitol, a sugar alcohol, is present in diet drinks, chewing gum, artificial sweeteners and in some fruits such as apples. These 2 substances are therefore likely to be commonly ingested by ED patients, representing a potential source of GI distress that would impact negatively on their nutritional management. In this context, F-S provocative testing could prove valuable in identifying those patients with symptom sensitivity to these substances. Such testing may be of particular importance in very low weight ED patients. Breath testing in association with the F-S challenge, however, does not appear to provide additional clinically useful information. Thus an F-S challenge without breath testing would be sufficient. This approach would also obviate the need for dietary restriction prior to the challenge, a restriction that is contraindicated in the treatment of ED patients in whom "normal" eating behavior is being established.

We chose a dose of F-S (25 g fructose and 5 g sorbitol) that had been previously evaluated in IBS patients<sup>[2,3]</sup>, and shown to produce a greater symptom response than a dose of 20 g fructose and 5 g sorbitol<sup>[9]</sup>. A recent study has supported a dose of 25 g fructose as the optimal challenge for testing for fructose malabsorption<sup>[17]</sup>. The dose of glucose was chosen based on that recommended for the evaluation of small bowel bacterial overgrowth<sup>[18]</sup>.

The mechanisms involved in the symptom response to F-S are not clear. The response was not related to the presence of F-S malabsorption or to the psychological characteristics of the patients. An osmotic effect is unlikely, given that the glucose challenge - of similar osmolality to the F-S solution - did not provoke symptoms. The mechanism, however, does appear to be a genuine physiologic phenomenon. A factor associated with low body weight, and presumably a significant negative energy balance, appears to be involved. A role of negative energy balance is also indicated by the observed increased menstrual disturbance among the symptom responders. Underlying disordered gut physiology in the ED patients, as evidenced by a prolongation of mouth-cecum transit time, is another factor of potential relevance. Despite this, there was no evidence for the presence of small bowel bacterial overgrowth in our patients, based on the glucose breath hydrogen testing and using accepted definitions<sup>[14,18]</sup>.

In conclusion, given the novel findings observed in

this study, further research should be undertaken to enable the formulation of more precise guidelines regarding F-S sensitivity and the dietary management of ED patients. Future studies should address the role of different F-S doses in relation to body weight and the extent to which various foods containing F-S provoke symptoms.

## ACKNOWLEDGMENTS

The assistance of the staff and patients of the Eating Disorders Unit, the Northside Clinic, Sydney, Australia is gratefully acknowledged.

## COMMENTS

### Background

Eating disorder (ED) patients display a high prevalence of gastrointestinal symptoms and functional gastrointestinal disorders such as irritable bowel syndrome (IBS). These symptoms may interfere with their nutritional management. Ingestion of fructose-sorbitol (F-S) is an established means of gastrointestinal symptom provocation in irritable bowel syndrome patients. Surprisingly, although ED patients are known to consume "diet" products containing fructose and sorbitol, their gastrointestinal symptom responses to F-S provocation have not been studied.

### Research frontiers

It remains controversial whether ingestion of F-S (25 g fructose and 5 g sorbitol) provokes symptoms in IBS by hydrogen production in the colon as a result of incomplete small bowel absorption. Because both fruit and sorbitol-containing "diet" products are frequently consumed by ED patients, ingestion of both these substances together may be an important factor in the genesis of gastrointestinal symptoms in ED patients. Furthermore, certain characteristics associated with ED, such as body weight, and behavioral and psychological features, could influence the responses to F-S symptom provocation.

### Innovations and breakthroughs

The key findings of this study are that F-S provoked gastrointestinal symptoms in more than half of the female ED patients, a significantly greater proportion than that found in healthy individuals; the response was specific for F-S ingestion; and there was a greater symptom response in patients at lower BMI values. Consistent with this last finding, symptom provocation was more common in anorexia nervosa patients. Hence negative energy balance appears to play a role in F-S sensitivity in these patients.

### Applications

As fructose and sorbitol are likely to be commonly ingested by ED patients, representing a potential source of gastrointestinal distress that would impact negatively on their nutritional management, F-S provocative testing could prove valuable in identifying those patients with symptom sensitivity to these substances. Further studies could address the role of different F-S doses in relation to body weight and the extent to which various foods containing F-S provoke symptoms.

### Terminology

Fructose: A monosaccharide, found naturally in fruit, including apples, grapes and stone fruit; Sorbitol: A sugar alcohol, present in diet drinks, chewing gum, artificial sweeteners and in some fruits such as apples.

### Peer review

This study documents the provocation of symptoms in patients with eating disorders who have been challenged with a fructose-sorbitol dose.

### Abstract

**AIM:** To determine if a nasojejunal tube (NJT) is required for optimal examination of enteroclysis and if patients can be examined only in the supine position.

**METHODS:** Data were collected from all patients undergoing small bowel (SB) magnetic resonance imaging (MRI) examination over a 32-mo period. Patients either underwent a magnetic resonance (MR) follow-through (MRFT) or a MR enteroclysis (MRE) in the supine position. The quality of proximal and distal SB distension as well as the presence of motion artefact and image quality were assessed by 2 radiologists.

**RESULTS:** One hundred and fourteen MR studies were undertaken (MRFT-49, MRE-65) in 108 patients in the supine position only. Image artefact was more frequent in MRE than in MRFT (29.2% vs 18.4%), but was not statistically significant ( $P = 0.30$ ). Adequate distension of the distal SB was obtained in 97.8% of MRFT examinations and in 95.4% of MRE examinations, respectively. Proximal SB distension was, however, less frequently optimal in MRFT than in MRE ( $P = 0.0036$ ), particularly in patients over the age of 50 years ( $P = 0.0099$ ). Image quality was good in all examinations.

**CONCLUSION:** All patients could be successfully im-

### INTRODUCTION

Investigation of small bowel (SB) pathology can be very difficult. Assessment of the terminal ileum (TI) by endoscopy is not optimal and conventional barium radiology (SB follow-through or SB enteroclysis) has a sensitivity of 23%-80% for the detection of lesions typical of Crohn's disease (CD)<sup>[1-3]</sup>. Wireless capsule endoscopy may allow for excellent visualisation of the SB mucosa and any abnormalities, but its specificity is lower than other methods<sup>[3]</sup> and it often does not clearly localise the area of the small intestine where a lesion is identified. There is also a small but definite capsule retention rate that contraindicates its use in SB strictures<sup>[4]</sup>. Computed tomography enteroclysis (CTE) has a good sensitivity of 71%-95% and an impressive specificity of 90%-98% and is superior to conventional enteroclysis<sup>[5,6]</sup>. A single abdominal CT, however, may increase a patient's lifetime risk of malignancy<sup>[7]</sup>, which is even greater in the younger population<sup>[8]</sup>. The sensitivity and specificity of SB magnetic resonance imaging (MRI) examinations are also higher in the evaluation of CD than CTE<sup>[9]</sup>. Although MRI cannot provide the consistently good mucosal detail as conventional enteroclysis, it, however, correlates with pathologic findings and does not use ionising radiation<sup>[10-12]</sup>.

Bowel contrast is required for SB distension and

adequate distension is required for optimal information on mucosal abnormalities, bowel distensibility and passage of the contrast. The difference between magnetic resonance (MR) SB enteroclysis (MRE) and MR SB follow-through (MRFT) is the administration of bowel contrast *via* a nasojejunal tube (NJT) for MRE, which is ingested orally for MRFT. It has been proposed that SB distension is best obtained with the use of a NJT, but patients often describe that placement of a NJT is very unpleasant. A NJT also reduces a potential benefit of MRI as it requires fluoroscopic radiation exposure to insert the tube<sup>[13]</sup>. Recent studies also suggest that MRFT is as sensitive as MRE in the diagnosis of ileal CD<sup>[14]</sup>. Although MRFT and MRI enteroclysis are excellently correlated with disease findings<sup>[15]</sup>, proximal SB distension may not be as optimal as that of MRFT<sup>[12,14,15]</sup>, suggesting that a NJT may still be required.

CD is one of the major indications for investigation of the SB, as approximately 70% of such patients will have inflammatory involvement of the TI. CD is a chronic, relapsing condition with an increasing prevalence<sup>[16]</sup> and may frequently present with intestinal fibrosis, stenosis and obstruction. Fibrosis and stricture formation are the most common indications for intestinal surgical resection<sup>[17]</sup>. Patients undergoing SB radiological investigations are usually examined in the prone position, as it has been suggested that this may result in better SB distension. This, however, is an unpopular technique especially in patients with stomas<sup>[18]</sup>, and it has been reported that the prone and supine positions are equivalent in terms of lesion detection and bowel wall feature visualisation<sup>[19]</sup>.

If optimal SB distension can be obtained without insertion of a NJT, then fluoroscopic radiation could be avoided, which is of particular importance because the predilection of IBD to affect younger patients who frequently require multiple investigations over their lifetime. The aims of this study were thus to assess the difference in the quality of imaging between MRE and MRFT in proximal and distal SB distension and the presence of artefact impairing diagnostic assessment, and to confirm whether imaging of patients in the supine position with a surface array coil can provide abdominal compression and good SB distension in quality studies.

## MATERIALS AND METHODS

All subjects were patients of a 450-bed tertiary institution located in Perth of Western Australia, which is also the site for the "Centre for Inflammatory Bowel Diseases", a specialist unit for the management of inflammatory bowel diseases. Data were collected from all patients undergoing MRFT or MRE over a 32-mo period.

### MRI preparation

Patients were randomly investigated by either MRFT or MRE. If a patient refused a NJT, or placement of the NJT failed due to technical reasons, a MRFT was undertaken. All patients drank only clear fluids for 6 h prior to their MRI and were nil by mouth for 2 h. The bowel contrast agent used was a polyethylene glycol-

water (PEG) solution (glycoprep-C, Pharmatel Fresenius Kabi, Australia). Patients who were to undergo a MRFT attempted to drink 1000 mL or more of the bowel contrast agent over 20 min. For a MRE, a NJT (Bilbao-Dotter, Cook, Australia) was placed under fluoroscope. PEG was injected manually through the NJT (from 60 mL/min to 120-150 mL/min). A total of 800-2000 mL was usually required to distend the SB to the TI, which varied depending on previous bowel resections, the presence of stenosing disease, and patient tolerance.

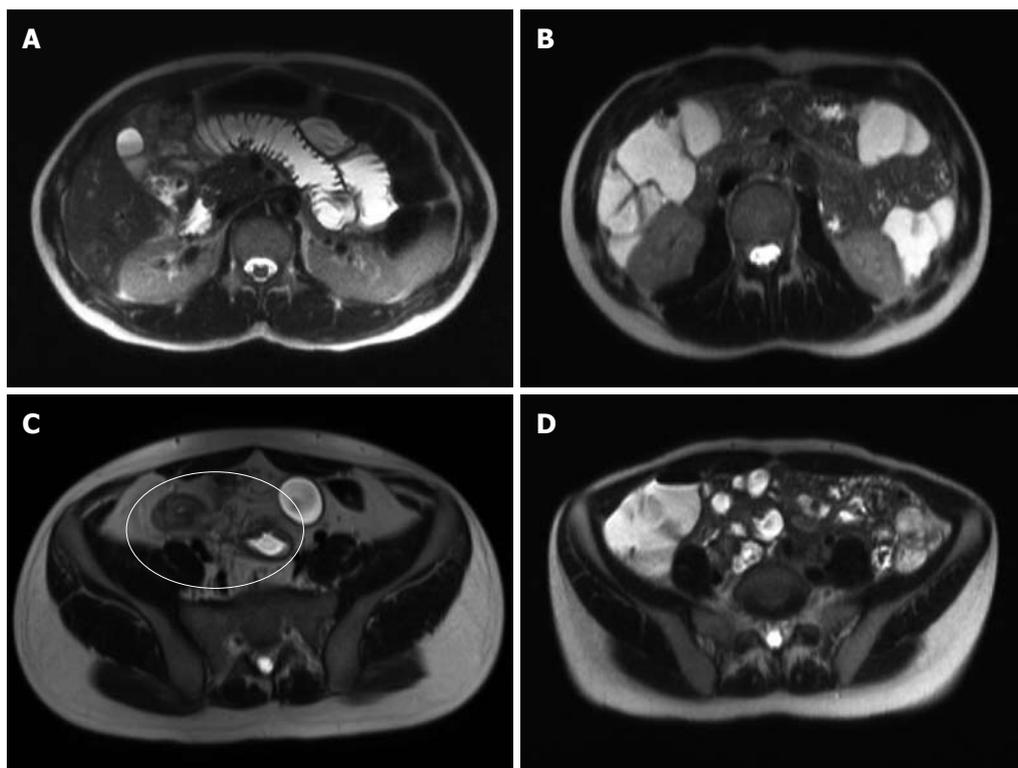

### MRI technique

Patients were imaged in the supine position using a 1.5T MRI system (Avanto SQ, Siemens Medical Solutions, Erlangen, Germany) with a surface array coil providing compression. In patients having undergone an ileostomy, a sponge was placed between the surface coil and stoma with the stoma bag empty.

A scout image was acquired to ensure adequate coverage. SB filling was dynamically assessed using a coronal 150 mm-thick single slab T2-weighted (HASTE) fat saturated sequence (TR 4500 ms, TE 749 ms, flip angle 180°, bandwidth 150 Hz/Px, FOV 350 mm, averages 1, concatenation 1, distance factor 50%, GRAPPA acceleration factor 2), which was acquired repeatedly without breath-holding to monitor retrograde stomach filling and SB distension. These images, combined into a cine loop, were used to assess stenotic lesions. If there was a doubt as to TI contrast filling, a single breath-hold coronal T2-weighted sequence (HASTE) (TR 2000 ms, TE 118 ms, flip angle 180°, bandwidth 195 Hz/Px, FOV 350 mm, averages 1, concatenations 2, no parallel imaging) with a 5 mm-thick slice was obtained with a 50% gap.

To reduce bowel peristalsis and prolong SB distension, 10 mg intravenous hyoscine butylbromide (Buscopan, Boehringer Ingleheim, Australia) was given if there were no contraindications. Once there was adequate SB filling, a coronal pre-contrast T1-weighted 3D gradient echo (VIBE) (TR 9.38 ms, TE 4.46 ms, flip angle 20°, bandwidth 630 Hz/Px, FOV 400 mm, averages 1, concatenation 1, phase over-sampling 25%, distance factor 20%, GRAPPA acceleration factor 2) with a 2.5 mm-thick slice was obtained. Gadodiamide (Omniscan, Amersham, Australia) was intravenously injected (0.2 mL/kg) with post contrast imaging commencing at 60 s. Post-contrast VIBE sequences were obtained in the coronal (imaging factors the same as pre-contrast VIBE) and axial (TR 3.37 ms, TE 1.22 ms, flip angle 12°, bandwidth 490 Hz/Px, FOV 320 mm, averages 1, concatenation 1, phase oversampling 0%, distance factor 20%, GRAPPA acceleration factor 2, a 2 mm-thick slice). The axial plane required 2-3 overlapping sections covering the upper and lower abdomen.

Further imaging was obtained in 2-3 blocks of the upper and lower abdomen, including a coronal steady-state free precession sequence (true FISP) (TR 3.65 ms, TE 1.83 ms, flip angle 64°, bandwidth 501 Hz/Px, FOV 380mm, averages 1) with a 6 mm-thick slice and 30% gap obtained with and without fat saturation, an axial steady-state free precession sequence (true FISP) (TR 3.69 ms, TE 1.83 ms, flip angle 64°, bandwidth 501 Hz/Px, FOV

**Figure 1** Images demonstrating good and poor proximal and distal small bowel (SB) distension. A: Axial T2 weighted HASTE image of the upper abdomen demonstrating good proximal SB distension; B: Coronal T2 weighted HASTE image demonstrating poor proximal SB distension; C: Axial T2 weighted HASTE image of the lower abdomen demonstrating good distal SB distension, abnormal bowel thickening and fistulous tracts between the abnormal bowel loops (circled); D: Axial T2 weighted HASTE image of the lower abdomen demonstrating poor distal SB distension.

350 mm, averages 1) with a 6 mm-thick slice and 30% gap obtained without fat saturation in 2-3 blocks of the upper and lower abdomen, a coronal T2-weighted half Fourier single shot turbo spin echo (HASTE) sequence (imaging factors as above) with a 5 mm-thick slice and 30% gap, and an axial T2-weighted half Fourier single shot turbo spin echo (HASTE) sequence (TR 1000 ms, TE 85 ms, flip angle 150°, bandwidth 391 Hz/Px, FOV 350 mm, averages 1, concatenation 1, GRAPPA acceleration factor 2) with a 6 mm-thick slice and 30% gap. If a site of pathology was identified at an overlap point on the axial images, then a further set of targeted axial true FISP and HASTE images were obtained.

For MRFT, an initial single breath-hold coronal T2-weighted sequence (HASTE) (imaging factors as above) with a 6 mm-thick slice and 30% gap was obtained. If there was adequate filling of the TI, buscopan was injected and routine imaging was obtained as above. With suboptimal filling of the TI, but sufficient bowel contrast proximally, reassessment was performed at 5-min intervals for 15 min. If there was still inadequate filling of SB loops, the patient was removed from the MRI unit and drank a further 500 mL of contrast prior to recommencing imaging.

#### **MRI assessment**

Each MRI was evaluated by consensus of two radiologists (CW and PS) with experience in both gastrointestinal and MR imaging. Image analysis was performed using a standardised worksheet. The quality of proximal and distal SB distension and the presence of artefact were assessed. Good distension

was defined as luminal fluid present within the bowel lumen allowing clear visualisation of both endoluminal surfaces. Poor distension was lack of the above (Figure 1). Artefact, generally related to poor breath-holding, was present if it rendered the images diagnostically impaired on both sequence planes through a region (Figure 2).

#### **Ethics**

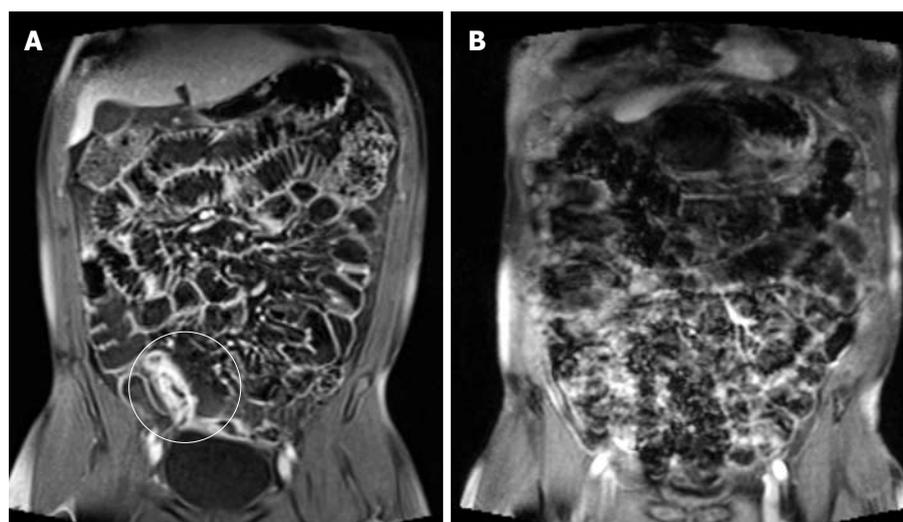

The Fremantle Hospital Human Research Ethics Committee deemed that patient consent was not required for this study as both MRFT and MRI are considered to be standard examination methods.

#### **Statistical analysis**

Logistic regression was undertaken by a statistician (KM) and considered significant at the 0.05 level. The significant effects and odds ratios were presented, along with 95% confidence intervals. Logistic regression was used to model separately the three responses: bowel distension proximal (good *vs* poor), bowel distension distal (good *vs* poor), and artefact (good *vs* poor), with potential predictors of treatment (tube or oral), sex, and age group subdivided into low age group under the age of 30 years, medium age group at the age of 30-50 years, and high age group over the age of 50 years.

## **RESULTS**

Data were collected from 114 MR examinations of SB performed in the supine position on 108 patients

**Figure 2** Images demonstrating the effect of motion artefact. A: Coronal post gadolinium VIBE demonstrating good distension of SB loops with negligible artefact and distal SB wall thickening with strong contrast enhancement consistent with active inflammatory CD (circled); B: Coronal post gadolinium VIBE demonstrating significant motion artefact precluding assessment of contrast enhancement and motion insensitive sequences (HASTE and TruFISP) which are, however, of diagnostic quality (images not shown).

**Table 1** Indication for 114 consecutive MRFT or MRE examinations performed on 108 patients

	Patients	MRFT	MRE
Gender: Male	41.2% (47/114)	32.65% (16/49)	47.7% (31/65)
Age (yr): mean (range) $\pm$ SE	40.7 (14-78) $\pm$ 16.5	39.1 (14-74) $\pm$ 15.4	43.6 (17-78) $\pm$ 17.6
Indication			
Known or suspected CD	86.0% (98/114)	93.8% (46/49)	80.0% (52/65)
Iron deficiency anaemia	7.0% (8/114)	0%	12.3% (8/65)
Resistant coeliac disease	3.5% (4/114)	6.1% (3/49)	1.5% (1/65)
Other	3.5% (4/114)	0%	6.2% (4/65)

MRFT: MR follow-through; MRE: MR enteroclysis; CD: Crohn's disease.

**Table 2** Small bowel (SB) distension and artefact in 114 consecutive MRFT or MRE examinations performed on 108 patients

	All Patients	MRFT	MRE
Good proximal bowel distension	76.3% (87/114)	65.3% (32/49)	84.6% (55/65)
Good distal bowel distension	93.9% (107/114)	97.8% (45/49)	95.4% (62/65)
No artefact	75.4% (86/114)	81.6% (40/49)	70.8% (46/65)
Good proximal and distal bowel distension	75.4% (86/114)	63.3% (31/49)	84.6% (55/65)

(41.7% males, 45/108) over a 32-mo period. A total of 49 MRFT and 65 MRE were assessed. No difference was found in male sex (32.7% *vs* 47.7%,  $P = 0.079$ ) or in age (39.1  $\pm$  15.4 years *vs* 43.6  $\pm$  17.6 years) between the MRE or MRFT patient groups. The primary indication for SB MRI imaging was assessment of CD, either for level of inflammatory activity or for investigation of obstructive symptoms (68.4%, 78/114). The remaining MRI imaging was for suspected CD involving the small intestine (17.5%, 20/114). Of the 114 examinations, 98 (86.0%) were thus for CD or suspected CD. Of the remaining 16 investigations, 8 were for unexplained iron deficiency anaemia, 4 for resistance coeliac disease, 1 for a suspected SB mass seen on wireless capsule endoscopy, 1 for unexplained abdominal pain, and 2 for investigation of SB obstruction, respectively (Table 1).

#### MRFT vs MRE

Proximal and distal SB distension and artefact were

assessed (Table 2). Proximal SB distension was more likely to be suboptimal (Figure 1) in MRFT than in MRE (65.3% *vs* 84.6%). No statistical difference was detected in good distal SB distension (97.8% *vs* 95.4%,  $P = 0.77$ ) between MRFT and MRE or between proximal SB distension and patient age or sex. Although the image artefact, which rendered the study diagnostically impaired (Figure 2), was present more frequently in MRE than in MRFT (29.2% *vs* 18.4%), it was not statistically significant ( $P = 0.30$ ). Good proximal and distal SB distension was observed in 84.6% (55/65) of the patients undergoing a MRE and in 63.3% (31/49) of the patients undergoing a MRFT, respectively.

Logistic regression findings were correlated with patient age (under 30 years, 30-50 years and over 50 years) and sex. While proximal SB distension was overall more likely to be suboptimal in MRFT than in MRE (OR = 4.365, 95% CI = 1.62-11.77,  $P = 0.0036$ ), age also had an impact on the presence of good proximal SB

**Table 3** Assessment of proximal SB distension in relation to MRI investigation, patient age and sex

	Proximal SB distension			P value
	Good proximal SB distension	Odds ratio	95% CI	
MRE	84.6% (55/65)	4.365	1.619-11.772	0.004
MRFT	65.3% (32/49)	Ref		
30-50 yr	86.7% (39/45)	4.882	1.463-16.294	0.010
< 30 yr	71.0% (22/31)	1.561	0.495-4.917	0.447
> 50 yr	68.4% (26/38)	Ref		
Female	77.6% (52/67)	1.646	0.616-4.395	0.320
Male	74.5% (35/47)	Ref		

distension. Patients aged 30-50 years were more likely to have good proximal SB distension than those aged over 50 years (OR = 4.882, 95% CI = 1.463-16.294,  $P = 0.009$ ). No statistically significant difference, however, was found between the patients aged less than 30 years, 30-50 years and over 50 years (Table 3). No statistically significant effect was observed in sex and no significant difference was detected in the diagnostic accuracy of the studies between the various age groups.

All patients were examined in the supine position alone. Nine examinations were undertaken in patients having undergone ileostomy (7.9% of examinations), 4 and 5 of these patients underwent a MRFT and a MRE, respectively. Good proximal and distal bowel distension was achieved in 77.8% (7/9) and in 100% of the patients (9/9), respectively, and image artefact was observed in only 1 patient (11.1%). These findings were very comparable to those in the overall group and no statistically significant difference was found in these parameters between the patients whether they underwent and did not undergo ileostomy.

## DISCUSSION

In our institution, CD or suspected CD is by far the most common indication for SB MR imaging, accounting for more than 85% of cases, which is primarily due to the frequency of involvement of the TI in CD and its transmural nature that may result in obstructive symptoms secondary to intestinal inflammation and/or fibrosis. Radiological investigations have undergone an evolution with both CTE and MRE demonstrating an impressive specificity and sensitivity in the assessment of SB CD. CTE, however, delivers ionising radiation, while MR provides a good soft tissue contrast without radiation, which may potentially differentiate between intestinal inflammation and fibrosis and may thus be superior to CT scanning<sup>[12,20,21]</sup>. For long-term safety issues regarding cumulative radiation exposure and potentially better diagnostic capabilities, MR examination of the SB appears preferable to CT.

Examination of the SB requires a bowel contrast to achieve adequate SB distension, which may either be taken orally or *via* a NJT. SB follow-through (SBFT) is dependent on a number of factors, such as the presence or absence of disease, the ability of patients to ingest a sufficient volume of oral contrast over a short period

of time, inter-individual variation in bowel transit time, and the type of contrast agent used<sup>[22]</sup>. Most radiological facilities routinely place a NJT despite a strong patient preference against it due to its discomfort. Our MRI service has paediatric radiology experience in performing MRFT studies with no placement of a NJT, using PEG according to the published techniques<sup>[23,24]</sup>. Adaptation of this technique for adults was used in this study, but proved difficult due to the significant time variability required for adequate SB filling with tightly scheduled MRI appointments. Since the MR technique used in our facility also requires real-time monitoring, overlapping images can be obtained when needed, thereby enhancing the quality of MR studies.

Our experience is similar to the published studies where the total investigation time (18-27 min, average 22.4 min) was achieved with NJT placement<sup>[11]</sup>, but it could vary as many as 15-240 min (average 65 min) when performed as a follow-through study<sup>[25]</sup>. It should be noted that the imaging time within a MRI unit is approximately the same for both MRFT and MRE. The extra time frequently required for a MRFT is due to the movement of patients in and out of the MRI unit more than once in order to determine SB filling and the need for further oral contrast, which, however, must be weighed against the extra time and radiologist skills required for NJT placement, the need for fluoroscopic radiation, and the strong patient preference against a NJT. Other methods, described to streamline the MRFT technique, however, still require 20-96.6 min of the study time and recurrent periods in and out of the magnet<sup>[22]</sup>, although it is potentially possible to reduce the imaging time to 15-20 min following oral ingestion of PEG over 30-45 min<sup>[26]</sup>.

Our findings regarding the image quality of MRFT and MRE are consistent with previous reports that oral contrast is as sensitive as NJT for distal ileal CD<sup>[27]</sup>. Our results, however, indicate that MRFT is inferior to MRE for proximal SB distension, particularly in the older age group (over 50 years), which may primarily be due to the fact that many of these patients have difficulty in consuming a sufficient volume of oral contrast over a short period of time. We did not record or assess the volume of bowel contrast used. It has been suggested that 900 mL of either an osmotic or a nonosmotic solution is sufficient to obtain duodenal distension and 1350 mL is sufficient to distend the distal jejunum and ileum *via* mouth<sup>[28]</sup>. We strongly encouraged our patients to drink at least 1000 mL of the oral contrast agent. There is often, however, a limit to how much a patient with obstructive symptoms can ingest orally and we have to accept that the finally ingested volume is the best possible for the individual. A recent paper has addressed this specific concern and identified that the SB could be reliably analyzed in healthy volunteers with a volume of 450 mL, and not unexpectedly, less reliably with a volume of 300 mL and 150 mL, respectively<sup>[29]</sup>.

The unpopular technique of imaging in the prone position, could be avoided in our cohort of patients, especially in patients with stomas<sup>[18]</sup>, by putting the patient in the supine position and using a large surface coil, and

sponge over the stoma if present, to apply abdominal pressure. This technique delivered similar SB distension in the patients having undergone ileostomy as in those who did not undergo ileostomy. Our findings in 15.4% of supine MRE studies having either poor proximal or distal SB distension are consistent with SBFT/enterography showing poor SB distension in 13.8% of patients examined in the prone position, and 16.1% of patients examined in the supine position<sup>[19]</sup>. In our study, and as has been observed by other investigators<sup>[26]</sup>, the image quality was still considered good despite the poor SB distension, and was not considered to have reduced the diagnostic accuracy of the examination. Our findings, and studies comparing SB distension examined in the prone and supine positions<sup>[19]</sup>, suggest that the two methods are equivalent in lesion detection and bowel wall feature visualisation.

The findings presented here suggest that both MRE and MRFT are comparable investigations with regard to distal SB bowel distension, image artefact and quality. We also observed no difference in the quality of studies performed in the limited number of patients having undergone ileostomy. Proximal SB distension, however, is frequently less optimal in MRFT than in MRE, but the examination of patients in the supine position is a viable option. Due to reduction in study duration and improved proximal SB distension, the authors prefer to primarily perform all studies in adult patients in the supine position with a NJT. In patients who are unable to tolerate a NJT, or the study is requested to examine the distal SB, a MRFT with oral contrast is an acceptable alternative, particularly in patients under the age of 50 years.

## COMMENTS

### Background

If optimal small bowel (SB) distension can be obtained without insertion of a nasojejunal tube (NJT), then fluoroscopic radiation could be avoided. This study was to assess magnetic resonance (MR) SB enteroclysis (MRE) and MR SB follow-through (MRFT) for proximal and distal SB distension, the presence of movement artefact, and whether imaging in the supine position provides quality studies with good SB distension.

### Research frontiers

Patients often describe that placement of a NJT is very unpleasant. A NJT also requires fluoroscopic radiation exposure to insert the tube. Recent studies suggest that MRFT is as sensitive as MRE in the diagnosis of ileal disease. This study assessed the optimal method of SB examination by MR and if patients could be examined in the supine position only.

### Innovations and breakthroughs

The findings demonstrate that the image quality of MRFT and MRE is equivalent. The results, however, indicate that MRFT is inferior to MRE for proximal SB distension, particularly in patients over the age of 50 years. The unpopular technique of imaging in the prone position, especially in patients with stomas, can be avoided by putting the patient in the supine position and using a large surface coil and sponge over a stoma if present to apply abdominal pressure.

### Applications

The findings demonstrate that MRE and MRFT are comparable investigations with regard to distal SB bowel distension, image artefact and quality, and examination of patients in the supine position is a viable option. Proximal SB distension, however, is less optimal in MRFT. Due to reduction in study duration and improved proximal SB distension, the authors prefer to perform all studies in the supine position with a NJT. In patients who are unable to tolerate a NJT, or the study is requested to examine the distal SB, a MRFT with oral contrast is an acceptable alternative, particularly in patients under the age of 50 years.

## Terminology

Magnetic resonance imaging (MRI) is a cross sectional imaging technique that does not utilize radiation and provides excellent tissue differentiation. MRE has the administration of bowel contrast via a NJT and patients undergoing a MRFT drink the bowel contrast. Good bowel distension is defined as luminal fluid present within the bowel lumen allowing clear visualisation of both endoluminal surfaces. Artefact, generally related to poor breath-holding, is present if it renders the images diagnostically impaired on both sequence planes through a region.

## Peer review

The paper is a large study assessing the quality of MRIs with the bowel contrast administered through a tube (ME enteroclysis) and contrast injected orally (MR follow-through) and whether or not MRI examination of patients in the supine position is adequate. The authors show that tube administration is the best and that patients in the supine position are OK.

### Abstract

**AIM:** To investigate the molecular mechanisms involved in coagulation factor expression and/or function during direct hyperplasia (DH)-mediated liver regeneration.

**METHODS:** Direct hyperplasia-mediated liver regeneration was induced in female C57BL/6 mice by administering 1,4-bis[2-(3,5-dichloropyridyloxy)] benzene (TCPOBOP), a representative hepatomitogen. Mice were weighed and sacrificed at various time points [Day 0 (D0: prior to injection), 3 h, D1, D2, D3, and D10] after TCPOBOP administration to obtain liver and blood samples. Using the RNA samples extracted from the liver, a comprehensive analysis was performed on the hepatic gene expression profiling of coagulation-related factors by real-time RT-PCR (fibrinogen, prothrombin, factors V, VII, VIII, IX, X, XI, XII, XIII $\beta$ , plasminogen, antithrombin, protein C, protein S, ADAMTS13, and VWF). The

corresponding plasma levels of coagulation factors (fibrinogen, prothrombin, factors V, VII, VIII, IX, X, XI, XII, XIII, and VWF) were also analyzed and compared with their mRNA levels.

**RESULTS:** Gavage administration of TCPOBOP (3 mg/kg body weight) resulted in a marked and gradual increase in the weight of the mouse livers relative to the total body weight to 220% by D10 relative to the D0 (control) ratios. At the peak of liver regeneration (D1 and D2), the gene expression levels for most of the coagulation-related factors (fibrinogen, prothrombin, factors V, VII, VIII, IX, XI, XII, XIII $\beta$ , plasminogen, antithrombin, protein C, ADAMTS13, VWF) were found to be down-regulated in a time-dependent manner, and gradually recovered by D10 to the basal levels. Only mRNA levels of factor X and protein S failed to show any decrease during the regenerative phase. As for the plasma levels, 5 clotting factors (prothrombin, factors VIII, IX, XI, and XII) demonstrated a significant decrease ( $P < 0.05$ ) during the regeneration phase compared with D0. Among these 5 factors, factor IX and factor XI showed the most dramatic decline in their activities by about 50% at D2 compared to the basal levels, and these reductions in plasma activity for both factors were consistent with our RT-PCR findings. In contrast, the plasma activities of the other coagulation factors (fibrinogen, factors V, VII, XIII, and VWF) were not significantly reduced, despite the reduction in the liver mRNA levels. Unlike the other factors, FX showed a temporal increase in its plasma activity, with significant increases ( $P < 0.05$ ) detected at D1.

**CONCLUSION:** Investigating the coagulation cascade protein profiles during liver regeneration by DH may help to better understand the basic biology of the liver under normal and pathological conditions.

## INTRODUCTION

The normal adult liver is largely quiescent and only a small percentage of the cells are undergoing cell division at any one time. However, the liver is one of the few organs in the mammalian system that can undergo rapid proliferation in response to various stimuli through a process known as liver regeneration. Liver regeneration is a well-orchestrated process in which hepatocytes and non-parenchymal cells rapidly proliferate *via* induction by two distinct pathways: (1) compensatory regeneration; and (2) direct hyperplasia (DH)<sup>[1,2]</sup>. In the former pathway, liver regeneration is triggered by a loss of functional liver mass, which can be observed in situations where the liver becomes necrotic due to chemical administration or portions of the liver lobes are physically removed by partial hepatectomy<sup>[3-5]</sup>. In the latter DH pathway, the liver regeneration can be initiated by a direct administration of hepatocyte mitogens, such as 1,4-bis[2-(3,5-dichloropyridyloxy)] benzene (TCPOBOP), thyroid hormone T<sub>3</sub>, phenobarbital or bile acids<sup>[3,4,6-8]</sup>.

The process of liver regeneration is known to involve a complex interaction of cytokine-mediated responses as well as pro-proliferative gene expression during the initiation, propagation, and termination phase<sup>[1,2]</sup>. Liver regeneration appears to adversely affect the production of other liver-specific proteins not directly involved in the regenerative process, including albumin and ornithine transcarbamylase. In terms of hemostasis, the production and secretion of the coagulation factors, anti-coagulant factors, and fibrinolytic factors are highly dependent on the hepatocytes in the liver<sup>[9-12]</sup>. There is evidence that some of the liver-specific proteins have temporal suppression in their production during compensatory liver regeneration<sup>[5,13,14]</sup>. Although the kinetics for the coagulation and/or fibrinolytic factors during compensatory liver regeneration have been investigated in the past<sup>[15,16]</sup>, comprehensive analyses assessing the gene expression profiles of the coagulation factors and their related proteins in combination with their plasma activities during DH-mediated liver regeneration have not yet been documented.

Recently, several reports have elucidated that fibrinolytic factors such as plasminogen and urokinase-type plasminogen activator are largely involved in promoting cancer cell invasion and liver regeneration<sup>[17,18]</sup>. It could thus be speculated that coagulation factors, which have an opposite function to fibrinolytic factors, might participate in modulating the liver regeneration process. In this context, elucidation of the coagulation factor profiles during the liver regeneration process may provide an important clue in clarifying the mechanism of liver

regeneration and in understanding the biological process of the blood coagulation system. To date, coagulation factor profiles during the TCPOBOP-induced liver regeneration process have yet to be documented, to the best of our knowledge.

In the present study, we induced liver regeneration in C57BL/6 mice by administering TCPOBOP; the most commonly used experimental procedure to induce DH-mediated liver regeneration. During this liver regeneration process, we investigated the gene expression profiles of coagulation factors and fibrinolytic factors as well as plasma activities of these factors at different time points following TCPOBOP administration.

## MATERIALS AND METHODS

### Animals

A total of 48 female C57BL/6 mice (10-12 wk old; The Jackson Laboratory, Bar Harbor, ME) were housed in an environmentally controlled room with alternating 12-h dark/light cycles (8:00 am lights on/8:00 pm lights off). The mice had *ad libitum* access to food and water. Female mice were exclusively used in this study, since there was a previous report documenting a gender-dependent effect by the liver in the response to TCPOBOP<sup>[19]</sup>. Experimental protocols were developed in accordance with the guidelines outlined by the local animal committee at Nara Medical University.

### Direct hyperplasia (DH)-mediated induction of liver proliferation

DH to the liver was induced by a single intragastric injection of a primary hepatomitogen, TCPOBOP (kindly provided by Dr. BA Diwan) as previously described<sup>[3,8,20]</sup>. Briefly, TCPOBOP was dissolved in dimethyl sulfoxide (DMSO)/corn oil solution and administered by gavage at a dosage of 3 mg/kg body weight.

### Liver harvesting and plasma sampling

Mice were weighed and sacrificed at various time points [Day 0 (D0: prior to injection), 3 h, D1, D2, D3, and D10] after the injection of TCPOBOP ( $n = 8$  mice/time point). Before sacrifice, blood samples were obtained from the retro-orbital plexus and anti-coagulated with 0.1 vol of 3.8% sodium citrate. The blood solution was centrifuged at 4°C, and plasma was separated for storage at -80°C until analysis. After sacrifice, the livers were harvested and weighed, and the liver lobes were snap-frozen in liquid nitrogen and kept at -80°C to preserve the integrity of the RNA until extraction.

### RNA isolation and quality controls

Total RNA was extracted from each tissue sample using the RNeasy Mini Kit (QIAGEN, Hilden, Germany) according to manufacturer's instructions. DNase I was used to digest and remove genomic DNA contamination. Aliquots of the total RNA samples were diluted in TE buffer and the concentration of each sample was measured at a wavelength of 260 nm ( $A_{260}$ ) using the

UV-1600 spectrophotometer (Shimadzu, Kyoto, Japan). Gene expression analyses were performed only when the  $A_{260}/A_{280}$  ratios ranged between 1.9 and 2.1, and the integrity of each RNA sample was confirmed by agarose gel electrophoresis.

#### Reverse transcription (RT) coupled to quantitative real-time PCR

Total RNA (1  $\mu$ g) was reverse-transcribed using oligod(T)<sub>16</sub> primers as described by the manufacturer (Omniscript RT Kit, QIAGEN). First-strand cDNA samples were subjected to quantitative PCR amplification using the StepOne Real-time PCR System (Applied Biosystems Japan Ltd., Tokyo, Japan). Each of the cDNA samples was examined to assess gene expression levels for housekeeping and coagulation factor genes. To normalize the gene expression of the coagulation cascade genes between the various time points following the activation of liver proliferation, the geometric mean of the two genes, peptidylprolyl isomerase A (*PPIA*) and ribosomal protein L4 (*RPL4*), were utilized as previously identified by our lab<sup>[20,21]</sup>. The coagulation factors analyzed in our study included fibrinogen (Fbg), prothrombin (PT), factor V (FV), factor VII (FVII), factor FVIII (FVIII), factor IX (FIX), factor X (FX), factor XI (FXI), factor XII (FXII), factor XIII  $\beta$  subunit (FXIII  $\beta$ ), and von Willebrand factor (VWF). In addition, gene expressions of plasminogen (Plg), antithrombin (AT), protein C (PC), protein S (PS), and a disintegrin-like and metalloproteinase with thrombospondin type 1 motif 13 (ADAMTS13) were also analyzed. TaqMan probes and primers for the target genes were purchased from Applied Biosystems (TaqMan Gene Expression Assay, Table 1). All the PCR analyses were performed using the following cycling conditions: 10 min at 95°C (initial melt), followed by 40 cycles of 15 s at 95°C and 1 min at 60°C. The specificity of the primers was verified by 2% agarose gel electrophoresis of the

amplicons derived from naïve mouse liver cDNAs. For quantification of gene expression, the cDNAs derived from total RNA extracted from pooled normal mouse livers were serially-diluted, and used to generate the reference standard curves.

#### Coagulation assays

Plasma activity of coagulation factors was measured by one-stage clotting assay using human plasma that was deficient for each specific coagulation factor (Sysmex, Kobe, Japan). The activities of FVIII, FIX, FXI, and FXII were measured based on the activated partial thromboplastin time (aPTT) and those of PT, FV, FVII, and FX were measured based on the prothrombin time (PT) using the KC10A Coagulometer (Amelung, Lemgo, Germany). Plasma mouse VWF antigen levels were assayed by ELISA using a primary antibody against human VWF (Dako, Glostrup, Denmark), and a secondary goat anti-human VWF-HRP antibody (Dako). Fibrinogen levels were measured by the Clauss method using bovine thrombin, and FXIII levels were measured by the Berichrom FXIII chromogenic assay (Dade Behring, Marburg, Germany). For all the assessments, pooled plasma collected from 50 normal C57Bl/6 mice was used as a standard.

#### Statistical analysis

Significant differences between two groups were analyzed by two-tailed Wilcoxon *t*-test using Excel (Microsoft) with ystat2006 software (Igakutosyosyuppan, Tokyo, Japan).  $P < 0.05$  was considered significant.

## RESULTS

#### Induction of the DH mode of liver regeneration using hepatomitogen TCPOBOP

As shown in Table 2, the mouse livers treated with

**Table 2** Increase in liver weight during the DH-mediated regenerative phase following TCPOBOP induction

	Body weight (g)	Liver weight (g)	LW/BW × 100
D0	22.44 ± 0.95	1.06 ± 0.06	4.73 ± 0.14
3 h	21.05 ± 0.88	1.10 ± 0.07	5.22 ± 0.26
D1	28.28 ± 2.08	1.63 ± 0.15	5.70 ± 0.16
D2	26.71 ± 1.49	2.05 ± 0.10	7.70 ± 0.12
D3	27.55 ± 2.29	2.38 ± 0.19	8.62 ± 0.09
D10	29.81 ± 0.91	3.15 ± 0.11	10.42 ± 0.16

LW/BW: Liver weight to body weight; TCPOBOP: 1,4-bis[2-(3,5-dichloropyridyloxy)] benzene. Quantitative changes in LW/BW ratio during the DH-regeneration phase at specific time points (D0, 3 h, D1, D2, D3, D10) following intragastric TCPOBOP injection (3 mg/kg body weight) ( $n = 8$  mice/time point). Livers were harvested and weighed to calculate the relative liver weight (as a percentage of body weight). All values were represented as the mean ± SE.

TCPOBOP were found to display an increase in organ size over defined time points as determined by the quantitative changes in the liver weight to body weight (LW/BW) ratio expressed as a percentage. Naïve LW/BW ratio (D0) was measured at  $4.73\% \pm 0.14\%$ , and there was a significant ( $P < 0.05$ ) increase in the ratio to  $5.22\% \pm 0.26\%$  as early as 3 h post-TCPOBOP administration. Over the 10 d period following the TCPOBOP injection, the ratio gradually increased ( $5.70\% \pm 0.16\%$ ,  $7.70\% \pm 0.19\%$ ,  $8.62\% \pm 0.09\%$ , and  $10.42\% \pm 0.16\%$ , at D1, D2, D3, and D10, respectively). At D10, the LW/BW ratio increased to 220% of the naïve LW/BW ratio at D0. We also observed that the body weight increased during the 10 d period, but its magnitude of increase was far less than that of liver weight. Furthermore, administering only the solvent (DMSO/corn oil) to the mice did not affect the LW/BW ratio significantly, confirming that the regenerative responses were caused by TCPOBOP (data not shown).

#### Gene expression levels of coagulation factors and other factors in the liver

Initial experiments were performed to assess the mRNA expression profile of 10 different coagulation factors (Fbg, PT, FV, FVII, FVIII, FIX, FX, FXI, FXII, and FXIII $\beta$ ) following TCPOBOP injection at distinct time points ( $n = 8$  livers/time point) using real-time RT-PCR. All of the data were normalized to the geometric mean of two housekeeping genes, *PPLA* and *RPLA*, and then calculated as a comparative ratio to the quiescent (control) liver at D0. Compared with values at D0, mRNA expression levels of all the analyzed coagulation factors, except for FX, were significantly ( $P < 0.05$ ) but temporally down-regulated during the most active phase of DH-mediated liver regeneration as shown in Figure 1. FX mRNA levels did not decrease during the DH-liver regenerative phase, and ultimately, the levels were significantly increased at D10 compared with D0. For most of the coagulation factor mRNAs that were down-regulated, the mRNA levels gradually recovered by D10 to the levels observed at D0, but there were several factors, particularly FXI, that remained significantly

lower ( $P < 0.05$ ) until D10.

In addition to coagulation factors, we assessed the mRNA expression levels for other factors involved in the regulation of the coagulation cascade, including Plg, AT, PC, PS, VWF, and ADAMTS13. As shown in Figure 2, the mRNA levels of Plg, AT, PC, and ADAMTS13 were down-regulated at D1 and D2 after the TCPOBOP injection, and slowly recovered by D10 to the levels detected in the quiescent state (D0). PS mRNA tended to be increased and, at times, significantly ( $P < 0.05$ ) elevated, throughout the DH-mediated liver regenerative phase.

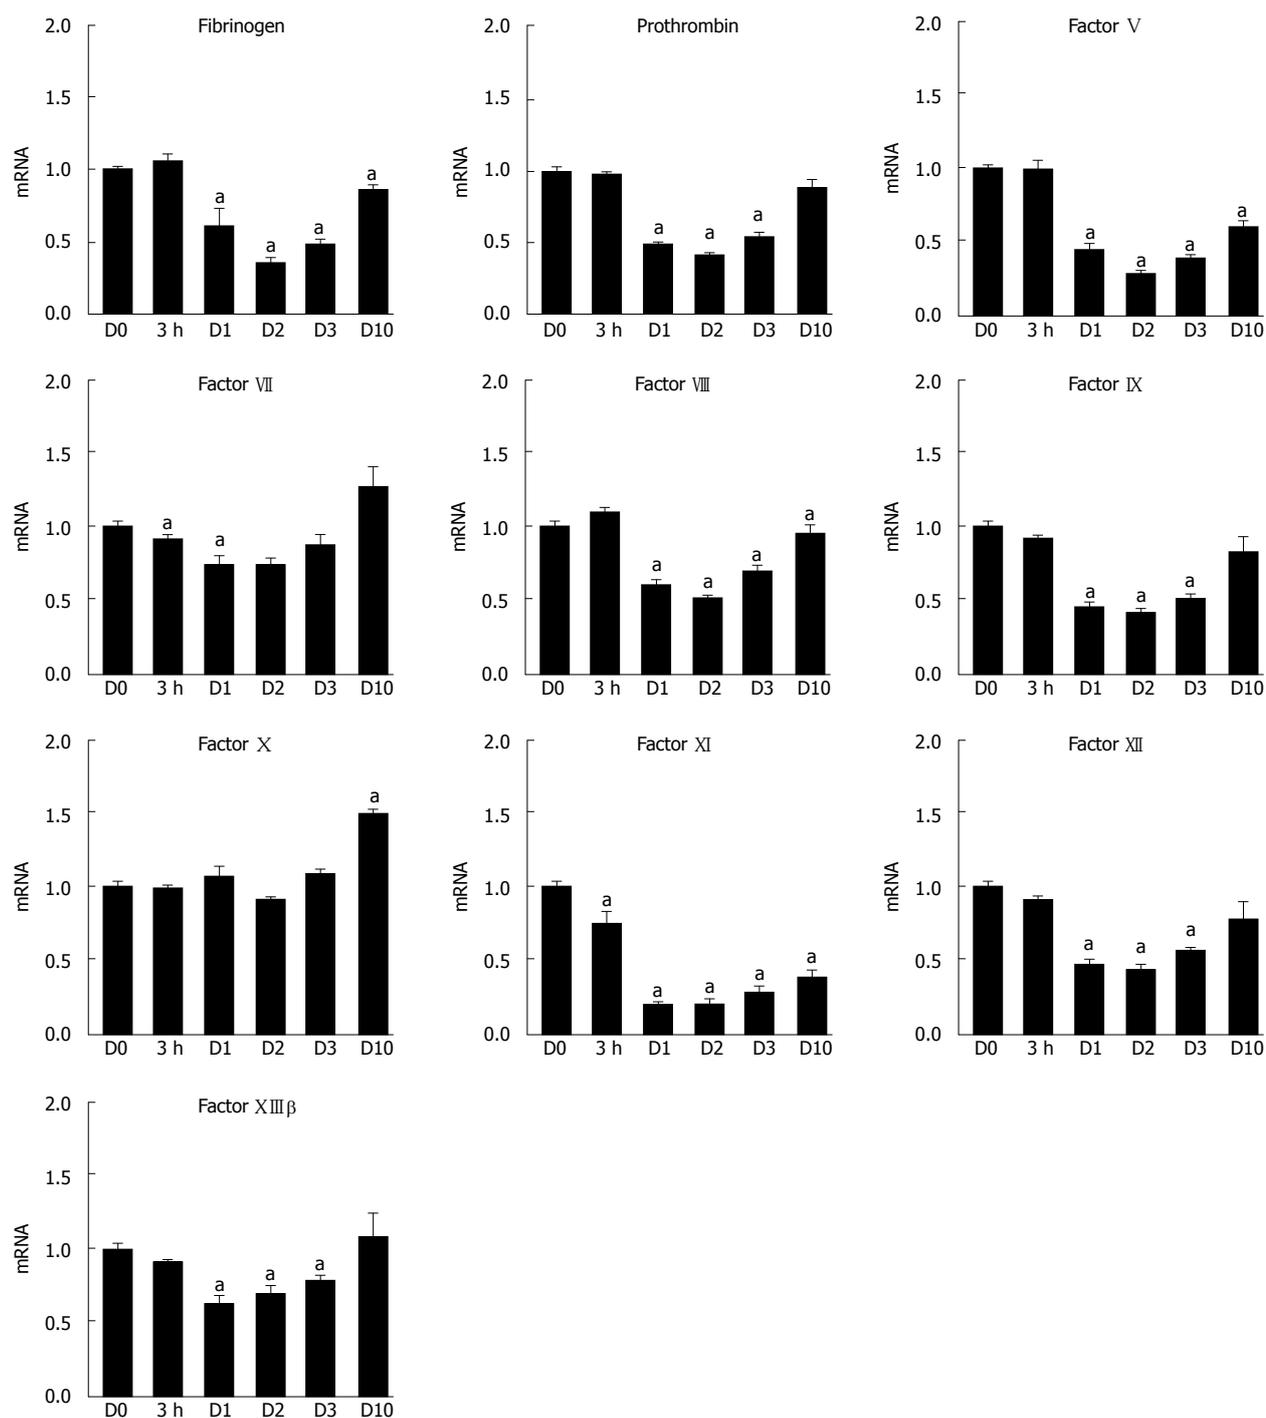

#### Plasma levels of coagulation factors

We then determined the changes in the plasma activity of the coagulation factors during the DH-mediated liver regenerative phase. As shown in Figure 3, we detected a significant decrease ( $P < 0.05$ ) in the plasma activities for 5 of the clotting factors (PT, FVIII, FIX, FXI, and FXII) during the regeneration phase compared with D0. Among these 5 factors, FIX and FXI showed the most dramatic decline in plasma activity by about 50% at D2 compared to the D0 levels. These reductions in plasma activity for FIX and FXI were consistent with our RT-PCR findings (Figure 1) following TCPOBOP injection. In contrast, the plasma activities of the other coagulation factors, Fbg, FV, FVII, and FXIII, as well as VWF, were not significantly reduced despite the reduction in the liver mRNA levels. Unlike the other coagulation factors, FX showed a temporal increase in its plasma activity, with significant increases ( $P < 0.05$ ) detected at D1.

## DISCUSSION

The present study demonstrated a comprehensive gene expression profile in the liver with corresponding plasma activities of coagulation factors and fibrinolytic factors during the liver regeneration phase induced by TCPOBOP, which is a hepatomitogenic compound. At the peak regenerative phase (i.e. D2 after TCPOBOP injection), the mRNA expression levels for most of the analyzed genes were temporally down-regulated followed by a compensatory recovery back towards the normal levels upon the completion of the regenerative activity (i.e. D10 after TCPOBOP injection). In contrast to the mRNA expression profile, the plasma activities for the coagulation factors showed varied responses. More specifically, PT, FVIII, FIX, FXI, and FXII demonstrated a temporal decrease in activity, FX showed a temporal increase in activity, and Fbg, FV, FVII, FXIII, and VWF did not markedly change throughout the regenerative period.

Liver regeneration is known to be an intrinsic function that can be induced through two distinct pathways: (1) compensatory regeneration and (2) direct hyperplasia (DH). In compensatory regeneration, tumor necrosis factor, interleukin-6, nuclear factor- $\kappa$ B, STAT3, and AP-1 are associated with the initiation of hepatocyte proliferation, but the process of DH-mediated liver regeneration appears to be independent of these cytokines<sup>[7,22]</sup>. At the level of gene expression, there are

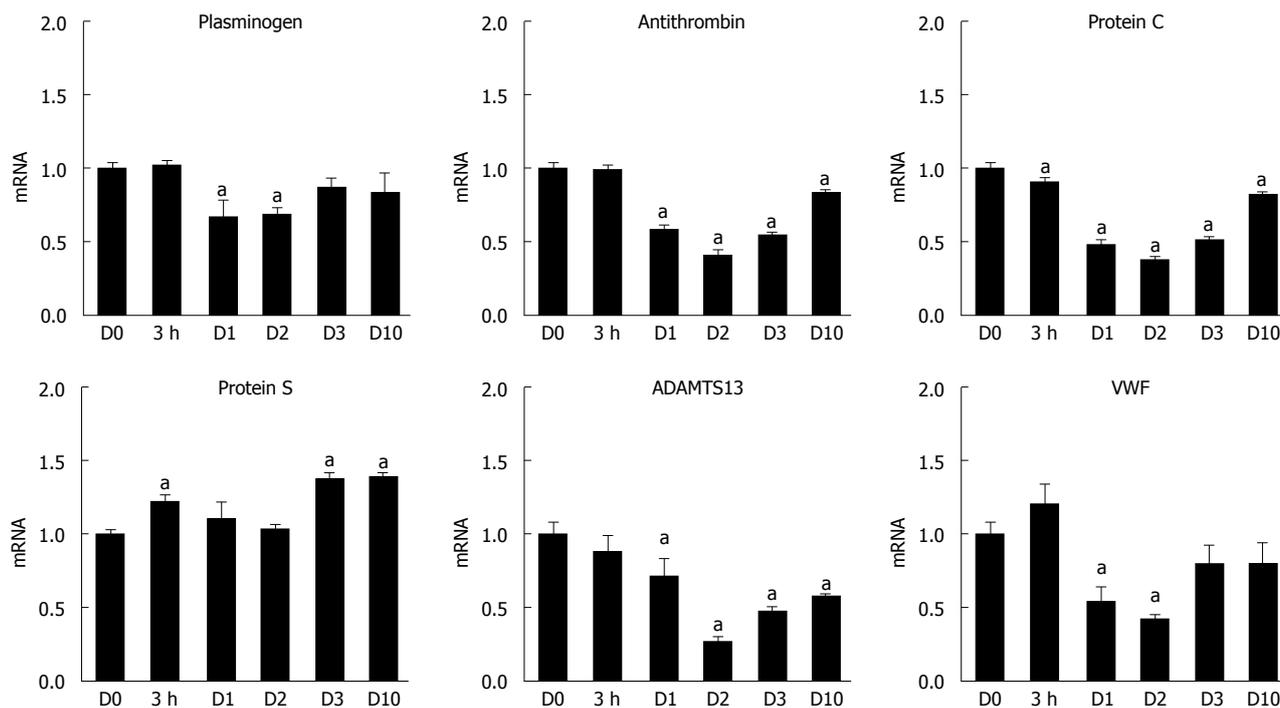

**Figure 1** Gene expression profiling of coagulation factors in the liver during the DH-mediated regenerative phase following TCPOBOP induction. The mRNA expression levels of 10 coagulation factors (fibrinogen, prothrombin, factors V, VII, VIII, IX, X, XI, XII, and XIII $\beta$ ) were assessed from mouse livers at D0, 3 h, D1, D2, D3, and D10 by real-time RT-PCR ( $n = 8$ /time point). The mRNA levels of each gene were normalized to the geometric mean of *PPIA* and *RPL4* mRNA levels. The values were expressed as a comparative ratio to the day 0 samples, and represented as the mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs D0.

distinct genetic pathways that are activated depending on the mode of liver regeneration. For example, there is a rapid induction of cyclin D1 as early as 8 h after the induction of the mode of DH, whereas cyclin D1 does not appear to be induced at any time point during compensatory regeneration<sup>[23]</sup>.

In this paper, we focused on the DH mode of liver regeneration, which is a unique process that mediates hepatocellular proliferation due to inoculation with primary hepatocyte mitogens<sup>[6,8]</sup>. Following the

administration of the mitogens, hepatocytes and other liver cell types demonstrate a rapid activation of DNA synthesis in which the peak of the cell division occurs between D1 to D2 leading to a subsequent increase in liver size and weight. Among the currently available hepatocyte mitogens, TCPOBOP, a synthetic ligand to the constitutive androstane receptor (CAR), has been shown to produce robust proliferation and growth in mouse livers<sup>[6,8]</sup>. The rate of regenerative activity at the peak phase of DH-mediated proliferation

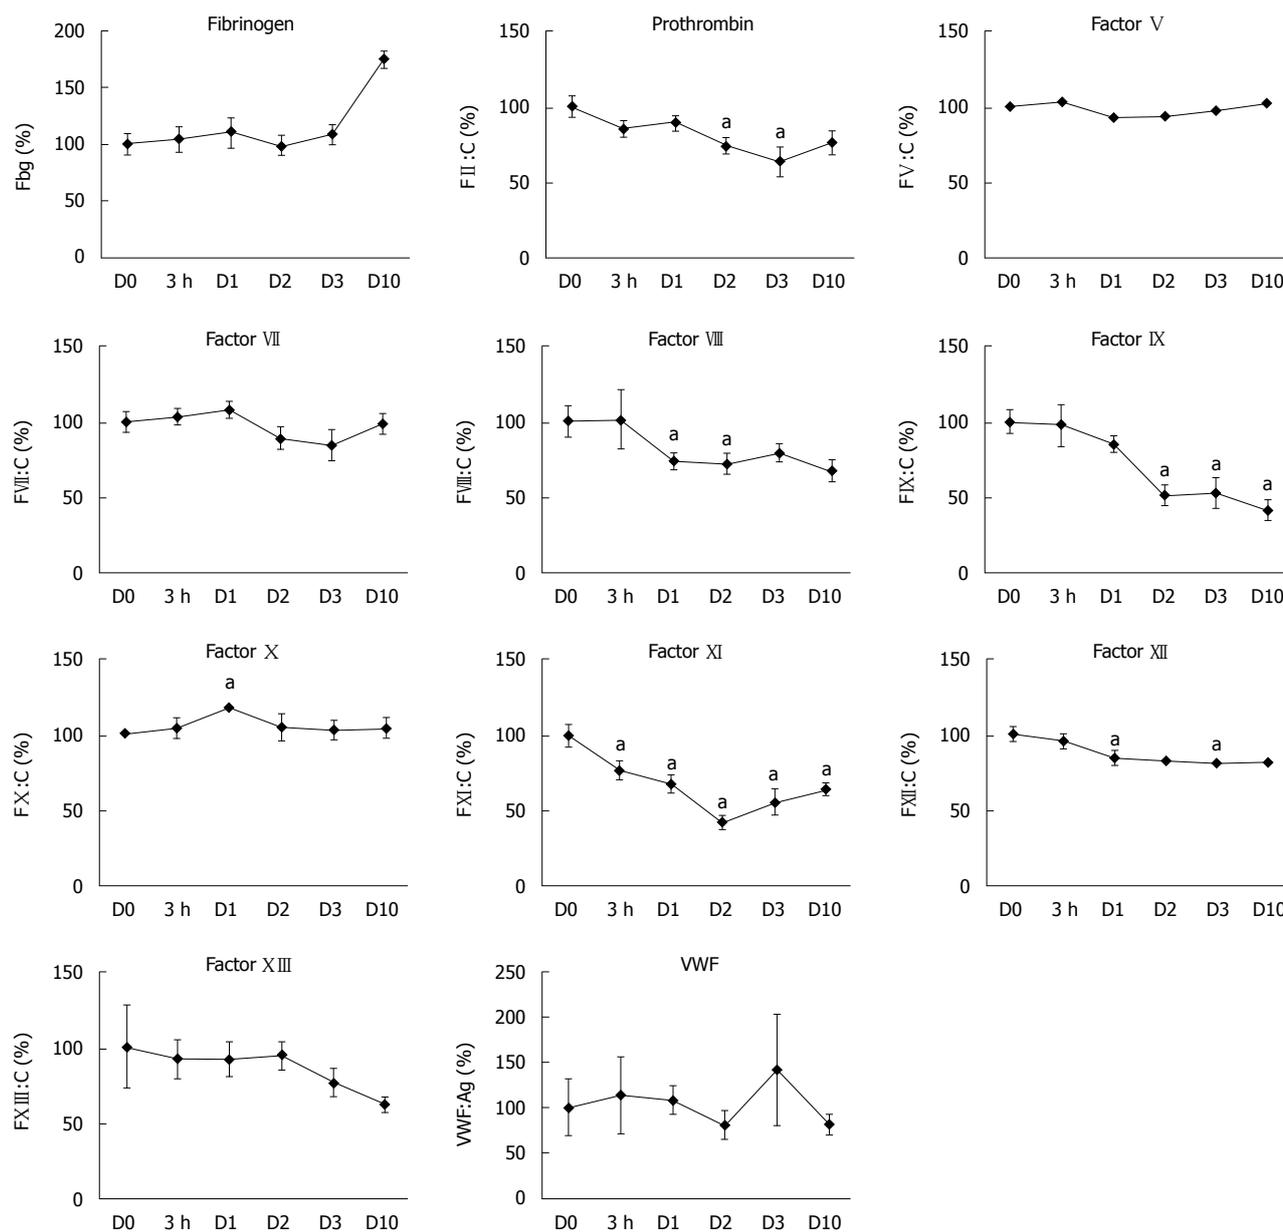

**Figure 2** Gene expression profiling of coagulation-related factors in the liver during the DH-mediated regenerative phase following TCPOBOP induction. The mRNA expression levels of 6 coagulation-related factors [plasminogen, antithrombin, protein C, protein S, a disintegrin-like and metalloproteinase with thrombospondin type 1 motif 13 (ADAMTS13), and von Willebrand factor (VWF)] were assessed in mouse livers at D0, 3 h, D1, D2, D3, and D10 by real-time RT-PCR ( $n = 8/\text{time point}$ ). The mRNA levels of each gene were normalized to the geometric mean of *PPIA* and *RPL4* mRNA levels. The values were expressed as a comparative ratio to the D0 samples, and represented as the mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs D0.

following TCPOBOP administration is more robust compared to the regenerative effect attributed to a partial hepatectomy-induced compensatory regeneration as observed by the BrdU labeling of proliferating hepatocytes<sup>[8]</sup>. Consequently, an active proliferation of hepatocytes at the same levels of previous reports was induced appropriately by the administration of TCPOBOP in the present study (Table 2)<sup>[8,20]</sup>.

In the face of a proliferative response in the liver, liver function can be adversely affected. It has been reported that gene expression levels of liver-specific proteins are temporally suppressed, which suggests that the regenerating liver sacrifices the production of liver-specific proteins, mainly plasma proteins, in order to promote the protein production required for cell division and growth<sup>[24,25]</sup>. These findings are supported by our previous report that gene expression of essential structural proteins for the cell, including  $\beta$ -actin, were significantly increased during liver regeneration<sup>[5,20]</sup>. In contrast to compensatory liver regeneration, there remains a paucity of information regarding the molecular changes in gene expression and production of liver-specific proteins, including coagulation factors, during liver regeneration through the DH mode. Since the majority of the coagulation factors and anti-coagulation factors are produced by hepatocytes, analysis of the liver to profile the gene expression of these factors would provide a comprehensive determination of the effect of proliferation on gene expression. In our analyses, we demonstrated that livers in the active phase of liver regeneration (D1 and D2) significantly down-regulated

the gene expression of almost all of the coagulation and fibrinolytic factors analyzed (Figures 1 and 3). The reduction in the coagulation cascade gene expression is consistent with previous studies in our lab whereby TCPOBOP-induced hepatocyte proliferation led to a marked down-regulation of other liver-specific genes, including albumin and ornithine transcarbamylase<sup>[8,20]</sup>. Interestingly, the decrease in gene expression for the coagulation cascade proteins did not necessarily correlate with the plasma protein activity for many of the analyzed genes, such as Fbg, FV, FVII, FX and FXIII. For these proteins, the plasma protein activity appeared to be maintained or elevated during the liver proliferation and growth phase even though the mRNA levels of these proteins were significantly reduced. The lack of reduced plasma activity could be related to a number of factors, including the threshold of mRNA expression needed for efficient translation of the coagulation factor, an extended half-life of the protein, enhanced translation and subsequent secretion of the proteins into the circulation, or the mass of liver needed to produce the coagulation proteins. Unlike the other coagulation factors, FIX activity remained significantly reduced throughout the liver regenerative phase even though the FIX mRNA profile returned towards normal levels in the face of increased liver mass. In order for FIX to become available in a biologically active and secretable form, it has been described that several post-translational modification steps are required within the hepatocytes. It may be speculated that the disparity between the low plasma FIX activity and revived liver

**Figure 3** Determination of plasma levels and activity for coagulation factors during the DH-mediated regenerative phase following TCPOBOP induction. Plasma activity levels of 10 coagulation factors (fibrinogen, prothrombin, factor V, VII, VIII, IX, X, XI, XII, and XIII) and plasma von Willebrand factor (VWF) antigen levels were assessed in mice during the DH-mediated regenerative phase. Activity levels of prothrombin, factor V, VII, VIII, IX, X, XI, and XII were measured by one-stage clotting assay, fibrinogen activities were measured by the Clauss method, factor XIII activities were measured by chromogenic assay, and VWF antigen levels were measured by specific ELISA. The plasma samples were obtained at D0, 3 h, D1, D2, D3, and D10 after TCPOBOP injection ( $n = 8$ /time point). The data were described as percentage of pooled normal plasma, and represented as the mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs D0.

mRNA levels is the result of insufficient recovery of such post-translational modification systems in the regenerated hepatocytes. Since FIX is a critical protein for mediating blood coagulation<sup>[11,12]</sup>, further investigation needs to be addressed for the elucidation of the mechanism producing the biologically active FIX during the regeneration phase.

The effect of proliferative stimuli on coagulation factors not produced in the hepatocytes is not well-established. VWF is known to be an important glycoprotein for platelet adhesion to wound sites as well as a carrier protein for FVIII, and to be largely produced in endothelial cells throughout the body, including the liver<sup>[26]</sup>. ADAMTS13, which is produced exclusively by hepatic stellate cells, is a

VWF-cleaving enzyme essential for preventing excessive thrombotic events in the body<sup>[27]</sup>. These proteins were found to have their mRNA expression significantly down-regulated during the active phase of DH-mediated regeneration (Figures 1 and 3). Proliferation of non-parenchymal cells in the liver has been shown to occur following DH-mediated stimuli, but the peak level of proliferation was found to occur 1-2 d following the peak normally observed in hepatocytes<sup>[8]</sup>. One possible explanation for the down-regulation of VWF and ADAMTS13 at the early regeneration phase could be associated with the early initiation, but lagging pace, of cell-cycle progression in the non-parenchymal cells.

In conclusion, this is the first detailed study to

investigate the liver gene expression profiles with corresponding plasma protein activity levels for a panel of coagulation factors and related coagulation cascade proteins during liver regeneration mediated by direct hyperplasia. Temporal down-regulation of gene expression was found to be associated with this mode of liver regeneration, while plasma activity levels showed mixed changes in activity depending on the factor being examined. These results suggest that there may be a common feature between two mechanisms involved in liver regeneration whereby the liver in the proliferative phase sacrifices the production of liver-specific proteins that are not essential for hepatocyte division and growth until the liver has completed or nearly completed the regenerative event. However, it is clear that the genetic profiles of these proteins cannot be simply answered by determining the expression and protein activity, but that other mechanisms are involved requiring further investigation as to how liver-specific proteins not involved in cell division and growth are regulated during DH-mediated liver regeneration.

## COMMENTS

### Background

Liver regeneration is a well-orchestrated process in which hepatocytes and non-parenchymal cells undergo rapid proliferation *via* induction by two distinct pathways: (1) compensatory regeneration; and (2) direct hyperplasia (DH). In the former pathway, liver regeneration is triggered by a loss of functional liver mass, which can be observed in situations where the liver becomes necrotic due to chemical administration or portions of the liver lobes are physically removed by partial hepatectomy. In the latter DH pathway, the liver regeneration can be initiated by direct administration of hepatocyte mitogens, such as 1,4-bis[2-(3,5-dichloropyridyloxy)] benzene (TCPOBOP), thyroid hormone T<sub>3</sub>, phenobarbital or bile acids.

### Research frontiers

There is evidence that some of the liver-specific proteins have temporal suppression in their production during compensatory liver regeneration. Although the kinetics for the coagulation and/or fibrinolytic factors during compensatory liver regeneration have been investigated, comprehensive analyses assessing the gene expression profiles of the coagulation factors and their related proteins in combination with their plasma activities during the DH-mediated liver regeneration have not yet been documented.

### Innovations and breakthroughs

In the present study, the authors induced liver regeneration in C57BL/6 mice by administering TCPOBOP; the most commonly used experimental procedure to induce DH-mediated liver regeneration. During this liver regeneration process, they investigated the gene expression profiles of coagulation factors and fibrinolytic factors as well as plasma activities of these factors at different time points following TCPOBOP administration.

### Applications

The systematic and thorough investigation of the molecular changes in the coagulation cascade during liver regeneration by DH will help to better understand the basic biology of the liver under normal and pathological conditions.

### Terminology

TCPOBOP is one of the currently available hepatocyte mitogens, and functions as a synthetic ligand to the constitutive androstane receptor, which has been shown to produce robust proliferation and growth in mouse livers.

## Peer review

In this study, the authors investigated the changes in expression and activity of several factors of the coagulation cascade during liver regeneration. The study is well presented and the figures are convincing.

### Abstract

**AIM:** To evaluate the role of endoscopic retrograde cholangiopancreatography (ERCP) in patients with sickle cell disease (SCD).

**METHODS:** Two hundred and twenty four SCD patients with cholestatic jaundice (CJ) had ERCP. The indications for ERCP were based on clinical and biochemical evidence of CJ and ultrasound findings.

**RESULTS:** Two hundred and forty ERCPs were performed. The indications for ERCP were: CJ only in 79, CJ and dilated bile ducts without stones in 103, and CJ and bile duct stones in 42. For those with CJ only, ERCP was normal in 42 (53.2%), and 13 (16.5%) had dilated bile ducts without an obstructive cause. In the remaining 22, there were bile duct stones with or without dilation. For those with CJ, dilated bile ducts and no stones, ERCP was normal in 17 (16.5%), and 28 (27.2%) had dilated bile ducts without an obstructive cause. In the remaining 58, there were bile duct stones with or without dilation. For those with CJ and bile duct stones, ERCP was normal in two (4.8%), and 14 (33.3%) had dilated bile ducts without an obstructive cause. In the remaining 26, there were bile duct stones with or without dilatation.

**CONCLUSION:** Considering the high frequency of

### INTRODUCTION

Sickle cell disease (SCD) is common in the Eastern Province of Saudi Arabia and it can affect any part of the body<sup>[1-3]</sup>. One of the main organs to be affected by SCD is the hepatobiliary system. However, this is variable in character and severity, and can be presented as a variety of symptoms, including cholelithiasis, choledocholithiasis, and cholestatic jaundice (CJ). CJ can be caused by several diseases and one of the common intrahepatic causes is sickling of red blood cells (RBC), which is also called hepatic crisis or hepatic sequestration (sickle cell hepatopathy)<sup>[4,5]</sup>. This can mimic extrahepatic bile ducts obstruction, which causes diagnostic and therapeutic dilemmas. There is also a high frequency of cholelithiasis and choledocholithiasis in patients with SCD<sup>[3,6-8]</sup>. It is of paramount importance to differentiate between these causes and one of the diagnostic and therapeutic modalities in the evaluation of patients with CJ is endoscopic retrograde cholangiopancreatography. Thus, we evaluated the role of endoscopic retrograde cholangiopancreatography (ERCP) in patients with SCD, with an emphasis on SCD cholangiopathy.

### MATERIALS AND METHODS

Over a period of 15 years (1993-2008), 224 patients with

**Table 1 ERCP findings in patients with cholestatic jaundice only (Total No. of patients = 79)**

Finding	n (%)
Normal	42 (53.2)
Dilated CBD without stones	11 (13.9)
Dilated CBD with stones	10 (12.7)
Dilated bile ducts with stones	6 (7.6)
Dilated bile ducts without stones	1 (1.3)
Dilated CHD without stones	1 (1.3)
Normal CBD with stones	1 (1.3)
Edematous inflamed papilla	4 (5.1)

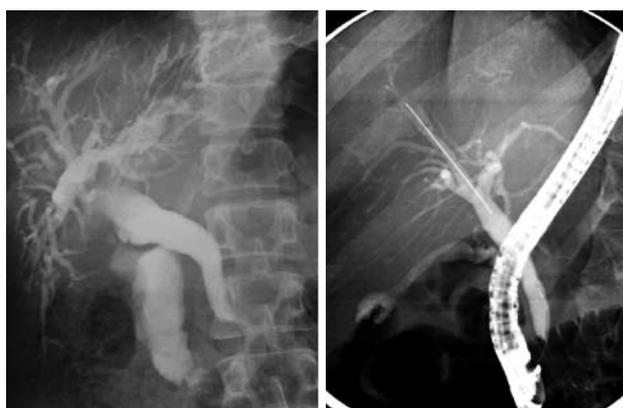

**Table 2 ERCP findings in patients with cholestatic jaundice and dilated bile ducts on ultrasound (Total No. of patients = 103)**

Finding	n (%)
Normal	17 (16.5)
Dilated CBD without stones	17 (16.5)
Dilated CBD with stones	30 (29.13)
Dilated bile ducts without stones	11 (10.7)
Dilated bile ducts with stones	17 (16.5)
Normal CBD with a stone	1 (0.98)
Choledochoduodenal fistula	2 (1.94)
Edematous inflamed papilla	8 (7.8)

ERCP: Endoscopic retrograde cholangiopancreatography; CBD: Common bile duct; CHD: Common hepatic duct.

SCD underwent 240 ERCP procedures. Their medical records were reviewed and the following information was obtained: age, sex, clinical presentation, investigations, indication for ERCP, abdominal ultrasound results, ERCP findings, therapeutic procedures at the time of ERCP, complications and outcome. All had an abdominal ultrasound and the indications for ERCP were based on clinical and biochemical evidence of CJ and ultrasound findings. Based on abdominal ultrasound findings, the patients were divided into three groups as follows: (1) those with normal ultrasound, (2) Those with dilated bile ducts but no stones, and (3) Those with bile duct stones. All ERCPs were performed in the radiology department using an Olympus TJF 240 or JF 260 side-viewing duodenoscope. This was done under general anesthesia with nasotracheal intubation for children less than 10 years of age, and under sedation using meperidine (1 mg/kg) and diazepam (0.1-0.2 mg/kg) for those above 10 years of age. The ampulla of Vater was cannulated with tapered or regular catheters and the biliary ducts were deliberately visualized under fluoroscopy using Hexabrix (320 mg diluted to 50%). Appropriate radiographs were obtained and, where indicated, sphincterotomy was performed using a 5F sphincterotome (Olympus) and bile duct stones, if found, were extracted with a basket, balloon extractor, or mechanical lithotripter.

**RESULTS**

Two hundred and twenty four patients with SCD underwent 240 ERCP procedures. There were 144 males and 80 females. Their mean age was 22.4 years (5-70 years). Their

mean hemoglobin S (HbS) was 76.8% (64.7%-92.3%) and their mean hemoglobin F (HbF) was 20.4% (5.1%-34.0%). Their mean total bilirubin was 224 g/L (55-395 g/L). Their mean direct bilirubin was 134 g/L (40-263 g/L). Their mean alkaline phosphatase was 486 IU/mL (81-1189 IU/mL) (Normal: 50-136 IU/mL). Their mean alanine transaminase (ALT) was 234.3 IU/mL (50-761 IU/mL) (Normal: 30-56 IU/mL) and their mean aspartate transaminase (AST) was 206.3 IU/mL (63-317 IU/mL) (Normal: 15-37 IU/mL). The indications for ERCP were: CJ only in 97, CJ and dilated bile ducts on ultrasound in 103, and CJ and bile duct stones on ultrasound in 42. The ERCP findings in each of these three groups are shown in Tables 1-3. In those with CJ only, there was a group of 13 patients (16.5%) with dilated bile ducts without an obstructive cause. In those with CJ and dilated bile ducts on ultrasound, there was a group of 28 patients (27.2%) with dilated bile ducts without an obstructive cause. In those with CJ and bile duct stones on ultrasound, there was a group of 14 patients (33.3%) with dilated bile ducts without an obstructive cause. In total 55 patients (24.6%) had dilated bile ducts without an obstructive cause or previous history of biliary duct stones (Figures 1 and 2).

The therapeutic procedures performed during ERCP are shown in Table 4. This included endoscopic sphincterotomy only in 42 out of the 55 patients (76.4%) who had dilated bile ducts without an obstructive cause. The remaining 13 patients were treated early in the study and no sphincterotomies were done. There was no mortality. Four patients developed minor bleeding from

**Figure 2** An ERCP showing markedly dilated bile ducts without an obstructive cause. Note the nasobiliary tube for drainage in the first image.

the sphincterotomy site. This was controlled with local adrenaline injection. Eight patients (3.3%) developed transient mild pancreatitis.

## DISCUSSION

Sickle cell disease is one of the common hemoglobinopathies in the Eastern Province of Saudi Arabia, where the frequency of Sickle cell trait can reach as high as 25% in some areas<sup>[1-3]</sup>. One of the common manifestations of SCD is jaundice, which can be caused by a variety of hepatobiliary diseases including CJ<sup>[3-5]</sup>. There are certain causes of CJ that are SCD related. One of these causes is intrahepatic sickling of RBC<sup>[4,5,9]</sup>. This is also called hepatic crisis or hepatic sequestration (sickle cell hepatopathy)<sup>[4,5]</sup>. This can lead to cholestasis and a clinical picture that can resemble extrahepatic bile duct obstruction which causes diagnostic and therapeutic dilemmas. Sickle cell intrahepatic cholestasis on the other hand is a more serious condition, characterized by acute onset of hepatomegaly, hyperbilirubinemia, coagulopathy, and acute liver failure<sup>[4,5]</sup>. Early identification of these is important as the process of sickling can be reversed by hydration and simple, or in severe cases, exchange blood transfusion. There is also a high frequency of cholelithiasis and choledocholithiasis in patients with SCD<sup>[3,6-8]</sup>. The frequency of cholelithiasis in patients with SCD is variable, ranging from 4% to 55%, and this increases with age<sup>[2,3,6-8]</sup>. In the general population with cholelithiasis, the incidence of common bile duct (CBD) stones has been reported to be 10%-15%, whereas in those with SCD it ranges from 18%-30%<sup>[10,11]</sup>. Due to this high incidence, routine intraoperative cholangiography has been advocated<sup>[10]</sup>. With the recent advances in laparoscopic cholecystectomy (LC), exclusion of CBD stones prior to LC is of great importance. ERCP has been shown to be valuable, both for the diagnosis and management of CBD stones, in patients with SCD who are undergoing or have undergone LC<sup>[12-14]</sup>. ERCP is also of great importance in evaluating SCD patients with CJ, whether this is due to intrahepatic or extrahepatic causes. Ultrasound is a simple, non invasive imaging technique, and although gallstones and intrahepatic and

**Table 4** Therapeutic procedures during ERCP

Procedure	n (%)
Endoscopic sphincterotomy only	42 (18.8)
Endoscopic sphincterotomy and stone extraction	79 (35.3)
Insertion of biliary stent	8 (3.6)
Endoscopic sphincterotomy, mechanical lithotripsy, and stone extraction	4 (1.8)
Insertion of a nasobiliary tube	4 (1.8)

extrahepatic bile duct dilatation are readily detected by ultrasound, common bile duct stones might be missed. ERCP, on the other hand, is more invasive but is the procedure of choice in suspected cases of extrahepatic bile duct obstruction. It provides direct visualization of the biliary tree and demonstrates the site and nature of the obstruction in more than 90% of patients. ERCP also provides therapeutic interventions, including endoscopic sphincterotomy and stone extraction, dilatation of strictures, and placement of stents and biliary drainage catheters<sup>[15-19]</sup>. This was the case in our series, where we found ERCP valuable both as a diagnostic and therapeutic procedure. The majority of bile duct stones (95.4%) in our series were removed via ERCP. ERCP however was normal and unnecessary in a significant number of our patients (27%) with SCD and CJ. This was specially so in those who presented with CJ only (53.2%). These patients most likely had CJ secondary to intrahepatic sickling of RBC. Hepatic crisis and hepatic sequestration resemble each other clinically, and the only differentiating point between the two is a sudden drop in hematocrit, as well as a sudden increase in liver size in those with hepatic sequestration<sup>[4,5]</sup>. Sickle cell intrahepatic cholestasis, on the other hand, is a more serious and often fatal complication of SCD where there is widespread intrahepatic sickling within the liver sinusoids leading to their blockage, vascular stasis with hepatic ischemia, and the striking feature is the highly elevated plasma bilirubin level<sup>[4,5,12,13]</sup>. It is possible that our patients with CJ and normal ERCP represent a benign variant of intrahepatic cholestasis or a form of what is called benign hyperbilirubinemia<sup>[5]</sup>. All our patients had hyperbilirubinemia, but their plasma AST, ALT and alkaline phosphatase levels were only moderately elevated. To support this, these patients subsequently recovered with conservative treatment including observation, hydration and, where indicated, blood transfusion. To overcome this and decrease the number of patients with normal ERCP, patients with CJ only should be evaluated further prior to ERCP, including endoscopic ultrasound (EUS) and magnetic resonance cholangiopancreatography (MRCP). However, these investigations are not readily available, and in these situations a period of observation and conservative management is to be advocated.

We found an interesting group of patients with SCD and CJ who had dilatation of the bile ducts without an obstructive cause (24.6%). There are several causes for bile duct dilatation, such as CBD stones, tumor of the head of pancreas or Ampulla of Vater,

**Figure 3** ERCP showing biliary sludge in a patient with SCD. An arrow indicates the site of biliary sludge.

and tumors or masses at the porta hepatis. None of our patients had an obstructive cause for the bile duct dilatation. The exact etiology of this dilatation is not known. However, we think this is a form of cholangiopathy that is a consequence of sickling in the end arteries of the biliary arterial tree leading to hypoxia and dilatation<sup>[16,17]</sup>. The bile ducts are supplied via the hepatic arteries and ischemic bile duct injury might occur when these vessels are injured or occluded. This will ultimately result in ischemic stricture of the bile ducts. This however, depends on the extent and velocity of the occlusive process. In patients with SCD, we feel that the occlusion, which is usually not complete, is of the peribiliary vascular plexus and is a result of sickling within these vascular channels. This will ultimately lead to hypoxia of the bile ducts leading to their dilatation rather than ischemia and stricture formation. This is SCD cholangiopathy and the extent of this is also variable, as was demonstrated in our series. We found patients with bile duct dilatation limited to the common bile duct, but there were also those who had dilatation involving both extra and intrahepatic bile ducts (Figures 1 and 2). Documenting this is of great importance, as these patients need to be followed up regularly for the possibility of developing bile duct stones. Cunningham, in a study of the common hepatic duct diameter in SCD patients, found only two patients with clinically silent enlargement based on ultrasonic evaluation of 95 patients<sup>[20]</sup>. Their patients, in contrast to our patients, were young with a mean age group of 16.8 years. Taking in consideration the high frequency of biliary sludge and the possibility of bile duct stones formation in these patients, 42 (76.4%) of our patients with dilated bile ducts without an obstructive cause had endoscopic sphincterotomy, as this could obviate the future development of bile duct stones (Figure 3). Thus, the value of endoscopic sphincterotomy in this group of patients needs to be evaluated further, as endoscopic sphincterotomy is not without complications.

## COMMENTS

### Background

Cholestatic jaundice (CJ) is common in patients with sickle cell disease (SCD) and can be caused by both intra and extra hepatic pathology. However, there are certain causes of CJ that are specific to patients with SCD. One of the common intrahepatic causes is sickling of red blood cells (RBC), which is also called hepatic crisis or hepatic sequestration (sickle cell hepatopathy). This can mimic extrahepatic bile ducts obstruction which causes diagnostic and therapeutic dilemmas. Endoscopic retrograde cholangiopancreatography (ERCP) is one of the diagnostic and therapeutic measures used in patients with CJ. The value of ERCP for patients with SCD needs to be evaluated.

### Research frontiers

CJ is common in patients with SCD and it is of therapeutic importance to define the cause as soon as possible. Ultrasound is a valuable, non invasive, investigation but it has limitations. ERCP, on the other hand, is invasive but more valuable, both as a diagnostic and therapeutic procedure. It provides direct visualization of the biliary tree and demonstrates the site and nature of obstruction. This is of importance in excluding extrahepatic causes of CJ in patients with SCD, and once this is excluded emphasis is concentrated on intrahepatic causes.

### Applications

Taking in consideration the high frequency of biliary sludge, and the possibility of bile duct stones formation in these patients, endoscopic sphincterotomy might obviate the future development of bile duct stones.

### Terminology

Sickle cell disease is a form of hemoglobinopathy that results from a single amino acid substitution of valine for glutamic acid in the 6th position among the 146 amino acids of the hemoglobin-beta chain.

### Peer review

This is an interesting study evaluating sickle cell cholangiopathy by ERCP.

### Abstract

**AIM:** To estimate the prevalence of celiac disease (CD) in adult patients with presumed irritable bowel syndrome (IBS).

**METHODS:** Between March 2005 and December 2008, 742 consecutive patients (293 male, median age 43 years, range 18-69 years) fulfilling the Rome II criteria for IBS were prospectively enrolled in the study. IBS was diagnosed *via* self-completed Rome II modular questionnaires. Anti-tissue transglutaminase (anti-tTG) serology was checked to initially recognize possible CD cases. Patients with a positive test were offered endoscopic duodenal biopsy to confirm the diagnosis of CD.

**RESULTS:** Thirty two patients (15 male, median age 41 years, range 19-59 years) were found to have organic diseases other than CD. Twenty four patients tested positive for anti-tTG antibodies, and duodenal biopsies confirmed the diagnosis in all of them. Thus, in this patient population with presumed IBS, 3.23% actually had CD.

**CONCLUSION:** CD is common in patients with presumed IBS. Routine screening for CD in patients with symptoms of IBS is recommended.

Jadallah KA, Khader YS. Celiac disease in patients with presumed irritable bowel syndrome: A case-finding study. *World J Gastroenterol* 2009; 15(42): 5321-5325 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5321.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5321>

### INTRODUCTION

Irritable bowel syndrome (IBS) is a highly prevalent disorder. It is found in 10% to 20% of individuals using standard diagnostic tools such as the Rome II criteria<sup>[1]</sup>.

Diagnostic approaches to suspected IBS rely on eliciting symptoms that satisfy specific criteria and performing limited tests to exclude organic diseases that produce similar symptoms<sup>[2]</sup>.

IBS can sometimes be difficult to distinguish clinically from adult-onset celiac disease (CD)<sup>[3-8]</sup>. A broad spectrum of symptoms and signs may be associated with untreated CD. In fact, many patients - especially those presenting in adulthood - have minimal or atypical symptoms<sup>[5,7-10]</sup>.

The recent development of highly sensitive and specific serologic assays for CD has led to the increased realization that the disease is more common than it was believed<sup>[11-15]</sup>. This justifies the concern that some IBS-labeled patients may in fact have CD.

Reports of prevalence of CD in IBS patients from the Middle East are scanty.

We aimed to estimate the prevalence of CD in patients masquerading as IBS, and also to describe their clinical features.

### MATERIALS AND METHODS

#### Study population

Ethical approval of the study was obtained from the

Table 1 The modified Marsh classification of celiac disease

Type	Intraepithelial lymphocytes per 100 enterocytes	Crypts	Villi
0	< 40	Normal	Normal
1	> 40	Normal	Normal
2	> 40	Increased	Normal
3a	> 40	Increased	Mild atrophy
3b	> 40	Increased	Marked atrophy
3c	> 40	Increased	Absent

Table 2 The distribution of patients according to gender and IBS type *n* (%)

IBS type	Gender		Total
	Male	Female	
C-IBS	140 (47.8)	217 (48.3)	357 (48.1)
D-IBS	84 (28.7)	122 (27.2)	206 (27.8)
C/D-IBS	69 (23.5)	110 (24.5)	179 (24.1)
Total	293	449	742

IBS: Irritable bowel syndrome; C-IBS: Constipation-predominant IBS; D-IBS: Diarrhea-predominant IBS; C/D-IBS: Alternating constipation-diarrhea IBS.

Institutional Review Board at King Abdullah University Hospital. The potential implication of a positive result for CD was explained to all participants, and their written consent was obtained.

The Rome II criteria for IBS were applied to 891 consecutive patients upon their first visit to our outpatient gastroenterology clinic in the period between March 2005 and December 2008. The inclusion criteria were: age greater than 18 years, fulfilling the Rome II criteria for IBS; condition not previously investigated; absence of lactose intolerance or giardiasis. The exclusion criteria were: history of gastrointestinal alarm symptoms or signs; unwillingness to be submitted to esophagogastroduodenoscopy and/or colonoscopy. Only 764 individuals were eligible to participate in the study, and 22 (2.9%) of these did not agree to sign a written consent and thus were excluded from the study.

### Laboratory testing

Testing for anti-tissue transglutaminase (anti-tTG) serology was performed using the ORG 540A Anti-Tissue-Transglutaminase IgA (ORGENTEC Diagnostika GmbH®).

Quantitative IgA anti-tTG test was determined using the ELISA method. The sensitivity and specificity of this test in our laboratory was previously estimated at 98% and 96%, respectively (unpublished data). Patients with a positive test were submitted to duodenal biopsy to confirm the possibility of CD.

Other investigations included complete blood count, serum chemistry panel, erythrocyte sedimentation rate, thyroid function tests, occult blood stool testing, and stool analysis for ova and parasites. Additionally, patients with diarrhea were put on a 3-wk lactose-free diet to exclude lactose intolerance.

Table 3 The prevalence of celiac disease in different types of IBS patients

	No. of study patients	No. of celiac cases	Prevalence of CD (95% CI)
C-IBS	357	6	1.68 (0.35, 3.01) <sup>a</sup>
D-IBS	206	14	6.80 (3.36, 10.23) <sup>a</sup>
C/D-IBS	179	4	2.23 (0.07, 4.40)
Total	742	24	3.23 (1.96, 4.50)

<sup>a</sup>Significantly different (*P*-value = 0.0026); CI: Confidence interval.

### Colonoscopy

All patients older than 45 years or with a family history of colorectal cancer, and those with a positive occult stool blood test were submitted to colonoscopy to rule out structural disease. Furthermore, in patients with diarrhea random colonic biopsies were taken to rule out microscopic colitis.

### Intestinal biopsy

Using a standard biopsy forceps, six specimens were taken from the second and third portion of the duodenum. All biopsies were reviewed independently by two histopathologists, and changes of CD were reported using the modified Marsh criteria (Table 1).

### Statistical analysis

Data were analyzed using the Statistical Package for Social Sciences (SPSS, version 15). Continuous data were described using mean, median, standard deviation, and range wherever appropriate. Categorical variables were described using proportions. The 95% confidence interval (CI) was used to calculate the interval estimate of the prevalence of CD. Differences in prevalence rates according to different types of IBS were tested using  $\chi^2$  test; a *P*-value of less than 0.05 was considered statistically significant.

## RESULTS

This study included a total of 742 patients (293 males and 449 females). Their distribution according to gender and IBS type is shown in Table 2. Thirty two patients (15 males and 17 females) with a median age of 41 years (range 19-59 years) were found to have organic diseases other than CD [14 hypothyroidism, three microscopic colitis (two collagenous and one lymphocytic colitis), six lactose intolerance, three ulcerative colitis, and six Crohn's disease]. Twenty four patients [14 diarrhea-predominant IBS (D-IBS), six constipation-predominant IBS (C-IBS), and four alternating constipation-diarrhea IBS (C/D-IBS)] tested positive for anti-tTG. The prevalence of CD in different types of IBS is summarized in Table 3. The prevalence of CD in patients with D-IBS (6.80%, 95% CI: 3.36, 10.23) was significantly higher than that in patients with C-IBS (1.68%, 95% CI: 0.35, 3.01). Duodenal biopsies confirmed the diagnosis in all 24 patients. The modified Marsh criteria (Table 1) were used for the grading of severity of histopathological

**Table 4** The demographic and clinical features of celiac disease patients

Variable	n (%)
Gender	
Female	13 (54.2)
Male	11 (45.8)
Age (yr)	
18-25	8 (33.3)
26-35	8 (33.3)
36-61	8 (33.3)
mean (SD)	33.5 (11.5)
Body mass index, mean (SD)	26.6 (3.5)
Duration of symptoms (mo), mean (SD)	26.8 (18.1)
IBS type	
C-IBS	6 (25.0)
D-IBS	14 (58.3)
C/D-IBS	4 (16.7)
Malabsorptive features	
Hypoalbuminemia	2 (8.3)
Hypocalcemia	2 (8.3)
Iron deficiency	4 (16.7)
None	16 (66.7)

changes. Among our CD patients, two had Marsh type 1, seven had Marsh type 3a, 10 had Marsh type 3b, and five had Marsh type 3c. Thus, in this patient population with presumed IBS, 3.23% (95% CI: 1.96-4.50) actually had CD. The age of patients with CD (13 females and 11 males) ranged from 18 to 61 years with a mean (SD) of 33.5 (11.5). About 58% of these patients belonged to the D-IBS type, while less than 17% had the C/D-IBS type.

The demographic and clinical features of CD patients are summarized in Table 4. Interestingly, only eight of the CD patients had signs of intestinal malabsorption on further laboratory testing, with iron deficiency being the most common abnormality. The duration of IBS symptoms before the diagnosis of CD ranged between 6 and 72 mo (average 26.8 mo). The body mass index (BMI) of our CD patients was surprisingly higher than the expected, with an average of 26.6. All patients diagnosed with CD were started on a gluten-free diet, with subsequent improvement of their IBS-like symptoms in periods ranging from 2 to 6 wk.

## DISCUSSION

A high prevalence of CD in patients with presumed IBS was found in the present study. This implies that even with strict application of the Rome II criteria, IBS patients may have undetected CD. The majority of our CD patients had severe histopathological changes in duodenal specimens according to the modified Marsh criteria<sup>[16]</sup>. The advanced histopathological changes most probably reflect long-standing, untreated disease in our patient population.

The prevalence of CD in several recent population studies from North America ranged from 0.5% to 1%<sup>[17-19]</sup>. Studies in Europe have shown that up to 1% of the adult population may have CD<sup>[11]</sup>. In contrast to its high prevalence in Western countries, CD is considered rare in

non-Western populations. However, recent studies from the Middle East, Africa and India showed prevalence as high as 7.6% in selected groups of patients<sup>[20-22]</sup>. To the best of our knowledge, studies on the prevalence of CD in adult Jordanians have never been carried out. A prevalence study of CD in thousands of blood donors in Jordan is being conducted by the authors of the present study. Based on an interim analysis of the data obtained thus far, a prevalence of one in 200 could be projected. Therefore, IBS patients would be 6.5 times more likely to have CD than the general population.

The diagnosing of CD is often delayed, perhaps owing to a failure to recognize the protean manifestations of this disease, especially in the adult population. Patients often have few or no gastrointestinal symptoms and can even be obese<sup>[5,8,10]</sup>. In fact, in the present study none of the patients had typical symptoms of CD, such as steatorrhea or weight loss, and the majority of them had an average BMI in the overweight range.

Previously regarded as a mainly childhood problem it is now recognized that CD affects mostly adults, with about one quarter of patients being diagnosed at over 60 years of age. In a study by Green *et al.*<sup>[8]</sup>, data obtained on 1138 people with biopsy-proven CD showed that the majority of individuals were diagnosed in their 4th to 6th decades. Our study showed that adult CD can manifest at any age. However, it appears that the Jordanian adult patient population tends to present at a relatively younger age, possibly because of differences in gene penetrance as well as a larger wheat consumption by Jordanians (135 kg/head year); data from the Department of Agriculture, Jordan).

Survey data in the United States indicate that the median time to diagnosis in CD patients is 12 mo, and that over 20% of patients have symptoms for 10 years before CD is suspected and diagnostic testing performed<sup>[5]</sup>. However, the true denominator of undiagnosed CD is not well defined, and evolving data from both Europe and the United States indicate that many adult CD patients probably remain undetected<sup>[6,11,23]</sup>. In our CD patient population the time to diagnosis ranged between 8 and 72 mo. The delay in diagnosis could be ascribed to the atypical manifestations of the disease, but we believe that limited access to tertiary health care centers in our country could be another contributing factor to the long lag time before diagnosis.

CD can present with a wide spectrum of insidious symptoms. These can mimic symptoms of IBS. Several studies have suggested that the incidence of CD in patients with presumed IBS is higher than that of the normal population. In their case-control study of 300 subjects fulfilling the Rome II criteria for IBS, Sanders and colleagues found that the patients were 7 times more likely to have biopsy-proven CD than matched controls<sup>[4]</sup>. Sixty six patients with IBS tested positive for the antibodies, and 4.6% had active CD as compared with 0.66% of the non-IBS matched controls. The authors concluded that patients who meet the Rome II criteria for IBS should be investigated routinely for CD. More recently, the same investigators reported a primary

care-based cross-sectional study in which 1200 patients were recruited and evaluated serologically for CD<sup>[24]</sup>. The prevalence of CD in this population sample was 1%, while in the 123 participants with IBS the prevalence of CD was 3.3%. Once again, the authors recommended that a low threshold for serological screening of patients with IBS symptoms would be an optimal strategy.

In a recent primary care-based, multicenter study from North America, 976 subjects with symptoms or conditions known to be associated with CD, including IBS, were serologically tested for CD<sup>[25]</sup>. A diagnosis of CD was established in 22 patients, and thus the prevalence of CD in the serologically screened sample was 2.25%. The most frequent reasons for CD screening in these 22 cases were bloating (12/22), thyroid disease (11/22), IBS (7/22), unexplained chronic diarrhea (6/22), chronic fatigue (5/22), and constipation (4/22). The authors concluded that an active case-finding strategy in the primary care setting is an effective way to improve the diagnostic rate of CD. Of interest, the group of patients with IBS or symptoms of IBS - such as bloating, diarrhea, and constipation - constituted the largest proportion of screening-detected patients in their study.

Conversely, other investigators suggested that the prevalence of CD is not increased in patients with IBS symptoms. Locke III and colleagues recently published the results of a case-control study<sup>[26]</sup>. Using a self-completed questionnaire, the researchers evaluated 150 adult subjects, of whom 72 reported having symptoms of IBS and dyspepsia, and 78 controls who reported no gastrointestinal symptoms. The total number of individuals with CD in each group was surprisingly high: two out of 50 with IBS (4%), two out of 24 with dyspepsia (6%), and two of the 78 controls (2.6%). The researchers concluded that CD alone cannot explain the presence of IBS or dyspepsia in the subjects. The results of their study are interesting, but the sample size is probably not large enough to reach statistical significance.

Other studies suggested that the prevalence of CD in adult patients with IBS is not higher than that in the general population. Hin and colleagues conducted a case-finding study of CD in a primary care setting<sup>[27]</sup>. None of their 132 patients with IBS symptoms had positive results for CD, suggesting that CD rarely masquerades as IBS. Yet, we believe that this study is limited because of the small sample size.

It is arguable that, similar to IBS patients, other patients with various functional gastrointestinal disorders (i.e. functional dyspepsia) could have a higher prevalence of CD. In a recent study from Italy<sup>[28]</sup>, the authors reported biopsy-proven CD in 2% of their 726 patients with presumed functional dyspepsia, and suggested that routine duodenal biopsy should be considered in all dyspeptic patients undergoing diagnostic esophagogastroduodenoscopy. The results of this Italian study are interesting, but we believe that further prevalence studies of CD in the functional dyspepsia population are needed to corroborate these results.

There are some limitations in the present study. First, IgA test was not checked for all patients, which could

underestimate the prevalence of positive serology for CD because of the strict dependence of the anti-tTG test on the level of IgA. Second, because of limited resources, we used the lactose-free diet test to rule out lactose intolerance instead of the more accurate hydrogen breath test. Because of the lower sensitivity and specificity of the lactose-free diet test, some patients with lactose intolerance could be misdiagnosed as IBS or vice versa.

In conclusion, the prevalence of CD in patients with presumed IBS is high. Therefore, serological testing should be considered for all individuals with symptoms of IBS. However, larger, multicenter studies are needed to settle the debate on the utility - or futility - of screening IBS patients for CD.

## COMMENTS

### Background

Celiac disease (CD) may present with a broad spectrum of subtle or atypical symptoms. Some patients with irritable bowel syndrome (IBS) may have minimally symptomatic CD. The value of screening IBS patients for CD remains a matter of debate.

### Research frontiers

There were several early published studies showing minimal, atypical clinical presentations of CD. The widespread availability of highly sensitive and specific serologic tests for CD has allowed for large population-based serologic surveys that have shown this disorder to be very common, especially in at-risk groups such as patients with symptoms of IBS.

### Innovations and breakthroughs

The present study underscores the importance of screening IBS patients for CD. The high prevalence of CD found in our large study population is in accordance with the findings of other investigators. However, scattered reports from different regions of the world assert that the prevalence of CD is not increased in patients believed to have IBS. Based on the results of our study, we believe that screening IBS patients for CD should be routinely performed.

### Applications

Because the manifestations of CD respond to a gluten-free diet, testing for CD in patients with presumed IBS may prevent prolonged morbidity and unnecessary health care costs. The results of the present study may contribute to raising the awareness of the protean manifestations of CD, as well as settling the ongoing debate on the utility of screening IBS patients for CD. Larger, case-control studies of undetected CD in patients believed to have IBS are required to establish vigorous clinical guidelines for both primary care physicians and gastroenterologists.

### Terminology

CD is an immune-mediated enteropathy triggered by the ingestion of gluten-containing grains in genetically susceptible individuals. A case-finding study is a term used to describe a method which involves screening a smaller group of people for specific disorders based on specific baseline clinical characteristics.

### Peer review

The peer reviewers of this article believe that it is a valuable contribution to the pertinent literature. The study draws attention to the protean manifestations of CD and the need to be aware of this common disease in particular in conditions such as IBS.

### Abstract

**AIM:** To ascertain the usefulness of a histological scoring system devised to assist in the interpretation of liver histology in neonatal cholestasis (NC).

**METHODS:** Liver biopsy specimens obtained from infants with NC referred to a tertiary pediatric unit in Malaysia were prospectively studied. The first author, blinded to the final diagnosis, devised the histological diagnosis based on a 7-feature (portal ductal proliferation, bile plugs in portal ductules, porto-portal bridging, lymphocytic infiltration in portal region, multinucleated hepatocytes, neutrophilic infiltration, hepatocellular swelling), 15-point (0 to 15) scoring system. The author classified the histological diagnosis as either biliary atresia (BA) or neonatal hepatitis (NH, all other diagnoses), and subsequently compared the author's diagnosis with the final diagnosis.

**RESULTS:** Eighty-four biopsy specimens obtained from 78 patients were reviewed. Without the scoring system, BA was correctly diagnosed by the author histologically in 30 cases, labelled as NH in 3. For other diagnoses, BA was excluded correctly in 33 cases and mislabeled as BA in 2 cases. The overall sensitivity for BA was 91%, specificity 86% and accuracy 88%. With the scoring system, a score of  $\geq 7$  had the best diagnostic utility to differentiate BA from other intrahepatic cholestasis histologically (sensitivity 88%, specificity 94%, accuracy 92%). Four patients with a score  $< 7$  had BA, and 3 patients with a score  $\geq 7$  had NH.

### INTRODUCTION

A priority in the investigation of infants with neonatal cholestasis (NC) is to distinguish non-obstructive from obstructive causes to facilitate timely surgery for infants with biliary atresia (BA)<sup>[1,2]</sup>. Liver biopsy is one of the most important diagnostic steps in the evaluation of NC and may be performed safely even in the smallest infants with local anaesthesia and sedation<sup>[3,4]</sup>. Percutaneous liver biopsy has been found to be particularly helpful in infants suspected of having BA in developing countries<sup>[5]</sup>.

Bile ductular proliferation, bile plugging, multinucleated giant cells, focal necrosis of liver parenchyma, extramedullary haemopoiesis and inflammatory cell infiltrate in the portal area are all well-recognised histological features of BA<sup>[3]</sup>. Bile ductular proliferation is considered a highly specific and sensitive feature, while the others are less specific and sensitive<sup>[6,7]</sup>. The histological features of neonatal hepatitis, on the other hand, are more heterogeneous<sup>[8,9]</sup>, with giant-cell hepatitis a prominent feature, but others such as diffuse hepatocyte degeneration, minimal degree of bile ductular proliferation, and portal infiltration of lymphocytes, eosinophils and neutrophils less specific<sup>[8,9]</sup>. Other authors noted that the only consistent hepatic histological feature of neonatal hepatitis was extramedullary haemopoiesis<sup>[10]</sup>. Recently, a mathematical approach have been devised to identify the most useful histological feature differentiating BA from

other causes of neonatal cholestasis<sup>[11]</sup>. However, it has not received wide attention due to its complex nature<sup>[11]</sup>.

We devised an objective, 7-feature, 15-point histological scoring system for the interpretation of liver histology to differentiate BA from other causes of NC. Its diagnostic usefulness was tested prospectively in a cohort of infants with NC referred to a tertiary pediatric unit in Malaysia.

## MATERIALS AND METHODS

This prospective, descriptive study was conducted in the Department of Paediatrics, University of Malaya Medical Centre (UMMC), Kuala Lumpur and was approved by the institutional medical ethics committee.

### *The process*

The first author (Lee WS), blinded to the final clinical diagnosis, conducted the entire histological interpretation process alone and reviewed the histology of liver biopsy specimens obtained from patients with NC. Histological diagnosis based on the biopsy materials available were made, initially without and subsequently with the histological scoring system. The histological diagnosis was then compared with the final clinical diagnosis to ascertain the diagnostic usefulness of the histological scoring system.

### *The patients*

All patients with NC referred to the Department of Paediatrics, UMMC from May 2002 to June 2005 were enrolled. NC was defined as the onset of clinically apparent jaundice within the first four months of life, with the conjugated bilirubin greater than 17  $\mu\text{mol/L}$  if the total bilirubin was less than 85  $\mu\text{mol/L}$ , or the conjugated bilirubin more than 20% of the total bilirubin if the total bilirubin was more than 85  $\mu\text{mol/L}$ <sup>[12]</sup>. All cases of BA were confirmed with operative cholangiogram, or demonstration of atretic gallbladder and/or extrahepatic biliary tree intra-operatively<sup>[13,14]</sup>. Diagnosis of other causes of NC were made according to standard and acceptable clinical practices and have been described previously<sup>[1,15]</sup>. The histology review process was conducted in December 2007, more than two years after the final patient in the study cohort was recruited to allow a firm clinical diagnosis to be made in all patients.

### *The biopsy materials*

All patients with NC who had a liver biopsy were identified. The liver histology slides were traced and were screened for suitability of interpretation by the first author. Any material with faded stain was noted. The original paraffin-embedded tissue block was re-sectioned and re-stained with H&E stain. The biopsy materials were screened for adequacy in size and the number of portal tracts present. All the portal tracts were observed for the number, size and shape of portal bile ductules. The average number of bile ductules present in all the visible portal tracts was noted.

## *Histology of neonatal cholestasis*

A review of the literature on the histological interpretation of neonatal cholestasis was performed<sup>[2,9-11,16-19]</sup>. The histological features indicative of BA are bile ductular proliferation, porto-portal bridging, and the presence of bile plugs in the portal ductules<sup>[3,10-12,16]</sup>. Histological features more indicative of neonatal hepatitis are portal lymphocytic infiltration, neutrophilic infiltration, multinucleated giant cells, and hepatocellular swelling<sup>[2,7,16]</sup>.

### *The histological scoring system*

For the purpose of histological interpretation, the histological diagnosis was designated as either BA or non-BA. A 15-point scoring system based on histology of liver biopsy, consisting of seven histological criteria regarded as sufficiently specific to differentiate BA from non-BA, was devised (Table 1). Generally a higher score was indicative of BA, while a lower score was less favourable for BA. From the distribution of the score tabulated against the final diagnosis, a cut-off value with highest sensitivity, specificity and diagnostic accuracy differentiating BA from non-BA was determined.

Bile ductular proliferation was considered to be present if the average number of ductules in the portal tract was more than five. The following criteria were used to grade the degree of bile ductular proliferation: no proliferation - average number of bile ductules per portal tract < 5; mild - average number of bile ductules per portal tract between 5 to 9; moderate - average number of bile ductules per portal tract  $\geq 10$ ; marked proliferation - elongated, attenuated, angulated bile ductules in addition to proliferation (average number of bile ductules per portal tract  $\geq 10$ ).

### *Blinded histological interpretation*

The author personally interpreted the histology slides blindly without knowledge of the clinical data or the final clinical diagnosis. The route of biopsy was noted by observing the size and shape of the biopsy materials. Generally biopsy materials obtained *via* the percutaneous route were long and slender, while materials obtained *via* laparotomy were wedge-shaped. The adequacy of the size of the materials and the number of portal tracts available for interpretation was noted.

A blinded histological diagnosis was made for each histological specimen and was labelled as BA, non-BA (including other causes of cholestasis) or a paucity of bile ductules. For the purpose of statistical analysis, biopsies obtained *via* different routes (percutaneous or operative) from the same patient were considered as separate cases.

For the purpose of ascertaining the diagnostic accuracy of the newly devised histological scoring system, a two-step interpretation was performed, firstly without the scoring system and them with the scoring system.

### *Un-blinding and comparing with final clinical diagnosis*

The author (Lee WS) was un-blinded and the initial histological diagnosis was compared with the final

**Table 1** Seven-feature, 15-point histological scoring system devised for the interpretation of liver biopsy materials in neonatal cholestasis<sup>1</sup>

Parameter	Histological characterization	Histological grade
Portal ductal proliferation	None	0
	Mild	1
	Moderate	2
Bile plug in portal ductules	Marked	3
	Absent	0

	Periportal/diffuse	0

<sup>1</sup>The higher the score, the more likely to be biliary atresia.

diagnosis. The sensitivity, specificity and diagnostic accuracy for various diagnostic methods were calculated using the following formulas where TP = true positive, TN = true negative, FP = false positive, and FN = false negative. Sensitivity = TP/(TP + FN); Specificity = TN/(TN + FP); Positive predictive value = TP/(TP + FP); Negative predictive value = TN/(TN + FN); Diagnostic accuracy = (TN + TP)/(TN + TP + FN + FP).

## RESULTS

During the study period, 84 liver biopsy specimens for histology were obtained from 78 patients who were referred for diagnostic workup of NC. Six patients had both percutaneous and surgical liver biopsies (Table 2). One biopsy specimen (percutaneous) was fragmented and was insufficient for histological interpretation. Thus the remaining 83 specimens were analysed. The final diagnosis of these 83 specimens from 78 patients with NC is shown in Table 3.

### Liver biopsy materials

The median age at biopsy for all patients was 63 d (Table 2). Fifty-three (64%) of the biopsy materials were obtained *via* the percutaneous route while 30 (36%) were obtained surgically. A review of the original histology slides showed that 55 original specimens were adequate for interpretation, while re-staining was necessary in specimens from 28 patients. All 30 specimens obtained during exploratory laparotomy contained more than 5 portal tracts for interpretation. Of the 53 biopsy specimens obtained *via* the percutaneous route, 25 (47%) specimens contained less than 5 portal tracts. In two specimens, no portal tracts were noted.

**Table 2** Characteristics of 83 liver biopsy specimens obtained from 78 patients with neonatal cholestasis

	Biliary atresia (n = 33)	Intra-hepatic cholestasis (n = 50)	All (n = 83)
Age at biopsy (d)			
Median (range)	65 (34-371)	62 (26-180)	63 (26-371)
Route of biopsy			
Percutaneous	16	37	53
Operative	17	13	30
Number of portal tracts			
< 5	4	20	24
≥ 5	29	30	59

**Table 3** Diagnostic accuracy of hepatic histology in patients with neonatal cholestasis-author's personal interpretation

	Author's histological diagnoses			
	Biliary atresia	Neonatal hepatitis	Paucity bile	Final clinical diagnosis ducts
Biliary atresia	33	30	3	
Idiopathic neonatal hepatitis	35	2	33	
Cytomegalovirus hepatitis	6	3	3	
PFIC	4	1	3	
Alagille syndrome	1			1
Parenteral nutrition-associated cholestasis	1		1	
Congenital hypothyroidism	1	1		
Caroli disease	1		1	
Severe asphyxia	1		1	
Total	83	37	45	1

PFIC: Progressive familial intrahepatic cholestasis; Sensitivity: TP/(TP + FN) = 30/(30 + 4) = 91%; Specificity = TN/(TN + FP) = 43/(43 + 7) = 86%; Diagnostic accuracy = (TP + TN)/(TP + TN + FN + FP) = (30 + 43)/83 = 88%.

### Blinded interpretation

The diagnostic accuracy of the author's blinded histological interpretation is shown in Table 3. BA was correctly diagnosed histologically in 30 cases, but was labelled as non-BA in three cases. Non-BA was identified correctly in 33 cases, and labelled as BA in 2 cases. The remaining 15 patients had intrahepatic cholestasis. The author's histological diagnosis was BA in 5 cases and neonatal hepatitis in 9 cases. In the only case with Alagille syndrome, paucity of interlobular bile duct was correctly identified. The overall sensitivity of the author's personal histological interpretation for BA was 91%, sensitivity 86% and diagnostic accuracy 88%.

### Incorrect histological diagnosis

Seven cases of neonatal hepatitis were mislabeled as BA while three cases of BA were mislabeled as non-BA during initial histology without the scoring system (Table 4). Of the 3 cases of BA misdiagnosed as non-BA, liver biopsies in 2 patients were performed early in the course of illness *via* the percutaneous route. The number of portal tracts was inadequate for interpretation in both cases.

The biopsy specimen of the first patient (NKC, performed at 34 d) contained less than 5 portal tracts (Figure 1A) with no portal bile duct proliferation. There was hepatocytic degeneration and swelling, and occasional

<sup>1</sup>Including cytomegalovirus hepatitis (*n* = 6), progressive familial intrahepatic cholestasis (*n* = 4), Alagille syndrome (*n* = 1), TPN-associated cholestasis (*n* = 1), hypothyroidism (*n* = 1), Caroli disease (*n* = 1), severe perinatal asphyxia (*n* = 1), idiopathic neonatal hepatitis (*n* = 35).

giant cell transformation. The patient had persistent pale stools. A radionuclide hepatobiliary scintigraphic study was non-excretory. The child had an exploratory laparotomy at 42 d of age, which confirmed BA. A second liver biopsy obtained surgically showed features of BA with bile ductular proliferation, canalicular bile plugs and intracellular cholestasis (Figure 1B).

The biopsy specimen of the second patient (SQ, at 45 d) was fragmented. The liver parenchyma showed giant cell transformation. There was cholestasis within the hepatocytes and bile plug formation was seen within the canaliculi. The patient has persistent pale stools and

had a laparotomy which confirmed BA.

The biopsy specimen of the third patient (LQY), obtained at laparotomy at 78 d of age, showed features of neonatal hepatitis (Figure 1C).

### Histological features indicative of biliary atresia

Seven histological features were assessed individually to ascertain their usefulness in differentiating BA from non-BA (Table 5). Three features were found to be present in more than 50% of cases of BA: moderate to severe bile ductular proliferation (91%), presence of bile plugs in bile ductules (70%) and porto-portal bridging involving more than 50% of portal tracts (71%; Tables 6 and 7).

The presence of moderate or severe bile ductular proliferation had the highest sensitivity (91%), specificity (88%) and positive predictive value (83%) for BA (Table 6). In addition to proliferation, the bile ductules were often elongated and tortuous (Figure 1A). The remaining four features, i.e. lymphocytic and neutrophilic infiltrations, giant cell transformation and hepatocytic swelling were uncommon in BA (between 3% and 21%).

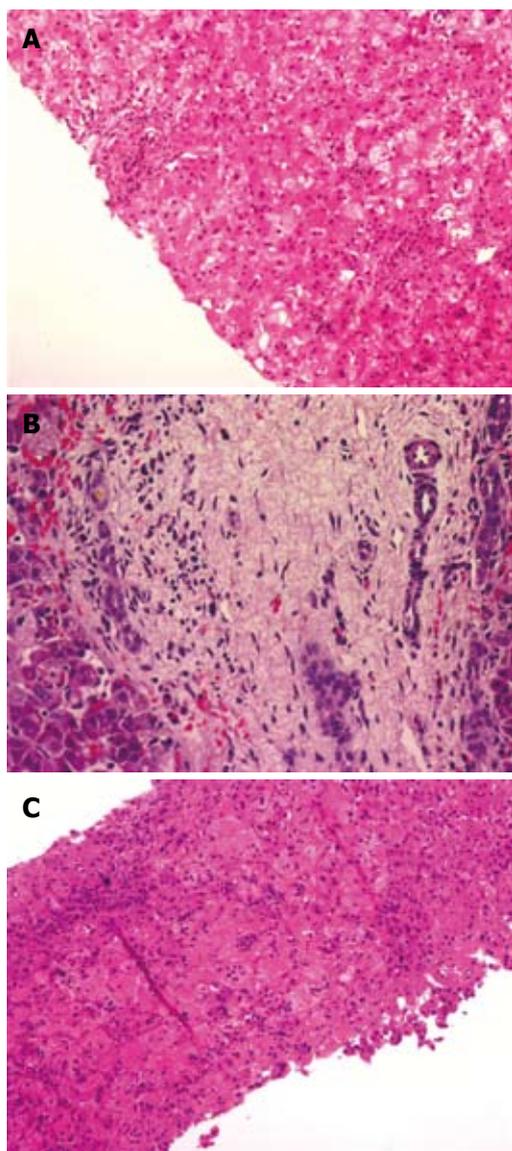

### Histological features of intrahepatic cholestasis

Generally, the features of intra-hepatic cholestasis were less sensitive and specific. The only histological feature noted to be present in more than 50% of patients with intrahepatic cholestasis was periportal or diffuse hepatocellular swelling (54%, Table 7). The remaining three features were noted to be present in 25% to 50% of intrahepatic cholestasis. Features indicative of BA (moderate to severe bile ductular proliferation, bile plugs in bile ductules, and porto-portal bridging involving more than 50% of portal tracts, were not common (between 13% and 14%).

Although not sufficiently sensitive (32%), diffuse giant cell transformations of hepatocytes were highly specific (97%) and has a positive predictive value of 94% for intrahepatic cholestasis. The other criterion, periportal or diffuse hepatocyte swelling was also specific (88%) and had a positive predictive value of 87%. The sensitivity was 54%.

### Histological scoring system (Table 8)

With a score of  $\geq 6$  to differentiate between BA and non-BA histologically, the diagnostic utility of the scoring

**Figure 1** Photomicrograph of liver biopsy (hematoxylin and eosin, original magnification  $\times 200$ ). A: A patient with biliary atresia obtained at 34 d of age (Patient NKC). A portal tract is shown here with no obvious bile ductular proliferation. There was hepatocytic degeneration and swelling. The original blinded histological diagnosis by the author was neonatal hepatitis; B: NKC obtained at 45 d of age. A portal tract is shown here with marked bile ductular proliferation, and bile plugs in bile ductules, typical of biliary atresia; C: A patient with biliary atresia (LQY) obtained at 78 d of life. There are multiple multinucleated giant cells, hepatocellular swelling and moderate lymphocytic infiltration. The original blinded histological diagnosis by the author was neonatal hepatitis.

system was: Sensitivity =  $29/(29 + 4) = 88\%$ ; Specificity =  $44/(44 + 7) = 86\%$ ; Positive predictive value =  $29/(29 + 3) = 91\%$ ; Diagnostic accuracy =  $(29 + 44)/83 = 88\%$ . With a score of  $\geq 7$ , the diagnostic utility of the scoring system was: Sensitivity =  $29/(29 + 4) = 88\%$ ; Specificity =  $47/(47 + 3) = 94\%$ ; Positive predictive value =  $29/(29 + 3) = 91\%$ ; Diagnostic accuracy =  $(29 + 47)/83 = 92\%$ ; Finally, using a score of  $\geq 8$ , Sensitivity =  $25/(25 + 8) = 76\%$ ; Specificity =  $47/(47 + 3) = 94\%$ ; Positive predictive value =  $25/(25 + 3) = 89\%$ ; Diagnostic accuracy =  $(25 + 47)/83 = 87\%$ . A score of  $\geq 7$  had the best diagnostic utility to differentiate between BA and other intrahepatic cholestasis histologically. With this score, four patients

with a score  $< 7$  had a final diagnosis of BA while three patients with a score  $\geq 7$  had neonatal hepatitis.

#### Comparison with pathologists' histological diagnosis

The results of the present study were compared with histological diagnoses made by the reporting pathologists (Table 9). The diagnostic accuracy of the present study (with scoring system, at 92%) was better than the diagnostic accuracy of 81% made by the reporting pathologists.

## DISCUSSION

The Cholestasis Guideline Committee of NASPGN recommends that a liver biopsy should be performed in most infants with undiagnosed cholestasis and should be interpreted by a pathologist with expertise in paediatric liver disease<sup>[12]</sup>. A percutaneous liver biopsy is recommended before performing a surgical procedure to diagnose BA. If the biopsy is performed early in the course of the disease (before 6 wk of age), biopsy may have to be repeated if the results are equivocal<sup>[12]</sup>.

In the present study, using conventional H&E staining in 83 liver biopsies obtained from 78 patients with NC, the overall diagnostic accuracy was 88% (Table 4). BA was correctly diagnosed histologically in 30 of 33 cases while non-BA was correctly diagnosed in 33 of 35 cases. This degree of diagnostic accuracy is in keeping with observations made by other authors<sup>[3,11,18]</sup>, but is lower than the degree of diagnostic accuracy reported by Lai *et al*<sup>[4]</sup>. Moyer *et al*<sup>[12]</sup> reported that with percutaneous liver biopsy, the sensitivity for BA was 89%-99% and specificity was 82.5%-98%.

In the present study, there were 10 histological misdiagnoses with H&E staining without the histological scoring system. Three cases of BA were missed. Of these, the biopsies in 2 cases were obtained early in life (34 and 45 d of age). In all three cases there was no prominent proliferation of bile ductules. In the remaining 7 cases, there was an overdiagnosis of BA in specimens obtained from patients who did not have BA.

With a histological scoring system devised to differentiate BA from other causes of NC using 7 histological criteria, the overall diagnostic accuracy was 92%, which was better than that without the scoring system (88%).

Histological interpretation of hepatic histology in patients with NC requires considerable skills which many general pathologists do not normally possess<sup>[11]</sup>. The advantage of a histological scoring system, in addition to its higher diagnostic accuracy, is that it provides a more objective and systematic way of assessing liver biopsy materials histologically. This may be the most important reason for the very high diagnostic accuracy achieved with this scoring system. In addition, since more than one criterion was used, it is less influenced by the adequacy of the biopsy materials. The seven histological criteria used in the scoring system during the present study were chosen based on the findings of other authors which showed the greatest discriminatory power between BA and other intrahepatic cholestatic disorders<sup>[9,11,16,17]</sup>.

Another advantage of the scoring system used in

statistical analyses using a logistic regression method. The accuracy, sensitivity, and specificity were 90.5%, 100% and 75.9%, respectively.

In the present study, the presence of moderate to severe bile ductular proliferation was the most consistent histological feature noted in BA, and was present in 30 of the 33 specimens analysed<sup>[11,16,17]</sup>. The other two features, i.e. bile plug in bile ductules and porto-portal bridging were not as consistent.

On the other hand, no single histological feature was consistently present in intrahepatic cholestasis. All four features analysed, i.e. lymphocytic and neutrophilic infiltration, giant cell transformation, and hepatocellular swelling, were present in 30% to 54% of cases of intrahepatic cholestasis. This is not surprising as intrahepatic cholestasis is a heterogeneous condition. Parenteral nutrition-associated cholestasis may cause

the present study was its non-complicated nature. Other authors have also attempted to devise a histological scoring system<sup>[10,11]</sup>. The scoring system reported by Zerbin *et al*<sup>[11]</sup> involved a series of initial complex

steatosis, bile ductular proliferation and, less commonly bridging fibrosis<sup>[20]</sup>. CMV hepatitis may cause intense hepatitis, giant cell transformation, intracytoplasmic inclusion bodies, bile stasis, inflammation, fibrosis and bile ductular proliferation<sup>[21,22]</sup>. On the other hand, conditions such as PFIC and Alagille syndrome caused a paucity of interlobular bile ducts<sup>[23]</sup>.

There are other advantages in using liver biopsies in the investigation of neonatal cholestasis besides its ability of achieving a high degree of diagnostic accuracy. Firstly, there is a shorter time delay of 1 to 3 d, compared to 3 to 5 d for radionuclide hepatobiliary scintigraphy<sup>[12]</sup>. In addition, percutaneous liver biopsy can be performed safely even in young infants<sup>[12]</sup>.

However, some difficulties remain in the interpretation of hepatic histology in neonatal cholestasis. One of these difficulties is inadequate biopsy materials obtained, especially *via* the percutaneous route. In the present study, while all the biopsy specimens obtained surgically contained an adequate number of portal tracts, slightly less than half (46%) of the specimens obtained *via* the percutaneous route contained less than 5 portal tracts for adequate interpretation. In 2 specimens, no portal tracts were observed. Thus, histological features indicative of BA which depend on an adequate number of portal tracts, such as bile ductular proliferation, bile plugs in bile ductules and porto-portal bridging, were not observed for adequate interpretation.

The present study shows that contrary to the claims made by some authors<sup>[24,25]</sup>, liver biopsy is a sensitive and specific method in the investigation of neonatal cholestasis. This study shows that with proper and adequate training in hepatic histology interpretation, the interpretation of liver histology in neonatal cholestasis can be achieved with sufficient sensitivity, specificity and accuracy.

In conclusion, histological interpretation of liver biopsies based on a 7-criteria scoring system had the highest sensitivity, specificity and diagnostic accuracy to differentiate BA from other intrahepatic cholestasis.

## COMMENTS

### Background

One of the most important priorities in the investigations of infants with neonatal cholestasis is to make an accurate diagnosis of obstructive causes such as biliary atresia to allow timely surgery, as early surgery for biliary atresia is one of the most important prognostic factors of successful outcome. However, there is considerable overlap in the clinical, biochemical and histological features of biliary atresia and other causes of neonatal cholestasis.

### Research frontiers

Making an accurate histological diagnosis for neonatal cholestasis has always been considered a challenge for many pathologists, particularly in the early neonatal period. Many previously reported attempts to histologically differentiate biliary atresia from other causes of neonatal cholestasis using a scoring system have not been widely accepted, mainly due to their complexities.

### Innovations and breakthroughs

In this study, the authors examined the diagnostic usefulness of a 7-feature, 15-point histological scoring system to differentiate biliary atresia from other causes of neonatal cholestasis histologically. It was found that when applied to biopsy specimens obtained from infants with neonatal cholestasis and when interpreted without a scoring system, this new histological scoring system offered good diagnostic accuracy. The diagnostic accuracy was better than the histological diagnosis made by reporting pathologists.

## Applications

By devising a new, objective histological scoring system with high sensitivity, specificity and diagnostic accuracy to differentiate biliary atresia from other non-obstructive causes, practising pathologists can make timely histological diagnoses in infants with neonatal cholestasis to avoid unnecessary surgery in those without biliary atresia, and early surgical correction in those with biliary atresia.

## Terminology

Neonatal cholestasis refers to the response of immature liver cells in the presence of various types of external insults. It is usually seen in newborn infants with somewhat immature liver function, and is characterized physiologically as a measurable decrease of bile flow, pathologically as the histological presence of bile pigment in hepatocytes and bile ducts, and clinically as the accumulation in blood and extrahepatic tissues of substances normally excreted in the bile. Although the insults to the liver may come in many different forms, there is considerable overlap in the clinical, biochemical and histological manifestations of neonatal cholestasis because the response of immature hepatocytes to external injuries is somewhat limited.

## Peer review

The article is a good attempt at making the diagnosis of neonatal hepatitis objectively. The authors have clarified the criteria for selection of the histological features differentiating biliary atresia from other causes of neonatal cholestasis. The basis of allotment of scoring points over each feature has also been clarified. The authors also noted that as compared to the diagnostic accuracy of the reporting histologists (81%), the diagnostic accuracy of the present scoring system (92%) was superior.

### Abstract

**AIM:** To investigate the association of fatty liver and smoking on metabolic syndrome and its components.

**METHODS:** This cross-sectional study enrolled participants who attended annual health screening at Shin Kong Wu Ho-Su Memorial Hospital from January to December 2005. A total of 3455 (1981 men and 1474 women) subjects were included in final analyses. Fatty liver was diagnosed using abdominal ultrasonography by trained gastroenterologists. The modified National Cholesterol Education Program Adult Treatment Panel III was used to define metabolic syndrome. The associations between smoking, fatty liver and metabolic syndrome were analyzed using multiple logistic regression.

**RESULTS:** Subjects with fatty liver, and who smoked tobacco, had the highest odds ratios (ORs) for high waist circumference [OR, 4.5 (95% CI: 3.3-6.1),  $P < 0.05$ ], hypertriglyceridemia [OR, 8.1 (95% CI: 6.0-10.9),  $P < 0.05$ ], low serum high-density lipoprotein cholesterol (HDL-C) [OR, 8.3 (95% CI: 6.1-11.3),  $P < 0.05$ ], and metabolic syndrome [OR, 9.5 (95% CI: 6.7-13.4),  $P < 0.05$ ] compared to subjects without fatty liver who did not smoke tobacco. We also found that the ORs for hypertriglyceridemia, low serum HDL-C, and metabolic syndrome for subjects with fatty liver who smoked tobacco had greater than the sum of the ORs for subjects with fatty liver who did not smoke

plus those who did not have fatty liver and who did smoke.

**CONCLUSION:** Fatty liver and smoking had a synergistic effect on metabolic syndrome and its components, especially for hypertriglyceridemia and low serum HDL-C.

### INTRODUCTION

Fatty liver is an increasingly recognized condition with growing prevalence in the modern world and is strongly associated with insulin resistance. The association between fatty liver and metabolic syndrome was broadly discussed in previous studies<sup>[1-9]</sup>. Fatty liver is often associated with central obesity, type 2 diabetes mellitus, dyslipidemia, and hypertension. Two studies based on Asian populations showed that Japanese subjects<sup>[1]</sup> with fatty liver had 5- to 9-fold risk of developing metabolic syndrome and Chinese subjects<sup>[6]</sup> had a 5.2-fold risk of developing metabolic syndrome. Lizardi-Cervera *et al*<sup>[3]</sup> found that the constellation of metabolic disturbances observed in subjects with fatty liver increased the risk of cardiovascular disease compared to those without fatty liver (OR, 4.7 *vs* 2.8). Fatty liver and metabolic syndrome are becoming important public health issues worldwide.

Smoking is a major risk factor for cardiovascular disease<sup>[10]</sup>. Previous studies have shown that smoking reduces insulin sensitivity or induces insulin resistance<sup>[10-15]</sup>

and enhances cardiovascular risk factors such as elevated plasma triglycerides (TG)<sup>[16-19]</sup>, decreased high-density lipoprotein cholesterol (HDL-C)<sup>[16,20]</sup> and hyperglycemia<sup>[11]</sup>. Furthermore, several studies show that smoking is associated with metabolic abnormalities and increases the risk of metabolic syndrome<sup>[21-24]</sup>. Nakanishi *et al.*<sup>[21]</sup> reported that subjects who habitually smoked tobacco had a 1.07- to 1.66-fold risk of developing metabolic syndrome compared to subjects who did not smoke, and the quantity of tobacco smoked had a dose-dependent relationship with the severity of metabolic syndrome.

Habitual smoking is a modifiable risk factor for metabolic syndrome and cardiovascular disease<sup>[10,19]</sup>. The most effective way for smokers to decrease the risk of metabolic syndrome and cardiovascular disease is to stop smoking<sup>[25]</sup>. However, Nakanishi *et al.*<sup>[21]</sup> found that smoking cessation was also associated with a 1.3-fold risk of metabolic syndrome due to subsequent body weight gain. Wada *et al.*<sup>[15]</sup> proposed that the effect of smoking on metabolic syndrome would remain over 20 years after smoking cessation.

The effects of fatty liver and habitually smoking tobacco on metabolic syndrome have not been previously addressed. The purpose of the present study was to investigate the possible interactive effects of fatty liver and smoking on metabolic syndrome and its components.

## MATERIALS AND METHODS

This retrospective cross-sectional study enrolled participants who voluntarily attended annual health screenings at the health center of the Shin Kong Wu Ho-Su Memorial Hospital from January to December 2005. Demographic data, medical histories, family histories regarding risk factors for metabolic syndrome, smoking habits, exercise habits, and alcohol consumption habits were collected through a self-administrated questionnaire. This study was approved by the Shin Kong Wu Ho-Su Memorial Hospital Institutional Review Board, and written informed consent was obtained from all participants. Hepatitis C ( $n = 109$ ), alcohol consumption more than three times per week ( $n = 77$ ), and subjects whose abdominal ultrasonographic findings revealed cirrhosis or other chronic liver parenchymal disease ( $n = 88$ ) were excluded from this study. Thus, a total of 3455 (1981 men and 1474 women) subjects were included in the final analyses.

At the time of examination, sitting blood pressure (mmHg) was measured by an automated oscillometric BP recorder Dinamap DPC 100X-EN (GE Medical Systems, Milwaukee, Wisconsin, USA) applied to the patient's left arm following a sufficiently long period of rest. Height and body weight were determined with a foot-to-foot bioelectric impedance analyzer (BF-220, Tanita Corp., Tokyo, Japan); these measurements were made to the nearest 0.1 cm and 0.1 kg, respectively, with subjects wearing light clothing. Body mass index (BMI, kg/m<sup>2</sup>) was calculated as body weight divided by the square of the individual's height. Waist circumference (WC, cm)

was measured midway between the lowest border of the ribs and the iliac crest in the horizontal plane, and to the nearest 0.5 cm, by trained nurses using an anthropometric non-stretchable tape after normal expiration.

Fasting blood samples were collected from all subjects after at least an 8-h fast. Serum levels of total cholesterol (mg/dL), low-density lipoprotein cholesterol (LDL-C, mg/dL), HDL-C (mg/dL), serum triglycerides (TG, mg/dL), and fasting blood glucose (FPG, mg/dL) were measured by an automated Hitachi 7600 clinical analyzer (Hitachi, Ltd., Tokyo, Japan).

Abdominal ultrasonographic examinations were performed by trained gastroenterologists using a Philips EnVisor M2540R (Philips, Andover, Minnesota, USA) without reference to the participants' history of liver disease, biochemical data, or other clinical findings. Using sonography, fatty liver was diagnosed on the basis of abnormally intense, high-level echoes arising from the hepatic parenchyma, liver-kidney difference in echo amplitude, echo penetration into the deep portion of the liver, and clarity of liver blood-vessel structure.

Subjects were classified as current smokers or non-smokers. Alcohol consumption was quantified as the number of drinking times per week, and subjects who drank more than three times per week were excluded before analysis.

### Definition of metabolic syndrome

Metabolic syndrome was defined as three or more risk factors as defined by the National Cholesterol Education Program Adult Treatment Panel III Guideline criteria and modified by the International Diabetes Federation specifically for the Chinese population, including (1) fasting glucose level  $\geq 100$  mg/dL, (2) serum triglyceride level  $\geq 150$  mg/dL, (3) HDL-C level (men  $< 40$  mg/dL, women  $< 50$  mg/dL), (4) systolic blood pressure  $\geq 130$  mmHg or diastolic blood pressure  $\geq 85$  mmHg, and (5) WC (men  $\geq 90$  cm, women  $\geq 80$  cm). The participants were allocated to one of four study groups according to their smoking status and ultrasonographic liver findings. Group 1 was defined as subjects who did not smoke and did not have fatty liver [fatty liver (-)/smoking (-)]. Group 2 was defined as subjects who did not have fatty liver, but currently smoked [fatty liver (-)/smoking (+)]. Group 3 was defined as subjects who showed ultrasonographic evidence of fatty liver but did not smoke [fatty liver (+)/smoking (-)]. Group 4 was defined as subjects who had ultrasonographic evidence of fatty liver and smoked concurrently [fatty liver (+)/smoking (+)].

### Statistical analysis

ANOVA was used for comparison of continuous variables. The  $\chi^2$  test was used for comparison of categorical variables. The association between smoking, fatty liver and metabolic syndrome components were analyzed using multiple logistic regression. We controlled confounding factors such as age, gender, drinking habit, and physical activity. A *P*-value less than 0.05 was defined as statistically significant. All statistical analyses

were performed using SAS statistical software, (SAS for Windows, version 8.02; SAS Institute Inc, Cary, NC, USA).

## RESULTS

Table 1 summarized the demographic data and lifestyle factors among the study subjects stratified by fatty liver and smoking habit. The fatty liver group had more men, higher BMI, and more alcohol drinkers compared to subjects without fatty liver. The frequency of regular exercise was similar for subjects with and without fatty liver. Furthermore, subjects who smoked tobacco also drank alcohol with greater frequency and exercised more regularly compared to subjects who did not smoke.

Table 2 summarized the clinical and biochemical characteristics of the study subjects. Participants with fatty liver had a significantly greater WC, FPG, blood

pressure and TG, and lower serum HDL-C compared to participants without fatty liver. Higher TG levels and lower HDL-C levels were found in the smoking group compared to subjects who did not smoke. Participants with fatty liver who smoked had the highest triglyceride levels (225.9 mg/dL) and the lowest HDL-C levels (44.3 mg/dL) among the four study groups.

The prevalence of metabolic syndrome abnormalities was significantly higher in the fatty liver group compared to subjects without fatty liver (Table 3). Subjects with fatty liver also had a higher prevalence of metabolic syndrome compared to those without fatty liver. Subjects who smoked had a higher prevalence of metabolic syndrome and more metabolic syndrome abnormalities, especially for higher TGs and lower HDL-C compared to subjects who did not smoke.

Table 4 showed the associations among fatty liver, smoking, and metabolic syndrome using multiple

<sup>a</sup> $P < 0.05$ . <sup>1</sup>Waist circumference in men  $\geq 90$  cm or in women  $\geq 80$  cm; <sup>2</sup>Systolic blood pressure  $\geq 130$  mmHg or diastolic blood pressure  $\geq 85$  mmHg; <sup>3</sup>High-density lipoprotein cholesterol in men  $< 40$  mg/dL or in women  $< 50$  mg/dL.

logistic regression. We found that subjects with fatty liver had significantly increased odds ratios (ORs) for developing metabolic syndrome and its components. Subjects who smoked had higher ORs for developing hypertriglyceridemia and low serum HDL-C, whether they had fatty liver or not. In addition, subjects with fatty liver who smoked had the highest ORs of high WC, hypertriglyceridemia, low HDL-C, and metabolic syndrome. We also found the ORs of hypertriglyceridemia, low HDL-C, and metabolic syndrome for subjects in group 4 [fatty liver (+)/smoking (+)] were greater than the sum of the ORs for subjects in group 3 [fatty liver (+)/smoking (-)] plus group 2 [fatty liver (-)/smoking (+)].

Table 5 showed the ORs for metabolic syndrome components among fatty liver groups. In comparison with subjects with fatty liver who did not smoke, subjects with fatty liver who smoked had significantly increased ORs for hypertriglyceridemia [OR, 1.5 (95% CI: 1.2-2.0),  $P < 0.05$ ], low HDL-C [OR, 2.7 (95% CI: 2.0-3.7),  $P < 0.05$ ] and metabolic syndrome [OR, 1.3 (95% CI: 1.0-1.8),  $P < 0.05$ ].

## DISCUSSION

In this study, we found that fatty liver was associated with an increasing OR for metabolic syndrome. The OR for developing metabolic syndrome increased significantly

among subjects with fatty liver compared to those without fatty liver. We also found that smoking was associated with high TG levels and low HDL-C levels. Subjects who smoked had increased ORs for hypertriglyceridemia and low HDL-C, whether they had fatty liver or not. Moreover, fatty liver and smoking seemed to have a synergistic effect on metabolic syndrome. The ORs for hypertriglyceridemia, low HDL-C, and metabolic syndrome for subjects in group 4 [fatty liver (+)/smoking (+)] had greater than the sum of the ORs for subjects in group 3 [fatty liver (+)/smoking (-)] group plus group 2 [fatty liver (-)/smoking (+)]. In fatty liver groups, subjects who smoked had a significantly increased OR for hypertriglyceridemia, low HDL-C and metabolic syndrome compared to subjects who did not smoke.

Metabolic syndrome and fatty liver were well discussed in previous studies. Insulin resistance played a pivotal role in the pathophysiology of both fatty liver and metabolic syndrome<sup>[26,27]</sup>. Furthermore, several studies showed that smoking induced insulin resistance or hyperinsulinemia and led to metabolic syndrome<sup>[1,3,23,28]</sup>. The associations between fatty liver, smoking, and metabolic syndrome were discussed in many studies individually, but the effect of interaction of fatty liver and smoking on metabolic syndrome was not investigated. In our study, subjects with fatty liver who smoked had a significantly increased risk of metabolic syndrome.

The effects of cigarette smoking inducing high plasma TGs and low HDL-C levels were shown in several studies<sup>[14,16-20,23,24,29,30]</sup>. While these studies provided evidence that smoking increased plasma TG and decreased HDL-C levels, most of these studies did not control potential confounding factors. Fatty liver also increased the risk of dyslipidemia such as hypertriglyceridemia and decreased HDL-C<sup>[3]</sup>. In our study, after controlling for confounding factors such as age, gender, drinking habit, and physical activity, the ORs for hypertriglyceridemia in subjects remained high: group 2 [fatty liver (-)/smoking (+)] 2.4 (95% CI: 1.8-3.2), group 3 [fatty liver (+)/smoking (-)] 5.3 (95% CI: 4.4-6.5), and group 4 [fatty liver (+)/smoking (+)] 8.1 (95% CI: 6.0-10.9) compared to subjects without fatty liver who did not smoke. Additionally, the ORs for low HDL-C were 2.0 (95% CI: 1.4-2.7) for group 2 [fatty liver (-)/smoking (+)], 3.4 (95% CI: 2.7-4.1) for group 3 [fatty liver (+)/smoking (-)], and 8.3

(95% CI: 6.1-11.3) for group 4 [fatty liver (+)/smoking (+)], compared to subjects without fatty liver who did not smoke. Thus, our study provided evidence that fatty liver and smoking increased the risk of hypertriglyceridemia and low HDL-C.

Cigarette smoking decreased insulin sensitivity through increasing circulating levels of insulin-antagonistic hormones (i.e. catecholamines, cortisol, and growth hormone) and increasing lipolysis, resulting in high circulating levels of free fatty acid<sup>[21]</sup>. Nicotine, carbon monoxide, and other metabolites from smoking also played important roles in insulin resistance. Furthermore, several mechanisms by which cigarette smoking promoted dyslipidemia were proposed, including decreased lipoprotein lipase activity, increased 3-hydroxy-3-methylglutaryl-CoA reductase activity, increased glucose-6-phosphatase dehydrogenase activity and increased central obesity<sup>[16]</sup>. Thus, both fatty liver and smoking increased plasma TG and decreased HDL-C by increasing insulin resistance and/or decreasing insulin sensitivity.

While there was no significant difference in WC in subjects without fatty liver, regardless of whether or not subjects smoked, the OR for central obesity was greater among smokers than non-smokers for subjects with fatty liver. These findings were consistent with a previous study<sup>[31]</sup>. Mizuno *et al*<sup>[31]</sup> proposed that WC showed no difference between non-obese subjects with or without a smoking habit. Nonetheless, WC was significantly higher in obese subjects who smoked than those who did not. Smoking seemed to accelerate visceral fat accumulation and promote obesity-related disorders.

Insulin resistance secondary to cigarette smoking decreased insulin-mediated glucose uptake and also resulted in hyperglycemia<sup>[11,32]</sup>. In present study, the ORs for hyperglycemia were 1.3 (95% CI: 0.8-1.9) for group 2 [fatty liver (-)/smoking (+)], 3.6 (95% CI: 2.9-4.6) for group 3 [fatty liver (+)/smoking (-)], and 2.8 (95% CI: 2.0-4.1) for group 4 [fatty liver (+)/smoking (+)], compared to subjects without fatty liver who did not smoke. Thus, fatty liver increased the risk of hyperglycemia, but the effect of smoking on blood sugar was not obvious.

The effect of smoking on blood pressure is controversial. Frati *et al*<sup>[10]</sup> showed that the acute effect of cigarette smoking increased blood pressure and heart rate, but this effect was not seen after the first hour. Geslain-Biquez *et al*<sup>[23]</sup> proposed that the frequencies of increasing blood pressures did not differ between smokers and non-smokers. Moreover, Weitzman *et al*<sup>[24]</sup> found that active smoking was associated with decreasing blood pressure. We found lower ORs for high blood pressure in smoking subjects with or without fatty liver. Fatty liver had a positive effect on elevating blood pressure, but smoking seemed to have a negative effect on raising blood pressure in present study.

There are several limitations in this study. First, since abdominal ultrasonography can only detect fatty liver when steatosis affects more than 33% of the liver parenchyma<sup>[33,34]</sup>, subjects in this study might be affected by fatty liver but not be detected. The impacting effects

of fatty liver on metabolic syndrome and its components might be underestimated. Second, the information of alcohol consumption was collected by the drinking times per week. We did not count the amount of alcohol units and the impacting effects of alcohol on metabolic syndrome components might be diluted. Besides, the smoking groups tended to have a higher prevalence of drinking, even though we excluded subjects who drank more than three times per week and using multiple logistic regression to adjust the impacting effects of alcohol on metabolic syndrome components, the effects of alcohol on metabolic syndrome components can not be totally ruled out. Third, the smoking data was collected by binary criteria in this study so the effects of smoking on metabolic syndrome components might be underestimated<sup>[35]</sup>.

In summary, fatty liver and smoking were closely related to insulin resistance<sup>[1-9,11-14,16,21-23,25,32]</sup>, and our study provided evidence that fatty liver and smoking had a synergistic effect on metabolic syndrome and its components, especially for triglyceride and HDL-C levels. We suggested that smoking cessation would have the great benefit of reducing the risk of metabolic syndrome, especially for subjects with fatty liver.

## COMMENTS

### Background

Metabolic syndrome is a frequent metabolic abnormality affecting approximately 20% of the nondiabetic population worldwide and increasing risks of cardiovascular diseases and mortality. Fatty liver and smoking increase the risk of developing metabolic syndrome through the pathogenetic factor of insulin resistance and were well discussed in previous studies separately. We aimed to investigate possible interactive effects of fatty liver and smoking on metabolic syndrome.

### Research frontiers

It was recognized that fatty liver, smoking and metabolic syndrome associated with insulin resistance would increase the risks of serious complications such as cirrhosis, hepatocellular carcinoma and cardiovascular diseases. We want to identify the interactive effect of fatty liver and smoking on metabolic syndrome and provide evidence for lifestyle modification and appropriate management.

### Innovations and breakthroughs

The authors provided evidence that fatty liver and smoking had a synergistic effect on metabolic syndrome and its components, especially for triglyceride and high-density lipoprotein cholesterol (HDL-C) levels.

### Applications

After identifying the synergistic effect of fatty liver and smoking on metabolic syndrome, the authors suggested that smoking cessation would have the great benefit of reducing the risk of metabolic syndrome, especially for subjects with fatty liver.

### Terminology

Metabolic syndrome: Metabolic syndrome is a cluster of metabolic abnormalities and is associated with waist circumference, serum triglycerides level, serum HDL-C level, blood pressure and fasting blood glucose (FPG) level. Fatty liver: Fatty liver is a clinicopathologic condition characterized by significant lipid deposition in the liver parenchyma.

### Peer review

This retrospective study investigated the possible interactive effect of fatty liver and smoking on metabolic syndrome. This study was based on a large scale population base ( $n = 3455$ ) and the results are interesting. Study results

suggested that smoking cessation would reduce the risk of metabolic syndrome, especially for people with fatty liver.

### Abstract

**AIM:** To investigate the role of the -347G→GA polymorphism in the progression of colorectal cancer (CRC).

**METHODS:** We designed a case-control study based on a population of CRC patients in China and normal healthy controls with no history of tumors or inherited diseases. Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analyses were used to genotype the variants, and immunohistochemical staining was performed to measure the expression of E-cadherin in different allele cases among the CRC patients and normal controls.

**RESULTS:** The GA-allele (G/GA heterozygous and GA/GA homozygous) did not increase the risk of CRC compared with the G-allele (OR = 1.232, 95% CI = 0.898-1.691). However, the frequencies of the GA-allele were higher in poorly differentiated ( $P = 0.002$ ) and proximal ( $P = 0.019$ ) CRC patients than in normal controls. We also observed that E-cadherin expression was lower in poorly differentiated CRC patients than in well differentiated CRC patients ( $P = 0.001$ ). Furthermore, E-cadherin expression was lower for the GA-allele than for the G-allele (G/G heterozygous) in CRC patients ( $P = 0.018$ ). In contrast, there was no

significant difference in E-cadherin expression for the G-allele and GA-allele in normal controls ( $P = 0.292$ ).

**CONCLUSION:** The -347G→GA promoter polymorphism in E-cadherin gene is associated with specific CRC features, and may be a prognostic factor rather than a susceptibility factor during the progression of CRC.

### INTRODUCTION

Colorectal cancer (CRC) is one of the most common cancers in Western countries<sup>[1]</sup>, and is becoming more prevalent in Asian countries, especially China<sup>[2]</sup>. The etiopathogenesis of CRC is considered to be multifactorial, and to include high red meat intake<sup>[3]</sup>, high alcohol intake<sup>[4]</sup> and smoking<sup>[5]</sup>. However, no single environmental or lifestyle factor has consistently been associated with the risk of CRC. Recently, more and more views support genetic predisposition as the basis of many diseases, especially cancers<sup>[6]</sup>. However, CRC is divided into hereditary and sporadic cases, which show distinct genetic alterations and exhibit different key events leading to neoplastic growth.

E-cadherin is one of the major constituents of cell-adhesion complexes in epithelial cells<sup>[7,8]</sup>. It is a 97-kDa transmembrane glycoprotein encoded by the E-cadherin gene (*CDH1*) located on chromosome 16q22.1. It plays important roles in the establishment of adherent-type junctions by mediating calcium-dependent cellular interactions, and is thought to be a tumor suppressor

protein<sup>[7]</sup>. Partial or total loss of E-cadherin expression occurs in the majority of human carcinomas<sup>[9]</sup>. Besides its role in physical cell-cell adhesions, E-cadherin is also thought to be involved in intracellular signaling in normal epithelial cells, since downregulation of this molecule in epithelial cells is frequently associated with tumor formation and differentiation<sup>[10]</sup>.

It is not yet understood how the expression of E-cadherin is regulated, and this may occur *via* loss of heterozygosity, gene mutations or methylation of the coding region. Recently, the promoter region of *CDH1* was reported to be highly polymorphic<sup>[11]</sup>. One of the polymorphisms is the -347G→GA (rs5030625) single nucleotide polymorphism (SNP) upstream from the transcriptional start site<sup>[12]</sup>. Just as nucleotide variations in the coding region of a gene can alter protein expression<sup>[12,13]</sup>, the -347G→GA polymorphism within the promoter region may change the transcriptional efficiency of *CDH1*. For example, the GA-allele has a weak transcriptional factor-binding strength and transcriptional activity compared with the G-allele<sup>[12]</sup>, suggesting that the GA-allele may be associated with tumor formation or differentiation.

In the present study, we carried out a hospital-based case-control study to explore the association of the *CDH1* -347G→GA polymorphism with sporadic CRC in China. In addition, we measured the expression of E-cadherin in different allele cases including CRC patients and normal controls by immunohistochemical staining to check the function of the -347G→GA polymorphism *in vitro*.

## MATERIALS AND METHODS

### Subjects

The study included 290 sporadic CRC patients and 335 normal healthy controls (Table 1) enrolled from The Affiliated Drum Tower Hospital of Nanjing University Medical School between 2004 and 2008. Most of the patients had recently received a final diagnosis of CRC and were scheduled for surgery if no clinical metastases were detected, or would receive chemotherapy. A small number of the CRC patients had previously received surgery or chemotherapy. None of the subjects were blood-related. Patients affected by CRC were considered eligible if they had a histological diagnosis and were free from any known diseases with a genetic predisposition. Controls were selected from trauma patients or puerperal women in the same hospital during this time period. None of the controls had a history of malignancy. All the subjects were interviewed by a trained interviewer using a pretested questionnaire to obtain information on their sociodemographic characteristics, dietary habits, smoking and drinking status, and their individual and family history of cancer. Sporadic CRC cases and controls were matched for age, sex, smoking and drinking history.

The study was approved by the Institutional Review Boards of the Drum Tower Hospital. All the participants provided written informed consent at the time of recruitment and agreed to blood collection.

### DNA extraction

Peripheral venous blood (5 mL) was drawn from each subject before they received surgery or chemotherapy, and was placed in tubes containing EDTA and stored at -70°C until analysis. Total genomic DNA was extracted using a purification kit (Promega, Madison, WI, USA) according to the manufacturer's instructions.

### Genotyping analysis

The *CDH1* -347G→GA polymorphism was genotyped by the PCR-RFLP method. A 447-bp fragment containing the -347G→GA polymorphism in the *CDH1* promoter was amplified with the following primers: forward, 5'-GCCCCGACTTGTCTCTCTAC-3'; reverse, 5'-GGCCA CAGCCAATCAGCA-3'. PCR amplification was carried out in a volume of 25  $\mu$ L containing 20 ng of genomic DNA, 1  $\mu$ L of primers, 20  $\mu$ mol/L each of the forward and reverse primers, 2.5  $\mu$ L of 10  $\times$  PCR buffer (Mg<sup>2+</sup>-free), 2  $\mu$ L of dNTP, 1.5  $\mu$ L of MgCl<sub>2</sub> and 0.5 U of Taq polymerase (TaKaRa Biotechnology, Dalian, China). The amplification was performed in a programmable thermal cycler (MWG Biotech AG, Ebersberg, Germany) as follows: 1 cycle of 95°C for 2 min; 35 cycles of 94°C for 1 min, 61°C for 1 min and 72°C for 1 min; and a final cycle of 72°C for 10 min. The PCR product was digested with *Ban*II (TaKaRa Biotechnology) at 37°C overnight (Figure 1A and B). After digestion, the products were separated by 3% agarose gel electrophoresis and stained with ethidium bromide (Figure 1C). GA/GA homozygous cases were represented by DNA bands of 332 and 116 bp. G/G homozygous cases were represented by DNA bands of 263, 116 and 68 bp. GA/G heterozygous cases displayed a combination of both alleles (332, 263, 116 and 68 bp).

**Figure 1** Genotyping analysis of the *CDH1* -347G→GA polymorphism by PCR-RFLP analysis. A: Structural diagram of the restriction enzyme analysis for *Ban*II; B: Schematic overview of the E-cadherin gene promoter PCR fragment and the locations of the *Ban*II restriction enzyme sites; C: RFLP analysis of the -347G→GA polymorphism using *Ban*II digestion. GA/GA homozygote: 332 and 116 bp; GA/G heterozygote: 332, 263, 116 and 68 bp; G/G homozygote: 263, 116 and 68 bp.

### Immunohistochemistry

CRC tissue samples were collected from CRC patients who underwent surgery. Normal colon tissue samples were collected from outpatients *via* colonic biopsies during colonoscopy examination.

Immunohistochemistry was carried out using the avidin-biotin-peroxidase complex method. The central region of CRC tissue samples and normal colon tissue samples were cut into 4- $\mu$ m sections, mounted on glass slides, deparaffinized and rehydrated by xylene and graded ethanol solutions. Endogenous peroxidase activity was blocked by incubation with 3% hydrogen peroxide for 20 min at room temperature. For antigen retrieval, the sections were heated in a pressure cooker for 5 min. The sections then were sequentially incubated with primary mouse antibodies against E-cadherin (Santa Cruz Biotechnology, Santa Cruz, CA, USA; dilution, 1:150; monoclonal antibody) overnight at 4°C, a biotinylated goat anti-mouse secondary antibody (Santa Cruz Biotechnology) for 30 min, and peroxidase-conjugated streptavidin for 10 min. Samples were colored with diaminobenzidine (Boster, Wuhan, China) and counterstained with hematoxylin. Images were captured under an Olympus-BX50F4 microscope (Olympus Corporation, Tokyo, Japan) and quantitatively analyzed using the Image-Pro Plus 6.0 software (Media Cybernetics, Bethesda, USA).

Sections of normal colorectal tissue were used as positive controls for E-cadherin staining. Negative controls were prepared by replacing the primary antibody with nonimmune IgG.

### Statistical analysis

The distributions of the clinical characteristics of the CRC patients and normal controls were analyzed by an unpaired two-tailed *t*-test. This test was also used to compare E-cadherin expression between the G-allele and

GA-allele. The  $\chi^2$ -test was used to test the differences in the allele frequencies between normal controls and CRC patients. The genotype data were further stratified by age, sex, smoking, alcohol intake, tumor location, pathologic grouping and clinical stage of CRC. The odds ratio (OR) and 95% confidence interval (CI) were calculated using an unconditional logistic regression model to evaluate the risk of the *CDH1* -347G→GA polymorphism for CRC. We performed all analyses with the SPSS 15.0 software package (SPSS Inc, Chicago, USA). Values of  $P < 0.05$  were considered statistically significant.

## RESULTS

All the recruited subjects were successfully genotyped. The study included 290 CRC patients and 335 normal controls with available data. The clinical characteristics of the study subjects are summarized in Table 1. No significant differences were noted in the distribution frequencies for sex, smoking and drinking.

As shown in Table 2, the G-allele and GA-allele frequencies were 52.8% and 47.2%, respectively, in the CRC patients, and 57.9% and 42.1%, respectively, in the controls. There was no significant difference between the patients and the controls ( $\chi^2 = 1.671$ ,  $P = 0.198$ ). A logistic regression analysis revealed that the GA-allele did not increase the risk of CRC (OR = 1.232, 95% CI = 0.898-1.691). However, when the CRC patients were stratified by age, sex, smoking, drinking, tumor location, pathologic grouping and clinical stage, the GA-allele frequency was higher in poorly differentiated CRC patients than in normal controls ( $\chi^2$ -test,  $P = 0.002$ ). In addition, the GA-allele frequency was higher in proximal CRC patients than in normal controls ( $\chi^2$ -test,  $P = 0.019$ ).

Immunohistochemical staining for E-cadherin was evaluated in 42 CRC patients (G-allele *vs* GA-allele: 20 *vs* 22) and 37 normal controls (G-allele *vs* GA-allele: 19 *vs* 18) (Figure 2). E-cadherin expression levels with the G-allele and GA-allele were compared between CRC patients and normal controls, as well as between poorly differentiated and well differentiated CRC patients (Figure 3). E-cadherin expression was significantly higher in normal controls, well differentiated CRC patients and the G-allele CRC patients than in CRC patients (*t*-test,  $P < 0.001$ ), poorly differentiated CRC patients (*t*-test,  $P = 0.001$ ) and the GA-allele CRC patients (*t*-test,  $P = 0.018$ ), however, there was no significant difference in E-cadherin expression between the G-allele and GA-allele in normal controls (*t*-test,  $P = 0.292$ ).

## DISCUSSION

Several molecular epidemiological studies have confirmed an association between the *CDH1* -347G→GA polymorphism and the risk of cancers, including gastric, colorectal and esophageal cancers<sup>[14,15]</sup>. The authors of these studies proposed that the *CDH1* -347G→GA polymorphism may be functional, and that the GA-allele could lead to transcriptional downregulation of *CDH1* and low expression of E-cadherin compared with the G-allele,

thereby increasing the risk of cancer. However, recent studies have indicated that some functional polymorphisms may play more important roles in the prognosis of cancer than in its formation<sup>[16,17]</sup>. To further investigate the association between the functional *CDH1* -347G→GA polymorphism and sporadic CRC, we conducted the present case-control study in a Chinese population.

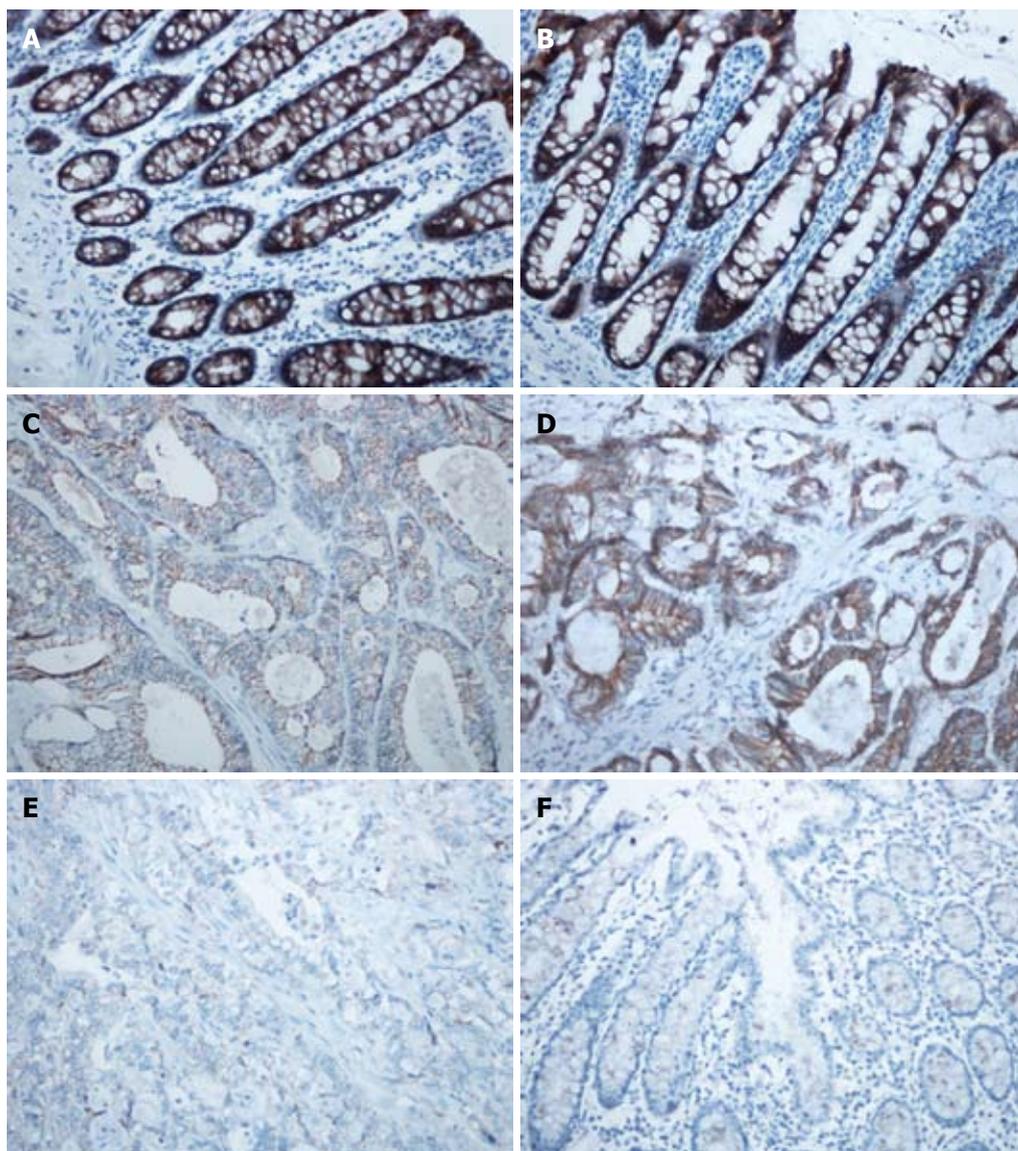

We found that the GA-allele did not increase the risk of CRC compared with the G-allele in this Chinese population. This finding is not consistent with the study by Shin *et al.*<sup>[18]</sup>, who reported that the GA-allele was associated with a significantly increased risk of CRC in Korea. Furthermore, their GA-allele frequency in normal controls (41/147, 27.9%) was obviously lower than the frequency observed in the present study (141/335, 42.1%). These discrepancies may be caused by racial differences. At the same time, we found that there was no significant difference in E-cadherin expression between the G-allele and GA-allele in normal controls, as evaluated by immunohistochemical staining. In other words, the GA-allele did not increase the risk of CRC or influence the expression of E-cadherin in normal controls.

However, the frequency of the GA-allele was significantly higher in our poorly differentiated and proximal CRC patients than in the normal controls. In addition, E-cadherin expression was lower in the poorly differentiated CRC patients than in the well differentiated CRC patients, and the E-cadherin expression was lower for the GA-allele than for the G-allele in CRC patients. Considering the above-described findings, the *CDH1* -347G→GA polymorphism did not appear to influence E-cadherin expression in normal controls. However, it

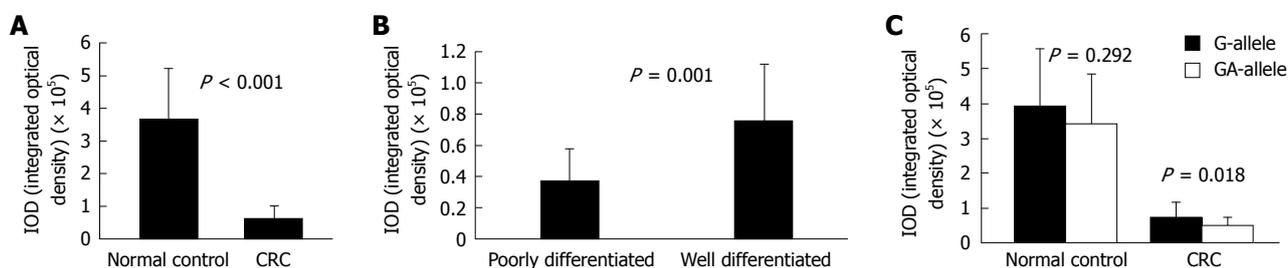

may play a role in the expression of E-cadherin after CRC formation, and may also be associated with the cell differentiation of CRC. These findings are reminiscent of the study of Cano *et al.*<sup>[19]</sup>, who found that the Snail gene family members were expressed in human carcinoma cells, especially poorly differentiated carcinoma cells, and could repress the transcriptional activity of *CDH1* through binding to a specified structure or zone in *CDH1*. We speculate that this specific structure or zone may be associated with certain functional polymorphisms.

Although the idea that E-cadherin is associated with tumors has been accepted by most researchers, the molecular mechanisms for the involvement of E-cadherin in tumor formation remain controversial. For example, it remains unknown whether E-cadherin acts as a susceptibility factor or a prognostic factor. Supporters of the former idea believe that loss of E-cadherin during tumor formation leads to accumulation of  $\beta$ -catenin in the cytoplasm, which could stimulate the  $\beta$ -catenin pathway<sup>[20]</sup>. However, several studies have shown that low expression of E-cadherin can occur after the formation of a tumor in response to alterations in the internal environment, such as hypoxic conditions, growth factor expression, tumor suppressor protein actions etc, all of which can modulate the expression of E-cadherin through various signaling pathways<sup>[21]</sup>. Therefore, it is possible that the *CDH1* -347G→GA polymorphism may change the transcriptional activity of *CDH1* after tumor formation by combining with other factors, and thereby influencing the differentiation of tumor cells.

In conclusion, we found that the *CDH1* -347G→

**Figure 2** Immunohistochemical staining for E-cadherin. A,B: E-cadherin expression in normal colorectal tissue with the G-allele (A) and GA-allele (B) (each,  $\times 200$ ); C,D: E-cadherin expression in well differentiated CRC with the GA-allele (C) and G-allele (D) (each,  $\times 200$ ); E: E-cadherin expression in poorly differentiated CRC with the GA-allele ( $\times 200$ ); F: Negative control ( $\times 200$ ).

**Figure 3** E-cadherin expression in colon tissues of different types. A: E-cadherin expression is significantly higher in normal controls than in CRC patients (*t*-test,  $P < 0.001$ ); B: E-cadherin expression is significantly higher in well differentiated CRC patients than in poorly differentiated CRC patients (*t*-test,  $P = 0.001$ ); C: There is no significant difference in E-cadherin expression between the G-allele and GA-allele in normal controls (*t*-test,  $P = 0.292$ ). However, E-cadherin expression is significantly higher for the G-allele than for the GA-allele in CRC patients (*t*-test,  $P = 0.018$ ).

GA polymorphism was associated with specific CRC features. Furthermore, the GA-allele was a repressive factor for the transcriptional activity of *CDH1*, but may begin to function after the formation of CRC and play

a role in the differentiation of tumor cells. This also implies that the *CDH1* -347G $\rightarrow$ GA polymorphism may be a prognostic factor rather than a susceptibility factor during the progression of CRC.

## COMMENTS

### Background

The progression of colorectal cancer (CRC) is a major cause of cancer death in Western populations, and is becoming more prevalent in Asian countries such as China. Although it is well known that high red meat intake, high alcohol intake and smoking are associated with the risk of CRC, host genetic factors may be one of the critical factors in carcinogenesis.

### Research frontiers

E-cadherin is thought to be involved in intracellular signaling in epithelial cells, since downregulation of this molecule in epithelial cells is frequently associated with tumor formation and differentiation. The -347G→GA polymorphism within the promoter region is considered to be functional, which may change the transcriptional efficiency of E-cadherin gene (*CDH1*).

### Innovations and breakthroughs

Most previous studies concentrated on the association of polymorphisms with the formation of carcinomas. This is probably the first report on the relationship between *CDH1* -347G→GA polymorphism and the prognosis of CRC, and we found that the -347G→GA polymorphism may be a prognostic factor rather than a susceptible factor during the progression of CRC.

### Applications

These findings may help doctors to choose an appropriate treatment for different CRC patients.

### Terminology

E-cadherin: E-cadherin is a 97-kDa transmembrane glycoprotein, which is one of the major constituents of cell-adhesion complexes in epithelial cells. *CDH1*: *CDH1* is the gene which encodes E-cadherin, and is located on chromosome 16q22.1.

### Peer review

It is a well-written and well-designed study, with large observed samples, and with important scientific merit.

### Abstract

**AIM:** To analyze the factors influencing radical (R0) resection rate and surgical outcome for malignant tumor of the pancreatic body and tail.

**METHODS:** The clinical and operative data and follow-up results of 214 pancreatic body and tail cancer patients were analyzed retrospectively.

**RESULTS:** One hundred and twenty/214 pancreatic body and tail cancer patients underwent surgical treatment; the overall resection rate was 59.2% (71/120), and the R0 resection rate was 40.8% (49/120). Compared with non-R0 treatment, the patients receiving an R0 resection had smaller size tumor ( $P < 0.01$ ), cystadenocarcinoma ( $P < 0.01$ ), less lymph node metastasis ( $P < 0.01$ ), less peri-pancreatic organ involvement ( $P < 0.01$ ) and earlier stage disease ( $P < 0.01$ ). The overall 1-, 3- and 5-year survival rates for pancreatic body and tail cancer patients were 12.7% (25/197), 7.6% (15/197) and 2.5% (5/197), respectively, and ductal adenocarcinoma patients had worse survival rates [15.0% (9/60), 6.7% (4/60) and 1.7% (1/60), respectively] than cystadenocarcinoma patients [53.8% (21/39), 28.2% (11/39) and 10.3% (4/39)] ( $P < 0.01$ ). Moreover, the 1-, 3- and 5-year overall survival rates in patients with R0 resection were 55.3% (26/47), 31.9% (15/47) and 10.6% (5/47), respectively, significantly better than those in patients with palliative resection [9.5% (2/21), 0 and 0] and in

patients with bypass or laparotomy [1.2% (1/81), 0 and 0] ( $P < 0.01$ ).

**CONCLUSION:** Early diagnosis is crucial for increasing the radical resection rate, and radical resection plays an important role in improving survival for pancreatic body and tail cancer patients.

### INTRODUCTION

Pancreatic carcinoma is one of the most fatal malignant diseases and ranks fifth in cancer mortality worldwide<sup>[1,2]</sup>. Survival after resection remains disappointing, with 5-year survival rates ranging from 10% to 29%<sup>[3-8]</sup>. Advances in diagnostic and operative techniques and in perioperative care have increased the resectability of pancreatic cancer, and have decreased rates of operative morbidity and mortality. The definition of a resectable tumor has become more clearly defined anatomically based on the availability of high-quality computed tomography (CT) scans<sup>[7-10]</sup>. Such imaging now permits a precise, preoperative, noninvasive assessment of tumor resectability and adds an important level of objectivity to the staging of patients for entry into clinical trials. Importantly, the role of laparotomy is now largely restricted to patients judged "resectable" on preoperative imaging<sup>[9,10]</sup>. For the 80%-90% of patients with pancreatic adenocarcinoma who have unresectable disease, biliary obstruction, when present, can be palliated using minimally invasive endoscopic techniques.

In patients with a malignant neoplasm in the body-

tail of the pancreas, splenectomy has a negative influence on long-term survival after resection<sup>[11,12]</sup>. The incidence of diabetes after spleen-preserving distal pancreatectomy for chronic pancreatitis is less than after *en-bloc* splenectomy<sup>[13-15]</sup>. Spleen salvage eliminates the risk of overwhelming infections. In the past decade, advances in surgical techniques have reduced the operative mortality rate of pancreatic resections to below 5% in high-volume centers, yet morbidity rates have remained essentially unchanged, ranging from 30% to 40%<sup>[11-16]</sup>.

The objective of this study was to analyze factors contributing to radical resection rate and outcome following radical resection for malignant tumors of the pancreatic body and tail.

## MATERIALS AND METHODS

### Patient characteristics

Two hundred and fourteen patients with malignant tumors of the pancreatic body and tail underwent radical pancreatectomy at the First Medical College of Wenzhou Medical College between January 2000 and December 2006, and at the First Affiliated Hospital of Zhejiang University between January 1990 and March 2002 and were eligible for study. The demographic and clinical courses of each patient were collected, including age, sex, and indication for radical pancreatectomy, concomitant splenectomy, symptomatology, diagnostic methods, operative management, pathology report, postoperative morbidity and mortality.

Of the 214 patients, 125 were men and 89 were women, with a mean age of 59.7 years (ranging from 15 to 81 years). Tumors were staged according to American Joint Committee on Cancer staging<sup>[17]</sup>, 11 patients (5.1%) were categorized into stage I, 6 patients (2.8%) into stage II, 16 patients (7.5%) into stage III, 62 patients (29.0%) into stage IVA and 119 patients (55.6%) into stage IVB. The preoperative diagnosis of pancreatic carcinoma was made using abdominal ultrasonography (US), CT, endoscopic retrograde cholangiopancreatography, magnetic resonance cholangiopancreatography and detection of serum tumor markers such as carcinoembryonic antigen, carbohydrate antigen 19-9.

### Surgical technique and definition of R0 resection

The main surgical techniques used for transection and closure of the pancreatic remnant included: (1) Anastomosis: the pancreaticojejunal end-to-end anastomosis was carried out followed Peng's invagination method<sup>[18]</sup>; (2) Closure by suture: the pancreas was transected with a knife, followed by identification of the main pancreatic duct and closure of the duct using single stitches of 2-0 silk suture. The parenchyma was then closed using single stitches of 2-0 silk suture; (3) In some cases, the suture line was reinforced by laying a fibrinogen/thrombin-coated collagen patch (Fibrin Sealant<sup>®</sup>, Guangzhou Bioseal Technology Co. Lt, China) onto the transected end; (4) In our university hospitals, radical resection, especially pancreatoduodenectomy, is performed only by

experienced surgeons who are the professors or directors of general surgery. Recently, most operations for pancreatic tumors have been performed by experienced surgeons in pancreatic disease.

In this study, R0 resection means negative resection margins and no residual tumor. If a frozen section taken of the cut pancreatic and bile duct margins was positive, more tissue was taken.

### Adjuvant therapy

In this study, all patients received regular or irregular adjuvant therapy (immuno-chemotherapy, radiotherapy and/or Chinese traditional drugs) after surgery, but no patients received neoadjuvant chemotherapy or radiation therapy before surgery.

### Definitions of postoperative complications

In this study, pancreatic leakage was defined as: (1) discharge from the postpancreatic drain  $\geq 50$  mL/d after postoperative day 3, and (2) an amylase level in drainage fluid exceeding three times that of the serum concentration. Postoperative mortality was defined as death occurring in the first 30 postoperative days or before discharge from the hospital. Other complications were categorized and defined as any of the following: intra-abdominal bleeding (requiring transfusion or operative intervention); gastrointestinal bleeding (requiring transfusion or endoscopic or operative intervention); intra-abdominal abscess (fluid requiring drainage and with positive bacterial culture); wound infection (purulent drainage requiring open packing); bile leak (bilious drainage from intraoperatively placed drains or bile collection requiring drainage); wound dehiscence (partial or total disruption of the fascial or all the layers of the incision).

### Follow-up

Follow-up information was obtained through office visits and telephone contact with the patients until the time of the patients' deaths or at the end of this study. In order to confirm the dates of deaths, if any, the data were verified at the regional station of the public records department for telecommunication and computer science. Local recurrence was defined as tumor relapse within the region or presence of a pancreatic stump. Distant metastases (or dissemination) were tumor lesions in other organs (outside the pancreas under treatment) such as liver and lung or remote lymph nodes, e.g. paraaortic lymph node. Upon their discharge from hospital, the patients were seen at least four times a year, i.e. every 3 mo, within the first 5 years, and every half a year thereafter. Physical examinations, basic routine X-ray examinations and abdominal US were performed. CT of the abdomen (twice a year), and if necessary the chest or head was added.

### Statistical analysis

The statistical analysis was performed with SPSS software (version 13.0; SPSS Inc, Chicago, Ill). All results are expressed as mean  $\pm$  SD. Univariate analyses of categorical variables were performed using  $\chi^2$  tests, and

**Table 1** The relationship between resection rate and clinicopathological variables (mean  $\pm$  SD) *n* (%)

Clinicopathological variables	Radicality		
	R0 resection ( <i>n</i> = 49)	R1 + R2 resection ( <i>n</i> = 22)	Bypass or laparotomy ( <i>n</i> = 49)
Tumor size (cm)	4.8 $\pm$ 1.3 <sup>b</sup>	7.9 $\pm$ 2.2	11.0 $\pm$ 3.8
Histopathological type			
Ductal adenocarcinoma ( <i>n</i> = 60)	15 (25.0) <sup>b</sup>	10 (16.7)	35 (58.3)
Cystadenocarcinomas ( <i>n</i> = 39)	25 (64.1)	7 (17.9)	7 (17.9)
Others ( <i>n</i> = 21)	7 (33.3)	6 (28.6)	8 (38.1)
Lymph node metastasis	16 (32.7) <sup>b</sup>	19 (86.4)	43 (87.8)
Peri-organ involvement <sup>1</sup>	26 (53.1) <sup>b</sup>	18 (81.8)	40 (81.6)
TNM staging			
Stage I + II ( <i>n</i> = 17)	17 (100.0) <sup>b</sup>	0	0
Stage III ( <i>n</i> = 16)	14 (87.5)	2 (12.5)	0 (0)
Stage IVA ( <i>n</i> = 34)	18 (52.9) <sup>2</sup>	7 (20.6)	9 (26.5)
Stage IVB ( <i>n</i> = 53)	0	13 (24.5)	40 (75.5)

<sup>b</sup>*P* < 0.01 vs R1 + R2 resection and bypass or laparotomy; <sup>1</sup>Peri-organ involvement included spleen, transverse colon, left kidney, stomach and their vessels; <sup>2</sup>Six gastric malignant tumors with pancreatic invasion, one pancreatic metastasis from renal cell carcinoma after operation, 11 pancreatic cystadenocarcinomas with splenic invasion.

the multivariate analysis was performed using a non-conditional logistic regression model expressed in odds ratios. To test the independence of the risk factors, the significant variables (*P* < 0.05) in the univariate analysis were entered into a multivariate logistic regression model with likelihood ratio forward selection with a criterion of *P* < 0.05.

## RESULTS

### Resection rate and clinicopathological features

Ninety-four of 214 patients with malignant tumor of pancreatic body and tail accepted non-surgical treatment, and 120 patients underwent surgery. The overall resection rate was 59.2% (71/120), and the R0 resection rate was 40.8% (49/120). R0 resections were those where the tumors were resected with clear surgical margins, as shown by intraoperative frozen sections and confirmed by definitive histopathological examination. Twenty-two patients underwent palliative resection (R1 or R2), 49 underwent bypass or laparotomy.

Compared with patients who underwent palliative resection (R1 + R2) (7.9  $\pm$  2.2 cm) or bypass/laparotomy (11  $\pm$  3.8 cm), the tumor size (4.8  $\pm$  1.3 cm) in patients who underwent radical resection was significantly smaller (*P* < 0.01). Similar results were found in patients with pancreatic cystadenocarcinoma [25.0% (15/60) vs 64.1% (25/39) and 33.3% (7/21), *P* < 0.01], less lymph node metastasis [32.7% (16/49) vs 86.4% (19/22) and 87.8% (43/49), *P* < 0.01] or less peri-organ involvement [53.1% (26/49) vs 81.8% (18/22) and 81.6% (40/49), *P* < 0.01]. Moreover, the radical resection rates in stage I + II and stage III were 100.0% (17/17) and 87.5% (14/16), which were much higher than those in stage IVA (52.9%, 18/34) and stage IVB (0) (*P* < 0.01) (Table 1).

**Table 2** Histopathological diagnosis of 120 patients with resected pancreatic malignant tumor

Histopathological classification	Cases
Ductal adenocarcinoma	60
Invaded and metastatic tumor	7
Pancreas invaded from gastrointestinal stromal tumor	6
Pancreatic metastasis from renal cell carcinoma	1
Cystadenocarcinomas	39
Serous cystadenocarcinomas	30
Mucinous cystadenocarcinomas	9
Endocrine malignant tumor	14
Insulinoma	3
Gastrinoma	11

Definitive histology of the resected lesions revealed a cystic tumor in a solid malignancy in 67 patients (60 ductal adenocarcinoma, six circumscribed infiltration of a gastrointestinal stromal tumor, one pancreatic metastasis from renal cell carcinoma), 39 cystadenocarcinomas (30 serous cystadenocarcinomas, nine mucinous cystadenocarcinomas), and 14 malignant endocrine tumors (Table 2).

### Procedures and postoperative complications

Forty-nine of 120 patients (40.8%) underwent R0 radical operation, including 22 with combined distal pancreatectomy and splenectomy, and 27 with spleen-preserving pancreatectomy. Postoperative complications occurred in 18 patients (15.0%) with pancreatic fistula (eight patients, 6.7%) being the most common, followed by intra-abdominal bleeding (4, 3.3%), gastrointestinal bleeding (2, 1.7%), incisional infection (3, 2.5%), and intestinal fistula (1, 0.8%). There was no operative mortality (defined as any death occurring within 1 mo after surgical procedure). Moreover, no detrimental effects of postoperative complications on oncologic efficacy of R0 pancreatectomy were found in this study.

### Long-term outcomes

Long term follow-up was performed using a standardized protocol. The median follow-up time was 23.1 mo, ranging from 4 to 83 mo. Seventeen patients with pancreatic carcinoma failed to follow-up and the overall follow-up rate was 92.1%. The 1-, 3- and 5-year overall survival rates in this group were 15.7% (31/197), 7.6% (15/197) and 2.5% (5/197), respectively. Moreover, the 1-, 3- and 5-year overall survival rates in patients with R0 resection were 55.3% (26/47), 31.9% (15/47) and 10.6% (5/47), respectively, which were significantly better than those in patients with palliative resection [9.5% (2/21), 0 and 0] or those with bypass/laparotomy [1.2% (1/81), 0 and 0] (*P* < 0.01, Table 3, Figure 1A). Among 49 patients with R0 resection, there was no significant difference in survival between the combined distal pancreatectomy and splenectomy group (*n* = 22) and spleen-sparing pancreatectomy group (*n* = 27) (*P* > 0.05) (Table 4). Furthermore, the 1-, 3- and 5-year overall survival rates [15.0% (9/60), 6.7% (4/60) and 1.7% (1/60), respectively] for pancreatic adenocarcinoma patients were worse than

**Table 3** The relationship between surgical radicality and survival *n* (%)

Surgical radicality	Cases with follow-up	1-yr survival	3-yr survival	5-yr survival
R0 resection ( <i>n</i> = 49)	47	26 (55.3) <sup>b</sup>	15 (31.9) <sup>b</sup>	5 (10.6) <sup>b</sup>
R1 + R2 (palliative resection ( <i>n</i> = 22)	21	2 (9.5) <sup>b</sup>	0	0
Bypass or laparotomy ( <i>n</i> = 49)	48	6 (12.5) <sup>b</sup>	0	0
Non-surgical treatment ( <i>n</i> = 94)	81	1 (1.2) <sup>b</sup>	0	0
Total ( <i>n</i> = 214)	197	25 (12.7)	15 (7.6)	5 (2.5)

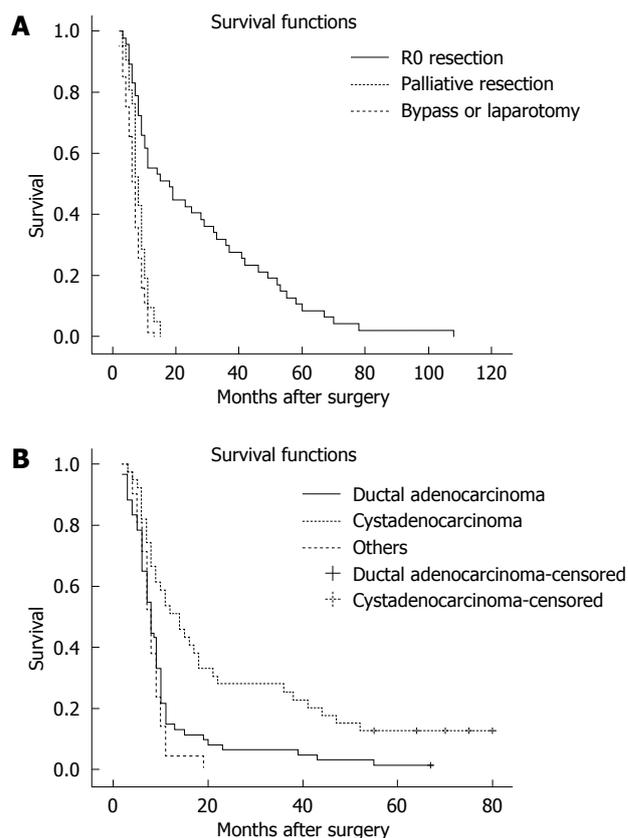

<sup>b</sup>*P* < 0.01 vs non-R0 resection, the 1-, 3- and 5-year survival rates were significantly longer.

those [53.8% (21/39), 28.2% (11/39) and 10.3% (4/39)] for pancreatic cystadenocarcinomas (Figure 1B, *P* < 0.01). In addition, the survival of patients with pancreatic adenocarcinoma of the body and tail was somewhat improved from the mid 1990s, but this improvement was not significant.

## DISCUSSION

It has been reported that less than 5% of all patients diagnosed with pancreatic carcinoma can expect to live for more than 5 years<sup>[1,2,19,23]</sup>. A radical pancreatic resection (R0) is an effective and safe method of treating various benign and malignant diseases of the pancreas. However, only 10%-20% of these individuals are candidates for surgical resection, which remains the only available chance for cure of this lethal disease<sup>[6,7,24]</sup>. Unfortunately delayed diagnosis, ineffective chemotherapy, lower radical resection rate, radiation resistance, and an intrinsic biologic aggressiveness of tumors all contribute to the poor prognosis associated with pancreatic cancer<sup>[1,2,5]</sup>.

Early detection and diagnosis are the key points to improve the outcome of pancreatic carcinoma, however almost 70% of patients with pancreatic carcinomas have unresectable disease at the time of initial diagnosis and are unable to undergo curative resection<sup>[1,5,6,25]</sup>. It has been reported that the resection rate is 20%-42.6% for pancreatic carcinoma, and the 5-year survival is 8.5%-10.6% after radical resection<sup>[1-4]</sup>. As for pancreatic carcinoma of the body and tail, the resection rate is much lower, only 10%-22%, and the prognosis is much poor because the tumor in this portion of the gland tends to invade surrounding organs and vascular structures<sup>[5,6]</sup>. Wu *et al*<sup>[5]</sup> compared clinical manifestations, pathological behavior and postoperative survival between malignant tumor of the pancreatic body and tail (*n* = 106) and malignant pancreatic head cancer (*n* = 451). The authors found postoperative median survival for resection of non-metastatic pancreatic body and tail cancer was significantly longer than similar resections in patients with metastatic disease. These results were no different than in those patients who had no resection. The overall and R0 resection rates in this study were 59.2% and 40.8%, respectively, and the 1-, 3- and 5-year overall survival rates in patients with R0

**Figure 1** Overall survival of malignant tumor of the pancreatic body and tail. A: Overall survival of 120 patients with malignant tumor of the pancreatic body and tail according to surgical radicality: Note the markedly increased survival time for patients who underwent radical resection (*P* < 0.01); B: Overall survival of 120 patients with malignant tumor of the pancreatic body and tail according to histopathological type: Note the markedly worse survival time for patients with ductal adenocarcinoma rather than cystadenocarcinomas (*P* < 0.01).

resection were 55.3%, 31.9% and 10.6%, respectively, which were better than those found in patients who had palliative resection or patients with bypass/laparotomy (*P* < 0.01). In addition, ductal adenocarcinoma patients had worse survival times than patients with pancreatic cystadenocarcinoma and other malignant tumors (*P* < 0.01). Liu *et al*<sup>[6]</sup> reported that factors influencing resection rate of pancreatic carcinoma included lymph node metastasis, tumor size and peri-pancreatic invasion, and the median survival times of radical resection, palliative resection and laparotomy for tumors of the body and tail of the pancreas were 18, 8 and 3.5 mo, respectively. Lim *et al*<sup>[26]</sup> collected a group of 396 patients aged > 65 years who were diagnosed with nonmetastatic pancreatic adenocarcinoma and found median survival was 17.6 mo, with 1- and 3-year survival rates of 60.1% and 34.3%, respectively. In this study, our findings revealed that compared with tumors which underwent palliative and bypass/laparotomy, the patients receiving R0 resections had smaller sized tumors, (*P* < 0.01), cystadenocarcinoma histopathology (*P* < 0.01), less lymph node metastasis (*P* < 0.01), less peri-pancreatic organ involvement (*P* < 0.01), and earlier stage (*P* < 0.01). These results indicate that small size, cystadenocarcinoma histopathology, lymph node metastases, and peri-

<sup>a</sup>*P* > 0.05.

pancreatic organ involvement were factors influencing the R0 resection rate.

Long-term survival after pancreatoduodenectomy for pancreatic carcinoma is far from excellent. The 5-year survival rate nears 10% and patients surviving more than 5 years are exceptional. It has been reported that the strongest predictors of survival are adjuvant combined chemoradiotherapy, small tumors (< 2 cm in diameter), negative lymph nodes, well-differentiated histology, undergoing surgery in a teaching hospital and high socioeconomic status<sup>[16,19,27]</sup>. A multivariate analysis of the 443 patients with periampullary adenocarcinoma from Yeo *et al*<sup>[28]</sup>, indicated that the most powerful independent predictors favoring long-term survival included a pathologic diagnosis of duodenal adenocarcinoma, tumor diameter < 3 cm, negative resection margins, absence of lymph node metastases, well-differentiated histology, and no reoperation. Schwarz *et al*<sup>[11]</sup> studied the outcomes in a group of patients (326 patients, 37 underwent splenectomy) with adenocarcinoma after distal and total pancreatectomy with or without splenectomy and concluded that splenectomy was a statistically significant unfavorable prognostic factor in survival, but not in postoperative morbidity. Shoup *et al*<sup>[4]</sup>, in a cohort with benign and low-grade malignant diseases (125 patients), reported that spleen preserving distal pancreatectomy is associated with lower infectious complications rate and reduced hospital stay, compared with distal pancreatectomy with splenectomy (*P* = 0.01 and *P* < 0.01, respectively). The median survival following resection was 15.9 mo compared to 5.8 mo in patients who were not resected (*P* < 0.0001). Actual 5- and 10-year survival rates were 22% and 18%, respectively, following extended resection, 8% and 8% following standard resection, and 0% and 0% if no resection was attempted because of locally unresectable disease. Patients undergoing extended resection for adenocarcinoma of the pancreatic body or tail have long-term survival rates similar to those for patients undergoing standard resection; they also have markedly improved long-term survival compared to those who are not considered resectable because of locally advanced disease.

Elective distal pancreatectomy is safer than pancreaticoduodenectomy but carries a high morbidity rate<sup>[5,6]</sup>. In the past decade splenectomy was associated with an increased septic complication rate<sup>[27]</sup>. Furthermore, several authors<sup>[12,24]</sup> suggested spleen preserving distal pancreatectomy in order to reduce postoperative septic complications. The technique of spleen preserving distal pancreatectomy and its absolute and relative contraindications have been described elsewhere<sup>[12,29]</sup>. In this study, the

postoperative complication rate was 15.0%, with pancreatic fistula (6.7%) being the most common, followed by intra-abdominal bleeding (3.3%), gastrointestinal bleeding (1.7%), incisional infection (2.5%), and intestinal fistula (0.8%). These are similar to previous reports<sup>[1,5,6,23]</sup>. Few retrospective studies have analyzed the influence of splenectomy in the postoperative course after distal pancreatectomy, while one study has analyzed this relationship after total pancreatectomy<sup>[29]</sup>. For example, Schwarz *et al*<sup>[11]</sup> reported that the median actuarial survival for pancreatic adenocarcinoma was 12.2 mo with splenectomy *vs* 17.8 mo without splenectomy (*P* < 0.005), and splenectomy (*P* = 0.02) as well as pathologic lymph node status (*P* = 0.0002), tumor diameter (*P* = 0.0004), and tumor differentiation (*P* = 0.007) were prognostic factors. In this study, there was no significant difference in survival between the combined distal pancreatectomy and splenectomy group and spleen-preserving pancreatectomy group.

In conclusion, early diagnosis is crucial for increasing the radical resection rate and radical resection plays an important role in the improvement of prognosis for patients with malignant tumors of pancreatic body and tail.

## COMMENTS

### Background

Pancreatic carcinoma is one of the most fatal malignant diseases and ranks fifth in cancer mortality worldwide. Survival after resection remains disappointing, with 5-year survival rates ranging from 10% to 29%. Advances in diagnostic and operative techniques and in perioperative care have increased the resectability of pancreatic cancer and have decreased rates of operative morbidity and mortality. The definition of a resectable tumor has become more clearly defined anatomically based on the availability of high-quality computed tomography scans. Such imaging now permits a precise, preoperative, noninvasive assessment of tumor resectability and adds an important level of objectivity to the staging of patients for entry into clinical trials. Importantly, the role of laparotomy is now largely restricted to patients judged "resectable" on preoperative imaging. The objective of this study was to analyze factors contributing to radical resection rate and outcome following radical resection of malignant tumors of the pancreatic body and tail.

### Research frontiers

Ways of improving the early diagnosis and radical resection are the hotspots in management of malignant tumors of the pancreatic body and tail.

### Innovations and breakthroughs

This study tries to find out the factors influencing early diagnosis and radical resection, by analysis of the factors which have effects on the resection rate of patients with malignant tumors of the pancreatic body and tail.

### Applications

By using those factors that influence early diagnosis and radical resection, we can evaluate objectively the "resectability" of each case with malignant tumors of the pancreatic body and tail.

### Terminology

This is a retrospective study on surgical treatment of malignant tumors of the pancreatic body and tail.

**Peer review**

The work is a retrospective analysis of the radical resection rate in 240 patients suffering from pancreatic cancer in two university hospitals from 1990 to 2006. The authors correctly point out that early diagnosis and curative resection is key to a positive outcome. The paper is well written and the data are adequately discussed.

### Abstract

**AIM:** To evaluate the impact of splenectomy on long-term survival, postoperative morbidity and mortality of patients with gastric cancer by performing a meta-analysis.

**METHODS:** A search of electronic databases to identify randomized controlled trials in The Cochrane Library trials register, Medline, CBMdisc (Chinese Biomedical Database) and J-STAGE, *etc* was performed. Data was extracted from the studies by 2 independent reviewers. Outcome measures were survival, postoperative morbidity and mortality and operation-related events. The meta-analyses were performed by RevMan 4.3.

**RESULTS:** Three studies comprising 466 patients were available for analysis, with 231 patients treated by gastrectomy plus splenectomy. Splenectomy could not increase the 5-year overall survival rate [RR = 1.17, 95% confidence interval (CI) 0.97-1.41]. The postoperative morbidity (RR = 1.76, 95% CI 0.82-3.80) or mortality (RR = 1.58, 95% CI 0.45-5.50) did not suggest any significant differences between the 2 groups. No significant differences were noted in terms of number of harvested lymph nodes, operation time, length of hospital stay and reoperation rate. Subgroup analyses showed splenectomy did not increase the

survival rate for proximal and whole gastric cancer. No obvious differences were observed between the 2 groups when stratified by stage. Sensitivity analyses indicated no significant differences regarding the survival rates ( $P > 0.05$ ).

**CONCLUSION:** Splenectomy did not show a beneficial effect on survival rates compared to splenic preservation. Routinely performing splenectomy should not be recommended.

### INTRODUCTION

Gastric cancer is a disease with a high incidence. It is estimated that approximately 21 500 new cases of gastric carcinomas and 10 880 deaths would occur in the United States in 2008<sup>[1]</sup>. There has been a trend toward proximal gastric carcinoma in Western countries<sup>[2,3]</sup>. In proximal gastric and gastroesophageal junction cancers, lymph node metastases are found more frequently in the splenic hilum<sup>[4]</sup>.

Extended lymph node dissection is regarded as essential for the treatment of gastric cancer<sup>[5]</sup>. Splenectomy is performed for the purpose of effective lymph node dissection around the splenic artery and splenic hilum and for direct invasion of the splenic hilum or spleen; however, the effect of splenectomy on the prognosis is controversial. Previous reports suggested that gastrectomy

with splenectomy resulted in better survival than gastrectomy alone in gastric cancer patients<sup>[6,7]</sup>. Some investigators have reported that splenectomy did not increase the survival rate<sup>[8-10]</sup>. In addition, the importance of the spleen as a part of the immune system and the immunological consequences of its removal have recently been stressed<sup>[11,12]</sup>.

However, recent clinical trials showed that gastrectomy with splenectomy could result in higher postoperative morbidity and mortality<sup>[13-15]</sup>.

The aim of this meta-analysis was to evaluate the impact of splenectomy on long-term survival of gastric cancer patients and to compare the postoperative morbidity and mortality of patients undergoing splenectomy with that of patients not undergoing splenectomy at the time of gastrectomy.

## MATERIALS AND METHODS

### Search strategy and study selection

We searched the electronic databases of PubMed (<http://www.ncbi.nlm.nih.gov/sites/entrez/>), the Cochrane Central Register of Controlled Trials ([http://www.mrw.interscience.wiley.com/cochrane/cochrane\\_clcentral\\_articles\\_fs.html](http://www.mrw.interscience.wiley.com/cochrane/cochrane_clcentral_articles_fs.html)), the J-STAGE Database (Japan Science and Technology Information Aggregator, Electronic) (<http://www.jstage.jst.go.jp/browse/>), and CBMdisc (Chinese Biomedical Database) (<http://dlib.edu.cnki.net/kns50/Navigator.aspx?ID=1>). Other websites and conference proceedings were searched, including those of the National Cancer Institute (<http://www.cancernet.nci.nih.gov/cancertopics>), the European Organization for Research and Treatment of Cancer (<http://www.eortc.be/>), the Southwest Oncology Group (<http://www.swog.org/>), ClinicalTrials.gov (<http://clinicaltrials.gov/>), the American Society of Clinical Oncology (<http://www.asco.org/portal/site/ASCO>). Moreover, the reference lists from relevant articles were screened for study inclusion. Eligible unpublished papers were also considered to be included, if known from consultation with Prof. Chen ZX and Prof. Chen JP.

The search strategy of Medline was as follows and was applied to other databases also: ["Stomach Neoplasms" (Mesh) AND "Carcinoma" (Mesh)] AND ["splenectomy" (MeSH) OR "spleen dissection" (textword) OR "spleen resection" (textword) OR "splenic preservation" (textword)] AND ["Comparative Study" (Publication Type) OR "follow-up studies" (Mesh) OR "Clinical Trial" (Publication Type) OR "Evaluation Studies" (Publication Type) OR "Multicenter Study" (Publication Type) OR "Random allocation" (Subheading) OR "Randomized Controlled Trial" (Publication Type/subheading) OR "Controlled Clinical Trial" (Publication Type) or "Research design" (Subheading)]. The electronic search was up to December, 2008 with no limitations regarding publication date and language.

### Inclusion and exclusion criteria

Only randomized controlled trials (RCTs) which compared the effectiveness or safety of splenectomy to

those of non-splenectomy were eligible.

The patients had been confirmed with gastric carcinoma by endoscopy and biopsy preoperatively. There was no limitation in the location of the gastric carcinoma and surgical procedure. There was no distant metastasis, the primary tumors were resectable, and the patients could tolerate the operation. Patients treated with chemotherapy, immunotherapy, *etc* perioperatively were included. There was no limitation in age, gender and race. Patients with splenectomy induced by iatrogenic injury were included because of the small number. Curative or palliative gastrectomies were included, but patients with other kinds of gastric tumors, such as lymphoma, other organ tumors or multiple gastric tumors (i.e. adenosquamous carcinoma) were excluded. Trials with uncertain or marked inequality of characteristics between groups at baseline were excluded.

### Selection, assessment and data extraction

In order to select studies for further assessment, 2 independent reviewers (Yang K, Zhang B) screened the title, abstract section and keywords of every record retrieved. Full articles were assessed if the information given suggested that the study conformed to our criteria described above. The final selection of studies was completed by 2 researchers (Yang K, Chen XZ). Any disagreements in quality assessment and data collection were discussed and resolved by a third reviewer (Hu JK) as the referee.

Data was extracted independently by 2 reviewers. Details of study sample (number in each arm), interventions (the details of splenectomy, as approach, as well as details of other treatments, such as adjuvant chemotherapy, immunotherapy, *etc*) and outcomes (5-year overall survival rate, postoperative mortality and morbidity and operation-related events) were extracted. Additionally, the year and country of study, the number and reason of withdrawals and dropouts and characteristics of patients were extracted.

If only survival curves were reported, the overall 5-year survival rates were extracted and converted from the figures as accurately as possible<sup>[16]</sup>.

When the trials had reported medians and ranges instead of means and standard deviations, we assumed medians were equal to means, and equated standard deviation to a quarter of the reported range. If neither a range nor any other measure of dispersion was reported, half of the mean or the median as standard deviation was used<sup>[17]</sup>.

Seven items relevant to the quality appraisal were used for assessment<sup>[18]</sup>: (1) whether the method of allocation was truly random; (2) whether there was proper concealment of allocation; (3) whether there was equality between the 2 groups at baseline in terms of prognostic features; (4) whether the eligibility criteria were described; (5) whether blinding of the outcome assessors was performed; (6) whether loss to follow-up in each treatment arm was demonstrated, and (7) whether intention-to-treat analysis was considered. Seven or 6 items were required for a trial to be rated as high quality, 5 or 4 items as fair quality and 3 or fewer as low quality<sup>[18]</sup>.

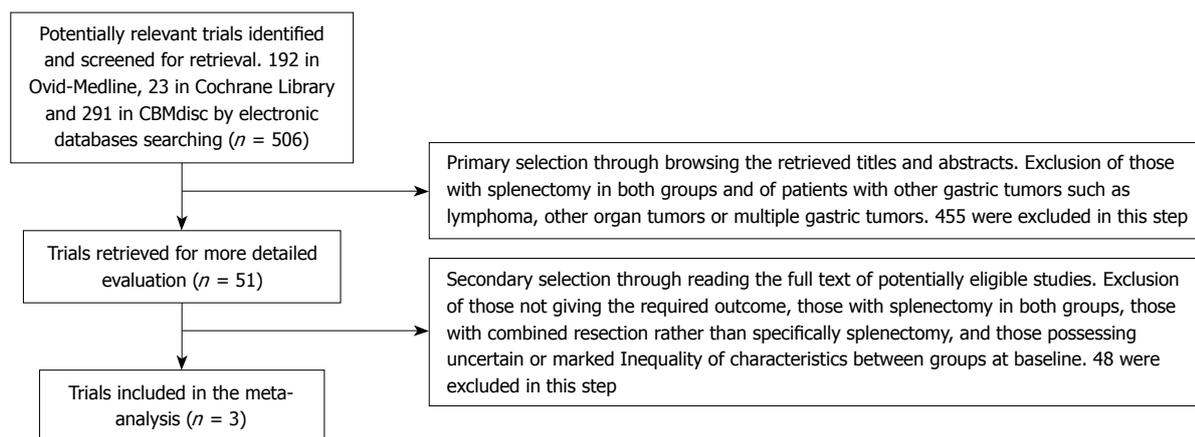

Figure 1 Flow chart showing study selection procedure.

Table 1 The characteristics of the included randomized trials

Study	Participants	Interventions	Outcomes
Csendes <i>et al</i> <sup>[63]</sup> , 2002	187 patients with gastric carcinoma entered this study. 97 patients with total gastrectomy and 90 patients with total gastrectomy and splenectomy	Total gastrectomy <i>vs</i> total gastrectomy plus splenectomy. The follow-up was at least 5 years	Five-year overall survival and survival by stage. Postoperative morbidity and mortality. Kaplan-Meier survival curve.
Toge <i>et al</i> <sup>[6]</sup> , 1985	The patients underwent total gastrectomy and had the main location of the tumor on lesser curvature region. They were divided into 2 groups at random: 41 in splenectomy (+) and 38 in splenectomy (-) groups	Splenectomy <i>vs</i> splenic preservation. The follow-up was at least 5 years	Duration of operation and hospital stay Kaplan-Meier survival curve. 5-year overall survival were from reported percentages data
Yu <i>et al</i> <sup>[64]</sup> , 2006	A total of 216 patients with proximal gastric cancer were randomized. 103 patients had the spleen preserved and 104 had a splenectomy	Splenectomy <i>vs</i> splenic preservation. Of the 207 patients, 7 were lost to follow-up (follow-up rate 96.6%) and mean duration of follow-up was 5.4 years	Harvested lymph nodes. Postoperative morbidity and mortality. Kaplan-Meier survival curve. 5-year overall survival were from reported percentages data

### Outcomes of interest and definitions

The primary outcome measures were 5-year overall survival rate, overall hospital or postoperative 30 d mortality, and overall morbidity rate, while the secondary outcome measure was operation-related events, the number of harvested lymph nodes, operation time, length of hospital stay and reoperation rate. One or more outcome measures should be available in the trials, or they were excluded.

### Statistical analysis

Weighted estimates of relative risks (RR) and weighted mean differences (WMD) with 95% confidence intervals (CI) were calculated for dichotomous data and continuous data respectively. The analyses were conducted using RevMan 4.3. A *P*-value < 0.05 was considered as statistically significant. Heterogeneities of treatment effect between trials were tested using a Chi-squared statistic with significance being set at *P* < 0.10, and the total variation across studies was estimated by I-square and divided into low, moderate and high levels, corresponding to the I-square of < 25%, 25%-50%, and > 50%<sup>[19]</sup>. If heterogeneities existed, one of the following techniques was undertaken to attempt to explain them: 1. Random effect model for meta-analyses; 2. Sub-group analyses; 3. Sensitivity analyses. Subgroup analyses stratified by the location of tumor and stage of tumor were performed.

Sensitivity analyses were performed only in high quality trials to avoid errors caused by poor quality studies<sup>[20]</sup>.

## RESULTS

### Included literature

There were 506 papers found in total (192 in Medline, 23 in Cochrane Library, 291 in CBMdisc, no new findings in other databases) and the selection was performed according to the inclusion/exclusion criteria stated above. Four hundred and fifty five trials were excluded in the primary selection through browsing the retrieved titles and abstracts and 48 trials<sup>[7-10,14-15,21-62]</sup> were excluded in the secondary selection through reading the full texts of potentially eligible studies. The flow chart of study selection is summarized in Figure 1.

Only 3 RCT trials<sup>[6,63,64]</sup> comparing the effectiveness and safety of splenectomy with gastrectomy to gastrectomy alone in patients with histologically proven gastric adenocarcinoma met the inclusion criteria. The details of included trials are listed in Tables 1 and 2.

A total of 466 patients were available for analysis, with 231 patients assigned treatment with gastrectomy plus splenectomy (treatment arm).

### Effectiveness

In this part, we used the number of patients alive as the

**Table 2** The quality of the included randomized trials

	No. of studies	Splenectomy (n <sup>1</sup> /N)	Splenic preservation (n <sup>1</sup> /N)	RR/WMD (95% CI)	P-value for effect size	P-value for heterogeneity	Effect model
Overall survival rate stratified by different length of follow-up	3	122/231	105/235	1.17 (0.97, 1.41)	0.1	0.85	Fixed
Postoperative morbidity and mortality							
Morbidity	1	16/104	9/103	1.76 (0.82, 3.80)	0.15	NA	Fixed
Mortality	2	6/194	4/200	1.58 (0.45, 5.50)	0.47	0.82	Fixed
Operation-related events							
No. of harvested lymph nodes	1	104 <sup>2</sup>	103 <sup>2</sup>	0.00 (-6.06, 6.06)	1	NA	Fixed
Operation time (min)	1	90 <sup>2</sup>	97 <sup>2</sup>	10.00 (-14.37, 34.37)	0.42	NA	Fixed
Length of hospital stay (d)	1	90 <sup>2</sup>	97 <sup>2</sup>	3.20 (-1.60, 8.00)	0.19	NA	Fixed
Reoperation	1	10/90	9/97	1.20 (0.51, 2.81)	0.68	NA	Fixed
Overall survival rate stratified by location of tumor (proximal and whole stomach)	2	93/190	84/197	1.14 (0.92, 1.41)	0.23	0.91	Fixed

<sup>1</sup>Represents the patients alive; <sup>2</sup>The summed number of patients in each group; RR: Relative risk; WMD: Weighted mean differences; CI: Confidence interval; NA: Not applicable.

number of events. The meta-analyses of trials showed that gastrectomy with splenectomy had no significant difference from splenic preservation on the 5-year overall survival rate, with RR of 1.17 (Table 3, Figure 2). The location and stage of the tumor had a major effect on the need for splenectomy to allow adequate hilar lymphadenectomy<sup>[10]</sup>. Thus we performed subgroup analyses with stratification by the 2 factors.

In the subgroup analyses, we also found that, for proximal and whole gastric cancer, splenectomy could not facilitate prolongation of survival. The RR of the 5-year overall survival rate was 1.14, which indicated splenectomy had no significant influence on survival rate compared to splenic preservation for proximal and whole gastric cancer (Table 3, Figure 2).

Then we analyzed the overall survival rate stratified by stage. Because of the limited number of included trials in this step, only one RCT<sup>[63]</sup> was used. The 5-year overall survival rates of patients with stage I, stage II and stage III in this RCT<sup>[63]</sup> were not significantly different between the 2 groups (all *P*-values > 0.05).

**Safety**

There was no clear and significant excess morbidity or mortality in the splenectomy group, with RR of 1.76 and 1.58 respectively, suggesting that postoperative morbidity and mortality did not occur more than in patients with splenic preservation. (Table 3, Figure 3).

**Operation-related events**

Non-significantly more lymph nodes were excised from patients undergoing splenectomy (WMD = 0.00 nodes). Operative time and length of hospital stay were not

significantly longer in the splenectomy group (WMD = 10.00 min and 3.20 d). There was no difference in reoperation rate between the 2 groups (RR = 1.20, Table 3).

**Sensitivity analysis**

The results of the sensitivity analysis, after excluding trials of low quality, are shown in Table 4. No significant differences were observed between the 2 arms in terms of the 5-year overall survival rate, and postoperative morbidity and mortality (RR = 1.14, 1.76 and 1.58, respectively).

**DISCUSSION**

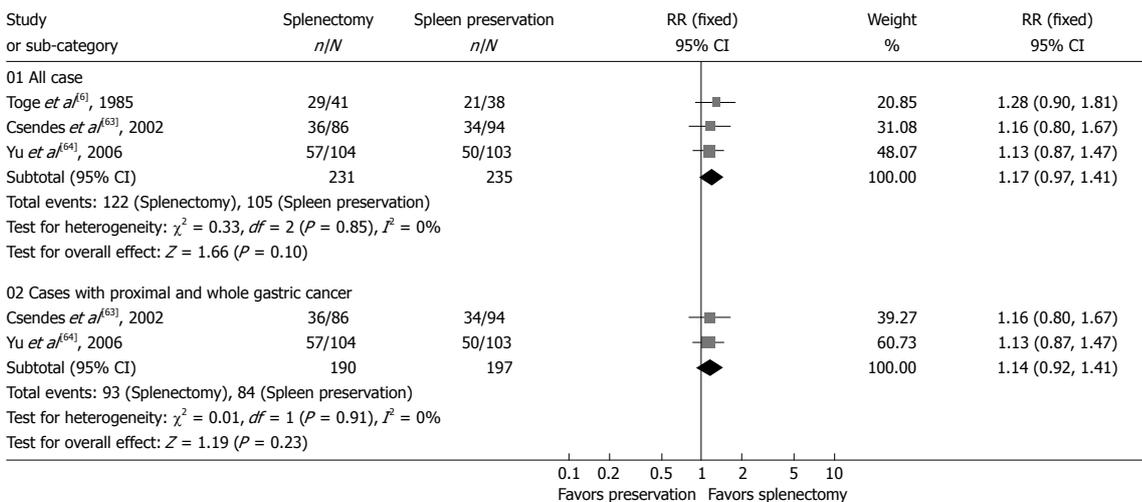

The incidence of proximal gastric cancers has increased<sup>[2,3]</sup>. Lymphography has demonstrated that the lymphatic flow from the left upper region of the stomach enters the lymph node in the splenic hilum and travels to the nodes around the celiac trunk along the splenic artery<sup>[65]</sup>. Thus it appears that splenectomy is more often performed for proximal gastric cancers<sup>[51]</sup>, and for a curative gastrectomy it is necessary to dissect the lymph nodes in the splenic hilum and the lymph nodes along the splenic artery. The frequency of metastasis to lymph nodes at the splenic hilum or along the splenic artery, which is associated with stage and tumor location, reportedly ranges from 8% to 10%<sup>[4,66]</sup>. Splenectomy has been recommended to facilitate lymph node dissection. Direct invasion of the spleen by gastric carcinoma is an exception requiring splenectomy<sup>[25]</sup>. The possibility that splenectomy could increase the survival rate of patients with gastric cancer has attracted much attention. Some prospective randomized controlled trials and retrospective analyses have been done or are

ongoing<sup>[67]</sup>, but the main results are controversial.

When we searched for trials for the meta-analysis, we found that the search results consisted mostly of retrospective analyses with a high level of heterogeneity. From these retrospective analysis, we could see in those

who underwent gastrectomy with splenectomy, the tumor was larger, the lesion was more commonly present in the upper stomach, grossly types 3 and 4 infiltration lesions were more frequent, depth of serosa invasion was greater, the rate of lymph node involvement was higher,

and advanced stages were more frequent. Furthermore, in many retrospective papers, distal gastrectomy (naturally without splenectomy) for distal cancer and total gastrectomy with splenectomy for advanced proximal cancer were simply compared without any adjustment. So we excluded these kinds of trials for a meaningful result. With respect to the 5-year overall survival rate, our results failed to suggest that splenectomy could result in greater benefit to the patients. When stratified by proximal and whole gastric cancer, a similar result was observed. In the sensitivity analysis, after we excluded the trials of low quality, no significant differences could be detected in 5-year overall survival rates for all the cases or for cases with proximal and whole gastric cancer.

Although we included only RCTs to guarantee the reliability and validity of the results, the eligible number of patients was far too small. So we carefully selected some non-RCTs with good balanced baseline characteristics for a meta-analysis. The quality of non-randomized studies was assessed by using the Newcastle-Ottawa Scale<sup>[68]</sup> with some modifications to match the needs of this study. The quality of the studies was evaluated by examining patient selection methods, comparability of the study groups and assessment of outcome. Finally we included 7 non-RCTs with 895 patients available for analysis (453 patients were treated by splenectomy). This analysis also showed splenectomy had no significant influence on survival rates compared to splenic preservation for all the cases and for patients with proximal and whole gastric cancer, with an OR of 0.77 (95% CI: 0.57-1.04) and 0.54 (95% CI: 0.24-1.23). In the splenectomy group postoperative morbidity (OR = 3.75, 95% CI: 2.69-5.23), rather than mortality (OR = 1.38, 95% CI: 0.12-16.35), occurred more than that of splenic preservation. Based on the above results, we found splenectomy could show a trend for survival in randomized trials, and the data from non-RCTs showed an opposite trend. This discrepancy in the overall survival and morbidity between RCTs and non-RCTs may derive from the relatively uncertain quality of the non-RCTs although the included trials had balanced baselines. This arises because, in non-RCTs, splenectomy was selected for gastric cancer patients with more advanced tumors, while the spleen was preserved in earlier stage cancers. Also, in the included non-RCTs, gastric cancer requiring splenectomy was usually more extensive or originated from the gastric body. The majority were histologically diffuse type, while tumors treated by distal gastrectomy were more commonly intestinal type and had better prognosis. Furthermore, the extent of lymphadenectomy, the type of gastrectomy, the other organs resected, *etc* would affect the outcome. With respect to the availability of relatively few high quality RCTs, more well-designed RCTs are needed to explore the effectiveness of splenectomy, especially for proximal and whole gastric cancer.

Whether splenectomy could increase the survival rate in patients with lymph node metastasis at the splenic hilum or along the splenic artery, there is too little evidence. One randomized controlled trial<sup>[64]</sup> reported no patients could survive for 5 years if lymph nodes at the hilum of the spleen were positive, and the 5-year

survival rate of positive lymph node metastasis along the splenic artery in the splenectomy arm or splenic preservation arm were 23.4% and 20.0%, respectively ( $P = 0.753$ ). Zhang *et al*<sup>[52]</sup> found that splenectomy did not show superiority to splenic preservation in patients with positive No. 10 and No. 11 lymph nodes ( $P = 0.284$ ). Kodera *et al*<sup>[39]</sup> reported that in patients who had histological evidence of metastasis to the splenic hilar nodes or the nodes along the splenic artery, pancreaticosplenectomy or splenectomy did not result in improved survival. As yet, there is no evidence to support that splenectomy could increase the survival rates of patients with metastasis to the lymph nodes at the splenic hilum or along the splenic artery.

Regarding the survival rates by stage, the included analyzable trials were too few. From previous reports<sup>[58,63]</sup>, no obvious differences were observed between the 2 groups. Here, we also should note that there were distinct methods for staging at the different periods; furthermore, differences between UICC (Union Internationale Contre le Cancer) and Japanese gastric cancer parameters existed. Thus more unified trials should be done for future evaluation.

In addition, the spleen is an important component of the reticuloendothelial system and constitutes 25% of the total lymphoid mass<sup>[69]</sup>. There was a 12-fold increased risk of septicemia compared with the general population after splenectomy<sup>[63]</sup>. On the other hand, the role of the spleen in tumor immunology is still controversial<sup>[70]</sup>. Therefore the indication for splenectomy is debatable.

Recent European clinical trials of gastrectomy showed that splenectomy was an important risk factor for postoperative morbidity and mortality<sup>[13-15]</sup>. The common complications after splenectomy were pancreatitis, pleural effusion, abdominal abscess, wound infection, pancreatic leakage, ileus and anastomotic leakage<sup>[57]</sup>. Splenectomy could easily induce gastric remnant ischemia, possibly contributing to the high frequency of anastomotic leakage and mortality<sup>[25]</sup>. Resection of proximal gastric cancer was associated with a higher postoperative morbidity than that of distal gastric cancer, and splenectomy was more often performed for proximal gastric cancers<sup>[71,72]</sup>. However, our results failed to go against splenectomy in terms of postoperative morbidity and mortality. At the same time, with respect to the operation-related events, splenectomy showed no significant difference from splenic preservation in harvested lymph nodes, operation time, length of hospital stay and reoperation rate. All in all, as there were limitations in the trial quality and numbers of included trials, more high quality studies are needed.

In conclusion, splenectomy has not yet shown superiority on survival rates compared to splenic preservation. Routinely performing splenectomy should not be recommended and well-designed large-scale RCTs are required.

## COMMENTS

### Background

Splenectomy is performed for the purpose of effective lymph node dissection around the splenic artery and splenic hilum and for direct invasion of the

splenic hilum or spleen in gastric cancer; however, the effect of splenectomy on prognosis has been controversial.

### Research frontiers

Some studies compared the effectiveness or safety of splenectomy to those of non-splenectomy, but the main results were controversial. The aim of this meta-analysis was to evaluate the impact of splenectomy on long-term survival, postoperative morbidity and mortality of patients with gastric cancer.

### Innovations and breakthroughs

The current study demonstrated that splenectomy could not yet show superiority on survival rates compared to splenic preservation.

### Applications

Routinely performing splenectomy should not be recommended in gastric cancer surgery. However, well-designed large-scale RCTs are expected to investigate the effectiveness and safety of splenectomy further.

### Peer review

This is an interesting article in a controversial area. An important meta-analysis that will contribute to the literature.

### INTRODUCTION

*Bacillus* species are aerobic, or facultatively anaerobic, gram-positive or gram-variable spore-forming rods. They are ubiquitous in the environment and are found in water, dirt, air, stools, and plant surfaces. They are relatively resistant to heat, due to spore formation, and they therefore grow easily during the storage of food and produce toxins that can cause food poisoning<sup>[1-3]</sup>. The pathogenicity of *Bacillus anthracis* (*B. anthracis*) is well known in mammals. Nonanthrax species within clinical materials, which were previously considered contaminants, have increasingly been identified as pathogens<sup>[4]</sup>. One of the nonanthrax species, *B. cereus* is reported in most cases as a human pathogen<sup>[4]</sup>. Occasional reports have appeared implicating other nonanthrax species, for example, *B. thuringiensis*, *B. alvei*, *B. circulans*, *B. licheniformis*, *B. macerans*, *B. pumilus*, *B. sphaericus*, and *B. subtilis* in systemic and gastrointestinal diseases<sup>[3,4]</sup>. However, *B. pantothenicus* has not been reported as a human pathogen in any English-language literature since 1950. Here, we report a case of liver abscess and sepsis caused by *B. pantothenicus* in an immunocompetent man who was successfully treated with cefotaxime and Netilmicin, followed by oral ciprofloxacin.

### Abstract

*Bacillus* species are aerobic, gram-positive, spore forming rods that are usually found in the soil, dust, streams, and other environmental sources. Except for *Bacillus anthracis* (*B. anthracis*), most species display low virulence, and only rarely cause infections in hosts with weak or damaged immune systems. There are two case reports of *B. cereus* as a potentially serious bacterial pathogen causing a liver abscess in an immunologically competent patient. We herein report a case of liver abscess and sepsis caused by *B. pantothenicus* in an immunocompetent patient. Until now, no case of liver abscess due to *B. pantothenicus* has been reported.

### CASE REPORT

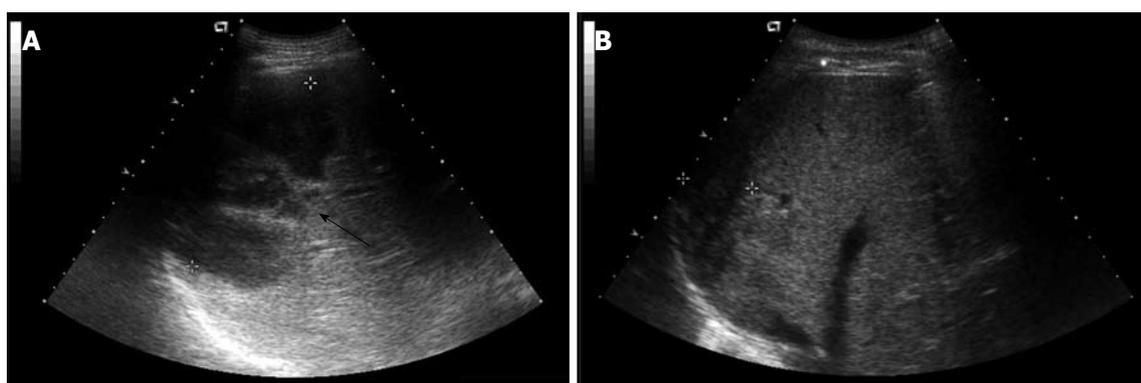

The patient, a 44-year-old man, was admitted to hospital complaining of high fever (40.2°C) and abdominal discomfort in right upper quadrant. A week before admission, he had been on a bicycle trip for two days alone and had eaten raw saltwater fish, which he had cleaned and cut himself. His past medical history was unremarkable.

His physical examination showed a body temperature of 40.2°C, blood pressure of 170/90 mmHg, a respiration rate of 20 breaths/min and a heart rate of 106 beats/min. He had tenderness on the right upper quadrant of his abdomen. Other findings were unremarkable.

Laboratory studies were as follows: hemoglobin concentration 12.6 g/dL; hematocrit 35.65%; leukocytes 16650/mm<sup>3</sup> (granulocytes 82.7%, lymphocytes 9.6%, and

**Figure 1 Contrast-enhanced computed tomography (CT) of the liver.** A: Abdominal CT scan showing a multi-loculated liver abscess (12 cm × 9 cm) in the posterior inferior (VI segment) and posterior superior segment of the right lobe (VII segment) of the liver (arrow); B: On hospital day 30, the liver abscess was almost absorbed.

**Figure 2 Abdominal ultrasonography (US) of the abdomen.** A: Abdominal US showing liver abscesses (12 cm × 9 cm) in segment 6 and 7, with multiple satellite pockets (arrow); B: Post-inflammatory change with completely healed abscess pocket after 51 d of treatment.

monocytes 5.0%); platelets 435 000/mm<sup>3</sup>; erythrocyte sedimentation rate 120 mm/h; C-reactive protein (CRP) 27.72 mg/dL; aspartate aminotransferase 121 IU/L; alanine aminotransferase 164 IU/L;  $\gamma$ -glutamyl transpeptidase 284 IU/L; alkaline phosphatase 397 IU/L; total bilirubin 1.5 mg/dL. Serologic assays for hepatitis A, B and C were negative. All other laboratory values were normal. An abdominal computed tomography (CT) scan revealed a multi-loculated liver abscess (12 cm × 9 cm) in the posterior inferior (VI segment) and posterior superior segment of the right lobe (VII segment) of the liver (Figure 1A and Figure 2A). After blood samples had been drawn for culture, empirical antibiotic therapy with cefotaxime, Netilmicin, and metronidazole was started. Two days later, a percutaneous drainage was performed. A purulent and odorous material was obtained, and it was immediately inoculated into aerobic and anaerobic culture material.

On the 6th hospital day, the results of blood cultures showed *B. pantothenicus* in all six blood sets that were sensitive to ampicillin, chloramphenicol, ciprofloxacin, clindamycin, erythromycin, gentamicin, oxacillin, teicoplanin, tetracycline, and vancomycin. In addition, amoeba antibodies were negative. Therefore, we discontinued metronidazole and maintained cefotaxime and Netilmicin. The culture of purulent material at drainage showed no growth of bacteria. On the 30th hospital day, a follow up CT scan was performed, which showed no abscess pocket (Figure 1B). Follow-up blood cultures grew no bacteria and he was discharged with oral ciprofloxacin. The patient has been followed up with control

visits and has shown no sign of a recurrence. Abdominal ultrasonography after 51 d of treatment showed a completely healed abscess pocket and remaining post-inflammatory changes (Figure 2B).

## DISCUSSION

*Bacillus* species, except for *B. anthracis*, rarely cause serious human infections. Occasionally, *Bacillus* species can be pathogens in certain clinical situations (e.g. patients with intravenous drug abuse, trauma, cancer, neutropenia, leukemia, receiving chemotherapy or indwelling central venous catheter) but are not usually pathogenic to immunocompetent individuals<sup>[5-7]</sup>. Clinical infections caused by *Bacillus* species (probably *B. cereus* in most cases) fall into six broad groups: (1) local infections, particularly of burns, traumatic or post-surgical wounds, and the eye; (2) bacteremia and septicemia; (3) central nervous system infections, including meningitis, abscesses, and shunt-associated infections; (4) respiratory infections; (5) endocarditis and pericarditis; and (6) food poisoning, characterized by toxin-induced emetic and diarrheagenic syndromes<sup>[2]</sup>.

*B. pantothenicus* was first described by Proom & Knight, following a nutritional analysis of mesophilic soil isolates of *Bacillus* species<sup>[8]</sup>. It was named because this strain required pantothenic acid to isolate it from different soil samples. They considered it to a species most closely resembling *B. circulans* but distinct from it, and subsequent studies confirmed the validity of the species<sup>[9-11]</sup>. Later isolations have been made from antacids, food, water, and

soil<sup>[9]</sup>. In the present case, the raw fish that the patient had eaten might have been contaminated with *B. pantothenicus*.

Organisms recovered from liver abscesses vary with the etiology. In liver infection arising from the biliary tree, enteric gram-negative aerobic bacilli and *enterococci* are common isolates<sup>[12]</sup>. Unless previous surgery has been performed, anaerobes are not generally involved in liver abscesses arising from biliary infections. In contrast, in liver abscesses arising from pelvic and other intra-peritoneal sources, a mixed flora, including aerobic and anaerobic species (especially *Bacteroides fragilis*), is common<sup>[12]</sup>. With hematogenous spread of infection, usually only a single organism is encountered; this species may be *Staphylococcus aureus* or a *streptococcal* species, such as *Streptococcus milleri*. Liver abscesses may also be caused by *Candida* species<sup>[12]</sup>. Amoebic liver abscesses remain a common clinical finding<sup>[13]</sup>.

We conducted a thorough keyword search for other cases of liver abscess due to *B. pantothenicus* in the web-based Medline database, but found none. However, there were two cases of liver abscess due to *B. cereus*. In one case, the patient was in good health<sup>[13]</sup>, but was admitted to hospital because of fever and, on CT scan, a liver abscess was shown. The treatment was started by empirical antibiotics and surgically drained, but the patient died on the 4th postoperative day due to acute peritonitis. *B. cereus* was isolated from a culture of the purulent material<sup>[13]</sup>. In the second case, the patient was diagnosed as Philadelphia chromosome-positive acute lymphoblastic leukemia (ALL) two years previously and admitted to hospital because of relapse of ALL<sup>[14]</sup>. *B. cereus* was isolated on blood culture. Multiple abscesses were found in the brain by magnetic resonant imaging (MRI) and in the liver by abdominal ultrasonography and computed tomography. *B. cereus* is susceptible to Minocycline, vancomycin, levofloxacin, and chloramphenicol and therefore they were administered to the patient. One month later, the multiple liver abscesses had disappeared but the patient died four months later due to deteriorated leukemia<sup>[14]</sup>.

The isolation of *Bacillus* species from blood cultures is clinically significant in 5%-10% of cases<sup>[15]</sup>. In the present case, *B. pantothenicus* was grown in six sets of blood cultures from different veins, with 30 min intervals between sets; thus we assume it is the true pathogen. The reason of for non-growth of *B. pantothenicus* in the purulent discharge might be the previous use of antibiotics before drainage.

Weber *et al*<sup>[16]</sup> tested 54 *B. cereus* isolates and 35 non-*cereus Bacillus* isolates for antimicrobial susceptibility and found almost uniform susceptibility to vancomycin, imipenem, gentamicin, and ciprofloxacin. Most non-*cereus Bacillus* isolates were susceptible to penicillins and cephalosporins, but almost *B. cereus* isolates were resistant to penicillins or cephalosporins, due to the presence of beta-lactamase<sup>[2,16]</sup>. Therefore, vancomycin appears to be the best treatment for *Bacillus* species infection, before the results of specific susceptibility are available<sup>[16]</sup>. However, *B. cereus* is also susceptible to clindamycin, gentamicin, chloramphenicol, and erythromycin<sup>[2,7,17-19]</sup>. In our case, empirical antimicrobial treatment with cefotaxime, Netilmicin and metronidazole for liver abscess was started before *B. pantothenicus* was iso-

lated in blood culture. After *B. pantothenicus* was identified, we discontinued metronidazole. We continued cefotaxime and Netilmicin, as most non-*cereus Bacillus* isolates are susceptible to cephalosporins. *B. pantothenicus* showed sensitivity to gentamicin and most importantly, the patient's clinical and laboratory course was improving with these antibiotics. Pyogenic liver abscesses are usually treated parenterally for two to three weeks, and for the following four to six weeks with oral agents. The patient's clinical response and follow-up imaging should be monitored to determine his response to therapy, for consideration of antibiotic duration and the need for further aspiration<sup>[12]</sup>. In this case, clinical and laboratory parameters became normalized and follow-up sonography showed complete healing of the abscess; therefore, we could stop antibiotics on the 51th hospital day.

In conclusion, we report the first case of liver abscess and sepsis caused by *B. pantothenicus* in an immunocompetent patient. The patient was successfully treated with a course of cefotaxime, Netilmicin, and metronidazole, followed by oral ciprofloxacin. This case demonstrates that unusual organisms can lead to unexpected and severe infections in patients who are previously healthy and have no obvious risk factors. It is important to consider unusual organisms as a cause of systemic infections and arrange appropriate microbiological investigations so as not to miss the clinical diagnosis.

### Abstract

Peutz-Jeghers syndrome (PJS), a rare autosomal dominant inherited disorder, is characterized by hamartomatous gastrointestinal polyps and mucocutaneous pigmentation. Patients with this syndrome have a predisposition to a variety of cancers in multiple organs. Mutations in the serine/threonine kinase 11 (*STK11*) gene have been identified as a major cause of PJS. Here we present the clinical and molecular findings of two unrelated Thai individuals with PJS. Mutation analysis by Polymerase Chain Reaction-sequencing of the entire coding region of *STK11* revealed two potentially pathogenic mutations. One harbored a single nucleotide deletion (c.182delG) in exon 1 resulting in a frameshift leading to premature

termination at codon 63 (p.Gly61AlafsX63). The other carried an in-frame 9-base-pair (bp) deletion in exon 7, c.907\_915del9 (p.Ile303\_Gln305del). Both deletions were *de novo* and have never been previously described. This study has expanded the genotypic spectrum of the *STK11* gene.

### INTRODUCTION

Peutz-Jeghers syndrome (PJS) is an autosomal dominant disorder with predisposition for cancer (OMIM 175200), and is characterized by the occurrence of multiple gastrointestinal hamartomatous polyps and pigmentation of the lips, buccal mucosa and digits<sup>[1]</sup>. PJS patients also have a significantly increased risk for developing benign and malignant tumors of multiple organs both in the gastrointestinal tract and in extragastrointestinal sites<sup>[2]</sup>. Cancers of the lung, pancreas, breast, ovary and testis have been observed<sup>[3-6]</sup>. Germline mutations in the serine/threonine kinase 11 (*STK11*) gene at 19p13.3 have been demonstrated to be responsible for most PJS cases<sup>[7, 8]</sup>. The *STK11* gene consists of nine coding exons and translates into a protein of 433 amino acids<sup>[8]</sup>. *STK11* is proposed to function as a tumor suppressor that acts as an early gatekeeper<sup>[9]</sup>, regulates cell polarity<sup>[10]</sup>, and controls cell cycle arrest, cell proliferation and apoptosis<sup>[11]</sup>.

PJS is the first cancer susceptibility syndrome caused

by inactivation of the serine/threonine kinase. Previous findings suggested that the combination of germline mutations and a defect of the second allele causing loss of heterozygosity in somatic cells was responsible for the phenotypic manifestations of PJS<sup>[8]</sup>.

At least 200 different disease-causing mutations in the *STK11* gene have been described with the majority being missense/nonsense mutations. The splice-junction alterations, insertions, and nucleotide or whole gene deletions have also been reported (<http://www.hgmd.cf.ac.uk>, accessed July 2009). Most *STK11* mutations affect the catalytic kinase domain and result in inactivation or loss of protein function.

In this study, we report the clinical and molecular characterization of two unrelated Thai PJS patients. Mutation analysis revealed that both patients carried *de novo* mutations. Both mutations were also novel. This is the first report of molecularly-confirmed PJS in Thai patients.

## CASE REPORT

### Patient 1

A 14-year-old Thai boy was referred for further management of intestinal obstruction. The patient developed abdominal pain with distension and melena 3 d after receiving appendectomy. He was diagnosed with intussusception for which he underwent surgical resection. Physical examination revealed hyperpigmentation on the lower lip, buccal mucosa, and digits. Endoscopic examination revealed multiple polyps in the stomach, small bowel and colon. No other family members had any features consistent with PJS.

### Patient 2

A 14-year-old Thai girl was referred for treatment of intestinal polyps. She presented with hematochezia and prolapse of a polypoid mass. Characteristic mucocutaneous pigmentation was also observed. Endoscopic examination demonstrated multiple polyps throughout the gastrointestinal tract. She underwent polypectomy three times. The resected polyps were found to have characteristic features of Peutz-Jeghers polyps. There was no history of gastrointestinal problems in either of her parents.

### Mutation analysis

Peripheral blood samples were obtained from the probands and their available parents after written informed consent. Total RNA and genomic DNA were extracted from peripheral blood using Qiagen RNA and DNA extraction kits according to manufacturer's instructions, respectively (Qiagen, Valencia, CA, USA). Reverse transcription was performed using ImProm-IITM reverse transcriptase (Promega, Madison, WI, USA), according to the manufacturer's instructions. PCR amplification of the entire coding sequence of the *STK11* gene was performed using primers as shown in Table 1. In brief, we used 50 ng of cDNA, 1XPCR buffer (Promega), 1.5 mmol/L MgCl<sub>2</sub>, 0.2 mmol/L dNTPs, 0.2 μmol/L of

**Table 1** Oligonucleotides and PCR conditions for *STK11* mutation analysis

	Primer sequences (5' to 3')	Annealing temperature (°C)

each primer and 0.5 U Taq DNA polymerase (Promega) in a volume of 20 μL using the following parameters: 35 cycles of 1 min at 94°C, 1 min at 60°C and 1 min 30 s at 72°C. PCR products were treated with ExoSAP-IT (USP Corporation, Cleveland, OH) according to the manufacturer's recommendations, and sent for direct sequencing (Macrogen Inc., Seoul, Korea). Sequence data were analyzed using Sequencher (version 4.2; Gene Codes Corporation, Ann Arbor, MI, USA). Mutations found in both patients were confirmed by direct sequencing of the genomic DNA using a set of primers and parameters according to their mutation sites (Table 1). The nucleotide position is in accordance with the *STK11* mRNA (Genbank Accession No. NM\_000455). The available parents were also tested for the identified mutation by PCR-sequencing.

## DISCUSSION

PCR-sequencing analysis of the entire coding sequence of *STK11* revealed that patient 1 was heterozygous for a novel deletion of a guanine at nucleotide position 182 (c.182delG) in exon 1 of the *STK11* gene (Figure 1, left upper panel). The loss of a guanine is expected to lead to a frameshift starting at codon 61 and introduce a premature stop codon at position 63. Sequencing his genomic DNA confirmed the presence of the c.182delG (Gly61AlafsX63) mutation. This mutation was not found in either parent (Figure 1, left lower panel).

Patient 2 was heterozygous for a novel in-frame 9-base-pair (bp) deletion (c.907\_915del9) in exon 7 (Figure 1, right upper panel). This identified mutation was confirmed by sequencing of the patient's genomic DNA. The 9-bp deletion results in absence of three amino acids in the kinase domain of the STK11 protein. The c.907\_915del9 was not detected in her mother. Her clinically unaffected father was unavailable for mutation analysis.

Both Thai patients fulfilled the clinical diagnostic criteria for PJS<sup>[12]</sup>. These include the presence of hamartomatous polyps and characteristic mucocutaneous pigmentation. Inactivating mutations in the *STK11* gene have been detected in 50%-94% of PJS patients. The highest mutation detection rate could be achieved if only patients who met the clinical criteria were considered and all mutation screening methods were used<sup>[12-15]</sup>. In this study, two different germline mutations were identified in the *STK11* gene and were found to be *de novo* as evidenced by their clinically unaffected parents

**Figure 1 Mutation analysis.** The left and right panels relate to c.182delG (p.Gly61AlafsX63) and c.907\_915del9 (p.Ile303\_Gln305del) mutations, respectively. Upper and lower panels are electropherograms of patients and unaffected parents, respectively. Each identified mutation is indicated by an arrow.

as well as molecular findings. Both mutations have never been previously described.

A novel heterozygous 1-bp deletion (c.182delG; p.Gly61AlafsX63) in exon 1 of the *STK11* gene was detected in patient 1. It resulted in a frameshift leading to premature termination of the codon at position 63. The mutation was not detected in his parents. Since codons 49-309 encode the catalytic kinase domain<sup>[16]</sup>, this truncated protein is expected to result in incomplete catalytic kinase domain leading to inactivation of the kinase activity as well as a complete loss of the C-terminal domain.

The second patient was heterozygous for a novel in-frame 9-bp deletion in exon 7 (c.907\_915del9; p.Ile303\_Gln305del). The 9-bp deletion results in absence of three amino acids in the kinase domain of the *STK11* protein. This alteration was close to another 9-bp deletion that has been previously described in PJS patients from different populations (c.908\_916del9; p.Ile303Asn; Arg304\_His306del) and involved similar residues. In addition, they were located at the conserved catalytic core of the kinase domain<sup>[7,17]</sup>. These findings confirmed an important role of these critical residues.

Several studies have been performed to analyze genotype-phenotype correlations in PJS. One such study showed that PJS patients with predominantly truncating mutations had breast carcinomas, whereas in-frame deletions in the ATP binding domain were rarely associated with cancers in PJS patients<sup>[18]</sup>. However, an analysis of the spectrum of cancers and the risk of these cancers with different types of *STK11* mutations in 419 PJS individuals suggested that there was no significant correlation between the type or site of mutation and the cancer risk<sup>[19]</sup>. Considering the correlation between

time to the onset of gastrointestinal symptoms and the mutation status, individuals with missense mutations of *STK11* had a later time to onset of the symptoms compared with those with truncating mutations<sup>[20]</sup>. A subsequent study showed a trend toward earlier age of intussusception onset in individuals with *STK11* truncating mutations; however, the difference was not statistically significant<sup>[21]</sup>. Our patient with a truncating mutation, c.182delG, in the *STK11* gene developed intussusception at the age of 14 years, close to the median time to onset of intussusception in those with *STK11* truncating mutations from both studies<sup>[20, 21]</sup>. To strengthen the genotype-phenotype correlations, larger and well-designed studies are still required.

Identification of the *STK11* mutation remains essential for a correct diagnosis of PJS and has important clinical implications. Genetic counseling and surveillance strategies which are of value in disease management could be provided for patients with PJS and their at risk family members regardless of their mutations identified.

In conclusion, we report on the clinical and molecular characterization of two unrelated Thai patients with PJS. Two novel potential pathogenic mutations, c.182delG (p.Gly61AlafsX63) and c.907\_915del9 (p.Ile303\_Gln305del) were identified expanding the mutational spectrum of *STK11*. This study demonstrates that the *STK11* gene is responsible for PJS across different populations and emphasizes the important role of genetic testing for definite diagnosis as well as appropriate genetic counseling.

## ACKNOWLEDGMENTS

The authors thank all the patients and their families for participation in the study.

### Abstract

Essential thrombocythemia is frequently associated with abdominal thrombotic complications including portal cavernoma as a consequence of chronic portal vein thrombosis. Essential thrombocythemia in a latent form is difficult to identify at onset due to the absence of an overt disease phenotype. In the presented case report, the diagnosis of essential thrombocythemia was initially missed because the typical disease phenotype was masked by bleeding and hypersplenism. The correct diagnosis was only reached when the patient experienced persistent thrombocytosis and pseudohyperkalemia after a shunt operation.

### INTRODUCTION

Portal cavernoma is the consequence of persistent portal vein thrombosis (PVT) which may be caused by a variety of conditions including cirrhosis, cancer, abdominal infectious disease and myeloproliferative disorders (MPD). Its related symptoms are gastrointestinal bleeding, splenomegaly and hypersplenism as a consequence of portal hypertension.

Essential thrombocythemia (ET) is the most prevalent MPD. It is characterized by persistent thrombocytosis with an estimated annual incidence between 0.77 and 2.53 per 100 000 population, and is relatively common in young females. The predominant clinical features are thrombosis and hemorrhage, as well as delayed occurrence of transformation into leukemia or other myeloid diseases<sup>[1]</sup>. We describe here a young woman suffering from portal cavernoma caused by latent ET, which was masked by bleeding and hypersplenism. The correct diagnosis was only reached when she experienced persistent thrombocytosis and pseudohyperkalemia after a shunt operation.

### CASE REPORT

A 36-year-old female was admitted for recurrent upper quadrant abdominal pain of one year and violent hematemesis two days before. She was found to have a low hemoglobin level, and received a transfusion in a local hospital. Physical examination revealed a non-tender and firm spleen with degree III enlargement. The patient denied the use of contraceptive agents and a history of vascular thrombosis. Laboratory investigations revealed a hemoglobin of 71 g/L, hematocrit of 26.8%, leukocyte count of  $12.4 \times 10^9/L$ , and a platelet count of  $313 \times 10^9/L$ . Viral hepatitis serology was negative. A slightly prolonged prothrombin time of 17.2/13.5 s and a partial thromboplastin time of 43.8/36.5 s were noted during coagulation screening. Liver and renal functions were within normal range. Computed tomography scan showed splenomegaly and varicose veins in the esophagus and gastric fundus (Figure 1). Portovenography showed non-visualization of the portal vein and splenic vein with the formation of lots of collaterals, confirming the presence of portal cavernoma (Figure 2).

Obvious cavernous transformation was found at the porta hepatis during surgery. Splenectomy and a mesocaval interposition shunt with prosthetic H-graft were per-

Figure 1 Computed tomography (CT) scan showed splenomegaly and varicose veins in the esophagus and gastric fundus.

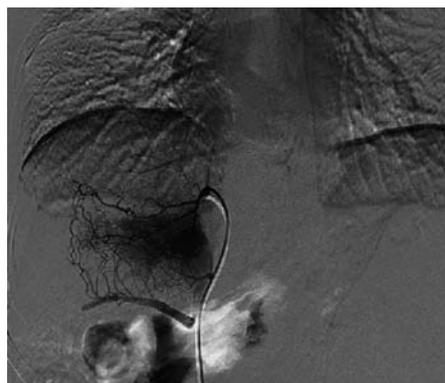

Figure 2 Portovenography showed non-visualization of the portal vein with formation of multiple collaterals in the hepatic hilum.

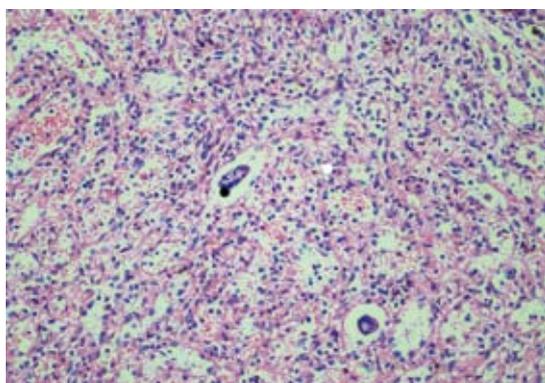

Figure 3 Spleen pathology showed chronic congestion and extramedullary hemopoiesis (magnification,  $\times 200$ ).

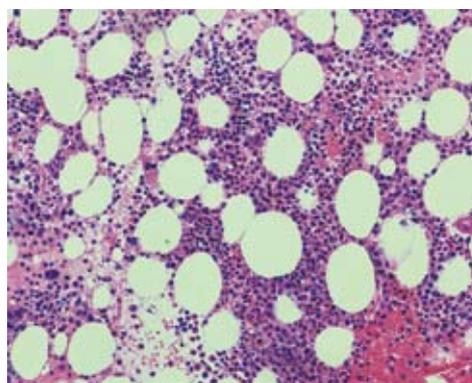

Figure 4 Bone marrow biopsy showed megakaryocytic hyperplasia (magnification,  $\times 200$ ).

formed. Pathological study of the spleen showed chronic congestion and extramedullary hemopoiesis (Figure 3). The patient received antithrombotic treatment with low-dose heparin immediately after surgery. When the platelet count progressively increased to  $1137 \times 10^9/L$  two weeks later, the patient was administered aspirin tablets 100 mg/d.

On postoperative day 18, routine laboratory investigations revealed hyperkalemia of 6.1 mmol/L, hemoglobin of 10.3 g/L, leukocyte count of  $14.7 \times 10^9/L$ , and platelet count of  $1551 \times 10^9/L$ . She denied any complaints and electrocardiogram was normal. Hyperkalemia repeatedly occurred despite the use of exchange resin and insulin. Pseudohyperkalemia was suspected after all the causes of hyperkalemia were excluded through detailed examination. Plasma potassium concentration was found to be within the normal range, while the serum concentration remained high. The diagnosis of pseudohyperkalemia was confirmed and the medical treatment for hyperkalemia was stopped. One month after surgery, the platelet count reached  $2246 \times 10^9/L$ . A hematology consultation was obtained to perform a bone marrow biopsy, which signified megakaryocytic hyperplasia (Figure 4) and negative Bcr/abl confluence gene. The diagnosis of essential thrombocythemia was established and the patient was started on hydroxyurea therapy under close hematological monitoring. After discharge from hospital, she was asymptomatic, and the platelet count decreased to  $629 \times 10^9/L$  within three months of surgery.

## DISCUSSION

Cavernous transformation of portal vein refers to the development of a network of tortuous collateral vessels bypassing the obstructive area due to chronic PVT. Once the liver blood supply decreases significantly, the compensatory mechanism is activated and collaterals begin to form within a few days of the obstruction and organize into a cavernomatous transformation in 3-5 wk. Symptom development is often insidious and related to the progression of portal hypertension. Cirrhosis and cancer are common causes in adults. Other possible etiological factors include abdominal surgery and trauma, pancreatic disease, splanchnic infection, other hypercoagulability associated disease, and the use of oral contraceptive medicines. Ogren *et al*<sup>[2]</sup> studied 23 796 autopsies in Sweden and found the population prevalence of PVT was 1.0%. They reported that 28% of PVT patients had cirrhosis, 23% primary and 44% secondary hepatobiliary malignancy, 10% major abdominal infectious or inflammatory disease and 3% had a myeloproliferative disorder. MPD with a combination of several prothrombotic factors constitute the most common identifiable causes among non-cirrhotic and non-tumoral PVT cases in the West with an estimated prevalence of 30%-60%<sup>[3,4]</sup>.

ET is frequently associated with thrombotic complications in the large abdominal vessels. Gangat *et al*<sup>[5]</sup> reported a prevalence rate of 4% for abdominal vein thrombosis

in 460 consecutive patients with ET, but did not provide detailed information on portal vein thrombosis. The risk factors for thrombosis in ET patients include age, thrombotic history, cardiovascular risk factors and genetic or acquired thrombophilia<sup>[6]</sup>. It seems likely that elevated platelet counts are implicated in thrombotic events in ET, however, the degree of elevation does not appear to be important. It is well documented that thrombosis may occur at relatively low platelet counts<sup>[7]</sup>. ET usually carries the best prognosis among the MPD, but abdominal vein thrombosis was identified as a risk factor for poor survival and appeared to be the result of excess death from leukemic or fibrotic transformation and hepatic failure<sup>[5]</sup>.

Treatment options for ET include aspirin (or an equivalent therapy) and cytoreductive therapy to control the platelet count such as hydroxyurea, anagrelide and interferon, however, there is still a lot of controversy regarding the role of anticoagulation in patients with chronic PVT. The management of bleeding varices due to MPD is not different from cirrhotic or cancer patients, but the prognosis is unquestionably better in the former cases<sup>[8]</sup>. It seems that the mortality rate from variceal bleeding in patients without liver disease is primarily related to underlying diseases other than bleeding itself<sup>[9]</sup>.

In our case, the diagnosis of cavernous transformation was definite on admission. MPD was not considered because the platelet count was only slightly elevated. After splenectomy, the platelet count increased very quickly, and even exceeded  $2000 \times 10^9/L$ . This suggested that the features of ET in peripheral blood cell counts are masked by hypersplenism. For patients with extreme thrombocytosis, active research is important to exclude latent MPD, although reactive thrombocytosis is usually a more common cause than ET. Recently the discovery of a mutation in V617F of the *Janus Kinase 2* gene in a significant proportion of ET patients provides a new strategy for molecular diagnosis<sup>[7]</sup>.

For patients with non-cirrhotic portal hypertension, in particular with extrahepatic portal vein thrombosis, portosystemic shunt surgery provides efficient and permanent decompression of the portal venous system without liver function deterioration or encephalopathy. Several authors have advocated preserving the spleen whenever possible especially in MPD, because the spleen may become a place for extramedullary marrow formation<sup>[9]</sup>. During surgery, we planned to perform a spleen-preserving splenorenal side-to-side shunt, but failed to find normal splenic veins, so converted to splenectomy and a mesocaval interposition (H-graft) shunt.

In the present case, the patient developed elevated serum potassium of 6.1 mmol/L with extreme thrombocytosis of  $1551 \times 10^9/L$  on postoperative day 18. Active research failed to find a cause of hyperkalemia, therefore

pseudohyperkalemia was suspected and plasma potassium level was measured to confirm the diagnosis. The phenomenon of pseudohyperkalemia was first reported in 1955, and has been commonly observed in patients with severe thrombocytosis, erythrocytosis and the presence of activated platelets<sup>[10]</sup>. It is characterized by a marked elevation of serum potassium concentration with normal plasma potassium level. Patients with pseudohyperkalemia are usually without any clinical manifestation of electrolyte imbalance. The main mechanism causing this phenomenon is the release of potassium from excessive cells *in vitro* during clotting of the sample. Pseudohyperkalemia has no harmful consequences and an aggressive therapeutic approach is unnecessary.

In summary, for patients with portal cavernoma, if no common causes such as cirrhosis and neoplasm are found, investigations into an uncommon cause of MPD is indicated using bone marrow biopsy and coagulation profile. It is important to realize that the features of ET in peripheral blood cell counts could be masked by hypersplenism.

### Abstract

Transplantation cannot be considered the most important therapeutic procedure for hepatocellular carcinoma (HCC). In France, no more than 2% of patients with HCC undergo a transplantation. Randomized controlled trial must assess the benefit to risk ratio of various potentially "curative" treatment procedures (transplantation, resection, radio-frequency ablation).

Braillon A. Hepatocellular carcinoma and evidence-based surgery. *World J Gastroenterol* 2009; 15(42): 5371 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5371.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5371>

### TO THE EDITOR

Rampone *et al*<sup>[1]</sup> stated that hepatocellular carcinoma (HCC) still remains a considerable challenge for sur-

geons and that transplantation is the most important therapeutic procedure. However, facts seem different for an evidence-based medicine adept<sup>[2]</sup>.

There is a challenge for the patient because yet no randomized controlled trial (RCT) has assessed the benefit to risk ratio of various potentially "curative" treatment procedures (transplantation, resection, radio-frequency ablation). RCT is feasible. Benefit of chemoembolization to patients with unresectable HCC and sorafenib in a palliative indication are evidence-based from RCT. Recruiting is not an issue since HCC is the fifth most common cause of cancer.

Transplantation cannot be considered the most important therapeutic approach. In France with 66 000 000 inhabitants, 7500 inhabitants die of HCC per year. In 2007, 1061 transplantations were performed for various conditions and 6% of the candidates died while on waiting list due to the shortage of organs<sup>[3]</sup>. In Europe, 15% of transplantations are performed for HCC<sup>[4]</sup>. Therefore, in France, no more than 2% of patients with HCC undergo a transplantation. Nevertheless, more than one out of four exceeds the Milan criteria, a situation which does not improve the results<sup>[4]</sup>. Again, data are missing, and the national agency in charge of transplantation does not publish survival after transplantation according to indications. However, they exist.

## ACKNOWLEDGMENTS

# Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

**Dr. Philip Abraham, Professor**, Consultant Gastroenterologist & Hepatologist, P. D. Hinduja National Hospital & Medical Research Centre, Veer Savarkar Marg, Mahim, Mumbai 400 016, India

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week  
<http://www.apdwcongress.org/2009/index.shtml>

October 7-11, 2009  
Boston Park Plaza Hotel and Towers, Boston, MA, United States  
Frontiers in Basic Cancer Research

October 13-16, 2009  
Hyatt Regency Mission Bay Spa and Marina, San Diego, CA, United States  
Advances in Breast Cancer Research: Genetics, Biology, and Clinical Applications

October 20-24, 2009  
Versailles, France  
Fifth International Conference on Tumor Microenvironment: Progression, Therapy, and Prevention

October 30-November 3, 2009  
Boston, MA, United States  
The Liver Meeting

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles should be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

#### Format

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kpn I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327  
CN 14-1219/R

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

Genome-wide association studies (GWAS) have been applied to various gastrointestinal and liver diseases in recent years. A large number of susceptibility genes and key biological pathways in disease development have been identified. So far, studies in inflammatory bowel diseases, and in particular Crohn's disease, have been especially successful in defining new susceptibility loci using the GWAS design. The identification of associations related to autophagy as well as several genes involved in immunological response will be important to future research on Crohn's disease. In this review, key methodological aspects of GWAS, the importance of proper cohort collection, genotyping issues and statistical methods are summarized. Ways of addressing the shortcomings of the GWAS design, when it comes to rare variants, are also discussed. For each of the relevant conditions, findings from the various GWAS are summarized with a focus on the affected biological systems.

Melum E, Franke A, Karlsen TH. Genome-wide association studies - A summary for the clinical gastroenterologist. *World J Gastroenterol* 2009; 15(43): 5377-5396 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5377.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5377>

### INTRODUCTION

The genetic epidemiology of gastrointestinal diseases has been hard to unravel, despite the fact that many of the diseases have a high sibling recurrence risk pointing to genetic risk factors<sup>[1,2]</sup>. However, over the last three years, with the recent advent of genome-wide association studies (GWAS), a wealth of susceptibility loci have been discovered. Several hundred GWAS have been reported to this end, with thousands of reports on novel disease genes and loci. Interestingly, inflammatory bowel disease (IBD) has been leading the race<sup>[3-17]</sup>. The genes and polymorphisms identified have revealed several biological pathways by which gastroenterological diseases develop and may eventually be treated. Although most of the associations are weak in a statistical sense [odds ratios (OR) of risk variants in the range of 1.1-1.2]<sup>[10,18]</sup>, they point to loci involved in biological systems worth investigating further with other methodologies. This current review includes studies published or available early online up to August 20, 2009.

The most important milestone in the development of GWAS has clearly been the HapMap project which involved genotyping of 1 million single nucleotide polymorphisms (SNPs) of the human genome in the first phase<sup>[19]</sup> and 3.1 million in the second phase<sup>[20]</sup>. Since the frequency of genetic variants varies between different geographical regions, genotyping was performed in populations from Nigeria (Yoruba), Japan, China and the United States [residents with ancestry from Northern and Western Europe, collected in 1980 by the Centre d'Etude du Polymorphisme Humain (CEPH) and used for other human genetic maps]. The HapMap website ([www.hapmap.org](http://www.hapmap.org)) reports on the frequencies of the SNPs and their correlation through linkage disequilibrium (LD). The HapMap resource has become an invaluable tool for genetic research<sup>[21]</sup>. By taking into account the information regarding LD in HapMap, companies have been able to select SNPs for the most recent genome-wide genotyping arrays that provide information on more than 90% of the

genetic variation in HapMap. In addition to SNPs selected *via* LD, modern genotyping arrays also contain markers with a high likelihood of biological relevance (e.g. non-synonymous SNPs leading to an amino acid change in the encoded protein), as well as probes designed to detect other types of genetic variation (e.g. deletions, insertions and duplications of DNA segments). Once completed, the currently ongoing 1000 genomes project (<http://www.1000genomes.org/>), which aims at sequencing 1000 individuals, will further add to the publicly available catalogues of genetic variants and aid in the design of novel genotyping products.

The GWAS design contrasts with the traditional hypothesis-driven studies of biomedical research. Initial criticism with regard to this design has been replaced by appraisal as the scientific community has realized that hypothesis-free data mining performed in a systematic manner<sup>[22]</sup> represents a powerful tool to pin-point biological systems and generate hypotheses for further research.

## PHASES OF A GWAS

Table 1 summarizes the different parts in the study design that make up a GWAS. In the following paragraphs, detailed points are discussed regarding the GWAS study design, both for the researcher planning to embark on a GWAS and the casual reader trying to interpret the findings of an existing study.

### Cohort collection

To maximize the power to detect even low-effect risk variants, the study panels of a GWAS should preferably contain DNA from as many patients and healthy controls as possible. However, this ideal is limited by several pragmatic factors such as the logistics of identifying and classifying patients, recruitment formalities and financial constraints. Given the significant investment, with a considerably higher price per sample than for genotyping of a few markers, great care should be taken in the sample collection process. The “lowest hanging fruits” with the highest risk effects were easily identified in the first round of GWAS and further studies in the same phenotypes will require larger study panels to identify the genes associated with a more modest risk.

The phenotype of the cases used in the study should be very homogeneous. For instance, for IBD it would be advisable to only include patients for whom long-lasting follow-up data is available in order to ensure the correct diagnosis was made (e.g. for IBD, 10% of the patients change diagnosis during the first year of the disease course<sup>[23]</sup>). Although a perfect phenotype description is the aim, a small misascertainment seems to only slightly reduce power<sup>[24]</sup>. If the alternative is not to do a study at all, slight uncertainties in phenotyping can probably be accepted and other aspects for increasing power applied instead.

To enrich the sample collection with risk alleles and thereby increase power, familiar cases<sup>[25]</sup>, which are believed to have the respective disease due to a larger

contribution of genetic factors, can be used. The risk estimates achieved in such a cohort should not be used to judge the risk effect of the allele in the general population, both due to enrichment of the associated alleles in these types of panels and preferential selection of the most associated markers (the so called ‘winner’s curse’)<sup>[26]</sup>. Therefore, replication of findings and final effect size calculations need to be performed in separate study panels sampled without bias.

In rare diseases or in meta-analyses (see separate section on this subject below), case-control cohorts recruited in different countries and even continents<sup>[18,27]</sup> might be necessary to make the study panels large enough to perform sensible genome-wide association analyses. The main challenge that arises when several case-control cohorts are combined is differences in allele frequencies between populations; a problem that is particularly pronounced in African populations<sup>[28]</sup>, but also needs to be taken into account when combining study panels of European descent<sup>[29]</sup>. Recently, analytical tools utilizing genome-wide SNP data for correction of population heterogeneity/stratification (e.g. the EIGENSTRAT software<sup>[30]</sup> and similar approaches<sup>[31]</sup>) have become available to generate non-inflated population stratification-corrected test statistics.

Healthy control data can be shared between groups working in different diseases, thereby reducing the cost of genotyping. Increasing the control-to-case ratio increases the power. This was recently done to an extreme degree in an Icelandic study with 37 196 controls and 192 cases<sup>[32]</sup>. It is important to keep in mind that the gain in power is minute when increasing the control-to-case ratio above 4. For example, the power at a *P*-value of  $5 \times 10^{-7}$  in a study including 1000 cases increases from 77% to 87% for an allele with a frequency of 0.2 and an OR of 1.4, by increasing the number of controls from 4000 to 10 000.

### Genotyping chips

The high density genotyping chips now available have the potential to assay up to 1 million markers (Affymetrix SNP 6.0 and Illumina 1M). In essence, the chips consist of dense arrays of specific labeled probes for given DNA sequences that will emit a light signal in the case of hybridization (binding of a matching DNA sequence in the investigated sample).

Since the price is lower, it has recently been suggested that the most cost-effective way to perform a GWAS is to continue using the older and cheaper arrays with medium density (300 000-500 000 SNPs) and then computationally determine untyped SNPs in the remainder of the genome by means of the HapMap reference (so called imputation)<sup>[33]</sup>. An even cheaper approach is to employ DNA-pooling<sup>[34]</sup>. This means that the DNA samples from several individuals are pooled together and subsequently used for genotyping. However, this design only yields estimated allele frequencies across all case or control samples instead of individual genotypes. Therefore, analyses relying on

**Table 1** Phases in the initiation and analysis of a genome-wide association study

Sample panel building
Cases and healthy controls of same ethnicity (for power estimates see figure 2)
Enrichment with early onset cases and/or familial cases
Keep variability in phenotype at a minimum
Establish replication cohort(s) after the same principles. Other, yet similar, ethnicities may be included, although matched healthy controls should be collected
Genotyping
Sample preparation (DNA extraction, calibration)
Genotyping chip (cost <i>vs</i> number of samples)
Genetic coverage
Initial quality control
Exclude samples failing platform-specific QC measures
Exclude samples with low call-rate
Exclude SNPs with a low genotyping rate
Exclude SNPs with a low minor allele frequency and those grossly out of Hardy-Weinberg equilibrium (e.g. $P < 10^{-4}$ )
Statistical analysis
Imputation of non-genotyped SNPs using HapMap as the reference
Single-point association analysis, if needed include covariates of interest in the present study (e.g. gender, sex, smoking, imputation uncertainties <i>etc.</i> )
Manually inspect cluster plots for highly significant SNPs that should be followed-up
Select 1-2 SNPs from each associated locus to take forward in replication
Replication
Genotype (preferentially independent technology) in a panel of cases and healthy controls that are properly sized to detect effects in the same range as seen in the discovery panel
Follow-up experiments
Highly depends on results, i.e. nature of genetic finding, and normally not part of the GWAS design

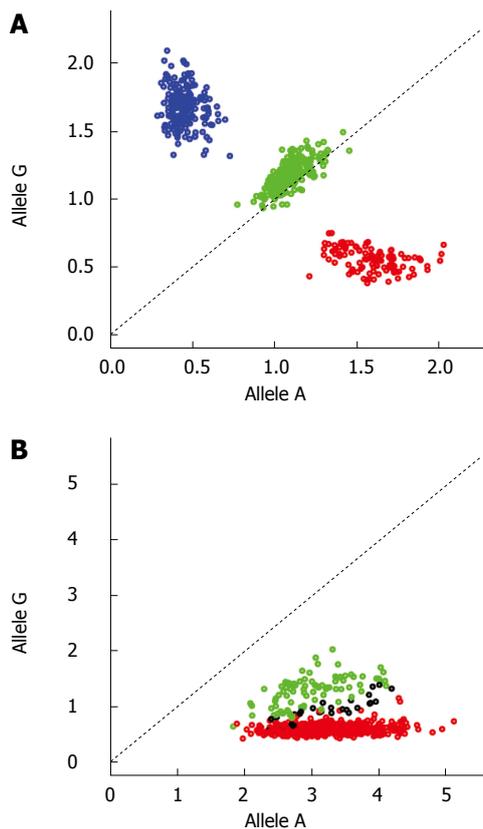

individuals' genotypes such as phenotype associations and imputation are not possible.

### Genetic coverage

As opposed to a candidate gene study, a GWAS aims to, as the name implies, assay the whole genome. Therefore, the genetic coverage of the employed genotyping array is of crucial importance. At present, the dbSNP database (<http://www.ncbi.nlm.nih.gov/sites/entrez>) of known SNPs includes over 12 million entries<sup>[35]</sup>, and of these almost 9 million are annotated as validated (for validation criteria see [http://www.ncbi.nlm.nih.gov/projects/SNP/snp\\_legend.cgi?legend=validation](http://www.ncbi.nlm.nih.gov/projects/SNP/snp_legend.cgi?legend=validation)). Due to LD, assaying all these SNPs in a GWAS is not necessary to achieve complete genome-wide coverage. The genetic information obtained at SNPs can depending on the rate of recombination within this genomic region - precisely predict the alleles of closely linked, un-genotyped markers. There are substantial differences in the coverage between the different commercially available SNP arrays, but simulation has demonstrated that this does not necessarily translate into an increased power for detecting disease-associated variants<sup>[36]</sup>. It is also important to keep in mind that a high overall coverage does not necessarily mean that an individual gene is well covered, and at the gene level, there are large differences in coverage between different genotyping platforms<sup>[37]</sup>. Coverage estimations also tend to be biased, as in most cases the HapMap is used as the reference which is, by itself, assumed to be partially biased in terms of selected SNPs and in terms of included populations. Therefore, SNP arrays that mostly include HapMap tagging SNPs will have a higher genetic coverage compared to arrays that include random SNPs when basing assumptions on the HapMap.

### Dataset quality

The sizes of modern genome-wide datasets are larger by many magnitudes than what was typical for a candidate gene study. For instance, in a GWAS with 1000 cases and 1000 controls using the Affymetrix SNP 6.0, the number of genotypes generated is  $1.8 \times 10^9$ . This huge amount of data renders automatic and semi-automatic procedures necessary, since manual processing is simply not feasible. In principle, this process can be divided into two steps (1) Exclusion of samples (low-performance samples, related individuals and population outliers) and (2) Exclusion of SNPs with evidence of bad performance. Partly this process has to be done iteratively as (a) influences (b) and vice-versa. Firstly, measures should be taken to ensure that the PCR and hybridization reaction are performed properly, and samples where this is not the case should be discarded at this stage or processed over again. Next, platform-specific quality measures should be applied (e.g. the QC-contrast for the Affymetrix SNP 6.0 chip<sup>[38]</sup>) to make sure the samples are within acceptable limits for the experiment as a whole. After this, genotype calling is performed, preferably in batches of similarly handled samples as batch effects can have an impact on the results<sup>[39]</sup>. Next, samples with a low call-rate (typically < 95%) and samples where there are mismatches between the gender recorded and the gender calculated based on the genotype data of the X chromosome are detected and should be excluded, since both of these measures can relate to poor performance on particular chips. The latter also can be due to sample mix-up. To avoid poor performing probes within otherwise acceptable arrays, SNPs with study-wise low genotyping rate (< 95%) should be removed along with SNPs with a low (< 1%) minor allele frequency. SNPs with a low minor

**Figure 1** Example of cluster plots for two SNPs. Plot A shows the plotting of the normalized intensity values for a SNP with good clustering. Each color represents the respective genotype (blue for GG, green for AG and red for AA). Plot B demonstrates the cluster plot for a SNP with bad clustering (same color coding as in A). Disease-associated SNPs demonstrating cluster plots as in B should be discarded as the significant associations at such SNPs are most likely technical artifacts.

allele frequency have a tendency to be mis-called by the clustering algorithm, since most likely only two instead of three clusters will be present in the signal intensity plots, with a significantly smaller heterozygote cloud. Even when one plans to use robust statistical tests, SNPs showing deviation (normal cut-off  $P$ -values  $10^{-4}$ - $10^{-7}$ ) from Hardy-Weinberg Equilibrium in the healthy controls (not in the case/patient panel) should be removed, since this is also an indication of low genotyping quality<sup>[40]</sup>. After these measures have been applied, the resulting SNP set can be forwarded to the initial association analysis for removal of duplicates, related individuals software and ethnic outliers with, for instance, PLINK<sup>[41]</sup> and EIGENSTRAT<sup>[30]</sup>. After the removal of duplicates, related individuals and ethnic outliers, the SNP-specific quality measures should be performed over again on a fresh dataset without these samples. As the genotyping is an automatic process with little user input, one should go back to the raw data after the chosen statistical test has been performed to manually inspect the clustering plots of top hits. An example of two typical cluster plots, one good and one bad, can be found in Figure 1. The SNPs with evidence of bad clustering should be discarded and not followed up.

### Imputation

To increase the number of SNPs to test for association,

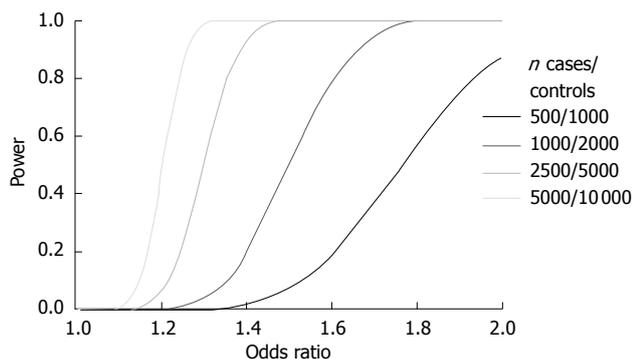

the use of imputation to estimate genotypes at un-genotyped loci has become popular. Imputation will also increase call rates at all typed SNPs to 100%. Given the former feature, researchers may choose less dense and therefore cheaper arrays. Another advantage is that the chance to be closer to the possible functional variant, and hence statistical power - increases with a denser SNP data set.

In brief, imputation relies on the LD and haplotype information contained in a reference dataset. The HapMap datasets are most commonly used, which the algorithm aligns with the genotyped SNPs to use LD information to estimate the genotype at the target locus. Imputation has already been available in software packages such as PHASE and fastPHASE<sup>[42,43]</sup>, however recent implementations such as MACH (<http://www.sph.umich.edu/csg/abecasis/MaCH/>), IMPUTE<sup>[44]</sup> and Beagle<sup>[45]</sup> specifically aimed at GWAS data are recommended<sup>[46]</sup> and have been shown to produce accurate and reliable results<sup>[47]</sup>. There are some differences between the software packages, with MACH and IMPUTE having the edge<sup>[47,48]</sup>, but in general, they produce comparable results.

### Statistical analysis

The goal of a GWAS is to identify the genetic variants that are statistically associated with the disease or trait in question. The first step to achieve this is normally to perform a single-locus association test, i.e. only a single SNP is considered at a time. As up to 1 million SNPs are assessed, it is impossible to have an *a priori* hypothesis about the genetic model expected. The statistical test used should therefore be robust and powerful to detect different genetic models (e.g. dominant, recessive and allele-dosage). As both the allele count and genotype count  $\chi^2$  tests do not meet these requirements, a trend-based test is normally recommended, for instance the Cochran-Armitage trend test. If it is sensible to include co-variables in the disease model (e.g. sex, age, BMI *etc.*), the best way is to use a logistic regression procedure and add these as covariates. For quantitative traits (e.g. enzyme levels), normal linear regression is applicable and could also include co-variables.

After the initial test statistics have been calculated, the genomic inflation factor should be determined (i.e. the median  $\chi^2$  test statistics observed divided by the expected test statistics) and a quantile-quantile plot (a plot of the observed *vs* the expected test statistics or the negative logarithm of the  $P$ -values) should be examined. The quantile-quantile plot should not, in the setting of a non-stratified dataset, show large deviations from the expected distribution in the lower tail. In the upper tail, deviation indicates possible disease association. A genomic inflation factor above 1 typically indicates the presence of population stratification (or a differential bias in genotyping)<sup>[49]</sup>. If the genomic inflation factor is above 1.1, methods for correcting for population heterogeneity should be considered. It is, however, important to note that a small increase in the inflation factor can be caused by disease-associated markers.

**Figure 2 Power calculations for different case-control study panel sizes.** Power calculations for different case-control study panel sizes using an allelic based association test and a  $P$ -value of  $P < 5 \times 10^{-7}$ . All calculations assume a minor allele frequency of 30% and 1:2 ratio of cases vs controls.

Most of the analytical methods described above are implemented in the software package, PLINK<sup>[41]</sup>. The analysis of a small number of cases and controls could in principle be analyzed on a standard desktop computer. However, for more computationally challenging analyses, e.g. imputation, and/or a large number of cases and controls, the use of a high-performance computing cluster with a comfortable batch job submission environment is desirable.

Methods looking at haplotypes<sup>[43,50]</sup> and gene-gene or SNP-SNP interactions (so called epistasis)<sup>[51]</sup> should also be applied. Recently, pathway-oriented analyses, i.e. analyzing SNPs that belong to genes in a common biological pathway<sup>[52-54]</sup>, have been proposed. We would recommend that these methods are first applied after the main associations in the dataset have been explored and replicated.

### Replication

Applying the traditional  $P$ -value cut-off of  $< 0.05$  for statistical significance to a GWAS leads to the fact, even in the presence of no association, that 5% of the tested SNPs are reported as statistically significant. In a typical GWAS where around 650 000 SNPs are tested, this means that 30 000-35 000 SNPs are reported to associate significantly with disease. To avoid this very large number of false-positive results, a very conservative  $P$ -value cut-off that is robust to correction using Bonferroni's method has been described, namely the term of a "genome-wide significant  $P$ -value". In the Wellcome Trust case-control consortium landmark paper<sup>[5]</sup> this level was set to  $P < 5 \times 10^{-7}$ . However, with new chips assaying over 1 million markers and even imputed results with more than 2 million markers, this genome-wide significance threshold might not be conservative enough. On the other hand, simulation studies have suggested the effective number of tests to be around  $10^{6[55]}$ ; the reason for this number being lower than the actual number of tested SNPs being the correlation between SNPs due to LD. In Figure 2 the power estimates for different sample sizes for different ORs are shown. A few studies have already, in the first round of analyses, been able to identify novel disease

loci at genome-wide significance<sup>[56-58]</sup>. As most studies do not achieve such robust associations in their initial phase, a two-staged design is applied. This means that the strongest associated SNPs are carried forward to another study panel and again tested for association. Corrections for multiple testing must be applied to the association results obtained in the second stage. Even when applying strict criteria for selection of SNPs for replication, normally only a few SNPs will replicate. While most often signifying that the original associations were due to type I errors, this can also be due to different effects of a disease variant in different populations, e.g. due to interaction with other genetic variants; so called epistasis<sup>[59]</sup>.

## BOWEL DISEASES (SEE TABLE 2 FOR DETAILS)

### Inflammatory bowel diseases - ulcerative colitis and Crohn's disease

Ulcerative colitis (UC) and Crohn's disease are the two major phenotypes of IBD with a combined incidence rate of 2.2 to 28.9 per 100 000 person-years in Caucasian populations<sup>[60]</sup>, giving rise to inflammation in the colon and the entire intestinal tract, respectively<sup>[61]</sup>. The sibling recurrence risks are estimated to be 15-35 for Crohn's disease and 6-9 for UC<sup>[1]</sup>. Besides the associations seen within the human leukocyte antigen (HLA)-complex<sup>[62-64]</sup>, there was one particularly notable and reproducible genetic discovery in gastroenterology before the advent of GWAS; the association of Crohn's disease with the *NOD2* (also known as *CARD15*) gene<sup>[65,66]</sup>. A thorough review of the relevant genetics, including the *NOD2* gene in Crohn's disease before the GWAS era, can be found elsewhere<sup>[67]</sup>.

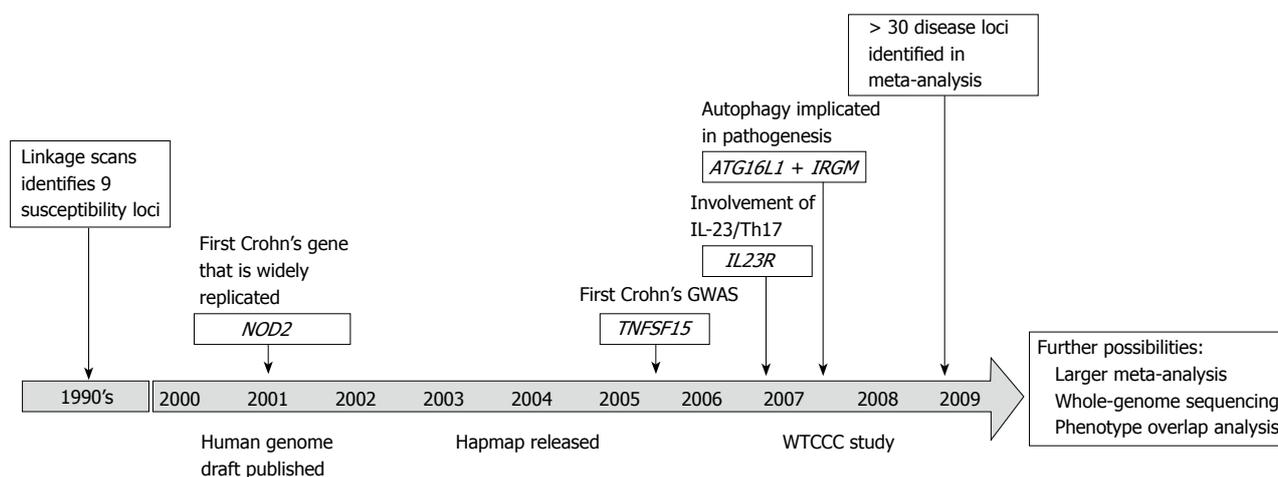

Figure 3 shows the development of Crohn's disease genetics over the last 10 years. The eight GWAS performed in Crohn's disease<sup>[3-9,15,17]</sup> have identified several loci influencing disease susceptibility and a recent meta-analysis implicated 20-30 additional loci<sup>[10]</sup>. It should be noted that the discovery panel and the replication panel used in the meta-analysis overlap with the previous studies and some of the confirmatory associations are biased, as the original study panel is also included. Many of the new findings in Crohn's disease segregate into particular biological pathways and functions. Two of the key pathways are autophagy and the IL-23/Th17 pathway. Autophagy is responsible for recycling of cellular organelles and long-lived proteins, and plays an important role in tissue homeostasis and in the processing of intracellular bacteria, which is also known as xenophagy. ATG16L1 may participate in this process *via* the regulation of Paneth cells<sup>[68]</sup>, whereas IRGM mediates autophagy of intracellular bacteria<sup>[69]</sup>. IL-23 stimulates the Th17 cell population to produce IL-17 and other pro-inflammatory cytokines involved in intestinal inflammation<sup>[70,71]</sup>. Interestingly, one of the first reported IBD genes by GWAS, *IL-23R*<sup>[4]</sup>, participates in the IL-23/Th17 pathway. Through pathway analyses<sup>[53]</sup>

Table 2 Genome-wide association studies in bowel disease

Disease	Genotyping platform	Number of cases/controls in discovery panel	Number of cases/controls in replication panel(s)	Novel Loci reported	Ref.	Independently replicated
Celiac disease	Illumina HumanHap300	778/1422	991/1489	<i>KIAA1109-TENR-IL2-IL21</i> (4q27)	[112]	[165,166]
Celiac disease Two papers extending the study above with follow-up of more markers	Illumina HumanHap300	767/1422	Paper 1: 1643/3406 Paper 2: 2220/3851	Paper 1: <i>1q31 (RGS1), 3p21 (CCR1, CCR2, CCRL2, CCR3, CCR5 and XCR1), 2q12.1 (IL18RAP), 3q25-3q26 (IL12A), 3q28 (LPP), 6q25 (TAGAP), 12q24 (LTK and ATXN2), Paper 2: 6q23.3 (TNFAIP3) REL</i>	[113,114]	( <i>1q31, 3p21, 3q25-26, 3q28</i> ) <sup>[167]</sup> ( <i>3q25-26, 12q24, 1q31, 3q28</i> ) <sup>[166]</sup> ( <i>IL18RAP</i> ) <sup>[168]</sup>

Ulcerative colitis	Illumina HumanHap300 and HumanHap550	1052/2571	1387/1115	<i>1p36, 12q15</i>	[12]	

Pediatric IBD (Crohn's and Ulcerative colitis)	Illumina HumanHap550	1011/4250	173/3481 + WTCCC Crohn's cohort	20q13 ( <i>TNFRSF6B</i> ), 21q22	[14]	(20q13) <sup>[202]</sup>
Colorectal carcinoma	Affymetrix 100k + Affymetrix 10k + Custom panel	960/984 (numbers for Affymetrix 100k, slightly more for the two other technologies)	4024/4042	8q24 (published simultaneously as study below)	[91]	[87-90,92-99]
Colorectal carcinoma	Illumina HumanHap550	930/960	7334/5246	8q24 (published simultaneously as study above)	[87]	[88-99]
Colorectal carcinoma Same discovery panel as study above, published separately	Illumina HumanHap550	930/960	7473/5984	<i>SMAD7</i>	[110]	[88]
Colorectal carcinoma Extension of the two studies above with a staged design	Illumina HumanHap550	922/927	Phase 2: 2854/2822 Phase 3: 4287/3743 Phase 4: 10731/10961	10p14, 8q23	[25]	
Colorectal carcinoma	Illumina HumanHap300 and HumanHap240S	1012/1012	Phase 2: 2 024/2 092 Phase 3: 14 500/13 294	11q23	[88]	[203]
Colorectal carcinoma	Illumina HumanHap550 + HumanHap300 and HumanHap240S	Phase 1: 1902/1929	Phase 2 - 39k SNPs: 4878/4914 13 406/14 012 (Total number, all markers not genotyped in entire panel)	<i>BMP4, CDH1, RHPN2, 20p12.3</i>	[18]	
Hirschsprung's disease	Affymetrix 500k	181/346	190/510	<i>NRG1</i>	[120]	

If the authors mainly reported one region with several candidate genes the region is listed with the candidates in the region in parentheses, while if a specific gene was reported this is listed. Where more than one panel was used, but jointly analyzed, the sum of cases and controls in these panels is listed.

**Figure 3 Historical milestones in Crohn's disease genetics.** Developments in the knowledge of the genetics of Crohn's disease. Only milestone gene discoveries are shown. With the publication of the Crohn's disease meta-analysis in 2009 the number of replicated loci is now greater than 30.

of other components of this pathway the importance has been further demonstrated<sup>[54,72]</sup>. Importantly, a “pathway-based” analysis approach also takes into account variants that do not pass the formal threshold for being taken forward for replication in a traditional GWAS.

Several genes originally shown to associate with Crohn's disease were recently shown to confer risk also for ulcerative colitis<sup>[73,74]</sup>. This indicates the presence of

shared pathogenetic mechanisms in these closely-related conditions. However, disease genes that are specific for UC also exist, such as variants in the *IL-10* gene<sup>[11]</sup>. This specific finding is supported by the fact that *il-10* *-/-* mice develop colitis<sup>[75]</sup> closely resembling human UC. Other UC-specific regions are found at chromosome 1p36 and 12q15<sup>[12]</sup>, however, at these loci, the exact disease genes remain to be identified. The association of classical HLA alleles and UC is well known<sup>[63]</sup>, and also

the GWAS SNPs near the HLA class II genes are among the most prominent findings<sup>[11,12]</sup>. Functional enquiries are needed to clarify how the general IBD genes and phenotype-specific UC and Crohn's disease genes operate in defining the IBD phenotype and even in affecting extraintestinal manifestations such as primary sclerosing cholangitis<sup>[64]</sup>.

Except for one study regarding Crohn's disease<sup>[15]</sup>, which identified the *TNFSF15* gene in a Japanese population, all GWAS in IBD have so far been performed in populations of Caucasian descent. Follow-up studies of *TNFSF15* have demonstrated differences in the effect across different populations<sup>[76,77]</sup>. This mirrors differences in IBD epidemiology in Asian populations compared to Caucasians<sup>[78]</sup>, and further GWAS in Asia are likely to yield insight into differences in genetic susceptibility to IBD between these populations.

Notably, Crohn's disease genes identified in adult patient populations show associations also in pediatric populations of the same disease<sup>[14,79-84]</sup>.

### Colorectal cancer

Colorectal cancer is one of the most important malignancies world-wide, responsible for approximately 500 000 deaths annually<sup>[85]</sup>. The relative risk in siblings is estimated to be between 2-7, depending on the site in the colon, with the right colon showing the highest heritability<sup>[86]</sup>.

The chromosome *8q24* locus is the most widely-replicated region for colorectal cancer discovered by GWAS<sup>[87-99]</sup>. This region has proven to harbor variants that predispose to several cancer types (e.g. prostate cancer and breast cancer<sup>[100-103]</sup>). As suggested by a recent publication<sup>[98]</sup>, there is most likely more than one cancer-associated mutation at this locus. It was recently shown that one of the lead SNPs (rs6983267) is related to *MYC* expression and the activity of key Wnt signaling pathways<sup>[104,105]</sup>. In prostate cancer, it has been noted that the effect sizes of the risk variants differ among populations, necessitating the need for further characterization, e.g. systematic re-sequencing<sup>[106]</sup> of this locus, to be performed in multiple ethnicities in parallel<sup>[107]</sup>. The association between colorectal cancer and genetic variants at chromosome *18q21*, most probably in the *SMAD7* gene, has been subjected to extensive characterization. This characterization has led to the identification of a novel SNP which influences expression levels of *SMAD7*, highlighting the importance of *SMAD7* expression in colorectal carcinogenesis<sup>[108]</sup>. Interestingly, a variant at chromosome *5p15* (rs401681), originally shown to confer risk for basal cell carcinoma, was recently reported to protect against colorectal carcinoma<sup>[109]</sup>. Most likely the causative variant(s) at this latter locus remain(s) to be defined. This finding is an example of the complexity of allelic associations at a disease locus.

Most of the disease loci discovered in colorectal cancer exhibit low ORs (~1.1-1.2). Identification of further disease loci would therefore necessitate a large number of cases and controls to achieve a sufficient

power. In a recent meta-analysis of two colorectal cancer GWAS studies<sup>[88,110]</sup>, totaling 13 315 individuals, and subsequent replication in 27 418 individuals<sup>[18]</sup>, as little as four novel loci (at chromosomes *14q22.2*, *16q22.1*, *19q13.1* and *20p12.3*, respectively) were identified. This picture contrasts with the situation in Crohn's disease where smaller study panels have detected more than 30 disease loci, and highlights the challenges of detecting disease loci in conditions with a low degree of heritability.

### Celiac disease

When exposed to gluten, a protein found in wheat, rye and barley, celiac disease patients develop inflammatory lesions with villi destruction in the small intestine<sup>[111]</sup>. The main genetic factor predisposing to celiac disease, the HLA-DQB1\*0201 variant, has been known for 20 years<sup>[62]</sup>. However, since this HLA allele is present at high prevalence also in individuals who do not develop celiac disease<sup>[62]</sup>, other genetic risk factors are likely to exist. One GWAS in celiac disease has been performed and published in three stages<sup>[112-114]</sup>. The first of these publications demonstrated that, besides markers in the HLA-complex, variants in the *IL2-IL21* region are associated<sup>[112]</sup>. Evidence concerning the involvement of a specific variant in this region was not possible due to strong LD in the region. Interestingly, this region has also been shown to associate with type I diabetes, rheumatoid arthritis and recently UC, hinting at the presence of a common factor for immune-mediated diseases<sup>[115-117]</sup>. To increase the likelihood of disease-gene identification in this GWAS data, additional non-HLA SNPs were subsequently subjected to genotyping in an even larger replication panel<sup>[113,114]</sup>. Solid evidence for association at several novel regions was obtained, several of which harbor genes of relevance to immunological components of celiac disease pathogenesis (such as the chemokine-receptor cluster at chromosome *3p21*, the *IL12A* locus at *3q25-3q26* and *TNFAIP3*). For other associations, e.g. the *LPP* gene at chromosome *3q28*, further studies are required to define how defective gene function could contribute to the pathogenesis. As for the *IL2-IL21* region, several of the loci also show associations with type I diabetes<sup>[118]</sup>.

### Hirschsprung's disease

For Hirschsprung's disease, a disease characterized by lack of ganglia in the colon, there are large ethnic differences in incidence and clear cases of family aggregation, both of which are good indicators of a genetic contribution to pathogenesis. For a large proportion of familial cases and a considerable amount of sporadic cases, it has long been known that mutations in the *RET* gene are important<sup>[119]</sup>. In a small GWAS, Garcia-Barcelo *et al*<sup>[120]</sup> recently made several important discoveries. Firstly, they confirmed the associations previously detected at the *RET* locus. Secondly, they identified strong associations at the *NRG1* gene. Thirdly, they reported a significant and strong interaction effect between *NRG1* and *RET* polymorphisms in the

Table 3 Genome-wide association studies in liver disease

Disease/trait	Genotyping platform	Number of cases/ controls in discovery panel	Number of cases/ controls in replication panel(s)	Novel Loci reported	Ref.	Independently replicated
Gallstone Chronic hepatitis B	Affymetrix 500k Illumina HumanHap550	280/360 179/934	2000/1202 Second stage: 607/1267 (12k SNPs) Third stage: 1300/2100	<i>ABCG8</i> <i>HLA-DPA/B</i>	[140] [132]	[142]
Liver enzymes	Affymetrix 500k (5636 samples) Illumina HumanHap550 (1200 samples), Two different Perlegen, custom arrays (879 samples)	7715	4704	ALT: <i>CPN1-ERLIN1- CHUK</i> <i>PNPLA3-SAMM50</i> ALP: <i>ALPL, GPLD, JMJD1C-REEP</i> GGT: <i>HNF1A</i> <i>PNPLA3</i>	[122]	
Non-alcoholic fatty liver disease	Perlegen Custom array (12k)	2111		<i>PNPLA3</i>	[127]	
Primary Biliary Cir- rhosis	Illumina HumanHap370 and Illumina, HumanHap300	505/1507	526/1206	<i>IL12A, IL12RB2</i>	[27]	
Drug-induced liver injury due to Flu- cloxacillin	Illumina 1M	51/282	23 cases (only HLA typed)	<i>HLA-B*5701</i>	[124]	
Response to hepati- tis C treatment	Illumina HumanHap610	1671		<i>IL28B</i>	[137]	

If the authors mainly reported one region with several candidate genes the region is listed with the candidates in the region in parentheses, while if a specific gene was reported this is listed. Where more than one panel was used, but jointly analyzed, the sum of cases and controls in these panels is listed.

combined discovery and replication panel. The *NRG1* gene is probably important in the development of the enteric nervous system and is thus a plausible biological candidate for a Hirschsprung's disease gene. Another interesting aspect of this study is that robust gene findings are possible even in small patient panels. This is probably more likely when the phenotype is clearly defined and shows early life debut, i.e. environmental factors are less likely to be influential.

## LIVER DISEASES (SEE TABLE 3 FOR DETAILS)

### Biochemical markers of liver disease

One of the most important clinical tools for detecting, diagnosing and monitoring liver diseases is the use of different biochemical parameters (often called 'liver enzymes'). It has long been known that there are genetic factors influencing the level of these enzymes, described in genetic terms as a genuine quantitative trait<sup>[121]</sup> that could either be due to (a) variants influencing the levels without any pathological condition present and/or (b) variants that are truly associated with liver disease and which indicates that undiagnosed cases of disease are the cause of the increased blood levels. Both of these entities are important to discover as: (a) may have practical implications for the handling of apparently increased levels in healthy individuals, while (b) may serve as early markers for liver disease in apparently healthy individuals. Yuan *et al.*<sup>[122]</sup> were able to identify 6 different loci associated with the levels of these enzymes (ALT: *CPN1-ERLIN1-CHUK* and *PNPLA3-SAMM50*, ALP: *ALPL, GPLD* and *JMJD1C-REEP*, GGT: *HNF1A*). A large meta-analysis of several GWAS

datasets recently suggested highly significant associations with bilirubin levels and variants at the *UGT1A1* and *SLCO1B1* loci<sup>[123]</sup>.

### Drug-induced liver injury

In a very small genome-wide analysis in terms of sample size, a highly significant association of variants at the *HLA-B* locus was detected in 51 cases of flucloxacillin-induced liver injury<sup>[124]</sup>. The identified SNP was in LD with the *HLA-B\*5701* allele and subsequent direct genotyping confirmed this with an effect size equaling an OR of 80.6 (95% CI: 22.8-284.9). Although no formal replication panel was investigated, as many as 20 out of 23 additional cases of flucloxacillin-induced liver injury were *HLA-B\*5701* positive. This shows that development of drug-induced liver injury is clearly dependent upon host factors of which HLA variants are probably key determinants<sup>[125]</sup>.

### Non-alcoholic fatty liver disease (NAFLD)

There is an increased number of subjects with NAFLD in siblings of overweight children with NAFLD, indicating the presence of genetic risk factors in this condition<sup>[126]</sup>. In a study evaluating the genetics of NAFLD using a quantitative measure (hepatic fat content measured by magnetic resonance imaging) an association with markers in the *PNPLA3* gene was recently reported<sup>[127]</sup>. Importantly, the association was independent of key confounders such as body mass index, alcohol consumption and diabetes. Noteworthy is that the low number of SNPs assayed in the GWAS (approximately 10 000) was sufficient to generate this highly interesting finding<sup>[128]</sup>. Whereas the function of the *PNPLA3* gene is not known, the finding is

substantiated by differential regulation of the gene in different metabolic states<sup>[129]</sup>. Since NAFLD is an increasingly common condition, it is interesting to note that this locus also shows associations with alanine transaminase levels in the liver enzyme population-based study mentioned above<sup>[122]</sup>.

### **Viral hepatitis**

Hepatitis B is one of the major causes of world-wide liver morbidity and mortality<sup>[130]</sup>. Part of the variability in clinical course<sup>[131]</sup> is related to viral properties, but there is strong reason to believe that host genetics are of importance. In a three-staged GWAS design, particular variants of the class II *HLA-DPA* and *HLA-DPB* genes were recently shown to be associated with chronic hepatitis B infection in Asian populations<sup>[132]</sup>. The HLA-complex is characterized by strong LD<sup>[133]</sup> and, as hinted at by other studies, distinct HLA genes may prove to be important<sup>[134]</sup>. To clarify this, verification of the Asian findings in Caucasian populations and supplementary mechanistic studies are needed. Chronic hepatitis C is a progressive liver disease, complicated by development of cirrhosis and hepatocellular carcinoma<sup>[135]</sup>. Treatment with pegylated interferon and ribavirin offers the potential of viral eradication in up to 80% of the patients<sup>[136]</sup>. In a GWAS of treatment response, variants in the *IL28B* gene were found to be associated in the three (European-Americans, African-Americans and Hispanics) ethnicities tested<sup>[137]</sup>, shedding light on the biological mechanisms operating to define treatment success.

### **Gallstones**

Defects of bile formation are likely to be important in the development of biliary calculi<sup>[138]</sup>, inspiring candidate gene studies of important transport proteins involved in this process<sup>[139]</sup>. Given this *a priori* knowledge, it was not surprising that the main disease locus in a German gallstone GWAS was *ABCG8*, encoding a component of the cholesterol transporter heterodimer ABCG5/G8<sup>[140]</sup>. Interestingly, the findings in previous linkage studies support the GWAS results<sup>[141]</sup>. The *ABCG8* effect is not specific to Caucasian populations, as is evident from a Taiwanese report<sup>[142]</sup>.

### **Primary biliary cirrhosis**

Primary biliary cirrhosis (PBC) is a chronic cholestatic liver disease characterized by autoimmune destruction of the biliary canaliculi. There is evidence for genetic factors being involved in pathogenesis with a sibling recurrence risk reported at approximately 10.5<sup>[2]</sup>. PBC has long been known to exhibit strong HLA associations<sup>[143,144]</sup>, so it was not surprising that SNPs in the HLA-complex were among the top hits of a recent GWAS<sup>[27]</sup>. Of particular interest were associations detected at the *IL12A* and *IL12RB* loci, strongly supporting the presence of autoimmune mechanisms in PBC pathogenesis. Genetic defects of the IL-12 pathway have been proposed in other autoimmune conditions and the findings in PBC

are thus in line with a paradigm where the majority of GWAS findings in these conditions seem to be common denominators rather than disease specific-findings<sup>[145]</sup>.

## **FURTHER POSSIBILITIES WITH THE GWAS APPROACH**

### **Meta-analysis**

The advent of imputation has facilitated integration of data from different genotyping platforms<sup>[10,146,147]</sup>. A meta-analysis of GWAS data sets in type 2 diabetes has highlighted the importance of risk variants with low effect sizes<sup>[148,149]</sup>. In this condition, one of the loci with a low effect size (OR < 1.2) is the *PPARG* locus, where the biological implications in terms of glitazone therapeutics in type II diabetes has long been proven. In gastroenterology, a large GWAS meta-analysis has so far only been performed in Crohn's disease, where more than 30 loci were detected<sup>[10]</sup>. There is also a potential for combining different but related phenotypes to increase power in discovering factors common to both entities. A common risk factor for Crohn's disease and sarcoidosis, both of which are characterized by granulomas, was discovered with such an approach<sup>[16]</sup>, and similar approaches can be defined for other clinical features of otherwise unrelated conditions<sup>[109,115]</sup>.

In this way, GWAS studies also herald collaboration between research groups in different countries and across scientific traditions, a trend which can possibly generate scientific initiatives and discoveries, even beyond the meta-analyses. In the Genetic Association Information Network (GAIN) consortium (<http://www.genome.gov/19518664>), the collaboration has been formalized and has led to a series of successful publications<sup>[150]</sup>. Interestingly, researchers have also released their datasets into the public domain, partly due to requirements from their funding sources (e.g. NIH). The release of data has been facilitated through the dbGAP interface<sup>[151]</sup>; however caution needs to be exercised in terms of data protection and privacy issues<sup>[152]</sup>.

### **Copy number variants (CNVs)**

In the present review we have focused on the typical findings of a GWAS; the associations between particular SNPs and a disease trait. The importance of further genetic and functional characterization of SNP findings is highlighted by the association between a deletion polymorphism at the *IRGM* locus and Crohn's disease<sup>[153]</sup>, a mutation which was later shown to alter the expression level of *IRGM*<sup>[154]</sup>. Interestingly, this deletion was perfectly correlated with a SNP in the first study reporting an association in this region<sup>[6]</sup>. With dense SNP arrays and the aid of imputation of un-genotyped markers, there is a good chance of detecting CNV associations through LD in this manner. In addition, the genotyping chips have separate probes for CNVs and specific computer algorithms can use these probes (and even the intensities from the SNP probes) to generate genotypes for CNVs at a given position. Most likely we

will see a number of studies, even in gastroenterology and hepatology, where the application of these algorithms will lead to the identification of disease-associated CNVs<sup>[155,156]</sup>.

### Deep re-sequencing

Due to the inherent design of the SNP arrays and the available SNPs in the HapMap, rare variants (frequency < 1%-10%) are not easily detected in a GWAS analysis<sup>[157]</sup>. Also for statistical reasons, the power for detecting such variants in the unbiased GWAS design is low. In addition to common variants influencing gene expression or protein function, a disease locus can be constituted by a multitude of rare variants with a high penetrance. This is a well-known phenomenon in monogenic diseases such as cystic fibrosis, where hundreds of rare disease-causing mutations have been defined<sup>[158]</sup>. Probably the typical situation at a disease locus is a combination of common and rare disease variants, as highlighted for the *NOD2* locus (20% rare, 80% common)<sup>[159]</sup>. Only the common variants are “visible” in the GWAS design, but this does not thus exclude the presence of additional disease-causing variants at a locus only detectable by careful investigation of the identified disease genes. The identification of a disease-related variant with a functional effect, even if only present in singular patients<sup>[160]</sup>, can yield important insight into the pathogenesis of a condition. Over the last few years second generation sequencing technology (also called next-generation) has become available. This technology is able to resequence large regions of DNA or even complete human individual genomes<sup>[161]</sup>. There are now three commercial platforms available (SOLiD from Applied Biosystems, 454/FLX from Roche and Genome Analyzer from Illumina), all of which offer unprecedented throughput when compared to traditional Sanger sequencing (which has been the gold standard since 1977<sup>[162]</sup>). The application of a combined re-sequencing/association study approach was recently demonstrated in type 1 diabetes with the identification of *IFIH1* variants with likely functional effects<sup>[163]</sup>. No such extensive re-sequencing studies have so far been performed in gastroenterology or hepatology.

### CONCLUSION

GWAS have proven to be an important tool for dissecting the genetic architecture of common diseases. The genotyping arrays and statistical tools are now mature and their application has been a huge success in gastroenterology. In crude numbers, in only 2-3 years, the approach has delivered many times the number of genes that were discovered during the first 15-20 years of gastroenterological disease genetics. As illustrated by several of the findings we have summarized in this review, the effect sizes are often low and can only be discovered with large case-control collections. Clearly, for some diseases (such as primary sclerosing cholangitis) this situation may not be achievable and complementary approaches (e.g. pathway analyses<sup>[52-54]</sup>) may be needed to

identify genetically defined disease mechanisms.

As we have argued in the present review, and which is also a view shared by the editors of prominent journals, the size of the study panels is important. Interestingly, however, several of the genes so far confirmed were initially detected in what was an apparently under-powered discovery panel (e.g. *TNFSF15* discovered in 94 cases<sup>[15]</sup>). In addition, clinically highly important findings have been made in small case-control panels<sup>[57]</sup>. Therefore, GWAS in smaller disease populations should also be welcomed, since identifying as little as a single disease gene can open broad avenues for future mechanistic studies<sup>[127]</sup>.

In addition to the results from recent GWAS, it is worth mentioning a gene identified through a classical candidate gene approach. After identification of the role of *XBP1* in endoplasmic reticulum stress in a mouse *xbp1* knock-out model, polymorphisms in this gene were tested in a large panel of IBD patients<sup>[164]</sup>. In terms of *P*-values, several of the IBD associations detected at this locus are below the detection limit of the “GWAS radar” and highlight why hypothesis-based candidate gene approaches still have a role in disease genetics.

Even in the case of large effect sizes, the new GWAS findings may not have immediate implications for clinical practice<sup>[124]</sup>, however, and what seems to be the bottom line of the present role of these studies in biology serves as a glimpse of the intricate pathology involved. Whereas few, if any, of the GWAS have provided a comprehensive mechanistic explanation as to how the detected polymorphisms affect disease risk, they have defined the priorities for basic research for decades to come. Ultimately, the challenge and goal for this research will be to define relevant diagnostic and prognostic markers as well as novel therapeutic options.

### Abstract

Peutz-Jeghers syndrome (PJS) is an inherited, autosomal dominant disorder distinguished by hamartomatous polyps in the gastrointestinal tract and pigmented mucocutaneous lesions. Prevalence of PJS is estimated from 1 in 8300 to 1 in 280000 individuals. PJS predisposes sufferers to various malignancies (gastrointestinal, pancreatic, lung, breast, uterine, ovarian and testicular tumors). Bleeding, obstruction and intussusception are common complications in patients with PJS. Double balloon enteroscopy (DBE) allows examination and treatment of the small bowel. Polypectomy using DBE may obviate the need for repeated urgent operations and small bowel resection that leads to short bowel syndrome. Prophylaxis and polypectomy of the entire small bowel is the gold standard in PJS patients. Intraoperative enteroscopy (IOE) was the only possibility for endoscopic treatment of patients with PJS before the DBE era. Both DBE and IOE facilitate exploration and treatment of the small intestine. DBE is less invasive and more convenient for the patient. Both procedures are generally safe and useful. An overall recommendation for PJS patients includes not only gastrointestinal multiple polyp resolution, but also regular lifelong cancer screening (colonoscopy, upper endoscopy, computed tomography, magnetic resonance imaging or ultrasound of the pancreas, chest X-ray, mammography and pelvic examination

with ultrasound in women, and testicular examination in men). Although the incidence of PJS is low, it is important for clinicians to recognize these disorders to prevent morbidity and mortality in these patients, and to perform presymptomatic testing in the first-degree relatives of PJS patients.

### INTRODUCTION

Peutz-Jeghers syndrome (PJS) belongs among the most important familial hamartomatous polyposis syndromes, and is associated with significant morbidity, variable clinical course and considerable predisposition to malignancy. This editorial will attempt to give an overview of up-to-date knowledge on diagnostic and therapeutic aspects of this disease.

### DEFINITION AND HISTORY OF PJS

PJS is an inherited, autosomal dominant disorder with variable inheritance, characterized by hamartomatous polyps in the gastrointestinal tract, mostly in the small bowel, and pigmented mucocutaneous lesions. PJS was first reported in a pair of identical twins with melanotic macules described by Connor in 1895 and illustrated by Hutchinson in 1896<sup>[1,2]</sup>. Later in life, the twins developed what are now known to be additional features of PJS; one died of intussusception at age 20 years, and the other died of breast cancer at the age of 52 years<sup>[3,4]</sup>.

The primary description of PJS was published by Peutz in 1921 in one Dutch family (the Harrisburg family)

as a gastrointestinal familial polyposis with pigmentations. Simultaneously occurring nasal polyposis was described in the original report by Peutz<sup>[5]</sup>. The pedigree of this original Dutch family continues to be followed<sup>[6,7]</sup>. Jeghers specified the description in 10 cases from different families in his work in 1949, and defined the relations between pigmented lesions, gastrointestinal polyposis and increased risk of carcinoma; approximately half of his patients suffered from gastrointestinal malignancy<sup>[3]</sup>. The eponym PJS was first used in 1954<sup>[8]</sup>. The first histological description of hamartomatous polyps was made in 1957 by Horrilleno and colleagues<sup>[9]</sup>. Since this time, descriptions have appeared of several different syndromes with the propensity to develop these polyps in the upper and lower gastrointestinal tracts. The hamartomatous polyposis syndromes are a heterogeneous group of disorders, which are inherited in autosomal dominant fashion. These syndromes include familial juvenile polyposis syndrome, PJS, phosphatase and tensin homolog gene (PTEN) hamartoma tumour syndromes (Cowden's and Bannayan-Riley-Ruvalcaba syndromes), multiple endocrine neoplasia syndrome 2B, hereditary mixed polyposis syndrome, Cronkhite-Canada syndrome, basal cell nevus syndrome, and neurofibromatosis 1. The hamartomatous polyposis syndromes represent only a small number (< 1%) of the inherited gastrointestinal cancer predisposition syndromes<sup>[10,11]</sup>.

A history of PJS with biographies of Peutz and Jeghers has been published<sup>[12]</sup>, and many early PJS papers have been made available online by the Jeghers Medical Index ([www.jeghers.com/pj\\_pubmed.aspx](http://www.jeghers.com/pj_pubmed.aspx)). The website [www.peutz-jeghers.com](http://www.peutz-jeghers.com) is another resource for PJS patients and healthcare providers.

Association of Cancer Online Resources (ACOR) is a large collection of cancer-related internet mailing lists, which have delivered over 1.5 million e-mail messages per week to subscribers across the globe. In addition to supporting the mailing lists, ACOR develops and hosts state-of-the-art internet-based knowledge systems that allow the public to find and use credible information relevant to their illness (PJS Online Support Group, <http://listserv.acor.org/archives/pjs.html>).

## PREVALENCE

The estimation of population prevalence of PJS differs between studies. The widest estimated range is from 1 in 8300 to 1 in 280000 individuals<sup>[11,13-18]</sup>. Probable prevalence is around 1 in 100000 people. The disease has variable penetrance, even within families; some members will only manifest hyperpigmentation, while others may manifest pigmentations and hamartomatous polyps.

Very important data are available thanks to different registries of polyposis. The St. Mark's Polyposis Registry ([www.polyposisregistry.org.uk](http://www.polyposisregistry.org.uk)) is the oldest in the world. This was started in 1924 by Dr. Cuthbert Dukes and Mr JP Lockhart Mummery. The statement made by Dr. Dukes in 1958 remains true today: *"It would be difficult to find a more promising field for the exercise of cancer control than a*

*polyposis family, because both diagnosis and treatment are possible in the precancerous stage and because the results of surgical treatment are excellent"*.

The Danish Polyposis Register was established in 1971 and the register became national in 1975.

American Family History Registries are also available on the net: [www.fascrs.org/patients/family\\_history\\_registries/](http://www.fascrs.org/patients/family_history_registries/).

## GENETICS AND PATHOPHYSIOLOGY

Genetic testing is suitable for confirmation of PJS. Nowadays, the only identifiable mutations causing PJS affect the STK11 (serine/threonine-protein kinase 11 alias LKB1) gene, located on chromosome 19p13.3. STK11 is the official designation for LKB1 by the Human Genome Organisation (HUGO); [www.genenames.org/data/hgnc\\_data.php?hgnc\\_id=11389](http://www.genenames.org/data/hgnc_data.php?hgnc_id=11389). This gene was identified in 1998. It encodes for a multifunctional serine-threonine kinase, important in second messenger signal transduction. The serine-threonine kinase modulates cellular proliferation, controls cell polarity, and seems to have an important role in responding to low cellular energy levels<sup>[15,19]</sup>. In the performance of this last role, the STK11 protein is involved in the inhibition of AMP-activated protein kinase (AMPK), and signals downstream to inhibit the mammalian target of rapamycin (mTOR; also known as FKBP12-rapamycin complex-associated protein or FRAP) pathway; the mTOR pathway is dysregulated in patients with PJS<sup>[15]</sup>. Although the exact mechanism of action of STK11 has not been outlined completely, the function of this protein product is likely to be important in growth inhibition. Genetic alterations in STK11 may represent loss of heterozygosity at a tumor suppressor gene locus.

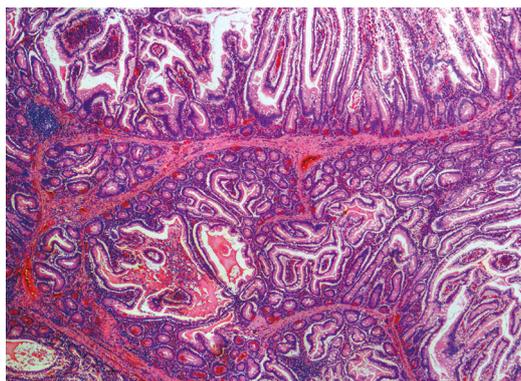

Recent studies have suggested the involvement of STK11 also in more common human disorders including diabetes mellitus and in a significant fraction of lung adenocarcinomas. These observations have increased the interest towards the signaling pathways of this tumor suppressor kinase<sup>[20]</sup>.

Genetic testing for STK11 mutations is available but they have variable sensitivity; in familial cases, 70%, in sporadic cases, from 30% to 67%. A significant proportion of familial and sporadic PJS may result from mutations in genes other than STK11 or so far unidentified means of LKB1 inactivation. In total, 91% of the studied families have shown LKB1 inactivation<sup>[11,13,14,16,17,19,21-23]</sup>. Variable penetrance and clinical heterogeneity make it difficult to determine the exact frequency of PJS<sup>[24]</sup>.

Germline mutations in the tumor suppressor gene PTEN (10q22-23) are responsible for a group of phenotypically diverse conditions, which have collectively been called the PTEN hamartoma tumor syndrome. These are rare autosomal dominant conditions different from PJS<sup>[15,22]</sup>.

## PATHOLOGY

The hamartomatous polyposis syndromes are chara-

**Figure 1** Hamartoma, a typical PJS polyp demonstrating the arborizing pattern of smooth-muscle proliferation. HE staining, magnification 100 ×. (Courtesy of Professor A. Ryska, MD, PhD).

**Figure 3** Hamartoma of the jejunum.

characterized by an overgrowth of cells native to the area in which they normally occur. It is important to note that there is an overgrowth of cells or tissues, at least initially, with no presumed neoplastic potential<sup>[14,22]</sup>. Hamartomatous polyps are composed of the normal cellular elements of the gastrointestinal tract, but have a markedly distorted architecture<sup>[11,15]</sup> (Figure 1). Microscopically, extensive smooth-muscle proliferation, with an elongated, arborized pattern of polyp formation, can be seen<sup>[15,16]</sup>. PJS-associated polyps can be differentiated from sporadic hamartomatous polyps and hamartomatous polyps associated with other syndromes by a unique smooth muscle core that arborizes throughout the polyp. PJS-type polyps do not have specific endoscopic features and can only reliably be distinguished from other types of polyps by histopathology. The unique PJS polyp pathology is best appreciated in PJS small intestine polyps<sup>[25]</sup>. The histopathology of PJS-associated gastric polyps can be similar to hyperplastic gastric polyps.

Larger hamartomas often contain foci of adenomatous tissue; a malignant development in a hamartomatous polyp has been described<sup>[7,26-28]</sup>.

## CLINICAL FEATURES AND NATURAL HISTORY OF THE DISEASE

Hyperpigmentation is present as mucocutaneous macules

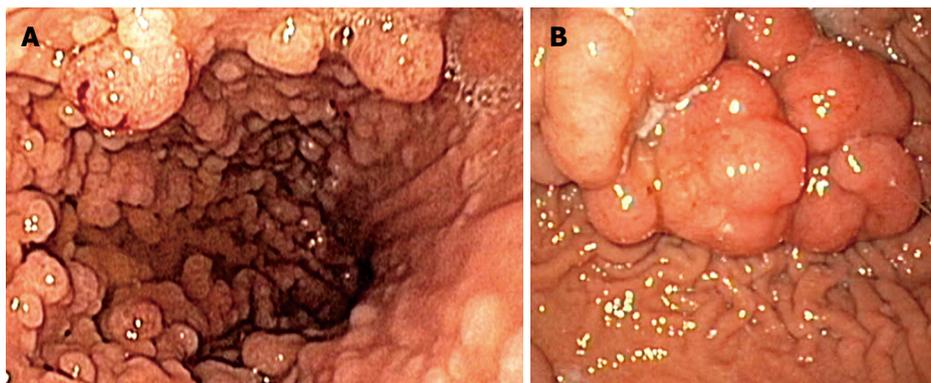

**Figure 2** Pigmentations of the lips and oral mucosa.

on the lips (Figure 2) and around the mouth, eyes, nostrils, and on the buccal mucosa; and sparsely on the fingers, soles of the feet, palms, anal area and intestinal mucosa. Characteristic pigmentations are present in 95% of the patients and are caused by pigment-laden macrophages in the dermis. They are typically flat, blue-gray to brown spots 1-5 mm in size. Malignant degeneration of these lesions is extremely rare. These macules can be distinguished from common freckles as the latter never appear in the oral cavity, are sparse near the lips and nostrils, and absent at birth. Hyperpigmentations can even disappear during adolescence. Diagnosis is defined by the presence of histopathologically confirmed hamartomatous polyps (Figure 1) and at least two of the following clinical criteria: family history, hyperpigmentation and polyps in the small bowel<sup>[11,13-17,21,22,29]</sup> (Figure 3).

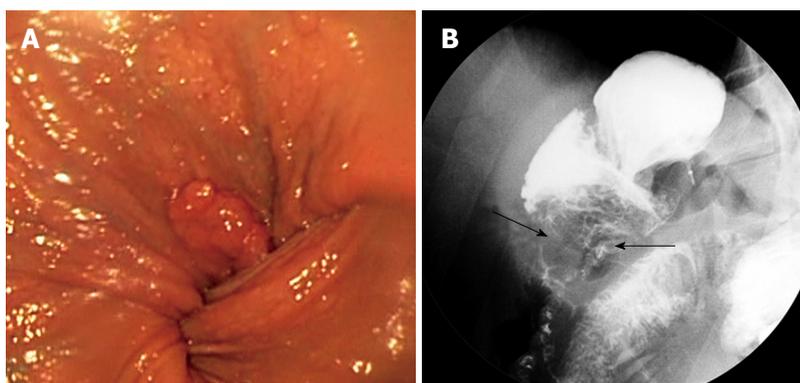

The median time to first presentation with polyps is about 11-13 years of age, and approximately 50% will have experienced symptoms by the age of 20 years<sup>[13,14]</sup>. During the first three decades of life, anemia, rectal bleeding, abdominal pain, obstruction and/or intussusception are common complications in patients with PJS<sup>[13,15]</sup>. Nearly half of the patients experience an intussusception during their lifetime, most often in the small intestine<sup>[30]</sup>.

The setting of 222 patients with PJS was presented by Utsunomiya *et al.*<sup>[31]</sup> in 1975. They presented patients with PJS in Japan ascertained between 1961 and 1974. The average age at diagnosis was 23 years in men and 26 years in women, with a male to female ratio of 1:1.13. Obstruction was observed in 42.8%, intussusception in 46.9%, most often in the small intestine, and rectal bleeding in 13.5% of the patients. The polyps occurred in the stomach in 48.6% (Figure 4A and B), small intestine 64%, colon 53.2%, and rectum 32%<sup>[31]</sup>. This study demonstrated the natural history of the disease despite this being based on surveys, and the study suffering some imperfections (e.g. cancer was found only in 28 of 222 patients).

Hearle *et al.*<sup>[32]</sup> have published a study of STK11 status and intussusception risk in PJS. According to this study, 135 (60%) of the probands possessed a germline STK11 mutation, and 109 (48%) probands had a history of intussusception at a median age of 15.0 years but with wide variability (range: 3.7-45.4 years). Median

**Figure 4** Hamartomas of the stomach. A: Multiple; B: Voluminous.

**Figure 5** Gastric outlet obstruction (same patient as seen in Figure 4B). A: Endoscopic view; B: fluoroscopy, mass of polyps marked by arrows.

time to onset of intussusception was not significantly different between those with identified mutations and those with no mutation detected, at 14.7 and 16.4 years, respectively. Similarly, no differences were observed between patient groups on the basis of the type or site of STK11 mutation<sup>[32]</sup>.

A quite rare but possible complication is gastric outlet obstruction caused by a giant gastric polyp<sup>[33-35]</sup> (Figure 4B and Figure 5). Children with PJS have a risk of numerous laparotomies due to the complications. Gastrointestinal screening of the small bowel should be started from childhood and when polyps develop they should be managed if possible by endoscopic resection<sup>[29,36]</sup>. PJS-related polyps occur most frequently in the small intestine. Over 90% of affected individuals will develop polyps in the small intestine during their lifetime. The incidence within the small intestine is greatest in the jejunum and progressively decreases in the ileum and duodenum<sup>[13,37,38]</sup>. Involvement of the colon (53% of patients), stomach (49%), and rectum (32%) is also seen<sup>[15,33-35]</sup>. Well-timed polypectomy may obviate the need for repeated urgent operations and extensive small bowel resections leading to short bowel syndrome<sup>[39,40]</sup>.

Extraintestinal polyps are also reported. Nasal polyposis is thought to be a rare complication. de Leng *et al*<sup>[41]</sup> have observed nasal polyposis in eight (15%) of 52 Dutch patients with PJS. The loss of heterozygosity, and the absence of eosinophilia suggest a distinct pathogenesis compared with sporadic nasal polyposis. In the same study, 11 of 12 PJS-associated nasal polyps were found to express cyclooxygenase-2 (COX-2) compared with 19 of 28 sporadic nasal polyps<sup>[41]</sup>. Six of 22 members of the

original Peutz pedigree have been diagnosed with nasal polyposis<sup>[6]</sup>. Three PJS patients have been reported with nasopharyngeal carcinoma<sup>[6,42]</sup>.

In a series of 72 PJS patients, three (4.1%) had gallbladder polyps<sup>[43]</sup>. Also reported are one PJS patient who required cholecystectomy for gallbladder obstruction by polyps, and one with common bile duct obstruction caused by polyps<sup>[44]</sup>. Two PJS patients have been reported with gallbladder cancer; one of whom had gallbladder cancer arising near but not in hamartomatous gallbladder polyps<sup>[31,45]</sup>. Several PJS patients have been reported with bile duct cancer (cholangiocarcinoma)<sup>[46,47]</sup>. Hamartomatous polyps in PJS patients have also been reported in the ureter<sup>[48]</sup>, respiratory tract<sup>[49,50]</sup> and on the tonsils<sup>[51]</sup>.

PJS is associated with specific genetic mutations and an increased lifetime risk of both gastrointestinal and extraintestinal malignancies<sup>[22]</sup>; i.e. pancreatic, lung, breast, uterine, ovarian and testicular malignancies (Sertoli cell tumors secrete estrogen and can lead to gynecomastia). Inherited forms of gastrointestinal cancer have attracted the attention of scientists over the past two decades, putting the accent on prevention. The possibility of developing any cancer by age 65 years was 37% in accordance with data from the St. Mark's Polyposis Registry<sup>[52]</sup>. Hearle *et al*<sup>[53]</sup> have analyzed the incidence of cancer in 419 PJS patients, and 297 of them had documented STK11/LKB1 mutations. Ninety-six cancers were found among these patients. The risk for developing cancer at ages 20, 30, 40, 50, 60 and 70 years was 2%, 5%, 17%, 31%, 60% and 85%, respectively. The most common cancers represented in this analysis were

of gastrointestinal origin. In non-gastrointestinal tumors, breast cancer was the most common, with the risk being 8% and 31% at ages 40 and 60 years, respectively. The cancer risk was similar in the STK11/LKB1 mutation positive and negative group<sup>[53]</sup>.

Mehenni *et al.*<sup>[42]</sup> have followed the cumulative incidence of cancer in 149 PJS patients with germline mutation(s) in LKB1, this being estimated using Kaplan-Meier analysis of time to cancer onset, and compared between relevant subgroups with log rank tests. Thirty-two cancers were found in LKB1 mutation carriers. Overall cancer risks at ages 30, 40, 50, 60 and 70 years were 6%, 18%, 31%, 41% and 67%, respectively. There were similar overall cancer risks between male and female carriers. However, there were overall cancer risk differences for exon 6 mutation carriers *vs* non-exon 6 mutation carriers. Most (22/32) of the cancers occurred in the gastrointestinal tract, and the overall gastrointestinal cancer risks at ages 40, 50, 60 and 70 years were 12%, 24%, 34% and 63%, respectively. In female patients, the risk of developing gynecological cancer at age 40 and 50 years was 13% and 18%, respectively. Mutations in exon 6 of LKB1 were associated with a higher cancer risk than mutations within other regions of the gene<sup>[42]</sup>.

In a meta-analysis of Giardiello *et al.*<sup>[54]</sup>, the cumulative risk of developing any cancer in PJS was 93%. Of all tumors associated with PJS, breast cancer poses the greatest risk, affecting 32%-54% of patients<sup>[54]</sup>. In their systematic study, Boardman *et al.*<sup>[55]</sup> have determined that the relative risk for all cancers in PJS patients significantly increased (RR = 9.9). The relative risk for gynecological and breast cancers in women was 20.3, and for gastrointestinal cancers, 50.3<sup>[55]</sup>. Screening recommendations for PJS patients includes not only gastrointestinal multiple polyp resolution, but also regular cancer screening.

## TREATMENT

There are two basic modalities in diagnosis and treatment of small bowel hamartomas: intra-operative enteroscopy (IOE) and double balloon enteroscopy (DBE).

DBE is a new enteroscopy method that allows examination and treatment of the jejunum and ileum in almost all patients. The system consists of a 200-cm enteroscope and a 145-cm over-tube which have soft latex balloons at their tips. By using these balloons to grip the intestinal wall, the endoscope can be inserted further without forming redundant loops of intestine<sup>[56]</sup>.

IOE is a combination of laparotomy (or laparoscopy) with endoscopy. It allows manipulation to ensure the entire small bowel is visualized and nearly all polyps are removed in an endoscopic or surgical manner<sup>[17]</sup>.

IOE was accepted as the ultimate diagnostic and/or therapeutic procedure for complete investigation of the small bowel, especially before the DBE era. A surveillance program published in the *British Journal of Surgery* in 1995 recommended IOE for small bowel polyps or abdominal pain in patients with PJS<sup>[22]</sup>. At that time,

IOE improved polyp clearance without the need for additional enterotomy and helped to reduce the frequency of laparotomy<sup>[56]</sup> (Figure 6).

The first clinical application of DBE occurred in 1999 and was reported 2001 by its inventor Yamamoto *et al.*<sup>[57]</sup>. DBE was established into clinical practice in 2003 and has taken the place of IOE for most indications. DBE is in most cases a suitable replacement for push enteroscopy, IOE, and to some extent, small bowel follow-through and computed tomography (CT)<sup>[58]</sup>. In spite of this, there is a small group of patients unsuitable for the DBE method. There could be some small intestinal adhesions after previous surgery making the DBE method impossible. It is necessary to inform all patients before DBE of possible surgical laparotomy with IOE or small bowel resection in case of failure of the DBE method<sup>[39]</sup>.

It is necessary to clear away all small intestinal polyps as far as it is possible (at least all polyps greater than 5 mm). Oncl *et al.*<sup>[59]</sup> have compared two groups of PJS patients. The first group of eight patients had only problem-focused surgery because of bleeding or obstruction. These patients required 23 further operations within 87 patient-follow-up-years (2.64 operations per year). The second group of three patients were operated upon using IOE, with removal of all small intestinal polyps. These patients did not require any further surgery within 21 patient-follow-up-years<sup>[59]</sup>. Timely clearance of all small intestinal polyps and careful screening is the gold standard for PJS patients.

## IOE

IOE is still a useful method for a specific group of patients (e.g. failure of DBE, adhesions, multiple small transmural lesions unresolvable by endoscopic methods, carcinoids, and blue rubber bleb nevus syndrome) and therefore it is necessary to be able to use this method. We started with IOE in our department in 1995, where more than 7000 gastrointestinal endoscopies are accomplished per year. Over the course of the following years, the average need for this investigation stabilized to 6-8 per year. After launching DBE in March 2006 in our endoscopy unit, the need for IOE dropped to 1-2 cases per year.

IOE still remains a unique method of small bowel investigation and a solution for some pathological findings. The investigation is invasive, therefore, precise indication is imperative. The procedure takes place in the operating theater with close cooperation with surgical team. One of the advantages of IOE is that there is a surgeon on the other side of the small bowel wall. This allows the endoscopist to be more invasive and calmer. Perfect teamwork by the surgeon, endoscopist and anesthesiologist is indispensable.

The day before the investigation, a standard colonoscopy preparation of the bowel is performed (oral sodium phosphate or macrogolum solution). All patients are investigated under general anesthesia and intubated. Over-inflation of the stomach is prevented by introducing

a nasogastric tube for permanent suction at the beginning of the procedure. The physician performing the endoscopy becomes a member of the operating team. All our IOEs are performed using standard laparotomy with a mid-small bowel enterotomy. Polyps are removed preferentially in an endoscopic manner using a polypectomy snare. Some bigger polyps were removed by surgical excision because it was easier and less time-consuming. The characteristic technical details of IOE have already been presented<sup>[39]</sup>.

### DBE

DBE has an accessory channel and good maneuverability in the distal small intestine, and it enables endoscopic treatment, including polypectomy. DBE is also useful for cases of difficult colonoscopy, providing success rates of total colonoscopy between 88%-100%. Although it has been a few years since its development, the usefulness of DBE is now well recognized. This challenging procedure has rapidly become popular and currently is used in many countries<sup>[60]</sup>. DBE is clinically useful for obtaining the diagnosis, starting treatment and providing therapeutic endoscopy. DBE is a useful and safe method of obtaining tissue for diagnosis and carrying out polypectomy<sup>[61]</sup>.

The investigation is performed after overnight fasting using oral procedures, or after bowel preparation using standard colonoscopy preparation (oral sodium phosphate or macrogolum solution) and anal (retrograde) procedures. Total inspection by DBE usually is achieved by a combination of sequential oral and anal intubation; success rates are reported to be 40%-80%<sup>[60]</sup>. To confirm total enteroscopy, we use Indian ink tattooing of the small bowel. Total enteroscopy is also confirmed in the case of reaching the cecum by an oral approach, which is achieved in 10% of all oral DBEs in our setting.

We have used CO<sub>2</sub> insufflation in DBE procedures regularly since 2007. We have had no complications with hyperinflation, the comfort of the patient rapidly increases, and this type of insufflation is helpful for easier and deeper insertion of the endoscope, because the absorption of CO<sub>2</sub> is 150 times faster than absorption of air in the bowel. Combination of water with simethicone is used routinely to do away with bubbles in the intestine.

Venous access is obtained before the procedure. All patients are monitored during the procedure, for oxygen saturation, heart rate, and blood pressure. Intravenous crystalloids are administered during DBE. Conscious sedation seems to be much better in DBE in comparison with general anesthesia. Abdominal pain is a very important warning signal, and it is necessary to terminate the procedure immediately in such cases. Intense pain may be a sign of inadequate pressure on the pancreas and high risk of post-DBE pancreatitis<sup>[62]</sup>. We use small intravenous repetitive doses of midazolam and pentazocine for conscious sedation (batch-wise).

The oral approach is preferred in all patients, because the number of polyps is significantly higher in the jejunum than the ileum. If panenteroscopy is not achieved by the oral approach, we perform Indian ink marking of the

small bowel. Control capsule enteroscopy is performed subsequently to locate possible additional polyps in an uninvestigated part of the small bowel (in the distal small bowel below the Indian ink tattooing). After finding such additional polyps, we continue with oral DBE and complete the polypectomy.

Endoscopic therapy in the small intestine, whose wall is very thin, should be performed with special care to avoid complications such as bleeding and perforation<sup>[63]</sup>. To prevent bleeding, we use only pure coagulation for cutting of hamartomas with a long stalk. If the stalk is long enough to prevent hypercoagulation of the intestinal wall, this method is safe and very useful. However, this method must be abandoned for polyps with a short stalk or for sessile polyps. The use of too much coagulation could lead to hypercoagulation of the intestinal wall and perforation within a few days after the procedure.

### Chemoprevention

Some recent studies have demonstrated the chemopreventive efficacy of rapamycin on PJS in a mouse model<sup>[64-66]</sup>. Rapamycin (sirolimus) is a macrolide compound with immunosuppressant properties that is obtained from *Streptomyces hydropiscus*. Rapamycin treatment led to a dramatic reduction in polyp burden and size. A significant reduction in microvessel density was seen in polyps from the rapamycin-treated mice compared to those from the control group. The antiangiogenic effect of rapamycin may play a role in polyp reduction<sup>[66]</sup>.

The potent antiproliferative activity of the macrolide antibiotic rapamycin is known to involve binding of the drug to its cytosolic receptor, FKBP12, and subsequent interaction with targets of rapamycin, resulting in inhibition of p70 S6 kinase. However, the downstream events that lead to inhibition of cell cycle progression remain to be elucidated. The antiproliferative effects of rapamycin are associated with prevention of mitogen-induced downregulation of the cyclin-dependent kinase inhibitor p27Kip1, which suggests that the latter plays an important role in the growth pathway targeted by rapamycin. Murine BC3H1 cells, selected for resistance to growth inhibition by rapamycin, exhibited an intact p70 S6 kinase pathway but had abnormally low p27 levels that were no longer responsive to mitogens or rapamycin. Fibroblasts and T lymphocytes from mice with a targeted disruption of the p27Kip1 gene had impaired growth-inhibitory responses to rapamycin. These results suggest that the ability to regulate p27Kip1 levels is important for rapamycin to exert its antiproliferative effects<sup>[67]</sup>.

A pilot open-label study starts this year in the University of Utah and recruiting of participants *via* the internet ([www.clinicaltrials.gov](http://www.clinicaltrials.gov)). Rapamycin analogs, which are already FDA-approved and are being used in more than 50 ongoing clinical trials, could one day be used for the treatment of PJS patients.

De Leng *et al*<sup>[68]</sup> have studied the presence of COX-2 in PJS. Moderate or high levels of epithelial COX-2 were present in 25% of hamartomas, including two hamartomas

with dysplastic changes, and 64% of carcinomas. The presence of COX-2 expression in PJS carcinomas and dysplastic hamartomas provides a rationale for chemoprevention with nonsteroidal anti-inflammatory drugs or COX-2 inhibitors. Focal immunohistochemical changes, which may indicate premalignant potential, were present in some nondysplastic PJS hamartomas. Molecular changes in carcinomas and dysplastic hamartomas in PJS are distinct from the usual adenoma-carcinoma sequence<sup>[68]</sup>.

The study of Udd *et al*<sup>[69]</sup> was designed to determine whether COX-2 inhibition reduced tumor burden in Lkb1(+/-) mice or PJS patients. Genetic interactions between COX-2 and Lkb1 in polyp formation were analyzed in mice with combined deficiencies in these genes. Pharmacological inhibition of COX-2 was achieved by supplementing the diet of Lkb1(+/-) mice with celecoxib. In PJS patients, COX-2 was inhibited with a daily dose of 2 × 200 mg celecoxib for 6 mo. Total polyp burden in Lkb1(+/-) mice was significantly reduced in a COX-2(+/-) (53%) and in a COX-2(-/-) (54%) background. Celecoxib treatment initiated before polyposis (3.5-10 mo) led to a dramatic reduction in tumor burden (86%) and was associated with decreased vascularity of the polyps. Late treatment (6.5-10 mo) also led to a significant reduction in large polyps. In a pilot clinical study, a subset of PJS patients (2/6) responded favorably to celecoxib with reduced gastric polyposis<sup>[69]</sup>. Both studies suggest that COX-2 chemoprevention is beneficial in the treatment of PJS.

Metformin has been shown to inhibit mTOR activity in breast cancer cells but is unable to inhibit mTOR in cells that lack STK11<sup>[70,71]</sup>. Based on these data, it is unclear how effective metformin would be in PJS patients who are germline haplo-insufficient for STK11 and in PJS neoplastic tissue that does not express STK11.

Lifestyle factors including excess weight, lack of exercise, smoking, and alcohol use are risk factors for the cancers associated with PJS. Although no study of PJS patients has shown that modification of these risk factors reduces cancer risk, all PJS patients should be advised to adopt a healthy lifestyle.

## OVERALL EXPERIENCE OF PJS PATIENTS

New endoscopic technology may improve management of intestinal polyposis<sup>[24,37]</sup>. Nowadays, DBE in combination with capsule enteroscopy are the gold standard for diagnosis and treatment of the small bowel<sup>[72]</sup>. These methods have replaced IOE in nearly all patients with PJS. Until only recently, primary surgical resection and IOE were the only available possibilities for treating polyps in the mid-small bowel in patients with PJS<sup>[73-76]</sup>. DBE and video capsule enteroscopy have changed this approach and it is now possible to not only to perform endoscopic surveillance and diagnose these lesions, but also to resect them<sup>[57,58,73,77,78]</sup>. Many reports on DBE have suggested that this new method may be able to replace at least IOE in many circumstances<sup>[63,79,80]</sup>.

Indications of IOE have diminished over recent

**Table 1** Benefits and drawbacks of endoscopic methods<sup>[39,77]</sup>

Method	Intra-operative enteroscopy	Double balloon enteroscopy
Benefits	All polyps removed in one procedure	Less invasive
	Partnership with a surgeon	Well tolerated
	Less time-consuming for endoscopist	Shorter sick leave
Drawbacks	Necessity of laparotomy	Often more than one procedure required
	Possibility of adhesions formation	Not feasible in some patients (because of adhesions)
	Longer convalescence	Longer procedure

years because of the development of DBE<sup>[57]</sup>. Despite its current introduction into clinical practice<sup>[80-82]</sup>, IOE is reserved for those cases in which DBE cannot be performed or fails to investigate the entire small intestine, especially to prevent excessive bowel resection. The advantages and disadvantages of IOE and DBE methods are summarized in Table 1.

Pennazio *et al*<sup>[83]</sup> have followed seven patients during a 10-year period. During the first period, five patients underwent emergency small bowel resection (two were operated on twice). Subsequently, three of four patients with diffuse polyposis underwent IOE during which, on average, 16 polyps per patient were removed (range: 10-25 polyps; mean diameter: 16 mm, range: 3-50 mm). The other three patients with polyps only in the proximal jejunum underwent periodic push enteroscopy alone (mean: three per patient), during which, a mean of 12 polyps per patient were removed (range: 7-15 polyps; mean diameter: 11 mm, range: 3-40 mm)<sup>[83]</sup>.

From 1999 to 2006 we performed seven IOEs in seven patients (four women and three men) in our single tertiary center. A total number of 182 polyps were removed during IOE; 179 by an endoscopist and three by a surgeon. From six to 75 polyps were removed per session (mean: 26). The largest hamartoma measured 4 cm in diameter. The age of the patients ranged from 20 to 50 years (mean: 31 years). The mean time of the endoscopic part of the procedure was not measured exactly; it was estimated at 60 min. We had no serious complications in the IOE group.

From 2006, we accomplished 11 DBEs in another seven PJS patients (five women and two men). In our DBE group, a total of 205 polyps were removed. The age of the patients ranged from 12 to 48 years (mean: 25 years). From one to 37 polyps were removed per session (mean: 13). All polyps were resolved using the endoscopic method (snare polypectomy). The largest hamartoma was 6 cm in diameter and was removed by a piecemeal technique without complications. The mean time required to carry out the DBE procedure was 113 min (range: 20-270 min). All patients from the DBE group were resolved by means of endoscopic polypectomy; none of them had to be operated on. We had no serious complications in the DBE group.

**Figure 6** Intra-operative enteroscopy. Polypectomy snare over a small polyp shines through the intestinal wall.

The endoscopist performing DBE should be trained not only in endoscopy, but also in polypectomy. He/she must be experienced and be able to resolve complications<sup>[73,77]</sup>. Moreover, it is necessary to have close collaboration with a surgeon in case of complications. Complete polypectomy in IOE or DBE can provide a longer symptom-free interval<sup>[39,40,77]</sup>.

In the series published to date, complications of DBE solely relating to the diagnostic procedure are rare. A recent retrospective multicenter survey in four countries has indicated a complication rate of 0.8% (13/1728) in diagnostic procedures and 4.3% (27/634) for therapeutic DBE, and there were no fatal cases<sup>[63,84,85]</sup>.

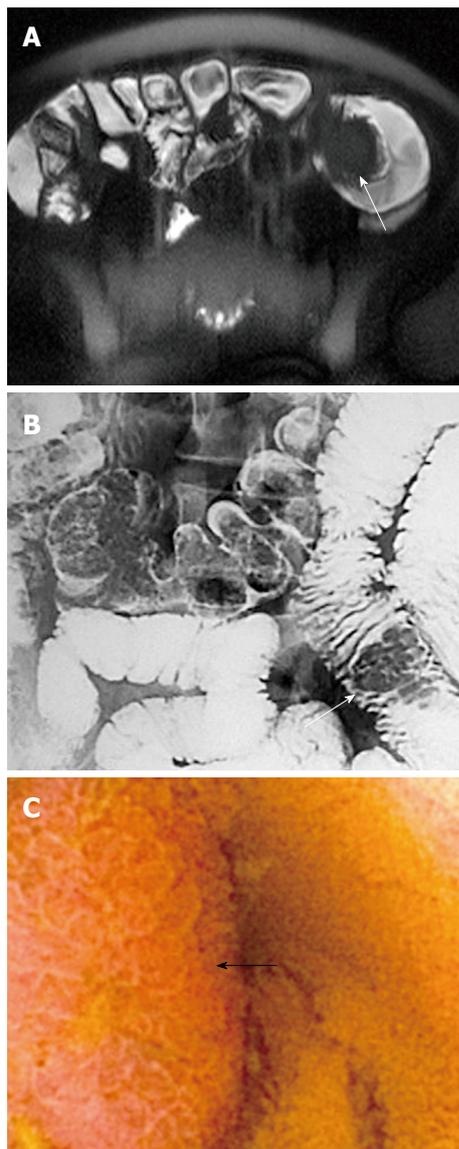

During DBE, careful attention must be paid not to insufflate too much air, because this induces intestinal loop formation and impedes deep advancement<sup>[73]</sup>. With CO<sub>2</sub> insufflation, we solved this problem completely. Hyperinflation in combination with oxygen desaturation is a common complication according to the literature<sup>[73]</sup>. Continual monitoring during the procedure is indispensable.

Quite a common complication could be bleeding after polypectomy<sup>[73]</sup>. We do not consider it to be serious if the patient's blood count does not drop and if the bleeding is resolved by the endoscopist without surgical support in the case of DBE.

A feared complication is perforation after polypectomy. Perforation has been reported in 2%-6.5% of patients<sup>[74,75]</sup>. Polypectomy of large polyps appears to be the procedure associated with the highest risk<sup>[74]</sup>.

## FOLLOW-UP AND MALIGNANCY SCREENING

It is necessary to find the optimal method for screening of small intestinal polyps. Previously, the only method was enteroclysis (Figure 7A). Recently, wireless capsule endoscopy has been found to detect more polyps than small bowel radiographic studies (Figure 7B). Capsule endoscopy is a feasible, safe and sensitive test for small bowel surveillance in patients with PJS, even in children. It is significantly more comfortable than barium

**Figure 7** Hamartoma of the jejunum (arrow). A: Magnetic resonance imaging; B: Enteroclysis; C: Capsule endoscopy.

enterography<sup>[86,87]</sup>. The use of capsule endoscopy permits earlier diagnosis, therefore, the clinical course of intestinal polyps has changed. These polyps are now seen before the occurrence of obstructive signs. Capsule endoscopy can detect polyps in the entire length of the small intestine, with a higher diagnostic yield compared to CT and magnetic resonance imaging (MRI) with enteroclysis, particularly for lesions less than 1 cm in diameter<sup>[88]</sup>. CT is another option for screening. CT with oral contrast has demonstrated greater sensitivity than small bowel radiography<sup>[15]</sup>. In our opinion, MRI with oral contrast is superior to CT, not only to prevent high doses of radiation in young people during CT, but also for higher accuracy of MRI enteroclysis. Unlike capsule endoscopy, MRI enteroclysis can determine the exact size of bigger polyps (Figure 7C). On the other hand, capsule endoscopy is more successful in finding small polyps. That is why we prefer a combination of both these methods, as do many others<sup>[73,87,89]</sup>.

All PJS sufferers have to be enrolled for lifelong

Table 2 Cancer screening in PJS patients<sup>[13-17,22]</sup>

Site of possible tumour	Age of screening initiation	Periodicity	Method of screening
Colon	15 yr <sup>1</sup>	2 yr <sup>2</sup>	Colonoscopy, CA 19-9
Oral parts of GIT	15 yr <sup>1</sup>	2 yr <sup>2</sup>	Gastroscopy
Small intestine	15 yr <sup>1</sup>	2 yr <sup>2</sup>	Capsule enteroscopy or MRI scan
Breast	21 yr	Monthly	Self-examination
		6-12 mo	Sonography or mammography, CA 125
Thyroid gland	18 yr	1 yr	Sonography, clinical examination
Pancreas	18 yr	1 yr	Sonography or CT or MRI scan
Uterus and ovaria	18 yr	1 yr	Sonography, clinical examination
Testes	18 yr	1 yr	Sonography, clinical examination
Lung	18 yr	5 yr?	X-ray, clinical examination

<sup>1</sup>Earlier in symptomatic persons; <sup>2</sup>Endoscopy each year as long as polyps are present, subsequently prolong intervals. PJS: Peutz-Jeghers syndrome.

screening because of the high risk of different carcinomas (Table 2). There have been some case reports in the literature of the occurrence of malignancy in very young patients, even in children<sup>[38,90]</sup>.

There is no consensus or organization-approved guidelines for cancer surveillance in PJS patients. Different protocols are used at Johns Hopkins Hospital<sup>[91]</sup>, St. Mark's Hospital<sup>[92]</sup>, the Mayo Clinic<sup>[93]</sup>, the University of Edinburgh<sup>[94]</sup>, Danish Polyposis Registry<sup>[95]</sup>, and the University of Newcastle (Australia)<sup>[96]</sup>. There are many differences between the protocols, but whichever protocol is used, it should be modified according to available resources, the individual patient's disease manifestations, psychosocial situation, and personal preferences.

It is necessary to perform consistent screening for possible malignancies in all patients with PJS: colonoscopy, upper endoscopy, CT, MRI or ultrasound of the pancreas, chest X-ray, mammography and pelvic examination with ultrasound in women, testicular examination in men, carbohydrate antigen 19-9 (CA-19-9), and cancer antigen (CA 125)<sup>[52-55]</sup>.

DBE together with capsule endoscopy are essential modalities for the management of small intestinal diseases. IOE is the ultimate method in those patients in whom complete DBE investigation is impossible because of adhesions or other technical complications. IOE will be reserved for those cases in which DBE could not be performed or fails to investigate the entire small intestine, especially to prevent excessive bowel resection<sup>[39,77]</sup>.

We currently perform all of these methods in our department: push-enteroscopy, DBE, IOE and wireless capsule endoscopy. We do not consider these methods competitive but complementary for proper indications.

Last but not least, the psychosocial impact of PJS is very important and deserves special attention. Results have shown that PJS patients suffer from mild depression even though physically they did not feel any impact from their condition compared to the general population. However, having PJS causes them to alter many important life decisions. This fact is important in developing a plan for care of these patients regarding genetic counseling and surveillance strategies for PJS patients<sup>[16,97]</sup>.

It is even possible to treat benign hyperpigmentation

of the face by means of laser therapy. Q-switched lasers are the preferred method. The treatment is effective<sup>[98]</sup>, but this is only complementary cosmetic therapy.

## CONCLUSION

In summary, timely polypectomy, preferably using the DBE method, are essential for patients with PJS. Follow-up of gastrointestinal polyps is necessary. The best combination of methods is capsule enteroscopy and MR enteroclysis. Lifelong screening of malignancies is indispensable on a regular basis. It is necessary to investigate all first-degree relatives of the patient. Although the incidence of PJS is low, it is important for clinicians to recognize these disorders to prevent morbidity and mortality in these patients, and to perform presymptomatic testing in patients at risk.

### Abstract

**AIM:** To investigate the level of gastric ghrelin in stomach mucosa of dyspeptic patients in relation to *Helicobacter pylori* (*H pylori*) infection, bacterial cytotoxicity, topography and gender.

**METHODS:** The study comprised 40 premenopausal women (19 *H pylori* positive) and 48 men (17 *H pylori* positive) with functional dyspepsia. All gastric biopsy specimens revealed normal mucosa or non-atrophic gastritis. Gastric ghrelin concentration was determined by Enzyme linked immunosorbent assay. The *cagA* and *vacA* strains of bacterial DNA were identified by multiplex polymerase chain reaction.

**RESULTS:** In general, infection with *H pylori* caused

an increase in gastric ghrelin level regardless of gender and stomach topography. Significantly more hormone was present in both, non-infected and *H pylori* positive female samples, as compared to males. The distribution of bacterial strains showed *cagA*(+) *vacA* s1m1 and *cagA*(-) *vacA* s2m2 genotypes as the most common infections in the studied population. A tendency to higher ghrelin levels was observed in less cytotoxic (*cagA* negative) strain-containing specimens from the antrum and corpus of both gender groups (without statistical significance).

**CONCLUSION:** An increase in gastric ghrelin levels at the stage of non-atrophic gastritis in *H pylori* positive patients, especially in those infected with *cagA*(-) strains, can exert a gastroprotective effect.

Gastric ghrelin in relation to gender, stomach topography and *Helicobacter pylori* in dyspeptic patients. *World J Gastroenterol* 2009; 15(43): 5409-5417 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5409.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5409>

### INTRODUCTION

Ghrelin is a peptide hormone that plays an important role in food intake, energy homeostasis and body-weight regulation. It is expressed in multiple tissues and exerts both, endocrine and paracrine/autocrine effects. This 28-amino acid peptide was discovered by Kojima *et al*<sup>[1]</sup> in 1999. Approximately 70% of the body pool of this hormone is produced by gastric X/A cells located in the corpus and fundus of the stomach and is secreted into the extracellular matrix and into the blood. Normal ghrelin levels in serum range from 145-160 fmol/mL

and rapidly drop after gastrectomy<sup>[2]</sup>. Ghrelin stimulates growth hormone (GH) release *via* the GHRH-dependent (growth hormone releasing hormone) mechanism acting on the growth hormone secretagogue receptor (GHS-R). Released GH and its mediator, insulin-like growth factor 1, affect a range of physiological processes<sup>[3]</sup>. It has been suggested that ghrelin exerts a gastroprotective role. Its level is significantly lower in gastric tumours than in normal gastric mucosa<sup>[4]</sup>.

Ghrelin possesses anti-proliferative effects on breast, lung and thyroid cell lines and exerts protective actions on the gastric mucosa<sup>[5]</sup>. In the alimentary tract, ghrelin increases acid secretion and stimulates gastric emptying *via* vagal activation<sup>[6]</sup>. Ghrelin levels change significantly depending on the body's energy requirements<sup>[7]</sup>. It is known that exogenous ghrelin significantly inhibits the activation of nuclear factor (NF)- $\kappa$ B and plasma tumor necrosis factor- $\alpha$ <sup>[8]</sup>. It is well known that *Helicobacter pylori* (*H pylori*)-mediated gastric inflammation critically depends on the efficient recruitment and activation of macrophages, with sufficient NF- $\kappa$ B activation<sup>[9]</sup>. This transcription factor plays an important role in activation of expression of proinflammatory cytokines. Studies are being conducted to determine the effect of sociological and environmental factors on ghrelin release.

There is a great deal of interest in the role of *H pylori* infection in oncogenesis. *H pylori* infection always induces chronic active gastritis, which, in the presence of other factors, can lead to the development of gastric cancer (GC). Thus, based on evidence that infections increase the risk of GC, *H pylori* was categorized as a class I carcinogen more than 10 years ago<sup>[10]</sup>. Only 15% of those colonized develop the disease, and the pathogenesis depends upon strain virulence, host genetic susceptibility, and environmental cofactors. Virulent factors include the *cag* pathogenicity island (PAI), which induces proinflammatory and proliferative epithelial cell signaling. The expression of various products encoded in the *cag* PAI is known to be involved in inducing inflammation, ulceration and carcinogenesis. Each *H pylori* strain possesses one *vacA* gene, which due to its genetic variability, can be either of type s1 or s2 in the polymorphic signal region or type m1 or m2 in the polymorphic mid-region<sup>[11]</sup>. Another PAI-associated gene is the *cagA* gene, expressed by the majority of *H pylori* strains, irrespective of the geographic origin and clinical diagnosis<sup>[12]</sup>. *H pylori vacA* s1m1 *cagA* virulent strains are significantly more frequent in patients with GC<sup>[13]</sup>. An increased predisposition to GC is thought to be associated with the presence of *H pylori cagA* strains<sup>[14]</sup>.

The aim of this study was to determine whether there is any correlation between gastric ghrelin level and *H pylori* infection in relation to bacterial strain cytotoxicity, patients' gender and stomach topography.

## MATERIALS AND METHODS

### Patients

The study comprised 88 patients with functional dyspepsia (classification according to Rome III criteria)<sup>[15]</sup>. Exclusion criteria included chronic or psychiatric illness, preg-

nancy, drug and alcohol abuse - defined as consumption of more than two alcoholic drinks per day and NSAIDs or PPIs administration during the 14 d prior to the study. Patients with histopathological changes higher than those of non-atrophic gastritis (according to Sydney System Scale update<sup>[16]</sup>) and with a body mass index (BMI) below 18 and above 29 kg/m<sup>2</sup> were excluded from the study. The study comprised 40 premenopausal women (mean age 42  $\pm$  13 years), of whom 19 were *H pylori* positive and 48 men (mean age 35  $\pm$  10 years), of whom 17 were *H pylori* positive. Initially, all the selected subjects had their BMI calculated (as body weight in kilograms divided by the square of their height in meters)<sup>[17]</sup>. The physical examinations were performed at fasting in the morning. Subjects underwent a routine endoscopic evaluation at enrolment (a gastroscopy with biopsy). From each patient, five biopsy specimens from the antrum and five from the corpus were taken. One of the samples was used to perform a urease test, and a second sample was used for histological assessment. Another sample was used to determine the bacterial strain, and the remaining two specimens, taken from the anterior and posterior wall of the antrum or corpus were used for ghrelin level determination.

Histological assessments were performed using haematoxylin-eosin and Giemsa staining. Two paraffin-embedded tissue blocks (from the antrum and corpus) were used for microscopic section preparation. From each paraffin block, two sections were obtained. The microscopic gastric mucosa assessment was based on criteria according to the updated Sydney System Classification<sup>[16]</sup>.

### Protein fraction isolation

Biopsy specimens were frozen in physiological saline at -20°C. DNA, RNA and protein fractions were extracted using a TriPure Isolation Reagent (Roche Diagnostic GmbH, Mannheim, Germany). Protein concentrations were assessed with the Biorad Protein Assay (BIO-RAD Laboratories, Hercules, CA, USA). Purified protein fractions were used to evaluate ghrelin levels in biopsy specimens by the immunoenzymatic enzyme linked immunosorbent assay (ELISA) method.

### Multiplex polymerase chain reaction (PCR)

Multiplex PCR reactions were performed with the use of specific primers for amplification of the *cagA* gene and subtypes of the *vacA* (s1/2 and m1/2) gene in biopsy specimens<sup>[18]</sup>. The tissue samples were suspended in lysis buffer (10 mmol/L Tris-HCl, 0.1 mol/L EDTA, 5% SDS, 100-200  $\mu$ g/mL proteinase K). The mixture was incubated at 50°C for 2 h, and then DNA was isolated by extraction with a mixture of phenol, chloroform and isoamyl alcohol and precipitated with ethanol. PCR products of the lengths: 350 base pairs (bp) (*cagA*), 259 bp (*vacA* s1), 286 bp (*vacA* s2), 567 bp (*vacA* m1) and 642 bp (*vacA* m2) were subjected to electrophoretic analysis on a 2% agarose gel.

### ELISA test

Ghrelin levels in gastric biopsy specimens were measured using the indirect ELISA "sandwich" test. A 96-well

Table 1 Characteristics of the patients included to the study (mean  $\pm$  SD)

MaxiSorp plate (NUNC Thermo Fisher Scientific, Roskilde, Denmark) was coated with chicken monoclonal antibodies against the C-terminal domain of human ghrelin (Abcam Ltd., Cambridge, UK) in carbonate buffer (pH 9.6). Plate wells were rinsed 5 times with PBS buffer and blocked with 1% BSA-PBS (SERVA Electrophoresis GmbH, Heidelberg, Germany) and protein fraction was added to the wells at a final amount of 1 mg per well. The plates were incubated at room temperature for 2 h. The wells were then rinsed five times with PBS, and rabbit polyclonal IgG antibodies against the N-terminal end of human ghrelin were added. The plates were incubated overnight at 4°C. HRP goat polyclonal antibodies against rabbit IgG (Abcam) were applied. The reaction was revealed by ABTS substrate (BIOMOL GmbH, Hamburg, Germany) at a 1 mg/mL concentration in phosphate-citrate buffer with H<sub>2</sub>O<sub>2</sub> (Chempur, Piekary Slaskie, Poland) for 20 min in darkness. Then, the absorbance was measured at 414 nm by the Synergy HT (BioTek, Winooski, VT, USA) plate reader. The measurements allowed us to obtain the values of ghrelin absorbance after subtraction of the background (the absorbance value of the well without gastric biopsy proteins). Test normalization was performed by analyzing a model curve obtained using commercially available hormone. The mean value of ghrelin levels determined in two specimens, taken from the anterior and posterior wall of the antrum or corpus of each patient was taken for further evaluations.

### Ethics

The study was conducted in accordance with the Declaration of Helsinki and with principles of the Good Clinical Practice. These studies were approved by the Ethical Commission of the Medical University of Lodz, Poland. Each patient before being enrolled into the research program was acquainted with the aim of the study and gave conscious, written consent to participate in the study.

### Statistical analysis

The Shapiro-Wilks'  $W$  test was used to analyze the normality of the distribution. The differences between median values of gastric ghrelin in two independent groups were calculated by the use of the nonparametric Mann-Whitney  $U$  test. In order to test the statistical significance of differences between the three groups we used the non-parametric Kruskal-Willis test. The gastric ghrelin level is shown as a box around the midpoint

(median) which represents the 25th and 75th percentiles. The whiskers outside of the box represent the non outlier data. Outlier data points are also plotted. The statistical significance of the difference for each test was identified by a two-tailed probability ( $P$ ).  $P$  values of less than 0.05 were considered significant.

## RESULTS

### Selection of patients

A total of 88 patients with functional dyspepsia, having normal mucosa or non-atrophic gastritis were enrolled in the study. Full characteristics of the patients including the mean age, BMI and alcohol consumption are given in Table 1.

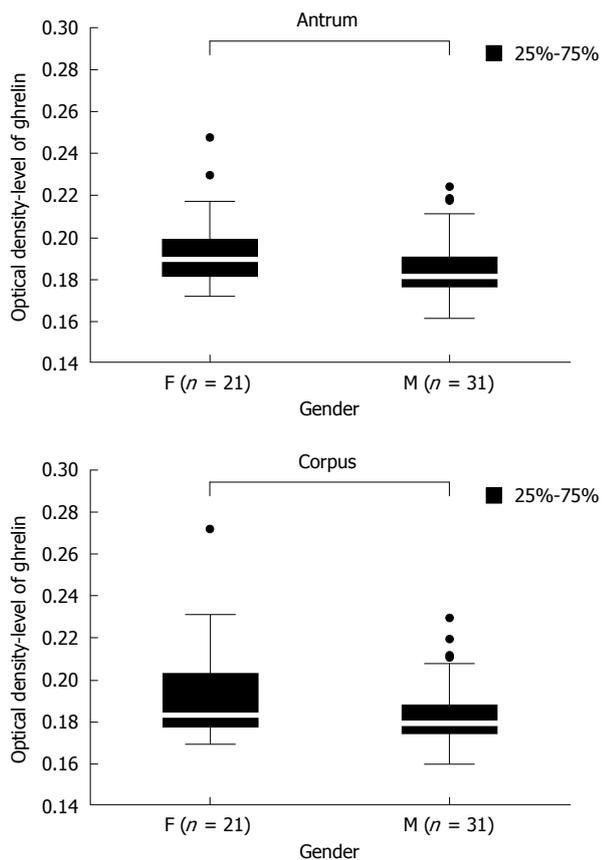

### Gastric ghrelin and gender in non-infected patients

There are no clear data concerning the dependence of gastric ghrelin level on patients' gender. Therefore the first groups analyzed were the controls, without *H pylori* infection, consisting of 21 premenopausal women (mean age 41  $\pm$  13 years) and 31 men (mean age 36  $\pm$  11 years). The levels of gastric ghrelin in the antrum and corpus were determined for each patient and then the mean values were calculated for the analyzed groups of patients. The results are presented in Figure 1 and show statistically significant [antrum: 0.189250 (F) *vs* 0.181000 (M),  $P = 0.004610$  and corpus: 0.183000 (F) *vs* 0.179000 (M),  $P = 0.017149$ ] higher levels of this hormone in female samples (F) compared to male samples (M), independent of gastric topography.

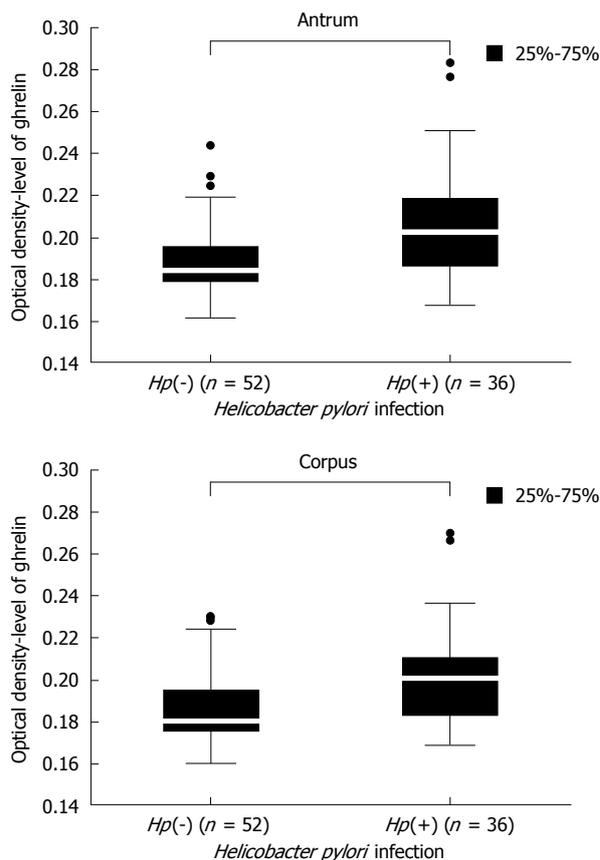

### Gastric ghrelin and gender in patients with *H pylori* infection

The first question was to clarify the influence *H pylori* infection on the level of gastric ghrelin. Data concerning this issue are not consistent and therefore we compared the levels of gastric ghrelin in samples from the antrum and corpus of *H pylori* negative [*Hp*(-)] and *H pylori* positive [*Hp*(+)] patients. These results are shown in Figure 2 and demonstrate that, independent of stomach topography, the levels of this hormone were elevated in infected specimens. Moreover, the observed differences between infected and non-infected groups of patients were statistically significant {antrum: 0.184000 [*Hp*(-)] *vs* 0.202500 [*Hp*(+)],  $P = 0.000000$  and corpus: 0.178000 [*Hp*(-)] *vs* 0.201000 [*Hp*(+)],  $P = 0.000000$ } (Figure 2).

Because the level of gastric ghrelin was higher in the stomach mucosa of women than in men, we performed a detailed analysis of ghrelin levels depending on *H pylori*

**Figure 1** Ghrelin levels in gastric biopsy specimens from the antrum and corpus of patients without *H. pylori* infection. The numbers (n) of female (F) and male (M) patients are given.

**Figure 2** Comparison of ghrelin level in *H. pylori* negative [Hp(-)] and *H. pylori* positive [Hp(+)] samples from the antrum and corpus of all screened patients. Population numbers are given.

**Table 2** Distribution of *Helicobacter pylori* strains in the study population of 19 women and 17 men in relation to gastric topography

<i>H. pylori</i> genotype	No. of patients (female/male)	
	Antrum	Corpus
<i>cagA</i> (-) <i>vacA</i> s2 m2	8 (5/3)	9 (6/3)
<i>cagA</i> (+) <i>vacA</i> s1 m1	17 (11/6)	17 (11/6)
<i>cagA</i> (+) <i>vacA</i> s1 m2	1 (1/0)	1 (1/0)
<i>cagA</i> (+) <i>vacA</i> s2 m2	2 (1/1)	1 (0/1)
<i>cagA</i> (+) <i>vacA</i> (+) genotype ndt	3 (0/3)	3 (0/3)
<i>cagA</i> (-) <i>vacA</i> (+) genotype ndt	5 (1/4)	5 (1/5)

For 8 patients the genotype of *vacA*(+) strains was not determined (ndt).

infection and sex. As shown in Figure 3, in both men and women, the levels of gastric ghrelin were higher, as expected, in *H. pylori* positive biopsy specimens {women antrum: 0.189250 [Hp(-)] vs 0.214667 [Hp(+)],  $P = 0.000002$ ; women corpus: 0.183000 [Hp(-)] vs 0.209250 [Hp(+)],  $P = 0.000214$ ; men antrum: 0.181000 [Hp(-)] vs 0.192250 [Hp(+)],  $P = 0.000664$ ; men corpus: 0.179000 [Hp(-)] vs 0.193000 [Hp(+)],  $P = 0.001514$ }, regardless of gastric topography. However, the differences in hormone levels between *H. pylori* negative and *H. pylori* positive patients were more prominent in female samples.

Next, we compared the levels of gastric ghrelin in *H. pylori* positive female and male samples. The screened groups (19 women and 17 men) were sufficient to obtain

statistically significant data, and indicated that in female samples the levels of hormone were higher than in male samples [antrum: 0.214667 (F) vs 0.192250 (M),  $P = 0.000375$  and corpus: 0.209250 (F) vs 0.193000 (M),  $P = 0.000292$ ] independent of stomach topography (antrum vs corpus) (Figure 4).

**Gastric ghrelin and *H. pylori* cytotoxicity**

The distribution of selected bacterial strains *vacA* and *cagA* in the study population was evaluated by multiplex PCR amplification of bacterial DNA (Table 2). The most common infections, with *cagA*(+) *vacA* s1m1 and *cagA*(-) *vacA* s2m2 strains, were observed in specimens from the antrum and from the corpus of both study groups. In contrast, the *cagA*(+) *vacA* s1m2 and *cagA*(+) *vacA* s2m2 strains were present in a minor number of patients only. Interestingly, in one case (a female patient), two different strains were detected: *cagA*(-) *vacA* s2m2 (in the corpus) and *cagA*(+) *vacA* s2m2 (in the antrum). Because of the varied distribution of *H. pylori* strains and the small number of patients within these groups, *H. pylori* infected subjects were combined into two subgroups: those without cytotoxin CagA gene [*cagA*(-)], and those with cytotoxin CagA(+) gene [*cagA*(+)].

As expected, all the evaluated *H. pylori* strains expressed *vacA* but differed with respect to the subtype combinations of s1/s2 and m1/m2. The percentage distribution of all studied subgroups (regardless of the

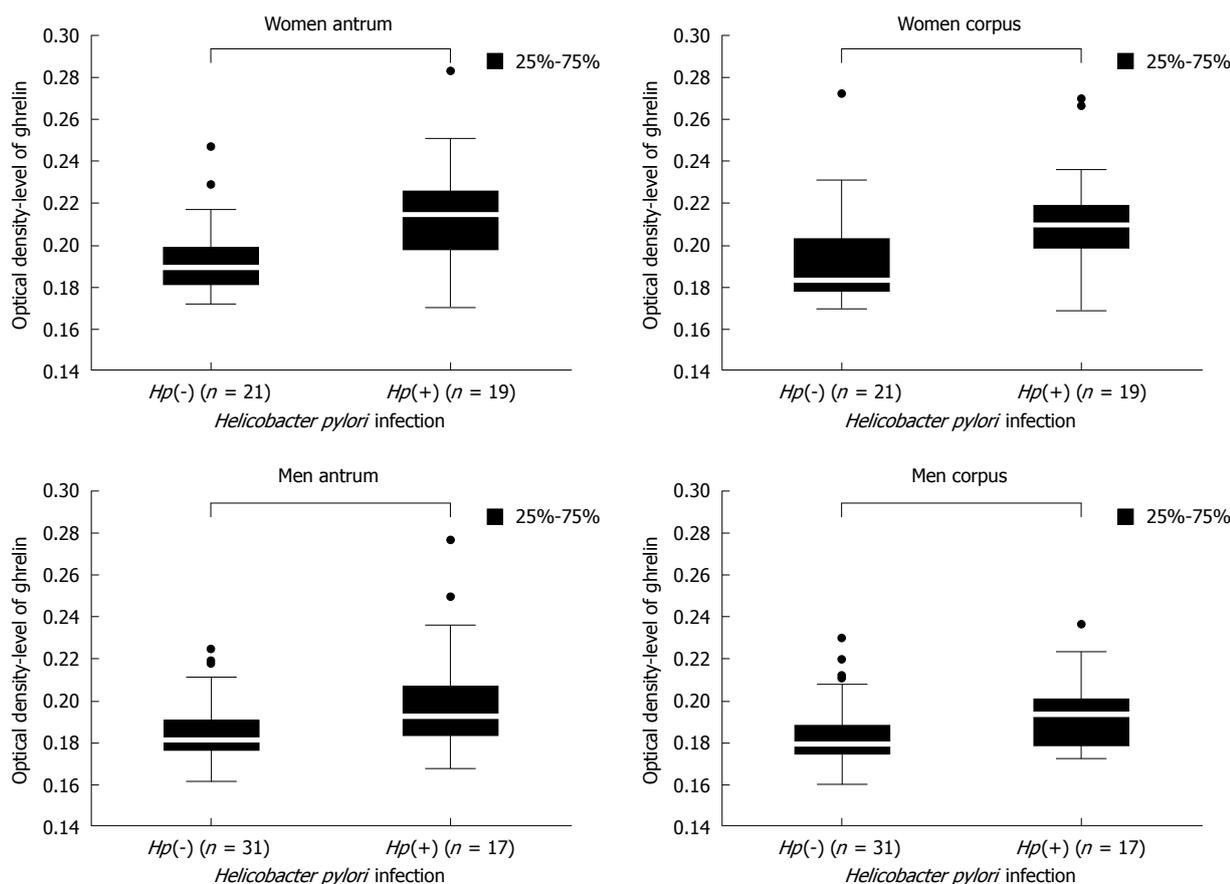

Figure 3 Comparison of ghrelin levels in *H pylori* negative [*Hp*(-)] and *H pylori* positive [*Hp*(+)] samples taken from the antrum and corpus of female and male patients. Population numbers are given.

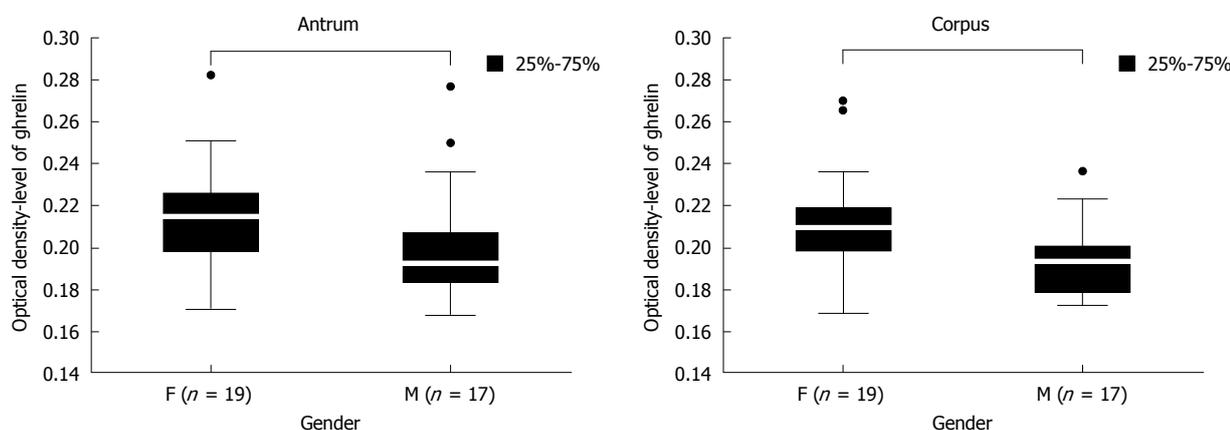

Figure 4 Ghrelin levels in gastric biopsy specimens taken from the antrum and corpus of female (F) and male (M) patients with *H pylori* infection. The numbers in both gender groups are given.

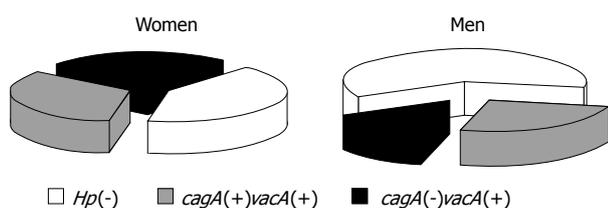

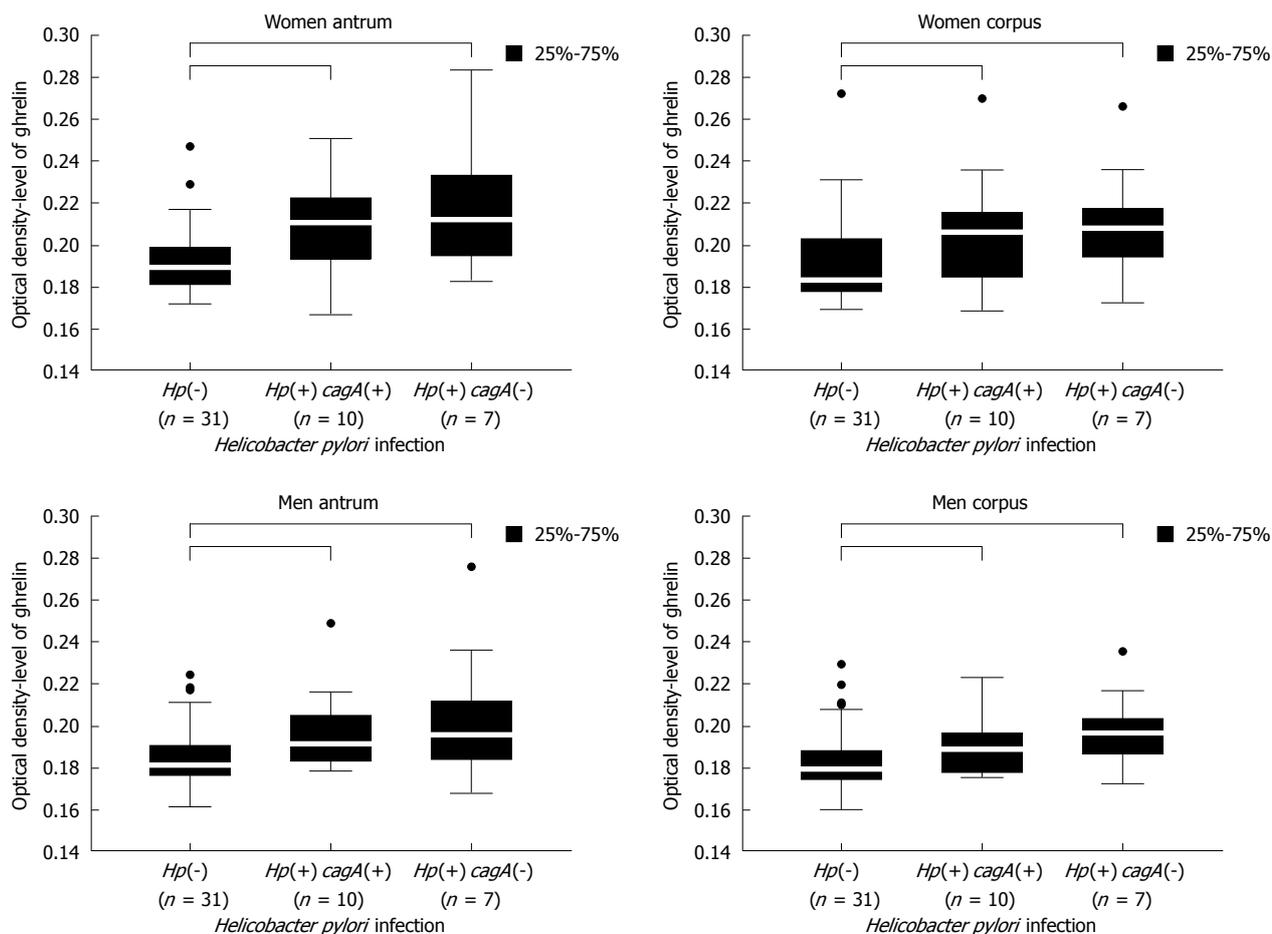

Figure 5 Distribution of subjects in each study group of female and male patients. Subjects without *H pylori* infection are marked as *Hp*(-), while the remaining subjects are *H pylori* positive with and without *cagA* expression (*cagA*(+)*vacA*(+) and *cagA*(-)*vacA*(+), respectively).

subtypes) is presented in Figure 5. The data showed that the biggest group of subjects was composed of those without *H pylori* infection. The percentage distribution of patients according to genotype varied according to gender. In men, the least common *H pylori* strain was *cagA*(-)*vacA*(+), whereas in women, the percentage distribution of all the genotypes was similar.

Due to the observed differences in ghrelin levels in the samples from women and men, the relationship between the hormone levels and *H pylori* cytotoxicity was evaluated separately for each gender.

**Figure 6** Ghrelin levels in female and male antrum and corpus gastric biopsies in relation to *H. pylori* strain cytotoxicity. The numbers in the patient populations are given.

**Female samples:** The results obtained for female samples (Figure 6) showed that ghrelin levels were higher in women infected with both, *cagA(+)/vacA(+)* and *cagA(-)/vacA(+)* strains compared to women without *H. pylori* infection {women antrum: 0.189250 [*Hp(-)*] vs 0.210500 [*Hp(+ cagA(+))*] vs 0.212000 [*Hp(+ cagA(-))*],  $P = 0.0002$  and women corpus: 0.183000 [*Hp(-)*] vs 0.206000 [*Hp(+ cagA(+))*] vs 0.208000 [*Hp(+ cagA(-))*],  $P = 0.0027$ }. No statistical significance was noted for differences in ghrelin levels in relation to strain cytotoxicity, although a tendency for higher amounts of hormone in the samples infected with *cagA(-)/vacA(+)* strains was observed.

**Male samples:** In *H. pylori* infected men the observed changes in gastric ghrelin levels were similar to the changes observed in female samples, but varied depending on gastric topography. Statistically significant increases in ghrelin levels were noted in the antrum {men antrum: 0.181000 [*Hp(-)*] vs 0.191250 [*Hp(+ cagA(+))*] vs 0.195500 [*Hp(+ cagA(-))*],  $P = 0.0028$  and men corpus: 0.179000 [*Hp(-)*] vs 0.188500 [*Hp(+ cagA(+))*] vs 0.196333 [*Hp(+ cagA(-))*],  $P = 0.0023$ }, however, the differences between ghrelin levels in relation to strain cytotoxicity were not significant (Figure 6). In corpus samples, an increase in ghrelin level was only caused by *cagA(-)/vacA(+)*, however, this increase was not statistically significant. Moreover, the

differences between hormone levels in samples carrying both studied *H. pylori* genotypes did not reach  $P < 0.05$ .

## DISCUSSION

The data available in the literature concerning both, the effects of *H. pylori* infection and patients' gender on ghrelin secretion are not consistent. Some authors claim that the level of circulating ghrelin is higher in women than in men<sup>[19]</sup>, but others maintain that it is similar in both sexes<sup>[20]</sup> and does not vary from childhood to adulthood<sup>[21]</sup> or undergo an age-related decrease<sup>[22]</sup>. In our studies we clearly demonstrated that in the case of gastric ghrelin, the hormone level was much higher in pre-menopausal women than in men (Figure 1). It was interesting to note that this relationship could also be seen in *H. pylori* infected patients (Figure 4), where the amount of ghrelin was higher in female specimens. Studies by Gualillo *et al.*<sup>[23]</sup> performed on rat stomach showed that gonadal hormones did not alter ghrelin mRNA, and suggested that ghrelin level was age- rather than gender-dependent. Therefore, one might conclude that higher hormone level in female mucosa might originate from altered hormone release rather than from a change in level of expression. Higher ghrelin level in pre-menopausal women positively correlates with lower testosterone level

when compared to that in postmenopausal women<sup>[19]</sup>, in whom testosterone level is higher. We speculate that higher gastric ghrelin levels in the premenopausal study group could exert a protective effect on gastric mucosa. GC incidence increases with age, and this malignant tumour is relatively rare in males and females under 45 years. In general, the incidence rates in females at a given age are equivalent to the rates in males at an age 10 years younger. The consistency of these differences has never been adequately explained although theories have been proposed that sex-specific hormones in females play a protective role against this malignancy<sup>[24]</sup>.

The influence of *H pylori* infection on gastric ghrelin level requires discussion. Most studies show that *H pylori* infection leads to decreased ghrelin secretion<sup>[25-27]</sup>. However, other reports suggest that serum ghrelin levels are similar in infected and non-infected patients<sup>[25]</sup>. In our studies, *H pylori* infected mucosa had more ghrelin than non-infected mucosa, regardless of gender and stomach topography (Figures 2 and 3). Moreover, we determined whether *H pylori* cytotoxicity could influence the level of ghrelin in gastric mucosa, since there is only very limited published information on the changes in ghrelin levels in relation to virulence of *H pylori* strains<sup>[28]</sup>. It is well known that the strains with higher virulence produce both CagA and vacuolating cytotoxin VacA. CagA protein is the product of *cagA* gene expression, which belongs to the group of genes defined as the “cytotoxicity island”. The *cagB*, *cagC*, *picA*, and *picB* genes also belong to this group. The *cagA* gene is present in about 60%-70% of *H pylori* strains. It is associated with prominent inflammatory and atrophic changes and increases the risk (3-6 times) of developing a peptic ulcer, gastric adenocarcinoma and lymphoma<sup>[29-32]</sup>. *H pylori* infection results in an increase in proliferative activity and affects the apoptotic processes of the glandular epithelium of the gastric mucosa. Although there are a variety of proposed mechanisms by which *H pylori* infection increases the risk of GC, it is thought that the primary mode of action involves the induction of long-term chronic inflammation<sup>[33]</sup>.

Because of the varied distribution of *H pylori* strains and the small number of patients with *vacA* s1m2 and s2m1 genotype in our studies (Table 2), the analysis comprised two groups of subjects - those infected with *H pylori* strains of *cagA*(-)*vacA*(+) genotype and those of *cagA*(+)*vacA*(+) genotype. We showed that bacterial strains of both genotypes increased ghrelin secretion in infected women and men compared to non-infected subjects (Figure 6), however, infection with *cagA*(-)*vacA*(+) strains showed a tendency to increase gastric ghrelin level more than infection with *cagA*(+)*vacA*(+) strains, although no statistical significance was reached.

It is worth noting that the results of the study discussed above and the conclusions drawn from them apply only to patients without advanced histopathological changes in the gastric mucosa. It is likely that *H pylori* infection leads to the early stage of inflammatory changes described as non-atrophic gastritis, which causes activation of protective mechanisms in the mucosa and results in an increase in gastric ghrelin expression. This increase

was more prominent in the gastric mucosa of both male and female patients infected with *cagA*(-)*vacA*(+) bacterial strains of lower cytotoxicity (Figure 6).

From the literature it can be concluded that ghrelin levels in the gastric mucosa significantly decrease with more advanced histopathological changes, especially after the atrophic gastritis stage<sup>[34,35]</sup>. It has been suggested that the level of this hormone can be considered as one of the markers of gastric mucosal change progression and, at the same time, can be one of the indications for gastroscopy.

The results of the study performed by Osawa *et al*<sup>[36]</sup> showed a significant decrease in gastric preproghrelin mRNA level 12 wk after *H pylori* eradication. These observations are inconsistent with our results. The discrepancies between our results (higher gastric ghrelin level in *H pylori* positive patients) and the previously published data<sup>[36-38]</sup> could have arisen due to different stages of gastric mucosa inflammatory changes (chronic, severe atrophic gastritis, peptic ulcer) in subjects enrolled in the study. Moreover, earlier reports did not analyze results for women and men separately, which, as our study suggests, is an important factor influencing gastric ghrelin level. The study on the impact of *H pylori* infection on ghrelin level is part of our research on the relationship between these bacteria and biosynthesis of the proteins possessing proapoptotic and antiproliferative activities, which are important in the process of carcinogenesis<sup>[39-41]</sup>.

In conclusion, based on the results obtained in our study, we may assume that an increase in gastric ghrelin levels at the stage of non-atrophic gastritis in *H pylori* positive patients, especially those infected with *cagA* negative strains can exert a gastroprotective effect. Future studies are needed to delineate the role of gastric ghrelin in pathological processes induced by *H pylori*.

## COMMENTS

### Background

Ghrelin is a peptide hormone that plays an important role in food intake, energy homeostasis and body-weight regulation. Ghrelin possesses anti-proliferative effects on breast, lung and thyroid cell lines and exerts a protective action on gastric mucosa. Its level is significantly lower in gastric tumors than in normal gastric mucosa. The published data on the effects of sociological and environmental factors on gastric ghrelin level are not consistent. One of these factors is *Helicobacter pylori* (*H pylori*) infection which always induces chronic active gastritis, and in the presence of other factors, can lead to the development of gastric cancer.

### Research frontiers

Investigation on the mechanisms involved in oncogenesis in the digestive tract-environmental factors related to bacterial infection.

### Innovations and breakthroughs

The authors demonstrate, for the first time, that premenopausal women have higher gastric ghrelin levels than men. The level of this appetite hormone increases in *H pylori* infection, and was higher in female samples. More cytotoxic *H pylori* strains expressing the *cagA*(+) gene had less of an effect on gastric ghrelin level. Expression of this hormone was also dependent on histopathological changes, and at the stage of non-atrophic gastritis in *H pylori* positive patients, especially those infected with *cagA* negative strains, may exert a gastroprotective effect.

### Applications

The data discussed in this paper are of value since they univocally demonstrate the influence of selected environmental and sociological factors on the level of expression of gastric ghrelin. The results may be used in future research to cor-

relate the level of gastric ghrelin with plasma ghrelin and to discuss the effect of selected factors on the hormone release process. Future studies are needed to delineate the role of gastric ghrelin in pathological processes induced by *H pylori*.

### Peer review

The authors demonstrate the increased protein levels of ghrelin in gastric biopsy specimens of *H pylori*-positive subjects compared to *H pylori*-negative subjects, particularly in virulent types of *H pylori*-carrying patients, and suggest a protective role of ghrelin. The authors also demonstrate the gender difference in this respect. The findings are interesting, but this reviewer strongly suggests that the authors should provide additional data on mRNA expression of ghrelin in gastric specimens or plasma levels of ghrelin, since increased ghrelin concentration in the stomach will be produced by either increased synthesis or decreased secretion from the stomach.

### Abstract

**AIM:** To evaluate the effects of growth hormone (GH) on the histology of small intestines which might be related to the role of insulin like growth factor (IGF)-I, IGF-binding protein 3 (IGFBP-3) and its receptors.

**METHODS:** Twelve week-old adult male Wistar albino rats were divided into two groups. The study group ( $n = 10$ ), received recombinant human growth hormone (rGH) at a dose of 2 mg/kg per day subcutaneously for 14 d and the control group ( $n = 10$ ) received physiologic serum. Paraffin sections of jejunum were stained with periodic acid shift (PAS) and hematoxylin and eosin (HE) for light microscopy. They were also examined for IGF-I, IGFBP-3 and IGF-receptor immunoreactivities. Staining intensity was graded semi-quantitatively using the HS-CORE.

**RESULTS:** Goblet cells and the cells in crypt epithelia

were significantly increased in the study group compared to that of the control group. We have demonstrated an increase of IGF-I and IGFBP-3 immunoreactivities in surface epithelium of the small intestine by GH application. IGF-I receptor immunoreactivities of crypt, villous columnar cells, enteroendocrine cells and muscularis mucosae were also more strongly positive in the study group compared to those of in the control group.

**CONCLUSION:** These findings confirm the important trophic and protective role of GH in the homeostasis of the small intestine. The trophic effect is mediated by an increase in IGF-I synthesis in the small intestine, but the protective effect is not related to IGF-I.

### INTRODUCTION

Growth hormone (GH) is a pituitary-derived polypeptide hormone that has diverse physiologic effects including the regulation of growth in long bones, carbohydrate, lipid metabolism, and metabolic functions of the liver<sup>[1]</sup>. The mitogenic effect of GH in the crypts of Lieberkuhn of the duodenum in hypophysectomized rats was first described by Leblond and Carriere in 1955<sup>[2]</sup>. Small intestine that is lined by epithelial cells with a rapid turnover rate has been considered as a potential target of GH<sup>[3,4]</sup>. Systemic administration of GH markedly increases trophic action in the small intestine and enhances the remnant bowel morphological and proliferative adaptation<sup>[3]</sup>.

Circulating GH binds to the GH receptor (GHR) in

target cells and stimulates the production of insulin like growth factor (IGF)-I in the liver and other target tissues including the intestine. The GHR is expressed throughout the epithelium and in the lamina propria, muscularis mucosa, submucosa, and muscularis propria. The presence of GH receptors in crypt and villus epithelial cells of rats suggests a direct cellular effect of GH on small intestinal growth<sup>[5]</sup>. GH action has traditionally been believed to be mediated by GH dependent hepatic production of IGF-I. However, with the discovery of various extrahepatic IGF-I synthesis sites, some of which are GH dependent, a paracrine/autocrine mechanism of action has been proposed<sup>[6]</sup>. IGF-I receptors have also been immunolocalized in the gastrointestinal tract of rats<sup>[7,8]</sup>. Locally expressed IGF binding proteins (IGFBPs) are known to modulate IGF-I action. Of six known high-affinity IGFBPs, IGFBP-3 has been of interest with respect to a role in regulating intestinal growth. Systemically administered IGF-I is known to increase the expression of IGFBP-3 in rat small intestine<sup>[9]</sup> and colon<sup>[10]</sup>, although there are segmental differences in the effects of circulating IGF-I on locally expressed IGFBPs, which correlate with segment-specific growth effects<sup>[9,10]</sup>.

GH action is primarily mediated by IGF-I, although both growth factors show tissue-selective effects. Specific binding sites for IGF-I, and GH are present in the small intestine and evidence suggests that circulating IGF-I and GH can interact with their respective functional intestinal receptors<sup>[2,11,12]</sup>. GH administration stimulates mucosal growth in normal rats<sup>[2]</sup>. GH action has been attributed to be the result of both a direct effect of GH, and an indirect stimulating effect on the target cells *via* IGF-I released locally or from the liver<sup>[3]</sup>. Specific GH receptors (GHR), IGF-I receptors, and local production of IGF-I have been shown throughout the epithelial and mesenchymal derived elements of the gastrointestinal tract<sup>[4,5]</sup>, implicating a complex interaction between direct and indirect effects of GH<sup>[12-14]</sup>. It has not yet been shown whether GH affects the small intestine directly or *via* IGF-I. Therefore, the objective of this study was to evaluate the morphological effects of GH on normal small intestines due to changes occurring in IGF-Rs and IGFBP-3 by administration of GH.

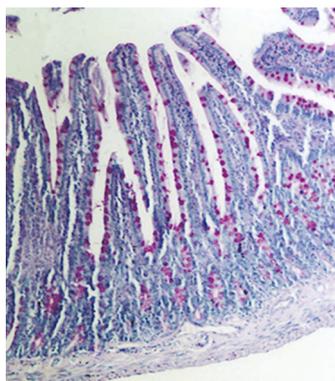

## MATERIALS AND METHODS

The animal facilities and protocols used in the present study were approved by the Animal Research Ethics Committee of the University of Celal Bayar. This study was performed in the Department of Histology and Embryology and Department of Pediatrics, between 2001 and 2002. Twelve week-old adult male Wistar albino rats (250-300 g) were included in the study. All animals were kept under standard conditions on a 12 h light/dark cycle and maintained at optimal temperature. The animals were fed with a standard diet and given free access to water. They were randomized into two groups. The study group ( $n = 10$ ) received recombinant human GH (Norditropin-Novo Nordisk, Denmark) at a dose of 2 mg/kg per day subcutaneously for 14 d and the control

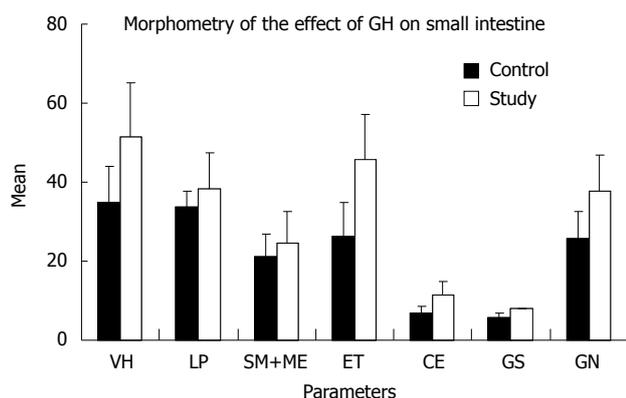

group ( $n = 10$ ) received the same volume of serum physiologic intracutaneously. Anesthesia was achieved by intraperitoneal injection of pentobarbitone. Animals were perfused intracardially with phosphate buffered saline (PBS) and subsequently with 10% formalin solution. The antrum of the jejunum was dissected and postfixed in 10% formalin solution for 24 h at room temperature. The samples were washed overnight with tap water and were dehydrated through a graded series of ethanol. They were incubated in xylene and then embedded in paraffin. Serial sections (5  $\mu$ m) were taken from both groups and collected onto gelatin-coated slides. Sections were deparaffinized at 60°C overnight, immersed in xylene and rehydrated through a graded series of ethanol. They were then washed in tap water and stained using either histochemical (H-E or PAS) or immunohistochemical (IGF-I, IGF-R, IGFBP-3) methods according to their routine protocols. H-E or PAS stained slides were mounted using entellan covered with glass cover slips prior to viewing and photographed under the Olympus BX-40 (Olympus, Tokyo, Japan) light microscope. Morphometric parameters were measured by three blinded observers using the Olympus BX-40 microscope with a video camera (JVC-TK-C 601, Tokyo, Japan) for digital imaging. Villus height as a distance from the tip of the villus to the villus-crypt junction, total epithelial thickness, villus/crypt ratio, and the size and the number of goblet cell were measured at 15 sites of the jejunum<sup>[15,16]</sup>.

An indirect immunofluorescence method was used to determine the immunoreactivities of IGF-I and IGFBP-3. Prior to preincubation in non-immune serum for 1 h, all slides were washed in PBS three times. Sections were then incubated with the primary antibody (Goat-anti-human IGF-I: DSL-2800 IRMA and anti-IGFBP-3; DSL-6600 IRMA, Diagnostic system Laboratories-Texas, USA) in a humid, sealed chamber at 4°C for overnight. Slides were then washed three times in PBS and the site of antigen-antibody reaction was revealed by incubation with fluorescence isothiocyanate (FITC)-conjugated anti-goat diluted 1:100, for 2 h at 4°C. After incubation, sections were rinsed and mounted. Control staining included omission of the primary antibody and replacement with rabbit nonimmune serum. Sections were examined in a fluorescence microscope (Olympus, Tokyo, Japan) equipped with filter setting for viewing FITC fluorescence.

An indirect immunoperoxidase method was used to determine the immunoreactivity of IGF-I Receptor. Deparaffinized sections were washed with PBS and treated with 0.1% trypsin solution. After that, they were washed with PBS and treated with 0.3% hydrogen peroxide for 10 min at room temperature to inactivate endogenous peroxidase activity. These sections were then washed in PBS and they were incubated with the primary antibody mouse monoclonal anti-IGF-I Receptor diluted 1:100 (Calbiochem, CA, USA) in a humid chamber overnight at 4°C. They were then incubated with avidin-biotin-horseradish peroxidase complex (anti-mouse immunoperoxidase antibody: Universal DAKO LSAB2 Kit, CA, USA) for 1 h. The colour reaction was developed using AEC Substrate System-containing 3-amino-9-ethylcar-

**Figure 1** Photomicrograph of the tunica mucosa (M) and muscularis mucosa (MM) of the small intestine in the GH-administered group. Villous hypertrophy and increased goblet cells were seen in the small intestine. PAS,  $\times 100$  (Original magnification).

**Figure 2** Morphometric criteria to determine the effects of growth hormone on small intestine. VH: The height of villus; LP: Lamina Propria; SM: Submucosa; ME: Muscularis externa; ET: Thickness of epithelium; CE: Crypt epithelial cell; GS: The size of goblet cell; GN: The number of goblet cells per villus. Height of the villi, epithelial thickness, and crypt epithelial cell number rats given GH were significantly increased ( $P < 0.01$ ). The size and the number of goblet cells were also significantly increased ( $P < 0.05$ ).

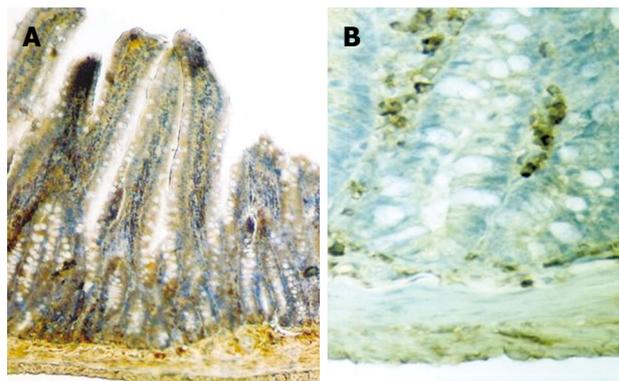

bazole (Dako, Glostrup, Denmark). Between each step, sections were washed three times in PBS. Sections were counterstained with Mayer's hematoxylin, dehydrated, and covered with mounting medium. Normal mouse serum was used as a negative control.

Three observers blinded to clinical information evaluated the immunohistochemical staining scores independently. Staining intensity was graded semi-quantitatively using the H-SCORE<sup>[17]</sup> which was calculated with the following equation:  $H\text{-SCORE} = \sum P_i (i + 1)$ , where  $i$  = intensity of staining with a value of 1, 2 or 3 (mild, moderate, or strong, respectively) and  $P_i$  is the percentage of epithelial cells stained with different intensity, varying between 0%-100%. Results were expressed as mean  $\pm$  SE. Differences between groups were statistically analyzed with one-way ANOVA.  $P$  value of  $< 0.05$  was considered significant.

## RESULTS

### Histological examination

Rats that were given GH displayed hypertrophy in the small intestine (Figure 1). Height of the villi ( $34.9 \pm 9.2$  vs  $51.6 \pm 13.8$ ), epithelial thickness ( $26.3 \pm 8.3$  vs  $45.7 \pm 11.7$ ), and crypt epithelial cell number ( $6.7 \pm 2.1$  vs  $11.4 \pm 3.7$ ) of these rats were significantly increased ( $P <$

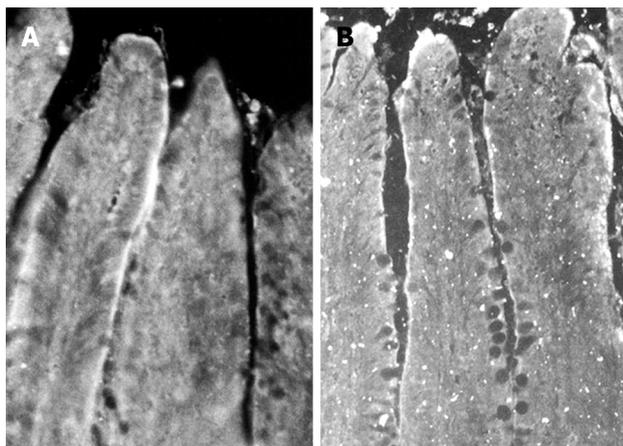

**Figure 3** Like growth factor (IGF)-R immunoreactivity pattern in small intestines of the rats in the study group given growth hormone (A) and control group (B) by using the immuno-peroxidase technique. While weak to moderate IGF-R immunostaining was observed in the epithelial cells of the small intestines in the control group, an increase in the immunostaining was seen in the study group. Note the strong immunoreactivity in the epithelial component and the moderately immunostained smooth muscle of the muscularis mucosa. Goblet cells display little or no immunoreactivity, in contrast to the dense immunoreaction in columnar cells of the study group.  $\times 100$  (Original magnifications).

$0.01$ ). The size ( $5.7 \pm 1.2$  vs  $7.8 \pm 1$ ) and the number ( $25.6 \pm 6.8$  vs  $37.9 \pm 9$ ) of goblet cells were also significantly increased ( $P < 0.05$ ). The morphometric results of the groups according to histologic criteria are shown in Figure 2.

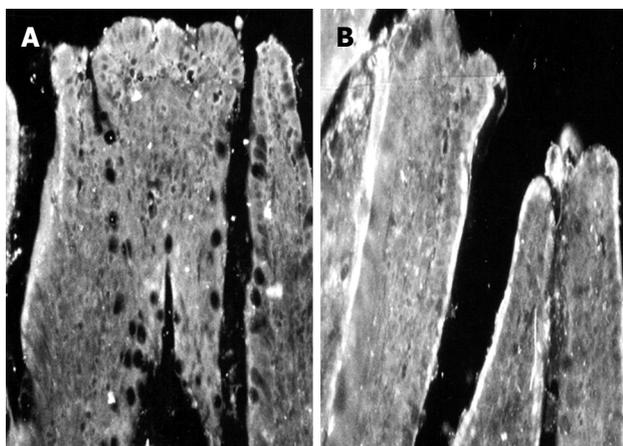

### Localization of IGF-R immunoreactivity

Immunohistochemical staining for the IGF-R showed specific staining in the crypts as well as the apical and basolateral membranes of villus epithelial cells of the control group. Immunoreactivity was primarily observed in the cytoplasm. All staining was similar to each other and they were considered to be of moderate intensity (++) staining. Crypt and villous columnar cells of the small intestine displayed moderate immunoreactivity, whereas goblet cells were weakly immunostained. No immunostaining was evident in occasional large goblet cells of the small intestine. Enteroendocrine cells of the intestinal mucosa were positively immunostained. Muscularis mucosae, muscularis externa and medial smooth muscle cells of vessels exhibited moderate immunoreactivity. Macrophages in the lamina propria and submucosa exhibited positive immunoreactivity in the control group (Figure 3).

There appeared to be a greater intensity of staining for the IGF-R in the study group compared with the control group, as shown in Figure 3 (intensity +++). Crypt epithelial cells and enteroendocrine cells of the intestinal mucosa were strongly positive immunostained (intensity +++). Weak or no immunostaining was evident in large goblet cells of the small intestine. Muscularis mucosae, muscularis externa and medial smooth muscle cells of vessels exhibited moderate immunoreactivity. Scattered macrophages in the lamina propria and submucosa exhibited intense immunoreactivity in the study group. There was also an increase in the intensity of IGF-R immunoreactivity as well as the number of

**Figure 4** Immunoreactivity of IGF-I was seen in the small intestine of the control group (A) and the study group (B) by using an immunofluorescence technique. Increased immunoreactivity was seen in the study group.  $\times 200$  (Original magnifications).

**Figure 5** Immunoreactivity of IGF-binding protein 3 (IGFBP-3) was seen in the small intestines by using an immunofluorescence technique in the control group (A) and the study group (B). Increased immunoreactivity was seen in the study group.  $\times 200$  (Original magnifications).

immunoreactive cells in general. The morphometry of immunoreactivities is shown in Table 1.

#### Localizations of IGF-I and IGFBP-3 Immunoreactivity

In the control group, both the immunoreactivities of IGF-I (Figure 4A) and IGFBP-3 (Figure 5A) were considered moderate in the small intestine (intensity +/++, respectively). Immunoreactivity was mainly localized on the surface epithelium. Rats that were given GH showed a statistically significant ( $P < 0.001$ ) increase in the immunoreactivities of IGF-I (Figure 4B,  $85.33 \pm 11.06$  vs  $195.00 \pm 9.00$ ) and IGFBP-3 (Figure 5B,  $91.00 \pm 16.82$  vs  $201.33 \pm 18.04$ ) which were determined by H-SCORE (Figure 6).

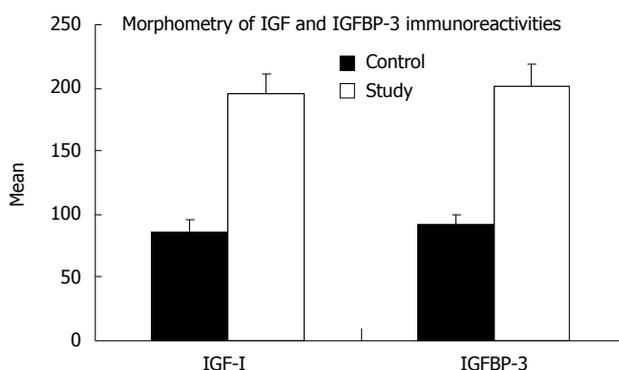

## DISCUSSION

In our study, histological examination revealed an increase in the wall thickness, villus height and crypt cell proliferation of the small intestine after GH admi-

**Table 1** Intensity of cellular localization of IGF-receptor in small intestines of the rats in the control and study groups

Cells	Control group	Study group

**Figure 6** IGFBP-3 and IGF-I immunoreactivities in rat small intestine epithelium in the control and the study groups using the indirect immunofluorescence method. (Weak immunostaining: +; Moderate immunostaining: ++; Strong immunostaining: +++). In rats that were given growth hormone, there was a statistically significant increase in the immunoreactivities of IGF-I.

nistration. Our findings have shown that systemic administration of GH increases intestinal growth by stimulating crypt cell production as has been reported by previous studies<sup>[10,17]</sup>. Trophic and promoting effects of GH on the small intestine as shown in human and animal studies have suggested that this peptide could be used in the treatment of patients with malabsorption and malnutrition caused by extensive disease or resection of the small bowel, as is the case in patients with the short bowel syndrome<sup>[10,17-19]</sup>. Exogenous GH has been particularly useful in gastrointestinal rehabilitation of patients with short bowel syndrome in some series<sup>[20-22]</sup>, although not all<sup>[23]</sup>.

In our study, a significant increase in the number of goblet cells was observed in the study group compared to that in the control group. Gastrointestinal epithelium is covered by a protective mucus gel composed predominantly of mucin glycoproteins which are synthesized and secreted by goblet cells<sup>[24]</sup>. This epithelium provides a barrier against potential injury threats of luminal acids, enzymes, bacteria and toxins<sup>[25]</sup>. This result suggests that GH could play a protective role on intestinal mucosa by increasing mucus-producing cells. A previous study has shown the protective effects of GH in rats receiving abdominal radiotherapy<sup>[26]</sup>. However, its functional role had not been clearly assessed *in vivo*.

Effects of GH could be mediated *via* the regulation of intermediate factors like IGF-I, the best known and most intensively studied among the factors. IGF-I is pro-

duced in the liver and other tissues in response to GH stimulation<sup>[27]</sup>. As expected, this had led the investigators to conclude that the local production and function of IGF-I were dependent on GH. However, it is now clear that IGF-I could have functions independent from GH. The results of our study have shown that IGF-I receptor immunoreactivity in crypt and villous columnar cells, enteroendocrine cells and muscularis mucosae was stronger in the study group compared to the control group. Immunoreactivity of Paneth cells was found negative and goblet cells displayed faint to moderate immunoreactivity. These results suggest that the effects of GH on crypt, villous columnar cell, enteroendocrine cells and muscularis mucosae can be mediated *via* IGF-I. In transgenic mouse studies, overexpression of the gene encoding IGF-I has been found to be associated with increased small bowel length, mucosal mass and crypt cell proliferation<sup>[28,29]</sup>. Wheeler *et al*<sup>[3]</sup> have shown that the effects of GH/IGF-I on crypt epithelial cell proliferation in human duodenal mucosa *in vitro*, were similar to the effects of IGF-I alone and were greater than GH alone, suggesting an action mediated solely by IGF-I. Sigalet *et al*<sup>[30]</sup> had demonstrated significant alteration in intestinal morphology of the rat by IGF-I treatment. It has been shown that systemic administration of GH increases trophic activity of the small intestinal mucosa and enhances morphologic and proliferative adaptation of the remnant bowel after surgical resection, both through a direct effect *via* GH receptor present in the gastrointestinal tract and through augmentation of IGF-I synthesis and activity<sup>[31,32]</sup>.

We found that goblet cells were weakly immunostained for IGF-I receptor both in the study and the control group. In another study that detected GH receptor, goblet cells showed faint to moderate immunoreactivity or were immunonegative<sup>[2]</sup>. These results suggested that GH could have direct effects on goblet cell proliferation of the rat small intestine. In the present study, enteroendocrine cells were positive for IGF-I receptor immunostaining in small intestines of rats given GH which may stimulate local or systemic IGF-I production. In addition to its trophic action, IGF-I receptor appears to be extremely important not only for IGF-I but also for modulation of the effects of other growth factors<sup>[33,34]</sup>. Overexpression of IGF-I receptor may promote trophic actions of other growth factors on small intestinal mucosa. Moreover, IGF-I, due to its trophic action, may increase the secretion of gastrointestinal hormones from enteroendocrine cells.

GH increases circulating levels of IGF-I and seems to enhance IGF-I expression locally in the intestinal mucosa<sup>[35]</sup>. A characteristic feature of IGF-I is its ability to bind high affinity IGF-BPs which are thought to modulate its actions<sup>[9,36]</sup>. One of the major functions of IGF-BPs is to control access to the receptors and consequently to modulate biologic responses of cells to IGF-I. IGF-BP-3 has the highest affinity for IGF and is the most abundant IGF-BP in plasma<sup>[6]</sup>. In this study, an increase in the immunoreactivities of IGF-I and IGF-BP-3 were observed in small intestines of GH-administered rats. This result

suggested that GH causes an increase in both IGF-I and IGF-BP-3 production in the small intestine. The plasma concentration of IGF-BP-3 is regulated by GH. IGF-BP-3 concentration that is low in GH deficient patients increases with GH treatment<sup>[6,36]</sup>. This increase is attributed to a direct effect of GH on IGF-BP-3 synthesis as well as the prolongation of the half-life of IGF-BP-3 by binding to other proteins<sup>[7]</sup>. Systemic administration of GH may cause binding of IGF-I and IGF-BP-3 to microvilli on the small intestinal epithelium of rats and may increase their synthesis directly. Thus, IGF-BP-3 may regulate tissue localization, distribution and access to IGF-I receptor that modulates the cell response to IGF-I.

Indeed, even in GH transgenic animals, only transient effects of GH excess on crypt proliferation were observed at weaning and were not sustained in adult animals despite maintained increases in mucosal mass through adulthood. This contrasts with IGF-I, in which a majority of studies in IGF-I transgenic mice and multiple *in vivo* models of IGF-I induction, including TPN and resection models, have demonstrated potent trophic actions of IGF-I accompanied by proliferative and anti-apoptotic actions. While these trophic actions of IGF-I may be beneficial to increase the mass of functional intestinal mucosa, they may also increase the risk of intestinal tumors. Despite the long-held view that GH is a trophic hormone and the proliferative effects of which are mediated by IGF-I, evidence in the healthy intestine suggests that IGF-I is a more potent enterotrophic factor than GH. This is found even when GH elevates plasma IGF-I to levels similar to those found in models of IGF-I infusion. Available evidence has suggested that the local expression of IGF-I occurs primarily in mesenchymal cells of the lamina propria of the normal intestine. IGF-I also has autocrine actions that increase the proliferation and growth of mesenchymal cells. Collectively, these results suggest that IGF-I derived from intestinal mesenchymal cells regulates the growth and function of neighboring epithelial cells, as well as mesenchymal cells themselves. Further support for this hypothesis comes from observations that levels of local IGF-I mRNA expression correlate with bowel growth during periods of altered nutrient status, resection, and disease<sup>[3,4,37]</sup>.

In summary, systemic administration of GH has caused proliferation of crypt epithelial cells, goblet cells and enteroendocrine cells in the small intestinal mucosa of rats. The number of IGF-I receptors in small intestinal mucosa, particularly in crypt epithelial and enteroendocrine cells, was increased. However, there was not an increase in the number of IGF-I receptors in goblet cells. Increases observed in mucosal height may be mediated through local rather than systemic IGF-I production, as IGF-I and IGF-BP-3 were found to increase in rats' small intestine particularly in the surface epithelium. Increased IGF-I expression has been observed after GH administration and GH exerts some of its effects through stimulation of IGF-I and IGF-BP-3 expression. GH improved villous morphology and small intestine homeostasis by affecting the cells through mediators. These

findings provide a basis for further studies on the role of GH in the regulation of gastrointestinal function and growth, in health and in colorectal diseases.

In conclusion, GH exerts trophic and protective effects on small intestinal mucosa by increasing IGF-I synthesis. It seems to exert its trophic actions *via* IGF-I by increasing number of IGF-I receptors on crypt and epithelial cells. IGF-I by itself does not have a role in protective action. Further research into the mechanism of action of GH and IGF-I is also needed to fully define the clinical appropriateness of these growth factors in particular settings.

## COMMENTS

### Background

Growth hormone (GH) has a lot of diverse physiologic effects. Systemic administration of GH markedly increases trophic action in the small intestine. The peripheral effects of GH are mediated by IGF-1. IGFBP-3 is a GH-dependent molecule and can be an important indicator of conditions associated with altered GH secretion and action. It is not known whether effects of GH on small intestine are direct or mediated *via* IGF-1.

### Research frontiers

To demonstrate histologic changes induced by GH in the small intestine and to define mechanisms of trophic and protective effects of GH on small intestine.

### Innovations and breakthroughs

This is the first study reporting the importance of IGF-1 as a mediator for protective and trophic effects of GH on small intestines. The authors' study demonstrated that trophic effects are related to IGF-1 while protective effects are not.

### Applications

Better understanding of trophic and protective effects of GH on small intestines provide researchers with an opportunity to observe the effectiveness of treatment of intestinal diseases like small bowel syndrome. Also IGF-1 treatment may be considered as a therapeutic option in such diseases.

### Peer review

The authors evaluate the effects of growth hormone on the histology of small intestines which might be related to the role of IGF-I, IGF-binding protein 3 (IGFBP-3) and its receptors. They find trophic effect is mediated by an increase in IGF-I synthesis in small intestine, but the protective effect is not related to IGF-I.

### Abstract

**AIM:** To investigate the expression and function of *Wolfram syndrome 1* gene (*WFS1*) during the development of normal pancreas.

**METHODS:** Pancreas from Sprague-Dawley rat fetuses, embryos, young and adult animals were used in this study. Expression levels of *WFS1* in pancreas of different development stages were detected by reverse transcription-polymerase chain reaction (RT-PCR) and Western blotting. To identify the cell location of *WFS1* in the developing rat pancreas, double-immunofluorescent staining was performed using antibodies to specific cell markers and *WFS1*, respectively.

**RESULTS:** Compared to E15.5, the highest level of *WFS1* mRNA was detected at E18.5, the level of *WFS1* mRNA in E15.5 and P0 was less, and at a lowest at adult ( $P < 0.05$  vs P0 and adult), respectively. Compare to E15.5, the highest level of *WFS1* was at P14 and lowest at P21 ( $P < 0.05$  vs P14 and P21), respectively. The *WFS1* positive staining is expressed in the normal developing rat pancreas mainly in the islet beta-cells and mesenchyme at each stage tested.

**CONCLUSION:** These results indicate that *WFS1* may be

### INTRODUCTION

The pancreas is a complex organ composed of 2 different cell populations, exocrine and endocrine cells. The acini and ducts form the exocrine pancreas, which produces and transports digestive enzymes into the duodenum. The endocrine component contains 4 types of cells that secrete hormones to regulate glucose metabolism and other physiological processes<sup>[1]</sup>. In rats, the pancreas develops from the foregut endoderm in 3 major steps: endoderm formation [embryonic day (E) 7.5], pancreatic morphogenesis (E10.5), and differentiation of endocrine and exocrine cells (E13.5). At approximately E16, the islet progenitor cells leave the contiguous epithelium, migrate through the adjacent extracellular matrix into the surrounding mesenchyme, and aggregate to form the islets of Langerhans. The islets are not completely formed until shortly before birth on E18-E19<sup>[2-4]</sup> and undergo further remodeling and maturation for 2-3 wk after birth<sup>[5]</sup>. Thus, the developing pancreas presents a challenge for developmental biologists because of the complex morphogenetic processes underlying the development of this organ. Until now, the factors that control the progressive development of pancreatic architecture and function have remained unclear. To

identify these functional factors we performed a gene array at E15.5, E18.5, birth and adult stages. The *Wolfram syndrome 1* gene (*WFS1*), was one of the factors found to be abundantly expressed in islet cells at E15.5 and E18.5 (data not shown). Wolfram syndrome (WS) is an autosomal recessive, progressive, neurodegenerative disorder characterized by diabetes mellitus and optic atrophy<sup>[6]</sup>. This disorder is also associated with diabetes insipidus and deafness, hence the acronym DIDMOAD (diabetes insipidus, diabetes mellitus, optic atrophy, and deafness). Other manifestations such as atonic bladder, ataxia, nystagmus and predisposition to psychiatric illness may also be present<sup>[7,8]</sup>. *WFS1*, discovered in 1998, was mapped to chromosome 4p16.1 by positional cloning<sup>[9,10]</sup>. The gene is composed of 8 exons spanning 33.4 kb of genomic DNA. The 3.6 kb mRNA encodes an 890-amino acid polypeptide named wolframin<sup>[9,11]</sup> with 9 predicted transmembrane domains, and belongs to a novel gene family. Biochemical studies in cultured cells indicate that *WFS1* protein is an integral, endoglycosidase H-sensitive membrane glycoprotein primarily localized in the endoplasmic reticulum<sup>[12]</sup>. Postmortem studies of the pancreas from subjects with WS have shown  $\beta$ -cell loss<sup>[10]</sup>. Mice with a disrupted *WFS1* were also reported to exhibit impaired glucose homeostasis accompanied by a progressive reduction of  $\beta$ -cell mass<sup>[13]</sup>. Thus, *WFS1* seems to play a role in the normal function of  $\beta$  cells, but little is known about its function during embryogenesis. To the best of our knowledge, no study has investigated the relationship between *WFS1* expression and pancreas development, and the expression of *WFS1* during pancreatic development in rats is poorly understood. Knowledge of the regional and temporal expression of *WFS1* will be useful in understanding its potential roles in pancreatic development. Therefore, we further examined the expression patterns of *WFS1* in rat pancreas during development.

## MATERIALS AND METHODS

### **Animals and preparation of rat pancreatic tissue**

Sprague-Dawley (SD) rats were purchased from the Animal Center of Nanjing Medical University (Nanjing, China). SD rats (2:1, male:female) were mated overnight. At noon the next day, if a vaginal plug was discovered, it was considered as Day 0.5 of gestation (E0.5). Embryos were removed at E15.5 and E18.5 from the uterus of pregnant rats, which were sacrificed by cervical dislocation. Pancreata from E15.5 and E18.5 rat embryos were isolated as previously described<sup>[14]</sup> under a stereomicroscope. Rat pancreata at postnatal (P) days 0, 7, 14, 21 and from adults, were directly isolated by the unaided eye. All experiments were conducted in accordance with the Chinese Law for Animal Protection and were approved by the local animal care committee. Five rats were used at each age stage. Dissected tissues were immediately rinsed 3 times with phosphate-buffered saline (PBS) to remove serum proteins, and fixed with 4% paraformaldehyde in PBS overnight for histology, or frozen in liquid nitrogen for RNA and protein isolation.

### **RNA extraction, reverse transcription-polymerase chain reaction (RT-PCR)**

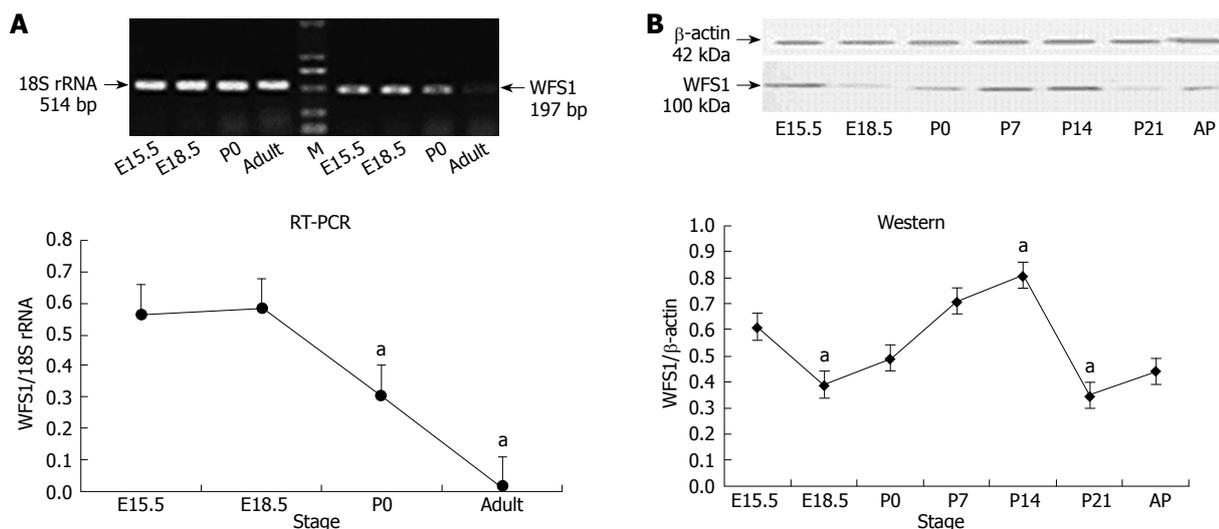

Total RNA was extracted from pancreata at each time point with TRIZOL reagent (Invitrogen Life Technologies, Burlington, Ontario, Canada), according to the manufacturer's instructions. The quality of the RNA was verified by agarose gel electrophoresis using ethidium bromide staining. For each PCR, 2  $\mu$ g of DNA-free total RNA with oligo (deoxythymidine) primers and reverse transcriptase were used. PCR was performed in 25  $\mu$ L reactions containing 25 ng of cDNA, 0.2 nmol of each primer pair, and 0.3  $\mu$ L of Taq DNA polymerase. PCR was carried out in a T-gradient Biometra PCR thermal cycler (Montreal Biotech Inc., Kirkland, Quebec, Canada) to determine the annealing temperature for *WFS1* primers. We used the following primer pairs: *WFS1*, forward: 5'-CTGCTCTTTTGCTGGTTCT-3', reverse: 5'-GATGTCCTTGGTGATGTCG-3' (497 bp); and 18S rRNA, forward: 5'-ACGAACCAGAGCCGAAAGC-3', reverse: 5'-GGACATCTAAGGGCATCACAG-3' (514 bp). PCR conditions were as follows: 2 min at 94°C, followed by up to 35 cycles of 94°C for 30 s, 54.3°C for 30 s, and 72°C for 1 min, with a final extension at 72°C for 5 min. To estimate the linear range of the nested reactions, we analyzed the PCR products for 10, 15, 20, 25, 30, and 35 cycles. The amplified products were analyzed on 1% agarose gels and visualized by ethidium bromide staining. The data were normalized for 18S rRNA expression.

### **Preparation of protein samples**

The pancreata was homogenized in a detergent lysis buffer containing 8 mol/L urea, 2% CHAPS, 40 mmol/L Tris, 65 mmol/L DTT and 2% IPG buffer. The lysate was then centrifuged at 15000 *g* for 1 h at 4°C. The total protein concentration of each sample was analyzed using a modified Bradford assay. All samples were stored at -80°C prior to the electrophoresis.

### **Western blotting analysis**

An equal amount of protein samples (50  $\mu$ g protein in 20  $\mu$ L buffer) from each time point were boiled in 3  $\times$  loading buffer (10 mmol/L Tris-HCl, pH 6.8 including 3% SDS, 5%  $\beta$ -mercaptoethanol, 20% glycerol and 0.6% bromophenol blue) for 3 min and separated by 12.5% SDS-PAGE and transferred to nitrocellulose membranes (Bio-Rad, Hercules, CA, USA). For blocking, membranes were incubated with 5% fat-free milk in Tris-buffered saline plus 0.05% Tween-20 (TBST) overnight at 4°C. The membranes were then incubated with the primary antibody (NB100-1918, rabbit polyclonal antibody to *WFS1*, diluted 1:1000, Novus Biologicals Littleton, CO, USA) (sc-47778 mouse polyclonal antibody to  $\beta$ -actin, diluted 1:1000, Santa Cruz Biotechnology Inc., USA) for 2 h at room temperature. After washing in TBST, the membranes were incubated with the peroxidase-linked goat anti-rabbit IgG conjugates (PIERCE, Prod 1858415) or peroxidase-linked goat anti-mouse IgG conjugates (sc-2055, Santa Cruz Biotechnology Inc. USA) for 1 h at room temperature. The membranes were then washed

A: *WFS1* mRNA measured by reverse transcription-polymerase chain reaction (RT-PCR). upper: from embryonic day (E) 15.5 to adulthood: *WFS1* mRNA expression was highest at E15.5 and E18.5. M: Marker; lower: *WFS1* mRNA expression was analyzed and normalized to 18S rRNA. Results are indicated in percentage above the 18sRNA value and are representative of three independent experiments. Compared to E15.5, the highest level of *WFS1* mRNA was detected at E18.5, the E15.5 and P0 was less, and at a lowest at adult ( $P < 0.05$  vs P0 and adult), respectively; B: Western blotting of *WFS1* protein in the pancreas of E15.5, E18.5, P0, P14, P21 and adult rats. upper: expression of *WFS1* protein (100 kDa) with  $\beta$ -actin (42 kDa) as a loading control. The position of the molecular weight markers are indicated on the left; lower: the expression of *WFS1* protein shows dynamic changes during rat pancreas development. Results are indicated in percentage above the e15.5 value and are representative of three independent experiments. Compare to E15.5, The highest level of *WFS1* was at P14 and lowest at P21 ( $P < 0.05$  vs E18.5, P14 and P21), respectively.

again in TBST, incubated in enhanced chemiluminescence reagents (ECL, Amersham Life Science, Cleveland, OH, USA) for 1 min, and exposed to VA 711 B Blue Sensitive X-ray films. Densitometric quantification of bands at sub-saturating levels was performed using the Syngenetool gel analysis software (Syngene, Cambridge, UK).

**Double fluorescence immunohistochemistry**

Tissues were fixed in 4% paraformaldehyde overnight at 4°C followed by a standard protocol of dehydration and paraffin embedding, and 5  $\mu$ m sections were cut. The paraffin sections were deparaffinized in xylene and rehydrated in graded ethanol and distilled water. The non-specific binding sites were blocked in 1% bovine serum albumin for 30 min. For *WFS1* protein and insulin, glucagon or vimentin double immunofluorescence, the rabbit anti-*WFS1* primary polyclonal antibody was applied and revealed using FITC-labeled Rabbit anti-goat IgG (1:400, sc-2777, Santa Cruz Biotechnology Inc., USA). Mouse anti-insulin primary polyclonal antibody (1:1000, Santa Cruz Biotechnology Inc., USA) or mouse anti-vimentin primary monoclonal antibody (1:1000, Chemicon Temecula, CA, USA) was then applied and revealed by cy3-labeled anti-mouse IgG (1:400, Chemicon Temecula, CA, USA). Sections were placed in Gel Mount Aqueous Mounting Medium (G0918, Sigma, USA) with a cover glass, and were examined under an Olympus BX51 microscope (Olympus Optical, Tokyo, Japan). Images were taken at a magnification  $\times$  400.

**Statistical analysis**

Analysis of the experimental data was performed using PD Quest 7.0 software and the paired Student *t*-test.  $P < 0.05$  was considered statistically significant. Data are presented as the mean  $\pm$  SD.

**RESULTS**

***mRNA expression of WFS1 in rat pancreas at different developmental stages***

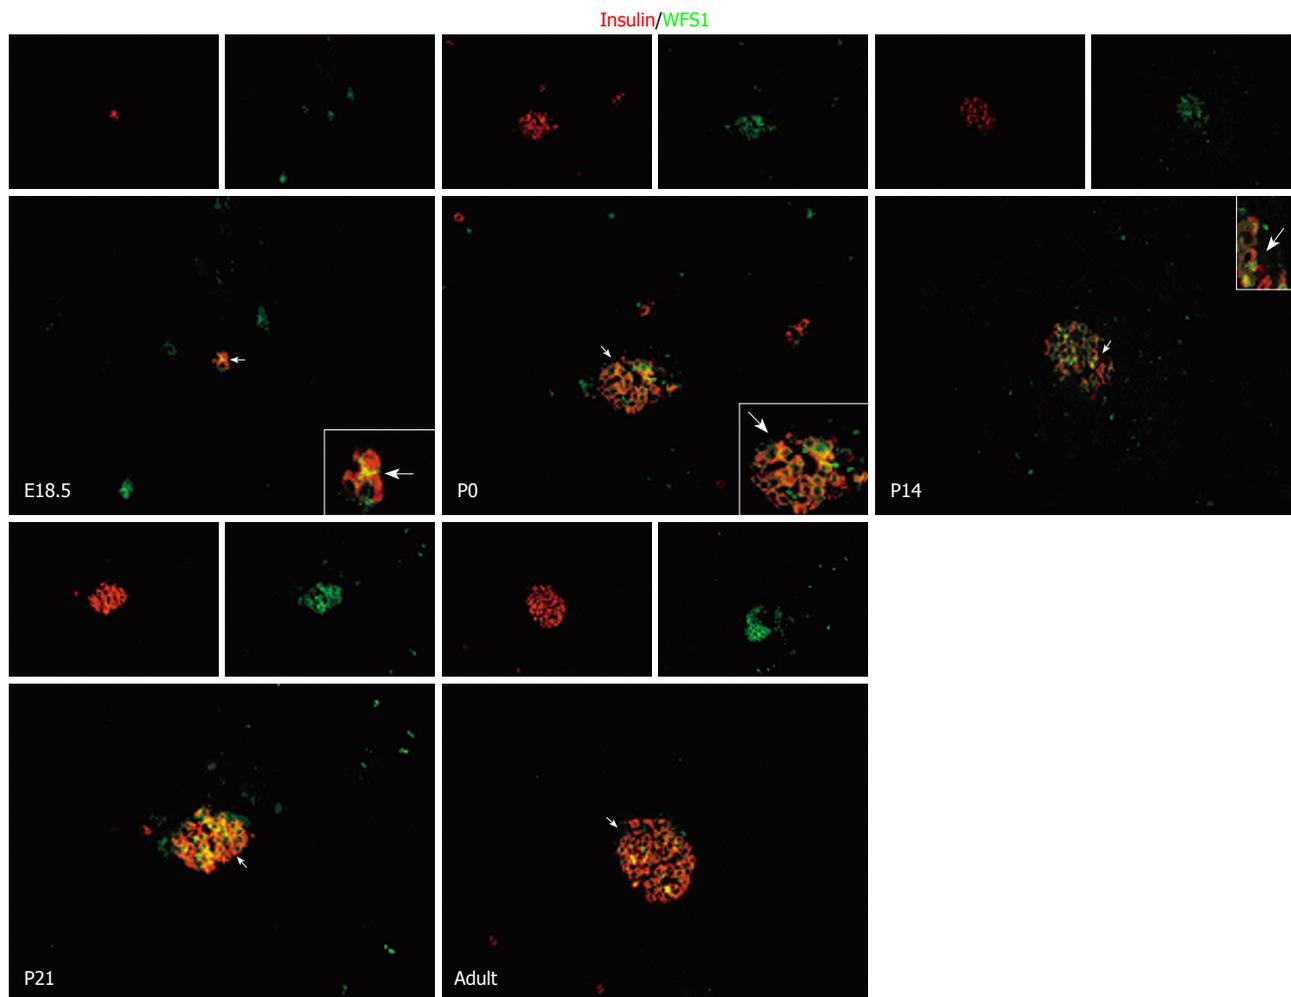

The mRNA expression levels of *WFS1* in rat pancreas during its development were examined by RT-PCR. 18S RNA as used as an internal control and assessed under the same conditions. As shown in Figure 1A, RT-PCR for the *WFS1* specific region yielded a band of the expected size (197 bp) in rat pancreas tissue at different developmental stages. The mRNA expression of *WFS1* was high at E15.5 and E18.5, started to decrease at birth, and continued to decline to adulthood.

***Protein expression of WFS1 in rat pancreas at different developmental stages***

We performed Western blotting using total protein samples extracted from pancreata obtained at E15.5, E18.5, P0, P7, P14 and P21 and from adult rats (Figure 1B).  $\beta$ -actin (42 kDa) was used as an internal control under the same conditions. Analysis of the blots showed that *WFS1* (100 kDa) protein was expressed in the pancreas. Densitometric quantification of each band showed that the expression of *WFS1* protein was high at E15.5, and then decreased until birth (P0). Subsequently, the level of *WFS1* protein increased gradually and peaked at P14. The expression of *WFS1* protein was lowest at P21. The level of *WFS1* protein was relatively high in the adult rat.

***Regional localization of WFS1 protein in rat pancreas at different developmental stages***

To determine the localization of *WFS1* protein during pancreatic development, serial pancreas sections (obtained at E18.5, P0, P14, P21 and in adulthood) underwent

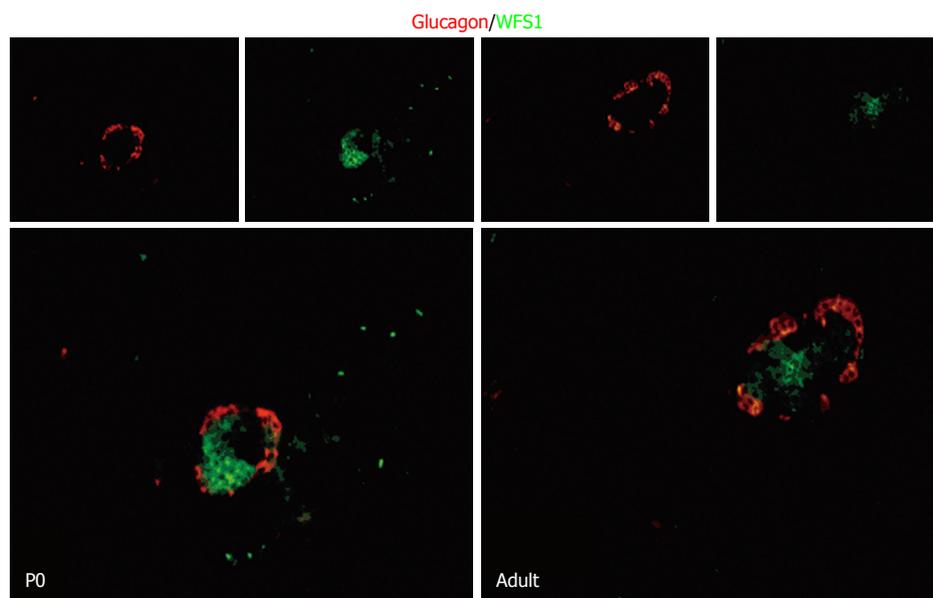

**Figure 2** Immunofluorescent localization of WFS1 protein and insulin in the pancreas of E18.5, P0, P14, P21 and adult rats. The WFS1 antibody was detected with an FITC (green)-labeled secondary antibody and the insulin antibody was detected with a Cy3 (red)-labeled secondary antibody. An overlap between WFS1 (green) and insulin (red) labeling is colored orange. Modest WFS1 staining is seen in the developing islets from E18.5 to adulthood, and overlaps insulin-positive  $\beta$ -cells. A few WFS1-labeled cells are scattered away from the islets. Primary objective magnification,  $\times 400$ . Insets, higher magnifications of the areas indicated by arrows for E18.5, P0 and P14.

double immunofluorescence. We found that WFS1 protein was co-expressed with insulin and could not be detected in  $\alpha$ -cells. As shown in Figure 2, there was a consistent overlap between the WFS1 protein-positive cells and cells labeled with insulin at each stage tested. This means that, during pancreatic development and remodeling, the WFS1 protein is continually expressed in  $\beta$  cells. As shown in Figure 3, there was little overlap between the WFS1 protein-positive cells and cells labeled with glucagon at any of the stages tested. This indicates that WFS1 protein is not expressed in  $\alpha$ -cells during development. Interestingly, we also found that WFS1-positive cells were scattered throughout the pancreas. Therefore, we performed further double immunofluorescence, which confirmed that WFS1 protein was co-expressed with vimentin in mesenchymal cells (Figure 4).

## DISCUSSION

Organogenesis involves 2 processes: morphogenesis, which is the shaping of an organ, and cytodifferentiation, which is the acquisition and expression of specialized

cellular functions within that organ<sup>[15]</sup>. During pancreatic development, specialized cell types are generated from progenitor cell populations and are precisely organized into the elaborate structure of the adult organ. Previously, most researchers focused on deriving functional islets from stem cells or other cell types. Gu *et al*<sup>[16]</sup> generated transcriptional profiles of enriched cells isolated from pancreata at 4 biologically significant stages of endocrine pancreas development (endoderm before pancreas specification, early pancreatic progenitor cells, endocrine progenitor cells and adult islets of Langerhans) to identify new endocrine regulatory genes and markers. With temporal and spatial analysis of genes expressed in embryonic endocrine cells, a database of potential progenitor cell markers was generated. In the present study, using a gene array, *WFS1* was found to be one of the genes that were specifically and highly expressed in islet cells at E15.5 and E18.5. Then, we used RT-PCR and Western blotting to analyze the expression of *WFS1* at 6 biologically significant stages of rat pancreas development: E15.5, E18.5, P0, P14, P21 and in adult rats. During the later embryonic period, the pancreatic cells

**Figure 3** Immunofluorescent localization of *WFS1* protein and glucagon in the pancreas of P0 and adult rats. The *WFS1* antibody was detected with an FITC (green)-labeled secondary antibody and the glucagon antibody (mouse monoclonal antibody) was detected with a Cy3 (red)-labeled secondary antibody on the same section. The overlap between *WFS1* (green) and glucagon (red) labeling is colored orange. *WFS1*-positive cells and glucagon-positive cells can be seen in 2 pancreas sections tested. Double-labeling with antibodies to *WFS1* and glucagon reveal that the cells labeled with *WFS1* are surrounded by  $\alpha$ -cells. Primary objective magnification,  $\times 400$ .

exhibit dramatic growth, differentiation and proliferation. Accordingly, it may not just be a concomitant phenomenon that the expression of *WFS1* protein is greater during the later embryonic period. The present study confirmed the changes in *WFS1* mRNA levels in the rat pancreas during development by RT-PCR.

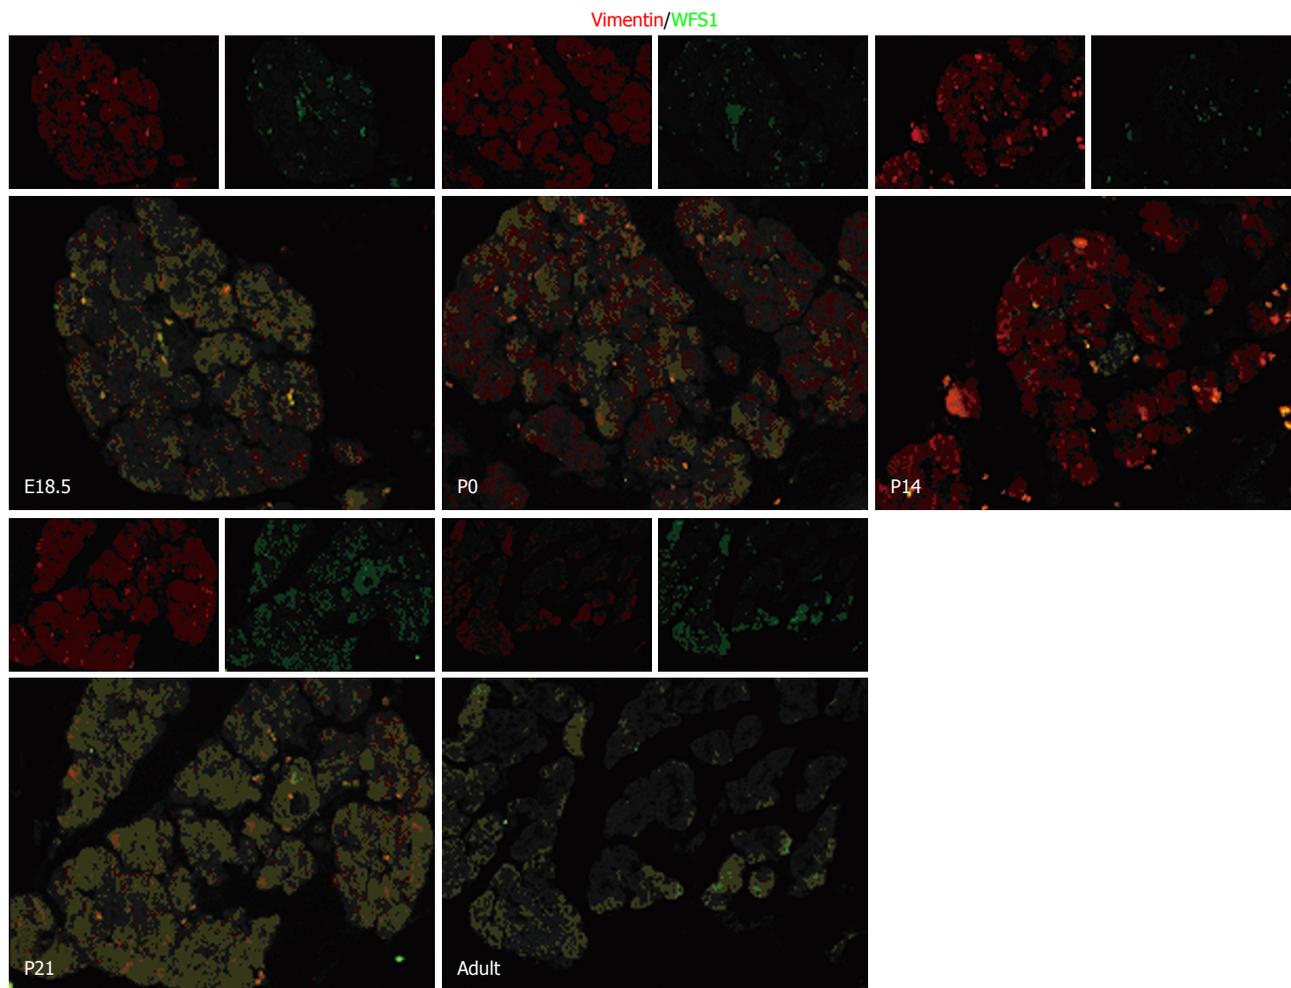

The architecture of the islet is completely formed shortly before birth; however, the function of the islet is not fully developed at this stage. It has been reported that the pancreas of neonatal rat undergoes further remodeling and maturation for 2-3 wk after birth<sup>[17]</sup>. The remodeling process includes a decrease in  $\beta$ -cell mass and enhanced islet neogenesis. The number of  $\beta$ -cells is mainly regulated by apoptosis and cell replication<sup>[18]</sup>. The results of Western blotting revealed that the *WFS1* protein level was highest during the postneonatal period, particularly P14. Although the function of wolframin is still not completely known, recent studies have revealed its localization to the endoplasmic reticulum and that it may play an important role in endoplasmic reticulum (ER) homeostasis by regulating  $\text{Ca}^{2+}$ <sup>[11,19]</sup>. During islet development, particularly in the ER at E15.5 and P14, secretory and transmembrane proteins involved in development regulation fold into their native conformation and undergo posttranslational modifications important for their activity and structure. Consequently, ER homeostasis and the *WFS1* protein may be important in islet development. It is well known that *WFS1* protein induces cation channel activity in ER membranes<sup>[11]</sup> and regulates calcium levels in the ER<sup>[19]</sup>. *WFS1* protein also plays a role in stimulus-secretion coupling for insulin exocytosis in pancreatic  $\beta$  cells<sup>[13,16,19,20]</sup>. Therefore, enhanced expression of *WFS1* protein in adults suggests that *WFS1* may retain its function in adult islets.

Surprisingly, the pattern of *WFS1* protein expression was not consistent with the pattern of *WFS1* mRNA

expression, as described above. This difference may result from post-transcriptional control, although the mechanisms need further investigation. RNA binding protein controls the various steps and the rate of transcription of microRNA, which regulates the destruction of RNA and changes in chromatin structure may be involved in the regulation of *WFS1* expression.

During remodeling in the perinatal period, apoptosis is an important mechanism that decreases  $\beta$ -cell mass. Apoptosis of  $\beta$ -cells is significantly increased in neonates compared with adult rats, and peaks at 2 wk of age<sup>[18]</sup>, while the highest level of *WFS1* protein was detected at the same time. It has been reported that ER stress induces *WFS1* expression in pancreatic  $\beta$ -cells<sup>[21]</sup> and the expression of *WFS1* is regulated by inositol requiring  $1\alpha$  (*Ire1* $\alpha$ ) and PKR-like ER kinase (PERK), central regulators of the unfolded protein response<sup>[22]</sup>. It has also been reported that *WFS1*-deficient pancreatic  $\beta$ -cells exhibit increased phosphorylation of RNA-dependent protein kinase-like ER kinase, chaperone gene expression and active XBP1 protein levels, indicating an enhanced ER stress response. Furthermore, the increased ER stress response was accompanied by impaired  $\beta$ -cell proliferation and increased caspase-3 cleavage<sup>[21]</sup>. Since the *WFS1* protein attenuates ER stress, maintains cell cycle progression and represses the apoptotic pathway, specifically in pancreatic  $\beta$ -cells, it may play an important role in the maintenance of  $\beta$ -cell mass by balancing  $\beta$ -cell growth (differentiation and proliferation) and  $\beta$ -cell death (apoptosis) during pancreatic remodeling.

During organogenesis, specialized cell types are generated from progenitor cell populations and are precisely organized into the elaborate structure of the adult organ. Numerous cell-cell communications and the initiation of complex inter-regulating genetic networks are involved to ensure the fidelity of organogenesis. Several

**Figure 4** Immunofluorescent localization of WFS1 protein and vimentin in the pancreas of E18.5, P0, P14, P21 and adult rats. The WFS1 antibody was detected with an FITC (green)-labeled secondary antibody and the vimentin antibody was detected with a Cy3 (red)-labeled secondary antibody on the same section. The overlap between AFP (green) and vimentin (red) labeling is colored orange. WFS1-positive cells can be detected in pancreas sections from E18.5 to adult. Double-labeling with antibodies to WFS1 and to vimentin revealed colocalization of these proteins in the same cells from E18.5 to adult. Primary objective magnification,  $\times 400$ .

studies have reported the role of mesenchymal and/or epithelial interactions in pancreatic development and suggested that multiple diffusible mesenchyme-derived factors may act on the developing epithelia to influence cell division, cell fate, differentiation, and to determine the proportion of endocrine vs exocrine tissue<sup>[23-26]</sup>. Examination of the ontogeny of *WFS1* in the developing rat pancreas revealed an intimate relationship between WFS1 protein and the mesenchymal and/or epithelial interactions<sup>[27]</sup> in pancreatic development. Vimentin is a marker for mesenchymal cells<sup>[28,29]</sup>. In the present study, the results of double immunofluorescence revealed that WFS1 protein was co-expressed with vimentin. This indicates that WFS1 protein is localized to the pancreatic mesenchyme shortly before birth on E18.5 and after birth. Previous studies revealed that the late embryonic stage is a key phase in late pancreatic organogenesis, in which a dramatic increase in the number of endocrine and exocrine cells with high levels of insulin and exocrine enzymes are observed. The islets are fully formed shortly before birth on E18.5 and undergo further remodeling and maturation after birth<sup>[26]</sup>. Considering the previous

reports of WFS1 protein function and the results of our experiments, we suggest that WFS1 protein plays an important role in many aspects of pancreas development. However, the underlying mechanism is not fully understood and needs further research, which may also provide new evidence to confirm the interactions between mesenchymal and epithelial cells.

In summary, our present study has, for the first time, demonstrated that WFS1 protein is localized to the mesenchyme in the rat pancreas by immunofluorescence. The dynamic expression of *WFS1* in the various developmental stages of the pancreas indicates that *WFS1* may be involved in many aspects of pancreatic development.

## COMMENTS

### Background

Wolfram syndrome (WS), caused by the mutant of the *Wolfram syndrome 1* gene (*WFS1*), is an autosomal recessive, progressive, neurodegenerative disorder accompanied by diabetes mellitus and optic atrophy. Although it has been reported that WFS1 protein is found to be enriched in endocrine progenitors vs non-endocrine progenitor cells at embryonic day (E) 13.5, its expression and function during the development of normal pancreas remain unknown.

**Research frontiers**

It is thought that the pancreatic endocrine cells including beta cells arise from duct epithelial cells, however much research has been done to explore a different source. Novel strategies would obviously benefit from the use of beta stem cells/progenitor cells.

**Innovations and breakthroughs**

*WFS1* expression has never been assessed in the developing pancreas and it is highly expressed in P14 on which the apoptosis rate of beta cells is at a high point. *WFS1* protein has been proved to be a downstream factor in the endoplasmic reticulum stress signal pathway.

**Applications**

This study reveals the possible mechanism of apoptosis in pancreas remodeling and may lead to new possibilities for diabetes therapy.

**Peer review**

This is a very interesting study that provides novel information that will be useful for the understanding of the role *WFS1* in pancreatic development as well as disease.

### Abstract

**AIM:** To evaluate the effects of angiotensin-1 (Ang-1) on adhesion of gastric cancer cell line BGC-823 and expression of integrin  $\beta$ 1, CD44V6, urokinase-type plasminogen activator (uPA) and matrix metalloproteinase-2 (MMP-2).

**METHODS:** BGC-823 cells were transfected transiently with adenovirus-Ang-1 (Ad-Ang-1). Cells transfected transiently with adenovirus-green fluorescent protein (Ad-GFP) and untransfected cells were used as a negative and blank control group, respectively. The cell adhesion rate between cell and extracellular matrix (ECM) was determined by cell adhesion assay. To investigate whether Ang-1 could reinforce gastric carcinoma metastasis, we performed migration and invasion assays in BGC-823 cells. The mRNA and protein expression of integrin  $\beta$ 1, CD44V6, uPA and MMP-2 were detected by reverse transcription polymerase

chain reaction and Western blotting, respectively. The expression of integrin  $\beta$ 1 and CD44V6 was measured by immunohistochemistry.

**RESULTS:** BGC-823 cells were transfected successfully. The adhesion rate increased significantly in the Ad-Ang-1 group ( $P < 0.05$ ). The Ad-Ang-1-transfected group had a significant increase in migration and invasion compared with that of the mock-transfected and Ad-GFP groups. The mRNA and protein expression of integrin  $\beta$ 1, CD44V6, uPA and MMP-2 in the Ad-Ang-1 group was higher than that in the Ad-GFP and blank control groups ( $P < 0.05$ ). Compared with mock-transfected and Ad-GFP groups, integrin  $\beta$ 1 and CD44V6 expression intensity greatly increased ( $P < 0.05$ ).

**CONCLUSION:** Transfection of Ang-1 into human gastric cancer cell line BGC-823 can significantly increase expression of integrin  $\beta$ 1 and CD44V6, by which cell adhesion and metastasis to the ECM are promoted.

### INTRODUCTION

Angiotensin-1 (Ang-1) has been identified *via* secretion trap and homology cloning techniques as a family of structurally related proteins that bind with similar specificity and affinity to a common endothelial-cell-specific receptor tyrosine kinase, Tie2<sup>[1-3]</sup>. Ang-1 is

required for correct organization and maturation of newly formed vessels and promotes quiescence and structural integrity of adult vasculature. However, its functions and mechanisms in tumors are not clear<sup>[4,5]</sup>. In addition to Tie receptors, Ang-1 has been found to bind integrins. Experiments with blocking antibodies, as well as cells deficient in certain integrins, suggest Ang-1 can bind several different integrins, including  $\alpha 2\beta 1$ ,  $\alpha 5\beta 1$ ,  $\alpha v\beta 3$  and  $\alpha v\beta 5$ <sup>[6-9]</sup>. Also, some researchers have confirmed that Ang-1 can support cell adhesion mediated by integrins<sup>[7]</sup>. Whether there is a relationship between Ang-1 and integrin  $\beta 1$  has not been established. In addition, Ang-1 can affect cell adhesion, and CD44V6 is a member of the cell adhesion family, therefore, we can infer that there is a relationship between Ang-1 and CD44V6. At the same time, in primary adenocarcinoma, cancer cell invasion is facilitated by interaction with the local stromal compartment, whereas metastatic growth requires the ability of the cancer cell to interact with the new host tissue before the cancer cells can invade and destroy the target organ. The local stromal compartment, which comprises inflammatory cells and fibroblasts, facilitates the process by secreting extracellular matrix (ECM)-degrading proteases, including matrix metalloproteinases (MMPs) and urokinase-type plasminogen activator (uPA). MMP-2 (also known as gelatinase A and the 72-kDa type IV collagenase) has the ability to degrade type IV collagen in the basement membrane, and it is one of the major stroma-derived MMPs. One proposed mechanism of MMP-2 activation is through the plasminogen activator/plasmin system, in which pro-uPA binds to uPA receptor (uPAR), through a specific amino-terminal sequence of its non-catalytic chain. This binding result in uPA activation, accelerates the conversion of plasminogen to plasmin on the cell surface, and localizes these enzymes to focal contact sites. Many studies have indicated that MMP-2 plays an important role in tumor invasion of the basement membrane. Therefore, we used adenovirus as a vector to transfect the cell line BGC-823, to explore the effects of Ang-1 on integrin  $\beta 1$ , CD44V6, uPA and MMP-2 of human gastric cancer cell line BGC-823, and study the mechanism of adhesion to the ECM and metastasis of gastric cancer.

## MATERIALS AND METHODS

### **BGC-823 cell line and cell culture**

Human gastric adenocarcinoma cell line BGC-823 (purchased by Chinese Academy of Sciences) was cultured in RPMI 1640 medium (Gibco) that contained 10% fetal bovine serum (FBS) and 10% penicillin/streptomycin, and maintained under an atmosphere of 5% CO<sub>2</sub> with humidity at 37°C.

### **Preparation of adenoviral vectors and the determination of multiplicity of infection (MOI)**

The recombinant adenovirus vector that carried Ang-1 and control adenoviral vector that carried green fluorescent protein (GFP) were constructed and kindly

provided by The First Affiliated Hospital of Nanjing Medical University<sup>[10]</sup>. The recombinant adenoviral vectors that expressed Ang-1 and GFP were amplified by infection of 293 cells. A suspension of 293 cells ( $5 \times 10^8$  cells/L) was added into the culture capsule. The linearized recombinant adenoviral vectors that expressed Ang-1 or GFP genes were co-transfected with Lipofectamine 2000 (Gibco) into 293 cells. The supernatant fluid that contained adenoviral vectors was transfected into more 293 cells after occurrence of a cytopathic effect. The viral extracts were propagated in 293 cells and were purified by CsCl (Sigma) density purification, and dialyzed and stored in dialysis buffer (Spectrum) with 10% glycerol at -70°C. Subsequently, the titer of each viral stock was measured by TCID<sub>50</sub>. 293 cells were seeded in 96-well plates ( $5 \times 10^7$  cells/L) for 24 h, and 100  $\mu$ L dilute supernatant fluid that contained adenoviral vectors ( $10^{-1}$ - $10^{-12}$ ) was added respectively. Then, we calculated the titer of each viral stock after the cells were incubated with the complexes for 10 d. Subsequently, BGC-823 cells were seeded in 96-well plates ( $1 \times 10^4$  cells/well). After 8 h exposure to control adenoviral vectors that contained medium at different MOI (10, 20, 30, 50 or 100) at 37°C, the medium was substituted with RPMI 1640 that contained 10% FBS. Forty-eight hours later, the cells that expressed GFP were counted by fluorescence microscopy to calculate efficiency of transfection. An MOI of 20 was the best.

### **Cell transfection**

BGC-823 cells were seeded in 96-well plates ( $5 \times 10^7$  cells/L) 24 h before adenoviral transfection at 60%-70% confluence in medium that contained 10% FBS. The cells were infected at an MOI of 20 in serum-free medium with Ad-Ang-1 and Ad-GFP as a control adenoviral vector. Except for the above two groups, one additional control group was used, which consisted of uninfected cells.

### **Cell adhesion assay**

Ninety-six-well plates were coated with 50  $\mu$ L 10 mg/L fibronectin at 4°C. At the same time, 96-well plates were coated with 50  $\mu$ L 10 mg/L BSA at 4°C as a control ECM. A total of  $1 \times 10^5$  cells in 100  $\mu$ L of the medium were plated in 96-well plates at 37°C. After 1 h, 96-well plates were washed with PBS, and the medium was replaced with 50  $\mu$ L 0.05% MTT solution and 150  $\mu$ L RPMI 1640, and incubated for 4 h. After incubation, the MTT solution was removed, and the cells were suspended in 150  $\mu$ L DMSO (Sigma). Absorbance was measured at 570 nm using a microplate reader (Bio-Rad Laboratories).

### **Invasion assays**

The ability of BGC-823 cells to migrate through Matrigel-coated filters was measured using Transwell chambers with 8- $\mu$ m pore polycarbonate filters coated with 300  $\mu$ g Matrigel in the top side of the filter. BGC-823 cells were mock-transfected or transfected with Ad-GFP or Ad-Ang-1 (MOI = 20). After 36 h, the cells were trypsinized, resuspended in serum-free medium, seeded on the top

compartment of the chamber, and incubated for 24 h. At the end of incubation, the cells were stained, and the cells and Matrigel on the top surface of the filter were removed carefully with a cotton swab. The invasive cells that adhered to the bottom surface of the filter were quantified under a light microscope ( $\times 200$ ) (Nikon, Japan). The data were presented as the average number of cells attached to the bottom surface from randomly chosen fields. Each treatment condition was assayed using triplicate filters, and filters were counted at five areas.

### Migration assay

The migration and invasiveness of BGC-823 cells were evaluated in six-well transwell chambers with upper and lower culture compartments that were separated by polycarbonate membranes with 8- $\mu\text{m}$  sized pores. The three types of cells were detached, washed twice in PBS, and resuspended in serum-free RPMI 1640 medium. A total of  $1 \times 10^5$  cells in 500  $\mu\text{L}$  were placed in the upper chamber of a Millicell Insert (Millipore, USA), and the lower chamber was filled with 1.6 mL RPMI 1640/10% FBS. After a 4 h incubation period, the cells in the upper chamber that did not migrate were scraped away gently, and adherent cells on the lower surface of the insert were stained with hematoxylin and eosin and photographed. Triplicate assays were performed for each group of cells.

### Reverse transcription polymerase chain reaction (RT-PCR) of integrin $\beta 1$ , CD44V6, uPA and MMP-2

Total RNA was isolated from BGC-823 cells using Trizol reagents (Invitrogen) according to the manufacturer's instructions, and utilized for RT-PCR. Primers designed for integrin  $\beta 1$  were as follows: forward, 5'-AATGAA GGGCGTGTGGTAG-3', and reverse, 5'-AGACAC CACTCGCAGATG-3'. Primers designed for CD44V6 were as follows: forward, 5'-GGCAACTCC TAGTAGTACAAC-3', and reverse, 5'-CAGCTGTCC CTGTTGTTCGAAT-3'. Primers designed for uPA were as follows: forward, 5'-TCTGTGTGTGGGACTGAT GC-3', and reverse, 5'-GCCCTGACCTGAATCACA AT-3'. Primers designed for MMP-2 were as follows: forward, 5'-CTAGACAAGGGCCACAGACC-3', and reverse, 5'-GAGGAAGCAAACCTCGAACA-3'. Primers designed for  $\beta$ -actin, which was used as a loading control for the RT-PCR, were as follows: forward, 5'-CCACCC ATGGCAAATTCATGGCA-3', and reverse, 5'-TCTAG ACGGCAGGTCAGGTCCAC-3'. After visualization of the PCR products by 20 g/L agarose gel electrophoresis with ethidium bromide staining gel, images were obtained and the densities of the products were quantified using a digital gel image analysis system (Pharmacia Biotech). The PCR fragments were identified according to their molecular mass using a DNA marker (DL 600 and 1200 marker, TaKaRa Biotech).

### Western blotting

Western blotting was utilized for the detection of integrin  $\beta 1$  and CD44V6. Cell lysates were prepared and separated by 15% SDS-PAGE and transferred to nitro-

cellulose membranes. Membranes were blocked for 1 h at room temperature in 5% milk solution. PAGE was detected by incubating the transferred membrane overnight at 4°C with anti-human rabbit monoclonal antibody (Cell Signaling Technology, USA) at 1:100 dilution in 5% milk solution. Secondary antibody, anti-rabbit IgG/horseradish peroxidase, was added and cells were incubated for 2 h at room temperature. The signal was detected by the ECL detection system (Amersham), according to the manufacturer's protocol, and imaged digitally by Kodak Formatter (Kodak, Japan).

### Immunocytochemistry for integrin $\beta 1$ and CD44V6

BGC-823 cells were prepared as a suspension that contained  $1 \times 10^8$  cells/L and were added to a six-well plate that contained many small glass slides. The cells were infected with recombinant adenovirus vector as before at 70% confluence on the glass slides. These small glass slides were taken out after 36 h. Expression of integrin  $\beta 1$  and CD44V6 was determined immunohistochemically with an anti-integrin  $\beta 1$  (Beijing Zhongshan Jinqiao Biotech), anti-CD44V6 mouse monoclonal antibody (Beijing Zhongshan Jinqiao Biotech), respectively, at a dilution of 1:100, and using the streptavidin-peroxidase technique with the SPtm kit (SP-9000; Maixin). Negative controls were prepared by substituting PBS for the primary antibodies, and known positive controls were included in each staining run. Finally, positive expression was measured *in situ* by Image-Proplus 4.5.

### Statistical analysis

Data are presented as mean  $\pm$  SE. Means among multiple groups were detected by one way ANOVA. Statistically significant differences were determined by  $Q$  test and were defined as  $P < 0.05$ .

## RESULTS

### Transfection efficiency of the adenovirus vector in BGC-823 cells

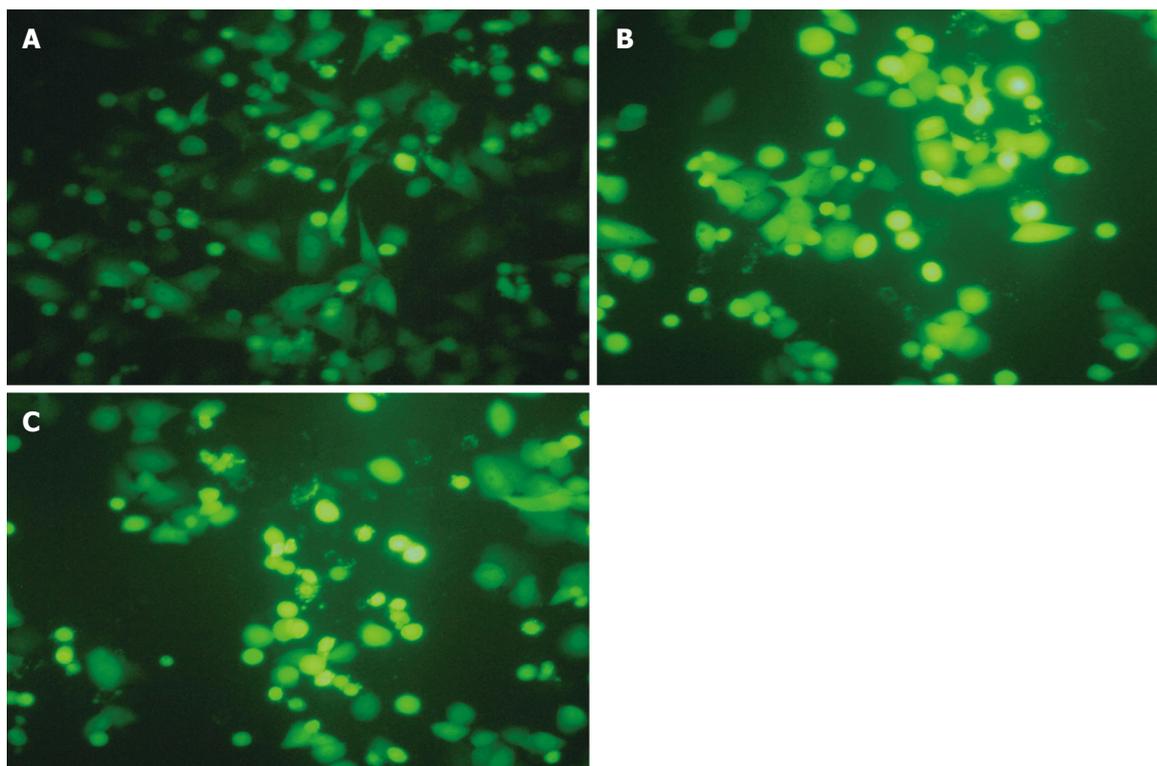

As MOI increased, the number of BGC-823 cells expressing GFP protein increased. None of cells could be transfected when MOI was 0 (Data was not shown). Nearly all the cells could be transfected when MOI was 20 (Figure 1A). However, became detached and died when MOI was 30 or 50 (Figure 1B and C).

### Cell adhesion assay

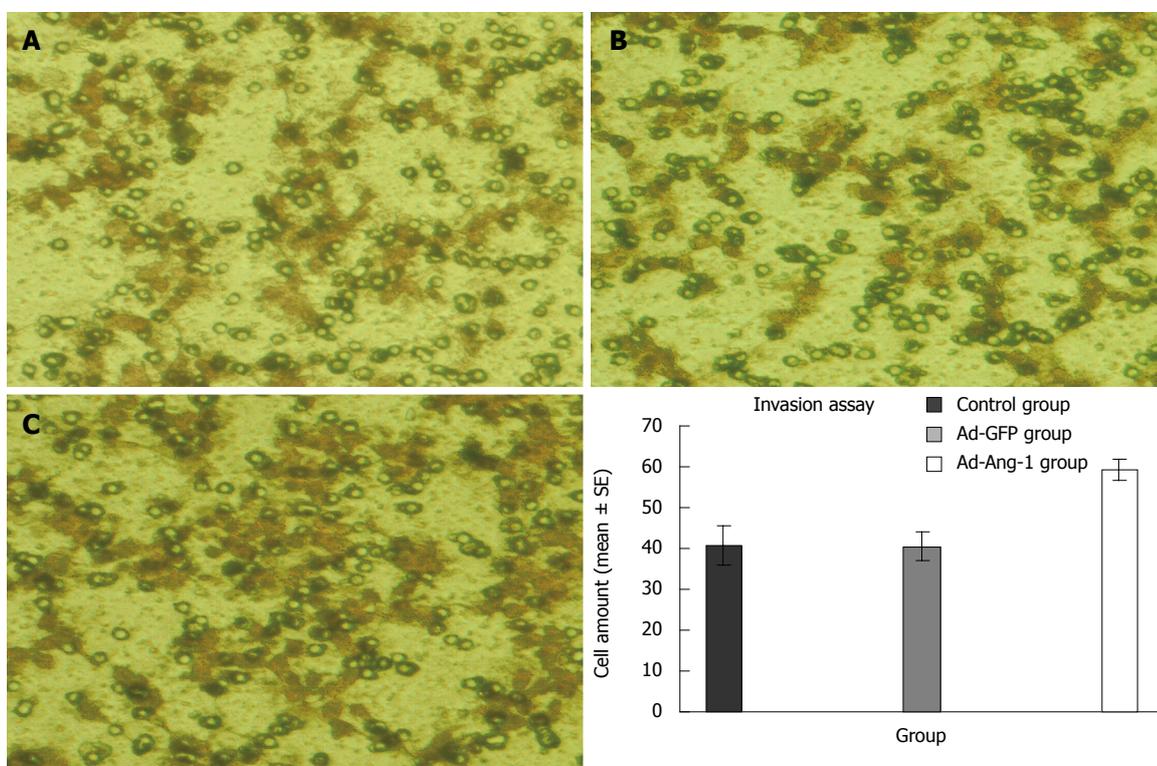

We analyzed the effects of BGC-823 cells on cell adhesion after transfection with Ang-1. Compared to control group, the rate of adhesion of integrin  $\beta 1$  and CD44V6 in the Ad-Ang-1 group greatly increased ( $P < 0.05$ ) (Table 1).

### Invasion assay

Overexpression of Ang-1 was induced by Ad-Ang-1. There was no difference between the control and Ad-GFP groups (Figure 2A and B). The Ad-Ang-1-transfected cells showed significantly greater invasion than the mock-transfected and Ad-GFP groups (Figure 2C). These results

**Figure 1** Expression of fluorescence in BGC-823 cells ( $\times 200$ ). As MOI increased, so did the number of BGC-823 cells that expressed GFP protein. A: Nearly all the cells could be transfected when MOI was 20; B: Most cells became detached and died at MOI = 30; C: Most cells became detached and died at MOI = 50. Diagrams are representative of at least three independent experiments.

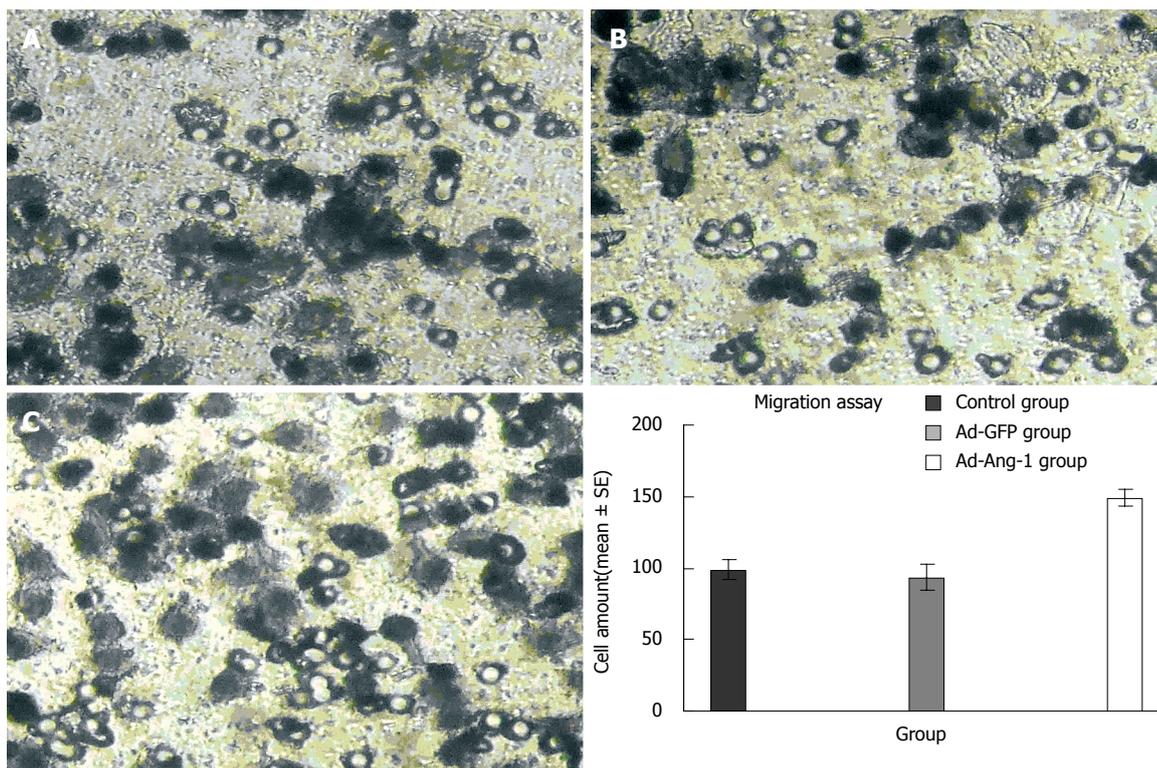

**Figure 2** Invasion assay in BGC-823 cells ( $\times 200$ ). A: Control group; B: Ad-GFP-transfected group; C: Ad-Ang-1-transfected group. There was no difference between the control and Ad-GFP groups. Ad-Ang-1-transfected cells had a significant increase in invasion compared with the mock-transfected and Ad-GFP groups ( $P < 0.05$ ). Diagrams are representative of at least three independent experiments.

provide evidence that Ang-1 enhances gastric carcinoma invasion ( $P < 0.05$ ).

**Migration assay**

Cell migration was greater in the Ad-Ang-1 group than

**Figure 3** Migration assay in BGC-823 cells ( $\times 200$ ). A: Control group; B: Ad-GFP-transfected group; C: Ad-Ang-1-transfected group. There was no difference between the control and Ad-GFP groups. In the Ad-Ang-1 group, there were more cells than in the control and Ad-GFP groups ( $P < 0.05$ ). Diagrams are representative of at least three independent experiments.

**Table 1** Cell adhesion assay (mean  $\pm$  SE)

Group	Experiment group cell A <sub>570</sub> /BSA group cell A <sub>570</sub>				Cell adhesion rate (%)
	1	2	3	4	
Control group	1.23 $\pm$ 0.071	1.28 $\pm$ 0.025	1.29 $\pm$ 0.032	1.28 $\pm$ 0.010	27.20
Ad-GFP group	1.172 $\pm$ 0.006	1.342 $\pm$ 0.036	1.264 $\pm$ 0.006	1.294 $\pm$ 0.016	26.80
Ad-Ang-1 group	1.756 $\pm$ 0.020	1.589 $\pm$ 0.007	1.502 $\pm$ 0.011	1.957 $\pm$ 0.005 <sup>a</sup>	70.10

<sup>a</sup>Compared to control group and Ad-GFP group  $P < 0.05$ . Cell adhesion rate = (experiment group cell A<sub>570</sub>/BSA group cell A<sub>570</sub>-1)  $\times$  100%. There was no difference between the control and Ad-GFP groups. Compared to the control and Ad-GFP groups, the rate of adhesion of integrin  $\beta$ 1 and CD44V6 in the Ad-Ang-1 group greatly increased ( $P < 0.05$ ).

in the control and Ad-GFP groups (Figure 3C), but there was no difference between the latter two groups (Figure 3A and B). These results demonstrate that Ang-1 enhances gastric carcinoma migration ( $P < 0.05$ ).

**RT-PCR of integrin  $\beta$ 1, CD44V6, uPA and MMP-2**

RT-PCR revealed that the mRNA expression of integrin  $\beta$ 1, CD44V6, uPA and MMP-2 was increased in the Ad-Ang-1-transfected group ( $P < 0.05$ ) (Figure 4).

**Western blotting of integrin  $\beta$ 1, CD44V6, uPA and MMP-2**

Western blotting revealed that protein expression of integrin  $\beta$ 1, CD44V6, uPA and MMP-2 was increased in the Ad-Ang-1-transfected group ( $P < 0.05$ ) (Figure 5).

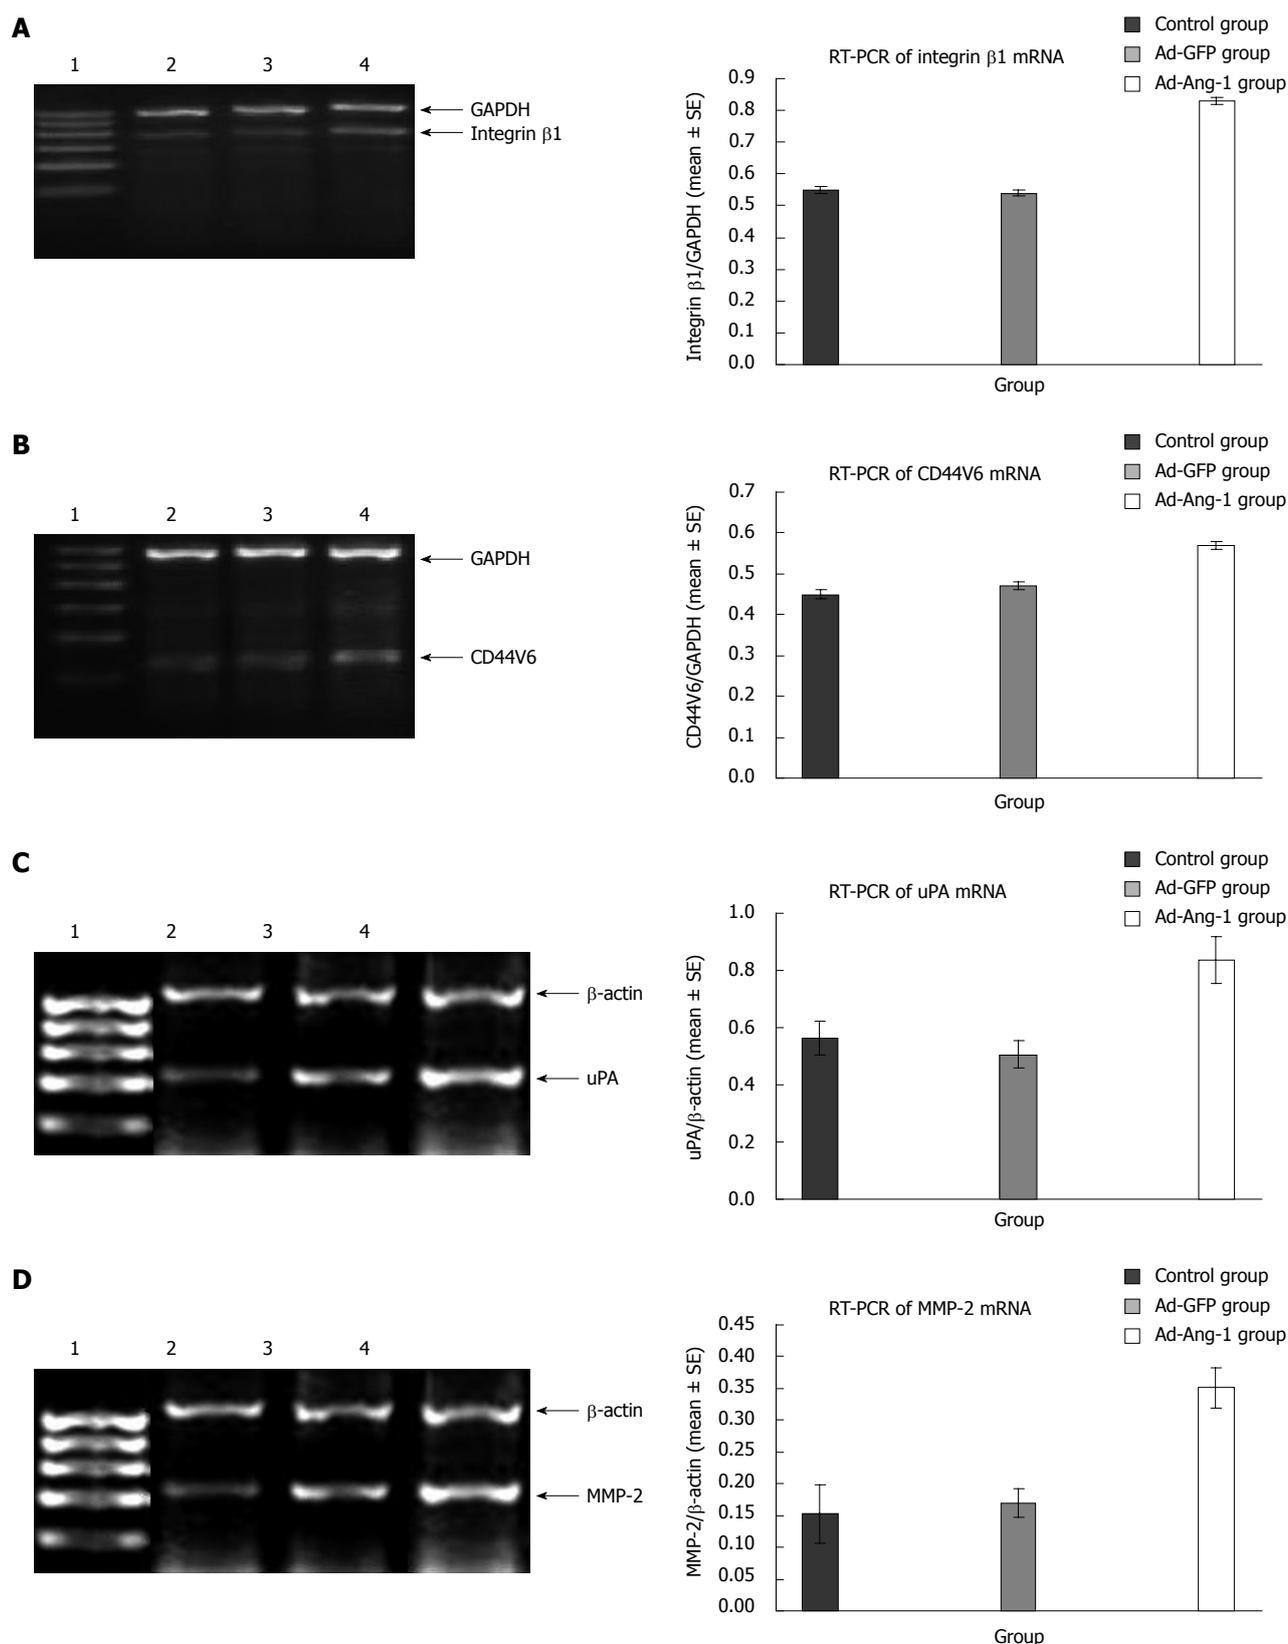

**Expression of integrin  $\beta$ 1 and CD44V6 protein**

Integrin  $\beta$ 1 and CD44V6 protein were both detected in BGC-823 cells in all three groups by using their

respective antibodies. The staining intensity of integrin  $\beta$ 1 in the Ad-Ang-1-transfected group was  $0.183 \pm 0.014$ , which was significantly higher than that in the control ( $0.114 \pm 0.023$ ,  $P < 0.05$ ) and Ad-GFP-transfected ( $0.149 \pm 0.013$ ,  $P < 0.05$ ) groups (Figure 6A). Compared with the other groups, expression of CD44V6 was also up-regulated (Figure 6B) ( $P < 0.05$ ). The staining intensity of this protein in the Ad-Ang-1-transfected group ( $0.147 \pm 0.011$ ) was higher than that in the control ( $0.089 \pm 0.007$ ) and Ad-GFP-transfected ( $0.065 \pm 0.021$ ) groups.

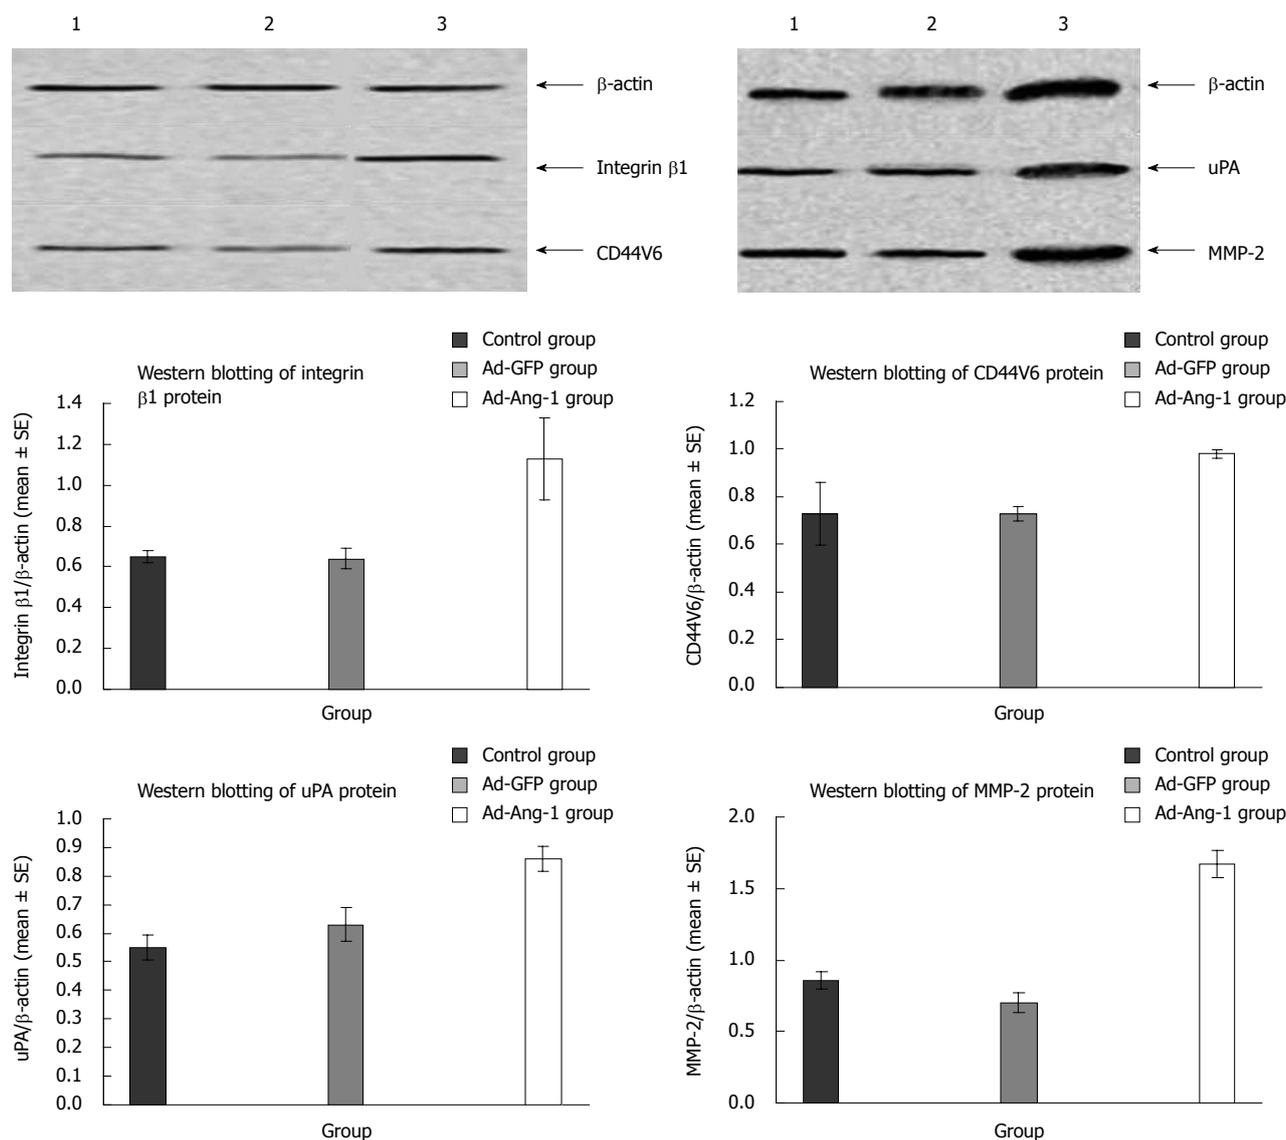

**DISCUSSION**

The angiopoietin family of morphogens has an essential function in vascular and lymphatic growth and remodeling<sup>[11]</sup>. The role of Ang-1 is controversial. Ang-1 is sequestered by peri-endothelial and vascular smooth muscle cells, and acts specifically on endothelial cells

**Figure 4** Expression of integrin  $\beta 1$  (A), CD44V6 (B), uPA (C) and MMP-2 (D) mRNA. 1: Markers: 100, 200, 300, 400, 500 and 600 bp; 2: Control group; 3: Ad-GFP-transfected group; 4: Ad-Ang-1-transfected group. A: Ang-1 group:  $0.830 \pm 0.010$ ; control group and Ad-GFP group:  $0.551 \pm 0.009$  and  $0.543 \pm 0.010$ , respectively; B: Ang-1 group:  $0.570 \pm 0.012$ ; control group and Ad-GFP group:  $0.451 \pm 0.014$  and  $0.472 \pm 0.013$ , respectively; C: Ang-1 group:  $0.837 \pm 0.081$ ; control group and Ad-GFP group:  $0.563 \pm 0.059$  and  $0.506 \pm 0.048$ , respectively; D: Ang-1 group:  $0.351 \pm 0.032$ ; control group and Ad-GFP group:  $0.153 \pm 0.046$  and  $0.170 \pm 0.023$ , respectively. These results show that the expression of integrin  $\beta 1$ , CD44V6, uPA and MMP-2 mRNA was increased in the Ang-1 group ( $P < 0.05$ ). Diagrams are representative of at least three independent experiments.

(ECs) through binding and activation of the cell surface tyrosine kinase receptor Tie2<sup>[12]</sup>. The angiotensin family

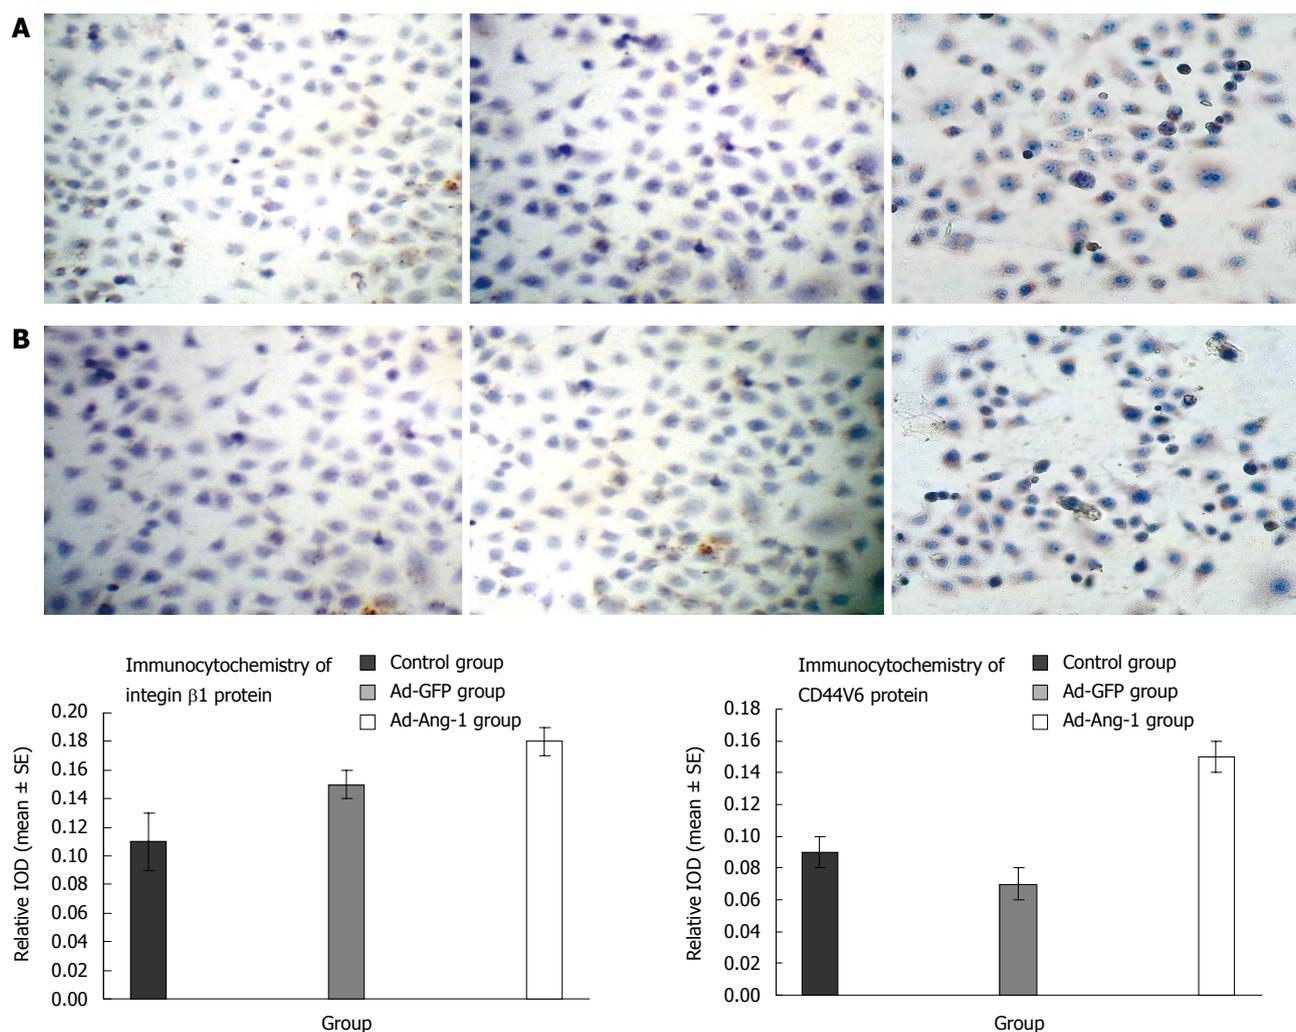

**Figure 5** Expression of integrin  $\beta$ 1 and CD44V6, uPA and MMP-2 protein. 1: Control group; 2: Ad-GFP-transfected group; 3: Ad-Ang-1-transfected group. After transfection with Ang-1, the protein level was greater than that in the control and Ad-GFP groups, but there was no difference between the control and Ad-GFP group. Diagrams are representative of at least three independent experiments.

of proteins contain an N-terminal coiled-coil domain, as well as a C-terminal fibrinogen-like domain that shares a high degree of homology to the analogous domains in the ECM proteins tenascin C and fibrinogen  $\gamma$  and  $\beta$ <sup>[11,2,13]</sup>. In a study of a pro-B cell line that stably expressed Tie2, it has been found that addition of Ang-1 to the culture medium enhanced cell adhesion to fibronectin<sup>[14]</sup>. In another study, fluorescence-activated cell-sorter Tie2-positive hematopoietic cells also responded to Ang-1 treatment with increased adherence to a fibronectin-coated substrate<sup>[15]</sup>. It has been shown recently that Ang-1 promotes cell adhesion<sup>[16]</sup>, and that this process is mediated by  $\alpha$ 5-integrin in ECs<sup>[17]</sup>. Moreover, the finding that Ang-1 can bind ECM extracts from carcinoma cells<sup>[17]</sup> has offered new insights into understanding the role of Ang-1 in modulating the angiogenic microenvironment.

Cancer progression depends on an accumulation of metastasis-supporting genetic modifications and physiological alterations. Often, these physiological

changes are regulated by cell signaling molecules, which target signal transduction pathways and ultimately, gene expression. Cell adhesion is the main step in cancer metastasis, and it is mediated by integrin heterodimers<sup>[18]</sup>. Cross-talk between integrins and growth factor receptors has been shown to coordinate biological processes through the regulation of downstream and inside-out signaling pathways<sup>[19-23]</sup>. Tyrosine kinase receptors and integrins share many downstream effectors.

Integrins have crucial roles in angiogenesis<sup>[24]</sup> and allow vascular cells to adapt their adhesive machinery to the so-called "provisional" ECM components, such as fibronectin, collagen and vitronectin, that are exposed by basement degradation around sprouting vessels<sup>[25]</sup>. Integrins  $\alpha$ v $\beta$ 3,  $\alpha$ v $\beta$ 5,  $\alpha$ 2 $\beta$ 1 and  $\alpha$ 5 $\beta$ 1 are upregulated in newly formed blood vessels<sup>[26,27]</sup>, and  $\alpha$ v $\beta$ 3 and  $\alpha$ v $\beta$ 5 antagonists inhibit angiogenesis *in vitro* and *in vivo*<sup>[28,29]</sup>. Integrins can exist in different functional states that regulate their biological functions<sup>[30]</sup>. Additionally,

**Figure 6** Expression of integrin  $\beta 1$  (A) and CD44V6 (B) protein ( $\times 200$ ). A: Expression of integrin  $\beta 1$  in the Ad-Ang-1-transfected group was  $0.183 \pm 0.014$ , which was significantly higher than that in the control group ( $0.114 \pm 0.023$ ,  $P < 0.05$ ) and Ad-GFP-transfected group ( $0.149 \pm 0.013$ ,  $P < 0.05$ ); B: Compared with the other groups, expression of CD44V6 was also up-regulated. The staining intensity for this protein in the Ad-Ang-1-transfected group ( $0.147 \pm 0.011$ ) was higher than that in the control group ( $0.089 \pm 0.007$ ,  $P < 0.05$ ) and Ad-GFP-transfected group ( $0.065 \pm 0.021$ ,  $P < 0.05$ ). Diagrams are representative of at least three independent experiments.

integrin  $\beta 1$  plays a key role in gastric cancer, and it can mediate cell adhesion.

Integrin  $\beta 1$  is a receptor of Ang-1, therefore, we speculate whether there is a relationship between integrin  $\beta 1$  and Ang-1. In addition, CD44 is a member of the immunoglobulin superfamily that is expressed on most epithelial and non-epithelial cells. Functionally, CD44 binds hyaluronate in the ECM to maintain tissue/organ structure, promote cell aggregation and mediate cell movement, and CD44 variant isoforms, especially CD44v6, have been identified as protein markers for metastasis in hepatocellular, breast, colorectal and gastric cancer<sup>[31-34]</sup>. Therefore, we speculate whether Ang-1 can affect the expression of CD44v6. Moreover, the expression of MMP-2 was stronger in metastatic tissues than in primary tumors. Up regulation of MMP-2 in neoplastic foci might be helpful to gastric carcinogenesis and metastasis<sup>[35]</sup>. In this model, the development of angiogenesis was highly dependent upon MMP-2 expression<sup>[36]</sup>. It has been reported that Ang-1 contributes to increased secretion of MMP-2 and decreased secretion of tissue inhibitors of metalloproteinase-2. Vascular

endothelial growth factor (VEGF) and Ang-1 have an immunomodulatory role in airway remodeling<sup>[37]</sup>. uPA is a serine protease that functions in the conversion of the circulating zymogen plasminogen to the active, broad-spectrum serine protease plasmin. Plasmin, in turn, mediates the pericellular proteolysis of ECM components, and activates other proteases such as MMPs and collagenases, which leads to further degradation and remodeling of the ECM. It has been found that uPA levels are elevated in various malignancies, including breast, pancreatic, gastric, lung and colorectal carcinoma<sup>[38]</sup>. uPA expression is correlated with enhanced VEGF-induced tumor angiogenesis and may play a role in invasion and nodal metastasis of gastric carcinoma, thereby serving as a prognostic marker of gastric cancer<sup>[39]</sup>. Human gastric cancer cell lines express uPA mRNA and activity, which correlates with their peritoneal seeding potential<sup>[40]</sup>. Therefore, we also detected the expression of uPA and MMP-2. We explored the effects of Ang-1 on integrin  $\beta 1$ , CD44V6, uPA and MMP-2 in the human gastric cancer cell line BGC-823, and studied the mechanism of adhesion and metastasis in gastric cancer.

We found that cell adhesion increased clearly in the Ad-Ang-1-transfected group. Therefore, we considered whether Ang-1 can affect the expression of integrin  $\beta$ 1 and CD44V6 through cell adhesion. We found that mRNA and protein expression of integrin  $\beta$ 1 and CD44V6 in BGC823 cells was enhanced, using RT-PCR, Western blotting and immunocytochemistry. We also found that Ang-1 affected the expression of uPA and MMP-2 to increase the invasiveness of gastric cancer. We suggest that there is a signaling pathway between Ang-1, integrin  $\beta$ 1, CD44V6, uPA and MMP-2, and through this pathway, Ang-1 can affect the attachment and metastasis of carcinoma.

## COMMENTS

### Background

Gastric carcinoma is one of the most common cancers worldwide. The mortality of gastric carcinoma is currently rising faster than for any other cancer in China. About 60% of patients die from metastasis of gastric cancer. Progression of this disease may be associated with overexpression of angiopoietin-1 (Ang-1).

### Innovations and breakthroughs

Recent reports have highlighted that Ang-1 has been found to bind integrin  $\beta$ 1 and matrix metalloproteinase-2 (MMP-2). Ang-1 may influence cell adhesion, invasion and migration. This is believed to be the first study to show that overexpression of Ang-1 can affect adhesion, invasion and migration of BGC823 cells through the expression of integrin  $\beta$ 1, CD44V6, MMP-2 and urokinase-type plasminogen activator (uPA).

### Applications

By understanding how Ang-1 affects attachment and metastasis, this study may represent a future strategy for therapeutic intervention in the treatment of patients with gastric carcinoma.

### Terminology

Ang-1 is a member of the angiopoietin family. It has essential functions in vascular and lymphatic growth and remodeling. Integrin  $\beta$ 1 and CD44V6 are members of the cell adhesion family. They mediated cell and extracellular matrix adhesion. MMP-2 and uPA are associated with tumor invasion and migration.

### Peer review

The present study demonstrates a role for Ang-1 in adhesion, migration and invasion of human gastric cancer cells. Specifically, transient transfection of Ang-1 increases attachment and migration of this cell line. The experimental design is well thought out and the results are intriguing.

### Abstract

**AIM:** To develop short hairpin RNA (shRNA) against heparanase, and to determine its effects on heparanase expression and the malignant characteristics of gastric cancer cells.

**METHODS:** Heparanase-specific shRNA was constructed and transferred into cultured the gastric cancer cell line SGC-7901. Stable subclonal cells were screened by G418 selection. Heparanase expression was measured by reverse transcriptase-polymerase chain reaction (RT-PCR), real-time quantitative PCR and Western blotting. Cell proliferation was detected by 2-(4,5-dimethyltriazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) colorimetry and colony formation assay. The *in vitro* invasiveness and metastasis of cancer cells were measured by cell adhesion assay, wound healing

assay and matrigel invasion assay. The angiogenesis capabilities of cancer cells were measured by tube formation of endothelial cells.

**RESULTS:** Stable transfection of heparanase-specific shRNA, but not of scrambled shRNA and mock vector, resulted in reduced mRNA and protein levels of heparanase. The shRNA-mediated knockdown of heparanase did not affect the cellular proliferation of SGC-7901 cells. However, the *in vitro* invasiveness and metastasis of cancer cells were decreased after knockdown of heparanase. Moreover, transfection of heparanase-specific shRNA decreased the *in vitro* angiogenesis capabilities of SGC-7901 cells.

**CONCLUSION:** Stable knockdown of heparanase can efficiently decrease the invasiveness, metastasis and angiogenesis of human gastric cancer cells. In contrast, stable knockdown of heparanase does not affect the cell proliferation.

### INTRODUCTION

Gastric cancer, a serious health problem, remains the second most common type of fatal cancer worldwide because of the invasiveness and metastasis of cancer cells<sup>[1,2]</sup>. Metastasis of tumor cells involves a multistep process, including detachment, invasion, migration, angiogenesis, adhesion to endothelial cells, extravasation, and regrowth in distant organs<sup>[3]</sup>. It has been established that the basement membrane (BM) and extracellular

matrix (ECM) act as a barrier to prevent tumor cells from invasion and metastasis<sup>[4]</sup>. Heparanase (HPA), a mammalian endo-beta-D-glucuronidase, is capable of degrading the heparan sulfate proteoglycans (HSPGs) in the ECM and BM, and is proposed to have a promoting role in cancer invasion, angiogenesis and metastasis<sup>[5]</sup>. In advanced gastric cancer, expression of HPA was frequently observed and correlated with histopathological parameters reflecting the invasiveness, metastatic potential and prognosis of gastric cancers<sup>[6,7]</sup>. Thus HPA may represent an important target for treatment of gastric cancer.

Currently, a variety of HPA inhibitors have been developed, including competitive heparin sulfate-mimicking compounds, neutralizing anti-HPA antibodies, modified non-anticoagulant species of heparin, and inhibitory small molecules<sup>[8]</sup>. It has been reported that inhibiting the expression of HPA can lead to inhibition of tumor invasiveness, metastasis and angiogenesis<sup>[9,10]</sup>. However, because of the multiple biologic activities of these compounds, the mechanism of their antitumor activity and its relation to HPA inhibition are not straightforward<sup>[8-11]</sup>. Moreover, the pleiotropic interactions of these compounds with the ECM and the cell surface might produce nonspecific and undesirable effects<sup>[8-11]</sup>. Thus, novel approaches are needed to reduce the role of HPA in cancer progression<sup>[8]</sup>.

In previous studies, genetic approaches targeting HPA have been regarded as a promising alternative. Antisense oligonucleotides, ribozymes, and short interference RNA (siRNA) have been developed to suppress HPA expression<sup>[12-15]</sup>. However, it still remains unknown whether stable transfection of short hairpin RNA (shRNA) can knockdown the HPA expression and decrease the invasiveness and metastasis of cancer cells. In the current study, the HPA-specific shRNA was constructed and transferred into cultured gastric cancer cells. We demonstrated, for the first time, that stable knockdown of HPA expression decreased the *in vitro* invasive, metastatic and angiogenic capabilities of gastric cancer cells.

## MATERIALS AND METHODS

### Cell culture

Human gastric cancer cell line SGC-7901 and human umbilical endothelial cell line (HUVEC) were purchased from the American Type Culture Collection and grown in RPMI1640 medium (Life Technologies, Inc., Gaithersburg, MD) supplemented with 10% fetal bovine serum (FBS, Life Technologies, Inc.), penicillin (100 U/mL) and streptomycin (100 g/mL). Cells were maintained at 37°C in a humidified atmosphere of 50 mL/L CO<sub>2</sub>.

### shRNA construct for heparanase knockdown and transfection

Oligonucleotides encoding a shRNA specific for the heparanase encoding sequence were subcloned into pGenesil-1 (Genesil Biotechnology, Wuhan, China). Annealed oligonucleotides were cloned downstream of the U6 promoter (primer 1 sequence, 5'-GATCCGGA

ATCAACCTTTGAAGAGCTATGGACACCTTAGT TGGAAACTTCTCTTTTGGAGCTCA-3'; primer 2 sequence, 5'-AGCTTGAGCTGAAAAAAGGAATCA ACCTTTGAAGAGTGTCCATAGCCTTAGTTGGA AACTTCTCG-3'). The sequence 5'-GATCCAGCAUC GUACGUAGGCCA GCTATGGACATCGTAGCAT GCATCCGGTCTTTTGGAGCTCA-3' (sense), and 5'-AGCTTGAGCTGAAAAAAGCAUCGUACGUAG GCCAGTGTCCATAGTCGTAGCATGCATCCGGTC G-3' (antisense) were used as a scrambled RNAi control. The constructs were verified by DNA sequencing. The plasmids pGenesil-1, pGenesil-scrambled, and pGenesil-HPA were transfected with Genesilencer Transfection Reagent (Genlantis, San Diego, CA), according to the manufacturer's instructions. Stable cell lines were screened by administration of G418 (Invitrogen, Carlsbad, CA).

### Real-time quantitative polymerase chain reaction (PCR)

Total RNA was isolated with RNeasy Mini Kit (Qiagen Inc., Valencia, CA, USA). The reverse transcription reactions were conducted with Transcriptor First Strand cDNA Synthesis Kit (Roche, Indianapolis, IN, USA). The PCR primers were designed by Premier Primer 5.0 software as the following: for human HPA 5'-GAATGGACGGACTGCTAC-3' and 5'-CCAAAGA ATACTTGCCTCA-3' amplifying a 261-bp fragment; for human GAPDH 5'-AGAAGGCTGGGGCTCATT G-3' and 5'-AGGGGCCATCCACAGTCTTC-3' amplifying a 258-bp fragment. Real-time PCR with SYBR Green PCR Master Mix (Applied Biosystems, Foster City, CA, USA) was performed using ABI Prism 7700 Sequence Detector (Applied Biosystems). The fluorescent signals were collected during the extension phase, Ct values of the sample were calculated, and HPA transcript levels were analyzed by 2<sup>-ΔΔCt</sup> method.

### Western blotting

Cellular protein was extracted with 1 × cell lysis buffer (Promega, Madison, WI, USA). Protein (50 μg) from each sample was subjected to 4%-20% pre-cast polyacrylamide gel (Bio-Rad, Hercules, CA, USA) electrophoresis and transferred to nitrocellulose membranes (Bio-Rad). For HPA (InSight Company, Rehovot, Israel) and GAPDH (Santa Cruz Biotechnology, Santa Cruz, CA, USA) detection, the primary antibody dilutions were 1:500 and 1:1000, respectively, followed by 1:3000 dilution of goat anti-rabbit horseradish peroxidase-labeled antibody (Bio-Rad). ECL substrate kit (Amersham, Piscataway, NJ, USA) was used for the chemiluminescent detection of signals with autoradiographic film (Amersham).

### Measurement of cell viability

Cell viability was monitored by the 2-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT, Sigma, St. Louis, MO, USA) colorimetric assay. Briefly, 20 μL of MTT (5 mg/mL) was added to each well. After 4 h incubation at 37°C, the cell supernatants were discarded, MTT crystals were dissolved with DMSO and the absorbance measured at 570 nm. Percent viability was defined as the relative absorbance of treated *vs* untreated

control cells. All experiments were done with 6-8 wells per experiment and repeated at least 3 times.

### **Colony formation assay**

The cells were seeded at a density of 300/mL on 35-mm dishes. Colonies were allowed to grow for 10-14 d. The medium was discarded and each well was carefully washed twice with phosphate buffered saline (PBS). The cells were fixed in methanol for 15 min, then stained with crystal violet for 20 min. Finally, positive colony formation ( $> 50$  cells/colony) was counted. The survival fraction for cells was expressed as the ratio of plating efficiency of treated cells to that of untreated control cells.

### **Cell adhesion assay**

$2 \times 10^4$  cells were inoculated into each ECM-coated well of 96-well plates that were precoated with 100  $\mu$ L of 20  $\mu$ g/mL matrigel (BD Biosciences, Franklin Lakes, NJ, USA), and incubated at 37°C in serum-free complete medium (pH 7.2) for 2 h. After incubation, the wells were washed 3 times with PBS and the remaining cells were fixed in 4% paraformaldehyde for 20 min at room temperature. The cells were stained with 0.1% crystal violet and washed 3 times with PBS to remove free dye. After extraction with 10% acetic acid, absorbance of the samples was measured at 570 nm.

### **Wound healing assay**

The cells were scraped with the fine end of 1-mL pipette tips (time 0). Plates were washed twice with PBS to remove detached cells, and incubated with the complete growth medium. Cell migration into the wound empty space was followed after 24 h and photographed.

### **Matrigel invasion assay**

The Boyden chamber technique (Transwell analysis) was performed. Briefly, the 8- $\mu$ m pore size filters were coated with 100  $\mu$ L of 1 mg/mL matrigel (dissolved in serum-free RPMI1640 medium). 600  $\mu$ L of RPMI1640 medium containing 10% FBS was added to the lower chambers. Homogeneous single cell suspensions ( $1 \times 10^5$  cells/well) were added to the upper chambers and allowed to invade for 24 h at 37°C in a CO<sub>2</sub> incubator. Migration was allowed to proceed for 24 h at 37°C. Cells remaining attached to the upper surface of the filters were carefully removed with cotton swabs. Migrated cells were stained with 0.1% crystal violet for 10 min at room temperature and examined by light microscopy. Quantification of migrated cells was performed according to published criteria<sup>[16]</sup>.

### **Tube formation assay**

Fifty microliters of growth factor-reduced matrigel was polymerized on 96-well plates. HUVEC cells were serum starved in RPMI1640 medium for 2 h. The endothelial cells were suspended in RPMI1640 medium preconditioned with subclonal SGC-7901 cells, added to the matrigel-coated wells at the density of  $5 \times 10^4$  cells/well,

and incubated at 37°C for 18 h. Tube formation was visualized using a Leitz inverted microscope equipped with a Sony color digital DXC-S500 camera. Quantification of antiangiogenic activity was calculated by measuring the length of tube walls formed between discrete endothelial cells in each well relative to the control.

### **Statistical analysis**

Unless otherwise stated, all data are shown as mean  $\pm$  standard error of the mean (SEM). Statistical significance ( $P < 0.05$ ) was determined by the Student *t*-test or analysis of variance (ANOVA) followed by assessment of differences using SPSS 12.0 software (SPSS Inc., Chicago, IL, USA).

## **RESULTS**

### **shRNA decreased HPA expression in gastric cancer cells**

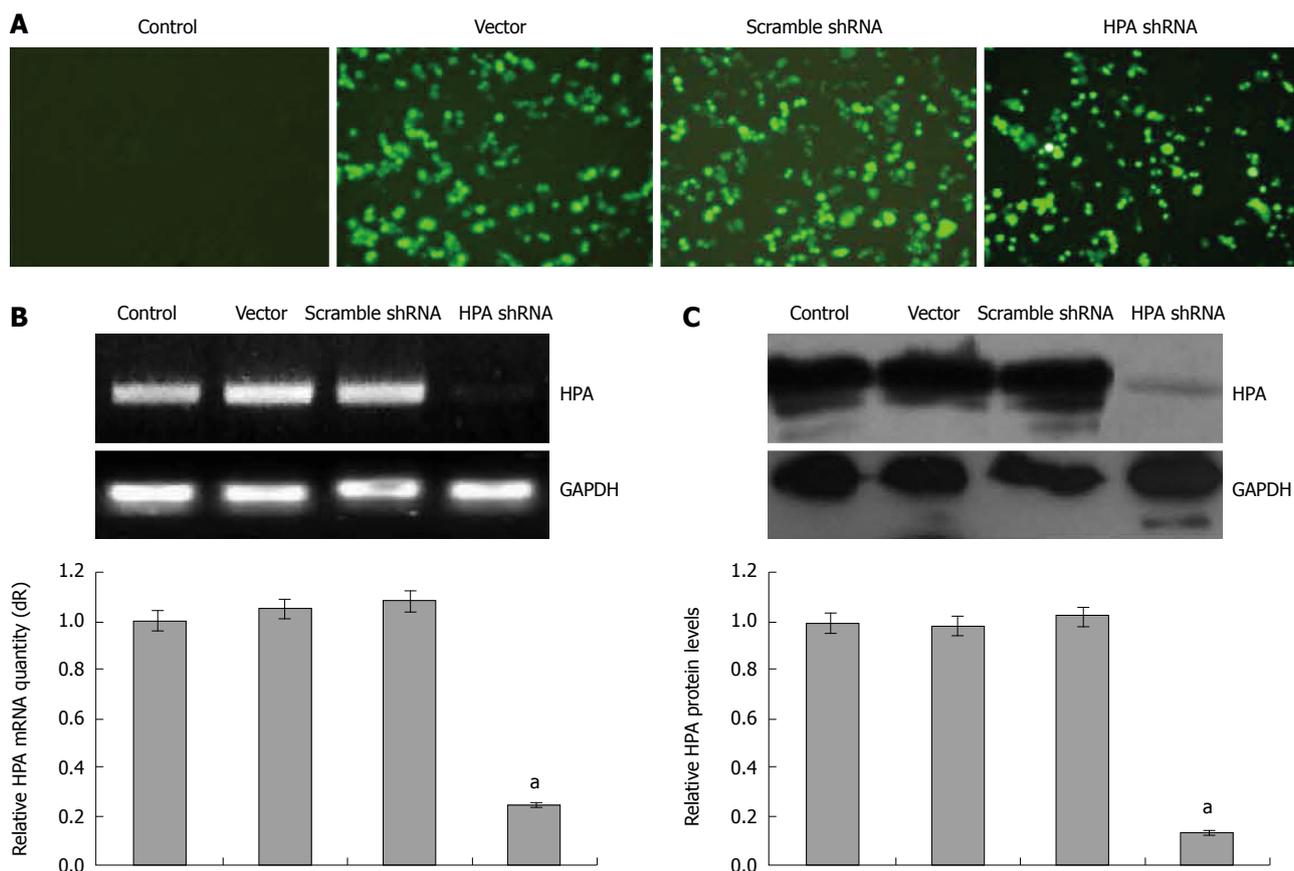

To examine the effects of shRNA on the expression of human HPA, gastric cancer SGC-7901 cells were transfected with pGenesil-1, pGenesil-scrambled, or pGenesil-HPA. The transfection efficiency was monitored by the enhanced green fluorescent protein (EGFP) reporter within these vectors. As shown in Figure 1A, 24 h after the Genesilencer-mediated transfection, EGFP was expressed within the cytoplasm of cancer cells. The subclonal cells were established by G418 selection. The mRNA and protein expression of HPA were examined by reverse transcriptase (RT)-PCR, real-time quantitative PCR and Western blot. As shown in Figure 1B and C, the HPA mRNA and protein could be detected in the parental cells, and stable transfection of the empty vector and scrambled shRNA did not affect the expression level of HPA. However, HPA was significantly decreased in the stable HPA shRNA-transfected cells. These results indicated that the HPA-specific shRNA used in this study was efficient in knockdown of the expression of HPA in gastric cancer cells.

### **Knockdown of HPA did not affect the *in vitro* cell proliferation of gastric cancer cells**

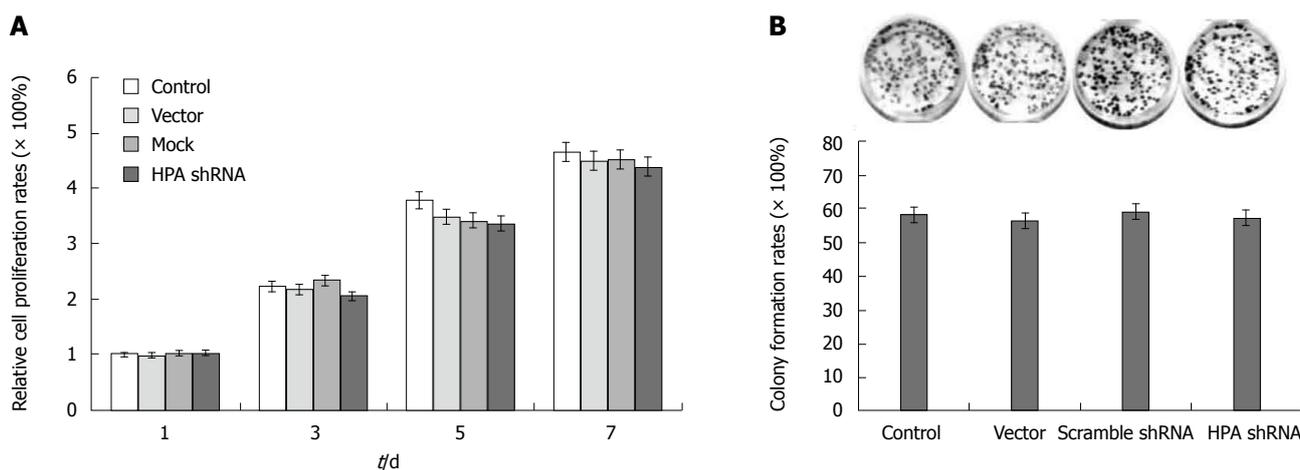

The effects of stable transfection of HPA shRNA on cell proliferation of SGC-7901 cells were measured by MTT colorimetric assay. We found that stable transfection of HPA shRNA or scrambled shRNA, did not affect cell proliferation, when compared to the parental cells and mock group (Figure 2A). In addition, the colony formation assay further revealed that stable transfection of HPA shRNA did not influence the cell proliferation of cultured SGC-7901 cells (Figure 2B). These results indicated that knockdown of HPA did not affect the *in vitro* cell proliferation of gastric cancer cells.

### **Knockdown of HPA decreased adhesion, migration and invasiveness of gastric cancer cells *in vitro***

As cell adhesion, migration and invasiveness are 3 critical steps involved in metastasis, and combined with the evidence that HPA plays critical roles in invasiveness

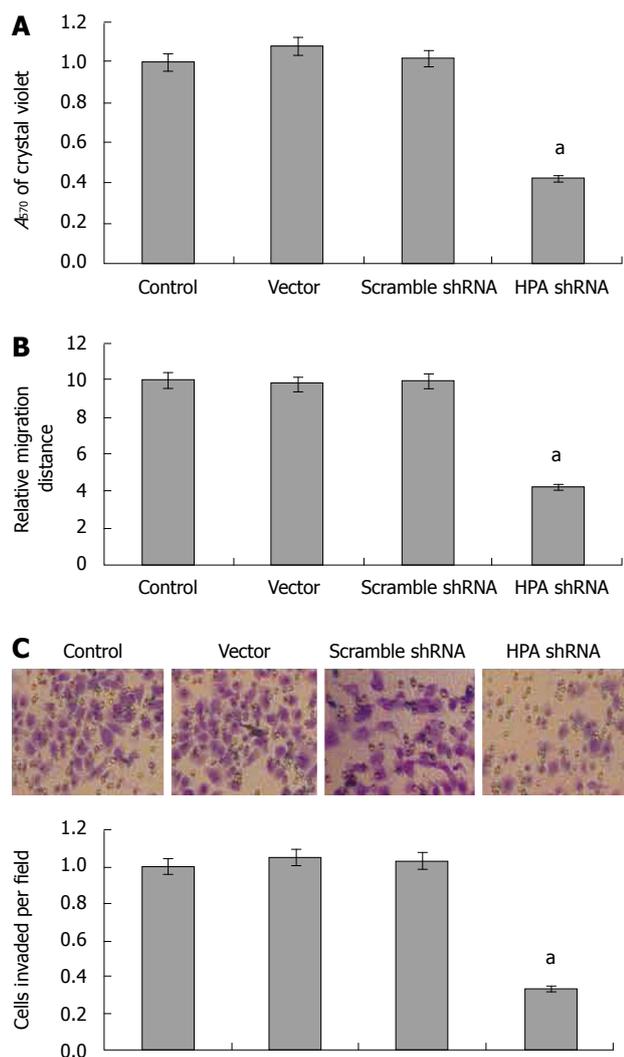

**Figure 1** shRNA suppresses heparanase expression in gastric cancer cells. A: The gastric cancer SGC-7901 cells were transfected with pGenesil-1, pGenesil-scrambled, and pGenesil-HPA. The transfection efficiency was monitored by the enhanced green fluorescent protein (EGFP) reporter within these vectors. The stable subclonal cells were screened by G418 selection; B: RT-PCR and real-time quantitative PCR indicated that stable transfection of empty vector (mock) and scrambled shRNA did not affect the mRNA level of heparanase. However, heparanase mRNA was significantly decreased in the stable shRNA-transfected cells; C: Western blot indicated that stable transfection of heparanase-specific shRNA, but not of scrambled shRNA or vector (mock), resulted in decreased heparanase protein expression in SGC-7901 cells. The symbol (\*) indicates a significant ( $P < 0.05$ ) decrease from parental cells. Experiments were performed in triplicate with essentially identical results.

**Figure 2** Stable knockdown of heparanase does not affect the *in vitro* cell proliferation of gastric cancer cells. A: MTT colorimetric assay indicated that stable transfection of shRNA did not affect the proliferation of SGC-7901 cells, when compared to the parental cells and mock group; B: In the colony formation assay, stable transfection of heparanase-specific shRNA, scrambled shRNA or vector (mock), did not influence the cell proliferation of cultured SGC-7901 cells. Experiments were performed in triplicate with essentially identical results.

and metastasis of cancer cells, we examined the effects of HPA shRNA on these characteristics of gastric cancer cells. In the adhesion assay, SGC-7901 cells stably transfected with HPA shRNA exhibited markedly reduced ability to adhere to the precoated matrigel,

when compared to parental cells and the mock group (Figure 3A). However, the cells stably transfected with scrambled shRNA and vector (mock) had similar ability to adhere as parental cells (Figure 3A). In addition, stable transfection of HPA shRNA into SGC-7901 cells resulted

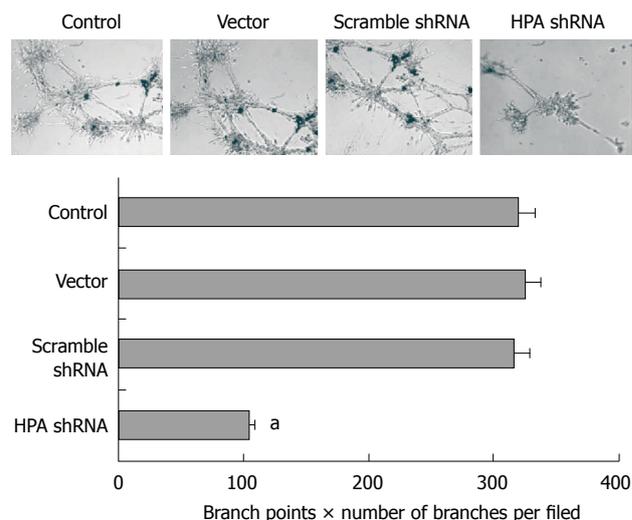

**Figure 3** Stable knockdown of heparanase abolishes the adhesion, migration and invasiveness of gastric cancer cells *in vitro*. A: In the adhesion assay, SGC-7901 cells stably transfected with shRNA exhibited a markedly reduced ability into adhere to the precoated matrigel, when compared to parental cells and vector (mock) group. However, the cells stably transfected with scrambled shRNA had similar ability for adhesion as parental cells; B: In the wound healing assay, the cells stably transfected with heparanase-specific shRNA demonstrated an impaired migration capacity when compared to the parental cells and vector (mock) group; C: In transwell analysis, stable transfection of shRNA abolished the invasive capabilities of SGC-7901 cells, when compared to the parental cells and vector (mock) group. The symbol (<sup>a</sup>) indicates a significant ( $P < 0.05$ ) decrease compared to parental cells. Experiments were performed in triplicate with essentially identical results.

in an impaired migration capacity, when compared to the parental cells and mock group as evidenced by the scratch migration assay (Figure 3B). Moreover, stable transfection of HPA shRNA decreased the invasive capabilities of SGC-7901 cells, when compared to the parental cells and mock group as evidenced by transwell analysis (Figure 3C). These results suggested that HPA-specific shRNA decreased the adhesion, invasiveness and metastasis of gastric cancer cells *in vitro*.

#### Knockdown of HPA inhibited the *in vitro* angiogenesis of gastric cancer cells

We further investigated the effects of HPA-specific

**Figure 4** Stable knockdown of heparanase inhibits *in vitro* angiogenesis of gastric cancer cells. Extensive tube formation of endothelial cells was observed in parental and vector (mock) groups. However, when the endothelial cells were treated by the medium preconditioned with stable heparanase shRNA transfected SGC-7901 cells, tube formation was suppressed. The symbol (<sup>a</sup>) indicates a significant ( $P < 0.05$ ) decrease compared to parental cells. Experiments were performed in triplicate with essentially identical results.

shRNA on the *in vitro* angiogenesis capabilities of SGC-7901 cells. As shown in Figure 4, extensive tube formation of endothelial cells was observed in parental and mock cells. However, when the endothelial cells were treated with medium preconditioned with stable HPA shRNA-transfected SGC-7901 cells, tube formation was significantly decreased (Figure 4). These results indicate that transfection of HPA shRNA markedly decreased the angiogenesis of gastric cancer cells *in vitro*.

## DISCUSSION

Invasiveness and metastasis is one of the characteristics of malignant cells<sup>[17]</sup>. Metastatic cancer cells invade parenchymal tissue and penetrate vascular channels to form satellite tumors in distant organs<sup>[17,18]</sup>. The ECM and BM provide a physical barrier to the migration of cancer cells<sup>[4]</sup>. HSPGs are the essential structural component of ECM and cell surfaces, and are composed of a protein core covalently linked to sulfated glycosaminoglycan<sup>[19]</sup>. The heparan sulfate side chains of HSPGs interact with other components of ECM, such as fibronectin, collagen, and laminin, to provide matrix assembly and stability<sup>[19]</sup>. HPA is the predominant enzyme responsible for degradation of heparan sulfate activity, which is involved in fundamental biologic processes associated with ECM remodeling and cell migration, such as development and morphogenesis, inflammation, angiogenesis, and cancer metastasis<sup>[20-22]</sup>. Many kinds of cells express HPA, such as metastatic tumor cells, proliferating endothelial cells, and activated leukocytes<sup>[23]</sup>. Numerous studies have indicated that HPA is highly expressed in tumors at both the mRNA and protein levels<sup>[24]</sup>. In addition, HPA plays an important role in sustaining the pathology of malignant tumors<sup>[24]</sup>. Expression of HPA is associated with the

aggressiveness of tumor cell lines<sup>[24]</sup>. Increased levels of HPA were detected in the sera of animals bearing metastatic tumors, in the sera of patients with cancer, and in the urine of some patients with aggressive metastatic disease<sup>[25]</sup>, reflecting an association between abnormal HPA secretion and metastatic disease. Thus, HPA is one of the targets for cancer therapy.

It has been established that many potent inhibitors, such as sulfated polysaccharides and heparin-mimicking polyanionic molecules, are capable of inhibiting HPA activity<sup>[8]</sup>. One representative of these inhibitors, PI-88, is being evaluated in a multicentre phase II clinical trial<sup>[26]</sup>. Heparin, other sulfated polysaccharides, and heparin-mimicking molecules that inhibit HPA enzymatic activity also reduce the incidence of metastasis in experimental animals<sup>[21]</sup>. However, because of the potential non-specific activity of these inhibitors and insufficient knowledge of the functional mechanisms of HPA, the application of HPA inhibitors in clinical trials may require further investigation, such as identification of the sugar residues in heparan sulfate adjacent to the HPA cleavage site and the crystallization and analysis of the 3-dimensional structure of the enzyme<sup>[8,27-30]</sup>. In hepatocellular carcinoma cell lines, antisense oligonucleotides decreased HPA expression and inhibited the invasiveness and angiogenesis of cancer cells<sup>[13]</sup>. Uno *et al.*<sup>[31]</sup> constructed an adenoviral vector carrying an antisense full-length human HPA cDNA, and found that HPA expression, and the *in vitro* invasiveness and metastasis of human lung cancer A549 cells were specifically inhibited. Downregulation of HPA by overexpression of either anti-HPA ribozyme or RNA silencing vector has been shown to not only inhibit HPA activity but also impair tumor invasiveness and metastasis, resulting in improved survival of tumor-bearing mice<sup>[14,15]</sup>. In highly metastatic B16-BL6 mouse melanoma cells, transfection of mouse HPA-specific siRNA resulted in a decrease in the invasiveness and metastasis of tumor cells<sup>[14]</sup>.

Previous studies indicated that the expression of HPA was frequently observed in advanced gastric cancers, and the frequency was significantly correlated with histopathological parameters reflecting invasive and metastatic potentials and prognosis of gastric cancers<sup>[6,7]</sup>. Our studies also demonstrated the overexpression of HPA protein in advanced gastric cancer (data not shown). However, it still remains largely unknown whether knockdown of HPA expression can decrease the invasiveness and metastasis of gastric cancer cells. In this study, we constructed HPA-specific shRNA and transfected into cultured SGC-7901 cells. The subclonal cells were generated for stable knockdown of HPA. We found that shRNA decreased HPA mRNA and protein in gastric cancer cells. Stable knockdown of HPA expression decreased the *in vitro* migration, invasiveness and metastasis of gastric cancer cells. However, stable knockdown of HPA expression did not affect the proliferation of SGC-7901 cells, which was consistent with previous findings in human SMMC7721 liver cancer cells and mouse *B16 L6* melanoma cells<sup>[13,14]</sup>.

Previous evidence showed that the cleavage of HSPGs

by HPA may release heparan sulfate-bound cytokines and growth factors from cell surface or from the ECM, such as basic fibroblast growth factor and vascular endothelial growth factor<sup>[29,32]</sup>. Thus, HPA may facilitate tumor cell invasiveness and neovascularization, both critical steps in tumor progression<sup>[33]</sup>. A pronounced correlation between HPA expression and tumor microvessel density has been reported<sup>[34]</sup>. In this study, we found that the angiogenesis of gastric cancer cells *in vitro* was decreased by stable shRNA transfection. To our knowledge, the data described here represent the first successful application of shRNA-mediated gene silencing to stably reduce the levels of HPA in gastric cancer.

In summary, we have demonstrated that stable knockdown of HPA expression can efficiently inhibit the invasiveness, metastasis and angiogenesis of human gastric cancer cells. It is likely that the inhibition of HPA expression possibly depresses the degradation of ECM and BM, thus inhibiting the invasiveness and metastasis of gastric cancer. Therefore, our study suggests that HPA-specific shRNA may be of potential value as a novel therapeutic strategy in human gastric cancer. Combined with our identical results of stable transfection of HPA-specific shRNA into bladder cancer cell lines (data not shown), we believe that this HPA-specific shRNA may be also applicable for the therapies of other cancers overexpressing HPA.

## COMMENTS

### Background

Previous studies have indicated that the heparanase (HPA) is correlated with histopathological parameters and poor prognosis of gastric cancers. Although their efficiencies in inhibiting the expression of HPA, the traditional HPA inhibitors may produce nonspecific and undesirable effects. Thus, novel approaches are needed to inhibit the role of HPA in cancer progression.

### Research frontiers

In recent years, genetic approaches targeting HPA have been regarded as a promising alternative. Antisense oligonucleotides, ribozyme, and small RNA interference (siRNA) have been developed to decrease the HPA expression. However, it remains unknown whether stable transfection of short hairpin RNA (shRNA) can knockdown the HPA expression and decrease the invasiveness and metastasis of gastric cancer cells.

### Innovations and breakthroughs

In the current study, the HPA-specific shRNA was constructed and transferred into cultured gastric cancer cells. The authors demonstrated, for the first time, that stable knockdown of HPA expression decreased the *in vitro* invasive, metastatic and angiogenic capabilities of gastric cancer cells. However, stable knockdown of heparanase does not affect the proliferation of gastric cancer cells.

### Applications

By understanding the effects of HPA-specific shRNA on the *in vitro* invasiveness, metastasis and angiogenesis capabilities of gastric cancer cells, this study may represent a future strategy for therapeutic intervention in the treatment of patients with gastric cancer. In addition, the HPA-specific shRNA may be also applicable for the therapies of other cancers overexpressing HPA.

### Terminology

HPA is a mammalian endo- $\beta$ -D-glucuronidase that is capable of degrading the heparan sulfate proteoglycans in basement membrane and extracellular matrix, and plays important roles in cancer invasion, angiogenesis and metastasis.

### Peer review

The authors examined the effects of HPA-specific shRNA on the cultured gastric cancer cells. It revealed that stable transfection of HPA-specific shRNA decreased the mRNA and protein levels of HPA in SGC-7901 cells.

The shRNA against HPA efficiently decreased the invasiveness, metastasis and angiogenesis of gastric cancer cells. The results are interesting and may represent a novel strategy for the treatment of gastric cancer.

### Abstract

**AIM:** To evaluate the efficacy of granulocyte colony stimulating factors (G-CSF) in liver transplanted patients with hepatitis C (HCV) recurrence and Pegylated-IFN  $\alpha$ -2b induced neutropenia, and to evaluate the impact of G-CSF administration on virological response.

**METHODS:** Sixty-eight patients undergoing antiviral treatment for post-liver transplantation (OLT) HCV recurrence were enrolled. All patients developing neutropenia received G-CSF.

**RESULTS:** Twenty three (34%) received G-CSF. Mean neutrophil count at the onset of neutropenia was 700/mm<sup>3</sup> (range 400-750/mm<sup>3</sup>); after 1 mo of G-CSF it increased to 1210/mm<sup>3</sup> (range 300-5590/mm<sup>3</sup>) ( $P < 0.0001$ ). Three patients did not respond to G-CSF. Treatment duration was similar in neutropenic and non-neutropenic patients. No differences in the rate of discontinuation, infections or virological response were observed between the two groups. G-CSF was protective for the onset of *de novo* autoimmune hepatitis ( $P < 0.003$ ).

**CONCLUSION:** G-CSF administration is effective in the case of Peg-IFN induced neutropenia increasing

neutrophil count, prolonging treatment and leading to sustained virological response (SVR) rates comparable to non-neutropenic patients. It prevents the occurrence of *de novo* autoimmune hepatitis.

### INTRODUCTION

Both interferons (IFNs) and pegylated interferons (Peg-IFNs) may induce neutropenia<sup>[1-4]</sup>. This side effect may limit adherence to treatment which is one of the most important factors related to virological response<sup>[1,5-7]</sup>.

In immunocompetent patients, neutropenia has not been associated with infections. However, in oncological immunodepressed patients neutropenia is associated with infections<sup>[8-10]</sup> and liver transplanted patients are immunosuppressed. In fact, liver transplanted patients have a high rate of infections reaching 56% within the first year post transplantation<sup>[11-13]</sup>. This ease at infections coupled to the baseline leucopenia induced by the immunosuppressive regimens challenging the management of these patients by the clinician.

There are no guidelines on the use of granulocyte colony stimulating factors (G-CSF) for the treatment of IFN induced neutropenia. Moreover, the impact of G-CSF administration during antiviral therapy for chronic hepatitis C has not been determined yet.

Nevertheless, the use G-CSF is becoming a standard of care in this setting, especially in liver transplanted patients, and is recommended by several authors<sup>[5,14-19]</sup>.

A recent study by our group showed that G-CSF administration has a protective effect for the development of *de novo* autoimmune hepatitis during antiviral therapy in transplanted patients<sup>[20]</sup>.

This effect is not surprising as G-CSF has been shown to have several immunological properties: induces T-regulator (T-regs) mobilization and activity, both directly and through the expansion of tolerogenic myeloid precursor and type 2 dendritic cells mobilization; moreover it skews the cytokine profile, inducing tolerogenic dendritic cells and T-regs, which finally suppresses T cell activity<sup>[21-26]</sup>.

The aims of the present study were to evaluate the efficacy of G-CSF use in liver transplanted patients with hepatitis C virus (HCV) recurrence and Peg-IFN  $\alpha$ -2b induced neutropenia, and to evaluate the impact of G-CSF administration on virological response.

## MATERIALS AND METHODS

Patients undergoing antiviral treatment for post orthotopic liver transplantation (OLT) HCV recurrence were consecutively enrolled in Bologna Liver Transplantation Centre between October 2001 and April 2005. All patients received Peg-IFN  $\alpha$ -2b at the dose of 1.0 mcg/kg once weekly (Peg-Intron®, Schering-Plough, Italy), and Ribavirin (Rebetol®, Schering-Plough, Italy) at a dose of 8-10 mg/kg per day. Transplanted patients had to fulfil the following criteria for antiviral treatment: detectable HCV-RNA by PCR, elevated ( $> 1.0 \times$ ) serum alanine aminotransferase (ALT) levels and histological features of HCV hepatitis on liver biopsy. Exclusion criteria were: evidence of decompensated liver disease, histological evidence of rejection and drug-related injury, HBsAg positivity, human immunodeficiency virus (HIV) positivity, moderate to severe anemia (Hb  $< 10$  g/dL), neutropenia (neutrophil count  $< 1000/\text{mm}^3$ ), thrombocytopenia (PLT  $< 50000/\text{mm}^3$ ), impaired renal function (creatinine clearance  $< 50$  mL/min), significant history of cardiovascular and psychiatric diseases, ongoing alcohol abuse and previous post-LT treatment with PEG-IFN. Hematologic determinations were carried out using conventional tests at baseline and weekly for the first month, then monthly until the end of the study.

All patients developing neutropenia during antiviral treatment received Granulocyte Colony-Stimulating Factor (G-CSF) (Granulokine®, Roche, Italy). Below 750/mmc neutrophils, G-CSF 300  $\mu\text{g}/\text{wk}$  was administered and in case of non significant response the dose was increased to 600  $\mu\text{g}/\text{wk}$ . When the neutrophil count did not increase satisfactorily, despite G-CSF administration, Peg-IFN dose was reduced. When neutrophils fell below 500/mmc despite G-CSF administration, antiviral treatment was discontinued. G-CSF treatment was continued until restoration of neutrophil count to values comparable

to the patient's baseline. None of the patients received azathioprine or mycophenolate mofetil.

All patients gave written informed consent according to the Ethical Committee Procedures of our Hospital for the administration of off label drugs.

## Statistical analysis

Data were analyzed on an intention-to-treat-basis. Results are presented as median (range). Non parametric tests were used to compare variables between groups (Wilcoxon,  $\chi^2$  test). All  $P < 0.05$  by the two-tailed test were considered significant. All data analyses were conducted using the MedCalc Package.

## RESULTS

Sixty-eight patients (46 males and 22 females), median age 59 (22-68 years) were enrolled in the study (Table 1). Ten patients were cirrhotic at enrolment. Twenty three (34%) received G-CSF according to our study design. Table 2 shows the baseline characteristics of patients developing neutropenia or not and of all patients together. The only factor related to neutropenia development was pre-treatment neutrophil count, which was significantly lower in patients who later developed neutropenia and were treated with G-CSF. Median neutrophil count at the onset of neutropenia was 700/mmc (range 400-750/mmc) and after one month

of G-CSF administration it increased to 1210/mmc (range 300-5590/mmc) ( $P < 0.0001$ ) (Figure 1). Mean G-CSF treatment duration was  $4.9 \pm 3.6$  mo. Three patients did not respond to G-CSF administration after one month; two patients had an improved neutrophil count with an increased dose of G-CSF and a reduction of Peg-IFN dose and continued treatment until the end of the planned 48 wk period, the other discontinued treatment. No patient had to reduce their Peg-IFN dose in the non-neutropenic group. Table 3 shows Ribavirin (RBV) and Peg-IFN dose modification during treatment in both groups. At multivariate analysis, several factors were evaluated (age, sex, time from OLT, type of immunosuppression, presence of cirrhosis, basal neutrophil count) but none was associated with non response to G-CSF.

The mean treatment duration was similar in neutropenic and non-neutropenic patients regardless of G-CSF administration and genotype (Figure 2A).

Causes of premature discontinuation are shown in Table 4. No significant differences in the rate of discontinuation were observed between the two groups (neutropenic and non-neutropenic) (Figure 2B).

Two severe infections were observed in the G-CSF group (1 pneumonia and 1 urinary infection) and 5 in the non-neutropenic patients (3 pneumonias, 1 liver abscess and 1 cytomegalovirus) ( $P =$  No significance) (Figure

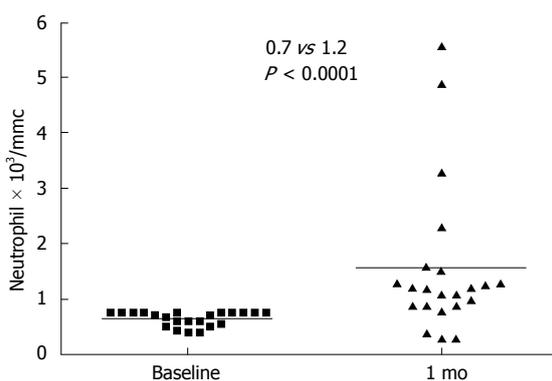

Figure 1 Neutrophil count response after 1 mo of granulocyte colony stimulating factors administration.

2C). Among neutropenic patients, the neutrophil counts were  $700/\text{mm}^3$  and  $900/\text{mm}^3$  respectively at the onset of infections. In non-neutropenic patients developing infections, the neutrophil count was  $> 1000/\text{mm}^3$  in all at the onset of neutropenia.

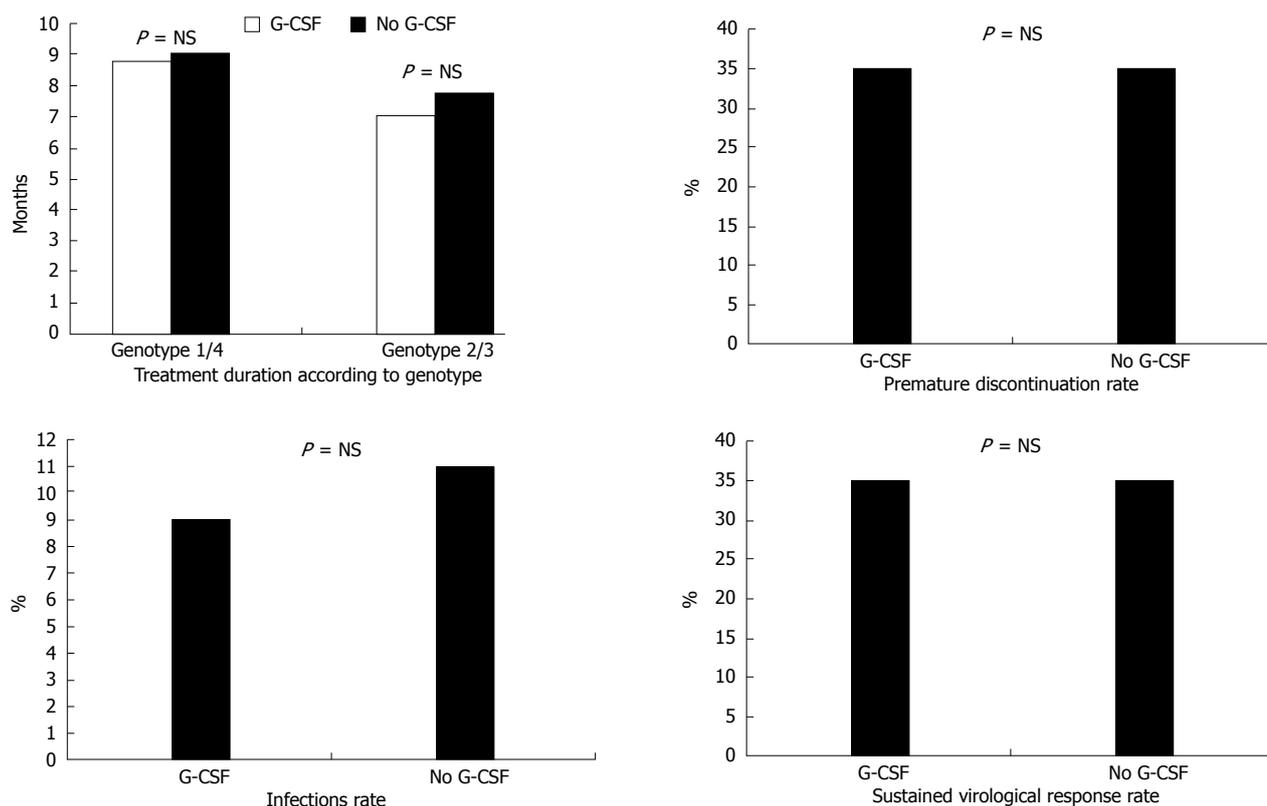

### Viral response

Sustained virological response was 30% in the G-CSF group versus 35% in the non-neutropenic patients ( $P =$  NS) (Figure 2D).

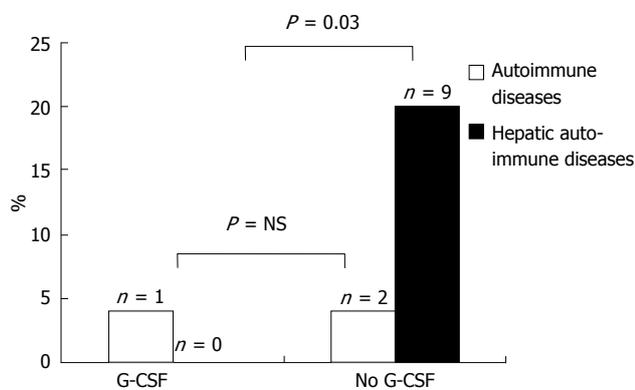

### Autoimmune diseases

In the G-CSF group no *de novo* hepatic autoimmune disease was observed, while 9 patients in the other group developed autoimmune hepatitis ( $P < 0.03$ ) (Figure 3). This pathological entity has already been extensively described by our group<sup>[20]</sup> and therefore won't be discussed in detail here. *De novo* autoimmune hepatitis diagnosis was performed in patients with an unexplained cause of graft dysfunction, after the exclusion of other known causes (infections, anastomoses complications, acute or chronic rejection) and the application of the International Autoimmune Hepatitis Group score<sup>[27]</sup>. This disease was related to severe patient and graft outcome; in fact two patients died and two had a graft failure with one patient re-enlisted for transplant. In our series no rejection episodes were observed.

The incidence of non hepatic autoimmune manifestations was similar in the two groups. One patient had autoimmune thyroiditis and another had systemic lupus erythematosus (SLE) responding to

**Figure 2** Comparison of treatment duration, premature discontinuation rate, infections rate and sustained virological response (SVR) rate between neutropenic patients treated with G-CSF and untreated non-neutropenic patients.

**Figure 3** Incidence of hepatic and systemic autoimmune diseases in neutropenic patients treated with G-CSF and untreated non-neutropenic patients.

steroid treatment<sup>[28]</sup> in the G-CSF group, while among non-neutropenic patients, one had autoimmune gastritis.

## DISCUSSION

Our data shows that G-CSF administration is effective in resolving neutropenia in transplanted patients treated with Peg-IFN  $\alpha$ -2b for HCV recurrence. The improvement or the resolution of neutropenia allowed us to prolong treatment duration to a time which is comparable to that of non-neutropenic patients and presumably contributed to patients reaching an SVR rate which was comparable in the two groups. G-CSF administration did not affect the rate of infections or the

occurrence of non hepatic autoimmune diseases, while it was a protective factor for the development of *de novo* autoimmune hepatitis. The only predictive factor related to the development of neutropenia during antiviral treatment was pre-treatment neutrophil count.

Clinical experience, mainly from studies in immunocompetent patients, suggests that maintenance of optimal dosages of Peg-IFN and RBV results in higher rates of SVR. Previous studies on liver transplanted patients have shown that, overall, a SVR between 30% and 45% is achievable<sup>[29-35]</sup>. Therefore, in our opinion, adjunctive treatments allowing the maintenance of optimal dosages of Peg-IFN and RBV during treatment are advisable. In our series the rate of SVR was not significantly different among patients treated and not treated with G-CSF. The lack of a statistically significant difference could be affected by the small number of patients, but the rate of SVR in neutropenic patients treated with G-CSF is comparable to what is reported in literature. Moreover, although not statistically significant, a larger proportion of patients had to reduce or suspend RBV in the G-CSF group, and this factor might have contributed to the smaller SVR rate in this group.

There are currently no guidelines on the use of G-CSF in IFN induced neutropenia. Therefore, no established common approach to its use is defined in both the immunocompetent and the transplanted patient. In this context we arbitrarily defined cut off values to begin G-CSF administration. In consideration of the immune depression of our patients we chose a high cut off level of 750 neutrophils/mm<sup>3</sup> for initiation of treatment in

order to prevent infections. We are aware that previous studies in immunocompetent patients did not show a correlation between the absolute number of neutrophils and infections<sup>[2,36,37]</sup>, but in immunodepressed oncological patients this correlation exists<sup>[8-10]</sup>; this induced us to choose a safer cut off value. Unfortunately ours was not a randomised study, because in our opinion it would be not ethical not to treat a severe neutropenia in a transplanted immunosuppressed patient. Nevertheless, in our study infections seemed to be independent of neutrophil count. Anyway, our study shows that G-CSF use in transplanted patients is safe and effective.

With regard to autoimmune diseases, our study suggests that G-CSF protected from *de novo* autoimmune hepatitis but not from other systemic autoimmune manifestations. This is not surprising, as G-CSF has been reported to have different effects in different autoimmune diseases<sup>[38-40]</sup>. This probably depends on the immune pathogenetic mechanisms underlying the different diseases. However, the apparently induced non hepatic autoimmune manifestations did not significantly impact on patients outcome while *de novo* hepatitis was severe and related to high patient and graft loss, suggesting that the onset of non hepatic autoimmune manifestations does not contraindicate G-CSF use in this population.

In conclusion, our study supports G-CSF administration in transplanted patients with HCV recurrence developing Peg-IFN induced neutropenia because it is effective in increasing the neutrophil count. G-CSF administration prolongs treatment duration in neutropenic patients leading to SVR rates which are comparable to that of non-neutropenic patients. A pre-emptive treatment with G-CSF could be advisable in patients with very low pre-treatment neutrophil counts. G-CSF seems to have a protective role against the occurrence of *de novo* autoimmune hepatitis, a recently defined pathogenetic entity related to a severe outcome. Prospective randomized studies are needed in order to evaluate the protective effect of prophylactic G-CSF administration to prevent this form of autoimmune hepatitis.

## COMMENTS

### Background

The treatment of liver transplanted patients with hepatitis C virus (HCV) recurrence is based on a combination of Pegylated Interferon (PegIFN) and Ribavirin, with disappointing results. A key factor for response to IFNs is adherence to treatment, which is challenging in immunodepressed patients in whom PegIFN dose reductions for neutropenia are often required. This study aims to evaluate the efficacy and the impact on virological response of granulocyte colony stimulating factors (G-CSF) administration in transplanted patients developing PegIFN related neutropenia.

### Research frontiers

There are no guidelines on the use of G-CSF for the treatment of IFN induced neutropenia. Moreover, the impact of G-CSF administration during antiviral therapy for chronic hepatitis C has not been determined yet. Nevertheless, the use of G-CSF is becoming a standard of care in this setting, especially in liver transplanted patients, and is recommended by several authors. A recent study by the authors' group showed that G-CSF administration has a protective effect on the development of *de novo* autoimmune hepatitis during antiviral therapy in transplanted patients.

### Innovations and breakthroughs

This is the first study conducted to investigate the efficacy of G-CSF in liver

transplanted patients with PegIFN induced neutropenia. It shows that G-CSF administration is effective at increasing the neutrophil count, prolonging treatment and leading to SVR rates comparable to those in non-neutropenic patients. Moreover, it confirms the observation that G-CSF has a protective role with regard to the occurrence of *de novo* autoimmune hepatitis.

### Applications

This study is of clinical interest to physicians treating recurrent HCV after liver transplantation. Based on the results, the use of G-CSF in liver transplanted patients with PegIFN induced neutropenia is advisable.

### Terminology

HCV recurrence: the reinfection of the graft by HCV post-liver transplantation is universal and is associated with a worse outcome. G-CSF is granulocyte colony stimulating factor hormone, which stimulates the bone marrow to produce granulocytes and stem cells

### Peer review

This work is an interesting pilot study describing the potential benefits of using G-CSF to treat IFN-induced neutropenia in recurrent HCV infection after liver transplantation.

### Abstract

**AIM:** To investigate factors predicting failure of percutaneous endoscopic gastrostomy (PEG) to eliminate gastroesophageal reflux (GER).

**METHODS:** Twenty-nine consecutive mechanically ventilated patients were investigated. Patients were evaluated for GER by pH-metry pre-PEG and on the 7th post-PEG day. Endoscopic and histologic evidence of reflux esophagitis was also carried out. A beneficial response to PEG was considered when pH-metry on the 7th post-PEG day showed that GER was below 4%.

**RESULTS:** Seventeen patients responded (RESP group) and 12 did not respond (N-RESP) to PEG. The mean age, sex, weight and APACHE II score were similar in both groups. GER (%) values were similar in both groups at baseline, but were significantly reduced in the RESP group compared with the N-RESP group on the 7th post-PEG day [2.5 (0.6-3.8) vs 8.1 (7.4-9.2,  $P < 0.001$ )]. Reflux esophagitis and the gastroesophageal flap valve (GEFV) grading differed significantly between the two groups ( $P = 0.031$  and  $P = 0.020$ , respectively). Histology revealed no significant differences between the two groups.

### INTRODUCTION

Gastroesophageal reflux (GER) is a common problem in critically ill patients and constitutes a major mechanism of esophageal mucosal injury or erosive esophagitis in mechanically ventilated patients<sup>[1,2]</sup>. Nasogastric tube (NGT) plays a significant role in the development of GER in these patients<sup>[3]</sup>. GER is considered to be a major risk for ventilator-associated pneumonia (VAP), which is associated with prolongation of Intensive Care Unit (ICU) stay and increased mortality<sup>[4,5]</sup>. The judicious use of NGT, the semi-recumbent position and the application of strategies to improve gastric emptying are the proposed measures for preventing GER and thus minimizing VAP<sup>[5-7]</sup>.

The relationship between percutaneous endoscopic gastrostomy (PEG) and subsequent development of GER is complex and not well understood. The reported effects of PEG on GER are contradictory. Some authors reported the development or worsening of GER after PEG<sup>[8,9]</sup>, while others claimed the opposite<sup>[10,11]</sup>. Johnson *et al*<sup>[11]</sup> reported that PEG tube placement decreases

GER by increasing the lower esophageal sphincter pressure (LES), and showed that the anterior apposition of the stomach by PEG has a similar effect to gastropexy and increases LES pressure. The latter was argued by Coben *et al*<sup>[12]</sup>, who found that gastrostomy tubes had no effect on basal LES pressure. Few studies, however, have evaluated the effect of PEG on GER in mechanically ventilated patients. In a prospective randomized trial, we have shown that PEG when combined with the semi-recumbent position and control of gastric residue, can decrease GER in the majority of these patients<sup>[13]</sup>. In this new prospective study we aimed to explore the factors that interfere with failure of PEG to reduce GER in critically ill, mechanically ventilated patients.

## MATERIALS AND METHODS

Patients eligible for this study were all mechanically ventilated, were tolerating nasogastric feeding *via* NGT and had prolonged ICU stay. Enteral feeding was performed at a continuous infusion rate of 80 to 100 mL/h. Exclusion criteria were unstable hemodynamic state, the administration of morphine, atropine, theophylline, barbiturates or cisapride, the presence of bloated intestine, and a past history of gastroesophageal reflux disease or hiatus hernia. The patients were divided into 2 groups based on whether GER decreased to less than 4% (responders, RESP group) or remained unchanged or worsened (non-responders, N-RESP group) after PEG placement. The institutional review board approved the study and informed consent was obtained from each patient's next of kin.

### Study design

Antacids, H<sub>2</sub> receptor blockers or proton pump inhibitors were withdrawn 7 d before the study; sucralfate (2 g twice daily *via* NGT) was provided thereafter for gastric mucosa protection. Patients were neither sedated nor paralyzed. Enteral feeding was stopped 6 h before and during the period of pH-metry, which was performed on a 24 h basis. Gastrostomy was performed by the pull through (Ponsky) technique the day after<sup>[14]</sup>. Monitoring of pH was repeated on the 7th post-PEG day in order to assess the effect of PEG on eliminating or reducing GER%.

On the second post-PEG day, patients were administered continuous drip PEG-feeding with a polymeric diet at 60 mL/h and an energy content of 1000 kcal/L (Fresenius, Bad Homburg, Germany). Patients were placed in a semi-recumbent position (30°) and the volume of the gastric nutrient residue was determined to obviate gastric stasis. This was realized by aspirating the gastric content with a syringe at 8-h intervals to verify if the nutrient volume exceeded 200 mL. If the volume did exceed 200 mL, feeding was withheld and if volume persisted, the nutrient was drained. Feeding was re-administered when the volume was decreased.

### Endoscopic evaluation

The presence or absence of hiatus hernia, reflux es-

ophagitis and the grading of gastroesophageal flap valve (GEFV) were examined and scored according to the criteria below by two endoscopists. Biopsy specimens were obtained from the lower 3 cm of the esophagus for histological examination.

**Reflux esophagitis:** Reflux esophagitis was graded according to the Los Angeles classification<sup>[15]</sup>.

**GEFV:** This was assessed by the grading system of Hill *et al*<sup>[16]</sup>, as follows: Grade I: Normal ridge of tissue closely approximated the shaft of the retroflexed scope. Grade II: The ridge is slightly less well defined and opens with respiration. Grade III: The ridge is barely present and the hiatus is patulous. Grade IV: There is no muscular ridge and the hiatus is wide open at all times. GEFV grades I and II were regarded as representing normal GEFV, while grades III and IV were regarded as representing abnormal GEFV.

**Esophageal pH-metry:** The presence of gastroesophageal reflux was demonstrated by using 24-h double sensor catheter system pH monitoring. Baseline and 7th d post-PEG pH-metry was carried out using the portable recorder Digitrapper Mk III (Synectics Medical AB, Stockholm, Sweden). Briefly, after ordinary NGT removal, the sensor probe was introduced *via* the nose into the stomach until acid pH was recorded with the distal sensor as previously described<sup>[13]</sup>. The probe was then slowly withdrawn until the distal sensor channel detected a sudden pH change from acid (< 4) to above 5. The electrode was then withdrawn another 5 cm. In this way, the distal and proximal sensors were located at 5 and 20 cm above the lower esophageal sphincter, respectively. The correct positioning of the electrode was verified at the end of pH-metry and before its withdrawal by a chest x-ray. The recording device measured pH values every 4 s and stored the mean of 20 values every 80 s. Gastroesophageal reflux was expressed as the percentage of time that the esophageal pH was less than 4 in the given 24-h period [GER (%)], with a value of > 4% considered abnormal<sup>[17]</sup>. Additionally, the number of reflux episodes per hour and the number of reflux episodes lasting longer than 5 min in 24 h were measured and recorded. The pH-metry from the lower esophageal sensor consistently recorded GER 15%-20% higher than that from the upper sensor. However, since the importance of reflux detection in the upper part of the esophagus is greater in relation to aspiration, only data from the upper sensor are presented.

### Histological evaluation

Biopsies were assessed by two experienced histopathologists and scored for surface ulceration (present or absent), basal cell hyperplasia (score 0-3), acute inflammatory infiltration of the epithelium (score 0-3) and the lamina propria (score 0-3) and presence of long papillae (score 0-3) to produce an overall histological score (ranging from 0 to 12). The interobserver variability was <

Grade II	6	5	
Grade III	1	3	

<sup>1</sup>LA classification; <sup>2</sup>GEFV: Gastroesophageal flap valve (grading after Hill classification<sup>[16]</sup>). <sup>a</sup>P < 0.05.

5%. In case of disagreement, reevaluation was performed jointly by the two observers so that a consensus could be reached. Complete surface ulceration was scored as 12 and no other epithelial changes were assessed. Overall histological score of 0-2 corresponded to grade zero, 3-4 corresponded to grade I, 5-8 to grade II and 9-12 to grade III histological esophagitis.

### Statistical analysis

Data are reported as median and inter-quartile range (Q1-Q3). Comparisons among groups (responders, non-responders) were made using the Mann-Whitney test. Comparisons (number of reflux episodes) within groups were performed by the Wilcoxon's rank sum test. The Pearson's  $\chi^2$  test or Fisher's exact test when appropriate, were used to examine the association between qualitative variables. The Spearman rank correlation coefficient ( $r_s$ ) was calculated to describe the relationships between variables. A P-value less than 0.05 was considered significant.

Table 2 Comparison of esophageal manometry findings between the RESP and N-RESP groups

	RESP group (n = 17)	N-RESP group (n = 12)	P value

Parameters are expressed in median (range). <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.001.

## RESULTS

### Patients' profiles

A cohort of 29 consecutive mechanically ventilated patients undergoing PEG was prospectively evaluated. Demographic data are listed in Table 1. Patients were divided into the RESP group (n = 17) and the N-RESP group (n = 12). The mean age, sex, weight and APACHE II score were similar in both groups. The reasons for PEG tube placement were as follows: cerebrovascular attack 48.2% (n = 14), neuromuscular disorder 13.7% (n = 4), COPD-pneumonia 20.6% (n = 6), and trauma 17.2% (n = 5). The median number of days of nasogastric tube placement before PEG was 29.5 in the RESP group *vs* 45 in the N-RESP group (NS, Table 1), which denotes a similar pre-PEG timing in the two groups.

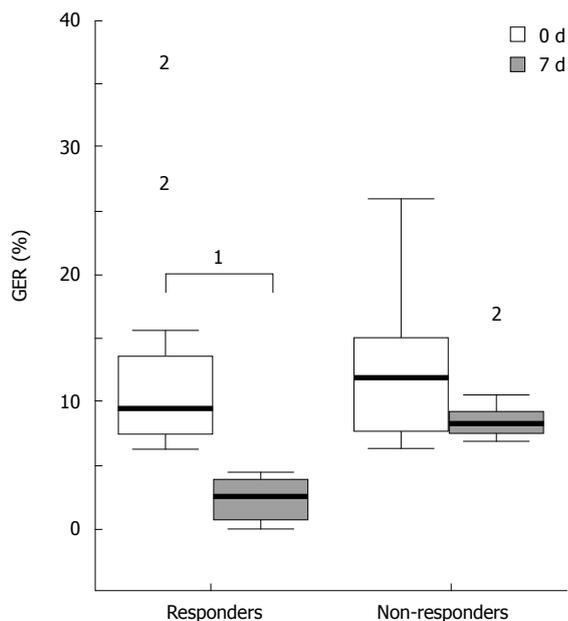

### Findings of pH monitoring

All variables from esophageal pH-metry are listed in Table 2. GER (%) values were similar in both groups at baseline, but were significantly reduced in the RESP group compared with the N-RESP group at the 7th post-PEG day (P < 0.001, Figure 1). The median (range) number of reflux episodes > 5 min and the number of reflux episodes/h decreased significantly at the 7th post-PEG day in the RESP group (P < 0.001) compared to baseline, but not in the N-RESP group (NS). Both variables were significantly higher at baseline in the RESP group compared with in the N-RESP group [7 (4-9) *vs* 3.5 (2-6), P = 0.045 and 8 (3-10) *vs* 2.9 (2-4.4), P = 0.020, respectively].

### Endoscopic findings

Reflux esophagitis assessed at PEG tube placement was observed in 100% of the study population (Table 3). There was a significant difference between the two groups: grade A:B:C:D = 11:6:0:0 in the RESP group (n = 17) *vs* 4:4:4:0 in the N-RESP group (n = 12), P = 0.031, respectively. The presence of reflux esophagitis correlated with GEFV grading ( $r_s = 0.465$ , P = 0.011). Hiatus hernia was not observed in any of the patients studied.

The GEFV appearance differed significantly between the two groups (P = 0.020, Table 3). Ten patients in the

**Figure 1** The median (interquartiles) variation in GER-% using two successive pH-metry readings performed in the responders (RESP) and non-responders (N-RESP) to PEG patients. <sup>1</sup>Denotes statistical significance; <sup>2</sup>Denotes outlier cases.

RESP group and 2 in the N-RESP group were evaluated as normal GEFV, while 7 and 10 patients, respectively, were evaluated as abnormal GEFV.

### Histologic findings

The histologic results are summarized in Table 3. The histology of esophageal biopsies was normal in 10.3% (2/17 and 1/12 in the RESP and N-RESP groups, respectively). There was no significant difference between the two groups: grade 0:1:2:3 = 2:8:6:1 in the RESP group ( $n = 17$ ) vs 1:3:5:3 in the N-RESP ( $n = 12$ ), respectively,  $P = \text{NS}$ . Histologic grading showed a good correlation with endoscopic grading ( $r_s = 0.705$ ,  $P = 0.000$ ).

Weaning from mechanical ventilation was achieved in 13/17 (76.4%) of responders within 10 (6.5-14) d, whereas 7/12 (58%) of non-responders required 13 (12-20) d (NS). Three patients in the RESP group (17.6%) and five in the N-RESP group (41.6%) died while in the ICU (NS). The deaths were unrelated to the PEG tube procedure.

## DISCUSSION

The results of this study confirm previous findings that PEG tube placement can eliminate GER in mechanically ventilated patients<sup>[13]</sup>. Our findings also provided evidence that the presence of severe reflux esophagitis and the gastro-esophageal flap valve grade are factors that predict failure of PEG to control GER in these patients.

The mechanisms that cause GER in mechanically ventilated patients differ from conscious patients<sup>[11]</sup>. Transient lower esophageal sphincter relaxation (TLESR) is believed to be the major mechanism of acid reflux in awake patients, with a defective basal LES pressure caused by hiatus hernia and straining associated with

increased abdominal pressure being contributing factors<sup>[18,19]</sup>. In contrast, the absent or very low basal LES pressure induced by mechanical ventilation, opiates, endotoxemia-related sepsis and nasogastric tube are the major causes of reflux in critically ill patients<sup>[1,2,7,20]</sup>. The latter is considered to be a key factor for both the development and the degree of GER<sup>[21]</sup>. In several studies, 48%-60% of ICU patients were found to have erosive esophageal lesions induced by GER, 3 or 5 d after NGT placement<sup>[2,22]</sup>. Furthermore, the degree of GER correlates with the duration of NGT. In an earlier study, we showed a positive correlation between the duration of nasogastric intubation and the degree of GER<sup>[13]</sup>. These findings were also validated in the current study, which showed 100% incidence of GER in patients with long-standing NGT.

Few data exist in the literature regarding the influence of PEG tube placement on GER in mechanically ventilated adult patients. We have reported the effectiveness of PEG in decreasing GER (%) by more than 60%, compared to baseline, at the 7th post-PEG day in 16 critically ill patients<sup>[13]</sup>. Our data are in agreement with previous findings and show a significant reduction in GER% at the 7th post-PEG day in 17/29 (58.6%) of the studied population. Similarly, both the number of reflux episodes/h and those lasting > 5 min were significantly reduced in the RESP group. However, this was not the case for the N-RESP group, although these variables were significantly increased at baseline in the former group of patients (Table 2). Overall, PEG tube placement improved (or at least did not deteriorate) both GER (%) and the two indices tested for gastroesophageal reflux. This is in agreement with previous findings which demonstrated that GER is not a contraindication to PEG<sup>[23]</sup>.

Reflux esophagitis occurs in approximately 25%-30% of critically ill patients undergoing endoscopy and GER is considered a major cause<sup>[1,7]</sup>. However, not all patients with gastroesophageal reflux have esophagitis. In this study, reflux esophagitis assessed by endoscopy, was present in 100% of the study population and showed a good correlation with GER ( $r_s = 0.465$ ,  $P = 0.011$ ). The increased incidence of reflux esophagitis and GER (%) in this study could be attributed to prolonged NGT placement [mean 29.5 (25-38) and 45 (25-53) d for the RESP and N-RESP groups, respectively] and to the removal of proton pump inhibitors 7 d prior to the study. It is well known that these agents bind with and inactivate the gastric parietal cell proton pump ( $\text{H}^+/\text{K}^+$ -ATPase) which, in turn, inhibits gastric acid production and raises gastric pH<sup>[24]</sup>.

Grading of GEFV differed significantly between the two groups ( $P = 0.020$ ). Approximately 83% of subjects with abnormal GEFV (grades III and IV) were in the N-RESP group vs 41% of the RESP group, suggesting that endoscopic grading of GEFV pre-PEG provides useful information for predicting failure of PEG to reduce GER.

Heikinen *et al*<sup>[25]</sup>, have demonstrated a poor valid-

ity between the severity of histologic evidence of esophagitis and significant GER. Our data are in keeping with this concept and showed no significant correlation between pre-PEG histological evaluation and the development of GER post-PEG. That is, evaluation of esophageal histology pre-PEG does not reliably predict the development of reflux after PEG placement.

Our study has some strengths and limitations. The strengths include the prospective design and the follow-up pH-metry on the 7th post-PEG day. In contrast, the study is limited due to the small sample size, so data should be extrapolated with caution.

In conclusion, the results of this study indicate that the endoscopic grading of GEFV and the presence of severe reflux esophagitis graded LA classification C or D are predisposing factors of failure of PEG to reduce GER in mechanically ventilated patients. We also provided evidence that gastroesophageal reflux is not a contraindication for PEG tube placement. The latter seems to eliminate or at least not exacerbate GER in these patients.

## COMMENTS

### Background

Gastroesophageal reflux (GER) is a common problem in mechanically ventilated patients and contributes to the development of esophageal mucosal injury and even erosive esophagitis.

### Research frontiers

One of the main factors that have been implicated in the pathogenesis of GER in these patients is the placement and duration of a nasogastric tube (NGT). NGT may lead to GER through relaxation of the lower esophageal sphincter (LES) pressure. The authors have previously shown that percutaneous endoscopic gastrostomy (PEG) can eliminate GER by disengaging patients from the presence of NGT. In this study, the aforementioned findings are further confirmed and the authors identified factors, including the presence of severe reflux esophagitis and gastroesophageal flap valve grade that predict failure of PEG to eliminate GER.

### Innovations and breakthroughs

The presence of NGT and mechanical ventilation are factors predisposing to the development of GER. However, few data exist regarding the effect of PEG tube placement in the prevention of GER in mechanically ventilated adult patients. In the present study the authors identified factors which could predict PEG failure to reduce GER.

### Applications

By identifying the factors that predict failure of PEG to decrease GER, this study may represent a reference in deciding which patients are likely to benefit from PEG tube placement and thus protect them from the development of esophagitis and even ventilator-associated pneumonia (VAP).

### Terminology

Percutaneous endoscopic gastrostomy: Percutaneous endoscopic gastrostomy (PEG) is a procedure in which a feeding tube is passed through the abdominal wall directly into the stomach under endoscopic guidance, enabling nutrients, medication and fluids to be delivered directly into the stomach; Gastroesophageal reflux: GER is defined as the movement of stomach contents (solids or liquids) into the esophagus, and is caused mainly by dysfunction of the lower esophageal sphincter.

### Peer review

This is an interesting prospective study that provides valuable information re-

garding factors that predict failure of PEG to eliminate GER. The results are interesting and suggest that severe reflux esophagitis and the gastro-esophageal flap valve grade are the main contributing factors.

### Abstract

**AIM:** To analyze manometric abnormalities in patients with isolated distal reflux and compare these findings in patients with erosive and non-erosive disease.

**METHODS:** Five hundred and fifty patients who presented to the outpatient clinic of Turkiye Yuksek Ihtisas Hospital with gastroesophageal reflux disease-like symptoms were enrolled. Each individual was evaluated with esophageal manometry, 24-h ambulatory pH monitoring, and upper gastrointestinal endoscopy. Manometric findings for the patients with isolated distal reflux were compared to findings in controls who were free of reflux disorders or hypersensitive esophagus. Findings for isolated distal reflux patients with and without erosive reflux disease were also compared.

**RESULTS:** Of the 550 subjects enrolled, 97 (17.6%, mean age 48 years) had isolated distal reflux and 100 had no abnormalities on ambulatory pH monitoring (control group, mean age 45 years). There were no significant differences between the isolated distal reflux group and control group with respect to age, body mass index, and esophageal body contraction amplitude (EBCA). Mean lower esophageal sphincter pressure was significantly higher in the control group ( $12.7 \pm 10.3$  mmHg vs  $9.6 \pm 7.4$  mmHg,  $P = 0.01$ ). Fifty-five (56.7%) of the 97 patients with isolated distal reflux had erosive reflux disease. There were no statistical differences between the erosive reflux disease and non-erosive reflux disease subgroups with respect to mean EBCA, lower esophageal sphincter pressure, or DeMeester score.

However, 13% of patients with gastroesophageal reflux disease had distal wave amplitudes  $\leq 30$  mmHg, whereas none of the patients with non-erosive reflux disease had distal wave amplitudes in this low category.

**CONCLUSION:** Patients with erosive and non-erosive disease present with similar manometric abnormalities. The only striking difference is the observation of very low EBCA exclusively in patients with erosive disease.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) is defined as the pathological retrograde movement of gastric contents into the esophagus. Patients with GERD are typically categorized into one of 3 groups: those without esophagitis [suffering from non-erosive reflux disease (NERD)]; those with esophagitis [suffering from erosive reflux disease (ERD)], and those with complicated forms of GERD<sup>[1]</sup>.

Non-erosive reflux disease is the most common presentation of GERD<sup>[2]</sup>. Peristaltic dysfunction of the esophagus is well documented in cases of GERD<sup>[3,4]</sup>. The main esophageal motility disorder in these patients is ineffective esophageal motility (IEM)<sup>[5]</sup>.

Gastroesophageal reflux can be classified as isolated proximal reflux (IPR), isolated distal reflux (IDR), or both proximal and distal reflux as determined by ambulatory pH monitoring. Whereas increased acid clearance time and IEM are strongly associated with IPR<sup>[6]</sup>, there are no data

that conclusively link motility disorders with IDR. Our aim in this study was to investigate manometric measurements in patients with IDR and compare the findings in individuals with and without erosive esophagitis.

## MATERIALS AND METHODS

Between January 2000 and July 2002, 550 patients with GERD-like symptoms were screened for the study. These individuals had typical GERD symptoms (acid regurgitation and heartburn) or extraesophageal symptoms (hoarseness, asthma-like clinical presentation, nocturnal cough, and nocturnal waking). They were evaluated at the outpatient clinic of Turkiye Yuksek Ihtisas Hospital's Gastroenterology Unit, which is a tertiary referral center. Demographic characteristics and body mass index (BMI) were recorded for each patient.

All subjects were referred to our motility unit for 24-h pH monitoring and manometric studies. Each was assigned to one of 5 groups according to the pH results: (1) those with IDR; (2) those with IPR; (3) those with both proximal and distal reflux; (4) those with hypersensitive esophagus; (5) those with normal findings.

All patients underwent gastrointestinal endoscopy. Individuals with GERD whose esophageal mucosa appeared normal on esophagogastroduodenoscopy were considered to have NERD. Those with varying degrees of esophagitis were considered to have ERD.

Patients were excluded if they had Barrett's esophagus, hiatal hernia, esophageal varices, connective tissue disease, primary esophagus disease, or had undergone endoscopic therapy. Informed consent was obtained from each participant and the study was approved by our hospital's ethics committee. All patients underwent esophagogastroduodenoscopy, esophageal manometry, and ambulatory 24-h pH monitoring as described below.

Esophagogastroduodenoscopy was performed after a 10-h fast using an Olympus GIF XQ endoscope (Tokyo, Japan). Local anesthesia was administered (1% xylocaine) and the esophagus, stomach and duodenum were evaluated. During endoscopy, special attention was paid to the distal esophageal mucosa. Patients with esophagitis were classified according to the Los Angeles classification<sup>[7]</sup>: Grade A, mucosal break < 5 mm in length; grade B, mucosal break > 5 mm; grade C, mucosal break continuous between > 2 mucosal folds; grade D, mucosal break > 75% of the esophageal circumference.

Esophageal manometry was carried out using a Medical Measurement Systems (MMS) unit (ver. 8.4i Beta) and an 8-channel Dent-sleeve catheter. Lower esophageal sphincter pressure (LESP) and esophageal body contraction amplitude (EBCA) were recorded. Based on these findings, patients were categorized as normal, hypotensive lower esophageal sphincter, or IEM<sup>[8]</sup>.

Ambulatory 24-h pH monitoring was performed using a Synetics Digrapper MHIII machine and double-channel, 15 cm antimony catheter. Findings were recorded and analyzed using Microsoft esophagram version 2.04. Based on the results, patients were categorized as normal, IDR, IPR, both proximal and distal reflux, or hypersensitive esophagus<sup>[9-12]</sup>. Hypersensitive esophagus

was defined if the symptom index for distal measurements (symptom index = number of symptoms at pH < 4 / total number of symptoms) was  $\geq 50\%$  while there was no measurable distal or proximal reflux.

Acid reflux was defined as a fall in esophageal pH below 4. All standard parameters (DeMeester score, percentage of time below pH 4, number of reflux episodes and number of long reflux episodes) were determined throughout the study period<sup>[13]</sup>.

A control group was established based on the combined results from the above battery of tests. Individuals who were free of abnormal esophageal conditions (distal or proximal esophageal reflux, or hypersensitive esophagus) comprised this group. Subjects were asked not to take antacids, H<sub>2</sub> blockers, prokinetic agents, or proton-pump inhibitors throughout the duration of the study. They were also directed not to consume acidic foods or foods containing bicarbonate during the study. During ambulatory pH monitoring, patients continued their normal daily routines. Throughout the 24 h of monitoring, individuals recorded their meal times, sleep periods and times of onset of heartburn complaints.

## Statistical analysis

All values are expressed as mean  $\pm$  SD. Comparisons between the study and control groups were made using the  $\chi^2$  test. The Student's *t* test was used to compare continuous variables between groups. *P*-values < 0.05 were considered significant.

## RESULTS

Of the 550 patients initially screened, 241 (43.8%) had combined proximal and distal esophageal acid reflux, 97 (17.6%) had IDR, 70 (12.7%) had IPR, 42 (7.6%) had hypersensitive esophagus, and 100 (18.2%) were free of these conditions. The latter 100 became the control group, with 42 women and 58 men of mean age  $44.9 \pm 12.8$  years. The 97 patients in the IDR group formed the study group, with 47 women and 50 men of mean age  $47.8 \pm 13.4$  years.

There were no significant differences between the IDR and control group means for age, BMI, and EBCA. However, mean LESP was significantly lower in the IDR group than in the control group ( $9.6 \pm 7.4$  mmHg *vs*  $12.7 \pm 10.3$  mmHg, *P* = 0.01) (Table 1).

Of the 97 patients with IDR, 42 (43.3%) had NERD and 55 (56.7%) had ERD. Of the 55 patients with ERD, 20 (36.4%) had grade A esophagitis, 18 (32.7%) had grade B esophagitis, 12 (21.8%) had grade C esophagitis, and 5 (9.1%) had Grade D esophagitis. In the ERD subgroup, mean age was  $45 \pm 13$  years, mean BMI was  $26.8 \pm 3.4$  kg/m<sup>2</sup>, mean DeMeester score was  $42.9 \pm 27.2$ , mean LESP was  $9.2 \pm 6.5$  mmHg, and mean EBCA was  $70.9 \pm 50.9$  mmHg (Table 2).

Patients in the NERD subgroup tended to be older than those in the ERD subgroup ( $51 \pm 13$  years *vs*  $45 \pm 13$  years, *P* = 0.03). There was no significant difference between the mean DeMeester scores for these 2 groups (Table 2). All 42 patients with NERD had EBCA > 30 mmHg,

	IDR group <i>n</i> = 97	Control group <i>n</i> = 100	<i>P</i> -value
Age (yr)	47.8 ± 13.4	44.9 ± 12.8	0.134
Sex (F/M)	47/50	42/58	0.512
BMI (kg/m <sup>2</sup> )	26.6 ± 3.8	26.2 ± 3.8	0.437
EBCA (mmHg)	73.6 ± 44.4	77.6 ± 41.0	0.507
LESP (mmHg)	9.6 ± 7.4	12.7 ± 10.3	0.019
DeMeester score	42.6 ± 24.3	6.2 ± 4.8	0.000

IDR: Isolated distal reflux; BMI: Body mass index; EBCA: Esophageal body contraction amplitude; LESP: Lower esophageal sphincter pressure.

whereas 7 (12.7%) of the 55 patients with ERD had EBCA ≤ 30 mmHg. This difference was statistically significant (*P* = 0.01). In all cases where EBCA was less ≤ 30 mmHg, the patient had severe esophagitis (Grade C or D).

## DISCUSSION

Gastroesophageal reflux refers to retrograde passage of gastric contents into the esophagus. This movement of material is not considered pathologic until symptoms or mucosal damage occur, but at that stage the condition is termed GERD. The most important mechanisms and phenomena that protect the esophagus from gastric reflux are esophageal peristalsis, salivary pH, and gravity. Several well-characterized abnormalities of LESP and esophageal peristalsis are known to increase gastroesophageal reflux and acid-induced mucosal damage<sup>[14]</sup>.

The most common esophageal motor disorder in patients with GERD is IEM, and 20%-50% of patients with GERD are affected<sup>[15]</sup>. Ineffective esophageal motility is defined as esophageal contractions of amplitude < 30 mmHg and/or a 30% or higher rate of nontransmission of wet swallows to the distal esophagus<sup>[6,8]</sup>.

IEM is also the most prevalent motility abnormality in patients with IPR and GERD-associated respiratory symptoms<sup>[16]</sup>. However, the relationship between IDR and IEM is not clear. In our study, we focused specifically on manometric findings in patients with IDR.

We detected no statistical differences between our IDR group and control group with respect to age, BMI or EBCA. However, we did note significantly lower mean LESP for the IDR patients. This finding is in accordance with other studies that have documented motility abnormalities in patients with GERD<sup>[3,17]</sup>.

The presence of erosive disease in the esophagus is another factor that is thought to promote esophageal motility disorders in patients with GERD<sup>[18]</sup>. Impairment of esophageal body contraction, as manifested by reduced contraction amplitude and aperistalsis, is a frequent finding in patients with ERD. Twenty percent of individuals with moderate esophagitis and 50% of patients with severe esophagitis show aperistalsis and hypotensive contractions<sup>[19]</sup>.

Somani *et al*<sup>[17]</sup> analyzed manometric findings in 47 patients with GERD. They found that distal esophageal contraction amplitude was lower in cases of severe

**Table 2** Comparison of parameters for the ERD and NERD subgroups of IDR patients

	ERD ( <i>n</i> = 55)	NERD ( <i>n</i> = 42)	<i>P</i> -value
Age (yr)	45.2 ± 13.3	51.2 ± 13.0	0.032
Sex (F/M)	25/30	22/20	0.511
BMI (kg/m <sup>2</sup> )	26.8 ± 3.4	26.3 ± 4.2	0.485
EBCA (mmHg)	70.9 ± 50.9	77.1 ± 34.5	0.497
LESP (mmHg)	9.2 ± 6.5	10.2 ± 8.6	0.526
DeMeester score	42.9 ± 27.2	42.1 ± 20.1	0.876

ERD: Erosive reflux disease; NERD: Non-erosive reflux disease.

esophagitis than in cases of mild esophagitis (*P* = 0.001). Frazzoni *et al*<sup>[20]</sup> analyzed esophageal manometric findings in 88 patients with NERD, 76 with ERD, and 56 with complicated esophagitis. They found that mean EBCA was significantly lower in the complicated esophagitis and ERD groups than in the NERD group, but observed no significant difference between the 3 groups with respect to mean LESP. In contrast with these results, Lemme *et al*<sup>[21]</sup> assessed 70 patients with ERD and 40 patients with NERD using esophageal manometry and detected no statistical differences between these groups with respect to mean numbers of low amplitude, non-transmitted, and normal waves. The authors suggested that IEM alone is unlikely to be the major determinant of abnormal esophageal acid exposure, and that it is not a prerequisite for development of esophagitis. Similarly, Martinek *et al*<sup>[22]</sup> evaluated 111 patients with NERD, 77 patients with mild to moderate ERD, 33 patients with severe esophagitis, and 92 individuals with no evidence of gastroesophageal reflux using esophageal manometry and pH monitoring. They found no significant differences between NERD and ERD groups with respect to mean LESP or frequency of IEM. Similar proportions of patients in each group had low LESP and hiatus hernia. Martinek *et al*<sup>[22]</sup> suggested that a variety of other factors, including genetics, mucosal defense, and acid clearance, may influence patients' susceptibility to developing ERD. Ho *et al*<sup>[5]</sup> observed that patients with IEM were no more likely to have endoscopic evidence of esophagitis than individuals with normal manometry findings. They concluded that esophageal injury is not always associated with IEM.

All of the above-mentioned studies included patients with GERD, but IDR and IPR patients were not analyzed as separate groups in these studies. These 2 conditions may feature different manometric characteristics, and this might explain the contradictory results found in these studies. To our knowledge, no study to date has analyzed manometric data from patients with IDR alone. We focused solely on this patient group and detected no significant differences between the ERD and NERD subgroups with respect to mean EBCA or mean LESP. However, 12.7% of our patients with GERD exhibited EBCA ≤ 30 mmHg, whereas none of those with NERD had distal wave amplitudes in this category. In all cases where EBCA was ≤ 30 mmHg, the patient had severe esophagitis.

Various abnormalities of esophageal motor function

are observed in patients with GERD. Our data suggest that, among patients with IDR, those with NERD and those with ERD exhibit similar types and severity of esophageal motility disorders. The only striking difference between these 2 patient subgroups is that individuals with ERD have a significantly higher frequency of very low EBCA, and this is limited to patients with severe esophagitis.

## COMMENTS

### Background

Gastroesophageal reflux disease (GERD) is defined as the pathological retrograde movement of gastric contents into the esophagus. Various esophageal motility disturbances which may be important in reflux are observed in patients with GERD. The main esophageal motility disorder in these patients is ineffective esophageal motility (IEM). Increased acid clearance time and IEM have been shown to be strongly associated with isolated proximal reflux. However, there are no data that conclusively link motility disorders with isolated distal reflux.

### Research frontiers

In the present study, patients with symptoms of GERD were evaluated with esophageal manometry, 24-h ambulatory pH monitoring, and upper gastrointestinal endoscopy. The manometric findings of patients with isolated distal reflux were compared with those who did not have pathological reflux. Among patients with isolated distal reflux, the manometric findings of patients who had erosive disease and non-erosive disease were also compared. There were no significant differences between the isolated distal reflux group and control group with respect to age, body mass index, and esophageal body contraction amplitude. Mean lower esophageal sphincter pressure was significantly higher in the control group. There were no differences between the erosive reflux disease and non-erosive reflux disease subgroups with respect to mean esophageal body contraction amplitude (EBCA), lower esophageal sphincter pressure, or DeMeester score. However, IEM was observed only in patients with erosive reflux disease.

### Innovations and breakthroughs

In this study, the authors evaluated the manometric findings in a homogenous group of patients with isolated distal reflux. In this context, it is distinct from other related studies, since manometric findings have not been thoroughly analyzed in this special patient population. They also compared these findings in patients with erosive and non-erosive disease which has not been done previously.

### Applications

This study, the authors believe, provides more insight into the pathophysiology of reflux disease. The finding of very low EBCA being observed only in patients with erosive disease might be helpful in identifying these patients.

### Terminology

NERD: Patients with this condition exhibit typical reflux symptoms caused by reflux of gastric contents into the esophagus, but have no visible esophageal mucosal injury. ERD: Patients have visible esophageal mucosal injury on endoscopy. IPR: The upper esophageal sphincter localization was determined by manometry and proximal reflux was determined by the proximal probe localization and upper esophageal sphincter. If the proximal probe was localized in the upper esophageal sphincter or above it, a single acid reflux synchronously occurring with distal probe was accepted as pathologic acid reflux; if the probe was localized under the upper esophageal sphincter, acid contact time > 1% of total time was accepted as pathologic in proximal reflux. IDR: De Meester score > 14.72 and acid contact > 4.0% of total time below pH 4 were accepted as pathologic in distal reflux.

### Peer review

The study addresses an important question, is well written, clear, and is accompanied by legible and clear tables. In addition, the results are well presented and the limitations of the study appropriately addressed. Appropriate controls were chosen for the study.

seropositivity was determined by an enzyme linked immunosorbent assay method against *H pylori* IgG.

**RESULTS:** Presence of *H pylori* infection was significantly inversely associated with esophageal SCC [adjusted odds ratio (AOR): 0.315-0.472, all *P*-value < 0.05] but positively associated with gastric adenocarcinoma (both cardia and non-cardia) (AOR: 1.636-3.060, all *P*-value < 0.05) in comparison to the three control groups. Similar results were not found in cancers of the oral cavity and colon.

**CONCLUSION:** Our findings support the finding that *H pylori* seropositivity is inversely associated with esophageal SCC risk, but increases the risk of gastric cardia adenocarcinoma.

### Abstract

**AIM:** To explore the role of *Helicobacter pylori* (*H pylori*) infection on the risk of digestive tract cancers.

**METHODS:** In total, 199 oral squamous-cell carcinoma (SCC), 317 esophageal SCC, 196 gastric cardia and non-cardia adenocarcinoma and 240 colon adenocarcinoma patients were recruited for serum tests of *H pylori* infection. Two hospital- and one community-based control groups were used for the comparisons. *H pylori*

### INTRODUCTION

It is widely accepted that chronic *Helicobacter pylori* (*H pylori*) infection, especially cytotoxin-associated gene A (CagA)-positive strains, causes non-cardiac gastric carcinoma via the intestinal metaplasia-carcinoma sequence<sup>[1,2]</sup>. However, there is debate in regard to the association between *H pylori* infection and gastric cardia adenocarcinoma. Most studies in Asian countries<sup>[3-5]</sup> have indicated an increased risk of cardia cancer in *H pylori*-infected subjects, while those in Western countries have reported a protective role

of *H pylori*<sup>[6]</sup> or a negative association<sup>[7-9]</sup> between these two.

Recently, cumulative evidence has indicated that *H pylori* infection plays a protective role in the development of reflux esophagitis<sup>[10,11]</sup> and esophageal adenocarcinoma (EA)<sup>[6,8,12,13]</sup>. In contrast, the relationship between *H pylori* infection and esophageal squamous cell carcinoma (SCC) is still inconclusive<sup>[8,14-17]</sup>. Very few studies have examined the role of *H pylori* infection on colon and oral cancers. Therefore, we aim to expand our esophageal SCC cases and to examine the relationship between *H pylori* infection and the risk of oral SCC, gastric cancer, especially gastric cardia adenocarcinoma and colon cancer, in a Taiwanese population.

## MATERIALS AND METHODS

### Selection of cases and controls

This was a hospital-based case-control study design. Three hundred and seventeen newly pathologically proven ESCC patients (301 males and 16 females) were recruited from two medical centers in the Kaohsiung metropolitan area in southern Taiwan, including the Kaohsiung Medical University Hospital (KMUH) and the Kaohsiung Veterans General Hospital (KVGH) between 2000 and 2007. The detailed information was described elsewhere<sup>[18]</sup>. Patients with newly pathologically proven oral SCC ( $n = 199$ ), gastric ( $n = 196$ ) and colon adenocarcinoma ( $n = 240$ ) were recruited from the KMUH in the same period.

The first hospital-based control group was recruited from the Department of Preventive Medicine in these two hospitals and matched with each esophageal SCC patient (case:control = 1:1-4) by gender, age (within a 4 year age difference) and hospitalization (within 4 wk after each case was identified). In this study, we randomly selected 1 out of 1-4 matched controls ( $n = 305$ , 289 males and 16 females) for each case to investigate the status of *H pylori* infection<sup>[19]</sup>. Twelve cases did not have suitable controls. In order to examine the different prevalence of *H pylori* infection from different areas or different sources of selection, we included another two comparison groups, defined as the second hospital-based control group and the community-based control group, in this study. The second hospital-based control group ( $n = 403$ , 374 males and 29 females) were originally used for the esophageal cancer study in National Taiwan University Hospital (NTUH) in Taipei<sup>[20]</sup>. They were cancer-free, had visited for a health check-up in NTUH, and had enough stored serum specimens for testing *H pylori* status during the same period of this study. The community-based control group ( $n = 395$ , 204 males and 191 females) consisted of healthy subjects living in Kaohsiung who voluntarily participated in one large multi-year study of childhood neoplasms at the same period of this study<sup>[14,21]</sup>. The second hospital-based and the community-based control groups were not matched by age and gender with our esophageal SCC patients.

All subjects provided blood samples before any treatment or blood transfusion for *H pylori* seropositivity. For those with positive *H pylori* antibodies, CagA status was further examined using an enzyme immunoassay. The institutional review boards at NTUH and KMUH reviewed and approved this study, and all participants signed written sheets of informed consent.

### Location of esophageal SCC and gastric adenocarcinoma

Lesions were classified with respect to their location in the upper, middle or lower third of the esophagus, described previously<sup>[22,23]</sup>. Gastric cardia adenocarcinomas were defined as a tumor centered within 3 cm distal to the gastroesophageal junction. There was no difficulty in distinguishing lower third esophageal cancer with cardia invasion from gastric cardia cancer extending to the lower esophagus, because SCC comprise more than 95% of esophageal cancers in Taiwan<sup>[24]</sup>. Cardia adenocarcinoma was classified as being of gastric origin, if Barrett's esophagus was not detected in the adjacent tissue.

### *H pylori* serology and CagA status

Non-heparinized whole blood was collected and serum was isolated and stored at  $-70^{\circ}\text{C}$  for subsequent analysis. A commercially available immunochromatographic screening test (Chembio *H pylori* STAT-PAK, Chembio Diagnostic System, Inc., Medford, NY, USA) utilizing a combination of *H pylori* antigen coated particles and anti-human IgG was used to qualitatively and selectively detect *H pylori* antibodies in serum<sup>[14]</sup>. According to the manufacturer's instructions, the sensitivity and specificity of STAT-PAK were 94% and 98%, respectively. Final readings were recorded after verification by at least two research technicians blinded to the status of cases and controls.

A commercial kit, Helori CTX IgG (ravo Diagnostika GmbH, Freiburg, Germany), was used to detect the IgG antibodies against serum CagA by enzyme immunoassay. The average optical density ( $A$ ) values of subject specimens, blank, negative and positive controls were calculated. The  $A$  of negative and positive controls must be always  $< 0.100$  and  $> 0.800$ , respectively, in each set of samples. The concentration of each sample was expressed as units obtained from the formula: sample  $A \times$  calibrator value (units)/calibrator  $A$ . Based on guidelines set forth by the manufacturer, we set negative and positive cutoff points for each concentration as  $< 5$  and  $\geq 5$  units, respectively. The research technicians were also blinded to the status of cases and controls.

### Statistical analysis

Multiple logistic regression models were used to examine the association between *H pylori* infection (seropositivity by STAT-PAK) and esophageal SCC risk using each of three control groups as a basis of comparison before and after adjusting for other covariates, including age (continuous), gender, educational levels ( $\leq$  primary school, junior high and high school, and  $>$  high school), cigarette

<sup>1</sup>CagA status was determined among the subjects with *H pylori* seropositivity (No CagA data was available in 3 esophageal SCC, 1 gastric non-cardia adenocarcinoma and 1 community-based control).

smoking, alcohol drinking and betel nut chewing. Information about betel nut chewing was not available in the community control, so it was not evaluated in the regression models when the community control was used as the control group. The data were analyzed using the SAS statistical package; all *P*-values were two-sided.

## RESULTS

Distribution of demographic variables and substance use for cancer cases and controls is summarized in Table 1. The majority of oral and esophageal SCC patients were male, and more than half of all cancer patients had an educational level of primary school or below. The ratio of women to men among the esophageal SCC was 3.5% (6/173) in KVGH, which is slightly lower, but not significantly different, than that in KMHU (6.9%, 10/144, *P*-value = 0.18). The mean age of the community con-

trol group (40.2 ± 6.2 years) was about 20 years younger than the other two control groups.

The *H pylori* seropositivity in esophageal SCC patients was 35.3%, which was consistently lower than those in the three controls (40.5%-59.3%) (Table 2). The seropositivity of *H pylori* among the ESCC patients was similar in those two hospitals: 36.1% (KMHU 53/147) and 34.7% (KVGH 59/170) (data not shown). In contrast, *H pylori* seropositivity in gastric adenocarcinoma patients (71.4%) was higher than that in all three control groups. *H pylori* seropositivity in gastric cardia and non-cardia adenocarcinoma patients was similar (Table 2). In addition, the prevalence of CagA-positive subjects among *H pylori*-infected cancer cases was 71.6%-85.9%, similar to that among *H pylori*-infected controls (76.8%-89.0%).

In multivariate analyses, there was still a significantly inverse association between *H pylori* seropositivity and esophageal SCC (AOR: 0.315-0.472, all *P*-values < 0.05).

Table 3 Association between *H pylori* infection and cancer risks

		Odds ratio (95% CI)	P-value	Adjusted odds ratio (95% CI) <sup>1</sup>	P-value
Oral SCC <i>vs</i>	1st hospital control	0.105 (0.787-1.553)	0.5640	0.961 (0.637-1.449)	0.8494
	2nd hospital control	0.627 (0.445-0.882)	0.0074	0.378 (0.190-0.751)	0.0055
	community control	1.342 (0.952-1.891)	0.0932	1.064 (0.622-1.820)	0.8211
Esophageal SCC <i>vs</i>	1st hospital control	0.470 (0.340-0.648)	< 0.0001	0.454 (0.290-0.710)	0.0005
	2nd hospital control	0.375 (0.277-0.508)	< 0.0001	0.315 (0.203-0.489)	< 0.0001
	community control	0.802 (0.591-1.089)	0.1581	0.472 (0.257-0.865)	0.0151
Gastric adenocarcinoma <i>vs</i>	1st hospital control	2.149 (1.465-3.152)	< 0.0001	2.015 (1.278-3.174)	0.0025
	2nd hospital control	1.715 (1.187-2.479)	0.0041	1.636 (1.071-2.501)	0.0228
	community control	3.672 (2.538-5.312)	< 0.0001	3.060 (1.650-5.674)	0.0004
Colon adenocarcinoma <i>vs</i>	1st hospital control	0.785 (0.549-1.123)	0.1857	0.595 (0.319-1.113)	0.1040
	2nd hospital control	0.882 (0.639-1.219)	0.4476	0.851 (0.581-1.245)	0.4055
	community control	1.888 (1.365-2.613)	0.0001	1.117 (0.612-2.039)	0.7177

<sup>1</sup>Compared to KMHU or NTUH controls: adjusting for age (continuous), gender (female *vs* male), educational levels ( $\leq$  primary school *vs* > high school; junior and high schools *vs* > high school), cigarette smoking (yes *vs* no), alcohol consumption (yes *vs* no) and betel nut chewing (yes *vs* no); Compared to community controls: Adjusting for the above factors except for betel nut chewing.

In the multivariate analyses of esophageal SCC and 1st hospital control, besides the significant protective effect of *H pylori*, we found that cigarette smoking (AOR = 2.608, 95% CI: 1.540-4.414), alcohol consumption (AOR = 5.078, 95% CI: 3.130-8.240), and betel nut chewing (AOR = 5.142, 95% CI: 2.916-9.065) are still the significant risk factors for esophageal SCC. However, we did not see any significant interaction between *H pylori* and any of those substances (tobacco, alcohol, and betel nut) in the multivariate analyses.

*H pylori* infection was positively related to gastric adenocarcinoma, including the cardia (AOR: 1.636-3.060; all *P*-values < 0.05), in comparison to all three control groups, after adjusting for other co-variables (Table 3). Oral SCC was found to have a significantly inverse association with *H pylori* infection (AOR = 0.378, 95% CI: 0.190-0.751), when compared with the 2nd hospital-based control group, but not the other two. *H pylori* infection was not significantly associated with colon cancer, compared with all three control groups.

## DISCUSSION

After expanding the case number of esophageal SCC patients, we still found an inverse association between *H pylori* seropositivity and esophageal SCC when compared to different control groups. Conflicting results were reported in the previous two prevalence studies about the relationship between the two in Sweden<sup>[8,17]</sup>. One nationwide case-control study conducted by Ye *et al*<sup>[8]</sup> used enzyme-linked immunosorbent assay (ELISA) to detect both serum *H pylori* and CagA antibodies in 85 esophageal SCC patients and 499 controls in Sweden. Initially, they did not find any significant association between *H pylori* seropositivity and esophageal SCC risk (AOR = 0.9, 95% CI: 0.5-1.6). Thus, the authors further categorized the study subjects based on both statuses of *H pylori* and CagA seropositivity. They found subjects with negative *H pylori* but positive CagA, to have a significant 3.0-fold risk of developing esophageal SCC, compared with those who were found to be negative for both<sup>[8]</sup>. But the insignificant find-

ing was noted in the group of both positive *H pylori* and CagA patients (AOR = 1.6, 95% CI: 0.8-3.3). That was a post-hoc statistical analysis, so the preliminary finding is a warranty for further confirmation. Siman *et al*<sup>[17]</sup> updated their nested case-control study and found neither *H pylori* (OR = 0.44, 95% CI: 0.15-1.2) nor CagA seropositivity (OR = 2.0, 95% CI: 0.24-infinity) was significantly associated with esophageal SCC risk (*n* = 37). Recently, two studies were conducted in two major endemic areas in China-Huaian City<sup>[15]</sup> and Linxian<sup>[16]</sup>. The population-based case-control study in Huaian (case number 107) showed those with positive findings for *H pylori* antibody to be at 3-fold risk of developing esophageal SCC (AOR = 3.19, 95% CI: 1.11-9.15)<sup>[15]</sup>. But, in the case-cohort study including 335 ESCC patients in Linxian, no association was found between esophageal SCC risk and positive finding for antibodies to either *H pylori* (Hazard ratio = 1.17, 95% CI: 0.88-1.57) or CagA (Hazard ratio = 1.08, 95% CI: 0.80-1.47)<sup>[16]</sup>. In these two areas, the predominant risk factors for ESCC were diet and nutrition, instead of cigarette smoking and alcohol consumption mostly found in Western countries and Taiwan. The Linxian research group suggested the difference in risk factors for esophageal SCC in different areas may affect the relationship between *H pylori* and esophageal SCC<sup>[16]</sup>.

In Taiwan, about 95% *H pylori* strain is CagA positive<sup>[25]</sup>. This study has shown that subjects with positive *H pylori* serology have > 85% CagA<sup>+</sup> strains in both esophageal SCC patients and controls, suggesting using IgG serology to measure *H pylori* infection can represent the CagA<sup>+</sup> strains in Taiwan. The relatively low seroprevalence of *H pylori* infection in the community control group may be due to younger age (average age = 40.2 years), compared to those in the two hospital-based control groups (average age = 57.1 and 60.0 years).

The exact mechanism by which *H pylori* infection affects the development of EA and esophageal SCC is still puzzling. The strongest risk factor of distal EA is Barrett's esophagus, a condition secondary to long-term gastroesophageal reflux disease, and *H pylori* colonization may protect against Barrett's esophagus<sup>[11,13,26]</sup>. Rich-

ter *et al*<sup>27</sup> also hypothesized that *H pylori* can prevent EA development through gastric atrophy and possibly by increased intragastric ammonia production. Ye *et al*<sup>8</sup> challenged this hypothesis by demonstrating an unaffected protective effect for EA after adjusting for gastric atrophy. However, they hypothesized that CagA<sup>+</sup> *H pylori* infection caused esophageal SCC through the pathway of gastric atrophy<sup>8</sup>. An atrophic stomach might enhance the overgrowth of bacteria and increase endogenous nitrosamines production, which causes esophageal SCC<sup>28</sup>. In contrast, another hypothesis is *H pylori*-induced gastric atrophy, which decreases intragastric acidity<sup>14</sup>, might protect the lower esophageal mucosa from repeated injury by acid exposure, and thus decrease the esophageal SCC risk in an Asian population<sup>29</sup>. Another mechanism concerning the protective effect of *H pylori* infection on esophageal cancer risk directly involves apoptosis<sup>30,31</sup>. Jones *et al*<sup>30</sup> found significantly increasing apoptosis in OE33 Barrett's-derived EA cells, but not in normal esophageal cells, after being treated with intact *H pylori* wild-type strains. Our *in vitro* study demonstrated similar apoptosis effect on esophageal SCC cells, but not in AGS cells, after being co-cultured with *H pylori*<sup>31</sup>. However, this proposed mechanism is still speculative and needs to be further verified.

The prevalence of *H pylori* infection in patients with cardia and non-cardia adenocarcinoma was about 70%, significantly higher than control subjects (about 56%), which was similar to the previous study done in China<sup>41</sup>. Fewer cardia cancer patients ( $n = 29$ ) were noted in our study, but the prevalence of *H pylori* and CagA seropositivity was similar to that in non-cardia cancer patients. Previous studies have linked *H pylori* colonization to carditis and intestinal metaplasia in the cardia, indicating a role distinct from Barrett's esophagus<sup>32,33</sup>. The subsites of gastric cancer were not well defined in some of the previous studies, but most researchers in Asian countries<sup>3-5,34</sup> supported at least a trend of positive association between *H pylori* seropositivity and proximal gastric cancer. On the contrary, observational studies in Western countries indicated no association<sup>7-9</sup> or inverse association<sup>6</sup> between *H pylori* seropositivity and cardia cancer. Further studies are needed to investigate the discrepancy of findings between Asian and Caucasian populations.

*H pylori* infection was not significantly associated with the risk of colon adenocarcinoma in this study. Hartwich *et al*<sup>35</sup> found a positive association between colon adenocarcinoma risk and *H pylori* seropositivity, especially CagA<sup>+</sup> strains. However, there are also reports indicating no association between *H pylori* seroprevalence and colorectal neoplasia<sup>36,37</sup>. In addition, a recent report from Taiwan did not find any association between *H pylori* infection by the <sup>13</sup>C-urea breath test and the risk of colon adenomatous polyp, which is the pre-cancer of colon adenocarcinoma<sup>38</sup>.

The effect of *H pylori* infection on oral SCC risk has not yet been determined. Our study found conflicting results when *H pylori* infection status in three comparison controls was compared to that in oral cancer patients.

Previous studies have shown that *H pylori* was detectable in the oral cavity by histopathologic diagnosis or polymerase chain reaction<sup>39,40</sup>, but this bacterium may be present as a transient organism because of the difficulty of surviving in the oral cavity<sup>41</sup>. Thus, further studies are necessary to elucidate the relationship between *H pylori* infection and oral cancer risk.

Several limitations were present in this study: (1) The control group is mainly for the comparison of esophageal SCC, but not for other digestive cancers; (2) This is a cross-sectional case-control study design; the causal relationship may be not clearly elucidated; (3) Like other epidemiological studies<sup>8,15-17</sup>, we only measured *H pylori* antibodies in human serum, which may not be representative for actual *H pylori* infection.

In summary, our study supports an inverse relationship between *H pylori* prevalence and esophageal SCC risk in Taiwan. In contrast, *H pylori* infection increases gastric adenocarcinoma risk, including the cardia and non-cardia. There is an inconsistent or negative association between *H pylori* infection and the risks of oral and colon cancers. The choice of the control groups in this study were mainly for the comparison of esophageal SCC, but not for other patient groups. Thus, the role of *H pylori* in digestive tract cancers, except esophageal SCC, in this study still requires further examination.

## COMMENTS

### Background

There is debate in regard to the association between *Helicobacter pylori* (*H pylori*) infection and gastric cardia adenocarcinoma. Recently, cumulative evidence has indicated that *H pylori* infection plays a protective role in the development of esophageal adenocarcinoma. In contrast, the relationship between *H pylori* infection and esophageal squamous cell carcinoma (SCC) is still inconclusive. Very few studies have examined the role of *H pylori* on colon and oral cancers.

### Research frontiers

This study aimed to explore the role of *H pylori* infection on the risk of digestive tract cancers, including cancers of the oral cavity, esophagus, stomach, and colon.

### Innovations and breakthroughs

*H pylori* seropositivity is inversely associated with esophageal SCC risk, but increases the risk of gastric non-cardia and cardia adenocarcinoma.

### Applications

Eradication of *H pylori* in all infected subjects should be cautious because *H pylori* might protect against other diseases, such as esophageal cancer.

### Terminology

STAT-PAK assay for *H pylori* is an immunochromatographic screening test to detect *H pylori* IgG antibodies in serum; Helori CTX IgG kit is an enzyme immunoassay to detect CagA (the virulent protein of *H pylori*) IgG antibodies in serum.

### Peer review

This is an important clinical observational study, indicating *H pylori* is not always a bad bug. Although *H pylori* can cause gastric non-cardia and cardia adenocarcinoma, it may protect against esophageal cancer.

### Abstract

**AIM:** To elucidate etiologic associations between *Helicobacter pylori* (*H. pylori*), lifestyle, environmental factors and gastric cardiac adenocarcinoma (GCA) among men.

**METHODS:** A hospital-based case-control study was conducted in Taiwan from 2000 to 2009. All cases were newly confirmed as primary GCA. Five controls were selected matching with age, sex, and admission date to each case. Participants were informed

of potential risk factors with a structured questionnaire by trained interviewers during hospitalization and provided a blood sample for the determination of *H. pylori* infection. Odds ratio (OR) and 95% confidence interval (95% CI) were used to evaluate risk, and a multivariate conditional logistic regression model was performed.

**RESULTS:** All participants recruited for this study were men, consisting of 41 cases and 205 controls. Results of the univariate analysis showed that significant factors associated with the etiology of GCA included *H. pylori* (OR = 2.69, 95% CI = 1.30-5.53), cigarette smoking (OR = 2.28, 95% CI = 1.05-4.96), working or exercising after meals (OR = 3.26, 95% CI = 1.31-8.11), salted food (OR = 2.51, 95% CI = 1.08-6.11), fresh vegetables (OR = 0.28, 95% CI = 0.09-0.80), fruits (OR = 0.19, 95% CI = 0.04-0.89), and rice as principal food (OR = 0.53, 95% CI = 0.30-0.85). Multivariate conditional logistic regression models indicated that a significantly elevated risk of contracting GCA was associated with working or exercising after meals (OR = 3.18, 95% CI = 1.23-9.36) and *H. pylori* infection (OR = 2.93, 95% CI = 1.42-6.01). In contrast, the consumption of fresh vegetables (OR = 0.22, 95% CI = 0.06-0.83), fruits (OR = 0.28, 95% CI = 0.09-0.79) and rice as principal food (OR = 0.48, 95% CI = 0.24-0.93) remained as significant beneficial factor associated with GCA.

**CONCLUSION:** Working or exercising after meals and *H. pylori* infection increase the risk of GCA, but higher intakes of rice, fresh vegetables and fruits reduce the risk.

## INTRODUCTION

The gastric cardiac adenocarcinoma (GCA) has attracted considerable attention recently as a consequence of the rapid increase in incidence, while the overall rate of gastric cancer has markedly declined in Western countries. Recent studies in China have also shown a statistically significant increasing trend of the disease in the last 16 years<sup>[1]</sup>. Another striking feature is the strong male predominance (the sex ratio being 6:1) among the patients<sup>[2]</sup>. However, no established risk factors can explain the male predominance. Previous studies evaluating the etiology of the GCA generally merged with data of both genders, which would distort the findings and dilute any associations. As the reasons for these variations of incidence remain uncertain, there emerged a critical need for epidemiological studies to identify risk factors in male as well as risk factors that might account for the rapid increases in incidence, although it is very rare.

Recent investigations suggest that obesity<sup>[3-5]</sup> and gastroesophageal reflux disease (GERD)<sup>[6]</sup> are important risk factors for GCA among the Western population<sup>[5]</sup>. A Swedish study found that GCA was related to GERD with an odds ratio of 2.3 (OR = 2.3, 95% CI: 1.2-4.3)<sup>[6]</sup>. Cigarette smoking is also a risk factor<sup>[7]</sup>, but with a lesser degree of strength for GCA<sup>[5]</sup>. Dietary factors are also thought to play an important role in the GCA etiology. Fresh vegetables and fruits have been inversely associated with GCA in several studies<sup>[7]</sup>. Diets high in cholesterol, animal protein and vitamin B12 increase the risk<sup>[8]</sup>, whereas several nutrients, particularly those found in plant food (fiber, ascorbic acid and carotenoids), are associated with a reduced risk of GCA<sup>[5,8]</sup>. Additionally, the use of supplemental calcium/Tums resulted in a significant risk of GCA in a US study<sup>[8]</sup>.

The other main candidate risk factor is the infection with *Helicobacter pylori* (*H pylori*). Evidences have shown that this infection increases the GCA risk in China and other East-Asian population<sup>[9-11]</sup>, but not in the Western population<sup>[12,13]</sup>. A US population-based case-control study even reported an inverse relationship between Cag<sup>+</sup>A strains (cytotoxin associated gene A positive strains) of *H pylori* and GCA<sup>[14]</sup>. The correlation between the GCA and cancer history in first-degree relatives suggests that inherited genetic susceptibility and shared environmental risk factors might contribute to cardiac carcinogenesis<sup>[15]</sup>. Great differences exist in lifestyles, diet habits and environment between Chinese and the Westerners. The features of Taiwanese lifestyle share many similarities with both the Chinese and the Westerners. Especially, some popular customs and traditions in Taiwanese are much alike to the Chinese. It would be interesting to know whether people in Taiwan share the risk factors of GCA similar to people in mainland China or in Western countries. We conducted the present study

to gain a better clue in the etiologic factors shared by lifestyles, diet, and other environmental exposures associated with GCA among men in Taiwan. We additionally investigated the association with *H pylori* infection.

## MATERIALS AND METHODS

### Study design

A hospital-based case-control study of matched pairs was derived from 2000 to 2009 in Kaohsiung City, Taiwan, to explore the risk factors of GCA associated with lifestyles, dietary habits, *H pylori* infection and other environmental exposure factors.

### Data sources

All subjects in our study were drawn from the Kaohsiung Medical University Chung-Ho Memorial Hospital, which has been accredited as a top-grade teaching hospital in southern Taiwan, and used by patients from all socioeconomic categories.
