### Abstract

**AIM:** To investigate whether the secretion of phosphatidylcholine (PC) in intestinal mucus occurs by apical secretion or *via* basolateral excretion and to determine its subsequent passage across the tight junctions to the apical mucus.

**METHODS:** We addressed this question using the polarized intestinally differentiated tumor cell line CaCo-2 grown on filters to confluence in Transwell culture chambers. The released PC and sphingomyelin (Sph) from apical and basolateral media were analyzed by mass spectrometry.

**RESULTS:** The secreted PC species were identical in both compartments indicating the same intracellular origin of PC. However, PC secretion into the basolateral compartment was more effective, and the PC:Sph ratio in the basolateral compartment was significantly higher than that in the apical compartment ( $8.18 \pm 1.84$  vs  $4.31 \pm 1.22$ ,  $P = 0.01$ ). Both pathways were temperature sensitive and were unaltered in the presence of cyclosporine.

**CONCLUSION:** The data demonstrate the PC secretion capacity of CaCo-2 cells and indicate two separated apical and basolateral release mechanisms.

### INTRODUCTION

The presence of phosphatidylcholine (PC) in intestinal mucus serves to protect the underlying mucosa from attack by the commensal bacterial flora which is of particular importance in the colon<sup>[1]</sup>. Recently it was shown that the mucus PC content is markedly reduced (up to 70%) in patients with ulcerative colitis (UC), irrespective of whether acute inflammation of the colon is present - when compared to controls or patients with Crohn's disease<sup>[2,3]</sup>. This suggests its significance in the pathogenesis of UC. Accordingly, therapeutic replacement of PC in UC was shown to be very effective<sup>[4-6]</sup>.

Furthermore, it was shown that apical PC secretion occurs mainly in the ileum, and is stimulated by bile acids<sup>[7]</sup>. It is assumed that lumenally secreted PC -after absorption of bile acids in the terminal ileum- is attracted to the mucosal surface and moves along the colonic wall towards the rectum driven by colonic motility<sup>[1]</sup>. The exposure of PC to phospholipases of commensal colonic bacteria thins the PC layer towards the rectum, the "last lawn" with least PC content<sup>[1]</sup>. This could explain the continuous spread of inflammation starting from the rectum in UC where an intrinsic low PC content in the mucus is already present. Moreover, the fact that PC is mainly secreted in ileum<sup>[7]</sup> and that it is significantly impaired in UC<sup>[2,3]</sup> could explain the occurrence of pouchitis after colectomy due to the lack of protective

PC in mucus. In contrast, pouchitis is not observed after colectomy for familial adenomatous polyposis (FAP).

PC within mucus is arranged as lamellar structures facing the luminal and mucosal surface of the mucus as well as liposomal structures within the layer. Of all phospholipids within the mucus, 60%-90% are reported to represent PC species<sup>[8,9]</sup>. This indicates a specific PC secretion mechanism. The conventional view of such a transport process would suggest apical secretion *via* vesicular excretion or by ABC-transporters similar to MDR 2/3 mediated translocation of PC at the apical pole of hepatocytes<sup>[10,11]</sup>. However, Alpers *et al*<sup>[12]</sup> claimed a predominant basolateral secretion mechanism with secondary back diffusion across the tight junctions and subsequent release into the mucus space.

To evaluate this secretion mechanism, we used the intestinally differentiated tumor cell line CaCo-2 which revealed a polarized growth in tissue culture. We addressed the following questions: (1) Is PC secretion detectable in CaCo-2 cells? (2) Does it occur apically, basolaterally or on both sides? (3) Are these secretion pathways identical? (4) What are the kinetic characteristics?

## MATERIALS AND METHODS

### Cell culture

CaCo-2 cells were cultured routinely at 37°C, 5% CO<sub>2</sub> in DMEM (GIBCO Invitrogen, Karlsruhe, Germany), containing 10% fetal calf serum (FCS), 1% penicillin/streptomycin, 1% sodium pyruvate (Sigma-Aldrich, Munich, Germany) and 1% nonessential amino acids (Sigma-Aldrich, Munich, Germany). Cells were seeded in 6-well Corning® Transwell® polyester membrane inserts (pore size 3.0 μm, membrane diameter 24 mm) (Corning COSTAR, USA), at a density of 10<sup>5</sup> cells/cm<sup>2</sup>. Cells were cultured for up to 21 d after reaching confluency to allow complete apical/basolateral polarization. Transepithelial electric resistance was checked regularly to verify appropriate polarization (World Precision Instruments, Berlin, Germany).

### Sampling for lipid measurement

For measurement of PC secretion, polarized CaCo-2 cells on filters were washed with FCS-free medium three times to remove extracellular lipids. They were then incubated in FCS-free medium containing 1% bovine serum albumin (BSA) (Sigma-Aldrich, Munich, Germany) for 16 h unless otherwise stated. Apical and basolateral media were collected and detached cells removed by centrifugation at 300 g for 5 min. All samples were stored at -80°C until further processing.

For experiments at different temperatures, CO<sub>2</sub>-independent medium (GIBCO Invitrogen, Karlsruhe, Germany) containing 1% w/v BSA was used. Where indicated, BSA was replaced by taurocholate (Sigma-Aldrich, Munich, Germany) at a concentration of 2.5 mmol/L. In addition, the following drugs were used at the following concentrations: (1) verapamil 500 μmol/L, (2) glibenclamide 50 μmol/L, (3) hydrocortisone

100 ng/mL, 500 ng/mL, and 1000 ng/mL, (4) cyclosporine 80 μmol/L (all Sigma-Aldrich, Munich, Germany). In experiments using hydrocortisone, cells were pre-incubated in regular medium containing the respective concentrations of hydrocortisone for 24 h to allow for changes in transcription. Experiments were performed in quadruplicate, except for the time-course experiments, which were performed in triplicate.

### Differential centrifugation

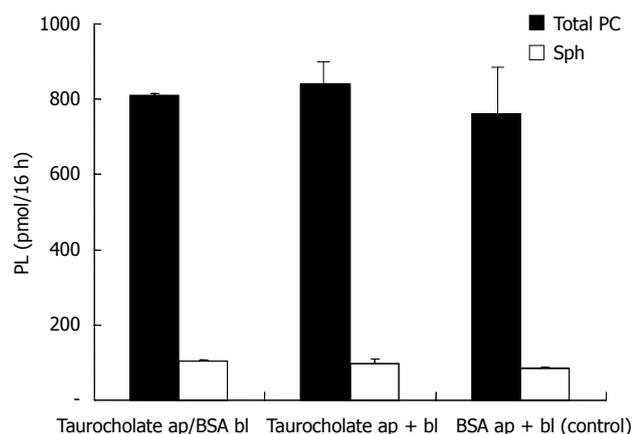

To retrieve particles of different sizes, the following standard setup was used. Cells were incubated as described above. The supernatant (SN) of the 300 g/5 min centrifugation was centrifuged at 1200 g for 20 min (P2). To obtain the next pellet the resulting SN was centrifuged at 10000 g for 30 min (P3). This SN was then centrifuged at 100000 g for 1 h (P4). Resulting pellets (P2-4) and the final supernatant were then subjected to lipid analysis.

### Lipid analysis

Lipids from the respective medium samples were extracted according to Folch<sup>[13]</sup>. Before lipid extraction, non-physiologic 1,2-didodecanoyl-sn-glycero-3-PC, 1,2-tetradecanoyl-sn-glycero-3-PC, 1,2-dieicosanoyl-sn-glycero-3-PC, 1,2-dido-cosanoyl-sn-glycero-3-PC as well as 1-pentadecanoyl-2-hydroxy-sn-glycero-3-PC, 1-arachidonyl-2-hydroxy-sn-glycero-3-PC and sphingomyelin (Sph) were added for internal standardization. The apical and basolateral media were dried with a speed vac. In brief 75 μL aqua dest and 50 μL of the lipid standard were added to each sample. 500 μL of methanol were added and the sample was vortexed for 5 min. 1000 μL chloroform was added and vortexed for 5 min. The supernatant of the 5 min/17000 g centrifugation was transferred to a new reaction tube. 300 μL aqua dest was added and vortexed again for 5 min. Phase separation was achieved by centrifugation at 500 g for 5 min. The lower organic phases were transferred to a separate glass tube and dried before resuspension for mass spectrometry.

### Nano-ESI tandem mass spectrometric analyses

Mass spectrometric analyses were performed with a triple quadrupole instrument [Finnegan MAT (San Jose, CA, USA) model TSQ 7000] equipped with a nano-electrospray source operating at a typical flow rate of 20 to 50 nL/min. The electrospray capillary was positioned at a distance of 0.5 to 1 mm away from the orifice of the heated transfer capillary which was maintained at 140°C. The instrument was used in the tandem MS mode. Argon was used as the collision gas at a nominal pressure of 2 mTorr. Crude lipid extracts, which had been dried completely, were resolved in 50 μL methanol/chloroform 2:1 (v/v), vortexed thoroughly, and infused into the capillary. The mass spectrometric resolution was set to about nominal mass resolution for the scan range of m/z 400 to 900. All specimens were analyzed in precursor ion scan mode for m/z 184. At least 150 consecutive scans, if possible more than 200 scans of 4-s duration, were averaged for each quantitative measurement.

**Figure 1 Release of phospholipids (PL) into the apical (ap) and basolateral (bl) media in the presence of BSA or taurocholate as solubilizing agents.** The figure illustrates no differences in the amount of PC and Sph secreted regardless of whether taurocholate was applied only apically (left), both apically and basolaterally (middle) compared to control (right) ( $P = ns$ ).

For quantification of the physiological PC and sphingomyelin species, regression curves were determined from the non physiological standards. Due to a general loss in sensitivity with increasing molecular weight, a set of four PC species was added as internal standards to bracket the profile of naturally occurring PCs. For the quantitative determination of Sph, we used a single internal standard. For correction of the measured values to the molar abundances, we used a calibration curve with the slope corresponding to that of PC.

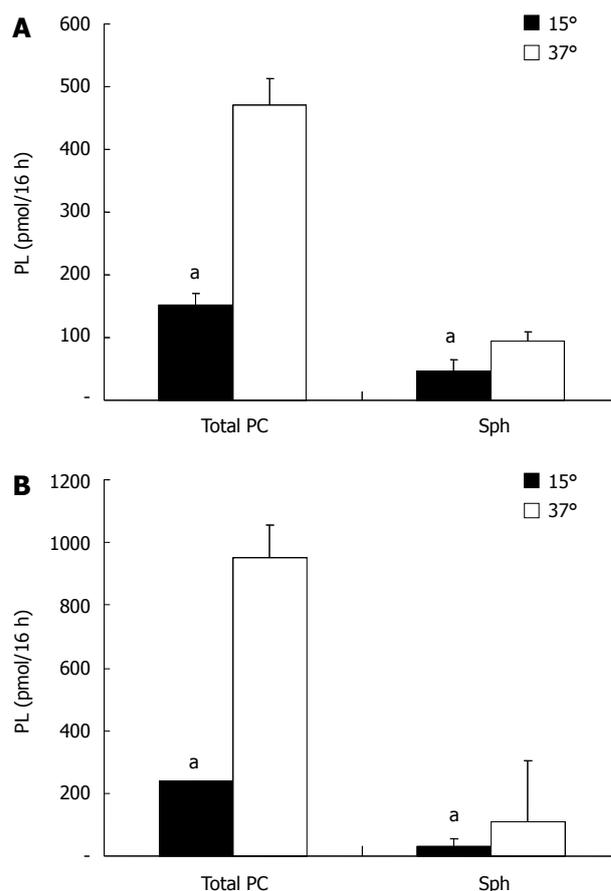

The most abundant physiological PC and Sph species were determined after comparison of all spectra. The molecular weights were related to the number of carbon atoms and double bonds with the help of a lipid data bank.

**Statistical analysis**

SPSS 16.0 was used for statistical analysis of the data. A Mann-Whitney-U-test was performed to analyze the differences between different conditions. Differences were considered significant, if  $P$  was  $< 0.05$ . In the time-course experiments a linear regression assuming a zero-crossing and applying the method of least squares was performed.

**RESULTS**

For polarization, CaCo-2 cells were grown on filters in Transwell culture dishes. Secretion of PC was examined in the apical and basolateral media containing, as lipid acceptors, taurocholate (2.5 mmol/L) or albumin (1% BSA). CaCo-2 cells showed PC secretion into both compartments. With regard to the acceptors of PC in both compartments (taurocholate or albumin), there was no difference recorded in the amount of PC or Sph released into the media (Figure 1). This indicated that under the experimental conditions employed, both acceptor molecules were present in excess and their capacity for PC and Sph solubilization was not

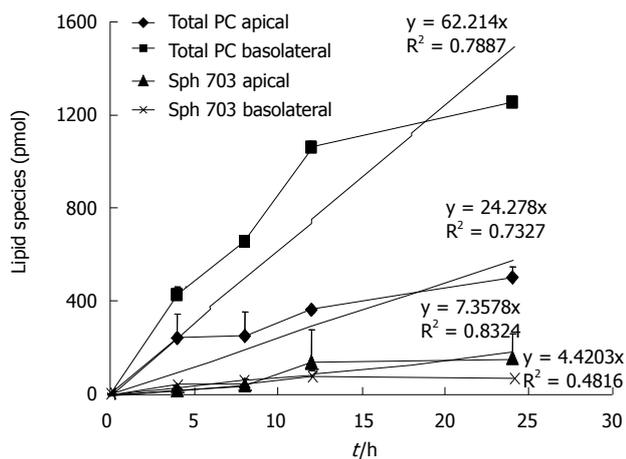

**Figure 2 Temperature dependency of phospholipid (PL) secretion.** Caco-2 cells were incubated either at 37°C or 15°C and secreted PC and Sph were measured. Both apical (A) and basolateral secretion (B) were drastically reduced at 15°C; apical PC by 68%, basolateral PC by 75%, apical Sph by 53% and basolateral Sph by 73% ( $^*P < 0.05$ ).

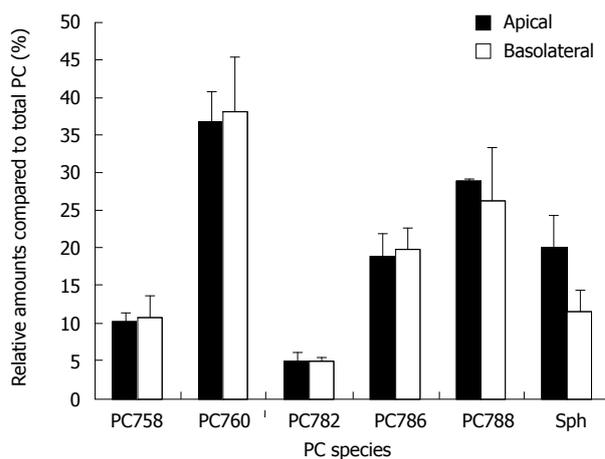

compromised. The secretion of PC and Sph in both compartments was temperature sensitive with a significant reduction in the secretion rate at 15°C. The degree of temperature-induced acceleration/deceleration of the transport rates was comparable for PC and Sph at each side. However, the total secretion rates towards the basolateral side were significantly more inhibited at 15°C than those at the apical side. This observed drop in secretion is typical for vesicular transport, because much lower transport rates in membrane carrier systems are expected at 15°C (Figure 2).

At 37°C the rate of secretion was significantly higher at the basolateral side compared to the apical side - also an indication of two different secretion capacities (Figure 3).

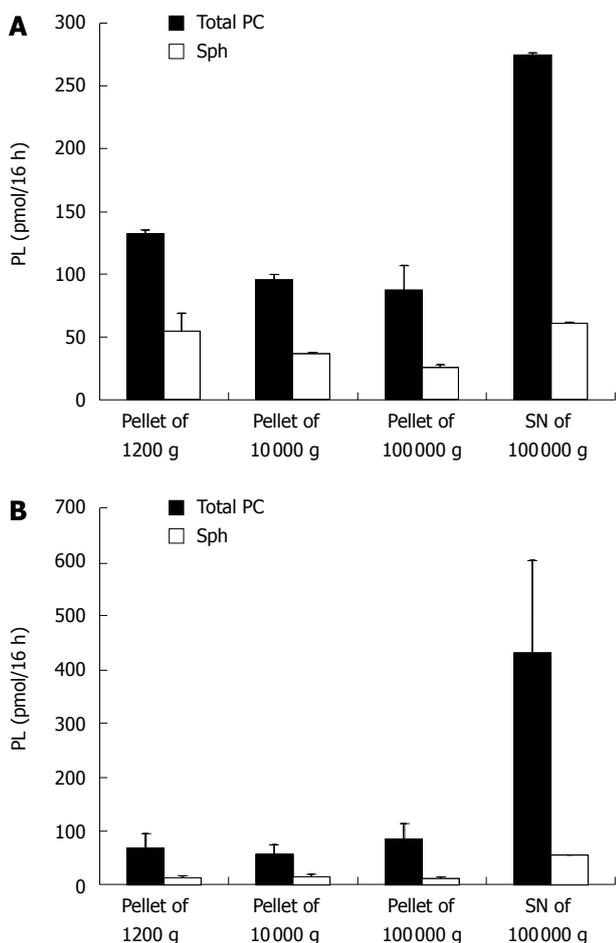

When the PC species and their secretion distribution on both sides were compared, they were virtually superimposable (Figure 4). This supports the concept that they originate from the same intracellular source. However, the relative fraction of Sph release compared to total PC release was significantly higher in the apical compartment. This corresponded to a higher level of Sph in the different pellets and the 100000 g supernatant of the apical compartment vs the basolateral compartment (Figure 5). Sphingomyelins are typical phospholipids of vesicular membranes in the secretory pathway<sup>[14]</sup>. A

**Figure 3 Time-course of phospholipid secretion.** An almost linear secretion up to 12 h with some decline in secretion towards 24 h was registered. The average secretion rate of PC was 24.3 pmol/h on the apical side and 62.2 pmol/h on the basolateral side. Sph was secreted apically at 4.4 pmol/h and basolaterally at 7.4 pmol/h. The regression line for each setup was drawn.

**Figure 4 Typical distribution pattern of phospholipid species secreted.** The PC species composition is similar in the apical and basolateral compartments. The relative amount of Sph 703 secreted is higher in the apical compartment ( $P < 0.05$  when comparing the ratio of Sph 703 to total PC in the apical and basolateral compartments).

**Figure 5 Distribution of secreted PL in pellets and supernatants obtained from the apical (A) and basolateral (B) compartments.** The majority of the PL is retrieved in the 100 000 g supernatant resembling a rather soluble fraction. In the medium of the basolateral compartment a reduced amount of PC and Sph could be found in the pellets, but more PC was found in the 100 000 g supernatant.

higher proportion of Sph compared to the “cargo”-PC is suggestive of smaller sized secretory vesicles (“containers”).

This is in line with the observation of a lower sensitivity towards temperature changes and a lower total apical PC secretion rate.

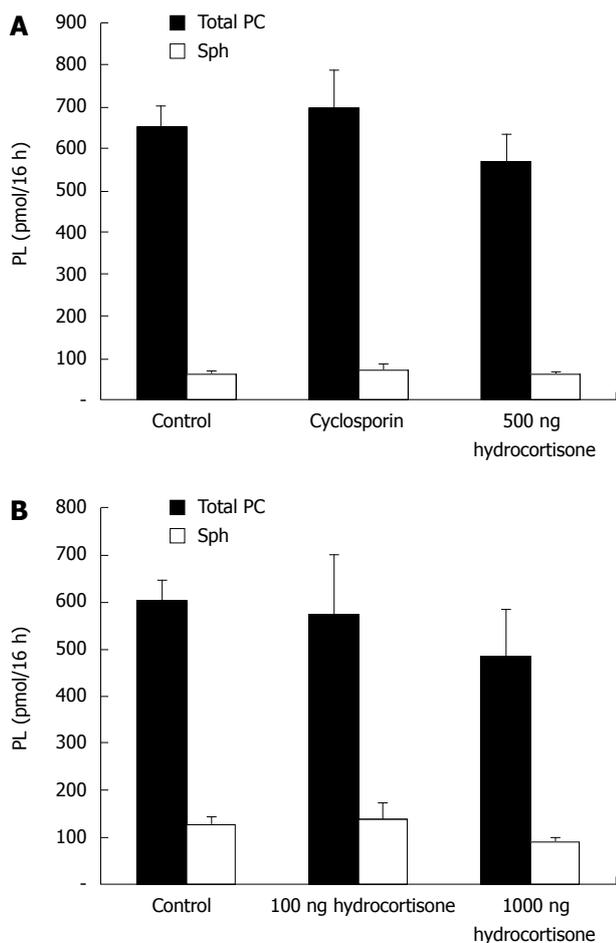

From a structural point of view, it would be easier for small sized vesicles to pass through the apical microvillous plasma membrane compared to large vesicles, which easily pass through the rather smooth basolateral side of the plasma membrane.

To further characterize the PC secretory pathway, we evaluated the effect of cyclosporine - a known inhibitor of ABC-transporters (Figure 6). No differences in transport rates were observed, underlying the hypothesis that PC secretion in intestinal mucosal cells more likely represents a vesicular excretion route. Similar results were obtained when other ABC-transport inhibitors (verapamil, glibenclamide and PSC833) were used (data not shown).

Since glucocorticoids are known to increase PC synthesis and excretion in the lung (surfactant), we evaluated their effects in CaCo-2 cells. Under the experimental conditions employed, no differences in secretion were detected (Figure 6). However, our experimental approach may have been too simple and unrefined to draw any further conclusions. It is possible that CaCo-2 cells do not express a glucocorticoid receptor.

## DISCUSSION

The small intestine is an organ which is highly active in transport-mainly from the luminal to the basolateral side. It manages the complete absorption of all food constituents. The fact that the intestinal mucosa also has a secretory pathway towards the luminal site is a rather unrecognized feature. Thus, the high secretion rate at the basolateral side could be explained by the essential role of intestinal mucosal cells in the absorption process, in particular of lipids (high lipid throughput). After uptake of fatty acids, monoglycerides, lysophospholipids, and fat soluble vitamins into the mucosal cell, they are

**Figure 6** Effect of cyclosporine and hydrocortisone on PL secretion. Cyclosporine and hydrocortisone did not affect the amount or distribution of PL secretion at the apical (A) and basolateral side (B) ( $P = ns$ ).

resynthesized to complex lipids (triglycerides, phospholipids), bound to apolipoproteins, and secreted at the basolateral side of mucosal cells *via* a vesicular pathway<sup>[14,15]</sup>. In contrast, at the microvillous side of the plasma membrane, it is sufficient to utilize a low capacity PC secretory pathway because mucus resembles a low PC-turnover compartment. Our experiments support the notion, that there are two separate PC secretion pathways in intestinal epithelial cells: a high capacity basolateral and a low capacity apical vesicular excretion route. This now needs confirmation by cellular imaging techniques and the use of native intestinal mucosal cells. The fact that 60%-90% of the phospholipids in mucus represent PC<sup>[8,9]</sup>, indicates a specific PC secretion mechanism. The highly enriched PC arrangement within lamellar membranes establishes the protective hydrophobic surface layer of the mucus<sup>[8,9]</sup>. In the case of ulcerative colitis, where a decrease in the mucus PC levels was detected, this may be due to impairment of PC synthesis, PC loading of secretory vesicles, apical membrane fusion and PC release into the mucus or adherence to mucus proteins. After verification of the data in native mucosal cell models, the experimental system can be used to examine whether the PC secretion mechanism can be modified for therapeutic purposes.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Intestinal mucus and the mucosal barrier are very important aspects of intestinal disease.

### Research frontiers

Impaired mucosal barrier function, its pathophysiology and its impact on inflammatory bowel disease have become a very important focus of research.

### Innovations and breakthroughs

The pathway by which phosphatidylcholine is secreted into the intestine to form mucus is not yet known. In this paper we provide evidence, that there are two separate secretion routes.

### Applications

The used methodology and the acquired results might be the basis for future work, to confirm the data *in vivo* and to elucidate the role of phosphatidylcholine in pathophysiology.

### Terminology

Phospholipids, mainly phosphatidylcholine are the constituents of intestinal mucus. Due to their hydrophobicity they are part of the intestinal barrier.

### Peer review

The reviewers appreciated the innovative approach and techniques of this work. These data need to be confirmed in other experimental setups.

### Abstract

**AIM:** To evaluate the use of three-dimensional imaging of pancreatic carcinoma using multidetector computed tomography (CT) in a prospective study.

**METHODS:** Ten patients with suspected pancreatic tumors were examined prospectively using multidetector CT (Somatom Sensation 16, Siemens, Erlangen, Germany). The images were evaluated for the presence of a pancreatic carcinoma and invasion of the peripancreatic vessels and surrounding organs. Using the isotropic CT data sets, a three-dimensional image was created with automatic vascular analysis and semi-automatic segmentation of the organs and pancreatic tumor by a radiologist. The CT examinations and the three-dimensional images were presented to the surgeon directly before and during the patient's operation using the Medical Imaging Interaction Toolkit-based software "ReLiver". Immediately after surgery, the value of the two images was judged by the surgeon. The operation and the histological results served as the gold standard.

**RESULTS:** Nine patients had a pancreatic carcinoma

(all pT3), and one patient had a serous cystadenoma. One tumor infiltrated the superior mesenteric vein. The infiltration was correctly evaluated. All carcinomas were resectable. In comparison to the CT image with axial and coronal reconstructions, the three-dimensional image was judged by the surgeons as better for operation planning and consistently described as useful.

**CONCLUSION:** A 3D-image of the pancreas represents an invaluable aid to the surgeon. However, the 3D-software must be further developed in order to be integrated into daily clinical routine.

### INTRODUCTION

Pancreatic carcinomas are the fourth most frequent cause of death from cancer worldwide. The prognosis remains poor with a relative 5-year survival rate of about 5%. The only procedure resulting in significantly longer survival is R0 resection with adjuvant chemotherapy<sup>[1]</sup>.

Computed tomography (CT) is considered the method of choice for the detection and preoperative staging of pancreatic carcinomas<sup>[1-6]</sup>. Currently, 16- and 64-row spiral CTs are increasingly becoming available, and these offer improved local resolution over older models. The high-resolution data sets gained from these also offer the option of three-dimensional image post-processing<sup>[7,8]</sup>.

In planning an operation, the location of the pancreatic tumor relative to the surroundings, surgically relevant vessels and adjacent organs is of utmost importance to the surgeon. The option of being able to assess the tumor volume in relation to the pancreatic tissue can also represent further valuable information.

In liver surgery, three-dimensional imaging is increasingly being used for the interactive planning of surgery in complex partial liver resections and living donors. Special procedures are used which - in addition to visualization - permit volumetric assessment of the primary data. Systems which can be used to gain additional information from the layer data include HepaVision2 (MeVis GmbH, Bremen, Germany)<sup>[9]</sup>, LiverLive (Navidez Ltd., Ljubljana, Slovenia), and Medical Imaging Interaction Toolkit (MITK) ReLiver (Deutsches Krebsforschungszentrum, Heidelberg, Germany).

The prerequisite for such procedures is the pre-processing step of segmentation, during which interesting regions of the image are marked on the section images. In a previous study, we have already shown that three-dimensional imaging of pancreatic tumors with semi-automatic segmentation is possible analogously to hepatic imaging<sup>[10]</sup>.

The aim of this study is to test in a prospective, clinically controlled study, whether the three-dimensional images of the pancreas and the surrounding structures gained using the CT data sets are useful to the surgeon in planning operations and for intraoperative orientation in patients with pancreatic carcinoma.

## MATERIALS AND METHODS

Between March 2006 and August 2006, ten patients were included in the study with suspected operable pancreatic carcinoma. The criterion for inclusion in the study was urgent clinical suspicion of a pancreatic carcinoma. The study had the approval of the local ethics committee.

All patients underwent 16-row multislice CT (Somatom Sensation 16, Siemens, Erlangen, Germany), using the hydro technique with administration of Ultravist 370<sup>®</sup> (Schering, Berlin, Germany).

The operative findings and the histological results obtained during the operation served as the gold standard.

The evaluation was carried out by two experienced radiologists using a standardized evaluation form. This covered the location, size, and peripancreatic extent of the tumor. The resectability of the carcinoma was also assessed.

### 16-row spiral CT

Patients were examined using 16-row spiral CT (Somatom Sensation 16, Siemens, Erlangen, Germany) using the hydro technique. This involves distension of the stomach and duodenum using 1.5 L of still water, intestinal paralysis through intravenous administration of 40 mg N-butylscopolaminium bromide (Buscopan<sup>®</sup>) and positioning the patient on the right side at an angle of 30°<sup>[4,11]</sup>.

Firstly, a native spiral CT of the abdomen was carried out. Then an examination was carried out in the arterial

Table 1 Examination parameters

	Native CT	Arterial phase	Portal venous phase
Anode voltage (kV)	120	120	120
Anode current (mAs)	140	170	185
Detector collimation	1.5 (slice: 6 mm)	0.75 (slice: 3 mm)	0.75 (slice: 3 mm)
Table feed (mm)	24	12	12
Reconstructed slice thickness (mm)	6	2/1	1.3/3; 2.1/0.5
Delay (s)		8	35

phase (delay 8 s) and in the portal venous phase (delay 35 s) using the Combined Application Reduced Exposure bolus technique with 120 mL contrast medium (Ultravist<sup>®</sup> 370, Schering AG, Berlin, 5 mL/s) (Table 1).

### Three-dimensional imaging

The data sets obtained from CT were transmitted *via* an internal data connection (Chili, Heidelberg, Germany) to the Department of Medical and Biological Informatics at the German Cancer Research Center. There, the vascular structures were transferred to a semantic model in which the vascular branches could be individually colored, shown, or removed from view. All segmentations were carried out by a radiologist using the software program MITK ReLiver. During the process, the liver, kidneys, duodenum, stomach, pancreas, and pancreatic tumor were segmented using interactive segmenting tools in the section images. It was found to be particularly time-saving to use a combination of an interactive regional growth procedure and a form-based interpolation procedure<sup>[12]</sup>. On this basis, it was possible to reduce the interaction time to a necessary minimum. Subsequently, the data from the vascular trees, the individually segmented organs and the tumor were fused into a three-dimensional scene.

These freely rotatable images were presented to the surgeon before and during the operation above the OP field, analogous to the three-dimensional image of the liver<sup>[11]</sup>. The surgeon also saw the conventional CT images before the operation, which were also available to him in the operating theater on a monitor. After the operation, on a questionnaire, the surgeon assessed the value of the three-dimensional image compared with that of the conventional CT images (Table 2).

The questionnaire included comments about representation of the tumor, tumor location, tumor invasion of the vessels and surrounding organs, how well the imaging material matched the operative site, the manageability of the images, a score by which the surgeon could grade how secure he felt looking at the CT or three-dimensional images, and possible changes in the operative strategy.

The individual points on the questionnaire were graded with marks ranging from 1 for excellent to 5 for very bad.

### Statistical analysis

Using the Wilcoxon test, we examined whether the

**Table 2** Questionnaire put to the surgeon assessing the value of the three-dimensional image *vs* conventional CT images

Depiction of the tumor	
How well can the tumor localization be assessed?	1 = excellent; 2 = good; 3 = mediocre; 4 = bad; 5 = very bad
How well can vascular invasion be assessed?	
How well can organ invasion be assessed?	
How comfortable are you with the image?	
How well does the imaging material match the operative situation?	Completely; partially; not at all
How manageable was the 3D view in comparison with CT?	Less complicated; equally complicated; more complicated
Was the operating strategy changed due to the images?	Yes; no

**Table 3** Three-dimensional reconstruction *vs* CT

Patients	Tumor image		Tumor localization		Vascular invasion		Organ invasion		Feel-good score	
	CT	3D	CT	3D	CT	3D	CT	3D	CT	3D
Φ	2.2	1.4	1.8	1.6	2.2	2.2	2.0	1.6	2.4	1.2
<i>P</i> -value	0.157		0.564		1.0		0.157		0.063	

1 = excellent, 2 = good, 3 = mediocre, 4 = bad, 5 = very bad.

differences between the CT and three-dimensional images were statistically relevant. The *P* values were calculated using SPSS for Windows XP.

## RESULTS

In nine patients, a pylorus-preserving Whipple procedure was carried out. In one patient, explorative laparotomy was performed with placement of a biliodigestive anastomosis and a gastrojejunostomy, since the patient's advanced age (80 years) made a portal vein resection seem too stressful.

Nine patients had adenocarcinomas of the pancreas and one had a serous cystadenoma. All carcinomas had grown beyond the margins of the organ and invaded the peripancreatic lipid tissue and the duodenum, and were thus staged histologically as T3. In one patient, invasion of the superior mesenteric vein was found intraoperatively.

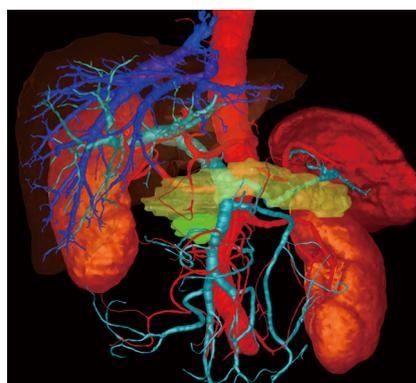

### Three dimensional imaging

The three-dimensional images of the pancreatic tumors, as evaluated on the questionnaire, were found to be graded more favorably with regard to assessment of tumor imaging, location, and invasion of the surrounding organs, and to the score indicating how secure the surgeon felt in assessing the images than the conventional CT examination. However, the differences were not statistically significant (*P* = 0.157, 0.564, 0.157, 0.063, respectively). In evaluating vascular invasion, the results were equally good for both procedures (*P* = 1.0) (Table 3).

The three-dimensional imaging correctly and completely matched the operative site in all cases.

The manageability of the three-dimensional image was deemed to be less complicated in four out of five cases and in one case to be equally good.

In one case the surgeon found that the three-dimensional image demonstrated much more clearly than the conventional CT image that there was no invasion of the portal vein (Figure 1). In a second case, extensive inva-

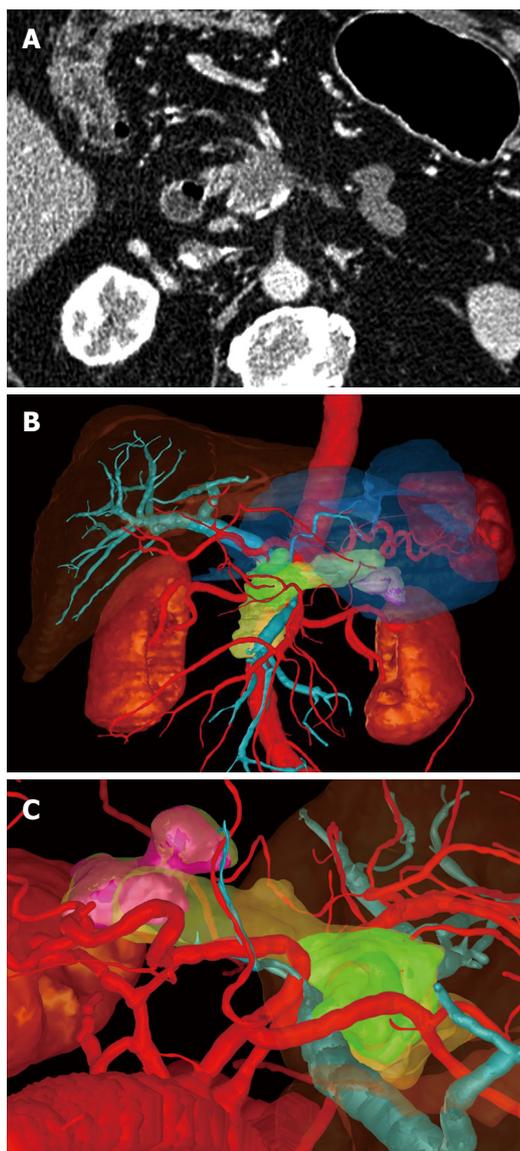

**Figure 1** Lateral view of the three-dimensional model of a pancreatic carcinoma (pale green) in the processus uncinatus. There is contact between the tumor and the superior mesenteric vein but no invasion.

sion of the portal vein by the tumor could be established in both types of image, but the extent of the invasion was demonstrated to the surgeon better in the three-dimensional image, enabling the tumor to be classified as a resectable stage T3 and explorative laparotomy was performed. Intraoperatively, this long-distance invasion was confirmed but no tumor resection was carried out due to the patient's advanced age; vascular replacement of the portal vein was deemed too stressful (Figure 2).

## DISCUSSION

Despite all the progress made in diagnosis and surgery, the prognosis for pancreatic carcinomas today is still poor. Surgical resection is the treatment of choice as a curative approach to pancreatic carcinomas. Thus, the main aim of diagnosis consists of correctly evaluating the surgically relevant vessels with regard to possible invasion in order to be able to safely distinguish between resectable and non-resectable pancreatic carcinomas.

Spiral CT is considered to be state of the art in the diagnosis of pancreatic carcinoma and in the evaluation of resectability in most centers<sup>[6]</sup>. The sensitivity of spiral

**Figure 2** Patient with stage T3 pancreatic carcinoma with portal vein invasion; the preoperative assessment was correct. A: Axial slice through tumor; B: Three-dimensional reconstruction, frontal view (tumor = pale green); C: Three-dimensional reconstruction, cranial view (tumor = pale green).

CT, as cited in the literature, for evaluating resectability in pancreatic carcinoma is between 81% and 96.3%<sup>[4,11,13-15]</sup>.

Due to the particular anatomical relationship between the pancreas and the surrounding vessels, three-dimensional reconstructions are helpful in presenting additional information about this relationship<sup>[16,17]</sup>.

For the surgeon, it is valuable to be able to see the tumor, both by itself and in the context of its surrounding structures, in three dimensions from all sides whereby particular interest is obviously accorded to the presence and extent of contact to the relevant vessels or surrounding organs. In addition, the surgeon can more easily assess the tumor volume in relation to healthy pancreatic parenchyma. With the aid of a freely rotatable, three-dimensional image, he can picture the extent of venous invasion more clearly (even before the operation) than is possible with two-dimensional, axial, coronal and sagittal images.

Thus, the surgeon is provided with as detailed a picture as possible of the field of operation even before the operation takes place. As far as we know, there are no studies so far available assessing the clinical value of three-dimensional image processing of pancreatic tumors. To date, the Harvard Medical School has produced reconstructions of the pancreas and the neighboring vascular systems, but has not clinically evaluated them<sup>[18]</sup>.

Three-dimensional reconstruction already has a firm place in orthopedics and neurosurgery, where only unmoving and fixed anatomical structures are represented without any great range of variation.

The use of this method in visceral surgery is more difficult, since the organs can move and in some cases are shifted and reshaped during respiration and since the rate of anatomical variability is high<sup>[10]</sup>.

In the field of hepatic imaging and in the context of living liver donors and before complex partial liver resections, three-dimensional imaging of the liver, hepatic vessels, and bile ducts has managed to become established in some centers. In this case, in addition to visualization, the volumetry of various liver sections is of interest. Moreover, the three-dimensional reconstruction can be used preoperatively to consider various resection options and to evaluate their technical feasibility with regard to vascular and bile duct anatomy and to the expected liver volume after surgery.

The prerequisite for three-dimensional imaging of the primary data is semiautomatic segmentation of the structures of interest such as pancreas, tumor, stomach, liver, spleen, kidneys and any cysts that might be present. In pancreatic tumors, however, the segmentation process is particularly time-consuming and problematic, since the margins between organ tissue and inflammatory processes or of the tumor and surrounding structures are hard to recognize due to growth beyond the organ borders. In addition, the preparation of data includes all important organs and vascular structures in the abdominal cavity in order to provide the surgeon with a maximum amount of context information so that possible problems in exposure of the pancreas can be included in the surgical planning.

This means that the reconstruction procedure for visualizing pancreatic carcinomas today still requires a great amount of effort both technically and in terms of time required. In addition, an objective and precise localization of the tumor is not possible because segmentation is always conducted according to the subjective interpretation of the radiologist.

An automatic image processing procedure cannot be used for segmenting the tumor since the differences in thickness between organ tissue and tumor are sometimes very slight and cannot be recognized by a computer program. However, there are very promising approaches to segmenting the organs which make a largely automatic procedure seem tangible. Statistical form models learn the mean organ form with its variants from training data. Using even the current models, it can be shown that the work of segmentation can be significantly reduced for the liver<sup>[19]</sup>.

For vessels, no automatic segmentation program

exists that can independently mark vascular cross-sections by using the good contrast provided by the various contrast medium phases of the CT examination and the high contrast differences associated with it. Three-dimensional imaging of the vessels, moreover, only depicts the inside of the visualized vessel since the contrast medium that is used for processing the reconstruction only fills the vascular lumen.

Tumor invasion of the relevant vessel can thus only be indirectly visualized, just as with two-dimensional CT images, e.g. on the basis of a sudden difference in vessel caliber or complete vascular occlusion.

In the present study, three-dimensional post-processing of the data sets was highly acclaimed by the surgeons. Analysis of the questionnaire showed that the three-dimensional image was graded better in most points than conventional CT images. Only evaluation of the vessels was graded equally for both procedures.

The so-called “feelgood score” was better for the three-dimensional image than the two-dimensional image in all the cases.

This explains why in two cases the surgeon indicated that he found extensive portal vein invasion and exclusion of portal vein invasion to be much clearer for him on the three-dimensional image than on the conventional CT images.

The manageability of the three-dimensional image in comparison to the conventional CT images was deemed less complicated in four out of five cases. In all the cases the findings presented in the three-dimensional image material matched the intraoperative situation completely.

In complex liver surgery, three-dimensional visualization has already been shown to meet with high acclaim by surgeons. Its advantage consists in providing the surgeon with information about vascular anatomy that is indispensable for planning living liver transplantation or in providing additional information about the percentage of residual hepatic tissue following resection.

In their clinical study of the value of three-dimensional data sets before complex liver resections and before living liver donations, Fischer and Lamade found that although three-dimensional presentation did not lead to an improved segment allocation of hepatic tumors in comparison to axial sections, the three-dimensional presentation meant that the position of the tumor within the liver as marked on a liver model was significantly improved. It was shown that the three-dimensional presentation did indeed lead to improved OP representation. Overall, three-dimensional presentation led to approaching a 31% higher precision in tumor localization and improvement in resection recommendations.<sup>[20,21]</sup>

This study also illustrated the disadvantage of this method. The three-dimensional representation of the findings can only be as good as the primary data sets from CT in conjunction with the experience of the radiologist in evaluating CT data. If contact between the tumor and the encircling wall of a vessel can be visualized over a long distance on CT, this will also be visible in the three-dimensional image and can be interpreted in most cases, and in both procedures, as invasion of the relevant vessel.

The three-dimensional reconstruction cannot improve on the examination; it can only present the situation in a more plastic form.

A three-dimensional image will thus generally not improve the assessment of the resectability of pancreatic carcinomas. Overall, this new procedure, however, seems to provide a good aid in preoperative planning for the surgeon in surgical therapy of pancreatic carcinoma.

It remains to be seen whether the method, which still involves a great deal of effort, will stand the test of practical daily routine or if the time and technical input necessary for post-processing the image material is too high to be integrated practically into clinical routine or if these factors can be significantly reduced.

One restriction on the present study is the very small case number. The calculated *P* values showed no significant differences. Thus further studies should be conducted with a larger number of patients.

In summary, it can be said that three-dimensional imaging of pancreatic carcinomas with the surrounding vessels and organs is currently constrained by the great deal of effort involved, but it does primarily provide the surgeon with valuable additional information.

## COMMENTS

### Background

In planning a resection of a pancreatic carcinoma, the location of the pancreatic tumor relative to the surroundings, surgically relevant vessels and adjacent organs is of utmost importance to the surgeon.

### Research frontiers

The aim is to provide better visualization of pancreatic carcinoma and peripancreatic vessels for the surgeon in the preoperative period.

### Innovations and breakthroughs

In complex liver surgery, three-dimensional visualization has already been shown to meet with high acclaim by surgeons, but this study is the first which used this technique in pancreatic carcinoma patients. Its advantage consists in providing the surgeon with information about peripancreatic vascular anatomy that is helpful for planning the resection of a pancreatic carcinoma.

### Applications

A three-dimensional image of the pancreas represents an additional, valuable aid to the surgeon. However, this method is still time-consuming. The software must be further developed to allow further automation of the segmentation to enable it to be integrated into daily clinical routine.

### Terminology

Segmentation: To circumscribe a freehand region-of-interest on each single CT-slice, where, for example, the tumour or the pancreas is seen.

### Peer review

This is a pilot study of 10 consecutive patients with suspected pancreatic carcinoma subjected to preoperative 3-D spiral CT reconstruction. This is the first such clinical study utilizing this technique.

### Abstract

**AIM:** To evaluate the utility of assessing iodized oil uptake with cone-beam computed tomography (CT) in transarterial chemoembolization (TACE) for small hepatocellular carcinoma (HCC).

**METHODS:** Cone-beam CT provided by a biplane flat-panel detector angiography suite was performed on eighteen patients (sixteen men and two women; 41-76 years; mean age, 58.9 years) directly after TACE for small HCC (26 nodules under 30 mm; mean diameter, 11.9 mm; range, 5-28 mm). The pre-procedural locations of the tumors were evaluated using triphasic multi-detector row helical computed tomography (MDCT). The tumor locations on MDCT and the iodized oil uptake by the tumors were analyzed on cone-beam CT and on spot image directly after the procedures.

**RESULTS:** All lesions on preprocedural MDCT were detected using iodized oil uptake in the lesions on cone-beam CT (sensitivity 100%, 26/26). Spot image depicted

### INTRODUCTION

Transarterial chemoembolization (TACE) is a regional therapeutic modality that has become an accepted treatment for unresectable hepatocellular carcinoma (HCC). Triphasic multi-detector computed tomography (MDCT) is commonly used for the detection and preprocedural localization of hypervascular HCCs greater than 1 cm in diameter<sup>[1-3]</sup>.

Diagnostic angiography using digital subtraction angiography (DSA) is performed before TACE in order to detect hypervascular HCCs. Occasionally, the small neoplastic foci are uncertain, and difficult to detect. Some studies have reported that the detection rate of small HCCs, less than 3 cm, in DSA was about 70%<sup>[4,5]</sup>, and other studies showed higher sensitivity in nodule detection in helical biphasic CT than in DSA<sup>[6]</sup>. This discrepancy can make it difficult to determine whether or not the same nodules exist on MDCT in cases of small tumor nodules.

Iodized oil retention pattern after TACE is a post-treatment prognostic marker and significant factors affect

local recurrence<sup>[7-9]</sup>, however, a method for evaluating this immediately after TACE, is to take a spot image. Follow-up unenhanced CT is usually performed within 1 mo after TACE, but it is sometimes difficult to determine whether there is washout of iodized oil uptake or initial failure of iodized oil uptake when there is partial iodized oil uptake in a lesion on the first follow-up CT. The exact method for comparing iodized oil retention in hypervascular nodules on preprocedural MDCT is to check the postprocedural CT directly after TACE and for this the patient must be transported from the angiography suite to the nearest CT scanner.

Cone-beam CT is a new technology provided by the combined angiography/CT suite that uses flat-panel detector (FD) technology. It provides images similar to those of CT and is able to obtain 3D reconstructions such as multiplanar reformat (MPR), maximum intensity projection (MIP), and 3D volume rendering (VR) with these data sets.

The purpose of this study was to evaluate the clinical value of cone-beam CT in the assessment of iodized oil uptake in TACE for small HCCs.

## MATERIALS AND METHODS

### Patients

From March 2006 to June 2006, eighteen patients (sixteen males and two females; 41-76 years; mean age, 58 years) with small HCCs (26 nodules; mean diameter 11.9 mm; range, 5-28 mm), underwent cone-beam CT and TACE consecutively. All patients had underlying liver cirrhosis. The diagnosis of HCC was made clinically in these patients by using typical imaging findings on MDCT and an elevated level of serum alpha fetoprotein. The size and location of the tumors were evaluated with triphasic MDCT before TACE (Figures 1 and 2). Eleven patients had previously undergone TACE for multiple nodules. The first TACE was performed in seven patients who were not candidates for surgery. According to our institutional guidelines, institutional review board approval was not required for this report.

### TACE

Angiography was conducted using the AXIOM Artis FD Biplane Angio suite with cone-beam CT (DynaCT, Siemens Medical Solutions, Erlangen, Germany). For angiography, a 5-Fr catheter was inserted using the Seldinger technique from the right common femoral artery into the celiac trunk. After confirming the location of the tumor and its feeding artery, a 3-Fr 100-cm-long microcatheter (Progreat; Terumo, Tokyo, Japan) with a 0.016-inch, 150-cm long guidewire covered by hydrophilic polymer (Radiofocus; Terumo, Tokyo, Japan), was advanced through a 5-Fr catheter into the peripheral portion of the feeding artery as close to the lesion as possible (Figures 1 and 2). If tumor staining or feeders were uncertain, cone-beam CT hepatic arteriography (cone-beam CTHA) was performed (contrast media injection rate was 2 mL/s; X-ray delay used in 1.5 s). After these baseline studies, TACE using an emulsion of epirubicin hydrochloride (Pharmorubicin; Ildong, Seoul, Korea) dissolved in me-

Discordance between the two modalities-5 nodules [over-: 9% (2/22), underestimated: 14% (3/22) in spot image]. CT: Computed tomography.

glumine ioxitalamate (Telebrix; Guerbet, Aulnay-sous-Bois, France) mixed with iodized oil (Lipiodol Ultra Fluid; Guerbet, Aulnay-sous-Bois, France) was performed. The end point of TACE was when an "oily portogram" was achieved. Finally, spot image and cone-beam CT were performed to determine the deposition of iodized oil.

### Cone-beam CT

Cone-beam CT acquisition was obtained using the following parameters: 10-s rotation; 0.4° increment; 1024 × 793 matrix in projections at zoom 0 after resampling; 217° total angle; and 11°/s, 27 frames/s, system dose 0.36 μGy/pulse, total 273 projections. The image reconstruction was performed on a commercially available dedicated workstation (X-Leonardo with DynaCT; Siemens Medical Solutions). The volume dataset was displayed on the monitor in the MPR.

### Image analysis

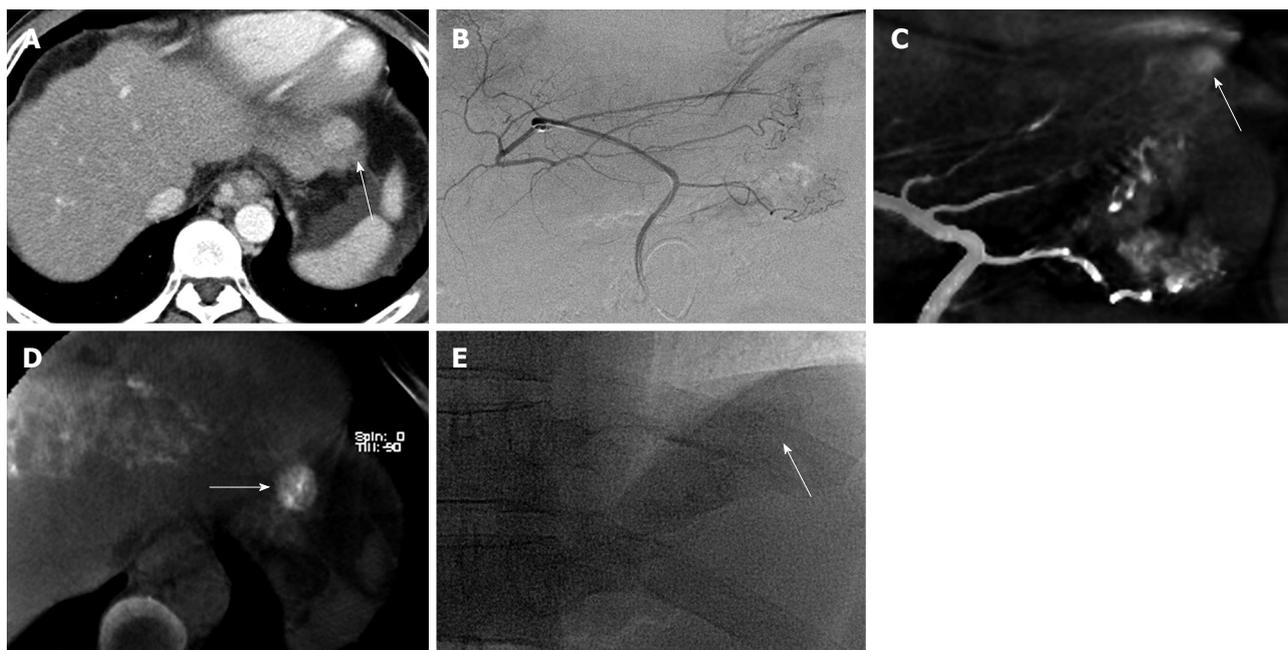

The tumor locations, as shown on MDCT, iodized oil uptake by the tumor in the lesion on cone-beam CT and spot image, were determined directly after the procedures were analyzed. The enhancing tumor locations as shown on MDCT and iodized oil uptake by the tumors were compared. The degree of iodized oil uptake by the tumor (excellent, 100% deposition of iodized oil in the lesion; good, 51%-99%; poor, ≤ 50%) on cone-beam CT and spot image were also compared. The spot images were evaluated at the workstation, while cone-beam CT images were evaluated by images created by MPR, and MIP (maximum intensity projection). All images were graded by two radiologists, and decisions were reached by consensus.

## RESULTS

Cone-beam CT was successfully completed in all study patients. It only took about 5 min to obtain MPR images. Cone-beam CT visualized the iodized oil uptake in all the nodules (26/26, sensitivity 100%), but spot image only visualized iodized oil uptake in 22 of the lesions (sensitivity 85%) (Figures 1 and 2).

### Degree of iodized oil uptake in tumors

The degree of iodized oil uptake was somewhat different in the two modalities (Table 1). Cone-beam CT depicted iodized oil uptake in the nodules more clearly than spot image. Two nodules were not seen in spot image but were clearly evaluated with cone-beam CT. There was discordance between the two modalities in 5 nodules and

**Figure 1** A 47-year-old man with hepatocellular carcinoma in S2 for 2nd TACE. A: Preprocedural late arterial phase MDCT scan reveals hypervascular HCC near the diaphragm (arrow); B: Left gastric angiogram shows aberrant left hepatic artery with no tumor staining in suspected area; C: Tumor staining (arrow) and feeder artery are found after acquiring MIP image from cone-beam CT hepatic arteriography (Cone-beam CTHA); D: Cone-beam CT directly after TACE shows good grade iodized oil uptake in S2 (arrow); E: Spot image shows subtle lipiodol uptake near the left hemidiaphragm (arrow), but nodular iodized oil uptake is not observed.

**Table 2** Degree of iodized oil uptake by the tumors according to size

Size	Degree of iodized oil uptake in spot image			Degree of iodized oil uptake in cone-beam CT		
	Excellent	Good	Poor	Excellent	Good	Poor
≤ 1	5	3	1	7	4	
≤ 2	6	4	2	8	2	3
≤ 3		1		1	1	
Total	11	8	3	16	7	3

Discordance in degree of iodized oil uptake occurred in nodules less than 2 cm (3 nodules less than 1 cm).

iodized oil uptake was over-(9%, 2/22) or underestimated (14%, 3/22) in spot image compared with cone-beam CT.

The iodized oil uptake in 4 nodules was not seen in spot image, two nodules were less than 1 cm, one was between 1 cm and 2 cm, and one was over 2 cm. The discordance between the two modalities occurred in nodules less than 2 cm (Table 2).

**Nodules with atypical enhancement patterns in MDCT**

Three nodules showed atypical enhancement patterns in MDCT, and additional dynamic magnetic resonance imaging (MRI) was performed for one nodule (Figure 2). Their feeders were uncertain on selective right or left hepatic arteriography, but were detected with cone-beam CTHA. Enhancement patterns and iodized oil uptake in the nodules are shown in Table 3.

**DISCUSSION**

Several treatment options for small HCCs have been

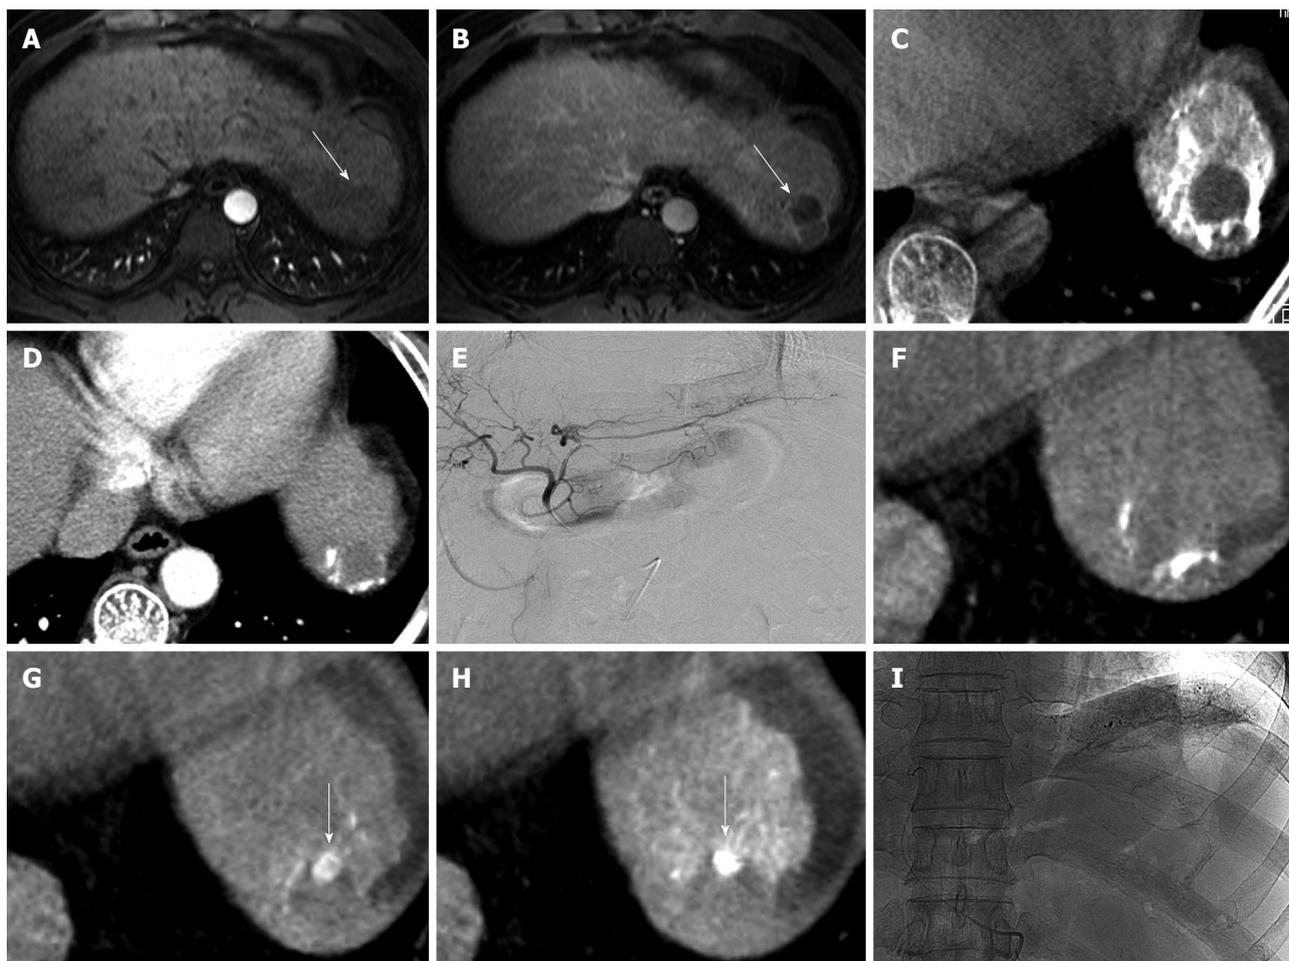

**Table 3** Enhancement patterns and iodized oil uptake in three nodules without typical enhancement patterns of HCCs on MDCT and MRI

Nodule	Modality	Phase		Degree of iodized oil uptake	
		EA	Delayed	Spot image	Cone-beam CT
1	CT	Subtle E	Washout	Poor	Poor
2 <sup>1</sup>	CT	No E	No E	Poor	Excellent
3	MRI	Subtle E	Washout	Invisible	Good

<sup>1</sup>Same patient in Figure 2. EA: Early arterial phase; Delayed: Delayed phase; Subtle E: Subtle enhancement; No E: No enhancement. HCC: Hepatocellular carcinoma; MDCT: Multi-detector row helical computed tomography; MRI: Magnetic resonance imaging.

introduced for patients who are not surgical candidates. These options include TACE, percutaneous ethanol injection (PEI), radiofrequency ablation (RFA), microwave coagulation therapy (MCT), laser thermal ablation (LTA), and combination therapy<sup>[10,11]</sup>. Among them, TACE is widely performed, because it is minimally invasive, repeatable, and more effective in combination with other treatments<sup>[10-13]</sup>.

TACE was found to be as effective as hepatic resection for early stage tumors when iodized oil was compactly retained within the tumor<sup>[8]</sup>. Iodized oil uptake pattern can be a prognostic index<sup>[7]</sup>. Various studies have suggested that iodized oil uptake in a tumor can correlate well with hepatic necrosis, and compact iodized oil uptake on unenhanced CT may represent necrosis<sup>[16,17]</sup>. Takayasu *et al*<sup>[6]</sup> reported that the highest degree of necrosis usually occurs immediately after TACE and the regrowth of viable cancer cells will occur later if complete necrosis of the tumor was not achieved. At this

**Figure 2** A 52-year-old man with HCC in S2 for 2nd TACE. A, B: Early arterial phase (A) and delayed phase (B) of MRI reveals nodule (arrow) in segment 2 with no enhancement (arrow); C: Cone-beam CT after TACE shows poor grade of iodized oil uptake by the tumor; D: Early arterial phase of MDCT shows washout of iodized oil uptake near nodule, but no enhancing portion within the nodule 3 mo later; E: Left hepatic angiogram during TACE reveals no tumor and feeding artery 1 mo later; F, G: Cone-beam CT with (F) and without (G) hepatic arteriography shows small enhancing nodule (arrow) in the nodule; H, I: Cone-beam CT after infusion of emulsion (H) shows excellent grade iodized oil uptake by the nodule (arrow). This case shows typical "nodule-in-nodule" appearance of HCC, but spot image (I) did not distinguish nodular uptake.

point, compact iodized oil uptake by the tumor directly after the procedure prevents regrowth of tumors, but to confirm this, only spot image is usually acquired. If the tumor is large enough to appear on spot images, it is easy to determine the degree of iodized oil uptake, but if the tumor is small, especially less than 2 cm, the degree of iodized oil uptake is incorrectly determined, which can cause tumor regrowth. It is also impossible to refuse chemotherapeutic agents directly if there is partial iodized oil uptake in a lesion on the first follow-up CT.

Cone-beam CT was first used in neuroendovascular procedures, and the image quality is sufficient to make a diagnosis when a complication is suspected<sup>[18]</sup>. In the era of assessing the degree of iodized oil uptake, cone-beam CT is also a convenient tool during and after TACE and clearly correlates with MDCT. If cone-beam CT images shows non-compact iodized oil uptake, immediate re-intervention can be achieved. The disadvantages of this CT-like image are low temporal resolution and a small field of view, however, it is sufficient to locate lesions previously diagnosed on MDCT<sup>[19]</sup>.

Takayasu *et al*<sup>[9]</sup> reported "targeted transarterial oily chemoembolization" which is a similar method to ours,

but these authors used a unified helical CT and angiography system. Our system is only a DSA machine without a helical CT system and has more simple structures.

The radiation dose from cone-beam CT was not measured, however, Hirota *et al*<sup>[20]</sup> measured the radiation dose of cone-beam CT with a flat-panel-detector digital angiography system (similar system with ours) and single helical CT using a cylindrical phantom model of CT dose index with a dosimeter. They reported that the radiation dose by cone-beam CT was less than that of single helical CT. In addition, the radiation dose from cone-beam CT can be calculated *via* a pre-set radiation dose (0.36  $\mu$ Gy/pulse) and total fluoro time (7.5 pulse/s, 10 s). Compared with nonenhanced MDCT for TACE follow-up, the calculated radiation dose of cone-beam CT is low.

Cone-beam CTHA placing the microcatheter in the nearest arteries was performed in only three nodules in this study. Another study<sup>[20]</sup> also reported this method, and this technique is very useful to confirm a perfusion area in the artery. Although a small number of cases were included in this study, this method is a very useful and time-saving technique in TACE and other interventional procedures, especially for small lesions.

In conclusion, cone-beam CT is a useful and convenient tool for assessing the iodized oil uptake by small hepatic tumors (< 3 cm) directly after TACE. In addition, in cases with suspected small HCC nodules without typical enhancement patterns on CT, cone-beam CTHA will be very useful, however, further study is required.

## COMMENTS

### Background

Iodized oil retention pattern after transarterial chemoembolization (TACE) is a posttreatment prognostic marker, and significant factors affect local recurrence, however, a method for evaluating this immediately after TACE is to take a spot image. Follow-up unenhanced computed tomography (CT) is usually performed within 1 mo after TACE, but it is sometimes difficult to determine whether there is washout of iodized oil uptake or initial failure of iodized oil uptake when there is partial iodized oil uptake in a lesion on the first follow-up CT.

### Research frontiers

Comparing iodized oil retention in small hypervascular nodules on preprocedural multi-detector row helical computed tomography (MDCT) directly after TACE is possible without transporting patients from the angiography suite to the nearest CT scanner.

### Innovations and breakthroughs

In the present study, the authors investigated the efficacy of cone-beam CT with regard to iodized oil uptake after TACE for small hepatocellular carcinoma (HCC)s.

### Applications

The study showed that cone-beam CT is a useful and convenient tool for assessing the iodized oil uptake by small hepatic tumors directly after TACE.

### Terminology

Cone-beam CT is a new technology provided by the combined angiography/CT suite that uses flat-panel detector technology. It provides images similar to those of CT and is able to make 3D reconstructions such as multiplanar reformat, maximum intensity projection, and 3D volume rendering with these data sets.

### Peer review

This is an interesting study which shows the advantages of assessing iodized oil uptake after TACE for small HCC with cone-beam CT. It may provide useful information for us.

### Abstract

**AIM:** To study the clinical outcomes of medical therapy in patients with right colonic diverticulitis.

**METHODS:** The records of 189 patients with right colonic diverticulitis which was finally diagnosed by computed tomography, ultrasonography, or operative findings were retrospectively reviewed.

**RESULTS:** Of the 189 patients hospitalized for right colonic diverticulitis, the stages of diverticulitis by a modified Hinchey classification were 26 patients (13.8%) in stage 0, 139 patients (73.5%) in stage I a, 23 patients (12.2%) in stage I b, and 1 patient (0.5%) in stage III. Medical therapy was undertaken in 185 of 189 patients (97.9%). One hundred and eighty three of 185 patients were successfully treated with bowel rest and antibiotics. Two patients in stage I b required a resection or surgical drainage because of an inadequate response to conservative treatment. Recurrent diverticulitis developed in 15 of 183 patients (8.2%) who responded to medical therapy. All 15 patients who suffered a second attack had uncomplicated diverticulitis, and were successfully treated with medical therapy.

### INTRODUCTION

Interestingly, there is a unique predilection for diverticular disease of the colon in Western and Asian populations, and is predominant in the left colon in Caucasians<sup>[1]</sup>, while much more common in the right colon in Asians<sup>[2]</sup>. Many studies have focused on left colonic diverticulitis and subsequently, therapeutic guidelines have been established, while that of right colonic diverticulitis still remains controversial<sup>[2-8]</sup>. In the past, the majority of patients with right colonic diverticulitis were faced with an operation for presumed appendicitis<sup>[3,4,9]</sup>. Thus, there is a lack of objective information for patients with right colonic diverticulitis compared with left colonic diverticulitis. Much of this information is based on case series data, which have relatively small sample sizes and the preoperative diagnosis was not made using imaging studies. Recent studies suggest that colonic diverticulitis can be correctly diagnosed by computed tomography (CT) scan<sup>[6,7,10]</sup>, or ultrasonography (US)<sup>[11-14]</sup>, and with the use of these imaging studies, right colonic diverticulitis is more common than has been previously assumed<sup>[7]</sup>. The aim of this study was to evaluate the clinical course and results of medical therapy in patients with right colonic diverticulitis, of which the final diagnosis was based on radiographic evidence from CT or US, or operative findings.

## MATERIALS AND METHODS

### Patients

Using computerized patient databases, we searched for all patients who were hospitalized with the diagnosis of colonic diverticulitis from January 1998 to August 2007 at Kyung Hee University Hospital, Seoul, Korea. Excluded were patients who were clinically suspected of having colonic diverticulitis without operative findings or radiologic evidence from CT or US, patients whose colonic diverticulosis alone was present without any evidence of inflammation, and those whose follow-up records were unobtainable. A total of 189 patients were retrospectively reviewed and data were collected with regard to age and sex, clinical presentation, location of disease, diagnostic studies (CT, US, barium enema, and colonoscopy), laboratory findings, type of complication, treatment modality, preoperative diagnosis, operative findings, type of operation, and outcome. The final diagnosis was based on radiographic evidence from CT or US, or operative findings. CT was performed in 138 patients (73%) and US was performed in 114 patients (60.3%). Both CT and US were performed in 80 patients (42.3%) and 17 patients underwent surgery without CT or US. Recurrence of diverticulitis was defined as the presence of the same symptoms and signs leading to re-hospitalization. Recurrence was tracked either by interviewing the patient or by telephone contact.

A modification of the Hinchey classification system was used to define the patients<sup>15,16</sup>. Patients were categorized into the six stages according to CT, US, or operative findings. Complicated diverticulitis is defined as diverticulitis associated with abscess, fistula, obstruction, or free perforation<sup>17</sup>. Therefore, uncomplicated diverticulitis included stage 0 and I a, whereas complicated diverticulitis included stage I b, II, III, and IV.

The data were analyzed using the chi-square test or Fisher's exact test. All *P* values of less than 0.05 were considered to be statistically significant.

## RESULTS

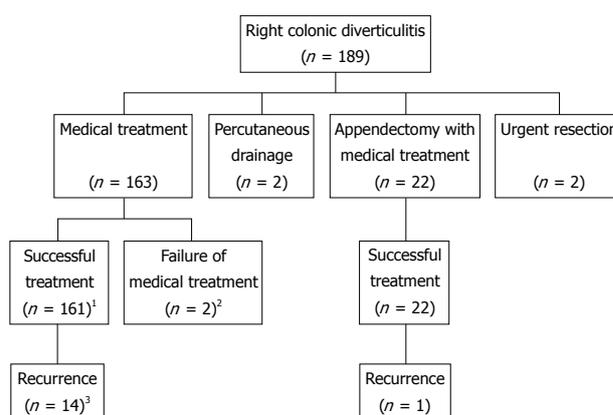

### Characteristics and presentation of patients

Of the 189 patients hospitalized for right colonic diverticulitis, 111 were men and 78 were women. The median age of the patients was 37 years (range, 14–88 years). The mean age of women (40.4 years) was not significantly different from that of men (36.7 years) (*P* = 0.088). One hundred and eight patients (57.1%) were under the age of 40 years. By a modified Hinchey classification, stages of diverticulitis present on admission were as follows: 26 patients (13.8%) in stage 0, 139 patients (73.5%) in stage I a, 23 patients (12.2%) in stage I b, and 0 (0%), 1 (0.5%), 0 (0%) patient in stage II, stage III and stage IV, respectively (Table 1). The majority of patients commonly presented with phlegmon. The majority of patients (87.3%) had mild diverticulitis (stage 0 or I a) on admission and only 24 patients (12.7%) had complicated diverticulitis. The average white blood cell count was  $11417 \pm 275$ . Fever was seen in 20.6% of patients.

**Table 1** Presentation of patients by a modified Hinchey classification<sup>15</sup>

Modified Hinchey classification	Total (n = 189)
0 Direct visualization of the diverticulum with Sx or Sign <sup>1</sup>	26
I a Confined pericolic inflammation (phlegmon)	139
I b Confined pericolic abscess	23
II Distant intraabdominal or retroperitoneal abscess	0
III Generalized purulent peritonitis	1
IV Fecal peritonitis	0

<sup>1</sup>Right abdominal pain, leukocytosis, or fever with no radiologic evidence of appendicitis. Sx: Symptom.

**Figure 1** Treatment and outcome of 189 patients with right colonic diverticulitis. <sup>1</sup>After successful medical treatment, seven patients had elective surgery at the surgeon's request; <sup>2</sup>One patient required a resection and another underwent surgical drainage; <sup>3</sup>After successful medical treatment, five patients had elective surgery at the surgeon's request.

### Treatment

Patients were initially managed with medical therapy alone, percutaneous drainage, or an urgent operation. Elective surgery was determined after a cooling-off period. Medical therapy was undertaken in 185 of 189 patients (97.9%), including 22 patients who incidentally underwent an appendectomy for presumed appendicitis (Figure 1). Two patients in stage I b underwent percutaneous drainage and two patients (one in stage I b and one in stage III) underwent urgent surgery (1 ileocecal resection, 1 right hemicolectomy). One hundred and eighty three of 185 patients were successfully treated with bowel rest and antibiotics. However, two patients in stage I b required a resection or surgical drainage because of an inadequate response to conservative treatment. Seven patients who were successfully treated with bowel rest and antibiotics had an elective operation at the surgeon's request.

### Recurrence

Recurrent diverticulitis developed in 15 of 183 patients (8.2%) who responded to medical therapy. The median interval to the onset of recurrence was 11 mo (range, 0.5–96 mo). The median disease free period was 44 mo (range, 0.5–129 mo). All 15 patients who suffered a

second attack had uncomplicated diverticulitis, and were successfully treated with medical therapy. One patient, an 80-year-old woman, experienced five episodes of right colonic diverticulitis, which were uncomplicated and successfully treated with medical therapy. Five of these 15 patients had an elective operation at the surgeon's request after successful conservative treatment. There were no deaths in these patients with right colonic diverticulitis.

### **Pathology and follow-up study**

A total of 15 patients underwent colonic resection. Nine of these 15 patients were reported to have multiple false diverticula. The pathologic reports of the other six patients contained no mention of the type of diverticulum.

During the original hospitalization, CT or US was supplemented by colonoscopy or double-contrast barium enema in 31 patients. In addition, 1 mo after recovery from an initial episode of diverticulitis, 60 patients agreed to re-evaluation by double-contrast barium enema (54 patients) or colonoscopy (six patients). In a total of 87 patients, including four patients duplicated, multiple diverticula were reported in 62 patients (71.3%) and a solitary diverticulum was reported in 13 patients (14.9%). The number of diverticulum could not be identified in 12 patients due to poor bowel preparation.

## **DISCUSSION**

The Hinchey classification and its several modifications have been used to define the stages of acute diverticulitis although the systems were mostly applied to left colonic diverticulitis<sup>[15,18]</sup>. In the present study, the diagnosis of right colonic diverticulitis was made in 167 of 172 (97%) patients using CT or US. The original Hinchey classification is not detailed enough to reflect right colonic diverticulitis with which the majority of patients have mild forms. We therefore used a modified system including subcategories in the early stage<sup>[15,16]</sup>. The majority of patients (87.3%) had uncomplicated diverticulitis (stage 0 or I a) on admission and the other patients even those with complicated diverticulitis had a relatively early stage (stage I b) such as pericolic abscess with the exception of one patient (stage III).

To date, no therapeutic guidelines for patients with right colonic diverticulitis have been established<sup>[5,6,9,19-21]</sup>. In contrast, practice parameters for the treatment of left colonic diverticulitis do exist<sup>[17]</sup>. Conservative treatment is recommended for uncomplicated left colonic diverticulitis because it results in resolution of the problem in 70% to 100% of patients<sup>[22-29]</sup>. In our study, all of the 165 patients with uncomplicated right colonic diverticulitis (stage 0 or I a) were successfully treated with bowel rest and antibiotics, including 22 patients who underwent an appendectomy for presumed appendicitis. We believe that patients with uncomplicated right colonic diverticulitis can be successfully treated with medical treatment in the same way as those with uncomplicated left colonic diverticulitis.

However, some authors advocate surgical resection for right colonic diverticulitis encountered during surgery

for presumed appendicitis<sup>[3-5]</sup>. Lo *et al*<sup>[3]</sup> reported their experience of 22 patients over an 11-year period. They performed preoperative US and CT in only one patient. At operation, an inflammatory phlegmon or indurated mass was found in 18 patients, however, colectomy with primary ileocolic anastomosis was performed in 21 patients including these 18 patients. Lane *et al*<sup>[4]</sup> reported a series of 49 patients over a 22-year period. The authors stated that because the pathophysiology of cecal diverticula may be different in the Asian population and the recurrence of symptoms may be more common in the Western population, conservative management may not be applicable to the Western population. A correct radiologic diagnosis was preoperatively made in only three patients. Immediate right hemicolectomy was performed in 39 patients at the time of laparotomy, but operative findings or the severity of diverticulitis was not provided. Fang *et al*<sup>[5]</sup> analyzed 85 patients during a 5-year period. Thirty four patients had right hemicolectomy, 9 patients had diverticulectomy, and 42 patients received conservative treatment (antibiotics or appendectomy plus antibiotics). In 34 patients receiving right hemicolectomy, the indications for surgery included repeated attack of symptoms in six and phlegmon, abscess, or perforation of the diverticulum in ten. In 42 patients receiving conservative treatment, ten patients developed recurrent diverticulitis and only three of these ten patients had complicated diverticulitis. However, the authors mentioned that the disease process of cecal diverticulitis might not be benign and recurrence of diverticulitis should be an indication for aggressive resection. In the above studies, we guess that all patients who underwent colonic resection would not essentially require surgery, and conservative treatment alone might have been sufficient in some patients. We believe that the correct pretreatment diagnosis for right colonic diverticulitis does not only avoid unnecessary surgery but also allows clinicians to determine optimal management according to the severity of the diverticulitis.

It is uncertain whether the pathophysiology of right colonic diverticulitis is really different between Asian and Western populations. Oudenhoven *et al*<sup>[7]</sup> reviewed 44 patients with right colonic diverticulitis in a Western population (including one Asian patient). Forty one patients were successfully treated conservatively and three patients underwent diverticulectomy. They concluded that the natural history of right colonic diverticulitis is benign and surgical intervention can be avoided in the vast majority of patients. In a large post-mortem survey of diverticular disease, Hughes<sup>[1]</sup> reported that the incidence of solitary cecal diverticula lies between 2.5% and 5%. Histologically all the diverticula were thin-walled, false diverticula and no case of cecal diverticulum had muscle in its wall. The author mentioned that congenital cecal diverticulum may largely be a pathological myth. Graham and Ballantyne<sup>[9]</sup> reviewed the American experiences. Among 128 histologic cases compiled from the medical literature, they found that 52 (41%) were true diverticula while 76 (59%) were, in fact, false diverticula. In addition, among 288 cases gathered from the literature, 233 (81%) were solitary, while 55 (19%) were multiple. In the

present study, nine of 15 patients who underwent colonic resection were reported to have multiple false diverticula. Of 87 patients receiving double-contrast barium enema or colonoscopy, multiple diverticula were reported in 62 patients (71.3%) and solitary diverticulum was reported in 13 patients (14.9%). The incidence of true or false diverticula in the right colon is not well known, particularly between Western and Asian populations. This is because the pathologic differentiation between true and false diverticula may be difficult once inflammation occurs<sup>[4]</sup>, and to our knowledge, the type of diverticula in right colonic diverticulitis has not been pathologically described in the Asian literature.

Some authors who advocate aggressive resection for right colonic diverticulitis assert that leaving the diseased foci *in situ* with the possibility of developing some serious complications later seems to be impractical and recurrence of diverticulitis should be an indication for aggressive resection. If recurrence is high and complications frequent, surgical resection is essentially required. However, after successful conservative treatment, a recurrence rate of 3.6% to 23.8% has been reported in the literature<sup>[5,7,8,20,21,30]</sup>. Ngoi *et al.*<sup>[31]</sup> reported a recurrence rate of 1.5%, but 38% of their patients underwent diverticulectomy. It is interesting to note that in these studies, there was little complicated diverticulitis in recurrent cases: Fang *et al.*<sup>[5]</sup> reported three complicated cases in 10 recurrences in 42 patients receiving conservative treatments, and Harada *et al.*<sup>[30]</sup> reported one complicated case in four recurrences in 29 patients. The other authors reported that all of the recurrent cases were uncomplicated diverticulitis, which responded well to medical therapy. Komuta *et al.*<sup>[8]</sup> mentioned that recurrent uncomplicated right colonic diverticulitis responded well to medical therapy regardless of the number of recurrences. In our study, 15 of 183 patients (8.2%) who responded to medical therapy developed recurrent diverticulitis. All 15 patients had uncomplicated diverticulitis, and were successfully treated with medical therapy. Therefore, we believe that if the recurrence rate after conservative treatment is not high and if complications are not frequent even after recurrence occurs, recurrence of right colonic diverticulitis should initially be an indication for medical treatment and not for surgery.

In conclusion, our results indicate that right colonic diverticulitis is essentially benign and image-guided conservative treatment is primarily required. Although our study is limited by the retrospective design and relatively few recurrent patients, our results suggest that recurrence after conservative treatment of right colonic diverticulitis is low, and rarely associated with complicated diverticulitis. Thus, recurrence of right colonic diverticulitis should initially be an indication for medical treatment, while surgical resection should be selectively considered for patients with complicated diverticulitis.

is much more common in Asian populations. There is a lack of information available on the clinical course and results of medical therapy for patients with right colonic diverticulitis compared with left colonic diverticulitis.

### Research frontiers

The final diagnosis of all patients with right colonic diverticulitis was based on radiographic evidence from computed tomography or ultrasonography, or operative findings. The majority of patients with right colonic diverticulitis had a mild form on admission and initially required medical therapy. Recurrent diverticulitis developed in 8.2%, but all recurrent patients had uncomplicated diverticulitis, and were successfully treated with medical therapy.

### Innovations and breakthroughs

Right colonic diverticulitis is essentially benign and image-guided conservative treatment is primarily required. The correct pretreatment diagnosis for right colonic diverticulitis does not only avoid unnecessary surgery but also allows clinicians to determine optimal management according to the severity of the diverticulitis. Even recurrence of right colonic diverticulitis should initially be an indication for medical treatment, while surgical resection should be selectively considered for patients with complicated diverticulitis.

### Terminology

Complicated diverticulitis is defined as diverticulitis associated with abscess, fistula, obstruction, or free perforation.

### Peer review

This is an interesting study about right colonic diverticulitis management that has been quite rarely discussed.

### Abstract

**AIM:** To investigate the dysfunction of the immunological barrier of the intestinal mucosa during endotoxemia and to elucidate the potential mechanism of this dysfunction.

**METHODS:** Male Wistar rats were randomly distributed into two groups: control group and lipopolysaccharide (LPS) group. Endotoxemia was induced by a single caudal venous injection of LPS. Animals were sacrificed in batches 2, 6, 12 and 24 h after LPS infusion. The number of microfold (M)-cells, dendritic cells (DCs), CD4<sup>+</sup> T cells, CD8<sup>+</sup> T cells, regulatory T (Tr) cells and IgA<sup>+</sup> B cells in the intestinal mucosa were counted after immunohistochemical staining. Apoptotic lymphocytes were counted after TUNEL staining. The levels of interleukin (IL)-4, interferon (IFN)- $\gamma$  and forkhead box P3 (Foxp3) in mucosal homogenates were measured by ELISA. The secretory IgA (sIgA) content in the total protein of one milligram of small intestinal mucus was detected using a radioimmunological assay.

**RESULTS:** This research demonstrated that LPS-

induced endotoxemia results in small intestinal mucosa injury. The number of M-cells, DCs, CD8<sup>+</sup> T cells, and IgA<sup>+</sup> B cells were decreased while Tr cell and apoptotic lymphocyte numbers were increased significantly. The number of CD4<sup>+</sup> T cells increased in the early stages and then slightly decreased by 24 h. The level of IL-4 significantly increased in the early stages and then reversed by the end of the study period. The level of IFN- $\gamma$  increased slightly in the early stages and then decreased markedly by the 24 h time point. Level of Foxp3 increased whereas sIgA level decreased.

**CONCLUSION:** Mucosal immune dysfunction forms part of the intestinal barrier injury during endotoxemia. The increased number and function of Tr cells as well as lymphocyte apoptosis result in mucosal immunodeficiency.

### INTRODUCTION

Endotoxemia can induce sepsis which is among the leading causes of death in noncardiac intensive care units (ICUs) in the US, with approximately 750 000 cases and up to 200 000 deaths per year<sup>[1]</sup>. An epidemiological investigation in 3665 ICUs in China showed that the overall hospital mortality of severe sepsis is 48.7%; the mean hospital cost is \$11 390 per patient at a mean cost of \$502 per patient per day<sup>[2]</sup>. Despite hospital mortality of 20% for simple sepsis and 40% or higher for severe sepsis or septic shock, there has nonetheless been improvement over the past decade<sup>[3]</sup>.

Lipopolysaccharide (LPS) is a component of the outer cell wall of gram-negative bacteria, which gives rise to

various manifestations of gram-negative endotoxemia and septic shock<sup>[4]</sup>. Endotoxemia-induced sepsis has been associated with deleterious functional and structural changes in many organs, such as the gastrointestinal tract<sup>[5]</sup>, lungs, and other organs. During sepsis, the most frequent complications within the gastrointestinal tract are mucosal barrier dysfunction and ileus<sup>[6]</sup>. One of the most important functions of the gastrointestinal tract is the ability to act as a mucosal barrier to infections. Mucosal barrier dysfunction plays an important role in the pathophysiology of sepsis by promoting bacterial stasis, bacterial overgrowth, and bacterial translocation, which can lead to the development of secondary infections and multiple organ failure<sup>[7]</sup>. Intestinal mucosal barriers consist of a mechanical barrier, a chemical barrier, an immunological barrier, and a biological barrier<sup>[8]</sup>. Damage to any one of these components causes mucosal barrier dysfunction. The immunological barrier is considered as the first line of defense of the intestinal mucosa from bacterial invasion<sup>[9]</sup> and plays an important role in the overall defense. It consists of Peyer's patches, which are the induction sites of the immune response, and diffused lymphoid tissue which are the effector sites. Intestinal mucosa immune responses rely largely on humoral immunity. The primary functions of the immunological barrier include<sup>[10-12]</sup> inhibiting bacterial adhesion to the mucosa so that they can be eliminated, neutralizing viruses and toxins, enclosing some antigens of acquired extraneous material to prevent systemic reactions, activating the complement 3 (C3) pathway, participating in the anti-infection effect, and protecting probiotics. Therefore, damage to the intestinal immune barrier will result in bacterial translocation and gut-derived endotoxemia.

Previous studies have discussed the changes to immunity during sepsis, but what happens to immunity, specifically the gut immunity, during endotoxemia before sepsis is not clear. Thus in the present study, changes to the number and function of intestinal mucosal immune cells in rats with endotoxemia were observed to investigate whether dysfunction of immunological barrier occurred during endotoxemia and to elucidate the potential mechanism of this dysfunction.

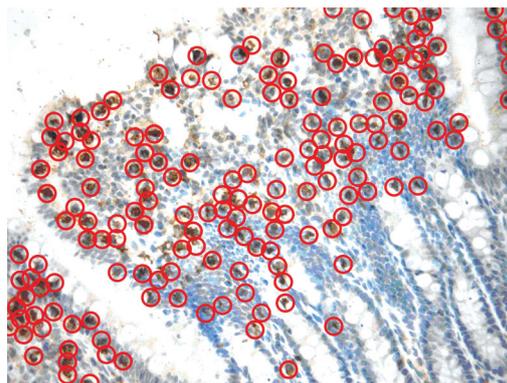

## MATERIALS AND METHODS

### Animals

Male Wistar rats weighing  $200.5 \pm 12.3$  g were purchased from Vital River Laboratories (Beijing, China). The rats were fed a standard laboratory chow diet (Vital River Laboratories) for 72 h before the experiment and maintained at  $24 \pm 1^\circ\text{C}$ , at a relative humidity of  $50\% \pm 1\%$  with a 12/12-h light/dark cycle. The animals were fasted for 12 h before the experiment, allowing free access to water. All animals were handled according to the institutional criteria for the care and use of laboratory animals in research.

### Methods

**Establishment of animal model:** A total of 80 animals were included and randomly distributed into the control

**Figure 1** A sample image of immunohistochemical staining and TUNEL staining. Some sample cells are circled to illustrate the positive cells that were counted (400 ×).

group (40 rats) and LPS (*Escherichia coli*, O55: B5, Sigma, St Louis, MO, USA) group (40 rats). In accordance with the study of Cheng *et al*<sup>[13]</sup>, endotoxemia was induced by a single caudal venous injection of LPS at 10 mg/kg, while control animals received caudal venous injections of saline. Ten animals were sacrificed in each group at each time point (2, 6, 12 and 24 h) after LPS infusion.

**Histological testing:** Small intestinal tissue was obtained from the middle part of the ileum. Samples were fixed in 4% paraformaldehyde and then observed by hematoxylin and eosin (HE) staining to explore the histopathological changes in the intestinal mucosa.

**Cytological testing:** A 5-cm-long tissue section with Peyer's patches cut off was obtained from the ileum near the cecum and observed by immunohistochemical staining after fixation in 4% paraformaldehyde to investigate immune cell changes in the mucosa. The fixed tissue was transferred to phosphate buffer solution (PBS) overnight at  $4^\circ\text{C}$  and then transferred to 30% sucrose for 2 h at  $4^\circ\text{C}$ . Then the tissue was mounted in optimum cutting temperature (OCT) embedding medium and placed on dry ice until frozen before cryosectioning of 4  $\mu\text{m}$  thick continuous slides. The slides were washed  $3 \times 5'$  (3 times, 5 min each) with PBT (Phosphate Buffer Saline with 0.02% Tween 20). Next, 500  $\mu\text{L}$  of diluted primary antibody in blocking buffer (containing 40 mL PBT, 400  $\mu\text{L}$  heat-inactivated goat serum, 400  $\mu\text{L}$  heat-inactivated donkey serum, 400  $\mu\text{L}$  10% Triton X-100) was added to each slide before they were covered and stored at  $4^\circ\text{C}$  overnight. The slides were then washed  $6 \times 5'$  with PBT before the addition of 500  $\mu\text{L}$  of diluted secondary antibody in blocking buffer to each slide. The slides were then covered and incubated at room temperature for 90 min before being washed  $6 \times 5'$  with PBT. The slides were then mounted with Vectashield. After staining, six clear-viewed slides were selected from each group and two viewing fields for each slide at high magnification (400 ×) were randomly selected for counting immune cells. Brownish-yellow stained lymphocytes were an indication of positive cells (Figure 1). Rabbit anti-rat cytokeratin 8<sup>[14]</sup>, integrin  $\alpha\text{E}2$ <sup>[15]</sup>, cluster of differentiation (CD) 4, CD8,

neuropilin-1 (NRP-1)<sup>[16]</sup> and immunoglobulin A (IgA) polyclonal antibodies were purchased from Biosynthesis Biotechnology (Beijing, China) to indicate microfold cells (M-cells), dendritic cells (DC), CD4<sup>+</sup> thymus dependent lymphocytes (T cells), CD8<sup>+</sup> T cells, CD4<sup>+</sup>CD25<sup>+</sup> T cells (regulatory T cell, Tr) and IgA<sup>+</sup> bursa dependent lymphocytes (B cells), respectively.

The terminal deoxynucleotidyl transferase mediated dUTP-biotin nick end labeling (TUNEL) assay was used to observe apoptotic lymphocytes in the small intestinal mucosa. The TUNEL kit was obtained from Roche Diagnostics (Indianapolis, IN, USA) to label apoptotic lymphocytes. The slides were deparaffinized in two changes of xylene for 5 min each, hydrated with two changes of 100% ethanol for 3 min each and 95% ethanol for 1 min, and then rinsed in distilled water. Slides were then incubated in TdT reaction buffer for 10 min before incubation in TdT reaction mixture for 1-2 h at 37-40°C in a humidified chamber. The reaction was stopped by rinsing the slides in stop wash buffer for 10 min. The slides were then rinsed 3 × 2' in PBT before incubation with FITC-Avidin D in PBS for 30 min at room temperature. Slides were then rinsed 3 × 2' in PBT, counterstained with PI or DAPI for 20 min and rinsed in PBS for 5 min. Slides were then mounted with Vectashield. Brownish-yellow stained lymphocytes were an indication of positive cells. The intraepithelial apoptotic lymphocytes were identified and counted.

**Detection of IL-4, IFN- $\gamma$  and Foxp3:** The small intestinal mucosa was stripped off by circumferentially pushing the muscularis with a moist cotton applicator, as described previously<sup>[17]</sup> and then weighed to prepare a 10% homogenate by adding an appropriate amount of normal saline. The homogenate was then centrifuged at 3000 × *g* for 10 min at 0°C. The supernatant was harvested and diluted with normal saline to make a 1% homogenate. The levels of interferon- $\gamma$  (IFN- $\gamma$ ), interleukin-4 (IL-4) and forkhead box P3 (Foxp3) in the homogenate were measured by enzyme-linked immunosorbent assays (ELISA) to evaluate the function of Helper T-cell (TH) 1, TH2 and Tr cells. The IFN- $\gamma$  and IL-4 ELISA kits were obtained from R&D Systems (Minneapolis, MN, USA). The Foxp3 ELISA kit was obtained from Adlitteram Diagnostic Laboratories (San Diego, CA, USA). The ELISA assays were performed according to the manufacturer's instructions.

**Detection of sIgA:** Secretory IgA (sIgA) was detected using a radioimmunological assay (RIA). A 10-cm-long tissue section was obtained from the small intestine, dissected and carefully washed with normal saline. Small intestinal mucus was collected into an Eppendorf tube, and 1 mL of 0.01 mol/L PBS was added into the Eppendorf tube. The solution was then centrifuged at 3000 × *g* for 10 min at 0°C. The supernatant was then harvested and the level of sIgA was measured by a double antibody sandwich RIA purchased from Beijing Nuclear Research Center (Beijing, China). The total protein level

of the intestinal mucus was assayed by the Bradford brilliant blue method simultaneously. The sIgA content in 1 mg of total protein from small intestinal mucus was detected.

### Statistical analysis

All statistical analyses were performed using the SPSS 15.0 software package. All data were expressed as the mean ± SD. Group comparisons were carried out using a one-factor analysis of variance. *P* < 0.05 was considered statistically significant.

## RESULTS

### Mortality of rats in different groups

During the course of the study there were no rats that died in the control group. A total of 5 rats died in the LPS group; 3 at 12 h and 2 at 24 h after LPS injection.

### Histological changes

As shown in Figure 2, the intestinal mucosa of saline-treated rats was complete and the villi were presented in an orderly fashion. Samples displayed no abnormal epithelial cell morphology and there was no evidence of congestion, edema or infiltration of inflammatory cells (Figure 2A). In contrast, the intestinal mucosal villi of rats with endotoxemia were loosened and atrophic where the epithelial cells were necrotic. The mucosa was edematous and infiltrated with inflammatory cells (Figure 2B-E). These abnormal changes to the intestinal mucosa were most obvious 12 h after LPS injection (Figure 2D).

### Numbers of immune cells and apoptotic lymphocytes in the intestinal mucosa

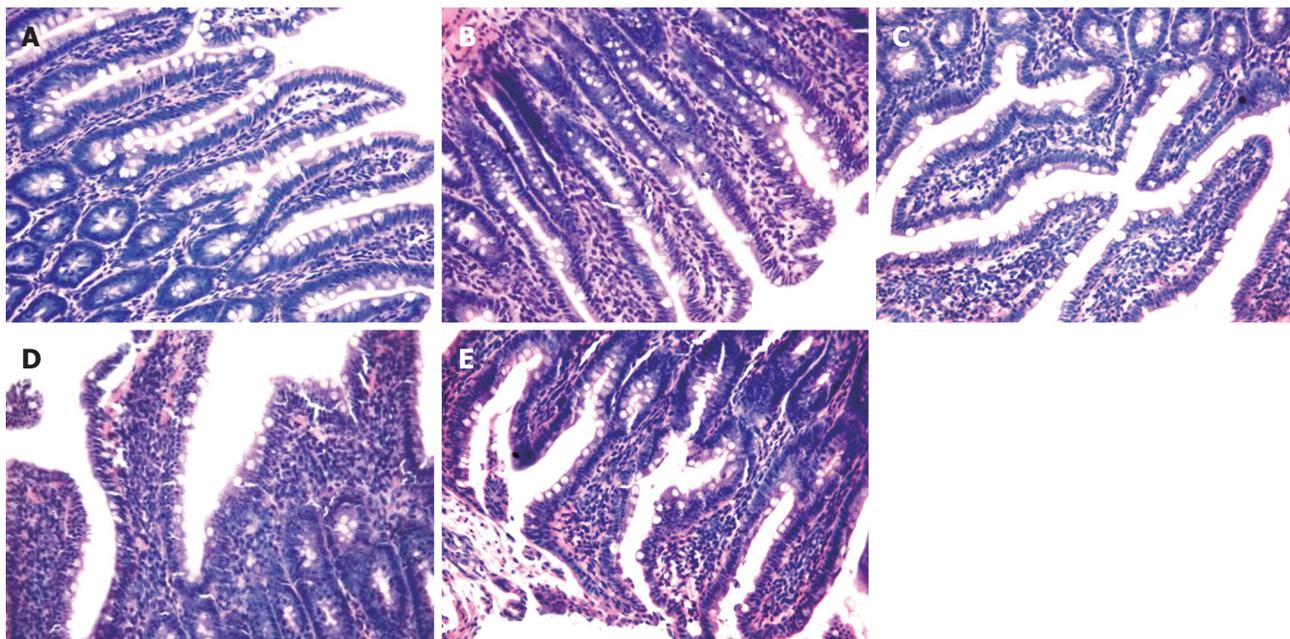

The effects on the immune system induced by LPS were assessed in the rat intestinal mucosa (Figure 3). We found that M-cell and CD8<sup>+</sup> T cell numbers in the small intestinal mucosa were significantly decreased 6 and 12 h after LPS challenge compared to controls. Furthermore, the number of DCs was significantly decreased after 2, 6 and 12 h. In contrast, the number of CD4<sup>+</sup> T cells was significantly increased after 6 and 12 h, before decreasing slightly by 24 h, although this decrease was not statistically significant. The number of Tr cells was significantly increased at 2, 6 and 12 h. The number of IgA<sup>+</sup> B cells and apoptotic lymphocytes were significantly increased at all time points.

### Levels of IL-4, IFN- $\gamma$ and Foxp3 in the small intestinal mucosa

As shown in Figure 4, the level of IL-4 was significantly increased in the small intestinal mucosa after 2 h before significantly decreasing after 6 and 12 h in LPS-treated animals compared with controls. The level of IFN- $\gamma$  was increased slightly after 2, 6 and 12 h before decreasing markedly by 24 h. The level of Foxp3 was significantly increased after 12 and 24 h.

### Level of intestinal mucus sIgA

As shown in Figure 5, LPS induced a significant decrease

**Figure 2** Representative images of the histological changes in the small intestinal mucosa of rats after LPS injection. A: The intestinal mucosa of normal rats was complete and the villi were in an orderly fashion with no abnormal morphology present in the epithelial cells, as well as no manifestation of congestion, edema or infiltration of inflammatory cells; B-E: Representative of the changes 2, 6, 12 and 24 h after LPS treatment. The intestinal mucosal villi of rats with endotoxemia were loosened and atrophic while the epithelial cells were necrotic and the mucosa was edematous and infiltrated with inflammatory cells. The LPS-induced changes to the intestinal mucosa were most obvious in the rats after 12 h.

in sIgA levels in rat intestinal mucus after 2, 12 and 24 h compared with controls.

## DISCUSSION

This study has demonstrated that LPS-induced endotoxemia results in small intestinal mucosa injury. The number of M-cells, DCs, CD8<sup>+</sup> T cells and IgA<sup>+</sup> B cells were decreased and the number of Tr cells and apoptotic lymphocytes were increased significantly. The number of CD4<sup>+</sup> T cells was increased in the early stages before slightly decreasing by the end of the study period. Similarly, the level of IL-4 was significantly increased at early time points and then reversed by the 24 h time point, while IFN- $\gamma$  levels were also increased slightly at early time points before decreasing markedly by the end of the study. The level of Foxp3 was increased whereas the level of sIgA decreased.

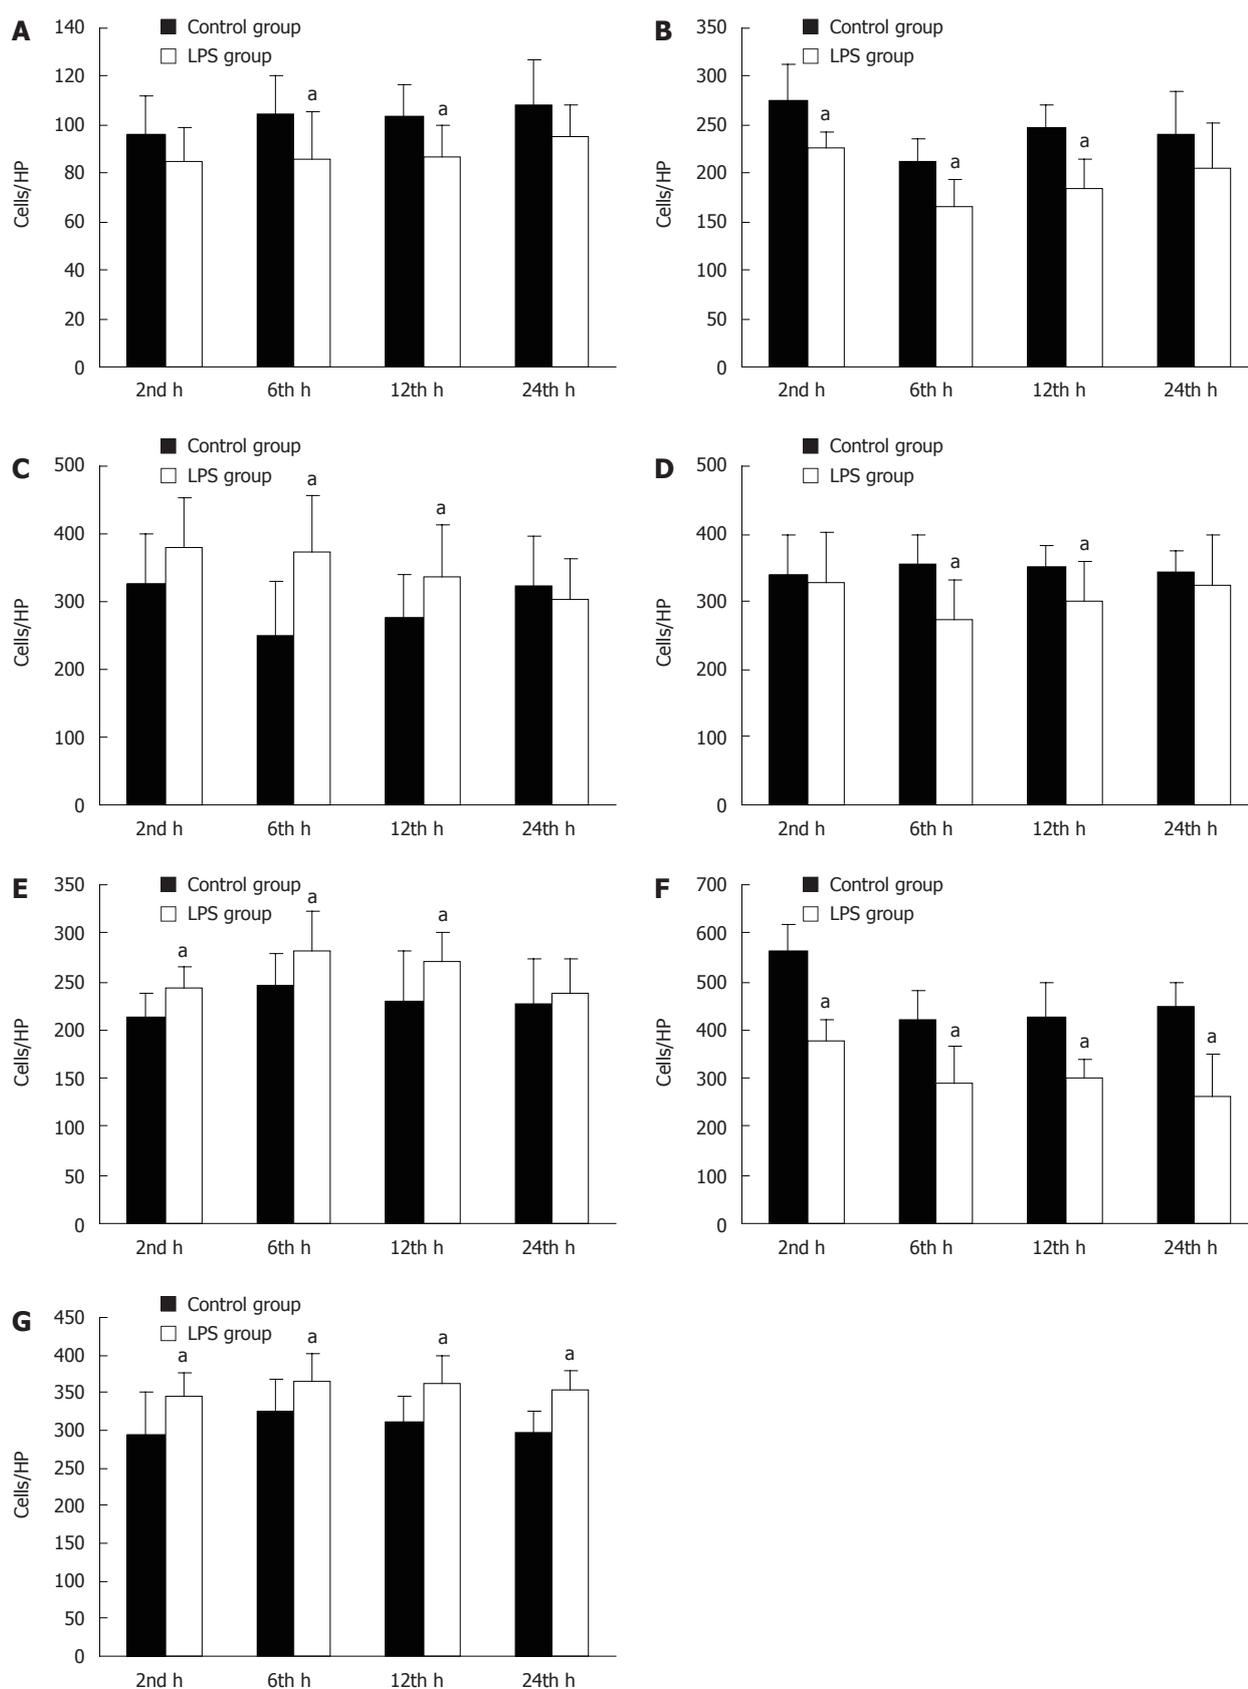

Many researchers have demonstrated that the digestive tract is the largest immune organ in the body<sup>[18]</sup>. The immune response of the digestive tract mucosa primarily relies on humoral immunity. The induction site of mucosal immune responses is at the Peyer's patches and the effector site is at the mucosa<sup>[19]</sup>. The mucosal immune response involves a number of processes: the M-cells of the Peyer's patches collect granular antigens and pass them to DCs and macrophages which can then activate the T cells. The activated T cells will further activate B cells and the latter will produce antigen-specific sIgA after homing to the effector site.

During endotoxemia, oxidative stress causes direct damage to cells and tissues and is involved in inflammatory cytokine production. The response of the immune

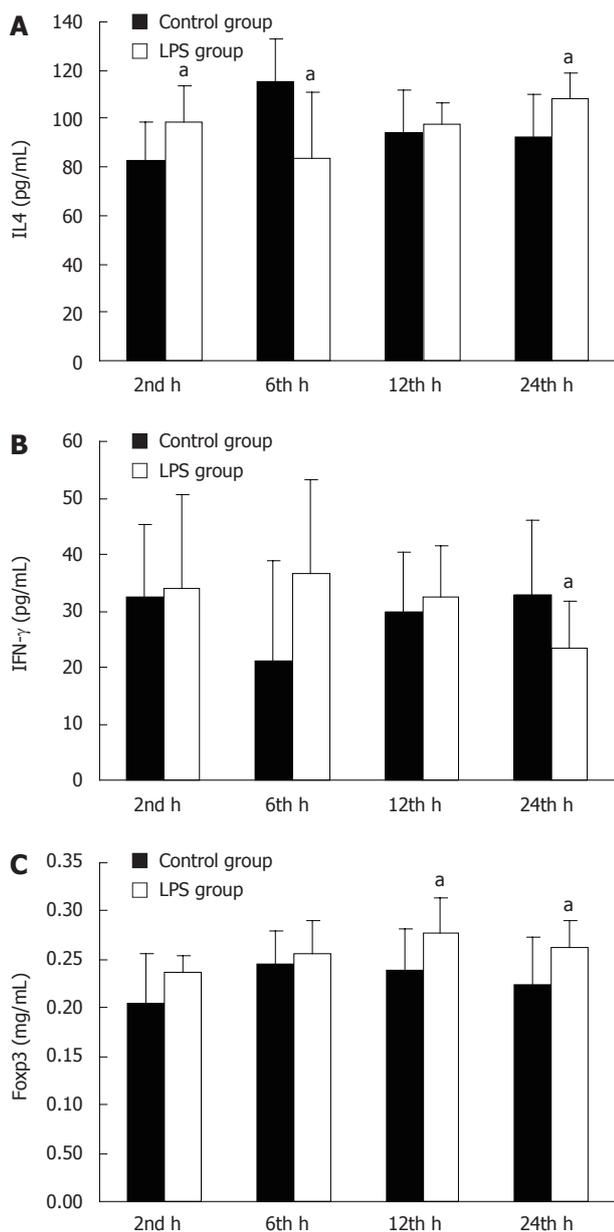

system to LPS is an inflammatory reaction in the early phase and anti-inflammatory reaction in the later period<sup>[20]</sup>.

LPS can activate phagocytes, stimulating them to release large amounts of cytokines and inflammatory factors which can further induce microcirculatory disturbances and intestinal epithelium injury, resulting in intestinal barrier damage<sup>[21]</sup>. In this study, it was observed that the small intestinal mucosa was injured in rats with endotoxemia, suggesting that the intestinal barrier was damaged and that the most severe damage occurred 12 h after LPS injection. This study also demonstrated that the immune function of the small intestinal mucosa changed most significantly after 12 h, indicating that the immune barrier dysfunction was a part of intestinal mucosal barrier injury.

To investigate the changes to local immune induction during endotoxemia we observed the numbers of M-cells and DCs in the intestinal mucosa. M-cells are a special kind of intestinal epithelium mucosa cell that can play a role by delivering antigen to antigen presenting cells (APCs). It is believed that the M-cell is the first step in intestinal immunity<sup>[22]</sup>. It has been observed that the number of M-cells decreased and the intestinal barrier was damaged during chronic intestinal inflammation and bacterial invasion<sup>[23]</sup>. In this study, we found the same change in M-cells during acute LPS stimulation, suggesting that endotoxemia could impair the first step of intestinal immunity. DCs are a kind of APC and a previous study by Hotchkiss *et al*<sup>[24]</sup> demonstrated DC depletion in patients with sepsis. In this study, a decrease in DC number was observed in the intestinal mucosa, suggesting the same change in rats with endotoxemia. The decreases in M-cell and DC numbers in the small intestinal mucosa in

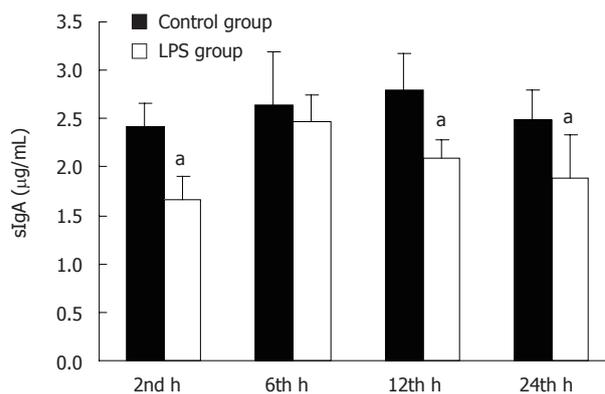

**Figure 3** The number of immune cells and apoptotic lymphocytes in the intestinal mucosa. A: The number of M-cells was significantly decreased after 6 and 12 h in the LPS group; B: The number of DCs was significantly decreased after 2, 6 and 12 h in the LPS group; C: The number of CD4<sup>+</sup> T cells was significantly increased after 6 and 12 h before slightly decreasing by 24 h in the LPS group; D: The number of CD8<sup>+</sup> T cells was significantly decreased after 6 and 12 h in the LPS group; E: The number of Tr cells was significantly increased after 2, 6 and 12 h in the LPS group; F: The number of IgA<sup>+</sup> B cells was significantly increased at all time points in the LPS group; G: The number of apoptotic lymphocytes was significantly increased at all time points in the LPS group. <sup>a</sup>*P* < 0.05.

**Figure 4** Levels of IL-4, IFN- $\gamma$  and Foxp3 in small intestinal mucosa. A: The level of IL-4 was significantly increased after 2 h and significantly decreased by 6 and 12 h in the LPS group; B: The level of IFN- $\gamma$  was increased slightly after 2, 6 and 12 h and decreased markedly by 24 h in the LPS group; C: The level of Foxp3 was significantly increased after 12 and 24 h in the LPS group. <sup>a</sup> $P < 0.05$ .

rats with endotoxemia implied that the induction of local immune responses was impaired.

T lymphocytes, especially the Tr cells, play a major regulatory role in mucosal immunity. T cells can be classified into CD4<sup>+</sup> T cells and CD8<sup>+</sup> T cells according to the different protein markers on their cell surface. TH cells and Tr cells belong to the CD4<sup>+</sup> T cell family. TH cells can be further divided into TH1 and TH2, where TH1 secretes inflammatory factors such as IFN- $\gamma$  to mediate the protective immune response while TH2 secretes anti-inflammatory factors such as IL-4 to mediate the non-specific immune response<sup>[25]</sup>. A previous study demonstrated a TH1/TH2 drift<sup>[26]</sup>, suggesting that the immune response progressed from being active to a sup-

**Figure 5** Small intestinal mucosa sIgA levels. The level of intestinal mucus sIgA was significantly decreased after 2, 12 and 24 h in the LPS group. <sup>a</sup> $P < 0.05$ .

pressed state during sepsis, while a further study demonstrated that it was Tr cells that mediated this drift<sup>[27]</sup>. In addition, other studies have demonstrated that Tr cells could selectively kill and directly suppress B cells<sup>[28,29]</sup>. It was reported that circulating Tr numbers were markedly elevated and induced immunoparalysis in sepsis<sup>[30]</sup>. The development and function of Tr cells can be investigated by the expression level of Foxp3<sup>[31]</sup>. CD8<sup>+</sup> T cells include cytotoxic T (Tc) cells and suppressor T (Ts) cells, which are the effector cells of cell immunity and suppressors of TH cells, respectively. In accordance with Bruder *et al*<sup>[16]</sup> study, we inferred Tr cell numbers from a single marker of NPR-1 positive cells in our study. We only observed the intraepithelial NPR-1 positive cells to exclude interference since NPR-1 can be expressed by other cells such as DCs. Our study showed that CD4<sup>+</sup> T cells increased in the early stages of endotoxemia before sepsis and then slightly decreased in the later phase, while CD8<sup>+</sup> T cells decreased and Tr cells increased in the small intestinal mucosa in rats with endotoxemia. It should also be noted that in this study the level of IL-4 increased at the beginning and then decreased by the end of the study whereas the level of IFN- $\gamma$  demonstrated the opposite change and the level of Foxp3 increased. Though a lot of activated immunological cells can secrete IL-4 and IFN- $\gamma$ , the effects of IL-4 and IFN- $\gamma$  remained unchanged. Similarly, Foxp3 is not exclusively expressed by Tr cells but also by activated effector T cells. The combination of an increase in NPR-1 cells and intestinal Foxp3 levels could suggest that Tr cells are increased. These results suggest a trend of immune changes whereby cellular immunity progressed from an active to a suppressed state during endotoxemia before sepsis. It can be concluded from this study that the rise in the number and function of Tr cells is one of the major reasons for immunosuppression in the small intestinal mucosa of rats with endotoxemia before sepsis.

IgA<sup>+</sup> B cells are identified by positive IgA staining, because only B cells produce IgA or have surface IgA. A previous study showing decreases in the level of sIgA, the number of IgA<sup>+</sup> B cells and the number of Gram-negative bacteria enclosed by sIgA in the intestinal tract during stress suggested that humoral immune function

was inhibited dramatically<sup>[32]</sup>. Our study demonstrated that the level of sIgA and the number of IgA<sup>+</sup> B cells diminished during endotoxemia, suggesting that LPS-induced endotoxemia inhibited humoral immune function of the digestive tract in accordance with the previous report. One explanation for this could be due to the rise in the number and function of Tr cells, as demonstrated in our study, which could lead to the suppression of B cell function.

Mongini *et al.*<sup>[33]</sup> reported that relocation of endotoxin after injury can increase the number of apoptotic lymphocytes. Our research demonstrated a similar change, with an increase in the number of apoptotic lymphocytes in the intestinal mucosa of rats with endotoxemia. This could contribute to the immunosuppression of the small intestine in rats with endotoxemia.

In conclusion, our study showed that mucosal immune barrier dysfunction was a part of intestinal mucosal barrier injury. Cellular immunity was active in the early phase of endotoxemia and suppressed in later periods, humoral immunity was abnormal and lymphocyte apoptosis was increased. Our study suggests that the increased number and function of Tr cells and the increase in lymphocyte apoptosis are the reasons for intestinal mucosal immunodeficiency. Based on these findings, an earlier protective or immunoregulative treatment aimed at gastrointestinal immune function may be of benefit to severely infected patients. We suggest future studies could be designed to test this hypothesis.

## COMMENTS

### Background

Immune dysfunction is one of the most frequent complications within the gastrointestinal mucosal barrier during sepsis. Mucosal barrier dysfunction plays an important role in the pathophysiology of sepsis by promoting bacterial stasis, bacterial overgrowth, and bacterial translocation, which can lead to the development of secondary infections and multiple organ failure. The changes of gastrointestinal immune function may appear at the beginning or even before sepsis.

### Research frontiers

Intestinal mucosal barriers consist of a mechanical barrier, a chemical barrier, an immunological barrier, and a biological barrier. The immunological barrier is considered as the first line of defense of the intestinal mucosa from bacterial invasion and plays an important role in the overall defense. This study observed the changes in the gastrointestinal immunological barrier during endotoxemia.

### Innovations and breakthroughs

Previous studies have discussed the changes to immunity during sepsis, but what happens to immunity, specifically the gut immunity, during endotoxemia before sepsis is not clear. In this study, changes to the number and function of intestinal mucosal immune cells in rats with endotoxemia were observed to investigate whether dysfunction of the immunological barrier occurred during endotoxemia and to elucidate the potential mechanism of this dysfunction.

### Applications

By observing the changes of gastrointestinal immune function, the study shows that the gastrointestinal immune dysfunction occurs during endotoxemia before sepsis. Thus, a protective or an immunoregulative treatment of gastrointestinal immune function should be used earlier in severely infected patients.

### Terminology

Lipopolysaccharides (LPS) are large molecules consisting of a lipid and a polysaccharide joined by a covalent bond; they are found in the outer membrane of Gram-negative bacteria, act as endotoxins and elicit strong immune responses in animals. Endotoxemia is the immune responses to LPS in animals. Cytokines: non-antibody proteins secreted by inflammatory leukocytes

and some non-leukocytic cells, which act as intercellular mediators. Sepsis is defined as infection plus systemic manifestations of infection.

### Peer review

This is a descriptive study of the effect of intravenous LPS on intestinal immune cells and cytokine levels in the rat. Straightforward and generally well written paper.

### Abstract

**AIM:** To investigate the safety and efficacy of implanting fibrin sealant with sustained-release ropivacaine in the gallbladder bed for pain after laparoscopic cholecystectomy (LC).

**METHODS:** Sixty patients (American Society of Anesthesiologists physical status was I or II and underwent LC) were randomly divided into three equal groups: group A (implantation of fibrin sealant in the gallbladder bed), group B (implantation of fibrin sealant carrying ropivacaine in the gallbladder bed), and group C (normal saline in the gallbladder bed). Postoperative pain was evaluated, and pain relief was assessed by visual analog scale (VAS) scoring.

**RESULTS:** The findings showed that 81.7% of patients had visceral pain, 50% experienced parietal, and 26.7% reported shoulder pain after LC. Visceral pain was significantly less in group B patients than in the other groups ( $P < 0.05$ ), and only one patient in this group experienced shoulder pain. The mean VAS score in group B patients was lower than that in the other groups.

**CONCLUSION:** Visceral pain is prominent after LC and can be effectively controlled by implanting fibrin sealant combined with ropivacaine in the gallbladder bed.

### INTRODUCTION

Since the widespread adoption of laparoscopic cholecystectomy (LC) in the late 1980s, LC has become the gold standard for chronic cholecystitis<sup>[1]</sup>. Postoperative pain after LC is generally less than that after open cholecystectomy, however, the postoperative pain experienced by patients still causes preventable distress. Treating postoperative pain is an important and primary objective, because it affects patients' comfort, postoperative morbidity, and, inevitably, social costs due to prolonged hospitalization and work inactivity. Pain after LC can be divided into three components, namely, visceral, parietal, and shoulder pain, with different intensities and time courses<sup>[2]</sup>. LC is mainly associated with visceral pain<sup>[3]</sup> which may refer to the shoulder in 35% to 60% of cases<sup>[4,5]</sup>. Various treatments have been proposed to make this surgery as pain-free as possible<sup>[6-8]</sup>. The main objective of this study was to assess the effectiveness of implanting fibrin sealant combined with ropivacaine in the gallbladder bed for pain control after LC.

### MATERIALS AND METHODS

The study was designed as a single-center, randomized trial. Of the 78 patients who underwent LC from October 2008 to August 2009, 60 patients (42 women, 18 men) were enrolled in this study, which was performed after approval was received from the Ethics Committee of Beijing Tongren Hospital, Capital Medical University. All patients whose American Society of Anesthesiologists (ASA) physical status were I or II underwent diagnostic abdominal ultrasound, liver function tests, and coagulation profile along with hematologic and biochemical investigations. Patients with previous major upper abdominal surgeries, choledocholithiasis, acute

cholecystitis, or conversion to open cholecystectomy were excluded from the study. Patients with a body mass index higher than 35, and those with diminished liver and kidney functions were not evaluated in this study. The visual analog pain evaluation scale (VAS) was introduced to the patients before surgery and the details of the study were explained to the patients. All patients stated that they understood the VAS. Patients who were unable to comprehend the scale were not included in the study. Only patients who were suitable and compatible with the study design were included. The patients were randomly divided into 3 equal groups with the help of computer-generated randomization numbers.

All patients underwent LC under a standard general anesthetic technique for premedication and during the intraoperative period. The anesthetist performed intraoperative, noninvasive monitoring. Ventilation was adjusted to maintain an end-tidal CO<sub>2</sub> pressure below 38 mmHg. Second-generation cephalosporin (cefoxitin) 1 g was injected intravenously before the induction of anesthesia. LC was carried out using the standard three-port technique, and CO<sub>2</sub> pneumoperitoneum pressure was maintained at 14 mmHg throughout the procedure. The procedures were performed by the same experienced surgeon. After complete hemostasis and the gallbladder bed washed with normal saline, the different treatments were performed according to the different groups. Group A: Fibrin sealant (5 mL) (Guangzhou Bioseal Biotech, Guangzhou, China) was implanted in the gallbladder bed. Group B: Fibrin sealant (5 mL) combined with ropivacaine (1 mg/kg body weight) was implanted in the gallbladder bed. Group C: The gallbladder bed was doused with normal saline only.

Following LC, carbon dioxide was evacuated through the ports by applying gentle pressure all over the abdomen. Gallbladders were taken out of the peritoneal cavity *via* the umbilical incision. Rescue analgesia (intramuscular dolantin 50 mg) or rescue antiemetic (intramuscular ondansetron 8 mg) was administered if the VAS was higher than 10 or the patient complained of vomiting. The amount of dolantin used was noted.

The degree of postoperative pain was assessed every 4 h in the first 12 h after surgery and then every 12 to 48 h, using a VAS (0 = no pain, 10 = worst possible pain), by nursing staff who were unaware of the perioperative intervention. The character of the pain was also assessed simultaneously. Visceral pain was defined as deep-seated pain located in the right hypochondrium or referred to the shoulder. Parietal pain was defined as incisional pain located at the trocar sites.

### Statistical analysis

Data were expressed as the mean  $\pm$  SE. All data were prepared and compiled using SPSS 16.0 software. Statistical differences were determined by ANOVA using the Dunnett procedure in non-repeated measures obtained by the mean postoperative VAS scores for the various groups. Categorical variables were recorded as numbers (percentages) and compared by using the  $\chi^2$  test with

Table 1 Patient characteristic data (mean  $\pm$  SE)

Variables	Group A	Group B	Group C
Age (yr)	41.6 $\pm$ 16.1	42.2 $\pm$ 14.7	40.8 $\pm$ 17.6
Weight (kg)	62.6 $\pm$ 18.3	65.3 $\pm$ 16.8	64.7 $\pm$ 19.1
Sex (M/F)	14/6	14/6	14/6
Duration of anesthesia (min)	106.7 $\pm$ 21.4	98.2 $\pm$ 24.3	103.7 $\pm$ 25.7
Duration of surgery (min)	66.4 $\pm$ 20.1	62.8 $\pm$ 19.5	68.5 $\pm$ 18.3

Yates correction. The threshold for statistical significance was considered  $P < 0.05$ .

## RESULTS

The 60 study patients (42 women and 18 men) varied in age from 25 to 63 years (median, 41.2 years). The three groups did not differ in mean age, body weight, or ASA status. None of the patients had a history of jaundice or gallstone pancreatitis. Eleven patients (18.3%) had previously undergone lower abdominal surgery. There was no significant difference in the duration of surgery among the three groups ( $P = 0.587$ ): 66.4  $\pm$  20.1 min for group A, 62.8  $\pm$  19.5 min for group B, 68.5  $\pm$  18.3 min for group C (Table 1).

The VAS score decreased after surgery in all patients. Analysis of variance followed by multiple comparisons using the Dunnett procedure, with group C used as a control, suggested that the mean VAS score for group B was significantly less than that for group A and C. The mean VAS scores for group A were lower than Group C, but the difference was not significant (Table 2).

The overall incidence of visceral, parietal, and shoulder pain in our study were 81.7%, 50.0%, and 26.7%, respectively. However, the incidence of visceral pain in group B was less than that in the other groups ( $P < 0.05$ ) (Table 3). The number of patients in group B experiencing visceral pain after surgery was also significantly lower

**Table 3** Character of pain after laparoscopic cholecystectomy *n* (%)

Group	<i>n</i>	Visceral	Parietal	Shoulder
A	20	18 (90.0)	10 (50.0)	7 (35.0)
B	20	12 (60.0)	9 (45.0)	1 (5.0)
C	20	19 (95.0)	11 (55.0)	8 (40.0)
Total	60	49 (81.7)	30 (50.0)	16 (26.7)

than that in the other groups ( $P < 0.05$ ). The overall incidence of parietal pain was 50.0% in group A, 45.0% in group B and 55.0% in group C ( $P > 0.05$ ). There was no difference in the incidence of parietal pain between the three groups. Only one patient in group B reported shoulder pain, as compared with 16 (26.7%) of the 40 patients in groups A and C ( $P < 0.01$ ).

Rescue analgesia (intramuscular pethidine hydrochloride 50 mg once) was administered if the VAS was higher than 10. The amount of pethidine hydrochloride used per capita in group B ( $2.5 \pm 11.2$  mg) was significantly lower than that in group A ( $30.0 \pm 25.1$  mg) and group C ( $25.0 \pm 25.6$  mg).

## DISCUSSION

Even though postoperative pain after LC is markedly less than that after open cholecystectomy, pain is still the patient's first complaint after LC<sup>[9]</sup>. Although postoperative pain is reduced compared to laparotomic surgery<sup>[10]</sup>, effective analgesic treatment still remains crucial for early patient discharge<sup>[11]</sup>. Usually, postoperative pain following LC peaks immediately after surgery, and decreases within 24 h, and then increases to a second or even a third peak later<sup>[12]</sup>.

The incidence of pain after laparoscopy may be attributed to the carbon dioxide gas (CO<sub>2</sub>) used to induce pneumoperitoneum<sup>[13,14]</sup>. CO<sub>2</sub> remains in the peritoneal cavity for several days after surgery and causes stretching of the phrenic nerve endings<sup>[15]</sup>, local hypothermia, and diaphragmatic irritation *via* carbonic acid<sup>[16]</sup>. The benefit of using intraperitoneal local anesthetics for shoulder and abdominal pain control has been proven<sup>[7,17-19]</sup>, however, several other studies did not confirm these findings<sup>[20-23]</sup>.

Pain after LC includes three components, visceral, parietal, and shoulder pain<sup>[3]</sup>. In the early postoperative period, many studies report that visceral pain is predominant, especially during the first hours after surgery<sup>[3]</sup>. At the same time, parietal pain is less intense because of the small incisions and limited damage to the abdominal wall. Shoulder pain may occur later with visceral pain. The most common location of postoperative pain is in the right upper quadrant, followed by the trocar site and the shoulder<sup>[24]</sup>.

In this study, all operations were progressed according to the line of least tissue damage. We took the gallbladder out of the peritoneal cavity *via* the umbilical incision which was less sensitive than the other incisions. Thus, we observed that parietal pain was mild in this study and did not contribute substantially to the VAS score.

Fibrin sealant has been an extremely effective and

widely used adjunct to surgical procedures for the control of diffuse slow bleeding over large surfaces. In addition, fibrin sealant has been used as a carrier for other compounds. Thus, it has been used to release medicines slowly at a fixed site which are therefore effective for a long time.

We observed a significant reduction in pain after gallbladder bed implantation of fibrin sealant combined with ropivacaine. This effect was indirectly reflected in the progressive reduction in both the VAS score and visceral pain in this group of patients. This suggests that the progressive reduction in the VAS score in this group of patients was primarily attributable to the effective control of visceral pain.

The VAS score for the patients with fibrin sealant alone implanted in the gallbladder bed was less than that of the control group, although the differences were not statistically significant. This suggests that the gallbladder bed with implanted fibrin sealant alone may lead to a slight relief in postoperative pain.

Verma *et al*<sup>[19]</sup> reported that visceral pain is prominent after LC and can be effectively controlled by 0.5% bupivacaine-soaked Surgicel in the gallbladder bed alone. They used bupivacaine 0.5% (2 mg/kg) instilled over the oxidized regenerated cellulose strips (Surgicel) in the gallbladder bed, and found that the postoperative pain was significantly less in these patients than in the control groups (bupivacaine infiltrated at the trocar sites and normal saline in the gallbladder bed and at the trocar sites).

These findings are in accordance with the anatomical characteristics of the phrenic nerve which supplies the gallbladder, porta hepatis, and liver, while sharing the root of nerves to the shoulder<sup>[25]</sup>. We used fibrin sealant carrying ropivacaine adhered to the gallbladder bed. Using this method, ropivacaine was released slowly and the stickiness of the fibrin sealant ensured that the drug remained in contact with the wound for a longer period of time. In our study, implanting fibrin sealant combined with ropivacaine in the gallbladder bed was effective in controlling shoulder pain, and only one of the patients in this treatment group experienced shoulder pain.

In conclusion, we conclude that implanting fibrin sealant combined with ropivacaine in the gallbladder bed is effective in controlling both visceral and shoulder pain after LC.

## COMMENTS

### Background

Even though postoperative pain after laparoscopic cholecystectomy (LC) is markedly less than that after open cholecystectomy, pain is still the patient's first complaint after LC.

### Research frontiers

According to the anatomical characteristics of the nerve which supplies the gallbladder, the use of fibrin sealant carrying ropivacaine adhered to the gallbladder bed can relieve postoperative pain.

### Innovations and breakthroughs

This study determined that implantation of fibrin sealant with sustained-release ropivacaine in the gallbladder bed could relieve the pain after LC.

### Applications

The implantation of 5 mL fibrin sealant combined with ropivacaine (1 mg/kg

body weight) in the gallbladder bed provided significant postoperative pain relief compared with the implantation of fibrin sealant alone.

### Terminology

Fibrin sealant can be used as a carrier for ropivacaine. With fibrin sealant, ropivacaine could be released slowly, and the stickiness of the fibrin sealant ensured that the drug remained in contact with the wound for a longer period of time.

### Peer review

The authors have assessed the use of a fibrin sealant with local anaesthetic in the gallbladder bed on post-operative pain after LC. Fibrin sealant with local anaesthetic was associated with lower post-operative pain scores.

### Abstract

**AIM:** To evaluate the role of genetic factors in the pathogenesis of idiopathic infant cholestasis.

**METHODS:** We performed a case-control study, including 78 infants with idiopathic infant cholestasis and 113 healthy infants as controls. Genomic DNA was extracted from peripheral venous blood leukocytes using phenol chloroform methodology. Polymerase chain reaction was used to amplify the multidrug resistance protein 3 (MDR3) R652G fragment, and products were sequenced using the ABI 3100 Sequencer.

**RESULTS:** The R652G single nucleotide polymorphism (SNP) was significantly more frequent in healthy infants (allele frequency 8.0%) than in patients (allele frequency 2.60%) ( $P < 0.05$ ), odds ratio, 0.29; 95% confidence interval, 0.12-0.84. The conjugated bilirubin in patients with the AG genotype was significantly lower than in those with the AA genotype ( $44.70 \pm 6.15 \mu\text{mol/L}$  vs  $95.52 \pm 5.93 \mu\text{mol/L}$ ,  $P < 0.05$ ).

**CONCLUSION:** MDR3 R652G is negatively correlated with idiopathic infant cholestasis. Children with the R652G SNP in Guangxi of China may have reduced susceptibility to infant intrahepatic cholestasis.

Multidrug resistance protein 3 R652G may reduce susceptibility to idiopathic infant cholestasis. *World J Gastroenterol* 2009; 15(46): 5855-5858 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5855.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5855>

### INTRODUCTION

Idiopathic infant cholestasis is of unknown etiology and can occur in either a sporadic or a familial form. Most affected infants have a good prognosis. Approximately 5%-10% have persistent inflammation or fibrosis, and a few develop more severe liver disease, such as cirrhosis. Although the cause of idiopathic infant cholestasis is unknown, genetic factors have been suggested by the existence of some other entities with cholestasis, such as familial intrahepatic cholestasis-1 mutation in progressive familial intrahepatic cholestasis type 1 (PFIC-1), bile salt export pump deficiency in PFIC-2<sup>[1-3]</sup>, multidrug resistance protein 3 (MDR3) deficiency in PFIC-3<sup>[4-6]</sup>.

Studies have investigated the involvement of MDR3 variants in the development of disease, and we were interested to note that the MDR3 R652G single nucleotide polymorphism (SNP) has a high allele frequency in generally healthy people<sup>[7]</sup>. Our aim was to study the MDR3 R652G SNP distribution frequency in idiopathic infant cholestasis and healthy infants and to determine whether there were any differences between them and, if so, their relevance.

### MATERIALS AND METHODS

#### Patients

Seventy eight infants were diagnosed with idiopathic infant cholestasis in the case group and there were 113 healthy infants in the control group. The patients were included in the study on the basis of the following crite-

ria: (1) a history of chronic cholestasis onset in the neonatal/infant period with unknown origin; (2) presence of hepatomegaly or hepatosplenomegaly; (3) persistent marked serum alanine aminotransferase (ALT) activity; (4) elevated total bile acid concentration and total bilirubin (TB), mainly marked conjugated bilirubin (CB); (5) absence of viral infections (such as hepatitis A virus, hepatitis B virus, hepatitis C virus, cytomegalovirus).

For patients and healthy infants, the following biochemical parameters were recorded: serum ALT and aspartate aminotransferase (AST);  $\gamma$ -glutamyltransferase ( $\gamma$ -GT) and serum TB and CB.

We received informed consent from all the subjects' guardians to take part in the study, and the protocol was approved by the local ethical committee of the Hospital.

### Polymerase chain reaction (PCR) amplified the MDR3 R652G and sequence analysis

Genomic DNA was extracted from peripheral venous blood leukocytes using standard phenol chloroform procedures. The DNA concentration was quantified by spectrophotometry. Primers for MDR3 R652G were forward (5'-CATCCATTTGGAGACACACACAC-3') and reverse (5'-GTAGCAGTCATCTGTGCCTGAA A-3')<sup>[7]</sup>. The primary PCR product fragments were 348 bp. PCRs for generating the R652G fragments were generally performed in a reaction volume of 50  $\mu$ L with 100 ng of genomic DNA, 1.5 U of *Taq* polymerase (Fermentas), 10  $\times$  PCR buffer (Fermentas), 1.5 mmol/L of MgCl<sub>2</sub> (Fermentas), 200  $\mu$ mol/L deoxynucleoside-5-triphosphate (Takara) and 20  $\mu$ mol of each primer. PCR conditions included an initial denaturation step at 95°C for 5 min, followed by 30 cycles of denaturation at 94°C for 30 s, annealing at 65°C for 30 s and extension at 72°C for 1 min. The PCR reaction was terminated after an extension step at 72°C for 10 min. The PCR products were analyzed by 2% agarose gel with 0.5  $\mu$ g/mL ethidium bromide and quantitated approximately with a DNA marker (Takara, DaLiang). The PCR products sequence analysis was run in the ABI 3100 automated DNA sequencer. Sequences were compared with the sequence of the MDR3 in GenBank (NG\_007118.1, GI: 169234676).

### Statistical analysis

Data are given as mean  $\pm$  SD. Comparison of the frequency of the R652G SNP was made between patients and controls, and the analysis of association with the phenotype was performed by  $\chi^2$  test or Fisher's exact test when appropriate. A *P*-value < 0.05 was considered statistically significant. The data was analyzed using SPSS 13.0. The odds ratio (OR) was calculated with the corresponding 95% confidence intervals (95% CI). Allele frequency was tested for the Hardy-Weinberg equilibrium.

## RESULTS

The study comprised 78 infants with idiopathic infant cholestasis and 113 controls. Details of the study groups are shown in Table 1. The mean total bilirubin was

Table 1 Clinical characteristics of the 78 idiopathic infant cholestasis patients (mean  $\pm$  SD)

	Patients	Controls
Age (mo)	1.8 $\pm$ 0.31	1.2 $\pm$ 0.25
TB ( $\mu$ mol/L)	194.43 $\pm$ 13.33 <sup>a</sup>	12.94 $\pm$ 5.15
ALT (U/L)	123.80 $\pm$ 11.63 <sup>a</sup>	29.09 $\pm$ 2.62
AST (U/L)	273.86 $\pm$ 27.90 <sup>a</sup>	34.43 $\pm$ 2.43
$\gamma$ -GT (U/L)	308.60 $\pm$ 46.30 <sup>a</sup>	30.22 $\pm$ 9.90

<sup>a</sup>*P* < 0.05 vs control. TB: Total bilirubin; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase;  $\gamma$ -GT:  $\gamma$ -glutamyltransferase.

Table 2 MDR3 R652G genotypes and allele frequencies in patients and controls *n* (%)

Groups	<i>n</i>	Genotypes			Allele frequency (%)	<i>P</i> -value
		A/A	A/G	G/G		
Patients	78	74 (94.9)	4 (5.1)	0	2.6	< 0.05 <sup>1</sup>
Controls	113	95 (84.1)	18 (15.9)	0	8.0	

<sup>1</sup>Fisher's exact test between patients and controls for genotype frequency. *P* = 0.022; OR, 0.29; 95% CI, 0.12-0.84.

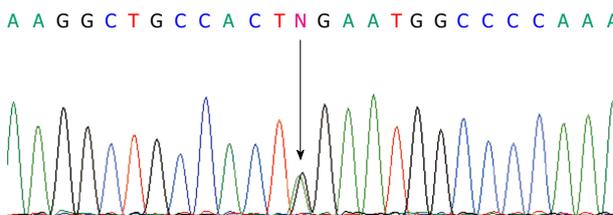

Figure 1 Sequence of the multidrug resistance protein-3 (MDR3) single nucleotide polymorphism R652G (A>G).

194.43  $\pm$  13.33  $\mu$ mol/L (normal  $\leq$  20  $\mu$ mol/L). The mean CB was 105.75  $\pm$  6.44  $\mu$ mol/L. The mean serum transaminase levels were 273.86  $\pm$  27.90 and 123.80  $\pm$  11.63 U/L for AST and ALT, respectively (normal  $\leq$  40 U/L), and mean serum  $\gamma$ -GT was 308.60  $\pm$  46.30 U/L (normal  $\leq$  50 U/L). The levels were all normal in the control group. All the patients had hepatomegaly, and 62 of the 78 cases had splenomegaly.

PCR products sequence analysis showed a heterozygous substitution A>G (Figure 1) in codon 652 which creates an amino acid substitution in codon R652G in exon 16. Distribution of the genetic polymorphisms in patients and controls is shown in Table 2. Test results showed that the R652G genotype distribution in the 2 groups was in line with the Hardy-Weinberg equilibrium, indicating that the selected sample was representative of the population. The patient AG genotype frequency was significantly lower than in the control group (*P* < 0.05). The AG genotype was negatively correlated with idiopathic infant cholestasis (OR, 0.29, 95% CI: 0.12-0.84) showing that the AG genotype has a protective effect in the normal population (Table 2).

### Biochemical markers comparison in patients with different genotypes

The patient group was divided into 2 sub-groups ac-

**Table 3** Comparison of clinical characteristics in patient sub-groups according to genotype (mean  $\pm$  SD)

	Patients A/A	Patients A/G
TB ( $\mu\text{mol/L}$ )	198.94 $\pm$ 14.85	91.65 $\pm$ 15.70
CB ( $\mu\text{mol/L}$ )	95.52 $\pm$ 5.93	44.70 $\pm$ 6.15*
ALT (U/L)	131.54 $\pm$ 11.91	92.50 $\pm$ 10.01
AST (U/L)	281.29 $\pm$ 28.26	129.25 $\pm$ 12.43
$\gamma$ -GT (U/L)	317.68 $\pm$ 47.64	77.00 $\pm$ 18.78

CB: Conjugated bilirubin. \* $P < 0.05$ .

according to genotype and serum biochemical parameters were compared. The CB of the AG genotype ( $44.70 \pm 6.15 \mu\text{mol/L}$ ) was significantly lower compared with that of the AA genotype ( $95.52 \pm 5.93 \mu\text{mol/L}$ ) ( $P < 0.05$ ). Other serum markers in the sub-groups with the 2 genotypes were not significantly different ( $P > 0.05$ ) (Table 3).

## DISCUSSION

Our study is the first report of the MDR3 R652G SNP in children in China. Our data showed that the R652G SNP had a significantly higher proportional distribution in normal infants than in idiopathic infant cholestasis patients. Moreover, in the cholestasis group, the CB of AG genotype patients had a lower mean value than in the AA genotype patients. It is known that CB is a very important index that can reflect the extent of intrahepatic cholestasis. For this reason, we can infer that the R652G variant has a specific protective effect in the normal population.

In previous studies, in the analysis of MDR3 gene sequence variants in different countries, the R652G SNP was the only protein-altering variant with high allele frequency in all groups. It was 7.3% in Caucasians, 1.4% in Japanese and 2.3% in Koreans<sup>[7]</sup>. In another study, the variant was 7.3% in healthy Caucasians, 8.6% in primary biliary cirrhosis patients and 12.8% primary sclerosing cholangitis patients<sup>[8]</sup>. R652G is a MDR3 gene mutation that results in non-synonymous amino acid substitutions but is not associated with disease. In Switzerland, a study showed that the MDR3 R652G variant was 7% in healthy Caucasians, 9% in drug-induced cholestatic patients and 4% in hepatocellular/mixed liver injury<sup>[9]</sup>. Pauli-Magnus *et al*<sup>[10]</sup> reported the R652G variant in 10% of intrahepatic cholestasis pregnancy cases and 16.3% in healthy controls.

The previous studies indicated that the R652G variant was prevalent in the general population. Furthermore, studies of MDR3 R652G in a variety of diseases showed no evidence that the R652G variant was related to disease. In our study, the R652G variant was 15.9% in healthy children, with a higher frequency than in infant cholestasis patients. Therefore, we believe that the AG genotype has a protective effect in infant cholestasis, and the AG genotype is likely to reduce the risk of children suffering from cholestasis. In this study, the proportion of the AG gene type in the normal population was higher than in

previous reports from other regions, possibly because of the existence of racial and geographic differences.

There is also another phenomenon whereby R652G may have a protective effect and reduce the risk of suffering from disease. Jacquemin *et al*<sup>[11]</sup> reported one patient with intrahepatic cholestasis of pregnancy carrying a R652G substitution, and whose biliary phospholipids were lower than other patients. Another study showed the A/G allele frequency was 6% in intrahepatic cholestasis of pregnancy patients and 17% in healthy controls in Sweden. The AA genotype subjects were more likely to suffer from cholestasis<sup>[12]</sup>. Our result also confirmed this conclusion.

A recent study of gallstones in sibling pairs and controls showed that R652G variant frequency was 18% in patients and 25% in controls. In the control sub-groups, subjects with the GG genotype had significantly lower cholesterol compared with those with the AA genotype. It is known that cholesterol is the raw material for synthesis of bile acids<sup>[13]</sup>. This gives an indication of the direction of future research.

It is worth noting that this is an interesting new result. Most of the MDR3 gene variants have reported an association with disease causation, such as PFIC and intrahepatic cholestasis of pregnancy<sup>[14,15]</sup>. In contrast, the R652G variant seems to have a protective effect. It has been assumed that the missense mutation R652G is a neutral polymorphism. Sequence comparisons of MDR3 genes identified that the glycine residue is conserved in other species such as rat and hamster. More research will be required to confirm that in the future.

In conclusion, the MDR3 R652G SNP is negatively correlated with cholestasis (OR, 0.29, 95% CI, 0.12-0.84). Children in Guangxi of China with the R652G variant may have reduced susceptibility to infant intrahepatic cholestasis.

## COMMENTS

### Background

Idiopathic infant intrahepatic cholestasis is a common clinical disease that can occur in either a sporadic or a familial form. The incidence of idiopathic infant intrahepatic cholestasis is very high in China. If not treated early, approximately 5%-10% of patients can have persistent inflammation or fibrosis, and a few develop more severe liver disease, such as cirrhosis.

### Research frontiers

All studies in recent years on the multidrug resistance protein 3 (MDR3) variants have involved the development of disease. However, an interesting phenomenon is that there was no positive evidence for the MDR3 R652G variant being involved in the pathogenesis of intrahepatic cholestasis. This study investigated the MDR3 R652G distributed allele frequency in idiopathic infant cholestasis and healthy infants to determine whether there were any difference and, if so, their relevance.

### Innovations and breakthroughs

Most studies have concentrated on MDR3 mutations in the pathogenesis of progressive familial intrahepatic cholestasis type 3, intrahepatic cholestasis of pregnancy and cholelithiasis. There have been few studies investigating MDR3 and idiopathic infant intrahepatic cholestasis. In order to evaluate the role of the MDR3 R652G variant in the pathogenesis of idiopathic infant cholestasis, the authors analyzed the MDR3 R652G polymorphism in a case-control study in Guangxi Chinese infants. The authors found that the R652G variant was significantly more frequent in healthy infants than in patients. The results showed that the R652G variant has a protective effect in healthy infants and reduces the possibility of suffering from idiopathic infant cholestasis. The result

was not the same as a previous study. The reason may be a result of ethnic population differences and the variability in geographical location.

### Applications

The study results suggest that the MDR3 R652G variant has a protective effect in healthy infants. This will give further information for comparing geographical regions, and it is very important to establish particular characteristics of MDR3 R652G that can be useful in the differential diagnosis of idiopathic infant cholestasis, and furthermore, may establish the influence of such a single nucleotide polymorphism (SNP) in prognosis.

### Terminology

MDR3 R652G: MDR3 R652G is a SNP of the MDR3 in the 652 coding site. The MDR3 is encoded by the ABCB4 gene, and the 652 coding site is located in ABCB4 exon 16. The R652G is a gene mutation where the adenine (A) mutates into guanine (G) which causes AGA>GGA resulting in arginine substitution by glycine (R652G).

### Peer review

The paper gives a significant contribution to basic science knowledge, as well as clinical practice. Publishing this manuscript will allow further comparison with data from other regions and help to clarify the pathogenesis of idiopathic infant cholestasis.

### Abstract

Somatostatinomas are extremely rare neuroendocrine tumors of the gastrointestinal tract, first described in the pancreas in 1977 and in the duodenum in 1979. They may be functional and cause somatostatinoma or inhibitory syndrome, but more frequently are non-functioning pancreatic endocrine tumors that produce somatostatin alone. They are usually single, malignant, large lesions, frequently associated with metastases, and generally with poor prognosis. We present the unique case of a 57-year-old woman with two synchronous non-functioning somatostatinomas, one solid duodenal lesion and one cystic lesion within the head of the pancreas, that were successfully resected with a pylorus-preserving Whipple's procedure. No secondaries were found in the liver, or in any of the removed regional lymph nodes. The patient had an uneventful recovery, and remains well and symptom-free at 18 mo postoperatively. This is an extremely rare case of a patient with two synchronous somatostatinomas of the duodenum and the pancreas. The condition is discussed with reference to the literature.

### INTRODUCTION

Somatostatinomas are extremely rare and account for < 1% of functional APUD (amine precursor uptake and decarboxylation) cell neuroendocrine tumors of the gastrointestinal tract<sup>[1,2]</sup>, with an annual incidence of 1 case per 40 million people<sup>[3]</sup>. Somatostatinomas usually occur within the pancreas but can also manifest in the duodenum, and less frequently in the jejunum and cystic duct<sup>[4-6]</sup>. Since the first description of somatostatinoma of the pancreas in 1977<sup>[7]</sup>, and duodenum in 1979<sup>[8]</sup>, 100-200 cases<sup>[1,2,9]</sup> have been described in the world literature, each occurring as a single lesion. A PubMed search resulted in a single case report of two somatostatinomas in the same patient, associated with type I neurofibromatosis<sup>[10]</sup>.

We present an extremely rare case with two synchronous non-functioning somatostatinomas, one solid duodenal lesion and one cystic lesion within the head of the pancreas, without other disorders such as von Recklinghausen's disease.

### CASE REPORT

A 57-year-old woman presented with moderate epigastric pain in January 2007. Clinically, she was found to have only mild tenderness in the epigastrium, and all laboratory data were within normal limits. Ultrasound (US) and computed tomography (CT) revealed a 3 cm × 3 cm tumor in the duodenum, which was causing narrowing of its lumen to 1 cm, as well as a mass with a gas-filled cyst within the head of the pancreas (Figure 1). A cyst was also found within the head of the pancreas. A barium meal confirmed the duodenal luminal narrowing, and the tumor position above the ampulla of Vater, and

**Figure 1** Computed tomography (CT) showing well-vascularized mass within the duodenum and in the head of the pancreas. There is also a cystic lesion containing gas within the pancreatic mass.

upper gastrointestinal endoscopy provided a histological specimen that indicated a neuroendocrine tumor.

At laparotomy, two separate masses were found, one within the medial wall of the descending duodenum, and the second within the head of the pancreas. There were no visible or palpable secondaries within the liver or the peritoneal cavity. As both tumors appeared resectable, we proceeded with a pylorus-preserving Whipple's procedure, as well as regional lymph node dissection. The postoperative recovery was uneventful and the patient remains well at 18 mo.

Macroscopically, the first lesion was a well-demarcated solid nodular suprapapillary tumor of the duodenum, 42 mm in its greatest diameter, 25 mm from the pylorus, and penetrating 15 mm through the duodenal wall to reach the superior margin of the head of the pancreas. There was no obvious intrapancreatic or choledochal infiltration of the tumor. A transverse section showed the tumor to be composed of soft grey/yellow granular and light brown nodular tissues (Figure 2A-D).

The second was a distinctive cystic and hemorrhagic lesion, with a tiny fistula with the duodenum, within the enlarged head of the pancreas. The lesion measured 36 mm in its greatest diameter, contained necrotic and hemorrhagic coagula, and was surrounded by a thin fibrotic pseudocapsule zone. The inner surface of the cyst contained a layer of spongy tan/light brown tissue. There were no other notable micromorphological findings in the remainder of the resected pancreatic specimen.

Histopathology of the duodenal tumor revealed a dominant micronodular and insular growth of epithelioid cells, with rare trabecular or solid microorganization, and without necrotic areas (Figure 3A). The tumor cells were packed tightly with a high degree of uniformity and ill-defined ovoid/polygonal shapes. Their round nuclei were situated centrally, with low nuclear anaplasia and two mitotic figures per 10 high-power fields. However, despite expansive growth and a clearly demarcated border, peritumoral venous infiltration and microinfiltration of the periduodenal fatty tissue was found frequently.

The pseudocystic lesion of the pancreas showed an

obvious neoplastic proliferation with similar histology seen within the thin neoplastic peripheral rim. This narrow peripheral zone was surrounded by a pseudocapsule, and the vast majority of cells contained within the cyst showed hemorrhagic and necrotic changes (Figure 3B). No extrapancreatic spread or involvement of the regional lymph nodes was found, although focal venous infiltration was observed.

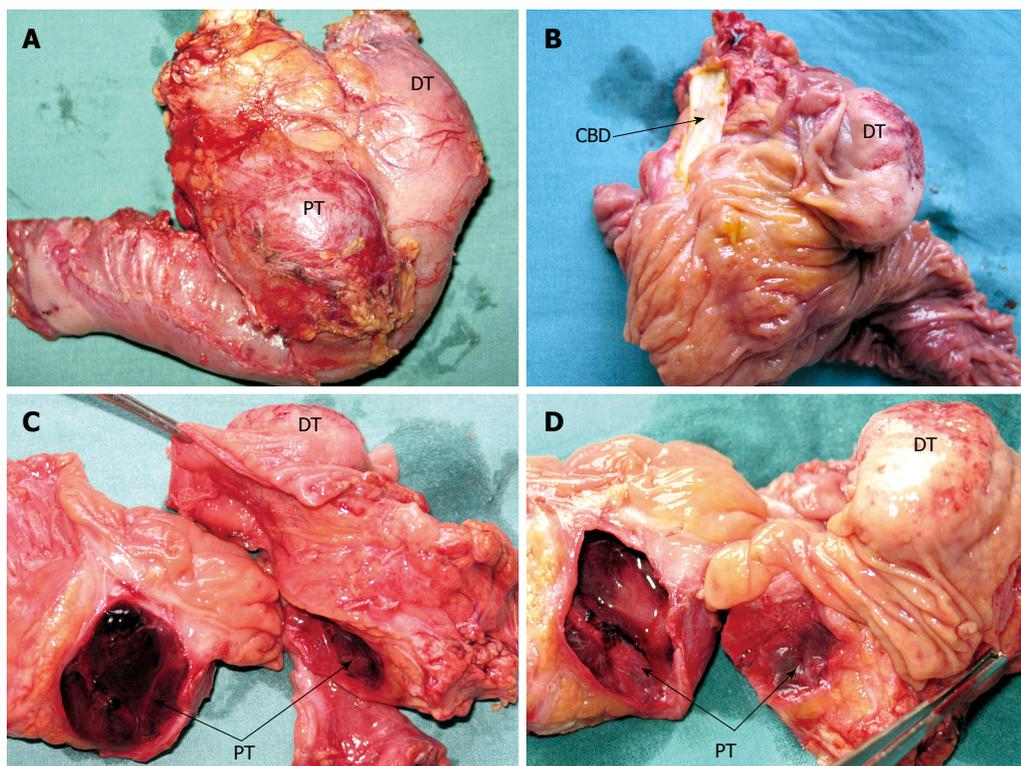

Immunohistochemistry confirmed that both tumors were derived from a similar cell origin. There was a significant cytoplasmic immunoreactivity of pan-neuroendocrine markers: chromogranin A occurred more intensely and frequently than synaptophysin (Figure 4A). There was strong somatostatin immunoreactivity in over half of the duodenal tumor cells (Figure 4B) and 70% of the pancreatic tumor cells (Figure 5A), where a small percentage of cells that coexpressed glucagon and pancreatic polypeptide immunoreactivity were also found. Proliferative activity measured using Ki-67 protein labeling indices was approximately 3.5% in both tumors (Figure 5B). The final histopathological diagnosis of somatostatinoma of the duodenum and the pancreas was made in tumor stages pTNP: 2T (T3+T2) N0 Mx LOVI. It was concluded that despite the absence of regional and distant metastases, neither tumor could be categorized as benign, given their histopathological features, size, mitotic counts and proliferative activities.

One and a half years after surgery, the patient is symptom-free, with normal US and scintigraphy of the liver.

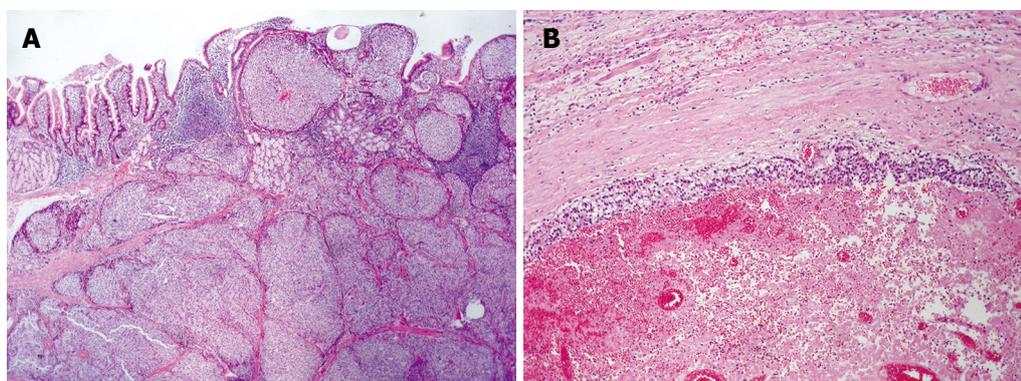

## DISCUSSION

Somatostatinomas are extremely rare gastrointestinal tumors with an annual incidence of 1 case per 40 million adults<sup>[5]</sup>. Two-thirds of somatostatinomas occur within the pancreas, with the duodenum being the next most common site<sup>[9]</sup>; although some authors have found equal frequencies<sup>[11]</sup>. They can occur at any age (range: 21-91 years)<sup>[1,9]</sup>, and pancreatic somatostatinomas show a slight female predominance (67%), with extrapancreatic sites being more often present in men<sup>[1]</sup>. Forty-five percent of cases exist as part of multiple endocrine neoplasia type I syndrome or von Hippel-Lindau disease<sup>[1]</sup> and it is vital to confirm or refute these associated conditions. Duodenal somatostatinomas may be associated with von Recklinghausen's neurofibromatosis<sup>[1,12,13]</sup>.

Differences exist between the pancreatic and extra-pancreatic types. Duodenal somatostatinomas usually are located in the second part of the duodenum, and most frequently in the ampullary or periampullary regions. Approximately 30% have lymph node or liver secondaries at the time of diagnosis, although these are less frequent when tumors are < 2 cm<sup>[9]</sup>. About two-thirds of these tumors contain psammoma bodies within the lumina of their glandular structures, and their biological behavior is similar to that of carcinoid tumors. As a result of their location, patients often present earlier with bile duct obstruction and jaundice, hence the reason for their earlier discovery, earlier surgery, smaller

**Figure 3** Histopathology. A: Mucosal and submucosal tumor infiltration of the duodenum, revealing an insular growth of rather uniform epithelioid cells (HE,  $\times 25$ ); B: The pancreatic tumor presenting as a hemorrhagic pseudocyst, with a thin peripheral layer of neoplastic proliferation (HE,  $\times 56$ ).

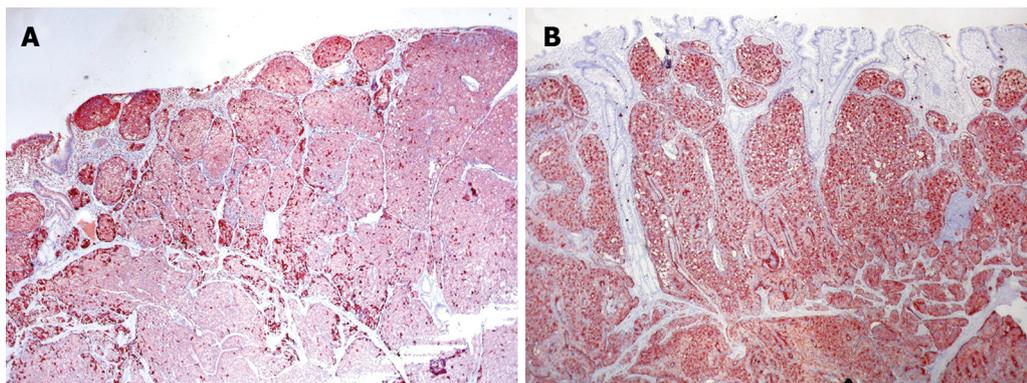

sizes and lower rates of metastasis<sup>[1,2,9]</sup>.

Almost 60% of pancreatic somatostatinomas are located in the head of the pancreas, and about 30% in the tail<sup>[1]</sup>. They usually are larger (mean size: 5-6 cm), and are considered more malignant with a 70% incidence of metastases<sup>[9]</sup>. Often the mass effect of the tumor itself leads to its diagnosis<sup>[11]</sup>.

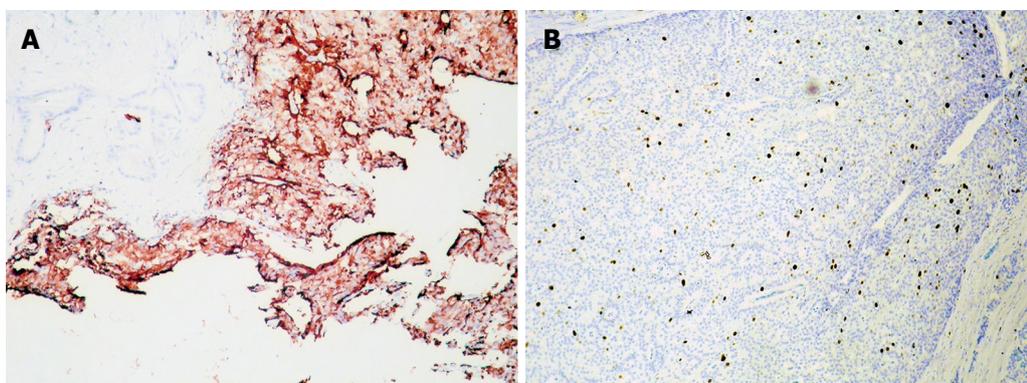

Although somatostatin is the main secretory product, at least 10% of somatostatinomas produce other hormones, including glucagon, gastrin, vasoactive intestinal peptide (VIP), insulin, calcitonin, and adrenocorticotrophic hormones<sup>[14-16]</sup>, and the clinical picture may be dominated by the effects of these secreted hormones<sup>[4]</sup>. Duodenal somatostatinomas more frequently secrete gastrin, VIP

and calcitonin<sup>[9]</sup>, while pancreatic somatostatinomas are also more likely to be multihormonal<sup>[11]</sup>.

Regardless of their plasma somatostatin levels, most patients present with indolent, nonspecific symptoms including vague abdominal pain, weight loss and a change in bowel habits<sup>[1,2]</sup>. The classical somatostatinoma or inhibitory syndrome, which includes cholelithiasis, mild diabetes mellitus and steatorrhea with diarrhea, is present in only a small number of patients<sup>[1,4]</sup>. The syndrome is the result of the inhibitory effects of somatostatin on endocrine and exocrine secretion, as well as its suppression of stomach and gallbladder motility<sup>[9]</sup>. It occurs far less with duodenal than other extrapancreatic somatostatinomas<sup>[1]</sup>, and this may be due to their earlier

**Figure 4** Duodenal tumor cells showing a non-homogeneous immunoreactivity against anti-chromogranin A antibody, but clear diffuse cytoplasmic immunohistochemical reactivity with anti-somatostatin antibody. A: Chromogranin A immunoreactivity,  $\times 56$ ; B: Somatostatin immunoreactivity, labeled streptavidin biotin (LSAB) method, aminoethylcarbazole (AEC) visualization,  $\times 56$ .

diagnosis, release of inactive peptides, or lower secretory activity of the smaller duodenal tumors<sup>[2]</sup>.

The preoperative diagnosis of somatostatinoma is extremely difficult to establish unless there is a high clinical suspicion based on the patient's symptomatology<sup>[1]</sup>, although elevated fasting serum levels of somatostatin that cause the somatostatinoma syndrome can be diagnostic, particularly if associated with tumors larger than 4 cm<sup>[1]</sup>. CT and magnetic resonance imaging often fail to identify small tumors of the duodenum<sup>[13]</sup>, and these are often discovered during upper gastrointestinal endoscopy. The diagnosis is then made based upon histological assessment of biopsy specimens during upper gastrointestinal endoscopy<sup>[1,13]</sup> or endoscopic US<sup>[17]</sup>, with the exact histopathological diagnosis ultimately based on the resected specimen<sup>[1,2]</sup>. Once the preoperative diagnosis is established, somatostatin receptor scintigraphy and positron emission tomography can localize accurately the disease<sup>[18]</sup>, and are particularly useful in identifying occult metastatic spread and recurrent disease<sup>[19]</sup>. Scintigraphy positive for metastatic spread can obviate unnecessary surgery<sup>[2]</sup>; similarly a negative scan can indicate that curative resection is a possibility<sup>[19]</sup>.

Surgical resection is the only form of curative treatment<sup>[1]</sup> smaller lesions (< 2 cm) by enucleation larger lesions with extensive Whipple's type resections<sup>[20]</sup> (due to

their common localization in the head of the pancreas and duodenum), or other similar anastomoses. Unfortunately, in only 60%-70% of surgical cases is the tumor completely resected<sup>[1,3]</sup>. Debulking surgery should also be considered in the presence of metastatic secondaries because this may lead to improved survival and quality of life, especially in those with somatostatinoma syndrome<sup>[1,21]</sup>. Indeed, palliation for bile duct obstruction, pain or hormonal excess is beneficial in most unresectable cases<sup>[1]</sup>.

For patients with liver secondaries that are not amenable to resection or ablation, hepatic artery embolization or chemoembolization may be an effective therapy for symptomatic palliation<sup>[22]</sup>. Adjuvant chemotherapy is not advocated after complete resection<sup>[1]</sup>, however, in locally unresectable cases or in metastatic somatostatinoma, chemotherapeutic agents have been used with moderate clinical responses<sup>[1,23]</sup>.

Somatostatinomas are slow-growing lesions and long-term survival is possible<sup>[1]</sup>, even with no intervention. Unfavorable prognostic predictors include tumor size > 3 cm, poor cytological differentiation, regional and/or portal vein metastases, a non-functioning tumor, and incomplete surgical resection<sup>[1]</sup>.

Ultimately, patients with localized disease and a successful resection are the most likely to achieve a cure<sup>[2]</sup>, however, even in the presence of metastases, the 5-year

survival for patients undergoing surgical resection with adjuvant chemotherapy approaches 40%<sup>[1]</sup>.

### Abstract

In this case report we describe the relationship between ferritin levels and hepcidin in a patient with alcohol-related spur cell anemia who underwent liver transplantation. We demonstrate a reciprocal relationship between serum or urinary hepcidin and serum ferritin, which indicates that inadequate hepcidin production by the diseased liver is associated with elevated serum ferritin. The ferritin level falls with increasing hepcidin production after transplantation. Neither inflammatory indices (IL6) nor erythropoietin appear to be related to hepcidin expression in this case. We suggest that inappropriately low hepcidin production by the cirrhotic liver may contribute substantially to elevated tissue iron stores in cirrhosis and speculate that hepcidin replacement in these patients may be of therapeutic benefit in the future.

### INTRODUCTION

Hepatic iron overload in alcohol related cirrhosis and the detrimental effect of excessive iron on hepatic tissues in this condition is well described<sup>[1]</sup>. Previous studies investigating whole-body retention of iron showed a two-fold increase in intestinal iron absorption in chronic alcoholism, and the underlying mechanism has not been identified<sup>[2]</sup>.

Hepcidin, a 25 amino acid peptide, is the recently described body iron storage regulator. Under physiological conditions, hepcidin expression is stimulated by stored tissue iron, inflammatory stimuli and repressed by anemia and tissue hypoxia<sup>[3]</sup>. Recently, interactions between various signals affecting hepcidin production by hepatocytes have been elucidated<sup>[4]</sup>. Hepcidin binds to the iron exporter protein ferroportin on the basolateral aspect of macrophages and enterocytes and causes internalization and degradation of this molecule<sup>[5]</sup>, rendering cells iron-loaded. The two major systemic effects of elevated hepcidin production are therefore reduction of intestinal iron uptake and reticulo-endothelial sequestration of iron.

As the erythron is the main user of iron, its requirement for red cell production is paramount. In the presence of anemia due to ineffective erythropoiesis, animal experiments have shown that an unidentified signal from bone marrow seems able to override the stimulus of elevated body iron stores, repressing hepcidin and allowing duodenal iron absorption to continue even in the presence of elevated iron stores<sup>[6]</sup>.

Spur cell anemia (SCA) is an interesting clinical condition in which both erythropoiesis and tissue iron stores are altered by excessive alcohol consumption such that sufferers develop severe tissue iron overload and ongoing hemolysis<sup>[7]</sup>. The hemolysis is due to structural abnormalities of red cell membranes, resulting in spiculated erythrocytes (acanthocytes) which undergo early splenic destruction<sup>[8]</sup>. Treatment of SCA has been disappointing and it is commonly viewed as an indicator of end-stage liver disease<sup>[9]</sup>.

We postulate that reduced hepcidin production in the cirrhotic liver might be a significant factor contributing to the body iron excess in this patient with end stage alcohol-induced cirrhosis and SCA who underwent orthotopic liver transplantation (OLT).

## CASE REPORT

The patient was a 55-year old female with a 10-year history of excessive alcohol consumption who, following hospitalization due to decompensation and alcoholic hepatitis, became abstinent in May 2005. She remained stable until March 2006 when she developed worsening jaundice. Hematological findings indicated that hemolysis was a significant contributory factor in the patient's jaundice. Subsequent investigations confirmed the diagnosis of SCA in the context of cirrhosis. She was referred for transplantation assessment in November 2006. She had an unconjugated hyperbilirubinaemia (230 U/L) and raised reticulocyte count ( $125 \times 10^9/L$ ). Hepatic synthetic function was relatively preserved with an INR of 1.5 and serum albumin concentration of 38 g/L. A blood film showed many acanthocytes with polychromasia and spherocytes. A transjugular liver biopsy showed micronodular cirrhosis and grade 1 siderosis. Her serum ferritin level at this time was greatly elevated at 600 ng/mL.

The patient decompensated further and was listed for transplantation. The blood film immediately before transplantation showed a predominance of acanthocytes (70%-80% of total red blood cells (RBC)), and there was a gradual reduction in acanthocytes over the 48 h following transplantation so that examination of a blood film at 48 h after surgery indicated that acanthocytes made up 50%-60% of total circulating RBCs.

The patient gave consent for blood and urine samples collection for the study (LREC 08/MRE09/2). Samples were taken immediately before and at 12, 36, 48 h and 2 mo after transplantation. Blood was analyzed for ferritin, hemoglobin, erythropoietin, IL-6 and CRP to assess the extent of hemolysis and inflammation. Hepcidin was measured by SELDI-TOF using  $Cu^{2+}$  loaded IMAC ProteinChip Arrays and stable isotope labeled hepcidin as an internal standard as previously described<sup>[10]</sup> and available *via* <http://www.hepcidin.bham.ac.uk/>. Urine samples were normalized with respect to protein concentration (20  $\mu$ g/mL, Bradford assay).

A sample of the explant liver was analyzed for hepcidin mRNA by q-RTPCR and this was compared with samples taken from 8 normal livers.

The hepcidin level in relation to hematological parameters is shown in Table 1. Hepcidin levels before transplantation were very low compared with the elevated ferritin. Following transplantation, hepcidin production rose with falling ferritin. At 2 mo after transplantation, the hepcidin production had fallen in the context of the normal serum ferritin. The urinary hepcidin/ferritin ratio rose progressively following transplantation.

Figure 1 shows that the rise and subsequent fall in urinary hepcidin following transplantation does not seem to be related to erythropoietin production which remains quite stable (except for one dip at 12 h coincident with a

Table 1 Urinary hepcidin levels in relation to haemoglobin and ferritin

Time	Urinary hepcidin (ng/mg)	Ferritin (ng/mL)	Hepcidin/ferritin ratio	Hb (g/dL)
0 h	5	542	0.009	7.0
12 h	8	349	0.023	10.7
36 h	100	404	0.248	9.8
48 h	112	413	0.272	9.3
2 mo	12	81	0.148	14.3

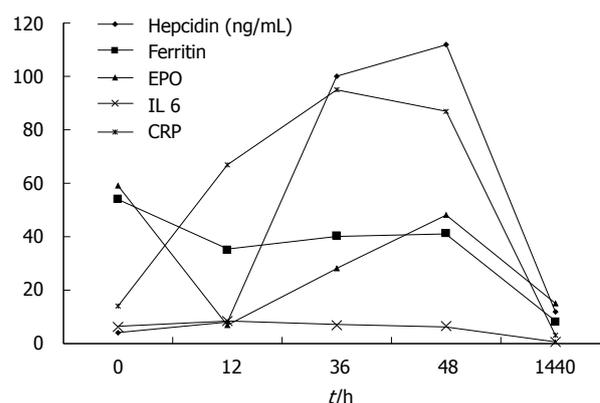

Figure 1 Variation in iron parameters with time.

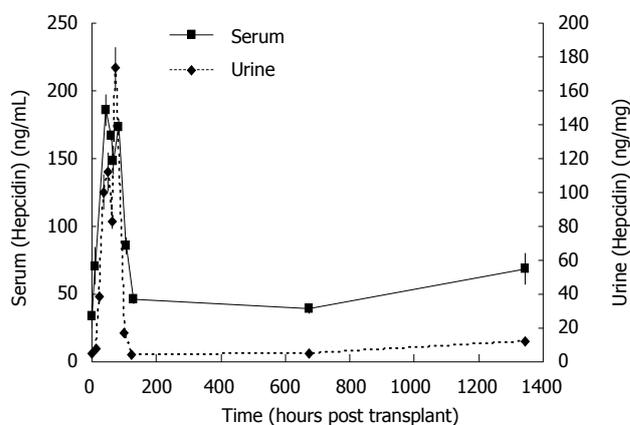

Figure 2 Correlation between urinary and serum ferritin.

two unit peri-operative blood transfusion). Similarly, IL6 levels did not vary greatly. CRP rose as expected in relation to the operation. This rise was not immediately accompanied with the dramatic rise in hepcidin production which was delayed for 12 h. Figure 2 illustrates a close correlation between urinary and serum hepcidin levels in this patient (Pearson correlation coefficient  $r = 0.958$ ).

We compared hepcidin mRNA expression in the explant liver with that in 8 normal livers from transplant donor tissues. Hepcidin mRNA expression in the explant liver from our patient was significantly lower than that in normal liver (data not shown).

## DISCUSSION

This case illustrates "inappropriate" low hepcidin production in an iron-over loaded cirrhotic patient with

alcohol-related SCA. Following successful transplantation, hepcidin production by the new liver increased accompanied with falling serum ferritin. "Appropriate" hepcidin production by the new liver would act to sequester iron in reticulo-endothelial stores and to repress duodenal iron uptake. At 2 mo after OLT, both hepcidin and ferritin fell to low levels.

One potential mechanism for pre-operative hepcidin repression would be high circulating erythropoietin level in the hemolyzing patient. Apart from a small reduction in EPO in the peri-operative period which co-incided with a blood transfusion, EPO remained relatively high in the post-operative period consistent with observed persistence of spur cells and the ongoing anemia. This hepcidin expression in the new liver increased progressively. It is likely that hepcidin production in the new liver during the early post-transplantation period remains somewhat muted in relation to the ongoing EPO stimulus.

IL6 stimulates hepcidin production acutely through the STAT pathway. In our patient IL6 was low before transplantation and did not rise in the peri-operative period. CRP did rise in the immediate post-transplantation period as expected. This may have had a bearing on the observed increase in hepcidin as inflammation is a major trigger to hepcidin production.

In our case, although the cirrhosis was undoubtedly alcohol-related, the patient had been abstinent for 2 years. This raises the possibility that, even in the absence of an ongoing stimulus, a persistent hepatic oxidative state, perhaps induced by iron overload, could trigger ongoing repression of hepcidin production. This illustrates potentially differential effects of acute stimulation of hepcidin perhaps *via* the IL6/STAT pathway and chronic repression mediated by oxidative stress<sup>[11]</sup>.

In summary, the cirrhotic liver in this patient with alcohol-induced spur cell anemia produced very little hepcidin in relation to circulating high ferritin levels and this deficiency was corrected by transplantation.

The mechanisms underlying reduced hepcidin production in this situation, in particular the role of oxidative stress as mediated through CHOP/CEBP, deserve further

studies in the setting of human alcohol-related cirrhosis. The influence of alcoholic cirrhosis on duodenal expression of iron transporter proteins and the influence of local effects related to oxidative stress and external factors such as erythropoiesis on human hepcidin production clearly deserve further prospective examinations.

### Abstract

Pancreatic endocrine tumors are rare but are among the most common neuroendocrine neoplasms of the abdomen. At diagnosis many of them are already advanced and difficult to treat. We report on an initially inoperable malignant pancreatic endocrine tumor in a 33-year-old woman, who received neoadjuvant peptide receptor radionuclide therapy (PRRT) as first-line treatment. This resulted in a significant downstaging of the tumor and allowed its subsequent complete surgical removal. Follow-up for eighteen months revealed a complete remission. This is the first report on neoadjuvant PRRT in a neuroendocrine neoplasm with subsequent successful complete resection.

### INTRODUCTION

Although pancreatic endocrine tumors (pNETs) are rare, they are among the most common neuroendocrine neoplasms of the abdomen<sup>[1]</sup>. pNETs account for less than 5% of all primary pancreatic malignancies. They are separated into functional (insulinomas, gastrinomas, glucagonomas, somatostatinomas) and non-functional pNETs. Non-functioning pNETs are pancreatic tumors with endocrine differentiation that lack a clinical syndrome of hormone hypersecretion. Up to 60% of non-functioning endocrine pancreatic tumors are already metastasized at diagnosis. In the advanced stage the pNETs still remains an interdisciplinary challenge. Pancreatic neuroendocrine tumors treatment by chemotherapy and radiation therapy has not demonstrated significant antitumoral effects. Because well differentiated neuroendocrine neoplasms usually express somatostatin receptors, they can be targeted with peptide receptor radionuclide therapy (PRRT) with palliative intention<sup>[2,3]</sup>. Several studies showed promising results in patients with advanced neuroendocrine tumors, with a partial response or disease stabilisation in palliative treatment<sup>[3,4]</sup>. But surgery still remains the gold standard in the management of pNETs<sup>[5]</sup>. Aggressive surgical resection can be performed safely and may improve both symptomatic disease and overall survival<sup>[6]</sup>. Prognostic indices such as tumor differentiation and the ability to achieve R0 resection have been linked to survival outcome. Here we describe the treatment of an initially inoperable pNET with peptide receptor radionuclides and show that this neoadjuvant treatment resulted in downstaging of the tumor and curative surgery.

### CASE REPORT

A 33-year-old woman was admitted to an external hospital

**Figure 1** Histological images.

A: Lymph node metastasis of a high differentiated neuroendocrine carcinoma showing a trabecular pattern (HE,  $\times 120$ ); B The cells are positive for synaptophysin ( $\times 120$ ); C: High membranous expression of somatostatin-receptor SSTR-2 ( $\times 120$ ); D: Macrophages (CD68-positive) as a sign for tumor necrosis after PRRT ( $\times 120$ ).

because of recurrent abdominal pain, flush attacks and diarrhea. CT revealed enlarged paraaortic lymph nodes, but no primary tumor. On exploratory laparotomy a tumor in the head of the pancreas was found and was thought to be a pancreatic ductal adenocarcinoma. This tumor was deemed inoperable because of the involvement of the mesenteric vessels and the paraaortic lymph nodes. Therefore only a lymph node biopsy was obtained. Histological investigation of the biopsy specimen revealed a lymph node metastasis (peripancreatic) of a highly differentiated neuroendocrine carcinoma that stained positive for chromogranin A and synaptophysin (Figure 1A and B). There was no expression of insulin, glucagon, somatostatin, or pancreatic polypeptide. The somatostatin receptor SSTR2 showed distinct membranous expression (Figure 1C). The tumor cells were only supported by small stromal tissue bands. A [ $^{68}\text{Ga}$ ]DOTA-1-Nal $^3$ -octreotide (NOC) PET/CT was performed to evaluate the somatostatin receptor status. Chromogranin A and serotonin serum levels were normal at all times. Finally, the patient was diagnosed as having a highly differentiated neuroendocrine pancreatic carcinoma, stage IV. Biotherapy with a somatostatin analogue failed. The patient still complained about flushes and diarrhea.

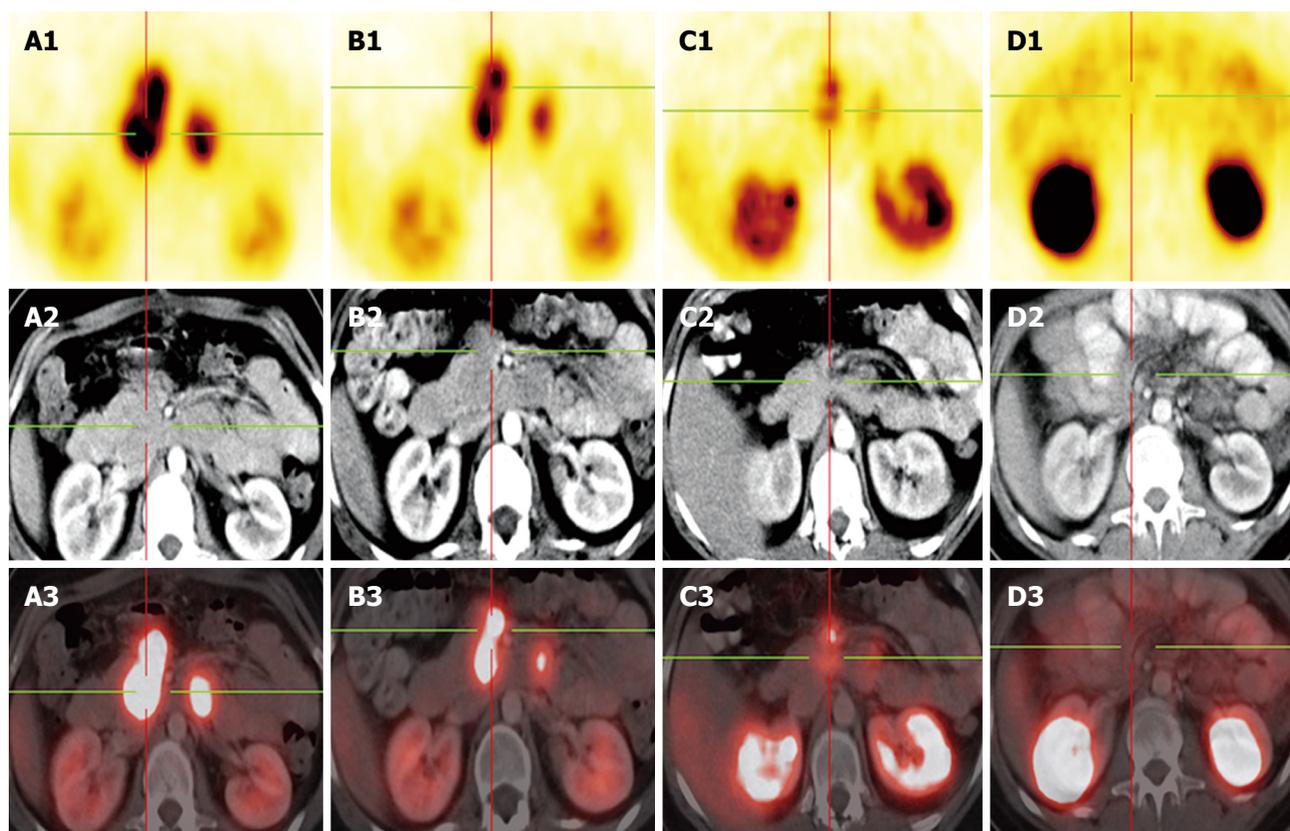

As the patient resolutely refused any chemotherapy, but was willing to undergo radioreceptor therapy, two cycles of PRRT were administered intravenously. The first cycle, administering 6000 MBq (162.1 mCi) [ $^{90}\text{Y}$ ]DOTA-TATE (DOTA-[Tyr $^3$ ] octreotate) was given in February 2007 and the second one, injecting 4500 MBq (121.6 mCi), in June 2007. To prevent nephrotoxicity, an amino acid infusion based on the protocol of Jamar *et al*<sup>[7]</sup> was used. Kidney function was measured by  $^{99\text{m}}\text{Tc}$ -DTPA using the single sample plasma clearance method for GFR calculation.  $^{99\text{m}}\text{Tc}$ -MAG3 was used for dynamic renal scintigraphy and for determination of

the tubular extraction rate (TER). The blood profile and routine laboratory parameters (electrolytes, liver function tests, creatinine, BUN *etc.*) were checked prior to therapy and then every month.

Mild grade 1 anemia and erythrocytopenia were noted as the only side effects. There was no other hematotoxicity or nephrotoxicity.

After 2 cycles the abdominal lymph node metastases had regressed significantly and PET/CT using [ $^{68}\text{Ga}$ ]DOTA-NOC and  $^{18}\text{F}$ -FDG ([ $^{18}\text{F}$ ]fluor-2-deoxy-glucose) performed in October 2007 indicated that the patient was operable. After every PRRT cycle a partial remission (EORTC criteria 1999) was detected (Figure 2B and C).

In November 2007, a pylorus-preserving pancreatoduodenectomy (Traverso-Longmire) was performed with en bloc resection of parts of the jejunum and its mesentery and lymph nodes (Figure 3). The operation specimen revealed a tumor in the head of the pancreas that was more than 2 cm in diameter and had metastasized to one mesenteric lymph node. Histologically, the endocrine tumor formed a trabecular pattern. The cell structures were embedded in well developed hyaline connective tissue, some parts of which were myxomatous. In the myxomatous area there were aggregates of CD68 positive macrophages that were occasionally positive for iron (Figure 1D). The tumor tissue infiltrated the surrounding pancreatic and interstitial tissue and also showed perineural infiltration. Immunohistochemically, about 5%-10% of the tumor cells expressed glucagon or somatostatin and were negative for insulin, serotonin and pancreatic polypeptide. The somatostatin receptor SSTR2 showed a distinct membranous staining pattern in all tumor cells. The lymph node was filled with tumor tissue. The final stage was ypT2 pN1 pM1(LYM) G3 R0 L0 V0<sup>[8]</sup>. The patient left the hospital 19 d after the operation. Six, twelve and

**Figure 2** Gallium-68 DOTA-NOC PET-CT in the follow up. A: Octreotide scan prior to PRRT-1, Gallium-68 DOTA NOC PET-CT and prior operation, showing multiple paraaortal lymph nodes next to the pancreas head; B: 3 mo after PRRT-1; C: 5 mo after PRRT-2 showing consistently decreasing mesenterial lymph nodes metastases with a decreasing SUV; D: Octreotide scan as follow up 18 mo after operation-complete remission.

**Figure 3** The pancreatic tumor with lymph node metastases (peripancreatic and one distal mesenteric lymph node metastasis) after pylorus-preserving duodenopancreatectomy and mesenteric lymphadenectomy *en bloc*.

eighteen months later a [<sup>68</sup>Ga]DOTA NOC PET/CT revealed a complete remission (Figure 2D).

## DISCUSSION

Advanced malignant pNETs are difficult to treat<sup>[9,10]</sup> and there are only a few studies on the resection of pNETs with extensive local spread. It seems, however, that patients with advanced malignant pNETs benefit from resection, because postoperative actuarial 5-year survival rates of up to 80% have been reported after extended tumor resection, even with synchronous metastasis<sup>[11,12]</sup>.

Nonetheless, the presence of liver or distant metastases is the prognostic factor determining survival<sup>[13]</sup>. In our patient, the diagnosis of a malignant well differentiated pNET was made on a biopsy specimen obtained during an explorative laparotomy. Tumor tissue showed a high expression of the somatostatin receptor SSTR2. Since the patient refused any chemotherapy, treatment with PRRT was performed. In the course of therapy an excellent downstaging of the initially inoperable tumor was reached. The oncology concept was changed from palliative to curative intent considering operability. PRRT is usually used as a palliative treatment<sup>[14]</sup>. Currently, there are no reports that deal with the use of radionuclide therapy as a neoadjuvant strategy in oncological surgery. Our case indicates that this therapy may be useful for downstaging and downsizing well differentiated neuroendocrine tumors, thereby achieving a higher operability rate. We recommend first performing [<sup>68</sup>Ga]DOTA-NOC PET/CT to evaluate the somatostatin receptor status<sup>[15,16]</sup>. If there is high SSTR expression PRRT will be effective<sup>[17]</sup>. In addition, staging of the patient after every cycle is required in order to evaluate the response and the operability. The tumor should be downsized to an extent in which a R0-resection should be feasible. In case of a relapse, which is not unlikely<sup>[11]</sup>, another course of PRRT is again a therapeutic option.

In conclusion, based on the encouraging results obtained in this case we believe that neoadjuvant PRRT is a novel approach in the treatment of surgically unrese-

ctable pNETs in patients with positive somatostatin receptor status.

### Abstract

We report a case of Cronkhite-Canada syndrome (CCS) associated with myelodysplastic syndrome (MDS). A 54-year-old woman, diagnosed as MDS the prior year after evaluation of anemia, visited our hospital with the chief complaint of epigastric discomfort. She also had dysgeusia, alopecia, atrophic nail change, and pigmentation of the palm, all of which began several months ago. Blood tests revealed severe hypoalbuminemia. Colonoscopy (CS) showed numerous, dense, red polyps throughout the colon and rectum. Biopsy specimens showed stromal edema, infiltration of lymphocytes, and cystic dilatation of the crypt. Her clinical manifestations and histology were consistent with CCS. We prescribed corticosteroids, which dramatically improved her physical findings, laboratory data, and endoscopic findings. This is the first report of CCS in a patient with MDS.

### INTRODUCTION

Cronkhite-Canada syndrome (CCS), first described by Cronkhite and Canada in 1955<sup>[1]</sup>, is a rare, acquired, nonfamilial syndrome with diffuse gastrointestinal (GI) polyposis, atrophic nail change, alopecia, cutaneous hyperpigmentation, diarrhea, abdominal pain, and other GI complications such as protein-losing enteropathy and malnutrition. Goto<sup>[2]</sup> and Takeuchi *et al*<sup>[3]</sup> reviewed 278 cases of CCS patients up to 1993 and found that 212 (76.3%) of them were Japanese. Except for cases of anemia caused by malnutrition, CCS with hematologic disorder has not been reported. This report is the first to describe a case of CCS in a patient with myelodysplastic syndrome (MDS).

### CASE REPORT

A 54-year-old woman visited our hospital with the chief complaint of epigastric discomfort for a month. She was diagnosed as MDS the prior year after evaluation of anemia following a routine check-up. She also suffered from dysgeusia, alopecia, and pigmentation of the palms several months ago. She and her family had no history of GI disease. Physical examination revealed a partial loss of capillus and supercilia, with blackish brown pigmentation in both palms (Figure 1).

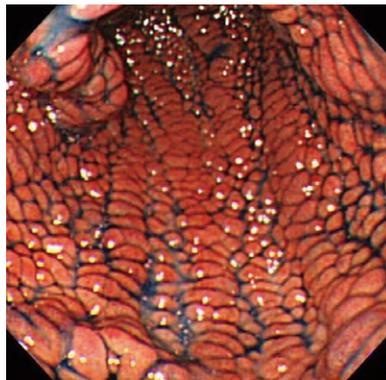

Partial loss of body hair including capillus and supercilia (Figure 1A) with blackish brown pigmentation was found in both palms (Figure 1B). Atrophic nail change was observed later (Figure 1C). Laboratory test showed that her white blood cell (WBC) count was 6400/ $\mu\text{L}$  (3000-6000), red blood cell (RBC) count was  $349 \times 10^4/\mu\text{L}$  ( $380-500 \times 10^4$ ), platelet count was  $9.7 \times 10^4/\mu\text{L}$  ( $12-38 \times 10^4$ ), C-reactive protein (CRP) was negative and erythrocyte sedimentation rate (ESR) was 40 mm/1 h, total protein was 5.7 g/dL (6.5-8.0), and serum albumin was 3.2 g/dL

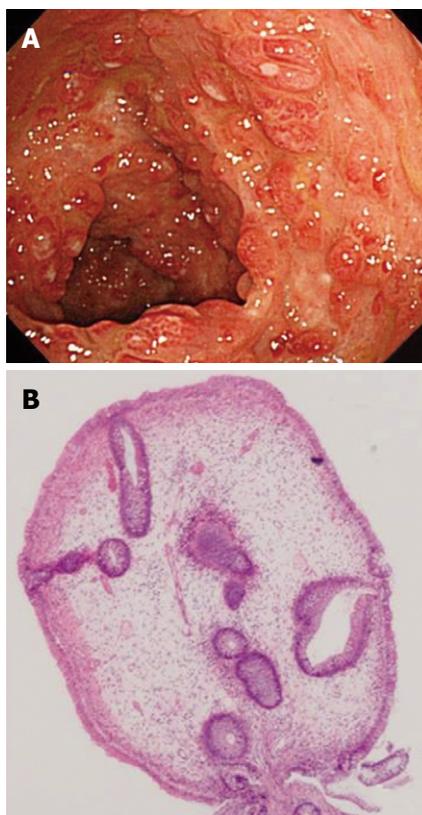

**Figure 1** Physical findings in our case at her first visit. A: Partial loss of the capillus and supercilia; B: Blackish brown pigmentation in both palms (black arrow); C: Atrophic nail change.

(4.0-5.0). Esophagogastroduodenoscopy (EGD), performed for further evaluation of the GI tract, revealed red and edematous granular polyps with giant folds, the so-called red-carpet-like polyposis of the stomach (Figure 2). A biopsy specimen displayed proliferation of connective tissue, edema, and infiltration of lymphocytes in the lamina propria. Since these findings could not confirm the diagnosis, we prescribed famotidine (20 mg per day) for nonspecific gastritis. Watery diarrhea gradually worsened, occurring up to 7 times per day at 2 wk after her first visit. Then, alopecia also worsened and atrophic nail change was observed.

Laboratory test displayed not only elevated CRP and ESR, but also hypoalbuminemia (Alb 3.2 g/dL). We suspected protein-losing enteropathy and performed colonoscopy (CS) for differential diagnosis, which showed numerous, dense, red polyps throughout the colon and rectum (Figure 3A). Biopsy specimens from the colon displayed cystic dilation of crypts and edematous stroma with inflammatory cell infiltration (Figure 3B). These physical and endoscopic findings were consistent with CCS, but CS findings did not exclude ulcerative colitis. We added salazosulfapyridine (3 g per day) and probiot-

**Figure 2** Esophagogastroduodenoscopy. Red and edematous granular polyps with giant folds, the so-called red-carpet-like polyposis of the stomach before treatment.

ics for diagnostic therapy. Diarrhea and alopecia were gradually relieved, but hypoalbuminemia increased to 1.8 g/dL. Three months after salazosulfapyridine treatment, we started corticosteroid therapy with intravenous prednisolone (40 mg per day) and then exchanged salazosulfapyridine to mesalazine (1500 mg per day). We tapered the dosage of prednisolone at two-week intervals in consideration of the clinical and laboratory changes in our patient. Diarrhea gradually became solid and the serum albumin level increased steadily to 2.5 g/dL one month later. At three months after treatment, we tapered prednisolone to 2.5 mg/d. Her clinical manifestations were

Figure 4 Clinical manifestations of the patient after treatment.

dramatically relieved (Figure 4). The CS findings were relieved and no neoplastic change was observed (Figure 5). The clinical course of this patient is depicted in Figure 6.

## DISCUSSION

CCS, first described by Cronkhite and Canada in 1955<sup>[1]</sup>, is a rare, acquired, nonfamilial syndrome with diffuse GI polyposis, atrophic nail change, alopecia, and cutaneous hyperpigmentation. Its etiology is apparently associated with the ectoderm abnormality<sup>[2,3]</sup>.

Therapeutic options comprise nutrition support, steroid therapy<sup>[4-6]</sup>, antiplasmin therapy<sup>[4,7]</sup>, mesalazine<sup>[8]</sup> and surgery<sup>[9]</sup>. Numerous cases for which corticosteroid treatment was effective have been reported, but corticosteroid therapy is regarded as a first-line therapy. In this case, although an insufficient effect of salazosulfapyridine and antiplasmin agents was observed, steroid therapy was also found to have dramatic effects.

The etiology of CCS remains unknown. Infection, mental stress, concomitant neoplasm, and immune abnormalities are regarded as triggering factors for CCS<sup>[3,10]</sup>. In addition, MDS has a high incidence (10%-20%) ac-

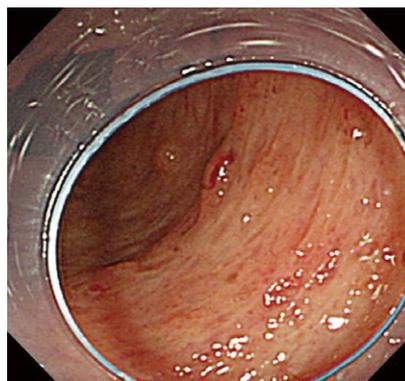

Figure 5 CS image after treatment.

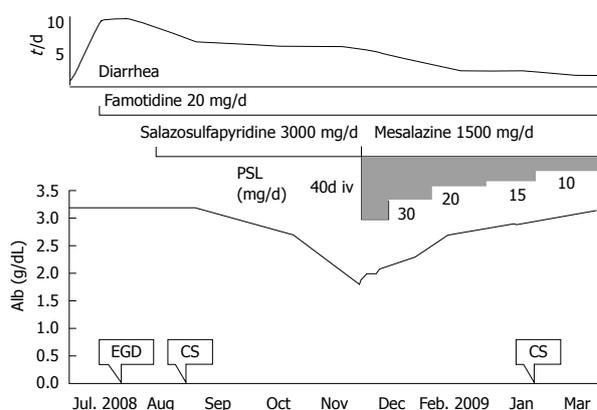

Figure 6 Clinical course of the patient.

companying autoimmune diseases, such as systemic lupus erythematosus and aortitis<sup>[11-13]</sup>. It is particularly interesting that GI autoimmune diseases, such as inflammatory bowel disease (IBD) and Behcet's disease, are also reported in patients with MDS. The etiology is considered to be an imbalance of various cytokines attributable to the abnormal level of multipotent stem cells. Reportedly, up-regulation of cytokines, such as TGF- $\beta$ , TGF- $\beta$  receptor, IL-6, and IL-7 receptors mapped to chromosome 8, related to inflammation and cell proliferation, plays an important role in the pathogenesis of patients having Behcet's disease with MDS and trisomy 8<sup>[14-16]</sup>.

This case was consistent with CCS, considering its typical clinical manifestations and histology. We infer the possibility that cytokine abnormalities induced by earlier MDS may have caused CCS in this case. However, the karyotype was not trisomy 8, 46, XX, or i(7) (q10). Moreover, inflammatory cytokine levels (IFN $\gamma$ , IL-6, IL-10, TNF- $\alpha$ ) were within normal limits. These results suggest that the etiology of this case is not associated with cytokine imbalance, as reported for Behcet's disease with MDS of trisomy 8.

In conclusion, we report a case of CCS in a patient with MDS. Although the association of CCS and MDS in this case remains uncertain, clarification of the CCS etiology is possible through accumulation of similar cases and results of further studies of the pathogenesis of MDS associated with autoimmune disease.

### INTRODUCTION

Spontaneous intrahepatic hemorrhage and liver rupture usually occur in patients with underlying hepatocellular carcinoma or adenoma<sup>[1,2]</sup>. This has also been described in patients with HELLP syndrome, Ehlers Danlos disease and graft-*vs*-host disease<sup>[3-6]</sup>. In this report, we described a rare case of spontaneous liver rupture in a patient with hypereosinophilic syndrome (HES), of which the diagnosis was delayed, resulting in a fatal outcome.

### CASE REPORT

A 48-year-old man with good past health was admitted because of fever associated with flu-like symptoms and left loin pain for a few days. Initial physical examination showed mild suprapubic and left loin tenderness, and urine dipsticks revealed microscopic haematuria. The chest radiograph was normal and initial blood tests showed eosinophilia and mildly deranged liver function (Table 1). The patient had no clinical signs of allergic reaction. Ultrasound examination of the abdomen revealed no abnormality in the hepatobiliary and urinary system. Urine microscopy showed microscopic haematuria. Ova or parasites were not detected in stool samples. The cultures from blood, sputum and urine were all negative.

Five days after admission, while awaiting further investigations, the patient suddenly developed hypovolemic shock. He rapidly deteriorated to pulseless electrical activity. Cardiopulmonary resuscitation was initiated immediately. He was pale and his abdomen was distended. His pulse returned after resuscitation with 2 L gelofusine. His hemoglobin level dropped from 14.5 to 5 g/dL. In addition, ultrasound examination of the abdomen confirmed the presence of free intraperitoneal fluid. The patient was given six units of unmatched blood during resuscitation. Owing to the unstable hemodynamic state and the diagnosis of exsanguinating intra-abdominal pathology, emergency laparotomy was arranged.

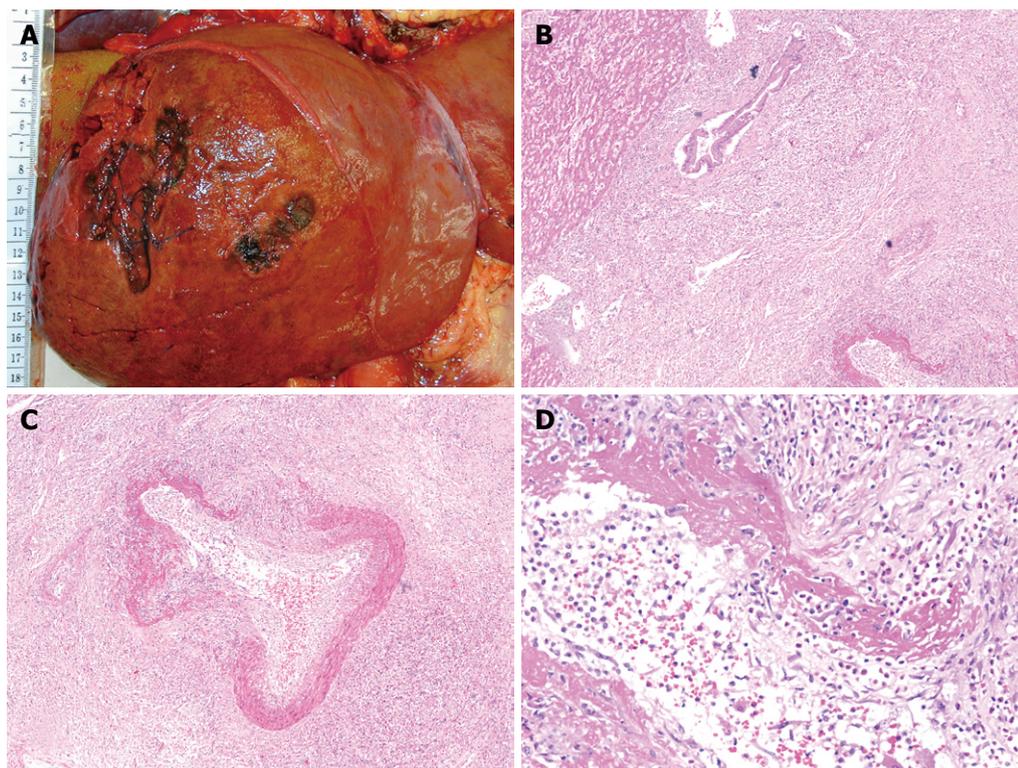

### Abstract

We report a rare case of spontaneous liver rupture in a patient with hypereosinophilic syndrome (HES), of which the diagnosis was delayed, resulting in a fatal outcome. The diagnostic criteria and treatment of HES with hepatic involvement were reviewed. The possible cause of spontaneous liver rupture in HES and its management were also discussed. To our knowledge, this is the first case report of spontaneous liver rupture in HES. We emphasized the need of a high index of suspicion in diagnosing HES, so that early treatment could be initiated.

<sup>1</sup>Elevated values.

On laparotomy, 4 L of blood in the peritoneal cavity and a 10 cm ruptured subcapsular haematoma at anterior sector of right lobe with capsular tear were found. Active bleeding was found at a 9 cm laceration of 5 cm deep at segment VI/VII of the liver (Figure 1A). The liver was not cirrhotic with no palpable space occupying lesion. No abnormality and retroperitoneal haematoma were detected in other intra-abdominal organs. Hemostasis was attempted by suturing the liver laceration and packing. Bleeding from

the raw surface was coagulated with a TissueLink device (TissueLink Medical Inc, Dover, U.S.). However, the patient developed coagulopathy with diffuse oozing after massive transfusion with blood products (10 units of platelet concentrates, 16 units of fresh frozen plasma, and 16 units of pack cells). He required high dose trabecular support during operation. Perihepatic packing was performed and the abdomen was closed. He finally succumbed 1 h after the operation at the intensive care unit.

Post-mortem examination of the patient confirmed the diagnosis of HES with diffuse eosinophilic infiltration to the heart, liver, pancreas, mesentery, kidneys and urinary bladder. Microscopic examination of the liver showed marked eosinophilic expansion in the portal tracts and dilated sinusoids. The portal tract hepatic arteries showed fibrinoid necrosis with eosinophilic infiltration (Figure 1A-D). The lacerated areas showed extensive tissue necrosis and eosinophilic infiltration.

## DISCUSSION

Eosinophilia, defined as an increased eosinophil count in peripheral blood and accumulation in various tissues<sup>[7]</sup>, can be caused by atopic disease, hypersensitivity reaction, parasitic infection, vasculitis and hematological disorders. It is also found in uncommon conditions, such as eosinophilic gastrointestinal disease, Churg-Strauss syndrome and HES<sup>[8]</sup>. The diagnostic criteria for HES, first described by Chusid *et al*<sup>[9]</sup> in 1975, include persistent peripheral blood eosinophilia for more than 6 mo with an absolute

eosinophil count greater than 1500 cells/ $\mu\text{L}$ , the presence of organ involvement by eosinophilic infiltration, and exclusion of secondary causes of eosinophilia<sup>[8]</sup>.

The common organ systems involved in HES are hematologic (100%), cardiovascular (58%), cutaneous (56%), neurologic (54%) and pulmonary (49%) systems<sup>[8]</sup>. Liver and gastrointestinal tract are involved in only 20%-30% of patients. Patients with hepatic involvement may develop chronic active hepatitis-like picture and some may suffer from Budd-Chiari syndrome secondary to strictures in inferior vena cava or hepatic veins as a result of eosinophilic infiltration<sup>[10]</sup>. Spontaneous rupture of bladder and esophagus due to eosinophilic infiltration has been reported in the literature<sup>[11,12]</sup>. To our knowledge, this is the first case report of spontaneous liver rupture in HES.

Patients with HES usually present with vague symptoms<sup>[8]</sup>, making its diagnosis difficult and delayed. In our case, the patient presented with fever and flu-like symptoms, which were not specific of any disease. Although his liver function was mildly deranged, the normal initial sonographic appearance of the hepatobiliary system gave further misleading reassurance to the clinicians in identifying the hepatic involvement. Without a high index of suspicion, it was difficult to diagnose HES early and to start treatment before the catastrophic event in our case, namely liver rupture and subsequent mortality.

In order to avoid end organ damage by HES, it is important to establish the diagnosis and start treatment accordingly. Secondary causes of eosinophilia, such as atopic disease, hypersensitivity reaction or parasitic infestation, should be excluded. For patients with deranged liver function, non-invasive investigations including ultrasound of the liver and biliary system and hepatitis serology should be performed to exclude common disorders of the hepatobiliary system. In patients suspicious of HES with hepatic involvement, liver biopsy can be performed to demonstrate eosinophilic infiltration of the liver<sup>[13,14]</sup>. After the diagnosis of HES is confirmed, specific tests on Fip1-like-1 and platelet-derived growth factor receptor  $\alpha$  (FIP1L1-PDGFRA) fusion gene mutation can guide further treatment using targeted therapy<sup>[8]</sup>.

Successful treatment using corticosteroids has been reported in patients with hepatic HES<sup>[13,14]</sup>. Studies also showed that patients with HES have a good response to targeted therapy according to the result of FIP1L1-PDGFRA<sup>[15,16]</sup>. HES patients showing positive FIP1L1-PDGFRA have a good response to imatinib mesylate, resulting in a normal eosinophil count<sup>[15]</sup>. For patients with negative FIP1L1-PDGFRA, mepolizumab (an anti-interleukin 5 antibody) can effectively stabilize the eosinophil count and reduce the daily steroid dose to less than approximately 7.5 mg prednisolone<sup>[16]</sup>.

The present case of liver rupture was likely caused by eosinophilic infiltration and fibrinoid necrosis of the vascular wall, leading to rupture of hepatic arteries as demonstrated in Figure 1B-D. Although reports are available on cardiopulmonary resuscitation (CPR)-related major liver injury<sup>[16]</sup>, this was unlikely in our case because

the event of deterioration occurred abruptly before the initiation of CPR. The right posterolateral located liver laceration in the absence of ribs fractures further made traumatic cause of the liver rupture unlikely. CPR-related liver trauma usually occurs in the left lobe where it is anatomically close to the point of chest compression<sup>[17]</sup>.

Management and prognosis of spontaneous liver rupture heavily depend on its severity and the hemodynamic stability of patients. For stable patients, non-operative management with transfusion or transarterial selective embolization of the feeding artery has been described with promising results<sup>[1,4]</sup>. For patients with hemodynamic instability or failure in non-operative treatments, surgery for haemostasis is recommended as in our case. Hemostasis can be achieved by temporary tamponade of the liver using packs and portal triad occlusion (Pringle manoeuvre)<sup>[18]</sup>. After initial operative resuscitation and identification of the site of bleeding, different surgical techniques, including direct suture ligation, hepatic resection, selective hepatic artery ligation and perihepatic packing, can be employed for hemostasis depending on the case scenario<sup>[17]</sup>. Despite all these methods, if patients develop coagulopathy, acidosis and multi-organ failure, the chance of survival is low.

Although the clinical course of HES is highly variable and dependent on the degree of organ involvement, early diagnosis and initiation of treatment are of paramount importance. Delay in diagnosis may lead to catastrophic complications. A high index of suspicion is crucial in the management of patients with eosinophilia.

### INTRODUCTION

The surgical treatment of coexistent aortic aneurysm and colorectal cancer (CRC) needs special consideration. The controversy is mainly whether to treat both diseases or treat either of them alone. If we choose to treat both, should we treat them simultaneously or as staged procedures? For a two-stage process, there is a significant risk of aortic aneurysm rupture, and a single-stage procedure has the disadvantages of technical difficulty and graft infection<sup>[1-3]</sup>. Lin *et al*<sup>[4]</sup> have proposed that the treatment priority should be given to life-threatening lesions. Such cases include the presence of an abdominal aorta aneurysm with a dangerously large diameter and synchronous obstructing or perforating CRC. Veraldi *et al*<sup>[5]</sup> have indicated that a one-stage procedure reduces the length of stay, avoids further surgical and anesthetic trauma, and does not increase graft infection.

We report a case of rectal cancer and concomitant aneurysm from the descending aorta to the common iliac artery, which is similar to a DeBakey type I aortic dissecting aneurysm, with a maximum diameter of 4.06 cm in the abdominal aortic segment and 6.51 cm in thoracic aortic segment. The patient was treated with the Dixon operation under conditions of controlled hypotension, without aneurysm rupture. At 2 years follow-up, the patient remained free of CRC and his aneurysm was stable.

### CASE REPORT

A 69-year-old man underwent anal examination after complaining of a change in bowel habits and rectal bleeding 2 years ago. Anal examination revealed a cauliflower-like lesion located 7 cm from the edge of the anus, which involved more than half of the rectal circumference. Abdominal computed tomography (CT) revealed the presence of a rectal tumor, which almost obstructed the bowel lumen (Figure 1). Medical history included smoking, diabetes, hypertension and thoracoabdominal aortic aneurysm for 6 years. After admission, the patient underwent chest radiography, which confirmed concomitant aneurysm and tracheal

### Abstract

The occurrence of concomitant aortic aneurysm and colorectal cancer is a rare medical entity, and controversy surrounds its optimal treatment. We report a case of rectal cancer and concomitant aneurysm from the ascending aorta to the common iliac artery. As with DeBakey type I aortic dissecting aneurysm, our patient was treated by rectal cancer resection, with preservation of the anus (Dixon operation) under controlled hypotension. Blood pressure was maintained at 80-90/50-60 mmHg and the pulse at 70-90 beats/min. The pathological examination of the surgical specimen showed a poorly differentiated T3N0 tumor. The patient had an uneventful recovery without aneurysm rupture, and was discharged from hospital on postoperative day 15 after 3 d adjuvant chemotherapy with oxaliplatin combined with calcium folinate and fluorouracil. The patient was given six courses of adjuvant chemotherapy in 6 mo, without recurrence or metastasis, and the aneurysm was still stable after 2 years follow-up.

Figure 1 Thickening of the rectal wall, with narrowing of the lumen.

Figure 2 Chest radiography confirmed concomitant aneurysm and tracheal compression.

compression (Figure 2). Advanced CT angiography revealed large ectasia of the ascending aorta, aortic arch and descending aorta, with a maximum diameter of 6.51 cm and mural thrombosis. In addition, the aneurysm extended to the abdominal aorta, internal-organ arteries and the right common iliac artery, with a length of 60 cm and a diameter of 4.06 cm in the abdominal aortic aneurysm (Figure 3). Elevation of carcinoembryonic antigen and blood urea nitrogen to 11.79 ng/mL and 13.60 mmol/L, respectively, allowed diagnosis of digestive tract tumor and renal inadequacy. A complete preoperative metastatic work-up was negative.

Complicating aneurysm increases the difficulty of managing advanced malignant disease. We treated this patient with the Dixon operation under conditions of controlled hypotension, with minimal blood pressure fluctuation, and renal function protection and blood sugar regulation. Intraoperative blood pressure was maintained at 80-90/50-60 mmHg and the pulse at 70-90 beats/min. The surgery was completed in 1.5 h. Postoperative blood pressure was < 100/60 mmHg and was maintained between 100/60 mmHg and 110/70 mmHg by glyceryl trinitrate administered by mini pump. The pathological examination of the surgical specimen showed a poorly differentiated T3N0 tumor.

The patient had an uneventful recovery, and he was discharged from hospital on postoperative day 15 after 3 d adjuvant chemotherapy with oxaliplatin combined with calcium folinate and fluorouracil. The patient was given six courses of adjuvant chemotherapy without

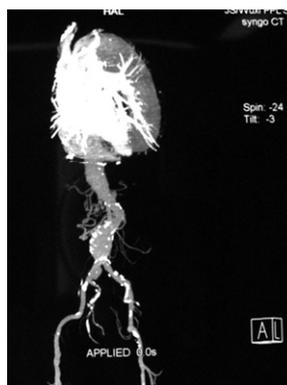

Figure 3 CT angiography of the aorta showed large ectasia from the ascending aorta to the right common iliac artery.

tumor recurrence or metastasis and the aneurysm was still stable after 2 years follow-up.

## DISCUSSION

The concomitant occurrence of aortic aneurysm and CRC appears to be increasing, from 0.5% to 2%<sup>[2]</sup>, as a result of the increase in the two individual diseases, which is caused by increased life expectancy and improved imaging capability in revealing additional asymptomatic disease<sup>[5]</sup>. Published studies are either small case series or limited retrospective reports<sup>[3,6]</sup>, therefore, the ideal treatment strategy represents a therapeutic dilemma<sup>[2]</sup>. Initial aortic aneurysm repair followed by CRC resection exposes patients to the risk of tumor progression before resection, although no study has shown the oncological implications of such a delay. Resection of CRC followed by staged aneurysmorrhaphy carries a significant risk of aortic aneurysm rupture in the perioperative period, particularly when the aortic aneurysm is > 5 cm in diameter<sup>[2]</sup>. Synchronous treatment of both lesions has been described but has the disadvantages of technical difficulties and graft infection, especially when the patient is in poor general condition.

Veraldi *et al*<sup>[5]</sup> have found, from Medline 1987-2005, a total of 229 cases of associated aortic aneurysm and CRC. Four emergency operations have been reported, one for rupture of the aortic aneurysm, two for unstable aneurysm, and one for diastatic rupture of the cecum by the stenosing neoplasm in the sigmoid colon. Including these four, there were 25 patients in all with only one disease treated. In 24 of these, intervention was carried out for CRC because of the advanced stage of the disease or poor general condition of the patient. In the remaining case, because of postoperative death, only the aneurysm was treated. From January 1988 to May 2006, 14 patients with both diseases were observed and treated in the University of Verona<sup>[5]</sup>. In one of these patients, only CRC was treated because of poor cardiac conditions, and the patient died after 2 mo from myocardial infarction.

Patients in poor general condition, who are treated for both diseases simultaneously or in stages face the risk of surgical fatality. Our patient had a rare true aneurysm similar to a dissecting aneurysm<sup>[7]</sup>. Usually, dissecting aneurysm is caused by an intimal tear or interstitial hemorrhage and requires emergency surgery, and has

a low survival rate. He had been protected by blood pressure control since his aneurysm was diagnosed 8 years ago. CT revealed that the aneurysm was in a steady state, and the diameter and distribution of the aneurysm showed no obvious changes in these 8 years. The aneurysm in our patient began from the ascending aorta and extended to the common iliac artery, which is a very rare occurrence, and the prognosis was beyond our expectation. This kind of aneurysm usually requires Bentall's procedure and the elephant trunk technique for artificial blood vessel replacement. Bentall's procedure is a cardiac surgery technique that involves composite graft replacement of the aortic valve, aortic root and ascending aorta, with reimplantation of the coronary arteries into the graft. For the elephant trunk technique, excess tubular graft material is inserted during ascending aortic and arch repair, to facilitate the subsequent treatment of distal aortic aneurysms. These operations are extremely hazardous.

Davies *et al*<sup>[8]</sup> have pointed out that treatment decisions should involve a balance between the risk of complications caused by the dilated aorta and those from the operation itself. The most devastating complication of an aneurysm is dissection, which leads to arterial occlusion and rupture and is almost invariably fatal. However, the risk of operation is also unmanageable. The risk of spinal cord injury, particularly in operations on the descending aorta<sup>[9]</sup>, is also significant. As a result of surgical risk and expense, our patient elected for conservative treatment for his aneurysm 8 years ago. When we were faced with the rare aortic aneurysm and CRC, we chose only to resect the CRC as a result of the great risks of the operation because of the patient's age, mural thrombosis, renal inadequacy, diabetes and hypertension. The postoperative recovery was satisfactory, with stable aneurysm and no cancer recurrence during follow-up.

Most surgeons agree that treatment priority should be focused on symptomatic or more life-threatening lesions in CRC and aneurysm. The largest retrospective study to date was reported by Lin *et al*<sup>[4]</sup> in 2007. In that study, 108 patients with synchronous aortic aneurysm and CRC were identified, and 92 were treated for both lesions. Thirty-five patients had CRC removed first, following two patients with aneurysm rupture while 2/35 people with aneurysm rupture had CRC removed first. Twenty-three patients with endovascular aortic repair were associated with shorter recovery and lower postoperative mortality rate. This modality offered potential treatment benefits in patients with suitable anatomy who have concomitant CRC. However, the treatment should be offered with caution because of the risk of sigmoid ischemia caused by inferior mesenteric artery occlusion. Sometimes the

single operation decision may be a better one. In the study of Lin *et al*<sup>[4]</sup>, 16 patients were treated for only one disease, because of advanced CRC, hepatic metastasis or ruptured aneurysm, and these patients had a good prognosis. The most important thing is that treatment decisions should involve striking a balance between the risk of the disease itself and the complications of the operation. However, likely aneurysm rupture presents a great challenge, and urgent aneurysm repair is required to preserve the patient's life.

In summary, in patients with aortic aneurysm and CRC, priority should be given to the more life-threatening lesion. If patients have heart disease or are in poor general condition, attempting to treat both CRC and aneurysm carries a great risk, and it may be possible only to treat one of the conditions.

### Abstract

A 48-year old male with longstanding and extensive pancolitis developed a high grade and rapidly lethal malignant lesion in the ascending colon characterized by a neuroendocrine carcinoma. Prior biopsies obtained from multiple sites in the colon during endoscopic surveillance were reported to show only inflammatory changes without dysplasia. Although operator-dependent, repeated endoscopic studies may have limitations during surveillance programs because the biological behavior of some colonic neoplastic lesions may have a rapid and very aggressive clinical course.

### TO THE EDITOR

An article recently published in *World Journal Gastroenterology* concerning two patients, aged 35 and 77 years

respectively, with left-sided ulcerative colitis, was of special importance<sup>[1]</sup>. In spite of colonoscopic and histologic follow-up in the previous year, both developed large neuroendocrine carcinomas in the rectum, and one patient was reported to have died due to multiple liver metastases.

We had a similar experience in a 48-year old male with longstanding extensive pan-ulcerative colitis for 16 years, first diagnosed in 1992. During the clinical course, his symptoms were initially treated and controlled with 5-aminosalicylates and corticosteroids. Endoscopic studies eventually showed virtually complete mucosal healing and biopsies showed only minimal inflammatory changes. No other immunosuppressive drugs or biological agents were used. During the last decade, he continued to use 5-aminosalicylates alone and remained completely asymptomatic. He underwent repeated surveillance colonoscopies with multiple site biopsies throughout the colon, which showed minimal inflammatory changes. Dysplasia was not reported in any colonic biopsy specimens. Approximately ten months after his last endoscopic procedure, he developed right upper quadrant abdominal pain. Blood studies, including liver chemistry tests, were normal, but an ultrasound and a computerized tomographic (CT) scan suggested possible liver metastases. In addition, the CT suggested a focal thickening area in the ascending colon. Colonoscopy confirmed an ulcerated sessile lesion. Histologic examination of the endoscopic biopsies showed an ulcerating tumor with predominant trebecular architecture and vascular stroma. The tumor cells had hyperchromatic nuclei with small nucleoli and scant pale-stained cytoplasm. Mitoses were numerous and there was abundant apoptosis, consistent with a high grade malignancy. Immunohistochemical stain for chromogranin and synaptophysin showed moderately intense staining of a neuroendocrine carcinoma. Tumor cells were positive for CK7 and negative for CK-20. Subsequent studies also showed pulmonary metastases and palliative chemotherapy was provided with FOLFOX B (12 cycles), but the disease remained progressive so FOLFIRI (10 cycles) was given. He died fourteen months after diagnosis.

Neuroendocrine carcinomas of the colon and rectum, accounting for less than 1% of colon and rectal cancers reported over more than a decade from Memorial Sloan-Kettering in New York, United States<sup>[2]</sup>, are very distinct from well-differentiated carcinoid tumors (or neuroendocrine tumors, using the World Health Organization schema discussed elsewhere<sup>[3]</sup>) seen with inflammatory bowel disease but often detected incidentally during surgi-

cal treatment<sup>[4,5]</sup>. About 70% of those classified as neuroendocrine carcinomas present with metastatic disease and appear to have a dismal prognosis with a reported overall mean survival of about ten months<sup>[2]</sup>. These carcinomas have been subdivided into small and large cell types based on their histological and immunohistochemical features, similar to those of pulmonary neuroendocrine cancers with most positively stained for neuroendocrine markers, such as chromogranin, synaptophysin and/or neuron-specific enolase<sup>[2]</sup>. Interestingly, in a report from Taiwan, there were 2 patients with small cell carcinomas that were believed to represent gastrointestinal metastases from a primary pulmonary site, possibly emphasizing the difficulty in defining their origin in some cases<sup>[6]</sup>.

Scattered reports are available on poorly differentiated neuroendocrine carcinoma with inflammatory bowel disease have been noted with an equally dismal outcome<sup>[7-9]</sup>. In a recent report by Grassia *et al*<sup>[1]</sup>, however, surveillance studies were completed during the preceding year, and yet, large lesions in the most distal colon were eventually detected later. Although the present case of pancolitis developed a carcinoma in the ascending colon, the surveillance efforts for longstanding extensive colitis failed, in spite of multiple site endoscopic biopsies for dysplasia over many years. While colonoscopic evaluation, especially in surveillance programs, remains operator-dependent, these cases emphasize that repeated and systematic endoscopic and histological evaluations have limits because the underlying biological behavior of some colonic neoplastic lesions

may result in a rapidly developing and aggressive clinical course.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles should be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kpn I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

**EDITORS FOR THIS ISSUE**

**Responsible Assistant Editor:** *Xiao-Fang Liu*  
**Responsible Electronic Editor:** *Xiao-Mei Zheng*  
**Proofing Editor-in-Chief:** *Lian-Sheng Ma*

**Responsible Science Editor:** *Ye-Ru Wang*  
**Proofing Editorial Office Director:** *Jian-Xia Cheng*

**NAME OF JOURNAL**

*World Journal of Gastroenterology*

**RESPONSIBLE INSTITUTION**

Department of Science and Technology of Shanxi Province

**SPONSOR**

Taiyuan Research and Treatment Center for Digestive Diseases, 77 Shuangta Xijie, Taiyuan 030001, Shanxi Province, China

### Abstract

Intractable bleeding from gastric and duodenal ulcers is associated with significant morbidity and mortality. Aggressive treatment with early endoscopic hemostasis is essential for a favourable outcome. In as many as 12%-17% of patients, endoscopy is either not available or unsuccessful. Endovascular therapy with selective catheterization of the culprit vessel and injection of embolic material has emerged as an alternative to emergent operative intervention in high-risk patients. There has not been a systematic literature review to assess the role for embolotherapy in the treatment of acute upper gastrointestinal bleeding from gastroduodenal ulcers after failed endoscopic hemostasis. Here, we present an overview of indications, techniques, and clinical outcomes after endovascular embolization of acute peptic-ulcer bleeding. Topics of particular relevance to technical and clinical success are also discussed. Our review shows that transcatheter arterial embolization is a safe alternative to surgery for massive gastroduodenal bleeding that is refractory to endoscopic treatment, can be performed with high technical and clinical success rates, and should be considered the salvage treatment of choice in patients at high surgical risk.

### INTRODUCTION

Acute bleeding is the most common complication of peptic ulcer disease and about half the cases of upper gastrointestinal bleeding (UGI) are caused by gastric and duodenal ulcers<sup>[1,2]</sup>. First-line endoscopy achieves bleeding control in as many as 98% of patients<sup>[3,4]</sup>. Despite these measures, the mortality rate in patients with bleeding peptic ulcers remains as high as 5% to 10%<sup>[5,6]</sup> due to a combination of advanced age, multiple co-morbidities, and high transfusion requirements<sup>[7]</sup>. Current treatment algorithms for massive UGI bleeding recommend aggressive correction of coagulation disorders followed by endoscopy<sup>[8,9]</sup>. Endoscopic therapy with epinephrine injection and heat probe coagulation is the most reliable method. Re-bleeding is usually managed with a second endoscopic attempt. Severe bleeding despite conservative medical treatment or endoscopic intervention occurs in 5% of patients<sup>[10]</sup> and requires surgery or transcatheter arterial embolization. Surgery is associated with mortality rates as high as 20% to 40%<sup>[11]</sup>. Although endovascular management is not included in the treatment algorithms for UGI bleeding described in surgical textbooks, selective catheter-directed embolization has been proposed as a less hazardous alternative to surgery, especially for high-risk patients<sup>[12,13]</sup>, and is now considered in many institutions as the first-line intervention for massive gastroduodenal bleeding after failed endoscopic treatment<sup>[12-15]</sup>. The

obvious advantage of transcatheter embolization is avoidance of a laparotomy in a critically ill patient. With the advent of metallic coils, gelfoam, and surgical glue, outcomes after embolization have compared favourably with those of surgery. The purpose of this review is to review the data on the indications, safety, effectiveness, and outcomes of embolotherapy in the treatment of acute UGI from gastroduodenal ulcers.

## KEYWORD SEARCH

We searched PubMed for studies of embolization for peptic ulcer bleeding published in English from 1992 to 2009. Further studies were sought by manually searching the reference lists of articles retrieved *via* PubMed. We then selected the articles that had well-defined indications for the intervention and offered a detailed description of the outcomes, including technical and clinical success rates, re-bleeding, re-intervention, need for surgery for bleeding control, and morbidity and mortality rates. To avoid selection bias associated with a small series, we excluded studies with fewer than 10 patients and anecdotal case-reports. Studies of patients with bleeding from causes other than peptic ulcers were also excluded. The results were tabulated as absolute numbers and percentages. Mean values of the outcome variables of interest were computed. Information on indications, technique, complications, and a variety of other topics of interest is presented as a narrative, in order to provide a better understanding of the current status and controversial aspects of the endovascular treatment of UGI bleeding from peptic ulcers.

## INDICATIONS

Transcatheter arterial embolization as an alternative to surgery for the control of UGI bleeding was introduced by Rösch *et al*<sup>[16]</sup> in 1972. Since then, arterial catheterization has become a useful diagnostic and therapeutic tool in selected populations<sup>[17]</sup>. The typical candidate presents with massive bleeding (transfusion requirement of at least four units of blood per 24 h) or hemodynamic instability (hypotension with systolic pressure less than 100 mmHg and heart rate of 100/min or clinical shock secondary to blood loss) that has not responded to conservative medical treatment combining volume replacement, proton pump inhibitors, and at least one endoscopic procedure aimed at controlling the bleeding<sup>[18]</sup>. At this point, surgery is offered to low-risk patients and percutaneous embolotherapy to high-risk patients. Finally, endovascular treatment can be used if the bleeding recurs after surgery<sup>[19]</sup>.

## TECHNIQUE

A transfemoral approach was used in most of the case-series retrieved by our literature search. A 5-French sheath is placed in the common femoral artery. Brachial access may be necessary when there is an acute angulation at the origin of the celiac axis. A variety of selective catheters can be used to cannulate the celiac artery

and to access the common hepatic artery. Once access is obtained, arteriography is performed to delineate the arterial anatomy and to identify contrast extravasation. If no extravasation is seen, then superselective catheterization of the gastroduodenal artery (GDA) (Figure 1), left gastric artery (Figure 2), or splenic artery (Figure 3) is performed, depending on the endoscopic evidence concerning the probable bleeding site. During this step, a microcatheter is useful but not indispensable. Arteriography after superselective cannulation might reveal extravasation that was missed during contrast injection into the main hepatic artery. When a dual supply to the bleeding area is suspected, both arterial sources must be embolized. This typically occurs with ulcers that erode the GDA: embolization in this case needs to start distally to prevent persistent “backdoor” bleeding from the right gastroepiploic and superior pancreaticoduodenal arteries, and should then move to the proximal side of the erosion. If no evidence of bleeding is found on the pre-embolization arteriogram, then blind embolization is performed, typically guided by the endoscopic findings regarding the bleeding site (Figure 4). Another useful manoeuvre in this scenario is the placement, during the pre-embolization endoscopy, of clips around the bleeding site. The clips remain in position for several hours and allow for an educated guess about the location of the bleeding arterial branch<sup>[20]</sup>. If, despite the injection of a contrast agent, no extravasation is seen, then the branches terminating at each clip are selectively catheterized using microcatheter techniques and embolized. Arteriography with multiple projections is necessary at this step to assess the relationship between each clip and the adjacent branches. Infusion of a fibrinolytic agent such as t-PA, intra-arterial anticoagulants, or vasodilators to temporarily increase the bleeding rate during angiography has been reported to facilitate the angiographic identification and localisation of the bleeding vessel<sup>[21]</sup>.

## COMPLICATIONS

Groin hematomas and contrast-related complications occur with the same frequency as during other endovascular procedures. Acute renal failure may develop as a result of multiple factors including contrast injection and intravascular volume depletion. Duodenal ischemia can result from embolization of terminal muscular branches or from embolization of the main GDA with polyvinyl alcohol (PVA) particles. Typical symptoms include persistent epigastric pain, nausea and, occasionally, vomiting. Endoscopy shows small multiple duodenal erosions consistent with healing ischemic lesions. Predisposing factors include previous abdominal surgery and/or radiation therapy. Conservative treatment with proton pump inhibitors and maintenance of NPO status is usually sufficient. Inadvertent embolization of the main hepatic artery can result in a broad spectrum of manifestations, ranging from temporary liver enzyme elevation to life-threatening hepatic failure, for which risk factors include cirrhosis and associated portal vein compromise<sup>[12]</sup>. Inadvertent placement of coils in the main branches of the

**Figure 1** Arteriogram images of bleeding from a bulbar duodenal ulcer in a 76-year-old man. A, B: Arteriogram showing contrast medium extravasated from a slender branch of the gastroduodenal artery (GDA) into the duodenum (arrows); C, D: After microcatheterization, selective glue embolization (radiopaque because of associated lipiodol (arrows) preserving the GDA ensured control of the bleeding, with no early or late recurrences.

celiac axis has been reported. Given the rich collateral circulation, however, coils in the left gastric or splenic artery rarely produce organ-threatening ischemia<sup>[22]</sup>. Duodenal stenosis can become a serious problem after GDA embolization. It is more common after superselective embolization of terminal muscular branches with surgical glue and can occur several years after successful embolization. Balloon dilatation can be attempted initially, although surgery is required in patients with persistent symptoms of duodenal obstruction<sup>[23]</sup>.

## OUTCOMES IN CASE-SERIES

We identified 13 studies (422 patients; mean age, 69 years) on the endovascular management of intractable gastrointestinal bleeding from gastroduodenal ulcers. Endoscopy was performed unsuccessfully in 98% of these patients (Table 1). The vast majority of the patients with major comorbidities and were considered at high surgical risk. Endovascular embolization was technically successful in 392 (93%) patients. A variety of embolic materials including coils, PVA particles, blood clot, gelfoam, and cyanoacrylate glue were used. The “sandwich” technique with placement of embolic material on either side of the bleeding vessel was used in most case-series to minimize the risk of recurrent bleeding due to collaterals. Active extravasation was present at the time of embolization in 53% of patients. The other patients underwent blind embolization guided by the endoscopy findings or by clips placed around the bleeding site. In the subgroup with technically successful embolization, the rate of bleeding cessation (clinical success rate) was 81% (Table 2).

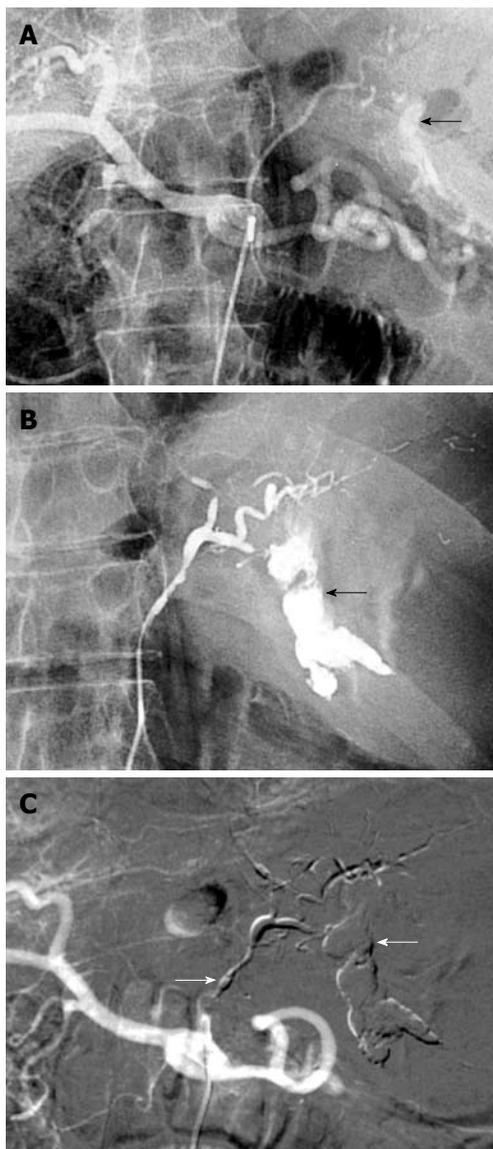

Overall, 25% (106/422) of patients had persistent bleeding. However, almost half of them responded to

NA: Not available.

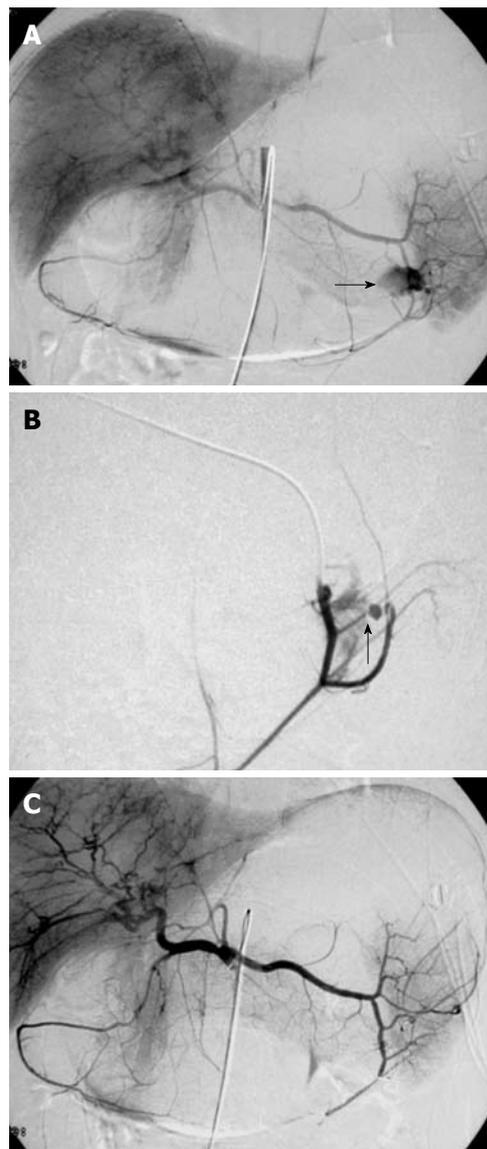

repeat embolization. Finally, 18% of patients overall underwent surgery for bleeding control (Table 2). Major and minor embolization-related complications developed in 4% of patients and included access-site complications,

**Figure 2** Bleeding Dieulafoy lesion in an 87-year-old man. A, B: Selective angiography shows contrast medium extravasation from the left gastric artery at the celiac trunk, indicating active bleeding (arrows); C: After arterial microcatheterization, bleeding was controlled after embolization of the left gastric artery using a Glubran/Lipiodol mixture (1:3) (arrows).

dissection of the target vessel, and hepatic or splenic infarction. The most significant long-term complication was duodenal stenosis, particularly after glue embolization of terminal muscular branches of the GDA. Overall 30-d mortality was 25% (Table 2). The data available in the study reports did not allow us to assess the causes of death or their relationship with the result of the embolization or need for further intervention. Although the mortality rates seem as high as those in several case-series of emergent surgery for UGI bleeding, they should be interpreted with the knowledge that most of the patients treated with embolotherapy had been turned down for surgery due to major co-morbidities and advanced age.

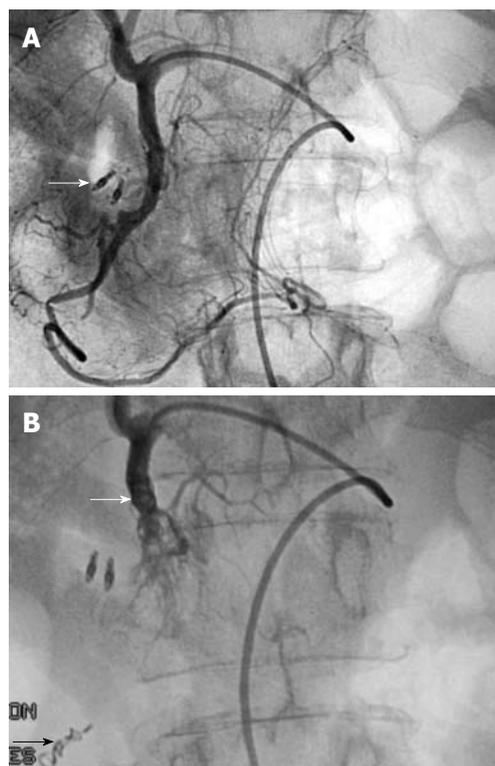

Given the variability in the way the results are reported and incomplete data on risk factors in the patient populations, we cannot draw conclusions regarding the impact of embolotherapy on mortality. Nevertheless,

**Figure 3** Digital subtraction images from a 37-year-old man with massive hematemesis. A, B: Selective angiography shows a bleeding ulcer in the fundus of the stomach. Extravasation of contrast medium from a branch of the left gastroepiploic artery is seen (arrows); C: The control angiogram after glue embolization throughout the splenic artery shows complete and selective occlusion of the bleeding branch, with no active bleeding. The patient was discharged from the hospital 4 d later.

several important points can be made. First, mortality and complication rates varied widely across the series, highlighting the influence of individual expertise and center volume on the outcomes. Second, the visualization of active extravasation followed by selective embolization was not consistently associated with a higher short-term clinical success rate. Possible explanations are the intermittent nature of gastrointestinal bleeding and the presence of bleeders missed by highly selective embolotherapy. Lastly, only 18% of the patients who initially underwent embolization finally needed surgery to control recurrent bleeding. Thus, embolotherapy considerably diminishes the need for laparotomy in patients with acute UGI bleeding from peptic ulcers.

A few of the most noteworthy case-series that raised

**Figure 4** Typical sandwich embolization in a 75-year-old woman with bleeding from a postbulbar duodenal ulcer at endoscopy. A: Angiography before embolization, guided by clip position (arrow): no evidence of active bleeding; B: Result after coil embolization of the distal and proximal GDA (with gelatine sponge in the arterial trunk), including the anterior and posterior superior pancreaticoduodenal arteries and the right gastropiploic artery, to prevent retrograde flow (arrows). No ischemic complications were reported.

interesting points are briefly summarized below. Ripoll *et al*<sup>[24]</sup> compared outcomes after embolization (31 patients) or surgery (39 patients) for bleeding from UGI peptic ulcers. Patients treated with embolotherapy were older (mean age, about 10 years older) and had higher rates of cardiovascular disease and anticoagulation treatment. Otherwise, co-morbidities were not different between the two groups. In the embolization group, the technical failure rate was 6.5% ( $n = 2$ ) and the re-bleeding rate was 29% ( $n = 9$ ). Four of the patients with persistent bleeding underwent surgical exploration. In the surgery group, the re-bleeding rate was 23.1% ( $n = 9$ ); five of these patients underwent a repeat surgical procedure for bleeding control. In addition, seven other patients required repeat surgery for complications from the initial operation. Overall, the embolization and surgery groups were not significantly different regarding the need for additional surgery (16.1% *vs* 30.8%, respectively) or survival (25.8% *vs* 20.5%, respectively). However, the re-intervention rate was considerably higher in the surgery group and the difference would perhaps have been statistically significant had the sample sizes been larger. Holme *et al*<sup>[25]</sup> reported on 40 consecutive patients who were referred for embolotherapy after unsuccessful endoscopic or surgical treatment. Long-term bleeding control was achieved in 26 (65%) patients. Of the 12 patients with active bleeding from a duodenal ulcer

**Table 2** Outcomes in case-series that included more than 10 patients treated with endovascular embolization for peptic ulcer bleeding over a 17-year period

The table shows the rates of clinical success, recurrent bleeding after technically successful embolization, need for surgery to control the bleeding, complications, and peri-procedural mortality.

at the time of embolization, 10 (83%) had the bleeding controlled; one of these patients experienced re-bleeding, which was managed by surgery. In this subgroup, lasting hemostasis was achieved in eight (75%) patients. The 28 other patients had no signs of active bleeding on the diagnostic angiogram and underwent blind GDA coil embolization. Among them, 11 (39%) experienced re-bleeding. The inability to accurately identify and selectively embolize the culprit vessel in this subgroup is the most likely explanation for the high re-bleeding rate. The group with active bleeding on the angiogram had a higher likelihood of lasting hemostasis (75% *vs* 66%), underlining the limited effectiveness of blind coil embolization of the GDA. In this series, 10 patients died, including five as a result of continuous bleeding. Of note, this series included 13 patients who underwent duodenotomy for surgical bleeding control then experienced re-bleeding that was managed endovascularly. Eriksson *et al*<sup>[20]</sup> reported a series of 10 patients who were referred for embolotherapy after endoscopy failed to control bleeding from acute duodenal ulcers. To guide the endovascular treatment, a metallic clip was placed to mark the edge of the ulcer next to the bleeding site. Embolization ensured bleeding control in eight patients; the two remaining patients required surgery. In six patients, the clip played a crucial role in identifying the bleeding vessel,

as there was no evidence of contrast extravasation on the angiogram. The clip was particularly useful in three patients: two patients had bleeding from a supraduodenal artery without connection to the GDA, and the remaining patient had bleeding from an erosion in the inferior pancreaticoduodenal artery that arose from the superior mesenteric artery. One of the series with the best follow-up data was described by Lang *et al*<sup>[23]</sup>, who reported immediate and long-term results in 57 patients with bleeding duodenal ulcers. Control of bleeding was achieved in 52 of 57 patients. Superselective terminal muscular branch embolization was as effective as embolization of the main GDA. In eight of these patients, a second catheter-based intervention was needed to achieve complete bleeding cessation. Importantly, 29 of the 52 patients whose embolization procedure was successful experienced re-bleeding during follow-up (up to 7 years), underlining the need for aggressive long-term risk factor modification and treatment of the underlying peptic ulcer disease. Long-term bleeding control was more common in the subgroup of patients who underwent selective terminal muscular branch embolization, compared to the individuals treated with embolization of the main GDA trunk (53% *vs* 27%,  $P = 0.084$ ). Long-term success in this series was related to the embolic material used. For occlusion of the muscular branch arteries, 6-cyanoacrylate had the highest success rate, whereas for occlusion of the main GDA, an epsilon-aminocaproic acid-induced blood clot was superior over the other modalities (coils, gelatine sponge particles, or PVA particles). Together with re-bleeding, duodenal stenosis was the most troublesome complication and developed in nine patients between 8 mo and 7 years after the embolization procedure. This complication was more common after superselective embolization of terminal muscular branches. Surgical correction of the stenosis was necessary in eight patients to address persistent symptoms. Another patient required multiple balloon dilatations for duodenal stenosis. Balloon dilatations were performed in one additional patient for recurrent symptoms of duodenal obstruction after surgical resection. We reported our experience managing 60 patients with peptic ulcer bleeding<sup>[26]</sup>. The technical success rate was 95%. In 37% ( $n = 22$ ) of patients, the angiography showed no contrast extravasation and, therefore, empiric embolization was performed based on the endoscopic findings prior to the procedure. Approximately 28% ( $n = 16$ ) of these patients experienced re-bleeding, and only three underwent repeat embolization. Interestingly, the univariate analysis showed that early re-bleeding was associated with several of the study variables including coagulation disorders, a longer time from shock onset to angiography, a larger number of red-blood-cell units transfused before angiography, having two or more comorbid conditions, and being treated with coils as the only embolic agent. The multivariate analysis identified two factors that significantly predicted failure of embolization, namely, the presence of coagulation disorders ( $P = 0.027$ ) and the use of coils as the only embolic

agent ( $P = 0.022$ ). The mortality rate was not different in the patient group with clinically successful embolization and in the group with failed embolization (22% *vs* 37%)<sup>[26]</sup>.

## TOPICS OF INTEREST

### **Predictors of favourable outcome**

In surgical case-series, mortality rates in patients who have UGI bleeding from gastroduodenal ulcers and who do not respond to conservative therapy have ranged from 17% to 43%<sup>[27,28]</sup>. Factors influencing mortality include advanced age, trauma or sepsis, recent major operation, lung or liver disease, and massive blood transfusions<sup>[28,29]</sup>. After embolization in patients who are too sick to undergo surgery, mortality rates were similar, with a range of 10% to 45%. A number of factors have been identified as influencing post-embolization mortality. One of the most important and common factors is the absence of early re-bleeding, especially after selective embolization of a vessel with contrast extravasation on the initial angiography. Patients with angiographic extravasation and successful embolization have considerably lower mortality rates compared to patients who require surgery after failed embolization (38% *vs* 83%, respectively)<sup>[30]</sup>. Coagulopathy correlates closely with clinical failure and death after embolization. Thus, patients with impaired coagulation are three times more likely to re-bleed after initially successful embolization and 10 times more likely to die as a result of bleeding, compared to those with normal coagulation<sup>[2,12]</sup>. Rescue surgery after a failed embolization attempt has a very high mortality rate that exceeds even the 50% rate associated with emergent surgery<sup>[31,32]</sup>. In other series, underlying medical problems such as cirrhosis and malignancy, had major impacts on the mortality rate. Finally, in patients with multiorgan failure, clinically successful embolization appears to offer the only chance for survival. In the case-series reported by Schenker *et al*<sup>[22]</sup>, the mortality rate was 96% in patients with multiorgan failure who did not respond to embolization *vs* 31% in those who did.

### **Choice of embolic agent**

A focus of greater controversy is the influence of the type of embolic agent on the clinical outcome. There is general agreement that embolic therapy is superior over vasopressin infusion for the treatment of UGI bleeding from gastroduodenal ulcers<sup>[17]</sup>. The choice of the best embolic agent remains a matter of debate. Coils alone inserted into the GDA or super selectively in the pancreaticoduodenal arteries have been used successfully by several authors<sup>[33-35]</sup>. Lang *et al*<sup>[23]</sup> compared several embolic agents in a case-series of 57 patients. Safety and efficacy were best with autologous blood clot for proximal GDA embolization and with tissue adhesive for occlusion of the distal vessels from the GDA. These authors reported a 40% rate of duodenal stricture with tissue adhesives, a finding that may be related to the use of tissue adhesives to embolize the terminal muscular branches, and not to the nature of the embolization agent. The same group reported a high rate of re-bleeding

when PVA particles or gelfoam were used alone. Similarly, Encarnacion *et al*<sup>[2]</sup> obtained a low success rate (62%) in their case-series, which chiefly included patients embolized with gelatine sponge alone. Good results have also been reported with cyanoacrylate<sup>[36,37]</sup> and with the combination of gelatine sponge and coils<sup>[38]</sup>. Most of these series included small study populations; therefore, no statistical conclusions can be drawn. Finally, Aina *et al*<sup>[12]</sup> compared embolization with coils alone *vs* coils combined with PVA particles or gelfoam. By multivariate regression analysis, the use of coils alone was associated with re-bleeding in patients with coagulopathy, a finding that supports the use of PVA or gelfoam in combination with coils in this patient subgroup. We also found that using coils alone was significantly associated with early re-bleeding<sup>[26]</sup>. Otherwise, the nature of the embolic agent does not seem to affect the clinical response or re-bleeding rate.

### **Blind or empirical embolization**

Blind embolization, defined as embolization without angiographic proof of extravasation, is also controversial. In a study comparing several groups of patients, Dempsey *et al*<sup>[30]</sup> found that blind embolization was not helpful in achieving bleeding control. The proportion of patients who required surgery for bleeding control was similar in the patients without angiographic evidence of contrast extravasation who did not undergo embolization and in the patients who underwent blind embolization. However, endoscopy - a crucial procedure for selecting the target vessel for blind embolization - was non-diagnostic in 39% of patients in this case-series<sup>[30]</sup>. Massive bleeding is often intermittent<sup>[39]</sup>; therefore, most groups perform embolization based on the endoscopic findings, even when no extravasation is visible on the angiogram. In the case-series by Aina *et al*<sup>[12]</sup> and us<sup>[26]</sup>, outcomes were not different between patients who underwent blind embolization and those who underwent embolization after angiographic identification of a bleeding site. Other researchers also advocate endoscopy-directed blind embolization<sup>[2,33,40]</sup>. Based on the data in the literature and our own experience, we believe that blind embolization is appropriate. The GDA should be embolized using the "sandwich technique", in which both ends of the artery are filled with coils to avoid retrograde bleeding from the superior mesenteric circulation. If smaller muscular branches terminating at a clip are suspected culprits, then they should be embolized with any of the available materials.

### **Marking with a metallic clip**

Clip placement during endoscopy can help to localize the vessel feeding the bleeding ulcer, even when there is no contrast medium extravasation after injection with the catheter into the common hepatic artery or the main trunk of the GDA. Clip placement is also helpful when the bleeding artery arises separately from the proper hepatic artery or the GDA. Superselective angiography guided by clip position is more likely to visualize the extravasation, thus making blind coil

placement unnecessary, increasing the efficacy of the procedure, and decreasing the risk of coil misplacement and inadvertent hepatic embolization<sup>[20,26]</sup>. The only limitation of this technique is the need for around-the-clock availability of an experienced interventionalist and gastroenterologist, which is easy to achieve only at high-volume centres. This approach increases the likelihood of successful embolization and is now routinely used at our centre. Even when extravasation is not visualized, the clips can guide the blind embolization procedure, as pointed out previously.

### **Risk for gastrointestinal tract necrosis**

Arterial embolization in the UGI tract above the ligament of Treitz is generally considered very safe because of the rich collateral supply to the stomach and duodenum. However, the risk of significant ischemia after embolization is increased in patients with a history of surgery in the same area<sup>[41]</sup> or with embolic agents that can advance far into the vascular bed such as liquid agents (e.g. tissue adhesives such as cyanoacrylate) or very small particles (e.g. gelatine sponge powder)<sup>[41-44]</sup>. Although cases have been reported at the acute phase, post-embolization ischemia usually presents as duodenal stenosis at the chronic phase. Lang *et al*<sup>[23]</sup> reported duodenal stenosis in seven of 28 patients after embolization of terminal vessels, mostly when tissue adhesive was used. In this series, duodenal stenosis after GDA embolization was far less common and occurred in only two of 29 patients who underwent more proximal GDA occlusion. No major gastric or duodenal ischemic events occurred in our case-series; coils were the most often used single embolic agents, and gelatine sponge plugs were used instead of powder. A tissue adhesive was used only when angiographic extravasation was considered massive, and one part of cyanoacrylate was then diluted in two parts of lipiodol to ensure rapid polymerization. In addition, the mixture was injected selectively into the bleeding vessel while taking care not to fill the normal branches<sup>[12]</sup>.

### **Angiographic embolization vs surgery**

To date, there has been no controlled trial comparing angiographic embolization to surgery as a salvage procedure for failed endoscopic therapy. Two retrospective comparisons showed at least similar efficacy in terms of rates of re-bleeding, morbidity, and mortality. Ripoll *et al*<sup>[24]</sup> retrospectively assessed the outcomes of 70 patients with refractory peptic ulcer bleeding: 31 patients underwent angiographic embolization, and 39 patients were managed with surgery. Although the patients treated with angiographic embolization were 10 years older on average and more often had heart disease, there were no major differences in the rates of re-bleeding (29% *vs* 23%) or mortality (26% *vs* 21%). Another retrospective comparison, by Eriksson *et al*<sup>[45]</sup>, included 40 patients who underwent angiographic embolization and 51 patients who underwent surgery after failed endoscopic therapy. The angiographic embolization group was older and had a higher co-morbidity rate. Nevertheless, 30-d mortality

was lower in the angiographic embolization group (3% vs 14%). These results are promising, and we are eagerly awaiting the results of randomized, controlled trials.

## CONCLUSION

Massive bleeding from a peptic ulcer remains a challenge. Optimal management required a multidisciplinary team of skilled endoscopists, intensivists, experienced UGI surgeons, and interventional radiologists. Endoscopy is the first-line treatment. The role for early elective surgery or angiographic embolization in selected high-risk patients to prevent re-bleeding remains controversial. However, technological advances including lower-profile catheter systems will probably broaden the indications for endovascular treatment of UGI bleeding from gastroduodenal ulcers after failed endoscopy. Although prospective studies are needed to compare these management strategies, the available data suggest that transcatheter arterial embolization is not only a good alternative to surgery, but should now be considered the salvage treatment of choice after failed endoscopic treatment. However, only high volume centers, with experienced and skillful interventional radiologists, have the opportunity to use this technique as an alternative treatment.

### Abstract

Tumor-host interaction at the invasive front of colorectal cancer represents a critical interface encompassing a dynamic process of de-differentiation of colorectal carcinoma cells known as epithelial mesenchymal transition (EMT). EMT can be identified histologically by the presence of "tumor budding", a feature which can be highly specific for tumors showing an infiltrating tumor growth pattern. Importantly, tumor budding and tumor border configuration have generated considerable interest as additional prognostic factors and are also recognized as such by the International Union Against Cancer. Evidence seems to suggest that the presence of tumor budding or an infiltrating growth pattern is inversely correlated with the presence of immune and inflammatory responses at the invasive tumor front. In fact, several tumor-associated antigens such as CD3, CD4, CD8, CD20, Granzyme B, FOXP3 and other immunological or inflammatory cell types have been identified as potentially prognostic in patients with this disease. Evidence seems to suggest that the balance between pro-tumor (including budding and infiltrating growth pattern) and anti-tumor (immune response or certain inflammatory cell types) factors at the invasive front of colorectal cancer may be decisive in determining tumor progression and the clinical outcome of patients with colorectal cancer. On one hand, the infiltrating tumor border configuration and tumor budding promote progression and dissemination of tumor cells by penetrating the vascular and lymphatic vessels. On the other, the host attempts to fend off this attack by mounting an immune response to protect vascular and lymphatic channels from invasion by tumor buds. Whereas standard pathology reporting of breast and prostate cancer involves addi-

tional prognostic features, such as the BRE and Gleason scores, the ratio of pro- and anti-tumor factors could be a promising approach for the future development of a prognostic score for patients with colorectal cancer which could complement tumor node metastasis staging to improve the clinical management of patients with this disease.

### INTRODUCTION

The tumor node metastasis (TNM) staging system from the American Joint Committee on Cancer/International Union Against Cancer (UICC) remains the most reliable prognostic indicator for patients with colorectal cancer<sup>[1]</sup>. Overall 5-year survival rates are reported at 65% and correspond closely to disease progression; patients with stage I disease have more favourable prognoses with 5-year survival rates exceeding 80%-90%. In contrast, patients with stage II, III and IV disease experience progressively worse outcomes with varying 5-year survival rates of 70%-85%, 44%-80% and < 10%, respectively<sup>[2]</sup>. It is recognized, however, that patients with tumors of the same TNM stage may be variable both in terms of prognosis and response to therapy.

A range of other histomorphological, molecular and protein biomarkers have additionally been investigated for their prognostic value independently of TNM stage. These tumor-related factors such as venous and lymphatic invasion, tumor grade, perineural invasion, histological

type, loss of heterozygosity at 18q, mutation in p53, tumor expression of vascular endothelial growth factor and thymidylate synthase are recognized as essential, additional or new and promising prognostic factors by the UICC<sup>[3,4]</sup>. In particular, microsatellite instability (MSI) status has revealed itself not only as a significant prognostic factor but also as an attribute categorizing colorectal carcinogenesis into two major pathways: the chromosomal instability (or microsatellite stable; MSS) and MSI pathways, the latter including both sporadic and hereditary Lynch syndrome [Hereditary non-polyposis colorectal cancer (HNPCC)] patients both demonstrating mismatch repair deficiencies and high level MSI (MSI-H)<sup>[5]</sup>.

Tumor-host interaction at the invasive front of colorectal cancer represents a critical interface where tumor progression and tumor cell dissemination ensue. The invasive tumor front encompasses a dynamic process of de-differentiation of colorectal carcinoma cells, a process known as epithelial mesenchymal transition (EMT)<sup>[6]</sup>. EMT can be identified histologically by the presence of “tumor budding”, a feature which is specific for tumors showing an infiltrating growth pattern<sup>[7]</sup>. Importantly, tumor budding and tumor border configuration have generated considerable interest as additional prognostic factors and are also recognized as such by the UICC<sup>[3,4]</sup>. Evidence seems to suggest that the presence of tumor budding or an infiltrating growth pattern is inversely correlated with the presence of immune and inflammatory responses at the invasive tumor front<sup>[8,9]</sup>. In fact, several tumor-associated antigens such as CD3, CD4, CD8, CD20, Granzyme B, FOXP3 and other immunological or inflammatory cell types have been identified as potentially prognostic in patients with this disease<sup>[10-16]</sup>.

Together, evidence seems to suggest that the balance between pro-tumor (including budding and infiltrating growth pattern) and anti-tumor (immune response or certain inflammatory cell types) factors at the invasive front of colorectal cancer may be decisive in determining tumor progression and the clinical outcome of patients with colorectal cancer.

The aim of this review is to outline the evidence supporting a pro-/anti-tumor factor model of colorectal cancer progression, one which highlights the dynamic interface between tumor and host-related factors at the invasive front of colorectal cancer.

## THE INVASIVE FRONT OF COLORECTAL CANCER: PRO-TUMOR FACTORS

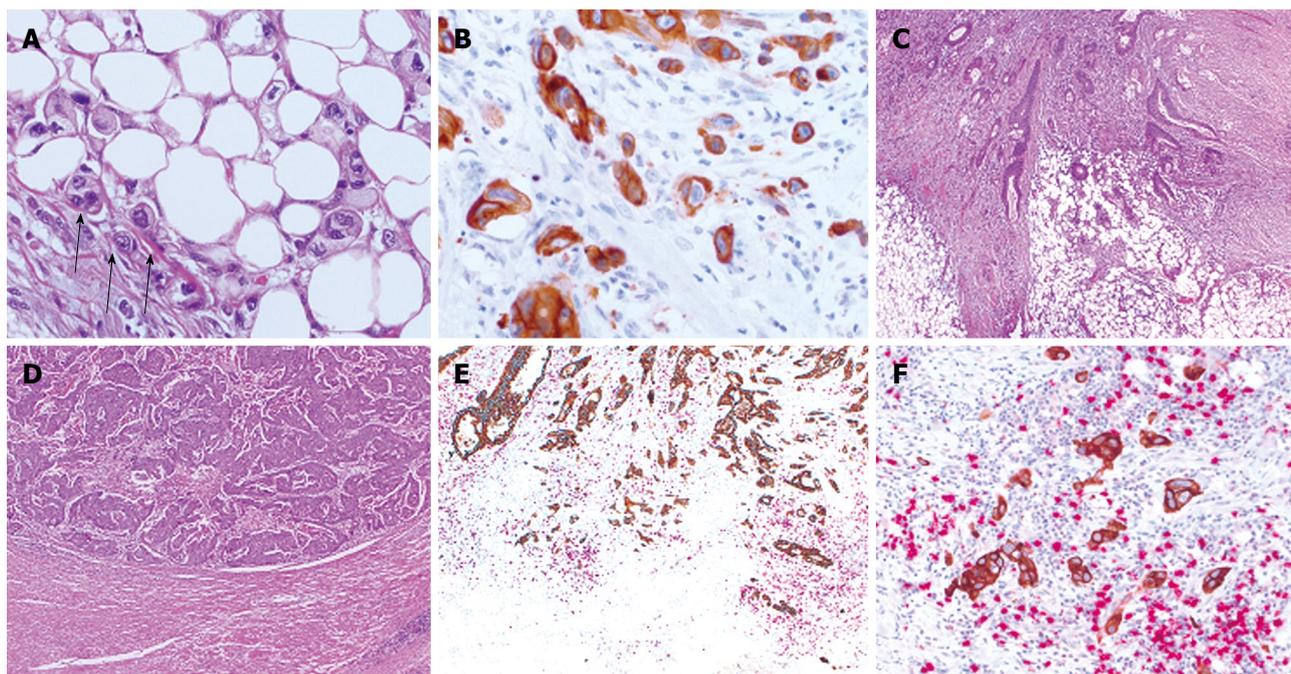

### *Tumor budding-migrating cancer stem cells (CSCs)?*

In 1985, a study of colonic adenocarcinoma in rats reported a peculiar feature at the invasive border of differentiated tumors<sup>[17,18]</sup>. Using both light and electron microscopy, Gabbert *et al*<sup>[18]</sup> observed neoplastic glands irregularly arranged into small strands and cords. In addition, they noted discontinuous small aggregates or single tumor cells which ultrastructurally did not possess junctional complexes, often had incomplete desmosomes,

missing or rudimentary basement membranes and absent or incomplete brush borders. They determined that at the invasive tumor front of colorectal cancer, differentiated tumors could acquire an undifferentiated phenotype. Their observation is credited for pioneering the concept known as de-differentiation at the invasive margin, which today is commonly referred to as “tumor budding”.

Tumor budding is a histological feature diagnosed at high magnification and is defined as single cells or clusters of up to four or five cells at the invasive tumor front<sup>[19]</sup>. Budding cells can be spotted using standard HE-stained tissue slides and their visualization is further facilitated using pan-cytokeratin stains (Figure 1A and B)<sup>[7]</sup>. The process of tumor budding is likened to EMT observed during gastrulation in embryonic development<sup>[7]</sup>. In the early phase of EMT, epithelial cells reduce intercellular contacts and cell-matrix contacts and reorganize the cytoskeleton to form cell membrane ruffles (lamellipodia) or cytoplasmic protrusions. Migration ensues and new cell-matrix contacts are formed providing cells with an anchorage for the contraction of the cell body. In colorectal cancer, tumor budding is a highly dynamic process giving temporal heterogeneity to the tumor.

Budding cells have been credited with the properties of malignant stem cells including the potential for redifferentiation both locally and at sites of distant metastasis and marking, what appears to be, the first histological event in tumor cell migration and invasion. Supporting this hypothesis further is the presence of “pseudopodia-like” cytoplasmic protrusions in tumor buds which have been identified by both electron microscopy and recently by immunohistochemistry with pan-cytokeratins<sup>[17,20]</sup>. These podia appear to be in direct contact with the adjacent interstitial tissue suggesting their formation occurs during tumor cell migration. Moreover, Shinto *et al*<sup>[21]</sup> recently suggested that cytoplasmic pseudo-fragments could be used as a marker for an activated budding phenotype that is associated with cell motility and increased invasiveness independent of the extent of budding. Not surprisingly, tumor buds have been shown to over-express proteins involved in extracellular matrix degradation and to under-express adhesion molecules. Previous studies on EMT and events occurring at the invasive tumor front implicate, in particular, the Wingless-INT (WNT) signaling pathway in the process of tumor budding evidenced by increased  $\beta$ -catenin immunohistochemical staining in tumor buds, a concomitant loss of E-cadherin and over-expression of laminin5 $\gamma$ 2 along with activation of transcriptional repressors SLUG, and ZEB1<sup>[22,23]</sup>. Over-expression of urokinase plasminogen activator receptor (uPAR), matrix metalloproteinase-7 and -9 (MMP7, MMP9), matrilysin, CD44, Ep-CAM, and extensive staining of  $\beta$ (III)-tubulin, a major constituent of microtubules, have all been reported<sup>[20,23-30]</sup> suggestive of the invasion and migration potential of tumor buds. Tumor buds seem to over-express CXCL12, a stromal cell-derived factor whose receptor CXCR4 is involved in chemotaxis and angiogenesis<sup>[31]</sup>. In addition, we recently documented the over-

**Figure 1** The invasive front of colorectal cancer. A: HE staining of colorectal cancer ( $\times 40$  magnification) showing tumor buds (arrows) at the invasive front; B: Pan-cytokeratin staining (CK22) highlighting tumor buds at the invasive front of colorectal cancer ( $\times 40$  magnification). Colorectal cancers with different tumor border configurations upon evaluation of HE staining at low magnification ( $\times 5$ ); C: Infiltrating tumor border configuration; D: Pushing tumor border configuration; E: Low ( $\times 5$ ); F: High ( $\times 20$ ) power magnification of double immunostaining for pan-cytokeratin (CK22) and anti-CD8 antibody highlighting "attackers" (tumor buds, brown) and "defenders" (CD8+ T-lymphocytes, red) at the invasive front of a colorectal cancer with infiltrating tumor border configuration.

expression of the putative colorectal CSC marker ABCG5 within tumor buds leading to a poorer outcome of patients including those with node-negative disease (Hostettler, *World J Gastroenterol*, in press). Whether a sub-population of tumor buds may in fact represent malignant stem cells is still an open question which necessitates further investigation.

### Prognostic impact of tumor budding

Since tumor budding appears to play a critical role in the initiation of metastasis, several authors have investigated the potential of this feature to predict dissemination of tumor cells to regional lymph nodes. A significant association between tumor budding and lymph node positivity has been consistently demonstrated correlating with tumor aggressiveness and more advanced TNM stage<sup>[32-43]</sup>. Tumor budding is frequently associated with poorly differentiated tumors, and with the presence of vascular and lymphatic invasion independently of disease extent<sup>[44-48]</sup>. Local tumor recurrence and distant metastasis to the lung and liver are also more commonly observed in patients with tumor budding<sup>[36,39,48-50]</sup> and additionally represent a reproducible prognostic factor in stage II patients<sup>[51]</sup>. Recently, Suzuki *et al*<sup>[52]</sup> found that tumor budding and venous invasion were significant predictors of local and distant metastases in patients with T1 stage colorectal cancers. Xu *et al*<sup>[53]</sup> demonstrated an increased rate of tumor budding in colorectal carcinomas with the aggressive micropapillary component. The presence of tumor budding has repeatedly been linked to poor clinical outcome, underlined by the adverse effect on overall survival independently of TNM stage<sup>[47,51,54]</sup>.

### Tumor growth pattern and prognosis

Tumor budding is closely linked to tumor growth pattern, a feature described by Jass *et al*<sup>[55]</sup> in 1987 which led to the proposal of an alternative prognostic classification system for rectal cancers<sup>[55,56]</sup>. The diagnosis of either a pushing (or expanding) or infiltrating tumor border configuration can be made at low magnification and is reproducible among pathologists thereby underlining its usefulness as a prognostic indicator (Figure 1C and D)<sup>[7]</sup>. The pushing tumor border is one in which margins are reasonably well-circumscribed and often associated with a well-developed inflammatory lamina. In contrast, the infiltrative tumor border is characterized by widespread dissection of normal tissue structures with loss of a clear boundary between tumor and host tissues.

Several studies have confirmed that an infiltrative tumor border configuration has a significant adverse prognostic impact in colorectal cancer and may predict local recurrence<sup>[57,58]</sup>. Our study group has also recently provided evidence for the improved stratification of stage II colorectal cancer patients based on the diagnosis of tumor border configuration. In particular, the 5-year survival rates for patients with stage II tumors decreased substantially from 80% in those with a pushing margin to 62.7% in patients with an infiltrating growth pattern, a survival rate similarly found in patients with stage III disease<sup>[59]</sup>. Considering that patients with stage III tumors are generally considered for adjuvant therapy<sup>[60]</sup>, the implications of these findings suggest that stage II patients with an infiltrating tumor margin should perhaps be considered for post-operative therapy. The addition of tumor border configuration to TNM stage improved

the prognostic classification of colorectal cancer patients by 17.9%. Since the presence of tumor budding can be strongly specific for an infiltrating, rather than a pushing/expanding growth pattern, it is not surprising that loss of cell-adhesion molecule E-cadherin and apoptosis activating factor-1, a pro-apoptotic molecule and over-expression of uPA and uPAR have all been reported as significant predictors of an infiltrating tumor border configuration in colorectal cancer<sup>[9,61]</sup>.

## THE INVASIVE FRONT OF COLORECTAL CANCER: ANTI-TUMOR FACTORS

Immunotherapy for patients with colorectal cancer represents a realistic alternative approach to treatment of this disease<sup>[62-64]</sup>. The last 20 years has seen a wide range of publications on tumor immunity and the prognostic impact of immune and inflammatory cell types in the microenvironment of colorectal tumors demonstrating promising results both *in vitro* and *in vivo*.

### Peritumoral inflammation

The presence of conspicuous peritumoral lymphocytic (PTL) inflammation, viewed as a distinctive “encapsulating” connective tissue mantle cap at the invasive front of colorectal cancer, is inversely correlated with the presence of tumor budding and positively associated with improved survival<sup>[19,65,66]</sup>. Jass<sup>[8]</sup> demonstrated that PTL infiltration in rectal cancer decreased with more advanced Dukes’ stage to 53%, 28% and 13% with Dukes’ A, B and C cases, respectively. In addition, the significantly worsened prognosis in patients lacking PTL inflammation at the tumor border was highlighted, while patients with moderate or pronounced infiltration performed significantly better independently of disease stage. The results have also been confirmed by other study groups<sup>[67]</sup>. However, the presence of PTL inflammation at the invasive front does not appear to be an independent prognostic factor in patients with this disease<sup>[59]</sup>. Nonetheless, PTL inflammation seems to be intimately linked with abundant CD8+ tumor infiltrating T-lymphocytes, further implicating tumor immunity in the defense against colorectal cancer.

### T-lymphocytes

Most studies to date confirm that a high rate of tumor infiltrating lymphocytes (TILs), in particular those located intra-epithelially characterized by CD4+ and CD8+ tumor-associated antigens are beneficial for patient outcome<sup>[68,69]</sup>. An abundant TIL count appears to be linked to earlier Dukes’ stage, decreased local recurrence rate following curative surgery and improved overall and disease-free survival time both in non-metastatic and metastatic patients undergoing hepatic resection<sup>[10,68-73]</sup>.

Galon *et al.*<sup>[13]</sup> evaluated by gene expression profiling and immunohistochemistry, the type, density and location (whether at the invasive margin or the tumor centre) of TILs in a large number of cases. They evaluated CD3, CD8, granzyme B and memory CD45RO T cells

and demonstrated a significant independent and positive effect of TILs on both recurrence and survival. Pages *et al.*<sup>[15]</sup> performed a comprehensive analysis of TILs focusing on early metastatic invasion. They found, by RT-PCR on 75 cases that mRNA levels of CD8, granzyme B and granzyme B and granzyme B were significantly greater in patients without vascular emboli, lymphatic and perineural invasion (collectively known as VELIPI) compared to those with these features and that CD45RO+ cells had independent prognostic value<sup>[15]</sup>. Diederichsen *et al.*<sup>[74]</sup> showed that a low CD4/CD8 ratio by flow cytometry was an independent prognostic factor for prolonged survival. In addition, Milasienė *et al.*<sup>[75]</sup> evaluated inter-epithelial CD3, CD4, CD8, CD20 and CD16 and found that increased levels of all these markers, particularly of the natural killer cell marker CD16 led to significantly improved overall outcome<sup>[11,75]</sup>. Moreover, regulatory T-cells expressing FOXP3+ has been shown to correlate with improved outcome independently of TNM stage<sup>[16,76]</sup>.

### Macrophages, mast cells, neutrophils and dendritic cells

In addition to T cells in colorectal cancer, a growing number of studies have demonstrated the clinical impact of dendritic cells, mast cells, macrophages and neutrophils on survival. An improved survival time and a preventative effect of mast cells on local recurrence and distant metastasis in patients with rectal tumors with high mast cell counts have been identified<sup>[77-79]</sup>. Further, the significant benefit of mast cell number on tumor progression in colorectal cancer was highlighted by Gounaris *et al.*<sup>[80]</sup> who reported that depletion of mast cells whether by pharmacological means or through generation of chimeric mice with genetic lesions in mast cell development led to remission of existing polyps. Moreover, Halazun *et al.*<sup>[81]</sup> found that an elevated neutrophil/lymphocyte ratio led to a poorer survival time and higher rate of recurrence in colorectal cancer patients undergoing surgery for liver metastasis.

Dendritic cells are the most potent antigen-presenting cells and as such are now one of the many important tools for tumor immunotherapy. Evidence is accumulating which suggests that the presence of dendritic cells may be of significant benefit to patients with colorectal cancer<sup>[82]</sup>. Using immunohistochemistry for CD83, Suzuki *et al.*<sup>[83]</sup> described the presence of mature dendritic cells at the invasive margin of cancer stroma and demonstrated by light and electron microscopy their formation into clusters with lymphocytes, the majority of which were CD45RO+ T cells. They conclude that mature CD83+ dendritic cells at the invasive margin promote T-cell activation for the generation of tumor specific immunity. Using electron microscopy, tumor-infiltrating dendritic cells were found to make contacts among themselves, with TILs and tumor cells. The presence of dendritic cells was found predominantly in early compared to later disease stages and mostly located in tumor surrounding tissue<sup>[84]</sup>. Dadabayev *et al.*<sup>[12]</sup> demonstrated that dendritic cells were significantly correlated with intra-epithelial CD4+ and CD8+ lymphocytes. Recently, HLA-DR

expressed constitutively on antigen-presenting cells such as dendritic cells and macrophages has also been found to correlate with the presence of TILs and PTLs as well as improved patient outcome<sup>[85]</sup>.

## THE INVASIVE FRONT OF COLORECTAL CANCER: MSI

Works by Banerjee *et al*<sup>[86]</sup> clearly show that MSI status (MSS; sporadic MSI-H and hereditary Lynch syndrome-associated colorectal cancers) should be taken into consideration when discussing tumor immunity in colorectal cancer. Compared to MSS tumors, both sporadic and hereditary MSI-H cancers from patients with Lynch syndrome (hereditary non-polyposis coli; HNPCC) are characterized by prolonged survival time, significantly more frequent PTL inflammation at the invasive front and by an inherent abundance of intra-epithelial TILs<sup>[87-94]</sup>. In contrast to MSS tumors which primarily arise following disruption of WNT signalling, sporadic MSI-H tumors are linked to mutations in TGF $\beta$ R II<sup>[95,96]</sup>. Baker *et al*<sup>[97]</sup> hypothesized that retention of TILs in MSI-H cancers may be a consequence of refractoriness to normal TGF- $\beta$  signalling. In a subsequent study, these authors show in more than 1000 MSS and 223 MSI tumors that an abundant CD8+ TIL infiltrate has a beneficial effect on survival time in MSS, but not MSI cancers<sup>[71]</sup>. Other authors confirm the abundance of CD8+ TILs and granzyme-positive cells as well as improved clinical outcome in patients with MSI-H compared to MSS colorectal cancers<sup>[98-100]</sup>. In addition, a positive correlation between apoptosis rates and higher TIL number has been described, a finding which could perhaps help to explain the improved prognosis seen in patients with MSI-H compared to MSS tumors<sup>[98,101]</sup>. Studies on T-reg cells such as FOXP3 and CD25+ have recently been undertaken<sup>[102]</sup>. Drescher *et al*<sup>[102]</sup>, evaluating both MSS and MSI-H cancers found that in contrast to CD8+ T-cells which may be involved in actively preventing growth and/or metastatic in MSI-H tumors, CD25+ cell counts were similar between MSS and MSI-H tumors suggesting no active immunosuppressive mechanisms in MSS cancers. Finally, the upregulation in MSI-H cancers of a large number of genes involved in immune response and increased levels of pro-inflammatory cytokines and cytotoxic mediators indicate an activated anti-tumor immune response in these tumors<sup>[86]</sup>.

## THE INVASIVE FRONT OF COLORECTAL CANCER: A BALANCE OF PRO- AND ANTI-TUMOR FACTORS

Several observations have led to the hypothesis that tumor progression and prognosis in patients with colorectal cancer is not based solely on the presence of pro-tumor or absence of anti-tumor factors but rather on the balance between the two. First, the presence of

tumor buds is inversely correlated with the presence of PTL inflammation and intra-epithelial CD8+ TILs<sup>[9,21]</sup>. In MSI-H cancers, where intra-epithelial TILs are abundant, PTL inflammation “encapsulating” the tumor at the invasive front and pushing tumor border are commonly seen, tumor budding is virtually absent<sup>[20]</sup>. When it occurs, tumor budding in the MSI-H lacks the full budding immunophenotype and the cytoplasmic podia which give budding cells a temporal dimension<sup>[20]</sup>. In a previous study on MSS colorectal cancers, we hypothesized that an intense peritumoral inflammatory reaction at the invasive front could be “nipping colorectal cancer in the bud” by specifically targeting budding cells for destruction<sup>[9]</sup>. We recently investigated CD8+ lymphocytes directly positioned in the microenvironment of the tumor buds. We could demonstrate that the ratio of CD8+ lymphocytes to tumor buds (CD8+/tumor budding index) out-performed both tumor budding or CD8+ lymphocytes alone as independent prognostic factors in two independent cohorts<sup>[103]</sup>. Using double immunostaining for CD8+ antibody and pan-cytokeratin, a ratio of 3:1 for CD8+ lymphocytes to tumor buds was a highly favourable phenotypic constellation associated with earlier pT stage, lymph node negativity, low tumor grade and absence of vascular and lymphatic invasion in addition to conferring a prolonged clinical outcome in both stage II and stage III colorectal cancer (Figure 1E and F). Although we cannot allude to the direct functional interaction between CD8+ lymphocytes and tumor buds themselves, the strong circumstantial relationship between the ratio of tumor budding and CD8+ lymphocytes in the microenvironment of budding cells appears, nonetheless, to be a reproducible and independent prognostic factor in colorectal cancer.

## DISCUSSION

The invasive front of colorectal cancer represents a dynamic interface between pro- and anti-tumor factors, which can be visualized as a balance between “attackers” (pro-tumor) and “defenders” (anti-tumor). On the one hand, the infiltrating tumor border configuration and its “cavalry” tumor budding promote progression and dissemination of tumor cells by penetrating the vascular and lymphatic vessels. On the other, the host attempts to fend off this attack by mounting an immune response using its “infantry”, in particular cytotoxic T lymphocytes, to protect vascular and lymphatic channels from invasion by tumor buds. Although evidence shows that both pro- and anti-tumor factors contribute prognostic information in a TNM-independent manner, the ratio of attackers and defenders may better capture the interaction at the invasive front which could translate into more powerful prognostic indicators.

Whereas standard pathology reporting of breast and prostate cancer involves additional prognostic features, such as the BRE and Gleason scores, the ratio of attackers/defenders could be a promising approach for the future development of a prognostic score for patients

with colorectal cancer which could complement TNM stage to improve the clinical management of patients with this disease.

### Abstract

Colorectal cancer (CRC) is the second most frequent malignant disease in Europe. Every year, 412 000 people are diagnosed with this condition, and 207 000 patients die of it. In 2003, recommendations for screening programs were issued by the Council of the European Union (EU), and these currently serve as the basis for the preparation of European guidelines for CRC screening. The manner in which CRC screening is carried out varies significantly from country to country within the EU, both in terms of organization and the screening test chosen. A screening program of one sort or another has been implemented in 19 of 27 EU countries. The most frequently applied method is testing stool for occult bleeding (fecal occult blood test, FOBT). In recent years, a screening colonoscopy has been introduced, either as the only method (Poland) or the method of choice (Germany, Czech Republic).

### INTRODUCTION

Colorectal cancer (CRC) poses a serious health problem in countries with a Westernized lifestyle. Over the last decade, a whole range of new technologies have been introduced in clinical practice to diagnose and treat the disease, with therapeutic modalities extending to advanced stages of the disease. Nevertheless, prevention undoubtedly remains the key to reducing morbidity and mortality. The introduction of national or transnational population-wide screening programs is a priority for the healthcare policy of individual states, and this is also being addressed at the highest level by European Union (EU) administrators. The approach of individual countries to screening programs varies significantly because of differences in health insurance systems and budgets. This summary article focuses on a brief description and comparison of these programs.

### EPIDEMIOLOGY

CRC is the second most frequent malignant disease in developed countries. The incidence of CRC is generally higher for men, and the risk of the disease increases with age, as the majority of cases are diagnosed in patients more than 50 years of age<sup>[1]</sup>. European countries rank highest in the global statistics, both in terms of incidence and mortality. In 1998 to 2002, the incidence of CRC in the USA for men and women was 38.6 and 28.3, respectively; in Europe, it was 38.5 and 24.6 [world age standardization (ASR-W)], as calculated per 100 000 inhabitants<sup>[2]</sup>. However, mortality over the same period of time was much higher in Europe than in the US, both for men and women: in the USA, the figures were 13.5 and 9.2, respectively, while in Europe, they were 18.5 and 10.7 (ASR-W), as calculated per 100 000 inhabitants<sup>[3]</sup>. A detailed comparison of data for European countries is made difficult because of the absence of a unified data

**Figure 1** Epidemiology of colorectal cancer in European countries. A: Incidence in international comparison-European countries; B: Mortality in international comparison-European countries. Table 1 Colorectal cancer incidence in European countries in 2006	
Parameter	Incidence
Countries with the highest incidence	> 70/100000 men (ASR-E): Hungary (106), Czech Republic (94.4), Slovakia (87.1), Switzerland (79.1), Germany (70.2) > 45/100000 women (ASR-E): Switzerland (55.6), Norway (51.2), Hungary (50.6), Denmark (48), Czech Republic (46), Germany (45.1)
Countries with the lowest incidence	< 40/100000 men (ASR-E): Albania (13.6), Greece (31), Bosnia Herzegovina (34.6), Republic of Moldova (38.7), Finland (39.2) < 26/100000 women (ASR-E): Greece (21.3), Albania (21.4), Romania (25.1), Spain (25.4)

Adapted from: Ferlay J, Autier P, Boniol M, Heanue M, Colombet M, Boyle P. Estimates of the cancer incidence and mortality in Europe in 2006. *Ann Oncol* 2007; 18: 581-592. ASR-E: European age standard.

source. Not all countries maintain sophisticated population and cancer registers, and it is sometimes necessary to obtain input data by projecting aggregated data. In this outline, figures available from international studies summarizing global and European epidemiologic data have been used<sup>[4,5]</sup>. A detailed comparison of countries within Europe using the ASR-W of incidence and mortality is presented in Figure 1. Most recent epidemiologic data on CRC for 2006 recalculated to the European age standard are given in Tables 1 and 2.

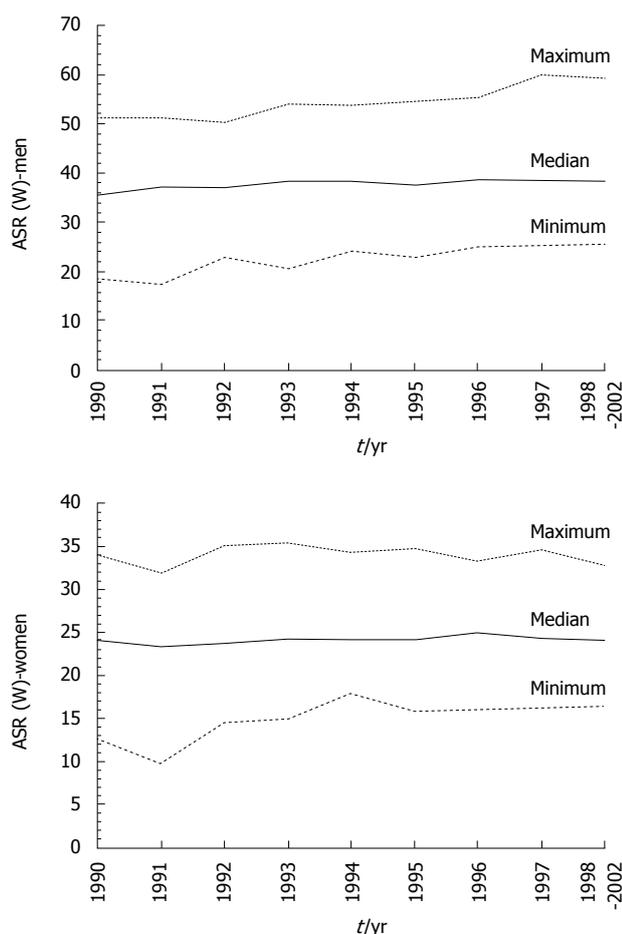

CRC comprises 12.9% of all newly-diagnosed carcinomas in the European population (men 12.8%, women 13.1%) and account for 12.2% of deaths caused by malignancy.

CRC is the second most frequent malignancy, after breast carcinoma (13.5% of all malignancies) and bronchogenic carcinoma (12.1% of all malignancies). It has been estimated that in 2006, 412000 people were diagnosed with CRC in Europe, and 207400 of them die of the disease<sup>[6]</sup>. The average incidence has shown a tendency to increase in recent years (2001-2005), with a year-on-year growth of 0.5%. Available data on time trends of CRC incidence and mortality are shown in Figures 2 and 3. A detailed analysis of individual diagnoses confirms that malignant disease of the colon is the most frequent, accounting for 57% of all cases (> 35 cases/10<sup>5</sup> inhabitants), followed by malignant diseases of the rectum

Table 2 Colorectal cancer mortality in European countries in 2006

Parameter	Mortality
Countries with the highest mortality	> 40/100 000 men (ASR-E): Hungary (54.4), Czech Republic (51), Slovakia (43.3), Croatia (40.7)
	> 20/100 000 women (ASR-E): Hungary (26.7), Slovakia (24.4), Czech Republic (24.1), Denmark (24.1), Norway (21.4)
Countries with the lowest mortality	< 20/100 000 men (ASR-E): Albania (7.3), Greece (15.5), Finland (17.9), Switzerland (19.1), Cyprus (19.3), Bosnia Herzegovina (19.5)
	< 12/100 000 women (ASR-E): Albania (9.9), Greece (10.8), Finland (11.3), Switzerland (11.6)

and rectosigmoid ( $> 22$  cases/ $10^5$  inhabitants) and tumors of the anus and anal channel ( $> 1.0$  cases/ $10^5$  inhabitants) (Table 3). According to recently published data, CRC-related mortality has stabilized or shown a slight decrease over recent years.

The most extensive population study monitoring the relative survival rate (RSR) is the EURO CARE program<sup>[7]</sup>, which takes registers of patients suffering from malignant diseases as a basis. Data have been gathered and evaluated since 1978. The most recent version, EURO CARE-4,

**Figure 3 Mortality trends of colorectal cancer in Europe.** As available in WHO database, countries with cancer registry (*Cancer Incidence in Five Continents, Vol. IX*). Adapted from: CancerMondial - WHO, International Agency for Research on Cancer, 2008. Available from: URL: <http://www-dep.iarc.fr/>; World Health Organization (2006), mortality database <http://www.who.int/whosis/whosis/>, United Nations, *World Population Prospects, the 2006 revision*. uses comparative analyses of data from the year 1995 to 1999, while data are also available for the years 2000 to 2002<sup>[8]</sup>. Data from the European population carcinoma register are also used in the CONCORD study<sup>[9]</sup>, which focuses on a systematic comparison of statistical data between Europe and Northern America. Apart from these two studies, data from population registers of carcinoma have been published for some European countries. Data available regarding the 5-year RSR show high variability across European countries, with borderline values in the Czech Republic (50%) on the one hand and Germany

**Table 3** Epidemiology of colorectal cancer in the Europe (96 individual cancer registries, 1998-2002)

Parameter incidence	Sex	C18-C21	Individual diagnoses		
			C18	C19-C20	C21
Crude incidence (cases/100.000 inhabitants)	Men	63.9	37.1	26.0	0.8
	Women	53.7	34.8	17.6	1.3
	All	58.6	35.9	21.7	1.1
ASR-E	Men	58.0	33.5	23.7	0.8
	Women	36.8	23.4	12.4	1.0
	All	45.8	27.6	17.3	0.9
ASR-W	Men	38.5	22.0	15.9	0.5
	Women	24.6	15.5	8.4	0.7
	All	30.6	18.3	11.7	0.6
Mean age (yr)	Men	69.1	69.7	68.2	65.4
	Women	71.3	71.9	70.4	67.7
	All	70.1	70.8	69.1	66.8
Ratio (males: females) (based on No. of cases)		1.1:1	1.0:1	1.4:1	0.6:1

Adapted from: Curado MP, Edwards B, Shin HR, Storm H, Ferlay J, Heanue M, Boyle P, editors. Cancer Incidence in Five Continents, Vol. IX. IARC Scientific Publications No. 160, Lyon: IARC, 2007. (60%) on the other hand<sup>[7-16]</sup> (Table 4). Several studies have confirmed a favorable time trend in the 5-year RSR; however, these results have to be interpreted carefully with respect to the hidden reasons leading to such positive conclusions. Evaluation of survival rate based on clinical studies of CRC is, unfortunately, rather rare, and therefore, it is impossible to make a representative evaluation of this indicator. This fact should be seen as a challenge when improving population registers of malignant diseases.

## SCREENING METHODS

CRC screening focuses on asymptomatic individuals more than 50 years of age. Age is a low (average) risk factor for sporadic CRC, that is, carcinoma in patients with negative family or case history of CRC or chronic inflammatory bowel disease; this type of carcinoma accounts for 70 to 95% of all CRC cases. Three groups of screening methods are currently used as indicated in Table 5.

Guaiac-based fecal occult bleeding test (gFOBT) is at present the most frequently used method in screening programs. It detects the peroxidase reaction of hemoglobin, which causes the detection paper impregnated with guaiac resin to turn blue. Dietetic provisions are necessary to exclude false-positive results. A recent study showed limited sensitivity of this test for both, advanced adenomas (11%) and carcinomas (13%)<sup>[17]</sup>. With the use of gFOBT, a decrease in mortality for CRC by 15 to 33% has been proved<sup>[18]</sup>.

Immunochemical fecal occult bleeding test (iFOBT) reacts exclusively to human hemoglobin, so no dietetic restrictions are necessary. Taking and assessing the stool samples are easier than is the case with gFOBTs, which may explain a higher participation rate in the target group. A wide range of qualitative and quantitative tests is presently available, with varying levels of sensitivity

and specificity. The advantage of quantitative tests is the possibility to set cut-off limits; the most frequently used values are 75 or 100 ng/mL. The disadvantage of iFOBT is its cost; however, the price is now approaching that of gFOBT, particularly for qualitative tests<sup>[19]</sup>.

New screening methods include tests which examine the stool for the presence of abnormal DNA. Studies published to date focused on the characteristics of the test rather than the reduction in CRC incidence or mortality. Generally, these tests have higher sensitivity but lower specificity than gFOBT. The major obstacle to their implementation in screening programs is price<sup>[20]</sup>.

Flexible sigmoidoscopy (FS) is an endoscopic examination with maximum reach to the splenic flexure. On the basis of the information available, this is a promising screening test, although the studies published to date do not show sufficient statistical significance to determine reduction in CRC mortality. The recommended interval varies from 3 to 5 years. The risk of serious complications is 0% to 0.03%<sup>[21]</sup>.

Unlike FS, colonoscopy also detects lesions in the proximal colon. Its biggest advantage is the possibility of removing pathological lesions within a single examination. It is more sensitive in detecting both adenomas and carcinomas, although limited information is available on reducing CRC incidence and mortality, and on the recommended interval between examinations. The risk of serious adverse events is higher than for FS, at 3 to 5 events per 1000 colonoscopies<sup>[22]</sup>. To date, no prospective, randomized, multicenter study has been published supporting a reduction in CRC incidence and mortality with the use of screening colonoscopy. Nevertheless, its implementation in screening programs is one of the most widely discussed topics and the American College of Gastroenterology recommends screening colonoscopy as a preferred screening test<sup>[23]</sup>. On the other hand, no study addressing reductions in the incidence and mortality rates through stool analyses would have been completed without the "gold standard" of colonoscopy.

Computed tomographic colonography (CTC) shows lesions in the colorectum by reconstructing two- and three-dimensional images. To date, no studies have been published assessing reduction in CRC incidence or mortality. The majority of studies have focused on comparing the characteristics of this method with colonoscopy. For larger polyps (over 10 mm), the sensitivity of the methods is comparable; for smaller polyps (less than 5 mm), flat and depressed adenomas, the sensitivity is much higher for optical colonoscopy. Results of studies assessing the effect in terms of reduction in incidence and mortality, cost-effectiveness, and the potential risk of radiation are awaited<sup>[24]</sup>.

Double contrast barium enema shows the entire colorectum, although with significantly lower sensitivity and specificity than colonoscopy or CTC. The percentage of undetected carcinomas is up to 22%. The test is no longer widespread and available, but still has a purpose in countries lacking sufficient resources for other examinations<sup>[25]</sup>.

CRC screening is a complex process which, to function properly, requires the coexistence of a number of factors, such as a functioning invitation-reminder system,

**Table 5** Screening methods

Type of method	Method
Stool tests	For presence of occult blood (FOBT) Guaiac-based (gFOBT) Immunochemical (iFOBT) For presence of abnormal DNA
Endoscopic examinations	Flexible sigmoidoscopy (FS) colonoscopy
Radiologic examinations	Computed tomographic colonography (CTC) Double contrast barium enema (DCBE)

media campaigns targeted at the general public, the development of recommendations for general practitioners, patient compliance, sufficient funding, stratification of risks, and last but not least the selection of the most suitable screening test. Of the above described tests, only the fecal occult blood tests meet the WHO criteria for screening. As published recently, most CRC screening strategies lead not only to a reduction in CRC incidence and mortality, but also to better control of the costs of CRC treatment, especially with increased chemotherapy costs for advanced CRC<sup>[26]</sup>.

## GENERAL ONCOLOGY PREVENTATIVE PROGRAMS IN EUROPE

In 1985, the Europe Against Cancer program was initiated, which aimed at a reduction of 15% in the number of deaths caused by tumors (from 1 000 000 to 850 000) by 2000. The program was implemented, thanks to the cooperation of professional and lay public, charities and anti-smoking groups, healthcare media, and healthcare workers. The project focused on three major areas: prevention, screening, and education. Results published show that although the planned goal was not achieved, the mortality due to tumors was reduced by 10% in the EU. In some countries (Austria and Finland), the desired reduction of 15% was achieved, while in others (Portugal and Greece), the mortality reduction was much lower<sup>[27]</sup>. The experience gained in this program served as a basis for the Recommendations of the Council of the EU for screening programs following comprehensive European quality assurance guidelines. In December 2003, these

recommendations were unanimously approved by the health ministers of the individual EU states. European guidelines for quality assurance of breast and cervical cancer screening have been developed by experts and published by the European Commission; quality assurance guidelines for CRC screening are currently under preparation<sup>[28]</sup>.

## CRC SCREENING IN EUROPE

In 2008, the Report on the Implementation of the Council Recommendation on Cancer Screening<sup>[29]</sup>, which provides the most comprehensive available data, was published; giving the definitions of program screening as requiring public responsibility by law or official regulation and supervision in contrast to “wild” screening outside of any program. In program screening, the screening test, the examination interval and the eligible group of persons should be specified. Organized screening should generally include a regional or national team responsible for the implementation, quality assurance and reporting of results. Comprehensive guidelines, rules and a quality assurance structure should be available. Population-based screening requires the identification and personal invitation of each person in the eligible target population (by an office or special agency). According to this report CRC screening is running or being established in 19 of 27 EU countries. The target group contains approximately 136 million individuals suitable for CRC screening (aged 50 to 74 years). Of this number, 43% individuals come from 12 countries where CRC population screening is performed or being prepared on either national or regional levels; 34% come from 5 countries where national population screening has been implemented (Finland, France, Italy, Poland, and United Kingdom). In 7 EU countries, national non-population based screening is carried out, which covers 27% of the target population. In 2007, gFOBT (which in 2003 was the only test recommended by the Council of the European Union) was used as the only screening method in twelve countries (Bulgaria, Czech Republic, Finland, France, Hungary, Latvia, Portugal, Romania, Slovenia, Spain, Sweden, and United Kingdom). Colonoscopy was the only screening method used in Poland. In six countries, two types of tests were used: iFOBT and FS in Italy, and gFOBT and

colonoscopy in Austria, Cyprus, Germany, Greece, and Slovak Republic. In the remaining eight states (Belgium, Denmark, Estonia, Ireland, Lithuania, Luxembourg, Malta, and the Netherlands), CRC screening has not been implemented yet. The age limit for the target population varies across EU countries (Table 6). In 2007, it was estimated that a total of 12 million individuals participated in CRC screening.

In the United Kingdom, a screening program was announced in 2004 and initiated in 2006, with the prospect of national coverage in 2009. It has been designed in two stages, with gFOBT examinations at 2-year intervals and colonoscopy for positive tests. In 2007, compliance was 52%. The program is carried out through regional centers

falling under one of five national hubs. The role of general practitioners is less significant here<sup>[30]</sup>.

In France, a screening program was initiated in 2003, based on gFOBT tests at 2-year intervals with colonoscopy for positive results. The role of general practitioners as coordinators is of crucial importance. The major advantage of the French program is its good organization, with a call-recall system comprising central management at national level and individual steps taken by centers in individual departments. Asymptomatic individuals aged from 50 to 74 are mailed gFOBT tests, with a reminder at three-monthly intervals for nonparticipants. Compliance in referred districts achieved 42%, and the overall positive test rate was 2.7%<sup>[31]</sup>.

In Italy, a nation-wide campaign was initiated in 2005; the implementation was entrusted entirely to 21 regional centers, including choice of the testing method. With state financial support, screening has been initiated in 11 regions to date, mostly in the industrial areas of northern Italy. In the Piedmont region, FS is the method of choice, in other regions immunochemical FOBT, with colonoscopy for positive tests. Compliance in iFOBT and FS programs was 44.6% and 51.4%, respectively. Positivity rate of iFOBT was 5.3% at first and 3.9% at repeat screening<sup>[32]</sup>.

In Spain, no screening program has taken place as yet. The main obstacle to its implementation is the highly heterogeneous healthcare system, in terms of organization and insurance coverage in individual self-governing units. Catalonia, for instance, considers implementation of country-wide screening in 2010, while in other regions only limited pilot studies have been held so far.

In Finland, a structured screening program was initiated in 2004. The target population, aged from 60 to 69 years (106 000 individuals), was randomized into two groups. Individuals in the screening group were mailed a gFOBT test at intervals of 2 years. The Finnish program shows a high level of compliance of the target population (70.8%), particularly for females<sup>[33]</sup>.

In the Netherlands, the optimum screening strategy is still being developed. It will be based on the results of studies currently taking place at major academic workplaces, comparing the effect of endoscopic procedures, various types of FOBTs, and fecal DNA analysis.

Poland is the only state at the moment using colonoscopy as the only screening method, without the alternative of FOBT. An opportunistic screening program was initiated in 2000, and by 2005, this had grown to 57 centers across Poland. The program is financed by the Ministry of Health, independent of the overall healthcare system. The target population (asymptomatic individuals aged 55-66 years) is recruited through general practitioners. High emphasis is placed on the quality control of colonoscopies, with complications reported for 0.1% of procedures, and no patient mortality. The advantage of the program is thorough monitoring and evaluation, including monitoring of interval cancers<sup>[34]</sup>.

Germany was the first country to introduce a population screening program (in 1976) based on annual gFOBT for individuals more than 44 years of age. Starting from 2002, it has been offering participants a choice between colonoscopy at 55 years of age and FOBT at annual intervals between 50 and 55 years of age. After 55 years of age, examinations are carried out at 2-year intervals. If the test results are positive, colonoscopy is indicated. Those who undergo a screening colonoscopy with no neoplasia detected at the initial examination are recommended reexamination in 10 years time if the first colonoscopy was carried out before they were 65 years. The positive feature of the screening and data gathering in Germany is the emphasis on staging the disease at the time of its diagnosis. Recent cost analyses have proven that this type of screening is cost-efficient<sup>[35]</sup>.

In the Czech Republic, CRC screening has many years of tradition<sup>[36,37]</sup>. The country was the second in the world to start screening nation-wide, in 2000. In the initial years, gFOBT was the first method offered to asymptomatic individuals more than 50 years of age by their general practitioners at preventative medical checks, followed by colonoscopy if tests were positive. From 2000 to 2008, 1 685 289 gFOBTs were carried out, of which 63 296 were positive (3.76%). In 2006, a central database for online data input was established. Between 2006 and 2008, 17 813 colonoscopies were carried out, indicated as a result of a positive FOBT; carcinoma was diagnosed in 1047 (5.9%) individuals, and 5362 (30.1%) adenomas were removed by endoscopic polypectomy. The participation of the target group, however, was only 20%<sup>[38]</sup>. In order to achieve a higher compliance rate, screening colonoscopy was added to current FOBT screening as an alternative method, in the same intervals as in the German program. Both, gFOBT and iFOBT are offered as well. The implementation of the newly designed program is supported by an intensive media campaign (<http://www.kolorektum.cz/index-en.php>).

The first study which focused on monitoring the effect of colonoscopy screening on reducing CRC incidence and mortality is NordICC (The Nordic-European Initiative on Colorectal Cancer), which is currently underway in northern states of Europe (Norway, Sweden, and Iceland), Poland, and the Netherlands. It will involve a minimum of 66 000 individuals aged 55 to 64 years. Individuals in the screening group will undergo a screening colonoscopy once in a lifetime. The primary objective is to compare incidence and mortality against the control group (with no screening) after 10 years<sup>[39]</sup>.

## CONCLUSION

CRC presents a serious public healthcare issue for the population of Europe. Understandably, the number of countries introducing population screening has been growing constantly. Although epidemiologic data differ in various European countries, implementation of screening programs in accordance with the principles spelled out in the Council Recommendation on Cancer Screening of 2 December 2003 may be expected to have a favorable effect on the burden of this disease in the population. Countries in the EU may benefit from unified policy, knowhow and central oncology registers, while economically less developed countries may draw on special funding for the development of preventative programs. At the same time, varying epidemiologic situations, economic conditions, and different systems of health insurance and organization of healthcare are factors that may limit the implementation of a unified screening program. Therefore, to respond to the needs of the member countries, the EU should consider adopting the recommendation of the World Gastroenterology Organization for CRC screening, possibly even in a modified form<sup>[40]</sup>. This is a cascade concept in which recommendations for individual countries are graded into six levels, depending on the resources available (financial

Table 7 Cascade concept

Level	Average risk	High risk
1	Colonoscopy in 10 years interval, from 50 years of age	Special procedure, for individual groups
2	Colonoscopy once in a lifetime, at 50 years of age	Special procedure, for individual groups
3	Flexible sigmoidoscopy in 5 years interval, from 50 years of age; colonoscopy to follow if positive	Special procedure, for individual groups
4	Flexible sigmoidoscopy once in a lifetime, at 50 years of age; colonoscopy to follow if positive	Special procedure, for individual groups
5	Flexible sigmoidoscopy once in a lifetime, at 50 years of age; colonoscopy to follow only if advanced adenoma is detected	Same as individuals with average risk, if resources are not available for colonoscopy
6	FOBT in annual interval after 50 years of age; if positively tested, colonoscopy or double contrast barium enema	Same as individuals with average risk, if resources are not available for colonoscopy

and professional) (Table 7). In the case of lack of funds, FOBT at intervals of 1 or 2 years for individuals with average risk is a realistic possibility. This open concept best fulfils the simple recommendation by Sydney Winawer, Co-Chair of IDCA (International Digestive Cancer Alliance): "The best screening test is the one that gets done...and gets done well. Do what you can with what you have".

In most European countries, fortunately, the majority of the population is covered by some form of health insurance, meaning that economic aspects need not critically affect the availability of screening programs. Although at the end of 2007, CRC screening was still not running or being established in 8 of 27 EU member states, some of which rank among the most developed economies of the world, additional programs are currently under development. Given the substantial burden of the disease, implementation and continuous improvement in CRC screening programs should remain high on the healthcare agenda in Europe.

### Abstract

Focal adhesion kinase (FAK) is a 125-kDa non-receptor protein tyrosine. Growth factors or the clustering of integrins facilitate the rapid phosphorylation of FAK at Tyr-397 and this in turn recruits Src-family protein tyrosine kinases, resulting in the phosphorylation of Tyr-576 and Tyr-577 in the FAK activation loop and full catalytic FAK activation. FAK plays a critical role in the biological processes of normal and cancer cells including the gastrointestinal tract. FAK also plays an important role in the restitution, cell survival and apoptosis and carcinogenesis of the gastrointestinal tract. FAK is over-expressed in cancer cells and its over-expression and elevated activities are associated with motility and invasion of cancer cells. FAK has been proposed as a potential target in cancer therapy. Small molecule inhibitors effectively inhibit the kinase activity of FAK and show a potent inhibitory effect for the proliferation and migration of tumor cells, indicating a high potential for application in cancer therapy.

### INTRODUCTION

Focal adhesion kinase (FAK) is a 125-kDa non-receptor protein tyrosine which was originally identified in chicken embryo cells transformed by v-Src<sup>[1]</sup> and BALB/c3T3 fibroblasts<sup>[2]</sup> and was shown to localize in focal adhesions as well. FAK is a non-receptor and non-membrane associated protein tyrosine kinase (PTK), which does not contain Src homology2 (SH2) or SH3 protein interaction domains<sup>[3]</sup>. FAK contains three main domains: a centrally located catalytic kinase domain, a large N-terminal domain comprising the FERM (FAK, ezrin, radixin, moesin) region and a C-terminal domain harboring the focal adhesion targeting<sup>[3-5]</sup>. Growth factors or the clustering of integrins facilitate the rapid phosphorylation of FAK at Tyr-397 in adherent cells and this in turn recruits Src-family PTKs, resulting in the phosphorylation of Tyr-576 and Tyr-577 in the FAK activation loop and full catalytic FAK activation<sup>[3,5]</sup>; while extracellular pressure can activate the FAK in suspended cells<sup>[6,7]</sup>.

FAK is associated with gastrointestinal diseases, here we will review the progresses which have been made in the researches about FAK in the gastrointestinal tract. Research data shows that FAK plays an important role in the restitution, cell survival and apoptosis and carcinogenesis of the gastrointestinal tract. Due to the crucial role of FAK in integrin-mediated signal transduction, which affects the regulation of cell survival, proliferation, spreading and migration, FAK has been proposed to be a potential target in cancer therapy. Antisense oligonucleotides, the entire C-terminal, non-catalytic domain of FAK (FAK related non-kinase-FRNK), siRNA

and small molecule inhibitors can affect and inhibit the activities and expression of FAK in various tumor cells. Small molecule inhibitors targeting FAK have been developed as potential cancer treatment modalities. PF-573228, PF-562271 and NVP-226 (TAE226) have already shown potent inhibitory effect for tumor cell growth *in vitro* and *in vivo*.

## RESTITUTION

After intestinal superficial mucosal injuries such as erosion, ulcerations, inflammatory bowel disease and infection, the repair of epithelial injury in the gastrointestinal tract begins in a process known as restitution<sup>[8]</sup>. The restitution is established through migration of viable epithelial cells from areas adjacent to or just beneath the injured surface to cover the denuded area, independent of cell proliferation and regulated by cytokines and growth factors<sup>[9-14]</sup>. Intestinal epithelial migration, proliferation and differentiation are essential to restitution<sup>[15]</sup>. FAK has been indicated to be involved in the integrin signaling which regulates the migration, proliferation and differentiation of various normal and cancer cells<sup>[16]</sup>. Correspondingly, FAK plays an important role in the mucosal restitution of the intestine.

It is well established that intestinal epithelial cells undertake a specialized phenotype adapted to motility and mucosal healing during mucosal restitution and FAK is involved in the cell signaling which regulates the intestinal epithelial migratory phenotype<sup>[17]</sup>. The disruption of actin stress fiber formation with reduced tyrosine phosphorylation of FAK and FAK in focal adhesions can suppress the repair of gastric mucosal injury and ulcer healing<sup>[18-20]</sup>. FAK plays a critical role in lysophosphatidic acid (LPA)-induced migration, lamellipodia formation and assembly of focal adhesions in intestinal epithelial cells<sup>[21,22]</sup>.

The expression and activation levels of FAK protein are linked to phenotypic changes which affect cell differentiation, function, adhesion and migration in various tissues<sup>[23-29]</sup>. Activated FAK<sup>397</sup> levels vary with differentiation and cell migration in Caco-2 and HT-29 human colon cancer cells<sup>[30]</sup>. The expression level of activated FAK is related to gastric wound healing *in vivo*<sup>[19,31]</sup>. Intestinal epithelial cell motility regulates FAK protein abundance at the mRNA level in both human Caco-2 and rat non-transformed IEC-6 intestinal epithelial cells<sup>[32]</sup>. It has been shown that immunoreactivity to FAK is decreased in cells migrating across matrix protein compared to static Caco-2 cells<sup>[33]</sup> and immunoreactivity to FAK and FAK<sup>397</sup> were lower in epithelial cells at the migrating edge of the ulcer<sup>[34]</sup>.

FAK mediates the mitogenic response to repetitive deformation in intestinal epithelial cells. Two deformation-activated signal pathways that converge upon FAK have been proposed: one is Src- and Rac1-independent-which stimulates FAK-Tyr397 phosphorylation, and the other is Src- and Rac1-dependent, which is required to further activate FAK by phosphorylation at FAK-Tyr576 (within the FAK kinase activation loop)<sup>[28]</sup>. Repetitive deformation stimulates intestinal epithelial motility

across fibronectin, which requires both Src activation and a novel Src-independent FAK-Tyr 925-dependent pathway activating extracellular signal-related kinase (ERK)<sup>[29]</sup>. Smad3-dependent disruption of the transforming growth factor- $\beta$  (TGF- $\beta$ ) signaling pathway impairs the healing of murine intestinal mucosal ulcers, which is followed by altering patterns of activated FAK and ERK immunoreactivity important for cell migration at the ulcer edge<sup>[15]</sup>.

Recently, the relationship between TGF- $\beta$  and FAK has been studied. TGF- $\beta$  was found to enhance FAK protein, mRNA levels and FAK promoter activity in human and rat intestinal epithelial cells<sup>[34]</sup>. TGF- $\beta$  also affected the restitution and proliferation partly mediated through its induction of FAK expression<sup>[35]</sup>. It is considered to play an essential role in embryogenesis, host response to tumors, and the repair response damaging the tissues by immune and non-immune reactions<sup>[36]</sup>.

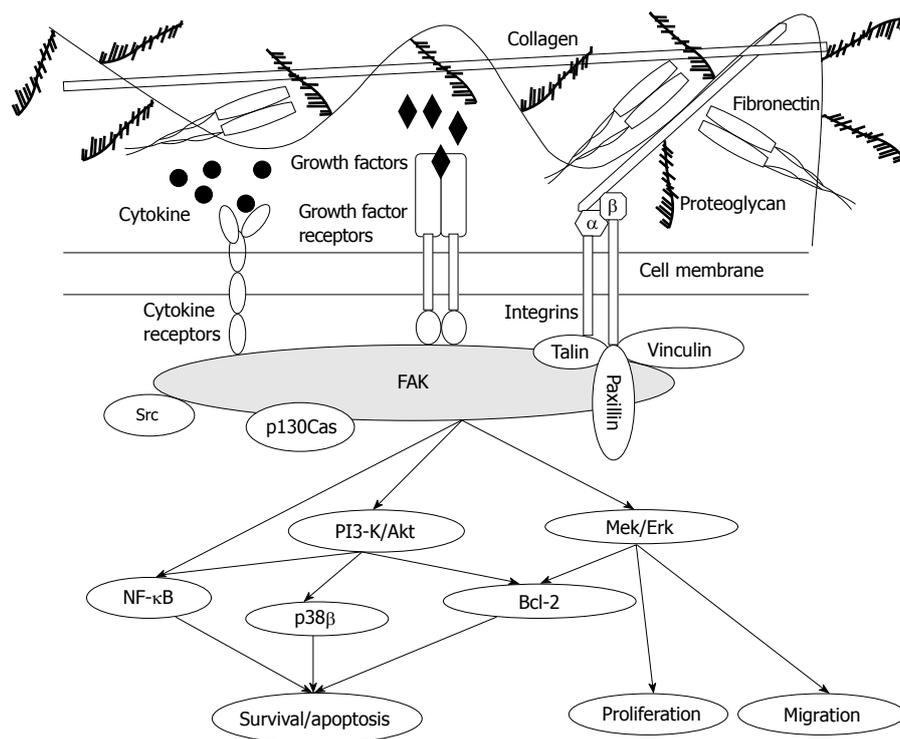

Taken together, the interaction between inflammatory cells, the extracellular matrix, locally released cytokines and growth factors guarantee efficient ulcer healing<sup>[31]</sup>. Tissue injury and wound healing spatially and temporally activate several growth factors and extracellular matrix facilitates the rapid phosphorylation of FAK at Tyr-397 and this in turn recruits Src-family PTKs, resulting in the phosphorylation of Tyr-576 and Tyr-577 in the FAK activated loop and other focal adhesive proteins including talin,  $\alpha$ -actinin, vinculin, paxillin and p130Cas (Figure 1)<sup>[3,5,16,37]</sup>. Activated FAK and cell adhesive protein transduce the signal to the Mek/Erk to down-regulate proliferation, differentiation and migration in the process of restitution. However, the detailed mechanism for the role of FAK in the process of restitution is still unknown.

## SURVIVAL AND APOPTOSIS

Programmed cell death, or apoptosis, is a complex and tightly regulated process that executes crucial roles in tissue homeostasis and repair<sup>[38,39]</sup>. It is well established that the Bcl-2 family of proteins plays a major role in cell survival and apoptosis<sup>[38,40,41]</sup>. Extracellular signals can affect the expression and/or functions of the Bcl-2 family by signaling events to determine if a cell lives or dies<sup>[42]</sup>. FAK is the canonical mediator of such extracellular signals which originate from integrin and growth factors<sup>[5]</sup>. Thus, FAK is related to cell survival and apoptosis in the gastrointestinal epithelium.

The detachment of intestinal epithelial cells from matrix induces apoptosis through the disruption of anti-apoptotic signals transduced by integrin/FAK/Src<sup>[43]</sup>. Induced FAK suppresses apoptosis by activating nuclear factor  $\kappa$ B (NF- $\kappa$ B) signaling in intestinal epithelial cells<sup>[44]</sup>. FAK inhibition in human intestinal epithelial cells produces anoikis while FAK induction in rat intestinal IEC-6 cells suppresses apoptosis<sup>[44,45]</sup>.

Recent studies in the function of FAK in survival and apoptosis of intestinal epithelial cells have focused on integrin/Fak/Src, PI3K/Akt and MEK/Erk pathways

**Figure 1** FAK mediates the extracellular signaling to regulate the proliferation, migration and survival/apoptosis of the cells. NF- $\kappa$ B: Nuclear factor  $\kappa$ B; FAK: Focal adhesion kinase.

which are all presumed to modulate the expression and function of multiple Bcl-2 homologs<sup>[42,44-46]</sup>. Many studies showed that integrin/FAK/Src modulate the PI3K/Akt and MEK/Erk pathways individually or in combination in different cell lines<sup>[5,42,47-55]</sup>. The Bcl-2 family is the central regulator of caspase activation which executed the cell-suicide program and play an anti- or pro-apoptotic role in cell apoptosis<sup>[56]</sup>. Butyrate-induced apoptosis of Caco-2 cells might occur *via* NF- $\kappa$ B activation together with a defective  $\beta$ 1 integrin-FAK-PI3-kinase pathway signaling<sup>[47]</sup>. A study showed that integrins, FAK, PI3-K/Akt-1, MEK/Erk, and p38 isoforms play distinct roles in the regulation of HIEC-6 cell survival and/or death, accompanied by modulating individual Bcl-2 homologs<sup>[46]</sup>.  $\beta$ 1 integrins/Fak/Src signaling down-regulated PI3-K/Akt-1 and MEK/Erk pathways in the suppression of anoikis, which play a role in the survival of differentiated cells, whereas the PI3-K/Akt-1 pathway is crucial for cell survival regardless of the state of differentiation<sup>[45]</sup>.  $\beta$ 1 integrins/Fak/Src signaling translates into integrated, complex regulatory functions by PI3-K/Akt-1 and MEK/Erk in the expression/activity of Bcl-2 homologs, as well as in the specific activation of the pro-apoptotic p38 $\beta$  SAPK isoform, thus determining their own requirement (or not) in the suppression of HIEC (Human Intestinal Epithelial Crypt) apoptosis/anoikis<sup>[42]</sup>.

Extracellular/Fak/Src signaling down-regulates PI3-K/Akt and MEK/Erk and further regulates the expression and activity of Bcl-2, and finally control the survival and apoptosis. PI3-K/Akt also specifically activates the apoptosis/anoikis driving p38 $\beta$  SAPK, and regulates the survival and apoptosis. Besides, extracellular/Fak/Src signaling has a new pathway to control the survival and apoptosis *via* regulating the NF- $\kappa$ B.

## CANCER

FAK is closely associated with cancer. Many studies have shown FAK over-expression in various tumor cells and its expression correlate with increased tumor malignancy. The alteration of FAK function in normal cells causes tumor progression.

FAK has been indicated to over-express at mRNA and protein levels in various tumors including gastrointestinal tumors. As early as in 1993, researchers found increased levels of FAK in 1 of 8 adenomatous tissues, in 17 of 20 invasive tumors, and in all 15 of 15 metastatic tumors, which suggests that FAK over-expression may result in changes in the signaling pathways involved in tumor cell invasion<sup>[57]</sup>. In human colon cancer cells, increased dosage of the FAK may contribute to the elevated protein expression during conversion from adenoma to carcinoma<sup>[58]</sup>. Quantitative realtime RT-PCR of gene expression levels in all gastrointestinal stromal tumors (GIST) indicated that FAK was over-expressed in malignant GIST<sup>[59]</sup>. Immunohistochemical analysis also demonstrated that FAK is over-expressed in colorectal, esophageal, pancreatic and mammary cancers, which indicated that FAK and P-FAK are involved in the carcinogenesis of digestive organs<sup>[60,61]</sup>. Another research group got similar results *via* immunohistochemistry, which showed that high levels of FAK and Src were predictive for recurrence of colorectal cancer<sup>[62]</sup>. The FAK expression level might be a valuable marker for the carcinogenesis and progression of some types of carcinoma<sup>[63,64]</sup>.

An increased expression of FAK is associated with the invasive potential of colon and breast tumors<sup>[65]</sup>. Immunohistochemical analysis of gastric cancer and colorectal cancer showed that the expression of FAK is more significantly associated with carcinogenesis,

differentiation and metastasis, and furthermore FAK may not only be a transformation-linked enzyme but also a progression-linked enzyme<sup>[63]</sup>. FAK over-expression of esophageal squamous cell carcinoma was related to cell differentiation, tumor invasiveness, and lymph node metastasis<sup>[66]</sup>. The expression of gastrin-releasing peptide (GRP) and its cognate receptor critically mediates a GRP-dependent phase of cell motility by phosphorylating FAK at multiple specific sites in colon cancer cells<sup>[30]</sup>. Gastrin can evidently promote invasiveness of Colo320 cells *via* the gastrin-gastrin receptor-FAK signal transduction pathway<sup>[67]</sup>.

Not only the expression level but also the activities of FAK are essential for the motility and invasion of cancer cells. Colon carcinomas exhibited a marked elevation in FAK tyrosine kinase activity and phosphotyrosine content and the catalytic activity of FAK is enhanced by its phosphotyrosine content<sup>[68]</sup>. The amount of total FAK and FAK phosphorylated at Y397 and Y407 correlates closely with the differentiation of human colon cancers<sup>[69]</sup>. The migratory phenotype of colon cancer cells is controlled by the combined activities of Src and FAK, and the recruitment of FAK to adhesive sites results in its phosphorylation by Src and other peripheral tyrosine kinases<sup>[70]</sup>.

The over-expression and elevated activities of FAK are associated with motility and invasion of cancer cells, however the exact mechanism is still unknown. Integrin $\alpha$ 2/FAK/ERK/ $\mu$ -calpain signaling pathway plays a critical role in tumor cell motility and these results would cause the interruption of FAK function at the early stages of colon tumorigenesis<sup>[71]</sup>. In a colon adenocarcinoma, cell proliferation and differentiation can occur concomitantly and these deregulated processes are controlled by autocrine secretion through the ErbB1/ERK1, 2 and FAK pathways<sup>[72]</sup>. The Cholecystokinin-2 receptor regulates the invasion and motility of colon cancer cells, and supports the role of CCK2R in the progression of colon cancer through the activation of FAK<sup>[73]</sup>. EGFR pathway substrate 8 could modulate the expression of FAK *via* mTOR/STAT3, which enable the cells to proliferate and migrate<sup>[74]</sup>. The mechanism of the increasing invasion of colon cancer cells by gastrin17 is probably that gastrin17 makes FAK-Tyr397 phosphorylate and localize to lamellipodia, causing the formation of FAK-Src-p130(Cas)-Dock180 signaling complex when it is bound to its receptor CCK-2 and the activation of Rac<sup>[75]</sup>. The engagement of  $\alpha$ 1-integrins with functional molecular scaffolds using FAK/Src and p130Cas/JNK is involved in human colon cancer cell invasion through the induction and activation of the MMP-2 and MMP-9 matrix metalloproteinases<sup>[76]</sup>. A model has been proposed to indicate how the interaction of FAK and SFKs down-regulate the MAPK/Erk1/2 and PI3K/Akt pathways in the early process of cell adhesion in SW480 colon cancer cells: Integrin engagement induces quick FAK-Y397 autophosphorylation and subsequent translocation of a fraction of FAK in raft compartments, FAK interacts only with Fyn in lipid domains, while it interacts with c-Src and Fyn in non-raft fractions. In parallel, PI3K/Akt signaling

is quickly activated which is dependent on lipid domain integrity, while MAPK/Erk1/2 signaling is activated with longer kinetics which is not dependent on lipid domain integrity. Both signaling pathways contribute to the adhesive process of SW480 cells<sup>[77]</sup>.

These data show the strong relationship between the expression and activity level of FAK and the generation and progression of gastrointestinal tumors, however the exact mechanism needs further studies.

### Inhibitor

Due to the crucial role of FAK in integrin-mediated signal transduction, which affects the regulation of cell survival, proliferation, spreading and migration, FAK has been considered a potential target in cancer therapy. There are many ways to suppress the activity and expression of FAK, thereby inhibiting the growth of tumor cells. The attenuation of FAK expression *via* antisense oligonucleotides induces detachment and apoptosis in tumor cells<sup>[78]</sup>. The entire C-terminal, non-catalytic domain of FAK (FAK related non-kinase-FRNK) is autonomously expressed in some cell types, and has been used as a dominant negative mutant to elucidate FAK function<sup>[79-82]</sup>. Specific short interfering RNA is often used to reduce the expression of FAK. Knockdown of FAK protein through FAK-SiRNA significantly inhibited LPA-induced migration of both IEC-18 and IEC-6 cells<sup>[22]</sup>.

As described earlier in this article, phosphorylation of Tyr-397 at FAK is essential to the phosphorylation of Tyr-576 and Tyr-577 in the FAK activation loop, full catalytic FAK activation, the activity of other adhesive protein and its downstream molecules which all play important roles in integrins or growth factors initiated signaling pathways. So targeting the phosphorylation of FAK seems to be promising for the cancer therapy. Small molecule inhibitors targeting FAK as potential cancer therapies have been developed. Sulindac sulfide (NSAID) and the phenolic antioxidant caffeic acid phenethyl ester were used to reduce the phosphorylation of FAK and cell invasion in human colon carcinoma cells<sup>[83]</sup>. Butyrate treatment results in a significant down-regulation of c-Src and FAK in human colon cancer cells and finally inhibits tumor growth and invasion<sup>[84]</sup>. Exposure of HT-29 cells to 10 mmol/L garcinol inhibited cell invasion and decreased the dose-dependent tyrosine phosphorylation of FAK, which suggests that garcinol reduces cell invasion and survival through inhibiting the downstream signaling of FAK<sup>[85]</sup>.

Recently, compounds PF-573228, PF-562271 and NVP-226 (TAE226) have been generated by two groups. These compounds are ATP analogs and effectively inhibit the kinase activity of FAK<sup>[86,87]</sup>. PF-573228 inhibited phosphorylation of FAK and its downstream effector paxillin, and affected cell migration and adhesion turnover<sup>[86]</sup>. But PF-573228 had little inhibitory effect on the growth and apoptosis of normal and cancer cells possibly because the FAK kinase activity is not essential for cell growth-proliferation mediated through FAK FERM regulation of p53<sup>[88]</sup>.

PF-562271 is a newly developed diaminopyrimidine-type compound that inhibits FAK and Pyk2 and shows a high degree of selectivity in the inhibition of PTKs<sup>[89]</sup>. PF-562271 have inhibited the tumor growth of prostate, pancreatic, colon, glioblastoma, and H460 lung xenotropic tumor models<sup>[89]</sup> and blocked bFGF-stimulated blood vessel angiogenesis as shown in chicken chorioallantoic membrane assays. Low dosage of PF-262271 potently blocked blood vessel sprouting without detectable changes in vascular leakage<sup>[88]</sup>. The oral administration of PF-562271 suppressed the growth and local spread of intratibial tumors and restored tumor-induced bone loss<sup>[90]</sup>. The combination of PF-562271 and sunitib could effectively block the growth and recovery of human hepatocellular carcinoma in a rat xenograft model<sup>[91]</sup>. PF-562271 has since moved to clinical trials, and has shown minimal toxicity along with tumor regression<sup>[92]</sup>.

TAE226 is a novel ATP-competitive tyrosine kinase small-molecule inhibitor designed to target FAK, and can effectively prevent FAK phosphorylation, ERK, S6 ribosomal protein phosphorylation and downstream signal transduction, as determined by decreased AKT. TAE226 inhibits insulin receptor (InsR) and insulin-like growth factor-I receptor (IGF-IR), albeit, 10 fold less potently (IC<sub>50</sub> = 44 nmol/L for InsR and IC<sub>50</sub> = 140 nmol/L for IGF-IR), and is a potent inhibitor of FAK (IC<sub>50</sub> = 5.5 nmol/L)<sup>[87,93]</sup>. TAE226 was shown to induce apoptosis in breast cancer cell lines<sup>[94]</sup>. Furthermore, TAE226 can significantly prolong the survival of animals bearing intracranial glioma xenografts and ovarian tumor cells orthotopic implantation<sup>[86,95]</sup>. TAE226 also showed a potent inhibitory effect of tumor cell growth in gastrointestinal tract. When esophageal adenocarcinoma cells were treated with TAE226, cell proliferation and migration were greatly inhibited with an apparent structural change of actin fiber and a loss of cell adhesion, which suggest that TAE226, a dual tyrosine kinase inhibitor for FAK and IGF-IR, might become a new remedy for Barrett's esophageal adenocarcinoma<sup>[96]</sup>. Furthermore, TAE226 has shown significant inhibitory effects on mTOR signaling and the esophageal cancer cell growth<sup>[97]</sup>. TAE226 can effectively suppress the growth of imatinib-resistant GIST cells, indicating its potential application for treating the imatinib-resistant GISTs<sup>[98]</sup>. So the small molecule inhibitors show a significant promise for cancer therapy.

## CONCLUSION

FAK plays a critical role in the biological processes of normal and cancer cells including the gastrointestinal tract. Research data shows that FAK plays an important role in the restitution, cell survival and apoptosis and carcinogenesis of the gastrointestinal tract, however the exact mechanism needs further studies. FAK is over-expressed in cancer cells and over-expression and enhanced activities of FAK are associated with motility and invasion of cancer cells. So FAK has been proposed as a potential target in cancer therapy. Small molecule inhibitors effectively inhibit the kinase activity of FAK

and show a potent inhibitory effect in the proliferation and migration of tumor cells, indicating a high potential for future application in cancer therapy.

were treated with kinase inhibitors and chemotherapeutic drugs. Apoptosis induction and cell viability were analyzed *via* flow cytometry and 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay.

**RESULTS:** TRAIL-R1 and -R2 were profoundly expressed on the HCC cell lines Huh7 and Hep-G2. However, treatment of Huh7 and Hep-G2 with TRAIL and agonistic antibodies only induced minor apoptosis rates. Apoptosis resistance towards TRAIL could be considerably reduced by adding the chemotherapeutic drugs 5-fluorouracil and doxorubicin as well as the kinase inhibitors LY294002 [inhibition of phosphoinositol-3-kinase (PI3K)], AG1478 (epidermal growth factor receptor kinase), PD98059 (MEK1), rapamycin (mammalian target of rapamycin) and the multi-kinase inhibitor Sorafenib. Furthermore, the antiapoptotic BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> play a major role in TRAIL resistance: knock-down by RNA interference increased TRAIL-induced apoptosis of HCC cells. Additionally, knock-down of MCL-1 and BCL-x<sub>L</sub> led to a significant sensitization of HCC cells towards inhibition of both c-Jun N-terminal kinase and PI3K.

**CONCLUSION:** Our data identify the blockage of survival kinases, combination with chemotherapeutic drugs and targeting of antiapoptotic BCL-2 proteins as promising ways to overcome TRAIL resistance in HCC.

### Abstract

**AIM:** To analyze the effect of chemotherapeutic drugs and specific kinase inhibitors, in combination with the death receptor ligand tumor necrosis factor-related apoptosis inducing ligand (TRAIL), on overcoming TRAIL resistance in hepatocellular carcinoma (HCC) and to study the efficacy of agonistic TRAIL antibodies, as well as the commitment of antiapoptotic BCL-2 proteins, in TRAIL-induced apoptosis.

**METHODS:** Surface expression of TRAIL receptors (TRAIL-R1-4) and expression levels of the antiapoptotic BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> were analyzed by flow cytometry and Western blotting, respectively. Knock-down of MCL-1 and BCL-x<sub>L</sub> was performed by transfecting specific small interfering RNAs. HCC cells

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common malignancy worldwide. It ranks at third place in the list of malignancies leading to death. Over the past decades the incidence of HCC has increased worldwide, especially in eastern Asia and sub-Saharan Africa<sup>[1,2]</sup>. HCC is clinically characterized by its invasiveness, poor prognosis and limited therapeutic opportunities, mostly due to the high resistance of HCC cells towards chemotherapeutic agents. Today, surgery is considered to be the only curative treatment procedure for most HCC patients<sup>[3]</sup>. However, in many patients, HCC is diagnosed at an advanced or metastasized stage. For the treatment of these patients, the Food and Drug Administration approved the multi-kinase inhibitor Sorafenib in 2007<sup>[4,5]</sup>, which highlights the fact that specific inhibition of survival pathways is an effective treatment option in HCC<sup>[6]</sup>.

Apoptosis is a genetically determined process of controlled cellular suicide<sup>[7]</sup>. Dysregulation of apoptosis is involved in the pathophysiology of liver diseases including hepatocarcinogenesis<sup>[8]</sup>. Resistance of HCC cells to apoptosis is a crucial aspect in cancer treatment because it impairs the efficacy of different therapy regimens<sup>[9]</sup>.

Tumor necrosis factor-related apoptosis inducing ligand (TRAIL) is a promising anti-tumor agent since it is capable of killing tumor cells *via* receptor-mediated apoptosis<sup>[10,11]</sup>. TRAIL ligates two different types of receptors: (1) death receptors triggering TRAIL-induced apoptosis, and (2) decoy receptors possibly inhibiting the TRAIL death-signaling pathway. Receptors TRAIL-R1 and -R2 contain an intracellular death domain (DD) motif essential for signal transduction. In contrast, TRAIL-R3 (DcR1) and -R4 (DcR2) appear to act as “decoys”, lacking a DD. Due to this fact they are capable of binding the ligand without effecting a death signal. Under certain conditions, a relative TRAIL resistance occurs in cells expressing high levels of DcR1 or DcR2.

Binding of an agonistic ligand or mAb to TRAIL-R1 or -R2 leads to the intracellular formation of a protein complex termed death inducing signaling complex (DISC). DISC formation includes the activation of the apical activator caspase 8, representing the initial point of receptor-related apoptosis signaling.

In addition to this receptor-related extrinsic pathway, there is an intrinsic pathway of apoptosis, which is crucial as a cellular response to DNA damage and oxidative stress. Central organelles for the intrinsic pathway are mitochondria, where a delicate balance between pro- and antiapoptotic BCL-2 proteins decides cell destiny. If DNA damage or other intrinsic triggers occur, proapoptotic BCL-2 proteins and mitochondria are activated. Subsequently, a

multimeric protein complex, designated as an apoptosome, is formed. The apoptosome cleaves caspase 9, which in turn activates the downstream effector caspase 3, where intrinsic and extrinsic pathways of apoptosis converge.

Notably, receptor-mediated caspase 8 activation can promote an activation of mitochondria by cleavage and subsequent activation of the proapoptotic BCL-2 protein, BID<sup>[12]</sup>. The crosstalk between extrinsic and intrinsic apoptosis pathways amplifies a death signal mediated by TRAIL, leading to a more effective execution of apoptosis.

MCL-1 and BCL-x<sub>l</sub> are antiapoptotic members of the BCL-2 family serving as protective factors against several death stimuli. Both proteins were found to be expressed at a high level in different solid tumor entities, including HCC<sup>[13-15]</sup>. Antiapoptotic BCL-2 proteins interact with proapoptotic BCL-2 proteins BAX and BAK, thereby inhibiting the activation of mitochondria. It appears that high expression levels of MCL-1 and BCL-x<sub>l</sub> provide resistance of tumor cells to chemotherapeutic drugs and TRAIL<sup>[16,17]</sup>.

Resistance towards TRAIL can be due to failure at any step in the death signaling cascade. For example, TRAIL resistance can be located at receptor level due to an inappropriate expression or at DISC level mediated by proteins counteracting DISC formation<sup>[18-20]</sup>. Furthermore, an inability to activate mitochondria during apoptosis, due to high expression levels of antiapoptotic proteins (e.g. MCL-1), can cause resistance towards TRAIL<sup>[16,21]</sup>. Finally, antiapoptotic pathways, such as phosphoinositol-3-kinase (PI3K)/Akt signaling, are aberrantly activated in various tumor cells, thus contributing to TRAIL resistance<sup>[22,23]</sup>.

In our study, we investigated whether TRAIL resistance in HCC cells can be overcome by combining TRAIL with chemotherapeutic drugs, inhibitors of survival signaling or targeted therapies against antiapoptotic BCL-2 proteins.

## MATERIALS AND METHODS

### Reagents and cell lines

HCC cell lines, Hep-G2 and Huh7, were purchased from ECACC. Cells were cultured in DMEM (Invitrogen, Karlsruhe, Germany), supplemented with 10% fetal calf serum (FCS, Biochrom, Berlin, Germany), 1% Pen/Strep (PAA laboratories, Pasching, Austria), 1% HEPES and 1% L-Glutamine (Cambrex, Verviers, Belgium). Cells were cultivated at 37°C with a concentration of 5% CO<sub>2</sub>. Transfection experiments were performed in OPTIMEM (Invitrogen).

Reagents were purchased from the following suppliers: recombinant TRAIL (with Enhancer applied in a concentration of 1 µg/mL) and SuperKillerTRAIL (SkTRAIL) from Alexis Biochemicals (SanDiego, CA, USA), goat anti-human IgG F(ab)<sup>2</sup> from Meridian Life Science (Cincinnati, USA), 5-fluorouracil (5-FU), doxorubicin (Doxo) from Sigma (Deisenhofen, Germany), SP600125, AG1478, PD98059, LY294002 and rapamycin (RAPA) from Calbiochem (Schwalbach, Germany). LBY135 was supplied from Novartis (Basel, Switzerland), Sorafenib (BAY 43-9006) from Bayer (Leverkusen, Germany).

**Viability test**

Cell viability was determined by a colorimetric 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. HCC cell lines were seeded onto 96-well plates. On day one after seeding, cells were treated as indicated. We added 10  $\mu$ L MTT (5 mg/mL) 48 h after treatment and incubated cells for a further 3 h at 37°C. Next, supernatant was discarded and cells were lysed by adding 100  $\mu$ L 1-propanol to each well followed by shaking plates till complete lysis. Absorbance was measured at 550 nm in a microtiter plate reader. A viability of 1 was defined as the absorbance of untreated cells.

**Coating of microtiter plates**

To ease ligand-receptor interaction with the crosslinking supplement IgG F(ab)<sub>2</sub>, 96-well plates were coated with IgG F(ab)<sub>2</sub> before seeding cells. One hundred microliters of sterile filtered 100 nmol/L sodium bicarbonate buffer (pH 9.2) containing 5  $\mu$ g/mL IgG F(ab)<sub>2</sub> was added to each well and incubated for 2 h at room temperature (RT). After replacement of F(ab)<sub>2</sub> buffer by cell culture media, plates were stored at 4°C. Coated plates were stable for at least 1 wk.

**RNAi and transfection**

To knock-down protein expression, we administered specific small interfering RNA (siRNA) against MCL-1 or BCL-xL. As a control we used siRNA specific for green fluorescent protein (GFP). The following siRNA sequences were applied (MWG Biotech, Ebersberg, Germany): BCL-xL, 5'-gcuuggauaaagaugcaATT-3' (sense) and 5'-uugcaucuuuauccaagcAG-3' (antisense), MCL-1, 5'-aagauacacagcuucucTT-3' (sense) and 5'-gagaacgucugugauacuuTT-3' (antisense), GFP, 5'-ggcuacguccaggagcgcacTT-3' (sense) and 5'-ggugcgcuccuggacguagcTT-3' (antisense). Here, capitals represent deoxyribonucleotides and lower case letters represent ribonucleotides. Huh7 cells were seeded onto 12-well plates and after 24 h transiently transfected in OPTIMEM with Lipofectamine RNAiMax (Invitrogen) according to the manufacturer's protocol. Expression levels were analyzed 24, 48 and 72 h after transfection *via* Western blotting analysis.

**Detection of apoptosis**

HCC cells were seeded onto 12-well plates and treated as indicated 1 d after transfection. Forty eight hours after treatment, cells were washed with cold PBS, collected and resuspended in a hypotonic buffer containing 0.1% (w/v) sodium citrate, 0.1% (v/v) Triton X-100, and 50  $\mu$ g/mL Propidium iodide (PI, Sigma). After 3 h incubation at 4°C, nuclei from apoptotic cells were quantified by fluorometric absorbance cell sorting according to the protocol of Nicoletti *et al*<sup>[24]</sup>.

**Cell lysis and Western blotting**

Cell lysis, SDS-PAGE and Western blotting were performed as described previously<sup>[13]</sup>. Immunodetection of proteins was performed using the following antibodies:

anti-BCL-xL (Labvison/NeoMarkers, Warm Springs Blvd. Fremont, Canada), anti-MCL-1 (Santa Cruz Biotechnology, Heidelberg, Germany) and anti- $\alpha$ -tubulin (Sigma) as loading control.

**Detection of receptor expression**

HCC cells were cultured as described and collected. Five hundred thousand cells for each receptor analysis were transferred to polystyrene tubes, washed twice with PBS and resuspended in PBS containing 0.5% BSA (Sigma). A specific monoclonal antibody to either TRAIL-R1, -R2, -R3, -R4 or unspecific mouse IgG1 as isotype control was applied at 5  $\mu$ g/mL. Cells were incubated for 20 min with gentle rocking at RT. Cells were washed twice in PBS and secondary fluorescein isothiocyanate-conjugated polyclonal goat antibody to mouse IgG1 (1:200 in PBS containing 0.5% BSA) was added, followed by incubation protected from light for 30 min with gentle rocking at RT. Cells were then washed and resuspended in PBS containing 0.5% BSA. Analysis of receptor expression was performed *via* flow cytometry. All antibodies were purchased from Alexis.

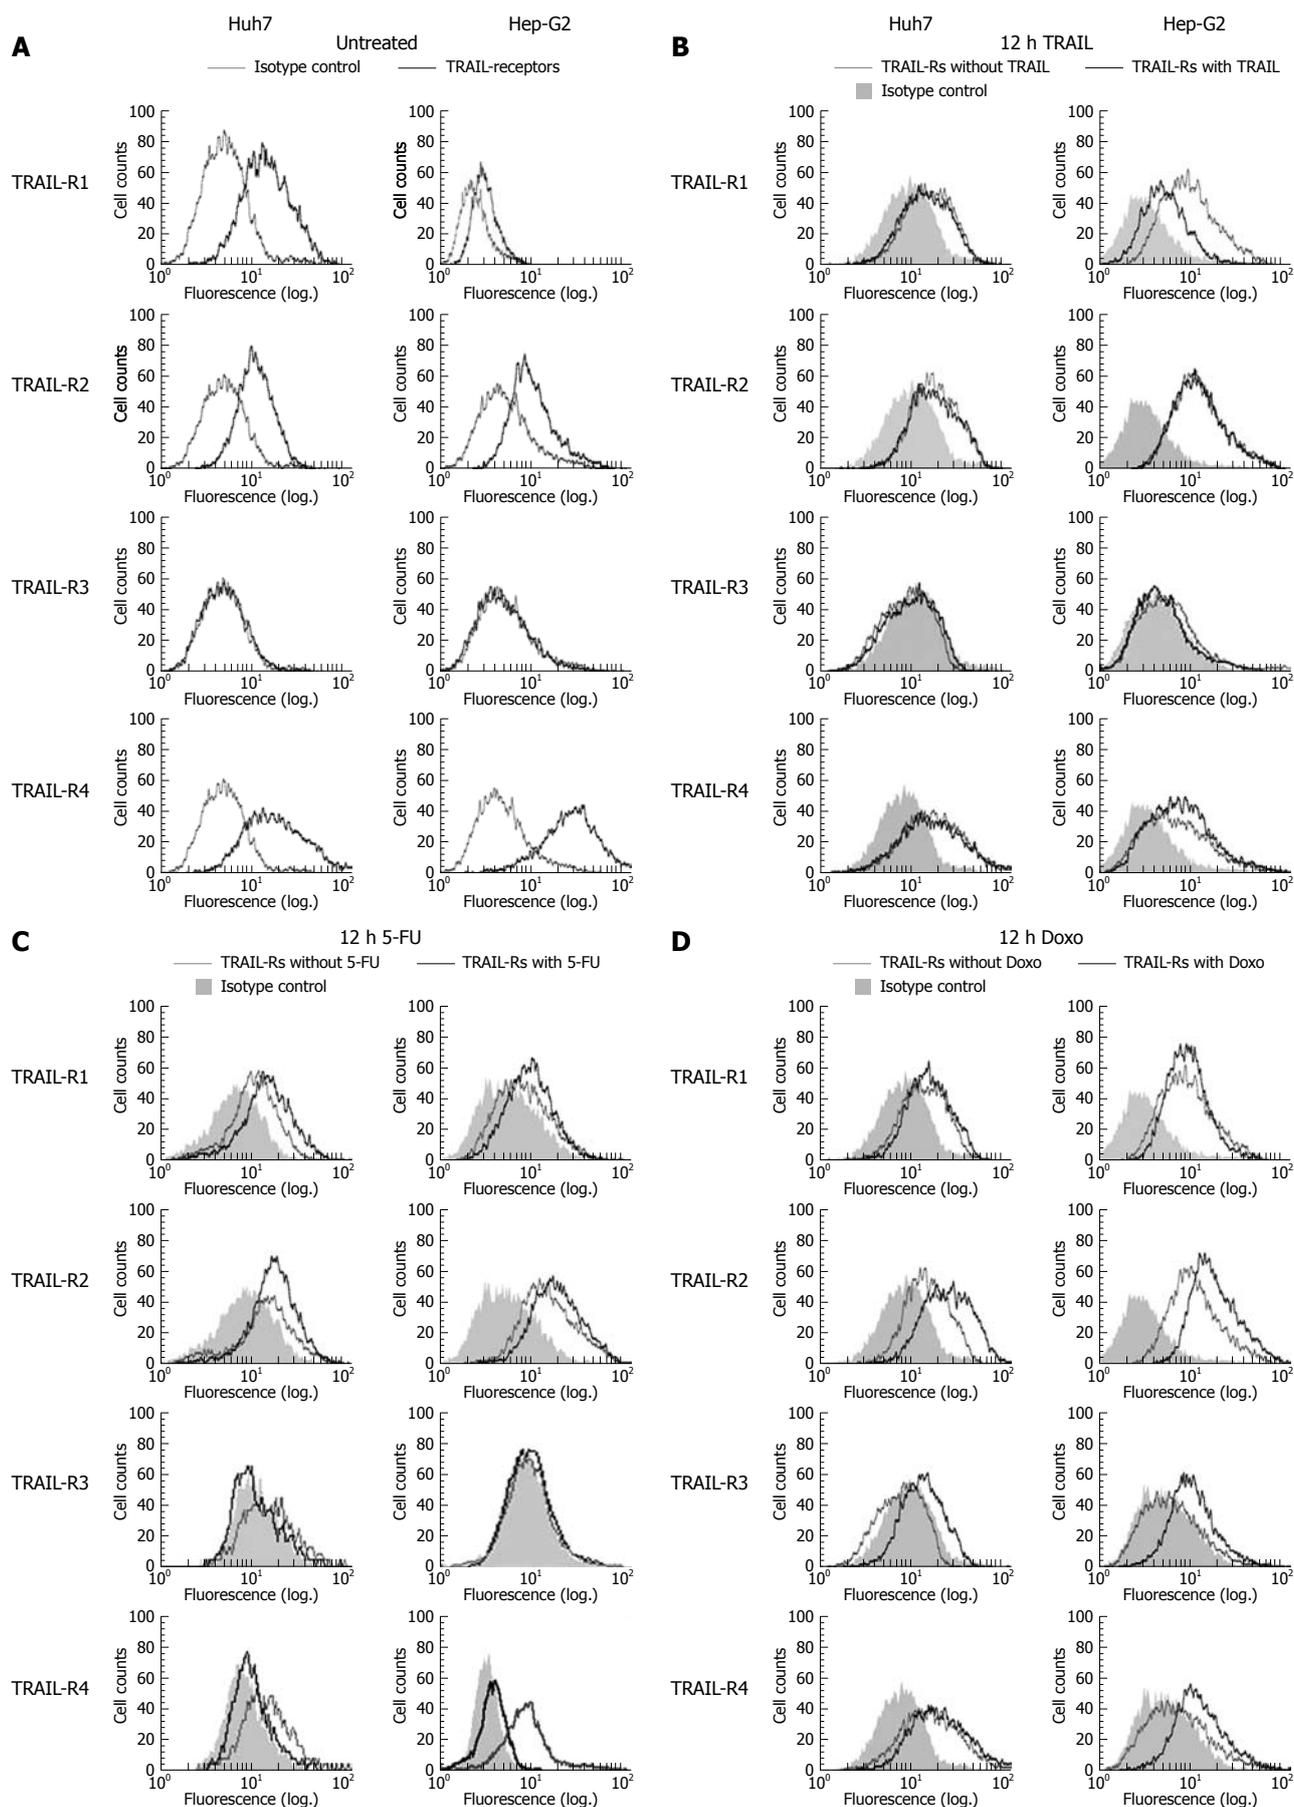

**Statistical analysis**

All results are expressed as mean  $\pm$  SD. Data were analyzed by students *t*-test (paired, two-sided) based on normal data distribution. *P* < 0.05 was considered significant.

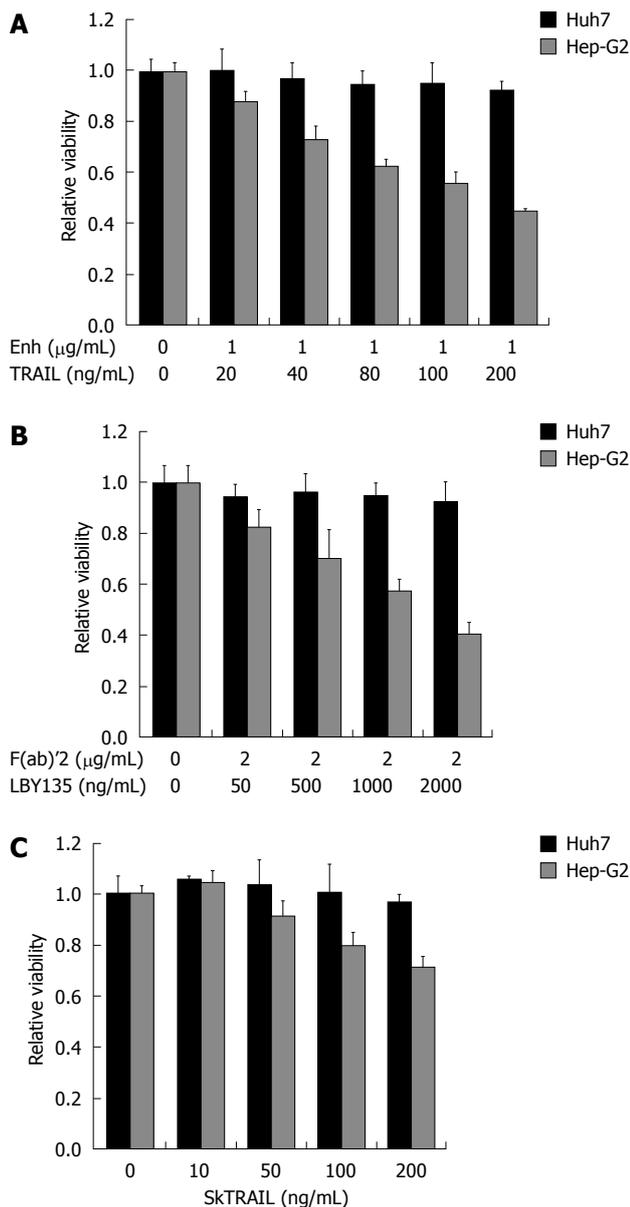

**RESULTS****TRAIL receptor expression in HCC cells upon treatment with TRAIL and chemotherapeutic agents**

It is known that TRAIL resistance can be mediated at the receptor level, either by low expression of TRAIL-R1 and -R2 or by a comparably high expression of TRAIL-R3 and -R4<sup>[25]</sup>. Firstly, we analyzed surface receptor expression of the HCC cell lines Huh7 and Hep-G2. Except for TRAIL-R3, all receptors were found to be expressed: we detected high expression levels of TRAIL-R1, -R2 and -R4 in both cell lines (Figure 1A). Next, we analyzed the expression levels after treatment with TRAIL and consequently the possibility of TRAIL-induced regulation in a feedback manner. After 12 h-treatment with TRAIL, we observed downregulation of TRAIL-R1 and a moderate upregulation of TRAIL-R4 in Hep-G2 cells. In contrast, no changes in receptor expression were detected in Huh7 cells (Figure 1B).

In order to study the effect of chemotherapeutics on TRAIL receptor expression, we treated HCC cells with 5-FU and Doxo, both applied for transarterial chemoembolization in patients with HCC<sup>[26]</sup>. 12 h-treatment with 5-FU resulted in upregulation of TRAIL-R1 and -R2 in both cell lines. In contrast, TRAIL-R3 was downregulated in Huh7 and unaffected in Hep-G2 cells. For TRAIL-R4, we observed a significant downregulation in both Hep-G2 and Huh7 cells (Figure 1C). 12 h-treatment with Doxo resulted in a slight upregulation of TRAIL-R1 in both cell lines. Remarkably, TRAIL-R2 was considerably upregulated. TRAIL-R3 surface expression

**Figure 1** Surface expression of tumor necrosis factor-related apoptosis inducing ligand (TRAIL) receptors on Huh7 and Hep-G2 cells. Flow cytometric analysis of TRAIL receptors was performed using monoclonal mouse IgG1, anti-TRAIL-R1, -R2, -R3, -R4 antibodies and secondary FITC-conjugated polyclonal goat anti mouse-IgG1 antibodies. Unspecific mouse IgG1 antibodies were used as isotype control. Receptor surface expression was analyzed in untreated Huh7 and Hep-G2 cells (A) and 12 h after treatment with 100 ng/mL rec. TRAIL + 1 µg/mL Enhancer (B), 50 µg/mL 5-fluorouracil (5-FU) (C) and 0.5 µmol/L doxorubicin (D). Diagrams are representative of at least two independent experiments. Doxo: Doxorubicin.

**Figure 2** TRAIL-induced apoptosis in hepatocellular carcinoma (HCC) cells. Huh7 and Hep-G2 cells were seeded onto 96-well plates and treated on day one after seeding with different TRAIL compounds. A: Cells were treated for 48 h with rec. TRAIL + 1 μg/mL Enhancer as indicated; B: Plates were coated with crosslinker IgG F(ab)2 for 24 h before seeding of cells. Cells were then treated for 48 h with LBY135 + 1 μg/mL F(ab)2 as indicated; C: Cells were treated for 48 h with SkTRAIL as indicated. Cell viability was analyzed by MTT assay. Viability is shown relative to untreated controls. Assays were performed in six-fold values and are representative of three independent experiments. Values are expressed as mean ± SD. Enh: Enhancer.

was detectable in both cell lines after Doxo treatment. TRAIL-R4 was upregulated in Hep-G2 and unaffected in Huh7 cells (Figure 1D).

#### Sensitivity of HCC cells towards different TRAIL compounds

Next, we determined sensitivity of HCC cells towards TRAIL-induced apoptosis. Firstly, we analyzed the effect of recombinant TRAIL in concentrations from 20 up to 200 ng/mL (combined with Enhancer, 1 μg/mL). Hep-G2 cells were sensitive towards recombinant TRAIL in a dose-dependent manner, whereas Huh7 were resistant

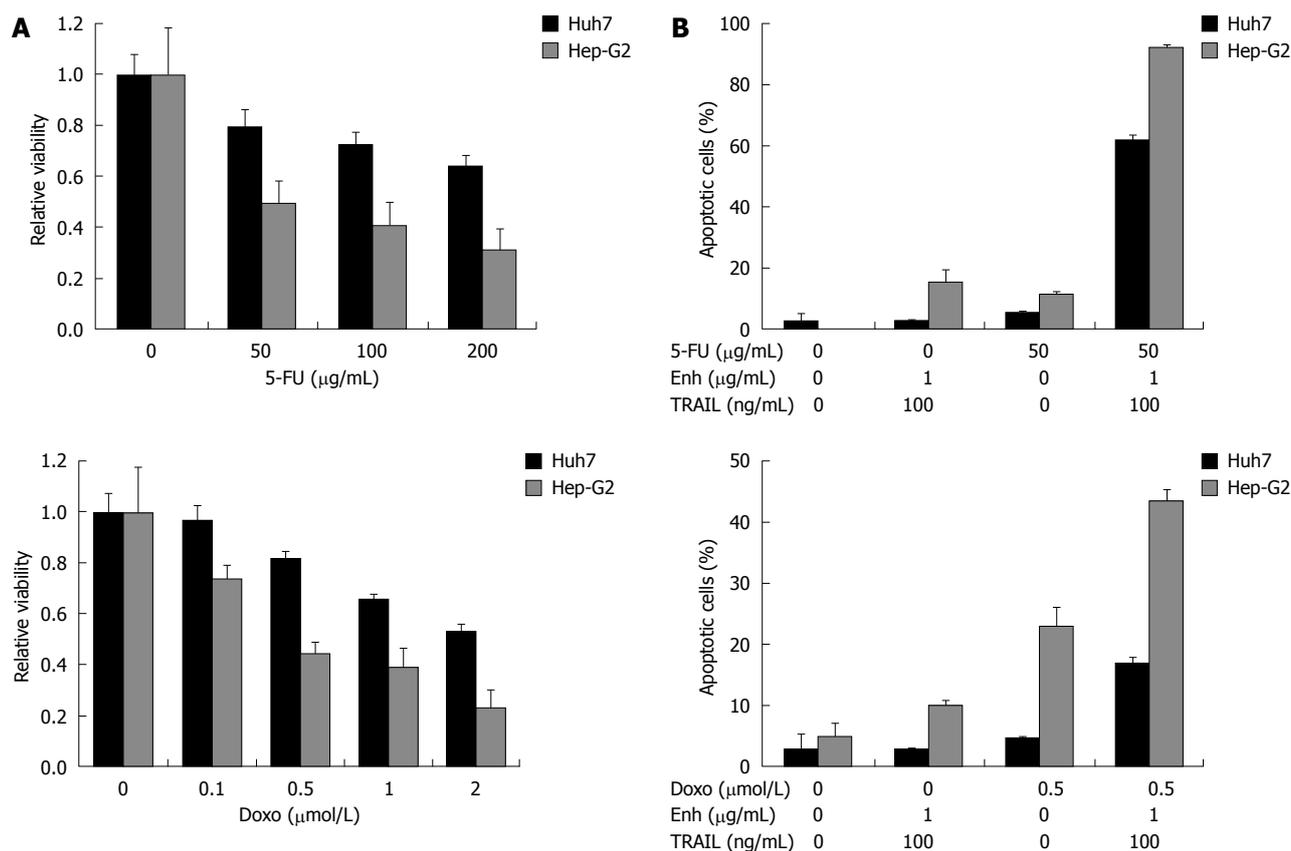

(Figure 2A). Next, we tested LBY135, a chimeric monoclonal antibody targeting TRAIL-R2, in concentrations from 50 to 2000 ng/mL, together with the cross linker F(ab)2 (2 μg/mL). To optimize the interaction between LBY135 and F(ab)2, we coated the plates with the F(ab)2-fragment before seeding the cells. Hep-G2 showed moderate sensitivity towards LBY135-induced apoptosis in a dose-dependent manner, whereas Huh7 cells were resistant (Figure 2B). To discover whether resistance was due to impaired interactions between enhancer or F(ab)2, the ligand and the receptor, we included SkTRAIL in our study. SkTRAIL interacts effectively with TRAIL receptors without additional supplements. Again, Hep-G2 cells revealed a dose-dependent sensitivity to SkTRAIL in concentrations from 10 to 200 ng/mL. In contrast, Huh7 cells were resistant to SkTRAIL (Figure 2C).

#### Treatment of HCC cells with TRAIL in combination with chemotherapy

Next, we analyzed whether HCC cells were sensitized to TRAIL-induced apoptosis by co-treatment with the chemotherapeutic drugs 5-FU and Doxo. As a first step, we analyzed whether the chemotherapeutics induced loss of viability if applied alone: after 48 h treatment of Huh7 and Hep-G2 cells with 5-FU (50, 100 and 200 μg/mL) and Doxo (0.1, 0.5, 1 and 2 μmol/L), we observed a dose-dependent decrease of cell viability (Figure 3A). Next, we applied these agents in concentrations which exhibited less significant cytotoxic effects, in combination with recombinant TRAIL (+ Enhancer 1 μg/mL). 5-FU (50 μg/mL) or TRAIL (100 ng/mL) did not induce apoptosis in Huh7 cells when administered alone. However, combination of 5-FU and TRAIL induced apoptosis in 62% of Huh7 cells. In Hep-G2 cells, TRAIL (100 ng/mL) induced apoptosis in 15% of cells. 5-FU treatment alone triggered apoptosis of 12% of Hep-G2 cells. 5-FU and TRAIL co-treatment of Hep-G2 resulted in 93% apoptotic cells (Figure 3B, upper panel). Next, we tested the combination of Doxo (0.5 μmol/L) and TRAIL (100 ng/mL). Doxo induced apoptosis in less than 5% of Huh7 cells, whereas the combination of Doxo and TRAIL resulted in 17% apoptotic cells. Treatment of Hep-G2 with Doxo alone induced apoptosis in 24% of cells, whereas Doxo and TRAIL in combination led to apoptosis rates of 43% (Figure 3B, lower panel).

#### Treatment of HCC cells with TRAIL in combination with specific kinase inhibitors

Antiapoptotic pathways such as PI3K/Akt, epidermal growth factor receptor (EGFR), [mitogen-activated protein kinase (MAPK)/extracellular signal regulated kinase (ERK) kinase] (MEK)/ERK are well known to be activated in malignant cells, thus contributing to cell cycle progression and tumor growth. Therefore, we analyzed whether inhibition of kinases involved in these pathways could overcome resistance towards TRAIL-mediated apoptosis. Firstly, we applied the multi-kinase inhibitor Sorafenib to inhibit RAF/MEK/ERK signaling, in escalating concentrations (2.5, 5 and 10 μmol/L). A dose-dependent decrease of cell viability in Huh7 and Hep-G2

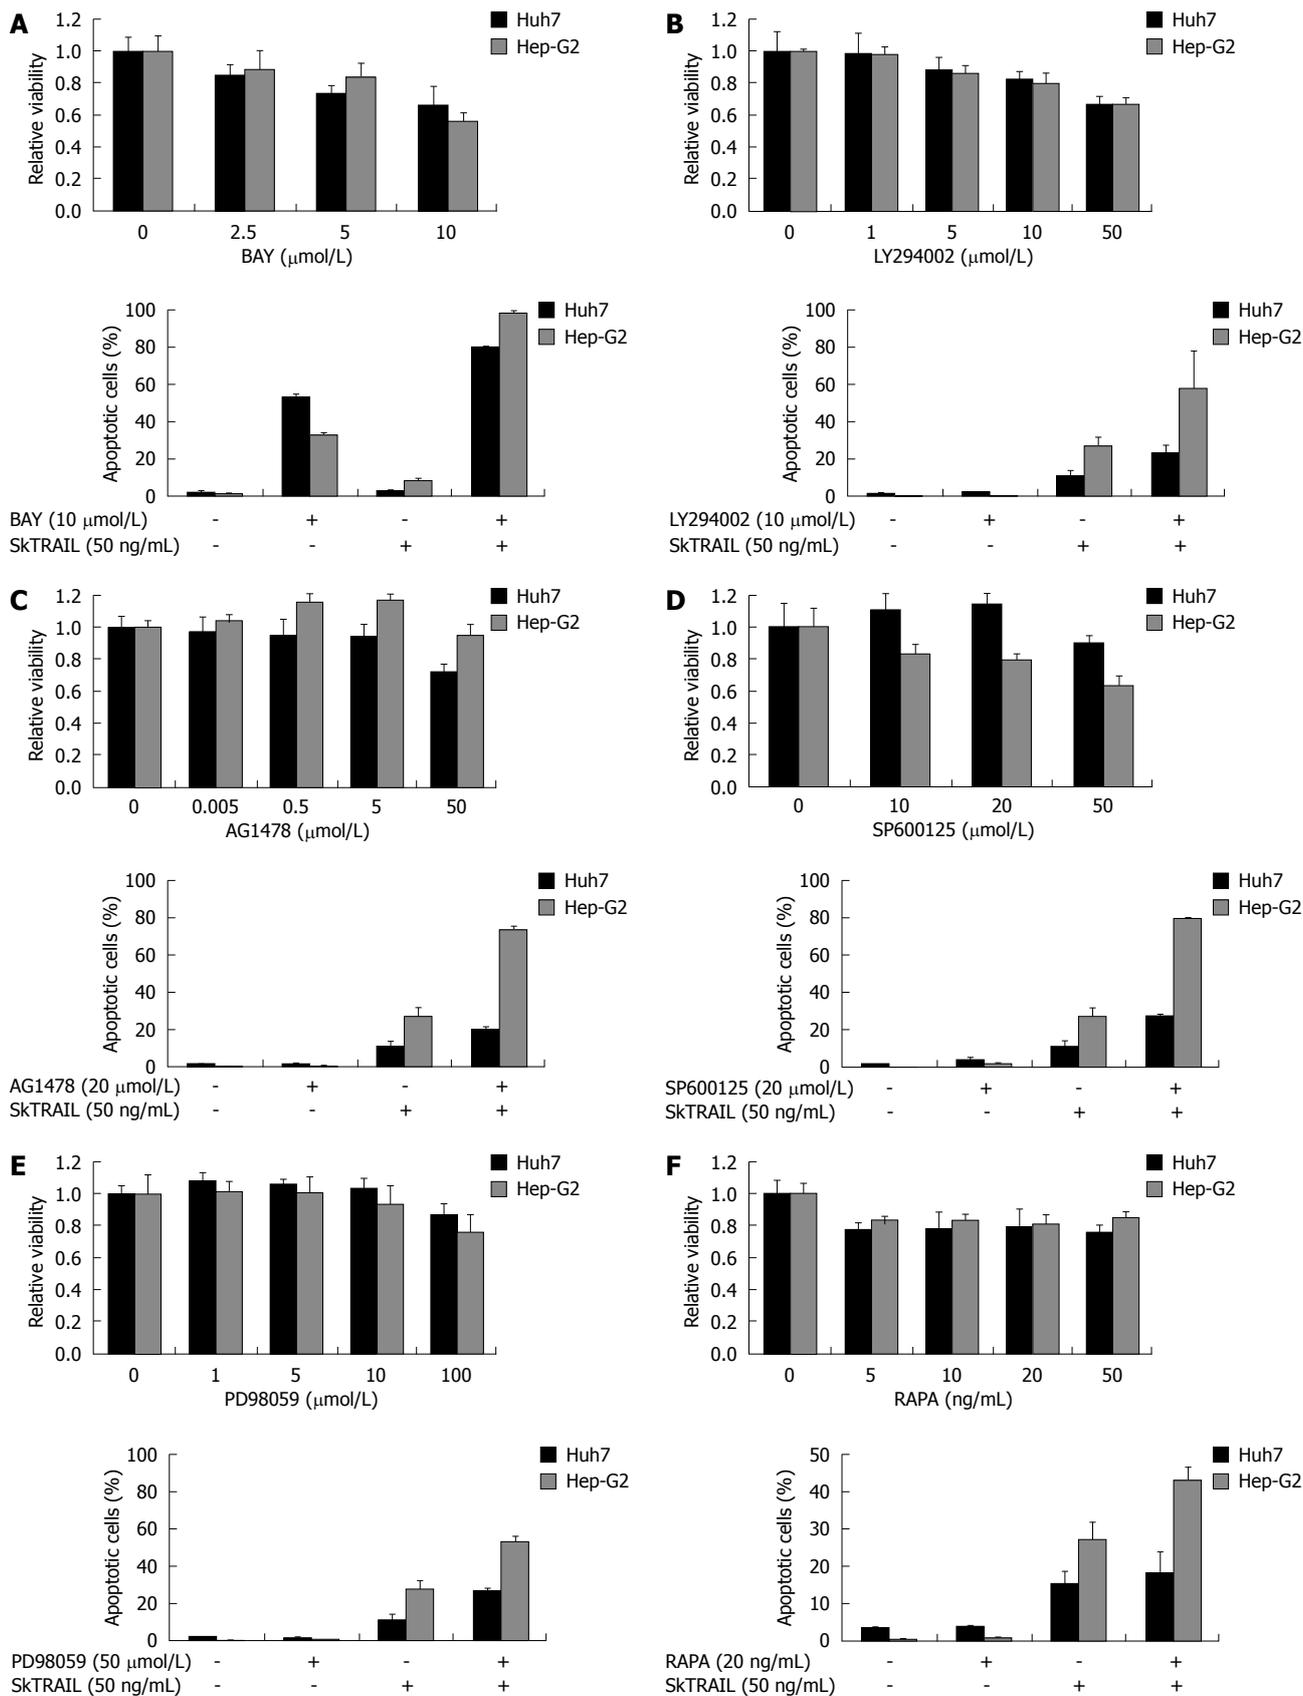

**Figure 3 Treatment of HCC cells with TRAIL in combination with 5-FU and doxorubicin.** Values are expressed as mean  $\pm$  SD. A: Huh7 and Hep-G2 cells were analyzed for cell viability after treatment with the chemotherapeutic agents 5-FU and doxorubicin alone. Cells were seeded onto 96-well plates and treated on day one after seeding. Cells were treated for 48 h with 5-FU (upper left panel) and doxorubicin (lower left panel) as indicated. Cell viability was analyzed by MTT assay. Viability is shown relative to untreated controls. Assays were performed in six-fold values; B: Apoptosis induction in Huh7 and Hep-G2 cells treated with 50  $\mu$ g/mL 5-FU (upper right panel) and 0.5  $\mu$ mol/L doxorubicin (lower right panel) either alone or in combination with 100 ng/mL TRAIL + 1  $\mu$ g/mL Enhancer. Cells were seeded onto 12-well plates, harvested 48 h after treatment and analyzed for apoptosis induction by flow cytometry. Assays were performed in triplicate and are representative of at least two independent experiments.

was observed (Figure 4A, upper panel). In a second step, we analyzed the impact of Sorafenib on TRAIL treatment. In Huh7 cells, Sorafenib (10  $\mu$ mol/L) induced apoptosis rates of 50%. Strikingly, the combination of SkTRAIL (50 ng/mL) and Sorafenib (10  $\mu$ mol/L) induced apoptosis in 80% of the cells. In Hep-G2 cells Sorafenib caused only minor apoptosis rates (33%). However, combination of TRAIL and Sorafenib led to 98% apoptotic cells (Figure 4A, lower panel).

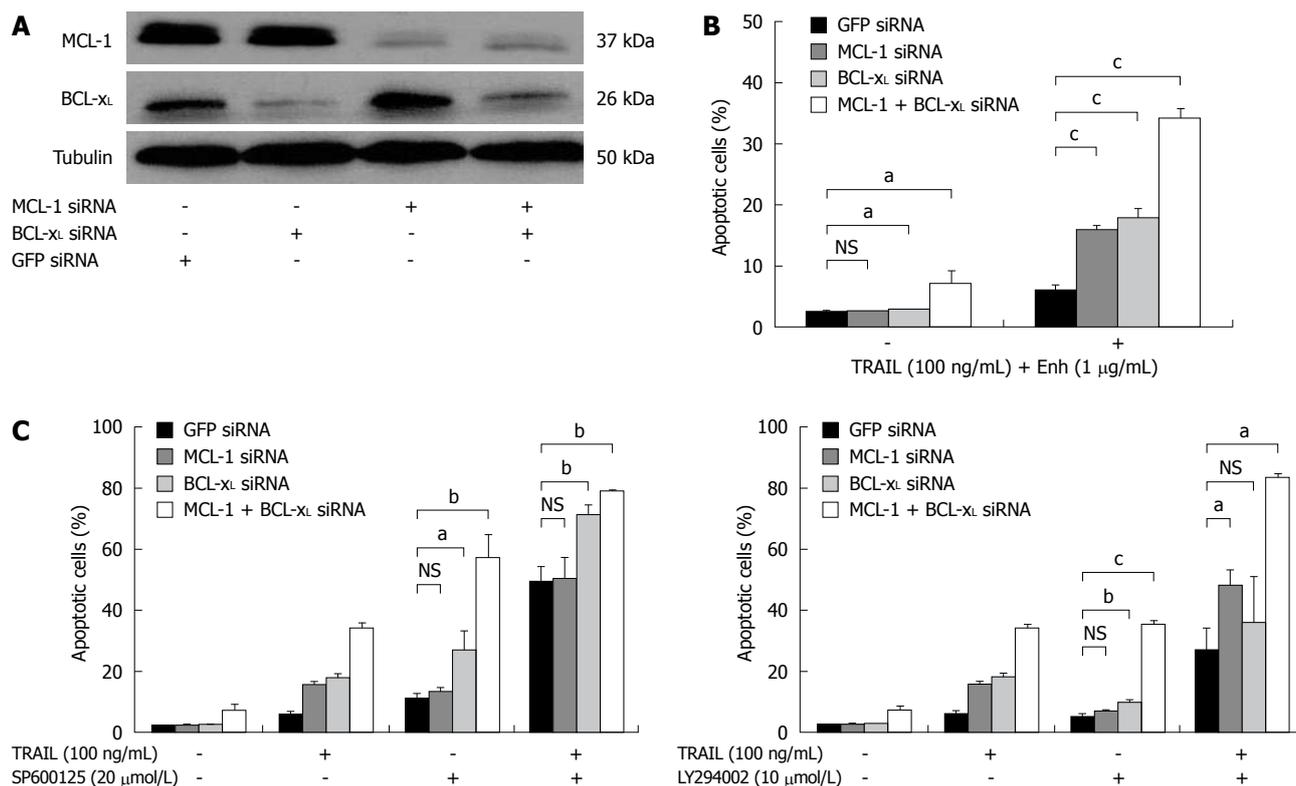

Next, we inhibited the PI3K/Akt pathway by application of the PI3K inhibitor LY294002. A slight decrease of cell viability was observed in Huh7 and Hep-G2 after 48 h treatment in concentrations lower than 50  $\mu$ mol/L (Figure 4B, upper panel). However, combination of LY294002 (10  $\mu$ mol/L) and SkTRAIL (50 ng/mL) doubled apoptosis rates in Hep-G2 cells to 59% compared to SkTRAIL treatment alone. In Huh7, we observed an increased rate of apoptosis after treatment with the combination of LY294002 and SkTRAIL compared to SkTRAIL alone (23% *vs* 11%, respectively. Figure 4B, lower panel). Furthermore, we used AG1478 to inhibit EGFR kinase. Interestingly, inhibition of EGFR kinase increased cell viability in Hep-G2 cells in concentrations up to 5  $\mu$ mol/L. In Huh7 cells, AG1478 caused no significant changes in cell viability when applied in low concen-

trations (Figure 4C, upper panel). AG1478 (20  $\mu$ mol/L) and SkTRAIL (50 ng/mL) co-treatment increased the rate of apoptotic cells to 27% in Huh7 and 74% in Hep-G2 cells (Figure 4C, lower panel). Next, we inhibited the c-Jun N-terminal kinases 1 and 2 (JNK1 and JNK2) with the anthrapyrazolone inhibitor SP600125. We observed increased cell viability in Huh7 cells and a slight, dose-dependent decrease of cell viability in Hep-G2 cells after 48 h of SP600125 treatment (Figure 4D, upper panel). Notably, a high percentage of cells were arrested in the G2 phase 48 h after treatment with the JNK inhibitor (data not shown). Combined treatment with SP600125 (20  $\mu$ mol/L) and SkTRAIL (50 ng/mL) led to 28% apoptosis of Huh7 and to 80% apoptosis of Hep-G2 cells (Figure 4D, lower panel). Next, we included a specific inhibitor of MAP kinase kinase (MEK), PD98059, in our study. Again, a death inducing effect of MEK inhibition alone was only observed when applied in high concentrations of more than 50  $\mu$ mol/L (Figure 4E, upper panel). However, in combination (50  $\mu$ mol/L PD98059 and 50 ng/mL SkTRAIL), a two-fold increase of apoptosis, compared to monotherapy with SkTRAIL, was detectable in Huh7 and Hep-G2 cells (Figure 4E, lower panel).

Finally, we inhibited mammalian target of rapamycin (mTOR) with rapamycin (Sirolimus). Rapamycin alone

**Figure 4 Treatment of HCC cells with TRAIL in combination with specific kinase inhibitors.** Viability of HCC cells treated with kinase inhibitors alone (upper panels). On day one after seeding of Huh7 and Hep-G2 cells onto 96-well plates, cells were treated with multi-kinase inhibitor Sorafenib (A), PI3 kinase inhibitor LY294002 (B), EGFR kinase inhibitor AG1478 (C), JNK inhibitor SP600125 (+ 0.2% DMSO as vehicle) (D), MEK inhibitor PD98059 (E) and mTOR inhibitor rapamycin (RAPA) (F) at the indicated concentrations for 48 h. Cell viability was analyzed by MTT assay. Viability is shown relative to untreated or 0.2% DMSO treated controls, respectively. Assays were performed in six-fold values. Values are expressed as mean  $\pm$  SD. Apoptosis induction in Huh7 and Hep-G2 cells treated with 10  $\mu\text{mol/L}$  Sorafenib (A), 10  $\mu\text{mol/L}$  LY294002 (B), 20  $\mu\text{mol/L}$  AG1478 (C), 20  $\mu\text{mol/L}$  SP600125 (+ 0.2% DMSO as vehicle) (D), 50  $\mu\text{mol/L}$  PD98059 (E) and 20 ng/mL rapamycin (F) in combination with 50 ng/mL SkTRAIL (lower panels). Cells were seeded 1 d before treatment onto 12-well plates, harvested 48 h after treatment and analyzed for apoptosis induction by flow cytometry. Assays were performed in triplicate and are representative of at least two independent experiments. Values are expressed as mean  $\pm$  SD.

**Figure 5** TRAIL-induced apoptosis in Huh7 cells after targeted therapy approaches and knock-down of BCL-xL and MCL-1. **A:** Huh7 cells were transfected with siRNAs (40 nmol/L) specific for MCL-1 and BCL-xL either alone or in combination. SiGFP was used as control. Whole cell lysates were prepared 24 h after transfection. MCL-1 and BCL-xL expression was analyzed by Western blotting.  $\alpha$ -Tubulin expression was used to control equal loading; **B:** 24 h after siRNA transfection, cells were treated for 48 h with 100 ng/mL TRAIL (+ 1 μg/mL Enhancer); **C:** 20 μmol/L SP600125 (left panel) or 10 μmol/L LY294002 (+ 0.2% DMSO as vehicle, right panel), either alone or in combination with 100 ng/mL TRAIL (+ 1 μg/mL Enhancer). Cells were harvested on day two after treatment and analyzed for apoptosis induction by flow cytometry. Assays were performed in triplicate and are representative of at least two independent experiments. Values are expressed as mean  $\pm$  SD. NS: Not significant. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>c</sup> $P < 0.001$ .

only caused a moderate decrease of cell viability (20%) in Huh7 and Hep-G2 cells (Figure 4F, upper panel). Combination of 20 ng/mL rapamycin with 50 ng/mL SkTRAIL resulted in a slight increase of apoptosis rates in Huh7 cells (18% *vs* 15% SkTRAIL alone) and a profound increase of apoptosis in Hep-G2 cells (43% *vs* 27%, Figure 4F, lower panel).

#### Treatment of HCC cells with TRAIL after knock-down of MCL-1 and BCL-xL

The antiapoptotic BCL-2 proteins, MCL-1 and BCL-xL, are profoundly expressed in tissues of human HCC, thus contributing to apoptosis resistance of HCC cells<sup>[13,15,27]</sup>. To analyze the role of antiapoptotic BCL-2 proteins in TRAIL-induced apoptosis, we manipulated their expression in Huh7 cells *via* specific siRNA-mediated knock-down. An effective reduction of MCL-1 and BCL-xL expression levels was observed 24 h after transfection (Figure 5A).

A knock-down of BCL-xL induced significant apoptosis in comparison to mock transfected cells ( $P < 0.05$ ). Knock-down of MCL-1 did not induce significant apoptosis rates. Additionally, combined knock-down of MCL-1 and BCL-xL induced spontaneous apoptosis in 8% of Huh7 cells ( $P < 0.05$ , Figure 5B). Downregulation of either MCL-1 or BCL-xL significantly enhanced susceptibility towards TRAIL-induced apoptosis (17% *vs*

6% and 18% *vs* 6%, respectively,  $P < 0.001$ ). Remarkably, we detected 34% apoptotic cells in Huh7 lacking BCL-xL and MCL-1 expression after treatment with TRAIL ( $P < 0.001$ , Figure 5B). Furthermore, we analyzed whether lack of MCL-1 and BCL-xL expression sensitized cells towards the JNK inhibitor SP600125 and the PI3K inhibitor LY294002. Inhibition of JNK and PI3K showed significantly enhanced anti-tumoral efficacy after knock-down of BCL-xL and MCL-1. In cells lacking BCL-xL expression, apoptosis was induced in 27% *vs* 11% of control cells after treatment with SP600125 (20 μmol/L) ( $P < 0.05$ , Figure 5C). In contrast, cells lacking MCL-1 did not show increased susceptibility to JNK inhibition (14% *vs* 11%, not significant, Figure 5C). Knock-down of MCL-1 and BCL-xL increased SP600125-induced apoptosis rates to 57% ( $P < 0.005$ , Figure 5C, left panel). Additionally, single knock-down of BCL-xL ( $P < 0.001$ ) and double knock-down of MCL-1 and BCL-xL ( $P < 0.001$ ) significantly increased apoptosis after combined treatment of SP600125 with recombinant TRAIL (100 ng/mL). Single knock-down of MCL-1 did not exhibit sensitizing effects (differences not significant, Figure 5C).

Next, we analyzed the effects of MCL-1 and BCL-xL knock-down in combination with the PI3K inhibitor LY294002. We observed a significant sensitizing effect of BCL-xL knock-down on LY294002-induced apoptosis in Huh7 cells ( $P < 0.005$ , Figure 5C, right panel). Knock-

down of MCL-1 did not increase LY294002-induced apoptosis. However, in Huh7 cells lacking both MCL-1 and BCL-x<sub>L</sub>, apoptosis rates increased to 35% after LY294002 treatment ( $P < 0.001$ ). Finally, we found an increased rate of apoptosis after combined treatment of LY294002 (10  $\mu\text{mol/L}$ ) with recombinant TRAIL (100 ng/mL) in cells lacking MCL-1 (48% *vs* 27% of mock transfected Huh7,  $P < 0.05$ ). A moderate sensitizing effect in cells lacking BCL-x<sub>L</sub> was observed (not significant). Importantly, the combined knock-down of MCL-1 and BCL-x<sub>L</sub> caused apoptosis rates of 83%, if cells were treated with a combination of LY294002 and recombinant TRAIL ( $P < 0.05$ , Figure 5C, right panel).

## DISCUSSION

Amongst the various approaches to induce apoptosis in tumor cells, application of the death receptor ligand TRAIL is very promising. Preclinical studies suggest that TRAIL induces apoptosis of tumor cells *in vivo* without lethal toxicities<sup>[28,29]</sup>. A major obstacle for the clinical use of TRAIL is its limited efficacy in monotherapeutic approaches in different tumor entities. Thus, it appears worthwhile to persist in investigating ways to enhance TRAIL's capacity for apoptosis induction. Resistance towards TRAIL can be caused at receptor level by inhibitory proteins and at mitochondrial level by antiapoptotic proteins<sup>[17,18,21]</sup>. For example, a diminished membrane expression of TRAIL-R1 and -R2, as well as reduced caspase 8 levels, mediate TRAIL resistance in myeloma cells<sup>[19]</sup>. In this present study we analyzed different approaches in sensitizing HCC cells to TRAIL-induced apoptosis.

TRAIL receptor expression was similar in the HCC cell lines Huh7 and Hep-G2. After TRAIL treatment, expression patterns changed only slightly in Hep-G2 cells. Strikingly, chemotherapeutic drugs influenced the expression pattern in HCC cells. Upregulation of TRAIL-R1 and profound upregulation of TRAIL-R2 after Doxo and 5-FU treatment in both cell lines might represent a potential mechanism of chemotherapy-mediated TRAIL sensitization. Interestingly, TRAIL-R3 (DcR1) was also upregulated after chemotherapy. This could also represent a mechanism of TRAIL resistance upon chemotherapy, since TRAIL-R3 acts as a decoy receptor. Notably, upregulation of TRAIL receptors in Huh7 cells which express mutated p53 suggests that receptor regulation occurs independently from p53<sup>[30]</sup>.

Several mAbs targeting TRAIL receptors and recombinant TRAIL agonists have already entered clinical trials<sup>[31-33]</sup>. In order to analyze the efficacy of different TRAIL compounds, we included LBY135, a chimeric antibody targeting TRAIL-R2, recombinant TRAIL and SkTRAIL in our study. We demonstrate that crosslinking elements IgG F(ab)<sup>2</sup> are mandatory for LBY135-induced apoptosis. Consistent findings were obtained for recombinant TRAIL, where combination with an enhancer is necessary to induce apoptosis. Comparing the death-inducing capacities of LBY135, TRAIL and SkTRAIL in HCC cells, we assume that TRAIL-R2 plays

a major role, which would be in line with observations in colon and breast cancer<sup>[34]</sup>. In contrast, it has been shown that chronic leukemia cells are selectively sensitive to TRAIL-R1<sup>[35]</sup>. Taken together, it appears likely that a cell type dependency determines the efficiency of TRAIL-mediated apoptosis induction, even if both TRAIL-R1 and -R2 are expressed.

Chemotherapeutic drugs such as Doxo and 5-FU have shown limited efficacy for the treatment of HCC<sup>[20]</sup>. However, anti-tumoral effects have been described for Doxo if administered into the liver *via* chemoembolization<sup>[26,36]</sup>. In our study we aimed to discover whether the combination of TRAIL with chemotherapy exerts anti-tumoral effects in HCC. Importantly, chemotherapy with Doxo or 5-FU increased TRAIL susceptibility in Hep-G2 cells and sensitized Huh7 cells towards TRAIL, opening the possibility of a treatment regime including reduced doses of chemotherapeutic drugs in combination with TRAIL.

The multi-kinase inhibitor Sorafenib has recently been approved for the therapy of advanced HCC. Sorafenib acts by inhibition of the RAF/MEK/ERK pathway and downregulation of MCL-1, leading to a disruption of survival signals in HCC cells<sup>[4,37]</sup>. In combination with TRAIL, Sorafenib profoundly increased apoptosis induction advocating TRAIL as a potential and effective agent for HCC treatment along with Sorafenib.

There is evidence that constitutive activation of various antiapoptotic pathways is a basic principle of tumor growth, cell cycle progression and apoptosis resistance. A well described antiapoptotic pathway is the PI3K/Akt signaling pathway, found activated in several tumor entities, including HCC<sup>[38]</sup>. The PI3K inhibitor LY294002<sup>[39,40]</sup> has already been employed in preclinical studies in combination with TRAIL. Consistent with data for prostate cancer and leukemia cells, our results indicate that blockage of PI3K by LY294002 overcomes resistance towards TRAIL in HCC cells<sup>[22,23]</sup>.

The mTOR, a protein with growing clinical relevance in oncology, is located downstream of PI3K<sup>[41]</sup>. The significant sensitization towards TRAIL in Hep-G2 cells by mTOR inhibition underlines a pivotal role of PI3K/Akt signaling for the resistance of HCC towards TRAIL.

In addition, the MAPK/ERK pathway exerts antiapoptotic effects in cancer cells. The MEK is a key component downstream of Raf serine/threonine kinases<sup>[42,43]</sup>. MEK inhibitors have been described as sensitizing human cancer cells to apoptosis, e.g. after treatment with chemotherapeutic agents<sup>[44,45]</sup>. In this study, we observed no apoptosis induction and only a slight decrease of cell viability after MEK inhibition in HCC cells. However, the combination of MEK inhibition and TRAIL caused a significant increase of TRAIL-induced apoptosis. This observation suggests that an aberrantly activated Raf/MAPK/ERK pathway plays a crucial role for TRAIL resistance in HCC.

Furthermore, we focused on the EGFR, which is an upstream receptor in Ras-Raf-MEK-ERK signaling<sup>[46]</sup>. It has been shown that overexpression of EGFR represents a protective factor against apoptosis stimuli in

HCC<sup>[47,48]</sup>. The combined treatment of TRAIL with the specific EGFR kinase inhibitor AG1478 caused a significant increase of TRAIL-induced apoptosis in HCC cells. Thus, EGFR blockage is another promising approach for TRAIL sensitization of HCC cells.

Recently, it has been shown that JNK inhibition sensitizes HCC cells, but not healthy hepatocytes, towards TRAIL-induced apoptosis<sup>[49]</sup>. In contrast, other results indicate that JNK activation is not relevant for TRAIL-induced apoptosis<sup>[50]</sup>. We found a significantly increased proapoptotic effect of TRAIL if combined with the JNK inhibitor SP600125.

Aberrant activity of survival signaling pathways exerts antiapoptotic effects at least in part *via* triggering of the expression of antiapoptotic proteins, such as antiapoptotic BCL-2 proteins. Importantly, antiapoptotic BCL-2 proteins, such as MCL-1 and BCL-x<sub>L</sub>, have been described as contributing to TRAIL resistance in cancer cells<sup>[51]</sup>. MCL-1 and BCL-x<sub>L</sub> mainly act by directly inhibiting their proapoptotic relatives BAX and BAK, thereby guarding the cell from various death stimuli. In addition, expression of antiapoptotic BCL-2 proteins is a prognostic factor for various tumor entities, e.g. expression of MCL-1 in breast and gastric cancer<sup>[52,53]</sup>. In the liver, MCL-1 has been found to be a key factor for apoptosis regulation<sup>[13,54,55]</sup>. A lack of MCL-1 causes increased rates of apoptosis and a significantly higher susceptibility towards chemotherapeutic treatment in HCC<sup>[54]</sup>. In addition, it has been shown that MCL-1 acts as a key factor for resistance towards TRAIL in leukemia cells<sup>[56]</sup>. In our study, we show that knock-down of MCL-1 or Bcl-x<sub>L</sub> increased TRAIL-induced apoptosis in HCC. Taking into consideration that there is a putative functional redundancy between these two proteins, we performed a double knock-down of MCL-1 and BCL-x<sub>L</sub>. Cells lacking both MCL-1 and BCL-x<sub>L</sub> expression showed profound spontaneous apoptosis, indicating that both proteins contribute to mitochondrial integrity in HCC cells. Importantly, HCC cells lacking MCL-1, BCL-x<sub>L</sub> or both showed an increased apoptosis rate after treatment with TRAIL. In summary, our data suggest a central role of MCL-1 and Bcl-x<sub>L</sub> for the resistance of HCC cells towards TRAIL-induced apoptosis.

Additionally, recent studies have revealed a synergistic effect of PI3K/Akt signaling with MCL-1 and BCL-x<sub>L</sub>, contributing to apoptosis resistance in cancer<sup>[57-59]</sup>. In our study, we treated HCC cells with TRAIL in combination with a PI3K inhibitor and with a knock-down of MCL-1 and BCL-x<sub>L</sub> *via* RNA interference. We found that cells lacking BCL-x<sub>L</sub> or lacking both MCL-1 and BCL-x<sub>L</sub> evolve a significantly increased sensitivity to apoptosis induced by PI3K inhibition. A knock-down of MCL-1 alone did not enhance LY294002-induced apoptosis. Importantly, we observed a profound increase of apoptosis in cells lacking MCL-1 and a rather low increase in cells lacking Bcl-x<sub>L</sub> after combined treatment with PI3K inhibitors and TRAIL. Strikingly, combined knock-down of MCL-1 and BCL-x<sub>L</sub> led to profound induction of apoptosis after treatment with PI3K inhibitors and TRAIL. In summary, our results suggest a major role of PI3K/Akt signaling in resistance towards TRAIL-mediated apoptosis and

emphasize the role of antiapoptotic BCL-2 proteins for TRAIL resistance of HCC cells.

A recent study showed that JNK1 exerts antiapoptotic effects *via* stabilization of MCL-1 in hepatocytes<sup>[60]</sup>. Therefore, we analyzed the role of MCL-1 and BCL-x<sub>L</sub> expression for the apoptosis-inducing capacity of JNK inhibitors and TRAIL. We found profoundly increased apoptosis rates after JNK inhibition in cells lacking BCL-x<sub>L</sub>, whereas cells lacking MCL-1 did not exhibit sensitivity towards JNK inhibition. Strikingly, a combined treatment of a JNK inhibitor and TRAIL caused major rates of apoptosis in cells lacking MCL-1 and BCL-x<sub>L</sub>. Furthermore, we could show that inhibition of JNK is not capable of inducing apoptosis alone unless BCL-x<sub>L</sub> is effectively downregulated in HCC cells, revealing a major role of BCL-x<sub>L</sub> for the resistance of HCC cells towards apoptosis induced by JNK inhibitors.

In conclusion, the application of recombinant TRAIL, as well as that of monoclonal antibodies targeting TRAIL receptors, is an encouraging therapeutic approach in cancer patients. However, resistance to TRAIL treatment is a common phenomenon in many cancer entities. The aim of our study was to provide novel treatment options to overcome resistance of HCC cells towards TRAIL-induced apoptosis. Our results demonstrate that TRAIL is an effective treatment option in HCC if combined with the chemotherapeutic drugs Doxo and 5-FU or kinase inhibitors, such as LY294002, AG1478 and PD98059. In addition, we revealed a pivotal role of the antiapoptotic BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> for HCC resistance towards TRAIL. Further studies are warranted to evaluate the potential of combined treatment approaches and clear the trail for clinical usage.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is the fifth most common malignancy worldwide. Numerous clinical trials have failed to establish an effective therapy regimen in patients with advanced or metastasized HCC. Thus, new strategies for these patients are mandatory. Defects in apoptosis signaling contribute to resistance of HCC cells towards the death receptor ligand tumor necrosis factor-related apoptosis inducing ligand (TRAIL), which is a promising anti-tumor agent since it is capable of killing tumor cells *via* receptor-mediated apoptosis. New combined treatment regimens have the aim of overcoming resistance towards TRAIL and to make TRAIL an effective treatment option in patients suffering from HCC.

### Research frontiers

Hyperactivation of the PI3K/Akt, EGFR and [Mitogen-activated protein kinase/extracellular signal regulated kinase (ERK) kinase] (MEK)/ERK survival pathways and decreased mitochondrial sensitivity due to overexpression of the BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> are key mechanisms of TRAIL resistance in HCC. Furthermore, resistance towards TRAIL can be located at receptor level, contributing to inefficient treatment of HCC cells with TRAIL compounds.

### Innovations and breakthroughs

Previous articles have demonstrated that TRAIL is an effective treatment option in HCC in a combined setup with sensitizing agents. In this study the authors demonstrate new treatment options for the sensitization of HCC cells towards TRAIL-induced apoptosis by combination of chemotherapeutic drugs doxorubicin (Doxo) and 5-fluorouracil (5-FU) or kinase inhibitors, such as LY294002, AG1478, PD98059 and SP600125 with TRAIL. In addition, the authors reveal a pivotal role of the antiapoptotic BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> for HCC resistance towards TRAIL. The importance of MCL-1 and Bcl-x<sub>L</sub> for mitochondrial integrity has been extensively studied in this study.

## Applications

TRAIL is an effective treatment option in HCC if combined with the chemotherapeutic drugs Doxo and 5-FU or kinase inhibitors, such as LY294002, AG1478, PD98059 and SP600125. These results open the possibility of a treatment regime which includes reduced doses of chemotherapeutic drugs in combination with TRAIL. The authors also revealed a pivotal role of the antiapoptotic BCL-2 proteins MCL-1 and BCL-x<sub>L</sub> for HCC resistance towards TRAIL. Thus, downregulation of these anti-apoptotic proteins alone (e.g. by application of so-called "BH3-only mimetics") is a promising approach for the treatment of HCC patients. "BH3-only mimetics" have already entered clinical trials in cancer patients.

## Terminology

Apoptosis, also described as programmed cell death, is a genetically determined process of controlled cellular suicide characterized by typical morphological changes, e.g. fragmentation of DNA. TRAIL ligates two different types of receptors: (1) death receptors triggering TRAIL-induced apoptosis and (2) decoy receptors possibly inhibiting the TRAIL death-signaling pathway. MCL-1 and BCL-x<sub>L</sub> are antiapoptotic members of the BCL-2 family serving as protective factors against several death stimuli. Antiapoptotic pathways such as PI3K/Akt, EGFR, MEK/ERK are well known as being activated in malignant cells, thus contributing to cell cycle progression and tumor growth

## Peer review

This is an interesting work, elegantly performed and with possible future clinical applications. Although the article contains a wealth of experimental details, making it a difficult reading for the uninitiated, I believe it will be of interest for both clinicians and basic science readers of the *World Journal of Gastroenterology* because of its possible clinical implications

### Abstract

**AIM:** To study whether selected bacterial 16S ribosomal RNA (rRNA) gene phylotypes are capable of distinguishing irritable bowel syndrome (IBS).

**METHODS:** The faecal microbiota of twenty volunteers with IBS, subdivided into eight diarrhoea-predominant (IBS-D), eight constipation-predominant (IBS-C) and four mixed symptom-subtype (IBS-M) IBS patients, and fifteen control subjects, were analysed at three time-points with a set of fourteen quantitative real-time

polymerase chain reaction assays. All assays targeted 16S rRNA gene phylotypes putatively associated with IBS, based on 16S rRNA gene library sequence analysis. The target phylotypes were affiliated with *Actinobacteria*, *Bacteroidetes* and *Firmicutes*. Eight of the target phylotypes had less than 95% similarity to cultured bacterial species according to their 16S rRNA gene sequence. The data analyses were made with repeated-measures ANCOVA-type modelling of the data and principle component analysis (PCA) with linear mixed-effects models applied to the principal component scores.

**RESULTS:** Bacterial phylotypes *Clostridium cocleatum* 88%, *Clostridium thermosuccinogenes* 85%, *Coprobacillus cateniformis* 91%, *Ruminococcus bromii*-like, *Ruminococcus torques* 91%, and *R. torques* 93% were detected from all samples analysed. A multivariate analysis of the relative quantities of all 14 bacterial 16S rRNA gene phylotypes suggested that the intestinal microbiota of the IBS-D patients differed from other sample groups. The PCA on the first principal component (PC1), explaining 30.36% of the observed variation in the IBS-D patient group, was significantly altered from all other sample groups (IBS-D vs control,  $P = 0.01$ ; IBS-D vs IBS-M,  $P = 0.00$ ; IBS-D vs IBS-C,  $P = 0.05$ ). Significant differences were also observed in the levels of distinct phylotypes using relative values in proportion to the total amount of bacteria. A phylotype with 85% similarity to *C. thermosuccinogenes* was quantified in significantly different quantities among the IBS-D and control subjects ( $-4.08 \pm 0.90$  vs  $-3.33 \pm 1.16$ ,  $P = 0.04$ ) and IBS-D and IBS-M subjects ( $-4.08 \pm 0.90$  vs  $-3.08 \pm 1.38$ ,  $P = 0.05$ ). Furthermore, a phylotype with 94% similarity to *R. torques* was more prevalent in IBS-D patients' intestinal microbiota than in that of control subjects ( $-2.43 \pm 1.49$  vs  $-4.02 \pm 1.63$ ,  $P = 0.01$ ). A phylotype with 93% similarity to *R. torques* was associated with control samples when compared with IBS-M ( $-2.41 \pm 0.53$  vs  $-2.92 \pm 0.56$ ,  $P = 0.00$ ). Additionally, a *R. bromii*-like phylotype was associated with IBS-C patients in comparison to control subjects ( $-1.61 \pm 1.83$  vs  $-3.69 \pm 2.42$ ,  $P = 0.01$ ). All of the above mentioned phylotype specific alterations were independent of the effect of time.

**CONCLUSION:** Significant phylotype level alterations

in the intestinal microbiotas of IBS patients were observed, further emphasizing the possible contribution of the gastrointestinal microbiota in IBS.

Diarrhoea-predominant irritable bowel syndrome distinguishable by 16S rRNA gene phylotype quantification. *World J Gastroenterol* 2009; 15(47): 5936-5945 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5936.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5936>

## INTRODUCTION

Irritable bowel syndrome (IBS) is a functional gastrointestinal (GI) disorder with a worldwide prevalence of 10%-20%<sup>[1]</sup>. The main symptoms include abdominal pain or discomfort, diarrhoea, constipation, abdominal bloating, and flatulence. The symptoms are associated with changes in the frequency and form of stool, improved by defecation, and they typically fluctuate with time. Although IBS does not predispose to malignancies, it essentially lowers the patients' quality of life. Multiple interacting mechanisms lie behind IBS aetiology<sup>[2,3]</sup>. These include psychological stress and disturbances, physiological features, such as altered GI motility and visceral hypersensitivity, low-grade inflammation, and bacterial gastroenteritis.

The possible role of the GI microbiota in IBS aetiology (for review, see Parkes *et al.*<sup>[4]</sup>) is supported by low-grade mucosal inflammation in the GI tract of IBS patients<sup>[5,6]</sup>, onset of GI symptoms after a gastroenteritis (generating a subset of patients diagnosed with post-infectious IBS<sup>[7,8]</sup>), and observations suggesting the presence of altered GI microbiota in IBS<sup>[9-12]</sup>. Recently, Gecse *et al.*<sup>[13]</sup> associated the elevated level of non-endogenous colonic serine protease in diarrhoea-predominant IBS patients with increased mucosal permeability and subsequent visceral hypersensitivity. The detected increase in the level of colonic serine protease was suggested to originate from intestinal bacteria. In addition, antibodies to bacterial flagellins A4-Fla2 and Fla-X associated with the *Clostridium* cluster XIVa are elevated in IBS compared to healthy controls<sup>[14]</sup>. The potential role of GI microbiota in IBS is further supported by studies where probiotics have alleviated IBS symptoms (for a review, see Spiller *et al.*<sup>[15]</sup>). In the recent study of Kajander *et al.*<sup>[16]</sup>, a multispecies probiotic was also shown to stabilize the gut microbiota, but the microbial alterations were not specified.

16S ribosomal acid (rRNA) gene based methods have identified almost 900 bacterial phylotypes in the human GI tract with, of which only 18% represent cultured species<sup>[17]</sup>. Richness estimates within an individual's colon extend to 300 phylotypes<sup>[18]</sup>, while a vast variation is introduced by disparities in the phylotype composition between individuals<sup>[18-20]</sup>. The main phyla found in 16S rRNA gene sequencing based studies are *Firmicutes*, *Bacteroidetes*, *Proteobacteria*, *Actinobacteria*, *Fusobacteria*, and *Verrucomicrobia*<sup>[18,21-23]</sup>.

Using culture-based techniques, the GI microbiota of IBS patients has been characterized to have less lactobacilli and bifidobacteria and an elevated amount of aerobes relative to anaerobes<sup>[24-26]</sup>. Specific divergences have been observed with quantitative real-time polymerase chain reaction (qPCR) assays targeting *Lactobacillus* spp, *Veillonella* spp, *Bifidobacterium* spp, *Clostridium coccoides*, and *Bifidobacterium catenulatum*<sup>[10]</sup>, and with 16S rRNA cloned sequence-based assays targeting phylotypes within the genera *Coprococcus*, *Collinsella*, and *Coproccillus*<sup>[11]</sup>. With a 16S rRNA gene-based phylogenetic microarray analysis targeting over a 1000 human intestinal phylotypes, the faecal microbiota of IBS patients and control subjects could be distinguished by hierarchical cluster analysis and stronger variation in the composition of the microbiota was seen in the IBS patients' profiles<sup>[12]</sup>. Furthermore, a higher degree of temporal instability among IBS patients has been detected with ribosomal RNA-based denaturing gradient gel electrophoresis<sup>[9]</sup>. Mucosal bacteria have also been found to be more abundant in IBS patients than in healthy controls<sup>[27]</sup>.

In this study, we applied a set of eight novel and six previously published<sup>[11]</sup> qPCR assays to the analysis of faecal samples obtained from IBS patients and healthy controls to detect possible aberrations in the GI microbiotas of IBS patients. The design of the novel qPCR assays was based on comparing the 16S rRNA clone libraries of IBS patients and healthy controls, but in this study three time-points per subject during a 6-mo survey were analysed instead of one<sup>[11]</sup>.

## MATERIALS AND METHODS

### Subjects and study design

Faecal samples were collected from 20 IBS patients and 15 healthy control subjects (Table 1) at time-points 0, 3 and 6 mo of a 6-mo follow-up period.

The IBS patients were recruited by experienced physicians and fulfilled the Rome II criteria<sup>[28]</sup>, except for three subjects who reported slightly less than 12 wk of abdominal pain during the preceding year<sup>[29]</sup>. All patients had undergone clinical investigation and endoscopy or barium enema of the GI tract less than a year prior to the study. Exclusion criteria included pregnancy, lactation, organic intestinal disease, other severe systematic disease, antimicrobial medication during the previous 2 mo, previous major or complicated abdominal surgery, severe endometriosis and dementia or otherwise inadequate cooperation capability. Patients with lactose intolerance

**Table 1** Characteristics of IBS patients and control subjects

	IBS-D	IBS-C	IBS-M	Controls
<i>n</i>	8	8	4	15
Age (yr): mean (range)	43.6 (26-60)	48.6 (24-64)	50.8 (31-62)	47 (25-64)
Gender (female/male)	4/4	9/1	3/1	10/5
Predominant bowel habit	Diarrhoea	Constipation	Mixed-type	-

IBS: Irritable bowel syndrome; IBS-D: Diarrhoea-predominant IBS; IBS-C: Constipation-predominant IBS; IBS-M: Mixed symptom-subtype IBS.

were included if they were reported to follow a low-lactose or lactose-free diet. All IBS patients were advised not to make any changes to their medication, including ongoing IBS medication (mainly commercial fibre analogues, laxatives, or antidiarrhoeals). The IBS patients formed the placebo group of a 6-mo probiotic intervention study<sup>[29]</sup>. They received daily a placebo capsule consisting of microcrystalline cellulose, magnesium stearate, and gelatine as the encapsulating material. Consumption of probiotic products was not allowed during the study.

Control subjects devoid of GI symptoms were also recruited and originally age- and gender-matched with the IBS patients as a whole<sup>[26]</sup>. Volunteers with regular intestinal disturbances, lactose intolerance, celiac disease, or antibiotic therapy during the preceding 2 mo of the study were excluded. The faecal samples of the controls and IBS subjects<sup>[9-11,26,29,30]</sup> have been studied previously. The novelty in the present study resides in the eight previously unpublished 16S rRNA phylotype targeting assays, the analysis of several time-points during the 6-mo survey, and in the in-depth statistical analysis of the results.

### Ethics

All participants gave their written informed consent and were told that they could withdraw from the study at any time. The Human Ethics Committee of the Joint Authority for the Hospital District of Helsinki and Uusimaa (HUS) approved the study protocol for the IBS patients. The ethical committee of the Technical Research Centre of Finland (VTT) approved the study protocol for the healthy controls.

### Extraction and purification of DNA from faecal samples

Faecal samples were preserved anaerobically immediately after defecation, stirred and aliquoted, and stored at -70°C within 4 h of delivery. For qPCR analysis, total DNA was isolated from 1 g of faecal material according to Apajalahti *et al.*<sup>[31]</sup>, which included removing the undigested particles from the faecal material by three rounds of low-speed (200 × *g*) centrifugation and collection of the bacterial cells with high-speed centrifugation (30 000 × *g*) at 15°C for 15 min using a Beckman Avanti<sup>TM</sup> centrifuge (Fullerton, CA, USA) with the rotor JA 25.50 or JLA 16.250 rotor, respectively. The bacterial cells were lysed after centrifugation with a combination of freeze-thaw

cycles (freezing for 1 h at -70°C and thawing for 15 min in a 37°C water bath), lysozyme and vortexing with glass beads. DNA concentrations were determined with a NanoDrop ND-1000 Spectrophotometer (NanoDrop products, Wilmington, DE, USA).

### Design of qPCR assays

Divergences detected by comparing the sequence data of 16S rRNA gene clone libraries of healthy controls and symptomatically sub-grouped IBS patients (diarrhoea-predominant IBS, IBS-D; constipation-predominant IBS, IBS-C; and mixed symptom-subtype IBS, IBS-M) were used as the basis for selection of qPCR targets<sup>[11]</sup>. Prior to cloning and sequencing, the faecal microbial genomes had been profiled and fractioned on the basis of genomic guanine-plus-cytosine content<sup>[11]</sup>. Partial 16S rRNA gene sequences encompassing the variable regions V1 and V2 combined from all four sample types were aligned using either the version Beta 2003-08-22 of ARB<sup>[11,32]</sup> or ClustalW 1.83<sup>[33]</sup>. For the ARB alignment, an aligned sequence database (ssu\_jan04\_corr\_opt.arb) was downloaded from the ARB home page (<http://www.arb-home.de>) and the in-house sequences<sup>[11]</sup> were aligned using the ARB-EDIT FastAlign function, followed by manual correction of the alignments with special attention to the ends of the sequences. Finally, the sequences were imported into an existing tree file of the database (Tree-Bacteria) by filtering the data against a sequence of similar length as the imported partial 16S rRNA gene sequences. Regions of the tree where sequences derived from one subject group (healthy *vs* IBS or healthy *vs* IBS subtypes) dominated over the other groups were considered as potentially interesting. In addition, a ClustalW 1.83 alignment (FAST DNA pairwise alignment algorithm option, gap penalty 3, word size 4, number of top diagonals 1 and window size 1) was constructed covering approximately 450 bp from the 5' end of the 16S rRNA gene and visually inspected and cut from the *Escherichia coli* position 430 (universally conserved GTAAA) with BioEdit version 7.0.5.3<sup>[34]</sup>. Distance matrices were calculated from the ClustalW alignment with Phylip 3.66 Dnadist<sup>[35]</sup> using Jukes-Cantor correction. The distribution of sequences into operative taxonomic units (OTUs) was determined using DOTUR<sup>[36]</sup> by applying the furthest neighbour rule option and 98% cut-off for sequence similarity. Uneven distribution of sequences originating from the different sample types within an OTU was used as criteria for qPCR target selection.

Potential primer target sites for specific quantitative analyses were assessed manually from ClustalW 1.83 alignments. Primer 3 online interface<sup>[37]</sup> and mfold 3.3 DNA-folding servers<sup>[38]</sup> were used for optimizing the final primer sequences and secondary structure analyses. The primer specificity against publicly available prokaryotic 16S rRNA sequences was checked with FASTA<sup>[39]</sup> provided by the European Bioinformatics Institute (<http://www.ebi.ac.uk/>) and against in-house 16S rRNA clone library sequences of human faecal origin, using the blastall option of Parallel BLAST<sup>[40]</sup> with Corona hardware

(<http://corona.csc.fi>) maintained by the Finnish IT Center for Science (CSC - Scientific Computing Ltd., Finland). The qPCR primers were synthesized commercially by Oligomer Oy (Helsinki, Finland). The clone sequences used to generate the standard curve in each qPCR assay were classified using The Ribosomal Database Project II Classifier<sup>[41]</sup>. The assays were named according to the most similar 16S rRNA gene sequence of a cultured bacterial species with the similarity percentages below 98% indicated.

### qPCR optimization and conditions

For each assay, the optimal annealing temperature and MgCl<sub>2</sub> concentration were defined using the iCycler iQ Real-Time Detection System (Bio-Rad, Hercules, CA, USA) associated with the iCycler Optical System Interface software (version 2.3; Bio-Rad). Actual samples were run as triplicates with optimized reaction conditions using SYBR Green I chemistry and 25 ng (specific phylotype targeting assays) or 0.5 ng (universal 16S rRNA gene assay) of faecal bacterial DNA. For all assays, the samples were run with different sample groups randomly mixed in the individual runs to minimize the effect of technical deviation between runs. Amplified clonal 16S rRNA genes were used as standards, ranging from 10<sup>2</sup> to 10<sup>7</sup> gene copies per reaction. The reaction mixtures consisted of a 1:75000 dilution of SYBR Green I (Lonza biosciences, Basel, Switzerland), 10 mmol/L Tris-HCl (pH 8.8), 50 mmol/L KCl, 0.1 % Triton X-100, 2-5 mmol/L MgCl<sub>2</sub>, 100 μmol/L each dNTP, 0.5 μmol/L each primer, 0.024 U Dynazyme II polymerase (Finzymes, Espoo, Finland) and 5 μL of either template or water. The amplification involved one cycle at 95°C for 5 min for initial denaturation, followed by 40 cycles of denaturation at 95°C for 20 s, primer annealing at the defined optimal temperatures for 20 s, extension at 72°C for 30 s and a fluorescence detection step at 80-89°C for 30 s. The specificity of the qPCR assays was checked with a reassociation curve analysis after amplification by slow cooling from 95°C to 60°C, with fluorescence collection at 0.3°C intervals for 10 s at each decrement. The qPCR efficiencies were calculated from the standard curves using the equation  $E = (10^{1/k}) - 1$ , where  $E$  and  $k$  stand for efficiency and slope, respectively.

### Statistical analysis

In the raw data from qPCR assays, microbe groups with low abundance were occasionally undetected (below qPCR detection limit). These values may not be truly zero or missing values, but are caused by limitations in the technical accuracy of the qPCR equipment. Therefore, for data analysis, zeros and missing values were imputed with the mean values obtained from the qPCR runs with the same primer pair applied to molecular grade water. If those too were undetected, the minimum of all the detected water runs was used.

After imputing the undetected values, the raw data was transformed to log<sub>10</sub> ratios of relative amount of 16S rRNA gene copies detected *vs* the amount of bacterial

16S rRNA gene copies detected with the universal qPCR assay. Using the ratio will, to some extent, control the sample specific variation due to lab procedures and sample handling affecting the overall bacterial concentration. All the statistical analyses were carried out with these values.

Statistical analyses were made with standard mixed-effect linear models having fixed effects for the time, and the IBS subtype, and a random effect for individual (taking into account the repeated measures from the same subject). In summary, this set up results in a repeated-measures ANOVA-type modelling of the data.

The model selection between whether to use the full model with interaction term between time and group and the age term, or the simpler model without interaction and the age was based on  $F$ -tests. The inference from the estimated models was based on the standard  $F$ -tests and  $t$ -tests.

For multivariate analysis of the data, principal component analysis (PCA) was used to visualize the data sets. Linear mixed-effects models were also applied to the first four principal component scores to quantify potential multivariate effects present in the data.

All the analyses were made with statistical programming language R 2.6.2<sup>[42]</sup> utilizing the package *lme* for mixed-effects linear models<sup>[43]</sup> and contrast for computing the contrasts.

## RESULTS

### Design and optimization of qPCR assays

A total of 14 qPCR assays were designed and optimized (Table 2) for analyzing alterations in the faecal microbiotas of IBS patients sub-grouped according to symptom subtype and healthy controls. The optimized annealing and detection temperatures ranged from 60°C to 67°C and 80°C to 89°C, respectively. For the universal assay, an annealing temperature of 50°C was used. The PCR efficiencies for the optimized qPCR reactions were above 80% with the exception of *Collinsella aerofaciens*-like, *Coprococcus eutactus* 97% and *Spiroplasma chinense* 84% assays.

Non-specific product peaks with a lower melting temperature than the desired product were observed for some of the faecal DNA samples in the reassociation analyses of several assays (*Bacteroides intestinalis*-like, *Butyrivibrio crossotus*-like, *Clostridium coeleatum* 88%, *C. eutactus* 97%, *S. chinense* 84%, *Ruminococcus torques* 91%, *R. torques* 94% and *Slackia faecicanis* 91%). The fluorescence detection temperatures in these assays were set above the melting point of the unspecific products to avoid detecting them.

### Analysis of faecal samples

The log<sub>10</sub> number of bacterial 16S rRNA gene copies detected ranged from 11.71 to 11.93 per gram of faeces (wet weight) and the average relative log<sub>10</sub> numbers of 16S rRNA gene copies detected with phylotype targeting assays in proportion to the universal bacterial assay ranged from -7.34 to -0.72 (Table 3; time-point specific averages are presented in Supplementary Table 1). Target

The number of subjects with target 16S rRNA gene copies detected above the calculated threshold value in any of the three samples analysed are given in parentheses. <sup>1</sup>Values are presented as averages of log<sub>10</sub>-values ± SD from three time-points (0, 3 and 6 mo). <sup>a</sup>P = 0.04, <sup>b</sup>P = 0.05, <sup>c</sup>P = 0.01, <sup>d</sup>P = 0.00.

bacterial phylotypes were detected from all samples with the *C. cocleatum* 88%, *Coprobacillus cateniformis* 91%, *Clostridium thermosuccinogenes* 85%, *Ruminococcus bromii*-like, *R. torques* 91%, and *R. torques* 93% assays (Table 3).

#### Divergences in the intestinal microbiota in IBS

In a PCA of the 14 phylotype targeting assays and three time-points (0, 3 and 6 mo), the IBS-D group differed from the control group (*P* = 0.01), IBS-M (*P* = 0.00),

**Figure 1** Principal component analysis (PCA) of fourteen 16S rRNA phylotypes quantified from faecal samples of irritable bowel syndrome (IBS) patients and healthy volunteers. **A:** The PCA plot with outermost data points within each sample group is outlined. The control samples are presented in green, the constipation-predominant IBS (IBS-C) in black, the diarrhoea-predominant IBS (IBS-D) in red and the mixed symptom-subtype IBS (IBS-M) in blue. Each time-point is presented as a separate point. To quantify the multivariate differences between the groups, linear mixed-effects models were applied to the first (x-axis) and the second (y-axis) principal component scores, which represent the dominant multivariate changes present in the data; **B:** The bars represent the relative contribution of each quantitative real-time PCR (qPCR) assay to the principal component 1 (PC1). On PC1 the IBS-D samples differed from the control ( $P \leq 0.01$ ), IBS-M ( $P \leq 0.01$ ), and IBS-C ( $P \leq 0.05$ ) samples; **C:** The bars represent the relative contribution of each qPCR assay to the principal component 2 (PC2). On PC2, the IBS-C patients diverged from the control subjects ( $P \leq 0.05$ ) and time-points. In addition, the second time-point (3 mo) diverged significantly from the first (0 mo,  $P \leq 0.01$ ) and the third (6 mo,  $P \leq 0.01$ ) time-points independent of sample group; The height of the bars in graphs in Figure 1B and C reflect the relative magnitude of the contribution and the direction the sign of the contribution (in relation to the other assays and to the axis in Figure 1A). For example, in PC1 (Figure 1B), the largest contributor is the *Coprococcus eutactus* 97% phylotype, while the samples on the right in Figure 1A (mostly IBS-D) tend to have higher concentrations of *Ruminococcus torques* 94% and lower concentrations of phylotypes with bars highly on the negative side. Similarly, on PC2 (Figure 1C) the samples with high PC2 value in the top part of the Figure 1A tend to have higher concentrations of the *Ruminococcus bromii*-like phylotype, and lower concentrations of the *Bifidobacterium catenulatum/Bifidobacterium pseudocatenulatum*-like phylotype. On PC2, the IBS-C patients diverged from the control subjects ( $P \leq 0.05$ ) and time-points. In addition, the second time-point (3 mo) diverged significantly from the first (0 mo,  $P \leq 0.01$ ) and the third (6 mo,  $P \leq 0.01$ ) time-points independent of sample group. qPCR: Quantitative real-time polymerase chain reaction; IBS-C: Constipation-predominant irritable bowel syndrome; IBS-D: Diarrhoea-predominant irritable bowel syndrome; IBS-M: Mixed-subtype irritable bowel syndrome.

and IBS-C ( $P = 0.05$ ) on the first principal component (PC1; Figure 1A and B). The *R. torques* 94% phylotype was unique in being more predominant in IBS-D (Figure 1A and B). On the second principal component (PC2), the IBS-C patients diverged from the control subjects ( $P = 0.03$ ; Figure 1A and C). Time-points were significantly different on PC1 and PC2 (data not shown).

Quantities of *C. thermosuccinogenes* 85%, *R. bromii*-like, *R. torques* 93%, and *R. torques* 94% phylotypes diverged between different IBS symptom subtypes and healthy subjects independent of the effect of time (Table 3). Relatively high levels of the *C. thermosuccinogenes* 85% phylotype were associated with IBS-M patients and control subjects compared with IBS-D patients. The relative amount of *C. thermosuccinogenes* 85% 16S rRNA gene copies detected in proportion to the universal assay were 0.08%, 0.05%, and  $< 0.01\%$  for the IBS-M, control, and IBS-D subjects, respectively. The *R. bromii*-like

phylotype was significantly ( $P = 0.01$ ) more abundant in the IBS-C (relative abundance 2.45%) than in the control (relative abundance 0.02%) subjects' samples and the *R. torques* 93% phylotype was significantly ( $P = 0.00$ ) more abundant in the control (relative abundance 0.39%) than in the IBS-M subjects' samples (relative abundance 0.12%). The lowest amount of *R. torques* 94% phylotypes was quantified in the control samples (relative abundance  $< 0.01\%$ ) significantly differing ( $P = 0.01$ ) from the relative amount detected among the IBS-D patients' samples (relative abundance 0.37%).

Additional time-point dependent divergences between the sample groups were also detected (Supplementary Table 1): The *B. intestinalis*-like and *C. cocleatum* 88% phylotypes were relatively abundant in the IBS-M and control samples, and were detected in lower amounts in the IBS-D patients' samples. The relative amounts of *C. aerofaciens*-like phylotype detected were lowest in samples of the IBS-D patients, whereas the relative

amounts of *R. torques* 91% phylotype were lowest in the control subjects' samples.

## DISCUSSION

The aim of this study was to test the capability of a set of qPCR assays targeting the 16S rRNA gene on a phylotype level to differentiate between IBS symptom subtypes and healthy controls. Eight novel and six previously published<sup>[11]</sup> qPCR assays were used to study faecal samples of 20 IBS patients grouped according to symptom subtype and 15 healthy controls at three time-points (0, 3 and 6 mo). None of the assays have previously been applied to samples from several time-points. The knowledge of putative alterations on phylotype level may be essential in association with health, as has been shown to be the case for *Faecalibacterium prausnitzii* in Crohn's disease<sup>[44,45]</sup>.

In our approach, the selection of faecal bacteria phylotypes for analysis was based on a comparison of clone sequence libraries of IBS patient symptom subtypes and healthy controls<sup>[11]</sup>. The amount of bacterial 16S rRNA genes detected with the universal qPCR was in accordance with previous findings<sup>[46]</sup>. Quantities relative to the amount of bacterial 16S rRNA gene copies detected with the universal bacterial qPCR assay were used in data analyses. The diarrhoea-predominant symptom subtype diverged significantly from the other IBS symptom subtypes and healthy controls in a PCA of all 14 qPCR analyses and three time-points (Figure 1). In addition, *C. thermosuccinogenes* 85%, *R. bromii*-like, *R. torques* 93%, and *R. torques* 94% phylotypes diverged between different IBS symptom subtypes and healthy controls independent of the time-point analysed (Table 3). According to the results presented here and in previous studies<sup>[10-12,47,48]</sup>, grouping of IBS patients based on their main symptom subtype is advisable in future studies.

The *C. thermosuccinogenes* 85% -phylotype represents an uncultured firmicute within the human GI microbiota. It was detected in significantly lower amounts in IBS-D patients' samples in comparison to healthy controls or IBS-C patients. The target sequence of the *C. thermosuccinogenes* 85% -assay has previously been found from human faecal samples in several studies<sup>[11,18,49]</sup> and from human mucosal biopsy samples taken from the caecum, descending and sigmoid colon, and the rectum<sup>[18]</sup>, implying that the phylotype truly represents a human intestinal bacterium. However, the closest isolated strain has negligible similarity according to the 16S rRNA sequence (85% similarity with *Ruminococcus* sp. 16442 strain 16S rRNA sequence).

The *R. bromii*-like phylotype was significantly more abundant in IBS-C patients than in healthy controls samples. *R. bromii* is a common starch degrader of the human intestinal microbiota<sup>[50]</sup>. The amounts of *R. bromii*-related phylotypes have been shown to increase with a diet high in resistant starch<sup>[51]</sup>. In the present study, the possible effect of diet could not be ruled out, but it is more likely that the slowed colonic transit in IBS-C, rather

than a dietary effect, results in a favourable environment for the *R. bromii*-like phylotype associated with IBS-C.

*Ruminococcus torques*, a resident mucin-degrading member of the human GI microbiota<sup>[52]</sup>, has been associated with the mucosa of Crohn's disease patients<sup>[53]</sup>. The specific target sequence of the *R. torques* 94% -assay applied in this study has been found from human faecal samples in several studies<sup>[19,54,55]</sup> and has also been associated with Crohn's disease<sup>[56]</sup>. In the present study, a comparatively higher abundance of *R. torques* 94% phylotype was linked with IBS-D in both the multivariate and assay specific analyses. The *R. torques* 91% phylotype was associated with IBS-D and IBS-M and the *R. torques* 93% phylotype was more abundant in IBS-M than in healthy controls. The target sequences of *R. torques* 91%, 93% and 94% are affiliated with *Lachnospiraceae* as is the 16S rRNA sequence of the strain A4 (DQ789118)<sup>[57]</sup> carrying the IBS associated flagellin Fla2<sup>[14]</sup>.

As a further support to our previous results<sup>[11]</sup>, a significantly lower abundance of the *C. aerofaciens*-like phylotype was associated with the IBS-C and IBS-D symptom subtypes at two of the time-points analysed. *Collinsella aerofaciens* (formerly *Eubacterium aerofaciens*) belongs to the order *Coriobacteriales* within the high G+C Gram-positive *Actinobacteria*. It is a prominent member of the endogenous human intestinal microbiota<sup>[58]</sup> and has previously been connected with a low risk of colon cancer<sup>[59]</sup>.

Significantly lower levels of several 16S rRNA gene phylotypes within the genus *Bacteroides* (*B. ovatus*, *B. uniformis*, and *B. vulgatus*) have previously been discovered among IBS-C patients in comparison to healthy controls, but no effect was seen with the *B. intestinalis*-like phylotype targeting probes<sup>[12]</sup>. All samples analysed in this study have previously been analysed with a *Bacteroides-Prevotella-Porphyrromonas* -group and a *B. fragilis* species-specific qPCR assay<sup>[10]</sup> without detecting any significant divergences. In this study, a *B. intestinalis*-like phylotype was quantified with qPCR and found to be least abundant in the IBS-D patient group and most abundant in the IBS-M patient group at the selected time-points. The seemingly contradictory results might be due to different specificities of the probes and primers used.

The qPCR assays presented here were based on a thorough analysis of IBS associated faecal bacterial 16S rRNA gene sequence data originating from the same samples and both the previously published partial 16S rRNA gene sequences. The qPCR assays detailed here will be valuable in upcoming IBS studies. A more thorough sequencing approach using novel high-throughput sequencing technologies<sup>[23]</sup> on IBS subjects' GI microbiota would be valuable in further investigating IBS-associated alterations within the GI microbiota.

The faecal microbiota of IBS patients has been associated with less temporal stability within individuals<sup>[47]</sup> and more variation between individuals<sup>[12]</sup> compared to that of the healthy controls. Therefore, the results of this study should be further confirmed with independent sample panels including both IBS subjects and healthy

controls. In addition, analyzing mucosal samples, in addition to luminal samples, would be of interest, since the mucosal and faecal microbiotas differ from each other<sup>[60]</sup>. Previously, IBS patients have been shown to have a slightly more abundant mucosal microbiota compared to that of healthy volunteers, but the difference was not statistically significant<sup>[27]</sup>. However, obtaining mucosal samples from IBS patients would require colonoscopy, which is not a regular procedure on IBS patients.

In conclusion, we observed alterations in the GI microbiota of IBS-D subjects with a multivariate analysis and several additional statistically significant differences were detected between the intestinal microbiotas of the different IBS subtypes and healthy controls in assay-specific analyses. Recovering the target bacteria of the *C. thermosuccinogenes* 85% and *R. torques* 94% qPCR assays would be essential for further analysis of their possible role in the human GI tract and their association to IBS. In the future, biomarkers associated to the GI microbiota could aid therapeutic trial follow-up, diagnosis and treatment of IBS patients.

## ACKNOWLEDGMENTS

We are grateful to Sinikka Ahonen, Anu Suoranta and Annemari Wickström for excellent technical assistance. This work was performed in the Centre of Excellence on Microbial Food Safety Research, Academy of Finland.

## COMMENTS

### Background

Irritable bowel syndrome (IBS) is a common gastrointestinal functional disorder that can greatly affect the patient's well being. Multiple interacting mechanisms, including alterations in the intestinal microbiota, are suspected to lie behind IBS aetiology.

### Research frontiers

Alterations in the gastrointestinal microbiota in association to health and disease have become an essential field of research in gastroenterology. For instance, indications of dysbiosis have been detected in relation to Crohn's disease. In this study, assays for analyzing phylotype specific bacterial alterations in association to IBS were developed and applied.

### Innovations and breakthroughs

The authors' results support the hypothesis of intestinal bacteria having a role in IBS, as significant phylotype specific alterations between the faecal microbiotas of IBS symptom subtype groups and healthy controls were detected. Furthermore, the results emphasize the importance of subgrouping IBS patients in future studies.

### Applications

An IBS-associated 16S ribosomal RNA (rRNA) gene sequence library data was used to design the real-time polymerase chain reaction (PCR) assays capable of differentiating IBS symptom subgroups and healthy controls in the test sample panel. The detected altering phylotypes might be useful as targets in diagnostic, therapeutic and host-microbe interaction studies.

### Terminology

The bacterial 16S rRNA gene is constructed from conserved and variable regions according to its phylogenetic origin. It enables the detection and quantification of microbes from environmental samples even when the bacteria cannot be cultivated. Real-time PCR targeting the 16S rRNA gene can be used to quantify bacterial subpopulations of 0.01% from faecal DNA samples.

### Peer review

The authors examined faecal bacterial phylotypes in eight diarrhea-predominant, eight constipation-predominant, four mixed symptom subtype IBS patients, and 15 control subjects with quantitative real-time polymerase chain

reaction assays. They found significant phylotype level alterations in the intestinal microbiotas of IBS patients.

### Abstract

**AIM:** To evaluate the safety of adding ketoprofen to pegylated-interferon (PEG-IFN) with or without ribavirin and the effect on viral kinetics, STAT1 activity and expression of 2'-5'-oligoadenylate synthetase (2'-5'OAS) in genotype 1 chronic hepatitis C in a phase II study.

**METHODS:** Forty-five patients were studied: fifteen were randomized to PEG-IFN plus ribavirin (PR), 16 to PEG-IFN plus ketoprofen and 14 to PR and ketoprofen. The

molecular study of IFN-dependent signal transduction was conducted in 9 patients from each group.

**RESULTS:** The combination of ketoprofen and PEG-IFN with or without ribavirin was safe and well tolerated. An early activation of STAT1 was observed in ketoprofen-treated patients, but this activation was less sustained over time. Conversely, ketoprofen plus PEG-IFN and ribavirin induced an early and sustained increase of 2'-5'OAS transcription starting 24 h after the first dose until the 36th wk. These data are consistent with the clinical results, showing a better sustained virological response and a lower relapse rate in patients receiving ketoprofen plus PEG-IFN and ribavirin.

**CONCLUSION:** The addition of ketoprofen to the standard therapy of chronic hepatitis C should be explored in larger randomized clinical studies.

Ketoprofen, peginterferon 2a and ribavirin for genotype 1 chronic hepatitis C: A phase II study. *World J Gastroenterol* 2009; 15(47): 5946-5952 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5946.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5946>

### INTRODUCTION

The treatment of chronic hepatitis C virus (HCV) infection has dramatically improved over the last 20 years. Interferon  $\alpha$  (IFN $\alpha$ ) was one of the first agents used to treat this infection, but its efficacy in terms of sustained virological response (SVR, i.e. sustained absence of HCV from serum up to 6 mo after stopping therapy)

was extremely poor<sup>[1]</sup>. Strategies to overcome this limitation have included increasing the duration of therapy or adding ribavirin (an antiviral drug) to the treatment regimen<sup>[2,3]</sup>. The introduction of a “pegylated” preparation substantially increased the antiviral activity of IFN $\alpha$ . Today, pegylated-interferon (PEG-IFN) in combination with ribavirin is the standard treatment for patients with chronic hepatitis C<sup>[4]</sup>. Large international controlled clinical trials have demonstrated that this combination therapy yields SVR rates in 54%-63% of treated HCV-infected patients<sup>[5-7]</sup>. However, patients infected with HCV genotype 1 are particularly resistant to antiviral treatment, as demonstrated by the lower SVR rates observed in this patient subset, ranging from 42% to 52%<sup>[5-7]</sup>. Thus, a substantial proportion of patients remain unresponsive to antiviral treatment.

IFN signaling pathways are activated by binding of IFN to its specific receptor, which induces autophosphorylation of protein tyrosine kinases Tyk-2 and Jak-1 on tyrosine residues, thus activating signal transducer and activator of transcription (STAT1 and STAT2) proteins. Activated STATs translocate to the nucleus where they activate the transcription of IFN-inducible genes, such as 2'-5'-oligoadenylate synthetase (2'-5'-OAS)<sup>[8]</sup>. Non-steroidal antiinflammatory drugs (NSAIDs) have been demonstrated to amplify the IFN signaling pathways and to enhance the anti-viral effect of IFN<sup>[9-14]</sup>. Furthermore, it has recently been found that acetylsalicylic acid suppresses HCV expression in a hepatoma cell line containing HCV subgenomic replicon<sup>[15]</sup>. However, clinical studies evaluating the use of NSAIDs in combination with standard IFN $\alpha$  in patients with chronic HCV infection have given conflicting results<sup>[16-20]</sup>, although results with ketoprofen have generally been encouraging<sup>[17-21]</sup>.

A rational approach to combination therapies for patients with chronic HCV infection demands a detailed knowledge of how the different drugs affect viral kinetics and IFN intracellular signaling. Therefore, we conducted a pilot phase II study to evaluate the effect of ketoprofen plus PEG-IFN with or without ribavirin compared with PEG-IFN plus ribavirin (PR) on viral kinetics, STAT1 activity and expression of the IFN-dependent gene 2'-5'-OAS in patients with chronic hepatitis C. We also assessed the safety and tolerability of these treatment schedules. In order to minimize the influence of HCV viral variability on our results, only patients infected with HCV genotype 1 were included.

## MATERIALS AND METHODS

### Patients

Treatment-naïve patients aged 18 to 65 years with chronic HCV infection genotype 1a or 1b were eligible for enrollment if they had: elevated alanine aminotransferase (ALT) levels within the previous 6 mo, a positive test for serum HCV-RNA and a liver biopsy specimen consistent with chronic hepatitis C obtained in the previous 12 mo. Patients were excluded if they had neutropenia (neutrophil count  $< 1.5 \times 10^9$  cells/L), thrombocytopenia (platelet count  $< 70 \times 10^9$  cells/L), anemia (hemoglobin

level  $< 12.0$  g/dL in women and  $< 13.0$  g/dL in men) or a medical condition that would be clinically worsened by anemia, serum creatinine levels more than 1.5 times the upper limit of normal, evidence of liver disease due to causes other than chronic HCV infection, human immunodeficiency virus positivity, esophageal varices, decompensated liver disease, organ transplant, severe or poorly controlled psychiatric disease (especially depression), malignant neoplastic disease, severe cardiac or chronic pulmonary disease, history of peptic disease, autoimmune disease (except controlled thyroid disease), seizure disorder, alcohol or drug dependency within 1 year of study entry, clinically significant comorbid conditions; and, if female, pregnancy or unwilling to use contraception.

### Study design

This was an open-label, randomized, phase II, pilot study. Patients eligible for the study were randomized into three groups: (1) PR group: patients received subcutaneous PEG-IFN $\alpha$ 2a 180  $\mu$ g/wk plus oral ribavirin 800 mg/d for 48 wk; (2) PEG-IFN plus ketoprofen (PK) group: patients received subcutaneous PEG-IFN $\alpha$ 2a 180  $\mu$ g/wk for 48 wk plus oral ketoprofen 200 mg twice daily for the first 4 wk and then 200 mg/d for the next 20 wk; (3) PEG-IFN plus ribavirin and ketoprofen (PRK) group: patients received subcutaneous PEG-IFN $\alpha$ 2a 180  $\mu$ g/wk plus oral ribavirin 800 mg/d for 48 wk plus oral ketoprofen 200 mg twice daily for the first 4 wk and then 200 mg/d for the next 20 wk.

After 24 wk, treatment was withdrawn in patients who did not experience a decrease from baseline in viral load of  $\geq 2$  log<sub>10</sub> IU/mL or a negative qualitative serum HCV-RNA. A safety assessment was conducted in these patients between 4 and 8 wk after their last dose of study drug.

After the 48-wk study there was a 24-wk treatment-free follow-up period. Virological response was defined as a negative test for qualitative serum HCV-RNA. An end of treatment response (ETR) was defined as undetectable levels of HCV-RNA at the end of treatment (week 48) and SVR was defined as undetectable levels of HCV-RNA at the end of follow-up (24 wk after treatment cessation). Relapsers were defined as patients who obtained an ETR, but relapsed after completion of treatment and tested HCV-RNA positive at the end of follow-up.

PEG-IFN $\alpha$ 2a and ribavirin were kindly supplied by Roche S.p.A., Monza (MI), Italy and ketoprofen by IBI (Istituto Biochimico Italiano) S.p.A., Aprilia (LT), Italy. All subjects gave written informed consent before entering the study. The study protocol and patient-informed consent forms were approved by the Institutional Ethics Committee of Azienda Ospedaliero-Universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, Italy (registration number: 58/2002/U) and the study was conducted according to the ethical guidelines of the Declaration of Helsinki.

### Study procedures

All patients underwent liver biopsy within 12 mo before entry. Each liver biopsy was scored according to the

histological activity index proposed by Knodell *et al*<sup>[22]</sup>. After the screening evaluations, laboratory parameters were monitored and recorded at regular intervals throughout the 48-wk study period and a physical examination was conducted at the end of treatment. Adverse events and serious adverse events were recorded throughout the study and up to the end of follow-up period.

Serum samples were collected from each patient before treatment (on day -1), at baseline (day 0), at 24 and 48 h after the first dose and at 1, 2, 4, 12, 24, 36, 48, 60 and 72 wk after the beginning of treatment. Quantitative HCV-RNA serum levels were assessed in all samples using a branched DNA assay (Versant<sup>®</sup> RNA 3.0 assay; Siemens, Milano, Italy). Virological response was assessed on weeks 1, 2, 4, 12, 24, 36, 48 and 72 by means of Transcription Mediated Amplification technique (Versant<sup>®</sup> HCV-RNA Qualitative Assay; Siemens, Milano, Italy; low limit of detection: 6 HCV IU/mL).

### RNA extraction and real-time quantitative polymerase chain reaction (RTQ-PCR)

Peripheral blood mononuclear cells (PBMCs) were collected from patients at 0, 24 and 48 h and at 1, 2, 4 and 36 wk after the beginning of treatment. Total RNA was extracted from PBMCs using an "RNeasy Protect Mini Kit" (Qiagen, GmbH, Hilden, Germany). Full length cDNAs were synthesized from 1 µg total RNA using the "Thermoscript RT-PCR system" kit (Invitrogen), according to the manufacturer's instructions.

Comparative RTQ-PCR was performed with the "Platinum SYBR Green qPCR SuperMix-UDG" kit (Invitrogen) and analyzed on Mx3000P apparatus from Stratagene.

A 0.2 µmol/L concentration of the following primers was used: for 2'-5'OAS forward 5'-ATTGACAGTGCT GTTAACATCATCC-3' and reverse 5'-GTGAGTTATG GAACACGACGAG-3'; for GAPDH forward 5'-GAAG GTGAAGGTCGGAGTC-3' and reverse 5'-GAAGAT GGTGATGGGATTTTC-3'. RTQ-PCR conditions used to amplify 2'-5'OAS and GAPDH cDNAs were: 95°C for 5 min, followed by 40 cycles comprising 30 s at 95°C, 30 s at 60°C and 1 min at 72°C. In order to check for DNA contamination, amplification of total RNA before cDNA synthesis was performed in parallel with amplification of the cDNA. Reactions were run in triplicate, and a mean value of the three samples was calculated. 2'-5'OAS mRNA levels were expressed as the relative amount of product adjusted for the level of GAPDH, using the Mx3000P software (Stratagene) and employing a comparative Ct ( $\Delta\Delta C_t$ ) value method. Dissociation curves were generated to ensure that a single amplicon had been produced.

### Western blotting

PBMCs were lysed with Ripa buffer containing 50 mmol/L Tris (pH 7.5), 100 mmol/L NaCl, 0.1% Nonidet P-40, 1 mmol/L EDTA, 2 mmol/L phenylmethylsulfonyl fluoride, 1 µg/mL aprotinin, 1 µg/mL of leupeptin and phosphatase inhibitors. Protein concentrations were measured

using a colorimetric assay (Bio-Rad, Hercules, CA, USA). Equal amounts of proteins were electrophoresed on SDS-PAGE. Proteins were transferred to PVDF membrane (Immobilon-PVDF, Millipore) and treated with 1:300 specific primary antibody anti-STAT1 (Santa Cruz Biotechnology, Inc., CA, USA) and its activated form (Biosource). After incubation with peroxidase-coupled secondary antibodies (Santa Cruz Biotechnology), the sheets were visualized by ECL kits (Amersham, GE Healthcare Life Science, Germany). Antibody anti-actin was purchased from Santa Cruz Biotechnology.

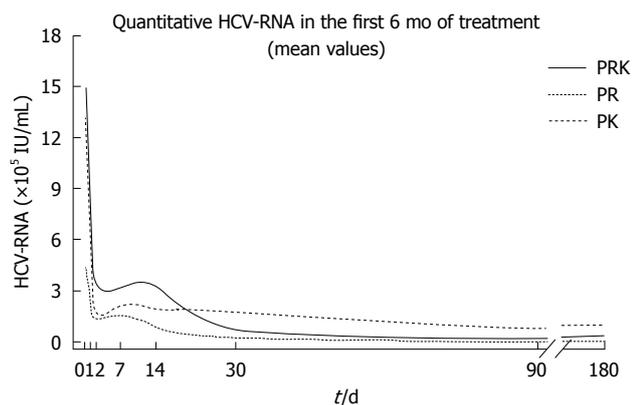

### Statistical analysis

This was a pilot study and therefore no formal sample size calculation was performed. Data were analyzed on an intention-to-treat basis. Patients who dropped out of the trial for any reason were classified as non responders. The safety population comprised all patients who received at least one dose of study drugs.  $\chi^2$  test and Mann-Whitney *U* test were used to compare quantitative and qualitative variables between the groups, respectively. Differences in virological response rates between treatment groups were analyzed using Fisher's exact test and/or Yates corrected  $\chi^2$  test, as necessary. A *P* < 0.05 was considered to be significant. Data analysis was carried out using the SPSS for Windows version 11.0.1. Plots of the viral load were carried out using SigmaPlot version 9.0.

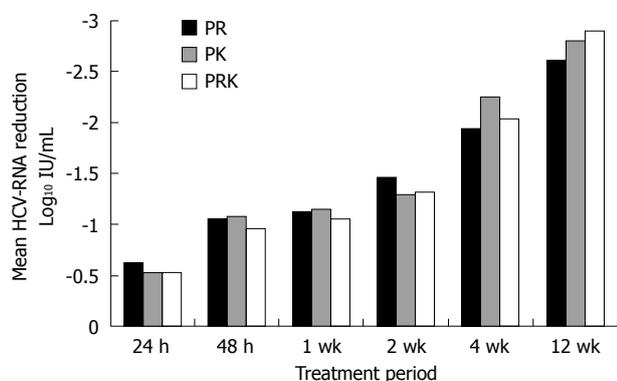

## RESULTS

Forty-five patients were enrolled: 15 were randomized to the PR group, 16 to the PK group and 14 to the PRK group.

The baseline characteristics of the three treatment groups are reported in Table 1. Patients were comparable with respect to age, gender, serum ALT levels and histological features. Overall, 4 out 15 (27%) of PR patients, 3 out 16 of PK (19%) and 2 out of 14 (14%) of PRK

**Figure 1** Mean hepatitis C virus (HCV)-RNA levels during the first 24 wk of treatment in patients with HCV genotype 1 infection receiving PEG-IFN $\alpha$ 2a plus ribavirin (PR) or PEG-IFN $\alpha$ 2a plus ketoprofen (PK) or PEG-IFN $\alpha$ 2a plus ribavirin and ketoprofen (PRK).

**Figure 2** Mean reduction from baseline in log<sub>10</sub> HCV-RNA levels in patients with HCV genotype 1 infection receiving PR or PK or PRK.

patients had a liver fibrosis score equal to 3. The viral load was significantly different between the three groups, being significantly lower in the PR group ( $P = 0.01$ ).

**Viral kinetics and antiviral activity**

Mathematical modeling of the decline in HCV-RNA serum levels revealed a triphasic response in all treatment groups (Figure 1). The rapid first phase (1-2 d) was similar in the three groups, although HCV-RNA levels were consistently higher in the PRK group during this time. A second, or “shoulder” phase was observed between 2 and 7-14 d, where the decline in HCV-RNA levels was faster in the PR group compared with both PK and PRK groups. In particular, the PR group showed a slight and progressive reduction of viremia over time after week 1. In the third phase (week 2 onwards), the decrease in HCV-RNA levels was slowest in the PK group while it was more rapid in the PRK group. In this latter group, HCV-RNA levels declined to those observed in the PR group by study end.

The mean log<sub>10</sub> reduction from baseline in HCV-RNA levels over the course of the first 12 wk of treatment is shown in Figure 2. At week 4, the mean log<sub>10</sub> decrease from baseline was comparable between the three groups (-1.95 in the PR group, -2.25 in the PK group and -2.05

**Table 2** Virological response rates by study group  $n$  (%)

	PR group ( $n = 15$ )	PK group ( $n = 16$ )	PRK group ( $n = 14$ )	$P$ -value

SVR	5 (56)	3 (33)	5 (56)	NS

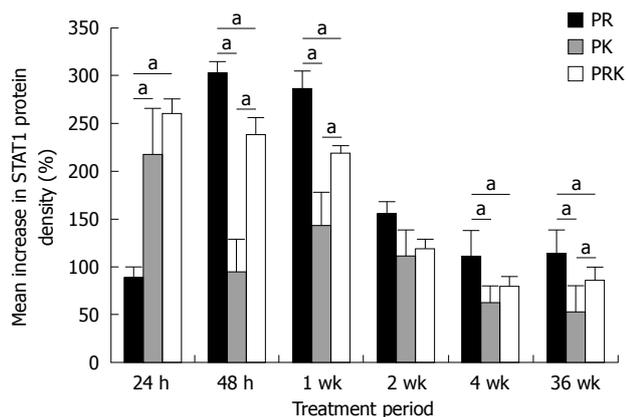

in the PRK group). As shown in Table 2, some patients had undetectable HCV-RNA levels as early as 7-14 d after starting treatment. The PR treatment group displayed an earlier virological response when compared with the other two groups (Table 2).

An ETR was obtained in 11/15 patients (73%) in the PR group, 11/16 (69%) in the PK group and 10/14 (71%) in the PRK group. During the treatment-free follow-up period, the relapse rate was lower in the PRK group than in both the other two groups, but the differences were not statistically significant. A SVR was obtained in 7 patients in the PR group (47%), in 5 in the PK group (31%) and in 8 in the PRK group (57%). No association was found between baseline viremia and SVR in any treatment group. However, in the subgroup of patients with high baseline viremia ( $> 700 \times 10^3$  IU/mL), 6/10 (60%) of the PRK group achieved a SVR compared to a quarter (25%) of the PR group and 3/8 (37.5%) of the PK group.

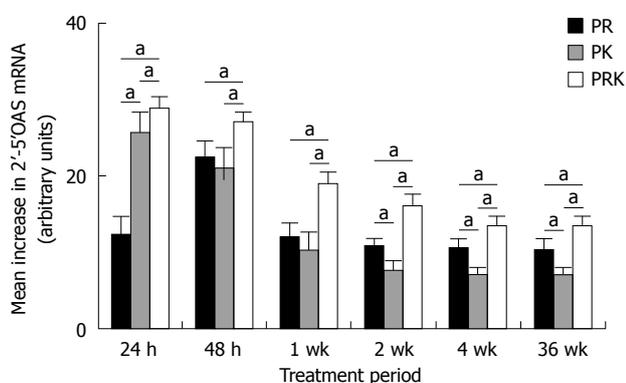

**Modulation of IFN signaling**

The first 9 randomized patients in each group were enrolled in the molecular study of IFN-dependent signal transduction. Their characteristics are described in Table 3.

A time course analysis of STAT1 activity over 36 wk by means of densitometric analysis was performed. STAT1 activity was consistently up-regulated, as shown by an increase from baseline in mean STAT1 density as early as 24 h after the first drug administration. Nevertheless, a difference between the three treatment groups can be seen in Figure 3. At 24 h, the increase from baseline in STAT1 density was significantly higher in both ketoprofen-

**Figure 3** Mean percentage increase from baseline in STAT1 protein density in patients with HCV genotype 1 infection receiving PR or PK or PRK. Data are presented as the mean ( $\pm$  SD) percentage increase over basal activity in STAT1, assessed by densitometric analysis. <sup>a</sup> $P < 0.05$ .

**Figure 4** 2'-5'-oligoadenylate synthetase (2'-5'OAS) induction in patients with HCV genotype 1 infection receiving PR or PK or PRK. Data are presented as the mean ( $\pm$  SD) fold increase over basal activity in 2'-5'OAS mRNA levels, assessed by RTQ-PCR. <sup>a</sup> $P < 0.05$ .

treated groups as compared with patients of the PR group. However, in PK patients STAT1 activation not only peaked earlier, but it also decreased more rapidly, while in the PRK group a strong STAT1 activation was still present after 1 wk. In contrast, in PR patients the activation of STAT1 peaked at 48 h, 24 h later than in both PK and PRK patients, but was still maintained at higher levels after 1 wk. A steady state was gained between 2 to 36 wk. Thus, the activation of STAT1 in the presence of ribavirin was slower and peaked later but was sustained longer as compared with that observed in the presence of ketoprofen. No relationship was found between STAT1 and viral load. There was no significant difference in STAT1 activity between patients with a SVR and non responders (data not shown).

The analysis of 2'-5'OAS mRNA levels by RTQ-PCR (Figure 4) showed that the presence of ketoprofen increased the transcription rate of this gene, especially early in treatment (24 h after the first dose). The addition of ketoprofen resulted in an early upregulation of 2'-5'OAS mRNA level and permitted the maintenance of this transcript at significantly higher levels in the PRK

group compared with the PR and PK groups, from the beginning of treatment until week 36. Finally, 2'-5'OAS mRNA levels were significantly higher in patients with a SVR than in non responders at each time point and in each group (data not shown).

### Safety

The type and frequency of adverse events were similar in the three treatment arms and are summarized in Table 4. Anemia, defined as hemoglobin level  $< 12.0$  g/dL in women and  $< 13.0$  g/dL in men, and neutropenia, defined as neutrophil count  $< 1000/\text{mm}^3$  were the most common side effects. However, only one patient in the PRK group met the hemoglobin criterion for ribavirin dose reduction (hemoglobin level  $< 10$  and  $\geq 8.5$  g/dL), while the dose of PEG-IFN was reduced because of neutropenia (neutrophil count of  $< 750$  and  $\geq 500/\text{mm}^3$ ) in one patient each in the PR and in PK group. The latter developed a pneumonia requiring antibiotic treatment. No patient experienced renal dysfunction. In particular, in no case did creatinine serum levels exceed the upper limit of normal range (1.2 mg/dL) during treatment. Time course evaluation of hemoglobin and creatinine serum levels during treatment in the three groups is reported in Table 5.

One patient each in the PR group and the PK group withdrew prematurely from the study. The patient in the PR group dropped out after 1 mo because of severe depression and the patient in the PK group dropped out after 6 mo because of poor compliance.

## DISCUSSION

The objective of this phase II study was to assess the safety of ketoprofen in combination with PEG-IFN $\alpha$ 2a with or without ribavirin in treatment-naïve patients with HCV genotype 1 infection, and the effect of these regimens on viral kinetics and IFN $\alpha$  signaling modulation. Our results showed that ketoprofen was safe and well tolerated. In particular, gastrointestinal-related adverse events were mild and did not lead to dose reduction or to premature treatment discontinuation in any patient. Given the importance of managing the tolerability of HCV antiviral treatment, our observation that the addition of ketoprofen to PEG-IFN and ribavirin is as well tolerated as the standard regimen is reassuring.

The kinetics of viral decay during treatment showed a triphasic response that was more evident in patients receiving ketoprofen, independent of the use of ribavirin. Following the first phase of rapid decline in HCV-RNA levels, patients receiving ketoprofen showed a pronounced “shoulder phase” starting 2 to 14 d after initiation of therapy. It has recently been suggested that the triphasic decline in HCV-RNA levels occurs only in patients in whom a majority of hepatocytes are infected before therapy<sup>[23]</sup>. Thus, the higher baseline viremia of both ketoprofen groups could help to explain the differences in viral kinetics between the groups receiving ketoprofen and the PR group. Interestingly, in the third and final phase, the HCV-RNA levels were lower in the two groups receiving ribavirin than in the PK group. This enhanced response to treatment in ribavirin recipients supports the hypothesis that ribavirin not only improves the anti-HCV immune response, but also had a mutagenic effect against HCV<sup>[23,24]</sup>. However, it should be pointed out that in both the PK and PRK groups, ketoprofen was administered only during the first 24 wk of treatment. Thus, the similarity between the PRK and PR groups in HCV-RNA levels during the final phase could be attributable to the absence of ketoprofen in the PRK group during this time.

As far as the IFN $\alpha$  signaling modulation is concerned, the activation of STAT1 occurred very early after treatment initiation in the two groups receiving ketoprofen, being evident after 24 h from the start of treatment. However, there was a rapid decline in STAT1 activation thereafter, particularly in the PK group. In contrast, the PR group exhibited the greatest activation after 48 h and this activation was more sustained over time compared with the ketoprofen-containing regimens. The mechanisms responsible for these differences in the control of IFN-induced responses probably include down-regulation and degradation of receptors<sup>[15]</sup>. Moreover, it has been demonstrated that both ribavirin and NSAIDs act synergistically with IFN- $\alpha$  in induction of STAT1 activation<sup>[13,25]</sup>, yet there was lower STAT1 activation in the PRK group compared with the PR group. Thus, an antagonistic effect between ketoprofen and ribavirin cannot be excluded.

On the other hand, our data demonstrated an early and sustained increase of 2'-5'OAS transcription in the PRK group compared with the PR group, suggesting that the addition of ketoprofen to the conventional combination therapy induces early activation of the IFN $\alpha$

pathway, followed by a better activation of the IFN $\alpha$ -dependent intracellular pathway.

Even if this study was not designed to assess antiviral efficacy, the clinical results are consistent with the molecular data. At baseline, the PR group had a significantly lower mean HCV viral load than both the PK and PRK groups. Thus, the proportion of patients with low viral load ( $\leq 700\,000$  IU/mL) was significantly higher in the PR group (73%) than in the PK (50%) or in the PRK group (29%). It is well known that in genotype 1 patients, baseline viral load is the best prognostic factor for response to antiviral treatment<sup>[5-7,26]</sup>. Thus, it was not surprising that patients in the PR group obtained a better virological response at week 4. Nevertheless, the SVR rate observed in the PRK group (57%) was better than that observed in PR (47%) and in PK (31%). Furthermore, among patients with high viral load ( $> 700\,000$  IU/mL), those of the PRK group obtained the better SVR (60% *vs* 25% and 38% in the PR and PK groups, respectively). It should be pointed out that our study was initiated before the optimal dose of ribavirin for patients with HCV genotype 1 (i.e. 1000 mg/d or 1200 mg/d according to body weight) was determined<sup>[7]</sup>. However, even if the dose of ribavirin utilized in this study was suboptimal and might have influenced the SVR, both groups receiving ribavirin had the same dose regimen.

In conclusion, considering that the use of ketoprofen does not add further side effects, is associated with better viral kinetics and early activation of the IFN signaling pathway, and in combination with PR improves virological response rates, this pilot study suggests the exploration of the clinical efficacy of this three-drug combination in well-designed randomized clinical trials. We conclude that such studies are warranted since, in this era of development of new drugs for HCV, the clinical use of novel compounds up till now has been hampered by toxicity issues and rapid promotion of drug-resistant HCV viruses<sup>[27]</sup>.

## COMMENTS

### Background

The current standard treatment for chronic hepatitis C with pegylated-interferon (PEG-IFN) and ribavirin is effective in approximately 50%-60% of patients, so that a substantial proportion of patients remain unresponsive. A rational approach to develop alternative therapeutic strategies for patients with chronic hepatitis C virus (HCV) infection demands a detailed knowledge of how the different drugs affect viral kinetics and IFN intracellular signaling. Non-steroidal antiinflammatory drugs (NSAIDs) have been demonstrated to amplify the IFN signaling pathways and to enhance the anti-viral effect of IFN. This phase II study evaluated the effect of ketoprofen (a NSAID) plus PEG-IFN with or without ribavirin compared with PEG-IFN plus ribavirin (PR) on viral kinetics, STAT1 activity and expression of the IFN-dependent gene, 2'-5'-oligoadenylate synthetase (2'-5'OAS), in patients with genotype 1 chronic hepatitis C.

### Research frontiers

The results of this pilot study support the proposal of an evaluation of the clinical efficacy of the addition of ketoprofen to the standard PR treatment for chronic hepatitis C in well-designed randomized clinical trials.

### Innovations and breakthroughs

This is the first study to report both molecular and clinical data about the use of ketoprofen in association with PEG-IFN $\alpha$  and ribavirin in chronic hepatitis C. The authors found that the addition of ketoprofen to the conventional combination therapy is associated with better viral kinetics and early activation of the IFN $\alpha$  signaling pathway, thus improving virological response rates.

## Applications

The results may stimulate further experimental and clinical investigations regarding the role of NSAIDs in association with IFN-based therapy in the context of HCV-related liver diseases.

## Terminology

IFN signaling pathways are activated by binding of IFN to its specific receptor, which induces autophosphorylation of protein tyrosine kinases Tyk-2 and Jak-1 on tyrosine residues, thus activating signal transducer and activator of transcription (STAT1 and STAT2) proteins. Activated STATs translocate to the nucleus where they activate the transcription of IFN-inducible genes, such as 2'-5'OAS.

## Peer review

The authors postulate that a larger trial should be done with this 3 drug combination, compared to standard of care. While a small study, there is useful data.

in the education-based study that recorded data from 3728 patients. The specialists overestimated the risk of GI complications with NSAIDs, underestimated the GI safety profile of coxibs, but were aware of the risk factors and of the current prevention strategies. Proton pump inhibitors were co-prescribed with NSAIDs in > 80% of patients with and without risk factors. The educational program had little impact on prescribing habits.

**CONCLUSION:** Specialists are informed of advances in NSAID-associated adverse effects and have high rates of GI-prevention therapy. Our educational program did not alter these rates.

### Abstract

**AIM:** To evaluate an evidence-based educational program for improving strategies for prevention of non-steroidal anti-inflammatory drug (NSAID)-associated gastrointestinal (GI) complications.

**METHODS:** Four hundred and fifty-six specialists replied to a questionnaire that covered issues related to NSAID-induced adverse effects. They also collected data from their last five consecutive patients before and after they had attended an evidence-based seminar on GI prevention strategies.

**RESULTS:** Four hundred and forty-one of 456 specialists (96.7%) participated in the survey, and 382 (83.7%)

### INTRODUCTION

Nonsteroidal anti-inflammatory drugs (NSAIDs) are prescribed extensively worldwide, with at least 20% of the adult population using them for at least 1 mo per year<sup>[1]</sup>. NSAID use is associated with a wide range of side effects, the most usual being those involving the gastrointestinal (GI) tract. Research in this field has progressed considerably, especially since the commercialization of cyclooxygenase 2 inhibitors (coxibs), and the amount of information published is impressive. Recent data derived from studies of the side effects associated with coxibs and traditional NSAIDs have received a good deal of attention in scientific and non-scientific

publications. Based on existing and new information, scientific organizations, regulatory agencies and influential journals have made recommendations regarding GI prevention strategies with NSAIDs<sup>[2-4]</sup>. These indicate that patients requiring NSAIDs should be evaluated for the presence of GI and cardiovascular (CV) risk factors, and should undergo prevention therapy when found to be at risk. Patients with a high risk of CV complications are to avoid coxibs and/or NSAIDs. Patients with GI risks should receive either a coxib, or concomitant therapy with misoprostol or a proton pump inhibitor (PPI). In all cases, the minimum effective dose and the shortest possible administration time should be a joint objective. In the light of all this knowledge, it remains unclear whether or not information has been translated into clinical practice.

Recent evidence indicates that prescribing patterns are far from appropriate; a trend that has become more pronounced since the withdrawal of rofecoxib from the market<sup>[5]</sup>. Reports suggest that, in Europe, up to 80% of patients with one or two risk factors for GI complications do not receive the appropriate prevention strategies<sup>[6,7]</sup> and that, in the United States, the lack of GI protection has grown since 2004<sup>[5]</sup>. In addition, some patients who are not at risk receive unnecessary therapy or receive inadequate and ineffective drugs that compromise their health and increase the cost of NSAID treatment<sup>[8,9]</sup>. The reasons for the lack of or inappropriate use of prevention strategies are unclear, but conflicting results or variations in their interpretation and divergences in the recommendations that they support<sup>[2-4,10,11]</sup> may have contributed to the confusion.

However, the aforementioned data and conclusions have been obtained at primary care level, therefore, the present study was designed firstly to evaluate the level of knowledge regarding NSAID-associated adverse effects among specialists treating patients with rheumatic diseases, and secondly, to evaluate whether an educational program based on a review of current evidence produced an improvement in the pattern of patient management.

## MATERIALS AND METHODS

The study was approved by the Regional Institutional Review Board of Aragón and carried out during 2006 to 2007. First, we conducted a nationwide survey of 456 specialists distributed across the country, and among those who had previously participated in similar studies and had delivered good-quality data, and that represented the most frequently occurring specialties among patients suffering from musculoskeletal conditions. Physicians received a letter from one of the researchers (Lanas A) explaining the purpose of the study, voluntary nature of participation, the confidentiality of the information provided, and absence of commercial purposes of the study. Physicians were questioned about issues related to NSAIDs and their adverse effects, with a special focus on research over the previous 4-5 years that may have affected clinical practice directly. Table 1 summarizes the main questions.

The educational program was designed to answer the objective of the study, which was to evaluate the impact of an evidence-based seminar on clinical practice, and to describe current practice in the prevention of GI adverse effects in the specialized setting. Only physicians who participated in the initial survey were invited to participate in the educational program. Firstly, doctors sent data of their last five consecutive patients visited in the office (phase I). These patients had to be at least 18 years old and taking or having been prescribed NSAIDs at the time of the visit. None of the data collected revealed the identity of the subjects. The responses were transmitted anonymously to one of the researchers (Sobreviela E), who entered the information into a database without including any data that could identify physicians or patients. Between 2 and 4 mo later, these specialists attended small group seminars that lasted approximately 2 h, and were based on current evidence in the field and received literature related to NSAID prevention strategies. These educational programs reviewed the main adverse effects associated with NSAIDs and coxibs, as well as risk factors, therapy-specific risks, the pros and cons of available prevention strategies, and treatment options for the cases most frequently encountered in clinical practice. The different therapeutic options, depending on the presence/absence of GI and CV risk factors<sup>[12,13]</sup>, were also reviewed and discussed. All these seminars were given by the same two investigators (Lanas A and Esplugues JV). Between 3 and 4 mo after the seminar, the same physicians again sent data of their last five consecutive patients, with the same inclusion criteria as described above (phase II of the educational program-based study).

### Statistical analysis

Data were analyzed using SAS software v.8.02 for Windows (SAS Institute, Cary, NC, USA). For categorical variables, absolute frequencies and percentages were obtained; for continuous variables, mean  $\pm$  SD, median, percentiles 25-75, maximal and minimum values and 95% CI were obtained. Significance related to categorical variables was obtained using the  $\chi^2$  test or Fisher's exact test. Comparisons reached statistical significance at  $P < 0.05$ .

## RESULTS

### Physician survey sub-study

Of a total of 456 invited physicians, 441 (96.7%) returned valid questionnaires. Those that responded had a mean  $14 \pm 8.6$  years of professional activity. Three hundred and seventy-four (84.8%) were members of one or more scientific societies, and 189 (42.9%) were aware that their respective societies had published guidelines or recommendations for the management of NSAIDs. Two hundred and eighty (63.4%) were orthopedic surgeons, 116 (24.7%) were rheumatologists, and 45 were other types of specialists (10.2%).

Only 24 (5.7%) doctors responded that NSAID use was not associated with GI toxicity; 368 (88.2%), a substantial majority, stated that NSAID use was associated with GI, renal, CV, or liver damage. A total of 207 (50.2%)

**Table 1** A summary of the main questions (from a total of 22) assessing physicians' knowledge of current evidence in the field of NSAID use and adverse effects

NSAID use is associated with adverse effects. Which of the following do you believe is not associated with NSAID use?
What is the expected annual incidence of upper GI complications in patients taking NSAIDs, as reported in the most recent large outcome studies?
The occurrence of dyspepsia in patients who take NSAIDs has been reported to be less than 25% (true or false)
NSAIDs may induce GI complications in the lower GI tract (true or false)
Which of the following factors do you believe is/are risk factors for GI complications in patients who take NSAIDs? (list)
Which of the following NSAIDs do you believe is more toxic to the GI tract? (list)
Concerning COX-2 selective inhibitors, for each of the following, indicate whether the statement is true or false:
They are not as effective as traditional NSAIDs in the treatment of OA or RA
The use of these compounds is associated with a 50% reduction in the risk of GI complications compared to NSAIDs
The concomitant use of low-dose aspirin reduces or eliminates the GI benefit of these compounds when compared to NSAIDs
The use of these compounds has been associated with an increased risk of CV events
In high-risk patients, the combination of NSAIDs plus a PPI is safer than a coxib alone
Concerning gastroprotective agents, indicate for each of the following statements whether they are true or false:
H2-RAs are effective in the prevention of gastric ulcers, duodenal ulcers, and GI complications
PPIs are effective in the prevention of gastric ulcers, duodenal ulcers, and GI complications
Misoprostol is effective in the prevention of gastric ulcers, duodenal ulcers, and GI complications
Which of the following agents has been proved to be effective in the treatment or prevention of NSAID-induced dyspepsia? (list)

NSAID: Nonsteroidal anti-inflammatory drug; GI: Gastrointestinal; CV: Cardiovascular; PPI: Proton pump inhibitor; H2-RAs: H2 receptor antagonists.

**Table 2** Responses to the question, "Which of the following factors do you believe is/are risk factors for GI complications in patients who take NSAIDs?" *n* (%)

	Rheumatologists	Orthopedic surgeons	Others	Total
History of peptic ulcer	115 (99.1)	275 (98.2)	21 (100.0)	411 (98.6)
History of complicated peptic ulcer	116 (100.0)	275 (98.2)	21 (100.0)	412 (98.8)
Age > 65 yr	114 (98.3)	229 (81.8)	18 (90.4)	361 (86.6)
Concomitant use of low-dose aspirin for CV prevention	114 (98.3)	228 (81.4)	19 (90.4)	361 (86.6)
Concomitant use of anticoagulants	112 (96.5)	247 (88.2)	20 (95.3)	379 (90.9)
<i>Helicobacter pylori</i> infection	103 (88.8)	257 (91.8)	19 (90.4)	379 (90.9)
Smoking	87 (75.00)	223 (79.6)	13 (61.7)	323 (77.5)
Dyspepsia history	73 (62.9)	250 (89.3)	19 (90.4)	342 (82.0)
Alcohol	105 (90.5)	257 (91.8)	20 (95.3)	382 (91.6)
High dose of NSAIDs	113 (97.4)	275 (98.2)	21 (100.0)	409 (98.1)

overestimated the overall rate of upper GI complications in NSAID users, and 261 (63.0%) stated that NSAID use could lead to complications of the lower GI tract. The two symptoms that doctors considered to be the most frequently reported by patients in relation to NSAID therapy were epigastric pain (67.1%) and heartburn (54.8%). The frequency of dyspepsia as an adverse effect of NSAIDs was underestimated by 45.2% of respondents. As summarized in Table 2, most identified the risk factors for GI complications in NSAID users; there were no differences between the responses of rheumatologists and orthopedists, which were the two main specialties represented by the participants. Indomethacin (61.9%), piroxicam (34.0%), diclofenac (18.5%) and ketorolac (11.0%) were considered to be the most gastrototoxic agents, while coxibs, paracetamol and metamizol were considered to be the safest for the GI tract.

When questioned about coxibs, 93 (22.5%) of the specialists believed them to be less effective than NSAIDs, but 84.6% said they were safer for the GI than NSAIDs were. However, 43.9% of the specialists stated that coxibs were more toxic for the GI tract than a combination of NSAID + PPI. Furthermore, 211 (52.2%) reported that concomitant low-dose aspirin reduced the GI benefit of coxibs, and 394 (94.7%) considered coxibs to be toxic to

the CV system; a proportion that fell to 72.7% ( $P = 0.140$ ) when the same question was asked about NSAIDs.

Over half of the physicians (56.1%) reported that histamine H2 receptor antagonists (H2-RAs) were effective in preventing ulcers and ulcer complications in NSAID users; almost all (98.5%) reported the same effect with PPIs. Responding about GI prevention therapy habits with NSAIDs, 217 (52.4%) took this precaution on a routine basis, 45.9% only when risk factors were present, and 5.3% only when patients were receiving long-term NSAID therapy. H2-RAs (44.6%), misoprostol (41.2%) and PPIs (94%) were considered to be effective for the prevention and treatment of NSAID-induced dyspepsia.

### **Effects of the educational program on patient management**

**Demographics and characteristics of patients:** Of 456 invited participants, 382 (83.7%) submitted information regarding 3728 patients over the two phases (1732 in phase I - before the evidence-based seminar, and 1722 in phase II - after the seminar). Two hundred and seventy-four patients were excluded for the following reasons: 43 were under the age of 18 years, and 231 lacked an NSAID prescription. Table 3 summarizes the main characteristics of the patients included in the study. No statistical

**Table 3** Characteristics of patients included in the educational program of the study<sup>1</sup> *n* (%)

Variable	Phase I ( <i>n</i> = 1732)	Phase II ( <i>n</i> = 1722)
Age (mean ± SD)	61.06 ± 13.37	60.81 ± 13.89
Female	1038 (60.4)	980 (57.6)
History of ulcer	238 (13.7)	307 (17.8)
History of ulcer bleeding	61 (3.5)	69 (4.0)
ASA use	167 (9.6)	168 (9.8)
CV history	203 (11.7)	205 (11.9)
Increased blood pressure	845 (48.8)	810 (47.0)
Anticoagulant use	126 (7.3)	120 (7.0)
Corticosteroid use	162 (9.3)	190 (11.0)
History of dyspepsia	782 (45.1)	766 (44.5)

<sup>1</sup>No statistical differences were found between patients enrolled in the two phases. Phase I: Before physicians attended the evidence-based seminar; Phase II: After the seminar; ASA: Aspirin.

**Table 4** Prescription of NSAIDs to patients in each of the two study phases of the educational program *n* (%)

Drug therapy	Phase I		Phase II	
	Before visit	After visit	Before visit	After visit
No NSAID therapy	718 (41.45)	162 (9.35)	653 (37.92)	190 (11.03)

differences were found between patients referred to in the two phases.

**NSAID treatment:** In both phases, ibuprofen (16.2% and 17.25% in phases I and II, respectively), diclofenac (13.2% and 13.8%) and aceclofenac (8.4% and 8.6%) were the three most frequently prescribed NSAIDs. Coxib prescription was low (3.5%). There was a statistically significant (*P* < 0.0001) increase in prescription rates of aceclofenac, celecoxib, ibuprofen, meloxicam and etoricoxib after the visit with the specialist, but this increase was similar in both phases (Table 4). The main reasons for prescribing NSAIDs was the diagnosis of osteoarthritis [1015 (63.24%) in phase I and 987 (61.96%) in phase II] or rheumatoid arthritis [148 (9.22%) and 186 (11.68%) in phases I and II, respectively]. In phase I, NSAID therapy was terminated in 15.98% of patients following the visit to the specialist, a similar percentage

**Table 5** Risk factors (RFs) of patients reported by doctors in the educational program according to either a non-restrictive or a restrictive definition<sup>1</sup> *n* (%)

Number of RFs	Non-restrictive		Restrictive	
	Phase I <sup>2</sup>	Phase II <sup>3</sup>	Phase I <sup>2</sup>	Phase II <sup>3</sup>
0	347 (20.03)	352 (20.44)	961 (55.48)	891 (51.74)
1	660 (38.11)	598 (34.73)	558 (32.22)	573 (33.28)
2	517 (29.85)	536 (31.13)	176 (10.16)	213 (12.37)
> 2	208 (12.01)	236 (13.70)	37 (2.14)	45 (2.61)
Total	1732 (100)	1722 (100)	1732 (100)	1722 (100)

<sup>1</sup>A non-restrictive definition of risk factors for NSAID-related complications included age > 60 years, history of dyspepsia, history of either complicated or non-complicated ulcer, concomitant therapy with NSAIDs and low-dose aspirin, or anticoagulants or corticosteroids. A restrictive definition of risk factors included age ≥ 70 years, history of complicated or non-complicated ulcer, concomitant therapy with NSAIDs and low-dose aspirin, or anticoagulants or corticosteroids; <sup>2</sup>In Phase I, the specialists received an anonymous questionnaire regarding data and prescriptions for their last five consecutive patients; <sup>3</sup>In Phase II, the process was repeated 4-5 mo later after specialists had attended an evidence-based seminar that reviewed current evidence on NSAID-related issues, with a focus on GI prevention strategies in NSAID users.

to that reported in phase II (17.77%). The duration of NSAID therapy after the visit was also similar in both phases. Most treatments were prescribed for a short duration (< 30 d) (74.8% and 72.04% in phases I and II, respectively). No significant differences were found between the two phases.

**NSAID treatment and dyspepsia:** In phase I, 1129 (66%) of 1710 patients who were seen had suffered or were suffering GI symptoms prior to the visit, and 65.6% of the 1129 were receiving NSAID therapy; a higher proportion than those who did not have symptoms before the visit 256/581 (45.6%) (*P* < 0.0001). After the visit, physicians increased the prescription of NSAIDs to a similar rate (88.8% and 94%) in both groups of patients (*P* = 0.0006 *vs* before the visit). Similar percentages were observed in phase II, and no differences were observed between the phases.

Among the patients with GI symptoms, 57.1% in phase I and 60.1% in phase II were undergoing treatment for symptom relief before the visit to the specialist, and about one-third of them were being treated with a PPI. After the visit to the specialist, almost all these patients with symptoms were prescribed PPI therapy (*P* < 0.0001). No differences were found between the two phases.

**Risk factors and prevention strategies:** The number of patients with risk factors depends on the definition of these factors. The two most prevalent risk factors were age and a history of dyspepsia. We present data for a restrictive definition (age > 70 years and excluding history of dyspepsia) and for a non-restrictive definition of those risk factors (e.g. age > 60 years and history of dyspepsia; Table 5). Very few patients with risk factors were switched from a traditional NSAID to a coxib alone; 54 (3.1%) *vs* 129 (7.4%) (*P* < 0.0001) before and after the visit to the specialist in phase I, and 42 (2.4%) *vs* 155

**Table 6** Proportion of patients on NSAID therapy that received concomitant therapy with a PPI or misoprostol after the medical visit, according to the number of RFs *n* (%)

Number of RFs	Non-restrictive		Restrictive

0	268/347 (77.2)	283/352 (80.4)	782/961 (81.4)	728/891 (81.7)
1	536/660 (81.2)	499/598 (83.4)	471/558 (84.4)	504/573 (87.9)
2	453/517 (87.6)	456/536 (85.1)	151/176 (85.8)	168/213 (78.9)
> 2	175/208 (84.1)	201/236 (85.2)	28/37 (75.7)	39/45 (86.7)

(9.0%) in phase II ( $P < 0.0001$ ). No differences between phases I and II were observed after the visit, although we observed a trend toward an increase in coxib prescription in phase II ( $P = 0.09$ ).

The most widely used strategy for prevention of GI complications in Spain is concomitant therapy with PPIs. In both phases of the study, physicians prescribed appropriate gastroprotection therapy for over 80% of patients with risk factors, with little therapeutic benefits observed after the educational program (Table 6). The study also reveals a similar pattern of gastroprotection prescription rates among patients without GI risk factors.

A sub-analysis of data in high-risk patients (defined as those with previous ulcer bleeding or those who were being treated with anticoagulants) showed that very few of these patients were prescribed NSAIDs without PPIs [11/163 (8.4%) in phase I, and 6/158 (4.08%) in phase II].

## DISCUSSION

We found that the majority of specialists who treat patients with rheumatic disease are aware of recent evidence concerning the adverse effects associated with traditional NSAIDs and coxibs. The study also revealed that gastroprotection-related prescribing rates by the specialists among at-risk patients receiving NSAIDs were high, and that an educational program aimed at influencing prescription patterns had little impact.

The first step in the process of implementing prevention strategies in NSAID-treated patients at risk of GI complications is to be familiar with the risk factors. We observed that the specialists who treat patients with different rheumatic conditions are well informed of these factors, which may explain the high rates of preventative prescriptions observed in our study population. Other recent findings in the field, such as the increased risk of CV events with coxibs and traditional NSAIDs, are also well known and may explain the use of short-term courses of treatment with these compounds.

Previous studies have reported that most patients on NSAIDs with one or more risk factors for GI complications were not prescribed prevention-related treatment<sup>[6,7]</sup>. This was not the case in our patient population, of which a high proportion showed risk factors and received concomitant prescription of NSAIDs with gastroprotective agents,

specifically PPIs. The reasons for this discrepancy are not clear, but previous studies were based on a primary care database and not on prescribing data obtained from specialists, who may be more aware of risk factors and strategies to reduce their impact. In addition, this study provides more recent data on prescribing habits than the above-mentioned studies<sup>[6,7]</sup>, which did report a tendency towards more appropriate prescribing rates with time.

This study differs from those carried out in the United States<sup>[5]</sup>, in one aspect specifically: the most prevalent prevention strategy in the current study was the concomitant prescription of PPIs and NSAIDs, while the prescribing rate of coxibs was low, in agreement with sales data for these compounds across Europe<sup>[14]</sup>. This difference between practices in the United States and Europe<sup>[15]</sup> may reflect a widespread belief among the participants in the current study that adding a PPI to a NSAID confers greater upper GI protection than administration of a coxib alone, a belief that is not based on evidence<sup>[16]</sup>.

Also of interest is our finding that the PPI prescribing rate was high among patients whose NSAID treatment was discontinued after a visit to the specialist, and in patients with no risk factors. Even considering the non-restrictive framework for risk factors, which includes a history of dyspepsia as justification for prescribing gastroprotectants, > 20% of patients from the overall study population who had no GI risk factors were being prescribed preventative therapies. This excess of PPI concomitant therapy is not intrinsically inappropriate, given that it may reduce the risk of complications in patients with a low risk of GI, but it does significantly increase the cost of NSAID therapy by an estimated 80%<sup>[17]</sup>. Even in a market in which generics are prescribed and promoted widely, this added expense is not to be disregarded. Furthermore, although PPI treatment is considered to be relatively safe<sup>[18]</sup>, the long-term treatment with these type of drugs is associated with some adverse effects, including an increased risk of GI infections, pneumonia and even hip fracture<sup>[19-22]</sup>. Finally, according to current guidelines, implementing unnecessary prevention strategies is incorrect medical practice.

The other major finding of our study was the failure of our educational program to have any real effect on prescribing habits, although the effect achieved may have been so small because of the baseline circumstances. We observed a minor and statistically insignificant increase in prescribing rates for the safest NSAIDs, including coxibs, and for gastroprotectants among patients running the highest risk of GI adverse effects; a change that would appear to be a result of the educational program. On the other hand, we saw no effect on declining prescribing rates for gastroprotectants among patients without GI risk factors. The shift towards an evidence-based approach to practice seems a challenging task.

A recent study demonstrated that intervention consisting of a combination of education and computer alerts improved gastroprotection<sup>[23]</sup> in at risk patients prescribed NSAIDs, but still the rates were far from being optimal. On the other hand, educational programs may lead to short-term improvements in our knowledge,

but the impact on clinical practice is modest, especially in the mid- to long-term<sup>[24]</sup>. As suggested previously<sup>[25]</sup>, successful educational tools are costly because they require regular feedback and reinforcement. In any case, our study suggests that a high proportion of specialists are well informed about the latest advances in the NSAID field and implement appropriate prevention therapies in at-risk patients, which suggests that continuing medical education is the key to progress.

Our study had some limitations. The information was not obtained from a database but from the records of the participating physicians. Therefore, it was possible that their records differed from actual practice. However, high PPI prescribing rates have been observed in other studies<sup>[26]</sup> and reflect the marked decrease in national rates of upper GI bleeding over the last 5 years. In addition, the survey results concerning the degree of knowledge were in accordance with the clinical practice reported. Another limitation was that the study involved only one time point of observation after completion of the educational program, which did not allow the short- or long-term effects of the program to be analyzed. Finally, the data obtained cannot be extrapolated to clinical practice at the primary care level, which accounts for a major part of NSAID prescribing rates. In fact, the concomitant prescribing rate of gastroprotectants in NSAID users before visiting the specialist (which may well reflect practices in primary care) was much lower than that observed after the visit. Obviously, if a continued drop in GI complications among NSAID users is the goal, prevention strategies should be implemented at all levels of care. Further research should be carried out at the level of primary care to detect areas for improvement and to design improved educational programs by which GI complications in NSAID users may be prevented. Finally one potential limitation of the study is the validity of our conclusions outside Spain. While some data may be country-specific (e.g. prescription rates of PPI), we believe that other aspects of the study can probably be extrapolated (e.g. usefulness of the educational approach, awareness of the specialist on the medical advance,) and therefore be of interest in other areas.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Advances in medical sciences may not be rapidly translated into medical practice. Also contradictory results reported in the literature may difficult appropriate medical care. Advances in the understanding of adverse effects of nonsteroidal anti-inflammatory drugs (NSAIDs) and prevention strategies have been enormous in the last 5 years.

### Research frontiers

It is not know whether specialists treating patients rheumatic diseases are aware of advances in the field of NSAID-associated adverse effects and whether these advances have been translated into medical practice. It has been tested whether specialists confronted with scientific evidence incorporate this into medical practice and modify prescription patterns to these patients.

## Innovations and breakthroughs

The study shows that specialists dealing with patients suffering from rheumatic diseases and prescribing NSAIDs in Spain are aware of the recent advances in the NSAID field, identify the main gastrointestinal risk factors and of the current available prevention strategies. The study detects inappropriate use of prevention strategies in patients being prescribed with NSAIDs. An evidence based seminar of the prevention strategies carried out with these specialist do not change their prescription patterns.

## Applications

The study was carried in one European country and it is unclear whether the data can be extrapolated to other countries, where prescription patterns have shown to be different. Nevertheless, the study shows other aspects that can be applied to other areas and countries: (1) Knowledge of evidence by the specialist is no automatically translated into clinical practice; (2) Modification of clinical practice based on scientific evidence needs a complex intervention.

## Terminology

Evidence based clinical practice refers to medical care which is applied to patients based on studies with sufficient scientific quality that have been published in peer-review and that have been accepted by the scientific community (guidelines, expert reports, scientific societies, etc.) as appropriate.

## Peer review

This is a well presented approach to evaluation of an evidence-based educational program for improving NSAID-associated prevention strategies.

### Abstract

**AIM:** To establish the frequency of hyperphosphatemia following the administration of sodium phosphate laxatives in low-risk patients.

**METHODS:** One hundred consecutive ASA I-II individuals aged 35-74 years, who were undergoing colonic cleansing with oral sodium phosphate (OSP) before colonoscopy were recruited for this prospective study. Exclusion criteria: congestive heart failure, chronic kidney disease, diabetes, liver cirrhosis, intestinal obstruction, decreased bowel motility, increased bowel permeability, and hyperparathyroidism. The day before colonoscopy, all the participants entered a 24-h period of diet that consisted of 4 L of clear fluids with sugar or honey and 90 mL (60 g) of OSP in two 45-mL doses, 5 h apart. Serum phosphate was measured before and after the administration of the laxative.

**RESULTS:** The main demographic data (mean  $\pm$  SD) were: age, 58.9  $\pm$  8.4 years; height, 163.8  $\pm$  8.6 cm; weight, 71  $\pm$  13 kg; body mass index, 26  $\pm$  4; women, 66%. Serum phosphate increased from 3.74  $\pm$  0.56 to 5.58  $\pm$  1.1 mg/dL, which surpassed the normal value (2.5-4.5 mg/dL) in 87% of the patients. The highest serum phosphate was 9.6 mg/dL. Urea and creatinine remained within normal limits. Post-treatment OSP se-

rum phosphate concentration correlated inversely with glomerular filtration rate ( $P < 0.007$ ,  $R^2 = 0.0755$ ), total body water ( $P < 0.001$ ,  $R^2 = 0.156$ ) and weight ( $P < 0.013$ ,  $R^2 = 0.0635$ ).

**CONCLUSION:** In low-risk, well-hydrated patients, the standard dose of OSP-laxative-induced hyperphosphatemia is related to body weight.

Hyperphosphatemia after sodium phosphate laxatives in low risk patients: Prospective study. *World J Gastroenterol* 2009; 15(47): 5960-5965 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5960.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5960>

### INTRODUCTION

The widespread use of colonoscopy for early detection of colorectal pathology has increased the use of osmotic laxatives for colonic cleansing. Among these, oral sodium phosphate (OSP) is the preparation of choice because is the best tolerated given the small volume in which it is administered, and it results in better colonic cleansing<sup>[1]</sup>. Under normal conditions, phosphate is absorbed in the small intestine and eliminated by the kidney as calcium phosphate<sup>[2]</sup>. Several complications associated with the use of OSP have been reported in recent years, especially hyperphosphatemia and acute and chronic renal failure. There is evidence linking these complications to conditions that increase the absorption of phosphate or render its renal elimination difficult. Although many of these complications are facilitated by dehydration and inadequate selection of patients when indicating the laxative<sup>[3-5]</sup>, some patients without such conditions also have been reported<sup>[6]</sup>. Most of the information comes from retrospective studies or case reports.

In this prospective clinical trial, we investigated the

frequency of hyperphosphatemia in low-risk ASA I - II patients<sup>[7]</sup>, who were chosen to avoid high-risk patients. To avoid dehydration, we administered 4 L of clear liquids. The main aim was to identify the percentage of patients with hyperphosphatemia following the administration of OSP for video colonoscopy, and before anesthesia induction. A secondary objective was to establish the frequency of dehydration and hypocalcemia.

## MATERIALS AND METHODS

### Patients and methods

This study was approved by the Institutional Review Board. From May to December 2007, 100 consecutive patients who underwent elective colonoscopy were enrolled. Inclusion criteria were: 18-75 years of age, ASA I and II physical status, written informed consent, and colon cleansing with OSP.

Individuals with congestive heart failure, chronic kidney disease, diabetes, liver cirrhosis, intestinal obstruction, decreased bowel motility, increased bowel permeability (Crohn's disease, ulcerative or ischemic colitis) and hyperparathyroidism were prevented from entering this trial. These conditions were ruled out in the pre-anesthetic evaluation by medical history and anamnesis. Those patients who refused to participate were also excluded. Patients who had not undergone colonic cleansing were also excluded.

All the participants received full information regarding the study protocol and procedures in the pre-anesthetic interview and signed the informed consent to participate. Vital parameters were measured and laboratory tests, including hematocrit, hemoglobin concentration, and serum osmolality, phosphate,  $\text{Ca}^{2+}$ , electrolytes, creatinine and urea were carried out.

Forty-eight hours before the test, a fiber- and dairy-free diet (without fruit and vegetable products) was prescribed, and from 20 to 26 h before the study, 4 L of clear liquids (tea, coffee, infusions, jelly, broth and drained juices, or isotonic drinks<sup>[8]</sup>) with sugar or honey (on demand) were administered up to 2 h before the test.

The day before colonoscopy, all the participants were given 90 mL (60 g) of OSP (fosfo-dom<sup>®</sup>; Laboratorio Dominguez S.A, Buenos Aires, Argentina) diluted in 400 mL of water in two divided doses, administered 5 h apart (17:00 pm and 22:00 pm) on the day before colonoscopy. Ten micrograms metoclopramide were also administered 1 h before the laxative.

The day after colonic cleansing and immediately before starting anesthesia with propofol and sevoflurane, blood pressure and heart rate were measured and a second venous sample was drawn and sent to the laboratory to assess hematocrit, hemoglobin, and serum osmolality, phosphate,  $\text{Ca}^{2+}$ , electrolytes, creatinine and urea. The results obtained were compared with those obtained at baseline.

The following formulas were used to calculate plasma volume, total body water and glomerular filtration rate: Plasma volume (PV) (Beaumont formula)<sup>[9]</sup> %PV:

Table 1 Demographic data (mean  $\pm$  SD)

Male:  $\text{TBW} - \text{W} = 2.447 - (0.09156 \times \text{age}) + (0.1074 \times \text{height}) + (0.3362 \times \text{weight})$ ; Female:  $\text{TBW} - \text{W} = -2.097 + (0.1069 \times \text{height}) + (0.2466 \times \text{weight})$ .

Glomerular filtration rate (GFR; mL/min) (Cockcroft-Gault equation)<sup>[11]</sup>:  $(140 - \text{age}) \times \text{weight kg} (\times 0.85 \text{ if female})/\text{creatinine} \times 72$ .

### Statistical analysis

All data are expressed as mean  $\pm$  SD. The Student *t* test was used to analyze normally distributed variables. A univariate linear correlation model that considered post-treatment OSP serum phosphate as a dependent variable was also performed. STATA<sup>®</sup> version 8.0 (StataCorp LP, <http://www.stata.com>) statistical software was used to carry out the statistical analysis.  $P < 0.05$  was considered as statistically significant.

## RESULTS

The main demographic data (mean  $\pm$  SD) were: age, 58.9  $\pm$  8.4 years; height, 163.8  $\pm$  8.6 cm; weight, 71  $\pm$  13 kg; body mass index (BMI), 26  $\pm$  4; women, 66% (Table 1). The main laboratory data (mean  $\pm$  SD) are shown in Table 2. Serum phosphate (mg/dL; mean  $\pm$  SD) increased from a basal value of 3.74  $\pm$  0.56 to 5.58  $\pm$  1.1 after OSP ( $P = 0.001$ ). Hyperphosphatemia appeared in 87% of the patients. The highest serum phosphate was 9.6 mg/dL. Post-OSP serum phosphate had a significant inverse correlation with GFR ( $P < 0.007$ ,  $R^2 = 0.0755$ , Figure 1A), TBW ( $P < 0.001$ ,  $R^2 = 0.156$ , Figure 1B), and weight ( $P < 0.013$ ,  $R^2 = 0.0635$ , Figure 1C). No correlation was observed between post-OSP serum phosphate and creatinine, height or BMI. The prevalence of hyperphosphatemia increased in parallel and steadily with stage of chronic renal disease according to the National Kidney Foundation classification<sup>[12]</sup>, which approached 80% for stage 1, 88% for stage 2, and 100% for stage 3.

After OSP,  $\text{Ca}^{2+}$  decreased significantly ( $P = 0.001$ ), although the difference was not clinically relevant. Pre- and post-OSP urea and creatinine levels remained within normal limits.

Plasma volume decreased by 3.65% after OSP. This represents a dehydration of  $< 1.46\%$ , which was not

significant<sup>[13,14]</sup>. There was a decrease in serum osmolality (Tables 1 and 2). There was a low incidence (4%) of hypotension (arterial pressure reduction  $\geq 30\%$ ) after colonic cleansing (Table 2).

## DISCUSSION

The osmotic effect of OSP causes dehydration<sup>[15]</sup>, an average loss of 3-4 L of fluids is estimated during colonic cleansing with 60 g OSP<sup>[16,17]</sup>. In support of these data, increases in the concentration of hemoglobin<sup>[18]</sup>, hematocrit and serum osmolality<sup>[15]</sup> have been reported. Several authors have stated that maintaining appropriate hydration is possible to dilute the urine, and reduce its calcium and phosphate concentration<sup>[19,20]</sup>. In consequence, the risk of calcium phosphate crystalluria and precipitation in the renal tubules is diminished<sup>[16,21]</sup>. Sanders *et al*<sup>[18]</sup> have corroborated the efficiency of intravenous hydration (average 2 L) during colonic cleansing for surgery, but this requires a hospital stay and makes ambulatory procedures difficult. Markowitz *et al*<sup>[21]</sup> has suggested that patients must be encouraged to drink eight cups of fluids (1920 mL) and Rex *et al*<sup>[19]</sup> have promoted taking 3.6 L of clear fluids.

Following the 1999 American Society of Anesthesiologists recommendations for all interventions that require general anesthesia or sedation, oral fluid intake is allowed up to 2 h before colonoscopic evaluation<sup>[22]</sup>. The rationale for the preoperative fasting is to reduce the content and acidity of the stomach, thus avoiding the risk of aspiration pneumonitis at induction of anesthesia<sup>[23,24]</sup>.

Since the seminal studies of Beaumont in 1833<sup>[25]</sup>, it is widely known that emptying of clear liquids is passive, without the need for gastric motility, and is completed in  $< 60$  min<sup>[26]</sup>. Clear fluids have a washing and dragging effect that allows the gastric content to move easily

**Figure 1** Correlation among phosphorus post-oral sodium phosphate (OSP) with glomerular filtration rate (GFR), total body water (TBW), and weight. A: Between phosphorus post-OSP and GFR; B: Between phosphorus post-OSP and GFR and TBW; C: Between phosphorus post-OSP and weight.

to the duodenum<sup>[27]</sup>. Patients with 2 h fasting with clear liquids (i.e. no liquid intake for 2 h before colonoscopy) had less volume and gastric acidity than those with complete 8 h fasting<sup>[28-32]</sup>. These results also have been reported in children<sup>[33-36]</sup>.

The absence of fluid intake before surgery favors the development of hypotensive reactions during anesthesia induction, as well as dehydration, hypoglycemia and a strong sensation of thirst and hunger that leads to irritability, especially in older patients and infants<sup>[8,37]</sup>. Clear liquid intake not only diminishes the risk of aspiration pneumonia and notably improves patient wellbeing, but it also facilitates adequate hydration.

To evaluate the changes produced by the administration of OSP, it was vital to avoid dehydration. We encouraged patients to freely take 4 L of clear liquids during colonic preparation, up to 2 h before the test. This did not

lead to a significant incidence of dehydration and hypotension, which was reinforced by no significant modifications in haemoglobin and hematocrit. The average reduction in PV was 3.65%, which represented dehydration of < 1.46%, which was not significant<sup>[13,14]</sup>. Besides, in contrast to Gutierrez Santiago's study<sup>[15]</sup>, we observed a decrease in the average osmolality. Only 4% of the patients developed hypotension, a degree of blood pressure reduction of 20%-30%. These results support the efficiency of this oral hydration regime for avoiding dehydration.

At the onset of our study, the suggested interval between doses was 5-10 h, and we used a 5-h interval. As 28% of the phosphate taken is retained by the body for up to 18 h<sup>[16,38]</sup>, recent studies have recommended longer intervals between doses<sup>[4]</sup>.

The maximum safe dose of sodium phosphate is 90 mL<sup>[39]</sup>. Several studies on the adverse effects of high doses of OSP have suggested that these should be avoided<sup>[2,3]</sup>, as is the case with their association with phosphate enemas<sup>[40-42]</sup>. If the recommended dose of 60 g (90 mL) is surpassed, or if the interval between doses is < 5 h, severe hyperphosphatemia could develop<sup>[2,19,39,43-46]</sup>.

Many authors make reference to the fact that administering laxatives and sodium phosphate enemas<sup>[40,41]</sup> leads to a slight though statistically significant increase in phosphorus and a decrease in calcium concentration<sup>[2,19,21,47-49]</sup>, due to intestinal absorption<sup>[2]</sup>. However, they have also suggested that well-hydrated adults who have normal renal function tolerate the amount of phosphate loading without showing significant adverse effects<sup>[6,4,49-52]</sup>. This trend was confirmed in our study, with a maximum registered plasma phosphate level of 9.6 mmol/L and a minimum calcium level of 0.5 mmol/L.

The serious electrolyte disturbances reported have appeared in patients in whom sodium phosphate was contraindicated: inflammatory colonic diseases (Crohn's disease, ulcerative colitis)<sup>[53,54]</sup>, delayed intestinal transit (megacolon, obstruction), and in conditions with intestinal vascular alteration (congestive heart failure, ischemic colitis)<sup>[49]</sup>. It also has been reported in patients with impaired renal function<sup>[55-57]</sup>, or who receive drugs that affect kidney perfusion (diuretics, angiotensin-converting enzyme inhibitors and angiotensin receptor blockers). To avoid the administration of OSP in the sub-clinical kidney disease, measurement of urea and creatinine is recommended<sup>[43]</sup>. Hyperphosphatemia has been observed in patients with dehydration, ascites<sup>[4]</sup> or vomiting<sup>[45]</sup>.

Fine *et al.*<sup>[57]</sup> have found that the mortality rate was 33%, and that the risk of death was high if serum phosphate increased beyond 32.69 mg/dL (10.56 mmol/L). Most of the deaths reported in the literature have been caused by arrhythmia or heart attack associated with electrolyte changes and dehydration<sup>[4]</sup>. Fatal cases have been observed among patients with a history of renal damage<sup>[41,43,50]</sup>, ischemic colitis<sup>[50]</sup>, cirrhosis<sup>[45]</sup>, and in elderly patients with normal renal function<sup>[42,58]</sup>. Azzam *et al.*<sup>[43]</sup> and Wexner *et al.*<sup>[5]</sup> have described high levels of phosphate and kidney damage in patients without previous kidney pathology.

Gutierrez-Santiago *et al.*<sup>[15]</sup> have found an increase in

phosphatemia in 57% of patients, while Lieberman *et al.*<sup>[51]</sup> have found it in 25%. Both studies were retrospective and they did not specify the patient's clinical condition. In our study in low-risk patients, we found an increase in phosphate in a significant percentage (87%). The average increase of serum phosphate was 1.84 mg/dL, which was less than that reported by Tan *et al.*<sup>[59]</sup> (3.09-3.18 mg/dL). The maximum plasma phosphate value registered was 9.6 mg/dL (3.1 mmol/L), which was twice the normal concentration. This result shows that OSP used as laxative is not free of complications, even in low-risk patients. These values do catch our attention because the careful selection of patients anticipated a much lower incidence. It is possible to assume that the wide hydration plan and careful selection of participants avoided reaching the values described by Fine *et al.*<sup>[57]</sup>.

All of the patients had normal urea and creatinine values before and after colonic cleansing. We linked the phosphate values with the TBW and GFR, and both showed a negative linear correlation with the increase in phosphate. We observed that the lower the GFR and TBW, the higher the chance of developing hyperphosphatemia. These parameters describe the relationship of weight with a specific function, which shows that the increase in phosphatemia has a negative linear correlation with weight. We avoided dehydration and there was no renal impairment, therefore, these findings contribute towards the concept that hyperphosphatemia is the result of an excessive dose of laxative, as suggested by Rex *et al.*<sup>[4]</sup>.

Tan *et al.*<sup>[2]</sup> have stated that the decrease in plasma calcium associated with OSP-induced hyperphosphatemia is the result of the binding of calcium to the high phosphate level, and thus, the tubular deposition that induces kidney damage. Gutierrez-Santiago *et al.*<sup>[15]</sup> have observed hypocalcemia in 36% of patients. In our study, the decrease in calcium concentration developed in 29% of the patients, but none had symptoms related to hypocalcemia.

The reported OPS-induced hypernatremia is the result of intestinal sodium absorption and can worsen due to dehydration<sup>[2,15]</sup>. We did not observe an increase of plasma sodium in our patients, which suggests that the hydration level achieved with this diet was appropriate.

The sodium and potassium exchange across the colonic epithelium can generate hypokalemia, which is accentuated by renal potassium loss induced as a consequence of the volume contraction-associated secondary aldosteronism<sup>[2,15]</sup>. The decrease in potassium in our sample coincided with that observed by Rex *et al.*<sup>[4]</sup>. It appeared in 4% of the patients and reached 2.4 mmol/L in one case.

Unlike previous studies by other investigators, we did not observe changes in plasma chloride values in our patients<sup>[4]</sup>.

The results in this study show that, in low-risk, well-hydrated patients, hyperphosphatemia following standard OSP doses is related to weight. This is the reason why we believe that, in low-weight patients, lower doses of the laxative should be administered. We consider that further studies are necessary to establish the adequate dose according to weight.

Oral hydration with 4 L of clear liquids during colonic preparation has proven its efficacy in avoiding dehydration.

The possibility of achieving high phosphate levels in low-risk, well-hydrated patients is certainly alarming, especially given the fact that few medical professionals currently take this possibility into account. These discoveries emphasize the need to carry out an adequate hydration and selection of patients to avoid administration of OSP to those individuals at risk of developing hyperphosphatemia or renal failure.

## COMMENTS

### Background

Colon cleansing is used widely for colonoscopic exploration and colonic and gynecological surgery. Oral sodium phosphate (OSP) solution is the osmotic laxative most commonly used for this purpose. It is known that OSP can induce severe hyperphosphatemia and hypocalcemia due to excessive absorption of phosphates, and there have been reports of deaths and irreversible dialysis-requiring renal insufficiency.

### Research frontiers

Hyperphosphatemia after OSP develops in patients with conditions that increase its intestinal absorption (ulcerative colitis, Crohn's disease, ischemic colitis), in conditions in which its elimination is difficult (kidney disease, dehydration, aging), or after OSP overdose (> 60 g). These findings have come from case reports and some rare retrospective studies. No prospective studies have investigated the prevalence of hyperphosphatemia in low-risk patients.

### Innovations and breakthroughs

This was a prospective study that was carried out in low-risk patients. Even though, the authors avoided the conditions that are known to facilitate hyperphosphatemia such as dehydration (inducing oral intake of 4 L of clear liquids) and the diseases described above, 87% of the patients had high serum phosphate levels. None of them developed symptoms of hypocalcemia, and there was no evidence of renal impairment. Hyperphosphatemia was related inversely to body weight. These results highlight the importance of being cautious with the administration of OSP in patients with contraindications and promoting aggressive oral hydration.

### Applications

Taking into account the results of this study, the authors recommend: performing preoperative evaluation aimed at avoiding administration of OSP laxatives to patients at risk; reducing the dose of OSP in patients with low weight; and avoiding dehydration with an adequate oral intake of clear liquids. Additional studies are necessary to establish the appropriate dose adjusted to body weight.

### Terminology

Hyperphosphatemia: serum phosphate levels above normal (2.5-4.5 mg/dL). Hypocalcemia: ionized calcium levels below normal values (1.0-1.35 mmol/L).

### Peer review

This paper presented provides reliable information on the side effects of OSP in low-risk patients. The conclusions addressed are useful for managing patients' prescribed OSP for colon cleansing.

Carcinoma of the middle bile duct: Is bile duct segmental resection appropriate? *World J Gastroenterol* 2009; 15(47): 5966-5971 Available from: URL: <http://www.wjgnet.com/1007-9327/15/5966.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.5966>

### Abstract

**AIM:** To compare survival between bile duct segmental resection (BDSR) and pancreaticoduodenectomy (PD) for treating distal bile duct cancers.

**METHODS:** Retrospective analysis was conducted for 45 patients in a BDSR group and for 149 patients in a PD group.

**RESULTS:** The T-stage ( $P < 0.001$ ), lymph node invasion ( $P = 0.010$ ) and tumor differentiation ( $P = 0.005$ ) were significant prognostic factors in the BDSR group. The 3- and 5-year overall survival rates for the BDSR group and PD group were 51.7% and 36.6%, respectively and 46.0% and 38.1%, respectively ( $P = 0.099$ ). The BDSR group and PD group did not show any significant difference in survival when this was adjusted for the TNM stage. The 3- and 5-year survival rates were: stage I a [BDSR (100.0% and 100.0%) vs PD (76.9% and 68.4%) ( $P = 0.226$ )]; stage I b [BDSR (55.8% and 32.6%) vs PD (59.3% and 59.3%) ( $P = 0.942$ )]; stage II b [BDSR (19.2% and 19.2%) vs PD (31.9% and 14.2%) ( $P = 0.669$ )].

**CONCLUSION:** BDSR can be justified as an alternative radical operation for patients with middle bile duct in

### INTRODUCTION

Extrahepatic bile duct cancer can be classified into hilar, proximal, middle and distal bile duct cancer (DBD) according to the portion of the involved bile duct. Hilar and proximal bile duct cancers (PBD-1) are classified into 5 types as described by Bismuth and Corlette<sup>[1]</sup>. This classification of extrahepatic bile duct cancers is due to the differences in the operative methods that are employed for cancers involving different portions of the bile duct. According to numerous reports, most surgeons consider bile duct resection with liver parenchyma resection to be the standard operation for hilar cholangiocarcinoma<sup>[2-4]</sup>. Pancreaticoduodenectomy (PD) is performed for DBD. Bile duct cancers confined to the middle bile duct (MBD) are rare because bile duct cancers have a tendency to spread along the bile duct wall. This is the reason why PD is usually undertaken for treating most MBD cancers. Yet there is still debate as to the appropriate operative procedure for the bile duct cancers that do not extend above the confluence or below the upper border of the pancreas. PD or bile duct segmental resection (BDSR) is performed at the surgeon's discretion. Clinicopathological studies on hilar and distal cholangiocarcinomas have been done by many authors<sup>[2-11]</sup>, and the results of BDSR for MBD have

been reported, but most of these studies involved a very limited number of cases, and the number of cases is not enough to justify BDSR as a standard treatment.

In the current study, a clinical review of patients who received BDSR (negative resection margins) with lymph node (LN) dissection for the Bismuth type I PBD-1 and also the patients with MBD was performed. We compared survival between BDSR group and PD for treating DBD.

## MATERIALS AND METHODS

Between November 1995 and May 2007, 379 patients underwent surgical procedures that were performed for treating extrahepatic cholangiocarcinomas at Samsung Medical Center. One hundred nine patients who underwent concomitant liver resection and 76 patients who underwent palliative procedures were excluded, and only the cases with bile duct adenocarcinomas that had been confirmed by pathologic assessment were included. There were 45 patients who underwent BDSR for PBD-1 or MBD (BDSR group), and 149 patients who underwent PD for DBD (PD group). A retrospective analysis was performed *via* a review of the medical records and by conducting telephone interviews. The clinicopathologic factors of the BDSR group that we analyzed were age, gender, the preoperative carbohydrate antigen 19-9 (CA19-9) level, serum bilirubin levels both at the time of admission and prior to surgery, preoperative biliary drainage, transfusion, the site of cancer, the extent of LN dissection [D1 (LN #12) or D2 (LN #12, #8, #13)], tumor size, histologic differentiation, TNM stage, LN metastasis and perineural invasion. To find the exact location of the tumor, ERCP or PTC and recently MRCP was done before surgery. Before surgery, biliary and GB CT scans were performed to see if there was invasion to adjacent tissues or organs. Angiography was used to detect any evidence of vascular invasion, but after 1999, we used the CT scan to rule out any vascular invasion. In the BDSR group, all patients underwent frozen section for both bile duct resection margins and to be confirmed as free from carcinoma intraoperatively and on permanent pathology. The tumor stage was based on the 6th edition of the American Joint Committee on Cancer cancer staging<sup>12</sup>. All patients were monitored at 6 mo intervals by measuring CA19-9 levels and performing a CT scan for 3 years and were checked annually at 6 mo intervals. Four patients (8.8%) in the BDSR group were lost to follow up.

### Statistical analysis

Survival of the BDSR and the PD groups was calculated by the Kaplan-Meier method, and the log-rank test was used to analyze differences. Only variables that were statistically significant on univariate analysis were included in the multivariate analysis, which was performed using a Cox proportional hazard regression model. Survival analysis of the PD group was done by the Kaplan-Meier method and comparison of survival between the BDSR group and the PD group was done by log-rank tests.  $\chi^2$  tests and a Mann-Whitney *U*-test were used for comparing

the postoperative complications and the length of the hospital stay between the 2 groups. *P* values less than 0.05 were considered statistically significant.

## RESULTS

### Clinical characteristics of the groups of patients who underwent BDSR for PBD-1 and MBD

Clinical characteristics of the groups of patients who underwent BDSR for PBD-1 and MBD are shown in Table 1. There were 45 patients who underwent BDSR for PBD-1 or MBD. There were 30 (66.7%) males and 15 (33.3%) females. The median age of the patients was 65 years (range: 37-76 years). BDSR with LN dissection and hepaticojejunostomy was done for all these patients, with negative proximal and distal bile duct resection margins being achieved in all 45 patients. The complications arising during the immediate postoperative period (within 1 mo) were analyzed. There were 9 patients with wound infections, pancreatitis, bile leakage and delayed gastric emptying. Dissection of the superior border of the pancreas was done due to the close distal resection margin in all 3 patients who showed postoperative pancreatitis. Of 45 patients, D2 LN dissection (LN #12, #8, #13) was done in 37 (82.2%) patients and D1 dissection (LN #12) was done in 8 (17.8%) patients. LN metastasis was present in 13 (28.8%) patients and perineural invasion was present in 32 (71.1%) patients. Nine (20%) patients had T1 lesions, 33 (73.3%) patients had T2 lesions and 3 (6.7%) patients had T3 lesions with invasion into the gallbladder without liver or pancreas invasion. Nine (20%) patients were stage I a (T1N0M0), 23 (51.1%) patients were stage I b (T2N0M0), and 13 (28.9%) patients were stage II b (T1-3N1M0). There were no stage II a (T3N0M0) patients. The median follow-up period was 25 mo (range: 4-104 mo) (Table 1).

Among the 45 patients, 3 patients (6.6%) underwent additional adjuvant treatment. Two patients with stage I b each had chemoradiation and radiation. One patient with stage II b had chemoradiation. There was no evidence of recurrence in all three patients. The recurrence rate was 44.4% ( $n = 20$ ). The stage specific recurrence rate was as follows: 24.4% ( $n = 11$ ) for stage I b and 20.0% ( $n = 9$ ) for stage II b. There were 12 locoregional recurrences, 5 liver metastases and 3 peritoneal carcinomatoses. Eleven patients underwent palliative treatment and 9 patients refused to go under extra treatment. The 3- and 5-year survival rates of the BDSR group were 51.7% and 36.6%, respectively. The median survival was 25 mo (mean: 31.27 mo). Univariate analysis showed cellular differentiation ( $P = 0.005$ ), the T stage ( $P < 0.001$ ), the LN status ( $P = 0.010$ ) and the TNM stage ( $P = 0.012$ ) to be significant factors that influenced patient survival (Table 1, Figure 1). However, there were no statistically significant independent risk factors that influenced patient survival on multivariate analysis.

### Comparison of survival between the BDSR group and the PD group

There were 149 patients in the PD group. There were

recurrences and 78 (52.3%) patients died of cancer-related causes. The survival of the BDSR group was compared with the group of patients who underwent PD for their DBD; these patients are known to have similar clinical characteristics as patients with PBD-1 or MBD (Table 2). The survival rate, postoperative complications and length of the postoperative hospital stay were the factors analyzed. The 3- and 5-year overall survival rates were 51.7% and 36.6% in the BDSR group, and 46.0% and 38.1% in the PD group (*P* = 0.099) (Figure 2A). The stage specific survival rates were compared between the BDSR group and the PD group. The 3-year and 5-year survival rates of the patients with stage I a disease were 100.0% and 100.0%, respectively, in the BDSR group, and 76.9% and 68.4%, respectively, in the PD group (*P* = 0.226) (Figure 2B). The 3-year and 5-year survival rates of the patients with stage I b disease were 55.8% and 32.6%, respectively, in the BDSR group, and 59.3% and 59.3%,

**Figure 2 Comparison of survival between the BDSR group and the pancreaticoduodenectomy (PD) group.** A: The 3-year and 5-year overall survival rates were 51.7% and 36.6%, respectively, for the BDSR group and 46.0% and 38.1%, respectively, for the PD group; B: The 3-year and 5-year survival rates of the patients with stage I a disease were 100.0% and 100.0%, respectively, for the BDSR group and 76.9% and 68.4%, respectively, for the PD group; C: The 3-year and 5-year survival rates of the patients with stage I b disease were 55.8% and 32.6%, respectively, for the BDSR group and 59.3% and 59.3%, respectively, for the PD group; D: The 3-year and 5-year survival of patients with stage II b disease were 19.2% and 19.2%, respectively, for the BDSR group and 31.9% and 14.2%, respectively, for the PD group.

respectively, in the PD group ( $P = 0.942$ ) (Figure 2C). The 3-year and 5-year survival rates of patients with stage II b disease were 19.2% and 19.2%, respectively, in the BDSR group, and 31.9% and 14.2%, respectively, in the PD group ( $P = 0.669$ ) (Figure 2D). Therefore, the BDSR group and the PD group did not show any significant difference in survival when this was adjusted for the TNM stage. Sixty one (40.9%) patients in the PD group experienced postoperative complications (pancreatic fistula, bleeding, delayed gastric emptying, wound infection, intraabdominal abscess, *etc.*). There were significantly less postoperative complications in the BDSR group (20.0% *vs* 40.9%, respectively,  $P = 0.01$ ). The length of the postoperative hospital stay was significantly shorter in the BDSR group (mean: 16.62 d *vs* 28.35 d, respectively,  $P = 0.035$ ).

## DISCUSSION

Classification of extrahepatic cholangiocarcinoma according to its anatomic location (proximal, middle, distal) was first proposed by Longmire<sup>[13]</sup> in 1976. There still exists some debate about the classification of MBD carcinoma since cholangiocarcinomas are very rarely located only in this section of the bile duct without infiltration into the proximal or distal bile duct. So there have been other classifications of the cholangiocarcinomas such as

that proposed by Nakeeb *et al.*<sup>[14]</sup> which results in a simpler classification of intrahepatic, hilar and distal cholangiocarcinoma. Jarnagin *et al.*<sup>[15]</sup> also proposed a 2-category system of proximal and distal bile duct cancer, with MBD cancer being in a separate category. Such interest in the classification of cholangiocarcinomas is due to the difference in surgical treatment according the different anatomic locations. Intrahepatic and perihilar cholangiocarcinomas are usually treated by liver resection<sup>[16-18]</sup>. In contrast, distal cholangiocarcinoma requires PD for complete tumor resection. Then what about tumors confined to the MBD? Different surgical treatments are possible for MBD cancers according to the distance between the hilum or the upper border of the pancreas, and also according to the experience and preference of the surgeon. For tumors with negative bile duct margins and no infiltration into vascular structures, BDSR is sometimes undertaken, albeit for only a small proportion of these tumors.

The most important issues for BDSR for PBD-1 or MBD is the radial margin, involvement of the portal vein or hepatic artery and LN dissection<sup>[10]</sup>. T1 and T2 tumors, and T3 tumors with infiltration only into the gallbladder and without vascular invasion, were included in this study. T3 or T4 tumors with vascular, liver or pancreas invasion require extended surgery due to the fact that R0 resection is impossible with BDSR in these

cases. Sufficient radical dissection of the LNs, and especially the LNs around the superior mesenteric artery (SMA), may be another issue. According to the general rules for surgical and pathological studies on cancer of the biliary tract by the Japanese Society of Biliary Surgery, in the case of PBD-1 LNs #12 (a1, a2, b1, b2, c, p1, p2, h) are classified as group 1 and LNs #8 (a, p) and #13 are classified as group 2. For MBD, LNs #12 (b1, b2, c) are classified as group 1 and LNs #12 (a1, a2, c, p1, p2, h), #8 (a, p) and #13 (1) are classified as group 2. Since the LNs around the SMA and #17 are classified as group 3, radical resection LN dissection (D2) is possible with BDSR.

There have been occasional reports of BDSR for treating extrahepatic cholangiocarcinoma in selected patients<sup>[7,8,19-22]</sup>. In the series from the Memorial Sloan Kettering Cancer Center<sup>[7]</sup>, only 13% of patients (6 of 45) were amenable to bile duct excision alone, while this figure was 8% (3 of 34) in the Veterans Hospital study<sup>[22]</sup>. But in most of these reports, risk factor evaluation was not possible due to the limited number of BDSR cases. In this study, 28.8% of the cases had LN metastases, and the LN status was a significant risk factor that affected survival. Furthermore, the cell differentiation, the T stage and the TNM stage were significant factors that affected the outcomes. It has been reported that the frequency of LN metastasis in DBD ranged from 30% to 68%<sup>[7,8,11,14,20,23]</sup>, and negative LN metastasis was a useful predictor of a favorable outcome for patients with DBD<sup>[7,8,14,23]</sup>. However, perineural invasion did not prove to be statistically significant, unlike the other studies that reported the risk factors for survival from cholangiocarcinoma in other parts of the biliary tree<sup>[24,25]</sup>.

In the present study, 3 patients underwent BDSR due to the lesion being close to the upper border of pancreas. All 3 patients developed postoperative pancreatitis. Two of these patients developed local recurrence in the remnant distal bile duct at 9 mo and 31 mo, respectively. Although the 2 cases mentioned were categorized as recurrences, they could also have been considered remnant bile duct cancer when the slow-growth of cholangiocarcinoma was taken into account. For a tumor that is close to the upper border of pancreas and resected bile margin reveals to be free of carcinoma, PD should be considered as a treatment option since the pattern of tumor spread along the periductal tissue can be assumed and it should secure sufficient distal bile duct resection margin.

A comparison of survival would be most accurate between 2 groups that received BDSR or PD for carcinoma confined to the proximal or MBD. But this was not feasible due to the small number of patients included in this category. So a different approach was selected in this study, and comparisons were made with the group of patients who received PD for DBD, which is known to have similar clinical characteristics with its proximal counterparts. Although several authors have reported that MBD had a worse prognosis than hilar or distal bile duct cancer<sup>[26-28]</sup>, other authors did not concur<sup>[8,29]</sup>. According to previous reports, the curative resection rates for DBD

have ranged from 56% to 100%<sup>[7,8,14,19-22]</sup>. However, the 5-year survival rate for DBD is not always high, with some reports showing a range of 14%-47%<sup>[7,8,11,14,19-23]</sup>. In the present study, the overall 3-year and 5-year survival rates of the BDSR group were 51.7% and 36.6%, respectively, which is similar to other published reports<sup>[7,8,11,14,19-23]</sup>. The stage specific overall survival between BDSR group and PD group was not statistically significant. The BDSR group had a significantly shorter postoperative length of hospital stay and fewer complications compared to the PD group. This comparison may not be so meaningful when taking into consideration that BDSR is a far less extensive and complicated operative method (fewer anastomoses). Thus, BDSR can be safely applied to patients with bile duct resection margin negative PBD-1 or MBD tumor rather than performing more extensive surgery such as PD.

In conclusion, to achieve a cure, the surgeon must obtain histologically negative margins on both the proximal and distal bile ducts and all tumor-bearing nodal tissue must be removed. BDSR with LN dissection can be an alternative treatment and may be justified in preference to a more radical operation for patients with PBD-1 or MBD when there is no pancreas, liver, vascular invasion and the both bile duct resection margins are negative.

## COMMENTS

### Background

Although radical bile duct segmental resection (BDSR) is performed by many surgeons in selected cases, there are scant clinical studies on the adequacy of this procedure.

### Research frontiers

To validate the adequacy of radical BDSR, the authors compared survival between a radical BDSR group and a pancreaticoduodenectomy group for treating distal bile duct cancers.

### Innovations and breakthroughs

Clinicopathological studies on hilar and distal cholangiocarcinomas have been done by many authors, and the results of BDSR for middle bile duct (MBD) have been reported, but most of these studies involved a very limited number of cases, and the number of cases is not enough to justify BDSR as a standard treatment.

### Applications

The surgeon must obtain histologically negative margins on both the proximal and distal bile ducts and all tumor-bearing nodal tissue must be removed. BDSR with lymph node dissection can be an alternative treatment and may be justified in preference to a more radical operation for patients with MBD.

### Peer review

Even if it is a retrospective study, the data reported are interesting and well documented.

### Abstract

**AIM:** To assess the safety, yield and clinical utility of percutaneous transgastric computed tomography (CT)-guided biopsy of pancreatic tumor using large needles, in selected patients.

**METHODS:** We reviewed 34 CT-guided biopsies in patients with pancreas mass, of whom 24 (71%) had a direct path to the mass without passing through a major organ. The needle passed through the liver in one case (3%). Nine passes (26%) were made through the stomach. These nine transgastric biopsies which used a coaxial technique (i.e. a 17-gauge coaxial introducer needle and an 18-gauge biopsy needle) were the basis of this study. Immediate and late follow-up CT images to detect complications were obtained.

**RESULTS:** Tumor tissues were obtained in nine pancreatic biopsies, and histologic specimens for diagnosis were obtained in all cases. One patient, who had a rare sarcomatoid carcinoma, received a second biopsy. One patient had a complication of transient pneumoperitoneum but no subjective complaints. An immediate imaging study and clinical follow-up detected neither hemorrhage nor peritonitis. No delayed procedure-related complication was seen during the survival period of our patients.

### INTRODUCTION

The diagnosis of a pancreatic mass detected by abdominal imaging can be difficult, and therapeutic decisions are based on the ability to diagnose or exclude malignancy<sup>[1]</sup>. Although most neoplasms are ductal adenocarcinomas, imaging modalities can not reliably be used to diagnose other malignant or benign conditions which may have different treatment options and prognoses<sup>[2]</sup>. Therefore, tissue diagnosis is often needed before surgery.

Computed tomography (CT)-guided biopsy for tissue diagnosis is well established<sup>[3-5]</sup>. In a prospective analysis of 125 procedures, CT-directed biopsy for pancreatic lesions had an accuracy of 95.2%<sup>[3]</sup>. An occasional limitation of the axial CT guidance of such interventional procedures is the presence of intervening vital structures which cannot be avoided even by using a gantry tilt technique<sup>[4]</sup>. Brandt *et al*<sup>[5]</sup> stated that there were no complications with fine, 21-gauge needle passage through the gastrointestinal tract. Fine needle biopsy for pancreatic lesions had an accuracy of 85%, whereas a large needle (16-19 gauge) had an accuracy of 92%<sup>[5]</sup>. Therefore, in daily practice, large needle biopsy could reduce the repeat biopsy rate. One experimental study in rabbits reported that the transgastric route with an 18-gauge cutting needle could

be used for pancreas biopsy, without apparent peritonitis or bleeding<sup>[6]</sup>. However, only a few studies have reported on the technique of large needle, transgastric-route biopsy of pancreatic lesions in humans<sup>[7,8]</sup>.

Since the initial description in 1992, tissue diagnosis under endoscopic ultrasonography (EUS) guidance has emerged as an important modality for evaluating patients with pancreatic lesions<sup>[9-11]</sup>. EUS-guided trucut needle biopsy using a 19-gauge needle, performed through the patient's stomach, is safe and accurate<sup>[11]</sup>. This procedure, however, is limited to selected patients who are willing to undergo endoscopy. Therefore, a transgastric approach using a large needle for CT-guided biopsy of the pancreatic lesion can be an alternative method of choice.

The aim of the present study was to assess the safety, yield, and clinical utility of percutaneous transgastric CT-guided biopsy in patients with pancreatic masses.

## MATERIALS AND METHODS

We reviewed the medical records of 34 consecutive CT-guided biopsies of a solid pancreatic mass from one institution (Taipei Veterans General Hospital, Taipei, Taiwan) over a 4-year period. All the patients were unwilling or failed to undergo EUS-guided biopsy. The indication for biopsy of these pancreatic masses was to obtain a diagnosis of malignancy from tissue before the patients received adjuvant chemotherapy or radiotherapy. Those patients with a resectable mass and scheduled for surgery were not included.

We analyzed the records of these biopsy procedures, and 24 had a direct path to the mass which did not pass through a major organ (71%). In one case (3%), the needle passed through the liver. Nine passes (26%) in eight patients were made through the stomach. These nine CT-guided biopsies performed with a transgastric approach were the basis of this study. The patients were one woman and seven men, with an average age of 65 years (range, 35-78 years).

Magnetic resonance imaging (MRI) or CT images before biopsy were reviewed by two experienced radiologists in a joint meeting, and the interpretation reached consensus. The proper pass route and the biopsy site were evaluated (Figure 1A). All patients were hospitalized and fasted overnight before the procedure. Biopsies were monitored with the patient in the supine position and performed on a CT scanner (Siemens, Germany). The reference scan was obtained first, and an opaque marker placed on the patient's abdomen (Figure 1B). The opaque marker consisted of several parallel segments of angiographic catheter. On the reference image, the accessible pass route and the distance were measured. The coaxial technique was applied with a 17-gauge coaxial introducer needle (Allegiance Health Corporation, McGaw Park, IL, USA) and an 18-gauge Temno biopsy needle (Allegiance Health Corporation, McGaw Park, IL, USA). The coaxial introducer needle penetrated the stomach wall as perpendicularly as possible, with its tip stopped on the edge of the target lesion (Figure 1C). Two to four strips of tissue were obtained in each procedure (Figure 1D).

An immediate follow-up CT image was obtained in all patients to detect possible complications. After each procedure, fasting was not necessary if there were no abnormal findings in follow-up CT images or complaints by the patients. All patients were observed in hospital until their condition was stable. Any delayed procedure-related complication was recorded on the patient's chart and by follow-up images.

## RESULTS

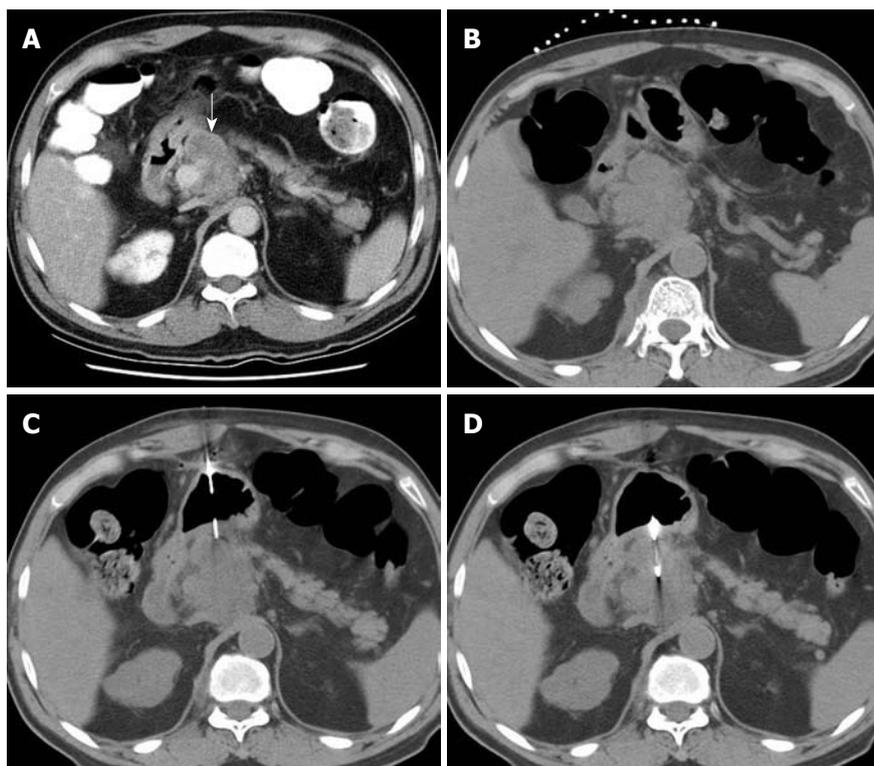

Table 1 shows basic data on our patients who underwent CT-guided transgastric biopsy. Nine biopsies of eight pancreas masses were successfully performed. The tumor sizes ranged from 20 to 75 mm (mean 48.5 mm). The tumor locations were the pancreatic body (62%) and pancreatic head (38%). Histologic diagnoses were obtained in all nine biopsies. There were five adenocarcinomas, one squamous cell carcinoma, one poorly differentiated carcinoma, and one sarcomatoid carcinoma. Because sarcomatoid carcinoma in the pancreas is very rare, our initial biopsy specimen was classified as atypical cells. A second biopsy of the same mass was then obtained and the specimen showed similar histologic findings. Our pathologist then revised the report as a sarcomatoid carcinoma.

One patient had transient, minimal pneumoperitoneum, but no abdominal pain or peritoneal signs were noted. The condition resolved after the patient fasted for 1 d, and was confirmed by an erect chest film. No patient had internal hemorrhage or peritonitis, confirmed by imaging study or during clinical follow-up. There were no late complications, such as tumor spread, in the follow-up images in our patients who had a survival of 1 to 19 mo.

## DISCUSSION

In this study, percutaneous puncture of a pancreatic mass was restricted to patients having advanced disease and who were not candidates for laparotomy. Histologic diagnosis was required in all patients scheduled for chemotherapy, radiotherapy, or both. Ihse *et al*<sup>[12]</sup> suggested that biopsy is not mandatory if the clinical suspicion of cancer is high and the surgical team has documented low postoperative mortality and morbidity rates.

Although percutaneous fine needle aspiration biopsy is well established in evaluating pancreatic masses<sup>[6]</sup>, this technique requires experienced cytopathologists for tissue diagnosis. The amount of aspirated material is often suboptimal for multiple histopathologic examination or certain analyses required to detect endocrine tumors of the pancreas<sup>[13]</sup>. Recently, Li *et al*<sup>[8]</sup> reported a successful diagnosis in 69 of 80 patients (86%) suspected of having pancreatic lesions using an 18-20-gauge cutting needle automated biopsy gun, with no serious complications. In our study, pancreatic biopsies were performed with an 18-gauge biopsy gun. A final histological diagnosis from pancreatic masses can be obtained with this method. In contrast, a correct diagnosis from percutaneous fine needle aspiration with limited tissue specimen may be difficult.

**Figure 1** A 67-year-old man with a pancreatic mass who had no safe route for approaching the target lesion during biopsy. A: Contrast-enhanced axial computed tomography (CT) scan shows a mass lesion (white arrow) in the pancreatic head; B: The patient was in the supine position, with opaque catheters placed on the abdominal wall as reference lines; C: Noncontrast CT image shows a 17-gauge coaxial introducer needle perpendicularly penetrating the gastric wall and the needle tip positioned at the edge of the target lesion; D: Noncontrast CT image shows an 18-gauge biopsy needle tip in the pancreatic mass.

<sup>1</sup>Greatest diameter; <sup>2</sup>Biopsy was performed twice. TP: Transient pneumoperitoneum; M: Male; F: Female; CT: Computed tomography.

In our study, we found that 29% of consecutive biopsies had no direct route for approaching the pancreatic mass without passing through a major organ. Nine passes were made through the stomach and one through the liver. The incidence of an indirect biopsy route was lower than that of previous CT-guided biopsies (40%) and higher than that of ultrasound-guided biopsies (24%)<sup>[5]</sup>. It is generally accepted and has been clinically proved that, for pancreas biopsy, a fine needle crossing the gastrointestinal tract, rather than through the liver<sup>[5]</sup>, is safe and will not result in complications<sup>[5]</sup>. One experimental study in rabbits reported that the transgastric route with an 18-gauge cutting needle could be used without apparent peritonitis and bleeding<sup>[6]</sup>. The EUS-guided trucut needle (19-gauge) biopsy of the pancreas, all performed transgastrically, has been claimed to be safe and accurate<sup>[11]</sup> in selected patients who agreed to undergo endoscopy.

The biopsy-related complication rate using fine needle is low (0.5% to 3%) and acute pancreatitis is the most frequent complication<sup>[14,15]</sup>. Zech *et al*<sup>[7]</sup> reported only one complication in 57 patients who developed acute

pancreatitis after a large core-needle biopsy of the pancreas. In the present study, all nine transgastric biopsies which penetrated both the anterior and posterior stomach walls were performed with 17-gauge coaxial transducer needles and then an 18-gauge biopsy gun. There were no immediate complications such as peritonitis or bleeding. One patient had transient pneumoperitoneum, which resolved after overnight fasting. Late complications, including tumor spread, were not found in follow-up images. However, our study was limited by a relatively short period of follow-up during the survival period of our patients.

The hole made by a gastrostomy catheter is larger than that caused by a biopsy needle. Some authors have reported no untoward effects after the removal of a 10 or 14 French catheter used for percutaneous gastrostomy<sup>[16]</sup>. The muscular layers run in three directions- oblique, circular and longitudinal- from the inner to the outer stomach wall. This arrangement is considered to be the reason why the stomach wall can be punctured without peritoneal leakage<sup>[17]</sup>.

In our study, the stomach was usually empty and

partly collapsed after overnight fasting. It is much more difficult to penetrate the stomach wall when it is “flaccid”. There are two tricks to piercing the stomach wall. The first is to keep the biopsy needle as perpendicular as possible to the gastric wall. If the biopsy needle was tangential, it would slide over rather than penetrate the gastric wall. The second is to advance the needle forcibly and quickly when penetrating the gastric wall. If the needle was advanced slowly, it would tent the gastric wall rather than piercing it. If the stomach wall is tented and can not be punctured, the needle should be withdrawn a little and then advanced again.

We conclude that percutaneous transgastric biopsy of the pancreas in selected patients with a combination of a 17-gauge introducer needle and an 18-gauge biopsy gun can be safe and has a high successful rate.

## COMMENTS

### Background

It is reasonable to obtain a histological diagnosis before treating patients who have pancreatic masses and are unsuitable or unwilling to undergo surgery. As the pancreas is a deep seated organ surrounded by other vital structures, it is a challenge for the physician to obtain an adequate specimen for histological examination. Endoscopic ultrasound-guided biopsy of pancreatic masses has been proved to be a safe and effective method. However, if the hospital has no such facilities or patients are unwilling or intolerant of the procedure, computed tomography (CT)-guided biopsy is an alternative method. In some cases, penetration of other vital organs is unavoidable when approaching the pancreatic mass. In this article, the authors clarified the safety and efficacy of percutaneous transgastric biopsy of pancreatic masses.

### Research frontiers

The stomach has three muscle layers and can be punctured without evidence of leakage. Percutaneous gastrostomy, either by endoscopy or fluoroscopy guidance, has been widely performed for a long time. Although only the anterior wall is punctured during gastrostomy and a catheter is put in place to block the hole, the authors think it would be safe to pierce both the anterior and posterior wall of the stomach using a large biopsy needle. An experimental study in rabbits also showed that it was safe to perform transgastric biopsy.

### Innovations and breakthroughs

Eight patients received 9 CT-guided transgastric biopsies of pancreatic masses located at the pancreas head or body without passing through vital organs. All procedures went smoothly. Only one patient had transient pneumoperitoneum which completely resolved the next day. Although this is a small series, their study shows that it is feasible to perform transgastric biopsy of a pancreatic lesion using a large needle.

### Applications

Besides pancreatic lesions, there are other types of pathology in the upper abdomen, such as enlarged lymph nodes or loculated fluid. Transgastric biopsy of lymph nodes or aspiration or drainage of fluid could be performed safely.

### Terminology

CT-guided biopsy uses CT scanning to perform a biopsy. When facing a deep seated lesion, or lesion blocked by gas, such as a lung nodule, CT scanning can provide better resolution and clearly shows the biopsy needle reaching the target.

### Peer review

As the authors stated in the introduction of the manuscript, endoscopic

ultrasonography guided biopsy of the pancreas is the gold standard to obtain sample tissue for histological diagnosis of pancreatic mass. Percutaneous transgastric CT-guided biopsy for patients with pancreatic mass should be considered an alternative.

### Abstract

**AIM:** To understand the clinicopathological characteristics and treatment selections and improve survival and provide valuable information for patients with intrahepatic cholangiocarcinoma (ICC).

**METHODS:** We retrospectively evaluated 5311 liver cancer patients who received resection between October 1999 and December 2003. Of these, 429 (8.1%) patients were diagnosed with ICC, and their clinicopathological, surgical, and survival characteristics were analyzed.

**RESULTS:** Upper abdominal discomfort or pain (65.0%), no symptoms (12.1%), and hypodynamia (8.2%) were the major causes for medical attention. Laboratory tests showed 198 (46.4%) patients were HBsAg positive, 90 (21.3%) had  $\alpha$ -fetoprotein > 20  $\mu$ g/L, 50 (11.9%) carcinoembryonic antigen > 10  $\mu$ g/L, and 242 (57.5%) carbohydrate antigen 19-9 (CA19-9) > 37 U/mL. Survival data was available for 329 (76.7%) patients and their mean survival time was 12.4 mo. The overall survival of the patients with R0, R1 resection and punching exploration were 18.3, 6.6 and 5.6 mo, respectively. Additionally, CA19-9 > 37 U/mL was associated with lymph node metastases, but inversely associated with

### INTRODUCTION

Patients with intrahepatic cholangiocarcinoma (ICC) are typically at an advanced pathological stage at the time of diagnosis, and are therefore associated with very poor prognosis. The incidence of ICC is increasing worldwide. The cause for this increase remains unknown and may be related to predisposing genetic and environmental factors<sup>[1,2]</sup>. The incidence rate of ICC is approximately 0.5-2.0/100 000 in males and slightly lower in females. In Europe and North America, ICC accounts for 10%-25% of liver cancers in males and even a higher proportion in females<sup>[1]</sup>. The etiology and pathogenesis of ICC are not known and remain to be defined, although many potential factors may contribute to it. For example, chronic biliary tract infection is generally recognized as the most common risk factor for ICC. A multidisciplinary synthetic therapy combining surgical resection with chemotherapy is the most widely used treatment protocol. Surgical resection is the therapeutic aspect with a capacity of curing ICC, while chemotherapy is mainly used for the

patients with unresectable or recurrent disease. Moreover, no conclusion has been reached as to whether adjuvant chemotherapy is effective in the control of ICC<sup>[3]</sup>. This may be because there are no standard chemotherapeutic protocols for ICC. Recently, Gemcitabine or Gemcitabine-based treatment has been a preferable choice to treat some ICC patients. Whether the patients with unresectable and non-metastatic ICC should be given liver transplantation treatment remains controversial, although the effect of liver transplantation for these patients was much better than that of palliative treatment<sup>[4]</sup>.

ICC often shows higher malignant grades and poorer prognosis than those of hepatocellular carcinoma (HCC). The 5-year survival rate of ICC is still less than 5%<sup>[5]</sup>. As a result, improving patients' survival with early detection and more aggressive treatment of ICC has been a focus of our research. Since ICC is a relatively rare neoplasm, to date, very few large-scale studies have been reported. In the current study, we have retrospectively assessed 429 cases of ICC that have undergone surgical treatment in the Eastern Hepatobiliary Surgery Hospital in Shanghai, China. We statistically evaluated the clinical characteristics, pathology, treatment, and prognosis of these patients to determine whether these parameters could contribute to a better prediction of patient survival.

## MATERIALS AND METHODS

### Patients

The study was approved by our institutional review board, and an informed consent was obtained from each patient. The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki. We retrospectively surveyed a total of 5311 patients with primary liver cancer who underwent surgical treatment in our hospital between October 1999 and December 2003. The pathological diagnoses of these patients included HCC, ICC, or mixed liver neoplasm. As a result, we obtained 429 cases of ICC from the total cases (8.1%). Clinicopathological characteristics for these patients were retrieved, including age, gender, the existence of cholelithiasis, chronic viral hepatitis, tumor size, number of lesions, existence of satellite lesions, lymph node metastases, extrahepatic metastases, cirrhosis, pathology (grade), tumor invasion, some routine tumor marker expressions [ $\alpha$ -fetoprotein (AFP), carbohydrate antigen 19-9 (CA19-9), and carcinoembryonic antigen (CEA)], surgical procedures, and survival data. For surgical procedures, R0 resection was defined as the *en bloc* resection with all margins histologically free of tumor, while R1 resection was defined as one in which the tumor mass was removed but section margins may not necessarily be tumor-free. Other patients underwent exploratory laparotomy for unresectable lesions. All patients were graded according to International Union Against Cancer (UICC) TNM classification, 1997 version. We attempted to follow all 429 patients, but only 329 were available for data analysis. The lost follow-up data in the 100 patients may be due to their death, loss of contact, or other unknown reasons.

### Statistical analysis

Statistical calculations and analyses were performed using SPSS11.0 software. Overall survival rate was plotted by the Life Table method. The univariate and multivariate predictors of prognosis were determined using univariate Cox regression analysis and the Cox proportional hazard model, respectively (Backward). The following variants were taken into account: age, gender, curative resection, lymph node metastases, number of intrahepatic lesions, satellite lesions, extrahepatic metastases, macroscopic tumor thrombi, pathology, cirrhosis, tumor size, encapsulation, microscopic tumor thrombi, tumor invasion, hepatitis B Virus (HBV) infection, AFP, CEA, and CA19-9. The Wilcoxon (Gehan) test was used to evaluate pair-wise comparisons between groups. The association between CA19-9 expression and clinicopathological parameters was analyzed using the  $\chi^2$  test and a logistic regression model.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Clinical features

The 429 ICC patients consisted of 301 men and 128 women, with ages ranging from 22 to 81 years, with a median age of 52 years. The main clinical manifestations included upper abdominal discomfort or pain (65.0%), an asymptomatic presentation (12.1%), hypodynamia (8.2%), abdominal distension (4.0%), jaundice (3.0%), nausea (2.8%), lower back pain (2.6%), abdominal mass, emaciation, and other symptoms (2.3%). Laboratory evaluations showed that 198 patients (46.4%) were HBsAg positive, 1 (1/321, 0.3%) was hepatitis C virus positive, 90 (21.3%) had AFP  $> 20$   $\mu\text{g/L}$ , 50 (11.9%) CEA  $> 10$   $\mu\text{g/L}$ , and 242 (57.5%) CA19-9  $> 37$  U/mL, as detected with an electrochemiluminescence immunoassay (Table 1).

Furthermore, 285 (66.4%) patients had only a single tumor mass, while additional 144 (33.6%) had multiple lesions. Tumor sizes were between 1.5 cm and 20 cm, with a mean size of  $7.1 \pm 3.8$  cm. Macroscopic satellite lesions were found in 99 cases, of these, 40 cases had  $\leq 3$  lesions and 59 cases had more than 3 lesions. In addition, there were 47 cases of macroscopic tumor thrombi with 32 intravascular thrombi (27 portal vein thrombi and 5 hepatic vein thrombi), 10 cases of bile duct thrombi, and 5 cases of concurrent thrombi. Lymph node metastases were found in 88 (20.5%) cases. Tumors metastasizing to lymph nodes at the porta hepatis and hepatoduodenal ligament accounted for 59.1% (52/88) while retroperitoneal metastases accounted for 27.2% (24/88). Extrahepatic metastases usually invaded into the diaphragm, abdominal wall, omentum, stomach, or duodenum (Table 1). TNM classifications are shown in Table 1.

### Surgical procedures and complications

All patients were preoperatively assessed and their operability was evaluated using computed tomography (CT), magnetic resonance imaging (MRI), or both. As a

result of preoperative assessment, 319 (74.3%) received R0 liver resection, 76 (17.7%) received R1 liver resection, and 34 (7.9%) received the exploratory laparotomy. Liver resection was performed using finger fracture and clamp crushing with intermittent Pringle's maneuver under room temperature. In all 395 patients (including R0 and

R1 resections), 237 underwent partial hepatectomy (172 tumors located within two or fewer segments and 65 within three or more segments), 51 segmentectomy or bisegmentectomy, 8 trisegmentectomy, 55 left hepatectomy, 26 right hepatectomy and 18 extended hepatectomy. Fifty-four patients also received common bile duct exploration for cholelithiasis or thrombus resection, 12 patients received Roux-en-Y cholangiojejunostomy, and 19 patients received resection of invading tissues or of organs surrounding liver. Thirty-five patients underwent lymph node dissection, among them 25 patients with and 10 patients without lymph nodes metastasis. Thirty-four patients were excluded from liver resection due to intrahepatic or extrahepatic metastasis and hepatic duct system invasion by tumor metastases or metastatic lymph node.

Five (1.2%) patients died within 1 mo after surgery, 3 of them died of hepatic failure, 1 died of intraperitoneal hemorrhage, and 1 died of adult respiratory distress syndrome (ARDS). Twenty-six (6.1%) patients had surgical complications, i.e. biliary leakage (13 cases), infection of pneumonia, subphrenic or, incision infection (7 cases), bleeding (4 cases), ARDS (1 case), and intestinal obstruction (1 case).

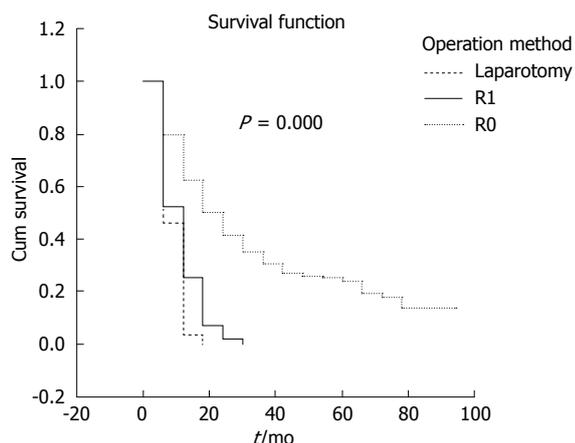

### Pathological features

After surgery, tumors were inspected macroscopically and microscopically, and the data indicated that poorly differentiated tumors accounted for 62.0%, while moderately and well differentiated tumors accounted for 36.7% and 1.3%, respectively. Microscopic tumor thrombi were found in 34.7% of the patients, and 89.4% of tumors did not have a pseudocapsule. One hundred and forty-six patients had cirrhosis in the liver, and of these 92 cases had small-nodule liver cirrhosis. Moreover, bile duct stones were observed in 10.7% (46/429) of patients.

### Prognosis and prognostic factors

The longest follow-up period is 8 years, but only 329 (76.7%) patients were available for data analysis, the rest patients were lost to follow-up after operation. Most the reasons for the lost follow-up is unknown but may be due to lost contact, death, or unspecified causes. Among these 329 patients, the mean survival time was 12.4 mo with 1-, 3- and 5-year survival rates of 50.9%, 22.2%, and 17.4%, respectively. The overall survival period for the patients with R0 resection was 18.3 mo with 1-, 3-, and 5-year survival rates of 62.5%, 30.2%, and 23.6%, respectively. The overall survival for the patients with R1 resection and punching exploration were only 6.6 and 5.6 mo. The overall survival in patients who received R0 resection was significantly higher than those who received R1 resection or punching exploration ( $P = 0.000$ , Figure 1 and Table 2).

Furthermore, the data from the univariate analysis found that prognostic factors included radical resection, lymph node metastases, satellite lesions, extrahepatic metastasis, tumor size, number of tumor lesions, and expression of CEA and CA19-9. The multivariate analysis further confirmed that radical resection, lymph node metastases, macroscopic tumor thrombi, tumor size, and

Lymph node metastases	0.432	0.218	0.048	1.540	1.004-2.361
Macroscopic tumor thrombi	0.455	0.206	0.027	1.576	1.053-2.360
Tumor size	0.159	0.080	0.046	1.173	1.003-1.372
CA19-9	0.191	0.085	0.024	1.210	1.025-1.428

CA19-9 were prognosis factors (Table 3). In addition, Chi-square tests showed that CA19-9 was associated with gender, age, tumor size, HBsAg positivity, and liver cirrhosis (Table 4). The logistic regression analysis revealed that CA19-9 was associated with lymph node metastases and inversely with liver cirrhosis (Table 5).

## DISCUSSION

### Risk factors of ICC

A recent review<sup>[2]</sup> showed the acknowledged risk factors in only a few cases of cholangiocarcinoma, which seem to be associated with chronic inflammation of the biliary epithelium (such as cholangiolithiasis, parasitic infection, intrahepatic biliary stones, and viral infection<sup>[6-10]</sup>). Primary sclerosing cholangitis is the most common known predisposing condition for cholangiocarcinoma in Western

countries<sup>[2]</sup>. In follow-up, or in examination of tissue specimens of cholangiocarcinoma, primary sclerosing cholangitis was found to account for 8%-40% of cholangiocarcinoma. In the current study, 198 patients were HBsAg-positive, accounting for 46.4% of cases, which is significantly higher than the estimated 10% HBV

carrier rate in Chinese population. This data indicate that HBV infection may be one of the risk factors for ICC. Moreover, an additional 60 patients were found to be serum positive for anti-HBc antibody, although they were negative for HBsAg, which is indicative of a past HBV infection. Combining HBsAg and anti-HBc expression, our study population had 60.4% patients with HBV or a history of HBV infection. However, it is unclear how HBV infection contributes to development of ICC. The association of cirrhosis with cholangiocarcinoma development may illuminate HBV infection as a risk factor for cholangiocarcinoma. HBV infection causes the majority of liver cirrhosis in Asian countries. Although other studies showed that hepatitis C virus infection was a risk factor for ICC<sup>[8-9]</sup>, our study did not confirm it because of very low infection rate (0.3%) in our patients.

### Diagnosis

Initial and early diagnosis of ICC could be very difficult to achieve due to the wide range of differential diagnoses. Features identified in CT or MRI evaluations are not typical for ICC, as minimal contrast may occur after enhancement. Therefore, some tumor markers, such as CA19-9, CEA and AFP, may add to the differential diagnoses or diagnostic guide for ICC, although these biomarkers may not be specific for ICC. In the current study, elevated CA19-9, CEA and AFP occurred in 57.5%, 11.9% and 21.3% of the patients, respectively, and 70.9% patients were found to express at least one of these markers. Previous studies did report expression of these biomarkers in association with ICC<sup>[11-13]</sup>; however, due to lack of a large number of patients, the exact rate of positive expression of these markers remained unrevealed until the information reported in this current study.

Nevertheless, it is well known that detection of AFP expression is routinely used for early diagnosis of HCC, and given the high infection rate of HBV in the Chinese population, HCC should be first considered in a patient with elevated AFP. In the present study, 23 patients exhibited an increased AFP ( $> 200 \mu\text{g/L}$  but  $\leq 1000 \mu\text{g/L}$ ), while highly increased AFP ( $> 1000 \mu\text{g/L}$ ) was found in 20 patients, accounting for 5.4% and 4.7% of cases, respectively. Therefore, ICC should also be taken into account for patients with elevated AFP. In addition, for patients with high levels AFP but negative in CA19-9 and CEA, ICC should also be considered before operation.

Furthermore, Positron Emission Computed Tomography (PET)/CT could be an alternative method for differential diagnoses of ICC, as it is superior to the enhanced CT in the diagnosis of extrahepatic or lymph node metastases<sup>[14]</sup>.

### Relationship between CA19-9 levels and clinical features

CA19-9 or known as sialylated Lewis antigen is a blood tumor marker and was discovered in patients with colon cancer and pancreatic cancer in 1981<sup>[15]</sup>. Previous studies found that CA19-9 expression was also prevalent in ICC<sup>[2]</sup>. In the current study, CA19-9 ( $> 37 \text{ U/mL}$ ) was found in 57.5% of ICC patients. Further analyses found

that CA19-9 positivity was significantly associated with gender, age, tumor size, cirrhosis, and HBsAg expression, while logistic regression analysis indicated that expression of CA19-9 was significantly associated with cirrhosis and lymph node metastases. ICC patients with CA19-9 ( $> 37 \text{ U/mL}$ ) presented a higher incidence of lymph node metastases. Other studies demonstrated association of positive CA19-9 and lymph node metastases of gastric and colorectal cancers<sup>[16-20]</sup>.

In addition, our study revealed that CA19-9 ( $> 37 \text{ U/mL}$ ) rate was lower in cirrhosis patients with positive HBsAg. The underlying mechanism for this remains unknown and needs further investigations. However, Schöniger-Hekele *et al*<sup>[21]</sup> reported that the combined elevation of CA19-9 and CA 125 was useful for diagnosis of the advanced fibrosis or cirrhosis. Their observation is definitely not compatible with the results of this current study.

### Surgical resection and prognosis

To date, surgical resection is still the primary and most effective means to cure ICC. Nevertheless, the selection methods used to determine a patient's suitability for surgery will directly affect the patient's chances of survival. In this study, the mean survival of patients receiving R0 resection was 18.3 mo, whereas the mean survival rate for patients with R1 resection was only 6.6 mo, indicating that radical resection is the most important factor in prolonging patient survival. Comparing R1 resection and exploratory laparotomy, the former exhibited a slightly better prognosis; however, this is not statistically significant ( $P = 0.36$ ).

Several other studies<sup>[22-27]</sup> showed that the 1-year survival rate of patients receiving R0 resection was between 61% and 83%, and the 5-year survival rate was between 22% and 63% (Table 6), indicating that their survival rates were much higher than those of our patients. Besides the different patient population and severity of the diseases, we proposed that this might be due to the different surgical methodology. For example, segmental resection is extensively used in Western countries, while non-anatomic resection is primarily used in China. The former is a more curative procedure owing to wider resection margins. The low rate of radical resection may be due to the invasion of local and portal hepatic ducts by ICC. Lymph node metastases and distant metastasis were often observed in patients with ICC.

However, it remains debatable whether extended radical operation in combination with lymph node dissection could improve survival rates. Some studies have reported that 1- and 3-year survival rates were 94% and 82%, respectively, after extended hepatectomy (including vessel resection and reconstruction) in patients with solitary tumors but without vascular invasion or extrahepatic or lymph node metastases<sup>[28]</sup>. However, rather than positive effects, increased morbidity was observed in patients with extended surgery that included anatomic hepatic resection, vessel resection and reconstruction, and extended lymph node dissection<sup>[29]</sup>.

<sup>1</sup>Two cases of death were excluded. NR: Not reported.

### Prognostic factors

The present study showed that favorable prognostic factors for ICC are: radical resection, no metastasis of lymph nodes, a small tumor diameter, no macroscopic tumor thrombi, and low levels of CA19-9. Among these favorable factors, radical resection, no metastasis of lymph nodes, and a small tumor diameter are consistent with previous studies<sup>[22,24,30,31]</sup>. This study also showed that macroscopic tumor thrombi and CA19-9 expression were prognostic factors for ICC. In addition, ICC with CA19-9 (> 37 U/mL) exhibited a higher grade of malignancy and prevalence of lymph node metastases. Ohtsuka *et al*<sup>[32]</sup> also reported that CA19-9 was a prognostic factor of ICC. Other studies demonstrated that macroscopic tumor thrombus is a key factor for poor prognosis of hepatocellular carcinoma<sup>[33-35]</sup>. As the incidence of macroscopic tumor thrombus is relatively low in ICC (only 11% in our current study), it could be easily missed, especially studies with a small sample size.

### Liver transplantation

Originally, the prognosis of ICC patients who received liver transplantation treatment was not satisfactory. In particular, Pascher *et al*<sup>[36]</sup> reported that 5-year survival rate reached 29% in a study, but did not exceed 18% in other four studies. However, most recent studies showed an improving 5-year survival rate between 33% and 42%<sup>[4,37]</sup>. Multivariate analysis revealed that single tumor, tumor-free margins, no lymph node metastasis, no jaundice, or no perineural invasion, and early TNM stage were associated with better prognosis<sup>[4,38,39]</sup>. Nevertheless, due to restricted resources of liver donors and poor prognosis after liver transplantation, it is still controversial whether the patients with unresectable and non-metastasis ICC should undergo liver transplantation. Further studies are needed to determine the criteria for selecting the patients who can benefit from liver transplantation. In addition, the effectiveness of adjuvant radiotherapy and chemotherapy both before and after transplantation remains to be defined.

In conclusion, our present study demonstrated that hepatitis B infection, CA19-9, CEA, and AFP are associated with ICC development. CA19-9 levels are associated with lymph node metastases, but inversely with cirrhosis. Radical resection (R0) is the key prognostic factor for ICC. Future studies should focus on evaluation of the molecule-targeted

therapy, and whether it can efficiently control this deadly disease so as to improve the survival of the patients.

## COMMENTS

### Background

Incidence of intrahepatic cholangiocarcinoma (ICC) is increasing worldwide and its prognosis is very poor. Thus, further studies on its clinical characteristics for early detection and on surgical treatment for better prognosis are urgently needed.

### Research frontiers

Early detection of ICC could focus on defining clinical characteristics and biomarker study. Surgery with radical resection always is the key factor to improve the survival of the patients. The effectiveness of chemotherapy is currently limited and novel approaches are needed.

### Innovations and breakthroughs

This study demonstrated that carbohydrate antigen 19-9 (CA19-9) is commonly elevated in ICC and associated with lymph node metastases, but inversely associated with liver cirrhosis, indicating that CA19-9 could further be evaluated for early detection and prognosis of ICC. In addition, hepatitis B virus infection is associated with cholangiocarcinoma and increased  $\alpha$ -fetoprotein (AFP) levels may also be considered for ICC, although AFP is a routinely used biomarker for hepatocellular carcinoma.

### Applications

This study provides an initial assessment of ICC and further studies are needed to confirm the findings, which can apply to future early detection, prediction of prognosis, treatment election, and differential diagnosis of ICC.

### Peer review

This is an interesting paper, with a large number of patients involved, which might be of benefit for future studies of ICC.

### Abstract

**AIM:** To compare neoadjuvant chemoradiotherapy and surgery with surgery alone for resectable esophageal carcinoma.

**METHODS:** We used MEDLINE and EMBASE databases to identify eligible studies and manual searches were done to ensure no studies were missed. Trial validity assessment was performed and a trial quality score was assigned.

**RESULTS:** Eleven randomized controlled trials (RCTs) including 1308 patients were selected. Neoadjuvant chemoradiotherapy significantly improved the overall survival compared with surgery alone. Odds ratio (OR) [95% confidence interval (CI),  $P$  value], expressed as neoadjuvant chemoradiotherapy and surgery vs surgery alone, was 1.28 (1.01-1.64,  $P = 0.05$ ) for 1-year survival, 1.78 (1.20-2.66,  $P = 0.004$ ) for 3-year survival, and 1.46 (1.07-1.99,  $P = 0.02$ ) for 5-year survival. Postoperative mortality increased in patients treated by neoadjuvant chemoradiotherapy (OR: 1.68, 95% CI: 1.03-2.73,  $P = 0.04$ ), but incidence of postoperative complications was similar in two groups (OR: 1.14, 95% CI: 0.88-1.49,  $P = 0.32$ ). Neoadjuvant chemoradiotherapy lowered the local-regional cancer recurrence (OR: 0.64, 95% CI: 0.41-0.99,  $P = 0.04$ ), but incidence of distant cancer recurrence was similar (OR: 0.94, 95% CI: 0.68-1.31,  $P = 0.73$ ). Histological subgroup analysis indicated that esophageal squamous cell carcinoma did not benefit from neoadjuvant

chemoradiotherapy, OR (95% CI,  $P$  value) was 1.16 (0.85-1.57,  $P = 0.34$ ) for 1-year survival, 1.34 (0.98-1.82,  $P = 0.07$ ) for 3-year survival and 1.41 (0.98-2.02,  $P = 0.06$ ) for 5-year survival.

**CONCLUSION:** Neoadjuvant chemoradiotherapy can raise the survival rate of patients with esophageal adenocarcinoma.

### INTRODUCTION

Esophageal carcinoma (EC) is the sixth commonest cause of tumor-related death around the world<sup>[1]</sup>. It is endemic in Asia, southern and eastern Africa, and northern France<sup>[2,3]</sup>. North America and many western European countries are low-incidence regions, but the nearly 6-fold increase in the incidence of esophageal adenocarcinoma (EAC) in the past three decades and the corresponding 7-fold increase in mortality are remarkable. Surgery has always been considered as the standard treatment for patients with resectable esophageal cancer, but the effectiveness of surgery alone was unsatisfactory and the median survival of patients treated by surgery alone rarely exceeded 18 mo<sup>[4]</sup>. So clinicians always make efforts to seek for new treatment strategies to prolong the survival time of patients with

EC. Recently neoadjuvant chemoradiotherapy plus surgery has been studied widely, but opinions vary among clinicians as to the therapeutic effect of the new method, and the outcomes of randomized controlled trials (RCTs) were not consistent. Published meta-analyses did not reach a consensus, some of which was short of enough RCTs or adopted unpublished data. The current study aims to perform a meta-analysis to compare neoadjuvant chemoradiotherapy plus surgery with surgery alone for resectable EC by enough eligible published RCTs to date.

## MATERIALS AND METHODS

Computerized bibliographic and manual searches were done to identify all eligible published literature between 1980 and 2008. MEDLINE and EMBASE were the primary source of RCTs, with the following key words: esophageal cancer, surgery, radiotherapy, chemotherapy, neoadjuvant chemoradiotherapy and RCT. Manual searches were performed by reviewing articles and abstracts cited in the published meta-analysis and RCTs.

The eligible studies must meet the following inclusion criteria: (1) It must be a prospective RCT which compares neoadjuvant chemoradiotherapy plus surgery with surgery alone in the initial management of resectable EC; (2) Outcomes must include survival data; (3) There was no statistical significance in factors such as sex, age, type of pathology, tumour stage between the two groups; and (4) Studies were analyzed by intention-to-treat patients. Trials were not excluded because of cancer histology (squamous cell carcinoma or adenocarcinoma) or language of publication. Unpublished reports, abstracts and theses were excluded. This meta-analysis was performed according to the QUOROM statement<sup>[5]</sup>.

All data were abstracted by three independent researchers and the methodological qualities of all RCTs were assessed by three aspects: blinding, randomization and handling withdrawals and dropouts<sup>[6]</sup>. If researchers had discrepancies in assessing RCTs, a consensus was reached by discussion.

Outcomes including 1-year survival, 3-year survival, 5-year survival, postoperative mortality, incidence of postoperative complication, incidence of local-regional cancer recurrence and incidence of distant cancer recurrence were analyzed. In two trials<sup>[7,8]</sup> we used the Kaplan-Meier estimate of the 1-year survival and 3-year survival in the two groups and the data for the 5-year survival was obtained from another trial<sup>[9]</sup> in the same way. The remaining data were directly available in the corresponding RCTs. Evaluation of therapeutic effectiveness, including survival rate and incidence of recurrence, was performed in all patients who were enrolled in these trials, but for postoperative events, data were calculated only based on the number of patients who underwent surgery as the denominator. Sensitivity analyses were performed to identify the effect of histological subtype (squamous cell carcinoma or adenocarcinoma) and

scheduling of neoadjuvant chemoradiotherapy (concurrent or sequential) on survival.

Data were analyzed by RevMan 4.2.10.  $\chi^2$  tests were used to assess heterogeneity of study results and a planned cut-off for significance of  $P \leq 0.05$ . If  $P > 0.05$ , we used a fixed effect model, otherwise we used a random effect model. The odds ratios (OR) among the frequency of events in both neoadjuvant chemoradiotherapy plus surgery group (CRT group) and surgery alone group (S group) was calculated and these OR are presented as a point estimate with 95% confidence intervals (CI) and  $P$  values in parentheses. The significance level was set at 5%. Funnel plot analysis did not suggest publication bias against negative trials.

## RESULTS

### Features of RCTs

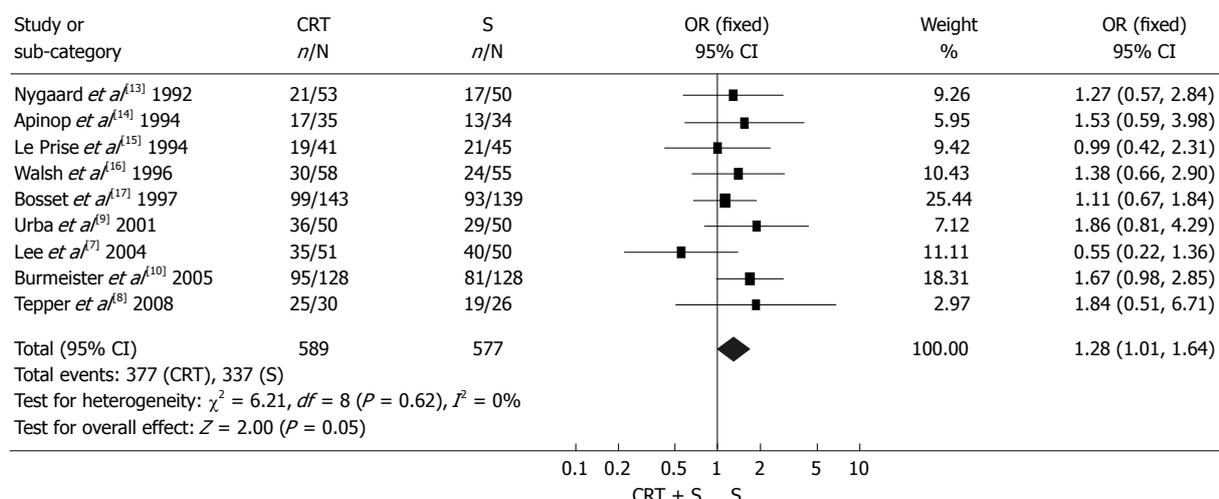

Eleven randomized studies were identified from 1980 to 2008 and the main features of the trials included in the meta-analysis are shown in Table 1<sup>[7-17]</sup>. All studies were published literature. Nine countries including Australia, United States of America, China, France, Ireland, Japan, Korea, Norway and Thailand were involved in the RCTs.

The studies were carried out from 1983 to 2002 and the literatures were published between 1992 and 2008. Because double blinding can not be performed due to the inherent difficulty of the design of the trial (e.g. chemotherapy and radiotherapy) and the method of randomization was not reported in most trials, the RCT quality scores ranged from 1 to 3 (5-point scale) and the average was 2.3<sup>[5,6]</sup>. Of these 11 studies, seven were restricted to patients with esophageal squamous cell carcinoma (ESCC) only, one was restricted to patients with EAC only, and the remaining three trials enrolled patients with either ESCC or EAC. The 11 RCTs included 1308 patients, 659 of whom received neoadjuvant chemoradiotherapy before surgery, and the remaining 649 patients received surgery alone. Nearly all the patients in the S group underwent surgery, yet there were more patients in the CRT group who had not completed the planned treatment regimen for various causes such as side effects of chemotherapy or metastasis of cancer before surgery. The tumor stage of the most patients in the 11 studies ranged from I-III (1987 UICC), but more advanced tumor stage (IVa) was also seen in two RCTs<sup>[9,11]</sup>. In addition, tumor stages were classified in the RCT by Le Prise *et al*<sup>[15]</sup> according to the 1978 American Joint Committee on Cancer, which was not a TNM staging. Finally tumor stage was not reported in the RCT by Walsh *et al*<sup>[16]</sup>.

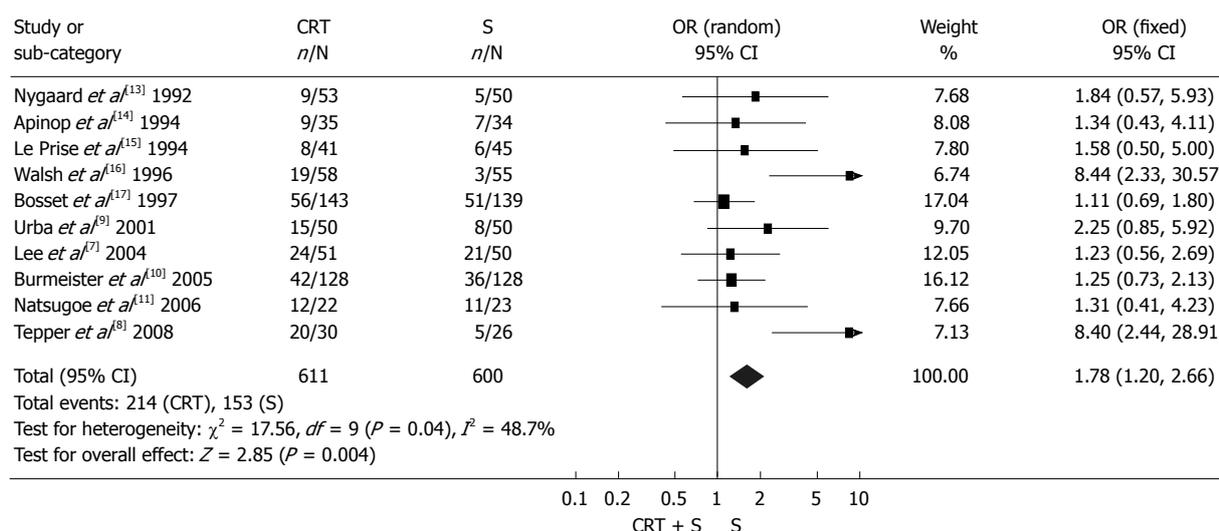

### Survival rate

The effect of neoadjuvant chemoradiotherapy on survival rate is shown in Figure 1. Obviously, there was statistical significance in survival rate between the two groups. OR (95% CI,  $P$  value), expressed as neoadjuvant chemoradiotherapy plus surgery *vs* surgery alone, was 1.28

Table 1 Features of all trials included in the meta-analysis

Country	Year of RCT published	SCC or AC	Schedule of radiotherapy	Schedule of chemotherapy	Concurrent or sequential	Time of surgery
Norway	1992	SCC	35 Gy 1.75 Gy/d 5 d/wk for 4 wk	Cisplatin: 20 mg/m <sup>2</sup> D1-5, D15-19 Bleomycin: 10 mg/m <sup>2</sup> D1-5, D15-19	Sequential	Not report
Thailand	1994	SCC	40 Gy 2 Gy/d 5 d/wk for 4 wk	Cisplatin: 100 mg/m <sup>2</sup> D1, 29 FU: 1000 mg/m <sup>2</sup> D1, D29-32	Concurrent	4 wk after completion of chemotherapy
France	1994	SCC	20 Gy 2 Gy/d D8-19	Cisplatin: 100 mg/m <sup>2</sup> D1,21 FU: 600 mg/m <sup>2</sup> D2-5, D22-25	Sequential	D42
Ireland	1996	AC	40 Gy 2.67 Gy/d	Cisplatin: 75 mg/m <sup>2</sup> D7 FU: 15 mg/kg D1-5	Concurrent	8 wk after CRT
France	1997	SCC	37 Gy 3.7 Gy/d 5 d/wk for 2 wk	D1-5, 8-12, 15-19 Cisplatin: 80 mg/m <sup>2</sup> D0-2	Sequential	2-4 wk after CRT
USA	2001	SCC and AC	45 Gy 1.5 Gy <i>bid</i> D1-5, 8-12, 15-19	Cisplatin: 20 mg/m <sup>2</sup> D1-5, 17-21 FU: 300 mg/m <sup>2</sup> D1-21	Concurrent	D42
China	2003	SCC	36 Gy 3 Gy/d D21-24, 28-31, 35-38	Vinblastine: 1 mg/m <sup>2</sup> D1-4, 17-20 Cisplatin: 25 mg/m <sup>2</sup> D2-5, D22-25 FU: 1000 mg/m <sup>2</sup> D1-5	Sequential	3 wk after CRT
Korea	2004	SCC	45.6 Gy 1.2 Gy <i>bid</i> D1-28	500 mg/m <sup>2</sup> D21-25 Cisplatin: 60 mg/m <sup>2</sup> D1, 21 FU: 1000 mg/m <sup>2</sup> D2-5	Concurrent	3-4 wk after completion of radiotherapy
Australia	2005	SCC and AC	35 Gy 2.33 Gy/d 5 d/wk for 3 wk	Cisplatin: 80 mg/m <sup>2</sup> D1 FU: 800 mg/m <sup>2</sup> D2-5	Concurrent	3-6 wk after completion of radiotherapy
Japan	2006	SCC	40 Gy 2 Gy/d 5 d/wk for 4 wk	Cisplatin: 7 mg/m <sup>2</sup> FU: 350 mg/m <sup>2</sup> 5 d/wk for 4-6 wk	Concurrent	35-40 d after CRT
USA	2008	SCC and AC	50.4 Gy 1.8 Gy/d 5 d/wk for 5.5 wk	Cisplatin: 100 mg/m <sup>2</sup> D1,29 FU: 1000 mg/m <sup>2</sup> D1-4, D29-32	Concurrent	3-8 wk after CRT

SCC: Squamous cell carcinoma; AC: Adenocarcinoma; CRT: Chemoradiotherapy.

Table 2 Survival rate estimates of patients with EC by schedule of chemoradiotherapy

Schedule of CRT	Overall survival	No. of studies	No. of patients		OR (95% CI)	P
			CRT + S	S		
Sequential	1 yr	3	237	234	1.12 (0.77, 1.64)	0.56
	3 yr	3	237	234	1.24 (0.82, 1.88)	0.31
	5 yr	2	191	188	1.24 (0.81, 1.91)	0.32
Concurrent	1 yr	6	352	343	1.41 (1.03, 1.94)	0.03
	3 yr	7	374	366	2.12 (1.20, 3.76)	0.01 <sup>1</sup>
	5 yr	5	265	261	1.72 (1.10, 2.71)	0.02

<sup>1</sup>Random effects model was used. EC: Esophageal carcinoma; CRT + S: Neoadjuvant chemoradiotherapy and surgery; S: Surgery; OR: Odds ratio; CI: Confidence interval.

(1.01-1.64,  $P = 0.05$ ) for 1-year survival, 1.78 (1.20-2.66,  $P = 0.004$ ) for 3-year survival and 1.46 (1.07-1.99,  $P = 0.02$ ) for 5-year survival. Subgroup analysis showed that there was no survival benefit from neoadjuvant chemoradiotherapy in EC patients when chemotherapy and radiotherapy were given sequentially. On the contrary, EC patients benefited from concurrent chemoradiotherapy. The corresponding OR (95% CI,  $P$  value) is shown in Table 2. Moreover, patients with ESCC did not get any survival benefit from neoadjuvant chemoradiotherapy and corresponding OR (95% CI,  $P$  value) is shown in

Table 3 Survival rate estimates of patients with ESCC for neoadjuvant chemoradiotherapy compared with surgery alone

Overall survival	No. of studies	No. of patients		OR (95% CI)	P
		CRT + S	S		
1 yr	6	368	368	1.16 (0.85, 1.57)	0.34
3 yr	7	390	391	1.34 (0.98, 1.82)	0.07
5 yr	5	293	295	1.41 (0.98, 2.02)	0.06

ESCC: Esophageal squamous cell carcinoma.

Table 3. In addition, another subgroup analysis indicated that the 3-year survival in CRT group was significantly higher than that of S group in patients of the USA and Europe, but in patients of Asia, it was a pessimistic result (Table 4).

### Morbidity after surgery

The resection rate in patients treated with surgery alone was markedly higher than that in patients treated with preoperative chemoradiotherapy (OR: 0.36, 95% CI: 0.24-0.54,  $P < 0.00001$ ), but patients treated with preoperative chemoradiotherapy were more likely to obtain a complete resection (R0 resection), which was defined as gross disease removed with negative margins (OR: 2.16, 95% CI: 1.58-2.97,  $P < 0.00001$ ) (Figure 2). Mortality

Review: Neoadjuvant chemoradiotherapy for resectable esophageal carcinoma: A meta-analysis  
 Comparison: CRT group vs S group  
 Outcome: R0 resection rate

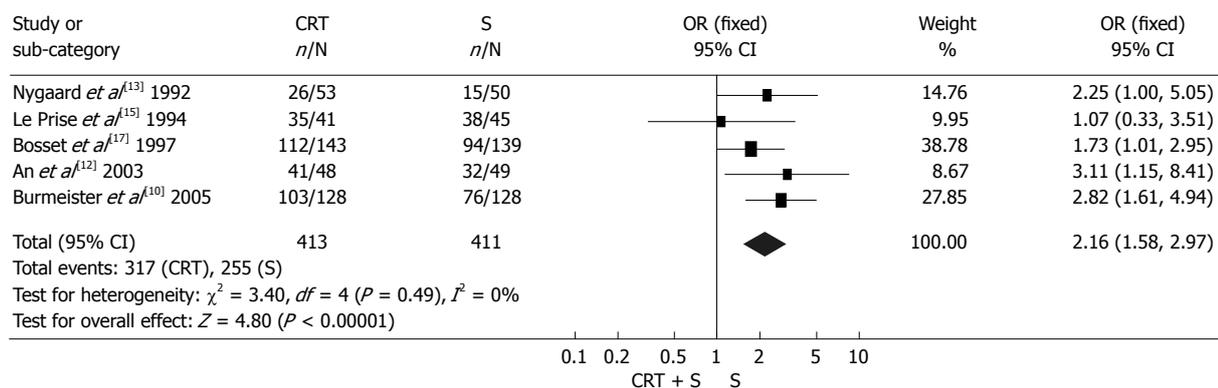

Figure 2 R0 resection rate in neoadjuvant chemoradiotherapy and surgery compared with surgery alone.

Review: Neoadjuvant chemoradiotherapy for resectable esophageal carcinoma: A meta-analysis  
 Comparison: CRT group vs S group  
 Outcome: Postoperative mortality

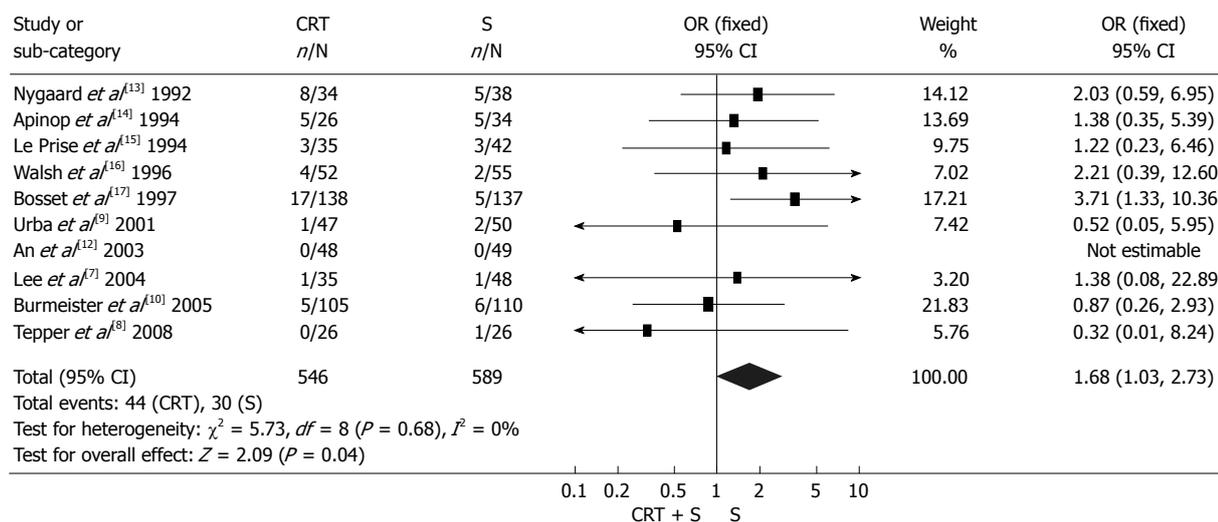

Figure 3 Postoperative mortality in neoadjuvant chemoradiotherapy and surgery compared with surgery alone.

Population	No. of studies	No. of patients		OR (95% CI)	P
		CRT + S	S		
USA	2	80	76	3.74 (1.77, 7.88)	0.0005
Europe	4	295	289	1.59 (1.09, 2.33)	0.02
Asia	3	108	107	1.27 (0.72, 2.24)	0.40

after surgery varied from 0% to 23.5% in CRT group (the highest mortality was in the RCT by Nygaard *et al*<sup>[13]</sup>) and from 0% to 14.7% in S group (the highest mortality was in the RCT by Apinop *et al*<sup>[14]</sup>). Mortality after surgery in CRT group was higher than that in S group (OR: 1.68, 95% CI: 1.03-2.73,  $P = 0.04$ ) (Figure 3). But if the RCT by Nygaard *et al*<sup>[13]</sup> or the RCT by Bosset *et al*<sup>[17]</sup> were excluded, there was no significant difference between the two groups and corresponding OR (95% CI,  $P$  value) was 1.66 (0.99-2.79,  $P = 0.06$ ) and 1.30 (0.75-2.28,  $P = 0.35$ ).

The postoperative complications included nonfatal and fatal complications. There was no significant difference between the two groups (OR: 1.14, 95% CI: 0.88-1.49,  $P = 0.32$ ) (Figure 4).

**Effect on recurrence**

First treatment failure was defined as unequivocal histological or radiological evidence of tumor recurrence for the first time after surgery wherever the tumor relapsed. Seven RCTs provided related data on tumor recurrence. The patients treated by preoperative chemoradiotherapy had lower incidence of local recurrence (OR: 0.64, 95% CI: 0.41-0.99,  $P = 0.04$ ) (Figure 5A), but the two groups had no significant difference in distant recurrence (OR: 0.94, 95% CI: 0.68-1.31,  $P = 0.73$ ) (Figure 5B).

**DISCUSSION**

Our meta-analysis indicated that patients treated by neo-

adjuvant chemoradiotherapy had more survival benefit compared with patients treated by surgery alone, including 1-year survival, 3-year survival and 5-year survival. But subgroup analysis demonstrated patients with ESCC could not benefit from neoadjuvant chemoradiotherapy. The meta-analysis performed by Fiorica *et al*<sup>[18]</sup> suggested that neoadjuvant chemoradiotherapy plus surgery significantly lowered the 3-year mortality compared with surgery alone, but there was no statistical significance between the two groups if all RCTs including patients with EAC were excluded. Another meta-analysis performed by GebSKI *et al*<sup>[19]</sup> demonstrated that both patients with ESCC and patients with EAC benefited from neoadjuvant chemoradiotherapy and corresponding OR (95% CI, *P* value) were 0.84 (0.71-0.99, *P* = 0.04) and 0.75 (0.59-0.95, *P* = 0.02). Since the former *P* value approached 0.05, our conclusion should be cautiously done. Thus we presume that only patients with EAC could benefit from neoadjuvant chemoradiotherapy. Another subgroup indicated patients in Europe and the USA benefited from neoadjuvant chemoradiotherapy; however, patients in Asia did not. This result indicated that different population had different response to neoadjuvant chemoradiotherapy and this may be associated with ethnic difference.

Though patients receiving neoadjuvant chemoradiotherapy had higher survival than patients treated by surgery alone, our meta-analysis showed that the incidence of surgery-related death was higher in the CRT group. Moreover, some patients lost the chance of surgery for the metastasis of tumor or some patients died before surgery for the aggravation of disease. Neoadjuvant chemoradiotherapy made local tissue harder and easier to bleed and as a result fatal postoperative complications such as anastomotic leakage and respiratory insufficiency increased. This may account for the higher postoperative mortality of patients in CRT group. However, sensitivity analysis showed no significant difference between the two groups after excluding the RCT by Nygaard *et al*<sup>[13]</sup>, performed between 1983 and 1988, which was the earliest one among all the RCTs included in this meta-analysis. Probably there was no effective treatment for severe postoperative complications due to the relative undeveloped medical conditions at that time. In fact, the postoperative mortality in the RCTs published after 2000 was significantly lower than those published before 2000. In a word, it is possible that the postoperative mortality of patients receiving neoadjuvant chemoradiotherapy is not significantly higher than that of patients treated by surgery alone under present medical conditions.

Outcomes of our meta-analysis revealed that patients treated by surgery alone had more possibility to undergo the scheduled surgery, however, the rate of complete resection in CRT group was higher than that in S group. This may account for the lower incidence of local recurrence in CRT group, which was another result of this meta-analysis. In the 11 RCTs, only part of patients in CRT group can obtain clinical relief or pathological response. Two RCTs<sup>[12,14]</sup> compared the survival time

between the patients who obtained clinical relief (including complete response and partial response) and the patients who failed to obtain clinical relief (including stable disease and disease progression), and found that the former was markedly greater than the latter. So, if some biological molecules can predict the response of EC patients to neoadjuvant chemoradiotherapy, EC patients will suffer from less physical miseries. Furthermore, this could avoid waste and enhance targeted treatment. Some studies<sup>[20-23]</sup> have indicated that Hsp27, DNA-PKcs, ERCC1 and c-erbB-2 were potential biological molecules, which were related to the response of EC patients to neoadjuvant chemoradiotherapy. Studies in this field are meaningful and promising.

One study reported that the effect of sequential chemoradiotherapy was superior to that of concurrent chemoradiotherapy in treating lung cancer<sup>[24]</sup>. In EC, however, outcome was exactly opposite to those obtained from lung cancer. This meta-analysis showed that EC patients only benefited from preoperative concurrent chemoradiotherapy. Concurrent chemoradiotherapy may work by inhibiting the growth of local tumor and micrometastasis, moreover concurrent chemotherapy can increase the sensitivity of tumor to radiotherapy.

Some studies<sup>[25-27]</sup> indicated that 40%-75% of patients with resectable EC (T1-3N0-1M0) judged according to clinical examination or surgery had subclinical metastasis or tumor had already invaded the adjacent organs or tissues. Accurate tumor staging is crucial to the prognosis of EC patients receiving surgery. Therefore, further measures should be taken to improve the accuracy of tumor staging. Currently, endoscopic ultrasound (EUS) is the most accurate method for staging EC for T and N stage<sup>[28]</sup>. Although helical computed tomography still appears insensitive for the identification of T4 or metastatic involvement of celiac lymph node disease in esophageal cancer, EUS with fine needle aspiration and FDG-PET [fluorine 18-labeled fluorodeoxyglucose (FDG) positron emission tomography (PET)] can make up for this shortcoming<sup>[29]</sup>. Part of patients in RCTs<sup>[9,11]</sup> included in this meta-analysis had metastasis of non-regional lymph nodes. Investigators considered those lymph nodes could be included in the radiation port and should be resected at surgery<sup>[9]</sup>. In fact, this condition belongs to IVa according to TNM staging. We suggest that EC patients (IVa) should not give up the chance of surgery, and they will benefit from neoadjuvant chemoradiotherapy plus surgery too.

In conclusion, this meta-analysis showed that patients with ESCC did not benefit from preoperative concurrent chemoradiotherapy and patients with EAC may be the real beneficiaries of the treatment protocol. Compared with patients treated by surgery alone, patients receiving neoadjuvant chemoradiotherapy more likely obtained complete resection and had lower local cancer recurrence. Neoadjuvant chemoradiotherapy was connected with a little higher mortality after surgery. But it did not increase the incidence of postoperative complications. In addition, patients in Europe and the USA more likely benefited

from neoadjuvant chemoradiotherapy than those in Asia, and this is worth of further studies.

## ACKNOWLEDGMENTS

We thank Hiroshi Okumura for providing detailed regimens of neoadjuvant chemoradiotherapy and Professor Bryan Burmeister for providing the data on the overall survival of non-squamous tumor patients.

## COMMENTS

### Background

Esophageal carcinoma (EC) is one of the major malignant diseases worldwide. Surgery alone cannot obtain satisfactory effects in patients with EC.

### Research frontiers

Neoadjuvant chemoradiotherapy has been a hotspot for EC treatment research. Several related randomized controlled trials (RCTs) have been published, but opinions vary among clinicians as to the therapeutic effect of the new method. It remains uncertain whether patients with resectable EC can benefit from neoadjuvant chemoradiotherapy.

### Innovations and breakthroughs

Several meta-analyses on the neoadjuvant chemoradiotherapy for EC have been published so far, some of which lacked adequate RCTs or used unpublished data. In this study, the authors collected relatively comprehensive data and all the data were from the published literature. It was found that patients with esophageal squamous cell carcinoma did not benefit from neoadjuvant chemoradiotherapy, while patients with esophageal adenocarcinoma (EAC) were the real beneficiaries. In addition, the authors analyzed the impact of geographical differences on the efficacy of the treatment protocol and found that patients in Europe and the USA more likely benefited from neoadjuvant chemoradiotherapy than those in Asia.

### Applications

Results of this study indicate that neoadjuvant chemoradiotherapy is an effective treatment protocol, which is beneficial to patients with EAC in Europe and the USA.

### Terminology

Neoadjuvant chemoradiotherapy: Chemotherapy and radiotherapy are given to patients with cancer before surgery.

### Peer review

This work is a meta-analysis including 11 randomized prospective studies that analyze the advantages of the use of the neoadjuvant chemoradiotherapy vs surgery alone in the treatment of the EC. The results are interesting and suggest that neoadjuvant chemoradiotherapy is beneficial to patients with EAC.

### Abstract

**AIM:** To investigate the effect of severe acute pancreatitis (SAP) on pharmacokinetics of Da-Cheng-Qi Decoction (DCQD) components in rats.

**METHODS:** Rats were divided into SAP group and sham-operation group as a control group ( $n = 6$ ). Rhein, chrysophanol, rheochrysidin, magnolol, hesperidin and naringin in DCQD were quantified in rat serum by high performance liquid chromatography tandem mass spectrometry for studying their pharmacokinetics.

**RESULTS:** Early absorption of each DCQD component was tended to degrade in SAP group after treatment with DCQD by gavage. The  $C_{max}$  (chrysophanol,  $P = 0.0059$ ; rheochrysidin,  $P = 0.0288$ ; magnolol,  $P = 0.0487$ ; hesperidin,  $P = 0.0277$ ; naringin,  $P = 0.0023$ ) and AUC (rhein,  $P = 0.0186$ ; chrysophanol,  $P = 0.0013$ ; magnolol,  $P = 0.001$ ; hesperidin,  $P = 0.0081$ ; naringin,  $P = 0.0272$ ) of DCQD component were obviously lower in SAP group than in control group. The  $T_{1/2\alpha}$  of chrysophanol and rheochrysidin ( $P = 0.0467$  and  $0.0005$ , respectively) and  $T_{max}$  of chrysophanol and rheochrysidin ( $P = 0.0101$  and  $0.0037$ , respectively) lasted longer in SAP group than in control group.

**CONCLUSION:** SAP can significantly impact the ab-

### INTRODUCTION

Acute pancreatitis, occurring suddenly and usually resolving after a few days of treatment, may become life-threatening if severe complications take place. Fulminant acute pancreatitis is more dangerous<sup>[1]</sup>. Severe acute pancreatitis (SAP), characterized by intricate mechanism, variant symptoms, grave prognosis and multiple complications, seriously threatens the life of patients and brings a heavy burden to the society, families and economy. Each year, about 210 000 patients with acute pancreatitis in the United States are admitted to hospitals<sup>[2]</sup>. Additionally, neither standard treatment nor other medications are available for SAP patients at present<sup>[3]</sup>. SAP, similar to Yangming Fushi syndrome (YMFSS) according to the traditional Chinese medicine, has been treated with purgative herbals throughout China for more than three decades<sup>[4-6]</sup>.

Da-Cheng-Qi Decoction (DCQD), a famous preparation of traditional Chinese medicine used in treatment of digestive diseases, is composed of *Dabuang* (Caulis Fibraureae), *Houpu* (Cortex Magnoliae Officinalis), *Zhishi* (immature bitter orange) and *Mangxiao* (Natrii Sulphas). It has been reported that DCQD can restore gastrointestinal function by facilitating motility, relieving enteroparalysis and evacuating "dry stool"<sup>[7]</sup>, prevent bacterial translocation and counteract with endotoxin, regulate  $Ca^{2+}$ - $Mg^{2+}$ -ATPase in the pancreatic acinar cells<sup>[8]</sup>. SAP

can be treated with Chinese herbal decoctions based on the above mechanism. However, no studies are available on the pharmacokinetics of such decoctions in acute pancreatitis. According to the theory “syndrome and treatment pharmacokinetics”, YMFSS should influence the pharmacokinetics of DCQD<sup>[9]</sup>, but it has not been proved experimentally up to date.

Thus, we quantified the DCQD components absorbed in rats with SAP characterized by YMFSS and studied the influence of SAP on the pharmacokinetics of DCQD components<sup>[10]</sup>.

## MATERIALS AND METHODS

### Animals

Male clean-grade, healthy Sprague-Dawley rats, weighing  $320 \pm 25$  g, at the age of  $90 \pm 5$  d, were used in this study. The rats were handled according to the University Guidelines and the Animal Ethics Committee Guidelines of the Animal Facility of the West China Hospital, maintained in air-conditioned animal quarters at  $22 \pm 2^\circ\text{C}$  with a relative humidity of  $65\% \pm 10\%$ , acclimatized to the facilities for 10 d, and then fasted for 24 h with free access to water prior to experiments.

### Materials, chromatographic and HPLC-mass spectrometry conditions

The structures of rhein, chrysophanol, rheochrysidin, magnolol, hesperidin, naringin and ibuprofen (internal standards) are presented in Figure 1. Reference standards for these components of DCQD and the internal standard (IS) were purchased from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). Methanol with a chromatographic grade was obtained from Tedia Company Inc. (USA). Acetic acid and ethyl acetate were bought from Chongqing Chemistry Co. Ltd. (Chongqing, China). Ammonium acetate, sodium hydroxide and hydrochloric acid (analysis grade) were purchased from Chengdu Kelong Chemical Reagent Factory (Chengdu, China). All aqueous solutions and buffers were prepared with deionized water from a Millipore RiosTM-16 water purifier (Millipore, Billerica, MA, USA)<sup>[11]</sup>.

High performance liquid chromatography tandem mass spectrometry (HPLC-TMS) system, consisted of a SIL-HTc autosampler and a LC-10ADvp pump, was provided by Shimadzu (Kyoto, Japan). API3000 triple-quadrupole LC-MS system was purchased from Applied Biosystems (Foster City, CA, USA). The system was controlled with Analyst 1.4.2 software. Separation was performed on a YMC-Pack ODS-A C18 column ( $5 \mu\text{m}$ ,  $150 \text{ mm} \times 4.6 \text{ mm}$ , YMC, Kyoto, Japan) and a C<sub>18</sub> guard column ( $5 \mu\text{m}$ ,  $4.0 \text{ mm} \times 2.0 \text{ mm}$ , Phenomenex Inc., Torrance, CA, USA). The mobile phase is consisted of methanol-water (92:8, v/v) at a flow rate of 0.3 mL/min. The column was maintained at ambient temperature and the injection volume was 80  $\mu\text{L}$ .

A mass spectrometer was operated using an electrospray source configured to the negative ion mode and quantification was performed by multiple reaction moni-

toring (MRM). Production mass spectra of the analytes are shown in Figure 1 where [M-H]<sup>-</sup> of each analyte was selected as the precursor ion, and the most abundant or specific fragment ion was selected as the production in MRM acquisition. Instrumental parameters were optimized for each analyte by infusing the corresponding standard solution at a flow rate of 5  $\mu\text{L}/\text{min}$ , using a syringe pump integrated into the API 3000 mass spectrometer. Nitrogen was used as a curtain, and auxiliary gas and air were used as a nebulizer gas. Electrospray conditions for the 6 major DCQD components and IS were curtain gas (6.0 L/min), ion-spray voltage (-4500 V), nebulizer gas (6.0 L/min), auxiliary gas (7.0 L/min), turbo temperature ( $4^\circ\text{C}$ ), respectively. Optimized mass spectrometry parameters for each DCQD compound and IS are listed in Table 1<sup>[11]</sup>.

Six calibration standards were prepared by spiking 200  $\mu\text{L}$  of blank plasma with 100  $\mu\text{L}$  of each working solution to obtain the plasma concentrations for rhein and rheochrysidin (5000, 3750, 2500, 1250, 625, 312.5, 156, 78.13, 39.1 and 19.53 ng/mL), and for chrysophanol, naringin, hesperidin and magnolol (879, 586, 390, 195, 97.7, 48.8, 24.4, 12.2, 6.1 and 3.1 ng/mL). Quality control (QC) samples were prepared to obtain plasma concentrations for rhein and rheochrysidin (3750, 625, 156 and 39.1 ng/mL) and for chrysophanol, naringin, hesperidin and magnolol (586, 97.7, 24.4 and 6.1 ng/mL). The spiked plasma samples (standard and QC samples) were pretreated and detected in each analytical batch along with the unknown samples<sup>[11]</sup>.

### Assay validation

Blank and spiked rat plasma chromatograms were compared to evaluate the selected method (Figure 2). Calibration curves were plotted from the peak area ratio of each analyte to IS *v* plasma concentrations using a 1/*c*<sup>2</sup> weighted linear least-squares regression model. The lower limit of quantification was set at the concentration of the lowest non-zero calibration standard ( $S/N \geq 10:1$ ) that could be measured with an acceptable accuracy and precision ( $\leq 20\%$  for both parameters). Intra- and inter-day precisions were determined by assessing the measured results of QC samples at low, medium and high concentrations (Table 1). Accuracy was determined as the difference in percentages between the mean and nominal concentrations detected (Table 1). Extraction recoveries of the 6 analytes were determined by comparing the peak areas obtained from rat plasma samples with those from the unextracted standard solutions at the same concentration (Table 1). Bench-top stability of the 6 analytes in rat plasma was determined by assessing the QC samples after stored for 2 and 4 h at room temperature. Freeze-thaw stability was detected after two cycles and long-term stability was determined by assessing the QC samples stored at  $-30^\circ\text{C}$  for 14 d. QC samples were prepared, injected and reinjected after the samples were maintained in the autosampler at  $8^\circ\text{C}$  for 12 d. Stability of the analytes was detected by comparing the measured results with those of freshly prepared samples at the same concentration<sup>[11]</sup> (Table 2).

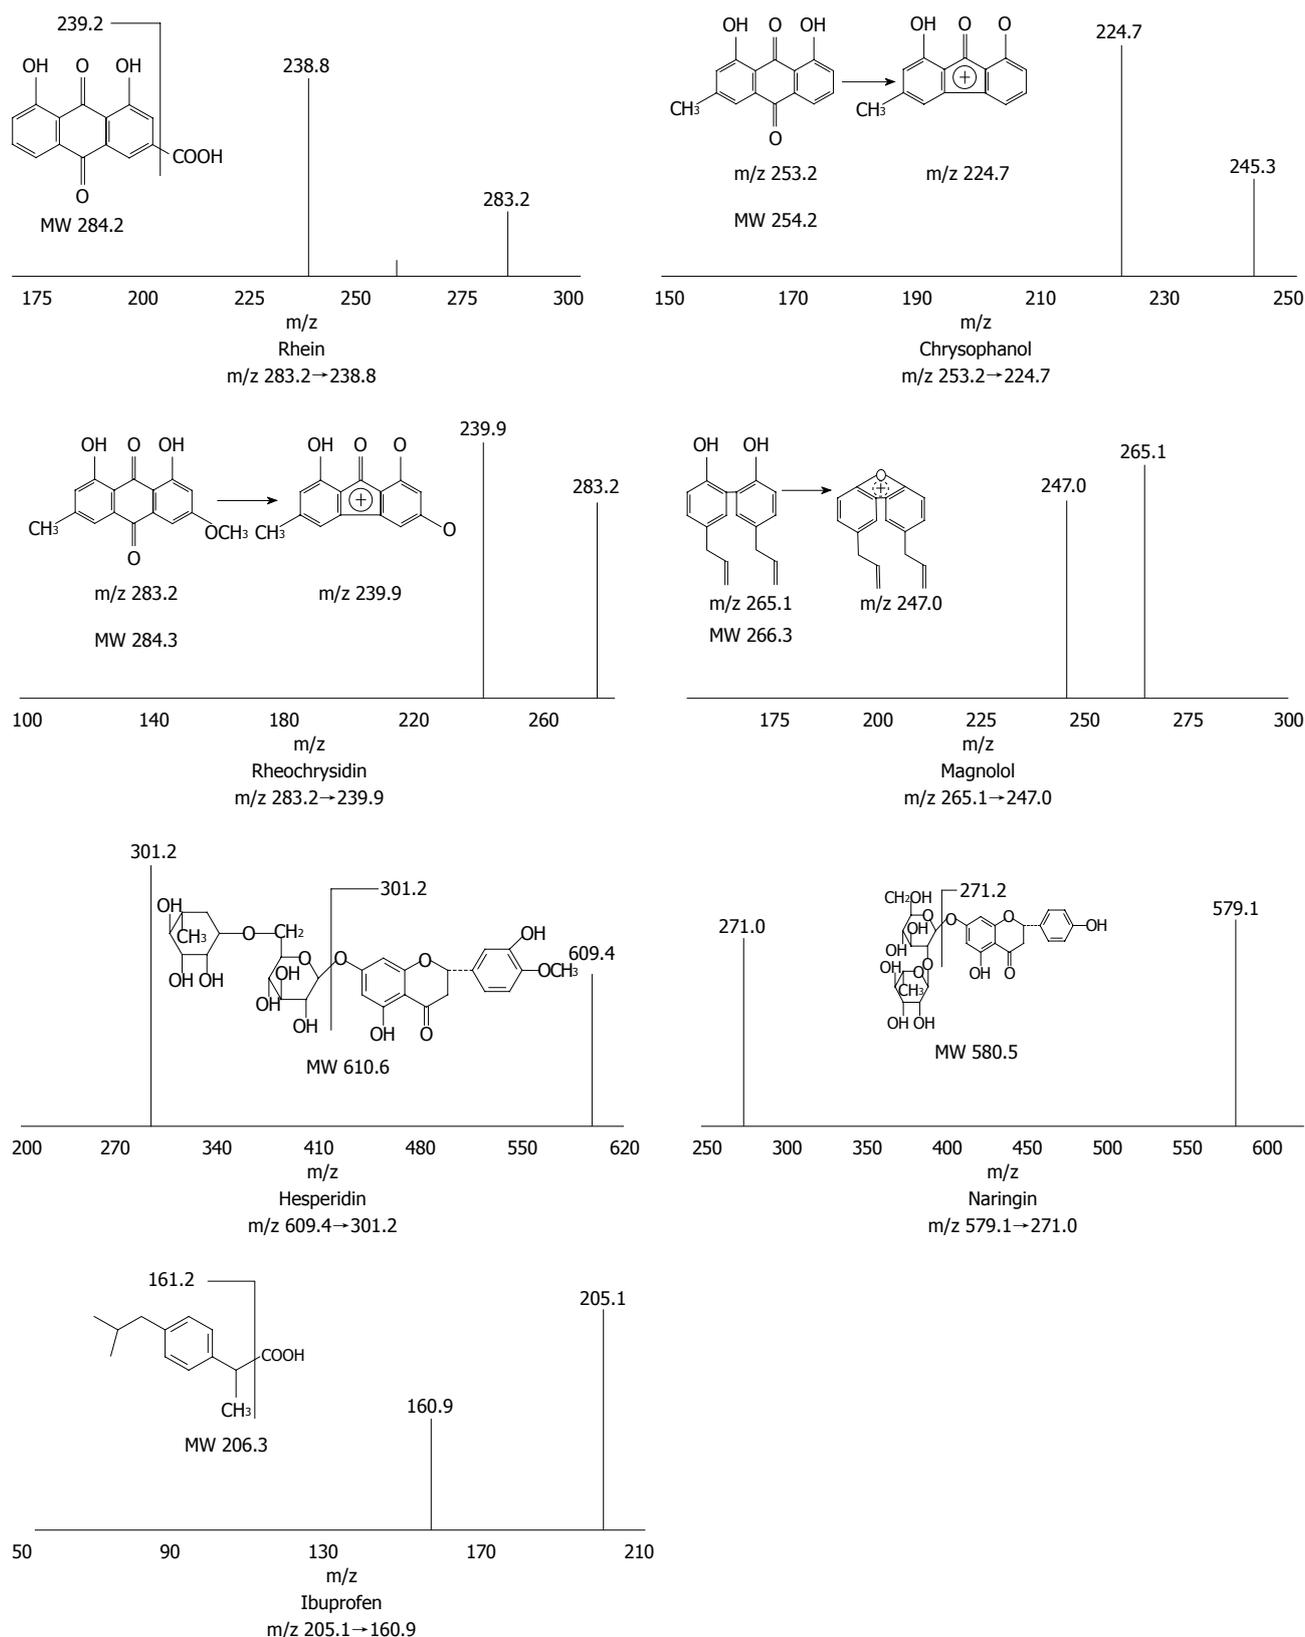

Figure 1 Product ion mass spectra (ESI-) and ion structures of the six major Da-Cheng-Qi Decoction (DCQD) components and internal standards.

### Induction of acute pancreatitis in rats

Acute pancreatitis was induced in rats. The animals were anesthetized with ethyl ether as previously described<sup>[12]</sup>.

### Preparation of Chinese drugs

*Dabuang*, *Houpu*, *Zhishi* and *Mangxiao* were purchased

from Chengdu Green Herbal Pharmaceutical Co. Ltd. (Chengdu, China) and authenticated by Professor Yang Song (Department of Pharmacognosy, Sichuan University, China). DCQD was routinely prepared with 6.0 g of *Dabuang*, 6.0 g of *Houpu*, 6.0 g of *Zhishi* and 6.0 g of *Mangxiao*. For crude drugs, the spray-dried DCQD was

DCQD: Da-Cheng-Qi Decoction; QC: Quality control.

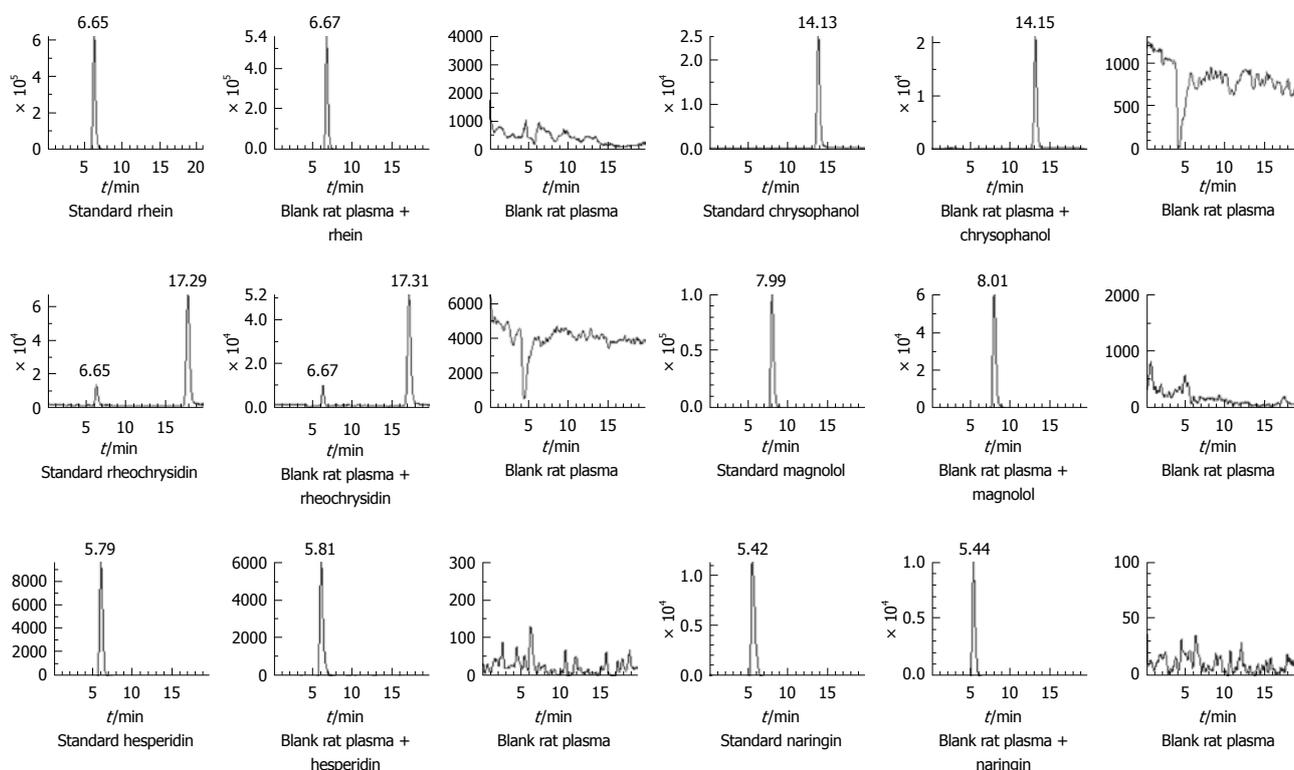

Figure 2 HPLC-TMS showing the six major DCQD components in plasma of rats in two groups.

reconstituted in water to a concentration of 1 g/mL. The contents of the six DCQD components were measured as previously described<sup>[13]</sup>. The crude DCQD preparation was administered through the duodenum of rats at a dosage of 20 g/kg. The voucher specimens were kept in our laboratory.

### *In vivo study*

Rats were randomly divided into SAP group and sham-operation group as a control group ( $n = 6$ ). Rats were given DCQD 2 h after operation. Blood sample (300  $\mu$ L) was collected into a heparinized eppendorf tube *via* the tail vein before and after (10, 15, 20, 30, 45 min and 1,

2, 4, 8, 12 h) DCQD was given. After centrifugation at 3000 r/min for 15 min, the plasma samples were stored at -80°C for analysis.

Rats in SAP and control groups were fed with laboratory rodent chow by gavage. Concentration of DCQD components in plasma was measured by HPLC-TMS. Concentration-time curves were plotted for various components from DCQD.

#### Assay procedure

HPLC-TMS for simultaneous determination of the six components has been validated in our laboratory<sup>[11,14]</sup>. Plasma samples were spiked with the IS (ibuprofen), acidified by HPLC and extracted twice using ethyl acetate. The HPLC-TMS system was operated under MRM modes using electrospray ionization in the negative ion mode.

#### Data collection and analysis

Data collection, peak integration and calibration were performed with Analyst 1.4.2 software. Calibration curves were plotted according to the peak area ratio of analytes to ISs, and the linear regression between plasma concentration and peak area ratio was weighed by  $1/x^2$ . Concentrations of QC and unknown samples were measured by interpolation from the calibration curves. Drug and statistics software programmed by the Chinese Pharmacological Society was used to process the plasma concentration data and compartment model fitting and then all the pharmacokinetic parameters were figured out. The results were expressed as mean  $\pm$  SD. The pharmacokinetic parameters of each DCQD component were compared with statistical software PEMS3.1 and

the difference was compared by sample pairing and *t*-test. *P* < 0.05 was considered statistically significant.

## RESULTS

#### Rhein in rats after a single dose of DCQD by gavage

The mean plasma concentration of rhein was obviously higher, the peak time ( $T_{max}$ ) of rhein was significantly shorter while the  $T_{1/2\alpha}$  was significantly higher, and the clearance rate (CL/F) and AUC of rhein were obviously lower in SAP group at each time point than in control group within 12 h after treatment with DCQD, suggesting that acute pancreatitis can impact the absorption, distribution and elimination of rhein in rats (Figure 3, Table 3).

#### Rheochrysidin in rats after a single dose of DCQD by gavage

The mean plasma concentration of rheochrysidin was significantly higher, the  $T_{max}$  of rheochrysidin was significantly shorter, and the  $T_{1/2\alpha}$  was significantly higher in SAP group at each time point than in control group within 12 h after treatment with DCQD, demonstrating that acute pancreatitis can affect the absorption distribution and excretion of rheochrysidin in rats (Figure 3, Table 3).

#### Chrysophanol in rats after a single dose of DCQD by gavage

The mean plasma concentration of chrysophanol was obviously lower, the  $T_{max}$  of chrysophanol was significantly longer, the  $C_{max}$  and AUC of chrysophanol were significantly lower, the  $T_{1/2\alpha}$  was significantly higher, and the CL/F was lower in SAP group than in control group

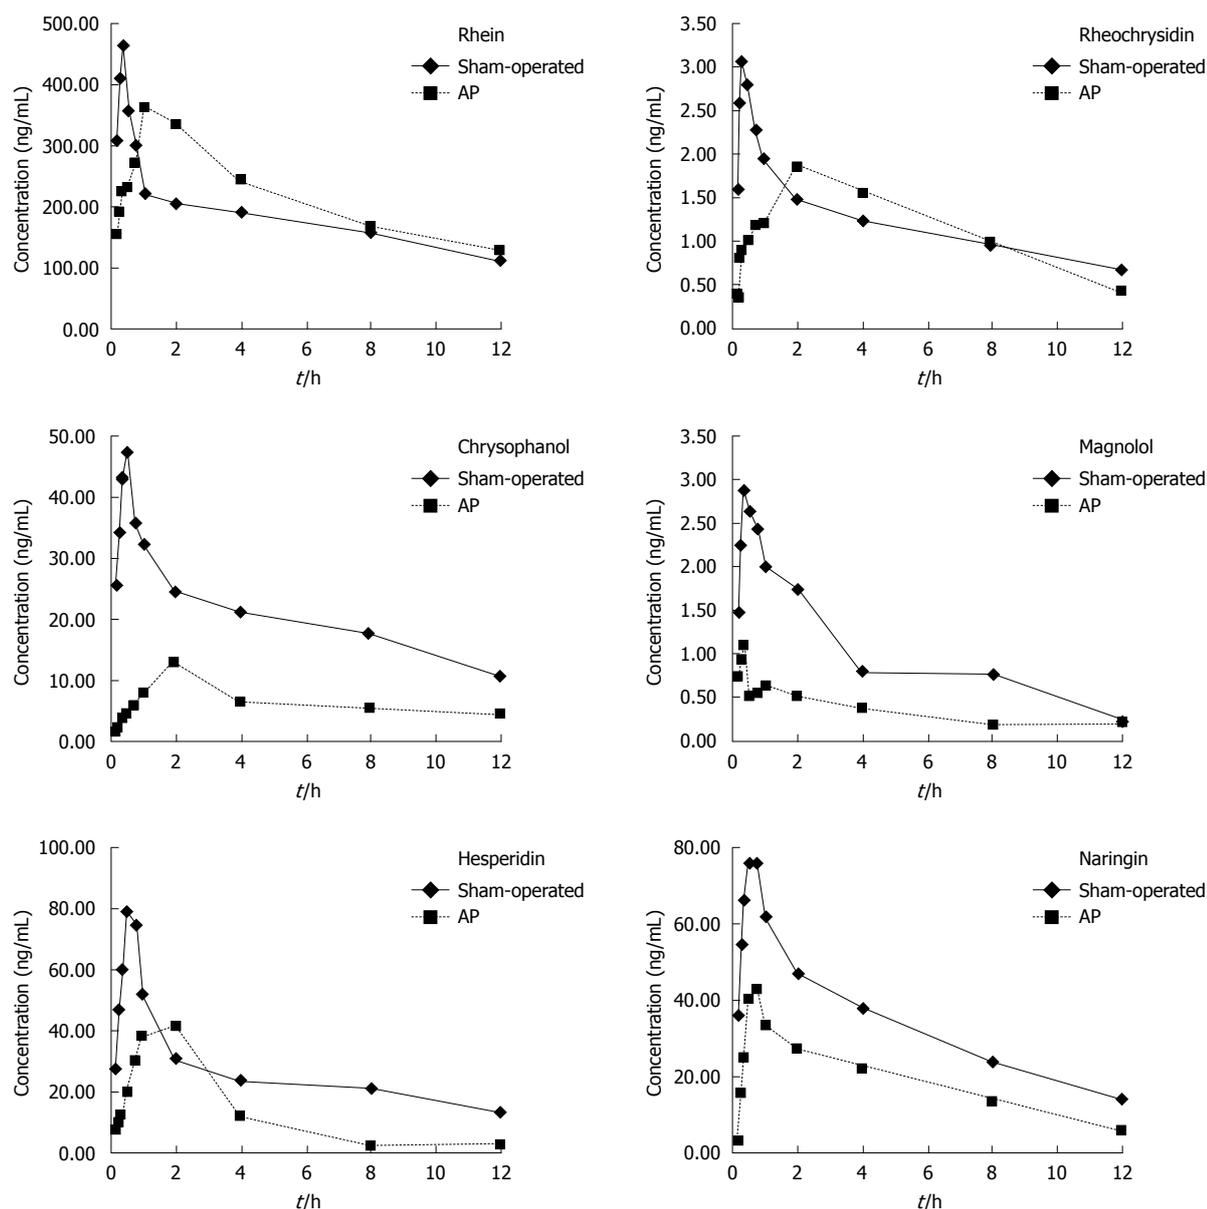

Figure 3 Plasma concentration-time curves for DCQD components in rats of the two groups ( $n = 6$ ).

with no difference in the mean retention time (MRT) between the two groups within 12 h after treatment with DCQD, suggesting that SAP can affect the absorption, distribution, and elimination of chrysophanol in rats (Figure 3, Table 3).

#### **Magnolol in rats after a single dose of DCQD by gavage**

The mean plasma concentration of magnolol was obviously lower, the  $C_{max}$  and AUC of magnolol were obviously lower while the  $T_{1/2\alpha}$ , MRT and  $T_{max}$  were similar between the two groups within 12 h after treatment with DCQD, suggesting that SAP can significantly affect the bioavailability of magnolol (Figure 3, Table 4).

#### **Hesperidin in rats after a single dose of DCQD by gavage**

The mean plasma concentration of hesperidin was obviously higher, the  $T_{max}$  of hesperidin was significantly longer, the  $C_{max}$  and AUC of hesperidin were significantly lower in

SAP group at each time point in control group within 12 h after treatment with DCQD, showing that acute pancreatitis can impact the absorption and distribution and pharmacokinetics of hesperidin in rats (Figure 3, Table 4).

#### **Naringin in rats after a single dose of DCQD by gavage**

The mean plasma concentration of naringin and the  $C_{max}$  and AUC of naringin were obviously lower in SAP group at each time point than in control group within 12 h after treatment with DCQD, revealing that acute pancreatitis can impact the absorption, distribution and bioavailability of naringin in rats (Figure 3, Table 4).

## DISCUSSION

In the present study, the early absorption of each DCQD component tended to degrade in SAP group, the  $C_{max}$  and AUC of DCQD components such as chrysophanol,

magnolol, hesperidin and naringin were obviously lower in SAP group than in control group, suggesting that lack of an effective blood volume and a systematic inflammatory response to organ damage in SAP rats would affect the distribution, metabolism and excretion of DCQD components<sup>[15]</sup>.

No significant difference was found in  $T_{1/2\alpha}$  and  $T_{max}$  of DCQD components such as magnolol and naringin between the two groups, which may be due to the way of modeling experiments. Rats were anaesthetized with ethyl ether and recovered 10 min later with free activity. Two hours after treatment with DCQD, the rats became conscious and maintained normal physiology, indicating that influence of anesthesia on physiology and pharmacokinetics in rats can be ignored<sup>[16]</sup>.

However, the  $T_{1/2\alpha}$  and  $T_{max}$  of rhein, rheochrysidin and chrysophanol were longer in SAP group in control group. In addition, the absorption of DCQD components was greatly affected by variant molecular constitutions and lower pH of SAP rats *in vitro*.

In summary, SAP can obviously impact the absorption and pharmacokinetic parameters of DCQD containing rhein, chrysophanol, rheochrysidin, magnolol, hesperidin and naringin in rats.

## COMMENTS

### Background

Severe acute pancreatitis (SAP), characterized by intricate mechanism, variant symptoms, grave prognosis and multiple complications, seriously threatens the life of patients and brings a heavy burden to the society, families and economy. Additionally, either standard treatment or other medications for SAP is available at present. In China, clinical and experimental researches on Da-Cheng-Qi Decoction (DCQD) have shown that DCQD is a valid prescription for the treatment of SAP.

### Research frontiers

SAP, similar to Yangming Fushi Syndrome (YMFSS) according to the traditional Chinese medicine, has been treated with purgative herbals throughout China for more than three decades. However, no studies are available on the pharmacokinetics of DCQD components in rats with acute pancreatitis.

### Innovations and breakthroughs

According to the theory "syndrome and treatment pharmacokinetics" in traditional Chinese medicine, YMFSS should influence the pharmacokinetics of DCQD, which has, however, not been proved experimentally up to date. This is the first study to report the effect of acute pancreatitis on the pharmacokinetics of DCQD components in rats.

### Applications

Acute pancreatitis was found to have certain effects on the pharmacokinetics of DCQD components in rats, showing that DCQD can be used in treatment of SAP.

### Peer review

The authors investigated the effect of acute pancreatitis on the pharmacokinetics of DCQD components in rats, which may contribute to the treatment of SAP.

### Abstract

The incidence of hepatocellular carcinoma (HCC) is increasing in the United States, and 50%-75% of patients with HCC will develop metastatic disease. Orbital metastases from HCC are extremely rare. We report the case of a 52-year-old male with known metastatic HCC, who presented with severe proptosis and diplopia. An orbital mass was identified on magnetic resonance imaging (MRI) and confirmed to have hypermetabolic activity on positron emission tomography/computed tomography. He received a palliative course of external beam radiation therapy to the right orbit. Intensity modulated radiation therapy (IMRT) was used to allow sparing of critical normal tissues in close proximity to the tumor. One month after completion of IMRT to 58 Gray in 30 fractions delivered over 6 wk, the patient had a complete clinical, radiologic (MRI) and symptomatic response. The patient continues to have local control in the orbit 1.7 years after therapy completion. All critical normal structures were kept below the tolerance dose using IMRT, and no toxicities were observed.

### INTRODUCTION

According to Surveillance, Epidemiology, and End Results data, the incidence of hepatocellular carcinoma (HCC) has been steadily increasing since the mid-1980s and thus presents an increasing health problem in the United States. The average, age-adjusted incidence rates for liver and intrahepatic bile duct cancer, two-thirds of which are HCC, rose from 3.2 per 100 000 persons in 1985 to 6.4 per 100 000 persons in 2005<sup>[1,2]</sup>. The incidence is 3-4 times higher in men than in women and is highest in the Asian population<sup>[2]</sup>. The prognosis for patients diagnosed with HCC is dismal with 5-year survival rates of 3%-5%<sup>[3]</sup>.

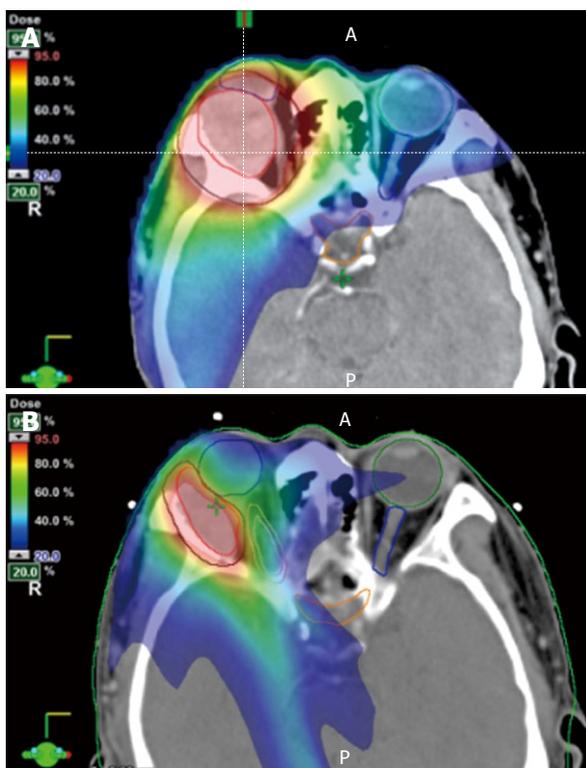

Approximately 50%-75% of patients with HCC will develop metastases during the course of their disease<sup>[4,5]</sup>. The most common sites of metastatic disease are the regional lymph nodes and lung. Less common sites of metastases include bone, brain, adrenal glands, and skin<sup>[4,6-9]</sup>. The orbit has been reported as a site of metastasis from HCC only 14 times in the literature, and information on the palliative response of this highly symptomatic condition with radiation therapy has been very sparse. We report a case of a patient with an orbital metastasis from HCC, who achieved a complete clinical and radiographic response to intensity modulated radiation therapy (IMRT).

### CASE REPORT

A 52-year-old Asian male with a history of hepatitis C but no known cirrhosis presented with elevated liver enzymes

**Figure 1** Axial (A) and coronal (B) T2 weighted MRI of the brain demonstrating the large soft tissue mass in the superior and lateral aspect of the right orbit (white arrows) prior to radiation treatment and resolution of mass on follow-up MRI 12 mo after treatment on axial (C) and coronal images (D).

**Figure 2** Three-dimensional contours for treatment planning demonstrate the gross target volume (GTV) encompassing the tumor (red contour) and the planning target volume (PTV, black contour) on initial (A) and boost (B) CT images. Doses from the initial 7 field intensity modulated radiation (IMRT) plan (A) are represented as color wash according to the scale shown in the figures, representing the range of 95% through 20% of dose coverage. The 7 field IMRT plan for the coned-down field (B) shows even tighter dose coverage and greater sparing of the right optic nerve (pink contour).

while being treated for polycythemia. High resolution triphasic spiral computed tomography (CT) scan of the abdomen demonstrated a well encapsulated, heterogeneous mass in the right lobe of the liver measuring 8.2 cm × 8.8 cm. Imaging characteristics were typical for HCC and  $\alpha$ -fetoprotein was 30 ng/mL. Percutaneous biopsy confirmed HCC in a background of cirrhosis. Exploratory laparotomy with intraoperative ultrasound suggested the need for extended hepatectomy for a curative approach but the volume of the future liver remnant was less than 30%. As such, surgical resection was not completed at

that time. Selective right transarterial chemoembolization, followed by portal vein embolization (PVE) of segments 4-8 was undertaken to promote atrophy of the tumor-bearing liver and hypertrophy of the future liver remnant. Four weeks following PVE, resection was again attempted but metastasis was identified in the future liver remnant. No extrahepatic disease was noted. He was subsequently treated with radioembolization using Yttrium-90.

Shortly after the Yttrium-90 therapy, he developed rapidly progressive diplopia and proptosis of the right eye. Physical examination showed severe proptosis, conjunctival hyperemia, excessive tearing, impaired vision, and limited extraocular muscle movement of the right eye. Magnetic resonance imaging (MRI) of the brain and orbits identified an extraconal 3.7 cm × 3.3 cm × 3.7 cm enhancing mass arising from the floor of the right anterior cranial fossa with extension to the right orbit, resulting in mass effect on the superior and lateral rectus muscles and globe (Figure 1). Positron emission tomography (PET)/CT confirmed a right orbital mass with a peak standardized uptake value (SUV) of 2.8.

He received a course of palliative radiation therapy to a dose of 40 Gray (Gy) in 20 fractions to the right orbit using 6 MV photons and IMRT (Figure 2A). The total gross tumor volume (GTV) was 15.8 cm<sup>3</sup>. A CT scan 10 d after treatment completion showed no response. MRI 1 mo after treatment completion showed the tumor to be decreased from the initial 3.7 cm × 3.3 cm × 3.7 cm to 3.7 cm × 2.8 cm × 3.7 cm. Clinical improvement in the proptosis was also observed. An IMRT boost to the right orbit of an additional 18 Gy in 10 fractions was then delivered (Figure 2B). The total volume of the GTV had decreased to 8.8 cm<sup>3</sup>. The total dose delivered was 58 Gy in 30 fractions over 86 d. The dose to the critical normal structures was kept below the tolerance dose and is presented in Table 1.

One month after receiving 58 Gy to the orbit, the patient reported complete resolution of the diplopia. On examination, his right extraocular muscles functioned normally and proptosis was no longer present. Follow-up PET/CT 1 mo after treatment completion showed decreased fluoro-deoxyglucose activity (peak SUV = 2.2) within the superolateral aspect of the right orbit. MRI of the brain 3, 12 and 17 mo after treatment demonstrated

**Table 1** Critical structures mean dose for original and boost IMRT plans

Structure	Original mean dose (Gy) (2 Gy/fx)	Boost mean dose (Gy) (1.8 Gy/fx)	Total dose (Gy)
Chiasm	6.98	3.55	10.52
Left eye	15.93	1.42	17.34
Left optic nerve	13.3	1.96	15.26
Right eye	30.7	3.96	34.65
Right optic nerve	34.09	6.46	40.55

IMRT: Intensity modulated radiation therapy; Gy: Gray.

complete resolution of the lesion (Figure 1). The patient is alive with controlled orbital disease 20 mo after the initial diagnosis of the orbital metastasis and 26 mo after his original HCC diagnosis. As a result of progression in the liver following Yttrium-90 therapy, he is currently receiving Sorafenib with effective systemic disease control.

## DISCUSSION

Orbital metastases are uncommon and account for 3%-7% of all orbital neoplasms<sup>[7,10,11]</sup>. The most common symptoms of orbital metastases include pain, proptosis, decreased vision or blindness, diplopia, displacement of the globe, exophthalmos, and occasionally enophthalmos. HCC very rarely metastasizes to the orbits, and only a total of 14 case reports of orbital metastases from HCC have been described (Table 2)<sup>[4-15]</sup>. Orbital metastases are usually associated with advanced disease and early mortality. The average survival after occurrence of the orbital metastases is approximately 10 mo<sup>[11]</sup>, although the prognosis ultimately depends on the systemic tumor burden<sup>[5]</sup>.

Among the 14 reported cases of orbital metastases from HCC (Table 2)<sup>[4-15]</sup>, only 4 received primary radiation as the palliative treatment in doses ranging from 30 to 54 Gy, and all showed a response. However, specific details of the radiation planning and treatment delivery in this challenging location are not available. Long-term effects of treatment are poorly understood because only one of the patients survived longer than 1 year after treatment<sup>[11,13]</sup>.

Our patient received a higher dose of radiation than used in the above case reports, and was the first to use IMRT for treatment of orbital HCC metastasis. The orbit is among the most challenging regions for radiation therapy because of the close proximity of dose-limiting critical normal structures, including the brain, ocular structures, and optic chiasm, that can all develop significant complications. IMRT enabled highly conformal treatment delivery and resulted in a durable complete radiologic response.

Our findings are in contrast to the common belief that HCC is a radioresistant tumor. Such reports frequently had to rely on older, less targeted radiation therapy techniques that were unable to spare normal tissues, thus severely limiting the deliverable radiation dose to the tumor to avoid serious toxicity to normal structures. This low tumor dose was not adequate to achieve a significant tumor response<sup>[16]</sup>. Our case shows that dose escalation to 58 Gy, enabled by IMRT, can afford effective local control in

HCC. Our observations are supported by studies showing a dose-response relationship for treatment of metastases from HCC. In a retrospective review by Park *et al*<sup>[17]</sup>, 91% of patients with intraabdominal lymph node metastases from HCC treated to  $\geq 50$  Gy<sub>10</sub> had an objective response compared to 65% of patients treated to lesser doses. Recent studies have also shown excellent local control and improved survival with the use of higher doses for primary HCC, delivered with conformal radiation therapy to the partial liver, that were previously intolerable<sup>[18,19]</sup>.

The tumor response in our patient is also characterized by a protracted time course. Symptoms improved slowly, and not until a treatment break and re-imaging 1 mo after a dose of 40 Gy, was the radiologic response evident. Such a slow response pattern may also have led to the conclusion that HCC is not a radio-sensitive tumor. However, the GTV reduction after a 5 wk break following 40 Gy allowed us to further escalate the dose to the orbital tumor, while effectively sparing the sensitive normal structures, especially the right optic nerve (Figure 2B). In conjunction with the highly conformal IMRT delivery, this interval tumor reduction and dose escalation resulted in a durable complete clinical and radiologic response.

Our case also illustrates the importance of 3-dimensional (3D) volumetric analysis of tumor imaging instead of diameter-based measurements for the assessment of tumor response. In the repeat CT for boost planning after 40 Gy, 3D tumor volumetry, determined by tumor delineation on each imaging slice and computation of the volume, demonstrated a reduced tumor volume from 15.8 to 8.8 cm<sup>3</sup>, a change of 44%. However, the diagnostic brain MRI 1 wk previously showed a decrease from 23.7 to 20.1 cm<sup>3</sup> in MRI diameter-based tumor volume

calculation, a change of 15%. Other studies have also shown that diameter-based measurements overestimate tumor size during and after radiation therapy compared to 3D volumetry. This is likely related to the irregular tumor configurations and non-linear tumor shrinkage, that are not adequately assessed by current gold standard diameter-based measurements<sup>[20]</sup>. The high precision of refined 3D volumetry-based measurements, which are easily obtained from treatment planning systems, can overcome the challenge of irregular tumor configuration<sup>[21]</sup>.

In conclusion, because of the increasing incidence and improvement in systemic treatment of primary HCC, the prevalence of symptomatic metastases from HCC will likely increase. Radiation therapy is an excellent treatment option for palliation of challenging metastatic sites, including the orbit, but higher doses than the typical 30 Gy in 10 fractions may be required. With targeted radiation techniques, such as IMRT, that enable sparing of normal critical structures, and 3D volumetric assessment of the response, tumor volume-adapted dose escalation to optimal tumoricidal dose levels can provide durable effective palliation of debilitating symptoms.

### Abstract

Superior mesenteric artery (SMA) syndrome is an uncommon disease resulting from compression of the third portion of the duodenum from the superior mesenteric artery. This disease shares many common manifestations with diabetic gastroparesis, including postprandial fullness, nausea, vomiting, and bloating. Therefore, it is often overlooked in diabetic patients. Here, we report a 41-year-old man with poorly controlled diabetic mellitus who developed SMA syndrome due to rapid weight loss. The diagnosis was confirmed by computed tomography and an upper gastrointestinal series. His condition improved after parenteral nutrient, strict sugar control, and gradual weight gain.

### INTRODUCTION

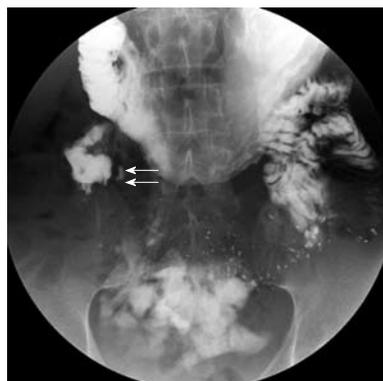

Superior mesenteric artery (SMA) syndrome, also known as Wilkie's syndrome or cast syndrome, is an uncommon disease resulting from superior mesenteric artery compression of the third portion of the duodenum. The clinical manifestations include postprandial fullness or pain, nausea, vomiting, and anorexia due to duodenal obstruction<sup>[1]</sup>. However, the symptoms are similar to those of diabetic gastrointestinal complications. Therefore, SMA syndrome could be misdiagnosed as diabetic gastroparesis. The delayed diagnosis of SMA syndrome might result in malnutrition, electrolyte imbalance, dehydration, and even death.

### CASE REPORT

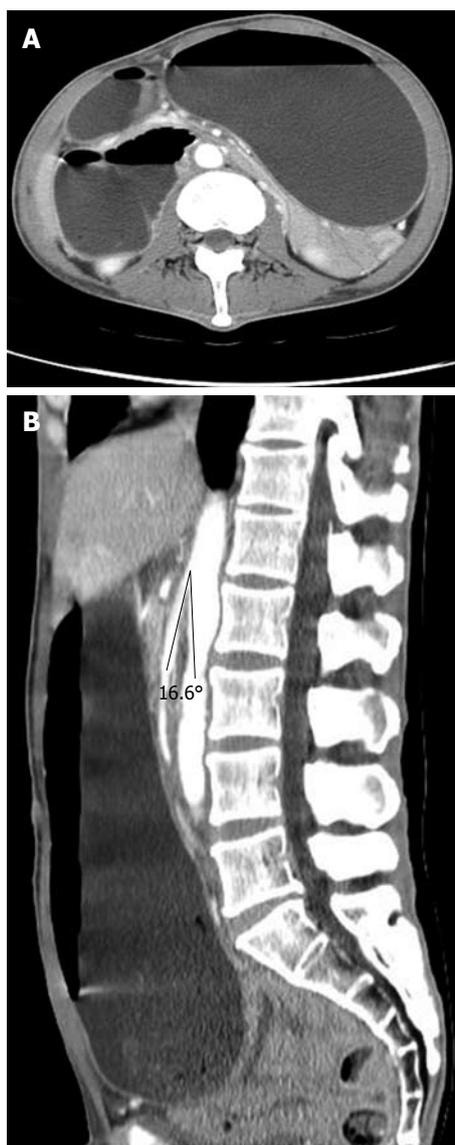

This 41-year-old male was diagnosed type 2 diabetes mellitus four years ago, but the disease was poorly controlled. He did not take any oral antidiabetic agent or insulin therapy for one year. He visited our emergency room complaining of abdominal discomfort and vomiting 30 min after meals for 1 wk. The associated symptoms included general weakness, bilateral lower leg numbness, and a gradual bodyweight loss of 26 kg over the last 3 mo. Physical examination showed a distended abdomen and positive succussion splash sign. His glycemic control was poor and glycosylated hemoglobin (HbA1c) was 11.4%. The abnormal hematologic and biochemical findings included mild anemia (Hgb: 11.7 g/dL) and hypokalemia (K: 3.3 mEq/L). The plain abdomen revealed dilated duodenal bulb and distended stomach with air-fluid level (Figure 1). The gastroduodenoscopy showed a distended stomach with much gastric residue. Therefore, a proximal small bowel obstruction was tentatively diagnosed. To achieve the final diagnosis, we arranged a series of examinations. The upper gastrointestinal series demonstrated a sharp cut-off at the 3rd portion of the duodenum (Figure 2). Compression of the third portion of the duodenum, an

**Figure 1** Abdominal X-ray showing a distended stomach with air fluid level in the stomach and duodenal bulb. The "Double bubble sign" was consistent with high small bowel obstruction.

**Figure 3** Upper gastrointestinal series showing an abrupt cut-off (short arrows) at the third portion of the duodenum.

**Figure 2** Computed tomography (CT) scan showing distended stomach and 2nd portion of duodenum (A); The angle between aorta and superior mesenteric artery (SMA) was 16.6° (B).

aortomesenteric distance of 4.1 mm (normal: 10-28 mm) and a reduction of the aortomesenteric angle 16.6° (normal: 25°-60°) were noted by computed tomography (CT) scan<sup>[2]</sup> (Figure 3). After inserting a nasogastric tube, it drained over 3000 mL turbid, green fluid. His

symptoms improved after nasogastric tube drainage and kept the left lateral decubitus position. We gave him total parenteral nutrition as a nutrition supply and controlled his sugar with an insulin pump for 2 wk. After 2 mo, his bodyweight increased from 44 to 50 kg and he returned to oral intake without subsequent symptoms.

## DISCUSSION

Diabetes mellitus is one of the most common chronic disease of the world and the prevalence of diabetes mellitus is over 10% in Taiwan<sup>[3]</sup>. Gastroparesis is reported in 5% to 12% of diabetic patients. The cardinal symptoms include postprandial fullness, nausea, vomiting, and bloating. Treatment for gastroparesis is prokinetics including metoclopramide, domperidone, and erythromycin<sup>[4]</sup>. However, SMA syndrome can cause the same symptoms as diabetic gastroparesis.

To our knowledge, only two studies have reported diabetic patients with SMA syndrome and all of them had bodyweight loss<sup>[5,6]</sup>. The average bodyweight loss was 29.6 kg (16-50 kg). One of the reported cases received an exploratory laparotomy and the other received intravenous nutrition treatment. In our report, the patient also had a gradually weight loss of 26 kg and improved after medical treatment. The bodyweight loss is a manifestation of the new diagnosis or the poor control of the diabetic patient. It might result in the delayed or missed diagnosis of the SMA syndrome as diabetic gastroparesis.

SMA syndrome is a disease of duodenal obstruction. Weight loss results in loss of the mesenteric fat pad and the superior mesenteric artery compresses duodenum. Bodyweight loss with superior mesenteric artery syndrome, including eating disorders, cardiac cachexia, HIV patients, hereditary motor and sensory neuropathy, have been reported<sup>[7-10]</sup>. The radiographic studies used to establish diagnosis include an upper gastrointestinal series, computed tomography (CT), CT angiography, conventional angiography, abdominal sonography, and magnetic resonance angiography (MRA)<sup>[2,11-13]</sup>. The prone or left lateral decubitus position is effective in the acute status. Conservative treatment with adequate fluid and electrolyte supply is necessary after nasogastric tube placement. Enteral jejunal tube feeding and parenteral nutrition are useful to increase bodyweight. Surgery is indicated when

the conservative treatment fails<sup>[1]</sup>. Laparoscopic duodeno-jejunoscopy has been successful in the cases with SMA syndrome<sup>[14]</sup>.

In conclusion, diabetic patients with gastrointestinal symptoms and bodyweight loss should be considered for SMA syndrome, despite the gastroparesis is the most common etiology. Computed tomography and upper gastrointestinal series are the reliable tools for diagnosis. Adequate nutrition supply is a useful treatment and the aim is bodyweight gain and symptom relief. Surgery is indicated when conservative treatment fails.

## Abstract

Aorto-esophageal fistula (AEF) is a rare and fatal disorder. It is also a life-threatening cause of massive upper gastrointestinal hemorrhage. Thoracic aortic aneurysm is the most common cause of AEF. Management of a patient with this disorder requires rapid diagnosis and immediate intervention, which is considered the best way to save the patient's life. We report a case of AEF misdiagnosed as esophageal polyp.

## INTRODUCTION

Aorto-esophageal fistula (AEF) is a rare and fatal disorder, although it was first described by Dubrueil in 1818. It is also a life-threatening cause of massive upper gastrointestinal hemorrhage. Thoracic aortic aneurysm is

the most common cause of AEF. Prompt diagnosis and emergent intervention are substantial to improve the survival of the patients. We report a case of an AEF due to a descending aorta pseudoaneurysm presenting as an esophageal polyp.

## CASE REPORT

A 62-year-old female patient was admitted to our emergency department for an episode of vomiting bright red blood, with melena and dizziness. Her initial vital sign was normal when she was in emergency. She had a history of intermittent slight chest pain for 2 years. A gastroscopy was performed which revealed a 4 cm fusiform polyp in the mid-esophagus (Figure 1). It was also diagnosed as esophageal polyp with endoscopic ultrasound. The patient was advised to take further examinations, but she refused. During the following 2 years, she received gastroscopy twice (Figure 2) which showed an orifice-like lesion on the top surface of the polyp. Barium radiography reported a 2cm filling defect in the same location (Figure 3). This patient had a history of rib fracture 20 years ago, but no hypertension or diabetes.

A subsequent enhanced computed tomography (CT) documented a descending aortic pseudoaneurysm that compressed the mid-esophagus (Figure 4). The gastroscopy taken after hospitalization documented the same result as before, without fresh blood or clot on the orifice. Twelve days later, she suddenly experienced a shock for her second hematemesis. Blood pressure dropped down to zero. Angiography was performed until her hemodynamic status was stabilized after blood transfusion and hemostasis. The contrast extravasated from the descending aorta rupture with a diameter of about 0.5 cm (Figure 5), which established a diagnosis as descending aortic pseudoaneurysm. A covered endovascular stent grafting was placed immediately. After confirmed to be in good condition by CT, she was discharged on the 10th postoperative day and has remained healthy since then.

## DISCUSSION

AEF, which constitutes approximately 10% of aorto-enteric fistulas, is associated with a high morbidity and mortality. Thoracic aortic aneurysm is the most common cause of AEF, other causes include carcinoma, trauma (including iatrogenic trauma), foreign body ingestion

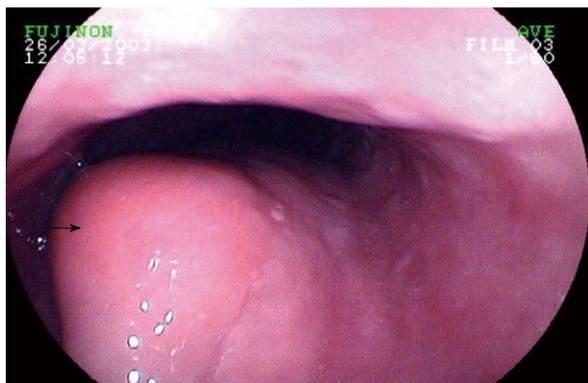

Figure 1 Gastroscopy showing a 4 cm fusiform polyp (black arrow) in mid-esophagus.

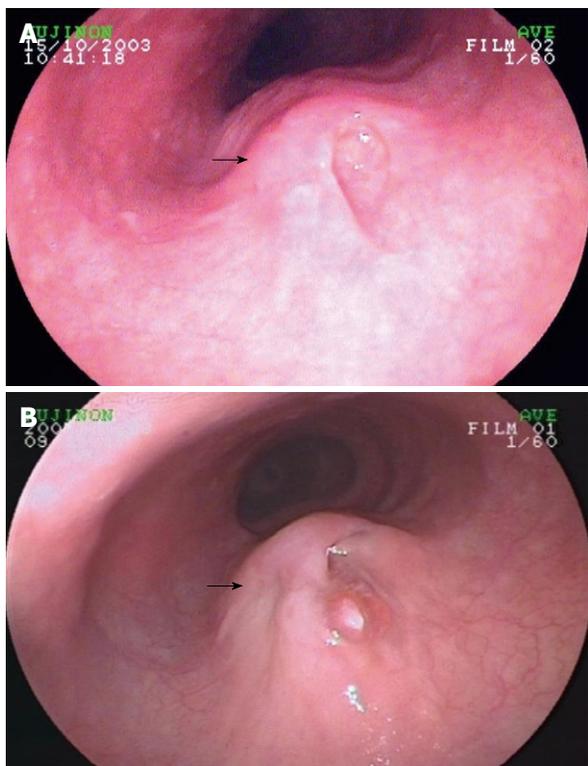

Figure 2 Gastroscopy showing an orifice-like lesion on the top surface of the polyp (black arrows). A: 1st; B: 2nd.

and tuberculous aortitis. Prompt diagnosis and emergent intervention are substantial to improve the survival of the patients. Its classical symptoms, named Chiari's triad, include dysphagia, mid-thoracic pain and sentinel minor hematemesis followed by exsanguination, as did our patient. Mid-thoracic pain may be caused by distension and dissection of the aortic wall, esophageal perforation, or tumor invasion. Spontaneous cessation of the sentinel minor hemorrhage may be caused by temporary occlusion of the fistula due to spasm of the arterial wall and/or periaortic hematoma, which is later digested by infection or gastrointestinal contents. Fifty-nine percent of the AEF patients had mid-thoracic pain, 45% experienced dysphagia, 65% had sentinel minor hematemesis, and 45% showed Chiari's triad<sup>[1]</sup>. Thus, intensive inquiry

Figure 3 Barium radiography reported a 2 cm filling defect (black arrow) in the mid-esophagus.

Figure 4 A subsequent enhanced computed tomography (CT) showing a descending aortic pseudoaneurysm (black arrow).

Figure 5 Aortography. The contrast extravasated from the descending aorta rupture with a diameter of about 0.5 cm (black arrow).

of patient's history and careful physical examination are necessary if AEF is suspected.

Early diagnosis is the key point to decrease the mortality from AEF. Endoscopy is always the first examination to be chosen. Endoscopy usually reveals esophageal compression in the mid-upper esophagus or a submucosal hematoma with bluish grey mucosa indicating the aorta wall. A pulsating mass covered with blood clots or a fistula opening is seldom seen. In our case, one of the causes for misdiagnosis is that gastroscopy showed a polyp with an orifice, without bluish grey mucosa or blood clot. However, whether gastroscopy is safe enough to AEF is still controversial. In our opinion, gastroscopy can be performed carefully for upper gastrointestinal

hemorrhage, except the definitive AEF is confirmed by CT or aortography<sup>[2,3]</sup>.

Subsequent CT or computed tomographic angiography, which is an accurate and non-invasive method for diagnosing AEF, can demonstrate the location of an aneurysm and its surrounding structures, especially esophagus. Barium radiography may display thoracic aortic aneurysm as an extrinsic compression<sup>[3]</sup>. Aortography is used for diagnosing the aneurysm, but rarely shows a fistula itself because of lacking blood. Moreover, aortography may provide more opportunities for endovascular aortic stenting in patients who are not actively bleeding<sup>[4,5]</sup>.

After definitive diagnosis, immediate repair is mandatory as surgical repairs offer the only chance to cure the patients with aneurysm and esophageal erosion. Surgery includes thoracic aorta replacement with a synthetic graft, use of cryopreserved arterial allografts and extra-anatomic bypass. Dacron graft is the most commonly used one. Primary repair and esophageal resection should also be done to avoid the complications of infection. In recent years, endovascular stent grafting has been used as an alternative to surgical treatment, but it has some limitations such as AEF remaining as it is, insufficient debridement or drain of mediastinum. Therefore, some authors suggested that an endovascular stent graft should only be used in patients with a high risk of open surgery<sup>[2,6]</sup>. Since 2005, Pirard *et al*<sup>[7,8]</sup> have attempted to combine endovascular with open surgical approach, which brings more hope to decrease the mortality of AEF.

In conclusion, AEF is an uncommon and life-threatening cause of upper gastrointestinal bleeding. The classical clinical triad, such as mid-thoracic pain or dysphagia,

a sentinel minor hematemesis followed by exsanguinations and gastroscopy will give a hint to suspected AEF, and thoracic CT scan or aortography can confirm this diagnosis. Surgery or endovascular stent grafting should be chosen individually. However, rapid diagnosis and immediate intervention are considered the best ways to save the patient's life.

### Abstract

Given the overwhelming evidence that both alcohol consumption and smoking accelerate the progression of hepatitis C virus (HCV)-induced liver disease, we evaluated the frequency of alcohol and smoking counseling of patients with HCV-induced liver disease by their primary care internists and gastroenterologists. One hundred and twenty-three medical records of consecutive patients with HCV-induced liver disease referred by an internist to a gastroenterologist for its management were reviewed. Patient gender, race, history of and counseling against alcohol and tobacco use by a physician and a gastroenterologist were obtained. A database was created using Microsoft Excel. There were 105 African-Americans, 12 Caucasians and six patients of other races/ethnicities. Forty-six (37%) patients were daily tobacco users and 34 (28%) patients were daily alcohol consumers. There was a statistically significant difference in the frequencies of alcohol ( $P = 0.0002$ ) and smoking cessation ( $P = 0.0022$ ) between gastroenterologists and internists. This study reveals that internists and gastroenterologists, alike, inadequately counsel patients with hepatitis C about tobacco and alcohol use.

### TO THE EDITOR

We read with interest the article by Scognamiglio *et al*<sup>[1]</sup> "Impact of hepatitis C virus infection on lifestyle", *World J Gastroenterol* 2007; 13(19): 2722-2726, which reveals that a greater number of patients with hepatitis C virus (HCV) infection could modify their behavior and lifestyle habits with regard to alcohol consumption when compared to tobacco use after the diagnosis of HCV infection. The authors also emphasized the importance of counseling patients about the effects of both tobacco and alcohol use on the liver in patients with HCV infection. Tobacco use and alcohol consumption alone have been shown to accelerate the progression of hepatitis C toward chronic hepatitis<sup>[1-3]</sup>. Furthermore, multiple studies have shown a synergistic effect of alcohol and tobacco use on the progression of hepatitis C to hepatocellular carcinoma (HCC)<sup>[1,4]</sup>. Independently, tobacco use is also associated with a decreased response to interferon treatment<sup>[1,3]</sup>. Given the above evidence of lifestyle factors on progression of hepatitis C toward chronic hepatitis or HCC, it is imperative that patients with HCV infection not only receive counseling on alcohol consumption but also on tobacco use. We evaluated the frequency of alcohol and smoking counseling of patients with HCV infection by their primary care internists and gastroenterologists.

A retrospective medical record review of patients with HCV infection who were referred by internists to gastroenterologists for management of their liver disease was conducted. The records were evaluated for documentation of alcohol consumption, tobacco use and physician counseling during an evaluation by internists or during consultation by gastroenterologists. One hundred

and twenty three records (75 females, 48 males) were reviewed. There were 105 African-Americans, 12 Caucasians and six patients of other races. Of the 123 patients, 36 (29%) were admitted to smoking, 24 (20%) reported daily alcohol consumption, and 10 (8%) were using both tobacco and alcohol. Ten of the 36 patients who were admitted due to tobacco use were counseled by their primary care internist about the dangers of smoking and were offered assistance in cessation. None of the patients who used tobacco were counseled by their gastroenterologist on the effects of smoking. There was a statistically significant difference ( $P = 0.0022$ ) between the internists' and gastroenterologists' frequencies of consultation on the effects of smoking. Of the 24 patients who drank alcohol daily, 14 (17%) were counseled about the effects of alcohol on the liver by gastroenterologists. Only one of the daily alcohol consumers was counseled about alcohol use by their internists ( $P = 0.0002$ ). There was a statistically significant difference in the frequency of alcohol counseling between gastroenterologists and internists.

It is essential that physicians counsel patients on the effects of both tobacco and alcohol use in the setting of HCV infection<sup>[1]</sup>. Additionally, the discrepancy between the frequencies of addressing smoking and alcohol cessation in patients with HCV infection by internists and gastroenterologists is interesting. This study is important because it reveals that physicians inadequately counsel patients with HCV infection about tobacco and alcohol use despite the overwhelming evidence that these factors accelerate the progression of HCV-induced liver disease toward chronic hepatitis or HCC. The potential fragmentation of counseling may be due to a presumed transfer of responsibility of alcohol counseling by the internist to the gastroenterologist. This can result in decreased counseling by internists about alcohol cessation. Similarly,

gastroenterologists may presume that smoking cessation counseling is the internist's responsibility. It is crucial that efforts are made to ensure that all physicians counsel patients about the effects of alcohol and tobacco use. It is uncertain whether the lapse in counseling is a result of a lack of knowledge about the synergistic effect of tobacco and alcohol use on the progression of HCV-induced liver disease toward chronic hepatitis or HCC, or whether there is simply a failure of both specialties to document their counseling practice.

Although this study is small, it may offer a partial explanation on the findings in study by Scognamiglio *et al*<sup>[1]</sup> on the decreased incidence of smoking modification *vs* alcohol modification in hepatitis C patients. Since hepatitis C treatment is often managed by specialty physicians, alcohol cessation may be emphasized rather than tobacco cessation. Further studies investigating counseling barriers on lifestyle modifications in patients with HCV infection, in both primary care and gastroenterology offices, are necessary to prevent progression of hepatitis C toward an already increasing incidence of HCC.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

Nonalcoholic fatty liver disease (NAFLD), ranging from simple steatosis to nonalcoholic steatohepatitis (NASH), and eventually cirrhosis and liver failure, is seen to be increasing amongst Western children. NAFLD rates are rising in parallel with the epidemic of childhood obesity, and in particular, fatty liver evolves more easily in NASH when poor dietary habits and sedentary lifestyle are combined. In fact, its general prevalence in the child population varies between 2.6% and 10%, but increases up to 80% in obese children. Since NASH is expected to become the most common cause of pediatric chronic liver disease in the near future, there is broad interest amongst clinical researchers to move forward, both in diagnosis and treatment. Unfortunately, to date, the expensive and invasive procedure of liver biopsy is seen as the gold standard for NASH diagnosis and few noninvasive diagnostic methods can be applied successfully. Moreover, there are still no approved pharmacological interventions for NAFLD/NASH. Therefore, current management paradigms are based upon the presence of associated risk factors and aims to improve an individual's quality of life, thus reducing NAFLD-associated morbidity and mortality. Today, lifestyle intervention (diet and exercise) is the treatment of choice for NAFLD/NASH. Thus far, no study has evaluated the potential preventive effect of lifestyle intervention on children at risk of NAFLD/NASH. Future studies will be required in this area with the perspective of developing a national program to promote nutrition education and increase physical activity as means of preventing the disease in individuals at risk. Here, we outline the clinical course,

pathogenesis and management of NAFLD in children, highlighting the preventive and therapeutic value of lifestyle intervention.

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD), a worldwide health problem principally affecting millions of people in Western countries, ranges from simple steatosis to nonalcoholic steatohepatitis (NASH), and eventually cirrhosis and liver failure. A few population-based studies have reported that NAFLD/NASH prevalence has been increasing over the past three decades, both in children and adolescents, presenting a worldwide problem<sup>[1-3]</sup>. The rate of prevalence, ranging from 2.6% to 10%, increases with age and the number of risk factors associated with NAFLD. The most prominent risk factor for NAFLD/NASH is overweight/obesity and the disease is most common in male adolescents<sup>[4,5]</sup>. Studies of the prevalence of NAFLD in overweight/obese children have reported values which range from 8% to 80%<sup>[2,4]</sup>. Discrepancies in prevalence data reported in these studies depend on the methods used for diagnosis<sup>[6-11]</sup>. In fact, although definitive diagnosis of NASH and fibrosis staging and grading requires liver biopsy, most studies have been limited to the use of indirect measures, such as elevated serum alanine transaminase (ALT) and ultrasound to predict histological outcome<sup>[4,12]</sup>.

The clinical course of NAFLD, as well as the management of fatty liver and steatohepatitis, is complicated by limited knowledge of the natural history and pathogenesis of the disease, and the paucity of safe and effective treatment modalities<sup>[1,13]</sup>. Most NAFLD children are asymptomatic and the few signs and symptoms that are observed are often nonspecific. NAFLD is a multifactorial disease that clinically may or may not comprise elevated serum ALT levels, hyperlipidemia, hyperglycemia and insulin resistance, associated with increased body weight and echogenic liver that is suggestive of hepatic steatosis<sup>[13-15]</sup>. Over the initial period of disease, many patients progress to the more advanced form of NAFLD, which combines the mentioned dysmetabolic pattern with severe liver injury, including steatohepatitis, necroinflammation and fibrosis<sup>[16]</sup>.

In contrast to the past, there is today, a widespread and growing recognition of the disease, but some aspects of its pathogenesis and multi-causality still remain obscure<sup>[17,18]</sup>. As a consequence, currently, it is only the presence of associated risk factors that contributes to updating the management program of pediatric NAFLD, which is essentially focused on improving the individual's quality of life, thus reducing NAFLD-associated morbidity and mortality. In this management program, lifestyle intervention (diet and exercise) is the best choice of treatment for NAFLD/NASH in children<sup>[19,20]</sup>. However, the potential preventive effect of lifestyle intervention on children at risk of NAFLD/NASH has still not been evaluated.

Here, we outline the clinical course, pathogenesis and management of pediatric NAFLD in children, and highlight the preventive and therapeutic impact of lifestyle intervention. In addition, we suggest further studies in the area of NAFLD prevention in children, but we also presume that soon a national program will be undertaken to promote nutrition education and increase the physical activity for preventing the disease in individuals at risk.

## CLINICAL COURSE AND PATHOGENESIS OF PEDIATRIC NAFLD

Pediatric NAFLD, as in adults, is defined as fat accumulation in the liver that exceeds 5%-10% by wet weight, in the absence of excessive alcohol consumption<sup>[21]</sup>. Although, the natural history of NAFLD is poorly understood in children, it is a multifactorial liver disease that comprises a large spectrum of clinical features: simple fatty liver accumulation (hepatic steatosis); steatosis accompanied by inflammation and other evidence of cellular injury, including various degrees of fibrosis (NASH); and end-stage liver disease, such as rare cases of cirrhosis and hepatocellular carcinoma<sup>[12,22]</sup>.

All genetic and environmental factors responsible for fatty liver and its progression to NASH are still obscure. The most widely accepted model is a "multiple hits" process (Figure 1), during which a first hit induces accumulation of fat in the liver, which causes hepatic steatosis, and renders hepatocytes more susceptible to

additional cofactors (i.e. oxidative stress, mitochondrial dysfunction, overproduction and release of pro-inflammatory cytokines, adipocytokine imbalance, and stellate cell activation), which induce persistent liver injury that leads to NASH<sup>[17,23,24]</sup>.

### Causes of hepatic steatosis

Hepatic steatosis is caused by imbalance between the delivery of fat in the liver and its subsequent secretion or metabolism. Fat accumulates in the liver for different reasons, in particular because of: excessive intake of dietary free fatty acids (FFAs), *de novo* hepatic lipogenesis, and great liver FFA influx caused by insulin resistance<sup>[25,26]</sup>. Interestingly, Donnelly *et al*<sup>[27]</sup> have demonstrated that liver FFA accumulation in NAFLD subjects derives from non-esterified fatty acids for about 60%-80%; *de novo* lipogenesis for 26%, and originates from diet for about 15%. These findings reinforce the hypothesis that several intracellular pathways may contribute to the accumulation of hepatic fat in NAFLD. These pathways include deregulation of  $\beta$  oxidation, decreased hepatic lipid export *via* very low-density lipoproteins, increased lipogenesis due to insulin-resistance-dependent activation of sterol regulatory element-binding protein (SREBP-1c), and glucose-regulated activation of carbohydrate response element-binding protein (ChREBP)<sup>[28]</sup>.

### Steatohepatitis and fibrosis

Several factors play central roles in the second-hit progression from simple steatosis to NASH. Various mechanisms have been proposed, including increased oxidative stress, inflammation, hepatocellular apoptosis and fibrogenesis<sup>[17,29,30]</sup>. There is accumulating evidence that oxidative stress and mitochondrial dysfunction are relevant in the pathogenesis of steatohepatitis, whatever its initial cause<sup>[31,32]</sup>. Moreover, oxidative stress and mitochondrial dysfunction, with insulin resistance, form a complex network of interactions, which promotes progressive liver injury (fibrosis), which causes chronic accumulation of liver FFA, antioxidant depletion, enhanced cytokine-mediated hepatotoxicity, and promotion of stellate cell activation and proliferation<sup>[33-35]</sup>. This last event ultimately results in increased inflammation, apoptosis and liver fibrosis<sup>[36]</sup>.

## MANAGEMENT OF PEDIATRIC NAFLD/ NASH: FIRST-LINE TREATMENT AND PROMISING THERAPEUTIC AGENTS

Significantly high levels of triglycerides, glucose, insulin, serum ALT, increased body mass index (BMI) and waist circumference (central adiposity) are all possible clinical features of pediatric NAFLD, which suggests that interventions on these variables can help to cure fatty liver, as well as to prevent progression to NASH<sup>[37]</sup>. On the other hand, resolution of histological abnormalities revealed by liver biopsy, is, at this time, the main target of NASH treatment<sup>[20,38]</sup>.

Several recent studies have been carried out to

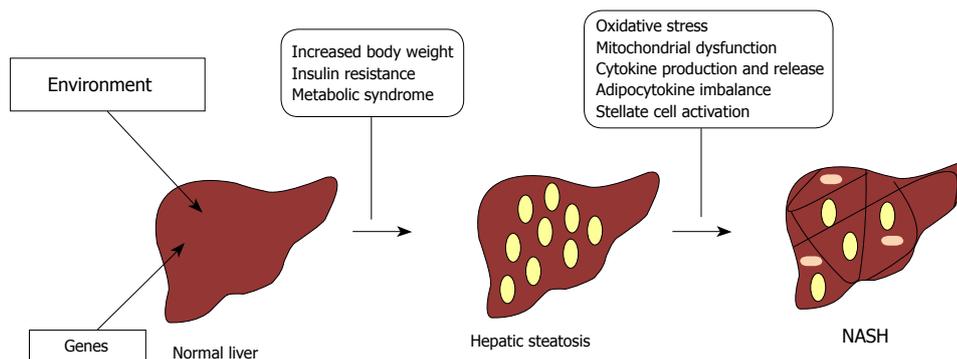

Figure 1 Nonalcoholic fatty liver disease (NAFLD)/nonalcoholic steatohepatitis (NASH) pathogenesis.

examine the effects of dietary composition on NAFLD/NASH in children<sup>[39-41]</sup>. However, some others have also looked at the effects of energy restriction combined with physical activity and pharmaceutical treatments (i.e. vitamin E)<sup>[42,43]</sup>.

#### Diet and exercise

As most NAFLD children are overweight/obese, weight loss may help to reduce pediatric NAFLD prevalence. Weight loss can be achieved through diet and proper exercise, it leads to significant improvement in serum ALT and liver histology in adults with NAFLD<sup>[44,45]</sup>. Studies on pediatric subjects have shown that moderate weight loss can improve serum BMI and levels of ALT, and reduce fatty liver infiltration and necro-inflammation, although no change has been demonstrated in degree of fibrosis<sup>[43,46]</sup>.

Based upon knowledge of NAFLD pathogenesis, a proper diet might be a low-glycemic index diet; in fact, a similar diet may lead to reduction in serum ALT and hepatic steatosis<sup>[47,48]</sup>. Nevertheless, a rapid and excessive caloric restriction and weight loss is not recommended because it might potentially increase dysmetabolism and liver injury<sup>[12]</sup>.

#### Vitamin E

As oxidative stress play a pivotal role in NASH pathogenesis, the use of natural antioxidants, such as vitamin E, is under investigation as a therapeutic approach for NASH patients. Vitamin E has been shown to improve ALT and liver histology in adults with NAFLD<sup>[49]</sup>. However, only one open-label study has demonstrated that 2-4 mo treatment with vitamin E normalizes serum ALT in obese children<sup>[50]</sup>. The efficacy of vitamin E is currently under investigation in a histology-based, double-blind, randomized, placebo-controlled study conducted by NASH Clinical Research Network, and its results will be available in 2010 (ClinicalTrials.gov Identifier: NCT00063635).

#### Insulin sensitizers

Most pediatric NAFLD patients present with insulin resistance, therefore, another approach to decreasing dysmetabolic and histological features associated with this liver disease is treatment with insulin-sensitizing

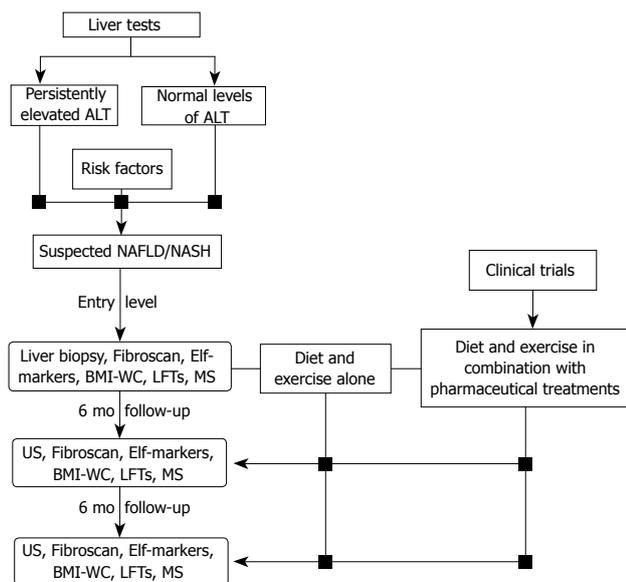

agents. Metformin, a biguanide, is the only insulin-sensitizing agent that has been evaluated for the treatment of pediatric NAFLD. Metformin seems safe and effective in treating type 2 diabetes in children<sup>[51,52]</sup>. In addition, metformin has been evaluated in several pilot studies, which have demonstrated a significant improvement in ALT and hepatic steatosis<sup>[3]</sup>. A pediatric, randomized controlled trial with metformin as a monotherapy in NAFLD is now underway (ClinicalTrials.gov Identifier: NCT00063635). Also, thiazolidinediones, such as pioglitazone and rosiglitazone, have been used successfully for improving insulin resistance and possibly liver histology in adults, but their use in children still requires an accurate control study before they can be considered for use in clinical practice<sup>[53-55]</sup>.

#### Ursodeoxycholic acid (UDCA)

UDCA may act as a cytoprotective and antioxidant agent. It is able to reduce ALT levels and improve liver histology in adults with NAFLD<sup>[56]</sup>. However, in a randomized control trial, Vajro *et al.*<sup>[57]</sup> have demonstrated by ultrasound that UDCA is ineffective in improving serum ALT or steatosis, both alone and in combination with diet. On the other hand, another randomized controlled trial has shown that UDCA in combination with vitamin E may improve serum ALT and liver histology, but also decrease hepatocellular apoptosis and restore serum levels of adiponectin<sup>[58,59]</sup>.

## PREVENTIVE AND THERAPEUTIC EFFECTS OF LIFESTYLE INTERVENTION ON SEVERITY AND OUTCOME OF NAFLD

Patients suffering early liver dysfunction, such as simple hepatic steatosis, or at risk of developing a severe disease, including NASH and cirrhosis, require early diagnosis and intensive treatment. As already discussed, treatment options are limited and dietary weight loss is recommended. Although diets are often difficult to adhere to, they also have an enormous preventive value. In fact, a management program (Figure 2) that incorporates and encourages an adequate diet and age-appropriate physical activities may not only promote a healthy lifestyle, but also prevent the development of NAFLD/NASH.

**Figure 2** Management flowchart for NAFLD/NASH treatment and prevention. EIf: Enhanced liver fibrosis; BMI-WC: Body mass index-waist circumference; LFTs: Liver function tests; MS: Metabolic syndrome; US: Ultrasonography.

### NAFLD-preventive effects of diet and exercise

Weight loss has been, until now, the only proven therapy for pediatric NAFLD. Thus, diet and exercise can be considered the first-line of defense for preventing the onset of NAFLD and progression to NASH in children at high risk. As demonstrated by several recent studies, the high-risk category comprises not only overweight/obese subjects, but also children with insulin resistance, metabolic syndrome, type 2 diabetes, and those with low birth weight<sup>[2,60,61]</sup>.

However, recommendations for lifestyle modifications should be chosen according to the patients' general health because very rapid weight loss might expose patients to severe metabolic consequences and increased mortality risk.

We recommend a hypocaloric diet of 25-30 cal/kg per day in case of overweight/obese subjects, and isocaloric diet (40-45 cal/kg per day) for normal-body-weight children. The amount of calories prescribed also takes into account physical activity and daily routines. Diet composition consists of low gastrointestinal carbohydrate (50%-60%), fat (23%-30%), and protein (15%-20%); a fat composition of two-thirds unsaturated and one-third saturated; and a  $\omega 6/\omega 3$  ratio of approximately 4:1, in accordance with the Italian Recommended Dietary Allowances. Diet is tailored to individual preferences to improve compliance, which may be particularly poor in children and adolescents. A moderate daily exercise program, consisting of 45 min/d of aerobic physical activity, is also recommended. At each visit, subjects or their parents fill out a 3-d dietary and physical activity recall to evaluate adherence to lifestyle recommendations. A multidisciplinary team including dietitians, hepatologists, endocrinologists, psychologists, and cardiologists evaluates and closely follows up the patients. Participants and their parents are instructed on how to exercise, and maintain adherence to the

**Table 1** Success and failure rates after therapeutic intervention in children with liver-biopsy-proven NAFLD *n* (%)

NAFLD: Nonalcoholic fatty liver disease; HOMA-IR: Homeostatic model assessment of insulin resistance; NAS: NAFLD activity score; ALT: Alanine transaminase.

exercise program, by a skilled exercise physiologist as part of our multidisciplinary program. Every 6 mo after treatment, children with NAFLD undergo ultrasonography, laboratory analyses, dietician evaluation and psychological tests. In Table 1, we report our success and failure rates after therapeutic intervention in children with biopsy-proven NAFLD.

Thus, recommendations for lifestyle intervention in children at high risk and in subjects with fatty liver should follow a program based on an integrated care model that encourages patients, as well as family members, to adopt diet and exercise goals to prevent NAFLD/NASH development.

### Integrated care model

NAFLD patients require a multidisciplinary approach that involves health professionals with different areas of expertise. This is even more crucial for pediatric patients, whose care also involves their families and other care providers, such as school personnel. In this respect, it is necessary to identify clearly a case manager with a strong leadership role, who can coordinate case management. Case management is defined as the process of planning, co-ordinating, managing and reviewing the care provided in order to ensure that it responds to the appraisal needs. The challenge of this model is for different professionals to work transversally and concurrently, placing the patient at the core of the system. An effective case management system should therefore be based on different steps<sup>[62]</sup>.

The first step is the strategic planning and preparation of services, which includes different activities, with the integration of skills in a team of professionals who identify and overcome individual and organizational barriers, to guarantee timely access to health care. Coordination, monitoring and evaluation of the results gained by the effort of these integrated teams should be conducted on a regular basis, because they are paramount to achieving proper implementation.

The second step is the management of information. In fact, in order to work in an integrated manner, it is essential to achieve good communication among all the professional specialties involved.

The third step of this model stems from the flow of information between the various professionals and

the patient. In this regard, there must be an educational function towards the patients and their relatives, in order that they may also become actively involved in the decisions and in the implementation of required treatments.

At the Bambino Gesù Hospital, this integrated care model is becoming the health-care model of choice. Beginning in 2003, the Liver Unit implemented the multidisciplinary outpatient clinic for the diagnosis and monitoring of patients affected by NAFLD/NASH. The hepatologist acts as case manager, establishes the individual patient's care program, and coordinates clinical activities with the goal of ensuring that all of them are conducted on the day of the outpatient visit.

In addition to the hepatologist, the multidisciplinary team includes: the endocrinologist, because these patients frequently present with metabolic syndrome, with a predisposition to hyperinsulinism, to glucose intolerance and to type 2 diabetes; the cardiologist, who takes care of cardiovascular issues, ranging from arterial hypertension to increased risk of cardiovascular diseases; the radiologist, for the monitoring of hepatic lesions; the dietician for following appropriate dietary changes and increased physical activity prescribed on an individual basis; and the psychologist to consider psychological attitudes which may have preceded, and perpetuate an unhealthy diet and sedentary life style.

As defined in the program, the results of health care and clinical outcomes are evaluated by the team, and are the object of collegial discussion in order to jointly identify obstacles and the most appropriate way to overcome them.

This organisational model, in which the case manager has a central role, guarantees the quality and efficiency of the multi-specialist care process, leading to a favorable cost/benefit ratio, both at the individual and societal level. In our hospital, this model has worked reasonably well. In fact, it has allowed us to improve considerably patient compliance and medication adherence, reaching values close to 80%<sup>[43]</sup>.

## CONCLUSION

NAFLD/NASH has become the leading cause of pediatric liver disease in westernized countries. Several trials are ongoing to establish pharmacological treatment of pediatric disease, but health and nutrition strategies, such as better exercise habits and comprehensive approach to weight management in the school and home surroundings, can reduce the public health impact of pediatric NAFLD. We believe that our integrated care model not only provides an efficient and effective model for the care management of NAFLD patients, who need the intervention of health-care providers with different background and expertise, but also offers a good starting point for a national program of nutritional education and exercise for preventing the disease in children at high risk (i.e. overweight/obese children).

### Abstract

The spectrum of non-alcoholic fatty liver disease (NAFLD) ranges from simple steatosis through steatohepatitis to advanced fibrosis and cirrhosis. Although the reason why only a minority of patients develop progressive forms of disease still remains largely unclear, recent research has identified genetic factors as a possible basis for this variation in disease presentation. Most of the studies have been focused on finding associations between advanced disease forms and selected single nucleotide polymorphisms in genes encoding various proteins involved in disease pathogenesis. Although there are many limitations regarding the study design and interpretation of published data, further carefully planned studies together with implementation of new genetic technologies will likely bring new insights into disease pathogenesis and potential benefits to the management of patients with NAFLD.

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) has emerged as the most common form of chronic liver disease. The spectrum of NAFLD ranges from simple steatosis through steatohepatitis (NASH) to advanced fibrosis and cirrhosis, and the minority of patients progress to end-stage liver disease requiring liver transplantation or develop hepatocellular carcinoma<sup>[1]</sup>. However, the vast majority of patients only have simple steatosis with a benign long-term prognosis. It has been observed that even when considering patients with similar environmental and metabolic NAFLD risk factors (diet, exercise, obesity and insulin resistance being the most important factors), they still differ largely in terms of disease phenotype and degree of progression<sup>[2]</sup>. This led to the research focus more recently being placed on genetic factors that may possibly have a role in NAFLD etiology, and genetic variability is now implied to be one of the most important determinants of disease phenotype and progression in individual patients.

### GENETIC INFLUENCES IN NAFLD

Possible genetic risk for advanced NAFLD was initially suggested in studies which showed coexistence of NASH and/or cryptogenic cirrhosis within several kindreds, and it was not invariably associated with similar major metabolic risk factors<sup>[3,4]</sup>. Further evidence comes from reports of ethnic differences in the prevalence of steatosis, NASH and cryptogenic cirrhosis. The prevalence of all forms of NAFLD was shown to be highest in Hispanic and lowest in African American populations, and this variability did not always correlate with differences in the prevalence of major risk factors<sup>[5-7]</sup>. Furthermore, it was reported that Asian patients with NAFLD had a significantly lower body mass index (BMI) than all other racial groups<sup>[8]</sup>.

As most of the common diseases today, NAFLD

is considered to be a genetically complex disorder. In complex diseases, several or many different genes interact with environmental factors in determining disease presence or its phenotype, and individual genes only have a small effect on disease risk and can therefore be very difficult to identify. Methods for detecting genes in complex disorders have included family-based linkage studies, hypothesis-based candidate gene allele association studies, genome-wide single nucleotide polymorphism (SNP) scanning and, recently, microarray and proteomic studies. Almost all of the data available on genes associated with NAFLD has so far come from the candidate gene association studies, where candidate genes are usually selected on the basis of their suggested role in disease pathogenesis, and the frequency of one or more known SNPs within or close to those genes is compared in cases and controls, in the search for a positive or negative association with the disease. Genes that are candidates for study in NAFLD have included genes influencing insulin resistance, fatty acid metabolism, oxidative stress, immune regulation and fibrosis development.

## GENETIC POLYMORPHISMS

### **Peroxisome proliferator-activated receptor $\gamma$ coactivator 1 $\alpha$ (PPARGC1A)**

*PPARGC1A* has been involved with different metabolic pathways, such as regulation of gene expression in glucose and lipid metabolism and transcriptional control of cellular metabolism, mainly through control of mitochondrial function and biogenesis<sup>[9,10]</sup>. Several studies have shown that *PPARGC1A* regulates several key hepatic gluconeogenic genes, is directly involved in the homeostatic control of systemic energy metabolism, and *PPARGC1A* Gly482Ser polymorphism has also been associated with the development of insulin resistance, obesity and diabetes<sup>[11-14]</sup>. *PPARGC1A* knockout mice are prone to develop hepatic steatosis due to a combination of reduced mitochondrial respiratory capacity and an increased expression of lipogenic genes<sup>[15]</sup>. Yoneda *et al*<sup>[16]</sup> therefore examined 15 SNPs in the *PPARGC1A* gene and found that the rs2290602 polymorphism was significantly associated with NAFLD (more closely with NASH than with simple steatosis), and the frequency of the T allele (allele with rs2290602 polymorphism) was significantly higher in the NASH patients than in the control subjects. They also found that intrahepatic *PPARGC1A* mRNA expression was significantly lower in the TT genotype group than in the GG or GT group. On the other hand, Hui *et al*<sup>[17]</sup> did not find any association between the Gly482Ser variant and NAFLD in Chinese Han people. However, they have reported a correlation between C161T PPAR- $\gamma$  gene SNP, consequent lower plasma levels of adiponectin and increased susceptibility to NAFLD.

### **Microsomal triglyceride transfer protein (MTTP)**

A higher incidence of -493G/T polymorphism in the MTTP gene promoter has been reported in patients with NAFLD; GG homozygosity was associated with

more severe liver histology and has been considered as a risk factor for NAFLD<sup>[18]</sup>. Gambino *et al*<sup>[19]</sup> suggested that NASH patients with GG homozygosity have more atherogenic postprandial lipoprotein profiles and lipoprotein metabolism, which leads to increased peroxidative liver injury.

### **Leptin**

Leptin is an adipocytokine whose main role is regulation of food intake. It probably has an important role in the pathogenesis of NAFLD; leptin-deficient ob/ob mice develop steatohepatitis when fed with a methionine-choline-deficient diet<sup>[20]</sup>. Common variants in the human leptin receptor (*LEPR*) gene have been associated with traits of metabolic syndrome such as obesity, insulin resistance, type 2 diabetes mellitus and altered lipid metabolism, and possibly with NAFLD<sup>[21-23]</sup>. The *LEPR* 3057 variant may link obesity to NAFLD in Chinese patients with type 2 diabetes mellitus through interference with leptin receptor signaling and regulation of lipid metabolism and insulin sensitivity<sup>[24]</sup>.

### **Adiponectin**

Adiponectin, an adipocyte-derived cytokine has an important role in mobilization, transport and muscle oxidation of free fatty acids leading to improvements in lipid profiles and insulin sensitivity<sup>[25,26]</sup>. High levels of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) mRNA in adipose tissue and high plasma TNF- $\alpha$  concentrations were detected in adiponectin-knockout mice, resulting in severe diet-induced insulin resistance<sup>[27]</sup>. Musso *et al*<sup>[28]</sup> reported that the adiponectin SNPs 45TT and 276GT/TT were more prevalent in Italian NAFLD patients than in the general population; these polymorphisms independently predicted the severity of liver disease in NASH and exhibited a blunted postprandial adiponectin response and higher postprandial triglyceride levels.

### **Hepatic lipase**

Zhan *et al*<sup>[29]</sup> investigated the prevalence of the hepatic lipase gene promoter polymorphism at position -514 in Chinese patients with NAFLD. They reported a higher frequency of the CC genotype and C allele in the NAFLD group and both the CC genotype and CT genotypes were associated with higher relative risk for development of NAFLD<sup>[29]</sup>.

### **Phosphatidylethanolamine N-methyltransferase (PEMT)**

Phosphatidylcholine is required for hepatic formation and secretion of very low density lipoproteins, and it has been shown that a choline-deficient diet leads to accumulation of fat droplets in hepatocyte cytosol and the development of fatty liver<sup>[30]</sup>. PEMT catalyzes *de novo* synthesis of phosphatidylcholine and is responsible for approximately 30% of phosphatidylcholine formed in liver, the rest of it being synthesized by another pathway from dietary choline. Song *et al*<sup>[31]</sup> showed that SNP (G to A substitution in exon 8) that leads to Val to Met substitution at residue 175 of PEMT is associated

Table 1 Studies of genetic polymorphisms in non-alcoholic fatty liver disease (NAFLD) included

Transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1)	Pro25Arg		

with significantly diminished activity of the enzyme, and determined the frequency of this polymorphism in NAFLD patients and controls. The loss of function AA genotype (Met/Met) occurred significantly more frequently in NAFLD patients than in control subjects, which led to the conclusion that genetically inherited low PEMT activity is an important risk factor for developing NAFLD. This was further proven in a Japanese study published by Dong *et al*<sup>[32]</sup>. Although the polymorphism is much rarer in the Japanese population than in Caucasians, the frequency of A allele was significantly higher in NASH patients compared with controls. NASH patients who were carriers of the Val175Met variant had significantly lower BMI and were more frequently non-obese than NASH patients who were wild-type homozygotes, further proving the role of this polymorphism as an independent risk factor for NAFLD development.

#### **Methylenetetrahydrofolate reductase (MTHFR)**

Sazci *et al*<sup>[33]</sup> investigated whether the C677T and A1298C polymorphisms of the MTHFR gene which lead to hyperhomocysteinemia and development of liver steatosis were associated with NASH. They found that the MTHFR 1298C allele was associated with increased risk for NASH in patients of both genders, C1298C genotype and C677C/C1298C compound genotype in female and C677C/A1298C compound genotype in male NASH patients.

#### **TNF- $\alpha$**

TNF- $\alpha$  has long been proven to be one of the key cytokines in the development of all chronic liver diseases. In NAFLD, it has been shown that it may cause hepatocyte injury and apoptosis, neutrophil chemotaxis, and hepatic stellate cell activation, as well as contribute to systemic and hepatic insulin resistance<sup>[34-36]</sup>. Crespo *et al*<sup>[37]</sup> found that obese patients with NASH compared to those without NASH have significantly increased liver expression of TNF- $\alpha$  and its receptor p55, as well as increased expression of TNF- $\alpha$  in adipose tissue. Valenti *et al*<sup>[38]</sup> investigated the relationship between insulin resistance,

occurrence of NAFLD and -238 and -308 TNF- $\alpha$  promoter polymorphisms known to be associated with an increased release of this cytokine. The prevalence of the 238 TNF- $\alpha$  polymorphism was higher in subjects with NAFLD than controls, and patients with these polymorphisms had higher insulin resistance indices. Tokushige *et al*<sup>[39]</sup> determined the prevalence of several TNF- $\alpha$  promoter region polymorphisms (positions -1031, -863, -857, -308 and -238) in a group of Japanese NAFLD patients and control subjects. There were no significant differences in the allele frequencies of any of the six polymorphisms among the group of patients with NAFLD and the control group, including the -238 polymorphism which was previously reported to be associated with NAFLD in Italian patients, but this polymorphism was much less frequent in the Japanese population<sup>[38]</sup>. However, the frequency of the -1031C polymorphism was significantly higher in the NASH group compared to the simple steatosis group, as was the frequency of the -863A polymorphism. The frequency of other polymorphisms did not differ significantly between the two groups. These two polymorphisms were also associated with higher levels of insulin resistance measured by HOMA-IR.

#### **Transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) and angiotensin II**

TGF- $\beta$ 1 and angiotensin II are two molecules that have been extensively studied in models of liver fibrogenesis. TGF- $\beta$ 1 has a major role in development of liver fibrosis by activation of hepatic stellate cells and stimulation of production of extracellular matrix proteins<sup>[40]</sup>. Besides its well-known effects in the cardiovascular and renal systems, angiotensin II also has an established role in liver fibrogenesis, and based on those observations, studies with angiotensin II receptor antagonists have been performed in patients with NASH<sup>[41,42]</sup>. There have been several suggestions that profibrotic effects of angiotensin II in heart and kidney are mediated by induction of transcription of TGF- $\beta$ 1<sup>[43,44]</sup>. Considering these data, and based on their previous study in hepatitis C patients, Dixon *et al*<sup>[45]</sup> investigated the relationship between the

presence of advanced fibrosis and angiotensinogen G-6A polymorphism or TGF- $\beta$ 1 Pro25Arg polymorphism in a group of severely obese patients. There was no correlation between either high angiotensin or TGF- $\beta$ 1 producing genotypes alone and hepatic fibrosis. However, patients who inherited both high angiotensin and TGF- $\beta$ 1 producing polymorphisms had a higher risk of advanced fibrosis. These data also support the hypothesis that angiotensin II stimulated TGF- $\beta$ 1 production promotes hepatic fibrosis.

A comprehensive list of the above-mentioned polymorphism studies is shown in Table 1.

## CONCLUSION

While all this and other evidence clearly indicates that genetic factors have a key role in determining susceptibility to advanced forms of NAFLD and its progression, the majority of studies mentioned here had small sample sizes and therefore limited statistical power, which makes it rather difficult to draw definitive conclusions. However, we believe that the development and wider availability of high throughput genetic technologies together with careful design and performance of large multicenter studies with adequate statistical power will soon provide new insights in this vast and very interesting area. Further study and new data on genetic effects have many potential benefits - advancement in understanding the pathogenesis of NAFLD, identification of new potential treatment targets, and, eventually, categorization of patients with respect to disease prognosis, leading to a change in management approach in specific subgroups of patients. Despite the currently limited data on genetic influences in NAFLD and all the difficulties in studying them, we believe that most of the variability in NAFLD presentation will eventually be attributed to and explained by variations in SNP frequencies and their effects on the function of factors involved in the pathogenesis of the disease.

### Abstract

There are limited data on celiac disease (CD) from India. The limited knowledge about CD in India might be attributed to several factors. The first meeting of the Indian Task Force for Celiac Disease was held in the Asian Institute of Gastroenterology, Hyderabad, India in December 2008. The objectives of the meeting were to focus research on prevalence of CD in the

wheat-eating Northern vs the rice-eating Southern Indian population, low-budget serological assays to study the underprivileged population, to involve other medical subspecialties in CD, to suggest proper legislation regarding wheat food labeling, and to organize affordable food substitutes for patients with celiac disease.

### INTRODUCTION

Celiac disease (CD) is an autoimmune disease that is caused by interaction of gluten in genetically predisposed individuals<sup>[1]</sup>. The diagnosis is based upon European Society for Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN)/United European Gastroenterology Foundation (UEGF) criteria<sup>[2]</sup>.

CD in India is submerged in an ocean of malnutrition. The limited research on CD in India can be attributed to several factors: (1) a common belief that CD is uncommon in India; (2) recognition of tropical sprue and gastrointestinal tuberculosis as major causes of chronic diarrhea and malabsorption syndromes; (3) non-realization that partial villous atrophy (PVA) may be a feature of CD; (4) more pressing problems of malnutrition; (5) lack of awareness regarding non-diarrheal manifestations of CD<sup>[3-5]</sup>.

The first meeting of Indian Task Force for Celiac Disease was held in the Asian Institute of

Gastroenterology, Hyderabad, India on December 6, 2008. The main objectives of this meeting were to evaluate the Indian data on CD and discuss future research. A panel of experts from different parts of India, who have special interest in CD, took part in this Task Force. Professor Mulder CJJ, VU University Medical Center, Amsterdam, also participated in the meeting as an international expert. All the participants addressed issues specific to CD and discussed the area of future research and the strategies to carry out these objectives. In addition, legal issues related to food labeling and availability of gluten-free food items in India were also discussed.

## EPIDEMIOLOGY OF CD IN INDIA

Based on epidemiological studies from Europe and the United States, 90% of CD remains undiagnosed. There are limited data on prevalence of CD from India<sup>[6-9]</sup>. The majority of data are from Northern India. The incidence of CD is increasing<sup>[10]</sup>. The prevalence of CD in India is probably not different from that in western Caucasian populations<sup>[11]</sup>. In a field study conducted among school children in Punjab, the estimated frequency of disease was 1 in 310 (0.3%)<sup>[12]</sup>. This prevalence is probably an underestimation. The siblings of CD patients have a high prevalence of CD (22%). In other studies, the prevalence of CD among the first-degree relatives has been reported to be 8%-25%<sup>[13-15]</sup>. There are regional variations in the prevalence of CD due to genetic and dietary factors, that is, the wheat-rice shift from the North to the South in India, which will be discussed in the next section.

## REGIONAL DIFFERENCES AND CHANGING EPIDEMIOLOGY IN INDIA

CD has a strong genetic predisposition. The main genetic factors are *HLA-DQ* genes, that is, the genes encoding DQ2 or DQ8 in the HLA complex. In the West, approximately 95% of CD patients have a DQ2 heterodimer comprised of DQB1\*02 and DQA1\*05, and most of the remaining 5% have a DQ8 heterodimer comprised of DQB1\*302 and DQA1\*03. Adequate data about DQ2 and DQ8 distribution in India are lacking<sup>[16-19]</sup>.

Regional differences in CD can be explained by genetic, dietary and immunological factors. High prevalence areas of CD such as Saharawis (North Africa, up to 5%) and Europe (1%) have a very high carrier rate of DQ2 and DQ8. On the other hand, Japan and Burkina Faso, which have very low prevalence of CD, have low or absent DQ2 and DQ8 carriage.

Dietary patterns also contribute to geographical differences in CD. Wheat consumption broadly parallels CD prevalence, being particularly low in the Far East and Sub-Saharan Africa. In India also, CD is reported frequently in high wheat-consuming states in Northern India.

Immune conditioning might also influence the development of CD. Dose of gluten in early childhood may be an important determinant of lifelong susceptibility.

Breast feeding during gluten induction probably reduces susceptibility<sup>[20]</sup>. Increased exposure to enteric infections in infancy confers modest increase (1.5 RR) in susceptibility to CD<sup>[21]</sup>.

## CASE FINDING IN HIGH-RISK GROUPS

A wide gap exists in India between the CD prevalence in the population (1%) and the prevalence based on diagnosis (0.02%-0.27%). Thus 90%-95% of CD remains undetected<sup>[22]</sup>. Several complications might occur among untreated CD subjects. Among non-diarrheal adult cases with gastrointestinal symptoms, diagnosis of CD and treatment with gluten-free diet results in a significant improvement in symptoms of abdominal pain, bloating and lactose intolerance. A twofold increase in standard mortality ratio has been reported in adult CD<sup>[23]</sup>. Excess mortality occurs in the first 5-10 years after diagnosis among subgroups of patients with malabsorption, delayed diagnosis and poor compliance. Enteropathy-associated T-cell lymphoma (EATL) is an important mortality risk in patients diagnosed above 50 years of age. There is a higher frequency of so-called associated disorders in CD in comparison to controls, such as endocrine disorders, type 1 diabetes mellitus and connective tissue disorders. Higher risk of malignancy in adult CD is known. Overpresentation of cancer occurs in the small bowel, esophagus and T-cell lymphoma. After diagnosis, despite dietary compliance, an increased risk was observed for EATL<sup>[24]</sup>. On the contrary, a protective role of gluten-free diet has been reported for these so-called associated malignancies<sup>[25]</sup>. The risk of breast cancer seems lower in CD. A higher frequency of CD occurs with autoimmune disorders. The incidence of autoimmune disorders in CD seems to be related to duration of gluten exposure<sup>[26]</sup>.

Targeted screening of CD might be important<sup>[27]</sup>. Among children, screening for CD in India is not indicated before age 1-3 years. Compliance with gluten-free diet and giving consent for small bowel biopsy are problems, because the subjects usually are not convinced about investigations and treatment in the absence of severe symptoms. Serological tests like tissue transglutaminase (tTGA) have a positive predictive value of 75%-80%, however, seronegative CD is well-recognized in milder degrees of villous atrophy<sup>[28]</sup>. In future, we have to define how to interpret serology positivity when biopsies are normal. There is no consensus regarding treating subjects with silent disease with positive serology.

## CD IN CHILDREN IN INDIA

CD was first reported in India in 1966<sup>[29]</sup>. The triad of symptoms of chronic diarrhea/malabsorption, failure to thrive and anemia were common until 2000 in India. However, the presentation of disease seems to have changed over the past few years. An upsurge has been observed by clinicians from North-West India. The so-called typical presentation is now below 50%<sup>[30-32]</sup>.

Symptomatic disease is just the tip of the iceberg but, because of the availability of new serological tests,

we are exploring the hidden CD groups in India. The demographic profile of CD in children in India is different from that in the West<sup>[33]</sup>. In one Indian study, the male/female ratio was 3:2. The sole atypical presentations were short stature in 20%, anemia in 14%, constipation in 5%, family history of CD in 5%, and rickets in 1.5% of patients. Common associations observed in children were IgA deficiency in 6%, asthma in 2%, type 1 diabetes in 1.5%, autoimmune hepatitis in 1.5%, seizures in 1.5%, juvenile rheumatoid arthritis in 0.7%, Down syndrome in 0.7%, and nephrotic syndrome in 0.7% of patients. The recent upsurge is due to factors like improved awareness among pediatricians, cost-effectiveness of serological tests, and increasing pediatric endoscopic facilities.

### CAPSULE ENDOSCOPY IN CD

Video capsule endoscopy (VCE) provides high resolution views of the small intestinal mucosa in a noninvasive manner. Characteristic mucosal abnormalities are seen on capsule endoscopy in CD, which include scalloping of mucosal folds, fissures or grooves, mosaic pattern, and absent or reduced mucosal folds<sup>[34]</sup>. Although esophagogastroduodenoscopy (EGD) and multiple duodenal biopsies continue to remain the gold standard, VCE may be used for initial diagnosis and follow-up of CD patients. VCE may be a reasonable alternative to upper gastrointestinal endoscopy in those patients who are strongly positive for tTGA or endomysial antibodies (EMAs), who are unwilling to undergo EGD. In patients with positive serology for CD and negative histology, VCE might be of help. VCE is useful in follow-up of patients of CD who remain symptomatic despite being on a gluten-free diet<sup>[35]</sup>.

### MAGNIFICATION ENDOSCOPY IN CD

The role of conventional endoscopy in the diagnosis of CD has been limited because of low and varying sensitivity and specificity. The small bowel mucosal damage associated with CD can be distributed unevenly and present as patchy villous atrophy, with some parts appearing normal and others severely diseased<sup>[36]</sup>. Endoscopic markers are not adequate to target biopsy sampling to sites of villous damage in the duodenum.

In the past few years, newly developed procedures and technologies have improved endoscopic recognition of the duodenum. These new technologies include the water immersion technique, chromoendoscopy, high-resolution magnification endoscopy, narrow band imaging, and optimal band imaging<sup>[37]</sup>. These new endoscopic techniques have increased the accuracy of CD diagnosis in patients with patchy villous atrophy, and achieve optimal accuracy for the recognition of severe villous atrophy<sup>[38]</sup>.

### HISTOLOGICAL FEATURES AND PROBLEMS IN INTERPRETATION

Diagnosis of CD is confirmed by biopsy, with a characteristic mucosal injury in association with a clinical

response to a gluten-free diet. Biopsy of the small bowel remains the gold standard for the diagnosis of CD<sup>[39]</sup>. Normal small intestinal mucosa contains long villi, varying in length depending on orientation and depth of biopsy. Histological features of CD comprise small intestinal mucosal injury, surface enterocyte damage, increased intraepithelial lymphocytes, crypt hyperplasia and villous blunting or flattening. A reliable histological diagnosis of CD requires lifelong adherence to a gluten-free diet, which is expensive, socially limiting and difficult on a contemporary diet with manufactured food stuffs. Pathologists should avoid overdiagnosis based on minimal nonspecific histological changes. The uniform classification according to Marsh and its modification as described by Rostami should be applied, which includes Marsh I lesion (lymphocytic enteritis); Marsh II (lymphocytic enteritis with crypt hyperplasia; Marsh IIIA in addition shows partial villous atrophy; Marsh IIIB, subtotal villous atrophy; and Marsh IIIC, total villous atrophy.

Jejunal biopsies are not necessary anymore if adequate duodenal biopsies are taken. Numerous intestinal disorders can present with a CD-like histology but are not responsive to a gluten-free diet, and therefore, are not CD cases. Villous atrophy is noted in various infections such as giardiasis, tropical sprue, HIV, Whipple's disease, and immune-mediated diseases. In the same way, increased intraepithelial lymphocytes (IELs) are seen in tropical sprue, after nonsteroidal anti-inflammatory use, Crohn's disease, and bacterial overgrowth. In cases of histological features suggestive of CD, the diagnosis should be based on ESPGHAN criteria.

Diagnosis of refractory CD, ulcerative jejunitis and EATL requires multiple biopsies. Identification of the two categories of refractory CD (RCD), Marsh type I without aberrant T cells and type II with aberrant T cells requires correlation with T-cell immunophenotyping by flow cytometric analysis and immunohistology. An increase in IELs in uncomplicated CD shows a phenotype of sCD3+, CD8+,  $\gamma^+$  population of T cells, which contrasts with RCD II, which shows an aberrant immunophenotype of sCD3- cCD3+, CD8-. Immunostaining methods using anti-CD3 and anti-CD8 antibodies distinguish active CD from RCD.

Pathologists should be attentive to recognize the less severe histopathological abnormalities of Marsh type I and II CD, and must be aware of the pitfalls in the assessment of mucosal biopsy specimens<sup>[40]</sup>. In general, we do not advise a gluten-free diet for Marsh type I lesions, unless serology (tTGA and EMA) is positive and the patients are symptomatic for CD.

### ATYPICAL CD

Atypical presentations of CD are on the rise in children and adults<sup>[41]</sup>. Patients may present with CD-related symptoms in other specialties, such as cardiology, hematology, ENT, endocrinology, dermatology and dental services. Clinicians should be aware of CD. Screening for CD should be considered in unexplained anemia, unexplained gastrointestinal symptoms, idiopathic

osteoporosis, unexplained infertility, first-degree relatives of CD patients, and autoimmune diseases.

## DIETARY COMPLIANCE IN CD

CD is well recognized in most parts of the world where wheat is the staple diet. Irrespective of the manifestations of CD, the mainstay of treatment is a gluten-free diet. Proper dietary compliance leads to alleviation of symptoms, improvement of anthropometry, improvement in quality of life, and prevention of EATL and osteoporosis. It is important to determine factors that affect dietary compliance. Non-compliance to any dietary modification is multifactorial and is determined by several socioeconomic and cultural factors. Dietary compliance can be assessed by questionnaires, serology or histology, or a combination of these methods.

In a study to determine factors to assess gluten-free dietary compliance, strict compliance was seen in 45%, 50% and 35% in pediatric, adolescent and adult populations, respectively. Temptation was the main reason for default in children. Ignorance combined with temptation were major problems in adolescents, whereas digression in adults was mainly due to sociocultural and economic factors. Overall compliance rates to GFD vary from 45% to 80%. tTGA normalizes in 75% of the compliant patients at 1 year and serves as a useful marker for medium-term compliance and beyond. Histological improvement lags behind serological response. Overall non-compliance was seen in 58% at 2 years<sup>[42]</sup>.

## MANAGEMENT PROBLEMS OF CD IN INDIA

The only treatment available for CD is strict adherence to a gluten-free diet for life. Data suggest that diagnosed but untreated patients with CD have significantly higher morbidity and mortality.

### Gluten-free diet

A gluten-free diet is defined as one that excludes wheat, rye and barley. Even small quantities of gluten may be harmful. The strict definition of a gluten-free diet remains controversial because of the lack of an accurate method to detect gluten in food, and the lack of evidence for what constitutes a safe amount of gluten ingestion. The patients and their relatives should be counseled by a trained dietician. Vitamin and mineral deficiencies, including iron, calcium, phosphorus, folate, B12, and fat-soluble vitamins should be looked for. It is important to have a team-based approach to management. In addition to treatment by a physician and participation in a local support group, consultation with a skilled dietician is essential (Table 1).

Dietary counseling of the patient and the family is the cornerstone of the treatment of CD. In India, it is common practice for families to purchase whole grain and have the flour processed at a small neighborhood flourmill, where other cereals like corn and rice are ground separately at a different time slot after cleaning

**Table 1** Key elements in the management of celiac disease (CD)

the grinding machine. Despite cleaning of the flour-making machine, there may be mixing during grinding of cereals. The mixing occurs in the initial part of cereal grinding, therefore, initial flour should not be used by the patients with CD. These measures are inadequate, and some quantity of wheat becomes mixed with other cereals and may be a factor for non-response in a strictly compliant patient. It might make sense for patients to use solely home grinding for gluten-free flour. The major problem is faced by the patients and families on certain occasions: birthday cakes, chocolates, ice creams, biscuits, social functions, and traveling (Table 2).

CD has come to attention of physicians in the past two decades. The number of patients diagnosed with CD is also limited. Therefore, the market value of gluten-free products and food items has not been properly realized. With time, the exact number of patients with CD is going to rise and there will be a requirement for commercially available food items. Besides, there is no legislation for gluten labeling in India, therefore, a patient with CD will not be able to know if any of the food items is safe.

## MANAGEMENT OF RCD

A small subset of CD patients fails to respond to a gluten-free diet. This condition is referred to as RCD, which can be either primary or secondary. There is no standard definition of RCD. Currently, RCD is defined as persisting or recurrent villous atrophy with crypt hyperplasia and increased IELs, in spite of a strict gluten-free diet for more than 12 mo<sup>[43]</sup>.

Before making a diagnosis of RCD, the following causes must be ruled out: (1) dietary non-compliance; (2) ubiquitous gluten source (pill capsules); (3) wrong initial diagnosis; and (4) associated disease, such as collagenous colitis, lactose intolerance, or bacterial overgrowth syndrome.

There are no clear clinical or biological markers that

predict the development of RCD. This disorder usually manifests in patients diagnosed in adulthood, and all reported cases have been patients diagnosed over the age of 40-50 years. The exact incidence of RCD amongst CD is not known. However, in a small subgroup of patients, the clinical and histological abnormalities persist or recur while taking a gluten-free diet. This non-responsiveness leaves a poorly understood syndrome known as RCD<sup>[4,38,40]</sup>. RCD may appear in a subgroup of CD patients with persistent histological abnormalities. In all patients screened for RCD, DQ2 and DQ8 need to be checked. In non-DQ2/DQ8 patients, the diagnosis of CD has to be reconsidered and differentiated from diseases such as autoimmune enteropathy. Most of the patients referred for RCD are affected by other diseases. Probably, the commonest cause of non-responsiveness is continued gluten intake. Exocrine pancreas insufficiency, hyperthyroid disease and collagenous colitis are other common explanations. Immunosuppressive treatment might moderate this. We suggest azathioprine and steroids in RCD- I (without aberrant T lymphocytes). However, in RCD- II (with aberrant T lymphocytes), we suggest chemotherapy. As the prognosis of EATL is extremely poor, the early detection of CD is crucial<sup>[44]</sup>.

## CONCLUSION

The spectrum of CD in India is changing. There is a need to start studies to estimate prevalence of CD all over India. This task can be accomplished by establishing nodal centers in different parts of the country. In addition, competent authorities must be approached with specific recommendations to make food labeling regarding gluten content legally mandatory. Based on available data and discussion, the following recommendations are made. (1) Common questionnaire to collect data at different centers needs to be developed. (2) Studies to estimate community prevalence of CD must be started. (3) Prevalence of CD in high-risk groups should be studied. (4) Simple and low-budget serological assays should be developed for studies in underprivileged individuals. (5) Genetic studies to identify HLA typing of CD patients in India can be taken up in a small sub set of patients. (6) Subspecialties like endocrinology and neurology must be approached and involved in the Indian Task Force. (7) Rapid assays for CD serology need studies among populations suffering from parasitic infections to look for interference with CD. (8) Proper legislation about wheat food labeling should be framed.

## ACKNOWLEDGMENTS

The authors sincerely acknowledge the help of Mrs Sylvia C Band and Mr Someswara Rao in preparing the manuscript.

### Abstract

**AIM:** To characterize the gastric myoelectric activity (GMA) and intra-abdominal pressure changes induced by emetic stimuli (apomorphine and cisplatin) in the ferret.

**METHODS:** GMA and intra-abdominal pressure were recorded in conscious, unrestrained ferrets surgically implanted with radiotelemetry transmitters. Animals were challenged with apomorphine (0.25 mg/kg *sc*) and cisplatin (10 mg/kg *ip*), and the emetic response was quantified *via* direct observation and intra-abdominal pressure recording for 1 and 4 h, respectively. The GMA was analyzed by spectral analysis; the parameters used to characterize the GMA were the dominant frequency (DF) and the repartition of spectral power in the bradygastric, normogastric and tachygastric frequency ranges.

**RESULTS:** Retches were identified on the intra-abdominal pressure trace as peaks  $0.30 \pm 1.01$  s in duration and  $59.57 \pm 2.74$  mmHg in amplitude, vomit peaks were longer ( $0.82 \pm 0.06$  s,  $P < 0.01$ ) and reached a higher pressure ( $87.73 \pm 8.12$  mmHg,  $P < 0.001$ ). The number of retches and vomits quantified

*via* direct observation [apomorphine:  $65.5 \pm 11.8$  retches + vomits (R+V), cisplatin:  $202.6 \pm 64.1$  R+V] and intra-abdominal pressure (apomorphine:  $68.3 \pm 13.7$  R+V,  $n = 8$ ; cisplatin:  $219.0 \pm 69.2$  R+V,  $n = 8$ ) were correlated ( $r = 0.97$ ,  $P < 0.0001$ ) and the timing of emesis was consistent between the 2 methods. Apomorphine induced a decrease in normogastria from  $45.48\% \pm 4.35\%$  to  $36.70 \pm 4.34\%$  ( $n = 8$ ,  $P < 0.05$ ) but the DF of the slow waves was not changed [ $8.95 \pm 0.25$  counts/min (cpm) *vs*  $8.68 \pm 0.35$  cpm,  $n = 8$ ,  $P > 0.05$ ]. Cisplatin induced a decrease in normogastria from  $55.83\% \pm 4.30\%$  to  $29.22\% \pm 5.16\%$  and an increase in bradygastria from  $14.28\% \pm 2.32\%$  to  $31.19\% \pm 8.33\%$  ( $n = 8$ ,  $P < 0.001$ ) but the DF ( $9.14 \pm 0.13$  cpm) remained unchanged ( $P > 0.05$ ). The GMA changes induced by cisplatin preceded the emetic response as normogastria was reduced for 1 h before the onset of emesis ( $57.61\% \pm 5.66\%$  to  $39.91\% \pm 5.74\%$ ,  $n = 6$ ,  $P < 0.05$ ). Peri-emesis analysis revealed that the GMA was significantly disturbed during and immediately after, but not immediately before, the emetic episodes.

**CONCLUSION:** The induction of emesis is reliably associated with a disrupted GMA, but changes may also occur prior to and following the emetic response.

### INTRODUCTION

Nausea and vomiting are components of the body's

defense response against toxins either ingested (e.g. plant alkaloids: nicotine, veratridine, emetine), or released following bacterial (e.g. *Staphylococcus aureus*, *Salmonella enterica*, *Vibrio cholerae*) or viral infection (e.g. norovirus, rotavirus)<sup>[1]</sup>. However, in the clinic, the emetic response can also be triggered inappropriately, for example, as a sequelae of anesthesia with surgery (postoperative nausea and vomiting)<sup>[2]</sup>, or as a side effect of cancer chemotherapy (e.g. cisplatin)<sup>[3]</sup>. In addition, nausea and vomiting are also commonly encountered during the pre-clinical and early clinical development of novel chemical entities (NCE) for a variety of therapeutic indications. Indeed, nausea and vomiting has been ranked second, after abuse liability, in the side effects negatively impacting on the development of NCE<sup>[4]</sup>.

Pre-clinical studies using species capable of emesis such as the ferret (*Mustela putorius furo* L.) or the least shrew (*Cryptotis parva*) correctly identified an emetic liability for several NCE. For example, emetic side effects were observed for phosphodiesterase-IV inhibitors<sup>[5]</sup>, a nicotinic receptor agonist<sup>[6]</sup>, and a cannabinoid CB1 receptor antagonist<sup>[7]</sup>, considered for the treatment of asthma, pain and obesity, respectively. Studies in the ferret also identified the anti-emetic potential of 5-hydroxytryptamine-3 (5-HT<sub>3</sub>) and tachykinin NK<sub>1</sub> receptor antagonists against cancer chemotherapy agents (see<sup>[8]</sup> for review), however, their more limited efficacy against nausea<sup>[9]</sup> could not be predicted from pre-clinical studies. Emesis can be divided into 2 components: the pre-ejection (or prodromal) phase and the ejection phase. The prodromal phase is characterized by sympathetic outputs such as cold sweating, skin vasoconstriction and pupil dilation. Additionally, under vagal control, the proximal stomach relaxes, delaying gastric emptying, and the retrograde giant contraction carries to the stomach intestinal contents. This phase is usually temporally correlated with the sensation of nausea<sup>[10]</sup>. Retching and emesis (vomiting), which constitute the ejection phase, are therefore end-stages in activation of the emetic reflex and there would be considerable utility in the identification of biomarkers induced at sub-emetic doses of a compound, which could be used to better identify the separation between a therapeutic dose and one with emetic liability (therapeutic index). Such biomarkers may provide insights into the potential for induction or detection and reduction of nausea, which remains controversial in studies using laboratory animals<sup>[4]</sup>.

In humans, correlates of nausea include an increase in plasma levels of vasopressin and changes in the electrogastrogram (EGG) frequency, rhythm and power<sup>[11]</sup>. The EGG reflects gastric myoelectric activity (GMA), or gastric slow waves; it is usually recorded from cutaneous abdominal electrodes to investigate the frequency of pacemaker activity, which underlies the genesis of gastric contractile activity<sup>[12]</sup>. However, the precise relationship of the EGG to motility itself is unclear<sup>[13]</sup> but tachygastria has been linked to gastric motor quiescence<sup>[14]</sup>. Of the 2 markers, only the recording of the gastric slow waves

provides a method amenable to telemetry with an adequate temporal resolution to examine relationships to emesis in unrestrained animals.

This paper reports the use of radiotelemetry in the conscious unrestrained ferret to record gastric slow wave activity and investigate the effect of the emetic challenges, apomorphine and cisplatin. Data are also included on telemetric recordings of intra-abdominal pressure following administration of emetic agents in this species. The results show that both apomorphine and cisplatin are associated with a reduction of normal gastric rhythm, and demonstrate the potential applicability of telemetric recording techniques to the study of emetic mechanisms and the identification and understanding of emetic liability of NCE. This provides insights into the changes in gastric function occurring prior to the onset of emesis and which, in humans, have been associated with the occurrence of nausea.

## MATERIALS AND METHODS

### Animals

Castrated male fitch (pigmented) ferrets (*Mustela putorius furo* L.) (1.17-1.65 kg) were obtained from Southland Ferrets (Invercargill, New Zealand). Prior to the experiments, they were housed communally in a temperature-controlled room at 24 ± 1°C, under artificial lighting with lights on between 06:00 am and 18:00 pm. Water and pelleted cat food (Tri Pro Feline Formula Cat Food, American Nutrition®, Utah, USA) were available *ad libitum* until the start of the experiments. All animals were then housed individually from the day of surgery to the end of the experiment. The experiments were conducted under the authority of a license provided by the Government of the Hong Kong SAR and approval from the Animal Experimentation Ethics Committee, The Chinese University of Hong Kong.

### Surgical techniques

**Telemetry transmitter implantation for GMA and abdominal pressure recording:** Anesthesia was induced with ketamine (20 mg/kg im; Alfasan, Holland) and maintained with isoflurane (Halocarbon Products Corporation, USA) about 1.5%, in a 3:1 O<sub>2</sub> to N<sub>2</sub>O ratio using a custom-made face mask and an anesthetic machine (Narkomed 2C, Drager, USA). Animals were placed on a heating pad (UCI#390 Analog moist heating pad, Rebirth Medical & Design, Inc., Taiwan) and the level of anesthesia was assessed and monitored throughout the surgery by the pedal withdrawal reflex. Following a midline abdominal incision, the antrum was exposed and the biopotential wires of the telemetry transmitter (C50-PTX, DSI, USA) were inserted in the muscle and secured in place by suturing the serosa. The body of the transmitter (with the pressure catheter) was inserted in the peritoneal cavity and sutured to the muscle layer on the side. The abdominal cavity was treated with antibiotic (Nebacetin®, Altana Pharma, Germany), sutured closed

in layers and covered with a permeable spray dressing (Opsite<sup>®</sup>, Smith and Nephew, UK).

**Analgesia and post-operative recovery:** Buprenorphine (0.05 mg/kg *sc*; Temgesic<sup>®</sup>, Schering Plough, UK) was given as a preoperative analgesic 15 min before the induction of anesthesia, and 12 h post surgery. Recovery was unremarkable and the wound healed within a week.

### Experimental design

Following surgery, animals were housed individually in observation cages (W49 cm × L61 cm × H49.5 cm). They were allowed to recover for at least 7 d prior to further experimentation. Some ferrets were administered apomorphine (0.25 mg/kg *sc*) at least 7 d prior to the administration of cisplatin (10 mg/kg *ip*). These doses of apomorphine and cisplatin have been shown to induce a reliable emetic response in the ferret<sup>[15,16]</sup>. At the end of the observation period, animals were killed with an overdose (> 100 mg/kg *ip*) of pentobarbital sodium (Dorminal<sup>®</sup>, Alfasan, Woerden, Holland).

Baseline telemetry recordings (GMA and abdominal pressure) were made for a least 1 h prior to presenting the animals with food, or an emetic challenge. Recordings then continued for 1 h in studies assessing the effect of food alone or apomorphine (0.25 mg/kg *sc*), or for 4 h in experiments assessing the action of cisplatin (10 mg/kg *ip*). Emesis was characterized by rhythmic abdominal contractions that were either associated with the oral expulsion of solid or liquid material from the gastrointestinal tract (i.e. vomiting), or not associated with the passage of material (i.e. retching movements). An episode of retching and/or vomiting was considered separate when the animal changed its location in the observation cage, or when the interval between retches and/or vomits exceeded 5 s<sup>[17]</sup>. The latency was defined as the time between the administration of the drug and the first emetic episode.

**Effect of feeding on GMA:** Food was withdrawn for 12-14 h before the start of the studies. The ferrets were then presented with 20 g of pelleted cat food, and all uneaten food was withdrawn 10 min later. This design was chosen to mimic human studies describing the effect of a meal on GMA in humans<sup>[12]</sup>. GMA data were analyzed during the 5 min period prior to presentation of food, and during a 5 min post-prandial period, starting 5 min after the uneaten food was withdrawn.

**Effect of apomorphine (0.25 mg/kg *sc*) and cisplatin (10 mg/kg *ip*) on GMA and abdominal pressure:** On the day of the experiment water was freely available but food was withdrawn for approximate 2 h before the start of the studies. Ferrets were presented with pelleted cat food and 30 min later animals were injected subcutaneously with apomorphine (0.25 mg/kg) or saline (0.5 mL/kg NaCl 154 mmol/L); or injected intraperitoneally with cisplatin (10 mg/kg) or saline (10 mL/kg NaCl 154 mmol/L).

**Drugs:** Cisplatin [cis-diamminedichloroplatinum(II), David Bull Laboratories, Victoria, Australia] was purchased as a sterile saline solution at an active concentration of 1 mg/mL. Apomorphine hydrochloride (Sigma-Aldrich, St. Louis, USA) was dissolved in sodium metabisulphite (526 μmol/L, Riedel-de Haën, Germany) and injected at a concentration of 0.5 mg/mL and a volume of 0.5 mL/kg *sc*. Doses are expressed as the free base.

### Telemetry system and analysis of the data

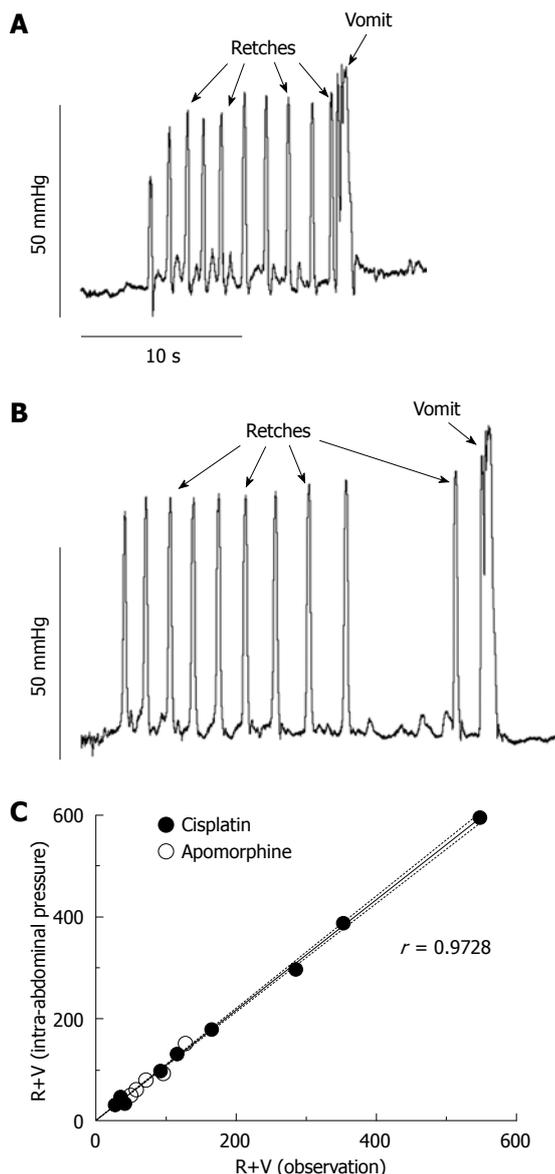

A DSI Dataquest<sup>®</sup> A.R.T. telemetry system (Data Science International, Minnesota, USA) was used. The GMA and intra-abdominal pressure were recorded using PhysioTel<sup>®</sup> C50-PXT Small Animal Transmitters. Telemetric signals were recorded *via* 2 receiver plates (PhysioTel<sup>®</sup> RPC-1) placed under the cages. The receivers were connected to a PC desktop computer *via* a matrix (Dataquest ART Data Exchange Matrix). An ambient pressure reference monitor (APR-1) was connected to the exchange matrix. Data was recorded with the Dataquest Acquisition software (DQ ART 4.0). Analysis of telemetry recordings was carried out using Spike2<sup>®</sup> (version 6.06, Cambridge Electronic Design, UK).

**Quantification of the retches and vomits *via* intra-abdominal pressure:** The abdominal pressure signal was recorded with a sampling frequency of 500 Hz. Retches and vomits were quantified from the intra-abdominal pressure recordings in a semi-automated manner. Thus, the traces of each ferret were inspected visually and then a detection threshold was set and pressure profiles corresponding to retches and vomits were isolated manually. To test the validity of this method, the number of retches + vomits (R+V) detected was compared to the number obtained *via* direct observation using a Spearman test for non-parametric correlation.

**GMA recordings:** The GMA signal was recorded with a sampling frequency of 1000 Hz; selected steps of the analysis procedure are presented in Figure 1. Briefly, a low pass finite impulse response (FIR) filter with a cut-off frequency of 2.5 Hz (transition gap: 10 Hz) was used to remove any signal with a frequency higher than 150 counts/min (cpm). The traces were then interpolated to a sampling frequency of 10.24 Hz and a second low pass FIR filter with a cut-off frequency of 0.3 Hz (18 cpm, transition gap: 0.1 Hz) was applied. This cut-off was chosen to filter out signals of probable cardiac (about 200 cpm in the ferret) and respiratory (33-36 cpm) origins<sup>[18]</sup>.

The following parameters were used to characterize the GMA (Figure 1): (1) the dominant power (DP, the highest power in the 0 to 15 cpm range); (2) the dominant frequency (DF, frequency bin with the highest power in the 0 to 15 cpm range); (3) the repartition of power in the bradygastric, normal and tachygastric ranges (i.e. bradygastria, normogastria and tachygastria). The DF

**Figure 2** Intra-abdominal pressure recordings. Intra-abdominal pressure was recorded via a telemetry transmitter in the abdominal cavity (C50-PTX, DSI®), showing emetic episodes—each composed of several retches and one vomit—induced by apomorphine (0.25 mg/kg sc) (A) and cisplatin (10 mg/kg ip) (B). Both recordings were obtained from the same animal. C: Correlation between the number of retches + vomits (R+V) induced by cisplatin (10 mg/kg ip) and apomorphine (0.25 mg/kg sc), quantified by direct observation and from the intra-abdominal pressure traces. Results plotted as individual values,  $n = 16$  (data obtained from 11 animals). Spearman correlation coefficient ( $r$ ), the linear regression (plain line) and 95% confidence interval (dotted line) are indicated on the graph.

increased by a ratio of  $6.80 \pm 3.61$ , to  $9.45 \times 10^{-4} \pm 2.84 \times 10^{-4}$  mV<sup>2</sup>. These changes were not statistically significant,  $P = 0.38$  and  $P = 0.13$  for the DF and DP respectively (paired  $t$ -tests,  $n = 10$ ).

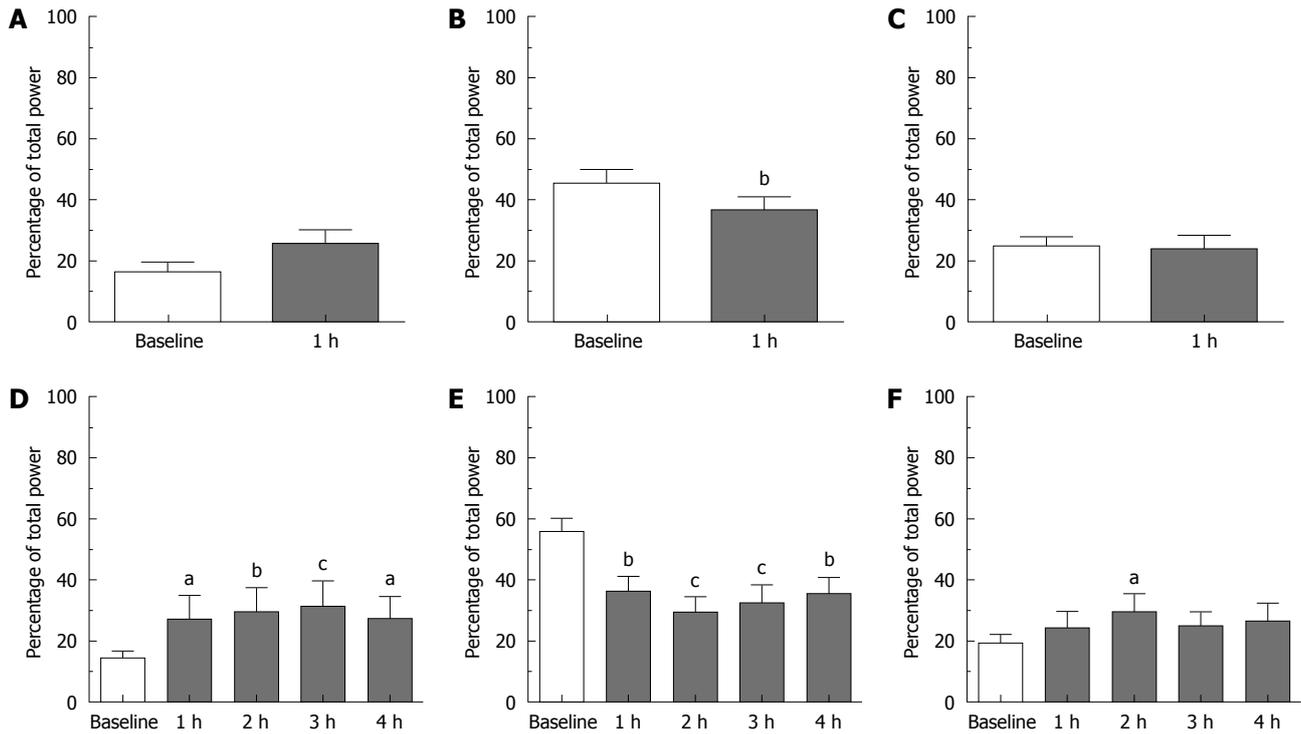

#### Effect of apomorphine and cisplatin on the GMA

**Effect of apomorphine:** During the 1 h that preceded the injection of saline (0.5 mL/kg sc), baseline bradycardia, normogastria and tachygastria were  $13.57\% \pm 3.53\%$ ,  $63.31\% \pm 9.99\%$  and  $16.26\% \pm 5.82\%$  of the total power, respectively. Baseline DF was  $9.54 \pm 0.26$  cpm

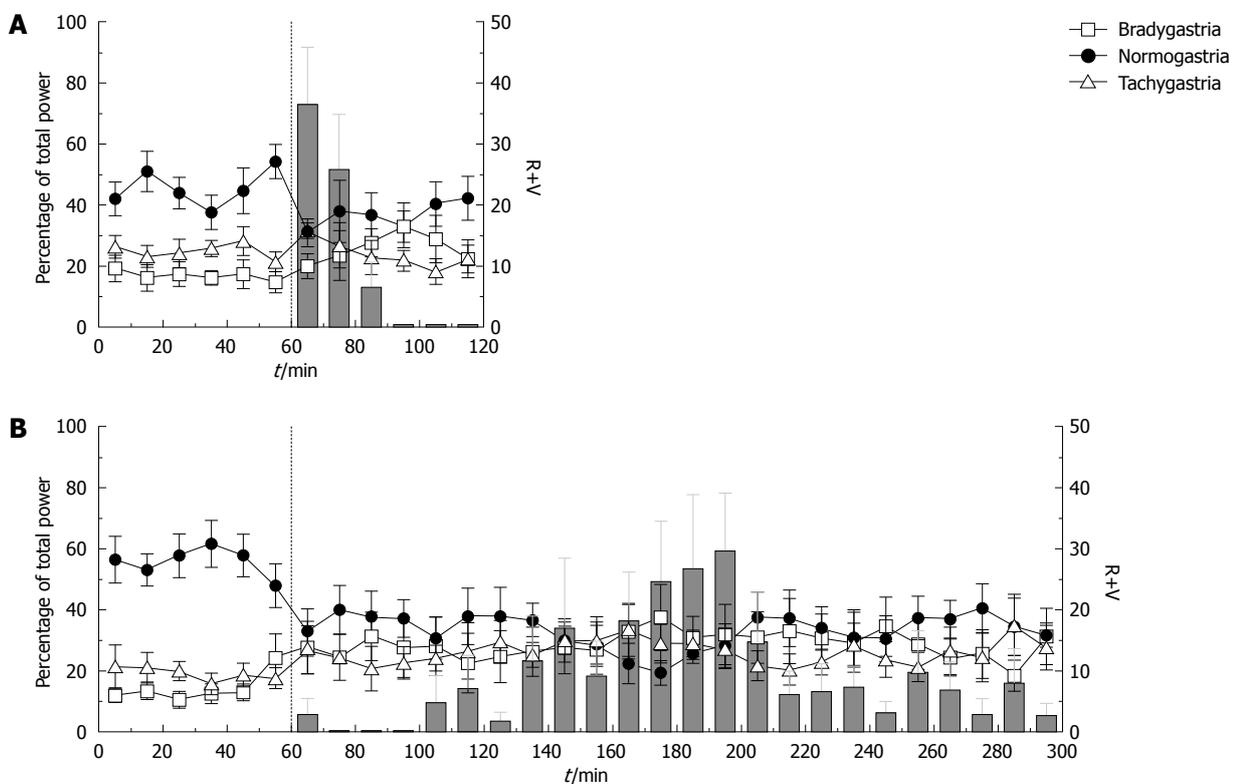

( $n = 4$ ). Following saline injection, the GMA repartition was  $15.14\% \pm 1.28\%$ ,  $57.40\% \pm 8.03\%$  and  $18.46\% \pm 6.13\%$  in the bradycardia, normal and tachygastria ranges respectively; the DF was  $9.73 \pm 0.24$  cpm. None of these values were significantly different from the baseline and no differences were detected between the saline and apomorphine groups during baseline ( $P > 0.05$ ). During the 1 h that preceded the injection of apomorphine, the GMA was repartitioned as follows: bradycardia:  $16.57\% \pm 3.17\%$ , normogastria:  $45.48\% \pm 4.35\%$  and tachygastria:  $25.66\% \pm 2.72\%$ ; DF:  $8.95 \pm 0.25$  cpm ( $n = 8$ ). As shown in Figures 3 and 4, following the administration of apomorphine, the percentage of power in the normal range decreased to  $36.70\% \pm 4.34\%$  ( $P < 0.01$ ), whereas the percentage of power in the bradycardia and the tachygastria ranges was not significantly altered:  $25.76\% \pm 4.65\%$  and  $22.77\% \pm 4.67\%$ , respectively ( $P > 0.05$ ). The DF did not change, and was  $8.68 \pm 0.35$  cpm following apomorphine [ $P > 0.05$ , two-way ANOVAs followed by Bonferroni post-tests,  $n = 8$  (apomorphine) and  $n = 4$  (saline)].

**Effect of cisplatin:** During the 1 h baseline recordings prior to the injection of saline (10 mL/kg ip), baseline bradycardia, normogastria and tachygastria were  $17.11\% \pm 5.35\%$ ,  $43.32\% \pm 6.37\%$  and  $25.85\% \pm 3.83\%$ , respectively; baseline DF was  $8.44 \pm 0.61$  cpm ( $n = 4$ ). The saline treatment had no significant effect on the GMA up to 3 h following intraperitoneal injection, however 4 h post injection the percentage of power in the tachygastria range was significantly increased compared to baseline to  $40.40\% \pm 8.31\%$  ( $P < 0.05$ ). During the 1 h baseline prior to the injection of cisplatin, the percentages in the bradycardia, normogastric and tachygastria ranges were  $14.28\% \pm 2.32\%$ ,  $55.83\% \pm 4.30\%$  and  $19.17\% \pm 3.08\%$ , respectively. The DF was  $9.14 \pm 0.13$  cpm ( $n = 8$ ). As shown in Figures 3 and 4, following the administration of cisplatin the percentage of power in the normogastric range decreased and reached a nadir in the second hour post-injection ( $29.22\% \pm 5.16\%$ ), whereas the percentage of bradycardia and tachygastria increased. Bradycardia reached a peak during the third hour after the injection ( $31.19\% \pm 8.33\%$ ) and tachygastria reached a peak during the second hour post-injection ( $29.56\% \pm 6.01\%$ ); the effects on normogastria and bradycardia were statistically significant during the entire observation period whereas the increase in tachygastria were only statistically significant 2 h post-injection ( $P < 0.05$ , Bonferroni post-tests compared to the 1 h baseline). The DF was not significantly altered after cisplatin administration ( $P < 0.05$ ). No differences could be detected at any time points between saline and cisplatin [ $P > 0.05$ , repeated measures two-way ANOVA followed by Bonferroni post-tests,  $n = 8$  (cisplatin),  $n = 4$  (saline)].

A secondary analysis was carried out only on the animals with a latency to the onset of emesis greater than 1 h ( $n = 6$ ). In these animals, the percentage of power in the normogastric range was significantly reduced in

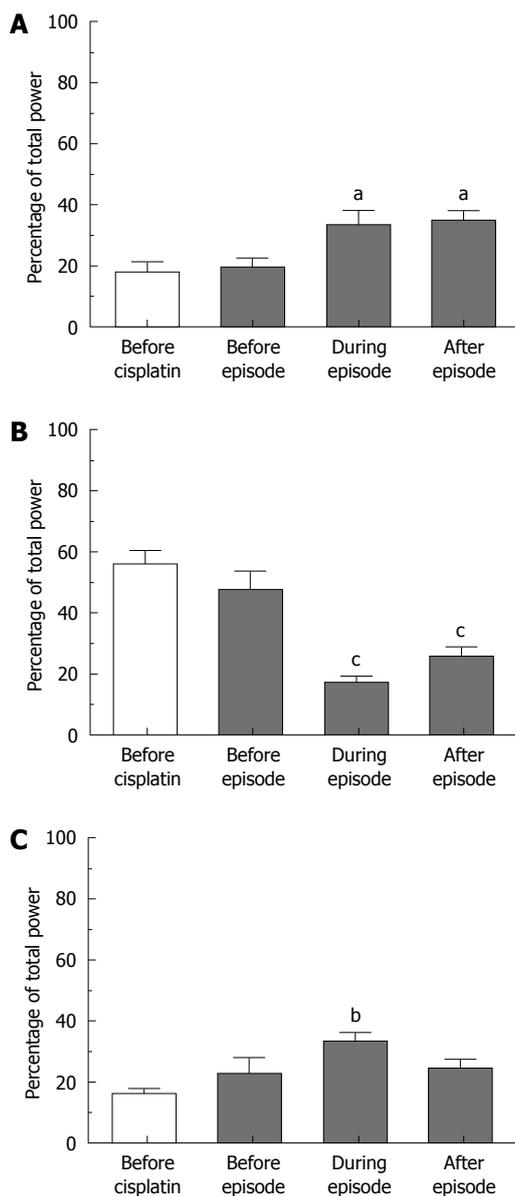

**Figure 3** Effect of apomorphine (0.25 mg/kg sc, A-C) and cisplatin (10 mg/kg ip, D-F) on the gastric myoelectric activity (GMA) in ferrets. The graphs represent the percentage of total (0-18 cpm) power in the bradygastric range [0 - (DF - 1 cpm), A and D], in the normogastric range [(DF - 1 cpm) - (DF + 1 cpm), B and E] and in the tachygastric range [(DF + 1 cpm) - 15 cpm, C and F]. Results are plotted as mean ± SE (n = 8). Differences compared to the effect of a dose of saline (sc or ip as appropriate, data not shown on this graph) were computed using two-way ANOVA (factors: treatment and time) and Bonferroni post-tests. Differences with baseline are indicated as <sup>a</sup>P < 0.05, <sup>b</sup>P < 0.01, <sup>c</sup>P < 0.001.

**Figure 4** Profile of emesis and GMA repartition in the bradygastric, normogastric and tachygastric ranges following the administration of apomorphine (0.25 mg/kg sc) (A) and cisplatin (10 mg/kg ip) (B) in the ferret. Data plotted as mean ± SE per 10 min, n = 8.

the first hour post-cisplatin injection from 57.61% ± 5.66% to 39.91% ± 5.74% (*P* < 0.05) even though no

emesis was observed during that period. Percentages of power in the bradygastric and tachygastric ranges

**Figure 5** Repartition of the GMA in the bradygastric (A), normogastric (B) and tachygastric (C) ranges before the injection of cisplatin, immediately before emetic episodes, during emetic episodes and immediately after emetic episodes induced by cisplatin (10 mg/kg ip) in the ferret. Results are plotted as mean  $\pm$  SE,  $n = 8$ . Differences compared to baseline are calculated using repetitive measures one-way ANOVA followed by Bonferroni post tests. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>c</sup> $P < 0.001$ .

were unchanged [ $P > 0.05$ , repeated measures two-way ANOVA followed by Bonferroni post-tests,  $n = 6$  (cisplatin),  $n = 4$  (saline)].

We investigated the GMA repartition surrounding and during emetic episodes; altogether, 40, 41, 62 and 41 determinations were used to characterize the GMA repartition before cisplatin and before, during and after emetic episodes, respectively. Bradygastric, normogastric and tachygastric values during the 10 min preceding the injection of cisplatin were  $17.67\% \pm 3.50\%$ ,  $56.00\% \pm 4.41\%$  and  $16.15\% \pm 1.66\%$  (mean  $\pm$  SE for 8 animals), respectively. Peri-emesis, the percentage repartition in all 3 ranges was significantly altered ( $P = 0.0085$ ,  $P < 0.0001$  and  $P = 0.0261$  for bradygastric, normogastric

and tachygastric respectively, repeated measures one-way ANOVAs, Figure 5). Bonferroni post-tests revealed that these values did not change significantly immediately before an episode (bradygastric:  $19.36\% \pm 3.02\%$ , normogastric:  $47.56\% \pm 6.18\%$  and tachygastric:  $22.87\% \pm 5.20\%$ ,  $P > 0.05$ ), but were altered during (bradygastric:  $33.08\% \pm 4.90\%$ , normogastric:  $17.23\% \pm 2.06\%$  and tachygastric:  $33.27\% \pm 3.00\%$ ,  $P < 0.05$ ) and immediately after emetic episodes (bradygastric:  $34.68\% \pm 3.33\%$ , normogastric:  $25.57\% \pm 3.27\%$  and tachygastric:  $24.38\% \pm 3.12\%$ ,  $P < 0.05$ ).

## DISCUSSION

### Recording and analysis of GMA in the ferret

The present study is the first report of ambulatory gastric myoelectric recordings in conscious unrestrained ferrets. The frequency of the gastric slow waves was  $9.12 \pm 0.23$  cpm (mean  $\pm$  SE of 12 animals), which is in accordance with post-prandial frequency of antral contractions ( $8.8 \pm 0.5$  cpm)<sup>[19]</sup>, and the frequency of the antral slow waves (9.5 cpm) reported by Diamant *et al.*<sup>[20]</sup> in abstract form; both were measured in conscious but restrained ferrets. In contrast to common protocols used to investigate the GMA in humans<sup>[21-23]</sup> and other animals (dog)<sup>[24,25]</sup>, which used a fixed normogastric range (typically 2.5-3 to 3.7-4 cpm in humans and 4-6 cpm in dogs)<sup>[12,26,27]</sup>, normogastric was defined according to each animal's intrinsic slow waves frequency during baseline. This was done for 2 reasons: (1) because of a relative paucity of literature, not enough data on the ferret's GMA was available to determine with confidence what the normogastric range should be (DF range 7.8-9.2 cpm in 12 animals in the present study) or how wide it should be; (2) the purpose of the present study was to focus on the changes induced by an experimental stimulus; setting the normogastric range relative to each individual animal reduced the influence of inter-animal variability and rendered the analysis more powerful to detect the effect of an emetic stimulus on the GMA in a limited number of animals.

Regarding the GMA analysis parameters, we chose to report the DF and compute the repartition of power in the normogastric, bradygastric and tachygastric ranges. An alternative analysis, which has been used in most preclinical studies<sup>[27-29]</sup> and some studies in humans<sup>[30]</sup>, consists of calculating the percentage of time during which the DF falls within each frequency range. The analysis parameters used in the present study were chosen as the power repartition encompass all the data present in the GMA signal and does not solely focus on the time at which the DF is included within a range of interest<sup>[12]</sup>.

### GMA changes induced by apomorphine and cisplatin

Similar GMA changes were observed following apomorphine and cisplatin; both stimuli induced a decrease in the percentage of power in the normogastric range, which was accounted for in the case of cisplatin by a clear increase in power in the bradygastric range,

without changing the DF. Our findings on the effects of apomorphine are partially supported by a number of studies in conscious, restrained dogs, which also reported a transient disruption of the gastric antral rhythm following the administration of apomorphine<sup>[31-33]</sup>. To the best of our knowledge, the present study represents the first clear evidence that apomorphine is associated with a reduction of normogastria for up to 1 h, which outlasts the emetic response as the last emetic episode was observed  $21.12 \pm 1.76$  min ( $n = 8$ ) post-apomorphine.

Regarding the effect of cisplatin, GMA changes were temporally correlated with the occurrence of emesis and maximal changes in the GMA repartition were observed when the emetic response was the most intense (2-3 h post cisplatin). However, GMA changes preceded the emetic response as evidenced by a decrease in normogastria during the first hour post-cisplatin in animals, which had not yet developed emesis during that period. Consistent with our findings, a recent study in the dog showed that cisplatin reduced the percentage of normal gastric slow waves in the hours preceding the onset of emesis and during the emetic response<sup>[34]</sup>. In the present study, a peri-emesis analysis revealed that normogastria was decreased and bradygastria and tachygastria were increased during and immediately after-but not immediately before-an emetic episode, which is in accordance with the short periods of dysrhythmia associated with emetic episodes have been reported in human patients during the administration of cisplatin<sup>[35]</sup>. Our findings are partly supported by human studies, which reported dysrhythmias in a few patients treated with anti-cancer chemotherapy. However, such events appeared to be transient rather than an overall change in slow wave activity<sup>[30,35]</sup>. The apparent differences in the effect of chemotherapy in human patients and in the ferret model could have four explanations:

(1) In the present study, the ferret model of acute cisplatin-induced emesis was used. This model uses a high bolus dose of cisplatin (10 mg/kg ip)-a highly emetic chemotherapeutic agent-to provoke an intense, reliable emetic response in all the animals, typically quantifiable over 4 h<sup>[36]</sup>. In human patients however, chemotherapy (platinum-based or not) is infused over hours and the emetic response is less reliable. Correspondingly, the GMA disturbance may be more severe in the ferret model than it is in human patients.

(2) Additionally, cancer patients treated with chemotherapy are not healthy subjects and their GMA may already be altered before they receive chemotherapy, rendering it less likely to detect an additional effect of the anti-cancer treatment. It is interesting that following a chemotherapy session, Riezzo *et al.*<sup>[30]</sup> reported a higher percentage of tachygastria in cancer patients compared to healthy volunteers. However, they did not compare the EGG repartition in the cancer patients prior to chemotherapy, the measurements were collected 7 d post-chemotherapy and the chemotherapy regimens were not reported, precluding any direct comparison with the present study.

(3) The use of anti-emetic prophylaxis may also have an influence on GMA, and 5-HT<sub>3</sub> receptor antagonists-commonly administered with chemotherapy and used in the 2 above-mentioned human studies-have been reported to reduce vection-induced dysrhythmias<sup>[37]</sup>.

(4) The analysis of the data is an important factor to consider; as discussed above, in the present study, the DF and the percentage repartition of the power in the bradygastric, tachygastria and normogastria ranges were computed. In contrast, Samsom *et al.*<sup>[35]</sup> identified bradygastria and tachygastria as intervals of at least 2 min, during which the DF was  $< 2.4$  cpm or  $> 3.6$  cpm and no overall assessment of normogastria was made, apart from the mean DF. Also, Riezzo *et al.*<sup>[30]</sup> calculated the percentage of successive spectra in which the DF falls within one of the 3 ranges, or used visual inspection of the waveform traces or the regular spiking activity (RSA).

### ***Intra-abdominal pressure recordings***

On the intra-abdominal pressure traces, retches were identified as brief peaks whereas vomits were more prolonged. These findings in the freely moving, conscious ferret are consistent with what McCarthy *et al.*<sup>[38]</sup> described in the decerebrate cat. Our technique represents a great advantage in that quantifying the retches and vomits from the intra-abdominal pressure traces is more accurate than from a video or even direct observation; the distinction between retches and vomits is unequivocal and abdominal pressure recordings enable precise analysis regarding the timing and the frequency of the retches. Further information regarding the central neuronal circuitry involved in the mechanism of various emetics and anti-emetics can be gained from, for example, the interval between retches, the pattern of retching preceding a vomit or the characteristics of episodes including a vomit and those of episodes of retches. The major disadvantage is that this is an invasive technique, which requires abdominal surgery.

## **CONCLUSION**

The use of telemetry enables the recording of gastric slow waves in freely moving, conscious animals; additionally, analysis of the emetic response *via* intra-abdominal pressure permits a more rigorous data collection and the investigation of the precise temporal correlation between gastric changes and emesis. Using an EGG-like analysis of GMA recordings, disruption of the gastric rhythm was detected in ferrets challenged with apomorphine and cisplatin. Both emetic stimuli were associated with a reduction of normogastria, and cisplatin increased bradygastria. The GMA changes were subtle and not detectable by a simple DF analysis but comparison of the power repartition of the gastric signal, before and after the emetic challenges, indicated a clear change, which was temporally correlated with the development of the emetic response but not restricted to the immediate peri-emetic period. In the ferret, recording and analysis of the GMA, which is a physiological correlate of nausea in

humans, will improve the understanding of the changes in gastric function associated with emesis.

## COMMENTS

### Background

Nausea is a subjective sensation, therefore impossible to study directly in animals. However physiological correlates of nausea have been identified in humans and include disruption of the gastric electrical rhythm. As nausea usually precedes the onset of emesis, recording the gastric electrical rhythm in animals potentially enables the detection of emetic pathway activation before the emetic threshold is reached.

### Research frontiers

The application of human biomarkers of nausea to an animal model enables the refinement of this model as it improves its translational potential. The research hotspot is the correlation of physiological events occurring around the time of vomiting, which may give insight into nausea.

### Innovations and breakthroughs

Recent *in vivo* research studies investigating the relationship between emesis and gastric myoelectric activity (GMA) have used either restrained or anesthetized animals (mainly dogs) with wires connected to the serosa and externalized through the skin. The use of telemetry represents a novel approach and the present study is the first report of GMA recording in freely moving animals, which represents an indisputable advantage in terms of animal welfare.

### Applications

The ferret is a species commonly used in emesis research and our approach could be integrated to standard study designs, therefore refining this animal model by enabling the detection of emetic pathway(s) activation before the emetic threshold is reached.

### Terminology

The GMA consists of electrical pacemaker signals, which trigger contractions of the stomach. Gastric dysrhythmia refers to a departure from the normal gastric electrical rhythm, the term encompasses bradygastria, tachygastria and gastric arrhythmia.

### Peer review

This is a well written manuscript from an established group expert in this field using a novel relevant approach to assess GMA and intra-abdominal pressure in the conscious ferret implanted with radiotelemetry transmitters.

### Abstract

**AIM:** To compare the diagnostic capability of multi-detector computed tomography (MDCT) and magnetic resonance imaging (MRI) for the detection of hepatocellular carcinoma (HCC) tumour nodules and their effect on patient management.

**METHODS:** A total of 28 patients (25 male, 3 female, mean age  $67 \pm 10.8$  years) with biopsy-proven HCC were investigated with 64-row MDCT (slice 3 mm native, arterial and portal-venous phase, 120 mL Iomeprol, 4 mL/s, delay by bolus trigger) and MRI (T1fs f12d TE/TR 2.72/129 ms, T2tse TE/TR 102/4000 ms, 5-phase dynamic contrast-enhanced T1fs f13d TE/TR 1.56/4.6, Gadolinium-DTPA, slice 4 mm). Consensus reading of both modalities was used as reference. Tumour nodules were analyzed with respect to number, size, and location.

**RESULTS:** In total, 162 tumour nodules were detected by consensus reading. MRI detected significantly more tumour nodules (159 vs 123,  $P < 0.001$ ) compared to MDCT, with the best sensitivity for early arterial phase MRI. False-negative CT findings included nodules  $\leq 5$  mm ( $n = 5$ ),  $\leq 10$  mm ( $n = 17$ ),  $\leq 15$  mm ( $n = 12$ ),  $\leq 20$  mm ( $n = 4$ ), and 1 nodule  $> 20$  mm.

MRI missed 2 nodules  $\leq 10$  mm and 1 nodule  $\leq 15$  mm. On MRI, nodule diameters were greater than on CT ( $29.2 \pm 25.1$  mm, range 5-140 mm vs  $24.1 \pm 22.7$  mm, range 4-129 mm,  $P < 0.005$ ). In 2 patients, MDCT showed only unilobar tumour spread, whereas MRI revealed additional nodules in the contralateral lobe. Detection of these nodules could have changed the therapeutic strategy.

**CONCLUSION:** Contrast-enhanced MRI is superior to 64-row MDCT for the detection of HCC nodules. Patients should be allocated to interventional or operative treatment according to a dedicated MRI-protocol.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world and the third most common cause of cancer death, with 600 000 to 1 million new cases being diagnosed each year<sup>[1,2]</sup>. In North America and Europe, the most common risk factors are alcoholic cirrhosis and chronic hepatitis C and hepatitis B infection<sup>[3-6]</sup>. Patient survival has not significantly improved in the last 30 years because most cases are still not diagnosed until the disease is already in an advanced stage, which limits the most effective therapeutic options<sup>[7]</sup>. Therefore, early tumour detection is one of the most important issues in HCC therapy<sup>[8]</sup>. Currently, magnetic

resonance imaging (MRI) and multidetector computed tomography (MDCT) are both equally used for HCC diagnosis, although in the past MRI has been reported to produce significantly higher detection rates<sup>[9-11]</sup>. State-of-the-art MRI provides fast imaging techniques with dynamic contrast-enhanced sequences to detect the mostly hypervascularized HCC tumour nodules with a high sensitivity and specificity. However, current developments in MDCT techniques provide better spatial resolution than MRI and quick scan times potentially cause fewer motion artifacts and improve the accuracy of MDCT. The exact number and the distribution of tumour nodules is crucial for allocating these patients to adequate treatment regimens; however, it is well known that particularly small nodules often remain undetected using radiological methods<sup>[8,12,13]</sup>. The purpose of this study was to compare the diagnostic capability of 64-row MDCT and MRI for the detection of hypervascularized tumour nodules in the cirrhotic liver to allow for adequate treatment.

## MATERIALS AND METHODS

Between July 2006 and July 2007, 28 patients with a suspected diagnosis of HCC on ultrasound or CT (25 male, 3 female, mean age  $67.0 \pm 10.8$  years, range 46-89 years) were included in the study protocol. Diagnosis was confirmed by liver biopsy of at least one of the tumour nodules in 25 cases (Table 1). According to the guidelines of the European Association for the Study of the Liver (EASL), the other 3 patients were diagnosed with two different imaging techniques by arterial hypervascularization of nodules  $> 2$  cm and/or a corresponding increase in serum levels of alpha-feto-protein<sup>[14]</sup>. For final diagnosis, all patients were included in this comparative imaging protocol that comprised contrast-enhanced MDCT and MRI in order to evaluate number, size, and location of HCC tumours for subsequent treatment allocation. The study protocol was approved by the local ethical review board. All patients gave their informed consent before entering the study.

The CT diagnosis was based on a triphasic contrast-enhanced protocol using a 64-row MDCT scanner (Brilliance 64<sup>®</sup>, Philips Medical Systems, Eindhoven, Netherlands, 120 kV, 200 mAs, collimation 64 mm  $\times$  0.6 mm, pitch 0.625, reconstruction interval 1.172 mm, slice thickness 5 mm native and 3 mm in contrast-enhanced phases). 1 mm slices were reconstructed for CT-angiography of liver arteries if the patients were considered for surgery. The contrast bolus consisted of 120 mL Iomeprol (Imeron 300<sup>®</sup>, Altana Pharma, Konstanz, Germany) administered at a flow rate of 4 mL/s using a bolus trigger technique (positioning of the respective region of interest (ROI) in the abdominal aorta just above the celiac trunk, threshold 150 Hounsfield Units (HU), start delay 10 s). The portal phase started with a delay of 50 s after reaching the threshold.

MRI was performed using a 1.5-Tesla MR scanner (Magnetom Vision<sup>®</sup>, Siemens Medical Solutions, Erlangen, Germany; software: syngo MR 2004A 4VA25A) with two body coils (CP Body Array Flex<sup>®</sup>). The study

protocol covered (1) T1w-2D-Flash fatsat (TE/TR 2.72/129 ms, flip 70°, slice 6 mm, matrix 256\*), (2) T2w TSE (TE/TR 102/4000 ms, flip 150° slice thickness 6 mm, matrix 256\*), (3) in phase and out of phase (TE/TR 2.36/4.76/108 ms, flip 70°, slice 6 mm, matrix 256\*), and (4) five dynamic contrast-enhanced T1w-3D-Flash fat sat sequences (TE/TR 1.56/4.6 ms, flip 15°, slice 4 mm, matrix 256\*) with 0, 20, 45, 90, and 300 s start delay after contrast material injection (0.1 mmol/kg Gadolinium-DTPA (Magnevist<sup>®</sup>, Bayer Schering Pharma AG, Berlin, Germany), 2 mL/s by power injector (Spectris<sup>®</sup>, Medrad, Dusseldorf, Germany).

All phases of the MDCT and MRI scans were independently analyzed by two independent investigators with respect to the number, size, and location of the tumours. Both investigators had at least 10 years experience in evaluating HCC in daily practice. In order to gain the highest diagnostic sensitivity, each nodule was rated positive whenever CT or MRI or both modalities were equivocally positive by both investigators in consensus. Positive diagnosis was based on the EASL and American Association for the Study of Liver Diseases (AASLD) guidelines which require hypervascularization in

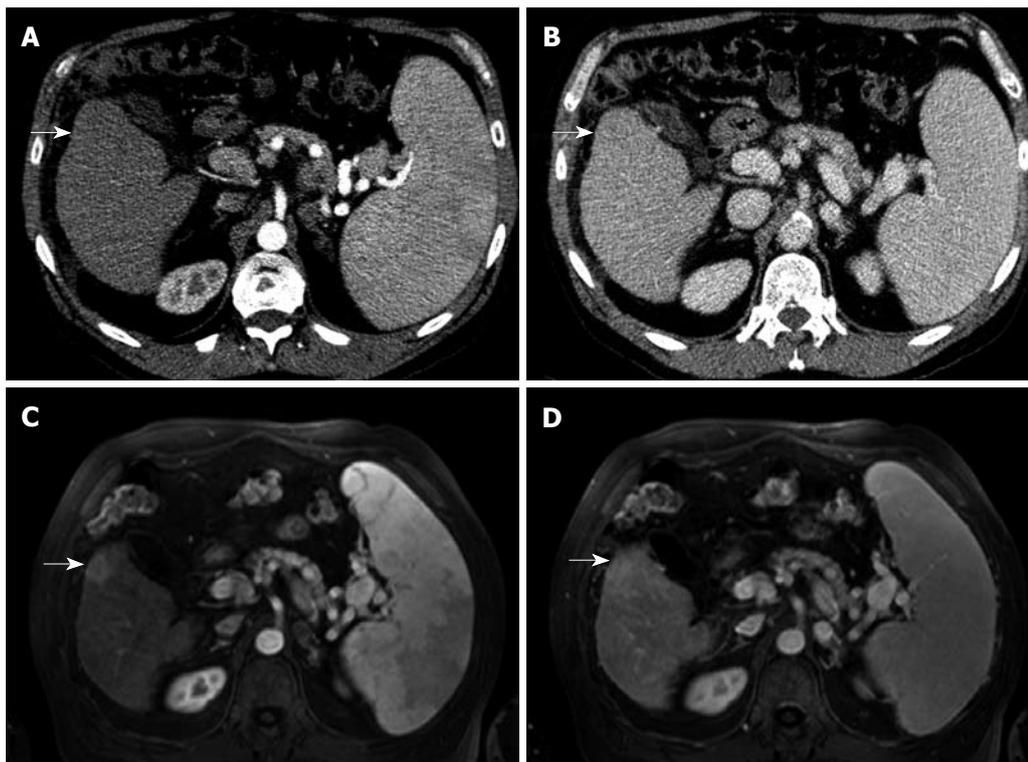

**Figure 1** 71-year-old man with biopsy-proven hepatocellular carcinoma (HCC). Detection of an additional tumor nodule by magnetic resonance imaging (MRI), size 12 mm (size category  $\leq 15$  mm). Multi-detector computed tomography (MDCT) demonstrates two hypervascularized tumor nodules in the contrast-enhanced arterial phase (A, arrow) but not in the portal venous phase (B, arrow). MRI arterial phase depicts one more tumor nodule (arrows) in the T2w (C) and the T1w contrast-enhanced early arterial phase (D).

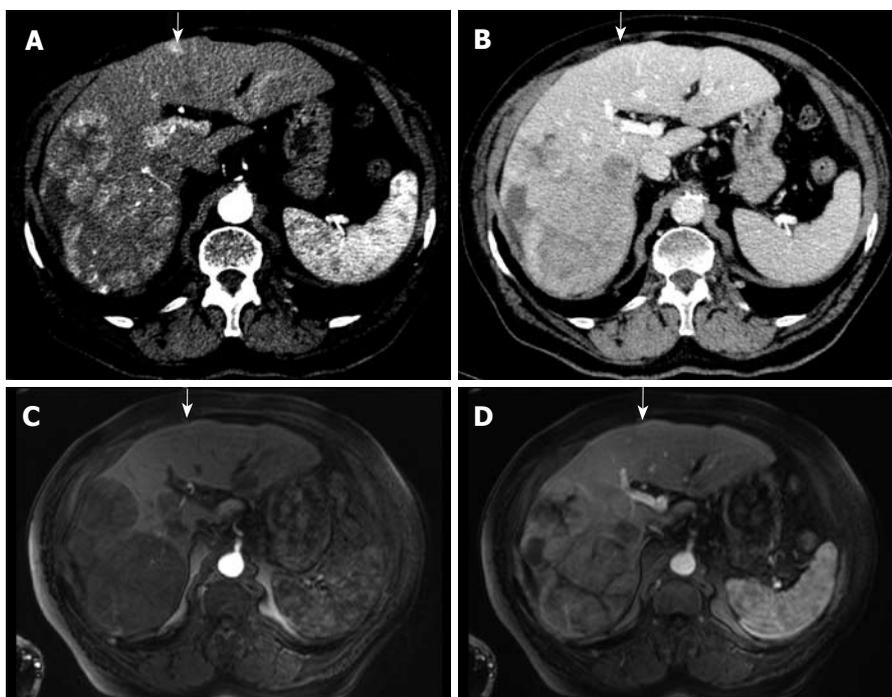

**Figure 2** 70-year-old man with biopsy-proven HCC. Detection of an additional tumour nodule by MRI, size 10 mm (size category  $\leq 10$  mm). MDCT does not show any contrast enhancement in the arterial (A, arrow) or portal venous phase (B, arrow). MRI arterial phase depicts one more tumour nodule (C, arrow) which is hypo- to isointense on the portal venous phase (D, arrow).

arterial phase and contrast washout in the early or delayed venous phase<sup>[15]</sup>. All but three cases were histologically proven by biopsy from one representative nodule. Biopsy proof from each nodule, however, is not feasible *in vivo* due to ethical reasons. The other three cases were not histologically proven because of poor coagulation status and inappropriate subcapsular location for biopsy in order to avoid tumor cell spreading. However, these cases fulfilled the diagnosis criteria according to EASL (hypervascularized nodules  $> 2$  cm in two imaging modalities).

All images were analyzed on a separate workstation with magnification. Tumour diameters were sized with a measuring tool integrated in the workstation software. All nodules visible in both modalities were compared in size. Additionally, the influence of HCC aetiology on tumour detection was analysed. Explanted liver specimens from patients who underwent liver transplantation (3  $\times$ ) or hemihepatectomy (1  $\times$ ) were analyzed pathologically. The specimens were cut in 4 mm slices in the same orientation as in CT and MRI in order to compare the findings. All nodules found by the

**Figure 3** 70-year-old man with biopsy-proven HCC. Detection of an additional tumour nodule by MRI, size 19 mm (size category  $\leq 20$  mm). MDCT demonstrates no hypervascular enhancement in the contrast-enhanced arterial phase (A, arrow) or the portal venous phase (B, arrow). MRI arterial phase depicts a hypervascularized area in the T1w phase (C, arrow) which became isointense in the portal venous phase (D, arrow).

**Figure 4** 82-year-old man with biopsy-proven HCC. Detection of an additional tumour nodule by MDCT. The contrast-enhanced arterial phase MDCT demonstrates large tumours in the right liver lobe and one additional hypervascularized nodule in segment 4 (A, arrow) but not in the portal venous phase (B, arrow). Contrast-enhanced MRI depicts the large tumours in the right liver lobe but not in segment 4 (arrows) in early arterial phase (C) and portal venous phase (D).

pathologist were correlated to the CT and MRI data and investigated histologically.

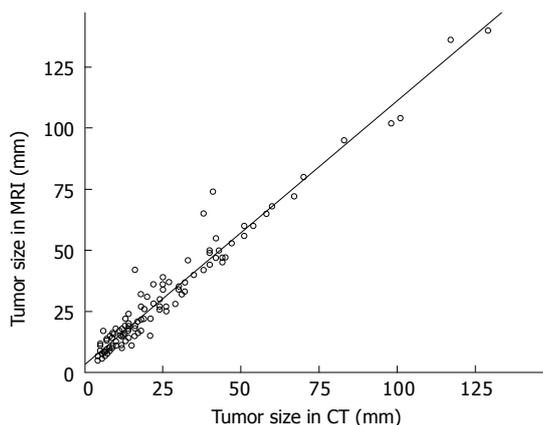

**Statistical analysis**

Sensitivity for tumour detection was calculated with “R” (R: A Language and Environment for Statistical Computing, R Foundation for Statistical Computing, Version 2.5.0, Vienna, Austria, 2007), including Geepack (Generalized

Estimating Equations). *P* values less than 0.05 were considered statistically significant. Statistical testing was performed by an independent statistician to avoid review bias.

**RESULTS**

Consensus reading of MRI and MDCT depicted a total of 162 nodules. On a per nodule basis, MRI detected

**Figure 5** Correlation of tumor sizes measured with MDCT and MRI using a scatterplot. There is a tendency towards greater diameters on MRI compared to MDCT ( $y = 1.08x + 3.2$ ).

**Table 2** Diagnostic impact of imaging protocols on tumour detection  $n$  (%)

Imaging protocols of MDCT and MRI	Tumour nodules detected
MRI, T1w 3D-Flash, arterial phase (20 s start delay)	158 (97.5)
MRI, T1w 3D-Flash, portal-venous phase (45 s start delay)	145 (89.5)
MRI, T1w 3D-Flash, equilibrium phase (90 s start delay)	127 (78.4)
MDCT, arterial phase (bolus trigger for start delay)	119 (73.5)
MRI, T1w 3D-Flash, delayed phase (300 s start delay)	115 (71.0)
MRI, T1w 3D-Flash, dynamic phase Phase (T1 native)	109 (67.3)
MRI, T1w 2D Flash native	104 (64.2)
MRI, Dual-GRE in-phase	98 (60.5)
MRI, Dual-GRE out-phase	96 (59.3)
MDCT, portal-venous phase (55 s start delay)	84 (51.9)
MRI, T2w TSE	72 (44.4)
MDCT, native phase	56 (34.6)

MDCT: Multidetector computed tomography; MRI: Magnetic resonance imaging.

significantly more nodules than MDCT (159 *vs* 123,  $P \leq 0.001$ , Figures 1-3), resulting in an overall sensitivity of 0.98 for MRI and 0.76 for MDCT. The best diagnostic sensitivity was ascertained for the early arterial phase MRI, followed by portal venous phase MRI, equilibrium phase MRI, arterial phase MDCT, and late phase contrast enhanced MRI (Table 2). For native MRI phases (T1w, T2w, Dual-GRE in/out phase) and native and portal venous MDCT phases, sensitivities were low. Negative MDCT findings included 5 nodules  $\leq 5$  mm, 17 nodules  $\leq 10$  mm, 12 nodules  $\leq 15$  mm, 4 nodules  $\leq 20$  mm, and 1 nodule greater than 20 mm. In contrast, MRI missed two nodules  $\leq 10$  mm and one nodule  $\leq 15$  mm. With respect to unilobular and bilobular tumour dissemination, MRI detected 7 MDCT-negative nodules in 2 patients which were located in the contralateral liver lobe and could have changed the therapeutic strategy if not detected. In contrast, the three nodules missed in MRI (Figure 4) had no influence on the treatment regimen because the patient had multinodular disease in both lobes.

Figure 5 shows the sizes of the nodules positive in

both, CT and MRI. Compared to MDCT, the diameters of the tumour nodules were slightly greater in MRI ( $29.2 \pm 25.1$  mm *vs*  $24.1 \pm 22.7$  mm,  $P < 0.005$ , Figure 5). The median lesion diameter was 15.5 mm (range 5 mm to 140 mm) in MRI compared to 12 mm (range 4 mm to 129 mm). Irrespective of the false-negative MDCT findings, tumour diameters were underestimated with MDCT in 43 nodules compared to MRI. In contrast, MRI underrated tumour diameter in only one case compared to MDCT (Table 3).

During the study period, three patients underwent liver transplantation and one was allocated to hemihepatectomy. The explanted specimens (three complete organs and one right liver lobe) were transected in 4 mm slices in transverse orientation for a comparative correlation with the respective MDCT and MRI slices (Figure 6). These four specimens revealed a total number of 20 tumour nodules, 16 of which were depicted by MRI (80%) and only 13 by MDCT (65%).

## DISCUSSION

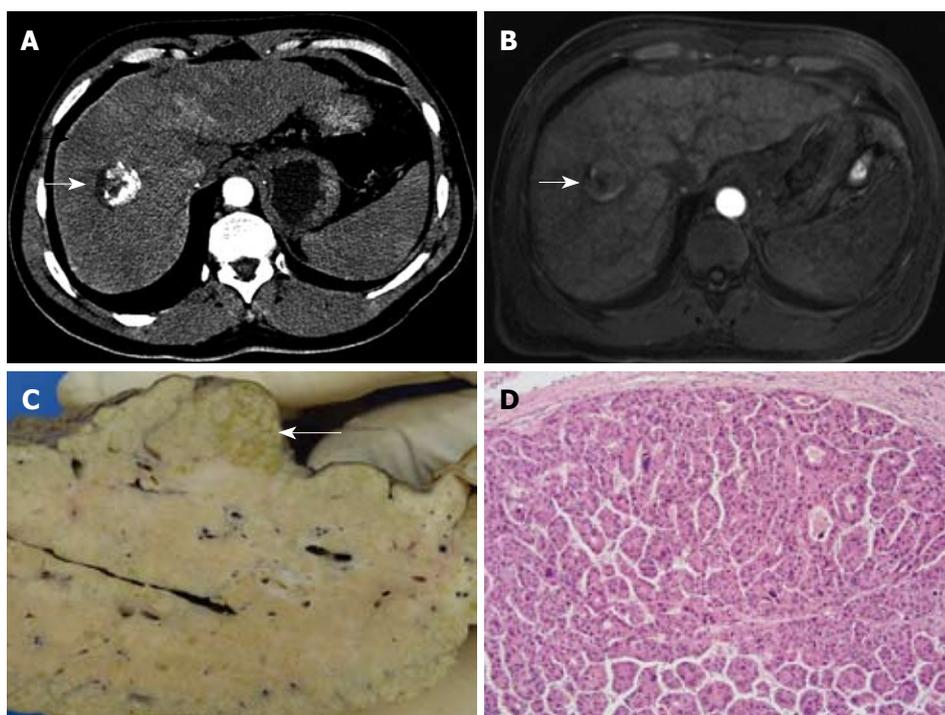

The main reason for the poor survival of HCC patients is the fact that most cases are not diagnosed until disease has reached an advanced stage, which limits the most effective therapeutic options<sup>[7]</sup>. HCC cases that fulfil the Milan criteria (one nodule  $< 5$  cm or three nodules  $< 3$  cm) might be indicated for liver transplantation with curative intention because it not only completely removes the tumour but also the critical precancerous liver cirrhosis<sup>[8]</sup>. However, a significant number of additional intrahepatic tumours have been missed in comparative radiological studies, particularly small nodules  $< 20$  mm<sup>[8,13,16]</sup>, calling the decision-making process into question. Moreover, resection and local tumour ablation with percutaneous ethanol injection (PEI) or radiofrequency ablation (RFA) might have curative potential if the tumour nodules are not multilobular and do not exceed defined nodule diameters<sup>[17]</sup>. Thus, for optimal treatment allocation, current efforts in diagnostic work-up focus on increasing the correctness of preoperative diagnosis with respect to number, size, and location of tumour nodules.

The purpose of the present study was to evaluate the diagnostic potential of 64-row MDCT and MRI for the detection of hypervascularized tumour nodules in the cirrhotic liver for adequate treatment allocation of HCC patients. MDCT has advantages compared to MRI, such as fewer motion artifacts due to much shorter scanning time (3 to 5 s *vs* 18-25 s) and higher spatial in-plane resolution (512\* *vs* 256\* Matrix). However, overall sensitivity of state-of-the-art 64-row MDCT has been demonstrated to be significantly inferior compared to contrast-enhanced MRI and thereby confirms respective findings from older studies with less sophisticated CT technology<sup>[9-11,18,19]</sup>. Recent data have reported slightly higher detection rates for MDCT compared to MRI<sup>[20]</sup>. In our study, however, the outstanding contrast resolution of MRI scored much better with greater sensitivity particularly in small lesions of  $\leq 10$  mm compared to MDCT (0.95 *vs* 0.48,  $P < 0.001$ ) which is in concordance

**Table 3** Results of consensus reading of MDCT and MRI: No. of detected tumour nodules by MDCT and MRI depending on tumour size scaling

	Negative	MRI					Total
		≤ 5 mm	≤ 10 mm	≤ 15 mm	≤ 20 mm	> 20 mm

<sup>1</sup>Nodules which appeared greater in MRI compared to CT; <sup>2</sup>Only the single nodule was bigger in CT compared to MRI.

**Figure 6** 54-year-old man with biopsy-proven HCC. False-negative finding in the two modalities. Contrast-enhanced early arterial and portal venous phase MDCT (A) and arterial and portal venous phase MRI (B) detected a 3 cm tumour in the right liver lobe (A, B, arrows) but failed to detect another tumour nodule at the posterior surface of the left liver lobe. The explanted liver specimen clearly depicts this additional 2 cm tumour nodule on gross-sectional pathology (C, arrow) and histology (D, 10 × magnification, HE staining).

with recent reports from the literature<sup>[18,21]</sup>.

Our study has some limitations. First, there was an obvious bias in patient recruitment since prior imaging results had suggested HCC in all patients before they entered the study protocol. Only 4 patients were diagnosed at an early stage with tumour nodules of small diameters so that they could be allocated to either local-ablative treatment with radiofrequency ablation or liver transplantation if they complied with the Milan criteria<sup>[8]</sup>. The majority, however, was diagnosed in an intermediate stage with multilobar disease and sometimes large tumour nodules which might have biased sensitivity. Second, the start delay for the arterial phase CT was 10 s after reaching the trigger threshold. This might have been slightly too short in light of recent reports<sup>[22]</sup> and could possibly explain the great difference between the sensitivity rates of MDCT and MRI. Third, for histological confirmation of HCC diagnosis, in most cases only one representative lesion was examined pathologically,

meaning that the diagnosis of additional tumour nodules relied on imaging only. Fourth, the reference diagnosis might not actually represent the final pathological diagnosis in all cases. For example, the explanted specimen of four cases (3 × liver transplantation, 1 × hemihepatectomy) revealed a total of 20 tumour nodules, whereas MRI and MDCT had depicted only 16 and 13, respectively. So far, we have to concede that even the dedicated MRI protocol used, underrated the intrahepatic tumour spread compared to histological examination. This is consistent with the findings of previous studies which demonstrated an even worse overall tumour detection rate of around 50%-70%<sup>[8,13,16]</sup>. Fifth, the consensus reading of MDCT and MRI could have potentially overestimated nodules in MDCT and MRI by mistaking a benign hypervascularized lesion for a malignant nodule due to the lack of an absolute standard of reference. However, in light of the specimens mentioned above, the underrating of the nodule numbers

and tumour spread is still a major issue for HCC diagnosis with both modalities.

Despite these limitations, the data demonstrate that diagnostic results depend considerably on the multiphasic imaging protocols. Although the early arterial phase in MRI depicts the greatest numbers of tumour nodules<sup>[23]</sup>, it potentially underestimates the real tumour spread in particular cases and might result in incorrect treatment allocation with respect to the Barcelona Clinic Liver Cancer (BCLC) classification<sup>[8,12,24-28]</sup>. Substantial efforts are required to improve the diagnostic correctness, and MRI seems to have better pre-requisites and a greater potential for future developments, either by improving MRI sequences or by employing more specific contrast materials<sup>[9,29-31]</sup>, the double contrast technique<sup>[32,33]</sup> or special imaging techniques<sup>[34]</sup>. Since MDCT failed to demonstrate equivalence with MRI, triphasic contrast-enhanced MDCT protocols might only be used in the first instance. However, if CT suggests local-ablative treatment, resection, or allocation to liver transplantation, dynamic multiphasic contrast-enhanced MRI should be used in order to exclude additional tumour nodules which would probably change the initial strategy.

In conclusion, dynamic contrast-enhanced MRI is superior to triphasic 64-row MDCT for detecting numbers, sizes, and distribution of HCC tumour nodules. HCC patients should be assigned to operative or interventional treatment according to a dedicated MRI protocol.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world and the third most common cause of cancer death with 600 000 to 1 million new cases being diagnosed each year. Due to the lack of specific early symptoms, most cases are not diagnosed until the disease is already in an advanced stage, which limits the most effective therapeutic options. That is why, although new treatments are available, patient survival has not significantly improved in the last 30 years. Therefore, early tumor detection is one of the most important issues in HCC therapy. The study was to compare the diagnostic capability of two imaging systems, computed tomography (CT) and magnetic resonance imaging (MRI), for tumor detection.

### Research frontiers

In recent years, an enormous improvement has been taking place in the field of imaging systems. With new generations of CT and MRI scanners available, the question arises, which one is the better technique to depict this tumor.

### Innovations and breakthroughs

Previous studies used older equipment, e.g. single slice CT. The advance in this study is the evaluation of a new scanner generation (64-row CT) which allows faster acquisition and therefore fewer motion artifacts with a lower slice thickness.

### Applications

This article should help radiologists, gastroenterologists and other physicians dealing with HCC patients in daily practice to use the correct method of imaging in the right patient.

### Peer review

The study aimed at determination of the nodule detection sensitivity of MDCT compared with MRI. The presentation of the data should be more concise.

### Abstract

**AIM:** To test the hypothesis that pain and affect rather than impaired emptying determine symptom severity in patients with gastroparesis.

**METHODS:** Adult patients with documented gastroparesis were enrolled prospectively in a single center and asked to complete the Gastroparesis Cardinal Symptom Index (GCSI), Hospital Anxiety and Depression Scale (HADS), the Short Form 12 (SF-12) as quality of life index, rate pain severity and answer 10 open-ended questions.

**RESULTS:** A total of 55 patients (44 women) participated. Idiopathic ( $n = 29$ ) or diabetic ( $n = 11$ ) gastroparesis and connective tissue disease ( $n = 8$ ) were the most common underlying causes. Antiemetics ( $n = 30$ ) and prokinetics ( $n = 32$ ) were most often prescribed. Seventeen patients used opioids on a daily basis. Nausea and/or vomiting ( $n = 28$ ), pain ( $n = 24$ ) and bloating ( $n = 14$ ) were most commonly listed as dominant symptoms. Patients subjectively attributed symptom improvement to nutritional and dietary therapy ( $n = 11$ ), prokinetics ( $n = 11$ ), antiemetics ( $n = 10$ ) or analgesic agents ( $n = 3$ ). In univariate analyses, the physical subscore of the SF-12 and HADS, but not gastric emptying delay or symptom duration significantly correlated with disease severity as measured by the GCSI. In multivariate analyses, the

combination of vomiting, bloating and depression best predicted the overall impact on quality of life.

**CONCLUSION:** The study confirms the importance of pain and affect in gastroparesis, which requires novel approaches to improve more effectively the quality of life in patients with this disorder.

### INTRODUCTION

Gastroparesis is an increasingly diagnosed functional disorder, characterized by delayed emptying of gastric contents. Considering the defining abnormality, prokinetics continue to play a primary role in managing this disorder<sup>[1-3]</sup>. However, cross-sectional and longitudinal studies have demonstrated a poor correlation between the documented delay in gastric emptying and symptom severity<sup>[4-6]</sup>. Moreover, motilin agonists do not improve symptoms even though they significantly accelerate gastric emptying<sup>[5,7-10]</sup>. Thus, other mechanisms must contribute to the clinical manifestation of gastroparesis, such as impaired gastric accommodation, altered distribution of ingested material within the stomach, and peripheral and/or central hyperalgesia<sup>[1-4]</sup>. The relative importance of any of these potential mechanisms remains unclear. More importantly, there is no evidence that medication that targets these abnormalities is indeed beneficial when used clinically. As we typically cannot change the underlying processes that lead to gastroparesis, treatment remains largely symptomatic with the primary goal of improving the overall quality of life of patients suffering from this, at times, disabling disorder.

We performed a cross-sectional study in patients with confirmed gastroparesis to define better the relative importance of key symptoms of gastroparesis, their

impact on the patients' functional status, and the potential differences between patient subgroups defined by the underlying etiology. The main hypotheses were: that pain significantly contributes to the impaired quality of life in patients with gastroparesis, and that affect plays an important role in determining symptom severity in patients with gastroparesis.

## MATERIALS AND METHODS

### Patient recruitment

Adult patients with confirmed gastroparesis seen by one investigator (Bielefeldt K) in the Digestive Disorders Clinic of the University of Pittsburgh Medical Center were invited to participate. Patients with gastroparesis had to be symptomatic for at least 6 wk and have objective evidence of impaired gastric function with delayed gastric emptying by scintigraphy, or documentation of retained food within the stomach after a 12-h fasting period obtained by endoscopy or contrast study. Structural abnormalities, such as gastric outlet obstruction or mechanical obstruction in the more distal gastrointestinal tract had to be excluded. The protocol was approved by the Institutional Review Board of the University of Pittsburgh (PRO8020059).

### Surveys

After obtaining informed consent, all patients were asked to provide basic demographic information, complete the Gastroparesis Cardinal Symptom Index (GCSI), the Hospital Anxiety and Depression Scale (HADS), and the Medical Outcomes Study Short Form 12 (SF-12).

The GCSI is a self-administered assessment tool developed for patients with gastroparesis. The original survey comprises three subscales: postprandial fullness/early satiation (4 items); nausea/vomiting (3 items), and bloating (2 items). Considering the potential importance of pain, pain rating was added to the scale and scored similarly to the other items. Internal consistency and test-retest reliability were 0.84 and 0.76, respectively<sup>[11]</sup>.

The HADS is a 14-item self-report questionnaire that asks patients to rate symptoms using statements that are converted into a numeric score between 0 and 3. The total score of can range between 0 and 21 for anxiety and depression. Extensive studies support an internal consistency exceeding 0.8. When used in different populations, scores of > 8 have a sensitivity around 80% for depressive or anxiety disorders<sup>[12]</sup>.

The SF-12 is a self-report measure of perceived health, which consists of 12 questions. Two summary scores are generated: a physical health factor score (PHS) and a mental health factor score (MHS). The scores have been constructed with the population norm for each score being 50. Compared with the more extensive Short Form 36 (SF-36), the measure has been shown to be valid with correlations of 0.905 for the SF-36 Physical Component Summary and 0.938 for the SF-36 Mental Component Summary<sup>[13]</sup>.

### Open ended questions

Patients were also asked a series of open-ended questions

(Table 1) that focused on the impact of gastroparesis on professional and private spheres of their lives. These questions included verbal assessments of the most significant symptoms, perceived treatment effects, and concerns related to the disease.

### Data abstraction

Clinical data about nature and duration of symptoms, severity, character, location of pain, weight changes, documented delay in gastric emptying, prior and ongoing treatment were abstracted after the clinical encounter, de-identified and linked to the survey data.

### Statistical analysis

Responses to open-ended questions were analyzed by two independent coders who were aware of the underlying diagnosis of gastroparesis, but were blinded to patient identity, survey data as well as duration and etiology of the disorder. The qualitative analysis focused on frequency rather than expressions of severity of factors. A codebook was generated to record responses. Statements supporting the code were highlighted and added to a master file that contained all qualitative data.

Dichotomous variables were analyzed using  $\chi^2$  statistics. Continuous and categorical variables are given as mean  $\pm$  SE. Group comparisons were performed using analysis of variance. The GCSI summary score and quality of life as measured by the SF-12 were defined as the main endpoints. In an initial univariate analysis, correlations between the main endpoints and between different measures and the main endpoints were analyzed using Spearman correlation. Only variables with  $P < 0.1$  were entered into the multilinear regression model.

## RESULTS

### Patients

Between June 2008 and February 2009, a total of 55 patients (mean age:  $42.4 \pm 1.9$  years; 81% women) agreed to participate (Table 2). Gastric emptying studies had documented delayed emptying in all but five patients, who could not tolerate or complete studies because of emesis. In these individuals, retained food ( $n = 4$ ) or a bezoar ( $n = 1$ ) had been demonstrated endoscopically prior to enrollment. Thus, all patients met the entry criterion of objectively documented impairment in gastric emptying. However, studies were not performed in a single center with differences in test meals, test duration and data reporting. In 26 patients, the half-emptying time for solid-phase gastric emptying had been calculated and given. One additional patient only underwent a gastric emptying study for liquids that showed a significant delay. In five patients, only gastric retention at 90 or 120 min was quantified and compared with institutional norms. In the remaining patients, only a qualitative comment described delayed gastric emptying without further quantification by radiologists in outside institutions. The mean half-emptying time for the available studies was  $319 \pm 50$  min.

The most common causes of gastroparesis were diabetes mellitus ( $n = 11$ ), connective tissue disease ( $n$

= 8), abdominal surgery or trauma (*n* = 4), osteogenesis imperfecta (*n* = 1), mitochondrial myopathy (*n* = 1) and Marfan syndrome (*n* = 1). In the remaining 29 patients, no underlying cause could be identified. Four of the patients with idiopathic gastroparesis recalled an acute illness prior to the onset of the disease, which suggested a post-infectious form of gastroparesis. Patients with idiopathic gastroparesis were significantly younger than those in the other two major groups (Table 2). Gastroparesis caused by connective tissue disease showed an expected female predominance, considering the preferential manifestation of systemic sclerosis in women<sup>[14]</sup>. Similarly, 90% of patients with idiopathic gastroparesis were women, while nearly half of the patients with diabetic gastroparesis were men (*P* < 0.05).

Symptoms of gastroparesis had been present for 32 ± 4 mo. Ten patients reported a significant weight loss that exceeded 5% of their body weight within the preceding 6 mo. The average weight loss for the entire group was 1.7 ± 0.7 kg. All but four patients (93%) complained about nausea. A sense of bloating, fullness and/or early satiation was present in 47 (87%) patients. At least mild pain was mentioned by 44 (81%) patients. The pain was primarily postprandial in 11 patients, with the remaining 34 participants complaining about constant discomfort. The pain was typically located in the epigastrium and described

as pressure (*n* = 18), sharp (*n* = 12) or burning sensation (*n* = 7). Three patients mentioned generalized abdominal pain. In one patient, the pain radiated to the right upper quadrant and in another to the chest.

Seven patients (6 idiopathic gastroparesis; 1 diabetic gastroparesis) reported undergoing a cholecystectomy for biliary dyskinesia after symptom onset, which led to transient improvement in five patients. However, symptoms recurred within 3 mo in all but one of these patients, who continued to do well for 4 years before experiencing recurrent problems. Within the month prior to enrollment, 32 (60%) patients were using prokinetic agents, most commonly metoclopramide (Table 3). Ten of these patients experienced at least moderate side effects with extrapyramidal motor disorders (*n* = 3) worsening fatigue (*n* = 5) or depression (*n* = 1), which led to discontinuation of the agent. One patient was switched to domperidone. Three patients with systemic sclerosis and gastroparesis complicated by chronic intestinal pseudo-obstruction were using octreotide (*n* = 2) or pyridostigmine (*n* = 1). A total of 30 (55%) patients required daily antiemetic medication, most commonly phenothiazines and/or ondansetron. Eighteen patients (33%) received chronic antidepressant medication; mostly serotonin reuptake inhibitors. In four

patients, tricyclic antidepressants or duloxetine were given to improve pain control. Regular use of benzodiazepines was reported by 16 (29%) patients. A total of 17 patients (31%) received chronic opioids for pain management. In two patients, narcotics were given for painful diabetic neuropathy. One patient had sickle cell anemia with severe bone pain. An additional patient with severe joint and muscle pain caused by systemic sclerosis and polymyositis used a fentanyl patch, which left 13 (24%) patients who were taking opioids daily for control of their abdominal pain. As opioids can impair gastric emptying, assessment of gastric function was performed after transient discontinuation of narcotics in all but the two patients who suffered from painful diabetic neuropathy. A total of 11 (20%) patients received nutritional support *via* enteral (*n* = 8) or parenteral (*n* = 3) nutrition.

**Survey data**

As shown in Table 4, the GCSI summary score demonstrated a moderate symptom severity for the entire group. Group comparisons only showed a trend for a lower overall score in patients with connective tissue disorders as the underlying etiology (*P* = 0.075). Figure 1A summarizes the individual symptom scores for the entire group. When asked to rate abdominal pain using the GCSI coding scale, the mean pain severity was 2.97 ± 0.24, which was similar to the subjectively rated severity of other symptoms. The pain rating correlated with the

**Figure 1 Symptom severity scores in patients with gastroparesis.** The individual GCSI scores are shown for the entire group (A). Component sub-scores for the GCSI and pain ratings are summarized for the three major patient groups, to allow comparison between the different etiologies of gastroparesis (B). Significant differences were seen for nausea (diabetes vs connective tissue disease) and pain (idiopathic vs connective tissue disease). CTD: Connective tissue disease; GCSI: Gastroparesis Cardinal Symptom Index.

pain scale of the SF-12 that assessed the impact of pain over the preceding month (*R*<sup>2</sup> = 0.22, *P* < 0.01), and the routinely assessed patient pain rating that addressed pain presence on the day of the clinic visit (*R*<sup>2</sup> = 0.36, *P* < 0.001). A group comparison of component scores revealed more significant nausea for patients with diabetic gastroparesis and higher pain scores for patients with idiopathic gastroparesis (Figure 1B).

Patients in all groups had moderately elevated scores for both anxiety and depression, without significant differences between the groups. Using the proposed cutoff score of > 8<sup>[12]</sup>, 40 participants (74%) met screening criteria for anxiety or depression. In 16 patients (29%), anxiety and depression were both above the proposed threshold for clinically relevant affective spectrum disorders.

Compared to a population norm of 50, the mental and the physical component of the SF-12 showed a significant impairment of health-related functional status. There were no significant differences between the groups.

The GCSI summary score showed a significant inverse correlation with the physical but not mental score of the SF-12. It was correlated positively with depression scores, but not HADS anxiety scores, age, symptom duration or degree of gastric emptying delay (Table 5). In order to identify the relative contribution of symptoms, we performed univariate analyses, correlating the physical health scale of the SF-12 with GCSI subscores and pain ratings. Based on these results, we performed

multiple linear regressions to identify the most important predictors of poor health function. A combination of GCSI subscores for nausea and bloating and the HADS score for depression best predicted the PHS subscore with an adjusted  $R^2$  of 0.44.

### Qualitative data

When asked to describe the impact of gastroparesis on their lives, most patients focused on the effects of interactions with family, friends or colleagues ( $n = 37$ ). Three main topics emerged in the more detailed analyses of responses. First, eating out, dinners or other social functions were seen as causing difficulties because of the limited ability to tolerate food ( $n = 26$ ). One patient explained these problems: “[With] every- and anything that goes on socially there is food. When you can’t eat, it is really hard to cope with. People feel funny asking you out to dinner or invite you to something where there will be food.” The second problem was related to fatigue, which made it difficult for patients to meet expectations ( $n = 14$ ) as exemplified by statements such as “I push myself to get out of bed every morning” or “I can barely make it through the day”. The third major topic revolved around the frustration and emotional impact of the disease as patients experienced difficulties interacting with others ( $n = 16$ ). One patient summarized her experience: “...enjoying life has become difficult because my mind is always on my stomach”.

Participants cited a significant strain on their relationships with partners and/or family members ( $n = 13$ ). Such problems could be a simple consequence of limitations imposed by their disease, as this woman explained: “...having to sleep sitting up doesn’t contribute to closeness with your partner”. A young mother with idiopathic gastroparesis reported that her disease “...has prevented me from caring for my children and participating in their activities”. In other cases, it was more anxieties and concerns in response to the physical evidence of illness, such as frequent vomiting: “...children - always frightened I will never get well or I will die”. Some patients reported a gradual withdrawal of others in the face of ongoing illness: “My friends don’t really call anymore because they know I am always feeling sick. ... I also broke off a wedding engagement with someone I was with for 9 years because he couldn’t stand how sick I was and felt I was holding him back”.

When asked about the impact of gastroparesis on their professional activity, three patients described themselves as retired and seven responded that they were on disability (in 2 cases, for reasons other than gastroparesis). An additional eight patients mentioned that they felt forced to quit jobs or school because of their disease. One patient who had successfully completed college education explained his difficulties: “...nausea is consuming... [making it] difficult to concentrate on anything else...” Another participant described the impact as being “...unable to work... therefore, I feel worthless. I feel like my stomach problems wasted everything I achieved”.

Patients were also asked to explain their most

bothersome symptoms and their concerns related to gastroparesis. Nausea or vomiting were listed by 28 participants, followed by pain ( $n = 24$ ), bloating ( $n = 14$ ) and emotional difficulties ( $n = 6$ ). Nearly half ( $n = 26$ ) of the patients mentioned the fear of an unrelenting chronic disease as their main concern, as shown by the following quote: “I worry that I’ll never feel like a normal person”. These concerns expressed themselves in some instances through anxiety that a more serious, perhaps even lethal disease caused the problems. Despite prior and extensive investigations and explanations, five patients were afraid that they had cancer.

When describing the perceived impact of treatment they had received for gastroparesis, patients most commonly listed the benefits of dietary and nutritional therapy ( $n = 11$ ), prokinetics ( $n = 11$ ) and antiemetics ( $n = 10$ ). However, 10 patients mentioned that no treatment had led to any improvement. Others reported benefits of acid suppression ( $n = 5$ ), relaxation techniques ( $n = 3$ ) and analgesics ( $n = 3$ ).

Patients also described their experiences with healthcare providers, with 15 (27%) expressing frustration or dissatisfaction. They primarily focused on a perceived lack of knowledge or understanding, which may have contributed to a perceived diagnostic delay and limited symptomatic improvement. One patient summarized her experiences: “I’ve had horrifying experiences from the medical community. Most physicians just say what you can [eat] or drink [like] Ensure”.

## DISCUSSION

Our results provide a cross-sectional picture of gastroparesis and its impact on patients seen in a tertiary referral center. Consistent with prior studies, most patients were women in their thirties and early forties, with the majority suffering from idiopathic forms of gastroparesis<sup>[11,15-18]</sup>. Overall disease severity as judged by the GCSI score, other symptom severity scores or the physical and mental component of the SF-12 were comparable to those reported in previously published studies<sup>[6,11,15,16]</sup>. Similarly, the frequency of different symptoms, such as nausea, vomiting, early satiation and pain, were consistent with prior reports<sup>[6,16,18-21]</sup>. About 10% of patients with idiopathic gastroparesis recalled an acute symptom onset after a flu-like illness, which suggested a post-infectious form of the disease. These results are slightly lower than previously reported<sup>[15,22]</sup>. We also did not see differences in the apparent clinical course based on patient recall, as all individuals with post-infectious forms of gastroparesis had symptoms for more than 1 year and complained about ongoing and at least moderately severe symptoms. However, the cross-sectional design and relatively small sample size do not allow definitive conclusions to be drawn. While the symptom pattern of patients with diabetic and idiopathic gastroparesis did not differ, patients with systemic sclerosis complained less about pain compared to the other groups, which may be important in management decisions<sup>[18]</sup>.

### **Impact of gastroparesis**

When asked to rate their overall health, more than two thirds used descriptors of fair or poor, which demonstrated the significant impact of gastroparesis, which is also shown by the low score in the physical functioning domain of the SF-12. We included a qualitative analysis of open-ended questions to capture important details that led to impairment of quality of life. Most of the comments focused on social interactions with family, friends or colleagues rather than symptoms. A striking finding was the high number of patients who reported significant problems in their professional activities that may have contributed to unemployment or disability. Despite a mean age below 45 years, only about one quarter of study participants was fully employed. The number of individuals not working and/or on disability benefit was higher than reported for inflammatory bowel disease<sup>[23,24]</sup>. Consistent with the impact of the disease on professional lives, more than half of the patients reported household incomes well below the national average, which also has been observed in other disorders associated with chronic pain<sup>[25]</sup>. Chronic illness certainly increases work absenteeism and may even result in permanent disability<sup>[26-29]</sup>. Our findings suggest a disproportionate impact in patients with gastroparesis, which corresponded with patient statements about their own disease experience and functional health status. Additional studies with larger patients groups and longitudinal design are needed to better define the effect of impaired gastric function on professional productivity.

Not surprisingly, our results also highlighted the importance of food intake. Dietary management and nutritional therapy primarily and appropriately target the caloric and nutritional value of ingested materials, which relies on changes in meal volume and frequency, food consistency, and in more severe cases, even enteral or parenteral alimentation<sup>[2,30]</sup>. Although successful in preventing the development of nutritional deficiencies, these measures do not address the hedonic and social aspects related to eating. Aversive reactions to the previously pleasant experience of food intake, the inability to fully participate in daily routines, such as dinners, fully meet professional obligations associated with eating or drinking, or enjoy dining out with friends reminded patients on a daily basis how the illness had changed their lives. The answers often hinted at resentments, when healthcare providers did not appreciate this fact and briefly told them that simple dietary adjustments would solve their problems, without acknowledging the tremendous impact on quality of life.

### **Gastroparesis and affect**

The high scores for anxiety and depression and patient statements certainly demonstrated the association between mood and impaired gastric function. Our design did not allow us to determine whether and how these factors are causally related. Interestingly, in the multivariate model, depression but not anxiety significantly contributed to the overall impairment in health status. Only one study has described the prevalence of depression in a large

group of patients with gastroparesis, with nearly one quarter carrying the diagnosis of depressive illness<sup>[15]</sup>. This figure corresponds with the reported chronic use of antidepressant medications in our patient group. Our findings also fall in line with previous results obtained in patients with functional dyspepsia, in whom depression significantly correlated with the physical domain of quality of life<sup>[31,32]</sup>. Recent evidence suggests that depression is the key determinant of symptom severity in functional dyspepsia, which is primarily mediated through somatization<sup>[33]</sup>. Considering the overlap between functional dyspepsia and gastroparesis, additional studies will be needed to better define the role of psychological mechanisms in disease severity and manifestations.

### **Pain and gastroparesis**

The recent consensus statement of the American Gastroenterological Association comments on pain in gastroparesis as being relatively common, but typically not the primary symptom or concern<sup>[3]</sup>. Our findings, especially the patient comments, argue against this statement, when one considers the high prevalence of pain and subjective pain ratings, which has been emphasized previously by Hoogerwerf *et al*<sup>[18]</sup>. The relevance of pain was also reflected in the treatments received by patients. Despite concerns about the use of opioids in patients with gastroparesis, about 30% of the patients regularly used narcotics. Only one study has mentioned specifically narcotic use in patients with gastroparesis, and has reported an even higher number of close to 50%, which may have been caused partly by selection bias, because all patients underwent implantation of a gastric electrical stimulator<sup>[16]</sup>. The interaction between narcotic use and impaired gastric emptying is admittedly complex, as opioids affect gastrointestinal motility. However, virtually all assessments of gastric function were performed when patients did not receive narcotics. It is thus unlikely that the documented delay in gastric emptying seen in our patients was solely a consequence of medication.

Beyond its prevalence, pain remains a significant challenge in managing gastroparesis. The conventional approaches with dietary and/or prokinetic therapy do not provide significant benefit<sup>[18]</sup>. Tricyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs) or serotonin/norepinephrine reuptake inhibitors have been used in functional dyspepsia and other visceral pain syndromes<sup>[34-36]</sup>. Although they may acutely lower pain thresholds in healthy volunteers<sup>[37-39]</sup>, efficacy in patients has not been demonstrated consistently<sup>[32,40,41]</sup>. Gabapentin or pregabalin similarly may decrease sensory thresholds acutely<sup>[42]</sup>, but have not been shown to possess true analgesic properties in patients<sup>[43]</sup>. Considering the negative impact of opioids on gastric emptying and their addictive potential, kappa opioids agonists have been tried in gastroparesis or functional dyspepsia, but were not superior to placebo<sup>[44,45]</sup>. In view of recent advances in our understanding of visceral sensory mechanisms, we will have to see whether other potential targets for pharmacological interventions, such as purinergic receptors, TRPV1 or TRPA1, will provide greater benefit for these patients<sup>[46,47]</sup>.

### **Gastroparesis and gastric emptying**

Although gastroparesis is defined by delayed emptying, our study did not show a correlation between symptom severity and half-emptying time as an objective and quantitative measure of this impairment. Only minor differences emerged in comparisons between symptomatic individuals with (gastroparesis) and without (functional dyspepsia) delayed gastric emptying, which did not allow differentiation between the groups based on symptoms only<sup>[6,48]</sup>. In addition, potent prokinetics have a limited or no impact on symptoms, which further argues against a primary role of transit delay as a determinant of disease severity<sup>[8,9]</sup>. Consistent with this conclusion, only a small fraction of patients reported subjectively perceived benefit when taking prokinetics. This relatively low response rate contrasts starkly with the relatively frequent adverse effects. More than one third of the patients who received metoclopramide had to discontinue the medication because of side effects; a rate that is in line with previous reports<sup>[1,2]</sup>. These results are likely caused by the complex pathophysiology of gastroparesis, which includes impaired accommodation, delayed emptying, hypersensitivity and (preexisting or secondarily evolving) affective spectrum disorders, all of which contribute to the clinical manifestation of the disorder<sup>[4,30]</sup>.

### **Study limitations**

As is true for most clinical studies, our investigation was conducted in a tertiary referral center, which biases and skews findings as a result of the likely higher proportion of difficult-to-treat patients. However, patient age, sex distribution, the high proportion of patients with idiopathic gastroparesis and self-reported symptom severity were comparable with prior studies that used similar scoring systems<sup>[4,15,16,49]</sup>. The relatively high number of patients with systemic sclerosis and the slightly smaller group of diabetic patients likely reflects institutional idiosyncrasies. A cross-sectional study design certainly comes with limitations. It enabled us to identify association between symptom severity and its potential determinants, from underlying etiology to treatment. Although we noticed an important impact of depressive symptoms, longitudinal studies are needed to better define this relationship and correlate time- and/or treatment-dependent changes in the various indices. Moreover, our data cannot identify psychological or physiological mechanisms that mediate the interactions between affect and symptoms, which will require more detailed investigations. Similarly, our study was not designed to measure systematically the effects of different treatments in patients with gastroparesis. More than half of the patients were enrolled during their initial encounter, with data thus reflecting the approaches of many referring physicians. We also used previously obtained data on gastric emptying, which provided less standardized but still objective evidence of impaired gastric function in all patients. Although appropriate for reducing increasing healthcare costs and typical for clinical practice<sup>[11]</sup>, it limited our ability to correlate fully this disease-defining

variable with symptom severity.

Taken together, our data raise questions about some of the key premises that we as clinicians use when approaching patients with gastroparesis. Delayed gastric emptying still remains the defining and only routinely available diagnostic tool to identify this disorder. However, it may detract from the much more complex pathophysiology and may even misguide our treatment. As we cannot cure the illness, our treatment has to focus on improving the overall quality of life. A paradigm shift may be needed to take into account the important influence of under-recognized and under-treated problems, such as pain or affect. Pain assessment should be included in the GCSI. Gastric electrical stimulation was initially thought to alter gastric motility, with investigators now increasingly speculating on its effect on visceral sensation and affect<sup>[20,50,51]</sup>. Some data are promising, especially in diabetic patients<sup>[16,20,50,52]</sup>. However, the high cost, frequent need of reoperation, and the limited benefit in patients with significant pain and/or idiopathic gastroparesis clearly force us to look for alternatives. Our results may be seen as initial, yet circumstantial evidence that supports psychologically based interventions, which have been quite successful in functional bowel disease and have shown promise in a small case series<sup>[53]</sup>.

## **COMMENTS**

### **Background**

Gastroparesis is a chronic disorder that is characterized by significant dyspeptic symptoms and delayed gastric emptying. Despite the defining abnormality in gastric motor function, prokinetics typically have limited efficacy, which leaves patients with persistent symptoms and poor quality of life.

### **Research frontiers**

Anxiety and depression play an important role in the clinical manifestation of many functional disorders, which range from irritable bowel syndrome to fibromyalgia. We prospectively enrolled patients with gastroparesis to better understand the relative importance of different gastrointestinal symptoms and associated or coexisting emotional factors on their quality of life.

### **Innovations and breakthroughs**

Our data highlight that depression plays a significant role in the overall impact of gastroparesis on quality of life. The findings also emphasize the importance of pain as a symptom of gastroparesis, which is under-appreciated and under-treated.

### **Applications**

The results stress the need to shift treatment strategies for gastroparesis away from approaches that simply try to accelerate gastric emptying. In our clinical assessment, we need to assess the different symptoms including pain, and design a therapy that takes into account the primary problems the individual patients experience. Because affect, especially depression, significantly impairs quality of life, diagnostic approaches and treatment should address emotional factors. In future research, we will have to define better the interrelationship between altered gastric function and emotion to understand underlying mechanisms. Interactions will likely be reciprocal, which raises the question of how much psychologically or psychiatrically oriented treatment may be beneficial in patients with gastroparesis.

### **Terminology**

Gastroparesis is a chronic disorder that is characterized by symptoms of nausea, vomiting, fullness and bloating after meals, and a delay in gastric emptying, which is typically determined using standardized scintigraphic tests.

### **Peer review**

The article fits into the increasing evidence that structural and especially functional disorders of the gastrointestinal tract should be seen as biopsychosocial phenomena that require more holistic diagnostic and therapeutic approaches.

### Abstract

**AIM:** To analyze the impact of the *GNAS1* T393C polymorphism on prognosis and histopathology of gastric cancer.

**METHODS:** Genomic DNA was extracted from paraffin-embedded tissues of 122 patients with primary gastric carcinoma and from the blood of 820 healthy white

individuals. Allelic discrimination was performed by quantitative real-time polymerase chain reaction. Genotyping was correlated with histopathologic parameters and with overall survival according to the Kaplan-Meier approach and with multivariate analysis by multiple stepwise regression.

**RESULTS:** Thirty-nine (32%) patients displayed a CC genotype, 57 (46.7%) a CT genotype and 26 (21.3%) a TT genotype. The frequency of the C allele (fC) in the patient group was 0.55, which was not significantly different from that of healthy blood donors. The distribution was compatible with the Hardy-Weinberg equilibrium. Analysis of clinicopathological parameters did not show any significant correlation of the T393C genotype with gender ( $P = 0.50$ ), differentiation ( $P = 0.29$ ), pT-category ( $P = 0.19$ ), pN-category ( $P = 0.30$ ), pM-category ( $P = 0.25$ ), R-category ( $P = 0.95$ ), the classifications according to WHO ( $P = 0.34$ ), Lauren ( $P = 0.16$ ), Goseki ( $P = 1.00$ ) and Ming ( $P = 0.74$ ). Dichotomization between C+ (CC+CT) and C-genotypes (TT), however, revealed significantly more advanced tumor stages ( $P = 0.023$ ) and lower survival rates ( $P = 0.043$ ) for C allele carriers.

**CONCLUSION:** The present study provides strong evidence to suggest that the *GNAS1* T393C allele carrier status influences tumor progression and survival in gastric cancer with higher tumor stages and a worse outcome for C allele carriers.

## INTRODUCTION

Gastric cancer has substantially decreased in incidence over the past decades, but it still remains one of the most common cancers in the world and the second most frequent cause of cancer-related death after lung cancer<sup>[1]</sup>. Most patients are diagnosed with advanced gastric cancer, and overall survival remains poor<sup>[2,3]</sup>. The 5-year survival rate for gastric cancer is still only at 40%<sup>[4,5]</sup>.

Of particular interest are prognostic factors, as they give the basis to identify gastric cancer patients with high-risk and poor prognosis. The identification of patients with poor outcome can help to set up novel treatment strategies at the beginning of treatment and may lead to better and more individualized therapy strategies with better survival<sup>[2]</sup>. Current efforts in research are therefore focused on the detection and validation of biomarkers and genetic markers that give additional information about prognosis to classical prognostic factors such as the TNM classification. The majority of new detected markers are related to properties of the tumor itself, e.g. somatic mutations or differential expression of genes or proteins. However, difficulties in standardization of such markers often prevent their routine application in clinical practice<sup>[6]</sup>.

In recent years, studies have focused on the detection of single nucleotide polymorphisms (SNPs) that have a prognostic impact in cancer. One major advantage of SNPs as prognostic markers is that they can be determined independently from the availability and quality of tumor material as they can be easily evaluated from a blood sample from individual patients.

The T393C polymorphism of the gene *GNAS1* is one such polymorphism. This SNP is located in exon 5 of the gene *GNAS1*, which encodes the ubiquitously expressed G $\alpha$ s subunit of heterotrimeric G proteins. Previous studies indicate that increased expression of G $\alpha$ s enhances apoptosis<sup>[7,8]</sup> and that G $\alpha$ s mRNA expression is different between T393C genotypes<sup>[9]</sup>. For various solid tumors, previous studies demonstrated that patient survival and tumor progression depended on T393C genotype<sup>[10-17]</sup>.

Until now, nothing has been published about the impact of the *GNAS1* T393C polymorphism on gastric cancer. Thus, the aim of the present study was to determine the influence of this polymorphism on prognosis in gastric cancer. Furthermore, we looked for possible correlations between the *GNAS1* T393C polymorphism and clinicopathological parameters.

## MATERIALS AND METHODS

### Patients

Of 159 patients, who were treated surgically between May 1996 and January 2005 for primary gastric carcinoma at the Department of General, Visceral and Cancer Surgery of the University of Cologne, 13 (8.2%) patients with a second tumor, a previous operation of the upper digestive tract or missing paraffin-embedded tissue from normal cells, and 24 (15.1%) patients with neoadjuvant

treatment received before surgery were excluded. Excluded patients did not differ in age and gender from the remaining patients.

All of the included 122 patients [median age 67.6 years, range 33-87 years; 78 (63.9%) male, 44 (36.1%) female] were initially treated by operation with curative intention. Gastroscopic examination, endoscopic ultrasound and computed tomography (CT) of the chest and abdomen were performed before surgery on all patients for clinical staging.

One hundred and six (86.9%) of the 122 patients underwent a gastrectomy with D2-lymphadenectomy (compartment I and II) and in 16 (13.1%) cases, a subtotal gastrectomy with D2-lymphadenectomy was performed. The median number of resected lymph nodes was 36.0 (range 15-80).

The present study was performed according to the guidelines of the local Research Ethics Commission.

### Histopathology

The specimens were removed *en bloc* and the lymph nodes of the specimens were dissected with the cooperation of surgeons and pathologists according to a standardized protocol. The resected specimens were routinely fixed in 5% phosphate-buffered formalin and embedded in paraffin. Histopathologic examination of all resected specimens consisted of a thorough and standardized evaluation of the tumor stage, residual tumour (R) category, grading and the number of resected and infiltrated lymph nodes. The gastric lymph nodes were documented according to the classification of the Japanese Research Society of Gastric Cancer (JRS GC) with lymph node groups 1 to 13<sup>[18]</sup>. The tumor localization was defined according to the International Classification of Diseases for Oncology. The lesions were further classified and graded in accordance with WHO recommendations, the Laurén-classification and tumor differentiation. Postoperative staging was performed according to the 6th edition of the TNM-classification of malignant tumors<sup>[19]</sup>.

### Genotyping

DNA was extracted from paraffin-embedded tissues from resection boundaries containing exclusively normal cells using a DNA extraction kit (QIAamp, Qiagen, Hilden, Germany) according to the manufacturer's instructions. Genotyping was performed in 96-well plates by 5' nuclease assay (TaqMan) using the ABI PRISM 7900HT Sequence Detection System (Applied Biosystems, Darmstadt, Germany).

The pre-developed TaqMan assay ID C\_9901536\_10 (Applied Biosystems, Darmstadt, Germany) was used for genotyping of *GNAS1* T393C polymorphism (dbSNP rs7121). Polymerase chain reaction (PCR) reactions contained 10 ng DNA, 200  $\mu$ mol/L dNTPs and 900 nmol/L primers (Figure 1).

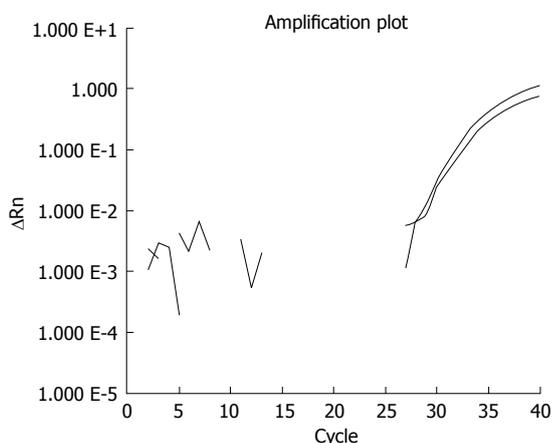

PCR conditions were: 95°C for 10 min followed by 40 cycles of 15 s at 92°C and 60 s at 60°C.

### Reference group

The Caucasian control sample consisted of 820 healthy

**Table 1** Allele frequencies and genotype distribution of *GNAS1* T393C polymorphism in 122 gastric cancer patients and in the reference group ( $n = 820$ )  $n$  (%)

T393C	Patients ( $n = 122$ )			Reference group ( $n = 820$ )			$\chi^2$	$P$	Odds ratio	95% CI
Allele	C 135 (55.3)		T 109 (44.7)	C 873 (53.2)		T 767 (46.7)	0.38	0.54	0.92	0.70-1.20
Genotype	CC 39 (32.0)	CT 57 (46.7)	TT 26 (21.3)	CC 235 (28.7)	CT 403 (49.1)	TT 182 (22.2)	0.37	0.54	0.92

white individuals who were recruited at the local Department for Transfusion Medicine, University Hospital, Essen. All samples were collected at random from subjects donating blood. The details of this sample have been published previously<sup>[12]</sup>.

### Statistical analysis

Associations between T393C genotype and clinicopathological parameters were evaluated using the  $\chi^2$  test. Pearson's  $\chi^2$  was used for Hardy-Weinberg analysis and to examine differences in allele frequencies between our patient group and the reference group. Relations to overall survival were evaluated with univariate analysis according to the Kaplan-Meier approach using the log-rank test to assess statistical differences between groups. Prognostic factors were determined by multiple stepwise regression analysis using the Cox model. Only potential prognostic factors were included in the multivariate analysis. The level of significance was set at  $P < 0.05$  and  $P$  values were for 2-sided testing. All statistical tests were performed using the Software Package SPSS for Windows, Version 17.0 (Chicago, IL, USA).

## RESULTS

### Genotype distribution and reference group

Thirty-nine (32.0%) patients displayed a CC genotype, 57 (46.7%) a CT genotype and 26 (21.3%) a TT genotype. The frequency of the C allele (fC) in the entire patient group was 0.55, which is not significantly different from that of healthy blood donors (Table 1). The distribution was compatible with the Hardy-Weinberg equilibrium.

### Clinicopathological characteristics

Clinicopathological characteristics of the whole patient

group with genotype distribution are displayed in Table 2. Thirty (24.6%) patients showed an early gastric carcinoma (pT1). In 73 (59.8%) cases, lymph node metastasis (pN+) was detected. An M1 category was found in 23 (18.9%) patients with localized peritoneal carcinosis, distant lymph node metastasis (M1 lymph) or single liver metastasis (M1 Hep). Patients with diffuse peritoneal or multiple liver metastasis had been treated non-surgically and were excluded from the study.

Analysis of clinicopathological parameters did not show any significant correlation of the T393C genotype with gender ( $P = 0.50$ ), differentiation ( $P = 0.29$ ), pT-category ( $P = 0.19$ ), pN-category ( $P = 0.30$ ), pM-category ( $P = 0.25$ ), R-category ( $P = 0.95$ ), or the classifications according to WHO ( $P = 0.34$ ), Laurén ( $P = 0.16$ ), Goseki ( $P = 1.0$ ), Ming ( $P = 0.74$ ) and UICC ( $P = 0.15$ ).

When genotypes were dichotomized in C+ (CC+CT) and C-genotypes (TT), a significantly higher rate of advanced tumor stages (stage III and IV), according to the UICC classification, was seen for C allele carriers ( $P = 0.023$ ). Only 6 (23.1%) of 26 patients with TT genotype were diagnosed with a tumor stage of III or IV. In contrast, an advanced tumor stage was detected in 50 (52.1%) of 96 C allele carriers.

### Univariate survival analysis

Overall survival dependent on T393C genotypes is displayed in Figure 2. The 5-year survival rate for patients with a TT genotype was 56.9% (SE  $\pm$  10.4%), followed by patients with CC genotype with a 5-year survival rate of 42.6% (SE  $\pm$  8.3%). Heterozygous CT patients showed a 5-year survival rate of 32.7% (SE  $\pm$  6.3%). Survival was not significantly associated with the T393C genotype when the three genotypes were compared ( $P = 0.082$ ). However, dichotomization between C+ (CC+CT) and TT demonstrated a significantly ( $P = 0.043$ ) lower survival rate for C allele carriers (Figure 3) with a 5-year survival rate for the C+ group of only 36.7% (SE  $\pm$  5.1%) *vs* 56.9% (SE  $\pm$  10.4%) for the TT group.

### Multivariate survival analysis

In the multivariate Cox regression analysis, known prognostic factors for gastric cancer (pT, pN, pM and R-category) and T393C genotype with dichotomization between C+ (CC+CT) and TT were included. pT-category ( $P < 0.001$ ), R-category ( $P = 0.022$ ) and pM-category ( $P = 0.027$ ) maintained their prognostic independence (Table 3). pN-category ( $P = 0.55$ ), and the T393C genotype ( $P = 0.33$ ) lost their prognostic independence.

## DISCUSSION

Gastric cancer is the fourth most common cancer with

Table 4 Summary of the effect of the *GNAS1* T393C polymorphism on various carcinomas

Cancer type	Yr	n	Effect	Benefit (survival)
Gastric cancer	2009	122	The present study demonstrates a significant survival benefit for the TT genotype with a 5-yr-survival rate of 56.9% vs the CC/CT group with a 5-yr-survival rate of only 36.7% ( $P = 0.043$ )	TT-genotype
Squamous cell cancer of larynx <sup>[15]</sup>	2008	157	Survival was significantly dependent on the T393C genotype in advanced American Joint Committee on Cancer (AJCC) stages (III-IV) with higher 5-yr survival rates for TT, followed by TC and CC ( $P = 0.0437$ )	TT-genotype
Oro- and hypopharyngeal squamous cell carcinoma <sup>[16]</sup>	2008	202	C homozygous patients displayed a higher risk for disease progression than T homozygous patients ( $P = 0.019$ ) and a higher risk for death ( $P = 0.015$ ). In multivariate analysis, besides cancer stage and tumor localization, the T393C polymorphism was an independent prognostic factor for disease progression and death	TT-genotype
Clear cell renal cell carcinoma <sup>[11]</sup>	2006	150	Tumor progression, development of metastasis and tumor-related death was significantly associated with the T393C polymorphism. In multivariate analysis CC patients were at highest risk for progression or tumor-related death compared with T-allele carriers ( $P = 0.018$ )	TT-genotype
Chronic lymphocytic leukemia <sup>[17]</sup>	2006	144	Median progression-free survival was significantly higher for T-allele carriers ( $P = 0.007$ ). In multivariate analysis, the T393C polymorphism kept its prognostic independence ( $P = 0.01$ ) besides of ZAP-70 ( $P = 0.005$ ) and Binet stage ( $P < 0.001$ ). Regarding overall survival, CC genotypes were significantly at highest risk for death compared to T-alleles both in univariate ( $P < 0.001$ ) and multivariate analysis ( $P = 0.002$ )	TT-genotype
Bladder cancer <sup>[10]</sup>	2005	254	Progression-free survival ( $P = 0.011$ ), metastasis-free survival ( $P = 0.001$ ) and cancer-specific survival ( $P = 0.014$ ) were significantly increased in TT genotypes compared with CC genotypes. In multivariate analysis, the T393C polymorphism kept its prognostic independence	TT-genotype
Sporadic colorectal cancer <sup>[12]</sup>	2005	151	In UICC stages I to II, the 5-yr survival rate was significantly ( $P = 0.009$ ) higher in TT genotypes (88%) compared with TC (71%) and CC genotypes (50%). In multivariate analysis, the T393C polymorphism was also an independent prognostic factor. No significant effect could be seen for UICC stages III to IV	TT-genotype
Cholangiocarcinoma <sup>[14]</sup>	2007	87	Disease-specific overall survival was significantly dependent on the T393C genotype ( $P = 0.02$ ), with TT genotypes showing reduced survival compared to patients carrying at least one C allele. In multivariate analysis (TT/C+) the T393C genotype kept its prognostic independence ( $P = 0.04$ )	CC-genotype
Breast carcinoma <sup>[13]</sup>	2007	279	Overall survival was significantly ( $P = 0.033$ ) associated with the T393C polymorphism with lowest survival rates for the TT-genotype and highest survival rate for the CC-genotype. In multivariate analysis, the TT-genotype still had a significant survival benefit compared to the CC genotype ( $P = 0.045$ )	CC-genotype
Esophageal cancer <sup>[28]</sup>	2009	51	T393C polymorphism was significantly associated with tumor response to Cisplatin/5-FU-based radiochemotherapy. 63% of the T allele carriers had a minor histopathologic response (MiHR) with more than 10% residual vital tumor cells in resection specimens. For the CC genotype MiHR was seen only in 20%. In binary logistic regression analysis, the T393C genotype kept its independence ( $P < 0.05$ )	CC-genotype

approximately 800000 new cases per year and the second leading cause of cancer-related death worldwide<sup>[20]</sup>. Many patients have advanced disease at the time of diagnosis, resulting in poor prognosis and high mortality<sup>[2,21,22]</sup>. Pre-treatment staging of the disease is of high importance as it provides the basis for selecting the most appropriate therapeutic strategy<sup>[23]</sup>. Based on the preoperative staging, patients with early stage tumors are treated by endoscopic mucosal resection, while patients with advanced tumors are treated by partial or total gastrectomy<sup>[5]</sup>. Accurate staging is also the basis for selecting patients for neoadjuvant, adjuvant or palliative treatment<sup>[24]</sup>. By identifying patients with poor outcome, novel treatment strategies could be set up at the beginning of treatment which can lead to better and more individualized therapy strategies with superior survival<sup>[2]</sup>.

The present study demonstrated that besides the known prognostic factors pT, pM, pN and R-category, the T393C polymorphism was also a significant prognostic factor in the univariate analysis with a survival benefit for homozygous TT patients. In addition, it demonstrated that compared to C allele carriers, homozygous TT patients were diagnosed with significantly less advanced tumor stages according to UICC, which is possibly the main reason why the T393C genotype lost its independence in the multivariate analysis.

The gene *GNAS1* is mapped to chromosome 20q13 and consists of 13 exons. Somatic activating mutations of *GNAS1* have been implicated in the etiology of McCune Albright Syndrome<sup>[25]</sup> and sporadic, isolated endocrine tumors<sup>[26,27]</sup> which supports a role of *GNAS1* in tumor initiation and progression.

Recent studies have shown that genotypes of the T393C polymorphism are significantly associated with survival of patients suffering from colorectal cancer, bladder cancer, clear cell renal carcinoma, intrahepatic cholangiocarcinoma, invasive breast carcinoma and squamous cell carcinoma of the larynx, oropharynx and hypopharynx (Table 4)<sup>[10-14]</sup>.

Comparable to previous results in bladder cancer, clear cell renal carcinoma and colorectal cancer, the present study also demonstrated significantly higher survival rates for TT genotypes in gastric cancer (Figure 3). Patients with the TT genotype showed a 5-year survival rate of 57%, whereas the 5-year survival rate for C allele carriers was only at 37%.

In contrast to our findings in gastric cancer and previous findings in the above-mentioned tumor types, an unfavourable clinical course for T allele carriers has been described in studies of invasive breast cancer and intrahepatic cholangiocarcinoma, suggesting that the biological effect of the T393C polymorphism may be different in different tumor types. In a recent study, we demonstrated that this polymorphism is a predictive molecular marker for tumor response to cisplatin/5-FU-based radiochemotherapy in esophageal cancer, with CC genotypes mostly showing a major response<sup>[28]</sup>.

*In vitro* experiments suggest that expression of G $\alpha$ s is associated with enhanced apoptosis<sup>[7,8]</sup>. The second messenger, cyclic AMP, which is generated by activated G $\alpha$ s,

seems to play a major role in this proapoptotic process. An increased concentration of the intracellular second messenger, cyclic AMP promotes apoptosis in several cell types including leukemic cells<sup>[29]</sup>, ovarian cancer cells<sup>[30]</sup>, and lymphoma cells<sup>[25]</sup>. Increased G $\alpha$ s expression in tissues of patients with TT genotypes may therefore confer enhanced apoptosis in 393T allele carriers. Hypothetically, this mechanism may contribute to the described more favorable clinical course and the less advanced tumor stages of homozygous TT patients. This hypothesis remains to be supported by additional functional studies which were beyond the scope of the present study. The T393C polymorphism as a risk factor for gastric cancer could not be established in the present study.

In conclusion, this study demonstrated for the first time that in primary gastric cancer, homozygous *GNAS1* 393T patients have less advanced tumor stages and higher survival rates than C allele carriers. These findings further support the concept of a general role for the *GNAS1* T393C polymorphism in tumor progression.

## COMMENTS

### Background

Identification of gastric cancer patients with poor outcome can help to set up novel treatment strategies at the beginning of treatment and may lead to better and more individualized therapy strategies with better survival. In recent years, studies have focused on the detection of single nucleotide polymorphisms (SNPs) as prognostic molecular markers in cancer.

### Research frontiers

The *GNAS1* T393C polymorphism is located in exon 5 of the gene *GNAS1*. In this study the authors describe, for the first time, the impact of this SNP in gastric cancer. The study demonstrates that the *GNAS1* T393C polymorphism affects tumor stage and prognosis in gastric cancer.

### Innovations and breakthroughs

For various solid tumors, previous studies have demonstrated that patient survival and tumor progression depend on the *GNAS1* T393C genotype. In the present study, the authors have described for the first time that the *GNAS1* T393C polymorphism affects tumor stage and prognosis in gastric cancer.

### Applications

The *GNAS1* T393C polymorphism will contribute to identifying high-risk patients with gastric cancer and might help to establish a more individualized treatment strategy for gastric cancer.

### Terminology

A single-nucleotide polymorphism (SNP) is a DNA sequence variation occurring when a single nucleotide - A, T, C, or G - in the genome differs between members of a species. The *GNAS1* T393C is located in exon 5 of the gene *GNAS1*. For several cancer types, studies have demonstrated that patient survival is affected by this SNP.

### Peer review

Overall, this paper provides information on *GNAS1* T393C allele carrier status which influences tumor progression and survival in gastric cancer, with higher tumor stages and worse outcome for C allele carriers.

tients with IBS. The most significant upregulation was seen for pro-inflammatory lysophosphatidylcholines. Other lipid groups that were significantly upregulated in IBS patients were lipotoxic ceramides, glycosphingolipids, and di- and triacylglycerols. Among the metabolites, the cyclic ester 2(3H)-furanone was almost 14-fold upregulated in IBS patients compared to healthy subjects ( $P = 0.03$ ).

**CONCLUSION:** IBS mucosa is characterised by a distinct pro-inflammatory and lipotoxic metabolic profile. Especially, there was an increase in several lipid species such as lysophospholipids and ceramides.

### Abstract

**AIM:** To investigate the pathophysiology of irritable bowel syndrome (IBS) by comparing the global mucosal metabolic profiles of IBS patients with those of healthy controls.

**METHODS:** Fifteen IBS patients fulfilling the Rome II criteria, and nine healthy volunteers were included in the study. A combined lipidomics (UPLC/MS) and metabolomics (GC × GC-TOF) approach was used to achieve global metabolic profiles of mucosal biopsies from the ascending colon.

**RESULTS:** Overall, lipid levels were elevated in pa-

### INTRODUCTION

Irritable bowel syndrome (IBS) is a functional bowel disorder characterised by abdominal pain or discomfort and an irregular bowel habit<sup>[1]</sup>. The prevalence is up to 20% in Western adults, which makes IBS the most common diagnosis in gastroenterology. The precise aetiology and pathophysiology of IBS are incompletely understood, despite extensive interest and investigation. The current knowledge does, however, suggest that altered gut motility, visceral hyperalgesia, and dysregulation of the brain-gut axis are central to IBS.

IBS is diagnosed by the presence of symptoms according to the Rome criteria<sup>[2]</sup>, with concomitant exclusion of organic diseases; hence, there is no specific biological,

radiological, endoscopic, or physiological marker for IBS. Medical treatment options for IBS are limited, possibly due to the lack of biomarkers and data about the pathophysiology of the condition. Different immune markers are among the most studied putative biomarkers in IBS. Increased mast cell counts, mast cells in close proximity to nerves, and mast cell mediators that are able to stimulate murine visceral sensory nerves appear to be characteristic of IBS<sup>[5-6]</sup>. Elevated plasma levels of pro-inflammatory interleukin (IL)-6 and IL-8 have been observed in IBS<sup>[7]</sup>, and peripheral blood mononuclear cells obtained from IBS patients produce higher amounts of tumour necrosis factor (TNF)- $\alpha$ , IL-1 $\beta$ , IL-6 and IL-12 than cells from healthy controls<sup>[8,9]</sup>. Furthermore, an increased number of immunocytes have frequently been observed in mucosa from IBS patients<sup>[10,11]</sup>. In addition to immune markers, other markers, such as 5-hydroxytryptamine (5-HT, serotonin) and gut hormones, have also been associated with IBS. Decreased expression of 5-HT has been associated with constipation-predominant IBS<sup>[12]</sup>. Elevated plasma 5-HT concentrations have been observed in a mixed IBS population<sup>[13]</sup> and in post-infectious IBS<sup>[14]</sup>, while the opposite was demonstrated in constipation IBS<sup>[14]</sup>. Moreover, IBS patients have also been demonstrated to have decreased 5-HT levels and turnover, and lower 5-HT transporter mRNA concentrations<sup>[14,15]</sup>.

The recent technological development of analytical instruments combined with rapid progress in bioinformatics has opened novel opportunities to quickly and simultaneously measure and model huge numbers of molecular metabolites in biological samples<sup>[16,17]</sup>. This metabolomic approach is considered a powerful tool for characterising complex phenotypes and developing biological markers for specific physiological states. Thus, metabolomics provides an interesting platform to investigate the pathophysiology of a complex syndrome like IBS at the molecular level. Studies on the molecular abnormalities in IBS are needed to understand the mechanisms behind the emergence of symptoms, and to enable the development of novel therapies.

The aim of the current study was to compare the global metabolic profiles of mucosal biopsies from IBS patients with those from healthy subjects using a high-throughput approach comprising lipidomics and metabolomics.

## MATERIALS AND METHODS

### Subjects

Sixteen adult IBS patients fulfilling the Rome II criteria<sup>[18]</sup> and without organic intestinal diseases were recruited to participate in the study. One statistical outlier IBS patient was left out of the analyses after an initial quality check of the results, and thus a total of 15 patients were analysed (Table 1). Nine healthy subjects (mean age 49 years, SD 14; 4 male) without organic intestinal diseases or gastrointestinal symptoms consistent with IBS and undergoing colonoscopy for clinical reasons were recruited as controls. The healthy subjects were either polyp control patients having a minimum of 3 years since the previous

polyp finding or anaemic patients. Inclusion criteria for all subjects were: an age between 20 and 65 years; normal blood count (erythrocytes, haemoglobin, haematocrit, MCV, MCH, MCHC, platelets, leukocytes); serum creatinine, alanine aminotransferase (ALT) and alkaline phosphatase (ALP) within reference values; and normal gut histology as evaluated by an experienced pathologist (PS). Subjects were excluded if they had a history of major or complicated gastrointestinal surgery, severe endometriosis, complicated abdominal adhesions, malignant tumours, were pregnant or lactating, or had received antimicrobials during the previous month. Patients with lactose intolerance were allowed to participate if they followed a continuous low-lactose or lactose-free diet.

The Human Ethics Committee of the Hospital District of Pirkanmaa, Finland, approved the study protocol. All subjects provided written informed consent.

### Sample collection and preparation

Mucosal biopsies (mean weight 5.2 mg/sample; SD 1.5) from the ascending colon were obtained from each subject during colonoscopy after bowel cleansing. The samples were immediately frozen at -20°C, and stored at -70°C until required for analysis. The samples for lipidomic analysis were weighed into Eppendorf tubes, and 10  $\mu$ L of 0.9% sodium chloride and 10  $\mu$ L of an internal standard mixture (10 lipid compounds, 0.1  $\mu$ g each) were added. The samples were extracted with 100  $\mu$ L of chloroform:methanol (2:1; two min vortexing, one h extraction time) and centrifuged (7800 *g*, 3 min). Of the lower organic phase, 60  $\mu$ L aliquots were transferred into vial inserts and 10  $\mu$ L of a standard mixture containing three labelled lipid compounds was added. The internal standard mixture contained the following lipid compounds with heptadecanoic acid (C17:0) as the esterified fatty acid: D-erythro-Sphingosine-1-Phosphate (C17 Base, Avanti Polar Lipids, Alabaster, AL, USA), LysoPC (Avanti Polar Lipids), MG (17:0)[rac] (Larodan Fine Chemicals, Malmö, Sweden), PG (17:0/17:0)[rac] (Avanti Polar Lipids), Cer (d18:1/17:0) (Avanti Polar Lipids), PS (17:0/17:0) (Avanti Polar Lipids), PC (17:0/17:0) (Avanti Polar Lipids), PA (17:0/17:0) (Avanti Polar Lipids), PE (17:0/17:0) (Avanti Polar Lipids), DG (17:0/17:0)[rac] (Larodan Fine Chemicals), and TG (17:0/17:0/17:0) (Larodan Fine Chemicals). The labeled standard mixture consisted of LysoPC (16:0-D3) (Larodan Fine Chemicals), PC (16:0/16:0-D6) (Larodan Fine Chemicals), and TG (16:0/16:0/16:0-13C3) (Larodan Fine Chemicals).

For water-soluble compounds, the samples were weighed into Eppendorf tubes and 10°C of 1000 ppm (mg/mL) labelled palmitic acid (16:0-16, 16, 16D3) was added as an internal standard. The samples were extracted with 500 µL methanol (two min vortexing, 0.5 h extraction time) and centrifuged (7800 g, 3 min). The separated supernatants were evaporated to dryness under nitrogen, and the residues were derivatised with 2% methoxyamine HCl in pyridine (MOX; 25 µL, 90 min at 30°C) and N-Methyl-N-trimethylsilyltrifluoroacetamide (MSTFA; 50 µL, 30 min at 37°C). All samples were run in duplicate.

### **Analysis of lipids by UPLC/MS**

Characterisation of lipid molecular species in colonic mucosa was performed by a lipidomics strategy using ultra performance liquid chromatography coupled to mass spectrometry (UPLC/MS, Waters Micromass Q-ToF Premier). The column (50°C) was a Waters Acquity UPLC™ BEH C18 (Waters Inc., Milford, MA, USA) 1 mm × 50 mm with 1.7 µm particles. The solvent system included: (A) ultra pure water (1% 1 mol/L NH<sub>4</sub>Ac, 0.1% HCOOH) and (B) LC/MS grade acetonitrile:isopropanol (5:2, 1% 1 mol/L NH<sub>4</sub>Ac, 0.1% HCOOH). The gradient started from 65% A and 35% B, reached 100% B in 6 min and remained there for the next 7 min. There was a 5 min re-equilibration step before the next run. The flow rate was 0.200 mL/min and the injected amount 1.0 µL. Lipid profiling was carried out using ESI+ mode, and the data were collected at a mass range of m/z 300-2000 with a scan duration of 0.08 s.

Lipids were identified using an internal spectral library or with tandem mass spectrometry. The normalisation of lipidomics data was performed as follows: all monoacyl lipids, except cholesterol esters (such as monoacylglycerols and monoacylglycerophospholipids), were calibrated with lysophosphatidylcholine lysoPC (17:0) internal standard; all diacyl lipids, except ethanolamine phospholipids, were normalised with phosphatidylcholine PC (17:0); the diacyl ethanolamine phospholipids were calibrated with phosphatidylethanolamine PE (17:0); and the triacylglycerols and cholesterol esters were calibrated with triacylglycerol TG (17:0). Other molecular species were normalised by lysoPC (17:0) for retention time < 310 s, PC (17:0) for retention time between 310 and 450 s, and TG (17:0) for higher retention times. Data was processed using the MZmine software, version 0.60<sup>[19]</sup>, and metabolites were identified using an internal spectral library or with tandem mass spectrometry (UPLC/MS/MS).

### **Analysis of water-soluble metabolites by GC × GC-TOF**

A broad screening of water-soluble metabolites was conducted by a comprehensive two-dimensional gas chromatography coupled to a high speed time-of-flight mass spectrometry (GC × GC-TOF)<sup>[20]</sup>. The instrument used was a Leco Pegasus 4D GC × GC-TOF with Agilent 6890N GC from Agilent Technologies, USA and CombiPAL autosampler from CTC Analytics AG, Switzerland. Modulator, secondary oven, and time-of flight mass spectrometer were from Leco Inc., USA. The GC

was operated in split mode (1:20) using helium as carrier gas at 1.5 mL/min constant flow. The first GC column was a relatively non-polar RTX-5 column, 10 m × 0.18 mm × 0.20 µm, and the second was a polar BPX-50, 1.10 m × 0.10 mm × 0.10 µm. The temperature programme was as follows: initial 50°C, 1 min → 280°C, 7°C/min, one min. The secondary oven was set to +30°C above the primary oven temperature. The second dimension separation time was set to 3 s. The mass range used was 40 to 600 amu and the data collection speed was 100 spectra/s. A commercial mass spectral library, Palisade Complete 600K, was used for identifying metabolites.

### **Statistical analysis**

Partial least squares discriminant analysis (PLS/DA) was utilized as a supervised modelling method using the SIMPLS algorithm to calculate the model. The contiguous-blocks cross-validation method and  $Q^2$  scores were used to develop the models. Top loadings for latent variables associated with drug-specific effects were reported. The VIP (variable importance in the projection) values were calculated to identify the most important molecular species for clustering of specific groups. Multivariate analyses were performed using Matlab, version 7.2 (Mathworks Inc., Natick, MA, USA), and the PLS Toolbox, version 4.0, for the Matlab package (Eigenvector Research Inc., Wenatchee, WA, USA). One statistical outlier IBS patient was left out of the analyses after an initial quality check of the results. Univariate comparisons for individual metabolites between the groups were performed using the Wilcoxon rank-sum test. A *P* value < 0.05 was considered statistically significant. To account for multiple comparisons, the False Discovery Rate (FDR)  $Q$ -value is also reported<sup>[21]</sup>.

## **RESULTS**

### **Lipidomic analysis**

By applying UPLC/MS, a total of 651 lipid peaks were found, and 75 of them were identified using the internal spectral library, as described by Yetukuri *et al.*<sup>[22]</sup>, or with tandem mass spectrometry using UPLC/MS/MS. PLS/DA analysis of lipidomic data revealed significant differences in the mucosal lipid profiles of IBS patients and healthy controls. Overall, lipid species were upregulated in biopsies from IBS patients compared to those from healthy subjects. The 20 lipids with the largest differences between the groups by fold change appear in Table 2. A significant upregulation in the concentrations of typical cell membrane metabolites, lysophospholipids, in IBS patients was the most obvious finding (Figure 1A). Other lipid groups with a significant contribution to the distinction between IBS patients and healthy controls were ceramides (Figure 1B), glycosphingolipids, and di- and triacylglycerols. All of these showed upregulation in the IBS group.

### **Metabolomic analysis**

Broad metabolite screening by GC × GC-TOF resulted in several hundred mucosal metabolites, of which 107 were

identified and kept in analyses. Based on PLS/DA analysis, a clear distinction between IBS cases and controls was obtained (Figure 2). Both upregulation and downregulation of metabolites were observed in IBS patients *vs* controls. The top ranked metabolites contributing to the distinction between the groups appear in Table 3.

The metabolite contributing most to the distinction was 2(3H)-furanone, a cyclic ester commonly produced in biochemical pathways, which was almost 14-fold upregulated in IBS patients compared to healthy subjects ( $P = 0.03$ ). The fold changes for other top ranked metabolites were clearly lower (a 3.7 to -2.7 fold change). Other basic metabolites frequently found in biochemical pathways, such as the second messenger, D-ribose, were also among the major factors contributing to the distinction between cases and controls. Organic, carboxylic acids were found to be both slightly downregulated (dodecanoic, azelaic,

and adipic acid) as well as slightly upregulated (decanoic acid) in IBS patients compared to healthy controls.

## DISCUSSION

Data on the molecular abnormalities in IBS are urgently

required, as the pathophysiology of the condition is largely unknown and current therapies are therefore also limited. In this study, the differences between colonic mucosa from IBS patients and healthy controls were investigated by employing two high-throughput metabolomic platforms, UPLC/MS based lipidomics and GC × GC-TOF based metabolomics. Data indicated multiple differences between IBS mucosa and healthy mucosa, including an increase in the IBS group of several lipid species, such as lysophospholipids and ceramides.

The present study is the first to utilise a metabolomic approach to investigate molecular differences between IBS patients and healthy controls. Metabolomics can be seen as an optimal tool for studying diseases with unknown or complex pathophysiology, as a global study of the metabolome is a non-targeted approach that requires no preselection of markers, in contrast to the traditional way of limiting the analysis to a predefined set of known compounds<sup>[23]</sup>. Recently, metabolomics has been utilised in the investigation of multiple diseases, e.g. inflammatory bowel disease<sup>[24]</sup>, obesity<sup>[25]</sup>, and cancer<sup>[26]</sup>.

In the present study, lipids - particularly lysophosphatidylcholines (lysoPCs) and ceramides - were the most upregulated molecules in IBS patients. Mounting data suggest that certain lipids, including phospholipid derivatives and ceramides, play a role in modulating and enhancing pain sensitivity<sup>[27,28]</sup>, which could be one explanation for their involvement in IBS pathophysiology. LysoPCs have not previously been associated with IBS, but studies indicate elevated levels of lysoPCs or phospholipase A2, an enzyme involved in lysoPC formation, in inflammatory bowel disease (IBD)<sup>[29,30]</sup>. A high lysoPC concentration has been suggested to impair mucosal barrier function and increase gastrointestinal permeability *in vivo* and *in vitro*<sup>[31-34]</sup>. The role of permeability defects in IBS is not fully elucidated, but a recent review by Camilleri and Gorman concludes that there appears to be at least one IBS subgroup with increased gut permeability<sup>[35]</sup>. Interestingly, lysoPCs have also been associated with vascular inflammation, endothelial dysfunction, and coronary atherosclerosis<sup>[36]</sup>, implying that lysoPCs might also play a role in the subtle type of mucosal inflammation present in IBS.

Lipids of the ceramide/sphingomyelin pathway are another lipid type that we observed to be altered in IBS. Previous studies indicate that ceramides might be involved in the pathology of IBD<sup>[37,38]</sup>, whereas no reports on ceramides in IBS are available. Ceramides have, however, been shown to be toxic in several cell types. Current data reveal a possible role for ceramides in the damage of cells and tissues, and ultimately in the development of chronic metabolic diseases, such as diabetes and cardiovascular disease<sup>[39]</sup>. The toxic effects of ceramides might be partly mediated *via* the production of reactive oxygen species in cells<sup>[40]</sup>. It has been proposed that, similar to lysophosphatidylcholines, epithelial oxidative stress might also contribute to gut barrier dysfunction<sup>[41]</sup>. Our results thus suggest that the molecular mechanism behind increased permeability could, to some extent, be similar in IBS and IBD.

Based on a global analysis of water-soluble metabolites, IBS cases and healthy controls were rather well separated into two distinct groups. The physiological relevance of the main molecules contributing to the separation is, on the other hand, less evident than in the case of lipid species. Differences were seen in basic metabolites, such as 2(3H)-furanone (also known as lactone) and D-ribose, both of which are produced in common biochemical pathways in cells. A recent study investigating a *Trichinella spiralis* infected mouse model of post-infectious IBS and utilizing metabolomics, demonstrated an increase in molecules involved in energy metabolism (lactate, citrate, and alanine) in the IBS group<sup>[42]</sup>. The authors suggest that this might reflect a muscular hypercontractility possibly present in IBS, though it should be underlined that this was an experimental model. Concerning organic acids, our results are in line with the study by Martin *et al*<sup>[42]</sup>, in that we found that organic acids contributed to the separation between cases and controls. Specifically, we did observe increased concentrations of alanine in the IBS group, but the difference between IBS and control groups was not significant (fold = 1.3,  $P = 0.14$ ). Organic acids are known to be produced by the intestinal microbiota, and a disruption in the acid profile could reflect a possible deviance in microbiota previously reported in IBS<sup>[43,44]</sup>. In further support of findings by Martin *et al*<sup>[42]</sup>, we detected elevated levels of creatinine in the IBS group. Creatine and creatinine are tightly interlinked with the energy metabolism in smooth muscle, and a raised creatinine concentration might be a sign of increased energy consumption and muscle contractility<sup>[45]</sup>.

The field of metabolomics is evolving rapidly, and it is already considered a sensitive analytical tool for investigating the health-disease continuum<sup>[17]</sup>. Like any method, however, it has its own limitations. As large numbers of metabolites are included in the studies, caution is necessary in the interpretation of results<sup>[16]</sup>. The relevance of a single identified biomarker might not be high, but it could be that systematic up- or down-regulation in specific groups of molecules (such as certain lipids in the current study) indicates a biologically relevant metabolite type. Another drawback of metabolomics is that a large proportion of spectral peaks are still unknown, and consequently more effort has to be placed on the compilation of standardised metabolite libraries<sup>[16,23]</sup>. Considering the current study setting, one obvious weakness is the small number of subjects. On the other hand, it is highly encouraging to see that IBS patients and healthy controls were fairly well differentiated, even with this limited sample size. Moreover, it would have been interesting to investigate whether differences between IBS and healthy subjects could also be observed in metabolic profiles from non-invasive tissues, such as faecal material or blood, as these are more easily obtained in clinical settings.

Taken together, our results suggest significant differences in the global mucosal metabolic profile between IBS patients and healthy controls. The current study is the first to attempt to identify colonic mucosal metabolites typical for IBS using a high-throughput

metabolomic approach. In this study, IBS was particularly characterised by an upregulation of specific lipid groups, such as lysophosphatidylcholines and ceramides. These lipid species have been associated with the modulation of pain sensitivity and gut permeability, and our data thus indicate that these molecules might be involved in the pathophysiology of visceral pain and gut barrier dysfunction associated with IBS.

## ACKNOWLEDGMENTS

The authors would like to express their deepest gratitude to Aino Oksanen, MD, PhD, Kristiina Söderlund, MD, Lea Veijola, MD, PhD and Ms. Anne-Maria Riihimäki for their invaluable help during the conduct of the study.

## COMMENTS

### Background

Irritable bowel syndrome (IBS) is the most common diagnosis in gastroenterology. The syndrome is classified as functional, and no biological marker exists for IBS. The precise aetiology and pathophysiology is not fully known, and this might partly explain why pharmacotherapy is considered rather ineffective.

### Research frontiers

More data on the molecular abnormalities in IBS are required to better understand the mechanism behind the emergence of symptoms, and to be able to treat the patients in a safe and efficient way.

### Innovations and breakthroughs

This study characterises the differences between colonic mucosa from IBS patients and healthy controls using two high-throughput metabolomic platforms, UPLC/MS based lipidomics and GC × GC-TOF based metabolomics. Metabolomics is a useful tool for investigating diseases with complex or unknown backgrounds, because it is possible to simultaneously measure and model a huge number of metabolites. Data indicated multiple differences between IBS mucosa and healthy mucosa, thus providing novel information about the pathophysiology of IBS. An increase in the IBS group of several lipid species, such as lysophospholipids and ceramides, was the major difference observed.

### Applications

By better understanding the mucosal abnormalities behind IBS, it might be possible to improve the diagnosis and therapy of patients.

### Peer review

This article is surely innovative, not only in the hypothesis, but also in the methodology. This could be a hot article if could be popularized appropriately. A review of the current literature indicates that the present article is a pioneer in its field.

### Abstract

**AIM:** To detect the prevalence of small bowel polyps by wireless capsule endoscopy (WCE) in patients with familial adenomatous polyposis (FAP).

**METHODS:** We examined prospectively 14 patients with FAP to assess the location, size and number of small-intestinal polyps. Patients' age, sex, years of observation after surgery, type of surgery, duodenal polyps and colorectal cancer at surgery were analyzed.

**RESULTS:** During WCE, polyps were detected in 9/14 (64.3%) patients. Duodenal adenomatous polyps were found in nine (64.3%) patients, and jejunal and ileal polyps in seven (50%) and eight (57.1%), respectively. The Spigelman stage of duodenal polyposis was associated with the presence of jejunal and ileal polyps. Identification of the ampulla of Vater was not achieved with WCE. Importantly, the findings of WCE had no immediate impact on the further clinical management of FAP patients. No procedure-related complications were observed in the patients.

**CONCLUSION:** WCE is a promising noninvasive new method for the detection of small-intestinal polyps. Further investigation is required to determine which phenotype of FAP is needed for surveillance with WCE.

### INTRODUCTION

Familial adenomatous polyposis (FAP) is a dominant inherited syndrome with an incidence of 1 in 11 000. It is caused by an alteration of the FAP (APC) gene that is located on chromosome 5q21, which causes multiple disorders of the development of the ecto-, endo- and mesoderm. The syndrome is characterized by the presence of adenomatous polyps in the gastrointestinal tract, mainly in the colon, rectum and duodenum, with a demonstrated adenoma-carcinoma sequence<sup>[1-3]</sup>. The duodenum is characterized by the presence of adenomas in 80% of patients with FAP and the development of periampullary cancer in 4%<sup>[4,5]</sup>. In patients who have undergone colectomy, periampullary cancer is the main cause of death. Between five and 10% of FAP patients die from upper gastrointestinal cancer, which is frequently periampullary in origin. In an attempt to prevent malignancy, a screening program appears to be mandatory to detect particularly those patients most at risk of developing the disease. Therefore, endoscopic surveillance of the second part of the duodenum with side-viewing endoscopy is advised. Since it was introduced in 2000, wireless capsule endoscopy (WCE) has opened the way for the noninvasive and painless test of the entire small intestine, thereby becoming the gold standard for endoscopic evaluation of the small bowel

in several clinical situations, including surveillance of polyposis syndromes. There have been only a few studies that have evaluated the utility of WCE in detecting small-intestinal polyps in patients with FAP<sup>[6-12]</sup>.

The aim of our prospective study was to investigate the diagnostic yield of WCE in being able to detect adenomatous polyps in a Greek FAP cohort, and to establish potential risk factors for small-bowel polyp development for a more targeted surveillance with WCE.

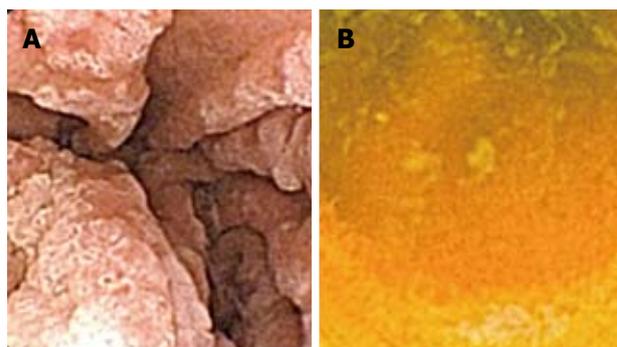

## MATERIALS AND METHODS

We performed an open prospective, non-randomized clinical trial from September 2007 to September 2008, which evaluated the use of WCE in FAP patients. The study was conducted in accordance with good clinical practice, as set forth by the Helsinki agreements and their later amendments. The study was approved by our hospital Ethics Committee and informed consent was obtained from all patients.

We included male and female patients, aged 18-70 years, who were referred to our clinic. Patients excluded were those with severe swallowing disorders, implanted cardiac pacemaker or other electronic devices, pregnant women, patients with a clinical suspicion of small-bowel obstruction/pseudo-obstruction, strictures or fistulas, and children under 10 years old<sup>[13,14]</sup>.

The following information was gathered from patients' records: age, sex, diagnostic [endoscopy, small-bowel radiography, computed tomography (CT)] and surgical procedures (type of colectomy and time of surgery) before WCE. All the procedures were performed on an outpatient basis, in the morning, after an overnight fast. Bowel preparation was performed with 4 L polyethylene glycol solution given 15 h before the procedure. Patients were allowed to drink clear fluids 2 h after capsule ingestion. Furthermore, the patients were able to maintain their normal activities while the capsule was passing through the digestive tract. Patients returned to the hospital 8 h after capsule ingestion. The registration device and the antennae were disconnected from the patient and a questionnaire about symptom occurrence and overall satisfaction with the procedure was completed. On each of the 2 d following the procedure, a telephone call was made to inquire about any symptoms and to confirm that the capsule had been expelled. In view that the major risk from WCE is capsule retention or impaction, all patients were instructed to contact the study staff should they develop any gastrointestinal symptoms during or after WCE.

Capsule videorecordings were reviewed by a single experienced endoscopist (Katsinelos P) who previously had performed more than 200 WCE procedures. A polyp was defined as a discrete mass of tissue that protruded into the bowel lumen. The location of small-bowel polyps was approximately estimated as duodenal (Figure 1A), jejunal, or ileal (Figure 1B), according to the timing of polyp appearance after entrance of the capsule to the duodenum, the total small-bowel passage time, and the endoscopic appearance of the small-

**Figure 1** Wireless capsule endoscopy (WCE) view. A: Large and small mushroom-shaped adenomas in the distal duodenum; B: Small ileal polyp.

intestinal mucosa. Entrance to the duodenum is easy to detect because it begins just after the pylorus, which can be identified easily. The location of small-bowel polyps was estimated by analyzing the WCE transit time between pylorus passage and ileocecal valve or pouch ileostoma. The duodenum was designated to be the small bowel that was visualized during the first 15 min after the capsule exited the pylorus, while the jejunum and ileum were designated to be the small bowel that was visualized after < 50% and > 50% of small-bowel transit time, respectively. Moreover, the prominent folds and high narrow villi characterized the jejunum, while fewer folds and shorter villi were observed in the ileum. WCE allows only an approximate estimation of the size of polyps, therefore, based on previous experience<sup>[11]</sup>, we classified polyps as small or large, using an open pylorus orifice (diameter 10 mm) as a reference for polyp size estimation. Small and large polyps were classified with a diameter < 10 mm and > 10 mm, respectively.

Following WCE, conventional endoscopy was performed within 2 wk in all patients. Standard duodenoscopy up to the second part of the duodenum was performed with a forward-looking gastroscope and a side-viewing duodenoscope, on an outpatient basis. To reduce motility artifacts, 20 mg butylscopolamine were administered intravenously. Biopsies and polypectomies were performed for staging of duodenal disease according to the Spigelman classification (Table 1)<sup>[15]</sup>.

The primary end point of the study was to identify the number and size of small-bowel polyps in each patient, and the secondary end point was the impact of WCE findings on the management of the patients.

## RESULTS

Fourteen patients (9 men, median age 34 years, range: 22-56 years) with FAP were recruited. Eight patients had undergone total proctocolectomy with ileal-pouch-anal anastomosis, four had undergone ileorectal anastomosis, and two were examined before colectomy (Table 2).

Endoscopic investigation of the entire length of the small bowel was achieved in all patients. The quality was considered as good except for one case in which food debris in the duodenum, jejunum and ileum made reading the film very difficult; in the last case, the procedure

**Table 1** Spigelman classification of duodenal polyposis (adenomas in FAP)<sup>[15]</sup>

	Number of points		
	1P	2P	3P
Number of polyps	1-4	5-20	> 20

FAP: Familial adenomatous polyposis; WCE: Wireless capsule endoscopy; IPAA: Ileal pouch-anal anastomosis; IRA: Ileorectal anastomosis; BS: Before surgery.

was repeated and the patient was asked to avoid food intake prior to the examination. Mean gastric and small-bowel transit time were 36 (range: 12-58) and 256 (range: 128-360) min, respectively. No abnormal additional findings were identified. Overall, 81 polyps, mainly small (96.3%), were detected by WCE. The presence, size and location of duodenal, jejunal and ileal polyps were related to the Spigelman stage of duodenal polyposis and age of the patient, but not sex (Table 3). None of the five young FAP subjects with Spigelman stage 0 had small-bowel polyps detected. Three large sessile polyps were found in the duodenum in one patient with Spigelman stage IV disease. All other polyps detected were small (Table 3). WCE was inferior diagnostically to standard duodenoscopy and gastroscopy regarding the second part of the duodenum and especially the ampullary region. The capsule technique could not identify the papilla of Vater in any of our patients and four small ampullary adenomas were missed by WCE as compared with duodenoscopy. Endoscopic polypectomy of duodenal adenomas was performed in five patients, and biopsies were taken from the rest of the patients. Histological

examination of the specimens confirmed the diagnosis of tubular or tubulovillous adenomas with low-grade dysplasia in one case with large polyps. We detected small ileal white-colored polyps with a normally appearing mucosal surface in two young patients (both Spigelman stage 0), and we classified these lesions as lymphoid hyperplasia, which occurs commonly in the terminal ileum and rectum associated with FAP, especially in young patients<sup>[16]</sup>.

All the patients described the procedure as comfortable and were willing to repeat it had it been deemed necessary. Difficulty/inability to swallow the capsule or clinically significant complications, including symptomatic capsule retention and aspiration, did not occur during the procedure. Five patients previously had undergone enteroclysis, and although a comparison of the two methods was not within the scope of this study, as there was a significant time lapse between them, all the patients preferred WCE when they were asked to compare it with enteroclysis. All patients reported no pain or discomfort when contacted 1 wk after the WCE examination.

## DISCUSSION

Small-intestinal adenomas can occur in FAP patients, but their prevalence varies, depending of the modality used for their detection<sup>[17]</sup>. The advent of WCE in 2000 has changed noticeably the diagnosis and management of numerous diseases of the small intestine, including polyps associated with FAP<sup>[14]</sup>. Our study shows that WCE is able to detect even small polyps in the entire small intestine in subjects with FAP. We found jejunal and ileal polyps to be common. The frequency and number of polyps and the length of small bowel involvement was found to increase with Spigelman classification (Table 3). All polyps were small except for three in the duodenum. These findings were similar to those previously reported by other studies<sup>[6-11]</sup>, although Iaquino *et al.*<sup>[12]</sup> have found the presence of duodenal adenomas to be the only clinical feature predictive of small-intestinal adenoma, but not associated with Spigelman

stage. We cannot define the true sensitivity of WCE for detection of small-bowel adenomas because the lack of visualization of the entire small-bowel mucosa by WCE leads to underestimation of polyp burden. To achieve this, we would have to compare the performance of WCE with that of the criterion standard of surgical enteroscopy. However, given the invasiveness and the high morbidity rate of the latter procedure, such a study would be extremely difficult to perform. The advent of double or single balloon enteroscopy of the small bowel may have opened a new avenue to gain less invasive access, even to polyps located in the distal small bowel. Double balloon enteroscopy appears to be equivalent to an intraoperative enteroscopy for scrutiny of small-intestinal polyps in FAP<sup>[17]</sup>. The region around the papilla of Vater was not visualized in any of our patients, which calls for the mandatory use of side-view duodenoscopy for staging duodenal disease.

Magnetic resonance enteroclysis combines the advantages of cross-sectional resonance with those of the volume challenge of conventional enteroclysis in the recognition and characterization of small-bowel-wall abnormalities, including initial tumors. There are few promising reports about the role of magnetic resonance enteroclysis and CT enteroclysis in the diagnostic algorithm of small-bowel neoplasms<sup>[18]</sup>. Whether the use of WCE in combination with these new diagnostic techniques will lead to earlier diagnosis of small-intestinal polyps in FAP patients remains to be elucidated in the future.

We observed no complications from WCE in our study. Other reports of WCE performed in individuals with FAP also have failed to detect any complications<sup>[6-12]</sup>.

Forward and side-viewing endoscopic surveillance for gastric and duodenal/periapillary neoplasia is recommended for all individuals with FAP<sup>[19,20]</sup>. The frequency of surveillance should be based on the Spigelman classification of duodenal polyposis<sup>[19,20]</sup>. However, the implication of jejunal and ileal adenomas in FAP is unknown. The risk of cancer distal to the duodenum in FAP has been reported much more rarely than that of duodenal and periampillary carcinoma<sup>[21]</sup>. The lack of data may rely on the fact that patients with FAP usually are not studied because of the low incidence of non-duodenal small-bowel cancer<sup>[21]</sup>. Therefore, should a search for small bowel adenomas with WCE be performed in all patients with FAP? Keeping in mind the high cost of WCE, identification of a subset of FAP patients who might be at the highest risk for developing small bowel tumor is desired. The analysis of germline APC gene mutation was not available in our patients, to compare with WCE findings. However, as reported by other investigators, the incidence of small-intestinal adenomas is correlated with mutations found in exon 15<sup>[22]</sup>. Mutations in this exon traditionally have been associated with a more aggressive phenotype<sup>[22,23]</sup>. The identification of genotypic factors that predict the phenotype of small-bowel adenomas is important. It has been suggested that WCE should be performed only in patients with exon 15 mutations<sup>[12]</sup>, thereby requiring

relative WCE surveillance. This approach may allow for a more cost-effective evaluation of FAP patients. Obviously, the current genotype-phenotype correlation must be confirmed in a larger cohort of FAP patients.

The frequency of WCE surveillance of jejunal and ileal adenomatous polyps in patients with FAP remains unknown. The detection of these small polyps in our study and previous studies had no immediate impact on the clinical management, other than establishing further surveillance intervals in these patients<sup>[6-12]</sup>. The tendency is for WCE to become the standard imaging modality for small-bowel surveillance, since Spigelman stage III and IV patients have a high burden of small-intestinal adenomas on WCE (Table 3). With the potential exception of the mentioned high risk of FAP patients developing small-bowel cancer, we recommend surveillance every 3-5 years in these patients; despite more data on the prevalence of small-bowel polyps in patients with advanced stage (III or IV) duodenal polyposis being needed to understand the utility of WCE in these groups. The small number of polyps observed in our FAP patients with Spigelman stage 0-II disease (Table 3) is in accordance with other studies<sup>[6-8]</sup>. We agree with other investigators<sup>[6-10]</sup> recommendations that WCE is not useful for routine small-bowel surveillance in these patients. Although management of jejunal and ileal polyps has not as yet been well defined considering the adenomatous nature of polyps in FAP, it seems reasonable to remove these polyps that are easily accessible by endoscopy. Whenever endoscopic polypectomy cannot be performed, although there is not enough evidence to propose surgical resection, surveillance with WCE seems advisable.

In conclusion, WCE is noninvasive, safe and comfortable, and can be performed on an ambulatory basis in FAP patients. It is effective for the detection of small-bowel polyps, but larger studies are needed to define better the impact of WCE on the clinical outcome of FAP patients with small-intestinal polyps, to elaborate which mutant gene carries the highest prevalence of small-intestinal adenomas, and to decide the timing of surveillance and polypectomy treatment by double or single balloon enteroscopy.

## COMMENTS

### Background

Endoscopic surveillance of the duodenum and periampillary area is recommended in patients with familial adenomatous polyposis (FAP), because 4% of patients develop cancer. However, the significance of the presence of jejunal and ileal polyps in patients with FAP is unknown.

### Research frontiers

FAP is a dominant inherited syndrome characterized by the presence of adenomatous polyps in the gastrointestinal tract, with a demonstrated adenoma-carcinoma sequence. In the present study, the authors investigated the diagnostic utility of wireless capsule endoscopy (WCE) in detecting small intestine polyps in a Greek FAP cohort.

### Innovations and breakthroughs

Few studies have evaluated the utility of WCE in detecting small-intestinal polyps and their clinical significance in patients with FAP. The rate of detection of small polyps in our patients was high but had no immediate impact on clinical management, other than establishing further surveillance intervals in these patients.

### Applications

This study represents a new role for WCE in the examination of the small intestine in FAP patients and emphasizes the need for a highly targeted surveillance based on Spigleman classification.

### Terminology

WCE is a technology that uses a swallowed video capsule to take photographs of the inside of the esophagus, stomach, and small intestine. Since it was introduced in 2000, it has become the gold standard for endoscopic evaluation of the small bowel in several clinical situations, including surveillance of polyposis syndromes.

### Peer review

This is an interesting observational study of the role of WCE in screening for small-intestinal polyps in a small cohort of patients with established FAP.

### Abstract

**AIM:** To compare postcholecystectomy patients with Sphincter of Oddi (SO) dyskinesia and those with normal SO motility to determine the psychosocial distress, gender and objective clinical correlates of dyskinesia, and contrast these findings with comparisons between SO stenosis and normal SO motility.

**METHODS:** Within a cohort of seventy-two consecutive postcholecystectomy patients with suspected SO dysfunction, manometric assessment identified subgroups with SO dyskinesia ( $n = 33$ ), SO stenosis ( $n = 18$ ) and normal SO motility ( $n = 21$ ). Each patient was categorized in terms of Milwaukee Type, sociodemographic status and the severity of stress-coping experiences.

**RESULTS:** Logistic regression revealed that *in combination* certain psychological, sociodemographic and clinical variables significantly differentiated SO dyskinesia, but not SO stenosis, from normal SO function. Levels of psychosocial stress and of coping with this stress (i.e. anger suppressed more frequently and the use of significantly more psychological coping strategies) were highest among patients with SO dyskinesia, especially women. Higher levels of neuroticism (the tendency to stress-proneness) further increased the likelihood of SO dyskinesia.

**CONCLUSION:** A motility disturbance related to psy-

### INTRODUCTION

Sphincter of Oddi (SO) dysfunction (SOD), characterized by recurring episodes of severe biliary-like abdominal pain following cholecystectomy, is one of a number of functional disorders of the biliary tract<sup>[1]</sup>. However, based on SO manometry, which is the “gold standard” for the diagnosis of SOD, the condition is a heterogeneous one, currently considered within the context of the functional disorders, but known to include both stenotic and non-stenotic (functional) groups. Thus, SO dyskinesia can be differentiated from SO stenosis, a structural defect of the sphincter orifice.

Unlike other functional gastrointestinal disorders (FGIDs)<sup>[2]</sup>, the psychosocial and gender concomitants of SOD have received little attention. In particular, psychosocial issues specifically relating to SO dyskinesia have not been addressed. Although two previous studies have implicated psychosocial factors in the genesis of symptoms in SOD, patients were not differentiated manometrically<sup>[3,4]</sup>. A more recent study found that health-related quality of life is impaired, and abuse histories are common, in SOD patients, but again patients were not differentiated manometrically<sup>[5]</sup>.

Given the strength of the relations between psychosocial disturbance and alterations in gastrointestinal transit, motor activity and sensitivity previously documented

in irritable bowel syndrome (IBS)<sup>[6-12]</sup>, our central hypothesis was that a similar association may exist with respect to SO dyskinesia. While the term stress or chronic stress can be viewed as a generic or umbrella term to include all features of a social stressor situation including psychophysiological effects, we have applied the term psychosocial distress to represent a person's experience of and transactions with a stressor situation including on-going attempts to gain or regain emotional and psychological equilibrium/control.

The aims of the present study, therefore, were to determine, among subgroups of postcholecystectomy patients exhibiting SO dyskinesia, SO stenosis ( $\pm$  dyskinesia) or normal SO motor activity: (1) whether levels of psychosocial distress are higher in patients with manometrically proven SO dyskinesia than in those with normal SO motor activity, and (2) whether higher levels of psychosocial distress are specific to SO dyskinesia (that is, relative to patients with SO stenosis), and (3) whether the presence of objective clinical criteria, according to the Milwaukee classification<sup>[13]</sup>, influences these associations. We chose specific psychological assessments of emotional state, personality and coping behaviour based on previously documented associations in other FGIDs<sup>[6-12]</sup>. Thus, during an individual's exposure to high levels of threat, powerful emotions such as fear, anger, anxiety and frustration are aroused and coping strategies, strongly influenced by personality and past experiences, are employed in an attempt to reduce the impact of both the emotions and the situation. A high level on any cluster of these psychological dimensions suggests high levels of psychosocial distress.

## MATERIALS AND METHODS

### Patients

The study population comprised seventy-two consecutive postcholecystectomy patients with biliary-like pain consistent with SOD [64 women, mean age 45 (SD  $\pm$  12) years], referred to the Gastrointestinal Investigation Unit for SO manometry. The presence of recurrent biliary-like pain fulfilling the criteria for SOD was confirmed from responses on the Bowel Disease Questionnaire (BDQ)<sup>[14]</sup> and defined according to the Rome criteria<sup>[1]</sup>, namely - episodes of pain in the right upper quadrant or epigastrium, rated by the patients as severe or very severe, steady and lasting from 30 min to 6 h. In all patients, organic disease had been excluded on the basis of normal physical examination, negative screening blood tests, negative gastroduodenoscopy and upper abdominal ultrasound or computed tomography scan, and the absence of calculi and strictures as demonstrated by endoscopic retrograde cholangiopancreatography (ERCP). Approval for the procedures was given by the Medical Research Ethics Committee of the Royal North Shore Hospital, and all subjects gave written informed consent.

### Clinical assessment

SO Milwaukee Type was determined according to Hogan *et al.*<sup>[13]</sup>, with patients sub-grouped into patients with objective clinical criteria (Types I & II), including

abnormalities of the biliary tree at cholangiography or abnormalities in hepatic biochemistry associated with episodes of pain, and patients without objective criteria (Type III) but with recurrent episodes of biliary-like pain. Thus, biliary-type I patients exhibited elevated liver biochemistries documented on two or more occasions, delayed contrast drainage, and a dilated common bile duct with a corrected diameter equal to or greater than 12 mm at ERCP; biliary-type II patients exhibited only one or two of the above criteria; while biliary-type III patients exhibited none of the above criteria<sup>[1]</sup>.

### SO manometry

Manometry of the SO was performed in standard fashion according to the technique of Toouli *et al.*<sup>[15]</sup>, using an Olympus JFIT10 duodenoscope and a triple-lumen catheter with inner lumen diameters each of 0.5 mm, an outer diameter of 1.7 mm and side holes radially orientated 2 mm apart (Wilson-Cook Medical, Winston-Salem, NC, USA). SO manometric tracings were analyzed by two experienced observers, blinded to the results of the symptom questionnaire. The following parameters<sup>[15,16]</sup> were determined: basal sphincter pressure, peak sphincter pressure, and phasic wave contractile frequency and propagation. Abnormalities of these parameters were defined as values outside normal ranges established previously using an identical recording technique<sup>[15]</sup>: basal pressure < 40 mmHg, contractile frequency < 8/min, and proportion of retrograde contractions < 50%. Complete inhibition of phasic contractions following cholecystokinin (CCK) was considered a normal CCK response. Failure of such a response, including a "paradoxical response" of the sphincter to CCK (i.e. increase in either the basal pressure and/or phasic contractions)<sup>[15]</sup>, was considered an abnormal response. SO manometric recordings were classified<sup>[15,17,18]</sup> as either: (1) sphincter dyskinesia, defined as an abnormally high basal pressure resolving after CCK, or an abnormally high phasic contractile frequency, and/or an elevated proportion of retrograde contractions, and/or an abnormal response to CCK in the absence of sphincter stenosis or (2) sphincter stenosis, defined as an abnormally high basal pressure persisting after CCK irrespective of the presence of some features of dyskinesia or (3) normal sphincter motor function. The presence of SO stenosis had hierarchical importance over any other feature of dyskinesia in stratifying patients.

### Psychosocial assessments

Psychometric measures assessed sociodemographic and psychological factors. The following data were collected prior to the SO manometry.

**Sociodemographic data:** Sex, age, marital status, highest education level, current employment status (i.e. whether working full-time, part-time or unemployed) and highest occupation level of self and father.

**Emotional distress/mood state:** Depression - in particular the affective component of a depressed mood state - was assessed using The Centre of Epidemiological Studies

Depression Scale<sup>[19]</sup> and state anxiety using the Spielberger State and Trait Anxiety Inventory (STAI)<sup>[20]</sup>. Responses on these scales reflect complementary dimensions of psychosocial distress arising from stressful life situations.

**Personality traits:** Trait anxiety (the tendency to anxious states) was also assessed from responses on the STAI<sup>[20]</sup>, and neuroticism (high scores reflect a tendency to stress-proneness and to excessive worry) and extroversion (orientation to things external or internal) were assessed using the Eysenck Personality Inventory<sup>[21]</sup>.

**Coping style:** The Defense Style Questionnaire (DSQ 40) measured the tendency to use emotion-focused coping defenses or strategies to reduce emotional distress classified as mature (e.g. using humor, suppression, anticipation, sublimation), immature (e.g. using denial, acting out, being passive aggressive) and/or neurotic [e.g. using pretence (pseudo-altruism), idealization, undoing, reaction formation]<sup>[22]</sup>. Normative and reliability data from patient and non-patient groups show these factors to have the internal consistency and the temporal stability of a trait measure - the mature dimension proving to be the primary discriminating factor<sup>[23]</sup>.

**Emotional suppression/expression:** The Courtauld Emotional Control Scale<sup>[24]</sup> assessed the tendency to suppress unwanted emotions such as anger and anxiety and the Anger Expression Scale<sup>[25]</sup> assessed the tendency to hold in anger (anger-in) to express anger (anger-out) and to control and/or resist becoming angry (anger-control). Anger-in and anger-out are empirically independent, factorially orthogonal dimensions<sup>[26]</sup>. Differences in the physiological effects of suppression *vs* expression of powerful emotions on autonomic, neuroendocrine and digestive functioning underlie the inclusion of these scales.

**Locus of control of behavior:** This scale<sup>[27]</sup> assessed the extent to which a person believes that personal efforts more than external factors can achieve a positive outcome.

Each of the above measures has established reliability and validity and relevance with respect to the investigation of the hypothesized links between psychosocial distress and the development of SO dyskinesia.

### Statistical analysis

Univariate and multivariate analyses were performed to compare the SO dyskinesia subgroup, and for comparison purposes the SO stenosis subgroup, with the normal SO motility subgroup, on a range of clinical, sociodemographic and psychological factors<sup>[28]</sup>. The relation of individual continuous variables such as age, sociodemographic and psychosocial factors was assessed by logistic regression, while  $\chi^2$  analyses were performed to determine any sex or clinical differences with respect to SO subgroups. Using a Stepwise regression - a model-building procedure by which sample data (not the investigator) determines order of entry into the model - an optimal subset of clinical, sociodemographic and psychological factors that had independent, statistically significant effects in relation to SO subgroups was then identified.

**Table 1** Clinical features of the post-cholecystectomy patient subgroups of SO dyskinesia, SO stenosis with or without dyskinesia and normal SO motility (mean  $\pm$  SD) *n* (%)

	SO dyskinesia ( <i>n</i> = 33)	SO stenosis ( <i>n</i> = 18)	Normal SO motility ( <i>n</i> = 21)
Age (yr)	45 $\pm$ 10	44 $\pm$ 13	48 $\pm$ 16
Gender: % female	91	89	86

<sup>1</sup>See text for further details; Model variance explained = 36.3%; B: Regression coefficient.

## RESULTS

SO manometry revealed evidence of SO dyskinesia (with no stenosis) (*n* = 33), SO stenosis [*n* = 18, some with concurrent SO dyskinesia features (*n* = 8)], or normal SO motility (i.e. no SO dyskinesia or SO stenosis (*n* = 21)). The three groups did not differ with respect to age, gender, or any of the independent clinical variables (Table 1), sociodemographic or psychological variables assessed.

When logistic regression was used to determine the effect of combinations of independent variables in relation to manometric outcome, however, a particular subset of clinical demographic and psychological variables significantly differentiated SO dyskinesia from normal SO motility (Table 2). In this model, variables positively associated with SO dyskinesia were being female, and the psychological variables of frequently suppressing anger, frequently using stress coping strategies, and neuroticism (the propensity to an overly anxious response to stressors). The negative association with abnormal motility (or positive association with normal motility) was related to the sociodemographic background, namely a lower occupational status of the patient's father. The variables of anxiety and depression were not associated with SO dyskinesia, nor were there positive associations with objective clinical criteria.

In contrast, duplicate analyses revealed no significant differences between patients with SO stenosis and those with normal SO motor activity, on psychosocial distress and gender and also on objective clinical criteria (data

not shown). This was the case whether the SO stenosis group included patients with ( $n = 18$ ) or without SO dyskinesia features ( $n = 10$ ).

## DISCUSSION

The novel finding in this study was the identification of a cluster of psychosocial and gender factors which together differentiate postcholecystectomy patients with manometric SO dyskinesia - but not those with SO stenosis - from those with normal SO motor activity. In comparison with the normal motor activity group, patients with SO dyskinesia, especially women, used significantly more stress-management strategies that were problem-focused (i.e. they suppressed anger more frequently) and emotion-focused (i.e. they frequently used mature and immature but not neurotic coping strategies), findings which implicitly represent on-going attempts to reduce psychosocial stress. While the prominence of the emotion anger (but not depression or anxiety) in the stress-coping profile reveals the potent nature of the psychosocial distress, for each individual the effectiveness of the particular range of coping strategies used to reduce emotional distress (and the associated physiological responses) is unclear. Thus, although patients with SO dyskinesia displayed a preference for strategies such as anticipation, humor, suppression, and sublimation (especially adaptive in the short term), other less effective (immature) strategies such as passive aggression and denial were also employed from time to time. Neurotic coping was rare in this group.

Our other major finding was that the biopsychosocial model of SO dyskinesia described above was, in essence, independent of objective clinical non-manometric criteria. This was despite the fact that the distribution of our patients with manometric evidence of SOD according to the Milwaukee classification was generally in keeping with that of other published reports: half of our patients with Type I exhibited stenosis, 61% of Type II exhibited sphincter dyskinesia, and 75% of Type III exhibited sphincter dyskinesia. The fact that our patients with Type III SOD exhibited a higher overall proportion of manometric dysfunction than published reports may reflect the fact that we employed CCK provocation, which is not now routinely undertaken in Units performing SO manometry. Moreover, our use of CCK considerably strengthens the distinction between SO hypertension due to sphincter hypertonicity and that due to a true fixed stenosis.

The significant association between psychosocial distress and sphincter dyskinesia is a new finding with respect to the sphincter of Oddi. It is, however, conceptually consistent with reports of similar links between stress and alterations in gut motility and sensation in patients with FGID categorized as IBS<sup>[29,30]</sup>. Studies using measures of stress-coping behavior similar to those used in the present study, suggest that higher levels of stress correspond with an increasing degree of dysmotility (and heightened perceptual sensitivity to mechanical distension) in the jejunum of women with

IBS<sup>[11]</sup>, and with the severity<sup>[9,12]</sup> and the extent (number of regions) of gut stasis<sup>[12]</sup>, especially gastric stasis, in mixed gender groups. Similar relations have been reported with respect to functional gut symptomatology. For example, higher levels of distress, assessed as outlined above, and also an objective measure of life stress, namely chronic stressor threat, are associated with a larger number of FGID syndromes<sup>[31]</sup>, with the overall intensity of FGID symptoms, and with the direction and extent of change in symptom intensity over time<sup>[7]</sup>. Also for patients with FGID, anger provoked in real life situations is the emotion which most strongly contributes to the net severity and extent of symptoms<sup>[31]</sup> and sensorimotor dysfunction<sup>[9,11]</sup>, while anger provoked in the laboratory inhibits antral motor activity in patients with these disorders in contrast to its enhancing effects on antral motor activity in healthy control subjects<sup>[32]</sup>. Consistent with all of these findings, the psychosocial distress model which described postcholecystectomy patients with SO dyskinesia in this study also included anger and female gender; these findings suggest both the potency of the stressful input on the one hand, and perhaps the more subtle and discriminating influence of sex hormones in SO motility on the other.

There is only very limited data available relating to psychosocial associations with SOD. Psychological disturbance has been implicated in one study<sup>[3]</sup> in the recurrence of biliary-type pain in some patients following cholecystectomy. In comparison to healthy controls, psychological factors assessed indirectly in terms of the number of concurrent multisystem gastrointestinal and non-gastrointestinal symptoms, was higher in patients with a diagnosis of SOD. However, patients were not differentiated manometrically in this study. In another report, psychological disturbance (anxiety, somatization, depression and obsessive-compulsive behavior) was found to be higher in patients with SOD Type III<sup>[4]</sup> than in other types. Interestingly, our findings did not confirm significantly higher levels of anxiety and depression in patients evaluated according to their manometric findings and not their Milwaukee criteria alone. In a longitudinal study, Jørgensen *et al.*<sup>[33]</sup> reported that psychological vulnerability (assessment prior to cholecystectomy in terms of the severity of multisystem somatic and neurotic symptoms) predicted failure to achieve a full recovery post-operatively, after controlling for age, sex, pre-operative pain characteristics, history of disease, type of surgery, histology and complications. The contribution of the present study is the notion that a stress-related sensorimotor dysfunction may help to explain the presence and the persistence of the syndrome for some patients with a diagnosis of SO dyskinesia, while high rates of recovery following endoscopic sphincterotomy in patients with manometric features of SO stenosis<sup>[16,34]</sup> suggest that fixed structural or anatomical defects may explain the syndrome in others. Indeed, an important feature of the stress-related sensorimotor dysfunction in this study is that it was determined in the absence of confounding influences arising from the presence of SO stenosis.

We are aware of the potential limitations of our

findings, especially the potential selection bias because patients with certain personality or mood-state characteristics may be more likely to seek medical attention than other patients, and also that recurrent pain may have influenced some of their responses to the various questionnaires. However, we sought to limit any such bias by also including patients with the same symptoms who had presented for medical care but were found to have sphincter stenosis. Moreover, as all patients reported intermittent episodes of pain as severe or very severe it was not feasible to relate the psychosocial measures to pain scores. Further studies will be required to confirm and extend these findings, as they are of potential clinical importance given that the psychological distress levels including clinical levels of anxiety and depression may be eminently treatable (e.g. with medication and/or psychotherapy). Although individual psychotherapies (e.g. biofeedback, cognitive-behavioral, psychodynamic, hypnotherapy), achieve reductions in emotional distress and symptom severity in patients with IBS, an integrated psychophysiological approach to the management of these disorders that is sensitive to the unique nature of each stressor situation would seem most likely to be helpful long term.

In summary, the close association found, for the first time, in this study between psychosocial distress and SO dyskinesia, but not between psychosocial distress and SO stenosis or normal SO motor activity, suggests that, for some patients with a diagnosis of SO dyskinesia, a stress-related motor dysfunction may help to explain the recurrence of their biliary-like symptoms following cholecystectomy. This is consistent with pathophysiological models of the FGIDs in general<sup>[35-37]</sup>.

## COMMENTS

### Background

Sphincter of Oddi (SO) dysfunction (SOD) is one of a number of functional disorders of the biliary tract. It is known to include both stenotic and non-stenotic (functional) groups. Thus, SO dyskinesia can be differentiated from SO stenosis, a structural defect of the sphincter orifice. Unlike other functional gastrointestinal disorders, the psychosocial and gender concomitants of SOD have received little attention. In particular, psychosocial issues specifically relating to SO dyskinesia have not been addressed.

### Research frontiers

Because of the strong relationships between psychosocial disturbance and alterations in gastrointestinal transit, motor activity and sensitivity previously documented in irritable bowel syndrome, we hypothesized that a similar association may exist with respect to SO dyskinesia.

### Innovations and breakthroughs

This is the first study to identify a cluster of psychosocial and gender factors which together differentiate postcholecystectomy patients with manometric SO dyskinesia - but not those with SO stenosis - from those with normal SO motor activity. The findings suggest that a stress-related motor dysfunction may help to explain the recurrence of biliary-like symptoms following cholecystectomy. This is consistent with pathophysiological models of the functional gastrointestinal disorders in general.

## Applications

These findings are of potential clinical importance given that psychological distress levels including clinical levels of anxiety and depression may be eminently treatable (e.g. with medication and/or psychotherapy).

## Terminology

Sphincter of Oddi dysfunction: a disorder characterized by recurring episodes of severe biliary-like abdominal pain following cholecystectomy. Sphincter dyskinesia: an abnormally high basal pressure resolving after cholecystokinin (CCK), or an abnormally high phasic sphincter contractile frequency, and/or an elevated proportion of retrograde contractions, and/or an abnormal response to CCK in the absence of sphincter stenosis. Sphincter stenosis: an abnormally high basal pressure persisting after CCK irrespective of the presence of some features of dyskinesia.

## Peer review

It is a solid research, well-written paper with reasonable conclusion. Although there are limitations to the study, these are nicely outlined and discussed.

### Abstract

**AIM:** To evaluate the usefulness of a balloon overtube to assist colorectal endoscopic submucosal dissection (ESD) using a gastroscope.

**METHODS:** The results of 45 consecutive patients who underwent colorectal ESD were analyzed in a single tertiary endoscopy center. In preoperative evaluation of access to the lesion, difficulties were experienced in the positioning and stabilization of a gastroscope in 15 patients who were thus assigned to the balloon-guided ESD group. A balloon overtube was placed with a gastroscope to provide an endoscopic channel to the lesion in cases with preoperatively identified difficulties related to accessibility. Colorectal ESD was performed following standard procedures. A submucosal fluid bleb was created with hyaluronic acid solution. A

circumferential mucosal incision was made to marginate the lesion. The isolated lesion was finally excised from the deeper layers with repetitive electrosurgical dissections with needle knives. The success of colorectal ESD, procedural feasibility, and procedure-related complications were the main outcomes and measurements.

**RESULTS:** The overall *en bloc* excision rate of colorectal ESD during this study at our institution was 95.6%. *En bloc* excision of the lesion was successfully achieved in 13 of the 15 patients (86.7%) in the balloon overtube-guided colorectal ESD group, which was comparable to the results of the standard ESD group with better accessibility to the lesion (30/30, 100%, not statistically significant).

**CONCLUSION:** Use of a balloon overtube can improve access to the lesion and facilitate scope manipulation for colorectal ESD.

### INTRODUCTION

Endoscopic submucosal dissection (ESD) has evolved to become one of the therapeutic options for the treatment of early stage gastric cancers in Asian countries<sup>[1,2]</sup>. In Japan, ESD has been increasingly applied to various levels of the gastrointestinal tract and results of initial experiences in a few high volume endoscopy centers have demonstrated the technical feasibility of this unique and aggressive approach, even in the colon. However, the

number of institutions allowed to perform this procedure is still restricted because colorectal ESD is technically more challenging, and may carry a higher risk of perforation and the most common sequela, bacterial peritonitis<sup>[3-6]</sup>. Inherited anatomic variability in the colon such as a long tubal structure, folds, or looping in mobile segments of the colon attached to the mesentery may hinder any endoscopic intervention in the colon. A further challenge arises from the need for a longer colonoscope; this can increase procedural workloads due to the need for careful, intuitive manipulation of the tip of the scope during needle knife dissections of the paper thin submucosal tissue plane<sup>[7,8]</sup>. At our institution, the gastroscope is therefore often preferentially used even for colorectal ESD, despite the shorter scope length, for deep scope intubation.

Use of a balloon overtube in enteroscopy provides optimal traction on the intestinal wall, thereby facilitating scope intubation. By inflation and withdrawal of a balloon attached to the tip of the overtube, the intestinal wall can be pleated on the overtube. This balloon overtube-guided technique has enabled a standardized total enteroscopy and has also provided a shorter direct access to the innermost locations in the gastrointestinal tract<sup>[9-11]</sup>. In addition, this approach has facilitated various interventions in the small intestine including biopsy, hemostasis and most recently polypectomy and endoscopic mucosal resection (EMR). Based on these results in the small intestine, we postulated that the a balloon overtube could form an ideal platform for colorectal ESD<sup>[12,13]</sup>.

We used a balloon overtube as an endoscopic channel and platform for colorectal ESD in cases in which access to the lesion with a gastroscope was difficult. Here we review the results of colorectal ESD in our institution to evaluate whether the balloon overtube-guided technique could improve access and scope manipulation during colorectal ESD.

## MATERIALS AND METHODS

### Patients

From October 2008 to March 2009 we performed colorectal ESD in 45 patients. The mean age of the patients was 70.7 years (range, 58 to 83 years). Indications for colorectal ESD were: 1. laterally spreading tumors (LST) over 20 mm in size, 2. lesions evaluated as being difficult to remove *en bloc* regardless of lesion size, e.g. local residual recurrent tumors after endoscopic removal and flat or depressed mucosal lesions. Histopathology of the lesions was preoperatively confirmed as adenoma or cancer with magnifying endoscopy or biopsy.

In all cases, access to the lesion was preoperatively evaluated using a therapeutic gastroscope (GIF Q260-J, Olympus, Tokyo, Japan). When circumferential access to the lesion with the tip of the endoscope was difficult, the access was considered difficult with a standard gastroscopic approach and the lesion was indicated for balloon overtube-guided ESD.

### Instrumentation and ESD procedure

**ESD procedure with a gastroscope:** A transparent cap (D201-11802; 2 mm Olympus, Tokyo, Japan) fitted thera-

peutic gastroscope (GIF-Q260-J, Olympus, Tokyo, Japan) was used for the conventional ESD group. The gastroscope is equipped with a water jet system, which supplies a continuous jet of high-pressure water to wash out blood and mucous during the endoscopic dissection. Two types of needle knives specially designed for ESD with minor modifications to the diathermy wire tip (Flex knife, KD-630L, Olympus, Tokyo Japan or Dual knife, KD-650Q, Olympus, Tokyo Japan) were used for the standard ESD procedure with a VIO300D high-frequency generator (ERBE, Elektromedizin, Tübingen, Germany). Ten percent sodium hyaluronate solution mixed with a small amount of indigo carmine and epinephrine hydrochloride was used as the injection solution to create a submucosal safety bleb<sup>[8]</sup>. A circumferential mucosal incision was made using one of the needle knives on endocut I (effect 2, interval 2, duration 2) mode. After the horizontal margination of the lesion from the surrounding normal mucosa, the electrosurgical dissection of the submucosal tissue plane was continuously performed with repetitive electrosurgical needle knife dissections. When bleeding and vascular structures were encountered, hemostasis were performed with point cauteries with the diathermy tip of the needle knife with Swift Coag mode 45W (effect 3) or a coagulation forceps (Coagrasper FD411-QR, Olympus, Tokyo, Japan) with Swift Coag mode 45W (effect 3). Patient posture rotations were carried out as needed to improve access to the lesion and deflect the overlying mucosa away from the dissection plane by gravity.

**Single balloon overtube-guided ESD:** Balloon overtube-guided ESD was performed with a standard diagnostic gastroscope (GIF-Q260, Olympus, Tokyo, Japan) with a 9.2-mm outer diameter. A balloon overtube with a 13.2-mm outer diameter, 11-mm inner diameter over-tube (ST-SB1, total length 1400 mm Olympus, Tokyo, Japan) designed for enteroscopy was shortened to 70 cm in length from the distal end leaving the balloon inflation tube intact. A gastroscope preloaded into the length-adjusted overtube was then inserted into the colon and the lesion was accessed using techniques similar to balloon enteroscopy (Figure 1). A transparent hood (D201-10704; 4 mm, Olympus, Tokyo, Japan) was attached to the tip of the endoscope. The procedural processes for ESD and the tool set used in the balloon overtube-guided procedure were the same for the ESD procedure performed without the overtube.

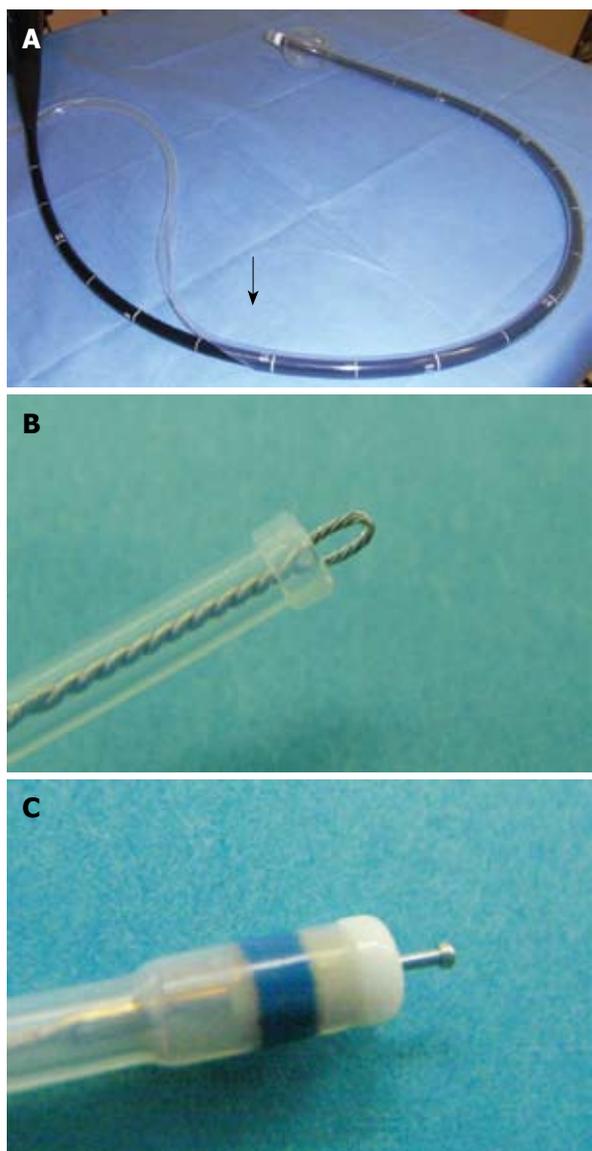

The study protocol was approved by the Institutional Ethical Committee of Kanto Medical Center NTT. Written informed consent was obtained from each patient before the ESD procedure.

### Statistical analysis

The significance of differences between patient characteristics and clinicopathological features was determined using  $\chi^2$  test, the Mann-Whitney *U* test, or Student *t* test as appropriate. *P* values < 0.05 were considered statistically significant.

## RESULTS

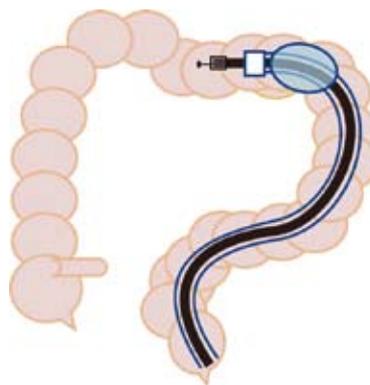

In the preoperative evaluation of accessibility with a

**Figure 1** Balloon over-tube and endoscopic submucosal dissection (ESD) devices. A: Single balloon over-tube shortened to 70 cm in length (arrow) from the distal end leaving the balloon inflation tube intact. A standard diagnostic gastroscope (GIF Q260, Olympus, Tokyo, Japan) is preloaded into the shortened over-tube; B: Flex knife (KD-630L, Olympus, Tokyo, Japan) used for ESD procedure; C: Dual knife (KD-650Q, Olympus, Tokyo, Japan) used for ESD procedure.

gastroscope, fifteen patients were identified as difficult, and were enrolled in the balloon overtube-guided ESD group. Thirty patients, who met the circumferential access criteria, were treated with the standard ESD method using a gastroscope without the overtube.

The overall *en bloc* excision rate of colorectal ESD was 95.6%. In the patients treated with the standard ESD method with a gastroscope, *en bloc* excision of the lesion was performed successfully in all 30 patients (100%). The lesions were located in the cecum in 2 patients, in the ascending colon in 10 patients, in the transverse colon in 2 patients, in the descending colon in 2 patients, in the sigmoid colon in 6 patients, and in the rectum in 8 patients. The median procedure time was 60 min (12-200 min). The median size of the lesion was 35 mm (SD: 13-98), and the median resected specimen size was 43 mm (17-112 mm).

**Figure 2** Scheme shows anchoring of the transverse colon with the single balloon over-tube.

There were no perforations, however, post-ESD bleeding occurred in one case, which required repeated endoscopic hemostasis.

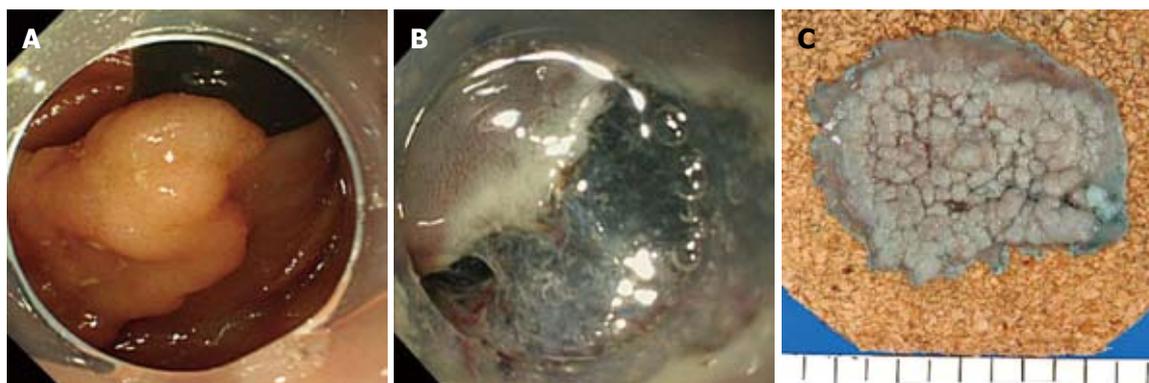

*En bloc* excision of the lesion was successfully achieved in 13 of the 15 patients (86.7%) in the balloon overtube-guided colorectal ESD group. In 2 cases of failure in the single balloon overtube-guided group, the endoscope did not reach the lesion due to elongation of the sigmoid colon. These two patients were eventually treated by piecemeal snare EMR using a colonoscope (CF-Q240L, Olympus, Japan). One lesion was located in the ascending colon and the other was in the transverse colon. Lesions in the balloon overtube-guided group were located in the transverse colon in 10 patients, the descending colon in 3 patients, the ascending colon in 1 patient and the sigmoid colon in 1 patient. The median procedure time was 80 min (30-160 min). The median size of the tumors was 27 mm (10-46 mm), and the median resected specimen size was 38 mm (18-57 mm). There were no severe complications such as perforation or bleeding.

There were no significant differences in the age ( $P = 0.352$ ), sex ( $P = 0.292$ ), lesion size ( $P = 0.472$ ), or resected specimen size ( $P = 0.597$ ) between the two groups. Lesions were more frequently located in the transverse colon in the balloon overtube-guided ESD group (10 vs 2,  $P < 0.001$ ). Operation time was longer in the balloon overtube-guided group ( $P = 0.050$ ).

On pathology, twenty lesions were diagnosed as tubular adenomas [44.4%, 15 in the ESD without overtube group, 5 in the ESD with overtube group;  $P = \text{NS}$  (not statistically significant)], and 25 were diagnosed as adenocarcinomas (55.6%, 15 in the ESD without overtube group, 10 in the ESD with overtube group;  $P = \text{NS}$ ). Four patients had submucosal invasion (3 in the ESD without overtube group, 1 in the ESD with overtube group,  $P = \text{NS}$ ) and one patient also had venous involvement. None of the patients had lymphatic involvement.

## DISCUSSION

The development of endoscopic snare polypectomy represents one of the most important achievements in the history of flexible endoscopy. This approach benefits patients enormously by reducing the physical burden associated with colonic polyp removal compared to traditional

**Figure 3** A colorectal laterally spreading tumor (LST) in the transverse colon that was difficult to approach with a standard endoscope. A: Retroflex view of the sessile granular-type lesion in the hepatic flexure of the transverse colon. The sharp angle of the colon made it difficult for a stabilized scope maneuver; B: Submucosal dissection plane with good elevation using hyaluronic acid injection; C: Gross specimen, showing the sessile, raised lesion resected *en bloc*.

surgical colectomy. Due to the limited size of the snare, removal of large polyps by snare polypectomy requires a piecemeal resection, which may lead to incomplete tumor removal. Local residual recurrence may occur after piecemeal colonic polyp excision in between 3% to 27% of cases<sup>[4]</sup>. In general, the majority of recurrent colorectal lesions are not clinically significant and can be managed with repeated endoscopic interventions. However, since some endoscopically removed lesions require additional surgical resection due to invasion into the deeper layers and vasculature, *en bloc* tumor excision is of interest not only for minimization of local tumor recurrence, but also for ensuring the precise histopathological evaluation of the sampled specimen<sup>[14]</sup>. In this study, three patients had shallow submucosal invasions and one patient had a solid submucosal invasion with vascular involvement that required additional surgical treatment. If it were possible to overcome the major technical difficulties associated with colorectal ESD, we believe this treatment could be an appropriate therapeutic option for colonic lesions that are difficult to remove *en bloc*, and this approach may be better accepted in western countries with a higher incidence of colonic polyps and cancers<sup>[15]</sup>.

In this study, preoperative evaluation showed that the majority of lesions in the transverse colon were in a difficult location and were assigned to the balloon overtube-guided group (10 *vs* 2). The transverse colon is the mobile segment most distant from the anus, and hence could be embarrassing due to the situation of the distal side of the colon. Mid-transverse colon may present as a sharp bend in patients with a redundant and drooping transverse colon. Reformation of sigmoid looping may generate friction for scope passage interfering with scope manipulation. Use of the balloon overtube provided an anchor on the colon wall giving optimal traction to maintain a shorter, straighter and more stabilized access to the lesion during ESD (Figure 2). Lesions that were preoperatively identified as being in a difficult location in the transverse colon could be accessed repeatedly using a diagnostic gastroscope by guidance of the balloon overtube, with the exception of one case with a surprisingly elongated sigmoid and severe adhesion. In addition, stabilized access *via* the overtube allowed direct and intuitive scope ma-

nipulation and *en bloc* tumor excision could be completed with the standard ESD technique in all attempts (Figure 3). Furthermore, a thin diagnostic gastroscope used in the balloon overtube-guided group could be more smoothly inserted into the submucosal tissue plane following a minimal mucosal isolation of the surgical margin. Once the cap fitted tip of the endoscope was inserted into the submucosal space thus created, electrosurgical dissection of the submucosa, the most error prone procedural process in ESD, could be safely performed with a clear visualization of the working field by deflecting the overlying isolated mucosa from the dissection plane. Although the single balloon-guided technique seems to be a promising approach to reduce the technical challenges of colorectal ESD, some important questions still remain unanswered. Two lesions, one located in the ascending colon and the other in the transverse colon were still difficult to access even with use of the balloon overtube. Both lesions were eventually treated with a colonoscope in a piecemeal fashion. In order to conclusively demonstrate that use of the balloon overtube can reduce technical difficulties in colorectal ESD, this novel approach should be directly compared with the standard ESD techniques using a colonoscope. Additionally, development of an overtube specially designed for the colorectal ESD of larger diameter to enable passage of a colonoscope could potentially reduce procedural difficulties and operation time further.

In conclusion, our preliminary experience suggests that the combined use of the balloon overtube and a thin diagnostic gastroscope is an effective and useful platform for colorectal ESD, especially in cases with difficult to access target lesions. Further studies are needed in which this novel technique is compared to the existing ESD techniques.

## COMMENTS

### Background

Endoscopic submucosal dissection (ESD) is technically more challenging for colorectal lesions than other locations in the gastrointestinal tract due to the anatomic characteristics of the colon and difficulties establishing stabilized manipulation of a long colonoscope.

### Research frontiers

Use of a balloon overtube in enteroscopy provides optimal traction on the intestinal wall thereby facilitating scope intubation. This balloon overtube-guided

approach has facilitated various interventions in the small intestine including biopsy, hemostasis and most recently polypectomy and endoscopic mucosal resection (EMR). Based on these results in the small intestine, the authors postulated that the balloon overtube could form an ideal platform for colorectal ESD. In this study, the authors reviewed the results of the balloon overtube-guided colorectal ESD technique.

### Innovations and breakthroughs

Colorectal ESD for the treatment of large superficial colorectal tumors is technically feasible, can improve *en bloc* resection rates, and is also less invasive compared to surgical treatment. However, colorectal ESD is technically more difficult and carries a higher risk of perforation than ESD at other levels of the gastrointestinal tract. Use of a balloon overtube improved access to the lesion and scope manipulation during colorectal ESD by shortening and straightening the access.

### Applications

If it were possible to overcome the major technical difficulties associated with colorectal ESD, the authors believe colorectal ESD could be an appropriate therapeutic option for colonic lesions that are difficult to remove *en bloc*, and this approach may be better accepted in Western countries with a higher incidence of colonic polyps and cancers.

### Terminology

ESD has evolved to become one of the therapeutic options for treatment of early stage gastric cancers in Asian countries. In Japan, ESD has been increasingly applied to various levels of the gastrointestinal tract and results of initial experiences in a few high volume endoscopy centers have demonstrated the technical feasibility of this unique and aggressive approach, even in the colon.

### Peer review

ESD for colorectal tumors is not generally recommended because of the technical difficulties and complications, including perforation. The authors performed ESD in 45 cases using gastroscope with a low perforation rate.

### Abstract

**AIM:** To evaluate the efficacy and complications of stereotactic body radiotherapy in localized paraaortic lymph node recurrence from colorectal cancer.

**METHODS:** From 2003 to 2009, 7 patients with paraaortic lymph node recurrence (1-3 lesions) from colorectal cancer were treated with stereotactic body radiotherapy. Total gross tumor volumes ranged from 4 to 40 mL. The doses were escalated from 36 Gy/patient to 51 Gy/patient and were delivered in 3 fractions.

**RESULTS:** One and 3 year overall survival rates were 100% and 71.4%, respectively, and median survival was 37 mo. Grade IV intestinal obstruction was reported in 1 of 7 patients. This patient received 48 Gy in 3 fractions with a maximum point dose to the intestine of 53 Gy and  $V_{45Gy} = 3.6$  mL. However, 6 patients received an intestinal maximum point dose of < 51 Gy and  $V_{45Gy}$  of < 1 mL, and did not develop any severe complications.

**CONCLUSION:** This pilot study suggests selected paraaortic lymph node recurrence (1-3 closed lesions) that failed to respond to chemotherapy can be potentially salvaged by stereotactic body radiotherapy.

**Key words:** Stereotactic body radiotherapy; Paraaortic lymph node recurrence; Colorectal cancer

### INTRODUCTION

Metastatic hepatic and pulmonary lesions from colorectal cancer (CRC) are commonly resected, and if tumorectomy for liver and lung recurrence from CRC is performed successfully, about 20% of patients are expected to achieve a long-term cure. On the other hand, isolated paraaortic lymph node (PALN) recurrences are rarely encountered from CRC. Moreover, surgical treatment in these cases is not widely accepted even when lesions are localized, due to their relative rarity, high postoperative morbidity, and poor prognosis. However, if such patients are left untreated, the survival rates are 31% at 1 year, 7.9% at 2 years, and 0.9% at 4 years<sup>[1,2]</sup>. Therefore, this patient subset is considered for various chemotherapy regimens. However, despite optimal treatment and initial response, overall survival approaches only 20 mo<sup>[3]</sup>. Furthermore, radiotherapy usually provides only temporary symptom relief in most cases.

On the other hand, stereotactic body radiotherapy (SBRT) is an emerging technology in the radiation oncology field. This technique utilizes stereotactic principles for localization and delivers multiple beams to well defined targets in a few fractions, and therefore, SBRT can deliver higher doses to tumors due to reduced mechanical error margins, and thus, causes less normal tissue damage. To our knowledge, no previous report has described the role of radiation, including conventional RT, intensity-modulated RT, and SBRT, for PALN recurrence from CRC, although several reports have been issued on the treatment of cervical cancer with isolated PALN recurrence, which responds well to both chemo- and radiation therapy<sup>[4-6]</sup>. Therefore, the aim of this study was to evaluate the feasibility and efficacy and

the complications associated with SBRT in patients with isolated PALN recurrence from CRC.

## MATERIALS AND METHODS

### Patients

From May 2003 to March 2009, we reviewed retrospectively 7 patients with isolated PALN recurrence from rectal cancer after curative resection who were treated with SBRT using a CyberKnife (Accuray Inc., Sunnyvale, CA). Isolated PALN recurrence was initially detected by computed tomography (CT) or by an elevated serum carcinoembryonic antigen (CEA) level during a routine check-up, and was confirmed by elevated standardized uptake values of paraaortic lesions by positron emission tomography (PET) or PET/CT. According to our hospital's protocol, patient eligibility criteria for curative SBRT for paraaortic lymph node recurrence from CRC were as follows: (1) resection of CRC after diagnosis; (2) PALN recurrence after primary cancer resection; (3) progression after chemotherapy for recurrence; (4) a single conglomerate recurrent node or 2-3 recurrent nodes in close proximity (< 1 cm); (5) a greatest tumor diameter of < 8 cm; and (6) an Eastern Cooperative Oncology Group (ECOG) performance score of 1 or 2. Exclusion criteria were as follows: (1) a tumor attached to the stomach or intestine by CT; (2) extra-lymphatic active lesion by CT or PET/CT; (3) more than three separate lymph nodes affected (4) time from primary operation to recurrence of < 6 mo; or (5) previous radiation therapy applied to the treatment site. Patients' characteristics are summarized in Table 1. Ages ranged from 47 to 73 years (median 59 years) and the male:female ratio was 5:2. All patients underwent primary tumor resection. Liver resection was also performed in 2 patients with liver metastasis. Adjuvant chemotherapy was performed in all patients. Initial pathologic stages were stage II in 2, stage III in 3, and stage IV in 2. Pathologic diagnoses were adenocarcinoma in all 7. Times between operation and first relapse ranged from 7 to 44 mo (median 21 mo). Three patients had a conglomerated LN and the other four had 2 or 3 separate enlarged lymph nodes on a paraaortic lesion. Greatest tumor diameters and heights were calculated using measurements taken from CT scans during planning, and are itemized in Table 1. Total gross tumor volumes (GTV) ranged from 4 to 40 mL (median 22 mL). After recurrence had been detected, all patients received chemotherapy based on 5-FU before SBRT. Chemotherapy regimens were variable because of the different initial adjuvant chemotherapy regimens used. All 7 patients demonstrated disease progression despite chemotherapy, and thus, were defined as non-responders. After performing SBRT, patients were followed up every 2 or 3 mo. When recurrence was detected after SBRT, salvage or palliative treatment was performed according to the status of recurrence. All patients provided written informed consent for SBRT. This study was approved by Institutional Review Board-approved protocol for SBRT at the Korea Institute of Radiological and Medical Sciences (KIRAMS).

### SBRT technique

In accord with our hospital protocol, gold fiducials

(4 mm long and 0.8 mm in diameter) were used as markers for tumor localization. Six fiducials were placed percutaneously on transverse processes of the spine located nearest tumors using an 18 gauge spinal needle under fluoroscopic guidance. Patients were immobilized using an Alpha Cradle (Smithers Medical products, North Canton, OH) 5-7 d after fiducial placement. Panning CT scans were performed with patients in the planned treatment position, and these images were then processed for the CyberKnife planning system. GTV were determined based on CT tumor visualizations. To better delineate tumor volumes, PET/CT images were used as a reference. Clinical target volumes (CTV) were considered to be identical to GTV. Planning target volumes (PTV) were CTV plus a 2-3 mm margin. Radiation doses were prescribed to the 76%-83% isodose line of the maximum dose covering the PTV (Table 1). Critical structures, such as the esophagus and spinal cord, were contoured. Treatment plans involved the use of hundreds of pencil beams shaped using a single 20, 25, or 30 mm diameter circular collimator. The method used to increase SBRT dose is described in detail in our previous report<sup>[7]</sup>. Briefly, the protocol adopted was follows; if at least 5 patients who received SBRT due to PALN from variable primary tumors (cervical cancer, CRC, or gastric cancer) did not develop Grade IV or V complications for 3-4 mo after radiation was administered, escalations of 1 Gy/fraction (to a total increase of 3 Gy/fraction) were administered for the next cohort. According to this protocol, total SBRT doses ranged from 36 to 51 Gy (median 48 Gy), and were delivered in 3 fractions. Maximum point dose limits were applied for critical organs, i.e. 18 Gy for the spinal cord and 24 Gy for the esophagus. No constraints were applied to limit intestinal or colon exposure. Table 1 summarizes SBRT dosage details.

### Survival and complications

Overall survival was calculated from the commencement of SBRT using the Kaplan-Meier method. Disease progression free survival was also measured from the commencement of SBRT to the date of local progression, distant metastasis, or both. All statistical calculations were performed using SPSS, version 13.0 (SPSS, Inc., Chicago, IL).

Tumor response during follow up was assessed using Response Evaluation and Criteria for Solid Tumors (RECIST)<sup>[8]</sup>. Local progression was defined as an increase in tumor size vs the previous CT image or the development of a new lesion in the radiation field. Regional failure was defined as the development of a new lesion in the PALN region.

Acute and late toxicities were defined as symptoms that developed within or after 3 mo of treatment completion, respectively. Toxicities were graded using the National Cancer Institute Common Toxicity Criteria version 3.0<sup>[9]</sup>. To identify factors related to complications, total CTV, intestinal maximum point dose ( $D_{max}$ ) and intestinal volume administered  $\geq 45$  Gy ( $V_{45}$ ) were calculated retrospectively (Table 1). Total CTV was defined as sum of the CTV of affected lymph node as determined by the CyberKnife planning system.  $V_{pre}$  was defined as the total volume administered the prescribed dose or more.

Table 1 Demographic data of 7 patients

Patient No.	Age (yr)/ Sex	Latent time (mo)	GTV (mL)	Dose (Gy)	Prescribed isodose (%)	Dmax of intestine (Gy)	V45 (mL)	Failure pattern	F/U (mo)	Final status

7	73/M	7	29	51	78	50	0.9	-	26	CDF

GTV: Gross tumor volume; AWD: Alive with disease; CDF: Continuously disease-free; DOD: Died of disease; Latent time: Disease free interval from operation to first relapse; F/U: Follow-up from commencement of SBRT to last follow-up or death; Lt SCLN: Left supraclavicular lymph node; Dmax: Maximum point dose of intestine; V45: Intestinal volume receiving 45 Gy or more; Vpre: Total volume receiving the prescribed dose or more; Parenthesis (mo) means the period from SBRT to detection of complication.

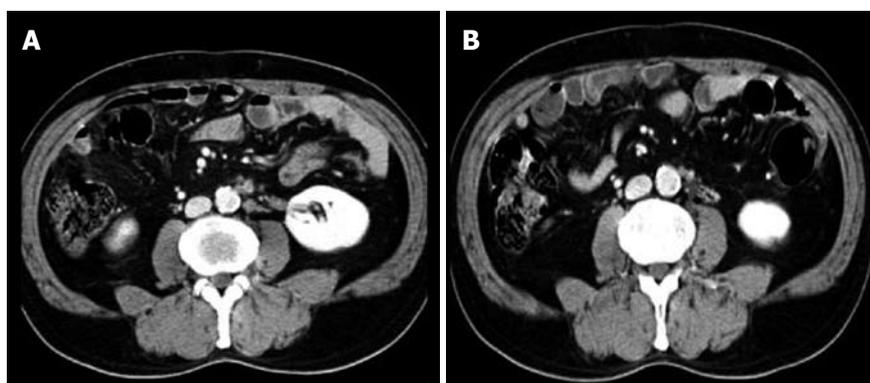

Figure 1 Computed tomography (CT) images obtained in a patient with paraaortic lymph node recurrence before (A) and 2 mo after (B) stereotactic body radiotherapy (SBRT).

## RESULTS

Follow up durations ranged from 15 to 70 mo (median; 26 mo). Final outcomes were as follows: 1 patient remained alive without evidence of disease; 2 patients remained alive with disease; 3 patients died of disease; and 1 patient died of an unrelated disease without recurrence (Table 1). During follow-up, 3 patients achieved a complete response and 4 patients achieved a partial response (Figure 1). One- and 3-year overall survival rates were 100% and 71.4%, respectively, and median survival was 37 mo. Local recurrence was observed at 13 mo after SBRT in patient No 6 (Table 1). Regional recurrence in the PALN region was observed in patient No. 5. However, 4 patients experienced distant failure with/without primary rectal recurrence (Table 1).

Grade I acute toxicity (nausea and vomiting) occurred in 2 patients at first date of SBRT, and these resolved spontaneously without medication. Grade 4 toxicity occurred in 1 patient (patient No. 6; Table 1). This patient had one conglomerated lymph node and another lymph node and had received 48 Gy in 3 fractions. Abdominal pain developed at 4 mo post-SBRT, and at 5 mo an obstruction was observed during a colon study. He underwent bypass surgery and recovered completely. A photograph of the excised obstructive lesion is shown in Figure 2. This patient had a larger CTV than CTV of the other patients. In this patient, the maximum point intestine dose was 53 Gy and V<sub>45Gy</sub> was 3.6 mL. No late complications occurred in any patients.

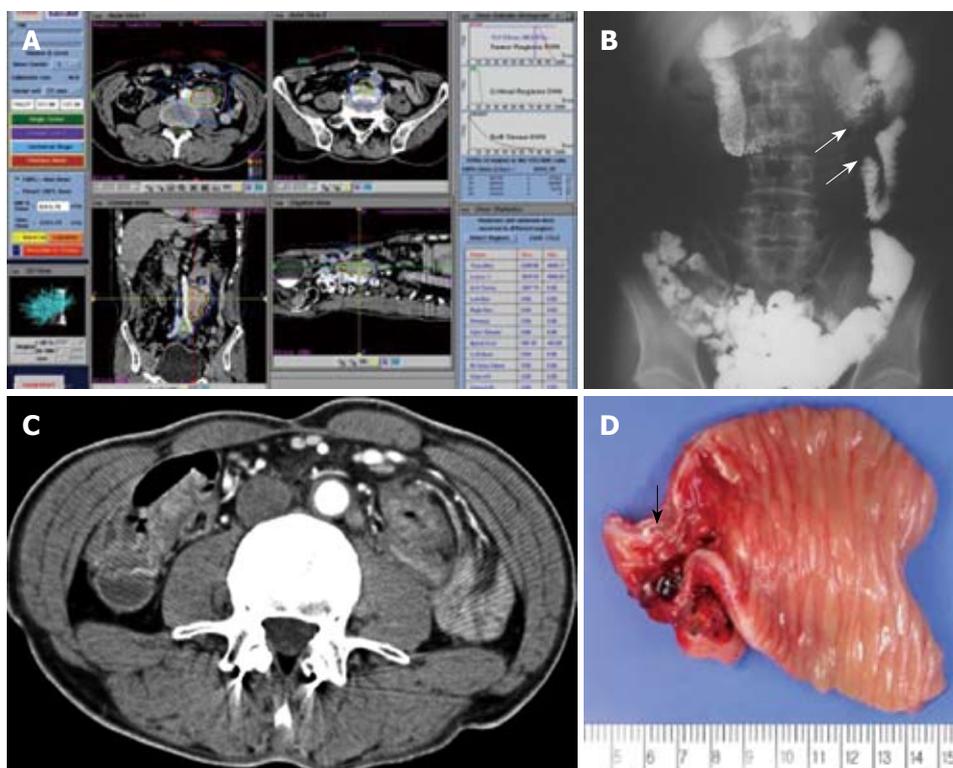

## DISCUSSION

The management of patients with locally recurrent rectal cancer is challenging. For technically resectable recurrent tumors, complete resection can be achieved by limited surgery and outcomes are relatively favorable. Vassilopoulos *et al*<sup>[10]</sup> and Pihl *et al*<sup>[11]</sup> reported 5-year survival rates of 49% and 42%, respectively, after resection for anastomotic recurrence. However, the treatment of isolated PALN recurrence from CRC is not well established. Recently, Min *et al*<sup>[12]</sup> categorized PALN recurrence as a retroperitoneal recurrence, which is a type of locoregional recurrence. Furthermore, several studies<sup>[13-16]</sup> have investigated the therapeutic efficacies of surgery for retroperitoneal, intraabdominal, and PALN recurrences, and several reported outstanding survival rates, which appear to have resulted from the selection of patients with a resectable mass at time of recurrence. In these studies, reported 5-year survival rates approached a maximum of 56% after complete resection, whereas they ranged from 0% to 7% after incomplete resection (Table 2). Because radical surgery is rarely feasible for PALN recurrence, traditionally, those affected have been considered for chemotherapy. However, despite optimal treatment and the achievement of initial response, patients invariably become non-responsive and achieve overall survivals approaching 20 mo. On the other hand, conventional radiotherapy has played a limited palliative role in the treatment of recurrent CRC involving locoregional recurrence, especially PALN

recurrence. The proximities of involved lymph nodes and critical organs, such as the spinal cord, intestine, and colon, often prevent the delivery of sufficient radiation to achieve local control when conventional radiation modalities are used. However, SBRT can deliver higher doses to tumor and cause less tissue damage. Furthermore, it can have three times the biological effect of fractionated radiation therapy. However, the SBRT field is usually directed at the tumor burden, and thus, the prophylactic effect of SBRT in peritumoral regions is limited which in turn means the incidence of regional failure after SBRT seems higher than that after conventional radiation therapy. Fortunately, in the present study, only 1 regional failure pattern was observed.

At our institute, SBRT has been utilized for isolated PALN from gastric or cervical cancer, and 3-year survival

rates of 43%<sup>[17]</sup> and 63%<sup>[18]</sup> have been achieved, respectively. In addition, an excellent 3-year overall survival rate of 71.4% was achieved in the present study. Accordingly, the findings of studies on PALN recurrence from variable primary cancers treated by SBRT appear to support our hypothesis that a subset of isolated PALN recurrence cases exist that are likely to pursue an indolent disease course and be salvaged by adjustable treatments.

Theoretically, rectal cancer is classified as a slow-growing tumor that is likely to respond better to hypofractionation. However, no recommended optimal doses, fraction numbers, or planning constraints for SBRT of PALN recurrence are available in the literature. SBRT doses and fractions for PALN recurrence from variable tumors were started at our hospital from 33 Gy in 3 fractions. In the

present study, converted 58 Gy in normalized total doses of 2 Gy was used, and escalated step by step<sup>[18]</sup>. Although, 1 of our patients developed grade 4 toxicity due to an intestinal obstruction and required surgery, this patient recovered after surgery. Specifically, this patient received 48 Gy in 3 fractions, and had a larger GTV than the other 6 patients. Based on our experience, we consider the factors that most contribute to severe complications are maximum point dose delivered to normal tissue and the volume of normal tissue administered a high dose. Therefore, we tentatively consider maximum intestinal point dose of 51 Gy or V<sub>45Gy</sub> < 1 mL as constraints of the intestine for SBRT.

Summarizing, the findings of this preliminary study suggest that selected isolated PALN recurrence patients that fail to respond to chemotherapy with 1-3 closely located attached lymph nodes may be salvaged by SBRT. However, a further larger-scale study is required to define optimal dose, intestinal constraints, and adequate indications for SBRT in recurrent CRC.

## COMMENTS

### Background

Isolated paraaortic lymph node (PALN) recurrences are rarely encountered from colorectal cancer (CRC). Moreover, surgical treatment in these cases is not widely accepted even when lesions are localized, due to their relative rarity, high postoperative morbidity, and poor prognosis. This patient subset is considered for various chemotherapy regimens. However, despite optimal treatment and initial response, overall survival approaches only 20 mo.

### Research frontiers

Stereotactic body radiotherapy (SBRT) is an emerging technology in the radiation oncology field. This technique utilizes stereotactic principles for localization and delivers multiple beams to well defined targets in a few fractions. SBRT can deliver higher doses to tumors due to reduced mechanical error margins, and thus, causes less normal tissue damage.

### Innovations and breakthroughs

Delivery of a therapeutic dose of radiation to the PALNs is limited by the sensitivity of the surrounding normal tissues, such as those in the gastrointestinal tract, liver, spinal cord, and kidneys. However recent technologies such as intensity-modulated RT, image-guided RT, and SBRT have allowed higher doses to be delivered to tumor and caused less normal tissue damage. SBRT could lead to better local control through delivery of a higher radiation dose to the tumor and this could ultimately translate into survival gain. Furthermore, SBRT requires complex planning and relatively long treatment times (30-45 min) but generally is completed in 3-5 treatments. SBRT is associated with few side effects because the treatment field is generally very small and treatment is precisely delivered.

### Applications

This pilot study suggests selected paraaortic lymph node recurrence (1-3 closed lesions) that failed to respond to chemotherapy can be potentially salvaged by stereotactic body radiotherapy.

### Terminology

Isolated PALN metastasis is defined as metastasis only to the PALNs. SBRT is an image-guided radiation method. SBRT is directed to extremely well-defined targets within the body. SBRT has evolved from the intracranial experience of stereotactic radiosurgery (single fraction treatment) or stereotactic radiotherapy (multiple fractions of treatment).

### Peer review

The authors evaluate efficacy and complications of stereotactic body radiotherapy in localized paraaortic lymph node recurrence from colorectal cancer. It is well written.

### Abstract

**AIM:** To compare a first diagnostic procedure of trans-bronchial needle aspiration (TBNA) with selection of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) or TBNA for mediastinal lymphadenopathy.

**METHODS:** Sixty-eight consecutive patients with mediastinal lymphadenopathy on computed tomography (CT), who required cytopathological diagnosis, were recruited. The first 34 underwent a sequential approach in which TBNA was performed first, followed by EUS-FNA if TBNA was unrevealing. The next 34 underwent a selective approach where either TBNA or EUS-FNA was selected as the first procedure based on the CT findings.

**RESULTS:** The diagnostic yield of TBNA as the first diagnostic procedure in the sequential approach was 62%. In the selective approach, the diagnostic yield of the first procedure was 71%. There was no significant difference in the overall diagnostic yield, but there were significantly fewer combined procedures with the selective approach.

**CONCLUSION:** Selecting either EUS-FNA or TBNA as the first diagnostic procedure achieved a comparable diagnostic yield with significantly fewer procedures than performing TBNA first in all patients.

### INTRODUCTION

Lung cancer is the commonest cause of mediastinal lymphadenopathy. For non-small cell lung cancer (NSCLC), which accounts for about 80% of lung cancers, mediastinal lymph node enlargement occurs in up to 38% of cases at diagnosis<sup>[1]</sup>. As surgical resection of NSCLC offers the best chance of cure in patients without distant metastases, the pathological confirmation of cancer spread to enlarged mediastinal lymph nodes is crucial to staging because this excludes curative surgical resection.

In the approach to suspected lung cancer without distant metastases, the lung mass is the initial target for cytopathological diagnosis. Following a diagnosis of NSCLC, mediastinal staging is the next step. In patients with mediastinal lymphadenopathy however, the mediastinum may be targeted first, even when a lung mass is present. This might achieve simultaneous diagnosis and mediastinal staging of lung cancer with a single procedure.

The esophagus and tracheobronchial tree offer endoluminal access to mediastinal lymph nodes, therefore endoscopic techniques such as endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) and trans-bronchial needle aspiration (TBNA) offer minimally invasive approaches for diagnosis of mediastinal lymphadenopathy.

Although EUS-FNA has a higher accuracy than TBNA, the transbronchial approach is preferred for anterior and right paratracheal lymph nodes. Real-time endobronchial ultrasound-guided TBNA (EBUS-TBNA) is now available but requires expensive specialized equipment and operator training. TBNA does not require specialized equipment and can be performed during the initial diagnostic bronchoscopy<sup>[2-4]</sup>. When we evaluated patients with mediastinal lymphadenopathy with bronchoscopy and TBNA, the diagnostic yield for mediastinal lymphadenopathy was 65%<sup>[3]</sup>.

We have also used EUS-FNA for cases in which TBNA was unrevealing or non-diagnostic, given its higher accuracy<sup>[4]</sup>. However, this resulted in subjecting these patients to two diagnostic procedures even though both procedures could be performed in the same outpatient session<sup>[4,5]</sup>.

We then hypothesized that bronchoscopy with TBNA need not be performed as the first procedure in all cases of mediastinal lymphadenopathy, and that by selecting the appropriate endoscopic procedure based on anatomical access, a higher diagnostic yield could be obtained after the first procedure. This could also result in subjecting the patient to fewer diagnostic procedures. Therefore, in this study, we compared an approach utilizing TBNA as the first diagnostic procedure with one utilizing selection of either EUS-FNA or TBNA.

## MATERIALS AND METHODS

Between December 2003 and June 2006, consecutive patients with mediastinal lymphadenopathy on thoracic computed tomography (CT) who presented to, or were referred to our respiratory division for cytopathological diagnosis were recruited for the study. Mediastinal lymphadenopathy was defined as a node larger than 1 cm in its short axis. The institutional review board of our hospital approved the study and informed consent was obtained for all the procedures.

### Sequential approach

During the first 16 mo of the study period, we employed a sequential approach for which bronchoscopy with TBNA was performed as the first diagnostic procedure, with or without other conventional bronchoscopic techniques. If TBNA was unrevealing on rapid on-site cytopathological evaluation (ROSE), EUS-FNA was performed immediately after TBNA, during the same session. Details of this approach and the results of the first 20 patients have been described when we explored the one-stop approach to mediastinal lymphadenopathy<sup>[4,5]</sup>.

### Selective approach

From April 2005, we employed a selective approach for which either EUS-FNA or TBNA was performed as the first diagnostic procedure. This was selected based on the predominant location of the lymphadenopathy on CT. If either the esophageal or transbronchial approach could access the nodes, the pulmonologist was left to

decide which procedure he deemed most appropriate. In general, TBNA was selected mainly for patients with right paratracheal lymphadenopathy, whereas EUS-FNA was the preferred option for left paratracheal lymphadenopathy. Subcarinal lymph nodes could be approached by either procedure. If TBNA was selected as the first diagnostic procedure, EUS-FNA remained a subsequent option.

### TBNA, EUS-FNA and ROSE

Bronchoscopy was performed by experienced pulmonologists using standard flexible videobronchoscopes (Olympus Optical Co. Ltd., Tokyo, Japan). Premedication with pethidine and atropine and sedation with midazolam were optional, while all patients received topical anesthesia with xylocaine. TBNA was performed blind with a Wang 22-gauge (MW 222) cytology needle (Bard Endoscopic Technologies, Billerica, MA, USA) at sites of mediastinal lymph node enlargement based on review of the CT scan. TBNA was performed before other conventional bronchoscopic procedures to avoid contamination.

EUS-FNA was performed as previously described using the curved linear array echoendoscope (GF-UC30P; Olympus) by experienced gastroenterologists<sup>[6]</sup>. Patients received topical anesthesia with xylocaine and sedation with a combination of midazolam and pethidine.

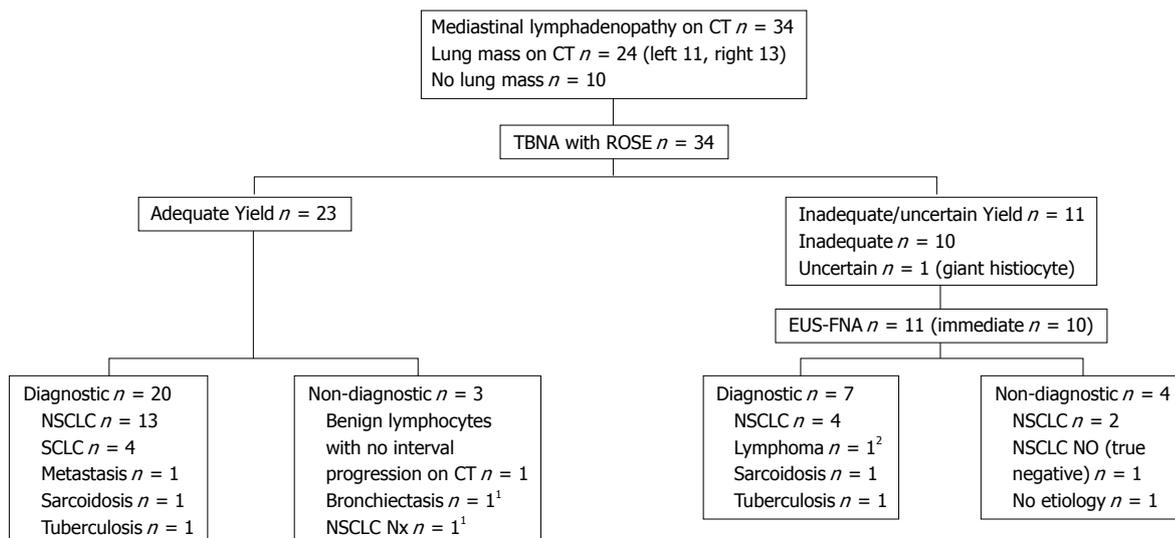

ROSE was employed to determine the adequacy of the needle aspirates. The aspirated material was blown onto a slide using the direct smear technique<sup>[7]</sup>. The smears were either air-dried and stained with Diff-Quik (American Scientific Products, McGraw Park, IL, USA) or fixed immediately in 95% ethanol and stained with Papanicolaou stain. Solid particles were fixed in formalin, routinely processed, and made into cell blocks for histological examination. The air-dried smears for Diff-Quik staining were reviewed immediately by an experienced cytotechnician. Endoscopists were then advised as to the need for additional needle aspirates (up to a maximum of six passes).

### Diagnostic yield

The final cytopathological diagnoses were made based upon analysis of the aspirated material by experienced cytopathologists. The diagnostic yield of TBNA was the number of patients in whom a definite diagnosis was made by TBNA over the total number of patients subjected to TBNA. The diagnostic yield after the first procedure was the number of patients in whom a definite diagnosis was made after the first procedure over the total number of patients. The overall diagnostic yield for each approach was the number of patients in whom a definitive diagnosis was made by needle aspiration over the total number of patients. When a diagnosis could not be made by either procedure, the final diagnostic categories were determined by review of further tests and clinical assessments.

### Statistical analysis

Descriptive statistics are presented as mean  $\pm$  SD. Discrete

**Figure 1 The sequential approach.** <sup>1</sup>False positive TBNA with ROSE; <sup>2</sup>False negative TBNA with ROSE. CT: Computed tomography; TBNA: Transbronchial needle aspiration; ROSE: Rapid on-site cytopathological evaluation; NSCLC: Non-small cell lung cancer; EUS-FNA: Endoscopic ultrasound-guided fine-needle aspiration.

variables were analyzed with  $\chi^2$  test and  $P < 0.05$  was defined as statistically significant.

## RESULTS

Sixty-eight consecutive patients with mediastinal lymphadenopathy on CT were recruited during the study period. The main indication for CT was suspected malignancy ( $n = 58$ ). Other indications included suspected pulmonary embolism ( $n = 4$ ), pyrexia of unknown origin ( $n = 2$ ), suspected aortic dissection ( $n = 1$ ), investigation of weight loss ( $n = 1$ ), suspected sarcoidosis ( $n = 1$ ), and follow-up of non-Hodgkin's lymphoma ( $n = 1$ ).

The baseline characteristics and diagnostic categories of the sequential group ( $n = 34$ ) and the selective group ( $n = 34$ ) were similar (Table 1).

Results of the sequential approach are shown in Figure 1. TBNA was performed at the following mediastinal sites according to regional lymph node map definitions as described by Mountain *et al*<sup>[8]</sup>: 4R in 10 patients, 7 in 24 patients, and 4L in 7 patients. The TBNA obtained adequate specimens in 23 of the 34 patients. In the remaining 11 patients, TBNA with ROSE showed the specimens to be inadequate or unrevealing, thus, EUS-FNA was performed immediately after bronchoscopy, at lymph node stations 7 (seven patients), 4L (10 patients) and 4R (one patient). Some patients had TBNA or EUS-FNA performed at more than one lymph node station. When the final cytopathological results were analyzed, TBNA with ROSE was falsely negative in one patient. In another patient, TBNA with ROSE showed a giant histiocyte and a decision was made to proceed with EUS-FNA. The final cytopathological diagnosis for both specimens returned as granulomatous inflammation. Results of the first 20 patients with this approach have been described previously<sup>[4]</sup>.

Results of the selective approach are shown in Figure 2. TBNA was performed in 22 patients in the following mediastinal sites: 4R (six patients) and 7 (19 patients).

**Table 1 Baseline characteristics and diagnostic categories of study population  $n$  (%)**

Variables	Sequential approach	Selective approach	$P$ value
No. of patients	34	34	
Male/female	24/10	25/9	
Age (mean $\pm$ SD, yr)	64.7 $\pm$ 11.2	65.1 $\pm$ 12.7

CT: Computed tomography; TBNA: Transbronchial needle aspiration; NSCLC: Non-small cell lung cancer; EUS-FNA: Endoscopic ultrasound-guided fine-needle aspiration.

EUS-FNA was performed as a first diagnostic procedure in 12 patients at lymph node stations 7 (12 patients), 4L (five patients) and 2R (one patient, Figure 3). In contrast to the sequential approach for which all 34 patients had TBNA performed first, 35% (12/34) of patients in the selective approach had EUS-FNA performed first, while the remaining 65% (22/34) had TBNA performed first. In the selective approach, TBNA was performed only for right paratracheal and subcarinal stations, whereas EUS was performed predominantly in the left paratracheal and subcarinal stations.

The diagnostic yield of TBNA as the first diagnostic test was 62% in the sequential approach, while the diagnostic yield of the first diagnostic procedure in the selective approach was 71%. The diagnostic yield of

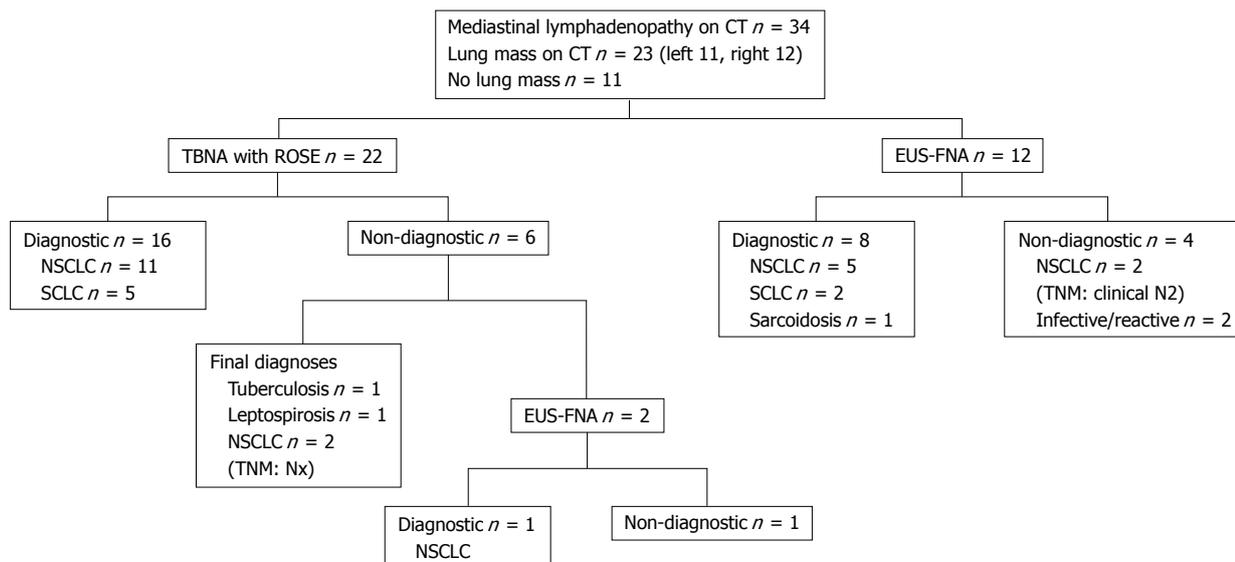

Figure 2 The selective approach.

Figure 3 CT showing right paratracheal lymphadenopathy that was sampled by EUS-FNA.

EUS-FNA was 67% (8/12). The overall diagnostic yield of the sequential approach was 79% (27/34) and that of the selective approach was 74% (25/34). There was no significant difference in the overall diagnostic yields. Significantly fewer combined diagnostic procedures (6% *vs* 32%,  $P < 0.05$ ) were required with the selective approach. The yield of TBNA was higher with the selective approach (73%) as compared to the sequential approach (62%). There were no complications with either TBNA or EUS-FNA, or damage to the bronchoscopes or endoscopes.

## DISCUSSION

The present study compared a diagnostic approach utilizing TBNA as the first diagnostic procedure with one in which EUS-FNA or TBNA was selected as the first procedure. The selection was based on whether the optimal anatomical approach was transesophageal or transbronchial. We found a higher diagnostic yield after the first diagnostic procedure with the selective approach, and this translated to a significant reduction in the number of diagnostic procedures performed.

The transesophageal and transbronchial routes to the mediastinum are complementary. The transesophageal approach has limited access to the right paratracheal nodes, therefore, the endobronchial route offers better access, as shown by Herth *et al*<sup>9</sup>. Therefore, the procedure of choice for right paratracheal lymphadenopathy with the selective approach was TBNA, unless CT showed a peri-esophageal location of these nodes that was easily accessed by EUS-FNA (Figure 3). Harrow *et al*<sup>10</sup> also have shown that the right paratracheal and subcarinal locations are predictors of a positive aspirate with TBNA. With the selective approach, TBNA was limited to these two locations, and the yield of TBNA improved from 62% to 73%.

Although mediastinoscopy remains the diagnostic standard for the mediastinal staging of lung cancer, with a sensitivity of 80%-85%, this invasive surgical procedure requires general anesthesia and has a morbidity and mortality rate of 2% and 0.08%, respectively<sup>[11]</sup>. In contrast, both TBNA and EUS-FNA are minimally invasive and can be performed in the outpatient setting under local anesthesia and sedation. EUS-FNA permits real-time visualization of needle sampling and has been shown to be highly accurate in the mediastinal staging of lung cancer, as well as in the diagnosis of mediastinal lymphadenopathy of unknown etiology<sup>[6,12-18]</sup>.

The development of EBUS-TBNA for mediastinal lymph nodes has lagged behind EUS-FNA by more than a decade<sup>[19,20]</sup>. As such, the new convex-probe EBUS is still not as widely available as EUS. Wallace *et al*<sup>[21]</sup> have suggested that the use of ultrasound-guided needle sampling of mediastinal lymph nodes in patients with suspected lung cancer, whether by EUS or EBUS, is superior to conventional TBNA. By combining EUS-FNA and EBUS-TBNA, they have achieved a near-complete medical mediastinoscopy, thus reinforcing the complementary nature these procedures<sup>[22]</sup>.

Our aim was not to achieve comprehensive staging of the mediastinum in the setting of lung cancer, but

rather, to demonstrate that, with appropriate selection of the first endoscopic procedure, a higher diagnostic yield could be obtained. This would mean that EUS-FNA could be selected as the first procedure, rather than routinely subjecting all patients to bronchoscopy. Indeed, a recent meta-analysis has suggested that EUS-FNA is the diagnostic test of choice for mediastinal lymphadenopathy<sup>[23]</sup>. In addition, the transesophageal route may be better tolerated as compared to the transbronchial route, with less coughing and the absence of obstruction of the needle by cartilaginous rings.

Most studies with EUS-FNA for mediastinal evaluation have been performed in patients only after confirmation of the diagnosis of NSCLC. Singh *et al*<sup>[24]</sup>, however, have demonstrated that EUS-FNA may be performed as the first diagnostic procedure for suspected lung cancer. In the setting of mediastinal lymphadenopathy in NSCLC, this diagnostic procedure also has enabled simultaneous mediastinal staging. Thus, besides showing that bronchoscopy need not be the first diagnostic procedure in patients with suspected lung cancer, they also have demonstrated that diagnosis and staging of lung cancer need not be performed sequentially or require multiple procedures. This highlights a paradigm shift where mediastinal staging is no longer performed only after confirming the diagnosis of NSCLC.

We believe that, in the diagnostic approach to the mediastinum, the transesophageal and transbronchial routes are complementary rather than competing. Instead of pitting TBNA against EUS-FNA, this study emphasizes that the complementary value of these endoscopic approaches is best exploited by appropriate procedure selection. Thus, when either EUS-FNA or TBNA was selected as the first procedure, the diagnostic yield increased from 62% to 71%, thereby significantly reducing the need for additional procedures. Targeting the mediastinum first to enable simultaneous diagnosis and staging, and optimizing the yield of the first diagnostic procedure may lead to fewer delays in the treatment of lung cancer patients. Devbhandari *et al*<sup>[25]</sup> have reported that a negative initial bronchoscopy in suspected lung cancer resulted in significant delays in diagnosis and treatment. In that study, initial bronchoscopy was diagnostic in less than 50% of cases.

The present study had several limitations. Firstly, this was not a randomized trial and the patient population was small. However, they were consecutive patients with similar baseline characteristics and diagnostic categories (Table 1). Secondly, a definitive diagnosis could not be made in all cases because some patients and their referring physicians declined further invasive surgical sampling. However, the aim of this study was to determine the diagnostic yield of the sequential and selective approaches rather than the accuracy of either endoscopic procedure. Thirdly, conventional TBNA was employed rather than EBUS-TBNA. This was because at the time of the study, EBUS-TBNA was not available at our center.

Three practical clinical points are highlighted here. Firstly, the cytopathological diagnosis of mediastinal lymphadenopathy may be achieved in the majority of

patients utilizing widely available endoscopic techniques. Secondly, targeting the mediastinum first may establish simultaneously diagnosis as well as mediastinal staging for patients with NSCLC. Finally, appropriate selection of the first diagnostic procedure may optimize the yield and minimize the number of procedures required for the diagnosis and/or staging of mediastinal lymphadenopathy. Thus, with the availability of EUS-FNA, bronchoscopy may no longer be required in selected patients with suspected lung cancer.

Endoscopic techniques are becoming essential high-utility tools in the investigative approach to the mediastinum. With the rapid evolution of newer endoscopic techniques, the physician's diagnostic armamentarium is likely to expand. The question of which is the most appropriate initial diagnostic procedure for mediastinal lymphadenopathy, given what is available, will become even more important. While awaiting further studies comparing the different emerging endoscopic techniques and combination of techniques, we suggest that the optimal diagnostic approach for mediastinal lymphadenopathy depends on selection of the most appropriate initial diagnostic procedure.

## COMMENTS

### Background

In the absence of distant metastasis, mediastinal staging remains crucial for determining prognosis and therapy of non-small cell lung cancer. An approach to patients with mediastinal lymphadenopathy regardless of whether a lung mass is present, is to target the mediastinum first. This may achieve simultaneous diagnosis and mediastinal staging with a single procedure, in the event of diagnosis of lung cancer, which is the commonest cause of mediastinal lymphadenopathy.

### Research frontiers

The transbronchial and transesophageal routes allow minimally invasive endoscopic needle sampling of mediastinal lymph nodes. These endoscopic procedures may be done under sedation in contrast to the gold standard mediastinoscopy, which requires general anesthesia.

### Innovations and breakthroughs

Minimally invasive mediastinal staging with endoscopic ultrasound-guided fine-needle aspiration and blind or endobronchial ultrasound guided transbronchial-needle aspiration may be a substitute for mediastinoscopy.

### Applications

Not all patients require all three procedures, therefore, appropriate initial procedure selection may be important in the diagnostic approach to mediastinal lymphadenopathy, because only a single procedure may be diagnostic in the majority of cases.

### Peer review

This is a very interesting topic for the readers of *World Journal of Gastroenterology*.

### Abstract

**AIM:** To evaluate whether adding azithromycin to first-line *Helicobacter pylori* (*H pylori*) eradication improved eradication and reduced side effects.

**METHODS:** Eligible articles were identified by searches of electronic databases. We included all randomized trials that compared azithromycin-containing with standard triple-therapy regimens for first-line treatment of *H pylori* infection. Statistical analysis was performed with Review Manager 5.0.10. Sub-analyses were also performed.

**RESULTS:** We identified 14 randomized trials (1431 patients). Pooled *H pylori* eradication rates were 72.01% (95% CI: 58.09%-85.93%) and 69.78% (95% CI: 66.47%-73.09%) for patients with or without azithromycin by intention-to-treat analysis, and the odds ratio (OR) was 1.17 (95% CI: 0.64-2.14). The occurrence of side effects differed significantly and was 15.81% (95% CI: 12.50%-19.12%) and 25.20% (95% CI: 21.44%-28.96%) for treatment with or without azithromycin, respectively, and the summary OR was 0.58 (95% CI: 0.41-0.82). Furthermore, the azithromycin-containing group had a lower occurrence of diarrhea, nausea and taste disturbance.

**CONCLUSION:** Our review suggests that azithromycin-containing triple-therapy regimens could be equally effective in eradication of *H pylori* compared with standard first-line triple-therapy regimens.

### INTRODUCTION

Infection caused by *Helicobacter pylori* (*H pylori*), one of the most common pathogens worldwide, causes chronic gastritis and increases the risk of peptic ulcer and gastric cancer. Although some *H pylori*-positive individuals are asymptomatic, many experience symptoms such as dyspepsia. It is increasingly common to screen patients, even those with mild symptoms, for *H pylori* infection, and to treat them actively. The first-line treatment for *H pylori* infection, as recommended by the Maastricht III Consensus Report, is 7-d triple therapy that includes clarithromycin, amoxicillin and a proton-pump inhibitor (PPI)<sup>[1]</sup>. Even though this triple therapy is effective and its short duration helps maintain patient compliance, a considerable number of patients experience undesirable side effects.

In first-line therapy, eradication rates using combinations of PPI-based triple therapies range from 75% to 98%, with most of them near 80%<sup>[2]</sup>. This signifies that up to 20% of patients are expected to be treatment failures, a value which could be even higher in areas with a high prevalence of resistant *H pylori* strains. The recommended second-line therapy is a quadruple regimen composed of tetracycline, metronidazole, bismuth salts and a PPI; however, the efficacy of this regimen is limited by poor compliance, treatment duration, number and dose of the prescribed drugs, and bacterial antibiotic resistance.

Gastroenterologists and microbiologists continue the search for new therapies because of the increasing number of target subjects for *H pylori* and the physiological and pharmacoeconomic burden of a second course of therapy.

Among the new options against *H pylori* brought to light recently, azithromycin has attracted substantial interest. Azithromycin is a macrolide antibiotic that has been shown to reach high concentrations in gastric tissue after oral administration; furthermore, these high concentrations are maintained for several days, which make it potentially useful in the eradication of *H pylori*<sup>3]</sup>. Clinical trials with triple therapy regimens that contain azithromycin have reported eradication rates of approximately 60%-80%, depending on the regimen and azithromycin dose used<sup>14,5]</sup>. However, results from some other available trials utilizing azithromycin have yielded conflicting results. The primary aim of the present meta-analysis was to evaluate whether adding azithromycin to *H pylori* eradication regimens could improve eradication and reduce side effects.

## MATERIALS AND METHODS

### Selection of studies

Studies evaluating azithromycin-containing triple therapy for the eradication of *H pylori* were considered. For the meta-analysis, the selection criteria were as follows: (1) articles that reported comparative randomized controlled trials (RCTs); (2) studies had to include at least two branches of treatment that consisted of (a) triple first-line therapy (one PPI and two antibiotics) and (b) azithromycin-containing triple regimen; (3) study population consisted of subjects who had never been treated for *H pylori* infection previously; and (4) data for successful eradication and/or side effects were available.

### Search strategy for identification of studies

Trials were identified by searching the Cochrane Controlled Trials Register (Issue 2, 2009), PubMed (1966 to May 2009), Embase (1980 to May 2009), Science Citation Index (1945 to May 2009) and the Chinese Biomedical Database (1981 to May 2009). A search strategy was constructed by using a combination of the following words: (*Helicobacter pylori* OR *H pylori*) AND (azithromycin). Articles published in any language were included. Reference lists from the trials selected by electronic searching were hand-searched to identify further relevant trials. We also conducted a manual search of abstracts from 1995 to May 2009 from the following congresses: International Workshop of the European Helicobacter Study Group, American Digestive Disease Week (DDW), and United European Gastroenterology Week (UEGW). Abstracts of the articles selected in each of these multiple searches were reviewed and those meeting the inclusion criteria were recorded. References of reviews on *H pylori* treatment with azithromycin, and from the articles selected for the study, were also examined for articles that met the inclusion criteria. Authors of some identified trials were asked whether they knew of additional studies, including unpublished randomized ones. In case of duplicate reports, or studies obviously reporting results from the same study population, only the latest published results were used.

### Data extraction

Standardized data abstraction sheets were prepared.

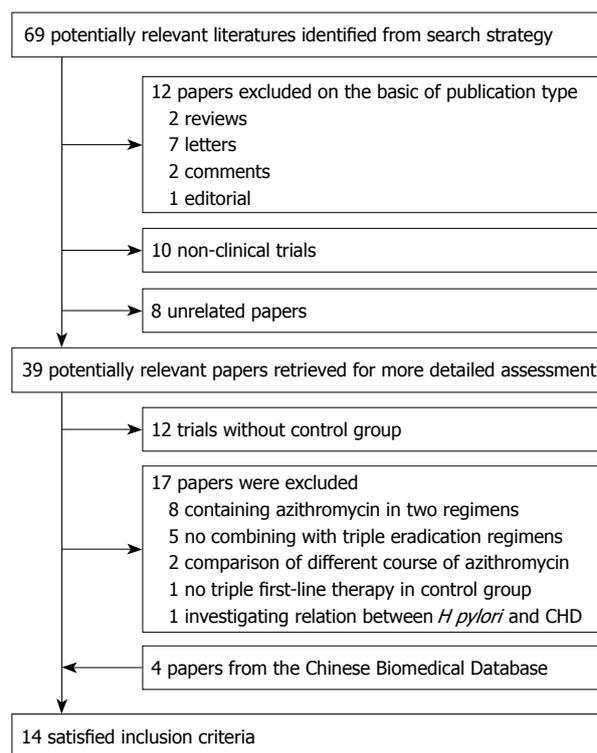

Figure 1 Flowchart of study selection. *H pylori*: *Helicobacter pylori*.

Data were exacted for study quality, dose and duration of azithromycin treatment, anti-*H pylori* regimens, and the number, sex and age of enrolled subjects, diagnostic methods of testing *H pylori* infection before enrolling and after completing the study, and scoring systems for assessing side effects. Key outcome data, such as eradication rates, occurrence of diarrhea, nausea, taste disturbance and abdominal pain were abstracted from all included studies. All articles were examined independently for eligibility by two reviewers. Disagreements were resolved by consulting a third reviewer. Quality was assessed using the Jadad score system based on three items, randomization, double blinding and description of withdrawals/dropouts. We considered that they were low quality when scores were < 3.

### Data synthesis

Data were entered into the Cochrane Collaboration review manager programme RevMan 5.0.10 (released on May 16, 2008). The outcome measure examined was the OR of improving *H pylori* eradication rates and reducing side effects with azithromycin compared to without azithromycin-containing triple regimens. Categorical variables were compared with the  $\chi^2$  test, and  $P < 0.05$  was considered statistically significant. Eradication rates and side effects were analyzed based on a fixed-effects model using the methods of Mantel-Haenszel<sup>6]</sup>, both by intention-to-treat and per-protocol. Heterogeneity between the studies was assessed by  $\chi^2$  test. Statistical significance of heterogeneity was set at 0.10. If significant heterogeneity existed, it would have been inappropriate to combine the data for further analysis using a fixed-effects model, while the random model was used for calculations.

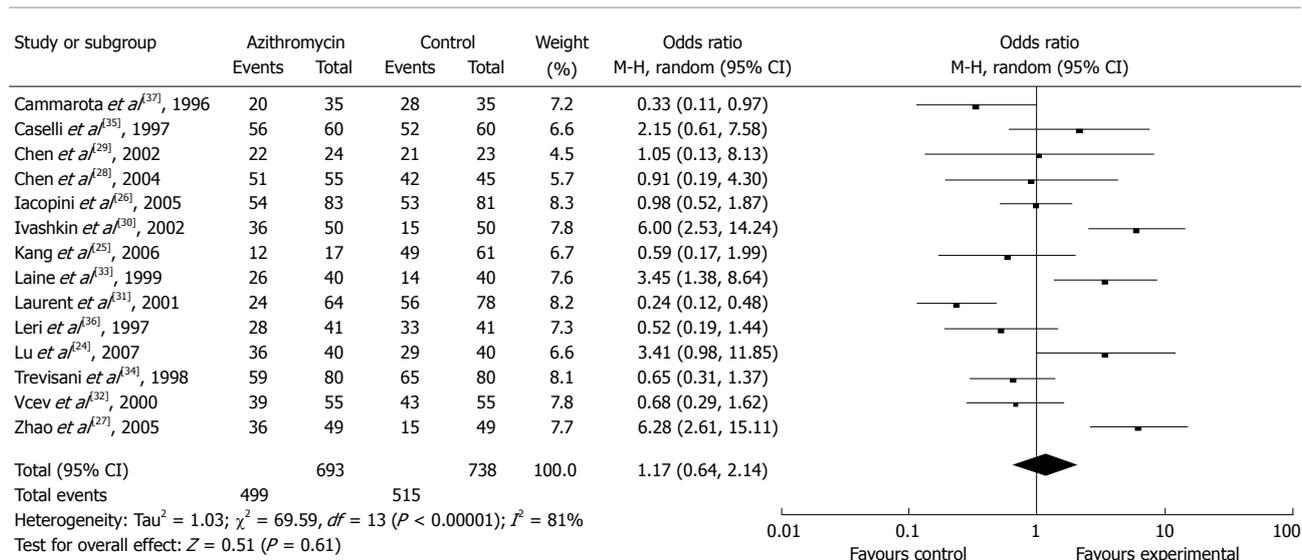

Figure 2 Effect of azithromycin-containing triple therapy versus standard triple therapy on eradication rates by intention-to-treat analysis.

### Sub-analyses

In the meta-analysis, sub-analyses of *H pylori* eradication efficacy were planned, depending on: (1) the type of drugs co-prescribed with azithromycin (combination with amoxicillin and a PPI was the most widely prescribed); (2) the duration and dose of azithromycin therapy; (3) age of the subjects involved; and (4) quality of the studies (based on quality score proposed by Jadad, see appropriate section). Finally, we used funnel plot asymmetry to detect any publication bias in the meta-analysis, and Egger's regression test to measure funnel plot asymmetry.

## RESULTS

### Description of the studies

The bibliographical search yielded a total of 69 studies. Of these, 12 articles were excluded owing to publication type, i.e. two reviews, seven letters, two comments, and one editorial. We excluded 18 articles (10 non-clinical trials and eight unrelated articles) after examining the title and abstract, which left 39 potentially relevant articles for more detailed assessment. Of these potential eligible articles, 12 trials without a control group were excluded, and then we excluded another 17 articles, because of no combining with triple eradication regimens<sup>[7-11]</sup>, containing azithromycin in two regimens<sup>[12-19]</sup>, comparison of different treatment course of azithromycin<sup>[20,21]</sup>, no triple first-line therapy in control group<sup>[22]</sup>, and investigating relation between *H pylori* eradication and coronary heart disease<sup>[23]</sup>. Furthermore, we identified four additional articles from the Chinese Biomedical Database (1981 to May 2009). Finally, 14 RCTs met the inclusion criteria<sup>[24-37]</sup>. The flowchart of reviews showed the detailed process of selection (Figure 1). The characteristics of 14 trials included in the meta-analysis are summarized in Table 1, including quality score.

### Eradication rates

Fourteen studies that described *H pylori* eradication rates were selected for the meta-analysis. Four of these

reported significantly improved eradication rates, and the remaining 10 had similar efficacy for *H pylori* eradication. Pooled eradication rates were achieved in 499 of 693 patients with azithromycin supplementation (72.01%, 95% CI: 58.09%-85.93%) and in 515 of 738 patients with azithromycin without regimen (69.78%, 95% CI: 66.47%-73.09%) by intention-to-treat analysis, the OR was 1.17 (95% CI: 0.64-2.14) (Figure 2). Overall, per-protocol eradication rates were 75.81% (95% CI: 72.44%-79.18%) and 72.44% (95% CI: 69.05%-75.83%) for azithromycin supplementation and azithromycin without regimen, respectively (OR 1.22, 95% CI: 0.61-2.43).

### Side effects

Total side effects were initially performed for meta-analysis. Data for the occurrence of side effects were obtained from 10 RCTs. Five of these studies reported a significant decrease in the occurrence of gastrointestinal side effects. The total number of side effects with azithromycin supplementation differed significantly from azithromycin without regimen: 15.81% (95% CI: 12.50%-19.12%) and 25.20% (95% CI: 21.44%-28.96%), and the summary OR was 0.58 (95% CI: 0.41-0.82) (Figure 3A). Individual symptoms during eradication therapy, such as nausea, diarrhea, abdominal pain, and taste disturbance were also analyzed. Incidence of diarrhea (2.13% *vs* 6.98%) (Figure 3B), nausea (3.85% *vs* 10.14%) (Figure 3C) and taste disturbance (3.17% *vs* 11.05%) (Figure 3D) were lower in the azithromycin supplementation group (OR: 0.33 *vs* 0.37 *vs* 0.28, 95% CI: 0.12-0.96 *vs* 0.14-0.96 *vs* 0.11-0.70).

### Sub-analyses

Sub-analyses for the meta-analysis were planned depending on subject age, symptoms before enrollment, course of azithromycin, and choice of antibiotics. We divided all eligible trials into long- and short-course subgroups, Az+A subgroup, Az+Lev subgroup and Az+M/T subgroup. There was no significant difference between the long-course and short-course subgroups; the summary ORs were 0.89 (95% CI: 0.43-1.85) and 1.56 (95% CI:

0.60-4.08), respectively (Figure 4A). For antibiotics sub-analysis, Az+A subgroup, Az+Lev subgroup and Az+M/T subgroup all had no significant difference; the summary ORs were 1.11 (95% CI: 0.32-3.89), 1.19 (95% CI: 0.51-2.81) and 1.20 (95% CI: 0.53-2.69), respectively (Figure 4B).

**Publication bias**

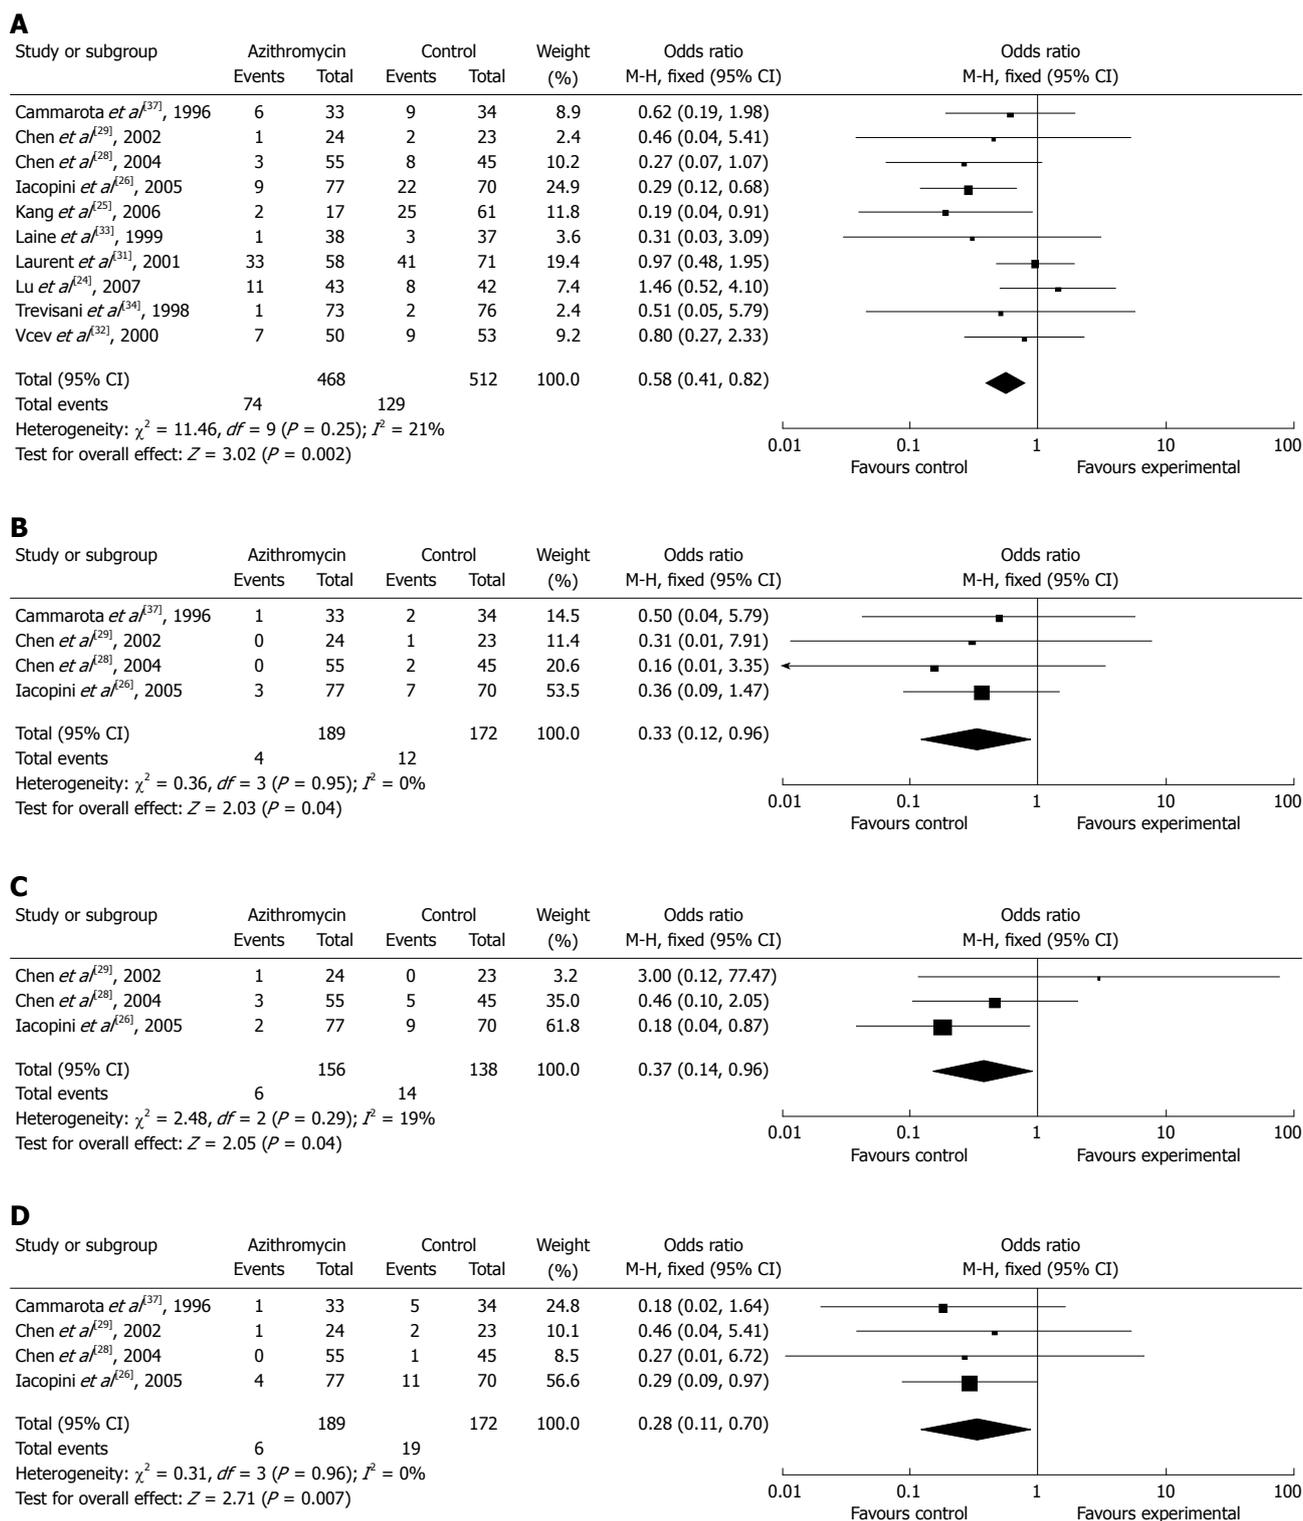

We found that the funnel plot had a slightly asymmetrical distribution, but Egger’s regression test<sup>[38]</sup> suggested no significant asymmetry of the funnel plot (P = 0.84), which indicated no evidence of substantial publication bias.

**DISCUSSION**

For *H pylori* eradication therapy, clinical trails are undertaken to search for simpler but equally or more effective regimens. The modern macrolides are a focus of attention from that point of view. Azithromycin, a new-generation macrolide, has some special attributes that make it a promising compound in regimens for *H pylori* eradication. Following the administration of a single oral dose, azithromycin readily accumulates in the human gastric mucosa, subsequently redistributes from mucosal tissue to the mucus layer, and from the mucus to gastric juice. There, it reaches gastric tissue concentrations that persist above the minimal concentration for 90% inhibition (MIC<sub>90</sub>) for *H pylori* (0.25 µg/mL) over a 5-d period, thus leading to exposure of the microorganism to consistent amounts of this drug. The high tissue affinity and the absorption of the drug after oral administration are reduced when given during or after a meal. The pharmacological properties of azithromycin make it possible to use shorter courses, therefore, the problem was to define an optimal dose and duration of azithromycin in triple therapy.

Azithromycin is able to reach high gastric concentrations that persist for several days, and therefore, it can be administered at a dose of 500 mg once daily for only 3 d during a 7-d triple eradication regimen. The published trials that have used this antibiotic have yielded conflicting results, and have reported a wide range of eradication rates. Administration with meals markedly reduces azithromycin absorption, therefore, this might account for the low eradication rates observed in some studies<sup>[21]</sup>. In treatment regimens in which azithromycin was given to fasting patients, the cure rate was in the range 86%-93%<sup>[13,37]</sup>. Recently, short-term treatments of only 3 d, using a PPI plus azithromycin 500 mg and tinidazole 1000-2000 mg daily, have been found to promote eradication in 81%-88% of cases<sup>[23,39]</sup>. In contrast with the results reported in early studies that have used azithromycin for 2 wk and in repeated daily doses<sup>[40]</sup>, side effects are scarce if the drug is administered once daily for a few days. In subanalyses, we also found that *H pylori* eradication rate had no significant difference between the long-course and short course subgroups.

*H pylori* eradication depends on a number of factors, including patient compliance, side effects, bacterial resistance, poor drug distribution or concentration, geographic differences, and socio-economic conditions. Optimization of *H pylori* eradication therapy remains an

**Figure 3** Effect of azithromycin-containing triple therapy versus standard triple therapy on the incidence of total side effects (A), diarrhea (B), nausea (C), and taste disturbance (D).

ongoing challenge worldwide. Although a great deal of research has focused on treatment of *H pylori* since the discovery of its crucial role in gastrointestinal disease, currently up to 25% of patients enrolled in clinical trials are treatment failures, even using the widely accepted and efficacious regimens that have gained inclusion in consensus guidelines<sup>[41]</sup>. A disappointing cure rate of < 80% after 7-d triple therapy was confirmed in

the present study. Guidelines often suggest that an acceptable success rate for a particular therapy against *H pylori* infection should be > 80% on an intention-to-treat basis. However, clinical trials with azithromycin have displayed considerable variation with respect to the regimens used and the results obtained. Eradication rates varying between 93% and 22% have been reported<sup>[20,30,42]</sup>. The results of our meta-analysis demonstrated pooled

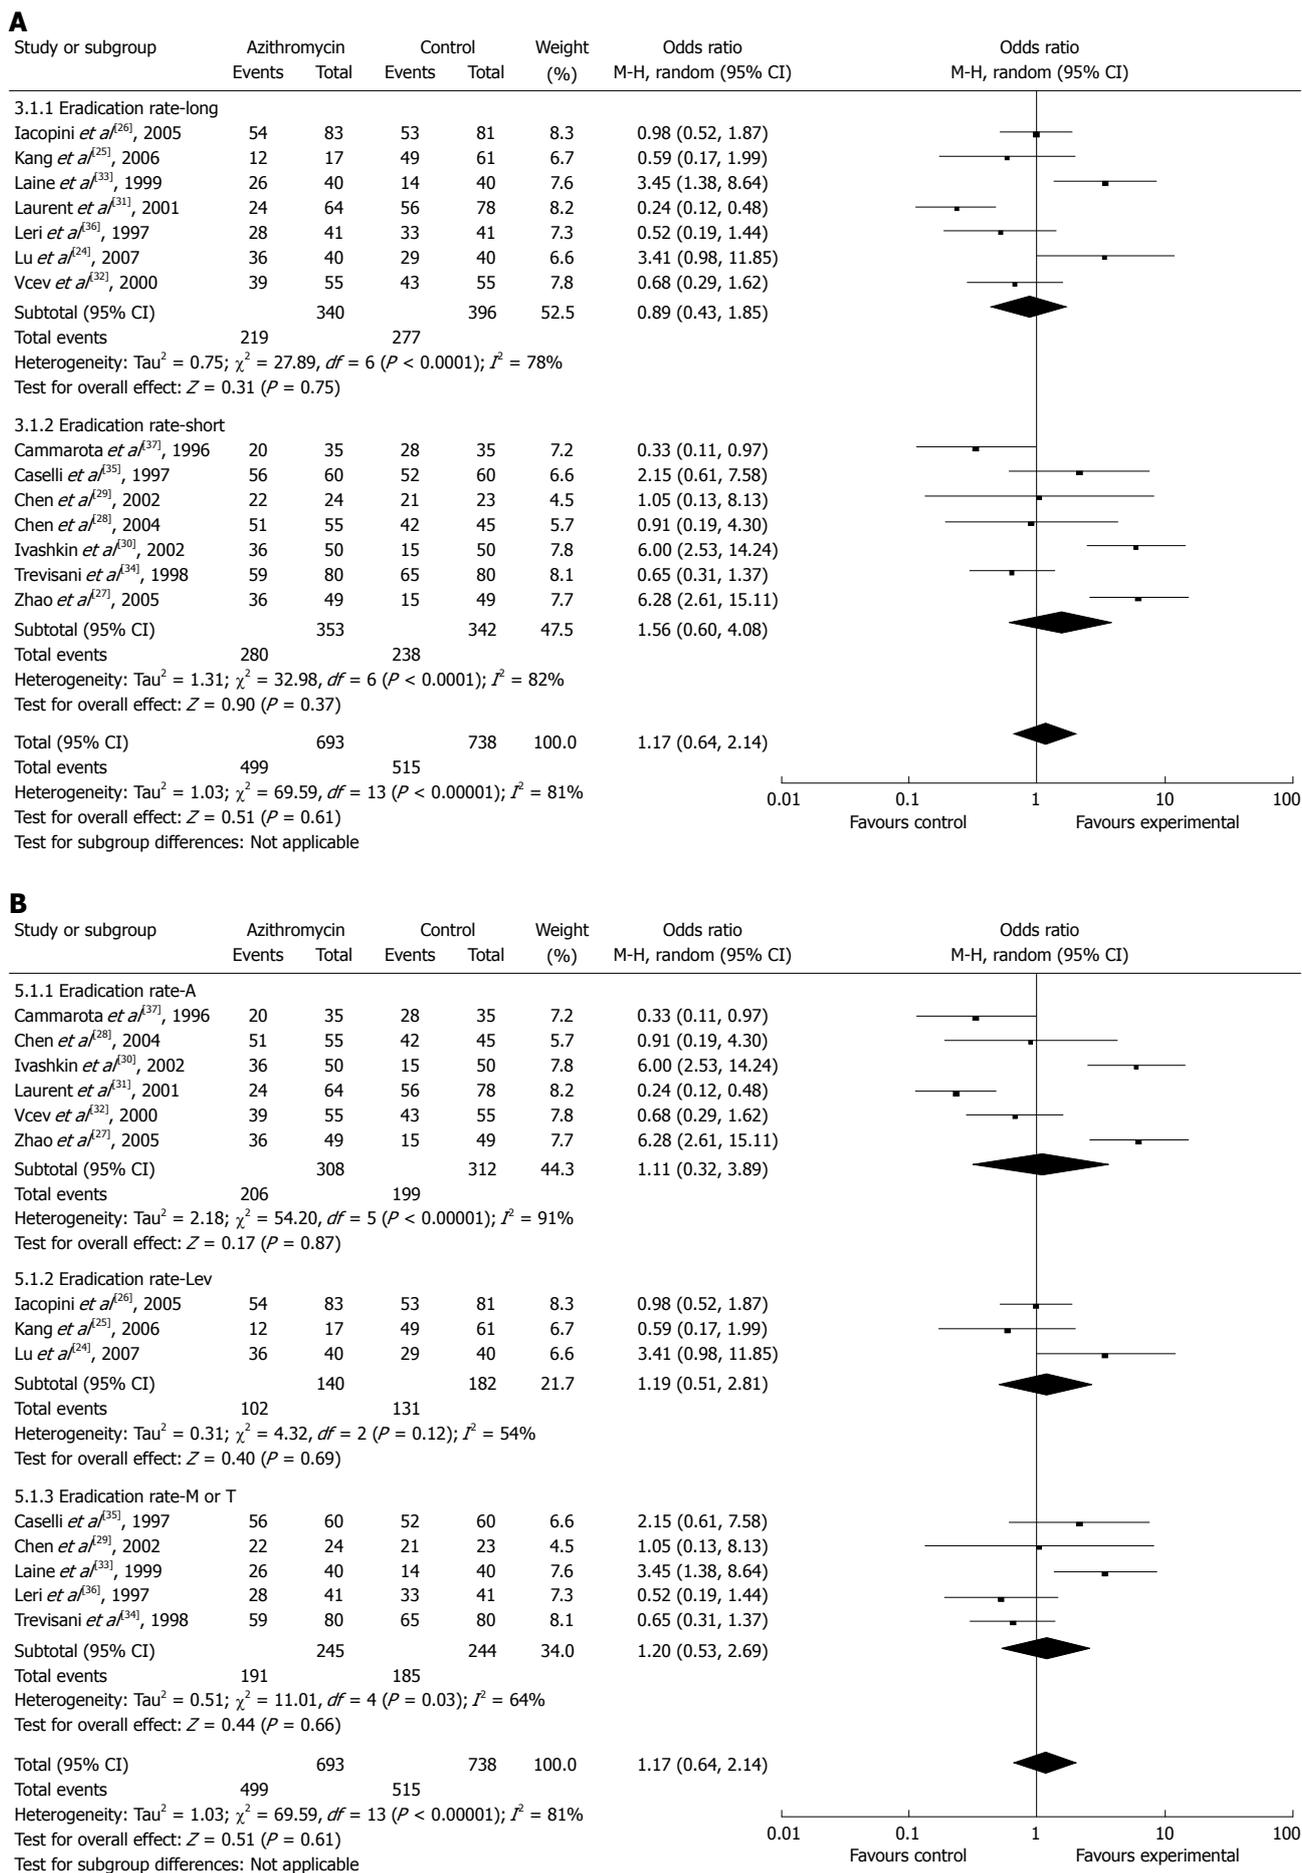

Figure 4 Meta-analysis of eradication rates by treatment course (A) and different antibiotics (B).

*H pylori* eradication rates were 72.01% and 69.78% for patients with or without azithromycin by intention-to-treat analysis, respectively, and no significant difference was observed between the two regimens.

*H pylori* has cross resistance to macrolides; e.g. a strain that is resistant to clarithromycin is resistant to every other macrolide. The level of clarithromycin resistance is unfortunately showing a tendency to increase. The effect of drug synergism is of great value in combination treatment to heal *H pylori* infection. Lepper *et al*<sup>[43]</sup> have demonstrated an *in vitro* synergistic effect of azithromycin and the PPI lansoprazole. They have speculated that this effect might enhance eradication rates even with macrolide-resistant *H pylori* strains, because of the unique pharmacological properties of the combination. Azithromycin could provide a potent anti-*H pylori* effect and could simplify the bulky triple therapy.

Antibiotic-associated gastrointestinal side effects such as diarrhea, nausea, vomiting, bloating and abdominal pain represent a serious drawback of anti-*H pylori* therapy, although they are mild in most cases, but usually result in non-compliance. The quadruple regimen is associated with a relatively high incidence of side effects. In contrast, azithromycin is generally well tolerated, and most side effects associated with its use are mild to moderate in severity and transient. In our systematic review, we found that the total number of side effects with azithromycin supplementation was significantly lower than with azithromycin without regimen: 15.81% *vs* 25.20%; the summary OR was 0.58 (95% CI: 0.41-0.82). Moreover, the incidence of diarrhea (2.13% *vs* 6.98%), nausea (3.85% *vs* 10.14%) and taste disturbance (3.17% *vs* 11.05%) were lower in the azithromycin supplementation group. Our results showed that azithromycin had a positive impact on some *H pylori* therapy-related side effects. Several methodological weaknesses may limit the validity and generalizability of our meta-analysis. For example, there were no studies involving patients from Africa and South America.

In summary, the conclusion of this systematic review and meta-analysis is that, for first-time treatment, azithromycin-containing triple therapy has equal efficacy to that of standard triple eradication therapy. A combination of azithromycin, amoxicillin and a PPI constitutes an encouraging empirical first-line strategy. Furthermore, azithromycin-containing triple therapy showed a lower occurrence of drug-related side effects.

## COMMENTS

### Background

Colonization with *Helicobacter pylori* (*H pylori*) causes a wide range of upper gastrointestinal disorders in humans. Unfortunately, eradication therapy is not always successful, and can even induce several side effects. Azithromycin has some special attributes that make it a promising compound in the regimens for *H pylori* eradication.

### Research frontiers

In first-line therapy, *H pylori* eradication rates using proton-pump inhibitor (PPI)-based triple therapy are about 80%. This signifies that up to 20% of patients are expected to be treatment failures and it could be even higher in areas with a high prevalence of resistant *H pylori* strains. In this study, the authors demonstrated that, for first-time treatment, azithromycin-containing triple therapy has equal efficacy to standard triple eradication therapy.

## Innovations and breakthroughs

Recent studies have shown that azithromycin is a promising compound in regimens for *H pylori* eradication. Our meta-analysis demonstrated that azithromycin-containing triple therapy has equal efficacy to standard triple eradication therapy, and has a lower occurrence of side effects. A combination of azithromycin, amoxicillin and a PPI constitutes an encouraging empirical first-line strategy.

## Applications

By understanding the effect of azithromycin in *H pylori* eradication, this study represents a new encouraging strategy for first-time treatment, and it could decrease the physiological and pharmacoeconomic burden of second courses of therapy.

## Terminology

Azithromycin is a new-generation macrolide and has some special attributes. It is able to reach high gastric concentrations that persist for several days, and therefore may be administered at a dose of 500 mg once daily for only 3 d during 7-d triple eradication therapy.

## Peer review

The authors performed a meta-analysis and demonstrated that azithromycin-containing triple therapy has equal efficacy to standard triple *H pylori* eradication therapy. This was an original and good study.

### Abstract

**AIM:** To analyze the performance value of high risk factors in population-based colorectal cancer (CRC) screening in China.

**METHODS:** We compared the performance value of the immunochemical fecal occult blood test (iFOBT) and other high risk factors questionnaire in a population sample of 13214 community residents who completed both the iFOBT and questionnaire investigation. Patients with either a positive iFOBT and/or questionnaire were regarded as a high risk population and those eligible were asked to undergo colonoscopy.

**RESULTS:** The iFOBT had the highest positive predictive value and negative predictive value in screening for advanced neoplasia. The iFOBT had the highest sensitivity, lowest number of extra false positive results associated with the detection of one extra abnormality for screening advanced neoplasias and adenomas. A history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, and chronic diarrhea also had a higher sensitivity than a history of adenomatous polyps in screening for advanced

neoplasias and adenomas. The sensitivity of a history of chronic cholecystitis or cholecystectomy was highest among the 10 high risk factors in screening for non-adenomatous polyps. A history of chronic appendicitis or appendectomy, chronic constipation, chronic diarrhea, mucous and bloody stool, CRC in first degree relatives, malignant tumor and a positive iFOBT also had higher sensitivities than a history of adenomas polyps in screening for non-adenomatous polyps. Except for a history of malignant tumor in screening for non-adenomatous polyps, the gain in sensitivity was associated with an increase in extra false positive results associated with the detection of one extra abnormality.

**CONCLUSION:** The iFOBT may be the best marker for screening for advanced neoplasias and adenomas. Some unique high risk factors may play an important role in CRC screening in China.

### INTRODUCTION

The incidence of colorectal cancer (CRC) is increasing rapidly, and there is a similar incidence in some Asian populations to that in Western countries because of a more "Westernized" lifestyle and dietary habits<sup>[1]</sup>. A relatively long time for malignant transformation, together with improved survival associated with early detection of cancer, makes CRC an ideal target for screening. In source-limited Asian countries, the fecal occult blood test (FOBT) is the first choice for CRC screening because of its better population impact<sup>[1]</sup>. However, bleeding from cancers and precancerous polyps may be intermittent and

most small colorectal neoplasias do not tend to bleed<sup>[2]</sup>. Therefore, the immunochemical FOBT (iFOBT) alone inevitably misses some important lesions that do not bleed, or bleed intermittently. The iFOBT and a high risk factors questionnaire approach as primary screening followed by full colonoscopy examination as follow-up screening, has been recommended by the Department of Disease Control, the Ministry of Health of China as the protocol for population-based CRC screening in China<sup>[3]</sup>. However, the performance value of the iFOBT and a high risk factors questionnaire is still unknown in CRC screening practice in China. According to the definition of high risk factors by American Cancer Society<sup>[4]</sup>, individuals at higher risk for CRC include "individuals with a history of adenomatous polyps (HAP)". Therefore we used the data available in CRC screening practice in China to examine the performance value of each high risk factor using an acknowledged high risk factor - HAP - as a reference in CRC screening practice in China.

## MATERIALS AND METHODS

### CRC screening protocol in China

The CRC screening protocol of China has been published in a recent study<sup>[5]</sup>. Subjects (age should be defined as  $\geq 40$  years and  $\leq 74$  years) who have one or more of the following items are considered to be at high risk of CRC and should undergo colonoscopy: (1) Positive results from the iFOBT; (2) First-degree relatives with CRC; (3) A personal history of cancers or intestinal polyps; (4) 2 or more of the following items: (a) chronic diarrhea; (b) chronic constipation; (c) mucous and bloody stool; (d) history of appendicitis or appendectomy; (e) history of chronic cholecystitis or cholecystectomy; (f) history of psychiatric trauma (e.g. divorce, death of relatives).

### Study population

From July 2006 to December 2008, a screening program was implemented following the CRC screening protocol recommended by the Ministry of Health of China, for individuals aged 40-74 years in Xiacheng District, Hangzhou City, China. Among 33778 targeted residents, 16918 declined, 3646 participated only in the questionnaire investigation, and 13214 (39.1%) undertook both the iFOBT and questionnaire investigation.

### Study design

The 33778 subjects, aged 40-74 years, who lived in Xiacheng District were enrolled as the target population for our CRC screening practice. Therefore the targeted population can be classified into average, intermediate or high risk individuals. The targeted population was contacted by Chronic Disease Control (CDC) staff to explain the aim of the study, with an invitation to undergo both tests.

The aim of primary screening was to determine the high risk population among the targeted population by the iFOBT and questionnaire approach. Therefore the primary screening test kits included an iFOBT kit (Acon Biotech Co. Ltd., Hangzhou, China), a detailed instruction sheet, a consent form, and a questionnaire containing high

risk items. The iFOBT kit used is a qualitative method, with a hemoglobin detection threshold of 200 ng/mL. Participants were asked to prepare a fecal sample from 3 areas of a stool specimen. No specific dietary restriction was stipulated.

The study was approved by the local ethics committee and all participants gave written informed consent.

### Identification of high risk subjects

All participants learned how to use the iFOBT kit and how to fill in the questionnaire sheet under guidance of CDC staff. Feces samples were processed and results were obtained at the central laboratory of the local CDC. Processing and evaluation were not automated but were performed by trained staff and under strict quality control (double reading, control of frequency of positive tests, reproducibility). Scrutineers of the iFOBT were blinded to the subject's medical records. The screening procedure was considered positive when at least one of the tests was positive. All positive cases resulting from the primary screening were regarded as high risk subjects and those eligible were invited to the follow-up colonoscopy examinations. The CDC staff and primary care managers were responsible for inviting eligible high risk subjects for further colonoscopy examination.

### Colonoscopy examination

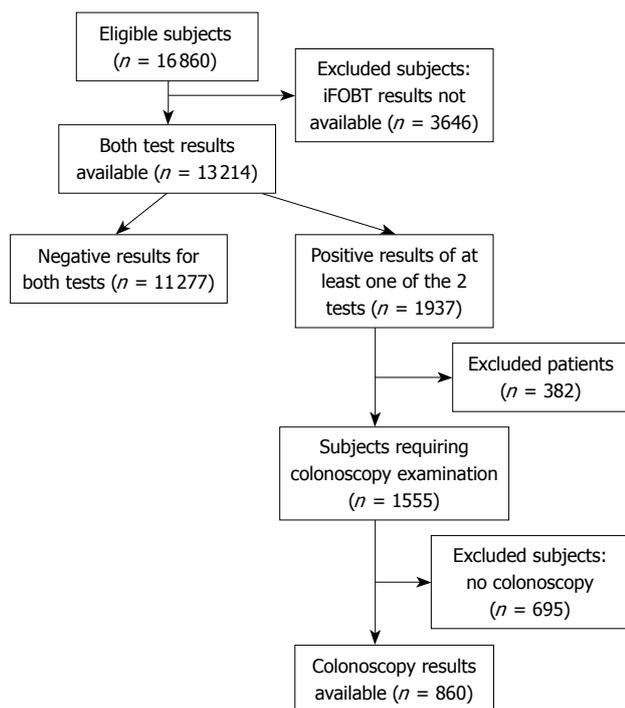

Colonoscopy examination was performed by gastroenterologists in endoscopy units of local hospitals and all participants gave written informed consent. The gastroenterologists recorded data using a standard form, including the quality of bowel preparation, the completeness of the colonoscopy, the number, size, and localization of any detected lesions, and the occurrence of complications. All polyps detected during the colonoscopy were immediately removed and/or biopsied for histologic diagnosis by pathologists. Those who were suspected of having CRC or had polyps that could not be removed endoscopically were referred for surgery. If a colonoscopy examination failed because of inadequate bowel preparation, inaccessibility of the cecum, or lack of satisfactory colonoscopy results, a subsequent colonoscopy would be performed within 1 mo.

### Pathologic examination

In subjects with more than one polyp, the most advanced pathological lesions or the largest lesion was included in the analysis. An advanced neoplasia was comprised of advanced adenomas (an adenoma measuring 10 mm or more in size, adenomas with high grade dysplasia, or an adenomas with villous component  $\geq 25\%$ ) and invasive cancer<sup>[6,7]</sup>. Non-adenomatous polyps included juvenile polyps, inflammatory polyps and hyperplastic polyps. Invasive cancer was defined as invasion by malignant cells through the muscularis mucosae. Intramucosal carcinoma and carcinoma *in situ* were categorized as high grade dysplasia. Pathologic slides of positive lesions were re-examined and diagnosed by consensus by pathologists.

### Statistical analysis

The population of participants in the primary screening

**Figure 1** Flow diagram of the study. iFOBT: Immunochemical fecal occult blood test.

comprised all patients who had given written consent ( $n = 16860$ ). Subjects who accepted only questionnaire investigation ( $n = 3646$ ) in the primary screening were excluded from the study. Subjects with at least one test positive ( $n = 1937$ ) were regarded as positive. A colonoscopy examination was not conducted in 382 subjects because of death, health problems, moving or other reasons. A further 695 subjects rejected a colonoscopy examination. Figure 1 provides a flow diagram of the study.

As the confirmatory procedure (colonoscopy examination) was restricted to subjects classified as positive in at least one of 2 tests (iFOBT and questionnaire examination) positive, the sensitivity of each high risk item could not be directly estimated. According to the theory originally suggested by Schatzkin *et al*<sup>81</sup>, we therefore compared the relative sensitivity (RSN) by calculating the ratio using HAP as reference. For example, if the number of true positive subjects for one high risk factor is denoted by  $m$  and the number of true positive subjects for HAP by  $n$ , RSN is calculated as  $m/n$ . Confidence intervals (95%) were calculated according to the formulae suggested by Cheng *et al*<sup>91</sup>. Using the theory recommended by Chock, the number of extra false positives associated with the detection of one extra true positive was denoted FP:TP, which was calculated as the ratio between the difference in the number of false positive subjects with one high risk factor versus HAP and the difference in the number of true positive subjects with one high risk factor versus HAP<sup>101</sup>.

## RESULTS

### Colonoscopic results of the iFOBT and questionnaire

A total of 21 CRC (2.4%) cases, 48 (5.6%) subjects with advanced adenomas, 147 (17%) subjects with adenomas,

**Table 1** Colonoscopy results of iFOBT and questionnaire  $n$  (%)

	Colorectal cancer	Advanced adenomas	Adenoma	Non-adenomatous polyps
iFOBT positive only	13 (61.9)	22 (45.8)	44 (29.9)	9 (16.7)
Both positive <sup>1</sup>	4 (19)	5 (10.4)	12 (8.2)	2 (3.6)
Only questionnaire positive	4 (19)	21 (43.8)	91 (61.9)	43 (79.7)
Total	21 (100)	48 (100)	147 (100)	54 (100)

<sup>1</sup>Both iFOBT and questionnaire positive. iFOBT: Immunochemical fecal occult blood test.

and 54 (6.3%) subjects with non-adenomatous polyps were detected in 860 colonoscopies. Table 1 shows colonoscopic results of the iFOBT and questionnaire. The iFOBT alone diagnosed 13 cases of cancer, 22 cases of advanced adenomas, 44 cases of adenomas, and 9 cases of non-adenomatous polyps while the questionnaire alone found 4 cases of CRC, 21 cases of advanced adenomas, 91 cases of adenomas, and 43 cases with non-adenomatous polyps. Four cases of CRC, 5 of advanced adenomas, 12 of adenomas, and 2 of non-adenomatous polyps were found in both positives. Table 2 shows the results of colonoscopy according to each high risk item. One perforation was recorded after colonoscopy (0.1%).

### The characteristics of the study population

Table 3 shows the characteristics of the study population. Of 13214 subjects who completed both the iFOBT and questionnaire investigation, 1937 had at least one positive test. The positive rate of the questionnaire investigation was markedly higher than that of the iFOBT (11.7% *vs* 3.6%). A colonoscopy examination was not conducted in 382 subjects (19.7%) because of death, health problems, or other reasons. A total of 860 (55.3%) subjects underwent colonoscopy. In subjects undergoing endoscopic examination, 60.3% were iFOBT positive only, 53.2% were questionnaire positive only, 64.9% were positive for both the iFOBT and questionnaire.

### Performance of high risk factors in screening for advanced neoplasia

Using HAP as the reference, the sensitivity of iFOBT was highest among all high risk factors. The sensitivities of history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, history of chronic diarrhea were also higher than that of HAP. The positive predictive value (PPV) and negative predictive value (NPV) of iFOBT were highest among all high risk factors for advanced neoplasias, but the gain in sensitivity was accompanied by an increase in FP:TP. The iFOBT had the lowest FP:TP ratio (Table 4).

### Performance comparison among high risk factors in screening for adenomas

Using HAP as standard, the sensitivity of iFOBT was also highest among 10 high risk factors. Higher sensitivities were also found in history of chronic appendicitis or appendectomy, chronic diarrhea, CRC in first degree relatives, and chronic cholecystitis or cholecystectomy. The

Table 2 Colonoscopy results of high risk questionnaire items

	Cancer	Advanced adenomas	Adenomas	Non-adenomatous polyps	Normal results
iFOBT	17	27	56	11	128
History of malignant tumor	1	3	9	7	41
Colorectal cancer (CRC) in first degree relatives	2	7	29	11	81
History of adenomatous polyps (HAP)	0	9	25	6	48
History of mucous and bloody stool	5	4	15	10	101
History of chronic diarrhea	2	10	29	10	120
History of chronic constipation	0	8	24	13	102
History of chronic appendicitis or appendectomy	3	9	33	14	122
History of chronic cholecystitis or cholecystectomy	3	14	50	19	169
History of psychiatric trauma	4	5	18	2	73

Table 3 Characteristics of the study population *n* (%)

	Subjects with 2 analyzable tests ( <i>n</i> = 13214)
Sex	
Male	5391 (40.8)
Female	7823 (59.2)
Age (yr)	
40-49	2711 (20.5)
50-59	4704 (35.6)
60-69	3683 (27.9)
70-74	2116 (16.0)
Positive items	
iFOBT	481 (3.6)
History of malignant tumor	172 (1.3)
CRC in first degree relatives	367 (2.8)
HAP	158 (1.2)
History of mucous and bloody stool	430 (3.3)
History of chronic diarrhea	709 (5.4)
History of chronic constipation	902 (6.8)
History of chronic appendicitis or appendectomy	1126 (8.5)
History of chronic cholecystitis or cholecystectomy	1538 (11.6)
History of psychiatric trauma	655 (5)

PPV of the iFOBT was 22.5%, just behind that of HAP (26%). The NPV of iFOBT was highest among all high risk factors. The gain in sensitivity was also accompanied by an increase in FP:TP ratio (Table 4).

### Performance comparison of high risk factors in screening for non-adenomatous polyps

Using HAP as standard, a history of chronic cholecystitis or cholecystectomy was the most sensitive marker in screening for non-adenomatous polyps. The sensitivities of other high risk factors except history of psychiatric trauma were also higher than that of HAP. The PPV of history of malignant tumor (10.6%) was highest among all high risk factors in screening for non-adenomatous polyps. Except for history of malignant tumor, the gain in sensitivity was accompanied by increase in the FP:TP ratio (Table 4).

## DISCUSSION

Colonoscopy is often regarded as the "gold standard" for detection of CRC<sup>[11,12]</sup>. Direct colonoscopy screening is the most accurate test for CRC. However because of its potential harm, acceptability<sup>[13]</sup>, availability, and expense<sup>[14]</sup>,

the use of colonoscopy as a one-step screening method for the whole targeted population is unpractical in China. The use of noninvasive screening tests in primary screening, such as iFOBT and questionnaire investigation, have been adopted as the large scale population screening program in China<sup>[15]</sup>. The iFOBT and questionnaire investigation focused on different aspects. The iFOBT can detect bleeding lesions and the questionnaire can find lesions which do not bleed or bleed intermittently. Thus they may have different performance in screening colorectal abnormalities. To the best of our knowledge, the current study is the first analysis comparing the performance value of high risk factors in mass CRC screening in China. Because confirmatory examination was limited to subjects who had at least one positive test, studies calculated the RSN and relative false-positive rate in comparing the 2 screening methods<sup>[16,17]</sup>.

Colorectal adenomatous polyps are recognized as pre-cancerous lesions and are responsible for most cases of CRC<sup>[18]</sup>. Thus far, the important indicator for transition from adenomas to cancer has been the pathologic characteristics of the advanced adenomas. Thus it is important to find advanced adenomas and block the adenoma-carcinoma sequence in CRC screening. The iFOBT had the highest PPV, NPV and RSN, and the lowest FP:TP ratio in screening for advanced neoplasias, indicating that the iFOBT may be superior to other factors in screening for advanced neoplasias. Though some studies in Asian countries have shown that iFOBT is effective in CRC screening<sup>[19,20]</sup>, iFOBT alone may not be enough in CRC screening, because iFOBT inevitably misses some important lesions which do not bleed or bleed intermittently. A history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, and chronic diarrhea also had higher sensitivity than HAP, indicating that these unique Chinese high risk factors can detect a larger number of advanced neoplasias. Some studies have found an increase in the risk of CRC following cholecystectomy for gallstones<sup>[21-27]</sup>. Cholecystectomy also influences the adenoma to cancer transition, ultimately predisposing to the development of CRC<sup>[28]</sup>. A study from France supported the hypothesis that the appendix, as a lymphoid organ, plays a protective role in colon carcinogenesis<sup>[29]</sup>. These unique Chinese high risk factors for CRC may play an important role in screening for advanced neoplasias because of their higher sensitivity, which contributed to detection of a greater number of advanced neoplasias.

**Table 4** Comparison of the performance of high risk factors in screening advanced neoplasias, adenomas, non-adenomatous polyps using HAP as reference

	Advanced neoplasias				Adenomas				Non-adenomatous polyps			
	PPV (%)	NPV (%)	RSN	FP:TP	PPV (%)	NPV (%)	RSN	FP:TP	PPV (%)	NPV (%)	RSN	FP:TP
iFOBT	17.70	95.70	4.9 (2.42-9.87)	2.29 (1.36-3.83)	22.50	85.10	2.24 (1.4-3.52)	2.58 (1.37-4.87)	4.40	93	1.8 (0.71-4.58)	16 (3.39-75.58)

CCC	5.80	87.40	1.9 (0.87-4.12)	15.13 (4.47-51.23)	16.90	82.80	2 (1.26-3.16)	4.84 (2.43-9.65)	6.40	93.80	3.2 (1.38-7.42)	9.3 (4.5-19.22)
HPT	7.60	91.80	1 (0.42-2.39)		15.30	82.60	0.72 (0.43-1.2)		1.70	93	0.33 (0.07-1.63)	

HMT: History of malignant tumor; FDR: History of CRC in first degree relatives; MBS: History of mucous and bloody stool; HCD: History of chronic diarrhea; HCC: History of chronic constipation; CAA: History of chronic appendicitis or appendectomy; CCC: History of chronic cholecystitis or cholecystectomy; HPT: History of psychiatric trauma; PPV: Positive predictive value; NPV: Negative predictive value; RSN: Relative sensitivity; FP:TP ratio: The ratio between the difference in the number of false positive subjects with one high risk factor *vs* HAP and the difference in the number of true positive subjects with one high risk factor *vs* HAP. Values for RSN and FP:TP are mean (95% CI). RSN > 1: Sensitivity of the high risk factor is greater than that of HAP.

It would be unsafe to ignore adenomas < 10 mm because 30% of cancer is derived from 6-9 mm adenomas<sup>[30]</sup>. The questionnaire detected a greater number of adenomas than the iFOBT in our screening study. We also found that the iFOBT still had the highest sensitivity among all high risk factors, followed by history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, and chronic diarrhea. The iFOBT may also be superior to other factors in screening for adenomas because of high PPV and NPV, high RSN and low FP:TP ratio. Higher sensitivities indicated the important performance value of these unique Chinese high risk factors.

A history of chronic cholecystitis or cholecystectomy was the most sensitive marker in screening for non-adenomatous polyps, followed by history of chronic appendicitis or appendectomy, and chronic constipation. Though subjects with non-adenomatous polyps were not regarded as having increased risk of CRC, these polyps do not require surveillance colonoscopy, they may serve as a precursor to CRC in subjects with specific genetic and other molecular characteristics<sup>[31-34]</sup>. Thus it would be unsafe to ignore these polyps.

The study had several drawbacks. Firstly, to evaluate screening test performances among the general population, the ideal is to obtain sensitivity and specificity for all individuals. Because only eligible high risk subjects were invited and only about 55% of population accepted the colonoscopy examination, these results may not be completely representative of the general population. Secondly, although all the study population accepted both the iFOBT and questionnaire investigation, the colonoscopy uptake rate of the iFOBT positive only was

higher than that of the questionnaire positive only. This would slightly overestimate the RSN of the iFOBT.

HAP, an acknowledged high risk factor was used as the reference to calculate the relative ratio in this study. Therefore the other variables being compared may be underestimated. Even so, the iFOBT and some unique Chinese high risk factors - history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, and history of chronic diarrhea - still play an important role because of the higher sensitivities than that of HAP. The iFOBT may be superior to other factors in screening for advanced neoplasias and adenomas.

## ACKNOWLEDGMENTS

We thank all the gastroenterologists in the local hospitals and all staff at Xiacheng Disease Control Center (CDC) for their assistance and participation.

## COMMENTS

### Background

The immunochemical fecal occult blood test (iFOBT) and high risk factors questionnaire approach as primary screening followed by full colonoscopy examination as follow-up screening, has been recommended as the colorectal cancer (CRC) screening guideline for population-based CRC screening in China. The performance value of the iFOBT and the high risk factors questionnaire is still unknown in CRC screening practice in China.

### Research frontiers

The limitation of the iFOBT is its low sensitivity for CRC. High risk factors for CRC among a Chinese natural population have been identified through a meta-analysis. The major advantage of the high risk factors questionnaire investigation is that it can detect lesions that do not bleed or bleed intermittently.

### Innovations and breakthroughs

This is believed to be the first study comparing the performance value of high risk factors in mass CRC screening in China. In this study, because participants with at least one positive factor were asked to undergo colonoscopy, the sensitivity of each high risk item could not be directly estimated. The authors therefore compared sensitivities by calculating the relative sensitivity using HAP (history of adenomatous polyps, an acknowledged high risk factor) as a reference.

### Applications

The study suggests that the iFOBT may be the best marker for screening advanced neoplasias and adenomas. Some unique Chinese high risk factors (history of chronic cholecystitis or cholecystectomy, chronic appendicitis or appendectomy, and history of chronic diarrhea) may play an important role in CRC screening in China because of higher sensitivities than that of HAP.

### Peer review

The authors have done much work in this study. The study is worthwhile and well performed.

### Abstract

**AIM:** To investigate the possible correlation between osteoglycin expression and gelatinase activity of mouse hepatocarcinoma Hca-F cells.

**METHODS:** A eukaryotic expression plasmid pIRESpu-ro3 osteoglycin(+) was constructed and transfected into Hca-F cells to investigate the possible correlation between osteoglycin expression and gelatinase activity of Hca-F cells cultured with extract of lymph node, liver, spleen or in DMEM medium. The activity of gelatinases was examined through zymographic analysis.

**RESULTS:** High expression of osteoglycin attenuated the gelatinase activity of Hca-F cells cultured with extract of lymph node, and at the same time, decreased the metastatic potential of Hca-F cells to peripheral lymph nodes *in vivo*.

**CONCLUSION:** High expression of osteoglycin decreases the gelatinase activity of Hca-F cells cultured with extract of lymph node; regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression.

**Key words:** Osteoglycin; Transfection; Hepatocellular carcinoma; Neoplasm metastasis; Genes; Gelatinases

High expression of osteoglycin decreases gelatinase activity of murine hepatocarcinoma Hca-F cells. *World J Gastroenterol* 2009; 15(48): 6117-6122 Available from: URL: <http://www.wjgnet.com/1007-9327/15/6117.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.6117>

### INTRODUCTION

Most cancer lesions metastasize through the lymphatic system and the status of regional lymph nodes is the most important indicator of a patient's prognosis<sup>[1]</sup>. But the molecular mechanism of lymphatic metastasis remains unclear. Hca-P and Hca-F are syngeneic mouse hepatocarcinoma cell lines, when inoculated subcutaneously in 615-mice, they metastasized only to the lymph nodes but not to other organs, Hca-P cells illustrated a low metastatic potential (lymphatic metastasis rate < 30%), while Hca-F cells showed a high metastatic potential (lymphatic metastasis rate > 80%)<sup>[2,3]</sup>. In our previous study, we found that osteoglycin was highly expressed in Hca-P cells and lowly expressed in Hca-F cells with suppressively subtracted hybridization (SSH) technique. Osteoglycin (OGN) is a member of proteoglycans (PGs) called small leucine-rich proteoglycans (SLRPs) residing in the extracellular matrix of connective tissues which are involved in matrix assembly, cellular growth and migration<sup>[4]</sup>. There are few reports about the relationship between osteoglycin and tumor metastasis. We subsequently transfected osteoglycin into Hca-F cells and found that high expression of osteoglycin inhibited the metastatic behavior of Hca-F cells<sup>[5]</sup>. However, the mechanism of osteoglycin regulating metastasis is elusive.

Gelatinases/type IV collagenases belong to matrix metalloproteinase (MMP) family, including gelatinase A (also known as MMP2, 72 kDa) and gelatinase B (also known as MMP9, 92 kDa), they are secreted in a proenzyme form and activated extracellularly<sup>[6]</sup>. Gelatin-

ases mainly degrade collagen IV and a number of other ECM proteins, such as Col I, V, VII, IX, fibronectin, laminin, elastin and vitronectin<sup>[7]</sup>. As the most frequently studied MMPs in tumor research, gelatinases are suggested to play critical roles in tumor invasion and metastasis<sup>[8]</sup>.

In this study, we resorted to gene transfection technique to explore the possible correlation between osteoglycin expression and gelatinase activity of murine hepatocarcinoma Hca-F cells with a high metastatic potential. We found that high expression of osteoglycin decreased the gelatinase activity of Hca-F cells cultured with extract of lymph node, and at the same time, decreased the metastatic potential of Hca-F cells to peripheral lymph nodes *in vivo*; regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression.

## MATERIALS AND METHODS

### Cell culture and animals

Mouse hepatocarcinoma Hca-P cells and Hca-F cells (established by Department of Pathology, Dalian Medical University) were cultured in DMEM (Invitrogen) supplemented with antibiotics (1 × penicillin/streptomycin 100 U/mL, Invitrogen), 10% FBS (Invitrogen) and cultured in a humidified incubator at 37°C with 50 mL/L CO<sub>2</sub>; inbred 615-mice (male, 8 wk old) were provided by Animal Facility of Dalian Medical University.

### Construction of targeting vector

The osteoglycin coding sequence was amplified by polymerase chain reaction (PCR). Briefly, total RNA from 1 × 10<sup>7</sup> Hca-F cells was isolated with Trizol (Invitrogen). A High Fidelity PrimeScript RT-PCR kit (TaKaRa) was used to synthesize the cDNA according to the manufacturer's protocol. PCR was carried out with primer sets P1, 5'-GAATTCATGGAGACTGTGCACTCTA-3' (forward), and P2, 5'-GCCGCCGCTTAGAAGTATGACCCTA-3' (reverse), containing *Eco*R I and *Not* I sites, respectively (underlined). Using obtained cDNA as a template, PCR was carried out under the following conditions: 30 cycles of denaturation for 10 s at 98°C, annealing for 15 s at 55°C, and extension for 60 s at 72°C. After digestion by *Eco*R I and *Not* I enzymes, the PCR product was cloned into pIRESpuro3 vector digested by the same enzymes and designated as pIRESpuro3 osteoglycin(+). Sequence and orientation were confirmed by DNA sequencing using a BigDye Terminator V3.1 cycle sequencing kit (Applied Biosystems).

### Cell transfection and screening

Hca-F cells incubated in antibiotic-free medium with 10% FBS (Invitrogen) were transferred to a 6-well culture plate and incubated at 37°C, CO<sub>2</sub> incubator to obtain 60%-80% confluence, and then were stably transfected with pIRESpuro3 and pIRESpuro3 osteoglycin(+) using *TransIT-LT1* Transfection Reagent (TaKaRa) according to the protocol provided by the manufacturer. Two µg plasmid DNA was added to each

transfection. The transfected Hca-F cells were selected by puromycin (Clontech) for 2 wk and maintained in medium containing 0.5 mg/L puromycin.

### RT-PCR analysis

For RT-PCR analysis of osteoglycin mRNA levels, total RNA was isolated from cells using Trizol (Invitrogen) and cDNA was synthesized with High Fidelity PrimeScript<sup>TM</sup> RT-PCR Kit (TaKaRa) according to the manufacturer's instruction. The sequences of the primers were as follows: F1: 5'-TTCTCCTGCTACTCTTCGTG-3' and R1: 5'-AAGCAGACACACAACAGGCA-3' for osteoglycin; and F1: 5'-CGGGACCTGACAGACTACC T-3' and R1: 5'-AGCACTGTGTTGGCATAGAG-3' for β-actin, respectively. PCR analysis was performed under the following conditions: 30 cycles of denaturation for 10 s at 98°C, annealing for 15 s at 55°C, and extension for 30 s at 72°C. The amplified products were analyzed by agarose gel electrophoresis using 1.6% gel, followed by ethidium bromide staining. The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

### Western blotting analysis

Western blotting analysis was carried out to evaluate osteoglycin protein levels. Cellular protein was extracted with lysis buffer [20 mmol/L Tris (pH 7.5), 150 mmol/L NaCl, 1 mmol/L MgCl<sub>2</sub>, 2 mmol/L EGTA, 10% glycerol, 0.15% sodium dodecylsulfate, 1% deoxycholate, 1% Triton X-100, and 1% anti-protease cocktail (Sigma)]. The extracted proteins were subjected to 10% sodiumdodecylsulfate-polyacrylamide gel electrophoresis, blotted onto polyvinylidene difluoride membranes (Invitrogen), then probed with goat anti-mouse osteoglycin polyclonal antibody and β-actin monoclonal antibody (Santa Cruz) followed by secondary antibody conjugated to horseradish peroxidase (Santa Cruz) and detected by enhanced chemiluminescence (Amersham Biosciences). The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

### In vivo tumor metastasis assay

Ninety inbred 615-mice were randomly divided into 3 groups. Hca-F cells (F), Hca-F cells transfected with pIRESpuro3 (F0), or Hca-F cells transfected with pIRESpuro3 osteoglycin(+) [F(+)] were inoculated subcutaneously at 2 × 10<sup>6</sup> tumor cells of approximately 0.05 mL cell suspension into the left foot of each mouse in each group. They were terminated on the 28th day after inoculation, the implanted tumor and their axillary lymph nodes, inguinal lymph nodes, and popliteal lymph nodes were hematoxylin eosin (HE) stained and examined under microscope. The mouse which had at least one metastatic axillary lymph node or one metastatic inguinal lymph node or one metastatic popliteal lymph node was considered as a metastatic mouse. The lymph node metastatic rate of tumor-burden mice = metastatic mice/total mice.

The lymph node metastatic rates of F, F0 and F(+) cells burden mice were calculated. The number of positive lymph nodes per mouse was also evaluated.

### Zymographic analysis

The F, Hca-P (P), F0 and F(+) cells were put into different wells at  $5 \times 10^5$ , and then added 50 mg extract of lymph node, liver or spleen respectively. The Dulbecco's Modified Eagle Media (DMEM) was placed into each well up to 1 mL. DMEM medium containing only F, P, F0 or F(+) cells, and DMEM medium added only extracts of lymph node, liver or spleen served as controls. These cells were cultured at 37°C for 24 h. The supernatant of cultured cells was collected by centrifugation at  $3000 \times g$ . Gelatinases contained in supernatants of each cell with or without extracts of lymph node, liver or spleen were detected through zymographic analysis according to the method described by Fridman<sup>[9]</sup>. The bands were analyzed with LabWorks (UVP GDS-800 Version 4.0).

### Statistical analysis

Data were presented as means  $\pm$  SD and analyzed by the Student's *t* test, analysis of variance and  $\chi^2$  test using SPSS 11.5.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Osteoglycin expression at mRNA and protein level

The relative mRNA and protein levels of osteoglycin were determined by RT-PCR and Western blotting analysis, respectively. Compared with F and F0 cells, F(+) cells showed significantly higher expression of osteoglycin at both mRNA and protein levels; however, no significant difference of osteoglycin expression was found between F0 and F cells. Transfection of osteoglycin into Hca-F cells resulted in high expression of osteoglycin at both mRNA and protein levels. Osteoglycin was highly expression at both mRNA and protein levels in P cells (Figure 1).

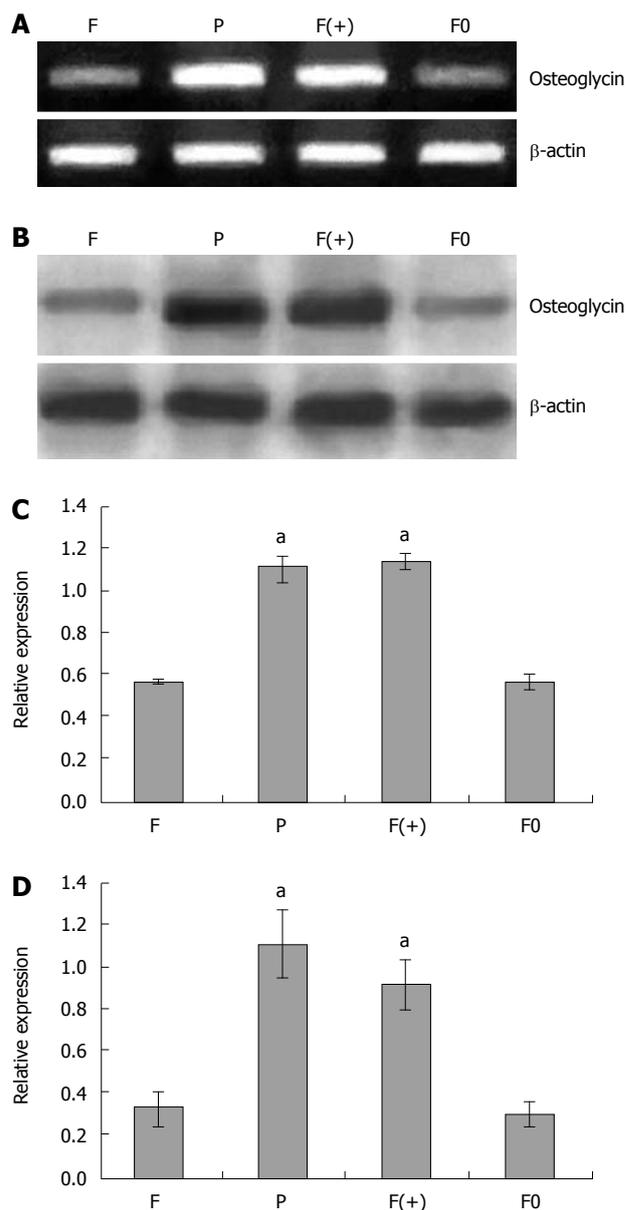

### In vivo tumor metastasis assay

F, F0 and F(+) cells were injected subcutaneously into the left foot of 615-mice. The implanted tumors were palpable on the 7th day after inoculation. On the 28th day after inoculation, 53.3% (16/30) F(+) cells burden mice developed lymphatic metastasis, while 80% (24/30,  $P < 0.05$ ) F cells burden mice and 83.3% (25/30,  $P < 0.05$ ) F0 cells burden mice developed lymphatic metastasis. Hca-F cells with transfected osteoglycin showed significant decrease in metastasis potential to lymph node (Figure 2). The result supported the fact that osteoglycin acted as a tumor lymphatic metastasis suppressed gene.

No significant difference was found in the number of positive lymph nodes per mouse in F(+), F and F0 cells burden mice.

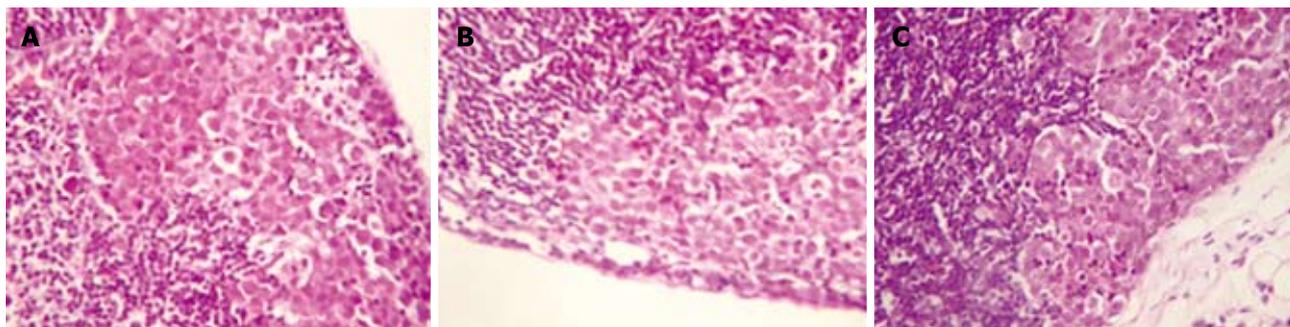

### Zymographic analysis

When cultured in DMEM, no cell produced any gelatinase (no gelatinase was detected in the supernatant of each cell). However, when cultured with extract of lymph node, all cells produced gelatinases (Pro-MMP-9, MMP-9 active, Pro-MMP-2 and MMP-2 active were detected in the supernatant of each cell). The quantity of gelatinases produced by tumor cells were closely associated with the metastatic potential of each tumor cell (quantity of

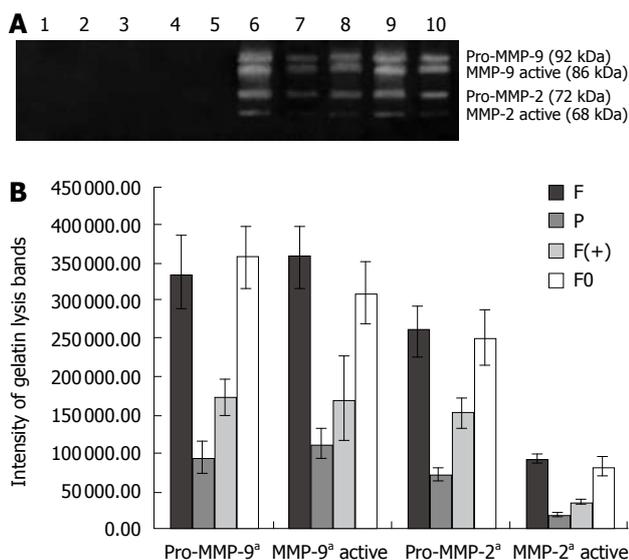

**Figure 1** Analysis of osteoglycin expression. RT-PCR analysis (A) and Western blot analysis (B) of osteoglycin expression in mouse hepatocarcinoma cells; relative signal intensities of osteoglycin mRNA (C) and protein (D) levels were normal as against those of  $\beta$ -actin by LabWorks (UVP GDS-800 Version 4.0) analysis (compared with F cells,  $^aP < 0.05$ ). F: Hca-F cells; P: Hca-P cells; F(+): Hca-F cells transfected with pIRESpuo3 osteoglycin(+); F0: Hca-F cells transfected with pIRESpuo3.  $\beta$ -actin was used as an internal control.

MMP2 and MMP9 detected in the supernatant of F and F0 cells were much higher than those detected in F(+) and P cells ( $P < 0.05$ ). High expression of osteoglycin *via* transfection of osteoglycin attenuated the secretion of gelatinases in Hca-F cells cultured with extract of lymph node (quantities of MMP2 and MMP9 detected in the supernatant of F(+) cells were much lower than those detected in F and F0 cells ( $P < 0.05$ ). The extract of lymph node did not contain any gelatinase (Figure 3). Gelatin lysis bands were found in the zymograms of the supernatant of all cells cultured with extract of liver, and the same gelatin lysis bands were found in the zymograms of the extract of liver, and their intensities were almost the same (Figure 4); gelatin lysis bands were also found in the

**Figure 2** Metastatic lymph nodes of tumor-burden mice inoculated with Hca-F cells (A), Hca-F cells transfected with pIRESpuro3 (B), or Hca-F cells transfected with pIRESpuro3 osteoglycin(+) (C). Lymph nodes of tumor-burden mice were HE stained and examined under microscope.

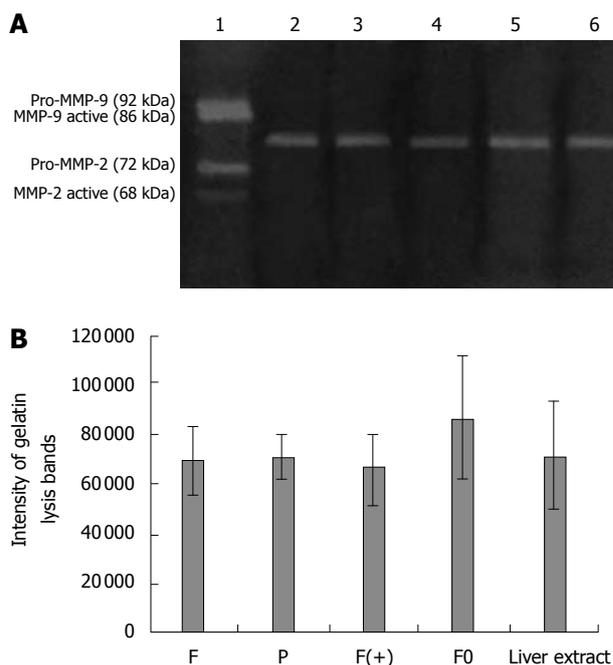

**Figure 3** Zymographic analysis of MMPs activity of tumor cells in DMEM with or without lymph node extract (A); the intensity of gelatin lysis bands obtained by scanning densitometry (LabWorks UVP GDS-800 Version 4.0, multiple comparisons, <sup>a</sup> $P < 0.05$ ) (B). 1. L; 2. F; 3. P; 4. F(+); 5. F0; 6. F; 7. P; 8. F(+); 9. F0. 10. Type IV collagenases. 1. L: lymph node extract; 2-5: cells in DMEM. 6-10: cells cultured with lymph node extract. zymograms of the supernatant of all cells cultured with extract of spleen, and in the zymograms of the extract of spleen, with similar intensities (Figure 5). Therefore, we think that all cells in the liver and spleen did not produce any gelatinases.

## DISCUSSION

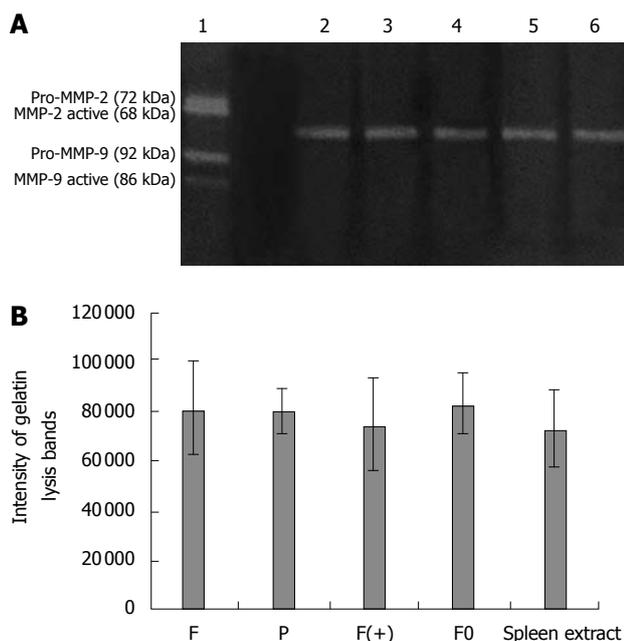

The metastatic potential of tumor cells is believed to be regulated by interactions between the tumor cells and their extracellular environment (extracellular matrix)<sup>[10,11]</sup>. Being a matrix molecule, osteoglycin participates in the organization and regulation of the extracellular matrix and might influence the tumor metastasis, as exemplified by studies *in vivo* that osteoglycin played a role in collagen fibrillogenesis<sup>[12,13]</sup>, a process essential in metastasis<sup>[11,12]</sup>. In addition to its extracellular matrix functions, osteoglycin, like other members of SLRPs, also plays a role

**Figure 4** Zymographic analysis of MMPs activity of tumor cells in liver extract (A); the intensity of gelatin lysis bands obtained by scanning densitometry (LabWorks UVP GDS-800 Version 4.0) (B). 1. in regulation of cell biological behavior<sup>[4]</sup>. As illustrated in the literature, the expression of mimecan was high at mRNA level in corneal keratocytes cultured in low-serum or serum-free media, but was attenuated if these cells were cultured in media containing serum<sup>[14]</sup>. Osteoglycin mRNA was absent or at a low level in the majority of cancer cell lines and tumors<sup>[15]</sup>. Bioactive such as p53, basic fibroblast growth factor, interferon- $\gamma$  and bone morphogenetic protein-1/tolloid-related metalloproteinases interacted with osteoglycin<sup>[16-20]</sup>. In the earlier studies, we found that osteoglycin was highly expressed in Hca-P cells and lowly expressed in Hca-F cells, and that osteoglycin acted as a tumor lymphatic metastasis suppressed gene<sup>[5]</sup>. However, no data identified intrinsic mechanism for osteoglycin regulation of tumor lymphatic metastasis.

Hca-P and Hca-F are syngenic mouse hepato-

**Figure 5** Zymographic analysis of MMPs activity of tumor cells in spleen extract (A); the intensity of gelatin lysis bands obtained by scanning densitometry (LabWorks UVP GDS-800 Version 4.0) (B). 1. carcinoma cell lines presenting a specific potential of lymphatic metastasis with a significant difference in their potential of metastasis<sup>[2,3]</sup>, which provide good experimental models for lymph node metastasis.

Cell adhesion to extracellular matrices is a determinant for cell migration and invasion<sup>[21,22]</sup>. Osteoglycin, being a matrix molecule, as we once assumed, would probably affect adhesive capacity of tumor cells, whereby influencing tumor migration and invasion. However, our previous work showed that adhesion was not responsible for the contribution of osteoglycin to lymphatic metastasis inhibition<sup>[5]</sup>. As the main mediators of extracellular matrix degradation, gelatinases play an important role in tumor metastasis as demonstrated in gastrointestinal cancer<sup>[23,24]</sup>, breast cancer<sup>[25]</sup>, hepatocarcinoma<sup>[26]</sup>, *etc.* Inhibition of the gelatinase activity can reduce the metastatic potential of cancer cells<sup>[27]</sup>. In the present study, high expression of osteoglycin *via* osteoglycin transfection attenuated the secretion of gelatinases (Pro-MMP-9, MMP-9 active, Pro-MMP-2 and MMP-2 active) in Hca-F cells cultured with extract of lymph node, and at the same time, decreased the metastatic potential of Hca-F cells to peripheral lymph nodes *in vivo*, which suggested that regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression. Moreover, osteoglycin expression only influenced gelatinase activity of Hca-F cells cultured with extract of lymph node, but failed to influence gelatinase activity of Hca-F cell cultured with extracts of liver and spleen or in DMEM medium, demonstrating a lymph node environment-selective metastasis suppression, which further supported the fact that osteoglycin acted as lymphatic metastasis suppression

gene. The mechanism of osteoglycin impact on gelatinases is unclear. Some of the SLRPs members bind and modulate TGF- $\beta$  and cytokines such as TNF- $\alpha$ <sup>[28,29]</sup> and play roles in EGFR activation pathway and the NF- $\kappa$ B signal transduction system as well<sup>[30,31]</sup>. And these bioactives (TGF- $\beta$ , TNF- $\alpha$ , EGF and NF- $\kappa$ B) are also the regulators of gelatinase activity<sup>[6,32]</sup>, which implicates that SLRPs might involve in the regulation of gelatinase activity. Further studies are needed to clarify the interaction between gelatinases and osteoglycin.

## COMMENTS

### Background

Lymphatic metastasis is responsible for the early stage of tumor metastasis and acts as the most important indicator of a patient's prognosis. But the molecular mechanism of lymphatic metastasis remains poorly understood.

### Research frontiers

The metastatic potential of tumor cells is believed to be regulated by interactions between the tumor cells and their extracellular environment (extracellular matrix). Matrix molecules play important roles in tumor metastasis. Osteoglycin, as one of matrix molecules, is suggested to play a part in matrix assembly, cell growth and migration. However, there has been no report on osteoglycin and tumor metastasis.

### Innovations and breakthroughs

The authors first report that osteoglycin acted as a tumor lymphatic metastasis suppression gene, and regulation of gelatinase activity might be one of mechanisms that osteoglycin contributes to lymphatic metastasis suppression.

### Applications

This study may help for therapeutic intervention in tumor metastasis.

### Terminology

Osteoglycin belongs to a small leucine-rich proteoglycan (SLRP) gene family, as one of the matrix molecules, it is reported to participate in the organization and regulation of the extracellular matrix. In addition to its extracellular matrix functions, osteoglycin, like other members of SLRPs, also plays a role in regulation of cell biological behavior, cell growth and migration, *etc.*

### Peer review

In this study, it was observed that osteoglycin upregulation, induced by its transfection into mouse hepatocarcinoma Hca-F cells, results in a decrease in gelatinase activity and metastatic potential of Hca-F cells. The effect of osteoglycin transfection on gelatinase activity has been convincingly demonstrated.

### Abstract

This case report describes an extremely rare complication of a Meckel's diverticulum: enterocutaneous fistula of the diverticulum. The presence of Meckel's diverticulum is a well known entity, but subcutaneous perforation of the diverticulum is very rare. Here we report the case of a patient with the complaint of a right lower quadrant abscess, preoperatively diagnosed as enterocutaneous fistula, which was determined intraoperatively to be a fistula resulting from Meckel's diverticulum.

### INTRODUCTION

Meckel's diverticulum is the most common congenital

anomaly of the gastrointestinal tract<sup>[1-4]</sup>. It is an outpouching of the distal ileum located at the antimesenteric border usually within 45-60 cm of the ileocecal valve<sup>[4]</sup>. The majority of Meckel's diverticulum cases are asymptomatic although they can, occasionally, cause complications such as bleeding, intestinal obstruction and/or inflammatory process<sup>[1-4]</sup>. The presentation as an abscess in the abdominal wall is a rare clinical entity. Because of insidious onset and subtle clinical signs of the resulting abscess, the diagnosis of such cases is often delayed. Meckel's diverticula such as those forming extensive abscesses may sometimes become complicated and require a prolonged treatment period. These complications should be kept in mind in order to avoid further sequelae. The diagnosis is difficult and is usually performed at surgery<sup>[2]</sup>. We here report a patient who developed a fistula between an inflamed Meckel's diverticulum and subcutaneous tissue, which is the first case in the literature.

### CASE REPORT

A 32-year-old woman with no previous abdominal surgery presented with a 48-h history of right abdominal pain, fever, nausea, vomiting and a palpable mass. There was no significant medical history. Examination of the abdomen showed a marked distension without peritonitis and a mass 8 cm × 5 cm in size. There were significant inflammatory signs such as local heat, swelling, edema and tenderness involving the entire right abdominal wall. Her body temperature was 38.5°C. Laboratory findings showed a white blood cell count of 28000, hemoglobin value of 115 gm/L, and a platelet count of 250000. The other laboratory investigations, including electrolytes and urinalysis, were within normal limits. Chest and abdominal X-ray revealed no abnormality. An abdominal ultrasound scan suggested a fluid collection in the right lower abdominal quadrant, which was evaluated to be an abscess. The magnetic resonance imaging (MRI) finding indicated a mass with a suspicious intraabdominal connection (Figure 1). The clinical, radiological and laboratory findings revealed the presence of a right lower abdominal quadrant abscess as the source of sepsis. The abdomen was opened immediately and the exploration revealed a Meckel's diverticulum with a connection to the right lower quadrant mass (Figure 2A-C). There was not any fluid contamination in the abdomen. A resection of the necrotic segment, Meckel's diverticulum and a functional end-to-

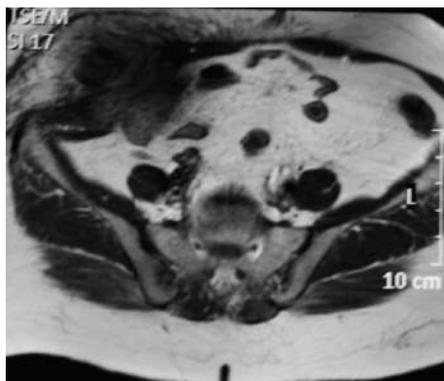

Figure 1 Pre-operative magnetic resonance imaging view of our case.

end anastomosis of the bowel were completed. Afterwards, debridement of the non-viable abdominal wall muscle groups and drainage of the abscess cavity were performed (Figure 2D). The bacterial culture revealed *Escherichia coli* and *Klebsiella pneumoniae* infection. The diverticulum was confirmed as Meckel's diverticulum by histological examination (Figure 3). The patient recovered without incident and was discharged after five days in hospital.

## DISCUSSION

Meckel's diverticulum is the most common end result of the spectrum of omphalomesenteric duct anomalies, which also include umbilical-ileal fistula, omphalomesenteric duct sinus, omphalomesenteric duct cyst, fibrous connection of the ileum to the umbilicus, and Meckel's diverticulum<sup>[1,2,5]</sup>. The lifetime risk of complications is estimated to be about 4%; 40% of which occur in children<sup>[1]</sup>. The presentation in children is most commonly with gastrointestinal bleeding from ectopic gastric or pancreatic mucosa, whereas adults more commonly develop obstruction, intussusception, ulceration, vesicodiverticular fistula, or tumor<sup>[1-6]</sup>. Regarding our case, we confronted a rare presentation of Meckel's diverticulum, which first emerged as enterocutaneous fistula. The etiopathogenesis of the disease can be explained by the direct contamination of the right anterior abdominal wall by an inflamed Meckel's diverticulum. The spread of resultant sepsis along the abdominal wall muscles, preperitoneal space and downward behind the inguinal ligament into the thigh, thus presented clinically as an abscess. A review of the literature suggests certain intra-abdominal inflammatory pathologies in the etiology of enterocutaneous fistula, such as diverticulitis, acute appendicitis, Crohn's disease, colorectal carcinoma, rectal trauma and primary staphylococcal abscess<sup>[7,8]</sup>. Therefore, we should define our case as a new reason for enterocutaneous fistula (Table 1). In the literature another interesting complication of Meckel's diverticulum has been described by Graziotti *et al*<sup>[9]</sup>. They presented a case where an ingested foreign body (chicken bone) entrapped in a Meckel's diverticulum eventually caused a vesicoenteric fistula.

Much rarer complications of Meckel's diverticula include neoplasms, with the most common being benign tumors reported as leiomyomas, angiomas and lipomas.

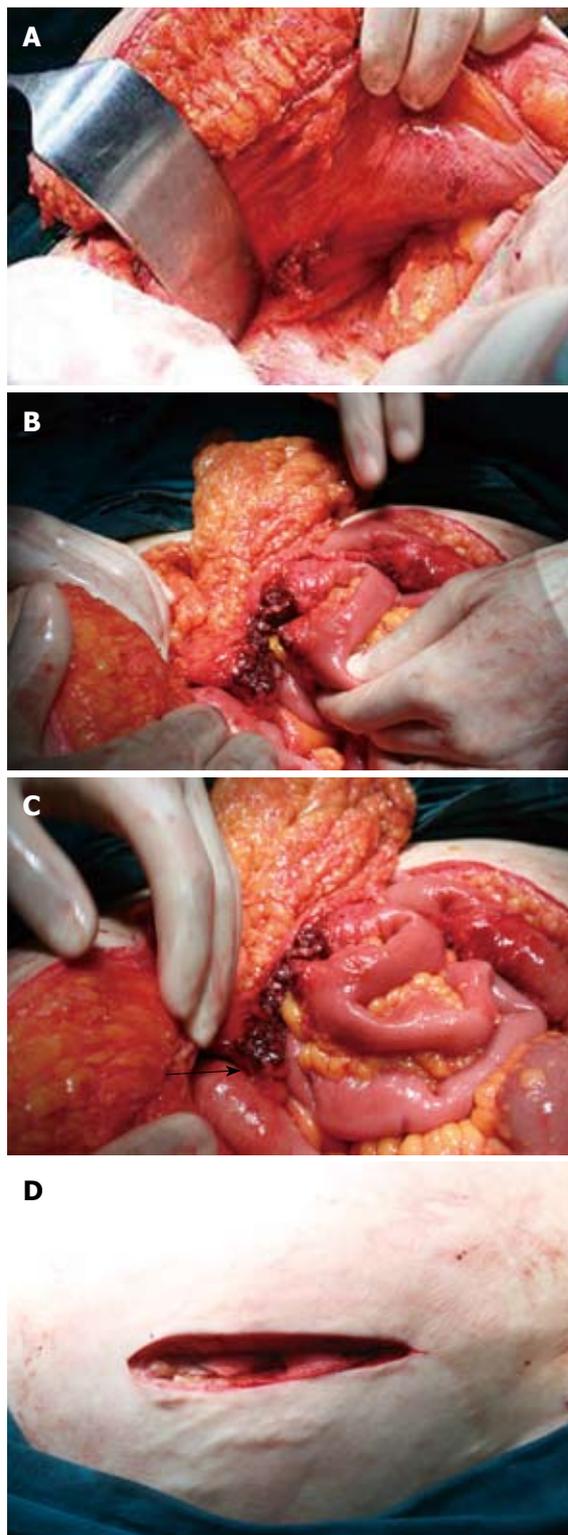

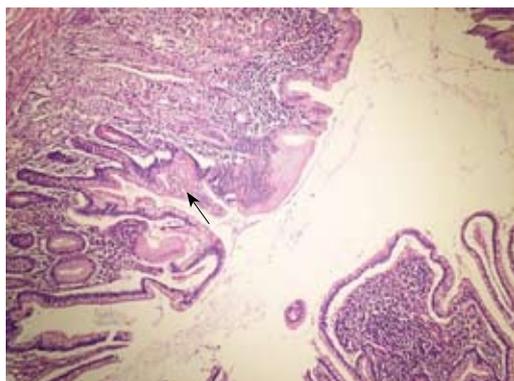

Figure 2 Intraoperative view of the meckel's diverticulum manifested by cutaneous abscess. A: The fistulization area of the diverticulum in the right lower abdominal wall; B: After retraction of the Meckel's diverticulum: intraabdominal view of the diverticulum and necrotic omentum; C: The intraoperative view of the perforated diverticulum (black arrow shows Meckel's diverticulum); D: The view of the abscess cavity.

Malignant neoplasms reported include adenocarcinomas, which commonly originate from the gastric mucosa, sarcoma, and carcinoid tumor<sup>[10]</sup>.

**Figure 3** Meckel's diverticulum (HE stain, × 100). Photomicrograph shows the diverticulum composed of all layers of intestinal wall. Normal small intestinal mucosa and a focus of (arrow) gastric mucosa line the diverticulum.

Clinical diagnosis of Meckel's diverticulum is rarely possible; less than 10% are diagnosed preoperatively<sup>[1,2]</sup>. It is therefore critical for surgeons to rule out Meckel's diverticulum in patients undergoing surgical evaluation for chronic abdominopelvic pain<sup>[5]</sup>. The correct diagnosis of Meckel's diverticulum before surgery is often difficult because a complicated form of this condition is similar to many other abdominal pathologies<sup>[1-5]</sup>. Arteriography and technetium pertechnetate scanning may be especially useful when there is significant bleeding or ectopic gastric mucosa<sup>[5]</sup>. In children, the single most accurate diagnostic test for Meckel's diverticula is scintigraphy with sodium <sup>99m</sup>Tc-pertechnetate. The diagnostic sensitivity of this scan has been reported to be as high as 85%, with a specificity of 95% and an accuracy of 90% in the pediatric age group. In adults, however, <sup>99m</sup>Tc-pertechnetate scanning is less accurate because of reduced prevalence of ectopic gastric mucosa within the diverticulum<sup>[10]</sup>. However, these scans are not readily amenable in an emergency situation.

Contrast-enhanced CT scan may be helpful in patients with enigmatic clinical symptoms of enterocutaneous fistula caused by Meckel's diverticulum. In vesicoenteric fistulas, cystoscopy has a key role in visualization of the fistula<sup>[6]</sup>.

Briefly, the lesson from this case is that Meckel's diverticulum should be kept in mind as one of the differential diagnoses of enterocutaneous fistula.

### INTRODUCTION

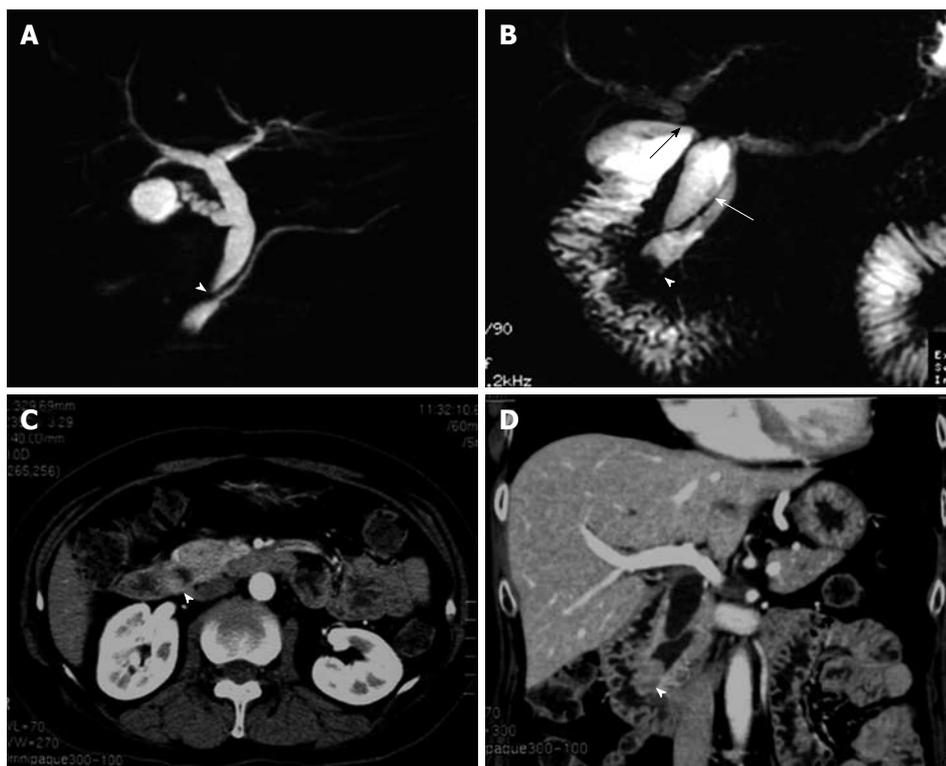

Pancreaticobiliary maljunction (PBM) is a congenital anomaly defined as a union of the pancreatic and biliary ducts outside the duodenal wall<sup>[1]</sup>. Due to the loss of control by the sphincter of Oddi, pancreatic enzymes reflux into the choledochus, especially in the C-P type of maljunction, in which the common bile duct joins the main pancreatic duct<sup>[1]</sup>. Consequently, PBM is frequently associated with choledochal cyst and sometimes biliary cancer; a large survey showed that the rate of developing biliary cancer was 10.6% and 37.9% in PBM with and without choledochal dilation, respectively<sup>[2]</sup>.

Once PBM is diagnosed, the development of cancer should be prevented by removal of the entire extrahepatic bile duct, even in patients without biliary dilation<sup>[3]</sup>. However, it has been reported that residual bile duct cancer could be found during the long-term follow-up period, even after termination of pancreatic enzyme reflux<sup>[4-6]</sup>, and Watanabe *et al*<sup>[6]</sup> reported that 23 (0.7%) of 1291 patients developed residual bile duct cancer after cyst excision. Besides residual bile duct cancer, other periampullary carcinomas have been reported, but they are very rare<sup>[7,8]</sup>.

In this paper, we report a case of carcinoma of the papilla of Vater that developed following treatment of PBM with choledochal dilation by choledochoduodenostomy. This is the first report of such a case, and particular attention is paid to the incidence, differential diagnosis, and treatment of periampullary neoplasms after treatment for PBM.

### Abstract

Pancreaticobiliary maljunction (PBM) is frequently associated with biliary cancer due to reflux of pancreatic enzymes into the choledochus, and even after surgery to correct the PBM such patients still have a risk of residual bile duct cancer. Here, we report the case of a 59-year-old female with carcinoma of the papilla of Vater which developed 2.5 years after choledochoduodenostomy for PBM. During the postoperative follow-up period, computed tomography obtained 2 years after the first operation demonstrated a tumor in the distal end of the choledochus, although she did not have jaundice and laboratory tests showed no abnormalities caused by the previous operation. As a result, carcinoma of the papilla of Vater was diagnosed at an early stage, followed by surgical cure. For early detection of periampullary cancer in patients undergoing surgery for PBM, careful long-term follow-up is needed.

**Figure 1** Imaging modalities for pancreaticobiliary maljunction and carcinoma of the papilla of Vater. A: Magnetic resonance cholangiopancreatography before first operation shows both maljunction of the main pancreatic duct and the choledochus (arrowhead) and the choledochal dilation, however there is no finding of neoplasm at the papilla of Vater; B: Magnetic resonance cholangiopancreatography at follow-up after first operation shows the tumor in the main pancreatic duct (arrowhead). In addition, the choledochoduodenostomy (black arrow) and the residual choledochus (white arrow) can be seen; C, D: Computed tomography obtained 2 years after choledochoduodenostomy for pancreaticobiliary maljunction shows the mass in the distal end of the common bile duct, which had not been detected before first operation (arrowheads).

## CASE REPORT

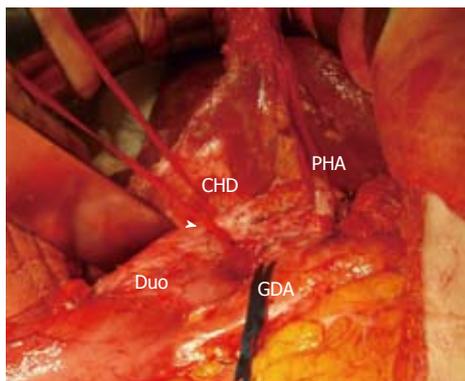

A 59-year-old female was referred to our hospital. She had undergone choledochoduodenostomy and cholecystectomy at another hospital 2.5 years earlier after diagnosis of PBM. Although imaging modalities obtained before surgery showed choledochal dilation, the minimally invasive operation was performed without excision of a choledochal cyst because the patient rejected blood transfusion preoperatively (Figure 1A). During the postoperative follow-up period, magnetic resonance cholangiopancreatography demonstrated a tumor in the main pancreatic duct and in the anastomotic site of the choledochus and duodenum from the first operation (Figure 1B). Computed tomography also showed a tumor in the distal end of the residual choledochus, which had not been observed before the first operation despite bile diversion (Figure 1C and D). Endoscopic retrograde pancreatography was then performed, and a 2-cm-diameter filling defect was demonstrated at the papilla of Vater, which was shown to be adenocarcinoma on cytology. Regardless of these findings, the patient did not complain of any symptoms such as jaundice or abdominal pain, and laboratory tests, including hepatobiliary enzymes and tumor markers, showed no abnormalities. With a diagnosis of carcinoma of the papilla of Vater after choledochoduodenostomy for PBM, the patient underwent pancreaticoduodenectomy. Despite moderate adhesions due to the previous operation, we were able to find common hepatic duct which was anastomosed to the duodenum (Figure 2). After Kocher maneuver, residual extrapancreatic choledochus was easily identified behind the anastomotic region and all the residual choledochus could be removed. Because the cancerous lesion was not found at the first operation or at preoperative examination, resection of all the residual bile

duct was thought to be sufficient for curative surgery. On pathology of the resected specimen, the tumor was found to be well-to-moderately differentiated adenocarcinoma of the papilla of Vater, with metastasis to the lymph nodes behind the head of the pancreas (Figure 3). The patient's postoperative course was uneventful, and there has been no cancer recurrence 1 year after the second surgery.

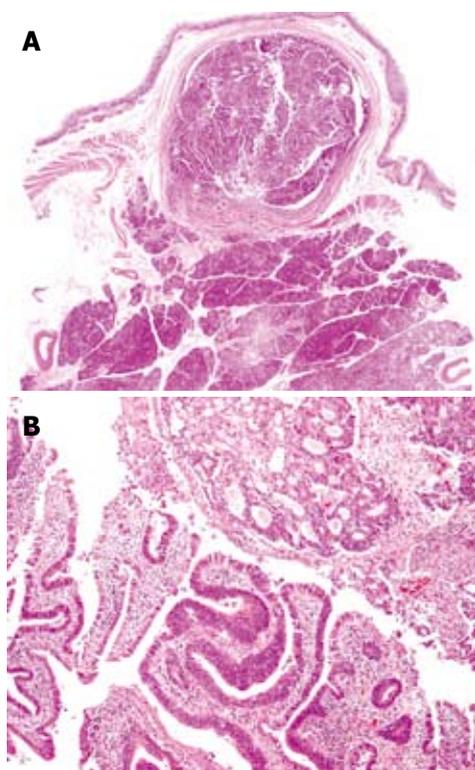

## DISCUSSION

Even after surgery that stops reflux of pancreatic enzymes into the choledochus and prevents the development of biliary cancer, patients with PBM still have a risk of developing residual bile duct carcinoma, both in the proximal duct and the distal end<sup>[6]</sup>. In the present case, carcinoma of the papilla of Vater was diagnosed 2 years after choledochoduodenostomy by computed tomography. In addition to complete excision of a choledochal cyst, careful long-term follow-up is necessary; the interval between excision of a choledochal cyst and cancer detection ranges from 1 to 19 years in several reports<sup>[6]</sup>.

Compared with other periampullary carcinomas, including those of the duodenum, bile duct, and pancreas, survival and resectability rates of carcinoma of the papilla of Vater are relatively high<sup>[9,10]</sup>. In addition to the fact that the rate of resection is one of the predictive factors for survival<sup>[9]</sup>, early detection is of great importance to provide benefit for patients with carcinoma of the papilla of Vater<sup>[11]</sup>. One of the most common manifestations at presentation in patients with carcinoma of the papilla of Vater is jaundice, as in the other periampullary carcinomas. However, jaundice is not usually observed in patients undergoing a diversion operation of the bile duct, as in the present case. Therefore, unless careful postoperative examinations of the periampullary region are performed,

**Figure 2** Intraoperative photograph of the second surgery. Common hepatic duct which was anastomosed to the duodenum was found. Behind this anastomotic region, residual choledochus was easily identified after Kocher maneuver. Arrow head indicates the region of choledochoduodenostomy. CHD: Common hepatic duct; Duo: Duodenum; PHA: Proper hepatic artery; GDA: Gastroduodenal artery.

**Figure 3** Pathological findings of the tumor. A: Close-up findings of the sliced specimen show a tumor growing mainly in the papilla of Vater. There is minimal invasion, which can hardly be seen at this magnification (HE stain,  $\times 1$ ); B: Histological findings of the tumor show adenocarcinoma composed of two different types of histology: moderately differentiated (upper) and well differentiated (lower) type (HE stain,  $\times 40$ ).

physicians may miss the chance to cure carcinoma of the papilla of Vater.

Compared to bile duct cancer, other residual biliary tree neoplasms are rare but can develop postoperatively. For example, a bile duct Schwannoma that developed 15 years after bypass operation and diversion of bile from a choledochal cyst has been reported<sup>[8]</sup>. Carcinoma of the papilla of Vater after choledochoduodenostomy

for PBM is also very rare and has never been previously reported. Though PBM is not a risk factor for carcinoma of the papilla of Vater<sup>[12,13]</sup>, which was detected only about 2 years after diversion of bile in the present case, inflammation due to the mixture of pancreatic enzymes with bile may have caused the carcinoma of the papilla of Vater in this case.

In summary, a case of carcinoma of the papilla of Vater that developed after choledochoduodenostomy for PBM was reported. In this present case, the lesion was detected at an early stage, and curative resection was performed, suggesting that careful, long-term follow-up of patients following surgery to treat PBM is necessary.

### Abstract

We report a rare case of hypereosinophilic syndrome (HES) presenting with intractable gastric ulcers. A 71-year-old man was admitted with epigastric pain. Initial endoscopic findings revealed multiple, active gastric ulcers in the gastric antrum. He underwent *Helicobacter pylori* (*H. pylori*) eradication therapy followed by proton pump inhibitor (PPI) therapy. However, follow-up endoscopy at 4, 6, 10 and 14 mo revealed persistent multiple gastric ulcers without significant improvement. The proportion of his eosinophil count increased to 43% (total count: 7903/mm<sup>3</sup>). Abdominal-pelvic and chest computed tomography scans showed multiple small nodules in the liver and both lungs. The endoscopic biopsy specimen taken from the gastric antrum revealed prominent eosinophilic infiltration, and the liver biopsy specimen also showed eosinophilic infiltration in the portal tract and sinusoid. A bone marrow biopsy disclosed eosinophilic hyperplasia as well as increased cellularity of 70%. The patient was finally diagnosed with HES involving the stomach, liver, lung, and bone marrow. When gastric ulcers do not improve despite *H. pylori* eradication and prolonged PPI therapy, infiltrative gastric disorders such as HES should be considered.

### INTRODUCTION

Hypereosinophilic syndrome (HES) is a rare disorder characterized by the overproduction of eosinophils in the bone marrow with persistent peripheral eosinophilia, tissue infiltration, and end-organ damage by eosinophil infiltration and the secretion of mediators<sup>[1]</sup>. The diagnosis of HES is based on marked eosinophilia exceeding 1500/mm<sup>3</sup>, a chronic course longer than 6 consecutive months, exclusion of parasitic infestations, allergic diseases and other etiologies for eosinophilia, and signs and symptoms of eosinophil-mediated tissue injury<sup>[1,2]</sup>. While HES can involve multiple organ systems, including bone marrow, heart, lung, liver, lymph node, muscle, and nerve tissue<sup>[1]</sup>, gastrointestinal tract involvement is rare<sup>[1-3]</sup>. To date, only a handful of cases of HES presenting with gastritis or enteritis have been reported worldwide<sup>[4-9]</sup>, and HES presenting with intractable gastric ulcers has not been reported. We report our case of a 71-year-old male patient with HES presenting with multiple intractable gastric ulcers with a review of the literature.

### CASE REPORT

A 71-year-old man presented with epigastric pain. He underwent cholecystectomy 20 years previously due to acute cholecystitis with gallstones, and has intermittently taken nonsteroidal anti-inflammatory drugs (NSAID) and corticosteroids on account of degenerative arthritis

**Figure 1** Esophagogastroduodenoscopy (EGD) and biopsy findings. A: Initial EGD findings revealed several active gastric ulcers in the antrum of the stomach; B: In the EGD findings after 2 mo, multiple gastric ulcers were still noticeable with only slight improvement; C: In the EGD findings after 14 mo, multiple gastric ulcers were still found in the antrum; D: Biopsy findings revealed prominent eosinophilic infiltrations > 20 cells/HPF (arrows) (HE stain,  $\times 400$ ).

for 15 years. Other symptoms, as well as his past medical and family history, were otherwise unremarkable. The initial physical examination showed a flat, soft abdomen with normoactive bowel sounds with no sign of direct or rebound tenderness and no hepatosplenomegaly. Thoracic auscultation revealed no remarkable results. Routine complete blood count reported a leukocyte count of  $7790/\text{mm}^3$  with 5.3% eosinophils, hemoglobin level of 12.1 g/dL, and a platelet count of  $198000/\mu\text{L}$ . There were no noteworthy findings on simple chest and abdominal radiography. No specific cardiac abnormalities on standard 12-lead electrocardiogram (ECG) or Doppler echocardiogram were detected. ECG revealed normal sinus rhythm and the echocardiogram showed normal global left ventricular systolic function (estimated ejection fraction 70%).

Esophagogastroduodenoscopy (EGD) findings revealed several active gastric ulcers in the antrum of the stomach (Figure 1A). Biopsy findings showed an ulcer with *Helicobacter pylori* (*H. pylori*). He underwent *H. pylori* eradication therapy (lansoprazole 30 mg twice a day, clarithromycin 500 mg twice a day and amoxicillin 1000 mg twice a day for 7 d) followed by a proton pump inhibitor (PPI) and gastroprotective agent therapy for 2 mo. Follow-up EGD and biopsy performed after 2 mo showed that *H. pylori* was eradicated, whereas multiple gastric ulcers were still noticeable with only slight improvement (Figure 1B). Follow-up endoscopy at 4, 6, and 10 mo showed persistent multiple gastric ulcers in the antrum despite continuous PPI treatment. Therefore, he was readmitted after 14 mo for etiological evaluation of the intractable gastric ulcers.

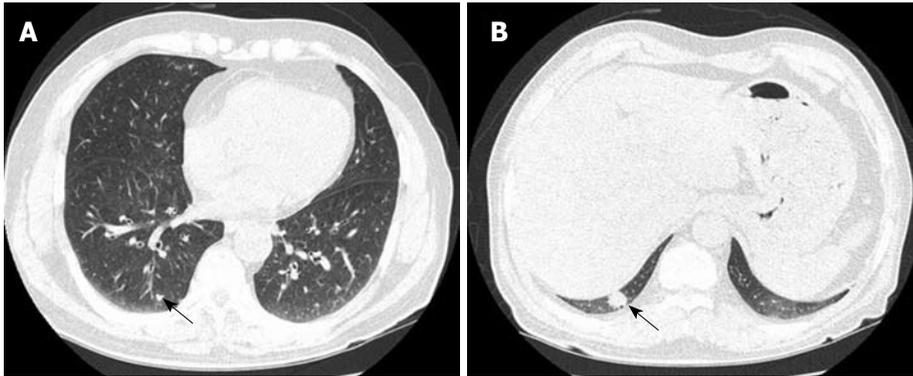

In the follow-up laboratory data, routine complete blood count showed a leukocyte count of  $18380/\text{mm}^3$  with 43% eosinophils, and an absolute eosinophil count of  $7903/\text{mm}^3$ . Serum chemistry showed: Aspartate

aminotransferase/alanine aminotransferase (AST/ALT), 39/97 IU/L; total bilirubin/direct bilirubin, 0.3/0.1 mg/dL; alkaline phosphatase, 235 IU/L; total protein/albumin, 7.3/3.2 g/dL; and BUN/Cr, 14/1.1 mg/dL. Serum immunoglobulin E level was elevated to 2147 kU/L. In pulmonary function tests, pre-bronchodilator FEV1 was 2090 mL (95% of predicted value) and the bronchodilator response was negative. The allergen skin test was negative. There were no parasites or ova in stool specimens. ELISA of paragonimiasis westermani, Clonorchis sinensis, cysticercus, and sparganum were negative. Anti-HIV antibody and anti-nuclear antibody were negative.

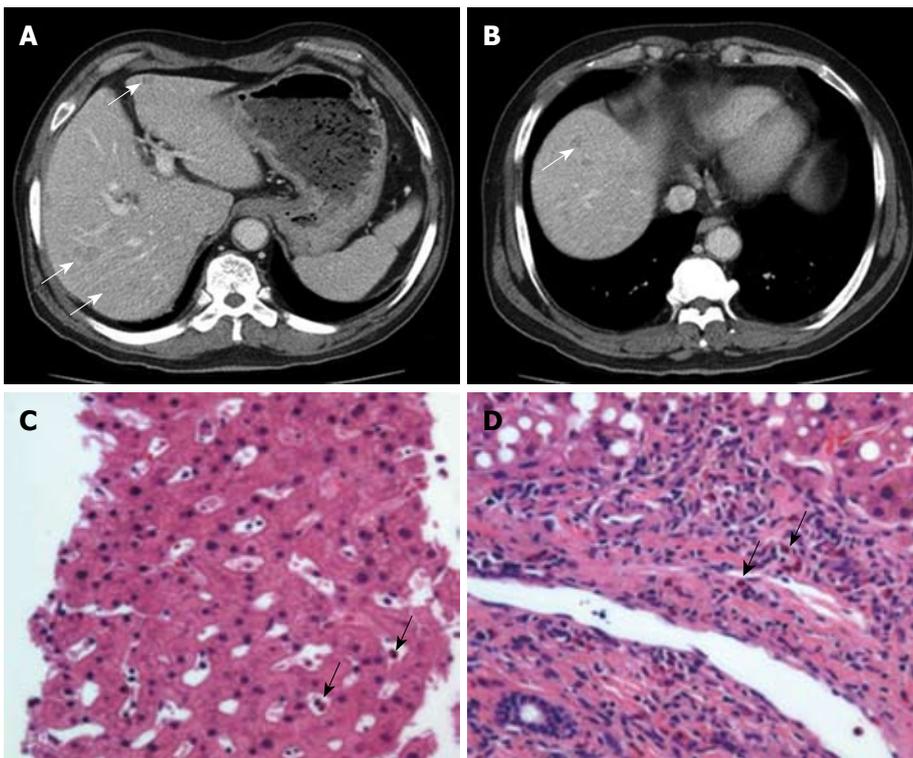

In the EGD findings, multiple gastric ulcers were still found in the antrum of stomach (Figure 1C). The endoscopic biopsy specimen revealed prominent eosinophilic infiltrations of > 20 cells/HPF (Figure 1D). A retrospective review of the previous endoscopic biopsy specimens disclosed eosinophilic infiltration at the antrum which was overlooked at the initial evaluation.

The chest computed tomography (CT) scan showed very tiny nodules in both lungs and approximately 15-mm-sized nodular lesions in the posterior basal segment of the right lower lobe (Figure 2A and B). In the abdominal-pelvic CT scan, multiple, small, and ill-defined low density lesions were found in both lobes of the liver (Figure 3A and B). The liver biopsy showed eosinophilic infiltration in the portal tract and sinusoid (Figure 3C and D).

The peripheral blood smear report showed that there were no immature or dysplastic cells or morphologically abnormal eosinophils. The bone marrow aspiration smear showed an M:E ratio of 3.8:1 and an elevated eosinophil count of 22.2% (Figure 4A). Bone marrow biopsy findings also indicated eosinophilic hyperplasia, with increased cellularity of 70% and normal distribution of erythroid, myeloid, and megakaryocytic cell lineages (Figure 4B). The Fip1-like 1-platelet-derived growth factor receptor A

**Figure 2** A chest CT scan showed very tiny nodules in both lungs (A) and approximately 15-mm-sized nodular lesions in the posterior basal segment of right lower lobe (B) (arrows).

**Figure 3** Abdominal-pelvic CT scan and liver biopsy findings. A, B: There were multiple, small, ill-defined low densities found in the liver (white arrows); C, D: Microscopically, eosinophilic infiltration was noted in the sinusoid and the portal tract (black arrows) (HE stain,  $\times 400$ ).

fusion gene (*FIP1L1-PDGFR4*) rearrangement was not detected and there were no cytogenetic abnormalities.

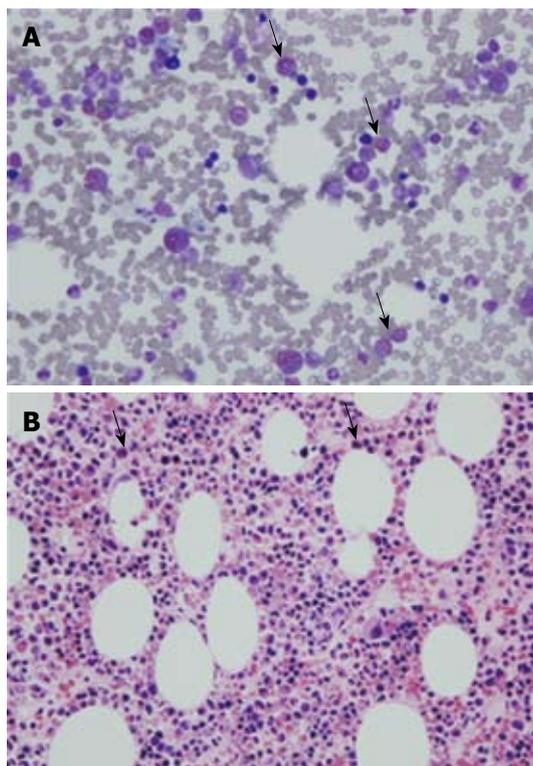

This patient was finally diagnosed with HES involving the stomach, liver, lung, and bone marrow. He was treated with oral prednisolone 60 mg/d and PPI. After two weeks of therapy, clinical manifestations rapidly improved and peripheral blood eosinophilia had subsided.

## DISCUSSION

HES is a rare disease characterized by unexplained persistent eosinophilia associated with multiple organ dysfunction<sup>[1,2]</sup>. In 1968, Hardy and Anderson<sup>[10]</sup> reported three patients with hypereosinophilia, hepatosplenomegaly, and cardiopulmonary symptoms, and first suggested that they had a nonmalignant disorder that belonged within the spectrum of disease termed hypereosinophilic syndrome. In HES, the degree of end-organ damage is heterogeneous, and there is often no correlation between the level or duration of eosinophilia and the severity of organ damage<sup>[1,3]</sup>. Also, the clinical manifestations are

variable from one patient to another, depending on target-organ infiltration by eosinophils<sup>[11]</sup>. Virtually any tissue or organ can be affected, but cardiac involvement is the major cause of the morbidity and mortality associated with HES<sup>[1,9,12]</sup>. We did not find cardiac involvement in our patient.

Since Chusid *et al*<sup>[13]</sup> reported the analysis of fourteen cases of HES in 1975, some cases of HES involving the gastrointestinal (GI) tract have been reported. Ichikawa *et al*<sup>[4]</sup> reported a case of probable HES with a gastric lesion, López Navidad *et al*<sup>[5]</sup> reported a case of HES presenting as a form of epithelioid leiomyosarcoma of gastric origin, and Levesque *et al*<sup>[6]</sup> reported two cases of HES with predominant digestive manifestations. In Korea, Jung *et al*<sup>[8]</sup> reported a case of HES presenting as colitis and You *et al*<sup>[9]</sup> reported a case of HES presenting with various GI symptoms. However, HES presenting with intractable gastric ulcers has not been reported. Our patient suffered from HES presenting with multiple intractable gastric ulcers as well as liver, lung, and bone marrow involvement. The exact mechanism of

**Figure 4 Bone marrow examination.** A: In the bone marrow aspiration smear, the M:E ratio was 3.8:1 and the eosinophil count was elevated to 22.2% (arrows); B: Bone marrow biopsy findings showed eosinophilic hyperplasia (arrows) with increased cellularity of 70% and erythroid, myeloid, and megakaryocytic cell lineages with a normal distribution pattern (HE stain,  $\times 400$ ).

eosinophil-related tissue damage, including gastric ulcer, is not known<sup>[3]</sup>, but the accumulation of eosinophils can have direct cytotoxicity through the local release of toxic substances, including cationic proteins, enzymes, reactive oxygen species, pro-inflammatory cytokines, and arachidonic acid-derived factors<sup>[14]</sup>.

The differential diagnosis of HES includes the disparate diseases associated with eosinophilia. Peripheral blood eosinophilia can be associated with allergic disorders, parasite infections, malignancies, and organ diseases, including eosinophilic gastroenteritis (EG) or eosinophilic pneumonitis due to eosinophilic infiltration<sup>[15]</sup>. In our patients, the bronchodilator response was negative and there was no symptom or sign of allergic disease. Even if allergic disease is present, the severe peripheral eosinophilia noted in our patient is unusual<sup>[15]</sup>. In addition, *FIP1L1-PDGFR $\alpha$*  gene rearrangement was not detected in bone marrow and there were no cytogenetic abnormalities. Therefore, we could rule out primary clonal eosinophilia such as eosinophilic leukemia.

HES may be confused with EG. The diagnosis of EG is based on the following three criteria: (1) the presence of gastrointestinal symptoms, (2) biopsies showing eosinophilic infiltration of one or more areas of the GI tract, or characteristic radiologic findings with peripheral eosinophilia, and (3) no evidence of parasitic or extraintestinal disease<sup>[16]</sup>. Because EG is also of unknown etiology, the distinction from HES must be made on clinical and pathologic bases<sup>[17,18]</sup>. Eosinophilic

gastroenteritis characteristically does not extend beyond the target organ<sup>[1,18]</sup>. Hence, EG lacks the multiplicity of organ involvement often found in HES and does not have the predilection to develop secondary eosinophil-mediated cardiac damage<sup>[1,18]</sup>. Thus, EG can usually be distinguished from HES, although individual patients may on occasion present with overlapping features that confound classification<sup>[1,18]</sup>. In our patient, multiple organ involvement was demonstrated, and there was no other possible cause of severe eosinophilia.

In patients with eosinophilia who lack evidence of organ involvement, specific therapy is not needed<sup>[1]</sup>. Such patients can have prolonged courses without the need for therapeutic intervention<sup>[1]</sup>. However, patients with vital organ involvement require treatment<sup>[1]</sup>. The goals in the management of HES are as follows: (1) reduction of peripheral blood and tissue levels of eosinophils; (2) prevention of end-organ damage; and (3) prevention of thromboembolic events<sup>[1,3]</sup>. Corticosteroids have been used for decades in the treatment of HES and, with the exception of PDGFRA-associated HES, remain the first-line treatment for most patients<sup>[17]</sup>. Typically high-dose prednisone (1 mg/kg per day or 60 mg/d in adults) can be initiated<sup>[1,3]</sup>. A good response to corticosteroid therapy is associated with a better prognosis<sup>[1]</sup>. If patients are refractory or intolerant to corticosteroids, alternative therapies must be considered. Cytotoxic agents, including hydroxyurea, can be considered as second-line therapy<sup>[1,3]</sup>. Immunomodulatory agents including IFN- $\alpha$ , cyclosporine, and alemtuzumab can also be used<sup>[17]</sup>. In patients with FIP1L1-PDGFR $\alpha$ -positive HES, imatinib mesylate (Gleevec<sup>®</sup>), which selectively inhibits a series of protein tyrosine kinases, is considered first-line therapy<sup>[17]</sup>.

In conclusion, we report a case of HES presenting with intractable gastric ulcers. The final diagnosis in this patient was HES involving the stomach, liver, lung, and bone marrow. Clinicians should bear in mind that gastric ulcers can develop in association with infiltrative disorders including HES. When gastric ulcers do not improve despite *H pylori* eradication and prolonged PPI therapy, an infiltrative gastric disorder, such as HES, should be considered.

### Abstract

We report a case of a 56-year-old woman with intrahepatic biliary cystadenoma (IBC) accompanying a tumor embolus in the extrahepatic bile duct, who was admitted to our department on October 13, 2008. Imaging showed an asymmetry dilation of the biliary tree, different bile signals in the biliary tree, a multiloculated lesion and an extrahepatic bile duct lesion with internal septation. A regular left hemihepatectomy *en bloc* was performed with resection of the entire tumor, during which a tumor embolus protruding into the extrahepatic bile duct and originating from biliary duct of segment 4 was revealed. Microscopically, the multiloculated tumor was confirmed to be a biliary cystadenoma with an epithelial lining composed of biliary-type cuboidal cells and surrounded by an ovarian-like stroma. An aggressive *en bloc* resection was recommended for the multiloculated lesion. Imaging workup, clinicians and surgeons need to be aware of this different presentation.

### INTRODUCTION

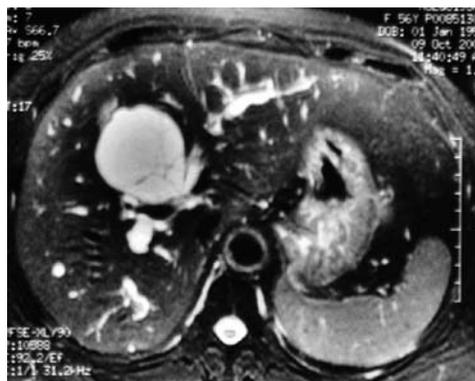

Intrahepatic biliary cystadenoma (IBC) is a rare benign epithelial tumor characterized by unicystic or multicystic growth, accounting for less than 5% of solitary non-parasitic cysts of biliary origin<sup>[1,2]</sup>. IBC was first described in 1892 by Keen<sup>[3]</sup>, followed by Edmondson as a multilocular cystic lesion lined by mucus-secreting cuboidal or columnar epithelium accompanying a densely cellular "ovarian-like" stroma<sup>[4]</sup>. The most common symptoms of IBC patients at presentation are abdominal pain and mass in which 35% have obstructive jaundice<sup>[1,5]</sup>. Knowledge about the pathogenesis of IBC is limited. IBC manifested as a tumor embolus in the extrahepatic bile duct occurs rarely. In addition, no other case report has yet described its clinicopathological features. We report a case of IBC with a tumor embolus in the extrahepatic bile duct with its clinicopathological features described and its diagnostic approaches and surgical procedures discussed.

### CASE REPORT

A 56-year-old woman with hypertension, diabetes and chronic B hepatitis was transferred to our hospital on October 13, 2008 due to a 2-wk history of right hypochondrial pain and spontaneously remitted jaundice. She denied nausea, vomiting, fever, shoulder or back pain. She was admitted to a local hospital but not received surgical treatment. Before admission, her peak bilirubin level was 434  $\mu\text{mol/L}$  and magnetic resonance cholangiopancreatography (MRCP) demonstrated a multiloculated cystic lesion in segment 4, measuring 5.5 cm in diameter, and an obviously dilated left intra- and extra-hepatic biliary tree (Figure 1) but no evidence of choledocholithiasis. The signal was different between extrahepatic and marginal bile ducts on T2-weighted magnetic resonance images (MRI)

**Figure 1** Magnetic resonance cholangiopancreatography (MRCP) showing the dilation of extrahepatic and intrahepatic bile ducts lacking of asymmetry.

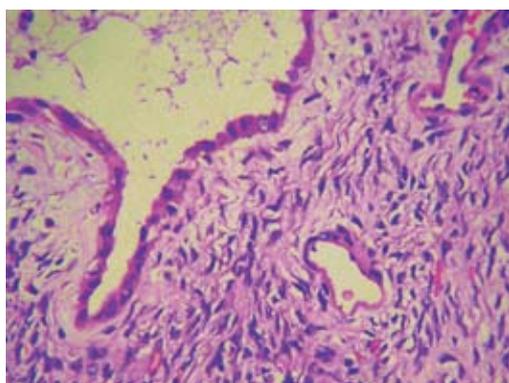

**Figure 2** Magnetic resonance imaging (MRI) showing different bile signals between the right and left intrahepatic ducts in a multiloculated lesion with internal septation.

**Figure 3** A tumor embolus originating from left intrahepatic duct with smooth surface protrudes the extrahepatic bile duct.

**Figure 4** Macroscopy revealing a multilocular cystic lesion containing serous fluid with tumor embolus protruding into the left hepatic duct and the extrahepatic bile duct.

**Figure 5** Postoperative pathology showing epithelial lining composed of biliary-type cuboidal cells surrounded by an ovarian-like stroma (400 ×).

showing thin septa in bile duct (Figure 2). The patient had no history of tobacco smoking, alcohol abuse or recent travel or previous surgery.

After admission, she demonstrated obstructive jaundice features, her bilirubin level declined spontaneously to 103.8  $\mu\text{mol/L}$ , carbohydrate antigen 19-9 (CA19-9) was elevated to 92.1  $\mu\text{g/L}$ , and carcinoembryonic antigen (CEA) level was normal. Abdominal ultrasound showed a dilated biliary tree and a multilocular cyst in segment 4. The extrahepatic bile duct (1.8 cm in diameter) was filled with fluid-like matters. Prior to a planned

left hepatectomy, percutaneous transhepatic biliary drainage (PTBD) of the right lobe was performed to decompress the right biliary system with an 8.5F tube. The TB level was 71  $\mu\text{mol/L}$  and 35.8  $\mu\text{mol/L}$ , respectively, before PTBD and hepatectomy. Volumetric computed tomography (CT) scan revealed that the ratio of remnant liver to total liver volume was 63.2%, with no change in cystic tumor size and no dilation of the right bile ducts, and CT scans showed a small septum in the extrahepatic bile duct, thus the cystic tumor was diagnosed as an intrahepatic tumor infiltrating the extrahepatic bile duct.

The patient underwent choledochotomy under general anesthesia on November 5, 2008, during which no palpable mass was found on the liver surface, but a tumor embolus originating from the intrahepatic duct of segment 4 with smooth surface that protruded into the extrahepatic bile duct was observed without mucus-secretion (Figures 3 and 4). Coexistence of a confluence variation in separate posterior right bile ducts and a variation in the replaced right hepatic artery from superior mesenteric artery was observed. A multiloculated cyst in segment 4 adhering to the bile duct wall of the anterior right lobe was found. So a regular left hemihepatectomy *en bloc* was performed with resection of the entire tumor, segment 5 and the wall of 8 bile ducts. The common hepatic duct was transected to facilitate reconstruction of

the orifice wall of the anterior right bile duct, and Roux-en-Y anastomosis between the hilar bile duct and jejunum was performed. Microscopically, the multiloculated tumor infiltrating the left hepatic duct was confirmed to be a biliary cystadenoma with an epithelial lining composed of biliary-type cuboidal cells and surrounded by an ovarian-like stroma (Figure 5). The bile duct margin was negative. The patient had an uneventful postoperative recovery. Follow-up imaging within twelve months showed no signs of local or distant tumor recurrence.

## DISCUSSION

IBC is an uncommon tumor of biliary tract, but IBC with a tumor embolus in the extrahepatic bile duct is rare. The clinical features of IBC, especially with a tumor embolus in the extrahepatic bile duct, are unclear. No risk factors for IBC have been identified, although its predominance in females suggests a hormonal factor for its etiology. The lesion grows slowly but it is believed to be premalignant<sup>[6]</sup>. Clinically, it can be differentially diagnosed from other cystic hepatic lesions, such as simple cysts, liver abscesses, cystic degeneration of a liver neoplasm, Caroli's disease, etc.<sup>[6,7]</sup>.

Imaging studies are of great importance in its diagnosis. Characteristic ultrasound, CT and MRI findings, including a multiloculated lesion with internal septation, a thickened and irregular wall, mural nodules and papillary projections, calcifications, and wall enhancements, have been well described<sup>[7,8]</sup>. However, IBC with a tumor embolus extending into the extrahepatic bile duct is uncommon and demonstrates some specific clinicopathological features, such as jaundice with spontaneous remission or recurrence<sup>[9]</sup>. Generally, jaundice often occurs when a big tumor embolus fills the extrahepatic bile duct. When the pressure of intra-biliary tract is high, the bile duct is dilated and the pressure of cystadenoma is counteracted, remitting the obstructive jaundice. The MRCP imaging manifestations of IBC, with a tumor embolus protruding into the extrahepatic bile duct, are different from those of IBC without a tumor embolus. In our case, MRCP showed different bile signals in the peripheral and extrahepatic bile ducts, while MRI and CT showed distinctive thin septa in the extrahepatic bile duct. In IBC with a tumor embolus in the extrahepatic bile duct, the extrahepatic bile duct was dilated much greater than the intrahepatic bile duct, and septa in the extrahepatic bile duct should be the main feature which is different from that of mucin-producing IBC without a tumor embolus, although their manifestations on MRCP are similar. Cystadenoma with an epithelial lining composed of biliary-type cuboidal cells is surrounded by an ovarian-like stroma. Before surgery for our patient, PTBD was performed with no mucin or serous fluid observed in the drainage. Since the tumor did not communicate with the bile duct tree, and was filled with serous fluid, intraductal papillary neoplasm of bile duct (IPNB) and biliary papillomatosis were excluded. This tumor develops intraductally but rarely infiltrates the distal bile duct. The base point of this tumor infiltrating the extrahepatic bile duct is intrahepatic, and the lower end

of its embolus is dissociated, thus facilitating complete resection of IBC with a tumor embolus as that without a tumor embolus<sup>[10-12]</sup>. Complete resection of the tumor provides the chance of cure. An early preoperative diagnosis of IBC is essential to improve the prognosis and survival of such patients.

In conclusion, IBC has a special growth manner<sup>[9,10,13-15]</sup>, but its clinical features have not been fully illustrated. Imaging workup, clinicians and surgeons need to be aware of its different presentations, such as recurrent jaundice, different bile signals on MRI, distinctive thin septa in extrahepatic bile duct, and asymmetry dilation of bile ducts. An aggressive complete resection of the lesion is recommended. Large randomized controlled trials are warranted.

### Abstract

Angeloni *et al* published a landmark study on the use of Coulter counters in spontaneous bacterial peritonitis (SBP) diagnosis. Riggio and Angeloni have recently published an editorial on the ascitic fluid analysis in diagnosis and monitoring of SBP. Herein, some points of interest are discussed.

Koulaouzidis A. Comments on the editorial by Riggio & Ageloni on the ascitic fluid analysis. *World J Gastroenterol* 2009; 15(48): 6137-6138 Available from: URL: <http://www.wjgnet.com/1007-9327/15/6137.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.6137>

### TO THE EDITOR

I read with great interest the editorial of Riggio & Angeloni on “The ascitic fluid analysis for diagnosis and monitoring of spontaneous bacterial peritonitis”<sup>[1]</sup>. In 2003, Angeloni *et al*<sup>[2]</sup> published the landmark paper, which set a new era in the diagnostic algorithm of spontaneous bacterial peritonitis (SBP), allowing many clinicians and laboratory staff to feel secure in switching from polymorphonuclear (PMN) manual count to the automated one.

I would like to comment on a few points presented in this editorial. First of all, I would appreciate if the authors could clarify the statement on the need for collection of 10 mL ascitic fluid (AF) in ethylenediaminetetraacetic acid (EDTA) containing tube. Universally, most of the EDTA tubes (“purple-top or red-top tubes”, used for blood collection) have a maximum capacity of 2.5-3.0 mL. If Riggio & Angeloni meant the universal containers, it is my understanding that these tubes, except for being sterile, they do not contain any anticoagulant. On top of that, only 1 mL of fluid is enough for most laboratories to do the differential diagnosis. I disagree with the statement that “following hospitalization of any cirrhotic patient with newly diagnosed ascites, a diagnostic paracentesis is advised”. In fact, all cirrhosis with ascites should have diagnostic paracentesis on hospital admission<sup>[3]</sup>.

There are indeed 4 well-disseminated practical guidelines and expert’s consensus reports, but many other national guidelines have been produced as well<sup>[4]</sup>.

Riggio & Angeloni’s comprehensive “Table 2” should list 90 AF samples and not 47 in the study by Wisniewski *et al*<sup>[5]</sup>, 2123 samples and not 1041 in the study by Nousbaum *et al*<sup>[6]</sup>, and 78 samples and not 72 in the study by Vanbiervliet *et al*<sup>[7]</sup>, although three studies have not been included<sup>[8-11]</sup>. In addition, Castellote *et al*<sup>[12]</sup> in a recently published paper argued that the leucocyte reagent strips may have a role in repeated paracentesis and hence management of SBP.

### Abstract

Mesenteric panniculitis is a rare disease characterized by chronic non-specific inflammation of mesenteric fat tissue. Several etiologic and/or associated factors have been reported in the literature so far. Although trauma or surgery is one of the potential etiologic factors for mesenteric panniculitis, to the best of our knowledge, no strong correlation has been shown in the literature until now.

### TO THE EDITOR

We read with a great interest the article “Mesenteric panniculitis: Various presentations and treatment regimens” by Issa *et al*<sup>[1]</sup> in the August issue of the *World Journal of Gastroenterology*.

Mesenteric panniculitis is a rare chronic inflammatory disorder of adipose tissue of the intestinal mesentery. This entity has several different names, such as mesenteric Weber-Christian disease, fibrosing mesenteritis, retractile mesenteritis, mesenteric lipodystrophy, and sclerosing mesenteritis. Its etiology still remains unclear, although a variety of possible causative and associated factors, such as infective and autoimmune causes, vascular insufficiency, prior abdominal surgery, and malignancy, have been reported<sup>[1-4]</sup>.

Issa *et al*<sup>[1]</sup> reported that 84% of patients with mesenteric panniculitis have a history of abdominal trauma or surgery as its etiological factor<sup>[2]</sup>. However, the actually reported rate of trauma or surgery as an etiologic factor is 4.76% rather than 84%<sup>[2]</sup>. A same mistaken rate of 84% has also been reported in a case series<sup>[3]</sup>, showing that trauma and surgery are closely correlated with mesenteric panniculitis. Upon reviewing the literature, we were not able to find this strong correlation in any study.

Several studies are available on the etiology of mesenteric panniculitis<sup>[1-4]</sup>. Daskalogiannaki *et al*<sup>[4]</sup> reported that mesenteric panniculitis is associated with 69.3% of malignancies, such as lymphoma, breast cancer, colon cancer, lung cancer and melanoma, demonstrating that mesenteric panniculitis is an associated and/or causative factor for malignancies. Although trauma or surgery is one of the potential etiologic factors, to the best of our knowledge, no strong correlation has been shown in the literature until now.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327, DOI: 10.3748) is a weekly, peer-reviewed, online, open-access (OA) journal supported by an editorial board of 1126 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in *WJG* will include the following. (1) Editorial: to introduce and comment on major advances in rapidly developing areas and their importance. (2) Frontier: to review recent developments and comment on current research status in important fields, and propose directions for future research. (3) Topic Highlight: this column consists of three formats, including: (a) 10 invited review articles on a hot topic; (b) a commentary on common issues associated with this hot topic; and (c) a commentary on the 10 individual articles. (4) Observation: to update the development of old and new questions, highlight unsolved problems, and provide strategies for their resolution. (5) Guidelines for Basic Research: as suggested by the title. (6) Guidelines for Clinical Practice: to provide guidelines for clinical diagnosis and treatment. (7) Review: to review systemically the most representative progress and unsolved problems, comment on current research status, and make suggestions for future work. (8) Original Article: to report original and innovative findings. (9) Brief Article: to report briefly on novel and innovative findings. (10) Case Report: To report a rare or typical case. (11) Letters to the Editor: to discuss and reply to contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest. (12) Book Reviews: to introduce and comment on quality monographs. (13) Guidelines: To introduce consensus and guidelines reached by international and national academic authorities on basic research and clinical practice

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments,

References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be

provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

#### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...etc. It is our principle to publish high resolution-figures for the printed and E-versions.

#### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

#### Notes in tables and illustrations

Data that are not statistically significant should not be noted.  $^aP < 0.05$ ,  $^bP < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of *P* values,  $^cP < 0.05$  and  $^dP < 0.01$  are used. A third series of *P* values can be expressed as  $^eP < 0.05$  and  $^fP < 0.01$ . Other notes in tables or under illustrations should be expressed as  $^1F$ ,  $^2F$ ,  $^3F$ ; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

#### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

#### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

#### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

#### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

#### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA concentration, *p* (CEA) =  $8.6 \pm 2.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23243641.

The format for how to accurately write common units and quantumms can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kpn I*, *Kpn I*, etc.

Biology: *H. pylori*, *E. coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

Telephone: +86-10-59080039

Fax: +86-10-85381893

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

### Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
