Patients were diagnosed with a primary histologically confirmed incident case of gastric cancer by pathologist as adenocarcinoma type. The pathologists were not aware of the clinical or endoscopic data. We used endoscopy to measure the distance between the gastroesophageal junction and the upper and the lower borders of the tumor. GCA was identified using an endoscope in a retroflexed position and defined as a tumor, and the majority of the tumors was within 5 mm of the squamocolumnar junction. Gastric cardiac cancers include small cancers located in the cardiac region of the stomach or large tumors located primarily in the cardiac region with slight involvement of the esophagocardiac junction<sup>[16]</sup>. Patients with non-cardia gastric cancer were excluded. Of the 52 cases of histologically confirmed primary GCA by pathologists and gastroenterologists, ten were women excluded in data analyses. One patient was too ill to participate. Eventually, 41 cases agreed to participate in the study.

For each case identified, 5 controls of matched with sex, age ( $\pm 3$  years), and admission date ( $\pm 2$  wk) were recruited from inpatients free of cancer in the Family Medicine Departments at the same hospital, including inpatients who came in for a general health check-up. And, subjects with stomach-related diseases were excluded. Overall, the majority of subjects in the control group were healthy, but some controls were patients with hepatitis B, diabetes mellitus, cataract, and/or benign prostate hypertrophy. Of 209 control subjects invited, 205 agreed to participate in the study.

With consent from subjects, trained professional interviewers performed face-to-face interviews at the hospital using a structured questionnaire. To minimize the variation between interviewers in handling the questionnaire, each interviewer interviewed cases and controls by pairs. We were unable to blind the interviewers to the status of cases or controls, but they were unaware of the study hypothesis and were trained to treat subjects with a similar manner. The structured questionnaire was designed to collect detailed information on sociodemo-

graphic characteristics, lifestyles such as cigarette smoking, alcohol drinking, areca quid chewing, and diet, the use of nutritional supplements and medication history, serologic assays, family history, and GERD symptoms.

Obesity was measured by body mass index (BMI), according to the height and weight measured at least 2 years prior to the interview. BMI was calculated as body weight in kilograms divided by the square of body height in meters ( $\text{kg}/\text{m}^2$ ). The habits of cigarette smoking, alcohol drinking, and areca quid chewing were quantified from information on the age at the initiating, quantity, frequency, and actual duration of consumption, and the cessation age. For analysis, a smoker was defined as someone who had smoked one cigarette or more per day for more than 1 year. Ex-smokers, ex-drinkers, and ex-chewers were defined as those who had quit the habit for more than 6 mo before being diagnosed with cancer or interviewed. Subjects were asked to report their usual consumption frequency of 15 food items more than 1 year before diagnosis or interviewed. This frequency of dietary history exposure was classified into 7 categories: (1) at least once or more per day, (2) three to six times per week, (3) less than three times per week, (4) at least once to three times per month, (5) less than once per month, (6) less than once per year, and (7) never. In addition to the food frequency questionnaire, we asked several questions about general dietary behaviors thought to be related to the digestive tract effect, such as principal food and whether with middle-intensity working or exercising at less than 30 min after meals.

Subjects were also asked to report whether they ever took any nutritional supplements at least 6 mo or longer, and, if so, the type and the frequency of tablets taken were queried. The use of medications history was also collected, such as aspirin, and non-steroidal anti-inflammatory drugs (NSAID).

A blood sample was obtained from subjects at the time of interview. Serum levels of IgG antibodies to *H pylori* and CagA were determined by antigen-specific ELISA. Subjects were first classified as *H pylori* positive or *H pylori* negative, and those who were *H pylori* positive were then classified as CagA positive or CagA negative. Finally, family history was defined as any first-degree relative self-reported by subjects as having been diagnosed with the gastric cancer or disease. To minimize unreliable information, we verified the reported information by asking the subject's family members for confirmation. GERD symptom was defined as someone presented with recurrent heartburn and regurgitation for more than 1 year before being diagnosed or interviewed. The frequency of GERD symptoms was also collected. A field supervisor inspected each subject's medical history and compared with the collected questionnaires, which were then transferred to coding sheets for analysis.

### Statistical analysis

All analyses were performed using STATA 7.0 statistical software. The analysis included  $\chi^2$  test for the similarity of demographic factors, and a multivariate technique de-

signed for matched case-control studies. Conditional logistic regression models were used to estimate odds ratio (OR) and 95% confidence interval (95% CI) for the associations between GCA and the covariates of interest. All analyses were performed controlling for age and education level to minimize the possible confounding effects. Sociodemographic characteristics, lifestyle and environmental exposure variables were categorized and compared between cases and controls to identify significant variables associated with GCA. We used the matched case-control data estimating in univariate and multivariate analyses of the relations among exposure factors, potential confounding variables, and cancer risk. The multivariate analysis was performed with no interaction terms to identify factors with the greatest impact on the fit of the model predicting the risk of GCA, taking into account other related exposure factors and covariates.

## RESULTS

### Demographic characteristics

To increase the study sensitivity of this male predominant disease, we confirmed 41 GCA male patients and enrolled 205 healthy male controls. Cases were older than controls, but not significant (average age:  $64.53 \pm 2.17$  years *vs*  $63.27 \pm 1.73$  years,  $P = 0.28$ ). BMI and other demographic characteristics were also comparable between these two groups (Table 1).

find significant associations between GCA and vitamin supplements and other supplements or medications such as iron, calcium tablet, zinc tablet, aspirin, and NSAID (Table 4).

The risk strength associated with family disease history is shown by adjusted OR in Table 5. To investigate the actual effects of family aggregation, we collected relevant information about patient's first-degree relatives. There were insignificant weak evidences to associate GCA risk with family anemia history and other forms of gastric disease as well as atrophy gastritis, gastric ulcer, lymphoma, gastric polypus, and gastric cancer. However, individuals with a family history of duodenal ulcer (OR = 0.82, 95% CI = 0.35-2.09) had a reduced nonsignificant risk for GCA.

All significant variables found in the univariate analyses were included in the multivariate conditional logistic regression analysis (Table 6). The significantly elevated OR for GCA were associated with working or exercising after meals (OR = 3.18, 95% CI = 1.23-9.36) and *H pylori* infection (OR = 2.93, 95% CI = 1.42-6.01). However, consumption of fresh vegetables (OR = 0.22, 95% CI = 0.06-0.83), fruits (OR = 0.28, 95% CI = 0.09-0.79), and rice as principal food (OR = 0.48, 95% CI = 0.24-0.93) remained as protective factors that reduced the risk of GCA.

## DISCUSSION

To our knowledge, this is the first study to explore simultaneously all aspects of factors that may associate with GCA, including *H pylori* infection, lifestyle, dietary and nutritional supplements taking history, and family history.

It took 10 years to identify 41 histologically confirmed primary GCA cases with useful data. But, this small sample size study has demonstrated important findings. The habit of working or exercising after meals was the strongest risk factors for GCA among men in Taiwan, which is consistent with the finding for Chinese population in Fujian Province<sup>[7]</sup>. One plausible biological explanation for this association is that working or exercising after meals may decrease blood supply in digestive tract and induce gastric ischemia to prolong the empty

time<sup>[17]</sup>. Besides, physical activity may increase the intra-abdominal pressure and wall tension in the digestive tract, and reduced gastric mucosal flow and ischemia<sup>[17]</sup>. And recent studies have indicated that the cardiac region differs from the rest of the stomach by remaining highly acidic after a meal<sup>[18]</sup>. Physical activity may thus increase the gastrointestinal transit time and also extend acid contact time between the gastric mucosa, cardiac region especially, and potential carcinogens in the stomach, eventually leading to an increased GCA risk.

Most of the studies from Western populations have found no significant association with *H pylori* in the GCA etiology<sup>[12,13]</sup>. Some studies even reported a reduced risk for the disease<sup>[14,19]</sup>. In contrast, most studies conducted in Asian population<sup>[9-11,20]</sup> have found elevated risks from *H pylori* infection. A meta-analysis of prospective studies, including only four studies, found no association between GCA and *H pylori*<sup>[21]</sup>. Of these, two studies from China indicated an elevated risk associated with infection while other two from Europe indicated a reduced risk. Clearly, our finding is consistent with observations in Asian studies, encouraging evidence of the harmful role of *H pylori* in the carcinogenic process for GCA. The divergent findings between European and Chinese leave a matter for future consideration.

However, we observed that CagA seropositivity played no significant role consistent with prospective studies from China<sup>[11]</sup> and Europe<sup>[10]</sup>. Of interest, CagA seropositivity was associated with a 6.2-fold greater risk for cancers in the upper one third of the stomach for Japanese (1.2-32.0)<sup>[12]</sup>. In contrast, CagA seropositivity (OR = 0.4, 95% CI = 0.2-0.8) was associated with a reduced GCA risk in the US<sup>[14]</sup>. The inconsistency of these findings may be due to the diversity of the studies in geography, and ethnicity among them because of important genetic components, host, and environmental heterogeneity.

Furthermore, the CagA antibodies measurement for each subject reduced our misclassification of *H pylori* status. This encourages the power of testing significance with such a small sample size in this study. Therefore, we suggest that *H pylori* measurement in early life is an important marker of GCA, and a future study to elucidate the transmission mechanism of *H pylori* infection for the GCA prevention relevancy is needed.

Salted food has been linked to stomach cancer risk<sup>[22-24]</sup>. We found that salted food was also associated with an increased risk for GCA. However, this risk disappeared in the multivariate statistical models. Salt is thought to induce an inflammatory process leading to the damage of the protective stomach mucosa. And, *H pylori* may interact with salt and enhances carcinogenesis after the gastric epithelium is damaged<sup>[24]</sup>. It may also increase cell susceptibility to carcinogenesis from salt intake<sup>[7]</sup>. Thus, we postulate that salt per se is not an independent carcinogen, as Cohen *et al*<sup>[25]</sup> argued, but a promoter of GCA.

Many studies have reported the protective effect from the intake of fresh vegetables and fruits against GCA<sup>[7,26,27]</sup>. We also showed a remarkably reduced risk of GCA for men consuming diet rich with fresh vegetables and fruits. In other words, the plant food was as-

sociated with a strong reduction in risk for GCA among men in Taiwan. Plant food is rich in fiber, ascorbic acid and carotenoids<sup>[5,8]</sup>. Several studies showed that dietary fiber was strongly related to a reduced GCA risk<sup>[18,27,28]</sup>. The protective mechanism of fiber is still unclear; it may play a cleansing role and could facilitate the removal of carcinogens at the epithelial surface<sup>[27]</sup> or promote the sloughing of damaged epithelial cells<sup>[8]</sup>. Ascorbic acid and carotenoids are both strong antioxidants in the process of gastric carcinogenesis. Nevertheless, our data not only confirmed the beneficial effect of fresh vegetables and fruits against GCA, but also suggested rice as the principal food is important against this disease.

This study showed that rice as principal food may well reduce the risk of GCA in Taiwan. Antioxidants and fiber effect in rice, with much lower protein composition than wheat and some other grains, may attribute to the anti-carcinogenicity<sup>[29-32]</sup>. The decreased protein content in meals may reduce gastric acid secretion<sup>[33]</sup>. Cardiac cancer in Western countries has been associated with normal or increased acid production<sup>[6]</sup>. Rice as principal food may lower acid secretion, thus reducing the GCA risk. According to our observation of the habit of working or exercising after meals or rice as principal food, similar to those of the West, we assume that chronic exposure to gastric acid plays a role in the aetiology of GCA. Although we failed to observe an association between GERD and the GCA risk, the result is well in agreement with other studies conducted in the US<sup>[31]</sup> and Taiwan<sup>[34,35]</sup>. GERD is less common in Asians than in Western population<sup>[34,36]</sup>. We, therefore, considered GERD as an indicator rather than a crucial cause of GCA.

Our results differed greatly from the Western studies<sup>[3,5]</sup> in the association with BMI. Similar to a recent North China study<sup>[37]</sup>, we found a negative association between obesity and GCA, although not significant. The reasons of the difference might be associated with the genetic background, cut-off points for BMI and lifestyle. Great differences exist in lifestyle and diet habits between Chinese and the Westerners. Asian populations historically eat low-fat diets<sup>[38]</sup> with more vegetables/fruits<sup>[39]</sup> and have a smaller BMI than Western populations<sup>[40]</sup>. This suggests that obesity is an indirect factor in the association with GCA for the men in Taiwan. Moreover, a recent China study has pointed out that the westernization in diet and eating habits is responsible for the higher risk of GCA in the urban area than in the rural area<sup>[41]</sup>.

Some studies found harmful effect from smoking for GCA<sup>[5,7,42,43]</sup>. The present study observed a significant risk associated with smoking, but it disappeared in the multivariate analysis. Thus, it may be attributed to the reinforcing factor but not an independent carcinogen for GCA. Besides, the sample size of GCA cases in this study might be not large enough to detect such a relationship; however, we still can not overlook its gravity.

A twin study assessing the contribution of hereditary and environmental factors has found that occupational exposures and viral infections make up the other 62% of the risk of developing stomach cancer. The statistical model used provided a perfect fit ( $P = 1.0$ ) in predicting

the involvement of major environmental factors plus minor genetic components for the risk of stomach cancer<sup>[44]</sup>. Our results support this notion, even though we have no direct witness to prove it. In our study, working or exercising after meals, vegetables, fruits and rice consumption and *H pylori* infection are significantly associated with GCA, but not in family history of gastric diseases with the familial (hereditary or nonhereditary) effects. This finding indirectly shows the etiological importance of environmental factors for GCA.

An important etiologic characteristic of GCA is the strong male predominance. This study did find 42 of 52 cases were men. Why did the strong male predominance exist among patients with GCA? As the family is the core unit of *H pylori* transmission<sup>[45]</sup> and childhood colonization has the same risks in males and females. The striking feature may be due to the fact that females work or exercise at the lower intensity than males, because of the Chinese social request of culture. Hence, males are at higher risk than females for GCA. Moreover, females have more frequent consumption of vegetables and fruits than males. Accordingly, we can find the fact of more protective effect in females than in males. Consequently, the strong male predominance will be continuously observed.

Our study is subject to some limitations. The major limitation is its relatively small sample size, as GCA remains a very rare disease not only worldwide but also in Taiwan<sup>[34]</sup>. But our stringent matching design has increased the effort in study precision and reduced bias<sup>[46]</sup>. Compared with published studies<sup>[3,19,21]</sup>, we are encouraged to have more GCA cases with no misclassification and no divergent effects. Another limitation found in this study is the potential for recall bias, a common limitation of case-control studies, as well as the recall bias of dietary and family history. It was not possible to adjust completely for biases such as the dietary recall bias. We did match, however, the time of hospital visits to avoid differences caused by seasonal dietary changes. Moreover, we used the structured questionnaire to collect categorized information to minimize errors in quantitative data caused by incorrect recall. Furthermore, family history data was only collected for first-degree relatives, such self-reported information is generally more reliable. And we did examine and reconfirm family histories by talking with other family members. But, it cannot still wholly excluded that some family histories may have been misclassified.

The advantage of this study was based on confirmed GCA cases validated by a panel of pathologists and gastroenterologists. The other strength in this study is our exact study design and statistical analysis. The high response rate (97.62% in cases and 98.09% in controls), absence of proxy interviews and the homogeneity of control group are the other important ones.

Despite the relatively low number of GCA cases, the main risk factors in Taiwan societies are well established. The epidemiological features of GCA in our study have in deed demonstrated that GCA is more closely governed by environmental factors. Concerning the etiology of GCA, unlike in the West, obesity, GERD and cigarette smoking may not be the independent contributing

factors for population in Taiwan. While lifestyle and dietary variables have an important role, infectious origin is still a major factor in the developing populations such as Taiwan. Our further analysis showed an interactive effect between working or exercising after meals and *H pylori* infection. The OR for GCA increased to 3.39 (95% CI 1.32-11.27), compared with individuals of neither working/exercising after meals and nor *H pylori* infection. In conclusion, this study suggests that healthy dietary habits to avoid the chronic exposure to higher and provocative gastric acidity and eradication of *H pylori* are important for the GCA prevention. Daily intake of fresh vegetables, fruits and rice as principal food should be encouraged for the beneficial effect to prevent GCA.

## ACKNOWLEDGMENTS

We thank the physicians and nurses in the Departments of Gastroenterology and Family Medicine, Kaohsiung Medical University Chung-Ho Memorial Hospital, for their assistance in this study.

## COMMENTS

### Background

The gastric cardiac adenocarcinoma (GCA) is a very rare disease. In recent decades, however, the incidence of the GCA has increased dramatically in many Western countries. An increasing trend in GCA is also observed in municipal regions but not in rural regions of China. Another striking feature is the strong male predominance among patients with GCA. Some of the reasons above are still unclear and require further epidemiological investigations.

### Research frontiers

The etiological factors associated with this rare disease remain unclear and require a comprehensive investigation in Taiwan. And no corresponding sex difference in the established risk factors for GCA can explain the male predominance. This is the first study which explores simultaneously all potentially factors associating with the disease among men, including *Helicobacter pylori* (*H pylori*) infection, lifestyle, diet and nutritional supplements intake history and family history of the disease in the Chinese population. And, this is the first study to explain the male predominance by sex differences in risk factor profiles of the disease.

### Innovations and breakthroughs

This study showed that working or exercising after meals, and *H pylori* infection may increase the risk of GCA. Moreover, the interactive effect between working or exercising after meals and *H pylori* infection augments the risk while rice as principal food and higher intakes of fresh vegetables and fruits may well reduce the risk.

### Applications

Avoiding laborious task after meals and diet control may help prevent GCA. Earlier detection and eradication of *H pylori* may refer to the clinical selective direction of prophylaxis and treatment of this disease.

### Peer review

This study evaluated retrospectively the risk factors of GCA among men. The results are interesting and suggest that working or exercising after meals and *H pylori* infection are important independent risk factors for GCA, but CagA strains of *H pylori* are not associated with this cancer. Furthermore, this study also demonstrates that rice as principal food and consumption of fresh vegetables and fruits may well reduce the risk of GCA.

### Abstract

**AIM:** To clarify the benefit of surgical excision for patients with extrahepatic metastases of hepatocellular carcinoma (HCC).

**METHODS:** We retrospectively reviewed the medical records of 140 patients with pathologically proven extrahepatic metastases of HCC and evaluated the outcomes of those who had undergone surgical resection (SR) for extrahepatic metastatic lesions. Prognoses made on the basis of extrahepatic metastatic sites were also examined.

**RESULTS:** The survival rates of patients who underwent SR of extrahepatic metastases were significantly better than those of patients who did not receive SR. For the SR group, 1- and 3-year survival rates were 24% and 7%, respectively, while for the non-resection group, the survival rates were 8% and 0%, respectively ( $P < 0.0001$ ). Survival rates related to metastatic sites were also significantly superior after SR of extrahepatic metastases: median survivals were 32 mo with lung metastasis, 10 mo with bone metastasis, 6.1 mo with brain metastasis.

**CONCLUSION:** SR can provide survival benefits for

### INTRODUCTION

Hepatocellular carcinoma (HCC) is an aggressive malignant tumor that occurs throughout the world. It is one of the leading causes of cancer-related death among people in East Asian countries. Recent progress in diagnostic tools has led to an improved prognosis for HCC patients because of enhanced detection of early and small HCC and better identification of those patients who qualify for hepatic resection (HR)<sup>[1-5]</sup>. Moreover, treatment trends towards aggressive multimodal therapy in patients with intra-hepatic HCC have also improved long-term outcomes<sup>[6-9]</sup>. Nevertheless, extrahepatic metastasis of primary HCC is still considered terminal-stage cancer, and the prognosis for patients at this stage continues to be poor due to limited effective treatment. Despite recognition of this situation, there appears to be no consensus among the medical community regarding treatment strategies for HCC patients with extrahepatic metastasis. Therefore, to improve the overall long-term survival of patients with HCC, more active treatment of extrahepatic metastases is necessary. Several studies have recently demonstrated that surgical resection (SR) of extrahepatic metastases is able to provide benefits for selected patients with HCC<sup>[10-13]</sup>. However, the role

of SR in HCC patients with extrahepatic metastases required further clarification. In this study, we present our experience with patients with extrahepatic metastases of primary HCC and evaluate the benefits of surgical removal of extrahepatic lesions.

## MATERIALS AND METHODS

### Patients

A total of 2245 patients with primary HCC were treated at the Department of Surgery, Chang Gung Memorial Hospital-Linkou Medical Center in Taiwan, during the study period between June 1988 and June 2008. Among them, medical records of 151 patients with pathologically proven extrahepatic metastases from primary HCC were retrospectively reviewed. Metastasis of HCC was confirmed for all patients by histological examination of specimens derived from either biopsy or excision of extrahepatic tumor lesions. Of the 151 patients, 11 were lost to follow-up; thus, the remaining 140 patients, including 108 men and 32 women, were enrolled in the present study.

### Diagnosis and treatment of intra-hepatic HCC

Intrahepatic primary or recurrent HCC was diagnosed by dynamic liver computed tomography (CT) scans and hepatic angiography, which shows hyperattenuation in the arterial phase and hypoattenuation in the late phase indicating hypervascular tumor mass. Ultrasound-guided biopsy was performed only when considered necessary.  $\alpha$ -fetoprotein was also routinely checked as a parameter of diagnosis.

Treatment of intrahepatic HCC consisted of multimodal therapeutic procedures including hepatic resection (HR), radiofrequency ablation, percutaneous chemical reagent injection, transcatheter arterial chemoembolization (TACE), or a combination of these treatment modalities. Treatment methods were selected for hospitalized HCC patients based on the following principles. HR was considered a priority for patients with intrahepatic HCC whenever the tumor was determined to be resectable. An alternative approach, such as local ablation or TACE, was performed as indicated if patients had systemic multiple tumors, a difficult tumor location, unsuitable conditions for HR, or refused surgical treatment. Patients might also have received concurrent or sequential multimodal treatments if conditions warranted.

### Diagnosis and treatment of extrahepatic HCC

Detection of extrahepatic HCC and determination of tumor location was accomplished through X-ray, CT, magnetic resonance imaging (MRI), or bone scintigraphy as indicated and under two conditions: namely, recurrent and concurrent. Recurrent extrahepatic HCC was noted during post-operative follow-up after treatment for primary HCC. Concurrent extrahepatic HCC was observed at the initial diagnosis stage of intrahepatic HCC. In order to ensure the significance and validity of our research, only those patients with pathologically

**Table 1** Clinical characteristics of patients with extrahepatic metastases of hepatocellular carcinoma

Characteristics	n (%)
Age (yr)	55.8 ± 14.4

Heart	2 (1.4)

proven extrahepatic metastasis of HCC were included in our study.

Treatment of extrahepatic metastasis varied according to the individual clinical characteristics of each patient. SR was selected for patients whose extrahepatic HCC was solitary, isolated, and considered resectable, and for whom intrahepatic tumor recurrence was not observed after previous treatment or for whom the intrahepatic tumor was completely treated by either HR or other treatment modalities. Systemic chemotherapy was reserved for those patients deemed unsuitable for SR. Radiotherapy was performed to relieve patients' symptoms as indicated.

### Follow-up

All patients were closely followed up at regular intervals until death or until the writing of this article. The duration of follow-up after first diagnosis of HCC ranged from 1 to 138 mo (median, 16 mo). Follow-up after diagnosis of extrahepatic metastasis ranged from 0.8 to 96 mo (median, 6.1 mo).

### Statistical analysis

All data were analyzed using the statistical software Prism 5.0 (GraphPad Software, San Diego, CA, USA). Survival rates were calculated by the Kaplan-Meier method, and the log-rank test was used to compare survival rates. Patients who died from surgical complications were excluded from the survival curve. A value of  $P < 0.05$  was considered statistically significant.

## RESULTS

### Clinical features of patients with extrahepatic metastases from HCC

The clinical characteristics of patients at initial diagnosis of extrahepatic metastases are summarized in Table 1. The average age of these patients was 55.8 years (range, 13 to 81 years). Predominant clinical elements were male gender (77%, 108/140) and a positive test for the

**Table 2** Clinical characteristics of patients who underwent surgical resection of extrahepatic metastases of hepatocellular carcinoma

Characteristics	n (%)
Age (yr)	54.1 ± 14.9
Male:Female	64:22
Hepatitis B virus surface antigen	46 (53)
Hepatitis C virus antibody	22 (21.4)
Concurrent treated intrahepatic lesion	
Yes	59 (69)
No	27 (31)
Location of metastatic tumor	
Lung	11 (12.8)
Bone	24 (27.9)
Brain	25 (29.1)
Soft tissue	24 (27.9)
Heart	2 (2.3)

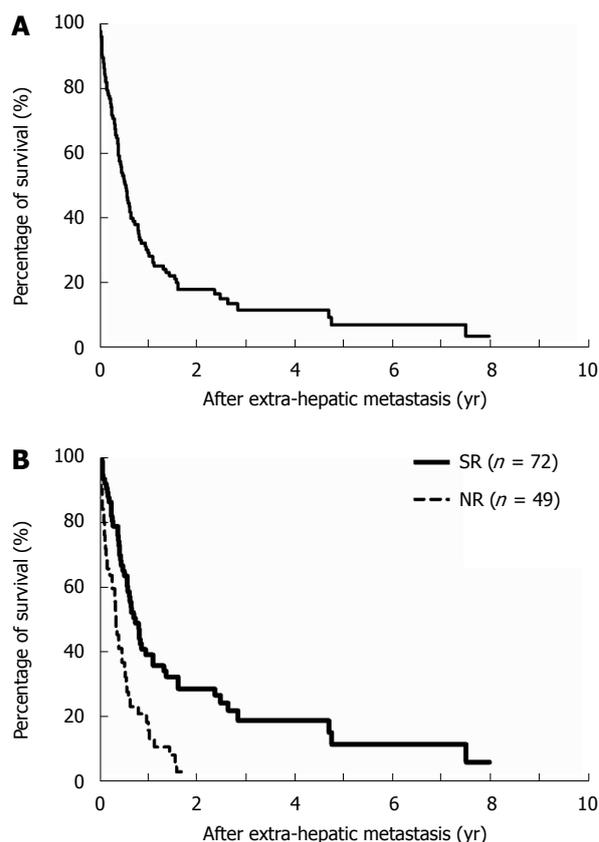

hepatitis B virus (47%, 66/140). These findings were similar to those of our previous reports on primary HCC<sup>[14,15]</sup>. Further, 66 patients (47%) had previously undergone HR for primary HCC. Among these patients, 7 had received multiple HRs for intrahepatic HCC and 2 had undergone liver transplantation. Extrahepatic metastases had occurred mainly at bone, brain, lung, and soft tissue locations. Patients categorized into the soft tissue group had extrahepatic metastases to intra-abdominal soft tissue (6 patients), intra-abdominal organs (4 patients), abdominal wall (16 patients), breast (1 patient), and skin plus subcutaneous tissue (8 patients).

SR of extrahepatic metastases of HCC was performed on 86 patients (64 male and 22 female; Table 2). Further, 59 out of 86 patients had intrahepatic tumors at the time of extrahepatic metastasis detection. Among these patients, 54 were also treated by TACE, local ablation, or a combination of both therapies for their intrahepatic lesion; thus, most patients received more than one course of treatment prior to resection of the extrahepatic lesion. Five patients underwent simultaneous HR for intrahepatic HCC and SR of extrahepatic metastases.

### Survival of patients

The median length of patient survival was 6.9 mo (range, 0.8 to 96 mo), and the overall 1-, 3-, and 5-year survival rates were 31%, 7%, and 4%, respectively, for all patients with extrahepatic metastases of HCC (Figure 1A). Long-term overall survival was significantly better in patients who underwent SR of extrahepatic metastases than in those who did not [non-resection (NR) patients]. The 1-year/3-year survival rates were 24%/7% for the SR group as compared with the 1-year/3-year survival rates of 8%/0% for the NR group (Figure 1B,  $P < 0.0001$ ).

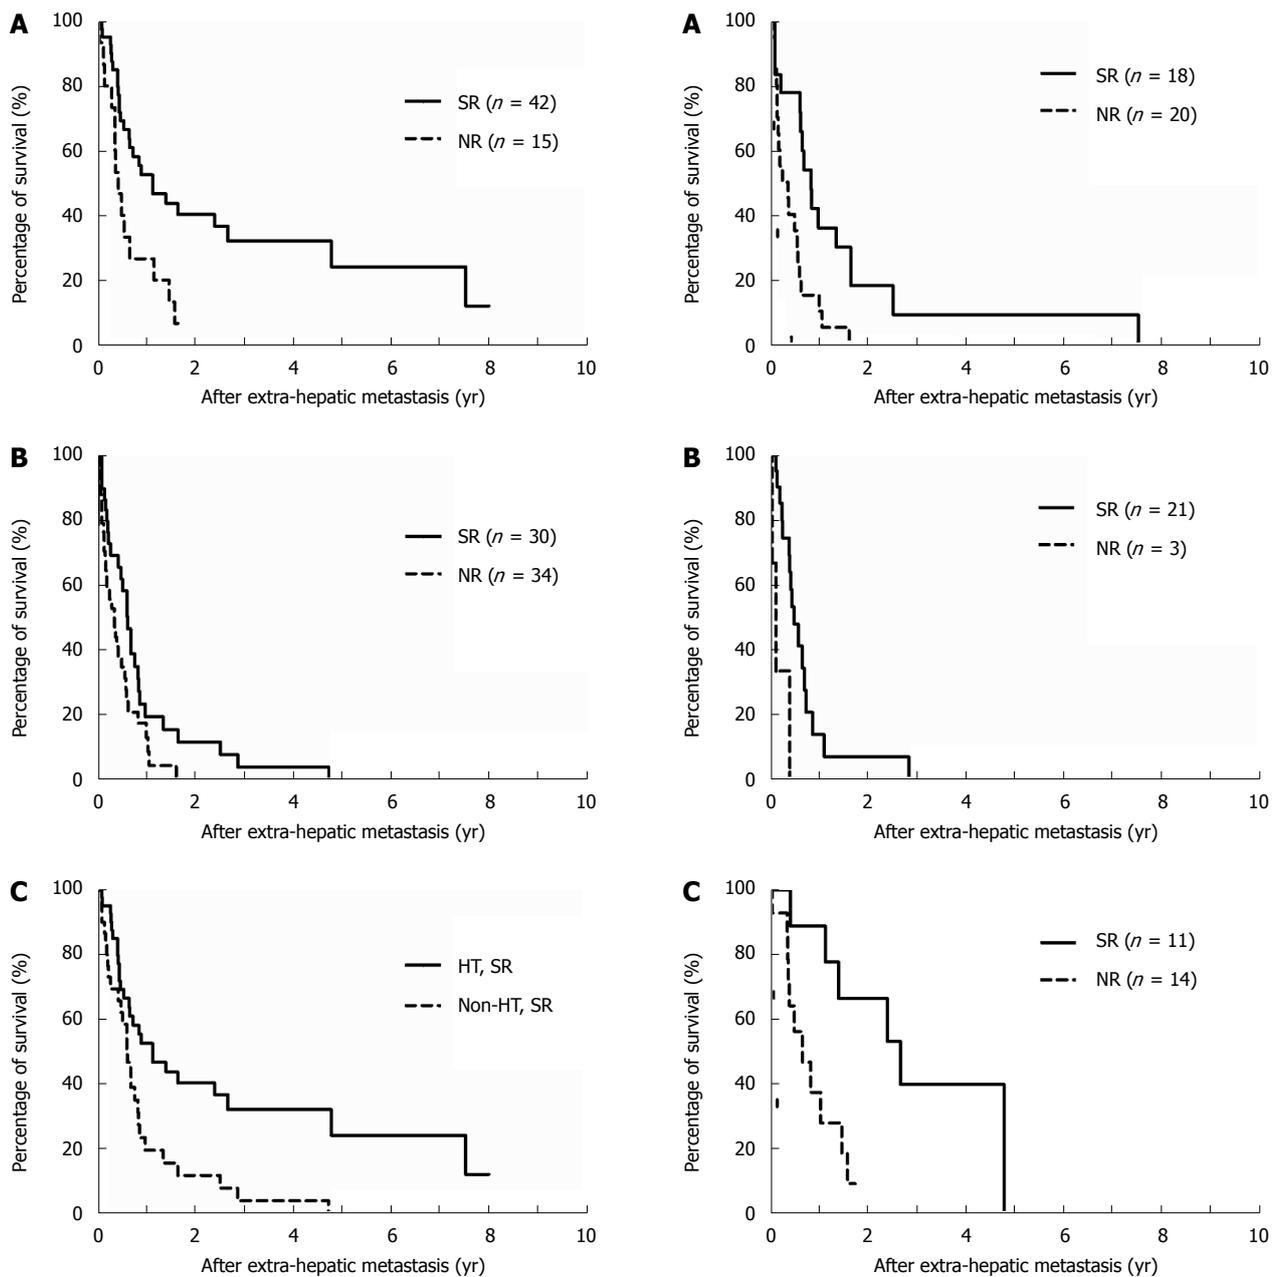

We further analyzed survival rates according to whether HR had been performed. Sixty-six patients had previously undergone HR (Table 1), including 5 patients who underwent simultaneous resection of intrahepatic and extrahepatic tumors at initial diagnosis and 61 patients who underwent resection of intrahepatic tumors followed by subsequent resection of extrahepatic tumor

**Figure 1** Survival rates. A: Overall cumulative survival curve of patients with extrahepatic metastases of HCC; B: Comparison of survival rates according to whether patients underwent surgical resection (SR) of extrahepatic metastases or not. NR: non-resection ( $P < 0.0001$ ).

recurrence. The outcome for patients who underwent SR was significantly better than that of the NR patients (Figure 2A and B), and the survival rate of SR patients in the HR group (1-year/3-year, 52.5%/32.1%) was considerably better than that of the non-HR group (1-year/3-year, 19.4%/3.9%,  $P = 0.0020$ ; Figure 2C).

The cumulative 1- and 3-year survival rates after extrahepatic metastases were 22.1%/4.1% for bony metastases, 11.8%/0% for brain metastases, 59.4%/20.8% for lung metastases, and 31.2%/27.3% for soft tissue metastases, respectively. The comparison of survival curves in relation to metastatic sites is depicted in Figure 3 and indicates that patients who received SR of extrahepatic HCC had a significantly better prognosis than patients in the NR group. The 1- and 3-year survival rates of the SR group *vs* the NR group by metastatic site were, respectively, 35.9%/9.0% (median survival, 10 mo) *vs* 10%/0% (median survival, 3.6 mo) for bony metastases (Figure 3A,  $P = 0.0022$ ); 13.6%/0% (median survival, 6.1 mo) *vs* 0%/0% (median survival, 1.7 mo) for brain metastases (Figure 3B,  $P = 0.0055$ ); 89%/40% (median survival, 32 mo) *vs* 37.5%/9.4% (median survival, 7.9 mo) for lung metastases (Figure 3C,  $P = 0.0063$ ); and 40.2%/40.2% (median survival, 10.1 mo) *vs* 16.7%/0% (median survival, 3.5 mo) for soft tissue metastases (Figure 3D,  $P = 0.0080$ ). Among those patients who had undergone SR, resection of lung metastases demonstrated

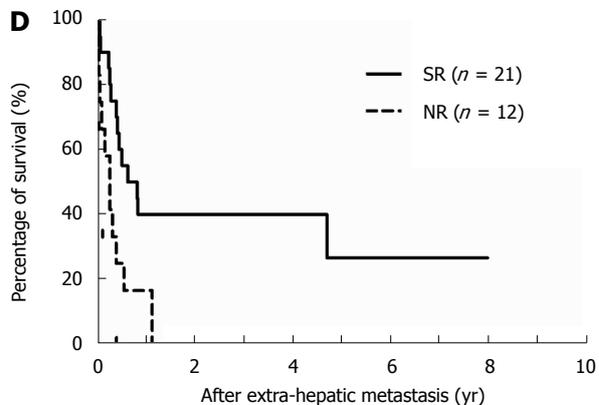

**Figure 2** Comparison of survival curves between surgical resection (SR) and non-resection (NR) groups for extrahepatic metastases in terms of patients (A) who had undergone previous hepatectomy for primary HCC ( $P = 0.0054$ ), and (B) who had not received hepatectomy ( $P = 0.0247$ ); (C) Among patients with surgical resection for extrahepatic metastases, the survival curve of the HT group was significantly better than that of the non-HT group. ( $P = 0.0020$ ).

most favorable outcomes when compared with the other metastatic sites (Figure 4,  $P < 0.05$ ).

**Patients with long-term survival**

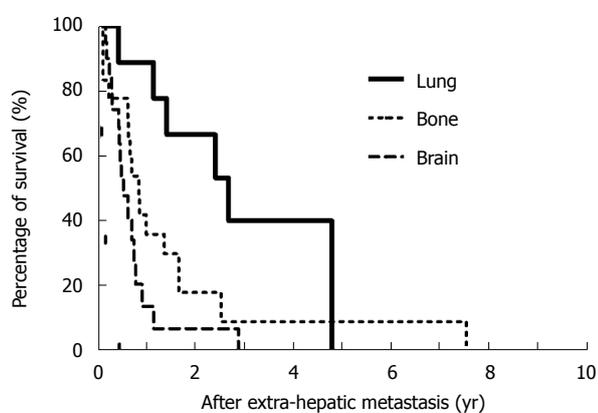

The clinical features of patients with favorable outcomes who survived more than 3 years after extrahepatic metastases diagnosis are listed in Table 3. Four patients had undergone HR and one had received TACE for their primary HCC. All patients had experienced intrahepatic recurrence and were treated by either TACE or local ablation after initial treatment. A solitary metastatic lesion at

**Figure 3** Comparison of survival curves between surgical resection and non-resection groups according to metastatic sites. A: Bone,  $P = 0.0022$ ; B: Brain,  $P = 0.0055$ ; C: Lung,  $P = 0.0063$ ; D: Soft tissue,  $P = 0.0080$ . The data show that surgical resection resulted in significantly better patient survival rates at all extrahepatic metastatic sites.

**Table 3** Clinical features of patients who underwent surgical resection for extrahepatic metastases from HCC with favorable outcomes

No. of patient	Age (yr)/ Sex	Treatments for intrahepatic HCC	Extrahepatic metastases		Follow-up after metastases (mo)	Outcome
			Duration to metastases (mo)	Location/Management		
1	44/Male	Hepatic resection: 1 time TACE: 1 time	7	Lung/wedge resection	40	Alive
2	36/Female	Hepatic resection: 1 time TACE: 1 time	16	T-spine/resection of tumor Lung/wedge resection	89	Dead
3	31/Female	Hepatic resection: 1 time TACE: 3 times	11	Transverse colon and peritoneal soft tissue/surgical resection	67	Alive
4	51/Male	Hepatic resection: 1 time TACE: 2 times PEI: 1 time RFA: 1 time	32	Peritoneal soft tissue/surgical resection	96	Alive
5	67/Male	TACE: 11 times PEI: 8 times	7	Abdominal wall/wide excision	57	Dead

**Figure 4** Among patients with surgical resection of extrahepatic metastases, the survival curves are compared according to metastatic sites. Patients who had undergone surgical resection of lung metastases benefit from better survival curves than patients with the other two metastatic sites. (Lung vs bone,  $P = 0.0418$ ; lung vs brain,  $P < 0.001$ ).

the 12th thoracic spine was noted in patient 2 (Table 3) 16 mo after hepatic resection, and another episode of isolated pulmonary metastasis was encountered in the subsequent 32 mo. Both events were successfully treated by SR, but the patient died 89 mo after initial detection of extrahepatic metastasis due to systemic metastases. Three patients were still living at the end of this study; follow-up of patient 4 has been ongoing for 96 mo after SR of his intra-abdominal metastatic lesion.

## DISCUSSION

HCC is an aggressive malignant neoplasm with dismal prognosis because of the high incidence of intrahepatic recurrence after initial treatment. However, recent trends towards aggressive treatment of intrahepatic recurrence with multimodal therapy have significantly improved the overall outcome of patients with HCC<sup>[6,9,16]</sup>. This trend, along with better treatment of intrahepatic HCC, may not only prolong a patient's survival but may also retard anticipated extrahepatic metastases. Because the prognosis of patients with extrahepatic metastases is considered very

poor and because there is limited information regarding treatment strategies for these patients, it is necessary to actively develop more aggressive treatment methods in order to further improve the long-term survival of HCC patients with extrahepatic metastases.

HCC is a hypervascular tumor and is believed to spread mainly through a hematogenous route, causing extrahepatic metastases. It has been reported that extrahepatic metastases occur in 13.5%-41.7% of HCC patients<sup>[17-20]</sup>; however, actual prevalence may be higher than that reported. Although all HCC patients are followed up at regular intervals for intrahepatic recurrence using a variety of diagnostic tools, not all patients receive complete examination for extrahepatic metastases. Moreover, the majority of patients with extrahepatic metastases experience no specific symptoms, and it is possible to overlook extrahepatic metastases upon examination. Therefore, increased detection of extrahepatic metastases suitable for aggressive treatment may provide great benefit to patients and improve overall survival of those with HCC.

Increasing evidence shows that SR of metastatic lesions with curative intent has become standard practice for the management of several malignancies. SR of isolated metastatic lesions from colorectal cancer, gastrointestinal stromal tumors, neuroendocrine cancers, renal-cell carcinoma and sarcoma is associated with favorable outcomes<sup>[21-24]</sup>. Furthermore, improvements in patient safety during complex surgeries have also lowered the threshold for more aggressive surgical intervention. Recently, several reports have shown that SR of HCC metastases prolonged survival in selected patients<sup>[10,11,13,25]</sup>. Our results appear to be comparable with those reports which indicated that patients who received SR of extrahepatic metastases had better outcomes than patients who did not receive SR. In addition, in our study, patients undergoing SR of lung metastases had better survival rates than patients with bony and brain metastases, which is comparable with previous reports that surgical resection of pulmonary metastasis from HCC has favorable outcome. Although the small number of patients involved in this study

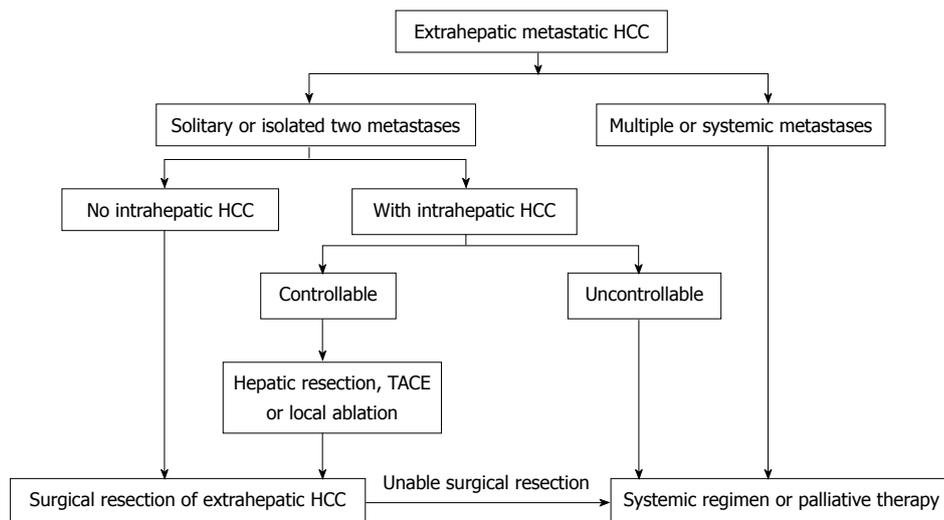

Figure 5 Suggested strategy for management of extrahepatic metastases from primary hepatocellular carcinoma.

might not reflect a real variation in outcomes due to metastatic location, we believe that our observations are valid. However, the difference in outcomes based on metastatic site may be related to the molecular biological pattern of HCC; therefore, further studies involving basic science and using a larger number of patients should be conducted to clarify the significance of our results.

Bony metastasis is one of the most frequent extrahepatic metastasis of HCC and occurs as multiple metastases in most patients<sup>[19,26,27]</sup>. In this study, the outcome of HCC patients with bony metastases was poor. Patients with metastases to bone had a median survival of 6.7 mo, which is similar to previous reports<sup>[28,29]</sup>. Data also indicate that the spine is the most common site of bony metastasis of HCC, and further studies suggest that surgical treatment for spinal metastatic HCC lesions usually improves quality of life instead of prolonging patient survival<sup>[30]</sup>. Nevertheless, prolongation of survival may still be achievable in selected patients, as observed in the current study. The longest survival of a patient who had undergone resection of metastasis at the left femoral shaft was 30 mo after the detection of extrahepatic metastasis.

Brain metastasis of HCC is relatively rare and is detected in less than 1% of HCC patients<sup>[20,31]</sup>. The overall prognosis of patients with brain metastases is extremely poor, and the most recent report showed that the median survival of these patients was only 6.8 wk after the detection of metastatic brain lesions<sup>[32]</sup>. Clinically, brain metastases are frequently associated with mass-producing hemorrhage, a condition requiring further surgical treatment. Although the surgical excision of brain metastases is considered a palliative treatment, several reports have also shown that a favorable outcome was achievable in patients with a single brain metastasis and good liver function and performance status<sup>[32,33]</sup>. Our study showed that patients who had undergone SR of brain metastases fared significantly better than NR

patients, with a median survival of 6.1 mo *vs* 1.7 mo. Thus, SR of metastatic brain lesions of HCC should be considered in specific patients not only to improve quality of life but also to prolong life expectancy.

Nonetheless, one might argue that patients who are not suitable for surgical resection are naturally in poorer condition than patients who underwent SR for extrahepatic metastasis. Indeed, although HCC with extrahepatic metastasis is considered the terminal-stage of TNM staging, the outcome of patients with systemic multiple metastases theoretically might be poorer than those of one or two isolated extrahepatic metastases. However, the accumulated data and this study have shown that SR of extrahepatic metastases can effectively provide real benefits for patients with HCC. Although there is no standard treatment for extrahepatic metastases of HCC, aggressive treatment in patients with HCC should be considered, not only in cases of intrahepatic HCC, but also in the event of extrahepatic metastases. Taking into consideration that there are no effective nonsurgical treatment modalities for extrahepatic metastases of HCC, surgical treatment may be the only modality available for curing selected patients. As our study has shown, patients who have undergone HR prior to SR for extrahepatic metastases had the best outcome, indicating that patients should be closely followed up at regular intervals after initial treatment of primary HCC to ensure early detection of extrahepatic metastases at a resectable stage.

In conclusion, we herein propose the following algorithm for surgical management of extrahepatic metastases from HCC (Figure 5). Surgical excision of extrahepatic metastases should be considered in patients with one or two isolated extrahepatic metastases if the patient has otherwise good performance status, good hepatic functional reserve, and well-controlled intrahepatic HCC. Although the retrospective nature of the current study and the small number of patients with resectable extrahepatic metastases makes it hard to compare outcome of patients undergoing SR for isolated

extrahepatic metastasis with those who do not receive SR, the marked differences we observed may prove helpful in the management of patients with HCC. Furthermore, to achieve better long-term outcomes of patients with HCC, as well as effective treatment of extrahepatic metastases, new promising treatments such as a novel systemic chemotherapy or targeting therapy should be developed.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is a common malignant tumor, and ranked within the top five of cancer-related deaths worldwide. Patients with extrahepatic metastases of primary HCC are clinically considered at terminal-stage cancer, and there is still no effective treatment as well as no consensus on treatment strategies for these patients. Recently, several reports have shown benefit of surgical resection of extrahepatic metastases from HCC. However, the role of surgical resection in the treatment of extrahepatic metastasis of primary HCC remains uncertain.

### Research frontiers

The concept of treating metastatic cancer has been changing recently. Patients with several types of metastatic cancers such as colon cancer, gastrointestinal stromal tumor, neuroendocrine cancer, sarcoma, renal cell carcinoma, *etc.* are considered to gain benefit from surgical resection of metastatic lesions. Therefore, it seems reasonable to attempt aggressive surgical resection for HCC patients with extrahepatic metastases.

### Innovations and breakthroughs

In the present study, the authors gathered their experience in the management of HCC, and further clarified the role of surgical resection in dealing with extrahepatic metastases from HCC. The results show that although the outcome of patients with extrahepatic metastases remains very poor, surgical resection could provide survival benefits for patients who had 1 or 2 isolated extrahepatic metastases under a prerequisite that patients has good performance status and good hepatic functional reserve, as well as successful treatment of intrahepatic HCC.

### Applications

According to results from the study, the authors have proposed an algorithm for the management of extrahepatic metastases. Since there is no effective treatment for extrahepatic metastases in this era, surgical resection might be an applicable option and provide better outcome for well selected patients.

### Peer review

The authors reviewed their experience in dealing with primary HCC with extrahepatic metastasis, and proposed a treatment strategy suggesting that surgical resection might provide benefit to patients.

### Abstract

Endoscopic ultrasonography (EUS) is a highly sensitive diagnostic method for the detection of small pancreatic carcinomas. Recently, there have been some reports describing the utility of contrast-enhanced harmonic EUS (CEH-EUS) which uses sonographic contrast agent for differentiation of a pancreatic mass. This report describes a case of small adenocarcinoma of the pancreas distinct from branch duct intraductal papillary mucinous neoplasm (IPMN) in which investigation by EUS took place every 6 mo and diagnosis was made accurately by additional CEH-EUS during the follow-up of the branch duct IPMN. A 68-year-old female was admitted to our hospital because of a branch duct IPMN in the pancreatic body. She had been followed-up by EUS every 6 mo. However, after 2 years EUS

demonstrated a low echoic area distinct from the branch duct IPMN which was vaguely discernible by EUS, and accurate sizing and differential diagnosis were considered difficult on the EUS imaging. CH-EUS with Sonazoid revealed a hypovascular tumor and we suspected small pancreatic carcinoma. The histopathological diagnosis was adenocarcinoma (10 mm) in the pancreatic tail, distinct from the branch duct IPMN of the pancreatic body. EUS and CEH-EUS may play an important role in the correct diagnosis of small pancreatic tumors, including synchronous and metachronous occurrence of IPMN and ductal adenocarcinoma of the pancreas.

### INTRODUCTION

Endoscopic ultrasonography (EUS) is now commonly used worldwide and is more sensitive for the detection of small pancreatic lesions when compared with transabdominal ultrasonography (US) or contrast-enhanced computed tomography (CE-CT)<sup>[1,2]</sup>. Recently, there have been some reports describing the utility of contrast-enhanced EUS (CE-EUS) and contrast-enhanced harmonic EUS (CEH-EUS) with sonographic contrast agent for differentiation of pancreatic masses<sup>[3-7]</sup>.

Intraductal papillary mucinous neoplasm (IPMN)

of the pancreas is a unique clinicopathological entity characterized by cystic dilatation of the main or branch pancreatic duct, mucus production and intraductal papillary growth<sup>[8-11]</sup>. Metachronous occurrence of IPMN and ductal carcinoma of the pancreas has been recently reported<sup>[12-15]</sup>. These authors concluded that special attention should be paid to the development of ductal carcinoma of the pancreas during the follow-up of IPMN. However, the detection of ductal carcinoma at an early stage is still difficult, even under close surveillance by imaging examinations such as abdominal US and computed tomography (CT) during the follow-up of IPMN.

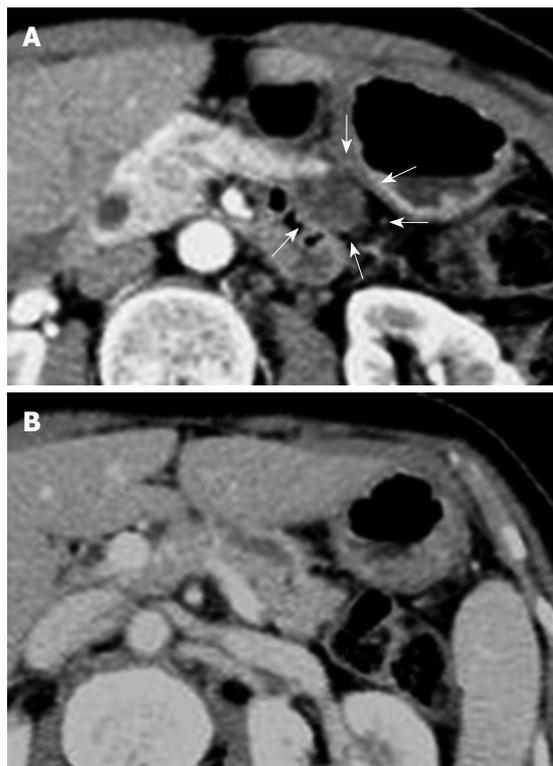

Here, we report a patient with small invasive ductal carcinoma of the pancreas that is distinct from branch duct IPMN. The lesion in this patient was detected by EUS and the diagnosis was established accurately by contrast-enhanced harmonic EUS during the follow-up of the branch duct IPMN.

## CASE REPORT

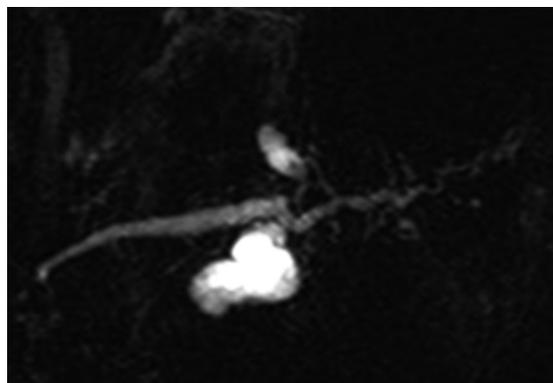

A 68-year-old female was admitted to our hospital because of a branch duct IPMN in the pancreatic body that was detected by contrast-enhanced computed tomography (CE-CT) (Figure 1). Magnetic resonance cholangiopancreatography (MRCP) (Figure 2) and EUS revealed a dilatation of the branch pancreatic ducts in the pancreatic body (22 mm × 9 mm, 8 mm × 5 mm); however, no nodules were found in the cyst and in any other parts of the pancreas. The patient was followed up by performing EUS every six months, as well as MRCP and CE-CT once a year. The size of the branch ducts was unchanged one year after the last MRCP (Figure 3). EUS performed at two years revealed a low echoic area that was distinct from the dilatation of the branch duct IPMN. This finding was vague and the area had unclear margins with a low echoic area, as assessed by EUS (Figure 4A). Thus, it was very difficult to determine the accurate size of the area and perform a differential diagnosis based on the EUS imaging. We performed CEH-EUS using an Olympus GF-UE260P apparatus (Olympus Medical Systems Co. Ltd., Tokyo, Japan) for endoscopy, Extended Pure Harmonic Detection (ExPHD) mode of ALOKA Prosound α-10 (ALOKA Co. Ltd., Tokyo, Japan) for image analysis and Sonazoid (15 μL/kg intravenously, Daiichi Sankyo, Tokyo, Japan; GE Healthcare, Milwaukee, Wisc., USA) as a contrast agent. CEH-EUS revealed the presence of a 10 mm hypovascular tumor, which led us to suspect a small carcinoma of the pancreas (Figure 4B). Pancreatoduodenectomy was performed. The histopathological diagnosis established was a moderately differentiated tubular adenocarcinoma in the 10 mm range at the maximum length of the pancreatic tail, which was distinct from the branch duct intraductal papillary mucinous adenoma of the pancreatic body (Figures 5 and 6).

## DISCUSSION

We report here the discovery of independent development of a ductal carcinoma of the pancreas during follow-up

**Figure 1** Contrast-enhanced computed tomography (CE-CT) scan of pancreas. A: A cystic lesion in pancreatic body (arrows); B: A dilatation of the main duct in the pancreatic tail. Solid masses were not observed.

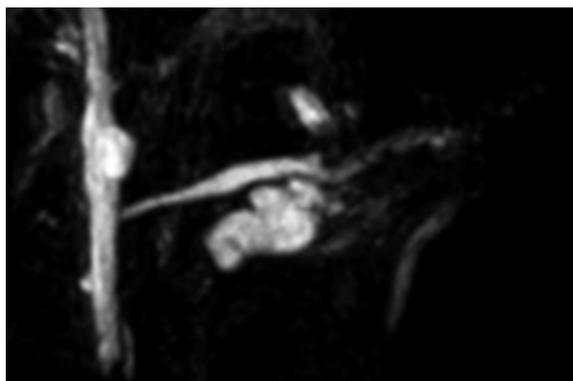

**Figure 2** Magnetic resonance cholangiopancreatography (MRCP) at initial examination showing dilatation of the branch duct.

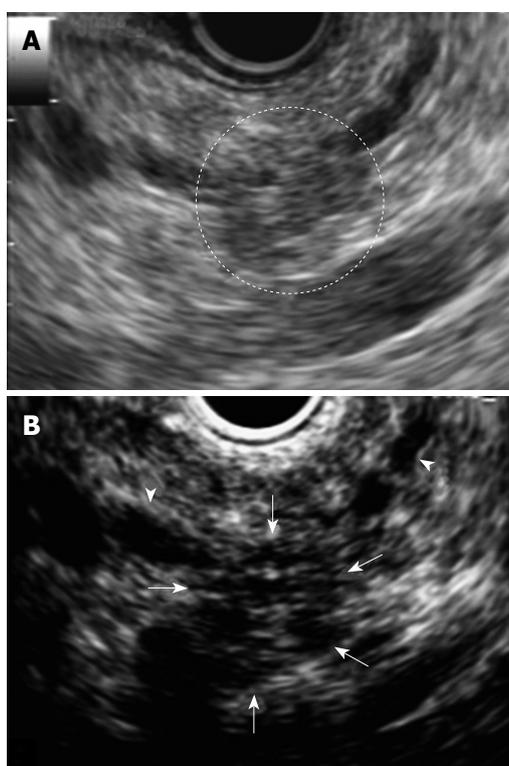

of an IPMN, similar to the metachronous occurrence of IPMN and ductal carcinoma of the pancreas which has been recently reported<sup>[13-15]</sup>.

Uehara *et al*<sup>[13]</sup> reported results from a follow-up study of 60 patients with branch duct IPMNs over an average period of 87 mo, and the follow-up was performed by US every three or six months. These authors detected ductal pancreatic carcinomas that were distinct from IPMN in 5 of 60 patients (8%). Four of the 5 ductal carcinomas detected during follow-up were resectable, but all of them were advanced cancer.

Tada *et al*<sup>[14]</sup> followed-up 197 cystic lesions of the pancreas, including 80 branch duct IPMNs and 117 non-IPMN cysts, for an average period of 3.8 years, and found 5 ductal carcinomas between 14 and 60 mo after

**Figure 3** The size of the branch ducts was unchanged one year after the last MRCP.

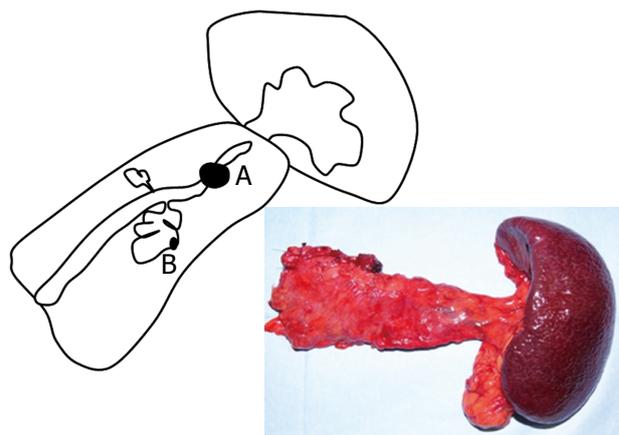

**Figure 4** Endoscopic ultrasonography (EUS) at two years later examination showing pancreatic tail. A: EUS showing low echoic lesion which is vague and the area had unclear margins in the pancreatic tail; B: Contrast-enhanced harmonic EUS showing a clear margin of 10 mm in diameter and hypovascular nodule compared with surrounding pancreatic tissue (arrows). MPD: Main pancreatic duct (arrowheads).

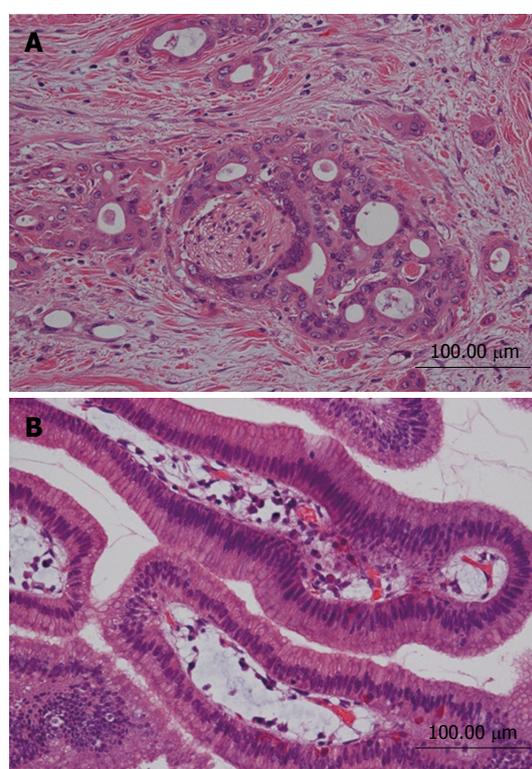

the diagnosis of the cystic lesions. In two patients, ductal carcinomas were < 2 cm in size, arising in apparently different sites from the cystic lesion. In one patient, the ductal carcinoma developed around the pre-existing cystic lesion. In the remaining two patients, the tumors were too large to evaluate any local relationship between carcinoma and cystic lesion.

These results indicate that the detection of ductal carcinoma at an early stage was still difficult even under close surveillance imaging examination such as US.

EUS is a highly sensitive diagnostic method for detection of pancreatic carcinoma, especially small

**Figure 5** Scheme showing the pancreatic body and tail by pancreatoduodenectomy. A: Intraductal papillary tumor of the pancreatic body; B: Invasive adenocarcinoma of the pancreatic tail.

**Figure 6** Histological appearance of two lesions (HE). A: Intraductal papillary mucinous adenoma; B: Moderately differentiated tubular adenocarcinoma.

pancreatic carcinomas. In the case reported here, the small pancreatic mass was not detected by CE-MDCT, US or MRCP. EUS was the only imaging technique that detected this mass. During the follow-up of branch duct IPMN, special attention should be paid to the occurrence of ductal carcinoma distinct from IPMN as detected by EUS. Recent reports have described the utility of contrast-enhanced EUS (CE-EUS) and CEH-EUS using sonographic contrast agent for the differentiation of pancreatic masses<sup>[3-7]</sup>. In the case reported here, CEH-EUS imaging using Sonazoid clearly distinguished the margin of the tumor and accurately measured the size of the lesion. Moreover, CH-EUS revealed that the mass was

hypovascular when compared with surrounding tissue, which suggested an adenocarcinoma of the pancreatic tail. Therefore, CEH-EUS should be used for the accurate diagnosis of small pancreatic tumors, including the synchronous and metachronous occurrence of IPMN and ductal adenocarcinoma of the pancreas.

Here, we reported a patient with a very small ductal carcinoma of the pancreas distinct from a branch duct IPMN. The performance of EUS every six months coupled with CEH-EUS imaging during the follow-up of the branch duct IPMN allowed the establishment of an accurate diagnosis of the disease.

### Abstract

Peliosis hepatis is a rare pathological entity and may cause fatal hepatic hemorrhage and liver failure. Here, we present a young male patient with aplastic anemia, who had received long-term treatment with oxymetholone. The patient suffered from sudden onset of intra-abdominal hemorrhage with profuse hemoperitoneum. The patient was treated successfully with a right hemihepatectomy and is in good health after 13 postoperative months. We suggest that peliosis hepatis be considered in patients with hepatic parenchymal hematoma, especially in patients under prolonged synthetic anabolic steroid medication. The possibility of a potentially life-threatening complication of massive intra-abdominal bleeding should also be considered.

### INTRODUCTION

Peliosis hepatis (PH) was first reported in the German literature in 1861 by Wagner, and named by Schoenlank in 1916<sup>[1]</sup>. It is a rare condition characterized by multiple small cystic blood-filled spaces from 1 mm to several centimeters in diameter in the hepatic parenchyma, resulting from the focal rupture of sinusoidal walls<sup>[2]</sup>. The etiology of PH is still unknown. Sinusoidal obstruction, hepatocellular necrosis, and direct injury to the sinusoidal barrier seem to be the most likely mechanism in adults<sup>[3]</sup>. PH is usually associated with chronic pathologic conditions, including cystic fibrosis, and human immunodeficiency virus (HIV) infection<sup>[4,5]</sup>. PH has also been reported after prolonged use of anabolic steroids (e.g. azathioprine<sup>[6]</sup>, 6-thioguanine, and 6-mercaptopurine<sup>[7]</sup>) and oral contraceptives<sup>[8]</sup>. PH varies from minimal asymptomatic lesions to larger massive lesions that may present with cholestasis, liver failure, portal hypertension, avascular mass lesion, or even spontaneous rupture<sup>[9]</sup>. Here, we report a case of a 20-year-old male patient with aplastic anemia who presented with hemoperitoneum. This patient had received long-term treatment with oxymetholone, and his imaging findings and extraphysiological changes were consistent with spontaneous hepatic rupture with PH. The patient was salvaged from a life-threatening hemorrhage by performing a right hemihepatectomy.

### CASE REPORT

The patient was a 20-year-old male who had been diagnosed with aplastic anemia 8 years previously and had received long-term anabolic steroid therapy. He presented with complaints of pain in the abdomen for one day and a seizure attack without any previous episode. The vital signs at presentation were blood pressure 84/44 mmHg, heart rate 140 beats/min, respiratory rate 24 breaths/min, and body temperature 36°C. The laboratory findings were white blood cell count  $5.1 \times 10^9/L$  (normal  $4 \times 10^9 - 10 \times 10^9/L$ ), hemoglobin 3.01 mg/dL (normal 13.1-17.5 g/L),

hematocrit 24.2% (normal 39%-52%), platelet count  $38 \times 10^9/L$  (normal  $140 \times 10^9 - 400 \times 10^9/L$ ), total bilirubin 1.287 mg/dL (normal  $< 1.3$  mg/dL), alkaline phosphatase 145 IU/L (normal  $< 220$  IU/L), alanine aminotransferase 495 IU/L (normal  $< 43$  IU/L), aspartate aminotransferase 332 IU/L (normal  $< 38$  IU/L), and prothrombin time 17.1 s (normal 11-15 s). Computed tomography (CT) of the brain was taken in the emergency department and revealed no specific abnormality, but the patient suffered from 3 more seizure attacks and became rapidly hypotensive and tachycardic, with abdomen distended and tense. The patient received a red blood cell (RBC) transfusion and fluid resuscitation. Abdominal and pelvic CT showed a laceration of the liver in the right lobe inferior portion and a moderate amount of hemorrhage (Figure 1). Suspecting spontaneous liver rupture with hemoperitoneum, the patient was transferred to the angiography unit for an emergency angioembolization of the right hepatic artery. The angiography showed multiple contrast filling small round lesions predominantly in the right hemiliver (Figure 2A). The right hepatic artery was selected, and gel-form embolization was attempted. On the venous phase angiogram, the peripheral portion of the right lobe of the liver was successfully embolized (Figure 2B). However, the patient continued to deteriorate, and hepatic and/or portal venous bleeding was suspected. An emergency exploratory laparotomy was performed.

Under general anesthesia, the patient was placed in the supine position. A bilateral subcostal incision was made and deepened to the peritoneum. On entering the peritoneal cavity, profuse hemoperitoneum was noted, and the liver was found to be lacerated on the right posterior sector. The Pringle maneuver was performed, but failed to lessen the bleeding. An urgent right hemihepatectomy was performed by the Kelly-clamp crushing method and the finger-fracture technique. After hepatectomy was done, the right upper quadrant was packed with a laparotomy gauze pad, and the peritoneal cavity was thoroughly examined. The remaining left hemiliver did not show gross abnormality nor did the other intraperitoneal organs. After the peritoneal cavity was irrigated with a warm saline solution, the packed gauze pad was removed and the cut surface was examined for further bleeding. Only minimal oozing was noted. Two closed suction drains were inserted at the hepatic cut surface, and the abdominal wall was closed layer by layer. A resected specimen showed extensive necrosis and hemorrhage and the cut surface of the liver parenchyma revealed small blood-filled cystic lesions (Figure 3A and B). The operation required 7 h, and 28 pints of leukoreduced RBC were transfused. The systolic blood pressure ranged from 90 mmHg to 130 mmHg throughout the operation.

Postoperatively, the patient was transferred to the intensive care unit and observed closely. When stable, the patient was admitted to the general ward on the 10th postoperative day, and oral intake was resumed. The drains were removed on the 20th postoperative day. The patient's vital signs were stable until the 17th postoperative day when body temperature began to rise abruptly

**Figure 1** CT of the abdomen showing laceration of the liver right lobe inferior portion (white arrow), with hyperdense fluid in the peritoneal cavity and liver parenchyma, suggesting acute blood collection in these areas (black arrows).

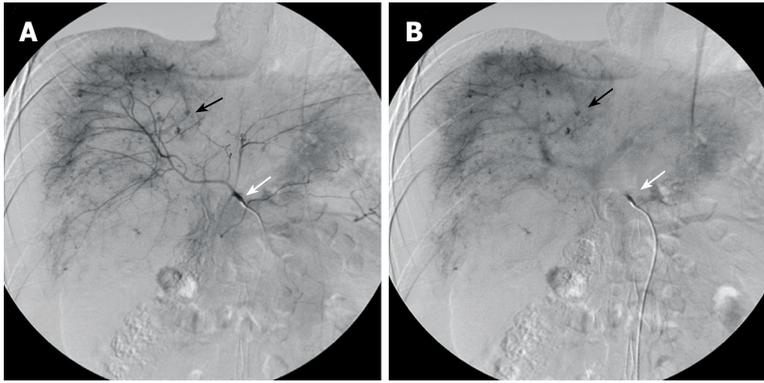

up to 38.5°C. Follow-up CT revealed an intraperitoneal abscess at the hepatectomy site. CT-guided percutaneous drainage was performed, and the patient's fever subsided with antibiotic therapy. The patient was discharged from hospital on the 46th postoperative day. The most recent follow-up was on the 13th postoperative month, and the patient was in good condition without significant complication from the surgery or PH.

The diagnosis of PH was determined from preoperative angiographic findings and histological features. Selective angiography of the celiac trunk showed hemorrhagic spots in the right hepatic parenchyma at the arterial phase with delayed washout at the portal venous phase. Microscopically, there were variable sized blood-filled cystic spaces, and hemorrhagic necroses were present adjacent to the peliotic spaces without lining endothelium (Figures 3 and 4).

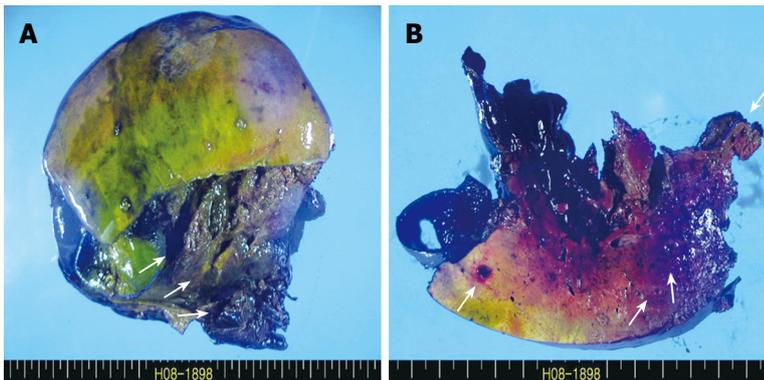

## DISCUSSION

Peliosis is an abnormality of the reticuloendothelial system and most commonly involves the liver. Occasionally, this condition may occur in the spleen and the bone marrow. Peliosis has mostly been reported in adult patients associated with chronic infections such as HIV<sup>[10]</sup> or the use of specific drugs<sup>[6,7,11]</sup>. In many cases, removal of the causative agent had caused regression of the disease<sup>[12]</sup>.

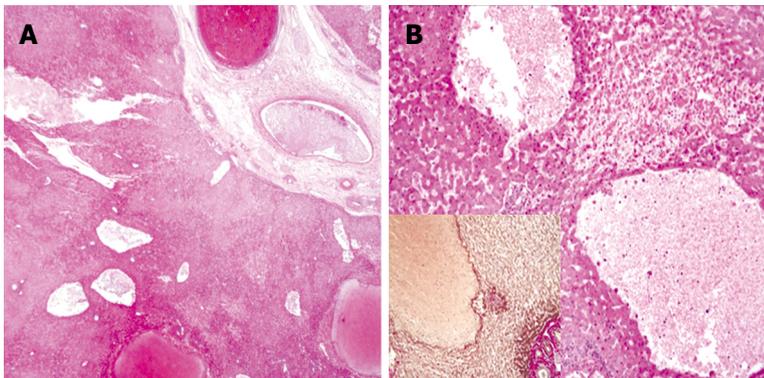

The exact pathogenesis of peliosis is unknown. PH is characterized by blood-filled cystic spaces from a few millimeters to 1 cm in diameter, but can reach up to 4 to 5 cm. Two morphological patterns of PH were described by Yanoff *et al*<sup>[13]</sup>. The parenchymal pattern is characterized by irregular blood-filled spaces, lined by fibrous tissue rather than the endothelium, which neither communicate with the central veins nor compress adjacent parenchymal cells. Instead, they associate with many areas of focal necrosis in the surrounding hepatic tissue. The phlebotatic pattern, the second morphological type, shows minimal hepatocyte necrosis. The regularly spherical, centrilobular blood-filled spaces are lined by endothelial cells and/or fibrotic tissue and freely communicate with hepatic sinusoids. They are an inte-

**Figure 2 Preoperative selective hepatic angiography.** A: Selective angiography of the celiac trunk (white arrow) shows hemorrhagic spots (black arrow) in hepatic parenchyma at the arterial phase. Note: Lesions are mainly distributed in the right hemiliver; B: Angiogram at the portal venous phase shows the lesions with delayed wash-out (black arrow).

**Figure 3 Gross findings.** A: Resected specimen shows extensive necrosis and hemorrhage (arrows); B: Cut surface of the liver parenchyma reveals small blood-filled cystic lesions (arrows).

**Figure 4 Microscopic findings.** A: Low magnification view shows variable-size, blood-filled cystic spaces (HE,  $\times 10$ ); B: High magnification view shows hemorrhagic necrosis in areas adjacent to peliotic spaces without lining endothelium (HE,  $\times 100$ ); Inset: immunohistochemical staining for reticulin ( $\times 100$ ).

gral part of the central vein, causing compression of the adjacent parenchymal cells, and they contain mural fibrin clots. However, Zak<sup>[1]</sup> considered these 2 morphological patterns to be one process, initiated by focal necrosis of the liver parenchyma, which transforms into an area of hemorrhage (parenchymal pattern). This pattern may progress to fibrous wall formation and endothelial lining around the hemorrhage (phlebotactic pattern), or it may heal by the resorption of blood. The phlebotactic pattern may heal by fibrin deposition, thrombosis, and sclerosis of vascular spaces. It has also been noted that a hyperplastic hepatocyte may be prolapsed into a terminal hepatic venule in anabolic steroid-induced peliosis. The theory that toxic substances may induce peliosis is supported by the finding of increased endothelial cell permeability with numerous RBCs in the space of Disse<sup>[14]</sup>. In the current case, the toxic substance that affected the sinusoidal wall was suspected to be the anabolic steroid oxymetholone, and the morphological characteristics

were consistent with the parenchymal pattern. Degott *et al*<sup>[15]</sup> also reported that peliosis could be secondary to fibrous thickening of the hepatic venule, possibly due to azathioprine in patients who had taken the drug long-term.

Eising *et al*<sup>[16]</sup> reported an increased tendency toward liver rupture following blunt trauma in patients with PH. In the present case, the patient had no trauma history, and the cause of the seizure attack was believed to be hemorrhagic shock induced by spontaneous liver rupture. In addition, the patient's usual platelet count was within the range of  $40 \times 10^9/L$  to  $70 \times 10^9/L$ , and the platelet count just prior to hepatic rupture was  $43 \times 10^9/L$ . To our knowledge, there has been no reported case of spontaneous liver rupture with this platelet level in the English literature. On the basis of these findings, we believe that the cause of spontaneous hepatic rupture in this patient was PH, and it was not the result of liver trauma or thrombocytopenia.

Interestingly, although systemic conditions were thought to be the cause of PH, the distribution of lesions within the liver was usually unilobar, favoring the right hemiliver. As far as we know, there has been no published report in the English literature on PH that mentions a preference in location. However, reported cases of liver rupture in PH patients are more common in the right lobe. Adam *et al*<sup>[17]</sup> and Toth *et al*<sup>[18]</sup> reported cases of PH rupture located in the left lobe of liver. But in other cases, the right lobe of the liver was the location of rupture<sup>[9,19-22]</sup>, including the current case. Although Saatci *et al*<sup>[23]</sup> reported a case of PH with multiple foci involving both right and left lobes by magnetic resonance imaging, the location of PH in most cases was unilobar, which may be explained by the distribution of hepatic blood flow. However further research is needed to verify the cause of differential distribution of PH rupture, as more case studies are reported. At the very least, it can be postulated that PH of the liver is a progressive disease that occurs in one lobe first, then extends to the whole liver, and hepatic rupture is distributed along with lesions.

PH is difficult to recognize, and the diagnosis often is missed or delayed because its appearance on radiological imaging is suggestive of a neoplasm or multiple abscesses. An ultrasound scan may show hypoechoic areas involving the liver with intraperitoneal fluid collection and a normal Doppler signal<sup>[24]</sup>. Occasionally, only subtle inhomogeneity is seen in the liver, which can also be seen in other diffuse liver parenchymal diseases. A contrast enhancement CT scan of the liver may show small lesions of a few millimeters to 1 to 4 cm in diameter. The lesions typically are hypodense in early arterial phase scans and enhanced in late venous phase. The CT appearance of PH can be difficult to differentiate from multiple abscesses, hemangiomas, and metastases. The diagnosis of PH on an angiography is made by visualizing multiple small accumulations of contrast material in the late arterial phase, which persists into the venous phase. This can be confused with irregular tumor vessels in focal nodular hyperplasia and adenomas. However, it is unclear if the angiography offers better diagnostic information than ultrasonography. In the current case, an emergency CT failed to show specific changes of PH other than that of hemoperitoneum caused by hepatorrhesis, and an angiogram was necessary to arrive at the diagnosis. A definitive diagnosis of PH was made from histological findings. A percutaneous needle biopsy can also be used to confirm the diagnosis. However, even when ultrasound-guided, the procedure has a high risk of a life-threatening hemorrhage<sup>[25]</sup>. Consequently, a laparotomy appears to be the more appropriate procedure when tissue confirmation is needed because it permits assessment of the macroscopic appearance of peliosis, and a liver biopsy can be performed with adequate hemostasis.

There is no specific treatment for PH. Hepatic artery embolization or partial hepatectomy has been reported<sup>[8,26]</sup>. Emergency liver transplantation is the ultimate

treatment in cases of imminent liver failure. The natural course of PH is not well known. Reports have described outcomes ranging from spontaneous resolution to hepatic failure or fatal intraperitoneal hemorrhage. Some reports have described the resolution of PH after withdrawal of causative drugs or after treatment of the associated conditions<sup>[12,26,27]</sup>. In other reports, patients presenting in fulminant hepatic failure eventually died. Fatal intraperitoneal hemorrhage has also been reported as another complication<sup>[9,28,29]</sup>. In summary, PH is an important disorder for consideration in the differential diagnosis of liver masses presenting acutely. PH is most often asymptomatic; in symptomatic patients, surgery should be reserved for cases when hemorrhage becomes life-threatening. Familiarity with imaging characteristics and awareness of this condition as a cause of hepatomegaly, hepatic failure, hepatic rupture, and hepatic hemorrhage can help in the early diagnosis of PH. Early removal of the known inciting agent may cause regression of this disease and prevent catastrophic complications. PH should be considered in all patients with known risk factors and presenting with typical morphological changes or hepatic mass, especially when the cause of the sudden onset of intraperitoneal hemorrhage is obscure. Although spontaneous regression of PH can occur in some patients, timely recognition and early treatment are essential to prevent life-threatening complications from the disease.

### Abstract

Hepatitis B has long been a serious public health problem both in Greece and in Albania. In the February 2009 issue of *World Journal of Gastroenterology*, Resuli *et al* presented the interesting epidemiological data concerning hepatitis B virus infection in Albania. The results of this study were discussed and several data from our similar research were provided.

### TO THE EDITOR

In the February 2009 issue of *World Journal of Gastroenterology*,

Resuli *et al*<sup>[1]</sup> presented the interesting epidemiological data concerning hepatitis B virus (HBV) infection in Albania. The authors studied the positive hepatitis B surface antigen (HBsAg) and antibody to hepatitis B surface antigen (anti-HBs) among 3880 unvaccinated residents in rural and metropolitan areas of Albania. In the entire study population, the prevalence of HBsAg and anti-HBs was 9.5% and 28.7%, respectively, demonstrating that despite the estimated two-fold reduction of HBsAg prevalence in the general population, Albania remains a highly endemic country.

It is well known that vertical (mother-to-infant) transmission of HBV infection occurs mostly during the perinatal period and is responsible for the majority of the disease burden in endemic areas. The risk of vertical transmission generally depends on the level of maternal infectivity, particularly on the presence of hepatitis B e-antigen (HBeAg) and HBV DNA level<sup>[2]</sup>. In the study by Resuli *et al*<sup>[1]</sup>, 7.3% of the pregnant women (mean age 27.4 years) were chronically infected with HBV and 36.3% were positive for antiHBs. Despite the absence of serological data about the antiHBc status, it seems that more than 40% of the Albanian pregnant women studied have been exposed to HBV (taking into consideration a proportion of women with isolated anti-HBc seropositivity).

Hepatitis B has long been a serious public health problem in Greece also. Historically, Greece used to have the highest burden of HBV infection in the European Union. An early hepatitis B prevention program introduced in 1982, targeting mainly the high-risk groups, did not significantly impact the disease incidence and prevalence. More recent universal HBV mass vaccination programs launched in the past decade have proved to be the key measure in decreasing the disease burden, as well as demographic and socioeconomic changes, safer medical and nursing practices, and finally, screening of the blood donors have significantly declined the chronic HBV infection in our country<sup>[3]</sup>. However, a substantial intromission of refugees, especially descending from countries, endemic for HBV infection (mainly from Albania), is likely to have influenced this trend.

In a study conducted between September 2008 and June 2009 in the Maternal and Perinatal Hospital of Athens "Elena Venizelou", we evaluated the current prevalence of HBV serological markers in a multinational population of pregnant women, residing in Greece. A

total of 1333 pregnant women (mean age 28.5 years) who delivered at the Departments of Obstetric and Gynaecology of the Hospital were prospectively evaluated. HBsAg, HBeAg, antibody to hepatitis B e-antigen (anti-HBe), antibody to hepatitis B core antigen (anti-HBc) and anti-HBs were detected by commercially available routine enzyme immunoassays (Abbott Laboratories, Abbott Park, Illinois, US). All women of the study population were screened for HBsAg, anti-HBc and anti-HBs, whereas HBeAg and anti-HBe were evaluated only in those who were positive for HBsAg. The mean difference between two groups was evaluated by Student's *t*-test after the equality of variances was controlled with the Levene's statistic, while one-way analysis of variance (ANOVA) was used to assess the differences in continuous variables among more than two study groups.

More than half of the study population had Greek origin (756/1333, 56.7%), 30.6% were descendents from Albania (408/1333) and 12.7% (169/1333) from Eastern European countries (Russia, Romania, Bulgaria). Overall, 4.4% (58/1333) of the women were HBsAg (+) and the vast majority of them (45/58, 77.58%) were Albanians. Among the Albanian women, the prevalence of HBsAg was 11% followed by 2.4% among the women from Eastern European countries. The prevalence of HBsAg among the Greek women (1.2%) was very low and significantly lower than the mean value of the non-Greek population studied (7.4%,  $P < 0.001$ ). More than half (52%) of the Albanian women exhibited seropositive anti-HBc followed by Eastern European women (22.5%), whereas only 6.5% of the Greek women had serological markers compatible with previous HBV exposure. Moreover, serological markers of past HBV infection with spontaneous

recovery [antiHBc (+) and antiHBs (+)] were observed in 13.9% of the whole study population. Among the Greek women, only 3.6% exhibited serological markers of spontaneous recovery from HBV infection in contrast to 32.7% among the Albanian women and 14.8% among the Eastern European women ( $P < 0.001$  in all cases). Interestingly, only 33.8% of the Greek women and 40.3% of the Albanian women ( $P = 0.15$ ) exhibited vaccination-induced protection against HBV infection, characterised by the presence of positive isolated antiHBs.

Our data are in accordance with those presented by Resuli *et al*<sup>11</sup>, supporting that HBV infection is endemic among Albanian pregnant women. However, it seems that the awareness of Albanian immigrants, who live and work in Greece, about the control of HBV infection, is rising steadily, as supported by the comparable vaccination-induced protection rates among the Greek and Albanian pregnant women observed in our study. The relatively low vaccination-induced protection rates observed suggest that more intense surveillance and immunisation programs, targeting pregnant women, are necessary to avoid vertical transmission of HBV infection.

## ACKNOWLEDGMENTS

# Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

**Meenakshisundaram Ananthanarayanan, Associate Professor**, Department of Pediatrics, Annenberg Bldg, Rm.14-24A, Box 1664, The Mount Sinai Medical Center, One Gustave L. Levy Place, New York, NY, 10029, United States

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Articles: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

This report presents a survey of current knowledge concerning one of the relatively frequent and severe complications of liver cirrhosis and associated ascites-spontaneous bacterial peritonitis. Epidemiology, aetiology, pathogenesis, clinical manifestation, diagnosis and present possibilities of treatment are discussed.

### INTRODUCTION

Spontaneous bacterial peritonitis (SBP) is defined as an infection of initially sterile ascitic fluid (AF) without a detectable, surgically treatable source of infection<sup>[1]</sup>. It is a frequent and severe complication of cirrhotic ascites, first described in the middle of the 1960s<sup>[2]</sup>. Sometimes spontaneous infection of ascites is divided into three subgroups: (1) Spontaneous bacterial peritonitis is defined as a positive bacterial finding in ascites, together with increased polymorphonuclear leukocytes in ascites ( $> 250$  cells/mm<sup>3</sup>)<sup>[3]</sup>. Microorganisms responsible for SBP are isolated in 60%-70% of cases. (2) Culture-negative neutrocytic ascites (CNNA) - ascites is sterile, bacterial infection is not demonstrable by culturing, only an increased number of polymorphonuclear leukocytes above the limit of 250 cells/mm<sup>3</sup> is revealed. Of course, it is necessary to eliminate another cause of increased leukocytes in ascites, e.g. previous antibiotic therapy, hepatocellular carcinoma, peritoneal carcinomatosis or tuberculosis, pancreatitis or bleeding into ascitic fluid. If the sample of ascites contains blood, SBP diagnosis is made by finding more than one neutrophilic granulocyte per 250 erythrocytes. If left untreated, about one-third of cases can show, after some time, positive bacteriological findings. Both symptoms and mortality in patients with CNNA are similar to the course of disease in patients with diagnosed SBP; 33%-57% of these patients also show a positive blood culture, which provides evidence of a systemic bacterial infection. Infection is also confirmed by the fact that in patients with previous CNNA, there is a more frequent occurrence of SBP and *vice versa*<sup>[4]</sup>. (3) Monomicrobial non-neutrocytic bacterascites (or only bacterascites) has rarely been described. In this disorder, positive bacterial cultivation is presented without increased leukocytes. It is usually revealed in Child-Pugh class A patients. Recovery from bacterascites can be spontaneous (in 60%-80%), or it can develop into typical SBP. Bacterascites is often quite asymptomatic, and antibiotics should only be used if symptoms appear and cultivation finding is persistent.

As mentioned above, SBP and CNNA are identical, both from the clinical point of view and the therapeutic approach; therefore, the consensus conference of the

International Ascites Club<sup>[5]</sup> has recommended not to differentiate between these two entities; even in the case of CNNA, SBP is spoken about, and an increased number of neutrophils in ascites is sufficient for the diagnosis. A spontaneous infection complicating ascites may appear even in malignant ascites<sup>[6]</sup>, however, it is found most often in cirrhotic ascites.

Early, mostly retrospective, studies described SBP in about 8% of patients with ascites; later prospective trials revealed SBP in 10%-30% of patients with ascites admitted to hospital<sup>[5,7,8]</sup>. SBP is found in about 5% of non-selected outpatients<sup>[9]</sup>. Lethality is very high. Older studies reported 80%-100% lethality connected with SBP<sup>[10]</sup>, which was probably given partly by the generally worse therapeutic possibilities in cirrhotic patients and lack of availability of effective antibiotics, but better results - 20%-40% as reported in later studies<sup>[11]</sup> - are, to a certain extent, due to early diagnosis and treatment.

However, lethality has not decreased over recent years<sup>[12]</sup>. Even the long-term prognosis in these patients has been unfavourable. In 40%-70% of patients, SBP relapses within 1 year<sup>[11]</sup>. One-year survival after previous SBP patients is only 30%-40%, two-year survival is 20% and in patients with a Child-Pugh score > 10 survival is even lower<sup>[13]</sup>.

## AETIOLOGY

G<sup>-</sup> bacteria are found in 65% of positive culture results-*Escherichia coli* (*E. coli*) and *Klebsiellae* are the most common and second most common agents, respectively<sup>[14]</sup>. The remaining agents are represented by G<sup>+</sup> cocci<sup>[1,7]</sup>. There is a difference in bacteria responsible for SBP in hospitalised and non-hospitalised patients. G<sup>-</sup> bacteria prevail in the first group of patients, while G<sup>+</sup> bacteria are found in the latter<sup>[9]</sup>.

Experiments modelling hepatic cirrhosis and the accompanying SBP in a rat resulted in discovery of agents in AF that differed from those in humans. It was mainly *Enterococcus faecalis* that was isolated from AF in the rat affected by cirrhosis induced by tetrachloromethane and SBP was of polymicrobial origin in one half of cases<sup>[15]</sup>. None of the above findings is typical of human patients suffering from SBP.

## PATHOGENESIS

Bacteria participating in SBP come from the digestive tract. Extraintestinal bacteria such as those from the respiratory apparatus, urogenital tract or skin are much less frequent. Catheters and other equipment used during invasive procedures represent another possible source of infection. It is currently hypothesised that SBP follows an episode of bacteremia during which, due to the constant exchange of fluids between the peritoneal and intravascular space, AF gets infected<sup>[14]</sup>. The development of SBP thus depends on the antibacterial capacity of AF (the so-called opsonin activity) which is positively correlated to the content of the total protein in AF and the immunocompetence of the patient. The organism reacts to the infection of AF by activating neutrophilic

granulocytes which migrate into the peritoneal cavity and trigger a complex cytokine cascade; the fact being documented, for example, by increased concentrations of interleukin 6 and tumour necrosis factor  $\alpha$  in AF.

There are four key elements of SBP pathogenesis: (1) small intestinal bacterial overgrowth, (2) increased intestinal permeability, (3) bacterial translocation, and (4) immunosuppression. These key elements are not separate, but interlinked.

### **Small intestinal bacterial overgrowth (SIBO)**

Considering bacteria commonly found in the gastrointestinal tract, only some of them frequently participate in translocation. The most frequent bacteria are *E. coli*, *Proteus spp.*, *K. pneumoniae* and other *Enterobacteriaceae*, *Pseudomonas aeruginosa*, *enterococci*, *streptococci* and *staphylococci* - i.e. organisms causing infections in immunocompromised individuals. Bacterial small intestinal overgrowth creates conditions favourable for translocation of the above-mentioned bacteria. Liver cirrhosis is one of the conditions accompanied by SIBO. The main reasons for SIBO in patients affected by liver cirrhosis can be summarised as reduced intestinal passage, abnormalities in bile secretion, hypochlorhydria, abnormalities in IgA production and malnutrition<sup>[16]</sup>. A total of 20%-60% cirrhotic patients are affected by bacterial overgrowth. SBP is more often diagnosed in alcoholics affected by liver cirrhosis and SIBO as compared to patients affected in the same way but without SIBO<sup>[17]</sup>. Some authors are doubtful about the importance of SIBO in the pathogenesis of SBP<sup>[18]</sup>; according to this study, SIBO is associated with the use of drugs decreasing secretion of HCl and this therapeutic approach can increase the risk of SBP. Bacterial translocation found in a healthy individual after ingestion of extremely high numbers of microorganisms<sup>[19]</sup> can serve as a distant parallel of the relationship between SIBO and bacterial translocation.

### **Increased intestinal permeability**

In severely ill patients, such as those with liver cirrhosis, small intestinal motility is impaired, resulting in bacterial overgrowth and the related translocation of microbes through dysfunctional mucosal barrier. The increased intestinal permeability and thus impaired function of the intestinal barrier are mainly due to portal hypertension. The consequences are dilated vessels in the intestinal mucosa, oedema of the lamina propria mucosae, fibromuscular proliferation, hypertrophy of the lamina muscularis mucosae and compromised integrity of the intestinal mucosa. Portal hypertension can play an important role, as can the toxic effects of alcohol, bile secretion disorders, malnutrition, decreased secretion of growth factors (insulin-like growth factor I), changes in the composition and flow of bile, or higher levels of nitric oxide. Increased intestinal permeability is likely to be proportional to the degree of portal hypertension, but independent of the severity and aetiology of liver disease<sup>[20,21]</sup>.

### **Bacterial translocation**

The term bacterial translocation was first used in 1979<sup>[22]</sup>.

Bacterial translocation is defined as either active or passive penetration of living microorganisms and their toxic products through the mucosal epithelial layer to the lamina propria mucosae. From there, microbes migrate to mesenteric lymph nodes and/or extraintestinal sites. Under normal circumstances, there are only small numbers of bacteria readily destroyed by the immune system in the lamina propria mucosae. Translocation is only possible if their numbers are high, up to  $10^8$  bacteria in 1 g of faeces<sup>[17]</sup>.

According to clinical significance, there are four degrees of bacterial translocation. Degree 0: Bacteria and/or their components penetrate the mucosa by various mechanisms: active intracellular penetration, diffusion, absorption, endocytosis or phagocytosis by macrophages; Degree 1: Bacteria and/or their components enter the mesenteric lymphatic system and penetrate it centripetally; Degree 2: Bacteria and/or their components are already detectable in the systemic circulation and certain organs. They may also pass directly into small intestinal venules and from there into the portal circulation. Some of the bacteria are probably even capable of intracellular passage through the muscularis propria into the peritoneal cavity; Degree 3: The organism is systemically overwhelmed by bacteria and/or their components, leading to a septic response.

Bacteria escaping both phagocytosis and destruction by the complement system may even get into the bloodstream. *Enterobacteria*, *staphylococci* and *enterococci* are capable of translocation, i.e. passing live across the intestinal epithelium to the mesenteric lymph nodes, blood and other organs, whereas most anaerobic organisms lack this ability. Bacterial translocation may be confirmed by positive culture from the mesenteric lymph nodes. The main mechanisms underlying the translocation are deficient local mucosal immune response, lower phagocytic activity of both macrophages and neutrophils, increased permeability of the intestinal barrier and the above-mentioned intestinal bacterial overgrowth<sup>[16,17]</sup>.

### **Immunosuppression**

Patients with liver cirrhosis suffer from decreased phagocytic activity of neutrophilic granulocytes and the mononuclear phagocytic system, deteriorated humoral immunity and decreased opsonin activity of AF<sup>[23]</sup>. Neutrophilic granulocytes of patients with hepatic cirrhosis show not only a decrease in the phagocytic activity, but also intracellular destruction of bacteria, deteriorated metabolic activities, frequent apoptosis and considerably reduced chemotaxis. For proper protection against bacteria, neutrophilic granulocytes have first to adhere to the vascular endothelium, then migrate to the endothelial cellular junctions, pass through by diapedesis and migrate further into the target tissue. Neutrophilic granulocytes of cirrhotic patients adhere to the vascular endothelium to a greater extent and their transendothelial migration is thus decreased<sup>[24]</sup>. Neutrophilic granulocytes show decreased chemotaxis probably due to the presence of inhibitors of chemotaxis in the blood plasma of the cirrhotic.

The opsonin activity of AF correlates with the concentration of immunoglobulins, complement, fibronectin and total protein in AF<sup>[5,25]</sup>. Patients with a reduced total protein content in AF are prone to the development of SBP.

## **CLINICAL MANIFESTATION**

SBP is particularly revealed in patients with more severe liver functional damage (Child-Pugh classification C), often after bleeding from the upper gastrointestinal tract due to portal hypertension and often recurs. The clinical picture is non-specific. In a lot of cases the infection is quite asymptomatic, common signs - subfebrile states, diffuse abdominal pain - are not very conspicuous. They are frequently manifested only by the occurrence or deepening of symptoms that accompany the course of liver cirrhosis - increased ascites and failure of diuretic therapy, deteriorated encephalopathy, vomiting, *etc.* Therefore, an active search for the ascites infection is necessary.

Diagnostic paracentesis with leukocyte investigation is recommended in all patients with ascites admitted to hospital as well as in cirrhotics (whether in hospital or not) with worsened ascites, who have presented with signs of abdominal or systemic infection (abdominal pain or tenderness, disturbed intestinal passage, fever, acidosis, peripheral leukocytosis) or with encephalopathy or worsened renal functions<sup>[5]</sup>. An active approach to the SBP diagnosis is extraordinarily important even from the prognostic point of view. If SBP is diagnosed at the first paracentesis carried out in all patients hospitalised with ascites, this infection has no influence on the patient's prognosis. However, if SBP appears over the course of studying these patients, the risk of lethality increases two-fold<sup>[26]</sup>. This can probably be explained by the damaged renal function under a longer-lasting untreated infection.

High lethality is not primarily associated with the severity of the infection, and patients do not die of sepsis. An infection only worsens the changes present in cirrhotic patients, especially blood supply and renal function<sup>[27]</sup>. Splanchnic vasodilatation occurring in cirrhotics is worsened due to endotoxemia; effective arterial blood volume decreases which can damage renal function and can cause hepatorenal syndrome. Patients who showed a higher level of urea and higher portal pressure at the moment of diagnosis of an infection are threatened with renal failure and the associated high lethality<sup>[28]</sup>.

## **DIAGNOSIS**

Diagnosis is relatively easy. SBP is diagnosed by revealing polymorphonuclear leukocytes in ascites  $> 250$  cells/mm<sup>3</sup> (less accurately at the increase of all leukocytes over 400/mm<sup>3</sup>). Reagent papers used for examining leukocytes in urine could be used for the immediate detection of leukocytes in ascites<sup>[29]</sup> although the sensitivity is not sufficient. A positive cultivation finding is not necessary for diagnosing SBP, it is usually revealed in about 30% of cases. Some trials have mentioned a higher bacteriological

detection if ascites is inoculated on the medium at the bedside as it is carried out for the investigation of blood culture - BactAlert test<sup>[30]</sup> - however, the advantage of this test has not been demonstrated by other studies<sup>[8,31]</sup>.

In the case of diagnostic doubts, the serum procalcitonin level (the limit of 0.75 ng/mL has 95% sensitivity, and 98% specificity) or the interleukin 6 level in ascites (the limit of 5.0 ng/mL has 100% sensitivity) may be determined<sup>[32]</sup>. Nowadays, examination of the ascites pH (for the diagnosis of SBP < 7.35) or arterial: ascites pH gradient (> 0.1) as recommended previously is no longer used.

## TREATMENT

Therapy should be initiated immediately after revealing increased leukocytes in ascites. Empiric antibiotic therapy, e.g. an intravenous third-generation cephalosporin, preferably cefotaxime in a single dose of 2 g is the recommended antibiotic drug. Mostly, it is sufficient to administer cefotaxime every 8 h as this regimen is as effective as its administration every 6 h<sup>[33]</sup>. Even a shorter length of application is possible, cefotaxime administered every 8 h for 5 d has the same effects as its 10 d application and from a practical and financial point of view, this regimen seems to be the most suitable. Two 3rd generation cephalosporins may alternatively be used-cefonicid (2 g every 12 h) or ceftriaxone 2 g/d<sup>[34]</sup>. In uncomplicated SBP (i.e. if diagnosed during preventive examination of ascites without clinical signs of infection) a combination of amoxicillin, clavulanic acid<sup>[35]</sup>, or ofloxacin 400 mg may be administered every 12 h for a period of 7-10 d<sup>[36]</sup>. Although more than 10 therapeutic studies have been published since 1985, clear proof of the efficacy of these antibiotics supported by evidence-based medicine is still missing, and treatment is based more on clinical experience<sup>[37]</sup>. Moreover, there are reports on increasing occurrence of enterobacteria resistant to the 3rd generation cephalosporins<sup>[38]</sup>, therefore, a large, well-designed randomised trial is necessary to ensure explicit demonstration of the effectiveness of each antibiotic drug.

As mentioned above, the high lethality is associated with damaged renal function due to impaired hypovolemia. Therefore, the efforts of expansion of intravascular volume could be contributory, and some studies have demonstrated that simultaneous application of albumin (as plasma expander) at a dose of 1.5 g/kg during the first 6 h and 1 g/kg on the 3rd d together with antibiotics decreased both the occurrence of renal damage and lethality<sup>[39]</sup>. This albumin replacement is recommended in patients with even clinical suspicion of SBP and serum creatinine > 1 mg/dL, blood urea nitrogen > 30 mg/dL, or total bilirubin > 4 mg/dL.

### Preventive treatment

Three groups of patients are at higher risk of SBP - patients with gastrointestinal bleeding, patients who have survived an episode of SBP and patients with low opsonic activity of ascites.

Preventive administration of antibiotics is recommended in the first two groups. Intravenous ceftriaxone

for 7 d or norfloxacin 400 mg twice a day for 7 d should be administered to prevent bacterial infections in patients with cirrhosis and gastrointestinal bleeding. Patients who have survived an episode of SBP should receive long-term prophylaxis with daily norfloxacin (400 mg once a day)<sup>[40]</sup> or trimethoprim/sulfamethoxazole. In these patients, liver transplantation should be considered as the lethality after passed SBP is higher than that after liver transplantation<sup>[5,13]</sup>. If transplantation is indicated, antibiotics should be applied until the operation. If transplantation is not indicated, according to literature, they should be applied for the rest of the patient's life. However, in clinical practice, an individual approach to each patient has been recommended.

Preventive application of antibiotics in the last group of patients at higher risk of infection - patients with the ascitic fluid protein < 15 g/L (i.e. with low opsonin activity) has not been generally recommended so far<sup>[41]</sup>. Long-term use of norfloxacin (or trimethoprim/sulfamethoxazole) can be justified in these patients if at least one of the following is present together with a low level of protein: serum creatinine > 1.2 mg/dL, blood urea nitrogen > 25 mg/dL, serum sodium < 130 mEq/L or Child-Pugh > 9 points with bilirubin > 3 mg/dL<sup>[42]</sup>.

Intraperitoneal re-infusion of concentrated ascites can effectively increase the protein level and opsonic activity of ascites<sup>[43]</sup>. On the other hand, it is not clear if just this procedure can reduce the risk of SBP in patients with low ascitic fluid protein.

Reports on possible influencing of bacterial translocation (and thus the development of SBP) using prokinetics<sup>[44,45]</sup> or probiotics<sup>[46]</sup> have appeared in the literature.

## CONCLUSION

Spontaneous infection of ascites is a very frequent and severe complication of ascites occurring in a high number of patients admitted to hospital with ascites. This infection must be actively searched for. Diagnostic paracentesis must be performed with examination of polymorphonuclear leukocytes in ascites in all patients suffering from ascites at the moment of their admission to hospital as well as in all cirrhotics with a sudden increase of ascites or worsening of their general condition.

If the number of polymorphonuclear leukocytes in ascites exceeds 250 cells/mm<sup>3</sup>, a positive bacteriological finding is not necessary, SBP is diagnosed and cefotaxime at the minimum dose of 2 g every 8 h for 5 d is administered. If patient has no clinical symptoms and SBP was diagnosed during preventive examination, ofloxacin 400 mg every 12 h for 7-10 d is an alternative. Although more studies are lacking, prevention of the development of simultaneous renal damage due to severe hypovolemia by administration of plasma expander (albumin at a dose of 1.5 g/kg during the first 6 h, and 1 g/kg on the third day) seems to decrease lethality.

Preventive application of antibiotics is indicated in two groups of patients with a high risk of developing SBP. Norfloxacin 400 mg twice a day is recommended

in patients with bleeding from the upper gastrointestinal tract and portal hypertension. The other group involves patients with previous SBP. As secondary prevention, norfloxacin 400 mg once a day is administered. Liver transplantation is recommended and antibiotics are applied until the surgery. Long-term administration (lifelong according to literature) is indicated in patients who are not indicated for transplantation.

### Abstract

Hepatocellular carcinoma (HCC) is the commonest primary malignancy of the liver. It usually occurs in the setting of chronic liver disease and has a poor prognosis if untreated. Orthotopic liver transplantation (OLT) is a suitable therapeutic option for early, unresectable HCC particularly in the setting of chronic liver disease. Following on from disappointing initial results, the seminal study by Mazzaferro *et al* in 1996 established OLT as a viable treatment for HCC. In this study, the "Milan criteria" were applied achieving a 4-year survival rate similar to OLT for benign disease. Since then various groups have attempted to expand these criteria whilst maintaining long term survival rates. The technique of living donor liver transplantation has evolved over the past decade, particularly in Asia, and published outcome data is comparable to that of OLT. This article will review the evidence, indications, and the future direction of liver transplantation for liver cancer.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the third most common cause of cancer death and the fifth most prevalent cancer in the world<sup>[1]</sup>. Cirrhosis itself is the major risk factor for the development of HCC<sup>[2-6]</sup>. Overall, 80%-90% of HCC develop in the context of liver cirrhosis<sup>[7]</sup>. Hepatitis B infection (HBV) particularly, can cause HCC in the absence of cirrhosis as a result of its direct carcinogenic effect<sup>[8]</sup>. Hepatitis B is the commonest cause of chronic liver disease in the East, whereas hepatitis C (HCV) and alcohol predominate in the West<sup>[9]</sup>. This has resulted in widespread geographical variation in HCC prevalence. In particular, in Asia and sub-Saharan Africa the incidence is far higher than in North America and Europe. In our Unit in London, 70% of patients with HCC on the background of liver disease have underlying chronic viral hepatitis; 40% have HCV, 30% HBV and a minority have a combined etiology including viral, steatohepatitis and/or alcoholic chronic liver disease.

The incidence of HCC is increasing in many parts of the world<sup>[10]</sup>. In the United States, for example, the rate of HCC has increased by 80% over the past 20 years<sup>[11]</sup>. This may be partly due to the fact that screening for HCC in patients with cirrhosis has become established practice. However, in our Unit over the past 5 years, only 55% of patients with HCC had their cancer detected as part of a screening program. Another likely reason for rising HCC incidence is the increasing burden of chronic viral hepatitis. In addition to HBV and HCV, both fatty liver disease and alcohol-related liver disease continue to rise. As a result, it is predicted that HCC prevalence will increase further over the coming decades.

Without specific treatment the prognosis is poor with median survival of early and advanced HCC being 6-9 mo and 1-2 mo, respectively<sup>[12]</sup>. Tumor resection in the context of cirrhosis and portal hypertension

leaves a residual cirrhotic liver which remains at risk of developing new lesions and a liver which is at risk of decompensation. Recurrence rates of 50%-70% have been reported after resection of HCC<sup>[13]</sup>. Many patients have advanced cirrhosis at presentation and are not eligible for resection. In addition, HCC is often multifocal and thus resection is not feasible.

## EVOLUTION

The initial liver transplants were performed by Starzl in 1963<sup>[14]</sup>. Four years elapsed before there was a long term survivor<sup>[15]</sup>. Over the subsequent decades advances in organ preservation and particularly prevention of organ rejection led to a steady rise in both transplant numbers and outcomes. With the widespread acceptance of OLT, transplantation for HCC was attempted. Unfortunately, the initial results of OLT for HCC showed disappointing short and long term survival rates and high levels of tumor recurrence<sup>[16]</sup>.

Given the huge demand for organs, transplantation needed to be limited to those with a good prognosis, and liver transplantation continued to flourish as the definitive treatment of end stage liver disease. A change in thinking arose from the following two observations. Firstly, finding small unexpected HCC in explanted livers did not affect the outcome of OLT<sup>[17]</sup>. Secondly, there was no significant difference in terms of overall survival between liver transplantation and resection in cirrhotic patients with hepatocellular carcinoma<sup>[18]</sup>. Furthermore, in small tumors, < 3 cm, whether uni- or bi-nodular, transplantation resulted in better survival than resection. This culminated in the development of the "Milan criteria" which has cemented OLT as an effective treatment for HCC.

## MILAN CRITERIA

The seminal study by Mazzaferro *et al*<sup>[19]</sup> in 1996 established OLT as a viable treatment for HCC. In this study in Milan, Italy, 48 patients with HCC and cirrhosis were followed and transplanted. Twenty eight patients had preoperative therapy, mainly transarterial chemoembolization (TACE). All patients fulfilled the following restrictive radiographic criteria: single lesion  $\leq$  5 cm, up to 3 separate lesions all less than 3 cm, no evidence of vascular invasion, no nodal or distant metastases. The aim of the criteria was to achieve a good prognosis in those who fulfilled them, avoiding a poor prognosis in those who exceeded them. The overall actuarial survival after 26 mo was 75% and recurrence-free survival was 83%. Patients who fulfilled these criteria on the basis of explant pathology had actuarial survival of 85% and recurrence-free survival of 92%. These rates are not dissimilar to the outcome of patients undergoing OLT without HCC. These criteria have become known as the "Milan criteria" and these results have been confirmed throughout the world.

## EXPANDED CRITERIA

Since the acceptance of OLT for the treatment of HCC,

excellent post-transplant survival has been reported in many centers. With increasing experience of OLT many centers have recognized that many explanted livers have had HCC beyond the size described in the "Milan criteria". These transplanted patients have been followed over time and many have had excellent 1- and 5-year survival. Also, advances in imaging have occurred in the past decade since these criteria were originally published. As a result several groups have attempted to broaden the restrictive limits. A group from the University of California at San Francisco (UCSF) have reported a 5-year survival of 75% using less restrictive criteria derived by retrospectively analyzing 2000 patients undergoing OLT<sup>[20]</sup>. This was achieved by using the following criteria: a maximum tumor size 6.5 cm or 2 lesions < 4.5 cm diameter with a total tumor diameter < 8 cm. The same group validated the 'San Francisco criteria' on 168 patients based on preoperative imaging assessments<sup>[21]</sup>. Various other groups have published expanded criteria with results not dissimilar to the original "Milan criteria"<sup>[22-28]</sup>. The same group in Milan has recently published retrospective data regarding outcome in 1112 patients exceeding the original Milan criteria<sup>[29]</sup>. In this study, a 71.2% 5-year overall survival could be achieved using the "up-to-7" criteria (HCC with 7 as the sum of the largest tumor (cm) and the number of tumors). It is clear that the larger the tumor size and number, the worse the outcome. Tumor understaging, by preoperative imaging of patients has been one of the major concerns for liberalizing the "Milan criteria"<sup>[30-32]</sup>. Also, there can be significant tumor progression during the waiting time to transplantation<sup>[33]</sup>. At the present time, the "Milan criteria" remains the only universally accepted and recurrently validated criteria.

## COMPARISON OF OLT TO OTHER TREATMENT STRATEGIES

Various treatment options are available for HCC including the surgical options as outlined above, and local ablative techniques such as radiofrequency ablation (RFA), transarterial chemoembolization (TACE), and percutaneous ethanol injection (PEI). Systemic chemotherapy has been unsuccessful in the studies thus far<sup>[34]</sup>. The local ablative treatments themselves are used as a palliative procedure or as a bridge to resection or transplantation. The only curative treatments are that of hepatic resection or transplantation.

The published observational studies to date suggest survival following OLT is at least as good as following resection in patients with adequate hepatic reserve<sup>[18]</sup>. Liver resection can leave residual liver which is of insufficient size to provide adequate function and as stated before, has the possibility of developing further lesions. In patients with well-compensated cirrhosis (Child Pugh A) and HCC, the decision whether to resect or transplant remains controversial. However, in the current realm of organ shortage and long waiting times, the decision to resect in this group appears attractive.

If tumor recurrence were to recur than salvage transplantation can be performed. This strategy has been retrospectively analyzed by different groups with conflicting outcome data. One retrospective study has shown no difference in either outcome or disease-free survival when comparing primary OLT to resection and salvage OLT<sup>[35]</sup>. In contrast, an observational series has shown primary OLT to have lower operative mortality, recurrence rates and survival rates<sup>[36]</sup>.

## REQUIREMENTS FOR LISTING

The United Network for Organ Sharing (UNOS) administers the allocation of organs for transplantation in the United States. UNOS provides a set of specific requirements<sup>[37]</sup> for listing patients with HCC: (1) Rough evaluation of the number and size of tumors and to rule out extra-hepatic spread by ultrasound, computed tomography (CT) or magnetic resonance imaging (MRI) plus CT of the chest; (2) Prelisting biopsy is not mandatory, however patients must have one of the following: (a) a biopsy confirming HCC; (b) a vascular blush corresponding to the area of suspected HCC; (c) an  $\alpha$  fetoprotein (AFP) > 200 mg/mL; (d) an arteriogram confirming a tumor; (e) a history of local ablative therapy (TACE, RFA, PEI); (3) Patients with chronic liver disease and a rising AFP > 500 mg/dL can also be listed even in the absence of discrete tumor on imaging studies; (4) The patient must not be a resection candidate; (5) Reimaging by CT or MRI every 3 mo is required to ensure continued eligibility for OLT.

## BRIDGING THERAPY

The “dropout” due to tumor progression whilst waiting for OLT is reported to be at least 20%<sup>[20]</sup>. This problem has furthered the use of local-regional adjuvant therapy (LAT) whilst awaiting transplantation such as TACE, RFA, and PEI. Unfortunately no randomized, controlled trials have been conducted to assess this approach<sup>[38]</sup>. As a result, there is no universal consensus as to the optimum bridging therapy prior to transplantation.

The ultimate aim of LAT is to provide complete tumor necrosis in an attempt to halt tumor progression. Analyses of explant specimens subjected to RFA and TACE have shown complete tumor necrosis rates of 47%-66% and 16%-27%, respectively<sup>[30,39,40]</sup>. A retrospective study looking at tumor necrosis in 61 patients did not find any particular modality of LAT to be superior<sup>[41]</sup>.

Retrospective analyses have shown that multi-modality local treatment is associated with a modest survival benefit<sup>[42,43]</sup>. As a result most units offer dual as well as single modality ablative treatments, in an attempt to reduce tumor progression and recurrence rates. Hepatic resection has also been used as a bridge to transplantation<sup>[44]</sup>. This is in contrast to the traditional view of resection and transplantation being opposing strategies. Unlike LAT which has been shown in studies to achieve only partial tumor necrosis, resection should

achieve the best tumor control. Resection also allows a thorough intra-operative assessment of liver status and tumor burden. A detailed histological analysis can be made of the resected specimen and can give invaluable information about the natural history of the tumor and the presence of microvascular invasion. Resection, however, is associated with increased risk and, as stated earlier, should only be attempted in well-compensated cirrhotic patients.

## PROGNOSTIC FACTORS

Conforming to the “Milan criteria”, in terms of tumor size and tumor burden, gives rise to 3-4-year recurrence-free survival rates of up to 92%<sup>[45-47]</sup>. Multivariate analysis has shown these to be the only independent variables predicting patient survival and tumor recurrence. Other biological factors such as tumor grading, microvascular invasion and microsatellites appear to play a role, but within the constraints of the size and number burden. These biological factors can only be accurately assessed post-transplantation or post-resection. The histological grade of the tumor can be assessed by lesional biopsy and several authors have recommended this approach<sup>[48-50]</sup>. Lesional biopsy does however carry the risk of tumor seeding which has been estimated at approximately 2%<sup>[51]</sup>. Furthermore, significant histological heterogeneity has been described in large tumors, which limits the utility of needle biopsy<sup>[52]</sup>.

A scoring system incorporating tumor differentiation in addition to tumor size and number has been validated in a 2007 French multicenter study<sup>[53]</sup>. In this study, tumor histology improved the Milan criteria in predicting post-transplant outcome. These results conflict with a more recent 100 patient study in which tumor differentiation did not predict HCC recurrence<sup>[54]</sup>.

## LIVING DONOR TRANSPLANTATION

Living donor liver transplantation (LDLT) has evolved over the past decade, mainly in response to the scarcity of donor livers. Deceased liver donation is particularly scarce in Asia, where organ donation rates are less than 5 donors per million population compared to 10-35 per million in Western countries<sup>[55]</sup>. This is also compounded by the fact that in most Asian countries HCC is the most common cancer and a frequent indication for OLT. LDLT, in particular right liver transplantation, has dramatically increased the number of potential donors. This can eliminate the problem of long waiting times and ‘dropout’ whilst waiting for an organ because of disease progression. Furthermore, as there is no direct ‘competition’ from other potential transplant recipients the restrictive criteria on tumor burden can be relaxed somewhat.

The results from LDLT appear to show good long term survival rates with retrospective studies showing comparable rates to OLT<sup>[56-58]</sup>. There are, however, published retrospective studies which show a higher rate of tumor recurrence than with conventional OLT<sup>[59-61]</sup>.

The reason for this is not entirely evident. It has been postulated that many candidates are not transplanted because of tumor progression whilst waiting for OLT; these patients, with more aggressive tumor biology, are then removed from the outcome analysis. In LDLT there is no protracted waiting time and hence the patients with aggressive tumors are transplanted.

LDLT has been performed, in some centers, in patients who have a tumor load beyond the Milan criteria with the consent of both the donor and recipient<sup>[62]</sup>. In addition, LDLT carries a risk to the donor during hepatectomy with morbidity and mortality rates of 14%-21% and 0.25%-1%, respectively<sup>[63]</sup>. This highlights the need for a universal consensus on the use of LDLT.

Akin to the published “expanded criteria” in OLT, several groups have attempted to determine an “expanded criteria” in LDLT. Using a scoring system including the measurement of “protein induced by vitamin K absence or antagonist- II” (PIVKA- II), a Japanese group have achieved a 5-year recurrence rate of only 4.9%<sup>[24,64]</sup>. PIVKA- II, also known as des-carboxyprothrombin, is an abnormal prothrombin protein found in the serum of patients with HCC and in patients with vitamin K deficiency or on warfarin therapy. It has been suggested as an alternative marker to AFP for the surveillance of HCC, but is not currently used as standard practice internationally. This study reported an 86.7% survival rate in patients with  $\leq 10$  tumors, all  $\leq 5$  cm (on pre-transplant imaging) and with PIVKA- II values  $\leq 400$  mAU/mL. Without the application of PIVKA- II, patients with  $\leq 10$  tumors, all  $\leq 5$  cm had similar 5-year recurrence rates as those conforming to the Milan criteria (7.3% vs 9.7%)<sup>[24,64]</sup>.

## CONCLUSION

Liver transplantation remains the definitive treatment for HCC complicating cirrhosis. Since the publication of the “Milan criteria”, OLT has progressed into a universally accepted treatment for HCC. The results of OLT for HCC continue to improve with time. The retrospective studies to date suggest outcome for OLT for HCC is only marginally worse than for end stage liver disease itself. Over the past decade LDLT has evolved but at present needs more stringent universal guidance on its usage. However, the results of LDLT for HCC seem slightly worse than for OLT but this may be a result of selection bias. The use of single or combined local ablative therapy in the period prior to OLT appears to be accepted. As operative techniques have improved, resection as a bridge to transplantation now appears a viable option in compensated cirrhotic patients. Resection also offers the ability to gain invaluable information about the tumor.

Undoubtedly further work will be published on expanded criteria for transplantation. The various studies to date have shown that acceptable long term outcomes are possible with OLT for HCC outside the “Milan criteria”. With time a new universal consensus will be required to standardize these ‘expanded’ criteria.

### Abstract

This article reviews the literature concerning rheumatic manifestations of inflammatory bowel disease (IBD), including common immune-mediated pathways, frequency, clinical course and therapy. Musculoskeletal complications are frequent and well-recognized manifestations in IBD, and affect up to 33% of patients with IBD. The strong link between the bowel and the osteo-articular system is suggested by many clinical and experimental observations, notably in HLA-B27 transgenic rats. The autoimmune pathogenic mechanisms shared by IBD and spondyloarthropathies include genetic susceptibility to abnormal antigen presentation, aberrant recognition of self, the presence of autoantibodies against specific antigens shared by the colon and other extra-colonic tissues, and increased intestinal permeability. The response against microorganisms may have an important role through molecular mimicry and other mechanisms. Rheumatic manifestations of IBD have been divided into peripheral arthritis, and axial involvement, including sacroiliitis, with or without spondylitis, similar to idiopathic ankylosing spondylitis. Other periarticular features can occur, including enthesopathy, tendonitis, clubbing, periostitis, and granulomatous lesions of joints and bones.

Osteoporosis and osteomalacia secondary to IBD and iatrogenic complications can also occur. The management of the rheumatic manifestations of IBD consists of physical therapy in combination with local injection of corticosteroids and nonsteroidal anti-inflammatory drugs; caution is in order however, because of their possible harmful effects on intestinal integrity, permeability, and even on gut inflammation. Sulfasalazine, methotrexate, azathioprine, cyclosporine and leflunomide should be used for selected indications. In some cases, tumor necrosis factor- $\alpha$  blocking agents should be considered as first-line therapy.

### INTRODUCTION

The association between arthritis and inflammatory bowel disease (IBD) was originally described in 1929<sup>[1]</sup>, but it was not until the 1950s when peripheral arthritis associated with IBD was distinguished from rheumatoid arthritis, and in the 1960s, the concept of spondyloarthropathy (SpA) was established<sup>[2-4]</sup>. Here, we present a review of all pertinent literature from Medline regarding rheumatic complications of IBD. We include original and review articles, as well as relevant case reports published from 1929 to 2009.

With time, clinical and experimental evidence of the close relationship between IBD and some rheumatic diseases, particularly seronegative SpAs, has grown. In fact, IBD is considered part of the concept of SpA<sup>[5]</sup>.

Some studies have shown that up to 70% of patients with SpA have inflammatory intestinal lesions, and up to 26% of patients with SpA who undergo ileocolonoscopy

have intestinal abnormalities compatible with Crohn's disease (CD). In fact, 6%-10% of patients with SpA develop IBD on follow-up; besides, studies with serial ileocolonoscopy have shown strong correlation between the presence of gut and joint inflammation in SpA<sup>[6-10]</sup>. Therefore, some authors have suggested that joint abnormalities are the initial manifestation of IBD, and after several years, these patients later may develop florid intestinal abnormalities. On the other hand, some studies that have evaluated extraintestinal manifestations of patients with IBD have shown that 36%-46% of patients have at least one extraintestinal manifestation, and rheumatic abnormalities are the most frequent (22%-33%)<sup>[11,12]</sup>. Besides, rheumatic manifestations are significantly more common in patients with disease confined to the colon. For instance, some patient series with ulcerative colitis (UC) have reported a prevalence of joint involvement of 62%<sup>[13]</sup>. Several studies have evaluated the prevalence of seronegative SpA in patients with IBD: 18%-45% of patients with IBD fulfill the criteria for SpA; 3%-9.9% fulfill diagnostic criteria for ankylosing spondylitis (AS); around 14% develop one or more clinical manifestations of SpA without fulfilling diagnostic criteria, and some of these patients (up to 24%) have asymptomatic sacroiliitis<sup>[14-18]</sup>.

## IMMUNOPATHOGENESIS OF GUT AND JOINT INFLAMMATION

### *Immunologic alterations shared by patients with IBD and SpA*

There have been interesting studies about the immunopathogenesis of IBD and SpA, which have shown alterations in key molecules that regulate the immune response in the gut of patients with SpA, and some of them are almost the same as those found in CD<sup>[19]</sup>. For instance E-cadherin, a transmembrane glycoprotein that mediates the intercellular adhesion of epithelial cells is expressed highly in the gut of patients with IBD<sup>[20]</sup> and in patients with SpA<sup>[21]</sup>, and subclinical acute and chronic gut inflammation, even in those without macroscopic lesions, which indicates that the alteration in the regulation of these proteins may be an early event in the development of gut inflammation. Besides, E-cadherin is a ligand of  $\alpha 4\beta 7$  integrin in intraepithelial T cells. Two studies have shown increased expression of this integrin in T cell cultures from the gut mucosa of patients with AS<sup>[22]</sup> and CD<sup>[23]</sup>. Increased expression of this integrin has been found in patients without histological signs of gut inflammation, which suggests that there are common abnormalities in patients with SpA and IBD that precede clinical inflammation.

Other alterations that are common in both groups of diseases are those described in CD4<sup>+</sup> T cells. Currently, four types of CD4<sup>+</sup> T cells have been described: Th1 cells are identified as interferon  $\gamma$  (IFN- $\gamma$ ) producers; Th2 cells produce primarily interleukin (IL)-4, IL-5, IL-10 and IL-13; Th17 cells produce mainly IL-17A and

they also produce IL-17F, IL-21, IL-22, granulocyte-macrophage colony-stimulator factor (GM-CSF), CCL-20, and potentially tumor necrosis factor (TNF) and IL-6. These cytokines have pro-inflammatory properties and they act on a broad range of cell types to induce the expression of several cytokines (TNF, IL-1 $\beta$ , IL-6, GM-CSF, G-CSF), chemokines (CXCL1, CXCL8, CXCL10), and metalloproteinases. On the other hand, regulatory T cells (Tregs) have a suppressor function; they influence the immune system by cell-to-cell contact and also *via* regulatory mechanisms that are still not fully elucidated. It is known that they are able to produce IL-10 and transforming growth factor (TGF)- $\beta$ , and it is interesting that Th17 and Treg developmental programs are reciprocally interconnected. Upon T-cell receptor stimulation, a naïve T cell can be driven to express Foxp3 and become a Treg cell in the presence of TGF- $\beta$ , but in the presence of TGF- $\beta$  plus IL-6 or IL-21, the Treg developmental pathway is abrogated, and instead, T cells develop into Th17 cells<sup>[24]</sup>. Initial studies have shown Th1 predominance in intestinal mucosa of patients with IBD and SpA, however, recent studies have suggested that, in both groups of patients, Th17 cells may have an important role in initiation and perpetuation of autoimmune inflammation. One study that involved 499 patients with CD and 216 with UC has shown increased IL-17F mRNA expression in intestinal biopsies of patients compared to controls<sup>[25]</sup>. A recent study has shown an increased proportion of Th17 cells in patients with SpA<sup>[26]</sup> and increased IL-17, IL-6, TGF- $\beta$  and IFN- $\gamma$  levels in synovial fluid of patients with SpA, when compared with patients with rheumatoid arthritis<sup>[27]</sup>. Also, some authors have suggested that dysfunction of Tregs participates in the immunopathogenesis of these diseases, and they have proposed their use as therapeutic agents in IBD<sup>[24,28]</sup>.

TNF- $\alpha$  is a pro-inflammatory cytokine that is produced mainly by macrophages and activated T cells. It is a key molecule in chronic inflammation of SpA and IBD. In the latter, the interaction between antigen-presenting cells (APCs) and intestinal bacterial flora contributes to the development of uncontrolled CD4<sup>+</sup> cell activation, which leads to the release of pro-inflammatory cytokines such as TNF- $\alpha$ , IL-6, IL-12, IL-23 and IL-17. In SpA, models of transgenic rats and clinical observations have suggested that pathogenic microorganisms and their interaction with APCs also have a crucial role in the initiation and perpetuation of the altered immune response that leads to joint and enthesitis inflammation. Additionally, increased intestinal permeability has been found in patients with SpA and IBD. This fact could alter the innate immune response to bacterial antigens<sup>[29]</sup>. These discoveries have had important therapeutic implications for these groups of patients.

Other relevant molecules involved in the pathogenesis of both groups of diseases are the toll-like receptors (TLRs) that play an important role in the innate immune response against pathogenic microorganisms. Several studies have shown increased expression of TLR-4 and TLR-2 in APCs of patients with SpA<sup>[30,31]</sup> and in intestinal

biopsies of patients with UC and CD<sup>[32-34]</sup>. The alterations in function and regulation of these molecules may have an important role in the initiation and perpetuation of chronic inflammation in these diseases<sup>[35]</sup>. There are studies that have correlated several mutations and genetic variations of these receptors with susceptibility for these diseases. The results are controversial, probably due to the heterogeneity of the patients and the ethnic groups that have been included in the studies<sup>[36-39]</sup>.

#### **Other immunopathogenic abnormalities in IBD and SpA**

Abnormal responses to certain microorganisms have been described in patients with IBD or SpA; for instance, increased levels of the same serotypes of *Klebsiella pneumoniae* have been found more frequently in patients with IBD and SpA, compared with healthy controls and controls with celiac disease<sup>[40]</sup>. Besides, several studies have shown increased levels of antibodies against *Klebsiella* antigens, and against collagens type I, III, IV and V in patients with CD or AS. There are molecular similarities between *Klebsiella* nitrogenase and HLA-B27 genetic markers and between *Klebsiella* pullulanase and collagen fibers types I, III and IV. Therefore, several authors have proposed that there may be molecular mimicry between *Klebsiella* and human molecules that could participate in the initiation and perpetuation of these diseases<sup>[41]</sup>, i.e. anti-*Klebsiella* IgA cross-reacts with HLA-B27 antigen, and antibodies to enteric bacteria are able to lyse lymphocytes from HLA-B27 patients with AS.

The participation of the HLA-B27 molecule in the immunopathogenesis of SpA has been well known since 1973 when Brewerton and Schlosstein detected its high prevalence in patients with AS, psoriatic arthritis (PsA), reactive arthritis and anterior uveitis<sup>[42]</sup>. Its functional relevance was demonstrated elegantly in 1990 by Hammer *et al.*<sup>[43]</sup>; their group developed a transgenic rat with the human HLA-B27 molecule. These rats developed a multisystemic inflammatory disease that had several clinical and histopathological similarities to SpA and IBD<sup>[43]</sup>. An important finding was that these rats did not develop joint or gut inflammation when they were in a bacteria-free environment, which supports the theory of the participation of microorganisms in the pathogenesis of these diseases<sup>[44]</sup>. Some studies involving patients with IBD have shown an association of HLA-B27 molecule with the presence of sacroiliitis, spondylitis, enthesitis, peripheral arthritis, erythema nodosum, uveitis and oral ulcers<sup>[14]</sup>.

Other genes have been associated with the clinical presentation of several arthropathies associated with IBD<sup>[45]</sup>. The Oxford Group has found an association of type 1 arthropathy (pauci-articular, self limited, with relapses) with HLA-DRB1\*0103, HLA-B35 and HLA-B24, while type 2 arthropathy (polyarticular, progressive) is associated with HLA-B44 in British patients<sup>[46]</sup>. One study that evaluated Spanish patients has found an association of the mini-haplotype TNF a6B5 with the presence of joint manifestations in patients with UC<sup>[47]</sup>. Another study has found that a polymorphism of the gene CARD15 is associated with the presence of gut inflammation in

patients with SpA, and the same polymorphism is over-represented in patients with CD<sup>[48]</sup>.

On the other hand, there is evidence to suggest that, for patients with IBD, tobacco use and history of appendectomy are risk factors for developing extraintestinal manifestations, particularly seronegative SpA and dermatological manifestations such as erythema nodosum and pyoderma gangrenosum<sup>[49]</sup>.

In summary, the autoimmune pathogenic mechanisms shared by IBD and SpA include genetic susceptibility to abnormal antigen presentation, aberrant recognition of self, the presence of autoantibodies against specific antigens shared by the colon and other extra-colonic tissues, and increased intestinal permeability. The response against microorganisms may have an important role through molecular mimicry and other mechanisms.

## **CLINICAL PRESENTATION OF THE RHEUMATIC MANIFESTATIONS OF IBD**

The rheumatic manifestations of IBD have been divided into peripheral arthritis, and axial involvement, including sacroiliitis, with or without spondylitis, similar to the presentation of classic AS. There may be other periarticular manifestations such as enthesopathy, which is the involvement of tendinous insertions, tendonitis, periostitis, clubbing and granulomatous lesions in joints and bones. There may also be osteoporosis and osteomalacia secondary to IBD and to its treatment<sup>[50]</sup>.

#### **Peripheral arthritis**

The frequency of peripheral arthritis in IBD ranges from 17% to 20%, and it is more common in CD<sup>[51]</sup>. In a retrospective study that included 1459 patients with IBD, peripheral arthritis was present in 6% of patients with UC and in 10% of patients with CD<sup>[52]</sup>. Another study has shown arthritis in 10%, enthesitis in 7%, and a history of arthritis in 29% in a group of patients with IBD<sup>[53]</sup>.

The Oxford Group<sup>[52]</sup> has classified the peripheral arthritis associated with IBD (also called peripheral enteropathic arthropathy) without axial involvement, as pauci-articular or polyarticular arthropathy (Table 1). In the pauci-articular form, joint symptoms are usually acute and self-limited; the joint involvement is asymmetric and migratory, with participation of both large and small joints, and lower limbs are more affected. Many episodes last from 6 to 10 wk but relapses are frequent and they tend to coexist with IBD relapses; these patients have high frequencies of other extraintestinal manifestations such as erythema nodosum and uveitis. It is interesting that in 31% of these patients the arthropathy may appear even 3 years before the diagnosis of IBD is made. On the other hand, the polyarticular form tends to have a chronic course and it may be destructive; its course is independent of IBD exacerbations and the coexistence of other extraintestinal manifestations is rare, except for uveitis<sup>[50,54]</sup>. Enthesopathy, particularly affecting the Achilles tendon or plantar fascia insertion are common manifestations.

Table 1 Classification of peripheral arthropathy associated with IBD

Type 1 (Pauci-articular)	Type 2 (Polyarticular)
Less than five joints	Five or more joints
Asymmetric involvement	Persistent inflammation for months or even years
Lower limbs more affected	May be erosive
Self limited episodes that last < 10 wk	Affects both large and small joints
Usually concomitant IBD relapse	It can be symmetric or asymmetric
High frequency of other extraintestinal manifestations	Clinical course is independent of IBD activity
	Associated with uveitis

IBD: Inflammatory bowel disease.

Wordsworth <i>et al</i> <sup>[60]</sup>	42	Referral center	ESSG	25 (CD)		36		

Rx: Radiography; MRI: Magnetic resonance image; ESSG: European Spondyloarthropathy Study Group.

In most of the cases, intestinal symptoms precede or coexist with joint manifestations, but in some patients, arthritis precedes the gut manifestations, even by several years. In a prospective study that included 123 patients with SpA, 6% of the patients developed CD from 2 to 9 years after the first joint symptom. For UC, some studies have described a temporal relationship between arthritis and gut inflammation relapses<sup>[50]</sup>; there have been case reports of patients that have developed arthritis at the same time as ileal pouchitis after total proctocolectomy for UC activity. However, other studies have shown that colectomy has almost no effect on joint inflammation<sup>[50,55]</sup>. The most consistent finding is that colon involvement increases the susceptibility to peripheral arthritis.

There have been isolated case reports about patients that have presented with progressive, destructive monoarthritis with granulomatous synovial inflammation, and CD has been diagnosed when extension studies have been carried out as part of the diagnostic workup<sup>[56]</sup>.

### AS and other forms of axial involvement

Axial involvement is part of CD and UC, although it is more common in CD (5%-22%) than in UC (2%-6%), and in general, the prevalence is 10%-20% for sacroiliitis and 7%-12% for AS<sup>[51,57,58]</sup>. A study that included patients from a referral center has shown that 30% of the patients with IBD had inflammatory low back pain, 33% had abnormal Shober index, and 30% had unilateral or bilateral grade I or II sacroiliitis. In fact, 35% of the patients fulfilled the European Spondyloarthropathy Study Group criteria for SpA<sup>[53,59]</sup>, and 10% fulfilled the criteria for AS. Other studies from referral centers have shown similar results and higher prevalence than for population

studies, which probably reflects referral bias<sup>[13,17,53,58,60]</sup> (Table 2).

The clinical picture is virtually the same as the one for patients with AS without extra-articular manifestations. Axial symptoms usually precede gut symptoms; clinical course is totally independent of the intestinal manifestations and intestinal surgery does not alter the course of SpA. Ankylosing spondylitis associated with IBD can develop at any age, whereas idiopathic AS usually starts before 40 years of age. In idiopathic AS, males are more affected than females (ratio 2.5:1), while in AS associated with IBD, the male to female ratio is 1:1<sup>[61]</sup>.

### LABORATORY AND OTHER DIAGNOSTIC WORKUP

The most common laboratory abnormalities are: anemia due to chronic inflammation and intestinal bleeding, leukocytosis, thrombocytosis, elevated acute phase reactants such as C reactive protein, and erythrocyte sedimentation rate. Perinuclear anti-neutrophil cytoplasm antibodies are found in up to 60% of patients with UC and in some patients with CD, and they seem to be directed against lactoferrin autoantigens<sup>[62]</sup>. Antinuclear antibodies and rheumatoid factor are usually absent. Synovial fluid may be inflammatory but sterile.

Anti-*Saccharomyces cerevisiae* antibodies (ASCAs) were first described in patients with CD (both IgG and IgA isotypes). Several studies have confirmed their relevance as markers of CD. One multicenter study has shown that their presence in patients with IBD, who are negative for ANCA, has a positive predictive value of 94.2% for CD,

and it is associated with severe clinical manifestations of this disease<sup>[63]</sup>. Another recent study has shown that the prevalence of ASCAs in patients with CD is 80.6%, and they have a sensitivity of 81%, specificity of 78%, positive predictive value of 45.5%, and negative predictive value of 95% when used as a single marker in patients with IBD<sup>[64]</sup>. One study that evaluated 87 SpA patients positive for HLA-B27 has found increased levels of IgA but not IgG ASCAs, particularly in patients with AS; although patients with increased levels of the antibody had no gastrointestinal symptoms. It remains unclear if these antibodies are associated with the development of IBD in patients with SpA, but this finding supports the etiopathogenic association of AS with IBD<sup>[65]</sup>.

Sacroiliitis and spondylitis in IBD are associated with the presence of HLA-B27, although in lower frequencies than in AS (33% *vs* 71%). Besides, patients with AS without HLA-B27 have a higher risk of developing IBD than those with HLA-B27<sup>[53]</sup>. The Oxford study<sup>[52]</sup> has shown an association of pauci-articular arthritis with the presence of HLA-B27 (27% *vs* 7% in controls), HLA-B35 (32% *vs* 15%) and HLA-DRB1\*0103 (33% *vs* 3%), while the polyarticular form was associated with HLA-B44 (62% *vs* 30%)<sup>[45]</sup>. Another study has shown that the presence of the shared epitope is associated with synovitis in patients with IBD without sacroiliitis<sup>[50,66]</sup>.

Radiological studies of peripheral joints have shown changes of acute arthritis such as increased volume of soft tissue. Erosions are uncommon in patients with self-limited arthritis. Patients with persistent arthritis may develop joint erosion and, if the hips are affected, there may be also loss of joint space. Axial radiographs show typical AS changes, although some studies have suggested that asymmetric sacroiliitis frequency may be higher<sup>[67]</sup>.

## OTHER RHEUMATIC MANIFESTATIONS ASSOCIATED WITH IBD

Less frequently, IBD has been associated with Sjögren's syndrome<sup>[68]</sup>, rheumatoid arthritis<sup>[69]</sup>, inflammatory myopathy and Takayasu arteritis<sup>[70,71]</sup>, although these come from isolated case reports and no confirmed clinical or pathophysiological association can be made. There has been one study that has evaluated the prevalence of fibromyalgia and spread of musculoskeletal pain in patients with IBD, which has found equal frequencies to those in the general population<sup>[72]</sup>. In addition, it is advisable to evaluate IBD patients for osteoporosis if they have received high-dose steroids for long periods, and to implement prophylactic measures such as calcium and vitamin D supplements<sup>[73]</sup>.

## TREATMENT OF RHEUMATIC MANIFESTATIONS OF IBD

Treatment depends on the severity of the clinical picture. Patients with mild oligoarthritis usually respond to relative rest, physiotherapy and intra-articular steroid in-

jections<sup>[74]</sup>. Most of the patients respond to nonsteroidal anti-inflammatory drugs because they control the symptoms and joint and enthesitis inflammation, but they do not stop joint destruction, and they may have important side effects including exacerbation of IBD<sup>[75,76]</sup> and produce small intestine and colon ulcers<sup>[77]</sup>. Hence, they are recommended for patients with mild exacerbations, to control symptoms in arthritis flares, but their use must be limited to the minimal effective dose and time.

Sulfasalazine and 5-aminosalicylic acid are often recognized as useful for IBD, and are efficacious for moderate peripheral arthritis in SpA and IBD-associated arthritis, particularly in UC<sup>[78,79]</sup>. Their usefulness in CD is less clear. Some studies have shown promising results, others, no benefit at all, to control CD-associated arthritis<sup>[80-82]</sup>. These drugs have no effect in the progression of aggressive arthritis and their utility in axial involvement is marginal; also, they do not prevent the appearance of IBD in patients with SpA<sup>[83]</sup>. Their beneficial effect may be explained by their anti-inflammatory effects in the intestinal wall, by normalizing its permeability and preventing antigen entrance through an abnormal intestinal wall<sup>[84]</sup>.

Immunosuppression with methotrexate, azathioprine, 6-mercaptopurine, cyclosporine and leflunomide has been successful in some patients with peripheral arthritis and other extraintestinal manifestations, although there are no controlled studies that have demonstrated their efficacy<sup>[74,85-88]</sup>, and the evidence of their efficacy comes from uncontrolled studies or case reports.

The description of the pathogenic mechanisms of SpAs and IBD have relevant therapeutic implications for both groups of diseases. The initial observation that intestinal manifestations of patients with both SpA and IBD improve with TNF- $\alpha$  blocking agents has led to the use of these medications in patients with IBD, with favorable results, particularly with infliximab and adalimumab in CD<sup>[89]</sup>. Currently, infliximab is a first-line treatment for patients with active AS associated with IBD, and other TNF- $\alpha$  blocking agents such as certolizumab that have shown good results for patients with IBD, are promising<sup>[90,91]</sup>.

Also, considering the pathogenic relationship between gut and joint inflammation in SpA, there are other agents with potential benefits in both diseases. Some of these include IL-10, IL-11, IL-6, intercellular adhesion molecule 1, mitogen-activated protein kinase and integrin ( $\alpha$ 4 and  $\alpha$ 4 $\beta$ 7) blockade, as well as TLR modulation<sup>[92-95]</sup>.

Some groups have proposed the use of probiotics for the treatment of patients with IBD and arthritis or AS. Their use is based on modulation of intestinal flora by bacteria and their products. The objective is to treat patients with persistent arthralgia in the early phases of the disease, before chronic damage is established, to improve the quality of life and have a positive influence on the natural course of the disease. Some interesting studies have demonstrated that these compounds improve experimental colitis in murine models and in patients with IBD. One of these models has shown that the anti-

inflammatory effect depends on the probiotic DNA, in an IFN-mediated response induced by TLR9. Further studies should evaluate these and other mechanisms in animal models<sup>[96,97]</sup>.

## CONCLUSION

Rheumatic manifestations of IBD include peripheral arthritis, enthesitis and axial involvement, and they are present in up to 62% of patients with IBD. There is an important immunopathogenic relationship between gut and joint abnormalities in patients with IBD. TLR variants and abnormalities, altered function and balance of T-cell subpopulations and their production of pro-inflammatory cytokines, as well as integrin and E-cadherin dysfunction are partially responsible for such a relationship, and research in these areas will help to clarify the pathogenesis of these complex diseases. Medical treatment of rheumatic manifestations of IBD includes sulfasalazine and mesalamine, immunomodulators and TNF- $\alpha$  inhibitors. New treatments for IBD directed against pro-inflammatory cytokines and the regulation of the immune response may have long-term benefits for rheumatic manifestations.

### Abstract

**AIM:** To investigate the diagnostic accuracy of acoustic radiation force impulse (ARFI) imaging as a noninvasive method for the assessment of liver fibrosis in chronic hepatitis C (CHC) patients.

**METHODS:** We performed a prospective blind comparison of ARFI elastography, APRI index and FibroMax in a consecutive series of patients who underwent liver biopsy for CHC in University Hospital Bucharest. Histopathological staging of liver fibrosis according to the METAVIR scoring system served as the reference. A total of 74 patients underwent ARFI elastography, APRI index, FibroMax and successful liver biopsy.

**RESULTS:** The noninvasive tests had a good correlation with the liver biopsy results. The most powerful test in predicting fibrosis was ARFI elastography. The diagnostic accuracy of ARFI elastography, expressed

as area under receiver operating characteristic curve (AUROC) had a validity of 90.2% (95% CI AUROC = 0.831-0.972,  $P < 0.001$ ) for the diagnosis of significant fibrosis ( $F \geq 2$ ). ARFI sonoelastography predicted even better F3 or F4 fibrosis (AUROC = 0.993, 95% CI = 0.979-1).

**CONCLUSION:** ARFI elastography had very good accuracy for the assessment of liver fibrosis and was superior to other noninvasive methods (APRI Index, FibroMax) for staging liver fibrosis.

### INTRODUCTION

The prognosis and clinical management of chronic liver diseases are highly dependent on the extent of liver fibrosis. This is particularly true in patients with chronic hepatitis C (CHC), which is the leading cause of cirrhosis in many countries. CHC progresses to cirrhosis through a sequence of morphological changes that reflect increasing fibrosis and architectural distortion<sup>[1]</sup>. Staging systems of varying complexity based on these morphological changes have been used in patient management as a guide to prognosis, and in clinical investigations as an estimate of natural history and response to therapy.

Liver biopsy is the current reference examination for the assessment of liver fibrosis. It is important to remember that a needle biopsy is merely a sample of the entire liver, and that scarring in chronic liver disease is typically irregularly distributed in the liver. Needle liver biopsy removes only about 1/50000th of the liver and carries substantial interpreter errors<sup>[2]</sup>. Liver biopsy is an invasive procedure with certain unavoidable risks and complications. Therefore, the development of noninvasive tests to assess hepatic inflammation and fibrosis has been an active area of research. Furthermore, as new antifibrotic therapies are studied, there is a growing need to develop noninvasive tests for fibrosis for use in clinical trials.

Several noninvasive methods have been proposed to stage liver fibrosis, including biochemical tests and imaging techniques. The biochemical tests consist of sophisticated indices and scores, or a large number of serological markers of liver fibrosis. However, the value of these diagnostic methods remains debated.

Among the imaging methods, transient elastography is a new technique that rapidly and noninvasively measures mean tissue stiffness. It is largely accepted that hepatic stiffness is related to the degree of fibrosis. Most clinical studies have been performed with FibroScan. Recently, acoustic radiation force impulse (ARFI) imaging sonoelastography has been proposed as an alternative method to assess liver elasticity. To the best of our knowledge, no study has compared ARFI sonoelastography and biochemical tests (APRI index, FibroMax) for the assessment of liver fibrosis.

The aim of our study was to evaluate the value of ARFI elastography for the diagnosis of liver fibrosis and to compare the accuracy of ARFI elastography, APRI index and FibroMax for staging liver fibrosis in patients who underwent liver biopsy for CHC.

## MATERIALS AND METHODS

### Study population

The study was a single-centered, prospective, blind comparison of ARFI sonoelastography, APRI index and FibroMax in 100 patients with CHC who underwent liver biopsy at the University Hospital Bucharest between January 2007 and June 2008. Patients with CHC were selected out of 215 patients who attended the University Hospital Bucharest for hepatic cytolysis.

Inclusion criteria were the presence of HCV RNA in serum without previous antiviral treatment and hepatic cytolysis [alanine aminotransferase (ALT) > 1.5 × normal]. Patients with other forms of chronic liver disease and those with ascites were excluded from the study.

Hepatitis C virus (HCV) infection was defined by the presence in the serum of anti-HCV antibodies using the third generation ELISA. HCV infection was confirmed by performing the COBAS TaqMan HCV test (Roche Molecular Systems, Inc., NJ, USA). This test is an *in vitro* amplification of the HCV nucleic acid, which

uses the High Pure System Viral nucleic acid kit (Roche Diagnostics Corp, IN, USA) for manual preparation and the COBAS TaqMan 48 analyzer (Roche Diagnostics Corp, IN, USA) for automatic amplification and detection. The RNA titer was expressed in IU/mL. The detection limit was > 15 IU/mL with a positive rate of 95%.

Patients who fulfilled the inclusion criteria were enrolled and underwent blood tests for APRI, FibroMax measurement, and ultrasound elastography on the day before the liver biopsy.

The study was approved by the local ethics committees and all individuals provided written informed consent prior to enrollment in the study.

### Biochemical evaluation of the liver

Liver function tests were performed prior to the liver biopsy. Blood samples were obtained under fasting conditions and routine liver function tests [ALT and aspartate transaminase (AST), total proteins, serum albumin and  $\gamma$  globulins,  $\gamma$ -glutamyl transferase (GGT), total bilirubin, alkaline phosphatase, international normalized ratio of prothrombin time] were performed. All were measured using Dade Behring reactants and the Dimension RXL analyzer (Dade Behring, FL, USA).

### APRI index

AST levels and platelet counts were measured with a Dimension RXL analyzer and a Hematology System analyzer (Beckman-Coulter, Inc., CA, USA). The APRI index was calculated as follows:  $\text{AST} / (\text{Upper Limit of Normal}) \times 100 / \text{platelet count} (10^9/\text{L})$ . The upper normal limit of AST was considered as 38 U/L.

### FibroMax

FibroMax (Biopredictive, France) is a new noninvasive panel of markers reported to predict advanced fibrosis. It contains five tests: FibroTest (to assess the degree of fibrosis); ActiTest (to assess the degree of activity, inflammation and necrosis); SteatoTest (to diagnose hepatic steatosis); NashTest (to diagnose nonalcoholic steatohepatitis); and AshTest (to diagnose severe alcoholic steatohepatitis). FibroMax combines the measurement of 10 indirect parameters adjusted for age, sex, weight and height:  $\alpha$ 2-macroglobulin, haptoglobin, apolipoprotein A1, total bilirubin, GGT, ALT, AST, fasting glucose, triglycerides and total cholesterol.

FibroMax serum samples were taken on the day before biopsy from patients in the fasting state. Biochemical parameters were measured using Dade Behring reactants and the Dimension RXL analyzer. Specific proteins,  $\alpha$ 2-macroglobulin, haptoglobin and apolipoprotein A1, were measured by immunonephelometry using the BN Pro-Spect Dade Behring system. Using FibroMax, fibrosis was staged on a scale of 0-4 with respect to the METAVIR fibrosis staging. For FibroTest, 0-0.21 fibrosis was staged as F0, 0.22-0.27 as F0-F1, 0.28-0.31 as F1, 0.32-0.48 as F1-F2, 0.49-0.58 as F2, 0.59-0.72 as F3, 0.73-0.74 as F3-F4, and 0.75-1 as F4.

### Ultrasound elastography

ARFI imaging is a new tissue strain imaging technology that utilizes sound waves to interrogate the mechanical stiffness properties of tissues. Virtual Touch tissue imaging and Virtual Touch tissue quantification (Siemens AG, Germany) are the first available applications to implement this technology. Unlike conventional B-mode sonography, which provides anatomical details based on differences in acoustic impedance, Virtual Touch imaging describes relative physical tissue stiffness properties. In complement, Virtual Touch™ tissue quantification provides accurate numerical measurements related to tissue stiffness at user-defined anatomical locations.

Conventional elastography, however, requires manual compression of the tissues in order to provide relative displacement between the mass and the surrounding structures and therefore an assessment of strain. This can be difficult to apply to abdominal structures because of the presence of the ribs and abdominal wall. ARFI technology quantifies stiffness without manual compression. Using the Virtual Touch application, the tissue is compressed by acoustic energy. Virtual Touch tissue quantification is a quantitative assessment of tissue stiffness, through measurement of shear wave speed. Shear waves are generated by displacement of tissue and attenuate approximately 10 000 times more rapidly than conventional ultrasound waves.

Prior to liver biopsy, the patients underwent liver ultrasonographic elastography, under fasting conditions, using ARFI imaging [Acuson S2000 (Siemens AG, Germany) with Virtual Touch tissue quantification software]. The system uses a standard ultrasonographic probe and offers elastography with a flexible metering box of 1 cm at variable depths. An acoustic push pulse transmitted by the transducer (3.5 MHz) toward the tissue induces an elastic shear wave that propagates through the tissue. The propagation of the shear wave is followed by detection pulses that are used to measure the velocity of shear wave propagation, which is directly related to tissue stiffness: speed increases with stiffness.

Liver stiffness was assessed by the same physician blinded to clinical and biological data. The measurements were performed on the right lobe of the liver through the intercostal spaces, with the patient lying in the decubitus dorsal position, with the right hand under the head and the head turned toward the left. The tip of the probe was covered with coupling gel and placed on the skin between the ribs at the level of the right lobe of the liver. The operator positioned the probe over the area of interest: segment eight of the right lobe, away from motion and portal/hepatic vessels, about 2 cm from the liver capsula, at a depth between 3.8 and 5.5 cm. When the target area had been located after optimizing the B-mode image, the operator pressed the button Virtual Touch tissue quantification, and asked the patient to stop breathing for a moment. Then, we observed the velocity of shear wave on screen. We used this protocol because we saw that, when the right lobe was scanned through the intercostal spaces with normal breathing, the variance of

measurement was low. A total of 12 valid measurements per patient were performed. In difficult patients, to obtain better access to the liver without excessive pushing or breath holding, the measurements were performed on patients lying in the left lateral decubitus position, or using a subcostal approach to the left lobe. The results of ARFI ultrasonographic elastography were expressed as liver propagation velocity (m/s). The success rate of liver elasticity measurements was calculated as the ratio between validated and total measurements. Results were expressed as the median value of the total measurements (12 measurements per patient) in m/s, with values ranging from 0.8 to 3.7 m/s. Only procedures with a success rate of at least 60%, and with the interquartile range of all validated measurements < 30% of the median value, were considered reliable.

### Histological assessment

Percutaneous liver biopsy was performed by senior operators using the Menghini technique with a 1.4-mm-diameter needle (Hepafix; B Braun Melsungen AG, Germany). After biopsy, the liver samples were fixed in formalin, paraffin embedded, and stained with hematoxylin-eosin and Masson's trichrome. All biopsy specimens were analyzed by an expert pathologist blinded to the biological and clinical data and to the results of ultrasound elastography. The length of each liver biopsy was established in millimeters and the number of portal tracts was counted.

Liver fibrosis and necroinflammatory activity were evaluated by the METAVIR scoring system. Fibrosis was staged on a four-point scale according to this score: F0 represented no fibrosis; F1, portal fibrosis without septa; F2, portal fibrosis and a few septa; F3, numerous septa without cirrhosis; and F4, cirrhosis. Necroinflammatory activity was also graded on a four point scale: A0, none; A1, mild; A2, moderate; A3, severe.

Steatosis was assessed according to the number of hepatocytes with degeneration, as follows: 0, none; 1, steatosis in 1%-10% of hepatocytes; 2, steatosis in 11%-33% of hepatocytes; 3, steatosis in 34%-66% and 4, 67%-100% of hepatocytes<sup>[3]</sup>.

### Statistical analysis

Results are presented as the mean  $\pm$  SD, counts and percentages. The results are illustrated as the median and 25th- to 75th-percentile values. The correlation between the noninvasive tests and liver biopsy was tested using the non-parametric Spearman's correlation coefficient. The overall validity was measured using area under the receiver operating characteristic curve (AUROC) with 95% CI. Cutoff values that defined prediction regions for each fibrosis stage were defined by a common optimization step that maximized the sum of the sensitivities in predicting the single stages. Finally, sensitivity, specificity, and positive (PPV) and negative predictive value (NPV) were calculated. The optimal cutoff was chosen at the highest left point on the curve. For all tests, significance was achieved at  $P < 0.05$ .

Table 1 Patient characteristics

Characteristics	Patients included (n = 74)
Sex (male/female)	32/42
Age (yr)	55.32 ± 9.6 (31-72)
BMI (kg/m <sup>2</sup> )	25.59 ± 4.03 (17.23-33.29)
AST (IU/L)	50.06 ± 32.36 (18-188)
ALT (IU/L)	67.06 ± 26.79 (20-147)
INR	1.12 ± 0.15 (0.9-1.74)
Bilirubin (mg/dL)	0.69 ± 0.32 (0.29-2.08)
Albumin (g/dL)	3.9 ± 0.55 (2.6-4.9)
Cholesterol (mg/dL)	192.36 ± 46.58 (120-311)
Triglycerides (mg/dL)	123.24 ± 73.33 (48-467)

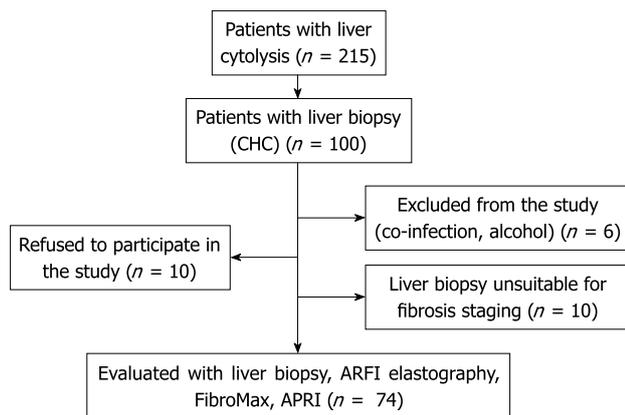

Figure 1 Diagram of patients with liver biopsy for CHC in the University Hospital Bucharest during the 18-mo study period.

## RESULTS

### Patient characteristics

A total of 100 patients underwent liver biopsy for CHC. The patients were selected out of 215 patients who attended the University Hospital Bucharest for hepatic cytolysis. Ten patients refused to participate and six were excluded: three had hepatitis B virus coinfection, and three had a current daily alcohol intake of at least 60 g/d. In 10 patients, liver biopsy was unsuitable for fibrosis staging with the length of sample < 15 mm.

Seventy-four patients underwent ARFI elastography, APRI index, FibroMax and successful liver biopsy (Figure 1). Demographic, clinical and biochemical characteristics of the patients included in the study are shown in Table 1.

### Histological characteristics

The median biopsy length was 20 mm (range: 15-25 mm); the number of portal tracts was 12 ± 4 (range: 8-16). Patient distribution according to METAVIR fibrosis stage and activity grade and steatosis are presented in Table 2.

### Relationship between liver elasticity and histological stages

Figure 2 shows the median value (95% CI) of liver elasticity compared with fibrosis stages according to METAVIR score. A high correlation of increasing liver stiffness with increasing stage of fibrosis was observed. The Spearman's correlation coefficient between the liver

Table 2 Patient distribution according to fibrosis stage, activity grade and steatosis

Fibrosis Stage	Activity Grade		Steatosis Grade		
	n (%)	n (%)	n (%)	n (%)	
0	1 (1.3)	0	1 (1.3)	0	24 (32.4)
1	9 (12.1)	1	32 (43.2)	1	23 (31.08)
2	25 (33.7)	2	29 (39.1)	2	12 (16.2)
3	19 (25.6)	3	12 (16.2)	3	11 (14.8)
4	20 (27.02)			4	4 (5.40)

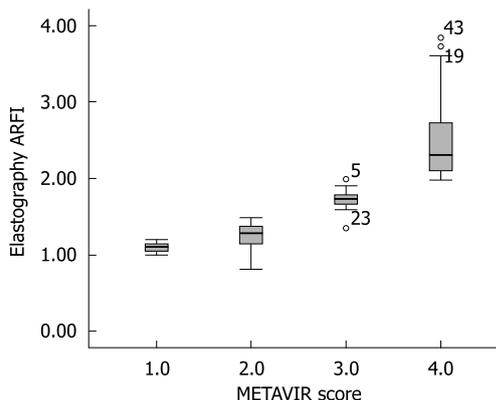

Figure 2 Box plot of METAVIR score and ARFI elastography. Top and bottom of boxes represent first and third quartiles, respectively. Length of box represents interquartile range within which 50% of values are located. Thick line through each box represents the median. Error bars mark minimum and maximum values (range). Small circles represent outliers. Skewed data for fibrosis stage 0/1 can be explained by the small number of patients in this group.

stiffness and the histological fibrosis stages was highly significant with a value of 0.919 ( $P < 0.001$ ). Steatosis is a frequent occurrence in CHC<sup>[4]</sup>. According to ANOVA test, no influence of the degree of activity or steatosis on elasticity values was observed in this study.

To determine the cutoffs that predicted each degree of fibrosis, we used the ROC curve method (Figure 3). ARFI elastography could predict fibrosis F2 or more, with a validity of 90.2% (95% CI AUROC = 0.831-0.972,  $P < 0.001$ ). The optimal cutoff point between F1 and F2 was 1.215. At this value, ARFI elastography had a sensitivity of 89.4% and a specificity of 100%.

ARFI sonoelastography predicted even better F3 or F4 fibrosis (AUROC = 99.3%, 95% CI = 0.979-1). The optimal cutoff between F3 and F4 was 1.54, with sensitivity and specificity of 97% and 100%, respectively. The specificity of 100% shows that all study patients who presented with a value of  $\geq 1.54$  upon sonoelastography had liver fibrosis F3 or more (confirmed by liver biopsy).

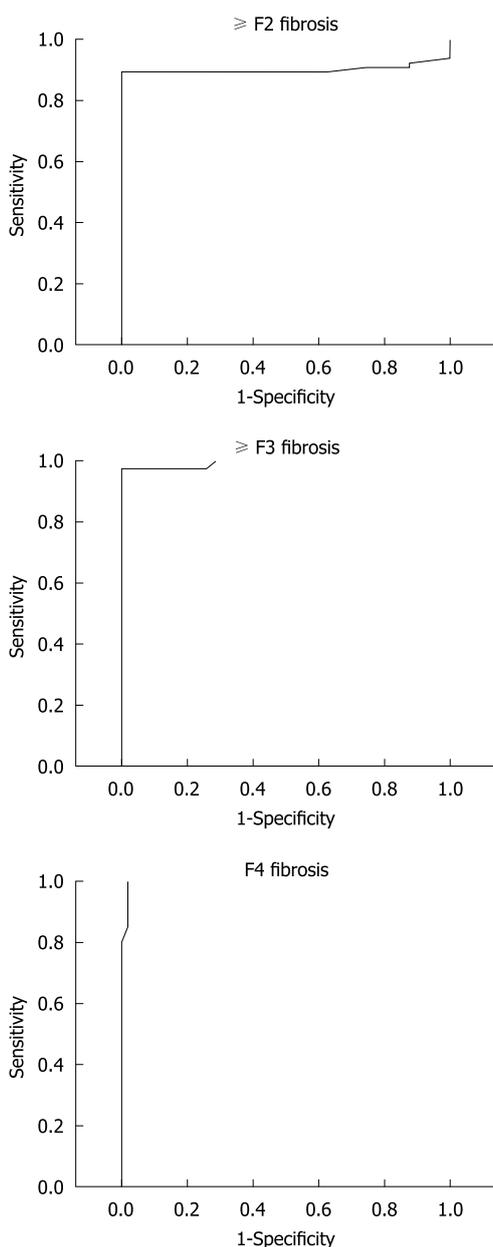

The same high validity was maintained as in predicting cirrhosis: (AUROC = 99.3%, 95% CI = 0.989-1).

The optimal cutoff in predicting cirrhosis was 1.94 with a sensitivity of 100% and a specificity of 98.1%. In other words, every patient in this study that had a sonoelastography result with a value < 1.94 did not have cirrhosis.

The most discriminative cutoff values of ARFI elastography are presented in Figure 4.

**Table 3 Most discriminative cutoff values of ARFI elastography**

	≥ F1	≥ F2	≥ F3	F4
Cutoff (m/s)	1.185	1.215	1.54	1.94
Sensitivity (95% CI)	89% (79-95)	100% (91-100)	97% (86-100)	100% (83-100)
Specificity (95% CI)	87% (47-99)	71% (53-85)	100% (90-100)	98% (90-99)
PPV (95% CI)	98% (91-99)	79% (65-89)	100% (90-100)	95% (76-100)
NPV (95% CI)	50% (23-76)	100% (86-100)	97% (85-100)	100% (93-100)
Positive likelihood ratio	7.1	3.5	3.5	54

**Figure 3 ROC curves: elastography predicting ≥ F2 fibrosis, ≥ F3 fibrosis and F4 fibrosis.**

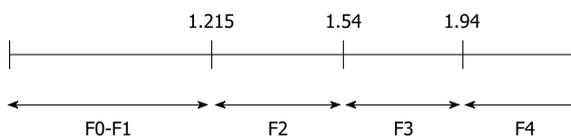

The corresponding sensitivity, specificity, PPV and NPV are shown in Table 3.

**Relationship between APRI index and FibroMax and histological stages**

A high correlation of increasing noninvasive measurements with increasing stage of fibrosis was observed. The

**Table 4 Noninvasive tests and their correlations with liver pathology**

	Noninvasive test	Correlation (Spearman coefficient)	95% CI	P
Liver biopsy	Elastography ARFI	0.919	0.872-0.949	< 0.001
	APRI index	0.712	0.572-0.811	< 0.001
	FibroMax	0.674	0.521-0.784	< 0.001

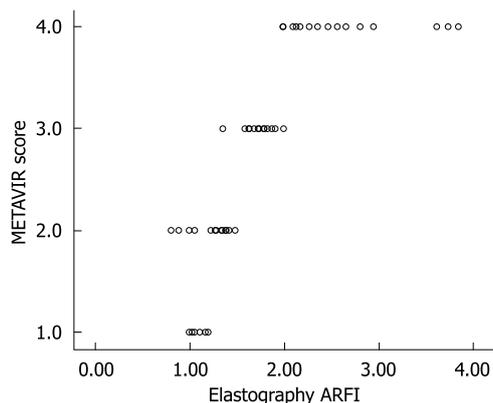

**Figure 4 Cutoff points for degrees of fibrosis.**

Spearman’s correlation coefficient between APRI index and FibroMax and the histological fibrosis stages was highly significant: 0.712 for APRI index and 0.674 for FibroMax. Table 4 shows the correlation between noninvasive tests and liver histology.

The correlation between two noninvasive tests should be better than with histological assessments for a correct prediction of liver fibrosis stage. The inter-test correlation coefficients, ARFI elastography/APRI index, and ARFI elastography/FibroMax were 0.712 and 0.718, respectively. All noninvasive tests used (Elastography ARFI, APRI index and FibroMax) were highly correlated with each other.

**DISCUSSION**

In chronic viral hepatitis, the knowledge of the stage of liver fibrosis is important for prognosis and for decisions about antiviral treatment<sup>[5]</sup>. Significant fibrosis (≥ F2) in these patients is an indicator for antiviral treatment, hence the great therapeutic value of a highly accurate diagnostic test. At present, liver biopsy is used as the reference standard for the assessment of liver fibrosis<sup>[2]</sup>. However, liver biopsy is becoming increasingly useless in the management of HCV-related chronic liver disease because of large sampling error, consistent inter-observer disagreement, unavoidable risks and complications, and the fact that it is a snapshot of a process that is everything but a static one. Replacement of liver biopsy in the assessment of chronic liver disease is the goal of any noninvasive technique. Therefore, a test with diagnostic performance for precise estimation

**Figure 5 Correlation between METAVIR and ARFI elastography.** Correlation between METAVIR and ARFI elastography showed that the overlap between stages F1 and F2 fibrosis limits the discriminatory value of the test in this context.

of the degree of liver fibrosis is of great therapeutic value. Previous studies have reported that transient elastography (FibroScan) can detect liver fibrosis and accurately predict significant fibrosis<sup>[5-11]</sup>. In the present study, we showed that APRI elastography should be taken into consideration as a noninvasive sonographical method for evaluation of liver fibrosis. A significant positive correlation between liver stiffness and the stages of fibrosis was noticed in patients with CHC. Significant AUROC for fibrosis F2 or more had a validity of 90.2% (95% CI AUROC = 0.831-0.972,  $P < 0.001$ ).

ARFI proved to be an even better predictor of F3 or F4 fibrosis (AUROC = 99.3%, 95% CI = 0.979-1). Early and rapid detection of significant fibrosis using this noninvasive procedure is essential since patients with significant fibrosis are at a high risk of developing complications, such as portal hypertension or hepatocellular carcinoma, and consequently need specific follow-up.

We considered ascites as one of the exclusion criteria from our study since ARFI, similar to Fibro-Scan, is performed in close contact with the liver. Nevertheless, ascites indicates the presence of cirrhosis, which makes noninvasive staging of fibrosis unnecessary<sup>[5]</sup>.

Liver elastometry with FibroScan is unsuccessful in patients with narrow intercostal spaces and in those with morbid obesity<sup>[7,8]</sup>. These are the major limitations of FibroScan measurements<sup>[12]</sup>. In the present study, patients with a body mass index (BMI) of up to 30 were enrolled, and ARFI elastography was performed successfully in all included patients. For the majority of the patients, the measurements were performed through a right intercostal space, and patients did not need to hold their breath during the examination. In difficult patients with narrow intercostal spaces, the examination was improved because of the subcostal approach to the left liver lobe. Elastography of the left liver lobe is especially helpful in obese patients. Rifai *et al*<sup>[13]</sup> have found recently that ARFI results of the right and left liver lobe were comparable ( $n = 26$ ,  $r = 0.44$ ,  $P < 0.03$ ). Furthermore, ARFI elastography is less time consuming than FibroScan. The new software allows one to do 12

measurements in under 1 min, as compared to FibroScan that does 10 measurements in under at least 4 min<sup>[9]</sup>.

The current study confirmed that, in CHC, no influence of steatosis or activity grade on correlation between elasticity values and fibrosis stages was observed. According to ANOVA test, the elasticity values were not affected by steatosis or activity grade. Similar results have been reported from studies analyzing transient elastography with FibroScan<sup>[7-9]</sup>.

Three noninvasive tests were performed. The tests had a good correlation with the liver biopsy results. The most powerful test in predicting fibrosis was ARFI elastography, with a non-parametric correlation coefficient of 0.919 (95% CI = 0.872-0.949,  $P < 0.001$ ). Other correlation coefficients were: 0.712 (95% CI = 0.572-0.811,  $P < 0.001$ ) for APRI index, and 0.674 (95% CI = 0.521-0.784,  $P < 0.001$ ).

In the present study, we found highly significant positive correlations between liver propagation velocity obtained with ARFI elastography and the METAVIR fibrosis stage. The correlation coefficients showed a linear relationship between ARFI elastography and liver biopsy fibrosis, but to determine the cutoffs that predicted each degree of fibrosis, we used the ROC curve method.

An AUC value of 0.902 (0.831-0.972) was obtained using ARFI elastography for the diagnosis of significant fibrosis ( $\geq F2$ ), with a cutoff value of 1.215 m/s. In comparison, three recent studies that analyzed the non-invasive assessment of liver fibrosis with FibroScan have revealed AUCs between 0.75 and 0.84 for the diagnosis of significant fibrosis ( $\geq F2$ )<sup>[7-9]</sup>. The ARFI sonoelastography predicted even better F3 or F4 fibrosis (AUROC = 99.3%, 95% CI = 0.979-1).

Considering the increased values of sensitivity and specificity, ARFI sonoelastography was shown to be a valuable investigative technique that could be of great help in the evaluation and follow-up of liver fibrosis.

At present, it is difficult to determine the real impact of ARFI elastometry in the early diagnosis of fibrosis in patients with CHC. Figure 5 clearly indicates an overlap observed between F0-F1 and F2. The increase in liver propagation velocity was more important between stages F2 (1.21 m/s) and F3 (1.54 m/s) than between stages F1 (1.18 m/s) and F2 (1.21 m/s). This is consistent with the fact that the increase in fibrous tissue is more important between stages F2 and F3 than between stages F1 and F2.

This limit of ARFI elastography (reduced discriminatory value between F1 and F2) was overcome by the fact that significant fibrosis ( $\geq F2$ ) is considered a hallmark of progressive liver disease. Studies have shown that antiviral treatment of patients with CHC prolongs life, improves quality of life, and is cost-effective<sup>[14,15]</sup>. However, treatment may be associated with severe side effects and the decision for treatment needs to be made on an individual basis. Patients with fibrosis stage F2 are at increased risk for developing cirrhosis with its complications (ascites, encephalopathy, or portal hypertension). Therefore, patients with fibrosis stage  $\geq F2$  have a stronger indication for treatment as compared with patients with no or mild fibrosis (F1)<sup>[16,17]</sup>.

Compared with fibrosis biomarkers, the disadvantage of liver elastometry is the absence of a large control group to assess the limit of normal values<sup>[14-18]</sup>. In studies using liver biopsy as a reference method, as in our study, the number of patients without fibrosis (F0) is very small.

Liver biopsy was considered the gold standard in our study because it is the only reference method available at present<sup>[1,19]</sup>. However, this technique is an invasive procedure that is known to have serious limitations. Various studies have shown that a single-needle liver biopsy can miss the diagnosis of cirrhosis in 20%-50% of patients<sup>[19]</sup>. To maximize the diagnostic yield of liver biopsy, we selected only the patients with a biopsy length > 15 mm and histological sections with at least eight portal tracts. The major advantage of ARFI liver elastography compared with liver biopsy is that it is painless, rapid, has no risk of complications, is very well tolerated and it is more representative of the entire liver parenchyma than is liver biopsy (1/50000 of the total liver mass)<sup>[2]</sup>.

To assess the performance of ARFI elastography, we have compared the liver propagation velocity with predictive blood tests (FibroMax) and APRI index in the same population. Our results showed that the most powerful test in predicting fibrosis was ARFI elastography. The high correlation between these three noninvasive tests suggests a sequential combination of them in algorithms used for staging liver fibrosis in patients with CHC.

In conclusion, our study showed that ARFI sonoelastography stands out on account of its very good correlation with liver biopsy (gold standard for evaluating liver fibrosis), good sensitivity and excellent specificity. It has proved to be a noninvasive imaging method, which is far superior to other methods investigated (APRI and FibroMax), for staging liver fibrosis. Further investigations on a larger number of patients are necessary to validate ARFI elastography as a noninvasive method of diagnosing liver fibrosis.

## COMMENTS

### Background

Liver biopsy is an invasive procedure with certain unavoidable risks and complications. Therefore, the development of noninvasive tests to assess hepatic inflammation and fibrosis has been an active area of research. Several noninvasive methods have been proposed to stage liver fibrosis, including biochemical tests and imaging techniques. The biochemical tests consist of sophisticated indices and scores, or a large number of serological markers of liver fibrosis. However, the value of these diagnostic methods remains debatable. Among the imaging methods, transient elastography, based on ultrasound, is a new technique that rapidly and noninvasively measures mean tissue stiffness.

### Research frontiers

Transient elastography is a noninvasive method with performance equivalent to that of serum markers for the diagnosis of significant fibrosis in patients with hepatitis C. Combining transient elastography with serum markers as first-line assessment could avoid liver biopsy in the majority of these patients. There is now a general consensus that liver fibrosis is potentially reversible. Follow-up biopsy is too insensitive for real-time monitoring of progression and regression of fibrosis. When considering anti-fibrotic therapy, it is important to recognize that fibrosis is a dynamic process. Clinical proof and monitoring of anti-fibrotic drug effects requires better noninvasive tests for fibrosis. Incorporation of noninvasive tests into large studies and therapeutic trials should be a priority in the next few years.

### Innovations and breakthroughs

Acoustic radiation force impulse (ARFI) imaging sonoelastography has been proposed as an alternative method to assess liver elasticity. No comparison of ARFI sonoelastography and biochemical tests (APRI and FibroMax) has been reported for the assessment of liver fibrosis.

### Applications

ARFI imaging could be applied to the noninvasive assessment of hepatic fibrosis initially, or after treatment. This study evaluated ARFI imaging in patients with chronic hepatitis C, but probably it could be used for other liver diseases that lead to fibrosis (we need further studies).

### Terminology

Elastography is a noninvasive method by which stiffness of soft tissue is evaluated.

### Peer review

The present study provides readers with a reliable, relatively inexpensive tool to measure liver fibrosis. It is a well designed, conducted and reported study.

### Abstract

**AIM:** To investigate the possible use of the multiple cytokine production modulator, Y-40138, as a novel immunotherapy in the rat nonalcoholic steatohepatitis (NASH) model.

**METHODS:** We allocated 6-wk-old male F344 rats to choline-supplemented, L-amino acid-defined (CSAA) diet (control group), CSAA diet + Y-40138 (control + Y-40138 group), choline-deficient, L-amino acid-defined (CDAA) diet (NASH group), or CDAA diet + Y-40138 (NASH + Y-40138 group). In each group, we measured the plasma alanine aminotransferase (ALT) levels, and the plasma and liver levels of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interferon- $\gamma$  (IFN- $\gamma$ ), and interleukin-10 (IL-10). Tissue specimens of phosphate buffered saline-perfused liver were subjected to hematoxylin and eosin staining, Azan staining, Sirius red staining, and immunohistochemical staining (for Kupffer cells and TNF- $\alpha$ ). We then extracted Kupffer cells from the collagenase-perfused livers using the Percoll gradient centrifugation method, and measured the TNF- $\alpha$  levels in the supernatant (*in vitro* TNF- $\alpha$  production by Kupffer cells) using an enzyme-linked immunosorbent assay kit.

**RESULTS:** In comparison to the NASH group, serum

ALT elevation was mild, production of serum and liver TNF- $\alpha$  and IFN- $\gamma$  was inhibited, and IL-10 production was increased in the NASH + Y-40138 group. Amelioration of liver histology was also noted in the NASH + Y-40138 group. Kupffer cell immunohistochemical staining revealed no differences between groups, whereas TNF- $\alpha$  immunohistochemical staining showed fewer stained cells in the NASH + Y-40138 group than in the NASH group. The TNF- $\alpha$  levels in the *in-vitro* Kupffer cell culture supernatant were lower in the NASH + Y-40138 group than in the NASH group.

**CONCLUSION:** Administration of Y-40138 to NASH model rats reduced hepatic inflammation and suppressed fibrosis. These results indicate that the multiple cytokine production modulator, Y-40138, is promising as a novel treatment for NASH.

### INTRODUCTION

In recent years, nonalcoholic steatohepatitis (NASH) associated with obesity and diabetes mellitus has attracted a great deal of attention. Despite no history of alcohol intake, the histological findings of NASH are similar to

those of alcoholic hepatitis, and it is a progressive condition. A 2-component theory has been proposed for the etiology of NASH, the underlying condition being simple steatosis, with a first component of fatty degeneration as a result of insulin resistance, followed by a second component of aggravating factors such as inflammatory cytokines, including tumour necrosis factor  $\alpha$  (TNF- $\alpha$ ), oxidative stress and endotoxins<sup>[1]</sup>. Kupffer cells, part of the innate immune system, produce various cytokines and are known to play a role in pathologies of the liver<sup>[2,3]</sup>. Abnormally functioning Kupffer cells are suspected to be involved in NASH<sup>[4]</sup>. Although the etiological mechanisms of NASH have not been fully elucidated, similar histopathological findings in NASH and alcoholic hepatitis suggest the existence of a common underlying mechanism. One possible mechanism is that increased endotoxin levels cause activation of Kupffer cells through surface Toll-like receptor-4 (TLR4), leading to increased expression of TNF- $\alpha$  and increased levels of reactive oxygen species (ROS)<sup>[5]</sup>. These induce inflammation and fibrosis, progressing to NASH.

It is known that the choline-deficient L-amino acid-defined (CDAA) fed rat model shows fatty accumulation and fibrosis, and after 16 wk the liver shows cirrhotic changes, and nodules appear as in hepatocellular carcinoma<sup>[6]</sup>. Although this model lacks obesity and insulin resistance, the 2 major characteristics of NASH in humans, the possible relation of Kupffer cells with inflammation, steatosis, and fibrosis may resemble human NASH<sup>[7]</sup>.

In this study, we administered Y-40138, which is a reciprocal cytokine production modulator, inhibiting production of TNF- $\alpha$  and interferon  $\gamma$  (IFN- $\gamma$ ), and promoting production of interleukin-10 (IL-10)<sup>[8,9]</sup>, to a CDAA-fed rat NASH model, to investigate its possible use as a novel immunotherapy for NASH.

## MATERIALS AND METHODS

### Animals and induction of NASH model

Male F344 rats (6-wk-old, weighing 180-200 g) were purchased from Japan SLC Inc. (Hamamatsu, Japan). The animals were housed in stainless steel mesh cages under controlled temperature ( $23 \pm 3^\circ\text{C}$ ) and relative humidity ( $50\% \pm 20\%$ ) conditions with 10 to 15 air changes per hour, and light illumination for 12 h a day. They were allowed access to tap water *ad libitum* throughout the duration of the study. CDAA and choline-supplemented L-amino acid-defined (CSAA) feeds were purchased from CLEA Japan Inc. (Tokyo, Japan). The details of both diets are described elsewhere<sup>[10]</sup>.

The study groups were fed a CDAA diet for 8 wk to produce NASH. After 8 wk, the control group rats (CSAA diet,  $n = 5$ ), control + Y-40138 group rats (CSAA + Y-40138 diet,  $n = 5$ ), NASH group rats (CDAA diet,  $n = 5$ ), and NASH + Y-40138 group rats (CDAA diet + Y-40138,  $n = 5$ ) were killed and bled from the portal vein. Plasma was obtained by centrifugation at 3000 g for 15 min, and stored at  $-20^\circ\text{C}$ . Liver tissues were excised after perfusion with phosphate buffered saline

*via* the portal vein. All procedures were approved by our Institutional Animal Care Committee, and conducted in accordance with the Nara Medical University Guidelines for the Care and Use of Laboratory Animals.

### Compounds

Y-40138 was obtained from Tanabe Mitsubishi Pharma Co. (Osaka, Japan), and dissolved in 0.5% hydroxypropyl methylcellulose solution. Y-40138 was orally administered to rats (10 mg/kg per day) for 8 wk.

### Plasma alanine aminotransferase (ALT)

The plasma ALT levels were measured in samples from rats of each group. The blood samples were centrifuged, and the plasma was collected and stored at  $-30^\circ\text{C}$  until used for ALT determination. The plasma ALT levels were measured using a 7170 Clinical Analyzer (Hitachi High-Technologies, Tokyo, Japan).

### Plasma TNF- $\alpha$ , IFN- $\gamma$ and IL-10

TNF- $\alpha$ , IFN- $\gamma$  and IL-10 concentrations were measured in plasma samples (50  $\mu\text{L}$ ) from rats from each group using an enzyme-linked immunosorbent assay (ELISA) kit (BioSource International, Camarillo, CA, USA).

### Liver TNF- $\alpha$ , IFN- $\gamma$ and IL-10

Liver tissue samples were frozen in liquid nitrogen, powdered, and 30 mg samples were homogenized in 1 mL of lysis buffer. TNF- $\alpha$ , IFN- $\gamma$ , IL-10 levels in the supernatant (50  $\mu\text{L}$ ) were measured using an ELISA kit (BioSource International).

### Histological examination

Liver tissue samples were fixed in 10% formalin, embedded in paraffin, and 5  $\mu\text{m}$  thick sections were cut from the paraffin blocks for staining with hematoxylin and eosin, Azan, and Sirius red. Histological grading and staging were performed using a modified scoring system based on the classifications of Matteoni *et al*<sup>[11]</sup> and Brunt *et al*<sup>[12]</sup>.

### Immunohistochemistry

Kupffer cell dynamics were analyzed by comparing cell counts in each group using immunohistochemical staining with anti-rat macrophage/dendritic cell monoclonal antibody (RM-4: Trans Genic Inc., Kobe, Japan), Vectastain ABC Elite Kit (Vector Laboratories, Burlingame, CA, USA), and DAB peroxidase substrate solution (Vector Laboratories), with counterstaining by Hematoxylin Mayer. The stained areas were analyzed and compared using NIH image software (Version 1.61, U. S. National Institute of Health, Bethesda, MD, USA).

TNF- $\alpha$  immunohistochemical staining was performed on the paraffin sections using an anti-rat TNF- $\alpha$ /TNFSF1A antibody (R&D Systems, Minneapolis, MN, USA). We then used Vectastain ABC Elite Kit, and DAB peroxidase substrate solution, with counterstaining by Hematoxylin Mayer. The stained areas were analyzed using NIH image software.

### Isolation and culture of Kupffer cells

Kupffer cells were harvested from the liver using isolation buffers according to a previously described procedure<sup>[13,14]</sup>. The livers were perfused *in situ* with Ca<sup>2+</sup>-free minimum essential medium (Sigma, St. Louis, MI, USA), followed by 0.3% pronase (Roche Diagnostics Co., Indianapolis, IN, USA) and 0.05% collagenase type IV (Wako, Osaka, Japan) in Dulbecco's modified Eagle's medium/F-12 (Sigma) at a rate of 10 mL/min through the portal vein. The liver was carefully removed and minced using scissors. The minced livers were further incubated in a shaker water bath with 0.035% pronase and 62.5 U/mL DNase (Sigma) in Dulbecco's modified Eagle's medium/F-12 at 37°C for 20 min. The samples were then filtered through gauze mesh, and the parenchymal cells were removed using low-speed centrifugation. Percoll (GE Healthcare, Little Chalfont, UK) was used for density gradient centrifugation of the cells. Kupffer cells were collected from the layer between 1.04 and 1.06, and cultured in RPMI 1640 supplemented with 10% fetal bovine serum and SAG (50 µg/mL streptomycin, 50 µg/mL ampicillin, 0.3 g/L L-glutamine). The viability of the cultured Kupffer cells was determined using trypan blue exclusion. Kupffer cells were seeded at a density of 5 × 10<sup>5</sup> cells/mL on 12-well plastic plates with RPMI-1640 medium. For the lipopolysaccharide (LPS)-stimulated group, Kupffer cells were then exposed to 1 µg/mL of LPS (Sigma-Aldrich Corp.) and incubated for 4.5 h at 37°C in 50 mL/L CO<sub>2</sub>-humidified air. Cells not treated with LPS were used as a control. TNF-α levels in the supernatant were measured using an ELISA kit.

The purity of the isolated Kupffer cells was over 98%, as examined by the uptake of 1 µm latex beads<sup>[15]</sup>, and the viability was over 97% using the trypan blue dye exclusion test.

### Statistical analysis

All results are expressed as mean ± SD. Analyses were conducted using Statview software (version 5.0, SAS Institute, Cary, NC, USA). The statistical differences between groups were evaluated using the paired *t*-test. A *P*-value < 0.05 was considered statistically significant.

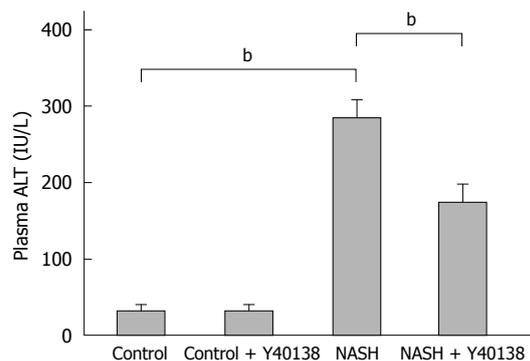

## RESULTS

### Plasma ALT levels

The mean plasma ALT level was 35.8 ± 4.7 IU/L in the control group, 38.3 ± 6.7 IU/L in the control + Y-40138 group, 279.0 ± 32.8 IU/L in the NASH group, and 171.3 ± 28.5 IU/L in the NASH + Y-40138 group. The NASH group showed a statistically significant elevation in the plasma ALT level in comparison to the control group (*P* < 0.01). The plasma ALT levels were significantly decreased in the NASH + Y-40138 group in comparison to the NASH group (*P* < 0.01) (Figure 1).

### Plasma TNF-α, IFN-γ and IL-10 levels

In comparison to the control group, the plasma TNF-α

**Figure 1** The plasma alanine aminotransferase (ALT) levels in the nonalcoholic steatohepatitis (NASH) group were significantly elevated in comparison to the control group. The plasma ALT levels in the NASH + Y-40138 group were significantly decreased in comparison to the NASH group (each group *n* = 5). <sup>b</sup>*P* < 0.01.

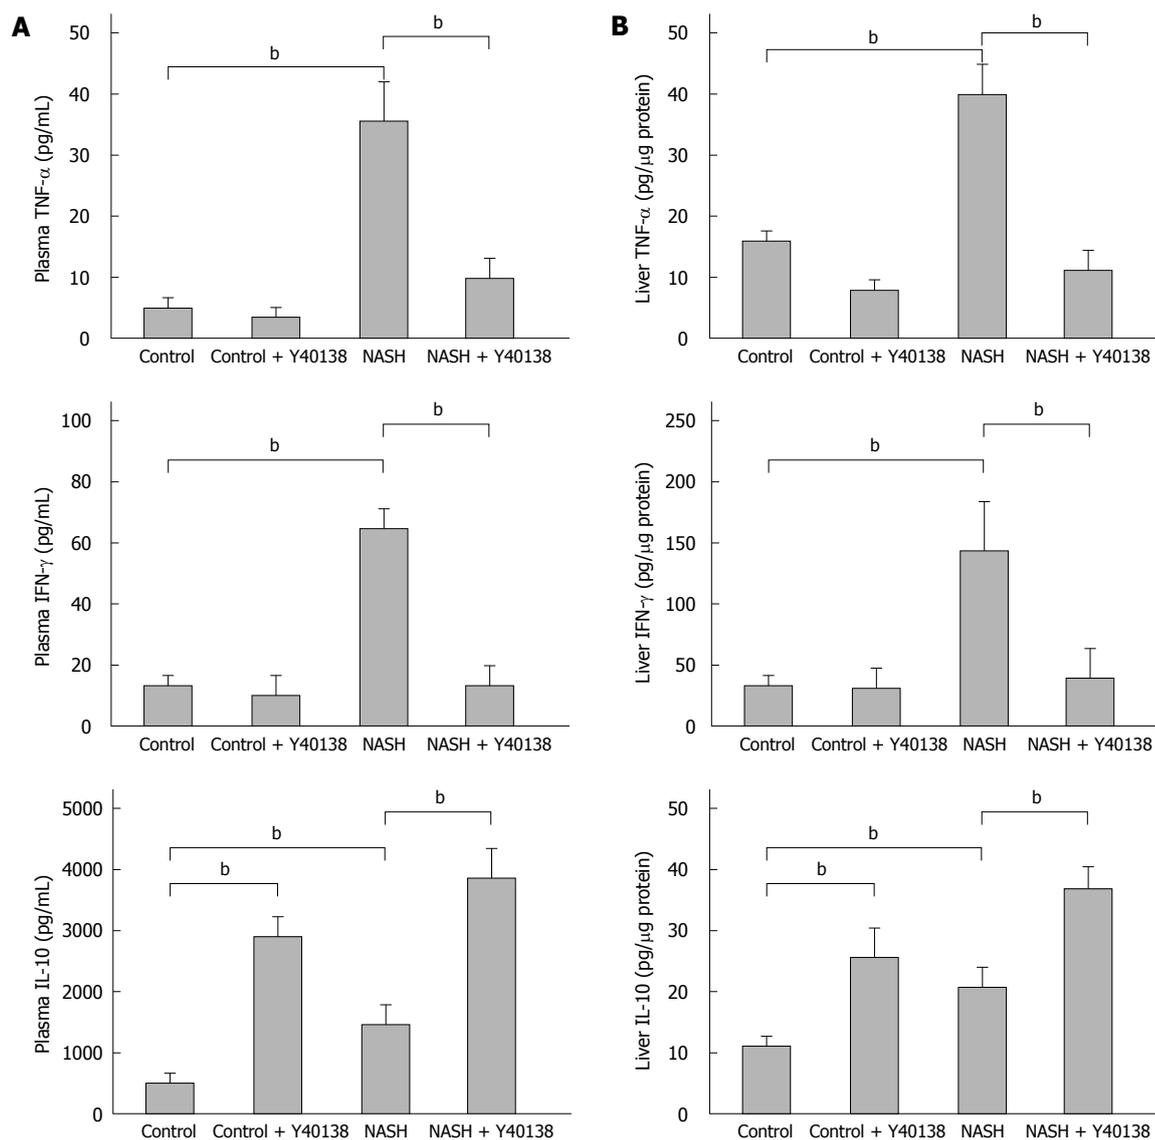

levels were significantly elevated in the NASH group (5.1 ± 1.4 pg/mL *vs* 35.2 ± 7.3 pg/mL, *P* < 0.01). The plasma TNF-α levels were significantly lower in the NASH + Y-40138 group (9.6 ± 3.6 pg/mL) than in the NASH group (*P* < 0.01). The plasma IFN-γ levels in the NASH group (62.4 ± 11.0 pg/mL, *P* < 0.01) were significantly elevated in comparison to the control group (12.3 ± 2.3 pg/mL). The plasma IFN-γ levels in the NASH + Y-40138 group (12.8 ± 6.3 pg/mL) were significantly decreased in comparison to the NASH group (*P* < 0.01). The plasma IL-10 levels in the control + Y-40138 group (2860 ± 350 pg/mL, *P* < 0.01) and the NASH group (1360 ± 380 pg/mL, *P* < 0.01) were significantly elevated in comparison to the control group (520 ± 96 pg/mL). The plasma IL-10 levels in the NASH + Y-40138 group (3820 ± 480 pg/mL) were significantly increased in comparison to the NASH group (*P* < 0.01) (Figure 2A).

### Liver TNF-α, IFN-γ and IL-10 levels

The liver TNF-α level in the NASH group was 39.1 ± 6.2 pg/µg protein, significantly higher than that in the control group (15.8 ± 3.6 pg/µg protein, *P* < 0.01). The liver TNF-α level in the NASH + Y-40138 group (12.4 ± 4.1 pg/µg protein) was significantly lower than that in the NASH group (*P* < 0.01). The liver IFN-γ level in the NASH group was 136 ± 39 pg/µg protein, significantly higher than that in the control group (36.3 ± 5.6 pg/µg protein, *P* < 0.01). The liver IFN-γ level in the NASH + Y-40138 group (45.6 ± 18.5 pg/µg protein) was significantly lower than that in the NASH group (*P* < 0.01). The liver IL-10 level in the control + Y-40138 group (24.7 ± 5.3 pg/µg protein) and the NASH group (19.3 ± 4.1 pg/µg protein) were significantly elevated in comparison to the control group (10.4 ± 2.5 pg/µg protein). The liver IL-10 level in the NASH + Y-40138 group (34.5 ± 4.3 pg/µg protein) was significantly higher than that in the NASH group (*P* < 0.01) (Figure 2B).

### Histological findings

In contrast to the control group, marked inflammation, fat deposition, and fibrosis were seen in the NASH

**Figure 2** Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interferon- $\gamma$  (IFN- $\gamma$ ), and interleukin-10 (IL-10) levels in the plasma and liver (ELISA method) in each group ( $n = 5$ ). A: The plasma TNF- $\alpha$  and IFN- $\gamma$  levels were significantly elevated in the NASH group, and the increase was attenuated in the NASH + Y-40138 group. The IL-10 levels were increased in the NASH group and further increased in the NASH + Y-40138 group rats. <sup>b</sup> $P < 0.01$ ; B: The liver TNF- $\alpha$ , IFN- $\gamma$  and IL-10 levels were significantly elevated in the livers of the NASH group rats. TNF- $\alpha$  and IFN- $\gamma$  levels were attenuated in the NASH + Y-40138 group. The IL-10 levels further increased in NASH + Y-40138 group rats. <sup>b</sup> $P < 0.01$ .

group, corresponding to Matteoni's type 4 and grade 3/ stage 3 of Brunt's NASH classification. The NASH + Y-40138 group findings corresponded to Matteoni's type 3 and Brunt's grade 2/ stage 2, and showed amelioration of inflammation and fibrosis in comparison to the NASH group (Figure 3).

#### Immunohistochemical findings

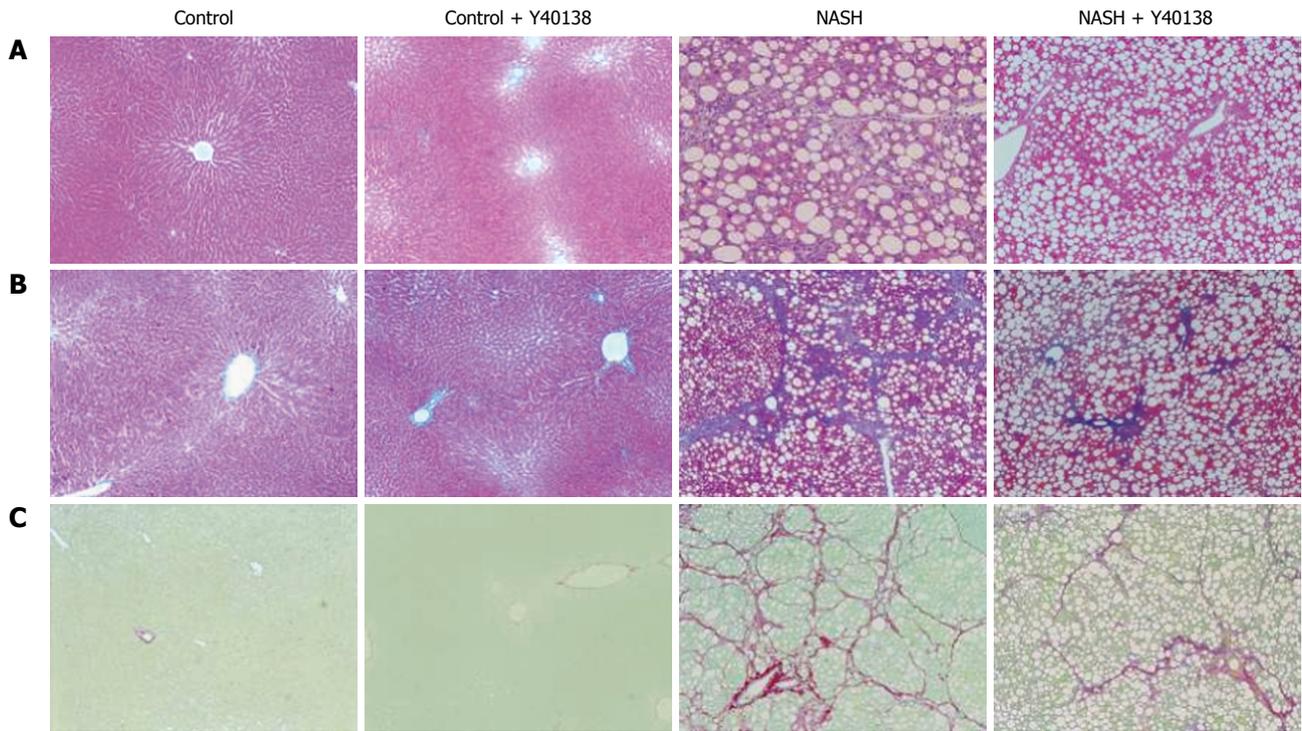

Kupffer cell immunohistochemical staining showed no significant difference in the number of stained cells per field between groups (Figure 4A and B). Moreover, quantitative analysis using NIH Image analysis software showed no significant difference between groups (Figure 4C).

The TNF- $\alpha$  immunoreactivity in the liver tissue samples from the NASH group rats was increased in comparison to the control group rats. Moreover, the

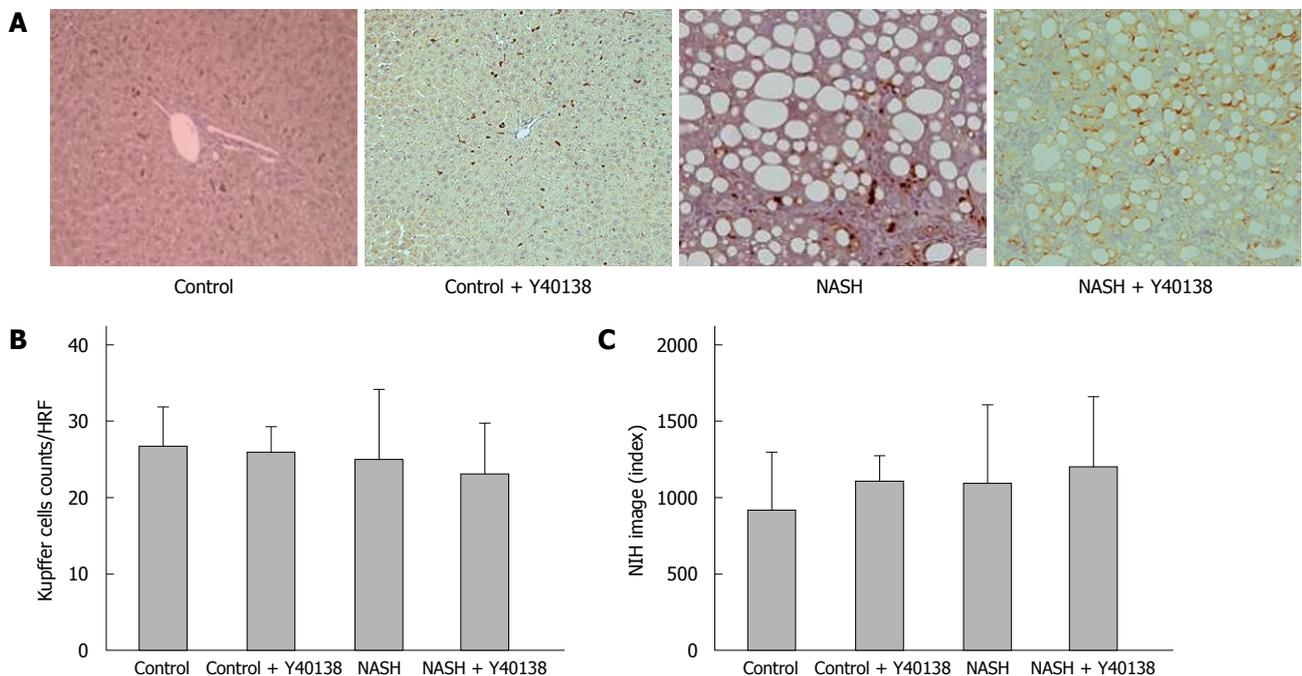

immunopositive areas in those animals were localized either to the periphery of fatty spots or to the non-parenchymal cells (Figure 5A). Semiquantitative analysis of TNF- $\alpha$  staining revealed significantly increased immunoreactivity in the livers of the NASH group rats ( $3250 \pm 390$ ) in comparison to the control group rats ( $260 \pm 80$ ) ( $P < 0.01$ ). Semiquantitative analysis of TNF- $\alpha$  staining revealed significantly decreased immunoreactivity in the livers of the NASH + Y-40138 group rats ( $820 \pm 350$ ) in comparison to the NASH group rats ( $P < 0.01$ ) (Figure 5B).

#### In-vitro TNF- $\alpha$ production by Kupffer cells

The viability of the cultured Kupffer cells was over 98% as determined by trypan blue exclusion. The basal TNF- $\alpha$  production by Kupffer cells isolated from the NASH group ( $26.6 \pm 3.4$  pg/mL) was equal to that

**Figure 3** Histological analysis of liver sections. A: Hematoxylin and eosin stain ( $\times 100$ ); B: Azan stain ( $\times 100$ ); C: Sirius red stain ( $\times 100$ ). Histological findings of liver tissue from the NASH group rats corresponded to Matteoni's type 4 and grade 3/stage 3 of Brunt's NASH classification. Sirius red staining revealed abundant collagen. NASH + Y-40138 group findings corresponded to Matteoni's type 3 and Brunt's grade 2/stage 2, and showed amelioration of inflammation and fibrosis in comparison to the NASH group ( $n = 5$ ).

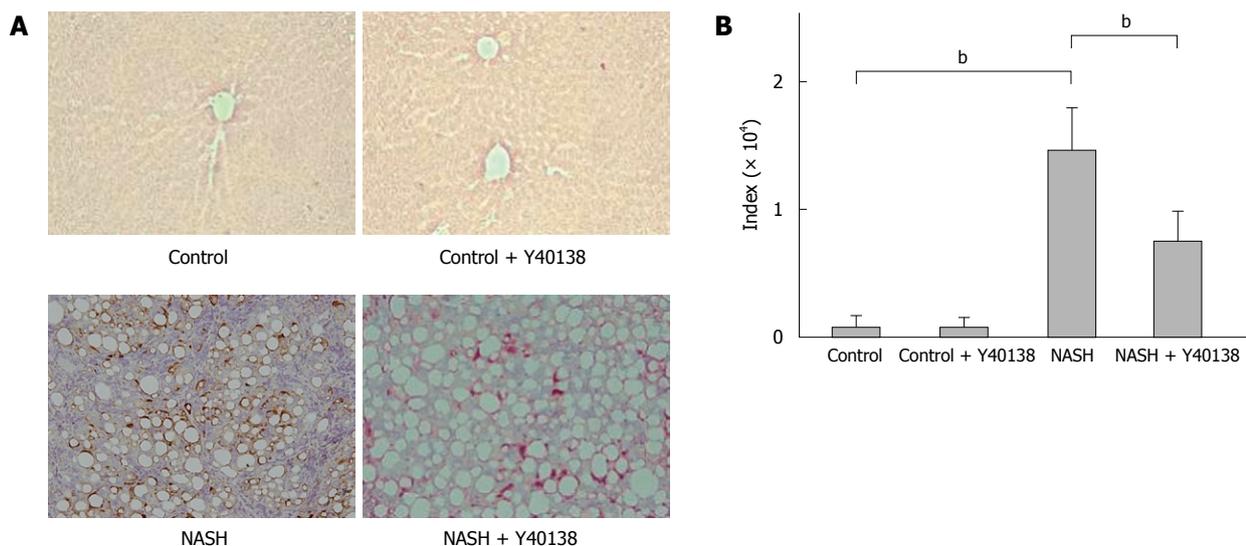

**Figure 4** Kupffer cell immunohistochemical staining, Kupffer cell number and semiquantification in the liver. A: Kupffer cell immunohistochemical staining ( $\times 200$ ). Brown-stained cells are positive; B: No significant differences were seen between groups in the stained cell counts per field; C: Quantitative analysis revealed no significant differences between groups ( $n = 5$ ). HRF: High rise filed.

from the control group ( $23.4 \pm 4.8$  pg/mL). After LPS stimulation, TNF- $\alpha$  production in the control group ( $48.9 \pm 7.5$  pg/mL) was significantly higher than the basal control level, and that in the NASH group ( $73.8 \pm 8.4$  pg/mL) was significantly higher than that in the control group ( $P < 0.01$ ). TNF- $\alpha$  production in the NASH + Y-40138

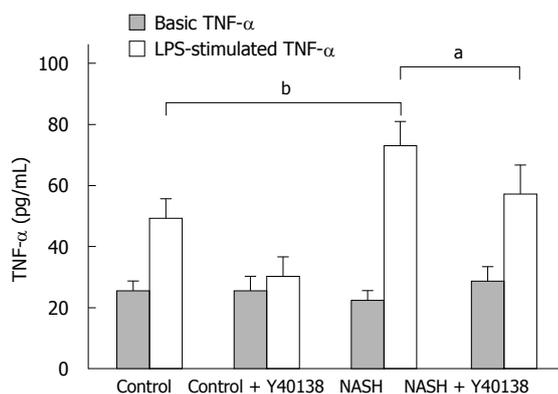

group ( $57.2 \pm 10.3$  pg/mL) was significantly lower than that in the NASH group ( $P < 0.05$ ) (Figure 6).

## DISCUSSION

Kupffer cells located in the hepatic sinusoids are important

**Figure 5** TNF- $\alpha$  immunohistochemical staining and semiquantification. A: TNF- $\alpha$  immunohistochemical staining ( $\times 200$ ). Brown-stained cells are positive; B: TNF- $\alpha$  immunoreactivities in the tissue samples from the NASH group were increased in comparison to the control group. The TNF- $\alpha$  immunoreactivities in the NASH + Y40138 group were decreased in comparison to the NASH group ( $n = 5$ ). <sup>b</sup> $P < 0.01$ .

**Figure 6** *In-vitro* TNF- $\alpha$  production by Kupffer cells. The basal TNF- $\alpha$  production by Kupffer cells isolated from the NASH group ( $26.6 \pm 3.4$  pg/mL) was equal to that in the control group ( $23.4 \pm 4.8$  pg/mL). After lipopolysaccharide (LPS) stimulation, TNF- $\alpha$  production in the control group ( $48.9 \pm 7.5$  pg/mL) was significantly higher than the basal control level, and was significantly higher in the NASH group ( $73.8 \pm 8.4$  pg/mL) than in the control group ( $n = 5$ ). <sup>b</sup> $P < 0.01$ . TNF- $\alpha$  production in the NASH + Y40138 group ( $57.2 \pm 10.3$  pg/mL) was significantly decreased in comparison to the NASH group ( $n = 5$ ). <sup>a</sup> $P < 0.05$ .

hepatic cells that possess phagocytic activity, antigen presenting activity, and produce inflammatory cytokines, making them responsible for the hepatic innate immunity. Inflammatory cytokines, in particular TNF- $\alpha$ , are reportedly involved in the etiology and progression of alcoholic hepatitis<sup>[16]</sup>. The histopathological findings in NASH are similar to those detected in alcoholic hepatitis, suggesting the existence of a common underlying mechanism. A possible mechanism is that increased endotoxin levels cause activation of Kupffer cells through TLR4, leading to increased expression of TNF- $\alpha$  and increased levels of ROS. These induce inflammation and fibrosis, progressing to NASH. The elevation in the hepatic tissue and plasma levels of TNF- $\alpha$  noticed in NASH<sup>[2]</sup> has been attributed to a combination of secretion by fat cells associated with obesity, and secretion by Kupffer cells activated by endotoxins<sup>[17]</sup>.

Once the trigger of TLR4 signal transmission has been initiated, Kupffer cells produce inflammatory cytokines including TNF- $\alpha$ , IL-1 $\beta$ , and IL-6, as well as the anti-inflammatory cytokine IL-10<sup>[18]</sup>. Kupffer cells also induce the inflammatory response through production of transforming growth factor-1, matrix metalloproteinase, platelet-derived growth factor, and ROS<sup>[19]</sup>. NASH is characterized by fatty deposition in the hepatocytes, inflammatory cell infiltration, with consequent liver fibrosis<sup>[20]</sup>.

Methionine/choline deficient (MCD) and CDAA diets are widely used to produce NASH animal models<sup>[4]</sup>. Although these animals models lack obesity and insulin resistance, 2 of the major characteristics of NASH in humans, the possible relation of Kupffer cells with inflammation, steatosis, and fibrosis may resemble the human NASH<sup>[7]</sup>. We also demonstrated decreased Kupffer cell phagocytic activity in this model<sup>[4]</sup>. Increased sensitivity to LPS, the TLR4 ligand, occurs in MCD and CDAA-induced NASH, triggering the production of inflammatory cytokines<sup>[3]</sup>.

TNF- $\alpha$  is a cytokine widely involved in biodefence and immune mechanisms based on inflammation, and continued overproduction is harmful to the organisms, with potentially serious toxicity, resulting in various morbidities<sup>[21]</sup>. Anti-cytokine antibodies such as infliximab are now widely used clinically as pharmacotherapy for inflammatory diseases<sup>[19]</sup>.

In contrast, IL-10 is produced by macrophages and T-cells and has anti-inflammatory properties, inhibiting the production of inflammatory cytokines such as TNF- $\alpha$ , IL-1 $\beta$ , IL-6, and IL-8<sup>[22]</sup>. Therefore, IL-10 has shown efficacy in models of sepsis and rheumatoid arthritis<sup>[23]</sup> and clinically useful therapeutic effects have been reported for IL-10 in the treatment of steroid-resistant Crohn's disease<sup>[24]</sup>.

The chemical name of the new synthetic compound Y-40138 is N-[1-(4-[4-(pyrimidin-2-yl) piperazin-1-yl]

methylphenyl) cyclopropyl] acetamide/hydrochloride. Its molecular formula is  $C_{20}H_{25}N_5O/HCl$ , its molecular weight is 387.91 (free base: 351.45). Although the site of action of Y-40138 has not yet been elucidated, it is known to have reciprocal actions in inhibiting production of TNF- $\alpha$  and IFN- $\gamma$ , and increasing production of IL-10, as well as inhibiting production of chemokines and inflammatory cell chemotaxis, mechanisms not seen in any other agents<sup>[8,9]</sup>. Previous studies on Y-40138 have demonstrated improved survival rates in a D-galactosamine/LPS-induced mouse fulminant hepatic failure model<sup>[25,26]</sup> and a LPS-stimulated mouse sepsis model<sup>[27]</sup>, and reduced ALT levels in a concanavalin A-induced mouse hepatitis model<sup>[28]</sup>.

In this study using the rat NASH model, we detected increased plasma levels of ALT and TNF- $\alpha$ , and confirmed increased TNF- $\alpha$  levels in the liver using ELISA and immunohistochemical staining. These results indicate that TNF- $\alpha$  is involved in this NASH model, as in alcoholic hepatitis. Administration of Y-40138 to these same model rats reduced the plasma levels of ALT and TNF- $\alpha$ , and also decreased the TNF- $\alpha$  levels in the liver. We detected increased levels of IL-10 in the peripheral blood and liver. The TNF- $\alpha$  production by the isolated Kupffer cells was similar in the control and NASH rats. Kupffer cells from the control rats were sensitive to LPS stimulation. Furthermore, those from NASH were more sensitive to LPS stimulation, suggesting that continuous inflammation leads to up-regulation of the LPS-induced TNF- $\alpha$  production by the activated Kupffer cells. Administration of Y-40138 to the same model rats decreased LPS-induced TNF- $\alpha$  production *in vitro*. We presume that IL-10 restrains the production of TNF- $\alpha$  and IFN- $\gamma$  *via* inhibition of the activation of Kupffer cells through STAT3 (signal transducer and activator of transcription 3).

In conclusion, the multiple cytokine production modulator Y-40138 ameliorated hepatic inflammation and inhibited fibrotic changes in the liver. These results indicate that Y-40138 is promising as a novel treatment for NASH. Y-40138 may have a role in suppressing the progress of hepatitis and prolonging the lives of patients with liver damage such as NASH in which cytokines and/or chemokines are involved.

## ACKNOWLEDGMENTS

We gratefully acknowledge Tanabe Mitsubishi Pharma Co. for generously providing us with Y-40138 for our study.

## COMMENTS

### Background

Kupffer cells, part of the innate immune system, produce various cytokines and are known to play a role in pathologies of the liver. Abnormally functioning Kupffer cells are thought to be involved in nonalcoholic steatohepatitis (NASH). Although the etiological mechanisms of NASH have not been fully elucidated yet, observing similar histopathological findings in NASH and alcoholic hepatitis suggests the existence of a common underlying mechanism. In this study, the authors administered the multiple cytokine production modulator, Y-40138, to NASH model rats, to investigate its possible use as a novel immunotherapy for NASH.

## Research frontiers

Administration of Y-40138 to NASH model rats reduced hepatic inflammation and suppressed fibrosis. These results indicate that the multiple cytokine production modulator, Y-40138, is promising as a novel treatment for NASH. Therefore, Y-40138 may contribute to suppressing the progress of hepatitis and prolonging the life of patients with liver damage such as NASH.

## Applications

The present study is an experimental research using the rat NASH model, which was made by feeding a choline-deficient L-amino-acid-defined diet to rats, to examine their innate immunity. The authors believe that Y-40138 is a useful immunotherapy for NASH.

## Terminology

The chemical name of the new synthetic compound Y-40138 is N-[1-(4-[4-(pyrimidin-2-yl) piperazin-1-yl] methylphenyl) cyclopropyl] acetamide/hydrochloride. Although the mechanism of action of Y-40138 has not been fully elucidated yet, it is known to have reciprocal actions in inhibiting the production of tumour necrosis factor- $\alpha$  and interferon- $\gamma$ , and increasing the production of IL-10, as well as inhibiting the production of chemokines and inflammatory cell chemotaxis, and no other agents are known to have such mechanisms.

## Peer review

This is an interesting study on the use of a cytokine modulator in the treatment of an experimental NASH model. The paper is well written and the research is well designed and executed.

### Abstract

**AIM:** To investigate the effects of macrophage migration inhibitory factor (MIF) on proliferation of human gastric cancer MGC-803 cells and expression of cyclin D1 and p27<sup>Kip1</sup> in them, and further determine whether the effects are related to the PI3K/Akt signal transduction pathway.

**METHODS:** Gastric cancer MGC-803 cells were cultured and then treated with 50 µg/L recombinant human MIF (rhMIF) with and without a PI3K inhibitor, LY294002 (25 µmol/L). MTT assay was used to detect the proliferation of MGC-803 cells. Cell cycle was detected by flow cytometry. Expression of cyclin D1 and p27<sup>Kip1</sup> mRNA was by reverse transcription-polymerase chain reaction. Protein expression of phosphorylated Akt (p-Akt), Akt, cyclin D1 and p27<sup>Kip1</sup> was examined by immunocytochemistry and Western blotting.

**RESULTS:** rhMIF significantly stimulated the proliferation of MGC-803 cells and cell cycle progression from G1 phase to S phase in a concentration- and time-dependent manner. After the MGC-803 cells were treated with rhMIF for 24 h, the expression of cyclin D1 was significantly up-regulated compared with the cells not treated with rhMIF at both mRNA and protein levels

( $0.97 \pm 0.02$  vs  $0.74 \pm 0.01$ ,  $P = 0.002$ ;  $0.98 \pm 0.05$  vs  $0.69 \pm 0.04$ ,  $P = 0.003$ ). The p27<sup>Kip1</sup> was down-regulated but only statistically significant at the protein level. rhMIF significantly increased the expression of p-Akt, which reached the peak at 30 min, but did not affect the expression of Akt. However, LY294002 inhibited all the effects of rhMIF.

**CONCLUSION:** Macrophage MIF increases the proliferation of gastric cancer cells, induces the expression of cyclin D1 at the transcriptional level and inhibits the expression of p27<sup>Kip1</sup> at the post-transcriptional level *via* the PI3K/Akt pathway.

### INTRODUCTION

Gastric cancer is the most common gastroenterological malignancy worldwide, with its incidence rate being the fourth among all cancers<sup>[1,2]</sup>. There are approximately 934 000 new cases, and 700 000 patients die of gastric cancer each year. Gastric cancer is the second leading cause of cancer-related death worldwide<sup>[3-5]</sup>, and remains a disease of poor prognosis. The 5-year survival rate of gastric cancer patients is generally below 20%. The current major therapies for gastric cancer include surgery, chemotherapy combined with or without radiotherapy, but their efficacy is not satisfactory. It is, therefore,

necessary to explore and investigate the tumorigenesis of gastric cancer and its novel therapy targets<sup>[6]</sup>.

Macrophage migration inhibitory factor (MIF) is a multi-functional cytokine, which is associated with inflammation and tumorigenesis<sup>[7,8]</sup>. Recent studies have shown that MIF is related to the initiation and progression of gastric cancer, but its underlying mechanism is not very clear<sup>[9-11]</sup>.

It has been reported that the effect of MIF on cell proliferation is relevant to cell cycle factors<sup>[12]</sup>. Cyclin D1 and p27<sup>Kip1</sup> belong to the family of cyclin proteins and cyclin-dependent kinase inhibitors (CDKI), which regulates cell cycle progression from the G1 phase to the S phase<sup>[13,14]</sup>. Over-expression of cyclin D1 and aberrant expression of p27<sup>Kip1</sup> can lead to the loss of control of cell proliferation and differentiation, thus promoting tumorigenesis<sup>[15]</sup>.

The phosphoinositol-3-kinases (PI3K)/Akt pathway has been considered an important signaling pathway that is involved in the regulation of cell proliferation and differentiation<sup>[16]</sup>. It has been reported that NF- $\kappa$ B activates the transcription target, *via* PI3K/Akt signaling, to promote gastric tumorigenesis<sup>[17]</sup>. In a recent study with a gastric cancer cell line, AGS, Kim *et al*<sup>[18]</sup> reported that inhibition of the PI3K/Akt/PKB pathway could enhance the mitochondrial death pathway. Another recent study indicates that anti-cancer effects of celecoxib on gastric cancer cells are partly mediated by down-regulation of Akt signaling<sup>[19]</sup>.

The aims of the present study were to investigate the effects of recombinant human MIF (rhMIF) on cell proliferation of human gastric cancer MGC-803 cells and cell cycle. Activity of Akt and expression of cyclin D1 and p27<sup>Kip1</sup> were examined. Whether the PI3K/Akt pathway is involved in the effects of rhMIF was further investigated, using a PI3K/Akt inhibitor, LY294002.

## MATERIALS AND METHODS

### Chemicals

rhMIF and PI3K specific inhibitor, LY294002, were purchased from PROSPEC (Rehovot, Israel) and Cell Signaling (Danvers, MA, USA), respectively. Primers for GAPDH, cyclin D1 and p27 were produced by Shanghai Sangon Biological Engineering Technology & Service Company, Ltd. (Shanghai, China). Mouse anti-human  $\beta$ -actin primary antibody was bought from Beyotime Institute of Biotechnology (Shanghai, China). Rabbit anti-human cyclin D1 primary antibody was purchased from Epitomics (Burlingame, CA, USA), and rabbit anti-human p27, rabbit anti-human phosphorylated Akt (p-Akt) and Akt primary antibodies were bought from Santa Cruz Biotechnology (CA, USA). Goat anti-mouse and goat anti-rabbit secondary antibodies were purchased from Beyotime Institute of Biotechnology (Shanghai, China) and BioDev-Tech (BioDev, Beijing, China), respectively. Epics-XL II flow cytometer was purchased from Beckman Coulter (Beckman, Fullerton, CA, USA).

### Cell culture

Gastric cancer cell line, MGC-803, was provided by the

Institute of Cancer Research, Nanhua University (China), and cultured in RPMI 1640 medium supplemented with 10% fetal bovine serum (FBS), 100  $\mu$ g/mL streptomycin and 100  $\mu$ /mL penicillin, and maintained at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub>. The cultured cells were then used in different experiments as described below.

### Cell proliferation assay (MTT assay)

Approximately  $2 \times 10^3$  cells/well were grown in 96-well microtiter plates and incubated overnight in 100  $\mu$ L of the culture medium. Cells were starved without FBS for 24 h at 70%-80% confluence and then treated with rhMIF at different concentrations (25, 50 and 100  $\mu$ g/L) with or without 1-h pretreatment with LY294002 (25  $\mu$ mol/L), for 12, 24 and 48 h, respectively. Cells without any treatment were used as controls. Twenty microliters of 5 mg/mL MTT (Sigma, St Louis, MO) labeling reagent was added to the designated well, and cells were incubated at 37°C for 4 h. The supernatant was removed, and then 150  $\mu$ L dimethyl sulfoxide (DMSO) was added to the designated well. After the plate was incubated at 37°C for 15 min, the absorbency was measured with a micro ELISA reader (Bio-Tek, Winooski, VT, USA) at a wavelength of 570 nm.

### Flow cytometry

Cells were harvested after treated with rhMIF, with or without 1-h pretreatment with LY294002 for 24 h as described earlier, and fixed with 75% cold alcohol at 4°C overnight. After washed with phosphate buffered saline (PBS), propidium iodide (PI) was added and cells were incubated at 4°C for 30 min. Cell cycle distribution was detected with an Epics-XL II flow cytometer (Beckman Coulter, Inc., Fullerton, CA, USA).

### Reverse transcriptase polymerase chain reaction (RT-PCR)

Cells were harvested after treated with rhMIF, with or without 1-h pretreatment with LY294002 for 24 h as described earlier. Total RNA was extracted from cells with a total RNA kit (BioDev, Beijing, China). One microgram of RNA was reversely transcribed to cDNA with thermoscript RT system reagent (MBI Fermentas, Glen Burnie, USA) according to its manufacturer's instructions. The primer sequences are as follows: cyclin D1, forward: 5'-CGTCCATGCGGAAGATC-3', reverse: 5'-CAGAGGGCAACGAAGGT-3' (406 bp); p27<sup>Kip1</sup>, forward: 5'-CGCAAGTGGAATTTTCGATT-3', reverse: 5'-ATGCGTGTCCCTCAGAGTTAGC-3' (215 bp); GAPDH, forward: 5'-CGGAGTCAACGGATTGTG-GTCGTAT-3', reverse: 5'-AGCCTTCTCCATGGTG-GTGAAGAC-3' (306 bp). PCR was performed according to the following conditions: denaturation at 94°C for 3 min, 40 cycles of denaturation at 94°C for 30 s, annealing at 57°C for 30 s and extension at 72°C for 2 min, followed by a final extension at 72°C for 10 min. Five microlitres of PCR product was used for agarose gel electrophoresis and analyzed using Alphamager 2200 (Imaging System, CA, USA).

### Western blotting

Whole cell lysates were prepared from cells with RIPA

lysis buffer containing protease inhibitors (Beyotime, Shanghai, China). Protein concentration was measured with a BCA protein assay kit (Beyotime, Shanghai, China). An aliquot of 40  $\mu\text{g}$  protein of each sample was subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis. Then, the protein was transferred to a PVDF membrane (Millipore, Billerica, MA). Non-specific binding was blocked with 5% non-fat milk for 2 h at 37°C. The membrane was immunodetected with anti-cyclin D1 (1:500), anti-p27<sup>kip1</sup> (1:500), anti-p-Akt (1:500), anti-Akt (1:500), anti- $\beta$ -actin (1:1000) primary antibodies overnight at 4°C, and then with corresponding HRP-conjugated secondary antibodies (1:2000). Antigen-antibody complexes were visualized with a luminol reagent (Santa Cruz, CA, USA), and the results were analyzed with Alphamager 2200.  $\beta$ -actin was detected as the loading control.

### Immunocytochemistry

Cells were grown on slides at a concentration of  $1.0 \times 10^6$  cells/mL, treated with rhMIF (50  $\mu\text{g}/\text{L}$ ) with or without 1-h pretreatment with LY294002 (25  $\mu\text{mol}/\text{L}$ ) for 24 h at 70%-80% confluence. Cells without any treatment were used as controls. The treated and control cells were fixed with 75% cold alcohol at 4°C overnight and then subjected to immunostaining using the streptavidin-peroxidase technique. In brief, endogenous peroxidase was blocked with 3%  $\text{H}_2\text{O}_2$  in PBS, and then with a normal goat serum blocking solution for 20 min at room temperature. The slides were incubated with anti-p-Akt, anti-cyclin D1 and anti-p27<sup>kip1</sup> primary antibodies (1:200 diluted with 0.01 mol/L PBS), respectively, for 60 min at room temperature. Slides that were incubated with PBS instead of primary antibodies were used as negative controls. After washed with PBS, the slides were incubated with corresponding HRP-conjugated secondary antibodies for 30 min. The color of immunostaining was developed with a diaminobenzidine solution and counterstained with hematoxylin.

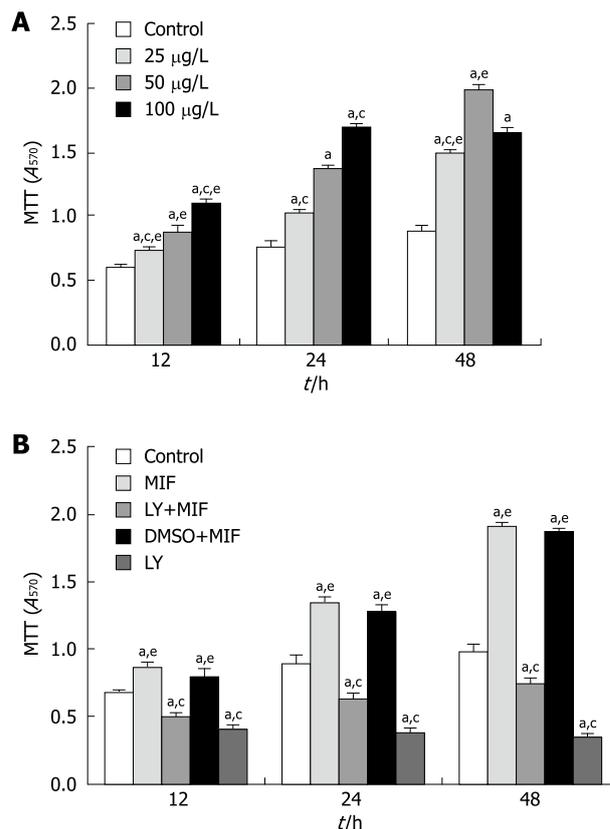

### Statistical analysis

Data were analyzed using SPSS 16.0 software. The results were expressed as mean  $\pm$  SD. Student *t*-test was used to determine the difference in numeric parameters between different groups.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Effects of rhMIF and LY294002 on the proliferation of MGC-803 cells

The MTT assay showed that treatment with rhMIF significantly increased the proliferation of MGC-803 cells in a dose- and time-dependent manner compared with the controls ( $P < 0.05$ ). The proliferation of MGC-803 cells reached its peak ( $1.823 \pm 0.04/0.647 \pm 0.02$ , 282%) when they were treated with 50  $\mu\text{g}/\text{L}$  rhMIF for 48 h (Figure 1A), which was significantly inhibited after 1-h pretreatment with 25  $\mu\text{mol}/\text{L}$  LY294002 ( $P < 0.05$ , Figure 1B). DMSO (the menstruum of LY294002, less than 0.1%) had little effect on the proliferation of MGC-803 cells.

**Figure 1** Effects of recombinant human migration inhibitory factor (rhMIF) and LY294002 on the proliferation of MGC-803 cells. A: MGC-803 cells were treated with 25, 50 and 100  $\mu\text{g}/\text{L}$  rhMIF for the indicated periods of time and cell proliferation was examined by MTT assay. <sup>a</sup> $P < 0.05$  vs control group; <sup>c</sup> $P < 0.05$  vs 50  $\mu\text{g}/\text{L}$  MIF group; <sup>e</sup> $P < 0.05$  vs 24 h group; B: With or without 1-h pretreatment with 25  $\mu\text{mol}/\text{L}$  LY294002, MGC-803 cells were exposed to 50  $\mu\text{g}/\text{L}$  rhMIF for the indicated periods of time, with a vehicle control of dimethyl sulfoxide (DMSO) (less than 0.1%) included. <sup>a</sup> $P < 0.05$  vs control group; <sup>c</sup> $P < 0.05$  vs MIF group; <sup>e</sup> $P < 0.05$  vs LY+MIF group. Data were represented as mean  $\pm$  SD of three independent experiments. DMSO (the menstruum of LY294002, less than 0.1%) had little impact on the rhMIF effect.

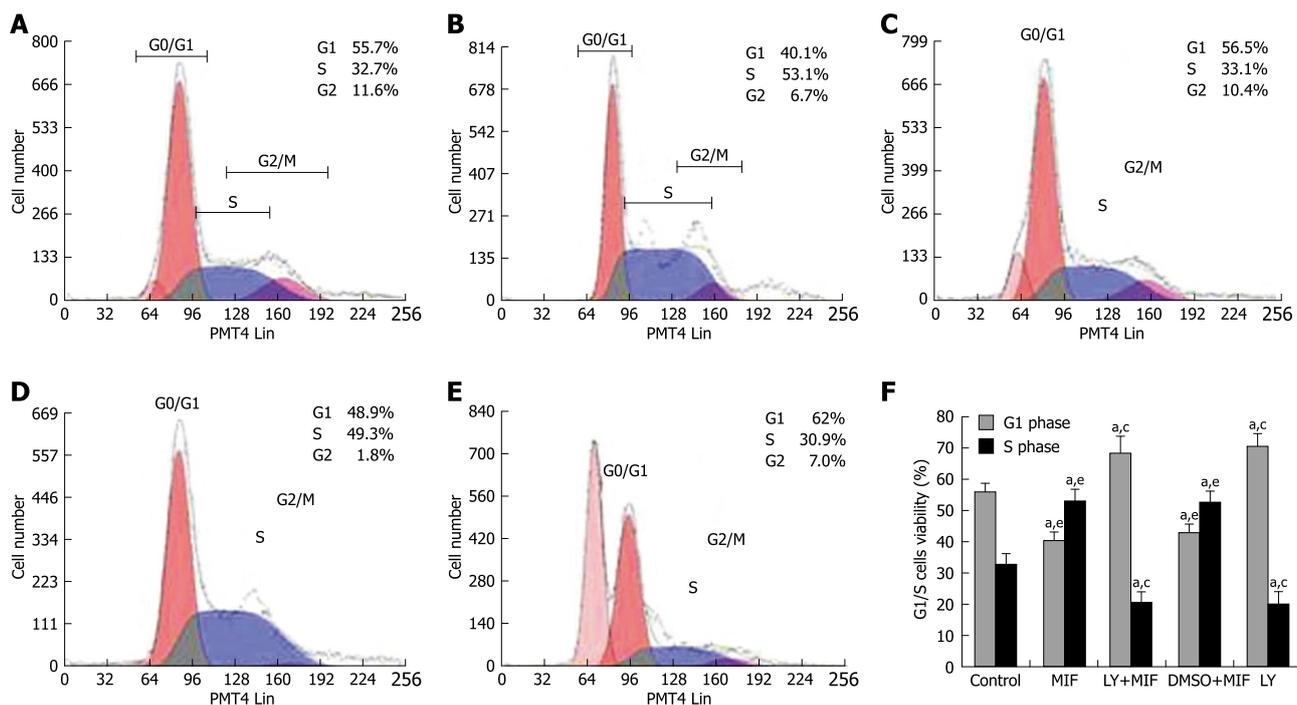

### Effects of rhMIF and LY294002 on the cell cycle of MGC-803 cells

The effect of rhMIF on cell cycle distribution is shown in Figure 2. rhMIF (50  $\mu\text{g}/\text{L}$ ) significantly induced the progression of MGC-803 cells from G1 phase to S phase ( $P < 0.05$ ), thus increasing the accumulation of cells in S phase. However, the cells treated with LY294002 were accumulated in G1 phase, namely G1 arrest, irrespective of rhMIF treatment ( $P < 0.05$ ). DMSO had little impact on the rhMIF effect (Figure 2).

### Effects of rhMIF and LY294002 on the mRNA and protein expression of cyclin D1 and p27<sup>kip1</sup> in MGC-803 cells

After treatment with 50  $\mu\text{g}/\text{L}$  rhMIF for 24 h, the mRNA level of cyclin D1 was increased significantly ( $P < 0.05$ ). However, 1-h pre-treatment with LY294002 reduced the mRNA expression irrespective of subsequent rhMIF treatment ( $P < 0.05$ , Figure 3A). DMSO had little impact on the rhMIF effect. Treatment with rhMIF or LY294002 had no effect on the mRNA level of p27<sup>kip1</sup> (Figure 3A).

Western blotting showed that after treatment with 50  $\mu\text{g}/\text{L}$  rhMIF for 24 h, the expression of cyclin D1

**Figure 2** Effects of rhMIF and LY294002 on cell cycle of MGC-803 cells. With or without 1-h pretreatment with 25  $\mu\text{mol/L}$  LY294002, MGC-803 cells were exposed to 50  $\mu\text{g/L}$  rhMIF for 24 h. A vehicle control of DMSO (less than 0.1%) was included. Cell lysates were prepared for the cell cycle detection. The cell cycle distribution was analyzed using an Eics-XL II flow cytometer. A: Control; B: MIF group; C: LY+MIF group; D: DMSO+MIF group; E: LY group; F: Quantification of G1/S viability(%) analysis of MGC-803 cells. Data were represented as mean  $\pm$  SD of three independent experiments. <sup>a</sup> $P < 0.05$  vs control group; <sup>b</sup> $P < 0.05$  vs MIF group; <sup>c</sup> $P < 0.05$  vs LY+MIF group. DMSO (the menstruum of LY294002, less than 0.1%) had little impact on the rhMIF effect.

protein was significantly up-regulated, but the expression of p27<sup>kip1</sup> protein was down-regulated ( $P < 0.05$ , Figure 3B). However, 1-h pretreatment with LY294002 prior to rhMIF treatment abrogated the effects of rhMIF on the expression of cyclin D1 and p27<sup>kip1</sup> proteins ( $P < 0.05$ ). Again, DMSO had little impact on the rhMIF effect (Figure 3B).

Immunocytochemistry demonstrated that the positive expression of cyclin D1 and p27<sup>kip1</sup>, in yellow or brown, was mostly located in the nuclei of MGC-803 cells, but rarely in the cytoplasm. rhMIF increased the expression of cyclin D1, but decreased the expression of p27<sup>kip1</sup> (Figure 4). However, 1-h pretreatment with LY294002 down-regulated the expression of cyclin D1 (Figure 4A), but up-regulated the expression of p27<sup>kip1</sup> (Figure 4B), which was consistent with the results obtained by Western blotting.

#### Effects of rhMIF on the expression of p-Akt and Akt in MGC-803 cells

Western-blotting showed that after treatment with different concentrations of rhMIF (25, 50, 100  $\mu\text{g/L}$ ) for 30 min, the expression of p-Akt in MGC-803 cells was up-regulated in a dose-dependent manner (Figure 5A,  $P < 0.05$ ). In addition, the cells treated with 50  $\mu\text{g/L}$  rhMIF for different periods of time (5, 15, 30 and 60 min) showed that the expression of activated Akt in MGC-803 cells started to increase at 5 min, reached its peak at 30 min, then decreased but remained at a level higher than that in the untreated control cells ( $P < 0.05$ , Figure 5B). Pretreatment with LY294002 prior to rhMIF treatment, however, inhibited the expression of p-Akt irrespective of

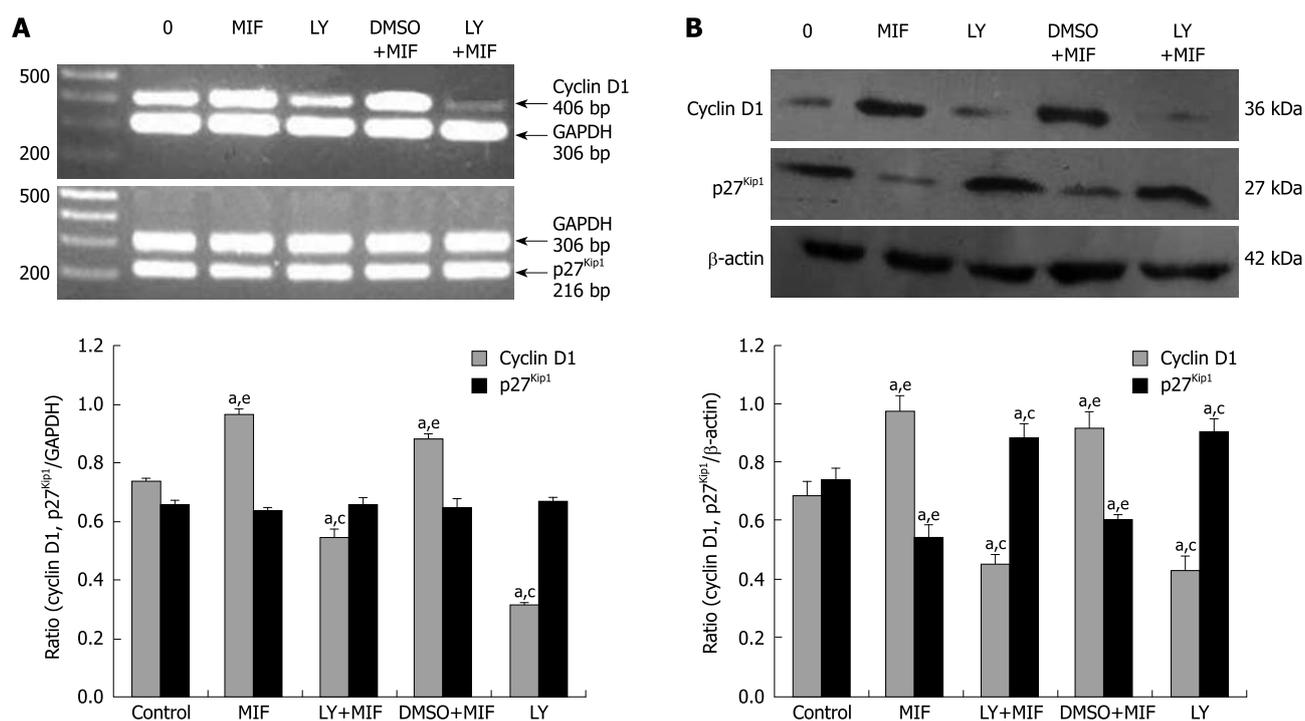

rhMIF treatment (Figure 5C). DMSO had little impact on the rhMIF effect. Both rhMIF and LY294002 had no effect on the expression of Akt (Figure 5A and C).

Immunocytochemistry showed that p-Akt was positively expressed in cytoplasm of the cells. rhMIF increased the expression of p-Akt. However, pre-treatment with LY294002 down-regulated the expression of p-Akt (Figure 5D).

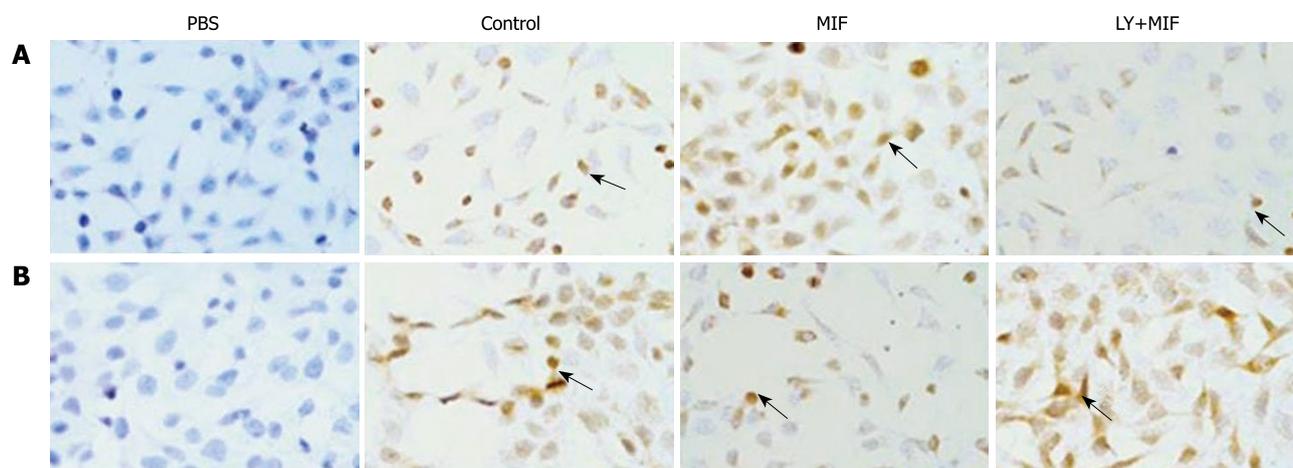

## DISCUSSION

MIF has multiple biological functions and plays an important role in inflammation as well as in carcinogenesis as a cytokine<sup>[20,21]</sup>. Increased expression of MIF has been reported in pre-cancerous, cancerous and metastatic tumors<sup>[10,22]</sup>. It has been shown that MIF-modulated cancer progress is associated with the ERK/MAPK, PI3K/Akt, and Rb-E2F pathways<sup>[22-25]</sup>. However, its detailed mechanism underlying inflammatory and malignant transformation as well as tumorigenesis needs to be further investigated.

In our study, rhMIF increased the MGC-803 cell proliferation in a dose- and time-dependent manner, and induced progression from G1 phase to S phase, leading to S phase arrest. It has been demonstrated that cyclin, cyclin-dependent kinase (CDK) and CDK inhibitor (CDKI) play a critical role in the orderly progression of cell cycle during the transition from G1 phase to S phase<sup>[26,27]</sup>. Since cyclin D1 is an important regulator of cell cycle progression, its increased expression contributes significantly to tumor development and malignant transformation<sup>[13,28]</sup>. p27<sup>kip1</sup>, an inhibitor of CDK, functions as

**Figure 3** Effects of rhMIF and LY294002 on the expression of cyclin D1 and p27<sup>kip1</sup> in MGC-803 cells. With or without 1-h pretreatment with 25  $\mu\text{mol/L}$  LY294002, MGC-803 cells were exposed to 50  $\mu\text{g/L}$  rhMIF for 24 h. A vehicle control of DMSO (less than 0.1%) was included. A: RT-PCR; B: Western blotting. The results were represented as mean  $\pm$  SD of three independent experiments. <sup>a</sup> $P < 0.05$  vs control group; <sup>c</sup> $P < 0.05$  vs MIF group; <sup>e</sup> $P < 0.05$  vs LY+MIF group. DMSO (the menstruum of LY294002, less than 0.1%) had little impact on the rhMIF effect.

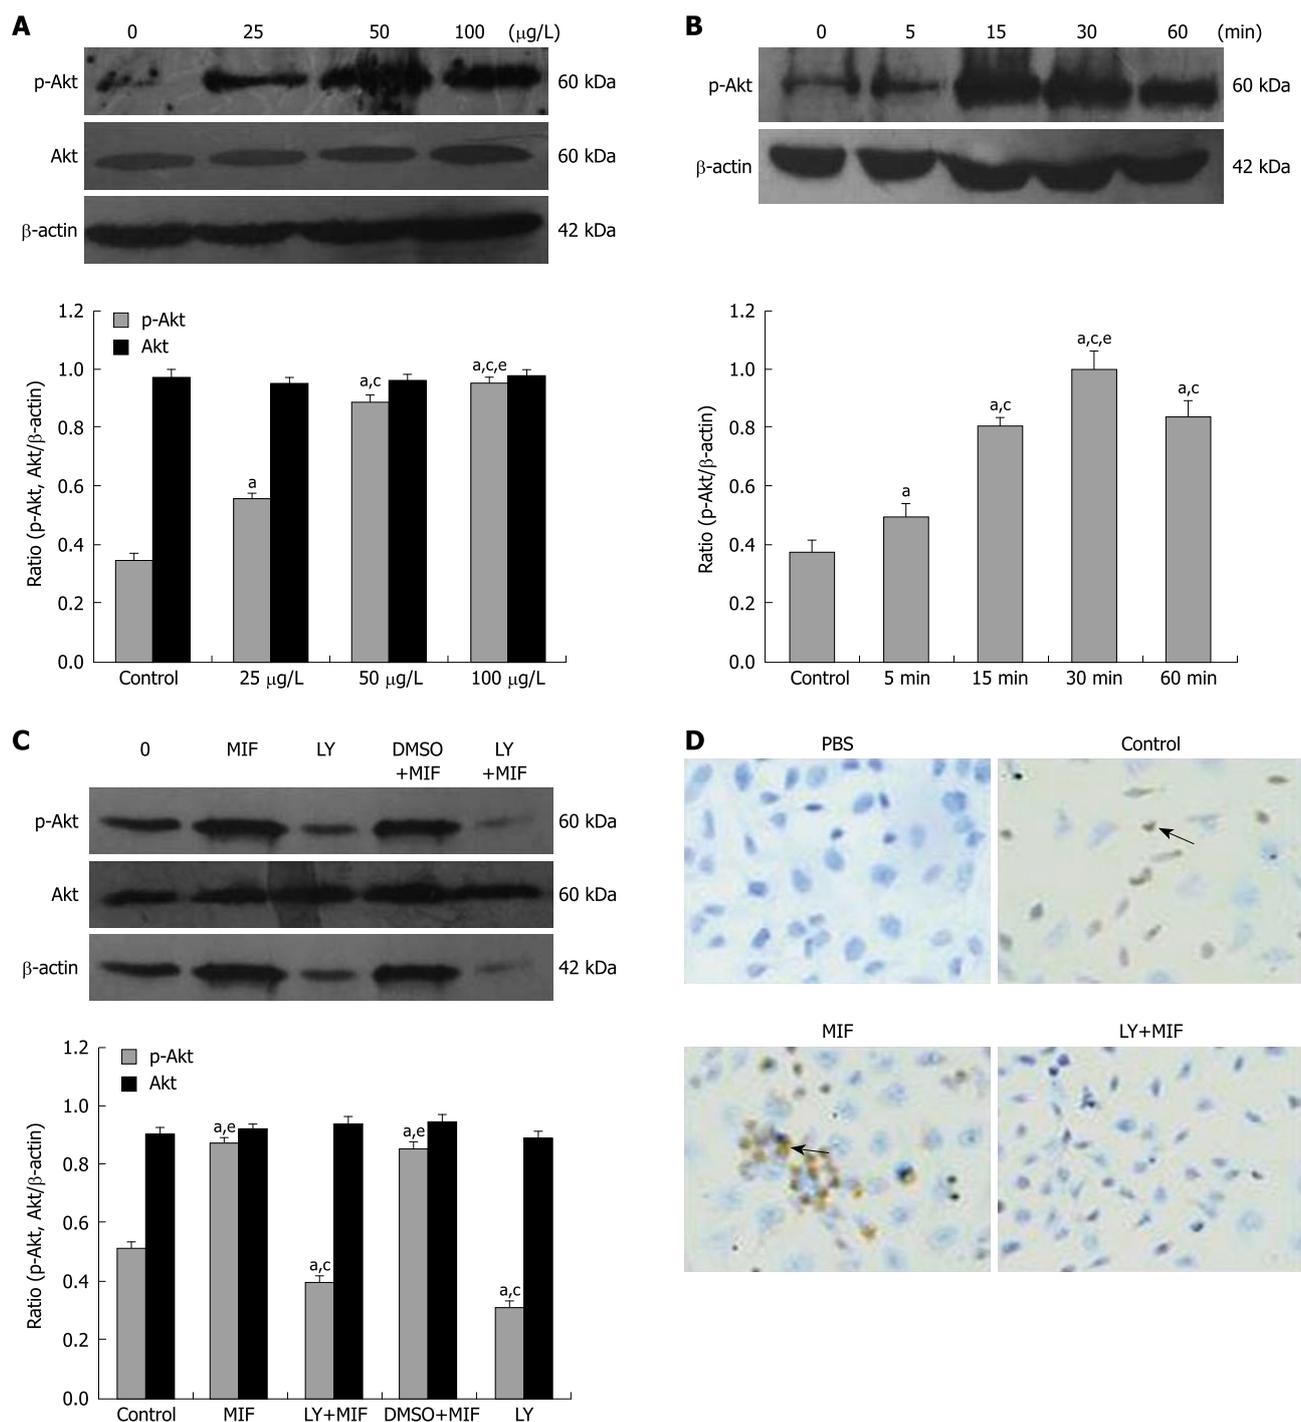

**Figure 4** Effects of rhMIF and LY294002 on the translocation of cyclin D1 (A) and p27<sup>kip1</sup> (B) in MGC-803 cells. With or without 1-h pretreatment with 25  $\mu\text{mol/L}$  LY294002, MGC-803 cells were exposed to 50  $\mu\text{g/L}$  rhMIF for 24 h. The arrow symbols represent immunocytochemical staining for nuclear and cytoplasmic expression of cyclin D1 (Original magnification,  $\times 200$ ) and p27<sup>kip1</sup> (Original magnification,  $\times 200$ ) in MGC-803. PBS: Phosphate buffered saline.

an integral brake of the cell cycle, thus also playing an important role in tumor suppression<sup>[29]</sup>. For example, deregulation of p27<sup>kip1</sup> has a profound effect on tumor progression in colorectal cancer and is suggested to be an accurate and independent prognostic marker<sup>[30]</sup>. Moreover, p27<sup>kip1</sup> may be a central target for growth regulation of the normal endometrium and for the pathogenesis of endometrial carcinoma<sup>[31]</sup>. In our study, rhMIF increased cyclin D1 mRNA expression, but had no effect on p27<sup>kip1</sup> mRNA expression. However, immunocytochemistry showed that rhMIF increased the expression of cyclin D1 protein and decreased the expres-

sion of p27<sup>kip1</sup> protein. These results were identified further by Western blotting. Therefore, our results indicate that rhMIF affects the cell cycle by inducing cyclin D1 and inhibiting p27<sup>kip1</sup>, thus promoting the proliferation of MGC-803 cells. In addition, rhMIF up-regulates the transcriptional cyclin D1, which is in contrast with the posttranscriptional protein reduction of p27<sup>kip1</sup> in cells. This phenomenon may be related to the degradation by its ubiquitin ligase<sup>[32,33]</sup>.

The PI3K/Akt pathway is crucial in tumorigenesis because the p-Akt can regulate the cell proliferation, apoptosis, angiogenesis and cell cycle by activating the

**Figure 5** Effects of rhMIF on the expression of p-Akt and Akt in MGC-803 cells. Cell lysates were isolated for Western blotting to detect the expression of p-Akt and Akt (A, B). A: MGC-803 cells were treated with 25, 50 and 100 µg/L rhMIF for 30 min. <sup>a</sup>*P* < 0.05 vs control group; <sup>c</sup>*P* < 0.05 vs 25 µg/L MIF group; <sup>e</sup>*P* < 0.05 vs 50 µg/L MIF group; B: MGC-803 cells were treated with 50 µg/L rhMIF at different time points (5, 15, 30 and 60 min). <sup>a</sup>*P* < 0.05 vs control group; <sup>c</sup>*P* < 0.05 vs 5 min group; <sup>e</sup>*P* < 0.05 vs 15 min and 60 min groups; C: With or without 1-h pretreatment with 25 µmol/L LY294002, MGC-803 cells were exposed to 50 µg/L rhMIF for 30 min with a vehicle control of DMSO (less than 0.1%) included, and then the expression of p-Akt and Akt was determined by Western blotting. <sup>a</sup>*P* < 0.05 vs control group; <sup>c</sup>*P* < 0.05 vs MIF group; <sup>e</sup>*P* < 0.05 vs LY+MIF group; D: The arrow symbols represent immunocytochemical staining for nuclear and cytoplasmic expression of p-Akt (original magnification, × 200) in MGC-803 cells. The results were represent as mean ± SD of three independent experiments. DMSO (the menstruum of LY294002, less than 0.1%) had little impact on the rhMIF effect.

downstream cell receptors or effectors<sup>[34-36]</sup>. Cinti *et al*<sup>[37]</sup> studied 50 cases of advanced gastric carcinoma using immunohistochemistry, showing a statistically significant direct correlation between p-Akt expression and depth of infiltration of the tumor, between the number of infiltrated lymph nodes and p34/cdc2 expression, and between prevalently nuclear p-Akt and cyclin D1 and cyclin E, but

an inverse correlation between nuclear pAkt and apoptotic index, and between cytoplasmic and nuclear pAkt and patient survival, suggesting that p-Akt may be considered an indicator of tumor progression and a prognostic factor for the survival of gastric cancer patients. Liang *et al*<sup>[38]</sup> reported that cellular prion protein up-regulates cyclin D1 at both mRNA and protein levels, thus promoting

cell proliferation and transition from G1 phase to S phase in gastric cancer GC7901 and AGS cells, at least partially by activating the PI3K/Akt pathway. Moreover, a PI3K specific inhibitor, LY294002, can significantly suppress the effects of cellular prion protein. In the present study, immunocytochemistry showed that rhMIF increased the p-Akt expression, activated p-Akt in a dose- and time-dependent manner, and induced the maximum Akt phosphorylation at 30 min. However, the total expression level of Akt remained unchanged, indicating that rhMIF affects specifically the activated Akt, namely the p-Akt. To further validate the involved Akt pathway in the effect of rhMIF on MGC-803 cells, the cells were pretreated with a PI3K specific inhibitor, LY294002, showing that LY294002 reversed or abolished all the effects induced by rhMIF, including the increased proliferation, cell cycle S arrest, up-regulation of cyclin D1 and p-Akt, down-regulation of p27<sup>Kip1</sup>, suggesting that rhMIF can induce the proliferation and cell cycle progression of MGC-803 cells *via* the PI3K/Akt pathway.

In conclusion, MIF increases the proliferation of gastric cancer cells, induces the expression of cyclin D1 at the transcriptional level and inhibits the expression of p27<sup>Kip1</sup> at the post-transcriptional level *via* the PI3K/Akt pathway. Further investigation is required to reveal whether macrophage MIF is a novel potential therapeutic target for the treatment of gastric cancer.

## COMMENTS

### Background

Gastric cancer is one of the most common gastroenterological malignancies worldwide and remains a disease of poor prognosis. It is necessary to investigate the gastric tumorigenesis and potential new therapies. Macrophage migration inhibitory factor (MIF) is a multi-function cytokine involved in inflammation, auto-immune disease and development of several cancers. Recent studies have shown that over-expression of MIF is associated with tumorigenesis of gastric cancer, but the underlying mechanism is unclear.

### Research frontiers

MIF induces cell proliferation through many signal pathways, but the mechanism underlying the regulation of immunoreaction and tumorigenesis is complicated. The PI3K/Akt signaling pathway plays an important role in the regulation of cell growth, proliferation and differentiation. Recent studies have shown that the proliferation of cancer cells is suppressed by blocking the PI3K/Akt pathway. In this study, we investigated the effects of rhMIF on the proliferation of gastric cells and cell cycle progression, and whether the expression of cyclin D1 and p27<sup>Kip1</sup> and the regulation of PI3K/Akt pathway are involved in the effects of rhMIF.

### Innovations and breakthroughs

The study found that MIF induced the proliferation of MGC-803 cells and promoted the cell cycle progression from G1 phase to S phase in gastric cancer MGC-803 cells, and that rhMIF executed its effects by up-regulating cyclin D1 and down-regulating p27<sup>Kip1</sup> through the PI3K/Akt signal pathway.

### Applications

The study explored the mechanism by which MIF induces the proliferation of gastric cancer MGC-803 cells and promotes cell cycle, indicating that MIF may be the potential target for gastric cancer therapy.

### Terminology

MIF, a T-cell-derived cytokine, was identified and named by Bloom and David in

1966. PI3Ks is involved in the regulation of cell proliferation, differentiation and apoptosis. The signal pathway through PI3K and its down-stream protein PKB or Akt are closely related to the human tumorigenesis.

### Peer review

In this study, the authors investigated whether the PI3K/Akt pathway is involved in the effect of rhMIF on the proliferation of MGC-803 cells, using a PI3K/Akt inhibitor, LY294002. Overall, the study is interesting and significant, and the data are presented in a clear and logical manner.

### Abstract

**AIM:** To investigate the effect of short-chain fatty acids (SCFAs) on production of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), cytokines and chemokines in human monocytes.

**METHODS:** Human neutrophils and monocytes were isolated from human whole blood by using 1-Step Polymorph and RosetteSep Human Monocyte Enrichment Cocktail, respectively. Human GPR41 and GPR43 mRNA expression was examined by quantitative real-time polymerase chain reaction. The calcium flux assay was used to examine the biological activities of SCFAs in human neutrophils and monocytes. The effect of

SCFAs on human monocytes and peripheral blood mononuclear cells (PBMC) was studied by measuring PGE<sub>2</sub>, cytokines and chemokines in the supernatant. The effect of SCFAs *in vivo* was examined by intraplantar injection into rat paws.

**RESULTS:** Human GPR43 is highly expressed in human neutrophils and monocytes. SCFAs induce robust calcium flux in human neutrophils, but not in human monocytes. In this study, we show that SCFAs can induce human monocyte release of PGE<sub>2</sub> and that this effect can be enhanced in the presence of lipopolysaccharide (LPS). In addition, we demonstrate that PGE<sub>2</sub> production induced by SCFA was inhibited by pertussis toxin, suggesting the involvement of a receptor-mediated mechanism. Furthermore, SCFAs can specifically inhibit constitutive monocyte chemotactic protein-1 (MCP-1) production and LPS-induced interleukin-10 (IL-10) production in human monocytes without affecting the secretion of other cytokines and chemokines examined. Similar activities were observed in human PBMC for the release of PGE<sub>2</sub>, MCP-1 and IL-10 after SCFA treatment. In addition, SCFAs inhibit LPS-induced production of tumor necrosis factor- $\alpha$  and interferon- $\gamma$  in human PBMC. Finally, we show that SCFAs and LPS can induce PGE<sub>2</sub> production *in vivo* by intraplantar injection into rat paws ( $P < 0.01$ ).

**CONCLUSION:** SCFAs can have distinct antiinflammatory activities due to their regulation of PGE<sub>2</sub>, cytokine and chemokine release from human immune cells.

## INTRODUCTION

The receptors for free fatty acids, including GPR40, GPR41, GPR42 and GPR43, constitute a subfamily of recently orphanized G-protein-coupled receptors (GPCRs) that are clustered on human chromosome 19q13.1<sup>[1]</sup>. They exhibit 30%-40% homology to one another and have diverse tissue distributions, yet all are activated by various free fatty acids, which function as intercellular lipid mediators through GPCRs<sup>[2,3]</sup>.

The free fatty acid receptors are functionally involved in both metabolism and the immune system. In contrast to GPR40 which is activated by medium- and long-chain fatty acids and abundantly expressed in the pancreatic islets<sup>[4-7]</sup>, GPR41 and GPR43 are functionally activated by short-chain fatty acids (SCFAs), including acetate, propionate and butyrate<sup>[8-10]</sup>. Although both receptors are activated by SCFAs, they have distinct tissue distribution profiles. GPR41 is preferentially expressed in adipose tissue, while GPR43 is highly expressed in hematopoietic tissues (such as spleen and bone marrow) and immune cells (particularly monocytes and neutrophils). Interestingly, the murine ortholog of GPR43 was initially identified as leukocyte-specific STAT-induced GPCR (LSSIG). It was reported that expression of both murine LSSIG and human GPR43 is induced during the differentiation of leukocyte progenitor cells to monocytes or neutrophils, suggesting their involvement in leukocyte function and host defense<sup>[11]</sup>.

SCFAs have long been known to modulate the immune response. Acetate, propionate and butyrate represent the most often described SCFAs that are capable of immune activation. SCFAs affect neutrophil function and migration<sup>[12-15]</sup>, and inhibit tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) or interleukin-1 $\beta$  (IL-1 $\beta$ )-induced vascular cell adhesion molecule-1 (and intercellular adhesion molecule-1) surface expression<sup>[16]</sup>. In addition, SCFAs reduce adherence of monocytes or lymphocytes to cytokine-stimulated human umbilical vein endothelial cells<sup>[17]</sup>, and inhibit interferon- $\gamma$  (IFN- $\gamma$ ) signaling<sup>[18,19]</sup>, a possible regulator of inflammation in inflammatory bowel disease (IBD). Although the molecular mechanisms of the effects of SCFAs remain to be elucidated, evidence in the literature indicates that SCFA-induced biological effects involve G-protein-mediated signaling<sup>[12,20]</sup>. GPR43, which is highly expressed in immune cells, could be the potential missing GPCR activated by SCFAs. GPR41 is also expressed in immune cells, but at lower levels compared to GPR43 and thus may play a lesser role<sup>[8-10]</sup>. As there are no well-validated specific drugs that can be used as tools to investigate the receptor, the emerging biology of these receptors is dependent on expression profiling. It is

believed that GPR43 is likely the main receptor contributing to the effect of SCFAs in immune cells. In human neutrophils, it was reported that SCFAs induced calcium flux and chemotaxis possibly through GPR43<sup>[9]</sup>. Nonetheless, the precise role of GPR43 in the effect of SCFAs in neutrophils needs to be established with the generation of a knockout model and specific small molecules. In addition, GPR43 is also highly expressed in monocytes and peripheral blood mononuclear cells (PBMC)<sup>[9]</sup>, and the effects of SCFAs in these important immune cells are of high interest, but are largely unknown.

SCFAs are produced by microbial anaerobic fermentation in the hindgut in millimolar (mmol/L) concentrations; therefore, the physiological site of GPR43 activation may be in the gut. Within the human colon, concentrations of acetate, propionate and butyrate were reported to be in the range of 20-43 mmol/L, 6-13 mmol/L and 6-15 mmol/L, respectively<sup>[21]</sup>. GPR43 has been reported to be expressed in human, mouse and rat colons<sup>[22-24]</sup>. Induction of anti-inflammatory activities by SCFAs in the colon may contribute to the bacterial evasion of the immune system<sup>[25]</sup>. GPR43-mediated activation may provide a link between the intestinal bacteria and the immune response in physiological and pathophysiological conditions.

We report the identification of new functional roles of SCFAs in production of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), cytokines and chemokines in human monocytes and in PBMC. We speculate that the effect of SCFAs is most likely through activation of GPR43, a potential therapeutic target for the development of an innovative treatment for colitis.

## MATERIALS AND METHODS

### *Isolation of human neutrophils, monocytes and PBMCs*

Human neutrophils were isolated from human whole blood by using 1-Step Polymorph (Accurate Chemical & Scientific Corp., Westbury, NY) according to the manufacturer's instructions. Human monocytes were isolated by RosetteSep Human Monocyte Enrichment Cocktail (StemCell Technologies, London, UK). Human PBMC were prepared by the Ficoll-Hypaque centrifugation method.

For the calcium flux assay, both human neutrophils and monocytes were treated with formate, acetate and propionate (Sigma, St. Louis, MO, USA) for 5-10 min. For measurement of PGE<sub>2</sub>, cytokines and chemokines, human monocytes and PBMC cells were incubated with formate, acetate, propionate and butyrate (Sigma, St. Louis, MO, USA) overnight.

### *Quantitative real-time polymerase chain reaction (PCR) analysis*

TaqMan primers and probes were designed with Primer Express software and purchased from ABI (Applied Biosystems, Foster City, CA, USA). The sequences of the human primers and probes for GPR41 and GPR43 are shown in Table 1. Quantitative real-time PCR was carried out with an ABI Prism 7900HT Sequence Detection System. The PCR reactions were prepared

**Table 1** Real-time polymerase chain reaction primers and probes designed for the detection and quantification of human GPR41 and GPR43

Gene	RefSeq ID	Forward primer	Reverse primer	Probe
GPR41	NM_005304	GCTTTGGGCCCTACAACGT	CCATGCCGGGCTTTC	TCCCATGTCGTGGGCTATACTGCG
GPR43	NM_005306	GGCTTCCCCGTGCAGTAC	ACCAGAGCTGCAATCACTCCAT	AGCTCTCCCCCGGCCTCTG

using the components from the iScript Custom One-Step RT-PCR Kit with ROX and assembled according to the manufacturer's instructions (Bio-Rad, Hercules, CA, USA). The final concentrations of the primers and probe in the PCR reactions were 200 nmol/L and 100 nmol/L, respectively. The fluorogenic probes were labeled with 6-carboxyfluorescein as the reporter and 6-carboxy-4,7,2,7'-tetramethylrhodamine as a quencher. Each 10  $\mu$ L PCR reaction contained 10 ng of total RNA. The RT-PCR reactions were performed in triplicate in a 384-well plate according to the following protocol: one cycle for 10 min at 50°C, followed by one 5 min cycle at 95°C, followed by 40 cycles at 95°C for 15 s and 60°C for 1 min. A eukaryotic 18S rRNA endogenous control probe/primer set (ABI) was used as an internal control for RNA quality.

The PCR data were quantified, based on a 12-point standard curve generated using 4-fold serial dilutions of a cDNA containing the gene of interest. The 4-fold dilutions began at 20000 fg. This procedure provides an absolute quantification of the amounts of GPR41 and GPR43 mRNA in a given sample.

### Calcium flux assay

Intracellular Ca<sup>2+</sup> assays were carried out as previously described with modifications<sup>[26]</sup>. Freshly isolated human neutrophils were resuspended at  $1 \times 10^6$  cells/mL in cell culture medium (RPMI 1640 with 2 mmol/L GlutaMAX and 5% fetal bovine serum) and incubated at 37°C, 50 mL/L CO<sub>2</sub>, for 1 h. Cells were spun and resuspended at  $1 \times 10^6$  cells/mL in a 1:1 mixture of cell culture medium and Calcium-4 no wash dye (Molecular Devices, Sunnyvale, CA, USA) containing a final concentration of 5 mmol/L probenecid (Sigma). The cells were seeded (50000/well) into poly-D-lysine-coated 384-well, black-wall, clear bottom microtiter plates (Becton Dickinson). Cells were sedimented in plates by spinning down briefly at low speed with no brake then incubated at 37°C, 50 mL/L CO<sub>2</sub>, for 1 h before assaying on a FLIPR-384 (Molecular Devices). Freshly isolated human monocytes were resuspended at  $1 \times 10^9$  cells/L in a 1:1 mixture of cell culture medium and Calcium-3 no wash dye containing a final concentration of 2.5 mmol/L probenecid. The cells were seeded (50000/well) into poly-D-lysine coated 384-well plates. Cells were dye loaded for 45 min at 37°C, 50 mL/L CO<sub>2</sub>, before assaying on a FLIPR-384.

Formate, acetate, propionate and butyrate (Sigma) were prepared in Hank's balanced salt solution, 25 mmol/L Hepes, and 0.1% bovine serum albumin. The maximum change in fluorescence over baseline was used to determine agonist response. The dose-response curves and EC<sub>50</sub> values were obtained by nonlinear regression (Prism 4; Graph Pad Software, San Diego, CA, USA).

### Measurement of PGE<sub>2</sub>, cytokines and chemokines

PGE<sub>2</sub> was measured by ELISA kit from Assay Designs (Ann Arbor, MI, USA). Cytokines and chemokines were measured by MesoScale ELISA (MesoScale Discovery, Gaithersburg, MD, USA) according to the manufacturer's instructions. To generate the conditioned media,  $1 \times 10^6$  cells per mL were resuspended in RPMI 1640 medium supplemented with 10% fetal bovine serum, 1 mmol/L L-glutamine, 10 mmol/L Hepes, 50000 U/L penicillin and 50  $\mu$ g/mL streptomycin; and seeded in 24-well plates for stimulation with SCFAs and/or incubation with selective inhibitors (Cayman Chemical, Ann Arbor, MI, USA), including MLnFP (methyl  $\alpha$ -linolenyl fluorophosphonate), a phospholipase inhibitor; 1400W, a selective iNOS inhibitor; SC-560, a selective cyclooxygenase-1 (COX-1) inhibitor; CAY10404, a selective COX-2 inhibitor; PTX, pertussis toxin. The tested concentrations of each inhibitor (except PTX) was chosen to be about 100 times of its IC<sub>50</sub> as reported in the data sheet provided by the manufacturer.

### Intraplantar injection of SCFAs into rat paws

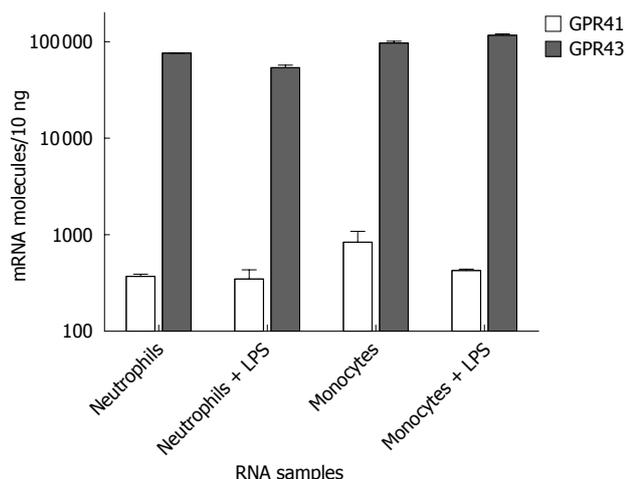

Sprague-Dawley male rats from Charles River Laboratories, 4 per group and approximately 200 g body weight, were anesthetized with isoflurane gas and the subplantar space of the paw injected with 0.1 mL of 100 mmol/L solutions of the SCFAs, either formate, acetate, propionate or butyrate prepared fresh in 0.9% saline. Lipopolysaccharide (LPS), *Escherichia coli* 0127:B8 (Sigma) was also injected at 3  $\mu$ g in saline either alone or in combination with 0.1 mL of 200 mmol/L sodium butyrate. Rats in the normal group were not injected. At 3 h post-injection, the rats were humanely euthanized and a uniform punch biopsy of the injected site was taken from each rat. The punch biopsies were immediately placed in PMSF (phenylmethanesulphonyl fluoride) buffer containing 10 g/L of indomethacin and frozen at -20°C. The tissues were homogenized in this collection buffer and assayed for PGE<sub>2</sub>.

All statistical analysis was performed by Mann-Whitney *U* test using GraphPad Instat version 3.06 for Windows XP (GraphPad Software, San Diego, CA, USA). All studies in animals were performed in accordance with the regulations specified by the National Institutes of Health Principles of Laboratory Animal Care (1985 revised version) and the Schering-Plough Research Institute Animal Care and Use Committee.

## RESULTS

### GPR43 is highly expressed in human neutrophils and monocytes

Both GPR43 and GPR41 are activated by SCFAs and

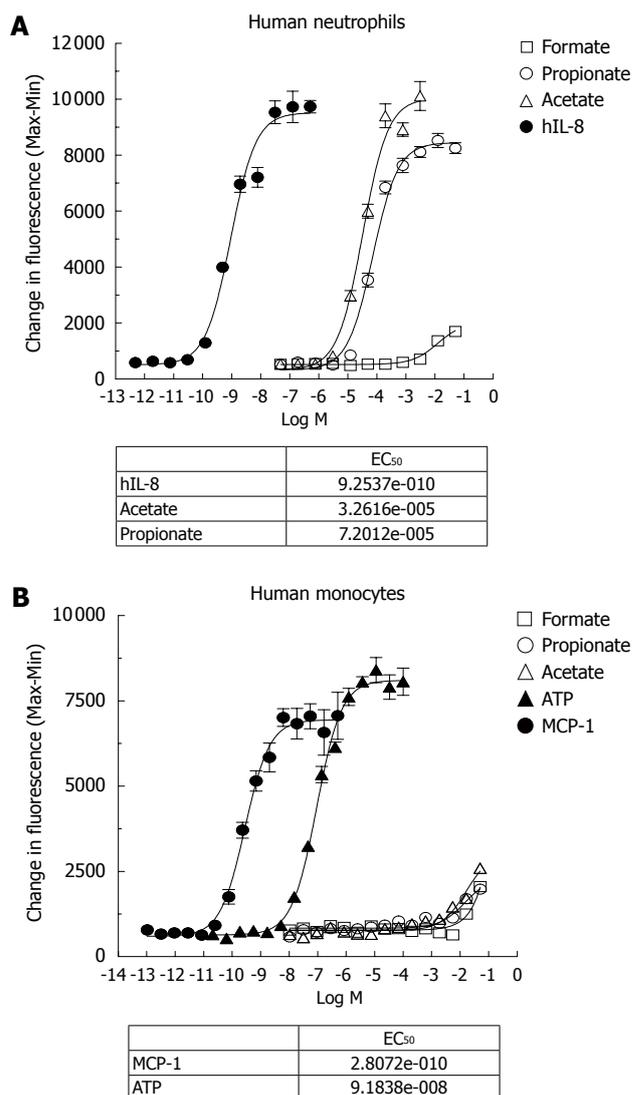

**Figure 1 GPR43 is highly expressed in human neutrophils and monocytes.** Human neutrophils and monocytes were isolated from human whole blood as described in Materials and Methods. Isolated human neutrophils or monocytes were stimulated with 100 ng/mL of lipopolysaccharide (LPS) for 3 h. RNAs were isolated and evaluated by Taqman analysis for absolute quantities of GPR43 and GPR41 mRNA molecules.

reported to be expressed in immune cells. To examine the role of GPR43 and GPR41 in human immune cells, we initially quantified their expression levels in human neutrophils and monocytes by Taqman analysis. Human neutrophils and monocytes were each isolated from human donors to 95% purity. Some of them were stimulated with LPS. RNAs were isolated and analyzed for GPR43 and GPR41 expression by Taqman. Figure 1 shows that GPR43 is expressed in both human neutrophils and monocytes at a much higher level than GPR41. It also appears that LPS stimulation did not affect their expression levels.

### SCFAs induce robust calcium flux in human neutrophils, but not in human monocytes

To investigate the biological activities of SCFAs, both purified human neutrophils and monocytes were exposed to various concentrations of SCFAs (formate, acetate and propionate) in a calcium flux assay. Formate was used as a negative control for the SCFAs. In addition, IL-8 was included as a positive control for neutrophil activation, while monocyte chemoattractant protein-1 (MCP-1) and ATP were used as the positive controls for monocyte activation. Since GPR41 couples to  $G_{i/o}$  only, SCFAs should not cause a calcium flux through this receptor, which was confirmed in a recombinant cell line expressing GPR41 (data not shown). Indeed, the agonist potency profile of the calcium response in human neutrophils (Figure 2A) was consistent with the GPR43 receptor response that has been described<sup>[9]</sup>. From 8 human donors, acetate had an average  $EC_{50}$  of  $58.25 \pm 12.44 \mu\text{mol/L}$  ( $n = 8$ ), and propionate had an  $EC_{50}$  of  $200.6 \pm 42.42 \mu\text{mol/L}$  ( $n = 8$ ). Formate was inactive and IL-8 had an  $EC_{50}$  about 1-2 nmol/L in human neutrophils. Acetate and propionate achieved the same maximal activation response as IL-8 in human neutrophils using this calcium flux assay.

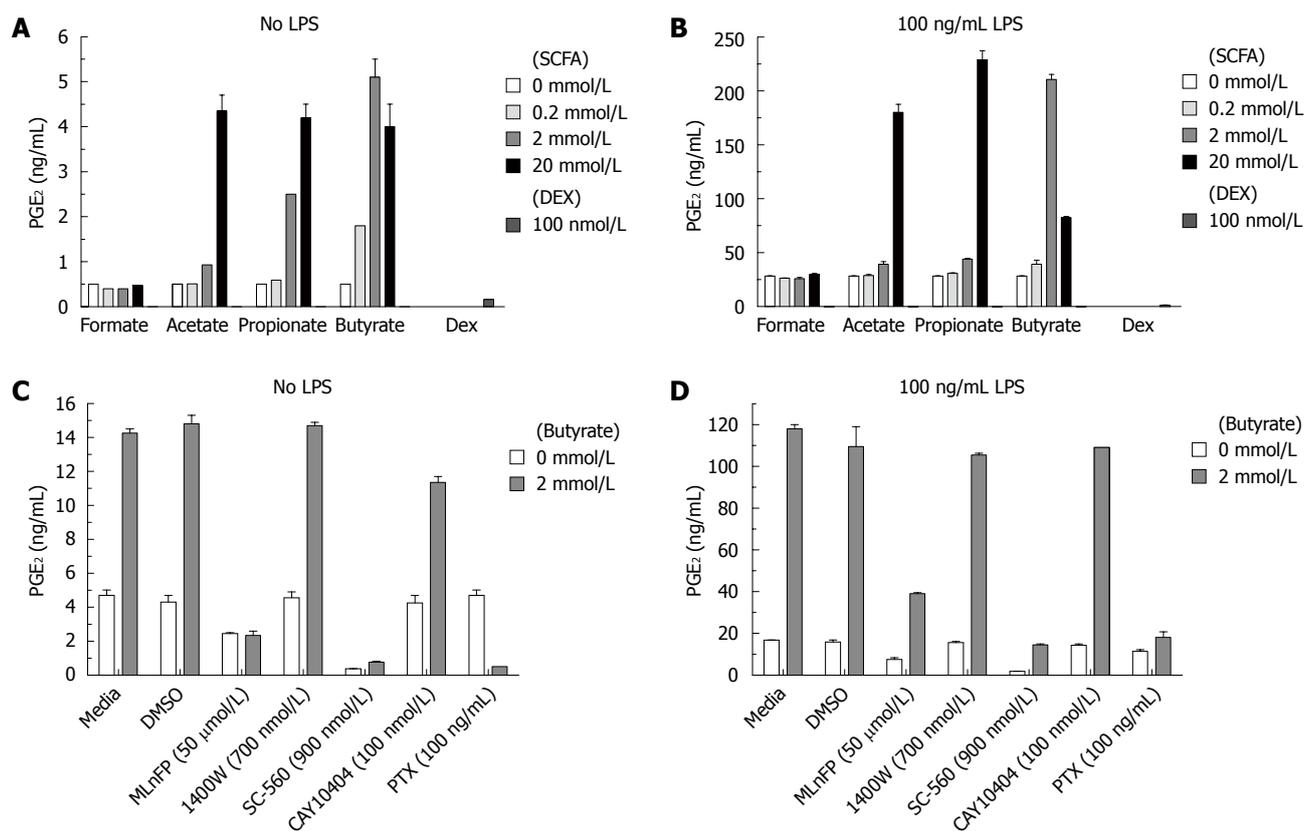

**Figure 2 Short-chain fatty acids (SCFAs) induce robust calcium flux in human neutrophils, but not in human monocytes.** Human neutrophils (A) and monocytes (B) were isolated and exposed to the indicated concentrations of formate, acetate and propionate for a calcium flux assay as described in Materials and Methods. Interleukin-8 (IL-8) is included as a positive control for human neutrophils, and monocyte chemoattractant protein-1 (MCP-1) and ATP for human monocytes. The dose-response curves and  $EC_{50}$  values were obtained by nonlinear regression using Graph Pad Prism 4 software.

On the other hand, Figure 2B shows that acetate and propionate, up to 100 mmol/L, did not induce significant calcium flux in human monocytes, while MCP-1 and ATP were able to induce robust calcium flux in the human monocyte preparation. It appears that the response of GPR43 to SCFAs for calcium flux is dependent either on cell type or on the state of differentiation of the cells. Indeed, it has been reported that propionic acid induced calcium mobilization in human neutrophils, but not in monocytes, platelets and lymphocytes<sup>[12]</sup>.

### SCFAs strongly induce PGE<sub>2</sub> production in human monocytes and the effect is receptor-mediated

To further explore the biological effects of SCFAs, human monocytes were isolated and incubated overnight with various concentrations of SCFAs in the presence

**Figure 3 SCFAs strongly induce PGE<sub>2</sub> production in human monocytes and the effect is receptor-mediated.** Freshly isolated human monocytes ( $1 \times 10^6$  cells/L) were incubated with the indicated concentrations of SCFAs or 100 nmol/L dexamethasone (Dex), and then cultured for 22 h without (A) or with (B) 100 ng/mL LPS. In a separate experiment (C, D), human monocytes were incubated with the indicated concentrations (in the parentheses) of inhibitors (described below) for 30 min, then with or without 2 mmol/L butyrate for another 30 min, and finally cultured for 22 h without (C) or with (D) 100 ng/mL LPS. The media and DMSO samples were used as controls with no inhibitors. All culture supernatants were assayed for PGE<sub>2</sub> by ELISA. MLnFP (methyl  $\alpha$ -linolenyl fluorophosphonate): Phospholipase inhibitor; 1400W: Selective iNOS inhibitor; SC-560: Selective cyclooxygenase-1 (COX-1) inhibitor; CAY10404: Selective COX-2 inhibitor; PTX: Pertussis toxin. (Cayman Chemical, Ann Arbor, MI). The tested concentrations of each inhibitor (except PTX) were chosen to be about 100 times its IC<sub>50</sub> as reported in the data sheet provided by the manufacturer.

or absence of LPS (100 ng/mL) as a proinflammatory stimulus. The supernatants were assayed for lipid mediators such as PGE<sub>2</sub>, proinflammatory cytokines and chemokines by either ELISA or Meso Scale Multi-Spot Discovery Technology. Dexamethasone was included in the experiment as a positive control for the induction of inhibition. Figure 3A shows that SCFAs alone strongly enhanced PGE<sub>2</sub> production in human monocytes across a panel of 10 human donors in a concentration-dependent manner. Furthermore, SCFAs synergistically enhanced the PGE<sub>2</sub> production induced by LPS in human monocytes (10 human donors), as shown in Figure 3B. The rank order of potency was butyrate > propionate > acetate, while formate was inactive. Dexamethasone at 100 nmol/L potently inhibited basal PGE<sub>2</sub> and LPS-induced PGE<sub>2</sub> production (Figure 3A and B). Similar results were obtained from 10 human donors. The culture supernatants were also assayed for PGI<sub>2</sub>, leukotriene B<sub>4</sub> (LTB<sub>4</sub>) and thromboxane B<sub>2</sub> (TXB<sub>2</sub>). SCFAs had no significant effect on these lipid mediators (data not shown), suggesting its effect on PGE<sub>2</sub> production is specific.

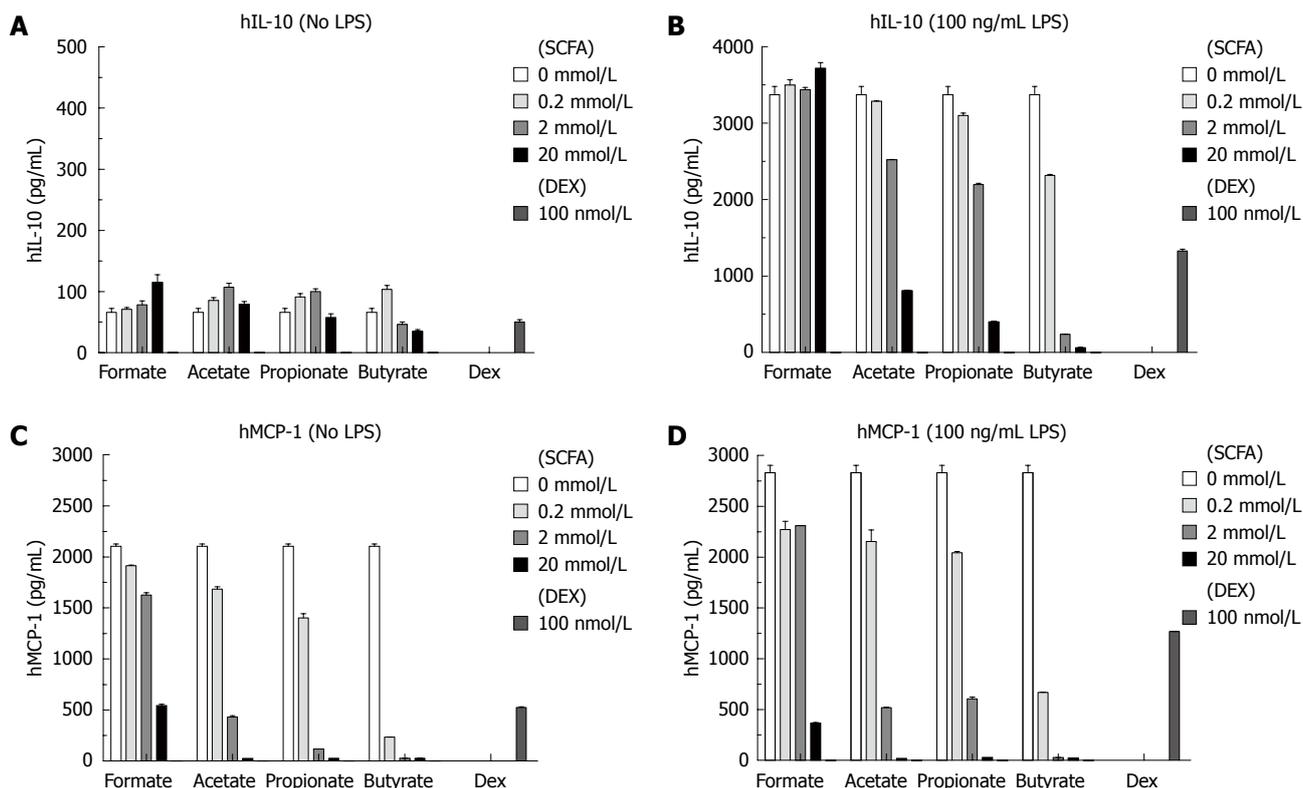

To examine possible mechanisms of PGE<sub>2</sub> production induced by SCFAs, human monocytes were preincubated with several inhibitors and then added to culture with butyrate and/or LPS. Figure 3C and D show that the

PGE<sub>2</sub> production induced by butyrate is inhibited by pretreatment with PTX, COX-1 and phospholipase inhibitors either in the absence or presence of LPS. In contrast, COX-2 and iNOS inhibitors had no effect on PGE<sub>2</sub> production induced by butyrate. The sensitivity to PTX suggests PGE<sub>2</sub> production induced by butyrate is receptor-mediated.

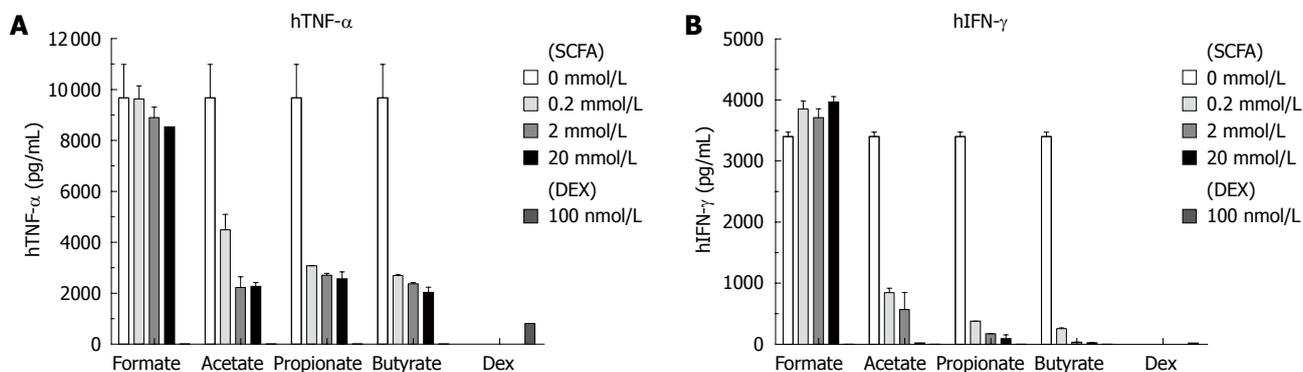

### SCFAs specifically inhibit LPS-induced IL-10 production and constitutive MCP-1 expression in human monocytes

The same culture supernatants described above were also analyzed for 8 proinflammatory cytokines including IL-1 $\beta$ , IL-2, IL-6, IL-8, IL-10, IL-12p70, IFN- $\gamma$ , TNF- $\alpha$  (Meso Scale Multi-Spot Discovery Technology). In the absence of LPS, SCFAs had no effect on the level of any of the 8 cytokines including IL-10, as shown in Figure 4A. In contrast, SCFAs specifically inhibited IL-10 production stimulated with LPS (Figure 4B), but had no effect on the other 7 cytokines with LPS stimulation (including LPS-induced production of IL-1 $\beta$  and TNF- $\alpha$ ). The effect of dexamethasone on the cytokine profile is consistent with what has been previously described; briefly, it inhibited LPS-induced production of IL-1 $\beta$ , IL-10 and TNF- $\alpha$ .

It is consistently observed that isolated human monocytes produce high levels of MCP-1 in the culture

**Figure 4** SCFAs specifically inhibit LPS-induced IL-10 production and constitutive MCP-1 expression in human monocytes. The culture supernatants as in Figure 3A and B were analyzed for 8 proinflammatory cytokines (including IL-1 $\beta$ , IL-2, IL-6, IL-8, IL-10, IL-12p70, IFN- $\gamma$ , TNF- $\alpha$ ) or 9 proinflammatory chemokines (including MCP-1, MCP-4, eotaxin, eotaxin-3, IL-8, IFN- $\gamma$  inducible protein-10, macrophage inflammatory protein-1 $\beta$ , macrophage-derived chemokine, thymus and activation-regulated chemokine) by Meso Scale Multi-Spot Discovery Technology. Only the data for IL-10 (A, B) and MCP-1 (C, D) are shown here. Similar results were obtained from 10 human donors.

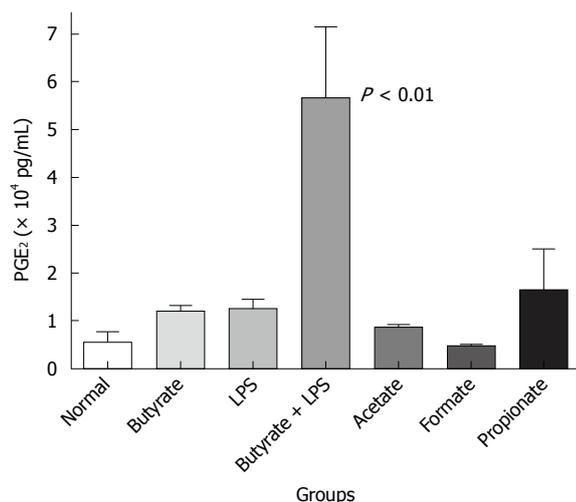

**Figure 5** SCFAs inhibit LPS-induced production of TNF- $\alpha$  and IFN- $\gamma$  in human peripheral blood mononuclear cells (PBMC) in a dose-dependent manner. Human PBMC isolated by Ficoll-Hypaque centrifugation procedure ( $1 \times 10^6$  cells/mL) were incubated with the indicated concentrations of short-chain fatty acids (SCFA) or 100 nmol/L dexamethasone (Dex), and then cultured for 22 h with or without 100 ng/mL LPS. Culture supernatants were analyzed for 8 proinflammatory cytokines including IL-1 $\beta$ , IL-2, IL-6, IL-8, IL-10, IL-12p70, IFN- $\gamma$ , TNF- $\alpha$  by Meso Scale Multi-Spot Discovery Technology. The data for TNF- $\alpha$  (A) and IFN- $\gamma$  (B) with LPS stimulation are shown here.

supernatants without stimulation. Figure 4C and D show that SCFAs inhibited this constitutive MCP-1 production in a concentration-dependent manner either in the absence or presence of LPS. SCFAs did not inhibit the constitutive high levels of eotaxin-3, macrophage-derived chemokine and macrophage inflammatory protein-3 $\beta$  in the cultures, suggesting that the effect of SCFAs on MCP-1 production is specific. In this experiment, 20 mmol/L formate showed some inhibition, which is likely the result of a nonspecific effect.

**SCFAs inhibit LPS-induced production of TNF- $\alpha$  and IFN- $\gamma$  in human PBMCs in a concentration-dependent manner**

To further confirm the effect of SCFAs, human PBMC were isolated by Ficoll-Hypaque centrifugation procedure and incubated with SCFAs and/or LPS. The culture supernatants were analyzed as before for PGE<sub>2</sub>, cytokines and chemokines. The effects of SCFAs on PGE<sub>2</sub>, MCP-1 and IL-10 production were similar to that observed in the isolated human monocytes. However, as shown in

**Figure 6 SCFAs induce PGE<sub>2</sub> production by intraplantar injection into rat paws.** The paw of male Sprague-Dawley rats was injected intraplantarly with 0.1 mL of 100 mmol/L formate, acetate, propionate or butyrate. Three micrograms of LPS in saline was also injected alone or in combination with 0.1 mL of 200 mmol/L butyrate. There were 4 rats per group. The normal group was not injected. Three hours post injection, rat paws were punched and fluids were collected in phenylmethanesulphonyl fluoride buffer with indomethacin. All punch fluids were assayed for PGE<sub>2</sub> by ELISA.  $P < 0.01$  for butyrate + LPS group vs normal group, Mann-Whitney  $U$  test.

Figure 5, SCFAs inhibited LPS-induced production of TNF- $\alpha$  and IFN- $\gamma$  in human PBMC in a concentration-dependent manner, an effect not observed in isolated human monocytes where IFN- $\gamma$  production was low and not stimulated by LPS addition. In the human PBMC experiment, dexamethasone inhibited LPS-induced production of IL-1 $\beta$ , IL-10, IFN- $\gamma$  and TNF- $\alpha$ .

#### SCFAs induce PGE<sub>2</sub> production by intraplantar injection into rat paws

To demonstrate the effect of SCFAs *in vivo*, SCFAs and LPS alone or in combination were injected by the intraplantar route into a rat paw. This was done to initiate an inflammatory response and determine what effect the butyrate would have on lipid mediator and cytokine induction. In the representative experiment shown in Figure 6, acetate, propionate and butyrate alone could induce PGE<sub>2</sub> production in rat paw. Formate was inactive and the level of PGE<sub>2</sub> was equivalent to that extracted from a normal (not injected) paw. In addition, suboptimal LPS also induced PGE<sub>2</sub> production and the combination of LPS and butyrate strongly enhanced PGE<sub>2</sub> production in a synergistic manner ( $P < 0.01$ ). These *in vivo* data, although preliminary in nature, support the effects of SCFAs on PGE<sub>2</sub> production observed in human monocytes and PBMC. Cytokine analysis was performed on the tissue homogenates but no clear pattern emerged that was similar to that obtained in the human monocytes and PBMC *in vitro* experiments. Sodium butyrate is extremely labile with a very high diffusion rate. Maintenance of a sufficient concentration in the paw subcutaneous space was a significant problem in these experiments.

## DISCUSSION

In this study, we have shown that SCFAs can induce either robust PGE<sub>2</sub> production alone or in synergy with LPS in human monocytes and PBMC. Since LPS stimulation did not affect the mRNA level of GPR43 and GPR41, the synergy is likely from 2 independent signaling pathways. This effect on PGE<sub>2</sub> production is specific, since other lipid mediators including PGI<sub>2</sub>, LTB<sub>4</sub> and TXB<sub>2</sub>, were not affected by SCFAs. Furthermore, this effect is receptor-mediated since it is sensitive to PTX.

Interestingly, we showed that SCFAs induced robust calcium flux in human neutrophils, but not in human monocytes. Our finding is consistent with the previous report that propionic acid induced calcium mobilization in human neutrophils, but not in monocytes, platelets and lymphocytes<sup>[12]</sup>. It is likely that SCFAs activate neutrophils and monocytes for the immune response through different signaling pathways that would be consistent with the different temporal roles of these cells in an inflammatory response. SCFAs induce calcium flux and chemotaxis in neutrophils which arrive early in an inflammatory response, while they regulate production of PGE<sub>2</sub>, cytokines and chemokines in monocytes which are also present in the inflammatory site but mature into macrophages during extravasation and remain at the site of inflammation until resolution.

This *in vitro* effect of SCFAs on human monocytes may have relevance to human diseases that target the intestinal tract. Among various prostanoids, PGE<sub>2</sub>, in particular, seems to play a critical role in inflammatory bowel disease (IBD) *via* the EP4 receptor, one of the four PGE<sub>2</sub> receptor subtypes (EP1-4)<sup>[27-31]</sup>. Among 8 prostanoid receptor-deficient mice, only EP4-deficient mice developed severe colitis with 3% dextran sodium sulphate (DSS) treatment. It is suggested that EP4 maintains intestinal homeostasis by maintaining mucosal integrity and downregulating the immune response<sup>[32]</sup>. Therefore, it is possible that SCFAs induce production of PGE<sub>2</sub> and play a protective role *via* the GPR43-expressing cells of the colon. Furthermore, we demonstrate that PGE<sub>2</sub> production induced by SCFAs was inhibited by a COX-1 inhibitor, but not a COX-2 inhibitor. This is consistent with the notion that in DSS-induced colitis, the significant reduction in PGE<sub>2</sub> resulted from decreased expression of COX-1, but not COX-2<sup>[33]</sup>.

In human monocytes, SCFAs specifically inhibited constitutive MCP-1 production and LPS-induced IL-10 production out of the total 16 cytokines and chemokines examined. The activities of SCFAs in our human monocyte cultures were all confirmed in human PBMC, which contain both monocytes and lymphocytes. We made the additional observation in these PBMC cultures that SCFAs would inhibit LPS-induced TNF- $\alpha$  and IFN- $\gamma$  production.

This unique effect of SCFAs on the production of cytokines and chemokines in monocytes and PBMC is relevant to the design of new therapies for colitis. Intestinal inflammation present in inflammatory bowel disease

is driven by the production of cytokines, chemokines and growth factors that draw in immune cells to the mucosa. It has been shown that MCP-1, IL-10, IFN- $\gamma$  and TNF- $\alpha$  were significantly upregulated in experimental colitis models<sup>[34,35]</sup>. Furthermore, the increased production of SCFAs from dietary fiber supplementation or probiotics administration inhibited the production of proinflammatory mediators and recovered damaged colonic mucosa in colitic animals<sup>[36,37]</sup>. These experiments show that SCFAs can inhibit multiple inflammatory mediators which may control intestinal inflammation. Clinical trial evidence for this use of SCFAs is still not widely available or accepted as a mainstream therapy.

We tried to design a model system *in vivo* to duplicate our *in vitro* findings. We present the results of a model system using the intraplantar space in the rat paw, a space from which there was limited diffusion of the injected SCFAs. We had previously tried injecting SCFAs into the pleural cavity and into the peritoneal cavity to induce an inflammatory response with and without suboptimal inflammatory stimuli such as LPS. However, SCFAs are extremely labile with a very high diffusion rate and require high concentrations to achieve their effect *in vivo*. Maintenance of a sufficient concentration of SCFAs at a local site or tissue space (such as the colon) has been a major challenge to obtain clear cytokine profiles and *in vivo* efficacy. Therefore, better pharmacological tools, such as GPR43 specific small molecules<sup>[38]</sup>, are needed to confirm our *in vitro* findings and further elucidate their biology. We were able to utilize the intraplantar space of the paw to illustrate the ability of SCFAs to synergize with LPS and induce mediator production but there was significant variability in this response.

The present findings of antiinflammatory activities of SCFAs in immune cells expand the database on these fatty acids as lipid mediators and may help explain the known beneficial effects of SCFAs in the colon and on colitis. Future studies are needed in knockout mice and with specific small molecules (both agonists and antagonists) to prove the exact molecular target for these effects of SCFAs.

## COMMENTS

### Background

Short-chain fatty acids (SCFAs) are produced by bacterial fermentation of dietary fiber in the hindgut in millimolar concentrations. They have long been known to modulate the immune response and have a beneficial effect in the colon and on colitis.

### Research frontiers

The molecular mechanism for the effect of SCFAs in immune cells of the gastrointestinal tract has not been characterized. Recently, a free fatty acid receptor GPR43 was found to be highly expressed in both neutrophils and

monocytes and identified to be activated by SCFAs. In neutrophils, SCFAs induce calcium flux and chemotaxis. However, the effect of SCFAs in monocytes is of high interest, but is largely unknown.

### Innovations and breakthroughs

This study showed that SCFAs can induce specific and robust prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) production either alone or in synergy with lipopolysaccharide in human monocytes and peripheral blood mononuclear cells (PBMC). Furthermore, SCFAs can specifically regulate production of monocyte chemotactic protein-1, interleukin-10, tumor necrosis factor- $\alpha$  and interferon- $\gamma$  in human monocytes and/or PBMC. Finally, we showed that SCFAs can induce PGE<sub>2</sub> production *in vivo* by intraplantar injection into rat paws.

### Applications

The present findings of antiinflammatory activities of SCFAs in immune cells expand the database on these fatty acids and may help explain the known beneficial effects of SCFAs in the colon and on colitis. Future studies are needed in knockout mice and with specific small molecules to prove the exact molecular target for these effects of SCFAs. The authors speculate that the action of SCFAs is most likely through activation of the free fatty acid receptor GPR43, a potential therapeutic target for the development of an innovative treatment of colitis.

### Peer review

This is a study in an important area of inflammatory activities of SCFAs and its effects on the related cytokines and chemokines. In the present paper, the authors examined the inflammatory activities of SCFAs and the production of the related receptors and analyzed the mechanisms. The experiments were well organized.

### Abstract

**AIM:** To investigate a genetic polymorphism of the *monocyte chemotactic protein-1* (MCP-1) gene in patients with spontaneous bacterial peritonitis (SBP).

**METHODS:** MCP-1 genotyping was performed in 23 patients with SBP and 83 cirrhotic control patients with non-infected ascites.

**RESULTS:** The frequency of carriers of the G-allele was lower in SBP patients but this difference did not reach statistical significance. However, in the subgroup of patients with alcoholic cirrhosis ( $n = 80$ ), carriers of the G-allele were significantly less frequent in SBP-patients (38.1%) than in cirrhotic controls (67.8%,  $P = 0.021$ ).

**CONCLUSION:** In patients with alcoholic liver cirrhosis, the -2518 MCP-1 genotype AA is a risk factor for the development of SBP.

**Key words:** Monocyte chemotactic protein-1; Chemokines; Spontaneous bacterial peritonitis; Polymorphism; Liver cirrhosis

### INTRODUCTION

Spontaneous bacterial peritonitis (SBP) is a common and potentially life-threatening complication in patients with cirrhosis. It is a prototypical infective disease in cirrhotic patients characterized by peritoneal neutrophil infiltration, which also serves as a diagnostic criterion for SBP (e.g. an ascites neutrophil count greater than  $250/\text{mm}^3$ )<sup>[1]</sup>.

Factors influencing the development of SBP in patients with liver cirrhosis are poorly understood. Previous studies have indicated that peritoneal macrophages of cirrhotic patients might contribute to the control of SBP or influence its associated pathology in human cirrhosis by producing high quantities of angiogenic peptides and nitric oxide<sup>[2-5]</sup>. Accordingly, elevated concentrations of proinflammatory cytokines are found in ascites of patients<sup>[6,7]</sup>.

Therefore, it is of particular interest to identify mechanisms underlying the recruitment and activation of macrophages/monocytes that infiltrate the ascites of cirrhotic patients. Chemotactic cytokines are known to be critical mediators of inflammatory cell trafficking into sites of injury and are crucial for the modulation of tissue injury, inflammation, and repair.

Monocyte chemotactic protein-1 (MCP-1) is one of the most potent chemokines for monocytes/macrophages and activated lymphocytes during infections<sup>[8]</sup>. In addition, several studies have shown that neutrophil infiltration is affected either directly or indirectly *via* MCP-1<sup>[9,10]</sup>.

Several lines of evidence indicate that MCP-1 might play a role in the recruitment and maintenance of the inflammatory infiltrate during liver injury. MCP-1 secretion is up-regulated during chronic hepatitis and correlates with the severity of hepatic inflammation<sup>[11-13]</sup>.

Furthermore, a previous study showed elevated MCP-1 levels in ascites of cirrhotic patients as compared to controls<sup>[14]</sup>. Moreover, during SBP, even higher MCP-1 levels were measured in ascites suggesting that this potent chemokine plays a pathophysiological role during the development and course of SBP.

Recently, a mutation in the distal regulatory region of the MCP-1 gene at position -2518 relatively to the transcription start site (based on the published sequence, Gene Bank accession number D26087) was identified (A-2518G)<sup>[15]</sup>. *In vitro* stimulated monocytes from individuals carrying a G-allele at -2518 produced more MCP-1 than cells from A/A homozygous subjects<sup>[15]</sup>. Several further studies have confirmed the functional effect of this single nucleotide polymorphism (SNP)<sup>[13,16-18]</sup>.

The prevalence of high MCP-1 producing genotypes has been shown to be associated with increased susceptibility and severity of several diseases, including bronchial asthma<sup>[19]</sup>, premature kidney graft failure<sup>[20]</sup>, Crohn's disease<sup>[21]</sup>, cutaneous vasculitis<sup>[22]</sup>, and tuberculosis<sup>[16]</sup>. Furthermore, this genetic polymorphism has been shown to be a risk factor for the progression of chronic viral hepatitis C infection<sup>[13]</sup>.

The aim of this study was to analyze the association of this functional promoter SNP of the MCP-1 gene with SBP.

## MATERIALS AND METHODS

### Patients and controls

We studied 106 patients with liver cirrhosis and ascites. Clinical charts of patients diagnosed with chronic liver disease at the medical department of the University of Regensburg during the period 2001-2007 were studied retrospectively. Based on the availability of DNA samples in an established tissue bank, patients were included in the study. Liver carcinoma, other neoplasms or HIV-infection were exclusion criteria. Clinical charts revealed diagnosis of SBP in 23 cases, while no SBP had ever occurred in 83 patients. In the majority of patients, chronic alcohol abuse was the cause of the underlying liver disease (Table 1). In the other patients, chronic hepatitis B or C infection and hemochromatosis were the cause of cirrhosis. Patients were considered to have alcohol related cirrhosis if alcohol intake had been in excess of 100 g/d for more than 10 years and if tests for viral, metabolic, and immune etiologies were negative. Patient characteristics are summarized in Table 1.

As an additional control group, 118 heavy drinkers without evidence of liver damage (90 male, 28 female; mean age: 42.5 ± 9.1 years) were analyzed. These unrelated individuals of German descent were recruited from an in-patient abstention program at the Department of Psychiatry of the University of Regensburg. Each

SBP: Spontaneous bacterial peritonitis.

subject met the criteria of alcohol dependence according to ICD-10 alcohol dependence according to DSM-IV (American Psychiatric Association, 1994) and ICD-10 (World Health Organization, 1992).

At the day of admission, several serum parameters were analyzed, including transaminases (alanine aminotransferase, aspartate aminotransferase,  $\gamma$  glutamyltransferase), and anti hepatitis B virus (HCV)- and hepatitis B virus (HBV)-antibodies. Previous and current drinking habits, family history of non-alcoholic liver diseases, and potential previous complications of advanced liver damages, such as ascites or esophageal varices, were examined. Furthermore, within 14 d after admission a clinical and ultrasound examination of the abdomen was performed. Only alcohol-dependent subjects with an alcohol consumption of at least 100 g/d for more than 5 years were included. Furthermore, clinical or sonomorphological indications for advanced liver damage and serological evidence of HBV or HCV infection were exclusion criteria.

Patients and controls were Caucasians and their geographical origin was Southern Germany. Informed consent was obtained from all patients and the study was approved by the local ethics committee.

### DNA isolation and MCP-1 genotyping

DNA isolation and MCP-1 genotyping were performed as described previously<sup>[13,23]</sup>. Briefly, genomic DNA specimens were prepared from 200  $\mu$ L blood using the QIAamp blood kit, following the manufacturer's instructions (Qiagen, Hilden, Germany). The G to A polymorphisms at position -2518 of the MCP-1 gene was analyzed by performing PCR and restriction fragment length polymorphism analysis. PCR was performed under standard conditions (35 cycles, annealing temperature: 55°C) in a total reaction volume of 50  $\mu$ L containing 2  $\mu$ L of diluted genomic DNA, using the following pair of primers: forward: 5'-CCGAGATGTTCCCAGCACAG-3' and reverse: 5'-CTGCTTTGCTTGTGCCTCTT-3'. PCR products were digested by *Pvu*II, and the resulting fragments were separated by electrophoresis in a 2% agarose gel and visualized by ethidium bromide staining. With the -2518 A polymorphic base, the recognition sequence 5'-CAG/CTG-3' is modified to 5'-CAG/CTA-3', which is not cut by *Pvu*II.

Table 2 Frequencies of -2518 MCP-1 genotypes *n* (%)

-2518 MCP-1 genotype	Cirrhotic patients with ascites ( <i>n</i> = 106)	Patients with alcoholic cirrhosis and ascites ( <i>n</i> = 80)	Heavy drinkers w/o cirrhosis ( <i>n</i> = 118)
A/A	45 (42.5)	32 (40.0)	64 (54.2)
A/G	51 (48.1)	39 (48.8)	47 (39.8)
G/G	10 (9.4)	9 (11.3)	7 (5.9)

### Statistical analysis

Results are expressed as mean  $\pm$  SD (range) or, when indicated, as absolute number and percent. Genotype frequencies are reported with their group percentages. Contingency table analysis and two-sided Fisher's exact tests were used for comparison of qualitative variables.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Characteristics of the study population

The clinical and epidemiological characteristics of SBP patients and cirrhotic control patients are summarized in Table 1. There was no statistical difference between patients with SBP and non-infected cirrhotic patients with ascites with respect to age, distribution of sexes, and serum laboratory findings, such as albumin, bilirubin, or prothrombin activity. However, the percentage of patients with chronic excessive alcohol abuse as the cause of liver cirrhosis was significantly higher in the SBP group (91.3% vs 71.1% in the cirrhosis group,  $P = 0.046$ ), which agreed with previous studies that showed greater susceptibility to infections, especially SBP, in alcohol-induced liver cirrhosis<sup>[24]</sup>.

### Frequency of the -2518 MCP-1 polymorphism in patients and controls

The frequencies of the different MCP-1 genotypes in our cohort of patients with liver cirrhosis and ascites are summarized in Table 2. In addition, genotype distribution in the subgroup of patients with chronic excessive alcohol consumption as an underlying cause of liver disease and cirrhosis is depicted. Furthermore, MCP-1 genotypes were analyzed in heavy drinkers without evidence of liver damage.

The frequency of individual genotypes in the group of heavy drinkers without cirrhosis was similar to those previously reported in other Caucasian control populations<sup>[19,20,22,25]</sup>. Genotype distribution did not differ significantly between the whole group of cirrhotic patients with ascites and the subgroup of patients with alcohol related cirrhosis. However, irrespective of the underlying cause of liver disease, the genotype AA was less frequent in cirrhotic patients with and without ascites (40.0% and 42.5%, respectively) as compared to heavy drinkers without evidence of liver damage (54.2%) although these differences did not reach statistical significance ( $P = 0.084$  and  $P = 0.060$ , respectively).

Most previous *in vitro* and epidemiological studies reported functional and disease-related differences between

Table 3 Frequencies of carriers of the G-allele of the -2518 MCP-1 promoter polymorphism in patients with SBP and cirrhotic control patients with ascites *n* (%)

-2518 MCP-1 genotype	Whole cohort ( <i>n</i> = 106)		Alcoholic cirrhosis ( <i>n</i> = 80)	
	No SBP ( <i>n</i> = 83)	SBP ( <i>n</i> = 23)	No SBP ( <i>n</i> = 59)	SBP ( <i>n</i> = 21)
A/G or G/G	52 (62.7)	9 (39.1)	40 (67.8)	8 (38.1)
A/A	31 (37.3)	14 (60.9)	19 (32.2)	13 (61.9)

-2518 MCP-1 genotypes AA and non-AA (i.e. carriers of the G-allele: genotypes AG and GG); therefore, we continued this differentiation throughout the following analysis and focused on the comparison of patients with no G-allele (AA-homozygotes) and carriers of the G-allele (genotypes AG and GG).

### Frequency of the -2518 MCP-1 polymorphism in patients with and without SBP

In our cohort of 106 patients with ascites, SBP has been diagnosed in 23 individuals (21.7%), while in 83 cirrhotic patients (78.3%), despite mostly long lasting episodes of ascites, no SBP had occurred. The frequency of carriers of the G-allele was lower in the SBP group but this difference did not reach statistical significance [9/23 (39.1%) vs 52/83 (62.7%),  $P = 0.057$ , Table 3]. Also, in the subgroup of patients with alcoholic cirrhosis (*n* = 80), carriers of the G-allele were less frequent in SBP-patients compared to patients without SBP, and in this case, the difference reached statistical significance [8/21 (38.1%) vs 40/59 (67.8%),  $P = 0.021$ , Table 3].

## DISCUSSION

The aim of this study was to analyze the association of the functional MCP-1 promoter polymorphism (A-2518G) with SBP. Interestingly, in patients with alcoholic liver cirrhosis, the genotype AA was significantly more frequent in SBP-patients than in cirrhotic control patients with ascites only. Previously, this MCP-1 genotype has been shown to be associated with reduced MCP-1 release of monocytes *in vitro* and MCP-1 tissue levels *in vivo*, respectively<sup>[13,16]</sup>.

Furthermore, in a previous study<sup>[14]</sup>, MCP-1 levels in ascites were significantly higher when compared with their levels in serum, suggesting a chemotactic gradient towards the peritoneal cavity, even in the absence of infection. This chemotactic gradient could be operative in the chemotaxis of monocytes/macrophages. Antigenic stimuli drive these cells to synthesize further proinflammatory cytokines and chemokines, and thus might also modify the systemic response to the infection. Furthermore, the chemotactic MCP-1 gradient might directly or indirectly favor leukocyte migration towards the peritoneal cavity, even in the absence of infection. We could speculate that in patients with SBP, higher MCP-1 ascites fluid levels are implicated in the infiltration of the peritoneal cavity. Furthermore, in several experimental models of acute peritonitis, high concentrations of MCP-1 have

been shown to have beneficial effects by recruiting macrophages and neutrophils to the site of infection<sup>[26-28]</sup>. Taken together these data indicate that, in patients with alcoholic liver cirrhosis, the -2518 MCP-1 genotype AA is a risk factor for the development of SBP, possibly *via* reduced MCP-1 ascites levels as compared to patients carrying the G-allele.

Interestingly, only in the subgroup of patients with chronic excessive alcohol abuse as the underlying cause of liver cirrhosis was the association between MCP-1 genotype and SBP found. In a previous study, patients with alcohol induced cirrhosis and patients with other hepatopathies showed similar MCP-1 serum and ascitic fluid levels<sup>[14]</sup>.

Notably, carriers of the G-allele of the MCP-1 polymorphism were more frequent in patients with alcohol induced cirrhosis than in heavy drinkers without evidence of liver damage. This difference did not reach statistical significance, but taken together with our previous finding that carrying the -2518 MCP-1 G-allele is a risk factor for disease progression in patients with chronic hepatitis C infection<sup>[13]</sup>, these data indicate that this functional SNP also affects fibrosis progression in patients with alcoholic liver disease. Thus, the same SNP appears to affect two related pathophysiological mechanisms (namely development of cirrhosis and SBP) but to different extents, depending on the underlying liver disease. Inflammatory and immune responses are altered in cirrhotic patients in general<sup>[29,30]</sup>; however, it has to be considered that there are differences between the underlying liver diseases leading to liver cirrhosis. This might be one explanation why it is more difficult to identify an association with the functional MCP-1 polymorphism and SBP in patients with liver disease other than alcoholic liver disease. Furthermore, in patients with alcoholic cirrhosis, the mean endotoxin concentration was significantly higher than in patients with non-alcoholic cirrhosis<sup>[31]</sup>, and bacterial translocation and endotoxin concentration have been shown to play an important role in the pathophysiology of SBP development<sup>[32]</sup>. In addition, it has been shown that LPS downregulates the specific MCP-1 receptor, CCR2, and abolishes macrophage infiltration in an animal model of acute infection<sup>[33]</sup>. Therefore, we speculate that higher LPS levels in patients with alcoholic liver disease are the reason why an association between the -2518 MCP-1 polymorphism and SBP was found only in the subgroup of patients with this underlying liver disease.

Finally, as in most genetic association studies, it has to be considered that the SNP investigated is in linkage disequilibrium to a different disease-associated genetic variation. Theoretically, this potential genetic variation might particularly affect the pathophysiology of alcoholic but not viral or other liver diseases. However, the high levels of MCP-1 in ascites in patients suffering from SBP and the functional relevance of the -2518 MCP-1 polymorphism demonstrated in several studies, argue against this hypothesis.

In summary, this is one of the first genetic association studies in patients with SBP. Our data indicate that the -2518 MCP-1 genotype AA is a risk factor for the

development of SBP in patients with alcoholic cirrhosis. Of course, our results have to be confirmed in a larger cohort of patients with independent and prospective studies. However, it is intriguing to speculate that genotyping might be helpful to identify cirrhotic patients with a higher risk of developing this life threatening complication and to apply prophylactic treatment specifically to this subset of patients.

## COMMENTS

### Background

Spontaneous bacterial peritonitis (SBP) is a potentially life threatening complication in patients with liver cirrhosis and ascites, caused by peritoneal neutrophil infiltration. However, factors leading to enhanced neutrophil infiltration of the peritoneal cavity with consecutive SBP are poorly characterized.

### Research frontiers

Monocyte-chemotactic protein-1 (MCP-1) is an important chemokine for several proinflammatory cells, and there exists a functional single nucleotide polymorphism (SNP) of the MCP-1 promoter (A-2518G) leading to higher MCP-1 expression in carriers of the G-allele. In the present study, the frequency of this MCP-1 SNP was analyzed in patients with SBP and liver cirrhosis.

### Innovations and breakthroughs

Accumulating evidence suggests that genotypes leading to increased MCP-1 production contribute to susceptibility and severity of diseases such as asthma, kidney graft failure, Crohn's disease, cutaneous vasculitis, tuberculosis, and chronic hepatitis C infection. This is the first genetic association study in patients with SBP to show that the -2518 MCP-1 genotype AA is a risk factor to development of SBP in patients with alcoholic cirrhosis.

### Applications

Genotyping of the -2518 MCP-1 SNP in cirrhotic patients might be beneficial to identify patients with increased risk for the development of SBP. Thus, early antibiotic treatment of such patients could help to decrease the mortality of this severe complication in liver cirrhosis.

### Terminology

SBP is an infection of the ascites in patients with liver cirrhosis, diagnosed by a neutrophil count greater than 250/mm<sup>3</sup> in the ascitic fluid. MCP-1 is one of the most potent chemokines for the recruitment of inflammatory cell-types during infection. For example, MCP-1 is upregulated in chronic hepatitis.

### Peer review

This retrospective study identified an association of a genetic polymorphism of the chemokine MCP-1 with increased risk to develop SBP in patients with alcohol-related liver cirrhosis. This is one of the first genetic association studies in patients with SBP and the results might be of high clinical relevance.

### Abstract

**AIM:** To compare the sensitivity and specificity of two imaging techniques, endoscopic ultrasound (EUS) and magnetic resonance imaging (MRI), in patients with rectal cancer after neoadjuvant chemoradiation therapy. And we compared EUS and MRI data with histological findings from surgical specimens.

**METHODS:** Thirty-nine consecutive patients (51.3% Male; mean age:  $68.2 \pm 8.9$  years) with histologically confirmed distal rectal cancer were examined for staging. All patients underwent EUS and MRI imaging before and after neoadjuvant chemoradiation therapy.

**RESULTS:** After neoadjuvant chemoradiation, EUS and MRI correctly classified 46% (18/39) and 44% (17/39) of patients, respectively, in line with their histological T stage ( $P > 0.05$ ). These proportions were higher for both techniques when nodal involvement was considered: 69% (27/39) and 62% (24/39). When patients were sorted into T and N subgroups, the diagnostic accuracy of EUS was better than MRI for patients with

### INTRODUCTION

Endoscopic ultrasound (EUS) is the most accurate imaging technique for evaluating local invasion of rectal cancer and perirectal lymph nodes. Its overall accuracy for T staging before radiation therapy (RT) ranges from 73% to 94%, and from 70% to 80% for N staging<sup>[1]</sup>. The findings of rectal EUS serve to decide the type of treatment: surgery or preoperative chemoradiation (RT-CT)<sup>[2]</sup>. The response to neoadjuvant therapy must also be assessed accurately in patients with rectal cancer.

The benefits of this treatment have been reported in different studies, reporting lower local recurrence rates in patients with locally advanced rectal tumors. Rectal EUS helps select a group with advanced locoregional disease (stage T3 or T4) in whom this preoperative treatment offers most benefit<sup>[3-5]</sup>.

The accuracy of EUS in staging rectal cancer ranges from 80% to 95% compared to 65%-75% for computed

tomography (CT) and 75%-85% for magnetic resonance imaging (MRI)<sup>[6-9]</sup>. There is still debate about the role of cross-sectional imaging to restage rectal cancer after RT-CT, and data are scanty on accuracy, sensitivity, and specificity rates, suggesting that these modalities are not efficient enough for restaging.

The aim of this prospective study was to evaluate the diagnostic accuracy of two imaging techniques, EUS and MRI, in patients with rectal cancer, before and after neoadjuvant RT-CT. We compared the EUS and MRI data with histological findings on surgical specimens.

## MATERIALS AND METHODS

Over a 2-year period (January 2007 to January 2009), 50 patients with histologically confirmed distal rectal cancer were referred to our Unit for rectal endosonography to stage the disease. Out of these, thirty-nine consecutive cases (51.3% Male; mean age:  $68.2 \pm 8.9$  years) were enrolled (drop-out from the study: 11 patients).

Both examinations were done, in random order, by two experienced endosonographers (> 300 rectal examinations/year) and an expert radiologist, before and after RT. The second examiner was blind to the first one's conclusions. Patients were included in the study if they had rectal cancer shown by either EUS or MRI, and were scheduled for neoadjuvant RT.

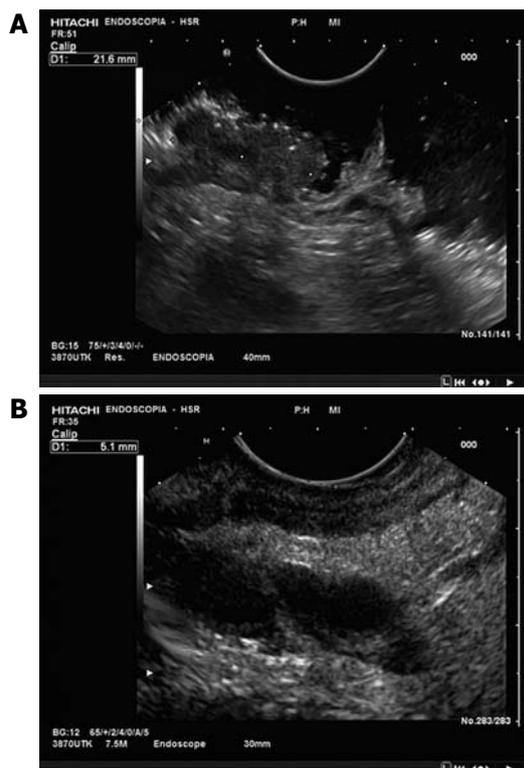

Usually, 30-40 d after termination of the RT protocol, patients were re-assessed by either EUS or MRI, followed by surgical excision during the same week. All patients gave informed consent.

Subjects with a history of rectal surgery, recurrent rectal cancer, or severe systemic illness were excluded from the study. Ten patients had neoplastic sub-stenosis of the lumen; therefore, it was not possible to evaluate their iliac lymph nodes by EUS.

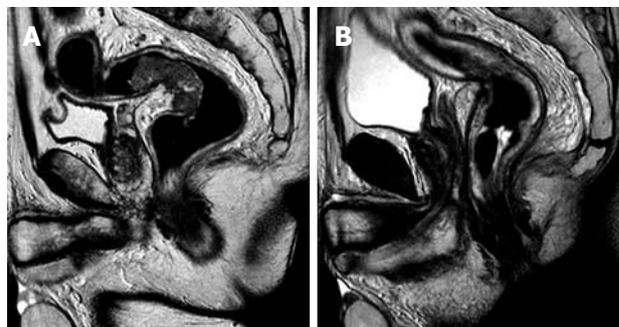

These two subgroups were formed to see whether the diagnostic accuracy of EUS or MRI was related to the tumor T stage after RT.

**EUS protocol:** Rectal EUS was performed using an oblique-forward viewing echo-endoscope (Pentax: FG-G36UX, FG-38UX, EG-3630U). All examinations were done with the patient lying on the left side under conscious sedation (midazolam i.v.). Patients were prepared with colonic lavage before EUS. The echo-endoscope was inserted and advanced beyond the lesion, under direct vision, to the rectosigmoid junction, high enough to detect iliac vessels on the EUS picture. Tumors were targeted to determine the depth of infiltration into or through the rectal wall. Frequencies commonly employed ranged from 7.5 to 10 MHz (Figure 1).

**MRI protocol:** All MRI examinations were performed on a 1.5T MRI scanner (Gyrosan Intera, Philips, The Netherlands). Iron contrast medium rectal distension and IM hypotonizing medication were performed. MRI examinations were performed before and after iv contrast media infusion (0.2 mL/kg). Multiplanar TSE T2 weighted sequences (TR: 4450, TE: 120, matrix:  $512 \times 344$ , NSA: 6, FOV: 240) were performed in order to local

**Figure 1 Rectal EUS.** A: Before neoadjuvant chemoradiation treatment: evidence of perirectal fat tissue invasion, with fat specculation; B: After neoadjuvant chemoradiation treatment: reduction of tumor size and perirectal fat invasion.

**Figure 2 Rectal MRI.** A: Before neoadjuvant chemoradiation treatment: evidence of perirectal fat tissue invasion, with fat specculation, and enlarged mesorectal lymph nodes; B: After neoadjuvant chemoradiation treatment: reduction of tumor size, perirectal fat invasion, enlarged lymph nodes; non-homogeneous mesorectal fat tissue.

stage rectal cancer; axial TSE T2 weighted sequences (TR: 3950, TE: 80, matrix:  $528 \times 372$ , NSA: 3, FOV: 370) were performed to analyze the presence of pathological lymph nodes (N). Axial FFE T1 weighted sequences (TR: 196, TE: 4.6, matrix:  $320 \times 216$ , NSA: 4, FOV: 250) with and without Fat Saturation, before and after contrast medium and sagittal FFE T1 weighted sequences (TR: 196, TE: 4.6, matrix:  $320 \times 216$ , NSA: 4, FOV: 250) with Fat Saturation, after contrast medium, were also performed. The MRI protocol used in our hospital is very similar to that commonly reported in the literature. Our Institute can be considered a medium-high flow hospital for rectal cancer staging; in fact, we performed at least 50 rectal contrast enhanced MRI in 1 year (Figure 2).

T4N0	0	0
T4N1	0	0
T4N2	0	0

**Neoadjuvant chemoradiation treatment:** Chemoradiotherapy consisted of administration of Oxaliplatin 100 mg/m<sup>2</sup> every 2 wk for three courses plus continuous infusion of 5-FU 200 mg/m<sup>2</sup>/die for six consecutive weeks. Concomitant hyperfractionated radiotherapy at a total dose of 45 Gy (1.25 Gy twice daily for 5 d every week with a four-field box technique, with 6-18 MeV photons) was started the same day as the second course of Oxaliplatin. EUS and pelvic MRI were repeated just before surgery to establish the clinical response.

**Surgical treatment:** Laparoscopic or laparotomic nerve sparing surgical resection (either low anterior or abdomino-perineal resection) with total mesorectal excision (TME) was scheduled 6-8 wk after completion of neoadjuvant treatment. Criteria for sphincter preservation were acceptable sphincter function, assessed with preoperative rectal manometry; and absence of direct invasion of the sphincter apparatus. These criteria remained unchanged throughout the treatment period. Creation of temporary loop ileostomy or colostomy was performed in selected cases as judged necessary by the surgeon.

### Rectal cancer staging

Rectal tumors were staged using the tumor-node-metastasis system (TNM)<sup>[10]</sup>.

### Statistical analysis

Pre-operative EUS and MRI findings were compared to assess the concordance between the two methods.  $\kappa$ -statistics were used to check how well EUS and MRI classified subjects in the T and N stage groups. The degree of agreement was quantified by weighted  $\kappa$ , which assumes the categories (T1, T2, *etc.*) are ordered and accounts for how far apart EUS and MRI are in classifying them.

EUS and MRI were repeated after RT, and the findings were compared with the T and N stages established on the basis of histological examination of surgical specimens. The proportions of concordant results between each method and histology were compared using the  $\chi^2$

**Table 2** Diagnostic accuracy (T and N-stage)

	All T	T0-T2	T3-T4	All N	N0	N 1-2
<i>n</i>	39	18	21	39	23	16
MRI	44%	33%	52%	62%	52%	75%
EUS	46%	44%	48%	69%	87%	44%

MRI: Magnetic resonance imaging; EUS: Endoscopic ultrasound.

test (2 × 2 table). Patients were considered all together and sorted into two subgroups according to their histological T stage: the first group had T0-T2 stage cancer and the second T3-T4.

## RESULTS

After neoadjuvant chemoradiation therapy, histological examination of surgical specimens was done for all patients, with the following results: 9 T0; 1 T1; 8 T2; 21 T3. Nodal involvement was N0 in 23; N1 in 14; N2 in 2. There were 18 patients with T0-T2 disease, 21 T3 (no T4), 23 without nodal metastasis (N0 disease) and 16 with N1-N2 disease. EUS and MRI correctly classified patients in line with their histological T stage in 46% (18/39) and 44% (17/39) (NS) of cases, respectively. These proportions were higher for both techniques when nodal involvement was considered: staging was correct in 69% (27/39) and 62% (24/39). Interestingly, when patients were sorted into T and N subgroups, the diagnostic accuracy of EUS was better than MRI for patients with T0-T2 (44% *vs* 33%, NS) and N0 disease (87% *vs* 52%,  $P = 0.013$ ). However, MRI was more accurate for patients with more advanced disease (both T and N) after RT, though these differences did not reach statistical significance (Tables 1 and 2).

## DISCUSSION

The prognosis for rectal cancer strongly correlates with the histopathological stage at diagnosis. Many imaging techniques are available, but each one differs in accuracy and applicability<sup>[11-13]</sup>. Accurate staging is important for planning surgery and deciding on adjuvant treatment.

ERUS (endorectal ultrasound) and MRI are considered to be the most accurate modalities for determining local tumor stage. Two recent meta-analyses have compared EUS, CT and MRI for rectal cancer staging. Bipat *et al*<sup>[14]</sup> found that ERUS was the most accurate modality when compared with CT and MRI for the evaluation of the T stage in rectal cancer. For lymph node involvement, the results of ERUS, CT and MRI were comparable. However, the T-staging system does not discriminate between T3 tumors with close or involved circumferential resection clearance. In this meta-analysis, the distance of the tumor from the rectal fascia or the anticipated circumferential resection clearance was not evaluated. Lahaye *et al*<sup>[15]</sup> conducted another meta-analysis regarding the accuracy of preoperative imaging for predicting the two most important risk factors that they recognized for local recurrence in rectal cancer; the circumferential resection

clearance and the lymph node status. Major progress has been made in the preoperative staging in rectal tumors by MRI and several authors have indicated that a tumor-free circumferential clearance of more than 1 mm can be predicted using this method. For nodal status, ERUS was slightly, but not significantly, better than MRI.

The introduction of trans-rectal EUS has made it easier to see the pattern of the layers of the rectal wall, improving treatment allocation by establishing the depth of tumor invasion more accurately<sup>[16-18]</sup>. EUS is the most accurate tool for evaluating local invasion of rectal cancer and perirectal lymph nodes. Its overall accuracy before radiation ranges from 73% to 94% in T staging, and from 70% to 80% in N staging. Comparative studies found EUS very accurate in staging rectal cancer from 80% to 95%, compared to 65% to 75% for CT and 75% to 85% for MRI<sup>[6-9]</sup>.

CT and MRI have proved disappointing for detecting small neoplastic lesions. MRI is not significantly superior to CT because of the limited resolution of conventional MRI techniques. It has, however, been reported useful in determining the status of the circumferential resection margin (meso-rectum), which is important for assessing the risk of local recurrence<sup>[19]</sup>.

Recent data suggest that EUS staging of rectal cancer after RT-CT is inaccurate<sup>[1]</sup>, while MRI seems to be cost-effective in selecting appropriate patients for neoadjuvant therapy and its use is justified for local staging. After RT-CT, EUS and MRI might be useful to demonstrate tumor shrinkage and down-staging in responsive tumors, which might occasionally disappear completely<sup>[17,18,20-23]</sup>. Increasing reflectivity and signal changes indicate fibrosis, but unless significant tumor bulk remains, neither modality seems to be able to exclude the persistence of tumor cells within fibrosis<sup>[24-28]</sup>.

Finally, EUS-FNA (endoscopic ultrasound-guided fine-needle aspiration) was proposed for N staging of rectal cancer following neoadjuvant chemoradiation<sup>[29]</sup>.

This study compared rectal EUS and MRI for staging rectal cancer before and, in particular, after neoadjuvant RT-CT. As reported in other studies, at the first staging examination after the diagnosis of rectal cancer, EUS and MRI offer similar accuracies. However, if we consider the degree of agreement between the two procedures in rectal cancer, EUS (without lymph node biopsy) and MRI give concordant results in T and N staging only in 64% and 54% of patients. Moreover, they only give concordant results for both T and N stages in one third of patients. The strength of agreement between EUS and MRI in staging advanced rectal cancer was very poor, implying that each method has limitations.

After RT, both EUS and MRI offered poor diagnostic performance in the assessment of T and N stages compared to the "gold standard", i.e. histological examination of surgical specimens. In the present study, compared to MRI, EUS offered significantly superior diagnostic accuracy in assessing nodal involvement after RT, giving much better results in patients with N0 disease. A higher proportion of false-positive results of MRI in patients without

**Figure 3** Rectal EUS and elastosonography before neoadjuvant chemoradiation treatment. Elastography showing hard tissue inside the lesion.

nodal metastasis are probably due to the effects of RT on perirectal tissues (edema, inflammation, and fibrosis), which renders MRI unreliable for excluding nodal disease. Both methods were weak in restaging the persistence and degree of tumor invasion of the rectal wall, and this might be mainly due to microscopic persistence (under-staging) in the wall or to inflammatory and scar changes in perirectal fat (over-staging). These might explain the lower sensitivity and accuracy of both methods in restaging after RT.

The recent development of elastosonography, a new real-time EUS modality that gives a fairly qualitative image of tissue elasticity, might improve the accuracy and sensitivity of EUS in this setting. In a preliminary report, we showed that adding elastosonography to real-time EUS boosted the accuracy in T staging of the disease<sup>[30]</sup>. The ability of elastosonography to distinguish tissues with different levels of elasticity means it can detect inflammatory (soft) tissues and tumor (hard) separately, particularly when the real-time modality does not exclude the suspicion of perirectal invasion (Figure 3).

Therefore, in the modern era of GI-oncology it seems that patients benefit mostly from interdisciplinary approaches. In considering the value of a diagnostic technique, based on its ability to influence the therapeutic choices by allowing a better selection of patients, we believe that in this situation these two modalities are complementary.

In conclusion, EUS and MRI are both accurate for staging rectal cancer. In particular, in pre-therapy staging, EUS is a good modality for T staging while MRI obtains other information, including the clearance. However, after RT-CT, neither method is reliable for establishing the T stage. EUS seems significantly better than MRI for assessing the N stage, but until significant improvements in both methods are achieved, their use in this setting should be considered only in controlled trials.

## COMMENTS

### Background

Endoscopic ultrasound (EUS) and magnetic resonance imaging (MRI) are both accurate for staging rectal cancer. However, after radiation therapy-computed tomography (RT-CT), neither method is reliable for establishing the T stage. EUS

seems significantly better than MRI for assessing the N stage but until significant improvements in both methods are achieved, their use in this setting should be considered only in controlled trials.

### Innovations and breakthroughs

This study compared rectal EUS and MRI for staging rectal cancer after neoadjuvant RT-CT.

### Peer review

This study compared rectal EUS and MRI for staging rectal cancer after neoadjuvant RT-CT and provides a good basis for selecting the best surgical or medical strategy in patients with rectal cancer.

### Abstract

**AIM:** To evaluate routine modified D2 lymphadenectomy in gastric cancer, based on immunohistochemically detected skip micrometastases in level II lymph nodes.

**METHODS:** Among 95 gastric cancer patients who were routinely submitted to curative modified D2 lymphadenectomy, from January 2004 to December 2008, 32 were classified as pN0. All level I lymph nodes of these 32 patients were submitted to immunohistochemistry for micrometastases detection. Patients in whom micrometastases were detected in the level I lymph node stations ( $n = 4$ ) were excluded from further analysis. The level II lymph nodes of the remaining 28 patients were studied immunohistochemically for micrometastases detection and constitute the material of the present study.

**RESULTS:** Skip micrometastases in the level II lymph nodes were detected in 14% (4 out of 28) of the patients. The incidence was further increased to 17% (4 out of

24) in the subgroup of T1-2 gastric cancer patients. All micrometastases were detected in the No. 7 lymph node station. Thus, the disease was upstaged from stage I A to I B in one patient and from stage I B to II in three patients.

**CONCLUSION:** In gastric cancer, true R0 resection may not be achieved without modified D2 lymphadenectomy. Until D2+/D3 lymphadenectomy becomes standard, modified D2 lymphadenectomy should be performed routinely.

### INTRODUCTION

The lymphatic stream from a gastric tumor is wide and complicated, thus the exact pattern of lymphatic drainage remains obscure and poorly understood. However, histologically confirmed metastatic infiltration of perigastric and extragastric lymph nodes has been defined as the strongest independent dismal prognostic factor for both early<sup>[1]</sup> and large<sup>[2]</sup> gastric cancer patients.

Micrometastases and/or isolated tumor cells have been reported as immunohistochemically detectable in 10% of early gastric cancer patients<sup>[3]</sup>, in 52.6% of T2N0 patients<sup>[4]</sup>, and in 21%<sup>[5]</sup> to 49%<sup>[6]</sup> of all node-negative gastric cancer patients.

Skip metastases are defined as the detection of metastatically infiltrated extragastric lymph nodes (level II), in the absence of perigastric lymph node (level I) involve-

ment<sup>[7]</sup>. Particularly in the subgroup of level I lymph node negative patients, the incidence of histologically detected metastases in the level II lymph nodes (skip metastases) ranges between 2.8% in cases of early<sup>[7]</sup> and 5%<sup>[8]</sup> to 17.4%<sup>[9]</sup> in all other gastric cancers. Moreover, even in patients with histologically classified level I lymph node negative early gastric cancer, micrometastatically infiltrated level II lymph nodes are immunohistochemically detected in 10% of them<sup>[10]</sup>.

Most authors<sup>[11-13]</sup> agree that, except for early gastric cancer patients<sup>[3]</sup>, patients with immunohistochemically detected micrometastases have significantly worse 5-year survival rates compared to patients with undetectable micrometastases. However, the incidence, clinical implications and clinical significance of skip micrometastases in level II extragastric lymph nodes in patients with gastric cancer have not been properly studied.

The aim of the present study was to evaluate retrospectively the necessity for routine modified D2 lymphadenectomy in all gastric cancer patients, (as a prerequisite for R0 resection for locoregional control of the disease), based on the immunohistochemical detection of micrometastases in level II lymph node stations in patients who had been classified histologically and immunohistochemically as level I lymph node negative and histologically as level II lymph node negative.

## MATERIALS AND METHODS

Between January 2004 and December 2008, 207 patients with a preoperative diagnosis of gastric adenocarcinoma were subjected to surgery with curative intent, in our department. None of them had undergone preoperative chemotherapy or radiotherapy. In 95 patients, a modified D2 lymphadenectomy was offered as the standard surgical procedure. Postoperatively, the standard histological examination by hematoxylin and eosin (HE) staining disclosed metastatic infiltration of at least one lymph node in the level I or II lymph node stations in 63 of these patients. Thirty-two patients were classified as pN0, since standard histology did not disclose any evidence of metastatic infiltration of level I and level II peri- and extragastric lymph node stations. All level I lymph nodes of these 32 patients were submitted to immunohistochemistry for micrometastases detection. Patients in whom micrometastases were detected in the level I lymph node stations ( $n = 4$ ) were excluded from further analysis.

The level II lymph nodes of the remaining 28 patients were studied immunohistochemically for micrometastases detection and constituted the material of the present study.

### **Surgical technique**

The proximal resection margin of the stomach was calculated according to the location of the primary tumor. At least a 6-cm tumor-free (based on the frozen section result) proximal resection margin from the most proximal macroscopic border<sup>[14]</sup> was achieved in all cases. The dissection of the regional lymph nodes was based on the

Japanese Classification of Gastric Carcinoma<sup>[15]</sup>. Thus, for D1 lymphadenectomy, the appropriate (depending on the location of the primary tumor) nos. 1-6 lymph node stations were included in the gastrectomy specimen, whereas in the modified D2 lymphadenectomy, the nos. 7, 8a, 9, 11p, 11d and 12a lymph node stations, were routinely dissected. The level II lymph node stations were recognizable as they had been sent separately to the Pathology Department with special indices demonstrating their exact location. Dissection of the No. 10 lymph node station, splenectomy or distal pancreatectomy was not performed in any of the patients. For staging of the tumors, the TNM classification system according to the AJCC Staging Manual, 6th edition, was used<sup>[16]</sup>.

### **Histopathology and immunohistochemistry**

Primary tumors and lymph nodes were fixed in formalin and embedded in paraffin. The presence or absence of lymph node metastasis was examined routinely by HE staining by using a representative cut section through the largest diameter of the lymph nodes.

One additional section of 4- $\mu$ m thickness from each node was prepared for immunohistochemical staining with a monoclonal anti-cytokeratin (CK) antibody cocktail (AE1/AE3; Dako, Glostrup, Denmark) that reacts with a broad spectrum of human CKs, to detect micrometastases and/or clusters of isolated tumor cells. Briefly, for AE1/AE3 immunostaining, paraffin-embedded sections were deparaffinized in xylene and rehydrated through graduated ethanol to water. Endogenous peroxidase activity was blocked by incubation for 30 min with a solution of 1% hydrogen peroxide, and antigen retrieval was performed by autoclaving sections in 0.01 mol/L citrate buffer, pH 6.0 for 20 min at 800 W. A monoclonal mouse anti-human CK antibody (clone AE1/AE3) was applied at a dilution of 1:50. The Dako Real Envision kit was then used. Diaminobenzidine was used as a chromogen. Lymphoid tissue was used as an internal negative control, while additional sections from the primary tumors were used as positive controls.

Based on the 6th TNM classification<sup>[16]</sup>, micrometastasis (N1mi) was defined as metastatic focus  $> 0.2$  mm but  $\leq 2$  mm, and cluster of tumor cells [N0 (+)] was defined as cluster  $< 0.2$  mm according to previously accepted conventions.

## RESULTS

Pathologic review did not detect patients with previously missed evidence of lymph node metastasis on conventional HE staining.

In four patients, micrometastases were detected in the level I lymph node stations. These patients were excluded from further analysis.

The remaining 28 patients were 16 men with a median age of 72.5 years (IR 69-75) and 12 women with a median age of 66.5 years (IR 58-69.5) (Table 1). Skip micrometastases in the level II lymph node stations were immunohistochemically detected in four patients ( $n = 4$ ). All micrometastases were detected in the No. 7 lymph node station.

Table 1 Characteristics of the study population

Parameter	n
Sex	16
Males	12
Females	0
Age (yr) (median + IR)	70.5 (63.5-74)
Tumor location	
Upper third	0
Middle third	6
Lower third	22
Histological type (WHO classification)	
Enteric type	19
Diffuse type	5
Mixed type	4
Differentiation	
High	4
Moderate	19
Low	5
T	
T1	4
T2	20
T3	4

The profiles of these patients are presented in Table 2. There were three female and one male patients, with T1 ( $n = 1$ ), T2a ( $n = 2$ ) and T2b ( $n = 1$ ) tumors, located in the lower third ( $n = 2$ ) or middle third ( $n = 2$ ) of the stomach. Thus, following micrometastases detection, the disease was upstaged from stage I A to I B in one patient and from stage I B to II in three patients.

Based on the above, the overall incidence of micrometastases detection was 25% (8 out of 32 patients), while skip micrometastases in the level II lymph nodes were detected in 14% (4 out of 28) of gastric cancer patients, who had been classified histologically and immunohistochemically as level I lymph node negative. Furthermore, the incidence of skip micrometastases was increased to 17% (4 out of 24) in the subgroup of T1-2 gastric cancer patients.

## DISCUSSION

The present study disclosed that skip micrometastases in the level II lymph node stations were detected in 14% (4 out of 28) of the patients, who had been classified histologically and immunohistochemically as level I negative. This incidence was further increased to 17% (4 out of 24 patients) in the subgroup of T1-2 gastric cancer tumors.

Despite AJCC/UICC guidelines, which require the pathological examination of at least 15 lymph nodes for accurate gastric cancer staging<sup>[16]</sup>, only 29% of gastric cancer patients had more than 15 lymph nodes retrieved<sup>[17]</sup>. However, D2 lymphadenectomy clearly offers the mean number of the required lymph nodes for pathological examination, independently to the pathologist<sup>[18]</sup>.

Although D2 lymphadenectomy is recommended by the Japanese Surgical Society as the surgical option for gastric cancer treatment<sup>[19]</sup>, its performance has not gained popularity worldwide, since prospective randomized studies<sup>[20-24]</sup> and meta-analysis<sup>[25]</sup> have revealed significantly higher postoperative morbidity and mortality

rates and no 5- and 11-year survival benefit compared to D1 lymphadenectomy.

D2 lymphadenectomy increases the long-term survival of gastric cancer patients with lymph node metastases, however, it has been proposed as unnecessary for patients without lymph node metastases<sup>[9]</sup>. On the other hand, D2 lymphadenectomy improves survival even in node-negative early gastric cancer patients, probably due to the resection of the coexisting micrometastases<sup>[26]</sup>.

Thus, the favorable overall survival rates which were published following the Japanese-type, compared to the Western-type gastric cancer surgery, indicate that, with more extended lymph node dissections, more R0 resections are achieved<sup>[27]</sup>. This probably leads to locoregional control of the disease, better outcome and increased survival<sup>[28]</sup>.

Three methods have been used for the identification of micrometastasis, serial sectioning, immunohistochemical staining, and reverse-transcriptase polymerase chain reaction (RT-PCR). Serial sectioning constitutes a histological method, which can detect lymph node metastasis previously missed by the conventional technique, but it may still fail to identify isolated tumor deposits<sup>[13]</sup>. RT-PCR has been reported as highly sensitive<sup>[29]</sup>, but it is compromised by false-positive results caused by biological contamination<sup>[30]</sup>. Positive RT-PCR results indicate the presence of tumor DNA, however, they may not indicate the presence of viable tumor cells<sup>[31]</sup>. Thus, immunohistochemistry with human anti-CK antibodies represents the most accurate method for micrometastasis detection<sup>[32]</sup> and the most frequently applied technique in research<sup>[3]</sup>. One limitation of the method is CK expression by some dendritic cells in the lymph nodes<sup>[33]</sup>.

Based on the results of studies in colorectal<sup>[34]</sup> and non-small cell lung cancer<sup>[35]</sup>, it has been proposed that N1(-)/N2(+) patients represent a subgroup of pN2 disease with more favorable prognosis<sup>[35]</sup>. However, the clinical significance of skip metastases in gastric cancer patients remains controversial. The controversies are related mainly to the small number of patients enrolled in skip metastasis studies<sup>[26]</sup>, the probably different prognosis of patients with histologically *vs* micrometastatically detected skip metastases<sup>[32]</sup>, and the concern that patients with histologically detected skip metastases may represent cases of overlooked histological metastasis or micrometastasis in level I lymph nodes, thus being misclassified as patients with skip metastasis<sup>[36]</sup>.

Saito *et al*<sup>[36]</sup> have reported 5-year survival rates of 70.2%, 62.0% and 31.2% in patients with skip metastases, metastases in level I lymph nodes and metastases in level II lymph nodes, respectively. The prognosis of patients with metastases in the level II lymph nodes was significantly worse than that of the patients with either skip metastases or metastases in the level I lymph nodes. The authors have indicated that the clinicopathological characteristics and the prognosis of patients with skip metastases were similar to patients with level I lymph node metastases, but not to the patients with level II lymph node metastases. On the other hand, Li *et al*<sup>[9]</sup> have concluded that the cumulative survival rate is not statistically different between gastric cancer patients with solitary skip lymph node metastases, compared to

Table 2 Profiles of the patients with skip micrometastases

Pt	Sex	Age (yr)	No. of LN retrieved	(+) LN station	Location of the tumor	T size (mm)	T stage	Histological type	Lymphatic invasion	Vessel invasion
1	F	62	51	7	L, post	4	T2b	Mixed	+	-
2	F	56	16	7	M, less	30	T1	Diffuse	-	-
3	M	54	38	7	M, less	17	T2a	Enteric	-	-
4	F	71	29	7	L, post	26	T2a	Diffuse	-	-

Pt: Patient; LN: Lymph node; T: Tumor; L: Lower third; M: Middle third.

patients with solitary level I lymph node metastases. Moreover, Park *et al.*<sup>[26]</sup> have reported that, in patients with positive nodes extending into the level II lymph nodes, the survival curves did not show significant differences between skip(+) and skip(-) groups of patients, which further supports the theory that the number but not the level of lymph node metastases has prognostic significance.

The result of the present study, that all skip micrometastases were detected in the left gastric artery lymph node station, probably indicates that the clinical application of the sentinel node biopsy technique in selected cases might be useful, and lead to selective lymphadenectomy. Although the method has been reported as highly accurate (< 10% false-negative results) in breast cancer surgery<sup>[37]</sup>, similar findings have not been confirmed in gastric cancer surgery, since 20%-36% of positive lymph nodes were located outside of the sentinel lymph node basin<sup>[38]</sup>. Thus, the method is recommended currently to be used in conjunction with D2 lymphadenectomy<sup>[39]</sup>.

It has been suggested that the most likely route for para-aortic lymph node metastases is from the left gastric artery nodes, passing by the celiac artery<sup>[40]</sup>. Other common sites of skip metastasis are the 8a and 9 lymph nodes (around the celiac artery). Thus, these lymph nodes should always be evaluated, regardless of the mode of operation, even in the case of minimally invasive surgery. Moreover, Yanagita *et al.*<sup>[41]</sup> have investigated the clinical significance of morphological distribution of metastatic foci (metastasis, micrometastasis or isolated tumor cells) in sentinel lymph nodes with gastric cancer, and have concluded that, in patients with non-marginal sinus type sentinel node metastasis, attention should be paid to the possibility of non-sentinel node or even pN2 metastases. Thus, if the sentinel node cannot be identified in the perigastric lymph nodes, those around the celiac artery lymph nodes should be explored to reduce the likelihood of false-negative results in sentinel node mapping<sup>[7]</sup>.

In conclusion, the present study addressed the fact that, in up to 17% of T1-2 gastric cancer patients, true R0 resection may not be achieved without modified D2 lymphadenectomy. Thus, until D2+ or even D3 lymphadenectomy becomes the standard surgical option, modified D2 lymphadenectomy should be considered as the surgical option of choice in gastric cancer patients.

## COMMENTS

### Background

R0 resection constitutes the prerequisite for the locoregional control of gastric

cancer. However, the extent of the oncologically required lymphadenectomy (D1 or D2) remains a matter of debate and contradictory results have been published.

### Research frontiers

True R0 resection is characterized by complete resection of all viable tumor cells. As histology detects metastases > 2 mm, immunohistochemistry can detect micrometastases between 0.2 and 2 mm or even isolated tumor cells.

### Innovations and breakthroughs

Immunohistochemistry with human anti-cytokeratin antibodies showed clearly that, in level II extragastric lymph nodes, viable tumor deposits (skip micrometastases) were present in 17% of the gastric cancer patients who had been classified previously as node-negative by conventional histology.

### Applications

By understanding that, without modified D2 lymphadenectomy, true R0 resection may not be achieved, the present study indicates the usefulness of routine modified D2 lymphadenectomy in all gastric cancer patients.

### Terminology

Modified D2 lymphadenectomy offering the mean number of the required lymph nodes for pathological examination, contributes to accurate staging of the disease, probably defying the subgroups of patients who may benefit from adjuvant therapy.

### Peer review

The authors suggest that D2 lymphadenectomy might be necessary for complete resection of T1-2 N0 gastric cancer, which highlights clearly that skip metastases may be an overlooked problem with standard resection performed routinely in many countries.

### Abstract

**AIM:** To compare the results of the anoscope of the PPH kit and a modified anoscope during stapled haemorrhoidopexy.

**METHODS:** The hospital records of 37 patients who underwent stapled haemorrhoidopexy between 2001 and 2006 were reviewed. The purse-string suture anoscope in the PPH kit was used on 15 patients (Group 1), and the modified anoscope was used on 22 patients (Group 2). Demographic characteristics of the patients, operation time, surgeon's performance, analgesic requirement, and complications were compared.

**RESULTS:** Operation time was significantly longer in Group 1 ( $42.0 \pm 8.4$  min vs  $27.7 \pm 8.0$  min,  $P = 0.039$ ). The surgeons reported their operative performance as significantly better in Group 2 (the results of the assessments were poor in ten, medium in four and good in one in Group 1, while good in all patients in Group 2,  $P < 0.001$ ). The need for haemostatic sutures was significantly higher in Group 1 (six cases) and was needed in two cases in Group 2 ( $P = 0.034$ ).

**CONCLUSION:** Operation time decreased and the

### INTRODUCTION

Stapled haemorrhoidopexy is not only a safe method that can be compared with conventional haemorrhoidectomy procedures, but also has advantages such as reduced postoperative pain and early return to work<sup>[1,2]</sup>. Moreover, some studies suggest the applicability of stapled haemorrhoidopexy as a day case procedure<sup>[3]</sup>. However, some complications were noted after stapled haemorrhoidopexy, such as rectal perforation, intra-abdominal haemorrhage, recto-vaginal fistula, and perirectal haematoma. These complications are not observed after conventional haemorrhoidectomy. In addition, although stapled haemorrhoidopexy is the most recent surgical method for the treatment of haemorrhoidal disease, the number of patients that developed pelvic sepsis after this surgical technique has reached the same number as after conventional haemorrhoidectomy<sup>[4-8]</sup>. It was suggested that these serious complications could be due to technical errors and could be avoided by eliminating the bite of the suture in deep layers of the rectum<sup>[9]</sup>.

The ideal purse-string suture must enable removal of a ring of the desired thickness from the most appropriate part of the rectum. One major obstacle to the surgeon during the operation is blockage of vision due

to internal haemorrhoids. If these internal haemorrhoids can be eliminated, then optimal purse-string suture can be performed<sup>[10]</sup>. Some studies suggest that after modification of the anoscope of the PPH stapler kit (Ethicon Endo-Surgery, Cincinnati, OH, USA), purse-string suture applications have been performed with relative ease<sup>[10-12]</sup>.

We first performed the stapled haemorrhoidopexy procedure in our clinic in 2001. We noticed the need for a modification of the anoscope of the PPH kit due to difficulties during the placement of the purse-string suture<sup>[10,11]</sup>. Subsequently, we tried several modifications of the anoscope and using the modified anoscope, purse-string sutures were performed with ease, and stapled haemorrhoidopexy was completed effectively.

In this study, the surgical findings and early postoperative results of patients in whom the purse-string suture anoscope of the PPH kit was used were compared with those of patients in whom the modified anoscope was used during stapled haemorrhoidopexy.

## MATERIALS AND METHODS

Hospital and follow-up records of patients with grade III and IV haemorrhoidal disease who underwent stapled haemorrhoidopexy in our clinic between 2001 and 2006 were reviewed retrospectively. Gender, degree of haemorrhoidal disease, preoperative treatment, operation time, performance of the surgeon, analgesic requirement, haemostatic sutures, histopathological examination of the excised ring, postoperative complications, and hospital stay were evaluated. Patients with associated proctological diseases such as anal abscess, anal fissure and fistula were excluded from the study. The patients were informed about the details of the procedure and written informed consent was obtained. The patients were grouped as: (1) the patients on whom the purse-string suture anoscope in the PPH kit was used (PA group), and (2) the patients on whom the modified anoscope was used (MA group). The modified anoscope was sterilized by ethylene oxide before use in each patient. The purse-string suture technique which has been described previously, was used in the MA group<sup>[10,11]</sup>. Stapled haemorrhoidopexy was completed using the stapler in the PPH (Ethicon Endo-Surgery, Cincinnati, OH, USA) kit in both groups. In the PA group, the surgeon waited for 30 s with the stapler closed after firing the stapler to ensure haemostasis. In the MA group, the surgeon waited for a total of 3 min, 90 s before and 90 s after firing the stapler. In the MA group, some of the operations were performed by inexperienced surgeons under the supervision of an experienced surgeon, whereas in the PA group an experienced surgeon performed the operations. The procedures were performed by six general surgeons, three of which were experienced. Diclofenac sodium 75 mg, IM was administered on demand after surgery, and pethidine HCl 50 mg, IM was given if diclofenac was insufficient. Patient age, gender, degree of haemorrhoidal disease, previous medical or surgical treatments, previous blood transfusions, histo-

pathological evaluation of the excised ring, the performance of the surgeons, postoperative analgesic requirement, early (during the first 30 d) or late (after the first 30 d) complications in both groups were investigated, and the differences between the groups were analyzed statistically.

In the first few postoperative hours, the surgeons were asked two questions in order to evaluate the procedure: Was the anoscope simple to use during the manipulation, and how would you evaluate your performance during the procedure? The surgeons who performed the operations were asked to evaluate their performances as good, moderate, or poor. The surgeons who performed operations in both groups evaluated their performances by making comparisons with their earlier experiences, however, the surgeons who performed operations only in Group 2 made their decisions without comparisons.

## Statistical analysis

SPSS 10.0 was used for statistical analysis. Considering numerical values, Student's *t* test was used for parametric measurements, and Mann Whitney *U* test for non-parametric measurements. Considering categorical values, Pearson's Chi-Square test was applied for parametric measurements and Fisher's exact correct test for non-parametric measurements. A *P* value less than 0.05 was considered statistically significant.

## RESULTS

The records of 37 patients, who underwent stapled haemorrhoidopexy for the treatment of haemorrhoidal disease were investigated. Two types of anosscopes were used to aid purse-string suture application: the purse-string anoscope in the PPH kit was used on 15 patients (40.5) between September 2001 and March 2004, and the modified anoscope was used on 22 patients (59.5) between December 2003 and May 2006.

Mean age of the patients was  $47.9 \pm 15.2$  years (range, 27-78 years), and  $49.0 \pm 11.9$  years (range, 30-70 years) for the PA group and the MA group, respectively. There were 11 male and four female patients in the PA group and 17 male and five female patients in the MA group. There were no statistically significant differences between the two groups with respect to age ( $P = 0.802$ ) and gender ( $P = 0.541$ ). Mean duration of complaints was  $94.8 \pm 83.5$  mo (range, 6 mo-20 years) for the PA group, and  $112.1 \pm 98.5$  mo (range, 6 mo-30 years) for the MA group. Mean postoperative follow up time was  $46.1 \pm 8.7$  mo (range, 36-66 mo) in the PA group and  $21.9 \pm 9.9$  mo (range, 10-39 mo) in the MA group.

When the disease stage was considered, nine patients had third degree, and six patients had fourth degree haemorrhoidal disease in the PA group, whereas; 17 patients had third degree, and five patients had fourth degree haemorrhoidal disease in the MA group. There were no statistically significant differences between the two groups with respect to stage of the disease ( $P = 0.222$ ).

Good	1 (6.7)	22 (100)	

When previous treatment modalities (medical, blood transfusion, surgery) were considered, there were no statistically significant differences between the two groups ( $P = 0.564$ ). General characteristics of the patients, intraoperative findings, and the differences between the two groups are shown in Table 1.

Mean duration of surgery was  $42.0 \pm 8.4$  min (range, 30-60 min) for the PA group, and  $27.7 \pm 8.0$  min (range, 18-45 min) for the MA group, and the difference was statistically significant ( $P = 0.039$ ) (Table 2). Additional haemostatic suture application after removal of the stapler was required in six cases (40.0) in the PA group and in two cases (9.1) in the MA group; and the difference was statistically significant ( $P = 0.034$ ). When the need for analgesics was considered, mean diclofenac sodium usage was  $1.9 \pm 1.5$  times (range, 0-6 times) in the PA group, and  $1.5 \pm 1.1$  times (range, 0-4 times) in the MA group. Mean pethidine HCL administration was  $0.8 \pm 1.1$  times (range, 0-3 times) in the PA group, and  $0.3 \pm 0.6$  times (range, 0-2 times) in the MA group. These differences between the groups were not statistically significant ( $P = 0.284$ , and  $P = 0.070$ , for diclofenac and pethidine, respectively) (Table 2). Urinary retention developed as an early complication in one patient in each group, and was relieved by urinary catheterization. Anal prolapse developed in one patient due to straining 8 h after the operation. Digital rectal examination revealed that the staple line was intact. Prolapsed mucosa was

**Table 2** Operation time, need for analgesics, and length of hospital stay of the patients, and the differences between the two groups (mean  $\pm$  SD)

	Group 1 (PA)	Group 2 (MA)	<i>P</i> value
Operation time (min)	$42.0 \pm 8.4$	$27.7 \pm 8.0$	0.039
Needs for analgesics (average dose)			
Diclofenac sodium	$1.9 \pm 1.5$	$1.5 \pm 1.1$	0.284
Pethidine HCL	$0.8 \pm 1.1$	$0.3 \pm 0.6$	0.070
Hospital stay (d)	$1.7 \pm 1.1$	$1.5 \pm 0.7$	0.449

reduced, and gauze sponges were applied to avoid recurrence. Gauze sponges were removed 12 h later and the patient was warned about straining. The patient was free of complaints 24 h later. Anal prolapse did not recur and the patient had normal bowel movements. Bleeding occurred in five patients (33.3) in the PA group and in seven patients (31.8) in the MA group. Bleeding was minor in all cases and no additional treatment was required. Bleeding ceased spontaneously within 24 h in five patients in each group, and after 48 h in two patients in the MA group. No delayed haemorrhage occurred. When early complications were considered, there were no statistically significant differences between the two groups ( $P = 0.685$ ). The mean hospitalization period was  $1.7 \pm 1.1$  d (range, 1-3 d) in the PA group, and  $1.5 \pm 0.7$  d (range, 1-3 d) in the MA group, and the difference was not statistically significant ( $P = 0.449$ ) (Table 2). The surgeons ranked their performance as poor ( $n = 10$ ), moderate ( $n = 4$ ), and good ( $n = 1$ ) in the PA group, and as good in all 22 operations in the MA group. The difference was statistically significant ( $P < 0.001$ ). An anal fissure developed 6 mo after surgery in one patient in the PA group, and treatment with lateral internal sphincterotomy was unsuccessful. Thrombosed external haemorrhoids developed 1 mo after surgery in one patient in the MA group, and excision of the piles was performed under local anaesthesia. A skin tag excision was performed in one patient in the MA group 7 mo postoperatively. When late complications in the two groups were considered, the difference was not statistically significant ( $P = 0.418$ ). Histopathological evaluation of the donuts showed that the specimens from 13 patients in the PA group included only mucosa and submucosa. Additionally, a mucosal adenoma was reported in one patient, and muscularis propria in another patient in this group. In the MA group, 19 donuts included only mucosa and submucosa, two donuts also included muscularis propria, and one included a mucosal adenoma. There were no statistically significant differences between the two groups ( $P = 0.933$ ).

## DISCUSSION

Achieving a perfect purse-string may be difficult in stapled haemorrhoidopexy, even after meticulous application of the technique<sup>[1]</sup>. The surgeon starts by placing the purse-string suture at a distance of 3-4 cm above the dentate line

and just deep enough to take the mucosa and submucosa, however, if internal haemorrhoids obscure the surgical field and if the tip of the needle causes bleeding while passing through the mucosa, further bites of the suture may not pass at the same distance and at the same depth<sup>[10,13,14]</sup>. This may result in an uneven purse-string suture which is closer to the dentate line, goes through deeper tissues, or which skips the mucosa in some parts. Consequently, some parts of the stapler line may be closer to the dentate line, or some parts of the donut may be thicker, or it may not be intact<sup>[4,5,14]</sup>. A stapler line close to the dentate line may cause acute or persistent pain, or bring about a risk of incontinence<sup>[15,16]</sup>. It has been reported that patients with a stapler line uniformly 22 mm above the dentate line needed fewer postoperative narcotic analgesics and returned to work earlier<sup>[1]</sup>. In the case of an incomplete donut or a donut with thin parts, this may increase the risk of bleeding during the early postoperative period or recurrence in the late period<sup>[17]</sup>.

Various modifications of the purse-string anoscope have been used for easier application of the suture and a new anoscope has been designed<sup>[10-12,18,19]</sup>. Yamamoto *et al*<sup>[12]</sup> indicated that they have been using their modified anoscope over the last 2 years. We have been using our modified anoscope since 2003.

This is the first study to compare the conventional anoscope, and a modified anoscope used during stapled haemorrhoidopexy. Although this study is limited by its retrospective nature, the two groups of patients were statistically comparable in terms of age, gender, stage of haemorrhoidal disease and previous treatment modalities.

Median operation time for stapled haemorrhoidopexy has been reported to be between 15 and 38 min (range, 5-150 min)<sup>[13,20-23]</sup>. Median operation time for the PA group in our study was higher than that reported in the literature; however, the range in operation time was similar. When the MA group is considered, both median operation time and median range were in accordance with the literature. There may be a number of explanations for the difference in operation time between the two groups in the present study. First of all, the PA group covered a time period where the surgeons who applied this method were less experienced. In addition, the purse-string suture had to be repeated several times in some patients in this group, and the number of patients who required haemostatic sutures was higher in this group. We propose that all of these factors prolonged the operation time. One explanation for the shorter operation time in the MA group may be that the application of the purse-string suture with the modified anoscope was much easier. It can also be said that the surgeons performed the operation in a shorter time, as they had gained more experience with the procedure. However, it should be emphasized that inexperienced surgeons performed some of the operations under the supervision of an experienced surgeon in this group. Moreover, the purse-string suture was possible on the first attempt in most patients, and haemostatic sutures were required in a smaller percentage of patients in this group (9.1% in the

MA group, and 40% in the PA group). The necessity for haemostatic sutures was reported to be 84% in a study in which the time elapsed before and after firing the stapler was not noted<sup>[21]</sup>. Nahas *et al*<sup>[22]</sup> reported that they waited 30 s after firing the stapler and the necessity for haemostatic sutures was 20%. Recalbuto *et al*<sup>[20]</sup>, in their study in which one min elapsed before and after firing the stapler, did not refer to the rate of haemostatic sutures, but reported the rate of bleeding as 6%. The PA group consisted of the initial patients who underwent haemorrhoidopexy surgery. Initially we paused for 30 s after firing the stapler for haemostasis. After the team gained some experience we increased the time before and after firing to 180 s considering that more efficient haemostasis could be achieved by longer compression on the vessels at the surgical site. When the two groups in the present study were compared with respect to the application of haemostatic sutures, it was observed that the number of patients who required additional sutures was significantly less in the MA group than in the PA group. This was an extra finding, and was not due to the features of the videoanoscope. A 3 min pause after closing the stapler may be tedious, but it is better than trying to apply additional haemostatic sutures if bleeding occurs after the stapler is removed. The haemostatic efficacy of keeping the stapler closed needs to be investigated by prospective controlled studies.

The rate of bleeding reportedly ranges between 5% and 85%<sup>[9,13,17,22]</sup>. The rates of bleeding in the PA group and in the MA group in the present study were 33.3% and 31.8%, respectively. Bleeding was minor in all cases and stopped in most patients within 48 h without any need for additional interventions. Urine retention rates observed in the PA and MA groups were in accordance with the literature<sup>[21]</sup>. We could not find a similar complication in the literature to the anal prolapse that we observed in one patient in the MA group. It did not seem to be due to anastomotic dehiscence because the stapler line was intact. The reasons for anal prolapse as an early postoperative complication may be due to excessive venous congestion and edema of internal haemorrhoids. Improvement of the clinical picture after reduction of the haemorrhoids confirmed this hypothesis.

The need for analgesics in each group was consistent with that reported in the literature<sup>[1,25]</sup>. None of the patients suffered from persistent pain. Hospital stay, reported in the literature as 0-2 d was similar to that in the present study<sup>[20]</sup>. When the two groups were compared in terms of late complications, there were no significant differences, also consistent with the literature<sup>[17,20,21,24]</sup>. Results of the histopathological examination of the specimens obtained in this study were similar to those reported in the literature, and no significant differences between the two groups in this study were noted<sup>[15]</sup>.

Satisfaction of the surgeons regarding technical performance during surgery was significantly higher in the MA group than in the PA group. As this was a retrospective study, it was difficult for the surgeons to remember their initial operations and commented so.

The decisions made by the surgeons were based on a comparison of the two anoscopes as they performed surgery in both groups, and they described their operative performances as better with the modified anoscope. In the MA group, the surgeons who performed the procedure for the first time did not have the chance to compare the anoscopes, but they too described their operative performance as good or sufficient. As all the surgeons noted that they would prefer to use the modified anoscope in future operations, we have been using only the modified anoscope for 4 years. These results need to be supported by prospective randomized studies.

In conclusion, with the help of our modified anoscope, the purse-string suture is easy to perform, the operation is completed in a shorter time, and the surgeons were more satisfied with their operative performances. Additionally, by waiting a total of 3 min, 90 s before and after firing the stapler, fewer haemostatic sutures were required. Using the modified anoscope, optimum application of the purse-string suture is achieved during stapled haemorrhoidopexy.

## ACKNOWLEDGMENTS

The authors thank Dr. Orhun Bengisu, Ismail Uzunkaya, and Mustafa Hakgonul for their assistance in producing the anoscope, and thank Dr. Seref Gulseren for his statistical advice.

## COMMENTS

### Background

Modification of the purse-string anoscope was required to achieve an easier purse-string suture during stapled haemorrhoidopexy, because the purse-string anoscope could not prevent protrusion of large haemorrhoids.

### Research frontiers

Stapled haemorrhoidopexy is not only a safe method that can be compared with conventional haemorrhoidectomy procedures, but also has advantages such as reduced postoperative pain and early return to work. However, some complications were noted after stapled haemorrhoidopexy. It was suggested that these serious complications could be due to technical errors and could be avoided by eliminating the bite of the suture in deep layers of the rectum. This study compared the surgical findings and early postoperative results of patients in whom the purse-string suture anoscope of the PPH kit was used, with patients in whom the modified anoscope was used during stapled haemorrhoidopexy.

### Innovations and breakthroughs

Recent reports have highlighted the importance of purse-string suture during stapled haemorrhoidopexy. Various modifications of the purse-string anoscope have been used for easier application of the suture. We have been using our modified anoscope since 2003. This is the first study to compare the conventional anoscope with a modified anoscope during stapled haemorrhoidopexy.

### Applications

Using the modified anoscope, optimum application of the purse string can be performed during stapled haemorrhoidopexy, and it may prevent serious complications of the procedure.

### Terminology

Stapled haemorrhoidopexy is an alternative operative procedure for haemorrhoidal disease. It depends on the removal and the anastomosis of the mucosa above the haemorrhoidal tissue using the PPH kit or a circular stapler. Purse-string suture placement is an important part of the procedure. Anoscopes help to perform the purse string suture placement.

## Peer review

The authors have compared modified anoscope for the application of the purse string to the standard purse string suture anoscope in the PPH kit. Although the technique using the modified anoscope is well described, this is the first paper comparing the 2 techniques. The manuscript is well written and flows well.

### Abstract

**AIM:** To clarify the significance of JC virus (JCV) T-antigen (T-Ag) expression in human gastric cancer.

**METHODS:** We investigated the relationship between T-Ag detected by immunohistochemistry and Epstein-Barr virus (EBV) infection, microsatellite instability (MSI), and genetic and epigenetic alterations in gastric cancers. Mutations in the *p53*, *β-catenin*, *KRAS*, *BRAF*, *PIK3CA* genes were analyzed by polymerase chain reaction (PCR)-single strand conformation polymorphism and DNA sequencing. Allelic losses were determined by PCR at 7 microsatellite loci. Aberrant DNA methylation was analyzed by MethyLight assay.

**RESULTS:** JCV T-Ag protein expression was found in 49% of 90 gastric cancer tissues. T-Ag positivity was not correlated with clinicopathological characteristics. T-Ag expression was detected in a similar percentage of EBV positive cancers (4 of 9, 44%) and EBV negative

cancers (35 of 73, 48%). T-Ag expression was detected in a significantly lower percentage of MSI-H cancers (14%) than in non MSI-H cancers (55%,  $P = 0.005$ ). T-Ag expression was detected in a significantly higher percentage of cancers with nuclear/cytoplasmic localization of  $\beta$ -catenin (15 of 21, 71%) than in cancers without (42%,  $P = 0.018$ ). *p53* mutations were detected in a significantly lower percentage of T-Ag positive cancers (32%) than in T-Ag negative cancers (57%,  $P = 0.018$ ). T-Ag positive gastric cancers showed a significant increase in the allelic losses and aberrant methylation compared with T-Ag negative gastric cancers ( $P = 0.008$  and  $P = 0.003$ ).

**CONCLUSION:** The results suggest that JCV T-Ag is involved in gastric carcinogenesis through multiple mechanisms of genetic and epigenetic alterations.

### INTRODUCTION

Viruses have been proposed to play an etiologic role in human cancers. JC virus (JCV) is a polyomavirus that ubiquitously infects humans worldwide, and more than 80% of the adult population carries antibodies against the virus<sup>[1]</sup>. JCV has been implicated in various types of human cancers<sup>[2-9]</sup>. It has been reported that JCV

sequences are frequently present throughout the normal human gastrointestinal tract and in colorectal and gastric cancers<sup>[2,9]</sup>.

JCV encodes a transforming gene, T-antigen (T-Ag), which is believed to mediate the oncogenic potential of the virus. T-Ag protein expression was specifically present in the nuclei of colon cancer cells, but not in any adjacent normal colonic epithelium<sup>[8]</sup>. Previous studies have identified multiple pathways including p53, pRb, IRS, NF1/NF2 and  $\beta$ -catenin, which may be dysregulated by T-Ag<sup>[4,10,11]</sup>. T-Ag can bind and inactivate p53, pRb, and the spindle assembly checkpoint protein Bub1, resulting in disruption of chromosomal integrity and cell cycle checkpoints<sup>[12,13]</sup>. T-Ag can also bind and stabilize  $\beta$ -catenin<sup>[4,11]</sup>. T-Ag protein expression, rather than the simple presence of JCV DNA sequences, has been significantly associated with chromosomal instability (CIN) and the methylator phenotype in colorectal cancers<sup>[8]</sup>. The possible involvement in aberrant methylation is thought to provide a secondary link to microsatellite instability (MSI) in colorectal cancers<sup>[8]</sup>. Therefore, it has been suggested that JCV is involved in colorectal cancers through multiple mechanisms of genetic and epigenetic alterations<sup>[8]</sup>. Bhattacharyya *et al*<sup>[14]</sup> recently reported the interplay between  $\beta$ -catenin and Rac1 that is initiated by T-Ag and results in stabilization of  $\beta$ -catenin and its presence in cell membrane ruffles. T-Ag and  $\beta$ -catenin synergistically activate Rac1, an event that can trigger several oncogenic factors<sup>[14]</sup>.

The association between T-Ag expression and aberrant promoter methylation in colorectal cancers suggests that this viral oncogene induces the methylator phenotype<sup>[8]</sup>. Genomic methylation is a host defense mechanism that silences the transcription of transposons and retroviruses that have accumulated in the mammalian genome<sup>[8,15,16]</sup>. Methylation of host cell genes is not unique to JCV and occurs with other oncogenic viruses. It has been suggested that the key protein triggering methylation events for the polyomavirus SV40 is T-Ag, which mediates cellular transformation of cultured epithelial cells by regulating the activities of key *de novo* DNA methyltransferases, such as DNMT3b<sup>[8,17]</sup>.

A significant correlation has been found between Epstein-Barr virus (EBV) and methylation of multiple genes in gastric cancers<sup>[18,19]</sup>. A mutually negative association between EBV and MSI has been reported in gastric cancers<sup>[20]</sup>. T-Ag protein expression was found in 9 (39%) of 23 gastric cancers, whereas no expression was observed in any of the non-cancer tissues<sup>[9]</sup>. In contrast to colorectal cancers<sup>[8]</sup>, however, little is known about the significance of T-Ag expression in gastric cancers. In the current study, we investigated the relationship between T-Ag protein expression and EBV infection, MSI, and genetic and epigenetic alterations in gastric cancers.

## MATERIALS AND METHODS

### Tissue samples

A total of 90 paired specimens of gastric adenocarcinoma and adjacent noncarcinoma tissue were obtained from Japanese patients who had undergone surgical treatment.

Informed consent was obtained from each patient. The tumor-node-metastasis (TNM) system of the American Joint Committee on Cancer and the International Union against Cancer was used for the pathologic diagnosis and classification of variables. Clinicopathological characteristics were as follows: age ( $69 \pm 10$  years), gender (59 male and 31 female), Lauren histology (44 intestinal and 46 diffuse), and pTNM stages (stage I, 23; stage II, 16; stage III, 30; stage IV, 21).

### Immunohistochemistry and in situ hybridization

Immunohistochemistry using a mouse monoclonal antibody against SV40 large T-Ag (clone PAB416, 1:100 dilution; Oncogene Research Products, San Diego, CA, USA), which cross-reacts with T-Ag of JCV, was performed as described previously<sup>[8]</sup>. Immunohistochemistry with an anti-human  $\beta$ -catenin monoclonal antibody (BD Transduction Laboratories, San Jose, CA, USA) was done as described previously<sup>[21]</sup>. Cancer cases were categorized into the following 4 groups corresponding to immunostaining patterns of  $\beta$ -catenin as described previously<sup>[21]</sup>: membranous, membranous staining pattern similar to that in normal epithelium; weak, no staining or weaker staining than normal epithelium; cytoplasmic, diffuse staining in the cytoplasm as well as at the cell membrane; accumulated, strong staining in the nucleus and cytoplasm. EBV infection was analyzed by *in situ* hybridization for *EBER-1*<sup>[20]</sup>.

### MSI analysis

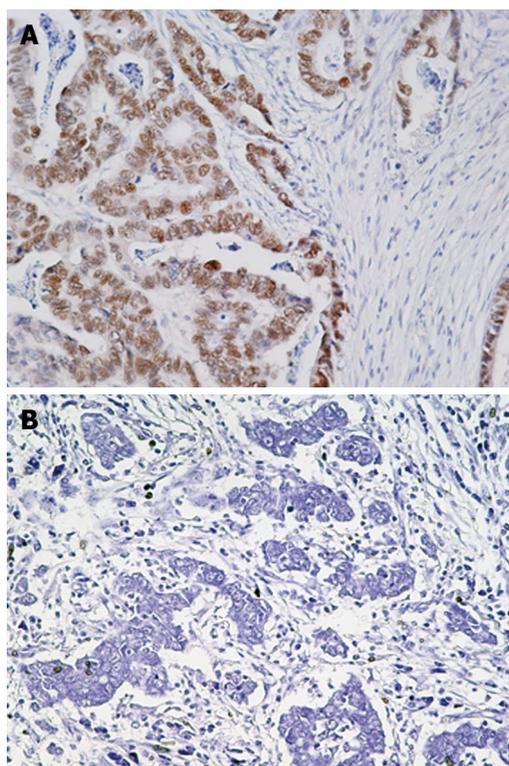

MSI was analyzed by polymerase chain reaction (PCR) using the mononucleotide (BAT26 and BAT25) and dinucleotide markers (D2S123, D5S346, and D17S250) proposed by the NCI workshop<sup>[22]</sup>. Based on the number of markers showing instability per cancer, cancers were divided into 3 groups; those with 2 or more of the 5 markers displaying instability (MSI-H), those with 1 of 5 markers displaying instability (MSI-low; MSI-L), and those with no instability (microsatellite stable; MSS).

### Mutation analysis

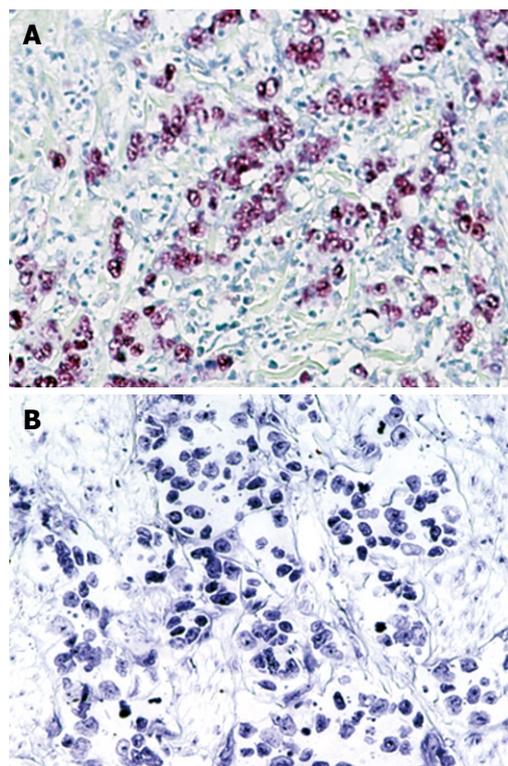

Mutations in exons 2-9 of *p53*, exon 3 of  *$\beta$ -catenin*, codons 12 and 13 of *KRAS*, codon 600 of *BRAF*, exons 9 and 20 of *PIK3CA* genes were analyzed by PCR-single strand conformation polymorphism and DNA sequencing as described previously<sup>[23-25]</sup>. Interstitial deletions spanning exon 3 of  *$\beta$ -catenin* was analyzed as described previously<sup>[24,25]</sup>.

### LOH analysis

LOH was analyzed as described previously<sup>[26]</sup>. Seven sets of microsatellite loci that are linked to tumor suppressor genes were used to identify significant allelic losses in gastric cancers. DNA was amplified by PCR at microsatellite loci linked to the *APC* locus on 5q21 (D5S505), possible tumor suppressor/senescence gene locus on 10p15 (D10S501 and D10S602), *p53* locus on 17p13 (TP53), *BRC1* locus on 17q21 (D17S855), and *DCC* locus on 18q21 (D18S58 and D18S61)<sup>[26]</sup>. Assessment of LOH was assigned when a tumor allele showed at least a 50% reduction in the relative intensity

**Figure 1** Immunohistochemistry for JCV T-Ag in gastric cancer tissues. A: Gastric adenocarcinoma positive for JCV T-Ag; B: Gastric adenocarcinoma negative for JCV T-Ag. Original magnification,  $\times 200$ .

**Figure 2** *In situ* hybridization for *EBER-1* in gastric cancer tissues. A: Gastric adenocarcinoma positive for *EBER-1*; B: Gastric adenocarcinoma negative for *EBER-1*. Original magnification,  $\times 200$ .

of 1 allele in cancer tissue compared with the matched non-cancer DNA as described previously<sup>[26]</sup>.

#### Quantitative DNA methylation analysis by real-time PCR (MethylLight assay)

Sodium bisulfite treatment of genomic DNA and MethylLight assay were performed as described previously<sup>[25,27-30]</sup>. We analyzed six promoters: calcium channel, voltage dependent, T type  $\alpha$ -1G subunit (*CACNA1G*), cellular retinoic acid binding protein 1 (*CRABP1*), neurogenin 1 (*NEUROG1*), *CDKN2A* (*p16*), *RUNX3*, and *SOCS1*. Primers, probes, and percentage of methylated reference (PMR, i.e. degree of methylation) were described previously<sup>[29,30]</sup>. The cutoff value of 4 (except for 6 in *CRABP1*) was based on previously validated data<sup>[28]</sup>.

#### Statistical analysis

The results were assessed for associations with clinicopathological parameters, using the following statistical tests: Student's *t* test for age, the Mann-Whitney test for depth of invasion, lymph node metastasis, and pTNM stage, and the chi-square test or Fisher's exact test for the remaining parameters.  $P < 0.05$  was considered significant. A  $P$  value between 0.05 and 0.10 was considered as a trend toward an association.

## RESULTS

### T-Ag protein expression in gastric cancers

T-Ag protein expression was found in 44 (48.9%) of 90 gastric cancers, whereas no expression was observed in

adjacent normal gastric epithelial cells or stromal cells (Figure 1 and data not shown). T-Ag positivity was not correlated with clinicopathological characteristics (data not shown).

### EBV infection

*EBER-1* expression was found in 9 (11.0%) of 82 gastric cancers, whereas no expression was observed in any of the non-cancer tissues (Figure 2). EBV infection was detected more frequently in diffuse type (7 of 44, 16%) than intestinal type (2 of 38, 5%), although this did not reach statistical significance. T-Ag expression was detected in a similar percentage of EBV positive cancers (4 of 9, 44%) and EBV negative cancers (35 of 73, 48%). The results for T-Ag protein expression and EBV infection were summarized in a Figure 3.

### MSI status

Following the NCI criteria, a total of 90 gastric cancers was classified as follows: 14 (16%) MSI-H, 10 (11%) MSI-L, and 66 (73%) MSS (Figure 4). T-Ag expression was detected in a significantly lower percentage of MSI-H cancers (14%) than in non MSI-H cancers (55%,  $P = 0.005$ ). None of the MSI-H tumors were EBV positive.

### Alterations of $\beta$ -catenin

Figure 5 shows representative results of immunohistochemistry for  $\beta$ -catenin in gastric cancer tissues. In normal gastric epithelium cells,  $\beta$ -catenin was moderately stained in a membranous distribution (Figure 5A), whereas fibroblasts, endothelial cells, and smooth muscle

Nucleotide substitution (amino acid change) is shown.

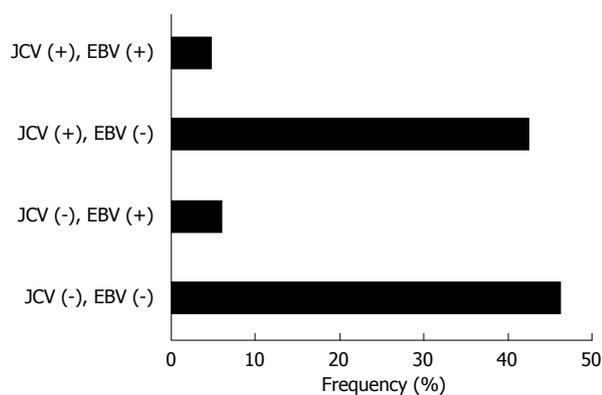

Figure 3 Classification of 90 gastric cancer tissues based on T-Ag protein expression and EBV infection.

cells were negative. Membranous, weak, cytoplasmic, and accumulated pattern was observed in 36 (40%), 33 (37%), 11 (12%), and 10 (11%), respectively. Neither point mutations nor interstitial deletions in exon 3 were detected (data not shown). T-Ag expression was detected in a significantly higher percentage of cancers with nuclear/cytoplasmic localization of  $\beta$ -catenin (15 of 21, 71%) than in cancers without (42%,  $P = 0.018$ ).

#### Mutations of the p53, KRAS, BRAF, PIK3CA genes in gastric cancer tissues

*p53* mutations were detected in 40 (44%) of 90 gastric cancer tissues. *p53* mutations were detected in a significantly lower percentage of T-Ag positive cancers (32%) than in T-Ag negative cancers (57%,  $P = 0.018$ ). *p53* mutations were detected in a significantly lower percentage of MSI-H cancers (14%) than in MSI-L cancers (60%,  $P = 0.028$ ) or in MSS cancers (48%,  $P = 0.021$ ). *KRAS* mutations were detected in only 5 (6%) of 90 gastric cancers. *BRAF* mutations were not detected. *PIK3CA* mutations were detected in 4 (4%) of 90 cancers. The exact mutations and their frequencies were described in a Table 1.

#### LOH analysis

Overall, 62 (69%) of 90 cancers had at least 1 LOH, with most frequent chromosomal losses observed on 17p (43%), followed by 18q (33%), 10p (27%), 5q (24%), and 17q (12%) (Figure 6A and B). Of 62 cancers with LOH, 4

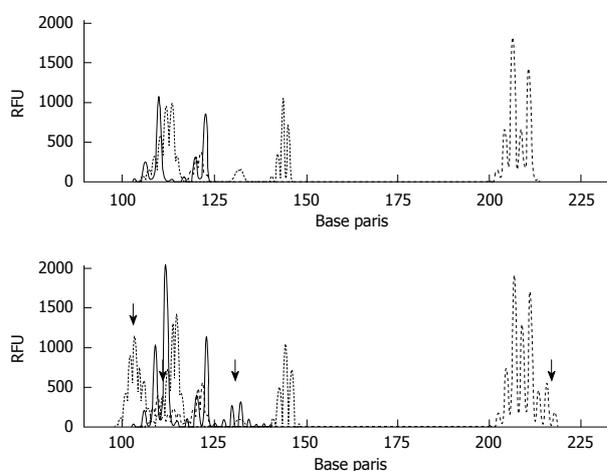

Figure 4 MSI analysis in gastric cancer tissues. MSI was analyzed by PCR using the mononucleotide (BAT26 and BAT25) and dinucleotide markers (D2S123, D5S346, and D17S250). Results of matched normal (upper panel) and tumor (bottom panel) samples (MSI-H) are shown. The arrows mean instability positive marker. RFU: Relative fluorescent units.

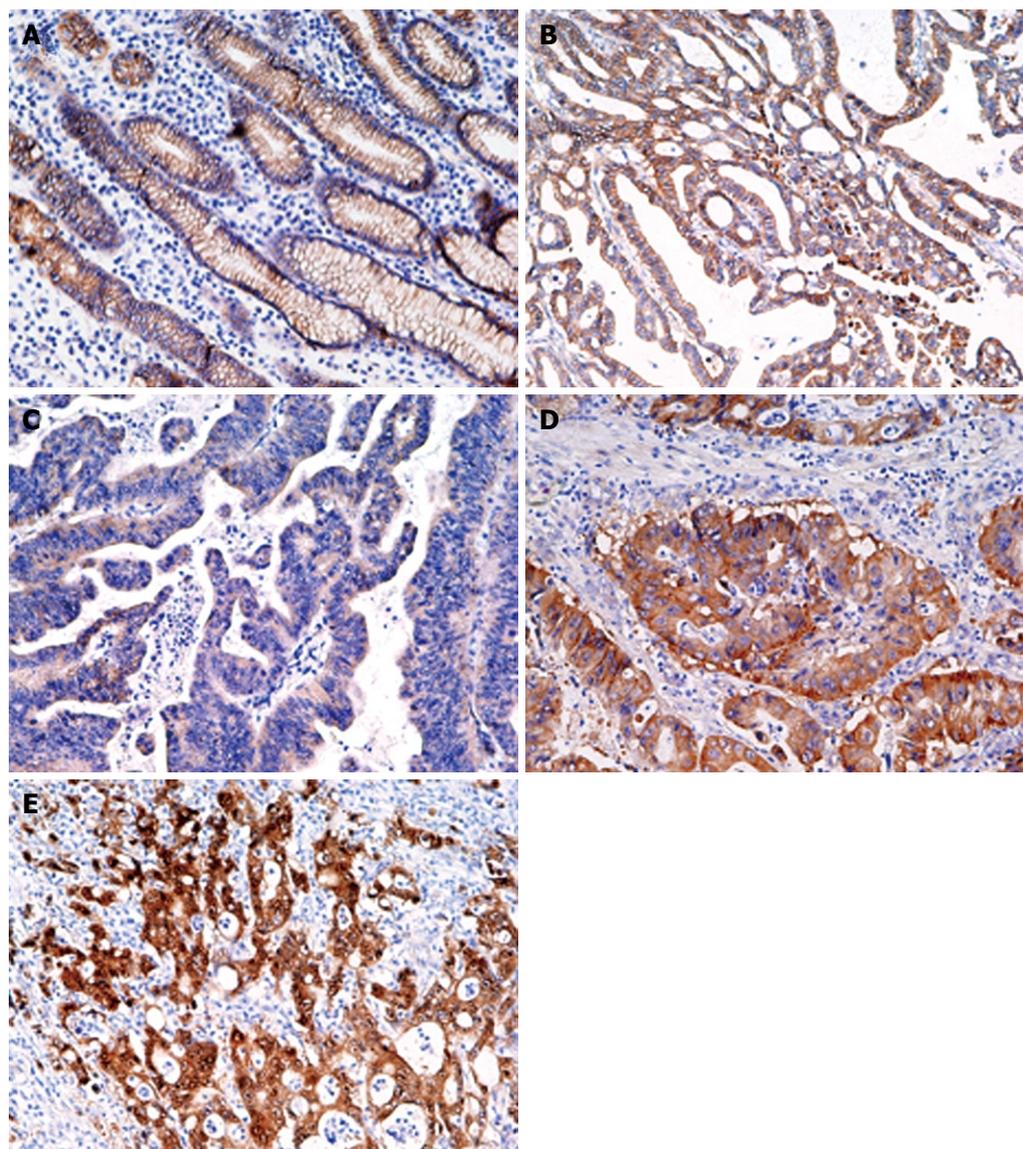

(6%) were also MSI-H. The data were expressed in terms of an allelic loss index (ALI), which reflects the number of chromosomal losses per the number of chromosomal loci showing heterozygosity but not MSI in each cancer specimen. T-Ag positive gastric cancers showed a significant increase in the ALI compared with T-Ag negative gastric cancers ( $0.41 \pm 0.12$  vs  $0.21 \pm 0.09$ ,  $P = 0.008$ ).

#### Methylation analysis

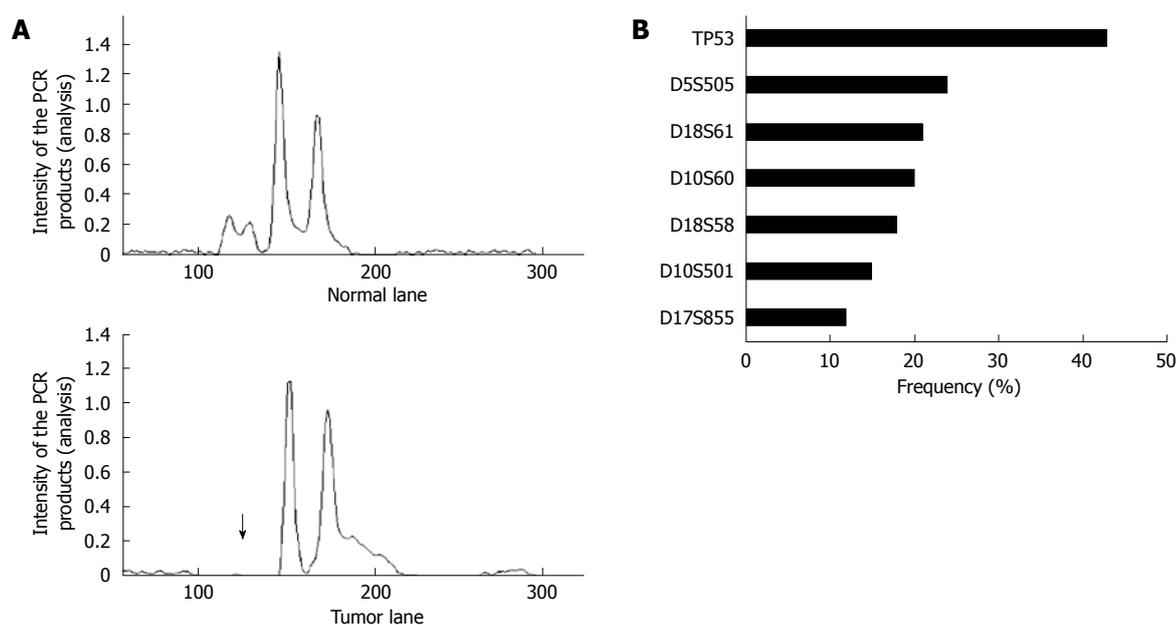

The results were summarized based on each individual marker (Figure 7A and B). The data were expressed in terms of a methylation index (MI), which reflects the number of abnormally methylated promoters per cancer specimen within the subsets of cancers. T-Ag positive gastric cancers showed a significant increase in the MI compared with T-Ag negative gastric cancers ( $3.01 \pm 0.92$  vs  $1.51 \pm 0.71$ ,  $P = 0.003$ ).

## DISCUSSION

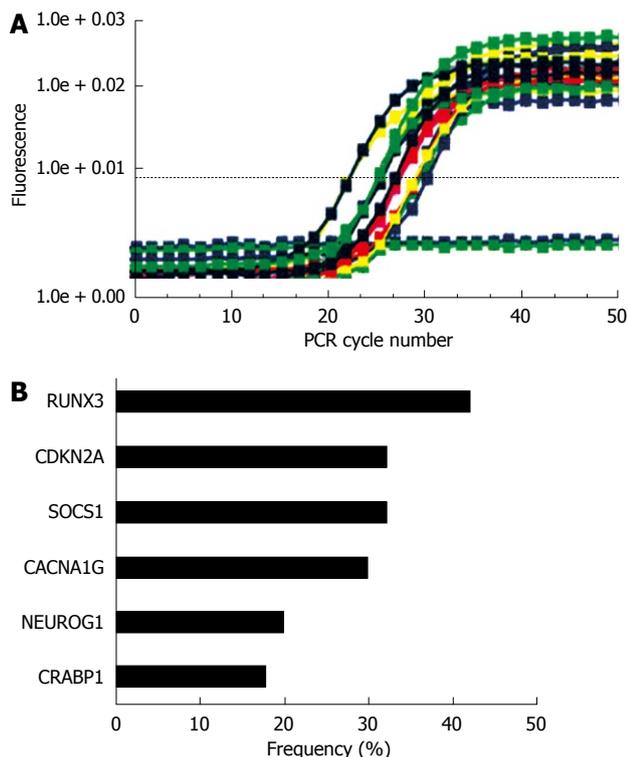

In the current study, T-Ag protein expression was positive in 44 (49%) of 90 gastric cancer tissues and it was observed specifically in gastric cancer cells but not in

**Figure 5** Immunohistochemistry for  $\beta$ -catenin in gastric normal (A) and cancer (B-E) tissues. A: Moderate membrane staining; B: Membrane staining pattern similar to that seen in normal epithelium; C: Weak staining; D: Diffuse staining in the cytoplasm and membrane; E: Strong staining of the nucleus and cytoplasm (Original magnification,  $\times 200$ ).

**Figure 6** LOH analysis in gastric cancer tissues. A: A representative example of a tumor with allelic loss in 5q21 (D5S505) is shown. The upper and bottom panels show the intensity plots of both the normal and tumor lane, respectively, demonstrating reduced relative intensity of allele one in the tumor sample (arrow) compared to the corresponding normal sample; B: LOH frequencies based on each individual marker.

**Figure 7** MethyLight analysis in gastric cancer tissues. A: Results of the *CRABP1* gene are shown. Bisulfite-converted DNA was used for quantitative methylation-specific PCR. The amount of hypermethylated DNA was determined by reading the midpoint of the linear portion of the S-shaped real-time curves, called the Ct point or threshold cycle. The Ct refers to the number of cycles it takes a sample to reach a specific fluorescence threshold; B: DNA methylation frequencies based on each individual marker.

the adjacent normal gastric epithelial cells or stromal cells. Previous study has also shown that T-Ag protein expression was found in 9 (39%) of 23 gastric cancers, whereas no expression was observed in any of the non-cancer tissues<sup>[9]</sup>. These results suggest an active role for this oncogenic protein in gastric carcinogenesis<sup>[9]</sup>.

The frequencies of EBV infection (11%) and MSI-H (16%) in this study were almost consistent with those reported in previous studies<sup>[20,31,32]</sup>. None of the MSI-H cancers were EBV positive. A mutually negative association between EBV and MSI has been reported in gastric cancers<sup>[20]</sup>. T-Ag was detected in a significantly lower percentage of MSI-H cancers (14%) than in non MSI-H cancers (55%). In contrast, T-Ag expression was present in similar frequencies in MSI-H and (8/15, 53%) and MSS/MSI-L (35/85, 41%) colorectal cancers<sup>[8]</sup>. From the view point of MSI, these results suggest a differential role of T-Ag in gastric and colorectal carcinogenesis.

T-Ag expression was detected in a significantly higher percentage of cancers with nuclear/cytoplasmic localization of  $\beta$ -catenin than in cancers without. T-Ag interacts with  $\beta$ -catenin, leading to its stabilization and resultant dysregulation of the WNT-signaling pathway in gastrointestinal cancers<sup>[4]</sup>. Neither point mutations nor interstitial deletions in exon 3 were detected. Although not analyzed in this study, the frequency of *APC* mutations is relatively low in gastric cancers. Therefore, T-Ag may play an important role in the stabilization of  $\beta$ -catenin in gastric cancers.

*p53* mutation was detected in a significantly lower

percentage of T-Ag positive cancers (32%) than in T-Ag negative cancers (57%). T-Ag can bind and inactivate *p53*<sup>[12]</sup>, resulting in disruption of chromosomal integrity and cell cycle checkpoints. Therefore, T-Ag expression may eliminate the selective pressure for *p53* mutations in a subset of gastric cancers.

A significant association was observed between T-Ag expression and allelic losses, being consistent with that in colorectal cancers<sup>[8]</sup>. It has been previously reported that the introduction of JCV into a diploid cell line leads to the rapid induction of CIN<sup>[33]</sup>. JCV can also induce CIN in a diploid colon cancer cell line RKO, which has wild-type *APC*, *p53*, and  $\beta$ -catenin genes<sup>[33]</sup>. These results suggest that T-Ag play a role in genomic damage during gastric carcinogenesis.

Significant association was also observed between T-Ag expression and aberrant methylation, being consistent with that in colorectal cancers<sup>[8]</sup>. A significant correlation has been found between EBV and methylation of multiple genes in gastric cancers<sup>[8,18,19]</sup>. These results suggest that JCV T-Ag and EBV play a similar role, at least in part, during gastric carcinogenesis.

Taken together, our results suggest that JCV T-Ag is involved in gastric cancers through multiple mechanisms of genetic and epigenetic alterations<sup>[34]</sup>. Further analysis is required to determine whether there is a plausible molecular mechanism by which JCV can induce genetic and epigenetic alterations in gastric carcinogenesis.

## COMMENTS

### Background

Gastric cancer is one of the most common cancer and leading cause of cancer-related death in the world. Understanding the molecular biological features of gastric cancer is necessary for early diagnosis and better prognosis. The potential role of viral infection in human cancer is receiving increasing attention.

### Research frontiers

A significant correlation has been found between Epstein-Barr virus (EBV) and methylation of multiple genes in gastric cancer. However, little is known about the significance of JC virus (JCV) T-antigen (T-Ag) expression in gastric cancers. In this study, the authors demonstrate that JCV T-Ag plays a key role in gastric carcinogenesis.

### Innovations and breakthroughs

This is the first study to report that JCV T-Ag plays a key role in gastric carcinogenesis. Furthermore, T-Ag expression was associated with nuclear/cytoplasmic localization of  $\beta$ -catenin, allelic losses and aberrant DNA methylation, suggesting that JCV T-Ag is involved in gastric carcinogenesis through multiple mechanisms of genetic and epigenetic alterations.

### Applications

JCV T-Ag expression could be future diagnostic and/or therapeutic targets in clinical settings. Understanding of a plausible molecular mechanism by which JCV can induce genetic and epigenetic alterations may represent a future strategy for therapeutic intervention in the treatment of patients with gastric cancer.

### Terminology

JCV: JCV is a polyomavirus that ubiquitously infects humans worldwide, and more than 80% of the adult population carries antibodies against the virus. EBV: EBV is a double-stranded DNA virus and takes a linear form in the viral particles. EBV was the first virus discovered from human neoplastic cells, a Burkitt's lymphoma cell lines. Microsatellite instability (MSI): MSI is a type of genetic instability characterized by length alterations within simple repeated microsatellite sequences.

### Peer review

This paper reports the characteristics of gastric cancer with JCV T-Ag expression. The authors showed that JCV T-Ag plays a key role in gastric carcinogenesis. The study sounds interesting and the information could be useful for other gastric cancer researchers.

### Abstract

**AIM:** To evaluate the safety of unsedated transnasal small-caliber esophagogastroduodenoscopy (EGD) for elderly and critically ill bedridden patients.

**METHODS:** One prospective randomized comparative study and one crossover comparative study between transnasal small-caliber EGD and transoral conventional EGD was done (Study 1). For the comparative study, we enrolled 240 elderly patients aged > 65 years old. For the crossover analysis, we enrolled 30 bedridden patients with percutaneous endoscopic gastrostomy (PEG) (Study 2). We evaluated cardiopulmonary effects by measuring arterial oxygen saturation (SpO<sub>2</sub>) and calculating the rate-pressure product (RPP) (pulse rate × systolic blood pressure/100) at baseline, 2 and 5 min after endoscopic intubation in Study 1. To assess the risk for endoscopy-related aspiration pneumonia

during EGD, we also measured blood leukocyte counts and serum C-reactive protein (CRP) levels before and 3 d after EGD in Study 2.

**RESULTS:** In Study 1, we observed significant decreases in SpO<sub>2</sub> during conventional transoral EGD, but not during transnasal small-caliber EGD (0.24% vs -0.24% after 2 min, and 0.18% vs -0.29% after 5 min,  $P = 0.034$ ,  $P = 0.044$ ). Significant differences of the RPP were not found between conventional transoral and transnasal small-caliber EGD. In Study 2, crossover analysis showed statistically significant increases of the RPP at 2 min after intubation and the end of endoscopy (26.8 and 34.6 vs 3.1 and 15.2,  $P = 0.044$ ,  $P = 0.046$ ), and decreases of SpO<sub>2</sub> (-0.8% vs -0.1%,  $P = 0.042$ ) during EGD with transoral conventional in comparison with transnasal small-caliber endoscopy. Thus, for bedridden patients with PEG feeding, who were examined in the supine position, transoral conventional EGD more severely suppressed cardiopulmonary function than transnasal small-caliber EGD. There were also significant increases in the markers of inflammation, blood leukocyte counts and serum CRP values, in bedridden patients after transoral conventional EGD, but not after transnasal small-caliber EGD performed with the patient in the supine position. Leukocyte count increased from  $6053 \pm 1975/L$  to  $6900 \pm 3392/L$  ( $P = 0.0008$ ) and CRP values increased from  $0.93 \pm 0.24$  to  $2.49 \pm 0.91$  mg/dL ( $P = 0.0005$ ) at 3 d after transoral conventional EGD. Aspiration pneumonia, possibly caused by the endoscopic examination, was found subsequently in two of 30 patients after transoral conventional EGD.

**CONCLUSION:** Transnasal small-caliber EGD is a safer method than transoral conventional EGD in critically ill, bedridden patients who are undergoing PEG feeding.

## INTRODUCTION

Small-caliber endoscopy of the upper gastrointestinal tract was developed and for transnasal esophagogastroduodenoscopy (EGD) and has been used frequently in the past decade<sup>[1-4]</sup>. Transnasal small-caliber EGD has improved the safety of the endoscopic examination, and has fewer adverse effects on cardiopulmonary function<sup>[5-10]</sup> and autonomic nerve function<sup>[11]</sup>, compared with transoral conventional EGD. Transnasal small-caliber EGD provides good operability compared to that of transoral conventional EGD<sup>[12]</sup>, and requires no special training<sup>[13]</sup>. For these reasons, unsedated transnasal small-caliber EGD is used routinely in endoscopic examinations of the upper gastrointestinal tract, often in preference to transoral conventional EGD.

Although we perform endoscopy on elderly and critically ill patients with increasing frequency, we have little information concerning the relative safety of transnasal small-caliber and transoral conventional EGD in these patient groups. Elderly patients do not frequently gag or choke during transoral conventional EGD. If transoral conventional EGD is safe and comfortable for the elderly, the value of transnasal small-caliber EGD is limited, since the smaller charge-coupled device in the endoscope may potentially reduce diagnostic accuracy for minute gastric lesions. The comparative safety of the two techniques should therefore be considered carefully for the treatment of elderly patients with higher risks for gastric cancer and cardiopulmonary diseases.

We compared the safety and tolerability of transnasal and transoral EGD in patients aged > 65 years old and in chronically bedridden elderly patients who required percutaneous endoscopic gastrostomy (PEG) feeding. We used a prospective comparative study and a crossover analysis to evaluate changes in hemodynamic and pulmonary function, and the risk of endoscopy-related aspiration pneumonia during EGD by each method.

## MATERIALS AND METHODS

These following prospective and crossover studies were conducted in accordance with the Declaration of Helsinki and approved by the ethics committee of Izumo City General Medical Center. In Study 1, we obtained written informed consent from all the participants. In Study 2, written informed consent was obtained from the key family members of the enrolled patients.

### Study 1

We compared changes in cardiopulmonary function

during unsedated transnasal small-caliber and transoral conventional EGD in patients aged > 65 years old.

**Patients:** Between July 2006 and April 2007, we enrolled 240 elderly patients (> 65 years old), who received EGD for their abdominal symptoms and for their annual medical check in the Izumo City General Medical Center, into the prospective comparison study. The first consecutive 120 patients were assigned to the transnasal small-caliber EGD (TN) group and the second consecutive 120 patients to the transoral conventional EGD (TO) group.

**Endoscopic procedure:** A single experienced endoscopist (M.Y.), certified by the Japan Gastroenterological Endoscopy Society, performed all of the examinations. Patients in the TN group were examined with a small-caliber videoendoscope (EG-530N; Fujinon Toshiba ES Systems Co. Ltd., Tokyo, Japan), 5.9 mm in diameter. Patients in the TO group were examined with a conventional endoscope (GIF-H260; Olympus Medical Systems, Tokyo, Japan), 9.8 mm in diameter. Patients who needed endoscopic biopsy and/or received a time-consuming chromoendoscopic examination were excluded from this study.

Patients in the TO group received throat anesthesia by application of 5 mL 2% lidocaine viscous (Xylocaine viscous; Astra Zeneca, Osaka, Japan) for 5 min. Nasal anesthesia was started in patients in the TN group by spraying a solution of 0.4% lidocaine and 0.5% naphazoline into the nostril. The patients were then instructed to inhale 2% lidocaine jelly (Xylocaine jelly; Astra Zeneca), and a 20 Fr catheter covered with lidocaine jelly was inserted into the deeper nasal cavity for 5 min. All the EGDs were performed with the patient in the left lateral recumbent position, and without administration of scopolamine butylbromide.

**Cardiopulmonary monitoring:** Systolic and diastolic blood pressure (BP), pulse rate (PR), and oxygen saturation by pulse oximetry (SpO<sub>2</sub>) were measured at the following four points during the endoscopic examination, to measure these parameters at the stabilized condition of patients: (1) baseline; (2) at 2 min and (3) at 5 min after endoscopic intubation; and (4) at the end of the examination. The values of BP, PR and SpO<sub>2</sub> were measured simultaneously with high sensitivity by the newly developed measuring system, Bedside Monitor PetiTelemo DS-7001 (Fukuda Denshi Co. Ltd., Tokyo, Japan). The rate-pressure product (PR × systolic BP/100) was also calculated as shown in previous reports<sup>[14,15]</sup>. Changes in each value were compared between TN and TO groups.

### Study 2

In the patients treated with PEG tube feeding, we performed periodic PEG tube exchanges during endoscopic observation every 6 mo. For these observations, an endoscopic method, transoral conventional or transnasal small-caliber was selected randomly for each patient by an envelop method, and switched at the next exchange (a

crossover design). Changes in cardiopulmonary parameters and markers of inflammation were measured during EGD, and blood leukocyte counts and serum C-reactive protein (CRP) concentrations were measured before and after EGD.

**Patients:** Between March 2007 and April 2008, 30 patients who were undergoing PEG feeding were enrolled. Reasons for PEG feeding included dysphagia caused by cerebral infarction, cerebral hemorrhage, subarachnoid hemorrhage, and other conditions. Their PEG tube exchanges were carried out routinely under endoscopic observation every 6 mo, using an instrument (transnasal small-caliber or transoral conventional endoscope) that was assigned randomly to each patient at enrollment. At the next tube exchange 6 mo later, the alternate method was used for each patient. The 30 patients were thereby divided into one initially transnasal, secondarily transoral (TN-TO,  $n = 15$ ) group, and one initially transoral, secondarily transnasal (TO-TN,  $n = 15$ ) group. In all of the enrolled patients, a bumper type kit (Ponsky Non-Balloon Replacement Gastrostomy Tube; Bard Limited, Salt Lake City, UT, USA) was used as a PEG tube. Each procedure for the PEG tube exchanges was not done when the patients had infectious diseases such as pneumonia, or urinary or hepato-biliary tract infection. Before PEG tube exchange, chest X-ray examination, urinalysis, and laboratory blood tests including peripheral blood count, inflammatory markers and hepato-biliary enzymes were done to confirm the absence of infectious diseases. In this study, PEG tube exchanges were not performed in patients who showed increases of leukocyte count or CRP and fever elevation before the procedure.

**Endoscopic procedure:** A single experienced endoscopist (M.Y., as in Study 1) performed all of the examinations, using the same endoscopes and pre-medication regimens as in Study 1. The procedure for PEG tube exchange by transnasal endoscope was similar to that by transoral endoscope. All the EGDs were performed with the patient in the supine position, and without administration of scopolamine butylbromide.

**Cardiopulmonary monitoring:** During each endoscopy procedure, systolic and diastolic BP, PR, SpO<sub>2</sub> and RPP were determined at the following three points: (1) baseline; (2) at 2 min after endoscopic intubation; and (3) at the end of the examination. Changes in each value were compared between TN and TO endoscopic studies.

**Evaluation of inflammatory response:** As markers of inflammation, body temperature, leukocyte counts and serum concentrations of CRP were measured. Body temperature was measured before and every 6 h after the endoscopy-guided exchange of PEG tube. Leukocyte counts and CRP were performed routinely before and 3 d after the procedure. If suspicious pneumonia was found, these parameters were examined more frequently. Further examination of pneumonia such as chest X-ray

**Table 1** Characteristics of patients enrolled in Study 1 (mean  $\pm$  SD)

	TN group	TO group	P value
Age (range, yr)	77.0 $\pm$ 7.7 (65-97)	76.7 $\pm$ 7.2 (65-95)	NS
Gender (M:F)	30:66	53:49	NS
Total procedure time (min)	8.46 $\pm$ 4.32	6.03 $\pm$ 2.50	0.001
Baseline cardiopulmonary parameters			
Systolic BP	131.4 $\pm$ 19.3	135.4 $\pm$ 21.8	NS
Diastolic BP	67.6 $\pm$ 12.3	70.5 $\pm$ 12.8	NS
RPP	100.2 $\pm$ 27.4	98.82 $\pm$ 25.7	NS
SpO <sub>2</sub>	98.1 $\pm$ 1.4	98.2 $\pm$ 1.4	NS

NS: Not significant; M: Male; F: Female.

examination and/or computed tomography (CT) was done when respiratory symptoms, fever elevation, and increased leukocyte count and/or CRP were found.

**Increased occurrence of aspiration pneumonia:** The incidence of aspiration pneumonia was also compared between the TN and TO groups. Pulmonary aspiration was defined by witnessed aspiration or tracheal suctioning of secretions including saliva as shown by previous studies on PEG procedures<sup>[16,17]</sup>. In patients with post-procedure elevation of inflammation markers and/or fever, aspiration pneumonia was evaluated by chest X-ray examination and/or CT. Pneumonia was diagnosed by the presence of new infiltrates of the lung associated with fever.

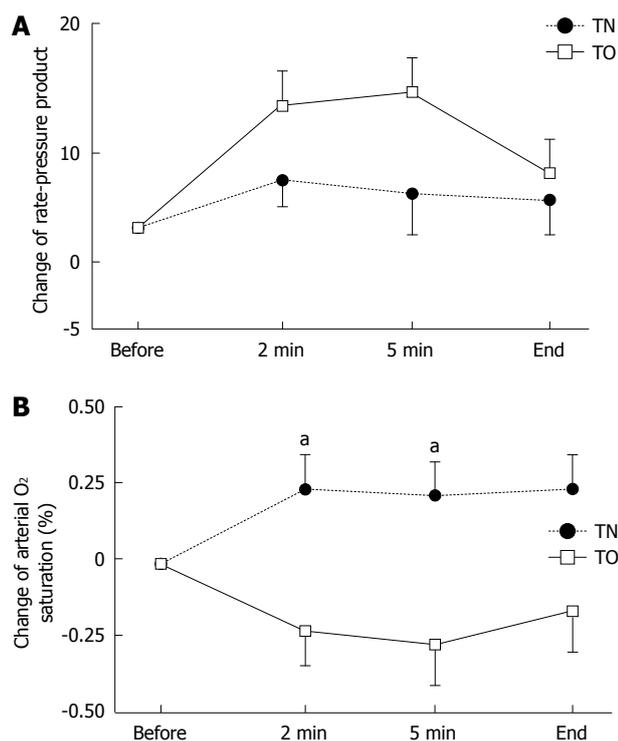

### Statistical analysis

Data for each comparison between groups were analyzed using the  $\chi^2$  and Wilcoxon signed rank tests. The latter test was done only when the Friedman test showed significant differences. Categorical data were compared using Student's *t* test or, where unequal variances occurred, Welch's test.  $P < 0.05$  was considered to be significant. All statistical analyses were performed using SPSS version 12.0 (SPSS Japan, Tokyo, Japan).

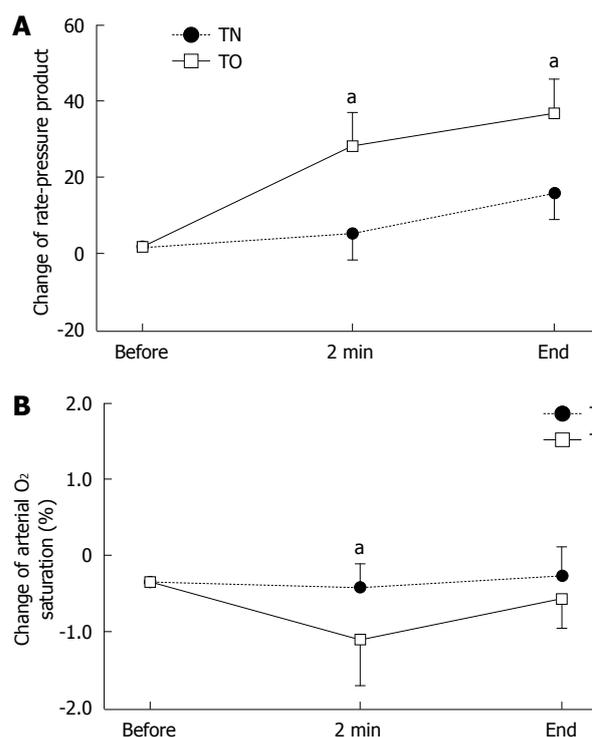

## RESULTS

### Study 1

Ninety-six and 102 elderly patients were analyzed finally as the TN and TO groups, respectively. Twenty-four and 18 patients were excluded since complete data could not be obtained, mainly because of the delay in measurement in the TN and TO groups, respectively. Characteristics of the enrolled patients in each group are shown in Table 1. Mean ages of these patients were 77.0 and 76.7 years, respectively. Total procedure time for EGD was 8.46  $\pm$  4.32 min in the TN group, and 6.03  $\pm$  2.50 min in the TO group. This difference in procedure time was statistically significant ( $P < 0.001$ ). No serious complications in cardiopulmonary function occurred in this study, although two patients experienced mild epistaxis during pre-medication for transnasal EGD. The baseline cardiopulmonary parameters, RPP and SpO<sub>2</sub>, did not show any significant differences (Table 1).

**Figure 1** Time course of changes in RPP and SpO<sub>2</sub> (Study 1). A: RPP tended to increase more in the TO group than in the TN group, although this difference did not reach statistical significance; B: SpO<sub>2</sub> fell significantly at 2 and 5 min after the start of transoral endoscopic examination. Bars show SE. <sup>a</sup>*P* < 0.05.

**Figure 2** Time course of changes in RPP and SpO<sub>2</sub> (Study 2). A: RPP increased significantly more in the TO group than in the TN group. B: SpO<sub>2</sub> fell significantly at 2 min after the start of examination in the TO group. Bars show SE. <sup>a</sup>*P* < 0.05.

	TN-TO group	TO-TN group	<i>P</i> value
Age (yr)	84.3 ± 7.9	80.7 ± 15.8	NS
Gender (M:F)	3:12	4:11	NS
Background pathological condition for PEG feeding			
Cerebral infarction	10	11	
Cerebral hemorrhage	2	3	
Subarachnoid hemorrhage	1	0	
Others	2	1	

	TN-EGD	TO-EGD	<i>P</i> value
Total procedure time (min)	4.36 ± 3.46	4.42 ± 3.18	NS
Baseline cardiopulmonary parameter			
Systolic BP	125.5 ± 25.3	122.6 ± 28.4	NS
Diastolic BP	70.1 ± 17.8	64.9 ± 20.1	NS
RPP	107.7 ± 44.6	101.3 ± 37.9	NS
SpO <sub>2</sub>	98.7 ± 1.7	95.4 ± 17.5	NS

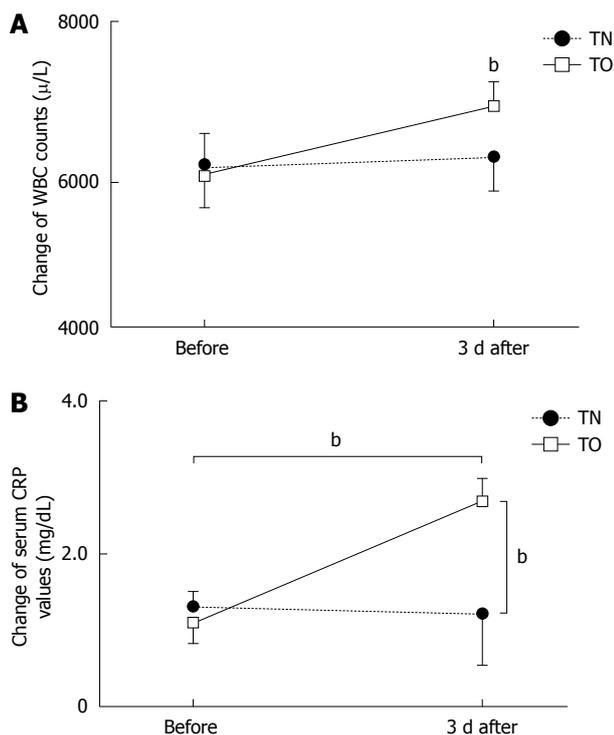

Changes in BP, PR and RPP during endoscopy did not differ significantly between the TN and TO groups, although these parameters tended to increase more in the TO group (Figure 1A). Values for SpO<sub>2</sub> in the TO group decreased significantly during EGD (-0.24% and -0.29% after 2 and 5 min) compared with those in the TN group (+0.24% and +0.18% after 2 and 5 min, *P* < 0.05). These findings suggested that transoral EGD affects pulmonary function more severely than transnasal EGD does in this group of patients (Figure 1B).

**Study 2**

We enrolled 30 patients who required PEG feeding: 15 in the TN-TO group and 15 in the TO-TN group. Characteristics of these patients are shown in Tables 2 and 3. Categorical data did not differ significantly between the TN-TO and TO-TN groups. Baseline cardiopulmonary parameters, RPP and SpO<sub>2</sub>, did not differ significantly.

Higher values of systolic and diastolic BP were found in the TO group than in the TN group after intubation for endoscopy, but these differences did not reach statistical significance. Values for RPP during and at the end of endoscopy were significantly higher in the TO group (26.8 and 34.6) than those in the TN group (3.1 and 15.2, *P* < 0.05), as shown in Figure 2A. The SpO<sub>2</sub> also significantly decreased at 2 min after the start of transoral EGD (-0.8%) in comparison with transnasal EGD (-0.1%, *P* < 0.05) (Figure 2B). Thus, in the bedridden patients with PEG feeding, examined in the supine position, transoral EGD disturbed cardiopulmonary function more strongly than did transnasal EGD.

Markers of inflammation also changed significantly in conjunction with endoscopy. Peripheral leukocyte count increased from 6053 ± 1975/L to 6900 ± 3392/L at 3 d after transoral EGD, as shown in Figure 3A (*P* < 0.001); and CRP values increased from 0.93 ± 0.24 mg/dL to 2.49 ± 0.91 mg/dL (*P* < 0.001) (Figure 3B). These data

**Figure 3** Changes in leukocyte counts (A) and CRP values (B) (Study 2). Counts and CRP increased significantly by the third day after transoral endoscopy (TO), but did not change after transnasal endoscopy (TN). Bars show SE. <sup>b</sup>*P* < 0.001.

also showed statistically significant differences at 3 d after PEG tube exchange between transnasal and transoral EGD (*P* < 0.001).

Aspiration pneumonia, possibly caused by the endoscopic examination, was subsequently found in two of 30 patients after transoral EGD. In these two cases, a significant drop in SpO<sub>2</sub> values was found during transoral EGD, and the elevation of inflammation makers (CRP values and leukocyte counts) was also found after the procedure with transoral EGD but not with transnasal EGD. Additionally, the witnessed aspiration or tracheal suctioning of secretions including saliva was observed in these two cases of transoral EGD. Both of these patients recovered after the administration of antibiotics.

## DISCUSSION

Transnasal small-caliber endoscopy, recently accepted for screening of the upper gastrointestinal tract, presents advantages apart from image quality, a noteworthy feature of transoral conventional endoscopy. Unsedated transoral EGD is well known to increase BP and PR, with an increased cardiopulmonary work load<sup>[2,4-6]</sup>. Recently, small-caliber endoscopes have been developed and used for EGD with the transnasal route. Several investigators have demonstrated that transnasal EGD with small-caliber endoscopes is feasible and tolerable<sup>[7-11]</sup>, since transnasal small-caliber EGD is less stimulative to the uvula, palatine arches and posterior part of the tongue, and does not induce gag reflex<sup>[6]</sup>. Therefore, the feasibility and tolerability of unsedated transnasal small-caliber

EGD strongly support its value as a standard screening procedure. However, the studies on transnasal small-caliber EGD were done mainly on relatively young patients aged < 60 years old. Elderly patients are believed to tolerate easily transoral EGD without excessive gagging or choking. Therefore, the clinical advantage of transnasal small-caliber EGD for this population may not outweigh the advantage of higher image quality obtained with conventional EGD. To determine the value of the transnasal small-caliber endoscope for screening older patients, we must first establish its tolerability and safety for this group. We have found no studies that specifically have addressed this issue.

In the first part of our study, we found no significant difference between transnasal and transoral endoscopy with respect to hemodynamic parameters. On the other hand, SpO<sub>2</sub>, a measure of pulmonary function, significantly declined during transoral endoscopy, although the decrease was small. The small decrease in SpO<sub>2</sub> is not clinically important for elderly patients in good physical condition. However, for elderly patients with cardiopulmonary diseases and resulting decreased basal SpO<sub>2</sub> value, further small decreases in SpO<sub>2</sub> are prone to have serious consequences. Patients long confined to bed (including most who require PEG feeding) may become susceptible to infectious pulmonary diseases as a result of swallowing disturbance or micro-aspiration that accompanies decreased SpO<sub>2</sub>. For safety in the periodic tube exchange, endoscopy-guided re-intubation of the PEG kit is recommended for these patients, because wrong replacement of the feeding tube can cause serious complications, such as peritonitis. This procedure requires that the patient remains supine, which increases the risk for aspiration of saliva and refluxed gastric contents. Transoral endoscopy may stimulate salivary secretion and thereby increase the risk of aspiration pneumonia. In addition, the supine position may influence specifically hemodynamic and/or pulmonary parameters during endoscopy. Previous studies have assessed only the hemodynamic changes that occur when PEG tube insertion is monitored with transnasal small-caliber endoscopy<sup>[18,19]</sup>. We have therefore measured pulmonary function and two markers of inflammation, as well as hemodynamic parameters, in this endoscopic examination (i.e. with the patient in the supine position). We consistently found advantages in the use of the transnasal small-caliber endoscope, with respect to both hemodynamic and pulmonary parameters. Significant increases in leukocyte counts and CRP values, which indicate systemic inflammatory disease, occurred only after transoral conventional endoscopy. Aspiration pneumonia was found in two cases after 30 transoral endoscopic procedures for the replacement of the PEG tube. PEG tube exchange is done in the supine position, therefore, the patients may have a higher risk of aspiration. However, no pneumonia was found after the procedure using the transnasal small-caliber endoscope. The transoral conventional endoscope may stimulate salivary secretion and further increase the risk of aspiration. Additionally, the oral cavity and saliva of bedridden patients with PEG feeding is prone to be infected by bacteria that may cause pneumonia. Use of the transnasal small-

caliber endoscope may therefore reduce the risk of this potentially serious complication of transoral conventional EGD in bedridden patients.

In conclusion, SpO<sub>2</sub> decreased significantly in elderly patients during transoral conventional EGD, but not during transnasal small-caliber EGD. Compared to transoral conventional EGD, transnasal small-caliber endoscopy may reduce the risk of aspiration pneumonia, when the patient must be examined in the supine position. Therefore, transnasal small-caliber EGD is a safer method than transoral conventional EGD in critically ill patients, such as those who are bedridden and undergoing PEG feeding.

## COMMENTS

### Background

Unsedated transnasal small-caliber esophagogastroduodenoscopy (EGD) is often used to examine the upper gastrointestinal tract. Its efficacy for elderly and critically ill patients, however, has not been fully evaluated. To evaluate the tolerability of transnasal EGD for elderly and critically ill bedridden patients, a prospective randomized comparative and a crossover study were undertaken.

### Research frontiers

Elderly patients, including those who are bedridden, do not frequently gag or choke during transoral conventional EGD. If transoral conventional EGD is safe and comfortable for them, the value of transnasal small-caliber EGD could be limited, because the smaller charge-coupled device in the endoscope may potentially reduce diagnostic accuracy for minute gastric lesions. This is believed to be the first published study concerned with the tolerability and safety of transnasal small-caliber endoscopy for critically ill patients.

### Innovations and breakthroughs

Other studies evaluating the tolerability and safety of transnasal endoscopy have focused mainly on younger patients, with a mean age < 50 years old. The data and viewpoints originated from elderly and critically ill patients and have not been published elsewhere.

### Applications

Significant decreases were observed in SpO<sub>2</sub> saturation during conventional transoral EGD, but not during transnasal small-caliber EGD. Significant increases were also found in the markers of inflammation in bedridden patients after transoral conventional EGD, but not after transnasal small-caliber EGD performed with the patient in the supine position.

### Peer review

This is a prospective study that compared the consequences of using two endoscopic devices (conventional and small caliber) in critically ill patients. The importance of this study is related to the fact that the use of small caliber endoscopes in diagnosis is becoming more common because of its tolerability and lack of sedation.

of MDM2-SNP309 *vs* wild-type T/T genotype in patients with HCC was not significant (OR = 1.265, 95% CI = 0.074-21.77) after adjustment for sex, hepatitis B or C virus infection, age, and cardiovascular disease/diabetes. Nevertheless, there was a trend that GG genotype of MDM2-SNP309 might increase the risk in HCC patients infected with hepatitis virus (OR = 2.568, 95% CI = 0.054-121.69). Besides, the homozygous MDM2-SNP309 genotype did not exhibit a significantly earlier age of onset for HCC.

**CONCLUSION:** Current data suggest that the association between MDM2-SNP309 GG genotype and HCC is not significant, while the risk may be enhanced in patients infected by hepatitis virus in Taiwan.

### Abstract

**AIM:** To investigate the risk association and compare the onset age of hepatocellular carcinoma (HCC) patients in Taiwan with different genotypes of MDM2-SNP309.

**METHODS:** We analyzed MDM2-SNP309 genotypes from 58 patients with HCC and 138 cancer-free healthy controls consecutively. Genotyping of MDM2-SNP309 was conducted by restriction fragment length polymorphism assay.

**RESULTS:** The proportion of homozygous MDM2-SNP309 genotype (G/G) in cases and cancer-free healthy controls was similar (17.2% *vs* 16.7%). Multivariate analysis showed that the risk of G/G genotype

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a prevalent type of cancer. It represents the fifth most prevalent cancer worldwide, and accounts for the top three causes of death in the Asia-Pacific region<sup>[1,2]</sup>. The risk factors associated with HCC include age, sex, alcohol, diet, and infection with hepatitis B virus (HBV) and/or hepatitis C virus (HCV)<sup>[2]</sup>. Most newly diagnosed HCC is reported in Asia (> 70%), in which chronic HBV infection accounts for 75% of cases worldwide<sup>[3]</sup>. Significantly, 55% of HCC cases are reported from the Chinese population<sup>[4]</sup>. Although the incidence rate of HCC is plausibly linked to geographic area and geo-economic conditions, it is possible that gene polymorphism may be associated with the risk of HCC<sup>[5,6]</sup>.

Single nucleotide polymorphism (SNPs) occur frequently in human genomes. SNPs can be detected once per 1000 bp in DNA sequences, on average, and may affect gene transcription and amino acid composition if they are located in gene regions. Several lines of evidence have shown that SNPs in genes such as small inducible cytokine B14 precursor (*SCYB14*), glial cell-derived neurotrophic factor family receptor  $\alpha$  1 (*GFR $\alpha$ 1*), corticotropin-releasing hormone receptor 2 (*CRHR2*), glucose-regulated protein 78 (*GRP78*), heat shock protein A1B (*HSPA1B*), DNA-methyltransferase-3B (*DNMT3B*),  $\alpha$ -fetoprotein (*AFP*) and *p53* R72P are associated significantly with HCC<sup>[6-12]</sup>. These SNPs localize in promoter regions, coding sequences, or even introns of individual genes, which suggests that the expression level and functions of affected genes can influence the incidence rate of HCC.

MDM2 oncoprotein is a direct negative regulator for the p53 tumor suppressor protein, which accounts for 50% of human cancers if deleted or with loss-of-function<sup>[13,14]</sup>. Overexpression of MDM2 by up to fourfold in transgenic mice that harbor wild-type p53 leads to complete tumorigenesis<sup>[15]</sup>. MDM2 overexpression also is associated with poor survival and is a useful predictive factor for poor prognosis in humans with liver cancer<sup>[16,17]</sup>. A genetic polymorphism located in intron 1 of the MDM2 gene, so called MDM2-SNP309 (a change from T to G, rs2279744) can enhance the binding of Sp1 general transcription factor to this promoter region and increase MDM2 gene transcription<sup>[18]</sup>. It has been suggested that this SNP is associated with the risk and early onset age of various human cancers<sup>[19]</sup>. Some studies have shown that MDM2-SNP309 is associated with the risk of HCC in Japanese and Moroccan patients with chronic hepatitis C, and Korean patients with chronic hepatitis B<sup>[20-22]</sup>. Although > 50% of HCC cases are reported from Asia, it remains largely unknown whether MDM2-SNP309 influences the risk and onset age of HCC in other countries in this region, except for Japan and Korea.

In this study, we initiated a hospital-based case-control study to investigate the risk association between MDM2-SNP309 and HCC in Taiwanese patients. We also examined whether HCC onset was earlier in patients with homozygous MDM2-SNP309 (G/G) compared to wild-type MDM2-SNP309 (T/T).

## MATERIALS AND METHODS

### **Patients and cancer-free healthy controls**

We studied 58 patients with HCC diagnosed by cancer specialists, and 138 cancer-free healthy adults enrolled from Taipei City Hospital Ren Ai Branch, Taiwan during 2007. All volunteers signed the consent form and filled out the structured questionnaire before providing their blood samples. All patients and 50 cancer-free healthy controls were tested for hepatitis B and C by anti-HBsAg, HBsAg, Anti-HBc IgG, and anti-HCV. Several risk factors associated with HCC were included in the questionnaire, including age, sex, alcohol intake, frequency of exercise, and cardiovascular diseases/diabetes. There was no other cancer type diagnosed in each patient. The sub-

jects were born in the Taiwan Island except five patients and four cancer-free healthy controls who had emigrated from mainland China. This study was approved by institutional review committee board of National Yang-Ming University and Taipei City Hospital.

### **MDM2-SNP309 genotyping**

Analysis of MDM2-SNP309 genotyping was conducted by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP), as described previously<sup>[23]</sup>. Genomic DNA was extracted from 200  $\mu$ L whole blood sample using the Qiagen Mini Blood DNA Extraction kit (Valencia, CA, USA). The DNA fragment that contained the MDM2 SNP309 was amplified by PCR using the forward (5'-CGGGAGTTCAGGGTAAAGGT-3') and reverse primer (5'-AGCAAGTCCGGTGCTTACCTG-3') (Protech Inc., Taipei, Taiwan). Each PCR reaction was conducted using 100 ng genomic DNA, 0.2  $\mu$ mol/L primer, 200  $\mu$ mol/L dNTP, 1.5 mmol/L MgCl<sub>2</sub>, 20 mmol/L Tris-HCl (pH 8.4), 50 mmol/L KCl and 1 U Platinum *Taq* DNA polymerase (Invitrogen, Carlsbad, CA, USA). The thermal cycler conditions were 94°C for 1-5 min; 40 cycles with denaturing at 94°C, annealing at 59°C, and elongation at 72°C for 30 s each; one cycle at 72°C for 10 min. Subsequently, 10  $\mu$ L of the PCR product was digested with 1 U *Msp*A1I restriction enzyme (New England Biolabs, Ipswich, MA, USA) at 37°C for 30-60 min. The T/T, T/G and G/G genotypes were identified as 233 bp/88 bp, 233 bp/187 bp/88 bp, and 187 bp/88 bp running on the 3% NuSieve agarose gel, respectively. The genotypes were confirmed by direct sequencing of the PCR products by the Sequencing Core Facility of Genomic Research Center in National Yang-Ming University.

### **Statistical analysis**

Whether the frequency of MDM2-SNP309 genotype obeyed the Hardy-Weinberg equilibrium was determined by an on-line public statistical tool (<http://www.genes.org.uk/software/hardy-weinberg.shtml>). Two-sample *t* test was used to evaluate the difference in age and body mass index (BMI) between cases and controls. Differences in sex, hepatitis frequency, HBV and HCV infection, alcohol intake, exercise, and incidence of cardiovascular diseases and diabetes between cases and controls were determined by Fisher's exact test. Multivariate logistic regression analysis was used to calculate the OR and 95% CI to determine the association between HCC risk and MDM2-SNP309 genotypes. The Kaplan-Meier survival analysis was used to describe the onset age of HCC, and the log-rank test was used to compare the median onset age between patients with GG and those with TT genotypes in MDM2 SNP309. *P* < 0.05 was considered statistically significant in all tests. All statistical analyses were performed with Statistical Analysis System ver. 9.1 (SAS Institute, Cary, NC, USA).

## RESULTS

We investigated 58 HCC patients and 138 cancer-free healthy controls to evaluate the risk association between

MDM2-SNP309 and HCC. The characteristics of these blood donors are summarized in Table 1. The mean ages were significantly different between cases and controls ( $65.9 \pm 10.14$  years *vs*  $40.2 \pm 15.24$  years) at the time that they joined this study. These participants were enrolled consecutively without pre-selection for age, therefore, this difference may confirm that HCC usually is found in elderly individuals. In HCC patients, > 80% had been infected with HBV or HCV, and two cases were infected with both HBV and HCV. In addition, the frequency of HCC patients infected with HBV was slightly higher than that of those infected with HCV. Other factors that may affect the incidence of HCC are also summarized in Table 1. Except for BMI and alcohol intake, other confounding factors exhibited a significant difference between HCC cases and cancer-free healthy controls. They were adjusted for the multivariate logistic regression model thereafter.

The frequency of MDM2-SNP309 distributed in wild-type (TT), heterozygous (TG) and homozygous (GG) genotypes are shown in Table 2. The genotype distributions in HCC cases and cancer-free healthy controls slightly departed from Hardy-Weinberg equilibrium (HCC,  $\chi^2 = 4.426$ ,  $P = 0.035$ ; controls,  $\chi^2 = 3.907$ ,  $P = 0.048$ ). It is impossible to predict the genotype of each blood donor, therefore, it is expected that this inconsistency may have been due to the small sample size. Although the frequency of wild-type MDM2-SNP309 genotype was lower in HCC cases than in cancer-free healthy controls, there was no significant difference found in the frequency of homozygosity between these two groups (Table 2). To determine the risk association between HCC and MDM2-SNP309

**Table 2** The risk evaluation of MDM2 SNP309 genotypic frequencies on the development of HCC *n* (%)

SNP309	Cases	Controls	OR (95% CI) <sup>1</sup>	<i>P</i> value
TT	11 (19)	35 (25.3)	1	
TG	37 (63.8)	80 (58)	1.016 (0.152-6.8)	0.99
GG	10 (17.2)	23 (16.7)	1.265 (0.074-21.767)	0.87
TG+GG	47 (81)	103 (57.5)	1.037 (0.757-6.862)	0.97
TT+TG	48 (82.8)	115 (83.3)	1	
GG	10 (17.2)	23 (16.7)	1.25 (0.123-12.66)	0.85

<sup>1</sup>The multivariate logistic regression model was used to calculate odds ratio adjusted for gender, infection of hepatitis virus (B or C type), age, cardiovascular disease and/or diabetes.

Hepatitis <sup>1</sup>	SNP309	Cases	Controls	OR <sup>2</sup>	95% CI	<i>P</i> value
Positive	TT	7 (14.3)	1 (10)	1.000		
	TG	32 (65.3)	7 (70)	2.340	0.11-49.655	0.59
	GG	10 (20.4)	2 (20)	2.568	0.054-121.687	0.63
	TG+GG	42 (85.7)	9 (90)	2.376	0.115-48.896	0.57
Negative	TT	4 (44.4)	19 (24)	1.000		
	TG	5 (55.6)	45 (57)	0.512	0.046-5.712	0.59
	GG <sup>3</sup>	0 (0)	15 (19)	-	-	-
	TG+GG	5 (55.6)	60 (76)	0.470	0.041-5.387	0.54

<sup>1</sup>Include HBV or HCV infected patients with HCC; <sup>2</sup>OR was adjusted for age, gender and cardiovascular diseases and/or diabetes; <sup>3</sup>OR was not estimated because the number in case was zero.

genotypes, multivariate logistic regression analysis showed that the OR of heterozygous (TG) and homozygous (GG) SNP309 genotypes was 1.016 (95% CI = 0.152-6.8,  $P = 0.987$ ) and 1.265 (95% CI = 0.074-21.767,  $P = 0.87$ ) compared to wild-type SNP309 genotype, respectively (Table 2). These OR values were adjusted for age, sex, infection with HBV or HCV, cardiovascular disease and/or diabetes. Comparison of homozygous MDM2-SNP309 (GG) genotype with common (TT) or heterozygous (TG) MDM2-SNP309 carriers showed that the adjusted OR was 1.247 (95% CI = 0.123-12.66,  $P = 0.852$ ). The TG or GG genotype of MDM2-SNP309 versus TT variant form exhibited an adjusted OR of 1.037 (95% CI = 0.757-6.682,  $P = 0.97$ ) (Table 2). These OR values are lower than those reported previously in Japanese, Korean and Moroccan populations<sup>[20-22]</sup>. Thus, current statistical results showed that risk association between MDM2-SNP309 genotype and HCC was not significant in the Taiwanese population.

We next investigated whether HBV or HCV infection influenced the effects of MDM2-SNP309 genotypes on patients with HCC. As shown in Table 1, 49 cases infected with HBV or HCV were analyzed by the logistic regression model. It revealed that the homozygous (GG) MDM2-SNP309 genotypes exhibited increased risk over the common (TT) genotype of MDM2-SNP309 (adjusted OR = 2.568, 95% CI = 0.054-121.687,  $P = 0.632$ ) (Table 3). The adjusted OR of TG or GG of MDM2-SNP309 genotype was 2.376 compared to TT genotype (95% CI =

**Figure 1** Comparison of age at diagnosis in HCC patients with wild-type (TT) and homozygous (GG) MDM2-SNP309 by the Kaplan-Meier method and the log-rank test. The survival fraction was the cumulative case-free survival rate against age at diagnosis of patients with HCC with different MDM2-SNP309 genotypes.

0.115–48.896,  $P = 0.575$ ). The broad range of 95% CI was due to the small sample size, while it seems plausible that the risk association between MDM2-SNP309 and patients with HCC may have been enhanced by viral hepatitis.

We compared the age at diagnosis for HCC patients who had different MDM2-SNP309 genotypes, and the median ages for TT, TG and GG genotypes were 68 (range 55–82), 66 (range 38–87) and 64.5 (range 51–73) years old, respectively. The arithmetic mean ages and SD for TT, TG and GG were  $69.1 \pm 8.23$ ,  $64.3 \pm 11.1$ , and  $62.5 \pm 7.88$  years old, respectively. Although the mean age of patients with homozygous MDM2-SNP309 genotype (GG) was 6.6 years lower than that of patients with wild-type MDM2-SNP309 genotype (TT), there was no significant difference between them by *t* test ( $P = 0.0844$ , 95% CI = -0.9835–14.1654). Besides, the Kaplan-Meier survival analysis showed that comparison of the age at diagnosis for HCC patients with GG and TT genotypes was not significantly different by log-rank test ( $P = 0.1489$ , Figure 1). Therefore, the current results suggest that MDM2-SNP309 is not associated with onset age of HCC in the Taiwanese population. However, a larger sample size may be necessary to confirm this observation.

## DISCUSSION

HCC commonly occurs in the Asia-Pacific region, and it also accounts for high morbidity and mortality in this area<sup>[2]</sup>. Although the incidence rate of male HCC patients is high in the Asia-Pacific region (14–36 per 100 000 men), it exhibits significant variance in different countries. The highest incidence rate of male HCC occurs in China and Taiwan, which is 58 and 53 per 100 000 men, respectively<sup>[2]</sup>. The main etiological agents that result in high incidence of HCC in the Asia-Pacific region include high infection rate with HBV and HCV, cirrhosis, family history, environmental contamination, diet, and  $\alpha$ -fetoprotein<sup>[4,24,26]</sup>. MDM2-SNP309 is a novel predictor for Japanese and Korean patients with HCC infected by HCV and HBV, respectively<sup>[20,21]</sup>. In this study, we examined the risk association between Taiwanese HCC

patients and MDM2-SNP309. Although the multivariate analysis showed that the association between MDM2-SNP309 and HCC in the Taiwanese population was not significant, there was a trend that homozygous (GG) or heterozygous (TG) MDM2-SNP309 genotype exhibited a higher risk in the subset of HCC patients infected with HBV or HCV. This is consistent with previous reports in Japanese and Korean patients with HCC, at least in part. Besides, our data failed to prove that MDM2-SNP309 could accelerate the development of HCC, although the median age at diagnosis of patients with homozygous MDM2-SNP309 genotype (GG) was 3.5 years lower than that of patients with the common genotype (TT). This result also agrees with the studies in the Japanese and Moroccan but not in the Korean population<sup>[20–22]</sup>. Therefore, the risk association and the effects of age onset between MDM2-SNP309 genotypes and HCC are likely to be dependent on the selected patient subgroups.

MDM2 negatively regulates p53 tumor suppressor protein. It is reasonable to expect that over-produced MDM2 will repress p53 function on cancer prevention. This hypothesis has been demonstrated in an MDM2 overexpression transgenic mouse model that develops systemic tumors. The putative effect of MDM2-SNP309 is to enhance the transcription of the MDM2 gene, and to affect the p53 regulatory pathway for tumor development. Several lines of evidence have demonstrated an association between MDM2-SNP309 and various sporadic or hereditary human cancers, including risk and earlier age onset. Nevertheless, non-supportive data are also reported to disagree that there is a risk association between MDM2-SNP309 and human cancers, even when the same cancer types are studied<sup>[27–36]</sup>. One of the reasons is likely to be the different subgroups of patients and races. For instance, a recent meta-analysis has demonstrated that the G allele of MDM2-SNP309 may affect breast cancer in the Chinese population rather than non-Chinese population<sup>[37]</sup>. Although HCC is a common cancer type in the Asia-Pacific region, its association with MDM2-SNP309 has only been reported in Japanese patients with chronic hepatitis C and in Korean patients chronically infected with hepatitis B virus<sup>[20,21]</sup>. HCC has the second highest cancer mortality in Taiwanese subjects who are vulnerable to be infection with HBV or HCV (<http://crs.cph.ntu.edu.tw/>). To the best of our knowledge, this is the first study to investigate the Taiwanese population to analyze the effects of MDM2-SNP309 genotypes on HCC development.

The sample size is the primary limitation of our study. The participants were from a single hospital, and most patients who suffered from HCC had a lack of enthusiasm to provide blood samples for analysis. Besides, the age distribution of cases and cancer-free healthy controls was significantly different. The patients were enrolled consecutively, therefore, this bias was not due to selection and was adjusted for in multivariate analysis. Another limitation is that sex distribution and incidence of hepatitis between cases and controls were not comparable. In HCC patients, the ratio of men to women was 3.46, and 84.5% of patients also had hepatitis. The mean ages at diagnosis for HBV- and HCV-infected HCC patients were  $59.53 \pm$

10.72 years and  $70.63 \pm 6.39$  years, respectively ( $P = 0.0002$ ). Male HCC patients were infected mainly by HBV (64.9%), while female HCC patients were infected by HCV (66.7%). Furthermore, the male/female ratio was 6.0 for HCC patients with HBV infection, while it was 1.375 for those with HCV infection. All of these results are similar to a previous study of 18 423 Taiwanese HCC patients enrolled from 1981 to 2001<sup>[2,38]</sup>. Therefore, the characteristics of HCC patients did not exhibit a significant discrepancy compared to a large cohort study in Taiwan, even though a small sample size was used in this study.

Several potential risk factors were also considered in this study. Frequent alcohol intake is considered to be an etiological agent for the Chinese population ( $OR = 1.88$ )<sup>[4]</sup>. In our study, there was no significant difference between cases and controls regarding alcohol intake. However, identification of alcohol intake is dependent on self-interpretation by participants, and it may lead to apparent bias. It has been reported that metabolic syndrome, such as obesity and diabetes may affect the incidence of HCC<sup>[39-41]</sup>. We adjusted for these factors in the multivariate logistic regression model to evaluate the risk association between MDM2-SNP309 and HCC in the Taiwanese population. Nevertheless, it remains important to collect more samples to evaluate the potential risk factors for HCC in the presence of various MDM2-SNP309 genotypes in the future.

In summary, this hospital-based case-control study showed that there was no significant association between MDM2-SNP309 and HCC in the Taiwanese population. In the subset with hepatitis B or C, the homozygous or heterozygous MDM2-SNP309 genotype tended to influence the incidence rate of HCC. Homozygous MDM2-SNP309 genotype did not significantly accelerate the development of HCC, even though the median age at diagnosis of patients with homozygous SNP309 was 3.5 years lower than that of patients with wild-type SNP309. In the future, we expect to use a larger sample size to further confirm the effect of MDM2 SNP309 on HCC in the Taiwanese population.

## ACKNOWLEDGMENTS

We thank Dr. Christine S Walsh for her suggestions on the genotyping experiment. We thank Mr. Yi-Nan Liao and Ms. Li-Chang Huang for the assistance on statistical software operation and blood collection, respectively.

## COMMENTS

### Background

The incidence and mortality rate of hepatocellular carcinoma (HCC) are among the highest in Taiwanese cancer patients according to the data from the Taiwan Cancer Registry (<http://crs.cph.ntu.edu.tw/main.php?Page=N1>). Recently, it has been reported that a single nucleotide polymorphism (SNP) in the promoter region of MDM2 oncogene, MDM2-SNP309, is associated with the risk of HCC in Japanese and Korean patients infected with hepatitis C and hepatitis B virus, respectively. However, it remains unclear whether this observation commonly occurs in other neighboring Asian populations.

### Research frontiers

To the best of our knowledge, this is the first study to investigate the associa-

tion between MDM2-SNP309 and HCC in Taiwanese, a population close to the Han Chinese, which also has a high incidence and mortality of HCC. The data showed that there was no significant association between HCC risk and MDM2-SNP309 in the Taiwanese population, while the association tended to increase in patients with hepatitis B or C virus infection.

### Innovations and breakthroughs

The incidence and mortality rate of HCC in Taiwan are comparable to those in Japan and Korea. Previous studies have shown that MDM2-SNP309 is associated with the risk of HCC in Japanese patients with chronic hepatitis C, and Korean patients with chronic hepatitis B. In this study, the authors demonstrated that MDM2-SNP309 genotype may not affect the risk of HCC in the Taiwanese population, except in those with a history of viral hepatitis, regardless of whether hepatitis B or C. This conclusion may be important for previous research groups to reevaluate whether hepatitis can increase the risk effect of MDM2-SNP309 on HCC. It is also an important parameter for other research groups that are dedicated to investigate the association between HCC and genetic polymorphism in the MDM2 gene and its related signaling pathways.

### Applications

The results are expected to provide information about MDM2-SNP309 genotyping for routine health and newborn screening for HCC in subjects with or without viral hepatitis.

### Terminology

MDM2-SNP309 is a genetic polymorphism that corresponds to nucleotide 309, starting from first nucleotide of intron 1 of the MDM2 gene.

### Peer review

This was a well-designed and well-conducted study on the association between polymorphisms in MDM2 gene promoter and HCC. The results are clearly presented and discussed. These results may help dissect the molecular alterations involved in HCC development in Taiwan.

### Abstract

**AIM:** To investigate the association of obesity and elevated alanine aminotransferase with insulin resistance and compare these factors with metabolic syndrome.

**METHODS:** We enrolled a total of 1308 male workers aged from 22 to 63 years. Data was extracted from the workers' periodic health check-ups in hospitals. All cases were from the community of northern Taiwan. This was a cross-sectional observational study from July to September in 2004. We grouped all cases into four groups, based on the quartile of homeostasis model assessment. The top fourth quartile group was defined as the group with insulin resistance. We performed multivariate logistic regression analysis for the odds ratio of the risk factors for insulin resistance.

**RESULTS:** Compared with metabolic syndrome, the coexistence of both factors had a 4.3-fold (95% CI: 2.7-6.8) increased risk, which was more than metabolic syndrome with a 3.6-fold (95% CI: 2.6-5.0) increased risk. The two factors had a synergistic effect. The synergistic index of obesity and elevated alanine aminotransferase (ALT) was 2.1 (95% CI: 1.01-4.3).

**CONCLUSION:** Obesity and elevated ALT are associated

### INTRODUCTION

Insulin resistance is a key feature of type 2 diabetes mellitus and it plays an important role in cardiovascular diseases<sup>[1]</sup>. Predicting insulin resistance is useful in preventing diabetes or cardiovascular disease. Insulin resistance can be directly measured with a hyperinsulinemic euglycemic clamp<sup>[2]</sup>. In addition, several parameters from less invasive methods have been demonstrated to be related to, or to predict, insulin resistance, such as obesity<sup>[3-5]</sup>, alanine aminotransferase (ALT) level<sup>[6]</sup>, metabolic syndrome, chronic inflammation status<sup>[5]</sup>, nonalcoholic fatty liver disease (NAFLD)<sup>[7,8]</sup>, and adiponectin level<sup>[9]</sup>. Some of these factors are easily measured (e.g. body weight and ALT) and the others are more complex (e.g. metabolic syndrome), not available in most laboratories (e.g. adiponectin), or are technique-dependent (e.g. sonographic NAFLD).

In Taiwan, the national health program provides a periodic examination for every adult older than forty. The program includes measurements of body height/weight, and ALT level. Measurement of insulin resistance, however, is not included in the program because of its inconvenience, although it is important for preventing cardiovascular disease.

Obesity is an ongoing problem in Taiwan and world-

wide<sup>[10,11]</sup>. It is associated with several conditions, of which insulin resistance might be the most important<sup>[12]</sup>.

Alanine aminotransferase (ALT) is a widely used laboratory test and abnormal ALT levels are common<sup>[13,14]</sup>. Elevated ALT has also been noted to be related to insulin resistance.

Besides being non-invasive, both obesity and ALT measurements are easily obtained and are inexpensive. Our purpose was to confirm the belief that that obesity and elevated ALT are important parameters of insulin resistance. We reported that the coexistence of both factors has a synergistic effect and the coexistence might be better than metabolic syndrome for predicting insulin resistance. The possible mechanism will be explored in the article. This result is helpful for preventing cardiovascular disease in public health.

## MATERIALS AND METHODS

Data from a total of 1308 male workers' health check-up records were analyzed. Data were collected *via* a questionnaire, including age (years), smoking status (packs per day), and alcohol consumption status (times per week). Anthropometrical data collected included systolic and diastolic blood pressure (mmHg), body weight (kg), height (cm), calculated body mass index, BMI (kg/m<sup>2</sup>), and waist circumference (cm). The laboratory measurements were conducted by Beckman Coulter auto-analyzer (model DxC 800 Synchron), and included triglyceride (mg/dL), high-density lipoprotein (HDL, mg/dL), aspartate aminotransferase (AST, U/L), alanine aminotransferase (ALT, U/L), and fasting plasma glucose (mg/dL). The insulin level (U/mL) was measured by the Abbott autoanalyzer (model AxSym). Insulin resistance was defined as the top quartile of HOMA<sub>IR</sub> (homeostasis model assessment)<sup>[2]</sup>. Obesity was defined as BMI  $\geq 27$  according to the modified criteria in Taiwan<sup>[11]</sup>. Abdominal obesity (or central obesity) was defined as a waist circumference  $\geq 90$  cm in men, according to the modified criteria from ATPIII for Asia subjects<sup>[15]</sup>. Elevated blood pressure, elevated triglyceride, low high-density lipoprotein, and elevated fasting glucose were defined based on previous ATPIII criteria for metabolic syndrome as systolic blood pressure  $\geq 130$  mmHg or diastolic blood pressure  $\geq 85$  mmHg, triglyceride  $\geq 150$  mg/dL, high density lipoprotein  $< 40$  mg/dL, and fasting glucose  $\geq 100$  mg/dL. Elevated ALT was defined as ALT  $> 40$  U/L (according to our laboratory and any cause, such viral hepatitis or alcoholism, was not ruled out). Smoking was defined as smoking more than one pack per day. Alcohol consumption was defined as drinking more than once per week. The Student's *t* test and chi-square test were used for analyzing continuous variables and categorical variables, respectively. Multivariate logistic regression was used to evaluate the relationship between insulin resistance and the risk factors. We introduced three models for multivariate logistic regression analysis for the odds ratio of the risk factors for insulin resistance. Model 1 showed the odds ratio of the risk factors

among which metabolic syndrome is regarded as five separate components. Metabolic syndrome is regarded as a single factor in model 2. Elevated ALT and obesity are regarded as two separate risk factors in model 1 and model 2. The coexistence of the two factors is regarded as a single factor and is compared with metabolic syndrome in model 3. To understand the synergistic effect of the risk factors, we introduced the synergistic index to see if the synergistic effect of obesity and elevated ALT was statistically significant<sup>[16]</sup>. This analytical study, limited to health check-up data, followed all the ethical criteria for human research<sup>[17]</sup>. The study protocol (TYGH09702108) was reviewed and approved by the Ethics Committee of the Taoyuan General Hospital.

## RESULTS

A total of 1308 male examinees were enrolled in the present study. The baseline characteristics of the study population stratified by HOMA<sub>IR</sub> are presented in Table 1. The mean age of the total population was 38.7 years (ranging from 22-63 years); increasing age with the higher HOMA<sub>IR</sub> was noted. A similar increasing trend was also presented in the other parameters except that a decreasing trend was noted in the HDL parameter. We also examined the significance of the trend of the increasing ALT level with insulin resistance through ANOVA analysis.

The abnormality prevalence of the four stratified categories according to the HOMA quartile, and the whole samples, are shown in Table 2. Similarly, the abnormality prevalence rates of all parameters (except smoking and drinking) increase with the higher HOMA<sub>IR</sub>.

In Table 3, after controlling for age, metabolic syndrome, hypercholesterolemia, elevated low-density lipoprotein, drinking, and smoking status, obesity has a 2.5-fold (95% CI: 1.7-3.6) and elevated ALT has a 2.1-fold (1.4-3.0) increased risk of insulin resistance in model 1. Each of these is more than at least three components of metabolic syndrome (abdominal obesity, elevated blood pressure, and hypo-HDL cholesterolemia). In model 2, obesity has a 3.0-fold (2.1-4.2) and elevated ALT has a 2.1-fold (1.5-2.9) increased risk of insulin resistance. Metabolic syndrome has a 2.6-fold (1.8-3.7) increased risk. On their own, both risk factors are similar to, or even more significant than metabolic syndrome. In model 3, we compared the coexistence of obesity and elevated ALT with metabolic syndrome. The coexistence of the two factors has a 4.3-fold (2.7-6.8) increased risk, far more than metabolic syndrome that has a 3.6-fold (2.6-5.0) increased risk. To examine the relationship between obesity and elevated ALT, we presented the synergistic effect of both factors in Table 4. It showed the synergistic index is 2.1 and it is statistically significant (95% CI: 1.0-4.3). Different odds ratios of obesity and elevated ALT in Tables 3 and 4 were noted due to different controlling factors.

Cigarette smoking	122 (37.3)	118 (36.2) <sup>a</sup>	108 (32.9)	109 (33.3)	457 (34.9)

<sup>1</sup>Obesity: Body mass index ≥ 27 kg/m<sup>2</sup>; Elevated ALT: ALT > 40 U/L; Abdominal obesity: waist circumference ≥ 90 cm in male adults; Elevated blood pressure: blood pressure ≥ 130/85 mmHg; Elevated fasting glucose: fasting glucose ≥ 100 mg/dL; Elevated triglyceride: triglyceride ≥ 150 mg/dL; Hypo-HDL cholesterolemia: HDL cholesterol < 40 mg/dL; Hypercholesterolemia: total cholesterol ≥ 200 mg/dL; Elevated LDL: LDL cholesterol ≥ 130 mg/dL; Alcohol consumption: more than once per week; Cigarette smoking: more than one pack per day. <sup>a</sup>P < 0.05 vs Q1 (χ<sup>2</sup> test).

**Table 3 OR of risk factors, presented as OR (95% CI)**

Model <sup>1</sup>	Model 1	Model 2	Model 3
Both obesity and elevated ALT	-	-	4.3 (2.7-6.8)
Obesity	2.5 <sup>2</sup> (1.7-3.6)	3.0 <sup>2</sup> (2.1-4.2)	-
Elevated ALT	2.1 <sup>2</sup> (1.4-3.0)	2.1 <sup>2</sup> (1.5-2.9)	-
Metabolic syndrome	-	2.6 <sup>2</sup> (1.8-3.7)	3.6 (2.6-5.0)
Abdominal obesity	1.6 <sup>2</sup> (1.2-2.2)	-	-
Elevated blood pressure	1.7 <sup>2</sup> (1.2-2.4)	-	-
Elevated fasting glucose	2.8 <sup>2</sup> (1.8-4.4)	-	-
Elevated triglyceride	2.2 <sup>2</sup> (1.6-3.1)	-	-
Hypo-HDL cholesterolemia	1.6 <sup>2</sup> (1.1-2.2)	-	-
Alcohol consumption	1.2 (0.8-1.7)	1.2 (0.8-1.6)	1.2 (0.9-1.7)
Cigarette smoking	0.9 (0.7-1.2)	0.9 (0.6-1.2)	0.9 (0.6-1.2)

<sup>1</sup>Risk factors of metabolic syndrome were regarded as five individual factor in model 1 and as a single factor in model 2; both obesity and elevated ALT were regarded as a single factor in model 3; <sup>2</sup>Significant odds ratio (OR), adjusted for age.

## DISCUSSION

Obesity is a worsening problem in Taiwan and worldwide<sup>[10]</sup>. Due to the variety of definition criteria, the prevalence rate varies. In Taiwan, the prevalence rate of

**Table 4 Synergistic effect of obesity and elevated ALT on insulin resistance<sup>1</sup>**

	OR (95% CI)	SI	95% CI
Neither obesity nor elevated ALT	1.0 Reference	No risk	-
Obesity only	2.3 (1.5-3.5)	One risk only	-
Elevated ALT only	1.8 (1.1-2.9)	One risk only	-
Obesity plus elevated ALT	5.5 (3.2-9.3)	2.1	(1.01-4.3)

<sup>1</sup>Insulin resistance is defined as the 4th quartile of the HOMA<sub>IR</sub>. SI: Synergistic index.

obesity (defined as BMI ≥ 27 in this article), surveyed in 2000-2001 were 15.9% and 10.7% in men and women separately, and the rate has progressively increased<sup>[11]</sup>. The prevalence rate of obesity in our study, which was conducted after 2001, is higher and is compatible with the trend of increasing prevalence. Obesity is associated with several comorbidities<sup>[10]</sup>, including coronary heart disease, stroke, NAFLD, and type 2 diabetes mellitus. Insulin resistance is present and important in the above clinical problems.

In our study, obesity alone is an important risk factor of insulin resistance. Similar results have also been published in other studies<sup>[3-5]</sup>. In contrast, weight reduction improves insulin resistance<sup>[18,19]</sup>, even if it is achieved by surgery<sup>[20]</sup>. However, not all obese subjects have insulin resistance<sup>[12]</sup>. Although the exact mechanism is still not fully understood, many factors have been found to induce insulin resistance through different pathways, such as increased non-esterified fatty acids (NEFAs), adipocyte dysfunction, leptin, adiponectin, chronic inflammatory status, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-6 (IL-6), monocyte chemoattractant protein-1 (MCP-1), and fat distribution<sup>[10,12,21]</sup>. Among these factors, NEFAs, released from dysfunctional adipocytes, might be the single most critical factor in modulating insulin sensitivity<sup>[10,12,21]</sup>.

ALT level is a widely used laboratory test in Taiwan. Elevated ALT is a common laboratory abnormality in a healthy population. The statistical database from the healthy population in the United States in 2003 showed the prevalence rate of abnormal transaminase was 20.8%, similar to previous findings (19.3%)<sup>[13]</sup>. Another study showed the prevalence rate in the male adolescent population was 12.4%, which was lower, but the population was younger<sup>[14]</sup>.

Our results show elevated ALT is a risk factor of insulin resistance, independent of metabolic syndrome. This conclusion has been also proposed in previous articles<sup>[6,22,23]</sup>. In Pima, in Indians with normal glucose tolerance, elevated ALT was associated with a decline in clamp-derived whole body insulin sensitivity, according to longitudinal analysis, and it predicted the development of type 2 diabetes in a prospective analysis<sup>[6]</sup>. This was extended to those with impaired glucose tolerance in another study<sup>[22]</sup>, in which a population of African-Americans and white subjects were analyzed. Burgert *et al.*<sup>[23]</sup> also noted a relationship between elevated ALT and reduced insulin sensitivity in obese children. Our study showed a similar result in Taiwanese adult males using community-based data. A semi-quantified result was also noted in a previous article<sup>[22]</sup>. Our study also showed the trend of a significantly increasing level of ALT in the more severe insulin-resistant group.

The causes of elevated ALT may be NAFLD, viral hepatitis, alcohol, or medications<sup>[24]</sup>. NAFLD is also a common clinical problem, and it has been proven to cause elevated ALT<sup>[25]</sup>. NAFLD was regarded as an explanation of the association between elevated ALT and insulin resistance in previous studies<sup>[6,26]</sup>. It has also been reported that hepatitis C induced insulin resistance<sup>[27]</sup>. This might be a partial explanation of the relationship between elevated ALT and insulin resistance. In contrast, alcohol intake in sufficient amounts can improve insulin resistance<sup>[8,28]</sup>. Many kinds of medication can induce elevated ALT, but there is a lack of evidence that medication leads to insulin resistance. One study in 1983 reported aspirin induced insulin insensitivity, but there were only eight subjects in the study<sup>[29]</sup>. The C-reactive protein (CRP) level might provide another explanation. A previous study indicated that the CRP level was higher

in subjects with elevated ALT than those with normal ALT<sup>[30]</sup>. Another study showed a high CRP level was related to insulin resistance<sup>[31]</sup>. From these studies, we might conclude that subjects with elevated ALT have a higher CRP level and further, are more insulin-resistant. The exact mechanism is, however, not well-understood. Further evidence is required.

Interestingly, there is a dramatically higher risk of insulin resistance in subjects with both elevated ALT and obesity. This result has seldom been discussed in the literature.

There are several studies concerning the association between obesity and elevated ALT, but the role of insulin resistance had not been identified in these studies<sup>[32,33]</sup>. In studies on the association between ALT level and insulin resistance, there was no analysis identifying the effect of obesity, but a significant relationship between body weight and ALT level were shown in the data<sup>[6,22]</sup>. Elevated ALT was associated with insulin resistance in obese subjects in previous studies, but it lacked comparative analysis between obese and non-obese subjects<sup>[23,30]</sup>.

What mechanism leads to the synergistic effect of obesity and elevated ALT? As discussed earlier, adipocyte dysfunction is regarded as the link between obesity and insulin resistance<sup>[21]</sup>, and its associated release of NEFAs (or free fatty acids) was regarded as the single most critical factor modulating insulin sensitivity<sup>[1,10,12,21]</sup>. In the model, adipocyte dysfunction results in increased circulating NEFAs, which further mediates insulin resistance. The excessive build-up of NEFAs in the liver leads to NAFLD, of which elevated ALT level is the best marker even within the reference interval<sup>[34]</sup>. Obesity coexisting with elevated ALT points to excessive NEFAs release and adipocyte dysfunction. This shows the existence of the link "from obesity to insulin resistance". Besides, in the cell module, TNF- $\alpha$ , and its effects on down-regulation of the nuclear hormone receptor peroxisome proliferator activated receptor- $\gamma$  (PPAR $\gamma$ ) strongly contributed to the effects of inflammatory cytokines on adipocytes<sup>[21]</sup>. Thus the inflammatory status results in adipocyte dysfunction. As elevated ALT is a reflection of systemic inflammation<sup>[6]</sup>, we concluded that coexistence of elevated ALT and obesity means the existence of inflammatory status, the excessive release of NEFAs, and their result: adipocyte dysfunction connecting obesity to insulin resistance.

Based on the models, most subjects with both obesity and elevated ALT should have insulin resistance. In our study, the actual prevalence rate of insulin resistance in the sub-group with both obesity and elevated ALT was almost 70% (not shown in table). This is compatible with our hypothesis.

The limits of this study deserve mention. First, insulin resistance was defined as the top quartile of HOMA<sub>IR</sub> (homeostasis model assessment), instead of a direct measurement. This might be less representative of insulin resistance, but more cases are available because of the more simple classification. Secondly, although our results showed a trend of increasing

ALT level with more severe insulin resistance, it still lacks an exact quantified relationship. More evidence is needed to confirm if there is a better cutoff value of ALT level or quantified relationship between ALT level and insulin resistance. Thirdly, cigarette smoking and alcohol consumption were recorded as more than one pack per day/once per week, instead of exact quantified data; therefore, it cannot be concluded that there was no relationship between smoking/drinking and insulin resistance based on our results.

In conclusion, obesity and elevated ALT have been shown to be associated with insulin resistance. The coexistence of both factors points to the existence of a linking mechanism between obesity and insulin resistance. The results suggest a synergistic effect on insulin resistance. The coexistence of these parameters might be better than metabolic syndrome for evaluating insulin resistance in clinical practice.

## COMMENTS

### Background

Insulin resistance is a key feature of type 2 diabetes mellitus and it plays an important role in cardiovascular diseases. Direct measurement of insulin resistance with hyperinsulinemic euglycemic clamp is invasive and inconvenient. For public health, less invasive methods are required. Many parameters have been proposed. Metabolic syndrome is one of the most popularly-used parameter.

### Research frontiers

This study proposed that obesity plus elevated alanine aminotransferase (ALT) might be better than metabolic syndrome for predicting insulin resistance due to its being non-invasive and convenience. This article also explored the mechanism linking obesity, elevated ALT, and insulin resistance.

### Applications

This study highlights the applications on public health since the measurements of obesity and ALT are easily obtained.

### Peer review

The content of the article will be interesting not only for the gastroenterologists, but also for other specialists. For understanding the quantified relationship between body weight or ALT level and insulin resistance, further investigations are required.

testosterone at later times after surgery was a better predictor of complications.

**CONCLUSION:** Patients with low testosterone level were prone to higher postoperative complications, which was evident in both sexes. However, further studies are necessary to support this result.

Does testosterone prevent early postoperative complications after gastrointestinal surgery? *World J Gastroenterol* 2009; 15(44): 5604-5609 Available from: URL: <http://www.wjg-net.com/1007-9327/15/5604.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5604>

### Abstract

**AIM:** To investigate the role of sex hormones in the early postoperative complications of gastrointestinal diseases.

**METHODS:** A total of 65 patients who underwent operations for gastric and colorectal diseases (mainly malignant diseases) were included in the study. Peripheral venous blood samples were collected at different times for analysis of estradiol, testosterone and progesterone. The only study endpoint was analysis of postoperative complications.

**RESULTS:** Patients of both sexes were uniform but postoperative complication rate was significantly higher in female patients ( $P = 0.027$ ). There was no significant association of estradiol and progesterone with postoperative complications. Testosterone levels in complicated patients were significantly lower than in uncomplicated patients ( $P < 0.05$ ). Area under the receiver operating characteristic curve showed that a lower value of testosterone was a predictor for higher complication rate ( $P < 0.05$ ), and a lower value of

### INTRODUCTION

There have been numerous reports of disparity in pathophysiology of different types of disease between male and female subjects, however, the reports have been quite diverse. Female sex is an independent predictor of mortality in patients with enterococcal bloodstream infections<sup>[1]</sup>. Women, in addition, might have a higher mortality among patients with necrotizing soft tissue infection<sup>[2]</sup>. Although most studies have suggested increased susceptibility to infectious complications among men, generally they have demonstrated a higher mortality rate for women from infections and sepsis<sup>[3-6]</sup>, but again, this is not universal<sup>[7-9]</sup>. On the other hand, male sex is an independent risk factor for the development of nosocomial bloodstream infection<sup>[10]</sup>, and is associated with in-hospital mortality in septic surgical patients<sup>[11]</sup>. Male sex is associated with anastomotic leakage in colorectal surgery<sup>[12]</sup>, as well as in rectal surgery<sup>[13-15]</sup>.

Female sex is an independent risk factor for early

postoperative complications of gastric cancer surgery<sup>[16,17]</sup>. Early postoperative complications of gastric cancer surgery are significantly more common in female patients, especially mortality and infection rate. Similarly, the duration of postoperative stay is significantly longer in female patients and they have more severe complications than male patients<sup>[17]</sup>.

We observed a significantly higher complication rate in female than male patients, therefore, we assumed that sex hormones may have influenced this disparity. Therefore, we conducted a prospective study to investigate the possible role of sex hormones in early postoperative complications.

## MATERIALS AND METHODS

### Patient characteristics

A total of 65 patients who underwent operations for gastric and colorectal diseases (mainly malignant diseases) from 2008 to 2009 were included in the study. We applied TNM classification and Duke's classification for gastric cancer and colorectal cancer, respectively. In gastric cancer patients, the majority was diagnosed with loco-regional advanced stage, and few patients were diagnosed as late stage (Table 1). There was one case of gastric polyp disease, one of malignant gastrointestinal stromal tumor, and one of mesenteric metastasis. The median age of the patients was 61 years (range: 22-82 years). All the operations were performed by senior consultants of a single department at Rui Jin Hospital, School of Medicine, Shanghai Jiao Tong University.

All the patients with early and resectable advanced gastric cancer (without significant distant metastases) underwent gastrectomy with D2 lymphadenectomy. Thirty partial and 17 total gastrectomies were performed for gastric cancer. One patient underwent total gastrectomy for gastric polyp disease and partial gastrectomy was performed for one malignant gastrointestinal stromal tumor. Anterior resection was performed on three patients, and one patient underwent abdominoperineal resection for rectal cancer. Three patients had partial colectomy and one underwent subtotal colectomy for colon cancer. One patient case of mesenteric metastasis was resected along with partial enterectomy.

The only study endpoint was analysis of postoperative complications. Complications were recorded in accordance with the definitions reported by Copeland *et al*<sup>[18]</sup>. Other complications were recorded separately.

### Blood sampling

This study was approved by the Hospital Institutional Review Boards for human subject research. All samples were obtained with informed consent. Patients on hormonal therapy or chemotherapy were excluded. Similarly, the patients with concomitant immunological disease were excluded. Peripheral venous blood samples were collected from 65 patients before operation (baseline measurements) and on postoperative day (POD)1, POD3, POD5, and POD7 for extensive analysis of their

variation at different times. Samples were collected into Venoject tubes containing EDTA.

### Laboratory tests

Assays for all parameters were performed in the laboratory of the Rui Jin Hospital. Venous blood was centrifuged at a speed 2500 r/min for 10 min, and serum was then preserved at -80°C, until further investigation. Estradiol, total testosterone and progesterone were measured using a Dxl 800 analyzer (Beckman-Coulter, Fullerton, CA, USA).

### Statistical analysis

The statistical analysis was performed with SPSS for Windows version 13.0 (SPSS, Inc, Chicago, IL, USA). Test of normality for all related variables were checked by the Shapiro-Wilk method, and a nonparametric statistical method (Mann-Whitney *U* test) was applied to the variables without a normal distribution. The means were compared by Student's *t* test in normally distributed cases. Differences in proportion were compared by Pearson's  $\chi^2$  test.  $P < 0.05$  was considered statistically significant.

## RESULTS

Fifteen patients with gastric disease and with non-gastric disease were compromised by different complications. There were several patients who had pyrexia of unknown origin with a high white blood cell count, but who did not have any diagnosis, mainly because of a lack of further investigation. The definition of postoperative complication introduced by Copeland *et al*<sup>[18]</sup> does not cover many complications that are common after gastrointestinal surgery, therefore, complications which

Baseline testosterone (ng/mL)	3.26	0.23	0.000

were confirmed clinically were also included. Details of all complications are summarized in Table 2. The sum of the individual complications was not equal to the total number of complications, and multiple complications were possible in a single patient. Patients of both sexes were uniform and there was no significant difference in age ( $P = 0.356$ ), physiological score ( $P = 0.616$ ) and operative severity score ( $P = 0.304$ ). However, there was a significant difference in complication rate between male and female patients ( $P = 0.027$ ). The complication rate for male and female patients was 21.4% and 47.8%, respectively. We analyzed the role of sex hormones in postoperative complications. Normal ranges of different sex hormones and demographics of patients according to sex are summarized in Tables 3 and 4, respectively.

There was no significant association of estradiol and progesterone with postoperative complications. Besides, the normal range of these hormones varies greatly at different times in a month in female patients, and there were not sufficient patients to stratify according to age

**Figure 1** Difference in testosterone level. A: Difference in mean testosterone level in complicated and uncomplicated patients; B: Male patients; C: Female patients.

or time period in women. Given the significant association between testosterone and postoperative complications, we focused additional analysis on this relationship. Testosterone decreased significantly after surgery in both sexes. Testosterone level in complicated patients was significantly lower ( $P < 0.05$ ) than in uncomplicated patients (Figure 1A).

Perioperative testosterone level was associated significantly with postoperative complication rate, and the result was similar for either overall complication rate or complications of gastric disease surgery alone (Table 5). Similarly, the difference was also significant after stratification of all complications according to sex. However, after stratification, we found there was no significant

			Lower bound	Upper bound
BASE	0.729	0.016	0.562	0.897
POD1	0.801	0.002	0.658	0.945
POD3	0.756	0.007	0.593	0.919
POD5	0.813	0.001	0.664	0.963
POD7	0.835	0.000	0.692	0.977

difference of testosterone level between complicated and uncomplicated patients during the first 3 d after surgery, in both sexes (Table 6). The median value of testosterone in complicated patients was approximately half of that in uncomplicated patients. The significance of the difference increased in later days after surgery, especially on POD5 and POD7. The result was similar in both sexes (Figure 1B and C).

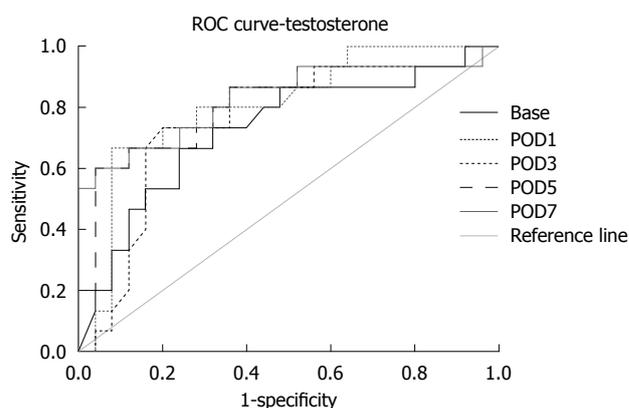

Area under the receiver operating characteristic curve showed that a lower value of testosterone was a predictor for higher complication rate (Table 7, Figure 2). A lower value of testosterone at a later time after surgery was a better predictor of complications (Table 8).

## DISCUSSION

Sex has been hypothesized to be a determinant of immunological variability after severe traumatic and surgical stress and, at least in animal models, accounts for differences in outcomes<sup>[3,7,19-22]</sup>. Some studies have demonstrated that altered levels of sex hormones rather than sex itself are related to postoperative complications. In particular, progesterone in male and testosterone in female subjects has an impact on survival. In both sexes, higher 17 $\beta$ -estradiol levels are associated clearly with shorter survival times<sup>[23]</sup>. However, we did not find a significant relationship between estradiol and postoperative complications. Unlikely, we observed a difference in progesterone level between complicated and uncomplicated patients. However, these observations were limited by the low number of patients, and variation of normal values

**Table 8** Sensitivity and specificity for different levels of testosterone

	Testosterone level	Sensitivity	Specificity
Base	$\leq 1.95$	70.0	68.9
POD1	$\leq 0.43$	60.0	84.4
POD3	$\leq 0.45$	73.3	80.0
POD5	$\leq 0.24$	60.0	90.0
POD7	$\leq 0.32$	66.7	92.0

**Figure 2** ROC curve for level of hormones at different times.

of this hormone at different times in female subjects made it difficult to obtain any conclusive result.

The uncertainty regarding the role of sex in influencing outcomes in humans may simply result from the clinical, phenotypic, and genetic diversity among populations, and the difficulty in detecting a difference due to these confounders. However, whether men and women respond differently to trauma or surgical insult, either in terms of the host response or the eventual outcome, is important for clinical care and the design of future research on anti-infective treatments or immunological regulators.

As mentioned above, our study was affected by the limitation of statistical calculation due to the low number of postoperative complications. Therefore, we could not analyze the differences in testosterone level in complicated and uncomplicated cases in different age groups, or its effect on different types of complications separately, because the number of patients and their relevant complications were low in those groups. It was still unknown whether the lower level of testosterone caused postoperative complications, or whether it was just a phenomenon observed in complicated patients. However, it was evident that even the preoperative level of testosterone was lower in patients who had complications after surgery. The testosterone level decreased significantly after surgery in all patients and it started to regain its preoperative level, or even higher, on POD3. However, the testosterone level in complicated patients did not regain its preoperative value, and moreover, it kept on decreasing. Even after controlling for sex by stratifying the group and looking at testosterone levels, the testosterone level decreased significantly in male and female patients with postoperative complications. Therefore, this observation

at least confirmed that the testosterone level had some kind of association with postoperative complications. However, without detailed investigation of the effects of other hormones, it was very hard to conclude that only testosterone was responsible for such disparity.

Although there were many limitations and unanswered questions in the present study, at least, our observations reflected that some kind of difference does exist between the sexes, which may be responsible for the disparity in postoperative complication rate. If a difference does indeed exist, it is possible that future studies will have to stratify for sex, infection source, and immunological phenotype. Similarly, future treatment strategy must be tailored for male and female patients separately, and different modes or treatment management will be necessary for the different sexes.

If there is an association between low testosterone level and postoperative complication rate, then serial tests of testosterone levels can easily identify the susceptible patients, and supplementary hormonal replacement therapy might be a novel treatment to prevent postoperative complications in such patients.

In conclusion, there was a significant association between testosterone and overall complications, and also with complications of gastric surgery. Association with testosterone was seen even after controlling for sex by stratifying the group and looking at testosterone levels. Postoperative complications were higher in patients who did not recover normal testosterone levels at POD5 or POD7. However, the results of this small-scale study need confirmation by a large cohort of patients, and prospective studies with hormone supplementation to reevaluate the role of testosterone in postoperative complications.

## COMMENTS

### Background

There have been numerous reports of disparity in pathophysiology of different types of disease between male and female patients, however, the reports have been quite diverse. Female sex is an independent risk factor for early postoperative complications of gastric cancer surgery. Early postoperative complications of gastric cancer surgery are significantly more common in female patients, especially mortality and infection rate. Similarly, the duration of postoperative stay is significantly longer in female patients, and they have more severe complications than male patients do.

### Innovations and breakthroughs

The authors found that there was a significant association between testosterone and overall complications, and also with complications of gastric surgery. Association with testosterone was seen even after controlling for sex by stratifying the group and looking at testosterone levels. Postoperative complications were higher in patients who did not recover normal testosterone levels at POD5 or POD7.

### Applications

By understanding the effect of sex hormones on postoperative complications, the present study might represent a future strategy for therapeutic intervention in the treatment of patients with gastrointestinal disease. If there is an association of low testosterone level with postoperative complication rate, then serial testing of testosterone level can easily identify the susceptible patients, and supplementary hormonal replacement therapy could be a novel treatment to prevent postoperative complications in these patients

### Terminology

Estradiol, testosterone and progesterone are sex hormones that are measured

to understand dysfunction in gonadal activity.

### Peer review

This study is unique and interesting. The authors studied the impact of sex hormones, especially testosterone, on the prevalence of complications after gastrointestinal surgery. This study gives us some valuable clues to explain why postoperative complications occur more frequently in female patients, as previously noted. It would also be useful in giving us a basis for clinical research to predict the occurrence of surgical complications.

### Abstract

**AIM:** To study the relationship between the polymorphisms in some cytokines and the outcome of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection.

**METHODS:** Samples were obtained from 203 patients infected with HBV and/or HCV while donating plasma in 1987, and 74 controls were obtained from a rural area of North China. Antibodies to HBV or HCV antigens were detected by enzyme-linked immunoassay. The presence of viral particles in the serum was determined by nested reverse-transcriptase polymerase chain reaction (PCR). Hepatocellular injury, as revealed by alanine aminotransferase (ALT) and aspartate aminotransferase level, was detected by a Beckman LX-20 analyzer. DNA was extracted from blood cells. Then, the single nucleotide polymorphisms of IL-2-330, IFN- $\gamma$ +874, IL-10-1082/-592 and IL-4-589 were investigated by restriction fragment length polymorphism-PCR or sequence specific primer-PCR.

**RESULTS:** Persistent infection with HBV, HCV, and HBV/HCV coinfection was associated with IL-2-330 TT genotype and T allele, IFN- $\gamma$ +874 AA genotype, and IL-10-1082 AA genotype. The clinical outcome of HBV and/or HCV infection was associated with IL-2-330 TT genotype and T allele, IFN- $\gamma$ +874 AA genotype, and IL-10-1082 AA genotype. IL-2-330 GG genotype frequency showed a negative correlation with clinical progression, IL-10-1082 AA genotype frequency showed a positive correlation and IL-10-1082 AG genotype frequency showed a negative correlation with clinical progression. HCV RNA positive expression was associated with IL-10-1082 AA genotype and the A allele frequency. Abnormal serum ALT level was associated with IL-10-592 AC genotype frequency and IL-4-589 CC genotype, CT genotype, and the C allele.

**CONCLUSION:** These results suggest that polymorphisms in some cytokine genes influence persistent HBV and HCV infection, clinical outcome, HCV replication, and liver damage.

Gao QJ, Liu DW, Zhang SY, Jia M, Wang LM, Wu LH, Wang SY, Tong LX. Polymorphism of some cytokines and chronic hepatitis B and C virus infection. *World J Gastroenterol* 2009; 15(44): 5610-5619 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5610.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5610>

### INTRODUCTION

The natural outcome in hepatitis B virus (HBV) and hepatitis C virus (HCV) infection varies dramatically among individuals. Infection with HCV is self-limited in a fortunate minority, while the majority of subjects develop persistent (chronic) infection<sup>[1,2]</sup>. Although infection with

HBV in adults progresses to the chronic phase in about 5%<sup>[3]</sup>, among those individuals with persistent HBV or HCV infection, the majority develop chronic hepatitis (CH), progressive fibrosis and even liver cancer<sup>[4,5]</sup>. However, there are some cases that never evolve into any significant liver disease within the patient's natural lifespan<sup>[6,7]</sup>. It remains unknown why patients infected with HBV and/or HCV frequently turn to be chronic and the outcome of HBV and/or HCV infection dramatically varies. Besides the pathogenesis of viral factors, the most important factor is the different immune response to HBV or HCV infection between individuals. For example, in patients infected with HBV/HCV, some show a strong reduction in CD4<sup>+</sup> T-helper (Th) and CD8<sup>+</sup> cytotoxic-T-lymphocyte (CTL) responses. This is likely to be crucial in clearance of acute viremia<sup>[8-10]</sup>. Another factor is thought to be immune tolerance to HBV/HCV infection. This contributes to explaining the different susceptibility to HBV/HCV infection. Many manifestations show that the immunity level of host correlates with relevant gene polymorphisms, especially with single nucleotide polymorphisms (SNPs) in the promoter region that regulates gene expression. Furthermore, the gene polymorphisms probably determine the outcome of the infection. This study investigated the screened Th1 cytokines, interleukin (IL)-2 (-330), interferon (IFN)- $\gamma$  (+874), and Th2 cytokines, IL-10 (-1082, -592) and IL-4 (-589) as candidate genes, to investigate the outcome of HBV/HCV infection.

## MATERIALS AND METHODS

### Subjects

We recruited 277 Han Chinese individuals from a rural area of Northern China (137 male and 140 female, aged 30-70 years, mean age  $50.20 \pm 10.43$  years), including 203 that were infected with HBV and/or HCV when they donated plasma in 1987, and 74 controls who had cleared HBV and HCV spontaneously. Plasma samples were evaluated by nested reverse-transcriptase polymerase chain reaction (nRT-PCR) and PCR. We diagnosed and excluded 28 patients with fatty liver. The infections had been diagnosed in 1993. Written informed consent for enrolling in the study was obtained from all the subjects. Patients were classified into the following groups. (1) Controls: 74 individuals (34 male and 40 female, mean age  $48.61 \pm 9.39$  years) who were negative for HBV and HCV antibodies. (2) Persistent HCV infection: 55 individuals (28 male and 27 female, mean age  $49.42 \pm 10.01$  years) who were positive for HCV antibodies but negative for HBV antibodies. (3) Persistent HBV infection: 69 individuals (39 male and 30 female, mean age  $52.74 \pm 13.17$  years) who had hepatitis B surface antigen and/or anti-hepatitis B core and/or anti-hepatitis B e antibodies, without HCV antibodies. (4) Persistent HBV and HCV coinfection: 79 individuals (36 male and 43 female, mean age  $50.01 \pm 8.56$  years) who had antibodies to HBV and HCV.

### Experimental and clinical diagnosis

Antibodies to HBV or HCV antigens were detected with an enzyme-linked immunoassay according to the manufacturer's instructions (Shanghai Kehua Bio-engineering Co. Ltd). The presence of hepatitis C viral particles in serum was determined by nRT-PCR. Hepatocellular injury, as revealed by alanine aminotransferase and aspartate aminotransferase level, was detected by a Beckman LX-20 analyzer. Clinical outcomes were diagnosed by evidence of viremia, liver transaminases and abnormal ultrasonography. Patients were diagnosed into four progressive hepatitis groups. (1) Healthy group: individuals negative for HBV and HCV antibodies, with normal liver transaminase levels and ultrasonography. (2) Mild CH group: patients with antibodies to HBV and/or HCV with mild abnormal liver transaminase and ultrasonography, but no evidence of viremia. (3) Moderate/severe CH: patients with antibodies to HBV and/or HCV with evidence of viremia, abnormal liver transaminase and/or abnormal ultrasonography. (4) Cirrhosis group: patients with antibodies to HBV and/or HCV and significantly abnormal ultrasonography. The diagnosis was performed using established methods for confirming cirrhosis<sup>[11]</sup>, with or without evidence of viremia, which had abnormal liver transaminase levels.

### DNA extraction

Blood specimens were collected in sodium citrate sterile tubes. Genomic DNA was extracted from 2-mL samples of whole blood and subsequently stored at  $-20^{\circ}\text{C}$  for genotype analysis. Genomic DNA extraction was performed using the guanidine-HCl method<sup>[12]</sup>.

### Gene polymorphism analyses of IL-2-330, IL-4-589 and IL-10-592

**Gene amplification:** IL-2-T330G, IL-4-C589T and IL-10-A592C gene polymorphisms were typed by restriction fragment length polymorphism-PCR. The primer sequences used are listed in Table 1. The 25- $\mu\text{L}$  final PCR volume was as follows: 20 ng DNA, 2.5  $\mu\text{L}$  10  $\times$  PCR Buffer (100 mmol/L Tris-HCl, pH 8.3, 500 mmol/L KCl), 200  $\mu\text{mol/L}$  dNTPs (400  $\mu\text{mol/L}$  dNTPs for IL-4-C589T), 1.5 mmol/L MgCl<sub>2</sub> (2.0 mmol/L MgCl<sub>2</sub> for IL-2-T330G), 10 pmol each primer, 1 U *Taq* polymerase (TaKaRa Biotechnology Co. Ltd., Dalian, China). PCR was carried out in an AmpGene DNA thermal cycler 4800 (America PE Corporation). After the initial denaturation step (95 $^{\circ}\text{C}$  for 2 min), the 35 cycles specified in Table 1 were employed. After the final cycle, the samples were kept at 72 $^{\circ}\text{C}$  for 7 min. Successful amplification was confirmed by using 2% agarose gel stained with ethidium bromide. The product size of each cytokine was described as in Table 2.

**Restriction enzyme digestion:** Restriction enzyme digestion was performed in 10- $\mu\text{L}$  volumes as follows: 2 U restriction enzyme, 1  $\mu\text{L}$  10  $\times$  Buffer, and the appropriate PCR product (4  $\mu\text{L}$  IL-2-T330G, 3  $\mu\text{L}$  IL-

Table 1 The position, polymorphism and primer sequence in IL-2, IL-4 and IL-10 genes

SNP position	Polymorphism	Primer sequence 5'-3'	PCR conditions
IL-2 -330	T→G	F: 5'-TATTCACATGTTTCAGTGTAGTTCT-3' R: 5'-ACATTAGCCCACACTTAGGT-3'	94°C, 48°C, 72°C for 1 min
IL-4 -589	C→T	F: 5'-ACTAGGCCTCACCTGATACG-3' R: 5'-GTTGTAATGCAGTCCTCCTG-3'	94°C, 57°C, 72°C for 30 s
IL-10 -592	A→C	F: 5'-CCTAGGTCACAGTGACGTGG-3' R: 5'-GGTGAGCACTACCTGACTAGC-3'	94°C/30 s, 60°C/45 s, 72°C/60 s

Table 2 Polymorphism position, product size, restriction enzyme, digestion fragments in IL-2-330, IL-4-589 and IL-10-592

SNP position	Product size (bp)	Restriction enzyme	Digestion fragments (bp)
IL-2-330 T/G	150	MaeI (Bio Basic Inc.)	150 26 + 124
IL-4-589 T/C	252	BsmFI (New England BioLabs)	252 60 + 192
IL-10-592 C/A	412	RsaI (Bio Basic Inc.)	412 236 + 176

4-C589T and 1  $\mu$ L 10  $\times$  BSA, 5  $\mu$ L IL-10-A592C). The digestion reaction of IL-2-T330G and IL-10-A592C was incubated at 37°C for 10 h, and the IL-4-C589T reaction at 65°C for 15 h. The digestive products were visualized on 3% agarose gel stained with ethidium bromide. The wild or mutant genotype was characterized by enzyme digestion fragments, as in Table 2.

#### Gene polymorphism analysis of IL-10-1082 and IFN- $\gamma$ +874

IL-10-G1082A and IFN- $\gamma$ +T874A gene polymorphisms were detected by sequence specific primer-PCR technique. For each sample, two parallel reactions were performed. For IL-10-1082, the forward allele-specific primers were either 5'-ACTACTAAGGCTTCTTTGGGAA-3' (for IL-10 allele A) or 5'-CTACTAAGGCTTCTTTGGGAG-3' (for IL-10 allele G), and the antisense primer was 5'-CAGTGC-CAACTGAGAATTTGG-3'. The product size was 258 bp. A human growth hormone sequence was used as an internal control. The control primers were 5'-GCCTTCCCAAC-CATTCCCTTA-3' and 5'-TCACGGATTCTGTGTGTGTTTC-3', and the product size was 429 bp. The 20- $\mu$ L final reaction volume contained: 2.0  $\mu$ L 10  $\times$  PCR Buffer (100 mmol/L Tris-HCl, pH 8.3, 500 mmol/L KCl), 200  $\mu$ mol/L dNTPs, 2.0 mmol/L MgCl<sub>2</sub>, 3.75  $\mu$ mol/L specific primer, 0.09  $\mu$ mol/L control primer, 20 ng DNA, and 0.5 U *Taq* polymerase. PCR was carried out in an AmpGene DNA thermal cycler 4800. The cycling conditions were 95°C for 2 min, and 10 cycles for 1 min at 95°C, 50 s at 65°C and 50 s at 72°C, followed by 20 cycles for 1 min at 95°C, 50 s at 59°C, and 50 s at 72°C, followed by a final extension for 7 min at 72°C. The PCR products were visualized on 1.5% agarose gel stained with ethidium bromide.

For IFN- $\gamma$ +874, the forward allele-specific primers were 5'-TTCTTACAACACAAAATCAAATCT-3' (for allele T) or 5'-TTCTTACAACACAAAATCAAATCA-3' (for allele A), and the anti-sense primer was 5'-TCAA-CAAAGCTGATACTCCA-3'. The product size was

262 bp. A human growth hormone sequence was used as an internal control. The control forward primer was 5'-TATGATCTCTGGCTAAGGAATG-3' and the anti-sense primer was 5'-TCAACAAAGCTGATACTCCA-3'. The product size was 440 bp. The 20- $\mu$ L final reaction volume contained 2.0  $\mu$ L 10  $\times$  PCR buffer (100 mmol/L Tris-HCl, pH 8.3, 500 mmol/L KCl), 200  $\mu$ mol/L dNTPs, 2.0 mmol/L MgCl<sub>2</sub>, 0.5  $\mu$ mol/L specific primer, 0.1  $\mu$ mol/L former control primer, 20 ng DNA, and 0.5 U *Taq* polymerase. PCR was carried out in an AmpGene DNA thermal cycler 4800. The cycling conditions were 94°C for 2 min, and 10 cycles for 30 s at 94°C, 40 s at 60°C and 40 s at 72°C, followed by 25 cycles for 30 s at 94°C, 40 s at 56°C, and 50 s at 72°C, followed by a final extension for 7 min at 72°C. The PCR products were visualized on 1.5% agarose gel stained with ethidium bromide.

#### Statistical analysis

The data were tested by the  $\chi^2$  test for the goodness of fit to the Hardy-Weinberg equilibrium (HWE) between the observed and expected genotype values. The frequencies of the alleles and genotypes among the groups were compared by the  $\chi^2$  test.  $P < 0.05$  was considered statistically significant. We calculated the OR and 95% CI.

## RESULTS

#### Hardy-Weinberg equilibrium (HWE) and characteristic distribution of age and sex

An HWE test was performed for all cytokine polymorphisms investigated in this study (Table 3). The distribution of these observed genotypes was not significantly different from the expected distribution according to HWE, except the IL-10-1082 polymorphisms, which revealed a deviation from HWE because of the lower frequency of wild-type homozygosity (the observed *vs* the expected frequency was 1.08% *vs* 10.91%). In IL-2-330, IL-4-589, IL-10-1082, IL-10-592 and IFN- $\gamma$ +874 gene polymorphisms, there were no significant differences in age and sex ( $P > 0.05$ ).

#### Genotype and allele distribution of IL-2-330, IFN- $\gamma$ +874, IL-4-589 and IL-10-1082 and -592 in persistent HBV and/or HCV infection

IL-2-330 TT, -330 GG and -330 TG are shown in Figure 1. The IL-2-330 polymorphisms showed obvious association with persistent HBV and/or HCV infection. IL-2-330 TT was associated with an increased risk, but IL-2-330 GG with a reduced risk of persistent HBV and/or HCV

Table 3 HWE test for cytokines

Locus	Observed homozygosity (%)		Expected homozygosity (%)		P value
	Wild-type genotype	Mutant genotype	Wild-type genotype	Mutant genotype	
IL-2-330	40.79	14.08	40.14	13.43	> 0.05
IFN- $\gamma$ +874	11.55	35.02	14.65	38.10	> 0.05
IL-4-589	3.25	50.54	6.94	54.24	> 0.05
IL-10-592	42.60	10.83	43.40	11.64	> 0.05
IL-10-1082	1.08	35.02	10.91	44.85	< 0.05

infection. The OR and 95% CI for IL-2-330 TT compared with -330 GG in HCV infection, HBV infection and HBV/HCV coinfection were 3.46 (1.17-10.20), 7.14 (2.13-23.81) and 2.93 (1.15-7.46), respectively. However, IL-2-330 TT/GG did not differ significantly between patients with HBV and/or HCV infection. The IL-2-330 T allele was associated with an increased risk, but the IL-2-330 G allele was associated with a reduced risk of chronic HCV and/or HBV infection. The OR and 95% CI for the IL-2-330 T allele compared with -330 G allele in HCV infection, HBV infection, and HBV/HCV coinfection were 1.82 (1.09-3.03), 2.26 (1.39-3.69) and 1.73 (1.10-2.73), respectively. However, the IL-2-330 T/G allele did not differ significantly between HBV and/or HCV infection (Table 4).

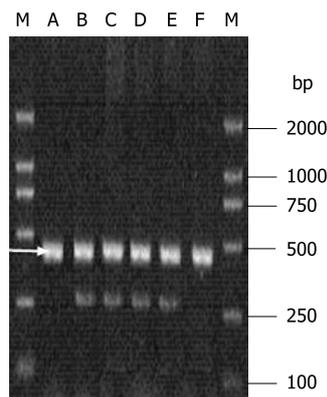

IFN- $\gamma$ +874 TT, +874 AA and +874 TA are shown in Figure 2. The IFN- $\gamma$ +874 polymorphisms showed

a significant association with persistent HBV and/or HCV infection. IFN- $\gamma$ +874 AA was associated with an increased risk, but IFN- $\gamma$ +874 TA with a reduced risk of persistent HBV and/or HCV infection. The OR and 95% CI for IFN- $\gamma$ +874 AA compared with +874 TA in HCV infection, HBV infection, and HBV/HCV coinfection were 3.23 (1.43-7.25), 2.70 (1.24-5.92) and 4.02 (1.88-8.55), respectively. However, IFN- $\gamma$ +874 AA/TA did not differ significantly between HBV and/or HCV infection. The IFN- $\gamma$ +874 T/A alleles did not differ significantly between all groups (Table 4).

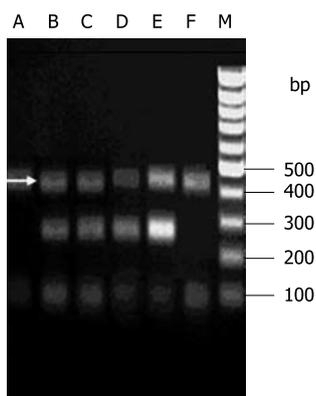

IL-10-1082 GG, -1082 AA and -1082 GA are shown in Figure 3. The IL-10-1082 polymorphisms showed a significant association with persistent HBV and/or HCV infection. IL-10-1082 AA was associated with an increased risk, but -1082 AG with a reduced risk of persistent HBV and/or HCV infection. The OR and 95%

**Figure 3 IL-10-1082 A/G SNP.** M: Marker; A and B: AA mutant genotype; C and D: AG genotype; E and F: GG wild-type genotype;  $\rightarrow$ : Internal control gene.

**Figure 4 IL-10-592 A/C SNP.** M: Marker; A and B: AC genotype; C and D: AA wild-type genotype; E and F: CC mutant genotype.

**Figure 5 IL-4-589 C/T SNP.** M: Marker; A and B: TT mutant genotype; C and D: CT genotype; E and F: CC wild-type genotype.

CI for IL-10-1082 AA compared with -1082 AG in HCV infection, HBV infection, and HBV/HCV coinfection were 2.34 (1.07-5.10), 2.29 (1.10-4.78) and 2.56 (1.25-5.21), respectively. However, IL-10-1082 AA/AG did not differ significantly between the subjects with HBV and/or HCV infection. The IL-10-1082 A/G alleles did not differ obviously between any of the subjects (Table 4).

The IL-10-592 polymorphisms are shown in Figure 4. The IL-10-592 A/C polymorphisms did not differ significantly between any of the groups (Table 4).

IL-10-589 TT, -589 CC and -589 TC are shown in Figure 5. IL-4-589 T/C polymorphisms did not differ significantly between any of the groups (Table 4).

#### **Association of IL-2-330, IFN- $\gamma$ +874, IL-4-589 and IL-10-1082 and -592 with clinical outcome of HBV and/or HCV infection**

The IL-2-330 polymorphisms showed a significant association with the outcome of persistent HBV and/or

HCV infection. IL-2-330 TT was associated with an increased risk, but -330 GG with a reduced risk of mild CH, moderate/severe CH, and cirrhosis. The OR and 95% CI for IL-2-330 TT compared with -330 GG genotype in patients with mild CH, moderate/severe CH, and cirrhosis were 3.42 (1.45-8.13), 3.29 (1.10-9.80), and 11.11 (1.32-90.91), respectively. However, IL-2-330 TT/GG did not differ significantly between patients with mild CH, moderate and severe CH, and cirrhosis. The IL-2-330 T allele was associated with an increased risk, but the -330 G allele was associated with a reduced risk of mild CH, moderate and severe CH, or cirrhosis. The OR and 95% CI for the -330 T allele compared with -330 G allele for patients with mild CH, moderate/severe CH and cirrhosis were 1.83 (1.20-2.80), 1.70 (1.02-2.82) and 2.75 (1.32-5.63), respectively. However, IL-2-330 polymorphisms did not differ significantly between patients with mild CH, moderate/severe CH, and cirrhosis (Table 5).

The IFN- $\gamma$ +874 polymorphisms showed a significant association with the clinical outcome of persistent HBV and/or HCV infection. IFN- $\gamma$ +874 AA was associated with an increased risk, but +874 TA with a reduced risk of mild CH, moderate/severe CH, and cirrhosis. There was significantly decreased IFN- $\gamma$ +874 AA genotype frequency in cirrhosis compared with moderate/severe CH patients. The OR and 95% CI for IFN- $\gamma$ +874 AA compared with +874 TA in patients with mild CH, moderate/severe CH, and cirrhosis were 3.09 (1.51-6.33), 3.85 (1.70-8.70) and 3.14 (1.08-9.17), respectively. The IFN- $\gamma$ +874 T/A alleles did not differ between any of the groups (Table 5).

The IL-10-1082 polymorphisms showed a significant association with the clinical outcome of persistent HBV

and/or HCV infection. IL-10-1082 AA was associated with an increased risk, but -1082 AG with a reduced risk of mild CH, moderate/severe CH, and cirrhosis. There was a significantly increased IL-10-1082 AA genotype frequency in cirrhosis compared with mild CH. IL-10-1082 AA showed a positive correlation with clinical outcome ( $\gamma = 0.99$ ,  $P = 0.00$ ), but the IL-10-1082 AG showed a negative correlation with clinical outcome ( $\gamma = -0.99$ ,  $P = 0.00$ ). The OR and the 95% CI for IL-10-1082 AA compared with -1082 AG in patients with mild CH, moderate/severe CH, and cirrhosis were 2.03 (1.03-3.98), 2.70 (1.24-5.88) and 4.26 (1.59-11.36), respectively. The IL-10-1082 G/A allele did not differ obviously in every group (Table 5).

The polymorphisms of IL-10-592 A/C and IL-4-589 C/T did not differ significantly in every group (Table 5).

#### **Association of IL-2-330, IFN- $\gamma$ +874, IL-4-589 and IL-10-1082 and -592 polymorphisms with HCV replication and abnormal alanine aminotransferase (ALT) level**

IL-10-1082 AA was associated with an increased risk, but -1082 AG was associated with a reduced risk of HCV RNA replication. The OR and 95% CI for IL-10-1082 AA compared with -1082 AG was 3.36 (1.67-6.76). IL-10-1082 A was associated with an increased risk, but -1082 G with a reduced risk of HCV RNA replication. The OR and 95% CI for IL-10-1082 A compared with -1082 G was 1.67 (1.08-2.57). The polymorphisms of

IL-2-330, IFN- $\gamma$ +874, IL-10-592 and IL-4-589 showed no association with HCV RNA replication (Table 6).

IL-10-592 AC showed an increased risk, but -592 AA showed a reduced risk of abnormal ALT. The OR and 95% CI for IL-10-592 AC compared with -592 AA was 2.83 (1.21-6.63). The IL-10-592 A/C alleles were not associated with abnormal ALT (Table 6).

The IL-4-589 CT/CC showed an increased risk, but -589 TT showed a reduced risk of abnormal ALT level. The OR and 95% CI for IL-10-589 CT and -589 CC compared with -589 TT genotype were 3.43 (1.47-8.00) and 8.25 (1.74-39.22), respectively, in patients with abnormal ALT. IL-4-589 C showed an increased risk, but -589 T showed a reduced risk of abnormal ALT level (Table 6). The OR and 95% CI for IL-10-589 C compared with -589 T was 2.31 (1.36-3.93).

The polymorphisms of IL-2-330, IFN- $\gamma$ +874 and IL-10-1082 were not significantly associated with abnormal ALT (Table 6).

## **DISCUSSION**

The natural outcome of HBV and HCV infection varies dramatically among individuals. HCV infection is self-limited in a fortunate minority, while the majority of subjects develop persistent (chronic) infection<sup>[1,2]</sup>. Although infection with HBV in adults progresses to the chronic phase in about 5%<sup>[3]</sup>, among those individuals with persistent HBV or HCV infection, the majority develop

CH, progressive fibrosis and even liver cancer<sup>[4,5,13]</sup>. However, some cases will never progress to any significant liver disease<sup>[6,7]</sup>. It remains unknown why the infection frequently turns into CH, and why the outcome with HBV and/or HCV infection varies dramatically. Cytokines play a crucial role in regulating the immune and inflammatory responses. Polymorphisms in the regulatory regions of the cytokine genes may influence their expression. Therefore, as genetic predictors of the disease susceptibility or clinical outcome, the polymorphisms of cytokine genes are potentially important.

IL-2 is a Th1 cytokine and has a powerful immunoregulatory effect on the stimulation of proliferation and activation of most T lymphocytes, natural killer cells, and B lymphocytes<sup>[14]</sup>. Some evidence has shown that the IL-2 levels of patients with moderate/severe CH and cirrhosis are decreased significantly more than those of healthy controls<sup>[15-17]</sup>. Other authors have observed that increased IL-2 expression is correlated with the grading/staging of chronic hepatitis C<sup>[18]</sup>. In this study, we found that the IL-2-330 SNP was associated with persistent HBV and/or HCV infection. The subjects with persistent HBV and/or HCV infections had significantly lower IL-2-330 GG genotype frequency and higher IL-2-330 TT genotype frequency than the controls. The subjects with IL-2-330 TT had a 3.46, 7.14 and 2.93 times higher risk of infection with HCV, HBV, or HBV/HCV. The subjects with chronic HCV and/or HBV infections had higher IL-2-330 T allele and lower -330 G allele frequencies,

respectively. The patients with the -330 T allele had a 1.82, 2.26 and 1.73 times higher risk of infection with HCV, HBV and HBV/HCV, respectively. At the same time, we also found an association between IL-2-330 SNP and clinical outcome of mild CH, moderate/severe CH and cirrhosis. Compared with the controls, the patients with mild CH, moderate/severe CH and cirrhosis had significantly higher IL-2-330 TT genotype frequency and lower -330 GG genotype frequency. IL-2-330 GG showed a negative correlation with clinical outcome ( $\gamma = -0.92$ ,  $P = 0.01$ ). Individuals with -330 TT genotype had a 3.42, 3.29 and 11.11 times higher risk of developing into mild CH, moderate/severe CH, and cirrhosis, respectively. Subjects with IL-2-330 T had a 1.83, 1.70 and 2.75 times higher risk of developing into mild CH, moderate/severe CH, and cirrhosis, respectively. These results indicate that the IL-2-330 TT genotype and the -330 T allele are not only the potential susceptibility gene for HBV and/or HCV infections, but also the gene that potentially determines clinical outcome. Moreover, the clinical outcome of HBV and/or HCV infection is associated with IL-2 level, as determined by the IL-2-330 polymorphisms. A plausible explanation for the association of IL-2-330 TT genotype and T allele with persistent infection and clinical outcome is derived from experiments that have shown that patients with the IL-2-330 TT genotype and T allele, with lower IL-2 production<sup>[5]</sup>, unsuccessfully eradicate the virus and become persistently viremic, which further results in susceptibility to HBV and/or HCV infection.

IFN- $\gamma$  is a Th1 cytokine and plays an important role in modulating almost all the immune responses, such as T-cell differentiation, anti-proliferative, antitumor, and antiviral activities<sup>[19,20]</sup>. Pravica *et al.*<sup>[21]</sup> have found that IFN- $\gamma$ +874 T/T genotype is often regarded as indicating high IFN- $\gamma$  production, and +874 A/A genotype as indicating low production. Some authors have found that plasma IFN- $\gamma$  concentrations in chronic hepatitis C patients decrease significantly<sup>[22,23]</sup>. Other authors have documented a correlation between the increase of IFN- $\gamma$  expression and grading in chronic hepatitis C infection<sup>[18,24,25]</sup>. In this study, compared with the controls, the IFN- $\gamma$ +874 AA genotype was found more frequently and the +874 TA genotype was found less frequently in subjects with persistent HBV and/or HCV infection. Subjects with +874 AA genotype have a 3.23, 2.70 and 4.02 times higher risk of HCV infection, HBV infection, and HBV/HCV coinfection, respectively. No difference was found in the IFN- $\gamma$ +874 T/A alleles among the groups. However, Liu *et al.*<sup>[26]</sup> have found that the frequency of IFN- $\gamma$ +874 A allele was significantly higher in patients with chronic HBV infection than in the controls (OR = 2.25, 95% CI = 1.69-2.99,  $P < 0.0001$ ). Moreover, compared with the controls, the patients with mild CH, moderate/severe CH, and cirrhosis showed a higher IFN- $\gamma$ +874 AA frequency and a lower IFN- $\gamma$ +874 TA frequency. Individuals with IFN- $\gamma$ +874 AA had a 3.09, 3.85 and 3.14 times higher risk of developing mild CH, moderate/severe CH, and cirrhosis, respectively. Compared with moderate/severe CH patients, cirrhosis patients showed a significantly decreased +874 AA genotype frequency. This probably resulted from the lower number of samples of cirrhosis. These results indicate that IFN- $\gamma$ +874 AA genotype is not only the potential susceptibility gene for HBV and/or HCV infection, but also the gene that potentially determines clinical outcome. A plausible explanation is that IFN- $\gamma$ +874 AA genotype produces a low level of IFN- $\gamma$ , which results in the cytolytic defect that promotes viral persistence and hepatic persistent infection that determines the clinical outcome of HBV and/or HCV infection.

IL-10 is an important anti-inflammatory cytokine secreted from Th2 cells. The levels of IL-10 production determine immune regulation, and the balance between the inflammatory and humoral responses. There are three confirmed SNPs in the IL-10 gene promoter. The -1082 GG genotype is associated with high IL-10 production, the -1082 GA with intermediate production, and the -1082 AA with low production. Polymorphisms at position -819 and -592 have no independent influence on IL-10 production<sup>[27]</sup>. There are contradictory reports about the exact effect of IL-10 promoter polymorphisms on the natural outcome of HBV and HCV infection. Some authors have found that plasma IL-10 level is decreased significantly in chronic hepatitis C patients<sup>[22,28]</sup>. Others have reported that the level of IL-10 in patients with chronic hepatitis C is higher than that in healthy individuals ( $P < 0.05$ ). The value of IL-10 showed a significant positive correlation with ALT<sup>[29,30]</sup>. In the present study, IL-10-1082 AA was associated with an increased

risk, but -1082 AG was associated with a reduced risk of persistent HBV and/or HCV infection. Subjects with IL-10-1082 AA had a 2.34, 2.29 and 2.56 times higher risk of persistent HCV infection, HBV infection and HBV/HCV coinfection, respectively. At the same time, IL-10-1082 AA is associated with an increased risk, but -1082 AG is associated with a reduced risk of mild CH, moderate/severe CH, and cirrhosis. Also, IL-10-1082 AA showed a positive correlation with clinical outcome ( $\gamma = 0.99$ ,  $P < 0.01$ ), but -1082 AG showed a negative correlation with clinical outcome ( $\gamma = -0.99$ ,  $P < 0.01$ ). Individuals with the -1082 AA genotype had a 2.03, 2.70 and 4.26 times higher risk of developing mild CH, moderate/severe CH, and cirrhosis, respectively. These results indicate that the IL-10-1082 AA genotype is not only a potential susceptibility gene for HBV and/or HCV infection, but also potentially determines clinical outcome. IL-10-1082 AA and -1082 A were associated with an increased risk, but IL-10-1082 AG and -1082 G were associated with a reduced risk of HCV RNA replication (OR = 3.36, 1.67, respectively). This result indicates that IL-10-1082 AA and -1082 A are associated with HCV RNA replication. The evidence shows that during persistent HCV infection, IL-10 may compromise the cellular immune response to the virus<sup>[31-33]</sup>. A plausible explanation is that IL-10 is an important anti-inflammatory cytokine. IL-10-1082 AA and -1082 A lead to lower IL-10 production<sup>[27]</sup> and persistent infection, which determines the clinical outcome of chronic infection. The IL-10-1082 polymorphisms had no significant association with plasma ALT level, which agrees with the results of Abbas *et al.*<sup>[34]</sup>. The IL-10-592 AC genotype frequency was significantly higher in patients with abnormal ALT (OR = 2.83). This result indicates that the IL-10-592 AC genotype is associated with abnormal ALT level and hepatocellular injury. Hepatocellular injury is probably caused by the decreased production of the anti-inflammatory cytokine IL-10, which results from linkage of the IL-10-592 and IL-10-1082 genes.

IL-4 is a Th2 cytokine and plays an important role in humoral immunity. IL-4 has the function of inhibiting the production of IFN- $\gamma$  and downregulating the differentiation of Th1 cells<sup>[35]</sup>. IL-4 has the function of modulating inflammatory responses by downregulating production of pro-inflammatory mediators and preventing inflammatory injury of the liver<sup>[36,37]</sup>. It has been described that the IL-4-589 T compared with the -590 C allele increases the strength of the IL-4 promoter<sup>[38]</sup>, which leads to high production of IL-4. The evidence has shown that IL-4 plays a key role in HBV and HCV infection pathogenesis. Some have reported that IL-4 levels are lower in patients infected with HCV<sup>[39]</sup>. Others have reported that IL-4 is significantly higher in chronic HCV infection with abnormal ALT than with normal ALT level<sup>[38,39]</sup>. In the present study, IL-4-589 polymorphisms were not significantly associated with persistent HBV and/or HCV infection or clinical outcome. However, we found that the IL-4-589 CT genotype and -589 CC genotype frequency was significantly higher than that

of -589 TT genotype frequency in patients with abnormal ALT level. Individuals with IL-4-589 CT and -589 CC genotype had a 3.43 and 8.25 times higher risk of abnormal ALT. Higher -589 C allele and lower -589 T allele frequencies in patients with abnormal ALT were observed; individuals with the -589 C allele had a 2.31 times higher risk of abnormal ALT. This result indicates that the IL-4-589 CC and -589 CT genotype and the -589 C allele are associated with liver inflammatory injury. Such injury is probably caused by the decreased production of anti-inflammatory cytokines such as IL-4 and IL-10.

In summary, the polymorphisms of IL-2-330, IFN- $\gamma$ +874, IL-10-1082 and -592 and IL-4-589 showed a significant association with the outcome of chronic HBV and/or HCV infection. The IL-2-330 TT/T allele, IFN- $\gamma$ +874 AA and IL-10-1082 AA were associated with increased risk, but IL-2-330 GG/G allele, IFN- $\gamma$ +874 TA and IL-10-1082 AG were associated with reduced risk of persistent HBV and/or HCV infection, and of developing mild CH, moderate/severe CH, and cirrhosis. The IL-10-1082 AA/A allele was associated with an increased risk, but the IL-10-1082 AG/G allele was associated with a reduced risk of HCV RNA replication. IL-10-592 AC and IL-4-589 CT/CC showed increased risk, but IL-10-592 AA and IL-4-589 TT showed reduced risk of abnormal ALT.

## COMMENTS

### Background

The natural outcome in hepatitis B virus (HBV) and hepatitis C virus (HCV) infection varies dramatically among individuals. Some infections are self-limited; some individuals progress to persistent HBV or HCV infection; and some develop chronic hepatitis, fibrosis and even liver cancer. The mechanisms are unknown. Besides viral pathogenic factors, a more important factor is the different immune response to HBV or HCV infection between individuals. T helper (Th)1 and Th2 cytokines determine host immunity level, which is regulated by polymorphisms in the promoter region of the Th1 and Th2 cytokines. Interleukin (IL)-2 (-330), interferon (IFN)- $\gamma$  (+874), IL-10 (-1082, -592), IL-4 (-589) should have some association with the outcome of HBV and/or HCV infection.

### Research frontiers

It remains unknown why subjects infected with HBV and/or HCV frequently develop chronic infection, and why the outcome of infection varies dramatically. Among infections with HBV/HCV, some show a strong reduction in CD4<sup>+</sup> T-helper and CD8<sup>+</sup> cytotoxic-T-lymphocyte responses. This is likely to be crucial in clearance of acute viremia. It is thought that immune tolerance to HBV/HCV infection may explain the different susceptibility to HBV/HCV infection. Many manifestations show that the immunity level of the host correlates with relevant gene polymorphisms, especially with single nucleotide polymorphisms in the promoter region, which regulates gene expression. Furthermore, the gene polymorphisms probably determine the outcome of the infection.

### Innovations and breakthroughs

The polymorphisms of IL-2-330, IFN- $\gamma$ +874, IL-10-1082 and -592 and IL-4-589 showed a significant association with the outcome of chronic HBV and/or HCV infection. The IL-2-330 TT/T allele, IFN- $\gamma$ +874 AA and IL-10-1082 AA were associated with increased risk, but the IL-2-330 GG/G allele, IFN- $\gamma$ +874 TA and IL-10-1082 AG were associated with reduced risk of persistent HBV and/or HCV infection, and of developing mild chronic hepatitis (CH), moderate/severe CH, and cirrhosis. The IL-10-1082 AA/A allele was associated with increased risk, but the IL-10-1082 AG/G allele was associated with reduced risk of HCV RNA replication. IL-10-592 AC and IL-4-589 CT/CC showed increased risk, but IL-10-592 AA and IL-4-589 TT showed reduced risk of abnormal ALT.

### Applications

These results suggest that polymorphisms in some cytokine genes influence persistent HBV and/or HCV infection, clinical outcome, HCV replication and

liver damage. Some cytokines, including IL-2, IFN- $\gamma$  and IL-10 might be beneficial to the clinical outcome of HBV and/or HCV infection. Some cytokines, including IL-4, might result in liver damage. These results provide a scientific basis for the further treatment of patients with chronic HBV and HCV infection and viral hepatitis.

### Terminology

IL-2 is a Th1 cytokine and has a powerful immunoregulatory effect on the stimulation of proliferation and activation of most T lymphocytes, natural killer cells, and B lymphocytes. IFN- $\gamma$  is a Th1 cytokine and plays an important role in modulating almost all the immune responses, such as T-cell differentiation, and anti-proliferative, antitumor, and antiviral activities. IL-10 is an important anti-inflammatory cytokine secreted from Th2 cells. The levels of IL-10 production determine immunoregulation, and the balance between the inflammatory and humoral responses. IL-4 is a Th2 cytokine and plays an important role in humoral immunity. IL-4 has the function of inhibiting the production of IFN- $\gamma$  and downregulating differentiation of Th1 cells.

### Peer review

This is interesting paper. These results suggest that the IL-10-1082 polymorphisms are associated with Hepatitis C viral replication and the IL-10-592 and IL-4-589 polymorphisms influence liver damage.

### Abstract

Lymphangioma, a benign neoplasm of the lymphatic system, is common in children but rare in adults. Its clinical manifestations include abdominal pain, nausea, vomiting and a palpable mass. However, abdominal sonography or abdominal computed tomography (CT) scan can also incidentally reveal lymphangioma. A larger or symptomatic lymphangioma is treated with total resection to prevent recurrence, infection, torsion and enlargement. Although lymphangioma rarely becomes malignant, its prognosis is generally good. We report a cystic lymphangioma of the spleen and retroperitoneum, which was incidentally found in a 56-year-old man who was hospitalized due to a colon mass. Physical examination showed no specific findings. Abdominal CT revealed a 5.7 cm, non-enhanced multilobulated cystic mass with multiple septa in the spleen and a 10 cm lobulated cystic mass in the para-aortic area. Splenectomy and retroperitoneal resection of the cystic mass were conducted. The endothelium

of splenic and retroperitoneal cyst was immunohistochemically stained with D2-40 antibody. The patient was finally diagnosed with splenic cystic and retroperitoneal cavernous lymphangioma.

### INTRODUCTION

Lymphangioma, a very uncommon neoplasm, is mainly found in children but rarely in adults<sup>[1,2]</sup>. In 1885, Frink reported the first lymphangioma in the spleen. Cases of splenic and retroperitoneum lymphangioma are rarely reported in adults. In our case, lymphangioma involved both the spleen and the retroperitoneum. Cases like ours, involving two organs, are extremely rare<sup>[3-5]</sup>. The clinical manifestations of lymphangioma include abdominal pain, fever, fatigue, weight loss and hematuria. However, it is sometimes asymptomatic<sup>[6,7]</sup>. We report, here, a case of a 56-year-old man who was hospitalized due to a colon mass. Lymphangioma in his spleen and retroperitoneum was incidentally found in abdominal computed tomography (CT). This case is very rare because lymphangioma was found both in his spleen and in his retroperitoneum.

### CASE REPORT

A 56-year-old man was hospitalized at a private clinic due to a suspected colon cancer detected at colonoscopy. He

**Figure 1** Enhanced abdominal CT and F-18 FDG Torso PET CT images of lymphangioma. A: A 5.7 cm lobulated & septated mass without enhancement in the spleen (white arrow); B: A 10 cm lobulated cystic mass in the paraaortic area (white arrow); C: A hypermetabolic lesion in the sigmoid colon mass (white arrow) and maxSUV 23 but no hypermetabolic lesion in the spleen and retroperitoneum.

had no history of any medical disease, and no weight loss, abdominal pain and dyspepsia. Physical examination revealed no palpable mass, tenderness or rebound tenderness in his abdomen with normal bowel sound. Laboratory studies had no specific findings except for creatinine (1.4 mg/dL). Abdominal X-ray did not reveal calcification, but abdominal CT showed a 5.7 cm non-enhanced cystic mass with septum in the spleen and a 10 cm lobulated cystic mass in the left paraaortic area (Figure 1A and B). PET CT revealed a hypermetabolic lesion in the sigmoid colon where the maxSUV was 23. However, no hypermetabolic lesion was found in the spleen or in the left paraaortic area (Figure 1C).

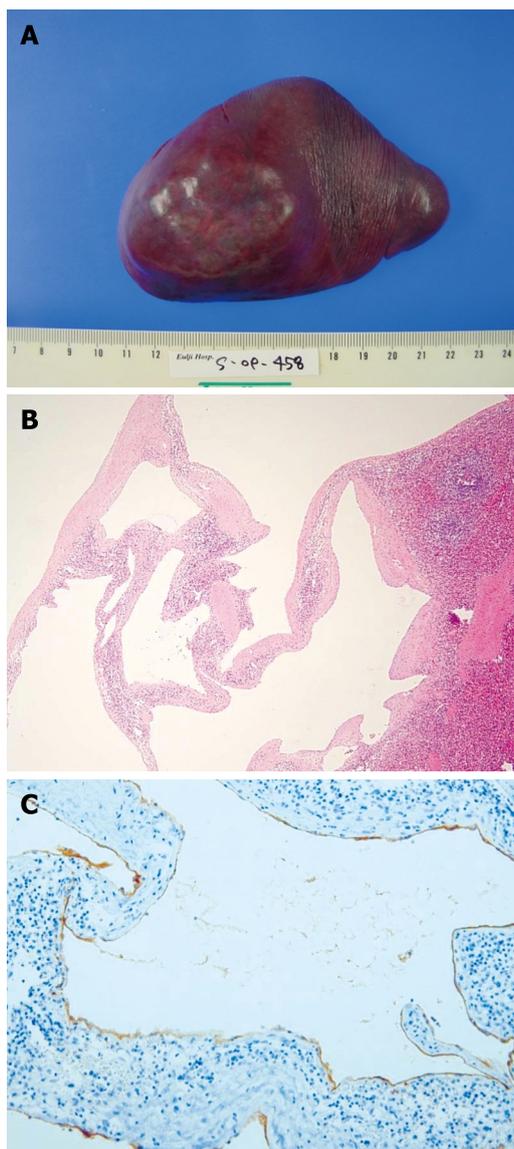

A 5 cm × 3 cm colon polyp with a neck and an intramural adenocarcinoma invading the lamina propria were found in the sigmoid colon. Splenectomy and resection of the retroperitoneal mass were conducted, during which a 4.5 cm × 3.5 cm bulging mass was exposed in the lower pole of the spleen (Figure 2A). The cut surface was composed of a multilobular cyst with a smooth inner surface. Histology showed thin fibrous walls of the cyst, which were different in size with no bleeding or necrosis (Figure 2B). In immunohistochemical study, the endothelium of splenic cystic mass was stained with D2-40 antibody (Figure 2C) and finally diagnosed as a cystic lymphangioma. The retroperitoneal mass was 4.5 cm × 4.5 cm × 2.5 cm in size, and its outer surface was lobular and yellow to brown in color (Figure 3A). The cut surface showed a sponge-like and ill-defined cyst.

Histology showed small cysts interspersed among fat, which were different in size, but had no calcification, bleeding, or necrosis (Figure 3B). In immunohistochemical study, the endothelium of retroperitoneal cystic mass was stained with D2-40 antibody (Figure 3C). The retroperitoneal mass was finally diagnosed as a cavernous lymphangioma. The patient was discharged 10 d after operation without complication.

## DISCUSSION

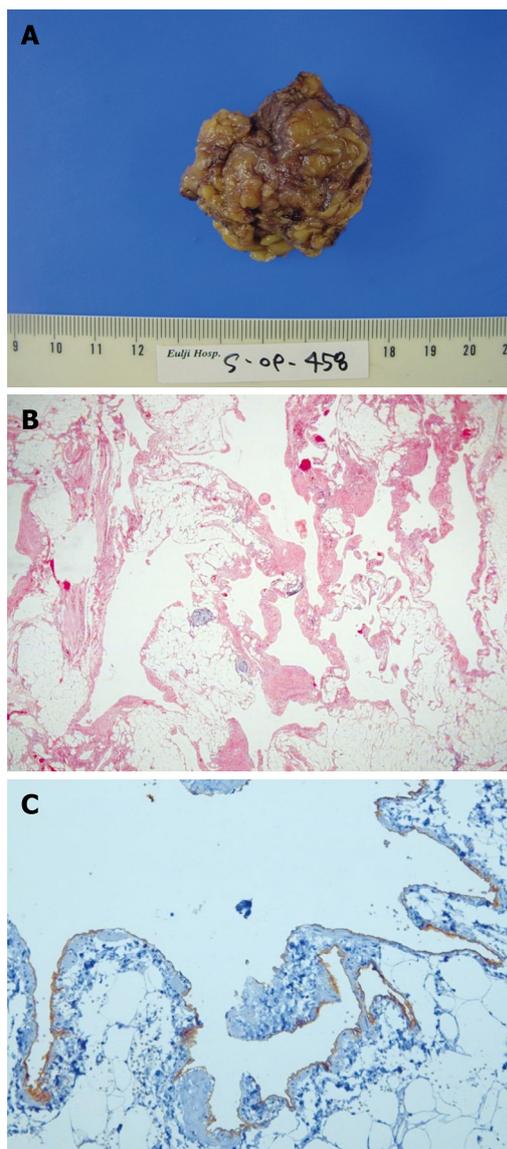

Cystic lymphangioma is a benign neoplasm composed of a malformation of the lymphatic system<sup>[1,2]</sup>. The incidence of lymphangioma occurring after 20 years of age

is very low. Lymphangioma generally occurs under the age of 2 years. There is no difference in the incidence between males and females<sup>[2]</sup>. The most commonly involved sites are the neck (75%) and axilla (20%). Lymphangioma is infrequently encountered in the mediastinum, adrenal gland, kidney, bone, omentum, gastrointestinal track, retroperitoneum, spleen, liver and pancreas<sup>[2,5]</sup>. There are two hypotheses for the causes and pathogenesis of lymphangioma, namely abnormal congenital development and bleeding or inflammation of the lymphatic system which causes an obstruction leading to additional lymphangiomas. The clinical manifestations of lymphangioma are left upper quadrant pain, abdominal distension, loss of appetite, nausea, vomiting and a palpable mass. However, lymphangioma can also occur without any symptoms<sup>[6,7]</sup>. Our case had no symptoms of lymphangioma and no palpable mass in the abdomen, and is unique because lymphangioma was found both in his spleen and in his retroperitoneum. Even if there are reports on cystic lymphangioma involving mesentery and retroperitoneum<sup>[2]</sup>, no report is available on lymphangioma involving both the spleen and the retroperitoneum in an asymptomatic patient. Lymphangioma involving more than two abdominal organs is rarely reported<sup>[2]</sup>. In our case, renal vein penetrated through the retroperitoneal lymphangioma, but retroperitoneal lymphangioma could be resected without impairment of the kidneys. Abdominal sonography can show a lowly attenuated mass and a highly attenuated inner part of lymphangioma, while abdominal CT may demonstrate multiple lowly attenuated, thin-walled, well-demarcated cysts and calcification in the cyst wall. The cystic surface can be divided by a septum and multiple lobules<sup>[7]</sup>. MRI may reveal a highly attenuated space in multiple lobules. Only a radiological image may have limitations in its diagnosis<sup>[6,7]</sup>. In this case, abdominal CT revealed a 5.7 cm cystic mass in the spleen and a 10 cm cystic mass composed of lobules in the paraaortic area. PET CT did not show highly metabolized lesions in the spleen or in the retroperitoneum of our case. Generally, lymphangioma is divided into capillary, cavernous and cystic types, with the cystic type being the most common<sup>[5]</sup>. Histology can show dilated lymphatic vessels surrounded by flat endothelial cells between fat, fibrotic

**Figure 2** Gross and microscopic images of splenic lymphangioma. A: A 4.5 cm × 3.5 cm bulging cystic mass in lower pole; B: HE staining of splenic lymphangioma, × 20; C: Immunostaining with D2-40 antibody (× 200) for cystic lining cells.

and lymphatic structures. Immunohistochemical staining can show a lymphangioma which is positive for keratin and HBME, and is negative for FV III-Rag, CD 31, CD 34 because it develops from the middle lobe<sup>[8]</sup>. Lymphatic vessel endothelial receptor-1, vascular endothelial growth factor-3, prox-1, and monoclonal antibody D2-40 are the markers for specific endothelial cells of lymphatic tissues, which are used in immunochemical studies of lymphangioma. In this case, the endothelium of splenic and retroperitoneal cystic mass was stained with D2-40 antibody and the splenic and retroperitoneal cystic mass was finally diagnosed as splenic cystic and retroperitoneal cavernous lymphangioma, based on the microscopic findings. Surgical treatment is needed to prevent recurrence, infection, rupture, and bleeding<sup>[5]</sup>. Conservative treatment modalities include aspiration, drainage and sclerosis, with a high risk of recurrence. However, an incidentally found small cyst needs not be resected, and the current treatment is

**Figure 3** Gross and microscopic images of retroperitoneal lymphangioma. A: A 4.5 cm × 4.5 cm × 2.5 cm retroperitoneal mass; B: HE staining of retroperitoneal lymphangioma, × 20; C: Immunostaining with D2-40 antibody (× 200) for cystic lining cells.

a partial splenectomy to remove it<sup>[5]</sup>. The post-operative recurrence rate is low and the rate of transformation into malignancy is very low as well. Complications are peritonitis, bleeding, abscess and torsion<sup>[9]</sup>. The natural regression rate is very low. If multiple lymphangiomas progress rapidly and are invasive, their prognosis could be poor<sup>[10]</sup>. In this case, a 5.7 cm splenic lymphangioma and a 10 cm lymphangioma were surgically removed and the patient was discharged 10 d later without any complication. Our case may be the first reported case of lymphangioma involving both the spleen and the retroperitoneum in an asymptomatic patient.

### INTRODUCTION

Acute myeloid leukemia (AML) affects middle-aged adults. When the disease involves soft tissue, it is called granulocytic sarcoma (GS). GS can present in the gastrointestinal tract but involvement of the appendix is uncommon. Furthermore, infiltration of the appendix by leukemic cells is also a rare manifestation of leukemia relapse. Herein, we report a 75-year-old man with AML-M2 who had been in partial remission for 1 year, and who presented with symptoms mimicking acute appendicitis as the initial manifestation of leukemia relapse. Subsequent pathological examination confirmed the diagnosis.

### CASE REPORT

A 75-year-old man was admitted for evaluation of right lower quadrant abdominal pain and fever for 3 d. He had partial remission of AML-M2 for 1 year, after chemotherapy with low dose cytarabine. His past history included hypertensive cardiovascular disease with congestive heart failure, coronary artery disease, and chronic obstructive pulmonary disease. Physical examination showed rebound tenderness over the right lower quadrant. The leukocyte count was  $35 \times 10^3/L$ , with 15% neutrophils, 26% lymphocytes, 1% monocytes, 2% eosinophils, 0% basophils, and 56% immature cells. Hemoglobin and platelet counts were 9.9 g/dL and  $64 \times 10^3/\mu L$ , respectively. C-reactive protein was 7.98 mg/dL. Abdominal computed tomography showed thickening of the appendiceal wall and periappendicular fat stranding (Figure 1). The diagnosis of acute appendicitis was made, and appendectomy was performed immediately after admission. Grossly, the appendix was gray in color and soft in consistency. Microscopically, the sections showed transmural infiltrates of myeloblasts, which were positive for myeloperoxidase, CD43 and CD34 immunohistochemical stains (Figure 2). Hence, AML-M2 with involvement of the appendix was diagnosed. Thereafter the patient received chemotherapy with low-

### Abstract

Acute myelogenous leukemia (AML) can involve the gastrointestinal tract but rarely involves the appendix. We report a male patient who had 1 year partial remission from AML and who presented with apparent acute appendicitis as the initial manifestation of leukemia relapse. Pathological findings of the appendix revealed transmural infiltrates of myeloblasts, which indicated a diagnosis of leukemia. Unfortunately, the patient died from progression of the disease on the 19th d after admission. Although leukemic cell infiltration of the appendix is uncommon, patients with leukemia relapse can present with symptoms mimicking acute appendicitis.

**Figure 2** Cross-section of the appendix specimen. A: Leukemia involving the appendix is characterized by transmural infiltrates of myeloblast cells (HE,  $\times 200$ ); B: These tumor cells are immunoreactive to myeloperoxidase protein (HE,  $\times 200$ ).

dose cytarabine (20 mg/kg for 12 d). However, he died from progressive disease complicated by septic shock and acute respiratory failure on the 19th d after admission.

## DISCUSSION

The incidence of GS is estimated to be 3% in living adult patients with AML and 4.7% in children<sup>[1,2]</sup>. Rappaport initially introduced the concept of acute lymphoblastic leukemia infiltrating the appendix<sup>[3]</sup>. In a review of the literature, AML involving the appendix has been described<sup>[1,3,4]</sup>. As a presentation of AML in adults, GS can involve various sites throughout the body but it is rare in the gallbladder and appendix. Bowel infiltration by leukemic cells, described initially in the 19th century, was thought to be a rare condition until autopsy studies in the 1960s and 1970s, which indicated a prevalence of this presentation in 10% to 53.3% of leukemia patients<sup>[5-8]</sup>. It has been reported that appendiceal involvement by leukemic cells occurs in approximately 3 of 36 patients (8.3%)<sup>[6]</sup>. Seven leukemia patients with involvement of the appendix, including our own, were identified in the literature. The survival time varied as shown in Table 1<sup>[1,4,6]</sup>.

Surgical management of patients with leukemia and

**Table 1** Seven cases of leukemia infiltration of the appendix described in the literature

No.	Sex/age	Type	Treatment	Survival time (d)
1	F/77	M3	Surgery	30
2	M/71	M2	Surgery	49
3-6	NA	NA	3 surgery	Hours to days
7 (Our case)	M/75	M2	Surgery	19

M: Male; F: Female; NA: Not available.

acute abdomen has not been advocated because of the high rate of operative mortality in the past<sup>[4,6]</sup>. However, there is some support for surgical management of appendicitis in acute leukemia as the most effective method of therapy<sup>[1,4,9]</sup>. Systemic chemotherapy is necessary in this setting for additional radiation or surgery in patients with GS<sup>[10]</sup>.

In conclusion, we report a rare case of AML who had been in partial remission for 1 year and presented with symptoms of acute appendicitis as the initial manifestation of leukemia relapse. Although leukemic cell infiltration into the appendix is uncommon, our case highlights the importance of differential diagnosis of acute appendicitis including recognition of possible leukemic involvement. The physicians should be aware of these conditions.

Talley NJ. So you aspire to be a Professor? *World J Gastroenterol* 2009; 15(44): 5626-5627 Available from: URL: <http://www.wjg-net.com/1007-9327/15/5626.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5626>

“The truth is that life is delicious, horrible, charming, frightful, sweet, bitter, and that is everything.” Anatole France (François-Anatole Thibault, 1844-1924).

When I was in medical school and early on in residency, I dreamed of undertaking research and becoming an academic but I did not really know how to start; in the end, I settled for trying to master internal medicine as I sweated to pass the formidable barrier examination for admission to Fellowship of the Royal Australasian College of Physicians (comprising both a written test and an even more challenging clinical “viva”). My entry into research was entirely fortuitous; having completed Basic Training I wanted a change (I like change), and I was lucky to learn from my father (a prominent Sydney gastroenterologist in private practice) that one of Australia’s most famous academic gastroenterologists, Professor Douglas (Doug) Piper, was looking for someone to undertake a PhD with him. Remarkably few had expressed an interest in doing so; a PhD would require 3 years of one’s life living on a National Health and Medical Research Council (NH&MRC) scholarship that would hardly keep body and soul together.

Figure 1 Nicholas J Talley, MD, PhD, FACP, FRACP, FRCP Chair.

Actually I was not sure I wanted to become a gastroenterologist (in fact, I favored neurology because my Dad was a gastroenterologist, and two Nicholas Talley’s in the specialty seemed a formula for confusion). However, I saw working with Doug as a real opportunity, so I took the risk and said yes, one of the best decisions of my life (Figure 1).

Professor Doug Piper was particularly interested in peptic ulcer disease, and our initial NH&MRC grant application (developed before the observation of spiral bacteria in the stomach had been announced), aimed to determine the natural history of peptic ulcer disease. This grant failed to attract funding, which at the time seemed quite devastating. Remarkably, this apparent setback turned out to be very fortunate, because we then were forced to look at alternative projects. Almost by chance we fell upon a common clinical problem; it had been long observed that most patients with ulcer-like symptoms had no ulcer crater or other obvious explanation for their complaints. Little was known about this mysterious and vague entity, then called non-ulcer dyspepsia, and the topic seemed ripe for a comprehensive clinical research project that would fulfill the requirements for a higher degree in Australia. As a clinician I became quite fascinated by the problem (I still am). After reading the proceedings from a Scandinavian symposium pointing out many of the gaps in knowledge (published by the makers of cimetidine, Smith Kline), I decided to pursue the topic. I was blissfully unaware of how difficult such a task might be, but had the gift of youthful enthusiasm and energy.

And so my odyssey began; with the help of Doug’s team I designed several protocols and set out to learn about the epidemiology, etiopathogenesis and treatment of non-ulcer dyspepsia. It was very hard the first year; there were the inevitable setbacks and it took a while to become used to research rather than full time practice. I

thought about quitting. But I learned that guts and grit count more than any other characteristic in the research setting. I undertook classes in clinical epidemiology and biostatistics which I loved, and learnt how to apply rigorous clinical research methods and avoid some of the obvious pitfalls. Momentum helps too; my first paper on the topic was published in 1985<sup>[1]</sup> and I caught the publishing bug (once you know how, it is great fun to collect, analyze and share your data with the world). The research efforts eventually spilled over into a two volume thesis entitled "Non-ulcer dyspepsia: A study of the psychosocial, environmental, clinical, therapeutic and prognostic aspects - with particular reference to a subgroup with dyspepsia of unknown cause (essential dyspepsia)." Doug used to say a thesis should be judged first by its weight and then by its quality, which I took to heart. The publication of several papers led to the offer of a fully paid Research Fellowship at Mayo Clinic in Rochester, Minnesota in the famous Gastroenterology Unit [headed then by a very prominent and brilliant expatriate Australian, Professor Sidney (Sid) Phillips]. Sid was an inspiring mentor who trained many of the most brilliant minds in motility research; I learned how to do physiological research and joined the staff during one of the happiest times of my life.

As my career trajectory exploded upwards, a further boost came after presenting new work as a very raw Assistant Professor of Medicine at Digestive Diseases Week. After the oral symposium, Douglas Drossman and Grant Thompson strode up to me to introduce themselves. I was invited to join a new consensus group that would meet in Rome; the idea was to develop diagnostic criteria for the first time for all of the functional gastrointestinal disorders, including non-ulcer dyspepsia (the precursor of the famous Rome criteria!). I said yes, and have been involved ever since with what is now known as the Rome Foundation (and the Rome I, II and III criteria-Rome IV is currently being planned).

So if you want to eventually reach the rank of Professor and, more importantly, contribute to our field, the formula in my mind is uncomplicated. Try to choose a great mentor first and foremost; they are the ones eager

to impart their knowledge, leave a legacy and develop the science (you can find most of the talented names on PubMed today with ease - look at how much and where they have published as a guide). Search for someone who thinks outside the box and has a strong team working with them; teams tend to perform best in the research world. The project is important too, but without the right mentor your chance of major success greatly diminishes. Second, in my humble view brains matter much less than drive. Be prepared to work hard and realize you will have to overcome all sorts of roadblocks to succeed; if you are prepared to be persistent and flexible, you will make it. Do not neglect to read the literature widely and deeply in your chosen topic area; critically appraise the science, know intimately all of the relevant papers, and look for the gaps (there are always many!). I tell my Research Fellows I know they will become experts by the time they complete their projects. Third, continuously develop your skill set. Learn how to not only do the science but also how to analyze, present and write it up. Submit and personally present your work at major international meetings whenever you have the opportunity; this is very good exposure, allows you to learn the state of the art and will promote making professional contacts around the world who will likely prove invaluable. Scientific presentation is a skill that can be learned and improves with practice; seek out ways to become a better public speaker. Above all, dedicate yourself to publishing any and all important data you generate (if your work is not published in a peer review journal, it essentially does not exist!). Serendipity helps too, but chance usually only plays a role if you are well prepared. If you follow these simple strategies, academic opportunities and promotion are almost guaranteed; it is straightforward to become a Professor once you learn the trade, and most importantly the journey is great fun too.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week  
<http://www.apdwcongress.org/2009/index.shtml>

October 7-11, 2009  
Boston Park Plaza Hotel and Towers, Boston, MA, United States  
Frontiers in Basic Cancer Research

October 13-16, 2009  
Hyatt Regency Mission Bay Spa and Marina, San Diego, CA, United States  
Advances in Breast Cancer Research: Genetics, Biology, and Clinical Applications

October 20-24, 2009  
Versailles, France  
Fifth International Conference on Tumor Microenvironment: Progression, Therapy, and Prevention

October 30-November 3, 2009  
Boston, MA, United States  
The Liver Meeting

November 15-19, 2009  
John B. Hynes Veterans Memorial Convention Center, Boston, MA, United States  
AACR-NCI-EORTC Molecular Targets and Cancer Therapeutics

November 21-25, 2009  
London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kpn I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327  
CN 14-1219/R

## Contents

<b>EDITORIAL</b>	5633	Emerging role of microRNAs in liver diseases <i>Bala S, Marcos M, Szabo G</i>
	5641	Acute pancreatitis in pregnancy <i>Pitchumoni CS, Yegneswaran B</i>
<b>REVIEW</b>	5647	Hepatitis C virus in Pakistan: A systematic review of prevalence, genotypes and risk factors <i>Waheed Y, Shafi T, Safi SZ, Qadri I</i>
<b>ORIGINAL ARTICLE</b>	5654	Shift work aggravates metabolic syndrome development among early-middle-aged males with elevated ALT <i>Lin YC, Hsiao TJ, Chen PC</i>
	5662	Intraluminal <i>versus</i> infiltrating gallbladder carcinoma: Clinical presentation, ultrasound and computed tomography <i>Lee TY, Ko SF, Huang CC, Ng SH, Liang JL, Huang HY, Chen MC, Sheen-Chen SM</i>
	5669	Inhibitory effect of emodin and Astragalus polysaccharide on the replication of HBV <i>Dang SS, Jia XL, Song P, Cheng YA, Zhang X, Sun MZ, Liu EQ</i>
	5674	Nicotinamide overload may play a role in the development of type 2 diabetes <i>Zhou SS, Li D, Sun WP, Guo M, Lun YZ, Zhou YM, Xiao FC, Jing LX, Sun SX, Zhang LB, Luo N, Bian FN, Zou W, Dong LB, Zhao ZG, Li SF, Gong XJ, Yu ZG, Sun CB, Zheng CL, Jiang DJ, Li ZN</i>
<b>BRIEF ARTICLE</b>	5685	Capsule endoscopy in suspected small bowel Crohn's disease: Economic impact of disease diagnosis and treatment <i>Leighton JA, Gralnek IM, Richner RE, Lacey MJ, Papatheofanis FJ</i>
	5693	Hepatic steatosis in overweight/obese females: New screening method for those at risk <i>Tarantino G, Pizza G, Colao A, Pasanisi F, Conca P, Colicchio P, Finelli C, Contaldo F, Di Somma C, Savastano S</i>
	5700	Outcome of nonerosive gastro-esophageal reflux disease patients with pathological acid exposure <i>Pace F, Pallotta S, Manes G, de Leone A, Zentilin P, Russo L, Savarino V, Neri M, Grossi E, Cuomo R</i>

	<b>5706</b>	Impact of age-related comorbidity on results of colorectal cancer surgery <i>Pedrazzani C, Cerullo G, De Marco G, Marrelli D, Neri A, De Stefano A, Pinto E, Roviello F</i>
	<b>5712</b>	Effect of ONO-4057 and tacrolimus on ischemia-reperfusion injury of the liver <i>Takeichi T, Uemoto S, Minamiguchi S, Takeyoshi I, Inomata Y, Tanaka K, Kobayashi E</i>
	<b>5716</b>	Glutathione-S-transferase (GSTM1, GSTT1) and the risk of gastrointestinal cancer in a Korean population <i>Piao JM, Shin MH, Kweon SS, Kim HN, Choi JS, Bae WK, Shim HJ, Kim HR, Park YK, Choi YD, Kim SH</i>
	<b>5722</b>	Gastric dysplasia may be an independent risk factor of an advanced colorectal neoplasm <i>Bae RC, Jeon SW, Cho HJ, Jung MK, Kweon YO, Kim SK</i>
	<b>5727</b>	Total laparoscopic liver resection in 78 patients <i>Zhang L, Chen YJ, Shang CZ, Zhang HW, Huang ZJ</i>
	<b>5732</b>	A simple taurocholate-induced model of severe acute pancreatitis in rats <i>Liu ZH, Peng JS, Li CJ, Yang ZL, Xiang J, Song H, Wu XB, Chen JR, Diao DC</i>
	<b>5740</b>	Single-center experience of 309 consecutive patients with obscure gastrointestinal bleeding <i>Zhang BL, Fang YH, Chen CX, Li YM, Xiang Z</i>
<b>CASE REPORT</b>	<b>5746</b>	Complete remission of gastric Burkitt's lymphoma after eradication of <i>Helicobacter pylori</i> <i>Baumgaertner I, Copie-Bergman C, Levy M, Haioun C, Charachon A, Baia M, Sobhani I, Delchier JC</i>
	<b>5751</b>	A case of asymptomatic fungal and bacterial colonization of an intragastric balloon <i>Coskun H, Bozkurt S</i>
<b>LETTERS TO THE EDITOR</b>	<b>5754</b>	Spontaneous bacterial peritonitis: Few additional points <i>Jain P</i>

<b>INSIDE FRONT COVER</b>		Online Submissions

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

**EDITORS FOR THIS ISSUE**

**Responsible Assistant Editor:** *Xiao-Fang Liu*  
**Responsible Electronic Editor:** *Yin-Ping Lin*  
**Proofing Editor-in-Chief:** *Lian-Sheng Ma*

**Responsible Science Editor:** *Jin-Lei Wang*  
**Proofing Editorial Office Director:** *Jian-Xia Cheng*

**NAME OF JOURNAL**

*World Journal of Gastroenterology*

**RESPONSIBLE INSTITUTION**

Department of Science and Technology of Shanxi Province

**SPONSOR**

Taiyuan Research and Treatment Center for Digestive Diseases, 77 Shuangta Xijie, Taiyuan 030001, Shanxi Province, China

**EDITING**

### Abstract

MicroRNAs are a class of small non-coding RNAs that are found in plants, animals, and some viruses. They modulate the gene function at the post-transcriptional level and act as a fine tuner of various processes, such as development, proliferation, cell signaling, and apoptosis. They are associated with different types and stages of cancer. Recent studies have shown the involvement of microRNAs in liver diseases caused by various factors, such as Hepatitis C, Hepatitis B, metabolic disorders, and by drug abuse. This review highlights the role of microRNAs in liver diseases and their potential use as therapeutic molecules.

### INTRODUCTION

The recent discovery of several types of non-coding RNAs

revealed that the transcriptomes of higher eukaryotes are much more complex than originally anticipated. The non-coding RNAs, including microRNAs (miRNA), piwi interacting RNAs, small nucleolar RNAs, small interfering RNAs, long non-coding RNAs and antisense RNAs, have newly-discovered roles in the biology of health and diseases. These RNAs serve as modulators of genes involved in various biological pathways, such as development, cell differentiation, cell proliferation, cell death, chromosome modifications, virus pathogenesis, and oncogenesis<sup>[1-3]</sup>. Among these RNAs, miRNAs are small RNA molecules of approximate 21 nucleotides that are present in most eukaryotes<sup>[4]</sup>. Since the discovery of the first miRNA, lin-4, in 1993<sup>[5]</sup>, more than 500 miRNAs have been reported in the mammalian genome<sup>[6]</sup>.

It is postulated that about 1%-5% of genes in animals encode miRNAs, while 10%-30% of protein-coding genes are predicted miRNA targets<sup>[7,8]</sup>, and have a specific miRNA signature in normal or cancer cells<sup>[9,10]</sup>. Although our understanding of the specific roles of miRNAs in cellular functions is only beginning, several studies have shown that miRNAs play a pivotal role in the most critical biological events, including development, proliferation, differentiation, cell fate determination, apoptosis, signal transduction, organ development, hematopoietic lineage differentiation, host-viral interactions, and carcinogenesis<sup>[4,11-13]</sup>.

### Overview of miRNAs

Despite the emerging critical role of miRNAs, the mechanism of their action is yet to be fully understood. The widely-known mode of gene regulation by miRNAs occurs at the post-transcriptional level by either specific inhibition of translation or induction of mRNA cleavage<sup>[14]</sup>. The essential role of miRNAs in cellular physiology was elegantly shown in mice lacking the Dicer enzyme that is required for the processing of the precursor miRNAs into the mature form<sup>[15]</sup>.

Until now, the major focus of miRNA research was on their role in the cytoplasm, however recent reports indicate a diverse role of miRNAs, such as regulation of target genes by acting at 5' UTR<sup>[16]</sup>, regulation of DNA methylation<sup>[17,18]</sup> and import of the mature miRNA into the nucleus, suggesting other functional modes<sup>[19]</sup>. It is becoming clear that miRNAs not only regulate gene expression at the post-transcriptional level, but they are also capable of modifying chromatin (Figure 1).

In this review, we discuss the role of the newly emerging class of RNA, miRNAs, in different types of liver diseases.

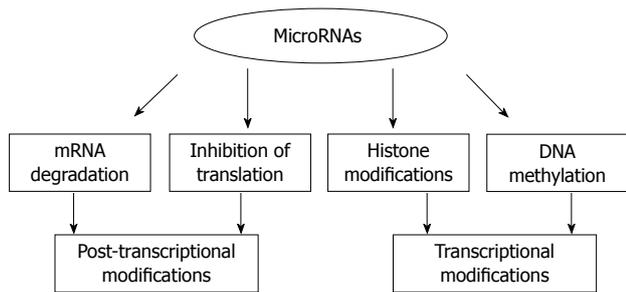

Figure 1 Various modes of gene regulation by miRNAs.

## MiRNAs in Liver Diseases

Improvements in the characterization and functional analysis techniques for miRNAs has not only uncovered their role in various cellular processes, but also revealed abnormal patterns of miRNA expression in various diseases, such as cancer<sup>[20]</sup>, viral infection<sup>[21]</sup>, inflammation<sup>[22]</sup>, diabetes<sup>[23]</sup>, cardiovascular<sup>[24]</sup>, and Alzheimer<sup>[25]</sup>. In this review, we focus on the involvement of miRNAs in liver diseases caused by various factors, such as viral hepatitis, fatty liver due to alcohol abuse or metabolic syndrome, drug-induced liver disease, and by auto-immune processes (summarized in Table 1).

### MiRNAs in host-viral response and viral hepatitis

Viruses are equipped with complex machinery to exploit the host biosynthetic pathways and to defend against host cellular responses<sup>[26]</sup>. Recent studies have revealed the involvement of miRNA-mediated RNA-silencing pathways during viral-host cell interactions<sup>[27]</sup>. However, little is known about the role of cellular miRNAs against viral infection in eukaryotic organisms. Interestingly, viruses not only exploit the cellular miRNAs, but also encode their own miRNAs, adding another layer of complexity<sup>[28,29]</sup>. Therefore, it is important to study the abundance and distribution of miRNAs within the host cell during viral replication and latency, which will help us to understand the molecular regulation by the host cellular system as well as the simultaneous attempts by viruses to overcome the host defense.

**Role of miRNAs in immune response:** The interaction of parenchymal and immune cells plays a unique role in the liver in response to liver insults by viruses, bacteria, toxins, or antigens. There is compelling evidence that characterizes miRNAs as key regulators of innate and adaptive immune responses<sup>[22,30]</sup> and, therefore, they might play a role in inflammatory, autoimmune, or viral diseases of the liver. The importance of miRNAs in the liver immune system is highlighted by the fact that mice lacking Dicer 1 function in the liver were unable to produce mature miRNA and showed progressive hepatocyte damage, apoptosis, and portal inflammation<sup>[31]</sup>.

The innate immune response is the first line of defense against noxious agents and is mediated by adaptors, such as the toll like receptors (TLRs), which recognize specific molecular patterns. Signals triggered by TLRs are involved in most liver diseases (from viral to inflam-

Table 1 Expression of miRNAs in liver diseases

Liver	Upregulated	Downregulated	Ref.
HCV	miR-215, miR-16, miR-199, miR-155, miR-146	miR-122, miR-320, miR-191	[53]
HBV	miR-181a, miR-200b and miR-146a	miR-15a	[56]
Drug overdose	miR-711 (liver), Plasma: miR-122 miR-15a, miR-21, miR-101b, miR-148a and miR-192	miR-29b(liver), miR-710 (plasma)	[62]
NAFLD	miR-122, miR-34a, miR-31, miR-103, miR-107, miR-194, miR-335-5p, miR-221 and miR-200a	miR-29c, miR-451, miR-21	[69,70]
ALD	miR-212, miR-320, miR-486, miR-705, and miR-1224	miR-27b, miR-214, miR-199a-3p, miR-182, miR-183, miR-200a, and miR-322	[71,72]
PBC	miR-328 and miR-299	miR-122a and miR-26a	[73]
Liver fibrosis	miR-27a, miR-27b, miR-30,	miR-9, miR-721 and miR-301	[80]
HCC	miR-18, miR-21, miR-221, miR-222, miR-224, miR-373 and miR-301	miR-122, miR-125, miR-130a, miR-150, miR-199, miR-200 and let-7 family members	[81,90-95]

HCV: Hepatitis C virus; HBV: Hepatitis B virus; NAFLD: Non-alcoholic fatty liver disease; ALD: Alcoholic liver disease; PBC: Primary biliary cirrhosis; HCC: Hepatocellular carcinoma.

matory conditions) as well as in liver regeneration<sup>[32]</sup>. Several miRNAs (such as miR-155 or miR-146a/b) have been implicated in the regulation of TLR-induced signaling and might associated with liver pathophysiology. In particular, miR-155 was upregulated in monocytes and macrophages both upon TLR2, TLR3, TLR4, and TLR9 stimulation and after exposure to cytokines such as tumor necrosis factor (TNF)- $\alpha$  and interferons (IFN)<sup>[33-35]</sup>. The exact function of this miRNA in macrophages is not completely clear, but it might exert a positive regulation on TNF- $\alpha$  release, through targeting genes involved in nuclear factor- $\kappa$ B (NF- $\kappa$ B) signaling or enhancing TNF- $\alpha$  translation<sup>[34]</sup>. miR-146 is also upregulated in response to TLR2, TLR4, and TLR5 stimulation in monocytes<sup>[33]</sup>. This miRNA seems to decrease the release of inflammatory mediators, such as interleukin (IL)-1 $\beta$  or IL-8<sup>[36]</sup>, possibly by downregulating IL-1 receptor-associated kinase 1 and TNF receptor-associated factor 6, and act as a negative regulator of TLR signaling<sup>[33]</sup>. Most of the studies describing the importance of these miRNAs in the innate immune response have been performed in macrophages or monocytes *in vitro*, and therefore the elucidation of specific miRNA functions *in vivo* in Kupffer cells, the resident liver macrophage, still awaits confirmation.

Neutrophil leukocyte infiltration in the liver is also a part of the innate immune response, which is common to liver injury, hepatic stress, or systemic inflammation signals<sup>[37]</sup>. Regulators of granulocyte function and activation, such as miR-223, might also be able to play a role in liver

disease. Several reports have shown that the transcription factor C/EBP $\alpha$  binds to the miR-223 promoter and enhances its expression<sup>[38-40]</sup>. Given the importance of antigen presentation in the liver, the involvement of miRNAs in this function could be also of interest. In line with this, Hashimi *et al.*<sup>[41]</sup> have recently shown that inhibition of both miR-21 and miR-34a in monocyte-derived dendritic cells led to a decrease in endocytic capacity and altered differentiation.

Apart from their role in the innate immune responses, miRNAs are associated with many aspects of both normal and abnormal immune adaptive responses, making them likely actors in autoimmune liver diseases or, particularly, viral hepatitis<sup>[22,30]</sup>. Virtually every T and B cell type seems to be associated with a different miRNA expression profile, and therefore an interesting avenue of research is to identify the miRNAs signature associated with specific liver diseases. Regarding specific miRNA functions, miR-181 has been described as a key quantitative regulator of T cell response to antigens<sup>[42]</sup>. MiR-150 plays a crucial role in B cell differentiation because its over-expression results in a selective defect in B cell development that blocks the transition from pro-B cell to pre-B cell<sup>[43]</sup>. Of note, miR-155 is implicated in both T and B cell function and differentiation promoting T helper 1 vs type 2 differentiation<sup>[44,45]</sup> and is essential in the production of antigen-specific antibodies<sup>[46]</sup>. These data highlight the importance of this miRNA as a central actor in immune regulation.

**Hepatitis C virus (HCV) infection:** HCV is an enveloped RNA virus of the Flavivirus family, and is capable of causing both acute and chronic hepatitis in humans by infecting liver cells. It is a major cause of chronic liver disease, with about 170 million people infected worldwide<sup>[47]</sup>. Up to 70% of patients will have persistent infection after inoculation, making it a fatal disease. The disease varies widely, from asymptomatic chronic infection to cirrhosis and hepatocellular carcinoma (HCC)<sup>[47]</sup>. Since the discovery of HCV, the treatment of hepatitis C has considerably improved by the use of pegylated interferons with ribavirin; however, more than 50% of people still do not respond to current medication and thus there is need for better drug therapy.

Recent studies have shown the involvement of miRNAs in the regulation of HCV infection. MiR-122 is first identified liver-specific cellular miRNA, which has been shown to enhance the replication of HCV by targeting the viral 5' non-coding region<sup>[48]</sup>. It appears that HCV replication is associated with an increase in expression of cholesterol biosynthesis genes that are regulated by miR-122 and hence is considered as a potential target for antiviral intervention<sup>[49]</sup>.

To date, there are some controversies around the role of miR-122 in HCV infection. Recently, Henke *et al.*<sup>[50]</sup> showed that miR-122 stimulates HCV translation by enhancing the association of ribosomes with the viral RNA. The findings describing the role of miR-122 in HCV replication are of special interest, not only because of its novel mode of action, but because they also provide the first evidence of miRNAs linked to

infectious disease. The development of therapeutic products to inhibit the miR-122 is believed to be an attractive approach to treat HCV patients.

By contrast, Sarasin-Filipowicz *et al.*<sup>[51]</sup> found that liver biopsies from chronic hepatitis C patients undergoing IFN therapy revealed no correlation between miR-122 expression and viral load. Moreover, they found markedly decreased miR-122 levels in people who did not have any virological response during later IFN therapy. These reports indicate that the role of miR-122 in HCV viral replication is still controversial and awaits future research.

While some host miRNAs are beneficial for the virus, others inhibit viral replication. Studies by Pedersen *et al.*<sup>[52]</sup> demonstrated that IFN- $\beta$  stimulation, an antiviral cytokine, induces numerous cellular miRNAs, specifically eight miRNAs (miR-1, miR-30, miR-128, miR-196, miR-296, miR-351, miR-431 and miR-448) that have sequence-predicted targets within the HCV genomic RNA. Overexpression of these miRNAs in infected liver cells considerably attenuated viral replication. From this report it seems that host miRNAs have evolved to target viral genes and inhibit their replication, and thus might represent part of the host antiviral immune response. Very recently, Peng *et al.*<sup>[53]</sup> carried out a computational study of hepatitis C virus associated miRNAs-mRNA regulatory modules in human livers. They found differential profiles of cellular miRNAs that target the genes involved in chemokine (16 genes such as *CXCL12 etc.*), B cell receptor, PTEN (13 genes), IL-6 ERK/ MAPK (18 genes; Ras, Erk3 and STAT3 *etc.*) and JAK/STAT signaling pathways, suggesting a critical role of miRNAs in the replication, propagation, and latency of virus in the host cell. Specifically, they found that miR-122, miR-320, and miR-191 were downregulated, whereas miR-215, miR-16, miR-26, miR-130, miR-199 and miR-155 were upregulated. These findings suggest that miRNAs have the potential to become novel drug targets in virally induced infectious or malignant diseases.

**Hepatitis B virus (HBV) infection:** HBV infection is a global problem and it can cause acute or chronic hepatitis B, liver cirrhosis, and, in some instances HCC<sup>[54]</sup>. The available therapy is only partially effective against the virus and development of better therapy remains an important issue. Little is known about the involvement of miRs during HBV infection. Considering the fact that cellular miRNAs play an important role in viral pathogenesis, it is likely that they have a role in HBV infection.

A differential miRNAs expression pattern was found in the livers of HBV and HCV infected individuals with hepatocellular cancer<sup>[55]</sup>. A total of nineteen miRNAs were clearly differentiated between HBV and HCV groups, out of which thirteen miRNAs were downregulated in the HCV group, whereas six showed a decreased expression in the HBV group. Some of the differentially regulated miRNAs between the HCV and HBV groups were miR-190, miR-134, miR-151, miR-193, miR-211, and miR-20. Interestingly, in the same study, it was shown that pathway analysis of targeted genes using infection-associated miRNAs could differentiate the genes into two groups. For instance,

in HBV-infected livers, pathways related to cell death, DNA damage, recombination, and signal transduction were activated, and those related to immune response, antigen presentation, cell cycle, proteasome, and lipid metabolism were activated in HCV-infected livers<sup>[55]</sup>.

In a second study, the profiling of cellular miRNAs of a stable HBV expressing cell line HepG2.2.15 and its parent cell line HepG2, showed that eighteen miRNAs were differentially expressed between the two cell lines<sup>[56]</sup>. Of them, eleven were upregulated and seven were downregulated. For instance, miR-181a, miR-200b, and miR-146a were found to be upregulated and miR-15a was downregulated. It remains to be evaluated if differentially regulated miRNAs could be exploited as potential biomarkers to differentiate between HCV and HBV in the initial stages of pathogenesis.

### **MiRNAs in drug-induced liver injury**

Drug-induced liver injury is a serious clinical health problem and is the leading cause of drugs being removed from the market<sup>[57]</sup>. Acetaminophen overdose is the most common cause of fulminant liver failure. Many studies have been carried out to identify reliable and sensitive early blood markers for liver injury using high throughput technologies<sup>[58]</sup>. However, these efforts have so far failed to yield markers that are superior compared to the existing aminotransferase-based markers, and the need for better and stable biomarkers persists. Increasing attention is being paid to circulating miRNAs as potential biomarkers because of their stability over enzymes or proteins<sup>[59-61]</sup>. However, not much is known about the roles of miRNAs in drug-induced liver injury. A study by Wang *et al*<sup>[62]</sup> showed differential miRNAs profiling in a mouse model of acetaminophen overdose. Significant differences were found in the levels of miRNAs in both liver tissues and plasma between control and acetaminophen overdosed animals. Using miRPortal ([www.miRportal.net](http://www.miRportal.net)), pathways involving antigen processing and presentation, apoptosis, B cell receptor signaling pathways, cytokine-cytokine receptor interaction, and cell cycles were found to be potential targets of miRNAs that showed decreased levels in the liver after acetaminophen exposure. In contrast, pathways involved in various signaling transduction and cell-cell interactions, such as gap-junctions, focal adhesion, and MAPK signaling pathways were potentially affected by miRNAs with increased levels in the liver<sup>[62]</sup>.

Interestingly, it was observed that most miRNAs that were found to decrease in the liver exhibited increased levels in the plasma in overdosed mice. For instance, miR-122 and miR-192 showed higher levels in plasma, but they were decreased in tissue, whereas miR-710 and miR-711 were elevated in liver tissues; however, they displayed lower levels in plasma after acetaminophen overdose. Moreover, liver specific miRNAs, such as miR-122 and miR-192, showed dose and time-dependent changes in the plasma that paralleled serum aminotransferase levels and liver injury on histopathology. These findings suggest the potential of using specific circulating miRNAs as sensitive and informative biomarkers for drug-induced liver injury.

### **MiRNAs in non-alcoholic fatty liver disease (NAFLD)**

NAFLD is the most common form of chronic liver disease worldwide and a major public health concern in the modern society<sup>[63]</sup>. It is characterized by excess fat accumulation in liver, which ranges from simple steatosis to steatohepatitis, and cirrhosis in the absence of heavy alcohol consumption<sup>[64]</sup>. The major risk factors for the development of NAFLD include metabolic syndrome, such as obesity, type 2 diabetes mellitus, and dyslipidemia<sup>[65]</sup>. Although progress has been made in understanding the factors causing NAFLD, more needs to be done to dissect the underlying regulatory networks. Compelling evidences indicate the role of miRNAs in energy metabolism and liver functions<sup>[66,67]</sup>. For instance, miR-143 has been shown to play a role in adipose differentiation<sup>[68]</sup>.

MiR-122, which was found to be upregulated in NAFLD, is known to regulate genes involved in fatty acid biosynthesis<sup>[69]</sup>, and administration of this miRNA antagonist into mice resulted in reduced levels of plasma cholesterol, increased hepatic fatty acid oxidation, and decreased synthesis of hepatic fatty acid and cholesterol.

Li *et al*<sup>[70]</sup> reported that eight miRNAs (miR-34a, miR-31, miR-103, miR-107, miR-194, miR-335-5p, miR-221 and miR-200a) were upregulated and three miRNAs (miR-29c, miR-451, miR-21) were downregulated in the livers of ob/ob mice. These findings suggested a connection between miRNAs and metabolic disorders, and the role of miRNA in NAFLD deserves further investigation.

### **Role of miRNAs in alcoholic liver disease (ALD)**

ALD, alcoholic hepatitis, and cirrhosis represent a major segment of liver diseases worldwide. A recent report by Dolganiuc *et al*<sup>[71]</sup> analyzed the miRNA expression profile in a murine model of ALD. Liver samples from mice fed an ethanol-containing diet (Lieber-DeCarli) showed features of alcoholic steatohepatitis and had an increased expression of miR-320, miR-486, miR-705, and miR-1224. On the other hand, decreased expression was found for several miRNAs, including miR-27b, miR-214, miR-199a-3p, miR-182, miR-183, miR-200a, and miR-322. Furthermore, livers from mice with alcoholic and with non-alcoholic fatty liver shared common alterations in their miRNA profiles (such as upregulation of miR-705 and miR-1224). However, the functions and physiological roles of these miRNAs in ALD are yet to be determined. Tang *et al*<sup>[72]</sup> have suggested a novel mechanism for ethanol-induced intestinal permeability. They found that ethanol intake resulted in the induction of miR-212, which in turn downregulated the Zonula occludens (ZOP) protein. The decrease in ZOP protein levels led to intestinal barrier disruption and thus increased intestinal permeability. The interest of this finding lies in the association of intestinal permeability with the development of ALD, therefore linking miR-212 with the pathogenesis of this disease.

### **Primary biliary cirrhosis (PBC)**

Recent studies indicate that the role of miRNAs is yet to be explored in liver diseases associated with autoimmune

aggression. In PBC, altered hepatic miRNA expression was found<sup>[73]</sup>. miRNA profiling of explanted livers from subjects with PBC revealed differential expression of thirty-five independent miRNAs compared to controls. Downregulation of miR-122a and miR-26a, and increased expression of miR-328 and miR-299, were confirmed by PCR in the PBC livers. The role of miRNAs in autoimmune hepatitis is yet to be studied.

### Liver fibrosis

Chronic hepatitis contributes to liver fibrosis, which has been linked to fibrosis due to fibrin deposition by hepatic stellate cells (HSC)<sup>[74]</sup>. The relationship between miRNAs and fibrosis has been shown in the context of specific diseases, such as diabetic kidney sclerosis<sup>[75]</sup> or myocardial fibrosis<sup>[76]</sup>, and some of the mechanisms described could be involved in common pathways of fibrosis in other diseases. A recent report by Kato *et al*<sup>[77]</sup> has described that transforming growth factor (TGF)- $\beta$  activates Akt kinase by enhancing the expression of both miR-216a and miR-217. These miRNAs, in turn, target PTEN, an inhibitor of Akt activation that has also been described to play a role in hepatic stellate cell activation<sup>[78]</sup>. Hepatic stellate cell activation has been identified as the major driver of liver fibrosis. Activation of HSC is associated with upregulation of various signaling pathways. In cirrhotic rat livers, HSC activation was associated with mitochondrial damage indicated by increased Bcl-2 and downregulated caspase-9 levels. The miRNA profile of the same rat HSC indicated upregulation of thirteen and downregulation of twenty-two, signaling pathways by miRNAs<sup>[79]</sup>. In another in vitro study, overexpression of miR-27a and miR-27b resulted in reversal of the activated phenotype of stellate cells to a more quiescent phenotype with increased fat accumulation and decreased proliferation<sup>[80]</sup>. The effects of miR-27a and miR-27b were mediated by regulation of the retinoid X receptor in the hepatic stellate cells.

Although there are only a few studies in the literature on miRNA genes and HCV-induced liver fibrosis, given the critical role of miRNA, its possible that they play a critical role in HCV infection, in the progression of fibrosis, and in the prediction of treatment response. Jiang *et al*<sup>[81]</sup> showed increased miRNA expression in cirrhotic and hepatitis-positive liver samples and suggested that important changes in miRNA expression occur during the development of chronic viral hepatitis and cirrhosis.

### HCC

HCC is the third-leading cause of death from cancer and the fifth most common malignancy worldwide<sup>[82]</sup>. Liver cancer is a complex disease with exceptional heterogeneity in cause and outcome, involving epigenetic and chromosomal instability<sup>[83]</sup> and abnormalities in the expression of both coding and non-coding genes, including miRNAs<sup>[84,85]</sup>. The major etiologies of HCC include chronic liver disease due to chronic hepatitis B or hepatitis C virus infection, alcoholic steatohepatitis, metabolic disorders such as nonalcoholic steatohepatitis or insulin resistance, hereditary hemochromatosis, and

immune-related diseases such as PBC and autoimmune hepatitis<sup>[86]</sup>.

There are several studies in the literature showing specific miRNA signatures in HCC formation<sup>[87-89]</sup> and progression that could be exploited as potential cancer biomarkers. Briefly, miR-18, miR-21, miR-221, miR-222, miR-224, miR-373, and miR-301 were reported to be upregulated<sup>[81,90,91]</sup> whereas miR-122, miR-125, miR-130a, miR-150, miR-199, miR-200, and let-7 family members<sup>[92-95]</sup> were found to be downregulated in HCC by most studies. These miRNAs target the genes involved in cell cycle and cell death regulation, including cyclin-dependent inhibitors *p27/CDKN1B* and *p57/CDKN1C*, or the PI3K antagonist phosphatase and tensin homolog (PTEN). Budhu *et al*<sup>[96]</sup> defined twenty miRNAs, as a HCC metastasis signature, and showed that the twenty-miRNA-based signature was capable of predicting survival and recurrence of HCC in patients with multinodular or solitary tumors, including those with early-stage disease. miR-219-1, miR-207, and miR-338 were the most highly upregulated, whereas miR-34a, miR-30c-1, and miR-148a were highly downregulated in metastasis cases. Target Scan analysis revealed that *SPTBN2*, *GTF2H1*, *PSCD3*, *VAMP3*, and *SLC20A2* are the target genes which were affected by multiple miRNAs related to metastasis and might be the part of signaling pathways that significantly contribute to this phenotype. Moreover, this miRNA signature was an independent and significant predictor of patient prognosis when compared to other available clinical parameters<sup>[96]</sup>. This study suggested that these twenty miRNAs can assist in HCC prognosis and might have clinical relevance. Further functional studies of these miRNAs could help to elucidate the mechanism leading to HCC metastasis. Deregulation of these twenty miRNAs in metastatic HCC implies that altered expression of their target genes might contribute to the development or recurrence of metastasis, and miR-122 is one example of this metastasis signature<sup>[97]</sup>.

## THE POTENTIAL OF MiRNAs IN DIAGNOSTICS, DISEASE PROGNOSIS, AND THERAPY

Increasing evidence indicates that miRNAs play an important role in a wide range of liver diseases, ranging from cancers and viral hepatitis, to metabolic diseases. The unique expression profile of miRNAs in different types and at different stages of cancer, and in other diseases, suggest that these small molecules can be exploited as novel biomarkers for disease diagnostics and might present a new strategy for miRNA gene therapy.

Recently, Kota *et al*<sup>[98]</sup> showed that administration of miR-26a, (which is under-expressed in HCC cells and downregulates cyclins D2 and E2) using adeno-associated virus (AAV) resulted in the inhibition of cancer cell proliferation, induction of tumor-specific apoptosis, and dramatic protection from disease progression without toxicity in a mouse model of HCC, suggesting the potential therapeutic use of miRNAs. This study

showed that anti-miRNA compounds could be delivered *in vivo* safely and with efficacy; thus opening the way for translation of these basic research findings to clinical applications. It is also important to consider other factors, because some miRNA genes such as miR-1 undergo methylation-mediated regulation in HCC cell lines<sup>[99]</sup>, suggesting a strong link between the DNA methylome and the miRNAome. In particular, there are some reports showing that the expression profiles of miRNA differ between malignant hepatocytes, malignant cholangiocytes, and benign liver cancer<sup>[90]</sup>, suggesting that miRNA profiling could be used as molecular diagnostic markers in liver disease.

## CONCLUSION

It is increasingly evident that miRNAs play a novel and important role in regulation of gene expression. In recent years, research focusing on small molecules such as miRNAs has intensified to understand their role in health and disease. The excitement of exploring their regulatory potential will remain for years to come, given the observation that miRNAs could be ideal therapeutic targets for many diseases. We are at the beginning of understanding of the diverse roles of miRNAs in fine-tuning biological pathways, and in future years we will have a better picture of this complex regulatory mechanism. Presently, there is need for miRNAs-based diagnostics and gene therapy; however, these techniques are in their infancy.

### Abstract

Acute pancreatitis (AP) is a rare event in pregnancy, occurring in approximately 3 in 10000 pregnancies. The spectrum of AP in pregnancy ranges from mild pancreatitis to serious pancreatitis associated with necrosis, abscesses, pseudocysts and multiple organ dysfunction syndromes. Pregnancy related hematological and biochemical alterations influence the interpretation of diagnostic tests and assessment of severity of AP. As in any other disease associated with pregnancy, AP is associated with greater concerns as it deals with two lives rather than just one as in the non-pregnant population. The recent advances in clinical gastroenterology have improved the early diagnosis and effective management of biliary pancreatitis. Diagnostic studies such as endoscopic ultrasound, magnetic resonance cholangiopancreatography and endoscopic retrograde cholangiopancreatography and therapeutic modalities that include endoscopic sphincterotomy, biliary stenting, common bile duct stone extraction and laparoscopic cholecystectomy are major milestones in gastroenterology. When properly managed AP in pregnancy does not carry a dismal prognosis as in the past.

### INTRODUCTION

Acute pancreatitis (AP) is a common problem with an annual incidence of 5 to 80 per 100000 of the general population. The incidence of AP in pregnancy varies and is approximately 1 in 1000 to 1 in 10000 births<sup>[1]</sup>. The wide variation in the incidence is influenced by the prevalence of its most important etiological factor i.e. gallstone disease. While biliary pancreatitis complicated 1 in 3300 pregnancies at a large public hospital in Dallas, Texas<sup>[2]</sup>, in southern California 1 in 1500 women were affected<sup>[3]</sup>. In a retrospective study from USA spanning 10 years Legro and Laifer<sup>[4]</sup> identified 25 cases of AP in pregnancy. Eleven of these 25 patients were diagnosed in the first trimester of pregnancy when physicians had to clearly distinguish between hyperemesis gravidarum and AP. In another study 43 pregnant women out of 147197 were diagnosed with AP<sup>[2]</sup>; 19% of these were diagnosed in the first trimester, 26% in the second, and 53% in the third trimester (one was postpartum), demonstrating that AP was more common with advancing gestational age, paralleling the frequency of gallstone diseases in pregnancy.

Older reviews of AP in pregnancy reported maternal and fetal mortality rates as high as 20% and 50% respectively<sup>[2,5-9]</sup>. The above data from the pre-endoscopic retrograde cholangiopancreatography (ERCP), pre-laparoscopic cholecystectomy era are not valid anymore. Contemporary reports document a much improved outcome of AP in pregnancy, when the management of AP secondary to gallstones has undergone substantial changes<sup>[10,11]</sup>. Hernandez *et al*<sup>[11]</sup> in 2007, based on a single center experience spanning 10 years, reported 34 episodes of

AP with no maternal deaths and a fetal loss of only 4.7%. Date *et al*<sup>[12]</sup> in 2008 compared conservative and surgical management of cholecystitis in pregnancy and noted no difference in fetal mortality (2.2% *vs* 1.2%,  $P = 0.57$ ), and there was no maternal mortality. The major changes are the availability of many options in abdominal imaging and less invasive therapeutic options. In addition to abdominal ultrasound (US) we have endoscopic ultrasound (EUS), magnetic resonance cholangiopancreatography (MRCP) and ERCP. The introduction of laparoscopic cholecystectomy in 1986 is a milestone that has reduced the morbidity of surgical intervention by open abdominal surgery even in high-risk pregnant patients. Above all the safe applications of therapeutic ERCP, endoscopic sphincterotomy (ES) have permitted delaying cholecystectomy to safer periods in pregnancy or postpartum.

The etiological associations of AP during pregnancy are similar to those in the general population. AP in pregnancy is most often associated with gallstone disease or hypertriglyceridemia. Gallstones are the most common cause of AP during pregnancy responsible for more than 70% of cases<sup>[2]</sup>. The incidence of gallstone related diseases including acute cholecystitis and biliary pancreatitis complicating pregnancy is 0.05%-0.8%<sup>[13]</sup>. Even in patients who had prior cholecystectomy, a biliary etiology may exist. The prevalence of microlithiasis after cholecystectomy is 5%-10%<sup>[14,15]</sup>. The pathogenesis of AP in gallstone disease is attributed to lodging or impaction of a stone or microlithiasis in the ampulla of Vater initiating premature activation of intracinar trypsinogen to trypsin.

## AP OF BILIARY ETIOLOGY IN PREGNANCY

The prevalence rate of gallstones varies with ethnicity. Native American Indians, Mexicans, Latin Americans and Pima Indians all have a high incidence while the incidence is lower in Asia and Africa. Many studies have reported a high incidence of gallstones in the population from northern states of India<sup>[16,17]</sup>. Gallbladder disease is strongly related to the metabolic syndrome, a problem that is growing in incidence all over the world<sup>[18-21]</sup>. Rapid weight loss is a recently recognized factor for microlithiasis and gallstones<sup>[22]</sup>. Although pregnancy itself is a risk factor, the risk increases with parity<sup>[23]</sup>. Weight gain and hormonal changes predispose pregnant women to biliary sludge and gallstone formation<sup>[24]</sup>. Identification of a biliary etiology for AP is important because as in the non-pregnant patient recurrence of AP episodes will occur in one-third to two-thirds of patients unless gallstones are removed<sup>[10,11,25-27]</sup>.

### **Pathogenesis of increased prevalence of gallstone in pregnancy**

Cholesterol secretion in the hepatic bile increases in the second and third trimester compared to bile acids and phospholipids, leading to supersaturated bile; in addition, fasting and postprandial gallbladder volumes are greater, with reduced rate and volume of emptying.

This large residual volume of supersaturated bile in the gallbladder of the pregnant patient leads to the retention of cholesterol crystals and eventual gallstones. The formation of biliary sludge and stones is strongly associated with frequency and number of pregnancies<sup>[25]</sup>.

Up to 10% of patients develop stones or sludge over the course of each pregnancy, with obesity and increased serum leptin being risk factors<sup>[28]</sup>. After delivery gallbladder motility becomes normal when sludge as well as stones may disappear<sup>[26,27]</sup>.

In evaluating pregnant patients with AP the four important questions to be answered are (1) does the patient have AP (establishing the diagnosis and ruling out other causes)? (2) if it is AP, what is the predicted severity? (3) is there a biliary etiology? and (4) what is the trimester of pregnancy?<sup>[29]</sup> The answer to the last question determines the choice of imaging studies and mode of therapy.

In the management initial blood tests are done to establish the diagnosis of AP and to assess the severity. Serum amylase and lipase levels are reliable markers of AP during pregnancy. The serum lipase level is unchanged during pregnancy, and the amylase level is either normal or only mildly elevated<sup>[30]</sup>. The alterations in blood chemistry in normal pregnancy do not hinder the assessment of severity. Elevation of serum alanine aminotransferase levels to > 3 times the upper limit of normal is a very sensitive biochemical marker of biliary pancreatitis<sup>[31,32]</sup>. Any abnormality of liver enzymes and bilirubin as well as rapid change in the levels should suggest a biliary etiology.

## IMAGING STUDIES

Abdominal ultrasound (AUS) with no radiation to the fetus is the initial imaging technique of choice to identify a biliary etiology. Gallstones as a potential cause of AP are identified by AUS in most cases<sup>[33]</sup>. However, it is insensitive for the detection of common bile duct stones or sludge. When a common bile duct (CBD) stone is suspected based on AUS or biochemical abnormalities EUS, a semi-invasive procedure of the biliary tree is an accurate modality for detecting common bile duct stones<sup>[34]</sup>. However EUS requires expensive equipment, intravenous sedation and technical expertise. EUS can be considered the best imaging study to evaluate CBD, although not for gallbladder stones. In expert hands small gallstones as well as sludge can be picked up by EUS, however it is operator dependent. EUS is appropriate prior to the consideration of therapeutic ERCP in patients where non-invasive imaging such as MRCP is not available, contraindicated or inconclusive. EUS has a high positive predictive value nearing 100% in detecting CBD stones and in many instances EUS is superior to MRCP<sup>[35]</sup>. EUS entails no radiation exposure and is extremely safe apart from a minimal sedation related risk. If a common bile duct stone is detected, an ERCP with sphincterotomy can be performed following the EUS study during the same sedation.

Magnetic resonance imaging (MRI) and MRCP provide multi-planar large field of view images of the

body with excellent soft-tissue contrast and images of bilio-pancreatic duct systems. MRCP does not require any contrast injections and has no risk of renal injury. MRCP is a preferred method of evaluating CBD in many clinical situations. There is paucity of data on the safety of MRI in the first trimester of pregnancy<sup>[36-38]</sup>. Some authors have raised concerns of thermal injury to the fetus in first trimester<sup>[39,40]</sup>.

According to the Safety Committee of the Society for Magnetic Resonance Imaging<sup>[41]</sup>, MR procedures are indicated in pregnant women if other non-ionizing forms of diagnostic imaging studies are inadequate, or if the examination provides important information that would otherwise require exposure to ionizing radiation [i.e. X-Ray computerized tomography (CT), *etc.*]. Gallstone pancreatitis is generally associated with small gallbladder stones and sludge<sup>[42]</sup>. Small ductal stones in particular, located in the distal CBD could be missed by MRCP<sup>[43]</sup>. Claustrophobia remains the major barrier in the use of MRCP and MRI.

CT scan of the abdomen is the most commonly used imaging modality in diagnosing and later on in assessing severity of AP among adults. It is not recommended in pregnant patients because of the fear of radiation exposure to the fetus<sup>[44]</sup>. In general CT is not the preferred modality of imaging in all trimesters of pregnancy in view of a small radiation risk to the fetus.

ERCP solely as a diagnostic study has lost its value because of the risks of radiation, incidence of AP post procedure, and the availability of safer procedures such as EUS or MRCP. ERCP increases the risk of complications and death from 5% to 10% and 0.1% to 0.2% respectively<sup>[45]</sup>. However, the clinical usefulness of therapeutic ERCP when indicated is unchallenged. Persistent biliary obstruction worsens the outcome, increases the severity of AP, and predisposes to bacterial cholangitis. ERCP along with ES helps to extract impacted gallstones and drain infected bile in severe AP<sup>[46]</sup>. Several reports have shown that ERCP can be carried out successfully in the management of symptomatic choledocholithiasis in pregnancy<sup>[47,48]</sup>. A major concern of this procedure is harmful ionizing radiation to the fetus. Tham *et al*<sup>[49]</sup> reported their experience with ERCP in pregnancy (15 patients over 5 years) with fetal dose radiation measurement. The fetal radiation dose could be reduced to a level less than that considered teratogenic. Kahaleh *et al*<sup>[50]</sup> looked at 17 ERCPs performed in pregnant women between January 1995 and August 2003. They reported a mean gestational age of 18.6 wk, mean fluoroscopy time of 14 s and an estimated fetal radiation exposure of 40 mrad. By limiting fluoroscopy time, shielding the pelvis and fetus with lead and avoiding direct X-ray films, the fetal radiation dose can be reduced to far below the maximum permissible doses. Performing MRCP or EUS before ERCP helps to identify patients who require therapeutic ERCP thus reducing the number of ERCP<sup>[51]</sup>.

## MANAGEMENT

Several recommendations below are mostly based on

expert opinion only and not confirmed by double blind/randomized controlled trials. The difficulties in performing such studies in critically ill pregnant patients are obvious.

### Nutrition

Although successful outcomes can be achieved in obstetric patients requiring parenteral nutrition, the frequency of maternal complications secondary to centrally inserted central venous catheters (TPN) is greater than that reported in non-pregnant patients<sup>[52]</sup>. Peripherally inserted central catheters may be preferable when parenteral nutrition is required during pregnancy. Enteral nutrition by naso-jejunal feeding is preferable to TPN<sup>[11]</sup> in patients with severe AP. Enteral nutrition is physiological, helps the gut flora maintain the gut mucosal immunity, reduced translocation of bacteria, while simultaneously avoiding all the risks of TPN.

### Antibiotics

The topic of prophylactic use of antibiotics is very controversial and the choice of antibiotic in pregnancy is difficult. However, in suspected cholangitis there is no controversy with regards to the need for appropriate antibiotic therapy. Patients with mild AP, normal CBD size with no evidence for cholangitis do not need antibiotics. In a pregnant patient there are concerns with regard to the antibiotic being transplacentally transferred to the fetus with a risk of teratogenicity. Metronidazole passes freely across the placenta. However, recent studies do not show any association with an increased risk of teratogenic effects with metronidazole<sup>[53,54]</sup>. Imipenem (N-formimidoyl thienamycin), belonging to the carbapenem class of antibiotics, has a broad spectrum of activity. It is currently classified as a category C in terms of its risk to the fetus. Although limited animal studies have shown no teratogenic risk or adverse fetal effects, data in humans are not available<sup>[55]</sup>. Quinolones have been classified as category C because adverse effects have been noted in some animal studies. However, there are no adequate studies in humans; the benefits may outweigh the risks. Ampicillin-sulbactam and piperacillin/tazobactam are classified as category B with no evidence of risk in humans. Regardless of initial drug regimen, therapy should be modified to reflect the organisms recovered in blood cultures and the clinical status of the patient.

### Management of underlying cause

**Management of gallstones:** In a pregnant woman with gallstones and CBD stones a major decision is on choice of procedure to clear the CBD of stones. The second decision is on timing and approach to cholecystectomy<sup>[56]</sup>. Factors which influence the decision include the trimester of pregnancy, presence or absence of CBD dilatation, cholangitis, and the severity of AP. AP patients with gallstones need to be evaluated for early cholecystectomy to prevent recurrence of AP later on in the pregnancy when it could be more serious and dangerous<sup>[25-27]</sup>. It is a well respected surgical concept that the second trimester is the best period for surgery since during this period organogenesis is complete and the uterus

is not big enough to obliterate the surgical view for laparoscopic approach. It has also been recognized that cholecystectomy during the second trimester is safe for both the mother and the fetus<sup>[10,12,57]</sup>.

Laparoscopic cholecystectomy in pregnant women offers all of the advantages of laparoscopic surgery in non-pregnant patients - reduced hospital stay, decreased narcotic use and a quick return to a regular diet compared to open surgery in pregnant women<sup>[58]</sup>. In the second trimester the gravid uterus does not interfere with visualization of the operative field. The indications for surgery in pregnancy are severity of symptoms, obstructive jaundice, acute cholecystitis intractable to medical treatment and peritonitis.

Four retrospective studies comparing open cholecystectomy *vs* laparoscopic cholecystectomy did not find any significant difference in maternal or fetal outcomes<sup>[12]</sup>. Gouldman *et al*<sup>[59]</sup> reviewed the available world literature on laparoscopic cholecystectomy in pregnancy and found 107 patients who had cholecystectomy during pregnancy. Most had been performed in the second trimester, with 10 and 16 patients in the first and third trimesters, respectively. Premature labor was rare, with only 2 of the 16 reported patients (12.5%) in the third trimester developing preterm labor, and these were successfully treated with tocolytics. Overall results were good with excellent maternal (100%) and fetal (96%) survival. There is a recent view that states when surgical intervention is warranted, laparoscopic cholecystectomy can be safely performed in any trimester<sup>[60]</sup> but it is a minority view. Performance of cholecystectomy is desirable in the second trimester as organogenesis is complete, and spontaneous abortions are less frequent than in the first trimester<sup>[61]</sup>.

ERCP with sphincterotomy and clearance of bile duct stones is indicated in patients with severe AP, with cholangitis, with strong evidence of persistent biliary obstruction, and in those who are post cholecystectomy as well as patients who are poor candidates for surgical therapy<sup>[25]</sup>. Pregnant women in the first and third trimester who are not ideal candidates for cholecystectomy fall in the last category. Biliary sphincterotomy rather than cholecystectomy may be appropriate when CBD stones are detected and cholecystectomy has to be delayed because of pregnancy. The effectiveness of ES in preventing further episodes of biliary pancreatitis, as an alternative to cholecystectomy in high risk patients has been demonstrated<sup>[48,62-69]</sup>. The indication for ERCP in patients with severe pancreatitis without significant cholestasis is controversial. At this time there is no evidence that therapeutic ERCP is required in all patients with biliary sludge during pregnancy.

The role of therapeutic ES in the management of pregnant patients with AP without CBD stones continues to be controversial<sup>[70]</sup>. Some advocate biliary stent placement rather than performing sphincterotomy and stone extraction and therefore, eliminating complications that accompany sphincterotomy. Farca *et al*<sup>[71]</sup> placed 10-French biliary stents without sphincterotomy in 10 patients, all of whom had uncomplicated pregnancies with normal deliveries. All underwent repeat ERCP with stent extraction and sphincterotomy post-partum and 8 had stones

extracted. In 2 patients, the stent remained in place for 7 and 8 mo, respectively, without the development of occlusion and or cholangitis. However, stenting carries risks of stent occlusion and cholangitis and the need for a second procedure.

**Hyperlipidemic pancreatitis:** Hypertriglyceridemia is the second most common cause of AP, when the serum triglyceride is > 1000 mg/dL. In the third trimester of pregnancy, there is a three-fold rise in serum triglyceride levels<sup>[72]</sup>. This is thought to be due to estrogen-induced increases in triglyceride synthesis and very low-density lipoprotein secretion<sup>[72]</sup>. Hypertriglyceridemia may be more severe in persons with familial hyperlipidemia, predisposing them to develop pancreatitis<sup>[73]</sup>. Rarer causes of AP that need to be considered in the differential diagnosis are hyperemesis during the first trimester; hyperparathyroidism; preeclampsia; and genetic mutations<sup>[74-76]</sup> and acute fatty liver of pregnancy. AP can also complicate the course of thrombotic thrombocytopenic purpura during pregnancy<sup>[77]</sup> and pregnancy induced hypertension<sup>[78]</sup>. Medication and alcoholism are extremely rare causes of AP in pregnancy.

No formal recommendations exist for gestational hypertriglyceridemia treatment in pregnancy at present. Treatment of hyperlipidemic AP is mostly supportive. These treatments include low fat diet<sup>[79,80]</sup>, antihyperlipidemic therapy<sup>[79,80]</sup>, insulin<sup>[79-81]</sup> (to increase lipoprotein lipase activity), heparin<sup>[79-81]</sup> (to increase lipoprotein lipase activity), and even plasmapheresis<sup>[79,82]</sup>.

## CONCLUSION

AP in pregnancy remains a challenging clinical problem to manage, with a relatively limited but expanding evidence base. Among the various etiological factors for AP in pregnancy, gallstone disease is the most common one. Abdominal ultrasound, CT scan, EUS and MRCP are the available imaging studies in diagnosing a biliary etiology for AP. Potential radiation to the fetus is a major disadvantage with CT scan, restricting their use substantially. Diagnostic ERCP is to be avoided whenever possible owing to the associated risks including bleeding, perforation, pancreatitis, fetal radiation, while abdominal ultrasound, MRCP and EUS do not carry these risks. The general management of AP in pregnancy is supportive and includes hospitalization, intravenous fluids, analgesia, and bowel rest. Laparoscopic cholecystectomy is ideally performed in the second trimester when the risk to fetus is the least and only limited technical problems exist as a result of an enlarging uterus. Whenever laparoscopic cholecystectomy is not feasible and the index of suspicion for a stone in the CBD is high based on AUS, MRCP or by EUS, ES or stenting serves to prevent recurrence of AP and allows postponement of laparoscopic cholecystectomy to a more suitable period. Hyperlipidemic pancreatitis and AP due to other etiologies are rare. The outcome of pregnant patients with AP has substantially improved with technical advances in imaging and therapeutic endoscopy.

### Abstract

In Pakistan more than 10 million people are living with Hepatitis C virus (HCV), with high morbidity and mortality. This article reviews the prevalence, genotypes and factors associated with HCV infection in the Pakistani population. A literature search was performed by using the keywords; HCV prevalence, genotypes and risk factors in a Pakistani population, in Pubmed, PakMediNet and Google scholar. Ninety-one different studies dating from 1994 to May 2009 were included in this study, and weighted mean and standard error of each population group was calculated. Percentage prevalence of HCV was  $4.95\% \pm 0.53\%$  in the general adult population,  $1.72\% \pm 0.24\%$  in the pediatric population and  $3.64\% \pm 0.31\%$  in a young population applying for recruitment, whereas a very high  $57\% \pm 17.7\%$  prevalence was observed in injecting drug users and  $48.67\% \pm 1.75\%$  in a multi-transfused population. Most prevalent genotype of HCV was 3a. HCV prevalence was moderate in the general population but very high in injecting drug users and multi-transfused populations. This data suggests that the major contributing factors towards increased HCV prevalence include unchecked blood transfusions and reuse of injection syringes. Awareness programs are required to decrease the future burden of HCV in the Pakistani population.

**Key words:** Hepatitis C virus; Prevalence; Genotypes; Blood transfusions; Injections

### INTRODUCTION

Hepatitis C virus (HCV) was discovered in 1989 as the major causative agent of non-A, non-B hepatitis<sup>[1]</sup>. It belongs to the *Flaviviridae* family and is a plus-stranded RNA virus<sup>[2]</sup>. About 200 million people are infected with HCV worldwide, which covers about 3.3% of the world's population<sup>[3,4]</sup>. HCV infection leads to chronic hepatitis in 50% to 80% of individuals<sup>[5]</sup>. It was estimated by the WHO in 2004 that the annual deaths due to liver cancer caused by HCV and cirrhosis were 308 000 and 785 000 respectively<sup>[6]</sup>.

Pakistan is a developing country of 170 million people with low health and educational standards. According to the human development index of the United Nations, it was ranked 134th out of 174 countries<sup>[7]</sup>. In Pakistan 10 million people are presumed to be infected with HCV<sup>[8]</sup>. Public health authorities are creating awareness about hepatitis through print and electronic media<sup>[9]</sup>, but still tremendous efforts are required to increase the awareness regarding various risk factors involved in HCV transmission. In developing countries, due to non-implementation of international standards regarding blood transfusion, reuse of needles for ear and nose piercing, reuse of syringes, injecting drug users, tattooing, shaving from barbers, unsterilized dental and surgical instruments are the main source of transmission of HCV. This article briefly presents the prevalence, genotypes and risk factors associated with HCV transmission in the Pakistani population.

### LITERATURE SEARCH

Articles were searched for in Pubmed, Google scholar and PakMediNet (for non-indexed Pakistani journals),

by using the key words; HCV in Pakistan, prevalence of HCV in Pakistan, epidemiological patterns of HCV in Pakistan, HCV in multi-transfused Pakistani population, HCV in general Pakistani population, HCV in Pakistani injecting drug users (IDUs) population, HCV in Pakistani health care workers, sexual transmission of HCV, injection use in Pakistan, blood banks/transfusion in Pakistan, awareness about HCV in Pakistani population and HCV genotypes in Pakistan. Inclusion criteria entailed the studies demonstrating the prevalence, genotypes and risk factors of HCV in the Pakistani population while studies with incomplete references were excluded. Two hundred and eighty-one different articles/abstracts/reports were obtained from the literature search, out of which 91, published from 1994 to May 2009, were included in this study.

## ANALYSIS

Table 1 includes various reports showing the percentage prevalence of HCV in different groups. Weighted mean of each population was calculated by using the formula:

$$\bar{x} = \frac{\sum_{i=1}^n \omega_i x_i}{\sum_{i=1}^n \omega_i}$$

Standard error of mean was calculated by using the formula:

$$SE_{\bar{x}} = \frac{s}{\sqrt{n}}$$

Results of each population group are presented in the form of mean  $\pm$  SE with 95% confidence interval.

## HCV PREVALENCE IN VARIOUS GROUPS

### General population

Ten different studies showed that the percent prevalence of HCV in the general adult population was  $4.95\% \pm 0.53\%$ <sup>[10-19]</sup>, while six studies showed a percent prevalence of  $1.72\% \pm 0.24\%$  in the pediatric population<sup>[20-25]</sup>. In Pakistan, military recruits are screened for HCV before induction; six different studies showed a percent prevalence of  $3.64\% \pm 0.31\%$  in candidates for military recruitment<sup>[26-31]</sup>. About 5% of infants obtained HCV infection transmitted from a mother carrying both HCV antibody and HCV RNA<sup>[32]</sup>; four studies in pregnant women showed the percent prevalence to be  $4.54\% \pm 3.5\%$ <sup>[33-36]</sup>. Volunteer blood donors are the healthiest population in a community and HCV prevalence in these individuals is a true reflector of a general population's health<sup>[9]</sup>; twelve different studies showed the percent prevalence to be  $3.78\% \pm 0.41\%$  in blood donors<sup>[17,37-47]</sup>.

### IDUs

It was estimated that there were about 5 million drug users in Pakistan, out of which 15% were regular IDUs<sup>[48]</sup>. There has been an increased shift among addicts from inhalatory to injectable drugs due to decrease in quality and availability of heroin (common inhalatory drug used in Afghanistan and Pakistan)<sup>[49]</sup>. The effect of injecting drugs is more intense and satisfying, and young drug users who switch over to injectables usually adopt it as the

main route of their drug administration<sup>[50]</sup>. Approximately 50% of IDUs reported by Altaf *et al*<sup>[51]</sup> in 2007 were in a treatment program; the majority of them wanted to get rid of their addiction but could not do so due to non availability or high charges by rehabilitation centers. The main reason for relapse was the economic crisis which most addicts suffer because the rehabilitation centers are not involved in the development of vocational skills among addicts. Four different reports showed a high  $57\% \pm 17.7\%$  prevalence of HCV among the IDUs<sup>[52-55]</sup>.

### Multi-transfused population

Thalassemic and hemophilic patients require life-long blood transfusions, so it is necessary to obtain screened blood from a reputable source, because the multi-transfused population is more prone to blood-borne pathogens. Arif *et al*<sup>[56]</sup> reported that only 15.8% of parents of thalassemic children knew the importance of blood screening. Six different reports showed an HCV percent prevalence of  $48.67\% \pm 1.75\%$  among the thalassemic and hemophilic population<sup>[56-62]</sup>.

### Health care workers

Health care workers are at high risk of HCV infection because they are dealing with blood, blood-related products and instruments which may carry transmissible pathogens. Hamid *et al*<sup>[63]</sup> reported that recapping of syringes is the key factor for receiving needle stick injuries in health care workers and that transmission of HCV by needle stick injury ranges from 2% to 10%. Two different reports showed an HCV percent prevalence of  $5.2\% \pm 0.63\%$  in health care workers<sup>[64,65]</sup>.

### Sexual transmission

It has been reported from the US that up to 20% of new HCV infections are due to sexual activity<sup>[66]</sup>. Two different reports from the USA and Congo indicate low HCV prevalence among commercial sex workers<sup>[67,68]</sup>. The main problems in Pakistan are illiteracy, lack of awareness about sexually transmitted diseases and low use of condoms among the sex workers. Saleem *et al*<sup>[69]</sup> reported in 2005 that 17% of female sex workers, 3% of male sex workers and 4% of hijras (transgender men) consistently used condoms during the previous month; 67% of female sex workers were illiterate, 34% of female sex workers were suffering from sexually transmitted infections. Homosexual activities were very high among street children who are sexually victimized or indulge in such activities; later on they adopt commercial sex in order to raise their income. Condom usage among the male homosexual population was very low. Four different studies showed an interspousal percent prevalence of  $17.24\% \pm 7.98\%$ <sup>[70-73]</sup>.

## RISK FACTORS

### Unsafe and unnecessary needles

The reuse of syringes and needles was a major factor contributing towards increased HCV prevalence<sup>[74,75]</sup>. It was reported that there are several small groups involved in recycling and repacking of used unsterilized

HCV: Hepatitis C virus; RIBA: Recombinant strip immunosorbent assay; ICT: Immunochromatographic test; ELISA: Enzyme linked immunosorbent assay; MEIA: Micro-enzyme immunoassay; EIA: Enzyme immunoassay; PCR: Polymerase chain reaction.

syringes, which were available in various drug stores. It was difficult for the public to differentiate between new sterilized syringes and recycled unsterilized syringes<sup>[76]</sup>. Janjua *et al*<sup>[77]</sup> reported that 68% of individuals received injections during the previous three months in Digri and Mirpur khas, two districts of Pakistan, out of which only 54% were from freshly opened syringes. The incidence

of sharing of injection equipment for the last injection was 8.5% in Hyderabad and 33.6% in Sukkur<sup>[54]</sup>.

In Pakistan, the number of estimated injections per person per year ranged from 8.2 to 13.6, which was the highest among developing countries, out of which 94.2% were unnecessary<sup>[51]</sup>. Household members who received four injections per year were 11.4% more prone

to HCV infection than who did not receive injection<sup>[78]</sup>. Khan *et al*<sup>[74]</sup> reported that if both oral and injectable medicine were equally effective, 44% of the Pakistani population preferred injectable medicine.

In 2000, the WHO recommended that countries should implement strategies to change the behavior of health care workers and patients in order to decrease the over-use of injections, to ensure the practice of sterile syringes and needles, and to properly destroy sharp waste after use<sup>[79]</sup>. It was reported that 59% of syringes were dumped into the general waste and not properly disposed of in the healthcare waste. Scavengers seeking valuable things from the waste are at high risk of receiving needle stick injuries from contaminated needles<sup>[76]</sup>.

### Blood transfusion

People in developing countries are mostly anemic, and are more prone to traumatic injuries and obstetric complications. Blood transfusion in these situations is life-saving. If blood is not properly stored or is carrying blood-borne pathogens, then the situation becomes more complicated. According to the WHO office in Pakistan about 1.2 to 1.5 million transfusions are carried out annually in Pakistan<sup>[80]</sup>. In 2000, Luby *et al*<sup>[81]</sup> reported that 50% of blood banks in Karachi recruited paid donors, 25% of donations were from volunteer donors and only 23% of the blood banks screened for HCV while 29% of them were storing blood outside the WHO recommended temperature.

In developing countries, blood transfusion is still a problem due to lack of organized infrastructure, continuous supply of electricity, and properly trained and educated staff. In Pakistan the main source of blood donations are replacement donors and the majority of these are friends and relatives of the patient. These donors donate blood due to fear of death of a relative, chance of further complication of disease or under family pressure. These donors mostly hide their health conditions from their relatives. Selection of donor and their proper screening are key factors to ensure safe transfusion. Safe blood donors are those whose donations are repeatedly negative on screening<sup>[17]</sup>. Sixty-six percent of Pakistanis are residents of rural areas where there is less access to blood transfusion services. To provide proper transfusion facilities to underdeveloped areas requires economic growth. Efforts are required to eliminate the transfusions from paid donors, to improve the safety of the blood supply<sup>[81]</sup>. These conditions can be overcome by development of a fair and organized system of blood screening and transfusion.

### Barbers

In third world countries like Pakistan, most of the barbers are illiterate and unaware of transmission of infectious agents through the repeated use of razors and scissors for different customers without sterilizing them first<sup>[82]</sup>. Janjua and Nizamy reported that only 13% of the barber community knew that hepatitis is a liver disease and that it could be transmitted by contaminated razors; 11.4% of them were cleaning razors with antiseptic solution while 46% of them were re-using razors<sup>[83]</sup>. Recent reports suggested that only 42% knew about hepatitis, 90% did

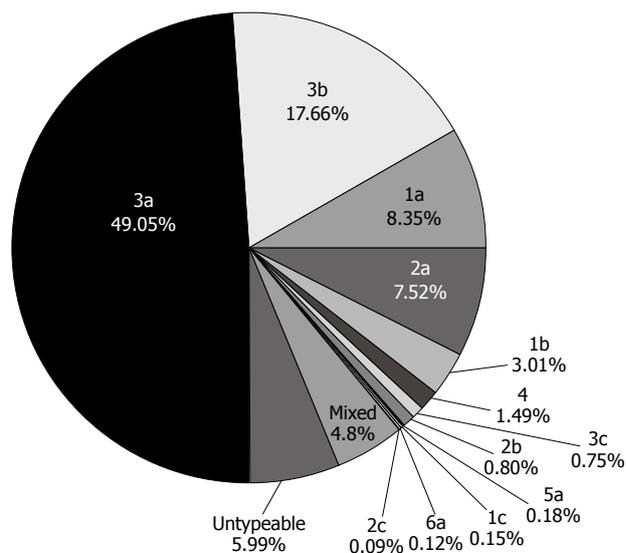

Figure 1 Hepatitis C virus (HCV) genotypes in Pakistan (2008)<sup>[95]</sup>.

not wash hands, 80% were not changing aprons and 66% were not changing towels after each customer. Circumcision is a very important religious procedure performed during early infancy both in rural and urban areas, and the barber community performing this procedure are mostly unaware of transmission of hepatitis by contaminated instruments<sup>[84]</sup>. Bari *et al*<sup>[85]</sup> identified the risk factors involved in transmission of HCV and reported that 70% and 48% of HCV patients had histories of facial and armpit shaving from barbers respectively.

### Awareness

In the Pakistani population there was moderate knowledge about HCV infection whereas awareness about various HCV risk factors was very low<sup>[31,86,87]</sup>. In a survey conducted at a family medicine clinic in Karachi, most of the participants had some educational background and were living in Karachi city. It was reported that 61% of participants believed that HCV was a viral disease, 49% believed that it could be transferred by needles and injections, 5.3% believed that it could be transmitted by ear and nose piercing, and 20.6% knew that it can cause cancer<sup>[86]</sup>. Kuo *et al*<sup>[82]</sup> reported in 2006 that HCV awareness was only 19% in the IDU population of Lahore and Quetta. Zuberi *et al*<sup>[88]</sup> reported that knowledge about HCV infection was related to the educational background of the participants. Public awareness programs are required to decrease the future burden of HCV infection in the Pakistani population.

## GENOTYPES

HCV is classified into eleven different genotypes, of which six are the major genotypes and these genotypes are further classified into many subtypes<sup>[89,90]</sup>. In 1997 it was reported in a small study that 87% of the individuals in Pakistan had genotype 3<sup>[91]</sup>. In 2004, a panel of 30 top gastroenterologists of the country met at a conference and reported that 75%-90% of HCV patients in Pakistan had genotype 3a<sup>[8]</sup>. Qazi *et al*<sup>[92]</sup> reported in 2006 that 71%

of patients had genotype 3 while only 10% had genotype 1. In 2007 it was reported that 81% of individuals had genotype 3 while only 9.5% had genotype 1<sup>[93]</sup>. Hakim *et al*<sup>[18]</sup> reported in 2008 that 51% of HCV patients had genotype 3a; 24% had 3a/3b co-infection and 16% had genotype 3b, while similar results were also reported by Afridi *et al*<sup>[94]</sup> who stated that 50% of HCV patients had genotype 3a followed by 3b and 1a. The most detailed study was conducted by Idrees and Riazuddin in 2008, who performed genotyping of 3351 patients and reported that genotype 3a was the most prevalent genotype in Pakistan; their results are summarized in Figure 1<sup>[95]</sup>.

## CONCLUSION

This study reviewed the seroprevalence of HCV among various population groups, along with risk factors and genotypes in Pakistan. HCV prevalence was observed in nearly 5% of the general population which is in parallel with the WHO estimates of HCV in Pakistan. High prevalence was observed in IDUs and the multi-transfused population, suggesting that the reuse of syringes was common among the injecting drug users, and that blood transfusions were not properly screened. Most prevalent genotype of HCV was 3a. The majority of HCV-positive patients had a history of facial and armpit shaving by barbers suggesting that the barbers shop was the key place for viral transmission. Condom usage was very low among the commercial sex workers and there was low awareness about sexually transmitted diseases amongst this group. In Pakistan, the number of estimated injections per person per year was very high because most Pakistanis think that injectable drugs are more efficacious than oral drugs. There was low awareness in people about the various risk factors associated with HCV transmission. Treatment of hepatitis is very expensive and is creating a huge burden on the country's economy. More emphasis should be given to the preventive measures of the disease in order to decrease the future health and economic burden; these include screened blood transfusions, proper sterilization techniques in clinics and hospitals, use of disposable syringes and razor blades. The government should take aggressive steps to create awareness among the general public by the use of media or by modifying the school syllabus.

## ACKNOWLEDGMENTS

We are thankful to Mr. Abdul Shakoor, Assistant Professor, Department of Statistics, Pir Mehr Ali Shah University of Arid Agriculture, Rawalpindi, Pakistan for his help in data analysis.

### Abstract

**AIM:** To examine whether shift work accelerates metabolic syndrome (MetS) development among early middle-aged males with elevated alanine aminotransferase (e-ALT).

**METHODS:** A retrospective, observational follow-up study on MetS development at a 5-year interval was conducted using health examination data. Nine hundred and ninety six male employees not fulfilling MetS criteria at screening were enrolled. Age, MetS-components, liver enzymes, serological markers for viral hepatitis, abdominal ultrasound, insulin resistance status, lifestyles, and workplace factors were analyzed.

**RESULTS:** The prevalence of elevated serum ALT (> 40 U/L, e-ALT) at baseline was 19.1%. There were 381 (38.3%) workers with long-term exposures to day-night rotating shift work (RSW). 14.2% of subjects developed MetS during follow-up. After 5 years, the workers with e-ALT had significantly unfavorable changes in MetS-components, and higher rates of MetS development, *vs* subjects with normal baseline ALT levels. Workers with both baseline e-ALT and 5-year persistent RSW (pRSW) exposure had the highest rate of MetS development. Also, e-ALT-plus-pRSW workers had a significant increase in MetS-components at

follow-up, compared with the other subgroups. After controlling for potential confounders, e-ALT-plus-pRSW workers posed a significant risk for MetS development (odds ratio, 2.7; 95% confidence interval, 1.4-5.3, *vs* workers without baseline e-ALT nor pRSW).

**CONCLUSION:** We suggest that all early middle-aged male employees with e-ALT should be evaluated and managed for MetS. Particularly in terms of job arrangements, impacts of long-term RSW on MetS development should be assessed for all male employees having baseline e-ALT.

### INTRODUCTION

Elevated serum alanine aminotransferase (ALT) is a common abnormality of health examinations among the middle-aged working population<sup>[1,2]</sup>. Nowadays, it is unavoidable that a large number of asymptomatic workers with elevated ALT (e-ALT), regardless of the underlying cause, are asked to do rotating shift work (RSW) on 24-h production lines<sup>[3]</sup>. In previous studies, e-ALT<sup>[4,5]</sup> and shift work<sup>[6,7]</sup> had been independently assessed for their associations with metabolic syndrome (MetS), which has been linked with cardiovascular disease (CVD)<sup>[8,9]</sup>, one of the leading death causes among working populations<sup>[10]</sup>. However, for early middle-aged workers with e-ALT in baseline conditions, few long-term follow-up studies assessed the association between RSW and MetS development. In terms of workplace health management and job arrangement, surveys for

the impact of RSW on MetS development among the subjects having e-ALT urgently required. In Taiwan, periodic health checkups are compulsorily for employees in many workplaces; thus we had the opportunity to utilize a retrospective follow-up study to assess the impact of RSW on MetS development among early-middle-aged workers having baseline e-ALT.

## MATERIALS AND METHODS

### Participants

In accordance with the Labor Health Protection Regulation of the Labor Safety and Health Act, 1203 male workers of an electronic manufacturing company underwent compulsory health checkups in 2002 and 2007. Final analysis of this follow-up study only included the subjects not fulfilling MetS criteria in 2002. Among the 1203 workers undergoing health examinations in both 2002 and 2007, 207 employees were excluded from study because they were screened previously with MetS. Final records of a total of 996 male workers constituted the cohort for the study and endpoint analysis. Hepatic virus infection is highly prevalent among Taiwanese adults<sup>[2]</sup>, our analysis included the hepatic virus carriers without MetS, and we controlled these factors in our final multivariate analysis. Most of the male employees of this electronics manufacturing company were residents of northern Taiwan.

The procedures and measurements of the health examinations took place in the morning, following an overnight fast, at a health-care unit of the factory. This health examination was open to all registered employees during every working day, 07:30 am to 09:30 am, for a 1-mo span. We suggested that the health checkups for the rotating shift workers be performed on the 3rd to 6th day of their day-duty. All the employees were requested to avoid drastic physical exercises (i.e. long-distance running, heavy weight lifting training etc) during the 3 d before undergoing the health examination.

Subjects' identities were anonymous and unlinked to the data. This analytical study, limited within health checkups records, followed the ethical criteria for human research, and the study protocol (TYGH09702108) was reviewed and approved by the Ethics Committee of the Tao-Yuan General Hospital, Taiwan.

### Demographics, job types, lifestyle data, and biological measurements

In 2002, a questionnaire about baseline personal history, including smoking habits, physical exercise, drinking, and dietary habits, was completed by the examinees. The day-night RSW was determined from the self-reported questionnaires in 2002 and 2007. The shifts on the 24 h production line were scheduled on a three-team/two-shift plan (6 d-shifts-three rest days-six night-shifts-three rest days, *etc.*). The day and night shifts started at 07:30 am and 19:30 pm, respectively.

Physical examination and blood tests were performed on all participants in both 2002 and 2007. The participants arrived at the health care unit in the morning, between

07:30 am and 09:30 am, after an overnight 8 h fast. The physical examination records included measurements of waist circumference, weight, height, and blood pressure. Waist circumferences were measured midway between the lowest rib and the superior border of the iliac crest. After being seated for 5 min, sitting blood pressure was measured with the dominant arm using digital automatic sphygmomanometers (model HEM 907, Omron, Japan), twice at a 5-min intervals; the mean of the reading was used for data analysis. After the physical examination, participants were placed in a reclined position, and venous blood (20 mL) from an antecubital vein of the arm was taken for subsequent tests. Blood specimens were centrifuged immediately thereafter, and shipped in the frozen state, using dry ice, to a central clinical laboratory in the Tao-Yuan General Hospital (certified by ISO 15189 and ISO 17025). Glucose [glucose oxidase method, intra- and inter-assay coefficient of variation (CV) < 5%], triglyceride (enzymatic method, intra- and inter-assay CV < 5%), high-density lipoprotein (HDL) (enzymatic method, intra- and inter-assay CV < 5%), ALT, aspartate aminotransferase (Japan Society of Clinical Chemistry method, intra- and inter-assay CV < 5%) assays were conducted by a Hitachi autoanalyzer model 7150 (Hitachi, Tokyo, Japan). hepatitis B virus (HBV) surface antigen, anti-HBV surface antibody and anti-HCV antibody were measured by the microparticle enzyme immunoassay using the AxSym System instrument (Abbott, Illinois, USA), with the intra-assay and inter-assay CV < 10%. Insulin was determined with an AxSym autoanalyzer (Abbott, Illinois, USA) radioimmunoassay, with the intra-assay and inter-assay CV < 10%.

### Abdominal sonographic examinations

Institutional Review Board of Tao-Yuan General Hospital did not agree to perform liver biopsies on apparently healthy subjects. Sonographic diagnosis for fatty liver is widely accepted in many epidemiological surveys<sup>[11]</sup>; therefore, we used this noninvasive method to diagnose fatty liver. In 2002, abdominal ultrasound examinations were performed using convex-type real-time electronic scanners (Toshiba SSA-340 with 3.75 MHz convex-type transducer) by three gastrointestinal specialists. These gastrointestinal specialists had 10-15 years of experience in abdominal ultrasound examinations, and were blind to the medical history as well as to the blood test results of the examinees.

### Definitions

**MetS:** The pre-MetS status was defined as one or two<sup>[12]</sup>, and the MetS designation was made if three or more of the following five criteria were fulfilled: Central obesity (waist circumference > 90 cm based on Taiwanese criteria<sup>[13]</sup>); Elevated blood pressure (defined as systolic blood pressure  $\geq$  130 mmHg or diastolic blood pressure  $\geq$  85 mmHg; Hyperglycemia, hypo-HDL cholesterolemia and hypertriglyceridemia (defined based on modified National Cholesterol Education Program Adult Treatment Panel III criteria<sup>[14]</sup> as: fasting sugar  $\geq$  100 mg/dL, HDL < 40 mg/dL, and triglycerides  $\geq$  150 mg/dL). We specified

the subjects with MetS outcome as those who were without MetS in 2002 but with MetS in 2007.

**e-ALT:** e-ALT was defined as ALT > 40 U/mL, according to the standard reference limits used at Tao-Yuan General Hospital and other by studies<sup>[15]</sup>.

**Insulin resistance:** Insulin resistance was calculated by the equation of homeostasis model assessment,  $HOMA_{IR} = \text{fasting insulin (U/mL)} \times \text{glucose (mmol/L)} / 22.5$ , and defined as the top quartile of  $HOMA_{IR}$ <sup>[16]</sup>.

**Persistent RSW (pRSW):** According to the Labor Health Protection Regulation of the Labor Safety and Health Act, periodical health examination ought to be performed on all registered employees working more than 1 year. These examinations took place annually for workers in this company. In the questionnaire, workers answered “yes” to “my job is a rotating shifting work”, indicating that the workers had done a rotating job for at least 1 year. Generally, this working pattern continues except for reasons of family events or promotions in this kind of factory. Those who did RSW for at least 1 year in the beginning and at the end of our follow-up were likely to have continued doing the same types of jobs. For the reasons mentioned above, we arbitrarily defined in our analysis of job type as: “pRSW” exposure was defined when the answers to the question in 2002 and 2007 were both day-night rotating shift work. Work information obtained through a self-administered questionnaire has been generally accepted in previous investigations<sup>[6,17]</sup>.

**Lifestyle factors:** For defining “ever been a smoker”, the question started with “Do you smoke? (1 Never, 2 Currently smoke, 3 Did but quit now)” and was followed by questions about quantity. We defined “ever been a smoker” as saying “yes” to question 2 or 3 and consuming at least 10 cigarettes daily for over 1 year. For defining “used to having snacks”, the question started with “Are you used to having snacks before sleeping?” and “Are you used to having snacks between meals?” and followed with questions about quantity. We defined the habits of having snacks in the present study as more than three times per week. The standard portions of examples for snacks (fruit products, milk products, fried food, nuts, beans products, meat, and alternatives) were explained to examinees in questionnaires. We defined “having routine physical exercise” as answering “doing exercises more than three times every week”. For defining “habitual drinker”, the question started with “Do you consume alcohol as usual? (1 No, 2 Yes)” and was followed by questions about frequency and quantity. We defined “habitual drinker” in this study as saying “yes” to question 2 and consuming it at least once per week for over 1 year.

**Sonographic fatty liver:** The definition of ultrasonic fatty liver was based on a comparative assessment of image brightness relative to the kidneys, under identical criteria<sup>[18]</sup>.

### Statistical analysis

Baseline characteristics and abnormal rates were compared between four subgroups divided by e-ALT and pRSW using ANOVA and Tukey’s test for continual variables and  $\chi^2$  test for categorical variables. Modes and ranges represented the initial, the 5th year and the changes of MetS-component numbers, were also tested by ANOVA and Tukey’s test. Baseline and the 5th year abnormality rates were compared using the  $\chi^2$  test. Multivariate logistic regression, adjusted for age, baseline insulin resistance status, MetS-components, pRSW exposure, exercise, smoking, drinking and diet behaviors, viral hepatitis infection, and fatty liver was used to estimate the adjusted odds ratios (OR) and 95% confidence intervals (CI) of risk factors for predicting MetS development. A two-sided *P*-value < 0.05 was considered statistically significant. SAS version 8.0 (SAS Institute, Cary, NC, USA) was used for all statistical analyses. Excel 2000 (Microsoft®, USA) was used for the statistical figure.

## RESULTS

### General and follow-up characteristics of the study population

Job descriptions are shown in Table 1. According to the characteristics of automatic production lines in such factories, most employees do light manual labor jobs or sedentary work. Tables 2 and 3 present baseline data of the overall and the four subgroups divided by initial e-ALT and pRSW exposures. Our sample population had an initial mean age of 32.1 years (SD 5.9 years); with total prevalence rates of e-ALT and pRSW of 19.1% and 38.3%, respectively. There were 14.2% (141/996) subjects who developed MetS within 5 years. At baseline, there were significant differences in age among the four subgroups; the subgroups with pRSW exposures were younger than the other two subgroups without pRSW exposures (30.9 and 31.4 years *vs* 32.8 and 32.6 years, Table 2). Baseline measurements of MetS-components, liver enzymes and insulin were significantly unfavorable in the two subgroups with e-ALT (Table 2). As shown in Table 3, baseline abnormality rates of MetS-components, hepatic virus infections, insulin resistance, and fatty liver were higher in the two groups with baseline e-ALT than in the subgroups with normal baseline ALT, though the baseline prevalence rates of central obesity and hyperglycemia were not significantly different among the four groups. Having snacks before bedtime and smoking habits prevailed in the group of pRSW with normal ALT, whereas other lifestyle parameters were not significantly different among the four groups. The overwhelming majority of pRSW workers (92.4%) were on-site workers (Tables 1 and 3).

### Changes of MetS-components and its numbers within follow up

Most of the 5th year and 5-year changes of abnormality rates for MetS-component were unfavorable in the two subgroups with baseline e-ALT, and particularly in the subgroup with e-ALT-plus-pRSW (Table 4). The

Model 5	Age, MetS-components, insulin resistance, hepatovirus infections, fatty liver, lifestyle and workplace factors	e-ALT: no; pRSW: yes	0.7	0.4-1.2
		e-ALT: yes; pRSW: no	1.3	0.7-2.3
		e-ALT: yes; pRSW: yes	2.7	1.4-5.3

<sup>1</sup>Each variant put into the model as categorical data. OR: Odds ratio; CI: Confidence interval.

shown on figure, the subgroup of e-ALT-plus-pRSW had a significantly increasing shift in numbers of MetS-component.

**Risk assessment for MetS development**

Table 5 shows the age-adjusted OR for MetS obtained by the step-by-step examinations. At the beginning, the age-adjusted OR of MetS development for the e-ALT workers without or with pRSW exposure

were 3.1 (95% CI: 1.9-5.0) and 4.7 (95% CI: 2.7-8.2) respectively. Combined with step by step examinations, after controlling for confounders of initial age, MetS-components, insulin resistance, liver status, lifestyle and workplace factors, the multivariate analysis indicated that the male workers with baseline e-ALT plus pRSW remained at a 2.7-fold (95% CI: 1.4-5.3) greater risk of developing MetS compared with those having neither initial e-ALT nor pRSW exposure. Male employees who

had initial e-ALT but without pRSW had an increased risk for progression to MetS when compared with those who initially had normal ALT. This result was significant but became insignificant when fatty liver was introduced as one of the controlling factors: adjusted OR of MetS development became to 1.3 (95% CI: 0.7-2.3) for the workers having initial e-ALT but without pRSW (Table 5).

## DISCUSSION

All the subjects in our sample population continued working in the company at least for 5 years, which reveals that our workers were in relatively stable occupational situations. Our conclusions from observations of a large and stable middle-aged working population will contribute to the surveys on MetS in such working groups.

### **e-ALT and MetS development**

The baseline e-ALT prevalence rate (19.1%) in our sample population was as high as that in other working populations<sup>[1]</sup>. Although not fulfilling MetS criteria at screening, the workers with e-ALT had significantly more unfavorable baseline measurements, as well as higher abnormality rates for most of the MetS-components (Tables 2 and 3), as compared with workers having normal baseline ALT. Similar findings were revealed in a previous cross-sectional study for young healthy men<sup>[19]</sup>. Our follow-up results (Table 4) demonstrated that the subjects initially having e-ALT tended display considerably raised abnormality rates of MetS-components within 5 years. Moreover, at the end of follow-up, the two subgroups with baseline e-ALT had significantly higher rates of MetS development than the other two subgroups with normal baseline ALT levels.

As a mortality predictor<sup>[20]</sup>, e-ALT represents many detrimental health conditions, including systemic inflammation<sup>[19,20]</sup>, which was reported to contribute to MetS development. In our step-by-step multivariate analysis (Table 5), the significant impacts of baseline e-ALT on MetS development among the workers without pRSW remained until we introduced an operator-dependent survey, fatty liver<sup>[21]</sup>, which has an extremely close relationship with e-ALT<sup>[15]</sup>, as a controlling factor. According to our statistical analysis, baseline e-ALT is associated with long-term development of manifold metabolic abnormalities and MetS among early middle-aged male workers. We suggest workplace MetS managements for all workers having e-ALT.

### **Changes of MetS-components among our male workers within 5 years**

Taking each MetS-component into consideration, most of the MetS-components abnormality rates increased as our population got older (Table 4); though some exceptions for hyperglycemia and hypo-HDL cholesterolemia were found in the subgroups with normal baseline ALT or without pRSW exposure.

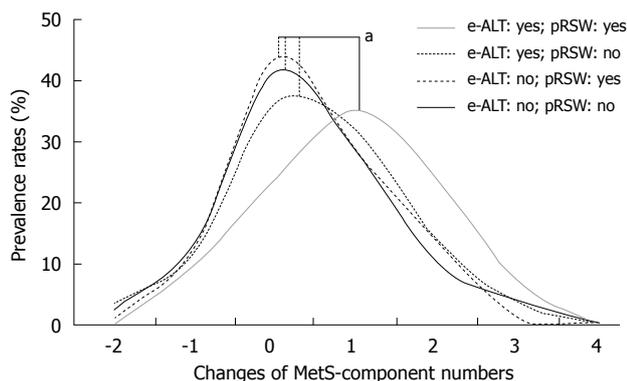

We demonstrated that the early middle-aged male workers with baseline e-ALT had increased abnormality rates of hyperglycemia, same as previous findings<sup>[22]</sup>.

Similarly, a significantly increased prevalence of hyperglycemia was found for workers with e-ALT-plus-pRSW, which was compatible with the findings that shift work can aggravate the insulin resistance<sup>[23]</sup>. In contrast, for the workers with normal baseline ALT levels, hyperglycemia showed an improving trend. These phenomena of improved blood sugar were dissimilar to the elderly population<sup>[24]</sup>, but have been shown in many follow-up observations for healthy adults<sup>[22,25]</sup>. Our early middle-age subjects with normal baseline ALT seemed to maintain the ability to stabilize blood sugar. In contrast, the subjects with baseline e-ALT displayed impaired abilities to improve their blood sugar levels, which might be related to pRSW exposure. Also, hypo-HDL was associated with an improving trend among our early-middle-aged males during follow-up, except for the e-ALT-plus-pRSW workers. This increasing trend of HDL has been mentioned among healthy adults<sup>[26]</sup>, but not found in the elderly<sup>[24]</sup>. As apparently healthy young adults get older, HDL might quantitatively increase in response to external stimuli<sup>[24,27]</sup> or internal challenges<sup>[28]</sup>, and this increase is likely to reach a plateau<sup>[29]</sup>. Our comparatively young healthy workers might not yet have reached their plateau, so they might have increasing HDL concentrations within our follow-up. However, when under chronic oxidative stress caused by simultaneous e-ALT<sup>[30]</sup> and shift work exposure<sup>[31]</sup>, our early middle-aged subjects might have significantly weaker capabilities for quantitatively increasing HDL.

### **Increasing MetS-component numbers and development of MetS among the workers with both baseline e-ALT and pRSW exposures**

Analyzing the number of MetS-components is informative in determining the CVD risk of the general population<sup>[9]</sup>. In addition, MetS-component numbers were reported in many convincing studies that closely linked them with damaged conditions of the whole human body: impaired cardiovascular conditions<sup>[32,33]</sup>, cognitive impairment<sup>[34]</sup>, and colon polyps<sup>[35]</sup>. Shift work is associated with the premature aging process<sup>[36]</sup>, and as demonstrated in our analyses (Table 4 and Figure 1), the e-ALT-plus-pRSW workers had significantly increased numbers of MetS-components in the end of follow-up. Thus, the impacts of shift work exposure on general health conditions of the e-ALT workers should receive close attention.

Some factors might confound our findings, such as: high prevalence of HBV and HCV among those with e-ALT at baseline, fatty liver might be linked with HCV carrier status, and the reduction in the amount of exercise in individuals who developed MetS. However, in the analysis carried out in consecutive steps for the male workers with e-ALT, all the other confounders did not remove the significance of pRSW on MetS development (Table 5, Model 3, 4 and 5). Our follow-up observations confirmed that persistent day-night RSW accelerates the progression toward MetS among the e-ALT workers. e-ALT can work with other risk factors to worsen the inflammatory state<sup>[30]</sup>, and shift work brings about long-term oxidative stress<sup>[31]</sup>, therefore a possible explanation for our male shift workers with e-ALT tending to develop

**Figure 1** Distributions of MetS-components number changes at 5-year follow-up, sub-grouped by elevated alanine aminotransferase and persistent rotating shift work. <sup>a</sup>ANOVA was conducted, using Tukey's test;  $P = 0.0015$ . e-ALT: Elevated alanine aminotransferase; pRSW: Persistent day-night rotating shift work; MetS: Metabolic syndrome.

MetS might be aggravated systemic chronic inflammatory reactions<sup>[37,38]</sup>.

Due to the dramatically rising occurrence rate of MetS, we strongly suggest screening, follow-up, and treatment of MetS for workers with both e-ALT and unavoidable long-term rotational shift work exposures.

#### Potential limitations

Some potential limitations of our analysis need to be considered.

Firstly, Taiwan National Health Insurance has provided comprehensive medical care, and for the pre-MetS subjects, it was possible that they could have had corrective management during our follow-up, and those actions might have led to protective effects<sup>[39]</sup>. In such a case, the main limitations of this observational investigation would be that we did not take into consideration the potential treatment effects for the at risk workers. Thus, our conclusion might be affected by the results of therapeutic management programs, and we might be underestimating risk factors for MetS development. Secondly, our shift workers with normal ALT were relatively young in our sample population (Table 2), as compared with workplace populations of other studies<sup>[6]</sup>. Physically, the advantage of youthfulness<sup>[6]</sup> might lead us to a statistically insignificant conclusion for the shift work exposures on MetS development among subjects with normal ALT (Table 5); the aging effect on MetS development is an important issue for such a young cohort, and requires further surveys. Lastly, we proposed that MetS development among our e-ALT shift workers might be closely linked to chronic inflammation; therefore direct inflammatory evidence<sup>[19]</sup> should be carefully surveyed in future investigations.

As for the increasing body of professional women occupying workplaces, it is important to compare the differences between genders in risk assessments for MetS development; thus all the present findings are worthy of being tested in future studies of female workers. In terms of health and safety, for the individuals who initially had MetS and were excluded of this study, it is necessary to assess their cardiovascular outcomes in future investigations.

In conclusion, for early middle-aged male workers, baseline and changes of MetS component abnormalities, as well as the development of MetS, are all associated with baseline e-ALT. In addition, long-term RSW exposures significantly aggravate MetS development among the workers having baseline e-ALT. We suggest all male workers having e-ALT should be carefully evaluated and managed for MetS. Particularly in terms of job arrangements, impacts of long-term RSW on MetS development should be assessed for all male employees having baseline e-ALT.

## ACKNOWLEDGMENTS

The authors would like to acknowledge the personnel of the Department of Family Medicine and Center of Health Management, Tao-Yuan General Hospital for their full support and generous assistance.

## COMMENTS

### Background

Elevated serum alanine aminotransferase (ALT) is a common abnormality of health examinations among middle-aged working populations. It is unavoidable nowadays that a large number of asymptomatic workers with elevated serum ALT levels might be asked to do rotating shift work (RSW) on 24-h production lines. In terms of workplace health management and job assignment, a 5-year follow-up study assessing the association between RSW and metabolic syndrome (MetS) development was conducted in Taiwan for male workers.

### Research frontiers

In some studies, elevated ALT (e-ALT) and shift work had been independently assessed for their associations with MetS, which is associated with cardiovascular disease, one of the leading causes of death among working populations. This survey takes these two risk factors together into consideration and obtained significant findings.

### Innovations and breakthroughs

Workers who had both baseline e-ALT and persistent RSW (pRSW) exposures (e-ALT-plus-pRSW workers) had a significantly high risk for MetS development among middle-aged male workers. In addition, e-ALT-plus-pRSW workers had a significant increase in MetS-component numbers at the end of follow-up, compared with the other workers. Finally, e-ALT-plus-pRSW workers had a significant risk for MetS development.

### Applications

All the workers with e-ALT should be carefully evaluated and managed for MetS. Particularly, MetS risk assessment must be emphasized for male employees having e-ALT and facing long-term RSW exposures.

### Peer review

The public health expert reviewers agreed the important area of research given the amount of shift work performed around the globe; they also pointed out that, given the large number of individual records and individuals examined, this is an important 5 years retrospective analysis of associated factors.

### Abstract

**AIM:** To compare clinical presentation and ultrasound (US) and computed tomography (CT) sensitivity between intraluminal and infiltrating gallbladder carcinoma (GBCA).

**METHODS:** This retrospective study evaluated 65 cases of GBCA that were categorized morphologically into the intraluminal-GBCA ( $n = 37$ ) and infiltrating-GBCA

( $n = 28$ ) groups. The clinical and laboratory findings, presence of gallstones, gallbladder size, T-staging, nodal status, sensitivity of preoperative US and CT studies, and outcome were compared between the two groups.

**RESULTS:** There were no significant differences between the two groups with respect to female predominance, presence of abdominal pain, serum aminotransferases level, T2-T4 staging, and regional metastatic nodes. Compared with the patients with intraluminal-GBCA, those with infiltrating-GBCA were significantly older ( $65.49 \pm 1.51$  years *vs*  $73.07 \pm 1.90$  years), had a higher frequency of jaundice (3/37 patients *vs* 13/28 patients) and fever (3/37 patients *vs* 10/28 patients), higher alkaline phosphatase ( $119.36 \pm 87.80$  IU/L *vs*  $220.68 \pm 164.84$  IU/L) and total bilirubin ( $1.74 \pm 2.87$  mg/L *vs*  $3.50 \pm 3.51$  mg/L) levels, higher frequency of gallstones (12/37 patients *vs* 22/28 patients), smaller gallbladder size (length,  $7.47 \pm 1.70$  cm *vs*  $6.47 \pm 1.83$  cm; width,  $4.21 \pm 1.43$  cm *vs*  $2.67 \pm 0.93$  cm), and greater proportion of patients with  $< 12$  mo survival (16/37 patients *vs* 18/28 patients). The sensitivity for diagnosing intraluminal-GBCA with and without gallstones was 63.6% and 91.3% by US, and 80% and 100% by CT, respectively. The sensitivity for diagnosing infiltrating-GBCA with and without gallstones was 12.5% and 25% by US, and 71.4% and 75% by CT, respectively.

**CONCLUSION:** In elderly women exhibiting small gallbladder and gallstones on US, especially those with jaundice, fever, high alkaline phosphatase and bilirubin levels, CT may reveal concurrent infiltrating-GBCA.

## INTRODUCTION

Gallbladder carcinoma (GBCA) is the sixth most common gastrointestinal malignancy in the United States, following cancer of the colon, pancreas, stomach, liver, and esophagus<sup>[1,2]</sup>. Nevertheless, GBCA is relatively uncommon with an estimated annual incidence of 1 or 2 cases per 100,000 people<sup>[2]</sup>. The nonspecific nebulous symptoms associated with GBCA make the early diagnosis of this uncommon entity a challenge. Approximately 50% of cases of GBCA are found incidentally during cholecystectomy or surgery for other reasons<sup>[3,4]</sup>. GBCA is a highly aggressive neoplasm with a 5-year survival rate of only 5%<sup>[1-3]</sup>. Although most patients present with advanced disease, aggressive radical surgical resection of GBCA has been reported with encouraging results<sup>[3-5]</sup>. Furthermore, survival of GBCA can be improved if early detection of the tumor can be achieved so that curative resection can be performed. Ultrasound (US) is the main initial diagnostic tool for suspected biliary lesions. It may be helpful for detecting GBCA although the infiltrative morphology of some tumors and the presence of gallstones, inflammation and debris may preclude tumor detection<sup>[6-9]</sup>. Computed tomography (CT) has been reported as a comprehensive tool for imaging and staging of GBCA<sup>[7-11]</sup>.

To the best of our knowledge, the influence of different tumor morphology on clinical presentation, as well as on US and CT sensitivity of GBCA detection, have not been well studied. The purpose of this study was to analyze the differences in clinical presentation and sensitivity of preoperative US and CT assessment between GBCA presenting as an intraluminal mass and an infiltrating tumor.

## MATERIALS AND METHODS

### Patients

The computer data bank of our hospital was searched for cases from 1995 to 2008 with the index terms "malignant neoplasm of gallbladder and extrahepatic bile ducts" and "malignant neoplasm of gallbladder" (International Classification of Diseases, 9th Revision, clinical modification code = 156, 156.0). The medical records of all patients with these discharge diagnoses were reviewed. Patients who had surgery and pathologically proven GBCA, as well as preoperative US and/or CT were included in this case series. The patients were categorized into two groups according to the gross tumor morphology and histopathological features of the GBCA. The intraluminal-GBCA group comprised patients with intraluminal tumor growths that protruded into the gallbladder lumen, which grossly appeared as polypoid, fungating or large intraluminal masses. The infiltrating-GBCA group consisted of patients with infiltrating carcinomas that appeared grossly as focal or diffuse areas of wall thickening, or induration in the gallbladder wall. This retrospective study was approved by the institutional review board of our hospital and informed consent was waived due to the retrospective and anonymous nature of the analysis.

### Imaging evaluation

Transabdominal US was performed with various scan-

ners including the Aloka SSD-650 (Aloka Co. Ltd., Tokyo, Japan), and the Acuson 128 XP/10 and Sequoia 512 scanners (Acuson, Mountain View, CA, USA) using a 3.5-MHz sector transducer. Abdominal CT was performed using a ProSpeed scanner (GE Healthcare, Milwaukee, WI, USA) or a Somatom Plus 4 scanner (Volume Zoom; Siemens, Forchheim, Germany) from the liver dome to the pelvic floor. An intravenous bolus of 85-100 mL iodinated contrast material (60%-76% diatrizoate meglumine) was injected at a rate of 2-3 mL/s *via* the antecubital vein before scanning. All images were reconstructed at intervals of 5-10 mm. Starting in 2003, all CT images were interpreted on a high resolution monitor (MGD 521MK II; BarcoView, Kortrijk, Belgium) *via* the picture archiving and communication systems (PACS) system (Centricity Workstation, version 2.0; GE Healthcare). All CT images recorded in hard copy before 2003 were scanned into the PACS system for review, and all measurements were done by applying the tools provided by the Centricity Workstation. A detailed retrospective review of the medical records, US and CT images and pathological findings of each patient was conducted jointly by two radiologists, a surgeon and a pathologist, and any discordance was resolved by consensus.

### Measurements

The clinical features (age, sex and presenting symptoms and signs), laboratory data (serum aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase and total bilirubin levels), and pathological findings (gallstones, tumor morphology, gallbladder size, histopathological evaluation of T-staging and nodal metastasis) were recorded. With pathology as the gold standard, the true-positive and false-negative results of preoperative US and CT were obtained, and the sensitivity of the imaging modalities was determined. The outcomes of our patients were also documented.

### Statistical analysis

The data are presented as mean  $\pm$  SD or number (%). The clinical, laboratory and pathological findings were analyzed and compared between the intraluminal-GBCA and infiltrating-GBCA group using the Wilcoxon rank sum test for continuous variables and Fisher's exact test or the  $\chi^2$  test for categorical variables. The sensitivity of preoperative US and CT for the diagnosis of GBCA between the two groups with and without gallstones also was analyzed. Statistical analysis was performed with SYSTAT software (SPSS, version 11.0, Chicago, IL, USA) and  $P < 0.05$  was considered statistically significant.

## RESULTS

### Clinical and laboratory information

Eight of 73 patients with a discharge diagnosis of GBCA were excluded from further study. Three of these patients refused surgery; three were considered poor candidates for surgery because of concurrent cardiac or pulmonary disease or old age; and the other two lacked preoperative US or CT images for review. A total of 65 patients who fulfilled the inclusion criteria were included. According to

the pathological findings, 37 patients (female:male = 23:14; mean age, 65.5 years) formed the intraluminal-GBCA group and the other 28 patients (female:male = 18:10; mean age, 73.1 years) formed the infiltrating-GBCA group.

The clinical and pathological data of both groups are compared in Table 1. Female preponderance was noted in both groups but the patients in the infiltrating-GBCA group were significantly older than those in the intraluminal-GBCA group ( $P = 0.02$ ). The presenting symptoms were, in combination or alone, right upper abdominal or epigastric pain or discomfort in 51 patients, jaundice in 23 and fever in 13. Ten patients were asymptomatic and were diagnosed incidentally. The infiltrating-GBCA group had a higher frequency of jaundice (46.4% *vs* 8.1%,  $P < 0.001$ ) and fever (35.7% *vs* 8.1%,  $P = 0.006$ ) than the intraluminal-GBCA group. There were no significant differences in the serum aspartate and alanine aminotransferase levels between the groups. However, the infiltrating-GBCA group had significantly higher levels of serum alkaline phosphatase (220.68 IU/L *vs* 119.36 IU/L,  $P = 0.03$ ) and total bilirubin (3.50 mg/dL *vs* 1.74 mg/dL,  $P = 0.011$ ) than the intraluminal-GBCA group.

### Pathological findings

The histological types in the intraluminal-GBCA group included 34 adenocarcinomas, one papillary adenocarcinoma, one sarcomatoid adenocarcinoma and one adenosquamous carcinoma. The maximal tumor length ranged from 1.1 to 3.8 cm (mean 2.3 cm). Among 34 intraluminal adenocarcinomas, five patients had no associated gallstones, while histopathological examinations revealed tumor development from the tubular or villotubular polypoid adenomas. The histological types in the infiltrating-GBCA group included 24 adenocarcinomas, two adenosquamous carcinomas, one clear cell carcinoma and one squamous cell carcinoma. The maximal thickness of the tumor ranged from 0.7 to 1.2 cm (mean 0.9 cm). Thirty-four of these 65 patients had gallstones and the number of stones ranged from one to 35. Twenty-six of these patients had > 3 stones with sizes ranging from 0.5 to 2.9 cm, and the other eight patients had 1-3 stones, with sizes varying from 0.3 to 2.7 cm. The infiltrating-GBCA group exhibited a significantly higher frequency of gallstones than the intraluminal group (78.6% *vs* 32.4%,  $P < 0.001$ ). Compared with the intraluminal-GBCA group, the infiltrating-GBCA group exhibited a significantly shorter gallbladder length (7.47 cm *vs* 6.47 cm,  $P = 0.032$ ) and width (4.21 cm *vs* 2.67 cm,  $P = 0.026$ ), and had a significantly lower frequency of T1 tumors (21.7% *vs* 3.6%,  $P = 0.038$ ). On the other hand, there were no significant differences between our two groups with respect to the frequencies of T2, T3, or T4 tumors, and the presence of regional metastatic lymph nodes.

### Preoperative US and CT

Comparison of preoperative US and CT diagnosis is summarized in Table 2. Twelve out of 37 (32.4%) patients in the intraluminal mass group had gallstones and 11 of them underwent US, with a sensitivity of 63.6% for preoperative diagnosis of GBCA, while five underwent CT, with a sensitivity of 80%. Twenty-two out of 28

**Table 1** Clinical and pathological data from 37 patients with GBCA presented as intraluminal mass, and 28 patients with GBCA presented as infiltrating tumor (mean  $\pm$  SD) *n* (%)

	Intraluminal mass	Infiltrating tumor	<i>P</i> value

(78.6%) patients in the infiltrating-GBCA group had gallstones and 16 of them underwent US, with a sensitivity of only 12.5% for preoperative diagnosis of GBCA, while 14 underwent CT, with a sensitivity of 71.4%.

Twenty-five out of 37 (67.64%) patients in the intraluminal mass group had no gallstones and 23 of them underwent US, with a sensitivity of 91.5% for preoperative diagnosis of GBCA, while 20 underwent CT, with a sensitivity of 100%. Only six out of 28 (21.4%) patients in the infiltrating-GBCA group had no gallstones and four of them underwent US, with a sensitivity of only 25% for preoperative diagnosis of GBCA, while four underwent CT, with a sensitivity of 75%.

None of the 22 patients (15 without and seven with gallstones) in the intraluminal-GBCA group with both preoperative US and CT (Figures 1 and 2), had a false-negative result for GBCA. However, among 10 patients (two without and eight with gallstones) in the infiltrating-GBCA group, US and CT results were true-positive for GBCA in only four patients (Figure 3). The US results were false-negative for GBCA in the remaining six patients (five with gallstones), and CT was true-positive in four (Figures 4 and 5).

### Outcomes

In the intraluminal-GBCA group, T1 tumors were found in eight patients, T2 in 11, T3 in 17, and T4 in one. Follow-up ranged from 3 to 115 mo (average 28.8 mo) and 16 patients (43%) survived < 12 mo (average survival, 9 mo). In the infiltrating-GBCA group, a T1 tumor was found in only one patient, T2 in nine, T3 in 16, and T4

**Table 2** Comparison of preoperative US and CT diagnosis of 37 patients with GBCA presented as intraluminal mass, and 28 patients with GBCA presented as infiltrating tumor

	Intraluminal mass	Infiltrating tumor
With gallstones	12	22
Preoperative US	11	16
True positive	7	2
False negative	4	14
Sensitivity (%)	63.6	12.5
Preoperative CT	5	14
True positive	4	10
False negative	1	4
Sensitivity (%)	80.0	71.4
Without gallstones	25	6
Preoperative US	23	4
True positive	21	1
False negative	2	3

True positive	20	3
False negative	0	1
Sensitivity (%)	100	75

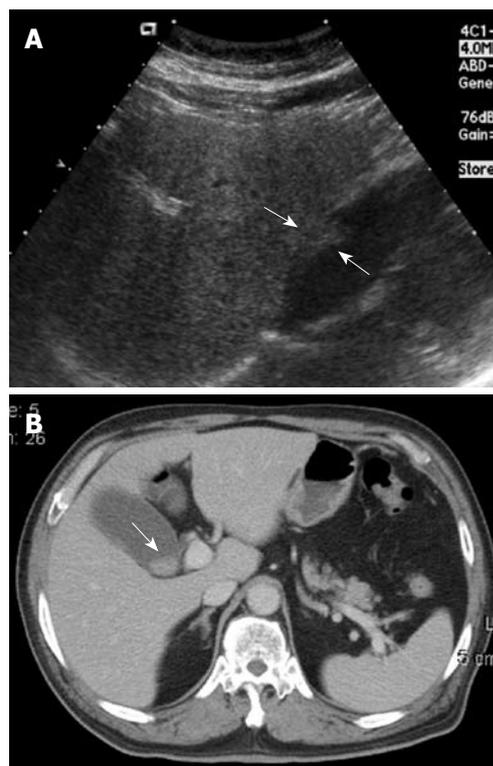

US: Ultrasound; CT: Computed tomography.

in two. Follow-up ranged from 1 to 160 mo (average 15.5 mo) and 19 patients (68%) survived < 12 mo (average survival, 4 mo). The percentage of patients with < 1-year survival in the infiltrating group was significantly higher than in the intraluminal-GBCA group ( $P = 0.017$ ).

## DISCUSSION

GBCA is a relatively uncommon cancer and is found incidentally in < 1% of 750 000 open cholecystectomies performed annually for gallstones in the United States<sup>[12]</sup>. Although GBCA is characterized by early local invasion of the liver and biliary tree, early diagnosis remains difficult because most patients present with nonspecific abdominal symptoms<sup>[2-5]</sup>. In the present study, most patients in both groups harbored T2 and T3 tumors and complained of chronic right upper quadrant or epigastric discomfort at presentation, but our results showed that intraluminal and infiltrating-GBCA might demonstrate different clinical manifestations. In patients with intraluminal-GBCA, T1 tumors were detected more commonly by US or CT incidentally as an asymptomatic gallbladder nodule, while patients with infiltrating GBCA exhibited a higher frequency of jaundice and fever, which mimicked acute cholecystitis. Although both groups showed similar abnormal mean levels of serum aminotransferases, patients with infiltrating-GBCA had significantly higher levels of serum alkaline phosphatase (220.7 IU/L *vs* 119.4 IU/L) and total bilirubin (3.5 mg/dL *vs* 1.7 mg/dL) than patients with intraluminal-GBCA.

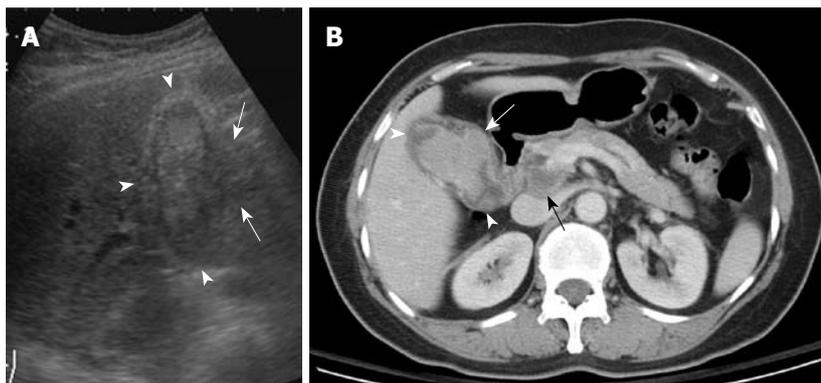

Epidemiological studies have shown that female sex, age, postmenopausal status, ethnic differences and gallstones are the most well-known factors for GBCA development<sup>[9,13-16]</sup>. A high prevalence of GBCA has been reported in New Mexico, Bolivia, Chile, Israel and Northern Japan, and a high prevalence of gallstones in these ethnic groups has also been found<sup>[14,15]</sup>. Chronic

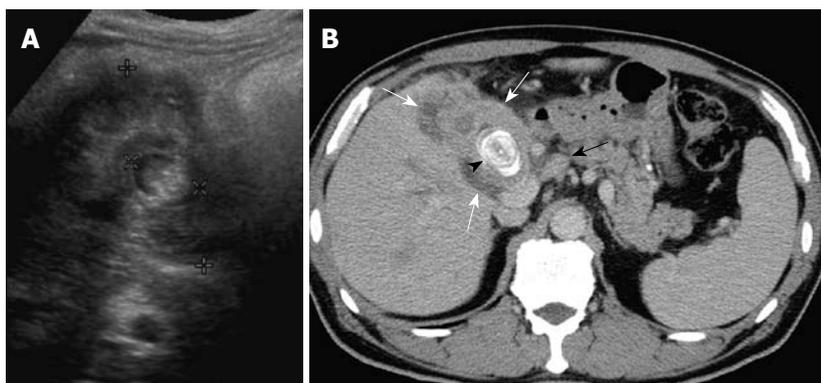

**Figure 1** A 68-year-old woman with intermittent dull right upper quadrant pain for 6 mo. A: Ultrasound (US) showed a sessile polypoid lesion (arrows) with a mildly uneven surface; B: Contrast-enhanced computed tomography (CT) showed an intraluminal polypoid lesion (arrow) with no apparent enlarged regional lymph node.

irritation of the gallbladder caused by gallstones and tumor-promoter activity in the bile in cholelithiasis patients may account for the development of GBCA<sup>[16,17]</sup>. In the present study, gallstones were identified in 34/67 patients (54%), with a lower incidence than in previous reports (64%-98%)<sup>[18-20]</sup>. Of note, our results showed that significantly more patients with infiltrating-GBCA (22/28 patients, 78.6%) harbored coexisting gallstones than patients with intraluminal-GBCA (12/37 patients, 32.6%). Coupled with the fact that patients with infiltrating-GBCA were significantly older (mean age, 73 years) and had significantly smaller gallbladders than those with intraluminal-GBCA, we concur with the postulation that gallstones with a long duration of gallbladder wall irritation may lead to mucosal dysplasia and subsequent neoplasia<sup>[19]</sup>.

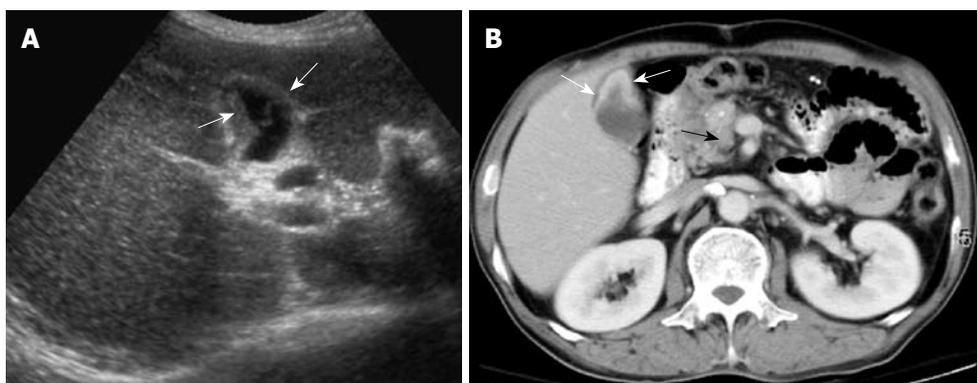

In contrast, more than two-thirds of patients with intraluminal-GBCA had no gallstones, and other predisposing factors of GBCA development including polypoid gallbladder lesions, choledochal cyst, pancreatobiliary duct anomalies, sclerosing cholangitis, porcelain gallbladder, cigarette smoking, typhoid carrier state, certain occupational and environmental carcinogens, and hormonal changes in women have also been described<sup>[9,13-15]</sup>. None of our patients had any history of congenital bile duct or pancreatobiliary lesions, porcelain gallbladder or sclerosing cholangitis, but they did have other less common factors such as chemical or carcinogen exposure. Gallbladder polyps that are > 1 cm, single,

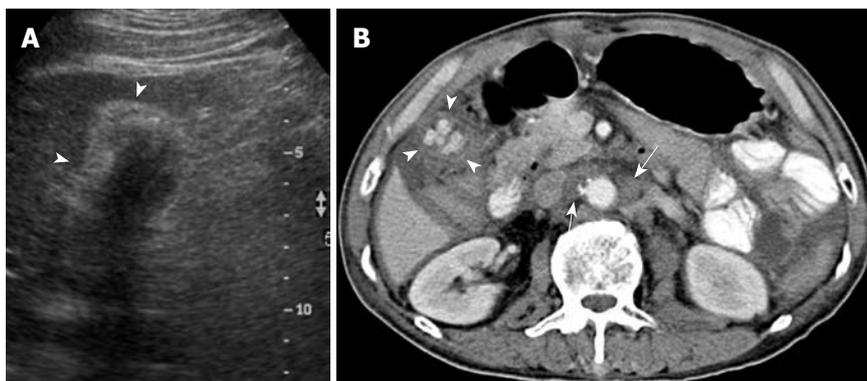

**Figure 2** A 78-year-old woman with right upper abdominal pain and progressive jaundice for 2 mo. A: US showed an intraluminal heteroechoic mass that occupied nearly the whole gallbladder (arrowheads), with focal extraluminal invasion (arrows); B: Contrast-enhanced CT showed a large lobulated mass within the gallbladder (arrowheads), with extracholecystic invasion (white arrow) and hepatoduodenal ligament lymph node metastasis (black arrow).

**Figure 3** A 77-year-old woman with right upper abdominal pain and jaundice for 1 mo. A: US showed a large gallstone (x cursors) encased by the diffusely thickened gallbladder wall, with a heteroechoic appearance (+ cursors); B: Contrast-enhanced CT showed diffuse, uneven wall thickening of the gallbladder (white arrows), with a large laminated gallstone (arrowhead) and hepatoduodenal ligament lymph node metastasis (black arrow).

**Figure 4** A 61-year-old man with dull right upper abdominal pain for 3 wk. A: US showed a relatively small gallbladder with focal wall thickening (arrows), which was misinterpreted initially as inadequate gallbladder distension; B: Contrast-enhanced CT was done because of persistent abdominal discomfort. It revealed relatively poor distension of the gallbladder with prominent enhancement of the focally thickened gallbladder wall (white arrows) and celiac lymph node metastasis (black arrow).

**Figure 5** A 78-year-old man admitted to the emergency room with right upper abdominal pain, fever and jaundice for 1 d. A: US showed a contracted gallbladder with a thickened wall (arrowheads) and multiple gallstones that obliterated underlying details, which mimicked chronic cholecystitis; B: Contrast-enhanced CT showed a relatively small gallbladder with uneven wall thickening (arrowheads), multiple gallstones and pericholecystic inflammatory stranding and fluid suggestive of gallbladder carcinoma (GBCA), with coexistent acute cholecystitis. Note the intercavaoortic and left para-aortic lymph node metastasis (white arrows).

sessile, and echogenic have been associated with a higher risk of malignancy, especially in patients > 60 years

old<sup>[15,21-23]</sup>. The present study showed that the maximal diameter of intraluminal-GBCA varied from 1.1 to 3.8

cm (mean 2.3 cm), while the mean age of the patients was 65.5 years. Of note, five of our patients with intraluminal adenocarcinoma had no gallstones, while histopathological examination revealed tumor development from tubular or villotubular polypoid adenomas. Furthermore, all eight T1 tumors in the intraluminal-GBCA group had diameters between 1.1 and 1.4 cm. Therefore, our results supported prophylactic cholecystectomy of a single intraluminal polyp or mass > 1 cm in diameter<sup>[15]</sup>.

Although many physicians express a relatively nihilistic approach to the treatment of GBCA, several studies have encouraged an aggressive surgical approach that might lead to improved survival<sup>[3-5]</sup>. Early detection and accurate preoperative diagnosis of GBCA is highly beneficial for surgical planning, especially in avoidance of laparoscopic surgery, which may induce recurrent tumors in the abdominal wall along the port track<sup>[24,25]</sup>. Abdominal US and CT are the most common modalities for assessing suspected hepatobiliary malignancies<sup>[6-11]</sup>. US allows the correct diagnosis in 70%-80% of advanced and 20%-30% of early gallbladder carcinoma cases<sup>[6-9]</sup>. The present study disclosed that US was fairly sensitive for detecting intraluminal-GBCA with gallstones (sensitivity 63.6%) and highly sensitive for intraluminal-GBCA without gallstones (sensitivity 91.3%). Intraluminal-GBCA may appear as a hypoechoic polypoid lesion (> 1 cm) that projects into the lumen, a fungating mass, or a large mass that replaces the gallbladder, on US<sup>[6-9]</sup>. In contrast, benign cholesterol or inflammatory polyps are usually multiple, hyperechoic and < 1 cm in diameter<sup>[6,21-23]</sup>. Intraluminal-GBCA with a fungate appearance or large mass can be distinguished by a heterogeneous echotexture and irregular border of the lesions, as well as intralesional or perilesional echogenic foci and acoustic shadowing caused by coexisting gallstones and tumoral calcification<sup>[7-9]</sup>. On the contrary, US has poor sensitivity for detecting infiltrating-GBCA, with and without gallstones (sensitivity of 12.5% and 25.0%, respectively). As demonstrated in the present study, possibly as a result of chronic gallbladder wall irritation by gallstones, and the infiltrating nature of the tumor, which might limit gallbladder expansion, the mean gallbladder size was significantly smaller in patients with infiltrating-GBCA than in those with intraluminal-GBCA. Subtle gallbladder wall thickening that leads to misinterpretation as chronic inflammatory changes, coexistence of acute cholecystitis and obliteration by concurrent gallstones or bile sludge are also factors that might hamper the US detection of infiltrating-GBCA<sup>[6]</sup>.

Similar to US, GBCA may appear as an intraluminal or infiltrating tumor upon CT<sup>[7-9]</sup>. Our study showed that CT was 80% and 100% sensitive, respectively, for detecting intraluminal-GBCA with and without gallstones. In contrast to US, CT offered 71.4% and 75% sensitivity, respectively, for detecting infiltrating-GBCA with and without gallstones. Focal or diffuse gallbladder wall thickening (maximal thickness from 0.7 to 1.2 cm, mean 0.9 cm) is the most common CT finding. This finding is nonspecific and may occur in a variety of conditions, including extracholecystic inflammatory processes such as hepatitis, pancreatitis, pyelonephritis, adenomyomatosis, and chronic

or xanthogranulomatous cholecystitis<sup>[24-27]</sup>. However, CT allows assessment of the condition of the liver, pancreas and kidney, and thus exclusion of secondary involvement of the gallbladder in extracholecystic inflammation is not difficult<sup>[24,25]</sup>. CT also is helpful for revealing adenomyomatosis with proliferation of the subserosal fat and intramural diverticula with small calculi, chronic cholecystitis with a double-layered small gallbladder and a weakly enhancing thin inner layer, and xanthogranulomatous cholecystitis with intramural hypoattenuated nodules in a thickened gallbladder wall<sup>[24-27]</sup>.

Our study was limited by its retrospective nature. First, all patients had surgically proven GBCA, and thus, it was not possible to establish a false-positive rate for US and CT. A prospective study is needed to validate the accuracy, specificity, and true- and false-predictive values of US and CT for intraluminal and infiltrating-GBCA, but due to the infrequency of GBCA, such a large-scale prospective study may be difficult. Second, only a small proportion of our patients underwent percutaneous cholangiography, radionuclide and magnetic resonance imaging studies and hence, the role of these studies in these two morphologically different types of GBCA could not be determined.

In summary, in contrast to intraluminal-GBCA, infiltrating-GBCA is overlooked easily on US. In elderly women with suspected small gallbladder and gallstones upon US, especially those with jaundice, fever, and high serum alkaline phosphatase and total bilirubin levels, CT is helpful in surveying underlying infiltrating-GBCA.

## COMMENTS

### Background

Gallbladder carcinoma (GBCA) is a relatively uncommon cancer with early local invasion of the liver and biliary tree, but early diagnosis remains difficult because most patients present with nonspecific abdominal symptoms. Ultrasound (US) and computed tomography (CT) have been reported as helpful tools for imaging and staging of GBCA. To the best of our knowledge, the influences of different tumor morphology on clinical presentation, as well as on US and CT sensitivity of GBCA detection have not been well studied.

### Research frontiers

US is the main initial diagnostic tool for suspected biliary lesions and may be helpful for detecting GBCA. GBCA may present as an intraluminal mass and an infiltrating tumor, and the infiltrative morphology of some tumors may render US assessment difficult. In addition, the presence of gallstones, inflammation and debris may preclude tumor detection by US. CT has been reported as a comprehensive tool for imaging and staging of GBCA, but its usefulness in patients with different tumor morphology has not been explored.

### Innovations and breakthroughs

The results demonstrated that, compared with patients with intraluminal-GBCA, patients with infiltrating-GBCA were significantly older, and had a significantly higher frequency of jaundice and fever, higher alkaline phosphatase and total bilirubin levels, higher frequency of gallstones, smaller gallbladder size and shorter survival. The sensitivity for diagnosing intraluminal-GBCA with and without gallstones was 63.6% and 91.3%, respectively, by US, and 80% and 100%, respectively, by CT. The sensitivity for diagnosing infiltrating-GBCA with and without gallstones was 12.5% and 25%, respectively, by US, and 71.4% and 75%, respectively, by CT.

### Applications

Intraluminal and infiltrating-GBCA exhibit different clinical presentations and features by US and CT. US and CT are fairly to highly sensitive for detecting intraluminal-GBCA with and without gallstones. Conversely, infiltrating-GBCA, especially when associated with gallstones, is overlooked easily by US. Further CT examination can

be useful in revealing underlying infiltrating-GBCA in elderly women with relatively small gallbladders and gallstones noted by US, particularly those with jaundice, fever, and high serum alkaline phosphatase and total bilirubin levels.

### Terminology

Intraluminal-GBCA denotes tumor growths that protrude into the gallbladder lumen, which appear grossly as polypoid, fungating or large intraluminal masses. Infiltrating-GBCA denotes infiltrating carcinomas that appear grossly as focal or diffuse areas of wall thickening, or induration of the gallbladder wall.

### Peer review

This is an interesting report of gallbladder cancer with differences in clinical presentation. Although it is of clinical significance, the presentation of the paper needs some modification.

### Abstract

**AIM:** To evaluate the anti-viral effect of emodin plus Astragalus polysaccharide (APS) in hepatitis B virus (HBV) transgenic mice.

**METHODS:** Sixty HBV transgenic mice (HBV TGM) whose weight varied between 18 and 24 g were randomly divided into 3 groups, with 20 mice in each group. Group A was the normal control, where the mice were treated with physiological saline; group B was the positive control where the mice were treated with lamivudine solution (100 mL/kg per day). Group C was the experimental group where the mice were treated with physiological saline containing emodin and APS (57.59 mg/kg per day and 287.95 mg/kg per day, respectively). The mice were treated daily for 3 wk. After 1 wk recovery time, the mice were sacrificed and serum as well as liver tissues were collected for ELISA and histological examination.

**RESULTS:** After 21 d treatment, HBV DNA levels in group B and group C significantly declined when compared with group A ( $P < 0.05$ ). However, a significant increase in HBV DNA content was observed in group B, whereas this phenomenon was not observed in group C. A reduction in the contents of HBsAg, HBeAg and HBcAg in the mice from group B and C was observed when compared with group A.

### INTRODUCTION

Hepatitis B is a global health problem, and affects about 400 million people worldwide, particularly in Asian and Western Pacific countries<sup>[1]</sup>. It is the leading cause of cirrhosis and liver cancer in China<sup>[2]</sup>. The current treatment strategy for hepatitis B is to eradicate replication and infection of hepatitis B virus (HBV) *in vivo* using anti-virus drugs such as interferon and nucleoside analogs such as lamivudine<sup>[3]</sup>. However, because of their side effects, low antiviral potency, and long treatment period, the actual effects of these treatments are neither ideal nor adequate<sup>[4]</sup>.

Chinese herbal medicine has been used for chronic liver diseases for thousands of years in China, and their efficacy has been confirmed by modern biological technology in recent years<sup>[5,6]</sup>. Emodin (1,3,8-tri-hydroxy-6-methylanthraquinone) is an active component of herbal medicine derived from the genera Rheum, Polygonum, Rhamnus and Senna<sup>[7]</sup>. Our previous study showed that emodin could inhibit the replication of HBV in human hepatoma cells *in vitro*<sup>[8]</sup>, suggesting its potential antiviral effect in hepatitis B treatment. Astragalus polysaccharide (APS) is a bioactive chemical in Astragalus membranaceus (AM) which has been used in medicine for centuries in China and is believed to exhibit immune-stimulatory, anti-viral, anti-oxidation and anti-tumor

effects<sup>[9-12]</sup>. A previous study performed *in vivo* has shown that Astragalus-Polygonum Anti-Fibrosis Decoction, in which APS is one of the main components, significantly inhibited liver fibrosis induced by hepatitis B and suppressed hepatic inflammation<sup>[13]</sup>, illustrating that APS may be helpful in eradicating HBV replication *in vivo*.

In this study, we investigated the antiviral effects of emodin and APS in HBV transgenic mice and found that the combination of emodin and APS suppressed HBV replication in HBV transgenic mice. Although lamivudine had a stronger direct inhibitory effect on HBV replication, emodin and APS showed no HBV recurrence 7 d after the last treatment, suggesting a long-lasting effect and may prove to be a potential therapeutic modality for hepatitis B infections.

## MATERIALS AND METHODS

### Reagents

Emodin was purchased from Tianxingjian Bio. Co. (Xi'an, China), and was diluted to 5.80 mg/mL using dH<sub>2</sub>O just before administration. APS was purchased from Hongsheng Biotech. Co. (Xi'an, China) and was diluted to 28.80 mg/mL in H<sub>2</sub>O just before administration. Lamivudine was kindly provided by GlaxoSmithKline (GSK) China Co, and was diluted to 5 mg/mL in dH<sub>2</sub>O.

### Animals and drug administration

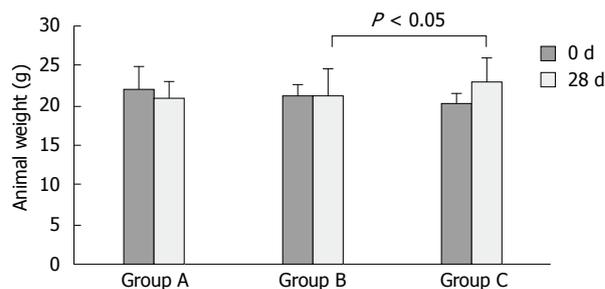

Sixty adult C57\_TgN (HBVadr2.0) SMMU mice weighing between 18-24 g with an equal number of males and females, were provided by the Laboratory Animal Center and Department of Cell Biology of the Second Military Medical University. The mice were randomly divided into three groups with 20 mice in each group. Group A was the normal control, where the mice were administered physiological saline; group B was the positive control where the mice were administered lamivudine solution (100 mL/kg per day). Group C was the experimental group where the mice were administered physiological saline containing emodin and APS (57.59 and 287.95 mg/kg per day, respectively). The mice were treated daily for 3 wk followed by one week of recovery time without any treatment. The mice were then sacrificed. Blood was sampled from the abdominal aorta, centrifuged at 4°C, and plasma was stored at -20°C for assays; liver tissues were collected for histological examination.

### Alteration in animal weight

The weight of each animal was measured just before the first drug administration and after sacrifice. The alteration in animal weight was calculated from these two values.

### Histological examination

Hepatic tissues were fixed using 4% paraformaldehyde phosphate-buffered saline (PBS, pH 7.4) and embedded in paraffin wax. After deparaffinization, 5 μm sections were stained with hematoxylin and eosin (HE), and liver condition was classified according to the standard formulae published by the China Medical Association in 1995.

**Figure 1** Animal weight alteration before and after the experiment. The weight of each mouse was determined before drug administration and before sacrifice after 28 d of experimentation, respectively. One-way ANOVA analysis indicated that there was no significant weight change between day 0 and day 28 in all three groups. However, increased weight was observed in group C compared with group B after 28 d of experimentation. Group A: Normal control; Group B: Lamivudine; Group C: Emodin and Astragalus polysaccharides.

### HBsAg & HBcAg expression in tissue

The surface antigen of the hepatitis-B-virus (HBsAg) and hepatitis B core antigen (HBcAg) were detected using immunohistochemical staining as previously described<sup>[13]</sup>. The stained slides were examined microscopically. Quantification of HBsAg and HBcAg positive cells was performed over several different areas of each section. The percentage of positive cells was evaluated by counting 100 cells (40 ×) in three consecutive tissue sections, and square scores were marked according to the following semi-quantitative criteria: 1: < 25% positive cells; 2: 26%-50% positive cells; 3: 51%-75% positive cells; 4: >75% positive cells. The intensity of the HBsAg staining within positive cells was evaluated, and the intensity scores were marked according to the following semi-quantitative criteria: 1: light yellow; 2: light brown; 3: chocolate brown. The final immunohistochemical reaction score (IRS) was calculated according to the formula IRS = positive staining scores × intensity scores.

### HBsAg and HBeAg quantification

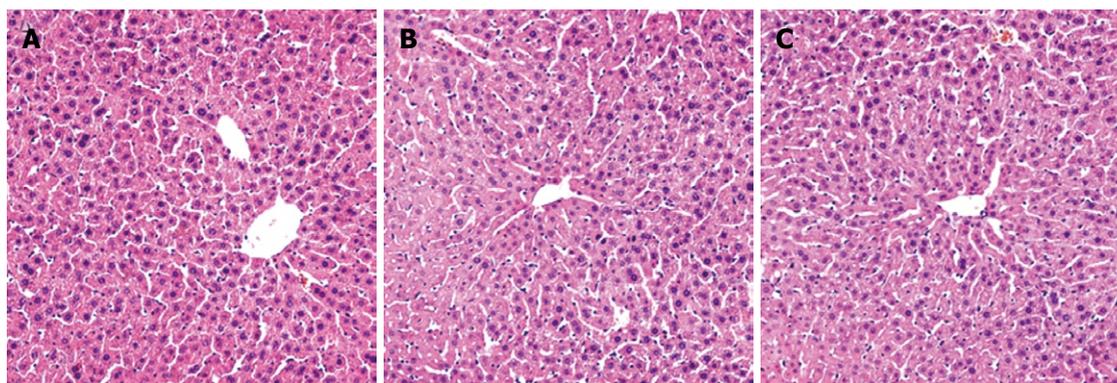

HBsAg and HBeAg (hepatitis B e antigen) levels in serum were determined using Enzyme-Linked Immunosorbent Assay (ELISA) (Huatai Biotechnologies Co, Shanghai, China) according to the manufacturer's instructions as previously described<sup>[14]</sup>.

### HBV DNA concentration determination

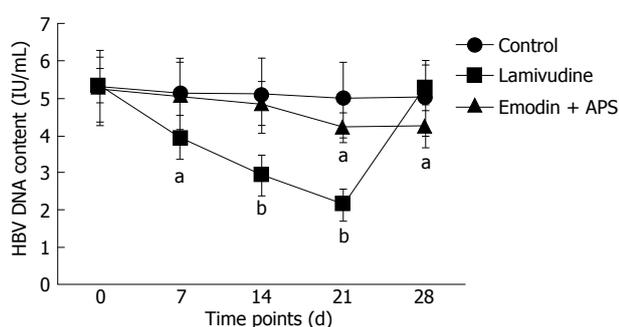

Blood was collected *via* the abdominal aorta after the mice were sacrificed. After centrifugation at 8000 r/min for 5 min, the serum was separated and stored at -20°C. HBV DNA content in serum was determined using real-time PCR (PG Biotech Co, Shenzhen, China) according to the manufacturer's instructions.

### Statistical analysis

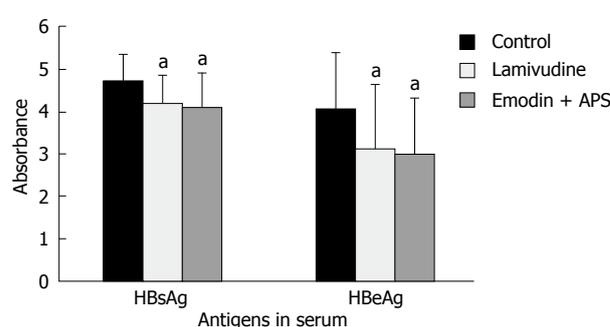

Data are presented as mean ± SE. Data was checked for normal distribution and equal variance. One-way ANOVA test analysis was carried out by SPSS 11.0 software. Differences were considered significant at *P* values of less than 0.05.

**Figure 2** HE staining of liver tissue from different groups (Original magnification,  $\times 200$ ). A: Normal control; B: Lamivudine; C: Emodin and Astragalus polysaccharides.

**Figure 3** Hepatitis B virus (HBV) DNA levels in serum. Mice were sacrificed at day 28 of the experiment. Blood was collected, serum was separated, and HBV DNA content was investigated using real-time PCR. Lower HBV DNA contents were observed in the lamivudine group except on day 28 of the experiment. Emodin + APS decreased serum HBV DNA content at day 21 and 28. Data was presented as mean  $\pm$  SE ( $n = 19$ ). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the control group at the same time point.

**Figure 4** HBsAg and HBeAg levels in serum. Mice were sacrificed at day 28 of the experiment. Blood was collected and serum was separated. HBsAg and HBeAg levels in serum were determined using ELISA. Lower HBsAg and HBeAg levels were observed in the lamivudine and emodin + APS groups. Data was presented as mean  $\pm$  SE ( $n = 19$ ). <sup>a</sup> $P < 0.05$  vs the control group.

## RESULTS

### Mice weight alteration

One mouse in group A died due to improper blood collection during the experiment at the third week. The other mice in all three groups were healthy during the experiments and their behaviour was normal. There was no significant weight alteration in the mice before or after the experiments. However, an increase in weight was observed in group C when compared with group B after 28 d of experimentation (Figure 1).

### Histological examination

At the end of the experiment, there was no significant difference in the macro-appearance of the livers from mice in the three groups. The livers were pink, soft and their borders were even. Morphologically, the liver structure was intact, with few necrotic hepatocytes, limited inflammatory cell infiltration and fibrous tissue formation (Figure 2).

### HBV DNA content in serum was reduced by lamivudine, emodin and APS

The use of real-time PCR showed that lamivudine significantly decreased serum HBV DNA content after one week of administration, and this inhibitory effect lasted up to 21 d. HBV DNA content increased to

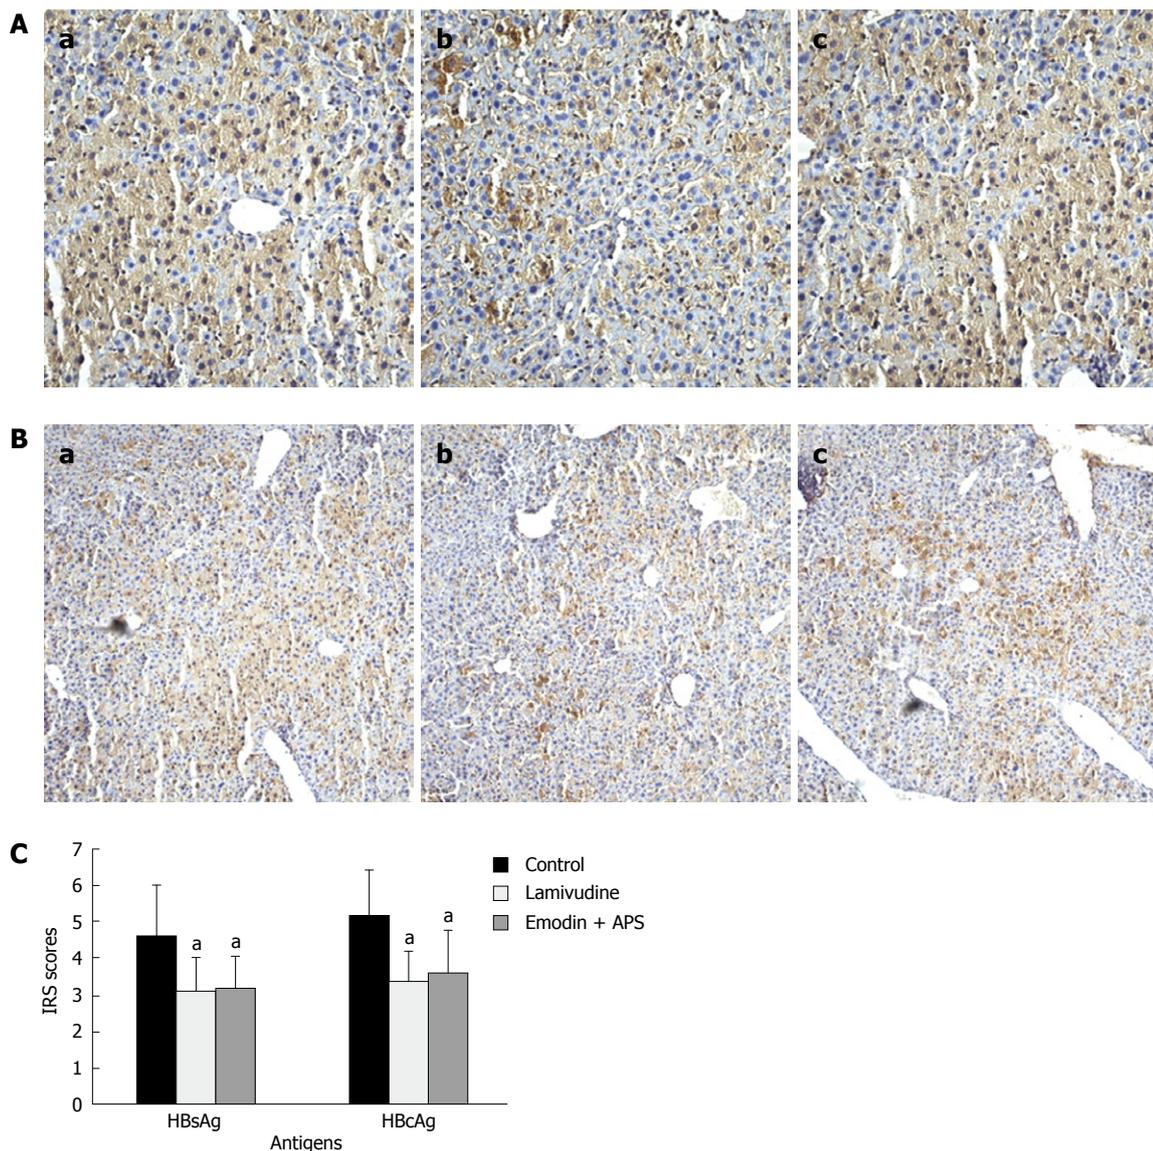

the original level when lamivudine administration was stopped for one week. However, emodin and APS did not decrease serum HBV DNA content after 7 or 14 d of administration (Figure 3), but reduced HBV DNA content after 21 d of administration, and this inhibitory effect lasted up to day 28, one week after administration ceased (Figure 3). There was no alteration in serum HBV DNA content in mice from the control group.

### Lamivudine and emodin + APS reduced HBsAg and HBeAg levels in serum

HBsAg and HBeAg levels in serum were determined using ELISA at day 28 of the experiment and showed that lamivudine and emodin + APS significantly decreased HBsAg and HBeAg levels in serum in the treated groups, compared with the control group ( $P < 0.05$ ). However, there was no significant difference in HBsAg and HBeAg levels between the lamivudine group and the emodin + APS group ( $P > 0.05$ ) (Figure 4).

### Lamivudine and emodin + APS inhibited HBsAg and HBcAg expression in hepatocytes

HBsAg and HBcAg expression in mouse liver tissue was also investigated using immunohistochemistry. HBsAg and HBcAg positive staining was brown or dark brown, and mainly localised within the cytoplasm. Both HBsAg and HBcAg were distributed throughout the liver tissue,

**Figure 5** HBsAg and HBcAg expression in hepatocytes (original magnification,  $\times 200$ ). Positive staining of HBsAg and HBcAg was brown or dark brown, and mainly localised in the cytoplasm. A: HBsAg; B: HBcAg; a: Control group; b: Lamivudine group; c: Emodin and Astragalus polysaccharides group; C: The immunohistochemical reaction score (IRS) was calculated according to the formula IRS = positive staining scores  $\times$  intensity scores. Lower HBsAg and HBcAg expression were observed in the lamivudine and emodin + APS groups. Data was presented as mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs the control group.

especially in the portal area and around the central vein area (Figure 5A and B). The positive ratios of HBsAg staining in hepatocytes were 80% (control group), 75% (lamivudine group) and 80% (emodin + APS group), respectively, and the positive ratios of HBcAg staining were 55% (control group), 45% (lamivudine group) and 50% (emodin + APS group), respectively. There was no significant difference in the positive ratios of HBsAg and HBcAg staining in hepatocytes between these three groups ( $P > 0.05$ ). However, lamivudine and emodin + APS decreased the positive staining of HBsAg and HBcAg in hepatocytes after analysis according to the IRS ( $P < 0.05$ ) (Figure 5C).

## DISCUSSION

The transgenic mouse model used in this study was established by integration of HBV genome into mouse genome using a microinjection method, and it has been

confirmed that HBV genes can be stably expressed, replicated and packaged in the mouse<sup>[15]</sup>. The present study showed that administration of lamivudine for 3 wk significantly reduced serum HBV DNA content. However, after ceasing administration for 1 wk, HBV DNA returned to the original level. Similar results were obtained following administration of lamivudine to hepatitis B patients, suggesting that this transgenic mouse model can mimic HBV infection in man.

Using real-time PCR, we found that emodin + APS significantly reduced serum HBV DNA content, although this effect was weaker than that observed with lamivudine. Interestingly, the reduction in serum HBV DNA content in the emodin + APS group lasted longer, compared with the lamivudine group. This suggests that emodin + APS had a weaker but long-lasting antiviral effect on HBV.

HBV antigens including HBsAg, HBcAg and HBeAg are important markers for hepatitis B development in

patients<sup>[16]</sup>. Our results indicate that emodin + APS significantly decreased the expression of these antigens in both serum and liver tissue and lamivudine had a stronger inhibitory effect. The mechanism of this inhibition is still largely unknown. Previous studies have shown that emodin can inhibit several different viruses such as herpes simplex virus (type I and II), parainfluenza virus and Coxsackie virus<sup>[17-20]</sup>. More importantly, our previous study demonstrated that emodin can inhibit HBV replication *in vitro*<sup>[8]</sup>. Therefore it is not surprising that emodin can inhibit HBV *in vivo*. APS has been used for chronic liver disease in China for thousands of years, and is known to increase CD3<sup>+</sup> and CD4<sup>+</sup> T-cells and the ratio of CD4<sup>+</sup>/CD8<sup>+</sup> T-cells in mice, suggesting an immunoregulative effect<sup>[10]</sup>. Therefore, the combination of emodin and APS not only resulted in inhibition of HBV replication, but also regulation of the immunologic system to eradicate HBV *in vivo*. This may explain the weaker and long-lasting effects of emodin + APS.

In conclusion, for the first time, we demonstrated that emodin and APS had a weak but long-lasting inhibitory effect on HBV replication *in vivo*, which may provide a new therapeutic option for hepatitis B infection.

## COMMENTS

### Background

The current treatment strategy for hepatitis B is to eradicate the replication and infection of hepatitis B virus (HBV) using anti-virus drugs such as interferon and nucleoside analogs such as lamivudine. However, the actual effects of these treatments are neither ideal nor adequate. The aim of this study was to evaluate the anti-viral effect of emodin plus Astragalus polysaccharide (APS) in HBV transgenic mice.

### Research frontiers

In this study, the authors found that the combination of emodin and ASP suppressed HBV replication in HBV transgenic mice, which might be a potential alternative treatment method for HBV patients.

### Innovations and breakthroughs

This is the first time that the combination of emodin and ASP was found to suppress HBV replication *in vivo*, which is valuable for anti-HBV drug screening in the future.

### Applications

This study provides valuable experimental evidence for future anti-HBV drug studies. It may provide an alternative strategy for therapeutic intervention in the treatment of patients with HBV.

### Terminology

Emodin (1,3,8-tri-hydroxy-6-methylantraquinone) is an active component of herbal medicine derived from the genera *Rheum*, *Polygonum*, *Rhamnus* and *Senna*. APS is a bioactive chemical in *Astragalus membranaceus* (AM) which has been used in medicine for centuries in China.

### Peer review

This is a well performed experimental study showing for the first time a moderate effect on *in-vivo* HBV replication of two molecules derived from Chinese Traditional Medicine drugs.

### Abstract

**AIM:** To investigate whether nicotinamide overload plays a role in type 2 diabetes.

**METHODS:** Nicotinamide metabolic patterns of 14

diabetic and 14 non-diabetic subjects were compared using HPLC. Cumulative effects of nicotinamide and *N*<sup>1</sup>-methylnicotinamide on glucose metabolism, plasma H<sub>2</sub>O<sub>2</sub> levels and tissue nicotinamide adenine dinucleotide (NAD) contents of adult Sprague-Dawley rats were observed. The role of human sweat glands and rat skin in nicotinamide metabolism was investigated using sauna and burn injury, respectively.

**RESULTS:** Diabetic subjects had significantly higher plasma *N*<sup>1</sup>-methylnicotinamide levels 5 h after a 100-mg nicotinamide load than the non-diabetic subjects ( $0.89 \pm 0.13 \mu\text{mol/L}$  vs  $0.6 \pm 0.13 \mu\text{mol/L}$ ,  $P < 0.001$ ). Cumulative doses of nicotinamide (2 g/kg) significantly increased rat plasma *N*<sup>1</sup>-methylnicotinamide concentrations associated with severe insulin resistance, which was mimicked by *N*<sup>1</sup>-methylnicotinamide. Moreover, cumulative exposure to *N*<sup>1</sup>-methylnicotinamide (2 g/kg) markedly reduced rat muscle and liver NAD contents and erythrocyte NAD/NADH ratio, and increased plasma H<sub>2</sub>O<sub>2</sub> levels. Decrease in NAD/NADH ratio and increase in H<sub>2</sub>O<sub>2</sub> generation were also observed in human erythrocytes after exposure to *N*<sup>1</sup>-methylnicotinamide *in vitro*. Sweating eliminated excessive nicotinamide (5.3-fold increase in sweat nicotinamide concentration 1 h after a 100-mg nicotinamide load). Skin damage or aldehyde oxidase inhibition with tamoxifen or olanzapine, both being notorious for impairing glucose tolerance, delayed *N*<sup>1</sup>-methylnicotinamide clearance.

**CONCLUSION:** These findings suggest that nicotinamide overload, which induced an increase in plasma *N*<sup>1</sup>-methylnicotinamide, associated with oxidative stress and insulin resistance, plays a role in type 2 diabetes.

## INTRODUCTION

Type 2 diabetes, characterized by insulin resistance and oxidative stress<sup>[1,2]</sup>, has reached epidemic proportions not only among adults, but also among adolescents in the past few decades, which has led to the hypothesis that type 2 diabetes is a result of gene-environment (diet) interactions, because the human genome has not changed markedly in such a short time<sup>[3-5]</sup>. However, what the environmental/dietary risk factors are and how they function remain unclear.

Nicotinamide, the amide of nicotinic acid, is the precursor for the coenzymes  $\beta$ -nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP), which function in many enzyme-catalyzed oxidation and reduction reactions. Therefore, nicotinamide homeostasis is vitally important for the body<sup>[6]</sup>. In humans, excess nicotinamide is methylated, oxidized or hydroxylated to  $N^1$ -methylnicotinamide, nicotinamide- $N$ -oxide or 6-hydroxynicotinamide, respectively, and then  $N^1$ -methylnicotinamide is further oxidized to the pyridones  $N^1$ -methyl-2-pyridone-5-carboxamide (2Py) and  $N^1$ -methyl-4-pyridone-3-carboxamide by aldehyde oxidase (AOX; EC 1.2.3.1). The major nicotinamide metabolites in human urine are 2Py and  $N^1$ -methylnicotinamide<sup>[7]</sup>. Although the nicotinamide metabolism pathway is well understood, however, the influence of the catabolic efficiency of excess nicotinamide on the body is not fully understood.

Since pellagra was found to be related to vitamin B<sub>3</sub> (niacin) deficiency in 1930s, more attention has been paid to the prevention of niacin deficiency. As a result, nicotinamide is used extensively as a food additive without having undergone full formal safety evaluation<sup>[8]</sup>, and the chronic effects of nicotinamide overuse are far from understood<sup>[9]</sup>. Nicotinic acid and nicotinamide frequently are reported to impair glucose tolerance and induce insulin resistance<sup>[10-12]</sup>. Recent evidence suggests that  $N^1$ -methylnicotinamide is involved in Parkinson's disease<sup>[9]</sup>. More importantly, the abrupt increase in prevalence of type 2 diabetes in the United States in the latter half of the 20th century<sup>[13]</sup> occurred roughly in parallel with the increase in per capita niacin content<sup>[14]</sup>. A similar situation occurred in China, in which food enrichment with niacin began in 1980s, followed by a sharp increase in the incidence of diabetes from 1% in 1980 to 5.5% in 2001<sup>[15]</sup>. However, whether type 2 diabetes pathogenesis involves nicotinamide overload is undetermined.

The present study aimed to compare nicotinamide metabolic patterns between diabetic and non-diabetic

subjects, and to investigate the relationship between nicotinamide overload and insulin resistance. We found that diabetic subjects exhibited slow  $N^1$ -methylnicotinamide clearance, and that  $N^1$ -methylnicotinamide could trigger oxidative stress and insulin resistance, which suggested that the association of nicotinamide overload with relatively slow  $N^1$ -methylnicotinamide detoxification and excretion might be at least partially responsible for the development of type 2 diabetes.

## MATERIALS AND METHODS

### Chemicals

Nicotinamide was purchased from Sigma (St. Louis, MO, USA). Nicotinamide tablets (50 mg/tablet) were purchased from Lisheng Pharma (Tianjin, China).  $N^1$ -methylnicotinamide was purchased from Takeda Chemical Industries (Osaka, Japan). Tamoxifen was from Kunshan Sanyou Pharmaceutical Adjuvant Factory (Kunshan, China). Olanzapine was obtained from Beijing Nordhuns Chemical Technology (Beijing, China).  $N^1$ -ethylnicotinamide and 2-Py were synthesized according to the methods described respectively by Hirayama *et al.*<sup>[16]</sup> and Holman *et al.*<sup>[17]</sup>.

### Nicotinamide load test in humans

This study was approved by the relevant ethics committee, and all the Chinese participants gave informed consent. Fourteen type 2 diabetic patients from eight families with a positive history (eight men and six women, mean age,  $55.3 \pm 10.2$ ; range, 36-75 years) and 14 age- and sex-matched healthy volunteers without a family history (mean age,  $53.8 \pm 10.8$ ; range, 39-75 years) participated in this study. Type 2 diabetes was defined as a fasting glucose level  $\geq 7.0$  mmol/L or current receipt of hypoglycemic medication. All subjects refrained from drugs, alcohol and caffeinated products for at least 12 h before the study. After an overnight fast, urine was collected and quantitated 1 h before, and 2, 4 and 5 h after loading with 100 mg nicotinamide. Venous blood was collected into sodium citrate tubes before and 5 h after nicotinamide loading, and separated by centrifugation (1500 g, 10 min). Aliquots of each plasma and urine sample were placed directly in liquid nitrogen and then transferred to  $-80^\circ\text{C}$  and  $-20^\circ\text{C}$ , respectively.

### Cumulative nicotinamide and $N^1$ -methylnicotinamide experiments

All animal experiments were conducted in accordance with institutional guidelines. Male Sprague-Dawley rats (180-220 g) were fed a standard rat chow. In nicotinamide experiment, rats were divided randomly into three groups ( $n = 6$  each) and fasted for 14 h before the experiment. In the two nicotinamide-treated groups, nicotinamide (100 or 400 mg/kg) was administered (intraperitoneally, ip) and repeated every 2 h for five doses. Glucose tolerance test was performed by injection of glucose (2 g/kg, ip) 2 h after the final nicotinamide injection. Blood glucose was measured 1 h after glucose injection. Blood was collected

by eye bleed into EDTA tubes under urethane anesthesia (1.5 g/kg, ip) 2 h after glucose administration. Plasma was separated by centrifugation (1500 g, 10 min). After plasma collection, the buffy coat and top fifth reticulocyte-rich layer of erythrocytes were discarded. Aliquots of plasma and erythrocytes, and harvested samples of liver and gastrocnemius muscle were plunged directly into liquid nitrogen and subsequently stored at -80°C until assay. The same protocol was used in the  $N^1$ -methylnicotinamide experiment, except that the two treated groups repeatedly received 100 or 400 mg/kg  $N^1$ -methylnicotinamide per injection and a total dosage of 0.5 or 2 g, respectively (each group,  $n = 6$ ).

### **AOX inhibition**

Rats in inhibitor-treated groups received subcutaneous tamoxifen (50 mg/kg) or olanzapine (20 mg/kg) twice daily for 4 d, and rats in each control group received vehicle only (each group,  $n = 6$ ). After an overnight fast, all the rats received nicotinamide (100 mg/kg, ip). Plasma samples were collected 5 h after nicotinamide administration as described above.

### **Chronic AOX inhibition**

Rats were divided initially into two groups: tamoxifen-treated (20 mg/kg per day, subcutaneously,  $n = 24$ ) and vehicle-treated (control,  $n = 8$ ). Eight control and eight tamoxifen-treated rats were sacrificed at the end of 7 wk. Liver samples were harvested and stored at -80°C for western blotting. The remainder of tamoxifen-treated rats was then divided into two groups treated with tamoxifen (20 mg/kg per day) with or without  $N^1$ -methylnicotinamide (100 mg/kg per day, subcutaneously), respectively. Two weeks after the treatment, glucose tolerance test was performed by injection of glucose (2 g/kg, ip) after an overnight fast. Blood glucose was measured before (fasting) and 1 h after glucose injection. Samples of plasma, liver and gastrocnemius muscle were harvested under urethane anesthesia (1.5 g/kg, ip) 2 h after glucose injection.

### **Thermal injury**

Rats in the burn group ( $n = 11$ ) were given a 40% total body surface area, full-thickness scald burn under ether anesthesia by immersion of the back in 95°C water for 15 s, as previously described<sup>[18]</sup>. Sham rats ( $n = 7$ ) were subjected to an identical procedure, except that they were immersed in 25°C water. All rats received glucose (2 g/kg, ip) 24 h after burning, with an overnight fast. Blood glucose was measured before (fasting) and 1 h after glucose dosing. Samples of plasma, liver and gastrocnemius muscle were harvested 2 h after glucose injection.

### **Sweat collection**

Five healthy young male volunteers aged 20-24 years participated in this study. After an overnight fast, whole body sweat was collected before and 1, 2 and 3 h after a single oral dose of 100 mg nicotinamide, by having the volunteers stay in a plastic bag during sauna treatment (80°C, 15 min), with stringent precautions to minimize

evaporative loss. Aliquots of sweat were placed in liquid nitrogen, and transferred to -80°C until analysis.

### **Assays of glucose, insulin and glycogen**

Blood glucose was measured using a glucometer (OneTouch Ultra; LifeScan Inc.). Plasma insulin was measured by radioimmunoassay using commercial kits (Beijing North Institute of Biological Technology, China). Muscle and liver glycogen contents were determined with Glycogen Assay Kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China).

### **H<sub>2</sub>O<sub>2</sub> assay**

Blood from healthy adult male volunteers was collected in EDTA-containing tubes and centrifuged (1500 g, 10 min). The plasma, buffy coat, and top fifth reticulocyte-rich layer of erythrocytes were discarded, and the remaining cells were washed three times in isotonic saline, and centrifuged (1500 g, 10 min). After the supernatant was discarded, the packed erythrocytes were transferred to Earle's Balanced Salt Solution presaturated with 95% O<sub>2</sub> and 5% CO<sub>2</sub> to make an erythrocyte suspension (20 μL packed erythrocytes/mL). Two hundred microliters of erythrocyte suspension was added to each well of a 96-well plate in the absence or presence of  $N^1$ -methylnicotinamide or 2Py at concentrations of 10 nmol/L to 100 μmol/L, and incubated for 3 h at 37°C. H<sub>2</sub>O<sub>2</sub> concentrations in the supernatant of cell cultures and in rat plasma were measured using an H<sub>2</sub>O<sub>2</sub> Assay Kit (Beyotime Biotechnology, Jiangsu, China).

### **NAD/NADH assay**

Human erythrocyte suspension (20 μL packed erythrocytes/mL Earle's Balanced Salt Solution) was incubated in 1.5-mL Eppendorf tubes with a 1.5-mm hole in the cover, for 4 h at 37°C in the presence or absence of  $N^1$ -methylnicotinamide (10 μmol/L). The tubes were centrifuged (1500 g, 15 min, 4°C) and the supernatant was discarded. Four hundred microliters of BioVision NAD/NADH Extraction Buffer (Mountain View, CA, USA) was added to each tube for 5 min to lyse the cells. The lysates were ultrafiltered using BioVision 10-kD cut-off filters (14000 g, 30 min, 4°C). Assays were performed using the NAD<sup>+</sup>/NADH Quantification Kits according to the manufacturer's instructions (BioVision). For rat tissue NAD/NADH assay, 20 mg frozen liver, 20 mg frozen muscle or 20 μL packed erythrocytes were homogenized in 400 μL BioVision NAD/NADH Extraction Buffer. The homogenate was ultrafiltered using BioVision 10-kD cut-off filters (14000 g, 30 min, 4°C). The assay was conducted following the manufacturer's instructions.

### **Western blotting**

Western blotting analysis of AOX was performed according to standard protocols. Briefly, 100 μg rat liver proteins were separated on 5%-8% SDS polyacrylamide gels and transferred to polyvinylidene difluoride membranes (Millipore, Bedford, MA, USA). The membranes were blocked in PBS that contained 0.1% Tween-20 and 5% non-fat dry milk for

30 min at room temperature, and incubated with antibody to AOX (1:250; BD Transduction Laboratories, Lexington, KY, USA) overnight at 4°C. Then, the membranes were washed by PBS-Tween followed by 1 h incubation at room temperature with horseradish peroxidase (HRP)-conjugated secondary antibody (1:5000; Santa Cruz Biotechnology, Santa Cruz, CA, USA) and detected using the enhanced chemiluminescence (ECL) (Amersham Life Science).

#### Determination of *N*<sup>1</sup>-methylnicotinamide, nicotinamide and 2Py

*N*<sup>1</sup>-methylnicotinamide, nicotinamide and 2Py were analyzed using an HPLC system that consisted of an LC-9A pump (Shimadzu, Kyoto, Japan), a Rheodyne 7725i sample injector with a 20- $\mu$ L sample loop (Rheodyne LLC, Rohnert Park, CA, USA), a Hypersil ODS C18 column (Thermo, Bellefonte, PA, USA), a Waters 470 fluorescence detector (Milford, MA, USA) for *N*<sup>1</sup>-methylnicotinamide measurements, and a UV3000 detector (Thermo Separations Products, Fremont, CA, USA) for 2Py detection. *N*<sup>1</sup>-methylnicotinamide concentration was analyzed by detecting its fluorescent 1,6-naphthyrindine derivatives according to the method of Musfeld *et al.*<sup>[19]</sup>, using 366 nm excitation and 418 nm emission wavelengths, with the mobile phase (10 mmol/L sodium heptanesulfonate, 50 mmol/L triethylamine and 22% acetonitrile in water, pH 3.2 with 85% H<sub>3</sub>PO<sub>4</sub>) at a flow rate of 1 mL/min. Nicotinamide was quantitated by the same procedure after quantitative conversion of nicotinamide to *N*<sup>1</sup>-methylnicotinamide using iodomethane, according to the method of Clark<sup>[20]</sup>. For analyzing urinary 2Py, 50  $\mu$ L 85% H<sub>3</sub>PO<sub>4</sub> and 0.45 mL water were added to each urine sample (0.5 mL). After brief vortex mixing, the samples were centrifuged (12000 *g*, 10 min). The supernatant was filtered through a 0.45- $\mu$ m filter for HPLC analysis. Standard solutions were prepared for calibration, which contained 0, 0.1, 1, 10 and 100  $\mu$ g/mL of pure 2Py in normal urine. The mobile phase (5% methanol, 10 mmol/L KH<sub>2</sub>PO<sub>4</sub>, 10 mmol/L triethylamine, pH 3.0 adjusted with 85% H<sub>3</sub>PO<sub>4</sub>) was delivered at 1 mL/min. UV detection was performed at 260 nm.

#### Statistical analysis

The data are presented as means  $\pm$  SD. Statistical differences in the data were evaluated by paired or unpaired Student's *t* test, or ANOVA as appropriate, and were considered significant at *P* < 0.05.

## RESULTS

#### Slow *N*<sup>1</sup>-methylnicotinamide clearance is a prominent feature of type 2 diabetes

The 5-h total urinary 2Py excretion after 100 mg nicotinamide load in the diabetic group was significantly less than that in the non-diabetic group (20.9  $\pm$  4.5 mg *vs* 24.3  $\pm$  4.1 mg, *P* < 0.05, Figure 1A and C), but urinary *N*<sup>1</sup>-methylnicotinamide excretion increased in the diabetic group (Figure 1B and D). The plasma *N*<sup>1</sup>-methylnicotinamide level 5 h after nicotinamide load was significantly higher in the diabetic than non-diabetic

group (Figure 2). It should be noted that there were no statistical differences in the basal urinary excretions of 2Py and *N*<sup>1</sup>-methylnicotinamide and the basal levels of plasma *N*<sup>1</sup>-methylnicotinamide between the two groups (Figures 1 and 2). These results suggest that slow plasma *N*<sup>1</sup>-methylnicotinamide clearance, which can be revealed by nicotinamide load test, may be a potential biomarker of type 2 diabetes.

#### High plasma *N*<sup>1</sup>-methylnicotinamide induces insulin resistance

We examined the effect of nicotinamide overload on rat glucose metabolism. Rats treated with cumulative doses of nicotinamide (2 g/kg) exhibited significantly higher levels of blood glucose and plasma insulin, but significantly lower muscle glycogen content than control rats after glucose load (Figure 3A). Another notable change after nicotinamide administration was that there was a marked increase in plasma *N*<sup>1</sup>-methylnicotinamide (Figure 3A), so we examined the effects of *N*<sup>1</sup>-methylnicotinamide. Cumulative doses of *N*<sup>1</sup>-methylnicotinamide (2 g/kg) had comparable effects to nicotinamide (Figure 3B), which suggested that the effects of nicotinamide overload might have been mediated by *N*<sup>1</sup>-methylnicotinamide.

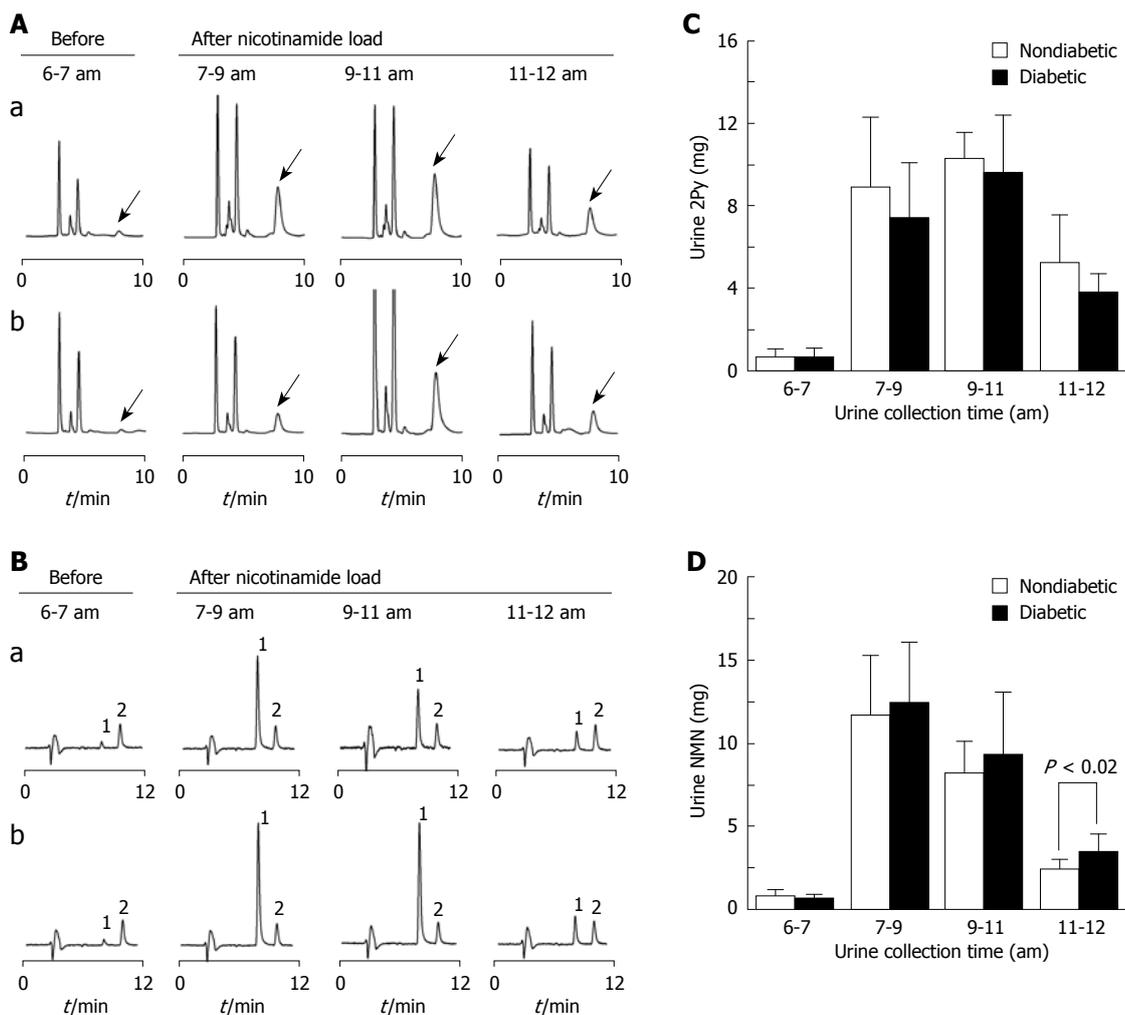

#### *N*<sup>1</sup>-methylnicotinamide triggers oxidative stress

Type 2 diabetes is associated with oxidative stress<sup>[1,2]</sup>. We therefore examined whether nicotinamide overload and high *N*<sup>1</sup>-methylnicotinamide levels were implicated in oxidative stress. The results showed that cumulative effects of nicotinamide (2 g/kg) or *N*<sup>1</sup>-methylnicotinamide (2 g/kg) led to a significant increase in rat plasma levels of H<sub>2</sub>O<sub>2</sub> (Figure 4A and B), a major reactive oxygen species (ROS) and common indicator of oxidative stress<sup>[2]</sup>. Such an enhancing effect was also observed in human erythrocytes *in vitro* at physiological concentrations of *N*<sup>1</sup>-methylnicotinamide (Figure 4C), whereas 2Py, the end product of nicotinamide, did not have an enhancing effect at the observed concentrations (10 nmol/L to 100  $\mu$ mol/L) (data not shown). These results indicate that high plasma *N*<sup>1</sup>-methylnicotinamide may induce systemic oxidative stress.

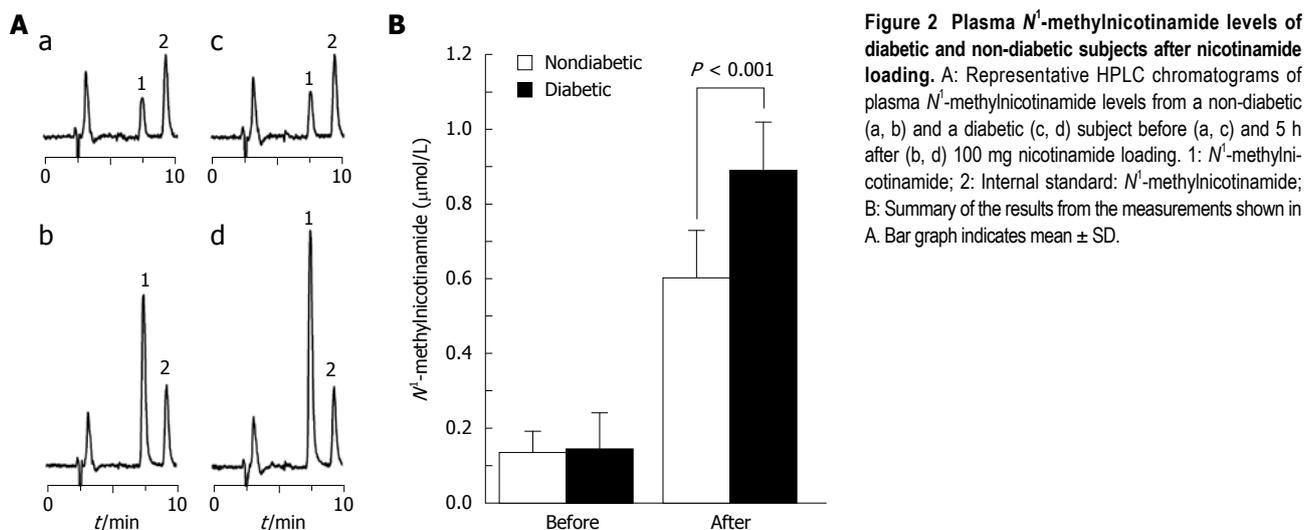

Increasing evidence has indicated that type 2 diabetes has abnormalities in the NAD<sup>+</sup>/NADH redox couple<sup>[21]</sup>. We therefore investigated whether *N*<sup>1</sup>-methylnicotinamide affected tissue NAD levels. Cumulative exposure to *N*<sup>1</sup>-methylnicotinamide significantly reduced rat muscle and liver NAD (NAD<sup>+</sup> + NADH) contents (Figure 4D and E). Notably, the erythrocytes of rats treated with cumulative doses of *N*<sup>1</sup>-methylnicotinamide (2 g/kg) exhibited a significant increase in NADH and decrease in NAD/NADH ratio (Figure 4F). A similar effect was observed in human erythrocytes *in vitro* (Figure 4G). These results suggest that *N*<sup>1</sup>-methylnicotinamide-induced oxidative stress may originate from imbalance in the NAD<sup>+</sup>/NADH redox couple.

#### AOX inhibition reduces *N*<sup>1</sup>-methylnicotinamide clearance

AOX is responsible for conversion of *N*<sup>1</sup>-methylni-

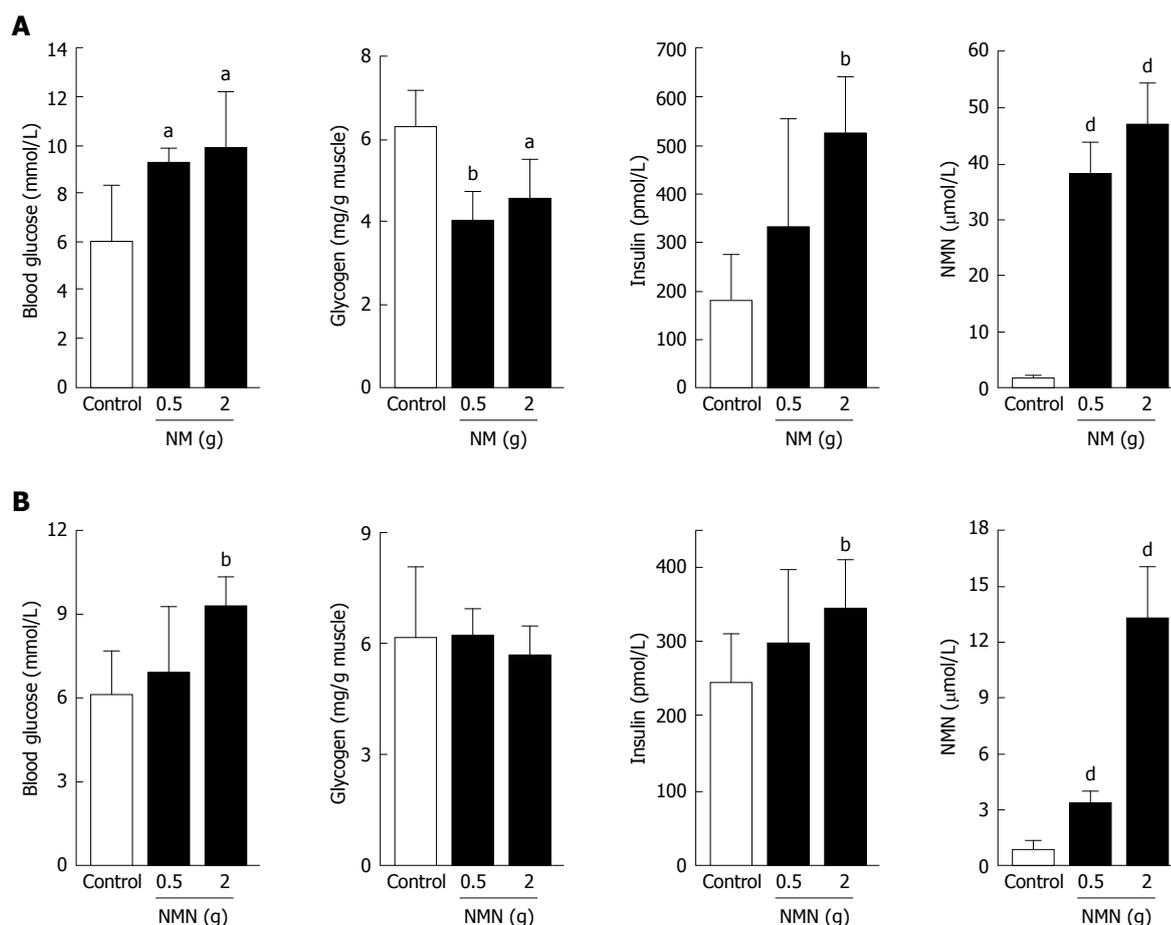

**Figure 1** Urinary excretion patterns of 2Py and *N*<sup>1</sup>-methylnicotinamide in diabetic and non-diabetic subjects. A and B: Representative HPLC chromatograms of urinary excretions of 2Py (indicated by arrow) and *N*<sup>1</sup>-methylnicotinamide (NMN) of a non-diabetic (Aa and Ba) and a diabetic (Ab and Bb) subject, before and after 100 mg nicotinamide loading at 7:00 am. Urine samples taken at given time were normalized to equal volumes before HPLC analysis; C and D: Summaries of the results from the measurements shown in A and B, respectively. Bar graphs indicate mean ± SD.

**Figure 2** Plasma *N*<sup>1</sup>-methylnicotinamide levels of diabetic and non-diabetic subjects after nicotinamide loading. A: Representative HPLC chromatograms of plasma *N*<sup>1</sup>-methylnicotinamide levels from a non-diabetic (a, b) and a diabetic (c, d) subject before (a, c) and 5 h after (b, d) 100 mg nicotinamide loading. 1: *N*<sup>1</sup>-methylnicotinamide; 2: Internal standard: *N*<sup>1</sup>-methylnicotinamide; B: Summary of the results from the measurements shown in A. Bar graph indicates mean ± SD.

cotinamide-to-2Py<sup>[22]</sup>. We examined changes in *N*<sup>1</sup>-methylnicotinamide clearance after rat AOX inhibition by the putative inhibitors tamoxifen and olanzapine<sup>[23]</sup>, both of which are known to impair glucose tolerance<sup>[24,25]</sup>.

The rats treated with tamoxifen (100 mg/kg per day) or olanzapine (40 mg/kg per day) for 4 d exhibited significantly higher plasma *N*<sup>1</sup>-methylnicotinamide levels than control rats 5 h after 100 mg/kg nicotinamide

**Figure 3** Effects of nicotinamide and *N*<sup>1</sup>-methylnicotinamide on glucose metabolism of rats. A: Changes in blood glucose, muscle glycogen, plasma insulin and plasma *N*<sup>1</sup>-methylnicotinamide in rats treated with or without cumulative nicotinamide (0.5 or 2 g/kg) after glucose loading; B: Comparable effects of cumulative *N*<sup>1</sup>-methylnicotinamide (0.5 or 2 g/kg). NM: Nicotinamide; NMN: *N*<sup>1</sup>-methylnicotinamide. <sup>a</sup>*P* < 0.05 vs control, <sup>b</sup>*P* < 0.01 vs control, <sup>d</sup>*P* < 0.001 vs control. Bar graphs show mean  $\pm$  SD.

loading (Figure 5A and B). Moreover, chronic tamoxifen treatment for 7 wk significantly reduced rat liver AOX protein expression (*P* < 0.05, Figure 5C). To further explore the role of nicotinamide overload in insulin resistance, we used tamoxifen plus *N*<sup>1</sup>-methylnicotinamide to mimic the conditions of relatively low AOX activity and excess nicotinamide intake. Rats treated with tamoxifen plus *N*<sup>1</sup>-methylnicotinamide exhibited significantly higher blood glucose and much lower liver glycogen content than those treated with tamoxifen alone after glucose loading (Figure 5D).

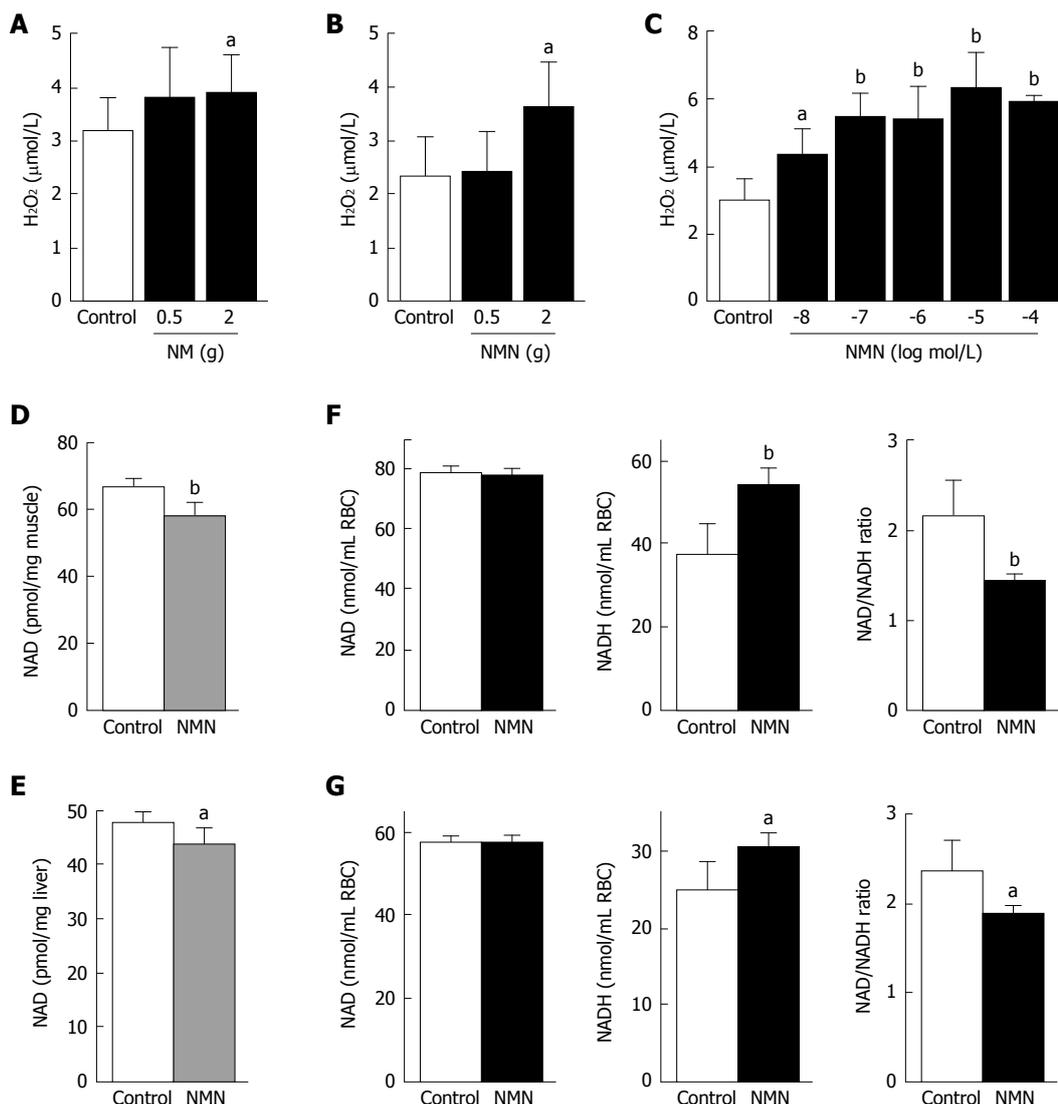

#### Skin involvement in *N*<sup>1</sup>-methylnicotinamide-mediated insulin resistance

If *N*<sup>1</sup>-methylnicotinamide is indeed involved in insulin resistance, then any factors related to *N*<sup>1</sup>-methylnicotinamide detoxification and excretion may affect insulin sensitivity. Of the factors, skin may be of particular significance because it takes part in *N*<sup>1</sup>-methylnicotinamide detoxification and excretion, respectively, through skin AOX<sup>[26,27]</sup> and sweat glands<sup>[28]</sup>. We thus explored the role of skin by analyzing human sweat excretion of nicotinamide and *N*<sup>1</sup>-methylnicotinamide after nicotinamide loading, or by assessing changes in plasma *N*<sup>1</sup>-methylnicotinamide

clearance of rats with severe skin damage. Importantly, we found that nicotinamide concentrations in the sweat 1 h after 100 mg nicotinamide loading was 5.3-fold higher than that in fasting sweat, whereas *N*<sup>1</sup>-methylnicotinamide concentrations were not significantly altered under such conditions (Figure 6A and B). This indicates that excess nicotinamide, without needing any conversion, is expelled through sweat. Moreover, this study found that rats with severe skin damage had a significant elevation in plasma *N*<sup>1</sup>-methylnicotinamide associated with high blood glucose and plasma insulin levels, but lower muscle glycogen content after glucose loading (Figure 6C).

## DISCUSSION

The main findings of this study were that: (1) nicotinamide overload elevates plasma levels of *N*<sup>1</sup>-methylnicotinamide associated with oxidative stress and insulin resistance; (2) the skin plays an important role in expelling excess nicotinamide and detoxifying *N*<sup>1</sup>-methylnicotinamide; and (3) diabetic subjects have slow plasma *N*<sup>1</sup>-methylnicotinamide clearance. These findings may contribute to explain the mechanism of oxidative stress and insulin resistance in a variety of clinical conditions.

**Figure 4** Effects of *N*<sup>1</sup>-methylnicotinamide on H<sub>2</sub>O<sub>2</sub> generation and NAD levels. A, B: Cumulative effects of nicotinamide (NM, 0.5 or 2 g/kg) and *N*<sup>1</sup>-methylnicotinamide (NMN, 0.5 or 2 g/kg) on rat plasma H<sub>2</sub>O<sub>2</sub> levels; C: H<sub>2</sub>O<sub>2</sub> concentrations in the supernatant of cultured human erythrocytes with or without 3 h exposure to different concentrations of NMN. For each concentration, *n* = 4; D, E: NAD (NAD<sup>+</sup> and NADH) contents in muscle (D) and liver (E) of rats treated with saline (control) or a cumulative dose of 2 g/kg NMN; F: NAD and NADH contents and NAD/NADH ratio in the erythrocytes (RBCs) of rats with or without cumulative exposure to NMN; G: NAD and NADH contents, and NAD/NADH ratio in human RBCs with (*n* = 4) or without (control, *n* = 4) 4 h exposure to 10 μmol/L NMN *in vitro*. <sup>a</sup>*P* < 0.05 vs control, <sup>b</sup>*P* < 0.01 vs control. Bar graphs indicate mean ± SD.

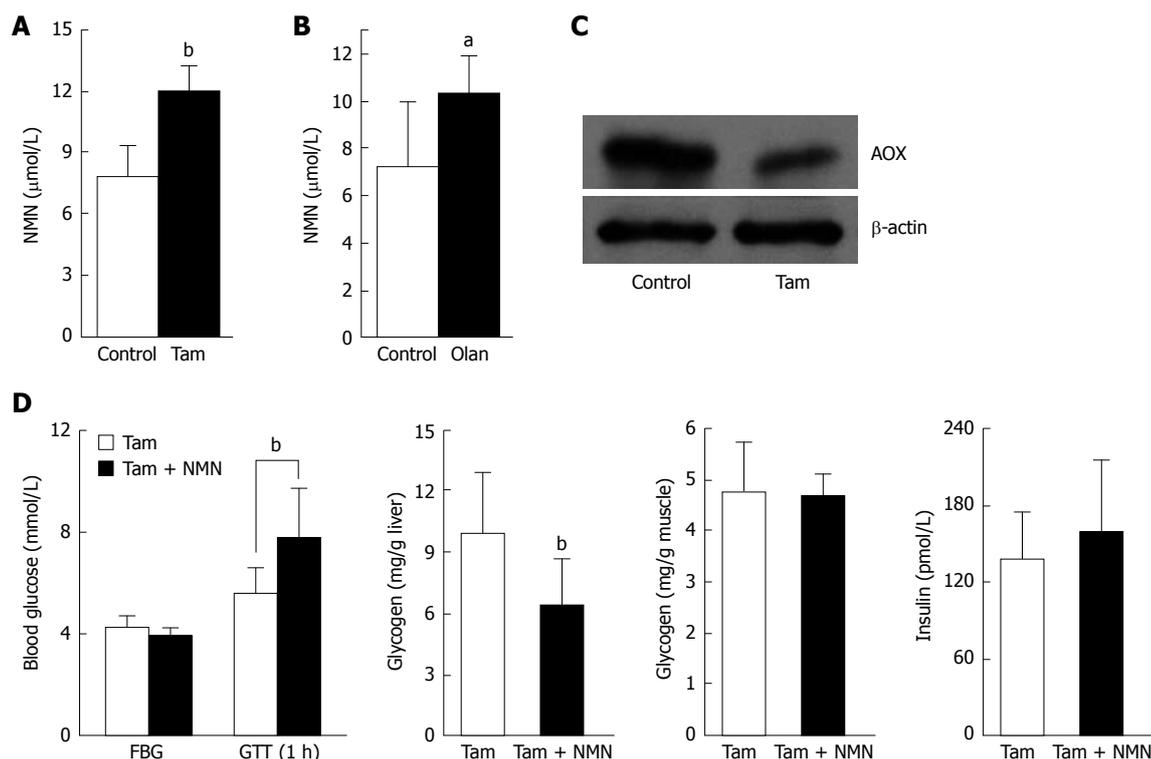

### *N*<sup>1</sup>-methylnicotinamide is a potent trigger of oxidative stress and insulin resistance

Insulin resistance and oxidative stress are the major hallmarks of type 2 diabetes<sup>[1,2]</sup>, but the mechanisms underlying the development of systemic oxidative stress and insulin resistance are unclear. Both nicotinic acid and nicotinamide have been reported to induce insulin resistance, which may lead to elevation of plasma insulin due to β-cell compensation<sup>[10-12]</sup>. Coincidentally, our data showed that nicotinamide overload induced acute insulin resistance in rats associated with high plasma levels of *N*<sup>1</sup>-methylnicotinamide; the methylation product of nicotinamide being more toxic than nicotinamide (> 6-fold)<sup>[29]</sup>. Importantly, diabetic subjects exhibited significantly higher plasma *N*<sup>1</sup>-methylnicotinamide levels than non-diabetic subjects after nicotinamide loading, which suggests its involvement in the toxic effects of nicotinamide overload. Indeed, this study

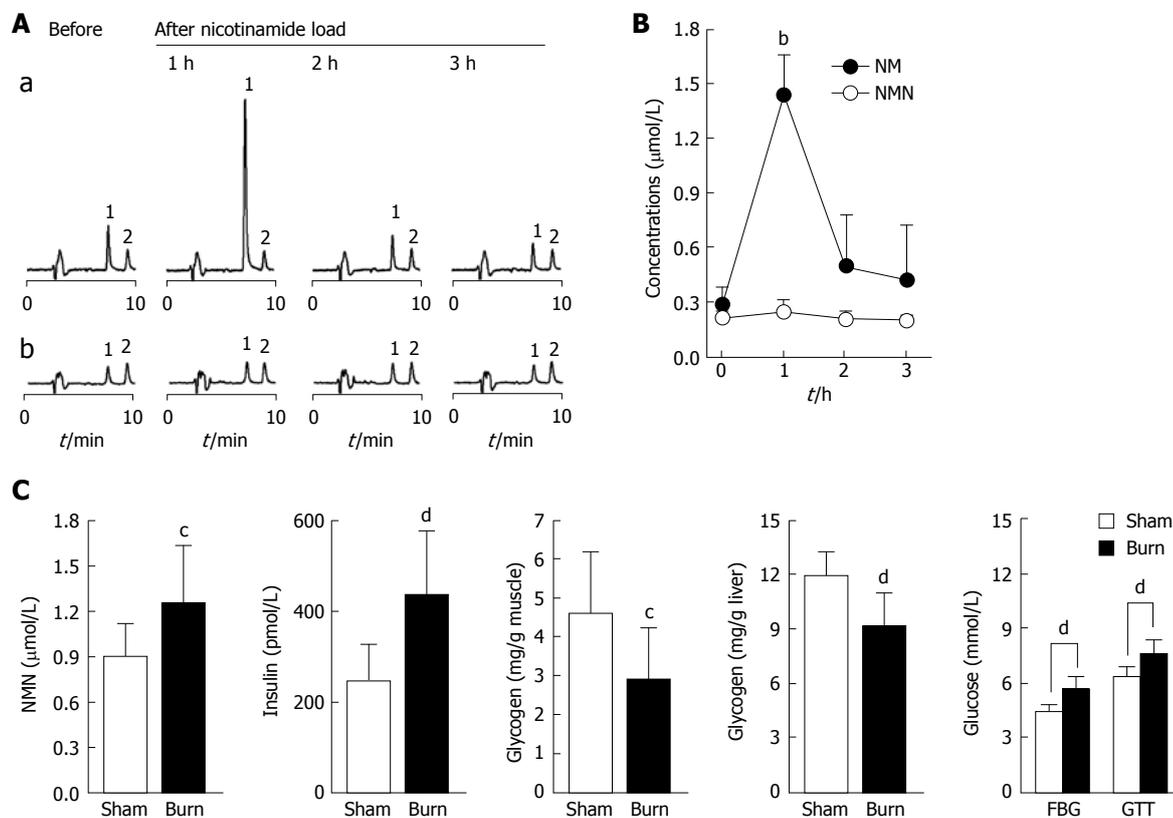

demonstrated that *N*<sup>1</sup>-methylnicotinamide mimicked the effect of nicotinamide overload, which suggested *N*<sup>1</sup>-methylnicotinamide mediation of the toxic effect.

Increasing evidence suggests that insulin resistance is due to an unfavorable internal environment because muscles resistant to insulin, when cultured *in vitro*, regain sensitivity to insulin<sup>[30-32]</sup>. Further evidence reveals that systemic oxidative stress may be responsible for triggering insulin resistance<sup>[1,33]</sup>. Consistent with previous research, this study found that *N*<sup>1</sup>-methylnicotinamide not only elevated plasma H<sub>2</sub>O<sub>2</sub> levels *in vivo*, but also directly stimulated H<sub>2</sub>O<sub>2</sub> generation of human erythrocytes *in vitro* at physiological concentrations, which indicates that *N*<sup>1</sup>-methylnicotinamide is a potent trigger of diabetic oxidative stress.

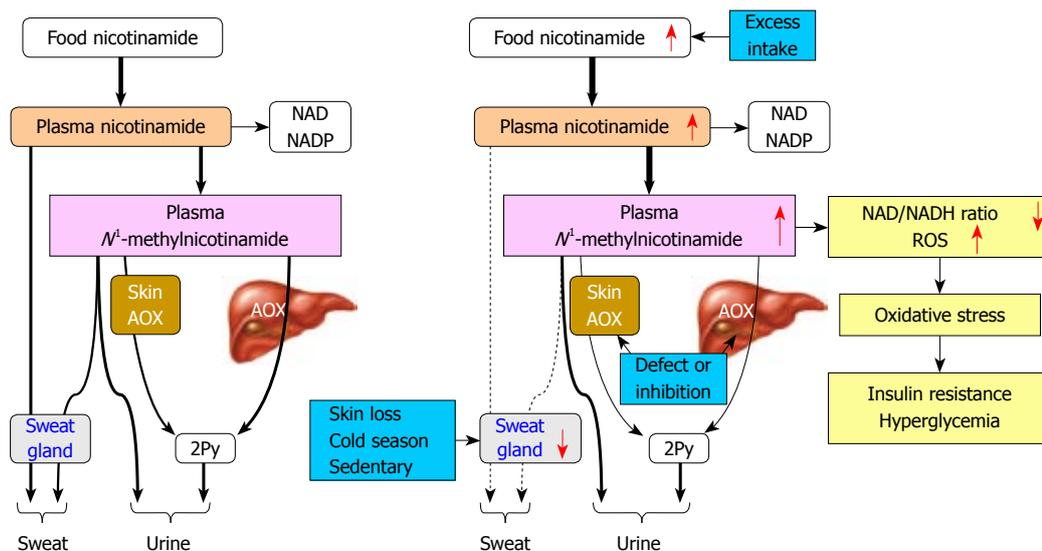

Oxidative stress may induce NAD depletion, a marker of cell injury<sup>[34,35]</sup>. Indeed, this study found that *N*<sup>1</sup>-methylnicotinamide-induced high plasma H<sub>2</sub>O<sub>2</sub> level was associated with a significant reduction in NAD content in

**Figure 5** Effects of aldehyde oxidase (AOX) inhibitors on plasma *N*<sup>1</sup>-methylnicotinamide levels and glucose metabolism in rats. A and B: Plasma *N*<sup>1</sup>-methylnicotinamide (NMN) levels 5 h after nicotinamide load (100 mg/kg, ip) in rats treated with or without AOX inhibitors tamoxifen (Tam, A) or olanzapine (Olan, B) (each group, *n* = 6). <sup>a</sup>*P* < 0.05 vs control, <sup>b</sup>*P* < 0.01 vs control; C: Liver AOX expression in rats with or without 7 wk tamoxifen treatment. The blot is representative of four independent experiments; D: Responses to a glucose tolerance test in rats after 9 wk treatment with tamoxifen with or without NMN (100 mg/kg per day) treatment in the last 2 wk. FBG: Fasting blood glucose; GTT (1 h): Blood glucose measured 1 h after glucose tolerance test. <sup>b</sup>*P* < 0.01 vs control. Bar graph indicates mean ± SD.

**Figure 6** Role of skin in nicotinamide metabolism and insulin resistance. A: Representative HPLC chromatograms showing changes of sweat nicotinamide (NM) and *N*<sup>1</sup>-methylnicotinamide (NMN) concentrations in a subject before and 1, 2 and 3 h after 100 mg nicotinamide loading. 1 and 2 in Aa are NM and internal standard *N*<sup>1</sup>-ethylnicotinamide, respectively; 1 and 2 in Ab are NMN and internal standard *N*-ethylnicotinamide, respectively; B: Summary of the measurements shown in A. <sup>b</sup>*P* < 0.0001 vs control; C: Comparison of plasma NMN and insulin levels, muscle and liver glycogen contents, and blood glucose between sham-burn (*n* = 7) and burn (*n* = 11) rats after glucose load. FBG: Fasting blood glucose; GTT: Blood glucose 1 h after glucose injection. Bar graphs show mean ± SD. <sup>c</sup>*P* < 0.05, <sup>d</sup>*P* < 0.01 vs control.

**Figure 7** Proposed model of the role of nicotinamide overload in the development of type 2 diabetes. Normally, if nicotinamide intake is slightly more than the body needs, excess nicotinamide will be detoxified rapidly and eliminated mainly via the  $N^1$ -methylnicotinamide to 2Py pathway, which involves liver and skin functions (left). Frequent excess nicotinamide intake, low  $N^1$ -methylnicotinamide detoxification, or sweat gland inactivity induces a substantial rise in plasma  $N^1$ -methylnicotinamide concentrations and residence time after each meal, and consequently induces oxidative stress and insulin resistance (right). The change trends are indicated by red arrows or line thickness.

the muscle and liver of rats. Then came the vital question: where did the excess systemic ROS originate? NADH-dependent ROS generation is an important source of intracellular ROS<sup>[34]</sup>. Accumulating evidence has indicated that diabetes shows a decreased cytosolic  $NAD^+$ / $NADH$  ratio in a variety of tissues<sup>[21]</sup>. Importantly, this study demonstrates that  $N^1$ -methylnicotinamide decreases  $NAD^+$ / $NADH$  ratio in rat erythrocytes *in vivo* and human erythrocytes *in vitro*. Thus, it is likely that diabetic oxidative stress is initiated by high plasma  $N^1$ -methylnicotinamide-induced imbalance in the  $NAD^+$ / $NADH$  redox couple. Many cellular processes are governed by the enzymes using  $NAD^+$ / $NADH$  as a cofactor<sup>[6,21,34]</sup>, therefore, it is not difficult to understand why a set of metabolic abnormalities happen in type 2 diabetes.

### Role of AOX in insulin resistance

Mammalian AOX is a molybdo-flavo enzyme involved in the detoxification of various endogenous and exogenous  $N$ -heterocyclic compounds<sup>[22,23]</sup>.  $N^1$ -methylnicotinamide is one of the substrates of AOX by which  $N^1$ -methylnicotinamide is oxidized to pyridones<sup>[7]</sup>, and thus, detoxified. AOX is expressed predominantly in the liver. Therefore, severe liver disease might be expected to reduce plasma  $N^1$ -methylnicotinamide clearance and subsequent insulin resistance. In fact, it is well known that liver cirrhosis is associated with high incidence of diabetes<sup>[36,37]</sup>. Pumpo *et al.*<sup>[38]</sup> have found that cirrhotic patients have high serum  $N^1$ -methylnicotinamide levels, both in basal values and after nicotinamide loading. Moreover, non-alcoholic steatohepatitis, the most prevalent liver disease in the western world, typically is associated with the metabolic syndrome that is characterized by insulin resistance, diabetes and hypertension<sup>[24]</sup>. Tamoxifen, a well-known inducer of non-alcoholic steatohepatitis<sup>[24]</sup>, is found to inhibit strongly AOX activity<sup>[23]</sup> and its expression (Figure 5C). Collectively,

it seems that the decrease in  $N^1$ -methylnicotinamide detoxification may be involved in hepatogenic insulin resistance.

AOX is also expressed in the skin<sup>[26]</sup>, which suggests skin involvement in  $N^1$ -methylnicotinamide detoxification. Moreover, as found in this study, human sweat glands can excrete excess nicotinamide. Therefore, decreased skin function may be implicated in  $N^1$ -methylnicotinamide-induced insulin resistance. In fact, severe burns may induce long-lasting insulin resistance, a well-documented but poorly understood phenomenon<sup>[31,39]</sup>. The present study demonstrated that severe burns significantly delayed  $N^1$ -methylnicotinamide clearance, which suggests that long-lasting post-burn insulin resistance may involve a decrease in nicotinamide detoxification and excretion.

### Relationship between lifestyle risk factors and nicotinamide overload

Environmental and lifestyle risk factors may trigger type 2 diabetes<sup>[3,4]</sup>. From our study, it emerges that the risk factors may involve nicotinamide overload. Firstly, excess nicotinamide may lead to high plasma  $N^1$ -methylnicotinamide, with subsequent oxidative stress and insulin resistance. In response to insulin resistance, the pancreatic  $\beta$  cells have to increase insulin secretion (hyperinsulinemia) compensatorily, which may eventually lead to  $\beta$ -cell failure and blood sugar levels being out of control. The result that tamoxifen-induced AOX inhibition plus  $N^1$ -methylnicotinamide impaired rat glucose tolerance (Figure 5D) implies that excess nicotinamide intake may be more harmful to those with a low  $N^1$ -methylnicotinamide clearance.

Secondly, dietary risk factors may be related to nicotinamide contents in foods. For example, meat, which is rich in nicotinamide, increases the risk of type 2 diabetes<sup>[40,41]</sup>. Moreover, food fortification with niacin may play a role in nicotinamide overload. If comparing the epidemic of type

2 diabetes in the United States<sup>[13]</sup> with the history of food fortification<sup>[14]</sup>, one can clearly see that the trend for rapid increase in the incidence of diabetes has occurred in parallel with the trend in mandatory niacin-fortification-induced increase in the per capita niacin consumption in the latter half of the 20th century. These facts may explain why the western dietary pattern, characterized by a high intake of meat and niacin-fortified foods, confers such a high risk of type 2 diabetes.

Thirdly, sedentary lifestyle risk factor may involve sweat gland inactivity. Sweat gland activity fluctuates according to ambient temperature; the most significant feature of the gland. Therefore, sweat gland inactivity is expected to slow nicotinamide catabolism and thereby increase the danger of developing insulin resistance. In fact, the cold season is known to worsen glucose metabolism<sup>[42,43]</sup>, whereas exercising sufficiently to sweat may reduce diabetic incidence<sup>[44]</sup>. Therefore, it is likely that sedentary lifestyle risk factors may be at least partially due to sweat gland inactivity by air-conditioned working/living environments.

It should be noted that large doses of nicotinic acid and nicotinamide may induce liver damage<sup>[45,46]</sup>, therefore, long-term investigation may be necessary to determine the relationship between chronic nicotinamide overload and non-alcoholic steatohepatitis. Historically, the epidemic of pellagra has been restricted mainly to those who have performed heavy industrial labor with poor nutrient supply<sup>[9]</sup>. Hence, the present study gives rise to an important social and public health issue as to whether foods need to be fortified with niacin (nicotinamide or nicotinic acid), when the people in developed countries have already been living in an age of over-nutrition and sweat gland inactivity.

In summary, it appears that gene-environment (diet) interactions may be a reflection, to some extent, of the outcome of combination of nicotinamide overload and relatively low  $N^1$ -methylnicotinamide detoxification and excretion. As summarized in Figure 7, the pathogenesis of type 2 diabetes may be at least partially due to long-term excess nicotinamide intake, and/or slowness in  $N^1$ -methylnicotinamide detoxification, and/or decrease in excess nicotinamide and  $N^1$ -methylnicotinamide excretion. This may lead to high plasma  $N^1$ -methylnicotinamide levels, and subsequently oxidative stress and insulin resistance. Therefore, reducing nicotinamide intake and facilitating excretion of nicotinamide metabolites may be a useful preventive and therapeutic intervention in type 2 diabetes.

## COMMENTS

### Background

Type 2 diabetes generally is accepted to be a result of gene-environment interaction, although the underlying mechanism is not clear. Of the environmental factors, diet appears to play a major role. In fact, the sharp increases in the incidence of diabetes in the United States in the latter half of the 20th century and in China in the past two decades of the 20th century followed food fortification with niacin (i.e. nicotinamide and nicotinic acid) beginning in the early 1940s in the United States and in the early 1980s in China. Moreover, niacin is reported frequently to impair glucose metabolism and cause liver injury. Thus, there is the possibility that the high prevalence of type 2 diabetes in these countries in the past few decades may involve niacin toxicity.

### Research frontiers

Type 2 diabetes is associated with increased systemic oxidative stress, a

factor responsible for the development of insulin resistance. How the systemic oxidative stress occurs is a major issue in type 2 diabetes.

### Innovations and breakthroughs

The present study demonstrated that the pathogenesis of type 2 diabetes may involve abnormal nicotinamide metabolism. Factors that induce nicotinamide overload and/or decrease in the detoxification and excretion of nicotinamide metabolites may lead to systemic oxidative stress and insulin resistance. The factors may include the frequent use of foods rich in nicotinamide and/or fortified with niacin, congenital enzymatic defects, liver diseases, and sweat gland loss or inactivity. The present study suggests that gene-environment interactions may reflect the outcome of increased nicotinamide intake and a decrease in its detoxification and excretion.

### Applications

Reducing nicotinamide intake and facilitating the excretion of excess nicotinamide may be a useful preventive and therapeutic intervention in type 2 diabetes.

### Peer review

This is an interesting study with human and experimental data, which investigated a clinically relevant issue, and gave an insight into the pathogenic mechanisms involved. The experiments were performed well and are presented well in the paper.

### Abstract

**AIM:** To model clinical and economic benefits of capsule endoscopy (CE) compared to ileo-colonoscopy and small bowel follow-through (SBFT) for evaluation of suspected Crohn's disease (CD).

**METHODS:** Using decision analytic modeling, total and yearly costs of diagnostic work-up for suspected CD were calculated, including procedure-related adverse events, hospitalizations, office visits, and medications. The model compared CE to SBFT following ileo-colonoscopy and secondarily compared CE to SBFT for initial evaluation.

**RESULTS:** Aggregate charges for newly diagnosed, medically managed patients are approximately \$8295. Patients requiring aggressive medical management costs are \$29508; requiring hospitalization, \$49074. At sensitivity > 98.7% and specificity of > 86.4%, CE is less costly than SBFT.

**CONCLUSION:** Costs of CE for diagnostic evaluation

of suspected CD is comparable to SBFT and may be used immediately following ileo-colonoscopy.

### INTRODUCTION

Crohn's disease (CD) is a chronic, transmural inflammatory bowel disease that primarily involves the small bowel. Symptoms of CD are often non-specific and vary among afflicted individuals. Symptoms may include abdominal pain, diarrhea, vomiting, gastrointestinal bleeding, iron deficiency anemia, weight loss, and fevers<sup>[1]</sup>. Crohn's disease can also be associated with extra-intestinal manifestations such as skin rashes, arthritis, and uveitis<sup>[2]</sup>. While any segment of the gastrointestinal tract can be affected, the small intestine is involved in approximately 70% of patients and up to 30% of patients will have their disease limited solely to the small bowel, particularly the ileum<sup>[2]</sup>.

There is no single test that establishes the diagnosis of CD. Diagnosis is based on a combination of clinical, endoscopic, radiographic, and laboratory findings. The sequence of diagnostic tests attempting to establish the diagnosis of CD is often based upon the patient's presenting symptoms. For example, when small bowel CD is suspected clinically, ileo-colonoscopy along with small bowel barium radiography [e.g. small bowel follow-through (SBFT)] has traditionally been performed<sup>[3]</sup>. However, barium radiographic studies are limited by poor sensitivity for detecting early lesions of CD (e.g. aphthous erosions/

ulcerations) and ileo-colonoscopy evaluation is confined to only the most distal 5-15 cm of the ileum (terminal ileum). In addition, the non-specific symptoms of CD often lead to delays in obtaining a definitive diagnosis and therefore the institution of appropriate and targeted disease therapy<sup>[4-6]</sup>. Rath *et al*<sup>[7]</sup> found that 38% of CD patients had an interval of more than a year between onset of symptoms and definitive diagnosis.

Because of delays in diagnosing small bowel CD, the costs to payers that are associated with indeterminate tests, repeat endoscopic and radiographic procedures, frequent physician visits, and hospitalizations are likely to be substantial<sup>[8,9]</sup>. Thus, there is a need for an efficient and effective algorithm of diagnostic tests leading to a definitive diagnosis of CD. Optimizing such a diagnostic pathway should have substantial benefits for both patients and payers.

Until recently, the small bowel has been the most difficult part of the gastrointestinal tract to evaluate endoscopically. Since being introduced in 2001, small bowel capsule endoscopy (CE) has facilitated easy access for direct investigation of the entire small bowel mucosa and as a result has revolutionized the diagnosis and management of small bowel diseases including obscure gastrointestinal (GI) bleeding, iron deficiency anemia, CD, polyposis syndromes/tumors, and celiac disease. Because of its ability to examine the entire mucosa of the small intestine, capsule endoscopy has the potential for diagnosing suspected CD patients earlier and as a result, direct costs of care may be reduced.

The aim of this study was to derive and evaluate a decision analytic model to determine the economic benefit of CE compared to ileo-colonoscopy and SBFT for the evaluation of suspected CD of the small bowel.

## MATERIALS AND METHODS

### Model design

We developed a comprehensive model comparing the direct costs of performing CE for the diagnosis and management of suspected CD in a hypothetical cohort of 10 000 patients. Each arm of the model includes the yield of an initial ileo-colonoscopy immediately followed by SBFT or CE based on current clinical practice and guidelines (Figure 1)<sup>[10-16]</sup>. If no diagnosis was made after initial ileo-colonoscopy, we assumed that patients would then receive either a SBFT or CE. In a secondary analysis, we eliminated the initial ileo-colonoscopy to determine the relative global costs using SBFT or CE as an initial diagnostic strategy (Figure 2).

In constructing the model to reflect accepted standards of care for suspected CD we used guidance from clinical experts in CD (JAL, IMG) and the 2005 International Conference on Capsule Endoscopy (ICCE) consensus statement<sup>[10-17]</sup>. For economic comparators, we utilized the economic analysis of Goldfarb *et al*<sup>[18]</sup> concerning evaluation of suspected CD using CE and publications identified by a systematic literature review for guidance in building and populating the model.

The Goldfarb economic analysis compared CE to traditional modalities for the diagnosis of suspected small bowel CD<sup>[18]</sup>. Based on published diagnostic yields of 69.6% for CE *vs* 53.9% for a combined approach with ileo-colonoscopy and SBFT, their analysis determined CE to be a less costly strategy as long as its diagnostic yield was 64.1% or greater. The authors also reported CE to be less costly as a primary diagnostic tool in this clinical setting<sup>[18]</sup>. These data are provocative, but CE and ileo-colonoscopy/SBFT as mutually exclusive diagnostic strategies may not translate into every day clinical practice. In addition, the included trials were not subjected to a systematic review analysis to evaluate for study heterogeneity.

### Model assumptions and definitions

**Literature review:** To estimate key model variables we performed a systematic literature review to investigate the evidence concerning the use of CE for evaluating suspected CD. The MeSH search terms and strategies employed by third party payers were used for identifying relevant publications. Multiple MEDLINE, EMBASE, COCHRANE TRIALS, and BIOSIS searches were completed using MeSH search terms including “capsule endoscopy”, “Pillcam”, “wireless endoscopy”, “wireless capsule endoscopy”, “video endoscopy”, “video capsule endoscopy”, “M2A capsule endoscopy”, “endoscopy”, “ileum endoscopy”, “ileal endoscopy”, “small bowel imaging”, “small intestine imaging”, “Crohn’s disease”, “Crohn’s disease diagnosis”, “Crohn’s disease radiology”, “Crohn’s disease imaging”, “Crohn’s disease costs”, “Crohn’s disease payments”, “Crohn’s disease reimbursement”.

A total of 891 citations were derived from the published literature searches (January 1970 - January 2008). 792 (89%) were published in English and 141 (16%) were review articles; 29 were published in German, 28 in Spanish, 7 each in Japanese and French, and 5 in Italian. In all cases, we reviewed full manuscripts/reports and case reports with sufficient evaluable information but did not include published abstracts. The literature reporting on ultrasound, magnetic resonance (MR), and computed tomography (CT) enterography in CD continues to grow but remains inconsistent in estimates of diagnostic yield and cost; consequently, we chose not to compare these techniques.

### Patients

Using a decision analysis software (TreeAge Pro Suite 2006 Release 0.3, Williamstown, MA), we evaluated a hypothetical cohort of 10 000 patients who had suspected CD as defined by the 2005 ICCE Consensus conference<sup>[17]</sup>. Ileo-colonoscopy was negative and was assumed to effectively exclude lesions within the reach of a colonoscope. Therefore, CD lesions modeled were defined to be located proximal to the distal terminal ileum.

This model estimates the total expected global costs to a third party payer of the initial diagnostic work-up as well as expected follow-up costs of managing these patients for one year after diagnosis of CD, including procedure-related adverse events, subsequent hospitalizations, office

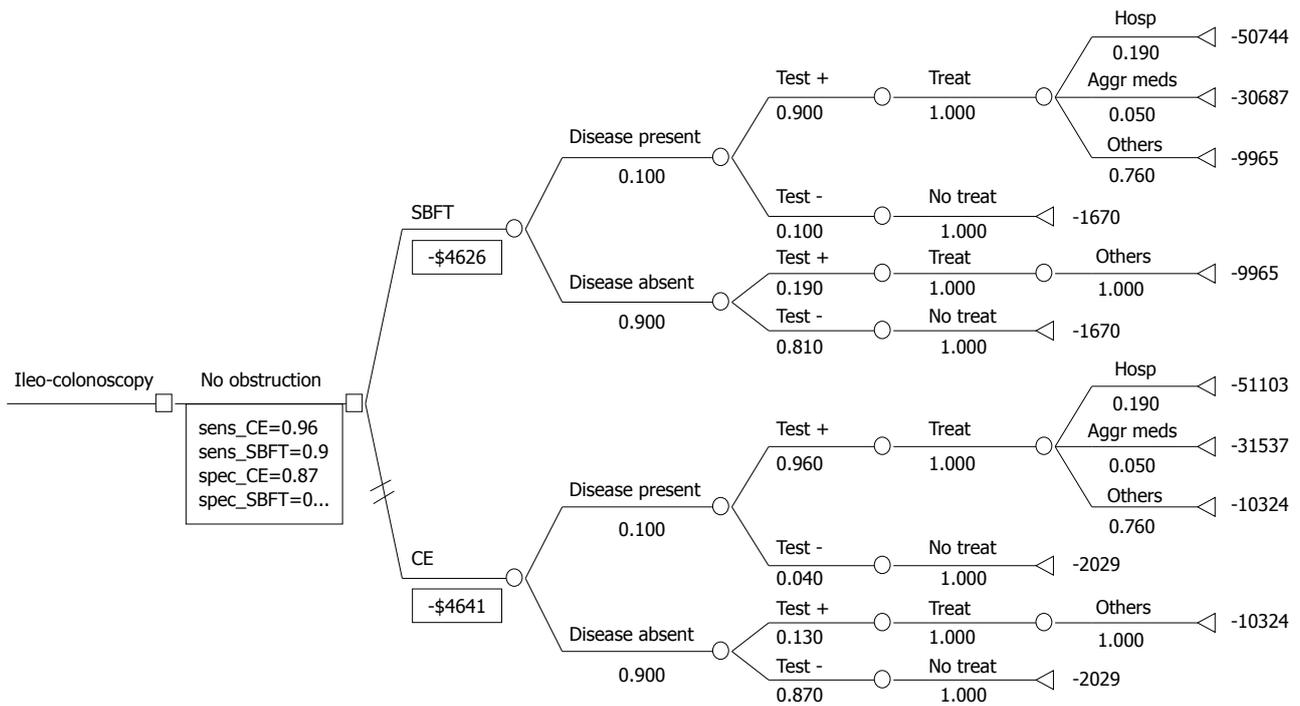

Figure 1 One-year cost model for diagnosis and management of suspected Crohn's disease (CD) of the small bowel with ileo-colonoscopy as first-line diagnostic technique. SBFT: Small bowel follow-through; CE: Capsule endoscopy.

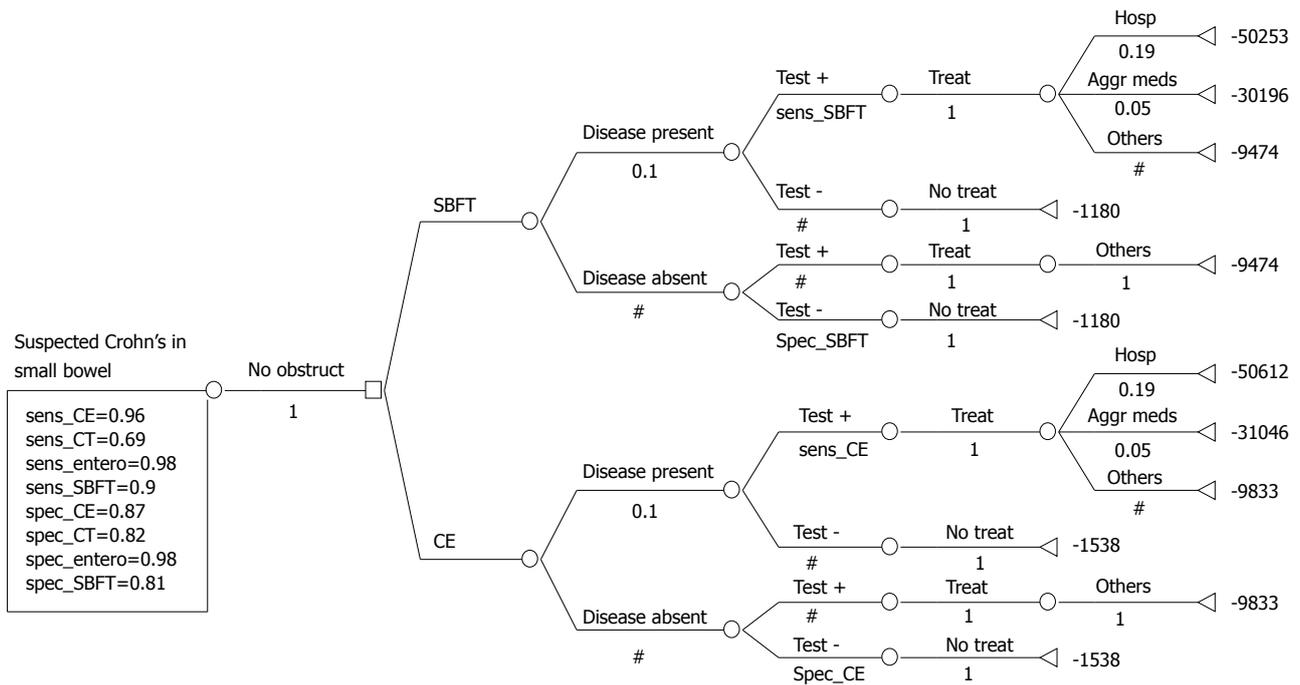

Figure 2 One-year cost model for diagnosis and management of suspected CD of the small bowel with ileo-colonoscopy/SBFT or capsule endoscopy as first-line diagnostic technique. CT: Computed tomography.

visits, laboratory tests, and medications. We chose this design because this economic model allows predictive modeling of the annual economic burden for a chronic disease like CD. Payers are concerned about the rate of medical resource utilization of both inpatient and outpatient services and are not generally interested in other burdens to the patient such as sick time off or other opportunity loss. In addition, because of enrollee turnover

rates in health plans, payers are most interested in models that study short-term (1-2 years) rather than long-term (> 2 years) economic burdens. Finally, payers are interested in imaging and diagnostic tests that are not additive (i.e. leads to treatment change without requiring further testing).

We developed a cost model based on the annual costs of care for diagnosis and management of a patient with suspected CD<sup>[19]</sup>.

Previously, Feagan *et al*<sup>[19]</sup> used medical claims data to identify and stratify patients with CD into three mutually exclusive disease severity groups: Group 1, required an inpatient hospitalization associated with a primary/secondary diagnosis of CD; Group 2, required aggressive pharmacotherapy, defined as chronic glucocorticoid (> 10 mg/d) or immunosuppressive drug (purine antimetabolites/methotrexate) therapy, for > 6 mo and/or anti-TNF monoclonal antibody therapy; or Group 3, all remaining patients (Table 1). As with prior economic evaluations and models reported in the biomedical literature, we used Medicare reimbursement data as surrogates of cost<sup>[18,19]</sup>. For tests and procedures, the model was populated with national average allowable 2007 Medicare reimbursement data (Table 2).

We were interested in determining total payer costs associated with the diagnostic evaluation and management of suspected CD. Therefore we evaluated typical hospitalization, outpatient, and medication costs associated with the care of a patient being evaluated for suspected CD of the small bowel. To estimate the added cost of anti-TNF monoclonal antibody therapy (e.g. Remicade<sup>®</sup>), we identified cost-effectiveness analyses on the use of these agents for treatment of aggressive CD. Recent literature has estimated that 25% of patients in this group would receive anti-TNF monoclonal antibody therapy<sup>[20,21]</sup>. Based on the reported shifts in utilization, we estimated an annual cost of \$65 000 for this class of drugs and calculated a weighted average cost of \$16 250 per patient to simulate the expected cost of these agents in the aggressive medical management group (Feagan *et al*<sup>[19]</sup> Group 2).

Annual costs were then estimated as a weighted average based on the likelihood of the correct diagnosis multiplied by the expected costs of follow-up care by each patient type. We estimated in-patient hospital costs by examining charge data from the Nationwide Inpatient Sample (NIS) which is one in a family of databases and software tools developed as part of the Healthcare Cost and Utilization Project (HCUP), a Federal-State-Industry partnership sponsored by the Agency for Healthcare Research and Quality (Rockville, MD). This database permits searches of in-patient costs according to ICD-9 disease classifications. The database includes historical information and permits comparisons to inflation-adjusted calculations.

The systematic literature review described above was used to identify mean sensitivity and specificity estimates for the comparator diagnostic techniques (Table 3). These values were used to populate the model as were the inflation-adjusted charges described in the manuscript by Feagan *et al*<sup>[19]</sup>. In addition, a series of sensitivity analyses, including a Monte Carlo analysis, were performed to determine the relative strengths and weaknesses of utilizing CE relative to other diagnostic testing options in patients with suspected CD. Monte Carlo simulation creates a multi-way sensitivity analysis. The base-case decision tree was repeatedly analyzed using inputs with appropriate distributions to determine the proportion

**Table 1** Aggregate charges for each therapeutic grouping used in model

Procedure	Group 1	Group 2	Group 3
Base charge <sup>1</sup>	\$49 074	\$13 258	\$8 295
Monoclonal therapy <sup>2</sup>	-	\$16 250	-
Colon/SBFT <sup>3</sup>	\$50 253	\$30 687	\$9 474
CE <sup>4</sup>	\$50 612	\$31 046	\$9 833

<sup>1</sup>Groups 1, 2, and 3 base annual charges adjusted for inflation from Feagan *et al* by consumer price index (CPI) to estimate 2007 charges; <sup>2</sup>Base annual charge for monoclonal (Infliximab) therapy for Crohn's disease was estimated as \$65 000. We assumed 25% of patients requiring aggressive medical management were treated with this agent and adjusted Group 2 by \$16 250; <sup>3</sup>Colon/SBFT procedure charge \$11 79; <sup>4</sup>CE procedure charge \$1538. SBFT: Small bowel follow-through; CE: Capsule endoscopy.

of runs each strategy was identified as the least costly initial strategy. The following variables were used in the simulation: costs and sensitivity of tests and rates of procedural complications. Each simulation performed included 10 000 trials. Adding the potential cost of complication(s) following possible capsule retention did not change the economic results (data not shown).

## RESULTS

Figure 2 depicts the derived cost model. All patients with suspected CD are initially examined with ileo-colonoscopy followed by SBFT or CE. Overall, patients evaluated and treated by the CE pathway cost \$4641 whereas those evaluated by SBFT cost \$4626, a difference of \$15 per patient slightly in favor of SBFT. Patients with positive small bowel findings on CE who required hospitalization cost \$51 103 and those requiring aggressive medical management cost \$31 537. These values were comparable to the SBFT pathway. In the secondary analysis, patients managed by CE as the initial diagnostic test cost \$4150 or \$15 per patient more than those initially evaluated with SBFT. These results were comparable to the prior results because of the lower cost of omitting an initial ileo-colonoscopy at an estimated cost of \$491.

We conducted a Monte Carlo simulation involving 10 000 patients undergoing evaluation for suspected CD. In evaluating the results shown in Figure 3, there is evidence that the probability of incurring a charge of at least \$1670 is > 97.5%; there is less than a 2.5% probability of incurring a charge of more than \$9965. The mean cost for evaluation of the patient with suspected small bowel CD is \$4601 ± 7467 (SD) for this 10 000 patient model cohort examined by ileo-colonoscopy first, immediately followed by SBFT. Likewise, there is evidence that the probability of incurring a charge of at least \$2029 is > 97.5%; there is less than a 2.5% probability of incurring a charge of more than \$10 324 in those evaluated by ileo-colonoscopy first, immediately followed by CE. The mean cost for evaluating a patient with suspected CD in that group is \$4604 ± 7563 (SD) for the 10 000 patient simulation. The results of the Monte Carlo simulation are essentially identical (\$4604 for SBFT

**Table 2 Procedure charges used for the model according to the 2007 medicare fee schedule**

HCPCS code	Procedure	Reimbursement	Colonoscopy w/SBFT	Capsule endoscopy

Aggressive medical management frequency (Group 2)	0.05	[18]
Other management frequency (Group 3)	0.76	[18]

vs \$4601 for CE) for each technique and represent a real-world scenario of relevant costs.

The results of one-way sensitivity analyses on the diagnostic sensitivity and specificity of SBFT and CE are shown in Figure 4 for patients who receive an initial ileo-colonoscopy. The graphs depict how sensitivity (x-axis) and cost (y-axis) (i.e. expected value) interplay. As expected, the cost of performing either test decreases with increasing sensitivity or specificity. The cost of performing SBFT vs CE is essentially equivalent over a wide range of sensitivity values, particularly in the highest ranges of sensitivity and specificity, which might be achieved by an experienced clinician. At a sensitivity > 95.1%, CE becomes less costly than SBFT; at a specificity of > 87.2%, CE is less costly than SBFT. As expected, the results are identical in the secondary analysis (data not shown).

**DISCUSSION**

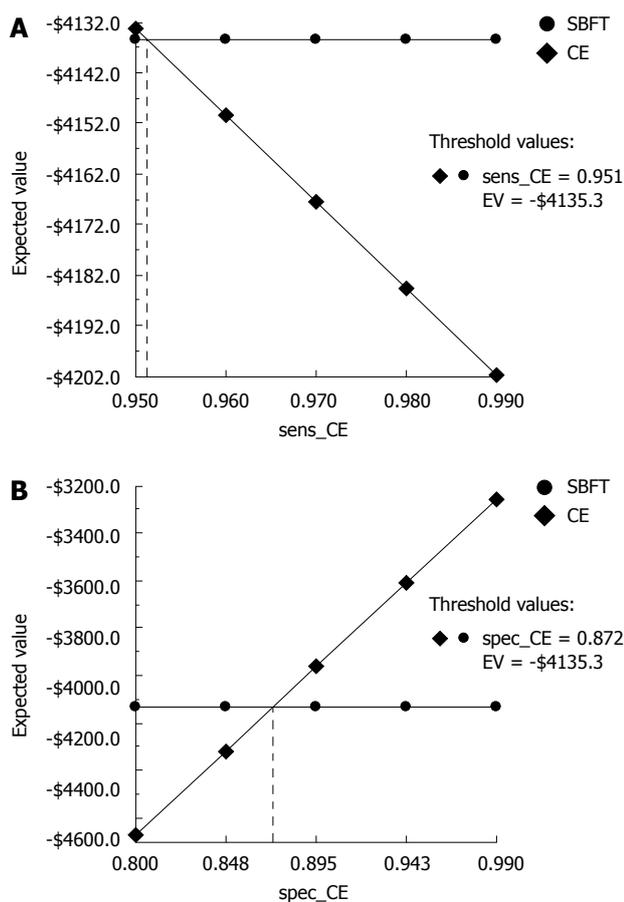

Capsule endoscopy is a valuable tool for the study of patients in whom a clinical suspicion of small bowel CD is raised. We found in this present study, applying a conservative costing methodology, incorporating ileo-colonoscopy with SBFT, and CE, demonstrates that CE is marginally less costly overall than use of SBFT despite CE being a slightly more costly test. Secondary analysis demonstrates the cost advantage of CE is robust over a wide range of diagnostic sensitivity and specificity values. Thus, following ileo-colonoscopy, there appears to be

**Figure 3 Monte carlo simulation at ileo-colonoscopy. A:** Monte carlo simulation at SBFT; **B:** Monte carlo simulation at CE.

evidence and a cost basis to encourage the use of CE initially (e.g. in place of SBFT) in diagnostic algorithms for suspected small bowel CD.

Suspected CD patients often go months and sometimes years without a definitive diagnosis, especially those with more mild or moderate symptoms and with disease that is isolated to the small bowel. For example, ileo-colonoscopy may be normal in such individuals and a functional bowel disorder may be suspected. Symptoms of CD, especially in the early stages, may mimic functional bowel disease, such as irritable bowel syndrome, confounding the differential diagnosis<sup>[19]</sup>. Radiographic diagnostic tests such as SBFT may not be sensitive enough to detect early small bowel mucosal changes (aphthae)

**Figure 4** Sensitivity analysis on CE sensitivity and specificity. A: Sensitivity analysis on sens\_CE; B: Sensitivity analysis on spec\_CE.

and enteroclysis, although a more sensitive test than SBFT is no longer routinely used due to the difficulty of performing the exam, its limited availability, and patient discomfort associated with the procedure. Moreover, exposure to radiation with these tests is a genuine concern among patients and physicians. As a result, these standard radiographic diagnostic testing approaches (SBFT and enteroclysis) can contribute to a delay in diagnosis and hence costs to the payer. While CT enterography may be a superior imaging modality to SBFT and enteroclysis for suspected CD, at present the test has limited clinical availability and as such, SBFT remains the initial study following ileo-colonoscopy in most clinical practices. For those patients with a negative ileo-colonoscopy and negative SBFT in whom obstructive symptoms raise concern for possible capsule retention, CT enterography or the Agile Patency Capsule performed prior to standard small bowel capsule endoscopy may be the next best option to evaluate these patients.

There are a number of limitations to this present study. The model inputs for the test characteristics for diagnostic tests were extracted from the literature based on clinical studies that included selected patients. These patient populations may not reflect the spectrum of patients seen in usual clinical practice. We have attempted however, to temper this limitation by performing sensitivity analyses over a wide range of model estimates,

including a Monte Carlo simulation<sup>[22]</sup>. Another limitation of this study is that there are only a limited number of publications that report findings on the use of CE for CD. Moreover, sample sizes in these trials have invariably been small. However, a meta-analysis of available prospective trials comparing CE with one or more alternate diagnostic modalities for the diagnosis of suspected or established CD, found an incremental yield of 43% (95% CI = 29% to 56%) for CE over SBFT for the diagnosis of small bowel CD, with a number needed to test of only 2 patients for an additional positive finding with CE<sup>[23]</sup>. An updated meta-analysis showed that the yield favors CE compared to SBFT for suspected CD<sup>[24-26]</sup>. Analysis of CE *vs* colonoscopy with ileoscopy (incremental yield with CE = 16%, 95% CI = 3% to 30%) and CT enterography/enteroclysis (incremental yield with CE = 32%, 95% CI = 3% to 61%) also found a significantly improved yield with CE. We utilized data from these meta-analyses to better populate our model estimates.

Our cost-analysis was limited to a third-party payer perspective, although there are additional relevant perspectives. For example, indirect costs to the patient and the cost to the gastroenterologist and their capacity to deliver care (provide CE examination) was not evaluated. In the case of the ability of gastroenterologists to provide care, CE is now a widely accepted diagnostic test that most gastroenterology practices have available and utilize. Moreover, the time horizon for this analysis was limited to one year. However, payers are most interested in models that study short-term (1-2 years) rather than long-term (> 2 years) economic burdens due in part to attrition of members in health plans.

Though CE is a promising technology for the evaluation of patients with CD, there are a number of concerns with its use in this population. The possibility of capsule retention due to known or suspected strictures is a concern in this patient group. The rate of capsule retention in the largest published series of CE for obscure gastrointestinal bleeding was 0.75% (7/934 patients) despite a negative SBFT in 6/7 patients<sup>[27]</sup>. All patients underwent surgical resection, and pathology explaining the reason for each patient's symptoms was found at the site of capsule impaction (a so-called therapeutic complication). Due to the stenosing nature of CD, however, a higher rate of capsule retention may be expected if CE is performed in these patients. Rates of capsule retention in patients with CD range from 0% to 13% despite small bowel imaging performed prior to CE in nearly all patients<sup>[28,29]</sup>. However, the rate of capsule retention is significantly higher in patients with known CD compared to those with suspected CD.

Perhaps the most significant issue facing CE in the evaluation of CD is the lack of specificity and its inability to provide pathologic confirmation of observed findings. In clinical studies, a variety of findings encompassing a broad range of severity have been described as potentially consistent with the diagnosis of CD, and thereby a positive result with CE. As a diagnosis of CD has far-reaching effects on the psychological and financial health

of patients as well as their physical health, caution in making this diagnosis based on subtle CE findings is appropriate. The long-term clinical significance of finding occasional mucosal breaks in the small bowel on CE is presently unclear, and will require prospective studies to clarify the issue.

In summary, this economic model, along with several clinical trials suggest that CE is a valuable tool in the diagnosis and subsequent management of patients with suspected CD. Data from the studies reviewed in this article suggest improved outcomes after CE due to targeted medical therapy for those patients found to have lesions consistent with CD, as well as a change in therapeutic strategy in those patients with normal capsule examinations<sup>[25,30]</sup>. The burden of delay in definitive diagnosis of a debilitating chronic disease is never more apparent than in CD where earlier intervention and treatment makes a significant clinical impact. New technologies and diagnostics, such as CE, require evidence from clinical and payer decision makers who demand rigorous proof of clinical and economic utility. This model provides economic evidence in favor of CE for use immediately following ileo-colonoscopy in the diagnostic pathway for suspected CD.

## COMMENTS

### Background

Using capsule endoscopy (CE) earlier in diagnosis of suspected Crohn's Disease (CD) may reduce direct costs of care due to ability to examine the entire mucosa of the small intestine; currently, no single test establishes this diagnosis.

### Research frontiers

Accurate, early diagnosis of CD is important to patient management decisions. Current therapies may be expensive and their potential inappropriate clinical use due to incorrect diagnosis is troublesome. CE represents a diagnostic technology that may improve overall diagnostic yield therein obviating potentially substantial clinical and economic loss.

### Innovations and breakthroughs

CE is an important breakthrough diagnostic technology that is used in a wide number of clinical settings. The present analysis considers its use in suspected small bowel CD. The findings here extend previous cost analyses. The economic model presented here is the first to combine diagnostic and therapeutic costs associated with this condition.

### Applications

The results of this study may assist in developing cost-effective diagnostic guidelines for evaluation of suspected CD.

### Terminology

Crohn's disease (CD) is a chronic, transmural inflammatory bowel disease that primarily involves the small bowel. Capsule endoscopy (CE) is a technique that directly visualizes the surface of the small bowel where abnormalities due to CD may be identified.

### Peer review

This study presents a valuable economic model that combines the cost-effectiveness of diagnosis and treatment of patients with suspected CD. The results demonstrate the value of capsule endoscopy in the overall management of patients with this condition. These results may be useful in future studies of cost-effective approaches to the diagnosis and treatment of CD as well as to considerations of diagnostic selection in clinical guidelines and practice.

### Abstract

**AIM:** To identify which parameters could help to distinguish the "metabolically benign obesity", which is not accompanied by insulin resistance (IR) and early atherosclerosis.

**METHODS:** Eighty two of 124 overweight/obese females formed the study population, which was divided into two groups (52 and 30 subjects, respectively) with and without IR according to a HO meostatic Metabolic Assessment (HOMA) cut-off of 2, and were studied in a cross-sectional manner. The main outcome measures were waist circumference, serum uric acid, high-density lipoprotein-cholesterol and triglycerides, alanine amino-transferase, blood pressure and the two imaging parameters, hepatic steatosis and longitudinal diameter of the spleen, which were measured in relation to the presence/absence of IR.

**RESULTS:** A variable grade of visceral obesity was observed in all subjects with the exception of three.

Obesity of a severe grade was represented more in the group of IR individuals ( $P = 0.01$ ). Hepatic steatosis, revealed at ultrasound, was more pronounced in IR than in non-IR subjects ( $P = 0.005$ ). The two groups also demonstrated a clear difference in longitudinal spleen diameter and blood pressure, with raised and significant values in the IR group. Metabolic syndrome was frequent in the IR group, and was not modified when adjusted for menopause ( $P = 0.001$ ). At linear regression, the  $\beta$  values of waist circumference and body mass index predicting HOMA were 0.295,  $P = 0.007$  and 0.41,  $P = 0.0001$ , respectively. Measures of spleen longitudinal diameter were well predicted by body mass index (BMI) values,  $\beta = 0.35$ ,  $P = 0.01$ , and by HOMA,  $\beta = 0.41$ ,  $P = 0.0001$ . Blood pressure was predicted by HOMA values,  $\beta = 0.39$ ,  $P = 0.0001$ . HOMA and hepatic steatosis were highly associated ( $\rho = 0.34$ ,  $P = 0.002$ ). Interestingly, IR patients were almost twice as likely to have hepatic steatosis as non-IR patients. Among the MS criteria, blood pressure was very accurate in identifying the presence of IR (AUROC for systolic blood pressure 0.66, cut-off 125 mm of Hg, sensibility 64%, specificity 75%; AUROC for diastolic blood pressure 0.70, cut-off 85 mm of Hg, sensibility 54.5%, specificity 75%).

**CONCLUSION:** As health care costs are skyrocketing, reliable and mainly inexpensive tools are advisable to better define subjects who really need to lose weight.

## INTRODUCTION

The incidence of both Overweight/Obesity (O/O) and Metabolic Syndrome (MS) is dramatically increasing. The generally accepted view is that being overweight causes similar health problems to that of obesity but to a lesser degree. The risk of death from all causes increases throughout the range of moderate and severe increases in body weight for both men and women in all age groups<sup>[1]</sup>. Further co-morbidities<sup>[2-4]</sup> are more frequent in O/O than in normal-weight females. Unless reversed, this trend predicts an epidemic of cardiovascular disease (CVD). Interventions are required to empower adults to increase physical activity and to modify eating habits. Nevertheless, it is mandatory to establish exactly which individuals should be treated and when. In fact, although the negative health consequences of O/O in the general population are well supported by the available published evidence, health outcomes in certain subgroups seem to be improved at an increased body mass index (BMI), a phenomenon known as the obesity survival paradox<sup>[5]</sup>. Furthermore, there is a high prevalence of clustering of cardiometabolic abnormalities among normal-weight individuals and a high prevalence of O/O individuals who are metabolically healthy<sup>[6]</sup>. Consequently, “metabolically benign obesity” which is not accompanied by insulin resistance (IR) and early atherosclerosis has recently been postulated to exist in humans<sup>[7]</sup>.

A way of getting to the grass-roots of the problem could be to tackle the mechanisms underlying O/O. Evidence that this phenomenon can be regarded as a low-grade chronic inflammatory state comes from numerous studies<sup>[8]</sup>. Moreover, inflammation links obesity to early tumor promotion<sup>[9]</sup>. Inflammatory disease could represent a compensatory mechanism for increased adipose tissue turnover<sup>[10]</sup>. Apart from diabetes and atherosclerosis, another associated high-risk condition is non-alcoholic fatty liver disease (NAFLD), the etiologic factors of which include IR<sup>[11]</sup>, high levels of serum interleukin-6 (IL-6)<sup>[12]</sup> and mitochondrial dysfunction<sup>[13]</sup>. The link between NAFLD and CVD has recently been established by the fact that the liver is involved in regulating/secretory numerous CVD risk factors<sup>[14]</sup>, notably a cytokine [tumor necrosis factor-alpha (TNF- $\alpha$ )], an acute-phase protein [C-reactive protein (CRP)], glucose, lipoproteins, coagulation factors (plasminogen activator inhibitor-1<sup>[15]</sup>) and a substance which increases blood pressure (angiotensin II<sup>[16]</sup>).

The NAFLD rate in the general adult population is increasing with large numbers, i.e. 20%<sup>[17]</sup>, in obese non-diabetic adults being much higher<sup>[18]</sup>. Obviously, a clear differentiation between “simple” fatty liver (FL) and non-alcoholic steatohepatitis (NASH) in the spectrum of NAFLD is quite impossible without liver biopsy which is not always performed for ethical and technical issues. For this reason, we generally speak of hepatic steatosis (HS). Ultrasound (US) is widely used to detect HS, without exposing subjects to ionizing radiations. Indeed, more specific imaging techniques<sup>[19]</sup> are costly and not always useful in close follow-up. Tsushima *et al*<sup>[20]</sup> first identified the so-called liver-spleen axis in NAFLD patients. It has recently been proposed that increased spleen volume and

serum levels of high sensibility (hs)-CRP contextually with HS, which “*per se*” unravels an inflammatory status<sup>[14]</sup>, characterize young adult obese subjects<sup>[21]</sup>. Up-to-date findings from a nationally representative sample of adults indicate that the prevalence of MS increases substantially with increasing levels of serum uric acid (UA)<sup>[22]</sup>. Actually, the menopause is associated with the aggravation of total cholesterol, LDL cholesterol and apolipoprotein B<sup>[23]</sup>, representing a physiologic event which should be taken into consideration when evaluating multiple cardiovascular risk factors in O/O females, even though this status is highly correlated with age. Finally, researchers have demonstrated that elevated alanine aminotransferase (ALT) levels are independently associated with increased CVD- or diabetes-related mortality<sup>[24]</sup>.

With numerous studies showing that O/O is a disease requiring long-term commitment to achieve the desired results, and that these results should be achieved as soon as possible<sup>[25]</sup>, we aimed to identify which parameters could help distinguish between healthy and non healthy O/O individuals, by individualizing the boundaries within which is possible to “watch and wait”. As health care costs are skyrocketing, the key point is to utilize tools which are reliable and mainly inexpensive. To achieve this aim we analyzed an anthropometric index, i.e. waist circumference (WC), in addition to the metabolic parameters, serum UA, high-density lipoprotein-cholesterol (HDL) and triglycerides, liver enzyme activity i.e. ALT, a CVD index, i.e. blood pressure, and two imaging parameters which were HS and spleen size, in relation to the presence/absence of IR.

## MATERIALS AND METHODS

This research was performed by screening 124 consecutive female subjects with established (at least 4 years) O/O from February 2008 to April 2009. The study was carried out according to the principles of the Declaration of Helsinki and an informed written consent was obtained from each patient.

### Exclusion criteria

Of the 124 initial subjects, 11 patients, who had undergone steroid therapy (four with bronchial asthma, five with rheumatoid arthritis and two with neuritis), as well as 15, who had received one or more of the following drugs, i.e. aspirin, metformin, statins and fibrates, were excluded from the study because these prior treatments may have caused a change in laboratory data. Three persons were excluded due to the detection of marked intestinal meteorism which made it difficult to perform US. Eight others were excluded due to the presence of co-morbidity (chronic viral hepatitis, alcohol abuse), and five subjects were considered drop-outs, because they avoided undergoing full laboratory-instrumental examinations.

### Inclusion criteria

The remaining 82 subjects whose median age was 46.5 (14-64) years, were divided into two groups on the basis of the presence or absence of IR, and formed the study

population. The degree of overweight or obesity was established on the basis of BMI cut-off points of 25-29.9, 30-34.9, 35-39.9 and  $> 40 \text{ kg/m}^2$ , respectively. Visceral obesity was identified by measuring WC at the midpoint between the lower border of the rib cage and the iliac crest. MS was defined according to the revised Adults Treatment Panel III (2001), and three or more criteria were considered: plasma glucose concentration of at least 100 mg/dL, WC  $> 88 \text{ cm}$ , serum HDL concentration  $< 50 \text{ mg/dL}$ , blood pressure of at least 130/85 mmHg, and serum triglyceride concentration of at least 150 mg/dL. HS was associated with recent US features of "bright liver", with or without aminotransferase increase of unknown origin, in the absence of other chronic liver disease. Women were classified as being menopausal if they had not menstruated in the 12 months before examination. IR status was determined by the HOmeostatic Metabolic Assessment (HOMA), which was assessed using the formula: fasting insulin ( $\mu\text{U/mL}$ )  $\times$  fasting glucose (mg/dL)/405<sup>[26]</sup>. As a stringent measure of IR, a value of HOMA  $> 2$  was introduced.

### Ultrasound evaluation

Sonographic measurements were performed using an ESAOTE *Technos* (Genoa, Italy). Briefly, spleen longitudinal diameter (SLD) was measured by postero-lateral scanning. The maximum length and the cranio-caudal were measured and then averaged. All the indices were measured thrice directly from the frozen images using an electronic caliper. The classification of "bright liver" or HS was based on the following scale of hyperechogenicity: 0 = absent, 1 = light, 2 = moderate, 3 = severe, pointing out the difference between the densities of the liver and the right kidney<sup>[27]</sup>.

### Blood pressure measurements

The systolic/diastolic blood pressure (SBP, DBP) was the average of three consecutive readings taken by the physician during the day, during usual practice hours, and after subjects had rested for five minutes in the sitting position.

### Laboratory data

Serum triglycerides, HDL, basal insulin, ALT, and UA were measured using standard in-house procedures. Hs-CRP was determined using an ELISA Kit, human CRP by BioSupply, UK with a sensibility of 0.03 mg/L and a range of normal values of 0.25-1.5 mg/L.

### Statistical analysis

HDL data, derived from a normally distributed population [Shapiro-Wilk test (S-W),  $P = 0.481$ ], are expressed as mean plus SD. Variables not normally distributed, such as age (S-W,  $P = 0.000$ ), BMI (S-W,  $P = 0.005$ ), SLD (S-W,  $P = 0.002$ ), WC (S-W,  $P = 0.002$ ), HOMA (S-W,  $P = 0.001$ ), DBP (S-W,  $P = 0.001$ ), SBP (S-W,  $P = 0.001$ ), triglycerides (S-W,  $P = 0.003$ ), UA (S-W,  $P = 0.001$ ), hs-CRP (S-W,  $P = 0.001$ ), and ALT (S-W,  $P = 0.001$ ), are expressed as median (range). HS grades were considered ordinals and managed in the same way. The difference

in medians was assessed by the Mann-Whitney test for independent samples. The difference in means of HDL was evaluated by the Two-Sample  $t$  test. The Two-Way Tables cross-tabulated one categorical row variable with one categorical column variable and the significance was set by the Pearson  $\chi^2$  test. Frequencies with a small number of the expected values were evaluated by Fisher's exact test. When cross-tabulation was stratified for another dichotomous variable, the Mantel-Haenszel  $\chi^2$  test was carried out. Tracking the degree of association between single parameters, i.e. HS scores and triglycerides levels, Spearman's rho for non uniform intervals was used. The Pearson's coefficient ( $r$ ) was employed to analyze the correlation between HOMA and HDL. When confronted with the question of how accurate a parameter was in identifying the presence of IR, the discrimination with relative cut-off was evaluated using receiver operating characteristic curve (ROC) analysis, graphically expressed as area under the ROC (AUROC). Sensitivity (true positive rate) and specificity (true negative rate) were also weighted for the same purpose. Optimal cut-off was considered the threshold value with the best specificity/sensitivity. To predict the presence of IR, the logistic regression (Enter Method), with relative odds ratios and 95% confidence intervals (CI), was employed utilizing as independent variables, US values for SLD and HS, BMI and WC measurements, blood pressure determinations and UA, HDL, and triglycerides data. To assess the independent effect of a quantitative variable, i.e. HOMA, on the prediction of spleen size (SLD) values and SBP/DBP determinations, linear regression analysis (least squares) was used, evaluating the standardized coefficient beta ( $\beta$ ). The same tool was used to verify the connection between IR severity and anthropometric measures. Factor analysis was applied to detect the structure in the relationships among variables selecting a subset of variables, which have the highest correlations with the principal component factors. The Cattell's Scree plot, with relative eigenvalues, was performed to screen the real factors. Extraction of the main components amounted to a variance maximizing (varimax) rotation of the original variable space. The critical value was calculated by the formula: doubling the Pearson's correlation coefficient for 1% level of significance (5.152)/square root of subjects minus 2, i.e. 0.576. The concordance correlation coefficient ( $\rho_c$ ), which measures precision and accuracy, was adopted to evaluate the degree of pair observations at US. Statistical analysis was performed operating on Systat 12 (Richmond, CA, USA) and MedCalc Version 10.4.8<sup>®</sup> (Frank Schoonjans) software packages.

## RESULTS

In order to allow readers to gauge the internal validity of this study, we determined the minimum required sample size, with a type 1 error of 0.01 and type 2 error of 0.01 when dividing the population in two groups using HOMA (difference of means = 1.8, SD of non-IR females = 0.4 and SD of IR females = 1.8), which was calculated in 26 subjects. In addition, to assess how well

**Table 1** Anthropometric, clinical, laboratory and ultrasound data of the study population

Variables [females (82)]	Median (Range) mean $\pm$ SD		P-value
	IR present (52)	IR absent (30)	
BMI (kg/m <sup>2</sup> )	33 (25-53.7)	32 (25.6-39.7)	0.78

SLD at US (mm)	115 (92-150)	102 (90-127)	0.0001
MS (n)	18	6	0.0001
Menopause (n)	20	11	0.9

<sup>a</sup>Fisher's exact test. IR: Insulin resistance; BMI: Body mass index; HS: Hepatic steatosis at US; US: Ultrasonography; DBP: Diastolic blood pressure; SBP: Systolic blood pressure; HDL: High-density lipoprotein-cholesterol; ALT: Alanine aminotransferase; hs-CRP: High sensibility C-reactive protein; SLD: Spleen longitudinal diameter at US; MS: Metabolic syndrome; n: No. of subjects.

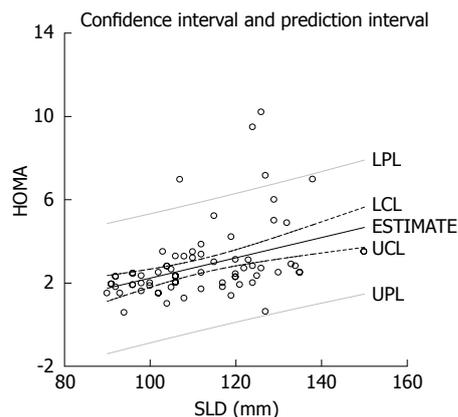

the study findings applied to the patients (external validity) the eighty two subjects divided into two cohorts of 52 and 30, were well balanced for BMI ( $P = 0.78$ ), WC ( $P = 0.45$ ) and age ( $P = 0.79$ ), but different for HOMA ( $P < 0.001$ ), and were studied in a cross-sectional manner.

### Prevalence

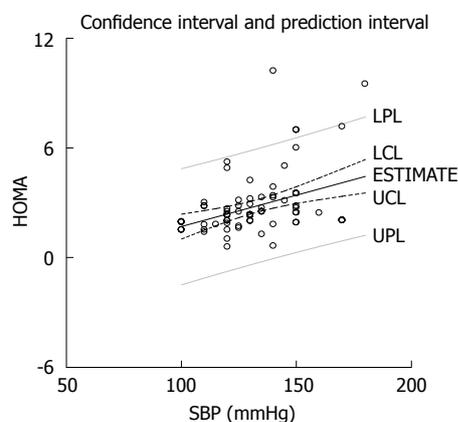

A variable grade of visceral obesity was determined in all subjects with the exception of three (two without IR). Only obesity of the severest grade was represented more in the patients with IR than in the non-IR patients ( $P = 0.01$ ). HS, revealed at US, was more pronounced in subjects with IR than in those without IR ( $P = 0.005$ ). MS was more frequent in IR patients than in non-IR patients. These figures were not modified when adjusted for menopause (Mantel-Haenszel  $\chi^2$  test,  $P = 0.001$ ). The same physiological status was unable to distinguish females with IR from those without IR. No difference in ALT activity was detected between the two cohorts on the basis of IR. The two groups demonstrated no resemblance when analyzing SLD, HS and blood pressure, with raised and significant values in the IR group (Table 1).

### Association & prediction

Anthropometric measurements in the study females showed a similar pattern of reliably predicting IR severity. In fact, the  $\beta$  values of WC and BMI in predicting HOMA were 0.295,  $P = 0.007$  and 0.41,  $P = 0.0001$ , respectively. HDL levels were not associated with HOMA values ( $r = 0.8$ ,  $P = 0.5$ ). SLD measures were well predicted by BMI values,  $\beta = 0.35$ ,  $P = 0.01$ , and by HOMA,  $\beta = 0.41$ ,  $P = 0.0001$  (Figure 1). SBP determinations were predicted by HOMA values,  $\beta = 0.39$ ,  $P = 0.0001$  (Figure 2). HOMA

**Figure 1** Prediction of spleen size by insulin resistance severity. SLD: Spleen longitudinal diameter at ultrasonography (US); HOMA: HOmeostatic metabolic assessment for insulin resistance; LPL: Lower prediction limit; LCL: Lower confidence limit; UCL: Upper confidence limit; UPL: Upper prediction limit.

**Figure 2** Prediction of systolic blood pressure by insulin resistance severity. SBP: Systolic blood pressure.

and HS scores at US were highly associated ( $\rho = 0.34$ ,  $P = 0.002$ ). In IR patients, the grade of HS severity was not correlated with serum triglycerides levels ( $\rho = 0.245$ ,  $P = 0.08$ ). IR patients were almost twice as likely to have HS as those who did not have IR. Further predictions are shown in Table 2.

The complex of WC, HOMA and SLD as well as age, HS and SBP had the highest correlations among the variables, contributing to the loading of the principal components (factor 1 and 2). Triglyceride concentrations (loading factor 3) seemed to play an isolated role (Figure 3).

### Accuracy

Among the MS criteria, blood pressure was very accurate in identifying the presence of IR (AUROC for SBP 0.66, cut-off 125 mm of Hg, sensibility 64%, specificity 75%; AUROC for DBP 0.70, cut-off 85 mm of Hg, sensibility 54.5%, specificity 75%).

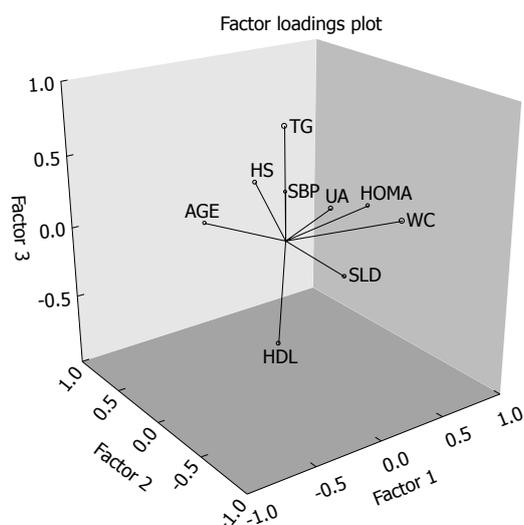

### Precision

The concordance correlation coefficient to evaluate the degree of intra-operator pair observations at US was high,  $\rho_c = 0.91$ .

**Table 2 Estimates in predicting insulin resistance**

Parameter	OR	Lower	Upper	P-value
SLD	1.073	1.027	1.121	0.002
SBP	1.045	1.015	1.075	0.003
DBP	1.046	1.003	1.090	0.036
HDL	1.022	0.974	1.072	0.378

## DISCUSSION

Authorities claim that (1) every subject with a body weight above the established criteria should be treated, stressing this point even to the extent of suggesting that just brief physician-nutritionist support by telephone could be useful in a busy primary care office<sup>[28]</sup>, (2) substantial numbers of overweight/obese individuals remain insulin-sensitive<sup>[29]</sup>. Consequently, the question we pose is: beyond IR, might some other indicators play a role in identifying novel targets, i.e. typology of O/O patients and timing of interventions<sup>[30]</sup>? Accordingly, we propose parameters which may be worth investigating when dealing with the phenotypically O/O and when it is neces-

sary to decide who the metabolically normal subjects are.

The body of pertinent knowledge based on data from the Third National Health and Nutrition Examination Survey testifies that each of the five components of MS, with the possible exception of obesity, independently predicts CVD<sup>[31]</sup>. In contrast, abdominal obesity, measured by WC, is a more accurate predictor of CVD risk than general obesity measured by BMI<sup>[32]</sup>, even though, for a given BMI, women have more subcutaneous adipose tissue and insulin-sensitivity than men<sup>[33]</sup>. However, controversy exists over the type of blood pressure increase. Previous results showed that SBP represents the most prevalent type in obese women<sup>[34]</sup>, being a stronger predictor of CVD than DBP<sup>[35]</sup>. Indeed, these data are challenged by more recent research based on longitudinal studies<sup>[36]</sup>. In addition, according to some other investigators, both blood pressure and plasma aldosterone correlate better with IR in men than in women<sup>[37]</sup>, whereas, there is widespread agreement that NAFLD predicts CVD<sup>[38]</sup>.

In the present study, it can be seen that our data in O/O females supports an association only between the more severe forms of adiposity and the highest grades of IR. Accordingly, MS was characterized by different values in the two groups with and without IR, and HOMA was correlated with severity of HS and to spleen size. The HS score was higher in IR patients, as was another index (hs-CRP), suggesting a possible link between inflammatory status and IR. These findings are consistent with the concept that a partially “benign” obesity, characterized by the absence of IR, lack of HS, or at most the presence of a “light” form of HS, low blood pressure, low expression of a marker of inflammation (SLD) exist in this particular population, at least during the course of this study.

When discussing possible mechanisms for our findings, we pinpoint the following with regard to the liver-spleen axis: (1) peripheral IR determines increased hepatic synthesis of free fatty acids (FFAs) and decreased synthesis of apolipoprotein B, both leading to HS; (2) TNF- $\alpha$ , through JNK-dependent IRS-1 Ser307 phosphorylation, contributes to IR and is responsible for the induction of IL-6 in the liver, both of which aggravate triglyceride accumulation; (3) the overproduction of IL-6, which has “*per se*” a source in visceral and subcutaneous fat, could represent the cause of spleen enlargement in patients with HS *via* uncoupling protein 2<sup>[39]</sup>; (4) a further origin of the increased splenic volume may be found in the accumulation of activated macrophages inside this organ *via* monocyte chemoattractant protein-1 which is over-expressed in adipose tissue<sup>[40]</sup>; (5) once infiltrated, these macrophages produce a large amount of TNF- $\alpha$  which increases the release of FFAs, resulting in HS. With regard to blood pressure, O/O subjects not only exhibit impaired endothelial function in small arteries but also increased arterial stiffness<sup>[41]</sup>. However, IR is associated with greater cardiac reactivity in young women<sup>[42]</sup>. Finally, a recent study performed on a large population showed that patients with HS have increased intima media thickness (IMT<sup>[43]</sup>).

The limitations and strengths of our study deserve

comment. Concerning the limitations, to verify CVD risk, we should have studied a US parameter marker of early atherosclerosis, e.g. IMT in our population, however, this index, as previously emphasized<sup>[43]</sup>, is correlated with HS grade. A further drawback may have been the lack of liver biopsies to assess the severity of NAFLD, even though the canonical difference between FL and NASH has been challenged recently<sup>[44]</sup>. Finally, we did not determine serum levels of folate which are related to elevated homocysteine or blood pressure. In relation to blood pressure, our data showed a new emerging trend, i.e. rather than focusing primarily on body weight, WC, or BMI as a health indicator, a number of scientists have suggested the use of a measure called Metabolic Fitness (MF). Authors define MF as “the absence of biochemical risk factors associated with obesity or elevated blood pressure”. These measures are much better indicators of chronic disease risk, and reductions in these risks factors are not always dependent on weight loss<sup>[45]</sup>.

Most people, who are unhappy with their weight, try to lose weight by changing unhealthy practices. This attitude could result in a dramatic increase in unrealistic goals. On the other hand, some lines of research support the notion that a lifestyle-modification program can reduce the risk of O/O-related comorbid conditions despite minimal or no weight loss. What is more, studies investigating weight loss have methodological limitations that restrict the applicability of findings to O/O patients assessed in clinical practice<sup>[46]</sup>. When we add all this evidence up, it does raise the question of what will our strategy in the near-to-medium term look like. This debate is still ongoing and is mainly related to health-related quality of life<sup>[47]</sup> and the not always favorable balance between costs and treatment outcomes.

## COMMENTS

### Background

The incidence of Overweight/Obesity in the last few years has dramatically increased in highly developed countries. There has also been a simultaneous rise in the frequency of metabolic syndrome. Being overweight causes similar health problems to that of obesity but to a lesser degree. The risk of death from all causes increases throughout the range of moderate and severe increases in body weight for both men and women in all age groups. Unless reversed, this trend predicts an epidemic of cardiovascular disease.

### Research frontiers

It has recently been postulated that “metabolically benign obesity” exists, and is not accompanied by insulin resistance and early atherosclerosis. We sought to identify which parameters could distinguish between healthy and non healthy overweight/obese individuals.

### Innovations and breakthroughs

We claim that “hepatocytes are the last cells to be involved in the progressive chain of fat accumulation and probably the first cells to tell us that something is wrong”. If our proposed parameters are to be adopted more widely, they must be validated in a range of settings and different populations; until then, the most important message is that researchers should identify tools that suit clinicians in their clinical setting, allowing them to screen appropriate cases, in order to improve identification of patients who need to lose weight.

### Applications

Interventions at home, in the office, and in the community are required to empower adults to increase physical activity and to modify eating habits. Nevertheless, before these intervention strategies are set up, it is mandatory to establish exactly which individuals should be treated and when.

### Terminology

The main outcome measures in this study are extremely common, i.e. waist circumference, serum uric acid, high-density lipoprotein-cholesterol and triglycerides, alanine aminotransferase, blood pressure and the two imaging parameters, hepatic steatosis and spleen longitudinal diameter.

### Peer review

This is quite an interesting article. The manuscript reports the studies on the use of simpler parameters in assessing the need for medical intervention with respect to healthy and non healthy overweight/obese individuals. It is suggested that adoption of simpler to perform measurements could not only reduce the cost of medical care but also provide more reliable identification of patients in need of weight loss.

### Abstract

**AIM:** To assess the management and outcome of nonerosive gastro-esophageal reflux disease (NERD) patients who were identified retrospectively, after a 5-year follow-up.

**METHODS:** We included patients with gastro-esophageal reflux disease (GERD) symptoms who had a negative endoscopy result and pathological 24-h esophageal pH-monitoring while off therapy. We interviewed them after an average period of 5 years (range 3.5-7 years) by means of a structured questionnaire to assess presence of GERD symptoms, related therapy, updated endoscopic data and other features. We assessed predictors of esophagitis development by means of univariate and multivariate statistical analysis.

**RESULTS:** 260 patients (137 women) were included. Predominant GERD symptoms were heartburn and

regurgitation in 103/260 (40%). 70% received a maintenance treatment, which was proton pump inhibitor (PPI) in 55% of cases. An average number of 1.5 symptomatic relapses per patient/year of follow-up were observed. A progression to erosive gastro-esophageal reflux disease (ERD) was found in 58/193 (30.0%) of patients undergoing repeat endoscopy; 72% of these were Los Angeles grade A-B.

**CONCLUSION:** This study shows that progression to ERD occurs in about 5% of NERD cases per year, despite therapy. Only two factors consistently and independently influence progression: smoking and absence of PPI therapy.

Pace F, Pallotta S, Manes G, de Leone A, Zentilin P, Russo L, Savarino V, Neri M, Grossi E, Cuomo R. Outcome of nonerosive gastro-esophageal reflux disease patients with pathological acid exposure. *World J Gastroenterol* 2009; 15(45): 5700-5705 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5700.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5700>

### INTRODUCTION

Evaluating the natural history of gastro-esophageal reflux disease (GERD) is useful for a number of reasons, as this knowledge may help to: (1) discern the percentage of the population that will progress from non-erosive to erosive disease with its complications, such as stricture, Barrett's oesophagus, and esophageal adenocarcinoma, or from exclusively esophageal to extraesophageal manifestations; (2) define, assess and validate predictivity of risk factors for such disease complications; (3) determine if medical, surgical or endoscopic therapies are able to positively modify the

natural course of the disease; and (4) determine the need for maintenance therapy to prevent complications and persistent symptoms.

Others<sup>[1,2]</sup> have pointed out that many factors make it difficult to study the natural history of GERD, notably the evolving definition of the disease and the lack of a diagnostic standard. As a consequence, few studies in the literature have addressed the issue of defining the natural history of erosive GERD, and even less that of nonerosive gastro-esophageal reflux disease (NERD) or extraesophageal GERD and complications.

Until recently, patients with endoscopic-negative reflux disease were considered to suffer from a milder disease<sup>[3]</sup>, i.e. requiring less intensive/prolonged treatment and possibly characterized by a better long-term prognosis. This concept was subsequently proven to be incorrect; as an example, the impairment in disease-related quality of life appears to be similar in GERD patients with or without endoscopic esophagitis and is related in both instances to symptom severity<sup>[4]</sup>. Also, the symptomatic acute response to proton pump inhibitor (PPI) drugs in patients with or without endoscopic mucosal damage may be worse in NERD<sup>[5,6]</sup>. Finally, after discontinuation of acute treatment, symptomatic relapse within 6 mo appears to affect a similarly high proportion of both GERD groups<sup>[7]</sup>.

Up till now, however, it has not been entirely clear whether and in what proportion GERD patients with symptomatic syndrome but without mucosal damage<sup>[8]</sup> may progress to disease with mucosal damage.

The aim of this study was to assess the outcome of NERD patients with pathological acid reflux at entry after a 5-year follow-up, in three Italian tertiary care centres. Additionally, we investigated which factors are related to development of esophagitis.

## MATERIALS AND METHODS

### Subjects

We retrospectively identified all patients referred to our outpatient departments during the period 1996-2003 for investigation of gastroesophageal (GER) disease symptoms. Subjects were included in the study provided that (1) they were off PPI therapy for at least the preceding 7 d, (2) had a negative upper gastrointestinal (GI) endoscopy, (3) had a 24-h esophageal pH-monitoring result showing pathological GER, i.e. a 24-h esophageal acid exposure greater than 4.4%, corresponding to the 95th percentile of normal Italian subjects and (4) were able to accept a telephone interview<sup>[9]</sup>. We interviewed the subjects after an average period of 5 years (range 3.5-7 years) by means of a structured questionnaire, already used in a previous study<sup>[10]</sup>, to assess presence and type of GERD symptoms (i.e. typical: heartburn or regurgitation, and atypical, i.e. chronic cough, pharyngodynia, hoarseness, chest pain), antireflux drug therapy (presence and type), updated endoscopic data and other features regarding their present clinical status. The questionnaire allowed the patient to identify the most

**Table 1** Clinical and demographic characteristics of patient population (mean  $\pm$  SD)

Age (yr)	49.5 $\pm$ 14
BMI	25.24 $\pm$ 3.7
EAE (%)	
24 h	6.8 $\pm$ 5.4
Upright	5.6 $\pm$ 6.6
Supine	6.8 $\pm$ 7.6
No. of smokers	132
Patients with predominant typical symptoms	103 (39.6%)
Patients with predominant atypical symptoms	142 (54.6%)
Patients with both typical & atypical predominant symptoms	15 (5.7%)

EAE: Esophageal acid exposure; BMI: Body mass index.

bothersome GERD symptom, be it typical or atypical, as the predominant one. Collected data at study entry included demographic characteristics, such as age, gender and body mass index (BMI), the reason for undergoing the examination, pattern of GERD symptoms (Table 1), and the results of index upper GI endoscopy and 24-h esophageal pH-metry. Both investigations were carried out while off PPI therapy.

### Statistical analysis

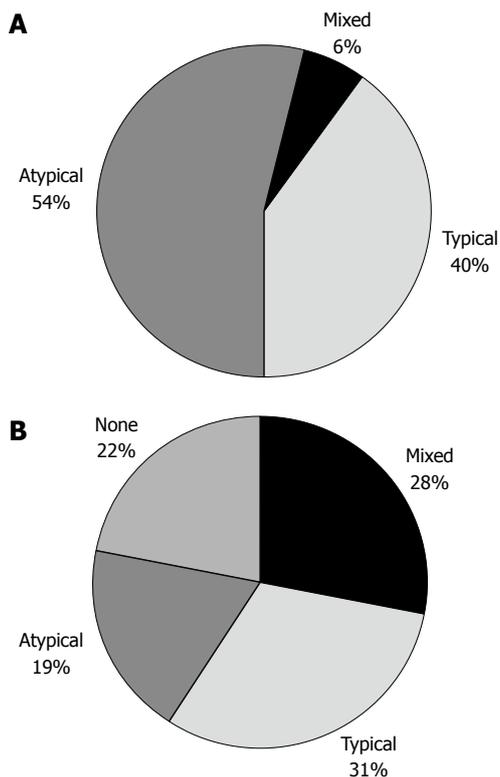

Descriptive statistics consisted of *t* tests for continuous variables and  $\chi^2$  tests for categorical variables. We conducted a univariate logistic regression to evaluate the influence of each risk factor, such as gender, age, BMI, smoking, typical and atypical symptoms, use of therapy, pH-monitoring reflux parameters, on the dependent variable, i.e. development of esophagitis. Significant prognostic factors were then subjected to a multivariate analysis with logistic regression to evaluate the association among the determinants while simultaneously controlling for the effect of other variables. We controlled for several covariates, and only variables with *P* > 0.1 were kept in the model. Statistical significance was defined by a two-sided alpha level of 0.05. A Cox model was ultimately used to construct the survival curves.

All analyses were performed using statistical software (SPSS, Chicago, Illinois, USA).

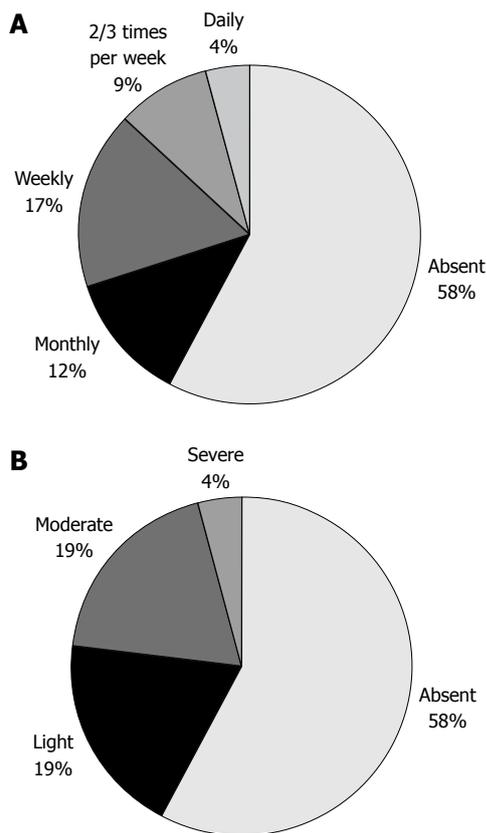

## RESULTS

We were able to identify 995 patients overall who were referred for GERD symptoms. 260 patients (137 women) satisfied the inclusion criteria and were included in the study. Mean age at the time of initial evaluation was 50  $\pm$  14 (SD) years, with a BMI of 25.24  $\pm$  3.72; 50% were smokers. The clinical and demographic characteristics of patients are listed in Table 1.

Predominant GERD symptoms were typical in 103/260 (40%), atypical in 142/260 (54%) and mixed, i.e. similarly dominating the clinical picture, in the remaining 15/260 (6%) (Figure 1A). The mean percentage time with pH < 4 was 7.1%  $\pm$  2.6%. At interview, after a median follow-up time of 5 years, typical symptoms

**Figure 2** Frequency (A) and severity (B) of heartburn at follow-up. Light: Not interfering with day or night activities; Moderate: Interfering with day or night activities, but bearable; Severe: Unbearable.

Risk factor	Odds ratio (95% CI)	P value
Smoking	3.1 (1.6-6.04)	0.0006
Regurgitation > 1/wk	3.5 (1.9-6.6)	0.0001
Severe regurgitation	2.6 (1.35-4.8)	0.005
Nocturnal regurgitation	2.4 (1.2-4.7)	0.01
Supine reflux time > 1.2	5.3 (0.8-38.9)	0.03
Continuing PPI therapy	0.3 (0.1-0.6)	0.001

Note that "continuing PPI therapy" has a negative odds ratio, and can therefore be considered as a protective factor against development of esophagitis. NERD: Nonerosive gastro-esophageal reflux disease; PPI: Proton pump inhibitor.

such as heartburn and regurgitation were still present in 80 patients (31%). The distribution of symptoms at follow-up is presented in Figure 1B.

Frequency and severity of heartburn and regurgitation at follow-up are presented in Figures 2 and 3, respectively. Most patients had received a maintenance treatment during the follow-up period and 181/260 (69.6%) of them were still on therapy; of these, the majority (55%) had been treated with PPIs, 35% had been treated with H2 receptor agonists and the remaining with non-antisecretory agents. Among patients treated with PPIs during the last year (100 subjects), 65% were taking a full dose, i.e. the dose usually used for acute therapy, and the remaining 35% were taking a half dose. In either case, only 44% were using a continuous therapy,

whereas the remaining 48% were using an intermittent one and only 8% used a true on-demand therapy. One hundred and ninety-three out of 260 included patients underwent repeat endoscopy during the follow-up period. An average number of 1.5 symptomatic relapses per patient/year of follow-up were observed with an average of  $1.6 \pm 0.3$  (SD) repeat endoscopies performed during the follow-up. Reason for repeat endoscopy was almost always symptom relapse. Despite active therapy, a progression to erosive gastro-esophageal reflux disease (ERD) was found in 58 patients (30.0%) overall; 72% of these cases were Los Angeles grade A or B.

In the univariate analysis, factors found to be significantly associated with the development of esophagitis were smoking, the presence of severe or nocturnal regurgitation and supine reflux time > 1.2% (but not upright or total reflux time), as well as the absence of continuous use of PPI therapy (Table 2). Interestingly, neither the age of the patient nor the BMI value (and in particular a BMI > 30) were found to influence the development of esophagitis. Table 3 shows the pH-metry parameters and the BMI values at presentation of those patients showing a progression vs. those not showing development of esophagitis.

In multivariate logistic regression analysis, only two factors were found to be independent predictors of development of esophagitis: smoking habit and the use of a continuous PPI therapy (Table 4).

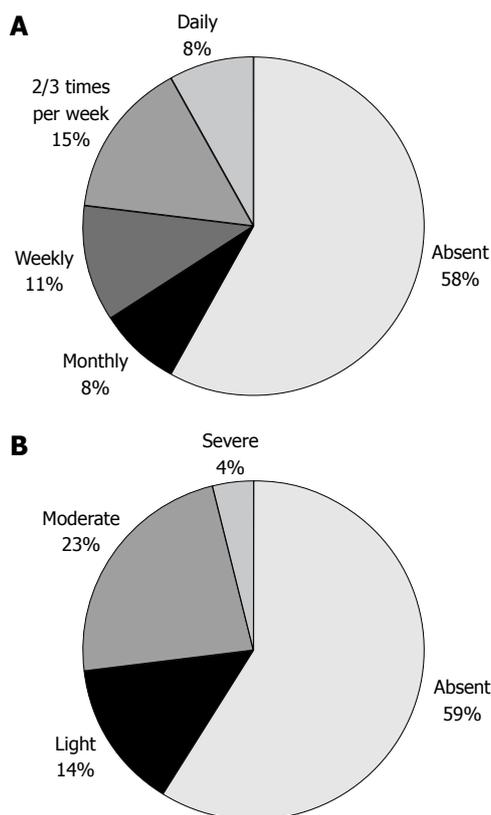

Figure 3 Frequency (A) and severity (B) of regurgitation at follow-up. For explanation of definitions, see legend of Figure 2.

### DISCUSSION

This retrospective study clearly shows that during a relatively long follow-up conducted in a sample of patients with NERD and pathological acid reflux, esophagitis develops in a clinically relevant proportion of patients (roughly one quarter); even in those undergoing a maintenance treatment. Smoking and the lack of a continuous PPI therapy are the only factors independently associated with the development of esophagitis, which, in our study, was predominantly grade A or B according to Los Angeles classification.

Our retrospective study is the largest ever conducted in a population of NERD patients further categorized on the basis of a pathological pH-monitoring.

We preferred to include only patients in whom an abnormal acid exposure could be demonstrated by 24-h esophageal pH monitoring for two main reasons: (1) to replicate the inclusion criteria we used in a previously published paper<sup>[11]</sup> and (2) to deal with a more homogeneous GERD patient population. In fact, as already demonstrated by others, a significant proportion of presumed NERD patients defined on the basis of symptoms alone do not have GERD<sup>[12]</sup>. It has been shown that, on the whole, pH testing is abnormal in about 45% of NERD patients, compared with 75% of patients with erosive esophagitis and 93% of patients with Barrett’s esophagus<sup>[13]</sup>. Thus, our population sample is not representative of the NERD population at large, but reflects a more homogenous subgroup of NERD patients, which can be defined as having a “true” acid-

Table 3 Baseline reflux parameters of pH-metry and BMI in patients showing a progression at follow-up vs those not showing development of esophagitis (mean ± SD)

Risk factor	Odds ratio (95% CI)	P value
Smoking	2.9 (1.4-6.2)	0.0055
Ongoing PPI therapy	0.2 (0.09-0.7)	0.04

related NERD. In fact, whereas the majority of NERD patients with abnormal pH test have > 75% of heartburn occurring during an acid reflux event, this happens in only 10% of NERD patients with a negative pH test<sup>[13]</sup>. The particular selection of our patients may be viewed as a limitation as far as the translational capability of the results. On the other hand, the patients have been more precisely defined than solely on the basis of presence of symptoms and negativity of endoscopic features. The natural history of patients such as ours is at present incompletely known; in a previous retrospective study of a small cohort of pH test-positive NERD patients we demonstrated a progression to erosive esophagitis in 5 out of 33 patients treated over a 6 mo period with antacids and/or prokinetics<sup>[11]</sup>. In a subsequent study<sup>[10]</sup>, we extended the observation time of the original patient group up to a median duration of 10 years. We found that almost all the patients we were able to trace (28/29) became affected by GERD symptoms when antisecretory drugs were discontinued, and therefore the majority (75%) were on such a therapy due to GERD symptoms. In addition, esophagitis was found in the vast majority of subjects in whom repeat endoscopy was performed (18/28). Thus, a considerable proportion of the original patient cohort indeed showed a progression from nonerosive to erosive disease within a long enough (> 5 years) time interval.

Other studies, such as that undertaken by Schindlbeck *et al*<sup>[14]</sup> or by McDougall *et al*<sup>[15]</sup>, support the concept that a progression to esophagitis occurs at least in a proportion of NERD patients with a positive pH test at presentation. These results are in keeping with those recently published by Fullard *et al*<sup>[16]</sup>, who performed a systematic review of studies conducted on GERD patients. In their review, they found that the annual progression rate for NERD patients (not further characterized by pH monitoring) ranged between 0% and 30%.

The multivariate analysis in our study found only two factors were independent determinants of a negative outcome, i.e. the development of esophagitis; namely

smoking and the lack of a continuous PPI therapy.

These results seem to indicate that the information obtained with esophageal pH-monitoring in NERD patients is not useful to predict the potential progression of such patients toward erosive esophagitis. This has already been observed in the literature in the past; for example, in our previous study<sup>[11]</sup> conducted on a small and different patient sample, we found that patients who developed endoscopic esophagitis did not have a more severe baseline pattern of GER pH-metrically measured compared with those who did not develop esophageal mucosal damage. Similarly, Cadiot *et al*<sup>[17]</sup>, in a multivariate analysis of factors predicting the development of esophagitis in patients with GERD symptoms, found that three independent factors contributed significantly to differentiating between patients with and without esophagitis; namely basal lower esophageal sphincter pressure, peak acid output and the number of reflux episodes during a 24 h period lasting more than 5 min, but not the total esophageal acid exposure time. Also a stepwise regression analysis, conducted on 66 GERD patients and 16 asymptomatic controls, found that hiatal hernia size and basal lower esophageal sphincter pressure, but not esophageal acid exposure or number of reflux episodes during a 24 h period lasting more than 5 min, significantly predicted presence and severity of esophagitis<sup>[18]</sup>. Moreover, Labenz *et al*<sup>[19]</sup> in a very large prospective study involving more than 6000 GERD patients (The ProGERD Study Initiative) found that no single factor or combination of factors was capable of predicting the presence of esophageal mucosal damage at multivariate analysis. In a case-control study of nearly 5000 patients with and without endoscopic reflux esophagitis investigated with a multivariate regression logistic analysis, Avidan *et al*<sup>[20]</sup> found that the only statistically significant factor associated with development of esophagitis was the presence of hiatal hernia. In both studies, however, no pH esophageal recording was performed. Moreover, all these studies were conducted on a mixed GERD population, e.g. patients with and without erosive esophagitis, and aimed at finding factors capable to discriminate these two categories.

Our study followed a different approach; we followed up a cohort of NERD patients and tried to locate factors potentially related to evolution into erosive esophagitis. The only similar study we were able to find in the literature is a study conducted in Japan, in which 47 patients with symptomatic GERD but without esophagitis (NERD) and 450 control subjects were endoscopically investigated at yearly intervals for 5 years, apparently without receiving any antisecretory therapy during this period<sup>[21]</sup>. The researchers found that among the group of NERD patients, esophagitis developed in 31.9% as compared with 11.3% in the control group ( $P < 0.01$ ), and that the risk of developing esophagitis was significantly related to absence of *Helicobacter pylori* infection ( $P < 0.01$ ), absence of gastric mucosal atrophy ( $P < 0.01$ ), elevated triglycerides during the 5-year follow-up ( $P < 0.05$ ), and an elevated BMI ( $P < 0.05$ ), with a Cox proportional

hazard model<sup>[21]</sup>. This study is however hardly transferable to clinical practice due to exclusion of adequate therapy during the 5-year of follow-up, which in our opinion is an insurmountable ethical drawback of the investigation.

The apparent lack of a relationship between extent of esophageal acid exposure time (and other pathophysiologic parameters of reflux and of esophageal motility) and development of esophagitis has been taken into consideration recently<sup>[22]</sup>, and it has been suggested that the majority of investigations conducted so far have overlooked the resistance of the esophageal mucosa. Although the effect of smoking on GERD symptoms and lesions is not clear-cut, it probably acts on different pathogenetic sites, including mucosal resistance. Smoking may in fact promote GER by several mechanisms including; attenuation of the tone at the lower esophageal sphincter<sup>[23,24]</sup>, a decrease in salivary flow and bicarbonate secretion with a resultant prolongation of acid clearance<sup>[25]</sup>, and a delay in gastric emptying<sup>[26,27]</sup>. Some additional effects of smoking and nicotine that may be relevant to GERD are; an increase in gastric acid and pepsin secretion, augmentation of duodeno-gastric bile reflux and attenuation of the protective mechanisms of the gastric mucosa, such as synthesis of prostaglandins, mucus and epidermal growth factor<sup>[28]</sup>. Finally, in a recent study conducted on a NERD population which included a pathological pH investigation, smoking was found to be an independent predictor of GERD symptoms at multiple linear regression analysis<sup>[29]</sup>.

In conclusion, our study shows that progression to ERD occurs in a considerable proportion of NERD patients (close to 5% per year) despite standard therapy, whereas symptomatic relapse occurs more frequently than once per year. Factors consistently and independently influencing this progression are smoking and the lack of a continuous PPI therapy during the follow-up period.

## COMMENTS

### Background

The natural history of nonerosive gastro-esophageal reflux disease (NERD) is not entirely known. In particular, data are lacking regarding the subgroup of NERD patients with abnormal esophageal pH monitoring. The authors conducted a study to assess the fate of these patients who were followed for a mean of 5 years after the index evaluation.

### Research frontiers

To evaluate by means of a multivariate analysis potential factors leading to a progression of the disease, e.g. the development of mucosal lesions.

### Innovations and breakthroughs

The present study showed that progression to erosive gastro-esophageal reflux disease occurred in about 5% of their NERD patients per year, despite therapy. Only two factors consistently and independently influenced progression: smoking and absence of proton pump inhibitor (PPI) therapy.

### Applications

Due to the clinically relevant number of NERD patients evolving to esophagitis, it is conceivable that the present guidelines for endoscopy in gastro-esophageal reflux disease (GERD) should be changed. In particular, the authors propose the repetition of upper gastrointestinal (GI) endoscopy at least once every 5 years.

### Peer review

The authors have conducted a retrospective study which provides useful information regarding the natural history of nonerosive reflux disease patients and the potential factors leading to esophageal mucosal lesions over 5 years of follow-up.

### Abstract

**AIM:** To analyze the correlation between preexisting comorbidity and other clinicopathological features, short-term surgical outcome and long-term survival in elderly patients with colorectal cancer (CRC).

**METHODS:** According to age, 403 patients operated on for CRC in our department were divided into group A (< 70 years old) and group B ( $\geq$  70 years old) and analyzed statistically.

**RESULTS:** Rectal localization prevailed in group A (31.6% vs 19.7%,  $P = 0.027$ ), whereas the percentage of R0 resections was 77% in the two groups. Comorbidity rate was 46.2% and 69.1% for group A and B, respectively ( $P < 0.001$ ), with a huge difference as regards cardiovascular diseases. Overall, postoperative morbidity was 16.9% and 20.8% in group A and B, respectively ( $P = 0.367$ ), whereas mortality was limited to group B (4.5%,  $P = 0.001$ ). In both groups, patients who suffered from postoperative complications had a higher overall comorbidity rate, with preexisting cardiovascular diseases prevailing in group B ( $P = 0.003$ ). Overall 5-year survival rate was significantly better

for group A (75.2% vs 55%,  $P = 0.006$ ), whereas no significant difference was observed considering disease-specific survival (76.3% vs 76.9%,  $P = 0.674$ ).

**CONCLUSION:** In spite of an increase in postoperative mortality and a lower overall long-term survival for patients aged  $\geq$  70 years old, it should be considered that, even in the elderly group, a significant number of patients is alive 5 years after CRC resection.

Impact of age-related comorbidity on results of colorectal cancer surgery. *World J Gastroenterol* 2009; 15(45): 5706-5711 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5706.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5706>

### INTRODUCTION

Colorectal cancer (CRC) generally is considered a disease of the elderly<sup>[1]</sup> because of its rising incidence with age<sup>[2-6]</sup>. It represents an important cause of morbidity and mortality in the elderly population<sup>[1]</sup>, which mainly undergo emergency surgery because of bowel obstruction or perforation<sup>[1,2,7-9]</sup>. Several authors have reported that elderly patients with CRC can be treated by standard surgical resection and surgery should not be denied on account of chronological age<sup>[1,3,8,10,11]</sup>. Comorbidity, previously different tumors, and poor performance status represent the early and late negative prognostic factors in elderly patients<sup>[1,2,7,10,12-15]</sup>. The purpose of this observational study was to evaluate our experience with CRC, to assess surgical and prognostic features of patients aged  $\geq$  70 years compared with younger patients, with special reference to related comorbidity.

## MATERIALS AND METHODS

### Population under study

Between January 1999 and March 2006, 420 patients with CRC were observed in our department. Among these, seven patients were not operated on because of their poor general status or advanced stage of disease, and 10 patients were lost at follow-up. Thus, 403 patients (229 male and 174 female) with a mean ( $\pm$  SD) age of  $67.2 \pm 11.5$  years (range 23-98 years) were analyzed retrospectively. According to the age at operation, two groups were considered: group A (< 70 years old; 225 patients) and group B ( $\geq$  70 years old; 178 patients).

### Preoperative assessment and staging

Upon admission, all patients were studied with colonoscopy, abdominal ultrasonography and computed tomography (CT) to gain a correct preoperative staging. All comorbidity was noticed and patients underwent clinical and instrumental examinations. Cardiac diseases were assessed as electrocardiographic or echocardiographic abnormalities, or pathology for which the patient was under specific treatment; vascular pathology as cases of hypertension treated with specific drugs; cerebrovascular pathology; pulmonary diseases as abnormal spirometry, or pathology for which the patient was taking medication. Surgical risk was evaluated preoperatively with ASA score by a senior anesthesiologist. Antibiotic and thromboembolic prophylaxis was performed in all patients. The presence of residual tumor (R category) and tumor stage (TNM) were defined on the basis of the criteria established by the Union International Contre Le Cancer (UICC).

### Surgical approach and techniques

The main goal of surgery was the complete removal of the tumour (R0 resection), although palliative resection was performed to treat tumor-related complications. Right and left hemicolectomy, low or very low anterior resection, or transverse colon resection were carried out as standard techniques for CRC, with vessel ligation and respecting oncological criteria. In the event of multiple and synchronous localization, the extent of resection was chosen case by case. Hartmann resection was performed rarely. Definitive loop colostomy or ileostomy was reserved for advanced tumors or patients with very bad performance status in the event of severe bowel obstruction. Temporary covering ileostomy at primary surgery was planned mainly for very low anterior resection for rectal cancer.

### Follow-up and statistical analysis

All clinical and surgical data were collected and stored in a PC database. The data concerning follow-up were collected during outpatient clinical examination and by contacting the family physician. The collected data included demographic and clinical characteristics, co-morbidity (cardiovascular, pulmonary and digestive diseases, diabetes mellitus and other tumors), site of neoplasm (colon or rectum), type of surgery (elective or emergency), presence of residual tumour (R0 or R1-2 resection), histological features, tumour stage (TNM) and Dukes' classification,

as well as postoperative morbidity and mortality. A particular effort was made to analyze comorbidity, postoperative complications and survival rates, to identify specific features of the two groups under study. Cardiovascular diseases included heart disease such as myocardial ischemia or valvular disease, both with hypertension and cerebrovascular disorders; and aortic as well as peripheral arterial disorders were also included. Digestive comorbidity included major gastrointestinal, hepatic or biliary-pancreatic diseases such as inflammatory bowel disease, pancreatitis, hepatic cirrhosis and portal hypertension. We also focused on patients who were affected by tumors other than CRC, including them in the "other tumor" comorbidity group. In assessing postoperative complications and mortality, events that occurred during hospitalization or within 30 d after operation were included in the analysis. Diseases such as pulmonary embolism, myocardial ischemia or acute renal failure, and surgical complications, such as anastomotic leakage or abdominal infection, were considered separately. Statistical differences in clinicopathological characteristics and comorbidity between the groups were assessed by the  $\chi^2$  test for categorical variables and Student's *t* test for continuous variables. Survival curves were calculated according to the Kaplan-Meier model. Survival curves were calculated for the two groups with regard to overall and disease-specific survival; operative mortality was calculated in the analysis. The log-rank test was used to assess the difference between the two groups.  $P < 0.05$  was considered significant.

## RESULTS

### Clinicopathological findings

Clinicopathological features and presence of comorbidity in the two groups are reported in Table 1. Among the 403 patients, we observed 106 tumors that arose from the rectum, 109 from the right colon, 20 from the transverse colon, and 160 from the descending or sigmoid colon. Multiple tumors were observed in eight cases. Rectal tumors prevailed in group A (31.6% *vs* 19.7%,  $P = 0.027$ ); otherwise, topographic distribution of colon cancer was rather homogeneous between the two groups. Elderly patients underwent emergency operation more frequently compared to younger ones, although the difference was not statistically significant (14% *vs* 9.3%,  $P = 0.094$ ). A potentially curative (R0) resection was achieved with a rate of about 77% in both groups ( $P = 0.512$ ). With respect to the Dukes' and TNM classifications, no significant differences were noted between groups A and B. As regards comorbidity, our findings suggest a significant difference between group A and B with an overall rate of 46.2% and 69.1%, respectively ( $P < 0.001$ ). By analyzing different comorbidity in each group, we found that patients aged  $\geq 70$  years had a 51.1% rate of cardiovascular diseases compared to 30.7% in the younger ones ( $P < 0.001$ ). Weak differences were noticed between group A and B with respect to pulmonary diseases ( $P = 0.048$ ) and other tumors ( $P = 0.050$ ). Other comorbidity did not show any significant features in either of the populations studied.

### Short-term postoperative results

The distribution of surgical procedures is reported in Table 2. Hartmann resection and palliative stoma were performed rarely, and mostly they were carried out in elderly patients. Concerning the postoperative period, overall morbidity was 16.9% and 20.8% in group A and B, respectively ( $P = 0.367$ ). No significant difference was observed as regards surgical complications, whereas medical adverse events were twofold greater in group B compared to group A (9% vs 4.8%,  $P = 0.122$ ). Among cardiovascular complications, acute heart failure or pulmonary edema was the most common postoperative morbidity. Among surgical complications, the percentage

**Table 2** Surgical procedures and postoperative results *n* (%)

	Group A ( <i>n</i> = 225)	Group B ( <i>n</i> = 178)	<i>P</i>
Postoperative mortality	-	8 (4.5)	0.001
Postoperative complications	38 (16.9)	37 (20.8)	0.367
Surgical complications	27 (12)	21 (11.8)	1
Medical complications	11 (4.9)	16 (9)	0.112
Operation			
Right hemicolectomy	53 (23.6)	61 (34.3)	
Left hemicolectomy	73 (32.4)	50 (28.1)	
Transverse colon resection	5 (2.2)	9 (5.1)

Lower anterior resection	78 (34.7)	43 (24.2)	
Hartmann resection	1 (0.4)	4 (2.2)	
Stoma	2 (0.9)	2 (1.1)	
Miscellaneous	4 (1.8)	1 (0.6)	
Anastomotic leakage rate	10 (4.4)	4 (2.3)	0.282

with anastomosis leakage was 3.5%, with a higher number of cases in group A (4.4% vs 2.3%,  $P = 0.282$ ). Overall postoperative mortality was 2% and it was limited to patients aged ≥ 70 years (4.5%,  $P = 0.001$ ) (Table 2).

### Preexisting comorbidity and short-term results

Table 3 shows the correlation between clinicopathological features, preexisting comorbidity and the occurrence of postoperative complications. The overall comorbidity rate was significantly higher in patients who developed postoperative complications in groups A and B. In group A, male patients experienced complications more frequently than females ( $P = 0.049$ ). In group B, preexisting cardiovascular diseases were significantly associated with postoperative complications ( $P = 0.003$ ). Other features did not influence significantly the postoperative course.

### Survival analysis

The 5-year survival rate for all 403 patients was 62.9%, whereas it was 76.4% for the R0-resected patients. Considering all causes of death, the overall 5-year survival rate was significantly better for group A (75.2% vs 55%,  $P = 0.006$ ) (Figure 1). Conversely, considering disease-specific survival (postoperative and tumor-related deaths only), no difference was observed between groups A and B (76.3% vs 76.9%,  $P = 0.674$ ) (Figure 2).

## DISCUSSION

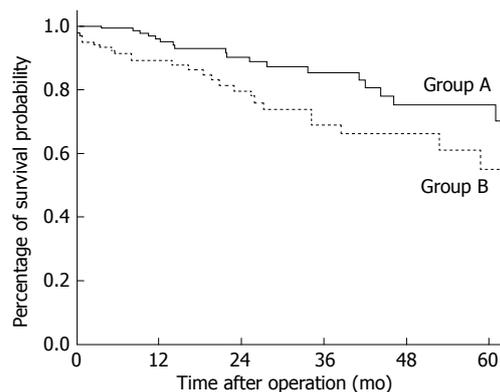

### CRC in the elderly

As for other tumors, the development of CRC is associated with increasing age. The reason for cancer development in the elderly can be explained by a longer duration of exposure to carcinogens, a lower ability to repair damaged DNA, and oncogene amplification or tumor suppressor gene malfunction. Furthermore, the progressive loss of immune surveillance can be considered to occur with aging<sup>[8,16]</sup>. Despite progress in surgical and perioperative care, a lot of physicians evaluate elderly patients by their chronological rather than biological age<sup>[17]</sup>. This attitude may explain why treatment is frequently conditioned in elderly people with malignancies. As a consequence, their therapeutic

management remains controversial. As a result of their age, elderly people usually suffer from other chronic illnesses in addition to colorectal malignancy. Nonetheless, surgical resection remains the treatment of choice, probably because surgery still represents the mainstay of therapy for CRC, and the most used option to treat bowel obstruction. In a recent study by Lemmens *et al*<sup>[18]</sup>, it has been demonstrated that age > 70 years, a tumor located in the rectum, emergency surgery, and the presence of concomitant chronic obstructive pulmonary disease or deep vein thrombosis increase the risk of developing a surgical complication. On the contrary, CRC patients without comorbidity developed surgical complications in < 30% of the cases.

**Figure 1** Kaplan-Meier estimates of survival probability for R0 population in group A (< 70 yr; 174 pts) and B (≥ 70 yr; 137 pts). Postoperative, tumor-related and -unrelated deaths were included (Log-rank test, *P* = 0.006).

**Figure 2** Kaplan-Meier estimates of disease-specific survival probability for R0 population in group A (< 70 yr; 174 pts) and B (≥ 70 yr; 137 pts). Postoperative and tumor-related deaths were included (Log-rank test, *P* = 0.674).

**Postoperative morbidity**

With reference to our results, we had a comparable postoperative morbidity rate<sup>[19]</sup>, with no statistically significant difference between the two groups. Considering medical complications, elderly patients had a twofold greater, even though not significant, rate of adverse events such as pulmonary embolism and myocardial ischemia. This may be due to a higher prevalence of cardiovascular diseases at the time of cancer diagnosis. Our previous study supports these data that show that cardiac complications are the most frequent in octogenarians affected by gastrointestinal carcinoma<sup>[20,21]</sup>. Based upon our findings, cardiovascular comorbidity has a significant influence on the development of postoperative complications in elderly as well as younger patients. As regards postoperative complications, we observed a low rate of complications with no difference between the two groups. Our data seem to confirm the possibility of achieving a very low percentage of adverse events in aged patients, with curative resection and overall anastomotic leakage rates equally successful in both groups.

**Comorbidity and postoperative complications**

Current literature supports the notion that a higher mortality rate in older patients can be attributed mainly to preexisting comorbid conditions<sup>[10,22]</sup>, such as congestive

heart failure, diabetes mellitus and chronic obstructive pulmonary disease<sup>[23]</sup>. It also emphasizes the role of interactions between disease conditions and CRC, and suggests that multiple comorbidity has a substantial effect on long-term survival. The number of comorbid conditions increases with age and the most frequent diseases are hypertension, other cardiovascular diseases and previous malignancy<sup>[1,12]</sup>. In agreement with other experiences, male patients have a higher prevalence of postoperative complications compared to females<sup>[24]</sup>, and an explanation may be found in the lower number of women suffering from cardiovascular diseases, especially at younger ages. Our data confirmed that elderly patients, in spite of an equal percentage of postoperative complications, have a higher mortality rate compared to younger patients<sup>[7,10,25,26]</sup>. The relationship between preoperative comorbid conditions and postoperative mortality has been demonstrated by previous studies<sup>[10,23,27-30]</sup>. Moreover, we assessed that in most of the eight patients who died, there was more than one comorbid condition. These results suggest that postoperative complications are tolerated poorly by elderly patients, particularly those suffering from comorbidity.

#### Overall and tumor-related survival

In the elderly population with CRC, the relationship between age and long-term outcome after surgery remains not yet completely defined, and the results on survival are still a matter of debate, with alternative conclusions<sup>[3,7]</sup>. Regarding overall survival, it has been demonstrated that it decreases with aging<sup>[1]</sup>. Nonetheless, disease stage influences specific tumor survival independently of age. It has been reported that the decrease in survival is more evident in very old patients, particularly those aged > 85 years. In this regard, our findings clarify that elderly people have a significantly worse overall survival rate compared to younger ones, but, after censoring cancer-unrelated deaths, survival rates become comparable. Thus, strictly considering tumor-related mortality, no difference was observed between the two groups. Other authors have supported our results<sup>[2]</sup> and have emphasized the relationship between early stage of the disease and a similar prognosis in elderly compared to younger patients. In spite of an increase in postoperative mortality and a shorter overall long-term survival for patients aged  $\geq$  70 years, it should be considered that, even among elderly patients, a significant number of patients is alive 5 years after CRC resection.

In conclusion, in agreement with previous studies, our findings suggest that a relevant positive outcome after a potentially curative resection should encourage surgical treatment of elderly patients with CRC. Comorbidity represents a risk factor for developing postoperative complications in younger and older patients. A higher risk of postoperative mortality seems to be a prerogative of elderly patients affected by other comorbid conditions, especially cardiovascular diseases. As a consequence, surgeons should be more cautious when confronted with elderly patients suffering from severe comorbidity. Even if treatment decisions in elderly patients with CRC should be

made on the basis of careful evaluation of cardiovascular and pulmonary parameters, surgical tumor resection clearly is encouraged by high rates of potentially curative resection and satisfactory long-term survival results.

## COMMENTS

### Background

Colorectal cancer (CRC) generally is considered to be a disease of the elderly. Several studies have reported that elderly patients with CRC can be treated by standard surgical resection, although some debate still exists on this topic.

### Research frontiers

The correlation between preexisting comorbidity, clinicopathological features, and short- and long-term outcomes was studied in elderly patients undergoing surgery for CRC.

### Innovations and breakthroughs

A particular effort has been made to analyze preexisting comorbidity, postoperative complications and long-term results, to identify features specific for elderly patients compared to younger ones.

### Applications

In spite of an acceptable increase in postoperative mortality and a shorter overall long-term survival, surgical resection provides encouraging results for patients aged  $\geq$  70 years.

### Peer review

The authors investigated the relationship between preexisting diseases and other clinicopathological features, perioperative surgical outcome, and survival in elderly patients with CRC treated by surgery. The conclusions are definite, and the contents are well-organized and well-written. The results give us some new ideas about the elderly population undergoing surgery for CRC.

### Abstract

**AIM:** To investigate the effects of a novel Leukotriene B<sub>4</sub> receptor antagonist and/or tacrolimus on ischemia-reperfusion in a rat liver model.

**METHODS:** Male Lewis rats were pretreated with ONO-4057 (100 mg/kg) and/or tacrolimus (1 mg/kg) orally, and divided into four experimental groups; group 1 (control), group 2 (ONO-4057), group 3 (tacrolimus), group 4 (ONO-4057 + tacrolimus).

**RESULTS:** There was a tendency for long survival in the groups treated with tacrolimus alone and ONO-4057 plus tacrolimus. Post-reperfusion serum aspartate aminotransferase levels decreased more significantly in ONO-4057 plus tacrolimus group ( $P < 0.01$ ), than in the tacrolimus alone group ( $P < 0.05$ ), compared to controls.

**CONCLUSION:** This study demonstrated that pretreat-

ment with ONO-4057 in combination with tacrolimus produced additive effects in a rat model of liver ischemia-reperfusion injury.

Effect of ONO-4057 and tacrolimus on ischemia-reperfusion injury of the liver. *World J Gastroenterol* 2009; 15(45): 5712-5715 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5712.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5712>

### INTRODUCTION

Neutrophils are mainly responsible for the physiopathological changes that occur after ischemia-reperfusion injury<sup>[1-3]</sup>. These cells are markedly activated when the ischemically damaged liver is transplanted. Experimental efforts have focused on understanding the etiology of ischemic injury and protecting the liver by pharmacological intervention<sup>[4-7]</sup>.

Pretreatment with certain immunosuppressive drugs has been shown to protect against neutrophil-mediated reperfusion injury<sup>[4,5]</sup>. Calcineurin inhibitors are thought to suppress both proinflammatory cytokine production and expression of adhesive molecules of neutrophils<sup>[8]</sup>. Recently, ONO-4057 (5-[2-(2-carboxyethyl)-3-{6-(4-methoxyphenyl)-5E-hexenyl}yphenoxy]valeric acid), an orally administered active leukotriene B<sub>4</sub> (LTB<sub>4</sub>) receptor antagonist, was developed and was shown to have an important effect on LTB<sub>4</sub>-induced neutrophil function<sup>[6,7]</sup>.

In this study, we investigated the effect of pretreatment with ONO-4057 alone and in combination with tacrolimus on ischemia-reperfusion injury of the liver in rats.

### MATERIALS AND METHODS

#### Animals

Male Lewis rats (Charles River, Hamamatsu, Japan),

5-6 wk of age, were used in this study. The animals were housed in a pathogen-free, temperature- and light-controlled environment with free access to food and water. The rats were anesthetized with ether for induction and maintenance. All experimental protocols were approved by the institutional review board of Kyoto University.

### Experimental groups

The animals were divided into four experimental groups: group 1, controls; group 2, ONO-4057; group 3, tacrolimus; and group 4, ONO-4057 and tacrolimus ( $n = 9$  in each group). The control groups received distilled water (DW) and  $\text{NaHCO}_3$  as a vehicle administered orally, and the other groups were pretreated with ONO-4057 (Ono Pharmaceutical Co., Ltd., Osaka, Japan) and tacrolimus (Fujisawa Pharmaceutical Co., Osaka). ONO-4057 was dissolved to a concentration of 30 mg/mL with  $\text{NaHCO}_3$ , and tacrolimus was dissolved to a concentration of 0.3 mg/mL with DW. ONO-4057 was administered orally at a dose of 100 mg/kg and tacrolimus orally at a dose of 1 mg/kg. All agents were administered 1 h before ischemia was induced.

### Ischemia-reperfusion model

**Whole-liver ischemia model:** Normothermic ischemia of the entire liver (with intestinal congestion) was induced as described previously<sup>[8]</sup>. Briefly, a midline incision was made after the animals were anesthetized with ether and the portal vein, hepatic artery, and bile duct were clamped for 40, 50 and 60 min with a vascular micro-clip. The clip was then released and the abdominal wall was closed using a continuous running suture. The animals were returned to their cages for survival analysis for the following 2 wk.

**Partial-liver ischemia model:** To obtain data about more severe normothermic ischemia damage of the liver without intestinal congestion, the left and middle portal vein and hepatic artery were occluded for 60 min according to the procedure of Kawano *et al.*<sup>[9]</sup> with a minor modification. This procedure induced 70% warm-ischemic liver damage, but 30% healthy liver remained to protect the animal's life. After reperfusion, the abdominal wall was closed, and the treated rats were observed. One mL of the peripheral blood were obtained at 3 and 6 h after de-clamping, then the liver was perfused with 10 mL cold saline and immediately taken out. The damaged part of the liver was used for histological assessment and measurement of liver-tissue myeloperoxidase (MPO).

### Serum measurements

Using the peripheral blood obtained from the experimental animals, serum transaminase concentrations [aspartate aminotransferase (AST); alanine aminotransferase (ALT)] were measured by an ultraviolet method using an automatic analyzer (Hitachi 7170, Tokyo, Japan).

### Histological examination

Hepatic samples were fixed in 10% buffered formaldehyde,

Table 1 Survival rates with various pretreatments

Duration of ischemia (min)	Survival rates (%)			
	Controls	ONO-4057	Tacrolimus	ONO-4057 + tacrolimus
40	6/6 (100)	6/6 (100)	NT	NT
50	6/6 (100)	6/6 (100)	NT	NT
60	2/9 (22)	4/9 (44)	6/9 (66)	5/9 (56)

NT: Non-tested.

embedded in paraffin, cut to 3 to 5  $\mu\text{m}$  thick, and stained with hematoxylin and eosin. The specimens were blindly analyzed to evaluate the histological damage according to the modified classification of Suzuki *et al.*<sup>[4]</sup>.

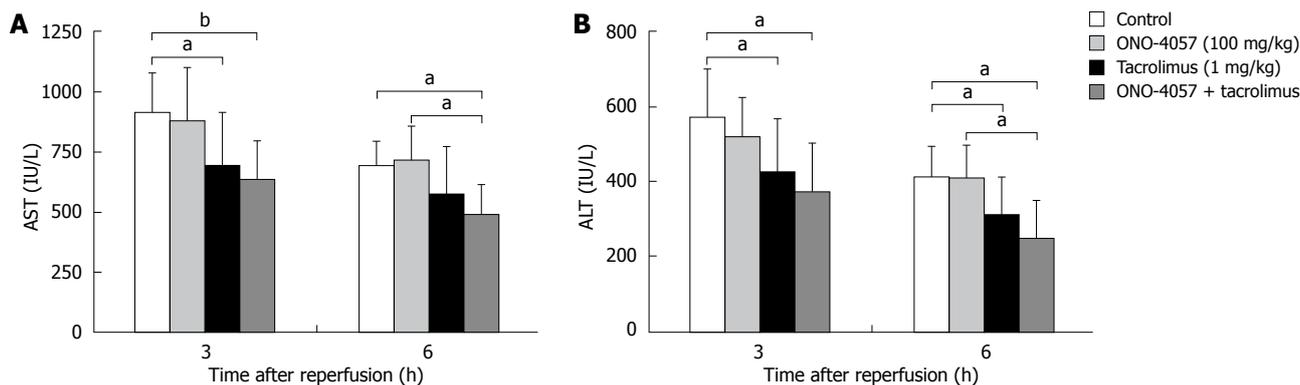

**Liver-tissue MPO activity:** MPO tissue level is considered to be an index of neutrophil infiltration in the liver. Liver samples obtained at 6 h after reperfusion were frozen in liquid nitrogen and stored at  $-70^\circ\text{C}$  until the time of measurement. Tissue samples were then homogenized in 10 mL phosphate-buffered saline and centrifuged at 100 000  $g$  and  $4^\circ\text{C}$  for 30 min. The resultant supernatant was assayed for MPO activity using the modified method of Shindler *et al.*<sup>[10]</sup>. Briefly, the reaction mixture, containing 10:1 of supernatant and 200:1 of 100 mol/L ABTS buffer with  $\text{H}_2\text{O}_2$ , was incubated in 96-well plate for 60 min at  $25^\circ\text{C}$ . The optical density at 414 nm was determined by a plate reader (SPECTRA max<sup>TM</sup> 340; Molecular Devices Co., CA, USA). The MPO activity was calculated using an extinction coefficient of  $(3.6 \times 10^4)/(\text{mol per cm})$  for ABTS and normalized to protein levels ( $\mu\text{mol}/\text{mg protein}$ ). The protein concentration was determined by the method of Lowry *et al.*<sup>[11]</sup>.

### Statistical analysis

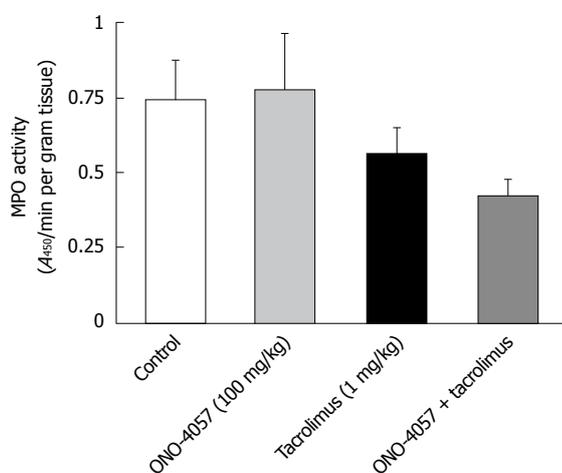

The repeated measurement analysis of variance (ANOVA) was performed among the groups. If repeated measurement ANOVA revealed a significant interaction, the statistical significance among the four groups at each time point was determined using post hoc tests. A  $P$  value of less than 0.05 was considered statistically significant.

## RESULTS

Survival after pretreatment with ONO-4057 and/or tacrolimus on whole-liver ischemia in rats is shown in Table 1. Because 40 to 50 min of whole liver ischemia in adult Lewis rats (about weighting 280-330 g) was sublethal, we initially evaluated the 40 to 50 min ischemic damage in young Lewis rats in this study. However, all rats that had undergone 40 or 50 min of whole-liver ischemia survived indefinitely. When the results of 60 min of ischemia were evaluated, there was no significant difference in survival rate among the groups. However, the survival rate was slightly higher in the groups treated with tacrolimus alone ( $P = 0.053$ ) and ONO-4057 plus tacrolimus. Serum AST values at 3 and 6 h after partial-liver ischemia-reperfusion are shown in Figure 1A. In the group pretreated with tacrolimus alone, the serum

**Figure 1** Serum transaminase levels after reperfusion. A: Aspartate aminotransferase (AST) levels after partial-liver ischemia for 60 min; B: Alanine aminotransferase (ALT) levels after partial-liver ischemia for 60 min. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

**Figure 2** Myeloperoxidase (MPO) activity after reperfusion.

AST value was significantly lower than the control group at 3 and 6 h after reperfusion ( $P < 0.05$ ), respectively. In the group pretreated with ONO-4057 plus tacrolimus, the AST level was more significantly lower compared with the control group ( $P < 0.01$ ). Pretreatment with ONO-4057 and tacrolimus produced additive effects, but not when compared with the group treated with tacrolimus alone. ONO-4057 alone could not decrease the transaminase levels. Serum ALT values demonstrated a similar pattern (Figure 1B).

The liver MPO levels after 6 h of reperfusion are shown in Figure 2. There was no significant difference among the groups in MPO activity. However, the MPO level in the group treated with ONO-4057 plus tacrolimus tended to be lower compared with that in the control group, although it was not statistically significant ( $P = 0.059$ ). At 6 h from the reperfusion after 60 min of partial liver ischemia, the liver damage (congestion, vacuolization, and necrosis) that was observed histologically was not significantly different among the groups.

## DISCUSSION

In liver transplantation, ischemia-reperfusion injury is one of the major factors that might influence early graft function and late changes. The importance of

neutrophils in the development of ischemia-reperfusion injury in the liver has been demonstrated<sup>[12,13]</sup>.

LTB<sub>4</sub>, a metabolite formed *via* the 5-lipoxygenase pathway from arachidonic acid, is one of the most potent chemotactic and proinflammatory mediators. LTB<sub>4</sub> causes neutrophil adhesion to vascular endothelial cells and infiltration into vascular endothelial cells. We investigated the effect of the LTB<sub>4</sub> receptor antagonist, ONO-4057, on hepatic ischemia-reperfusion injury to determine whether they affect neutrophil infiltration into the liver and attenuate neutrophil-induced post-ischemic injury. Recent reports have also shown that some immunosuppressive drugs protect or attenuate the neutrophil-mediated ischemia-reperfusion injury in various organs (liver, small intestine, kidney, and heart)<sup>[5,14,15]</sup>. As tacrolimus has variable effects<sup>[16]</sup>, we tested the effect of a combination of ONO-4057 with tacrolimus. The results showed that ischemia-reperfusion injury in the liver was not reduced by pretreatment with ONO-4057 alone. Tacrolimus was necessary for protection from I/R injury. Pretreatment with ONO-4057 had additive effects on the protective function of tacrolimus. Although the I/R damage was significantly prevented with the use of Tac and ONO-4057, the main damage might be related directly to the role of immunosuppressants. The suppression of the elevation of transaminases after I/R in this experiment might be mainly caused by the effect of tacrolimus. The MPO level in the liver specimens and the blood level of the transaminases did not correlate well in this study. MPO levels might be affected sub-significantly by the ONO-4057-mediated modification of neutrophil infiltration, but it did not directly prevent the hepatic damage.

Hepatic ischemia-reperfusion injury is caused by many factors, and this study has limited because it only focused on neutrophils' infiltration. Two main causes have been reported for I/R injury; oxygen free radicals and neutrophil-mediated damage. Recent reports showed a beneficial effect of neutrophil-mediated inhibitors, such as neutrophil elastase inhibitor and tissue factor pathway inhibitor, on hepatic reperfusion injury<sup>[17,18]</sup>. In another study, treatment with leukotriene biosynthesis inhibitor (L664,536) had no effect on hepatic injury, although LTB<sub>4</sub> formation was inhibited<sup>[19]</sup>. We showed the added effect

of a LTB<sub>4</sub> receptor antagonist and immunosuppressive drug. As ONO-4057 has been also reported to have an immunosuppressive effect in allogenic rat liver grafts<sup>[20]</sup>, co-administration of ONO-4057 and tacrolimus might be reasonable for liver transplantation. Before any clinical trials, experiments using the transplantation model might be necessary.

In conclusion, our data showed that pretreatment with ONO-4057 in combination with tacrolimus produced additive effects in liver reperfusion-injury of rat, although treatment with ONO-4057 alone had no effect.

## COMMENTS

### Background

Ischemia-reperfusion injury is a major factor that might influence early graft function in liver transplantation. In this study, we investigated the effect of oral administration, a novel Leukotriene B<sub>4</sub> (LTB<sub>4</sub>) receptor antagonist, and/or Tacrolimus on ischemia-reperfusion of rat liver model.

### Research frontiers

In ischemia-reperfusion injury of the liver, an excessive inflammatory response is considered as a key mechanism. The role of neutrophils in ischemia-reperfusion injury has recently been the focus of several investigations. In this study, we focused the importance of neutrophils.

### Innovations and breakthroughs

We tested the combined effect of a LTB<sub>4</sub> receptor antagonist with Tacrolimus for ischemia-reperfusion injury of the liver.

### Applications

The findings in this study support the hypothesis that co-administration of ONO-4057 and tacrolimus might be reasonable for liver transplantation in the future.

### Peer review

This manuscript is sufficiently written and provides information concerning therapeutic options in I/R injury of the liver.

### Abstract

**AIM:** To evaluate the association of glutathione S-transferase mu (GSTM1) and glutathione S-transferase theta (GSTT1) null genotypes with the risk of gastric cancer (GC) and colorectal cancer (CRC) in a South Korean population.

**METHODS:** We conducted a population-based, large-scale case-control study including 2213 GCs, 1829 CRCs, and 1699 controls. Null and non-null genotypes

of GSTM1 and GSTT1 were determined using real-time PCR.

**RESULTS:** The null genotypes of GSTM1 and GSTT1 were not significantly associated with elevated risk of gastric (OR = 1.070, 95% CI = 0.935-1.224; OR = 1.101, 95% CI = 0.963-1.259, respectively) or colorectal cancer (OR = 1.065, 95% CI = 0.923-1.228; OR = 1.041, 95% CI = 0.903-1.200, respectively). The frequency of the combined null GST genotype was not different between the two cancer groups and controls. Moreover, smoking, drinking, and age did not modify the association between these genotypes and the risk of gastric or colorectal cancer.

**CONCLUSION:** GSTM1 and GSTT1 null genotypes were not associated with increased risk of GC or CRC in Koreans.

Glutathione-S-transferase (GSTM1, GSTT1) and the risk of gastrointestinal cancer in a Korean population. *World J Gastroenterol* 2009; 15(45): 5716-5721 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5716.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5716>

### INTRODUCTION

Gastric cancer (GC) and colorectal cancer (CRC) are the most common malignancies in Korea. Environmental factors, such as diet, infection, and smoking, and genetic factors have been shown to play a role in the development of these malignancies<sup>[1-4]</sup>.

The glutathione S-transferase (GST) enzymes

are involved in detoxification of many potentially carcinogenic compounds. The enzymes are encoded by at least five distantly related gene families (the alpha, mu, pi, sigma, and theta GSTs). In humans, marked interindividual differences exist in the expression of mu (GSTM1), and theta (GSTT1) GSTs<sup>[5]</sup>. The GSTM1 and GSTT1 null genotypes have been linked to increased risk of developing lung, bladder, colon, and skin cancers<sup>[5-7]</sup>, and several studies have shown that GSTM1 and GSTT1 null genotypes were associated with increased risk of GC<sup>[8,9]</sup> and CRC<sup>[10]</sup>. However, some data have suggested that no relationship exists between the GSTM1 or GSTT1 null genotype and the risk of GC<sup>[11,12]</sup> or CRC<sup>[13,14]</sup>. The contradictory results regarding the association between GSTM1 and GSTT1 null genotypes and the risk of GC or CRC may be due to limited sample sizes or differences in the ethnicities or differences in the genetic subtypes studied, or they may also be attributable to differences in exposure to environmental factors. However, the majority of the reports involved small sample sizes, so the association of the GSTM1/GSTT1 null genotype and the risk of GC and CRC need to be confirmed in studies with larger numbers of samples.

The present study aimed to evaluate the association of the GSTM1 and GSTT1 null genotypes with the risk of GC and CRC, and to determine whether smoking, alcohol consumption, and age modify the association between these polymorphisms and GC or CRC risk.

## MATERIALS AND METHODS

### Ethics

This study was approved by the Institutional Review Board of the Chonnam National University Hwasun Hospital in Hwasun, Korea, and all patients provided informed written consent.

### Subjects

The study included 4042 newly diagnosed cancer cases (2213 GC and 1829 CRC) and 1699 controls. The cases were histologically confirmed at the Chonnam National University Hwasun Hospital (Jeollanam-do, Korea), between April 2004 and June 2008. Cases with secondary or recurrent tumors were excluded. The tumor stages were classified according to the TNM classification, including clinical or pathological TNM stages. GC was classified by anatomical site as cardia (C16.0) or non-cardia (C16.1-16.8) and by histological type as intestinal, diffuse, or mixed type.

The control group ( $n = 1699$ ) consisted of participants in the Thyroid Disease Prevalence Study conducted from July 2004 to January 2006 in Yeonggwang and Muan Counties of Jeollanam-do Province and in Namwon City of Jeollabuk-do, Korea<sup>[15]</sup>. At the time of peripheral blood collection, all case and control subjects provided their informed consent to participate in this study.

### Blood samples and DNA isolation

Blood samples were collected in EDTA-containing tubes, and DNA was extracted from the buffy coat for genotyping. Genomic DNA was extracted using a

QIAamp DNA Blood Mini Kit (Qiagen, Valencia, CA) according to the manufacturer's protocol.

### Genotyping

GSTM1 and GSTT1 genotyping was performed using a TaqMan allelic discrimination assay with previously described primers and modified probes<sup>[16]</sup>. Real-time PCR was performed using a Rotor-Gene 3000 multiplex system (Corbett Research, Sydney, Australia) in a 10- $\mu$ L reaction volume containing 200 nmol/L PCR primer, 10 nmol/L CY5-labeled probe for GSTT1, 100 nmol/L FAM-labeled probe for GSTM1, 0.5 U of *f-Taq* polymerase (Solgent, Daejeon, Korea), and 40 ng of genomic DNA. The primer and probe are as follows: GSTM1, Forward, 5'-GGAGACAGAAGAGGAGAAGATTTC-3', Reverse, 5'-GCCCAGCTGCATATGGTTGT-3', Probe, FAM-CCATGGTCTGGTTCTCCAAAATGTCCA-BHQ1; GSTT1, Forward, 5'-CTTCCAGGAGGCCCATGAG-3' Reverse, 5'-CAGGGCATCAGCTTCTGCTT-3', Probe, CY5-AAGGACTTCCCACCTGCAGACCCC-BHQ3.

### Statistical analysis

Statistical analysis was performed using SPSS for Windows version 17.0. The descriptive data for the major characteristics of study groups are expressed as mean (range) and percent. We used *t*-tests to determine statistical differences in the continuous variables and  $\chi^2$  tests for the categorical variables. Adjusted odds ratios (OR) and their 95% confidence intervals (95% CI) were calculated using logistic regression models with adjustments for age and sex to estimate the association between genotype and GC or CRC. Interactions of genotype with smoking, alcohol consumption, and age were estimated using the logistic regression model, which included an interaction term as well as variables for exposure (smoking and alcohol drinking), genotypes, and potential confounders (sex and age). Subjects with wild-type genotypes were considered to have baseline risk. The subjects for which there was missing data for smoking, drinking, anatomical site, and histological type TNM staging were excluded in interaction analysis related with these variables. All tests were conducted at the  $P = 0.05$  level of significance.

## RESULTS

We included 2213 cases of GC, 1829 cases of CRC, and 1699 cancer-free controls in the present study. The demographic characteristics of subjects are shown in Table 1. The proportion of men in the cancer cases was higher than that in the controls, and cases in both cancer groups tended to be older than controls. The proportion of smoking in GC cases was higher than that in the controls, but in CRC cases was lower than that in the controls. The proportion of drinking in both cancer groups was lower than that in the controls.

The frequency distributions of the GSTM1 null genotype in the control, GC, and CRC groups were 54.3%, 55.4%, and 54.9%, respectively. The frequency distributions of the GSTT1 null genotype in the control, GC, and CRC groups were 50.5%, 53.0%, and 51.9%,

<sup>a</sup>GC compared with control,  $P < 0.05$ ; <sup>c</sup>CRC compared with control,  $P < 0.05$ . GC: Gastric cancer; CRC: Colorectal cancer; GSTT1: Glutathione S-transferase theta; GSTM1: Glutathione S-transferase mu.

respectively. No significant differences were observed in the frequencies of the GSTT1 and GSTM1 genotypes between cancer patients and controls (Table 1).

The GSTM1 and GSTT1 null genotypes were not significantly associated with risk of GC (OR = 1.070, 95% CI = 0.935-1.224; OR = 1.101, 95% CI = 0.963-1.259, respectively) or CRC (OR = 1.065, 95% CI = 0.923-1.228; OR = 1.041, 95% CI = 0.903-1.200, respectively). The GSTM1 and GSTT1 null genotypes were not significantly associated with the risk of GC or CRC, classified according to TNM stage, tumor site or histology type (GC) (Tables 2 and 3).

Smoking, alcohol consumption and age did not modify the association between the GSTM1 and GSTT1 null genotypes and the risk of GC or CRC (Tables 2 and 3).

No difference in the frequency of the combined GSTM1 and GSTT1 null genotype was observed between the two cancer groups and controls (Table 4).

## DISCUSSION

The present large-scale study investigated the association

Table 2 GST (M1, T1) genotypes in relation of GC risk stratified by some factors

	GSTM1 (null)		GSTT1 (null)

between GSTM1 and GSTT1 null genotypes and susceptibility to GC and CRC in a South Korean population. In this study, we observed no significant association between either type of cancer and the GSTM1 and GSTT1 null genotypes. Additionally, no difference was observed in the frequency of the combined GST (M1 and T1) null genotype between the two cancer groups and controls. Moreover, smoking did not modify the association between these polymorphisms and risk of GC or CRC.

The reports examining the GSTM1 and GSTT1 null genotypes and their association with gastric cancer are quite inconsistent. Two reports suggested that the GSTM1

**Table 4** Combined GSTT1/GSTM1 genotype frequencies and their associations with risk GC, CRC *n* (%)

Combined genotypes	GC	CRC	Controls	OR <sup>1a</sup> (95% CI)	OR <sup>1b</sup> (95% CI)

T1(-)/M1(-)	800 (29.1)	648 (29.0)	467 (27.5)	1.17 (0.97-1.41)	1.11 (0.91-1.36)

Adjusted for age, sex; OR<sup>1a</sup> for gastric cancer; OR<sup>1b</sup> for colorectal cancer.

null genotype increased GC risk<sup>[8,10]</sup>, and three reported that the GSTT1 null genotype increased GC risk<sup>[9,17,18]</sup>. However, our results suggest that no associations exist which is in line with the majority of reports<sup>[11,12,19-21]</sup>. In studies of Korean populations, no significant associations were detected between the GSTM1 and GSTT1 null genotypes and GC risk. One study conducted in Iksan, Korea, reported that the GSTM1 and GSTT1 null genotypes had no association with the risk of GC (for GSTM1 null, OR = 0.86 and 95% CI = 0.49-1.51; for GSTT1 null, OR = 0.97 and 95% CI = 0.55-1.71)<sup>[12]</sup>. Hong *et al.*<sup>[20]</sup> reported similar results. Another study suggested that the GSTM1 and GSTT1 null genotypes were not associated with the risk of GC overall, but that in individuals who consumed kimchi, a spicy Korean food made with fermented cabbage, the GSTM1 and GSTT1 non-null genotype increased the risk of GC<sup>[19]</sup>. Two meta-analyses, by La Torre *et al.*<sup>[22]</sup> and Boccia *et al.*<sup>[23]</sup> suggested that the GSTM1 and GSTT1 null genotypes have no effect on the risk of GC per se, but may modulate tobacco-related carcinogenesis of gastric cancer.

Two studies reported that the GSTT1 null genotype increased the risk of CRC<sup>[10,24]</sup>, and three studies reported decreased CRC risk, one for the GSTM1 null<sup>[25]</sup> and two for the GSTT1 null genotype<sup>[26,27]</sup>. However, five studies suggested that the GSTM1 and GSTT1 null genotype are not related to CRC risk<sup>[4,8,13,14,28]</sup>. One Korean study suggested that the genotypes of GSTM1 are associated with cancer occurrence in individuals carrying the hMLH1/hMSH2 mutation who were family members of patients with hereditary nonpolyposis colorectal cancer<sup>[29]</sup>.

The conflicting results regarding the associations between GSTM1 and GSTT1 null genotypes and risks for GC and CRC may be due to limited sample size or differences in the ethnicities or genetic subtypes studied, and they may also be attributable to differences in exposure to environmental factors.

Polycyclic aromatic hydrocarbons (PAHs) are the main carcinogens in tobacco smoke. The ultimate carcinogen (PAH-DE) can be detoxified through conjugation with glutathione by GSTs, which are phase II enzymes<sup>[30]</sup>. Individuals with the null genotype of GSTM1 or GSTT1 would have less capacity for detoxification of PAHs, which would potentially increase their risk of chemical carcinogenesis. However, our data suggested that smoking did not modify the association between the GSTM1 and GSTT1 null genotypes and the risk of GC or CRC.

Four studies examined the interaction between smoking, GSTM1 or GSTT1 polymorphisms, and the risk of GC<sup>[10,11,18,21]</sup>. One study suggested that smoking modi-

fies the association between the GSTM1 null genotype and the risk of GC<sup>[21]</sup>. In contrast, three studies reported that smoking did not modify the association between the GSTM1 and/or GSTT1 null genotype and GC risk<sup>[10,11,18]</sup>, in line with our results. Additionally, six studies evaluated the interaction between smoking, the GSTM1 or GSTT1 null genotype, and the risk of CRC<sup>[13,25,31-34]</sup>. Two studies reported that smoking modifies the association between the GSTM1 and/or GSTT1 null genotype and CRC risk<sup>[13,31]</sup>. However, four studies reported no interaction between the GSTM1 and/or GSTT1 null genotype and smoking in CRC risk<sup>[25,32-34]</sup>, in agreement with our results.

Our study suggests that alcohol consumption did not modify the association of GSTM1 and GSTT1 null genotypes with the risk of GC or CRC, which is consistent with previous studies regarding GC<sup>[9,11,18]</sup>. However, no studies have been reported examining whether alcohol consumption modifies the association of the GSTM1 or GSTT1 null genotype with the risk of CRC.

The detoxification potential of the GSTs was observed to decrease with age<sup>[35]</sup>. Yeh *et al.*<sup>[24]</sup> reported that men aged  $\leq 60$  years with the GSTT1 null genotype were at significantly increased risk of rectal cancer, and one study reported the GSTT1 null genotype was not associated with the risk of GC, classified according to age less than or greater than 60 years<sup>[17]</sup>. However, the present study suggested that age does not modify the association between GSTM1 and GSTT1 null genotypes and the risk of GC or CRC.

In our data, the GSTM1 and GSTT1 null genotypes were not significantly associated with the risk of GC or CRC, classified according to TNM stage, tumor site, and histology type (GC). To the best of our knowledge, no reports have been published regarding the GSTM1 and GSTT1 null genotypes and GC or CRC risk classified according to TNM stage.

Two studies investigated the association between the GSTM1 and GSTT1 null genotypes and the risk of cardia or non-cardia GC, and both studies suggested that no significant association exists<sup>[3,36]</sup>, in line with our result. Seow *et al.*<sup>[37]</sup> reported that the GSTM1 and GSTT1 null genotypes were not associated with the risk of CRC, classified according to location of the tumor in the colon or the rectum. Suzuki *et al.*<sup>[38]</sup> reported finding no association between the GSTM1 null genotype and the risk of intestinal type or diffuse type GC, and Agudo *et al.*<sup>[3]</sup> reported finding no association between the GSTT1 null genotype and the risk of intestinal type or diffuse type GC, consistent with our results.

In our data, smoking was associated with increased risk

of GC, but with decreased risk of CRC. Previous studies reported that smoking increased the risk of GC<sup>[39]</sup>, in line with our results. The association between smoking and CRC has been inconsistent among studies. A recent meta-analysis suggested that smoking is significantly associated with CRC incidence<sup>[40]</sup>. In our data, drinking was associated with decreased risk of both cancer groups. Drinking probably does not affect overall risk of stomach cancer, but there is some evidence that drinking may increase the risk of GC<sup>[41]</sup>. The relationship between drinking and CRC risk has been controversial, but a meta-analysis found that high consumers of alcohol had an elevated CRC risk<sup>[42]</sup>. We could not rule out the possibility that differential misclassification bias may have occurred in our study, because we retrospectively gathered information about smoking and drinking from electronic medical records in both case groups, while cross-sectional surveys were used to gather information about smoking and alcohol in controls.

The major strength of our study was its large sample size. Ours was the first investigation of the risk of GC and CRC according to the GSTM1 and GSTT1 null genotypes in a large Korean population.

The limitations of our study must also be acknowledged. First, the study did not consider genetic polymorphisms of other cancer related genes. Second, the study considered a limited number of environmental factors (smoking and alcohol consumption), and other environmental factors such as dietary intake were not considered.

In conclusion, the results of the present population-based, large-scale case-control study suggest that in a Korean population, the GSTM1/GSTT1 null genotype does not modulate an individual's susceptibility to GC or CRC, and that smoking, alcohol consumption, and age do not modify the association between these genotypes and the risk of GC or CRC.

## COMMENTS

### Background

Gastric cancer (GC) and colorectal cancer (CRC) are the most common malignancies in Korea. Environmental factors and genetic factors have been shown to play a role in the development of these malignancies.

### Research frontiers

The glutathione S-transferase enzymes are involved in detoxification of many potentially carcinogenic compounds. Several studies have shown that glutathione S-transferase mu (GSTM1) and glutathione S-transferase theta (GSTT1) null genotypes were associated with increased risks for GC and CRC. But some data suggested no relationship between GSTM1/GSTT1 null genotype and the risk of GC and CRC.

### Innovations and breakthroughs

This is the first investigation of the risk of GC and CRC according to the GSTM1 and GSTT1 null genotypes in a large Korean population. It also aimed to determine whether smoking, alcohol consumption, and age modify the association between these polymorphisms and GC or CRC risk.

### Applications

This study suggested that GSTM1 and GSTT1 null genotypes were not associated with increased risk of GC or CRC in Koreans. Smoking, drinking, and age did not modify the association between these genotypes and the risk of gastric or colorectal cancer. Future research should focus on other parts of the GST genotype to understand its role and risk of gastric and colorectal cancer in Korean population.

### Terminology

GST: Glutathione-S-transferase is a Phase II detoxification enzyme. The

enzymes are encoded by at least five distantly related gene families (the alpha, mu, pi, sigma, and theta GSTs). In humans, marked interindividual differences exist in the expression of mu (GSTM1), and theta (GSTT1) GSTs.

### Peer review

This is the first investigation of the risk of GC and CRC according to the GSTM1 and GSTT1 null genotypes in a large Korean population. It also determined whether smoking, alcohol consumption, and age modify the association between these polymorphisms and GC or CRC risk. Although results of this study show no association between the null genotypes of GSTM1 and GSTT1 and risk of gastric and colorectal cancer, and no-association results are not as attractive as positive associations, I feel they should be presented to the scientific audience in order not to create a literature bias towards publishing only studies with positive associations.

### Abstract

**AIM:** To evaluate the relationship between gastric dysplasia and *Helicobacter pylori* (*H pylori*) and the occurrence of colorectal adenoma, and to define the necessity for colonoscopy in patients with gastric dysplasia or *H pylori* infection.

**METHODS:** From May 2005 to February 2008, 133 patients with established gastric dysplasia by gastroduodenoscopy (EGD) were additionally investigated by colonoscopy. The authors compared results with those of 213 subjects who underwent both EGD and colonoscopy during the same period at the author's Health Promotion Center as a control group. *H pylori* infection was evaluated in both the gastric dysplasia and control groups.

**RESULTS:** The mean age of all 346 study subjects was  $54.1 \pm 10.5$  years, and there were 258 (73%) men and 87 (27%) women. No significant difference was found between the *H pylori* positive and negative subjects in terms of the prevalence of colorectal adenoma and advanced colorectal adenoma ( $P = 0.261$ ). Patients with gastric dysplasia showed no elevated risk of colorectal adenoma (OR = 0.910, 95% CI: 0.587-1.411,  $P = 0.738$ ), but had a significantly higher risk of having advanced colorectal adenoma (OR = 3.382, 95% CI: 1.700-6.342,  $P = 0.000$ ).

### INTRODUCTION

Colorectal carcinoma is one of the most common cancers and is the second leading cause of cancer-related mortality in the United States<sup>[1]</sup>, and the fourth leading cause of cancer-related mortality in Korea<sup>[2]</sup>. The etiologies and risk factors of colorectal neoplasms have attracted research attention for several decades, especially in association with *Helicobacter pylori* (*H pylori*) or gastric dysplasia. *H pylori* infection is a well-known cause of chronic gastritis, peptic ulcers<sup>[3,4]</sup>, gastric adenocarcinoma<sup>[5]</sup>, and gastric lymphoma<sup>[6]</sup>, and several reports have suggested that *H pylori* infection increases the risk of colorectal adenoma and adenocarcinoma<sup>[7-9]</sup>; however, other reports disagree<sup>[10,11]</sup>. Furthermore, several have concluded that gastric adenoma and carcinoma may be indicators of colorectal adenoma or carcinoma<sup>[12,13]</sup>, and it is accepted that both gastric adenoma and colorectal adenoma have a high potential for malignant transformation<sup>[14-16]</sup>. The aims of this study were to evaluate relations between gastric dysplasia and *H pylori* infection and the occurrence of colorectal adenoma and to define the need for colonoscopy in patients with gastric dysplasia or *H pylori* infection.

## MATERIALS AND METHODS

### Patients

From May 2005 to February 2008, 133 consecutive patients with established gastric dysplasia (the gastric dysplasia group), as determined by gastroduodenoscopy (EGD) at our institute, were additionally subjected to colonoscopy, after obtaining informed consent, within 3 wk of EGD. We defined gastric adenoma as gastric dysplasia. The presence of gastric dysplasia and colorectal adenoma were confirmed histologically using specimens obtained by endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD), or polypectomy. We also enrolled 213 consecutive subjects who underwent both EGD and colonoscopy for the purpose of screening at the Health Promotion Center at Kyungpook National University Hospital as a control group during the same period. We reviewed endoscopic findings and pathology specimens retrospectively. The subjects who were included in the control group had no symptoms and no gastric dysplasia. Patients with any kind of malignancy and those with a previous history of colorectal surgery were excluded. Subjects with either family history of colorectal adenocarcinoma or adenoma or gastric cancer were also excluded. This study was approved by our Institutional Review Board.

### Diagnosis of *H pylori* infection

*H pylori* infection was diagnosed by biopsy, CLO test (GASTREX, Warsaw, Poland), or by using an urea breathing test (UBT, Otsuka, Tokyo). The specimens for the CLO test were obtained from both the antrum and the distal body of the stomach during EGD. Cresyl violet staining was used for the pathologic diagnosis of *H pylori* infection. The cut-off value of the UBT was 2.5‰. *H pylori* infection was diagnosed when two of the above three methods were positive.

### Colonoscopic diagnosis

Cecal intubation was successful in all patients. All lesions found during colonoscopy were removed by biopsy, polypectomy, EMR, or ESD. Advanced colorectal adenoma was defined as a size larger than 1 cm, a villous or tubulovillous adenoma histology, or adenoma with high-grade dysplasia.

### Statistical analysis

We compared age and sex distributions, the presence or absence of colorectal adenoma, colorectal adenoma sizes and histology, and *H pylori* infection states in the gastric dysplasia and control groups. Variables were compared using the  $\chi^2$  or independent *t*-tests, depending on the nature of the data. Fisher's exact test was used when numbers were small. Odds ratios (ORs) and 95% CIs were used to describe associations. ORs with corresponding 95% CIs were obtained by conditional logistic regression analysis. *P* values of < 0.05 were considered statistically significant, and statistical calculations were performed using SPSS version 14.0 software for Window (SPSS Inc. Chicago, IL, USA).

Table 1 Baseline characteristics of gastric dysplasia and control group

	Gastric dysplasia ( <i>n</i> = 133)	Control ( <i>n</i> = 213)	<i>P</i> -value

Advanced adenoma: Advanced colorectal adenoma.

## RESULTS

### Clinical characteristics of the gastric dysplasia and control groups

The mean age of all 346 study subjects was 54.1  $\pm$  10.5 years, and there were 258 men (73%) and 87 women (27%). The gastric dysplasia group was older than the control group (*P* = 0.0005). In the gastric dysplasia group (*n* = 133), colorectal adenoma was diagnosed in 55/133 (41%) and advanced colorectal adenoma in 28/133 (21%). In the control group, colorectal adenoma was diagnosed in 93/213 (44%), and advanced colorectal adenoma in 16/213 (7.5%). No significant difference was observed between the gastric dysplasia and control groups in terms of the prevalence of colorectal adenoma (*P* = 0.5220), and no significant difference was observed between the *H pylori* positive and negative groups in terms of the prevalence of gastric dysplasia, colorectal adenoma, or advanced colorectal adenoma (*P* = 0.2610). Furthermore, no significant difference was observed between the gastric dysplasia and control groups in terms of the sizes of advanced colorectal adenomas (10.50  $\pm$  3.107 mm *vs* 11.92  $\pm$  8.722 mm, respectively, *P* = 0.5860) (Table 1).

### Clinical characteristics of the advanced colorectal adenoma positive and negative groups

Mean age in the advanced colorectal adenoma positive group was greater than in the negative group (*P* = 0.0002). However, group sex distributions (*P* = 0.0600) and *H pylori* (*P* = 0.1060) infection statuses were not different significantly different (Table 2).

### Comparisons of the colorectal adenoma and advanced colorectal adenoma groups

Those with colorectal adenoma or advanced colorectal adenoma were older than those without (Table 3). Moreover, those with gastric dysplasia showed no increased risk of having colorectal adenoma (OR = 0.910, 95% CI: 0.587-1.411, *P* = 0.7380), but they had a significantly higher risk of having advanced colorectal adenoma (adjusted OR = 3.283, CI: 1.700-6.342, *P* = 0.0004) (Table 3). This result was supported by multivariate analysis (Table 4).

**Table 2** Baseline characteristics of advanced adenoma (+) and (-) group

	Advanced adenoma (+) (n = 44)	Advanced adenoma (-) (n = 302)	P-value
Age (mean ± SD)	60.8837 ± 8.55294	53.1419 ± 10.43410	0.0002
Sex [M/F n (%)]	38/6 (86/14)	221/81 (73/27)	0.0600
<i>H pylori</i>			0.1060
(+) n = 204	21	183	
(-) n = 142	23	119	

## DISCUSSION

This study shows that the risk of advanced colorectal adenoma is elevated in patients with gastric dysplasia, and thus, supports the notion that colorectal cancer risk is increased by gastric adenoma, as has been reported previously<sup>[12]</sup>. In addition our study concurs with the findings of a previous study, in which it was found that two of six patients with diffuse gastric adenoma had colon polyps and 40 of 73 patients (54.8%) with gastric polyps had colorectal adenomatous polyps<sup>[17]</sup>. In the present study, 55 of 133 patients (41%) with gastric dysplasia had colorectal adenomatous polyps and 28 of 133 (21%) had advanced colorectal adenomatous polyps. The present study concurs with another study, in which it was found that eight of eleven patients with duodenal adenomas had colonic polyps<sup>[18]</sup>. Furthermore, the present study agrees with other studies concerning the elevated risk of gastric polyps in patients with sporadic colonic polyps<sup>[19]</sup>. Shemesh *et al*<sup>[20]</sup> reported that two of 100 patients with 1-4 colorectal polyps had gastric adenoma, 3 of 80 patients (3.5%) with 5 or more colorectal polyps had gastric adenoma, 3 of 80 patients with colon cancer had gastric adenoma, and one of 100 patients without colorectal adenoma and cancer had gastric adenoma, and these findings are also in line with those of the present study. The progression of colorectal adenoma to colon cancer is known to be associated with an adenoma size larger than 10 mm, more than three lesions, a villous, tubulovillous or high grade dysplastic histology, and the presence of genetic abnormalities<sup>[21-24]</sup>. Genetic abnormalities in colon cancer are very similar to those in gastric cancer<sup>[25,26]</sup>, especially concerning mutations of the *p53*<sup>[27,28]</sup>, *APC*<sup>[29,30]</sup>, *DCC*<sup>[31,32]</sup>, and *K-ras* genes<sup>[33,34]</sup>. Genetic abnormalities are well known to be associated with upper gastrointestinal polyps and with hereditary colonic polyposis syndromes<sup>[25,26]</sup>, which include familial polyposis coli<sup>[25,26]</sup>, Gardner's syndrome, Peutz-Jeghers' syndrome, Cowden's syndrome, Cronkhite-Canada syndrome, hereditary flat adenoma syndrome, and others. In the present study, we deliberately excluded patients with HNPCC, suspected HNPCC, or FAP to avoid the influence of such genetic factors.

Gastric adenoma or dysplasia have high rates of malignant transformation (up to 75%<sup>[14-16,19-21]</sup>). Accordingly, regardless of the existence of colorectal adenoma, treatment of gastric dysplasia by EMR or ESD is inevitable. Moreover, the above-mentioned relations suggest that the pathogenesis of gastric dysplasia and colorectal

**Table 3** Statistics of colorectal adenoma and advanced adenoma groups

aOR: Adjusted odds ratio; G. dysplasia: Gastric dysplasia.

adenoma are similar. Several other controversial factors may increase the risk of colorectal cancer development, e.g. an increased serum gastrin level<sup>[35]</sup>, *H pylori* infection<sup>[6-11]</sup> and *Streptococcus bovis* bacteremia<sup>[36]</sup>. However, previous studies have concluded that the presence of *H pylori* infection and an elevated serum gastrin level are not associated with elevated risks of colorectal neoplasm development. Recently, some studies have concluded that increased serum gastrin levels due to the use of proton pump inhibitors do not predispose the development of a colorectal neoplasm. In the present study, we included only gastric dysplasia and *H pylori* infection status to examine the risk of colorectal adenoma development. No significant association was found between *H pylori* infection and colorectal adenoma, which concurs with another study<sup>[10,11]</sup>, and thus, it appears that an agent other than *H pylori* is responsible for co-pathogenesis of colorectal adenoma<sup>[35]</sup>.

The aim of several studies on colorectal adenoma has been to reduce colorectal cancer mortality and morbidity. To achieve this aim, the early diagnoses and treatment of precancerous lesions, like colorectal adenoma and early colorectal cancer, are of the utmost importance, especially, in those deemed to be at high risk group by early surveillance colonoscopy<sup>[37,38]</sup>. Some studies have recommended that gastric cancer patients undergo colonoscopy due to a substantial risk of their developing colon cancer<sup>[13]</sup>. In another study, haemoccult studies were recommended for early detection of colorectal tumors in patients with gastric polyp<sup>[39]</sup>. In addition, it has been reported that the rates of occurrence of colorectal adenoma in gastric adenoma and carcinoma patients are increasing<sup>[12]</sup>. In common with other studies, the present study reveals that gastric dysplasia is an indicator of advanced colorectal adenoma, which is an important risk factor of colorectal cancer. Accordingly, we emphasize the need for colon surveillance in elderly patients with gastric dysplasia because of their elevated risk of developing advanced colorectal adenoma, which is an important risk factor of colorectal cancer, regardless of *H pylori* infection.

Several limitations of the present study should be considered. First, the sample size was small, which introduces the possibility of a type II error, and we could not collect age and sex-matched controls. Second, selection bias is possible due to the retrospective nature of the study. Third, insufficient information was obtained regarding alcohol consumption, smoking status, and

Table 4 Multivariate analysis of colorectal adenoma and advanced adenoma groups

G. dysplasia	0.022	0.053	0.421	0.6740	-0.082 to 0.127	0.289	0.077	3.741	0.0004	0.137 to 0.440

serum gastrin, cholesterol, and glucose levels, which were recently proposed as risk factors of gastric dysplasia<sup>[35]</sup>. Fourth, the mean age of the gastric dysplasia group was greater than that of the control group, because the patients who visited our health promotion center were much younger than the gastric dysplasia patients. Accordingly, although age-adjusted odds ratios for advanced colorectal adenoma were statistically significance, we cannot exclude the possibility of an age-related bias.

Even though there were several reports that *H pylori* infection increased the risk of colorectal adenoma and adenocarcinoma<sup>[7-9]</sup>, our report reveals that *H pylori* infection is not a risk factor for advanced colorectal polyps, but that gastric dysplasia and an advanced age are. Thus, we infer that genetic and environmental factors probably importantly contribute to the development of advanced colorectal polyps, because patients are continuously exposed to those factors. However, the environmental factors involved have not been identified as yet. Thus, further diverse complex study models are required to clarify the relationship between gastric dysplasia, *H pylori*, and colorectal adenoma, and identify the environmental factors concerned. Moreover, a large prospective case-controlled study is required to determine whether the presence of gastric dysplasia is an indication for colonoscopy and what intervals would be recommended for patients with gastric dysplasia.

## COMMENTS

### Background

Over the last decades, several studies have been performed on the etiologies and risk factors of colorectal neoplasms, especially on the association with *Helicobacter pylori* (*H pylori*) and gastric dysplasia. This study was performed to define the necessity of screening colonoscopy in patients with gastric dysplasia or *H pylori* infection.

### Research frontiers

Several controversial factors might increase the risk of colorectal cancer development, for example, increased serum gastrin level, *H pylori* infection and *Streptococcus bovis* bacteremia, and so on. In this study, the authors demonstrate the relations between gastric dysplasia and the occurrence of advanced colorectal adenoma.

### Innovations and breakthroughs

Even though there were several reports that *H pylori* infection increased the risk of colorectal adenoma and adenocarcinoma, this report reveals that *H pylori* infection is not a risk factor for advanced colorectal polyps; however, gastric dysplasia and an advanced age are. Thus, genetic and environmental factors probably contribute to the development of advanced colorectal polyps, because of continuous exposure to genetic and environmental factors.

### Applications

This result could emphasize the need for colon surveillance in elderly patients with gastric dysplasia because of their elevated risk of developing advanced

colorectal adenoma, which is an important risk factor of colorectal cancer, regardless of *H pylori* infection.

### Peer review

The authors examined the relation between gastric dysplasia and *H pylori* and advanced colorectal adenoma. However, a large prospective case-controlled study is required to determine whether the presence of gastric dysplasia is an indication for colonoscopy and what intervals would be recommended for patients with gastric dysplasia.

### Abstract

**AIM:** To summarize the clinical experience of laparoscopic hepatectomy at a single center.

**METHODS:** Between November 2003 and March 2009, 78 patients with hepatocellular carcinoma ( $n = 39$ ), metastatic liver carcinoma ( $n = 10$ ), and benign liver neoplasms ( $n = 29$ ) underwent laparoscopic hepatectomy in our unit. A retrospective analysis was done on the clinical outcomes of the 78 patients.

**RESULTS:** The lesions were located in segments I ( $n = 3$ ), II ( $n = 16$ ), III ( $n = 24$ ), IV ( $n = 11$ ), V ( $n = 11$ ), VI ( $n = 9$ ), and VIII ( $n = 4$ ). The lesion sizes ranged from 0.8 to 15 cm. The number of lesions was three ( $n = 4$ ), two ( $n = 8$ ) and one ( $n = 66$ ) in the study cohort. The surgical procedures included left hemi-hepatectomy ( $n = 7$ ), left lateral lobectomy ( $n = 14$ ), segmentectomy ( $n = 11$ ), local resection ( $n = 39$ ), and resection of metastatic liver lesions during laparoscopic surgery for rectal cancer ( $n = 7$ ). Laparoscopic liver resection was successful in all patients, with no conversion to open procedures. Only four patients received blood transfusion (400-800 mL). There were no perioperative complications, such as bleeding and biliary leakage. The liver function of all patients recovered within 1 wk, and no liver failure occurred.

**CONCLUSION:** Laparoscopic hepatectomy is a safe and feasible operation with minimal surgical trauma. It should be performed by a surgeon with sufficient experience in open hepatic resection and who is proficient in laparoscopy.

### INTRODUCTION

Laparoscopic hepatectomy (LH) was first described in 1995 by Cuesta *et al*<sup>[1]</sup> and it remains an appealing concept: major surgery with a potential for bleeding, carried out using a minimally invasive approach. While the laparoscopic approach has been championed, notably by Cherqui *et al*<sup>[2]</sup> and Buell *et al*<sup>[3]</sup>, it is carried out in only a few centers and has not become a widely accepted surgical technique. In general, laparoscopic liver resection offers some advantages over an open approach. There is less postoperative pain, early mobilization, minimal ileus, earlier resumption of oral intake and shorter hospital stay<sup>[4-7]</sup>. Initial minor hepatectomy for lesions located in superficial segments has been considered possible<sup>[8,9]</sup>, with the development of laparoscopic instruments and parenchymal transection devices, combined with improved understanding of the vascular anatomy of the liver, it is now accepted widely that laparoscopy will be used increasingly in liver surgery<sup>[10]</sup>.

Between November 2003 and March 2009, we performed total laparoscopic hepatectomy in 78 patients with liver neoplasms, the results of which were encouraging.

### MATERIALS AND METHODS

#### Patients

Between November 2003 and March 2009, 78 LHs were performed in the Hepato-biliary Surgery Department at Sun Yat-sen Memorial Hospital of Sun Yat-sen University. Seventy-eight patients with liver neoplasms

(50 men and 28 women), including primary liver carcinoma ( $n = 39$ ), secondary liver carcinoma ( $n = 10$ ), and benign liver neoplasm ( $n = 29$ ). The mean age was 46.6 years (range, 20-82 years). Preoperative liver function was as follows: Child classification A ( $n = 52$ ), B ( $n = 22$ ) and C ( $n = 4$ ). Evidence of cirrhosis, based on clinical and/or morphological abnormalities, was not considered an absolute contraindication in the absence of decompensated cirrhosis. There was no upper limit on neoplasm size, and LH was contraindicated if venous or biliary reconstruction was required.

### Surgical procedure

All procedures were performed under general endotracheal anesthesia and after obtaining informed consent. All resections were performed with the patient in the supine position. The surgeon stood between the patient's spread legs, the first assistant on the left side of the patient and the camera assistant on the right. The pneumoperitoneum was insufflated by umbilicus puncture and controlled electronically at a constant abdominal pressure of 12 mmHg. A 5-mm trocar placed at the umbilical port was used for abdominal exploration with a 30° laparoscope. The trocar insertion sites depended on the location of the hepatic lesion. The surgical technique was as follows. For mobilization of the liver, the falciform and round ligaments were divided by an endoscopic ultrasonic scalpel (LLC, Guaynabo, Puerto Rico). In the case of left hepatectomy, the left liver lobe was mobilized by dividing the left triangular, coronary, and hepato-gastric ligaments. In the case of right segmentectomy, the right coronary ligament was divided. It was not necessary to divide the ligament if the lesion was located at the edge of the liver. Laparoscopic ultrasonography (Esaoite Biomedica, Genoa, Italy) was used for localization of the tumor and the supply vessels, demonstration of satellite nodules, and demarcation of an adequate tumor-free margin. To achieve afferent blood control in anatomical left liver resection, including left segmentectomy, left lateral lobectomy, and left hemihepatectomy, the portal pedicles were dissected outside the liver parenchyma, and the portal venous branch, hepatic arterial branch, and bile duct were separated, clipped and divided. When the branch was too large to apply clips, it was divided with an endoscopic linear stapler (Tyco Healthcare, Norwalk, CT, USA). In right liver resection, the supply vessels of the target segment were found by laparoscopic ultrasonography, and were clipped or divided with an endoscopic linear stapler extraparenchymally. To achieve efferent blood control, the inferior vena cava and left hepatic vein were dissected, and the trunk of the left hepatic vein was clipped with a 12-mm hemoclip, but was not divided before parenchymal division. Liver surface tissue transection was performed using an endoscopic ultrasonic scalpel, while deep parenchyma dissection was performed using LigaSure (Valleylab, Boulder, CO, USA); larger biliary and vascular radicals were clipped and divided. After careful hemostasis, fibrin glue sealant (FibinGluRAAS; Shanghai Raas Blood Products, China) was applied to the raw surface. The specimen was extracted using a plastic bag through an extending port site.

### Assessment of operation

Surgical complications included biliary fistula, hemorrhage and incisional hernia. All patients underwent liver function tests and abdominal computed tomography (CT) before discharge. All patients underwent follow-up examination at 1-mo intervals after operation, and the follow-up examinations included clinical examination, liver function tests, and abdominal ultrasonography. No patient was lost at follow-up.

## RESULTS

### Operative results

Hepatic resection was performed laparoscopically in all 78 patients. There were no operative deaths and no conversions to laparotomy. The mean operation time was 165 min (range, 60-390 min). The mean blood loss was 288 mL (range, 10-1000 mL); only four patients received blood transfusion (400-800 mL). The mean size of the lesions was 6.2 cm (range, 0.8-15 cm) and the mean width of the specimen margins was 1.2 cm (range, 0.5-6 cm). The number of lesions was three ( $n = 4$ ), two ( $n = 8$ ), and one ( $n = 66$ ) in the study cohort. Details of tumor sites are summarized in Table 1; Types of laparoscopic hepatectomy are given in Table 2; Details of histologic results are summarized in Table 3.

### Postoperative recovery

There were no postoperative deaths or complications, such as bleeding and biliary leakage. Liver function returned to preoperative levels within 1 wk. Oral intake was begun on postoperative day 2. The mean postoperative hospital stay was 5.6 d (range, 2-10 d). The patients were discharged without narcotic analgesia. At the first postoperative month, all patients had resumed normal activities.

### Follow-up

The mean follow-up was 30 mo (range, 2-60 mo). No port site metastasis was noted during follow-up in any patient who had hepatectomy for malignant lesions. Recurrence was detected in four patients with primary hepatocellular carcinoma and one with intrahepatic cholangiocarcinoma within 2 years. Two patients with primary hepatocellular carcinoma underwent a second LH for a recurrent lesion, and the other patients had transcatheter arterial chemoembolization and radiofrequency ablation (RFA). New isolated lesions in the liver were detected in two patients with rectal carcinoma within 1 year postoperatively, and were treated with RFA.

## DISCUSSION

Laparoscopic liver resection has been viewed with skepticism because of concerns regarding parenchymal transection, bleeding control, bile leakage and incomplete resection<sup>[3,11,12]</sup>. The present study suggests that LH may be safe and feasible in selected patients. The indication for laparoscopic liver resection should be selected with care because of the technical difficulty, and the size and location of the neoplasm must be evaluated before surgery. In patients with neoplasms located in the left liver lobe and the anterior and inferior liver segments (IVb, V and VI), LH has been shown to be safe. On the other hand, neoplasms located in the right lobe and the posterior and superior liver segments (I, IVa, VII and VIII) are technically more demanding and should be approached with caution<sup>[13,14]</sup>. In our cohort, most lesions (91%) were located in segment II, III, IV, V and VI, and no lesion located in segment VII was treated because of the difficulty of exposure. A neoplasm < 6 cm in size is thought to be preferred<sup>[15,16]</sup>. In fact, we believe the size of the neoplasm is not as important as its location for LH. We performed laparoscopic left hemi-hepatectomy in four patients with 10-15-cm neoplasms in the left liver lobe, but without invasion of the inferior vena cava and the root of the hepatic vein. No conversion to laparotomy in our cohort may have been, at least in part, because of the choice of indication before surgery.

One of the main concerns during hepatectomy is minimizing blood loss and avoidance of blood transfusion<sup>[17,18]</sup>. In our experience, laparoscopic surgery may provide better visualization of deep vascular structures and more precise and accurate surgery. To avoid injury

Figure 1 Computed tomography (CT) image before operation, which showed the lesion on the right lobe of the cirrhotic liver.

Figure 2 After laparoscopic hepatectomy (LH), the lesion disappeared and the volume of liver increased clearly.

to the hepatic veins, caution should be exercised during manipulation of secondary hilar structures, and the hepatic veins should be transected in the parenchyma using clips or an endoscopic linear stapler. Conversion to laparotomy is mandatory when a large venous injury occurs, even if initial laparoscopic control of the wound has been achieved<sup>[11]</sup>. In the early stage of LH, bleeding during parenchymal transection due to a lack of effective devices is another important cause of blood loss, but there are now numerous excellent devices for dividing the parenchyma, including an ultrasonic scalpel, microwave tissue coagulator, water jet dissector, LigaSure, Cavitron ultrasonic surgical aspirator, argon beam coagulator, Peng's Multifunction Operative Dissector, and TissueLink<sup>[19-26]</sup>. Based on our experience, using an ultrasonic scalpel and LigaSure to transect the liver facilitates good hemostasis, clear anatomy, less effusion, and minor damage to liver function. The average blood loss was only 200 mL in our 78 cases. Another concern that occurs during LH when resecting a malignant neoplasm involves achieving a disease-free resection margin<sup>[27,28]</sup>. We believe a 1-cm free surgical margin can be obtained using laparoscopic ultrasonography. In our research and a European multicenter study, there was no evidence that the use of a laparoscopic technique increases the risk of local recurrence and port-site metastases<sup>[29,30]</sup>. LH carries the potential risk of gas embolism caused by a pneumoperitoneum during hepatic vein division<sup>[31]</sup>. Although this potential complication

appears to be rare, we utilized several precautions to avoid embolic events, including careful dissection of the hepatic vein, a low-pressure pneumoperitoneum, and preventive obstruction of the left hepatic vein with a 12-mm hemoclip.

LH has the advantage of minimal scarring and fewer adhesions, thereby increasing the feasibility of repeat liver resection. We performed repeat laparoscopic liver resections in two patients for recurrent lesions, and the results were satisfactory. LH may very well become the gold standard for tumor control in patients with hepatocellular carcinoma awaiting liver transplantation<sup>[32]</sup>. The choice of an incision is a dilemma in the colorectal cancer patient complicated by liver metastasis. The present study has shown that simultaneous laparoscopic resection of colorectal cancer and synchronous liver metastases is feasible and safe. Indeed, we performed this operation successfully in seven patients with five or six ports, just one or two more than laparoscopic resection of colorectal cancer, and no complications occurred. LH also has an irreplaceable advantage in patients with poor liver function. We performed LH in four patients with cirrhosis and Child C liver function in whom liver resection *via* laparotomy carried a high risk of complications. They all recovered rapidly without development of ascites and jaundice. In one hepatocellular carcinoma patient with cirrhosis and hepatitis C infection, liver function did not improve following medical treatment, yet returned to normal within 5 d after local laparoscopic tumor resection. LH might improve the postoperative course of patients with cirrhosis for the following reasons: (1) preservation of the abdominal wall and the round ligament avoids interruption of collateral circulation; (2) less mobilization and manipulation of the liver reduces liver trauma; and (3) non-exposure of abdominal viscera restricts fluid requirements and decreases electrolytic and protein losses<sup>[33-35]</sup>. We suggest that local laparoscopic liver tumor resection in patients with cirrhosis not only treats the tumor, but also creates a damaged liver environment with minimal liver load, which provides ideal conditions for regeneration of remnant liver. In fact, with CT scanning, we confirmed that the volume of the liver increased after LH in these patients (Figures 1 and 2).

Lastly, we advocate LH as a complex procedure that requires experience and different skills from those of open surgery because of the 2D representation of the operative site, limited tactile feedback, and the need for eye-hand coordination skills. The surgeons in our study all had sufficient experience with open hepatic resection and proficient skills in laparoscopic procedures, and also had the ability to manage the various complications of liver resection.

## COMMENTS

### Background

With the development of laparoscopic instruments and parenchymal transection devices, combined with the improved understanding of the vascular anatomy of the liver, it is now accepted widely that laparoscopy will be used increasingly in liver surgery.

### Research frontiers

The underlying intent of laparoscopic surgery for liver neoplasms is to provide curative resection while minimizing complications. In this study, the authors

demonstrated that laparoscopic hepatectomy (LH) could be safe and feasible, with minimal trauma.

### Innovations and breakthroughs

This manuscript described the retrospective evaluation of a significant cohort of patients who underwent LH at a single center. The good clinical outcome depended on the reasonable choice of indication, suitable parenchymal transection devices, and sufficient experience in hepatic resection and laparoscopy.

### Applications

LH could be performed in most patients with liver neoplasms, particularly in patients with cirrhosis and those with colorectal cancer and synchronous liver metastases.

### Terminology

Liver resection is always considered a major operation, with blood loss and lengthy hospitalization. LH could benefit patients in need of liver resection, with better cosmetic results, less postoperative pain and shorter hospital stay.

### Peer review

Interesting report about a single centre experience with 78 laparoscopic liver resections of different kind for different indications in different liver diseases.

### Abstract

**AIM:** To investigate gut barrier damage and intestinal bacteria translocation in severe acute pancreatitis (SAP), a simple rat model of SAP was induced and studied.

**METHODS:** Pancreatitis was induced by uniformly distributed injection of 3.8% Na taurocholate (1 mL/kg) beneath the pancreatic capsule. Rats in the control group were injected with normal saline in the identical location.

**RESULTS:** Serum amylase, plasma endotoxin, intestinal permeability, and pancreatitis pathology scores were all markedly higher in the pancreatitis group than in the control group ( $P < 0.01$ ). The bacterial infection rate was significantly higher in the SAP group than in the control group ( $P < 0.01$ ), observed in parallel by both bacterial culture and real-time polymerase chain reaction. Acute damage of the pancreas was observed histologically in SAP rats, showing interstitial edema, leukocyte infiltration, acinar cell necrosis and hemorrhage. The microstructure of the intestinal mucosa of SAP rats

### INTRODUCTION

A close link has been demonstrated between intestinal bacteria translocation and infection in pancreatic necrosis, which is a main predictor of clinical outcome in patients with severe acute pancreatitis (SAP)<sup>[1]</sup>. Although a multitude of animal models<sup>[2-5]</sup> have been used to study the mechanism of bacterial translocation, its exact origin, route, and mechanism are still unclear. The main reason for this uncertainty is the lack of an "ideal" animal model of acute pancreatitis (AP), especially for the purpose of studying bacterial translocation.

Taurocholate-induced pancreatitis animal models are commonly used nowadays, especially the model induced by perfusion of taurocholate into the biliary or pancreatic duct, which is thought to most closely resemble clinical biliary pancreatitis. However these models have some shortcomings such as prolonged

preparation time, difficult operation, high death rate, and potential infection of the pancreas when puncturing through the gut, which limit their further popularity in study of bacterial translocation in SAP.

To overcome these shortcomings, in this paper we induced a taurocholate pancreatitis rat model by uniformly distributed injection of taurocholate directly beneath the pancreatic capsule. Gut barrier damage and intestinal bacterial translocation were studied and the advantages of the model were characterized.

## MATERIALS AND METHODS

### **Animals and animal procedures**

Thirty two specific pathogen-free rats (half male and half female, obtained from the Experimental Animal Center of Guangdong Province, China), were randomly divided into 2 groups (16 rats in the experimental group, 16 in the control group). Average weight at the time of the experiment was  $250 \pm 20$  g. Anesthesia was performed with intraperitoneal injection of 10% chloral hydrate 3 mL/kg.

The study and all procedures were approved by the Institutional Animal Care and Use Committee of Sun Yat-sen University, China.

### **Model induction procedure**

Pancreatitis group: rats were fasted for 12 h before the operation. A 10 mm median laparotomy was made and the pancreas was well exposed. The pancreatic capsule was gently lifted up, and 3.8% Na taurocholate 1 mL/kg was injected beneath the pancreatic capsule and distributed by making a bubble of taurocholate, about 2-3 mm in diameter at every injection point. Several minutes later, the pancreatic tissue would become dark purple, swell, and bleed locally. Then the abdominal organs were gently repositioned, and the peritoneal cavity was doused with about 50 mL of normal saline. Finally the abdominal wall was sutured.

In the control group, rats were injected similarly with normal saline 1 mL/kg in place of Na taurocholate.

### **Post-surgery breeding**

After surgery, rats were housed in a dry and clean room at a temperature of 20-26°C, and 12 h later standard chow and water were freely available. Mortality was observed and recorded every day.

### **Determination of serum amylase and plasma endotoxin level**

Serum amylase and plasma endotoxin were detected by routine clinical chemistry methods. Serum amylase was measured at 3 time points, namely 6, 24 and 48 h. On the 4th and 7th days, plasma endotoxins of every live rat were measured.

### **Determination of gut permeability by measurement of serum fluorescent isothiocyanate dextran (FITC-Dextran) in the superior mesenteric vein (SMV)**

FITC-Dextran (Sigma), a polysaccharide macromolecule with a fluorescent marker, fluorescein isothiocyanate, can-

not be digested and absorbed when in the normal alimentary tract, but can pass through the damaged gut barrier into capillaries of the gut, and finally into the blood of the SMV when intestinal permeability is increased<sup>[6-9]</sup>. The concentration of FITC-Dextran in the SMV depends on the dose of the drug and the severity of gut barrier damage. In this study, rats were perfused with 1 mL of 0.5% FITC-Dextran through a small tube placed in the stomach *via* the mouth, and 12 h later SMV blood samples were taken to measure the FITC-Dextran concentration as follows: blood was centrifuged at 1000 r/min, the supernatant was obtained, and absorbance was detected on a spectrofluorometer (Thermo Ltd., USA) at an excitation wave of 490 nm and transmission wave of 520 nm; the concentration of FITC-Dextran was finally calculated according to the standard curve of FITC-Dextran.

### **Bacterial culture for detection of infection rates and real-time polymerase chain reaction (PCR) to quantify the total number of translocated bacteria**

One millilitre of blood from the inferior vena cava, 0.1 g mesenteric lymph node (MLN) tissue, 0.3 g pancreas tissue and 1 g liver tissue were taken from each rat under sterile conditions by laparotomy. Every sample had 1 mL saline added followed by homogenization by triturating, then uniform smearing on 4 brain heart solid culture medium (Hopebiotechnology Co. Ltd., Qingdao, China), 2 of which were placed in a 37°C thermostat, the other 2 were placed in an anaerobic jar, tightly closed and put in a 37°C thermostat. Results were observed and recorded 48 h later.

The same quantities of samples as above were taken for real-time PCR. Total bacterial genomic DNA was extracted by the DNeasy Blood & Tissue kit (Cat. 69506, Qiagen, USA) according to the manufacturer's instructions. Li *et al.*<sup>[10]</sup> confirmed the appropriateness and effectiveness of this kit for studying gut microbial ecology. The universal PCR primer sets for total bacteria (forward: TCCTACGGGAGGCAGCAGT; reverse: GGACTACCAGGTATCTAATCCTGTT) used in this study were designed for a region in 16S rRNA and had been well demonstrated by other researchers to be uniformly successful in detecting a wide range of bacteria in samples of dentine<sup>[11]</sup> and feces<sup>[12]</sup>. Real-time PCR was performed with the ABI-Prism 7900 Sequence Detection System (Applied Biosystems, USA). The PCR reaction was performed in a total volume of 25  $\mu$ L, containing SYBR Green Real-time PCR Master Mix (TOYOBO Inc., Japan) 12.5  $\mu$ L, with 200 nmol/L of each of the forward and reverse primers and 2 ng of DNA for each reaction. The PCR reaction conditions for amplification of DNA were 95°C for 1 min and 40 cycles of 95°C for 20 s and 60°C for 1 min. Data analysis was performed using Sequence Detection Software supplied by Applied Biosystems.

### **Pancreatic pathology**

The pancreas was cut, formalin-fixed and embedded in paraffin, and 4  $\mu$ m sections were cut and stained with hematoxylin and eosin. The pancreatitis pathology score of every rat at both the 4th and 7th days were

**Table 1 Pancreatitis histopathology: Schmidt Scoring Criteria**

	Score			
	0	1	2	3
Interstitial edema	None	Interlobular	Lobule involved	Isolated island-like acinar cells
Leukocyte infiltration	None	< 20%	20%-50%	> 50%
Acinar cell necrosis	None	< 5%	5%-20%	> 20%
Hemorrhage	None	1-2 points	3-5 points	> 20%

The Schmidt Scoring Criteria of pancreatitis pathology includes 4 aspects, including interstitial edema, inflammatory infiltration, parenchymal necrosis and hemorrhage, all of which were given scores of 0-3 according to the severity of the disease.

determined according to the severity of pancreatic damage by a pathologist using a double-blind method, according to the Schmidt Scoring Criteria<sup>[13]</sup> (Table 1).

### Intestinal mucosa electron microscopy

The 4th day, which was the mid-term course of the illness, was chosen to determine the microstructural changes in the intestinal mucosa. In order to sample from the same intestinal location of all rats, a 2 cm section of the distal ileum (next to the ileocecal valve) was taken and quickly placed in fixative solution, and sent to the Electron Microscopy Center of Sun Yat-sen University for electron microscopy examination.

### Animal mortality

Daily observation of animal deaths was made for 7 d. The cumulative mortality rate was calculated daily.

### Statistical analysis

Data were displayed as the mean  $\pm$  SE. Statistical significance was calculated by one-way analysis of variance or the  $\chi^2$  test, using the Sigma Plot Software Package (Systat Software Inc, Point Richmond, Ca, USA).

## RESULTS

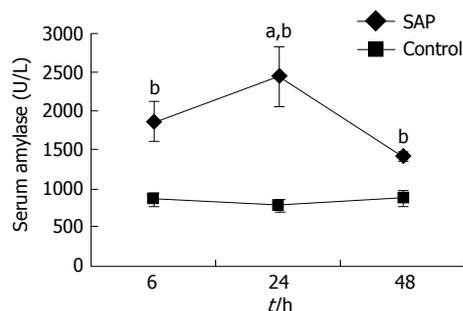

### Abnormal performance of rats

**Pancreatitis group:** Several minutes after injection of taurocholate beneath the pancreatic capsule, the pancreas was found to become swollen, dark purple, with partial subcapsular hemorrhage. The rats took more time to wake after surgery than control rats, and were tired on the first day with reduced activity, no appetite, and slow responses. Conditions became worst on the 2nd and 3rd days, when some rats were lethargic, had conjunctival congestion or petechiae, abdominal distention and hyperventilation and some rats died. However after the 4th day, the surviving rats would always recover gradually.

**Control group:** Rats awoke soon after operation, recovered in 6-8 h with normal characteristics and activity. 24 h later the rats performed as normal, and with no deaths.

### Feasibility of the surgical procedure

Uniformly distributed injections beneath the pancreatic

**Figure 1 Amylase level in serum.** Compared with control animals, serum amylase levels in severe acute pancreatitis (SAP) rats were higher at each time point (6, 24 and 48 h),  $^bP < 0.01$ . At 24 h, the amylase level of the pancreatitis model reached a peak, and was higher than the other 2 time points,  $^aP < 0.05$ .

capsule were successfully achieved in all animals and required an average of  $15 \pm 2$  min per animal when the technique was well mastered. The cumulative death rate at 7 d in the pancreatitis group was about 30%, with most occurring on the 3rd and 4th days (about 80% of all), while no deaths occurred in the control group.

There were 2 main points of note during the operation. First, a puncture too deep into the pancreatic parenchyma could injure the pancreatic veins and cause direct bleeding, but simply pressing with aseptic gauze for a moment would stop this. Second, if the syringe needle pierced through the pancreatic capsule, or taurocholate bubbles under the pancreatic capsule burst, the taurocholate could go into the abdominal cavity and cause biliary peritonitis. However, as a whole, the operation itself was simple and safe, causing few complications.

### Rat autopsy

Autopsies were carried out on dead rats. In all cases, much yellow or bloody exudate with a slight smell would come out of the peritoneal cavity when the abdomen was opened. The intestine would expand to 2-3 times of normal with gas and fluid inside and with a thinner wall. The pancreas was swollen and dark colored with some local hemorrhagic spots. Yellow-white saponified spots were always found in the peripancreatic omentum and retroperitoneum. The lower part of the spleen was always dark black. A pancreatic or hepatic abscess could be observed if the rat died after the 4th day or later.

### Serum level of amylase

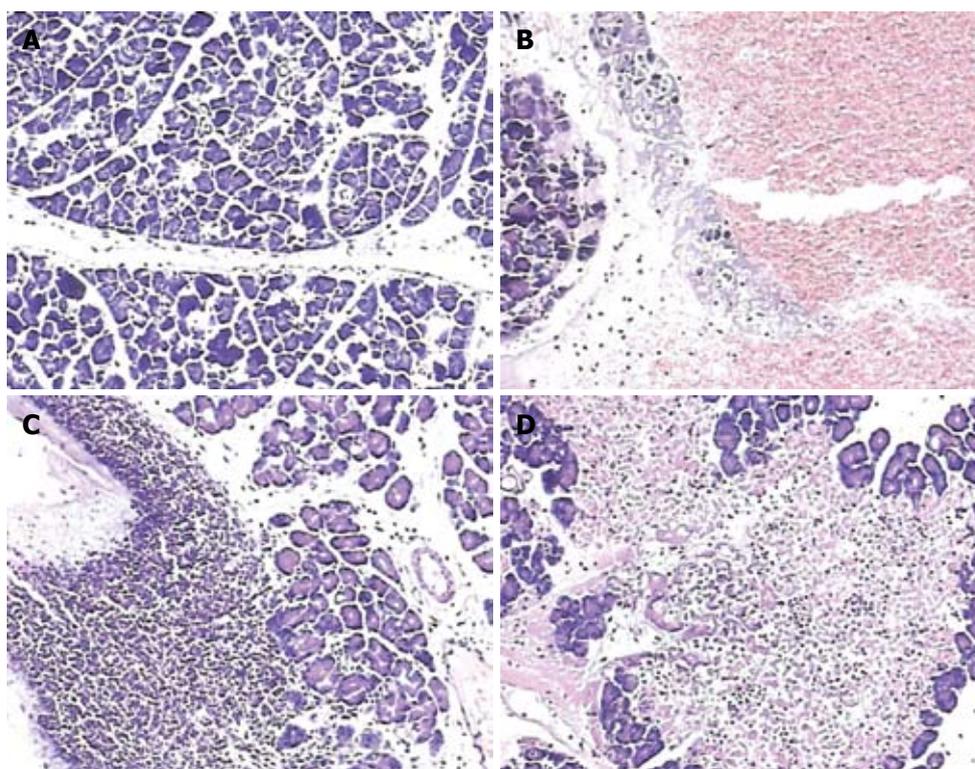

In pancreatitis rats, compared with the control group, serum amylase began increasing 6 h after the operation, and the level reached a peak at 24 h, remaining higher than the control group 48 h later (Figure 1).

### Pancreatic histology

Microscopic pancreatic damage was pronounced in pancreatitis animals in the first 48 h and showed a progressive disease course; 6 h after pancreatitis induction, typical pathological features were edema and hemorrhage (Figure 2B), while apparent leukocyte infiltration was observed 24 h after operation (Figure 2C), and areas of acinar cell necrosis could be observed 48 h after operation

Groups ( <i>n</i> = 8)	Score				Total
	Interstitial edema	Leukocyte infiltration	Acinar cell necrosis	Hemorrhage	
Control					
4 d	0.13 ± 0.33	0.13 ± 0.33	0	0	0.25 ± 0.67
7 d	0.13 ± 0.33	0	0	0	0.13 ± 0.33
SAP					
4 d	1.5 ± 0.76 <sup>a</sup>	2.38 ± 0.74 <sup>a</sup>	1.75 ± 0.71 <sup>a</sup>	0.75 ± 1.17 <sup>a</sup>	6.38 ± 2.20 <sup>a</sup>
7 d	1.25 ± 0.46 <sup>b</sup>	2.13 ± 0.99 <sup>b</sup>	1.5 ± 0.54 <sup>b</sup>	0.50 ± 1.07 <sup>b</sup>	5.38 ± 1.77 <sup>b</sup>

In this table, the pancreatitis pathology scores in severe acute pancreatitis (SAP) rats were significantly higher than in control rats in every single aspect as well as the total score, both on the 4th day (<sup>a</sup>*P* < 0.01) and on the 7th day (<sup>b</sup>*P* < 0.01).

**Figure 2 Pancreatic pathology (HE, × 100).** A: Normal pancreatic histology; B: Pancreatic damage induced 6 h after pancreatitis induction. Typical pathological features were edema and hemorrhage; C: Apparent leukocyte infiltration was observed 24 h after surgery; D: Pancreatic pathology induced 48 h after surgery, showing a confluent area of acinar cell necrosis.

(Figure 2D). The control animals were observed without such abnormalities, and had normal pancreatic gland lobules and cells. (Figure 2A)

On both the 4th and 7th days, pancreatitis pathology scores according to the Schmidt criteria were observed to be significantly higher in the pancreatitis group than in the control group in all 4 single aspects, as well as the total score (*P* < 0.01, Table 2), showing that significant damage had occurred in the pancreas of SAP rats.

### Serum endotoxin

The serum endotoxin level was a sign of intestinal permeability and pancreatitis severity. The plasma endotoxin levels in the pancreatitis group were about 5-7 times higher than that in the control group on both the 4th and 7th days (*P* < 0.01), though the level had decreased almost a half on the 7th day compared to the 4th day (Figure 3).

### Intestinal permeability

FITC-Dextran concentration in the SMV was a sign of intestinal permeability. In this study, FITC-Dextran levels in the SMV of pancreatitis rats were observed to be significantly higher than that of control rats on both the 4th and 7th days (*P* < 0.01, Figure 4), indicating higher intestinal permeability in the pancreatitis rats.

### Ultrastructural changes of the iliac mucosa

Microvilli of iliac mucosa in pancreatitis rats (Figure 5A) were shortened, about half the length of those of the control rats (Figure 5C), and with a loose structure, and some points had disappeared. Tight junctions and intermediate junctions of villous cells in SAP rats were unclear with discontinuities (Figure 5B), while intact and clear junctions between villous cells were seen in control rats (Figure 5D).

**Table 3** Infection determined by the bacterial culture method

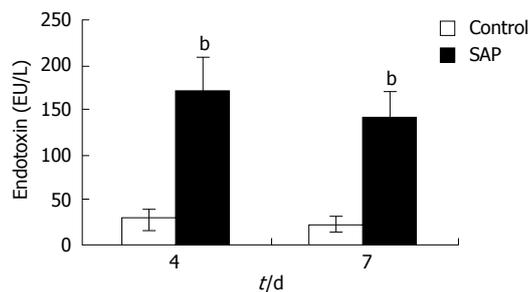

Groups (n = 8)	Infected organs number														
	Blood			MLN			Pancreas			Liver			Total		
	Ae	Ana	T	Ae	Ana	T	Ae	Ana	T	Ae	Ana	T	Ae	Ana	T
Control															
4 d	0	0	0	0	1	1	0	0	0	0	0	0	0	1	1
7 d	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
SAP															
4 d	3	2	3	6	6	6	7	7	7	7	7	7	23	22	23 <sup>a</sup>
7 d	3	3	3	5	6	6	7	8	8	5	5	5	20	22	22 <sup>b</sup>
Total	6	5	6 <sup>c</sup>	11	13	13	14	15	15	12	12	12	43	45	46

Infection rates of each organ and overall in the SAP group were higher than that in the control group, both on the 4th day (<sup>a</sup> $P < 0.01$ ) and 7th day (<sup>b</sup> $P < 0.01$ ); Compared with the other 3 types of organ, the infection rate of blood was lowest, <sup>c</sup> $P < 0.05$ . MLN: Mesenteric lymph nodes; Ae: Aerobes; Ana: Anaerobes; T: Total.

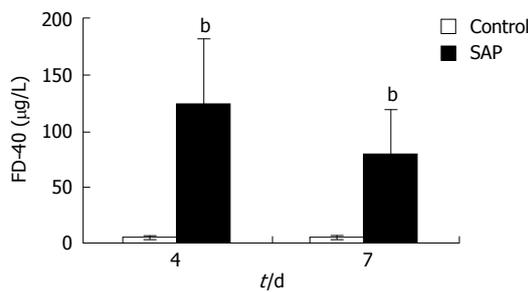

**Table 4** Bacterial translocation detected by real-time polymerase chain reaction

	Samples (n = 16)			
	Blood	MLN	Pancreas	Liver
Infected number in control group	0	1	0	0
Infected number in SAP group	5 <sup>a</sup>	10 <sup>a</sup>	13 <sup>a</sup>	12 <sup>a</sup>
Bacteria number (transformed by log <sub>10</sub> )	5.43 ± 0.847	6.48 ± 1.56	7.70 ± 0.766 <sup>b</sup>	6.57 ± 1.44

<sup>a</sup> $P < 0.01$ , compared with the "Infected number" in the control group; <sup>b</sup> $P < 0.05$ , compared with the "Bacteria number (transformed by log<sub>10</sub>)" in blood, MLN and liver.

**Figure 3** Endotoxin level in serum. On the 4th and 7th days, the serum endotoxin level was markedly higher in the pancreatitis group compared to the control group, <sup>b</sup> $P < 0.01$ .

**Figure 4** FITC-Dextran (FD-40) levels of serum in the superior mesenteric vein (SMV). The serum level of FD-40 in SMV was significantly higher in the pancreatitis group than in the control group on the 4th and 7th days, <sup>b</sup> $P < 0.01$ , though the level had decreased almost a half between days 4 and 7.

### Bacterial culture results

The copies of translocated bacteria differed greatly among pancreatitis rats, sometimes by  $10^3$  times, so it was difficult to define the statistics on bacterial numbers by the bacterial culture method. Therefore we chose the infection rate as a variable to compare the bacterial translocation in the 2 groups by the agar plate culture method. Results showed that infection rates of all the 4 types of organ were higher in the pancreatitis group than in the control group ( $P < 0.01$ ). When comparison was made among the infected rats of the 4 kinds of organs, blood of the inferior vena cava was found to have the lowest rate ( $P < 0.05$ , Table 3).

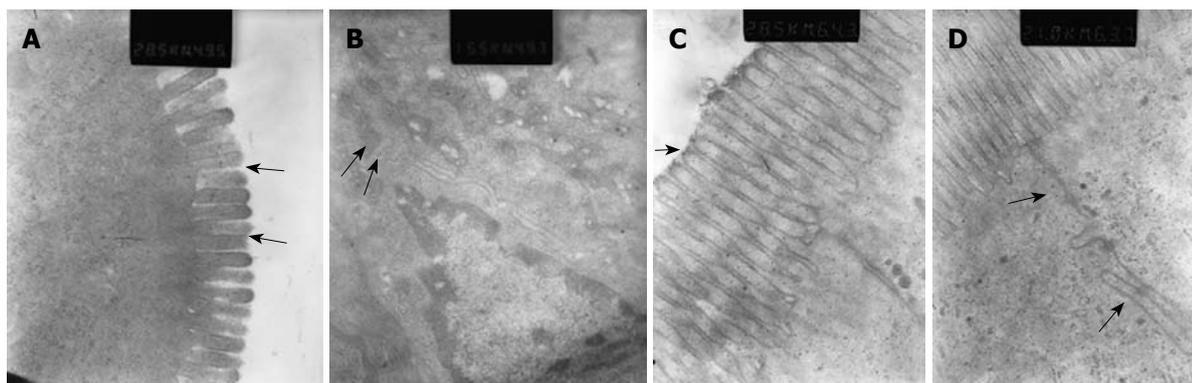

### Real-time PCR results of bacterial translocation

The infection rates detected by real-time PCR were mainly the same as that by bacterial culture. Infection rates by the culture method in MLN and pancreas were a little higher than that by real-time PCR method (MLN 12 to 10,

pancreas 15 to 13), which may result from contamination during culture. An advantage of the real-time PCR method was its accuracy of bacterial enumeration. In this study, the results of bacterial number had been transformed by log<sub>10</sub> for the purpose of better statistics. It was observed that the pancreas had the highest number of bacteria of the 4 kinds of organs ( $P < 0.05$ ), which may relate to necrosis and hemorrhage in pancreas tissue as a good medium for bacteria breeding (Table 4).

## DISCUSSION

Pancreatitis is a distressing disease clinically, especially SAP, which is associated with considerable mortality, as high as 30%-40%. The main features of this condition are pancreatic necrosis and associated sepsis, with both localized and systemic inflammatory response syndromes<sup>[1,14]</sup>. Infection of pancreatic necrosis is regarded to be

**Figure 5 Distal iliac mucosa electron microscopy.** A: Changes of microvilli in a SAP rat, showing loose, shortened microvilli, with some points lost (arrows) (Original magnification,  $\times 28.5$  K); B: Changes of the intermediate junction in a SAP rat, which was unclear with breakage in some parts (arrows) ( $\times 15.5$  K); C ( $\times 28.5$  K) and D ( $\times 21.0$  K) are representative electron microscopy images of the iliac mucosa in control rats, showing long, tight microvilli (arrow) and intact intermediate junctions (arrows).

a main predictor of outcome during SAP, and bacterial translocation of intestinal flora is considered to be the cause of pancreatic infection<sup>[15]</sup>.

Since Bernard first introduced an AP model of rabbits by injection of bile and olive oil into the pancreatic duct 150 years ago, animal experiments have become an irreplaceable method to study the pathophysiology, diagnosis and treatment of AP which, compared with clinical trials, have many advantages such as accessible subjects, standardization of the degree of the lesion, practicability of invasive inspection, adequate tissue samples, practicability of prophylactic treatment.

Nowadays there are many kinds of experimental models used to study bacterial translocation in AP. An ideal model of AP should encompass several features including easy reproducibility, with the ability to vary the severity of AP in a standardized manner according to the experimental aim, and to mimic the morphology and pathophysiology of the human situation<sup>[16]</sup>. At present, several commonly used experimental models were developed to imitate the human biliary pancreatitis, including duodenal loop, biliopancreatic duct ligation, and biliopancreatic duct perfusion.

A duodenal loop in rats can lead to AP of varying severity<sup>[17]</sup>. However, block of the gastrointestinal tract leads to mucosal atrophy and functional changes to the mucosal barrier<sup>[18]</sup>. Obstruction of bile flow into the intestine was shown to reduce intestinal motility, causing small bowel bacterial overgrowth and increased bacterial translocation<sup>[19-21]</sup>. Furthermore, the reflux of duodenal contents, including bacteria, into the biliopancreatic duct will confound the bacterial infection of the pancreas. All these limit its popularity.

The duct ligation model, in which the common biliopancreatic duct is surgically clipped or tied at the sphincter of Oddi complex, could produce moderate pancreatitis with minimal acinar cell necrosis only in American opossum inducing SAP. There are several factors that limit its use. First, obstruction of bile flow into the intestine causes small bowel bacterial overgrowth and bacterial translocation<sup>[20]</sup>. Second, induction of jaundice would impair the immune system to an uncertain degree and make the research result inaccurate. Third,

exclusion of pancreatic proteases in the gut lumen alters intestinal permeability, which does not truly occur in human pancreatitis<sup>[22,23]</sup>.

The duct perfusion model, usually made by perfusion of taurocholate after puncturing the duodenum and cannulating the papilla of Vater, was the most popular model of AP, with etiology resembling human biliary pancreatitis and with the advantage of quick induction of AP and reproducibility of results. However several potential confounders exist in it for study of bacterial translocation. The introduction of duodenal bacteria, through the papilla of Vater into the biliopancreatic duct could potentially affect the result of pancreatic infection; duodenal puncture and intestinal handling during surgery may also potentially affect the mucosal barrier function<sup>[24]</sup>. A complicated surgical procedure and prolonged time are other shortcomings of it.

In 2002 Wu *et al.*<sup>[20]</sup> first reported that pancreatic subcapsular injection of 3.8% Na taurocholate could establish an SAP animal model with multiple organ dysfunction in rats, but with a high mortality rate (90% in a week), which may be related to excessive use of 3.8% Na taurocholate (1 mL/rat) and of small rats (body weight about 100 g). This study used pancreatic subcapsular injection of 3.8% Na taurocholate (1 mL/kg) in rats of about 250 g body weight, and successfully established a model of AP. AP rats showed abnormal performance resembling human disease and the autopsy was in line with the performance of human SAP as well. The serum amylase level and pancreatic tissue pathology gave a clear diagnosis of AP. Changes of serum amylase levels in the AP group were similar to that in human disease, and increased significantly 6 h after induction, reaching a peak in 24 h and remaining at a higher level 48 h later. Pancreatitis pathology showed interstitial edema of the pancreas 6 h after model induction, with local hemorrhaging and slight inflammatory infiltration. Lesions developed progressively to moderate necrosis with obvious inflammatory infiltration 48 h later. The pancreatic pathology score on the 4th and 7th days showed a clear phenomenon of necrotic pancreatitis, including interstitial edema, leukocyte infiltration, acinar cell necrosis and hemorrhage. The scores of edema and hemorrhage in

the pancreatitis group were less than that of necrosis and inflammatory infiltration, which may be related to edema absorption and hematoma organization after several days. Some other organs were involved, peripancreatic calcified plaques formed, with liver and spleen ischemia, intestinal expansion, peritoneal exudates, and even death. Severity reached a peak in the medium term of the disease (3rd and 4th days), with the highest mortality, and although some indices were still high on the 7th day, few deaths occurred after 7 d, which may be related to the adaptation of the body or a sign of recovery. The cumulative mortality rate in 7 d was moderate, about 30%.

Agar plate culture is nowadays the gold standard method for bacterial measurement, however it has some shortcomings such as prolonged time and inaccuracy that limit early detection of bacterial translocation in the clinic. Recently, a real-time PCR method has been demonstrated successfully in the fast and accurate detection of bacteria in samples of blood, feces, and dentine; however few results are available on its use to detect bacteria in parenchymal organs such as lymphoid tissue, spleen, *etc.* Our study confirmed its use in enumeration of bacteria in this AP model in samples of not only blood but also parenchymal organs. Infection rates of all the 4 types of organ in the SAP group were significantly higher than that of the control group with quite similar results detected by bacterial culture or real-time PCR. Infection rate and bacterial number of inferior vena cava blood in the SAP group were both much lower than that of the other organs, while the MLN had a similar infection rate and bacterial number to that of the liver, suggesting a lymphatic route of bacterial translocation may exist in this SAP model.

A damaged intestinal barrier is thought to be a key factor for bacterial translocation in SAP<sup>[25-28]</sup>. In this study, obvious gut barrier damage was observed, with the FITC-Dextran in the SMV and endotoxin levels both significantly increased in AP rats compared to control rats. Electron microscopy of the intestinal mucosa directly showed the damage in the mucosa cells, with microvillus atrophy and intercellular junction disruption.

This rat model requires an invasive laparotomy, with some inevitable potential confounding factors, such as anesthesia, trauma, stress and so on, but few other potential confounding factors existed in it. The surgical procedures were so simple that they could be finished in 15 min once the skills were mastered. No other organs except the pancreas were affected during the surgery, therefore avoiding some potential factors that could affect the measurement of bacterial translocation.

In conclusion, in this study we induced a simple taurocholate pancreatitis model in rats to study the situation of intestinal barrier damage and bacterial translocation in SAP. The results confirmed the situation, as observed clinically, that intestinal barrier damage and bacterial translocation exist in SAP with endotoxemia. However the exact pathophysiologic mechanism of bacterial translocation in SAP is still unknown and needs more intense research for the purpose of determining better preventative measures and treatment of SAP in the clinic.

## COMMENTS

### Background

Severe acute pancreatitis is associated with considerable mortality, as high as 30%-40%. Infection of pancreatic necrosis is regarded to be a main predictor of outcome during severe acute pancreatitis (SAP), and bacterial translocation of intestinal flora is considered to be the cause. Although a multitude of animal models have been used to study the mechanism of bacterial translocation, the exact origin, route, and mechanism of bacterial translocation causing infection of the necrotic pancreas are still unclear.

### Research frontiers

There are now many kinds of experimental models used to study bacterial translocation in acute pancreatitis (AP). However, an "ideal" animal model of SAP was lacking, and should encompass several features including easy reproducibility, ability to vary the severity of AP in a standardized manner, and similar morphology and pathophysiology to that of the human situation.

### Innovations and breakthroughs

A new simple model of SAP in the rat was induced by Na taurocholate, and results showed that significant gut barrier damage and intestinal bacterial translocation occurred in this SAP rat model, with few potential study confounders and with a shorter induction time compared to other commonly used animal models of SAP, suggesting that it may be an appropriate animal model for the study of gut barrier damage and bacterial translocation in SAP.

### Applications

In future, this simple taurocholate-induced rat model may be used in the study of SAP, especially to determine the exact origin, route, and mechanism of bacterial translocation causing infection of the necrotic pancreas.

### Terminology

Intestinal bacterial translocation: normally, intestinal bacteria cannot go through the gut barrier and into the blood or other organs. In the situation of SAP or other severe disease such as shock or major burns, the gut barrier would be damaged and the intestinal permeability increased, causing the intestinal bacteria to translocate from the gut to blood or even other distant organs and induce sepsis, septicemia or even death.

### Peer review

This is a well performed research trying to induce a new simple rat model of SAP, and results definitely showed it was an appropriate animal model for study of bacterial translocation in SAP, with significant gut barrier damage and intestinal bacterial translocation observed but with few potential confounders.

### Abstract

**AIM:** To investigate the diagnostic yield of capsule endoscopy (CE) in patients with obscure gastrointestinal bleeding (OGIB), and to determine whether the yield was affected by different bleeding status.

**METHODS:** Three hundred and nine consecutive patients (all with recent negative gastric and colonic endoscopy results) were investigated with CE; 49 cases with massive bleeding and 260 cases with chronic recurrent overt bleeding. Data regarding OGIB were obtained by retrospective chart review and review of an internal database of CE findings.

**RESULTS:** Visualization of the entire small intestine was achieved in 81.88% (253/309) of cases. Clinically positive findings occurred in 53.72% (166/309) of cases. The positivity of the massive bleeding group was slightly higher than that of the chronic recurrent overt bleeding group but there was no significant difference (59.18% vs 52.69%,  $P > 0.05$ ) between the two groups. Small intestinal tumors were the most common finding in the entire cohort, these accounted for 30% of clinically significant lesions. In the chronic recurrent overt bleeding group angioectasia incidence reached more than 29%, while in the massive bleeding

group, small intestinal tumors were the most common finding at an incidence of over 51%. Increasing patient age was associated with positive diagnostic yield of CE and the findings of OGIB were different according to age range. Four cases were compromised due to the capsule remaining in the stomach during the entire test, and another patient underwent emergency surgery for massive bleeding. Therefore, the complication rate was 1.3%.

**CONCLUSION:** In this study CE was proven to be a safe, comfortable, and effective procedure, with a high rate of accuracy for diagnosing OGIB.

### INTRODUCTION

Obscure gastrointestinal bleeding (OGIB) is defined as recurrent or persistent bleeding or iron deficiency anemia after a negative result from gastric and colonic endoscopy<sup>[1]</sup>. OGIB accounts for approximately 5% of all gastrointestinal (GI) bleeding and lesions in the small bowel<sup>[2]</sup>. Previous capsule endoscopy (CE) investigations of small intestine showed the value in finding small intestinal diseases, especially inflammatory bowel disease and OGIB. CE is a tool that allows for visualization of mucosa throughout the entire small bowel and it has already gained widespread clinical acceptance. CE has been shown to be superior to push enteroscopy<sup>[3,4]</sup>, small bowel follow-through<sup>[5]</sup> and computed tomography

(CT) scan<sup>[6]</sup> in detecting bleeding lesions in the small intestine. Early reports indicated that 45%-66% of patients with OGIB were detected by CE<sup>[3,5,7]</sup>. Despite promising preliminary results, published studies were limited to small groups of patients. In this study a large group of OGIB patients were investigated by CE examination, including obscure-overt and a few obscure-occult patients. We divided these patients into a massive bleeding group (bloody stool or circulatory failure, serious anemia) and a chronic recurrent overt occult bleeding group (melena). Therefore, we investigated the outcome of CE in a large group of patients with OGIB from a single institution and determined whether the results of CE for OGIB patients were related to bleeding status. Also, the selection of OGIB candidates for successful CE evaluation was discussed in our study.

## MATERIALS AND METHODS

### Patients

Three hundred and nine cases underwent CE for the indication of OGIB at our institution from May, 2003 to April, 2008. All patients suffering at least two episodes of bleeding prior to CE had undergone endoscopy without localization of a bleeding lesion. Data of the 309 cases were obtained by retrospective chart review. Data included: age, gender, inpatient or outpatient status, status of GI bleeding (massive bleeding *vs* chronic recurrent overt occult bleeding), median units of red blood cells (RBCs) transfused, mean hemoglobin value prior to endoscopic evaluation, prior radiographic evaluation, computed tomography (CT) evaluation, and lesion diagnosis confirmed by surgery. CE data collected included: whether the entire small intestine was visualized, CE findings in the small intestine and whether complications occurred. Pregnant women, patients with pace-makers or intestinal obstruction were excluded from the study. The study was approved by the local ethics committees.

### Examination with CE

The Given Diagnostic Imaging System (Yoqneam, Israel) was used in our study. This system is composed of three main subunits: an ingestible capsule endoscope, a data recorder, and a workstation. On the day before the examination, patients were allowed to be on a semi-liquid diet and received complete colonic irrigation (polyethylene glycol 4000, PEG4000) 12 h before the examination. Patients were deprived of water for 4 h and defoamer (simethicone) was administered orally 30 min prior to the examination, respectively. Informed consent was obtained. Four hours after swallowing the capsules, subjects were allowed to take light snacks such as milk. During the examination, subjects were allowed to move freely but exposure to any strong electromagnetic field would be avoided. Eight hours later, data recorded would be downloaded to a RAPID workstation for graphic analysis. All capsules were for single use only.

### Data analysis

Findings on CE were classified as diagnostic and non-

**Table 1** Baseline characteristics of patients with OGIB (*n* = 309)

Item	All ( <i>n</i> = 309)	Massive bleeding ( <i>n</i> = 49)	Chronic recurrent overt bleeding ( <i>n</i> = 260)
Mean age ± SD (yr)	55.5 ± 16.6	52 ± 19.1	56.1 ± 16.1
Years (range, yr)	13-87	13-87	15-86
Gender <i>n</i> (%)	150 M (48.5), 159 F (51.5)	27 M (55.1), 22 F (44.9)	123 M (47.3), 137 F (52.7)
Patient status ( <i>n</i> )			
Outpatient	141	0	141
Inpatient	168	49	119
Median units of RBCs transfused (U/mL)	4.63 ± 4.23	8.00 ± 6.46	4.00 ± 6.85
Mean Hb value (range, g/dL)	8.73 (4.52-12.10)	6.20 (4.52-9.85)	9.21 (6.56-12.10)

RBCs: Red blood cells; Hb: Hemoglobin; M: Male; F: Female.

diagnostic lesions. Examples of non-diagnostic lesions included red spots, white spots, erythema, scatter lymphangiectasia, active bleeding, blood clots, or small polyps. Examples of diagnostic lesions included angioectasias, tumors, or ulcers, obvious small bowel inflammation, and roundworms. A diagnostic lesion had to definitely or probably account for the patient's bleeding and was diagnosed by two experienced endoscopists.

### Statistical analysis

Statistical methods included  $\chi^2$  analysis for comparison of the positive diagnostic yield of CE between patients with acute large bleeding and chronic recurrent overt occult GI bleeding. SPSS 16.0 (SPSS Inc. Chicago, IL) was used in our study, and *P* < 0.05 was considered a statistical significance.

## RESULTS

### Patient baseline characteristics

The 309 cases with OGIB in this study are listed in Table 1 with regard to their baseline characteristics. Prior to CE, for all patients, the cause of OGIB could not be identified with either gastroscopy or colonoscopy. Among them, 39.16% (121/309) underwent a CT scan to detect the source of GI bleeding at the same time, and the percentage of patients who finally underwent surgical operation was 11% (34/309).

### Results of CE

**Completion of CE:** Of all CE procedures performed, 81.88% (253/309) extended through the entire small intestine. However, the rate of going right through the intestine in the chronic recurrent overt bleeding group was higher than that of the massive bleeding group (83.85% *vs* 69.39%, *P* = 0.017, respectively). Four cases with gastric motility disorder resulting in the capsule remaining in the stomach during the entire test were compromised, and another case resulted in emergency surgery because of the large amount of bleeding.

**The diagnostic ability of CE:** The yield of CE, defined

SAME: Superior mesenteric artery embolus; SB: Small bowel; BRBNS: Blue rubber bleb nevus syndrome.

as diagnostic lesions as the source of OGIB, was 53.72% (166/309) in the entire cohort and slightly higher in those patients with massive bleeding compared to those in the chronic recurrent overt bleeding group, with no significant statistical difference between groups (59.18% *vs* 52.69%, *P* > 0.05, respectively) (Table 2).

Small bowel angioectasias and small bowel tumors (masses) were common and accounted for over 28% of lesions in the entire cohort (Table 3). In the chronic recurrent overt bleeding group, angioectasia incidence was over 29% (Table 3), while in the massive bleeding group small bowel tumors were a common finding at over 51%. Angioectasias were the second most common lesion and accounted for 22.2%, while Crohn's disease was in third place (Table 3).

**Age and diagnostic yield of CE:** Increasing patient age was associated with positive diagnostic yield of CE and the findings of OGIB were different according to age range. In the 20-40 years age group, Crohn's disease was found in almost 45.5% (15/33) of cases, and in the 40-60 years age group, tumor incidence was 46.2% (26/56). Angioectasias occurred in over 50% (39/73) of cases when the patients' age was over 60 years (Figure 1).

**Figure 1** Lesions detected by capsule endoscopy (CE) for different age ranges. 1: Crohn's disease; 2: SB tumor; 3: Non-specific enteritis; 4: SB tumor; 5: Crohn's disease; 6: Angioectasias; 7: Angioectasias; 8: SB tumor; 9: Ucler.

**Failed diagnoses of CE:** Among the non-diagnostic studies, 15 cases were diagnosed by further examinations, such as CT scan, angiography, and surgery. In the massive bleeding group, two cases were negative and three cases were actively bleeding with unavailable diagnostic lesions. In the chronic recurrent overt bleeding group, four cases were actively bleeding but without diagnostic lesions. One case was diagnosed as tumor but finally confirmed as Meckel's diverticulum by surgical operation. One case was diagnosed by CE as ulcer and was confirmed as tumor by surgical operation. Four cases were negative.

## DISCUSSION

OGIB is the main indicator of the appropriateness of CE as a diagnostic procedure. Many studies have demonstrated a high degree of usefulness of CE as a diagnostic method. The common findings of OGIB reported are angioectasias, small bowel tumor or mass, inflammation, Meckel's diverticulum, *etc.* Barium small bowel examination, angiography and push enteroscopy were the common evaluations for OGIB before the development of CE. Barium showed a diagnostic rate of 3%. Angiography was an invasive method, with a diagnostic rate of 27%-77%, requiring a blood flow > 0.5 mL/min, while push enteroscopy could not reach the lower part of the small bowel and had a diagnostic rate of 19%-32%. Recently, double-balloon enteroscopy (DBE) has been introduced for the diagnosis of OGIB, as reported by a meta analysis<sup>[8]</sup>. The diagnostic yield from CE was significantly higher than that of DBE without the combination of oral and anal insertion approaches [137/219 *vs* 110/219, OR 1.67 (95% CI: 1.14-2.44), *P* < 0.01, respectively], but not superior to the yield of DBE with combination of those two insertion approaches [26/48 *vs* 37/48, OR 0.33 (95% CI: 0.05-2.21), *P* > 0.05, respectively]. However, the DBE is invasive and patients are not as tolerant of this method. CE is the only non-invasive method which can examine the whole small intestine.

All cases in our study could tolerate well the CE examination. Five cases were compromised, one in the chronic recurrent overt bleeding group because of capsule

**Figure 2 Angioectasias.** The red spot is the site of angioectasias (arrow).

**Figure 4 Hemangioma.** The red-blue bubble is the site of hemangioma (arrow).

**Figure 3 Mesenchymoma.**

retained in the stomach, and four in the massive bleeding group. Among these four cases, three were compromised because of somatostatin; the capsules were all retained in the stomach due to disorders of gastric mobility. In one Crohn's patient CE was obstructed. No other complication occurred. Therefore, the complication rate was 1.3%. Technical problems and complications of CE are infrequent. Former studies showed a rate of CE complications ranging from 0.75%-5%<sup>[9-11]</sup> and also that the existence of patients who had difficulty swallowing the capsule was a rare event. In patients with known altered gastric mobility, the problem could be easily solved by endoscopic placement of the capsule into the duodenum<sup>[12,13]</sup>.

In our study, CE progressed through the whole small bowel in 81.55% (253/309) of patients, and complete progression rate in the chronic recurrent overt bleeding group was higher than that of the massive bleeding group. CE did not reach the ileocecum because of retention in the intestine due to motility disorder or stricture of the intestinal lumen. Capsule retention occurred almost universally at the site of lesions. In these patients, surgical intervention to retrieve the trapped capsule also allowed for resection of the small bowel involved in the lesion. CE retention by the lesions in our study was found in small bowel Crohn's disease cases and small bowel tumors.

The bowel preparation with PEG and simethicone ensured a good quality of pictures. The 309 patient cohort in our study is the largest series in published studies. The diagnostic rate in our study was 53.72%, which was similar to previous published studies. The diagnostic accuracy yield of CE in published reports ranges from a rate of 30% to 92%, mainly depending on the definition of positive findings and the status of bleeding investigated<sup>[3,5,9,14-16]</sup>. The

yield in a series of 260 patients previously reported was 53%. In patients with ongoing obscure overt GI bleeding the yield was 87%, and 46% in patients with obscure occult bleeding<sup>[11]</sup>. In this present study we included the presence of active blood as a positive finding. We discovered that the diagnostic rates in both the massive bleeding group and the chronic recurrent overt bleeding group were not statistically significantly different; 59.18% (29/49) and 52.69% (137/260), respectively. These results demonstrate that CE is the first diagnostic option for patients with massive bleeding, since the diagnostic rate was not affected by blood in the small bowel lumen. The relationship between the timing of the procedure and the diagnostic yield of CE remains a controversial issue. Pennazio *et al*<sup>[9]</sup> found the highest yield in patients with ongoing GI bleeding, and therefore argued for ordering a CE procedure earlier in the setting of obscure overt bleeding. One would presume that blood in the GI tract would mask visualization of the mucosa and that lesions could easily be missed. Delaying CE until after an acute bleed may allow for clearance of residual blood and better visualization of the mucosa and suspicious lesions. However, our study demonstrated that acute large bleeding did not affect the diagnostic rate.

The definition of a positive finding on CE is an important idea not addressed in early reports<sup>[17]</sup>. Although experts have begun to address this issue, final consensus has not yet been reached<sup>[17-19]</sup>. For the purposes of this study, nonspecific mucosal changes such as red spots, erythema, scatter lymphangiectasia and thickened folds were considered to be clinically insignificant. Lesions such as angioectasias, tumors, masses or ulcers were included as positive findings in this series if they could completely or partially account for the GI bleeding. In our study, active bleeding but without definite lesion was described as a non-diagnostic finding. Figures 2-6 show the typical lesions found in our study.

There were 15 cases confirmed as being a pseudo-negative result surgically. Five were in the massive bleeding group; 2 of these on CE were negative, and 3 of them found only active bleeding but without diagnostic lesions. Ten cases were in the massive bleeding group, 4 of them on CE were negative, and 4 of them found only active bleeding but without diagnostic lesions. One case was diagnosed as tumor but finally confirmed as Meckel's diverticulum by surgery, while another case indicating an ulcer was confirmed as small tumor by surgery.

Figure 5 Lymphoma.

Figure 6 Crohn's disease.

CE can completely cover the whole GI tract and the procedure is well tolerated. It may provide false-positive and false-negative findings due to the possibility of uncontrollable movement and low-resolution pictures taken<sup>[20]</sup>. It was recently reported that CE missed an advanced small intestinal cancer that was later diagnosed with push enteroscopy<sup>[21]</sup>, suggesting that CE is not an exclusive procedure but one complementary to other diagnostic tools in the assessment of small intestinal lesions. In Mehdizadeh's series<sup>[22]</sup>, CE found a potential bleeding source in 63 patients, but 34.9% (22/63) of them received negative results in the following DBE procedure. In our study, failed or negative findings of CE may have resulted from four main reasons: (1) growth pattern of lesions: transmural and extra-mural lesions could not be detected by CE; some angioectasias could only be detected by microscope; (2) technical factors of CE: the visual field of CE was only 140°, which perhaps leads to a blind spot; some lesions could be omitted due to movement of CE which could not be controlled. One case with Meckel's diverticulum was diagnosed as small bowel tumor because of only partial views of the lesion; (3) cleanness of small bowel: in our study all cases were prepared with PEG and simethicone prior to examination and the visualization of CE was better than without any preparation, but in some cases, bubbles and food debris still affected the visualization. Delay of gastric motility caused by disease or drugs such as somatostatin would retain the capsule in the stomach, which could not go through the whole small bowel during the working time. The large number of false positives may result from the definition of clinically significant *vs* clinically insignificant findings.

In this study, common findings of lesions with OGIB were small bowel tumor (mass), angioectasias and

Crohn's disease. In the massive bleeding group, common findings of OGIB were small bowel tumor or mass and angioectasias, while in the chronic recurrent overt bleeding group common findings of OGIB were angioectasias, small bowel tumor (mass), and Crohn's disease. A higher positive percentage of small intestine tumors was found compared with all previous studies published due to the definition of diagnostic lesion. Some of the angioectasias discovered in our study cannot be assumed to contribute to the bleeding, and these cases were not included in the positive findings.

In this study, younger patients were more often found to have Crohn's disease, and older patients (older than 60 years) were prone to have angioectasias, while between 40 and 60 years, tumors accounted for a bigger proportion. According to the American Gastroenterological Association (AGA)<sup>[23]</sup>, younger patients are likely to have small intestinal tumors, Meckel's diverticulum, Dieulafoy's lesion, and Crohn's disease, while older patients (older than 40 years) are prone to bleeding from vascular lesions, which comprise of up to 40% of all causes, and nonsteroidal anti-inflammatory drug-induced small bowel disease. Our finding was somewhat different from the AGA. Thus, in clinical work, patients who are suspected of having Crohn's disease should be examined by CE as early as possible.

In summary, tolerance of administration, higher diagnostic yield, improvement in patient outcome and lower complication rate make CE an important advance in the diagnosis of OGIB. The AGA strongly recommended the CE as the first choice for OGIB. In our large cohort undergoing clinical investigation, we demonstrate that diagnostic rate of OGIB is determined by the definition of a clinically significant lesion. In addition, the massive bleeding status did not affect the positive detection rate.

## COMMENTS

### Background

Capsule endoscopy (CE) is a tool for visualization of mucosa throughout the entire small bowel. It has already gained a wide clinical acceptance in the evaluation of obscure gastrointestinal bleeding (OGIB). Despite promising preliminary results, published studies were limited to small groups of patients with heterogeneous indications.

### Research frontiers

CE is now commonly performed for gastrointestinal bleeding of obscure origin. However, reports about large groups of patients with OGIB receiving CE are rare in the literature up till now.

### Innovations and breakthroughs

Published studies of CE in the diagnosis of OGIB were limited to small groups of patients. The study analyzed a large group of OGIB patients, so the finding will be more objective. The authors concluded that the clinically important findings by CE in patients with OGIB were not affected by the different bleeding status, but disease diagnosis by CE is related to different bleeding status and ages. Small bowel tumor was the most common finding in general and also in the massive bleeding group. Angioectasias accounted for the majority of cases in the chronic recurrent overt bleeding group.

### Applications

CE is now widely used to diagnose small bowel diseases, especially in patients with OGIB. More and more patients who are suspected of having small bowel diseases are diagnosed using CE with less discomfort, less time taken and also fewer financial costs.

**Terminology**

CE is a device that can be easily swallowed by patients. It can progress through the whole digestive tract and take two photos every second. These photos can be studied on a workstation.

**Peer review**

The study is well constructed. It is a retrospective review of all the OBIG cases from a single referral centre and is, admittedly, one of the biggest series of its kind. Other than that though, it simply confirms findings of previous reports in the field.

### Abstract

Burkitt's lymphoma is a highly aggressive non-Hodgkin lymphoma, often presenting in extra-nodal sites. It generally has a poor spontaneous outcome and needs aggressive treatment with systemic and intrathecal chemotherapy. Occurrence at the gastric site is rare. We report the case of a 39-year old woman who presented with a prominent ulcerated lesion of the antrum corresponding histologically to a Burkitt's lymphoma associated with *Helicobacter pylori* (*H pylori*) infection. Interphase fluorescence *in situ* hybridization (FISH) demonstrated *c-MYC* gene rearrangement in tumour cells without *BCL2* or *BCL6* gene translocations. Ulcer healing and tumour regression with a complete histological response were obtained 8 wk after *H pylori* eradication. In spite of this complete remission, taking into account the high risk of recurrence, the patient received systemic and intrathecal chemotherapy. Two years later, the patient remained in complete remission. This is the first report of a gastric Burkitt's lymphoma responding to *H pylori* eradication. These findings raise

### INTRODUCTION

The stomach is the most common site of extranodal malignant lymphomas, constituting 30%-45% of all extranodal malignant lymphoma and 1%-7% of all gastric malignancies<sup>[1]</sup>. The most common gastric lymphomas are extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT), characterized by an infiltration of the mucosa by centrocyte-like B-cells associated with lymphoepithelial lesions, and diffuse large B cell lymphomas (DLBCL)<sup>[2]</sup>. This last terminology is commonly used to describe *de novo* DLBCL or DLBCL associated with a low grade component. Burkitt's lymphoma (BL) is a highly aggressive non-Hodgkin lymphoma, often presenting in extranodal sites or as acute leukaemia. The incidence of gastric BL is low compared to other types of gastric lymphomas, although its true incidence is not yet defined<sup>[3]</sup>.

There is a close link between *Helicobacter pylori* (*H pylori*) and gastric MALT lymphomas and probably also with gastric DLBCL<sup>[4,5]</sup>. But the possibility of an association between *H pylori* and gastric BL has only been suggested

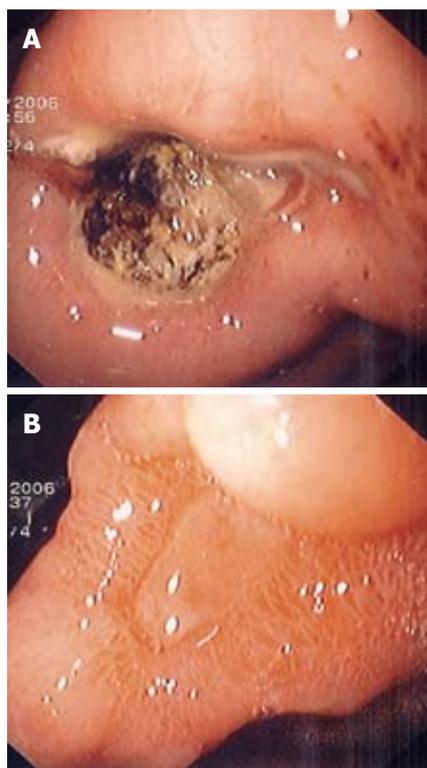

in occasional cases in children<sup>[6,7]</sup>. Eradication of *H pylori* is now well established as the first line treatment of gastric MALT lymphoma<sup>[8]</sup> and reports in the literature show 60%-80% remission rates<sup>[9-11]</sup>. In addition, several cases of complete remission of gastric DLBCL after *H pylori* eradication have been reported<sup>[12-16]</sup>. On the contrary, BL is known to require aggressive chemotherapy in order to induce remission, with systemic and intrathecal chemotherapy, and the impact of *H pylori* eradication on gastric BL has never been evaluated. We describe the first case of complete remission of a gastric BL in an adult patient following *H pylori* eradication.

## CASE REPORT

A 39-year old woman underwent a first gastroscopy in January 2006. She had complained of abdominal pain for 3 mo. She had no previous history of peptic ulcer disease. Examination revealed no palpable mass in the abdomen, ascites or superficial lymphadenopathy. A barium contrast radiography of the stomach showed an important ulcerated lesion of the antrum on the lesser curvature, suggesting malignancy. The patient underwent a gastroscopy that confirmed the ulcer at the angularis, measuring 5 cm × 5 cm (Figure 1A).

Histologic examination of gastric biopsies showed a diffuse infiltration of the mucosa by atypical lymphoid cells with a CD20+, CD3- immunophenotype and a diagnosis of “*de novo* DLBCL” was made initially by the local pathologist. *H pylori* corpuscles were observed histologically using modified Giemsa stain, and the patient was treated for *H pylori* eradication with pantoprazole 40 mg twice daily, amoxicillin 1 g twice daily and clarithromycin 500 mg twice daily for one week. Then she continued pantoprazole 40 mg once daily for three weeks and was referred to our gastroenterology unit four weeks later for further management of her disease. Initial gastric biopsies were reviewed by an expert hematopathologist (CCB) and additional immunostains and molecular studies were performed. The ulcerated mucosa was diffusely infiltrated by monotonous medium-sized lymphoid cells with round nuclei, scarce cytoplasm and starry sky pattern at low magnification (Figure 2A and B). Numerous mitoses were observed. *H pylori* were detected in biopsy specimens. Immunohistochemistry showed that the lymphoid cells were CD20+, CD5-, CD10+, BCL2-, BCL6+, MUM1-, P53+ and 100% of tumour cells were Ki67 positive (Figure 2C and D, and Figure 3A-C). *In situ* hybridization using EBERS probes was performed and EBV transcripts were not detected in tumour cells. Interphase fluorescence *in situ* hybridization (FISH) analysis was performed on formalin-fixed paraffin-embedded (FFPE) tissue sections using split signal FISH DNA probes for *c-MYC*, *BCL2* and *BCL6* (Dako AS, Glostrup, Denmark) according to the manufacturer's recommendations (www.euro.fish.org). *C-MYC* gene rearrangement was observed in tumour cells without *BCL2* or *BCL6* gene rearrangement (Figure 3D). All these findings were in accordance with the diagnosis of BL.

Follow up endoscopy performed 6 wk after initiation

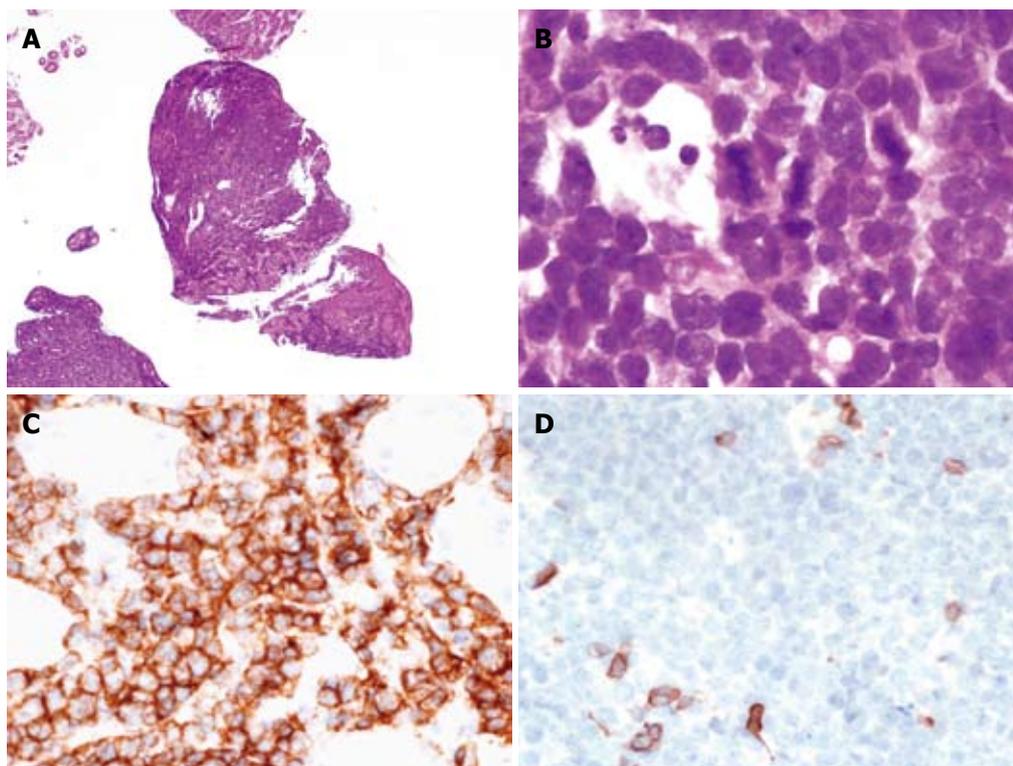

**Figure 1** Endoscopic aspect of the gastric lesion before and after *Helicobacter pylori* (*H pylori*) eradication. A: Oesophagogastroduodenoscopy shows a large ulcer at the angularis; B: Ulcer healing 3 mo after *H pylori* eradication.

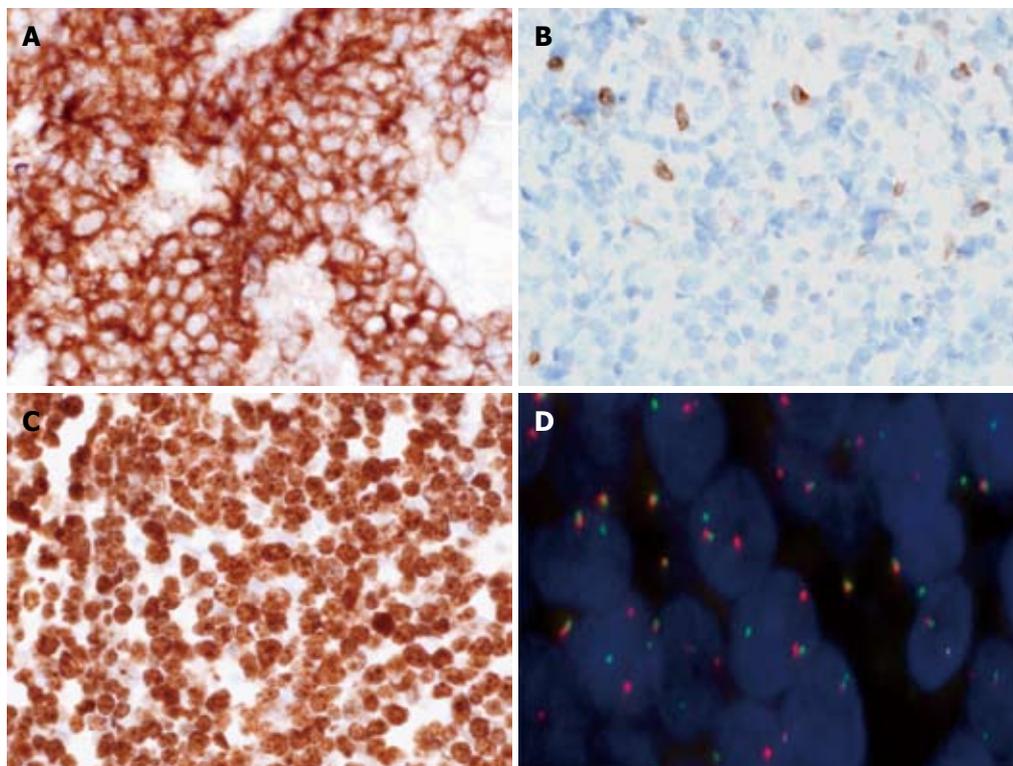

of *H pylori* eradication therapy showed the ulcer size had decreased, measuring 3 cm in diameter, and histological analysis of gastric biopsies showed complete remission of the disease and absence of *H pylori*. Endoscopic ultrasonography showed a markedly increased thickness of the gastric wall (10 mm) with disappearance of the layer structure on the lesser curvature of the antrum and with a perigastric lymphadenopathy measuring 7 mm in diameter.

Appropriate investigations were performed to stage the lymphoma. Blood cell counts and biochemical parameters, including LDH and  $\beta$ 2microglobulin level, and hepatic biology were normal. An EBV serology test showed IgG positive and IgM negative viral capsid antigen (VCA) and Epstein-Barr nuclear antigen (EBNA), reminiscent of “an old infection”. Human immunodeficiency virus serology was negative. Bone marrow biopsy and lumbar puncture were normal. Abdominal computed tomography showed an important increase in gastric wall thickness. As a perigastric lymphadenopathy was present at endoscopic ultrasonography, the patient was classified as stage IIE according to the Ann Arbor classification. The International Prognostic Index, including age (older or not than 60 years), LDH level (normal or elevated), tumour stage (I, II/III, IV), number of extranodal sites involved by disease (0 or 1/more than 1), patient performance status (less or more than 2), was scored 1 (low-risk group).

A new endoscopy with biopsy was performed one month later and showed complete healing of the ulcer (Figure 1B), and persistent histological remission of the disease. In spite of the absence of residual disease, taking

**Figure 2 Morphological and immunohistochemical features of the disease.** A: At low magnification, the gastric mucosa is diffusely infiltrated by medium sized lymphoid cells (HE,  $\times 25$ ); B: Tumour cells are medium sized with scarce cytoplasm, round nuclei and fine chromatin; numerous mitoses are observed; tangible body macrophages are present (HE,  $\times 1000$ ); C: Immunohistochemistry shows that the tumour cells are CD20+,  $\times 400$ ; D: CD5-,  $\times 400$ .

**Figure 3 Immunohistochemical and cytogenetic features of the disease.** A: Tumour cells are CD10+,  $\times 400$ ; B: BCL2-,  $\times 400$ ; C: 100% of tumour cells are Ki67+,  $\times 400$ ; D: Fluorescence *in situ* hybridization (FISH) performed with split signal FISH DNA probes for *c-MYC* revealed distinct red and green split signals in many nuclei, consistent with *c-MYC* gene rearrangement, beside yellow fusion signals for the non-rearranged alleles,  $\times 1000$ .

into account the high risk of lymphoma recurrence, she then received systemic chemotherapy, which consisted of

cyclophosphamide, vincristine, prednisone, doxorubicin and methotrexate, associated with intrathecal injection of

methotrexate, until August 2006. The gastric endoscopic aspect with systematic biopsies was checked every 6 mo. The last outcome visit, in March 2008, with a new scanography and a new endoscopy and endoscopic ultrasonography confirmed the complete remission of the disease.

## DISCUSSION

BL is a mature aggressive B-cell lymphoma, characterized by a high degree of proliferation of the neoplastic cells and deregulation of the *c-MYC* gene<sup>[17,18]</sup>. It is a distinct entity that occurs sporadically worldwide, sometimes associated with immunodeficiency or immunosuppression, and is endemic in central Africa (the lymphoma belt of Africa). Cells in both sporadic and endemic forms of BL are B lymphocytes that have clonal immunoglobulin (*IG*) gene rearrangement and 8q24/*MYC* translocation to the *IG* heavy chain region, 14q32 or less commonly at the lambda 22q11 or kappa 2p12 light chain loci. Epstein Barr virus and malaria are recognised as important cofactors of endemic BL. A combination of these two diseases seems to boost the incidence of endemic BL in the lymphoma belt by a factor of 100-150. But this disease can occur in the absence of both of these infections and arboviruses and plant tumour promoters are other possible local cofactors. There are probably other cofactors which are unknown.

The stomach is the most common site of extranodal malignant lymphomas. The incidence of gastric BL is low as compared to other types of gastric lymphomas, although its true incidence is not yet defined. Like other types of BL, gastric BL is known to have a highly aggressive clinical course. However, one study including 21 patients with a gastric BL, showed a better outcome for these patients as compared to 26 non-gastric BL with a long-term survival of 90%. An especially good outcome was observed when the disease was localized to the stomach and the authors concluded that, in this case, prognosis of BL and DLBCL could be similar. This observation suggested a common pathogenesis<sup>[3]</sup>.

There is a close association between *H pylori* and gastric lymphomas<sup>[4]</sup>. But the link between *H pylori* and BL has not been demonstrated yet. *H pylori* plays an important role in the development and growth of MALT lymphoma and its eradication has been shown to achieve durable regression in 56% to 100% of patients with early stage low-grade gastric MALT lymphoma<sup>[8-11]</sup>. *In vitro* co-culture of *H pylori* with tumour B cells in the presence of non-neoplastic T cells proved that the bacteria were able to induce proliferative responses of MALT lymphocytes but not large B cells<sup>[19]</sup>. Therefore, DLBCL of the stomach were generally believed to be *H pylori*-independent, and unlikely to respond to antibiotic therapy. However, in addition to sporadic cases, one prospective study of 24 patients with DLBCL has shown that antibiotic therapy could also result in complete remission in patients with early stage gastric DLBCL with low grade components<sup>[15]</sup>. The same authors compared two prospective studies of the efficacy of *H pylori* eradication

in the treatment of early-stage MALT lymphoma and DLBCL of the stomach and showed that the therapeutic efficacy of antibiotics for stage IE gastric high grade transformed MALT lymphoma was similar to their efficacy in stage IE low-grade lymphoma. It was suggested that the response was possible only in DLBCL with low grade component and more frequent in cases of superficial gastric wall involvement and in the absence of BCL10 protein nuclear expression<sup>[16-20]</sup>.

Histologically, the distinction between diffuse large B cell lymphoma and BL is sometimes difficult, especially in adult patients. It is well known that these two entities may show overlapping morphological and immunohistochemical features<sup>[21,22]</sup>. Whether this case represents "a B cell lymphoma, unclassifiable, with features intermediate between diffuse large B cell lymphoma and Burkitt lymphoma", a provisional entity defined in the recent 2008 World Health Organization (WHO) classification of lymphoid neoplasms may be discussed<sup>[2]</sup>. However, this case met all the characteristic morphological (starry sky appearance, monotonous medium sized tumour cells with round nuclei and scarce cytoplasm), immunohistochemical (CD10+, BCL2-, 100% Ki67 positivity) and cytogenetic (*MYC* translocation without *BCL2* or *BCL6* translocation) diagnosis criteria of BL according to the 2008 WHO classification, therefore excluding the hypothesis of *de novo* DLBCL.

In the present case, eradication of *H pylori* was performed before the definitive histological results were available. So, we had the opportunity to observe the first case of BL remission following *H pylori* eradication in an adult patient. This observation highlights the potential role of an infectious agent, notably *H pylori*, as a cofactor in the development of BL and suggests that *H pylori* eradication should be systematic in the context of *H pylori* positive gastric BL in association with conventional chemotherapy regimens.

### Abstract

Intragastric balloon therapy, as a part of a multidisciplinary weight management program, is an effective short-term intervention for weight loss. Although the insertion procedure is easy and generally well tolerated by patients, a few complications can occur. We report here a heavy smoker with intragastric balloon insertion complicated by colonization with opportunistic organisms. The 27-year-old female, body mass index 35.5 kg/m<sup>2</sup>, had a BioEnterics® Intragastric Balloon inserted under conscious sedation without any peri-operative complications. Six months later, when the standard removal time arrived, the balloon was seen to be covered with a necrotic white-gray material. Microbiological examination revealed *Enterobacter cloacae* and *Candida* species yeast colonies. We recommend that asymptomatic fungal and/or bacterial colonization should be considered among the complications of the intragastric balloon procedure, despite its rarity.

### INTRODUCTION

Obesity will be one of the 21st century's most important problems and will become a worldwide epidemic. In 2015 approximately 2.3 billion people will be overweight and 700 million people will be reported to be obese<sup>[1]</sup>. Obesity treatment options consist of a calorie-restricted diet, lifestyle modification, medical treatment, endoscopic intragastric balloon application and bariatric surgery<sup>[2]</sup>. In 1982, the intragastric balloon was used for the first time by Nieben *et al*<sup>[3]</sup>, who observed that long-lasting and well-tolerated gastric bezoars can result in significant weight loss.

Intragastric balloon therapy, as a part of a multidisciplinary weight management program is an effective short-term intervention for weight loss. In experienced hands the application and removal of the intragastric balloon is easy and has relatively low morbidity and mortality compared to bariatric surgery<sup>[4,5]</sup>.

The major complications of the intragastric balloon are intolerance, gastric ulcers, gastric erosion and esophagitis, spontaneous deflation of the balloon, ongoing vomiting for 1-3 wk or more, abdominal pain and gastroesophageal reflux. There are also a few reported cases of gastric perforation, dilatation and small intestinal obstruction<sup>[6,7]</sup>.

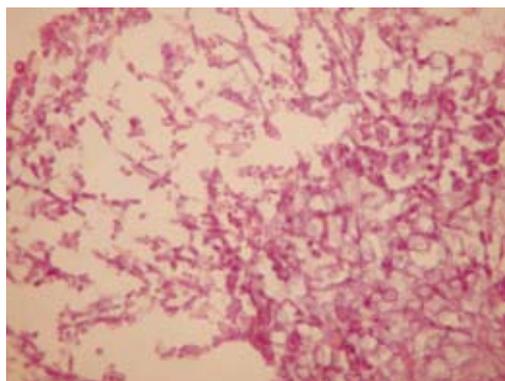

We present here an asymptomatic intragastric balloon infected by *Candida* and *Enterobacter* species which has not been encountered previously in the literature, and we discuss possible and probable causes.

### CASE REPORT

A 27-year-old female, heavily smoking patient, 91 kg in weight and body mass index (BMI) 35.5 kg/m<sup>2</sup> had a BioEnterics® Intragastric Balloon (BIB; BioEnterics Corporation, California, USA, S/N: 123456789) inserted. The patient was premedicated with 0.05 mg/kg iv midazolam (Dormicum Roche, Turkey) for 10 min before the insertion and an additional 0.5-0.75 mg/kg

**Figure 1** Removed silicon balloon covered with a necrotic white-gray material.

**Figure 2** Necrotic material with mycotic hyphae and spores (HE, x 600).

propofol (Diprivan, Astra Zeneca, Turkey) was given iv during the application to attain deeper sedation<sup>[8]</sup>. Under video-endoscopic view, the balloon was positioned in the stomach and inflated with 550 mL NaCl 0.09% mixed with 10 mL methylene blue solution. The upper gastrointestinal endoscopic findings were normal. As is common, the patient experienced intense nausea, vomiting and cramping abdominal pain in the first 48 h. With appropriate medical support these standard complaints subsided significantly by the fifth day after the procedure. In the following days the patient was given a 1200 kcal/d diet. The balloon was removed according to protocol on the 180th d after placement. On the 180th d, the patient's weight was 69 kg, with BMI 26.9 kg/m<sup>2</sup>, excess weight loss 62.8%, and excess BMI loss 81.4%. During the removal of the balloon, endoscopy revealed normal esophageal and gastric mucosal surfaces except slight gastritis. However, the surface of the silicon balloon was covered with a necrotic white-gray layer (Figure 1). This necrotic material covered almost 80% of the total surface of the balloon. The balloon had been removed endoscopically with no problems. Histopathologic examination revealed a few fungal hyphae, polymorphonuclear infiltration of leukocytes and mononuclear cells (Figure 2), with active and chronic inflammation. Gram staining showed epithelial cells, leukocytes, gram-negative bacilli and yeast cells. With Ziehl-Nielsen staining, acid-resistant bacilli were not seen. Microbiologic examination revealed *Enterobacter cloacae* and *Candida* species yeast colonies. The patient was discharged with appropriate non-specific supportive treatment without any clinical problems. The patient was evaluated endoscopically after a 3-mo clinical follow-up and no pathology was found.

## DISCUSSION

Intra-gastric balloon application has relatively low morbidity and mortality compared to other bariatric procedures. In particular it is the primary choice for excessively morbidly obese patients who are prepared to undergo surgical bariatric procedures.

The complication rate is extremely variable between studies. This is because minor complications can easily be managed by phone calls or during scheduled visits. The major complications of the intra-gastric balloon procedure are balloon intolerance (7%), gastric ulcer (0.4%),

gastric erosion and esophagitis (18.2%), spontaneous deflation of the balloon (3%-23%), ongoing vomiting for 1-3 wk or more (0%-15.9%), abdominal pain (5%), and gastroesophageal reflux (1.8%). There are also a few reported cases of gastric perforation (0.1%-0.21%), dilatation and small intestinal obstructions (0.17%-0.8%)<sup>[5-7]</sup>. Infection arising from intra-gastric balloon insertion is not a common issue. There is no such published case in the literature.

The isolated microorganism, *Enterobacter cloacae* is a gram-negative bacillus. Frequently, it causes nosocomial infections in patients in whom respiratory support instruments or catheterizations are applied, or it appears as opportunistic infections in patients with immunodeficient and debilitating diseases<sup>[9]</sup>.

*Candida* is a yeast and the most common cause of opportunistic mycoses worldwide. It is also a frequent colonizer of human skin and mucous membranes. *Candida* is a constituent of the normal flora of the skin, mouth, vagina, and stool<sup>[10]</sup>.

Colonization of soft lining materials with microorganisms, particularly *Candida* species, is a common clinical problem. The intra-gastric balloon has a silicon elastomer structure and da Silveira *et al*<sup>[11]</sup> mentioned in their paper that silicone-based soft lining materials are more susceptible to *Candida* adhesion.

Candidiasis of the gastrointestinal system mostly affects the esophagus and the infection is seen as patch plaques on the mucosa<sup>[12]</sup>. Although a typical fungal infection was not detected in the esophagus of our patient, such contamination can not be excluded and may have occurred during endoscopic intervention, i.e. the balloon passage through the oral cavity or during its application.

Of the predisposing factors causing gastric candidiasis, delayed gastric emptying and gastric stasis have been proposed. It is a well known issue that one of the mechanisms of action of the intra-gastric balloon is to delay gastric emptying<sup>[13]</sup>. Thus the slowing down of normal peristalsis of the stomach by the intra-gastric balloon may allow opportunistic organisms to colonize more readily.

The patients in whom an intra-gastric balloon is inserted should take proton pump inhibitors during application of the balloon because of gastric hyperacidity. These proton

pump inhibitors result in a hypochlorhydric gastric medium which makes opportunistic infections more likely<sup>[14-17]</sup>.

The important feature identified in the present case was that she was a heavy smoker. It is known that cigarette smoke has many effects on the gastric mucosa. These can result in progression from gastritis to gastric ulcers and even carcinoma. Smokers appear to be at higher risk of becoming infected with *Helicobacter pylori* (*H. pylori*) and this increased risk may result from the adverse effects of smoking on antioxidants or the immune system which may interfere with normal protection against *H. pylori*<sup>[18-20]</sup>.

Because the infection detected on the balloon was a colonization rather than a systemic infection we recommended appropriate non-specific supportive treatment for the patient. However, we recommend systemic antifungal and antibacterial treatment for patients in whom the gastrointestinal integrity is damaged, who are immunocompromised or who are scheduled for bariatric surgery.

We present here a heavy smoker with an intragastric balloon infection. In our series of 201 endoscopic removals of 263 intragastric balloons, this case was the only one with such an infection. The rare incidence of colonization leads us to believe that this kind of infection may be multifactorial, and no single cause can be highlighted. In patients who receive an intragastric balloon, predisposing factors for opportunistic infections such as gastric stasis, smoking and antacid medications should be taken into consideration and patients monitored for these infections. Any asymptomatic balloon infection, especially opportunistic pathogens, should be treated with appropriate medications if the integrity of the gastrointestinal system is damaged.

### Abstract

Spontaneous bacterial peritonitis (SBP) is a treatable complication of decompensated cirrhosis. Coagulopathy with evidence of hyperfibrinolysis or clinically evident disseminated intravascular coagulation precludes paracentesis. Alcoholic hepatitis with fever, leucocytosis and abdominal pain should be evaluated for SBP. Oral ofloxacin is as effective as parenteral cefotaxime in treatment of SBP except for inpatients with vomiting, encephalopathy, or renal failure. Albumin is superior to hydroxyethyl starch in treatment of SBP.

Jain P. Spontaneous bacterial peritonitis: Few additional points. *World J Gastroenterol* 2009; 15(45): 5754-5755 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5754.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5754>

### TO THE EDITOR

We read with great interest the article "Spontaneous bacterial peritonitis" by Koulaouzidis *et al*<sup>[1]</sup> in March 7, 2009 issue of *World Journal of Gastroenterology*. The review was extensive. However, some points may be useful for the management of patients with spontaneous bacterial peritonitis (SBP).

Serious complications unusually occur in paracentesis, but a subgroup of patients with renal failure should be carefully monitored. Pache *et al*<sup>[2]</sup> observed 9 bleeding complications in their study of 4729 paracentesis patients, which were probably due to qualitative platelet abnormality in 8 patients with renal failure.

Coagulopathy precludes paracentesis only when there is clinically evident hyperfibrinolysis or disseminated intravascular coagulation<sup>[3]</sup>. Ascitic fluid leak post paracentesis can be prevented by inserting a needle along the Z-track and keeping the patient in the right lateral position for a few hours.

Biochemical tests are required for total protein and albumin in each ascitic fluid sample whereas optional tests are required for glucose and lactate dehydrogenase levels<sup>[3]</sup>.

Ascitic fluid culture should be performed before antibiotics are used because even a single dose of antibiotics causes the culture to produce no growth of bacteria in 86% of cases<sup>[4]</sup>.

Patients with alcoholic hepatitis present with fever, leukocytosis and abdominal pain mimicking SBP. An elevated ascitic fluid polymorphonuclear count in these patients is not due to peripheral leukocytosis<sup>[5]</sup> but may represent SBP. Empiric treatment with antibiotics can be discontinued after 48 h if ascitic fluid, blood and urine cultures are negative.

Oral ofloxacin (400 mg, twice a day for an average of 8 d) is as effective as parenteral cefotaxime against SBP when the patients do not have vomiting, shock, grade II (or higher) hepatic encephalopathy or serum creatinine > 3 mg/dL<sup>[6]</sup>.

Sigal *et al*<sup>[7]</sup> have shown in their study that albumin should be used in SBP patients with their serum creatinine > 1 mg/dL, blood urea nitrogen > 30 mg/dL, or total bilirubin > 4 mg/dL, and not used in patients without such indications. Albumin is superior to hydroxyethyl starch in treatment of SBP<sup>[8]</sup>.

Fernández *et al*<sup>[9]</sup> in their randomized trial have shown that daily norfloxacin can prevent SBP and hepatorenal syndrome and has a survival advantage in patients with their ascitic fluid protein < 1.5 gm/dL and at least with one of the following indications, namely serum creatinine  $\geq$  1.2 mg/dL, blood urea nitrogen  $\geq$  25 mg/dL, serum sodium  $\leq$  130 mg/L, Child-Pugh  $\geq$  9 points, and bilirubin  $\geq$  3 mg/dL.

Intermittent dosing of double, enforced trimethoprim-sulfamethoxazole (5 doses per week) or ciprofloxacin (single oral dose of 750 mg per week) may be ineffective against resistant flora<sup>[10]</sup>.

In conclusion, proper selection of patients for paracentesis, high index for suspected SBP in alcoholic hepatitis patients and albumin treatment can help the management of SBP.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week  
<http://www.apdwcongress.org/2009/index.shtml>

October 7-11, 2009  
Boston Park Plaza Hotel and Towers, Boston, MA, United States  
Frontiers in Basic Cancer Research

October 13-16, 2009  
Hyatt Regency Mission Bay Spa and Marina, San Diego, CA, United States  
Advances in Breast Cancer Research: Genetics, Biology, and Clinical Applications

October 20-24, 2009  
Versailles, France  
Fifth International Conference on Tumor Microenvironment: Progression, Therapy, and Prevention

October 30-November 3, 2009  
Boston, MA, United States  
The Liver Meeting

November 15-19, 2009  
John B. Hynes Veterans Memorial Convention Center, Boston, MA, United States  
AACR-NCI-EORTC Molecular Targets and Cancer Therapeutics

November 21-25, 2009  
London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports/Science Edition, Index Medicus, MEDLINE, PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, PubMed Central, Digital Object Identifier, CAB Abstracts, and Global Health. ISI, Thomson Reuters, 2008 Impact Factor: 2.081 (32/55 Gastroenterology and Hepatology).

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles should be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kpn I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327  
CN 14-1219/R

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

Ten hepatitis B virus (HBV) genotypes (A-J) and 34 HBV subgenotypes have been identified so far. HBV genotypes and subgenotypes have distinct geographical distributions, and have been shown to differ with regard to clinical outcome, prognosis, and response to interferon treatment. Infection with subgenotype A2 is frequently associated with high viral load, resulting in acute infection *via* horizontal transmission. Genotypes A and B are more sensitive to interferon treatment than genotypes D and C, respectively. Genotype B is more frequent in acute hepatitis than genotype C, whereas genotype C (C2) is more frequently associated with an increased risk of hepatocellular carcinoma (HCC), mostly cirrhotic, as compared with genotype B (B2). Genotype mixture is associated with high viral load and worse outcome of HBV infection. HBV mutations in the S genes, especially amino acids substitution at position 145 (G145R), are associated with immune escape, whereas mutations in the PreS or S genes which impair HBsAg secretion could present a risk to blood safety. HBV variants harboring mutations in the viral polymerase gene that confer resistance to nucleoside analogs may be selected during antiviral therapy. Different genotypes have distinct mutation patterns in the PreS and Enh II/BCP/Precore regions. PreS deletions, C1653T, T1753V, and A1762T/G1764A are associated with an increased risk of HCC. HCC-associated HBV mutants may not transmit *via* mother-to-child transmission, and are likely generated during HBV-induced pathogenesis. Examination of HBV mutations alone or in combination and host genetic suscep-

tibility will be helpful in classifying the HBV-infected subjects who will develop HCC and need active antiviral treatments.

Cao GW. Clinical relevance and public health significance of hepatitis B virus genomic variations. *World J Gastroenterol* 2009; 15(46): 5761-5769 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5761.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5761>

### INTRODUCTION

Hepatitis B virus (HBV) belongs to the hepadnaviridae, a family of enveloped viruses with an incomplete double-stranded DNA genome of 3.2 kb. The double-stranded DNA genome of HBV contains four overlapping open reading frames that encode the surface protein, the core protein, a polymerase, and a multifunctional nonstructural protein called X. The PreS region, which consists of PreS1 (nucleotides 2848-3204) and PreS2 (nucleotides 3205-154) domains, overlaps a region encoding the polymerase gene. The enhancer II (Enh II; nucleotides 1636-1744) and basic core promoter (BCP; nucleotides 1751-1769) regions overlap with the X gene (nucleotides 1374-1835).

Infection with HBV is a major public health problem. Approximately 45% of the world's population lives in regions where HBV infection is endemic. Approximately 2 billion people have been exposed to HBV, and more than 300 million are chronically infected with HBV<sup>[1]</sup>. In Asia and most of Africa, chronic HBV infection is common and usually acquired perinatally or in childhood<sup>[2]</sup>. Chronic HBV infection is one of the most important determinants of the occurrence of liver cirrhosis (LC) and hepatocellular carcinoma (HCC). Most HCC

cases (> 80%) occur in either Eastern Asia or in sub-Saharan Africa where HBV is endemic<sup>[3]</sup>. HBV infection contributes to more than 50% of HCC cases worldwide and 70%-80% of HCC cases in highly HBV endemic regions. The relative risks of HCC among people infected with HBV ranges from 5 to 49 in case-control studies and from 7 to 98 in cohort studies<sup>[4]</sup>. The incidence of HCC (per 100 000 person/year) among people with chronic HBV infection ranges from 400 to 800 in males and from 120 to 180 in females<sup>[4]</sup>. Standard HBV vaccination dramatically decreases HCC prevalence among vaccinees aged 6-19 years<sup>[5]</sup>. HBV genomic variations, including genotypes, subgenotypes, and HBV mutations in the PreS region and the Enh II/BCP/Precore region are associated with the development of LC and HCC in different HBV replication and hepatitis B e antigen (HBeAg) status.

## HBV GENOTYPES/SUBGENOTYPES AND THEIR CLINICAL RELEVANCE

### *Distribution of HBV genotypes and subgenotypes*

Eight genotypes (genotypes A-H) have been identified by a sequence divergence greater than 8% in the entire HBV genome or a sequence divergence greater than 4% in the S region<sup>[6]</sup>. HBV isolated in Vietnam and Laos has been suggested to form a ninth genotype I<sup>[7,8]</sup>. The designation has been questioned due to complex recombination. Recently, a HBV strain isolated from a Japanese patient has been provisionally designated HBV genotype J. HBV genotype J is closer to gibbon/orangutan genotypes than to human genotypes in the P and large S genes and closest to Australian aboriginal strains and orangutan-derived strains in the S gene, whereas it is closer to human than ape genotypes in the C gene<sup>[9]</sup>. Genotypes have further been separated into subgenotypes if the divergence in whole nucleotide sequence is between 4% and 8%<sup>[10]</sup>. Currently, subgenotypes 1-5 of genotype A, subgenotypes 1-8 of genotype B, subgenotypes 1-8 of genotype C, and subgenotypes 1-7 of genotype D have been identified<sup>[11-37]</sup>. HBV genotypes and subgenotypes have distinct geographical distributions (Table 1), and often present demographic characteristics. HBV genotype A1, A3, A4, and A5 are endemic in Africa, especially in West Africa, whereas genotype A2 is endemic in Europe<sup>[11-15]</sup>. Genotypes B and C are predominant in Asian and Pacific islanders<sup>[6,10,16-22,28]</sup>. Of HBV genotypes B and C, subgenotypes B2 and C2 are endemic in most parts of Asia. Subgenotype B1 is endemic in Japan<sup>[16]</sup>. Subgenotype C4 is encountered in Aborigines from Australia, and frequently termed as the Australian aboriginal strain<sup>[9,19]</sup>. Subgenotypes B3-B8, C1, C3, and C5-C8 have been isolated in South Asia, especially in Indonesia and the Philippines<sup>[17-22,28]</sup>. Genotype D is endemic in the entire Old World including Africa, Northern and South Eastern Asia, the Mediterranean area, and most European countries<sup>[13,23-26,32-34,37]</sup>. Subgenotype D1 is predominant in Moslem ethnicity. Subgenotype D2 is endemic in Russia and the Baltic region<sup>[26,32]</sup>. Subgenotypes D2, D3, and D5 have been found in In-

dia<sup>[32]</sup>. Subgenotypes D4 and D6 are endemic in Oceania and Indonesia, respectively<sup>[19,33]</sup>. A new subgenotype D7 has been found in Tunisia<sup>[34]</sup>. HBV genotype E is endemic in Western and Central Africa<sup>[13,27,35]</sup>. HBV genotypes F, G, and H are endemic in America<sup>[29-31,36]</sup>. More subgenotypes have been found in South Asia, Oceania, and Africa than other areas in the world, probably indicating evolutionary history of HBV. The distribution of HBV genotypes often provides clues about human migration. HBV genotype B is more frequent than genotype C in Taiwan<sup>[38,39]</sup>. Although genotype C is more frequent than genotype B in Mainland China<sup>[40]</sup>, HBV genotype B accounts for more than 80% in Zhangzhou (our unpublished data), a city at the coastal line of Fujian Province of Mainland China where early Taiwan residents had migrated from. Subgenotype C1 is endemic in Southern Guangdong Province of Mainland China<sup>[41]</sup>, this subgenotype is also endemic in Hong Kong<sup>[42]</sup>. Hong Kong residents are mostly from Southern Guangdong Province of Mainland China. HBV genotype E is endemic in Africa. As genotype E is essentially absent from the Americas despite the Afro-American slave trade until at least the beginning of the 19th century, genotype E strains may have been introduced into the general African population only within the past 200 years<sup>[14,35]</sup>. The genetic diversity of HBV and the geographical distribution of its subgenotypes provide a tool to reconstruct the evolutionary history of HBV and may help to complement genetic data in the understanding of the evolution and past migrations of man<sup>[19]</sup>.

### *Genotype mixture and its clinical relevance*

In an HBV endemic area, infection with more than one HBV genotype often results in genotype recombination and genotype mixture (co-infection or super-infection with multiple HBV genotype in an infected person). With the use of multiplex PCR, a genotype mixture has been frequently identified in the HBV-infected subjects<sup>[43,44]</sup>. HBV genotype mixture has been associated with high viral load in patients with chronic hepatitis B (CHB) as compared with patients with a single genotype, also associated with increased *in vitro* HBV replication<sup>[45]</sup>. In our recent study, the prevalence of genotype mixture in asymptomatic hepatitis B surface antigen (HBsAg) carriers (ASC), patients with HCC, and patients with CHB is 5.4%, 10.6%, and 13.7%, respectively. Genotype mixture (mostly mixed genotype B with genotype C) is associated with higher viral load and more severe course of the disease than HBV genotype C alone<sup>[40]</sup>. These results indicate that co-infection or superinfection with multiple genotypes is associated with worse prognosis of HBV infection.

### *Clinical relevance of HBV genotypes/subgenotypes*

HBV genotypes and subgenotypes have been shown to differ with regard to clinical outcome, prognosis, and response to antiviral treatment. Infection with HBV genotype A is associated with high viral load which facilitates viral transmission. High replication rates of genotype A

Table 1 Geographic distribution and important clinical relevance of HBV genotypes and subgenotypes

Genotype	Subgenotype	Geographic distribution	Important clinical relevance	Ref.
A	A1	Africa	ND	[13-15]
	A2	Europe	Acute infection, chronicificaton, more sensitive to interferon treatment than genotype D	[11,12,47,48]
	A3	West Africa	ND	[13-15]
	A4	West Africa	ND	[15]
	A5	West Africa	ND	[14,15]
B	B1	Japan	Fulminant hepatitis	[16]
	B2	Most of Asia, except Korea	Acute hepatitis, HCC in mostly those younger than 50 years	[6,10]
	B3	Indonesia	ND	[17,18]

I	ND	Vietnam, Laos	ND	[9]
J	ND	Japan (might be from Borneo)	HCC	

HBV: Hepatitis B virus; ND: Not determined; HCC: Hepatocellular carcinoma.

in adults lead to an increased risk of horizontal transmission of HBV by sexual activity because a high concentration of HBV DNA in serum is associated with high concentrations in semen and other body fluids of HBV carriers<sup>[46]</sup>. Genotype A also tends to cause chronic infection following an acute course. This has been demonstrated in Japan where genotype A introduced from Europe has started to increase sharply in patients with acute infection since 1991, and gradually in those with chronic infection<sup>[47]</sup>. As compared with HBV genotype D endemic in Europe, genotype A is more sensitive to interferon  $\alpha$  treatment<sup>[48]</sup>. Spontaneous HBeAg seroclearance was significantly higher in genotype A carriers than in carriers of genotypes A, B, D, and F. After losing HBeAg, those with genotypes C and F were more likely to revert to the HBeAg-positive state<sup>[49]</sup>. Infection with subgenotype B2 is associated with HCC or HCC recurrence in young, mostly noncirrhotic, patients in Mainland China and Taiwan<sup>[39,40,50]</sup>, whereas infection with subgenotype

B1 is frequently associated with fulminant hepatitis B in Japan<sup>[16]</sup>. Infection with HBV genotype C is associated with increased risks of LC and HCC at an older age as compared with infection with the HBV genotype B<sup>[38,51,52]</sup>. Although HBV subgenotypes C1 and C2 are associated with the risk of HCC, only HBV subgenotype C2 is independently associated with an increased risk of HCC<sup>[53]</sup>. Genotype B has recently been shown by us to be more likely to cause acute hepatitis B, while the serum viral load of ASCs with genotype B is significantly higher than that of ASCs infected with genotype C<sup>[54]</sup>. As compared with genotype C, HBV genotype B has been shown to be associated with earlier HBeAg seroconversion, and associated with better response to interferon therapy in HBeAg-positive chronic hepatitis<sup>[55,56]</sup>. Early HBeAg seroconversion typically confers a favorable outcome<sup>[57]</sup>. In HBeAg-negative patients, detectable HBV DNA and HBV genotype C are associated with more severe liver damage<sup>[58]</sup>. Thus, infection with HBV genotype C is as-

sociated with worse clinical outcome as compared with genotype B. Data from India have shown that HBV sub-genotype D1 is significantly associated with chronic liver disease, whereas HBV subgenotype D3 is significantly associated with occult HBV infection. No apparent clinical relevance was observed in those infected with HBV subgenotypes D2 and D5<sup>[32]</sup>. There are very limited data on the association of genotype E with its clinical relevance. Population-based prospective cohort studies have found that HBV genotypes C and F are associated with the highest risk for HCC or LC<sup>[59]</sup>. HBV genotypes E, F, and H appear to be sensitive to IFN- $\alpha$  treatment<sup>[60]</sup>. The recombination of two genotypes is frequent in the area where the two genotypes are endemic<sup>[6,15,61]</sup>, probably due to the selection of viral growth advantage. Lower rates of response to IFN- $\alpha$  treatment in patients with HBV genotype G might be related to the frequent occurrence of double infection<sup>[60]</sup>.

## CLINICAL AND PUBLIC HEALTH SIGNIFICANCE OF HBV MUTATIONS

### **Association of HBV PreS and S region mutations with immune escape, occult infection, and the development of HCC**

HBV genomic variations in the PreS and S regions which are selected during the infection course are of clinical and public health importance. The HBV envelope is composed of 3 forms of HBsAg, the so-called large (L, coded for by the PreS1/S2/S gene), middle (M, the PreS2/S gene), and small (S, the S gene) proteins. The small or major peptide is 226 amino acids in length, and the M and L proteins are assembled by amino-terminal extension of 55 amino acids at the PreS2 domain and of 108-119 amino acids of the PreS1 domain. HBsAg is the main target for viral neutralization, either by natural or vaccine-induced anti-HBs. A central major hydrophilic region (MHR, approximately residues 103-173) exposed at the surface of viral particles. The MHR itself is structured into five regions, including three central loops held together by disulphide bonds. The immunodominant "a" determinant (residues 124-147), against which most neutralizing antibodies are directed and which is the major target of HBsAg detection tests, is formed by loops 2 and 3<sup>[62]</sup>. HBV with mutations in the portion of the S gene coding the "a" determinant of hepatitis surface antigen, including a glycine to arginine substitution at position 145 (G145R) and other S gene mutations in the region of amino acids 120-147, can potentially evade neutralizing anti-HBs antibody and infect vaccinated people. G145R is by far the most common immune escape mutant, whereas the most important immune escape mutants with substitutions outside of the "a" determinant is P120S/T. Mutations in the S genes within "a" determinant (but not G145R) are partially responsible for occult HBV infection, which are characterized by the presence of HBV DNA in serum in the absence of detectable HBsAg, and could present a risk to blood safety<sup>[63]</sup>. Mutations in PreS are also associated with occult HBV infection<sup>[64]</sup>, probably due

to the inactivation of the overlapping PreS2/S promoter which causes impaired HBsAg secretion.

The 5' flanking region of the S gene coding the PreS1 and PreS2 domains is overlapped by the region of the P gene coding the spacer domain of the viral polymerase. Genotype D and non-human primate isolates inherently have a 33 nucleotide deletion at or near the beginning of the PreS1 open reading frame<sup>[10,62]</sup>. The PreS1 protein contains the hepatocyte binding site (amino acids 21-47) and is known to be essential for virion assembly and for the transporting of virions out of the hepatocyte<sup>[65]</sup>. The PreS1 and PreS2 regions play an essential role in the interaction with immune responses because they contain several epitopes for T or B cells<sup>[66]</sup>. There is little evidence supporting the idea that PreS mutants are transmissible, therefore, the PreS mutation might generate during the pathological process following the infection. The PreS mutations emerge in chronic infections, often in patients treated with interferon, and seem to represent desperate attempts to escape from host immune surveillance<sup>[62]</sup>. Many of the mutations affecting the PreS domains of the envelope proteins are deletions. More recently, PreS deletions are frequently associated with an increased risk of HCC, especially in those infected with HBV genotype C<sup>[66-69]</sup>. Our recent meta-analysis showed that the frequencies of the PreS deletion mutation consecutively increased during the progression of chronic HBV infection from ASC states to LC or HCC ( $P_{trend} < 0.001$ ), while the frequencies of mutations at the promoter sites of PreS1 and PreS2 were significantly higher in the patients with HCC than in the patients without HCC ( $P < 0.001$ ,  $P = 0.032$ , respectively)<sup>[70]</sup>. It is suggested that PreS deletion and nucleotide substitution mutations at the promoter sites of PreS1 and PreS2 may serve as useful biomarkers for predicting the clinical outcomes of HBV-infected patients, especially for predicting HCC.

### **Polymerase mutations associated with drug resistance**

HBV variants harboring mutations in the viral polymerase gene that confer resistance to antiviral drugs may be gradually selected during long-term antiviral therapy with nucleoside analogs. The main polymerase gene mutations conferring resistance to nucleoside analogs have been well characterized. Lamivudine resistance mutants harbor a M204V or I substitution in the YMDD motif of the C domain of the polymerase/reverse transcriptase. Adefovir resistance mutants harbor a N236T and/or A181V amino acid substitution in the D and B domains of viral polymerase, respectively<sup>[71,72]</sup>. Entecavir resistance mutations occurred on a background of lamivudine resistance, as these patients received entecavir for lamivudine failure, with a combination of substitutions I169T and M250V, or T184G and S202I. These additional mutations clearly conferred an increased level of entecavir resistance compared to the initial lamivudine resistant strain<sup>[62]</sup>. Resistance to telbivudine has been associated with a M204I mutation in the viral polymerase<sup>[73]</sup>. Table 2 summarizes drug-resistance-associated amino acid substitutions in the 5 domains of HBV polymerase. On the other hand, the reappearance of wild-type virus

Table 2 HBV mutations associated with drug resistance

Nucleoside analogs	Mutations in the polymerase domains (amino acids)				
	A	B	C (YMDD)	D	E
Lamivudine/Emtricitabine	-	V173L L180M	M204I/V	-	-
Adefovir	-	A181V	I233V	N236T	-
Entecavir	-	I169T T184G	S202I	M250V	-
Telbivudine	-	-	M204I	-	-
Famciclovir	-	L180M	-	-	-

-: Not reported.

as the major viral population after cessation of drug treatment is probably due to persistence of non-mutated cccDNA molecules in hepatocytes even after long-term drug treatment<sup>[62,74]</sup>. Naïve patients infected with adefovir resistance mutants have been reported<sup>[71]</sup>. In this case, drug resistant mutants transmitted to a naïve subject may be stable since there will be no competition with wild-type virus.

#### The association of viral mutations in the Enh II/BCP/Precore region with hepatocarcinogenesis

The core promoter, positively and negatively regulated by Enhancer II and to some extent by Enhancer I, controls the transcription of precore mRNA and pregenomic RNA that can be the mRNA for both core protein and the viral polymerase and is the template for viral replication. HBeAg expression indicates active viral replication. There are two classes of mutants that affect HBeAg expression, BCP mutants and precore mutants. Although viral loads are generally several logs lower in HBeAg-negative patients than in HBeAg-positive patients and children born to HBeAg-positive mothers have a much higher risk of contracting chronic HBV infection than children born to HBeAg-negative mothers<sup>[62]</sup>, some combined mutations in the Enh II/BCP/Precore region like 1766/1768, 1762/1764/1766, 1753/1762/1764, and 1753/1762/1764/1766 mutations have been associated with high HBV DNA production in the *in vitro* transfection studies<sup>[75,76]</sup>. HBV core promoter mutations other than those at 1762/1764 appear to upregulate viral DNA replication and, at the same time, greatly reduce HBeAg production. Although expression of HBeAg has been associated with an increased risk of HCC in a prospective study<sup>[77]</sup>, high viral load in HBeAg-negative patients is often associated with worse outcome of chronic HBV infection, especially in those with HBV carrying mutations at the PreS and Enh II/BCP/Precore regions<sup>[66,78-82]</sup>.

Several mutations at the Enh II/BCP/Precore region have been recently associated with an increased risk of HCC. These mutations include C1653T, T1753V, T1766/A1768, and A1762T/G1764A<sup>[81-92]</sup>. Our recent meta-analysis using published data up to August 31, 2008 has shown that C1653T, T1753V, and A1762T/G1764A are each associated with an increased risk of HCC, whereas precore mutations G1896A and C1858T are not associ-

ated with the risk of HCC, regardless of HBeAg status and HBV genotype<sup>[70]</sup>. A1762T/G1764A has been shown to be a valuable biomarker for identifying a subset of male HBsAg carriers who are at extremely high risk of HCC in a prospective study<sup>[92]</sup>. In a community-based prospective study, A1762T/G1764A and genotype C have been associated with an increased risk of HCC, whereas G1896A in the precore region has been associated with decreased risk of HCC<sup>[84]</sup>. G1896A has been associated with fulminant hepatitis in Japan<sup>[93]</sup>. Since the Enh II/BCP/Precore region overlaps with X gene in the HBV genome, mutations in the Enh II/BCP/Precore region should be included in evaluating the role of HBV X protein on the development of HCC. That is to say, the mutated X protein might be more carcinogenic than the wild-type X protein in HBV-induced hepatocarcinogenesis.

C1653T, T1753V, and A1762T/G1764A are increasingly more prevalent as chronic HBV infection progresses from the asymptomatic HBsAg carrier state to liver cirrhosis or HCC, indicating that these mutations accumulate before the diagnosis of HCC<sup>[70]</sup>. This finding suggests that these HBV mutations may serve as useful biomarkers for predicting clinical outcomes of the patients with CHB, especially with regard to predicting whether they will develop HCC. Like the PreS mutants, HCC-associated HBV mutants in the Enh II/BCP/Precore region, e.g. A1762T/G1764A mutants, may not transmit *via* mother-to-child vertical transmission because the children whose mothers carrying HBV mutants were mostly found to be infected with wild-type form of the same viruses<sup>[94,95]</sup>. These HBV mutations are likely generated during HBV-induced pathogenesis. A1762T/G1764A is frequently detected approximately 10 years before the diagnosis of HCC<sup>[70]</sup>. It is therefore necessary to set up likely checkpoints in the life time for the examination of the HCC-associated HBV mutations in HBV-infected subjects. Recent epidemiological studies demonstrated that male sex, old age, high HBV DNA (> 10000 copies/mL), viral mutations in the PreS and the Enh II/BCP/Precore regions, HBV genotypes (C and F), cirrhosis, and family history were associated with an increased risk of HCC<sup>[50-52,65,79-92,96,97]</sup>. Further study should focus on systemic evaluation of these risk factors for the prediction of HCC.

Combined HBV mutations in the PreS and the Enh II/BCP/Precore regions are becoming important in evaluating HCC risk of HBV-infected subjects<sup>[66,69,98]</sup>. In a meta-analysis, we have demonstrated that the frequencies of A1762T/G1764A+C1653T (8.6%), A1762T/G1764A+T1753V (14.6%), A1762T/G1764A+PreS mutation (2.2%), and A1762T/G1764A+C1653T+T1753V (3.2%) are low in ASCs, whereas the frequencies of A1762T/G1764A-based combined mutations are statistically significantly higher in patients with HCC than in patients without HCC<sup>[70]</sup>. For the prediction of HCC in HBV-infected subjects, A1762T/G1764A alone has a sensitivity and specificity of 70.6% (95% CI = 68.7% to 72.5%) and 60.6% (95% CI = 68.7% to 62.0%), respectively, whereas C1653T+T1753V and A1762T/G1764A+C1653T+T1753V has high specificity [92.6% (95% CI = 89.2% to 96.0%) and 93.9% (95%

CI = 90.5% to 97.2%), respectively] but low sensitivity [20.6% (95% CI = 14.9% to 26.3%) and 24.3% (95% CI = 17.5% to 31.1%), respectively]<sup>[70]</sup>. These mutations, alone or in combination, might be reasonably arranged as predictive markers for the prediction of HCC.

## INTERACTIONS BETWEEN HBV AND HOST SUSCEPTIBLE GENES

HBV genetic variations are necessary but insufficient for HBV-induced hepatocarcinogenesis. HBV genotype-associated mutations might be selected by the host immune system and in turn promote host hepatocarcinogenesis. It is possible that the mutated X protein could transactivate host oncogenes responsible for the development of HCC or that transactivators encoded by some oncogenes select the specific HBV mutations during HBV-induced hepatocarcinogenesis. There are many important trans-activating nuclear factors binding sites located in the PreS and the Enh II /BCP/Precore regions<sup>[66,69,70]</sup>. Mutations in the PreS and the Enh II /BCP/Precore regions might alter the binding ability of some potential trans-activating factors and therefore alter viral replication and/or change expression profiling of some related host genes. The genetic predisposition of some host genes like *MDM2* and *p53* gene polymorphisms, cytokine and TGF- $\beta$ 1 gene polymorphisms, and DNA repair gene polymorphisms have been associated with HBV-induced hepatocarcinogenesis<sup>[99-102]</sup>. Our recent study demonstrated that nuclear factor  $\kappa$ B1 gene promoter *NFKB1*-94ATTG2 allelic carriage,  $\kappa$ B $\alpha$  gene promoter *NFKBLA*-826T and *NFKBLA*-881AG allelic carriage, and HBV genotype C are independently associated with an increased risk of HCC, while the estimated haplotype frequency of *NFKBLA* promoter -881G-826T-519C is significantly higher in the patients with HCC than in the HBV-infected subjects without HCC<sup>[103]</sup>. Even so, it is largely unknown so far how HBV variations interact with host genetic susceptibility. Understanding the interactions between HBV genetic variations and host genetic susceptibility is undoubtedly helpful in classifying the HBV-infected subjects who will develop HCC in future and need active anti-viral treatments and extensive surveillance of HCC.

## CONCLUSION

Ten HBV genotypes (A-J) and 34 subgenotypes have been identified so far. HBV genotypes and subgenotypes have distinct geographical distributions, and have been shown to differ with regard to clinical outcome, prognosis, and response to interferon treatment. Infection with subgenotype A2 is frequently associated with high viral load, resulting in acute infection *via* horizontal transmission. Genotypes A and B are more sensitive to interferon treatment than genotypes D and C, respectively. Genotype B is more common in acute hepatitis than genotype C, whereas genotype C (C2) is more frequently associated with an increased risk of HCC, mostly cirrhotic, as compared

with genotype B (B2). Genotypes C and F are frequently associated with the development of HCC. Viral load of the patients with genotype mixture is usually higher than that of those infected with unique genotype. HBV mutations in the S genes, especially amino acid substitutions at position 145 (G145R), are associated with immune escape, whereas the mutations in the PreS or S genes which cause impaired HBsAg secretion could present a risk to blood safety. HBV variants harboring mutations in the viral polymerase gene that confer resistance to antiviral drugs may be selected during antiviral therapy with nucleoside analogs. Genetic diversity of HBV is partly due to virus/host interactions and partly due to parallel evolution in geographically distinct areas. Different genotypes have a distinct pattern of mutations in the PreS and Enh II /BCP/Precore regions. PreS deletions, C1653T, T1753V, and A1762T/G1764A are associated with an increased risk of HCC. HCC-associated HBV mutants may not transmit *via* mother-to-child vertical transmission, and are likely generated during HBV-induced pathogenesis. Frequent examination of HBV mutation alone or in combination as well as genetic susceptibility will be helpful in classifying the HBV-infected subjects who will develop HCC and need active anti-viral treatments.

## INTRODUCTION

In recent years, endoscopic image quality has improved as the devices have advanced technologically. Although techniques such as chromoendoscopy, high resolution and magnification endoscopy, narrow band imaging, and auto-fluorescence imaging improve the visualization and detection of mucosal lesions, biopsy of the targeted lesion must still be performed for a formal histological diagnosis of cellular and architectural atypia.

Suspicious areas identified during endoscopy are targeted and biopsied or removed endoscopically. However, there are several disadvantages that may be associated with biopsies or endoscopic resection, including bleeding or perforation. Non-representative biopsies may miss relevant portions of tissue, leading to underestimation of the diagnosis. Random biopsy sampling or endoscopic resection for non-neoplastic lesions can also be time-consuming. It would be ideal if a definite diagnosis could be made during endoscopy without a biopsy.

Recent technological advances in miniaturization have allowed for a confocal scanning microscope to be integrated into a conventional flexible endoscope, or into trans-endoscopic probes, a technique now known as confocal endomicroscopy (CEM) or confocal laser endomicroscopy (CLE). This newly-developed technology has enabled endoscopists to collect real-time *in vivo* histological images or “virtual biopsies” of the gastrointestinal (GI) mucosa during endoscopy, and has stimulated significant interest in the application of this technique in clinical gastroenterology<sup>[1-8]</sup>.

This report aims to evaluate the current data on the utility of this new technology in clinical gastroenterology and its potential impact in the future, particularly in the screening or surveillance of GI neoplasia.

## PRINCIPLES OF CONFOCAL MICROSCOPY

Confocal microscopy has been used in the biological sciences since 1961 when the concept of optical sectioning of a biological specimen was introduced.

## Abstract

Recent technological advances in miniaturization have allowed for a confocal scanning microscope to be integrated into a conventional flexible endoscope, or into trans-endoscopic probes, a technique now known as confocal endomicroscopy or confocal laser endomicroscopy. This newly-developed technology has enabled endoscopists to collect real-time *in vivo* histological images or “virtual biopsies” of the gastrointestinal mucosa during endoscopy, and has stimulated significant interest in the application of this technique in clinical gastroenterology. This review aims to evaluate the current data on the technical aspects and the utility of this new technology in clinical gastroenterology and its potential impact in the future, particularly in the screening or surveillance of gastrointestinal neoplasia.

De Palma GD. Confocal laser endomicroscopy in the “*in vivo*” histological diagnosis of the gastrointestinal tract. *World J Gastroenterol* 2009; 15(46): 5770-5775 Available from: URL:

To create confocal images, a low-powered laser (an argon-ion laser that generates an excitation wavelength of 488 nm, blue laser light) is focused by an objective lens into a single point, within a fluorescent specimen. The same lens is used as both the condenser and objective folding. The point of illumination thus coincides with the point of detection within the specimen. Light emanating from that point is focused through a pinhole to a detector, and light emanating from outside the illuminated spot is rejected. The illumination and detection systems are in the same focal plane and are termed “confocal” (Figure 1).

After passing the pinhole, the fluorescent light is detected by a photodetection device (a photomultiplier tube or avalanche photodiode), transforming the light signal into an electrical one that is recorded by a computer. All detected signals from the illuminated spot are captured and measured.

As the laser scans over the plane of interest, a whole image is obtained pixel-by-pixel and line-by-line, whereas the brightness of a resulting image pixel corresponds to the relative intensity of detected fluorescent light.

The gray-scale image created is an optical section representing one focal plane within the examined specimen.

Confocal microscopy provides the capacity for direct, non-invasive, serial optical sectioning of intact, thick, living specimens with a minimum of sample preparation as well as a marginal improvement in lateral resolution. Because confocal images depend on fluorescence, a fluorescent dye (contrast agent) is required to make objects visible.

## CONTRAST AGENTS

A fluorescent contrast agent is used and is needed to achieve high contrast images using CEM. Potentially suitable agents in humans are fluorescein, acriflavine, tetracycline or cresyl violet. The contrast agents can be applied systemically (fluorescein, tetracycline) or topically (acriflavine, cresyl violet) by using a spraying catheter. Of these, intravenous fluorescein sodium (10%) and topically applied acriflavine (0.2%) have been most commonly used in humans. No data is so far available on the use of tetracycline and cresyl violet.

Fluorescein is an agent used for diagnostic fluorescein angiography or angioscopy of the retina and iris vasculature.

After intravenous injection, fluorescein binds extensively to serum albumin in the bloodstream. The unbound contrast diffuses across capillaries, entering the tissue and staining the extracellular matrix of the surface epithelium and the lamina propria for up to 30 min<sup>[9]</sup>. Cell nuclei and mucin are not stained by fluorescein and therefore appear dark. The mucosal structures that can be identified after fluorescein administration include enterocytes, cellular infiltrate, surface epithelial cells, blood vessels, and red blood cells. Fluorescein is a highly safe agent whose major side effects are short term (1-2 h) and include yellowish skin discoloration and 1-2 d

of bright yellow-colored urine. Nausea and vomiting were reported during angiography and were transient and minor. Serious side effects, such as anaphylaxis or cardiac or respiratory effects, are extremely rare, and to date, have not been recorded in CEM.

Topical acriflavine is highly specific for labeling acidic constituents, and stains the nuclei of superficial layers of the mucosa. The staining provides clear visualization of cell nuclei in the uppermost mucosa and may allow better differentiation between intra-epithelial neoplasia and cancer of the GI tract. Although there has been a hypothetical concern about the risk of mutagenesis, no severe adverse reactions have been reported after the topical use of acriflavine. However, concerns about DNA damage by acriflavine stain have reduced its use in humans.

Fluorescein and acriflavine can also be used simultaneously which adds to the labeling properties.

## EQUIPMENT

CLE can be performed currently with 2 devices: (1) integrated into an endoscope (Pentax, Tokio, Japan, herein termed eCLE); and (2) as a stand-alone probe (herein termed pCLE) capable of passage through the accessory channel of most endoscopes (Cellvizio, Mauna Kea Technologies, Paris, France)<sup>[10-14]</sup>.

### ***The Pentax EG-3870CIK (upper endoscope) and EC-3870CILK (colonoscope)***

The components of the confocal laser endoscope are based on the integration of a confocal laser microscope in the distal tip of a conventional video endoscope, which enables confocal microscopy in addition to standard video endoscopy (Figure 2). The diameter of both the distal tip and the insertion tube is 12.8 mm. The distal tip contains an air and water jet nozzle, 2 light guides, an auxiliary water jet channel (used for topical application of the contrast agent) and a 2.8 mm working channel. This imaging system provides confocal imaging using an incident 488 nm wavelength laser, and enables the detection of fluorescence of 505-585 nm wavelength, with reduced image noise compared with the reflectance confocal systems. CLE imaging data are collected at a scan rate of rate of 1.6 frames per second (1024 × 512 pixels) or 0.8 frames per second (1024 × 1024 pixels) with an adjustable depth of scanning ranging from 0 to 250 μm, a field of view of 475 μm × 475 μm, a lateral resolution of 0.7 μm, and an axial resolution of 7 μm. Confocal images are generated simultaneously with the endoscopic images and the endoscope working channel can still be used.

### ***The Cellvizio® Endomicroscopy System***

The Cellvizio® Endomicroscopy System (Figure 3) is based on a different catheter probe with a semiconductor laser that oscillates at 488 nm. The latest model of Cellvizio confocal miniprobes created for GI tract applications include CholangioFlex, GastroFlex, ColoFlex, GastroFlex-UHD, and ColoFlex-UHD. CholangioFlex probes designed for use during endoscopic retrograde

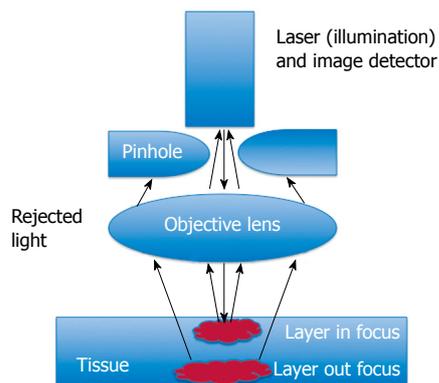

Figure 1 Schematic of confocal endomicroscopy principles.

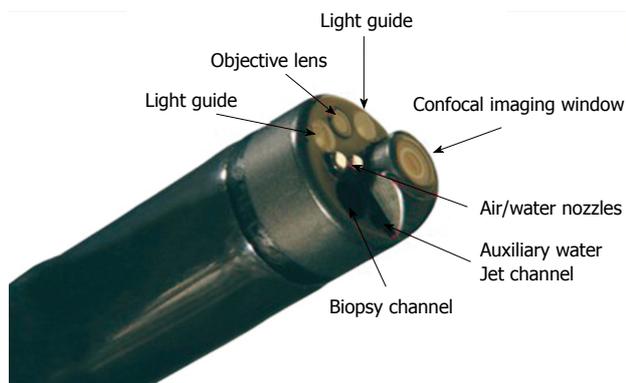

Figure 2 The endoscope-based confocal laser endomicroscopy (eCLE) imaging system: the distal tip.

cholangiopancreatography require an endoscope accessory channel of at least 1.2 mm, whereas the other probes, which are designed for use in esophagogastroduodenoscopy and colonoscopy, require a channel larger than 2.8 mm. All probes generate dynamic (12 frames per second) images with a scanning field of 30 000 pixels.

This system has a field of view of 240-600  $\mu\text{m}$  (CholangioFlex probes: 325  $\mu\text{m}$ ; GastroFlex and ColoFlex: 600  $\mu\text{m}$ ; GastroFlex-UHD and ColoFlex-UHD: 240  $\mu\text{m}$ ) with a lateral resolution of 1-3.5  $\mu\text{m}$  (the lateral resolution for CholangioFlex and for GastroFlex and ColoFlex probes is 3.5  $\mu\text{m}$ ; the lateral resolution for GastroFlex-UHD and ColoFlex-UHD is 1  $\mu\text{m}$ ). This system has a fixed imaging plane depth, and different confocal miniprobes are required to vary the depth of imaging. The depth of imaging for CholangioFlex probes is 40-70  $\mu\text{m}$ , 70-130  $\mu\text{m}$  for GastroFlex and ColoFlex), and 55-65  $\mu\text{m}$  for GastroFlex-UHD and ColoFlex-UHD.

Single video frames are reconstructed by a special computer algorithm ("mosaicing") in an image with an enlarged field of view (4 mm  $\times$  2 mm).

## PROCEDURE

Once a suspicious area of the mucosa is identified, contrast agents (fluorescein and/or acriflavine) can be given, and a CEM examination of the targeted area is performed by placing the distal tip of the endoscope or

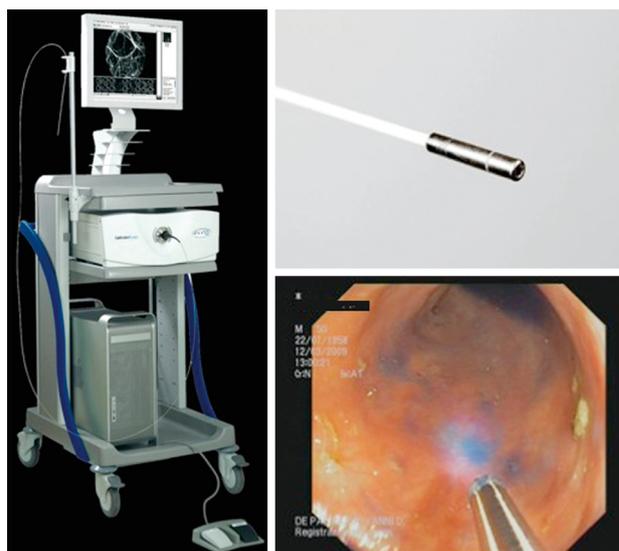

Figure 3 The probe-based CLE (pCLE) imaging system.

the distal tip of the catheter probe against the targeted mucosa. Gentle suction and/or an endoscopic cap can be used to stabilize the equipment and minimize excessive movement, which is important to reduce movement artifacts during imaging. At the area of interest, images can be obtained using an image-capture foot pedal and stored digitally.

## INTERPRETATION OF CLE IMAGES

The orientation of the "cut" plane of confocal *in vivo* histological images is horizontal whereas in conventional histological specimens it is longitudinal. CLE images cannot display a simultaneous overview of the mucosal and submucosal structures, unlike conventional histology. CLE images provide a thorough view of the mucosal architecture and allow rapid differentiation between normal, regenerative, and neoplastic mucosa of the GI tract. Differentiation between grades of intra-epithelial neoplasm by CEM, however, is not yet possible with the currently available staining techniques.

Endoscopists who perform CEM require a fundamental knowledge of the normal and disease micro-architecture of the GI tract. An onsite pathologist or at least a review of the stored images by a pathologist and correlation with biopsy histology is recommended during the learning process.

Some studies of the learning curve for CLE performed by endoscopists demonstrates that highly accurate, efficient *in vivo* prediction of Barrett's esophagus can be achieved after approximately 20-30 independently performed CLE procedures.

Normal and pathological aspects of CLE imaging of the upper and lower GI tract are shown in Tables 1-3 and Figures 3-5.

## CLINICAL DATA

The current potential indications for CLE imaging are

Table 1 Confocal criteria for squamous cell epithelium and carcinoma

	Squamous cell epithelium	Squamous cell neoplasia
Cellular criteria	Dark, homogeneous epithelial cells; regular architecture and clearly visible borders	Dark cells with different sizes; no clearly visible borders; irregular architecture
Vascular criteria	Capillaries directed to luminal epithelium without leakage of fluorescein	Twisted and irregular vessels; elongated capillaries; capillary leakage

Table 2 Confocal laser endomicroscopy (CLE) classification of Barrett's esophagus

Confocal diagnosis	Vessel architecture	Crypt architecture
Gastric-type epithelium	Capillaries with a regular shape only visible in the deeper parts of the mucosal layer	Regular columnar-lined epithelium with round glandular openings and typical cobblestone appearance
Barrett's epithelium	Subepithelial capillaries with a regular shape underneath columnar-lined epithelium visible in the upper and deeper parts of the mucosal layer	Columnar-lined epithelium with intermittent dark mucin in goblet cells in the upper parts of the mucosal layer. In the deeper parts, villous, dark, regular cylindrical Barrett's epithelial cells are present
Neoplasia	Irregular capillaries visible in the upper and deeper parts of the mucosal layer. Leakage of vessels leads to a heterogeneous and brighter signal intensity within the lamina propria	Black cells with irregular apical and distal borders and shapes, with strong dark contrast against the surrounding tissue

Table 3 CLE classification of patterns in colorectal lesions

Grading	Vessel architecture	Crypt architecture
Normal	Hexagonal, honeycomb appearance that presents a network of capillaries outlining the stroma surrounding the luminal openings of the crypts	Regular luminal openings and distribution of crypts covered by a homogeneous layer of epithelial cells, including goblet cells
Regeneration	Hexagonal, honeycomb appearance with no increase or only a slight increase in the number of capillaries	Star-shaped luminal crypt openings or focal aggregation of regular-shaped crypts with a regular or reduced amount of goblet cells
Neoplasia	Dilated and distorted vessels with increased leakage; irregular architecture, with little or no orientation to the adjoining tissue	Ridge-lined irregular epithelial layer with loss of crypts and goblet cells; irregular cell architecture, with little or no mucin

broad and include almost all current applications of endoscopic biopsy.

Unequivocally, this technology is best used in conjunction with other "red-flag" techniques because of its minute scanning area, and thus is only appropriate for classification of tissue at a site already detected by standard or optically enhanced endoscopy. Ideally, the no-dye "red-flag" techniques such as narrow band imaging or auto-fluorescence imaging, should be used to screen the mucosa for "areas of interest", which can then be interrogated by CEM for a "histological" diagnosis. An example would be use of narrow-band imaging to detect regions of suspicion in Barrett's esophagus, followed by CLE to confirm intraepithelial neoplasia, and guide immediate therapy.

The confocal laser endoscope can be used routinely for screening and surveillance. Suspicious lesions can be examined in a targeted fashion by placing the endomicroscopy window onto the lesion. Confocal images can be graduated according to cellular and vascular changes. The images correlate well with conventional histology after targeted biopsies.

Numerous studies have addressed the clinical applications of CLE, in particular in the study of precancerous

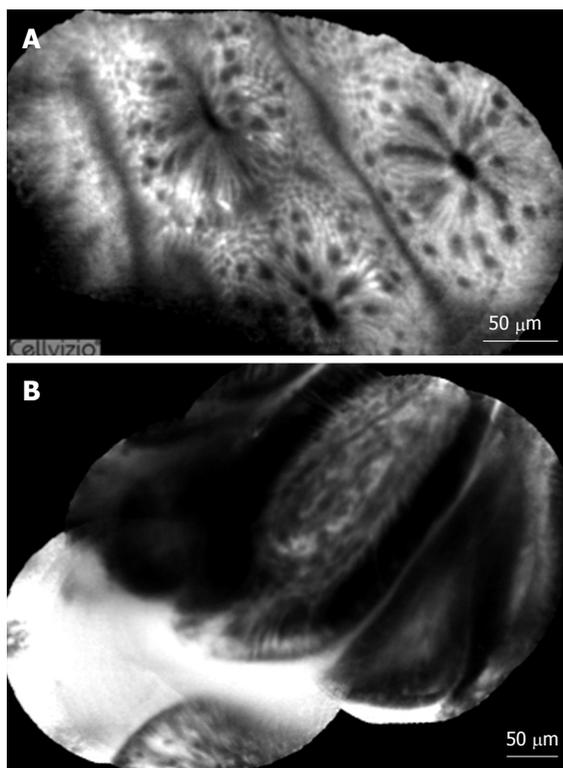

lesions of the upper and lower GI tract<sup>[15,16]</sup>.

In patients with Barrett's esophagus, CLE can diagnose Barrett's epithelium and Barrett's-associated neoplastic changes with an accuracy > 90% for both e-CLE or p-CLE<sup>[17-23]</sup>.

CLE in the stomach allows good visualization of normal and pathologic gastric pit patterns, making it a potentially useful tool for diagnosis of gastric cancer and precancerous conditions. Direct *in vivo* identification of *Helicobacter pylori* infection can be obtained<sup>[24-27]</sup>.

In patients with suspected celiac disease, confocal endomicroscopy can demonstrate villous atrophy and an increased number of intraepithelial lymphocytes, enabling immediate *in vivo* diagnosis of celiac disease<sup>[28]</sup>.

The presence of neoplastic changes in a colonic mucosa can be predict with high accuracy (> 95%). CLE has several potential roles in polyp management. The best-studied application is to distinguish between hyperplastic and adenomatous polyps, thus negating the need to remove hyperplastic polyps. In patients with long-term ulcerative colitis, chromoscopy with supplemental CEM, has recently been shown to further increase the yield for intraepithelial neoplasia above and beyond methylene blue. pCLE also has the capacity

**Figure 4** pCLE fluorescein sodium 10% imaging of the normal colon (A) and normal duodenum (B).

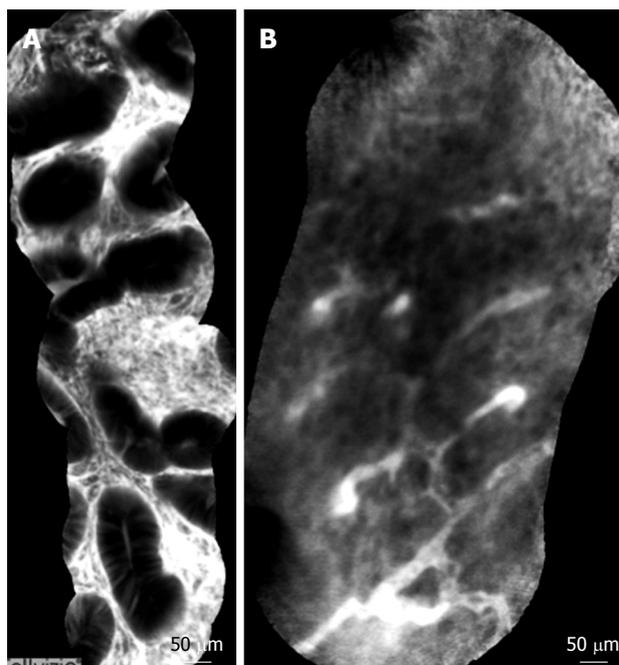

to differentiate normal from inflamed tissue, and thus target biopsies for the purpose of grading and mapping the extent of colitis<sup>[29-34]</sup>.

CEM can also be helpful for the diagnosis of microscopic colitis in patients with chronic diarrhea. In patients with collagenous colitis, it allows direct *in vivo* visualization of collagenous bands under the epithelial layer of the colon, and in patients with lymphocytic colitis, it can demonstrate crypt distortion and an increased distance between the colonic crypt. Thus, CLE has the potential to replace or direct a large number of random biopsies in patients with chronic diarrhea, where the confocal image is normal<sup>[35-37]</sup>.

Pancreato-biliary applications are under way using the probe-based CLE. The major role of pCLE in the bile duct is likely to detect cancer in indeterminate bile duct and pancreatic strictures<sup>[38,39]</sup>.

## CONCLUSION

CLE is a rapidly emerging field of gastroenterology that bridges the interface between endoscopy and histology. It further expands our ability to image living tissue in real time and to provide therapy in the same setting. The immediate impact will be the ability to target biopsies much more precisely, and eliminate a large number of random biopsies. Currently available devices for CEM have a very narrow field of view and allow only visualization of the superficial mucosal layer of the GI tract. Further technological developments are needed to enlarge the field of view, which will facilitate the use of CEM for cancer screening and surveillance. Increased

**Figure 5** pCLE fluorescein sodium 10% imaging of an adenomatous colonic polyp (A) and colonic adenocarcinoma (B).

depth of penetration is also needed to assess depth of invasion during cancer staging.

### Abstract

Liver regeneration is a complex and well-orchestrated process, during which hepatic cells are activated to produce large signal molecules in response to liver injury or mass reduction. These signal molecules, in turn, set up the connections and cross-talk among liver cells to promote hepatic recovery. In this review, we endeavor to summarize the network of signal molecules that mediates hepatic cell communication in the regulation of liver regeneration.

### INTRODUCTION

The liver is a vital organ. It has a wide range of functions, which include synthesis, metabolism, storage and

redistribution of amino acids, proteins (e.g. albumin and acute-phase proteins, enzymes and cofactors), carbohydrates, fats and vitamins. It also is involved in detoxification through: (1) removal of waste and xenobiotics, by breakdown of insulin and other hormones, hemoglobin, toxic substances, and medical products of drugs; (2) conversion of ammonia to urea; and (3) production and excretion of bile. The parenchymal cells (hepatocytes), which make up 70%-80% of hepatic cells, carry out most of these functions. The other 20% comprise the non-parenchymal cells, which include Kupffer cells, stellate cells, sinusoidal endothelial cells (SECs), biliary epithelial cells, lymphocytes, and oval cells<sup>[1]</sup>.

The liver is the only organ that can regenerate fully after injury in mammals<sup>[2]</sup>. When the liver is subjected to surgery, toxic substances, or viral infection, it has an amazing regenerative ability to restore functional hepatic mass. Injury induces the priming of recovery mechanisms with large changes in hepatic composition, such as activation of non-parenchymal cells, production and activation of multiple factors. These factors further lead to proliferation of hepatocytes and non-parenchymal cells, recovery and re-establishment of tissue architecture. When the liver recovers its normal volume and function, the regenerative response is terminated. Liver regeneration is actually compensatory hyperplasia, which is mediated typically by the proliferation of surviving hepatocytes<sup>[3]</sup>. When hepatocyte proliferation is inhibited, oval cell proliferation occurs<sup>[4]</sup>. This review endeavors to summarize the roles of hepatocytes and non-parenchymal cells, as well as signal communication among the hepatic cells during liver regeneration.

### FUNCTION OF VARIOUS TYPES OF LIVER CELL REGULATED BY DIFFERENT SIGNAL MOLECULES

#### Hepatocytes

Hepatocytes are organized into single-cell plates in mammals separated by vascular channels (sinusoids). Hepatocytes perform most liver functions such as synthesis, storage, metabolism and transformation of carbohydrates, amino acids, proteins, fats and vitamins, and detoxification, modification and excretion of exogenous and endogenous substances. The hepatocyte also initiates the formation and secretion of bile. During

liver regeneration, hepatocytes are primed to proliferate, maintain metabolic function, secrete interleukin (IL)-6, proteases and protease inhibitors, and hepatocyte growth factor (HGF)<sup>[5]</sup>.

### **Kupffer cells**

Kupffer cells are liver-resident macrophages with a pronounced phagocytic and endocytic capacity mainly located within the sinusoids<sup>[6]</sup>. Kupffer cells play an important role in the clearance of senescent and damaged erythrocytes. Kupffer cells also secrete potent mediators of the inflammatory response<sup>[7]</sup>. During the priming phase of liver regeneration, Kupffer cells are activated and secrete pro-inflammatory cytokines, most prominently tumor necrosis factor (TNF)- $\alpha$ , IL-6, and IL-1 $\beta$ , which can initiate the acute phase response in hepatocytes<sup>[8]</sup>. Small-for-size orthotopic liver transplantation may often cause graft failure. In a mouse partial 30% liver transplantation model, interruption of TNF- $\alpha$  signaling by Kupffer cell inactivation through administration of pentoxifylline and GdCl<sub>3</sub>, or the use of *Tnfr-1*<sup>-/-</sup> mice improves animal survival and enhances liver regeneration. These results are partly due to the fact that inhibition of TNF- $\alpha$  reduces leukocyte adherence, and improves portal flow and microcirculation<sup>[9]</sup>.

### **Hepatic stellate cells (HSCs)**

HSCs, also known as Ito cells, fat-storing cells or liver fibroblasts, are located in the space of Disse between the hepatocytes and the hepatic sinusoidal endothelial lining. In normal liver, HSCs sustain a quiescent state. Quiescent HSCs represent 5%-8% of liver cells, store 80% of total body retinol (vitamin A) as cytoplasmic lipid droplets, control turnover of extracellular matrix (ECM), and regulate the contractility of sinusoids<sup>[5-7]</sup>. Following hepatic damage, HSCs trans-differentiate into ECM-secreting myofibroblasts (activated HSCs)<sup>[10]</sup>, with the loss of retinol-rich droplets<sup>[11]</sup>. HSCs can secrete ECM proteins, including laminins, collagens and proteoglycans, growth factors such as HGF, fibroblast growth factor (FGF), transforming growth factor (TGF)- $\beta$  and cytokines such as IL-6, and produce some matrix metalloproteinases and tissue inhibitors of metalloproteinases<sup>[5]</sup>. The HSC is the major cell type involved in liver fibrosis. HSCs also behave as professional liver-resident antigen-presenting cells (APCs)<sup>[6,11]</sup>. A recent study has suggested that quiescent HSCs of rats retained within the space of Disse express stem/progenitor cell markers (e.g. CD133 and Oct4) and possess a differentiation potential. The space of Disse acts as a HSC niche, which is similar to the stem cell niche. These characteristics of quiescent HSCs are determined by the special microenvironment in the space of Disse, which is composed of basal lamina proteins (laminin and collagen type IV), sympathetic innervation and the adjacent cells. The adjacent cells include SECs, which release stromal cell-derived factor-1 to attract HSCs *via* the cysteine-X-cysteine receptor 4, and hepatocytes, which synthesize  $\beta$ -catenin-dependent Wnt ligands and Jagged-1 to attract HSCs through Wnt receptor frizzled, and to have direct physical interactions with HSCs through

Jagged-1 receptor notch<sup>[11-13]</sup>.

Neurotrophin receptor p75<sup>NTR</sup> is a low-affinity pan-neurotrophin receptor that belongs to the TNF receptor superfamily. In the diseased liver, p75<sup>NTR</sup> is expressed in HSCs. When p75<sup>NTR</sup> is activated, it activates the Rho/Rho kinase pathway, which enhances actin filament formation and phosphorylation of cofilin in a ligand-independent manner. This pathway contributes to the transition of quiescent stellate cells into myofibroblast-like cells that are important cellular sources of HGF. HGF drives healthy hepatocytes into proliferation. During perpetuation of trans-differentiation, secretion of pro-nerve growth factor (NGF) or NGF by neighboring regenerating hepatocytes leads to ligand-induced activation of apoptotic pathways, including the neurotrophin receptor interacting factor/TNF receptor-associated factor/Ras-related C3 botulinum toxin substrate/c-Jun N-terminal kinase/caspase pathway in stellate cells. In mice, depletion of p75<sup>NTR</sup> exacerbates liver pathology and inhibits hepatocyte proliferation *in vivo*. p75<sup>NTR</sup><sup>-/-</sup> HSCs fail to differentiate into myofibroblasts and do not support hepatocyte proliferation<sup>[14,15]</sup>.

### **SECs and biliary epithelial cells**

Liver SECs constitute the wall of the hepatic sinusoid and separate hepatocytes from the sinusoidal blood. They perform an important filtration function due to the presence of open fenestrations, with an average diameter of 120 nm, which allow free diffusion of many substances, but not of particles of the size of chylomicrons, between the blood and the hepatocyte surface. SECs have large endocytic and metabolic capacity for many ligands including glycoproteins, lipoproteins, ECM components (e.g. hyaluronate, collagen fragments, fibronectin, or chondroitin sulfate proteoglycan), immune complexes, transferrin and ceruloplasmin. SECs may function as APCs in the context of both major histocompatibility complex (MHC)-I and MHC-II restriction, with the resulting development of antigen-specific T cell tolerance. They are also active in the secretion of cytokines (IL-6), HGF, TGF- $\beta$ , eicosanoids (i.e. prostanoids and leukotrienes), endothelin-1, nitric oxide, and some ECM components<sup>[5,7]</sup>.

Biliary epithelial cells (cholangiocytes) constitute the bile ducts in hepatic portal triads. Cholangiocytes may transport water, ions and solutes; secrete growth factors and peptides that mediate cross-talk with other cells of the liver in a paracrine mode; secrete chemokines (e.g. monocyte chemoattractant protein-1) and cytokines (e.g. IL-6) and express adhesion molecules that attract effector leukocytes and promote the clearance of infected cells; and promote fibrogenesis by attraction of HSCs<sup>[5,16]</sup>.

Notch-1 and Jagged-1 are expressed in bile duct cells and hepatocytes in normal rat liver. Moreover, Notch-1 is also expressed in endothelial cells of the sinusoids and small vessels. After partial hepatectomy (PH) in rats, both Notch-1 and Jagged-1 proteins are upregulated and mainly exist in periportal hepatocytes. Notch receptor expressed in endothelial cells may be stimulated by its ligand Jagged, which is highly expressed in proliferating hepatocytes. Such interactions between ligands/receptors cause a decrease in endothelial cell proliferation and

promote formation of mature sinusoids. The Jagged/Notch signal is required to maintain a differentiated phenotype of bile duct cells, but more functions of Jagged/Notch signaling in bile duct cell proliferation and duct assembly remain vague<sup>[17]</sup>.

### **Dendritic cells (DCs), natural killer (NK) cells and NKT cells**

Interstitial liver DCs play important roles in innate and adaptive immunity. The outcome of liver DCs interacting with the antigen-specific T cells determines the balance between tolerance and immunity. Systemic and local environmental factors influence hepatic DC migration, maturation, and function<sup>[18]</sup>.

After 75% PH in male C57BL/6 mice, CD11c<sup>+</sup> (DC marker) liver (L)DCs increased significantly within 6 h and maintained an inherent, immature phenotype in both PBS- and Flt3L (fms-like tyrosine-3 ligand, a hematopoietic growth factor that expands dramatically the number of DCs in lymphoid and non-lymphoid tissues, including the liver, without changing their maturation state)-pretreated mice<sup>[19]</sup>. The increase was more notable in mice pretreated with Flt3L compared with PBS. The numbers of CD11c<sup>+</sup> LDCs returned to pre-hepatectomy levels by 24 h. The expanded LDC population showed increased IL-10 and reduced interferon (IFN)- $\gamma$  gene transcription 6 h after PH. The concomitant increase in expression of the anti-inflammatory cytokine IL-10 suggests that LDCs are involved actively in promoting a state of local immunosuppression. The decrease in IFN- $\gamma$  is associated with inhibition of hepatic NK cell lytic activity. LDCs isolated from the liver 6 h after 75% PH exhibit enhanced estrogen receptor expression, concomitant with increased serum 17- $\beta$ -estradiol levels. Flt3L-treated mice showed a significant increase in proliferating cell nuclear antigen labeling index compared with PBS-treated mice at 12, 24, 48 and 72 h after 40% PH, with a peak at 48 h. These results indicate that the increased numbers of estrogen-exposed DCs may play a key role in local immune suppression and promote progression of liver regeneration, by altering the balance toward a Th2-like microenvironment<sup>[19]</sup>.

NK cells are cytotoxic large granular lymphocytes derived from CD34<sup>+</sup> hematopoietic stem cells. NKT cells have three categories: I type (classical, V $\alpha$ 14-J $\alpha$ 18<sup>+</sup>TCR/CD1-dependent); II type (non-classical, all other CD1d-dependent T cells); and NKT-like cells (CD1d-independent NK1.1<sup>+</sup> T cells). NK and NKT cells are components of the innate immune system and participate in the inflammatory processes during hepatic injury. NK and NKT cells also contribute to adaptive immune responses by interacting with APCs<sup>[20]</sup>. NK and NKT cells accelerate liver injury through production of pro-inflammatory cytokines and killing hepatocytes. NKs inhibit liver fibrosis *via* killing early-activated and senescent-activated stellate cells and producing IFN- $\gamma$ . For the regulation of liver fibrosis, NKT cells appear to be less important than NK cells as a result of hepatic NKT cell tolerance<sup>[21]</sup>.

Treatment of mice with murine cytomegalovirus

(MCMV) infection and toll-like receptor (TLR)3 ligand poly I:C results in the activation of NK cells to produce IFN- $\gamma$  and attenuates liver regeneration after PH. NKT cells may only play a minor role in the negative suppressive effects of MCMV and poly I:C on liver regeneration<sup>[22]</sup>. However, in HBV transgenic (HBV-tg) mice, PH-induced liver regeneration is delayed. The impaired liver regeneration is related to the increased activation and number of NKT cells and their enhanced IFN- $\gamma$  production. NKT cells usually are activated by antigen-loading CD1d on APCs and soluble cytokines, such as IL-12 that is produced by Kupffer cells. Elevated CD1d on hepatocytes contributes to NKT cell activation and subsequent impairment of liver regeneration in HBV-tg mice. The impairment of liver regeneration in HBV-tg mice is largely ameliorated by NKT cell depletion, but not by NK cell depletion<sup>[23]</sup>.

Pretreatment of V $\alpha$ 14 NKT/J $\alpha$ 281<sup>+/+</sup> mice with IL-12 or  $\alpha$ -galactosylceramide ( $\alpha$ -GalCer) 5 d before PH induced activation of NKT cells. The activated NKT cells expressed increased mRNA levels for TNF- $\alpha$  and IFN- $\gamma$  and enhanced liver injury at 24 h after PH. Hepatic NKT cells rather than Kupffer cells might produce TNF- $\alpha$  after the administration of IL-12 or  $\alpha$ -GalCer. TNF- $\alpha$  produced by activated V $\alpha$ 14 NKT cells was more than sufficient to enhance liver damage during the early phase of liver regeneration. The regenerating hepatocytes were destroyed specifically through the TNF receptor 1 (TNFR1) mediated TNF- $\alpha$ /TNFR1 pathway, which led eventually to impaired liver regeneration<sup>[24]</sup>. However, in another study, in mice injected with  $\alpha$ -GalCer 36 h after 70% PH, the induced activation of NKT cells greatly enhanced hepatocyte mitosis 44 h after surgery, *via* the TNF- $\alpha$ /TNFR1 and Fas/FasL-mediated pathways, accompanied by increased expression of TNFR1 and FasL in liver NKT cells<sup>[25]</sup>.

### **Stem cells and progenitor cells**

After injury, liver regeneration occurs typically through replication of existing hepatocytes, however, when hepatocyte proliferation is attenuated or blocked, the liver is repopulated by induction, proliferation, and differentiation of the progenitor cell compartment. Hepatic progenitor cells are rare quiescent cells that are thought to reside in the canals of Hering. The oval cells are a type of liver progenitor cells that express markers in common with cholangiocytes and embryonic hepatocytes in rodents<sup>[4,26-28]</sup>. Oval cells are characterized by expressing phenotypic markers such as A6<sup>[27,28]</sup> and thymus cell antigen 1, and  $\alpha$ -fetoprotein (AFP)<sup>[29]</sup>.

Oval cells are much less sensitive to TGF- $\beta$ -induced growth inhibition than hepatocytes *in vivo* and *in vitro*. These results are partly due to Mothers against decapentaplegic homolog (Smad)6 intervention. Smad6 is present in much higher amounts in oval cells (LE-2 and LE-6 cells) compared with hepatocytes (AML-12 cells or primary hepatocytes). The significant levels of Smad6 in oval cells inhibit TGF- $\beta$  signaling by associating with the type I receptor, thereby interfering with Smad2 phosphorylation by the activated receptor complex, which

prevents translocation of Smad2 to the nucleus, and subsequent target gene transcription<sup>[4]</sup>. The combination of IFN- $\gamma$  with lipopolysaccharide (LPS) or TNF- $\alpha$  causes a reversible cell cycle arrest in cultured hepatocytes (AML-12 cells), but stimulates DNA replication in oval cells (LE-6 cells). Hepatocyte cell cycle arrest is caused, at least in part, through NO release produced by inducible NO synthase after IFN- $\gamma$ /LPS or IFN- $\gamma$ /TNF- $\alpha$  administration<sup>[26]</sup>.

The hepatic expression of *lymphotoxin- $\beta$*  (*Lt- $\beta$*  or *Tnf- $\beta$* ) and *Ifn- $\gamma$*  produced by oval cells is upregulated and promotes oval cell-mediated liver regeneration in a choline-deficient, ethionine-supplemented (CDE) diet/PH mouse model. In *Lt- $\beta$*  knock-out (KO), *Lt- $\beta$*  KO, and *Ifn- $\gamma$*  KO mice, oval cell-mediated liver regeneration is impaired, which confirms a role for LT- $\beta$ /LT- $\beta$ R and IFN- $\gamma$  in oval cell-mediated liver regeneration<sup>[27]</sup>.

Gp130-mediated IL-6 signaling may play a role in oval cell proliferation *in vivo*. In livers of *IL-6*<sup>-/-</sup> mice fed with a CDE diet, the numbers of oval cells were reduced compared with *IL-6*<sup>+/+</sup> control mice. The hyperactive signal transducer and activator of transcription (STAT)3 signaling *Gp130*<sup>Y757F</sup> mouse model was derived when the tyrosine 757 residue of gp130 was mutated to a phenylalanine that prevented suppressor of cytokine signaling proteins (SOCS)3 binding and Src homology 2 (SH2) domain-containing protein-tyrosine phosphatase (SHP)2/RAS/extracellular signal-regulated kinases (ERK) signaling upon gp130 activation. Hyperactive STAT3 signaling in *Gp130*<sup>Y757F</sup> and *Socs3*<sup>-/-</sup> *LAAb* (*Socs3*<sup>-/-</sup>) mice fed a CDE diet results in increased oval cell proliferation compared with wild-type and gp130-mediated hyperactive ERK1/2 signaling (*Gp130*<sup>ΔST3</sup>) mice. However, SOCS3 overexpression or ERK1/2 activation inhibits oval cell proliferation in oval cell lines<sup>[28]</sup>. Proliferation of oval cells is associated with activation of nuclear factor (NF)- $\kappa$ B and STAT3 during oval cell-mediated liver regeneration in a 2-acetylaminofluorene (AAF)/PH rat model. Sustained NF- $\kappa$ B signaling has a critical role in protecting oval cells against apoptosis during stem cell-mediated liver regeneration. STAT3 plays a important role in driving proliferation and regulating differentiation of the hepatic stem cell progenies<sup>[30]</sup>.

Connective tissue growth factor (CTGF or CCN2) is a secreted matricellular protein that belongs to the CCN family. This protein comprises four mosaic conserved modules. CTGF normally is expressed at a very low level in the liver. However, when the liver suffers from chronic or acute injury, CTGF level is upregulated in diverse repair processes<sup>[29]</sup>. Recruitment and proliferation of Thy-1<sup>+</sup> oval cells is a hallmark of liver regeneration in rats after 2-AAF/PH. Sorted Thy-1<sup>+</sup> oval cells in rats after 2-AAF/PH express a high level of *Ctgf* gene accompanied by upregulated CTGF protein expression. Blocking CTGF induction by iloprost (a known inhibitor of CTGF synthesis) significantly decreased the oval cell proliferation and lowered the level of AFP expression as compared with control animals. These results suggest that CTGF induction is important for robust oval cell proliferation

after 2-AAF/PH treatment in rats<sup>[31]</sup>. Yeast two hybrid experiments have identified that fibronectin (FN) is a CTGF-binding protein. FN that binds to modules I and IV of CTGF and co-localizes with CTGF on the provisional hepatic ECM around the periportal regions promotes oval cell adhesion and migration, thereby facilitating oval cell activation<sup>[29]</sup>.

In 2-AAF/PH-treated rats, hepatocytes strongly express multidrug resistance protein 1b, but oval cells express high levels of active multidrug resistance associated protein (Mrp)1 and Mrp3. Mrp1 functions mainly as a cellular efflux pump of cysteinyl-leukotrienes and glutathione-S-conjugates, and Mrp3 as a pump for glucuronides and mono- and divalent bile salts, thus Mrp1 and Mrp3 may have a role in removing exogenous and endogenous toxic drugs/metabolites from oval cells, and facilitate oval cell proliferation in conditions of severe hepatotoxicity<sup>[32]</sup>.

Sympathetic nervous system inhibition using prazosin (PRZ, an  $\alpha$ -1 adrenoceptor antagonist) or 6-hydroxydopamine (6-OHDA, an agent that induces chemical sympathectomy) significantly enhanced hepatic accumulation of oval cells and reduced liver damage in mice fed antioxidant-depleted diets to induce liver injury. Neither PRZ nor 6-OHDA affects the expression of cytokines, growth factors, or growth factor receptors that are known to regulate progenitor cells<sup>[33]</sup>.

The plant lectin concanavalin A (Con A) may induce T cell-mediated hepatitis in mice. Following PH, ConA-treated mice show significantly impaired early regenerative responses, such as decreased cyclin D1 and E expression and STAT3 activation within hepatocytes, in conjunction with reduced IL-6 production, increased IFN- $\gamma$ , TGF- $\beta$  and p21<sup>waf</sup> expression, and increased TGF- $\beta$ -induced Smad2 phosphorylation. However, Con A may induce an increase in the number of NK cell-sensitive oval cells (CD117, AFP, albumin, and cytokeratin-positive cells) and hematopoietic-like cells (Sca-1<sup>+</sup> cells) in these mice<sup>[34]</sup>. Furthermore, much more accumulated lipid was seen in the liver of mice with Con A-induced hepatitis, by Oil Red O staining<sup>[35]</sup>.

The IL-6/gp80/gp130 signaling system contributed to rapid expansion of the progenitor cell populations including liver hematopoietic progenitor cells and liver epithelial progenitor cells in a Con A/PH-mediated mouse liver injury model<sup>[36]</sup>.

## SIGNAL COMMUNICATION THAT OCCURS IN THE PROGRESSIVE PHASES OF LIVER REGENERATION

Liver injury causes significant changes in the expression and activity of a variety of signal mediators produced by hepatic cells, endocrine glands and platelets. These molecules include complement components C3 and C5; cytokines (TNF- $\alpha$  and ILs); growth factors [TGF, epidermal growth factor (EGF), platelet-derived growth factor, vascular endothelial growth factor (VEGF), FGF,

insulin-like growth factor (IGF)-I, and HGF]; hepatic ECM; extracellular proteases and protease inhibitors; hormones [insulin, growth hormone (GH), thyroid hormone, vasopressin, prostanoids, and endothelin-1] and neurotransmitters (serotonin); metabolites [bile acids, reactive oxygen species (ROS), NO, lipids, glutathione, S-adenosylmethionine, and sphingosine-1-phosphate]; and chemokines<sup>[1,5,7,37-42]</sup>. Liver regeneration progression is highly coordinated by the signal communication between hepatocytes and non-parenchymal cells, and is also influenced by endocrine glands, sympathetic innervation, and blood circulation. The progression of liver regeneration is segmented into several phases. Here, we describe the mechanisms of liver regeneration in each phase.

### Priming phase

In models of liver injury induced by toxins, such as CCl<sub>4</sub>, or Fas ligand, the hepatocytes are damaged and undergo necrosis, for which, the growth factor- and cytokine-mediated pathways are similar to those in PH models<sup>[1]</sup>. Liver injury causes the release of ROS and LPS, which trigger the activation of the complement system. After complement activation, cleavage of C3 or C5 leads to the generation of the potent anaphylatoxins C3a and C5a. LPS, C3a and C5a in turn activate the non-parenchymal cells such as Kupffer cells, through the cell surface receptor TLR4 and G protein-coupled receptors C3aR and C5aR, which causes activation of the NF- $\kappa$ B signaling pathway and the production of cytokines such as TNF- $\alpha$  and IL-6. TNF- $\alpha$  then interacts with TNFR on Kupffer cells, which stimulates intensive synthesis of TNF- $\alpha$  and IL-6. Furthermore, SECs, HSCs, biliary epithelial cells and hepatocytes may also produce IL-6<sup>[5,43,44]</sup>. The cytokines TNF- $\alpha$  and IL-6 are responsible for priming the quiescent hepatocytes into the cell cycle (G0 to G1) through binding to their receptors TNFR1 and IL-6R; activating the NF- $\kappa$ B, JAK/STAT3 and MAPK signal pathway; initiating the transcription of immediate early genes; and sensitizing hepatocytes to the proliferative effects of growth factors<sup>[37]</sup>.

### Proliferative phase

In rat liver PH models, the rate of DNA synthesis in hepatocytes begins to increase after about 12 h and peaks around 24 h. However, induction of DNA synthesis occurs later in the non-parenchymal cells (at about 48 h for Kupffer, biliary epithelial and stellate cells, and at about 96 h for endothelial cells). Subsequent levels of DNA synthesis in hepatocytes are lower, as complete restoration of liver mass requires an average of about 1.66 cycles of replication in all cells. By comparison, the peak in DNA synthesis in mice occurs later (36-40 h after PH) and varies between strains<sup>[1,45]</sup>. Many growth factors and growth factor-binding proteins are produced to promote the progression of liver regeneration.

The bulk of IGF-I is synthesized by hepatocytes, but is also produced by other types of non-parenchymal liver cells. Hepatic IGF-I synthesis is not only regulated

by growth hormone, insulin, and IGF-I, but also by cytokines released from activated Kupffer (IL-1, TNF- $\alpha$  and TGF- $\beta$ ) or stellate (TGF- $\alpha$  and TGF- $\beta$ ) cells<sup>[7]</sup>. The biological actions of IGF-I are mediated through its physiologic receptor IGF-1R and insulin receptor. The activity of IGFs is modulated by a family of high-affinity binding proteins (IGFBP-1-6) and IGFBP proteases<sup>[46]</sup>. HGF is produced mainly by HSCs, but also by hepatocytes, SECs, and performs its functions through interacting with its receptor c-met<sup>[5]</sup>. The EGF family consists of several members, including EGF, TGF- $\alpha$ , heparin-binding EGF-like growth factor (HB-EGF), amphiregulin (AR),  $\beta$  cellulin, and epiregulin<sup>[47]</sup>. HB-EGF is expressed mainly in Kupffer and endothelial cells<sup>[48]</sup>; TGF- $\alpha$  is synthesized mainly by hepatocytes<sup>[49]</sup>; expression of AR is induced by hepatocytes, Kupffer cells and HSCs<sup>[50,51]</sup>; and these factors transmit their signal through EGF receptor.

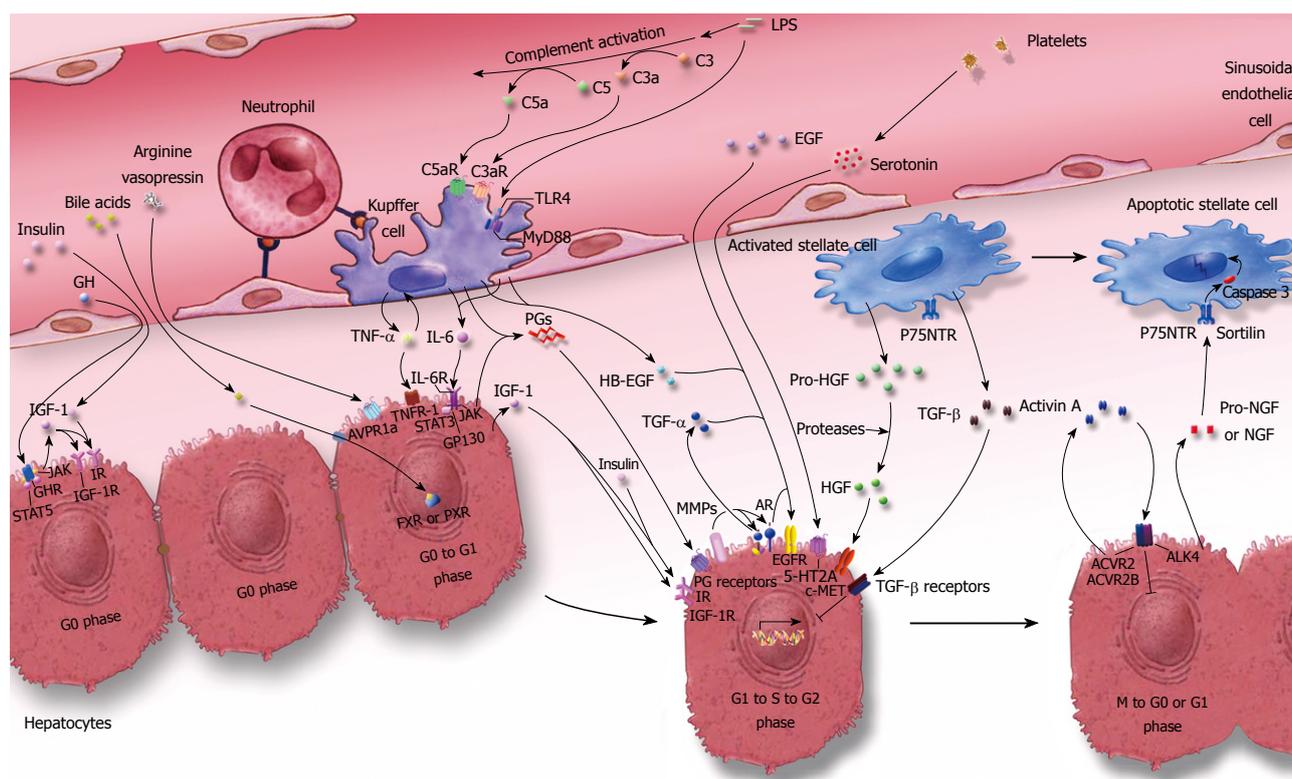

Most growth factors are usually formed in an inactive precursor bound with ECM or integral to membrane. During liver regeneration, extracellular protease activation and ECM degradation occur in the first few hours before hepatocyte DNA synthesis and division, and growth factors are released and activated from the bound ECM or cell membrane by the extracellular protease<sup>[5]</sup>. These activated growth factors binding to their corresponding receptors drive hepatic cells into DNA replication and mitosis. Furthermore, factors such as insulin from the pancreas, EGF from the duodenum or salivary gland, norepinephrine from the adrenal gland, triiodothyronine from the thyroid gland, GH from the anterior pituitary gland, arginine vasopressin (AVP) from the posterior pituitary, serotonin from platelets, and prostaglandins (PGs) from Kupffer cells and hepatocytes are also involved in the process of liver regeneration<sup>[1,38,52-54]</sup>.

### Remodeling phase

After cell division, hepatocytes are formed in clusters that no longer associate with sinusoids. The nascent endothelial cells travel among cell clusters to form sinusoids that will line hepatocyte plates. VEGF, angiopoietin and their receptors Flt-1 (VEGF-R1), Flk-1/KDR (VEGF-R2), Flt-4 (VEGF-R3), and Flt3/Flk2, as well as tyrosine kinase containing immunoglobulin and epidermal growth factor homology domain (Tie)-1 and Tie-2 might be involved in this process<sup>[5,55]</sup>. Meanwhile, biliary epithelial cells rebuild the biliary tree in hepatic portal triads. Synthesis of new ECM, vasculature and biliary tree then reestablishes tissue architecture.

### Terminating phase

TGF- $\beta$  and activin A belong to the TGF- $\beta$  superfamily of cytokines. TGF- $\beta$  is produced mainly in HSCs, but is also expressed in SECs and Kupffer cells<sup>[4,5]</sup>. In the liver, activin A is synthesized predominantly in hepatocytes, but is also expressed in non-parenchymal cells under pathological conditions. Activin A is an autocrine growth inhibitor that is produced in hepatocytes, and is involved in inhibiting the proliferation of hepatocytes,

**Figure 1** Scheme depicting the network of signaling among hepatic cells and blood during liver regeneration. After liver injury such as PH, gut-derived factors such as LPS reach the liver through the portal blood supply. LPS activate the complement system, which releases the anaphylatoxins C3a and C5a. LPS, C3a and C5a activate Kupffer cells through TLR4, C3aR and C5aR, and further lead to production of TNF- $\alpha$  and IL-6. These factors are involved in priming the hepatocytes from G0 to G1 phase. Insulin, GH, bile acids, AVP, platelet-derived serotonin, and EGF from the blood, cooperating with PGs, HB-EGF, HGF, as well as IGF-1, TGF- $\alpha$  and AR from different hepatic cells, promote hepatocyte transition from G1, through S and G2, to the M phase of the cell cycle. TGF- $\beta$  produced mainly by HSCs inhibits G1 to S phase transition of hepatocytes, and TGF- $\beta$  signalling is blocked during the proliferative phase. Pro-NGF or NGF produced by the neighboring regenerating hepatocytes promotes the termination of the activated state of HSCs by pro-NGF- or NGF-induced apoptotic pathways. When the liver mass is restored to its normal volume, the increased signaling by activin A, apoptosis and other factors may promote termination of liver regeneration. The prototype of this figure is originated from reference<sup>[43]</sup>.

inducing the differentiation of hepatocytes, augmenting the tubulogenesis of SECs, and stimulating collagen production in HSCs<sup>[56]</sup>.

TGF- $\beta$  and activin A may bind to their high-affinity cell surface type II receptor TGFBR2/T $\beta$ R II and ACVR2/ActR II or ACVR2B/ActR II b, respectively, either directly or *via* co-receptors, and recruit and activate their cell surface type I receptors TGFBR1/ALK5 (T $\beta$ R I), ACVRL1/ALK1, ACVR1/ALK2 and ACVRL1/ALK1, ACVR1/ALK2, ACVR1B/ALK4, respectively, which leads to activation of their downstream Smad signal pathway<sup>[57,58]</sup>. TGF- $\beta$  inhibits G1 to S phase transition in hepatocytes, but TGF- $\beta$  signaling is blocked during the proliferative phase; furthermore, intact TGF- $\beta$  signaling is not required for the termination of liver regeneration<sup>[1,59]</sup>. When the liver mass restores its normal volume, the increased signaling by activin A, apoptosis and other factors<sup>[59]</sup>, and the decreased expression and activation of promoting proliferation factors due to the restored ECM and tissue architecture may promote termination of liver regeneration. Figure 1 depicts the main signal communication network that occurs in the progression of liver regeneration.

Following liver injury, the expression and activity of signal molecules produced by activated hepatic cells

are controlled in a time- and micromilieu-dependent mode. The direct interactions among hepatic cells and the indirect interactions mediated by secreted signal molecules with hepatic cells constitute the dynamic recovery process of liver regeneration. Many more signal molecules and pathways are involved in the regulation of liver regeneration than those mentioned above. Further study will reveal more facts about the mechanisms of liver regeneration.

## CONCLUSION

Liver regeneration is a very complex process, which is accompanied by a highly regulated intercellular and intracellular signal communication network. The extracellular signal molecules that regulate the progression of liver regeneration are produced by hepatic cells, endocrine glands and platelets in autocrine, paracrine, juxtacrine and endocrine modes. Most of these signal molecules are inactive precursors that need to be further processed into a mature form by activated proteases in ECM or on membrane of adjacent hepatic cells. The extracellular signaling interfaces with intracellular signals through their specific receptors. Liver regeneration is highly coordinated by the cross-talk between these signal

molecules and hepatic cells. Liver has a regenerative ability to restore functional hepatic mass after liver injury, but under some pathological conditions, the recovery of liver is not autonomous, so the study of the pathogeny of the diseased liver is more significant, to provide methods for treating patients with liver damage.

### Abstract

The etiopathology of inflammatory bowel disease (IBD) remains elusive. Accumulating evidence suggests that the abnormality of innate and adaptive immunity responses plays an important role in intestinal inflammation. IBD including Crohn's disease (CD) and ulcerative colitis (UC) is a chronic inflammatory disease of the gastrointestinal tract, which is implicated in an inappropriate and overactive mucosal immune response to luminal flora. Traditionally, CD is regarded as a Th1-mediated inflammatory disorder while UC is regarded as a Th2-like disease. Recently, Th17 cells were identified as a new subset of T helper cells unrelated to Th1 or Th2 cells, and several cytokines [e.g. interleukin (IL)-21, IL-23] are involved in regulating their activation and differentiation. They not only play an important role in host defense against extracellular pathogens, but are also associated with the development of autoimmunity and inflammatory response such as IBD. The identification of Th17 cells helps us to explain some of the anomalies seen in the Th1/Th2 axis and has broadened our understanding of the immunopathological effects of Th17 cells in the development of IBD.

### INTRODUCTION

Current evidence strongly suggests that inflammatory bowel disease (IBD) arises from a disruption of mucosal immune homeostasis in genetically susceptible individuals, resulting in altered processing of enteric antigens, pathogenic T cell activation, and chronic inflammation<sup>[1-3]</sup>. Although the etiology of IBD remains unclear, accumulating evidence has indicated that dysfunction of the mucosal immune system plays an important role in the pathogenesis of IBD. Among a variety of inflammatory cells in the gut, mucosal CD4<sup>+</sup>T cells are thought to play a central role in both the induction and persistence of chronic inflammation by producing proinflammatory cytokines. Studies have indicated that Th1-related cytokines [e.g. tumor necrosis factor (TNF), interferon (IFN)- $\gamma$ , interleukin (IL)-12] as well as Th17-associated cytokines (e.g. IL-17A, IL-21, IL-23) are markedly increased in inflamed mucosa of CD, whereas the cytokine profiles in inflamed areas of UC seem to exhibit increased production of the Th2 cytokines such as IL-5 and IL-13<sup>[1-3]</sup>. These proinflammatory cytokines are potent *in vitro* stimulators of intestinal mucosal effector functions including T cell and macrophage proliferation, adhesion molecule expression, chemokine expression, and secretion of other proinflammatory cytokines.

### Th17 CELLS AND THE DIFFERENTIATION REGULATION

CD4<sup>+</sup>T cells play an important role in the initiation of immune responses by providing help to other cells and by taking on a variety of effector functions during immune reactions. Upon antigenic stimulation, naive CD4<sup>+</sup>T cells are activated, expand and differentiate into different effector subsets such as Th1 and Th2 cells

characteristic of the production of distinct cytokines and effector functions<sup>[4,5]</sup>. Th1 cells produce IFN- $\gamma$  and lymphotoxin and can mobilize the cellular arm of the immune system to combat intracellular pathogens. Th2 cells secrete IL-4, IL-13, and IL-25, which are essential for the generation of appropriate classes of antibodies and for the elimination of extracellular pathogens<sup>[4,5]</sup>.

The identification of the IL-17 family of cytokines as well as the IL-23-mediated expansion of IL-17-producing T cells uncovered a new subset of Th cells, designated as Th17 cells<sup>[6,7]</sup>. Th17 cells require specific cytokines and transcription factors for their differentiation. Although the function of this cell subtype is not completely elucidated, emerging data suggest that Th17 cells may play an important role in host defense against extracellular pathogens, which are not efficiently cleared by Th1-type and Th2-type immunity. The first pathogen implicated in a Th17 response was observed in human Lyme arthritis caused by *Borrelia burgdorferi*, in which *B. burgdorferi*-derived lipopeptides could stimulate the production of IL-17A by T cells from synovial fluid, leading to a Th17 lineage differentiation<sup>[8]</sup>. Previous work has demonstrated that Th17 cells with specificity for self-antigens lead to severe autoimmunity in various animal models. In the murine model of psoriasis, evidence has shown that Th17 cells along with their upstream cytokines (e.g. IL-23) and their downstream effector cytokines (e.g. IL-22) might play a critical role in the pathogenesis of psoriasis<sup>[9,10]</sup>. Moreover, increased levels of IL-17 produced by Th17 cells have been observed in murine models of rheumatoid arthritis and correlate with more severe joint damage<sup>[11]</sup>.

The IL-17 cytokine family is a recently discovered group of cytokines, which includes six members, IL-17A, IL-17B, IL-17C, IL-17D, IL-17E (or IL-25) and IL-17F, and act *in vitro* and *in vivo* as potent proinflammatory cytokines<sup>[6]</sup>. IL-17 can induce the expression of proinflammatory cytokines (such as IL-6 and TNF), chemokines (such as KC, MCP-1 and MIP-2) and matrix metalloproteases, which mediate tissue infiltration and tissue destruction<sup>[12]</sup>. It is also involved in the proliferation, maturation and chemotaxis of neutrophils<sup>[13]</sup>. In agreement with this point, mice deficient in the IL-17 receptor (IL-17R) are more sensitive to lung bacterial infection because of reduced recruitment of neutrophils to the lung<sup>[14]</sup>. In contrast, overproduction of IL-17 in the lungs leads to chemokine expression and tissue inflammation infiltrated by large amounts of leukocytes<sup>[15]</sup>. Moreover, IL-17 is able to costimulate T cells and enhance the maturation of dendritic cells<sup>[16]</sup>. Taken together, these data indicate that IL-17 has pleiotropic activities, functions through the adaptive and innate immune system to promote immune response, and plays an important role in immune responses.

Several cytokines have been reported to be associated with the development and/or proliferation of Th17 cells. Neutralization of IFN- $\gamma$  and IFN- $\alpha$  *in vitro* increases the number of IL-17-producing cells generated by IL-23 stimulation. The number of Th17 cells is further increased by the addition of an IL-4-neutralizing antibody, indicating that IL-4 and IFN- $\gamma$  could inhibit the IL-23-driven

expansion of Th17 cells<sup>[17]</sup>. IL-2, a cytokine important for growth and survival of Th1 and Th2 subsets, is also involved in the long-term expansion and survival of Th17 cells, since restimulation of differentiated Th17 cells with IL-2 could abolish IL-17 production and induce IFN- $\gamma$  production<sup>[18]</sup>. In addition, the differentiation of Th17 cells might also require costimulatory signals distinct from those involved in the differentiation of Th1 and Th2 cells. These studies of the costimulatory requirements of Th17 cells were undertaken to determine which costimulatory molecules are important for IL-6- and TGF- $\beta$ -mediated differentiation of Th17 cells. However, recent work has also demonstrated that Th1-derived IFN- $\gamma$  could trigger antigen-presenting cells to produce IL-23 and then induce memory Th17 cell expansion in a B7-H1-independent manner<sup>[19]</sup>. These data indicate that this complex differentiation of Th17 cells may be dependent on various cytokine milieu.

IL-23 is a heterodimeric protein, which is a member of the IL-12 family of cytokines. It is composed of a p19 subunit in addition to a p40 subunit, which is also a component of IL-12<sup>[20]</sup>. IL-23 functions through the receptor-signaling complex, which is composed of its distinct receptor (namely IL-23R) and IL-12R $\beta$ 1<sup>[21]</sup>. Because IL-23 and IL-12 share a common p40 subunit and IL-12R $\beta$ 1, IL-23 may function like IL-12 to trigger Th1 response. However, p19-deficient mice could contribute to normal Th1 response but could not promote the production of IL-17 cells<sup>[22]</sup>. Other work has demonstrated that Th17 cells are absent in IL-23<sup>-/-</sup> mice, and could not be amplified and survive albeit in the presence of normal Th17 cells *in vivo*<sup>[23]</sup>. Studies have shown that IL-23R is not expressed on naïve T cells, therefore IL-23 could not induce naïve T cells to differentiate into Th17 cells, but could promote Th17 cells amplification<sup>[24]</sup>. These data imply that IL-23 could provide survival signaling to induce the differentiation of Th17 cells. Recently, increasing evidence has shown that IL-1 $\beta$  and IL-23 are required for the generation of Th17 cells and differentiation<sup>[25]</sup>. Naïve T cells stimulated with TGF- $\beta$  plus IL-6 could secrete large amounts of IL-17, whereas IL-23 could trigger the proliferation of Th17 cells from activated memory T cells, only the combination of IL-6 plus TGF- $\beta$  is sufficient to induce differentiation of Th17 cells from naïve T cells<sup>[25]</sup>. Moreover, IL-1 $\beta$  and TNF could increase the number of Th17 cells generated *in vitro* in the presence of IL-6 plus TGF- $\beta$ <sup>[26]</sup>. These data suggest that an inflammatory milieu could regulate the expression of IL-23R on Th17 cells and thereby allow IL-23 to sustain and strengthen the Th17 phenotype.

IL-27 is another IL-12 family member and has been found to downregulate Th17 cell development<sup>[27,28]</sup>. IL-27 is a heterodimeric cytokine composed of Epstein-Barr virus-induced gene 3 (*EBI-3*) and p28 chains. Activation of T cells in the presence of IL-27 induces T-bet, a transcription factor critical for the differentiation of naïve CD4<sup>+</sup> T cells into Th1 cells. However, IL-27R-deficient mice develop severe immunopathology resulting from a general dysregulation of effector T cell responses not restricted to any particular Th cell subtype<sup>[29,30]</sup>. The absence of IL-27-mediated signaling exacerbates

neuroinflammation, enhances the generation of Th17 cells and increases the number of IL-17-expressing T cells in inflamed tissue. The transcription of the two subunits of IL-27 is differentially regulated, leading to the immunosuppressive effects of IL-27. *EBI-3* is strongly induced by Toll-like receptors (TLRs) and the stimulation of TLR results in the binding of NF- $\kappa$ B complexes to a promoter region of the *EBI-3* gene, while activation of TRIF downstream of TLR3 or TLR4 is critical in the induction of p28<sup>[28]</sup>. IL-27, independently of IFN- $\gamma$ R and IL-6R signaling, can inhibit the differentiation of Th17 cells triggered by IL-6 and TGF- $\beta$ . Previous work has demonstrated that T-bet and the suppressor protein SOCS3 are not involved in the IL-27-mediated inhibition of Th17 cells, but that the transcription factor STAT1 seems to be required for the suppressive effect of IL-27 on the development of Th17 cells<sup>[27,28]</sup>.

ROR $\gamma$ t, an orphan nuclear hormone receptor, is expressed by fetal lymphocyte tissue-inducer cells and participates in the formation of lymph nodes and Peyer's patches, intestinal lymphocyte tissue-inducer-like cells and immature thymocytes<sup>[31]</sup>. Interestingly, ROR $\gamma$ t is also found to be expressed by differentiated Th17 cells and IL-17-producing T cells present in the intestinal lamina propria (LP). Consistent with this, Th17 cells are observed to be absent in ROR $\gamma$ t-deficient mice, whereas transduction of naive T cells with a ROR $\gamma$ t-encoding retrovirus could induce IL-17 production. These data indicate the importance of ROR $\gamma$ t in the differentiation of Th17 cells<sup>[32]</sup>. In addition, a recent study has observed that ROR $\gamma$ t-deficiency could not abolish Th17 cell generation and that Th17 cells also express high levels of another related nuclear receptor ROR $\alpha$ <sup>[33]</sup>. Importantly, ROR $\alpha$  deficiency results in reduced IL-17 expression, while coexpression of ROR $\alpha$  and ROR $\gamma$  synergistically leads to Th17 cell differentiation. Thus, these data indicate that Th17 differentiation is directed by two lineage-specific nuclear receptors, ROR $\alpha$  and ROR $\gamma$ <sup>[33]</sup>.

## PATHOGENIC ROLE OF Th17 CELLS IN IBD

It was widely believed that the chronic intestinal inflammation characteristic of human IBD is the consequence of pathogenic Th1 CD4<sup>+</sup> cell responses against the luminal flora, especially in CD, which in turn is driven by proinflammatory cytokines such as IL-12 and TNF<sup>[1-3]</sup>. Animal models of IBD support this hypothesis as intestinal inflammation could be blocked by treatment with monoclonal antibodies specific for IL-12 or TNF<sup>[34,35]</sup>. In recent years, studies on the Th17 cell subset has highlighted our understanding of the formation of human inflammatory diseases, which helps us to explain some of Th1/Th2 balance of abnormal phenomena, particularly in human IBD.

Evidence has shown that high numbers of CD4<sup>+</sup> Th17 cells are found in the colonic LP of the ileum and colon but not the duodenum, jejunum, mesenteric lymph nodes or spleen in conventionally-raised mice, and that these cells are highly infiltrated in inflamed areas of colitic

mice<sup>[36,37]</sup>. Further analysis confirmed that commensal gut flora contribute to the expansion of these CD4<sup>+</sup> Th17 cells, leading to intestinal mucosal inflammation. In terms of mucosal immunity, the IL-23/IL-17 axis has been observed to play an important role in normal intestinal homeostasis, although the precise actions of these cytokines in the gut remain to be fully delineated. To date, IL-17 and other Th17-associated cytokines (e.g. IL-22, IL-23) have been found to have protective effects or pathogenic effects dependent on other effective factors in local tissue. Previous study has demonstrated that IL-23 is mainly expressed by LP dendritic cells in the terminal ileum of normal mice and the frequency of Th17 cells in the intestinal LP is markedly higher than their frequency in peripheral lymphoid tissues<sup>[38]</sup>. Evidence has shown that IL-23 may have important immune protective effects in the gut and that IL-23<sup>-/-</sup> mice exhibited enhanced susceptibility and mortality following infection with the intestinal bacterial pathogen *Citrobacter rodentium*<sup>[38]</sup>. Interestingly, *C. rodentium*-infected IL-23<sup>-/-</sup> mice still generate potent mucosal Th17 responses, suggesting that IL-23-mediated protective responses need not necessarily involve IL-17 production<sup>[25]</sup>. Similarly, although studies in various murine colitis models have implied that IL-23-driven intestinal pathology is associated with increased IL-17 production, a plethora of other inflammatory cytokines have also been found to be elevated in the inflamed colon, including IL-1 $\beta$ , IL-6, IFN- $\gamma$  and TNF<sup>[39]</sup>. In many of the T cell-dependent IBD murine models, Th1 cells clearly predominated in inflamed mucosa and inhibition of Th1 responses could attenuate disease<sup>[1-3]</sup>. Moreover, the observations that IL-23 also drives chronic colitis mediated by cells of the innate immune system are also consistent with the hypothesis that IL-23-mediated intestinal inflammation need not necessarily involve Th17 cells<sup>[39,40]</sup>.

IL-17 mRNA has been found to be highly expressed in inflamed mucosa from both UC and CD patients, and immunohistochemistry revealed that CD68-positive cells express IL-17<sup>[41]</sup>. Recent work<sup>[42]</sup> has also demonstrated that most of the transcripts for Th17-related cytokines were increased in both UC and CD compared to normal controls, but more abundant in UC than in CD. In contrast, up-regulation of IFN- $\gamma$  mRNA was marked in CD LP CD4<sup>+</sup> T cells. Up-regulation of IL-23p19 mRNA was detected in colonic mucosa from both UC and CD patients. The significance of Th17 immunity in UC was further supported by the finding that recombinant IL-23 actually enhanced IL-17 production by LP CD4<sup>+</sup> T cells in UC, but had a lesser effect on LP CD4<sup>+</sup> T cells in CD. Since the Th1 pathway has been reported to antagonize the Th17 pathway *via* various mechanisms, IFN- $\gamma$  or IL-12 could actually suppress IL-17 production by human LP CD4<sup>+</sup> T cells. Therefore, we can hypothesize that excess IFN- $\gamma$  production by Th1 cells in CD patients may negatively affect the IL-17 production by Th17 cells in CD, despite the fact that Th17 cells are present in CD mucosa.

A previous report has shown that IL-23 can enhance IFN- $\gamma$  production by LPMCs from CD patients and that the mucosal IL-23p19 expression levels were correlated with IL-17 in UC and IFN- $\gamma$  in CD<sup>[43]</sup>. These results

suggest that IL-23 may enhance the production of distinct cytokines between UC and CD patients, thereby contributing to the local Th1/Th17 balance in IBD. Additionally, IL-21, belonging to the IL-2 family, has been described to play an important part in the differentiation and maintenance of Th17 cells<sup>[44,45]</sup>. Comparing the Th1, Th2, and Th17 subsets, the largest amounts of IL-21 are produced by Th17 cells. IL-21 produced by differentiating Th17 cells may act in a positive feedback loop, which amplifies the precursor frequency of Th17 cells<sup>[44,45]</sup>. Recently, our study found that IL-21 facilitated IBD CD4<sup>+</sup> T cells to differentiate into Th17 cells, characterized by increased expression of IL-17A and ROR $\gamma$ t. Thus, we proposed that IL-21 might be involved in the pathogenesis of IBD and blockage of IL-21R signaling may have therapeutic potential in IBD<sup>[46]</sup>.

The exact role of IL-17 and Th17 cells in intestinal pathology and homeostasis is currently not well understood. IL-17 may have some protective functions in the epithelial layer, as it has been shown to fortify tight junction formation between epithelial cells *in vitro*<sup>[47]</sup>, and treatment of mice with anti-IL-17 neutralizing antibody actually enhanced the severity of colitis induced by administration of dextran sodium sulphate<sup>[48]</sup>. In contrast, a recent study comparing the ability of Th1 and Th17 cells to induce colitis in mice has proven that Th17 cells are significantly more pathogenic than their Th1 counterparts<sup>[49]</sup>.

So far, there have been few studies that have employed selective blockade of IL-17 during intestinal inflammation. However, in IL-10<sup>-/-</sup> mice, treatment with anti-IL-17 specific antibody had little impact on colitis unless anti-IL-6 antibody was also co-administered<sup>[48]</sup>, suggesting that IL-17 may synergize with other inflammatory mediators in the gut. Recent studies have highlighted further potential heterogeneity within Th17 cell populations by demonstrating that some may even secrete IL-10<sup>[50]</sup>, a factor known to inhibit intestinal inflammation. Thus, it is possible that the actions of Th17 cells may differ dependently on other factors that may be present in the local environment. In the normal intestine, the primary function of Th17 cells may be like sentinels which contribute to maintaining epithelial barrier function, whereas in sites of chronic intestinal inflammation, high levels of IL-23 may activate their full pathogenic and anti-bacterial functions.

## CONCLUSION

Through the potential role of Th17 cells in IBD animal models of chronic intestinal inflammation as well as in human IBD, target therapy directed against the Th17/IL-17 axis may have a therapeutic role in the treatment of intestinal mucosal inflammation. However, the precise mechanisms of the Th17/IL-17 axis in intestinal homeostasis should be further elucidated in murine models and human IBD patients.

### Abstract

**AIM:** To study the role of advanced glycation end products (AGE) and their specific receptor (RAGE) in the pathogenesis of liver fibrogenesis.

**METHODS:** *In vitro* RAGE expression and extracellular matrix-related gene expression in both rat and human hepatic stellate cells (HSC) were measured after stimulation with the two RAGE ligands, advanced glycation end product-bovine serum albumin (AGE-BSA) and N<sup>ε</sup>-(carboxymethyl) lysine (CML)-BSA, or with tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ). *In vivo* RAGE expression was examined in models of hepatic fibrosis induced by bile duct ligation or thioacetamide. The effects of AGE-BSA and CML-BSA on HSC proliferation, signal transduction and profibrogenic gene expression were studied *in vitro*.

**RESULTS:** In hepatic fibrosis, RAGE expression was enhanced in activated HSC, and also in endothelial cells, inflammatory cells and activated bile duct epithelia. HSC expressed RAGE which was upregulated after stimulation with AGE-BSA, CML-BSA, and TNF- $\alpha$ .

RAGE stimulation with AGE-BSA and CML-BSA did not alter HSC proliferation, apoptosis, fibrogenic signal transduction and fibrosis- or fibrolysis-related gene expression, except for marginal upregulation of procollagen  $\alpha 1(I)$  mRNA by AGE-BSA.

**CONCLUSION:** Despite upregulation of RAGE in activated HSC, RAGE stimulation by AGE does not alter their fibrogenic activation. Therefore, RAGE does not contribute directly to hepatic fibrogenesis.

### INTRODUCTION

Advanced glycation end products (AGE) are formed *in vitro* and *in vivo* from non-enzymatic glycation of the amino groups of proteins with reducing sugars such as glucose. Although serum levels of AGE are usually low due to constant turnover, they can be detected *in vivo* once levels of reducing sugars are elevated, as occurs in diabetes<sup>[1]</sup>. Thus, glycated hemoglobin in the serum of diabetic patients was the first described physiologically relevant AGE<sup>[2]</sup>. Interest in AGE has increased since several studies suggested that AGE may be responsible for pathological features associated with diabetes. For example, in endothelial cells, AGE were shown to increase the expression of pro-coagulant activity,

induce expression of vascular cell adhesion molecule-1, and promote nuclear translocation of nuclear factor- $\kappa$ B (NF- $\kappa$ B). In mononuclear phagocytes, AGE induce the production of platelet-derived growth factor, increase migration, and drive NF- $\kappa$ B activation<sup>[3,4]</sup>.

AGE interact with several receptors, such as the receptor for advanced glycation end products (RAGE), 80K-H phosphoprotein, galectin-3, lactoferrin, scavenger receptors such as SRA or SRB I, and CD36<sup>[5,6]</sup>. RAGE, a member of the immunoglobulin superfamily of cell surface receptors, is expressed in a variety of tissues and interacts with several AGE ligands, especially with N<sup>ε</sup>-(carboxymethyl) lysine (CML)<sup>[4]</sup>.

However, while a role for RAGE in the progression of diabetic vasculopathy and kidney failure has been established<sup>[7-9]</sup>, its role in hepatic fibrosis is poorly understood. This is important due to the emerging epidemic of nonalcoholic steatohepatitis (NASH) related to obesity and the metabolic syndrome, conditions that are associated with increased AGE and RAGE and hepatic fibrosis<sup>[10-12]</sup>. RAGE expression has been described in inflammatory cells<sup>[13]</sup> and in activated hepatic stellate cells (HSCs)<sup>[14]</sup>, the major fibrogenic effector cells that can undergo activation to myofibroblasts producing the excess extracellular matrix in hepatic fibrosis<sup>[15]</sup>. Many features of this activation process are mimicked by spontaneously occurring activation on tissue culture plastic *in vitro*<sup>[16,17]</sup>. While certain cytokines, growth factors and culture conditions and, as recently demonstrated, AGE<sup>[18]</sup>, can modulate HSC activation and extracellular matrix (ECM) synthesis, the functional contribution of AGE and RAGE expression to fibrogenic activation of HSC and to hepatic fibrosis remains to be elucidated.

We have therefore studied whether physiological AGE concentrations occur in the serum of patients with diabetes<sup>[11,19]</sup>, and whether AGE-RAGE interactions are involved in the progression of liver fibrosis. To this end we investigated RAGE expression in HSC *in vitro*, and in normal and cirrhotic livers *in vivo*. Furthermore, the effects of AGE and the key proinflammatory cytokine tumor necrosis factor (TNF)- $\alpha$  on HSC RAGE expression and on the proliferation, kinase activation and profibrogenic and fibrolytic gene expression of HSC were determined.

## MATERIALS AND METHODS

### Synthesis of AGE and CML-modified BSA

For preparation of AGE-modified bovine serum albumin (BSA), 0.6 mmol/L BSA and 0.16 mmol/L D-glucose were dissolved in 20 mL PBS, sterile filtered, incubated for 60 d at 37°C and dialyzed against PBS under sterile conditions to remove unreacted D-glucose. Control BSA was incubated in parallel in the absence of D-glucose. Preparation of CML-modified BSA was carried out as previously described<sup>[20]</sup>.

Glycation of AGE-BSA and CML-BSA was determined using the 2,4,6-trinitrobenzenesulfonic acid (TNBS) assay<sup>[21]</sup>, resulting in a 45.6% and 36.5% glycation of lysines for AGE-BSA and CML-BSA, respectively.

After endotoxin removal with the Detoxi-Gel™ (Pierce, Rockford, IL), the final endotoxin concentration determined with the E-toxate® endotoxin detection kit (Sigma, Taufkirchen, Germany) was below 0.04 and 0.02 ng/mL for AGE-BSA and CML-BSA, respectively.

### Cell lines

Cell lines were cultured as previously published<sup>[20]</sup>. The fully activated rat HSC line HSC-T6 (kind donation of Dr. SL Friedman, NY)<sup>[22]</sup>, the moderately activated rat HSC line CFSC-2G (kindly provided by Dr. M Rojkind, Washington, D.C.)<sup>[23]</sup> and human HSC of passage 3 to 5 (kind gift of Dr. M Pinzani, Florence, Italy)<sup>[24]</sup> were maintained as previously described (references see below).

**Cell culture and animal experimentation:** Animals were treated according to the Council of International Organizations of Medical Sciences for the Care and Use of Laboratory Animals in Research. The experimental protocol was approved by the Animal Care Committee of the University of Erlangen-Nuremberg.

**Isolation of rat primary hepatocytes:** Hepatocytes were freshly isolated from male Wistar rats (190-200 g, Charles River, Sulzfeld, Germany) according to a modified two-step collagenase perfusion method<sup>[25]</sup> as previously described in detail<sup>[26]</sup>. Experiments were performed 6 h after plating with cell viabilities  $\geq$  85% as determined by Trypan Blue exclusion.

**Isolation of rat primary hepatic stellate cells:** HSC were isolated from male Wistar rats (retired breeders, 400-500 g) as described<sup>[27]</sup>. Cell viability was usually between 95%-98%. The purity of HSC was confirmed by their stellate shape, and autofluorescence of the cytoplasmic lipid-droplets at 390 nm. Freshly isolated HSC were activated by culture on plastic in the presence of 10% fetal calf serum (FCS) for 1, 5, and 10 d prior to lysis and RNA extraction. HSC plated for 1 d were designated as quiescent, those cultured for 5 and 10 d as partially and fully activated, respectively.

**Experimental liver fibrosis:** Experimental liver fibrosis was induced in groups of four adult male Wistar rats weighing about 400 g as follows: (1) bile duct ligation (BDL) for 6 wk, (2) thioacetamide (TAA) treatment, 200 mg/g body weight thrice weekly for 12 wk, as previously published<sup>[27]</sup>. Sham-operated rats served as controls. After sacrifice of all animals, pieces of the right and left liver lobes were removed, fixed in 4% formalin and paraffin embedded, or snap frozen in liquid nitrogen for further analysis.

For RNA analysis 150-200 mg of tissue were homogenized in 1 mL RNAPure for 30 s and an aliquot representing 10 mg of tissue was mixed with 900  $\mu$ L fresh RNAPure. Morphology of connective tissue was evaluated with hematoxylin-eosin and Sirius Red staining.

**Immunohistochemistry:** For immunohistochemical analysis specimens from two different liver segments were

studied. Sequential deparaffinized sections were blocked with avidin and biotin. After antigen retrieval in a decloaking chamber for 30 s at 120°C in Target Retrieval Solution, pH 6.0 (Dako), sections were incubated overnight at room temperature with monoclonal antibodies to RAGE (1:30, kindly provided by Dr. B Weigle (Dresden, Germany), CD3 (1:10, Serotec MCA 772), CD45 (1:50, Serotec MCA 43R), CD68 (1:30, Serotec MCA 341R), and  $\alpha$ -smooth muscle actin (SMA) (1:30, DAKO M 0851), followed by biotinylated horse anti-mouse IgG and streptavidin-biotin alkaline phosphatase<sup>[29]</sup>. Sections were developed using Fast Red and nuclei counterstained with hematoxylin. RAGE was additionally detected with the catalyzed signal amplification system as previously described<sup>[29,20]</sup>. For double staining, the slides were treated with a Double Staining Enhancer (Zytomed 50-056) for 30 min before application of the secondary antibody. RAGE-antibody was first applied, followed by the other antibodies developed with Fast Red (RAGE) and with Fast Blue. The co-expressions of RAGE and of CD3, CD68 and of  $\alpha$ -SMA inside the liver (portal and lobular areas) were counted in ten randomly selected high-power fields (400  $\times$  magnification) using ImageAccess Enterprise 5 software (Imagic Bildverarbeitung, Glattbrugg, Switzerland). The number of immunohistochemically positive cells are given as the percentage of all cells (RAGE) and the respective cell population (CD3, CD68 and of  $\alpha$ -SMA) in the studied areas.

### SDS-PAGE and Western blotting

Preconfluent (80%) HSC lines, HSC-T6 and CFSC-2G, were seeded at 20 000 cells per well in 24-well plates, washed and incubated with 10-100  $\mu$ g/mL BSA, AGE-BSA, or CML-BSA, or with 0-10 ng/mL TNF- $\alpha$  (Sigma) in serum-free medium. Protein extraction and Western blotting were performed as previously described<sup>[20]</sup>.

### Quantitative real time PCR

Total RNA was isolated using peqGOLD RNApure reagent (PeqLab Biotechnologie, Erlangen, Germany) and reverse transcribed, followed by real time RT-PCR using a LightCycler instrument (Roche, Mannheim, Germany), as described in detail elsewhere<sup>[27,30,31]</sup>, and the TaqMan principle<sup>[32]</sup>. Results were normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) or  $\beta$ 2-microglobulin amplified in a parallel reaction. The specific sense and antisense oligonucleotide primers and probes have been published<sup>[31,20]</sup>.

### Cell proliferation

Cell proliferation of CFSC-2G and HSC-T6 cells was determined using BrdU incorporation according to the manufacturer's protocol (Roche, Mannheim, Germany) as recently described<sup>[33]</sup>.

### Determination of p44/42 and p38 MAPK activity

These enzyme activities were determined as previously described<sup>[27]</sup> using Western Blotting with antibodies to phosphorylated and total ERK1/2 MAPK (Thr202/Tyr204, 1:2000) and anti-phospho-p38 MAPK (Thr180/Tyr182, 1:1000) (from Cell Signaling Technology,

Frankfurt, Germany). Phospho-specific signals were normalized to unphosphorylated kinase signals.

### Statistical analysis

Statistical analysis was performed with SPSS v. 16.0 (SPSS GmbH Software, Munich, Germany). Student's *t* test and univariate ANOVA (analysis of variance) was used to test for differences between two and more groups, respectively ( $P < 0.05$  was significant). All graphs represent the mean  $\pm$  SD and were performed at least in triplicate.

## RESULTS

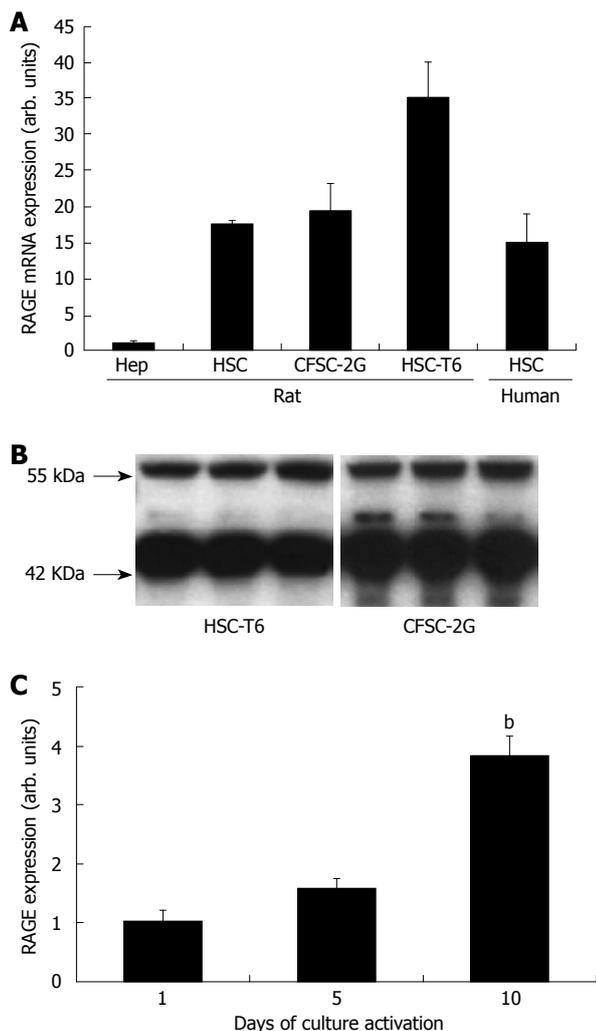

### Expression of RAGE by hepatic stellate cells

Freshly isolated rat HSC, and the rat HSC lines HSC-T6 and CFSC-2G, as well as human HSC, expressed significant RAGE transcripts and protein (Figure 1A and B). During culture, activation of freshly isolated rat HSC RAGE transcripts was upregulated 1.6- and 3.8-fold, respectively, on days 5 and 10 of primary culture (Figure 1C). Culture activation of HSC was associated with highly increased expression of procollagen- $\alpha$ 1(I) and  $\alpha$ -SMA mRNA which were upregulated  $> 100$ -fold and  $> 50$ -fold after 5 and 10 d of activation (data not shown).

### Upregulation of RAGE mRNA in rat models of cirrhosis

In cirrhotic livers of rats subjected to BDL, RAGE transcripts were upregulated 4-fold as compared to healthy controls ( $P < 0.01$ ), whereas in thioacetamide (TAA)-induced cirrhosis RAGE mRNA expression remained unchanged. Fibrosis-related transcripts such as  $\alpha$ -SMA, procollagen- $\alpha$ 1(I), matrix metalloproteinase (MMP)-13, and tissue inhibitor of metalloproteinase (TIMP)-1 mRNA were highly upregulated in both fibrosis models (Table 1).

Immunohistochemistry of normal livers showed a significantly lower expression of RAGE protein compared to the fibrotic/cirrhotic livers ( $P < 0.001$ , Table 2 and Figure 2A), with predominant expression in portal vein and arterial endothelial cells and sparse expression in lymphocytes and myofibroblasts in the hepatic lobule. Hepatocytes did not express RAGE. In BDL livers RAGE protein was highly expressed in bile duct proliferating epithelia, in periductular  $\alpha$ -SMA positive myofibroblasts and in inflammatory cells that were identified as CD3-positive T-lymphocytes and CD68-positive macrophages by use of double staining immunohistochemistry (Table 2, Figure 2A and B). In TAA cirrhosis the number of RAGE-expressing cells was less pronounced than in biliary cirrhosis, in concert with lower RAGE gene expression and fewer inflammatory cell infiltrates, being primarily expressed by macrophages, as opposed to mostly T-lymphocytes and proliferating bile duct epithelia in BDL-cirrhosis (Table 2 and Figure 2B). Only a few  $\alpha$ -SMA- and RAGE-positive myofibroblasts were detected in portal areas and septa of both models. The expression of RAGE by endothelial cells in the cirrhotic livers was slightly enhanced in areas of neo-capillarization compared to normal controls (Figure 2A).

**Figure 1** RAGE expression in hepatic stellate cells (A, B) and upregulation of RAGE expression during activation of HSC (C). A: Bars represent RAGE mRNA expression, as determined by real time quantitative PCR relative to GAPDH mRNA, by freshly isolated rat hepatocytes (Hep), 10 d culture-activated primary rat HSC, CFSC-2G and HSC-T6 HSC lines, and human HSC; B: RAGE protein is detected as a 57 kDa band after SDS-PAGE of cell lysates and Western blotting with a monoclonal anti-RAGE IgG. Experiments were repeated at least three times with similar results; C: Freshly isolated rat HSC were culture-activated for 1, 5, and 10 d and RAGE mRNA expression was quantified by real-time PCR. Bars represent mean RAGE expression  $\pm$  SD in arbitrary units relative to GAPDH from at least three individual experiments. Values were normalized to 50 ng of extracted RNA transcribed into cDNA. <sup>b</sup> $P < 0.01$  vs 1 d activation. RAGE: Receptor for advanced glycation end products; HSC: Hepatic stellate cells; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

### Regulation of RAGE expression in HSC: induction by AGE and TNF- $\alpha$

Incubation of CFSC-2G and HSC-T6 HSC with 50  $\mu$ g/mL AGE-BSA significantly ( $P < 0.001$ ) upregulated RAGE protein expression by 2-3 fold (Figure 3A). While CFSC-2G cells were more sensitive to AGE-BSA, the highest concentration, 100  $\mu$ g/mL, was not effective in either cell line. Addition of 50  $\mu$ g/mL CML-BSA increased RAGE protein expression about 2 fold in both cell lines ( $P < 0.05$ ) (Figure 3B).

Similarly, TNF- $\alpha$  upregulated RAGE protein expression significantly ( $P < 0.01$ ) in both CFSC-2G and HSC-T6 HSC (Figure 3C). Again, a greater RAGE induction was

**Table 1** Expression of RAGE and ECM-related genes in rats cirrhotic due to BDL and TAA treatment

	Control	BDL	TAA
RAGE	1.00 $\pm$ 0.31	3.89 $\pm$ 0.92 <sup>b</sup>	1.44 $\pm$ 0.47

Quantitative analysis of the immunohistochemical co-expression of RAGE with CD3, CD68 and  $\alpha$ -SMA in normal controls and livers with cirrhosis due to BDL or TAA-intoxication using double staining immunohistochemistry and image analysis. Mean of cells [%] ( $\pm$  SD) per 10 high power fields. Quantitative assessment as described in material and methods. <sup>1</sup>Mainly endothelial cells in the portal areas; <sup>2</sup>Vascular smooth muscle cells, subset of activated HSC; <sup>3</sup>Focally highly expressed by proliferating bile duct epithelia; <sup>4</sup>Mainly around proliferating bile ducts; <sup>5</sup>Mainly at the portal interface and septa. P: Portal; L: Lobular.

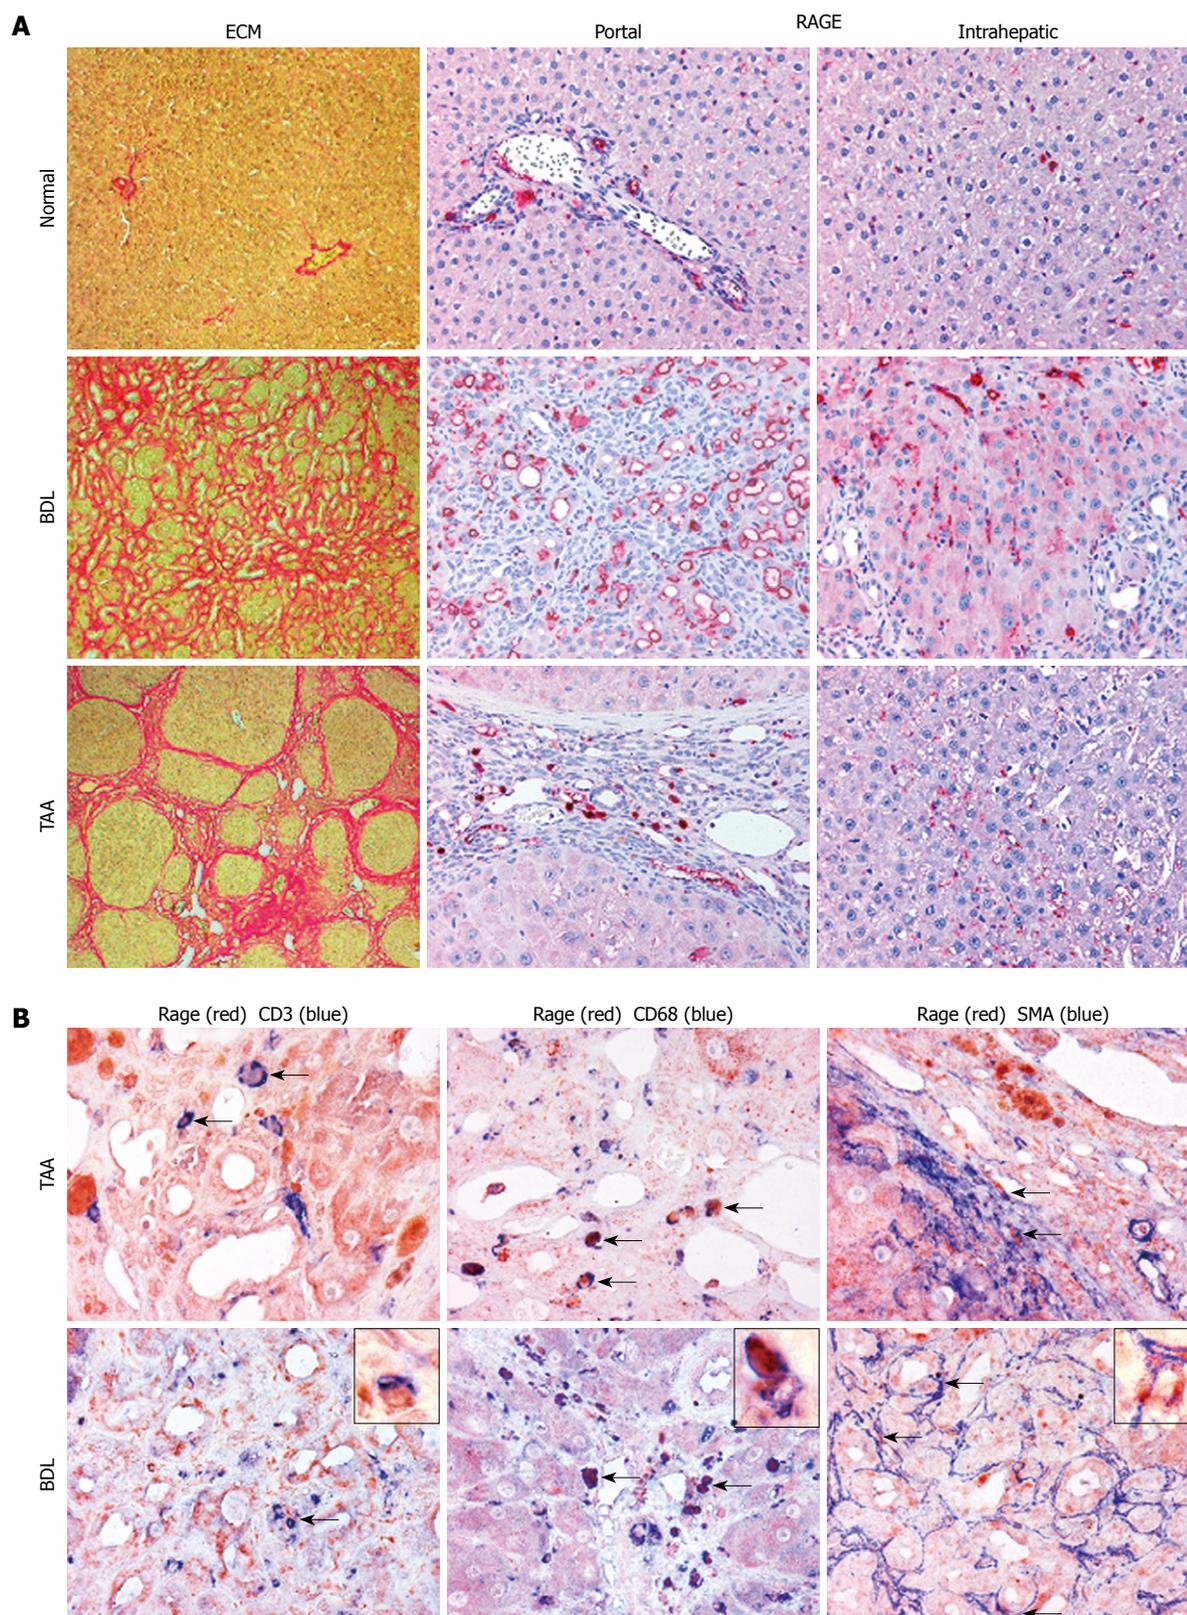

observed in CFSC-2G cells, where 0.1 ng/mL TNF- $\alpha$  resulted in a nearly 3-fold ( $P < 0.001$ ) upregulation of RAGE expression.

### AGE do not modulate extracellular matrix-related gene expression in HSC

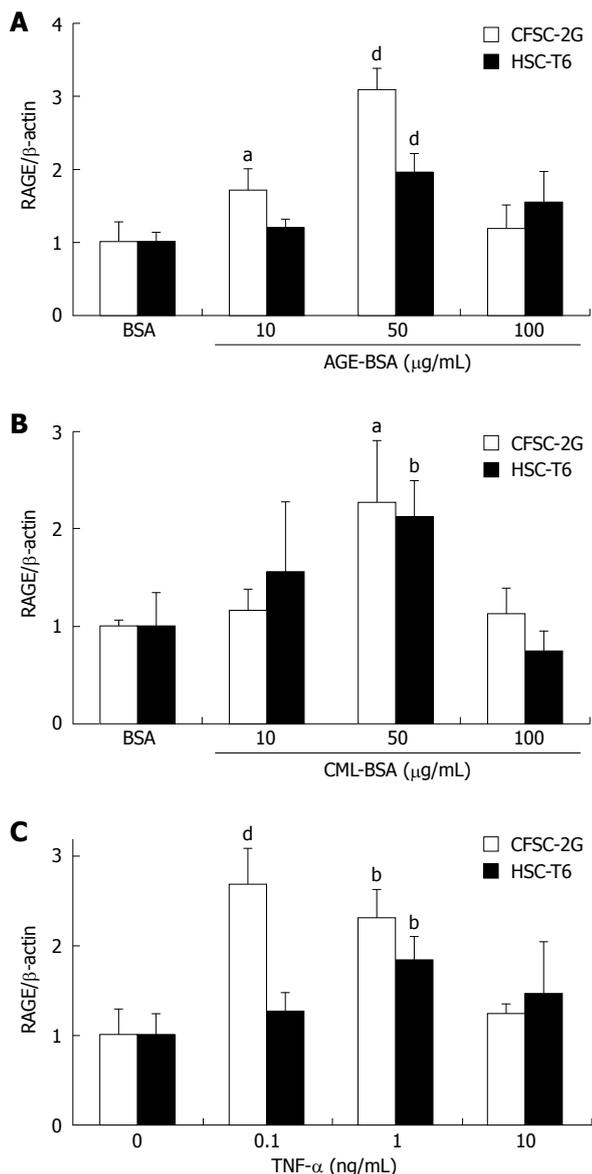

Incubation of CFSC-2G HSC with 50  $\mu$ g/mL AGE-BSA or CML-BSA did not significantly modify transcript levels of transforming growth factor (TGF)- $\beta$ 1,  $\alpha$ -SMA, and MMP-13, or RAGE itself, except for a marginal (23%,  $P < 0.05$ ) but reproducible upregulation of procollagen- $\alpha$ 1(I) mRNA by AGE-BSA (Table 3). These results could be confirmed in HSC-T6 and human HSC (data not shown).

### AGE do not modify hepatic stellate cell proliferation or p42/44 and p38 MAPK activation

CFSC-2G and HSC-T6 cells were exposed to 1-1000  $\mu$ g/mL AGE-BSA for 24 h, and DNA synthesis was assessed by BrdU incorporation. As opposed to the mitogen FCS, AGE-BSA did not induce DNA synthesis

**Figure 2** Cell-specific expression patterns of RAGE in normal and cirrhotic rat livers. **A:** Portal and lobular expression patterns of RAGE in normal liver and in livers of rats with cirrhosis due to BDL or TAA treatment (magnification,  $\times 200$ ). Parallel sections were stained for collagen with picrosirius red. In normal liver, minor RAGE expression was found in endothelial cells of portal veins and arteries, in bile duct epithelia as well as in lymphocytes, macrophages and (myo-) fibroblasts in the hepatic lobular areas. No RAGE expression was found in hepatocytes. RAGE was clearly upregulated in cirrhosis induced by BDL and TAA, with higher numbers of RAGE-expressing cells in BDL, mainly attributable to a prominent contribution by proliferating bile duct epithelial cells. In areas of lobular fibrosis, perisinusoidal endothelia started to express RAGE, apparently in parallel with sinusoidal capillarization; **B:** Double labeling immunohistochemistry for RAGE (in red) in combination with CD3 (T-lymphocytes), CD68 (macrophages), and  $\alpha$ -SMA (myofibroblasts) (in blue), magnification  $\times 400$  being exemplarily highlighted with insets (magnification,  $\times 1000$ ). In both cirrhosis models, mainly CD3-positive T-lymphocytes and CD68-positive macrophages expressed RAGE, independently of their microanatomic locations (portal, interface, septal or intrahepatic). Additionally, RAGE was more colocalized with macrophages than with T-lymphocytes independent of the cirrhosis model. RAGE expression was also found on  $\alpha$ -SMA-positive myofibroblasts, either localized around periportal bile duct proliferations in BDL or in the interface and septal area in TAA-induced cirrhosis (co-localization indicated by arrows). BDL: Bile duct ligation; TAA: Thioacetamide; SMA: Smooth muscle actin; ECM: Extracellular matrix.

**Figure 3** Advanced glycation end product-bovine serum albumin (AGE-BSA) (A), N<sup>ε</sup>-(carboxymethyl) lysine (CML)-BSA (B) and tumor necrosis factor (TNF)-α (C) upregulate RAGE protein expression in hepatic stellate cells. Mean RAGE protein expression as determined by quantitative Western blotting from extracts of rat HSC lines relative to β-actin. Cells were incubated for 24 h and results are derived from at least three independent experiments and expressed as mean ± SD. Data are shown as x-fold increase compared to cells incubated with BSA alone. <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01, <sup>d</sup>P < 0.001 vs BSA.

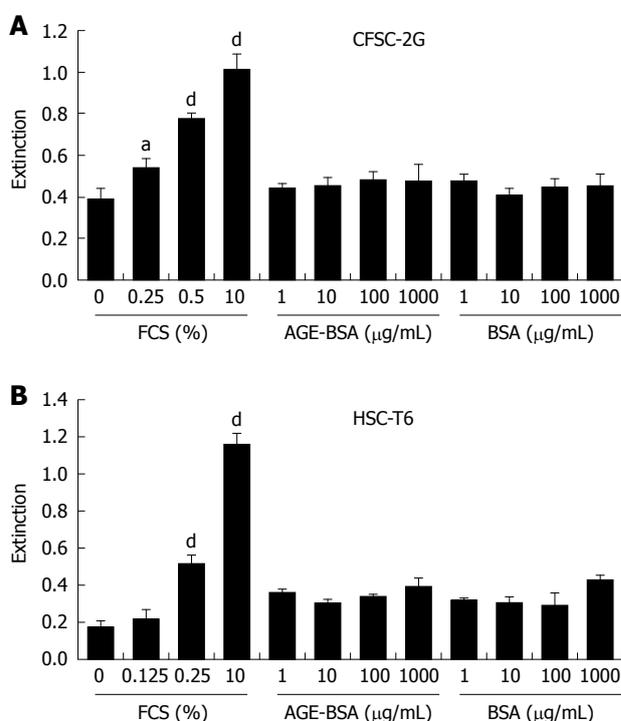

in these cells (Figure 4). In addition, cell numbers remained unchanged after addition of AGE-BSA (data not shown). In line with the proliferation data, AGE-BSA did not induce p44/42 (Figure 5A) or p38 (Figure 5B) MAPK activation when compared to 10% FCS as positive control.

## DISCUSSION

Our findings show that RAGE, a prominent receptor for AGE, is expressed in hepatic stellate cells (HSC) derived from various species. Our data are in line with previous studies showing the RAGE upregulation in single culture-activated HSC either of rat or human origin<sup>[14,18]</sup>.

	BSA	AGE-BSA	CML-BSA
RAGE	1.00 ± 0.14	1.20 ± 0.11	1.26 ± 0.07
TGF-β1	1.00 ± 0.06	1.12 ± 0.21	0.99 ± 0.07
Procollagen-α1(I)	1.00 ± 0.08	1.23 ± 0.06 <sup>a</sup>	1.12 ± 0.19
α-SMA	1.00 ± 0.14	1.20 ± 0.20	1.16 ± 0.04
MMP-13	1.00 ± 0.05	1.09 ± 0.14	0.97 ± 0.09

CFSC-2G HSC were incubated with 50 µg/mL BSA, AGE-BSA, or CML-BSA for 24 h. RAGE, TGF-β1, procollagen-α1(I), α-SMA, and MMP-13 transcript levels are expressed relative to GAPDH and as n-fold increase compared to cells treated with BSA alone (means ± SD of at least three individual experiments). <sup>a</sup>P < 0.05 vs BSA. ECM: Extracellular matrix; HSC: Hepatic stellate cells; AGE: Advanced glycation end product; BSA: Bovine serum albumin; CML: N<sup>ε</sup>-(carboxymethyl) lysine; TGF: Transforming growth factor.

**Figure 4** AGE do not stimulate DNA synthesis in hepatic stellate cells. DNA synthesis as a surrogate of proliferation was determined in CFSC-2G (A) and HSC-T6 (B) HSC after a 24 h incubation with increasing concentrations of FCS, AGE-BSA or CML-BSA in 0% FCS. Data are results of six independent experiments and expressed as mean ± SD. <sup>a</sup>P < 0.05, <sup>d</sup>P < 0.001 vs 0% FCS.

Using different experimental hepatic fibrosis models in rats we found that transcript levels of RAGE correlate well with RAGE protein expression in agreement with our immunohistochemical co-localization studies. Compared with earlier studies of RAGE expression in other organs<sup>[4]</sup>, we could detect RAGE not only in myofibroblasts (HSC) and endothelial cells, but also in lymphocytes, macrophages/small Kupffer cells and proliferating bile duct epithelial cells. These results are in contrast to prior studies that either identified RAGE expression in bovine hepatocytes *in vivo*<sup>[34]</sup>, or exclusively in HSC and myofibroblasts, but not in hepatocytes, sinusoidal endothelial or Kupffer cells<sup>[14]</sup>. The reasons for these discrepancies may be the use of different

**Figure 5** AGE-BSA does not activate p44/42 (A) and p38 (B) MAPK signaling in hepatic stellate cells. Kinase phosphorylation was determined in CFSC-2G and HSC-T6 HSC using quantitative western blotting with phosphospecific antibodies relative to total kinase antibodies after a 10 min incubation with increasing concentrations of AGE-BSA or CML-BSA in 0% to 10% FCS. Bars represent n-fold phosphorylation compared to controls with 0% FCS and results are derived from at least three individual experiments.

antibody reagents with different specificities. We used an antibody that has been characterized thoroughly and found to react specifically with cells on tissue sections<sup>[28]</sup>. In addition, we could partly confirm our *in vivo* data with our *in vitro* studies using various types of HSC.

During culture-activation of HSC, RAGE expression was increased significantly. This increase was paralleled by the known upregulation of major transcripts related to fibrosis progression, i.e. TGF- $\beta$ 1, the most prominent profibrogenic cytokine; procollagen  $\alpha$ 1(I), a precursor of the major fibrillar collagen; TIMP-1, the central inhibitor of matrix metalloproteinases (MMP); and  $\alpha$ -SMA, a marker for HSC activation<sup>[16,17]</sup>.

Enhanced RAGE expression in hepatic fibrogenesis was further shown in rats with cirrhosis induced by BDL and TAA treatment, which was in line with prior findings in CCl<sub>4</sub>-induced hepatic fibrosis where RAGE transcript and protein levels were upregulated until 6 wk after the completion of CCl<sub>4</sub> treatment<sup>[55]</sup>. Differences in RAGE expression may be due to the lack of inflammation in TAA-treated animals, since TAA treatment was stopped one week prior to tissue removal. Progressive injury, however, was still present in bile duct-ligated animals at the time of sacrifice, with enhanced numbers of CD68-positive macrophages/small Kupffer cells and CD3-

positive T-lymphocytes as compared to the TAA-cirrhosis model. Furthermore, we showed that  $\alpha$ -SMA-positive HSC/myofibroblasts of the septal or portal interface, representing the prominent fibrogenic effectors, expressed RAGE in both fibrosis models.

In studies of diabetes-associated cardiovascular and renal disease, an upregulation of RAGE has been linked to enhanced levels of AGE<sup>[7,9]</sup>, in association with epithelial-myofibroblast transdifferentiation<sup>[36]</sup> and induction of fibrogenesis<sup>[37-39]</sup>. Additionally, inhibition of the interaction of AGE-RAGE with neutralizing monoclonal anti-RAGE antibodies or the AGE cross-link disrupting agent ALT-711 prevented pathological effects of hyperglycemia in blood vessels and kidneys<sup>[8,40]</sup>.

Our results show that AGE-BSA, as well as the specific RAGE ligand CML-BSA, upregulated the expression of the receptor itself in HSC. This phenomenon was reported previously in human vascular and umbilical vein endothelial cells<sup>[41]</sup>, where 50  $\mu$ g/mL AGE-BSA induced a 2- and 2.5-fold increased RAGE protein expression, respectively, compared to untreated cells. Other studies showed that certain vascular domains, renal glomeruli or intima media and adventitia of the aorta exhibit increased RAGE expression<sup>[42]</sup> and that interactions of AGE with RAGE resulted in autoinduction of RAGE expression<sup>[43]</sup>. Our observed reduction of response using higher concentrations of AGE-BSA could reflect receptor saturation, downregulation, or an antagonist effect on RAGE expression.

Addition of the proinflammatory cytokine TNF- $\alpha$  to HSC upregulated RAGE protein and mRNA expression up to 3-fold, in accordance with previous studies showing that RAGE is upregulated in inflamed tissues<sup>[44]</sup>. Interestingly, the blockade of RAGE by murine-soluble RAGE as decoy could decrease acetaminophen-induced hepatotoxicity<sup>[45]</sup> and liver injury in an ischemia and reperfusion model in mice<sup>[46]</sup>. Furthermore, an approximately 2-fold increase of RAGE protein expression after incubation of human microvascular endothelial cells with up to 100 ng/mL TNF- $\alpha$  has been reported<sup>[41]</sup>. In the present study, however, RAGE expression peaked at 0.1 and 1 ng/mL TNF- $\alpha$  and decreased to baseline levels at 10 ng/mL TNF- $\alpha$ , apparently due to receptor downregulation at high concentrations and this indicated a greater sensitivity of HSC than that of human microvascular endothelial cells to TNF- $\alpha$ . Increased RAGE expression under inflammatory conditions, such as those triggered by TNF- $\alpha$ , may result in enhanced binding of AGEs to RAGE, further increasing RAGE expression and expression of proinflammatory cytokines. This could be relevant for patients with insulin resistance, overt diabetes, and obesity, who frequently present with hepatic inflammation and fibrosis, i.e. patients with NASH.

The upregulated RAGE expression in HSC may lead to the conclusion that AGE-RAGE interactions play a role in hepatic fibrogenesis. However, in contrast to upregulation of RAGE by AGE/CML-AGE and TNF- $\alpha$ , we clearly showed that AGE-BSA and CML-BSA were unable to induce expression of fibrosis or

fibrolysis-related genes in CFSC-2G or HSC-T6 HSC. Using another experimental approach Xia *et al*<sup>[35]</sup> showed that targeting of RAGE by specific siRNA downregulated fibrogenesis-related transcripts *in vitro* and *in vivo*. Of note, we took great care to synthesize AGE-BSA and CML-BSA in a sterile environment and to remove any remaining endotoxin contamination in the products. Possible discrepancies between previously published cellular effects of AGE and the present lack of induction may be explained by the presence of endotoxin in previously synthesized AGE preparations.

Another pathogenic feature of HSC activation, besides migration, apoptosis, ECM synthesis, or contractility, is increased proliferation<sup>[47]</sup>. According to our experimental setup, we can conclude that AGE do not alter hepatic fibrogenesis through induction of HSC proliferation.

Previous studies of endothelial cells and monocytes, especially mononuclear phagocyte-derived dendritic cells of the liver after massive liver injury<sup>[13]</sup>, showed that interactions of AGE with RAGE induce, besides RAGE, the expression of proinflammatory cytokines, such as TNF- $\alpha$  and interleukin-1 and -6<sup>[41]</sup>. These events are mediated by activation of redox-sensitive signaling pathways involving NADPH oxidase, or mitogenic pathways involving the small G-protein Ras that lead to activation of mitogen-activated protein kinases (MAPK), or involving nuclear factor- $\kappa$ B (NF- $\kappa$ B). Since no data on AGE-induced MAPK activation in HSCs exist, we aimed to investigate whether RAGE upregulation by AGE may be due to stimulation of MAPK signal transduction pathways. We could not find any stimulatory effect of endotoxin-free AGE-BSA or CML-BSA on activation of p44/42 MAPK, which mediates cellular growth and differentiation, and p38 MAPK, which regulates cytokine expression and controls cellular responses to cytokines and stress. Again, this contrasts with previous reports showing that interaction of AGE with RAGE induced intracellular signaling pathways involved in inflammatory responses including MAPK or NF- $\kappa$ B activation<sup>[48]</sup>. Moreover, downregulation of RAGE by specific siRNAs was associated with NF- $\kappa$ B degradation supporting the linkage of RAGE to the NF- $\kappa$ B pathway<sup>[35]</sup>. Only a single study indicated that AGE may not uniformly play a role in cellular activation<sup>[49]</sup>.

In summary, the present data do not support a direct role of AGE and AGE-RAGE axis in the fibrogenic activation of HSC, such as profibrogenic ECM-related gene expression, signal transduction, or proliferation. However, the finding that RAGE in HSC is upregulated during their activation *in vitro* and in HSC/myofibroblasts, macrophages/small Kupffer cells, endothelia of neo-capillarization and proliferating bile duct epithelia during fibrogenesis *in vivo* does not exclude the possibility that RAGE may drive fibrogenesis indirectly, e.g. *via* soluble factors that are released from these non-HSC cell types. This could still have relevance for patients with insulin resistance and NASH who display elevated serum and tissue levels of AGE<sup>[1,50]</sup>. Whether the observed RAGE upregulation may contribute to fibrosis *via* these indirect pathways needs to be investigated in further studies using

either co-culture experiments, gene modified animals, or the administration of AGEs to animals with experimental liver fibrosis.

## ACKNOWLEDGMENTS

We thank Christa Winkelmann, Gisela Weber, and Kunigunde Herbig (Department of Pathology, University of Erlangen-Nuremberg, Germany) for their expert technical assistance. The anti-RAGE IgG was kindly donated by Dr. B Weigle, Medical University of Graz, Austria, and the human hepatic stellate cells by Dr. M Pinzani, University of Florence, Italy. In addition, we thank Monika Pischetsrieder (Institute of Pharmacy and Food Chemistry, University of Erlangen-Nuremberg, Germany) for contributing to the concept of this study and fruitful discussion of the results.

## COMMENTS

### Background

Advanced glycation end products (AGE) and their specific receptor (RAGE) play an important role in the pathogenesis of inflammation and fibrosis in diabetes mellitus. While RAGE has been detected in numerous tissues, its role in organs such as the liver which are also exposed to (circulating) AGE remains largely unexplored.

### Research frontiers

The study of liver fibrosis is a challenging research area due to the enormous socio-epidemiologic and medical-therapeutical impact of chronic liver diseases which frequently progress to cirrhosis. We have made tremendous progress in our understanding of the pathomechanisms underlying liver fibrosis progression, including the structural components of the hepatic scar tissue (extracellular matrix), the molecules that are central to its excess deposition and to its removal, and the direct and indirect effector cells that drive fibrosis progression, i.e. fibrogenesis (Friedman, Gastro 08; Schuppan and Afdhal, Lancet 08). Recent studies suggested an association of an activated AGE-RAGE-axis with fibrogenesis, but clear functional data were lacking.

### Innovations and breakthroughs

The findings suggest a more indirect than direct effect of the AGE-RAGE-axis on liver fibrogenesis and rule out a direct effect of AGE on the fibrogenic effector cells, i.e. hepatic stellate cells.

### Applications

Future applications depend on additional studies that would explore the putative indirect effects of RAGE on fibrogenesis, e.g. *via* cytokines produced by AGE-activated macrophages, biliary duct epithelia or endothelial cells. This could facilitate the development of specific AGE-RAGE-inhibitors that could generate a novel class of therapeutics, especially in conditions where AGE play a prominent role, such as non-alcoholic fatty liver disease.

### Terminology

AGE are formed *in vitro* and *in vivo* from non-enzymatic glycation of the amino groups of proteins with reducing sugars such as glucose. AGE can be detected *in vivo* once levels of reducing sugars are elevated as occurs in diabetes. AGE interact with several receptors, most specifically with the receptor for advanced glycation end products (RAGE). RAGE is a member of the immunoglobulin superfamily of cell surface receptors which are expressed in a variety of tissues.

### Peer review

The originality of this study resides in the broad and exhaustive study of RAGE expression in two well-defined and complementary rodent models of liver fibrosis, the use of different cells and cell lines, and extensive *in vitro* stimulation studies of hepatic stellate cells with AGE to assess their effect on the expression of extracellular matrix component and matrix dissolving metalloproteinases. This broad approach is novel and has for the first time provided clear results as to the effect of stimulation of the AGE-RAGE axis in hepatic stellate cells and the putative fibrogenic role it plays in fibrogenic activation of macrophages/Kupffer cells, endothelia or biliary duct epithelia.

### Abstract

**AIM:** To investigate the characteristics of slow electrical waves and the presence of transient receptor potential melastatin-type 7 (TRPM7) in the human gastrointestinal (GI) tract.

**METHODS:** Conventional microelectrode techniques were used to record intracellular electrical responses from human GI smooth muscle tissue. Immunohistochemistry was used to identify TRPM7 channels in interstitial cells of Cajal (ICCs).

**RESULTS:** The human GI tract generated slow electrical waves and had ICCs which functioned as pacemaker cells. Flufenamic acid, a nonselective cation channel blocker, and 2-APB (2-aminoethoxydiphenyl borate) and  $La^{3+}$ , TRPM7 channel blockers, inhibited the slow

waves. Also, TRPM7 channels were expressed in ICCs in human tissue.

**CONCLUSION:** These results suggest that the human GI tract generates slow waves and that TRPM7 channels expressed in the ICCs may be involved in the generation of the slow waves.

### INTRODUCTION

Smooth muscles in the gastrointestinal (GI) tract are spontaneously active with rhythmic generation of slow electrical waves<sup>[1]</sup>. The slow waves determine the frequency and amplitude of the phasic contractions of GI muscles<sup>[2]</sup>. Slow waves originate in specialized regions such as the border between the circular and longitudinal muscle layers in the stomach and small intestine and along the submucosal surface of the circular muscle layer in the colon<sup>[3]</sup>. Each pacemaker region is populated by interstitial cells of Cajal (ICCs), and many studies have demonstrated the pacemaker role of these cells<sup>[4-9]</sup>. ICCs generate spontaneous inward currents and slow wave-like depolarizations<sup>[10,11]</sup>. Slow waves propagate within the ICC networks, conduct into smooth muscle cells *via* gap junctions, and initiate phasic contractions by activating  $Ca^{2+}$  entry through L-type  $Ca^{2+}$  channels. The pacemaker currents of the murine small intestine are due mainly to periodic activation of non-selective cation channels

(NSCCs)<sup>[12]</sup>.

In *Caenorhabditis elegans*, the melastatin-type transient receptor potential (TRPM) channel, particularly TRPM7, was suggested as being involved in the defecation process<sup>[13]</sup>. Also recently, we suggested that TRPM7 was a good candidate for the NSCC in ICCs of the murine small intestine<sup>[14]</sup>. TRP channels were first cloned from *Drosophila* species and constitute a superfamily of proteins that encode a diverse group of Ca<sup>2+</sup>-permeable NSCCs<sup>[15]</sup>. The TRP family is divided into 7 subfamilies: classical TRPs (TRPC), which display the greatest similarity to *Drosophila* TRP; vanilloid TRPs (TRPVs); TRPMs; mucolipin TRPs; polycystin TRPs; NOMPC (no mechanoreceptor potential C) TRP; ankyrin 1 TRPs. TRPC channels mediate cation entry in response to phospholipase C activation, whereas TRPV proteins respond to physical and chemical stimuli, such as changes in temperature, pH, and mechanical stress. The TRPM family members differ significantly from other TRP channels in terms of domain structure, cation selectivity, and activation mechanisms<sup>[15]</sup>.

The characteristics of the slow wave and the presence of TRPM7 in human GI tract have not yet been investigated. Therefore, we undertook to investigate the characteristics of the slow wave in the human GI tract and the involvement of TRPM7 in ICCs.

## MATERIALS AND METHODS

### Human tissue preparation

The segments of human colon or small intestine used in this study were obtained from cancer patients of either sex ranging in age from 46 to 59 years as discarded surgical tissue during operations. The protocol was approved by the human subjects research committees at Seoul National University College of Medicine. A segment of colon or jejunum was opened along the mesenteric border, and the mucosal layers, the serosal layers and a part of the longitudinal layers were carefully peeled away under a dissecting microscope. A tissue segment (about 0.5 mm wide and 0.5 mm long) was pinned out on a silicone rubber plate with the serosal side uppermost, and the plate was fixed at the bottom of an organ bath. The preparation was continuously perfused with CO<sub>2</sub>/bicarbonate-buffered Tyrode solution at 36-37°C and equilibrated for 2 h before the experiment, at a constant flow rate of about 2 mL/min.

### Intracellular recording of electrical activity

Conventional microelectrode techniques were used to record intracellular electrical responses from smooth muscle tissues, and the glass capillary microelectrodes, filled with 3 mol/L KCl, had tip resistances of 40-80 MΩ. Electrical responses recorded *via* a high input impedance amplifier (Axoclamp-2B, Axon Instruments, USA) were displayed on a cathode ray oscilloscope (SS-7602, Iwatsu, Osaka, Japan) and also stored on a personal computer for later analysis.

### Solutions and drugs

The ionic composition of the CO<sub>2</sub>/bicarbonate buffered-

Tyrode solution was as follows (mmol/L): NaCl 116, KCl 5.4, CaCl<sub>2</sub> 1.5, MgCl<sub>2</sub> 1, NaHCO<sub>3</sub> 24, glucose 5. The solutions were aerated with O<sub>2</sub> containing 5% CO<sub>2</sub>, and the pH of the solutions was maintained at 7.3-7.4. Drugs used were flufenamic acid, 2-aminoethoxydiphenyl borate (2-APB), lanthanum ion (La<sup>3+</sup>) and nifedipine (all from Sigma, USA). Drugs were dissolved in distilled water, and added to CO<sub>2</sub>/bicarbonate buffered-Tyrode solution to the desired concentrations, immediately prior to use. Addition of these chemicals to the Krebs solution did not alter the pH of the solution.

### Immunohistochemistry

Whole-mount preparations from the colon or small intestine of human were used for immunohistochemistry. Experimental protocols approved by Seoul National University were followed. For whole-mount preparations, the mucosa was removed by sharp dissection, and the remaining muscle layer was stretched before fixation. Whole-mount preparations were fixed in cold acetone (4°C) for 5 min. After fixation, they were washed in phosphate-buffered saline (PBS; 0.01 mol/L; pH 7.4) and immersed in 0.3% Triton X-100 in PBS. After blocking with 1% bovine serum albumin (Sigma) in 0.01 mol/L PBS for 1 h at room temperature, they were incubated with a rat monoclonal antibody raised against c-kit (Ack2; eBioscience) at 0.5 μg/mL or goat polyclonal antibody against TRPM7 (Abcam, Cambridgeshire, UK) in PBS for 24 h (4°C). After a rinse in PBS at 4°C, they were labeled with the fluorescein isothiocyanate-coupled donkey anti-goat immunoglobulin G secondary antibody (1:100; Jackson ImmunoResearch Laboratories, Baltimore, MD, USA) or Texas red-conjugated donkey anti-rat immunoglobulin G (1:100; Jackson ImmunoResearch Laboratories) for 1 h at room temperature. Control tissues and sections were prepared by omitting either the primary or secondary antibodies from the incubation solutions.

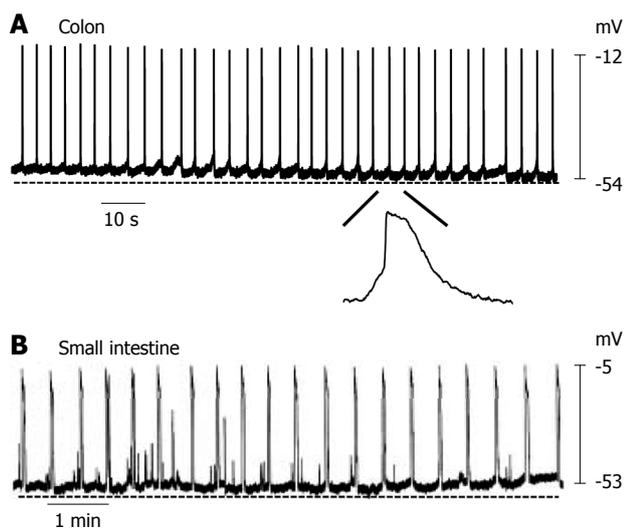

### Statistics analysis

All data are expressed as mean ± SE. The Student *t*-test for unpaired data was used to compare control and experimental groups. A *P*-value < 0.05 was considered statistically significant.

## RESULTS

### Spontaneous electrical activities recorded from intact tissue preparations of human colon and small intestine

In intact human colon preparations, most of the tissues generated slow electrical waves (Figure 1A). The membrane potential of cells generating slow waves with the most negative value (equal to the resting membrane potential) ranged between -54.7 mV and -68.7 mV (mean -61.9 ± 1.9 mV, *n* = 6; each *n* value represents the number of human tissues used). Slow waves had a frequency of 18.1 ± 2.1/min (*n* = 6). In intact human small intestine preparations, most of the tissues generated slow waves (Figure 1B). The membrane potential of cells generating slow waves ranged between -51.2 mV and -63.5 mV (mean -57.3 ± 5.2 mV, *n* = 5). Slow waves had a frequency of 3.1

**Figure 1** Spontaneous electrical activity of smooth muscle cells in human colon and small intestine. A: Colonic smooth muscle cells produced slow waves with a frequency of  $18.1 \pm 2.1/\text{min}$ ; B: Small intestinal smooth muscle cells also produced slow waves with a frequency of  $3.1 \pm 0.5/\text{min}$ .

$\pm 0.5/\text{min}$  ( $n = 5$ ). These results suggest that the GI tract in humans can generate slow waves and have ICCs which function as pacemaker cells.

### Pharmacological properties of slow waves in human colon

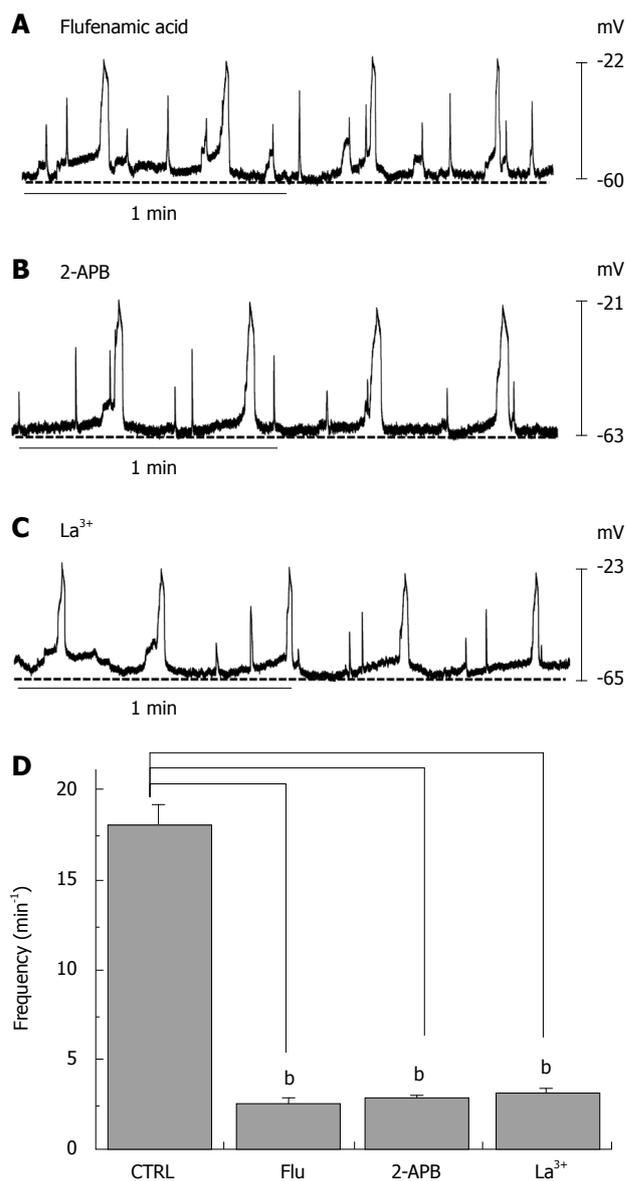

We investigated the effect of a nonselective cation channel blocker and several TRPM7 channel blockers on the slow waves recorded from human colon tissue. First, we investigated the effects of flufenamic acid, a nonselective cation channel blocker. When flufenamic acid was applied in the bath solution, the slow waves were inhibited ( $2.6 \pm 0.3/\text{min}$ ) (Figure 2A and D). As indicated previously, 2-APB is known to inhibit TRPM7 channels<sup>[16]</sup>. When 2-APB was applied in the bath solution, the slow waves were inhibited in a concentration-dependent manner ( $2.8 \pm 0.2/\text{min}$ ) (Figure 2B and D). Again, as described previously, TRPM7 has been shown to be blocked by trivalent ions such as  $\text{La}^{3+}$ <sup>[17]</sup>. When  $\text{La}^{3+}$  was applied in the bath solution, the slow waves were inhibited ( $3.2 \pm 0.2/\text{min}$ ) (Figure 2C and D). These results indicate that NSCCs and TRPM7 in ICCs may be involved in the generation of the slow wave in the human GI tract.

### Expression of TRPM7 protein in ICC of native tissues

To test this possibility more directly, we examined the expression of TRPM7 in ICCs in human tissues. Expression of TRPM7 proteins was investigated by immunohistochemistry. Double staining with anti-c-kit (a marker of ICCs) and anti-TRPM7 antibodies showed TRPM7 immunoreactivity in c-kit-immunopositive ICCs in the human colon (Figure 3), and human small intestine (Figure 4).

## DISCUSSION

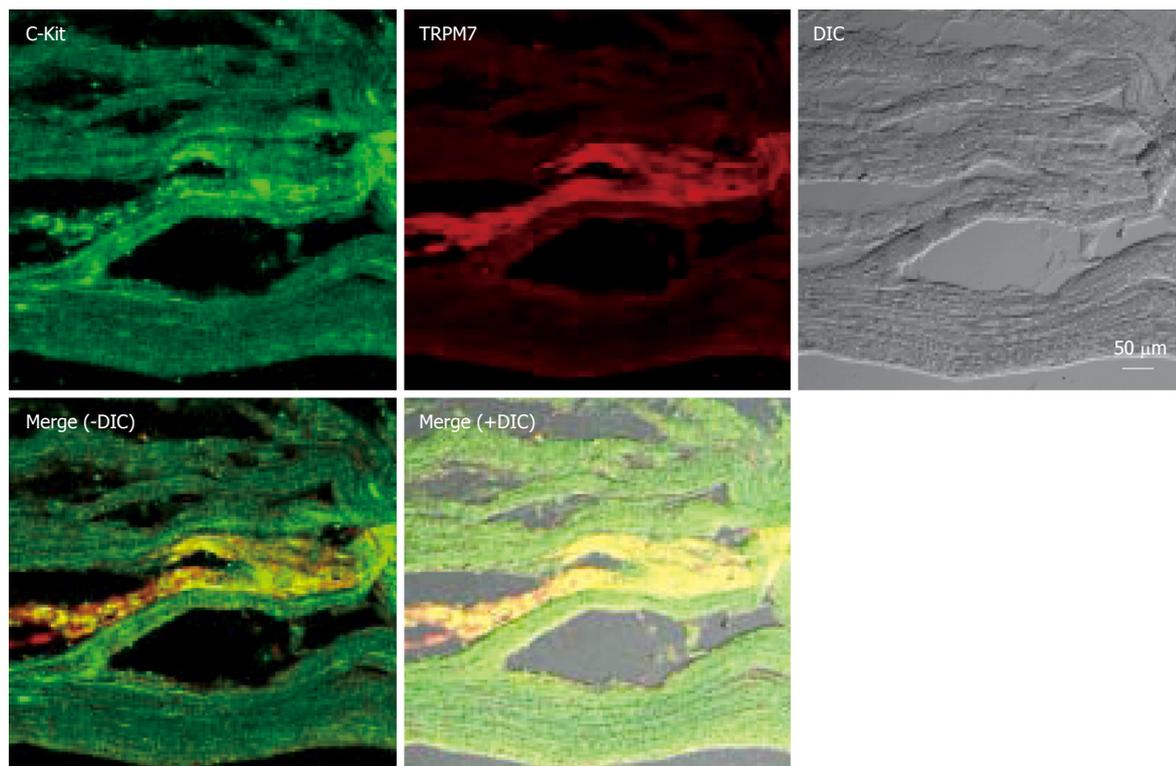

GI smooth muscles are spontaneously active, and

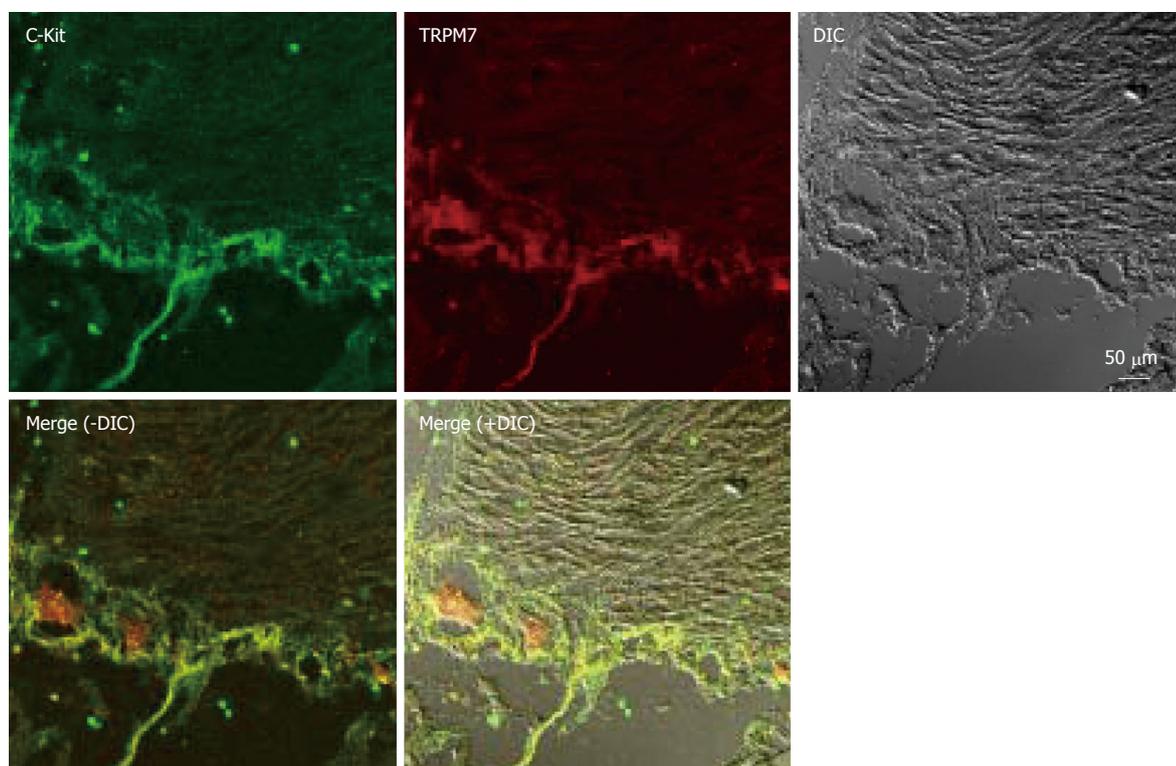

**Figure 2** Effects of flufenamic acid, 2-aminoethoxydiphenyl borate (2-APB) and  $\text{La}^{3+}$  on electrical responses. Flufenamic acid ( $50 \mu\text{mol/L}$ , A), 2-APB ( $50 \mu\text{mol/L}$ , B) or  $\text{La}^{3+}$  ( $50 \mu\text{mol/L}$ , C) were applied while recording electrical activity of isolated smooth muscles of the human colon. All drugs inhibited the spontaneous electrical activity; D: The histograms summarize the frequency of spontaneous electrical activities in human colon with flufenamic acid, 2-APB, and  $\text{La}^{3+}$ . <sup>b</sup> $P < 0.01$ .

generate rhythmic slow electrical waves<sup>[1]</sup>. The slow waves originate in the ICCs distributed in the GI tract<sup>[4-9]</sup>. ICCs express c-kit immunoreactivity and form gap junctional connections with ICCs and with smooth muscle cells<sup>[18-20]</sup>. Many types of ICC with different immunohistochemical and electrical properties, such as myenteric ICC (ICC-MY), intramuscular ICC, deep muscular plexus ICC and submucosal ICC, are distributed in the GI tract<sup>[21]</sup>. In animal models lacking ICC-MY, the slow waves in the small intestine are strongly attenuated, indicating that these cells are indeed essential for pacemaking activity in the GI tract<sup>[6,22]</sup>.

Research into the distribution and function of ICCs was greatly stimulated by discovering that ICCs express

**Figure 3** Expression of transient receptor potential melastatin-type 7 (TRPM7) protein in human colon. Double labeling of TRPM7-like immunoreactivity (red) and c-kit-like immunoreactivity (green) within smooth muscle layers of the human colon. The mixed color yellow indicates the colocalization of both TRPM7-like and c-kit-like immunoreactivity (bar = 50 μm). DIC: differential interference contrast.

**Figure 4** Expression of TRPM7 protein in human small intestine. Double labeling of TRPM7-like immunoreactivity (red) and c-kit-like immunoreactivity (green) within smooth muscle layers of human small intestine. The mixed color yellow indicates the colocalization of both TRPM7-like and c-kit-like immunoreactivity (bar = 50 μm).

c-kit, and signaling *via* kit protein is necessary for development and maintenance of the ICC phenotype<sup>[7,23]</sup>. ICCs are involved in physiological GI motility, therefore

have clinical importance in many bowel disorders, including inflammatory bowel disease, chronic idiopathic intestinal pseudo-obstruction, intestinal obstruction with

hypertrophy, achalasia, Hirschsprung disease, juvenile pyloric stenosis, juvenile intestinal obstruction, and anorectal malformation<sup>[21]</sup>.

Discovering the molecules involved in the generation of pacemaker activity in ICCs may lead to dramatic new therapies for chronic GI diseases that result in lifelong suffering.

Strege *et al.*<sup>[24]</sup> suggested that a mechanosensitive Na<sup>+</sup> channel current is present in human intestinal ICC and appears to play a role in the control of intestinal motor function. Also in human jejunum, each ICC-MY generates spontaneous pacemaker activity that actively propagates through the ICC network, and the pacemaker activity was dependent on inositol-1,4,5-triphosphate receptor-operated stores and mitochondrial function<sup>[25]</sup>. Although some papers have identified the ion channels in ICCs<sup>[10,11,26,27]</sup>, there is little known about the ionic basis of its pacemaker activity. Recently, we used electrophysiological, molecular biological, and immunohistochemical techniques to establish the close relationship between NSCCs in ICCs and a mammalian TRP homologue, TRPM7 and found that TRPM7 is required for murine intestinal pacemaking<sup>[14]</sup>.

Little is known about the involvement of TRPM7 channels in ICCs in the human GI tract. In this study, we found that the human GI tract generated slow waves and various pharmacological properties of the slow waves were the same as those of TRPM7. Also, immunohistochemistry showed abundant and localized expression of TRPM7 protein in the human GI tract. TRPM7 has been suggested to have a central role in cellular Mg<sup>2+</sup> homeostasis<sup>[28]</sup>, in central nervous system ischemic injury<sup>[29]</sup>, in skeletogenesis in zebrafish<sup>[30]</sup>, in the defecation rhythm in *C. elegans*<sup>[31]</sup>, in cholinergic vesicle fusion with the plasma membrane<sup>[31]</sup>, in phosphoinositide-3-kinase signaling in lymphocytes<sup>[32]</sup>, in cell death in gastric cancer<sup>[33]</sup>, in osteoblast proliferation<sup>[34]</sup>, and in breast cancer cell proliferation<sup>[35]</sup>.

The physiological role of TRPM7 channels in ICCs in human GI tract requires more investigation. As a primary molecular candidate for the NSCC responsible for pacemaking activity in ICCs, TRPM7 may be a new target for pharmacological treatment of GI motility disorders.

## COMMENTS

### Background

Previously, transient receptor potential melastatin-type 7 (TRPM7) was found to be required for intestinal pacemaking activity in mice. However, in the human gastrointestinal (GI) tract, the characteristics of slow electrical waves and the presence of TRPM7 has not been investigated.

### Research frontiers

The human GI tract generates slow waves and TRPM7 channels are expressed in interstitial cells of Cajal (ICCs).

### Innovations and breakthroughs

The human GI tract generates slow waves and has ICCs functioning as pacemaker cells. Flufenamic acid, a nonselective cation channel blocker, and 2-APB (2-aminoethoxydiphenyl borate) and La<sup>3+</sup>, TRPM7 channel blockers, inhibited the slow waves. Also, TRPM7 channels were expressed in ICCs in human tissues.

### Applications

TRPM7 protein may be a new target for pharmacological treatment of GI motility disorders.

## Peer review

The authors well demonstrated the involvement of TRPM7 in ICCs and characterized the pharmacological properties of slow waves in the human GI tract. The finding will form the basis for future treatments of GI motility disorders and is a useful addition to the literature.

### Abstract

**AIM:** To evaluate the utility of diffusion-weighted imaging (DWI) in screening and differential diagnosis of benign and malignant focal hepatic lesions.

**METHODS:** Magnetic resonance imaging (MRI) examinations were performed using the Signa Excite XI Twin Speed 1.5T system (GE Healthcare, Milwaukee, WI, USA). Seventy patients who had undergone MRI of the liver [29 hepatocellular carcinomas (HCC), four cholangiocarcinomas, 34 metastatic liver cancers, 10 hemangiomas, and eight cysts] between April 2004 and August 2008 were retrospectively evaluated. Visualization of lesions, relative contrast ratio (RCR), and apparent diffusion coefficient (ADC) were compared between benign and malignant lesions on DWI. Superparamagnetic iron oxide (SPIO) was administered to 59 patients, and RCR was compared pre- and post-administration.

**RESULTS:** DWI showed higher contrast between malignant lesions (especially in multiple small metastatic cancers) and surrounding liver parenchyma than did contrast-enhanced computed tomography. ADCs (mean  $\pm$  SD  $\times 10^{-3}$  mm<sup>2</sup>/s) were significantly lower ( $P < 0.05$ ) in malignant lesions (HCC:  $1.31 \pm 0.28$  and liver metastasis:  $1.11 \pm 0.22$ ) and were significantly higher in benign lesions (hemangioma:  $1.84 \pm 0.37$  and cyst:  $2.61 \pm 0.45$ ) than in the surrounding hepatic tissues. RCR between malignant lesions and surrounding hepatic tissues significantly improved after SPIO administration, but RCRs in benign lesions were not improved.

**CONCLUSION:** DWI is a simple and sensitive method for screening focal hepatic lesions and is useful for differential diagnosis.

Role of diffusion-weighted magnetic resonance imaging in the differential diagnosis of focal hepatic lesions. *World J Gastroenterol* 2009; 15(46): 5805-5812 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5805.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5805>

### INTRODUCTION

Diffusion is the thermally induced motion of water molecules, which is also referred to as Brownian motion<sup>[1]</sup>. Diffusion-weighted imaging (DWI) is a new magnetic resonance imaging (MRI) technique that provides imaging of diffusion in biological tissues.

DWI has been reported to be useful in evaluating the early stages of brain ischemia<sup>[2-4]</sup>. Recent technical developments have reduced the image distortion associated with this technique and have increased the signal-to-noise ratio, thus making DWI of the body feasible<sup>[5,6]</sup>. Screening, accurate detection, and characterization of focal hepatic lesions are important for planning

treatment of malignant hepatic lesions. The differential diagnosis of malignant and benign focal hepatic lesions remains a diagnostic challenge; however, to improve the diagnosis of such lesions, new methods for existing modalities, such as MRI, computed tomography (CT), angiography, and ultrasonography are being developed.

Recently, some studies have reported that the apparent diffusion coefficient (ADC), which is one of calculated parameters of DWI, might be useful for differential diagnosis of benign and malignant lesions in the liver<sup>[7]</sup>. Superparamagnetic iron oxide (SPIO)-enhanced MRI was reported to be as useful as CT during arteriography and CT during hepatic arteriography for diagnosing metastatic liver tumors<sup>[8,9]</sup>. SPIO improves the contrast-to-noise ratio (CNR) between focal hepatic lesion and the surrounding liver parenchyma on T2-weighted imaging<sup>[9]</sup>. SPIO has also been reported to further improve the performance of DWI of the liver because SPIO reduces the signal in normal liver parenchyma<sup>[10]</sup>.

The purpose of the present study was to retrospectively evaluate the utility of DWI in screening, accurate detection, and differential diagnosis of benign and malignant focal hepatic lesions.

## MATERIALS AND METHODS

### Patients

We retrospectively evaluated 70 patients (52 men and 18 women; age, 39-86 years; mean age, 65.3 years) with 85 lesions [29 hepatocellular carcinomas (HCC), four cholangiocarcinomas, 34 metastatic liver cancers, 10 hemangiomas, and eight cysts] who had been examined between April 2004 and August 2008. The locations of each focal hepatic lesion were: posterior segment in 32, anterior segment in 33, median segment in 15, and lateral segment in five patients. These lesions measured 1.0 to 10.0 cm (mean 3.1 cm) along their long axes on CT images.

The criteria for selecting patients to evaluate in the present study were as follows: (1) the diagnoses of HCC were pathology confirmed in 25 lesions and other lesions were confirmed by measurement of the serum  $\alpha$ -fetoprotein (AFP) level, clinical data, ultrasonography, angiography and CT or MRI or both; (2) hepatic metastasis of primary lesions was pathologically confirmed; (3) the diagnosis of cholangiocarcinomas was pathologically confirmed in three lesions and the other lesion was confirmed by clinical data, ultrasonography, CT and MRI; (4) the diagnosis of cavernous hemangioma and hepatic cysts was confirmed by clinical data, ultrasonography, CT or MRI or both, and follow-up observation.

### Imaging protocol

MR examinations were performed using the Signa Excite XI Twin Speed 1.5T system (GE Healthcare, Milwaukee, WI, USA) with a four-channel torso-array coil. Diffusion weighted single-shot echo-planar imaging was performed

in individual patients using the following parameters: repetition time/echo time (TR/TE) = 6000/73.1 ms, 7-8 mm thickness, water selective excitation for fat suppression, matrix size = 128 × 128, field of view = 36 cm × 36 cm, number of excitations = 6.0, slice thickness/gap = 8 mm/0 mm, 20 axial slices, scan time = 2 min 24 s, *b* value = 0 and 1000 s/mm<sup>2</sup>, under free breathing. A parallel imaging technique, array spatial sensitivity encoding technique (ASSET) was used. Motion-probing gradient pulses were placed along three orthogonal oblique directions. Additional post-contrast-enhanced DW images were obtained after intravenous administration of SPIO (Resovist; Bayer Schering Pharma AG, Berlin, Germany). The dose of SPIO was 0.016 mL/kg, corresponding to 0.45 mg/kg of Fe.

Contrast enhanced CT was conducted using the LightSpeed ultra 16-MDCT scanner (GE Healthcare, Milwaukee, WI, USA) with pre- and postcontrast triple-phase (arterial, portal venous, and equilibrium phase) scans after injection of 80 to 100 mL of Iopamidol (Iopamiro; Bayer Schering Pharma AG, Berlin, Germany) at an injection rate of 1.5 to 3.0 mL/s.

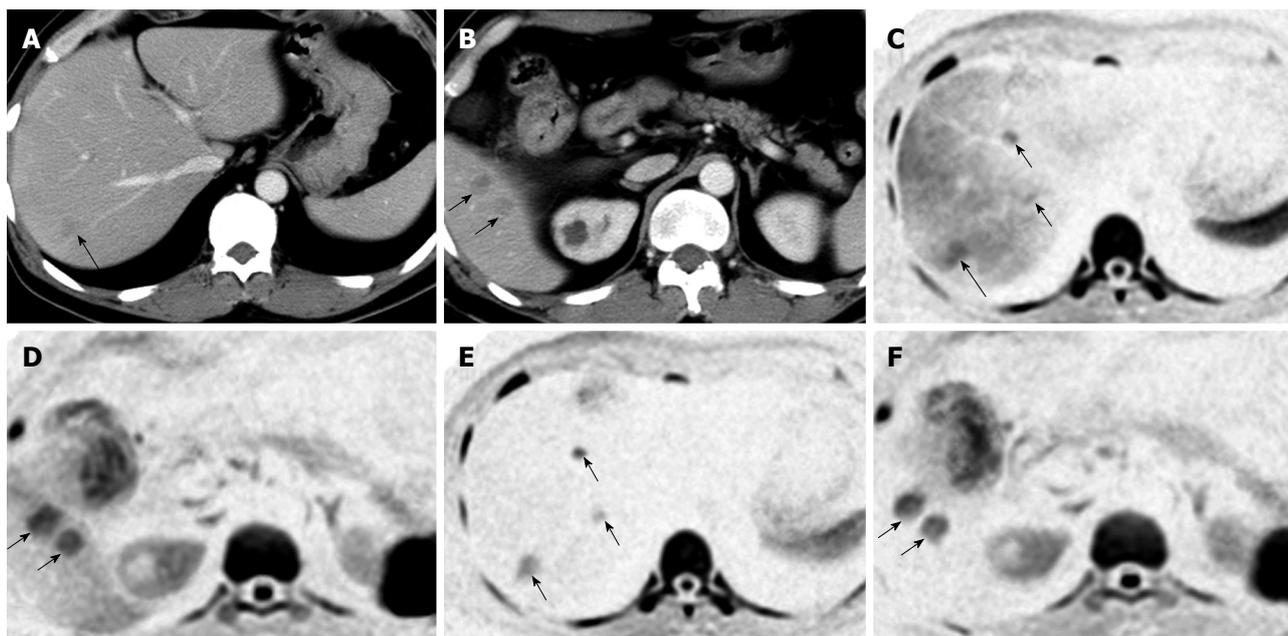

Visualization of lesions, relative contrast ratio between the lesion and surrounding liver parenchyma (RCR), and ADC values were compared between benign and malignant lesions on DWI. Analysis and measurements of DWI data was performed using the GE FUNCTOOL software. All regions of interest (ROI) were created as large as possible in each lesion. In cases with multiple lesions, only the most conspicuous lesion was selected for quantitative measurements. If different types of lesions were mixed (for example, hepatocellular carcinomas and cysts), each lesion was measured.

### Visualization of lesions

All but two lesions (CT examinations were not performed in one case of metastatic liver cancer and hemangioma.) were evaluated. Two diagnostic doctors performed a visual evaluation of each selected CT image (best phase for CT examinations in individual lesions) and DWI (only before SPIO administration) based on mutual agreement. They classified the visualization of lesions on CT and DWI into three categories according to the following criteria. Grade 1: no or slight visualization and unclear margin. Grade 2: moderate visualization and clear margin. Grade 3: marked visualization and very clear margin.

### RCR measurements

SPIO was administered to 59 patients (18 HCC, 26 metastatic liver cancers, 10 hemangiomas, seven cysts) and the RCR was compared before and after SPIO administration to differentiate between benign and malignant lesions. The RCR was calculated by the following equation:  $RCR = SI_{\text{lesion}}/SI_{\text{liver}}$ , where  $SI$  is signal intensity of the lesion and  $SI_{\text{liver}}$  was evaluated from hepatic tissue surrounding the lesion. In this paper, the conventional contrast-to-noise ratio analysis was not employed because the standard deviation of the

	DWI	0	0	4
Cyst <sup>a</sup> (n = 8)	CT	0	1	7
	DWI	8	0	0
Hemangioma <sup>a</sup> (n = 9)	CT	0	8	1
	DWI	5	2	2

Meta: Metastatic liver cancer; HCC: Hepatocellular carcinoma; DWI: Diffusion-weighted imaging; CT: Computed tomography. <sup>a</sup>*P* < 0.05.

background could not be measured easily in the images obtained using ASSET<sup>[11]</sup>.

### ADC measurements

ADCs of both focal hepatic lesions and surrounding liver parenchymas (26 HCC, 32 metastatic liver cancers, four cholangiocarcinomas, 10 hemangiomas, eight cysts) were measured in 65 patients. Lesions in the lateral segments were excluded for ADC measurement because their ADC could not be correctly measured in the DWI sequences without simultaneous cardiac gating<sup>[12]</sup>.

### Statistical analysis

ADC and SI were measured twice and averaged. All data are expressed as mean ± SD. The visualization data was statistically analyzed by Wilcoxon's signed rank test, and RCR and ADC were analyzed by Student's *t* test using Prism 4.0 software (GraphPad Software, Inc., San Diego,

CA, USA). A *P* value of < 0.05 was considered statistically significant.

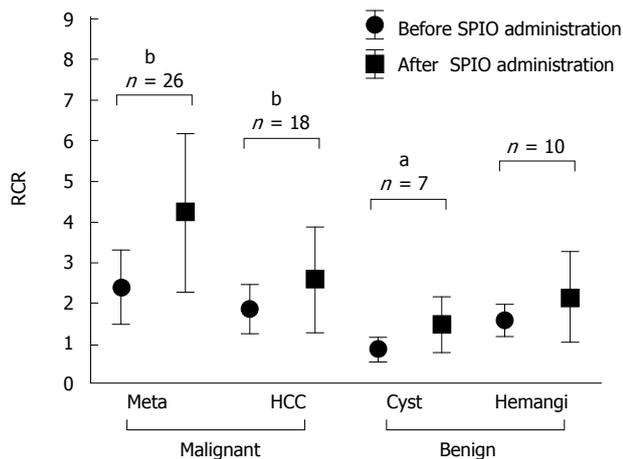

## RESULTS

### Visualization of lesions

Most malignant lesions were significantly more clearly visualized on DWI than on CT (Table 1). In particular, multiple small focal hepatic lesions were visualized clearly on DWI (Figure 1). Two malignant lesions were not detected on DWI, even though they could be easily detected on enhanced CT. These lesions were HCC just under the diaphragm of the lateral segment with liver cirrhosis. Benign lesions, by contrast, were significantly more poorly visualized on DWI than on CT. Similar to the results of several articles published previously<sup>[13]</sup>, cysts showed low or no signal intensities in six of eight cases on DWI (in these cases, no signal intensity means lower signal intensities than background signal intensities.). DWI visualized most hemangiomas; however, CT was better than DWI for the visualization of hemangiomas.

### RCR measurements

The average RCR on DWI before and after SPIO administration is shown in Figure 2. RCR seemed to be significantly improved after SPIO administration in malignant lesions that were metastatic liver cancers (before:  $2.39 \pm 1.28$ , after:  $4.23 \pm 1.34$ , *n* = 26) and HCC (before:  $1.85 \pm 0.58$ , after:  $2.59 \pm 1.28$ , *n* = 18). On the other hand, the RCR was not significantly improved in benign lesions after SPIO administration. The RCR of cysts was  $0.86 \pm 0.30$  (*n* = 7) before SPIO administration, because the SI of cysts was lower than background SI on DWI. Therefore, the RCR of cysts increased after SPIO

**Figure 2** Relative contrast ratio (RCR) of focal hepatic lesions visualized by diffusion-weighted imaging (DWI) before and after the administration of superparamagnetic iron oxide (SPIO). Meta: Metastatic liver cancer; HCC: Hepatocellular carcinoma; hemangi: Hepatic hemangioma. <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01.

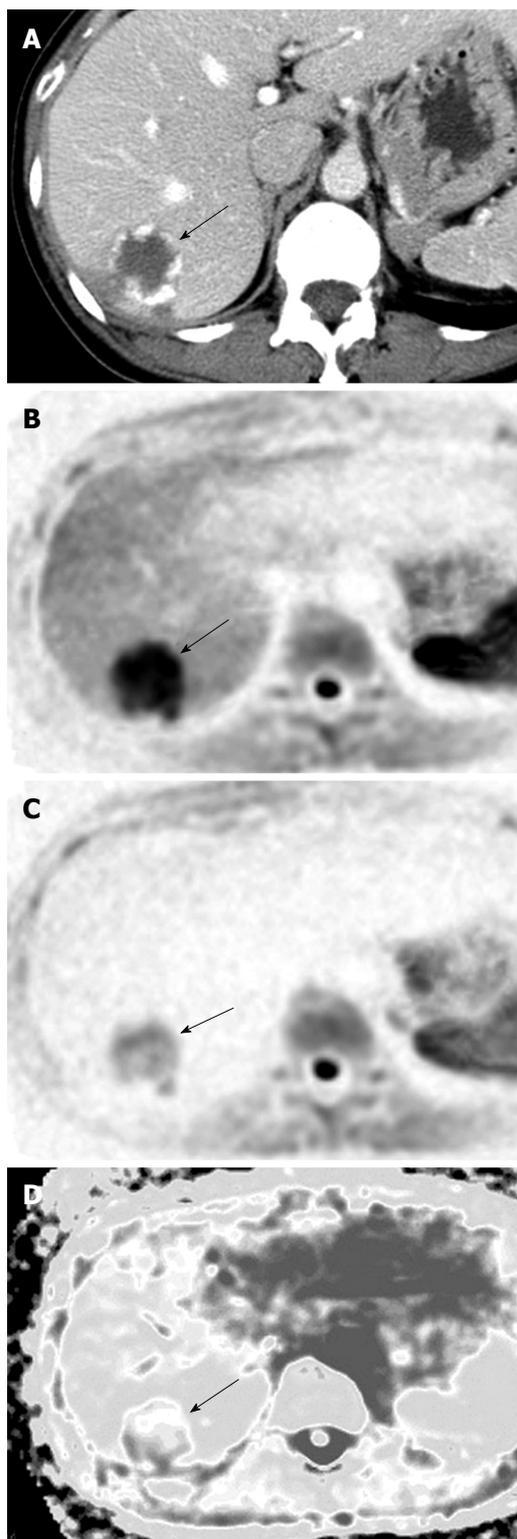

administration ( $1.48 \pm 0.65$ ) as a result of a decrease in the SI of the liver. The RCR of hemangiomas was  $1.58 \pm 0.38$  ( $n = 10$ ) before and  $2.15 \pm 1.10$  after SPIO administration. This was not statistically significant. The RCRs of hemangiomas were reduced in three lesions after SPIO administration. One example is shown in Figure 3.

Figure 4 is a case in which multiple small cysts and metastatic tumors of colon cancer were colocalized in the liver. Both cysts and cancers expressed high signal intensities in T2-weighted MR imaging. In contrast, only the metastatic nodules were expressed on DWI after SPIO administration.

**ADC measurements**

Generally speaking, the lesions showing high signal intensity on DWI demonstrate low ADCs. The average ADCs in our study are shown in Figure 5. The ADCs (mean  $\pm$  SD  $\times 10^3$  mm<sup>2</sup>/s) of malignant lesions, both HCC ( $1.31 \pm 0.28$ ,  $n = 26$ ) and metastatic liver cancer ( $1.11 \pm 0.22$ ,  $n = 32$ ), were significantly lower than the ADCs of the surrounding hepatic tissues. The ADC of cholangiocarcinomas was  $1.33 \pm 0.23$  ( $n = 4$ ). Although this was lower than the ADC of the surrounding hepatic tissue, the difference was not significant.

In benign lesions, the ADCs of both cysts ( $2.61 \pm 0.45$ ,  $n = 8$ ) and hemangiomas ( $1.84 \pm 0.37$ ,  $n = 10$ ) were significantly higher than the ADC of the surrounding hepatic tissue. A representative hemangioma is shown in Figure 3, which expressed high signal intensity and high RCR on DWI. The ADC of the hemangioma was high even though their signal intensity was higher than the surrounding hepatic tissue on DWI. A representative hepatic cyst case is shown in Figure 6. The cyst expressed nearly no signal intensity on DWI after SPIO administration. However, the cyst revealed a higher ADC value than the surrounding hepatic tissue on the ADC map.

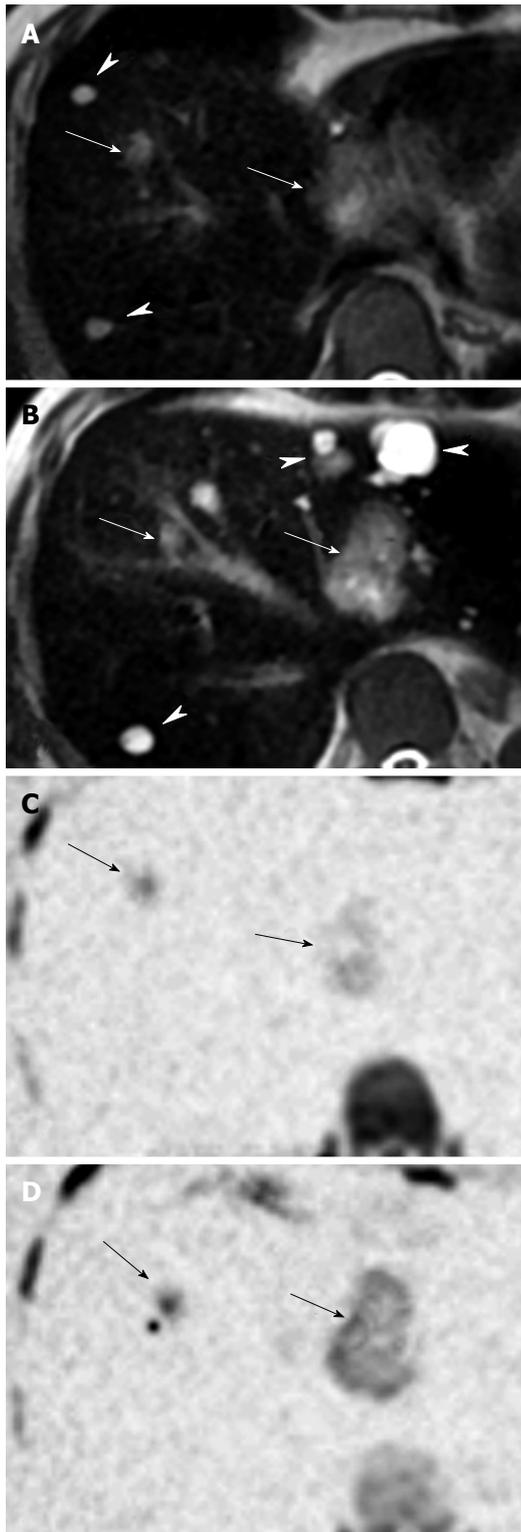

**Figure 3** A case of hepatic hemangioma. A: Dynamic computed tomography in the portal phase showing a low-density mass with a marginal stain at the S7 lobe (arrow). This is a typical staining pattern for hemangiomas; B: The hemangioma (arrow) expressed high signal intensity on diffusion-weighted imaging; C: The intensity of this signal was reduced after administration of superparamagnetic iron oxide (arrow); D: The hemangioma showed a high apparent diffusion coefficient (ADC) value on the ADC map (arrow).

and concisely evaluate malignant lesions. DWI has recently emerged as a tool for detecting cancers in the abdominal organ field<sup>[5,13,14]</sup>. Positron emission imaging is currently used as a powerful screening tool for malignancy<sup>[15]</sup>. Some

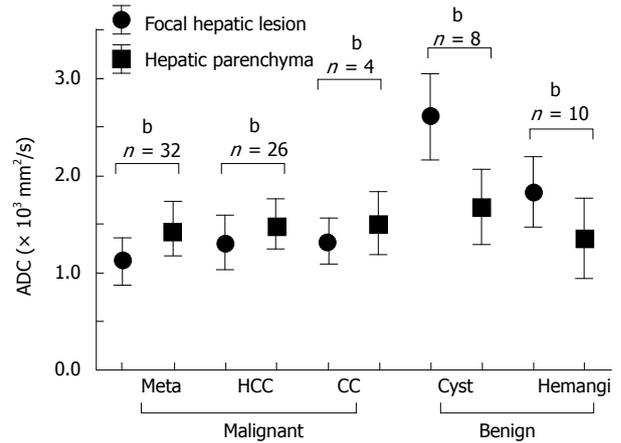

**DISCUSSION**

Surgeons need new imaging modalities that can precisely

articles have reported that SPIO-enhanced T2-weighted MR imaging and CT during arteriportography have the best ability to diagnose metastatic liver cancer<sup>[8,9,16]</sup>. However, even with use of these modalities, differentiating

between malignant tumors and intrahepatic vascular structures (e.g. arteriportal shunts and thin vessels) or benign lesions (e.g. small cysts and hemangiomas) is sometimes difficult. One of the purposes of the current study was to evaluate the potential of DWI for differentiating malignant from benign lesions.

Nasu *et al*<sup>[17]</sup> reported the sensitivity of DWI for detecting small metastases to be higher than that of SPIO-enhanced T2-weighted MR imaging because metastatic tumors tended to appear larger on DWI than on T2-weighted images, and intrahepatic vascular signals were suppressed on DWI. Parikh *et al*<sup>[18]</sup> also reported that DWI was better than standard breath-hold T2-weighted imaging for the detection of focal hepatic lesions. In particular, they found much higher contrast between HCC and cirrhotic liver on DWI than on T2-weighted images. The contrasts between HCC and cirrhotic liver on DWI in the present study, however, were not higher than that between metastatic liver cancer and surrounding hepatic tissue. This finding might have been because the signal intensity of HCC was not so high as metastatic tumors and the signal intensity of the cirrhotic liver was irregularly increased in our study (data not shown), probably because of marked liver fibrosis, as previously noted<sup>[19-21]</sup>. High signal intensities were found in most malignant focal hepatic lesions and DWI was useful for identifying them, as it was in previous studies<sup>[17,18]</sup>.

However, the findings of benign lesions differed from malignant lesions. Cysts and hemangiomas are most frequently found in the benign lesions of the liver. In the present study, the cysts had low or no signal intensities and hemangiomas had high or low signal intensities, similar to previous studies<sup>[22]</sup>. Such lesions are usually diagnosed using major imaging modalities, such as ultrasonography and enhanced CT. However, because these lesions are small and multiple, differential diagnosis against malignant focal hepatic lesions is often difficult, even using these modalities. The characteristics of cysts on DWI, however, in which the cysts express low or no signal intensities, can enable differential diagnosis against malignant focal hepatic lesions, as shown in Figure 4.

Administration of SPIO in the present study reduced the signal intensity of liver parenchyma on DWI and increased the RCR of malignant focal hepatic lesions, but did not often increase the RCR of hepatic hemangiomas. Therefore, SPIO was quite useful for differential diagnosis, especially between small metastatic liver cancers and hepatic hemangiomas.

We used a high *b* value (1000 s/mm<sup>2</sup>) for DWI because a high *b* value allows delineation of malignant tumors with excellent conspicuity owing to the generally suppressed background noise. Furthermore, the differences in the RCR between malignant and benign lesions were increased with a high *b* value. However, this characteristic of DWI occasionally hinders defining the anatomical location of the abnormal signal on DWI. Therefore, the location of the signal must be correlated with ordinary T2 images by making the slice thickness, interslice gap, and fields of view uniform among these

images. Recent developments in fusion software can readily resolve this problem by anatomically overlapping DWI onto ordinary T2 images. Such fused images might allow improved detection of malignant tumors<sup>[22]</sup>.

ADC is a quantitative parameter calculated from DWI. ADC combines the effects of capillary perfusion and water diffusion in the extracellular and extravascular space<sup>[1]</sup>. ADC is helpful for characterizing focal and diffuse diseases in the body. Several studies have reported that ADC can contribute to the differential diagnosis of benign and malignant focal lesions in the liver<sup>[7,18,23]</sup>.

Our results also revealed the contribution of ADC to the characterization of focal hepatic lesions. The ADC of malignant lesions was significantly lower than that of the surrounding hepatic tissue, whereas the ADC of benign lesions was higher than that of the surrounding hepatic tissue. Benign lesions, hemangiomas, and cysts in particular had high ADCs, even if they had high signal intensities on conventional DWI. The signal intensity of DWI includes both restricted diffusion and the effect of tissues with high T2 relaxation times, which is called the "T2 shine-through" effect. This might be why hemangiomas and cysts sometimes have high signal intensities on DWI. In any case, those results will be useful for differential diagnosis of malignant and benign focal hepatic lesions. For large lesions, however, the ADC was often markedly inhomogeneous on the locations and slices in the lesion. ADCs also seem to differ according to the machine used, the set-up conditions of the machine, and each human body<sup>[24]</sup>. Thus, ADC must be carefully used in the evaluation of lesion characteristics.

A few malignant lesions could not be visualized by DWI in our study. These lesions were mainly located on the left lobe, just under the diaphragm. DWI is known to be extremely sensitive to motion. During clinical image interpretation of MRI, a signal drop is often encountered in the lateral segment of the liver, which is assumed to be due to cardiac pulsation. Not only the signal intensity of DWI, but also ADC, is thought to be incorrect for the lateral segment just under the diaphragm<sup>[12,23,25]</sup>. Further studies need to be conducted to better understand the characteristics of DWI.

This study had some limitations. First, the subjects were a heterogeneous group, and the number of cases was relatively small. Second, histological proofs were not completely obtained, especially for the benign lesions. Therefore, the sensitivities and specificities of DWI cannot be reported here. Third, placement of the region of interest cursor might not be objective enough for measuring ADC and RCR. Additionally, inhomogeneity of hepatic lesions and motion may have affected the accuracy of the calculations, because the DWI was acquired with free breathing<sup>[25]</sup>.

Despite these limitations, we believe that DWI is a very useful imaging modality for identifying malignant focal lesions in the liver. Recently, a new MRI contrast medium, gadolinium-ethoxybenzyl-diethylenetriamine pentaacetic acid (Gd-EOB-DTPA), has been used for diagnosis of HCC. We plan to combine both Gd-EOB-

DTPA and DWI for diagnosing focal hepatic lesions.

In conclusion, DWI is a simple and sensitive method for screening focal hepatic lesions. SPIO administration can effectively improve the RCR of metastatic liver cancers. ADC measurement is occasionally helpful for differential diagnosis of malignant and benign small focal hepatic lesions.

## COMMENTS

### Background

Screening, accurate detection and characterization of focal hepatic lesions are important for planning treatment of malignant hepatic lesions. Recently, some studies have reported that the apparent diffusion coefficient (ADC), which is one of calculated parameters of diffusion-weighted imaging (DWI), might be useful for differential diagnosis of benign and malignant lesions in the liver. Superparamagnetic iron oxide (SPIO) has been reported to further improve the performance of DWI of the liver because SPIO reduces the signal in normal liver parenchyma. This study aimed to evaluate the usefulness of DWI in screening and differential diagnosis of benign and malignant focal hepatic lesions.

### Research frontiers

In some previous studies, the ADC of benign lesions, such as hepatic cysts and hemangiomas, was reported to be higher than that of malignant lesions, such as hepatocellular carcinoma and metastasis. However, ADC seems differ according to the machine used, the set-up conditions of the machine, and each human body. In this study, the authors compared ADC of focal hepatic lesions with its surrounding hepatic parenchyma for this differential diagnosis. Only a few studies have statistically evaluated the contrast changes in focal hepatic lesions after SPIO administration.

### Innovations and breakthroughs

This is the first report indicating that these simple ADC and RCR patterns are useful for the differential diagnosis of benign and malignant focal hepatic lesions.

### Applications

DWI can be used for differential diagnosis of focal hepatic lesions using calculation of ADC or RCR after SPIO administration. This is a simple and concise method that is easily available, not only to the radiologist, but also the physician and surgeon. DWI also should become a good diagnostic tool for other intra-abdominal organs.

### Terminology

Diffusion is the thermally induced motion of water molecules, which is also referred to as Brownian motion. DWI is a new magnetic resonance imaging (MRI) technique that provides images of the diffusion in biological tissues. The ADC is a quantitative parameter calculated from DWI and it combines the effects of capillary perfusion and water diffusion in the extracellular extravascular space. SPIO is a liver-specific particulate MRI contrast agent that is taken up by the reticuloendothelial system of the liver and improves the focal hepatic lesion-to-liver contrast-to-noise ration and hepatic tumor detection.

### Peer review

This is a retrospective study. The authors presented the results of their study and they reviewed the literature related with this subject. As a conclusion; the authors recommended that DWI by MR was a simple, sensitive and useful method for screening focal hepatic lesions and their differential diagnosis.

### Abstract

**AIM:** To construct the recombinant lentivirus expression plasmid, pLenti6/V5-NT4 p53(N15)-antennapedia (Ant), and study its effect on HepG2 cells.

**METHODS:** Plasmid pLenti6/V5-NT4 p53(N15)-Ant was constructed incorporating the following functional regions, including signal peptide sequence and pro-region of neurotrophin 4, N-terminal residues 12-26 of p53 and 17 amino acid drosophila carrier protein, Ant. Hepatocellular carcinoma (HepG2) cells were used for transfection. 3-[4,5-dimethyl-thiazol-2yl]-2,5 diphenyl tetrazolium bromide (MTT) assay, lactate dehydrogenase (LDH) release assay, transmission electron microscopy (TEM) and flow cytometric analysis (FCM) were employed to investigate the effects of LV-NT4(Si)-p53(N15)-Ant *in vitro* on HepG2 cells. *In vivo* experiment was also performed to investigate the inhibitory effect of LV-NT4(Si)-p53(N15)-Ant on tumor growth in nude mice.

**RESULTS:** LV-NT4(Si)-p53(N15)-Ant significantly suppressed the growth of HepG2 cells. MTT assay showed that the growth of HepG2 cells was much more significantly inhibited by LV-NT4(Si)-p53(N15)-Ant than by LV-EGFP. The inhibition rate for HepG2 cell growth in the two groups was 46.9% and 94.5%, respectively, 48 h after infection with LV-NT4(Si)-p53(N15)-Ant, and was 33.9% and 95.8%, respectively, 72 h after infection with LV-NT4(Si)-p53(N15)-Ant ( $P < 0.01$ ). Light microscopy and TEM showed morphological changes in HepG2 cells infected with LV-NT4(Si)-p53(N15)-Ant, but no significant changes in HepG2 cells infected with LV-EGFP. Changes were observed in ultra-structure of HepG2 cells infected with LV-NT4(Si)-p53(N15)-Ant, with degraded membranes, resulting in necrosis. LDH release from HepG2 cells was analyzed at 24, 48, 72 and 96 h after infection with LV-NT4(Si)-p53(N15)-Ant and LV-EGFP, which showed that LDH release was significantly higher in LV-NT4(Si)-p53(N15)-Ant treatment group (682 IU/L) than in control group (45 IU/L,  $P < 0.01$ ). The longer the time was after infection, the bigger the difference was in LDH release. FCM analysis showed that LV-NT4(Si)-p53(N15)-Ant could induce two different kinds of cell death: necrosis and apoptosis, with apoptosis being the minor type and necrosis being the main type, suggesting that LV-NT4(Si)-p53(N15)-Ant exerts its anticancer effect on HepG2 cells by inducing necrosis. The *in vivo* study showed that LV-NT4(Si)-p53(N15)-Ant significantly inhibited tumor growth with an inhibition rate of 66.14% in terms of tumor size and weight.

**CONCLUSION:** LV-NT4(Si)-p53(N15)-Ant is a novel recombinant lentivirus expression plasmid and can be used in gene therapy for cancer.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common causes of death worldwide, especially in Asian countries<sup>[1]</sup>. To date, none of the conventional treatment modalities can completely eradicate HCC cells. In recent years, gene therapy has been evaluated as a novel treatment modality for HCC<sup>[2-5]</sup>, while conventional treatment modalities, including surgery, chemotherapy and liver transplantation, are still used<sup>[6-8]</sup>.

*p53* is an important tumor suppressor gene which regulates many important cellular activities, including apoptosis. Mutations and deletions of the *p53* gene are common in HCC in a number of geographic regions. Since the mutation incidence ranges 5%-50%, *p53* has become an ideal target for gene therapy. Kanovsky *et al*<sup>[9]</sup> and Do *et al*<sup>[10]</sup> reported that a *p53* peptide, synthesized from residues 12-26 and fused with the *Drosophila* carrier protein antennapedia (Ant), can induce rapid tumor cell necrosis in all breast and pancreatic cancer cell lines irrespective of its status and exhibits a low cytotoxicity to normal cells, which is uncommonly observed in traditional cancer therapy. Human HCC cell line, HepG2, contains the wild-type *p53* gene and can thus be used in research of the relation between HCC and *p53* peptide gene therapy.

It is important to study the transfer of fusion gene and the secretion of expressed protein for the assessment of enhanced cancer-killing effects of a protein. In this study, NT4 signal peptide and its pro-region were used as the regions responsible for protein and peptide secretion from cells. Lentivirus gene expression plasmids were constructed for NT4(Si)-ADNF-9 and NT4(Si)-NAP fusion proteins containing the NT4 signal peptide and pro-region to enhance their expression. The restriction enzyme site *Nae*I at the NT4 signal peptidase fissure site and two restriction enzyme sites, *Bam*H I and *Xho* I, in NT4(Si)-*p53*(N15)-Ant could ensure the correct construct. A novel recombinant lentivirus expression plasmid, pLenti6/V5-NT4 *p53*(N15)-Ant, was constructed, containing a signal peptide sequence and pro-region of neurotrophin 4 (NT4) fused to *p53*(N15)-Ant peptide. Its effect on HepG2 cells, both *in vitro* and *in vivo*, was investigated.

## MATERIALS AND METHODS

### Cells and cell culture

Human hepatoma HepG2 cells containing wild-type *p53* were cultured in RPMI 1640 containing 10% fetal bovine serum (FBS). 293T human kidney cells were

grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% FBS, 100 U/mL penicillin and 100 µg/mL streptomycin at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>. All cell lines were supplied by Xi'an Huaguang Bioengineering Company (Xi'an, China).

### Plasmid construction and virus titration

*p53*(N15)-Ant was synthesized by Beijing Sun Biotechnology Co, according to Kanovsky *et al*<sup>[9]</sup> and Genbank. Two restriction enzyme sites (*Nae* I and *Xho* I) were introduced upstream and downstream of this sequence, respectively. *p53*(N15)-Ant was subcloned into pGEM-T-easy for sequencing, then into pBV220/NT4. Signal peptide sequence and pro-region of NT4 were cloned from human genomic DNA and subcloned into the *Bam*H I / *Nae* I sites of pBV220. After digestion with restriction enzymes, the resulting NT4 *p53*(N15)-Ant gene with *Bam*H I and *Xho* I sites from the pBV220/NT4-*p53*(N15)-Ant plasmid was inserted into the multiple cloning site of the expression plasmid, pLenti6/V5-D-TOPO (Invitrogen) containing a cytomegalovirus (CMV) promoter, upstream of the inserted gene. The resulting plasmid was named pLenti6/V5-NT4 *p53*(N15)-Ant.

To generate a control plasmid containing green fluorescent protein, EGFP was amplified from EGFP-C2 by PCR. The sequences of sense and anti-sense primers are 5'CGGGATCCATGGTGAGCAAGGGCGAGG-3' and 5'CGCTCGAGTCAAGTCCGGCCGGACTTGTAC-3', respectively. The resultant PCR fragments were digested with *Bam*H I and *Xho* I (underlined), subcloned into pLenti6/V5-D-TOPO, and verified by DNA sequencing.

The four-plasmid-based lentiviral expression system was purchased from Invitrogen. Briefly, four kinds of plasmid including 4.2 µg of pLP1, 2 µg of pLP2, 2.8 µg of pLP/VSVG and 3 µg of lentivector pLenti6/V5-NT4 *p53*(N15)-Ant or pLenti6/EGFP, were cotransfected into 293T cells using the calcium phosphate coprecipitation method. The conditioned medium was harvested 72 h after transfection and filtered through a 0.45 µm filter. Concentrated viral stocks were prepared by ultra-centrifugation of 3 mL conditioned medium at 50 000 *g* for 1.5 h at 4°C in a SW41 rotor (Beckman). The pellet was resuspended in 30 µL complete medium and stored at -80°C. The resulting recombinant lentivirus was named LV-NT4 *p53*(N15)-Ant and LV-EGFP, respectively.

Viral titer was measured by assessing the viral p24 antigen concentration using ELISA (Beckman Coulter, Fullerton, California, USA), showing that one microgram per milliliter of p24 corresponds to approximately  $2 \times 10^6$  transducing units per milliliter of EGFP virus, as assessed by titration in 293 T cells.

### Lentivirus-mediated gene transfer and expression in HepG2 cells

HepG2 cells were seeded into 6-well plates at a density of  $1 \times 10^6$  cells/well, allowed to adhere for 24 h, and then infected with EGFP lentivirus at multiplicities of infection (MOI) of 4 transducing units (TU)/cell. EGFP-positive cells were observed and counted under a fluorescence microscope 48 h after infection.

Expression of the *NT4 p53(N15)-Ant* gene was detected by reverse transcription-polymerase chain reaction (RT-PCR). HepG2 cells were seeded in 100 mL culture flasks at a density of  $1 \times 10^6$  cells/flask and infected with NT4-p53(N15)-Ant lentivirus at a MOI of 4 TU/cell. Forty-eight hours after infection, HepG2 cells were scraped from the flask surface with a brush (Paro-Isola, Thalwil, Switzerland). Total RNA was extracted using Trizol reagent (Gibco). A reverse transcription (RT) step was carried out for 60 min at 37°C using 1 µg total RNA treated with DNase and M-MLV reverse transcriptase (Invitrogen, USA) in the presence of random primers. PCR was performed in 50 µL reaction volume containing 10 µL (about 2.5 ng) cDNA, 1 µL of 10 mmol/L dNTP, 1 U of Taq DNA polymerase, 5 µL of  $10 \times$  Taq buffer, and 1 µL 50 pmol of forward primer (5'-CG GATCCATGCTCCCTCTCCCTCATGC-3') and reverse primer (5'-CCTCGAGTCATCCGCGCTGTACCTTTACC-3') of the *NT4 p53(N15)-Ant* gene. Samples were subjected to RT-PCR at the following conditions: pre-denaturation for 5 min at 94°C, followed by 30 cycles of denaturation for 60 s at 94°C, annealing for 60 s at 60°C, extension for 90 s at 72°C, and a final extension for 5 min at 72°C. The RT-PCR products were separated by electrophoresis on 2% agarose gels (Qiagen, USA).

#### **Immunohistochemical detection of p53(N15)-Ant expression in lung cancer H1299 cells**

H1299 cells (null for p53) were seeded onto cover slips and infected with LV-NT4(Si)-p53(N15)-Ant at a MOI of 4 TU/well. Polybrene was added to a final concentration of 8 µg/mL. Twelve hours after infection, 2 mL of a new DMEM medium was added. Forty-eight hours after infection, H1299 cells were washed and fixed with cold acetone. Protein expression of p53(N15)-Ant in H1299 cells was determined by immunocytochemical staining with anti-p53 antibody (DO-1) (Santa Cruz Biotechnology, Santa Cruz, CA, USA) using the Vectastain Elite ABC kit following its manufacturer's instructions (Vector Laboratories, Burlingame, CA, USA).

#### **MTT assay**

To determine the effect of lentivirus-NT4(Si)-p53(N15)-Ant on HCC, HepG2 cells were seeded in 96-well plates at a concentration of  $5 \times 10^3$  cells, grown for 24 h, infected with lentivirus-NT4(Si)-p53(N15)-Ant or lentivirus-EGFP at a MOI of 4 TU/cell with polybrene (8 µg/mL) for 12 h. The culture medium was then replaced with a fresh medium. MTT assay was performed at different time points (24, 48 and 72 h) after infection with lentivirus according to its manufacturer's instructions (Xi'an, China).

#### **Examination of HepG2 cell morphology under light microscope**

After infection with NT4(Si)-p53(N15)-Ant, morphology of HepG2 cells was observed under an inverted light microscope and recorded.

#### **Examination of ultra-structure of HepG2 cells under electron microscope**

Forty-eight hours after infection with NT4(Si)-p53(N15)-Ant, HepG2 cells were trypsinized, fixed with 2.5% glutara-

ldehyde for 2 h at 4°C, washed with 0.1 mol/L dimethyl arsenic trioxide buffer, fixed with 1% osmium acid for 2 h, dehydrated, and then embedded in 618 domestic epoxy resin, followed by polymerization for 24 h. The embedded block was cut into ultra-thin sections. The sections were double stained with uranyl acetate and lead citrate, and observed under a transmission electron microscope.

#### **LDH release assay**

To determine LDH leakage into the extra-cellular fluid, supernatant was collected at different time points (24, 48, 72, and 96 h) after infection with NT4(Si)-p53(N15)-Ant. LDH in the supernatant was detected with a RA-100 automatic biochemical analyzer.

#### **Annexin V and PI double staining**

When HepG2 cells were grown to  $2 \times 10^5$ /mL, they were seeded into 9-well plates at a volume of 3 mL/well, and left to adhere for 24 h. The cells were then divided into control group and lentivirus treatment group. The cells in control group were grown in a serum-free medium. Forty-eight hours after infection with lentivirus, the cells were washed twice with PBS at 4°C, re-suspended in 250 µL of a combination buffer solution, and the cell concentration was adjusted to  $1 \times 10^5$ /mL. Five microliter of Annexin V/FITC and 5 µL of 20 µg/mL propidium iodide were added to 100 µL of cell suspension. After incubation in the dark for 15 min, the cells were analyzed by flow cytometry (FCM).

#### **Inhibition of HepG2 cells in nude mice by LV-NT4(Si)-p53(N15)-Ant**

Twenty 6-8 wk old male and female BALB/c (nu/nu) mice, weighing  $20.3 \pm 2$  g, were purchased from Laboratory Animal Center, Fourth Military Medical University (Xi'an, China).

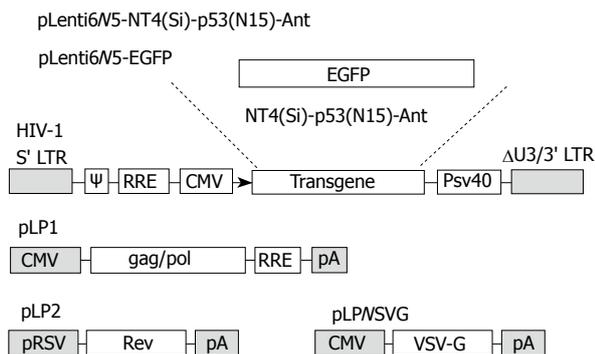

HepG2 cells ( $2 \times 10^5$ ) were injected subcutaneously on the right side of each mouse's back to induce tumor formation. The animals were divided into three groups when the tumor volume reached 30 mm<sup>3</sup> with 0.1 mL LV-NT4(Si)-p53(N15)-Ant ( $2 \times 10^6$  TU/mL) injected into their tumor. Mice treated with PBS and LV-EGFP served as controls with 0.1 mL LV-EGFP ( $2 \times 10^6$  TU/mL) injected into their tumor (injection at different directions). Infection efficiency of lentivirus was observed under a confocal laser scanning microscope one week after infection.

The animals were sacrificed 3 wk after injection of lentivirus. Tumors were removed and weighed with their size measured using a vernier caliper and their volume calculated according to the following formula:  $(3.14 \times L \times W \times H)/6$ . Tumors were fixed in 4% formaldehyde and embedded in paraffin. Tumor tissue was cut into 5-µm thick sections which were stained with HE.

Tumor growth inhibition rate =  $(A-B)/A \times K$ , where A is the average tumor weight of control group, B is the average tumor weight of treatment group, K represents 100%.

#### **Statistical analysis**

The data were expressed as mean  $\pm$  SD. LDH release and

**Figure 1** Packaging system of LV-NT4(Si)-p53(N15)-Ant and LV-EGFP. The packaging system: lentiviral vector, pLenti6/V5-D-TOPO, contains HIV-1 5'LTR, packaging signal ( $\psi$ ), RRE sequence, CMV promoter and 3'LTR from which some regulatory sequences are deleted, resulting in "self-inactivation" of lentivirus after transduction of the target cells. pLP1, pLP2 and pLP/VSVG are three helper plasmids, which provide structural and replication proteins to produce lentivirus.

MTT were analyzed by *t*-test and  $\chi^2$  test, respectively. The data for animal experiment were processed by analysis of variance. Data analysis was performed using the SPSS 15.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Construction of lentivirus vector expressing NT4-p53(N15)-Ant or EGFP

The lentivirus expression vector, pLenti6 V5-D-TOPO we constructed, contains the elements required for virion packaging, such as 5' and 3' long terminal repeats and  $\psi$  packaging signal. The packaging system of LV-NT4(Si)-p53(N15)-Ant and LV-EGFP is shown in Figure 1.

The DNA sequence of the *p53(N15)-Ant* gene was identical to those of *p53(N15)* and 17 amino acid Ant<sup>[9]</sup>. The length of NT4-p53(N15)-Ant was 349 bp, including a 247 bp fragment of the signal peptide sequence and pro-region of neurotrophin 4 with the two restriction sites (*Bam*H I and *Nae* I). The DNA fragment of *p53(N15)-Ant* was 108 bp with *Nae* I and *Xho* I. Digestion of pLenti6/V5-NT4-p53(N15)-Ant with *Bam*H I and *Nae* I followed by electrophoresis verified that the NT4-p53(N15)-Ant secretory expression cassette was correctly inserted into the multiple cloning site (MCS) of pLenti6/V5-D-TOPO, and pLenti6/V5-EGFP was confirmed in the same way as pLenti6/V5-NT4-p53(N15)-Ant.

### Gene transfer and lentivirus expression in HepG2 cells

Fluorescent microscopic analysis showed that EGFP was expressed in over 60% of HepG2 cells 48 h after infection with pLenti6/V5-EGFP at a MOI of 4 TU/cell (Figure 2A and B).

### Expression of NT4-p53(N15)-Ant in lentivirus-delivered H1299 cells

Since H1299 cells lack of the *p53* gene (null-*p53*), H1299 lung cancer cells were used as target cells for the expression of *p53(N15)-Ant*. *p53* protein could not be detected with immunohistochemical staining before or after infection with LV-EGFP (Figure 2C). However, 48 h

after infection with LV-NT4(Si)-*p53(N15)-Ant*, *p53* protein was mainly expressed in cytoplasm of H1299 lung cancer cells (Figure 2D). Anti-DO-1 could identify and bind to amino acids 11-25 of *p53*, suggesting that LV-NT4(Si)-*p53(N15)-Ant* can effectively infect the target cells and express the *p53* fusion peptide.

### Killing effect of lentivirus-NT4 p53(N15)-Ant on HepG2 cells in vitro

HepG2 cells, infected with pLenti6/V5-NT4-p53(N15)-Ant in our study, were significantly killed, whereas pLenti6/V5-EGFP had no effect on cell viability, suggesting that growth of HepG2 cells can be inhibited by the transferred exogenous gene rather by viral toxicity (Figure 3).

### Morphological changes in HepG2 cells observed under light microscope

Significant morphological changes were observed in HepG2 cells at different time points after infection with LV-NT4(Si)-*p53(N15)-Ant* but not after infection with LV-EGFP and LV-NT4(Si)-*p53(N15)-Ant* (Figure 4). However, the cells became swollen and their boundary was blurred 48 h after infection with LV-NT4(Si)-*p53(N15)-Ant*, while their viability was significantly declined with noticeable cell shrinkage, fragments and detachment 72 h after infection with LV-NT4(Si)-*p53(N15)-Ant*, but without significant morphological changes 72 h after infection with LV-EGFP infection.

### Changes in ultra-structure of HepG2 cells observed under electron microscope

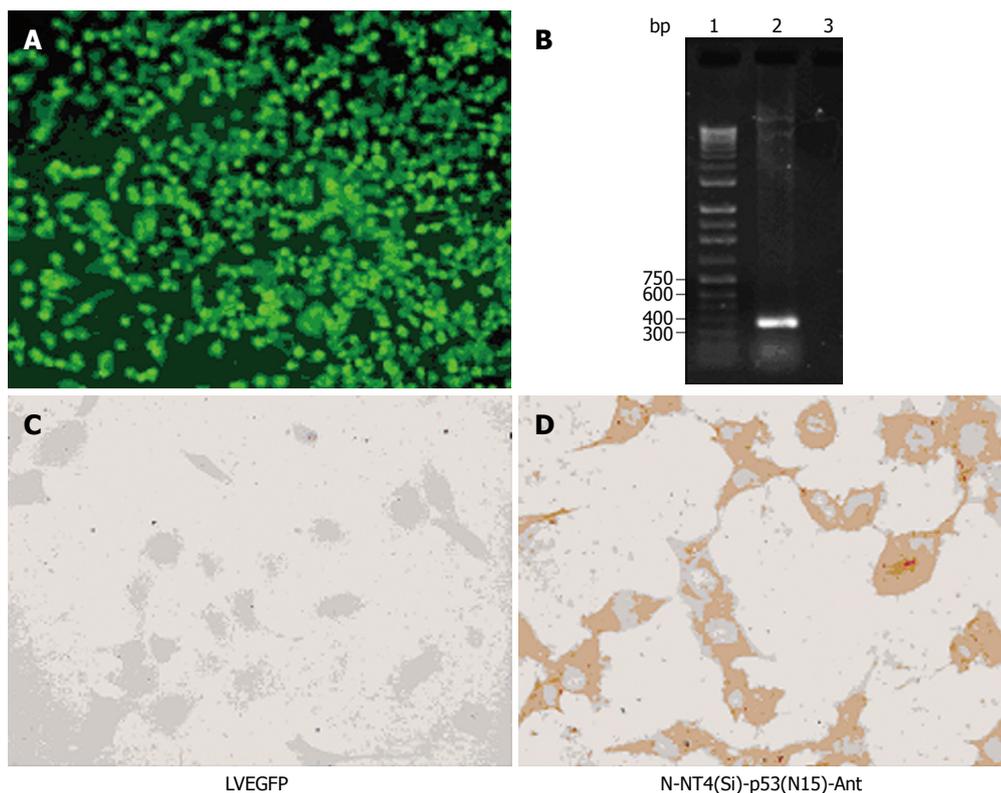

Forty-eight hours after infection with LV-EGFP, the membranes and nuclear membranes of HepG2 cells were intact with some crimples in the nuclear membranes, some microvilli on the surface of HepG2 cells, normal structure of mitochondria and ER (Figure 5A), and 2 completely divided HepG2 cells (Figure 5B), suggesting that LV-EGFP has no significant effect on cell growth and division. Forty-eight hours after infection with LV-NT4(Si)-*p53(N15)-Ant*, significant changes in ultra-structure of HepG2 cells, as well as in cell membranes and mitochondria, were observed under electron microscope. Cell membranes were incomplete with several fractures and the cells appeared to leak contents. Mitochondria were swollen with vacuolization. Vacuoles were also seen under the nuclear membrane with bare nuclei (Figure 5C and D). These findings suggest that NT4(Si)-*p53(N15)-Ant* may exert its anticancer effect mainly by inducing necrosis of cell membranes.

### Determination of LDH release

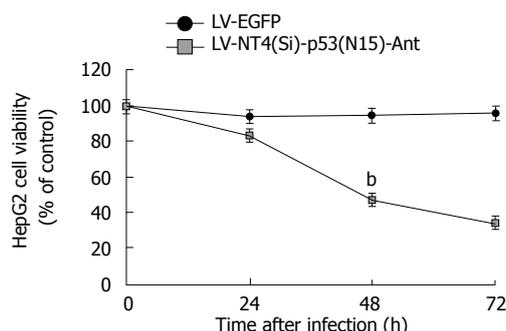

LDH was significantly increased in LV-NT4(Si)-*p53(N15)-Ant* treatment group, but not in LV-EGFP treatment group, with no significant difference between the two groups. The longer the time was after the infection, the greater the difference was between the groups, suggesting that cell membranes are damaged.

### Annexin V-PI double staining

Flow cytometry (FCM) was employed to detect the

**Figure 2** Fluorescent microscopic analysis and immunohistochemical staining. Fluorescence microscopy analysis showing EGFP expression in HepG2 cells (A), agarose gel electrophoresis of RT-PCR products from HepG2 cells (B) [lane 1: 1.0 kb DNA ladder; lane 2: RT-PCR products from cells infected with LV-NT4(Si)-p53(N15)-Ant; lane 3: negative controls infected with LV-EGFP], immunohistochemical staining showing no p53 protein (C), and p53 protein expression in cytoplasm of HepG2 cells (D) 48 h after infection with LV-NT4(Si)-p53(N15)-Ant.

**Figure 3** Cytotoxicity of LV-NT4(Si)-p53(N15)-Ant to HepG2 cells at different time points (24, 48 and 72 h) after infection with lentivirus. <sup>b</sup>*P* < 0.01 vs LV-EGFP.

fluorescence intensity after HepG2 cells were double-stained with Annexin V and PI. A plot composed of 4 quadrants was detected by flow cytometry, which showed that the number of necrotic cells was significantly greater in LV-NT4(Si)-p53(N15)-Ant treatment group than in LV-EGFP treatment group 48 h after infection with lentivirus. The apoptosis level was also higher in cells expressing LV-p53(N15) than in controls. However, the number of necrotic cells was still much greater than that of apoptotic cells (Figure 6), suggesting that the NT4(Si)-p53(N15)-Ant gene kills tumor cells mainly by inducing necrosis of cell membrane.

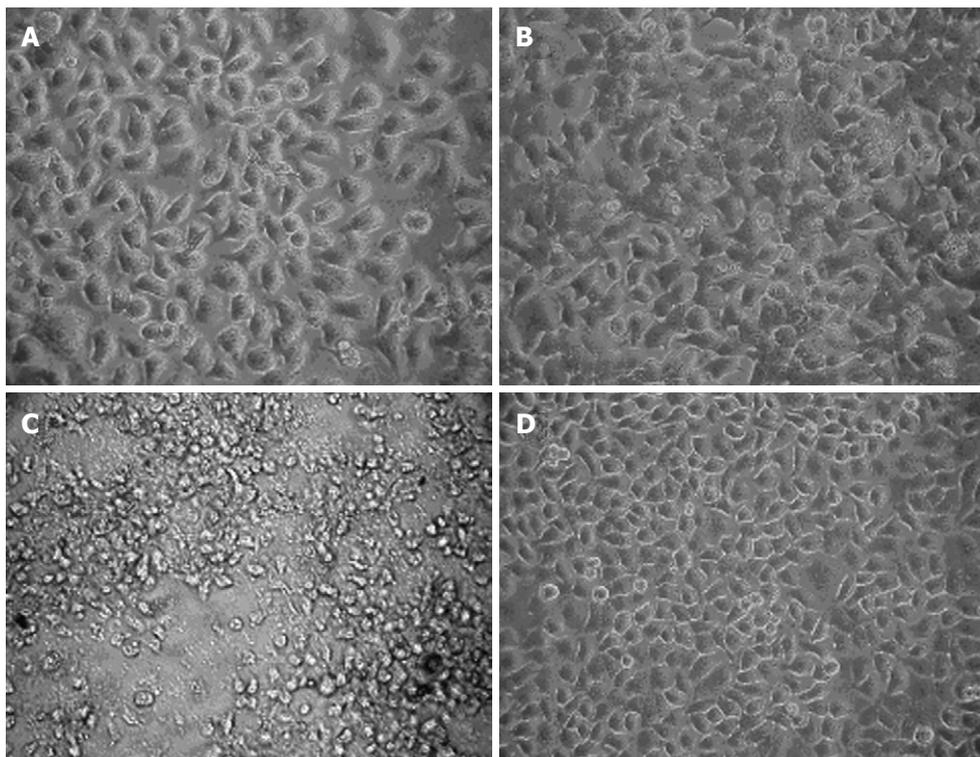

**Inhibition of HepG2 cell growth in nude mice by LV-NT4(Si)-p53(N15)-Ant**

Nude mice developed tumor mass within 10 d after inoculation with HepG2 cells. Three weeks after infection with lentivirus, the size and weight of tumor mass were measured (Figure 7A and B). The inhibition

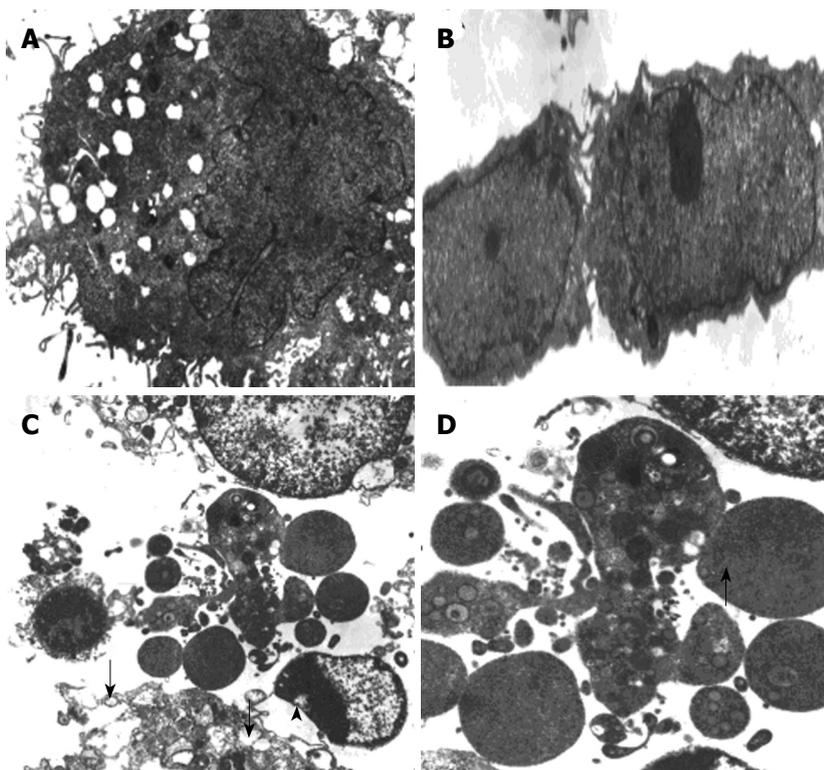

rate of tumor growth for LV-NT4(Si)-p53(N15)-Ant was 66.14%.

**DISCUSSION**

p53 protein plays an essential role in cell activities<sup>[11,12]</sup>. Under various stress conditions, such as genotoxic damage, hypoxia, ribonucleotide depletion or oncogene activation, p53 molecule accumulates and is activated. Activated p53 acts as a transcription factor and activates or represses a variety of genes involved in cell-cycle regulation, induction of apoptosis or senescence. Therefore, the *p53* gene represents an ideal target for cancer therapy. In non-stressed cells, p53 protein is present at a very low cellular concentration, because it interacts with the hdm2 protein, the human analogue of murine mdm2, which acts as a ligase of ubiquitin<sup>[13,14]</sup> and promotes p53 degradation<sup>[9,10]</sup>. Recent advances in regulation of p53 by hdm2 offer the possibility of generating new anticancer agents that activate wild-type p53 in tumors. Since hdm2 down-regulates p53, inhibition of this interaction would lead to an accumulation of p53 in tumor cells, eventually inducing their death<sup>[10,15]</sup>. p53(N15)-Ant has been considered a novel cancer therapeutic peptide because it induces cancer cell death and does not seem to be cytotoxic to normal cells and may, therefore, prove useful as a general anticancer agent. In this study, we focused on how to improve the anticancer effect of peptide therapy by employing two strategies. The first was to enable the expressed therapeutic peptide to be secreted, and the second was to use the lentivirus gene transfer system. It is well-known that the signal peptide is located at the terminal of amino acid sequence of a secreted protein and plays an important role in protein targeting

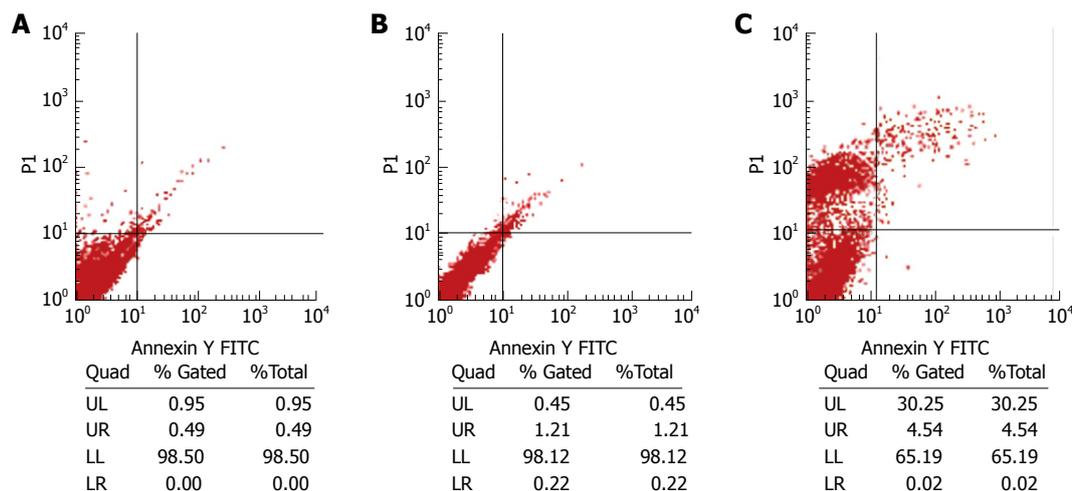

**Figure 4** Morphological changes in HepG2 cells 24 h (A), 48 h (B), 72 h (C) after infection with LV-NT4(Si)-p53(N15)-Ant and 72 h (D) after infection with LV-EGFP ( $\times 400$ ).

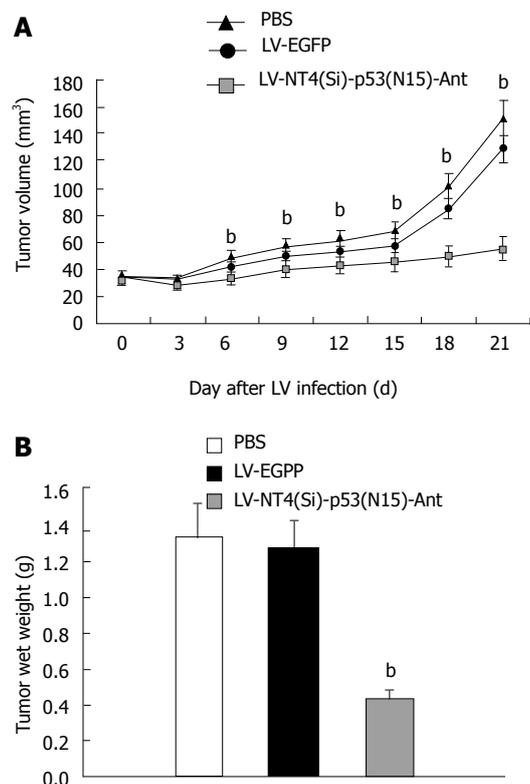

**Figure 5** Ultra-structure of HepG2 cells 48 h after infection with LV-EGFP (A, B) and LV-NT4(Si)-p53(N15)-Ant (C, D) ( $\times 5000$ ). A: Forty-eight hours after LV-EGFP infection, the cell membranes and nuclear membranes of HepG2 cells were intact; there were some crimples in the nuclear membranes and some microvilli on the surface of cells. The structure of mitochondria and ER was normal; B: Forty-eight hours after LV-EGFP infection, there were two HepG2 cells which had just completed division and this phenomenon suggested that LV-EGFP did not have a significant effect on cell growth and division; C: Forty-eight hours after LV-NT4(Si)-p53(N15)-Ant infection, it can be seen that cell membranes were incomplete and several fractures (arrows) were seen. Cell contents also appeared to be leaking. Mitochondria were swollen and showed vacuolization. Vacuoles were also seen under the nuclear membrane (arrowhead); D: Forty-eight hours after LV-NT4(Si)-p53(N15)-Ant infection, the remaining bare nuclei (arrow), after cytoplasm collapse can be seen.

and translocation in both prokaryotic and eukaryotic cells. NT4 is a member of the neurotrophin family, involved in controlling survival and differentiation of vertebrate neurons<sup>[16]</sup>. Besides the common features of neurotrophins, NT4 has many unusual features. Unlike other neurotrophins, the expression of NT4 is ubiquitous and less influenced by environmental signals<sup>[17]</sup>. In the present study, NT4 structure analysis showed that the human NT4 initiation codon was followed by a signal

peptide sequence, a pro-region and an apparent dibasic cleavage site, which was followed by the sequence of the mature NT4. The signal peptide sequence and pro-region of human NT4 are notably shorter (by = 243 bp) than those of other neurotrophins<sup>[18]</sup>. In our previous study, the pre-protein NT4 could be cleaved into the signal peptide and the mature protein by *Escherichia coli* (*E. coli*) endopeptidase. There is a native NaeI enzyme site in front of the site in the NT4 signal peptide,

**Figure 6** Flow cytometry analysis of HepG2 cells without treatment (A), 48 h after infection with LV-EGFP (B) and LV-NT4(Si)-p53(N15)-Ant (C) after stained with Annexin V and propidium iodide. The left lower quadrant represents normal cells (An-PI-), the right lower quadrant represents early apoptotic cells (An+ PI-), the right upper quadrant represents apoptotic cells and necrotic cells (An + PI +), the upper left quadrant represents early necrotic cells (An-PI +).

**Figure 7** Tumor growth curve (A) and tumor wet weight (B) after treatment with LV-NT4(Si)-p53(N15)-Ant. A: Tumor growth curve after treatment with LV-NT4(Si)-p53(N15)-Ant. Tumors grew rapidly in the PBS and LV-EGFP groups, while the tumor growth was significantly inhibited in the LV-NT4(Si)-p53(N15)-Ant group 3 wk after infection. There was no statistical significance between the PBS group (151.0 ± 50.1 mm<sup>3</sup>) and the LV-EGFP group (128.5 ± 45.3 mm<sup>3</sup>) in terms of tumor volume (*P* > 0.05). But the tumor volume in the LV-NT4(Si)-p53(N15)-Ant group (55.1 ± 18.7 mm<sup>3</sup>) was significantly less than that of the PBS and LV-EGFP groups (<sup>b</sup>*P* < 0.01); B: Tumor wet weight after treatment with LV-NT4(Si)-p53(N15)-Ant. There were no significant differences in the wet weight of tumors between the two control groups: PBS group 1.33 ± 0.93 g vs LV-EGFP group 1.27 ± 1.04 g (*P* > 0.05). But the wet weight of the LV-NT4(Si)-p53(N15)-Ant treatment group (0.43 ± 0.77 g) was significantly less than that of the two control groups (<sup>b</sup>*P* < 0.01).

convenient for the expression of other exogenous peptides in a secretory manner. It has been shown that it is not only feasible, but also improves the therapeutic effect<sup>[19]</sup>. In this study, we successfully constructed a LV containing the NT4(Si)-p53(N15) fusion gene with *in vitro* recombinant DNA technology.

To transfer the NT4(Si)-p53(N15)-Ant gene into the target cells and to achieve a consistent expression, selection of the gene transfer vector is a critical step. Lentiviruses, such as HIV and SIV, are a new generation of vectors and have many advantages over the traditional virus vectors, such as retroviral or adenovirus vector. These LVs can infect both dividing and non-dividing cells and efficiently integrate into the host DNA, thus providing stable transgene expression over several months<sup>[20,21]</sup>. At the same time, LV is very safe because all lentivirus accessory genes have been removed, virus production components have been split into 3 or 4 separate parts, and self-inactivating deletions have been introduced into the vector<sup>[21,22]</sup>. Since the aim of cancer gene therapy is to remove all cancer cells including those in a precancerous stage, only extensive gene transfer and long-term gene expression in cancer cells are appropriate. Thus, LV has a greater promise to become an ideal vector for gene delivery.

In this study, MTT assay showed that LV-NT4(Si)-p53(N15)-Ant could significantly induce HepG2 cell death 48 h after infection, LDH was significantly increased in the LV-NT4(Si)-p53(N15)-Ant treatment group but not in the LV-EGFP treatment group, suggesting that the cell membranes are damaged. Moreover, cytotoxicity occurred in a time-dependent manner. The ultra-structure of HepG2 cells, especially cell membranes and mitochondria, was significantly changed after infection with LV-NT4(Si)-p53(N15)-Ant, which was different from that during apoptosis and necrosis. In addition, FCM revealed that two cell death modes (apoptosis and necrosis) occurred 48 h after infection with LV-NT4(Si)-p53(N15)-Ant with necrosis being common and apoptosis being rare, revealing that LV-NT4(Si)-p53(N15)-Ant exerts its effect on HCC mainly by inducing necrosis of cell membranes.

thus ensuring the correct cleavage of therapeutic peptide, and making this signal peptide sequence highly

This is probably related to the process of LV infection, integration of the therapeutic gene into the host genome and gene expression.

The *in vivo* study also showed that LV-NT4(Si)-p53(N15)-Ant significantly inhibited tumor growth. Since p53(N15) contains overlapping sequences from the p53 mdm-2 binding domain, p53(N15)-Ant peptide may block the interaction of mdm-2 with other proteins. Recently, a study investigating the secondary structure of the p53 fusion peptide has revealed that p53(N15)-Ant peptide plays an important role in membrane interaction<sup>[15]</sup>, showing that p53(N15)-Ant peptide forms distinctive S-shape helix-loop-helix structures, which can rapidly disrupt cancer cell membranes by forming a toroidal-like pore, resulting in necrosis. The two mechanisms exist simultaneously.

In conclusion, we have established a way to express lentivirus-introduced p53(N15)-Ant 32-peptide. The growth of HepG2 cells can be significantly inhibited by LV-NT4(Si)-p53(N15)-Ant. LV-NT4(Si)-p53(N15)-Ant gene therapy may be used as a novel anticancer strategy. Further study on the biological characteristics of the p53 peptide is needed by transfecting LV-NT4(Si)-p53(N15)-Ant into other cancer cell lines.

## COMMENTS

### Background

Peptide has emerged as a new anticancer agent in recent years. Numerous reports suggest that many low molecular weight peptides possess an anticancer effect but have almost no cytotoxic effect on normal cells. p53(N15)-Ant has been considered a novel cancer therapeutic peptide because it induces cancer cell death and does not seem to be cytotoxic to normal cells.

### Research frontiers

It has been reported that p53 peptide, synthesized from residues 12-26 and fused with *Drosophila* carrier protein antennapedia (Ant), induces rapid tumor cell necrosis in all breast and pancreatic cancer cell lines tested, irrespective of the p53 status, whereas it shows a low cytotoxicity to normal cells. In this study, the authors constructed a novel recombinant lentivirus expression plasmid LV-NT4(Si)-p53(N15)-Ant and demonstrated its anticancer effect.

### Innovations and breakthroughs

The signal peptide plays an important role in protein targeting and translocation in both prokaryotic and eukaryotic cells. In this experiment, the authors used the NT4 signal peptide to enable the therapeutic peptide to be secreted. Lentivirus vectors were also employed. LV-NT4(Si)-p53(N15)-Ant was constructed and successfully cultured at a high titer and verified to induce necrosis of cancer cells.

### Applications

This work has established a way to express lentivirus-introduced p53(N15)-Ant 32-peptide. LV-NT4(Si)-p53(N15)-Ant dependent gene therapy may be a promising novel anticancer strategy. p53(N15)-Ant may represent a promising agent of gene therapy for hepatocellular carcinoma.

### Terminology

NT4 signal peptide and its pro-region are protein sequences that can direct the secretion of proteins and peptides from cells. Such a mechanism is thought to be helpful in fusion peptide gene therapy as it can enhance the therapeutic effect.

### Peer review

In this study, Song *et al* showed that the constructed lentivirus vector expressed in cancer cells could inhibit the growth of HepG2 cells. This vector can induce necrosis and apoptosis, and inhibit tumor growth *in vivo*. The study in general is significant and interesting.
