homogeneous. As shown by the immunohistological staining in Figure 5C, transduction seemed limited to the peripheral layers of the explants. This non-homogeneous transduction pattern underscores the importance of co-transduction with an internal control when using this system to test the effect of retargeting of gene therapy vectors.

The possibility of culturing pancreatic slices for up to 3 d also seems long enough to study the transduction with other types of viral vectors such as lentiviral vectors and adeno associated virus (AAV). To explore this possibility we incubated normal pancreas with adeno-associated virus serotype 2-GFP (AAV2-GFP) or with lentivirus-GFP. Upon incubation with AAV-GFP, the fluorescence levels were comparable to those obtained with Ad-GFP (Figure 5B). In contrast, fluorescence was below detection limit when using lentivirus-GFP. As shown in Figure 5D, only a few cells were transduced by lentiviral vectors and expressed GFP. This poor transduction by lentiviral vectors may have been due to the vigorous shaking of the slices in combination with a low affinity of this vector for this tissue. Another possible cause is the fragility of lentiviral vectors. Production of proteases and/or lipases by these slices will affect lentiviral vector integrity and reduce transduction.

## DISCUSSION

The limited intervention options for advanced and

metastasized pancreatic cancer require new treatment modalities such as gene therapy. The preclinical adenovirus-mediated gene therapy study models primarily rely on cultured cells and the xenograft nude mouse model. Both remain a poor representation of *in vivo* pancreatic cancer. Pancreatic cell lines acquire new genetic defects upon multiple passages *in vitro* and after subcutaneous injection *in vivo*<sup>[22]</sup>. Moreover, xenograft tumors lack the natural interaction between tumor cells, stromal cells, normal cells and extracellular matrix. This is an important drawback since anatomical barriers such as fibrosis are a major hurdle for adenovirus spreading through the tumor<sup>[23]</sup>.

For these reasons, primary human tissue specimens seem more comparable to the *in vivo* situation and may provide a better prediction of virus-host interactions.

We studied the tissue slice system for culturing *ex vivo* pancreatic explants. Other groups have already reported slice culture of various organs from different species<sup>[15-17,24]</sup>. Here, we demonstrated that this technique is also feasible for pancreatic tissue using the Krumdieck tissue slicer. Independently of the medium formulation, normal pancreas was viable for up to 6 d. Since the inner cell layers seemed more viable than the peripheral layers, oxygen and nutrient diffusion through the slices does not seem limiting. Microscopic examination of normal slices revealed an epithelial-like cell sheet surrounding the explants. This is in accordance with the findings of Hoem *et al*, who cultured *ex vivo*

pancreas for up to 6 wk<sup>[13]</sup>. They hypothesized that these cells have a ductal or acinar cell origin, possibly resulting from transdifferentiation caused by prolonged culturing. Others showed that this so-called acinar-ductal transdifferentiation *in vitro* indeed depends on medium formulation<sup>[25]</sup>. The loss of ductal and acinar cells from these explants may explain the decrease of amylase secretion by the slices over time.

We also showed that pancreatic adenocarcinoma explants can be cultured while retaining moderate to good viability and morphology. Resection specimens are small and the amount of tissue available for research purposes therefore is very limited. Manual dissection to fragments led to inhomogeneous samples that could not be used for further study. To optimize the yield of slices, we therefore used an automatic tissue slicer. The size of the resection specimens varied, and to be able to generate uniform slices, the specimens were included in low melting agarose. Upon stabilizing the tumor cubes in this manner, a significant number of slices could be obtained from limited amounts of tissue. This method does result in slices comparable in size and viability, with minimal loss of tissue. As such, this method seems superior to manual processing that resulted in slices with a high degree of heterogeneity and limited survival of explanted tissue<sup>[14]</sup>. Furthermore, with this technique, several slices can be obtained from a small resection specimen. This enabled us to compare different viral vectors and experimental conditions in the resection specimens derived from each patient.

We were able to culture these slices for at least 3 d with good morphology. This period is sufficiently long to study the transduction efficiency since most viral vectors need between 48 and 72 h for optimal expression. We showed that adenovirus infects and transduces pancreatic slices efficiently. In addition, we showed that simultaneous transduction of slices with a control and experimental virus expressing different reporter genes provides an elegant procedure to determine adenoviral transduction efficacy while correcting for variability in tissue viability and composition. In this respect, this system seems highly suitable for determining the efficacy of adenoviral vectors that target pancreatic cancer cells. Transduction experiments with such infectivity-enhanced adenoviral vectors in slices from normal tissue and tumor tissue will indicate their targeting specificity. Others have already shown that slices that maintain viability for at least 3 d are suitable for replication of CRAds<sup>[17,24]</sup>. Therefore, our tissue explant system seems suitable to test the transduction efficacy of CRAds, and more especially, to investigate the increased efficacy of infectivity-enhanced CRAds. However, an optimal comparison of actual oncolytic potency of CRAds requires several rounds of replication and therefore a prolonged culture time. For these investigations, patient-derived multicellular cancer spheroids seem more suitable<sup>[26,27]</sup>.

In addition to adenoviral transduction, these slices were efficiently transduced by AAV-2 but poorly by lentiviral vectors. These two vectors have been shown to be suitable for correction of inherited disorders in pre-

clinical models. Based on the transduction seen here, these slices can be used to investigate whether these vectors can be targeted; for instance, to the islet cells with the aim of providing correction for diabetes<sup>[28]</sup>.

In conclusion, we have developed a system that allows processing of minimal amounts of pancreatic tissue from resection specimens. The generated thin, homogenous and viable tissue slices retain their morphology for at least 3 d. Furthermore, with this method, a sufficient number of slices can be obtained from minimal amounts of tissue, enabling the comparison of several experimental conditions within a single tumor specimen.

## ACKNOWLEDGEMENTS

We acknowledge Jan Dekker for his technical assistance and professor DJ Gouma for providing resection material.

## COMMENTS

### Background

Pancreatic cancer is a devastating disease for which at present no therapy is available. Gene therapy was shown to be effective in preclinical animal models and was expected to improve the poor prognosis for patients suffering from pancreatic cancer. However, in patients, these methods lacked efficacy due to poor transduction of cancer cells. Therefore, other models more comparable to the situation in patients are essential for predicting the clinical efficiency of novel therapies such as gene therapy.

### Research frontiers

To circumvent the low coxsackie- and adenovirus receptor expression in human cancers in patients, retargeting of adenovirus to receptors highly expressed on human cancers is an essential step to improve their clinical efficacy.

### Innovations and breakthroughs

Available animal models for pancreatic cancer do not reliably predict the clinical efficacy of retargeted adenoviral vectors. In this study, we present a tissue slice model more representative of the situation in patients as a model to predict the clinical efficacy of retargeted adenoviral vectors.

### Applications

This tissue slice model is suitable for determining the efficiency of viral vectors retargeted to pancreatic cancer. In addition, this system can be used for pre-clinical *ex-vivo* studies of novel drugs to treat pancreas cancer.

### Peer review

This was a well-performed study in an area of interest to gastroenterologists and pancreatologists in particular.

### Abstract

**AIM:** To investigate and predict enteral nutrition problems after percutaneous endoscopic gastrostomy (PEG).

**METHODS:** We retrospectively analyzed data for 252 out of 285 patients who underwent PEG at our hospital from 1999 to 2008. Enteral nutrition problems after PEG were defined as: (1) patients who required  $\geq 1$  mo after surgery to switch to complete enteral nutrition, or who required additional parenteral alimentation continuously; or (2) patients who abandoned switching to enteral nutrition using the gastrostoma and employed other nutritional methods. We attempted to identify the predictors of problem cases by using a logistic regression analysis that examined the patients' backgrounds and the specific causes that led to their problems.

**RESULTS:** Mean age of the patients was 75 years, and in general, their body weight was low and their overall condition was markedly poor. Blood testing revealed that patients tended to be anemic and malnourished. A total of 44 patients (17.5%) were diagnosed as having enteral nutrition problems after PEG. Major causes of

the problems included pneumonia, acute enterocolitis (often *Clostridium difficile*-related), paralytic ileus and biliary tract infection. A multivariate analysis identified the following independent predictors for problem cases: (1) enteral nutrition before gastrectomy (a risk reduction factor); (2) presence of esophageal hiatal hernia; (3) past history of paralytic ileus; and (4) presence of chronic renal dysfunction.

**CONCLUSION:** Enteral nutrition problems after PEG occurred at a comparatively high rate. Patient background analysis elucidated four predictive factors for the problem cases.

### INTRODUCTION

Percutaneous endoscopic gastrostomy (PEG) was first introduced by Gauderer *et al* in 1980<sup>[1]</sup>. Since that time, it has become one of the most useful and established enteral nutrition techniques performed at treatment centers. Compared to the use of a nasogastric tube, enteral nutrition using a PEG tube offers numerous advantages, including reduced laryngopharyngeal discomfort and a lower risk of aspiration lung disease<sup>[2,3]</sup>. When performing PEG, the associated risks must always be kept in mind. While various devices have been developed<sup>[4,5]</sup>, the frequency of adverse events is higher as compared to other nutritional methods, since PEG is based on a surgical technique<sup>[6-8]</sup>. Additionally, even

if PEG is successful, patients often encounter enteral nutrition problems after surgery. We investigated and analyzed the etiology of these problems in patients seen at our hospital.

## MATERIALS AND METHODS

### *Patients and gastrostomy*

Of the 285 patients who underwent PEG at our center from April 1999 to April 2008, we were able to statistically analyze the data for 252 subjects (157 males, 95 females). Our center admits many elderly patients who present poor general conditions in addition to having problems with ingesting food orally. PEG is primarily performed in the gastroenterology department after a request from a different department. After PEG is scheduled, upper gastrointestinal endoscopy is performed preoperatively in all cases, and abdominal computed tomography (CT) is carried out as needed in order to ascertain whether PEG can be done. If patients are taking anticoagulant or antiplatelet agents, a drug-free period is established, which depends on the type of drug being taken.

All patients in the present study underwent gastrostomy using the pull method<sup>[1]</sup>. With the exception of one patient, no sutures were used to fix the abdominal and gastric walls at the gastrostomy site. In general, antibiotics were administered intravenously for 3 d following PEG. Two days after surgery, lukewarm water was injected, followed by injection of enteral nutrients starting 4 d after the surgery. A switch to enteral nutrition using the PEG tube was initiated 7-10 d after surgery. At our clinical center, we have been using PEG clinical paths since June 2003.

### *Data analysis*

In the present study, patients were considered to have a problem with enteral nutrition after PEG if they met one of the following criteria: (1) patients who required  $\geq 1$  mo after surgery to switch to complete enteral nutrition, or who required additional parenteral alimentation continuously; or (2) patients who abandoned switching to enteral nutrition using the gastrostoma and employed other nutritional methods. The data on the patients' backgrounds and suspected reasons for their problems were collected and used for further analysis. To analyze the predictors among the problem cases, we chose 26 candidates that we believed could possibly have an influence on the postoperative enteral nutrition (Table 1). Binomial logistic regression analysis was performed using statistical software (SPSS Base 11.0j and SPSS Regression Models 9.0J; SPSS Japan Inc., Tokyo, Japan), with the presence or absence of enteral nutrition problems after PEG employed as the dependent variable. Since it was necessary to analyze numerous factors, univariate analysis was conducted to narrow down the candidates based on the significance probability ( $P < 0.1$ ). Independent predictors were determined by conducting multivariate analysis based on a step-down procedure that used likelihood ratios.

Subsequently, after subjects were grouped in relation to each predictor, problem characteristics were investigated.

## RESULTS

### *Patients' background factors*

Table 2 shows the background factors for the 252 patients. Mean age of the patients was 75 years (range, 38-99 years), with men making up approximately 60% of the group. As to the general physical conditions, body weight was low and overall condition was markedly poor. Blood testing revealed that the patients tended to be anemic and malnourished prior to gastrostomy. There were inflammatory reactions in many patients. Cerebrovascular disorders accounted for about 70% of the underlying diseases. Even though the majority of the patients had central nervous system diseases, disuse syndrome and senile dementia were also noted. PEG was performed for enteral nutrition in all patients.

### *Cases of enteral nutrition problems after PEG*

A total of 44 (17.5%) out of 252 patients exhibited enteral nutrition problems after PEG. There were 33 cases that met criterion (1), and three cases required continuous supportive parenteral alimentation. In 30 of these cases, the mean number of days required to switch to enteral nutrition was  $69 \pm 31$  (mean  $\pm$  SD) d (range 32-145 d). Eleven cases met criterion (2).

Table 3 shows causes of the enteral nutrition problems for each of the criteria. Although various events were confirmed, pneumonia, paralytic ileus, acute enterocolitis and biliary tract infection were the most frequently seen in both criterion groups. In the pneumonia and acute enterocolitis patients, aspiration pneumonia and *Clostridium difficile*-associated enteric disease (CDED) accounted for the majority of the cases, respectively. For criterion (2), aggravation of chronic renal dysfunction and heart failure were noted.

### *Statistical analysis*

In 252 patients, univariate analysis was performed for each of the 26 factors with the presence or absence of enteral nutrition problems after PEG used as the dependent variable (Table 1). Candidate predictors were narrowed down to the following: "enteral nutrition before gastrectomy"; "hemoglobin level the day before gastrostomy"; "albumin level the day before gastrectomy"; "presence of esophageal hiatal hernia"; "past history of paralytic ileus"; "past history of aspiration pneumonia"; and "presence of chronic renal dysfunction". A step-down procedure that employed likelihood ratios was used for the seven items subjected to multivariate analysis. The following four factors were identified as independent predictors for cases with enteral nutrition problems after PEG: (1) enteral nutrition before gastrectomy; (2) presence of esophageal hiatal hernia; (3) past history of paralytic ileus; and (4) presence of chronic renal dysfunction (Table 4). The sensitivity, specificity and overall accuracy using the prediction model were 30.0%, 97.0% and 85.8%,

respectively. After the deletion of unselected factors, the sensitivity and overall accuracy were improved.

### Investigation of each predictor

Table 5 summarizes the actual causes of the patients' problems for each predictor. Because enteral nutrition before gastrectomy is a risk reduction factor, we decided to investigate cases of parenteral alimentation before PEG. While pneumonia accounted for about 30% of the problems, paralytic ileus, acute enterocolitis and biliary tract infection were also noted. In the enteral nutrition group, blood albumin and hemoglobin levels prior to gastrectomy were significantly higher than those seen in parenteral alimentation group [mean ± SD; albumin level (g/dL): 3.3 ± 0.4 *versus* 3.1 ± 0.4, *P* < 0.001; hemoglobin level (g/dL): 11.9 ± 1.7 *versus* 11.1 ± 1.6, *P* < 0.001; unpaired *t*-test]. In cases with esophageal hiatal hernia,

pneumonia accounted for about 45% of the problems. In addition, the majority of these cases were caused by aspiration. On the other hand, in cases with a past history of paralytic ileus, the most frequent cause was a recurrence of ileus. Similarly, in cases with chronic renal dysfunction, an aggravation of chronic renal dysfunction accounted for about 30% of the cases.

## DISCUSSION

Although predictors for postoperative enteral nutrition problems can be used to determine indications for PEG, there are no studies that have specifically examined these factors. In the current study, most patients were elderly and suffering from cerebrovascular disorders or dementia, and their general condition was markedly poor. Due to long-term recumbency and undernutrition,

ASO: Arteriosclerosis obliterans; CV: Central vein.

these patients had various infections. The current report presents useful information for gastroenterologists who perform PEG in patients with similar backgrounds.

The enteral nutrition problems that occurred after PEG were defined according to previously described criteria. We excluded cases in which there was switching to enteral nutrition within 1 mo after PEG, as we believe that there are few disadvantages for such patients. We also excluded cases where the reason for the problem was unclear, even if these patients required longer than 1 mo to switch to enteral nutrition.

Our results demonstrated that enteral nutrition problems after PEG occurred at a comparatively high rate. Although various causes were confirmed, few cases were determined to be a direct complication of PEG. For both of the inclusion criteria, pneumonia occurred most frequently, although enterocolitis, paralytic ileus and biliary tract infection were also noted. Aspiration pneumonia accounted for the majority of the pneumonia cases. We also noted that cerebrovascular disorders accounted for approximately 70% of the underlying diseases. It is possible that dysphagia may promote aspiration in these patients. In and by itself, paralytic ileus can cause enteral nutrition problems. Furthermore, it may also promote or aggravate aspiration pneumonia,

as bowel paralysis induces vomiting or gastrointestinal reflux<sup>[9]</sup>. In acute enterocolitis patients, CDED accounted for the majority of the cases. CDED is a drug (antibiotics)-induced enteric disease and we have previously reported that CDED can occur, with onset of the disease noted soon after the PEG procedure<sup>[10]</sup>. In this study, we confirmed that the CDED that occurred after PEG was able to interrupt enteral nutrition over a long period of time. In almost all cases of biliary tract infection, stones or sludge were noted in the gallbladder. Other studies have reported that when patients are switched to enteral nutrition from parenteral alimentation, there is an increase in cholestasis, along with a sudden contraction of the gallbladder<sup>[11,12]</sup>. These events may promote obstruction and infection within the bile duct system.

We attempted to determine predictors for problem cases and our results indicated that only enteral nutrition before PEG was a risk reduction factor. Our analysis demonstrated there was a small but significant probability that preoperative enteral nutrition strongly inhibited enteral nutrition problems after PEG. As compared to parenteral alimentation, enteral nutrition offers the following advantages: (1) maintains a favorable and natural alimentation; (2) maintains gastrointestinal function; and (3) provides a check on the safety of enteral nutrition prior to the PEG procedure<sup>[13-15]</sup>. Actually, we noted that aspiration pneumonia after vomiting or gastrointestinal disorder occurred in cases of preoperative parenteral alimentation. In addition, there was one patient after the PEG procedure who was afflicted by a central-venous-catheter-caused infection. Our results also showed that blood albumin and hemoglobin levels prior to gastrectomy were significantly higher in the enteral nutrition group. Therefore, if parenteral alimentation cases are scheduled for PEG, the procedure should be performed after switching to enteral nutrition.

Among the three risk factors examined, the presence of an esophageal hiatal hernia had the strongest association with the enteral nutrition problems that are found after PEG. In these cases, pneumonia accounted for about 45% of the causes, with the majority of the pneumonia cases occurring due to aspiration. Previous studies have shown that aspiration is a complication of esophageal hiatal hernia and gastroesophageal reflux disease<sup>[16]</sup>. Recently, Kitamura *et al* reported that esophageal hiatal hernia was a risk factor for aspiration pneumonia after PEG<sup>[17]</sup>. Our results indicate that preoperative upper gastrointestinal endoscopy is important for predicting enteral nutrition problems after PEG. After PEG, the posture of patients with esophageal hiatal hernia needs to be evaluated during nutrition. In addition, in such situations, it may also be necessary to consider using half-solid enteral nutrients<sup>[18-20]</sup>. In patients with a past history of paralytic ileus, the recurrence of ileus accounted for about 40% of the causes. As chronic bowel dysfunction plays a role in the background of idiopathic paralytic ileus, its recurrence is not all that rare<sup>[21]</sup>. In such cases, a rapid increase of enteral nutrient

after PEG may be responsible for the recurrent paralytic ileus. When there is coadministration of enterokines activators or gradual increases of enteral nutrients, this may prevent such recurrences<sup>[22,23]</sup>. In cases with chronic renal dysfunction, an aggravation of renal dysfunction or heart failure accounted for about 60% of the causes. In most cases, there was an eventual discontinuation of the enteral nutrition after PEG. Therefore, in patients with poor renal function, the indication for PEG needs to be very carefully investigated. In addition, after performing PEG in such cases, it is necessary to finely control the infusions and medications by performing frequent blood

or X-ray tests.

Previous studies have reported that patients with diabetes or low body weight have a high frequency of complications<sup>[24,25]</sup>. However, body mass index, fasting blood sugar levels and the presence of diabetes mellitus were not identified as predictors of enteral nutrition problems after PEG. In the present study, most patients were elderly, displayed a markedly poor general condition and tended to be underweight, malnourished and anemic. A bias in patient background factors may also have affected our analysis. Based on the mean preoperative blood glucose levels, it is also quite possible that a stricter control of the diabetes could have suppressed an increased number of adverse events. Although our univariate analysis indicated that blood albumin and hemoglobin levels obtained on the day before PEG could be regarded as strong candidates, both were excluded by multivariate analysis. In the enteral nutrition group, blood albumin and hemoglobin levels obtained the day before gastrectomy were significantly higher than those found in the parenteral alimentation group. Therefore, the relevance of these factors may have affected our current analysis.

## CONCLUSION

Enteral nutrition problems after PEG occurred at a comparatively high rate. Analysis of patient background factors elucidated four predictors for these problem cases. Since characteristic causes exist for these respective predictors, it may be possible to analyze causal relationships and mechanisms of onset, thereby making it possible to devise several preventative methods.

## COMMENTS

### Background

Percutaneous endoscopic gastrostomy (PEG) has become one of the most useful and established enteral nutrition techniques. However, since PEG is based on a surgical technique and is mainly performed in elderly individuals with poor general conditions, the frequency of adverse events is higher compared to other methods of nutrition. Even if PEG is successful, patients often encounter enteral nutrition problems after surgery.

### Research frontiers

Although knowledge of predictors of postoperative enteral nutrition problems may provide useful information, there are no studies that have specifically examined such predictors. The authors investigated the etiology of these problems, and tried to predict enteral nutrition problems after PEG.

### Innovations and breakthroughs

The authors showed that enteral nutrition problems after PEG occurred at a comparatively high rate. Analysis of patient background factors elucidated the following four predictors for these problem cases: (1) enteral nutrition before gastrectomy; (2) presence of esophageal hiatal hernia; (3) past history of paralytic ileus; and (4) presence of chronic renal dysfunction.

## Applications

Predictors for postoperative enteral nutrition problems can be used to determine indications for PEG. Since specific causes exist for these predictors, it may be possible to analyze causal relationships and mechanisms of onset, thereby making it possible to devise several preventive methods.

## Peer review

This study reports a large number of patients with PEGs and identifies factors that seem to predict failure of enteral nutrition. This is likely to be of interest to readers and provides some novel data. In addition, the discussion gives some ideas about how to address individual patients with poor prognostic factors.

### Abstract

**AIM:** To investigate whether carnitine deficiency is a risk factor during the development of diethylnitrosamine (DENA)-induced hepatic carcinogenesis.

**METHODS:** A total of 60 male Wistar albino rats were divided into six groups with 10 animals in each group. Rats in group 1 (control group) received a single intraperitoneal (i.p.) injection of normal saline. Animals in group 2 (carnitine-supplemented group) were given L-carnitine (200 mg/kg per day) in drinking water for 8 wk. Animals in group 3 (carnitine-depleted group) were given D-carnitine (200 mg/kg per day) and mildronate (200 mg/kg per day) in drinking water for 8 wk. Rats in group 4 (DENA group) were injected with a single dose of DENA (200 mg/kg, i.p.) and 2 wk later received a single dose of carbon tetrachloride (2 mL/kg) by gavage as 1:1 dilution in corn oil. Animals in group 5 (DENA-carnitine depleted group) received the same treatment as group 3 and group 4. Rats in group 6 (DENA-carnitine supplemented group) received the same treatment as group 2 and group 4.

**RESULTS:** Administration of DENA resulted in a significant increase in alanine transaminase (ALT), gamma-glutamyl transferase (G-GT), alkaline phosphatase (ALP), total bilirubin, thiobarbituric acid reactive substances (TBARS) and total nitrate/nitrite (NOx) and a significant decrease in reduced glutathione (GSH), glutathione peroxidase (GSHPx), catalase (CAT) and total carnitine content in liver tissues. In the carnitine-depleted rat model, DENA induced a dramatic increase in serum ALT, G-GT, ALP and total bilirubin, as well as a progressive reduction in total carnitine content in liver tissues. Interestingly, L-carnitine supplementation resulted in a complete reversal of the increase in liver enzymes, TBARS and NOx, and a decrease in total carnitine, GSH, GSHPx, and CAT induced by DENA, compared with the control values. Histopathological examination of liver tissues confirmed the biochemical data, where L-carnitine prevented DENA-induced hepatic carcinogenesis while D-carnitine-mildronate aggravated DENA-induced hepatic damage.

**CONCLUSION:** Data from this study suggest for the first time that: (1) carnitine deficiency is a risk factor and should be viewed as a mechanism in DENA-induced hepatic carcinogenesis; (2) oxidative stress plays an important role but is not the only cause of DENA-induced hepatic carcinogenesis; and (3) long-term L-carnitine supplementation prevents the development of DENA-induced liver cancer.

## INTRODUCTION

Liver cancer is one of the most common malignancies worldwide, especially in Asia and Africa<sup>[1]</sup>. Hepatocellular carcinoma accounts for about 80%-90% of all liver cancer and is the fourth most common cause of cancer mortality<sup>[2]</sup>. Major risk factors for liver cancer include hepatitis viral infection, food additives, alcohol, aflatoxins, environmental and industrial toxic chemicals, and air and water pollutants<sup>[3,4]</sup>. Diethylnitrosamine (DENa) is a well known potent hepatocarcinogenic agent present in tobacco smoke, water, cured and fried meals, cheddar cheese, agricultural chemicals, cosmetics and pharmaceutical products<sup>[5-7]</sup>. DENa is known to induce damage in many enzymes involved in DNA repair and is normally used to induce liver cancer in experimental animal models<sup>[8]</sup>. Although there are many strategies for the treatment of liver cancer<sup>[9-11]</sup>, the therapeutic outcome of this cancer remains very poor. Therefore, prevention seems to be the best strategy for lowering the incidence of this disease. Recently, considerable research has been carried out in the search for natural or synthetic compounds as a means of chemically preventing liver cancer<sup>[12-18]</sup>. In this regard, many compounds have been tested with proved efficacy against experimentally-induced hepatocarcinogenesis. These compounds include morin<sup>[12]</sup>, silymarin<sup>[13]</sup>, garlic<sup>[14]</sup>, star anise<sup>[15]</sup>, ganfujian granule<sup>[1]</sup>, apigenin<sup>[16]</sup> and the crude extracts of *agarcus blazei*<sup>[17]</sup>.

L-carnitine is a naturally occurring compound that is primarily located in mitochondria and possesses potential protective effects against many mitochondrial toxic agents<sup>[18-20]</sup>. It is derived from two sources: endogenous synthesis, in the liver and kidney, and from exogenous dietary sources such as red meat and dairy products<sup>[19,21]</sup>. L-carnitine is an essential cofactor for the translocation of long-chain fatty acids from the cytoplasmic compartment into mitochondria, where beta-oxidation enzymes are located for ATP production<sup>[22]</sup>. It has been reported that mitochondrial injury may exert a major influence on carcinogenesis<sup>[23]</sup>. Consistent with this hypothesis, Chang *et al*<sup>[24]</sup> have reported that mitochondrial dysfunction plays an essential role in hepatocarcinogenesis *via* production of reactive oxygen species (ROS), and that L-carnitine inhibits pre-neoplastic lesions and prevents hepatocarcinogenesis in Long Evans Cinnamon rats as a model of hepatocarcinogenesis. Furthermore, earlier studies have reported that carnitine effectively inhibits mitochondrial injury induced by ROS and mitochondria-dependent apoptosis<sup>[25-27]</sup>. In addition, L-carnitine prevents the accumulation of free fatty acids and their toxic intermediates, thus preventing their harmful effects on mitochondrial and cell membranes<sup>[20,26,28]</sup>. Despite the liver being the main organ responsible for endogenous synthesis of L-carnitine, we were unable to find any previously published studies investigating the role of long-term endogenous carnitine depletion and/or carnitine deficiency during induction of hepatic carcinogenesis. Therefore, this study was initiated with the following specific aims: (1) to determine whether or not endogenous

carnitine depletion and/or carnitine deficiency is a risk factor during the development of hepatic carcinogenesis and; (2) to gain insights into the possibility of mechanism-based protection by L-carnitine supplementation against DENa-induced hepatocarcinogenesis.

## MATERIALS AND METHODS

### Animals

Adult male Wistar albino rats, weighing 180-200 g, were obtained from the Experimental Animal Care Center, College of Pharmacy, King Saud University (KSU), Riyadh, Kingdom of Saudi Arabia (KSA) and were housed in metabolic cages under controlled environmental conditions (25°C and a 12 h light/dark cycle). Animals had free access to pulverized standard rat pellet food and tap water unless otherwise indicated. The protocol of this study was approved by the Research Ethics Committee of College of Pharmacy, KSU, Riyadh, KSA.

### Materials

DENa and carbon tetrachloride (CCl<sub>4</sub>) were purchased from Sigma Chemical Co. (St. Louis, MO, USA). DENa was dissolved in saline and injected in a single dose (200 mg/kg, i.p.) to initiate hepatic carcinogenesis, while CCl<sub>4</sub> was used in a single dose (2 mL/kg) by gavage as 1:1 dilution in corn oil to stimulate liver cell proliferation and regeneration according to previously published protocols<sup>[29,30]</sup>. L-carnitine, D-carnitine and mildronate (trimethylhydrazinium propionate) were kindly supplied by Dr. Menotti Calvani, (Sigma-Tau Pharmaceuticals, Pomezia, Roma, Italy). All other chemicals used were of the highest analytical grade.

### Carnitine-depleted rat model

Animal models of carnitine deficiency have been developed by many investigators<sup>[31-33]</sup>. In the current study, carnitine deficiency was induced in rats by administration of D-carnitine (200 mg/kg per day) and mildronate (200 mg/kg per day) in drinking water. Depletion of L-carnitine by D-carnitine occurs *via* an exchange of the D- and L-isomers across the cell membrane where intracellular L-carnitine has been shown to exchange with extracellular D-carnitine<sup>[31]</sup>. Moreover, mildronate inhibits carnitine biosynthesis by inhibition of the gamma-butyrobetaine hydroxylase enzyme<sup>[32,33]</sup>.

### Experimental design

To achieve the ultimate goal of this study, a total of 60 adult male Wistar albino rats were divided into six groups with 10 animals in each group. Rats in group 1 (control group) received a single intraperitoneal (ip) injection of normal saline (2.5 mL/kg). Animals in group 2 (carnitine-supplemented group) were given L-carnitine (200 mg/kg per day) in drinking water for 8 wk. Animals in group 3 (carnitine-depleted group) were given D-carnitine (200 mg/kg per day) and mildronate (200 mg/kg per day) in drinking water for 8 wk. Two weeks after the experiment began, the animals in groups 1, 2 and 3

received a single dose of corn oil (0.5 mL/150 g body weight) by gavage. Rats in group 4 (DENA group) were injected with a single dose of DENA (200 mg/kg, i.p.) and 2 wk later received a single dose of CCl<sub>4</sub> (2 mL/kg) by gavage as 1:1 dilution in corn oil. Animals in group 5 (DENA-carnitine depleted group) received the same dose of DENA as group 4 and the same dose of D-carnitine-mildronate as group 3. Animals in group 6 (DENA-carnitine supplemented group) received the same dose of DENA as group 4 and the same dose of L-carnitine as group 2. At the end of the treatment protocol, animals were anesthetized with ether and blood samples were drawn from the orbital venous plexus. Serum was separated by centrifugation for 5 min at 1500 g and stored at -20°C until analysis. This was then used to determine ALT, G-GT and ALP activities and total bilirubin. All animals were sacrificed by decapitation and their livers were rapidly excised, weighed, washed with saline, blotted with a piece of filter paper and homogenized in normal saline or 6% perchloric acid, as indicated in the procedures of measurement of each parameter, to yield a 10% (w/v) tissue homogenate, using a Branson sonifier (250 VWR Scientific, Danbury, Conn., USA). Liver specimens from each group were removed for histopathological examination. The specimens were fixed in 10% neutral buffered formalin, sectioned at 3 µm and stained with hematoxylin and eosin (H & E) stain for light microscopic examination. To avoid any type of bias, the slides were coded and examined by a histopathologist who was blinded to the treatment groups.

#### Measurements of liver function

The activities of ALT, G-GT and ALP as well as total bilirubin in serum were determined using Randox commercially available kits (Randox Laboratories Ltd., Diamond Road, Crumlin, Co. Antrim, UK).

#### Determination of reduced glutathione and lipid peroxidation in liver tissues

The tissue levels of the acid soluble thiols, mainly GSH, were assayed spectrophotometrically at 412 nm, according to the method of Ellman<sup>[34]</sup> using a Shimadzu (Tokyo, Japan) spectrophotometer. The content of GSH was expressed as µmol/g wet tissue. The degree of lipid peroxidation in liver tissues was determined by measuring thiobarbituric acid reactive substances (TBARS) in the supernatant tissue from the homogenate<sup>[35]</sup>. The homogenates were centrifuged at 1500 g and the supernatant was collected and used for the estimation of TBARS. The absorbance was measured spectrophotometrically at 532 nm and the concentrations were expressed as nmol TBARS/g wet tissue.

#### Determination of glutathione peroxidase and catalase activity in liver tissues

The activity of glutathione peroxidase (GSHPx) was determined according to the method of Lawrence and Burk<sup>[36]</sup>. The changes in the absorbance at 340 nm were recorded at 1 min interval for 5 min and the results were expressed as µmol/min per g tissue. The catalase

(CAT) activity was determined spectrophotometrically by the method of Higgins *et al.*<sup>[37]</sup> which is the assay of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). The activity was expressed as µmol/min per g tissue using the molar absorbance of 43.6 for H<sub>2</sub>O<sub>2</sub>.

#### Determination of total nitrate/nitrite concentrations in liver tissues

Total nitrate/nitrite (NO<sub>x</sub>), an index of nitric oxide (NO) production, was measured as the stable end product, nitrite, according to the method of Miranda *et al.*<sup>[38]</sup>. The assay is based on the reduction of nitrate by vanadium trichloride combined with detection by the acidic Griess reaction. The diazotization of sulfanilic acid with nitrite at acidic pH and subsequent coupling with N-(10 naphthyl)-ethylenediamine produced an intensely colored product which was measured spectrophotometrically at 540 nm. The levels of NO<sub>x</sub> were expressed as µmol/g wet tissue.

#### Determination of total carnitine levels in liver tissues

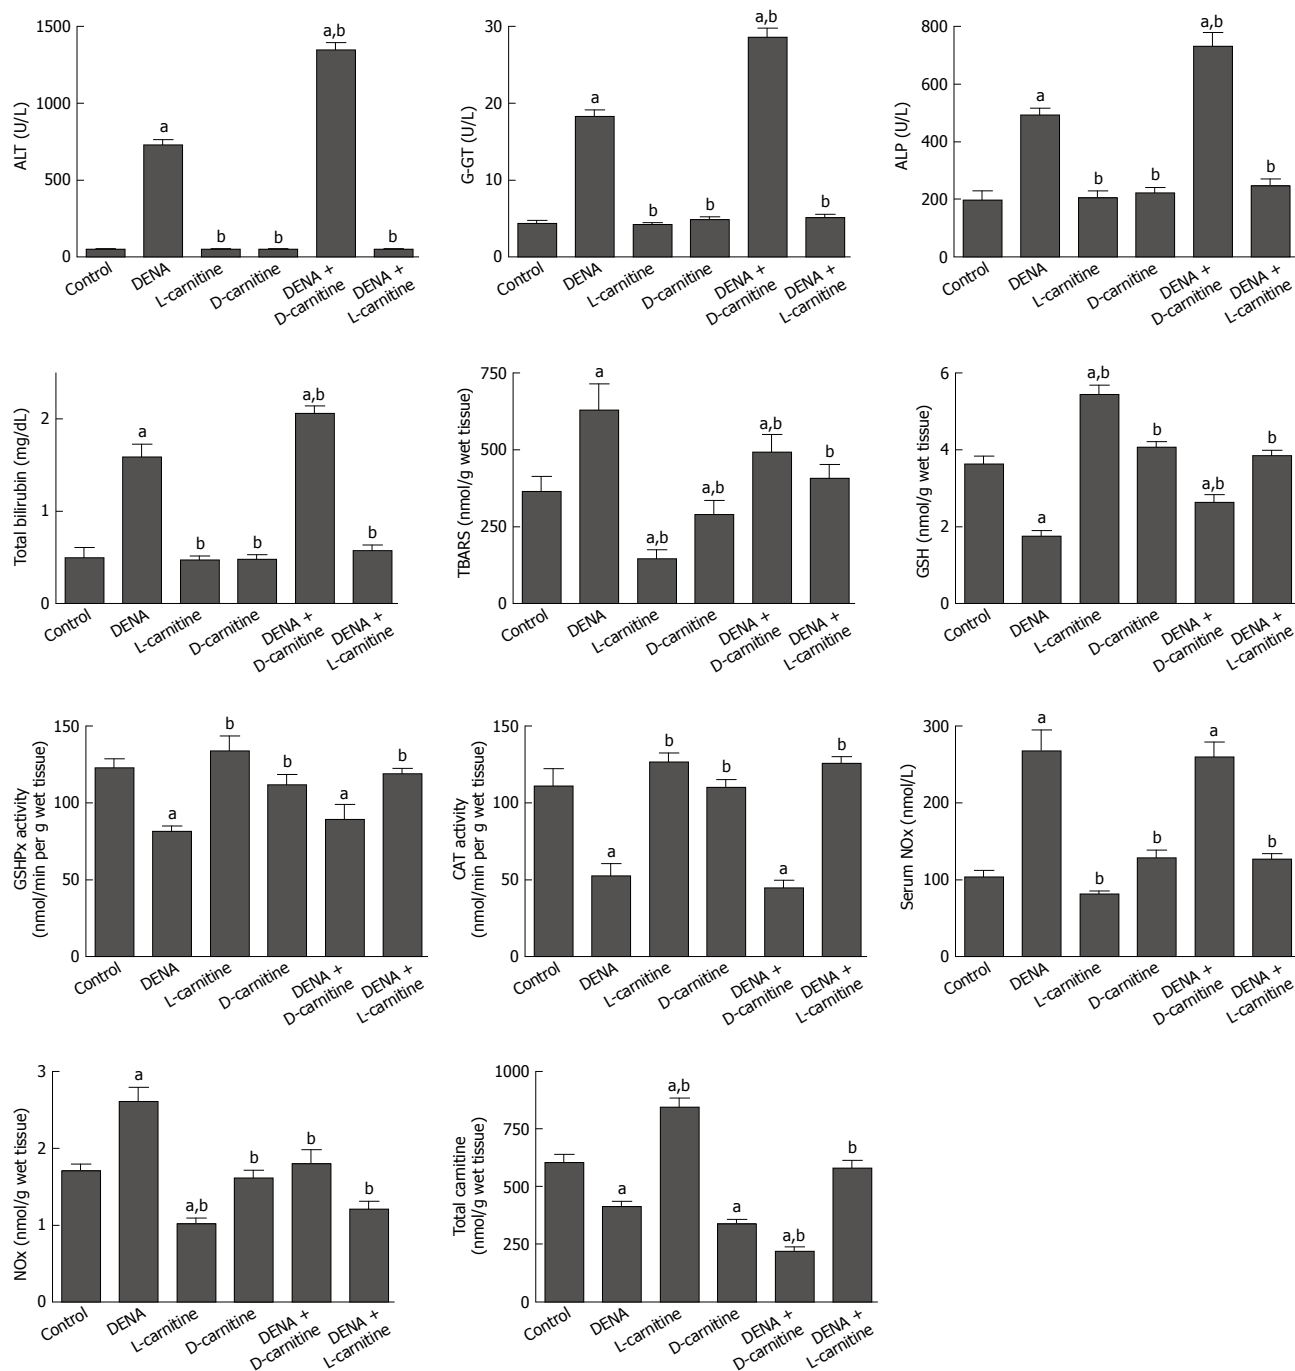

Liver homogenate was prepared in ice-cold 6% perchloric acid and centrifuged at 8000 g for 10 min. Part of the supernatant was used for the estimation of free carnitine, while the remainder was used for the determination of long-chain acyl carnitine after hydrolysis in 1 mol/L KOH at 65°C for 1 h according to Alhomida<sup>[39]</sup>. Carnitine was determined using HPLC after pre-column derivatization with L-aminoanthracene as previously described by Longo *et al.*<sup>[40]</sup>. The mobile phase was prepared by mixing 700 mL of 0.1 mol/L ammonium acetate, pH 3.5, with 300 mL of acetonitrile. Chromatographic separation was performed at a flow rate of 1.5 mL/min, using a Kromasil column (C18, 25 cm × 4.6 mm) from Saulentechnik Knayer, Berlin, Germany. The excitation and emission wavelengths of the spectrofluorimeter were 248 and 418 nm, respectively.

#### Statistical analysis

Differences between obtained values (mean ± SE, *n* = 10) were carried out by one way analysis of variance (ANOVA) followed by the Tukey-Kramer multiple comparison test. A *P* value of 0.05 or less was considered statistically significant.

## RESULTS

Eight weeks after the experiment began, the administration of DENA resulted in a significant 16.6-fold, 316%, 152%, and 219% increase in serum ALT, G-GT, ALP and bilirubin, respectively, as compared to the control group. Long-term administration of either L-carnitine or D-carnitine alone for 8 wk showed a non-significant change. In carnitine-depleted rats, DENA resulted in a significant 85%, 56%, 49% and 29% increase in serum ALT, G-GT, ALP and bilirubin, respectively, as compared to DENA alone. Interestingly, administration of L-carnitine in combination with DENA resulted in a complete reversal of DENA-induced increases in serum ALT, G-GT, ALP and bilirubin, compared to the control values (Figure 1).

**Figure 1** Effect of DENA on serum liver function indices, oxidative stress biomarkers, activities of antioxidant enzymes, NOx concentration and total carnitine levels in liver tissues from carnitine supplemented and depleted rats. Data are presented as mean  $\pm$  SE ( $n = 10$ ). <sup>a</sup> $P < 0.05$  vs control; <sup>b</sup> $P < 0.05$  vs DENA, at  $P < 0.05$  using ANOVA followed by Tukey-Kramer as a post ANOVA test.

The effects of DENA on the oxidative stress biomarkers, TBARS and GSH, in liver tissues from carnitine-supplemented and -depleted rats are shown in Figure 1. DENA resulted in a significant 73% increase in TBARS and a significant 52% decrease in GSH, as compared to the control group. Long-term administration of either L-carnitine or D-carnitine alone for 8 wk resulted in a significant decrease in TBARS and a significant increase in GSH as compared to either the control or the DENA groups. Moreover, L-carnitine resulted in a complete reversal of the DENA-induced decrease in GSH and increase in TBARS in liver tissues,

compared to the control values.

Administration of DENA resulted in a significant 34% and 52% decrease in GSHPx and CAT, respectively, as compared to the control group. Long-term administration of either L-carnitine or D-carnitine alone for 8 wk showed a non-significant change, as compared to the control group. In carnitine-supplemented rats, L-carnitine resulted in a complete reversal of the DENA-induced decrease in GSHPx and CAT in liver tissues compared to the control values (Figure 1).

Administration of DENA resulted in a significant 157% and 54% increase in the levels of NOx in serum

**Figure 2 Photomicrographs of liver specimens stained with H&E.** A: Liver from control rat showing normal liver histology with unremarkable central vein (A1,  $\times 20$  and A2,  $\times 40$ ); B: Liver from rat treated with DENA showing central vein surrounded by extensive necrosis and inflammatory infiltrate (B1,  $\times 20$ ), considerable hepatocyte necrosis represented with arrows (B2 and B3,  $\times 40$ ) and portal tract with bile duct proliferation and marked atypia (B4,  $\times 20$ ); C: Liver from rat treated with DENA plus D-carnitine-mildronate showing diffuse bridging fibrosis and nodule formation (C1,  $\times 10$ ) and bile ducts with marked reactive atypia showing nuclear enlargement, high nuclear/cytoplasmic ratio and prominent nucleoli (C2 and C3,  $\times 40$ ); D: Liver from rat treated with DENA and L-carnitine showing normal liver (D1,  $\times 20$ ) with unremarkable central vein (D2,  $\times 40$ ) and hepatic lobule with a focus of inflammatory infiltrate but no necrosis (D3,  $\times 40$ ).

and liver tissues, respectively, as compared to the control group. Long-term administration of either L-carnitine or D-carnitine-mildronate alone for 8 wk showed a non-significant change. In carnitine-supplemented rats, L-carnitine resulted in a complete reversal of the DENA-induced increase in NOx levels in serum and liver tissues compared to the control values (Figure 1).

Treatment with DENA resulted in a significant 32% decrease in total carnitine level in liver tissues, whereas long-term administration of D-carnitine-mildronate resulted in a significant 44% decrease in total carnitine level in liver tissues, as compared to the control group. Administration of L-carnitine resulted in a significant 40% increase in total carnitine level in liver tissues as compared to the control group. Administration of DENA to D-carnitine-mildronate-treated rats resulted in a significant 64%, 47% and 36% decrease in total carnitine content in liver tissues as compared to the control, DENA and D-carnitine-mildronate treatments, respectively. In carnitine-supplemented rats, L-carnitine resulted in a complete reversal of the DENA-induced decrease in total carnitine content in liver tissues compared to the control values (Figure 1).

Liver sections from control rats showed normal liver histology with unremarkable central veins (Figure 2A). Animals treated with DENA showed central veins surrounded by extensive necrosis and inflammatory infiltrate, clusters of hepatocyte necrosis and the portal tract with bile duct proliferation and marked atypia (Figure 2B). In carnitine-depleted rats, DENA-induced progressive histopathological and pre-neoplastic lesions that manifested as diffuse bridging fibrosis connecting central veins to portal tracts and nodule formation, bile ducts with marked reactive atypia showing nuclear enlargement, high nuclear/cytoplasmic ratio and prominent nucleoli (Figure 2C). Liver sections from rats treated with DENA and L-carnitine showed normal liver histology with unremarkable central veins, hepatic lobule with few scattered foci of inflammation, no evidence of necrosis, cirrhosis and no reactive atypia (Figure 2D).

## DISCUSSION

Chemoprevention is defined as the use of naturally occurring and/or synthetic compounds in cancer therapy

in which the occurrence of cancer can be entirely prevented, slowed or reversed<sup>[13]</sup>. Using Long Evans Cinnamon rats as a model of hepatocarcinogenesis, Chang *et al* was the first to report that L-carnitine inhibited pre-neoplastic lesions and prevented hepatocarcinogenesis<sup>[24]</sup>. In our laboratory, earlier and more recent studies have demonstrated that carnitine deficiency is a risk factor and should be viewed as a mechanism in cisplatin-induced nephrotoxicity<sup>[41,42]</sup>, cardiomyopathy<sup>[43]</sup> and hepatotoxicity<sup>[44]</sup>. Although, the liver is the main organ responsible for endogenous synthesis of L-carnitine, we were unable to find any studies investigating the role of carnitine deficiency during DENA-induced hepatic carcinogenesis. Taken together, this prompted us to study whether or not long-term endogenous carnitine depletion is a risk factor during DENA-induced hepatic carcinogenesis.

The data presented here demonstrated that DENA increased serum indices of liver function including ALT, G-GT, ALP and total bilirubin (Figure 1) and caused severe histopathological lesions in liver tissues (Figure 2B). It is well known that the elevation of ALT and G-GT activities is repeatedly credited to hepatocellular damage<sup>[45]</sup>. Also, the increase in ALP reflects a pathological alteration in biliary flow<sup>[46]</sup>. G-GT is an enzyme embedded in the hepatocyte plasma membrane, mainly in the canalicular domain, and its liberation into serum indicates damage to the cell and thus injury to the liver<sup>[12,46]</sup>. It is important to point out that serum G-GT activity is considered to be one of the best indicators of liver damage<sup>[46]</sup>. In the current study, this observed increase in serum indices of liver function due to DENA could be a secondary event following DENA-induced lipid peroxidation of hepatocyte membranes, with a consequent increase in the leakage of ALT, G-GT, ALP and total bilirubin from liver tissues. An elevated level of serum indices of hepatocellular damage has been previously reported in many models of DENA-induced hepatocellular degeneration<sup>[12,17,47,48]</sup>. Interestingly, long-term administration of L-carnitine prevented the increase in hepatic enzymes, suggesting that L-carnitine may have a potential protective effect against DENA-induced liver damage. This effect could be due to stabilization of hepatocyte membranes by L-carnitine with the consequent decrease in the leakage of liver enzymes. Indeed, the interaction of L-carnitine with sarcolemmal phospholipids and mitochondrial membranes has been previously reported<sup>[49]</sup>. In carnitine-depleted rats, DENA produced a progressive increase in the activities of liver enzymes as well as massive degenerative changes and evidence of pre-neoplastic lesions in liver tissues (Figure 2C). Our results are consistent with the data presented by Hytiroglou *et al*<sup>[50]</sup>, which showed that precancerous lesions which may be detected in chronically diseased livers included clusters of hepatocytes with atypia and an increased proliferative rate.

Data from this study revealed that DENA significantly increased NOx and TBARS and decreased GSH, GSHPx and CAT in liver tissues, suggesting that reactive oxygen and nitrogen species induced by

DENA play an important role in DENA-induced hepatic carcinogenesis. Increased generation of ROS and decreased antioxidant enzymes in liver tissues has been reported in many models of DENA-induced hepatocellular carcinoma<sup>[12-15]</sup>. It has been reported that ROS play a major role in tumor promotion through interaction with critical macromolecules including lipids, DNA, DNA repair systems, and other enzymes<sup>[51]</sup>. Moreover, NOx is known to inhibit DNA repair proteins, thereby inhibiting the ability of the cell to repair damaged DNA<sup>[52,53]</sup>. Data presented here demonstrated that long-term administration of both L-carnitine and D-carnitine completely reversed the increase in TBARS and NOx and the decrease in GSH, CAT and GSHPx induced by DENA in liver tissues. Our results are consistent with previous studies that have reported that the D- and L-forms of carnitine and its short-chain derivatives have similar non-enzymatic free-radical scavenging activity<sup>[41,54,55]</sup>. Although, L-carnitine and D-carnitine have similar anti-lipid peroxidation activity, our study indicated that L-carnitine prevented the progression of DENA-induced hepatic carcinogenesis, while D-carnitine-Mildronate aggravated these lesions. Therefore, it is suggested that oxidative stress is not the only cause of DENA-induced hepatic carcinogenesis and that carnitine deficiency plays an important role.

The data presented here showed that DENA significantly decreased total carnitine in liver tissues. This effect could be a secondary event following inhibition of endogenous carnitine biosynthesis and/or decreased carnitine transport in DENA-induced hepatocellular damage. This hypothesis is consistent with data presented by Krahenbuhl *et al*<sup>[56]</sup> which showed that biosynthesis of carnitine is decreased in rats with liver cirrhosis. It seems that our results are unique since there is no available data on the effect of DENA on hepatic carnitine content. The level of carnitine in hepatocytes is controlled by the specific carnitine transporter (OCTN-2) and endogenous synthesis<sup>[18,19]</sup>. Decreased expression of OCTN-2 has been reported in the acute hepatitis phase in Long Evans Cinnamon rats as a model of hepatocarcinogenesis<sup>[24]</sup>. Also, OCTN-2 located on hepatocyte membranes might be destroyed when exposed to ROS induced by DENA.

Although, D-carnitine-mildronate alone decreased hepatic carnitine content more than DENA, only DENA increased ALT, G-GT, ALP and total bilirubin. This argues against carnitine deficiency as a risk factor in DENA-induced hepatic carcinogenesis. A possible explanation for this is that D-carnitine, *via* its non-enzymatic antioxidant activity, causes stabilization of hepatic membranes and prevents the leakage of liver enzymes, whereas DENA, *via* the increasing generation of ROS, causes irreversible modification of membrane structures and functions with the consequent increase in liver enzymes. This marked decrease (64%) of carnitine level in liver tissue after combined treatment with DENA and D-carnitine-mildronate was parallel to the marked increase in ALT, G-GT, ALP and the massive histopathological lesions in liver tissues, which may point to carnitine deficiency as a possible risk factor during DENA-induced hepatic

carcinogenesis. Most probably, D-carnitine-mildronate *via* its depletion of L-carnitine, and DENA partly through generation of ROS and partly due to carnitine depletion produced such aggravated hepatocellular damage.

In this study, the chemopreventive effects achieved by long-term administration of L-carnitine against DENA-induced hepatic carcinogenesis is in good agreement with the data presented by Chang *et al.*<sup>[24]</sup> which showed that L-carnitine inhibits pre-neoplastic lesions and prevents hepatocarcinogenesis in Long Evans Cinnamon rats as a model of hepatocarcinogenesis. Administration of L-carnitine will facilitate beta-oxidation, thereby minimizing the toxic effects of the free form of long-chain fatty acids and their intermediates in mitochondria. Consistent with this hypothesis is a report indicating that administration of L-carnitine decreased free fatty acids in serum and tissues, and prevented tissue injury in mice with juvenile visceral steatosis that lacked a carnitine transporter<sup>[57,58]</sup>. In conclusion, data from this study suggest for the first time that: (1) carnitine deficiency is a risk factor and should be viewed as a mechanism in DENA-induced hepatic carcinogenesis; (2) oxidative stress plays an important role but is not the main cause of DENA-related hepatic carcinogenesis; and (3) long-term L-carnitine supplementation prevents the development of DENA-induced liver cancer. Therefore, carnitine supplementation alone or in combination with other natural chemopreventive compounds could be used to prevent, slow or reverse the occurrence of liver cancer.

## COMMENTS

### Background

Liver cancer is one of the most common malignancies worldwide, especially in Asia and Africa. In the last few years, considerable research has been carried out in the search for natural materials or foods as a means of chemically preventing liver cancer. L-carnitine is a naturally occurring compound which is primarily located in mitochondria and possesses potential protective effects against many mitochondrial toxic agents. It is derived from two sources: endogenous synthesis in the liver and from exogenous dietary sources such as red meat and dairy products. Despite the liver being the main organ responsible for endogenous synthesis of L-carnitine, the role of endogenous depletion and/or supplementation of L-carnitine during induction of hepatocarcinogenesis has not yet been studied.

### Research frontiers

Absolute or relative carnitine deficits develop in chronic congestive heart failure, acute myocardial ischemia, diseases of peripheral blood vessels, and disturbances of lipid metabolism. However, the role of carnitine deficiency or supplementation during the development of hepatocarcinogenesis has not been addressed. In this study, the authors demonstrate that carnitine deficiency is a risk factor and should be viewed as a mechanism during the development of hepatic cancer.

### Innovations and breakthroughs

Recent studies have highlighted the importance of L-carnitine in protecting against anticancer-drug-induced fatigue and multiple organ toxicity. This is the first study to report that carnitine deficiency is a risk factor and should be viewed as a mechanism during the induction of hepatic carcinogenesis, and that long-term L-carnitine supplementation prevents the development of liver cancer. Therefore, carnitine supplementation alone or in combination with other natural chemopreventive compounds could be used to prevent, slow or reverse the occurrence of liver cancer.

### Applications

By understanding that carnitine deficiency provokes hepatocarcinogenesis, this study may represent a future strategy in preventing the occurrence of liver cancer by carnitine supplementation.

## Peer review

This is a well written and well structured paper that provides new insights on the protective action of L-carnitine in the development of liver cancer. Interestingly, the scavenger action of L-carnitine against reactive oxygen species was not the only mechanism in exerting the protection.

### Abstract

**AIM:** To study the alterations in *p53* gene among Indian gastric cancer patients and to correlate them with the various clinicopathological parameters.

**METHODS:** A total of 103 gastric cancer patients were included in this study. The *p53* alterations were studied by both immunohistochemical method as well as polymerase chain reaction (PCR)-single strand conformation polymorphism (SSCP) analysis. We only studied four (exon 5, 6, 7, and 8) of the 11 *p53* exons. The alterations in *p53* were also correlated with respect to various clinicopathological parameters.

**RESULTS:** Among 103 cases, p53 over-expression and alteration were detected in 37 (35.92%) and 19 (18.44%) cases, respectively. Most of the *p53* alterations were found at exon 5 (31.54%), followed by exon 6 (26.31%), exon 7 (21.04%) and exon 8 (21.04%). A significant correlation of p53 over-expression was found with *p53* alteration ( $P = 0.000$ ). Concordance between *p53* alteration (as detected by SSCP) and over-expression [as detected by immunohistochemistry (IHC)] was found in 75% cases. We found that IHC-positive/SSCP-negative cases accounted for 21% of cases and IHC-negative/SSCP-positive cases accounted for remaining 4% cases.

**CONCLUSION:** Our results show that *p53* gene

mutations are significantly correlated with p53 protein over-expression, with 75% concordance in over-expression and alteration in the *p53* gene, but 25% discordance also cautions against the assumption that p53 over-expression is always associated with a gene mutation. There may be other mechanisms responsible for stabilization and accumulation of p53 protein with no evidence of gene mutation that reflect an accumulation of a non-mutated protein, or a false negative SSCP result.

Karim S, Ali A. Correlation of p53 over-expression and alteration in *p53* gene detected by polymerase chain reaction-single strand conformation polymorphism in adenocarcinoma of gastric cancer patients from India. *World J Gastroenterol* 2009; 15(11): 1381-1387 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1381.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1381>

### INTRODUCTION

Gastric cancer is a common disease worldwide<sup>[1]</sup> and also one of the leading causes of cancer death (5th in male and 6th in female) in India<sup>[2]</sup>. Its pattern and incidence vary widely between different parts of the world. Costa Rica and Japan have the first and second highest rate in the world with a death rate of 77.7 and 50.5 per 100 000, respectively<sup>[1,3]</sup>. In the United States, 12 100 deaths from gastric cancer were expected during 2003 with a death rate of 6.8 per 100 000<sup>[4]</sup>. The overall age-adjusted incidence (world population) of gastric cancer in Jordan is 5.8 per 100 000<sup>[5]</sup>. The burden of new cancer cases has been estimated in the year 2002 based on the National Cancer Registry Programme in India. The number of

new digestive tract cancer cases was estimated to be approximately 145 000; out of which stomach cancer comprised 23 785 cases in men and 11 890 in women<sup>[6]</sup>. Although aggressive surgical resection has improved the overall outcome of patients with this carcinoma, results of surgical resection for advanced cancer are still poor, and the search for predictors of disease survival and response to therapy is therefore mandatory<sup>[7]</sup>. The molecular biology of gastric cancer has been widely studied in the developed world, particularly in Japan<sup>[8-11]</sup>. However, only a few scattered reports from the developing world have been published<sup>[12-16]</sup>, and there are no similar published data reported from India. The molecular events leading to the development of gastric cancer are largely unknown, but there is now enough evidence to suggest that the functional inactivation of *p53* gene through allelic loss and point mutation plays an important part<sup>[17,18]</sup>.

Several genetic alterations have been shown to play a significant role in tumorigenesis. By and large, the most frequently observed molecular changes occur in the *p53* gene<sup>[19]</sup>. The *p53* gene encodes a protein involved in control of the cell cycle and acts as a negative regulator in the cell's response to damaged DNA<sup>[20]</sup>. Functional alteration of *p53* protein can occur through several mechanisms: point mutations, deletions, rearrangements in the *p53* gene, binding with viral proteins, binding with cellular proteins, and oligomerization<sup>[21]</sup>. Wild-type *p53* protein has a very short half-life, whereas mutated *p53* is stable and can accumulate at high concentration in the nuclei of tumor cells. As a consequence, immunohistochemical staining with specific antibodies can be used to detect mutant *p53* protein. Detecting the precise alteration occurring at the genetic level is much more laborious and costly. The most widely used molecular approach is single strand conformation polymorphism (SSCP) analysis of DNA fragment amplified by polymerase chain reaction (PCR)<sup>[22]</sup>, with subsequent sequence analysis. The sensitivity of SSCP is influenced by the experimental conditions, and by the length of the amplified fragment under study.

The aim of present study was to determine *p53* status in Indian gastric cancer patients, who have undergone gastrectomy, and correlate it with various clinicopathological parameters. This study also correlated immunohistochemical staining of *p53* protein with SSCP analysis of the PCR-amplified DNA.

## MATERIALS AND METHODS

### Tumor specimens

From April 2002 to February 2007, cancerous and normal mucosa samples taken from 128 consecutive patients with suspected gastric cancer were enrolled for the study. Cancerous and normal mucosa samples collected from various hospitals after gastrectomy were aliquoted into two sterile tubes. The aliquots for histological and immunohistochemical studies were stored at 4°C in 10% buffered formalin. On the other hand, aliquots for PCR-SSCP studies were stored at -20°C in 1X PBS until DNA extraction. The tissue

specimen for SSCP analysis was taken from the center of the tumor mass. No patients had undergone previous chemotherapy or radiotherapy. All the clinicopathological data were collected prospectively and registered in the database. A detailed histopathological examination was performed to determine the depth of invasion on the gastric wall and the extent of metastases within regional lymph nodes. Among 128 cases, 25 were found to be histopathologically negative for gastric cancer and thus were excluded from the study. The remaining 103 cases were from West Bengal ( $n = 60$ ), Jammu & Kashmir ( $n = 30$ ) and New Delhi ( $n = 13$ ). Patients included males ( $n = 78$ ) and females ( $n = 25$ ) with a mean age of 56 years (range 25-71 years). The clinical stage was determined by the tumor, node, metastasis (TNM) system<sup>[23]</sup> and histological diagnosis was made according to the classification of Lauren<sup>[24]</sup>.

### Immunohistochemical staining

For immunohistochemical analysis of *p53* protein, 4- $\mu$ m-thick tissue sections were cut and stained with anti-*p53* monoclonal antibody (DO7, Biogenex Laboratories, San Ramon, USA) by streptavidin-biotin immunoperoxidase technique (LSAB) using the standard avidin-biotin-complex (ABC) method, followed by antigen retrieval by microwave technique as previously described<sup>[25,26]</sup>. Briefly, 4- $\mu$ m-thick sections were first mounted on glass slides, treated with methanol (with 4%  $H_2O_2$ ) for 30 min, and incubated with anti-*p53* monoclonal antibody (1:100 dilution; DO1 and DO7, Biogenex Laboratories, San Ramon, USA) overnight at 4°C in a humid chamber. After washing thrice with PBS, slides were incubated with biotinylated anti-mouse IgG antibody (DAKO-LSAB kit, Peroxidase, M/s Dakopatts, Denmark) for 30 min at room temperature and developed using HRP-streptavidin and diaminobenzidine tetra hydrochloride (Sigma, St. Louis, USA). The slides were incubated at room temperature for 5-10 min under microscopic control till the optimum development of brown-colored product. Finally, sections were counterstained with Harris hematoxylin and mounted in DPX. The reaction was considered as positive when a strong coloration of the cell nucleus was evident. Sections with nuclear staining in less than 10% of the tumor cells were regarded as negative. Positive *p53* nuclear staining was categorized into three patterns as follows: (+), only a few scattered positively stained cells (10%-25% of all tumor cells); (++) , localized aggregation of positively stained cells (26%-70% of all tumor cells); and (+++) , diffuse aggregation of positively stained cells (more than 70% of all tumor cells). Over-expression of the *p53* protein was defined when a (++) or (+++) staining pattern was observed. Negative control sections were processed immunohistochemically without incubating with the primary antibody and positive control sections were from a breast cancer tissue known to express high level of *p53*.

### Genomic DNA isolation and PCR amplification of the *p53* exons

Genomic DNA was isolated from tissues of gastric

Table 1 Detail of the primers and cycling parameters

<i>p53</i> exons	Sequence (5'-3')	Cycling parameters <sup>1</sup>	PCR product (bp)
5	Sp5F: TGTCACCTGTGCCCTGACT Sp5R: CAGCCCTGTCGTCCTCCAG	45 s denaturation at 94°C, 30 s annealing at 54°C, 1 min extension at 72°C	266
6	Sp6F: GCCTCTGATTCCCTACTGAT Sp6R: TTAACCCCTCCTCCAGAGA	45 s denaturation at 94°C, 30 s annealing at 53°C, 1 min extension at 72°C	160
7	Sp7F: ACTGGCCTCATCTTGGGCCT Sp7R: TGTCAGGGTGGCAAGTGGC	45 s denaturation at 94°C, 30 s annealing at 56°C, 1 min extension at 72°C	180
8	Sp8F: TAAATGGGACAGGTAGGACC Sp8R: TCCACCGCTTCTTGTCCTGC	45 s denaturation at 94°C, 30 s annealing at 54°C, 1 min extension at 72°C	230

<sup>1</sup>Initial denaturation of 10 min at 94°C and final extension of 10 min at 72°C were used in all amplifications. Number of cycles in all amplifications was 35.

**Figure 1** SSCP analysis of exons 5, 6, 7 and 8 of *p53* gene. Wild-type and one tumor sample containing mutation are shown for each exon. Only single-strand DNA bands are shown. Heterodimers and double-stranded bands have been omitted.

cancer patients by a modified proteinase K digestion and phenol/chloroform extraction technique. All four exons (5, 6, 7 and 8) were amplified separately and details of the primers and PCR cycling parameters used are mentioned in Table 1. The standard PCR reaction contained 0.5 µg genomic DNA, 200 µmol/L dNTPs, 1X PCR buffer, 1.5 mmol/L MgCl<sub>2</sub>, 1 U of Taq DNA polymerase and 0.3 µmol/L of each primer. Each PCR reaction contained negative controls, where only water was added in place of genomic DNA. The PCR products were electrophoresed on a 20 g/L agarose gel to check the amplification. Samples with positive amplifications were processed for SSCP analysis.

### SSCP analysis

Non-radioactive SSCP was performed as described previously<sup>[27]</sup> with slight modification. A 2-µL volume of PCR product was denatured in 5 µL of formamide loading buffer by boiling for 10 min. Denatured samples were loaded onto 120 g/L acrylamide non-denaturation gel and electrophoresed at a constant 100 V for 4-6 h. Images of the ethidium-bromide-stained gels were captured using the BioRad Gel Documentation system. Samples with mobility shifts were verified by a second independent PCR-SSCP where silver staining was done for the same.

### Statistical analysis

Descriptive statistics i.e. mean, standard deviation and frequency distribution were calculated for all the variables in the study. According to the different categories for the categorized variables,  $\chi^2$  test was used to estimate

the significance level of the association among them. Student's *t*-test, Pearson correlation and analysis of variance were applied for the continuous variables according to the categories, wherever applicable. *P* < 0.05 was considered statistically significant. SPSS.60 software (SPSS Inc, Chicago, USA) was used for these calculations.

## RESULTS

### Detection of *p53* gene mutation by SSCP analysis

The *p53* exons 5, 6, 7 and 8 were successfully amplified from all 103 cases which gave expected PCR fragments of 266 bp, 160 bp, 180 bp, and 230 bp, respectively. After SSCP analysis, altered *p53* was identified by the presence of one or two extra bands migrating above or below the normal single-stranded products (Figure 1). Occasionally, mutant bands were also detected between the single and double-strand bands that may have been caused by formation of normal-mutant heterodimers. However, normal *p53* banding pattern was also observed among all cases. SSCP data showed that 17.47% (19/103) of the cases were harboring altered *p53* (Table 2). Out of these 19 cases, six showed alterations in exon 5, five in exon 6, four in exon 7 and four in exon 8. We further observed that the positivity for *p53* mutations was relatively higher in intestinal-type carcinoma (22.44%, 11/49) as compared to diffuse-type (15.66%, 7/45) adenocarcinoma<sup>[28]</sup> (Table 3).

### Detection of *p53* protein over-expression by immunohistochemistry (IHC)

We used DO-7 to detect *p53* over-expression by IHC

**Table 2** Relationship between p53 protein over-expression detected by IHC and p53 gene mutation detected by SSCP analysis of 103 gastric carcinomas *n* (%)

IHC status	SSCP-negative	SSCP-positive	Total	<i>P</i>

staining. Overall, 35.92% (37/103) of gastric carcinomas exhibited positive nuclear staining (Figure 2). The concordance of results between SSCP and IHC (i.e. both positive and negative) was 75% (Table 2). In addition, 21% of carcinomas (22/103) stained positively by IHC but failed to display any mutation by SSCP, while the remaining 4% (4/103) displayed mutant bands by SSCP but showed no staining by IHC.

## DISCUSSION

The present study describes the status of p53 gene mutation and over-expression in Indian gastric cancer patients. The association between p53 abnormalities and pathological characteristics of tumor was also assessed. Mutations of the p53 gene are the most common genetic alteration, known to occur in a wide range of human cancers<sup>[19]</sup>. A number of studies have reported the frequency of p53 alteration in gastric cancer, showing p53 mutation in 18%-58%<sup>[18,29,30]</sup> and p53 protein over-

**Figure 2** Immunohistochemical staining of p53 protein in diffused type-poorly differentiated gastric cancer. p53 protein over-expression is seen primarily on cell nucleus. A: Positive nuclear staining ( $\times 200$ ); B: Positive nuclear staining ( $\times 400$ ); C: Negative control ( $\times 200$ ).

expression in 26%-65% of gastric adenocarcinoma<sup>[31,32]</sup>. Under normal conditions, wild-type p53 protein is rapidly degraded but in carcinomas, the acquisition of a mutant genotype is thought to increase the half-life of the mutant protein, which leads to accumulation and detection by immunohistochemical techniques, an indirect method of screening tumors for mutation within the p53 gene. However, a number of discordant results have been reported<sup>[33,34]</sup>. p53 over-expression can also reflect the accumulation of wild-type protein, which is stabilized *via* a mechanism other than mutation—for example, by binding with SV40 T antigen, which greatly increases the half-life of the protein<sup>[35]</sup>. In the present study, we have attempted to address this issue by comparing p53 gene mutation and protein over-expression in a large number of gastric tumors. We analyzed here only exons 5 to 8; because most of the p53 mutations have previously been found to be clustered in

the highly conserved domains that roughly correspond to exons 5-8<sup>[36]</sup>. Although approximately 90% of the *p53* point mutations have been reported from exons 5-8, the individual incidence rate of *p53* mutations in these exons is not known<sup>[37,38]</sup>. Although our study is primarily focused on exons 5 to 8, mutations in other exons (13%-22%) could account for some negative SSCP cases<sup>[39,40]</sup>.

Several studies have addressed the relationship between p53 protein accumulation and *p53* alteration in different tumor types<sup>[41-43]</sup>. The concordance rates between IHC staining and SSCP (both negative and positive) fall within a relatively wide range (50% to 80%), but this probably depends on differences both in methodology and tumor type. In the present study, for establishing a relationship between *p53* gene mutation and p53 protein accumulation, gastric carcinomas were analyzed for exons 5, 6, 7 and 8 of the *p53* gene. We found that p53 protein was over-expressed in 35.92% cases and *p53* gene was mutated in 17.47% of cases. A comparison of PCR-SSCP and immunohistochemical findings showed concordant (i.e. both positive and negative) results in 75% of the cases. In particular, 15 (78.94%) of the 19 cases showing a *p53* gene mutation were also positive for p53 protein accumulation on IHC, while 22 (26%) of the 84 cases without mutation were positive on IHC. In 26 (25%) cases, the immunohistochemical and SSCP results were discordant; negative IHC/positive SSCP in four and positive IHC/negative SSCP in 22. The presence of *p53* gene mutations was significantly correlated with p53 protein over-expression ( $P = 0.000$ ).

Accumulation of p53 protein with no evidence of gene mutation may either reflect an accumulation of a non-mutated protein, or a false-negative SSCP result. The sensitivity of SSCP analysis is still a matter of debate; not only does it depend on the experimental conditions (i.e. temperature, ionic strength and presence or absence of glycerol), but also on the length of the amplified fragment being analyzed<sup>[44]</sup>. Sheffield *et al.*<sup>[45]</sup> reported that SSCP sensitivity dramatically decreased with increasing fragment size; the percentage of single base substitution detected by SSCP was 90% when the amplified fragment was 135 bp, 70% when it was 200 bp, and 67% as fragment size exceeded 300 bp<sup>[46]</sup>. As the amplified fragment length we analyzed was 266 bp for exon 5, 160 bp for exon 6, 180 bp for exon 7 and 230 bp for exon 8, SSCP sensitivity for exon 5 and 8 might have been less than 70%. Although our study focused on exons 5 to 8, where the majority of the mutations are thought to be localized<sup>[38]</sup>, mutations in other exons (13%-22%) could account for some negative SSCP cases<sup>[39,40]</sup>. A false-negative SSCP result may also occur when the tissue is not sufficiently represented in tissue from which the DNA is extracted. The search for *p53* gene mutation by molecular assays is important for defining the functional alterations that are derived from the different mutations. In this regard, it might be advisable to study all of the exons of the *p53* gene. We can justify the inconsistent cases of SSCP and IHC by

some possible explanations: first, there may be mutations in exons other than those we examined; second, binding of wild-type p53 protein to a cellular oncogene might have led to an elongated half-life; and third, the proportion of alleles containing *p53* mutations may be relatively low, and not shown up in the analysis<sup>[47]</sup>.

It was reported that wild-type p53 proteins could combine with viral oncoproteins or cellular oncoproteins to enhance their stability and prolong their half-life, leading to p53 protein accumulation in cells. In such cells, IHC staining was still positive even without *p53* gene mutations; furthermore, about 10% of *p53* gene mutations could take place outside of exons 5-8. Therefore, the positive rate of PCR-SSCP targeting only exons 5-8 was usually lower than that of IHC<sup>[20,47-49]</sup>.

In conclusion, PCR-SSCP is a simple and rapid method for the evaluation of *p53* gene mutations and its association with immunohistochemical analysis of the p53 protein expression might provide a more precise use of *p53* as a prognostic marker in gastric cancer.

## ACKNOWLEDGMENTS

The authors would like to thank Dr. P Sahni (Department of Gastroenterology Surgery, AIIMS, New Delhi), Dr. A Roy (Roy & Trivedi Diagnostics, Kolkata) and Dr. SA Zargar (Govt. Medical College, Srinagar) for providing surgical specimens. We thank Dr. S Saxena (Director, Institute of Pathology, ICMR, New Delhi) for providing clinicopathological facilities. We also acknowledge Dr. Shahina Begum, Dr. Md Tauqeer Alam, Chandra Prakash, Gulrooh Barha, and Zeenat Mirza for fruitful discussion while writing the manuscript.

## COMMENTS

### Background

Gastric cancer is a common disease worldwide, including India. The molecular events leading to the development of gastric cancer are largely unknown, but various lines of evidence suggests that the functional inactivation of the *p53* gene plays an important role. The p53 protein is involved in control of the cell cycle. Wild-type p53 protein has a very short half-life, whereas mutated p53 is stable and can accumulate at high concentration in the nuclei of tumor cells, and is detected by immunohistochemical staining with specific antibodies. Polymerase chain reaction (PCR)-single strand conformation polymorphism (SSCP) analysis was done to screen and detect the presence of any point mutation in *p53* gene.

### Research frontiers

In general, the present study is a part of cancer research that is aimed at mutational analysis of the *p53* gene among gastric cancer patients. To the best of our knowledge, this is the first study where an attempt has been made to correlate the *p53* gene mutation with various clinicopathological features among Indian gastric cancer patients.

### Innovations and breakthroughs

Authors have analyzed the status of p53 protein expression by immunohistochemistry (IHC) and *p53* gene mutation by PCR-SSCP among gastric cancer cases. This study also provides a significant correlation between immunohistochemical staining of p53 protein and SSCP analysis of the PCR amplified DNA.

### Applications

PCR-SSCP in association with IHC of the p53 protein may provide a more precise use of *p53* as a prognostic marker for gastric cancer.

### Terminology

SSCP is a technique used to screen and detect the mutational change at

the single nucleotide level. Additional bands of DNA is an indication of gene alteration. IHC is a technique used to detect the mutated p53 protein in the nucleus of cancer cells. Mutation in the p53 gene leads to increased half-life and accumulation of p53 protein in the nucleus.

### Peer review

The paper describes p53 alterations among gastric cancer patients in India. The alterations were studied by IHC and PCR-SSCP analyses. A significant correlation of p53 over-expression and alteration in p53 gene detected by SSCP was found. It is an interesting study and this is also the first such study from an Indian population, including a large sample from a long research period.

## INTRODUCTION

Over the last 10 years, the early diagnosis and development of new therapies have increased the survival time and disease-free survival of women with breast cancer, but long-term survivors are also at risk of developing distant metastases. Breast cancer is usually associated with lymphatic spread and blood metastases to the lung, bones and liver. In this paper, we report a case of isolated gastrointestinal metastasis from breast carcinoma, which mimicked primary anal cancer.

## CASE REPORT

On July 2000, an 88-year-old woman presented with a right latero-cervical mass that was hard and increasing in volume, which extended up to the supraclavicular region. Physical examination showed a right breast tumor (1 cm in diameter) of the superior external quadrant, with some palpable homolateral axillary nodes. Abdominal ultrasonography and bone scanning did not reveal metastases, but thoracic computed tomography (CT) showed mediastinal lymph nodes < 1 cm in size. Carcinoembryonic antigen (CEA) and cancer antigen 15.3 (CA15.3) level was normal. The patient underwent right external superior quadrantectomy with right axillary and latero-cervical lymphadenectomy. The histological examination showed an infiltrating lobular carcinoma (ILC) with metastases in all 10 nodes removed (pT1/G2/N2). Immunohistochemical staining was positive for estrogen receptor (ER) protein (90%) and c-erbB2. The tumour cells showed a low mitotic index (15%).

The patient received postoperative radiotherapy and hormonal therapy (tamoxifen). Four years later, some new right axillary lymph node metastases were discovered at physical examination and therefore removed. The histological examination confirmed the diagnosis of lymphatic metastasis from ILC. Two months after lymphadenectomy, the patient presented with tenesmus and a painful anal polypoid lesion (Figure 1). The mass was removed for biopsy. The immunohistochemical staining was similar to primary breast tumor [95% ER and 10% progesterone receptor (PR)], which suggested a breast origin (Figure 2). Mib1 was 25% positive, while c-erbB2 was negative. No other site of disease was found by abdominal CT and bone scintigraphy. Radiotherapy was chosen for

## Abstract

We report a case of isolated gastrointestinal metastasis from breast lobular carcinoma, which mimicked primary anal cancer. In July 2000, an 88-year-old woman presented with infiltrating lobular cancer (pT1/G2/N2). The patient received postoperative radiotherapy and hormonal therapy. Four years later, she presented with an anal polypoid lesion. The mass was removed for biopsy. Immunohistochemical staining suggested a breast origin. Radiotherapy was chosen for this patient, which resulted in complete regression of the lesion. The patient died 3 years after the first manifestation of gastrointestinal metastasis. According to the current literature, we consider the immunohistochemistry features that are essential to support the suspicion of gastrointestinal breast metastasis, and since we consider the gastrointestinal involvement as a sign of systemic disease, the therapy should be less aggressive and systemic.

**Figure 1** The lesion as it appeared macroscopically at the time of diagnosis.

this patient, which led to complete regression of the lesion, but later an anal stenosis appeared without any changes in defecation. Treatment with anastrozole was then started. At follow-up, there was no evidence of progressive disease for 2 years, after which the level of CA15.3 began to increase, and some new right axillary lymph nodes metastases appeared. The patient underwent axillary lymphadenectomy and adjuvant hormonal therapy was continued.

Six years later, during follow-up, abdominal CT showed a suspicious increase in antral wall thickness, but endoscopic examination revealed only a peptic stenosis that was treated by pneumatic dilatation. Twelve months later, the patient underwent local radiotherapy for a relapse of anal lesions. Two months afterwards, during umbilical hernioplasty a diagnosis of peritoneal carcinosis was made. The patient died 3 years after the first manifestation of anal metastasis and 6 years after the diagnosis of breast cancer.

## DISCUSSION

Gastrointestinal metastases of breast cancer are rare and usually associated with disseminated disease. The most frequent organ involved is the stomach<sup>[1,2]</sup>. Survival after diagnosis of gastrointestinal metastases is poor, with few patients surviving beyond 2 years. The average survival from time of recurrence is 12-16 mo<sup>[1,2]</sup>.

Despite their rare clinical manifestations (only 0.07% of cases)<sup>[3]</sup>, some necropsy studies have described an incidence rate of colon involvement that varies from 3% to 18%<sup>[4,5]</sup>. The risk of a second primary tumor following breast cancer is about 12%<sup>[6]</sup>, and the incidence of metachronous primary colorectal cancer is estimated to be about 1%<sup>[7,8]</sup>. In a review of the literature, we found 15 cases of solitary rectal metastasis from breast carcinoma, but only one case of anal localization has been reported<sup>[9]</sup> and none from lobular breast carcinoma. Breast ILC is responsible for the majority of metastases in the GI tract, with a metastasis rate of 4.5% *vs* 0.2% from infiltrating ductal carcinoma<sup>[10]</sup>.

Clinical-histological features that lead us to suspect a diagnosis of gastrointestinal breast metastasis versus primary colon cancer are: (1) ER or PR protein and gross cystic disease fluid protein (GCDFFP-15) are strongly positive in metastatic breast carcinomas<sup>[10-12]</sup>;

**Figure 2** Positive immunohistochemical staining in anal lesion. A: ERs ( $\times 4$ ); B: PRs ( $\times 10$ ).

(2) absence of dysplasia in adjacent colonic epithelium suggests a metastatic growth; and (3) history of breast cancer. However, some authors have shown the presence of cells positive for ER or PR in colorectal cancer, but their concentration tends to be lower than in breast cancer<sup>[13,14]</sup>. In our case, GCDFFP-15 was not tested for, but the immunohistochemical staining of anal biopsy was strongly positive for ERs (90%). The disease-free interval between primary breast cancer and gastrointestinal involvement varies from synchronous presentation to up to 30 years<sup>[1]</sup>.

If we consider that gastrointestinal involvement is a sign of systemic disease, systemic therapy should be initiated. In the literature, a common attitude towards isolated gastrointestinal lesions is to undertake local surgical treatment associated with hormonal or chemotherapy. Surgery is usually necessary for an exact diagnosis or for acute clinical manifestations. In our case, the diagnosis was made easily as the tumor was external to the anal canal, therefore, a more aggressive approach such as anorectal amputation (Miles' operation) was excluded.

## CONCLUSION

It is very difficult to suspect anal metastasis from breast cancer by formulating the diagnosis by clinical, endoscopic and radiological features. Only a previous history of breast cancer and immunohistochemical analysis of anal biopsies compared with original breast carcinoma pathology allows a correct diagnosis. On the other hand, accurate identification of the disease

is essential since the treatment is different in the case of primary or secondary cancer. In the case of breast secondaries, several schedules of chemo- and hormonal therapy for ER/PR-positive tumors are of great benefit. Radiotherapy is strongly recommended in elderly patients rather than surgery, which should be limited to obtaining a diagnosis, or in cases with complications.

## ACKNOWLEDGMENTS

We would like to thank Mrs Marian Fuscoe for kindly revising the manuscript.

### Abstract

We present the case history of a 3-year-old girl who was examined because of severe dystrophy. In the background, cow's milk allergy was found, but her body weight was unchanged after eliminating milk from her diet. Other types of malabsorption were excluded. Based on nasal regurgitation and facial dysmorphisms, the possibility of DiGeorge syndrome was suspected and was confirmed by fluorescence *in situ* hybridization. The authors suggest a new feature associated with DiGeorge syndrome.

### INTRODUCTION

The main consequences of developmental abnormalities

of the third and fourth branchial pouches are congenital heart defect, hypoparathyroidism, hypoplasia or aplasia of the thymus, velopharyngeal insufficiency and facial dysmorphism; the clinical picture is named DiGeorge syndrome. Apart from these major symptoms, many others including low muscle tone, short stature, hypothyroidism, kidney problems, developmental delay, psychiatric disorders and learning difficulties are often present<sup>[1]</sup>. In 40%-90% of children with DiGeorge syndrome feeding difficulties are also present<sup>[2]</sup>; nasal regurgitation is one of the first manifestations of a feeding abnormality in this group<sup>[2]</sup>. Eicher *et al*<sup>[3]</sup> convincingly demonstrated, by videofluorography, that dysmotility through the pharyngoesophageal segment is the major cause of dysphagia in this syndrome. Recently, failure of upper esophageal sphincter relaxation was also demonstrated by a videomanometric technique in three children with velocardiofacial syndrome<sup>[4]</sup>. Dysmotility of the upper gastrointestinal tract, velopharyngeal insufficiency and associated celiac disease<sup>[5]</sup> may all contribute to developmental delay in DiGeorge syndrome.

Here we present a case of an almost 3-year-old girl with cow's milk allergy whose extreme dystrophy was not improved after eliminating milk from the diet, and in whom DiGeorge syndrome was later diagnosed as the background to the symptoms.

### CASE REPORT

The girl was born after an uneventful pregnancy at the 38th week of gestation with a birthweight of 2950 g, and Apgar scores of 10-10 at 5 and 10 min. She was breast fed for 6 mo, her development was normal, and her body weight was 5500 g at the age of 6 mo. However, after finishing breast feeding and changing to follow-on formula, her body weight did not increase. In addition, episodes of infections with 38°C-38.5°C fever appeared, and several times, antibiotic treatments were initiated. Her mother reported that the infant sometimes had nasal regurgitation. No gross abdominal complaints were observed, and only moderate reflux was detected by ultrasonography. At 11 mo of age, routine laboratory tests and abdominal ultrasound were normal. An anti-endomysial antibody test, chloride sweat test, and stool cultures were negative. To exclude celiac-like lesions, a small bowel biopsy was performed, but normal bowel mucosa was found. With a background of dystrophy, cow's milk and soy-protein allergy was diagnosed by

Figure 1 Facial dysmorphisms in our patient.

specific immunoglobulin E (IgE) assay. The hypotonic musculature was explained as the result of dystrophy, and her creatine kinase level was only slightly elevated (276 U/L, normal range: < 200 U/L). Milk was removed from her diet and oral iron therapy was administered; however, her body weight did not increase. At 17 mo of age, reflux was no longer detectable, her appetite was normal, but still no weight gain was observed.

At 20 mo, the girl was admitted to our department for further examinations to resolve the cause of the severe dystrophy. Her body weight was 6000 g (< 3rd percentile) and her length was 76 cm (< 3rd percentile). In association with the signs of dystrophy, moderate psychomotoric retardation was seen and some minor anomalies were found during physical examination. These included ocular hypertelorism, micrognathia, flat nasal bridge, bulbous nasal tip, short philtrum, and slightly rotated ears (Figure 1). Laboratory tests including blood count, electrolytes, liver enzymes, pre-albumin, albumin, ammonia, iron and Ig levels, as well as the carbohydrate malabsorption test were normal. Serum amino acids showed a normal pattern. Otolaryngologic examination revealed dysfunctional soft palate movement. Echocardiography found a chorda tendinea in the left ventricle, which was thought to be a normal variant. Psychologic testing showed mental retardation (IQ: 61.6).

Based on facial dysmorphism, the nasal regurgitation seen earlier and the newly diagnosed velopharyngeal insufficiency, the possibility of DiGeorge syndrome was considered. Our suspicion was confirmed by fluorescence *in situ* hybridization analysis which showed microdeletion on the long arm of one of chromosome 22. We were unable to visualize the thymus either by X-ray examination, or by thoracic ultrasound. Flow cytometric analysis did not reveal immunodeficiency; the number of T lymphocytes was 3052/ $\mu$ L (normal range: 2100-6200/ $\mu$ L). A normal cytokine response occurred after stimulating her lymphocytes with bacterial lipopolysaccharide. The ionized calcium, serum parathyroid hormone, thyroid stimulating hormone and vitamin D levels were in the normal range

[1.22 mmol/L (normal: 1.1-1.3 mmol/L), 1.9 pmol/L (normal: 1.6-6.9 pmol/L), 2.96 mU/L (normal: 0.27-4.2 mU/L), 155 nmol/L (normal: 47.7-170 nmol/L), respectively]. The daily calorie intake calculated from the dietary record of the mother was about 800-900 kcal, therefore hypercalorization was recommended (1200-1300 kcal/d). Following administration of this diet, her body weight began to increase, but it still remained below the 3rd percentile line.

The frequency of upper airway infections increased and *Candida* was cultured from the stools, therefore, long-term antifungal therapy was started. She complained of indefinite pain of the upper limbs. At 2 years of age she was hospitalized several times because of pneumonia. At this time the serum total calcium level was decreased (1.8 mmol/L; normal: 2.1-2.4 mmol/L), so calcium-gluconicum and cholecalciferol were given in doses of  $3 \times 500$  mg/d and 400 IU/d, respectively. At the next examination, the total calcium level was found to be decreased further (1.54 mmol/L), the ionized calcium level was also low (0.68 mmol/L), and hyperphosphatemia (2.33 mmol/L; normal: 1.0-2.0 mmol/L) and hypoparathyroidism (1.58 pmol/L) were found. Cholecalciferol was changed to calcitriol ( $1 \times 0.25$   $\mu$ g/d). The total calcium level began to increase after a week of calcitriol administration (1.87 mmol/L). Calcium homeostasis normalized following a month of calcitriol therapy.

## DISCUSSION

The diagnosis of DiGeorge syndrome in the present case was rendered difficult by the apparent explanation of the failure to thrive as serologically verified cow's milk allergy. Though our patient had neither atopic dermatitis nor recurrent episodes of obstructive bronchitis, which often accompany symptoms of cow's milk allergy<sup>[6]</sup>, cow's milk-protein-specific IgE levels indicated cow's milk allergy. However, diagnosing cow's milk allergy and eliminating milk from the diet did not result in the expected weight gain. So cow's milk allergy on its own did not explain the failure to thrive in our patient. Mention of nasal regurgitation provided important information, because this is a classic finding in infants with DiGeorge syndrome<sup>[2]</sup>. Detailed physical examination revealed minor anomalies (Figure 1) that fit well into the suspected diagnosis. A cardiac defect was admittedly absent in our patient; however, in about 20% of patients with DiGeorge syndrome there is no heart disease<sup>[1]</sup>.

Dysmotility of the upper gastrointestinal tract is a well known complication in DiGeorge syndrome<sup>[2-4]</sup>, which together with growth hormone deficiency, hypothyroidism and velopharyngeal insufficiency may lead to developmental delay and dystrophy. Digilio *et al* reported that 8.3% of their patients with DiGeorge syndrome had body weight below the 3rd percentile and all of them were younger than 5 years of age. They also presented a 2-year-old girl who had high level of anti-endomysial antibodies and in whom celiac disease was

diagnosed after jejunal biopsy<sup>[5]</sup>. As far as we know our case is the first in which an association between cow's milk allergy and DiGeorge syndrome is represented.

In summary, we recommend screening for DiGeorge syndrome in patients with classical diseases of the gastrointestinal tract if poor weight gain is also present. Nasal regurgitation during infancy is an important sign that suggests the possibility of DiGeorge syndrome.

### Abstract

Eosinophilic cholangiopathy is a rare condition characterized by eosinophilic infiltration of the biliary tract and causes sclerosing cholangitis. We report a patient with secondary sclerosing cholangitis with eosinophilic cholecystitis. A 46-year-old Japanese man was admitted to our hospital with jaundice. Computed tomography revealed dilatation of both the intrahepatic and extrahepatic bile ducts, diffuse thickening of the wall of the extrahepatic bile duct, and thickening of the gallbladder wall. Under the diagnosis of lower bile duct carcinoma, he underwent pylorus-preserving pancreatoduodenectomy and liver biopsy. On histopathological examination, conspicuous fibrosis was seen in the lower bile duct wall. In the gallbladder wall, marked eosinophilic infiltration was seen. Liver biopsy revealed mild portal fibrosis. He was diagnosed as definite eosinophilic cholecystitis with sclerosing cholangitis with unknown etiology. The possible etiology of sclerosing cholangitis was consequent fibrosis from previous eosinophilic infiltration in the bile duct. The clinicopathological findings of our case and a literature review indicated that eosinophilic cholangiopathy could cause a condition mimicking primary sclerosing cholangitis (PSC). Bile duct wall thickening in patients

### INTRODUCTION

Benign disorders such as primary sclerosing cholangitis (PSC), IgG4-related autoimmune pancreatitis, eosinophilic cholangitis, intraductal stone disease, surgical or blunt abdominal trauma, intra-arterial chemotherapy, and portal biliopathy can present with obstructive jaundice. Eosinophilic cholangiopathy is also one of the causes of sclerosing cholangitis<sup>[1-3]</sup>. The literature contains only about 40 case reports on eosinophilic cholangiopathy<sup>[4-6]</sup>, and therefore, little attention has been paid to this condition. The disease is characterized by a dense transmural eosinophilic infiltration of the biliary tract. It is highly responsive to oral steroid therapy<sup>[4-6]</sup>. Surgery, including bile duct resection, is unnecessary if a diagnosis of eosinophilic cholangiopathy is made; therefore, a detailed histopathological examination of this disease has not yet been performed.

Sclerosing cholangitis from the above-mentioned etiology is sometimes difficult to differentiate from PSC. PSC patients in Japan have a higher incidence of eosinophilia, a less frequent association with

inflammatory bowel disease, and a relatively frequent association with chronic pancreatitis, compared with those in Western countries<sup>[7,8]</sup>. Establishment of the concept of IgG4-related sclerosing cholangitis accompanying autoimmune pancreatitis has resulted in solutions for the different clinical characters of PSC between Western countries and Japan, except for the higher incidence of eosinophilia in Japan<sup>[9,10]</sup>.

We present a patient with sclerosing cholangitis and eosinophilic cholecystitis mimicking lower bile duct carcinoma, who underwent pancreatoduodenectomy and liver biopsy. To the best of our knowledge, this is the first reported case of eosinophilic cholangiopathy in which all layers of the bile duct wall and liver were histopathologically examined. This case was suggestive of an etiology of bile duct obstruction of eosinophilic cholangitis and PSC with eosinophilia.

## CASE REPORT

A 46-year-old Japanese man with jaundice was admitted to our hospital. Ten months earlier, he had developed liver dysfunction with jaundice, which improved by conservative therapy. He had repeated episodes of urticaria from the age of 40 years. Physical examination disclosed no abnormalities except for scleral icterus and mild tenderness in the right upper quadrant of the abdomen. Liver function test results at admission were as follows: aspartate aminotransferase (AST), 37 U/L; alanine aminotransferase (ALT), 36 U/L; alkaline phosphatase (ALP), 695 U/L;  $\gamma$ -glutamyl transferase (GGT), 179 U/L; total bilirubin, 12.3 mg/mL. Total white blood cell count was 3900, with a differential cell count of 59% neutrophils (normal range, 40%-69%), 3% eosinophils (1%-8%), and 31% lymphocytes (21%-49%). Hepatitis virus screening was negative and no tumor markers were elevated. Computed tomography (CT) revealed dilatation of both the intrahepatic and extrahepatic bile ducts. Diffuse thickening of the extrahepatic bile duct wall and thickening of the gallbladder wall were identified on CT (Figure 1). Endoscopic retrograde cholangiography (ERC) showed an obstruction of the lower bile duct (Figure 2). Endoscopic naso-biliary drainage was performed. Upper gastrointestinal endoscopy showed no abnormal findings other than atrophic gastritis. Pylorus-preserving pancreatoduodenectomy and wedge liver biopsy were performed under the diagnosis of lower bile duct carcinoma. After the operation, minor leakage of pancreatojejunostomy developed, and conservative treatment was successful. The patient is alive without any symptoms 6 years and 6 mo after the operation at the time of writing.

In the resected specimen, the bile duct was slightly thickened and there was a narrow stenotic segment at the lower edge of the common bile duct. There was neither elevated lesion nor ulceration in the epithelium of the bile duct. The gallbladder was 11  $\times$  6 cm with thickened wall, but had neither elevated lesion nor ulceration in the epithelium.

**Figure 1** CT demonstrating dilatation of both the intrahepatic and extrahepatic bile ducts, diffuse thickening of the wall of the extrahepatic bile duct (arrow), and thickening of the gallbladder wall (arrowhead).

**Figure 2** ERC showing an obstruction of the lower bile duct (arrow).

On histopathological examination, conspicuous fibrosis was seen diffusely in the bile duct wall (Figure 3A). Mild inflammatory cell infiltration, mainly composed of lymphocytes and plasma cells, was seen. Eosinophilic infiltration was very mild, and in some areas eosinophilic leukocytes were not detected (Figure 3B). Accordingly, this case was not diagnosed as definite eosinophilic cholangitis. However, careful observation revealed some areas with scattered eosinophilic leukocytes (Figure 3C). In the gallbladder wall, marked eosinophilic infiltration was seen (Figure 4), as well as scattered lymphocytes and plasma cell infiltration. Thickened fibromuscular layer and slight fibrosis in the subserosal layer were present. Hyperplastic change without atypia was identified in the gallbladder epithelium. There was no evidence of malignancy in either the bile duct or gallbladder. IgG4 immunostaining revealed hardly any positive plasma cells in the bile duct and gallbladder wall. Liver biopsy revealed mild portal fibrosis and concentric layers of fibrotic tissue surrounding the bile duct (Figure 5). This case was then definitively diagnosed as eosinophilic cholecystitis with sclerosing cholangitis of unknown etiology. However, focal infiltration of eosinophilic leukocytes in the bile duct wall suggested the possibility of eosinophilic cholangitis with very mild eosinophilic infiltration.

## DISCUSSION

Sclerosing cholangitis is classified into two entities: PSC

**Figure 3** Histological examination of the bile duct wall. A: Conspicuous fibrosis was seen diffusely in the bile duct wall; B: Eosinophilic infiltration was very mild, and in some areas eosinophilic leukocytes were not seen; C: There were some areas with scattered eosinophilic leukocytes.

and secondary sclerosing cholangitis (SSC)<sup>[2,11]</sup>. SCC is morphologically similar to PSC but it originates from a known pathological process. SSC includes IgG4-related autoimmune pancreatitis, eosinophilic cholangitis, intraductal stone disease, surgical or blunt abdominal trauma, intra-arterial chemotherapy, portal biliopathy, hepatic inflammatory pseudotumor, and AIDS-related cholangiopathy<sup>[2,11]</sup>.

In the present case, a certain diagnosis of eosinophilic cholecystitis or cholangiopathy could be made. Eosinophilic cholangiopathy is a rare benign cause of biliary obstruction<sup>[1,3-6]</sup>. It is characterized by dense transmural eosinophilic infiltration of the biliary tract. When eosinophilic infiltration is localized in the bile duct, it is termed eosinophilic cholangitis. When it involves the gallbladder, it is called eosinophilic cholecystitis. Eosinophilic cholangiopathy is the term used to describe changes in either or both of them<sup>[5,12]</sup>.

**Figure 4** Histological examination showing marked eosinophilic infiltration in the gallbladder wall.

**Figure 5** Liver biopsy showing mild portal fibrosis and concentric layers of fibrotic tissue surrounding the bile duct.

The cause of this disease is unknown. In more than half of the reported cases, eosinophilic infiltration is seen not only in the biliary tract but also in other organs, including the stomach, colon, pancreas, liver, and kidney<sup>[4-6,13]</sup>. Eosinophilic cholangiopathy is thought to be part of a spectrum of diseases caused by eosinophilic infiltration of tissues and organs with or without peripheral eosinophilia. The recognition of peripheral eosinophilia (especially in the absence of leukocytosis) is important. However, peripheral eosinophilia was present in only about half of the reported cases<sup>[6]</sup>. Some authors reported that patients with eosinophilic cholangitis had been treated successfully with oral corticosteroids<sup>[4-6]</sup>. In fact, a few cases of eosinophilic cholangitis have been resolved within 3 wk, even without steroids<sup>[1,3]</sup>.

Bile duct wall thickening is a characteristic finding of eosinophilic cholangitis on imaging modalities<sup>[4,6,14]</sup>. Thickening of the wall of the biliary tree usually, but not always, leads to biliary obstruction<sup>[6]</sup>. In most cases, bile duct stricture is located diffusely from the hepatic hilum to the intrahepatic biliary tree, but there is a report describing lower bile duct stricture in a patient with eosinophilic cholangitis<sup>[5]</sup>. The cause of thickening and obstruction of the biliary tract in patients with eosinophilic cholangitis is unclear because no resected case has been reported. Ours is believed to be the first reported case of eosinophilic cholangiopathy in which all layers of the biliary tract wall were histopathologically

examined. The most plausible cause of sclerosing cholangitis in our case was eosinophilic cholangiopathy, based on the fact that there was marked eosinophilic infiltration in the gallbladder wall and scattered eosinophilic infiltration in the bile duct wall. Close examination of all layers of the bile duct wall enabled us to find focal infiltration of eosinophilic leukocytes.

Experimental studies have demonstrated the close relationship between eosinophilic infiltration and fibrosis. It is considered that eosinophils play an important role in the fibrotic conditions of different etiopathology, including endomyocardial fibrosis, scleroderma and scleroderma like-conditions, idiopathic pulmonary and retroperitoneal fibrosis, asbestos-induced lung fibrosis, wound repair, and tissue remodeling<sup>[15,16]</sup>. It has been demonstrated that transforming growth factor- $\beta$ , a cytokine known for its ability to promote fibrosis, is produced by human eosinophils from patients with blood eosinophilia<sup>[16,17]</sup>. Ten months before admission, our case had developed liver dysfunction with jaundice, which was diagnosed by observation only. This means that eosinophilic cholangitis might have existed 10 months earlier. This led to speculation that the etiology of our sclerosing cholangitis case was consequent fibrosis from previous eosinophilic infiltration in the bile duct wall. In this regard, bile duct thickening in patients with eosinophilic cholangitis might correspond to fibrosis.

Peripheral eosinophilia was observed in 27% of PSC in Japan, although reports of eosinophilia in PSC in other countries are rare<sup>[8,18]</sup>. Based on the liver biopsy findings and cholangiography, the present case was not diagnosed as PSC. However, in some cases, eosinophilic cholangiopathy causes sclerosing cholangitis, which closely resembles PSC. In patients with eosinophilic cholangitis without peripheral eosinophilia, a differential diagnosis from PSC is difficult without bile duct biopsy. Eosinophilic cholangiopathy might also be confused with PSC with eosinophilia. There is a case report of PSC associated with increased peripheral eosinophilitis and serum IgE<sup>[19]</sup>. In that report, a 20-year-old Japanese man received oral corticosteroid therapy and improved in a few days. The possibility that he had eosinophilic cholangitis is high from the viewpoint of his clinical course, although a definite diagnosis could not be made because histopathological material was unavailable.

In summary, we have reported a case of SSC with eosinophilic cholecystitis. Close examination of the biliary tract of the resected specimen and a literature review suggested that bile duct wall thickening in patients with eosinophilic cholangitis may be due to fibrosis of the bile duct wall and that eosinophilic cholangiopathy might be confused with PSC with eosinophilia. Confirmation will depend on further investigations.

### Abstract

Angiomyolipomas (AMLs), a form of benign mesenchymal hamartoma, arise primarily in the kidneys of patients with or without tuberous sclerosis. Extra-renal AMLs are very rare and are most commonly found in the liver. AMLs of the small intestine are exceedingly rare. Here, a case of a 28-year-old man, who presented with ileal intussusception caused by ileal AML is reported. The clinicopathological and immunohistochemical findings of ileal AMLs are discussed and the literature on small intestinal AMLs is reviewed.

### INTRODUCTION

Angiomyolipomas (AMLs), benign mesenchymal tumors, are composed of blood vessels, smooth muscle cells, and mature fat cells. These mesenchymal hamartomas arise primarily in the kidney<sup>[1]</sup> and extrarenal AMLs are very rare. AMLs of the small intestine are exceedingly rare and, to the best of our knowledge, only three cases have been reported in the literature<sup>[2,3]</sup>. Herein, a case of ileal AML, manifested by small intestinal intussusception, is presented. This occurred in a 28-year-old man, and was confirmed by microscopic examination and immunohistochemical staining after right hemicolectomy.

### CASE REPORT

A 28-year-old man presented to the emergency room complaining of progressive abdominal cramping pain, accompanied by nausea and vomiting for 6 h. He had no significant medical history except for having been admitted with pneumothorax 13 years previously. The pain was located over the right lower quadrant of the abdomen. He had no change in bowel habits, bloody stools, or tenesmus. Physical examination showed a palpable mass over the right lower quadrant with direct tenderness. Increased bowel sounds were noted during auscultation. Laboratory findings were normal; red blood cell count  $5.02 \times 10^6/\text{mm}^3$ , hemoglobin 15.7 g/dL and hematocrit 44.1%, platelets  $237 \times 10^3/\text{mm}^3$ , and white blood cell count  $7700/\text{mm}^3$ . Serum analysis was as follows: total protein 8.6 g/dL, aspartate aminotransferase 19 U/L, alanine aminotransferase 13 U/L, blood urea nitrogen 13.5 mg/dL, and creatinine 0.7 mg/dL. An enhanced computed tomography (CT) scan of the abdomen showed ileocolic intussusception caused by an abnormal 3.0-cm soft tissue mass with increased thickness of the wall (Figure 1A). There was no evidence of any other soft tissue mass either in the liver or in the kidney. Colonoscopic examination could not be performed because of severe abdominal pain. The patient underwent surgery with the diagnosis of intussusception. During an exploratory laparotomy, the main polypoid mass was located approximately 60 cm from the ileocecal valve. An ileo-ileal intussusception, about 15 cm in length, was found. This mass protruded into the right colon, including the cecum. A right hemicolectomy was uneventfully performed.

Grossly, an approximately 3 cm × 3 cm × 2.5 cm sized polypoid mass was located in the ileum, 60 cm from the

**Figure 1** Enhanced abdominal CT and photograph of the pathological specimen. A: A soft tissue mass with fatty-tissue attenuation in the terminal ileum, and with intussusception is shown (arrow); B: Grossly, an approximate 3 cm × 3 cm × 2.5 cm sized polypoid mass was located in the ileum, 60 cm from the ileocecal valve (arrow).

**Figure 2** Photomicrograph of the histopathological specimen. A: The specimen was composed of three tissue components: mature adipose tissue (arrowhead) and smooth muscle surrounding thick-walled, medium-sized, vascular channels (arrow) (HE, × 40); B: Immunohistochemistry (IHC) staining showed that the proliferating smooth muscle cells were positive for  $\alpha$ -SMA (IHC, × 40); C: Smooth muscle cells showed immunoreactivity for desmin (IHC, × 40); D: The scattered small blood vessels showed immunoreactivity for CD34 (IHC, × 40).

ileocecal valve, and many small polyps were located in the ileum about 25 cm from the ileocecal valve (Figure 1B). The cut surface of the main mass was grayish-yellow in color, with a lobulated appearance and exhibiting no hemorrhage or necrosis. Microscopically, it revealed a mixture of three components: mature adipose tissue, thick-walled vessels, and interspersed areas of spindle-shaped smooth muscle cells (Figure 2A). Immunohistochemically, the smooth muscle cell components of this lesion were consistently positive for  $\alpha$ -smooth muscle actin (SMA; Clone 1A4; dilution 1:100; Dako; Figure 2B), desmin (Clone D33; dilution 1:200; Dako; Figure 2C), and vimentin (Clone V9; dilution 1:100; Novocastra). The vascular components were immunoreactive for CD34 (Clone QBEnd/10; dilution 1:50; Novocastra; Figure 2D), but tumor cells were negative for HMB-45 (Novocastra, 1:60) and C-kit (Clone 104D2; dilution, 1:200; Dako). The final pathological diagnosis was AML. The numerous small polyps were diagnosed as lymphoid polyps. The postoperative course was uncomplicated, and the patient was discharged 8 d later. He was seen in the outpatient department for follow-up, and had no tumor recurrence over the subsequent 6 mo.

## DISCUSSION

AMLs are histologically benign tumors derived from mesenchymal tissue. The vast majority of AMLs arise in the kidney. In 45 to 80% of patients, they are associated with tuberous sclerosis, a multi-systemic disease with autosomal dominant inheritance, and the occasional association with the triad of epilepsy, mental retardation, and adenoma sebaceum<sup>[1]</sup>. Extrarenal AMLs are very rare and have been reported in the liver<sup>[4]</sup>, nasal cavity<sup>[5]</sup>, vagina<sup>[6]</sup>, spermatic cord<sup>[7]</sup>, skin<sup>[8]</sup>, mediastinum<sup>[9]</sup>, and gastrointestinal (GI) tract, including the colon<sup>[10-13]</sup> and small intestine<sup>[2,3]</sup>. AMLs arising in the GI tract are extremely uncommon and usually present with melena, anemia, diarrhea, abdominal pain, and may even be clinically asymptomatic<sup>[10-13]</sup>. Radiological diagnosis of extrarenal AMLs is difficult because of the rarity of the condition. CT is an effective means of imaging and identifying AMLs. Thin-section (3-5 mm) scanning is performed in an attempt to show fatty-tissue attenuation. Sonography can suggest the diagnosis, showing a well-defined hyperechoic lesion, but it is not diagnostic. On magnetic resonance imaging, lesions are bright on T1-

weighted images and dark on fat-suppressed images<sup>[3]</sup>. Surgical excision is the treatment of choice, but inadequate resection may result in rapid local recurrence<sup>[14,15]</sup>. Microscopically, most AMLs are composed of a variable mixture of mature fat, thick-walled poorly organized blood vessels, and smooth muscle (classic triphasic histology). Rarely, striking degrees of nuclear atypia may be seen in smooth muscle cells, raising the possibility of malignancy. Cells associated with thin-walled, branching vessels with a pattern similar to lymphangioliomyoma is another variation of the smooth muscle component. The lipomatous component consists typically of mature adipose tissue but may contain vacuolated adipocytes, suggesting lipoblasts, thus mimicking a liposarcoma. The blood vessels are thick-walled and lack the normal elastic content of arteries. AMLs with a prominent vascular component may mimic a vascular malformation. Immunohistochemically, AMLs are characterized by coexpression of melanocytic markers (HMB45) and smooth muscle markers (SMA). However, previously reported cases of intestinal AML<sup>[2,3,10-13]</sup> showed only focal or no immunoreactivity for HMB45, and the present case was also negative for HMB45. AMLs usually grow slowly. Malignant changes of AML are rare, and only sporadically reported cases have been documented in lesions arising in the kidney. However, to date, AMLs arising in the GI tract have never been reported to have malignant changes.

Only three cases of AML of the small intestine have been previously reported<sup>[2,3]</sup>. All of the reported cases

of small intestinal AMLs are summarized in Table 1. The mean age at diagnosis was 49 years. In renal AMLs, the ratio of male to female patients was 1:9<sup>[14]</sup>. All of the reported cases of small intestinal AMLs occurred in females, whereas the case presented here occurred in a male. None of the cases were associated with tuberous sclerosis. Three patients with the ileal lesion presented with intussusception, while the patient with the duodenal lesion did not. The tumor sizes ranged from 2 to 4 cm. Also, all four lesions appeared grossly to have a single polypoid pattern.

In conclusion, small intestinal AML is a very rare disease and preoperative diagnosis is difficult. When a patient has abdominal pain with associated ileal intussusception, AML should be considered in the differential diagnosis.

### INTRODUCTION

Congenital absence of the splenic artery is a very rare condition. Only two cases have been reported to date<sup>[1,2]</sup>. Both cases were associated with gastric bleeding and in both cases a normal splenic vein was present. To the best of our knowledge, congenital absence of the splenic artery accompanied with splenic vein absence has not been reported. We report a case of a patient with congenital absence of the splenic artery and congenital absence of the splenic vein, found during work-up of epigastric discomfort.

### CASE REPORT

A 61-year-old woman was admitted to our hospital with postprandial epigastric discomfort of 15 d duration. The patient had no significant medical background and family history of disease. The patient had no history of alcohol intake or use of non-steroidal anti-inflammatory medications or tobacco. No abnormal findings were seen after a physical examination and laboratory testing. Upper gastrointestinal endoscopy showed a meandering, dilated, pulsatile vessel in the fundus (Figure 1), and severe stenosis with an active ulcer in the proximal part of the second portion of the duodenum, without active mucosal inflammation seen at other sites of the stomach and bulb. The endoscope (H-260; Olympus Optical, Tokyo, Japan) could not pass beyond the stenosis, and the duodenal second portion was observed by the use of a small-caliber upper endoscope (XP-260; Olympus Optical, Tokyo, Japan). There were no abnormalities in the other area of the second portion of the duodenum. *Helicobacter pylori* (*H. pylori*) infection was discovered using the rapid urease test. Double contrast gastrography showed acute angulation and an approximately 1-cm long focal stenosis located between the duodenal bulb and second portion of the duodenum (Figure 2).

### Abstract

Congenital absence of the splenic artery is a very rare condition. To the best of our knowledge, congenital absence of the splenic artery accompanied with absence of the splenic vein has not been reported. We report a case of the absence of the splenic artery and vein in a 61-year-old woman who presented with postprandial epigastric discomfort. Upper gastrointestinal endoscopy showed a dilated, pulsatile vessel in the fundus and duodenal stenosis. An abdominal computed tomography (CT) scan revealed absence of the splenic vein with a tortuously engorged gastroepiploic vein. Three-dimensional CT demonstrated the tortuously dilated left gastric artery and the left gastroepiploic artery with non-visualization of the splenic artery. After administration of a proton pump inhibitor, abdominal symptoms resolved without any recurrence of symptoms during 6 mo of follow-up.

**Figure 1** Upper gastrointestinal endoscopy showing a meandering, dilated, pulsatile vessel in the fundus.

**Figure 2** Double contrast view of the duodenum showing the acute angulation and stenosis between the duodenal bulb and second portion of the duodenum.

**Figure 3** Abdominal CT findings. A: Oblique sagittal view demonstrates the absence of the splenic vein with confluence of the superior mesenteric vein (arrow) and the presence of the tortuously engorged gastroepiploic vein in the pancreas (asterisk), forming the main portal vein (arrowhead); B: Axial image of the abdomen shows the tortuously engorged gastroepiploic vein in the pancreas.

The use of abdominal computed tomography (CT) revealed the absence of the splenic vein as seen on a normal pancreatic and splenic image. The presence of a tortuously engorged, gastroepiploic vein located in the anterior portion of the pancreas was seen (Figure 3). Three-dimensional CT imaging demonstrated the presence of a tortuously dilated left gastric artery and left gastroepiploic artery with non-visualization of the splenic artery (Figure 4). It was concluded that the abnormally dilated vessel in the gastric fundus was the dilated left gastric artery. The patient was treated with 20 mg oral rabeprazole once a day. As the abdominal symptoms of the patient were gradually improving, the patient was discharged from the hospital and has been monitored with the use of regular check-ups. Three months later, follow-up endoscopy showed decreased activity of the duodenal ulcer, but the duodenal stenosis was sustained. The patient has remained asymptomatic for 10 mo.

## DISCUSSION

A splenic artery that originates from the celiac trunk is the most common form according to the classic anatomical description of the splenic artery as described by Michels<sup>[3]</sup>. Occasionally the splenic artery may arise from the aorta or the superior mesenteric artery, and a double splenic artery may rarely form<sup>[4]</sup>. However, congenital absence of the splenic artery is an extremely rare occurrence.

The splenic vein follows a course located along the posterior aspect of the pancreas, and the splenic vein is

**Figure 4** Three dimensional CT image demonstrates the tortuously dilated left gastric artery (arrow) and the left gastroepiploic artery (arrowhead) with non-visualization of the splenic artery.

encircled by pancreatic tissue. The hilum of the spleen receives both the short gastric and left gastroepiploic veins. The splenic vein may also receive the coronary and inferior mesenteric vein at the junction with the superior mesenteric vein to form the portal vein<sup>[5,6]</sup>. When obstruction to normal flow occurs, venous blood returns to the portal vein by several collateral routes, including the short gastric vein and left gastroepiploic vein<sup>[7-9]</sup>.

Two cases of congenital absence of the splenic artery<sup>[1,2]</sup> and only one case of congenital absence of the splenic vein<sup>[10]</sup> have been reported to date. However, the present case is believed to be the first case of congenital absence of the splenic artery and congenital absence of the splenic vein together. In the two previous cases of

congenital absence of the splenic artery, gastrointestinal bleeding from a gastric mucosal lesion secondary to abnormally formed collateral blood flow was determined on arteriograms. Non-visualization of the splenic artery and filling of the intrasplenic branches *via* the collateral vessels was demonstrated. The two cases were treated with surgery due to repeated hematemesis<sup>[1,2]</sup>. The previous case of congenital absence of the splenic vein showed gastric bleeding due to the presence of isolated gastric varices, which was diagnosed by the use of abdominal CT angiography. Marked torturous engorgement of the gastroepiploic vein was seen and the patient was treated with the use of conservative therapy<sup>[10]</sup>. In the present case, there was a prominent vessel in the fundus without an overlying mucosal abnormality and hemorrhage. The differential diagnosis of the prominent fundal vessel included gastric varices resulting from cirrhosis, pancreatitis, cancer, a splenic vein thrombosis, splenic vein stenosis, a splenic artery aneurysm, surgery, coagulopathy<sup>[11-13]</sup> and the presence of collateral arterial vessels resulting from congenital absence of the splenic artery or the presence of an occluded splenic artery<sup>[14]</sup>. This patient had no evidence of cirrhosis, pancreatitis, a pancreatic neoplasm or coagulopathy, but the patient had a prominent, pulsatile vessel suggesting the presence of an artery.

In the present case, CT angiography demonstrated the presence of a dilated left gastric artery and left gastroepiploic artery without visualization of the splenic artery. The splenic vein is located at the posterior portion of the pancreas<sup>[5,6]</sup>, but in this case, abdominal CT images revealed absence of the splenic vein and the presence of a tortuously engorged, gastroepiploic vein at the anterior portion of the pancreas. Therefore, we diagnosed the case as a congenital absence of the splenic artery and congenital absence of the splenic vein. This patient complained of postprandial epigastric discomfort and the symptoms were caused by duodenal stenosis and acute angulation complicated by the presence of a chronic duodenal ulcer. The cause of the duodenal ulcer and deformity was not clear. This patient had no history of excessive alcohol intake, use of nonsteroidal anti-inflammatory drugs or tobacco use, and had a normal gastrin level, but the patient showed a positive result in a rapid urease test. Undoubtedly, *H pylori* infection is a major cause of duodenal ulcers<sup>[15]</sup>, but there is the possibility that a duodenal ulcer may have repeatedly developed due to other causes in this patient. We hypothesized that the duodenal ulcer resulted from sustained pressure and ischemia in the duodenal mucosa by the presence of abnormally dilated collateral

submucosal vessels secondary to absence of the splenic artery, and inadequate venous drainage through the collateral veins secondary to the absence of the splenic vein, which subsequently caused a duodenal deformity.

In conclusion, absence of the splenic artery and vein accompanied with a duodenal ulcer and deformity is a unique and very rare condition. When gastroduodenal mucosal lesions with prominent pulsatile gastric vessels in the fundus are present, although rare, the congenital absence of the splenic artery with or without the accompanying absence of the splenic vein should be considered for the differential diagnosis.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: Introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Leader Frontier: Comment on excitement and existing problems of core fields, and offer suggestions for the future research; (3) Topic Highlight: Experts in gastroenterology and hepatology to focus on certain individual hot topics and try to provide answers to the clinical questions on the topics; (4) Observation: Which updates the development of old and new questions, highlights unsolved questions, and provides strategies on how to solve the questions; (5) Guidelines for Basic Research: Which provides Guidelines for basic research; (6) Guidelines for Clinical Practice: Which provides guidelines for clinical diagnosis and treatment; (7) Review Articles: Summarize the representative progress in core scientific disciplines, comment on the research status, and make suggestions for the future work; (8) Original Articles: Originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: Briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: Report a rare or typical case; (11) Letters to the Editor: Discuss and make reply to the contributions published in *WJG*, or introduce and comment on a controversial issue of general interest; (12) Book Reviews: Introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: Guidelines or common understanding for gastroenterology and hepatology from international academic committee.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The trial register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS AND DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Del Poggio P, Colombo S. Is transient elastography a useful tool for screening liver disease? *World J Gastroenterol* 2009; 15(12): 1409-1414 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1409.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1409>

## Abstract

Transient elastography (TE) is a new non invasive tool for measuring liver stiffness, which is correlated to the histologic stage of liver fibrosis. Several studies in chronic liver disease (CLD) have determined a good accuracy of TE in predicting significant fibrosis and an optimal accuracy in predicting cirrhosis. Normal liver stiffness ranges between 3.3-7.8 KPa and using a cut off of 7.1 KPa, significant fibrosis and cirrhosis can be excluded with a very high negative predictive value (NPV). Positive predictive value (PPV) for the diagnosis of cirrhosis is lower using just a single scan but increases to 90% if high stiffness values are confirmed by a second independent scan. However the presence of fatty liver and metabolic syndrome slightly increases the readings and may reduce the accuracy of the test. It is uncertain if this increase is related to the presence of steatofibrosis or if it is caused by steatosis itself. TE can be used in screening patients attending the liver clinics to identify those with significant fibrosis or cirrhosis and may be particularly useful in discriminating HBV inactive carriers from chronic hepatitis B patients. TE, however, is not reliable in predicting the presence of esophageal varices in cirrhotics. Another potential indication for TE is the systematic screening of populations at high risk for CLD, such as intravenous drug users and alcoholics, but further studies are needed to determine its diagnostic accuracy in these settings.

## INTRODUCTION

Transient elastography (TE) is a new non invasive tool for measuring liver stiffness, which is correlated to the histologic stage of liver fibrosis<sup>[1]</sup>. The device (Fibroscan) generates an elastic wave by means of a vibrator applied to the thoracic wall at the level of the right liver lobe. The vibrator produces a shot and a low amplitude shear wave propagating through the liver parenchyma. The velocity of propagation is directly proportional to liver stiffness and is automatically calculated by the instrument. The range of measurements, expressed in kilopascals, varies from 2.5 to 74 KPa.

Many studies have been published on the use of TE in patients with already diagnosed chronic liver disease (CLD) but few have addressed the issue of its possible use as a first line examination in the liver clinic or in facilities where patients at risk of liver disease are attending.

## HOW TO TAKE AND INTERPRET THE MEASUREMENTS

In order to obtain valid and reproducible measurements the probe should be placed at the center of the right liver lobe, two intercostal spaces below the upper liver margin and at the level of the anterior or middle axillary line. If measurements are taken below this point and too close to the lower liver edge both the percentage of valid shots and the median stiffness tend to decrease<sup>[2]</sup>. Ultrasound assistance to locate the upper liver margin is usually unnecessary if the patient is reasonably thin because the liver can be recognized by percussion alone. The device incorporates an M-mode window enabling the operator to locate the liver parenchyma and avoid both ribs and lung. If the shot does not generate a readable wave the software classifies the measurement as unsuccessful. Liver stiffness

is defined as the median of 10 successful measurements and according to the manufacturer's recommendations at least 60% of the shots should be successful for each exam. The main reason for unsuccessful examination in the Western world is patients being overweight, while in the East intercostal spaces which are too narrow often hamper the appropriate contact of the probe. Overall failure rates in different studies range between 2.4% and 9.4%<sup>[3-6]</sup>. The presence of diabetes and being a transplant recipient have also been identified as independent predictors of failure in a recent study of 215 patients with CLD<sup>[7]</sup>. TE cannot be performed in ascitic patients because the interposed fluid blocks the progression of the shear wave. Other contraindications are pregnancy and the presence of a cardiac pacemaker because there are no safety studies on the use of TE in these conditions. TE is easy to perform, quick and reproducible although fatty liver and a low fibrosis stage may decrease reproducibility<sup>[3]</sup>. TE can also be easily learnt and performed by nurses<sup>[8]</sup> and the results are immediately available, thus saving physician's time and rendering this method particularly suitable for screening a large number of patients.

The validity of the results depends on one important parameter: the variability of measurements. This is reflected by the interquartile range (IQR), representing the range of values including 50% of patients above and below the median. According to the manufacturer's suggestion the IQR/median stiffness ratio should not exceed 30% of the median value, although it seems that 20% could assure the best concordance between liver biopsy and TE<sup>[9]</sup>. There are no studies specifically dealing with the problem of excessive variability of readings and therefore the interpretation of results is derived more from personal experience and from the manufacturer's advice than from observational data. It is still unknown if variability is observed only in diseased or also in normal livers and how this variability affects the interpretation of the test. The cause may be an improper examination technique or it may be inherent to the liver disease itself e.g. in macronodular cirrhosis stiffness may change in different areas of the liver. When variable readings are obtained it is important to check if the probe is perpendicular to the thoracic wall, that the vibrator is not touching against a rib and if the elastographic wave is straight and narrow. If the wave that has been generated is broad, bifid or angulated the software may reconstruct the velocity curve in different parts of the wave and give variable readings. It is important in these cases to obtain a "good" elastogram. This can be obtained by placing the probe in the middle of the right lobe and avoiding contact with the rib as that may dampen the shot and distort the shear wave.

## WHAT ARE THE NORMAL VALUES OF TRANSIENT ELASTOGRAPHY?

Paradoxically many studies have been published in CLD patients, but only three in apparently normal subjects (Table 1): the first as a full paper<sup>[10]</sup> the second as a letter<sup>[11]</sup> and the third as an abstract<sup>[12]</sup>. In the first study,

**Table 1** Liver stiffness in the normal population and factors influencing its measurement

	Corpechot C <sup>[11]</sup>	Roulot D <sup>[10]</sup>	Colombo S <sup>[12]</sup>
Number of subjects	71	429	327
Population	Healthy volunteers	Medical check-up	Blood donors

Metabolic syndrome	-	Increased <sup>3</sup>	-
Fatty liver	-	-	Increased <sup>3</sup>

<sup>1</sup>Range; <sup>2</sup>Standard deviation; <sup>3</sup>At multivariate analysis.

performed by Roulot, 429 apparently healthy subjects attending a free health check were studied by a single operator. Only values with an IQR/median stiffness of less than 30% were considered in the analysis, thus overcoming the problem of variability. Results could be obtained in 93.4% of the subjects, indicating that TE has a low failure rate in the general population. However, the percentage of failures rose to 25% in obese individuals (BMI > 30 kg/m<sup>2</sup>) and 88% in morbid obese individuals, confirming that TE is not a good method for screening overweight people. This is a significant drawback, because many obese subjects have fatty livers and need a rapid, non invasive method to rule out significant fibrosis. Using the 5th and 95th centiles normal values were set between 3.3-7.8 KPa in women and 3.8-8 KPa in men. In the main studies of TE in chronic liver disease<sup>[13-18]</sup> the mean cut-off for significant fibrosis was established between 7 and 8 KPa, (Table 2), which is higher than the 95th centile of normal subjects. TE can thus reliably distinguish normal individuals from patients with significant fibrosis, although overlap exists with mild fibrosis. In addition none of the normal subjects studied by Roulot had values higher than 13-17 KPa, which is considered the cut off range for cirrhosis of all etiologies (Table 3).

Our group reproduced the same results in voluntary blood donors<sup>[12]</sup>: in the absence of fatty liver we observed a mean normal liver stiffness of 4.6 KPa ± 1.52 SD. Using 6.9 as the optimal cut off for normal individuals and comparing it with the cut offs from the literature, we obtained a 96% NPV for ruling out significant fibrosis and a 100% NPV for ruling out cirrhosis. In conclusion, normal subjects can be reliably differentiated from CLD patients. TE could thus be proposed as a good screening tool to detect significant fibrosis and as an optimal tool for the detection of cirrhosis, irrespective of the etiology.

## DO STEATOSIS AND TRANSAMINASE LEVELS AFFECT THE READINGS?

An important finding of Roulot's paper is that mean stiffness was found to be 1.3 KPa higher in subjects with metabolic syndrome than in those without.

AUROC	0.97	0.93	0.95	0.97	0.91	0.95	0.96	0.96	0.92	0.99

Metabolic syndrome was also the main predictor of increased stiffness after adjustment for age, sex, BMI and liver enzymes. This finding suggests that the normal ranges for liver stiffness should be shifted upwards in overweight patients with metabolic syndrome. However no ultrasound examination was performed in this study and therefore it was unknown if the increased stiffness was dependent on metabolic syndrome itself or on fatty liver. To answer this question we investigated 327 healthy blood donors using TE and abdominal ultrasound performed on the same day by two operators with good concordant readings<sup>[11]</sup>. Similarly to Roulot's study we had a very low failure rate (2.4%) confirming the good applicability of TE in population studies. At multiple regression analysis we found that the degree of steatosis, and not BMI, sex, age and liver enzymes, was related to liver stiffness. The central issue is whether steatosis itself increases liver stiffness or if it is caused by an underlying steatofibrosis. Data from the literature are inconclusive: in one study patients with chronic hepatitis C and the same fibrosis stage had increased liver stiffness if they had concomitant fatty liver<sup>[19]</sup>. In addition, there was a close relationship between the augmentation of liver stiffness and the degree of steatosis. However studies in chronic hepatitis B have shown that patients with the same stage of fibrosis had lower<sup>[20]</sup> or equal stiffness<sup>[21]</sup> in the case of accompanying steatosis. It seems unlikely that steatosis might influence liver stiffness in discordant ways depending on the type of hepatitis and therefore further studies are needed to clarify this issue.

Another possible confounding factor is the effect of transaminase (ALT) level. It is well known that acute hepatitis may spuriously cause extreme and transient elevations of liver stiffness<sup>[6,22,23]</sup>, but also minor ALT elevations can alter TE readings and cause discordance with histological stage<sup>[24]</sup>. If elevated ALT may overestimate fibrosis stage the opposite is also true: e.g.

elderly patients with normal or minimally elevated ALT may have their fibrosis stage underestimated. An algorithm has been proposed to correct for the underestimation of fibrosis in the elderly, but this algorithm has not yet been validated<sup>[24]</sup>. In conclusion, abdominal ultrasound and ALT determination should always be used together with TE in population screening.

## NEW TECHNIQUES: REAL TIME ELASTOGRAPHY

From the above considerations it would be attractive to use a new device incorporating liver stiffness measurements with conventional ultrasound. This task could be accomplished by real time ultrasonography. This technique is performed with conventional ultrasound probes and equipment such as Hitachi EUB-8500 and EUB-900 machines. The examined tissue is divided into up to 30000 finite elements and compression is applied with the probe itself to the skin overlying the liver. During compression the displacement of each element is measured and recorded: in hard tissue the amount of displacement is low, whereas in soft tissue the amount of displacement is high. The calculation of soft tissue elasticity distribution is performed in real time and the results are presented in a colour-coded scale with a conventional B-mode image in the background. Liver stiffness can thus be determined during a conventional routine upper abdominal ultrasonography. This new technique is rapid and cheaper than Fibroscan, but its accuracy should be tested against classic TE and liver biopsy. In one study comparing liver biopsy and real time ultrasonography the areas under the receiver operating curve (AUROC) were inferior to TE: 0.75 for equal or higher than F2 fibrosis, 0.73 for equal or higher than F3, 0.69 for F4 and APRI itself performed better than the new technique<sup>[25]</sup>. Using heart beats instead of manual

compression for displacement<sup>[26]</sup> may improve the accuracy and lead to better standardization. Clearly more studies are needed and at this time only TE has sufficient body of evidence to be proposed for screening studies.

## WHEN TRANSIENT ELASTOGRAPHY CAN BE USED AS A FIRST LINE EXAMINATION

TE could theoretically be used to screen patients attending the liver clinic in order to identify: (a) patients with chronic hepatitis B and C with significant fibrosis, to establish an indication for antiviral therapy; (b) patients with non alcoholic fatty liver disease (NAFLD) or non alcoholic steatohepatitis with significant fibrosis in which aggressive dietary intervention or new therapies could be proposed; (c) patients with liver cirrhosis, in order to start sonographic surveillance for hepatocellular carcinoma; (d) patients with liver cirrhosis and significant portal hypertension, in order to start endoscopic surveillance of esophageal varices.

Outside the liver clinic TE could also be used to systematically screen populations at high risk for liver disease e.g. intravenous drug addicts or alcoholic patients attending rehabilitation programs.

In the clinical setting accuracy for the diagnosis of cirrhosis is higher than for significant fibrosis with a median AUROC of 0.95 *vs* 0.86 irrespective of the etiology of liver disease (Tables 2 and 3). The best accuracy is achieved in ruling out cirrhosis, with a NPV close to 100%<sup>[1]</sup>. It should be stressed that despite similar AUROCs, cut offs for significant fibrosis and cirrhosis vary according to etiologies, being lower for hepatitis B, intermediate for hepatitis C and higher for NAFLD or alcoholic liver disease. In chronic hepatitis C and NAFLD there is a continuous spectrum of fibrosis irrespective of ALT levels and therefore it would be preferable to use ranges of values instead of cut-offs<sup>[1]</sup>. On the contrary, in hepatitis B virus infection there is no spectrum of continuity between the inactive carrier state and the chronic hepatitis B patient<sup>[27]</sup> and the use of a cut off value would be appropriate. TE can reliably differentiate the inactive carrier from chronic hepatitis B. In a recent paper<sup>[14]</sup> the mean stiffness value of the liver of an inactive carrier was found to be 5 KPa  $\pm$  1.8 SD, which is similar to normal controls and different from chronic hepatitis B patients with significant fibrosis. Therefore, if a patient suspected to be an inactive carrier has normal stiffness and elevated ALT, another cause for the increased ALT levels should be sought e.g. concomitant NAFLD. The capacity of correctly identifying chronic HBV carriers could be of immense value in regions with high prevalence of HBsAg, where it could be used together with ALT measurement as a quick and cheap screening test for a large proportion of the population.

If TE is a useful tool to diagnose significant fibrosis and cirrhosis in CLD patients and to define the inactive HBsAg carrier, it is not so for predicting portal hypertension and esophageal varices. In fact a

good correlation between stiffness and hepatic-vein portal gradient (HVPg) was found only up to HVPg values of 10-12 mmHg, whereas for higher values the correlation was suboptimal<sup>[28]</sup>. This could be explained by the fact that TE measures the initial rise of portal pressure caused by the accumulation of a fibrillar matrix, but not the complex hemodynamic changes of late portal hypertension<sup>[29]</sup>. Accordingly TE was not accurate in prediction of esophageal varices, with an AUROC ranging from 0.76 to 0.84 in various studies<sup>[29-31]</sup>. Although sensitivity was good (71%-96%), specificity and positive predictive values (PPV) were low (60%-80% and 48%-54%) and overall accuracy was inferior compared to simple tests like platelet count/spleen diameter ratio<sup>[32]</sup>. Another problem arising from these studies is the wide range of proposed cut offs, varying from 13.9 to 21.3 KPa for all varices and from 19 to 30 KPa for F2 varices<sup>[30,31]</sup>. The optimal cut offs therefore are still to be defined.

It would also be interesting to determine a cut off for liver stiffness associated with an increased risk for hepatocellular carcinoma, thus warranting enhanced surveillance for this type of patient. This issue was addressed in only one study<sup>[33]</sup> in which 144 patients with cirrhosis or advanced fibrosis of varying etiologies were studied with TE and appropriate imaging. According to the authors, a cut of 53.7 KPa could identify cirrhotics harbouring hepatocellular carcinoma with good specificity (87%) and high NPV (90%). PPV and sensitivity were however too low (around 30%) to propose TE as a screening tool for determining the risk of hepatocellular carcinoma. Moreover the conclusions were drawn from only 19 liver cancer patients and clearly more studies are needed in larger cohorts of patients.

In different settings from liver clinics, TE has been studied in IVDU<sup>[34]</sup> and alcoholics participating in a rehabilitation program (Melin P, personal communication). In the first study, conducted in Denmark, 434 IVDU from 6 methadone clinics were studied<sup>[34]</sup>. Among the 394 subjects in which TE could be performed, 11 % had cirrhosis (> 12 KPa) and 16% significant fibrosis (8-12 KPa). Twenty-five patients with stiffness > 12 KPa had a repeated TE measurement at the time of liver biopsy. It is interesting to note that 6 patients had a stiffness < 12 KPa at the second scan and all of them had mild fibrosis at biopsy, while only 1 out of 19 patients confirmed at the second scan had mild fibrosis. The authors conclude that two consecutive and concordant scans are needed in order to establish a confident diagnosis of cirrhosis. In fact, PPV for the diagnosis of cirrhosis increased from 50% to 94% after 2 independent scans. The take home message of this study is that in population screening, it is advisable to confirm all elevated results with a second independent scan.

## CONCLUSION

In conclusion, there are not enough data to recommend TE as a screening tool outside of liver clinics and

specific studies are needed on high risk populations. On the basis of existing evidence we can conclude that TE has a high NPV to exclude cirrhosis. PPV is low with a single scan but can increase to 90% if high stiffness values are confirmed by a second independent scan. Accuracy for diagnosing significant fibrosis is lower than for cirrhosis and different cut offs must be taken into account. However, TE is not useful for the prediction of esophageal varices, because PPV is low and cut-offs are still undefined.

### Abstract

The treatment of isolated segmental, sectoral and right hepatic bile duct injuries is controversial. Nineteen patients were treated over a 26-year period. Group one was comprised of 4 patients in whom the injury was primarily repaired during the original surgery; 3 over a T-tube, 1 with a Roux-en-Y. These patients had an uneventful recovery. The second group consisted of 5 patients in whom the duct was ligated; 4 developed infection, 3 of which required drainage and biliary repair. Two patients had good long-term outcomes; the third developed a late anastomotic stricture requiring further surgery. The fourth patient developed a small bile leak and pain which resolved spontaneously. The fifth patient developed complications from which he died. The third group was comprised of 4 patients referred with biliary peritonitis; all underwent drainage and lavage, and developed biliary fistulae, 3 of which resolved spontaneously, 1 required Roux-en-Y repair, with favorable outcomes. The fourth group consisted of 6 patients with biliary fistulae. Two patients, both with an 8-wk history of a fistula, underwent Roux-en-Y repair. Two others also underwent a Roux-en-Y repair, as their fistulae showed no signs of closure. The remaining 2 patients had spontaneous closure of their biliary fistulae. A primary repair is a reasonable alternative to ligation of injured duct. Patients with ligated ducts may develop complications. Infected ducts require further surgery. Patients with biliary peritonitis must be treated with drainage and lavage. There is a 50% chance that a biliary fistula will close spontaneously. In cases where the biliary fistula does not close within 6 to 8 wk, a Roux-en-Y anastomosis should be considered.

### INTRODUCTION

Dangerous anatomy, dangerous pathologies and dangerous surgery are all factors which lead to bile duct injuries in both open and laparoscopic cholecystectomy<sup>[1]</sup>. Dangerous anatomical variants of the right liver bile ducts are known to occur in around 15%-20% of patients, and may be injured during cholecystectomy. These operative sectoral and segmental bile ducts injuries (SSBDI) can often pass by unnoticed and without serious symptoms, and thus the frequency is likely to be far higher. They can however also lead to serious complications such as cholangitis and liver abscesses or biliary fistula and peritonitis.

The treatment of SSBDI is controversial, and the different approaches often depend on the timing of the diagnosis and the types of complications. This study reviews our management of SSBDI.

### ISOLATED SEGMENTAL, SECTORAL AND RIGHT HEPATIC BILE DUCT INJURIES

Dangerous anatomy, dangerous pathologies and dangerous surgery are all factors which lead to bile duct injuries in both open and laparoscopic cholecystectomy<sup>[1]</sup>. There are three main dangerous anatomical variants. Firstly, the cystic duct may be near to the segmental (Figure 1A), or sectoral bile duct (Figure 1B) so that these ducts may be injured during dissection, transection or occlusion of the cystic duct. Secondly, the

**Figure 1 Cystic duct.** A: near a segmental bile duct; B: very close to the sectoral bile duct.

**Figure 2 Cystic duct.** A: Cystic duct joining the segmental; B: Sectoral hepatic ducts that could be misinterpreted as cystic ducts; C: Right hepatic ducts that could be misinterpreted as cystic ducts.

cystic duct may join one of these ducts, instead of the common bile duct (Figure 2A-C) so that one of them may be misinterpreted as a cystic duct and so transected, resected and occluded. Thirdly, the cystic duct may join the convergence of the sectoral or hepatic ducts (Figure 3A and B) so that the common bile duct may be misinterpreted as a cystic duct and so transected and resected.

Dangerous anatomical variants of the right liver bile ducts are known to occur in around 15%-20% of patients, and may be injured during cholecystectomy. These operative isolated segmental, sectoral and right hepatic bile duct injuries can pass by unnoticed and without serious symptoms, and thus the frequency is likely to be even greater. They can however also lead to serious complications such as cholangitis and liver abscesses or biliary fistula and peritonitis. The treatment of isolated segmental, sectoral and right hepatic bile duct injuries is controversial, and the different approaches often depend on the timing of the diagnosis and the types of complications.

We retrospectively reviewed the management of isolated segmental, sectoral and right hepatic bile duct injuries treated in our centre over a 26 year period (1982-2008). The 19 patients (14 women, with a mean age of 51 years) were divided into 4 groups in order to better analyze the different approaches (Table 1). The first group was comprised of 4 patients in whom the injury was recognized at the time of original surgery. Each patient

**Figure 3 Cystic duct joins the convergence of the sectoral (A) and hepatic ducts (B).**

underwent a primary repair, 3 over a tiny T-tube inserted into the common bile duct and then passed through the anastomosis, and 1 patient had an anastomosis of the injured duct with a Roux-en-Y jejunal limb (Figure 4). All the 4 patients had an uneventful recovery and continue to remain well to this day.

The second group consisted of 5 patients in whom the injured duct was ligated. Four of the patients developed cholangitis, 2 of them then also developed liver abscesses requiring drainage and biliary repair. Two patients had good long-term outcomes, the third developed a late anastomotic stricture which was then successfully resolved by further surgery, while the fourth patient developed a small temporary bile leak and pain which resolved spontaneously and required no further treatment. The fifth patient developed serious complications (a liver abscess, an abdominal wound disruption, and pneumonia) from which he finally died.

The third group was comprised of 4 patients referred from other hospitals with neglected biliary peritonitis which had lasted for several weeks. All the 4 patients underwent laparotomy, drainage and lavage. All the 4 developed an external biliary fistula through the subhepatic drain, 3 of which resolved spontaneously, and 1 of which required Roux-en-Y repair. All 4 patients had good long-term outcomes.

The final group consisted of 6 patients with external biliary fistulae which had lasted for between 2 and 8 wk, also referred from other hospitals. Two patients, both with an 8 wk history of a fistula, underwent immediate Roux-en-Y repair. Two other patients also underwent a Roux-en-Y repair, as their fistulae showed no signs of spontaneous closure (Figure 5). The remaining 2 patients had spontaneous closure of their biliary fistulae and required no further treatment (Figure 6).

Thus 12 (63%) patients in this series underwent some form of repair, 3 over T-tube and 9 with Roux-en-Y anastomosis. Repair was not necessary in 6 (32%) patients. 5 of the 10 patients with biliary fistula formation required Roux-en-Y repair, while 5 had spontaneous resolution. One patient (5%) who had duct ligation died.

No single method of treatment for isolated

**Figure 4** Cholangiography. A: An operative cholangiography with missing ducts within segments V and VIII; B: Cholangiography of the injured anterior sectoral duct; C: A schematic of the biliary anatomy before the injury took place (the anterior sectoral duct was misinterpreted as a cystic duct); D: Following hepatico-jejunostomy.**Figure 5** Demonstrates a case with an external biliary fistula that required Roux-en-Y repair. A: Fistulography showing the right hepatic duct; B: ERCP showing the rest of the biliary tree; C: A schematic of the biliary anatomy before the injury took place (the right hepatic duct was misinterpreted as a cystic duct); D: Following hepatico-jejunostomy.

segmental, sectoral and right hepatic bile duct injuries is universally accepted. Some authors believe that due to the uncertain outcomes and potentially harmful complications of reconstructive surgery, simple ligation

of injured ducts is the treatment of choice. This is felt to be the case irrespective of the size of the injured duct<sup>[2]</sup>, as unobstructed drainage of up to 50% of an otherwise normal liver, through either the right or left

**Figure 6** A biliary fistula that resolved spontaneously. A: Fistulography showing the ducts within segment V; B: ERCP showing the rest of the biliary tree; C: The entire biliary tree if the injury hadn't take place; D: A schematic of the biliary anatomy prior to injury.

unaffected ducts, is adequate to restore normal liver function; even with the obstructed lobe remaining in situ<sup>[3,4]</sup>. The non-draining lobe of the liver would then undergo progressive asymptomatic atrophy, and not require further treatment; so long as it was completely obstructed and free from infection, and that there was normal biliary flow from the residual 50% of the liver<sup>[3-5]</sup>. Although the incidence of “free communication” between the two main hepatic ductal systems above the hilum has been reported in up to 50% of patients<sup>[6]</sup>, there is no evidence that the bile from an obstructed ductal system drains through the other unobstructed ducts. Other authors believe that wherever possible isolated segmental, sectoral and right hepatic bile duct injuries should be immediately repaired if recognized, in order to restore normal anatomy and function<sup>[7,9]</sup>.

We favour a primary repair whenever an injury is recognized at original surgery. An end-to-end anastomosis over a tiny T-tube inserted in the common bile duct can be performed if the duct is of a reasonable size (at least 4 mm). There must be no loss of duct tissue, ductal tears or thermal injury, and the repair must be technically perfect using interrupted 5/0 slow-absorbable sutures. We believe that the end-to-end anastomosis is not indicated in injuries close to the common bile duct as any eventual stricture of the anastomosis may cause a stricture of the main bile duct. A Roux-en-Y hepaticojejunostomy can be performed in other situations and where the remaining duct is large enough to accommodate sutures.

Patients with isolated segmental, sectoral and right hepatic bile duct injury have also been successfully treated by nonsurgical methods such as endoscopic and/or percutaneous drainage and stenting<sup>[10]</sup>. In some rare cases with high hepatic injuries segmental liver resection has even been performed in order to avoid long-term transhepatic stenting and its complications such as cholangitis and late stricture formation<sup>[11]</sup>.

Although surgeons have different approaches to the treatment of isolated segmental, sectoral and right hepatic bile duct injury recognized during or soon after the original surgery, there is no major disagreement in the treatment of cases with infection, biliary peritonitis and biliary fistula. Infection is treated stepwise, initially

with antibiotics and percutaneous biliary drainage where possible, and if required with a Roux-en-Y repair<sup>[5]</sup> or even with hepatic resection of the infected parenchyma and ducts<sup>[3]</sup>. Biliary peritonitis requires drainage and lavage, previously by laparotomy and now more commonly by laparoscopy, in order to prevent abdominal abscesses<sup>[12]</sup>. Biliary fistulae are treated conservatively. If they fail to resolve spontaneously then a biliary repair with a Roux-en-Y may be necessary<sup>[13]</sup>.

Thus in conclusion, a primary repair, where possible, is a reasonable solution for isolated segmental, sectoral and right hepatic bile duct injury recognized during the original surgery; the larger the duct the greater need for primary repair. A patient with a ligated duct may develop an infection, and so should be closely followed up for several weeks. Infected ducts require further surgery and usually a Roux-en-Y repair. In the past, patients with biliary peritonitis were treated with open laparotomy, drainage and lavage of the abdominal cavity. Nowadays, lavage and drainage can be successfully carried out laparoscopically or even percutaneously. Biliary fistulae should be followed for several weeks as there is a 50% chance of spontaneous closure. In cases where the biliary fistula does not close within 6 to 8 wk, the patient should probably undergo a Roux-en-Y anastomosis without further delay.

## ACKNOWLEDGEMENTS

I would very much like to thank Dr. Henry Dushan for his critical review and assistance in the writing of this paper in English.

### Abstract

Data from both basic research and clinical experience continue to suggest that mesalamines and thiopurines are effective and efficient for the maintenance of remission of inflammatory bowel diseases. Several decades following the formalization of their indications, attention on these two drugs has been fostered by recent achievements. Demonstration of the ability of mesalamine to activate a colonocyte differentiation factor has shed light on its chemopreventive effects on colorectal cancer; in addition to their anti-proliferative efficacy, thiopurines have been shown to be specific regulators of apoptosis. The two drugs are often co-administered in clinical practice. Recent advancements have shown that mesalamines exert a positive synergism in this context, insofar as they can inhibit side-methylation of thiopurines and hasten the function of the main immunosuppressive pathways. Considering that up to 40% of patients cannot tolerate thiopurines, such renovated targets have stimulated efforts to improve compliance by research on the toxicity mechanisms. The definition of genetic polymorphisms in the enzymes of thiopurine metabolism, and the uncovering of synergistic drug interactions, such as that with allopurinol, are just two of the results of such efforts. Interaction between basic research and clinical practice

### INTRODUCTION

Maintenance of remission of inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease (CD) is a crucial target for at least two reasons: unchecked bowel inflammation behaves as an independent factor in colon cancer development<sup>[1]</sup>, and the inflammatory pathways do mutate in relapsing inflammatory bouts, thus favoring development of drug unresponsiveness and activation of apoptosis-resistant non-professional immunocytes<sup>[2]</sup>. Two classes of drugs form the traditional arsenal for IBD remission maintenance: mesalamines and thiopurines, and the remainder of this review emphasizes that they are far from being set aside. Mesalamines and thiopurines share a few facts in common: they have both been studied in the second half of the last century for indications that were eventually changed; they were studied by two female scientists, one of them was awarded the Nobel prize; they are both effective and cheap; and they both continue to remain under the limelight as novel pharmacological actions are being uncovered beyond those already known. Mesalamines and thiopurines are

often co-prescribed, and among other topics, we shall review the pros and cons of this association.

## MESALAMINES

### Brief history

The ancestor of mesalamine is a compound named salazopyrin (SASP) made by a sulfamidic moiety linked by an azo bond to 5-aminosalicylic acid (5-ASA). Such combined anti-bacterial and anti-inflammatory actions came to the attention of the Swedish rheumatologist Nanna Svartz, who believed that the joint lesions in her patients may have been caused by latent infections and inflammation. In the early 1940s, while giving SASP to her rheumatic patients, to take advantage of its double actions, she noticed an improvement in IBD in co-morbid subjects. Her observations were reported in 1942<sup>[3]</sup> and were to be confirmed in a controlled fashion 20 years later<sup>[4]</sup>. The abandonment of the infectious theory in rheumatoid arthritis and the acknowledgement that the significant allergic toxicity of SASP was mainly caused by its sulfa moiety led to the development of 5-ASAs compounds in the following decades, which are known as mesalazine in Europe and as mesalamine in the US.

### Pharmacology, metabolism, and mechanism of action of 5-ASA

Upon ingestion, 5-ASA is partially oxidized in the stomach, absorbed in the proximal gut, and acetylated in the liver. Although it is not as efficiently absorbed in the terminal gut, the efficiency of the above described processes causes a significant portion of 5-ASA to be transferred to the bloodstream, thus posing the need for an efficient carrier to effect drug delivery to distal areas of disease. Diverse ways to address the need for the distal delivery of 5-ASA have been pursued in the last decades: use of a pH-dependent carrier that releases the active drug distal to the ileo-cecal valve, an ethyl-cellulose capsule to release 5-ASA evenly in the digestive lumen, or, the synthesis of dimers in which the azo bond is supposed to be broken by the colonic flora<sup>[5]</sup>. *In vitro*, 5-ASA has been shown to share several pharmacological properties with non-steroidal anti-inflammatory compounds, including: inhibition of nuclear factor (NF)- $\kappa$ B-dependent inflammatory pathways<sup>[6]</sup>; limitation of the oxidative stress in epithelial cells<sup>[7,8]</sup>; increase in the cellular heat-shock protein response<sup>[9]</sup>; inhibition of leukotriene production<sup>[10]</sup>; and modulation of prostaglandin metabolism<sup>[11]</sup>.

### Indications

The indications for mesalamines do differ between UC and CD. At least one study<sup>[12]</sup> has claimed that SASP is superior to placebo in the treatment of active left-sided CD. On the contrary, the results are mixed as to the indication for remission maintenance; a recent review<sup>[13]</sup> has recommended that prescription of mesalamines for the maintenance of CD be avoided. Regarding the management of UC, there are different data. In one large study<sup>[14]</sup>, mesalamine doses ranging between 1 and

**Table 1** Adverse effects of mesalamine and thiopurines in a cohort of IBD patients<sup>[18]</sup>

Event	Number	Percentage (%)
Mesalamine (n = 44)		
Pulmonary dysfunction	3	6.8
Pancreatitis	1	2.2
Hemolytic anemia	1	2.2
Intolerance to local drug vehicle	1	2.2
Platelet reduction	1	2.2
Diarrhea	1	2.2
Total	8	17.8
Thiopurines (n = 57)		
Leukopenia	10	17.5
Hepatic damage	5	8.77
Infection	4	7.0
Pancreatitis	4	7.0
Idiosyncrasy	2	3.50
Nausea	1	1.75
Malignancy	1	1.75
Total	27	47

4 g/d have been shown to induce remission in 30% of patients, as compared with 12% remission achieved by placebo. A recent Cochrane<sup>[15]</sup> analysis has shown that all of the FDA-approved formulations can offer a 30% therapeutic gain over placebo.

### Toxicity

Although they are prescribed worldwide, SASP/mesalamines can exert occasionally complex toxicity that targets the skin, kidneys, pancreas, liver and cardiovascular system. As a result of the sulfa moiety, SASP can target the skin more often with manifestations ranging from rashes to major Stevens-Johnson lesions. In contrast, the phenacetin-like structure confers on mesalamine the ability to effect necrosis of the renal papilla, thus explaining the concern for clinically meaningful renal toxicity. In an English survey<sup>[16]</sup>, the frequency of 5-ASA-related interstitial nephritis was 11.1 cases per million prescriptions, with the figure being 7.5 for pancreatitis. The lung manifestations linked with mesalamine deserve particular attention<sup>[17]</sup>, being probably based on allergic mechanisms shown to occasionally cause a range of lung damage from eosinophilic pneumonitis to bronchiolitis obliterans. In our series<sup>[18]</sup>, an unexpected percentage of 6.8% patients out of 44 that received mesalamine showed respiratory distress or pleuro-pneumonitis (Table 1).

## THIOPURINES

### History

Belonging to the class of fraudulent nucleotides, the thiopurines are expected to exert a prevalent anti-proliferative and immunosuppressive effect by interfering with DNA replication and causing strand breakage. The thiopurines received a lot of attention in the 1950s and 60s from Gertrud Elion and George Hitchings, who aimed at exploiting their anti-proliferative actions for the treatment of pediatric malignancy. Some of the shrewd

perceptions of Elion, including the attempt to hasten the antineoplastic effects by adding the synergic drug allopurinol (see below), were already contained in her manuscripts of the 1960s<sup>[19]</sup>, and such work led to her award of the Nobel prize in 1988<sup>[20]</sup>. In the following years, the oncological indications for thiopurines were challenged by the release of more potent antineoplastic drugs; However, an anecdotal claim at the beginning of the 1960s<sup>[21]</sup> opened the era of their use for IBD, an era that it still far from being concluded.

### Metabolism and mechanism of action

6-mercaptopurine (6-MP), derived in the liver after non-enzymatic, glutathione-dependent, elaboration of the pro-drug azathioprine (AZA) opens the thiopurine metabolic cascade, which leads to the final synthesis of the immunosuppressive 6-thioguanine metabolites (6-TGNs). While AZA is mostly prescribed in Europe, 6-MP is preferred in the US. At the initial pathway, two enzymatic systems compete for the common substrate 6-MP: thiopurine methyltransferase (TPMT) catalyzes the formation of the methylated non-immunosuppressive compounds of methyl-mercaptopurine (MMP); and hypoxanthine-guanine-phosphoribosyl-transferase (HGPRT) leads to the synthesis of 6-thio-inosine-monophosphate. This metabolite may either enter a phosphorylation loop regulated by a pyrophosphatase (ITPase), or it may undergo elaboration by a dehydrogenase to form 6-TGN, which finally exerts their specific DNA strand breakage effect by incorporation into the DNA replication pathways (Figure 1). A few typical features of the toxicity of thiopurines can be accounted for by at least three points of genetic/biochemical variability, as contained in the described metabolic pathway. Also, such points have recently become the target for finely tuned interventions that are aimed at modulating the patterns of the metabolic cascade, and at restraining the clinical meaningfulness of the relevant thiopurine toxicity<sup>[22]</sup>. The three points include: the genetic polymorphism of TPMT; the possibility to inhibit the enzyme xanthine oxidase by allopurinol (Elion's initial idea); and the ITPase polymorphisms. The following paragraph on toxicity gives more insight into this matter.

### Indications

The immunomodulatory action of thiopurines is characterized by a delayed onset that may take 3 mo. This feature, caused by some fine aspects of their immunomodulatory mechanisms as described below, has traditionally made the thiopurines specific remission maintenance drugs. A pivotal controlled study in 1980 has shown that 6-MP is superior to placebo for fistula closure and steroid sparing in CD<sup>[23]</sup>. Drug withdrawal experiments have shown a significant trend to relapse, with > 50% of the withdrawal patients relapsing at the third year of follow-up<sup>[24-26]</sup>. The efficacy of AZA in the maintenance of UC has been suggested by a similar withdrawal experiment conducted in 1992: out of 79 patients in remission on AZA and randomized to either continue or withdraw treatment, 36% of the former

**Figure 1 Thiopurine metabolism.** For a caption to this figure please refer to metabolism and toxicity paragraphs and ref. 22. <sup>1</sup>TPMT is polymorphic and can be inhibited by mesalamine; <sup>2</sup>Xanthine oxidase can be inhibited by allopurinol; <sup>3</sup>ITPase is polymorphic.

relapsed during follow-up, but as many as 59% of the latter relapsed<sup>[27]</sup>. Several multicenter and monocentric studies, including one from our group<sup>[28]</sup>, have confirmed the efficacy of thiopurines in the maintenance of remission and avoidance of colectomy for UC. In particular, we were able to show that AZA is effective in the maintenance of fastidious forms of UC that are initially responsive to cyclosporin<sup>[29]</sup>.

### Toxicity

Owing to the high degree of genetic polymorphism that affects a few of the key enzymes in their metabolic pathway, thiopurines tend to exert varied toxicity. A recent relevant review<sup>[30]</sup> includes the following: leukopenia 1.3%-12.6%; infection 0.3%-7.4%; liver damage 0%-4.2%; pancreatic damage 0%-4%; gastric intolerance 1.3%-6%; idiosyncratic reactions 0%-3.9%; and drug withdrawal 5.7%-22%. These figures have been upgraded in a recent review, which estimates that up to 40% of the subjects assigned to thiopurine treatment cannot benefit from these drugs because of the adverse effects<sup>[31]</sup>, and do not differ from our monocentric experience<sup>[18]</sup> in which, of 57 IBD patients receiving thiopurines, 25 (43%) experienced adverse effects including leukopenia (17.5%), hepatic damage (8.7%), and infection (7.0%) (Table 1). Attempts at understanding and preventing leukopenia and hepatic and pancreatic events have brought about a significant increase in our basic knowledge. Examination of the thiopurine pathway suggests that leukopenia may chiefly be caused by dysfunction of the side methylator enzyme TPMT, which allows HGPRT to form excess levels of the bone-marrow-toxic 6-TGNs. Indeed, studies of TPMT activity have found it to be uneven, and the gene that encodes for TPMT has been shown to have a degree of polymorphism, as follows. Determination of erythrocyte TPMT activity has led to identification of three subsets of subjects: 90% show high activity; 10% show intermediate activity; and 0.3% are almost devoid of TPMT. The latter (1:300 in the Caucasian population) have a significant risk of developing fatal leukopenia if exposed to thiopurines. TPMT is encoded for by a highly polymorphic 27-kb long gene that is localized to chromosome 6p22.3. Seventeen

variant alleles have so far been described: three of these (TPMT\*2, TPMT\*3A, TPMT\*3C) can cause the synthesis of an unstable protein, caused by an altered tertiary structure, and have been causally linked with 80%-95% of all cases of null TPMT activity. Such information in the last two decades has fostered the search for a screening test and has led to the standardization and release of commercial kits that are allegedly able to identify homozygous subjects at risk for developing fatal leukopenia. Such TPMT studies have provided the paradigm of the neonatal pharmacogenomic studies and have shown the extent of the clinical impact of these studies. If a hypoactive TPMT can cause leukopenia, recent studies<sup>[32]</sup> have suggested that hyperactivity of the enzyme may cause accumulation of an excess of methylated by-products and liver damage that may affect up to 10% of the so-called hypermethylator subjects. This problem has been addressed<sup>[31]</sup> by the co-prescription of allopurinol. By inhibiting xanthine oxidase and the production of the inactive thiouric acid, a 30% lower AZA dose can be administered, thus reducing the substrate for the hyperactive TPMT. Idiosyncratic pancreatitis has been claimed to respond to this strategy. In addition, idiosyncratic response to thiopurine, as shown by fever and flu-like syndromes, has been shown to be avoided by allopurinol. In these cases, probably the accumulation of ill-defined methylated toxins in the area of a polymorphic ITPase is the culprit. Although promising, research in the area of ITPase polymorphisms is still in its infancy.

## CO-PRESCRIBED MESALAMINES AND THIOPURINES

### *Frequency in clinical practice*

Data from a recent survey conducted by us and other four Italian centers has revealed a frequency of co-prescription of 71%.

### *Evidence of synergism between the two drugs*

This comes essentially from withdrawal data in clinical practice. In two independent reports, others and ourselves have shown that patients on AZA and mesalamine in remission from their UC may relapse severely and progress to eventual colectomy if mesalamine is withdrawn; a consistent fall in the blood concentration of 6-TGNs is found in these circumstances<sup>[33,34]</sup>. In addition, the above cited review has shown that regular mesalamine therapy behaves as the only independent factor of continuous remission before AZA withdrawal.

### *Mechanisms underlying the synergy*

As illustrated above (Figure 1), the purine metabolic pathway unfolds primarily following a process by which the pro-drug AZA is finally converted to the metabolites of 6-TGN. The immunosuppressive power of this biochemical machinery depends on the accumulation of the latter compounds, insofar as they are able to decrease the number of dividing lymphocytes by DNA strand breakage. The immunosuppressive steps of

the pathway may be influenced by diversion of the metabolites towards two side-streams at the beginning of the process: one, catalyzed by TPMT, leads to the production of MMP, and the other, catalyzed by xanthine oxidase, produces thiouric acid, both of which are devoid of immunosuppressive activity. Of the two, TPMT has resulted in the most protean system, being under the influence of both genetic polymorphism and drugs. 5-ASA compounds have shown strong affinity for TPMT<sup>[35]</sup>, with a significant inhibitory activity that results in increased feeding of metabolites towards the main axis, which results in a boost to the immunosuppressive power of the pathway. Mesalazine, sulphasalazine and olsalazine have all been shown to influence TPMT activity, with the effects emerging at both the biochemical and clinical levels, as detailed below.

### *Results from clinical reports*

An increase of the effectiveness of AZA in relation to administration of mesalamine, and a concomitant increase in 6-TGN concentration, with attendant leukopenia, have been described in several studies<sup>[36-39]</sup>. Two other studies, on the contrary, have failed to find an advantage from co-prescription, whereas increased toxicity that has hastened the need to discontinue AZA has been emphasized<sup>[40,41]</sup>. The overall available evidence speaks in favor of co-prescribing AZA and 5-ASAs. Together with allopurinol, the mesalamines seem to offer an effective strategy to optimize AZA administration in hypermethylator patients. Whether this readily translates into improved clinical outcomes remains debatable. A recent systematic review<sup>[42]</sup>, although not providing a definitive answer, has concluded that co-administration of thiopurines and mesalamines can lead to a decreased risk for colorectal cancer in long-standing disease.

## REAPPRAISAL OF THE INDICATIONS FOR MESALAMINES: CHEMOPREVENTION

### *Background*

Both CD and UC are known as pre-cancerous lesions, with the risk for transformation becoming significant within 8 years of the diagnosis of UC, and attaining 7%-14% at 25 years<sup>[43]</sup>. Two orders of evidence achieved in the last decades have focused attention on mesalamine as a chemopreventive agent against UC-dependent colorectal cancer. On one hand, a pivotal paper<sup>[1]</sup> has shown that unchecked inflammation acts independently in the promotion of cancer through dysplasia; and on the other hand, modern technology has provided evidence that mesalamine can exert a specific anti-neoplastic action thanks to its ability to interfere with both prostaglandins and nuclear transcription factors for the pro-inflammatory cytokines. The next question was whether mesalamine can protect against colon cancer *in vivo*. A literature search has retrieved at least three retrospective studies of correlation offering relevant answers: a 3-mo course of SASP significantly reduced

the cancer risk in a population of 3000 patients with colitis; in two subsets of colitis patients, of whom, only one received therapeutic doses of 5-ASA, the eventual percentage of cancer development was 3% *vs* 31%, respectively; and in the final study of 102 patients, the drug-induced risk reduction in cancer was 75%-90%<sup>[44]</sup>.

### Mechanisms

Peroxisome proliferator activated receptor gamma (PPAR- $\gamma$ ). PPAR- $\gamma$  is a nuclear receptor that belongs to a family of at least 50 members that are involved with an array of biological functions. Once located to the nucleus and heterodimerized with retinoid X receptor alpha, PPAR- $\gamma$  begins to regulate four gene classes. Such a gene complex is known to direct four major biological functions: metabolism, proliferation, signal transduction, and cell motility. PPAR- $\gamma$  is maximally expressed in the gut, with a gradient increasing from the proximal to the distal bowel. A local negative gradient of expression has been shown in the colon, with the lowest expression levels found in the distal colon; microscopically, the expression is high among the proliferating cells of basal crypts and progressively fades away from bottom to top, to almost indistinguishable levels in cells that detach from the crypt apex and fall free in the lumen. This clearly depicts PPAR- $\gamma$  as a potent differentiation factor that exerts its pivotal role in an environment where a dramatic proliferative drift completely renews the epithelium every 3 d.

These effects favor the candidacy of PPAR- $\gamma$  to be identified among the effective antineoplastic agents in the colon. The insulin-sensitizing drugs, the glitazones, which bind PPAR- $\gamma$  show anticancerous activity in animal models. Hemizygous knock-out animals for PPAR- $\gamma$  show lesser resistance to carcinogenic treatments. At this point, the final crucial question is whether mesalamines can bind PPAR- $\gamma$ , and two lines of evidence have contributed to the answer: (1) colitic animals that are heterozygous for PPAR- $\gamma$  respond least to 5-ASA, which implies a role for PPAR- $\gamma$  in the mediation of the antineoplastic effect of 5-ASA; and (2) 5-ASA can be accommodated into a loop in the structure of PPAR- $\gamma$  through hydrogen bonding. Taken together, the above indicate that 5-ASA can exert a chemopreventive action against UC-related colorectal cancer, and this action is mediated through anti-inflammatory activity, and depends on its binding to a potent differentiation factor of colonocytes<sup>[45,46]</sup>.

## REAPPRAISAL OF THE POTENTIAL OF THIOPURINES: IMMUNOMODULATION

IBD patient caregivers have long become familiar with one of the hallmarks of the action of thiopurines: a latency of effect that may last for 3 mo. Traditionally, this delay has been attributed to the time supposed to be required for the 6-TGN metabolites to saturate myeloid precursors and exert their anti-proliferative effects, a tenet that has recently been challenged on the basis of two lines of evidence<sup>[47,48]</sup>: (1) the use of an intravenous load

of AZA has not significantly reduced the latency; and (2) the process of myeloid cell saturation has been shown to be completed within 2 wk. The results of further studies prompted by these doubts have contributed to uncover that, well beyond their known anti-proliferative capacity, the thiopurines may exert a more finely tuned immunoregulatory action that is largely independent from DNA strand breakage and immune cell death. Focus on this novel aspect of their action is maintained by two recent publications.

Already back in 2003<sup>[49]</sup>, the Neurath group had shown that thiopurines can induce T-cell apoptosis in controls as well as in IBD patients, by replacing GTP as a ligand for the Rac-1 receptor, thus hindering its main function of inducing NF- $\kappa$ B. This process is CD-28-dependent and triggers a mitochondrial pathway to apoptosis. This study was the first to demonstrate that a product of the intermediate thiopurine metabolism (6-thioguanine triphosphate, as generated from the phosphorylation loop described above) cannot simply break the native DNA, but specifically triggers apoptosis directed towards the autoimmune clones at the root of IBD perpetuation. This provides a fine immunological indication for the use of thiopurines, and hints at a disease-modifying role that is still to be studied.

The Ben-Horin group in Israel has recently developed research on this apoptosis process further, and has concentrated on timing and mechanistic issues<sup>[50]</sup>. Using a double *in vitro* and experimental approach in animals, they have gathered evidence that thiopurines effect a proliferative arrest of T lymphocytes, without any apoptotic effect being obvious until the fifth day post-stimulation. During this latency, these lingering T lymphocytes are still capable of adherence and mediating inflammation; thus, the immunological events lying behind the clinical latency of thiopurines have been uncovered. In their second set of experiments, this time conducted *in vivo*, they have shown that the animals must be exposed for > 1 mo to mercaptopurine before it restricts the memory pool to antigenic re-challenge. These data depict thiopurines as fine immunomodulators that require several weeks to express full-blown activity. Far from being speculative laboratory exercises, these approaches serve (1) to remind the clinician of the underlying reasons for the specific indication for thiopurines, as maintenance drugs; and (2) to remind doctors to reiterate to their patients the need for maximum compliance in order to maximally exploit the drug and benefit from the longest disease-free period.

## CONCLUSION

Despite the time elapsed since their initial study, mesalamines and thiopurines continue to remain under investigation as research from basic immunology fosters novel clinical approaches, as shown by a few publications that have appeared even while preparing this review. Mesalamine has recently been proposed as the first candidate drug to be endowed with a disease-modifying role in UC<sup>[51]</sup>. Another review<sup>[52]</sup> has raised the question of

the timing of the introduction of AZA for IBD, and has proposed to use it earlier in a top-down strategy in order to best exploit its effects, chiefly the mucosal-healing potential. Finally, mesalamines and thiopurines, together with cyclosporin, are still considered unbeaten in terms of cost-effectiveness, when compared with the most recent drugs made by genetic engineering, and have been awarded the status of “backbone therapy” for IBD<sup>[53]</sup>.

### Abstract

Acute pancreatitis is an inflammatory disease of the pancreas. The etiology and pathogenesis of acute pancreatitis have been intensively investigated for centuries worldwide. Many causes of acute pancreatitis have been discovered, but the pathogenetic theories are controversial. The most common cause of acute pancreatitis is gallstone impacting the distal common bile-pancreatic duct. The majority of investigators accept that the main factors for acute biliary pancreatitis are pancreatic hyperstimulation and bile-pancreatic duct obstruction which increase pancreatic duct pressure and active trypsin reflux. Acute pancreatitis occurs when intracellular protective mechanisms to prevent trypsinogen activation or reduce trypsin activity are overwhelmed. However, little is known about the other acute pancreatitis. We hypothesize that acute biliary pancreatitis and other causes of acute pancreatitis possess a common pathogenesis. Pancreatic hyperstimulation and pancreatic duct obstruction increase pancreatic duct pressure, active trypsin reflux, and subsequent unregulated activation of trypsin within pancreatic acinar cells. Enzyme activation within the pancreas leads to auto-digestion of the gland and local inflammation. Once the hypothesis is confirmed, traditional therapeutic strategies against acute pancreatitis may be improved. Decompression of pancreatic duct pressure should be advocated in the treatment of acute pancreatitis which may greatly improve its outcome.

### INTRODUCTION

Acute pancreatitis, an inflammatory disease of the pancreas, is mild and resolves itself without serious complications in 80% of patients, but it has complications and a substantial mortality in up to 20% of patients<sup>[1]</sup>. Its etiology and pathogenesis have been intensively investigated for centuries worldwide<sup>[2]</sup>. In 1856, Claude Bernard suggested that bile reflux into the common pancreatic duct could trigger acute pancreatitis<sup>[3]</sup>. Several subsequent studies led to theories fuelling the debate until 1901<sup>[4]</sup>, when Eugene Opie proposed that gallstone migration into the common bile duct is the main cause of acute pancreatitis<sup>[5]</sup>. Since then, many other causes of pancreatitis have been discovered<sup>[6]</sup>. However, the pathogenesis of acute pancreatitis is still controversial to date. Several theories attempt to explain the pathogenesis of acute pancreatitis. In terms of disease pathogenesis, whether acute pancreatitis is really one entity or it comprises a group of distinct pathogenic entities remains unclear. From a pathogenic perspective, acute pancreatitis is an identity crisis<sup>[7]</sup>.

### CAUSES OF ACUTE PANCREATITIS

There are many causes of acute pancreatitis, which can be easily identified in 75%-85% of patients. In developed countries, obstruction of the common bile duct by stones (38%) and alcohol abuse (36%) are the most frequent causes of acute pancreatitis<sup>[3,8]</sup>. Gallstone-induced pancreatitis is caused by duct obstruction by gallstone migration. Obstruction is localized in the bile duct and pancreatic duct, or both. Duct obstruction promotes pancreatitis by increasing duct pressure and subsequent unregulated activation of digestive

enzymes<sup>[9]</sup>. Alcohol abuse is the second most frequent cause of acute pancreatitis, but the correlation between alcohol and pancreatitis is not completely understood<sup>[10]</sup>. In experimental models, Gorelick showed that ethanol directly sensitizes acinar cells to cholecystokinin stimulation. As the development of pancreatitis might be affected by both genetic and environmental factors, failure to inhibit trypsin activity or to wash active trypsin into pancreatic ducts might promote alcoholic pancreatitis<sup>[11]</sup>. In fact, the exact mechanism underlying alcoholic acute pancreatitis has not been extensively elucidated.

Pancreas divisum, a common congenital anatomical variant of the pancreatic duct in about 7% of autopsy series, results from the absence of fusion between the dorsal and ventral ductal systems. The possible consequence of pancreas divisum is a stenosed or inadequately patent minor papilla, preventing normal drainage of pancreatic secretions and leading to increased intraductal pressure. However, whether pancreas divisum is related to pancreatitis is highly controversial<sup>[12]</sup>. Whether dysfunction of sphincter of Oddi can trigger acute pancreatitis by increasing intrapancreatic duct pressure is also controversial<sup>[13]</sup>. Biliary sludge refers to a viscous bile suspension that contains cholesterol crystals and calcium bilirubinate granules embedded in strands of gallbladder mucus. Sludge is associated with bile stasis, long-lasting fast, distal bile duct obstruction, and total parenteral feeding. Most patients with biliary sludge are asymptomatic. Biliary sludge is commonly seen in patients with recurrent acute pancreatitis of unknown origin, and cholecystectomy might prevent the recurrence of pancreatic disease<sup>[14]</sup>.

Intraduct papillary mucinous tumor might be another cause of acute pancreatitis. Tumor or mucus produced by it obstructs the main pancreatic duct and its side branch, or both. Logically, the consequence is increased pancreatic duct pressure caused by pancreatic hyperstimulation and pancreatic duct obstruction. Thus, these tumors might trigger acute pancreatitis through the same mechanisms underlying acute biliary pancreatitis<sup>[15]</sup>.

Endoscopic retrograde cholangiopancreatography (ERCP) is a potential cause of acute pancreatitis. Asymptomatic hyperamylasaemia occurs in 35%-70% of patients after the procedure. ERCP has a higher risk of inducing acute pancreatitis when it is performed to treat Oddi sphincter dysfunction than to remove gallstones in the bile duct. Other risk factors for post-ERCP pancreatitis include young age, female sex, number of attempts to cannulate papilla, and poor emptying of pancreatic duct after opacification. Prevention of post-ERCP pancreatitis in high-risk patients might be achieved by placing a temporary pancreatic stent<sup>[16]</sup>.

Hypercalcaemia is another rare and inconsistent cause of acute pancreatitis. Because the incidence of pancreatitis is low in patients with chronic hypercalcaemia, additional factors are probably needed to induce pancreatitis<sup>[17]</sup>. Drugs rarely induce acute pancreatitis. Cases of drug-induced pancreatitis have been reported<sup>[18]</sup>. Many infectious agents are associated

with acute pancreatitis, but no microorganism has ever been identified within the pancreas. However, it was reported that acute pancreatitis is associated with viral or bacterial infections, and infestation with parasites<sup>[19]</sup>. Although a few researchers speculated that unexplained recurrent acute pancreatitis might be associated with some known genetic mutations, no decisive and persuasive evidence supports the notion<sup>[20]</sup>.

In summary, many causes of acute pancreatitis have been discovered. The main causes are gallstone migration and alcohol abuse. Other causes are uncommon, situational, or controversial. Although there are many theories about the pathogenesis of acute pancreatitis, they are still controversial. These causes have not yet been completely elucidated.

## MULTIPLE AND CONTROVERSIAL PATHOGENETIC THEORIES

For centuries, the pathogenesis of acute pancreatitis has been intensively investigated worldwide<sup>[2]</sup>. Many theories have been proposed attempting to explain the pathogenetic mechanisms underlying acute pancreatitis<sup>[21]</sup>. The important theories about the pathogenesis of acute pancreatitis include bile-pancreatic duct common pathway theory, pancreatic autodigestion theory, gallstone migration theory, enzyme activation theory, kinin and complement system activation theory, microcirculation disturbance theory, leukocyte excessive activation theory, pancreatic acinar cell apoptosis and necrosis theory, all of which are still controversial<sup>[22]</sup>. They can only explain the pathogenesis of some specific pancreatitis cases, or specific aspects of pathogenetic process of some forms of acute pancreatitis. In fact, no ideal theories on the pathogenesis of acute pancreatitis are available at present.

Although 70%-80% of acute pancreatitis cases are due to alcohol abuse and gallstones, the exact mechanisms by which they initiate acute pancreatitis are unknown. In addition, because of its rapid course and the relative inaccessibility of pancreatic tissue for examination during pancreatitis, investigations of the mechanisms underlying these pathobiologic processes have been hampered. Considering these obstacles, investigators have turned to animal models of acute pancreatitis to reveal the molecular steps initiating these pathobiologic responses to identify potential targets for therapeutic intervention<sup>[23-25]</sup>. Although the exact mechanisms underlying acute pancreatitis caused by alcohol and gallstones in humans have not been established, key steps in mediating the pathobiologic processes that define acute pancreatitis can be identified from animal models, and used to develop therapies that can be ultimately tested in human pancreatitis<sup>[26]</sup>.

Since early in the twentieth century, a good many of experimental studies based on animal models have been carried out<sup>[27]</sup>. Many research results support that bile reflux and pancreatic auto-digestion by trypsin are central to the pathogenesis of gallstone pancreatitis<sup>[28]</sup>. A century later, the following questions still remain to be

answered: whether it is rational to examine the possibility that gallstone pancreatitis develops without reflux of bile into the pancreatic duct, whether trypsinogen activation is an effect rather than the cause of pancreatitis, whether active trypsin is essential for the development of acute pancreatitis or whether it is merely a secondary factor that exacerbates pancreatitis. It has been shown that bile reflux is not a necessary factor for acute pancreatitis<sup>[29]</sup>. In opossum, merely ligation of the pancreatic duct can cause necrotizing acute pancreatitis<sup>[30]</sup>, but in rats or in rabbits, this causes apoptosis and atrophy of pancreas<sup>[31]</sup>, suggesting that further study is needed to elucidate the pathogenesis of acute pancreatitis in order to explain the paradoxical experimental results with different animals.

Considering various causes of acute pancreatitis, the question of whether each cause of acute pancreatitis corresponds to specific pathogenesis or various causes of acute pancreatitis actually possess a common pathogenesis should be answered. We hypothesize that, irrespective of the etiology of acute pancreatitis, there is a common pathway that triggers various forms of acute pancreatitis.

## COMMON PATHOGENESIS AND VARIOUS CAUSES OF ACUTE PANCREATITIS

The etiology and pathogenesis of acute pancreatitis have been intensively investigated<sup>[2]</sup>, but the pathogenetic theories are controversial. The predominant theories of acute biliary pancreatitis are common pathway theory and gallstone migration theory, which consent that the key factor for acute biliary pancreatitis is bile-pancreatic duct obstruction, which increases pancreatic duct pressure, bile reflux, trypsin activation and pancreatic auto-digestion<sup>[32]</sup>. Acute pancreatitis occurs when intracellular protective mechanisms to prevent trypsinogen activation or reduce trypsin activity are overwhelmed<sup>[33]</sup>. However, these theories are controversial.

Although pancreatic duct obstruction may play an important role in the pathogenesis of gallstone pancreatitis, it is not sufficient to cause the morphological changes of acute pancreatitis<sup>[34]</sup>, indicating that other events must occur if the changes induced by pancreatic duct obstruction lead to acute pancreatitis. Although acinar hyperstimulation has often been implicated in acute pancreatitis pathogenesis, there is no evidence that supports it<sup>[35]</sup>. We hypothesize that pancreatic acinar hyperstimulation, in the presence of duct obstruction, triggers and exacerbate acute pancreatitis.

We speculate that the main preconditions that trigger acute biliary pancreatitis are pancreatic hyperstimulation and bile-pancreatic duct obstruction, which increase pancreatic duct pressure, active trypsin reflux, and unregulated activation of trypsin within pancreatic acinar cells. Enzyme activation within the pancreas leads to auto-digestion of the gland and local inflammation. However, little is known about the other causes of acute pancreatitis.

We hypothesize that there is a common pathogenic pathway that triggers various forms of acute pancreatitis: acute biliary pancreatitis and other forms of acute pancreatitis. In our hypothesis, there are various causes which may cause acute pancreatitis and lead to pancreatic duct obstruction and blockage of pancreatic juice outflow under certain circumstances. In the presence of exocrine pancreatic hyperstimulation, pancreatic duct pressure, active trypsin reflux, and unregulated activation of trypsin within pancreatic acinar cells would increase. When intracellular protective mechanisms to prevent trypsinogen activation or reduce trypsin activity are overwhelmed, acute pancreatitis occurs.

## CONCLUSION

Acute pancreatitis has been intensively studied for centuries. Many causes of acute pancreatitis have been discovered, but its pathogenetic theories are multiple and controversial. The true nature of acute pancreatitis still remains to be elucidated. The causes of acute pancreatitis are various, and its mechanism is common. Once the hypothesis is confirmed, traditional therapeutic strategies against acute pancreatitis may be improved, and decompression of pancreatic duct pressure should be advocated in the treatment of acute pancreatitis which may greatly improve the outcome of acute pancreatitis<sup>[36,37]</sup>.

did not change  $\alpha$ -SMA levels, while TGF- $\beta$ 1 treatment for 6 d significantly increased  $\alpha$ -SMA production. Short term incubation (6 h) with TGF- $\beta$ 1 enhanced CLPF migration, while long term treatment (6 d) of CLPF with TGF- $\beta$ 1 reduced migration to 15%-37% compared to untreated cells. FN and FN isoform mRNA expression were increased after short term incubation with TGF- $\beta$ 1 (2 d) in contrast to long term incubation with TGF- $\beta$ 1 for 6 d. After induction of migration, TGF- $\beta$ 1-preincubated CLPF showed higher amounts of FN and its isoforms and lower levels of total and phosphorylated FAK than untreated cells.

**CONCLUSION:** Long term incubation of CLPF with TGF- $\beta$ 1 induced differentiation into myofibroblasts with enhanced  $\alpha$ -SMA, reduced migratory potential and FAK phosphorylation, and increased FN production. In contrast, short term contact (6 h) of fibroblasts with TGF- $\beta$ 1 induced a dose-dependent increase of cell migration and FAK phosphorylation without induction of  $\alpha$ -SMA production.

Transforming growth factor- $\beta$ 1 induces intestinal myofibroblast differentiation and modulates their migration. *World J Gastroenterol* 2009; 15(12): 1431-1442 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1431.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1431>

## Abstract

**AIM:** To investigate the effects of transforming growth factor  $\beta$ 1 (TGF- $\beta$ 1) on the differentiation of colonic lamina propria fibroblasts (CLPF) into myofibroblasts *in vitro*.

**METHODS:** Primary CLPF cultures were incubated with TGF- $\beta$ 1 and analyzed for production of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA), fibronectin (FN) and FN isoforms. Migration assays were performed in a modified 48-well Boyden chamber. Levels of total and phosphorylated focal adhesion kinase (FAK) in CLPF were analyzed after induction of migration.

**RESULTS:** Incubation of CLPF with TGF- $\beta$ 1 for 2 d

## INTRODUCTION

Transforming growth factor- $\beta$  (TGF- $\beta$ ) is involved in multiple fundamental biological processes such as cell proliferation<sup>[1-3]</sup>, cell migration<sup>[4-8]</sup>, cell differentiation<sup>[9]</sup>, extracellular matrix deposition<sup>[6,7,10,11]</sup>, and immune responses<sup>[12]</sup>. TGF- $\beta$  is secreted by a variety of cells

including platelets, monocytes, macrophages, and lymphocytes. It is thought to play a critical role in embryogenesis, host response to tumors, and the repair response that follows damage to tissues by immune and nonimmune reactions<sup>[8]</sup>.

TGF- $\beta$  not only affects remodeling during normal wound healing after tissue injury, but also enhances fibrogenesis. Therefore, it is an important mediator in multiple fibrotic diseases, including pulmonary fibrosis, liver fibrosis, chronic pancreatitis<sup>[12]</sup>, and in stricture formation in Crohn's disease (CD)<sup>[13]</sup>. Increased expression of TGF- $\beta$ , especially of the isoform TGF- $\beta$ 1, has been demonstrated in fibrotic tissues and regions of increased extracellular matrix deposition<sup>[12]</sup>. TGF- $\beta$  changes the balance between extracellular matrix synthesis and degradation, inducing an increase in the synthesis of matrix components and a parallel decrease in the matrix-proteolytic activity<sup>[11,12]</sup>.

TGF- $\beta$  is synthesized as a pro-form which can be activated by multiple mechanisms. After activation of latent TGF- $\beta$  and binding to its receptors, the activated receptors phosphorylate and assemble cytoplasmic Smad proteins. Subsequently, Smad complexes move to the nucleus as transcriptional regulators<sup>[12,14]</sup>.

TGF- $\beta$  is also a potent chemoattractant for human dermal fibroblasts. Intact disulfide bonds and perhaps the dimeric structure of TGF- $\beta$  are essential for its ability to stimulate migration of fibroblasts, since reduction of TGF- $\beta$  results in a marked loss of its chemoattractant potency<sup>[8]</sup>.

Fibroblast migration plays an important role in tissue formation and wound healing. Following injury, tissue repair takes place involving inflammation, new tissue formation and scar constitution<sup>[15]</sup>. Migration of fibroblasts into and through the extracellular matrix during the initial phase of wound healing appears to be a fundamental component of wound contraction. In recent studies, we found that colonic lamina propria fibroblasts (CLPF) conditioned media induce migration of primary human CLPF in the modified Boyden chamber<sup>[16]</sup>. Furthermore, we demonstrated that fibronectin (FN) was mainly responsible for the autocrine induction of CLPF migration and was an essential requirement for the induction of CLPF migration, since different growth factors enhanced CLPF migration only in the presence of conditioned medium or recombinant FN<sup>[16]</sup>. Reduced and enhanced migratory potential of CLPF correlated with decreased and increased amounts of FN or FN isoforms, respectively<sup>[17]</sup>. FNs occur in up to 20 different isoforms as a result of alternative splicing of the primary transcript in the two homologous type III domains named ED-A and ED-B and the one non-homologous repeat termed III CS<sup>[18-22]</sup>. The ED-A and ED-B segments are either entirely included or excluded. The type III repeat may be included, excluded, or partially included in FN<sup>[23-25]</sup>.

The alternatively spliced FN isoforms show distinct functional differences. The expression of FN containing ED-A and ED-B domains is significantly increased during physiological wound healing and pathological

tissue fibrosis<sup>[26]</sup>. Changes in the migratory potential of CLPF from patients with CD were associated with changes in FN isoform level, while the expression of integrin  $\alpha$ 5 $\beta$ 1, the main FN receptor on the surface of CLPF, was unchanged<sup>[17]</sup>.

The differentiation or activation of fibroblasts into myofibroblasts is an important step in tissue repair. Transient appearance of myofibroblasts is a feature of normal wound healing, but the persistence of these activated cells is associated with excessive collagen deposition and fibrosis<sup>[9]</sup>. Their prolonged presence and over-representation are hallmarks in the pathophysiology of tissue fibrosis<sup>[27]</sup>. TGF- $\beta$ 1 potently stimulates the production of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) and stress fiber formation in fibroblasts and therefore their differentiation into myofibroblasts<sup>[9]</sup>.

Since the regulation of migration and differentiation of intestinal fibroblasts is an important mechanism during intestinal wound healing and fibrosis, the effect of TGF- $\beta$ 1 on these processes and on FN and FN isoform production was investigated in this study.

## MATERIALS AND METHODS

### Patients

Primary CLPF cultures were obtained from endoscopic biopsies or surgical specimens taken from healthy areas of the mucosa of patients undergoing surveillance colonoscopy or surgery for colorectal carcinoma. The study was approved by the Ethics Committee of the University of Regensburg.

### Isolation and culture of human colonic fibroblasts

Human CLPF were isolated and cultured as described earlier<sup>[28]</sup>. Briefly, mucosa from surgical specimens was cut into 1 mm pieces while the biopsies were used directly for the isolation of CLPF. Epithelial cells were removed in Hank's Balanced Salt Solution without  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  (PAA, Cölbe, Germany) with 2 mmol/L EDTA (SIGMA, Deisenhofen, Germany). The remaining tissue was rinsed and then digested for 30 min at 37°C with 1 mg/mL collagenase 1 (SIGMA), 0.3 mg/mL DNase I (Boehringer, Mannheim, Germany) and 2 mg/mL hyaluronidase (SIGMA) in PBS (Gibco, Karlsruhe, Germany). The isolated cells were cultured in 25 cm<sup>2</sup> culture flasks (Costar, Bodenheim, Germany) with DMEM containing 10% FCS, penicillin (100 IE/mL), streptomycin (100  $\mu$ g/mL), ciprofloxacin (8  $\mu$ g/mL), gentamycin (50  $\mu$ g/mL) and amphotericin B (1  $\mu$ g/mL). Non-adherent cells were removed by subsequent changes of medium. The remaining cells were used between passage 3 and 8.

### Incubation of CLPF with TGF- $\beta$ 1

CLPF were incubated for two days or six days with 0, 0.1, 1, 10 and 50 ng/mL of TGF- $\beta$ 1 (Biozol, Germany) in serum-free medium. The culture medium of 6 d treated cells was changed after 3 d and new TGF- $\beta$ 1 was added for a further three days. Subsequently, cells were used for investigation of  $\alpha$ -SMA production, cell

migration, quantitative mRNA analysis, FN, and FAK production.

#### **Wounding assay: Induction of CLPF migration with platelet derived growth factor-AB**

CLPF were incubated for 6 d with or without 10 ng/mL of TGF- $\beta$ 1 (Biozol, Germany) in serum-free medium. The medium was changed after three days and new TGF- $\beta$ 1 was added for a further three days. The cells cultured in 5 cm dishes were wounded with a comb, washed and incubated for a further 4 h with different concentrations of platelet derived growth factor (PDGF)-AB (R&D Systems, Minneapolis, MN, USA; 0, 5, 10, and 20 ng/mL). Cells were harvested and used for quantitative analysis of FN and FN splicing form mRNA and for Western blot analysis of FN and FN-splicing form protein as well as levels of total and phosphorylated FAK.

#### **Immunocytochemical staining**

For immunocytochemical staining of  $\alpha$ -SMA, 20 000 cells were seeded onto LabTek® Chamber slides (Nunc, Wiesbaden, Germany) and fixed with ice-cold acetone. Immunocytochemical stainings were performed according to the manufacturer's APAAP protocol (Dako, Hamburg, Germany). The anti  $\alpha$ -SMA antibody (1:25, clone 1A4, Dako) was used to investigate the differentiation of CLPF into myofibroblasts. IgG2a (MOPC-141, Sigma) was used as an isotype control.

#### **Western blotting**

Western blot analysis was performed as described earlier<sup>[17,29]</sup>. Protein detection was carried out with a specific antibody to  $\alpha$ -SMA (clone 1A4, Dako, Hamburg, Germany) and incubation with peroxidase-conjugated secondary antibody. Protein bands were visualized using a commercial chemoluminescence detection kit (ECL Plus; Amersham) according to the manufacturer's protocol. Loading was checked by Ponceau S staining.

For FN and FAK protein immunoblots specific antibodies to FN (1:1000; 35041A, Pharmingen), FN ED-A (1:400; clone IST-9, Abcam), FN ED-B (1:200; PhiloMab-2, Philogen), FAK (1:666; Chemicon), phosphoFAK (1:1000; Biosource) and  $\beta$ -actin (1:10000; Chemicon) were used. After washing of the membranes horseradish peroxidase-conjugated secondary antibodies (Santa Cruz, CA) were added and incubated with chemiluminescent substrate (ECL Plus; Amersham Biosciences, Arlington Heights, IL) for 5 min before a film (Amersham Biosciences) was exposed.

After exposure, the antibody was stripped from the membrane with Re-Blot Plus-Strong (Chemicon, Hofheim, Germany) for 15 min and the blot was blocked again with 5% milk in 0.1% Tween 20-TBS before using it for the next antibody.

#### **Migration assays**

Migration assays were performed in a modified 48-well Boyden chamber as described earlier<sup>[28]</sup>. A polycarbonate filter (8  $\mu$ m pore size, polyvinylpyrrolidone-free,

Gerbu Biotechnik, Gaiberg, Germany) divided the chamber into an upper and a lower compartment. Each test substance was placed in the wells of the lower compartment in replicates of three. Conditioned media with or without PDGF-AB, IGF-I (R&D Systems), EGF (Biosource, Germany) or TGF- $\beta$ 1 (Biozol) were tested. DMEM high glucose medium with or without 1% bovine serum albumin (BSA, SIGMA) served as negative controls. A total of 20 000 CLPF/well in DMEM high glucose medium with 1% BSA were seeded into the wells of the upper compartment of the Boyden chamber. The Boyden chamber was incubated at 37°C in 10% CO<sub>2</sub> atmosphere for 6 h. The filter was removed from the chamber and the non-migrated cells on the upper side of the filter were scraped off with a rubber policeman. The migrated cells on the lower side of the filter were fixed and stained with Hemacolor staining kit (Merck, Darmstadt, Germany) and counted in 4 microscopic high power fields of view (hpf) at a 400-fold magnification. Unless otherwise indicated, each experiment was repeated at least three times ( $n = 3$ ).

#### **Conditioned media**

The culture medium was removed from a confluent CLPF monolayer. The cells were washed twice with PBS and subsequently cultured with DMEM lacking FCS for 24 h. The conditioned medium was centrifuged to remove all cell debris and stored at -20°C for no more than 3 mo.

#### **RNA isolation and cDNA synthesis**

For the isolation of total RNA stimulated and unstimulated primary human CLPF cultures were washed twice with PBS. CLPF were scraped off, centrifuged for 5 min, and resuspended with lysis buffer from the RNeasy® kit (Qiagen, Hilden, Germany). Total RNA was prepared from these CLPF according to the manufacturer's protocol and stored at -80°C. The isolated RNA was reverse transcribed using the Promega Reverse Transcription System (Promega, Madison, WI, USA).

#### **Quantitative mRNA analysis by real-time PCR**

Amounts of FN, ED-A and ED-B mRNA were quantified by real-time PCR as previously described<sup>[17]</sup>.

Released reporter dye fluorescence during 40 cycles of amplification was monitored using Sequence Detector software (SDS version 2.0, PE Applied Biosystems). Reporter dye fluorescence versus PCR cycles was plotted. A threshold was set in the exponential phase of the fluorescence curves. The threshold cycle numbers (Ct) were calculated.

Ct values of GAPDH were subtracted from those of FN isoforms:  $dCt = Ct(\text{FN isoforms}) - Ct(\text{GAPDH})$ . The mean value of dCt values was calculated. The values of cDNA from stimulated CLPF were subtracted from those of untreated cDNA of the same CLPF:  $ddCt = dCt(\text{stimulated}) - dCt(\text{unstimulated})$ . The relative start

amount of cDNA was calculated in consideration of the exponential amplification:  $x = 2^{-ddCt}$ .

### Statistical analysis

All data are given as mean  $\pm$  SE. The Student's *t*-test was used for analysis of parametric data, while the Mann-Whitney Rank Sum Test was used for evaluation of non-parametric data. Real time PCR data were pictured as boxplots.  $P < 0.05$  were considered to be statistically significant.

## RESULTS

### Effect of TGF- $\beta$ 1 on $\alpha$ -SMA production of CLPF

To investigate the effect of TGF- $\beta$ 1 on  $\alpha$ -SMA production of CLPF, CLPF were incubated with different concentrations of TGF- $\beta$ 1 in serum-free medium. Subsequently, APAAP-staining of  $\alpha$ -SMA or its isotype control IgG2a $\kappa$  was performed. Since there was no remarkable change in  $\alpha$ -SMA production after treatment for one day or two days with 0.1, 1, and 10 ng/mL TGF- $\beta$ 1 (data not shown), we compared  $\alpha$ -SMA production of CLPF incubated for two days (Figure 1A) or six days (Figure 1B) with 0, 10 and 50 ng/mL TGF- $\beta$ 1. A time- and dose-dependent increase of  $\alpha$ -SMA was observed: short-term treatment with 50 ng/mL TGF- $\beta$ 1 resulted in enhanced  $\alpha$ -SMA production, however, after long-term incubation  $\alpha$ -SMA was detected in almost all cells.

In order to confirm these results, Western blot analysis was performed (Figure 2A). CLPF treated for two days or six days with 10 ng/mL or 50 ng/mL TGF- $\beta$ 1 were lysed and levels of  $\alpha$ -SMA were detected. In each lane 30  $\mu$ g/mL cell lysate protein were loaded and the loading was checked by Ponceau S staining (Figure 2B). Western blot data confirmed the induction of  $\alpha$ -SMA production by long-term incubation of CLPF with TGF- $\beta$ 1 in contrast to short-term incubation, where no  $\alpha$ -SMA was detected.

### Effect of TGF- $\beta$ 1 on the migration of CLPF

Since TGF- $\beta$ 1 potently stimulated the production of  $\alpha$ -SMA in CLPF and as a consequence their differentiation into myofibroblasts, we investigated the effect of long term TGF- $\beta$ 1 incubation on the migration of CLPF. Because 10 ng/mL TGF- $\beta$ 1 induced similar  $\alpha$ -SMA levels as 50 ng/mL TGF- $\beta$ 1 (Figure 2), we treated CLPF for six days with 10 ng/mL TGF- $\beta$ 1 and performed migration assays in the presence of PDGF-AB, IGF- I, EGF and TGF- $\beta$ 1 diluted in 24 h CLPF-conditioned medium in a modified Boyden chamber (Figure 3). The Boyden chamber was incubated at 37°C in 10% CO<sub>2</sub> atmosphere for 6 h. We reported earlier that growth factors like PDGF-AB, IGF- I, EGF and TGF- $\beta$ 1 diluted in conditioned media enhance CLPF migration<sup>[28]</sup>. However, pre-incubation of CLPF with TGF- $\beta$ 1 for six days significantly decreased CLPF migration. This decreased migratory potential of myofibroblast-like CLPF could not be re-enhanced by addition of growth factors (Figure 3).

Migration assays with different dilutions of PDGF-AB in conditioned medium showed that short-term incubation (6 h) in the modified Boyden chamber enhanced migration of TGF- $\beta$ 1-untreated CLPF in a dose-dependent manner (Figure 3A). Addition of 5 ng/mL PDGF-AB to CLPF conditioned medium increased migration up to 60% ( $64 \pm 5$  cells/hpf) when compared to conditioned medium without additional PDGF-AB (control,  $44 \pm 4$  cells/hpf). Addition of 20 ng/mL PDGF-AB to CLPF conditioned medium induced a more than two-fold migration rate ( $121 \pm 19$  cells/hpf) when compared to control. Pre-incubation of CLPF for six days with 10 ng/mL TGF- $\beta$ 1 reduced migration to 37% ( $16 \pm 2$  cells/hpf) when compared to untreated CLPF ( $44 \pm 4$  cells/hpf) and could not be re-enhanced by PDGF-AB ( $P < 0.0001$ ; Figure 3A).

Similar results were obtained in migration assays using different concentrations of IGF- I, EGF or TGF- $\beta$ 1 in conditioned medium (Figure 3B-D). Addition of the growth factors to the conditioned medium enhanced the migration of TGF- $\beta$ 1-untreated CLPF, although the effect was not as strong as with PDGF-AB. Again, pre-incubation of CLPF for six days with TGF- $\beta$ 1 led to a reduced migratory potential of the cells and could not be re-enhanced by the growth factors IGF- I (Figure 3B: 100 ng/mL,  $P < 0.005$ ; 200 ng/mL,  $P < 0.05$ ; 300 ng/mL,  $P < 0.0001$ ), EGF (Figure 3C: 10 ng/mL,  $P < 0.05$ ) or TGF- $\beta$ 1 (Figure 3D: 10 pg/mL,  $P < 0.005$ ; 20 pg/mL,  $P < 0.0001$ ; 30 pg/mL,  $P < 0.05$ ).

### Effect of TGF- $\beta$ 1 on the production of FN and FN isoforms

It is known that TGF- $\beta$ 1 promotes the insertion of the ED-A domain in FN<sup>[30,31]</sup> and we have recently shown that changes in the migratory potential of CLPF were correlated with changes in FN isoform production<sup>[17]</sup>. For this reason, the effect of TGF- $\beta$ 1 on splicing of FN mRNA in CLPF was assessed. CLPF were incubated with different TGF- $\beta$ 1 concentrations for two days or six days and the amounts of FN, FN ED-A-, and FN ED-B were determined. Therefore the cells were treated with 10 ng/mL and 50 ng/mL TGF- $\beta$ 1 and untreated cells were used as controls. For the comparison of mRNA expression quantified by real time PCR untreated controls were set as 1. The results of 7 independent experiments were evaluated statistically (Figure 4).

After two days incubation with 10 ng/mL TGF- $\beta$ 1 total FN mRNA expression was increased 20-fold and 25-fold with 50 ng/mL (both  $P < 0.005$ , paired *t*-test). When CLPF were incubated for six days, FN mRNA was increased 6-fold with 10 ng/mL TGF- $\beta$ 1 and 10-fold with 50 ng/mL TGF- $\beta$ 1 compared to control (Figure 4A).

mRNA amounts of FN ED-A and FN ED-B were increased 20-fold ( $P < 0.05$ ) and 13-fold ( $P < 0.005$ ), respectively, with 10 ng/mL TGF- $\beta$ 1 after two days, while after six days 5-fold (FN ED-A,  $P < 0.05$ ) or 3-fold (FN ED-B,  $P < 0.05$ ) increased mRNA levels compared to controls were found (Figure 4B and C). Treatment with 50 ng/mL TGF- $\beta$ 1 for 2 d caused a 23-fold ( $P < 0.01$ ) increase of FN ED-A mRNA which

**Figure 1** Effect of TGF- $\beta$ 1 on  $\alpha$ -SMA production in CLPF. CLPF were incubated for 2 d (A) or 6 d (B) with 0, 10 and 50 ng/mL TGF- $\beta$ 1. Subsequently, APAAP-staining of  $\alpha$ -SMA ( $\alpha$ -actin) or its isotype control IgG2a was performed. Incubation of CLPF for 6 d with 10 ng/mL or 50 ng/mL TGF- $\beta$ 1 showed the greatest effect on  $\alpha$ -SMA, since almost all cells showed a red staining for  $\alpha$ -SMA.

was reduced to 6-fold after a further four days. mRNA amounts of FN ED-B was 15-fold ( $P < 0.01$ ) after two days and reduced to 4-fold ( $P < 0.05$ ) after six days (Figure 4B and C).

Together these data indicate that TGF- $\beta$ 1 causes a strong increase in mRNA expression of FN and migration inducing FN isoforms. However, this effect was not maintained but was clearly reduced after six

days. Values obtained after six days of incubation were not statistically different to unstimulated controls despite the presence of TGF- $\beta$ 1. On average, FN mRNA amounts were 70% lower after pre-incubation with 10 ng/mL TGF- $\beta$ 1 for six days than after pre-incubation for two days ( $P < 0.05$ ), while FN ED-A and FN ED-B ( $P < 0.05$ ) mRNA levels were reduced by 80%. Similar data were obtained for incubation with 50 ng/mL

**Figure 2** Effect of TGF- $\beta$ 1 on  $\alpha$ -SMA protein production. Control CLPF were incubated for 2 d or 6 d with 0, 10, and 50 ng/mL TGF- $\beta$ 1 in serum-free medium. Subsequently the cells were washed and lysed. Amounts of  $\alpha$ -SMA were analyzed by Western blotting (A). Equal loading was confirmed by Ponceau S staining (B). Incubation of CLPF for 6 d with 10 ng/mL or 50 ng/mL TGF- $\beta$ 1 markedly enhanced  $\alpha$ -SMA production.

TGF- $\beta$ 1 for six days *versus* stimulation for two days (total FN 55% lower ( $P < 0.05$ ) after six days compared to two days, FN ED-A and FN ED-B 75% lower ( $P = 0.05$ ).

In addition, TGF- $\beta$ 1-mediated induction of FN and FN splice variant production was confirmed by Western blot analyses. A time- and dose-dependent increase of total FN, FN ED-A and FN ED-B was detected after TGF- $\beta$ 1 treatment (Figure 5). In contrast to the findings for mRNA expression after six days TGF treatment higher levels of FN, ED-A and ED-B protein compared to two days were observed. In the absence of TGF- $\beta$ 1, levels of FN and FN isoforms were low and did not differ between two- and six- day cultures. A concentration of 0.1 ng/mL TGF- $\beta$ 1 did not show a significant effect while 1 ng/mL TGF- $\beta$ 1 induced an increase in FN and FN ED-A production after two days and six days compared to untreated cells. After two days FN ED-B protein was only found after incubation with TGF- $\beta$ 1 concentrations of 10 ng/mL and 50 ng/mL, while this isoform could be detected after six days with 1, 10, and 50 ng/mL TGF- $\beta$ 1. The most prominent effect on FN, FN ED-A, and FN ED-B production was observed after six days incubation with 50 ng/mL TGF- $\beta$ 1.

#### Effects of TGF- $\beta$ 1 and PDGF-AB on FN and FN isoforms in a wounding model

Because of the observed reduced migratory potential of CLPF incubated long-term with TGF- $\beta$ 1 but increased protein levels of migration inducing factor FN and FN splice variants, we analyzed migrating cells in a wounding

assay in more detail. CLPF were pre-incubated with and without 10 ng/mL TGF- $\beta$ 1 in serum free medium (six days). The CLPF monolayer was wounded with a comb, migration was induced by incubation with different concentrations of PDGF-AB (0, 5, 10, 20 ng/mL) in conditioned medium for 4 further hours and mRNA amounts of FN isoforms were assessed (Figure 6).

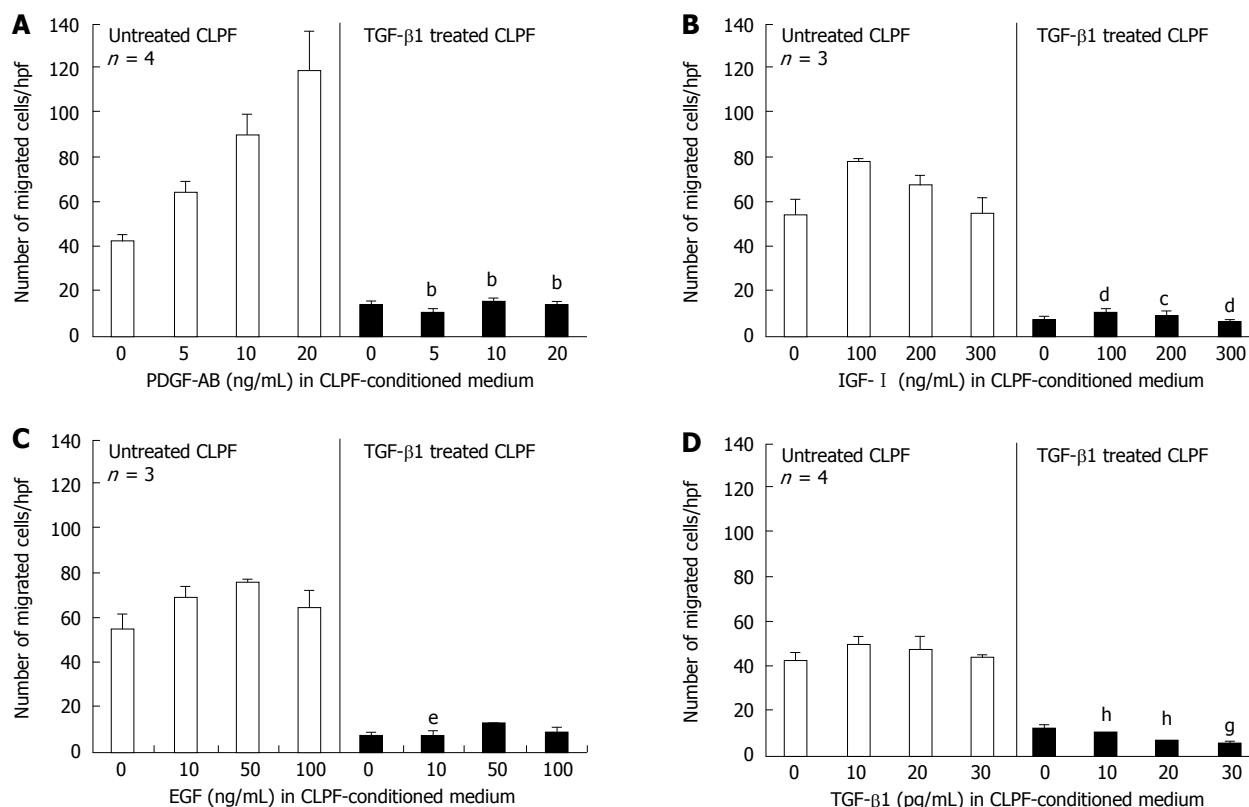

While CLPF without TGF- $\beta$ 1 pre-treatment displayed a slight PDGF-dependent increase in the expression of FN, FN ED-A, and a slight decrease in FN ED-B mRNA in this wounding assay, TGF- $\beta$ 1 pre-treated cells displayed a stronger enhancement of FN, FN ED-A, and FN ED-B mRNA-expression.

After stimulation with 5, 10, and 20 ng/mL PDGF-AB in conditioned medium FN mRNA-expression was 4.5- (Paired *t*-test,  $P < 0.05$ ), 4- ( $P < 0.01$ ), and 4.5-fold ( $P < 0.05$ ) increased in TGF- $\beta$ 1 pre-treated and 2-, 3.5-, and 1.5-fold enhanced in TGF- $\beta$ 1 untreated CLPF as compared to the control, respectively (Figure 6A). PDGF-AB stimulation of pre-incubated CLPF led to 3- (5 ng/mL PDGF,  $P < 0.005$ ), 2.5- (10 ng/mL PDGF,  $P < 0.01$ ), and 4-fold increases (20 ng/mL PDGF,  $P < 0.05$ ) in FN ED-A mRNA expression, whereas TGF- $\beta$ 1 unstimulated cells showed a 2- ( $P < 0.05$ ), 3.5-, and 1.5-fold enhancement, respectively (Figure 6B). PDGF caused a 3- (5 ng/mL,  $P < 0.01$ ), 2.5- (10 ng/mL,  $P < 0.01$ ), and 3-fold increase (20 ng/mL,  $P < 0.01$ ) in FN ED-B mRNA in TGF- $\beta$ 1-treated CLPF and a 1.5-, 2.5- (5 and 10 ng/mL,  $P < 0.01$ ), and 1.5-fold (20 ng/mL) enhancement in TGF- $\beta$ 1 untreated cells (Figure 6C).

In summary, pre-treatment of CLPF with TGF- $\beta$ 1 (six days) and subsequent treatment with PDGF-AB (4 h) after wounding causes a much stronger induction of FN mRNA expression than without TGF- $\beta$ 1 pre-treatment.

After TGF- $\beta$ 1-incubation, wounding, and incubation without PDGF-AB mRNA levels of total FN, FN ED-A, and FN ED-B increased significantly by 4-fold when compared to TGF- $\beta$ 1- and PDGF-AB-untreated controls ( $P < 0.05$  for FN and FN ED-A; FN ED-B  $P < 0.005$ ). With 5 ng/mL PDGF-AB mRNA amounts of FN splice forms doubled by TGF- $\beta$ 1-stimulation [FN ED-A ( $P < 0.05$ )]. After TGF- $\beta$ 1 pre-stimulation expression of FN and FN ED-B rose by 20% compared to untreated cells, while FN ED-A expression was even decreased by 30%. With 10 ng/mL TGF- $\beta$ 1 and 20 ng/mL PDGF-AB, after cell wounding total FN expression showed a 3-fold ( $P < 0.05$ ), FN ED-A expression a 2.5-fold ( $P = 0.06$ ), and FN ED-B expression a 2-fold ( $P < 0.005$ ) increase.

Western blot analyses of protein production confirmed these findings on mRNA expression (Figure 7). Protein amounts of FN, FN ED-A, and FN ED-B were strongly increased by TGF- $\beta$ 1 incubation. In comparison to TGF- $\beta$ 1 untreated controls the levels of FNs were enhanced after wounding and further enhanced by addition of PDGF-AB in conditioned medium. No significant differences were observed between protein amounts in TGF- $\beta$ 1 pre- and not incubated CLPF by PDGF-treatment, respectively. FN

**Figure 3** Effect of TGF- $\beta$ 1 on growth factor-induced migration of CLPF. Control-CLPF were treated for 6 d with 10 ng/mL TGF- $\beta$ 1 and subsequently migration assays in the presence of PDGF-AB, IGF- I, EGF and TGF- $\beta$ 1 diluted in 24 h CLPF-conditioned medium were performed in the modified Boyden chamber. TGF $\beta$ 1 treatment of CLPF significantly decreased the migratory potential, which could not be re-enhanced by cell migration-inducing growth factors. Statistics: The Mann-Whitney Rank Sum Test was used for the evaluation of the non-parametric data. A: <sup>b</sup> $P < 0.0001$  vs unstimulated CLPF; B: <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.005$  vs unstimulated CLPF; C: <sup>e</sup> $P < 0.05$  vs unstimulated CLPF; D: <sup>g</sup> $P < 0.05$ , <sup>h</sup> $P < 0.01$  vs unstimulated CLPF.

ED-B protein levels of CLPF without pre-treatment were barely detectable.

#### Effects of TGF- $\beta$ 1 on FAK phosphorylation in a wounding model

We have demonstrated in previous studies that enhanced cell migration of CLPF was associated with higher FAK phosphorylation and total FAK protein production<sup>[29]</sup>. Therefore, we determined TGF- $\beta$ 1-modulated FAK production and phosphorylation by Western blot (Figure 8) in CLPF that were induced to migrate by wounding and stimulation with PDGF-AB in conditioned medium. Pre-incubation of CLPF with 10 ng/mL TGF- $\beta$ 1 for six days decreased FAK phosphorylation as compared to untreated controls. In addition, levels of FAK protein were reduced by TGF- $\beta$ 1 stimulation. CLPF that were not pre-treated with TGF- $\beta$ 1 contained enhanced levels of FAK with a constant higher FAK phosphorylation that was highest with an addition of 5 ng/mL PDGF-AB when compared to CLPF not treated with TGF- $\beta$ 1.

## DISCUSSION

In this study we demonstrate that TGF- $\beta$ 1 potently stimulates the production of  $\alpha$ -SMA in CLPF and therefore their differentiation into myofibroblasts as a result of long term contact. This differentiation into myofibroblasts is accompanied by a reduced migratory

potential, reduced FAK phosphorylation and increased synthesis of FN as a component of extracellular matrix (ECM).

Myofibroblast differentiation and activation by TGF- $\beta$ 1 is a critical event in tissue repair and the pathogenesis of human fibrotic diseases. Myofibroblasts and TGF- $\beta$ 1 are key elements for the generation of contractile force associated with wound contraction and pathological contractures as in the development of tissue fibrosis. Myofibroblasts are characterized by the presence of  $\alpha$ -SMA-containing stress fibers, vinculin-containing fibronexus adhesion complexes, and FN fibrils containing the ED-A splice variant<sup>[32]</sup>. TGF- $\beta$ 1 promotes contraction of collagen gels by fibroblasts through their differentiation into myofibroblasts<sup>[33]</sup>. In addition, TGF- $\beta$ 1 induces a dose-dependent increase in the generation of contractile force and a concomitant increase in the production of  $\alpha$ -SMA<sup>[32]</sup>.

In the current study much higher TGF- $\beta$ 1 doses were required to induce  $\alpha$ -SMA production than in the studies by Simmons *et al.*<sup>[9]</sup> and Vaughan *et al.*<sup>[32]</sup>. This may be a cell-type-specific effect. Simmons *et al.* used CCD-18Co fibroblasts isolated from the colon of a 2.5 mo old child, while in this study intestinal fibroblasts of adults have been used. Vaughan *et al.*<sup>[32]</sup> used myofibroblasts obtained as explant cultures or by collagenase digestion of palmar aponeurosis from patients with Dupuytren's disease. Therefore, it may be

**Figure 4** Quantitative mRNA analysis of FN (A) and the splicing forms FN ED-A (B) and FN ED-B (C) by real-time PCR in TGFβ1 stimulated CLPF. TGFβ1 stimulated and untreated control-CLPF ( $n = 7$ ) were lysed and mRNA was isolated. The cDNA start concentration of the untreated control group was set as 1. Compared to the control cells a dose-dependent increase in mRNA expression of FN, FN ED-A, and FN ED-B was determined. TGFβ1-stimulation for 2 d caused a higher increase in FN mRNA expression than after 6 d. Paired  $t$ -test: <sup>a</sup> $P < 0.005$ ; <sup>b</sup> $P < 0.01$ ; <sup>c</sup> $P < 0.05$ .

that fibroblasts obtained from palmar aponeurosis react more sensitively to TGFβ1 than CLPF.

Myofibroblast differentiation by TGFβ1 is dependent on cell adhesion and integrin signaling *via* FAK. TGFβ1 induces tyrosine phosphorylation of the autophosphorylation site Tyr-397 of FAK, an effect that is dependent on cell adhesion and is delayed relative to early Smad signaling. Pharmacologic inhibition of FAK or expression of kinase-deficient FAK, mutated by substituting Tyr-397 with Phe, inhibited TGFβ1-induced α-SMA production and stress fiber formation<sup>[34]</sup>. In the current study we found that long term incubation

**Figure 5** Effect of TGFβ1 on FN, FN ED-A, and FN ED-B protein in CLPF after 2 d and 6 d. Control-CLPF were incubated for 2 d or 6 d with 0, 0.1, 1, 10, and 50 ng/mL TGFβ1 in serum-free medium. Subsequently cells were washed and lysed. Amounts of FN were quantified by Western blotting. Loading was checked by β-actin production. Incubation of CLPF for 6 d with TGFβ1 markedly enhanced the levels of FN, FN ED-A, and FN ED-B.

with TGFβ1 reduced FAK phosphorylation and this was associated with a decreased migratory potential. TGFβ1 untreated CLPF displayed a PDGF-dependent increase of FAK-phosphorylation that correlated with an enhanced migration.

FAK is a nonreceptor protein tyrosine kinase involved not only in adhesion but also in cell migration. FAK-deficient fibroblasts exhibit defects in cell migration and elevated numbers of cell-substratum contact sites<sup>[35]</sup>. The reduced migratory behavior of CD- and ulcerative colitis (UC)-CLPF is accompanied by a reduction of FAK and FAK phosphorylation<sup>[29]</sup>.

TGFβ1 production is increased in myofibroblasts at sites of fibrosis in experimental enterocolitis and CD<sup>[9]</sup>. In CD, increased TGFβ1 expression is transmural whereas in UC, the increase is confined to the lamina propria and submucosa. The distribution of TGFβ1 coincides with the distribution of the inflammatory infiltrate as well as an increase in the collagen type III:I ratio in both CD and UC<sup>[36]</sup>. Additionally, TGFβ1, -β2, -β3 and their receptors are increased in fibrotic CD mucosal tissue samples<sup>[13]</sup>. Therefore, it may be assumed that a reduced migratory potential of inflammatory bowel disease (IBD)-CLPF<sup>[29]</sup> is a result of enhanced α-SMA production and enhanced formation of focal contacts induced by increased levels of TGFβ1 in the tissue. However, we could not find higher α-SMA levels in *ex vivo* cultures of CD- and UC-CLPF compared to cultures isolated from control mucosa (data not shown). Therefore, a differentiation of IBD-CLPF into myofibroblasts was not the reason for the reduced migratory potential of these cells.

**Figure 6** Quantitative mRNA analyses of FN (A) and the splicing forms FN ED-A (B), and FN ED-B (C) by real-time PCR in CLPF treated with TGF- $\beta$ 1. Control CLPF ( $n = 7$ ) were pre-incubated with and without 10 ng/mL TGF- $\beta$ 1 for 6 d, the monolayer wounded with a comb, and incubated for further 4 h with increasing concentrations of PDGF-AB in conditioned medium. mRNA was isolated and cDNA transcribed. cDNA start concentration of the untreated control (0 ng/mL TGF- $\beta$ 1 and 0 ng/mL PDGF-AB) was set as 1. Paired  $t$ -test:  $^aP < 0.005$ ;  $^bP < 0.01$ ;  $^cP < 0.05$ .

Contrasting migration-modulating effects of TGF- $\beta$  are described in the literature. Ellis *et al*<sup>[7]</sup> report a diverse pattern of motogenic response to the three TGF- $\beta$  isoforms. Migration of subconfluent fibroblasts into 3D collagen gels was inhibited by all three TGF- $\beta$ -isoforms, whereas migration of confluent cells was unaffected by TGF- $\beta$ 1 and TGF- $\beta$ 2, but stimulated by TGF- $\beta$ 3<sup>[7]</sup>. Postlethwaite *et al*<sup>[8]</sup> reported that TGF- $\beta$ 1 is a potent chemoattractant in the Boyden chamber for human dermal fibroblasts. Inhibitory effects of TGF- $\beta$ 1 on fibroblast migration into 3D collagen gels are in marked

**Figure 7** FN, FN ED-A, and FN ED-B protein levels of TGF- $\beta$ 1-pre-stimulated and unstimulated control CLPF in a wounding assay. Isolated proteins were analyzed by Western blotting. Protein levels of FN, FN ED-A, and FN ED-B were increased by TGF- $\beta$ 1-pre-treatment compared to untreated control. Loading was checked by Ponceau S staining.

**Figure 8** Analysis of FAK phosphorylation and FAK protein production of CLPF after TGF- $\beta$ 1 incubation in a wounding assay. Isolated proteins were analyzed by Western blotting. Phospho-FAK and FAK decreased after 6 d TGF- $\beta$ 1 pretreatment in comparison to untreated controls. Loading was checked by Ponceau S staining.

contrast to reports indicating that TGF- $\beta$ 1 stimulates the migration of human skin fibroblasts in the modified Boyden chamber<sup>[6]</sup>.

Previously we investigated the effect of TGF- $\beta$ 1 on CLPF migration in the modified Boyden chamber after a 6 h incubation period<sup>[28]</sup> and found a significant migration-inducing effect of TGF- $\beta$ 1. Here we report that long term incubation for 6 d with TGF- $\beta$ 1 induces a marked reduction of migration in subsequent migration assays. This discrepancy obviously was determined by the time TGF- $\beta$ 1 could act on the target cells.

**Figure 9** Schematic illustration of the role of TGF- $\beta$ 1, FN, and FAK in the development of fibrosis in CD. After wounding TGF- $\beta$ 1 is produced by different cell types and connective tissue cells. CLPF increase FAK phosphorylation and migrate into the wound along the TGF- $\beta$ 1 gradient. FN that is also produced during migration induction and secreted at the site of injury may lead to an additional enhancement of the migratory gradient. Long term contact with TGF- $\beta$ 1 within the wound allows fibroblasts to differentiate into myofibroblasts. These cells have a reduced migratory potential and support wound healing via wound contraction and production of extracellular matrix deposition like FN. Phosphorylation of FAK is reduced after longer contact with TGF- $\beta$ 1 due to the differentiation into ECM-producing myofibroblasts.

Addition of 10 ng/mL and 50 ng/mL TGF- $\beta$ 1 resulted in a dose-dependent increase of FN, FN ED-A, and FN ED-B expression. After two days incubation, expression of FN and the splice forms significantly increased. Enhanced mRNA expression was also observed after 6 d incubation with TGF- $\beta$ 1 but was not as high as after 2 d. On the other hand, after six days higher protein levels of total FN and FN isoforms were observed in comparison to the unstimulated two day control. Therefore, the reduced migration of CLPF after six days incubation with TGF- $\beta$ 1 is accompanied by enhanced protein levels of FN and FN isoforms. This increased production of FN and FN isoforms might lead to enhanced cell adhesion. Other groups also report that fibroblast attachment is significantly increased after TGF- $\beta$ 1 treatment<sup>[36]</sup>. Nevertheless, cell adhesion was not addressed in our investigations.

In CLPF treated for six days with TGF- $\beta$ 1, after wounding and PDGF-AB incubation increased protein levels of FN, FN ED-A, and FN ED-B were found when compared to untreated controls. In these cells FAK protein and FAK phosphorylation were reduced. This reduced FAK phosphorylation correlated with the observed reduced migratory potential after long term incubation with TGF- $\beta$ 1.

In conclusion, long term incubation of intestinal fibroblasts with TGF- $\beta$ 1 induced differentiation into myofibroblasts with an enhanced  $\alpha$ -SMA production and a reduced migratory potential that was accompanied by decreased FAK production and phosphorylation. In contrast, short term contact of CLPF with TGF- $\beta$ 1 induced a dose-dependent increase of cell migration without induction of  $\alpha$ -SMA. Therefore, the following scenario is conceivable: after wounding TGF- $\beta$ 1 is produced by different cell types and connective tissue

cells, like CLPF, migrate towards the wound along the TGF- $\beta$ 1 gradient. Long-term contact with TGF- $\beta$ 1 in the wound allows the fibroblasts to differentiate into myofibroblasts. Myofibroblasts support wound healing *via* wound contraction and production of extracellular matrix deposition. In pathological situations the local increase in immigrated cell numbers with reduced dispersing potential and increased deposition of extracellular matrix may finally lead to tissue fibrosis. FN that is produced during the induction of migration and secreted at the site of injury may lead to an additional enhancement of the migratory gradient (Figure 9). The phosphorylation of FAK is reduced after longer contact with TGF due to the differentiation into ECM-producing myofibroblasts.

However, this model remains speculative, since the modulating influence of other factors on fibroblast migration and the complex interactions of fibroblasts with immune cells or epithelial cells certainly play an important role in wound healing, too.

The role of TGF- $\beta$  and the mechanism of mucosal wound healing or intestinal tissue fibrosis require further investigation to develop therapies for the modulation of the mucosal healing response in IBD.

## ACKNOWLEDGMENTS

The authors thank the doctors and nurses of the Endoscopy department and the surgeons and pathologists of the University of Regensburg for their ongoing great cooperation, and most important all patients that agreed to give biopsies and tissue samples without whom this study would not have been possible. The authors thank Michael Göke, MD, for fruitful discussions.

## COMMENTS

### Background

Migration of colonic lamina propria fibroblasts (CLPF) plays an important role during the progression of fibrosis and fistulae in Crohn's disease. Transforming growth factor- $\beta$  (TGF- $\beta$ ) is involved in the regulation of cell migration, cell differentiation, extracellular matrix deposition, and immune responses. In recent studies, the authors found that CLPF conditioned media induced migration of primary human CLPF and that fibronectin (FN) was mainly responsible for the autocrine induction of CLPF migration. Since the regulation of migration and differentiation of intestinal fibroblasts is an important mechanism during intestinal wound healing and fibrosis, the effect of TGF- $\beta$ 1 on these processes and on FN and FN isoform production was investigated in this study.

### Research frontiers

A high number of patients with Crohn's disease have to undergo surgery because of fibrotic disease. The mechanism of stricture formation and the role of TGF- $\beta$  in this are not well understood.

### Innovations and breakthroughs

This study adds to the understanding of the role of TGF- $\beta$  in intestinal wound healing and stricture formation. It shows that TGF- $\beta$  can both be beneficial and detrimental depending on the duration of secretion.

### Terminology

Colon lamina propria fibroblasts (CLPF): CLPF are mesenchymal cells of connective tissue that are in an activated state and locally agile. After differentiation into myofibroblasts cells are in a less active state, concerned with maintenance. Transforming growth factor (TGF): TGF- $\beta$ 1 is a cytokine that on the one hand stimulates migration of fibroblasts and on the other hand potentially stimulates the production of  $\alpha$ -smooth muscle actin and stress fiber formation in fibroblasts and therefore their differentiation into myofibroblasts. Fibronectin (FN): FN is an extracellular matrix protein that is mainly responsible for the autocrine induction of CLPF migration and is essentially required for the induction of CLPF migration. Focal adhesion kinase (FAK): FAK is a nonreceptor protein tyrosine kinase involved not only in adhesion but also in cell migration. Enhanced migration of CLPF is associated with higher FAK phosphorylation and total FAK protein production. Myofibroblast differentiation by TGF- $\beta$ 1 is dependent on cell adhesion and integrin signaling via FAK.

### Peer review

The authors investigated the effects of transforming growth factor- $\beta$  (TGF- $\beta$ ) on the differentiation of colonic lamina propria fibroblasts (CLPF) into myofibroblasts *in vitro*. They found that long term incubation of CLPF with TGF- $\beta$ 1 induced differentiation into myofibroblasts with enhanced  $\alpha$ -SMA, reduced migratory potential and FAK-phosphorylation, as well as increased FN production. In contrast, short term contact (6 h) of fibroblasts with TGF- $\beta$ 1 induced a dose-dependent increase of cell migration and FAK-phosphorylation without induction of  $\alpha$ -SMA production. The study is well designed, the methods they use are sound and their results are reliable.

## Abstract

**AIM:** To study the expression and phosphorylation of extracellular signal-regulated kinase (ERK) 1 and ERK2 in multidrug resistant (MDR) hepatocellular carcinoma (HCC) cells.

**METHODS:** MDR HCC cell lines, HepG2/adriamycin (ADM) and SMMC7721/ADM, were developed by exposing parental cells to stepwise increasing concentrations of ADM. MTT assay was used to determine drug sensitivity. Flow cytometry was employed to analyze cell cycle distribution and measure cell P-glycoprotein (P-gp) and multidrug resistant protein 1 (MRP1) expression levels. ERK1 and ERK2 mRNA expression levels were measured by quantitative real-time PCR (QRT-PCR). Expression and phosphorylation of ERK1 and ERK2 were analyzed by Western blot.

**RESULTS:** MTT assay showed that HepG2/ADM and

SMMC7721/ADM were resistant not only to ADM, but also to multiple anticancer drugs. The P-gp expression was over 10-fold higher in HepG2/ADM cells than in HepG2 cells ( $8.92\% \pm 0.22\%$  vs  $0.88\% \pm 0.05\%$ ,  $P < 0.001$ ) and over 4-fold higher in SMMC7721/ADM cells than in SMMC7721 cells ( $7.37\% \pm 0.26\%$  vs  $1.74\% \pm 0.25\%$ ,  $P < 0.001$ ). However, the MRP1 expression was not significantly higher in HepG2/ADM and SMMC7721/ADM cells than in parental cells. In addition, the percentage of MDR HepG2/ADM and SMMC7721/ADM cells was significantly decreased in the G0/G1 phase and increased in the S phase or G2/M phase. QRT-PCR analysis demonstrated that the ERK1 and ERK2 mRNA expression increased apparently in HepG2/ADM cells and decreased significantly in SMMC7721/ADM cells. Compared with the expression of parental cells, ERK1 and ERK2 protein expressions were markedly decreased in SMMC7721/ADM cells. However, ERK2 protein expression was markedly increased while ERK1 protein expression had no significant change in HepG2/ADM cells. Phosphorylation of ERK1 and ERK2 was markedly decreased in both HepG2/ADM and SMMC7721/ADM MDR cells.

**CONCLUSION:** ERK1 and ERK2 activities are down-regulated in P-gp-mediated MDR HCC cells. ERK1 or ERK2 might be a potential drug target for circumventing MDR HCC cells.

Yan F, Wang XM, Pan C, Ma QM. Down-regulation of extracellular signal-regulated kinase 1/2 activity in P-glycoprotein-mediated multidrug resistant hepatocellular carcinoma cells. *World J Gastroenterol* 2009; 15(12): 1443-1451 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1443.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1443>

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the third cause of cancer-related death<sup>[1,2]</sup>. Drugs used in the treatment of HCC are cytotoxic with a high risk of side effects and none of them is specific for HCC<sup>[3]</sup>. Moreover, HCC is a hypervascular solid cancer characterized by a high degree of drug resistance<sup>[4]</sup>. Multidrug resistance (MDR) to chemotherapeutic agents plays a major role in the failure of cancer therapy<sup>[5]</sup>. MDR phenotype, an intrinsic or acquired cross-resistance to a variety of structurally and functionally unrelated drugs, is almost constantly expressed in HCC and represents one of the major problems in cancer eradication by limiting the efficacy of chemotherapy<sup>[6]</sup>. Resistance to therapy can result from decreased drug uptake, increased DNA repair or drug inactivation<sup>[7]</sup>.

Mitogen-activated protein kinase (MAPK) pathway is an attractive target or therapeutic intervention in cancer due to its integral role in the regulation of cancer cell proliferation, invasiveness, and survival. Pharmaceutical agents can inhibit various kinases and GTPases comprising the pathway<sup>[8,9]</sup>. Extracellular signal-regulated kinase (ERK) 1/2 is a member of the MAPK family. ERK1 and ERK2 are isoforms of the "classical" MAPK<sup>[10]</sup>. The activity of ERK1/2 has been implicated in the regulation of embryonic morphogenesis, cell proliferation, tumor transformation, and apoptosis<sup>[11]</sup>. It has been recently found that P-gp expression in the MDR1-transduced human breast cancer cell lines MCF-7/MDR and MDA-MB-231/MDR is positively regulated by the ERK pathway and blockade of the MEK-ERK-RSK pathway can suppress cell surface P-gp expression by promoting its degradation<sup>[12]</sup>. In addition, there are several lines of evidence that modulation of ERK activation may reverse MDR in prostatic, gastric and hematopoietic cancers<sup>[13-16]</sup>. However, there is little evidence that ERK activity is related to MDR of HCC.

The aim of this research was to study the crucial kinases of ERK pathway, including expression and phosphorylation (activity) of ERK1 and ERK2 in MDR HCC cell lines, and to explore whether the relationship between MDR and ERK1/2 kinases involves specific molecular aspects of these cell lines. Once they are well characterized, the ERK pathway might be exploited for overcoming MDR of HCC.

## MATERIALS AND METHODS

### Cell culture

Human HCC cell lines, HepG2 and SMMC7721, were purchased from Institute of Biochemistry and Cell Biology, Shanghai Institutes for Biological Science, Chinese Academy of Sciences. HepG2 was cultured with DMEM (HyClone, Logan, UT, USA) and SMMC7721 was cultured with RPMI-1640 (HyClone, Logan, UT, USA). Both media were supplemented with 10% calf serum (HyClone, Logan, UT, USA) and maintained at 37°C in a humidified atmosphere containing 50 mL/L

CO<sub>2</sub> and 950 mL/L air. Multidrug resistant human HCC cell lines, HepG2/adriamycin (ADM) and SMMC7721/ADM, were developed by our group. To develop the HepG2/ADM and SMMC7721/ADM cells, ADM (Pharm-sh Pharmaceutical Co., Ltd., Shanghai, China) was added respectively to HepG2 and SMMC7721 cells at a stepwise increasing concentration from 0.01 to 0.2 mg/L. Resistant cells were selected by removing the non-resistant dead cells. Multidrug resistance was maintained by culturing the cells with 0.2 mg/L ADM and MDR cells were named HepG2/ADM and SMMC7721/ADM.

### Measurement of cellular sensitivity to anticancer drugs

MTT (Sigma-Aldrich, St. Louis, MO, USA) assay was used to determine drug sensitivity. Sensitivity of cultured HepG2/ADM and SMMC7721/ADM cells to anticancer drugs, including ADM, fluorouracil, cisplatin, cyclophosphamide, mitomycin and vincristine (Pharm-sh Pharmaceutical Co., Ltd., Shanghai, China), was detected, respectively<sup>[17]</sup>. IC<sub>50</sub> value was assessed by probit regression analysis using SPSS11.5 statistical software. Resistance index (RI) was calculated according to the formula: RI = IC<sub>50</sub> for MDR cells / IC<sub>50</sub> for parental cells.

### Flow cytometric analysis of cell cycle distribution

Cultured HepG2/ADM and SMMC7721/ADM cells and their parental cells were collected respectively through trypsinization, washed with ice-cold PBS, centrifuged at 500 × g for 5 min at 4°C, washed twice with ice-cold PBS and fixed in 70% ethanol for 2 h at 4°C. Samples were rehydrated with PBS and the cells were incubated for 30 min at room temperature with a propidium iodide staining solution in PBS containing 0.2 mg/mL propidium iodide, 0.2 mg/mL DNase-free RNase A (Roche, Basel, Switzerland), and 0.1% Triton X-100. Using red propidium-DNA fluorescence, 4000 events were acquired with a Epics<sup>®</sup> XL Beckman Coulter FACS machine (Beckman Coulter Inc., Fullerton, CA, USA) for each sample and the percentage of cells in G0/G1, S and G2/M phases of the cell cycle was calculated using the System II<sup>™</sup> software (Beckman Coulter Inc., Fullerton, CA, USA).

### Flow cytometric analysis of cell p-gp and mrp1 expression level

Cultured MDR and parental cells were collected as above. Then, samples were immunostained with P-glycoprotein antibody (FITC) (Cat.ab66250, Abcam plc, Cambridge, UK) and MRP1 antibody (FITC) (Cat.No.557593, BD Biosciences Pharmingen, San Diego, CA, USA), respectively, according to the proper protocol. The cells were fixed and permeabilized with a BD Cytotfix/Cytoperm<sup>™</sup> solution (Cat.No.554722, BD Biosciences, San Jose, CA, USA) before they were immunostained with MRP1 antibody (FITC). Flow cytometry was carried out with a fluorescent-activated cell scan (FACS) using the System II<sup>™</sup> software. Fluorescence of the cells treated with fluorescent isotype control IgG (Cat.ab18455, Abcam plc) was evaluated in each experiment to measure the level of background fluorescence of negative cells.

Table 1 Determination of IC<sub>50</sub> and resistance index of different anticancer drugs (mean  $\pm$  SD)

	IC <sub>50</sub>		Resistance index	IC <sub>50</sub>		Resistance index
	HepG2	HepG2/ADM		SMMC7721	SMMC7721/ADM	
Adriamycin (mg/L)	0.0063 $\pm$ 0.0022	0.135 $\pm$ 0.053	21.43	0.0139 $\pm$ 0.008	0.266 $\pm$ 0.036	19.14
Fluorouracil ( $\mu$ mol/L)	1.114 $\pm$ 0.271	25.34 $\pm$ 2.38	22.75	0.689 $\pm$ 0.082	48.5 $\pm$ 2.57	70.39
Cyclophosphamide (mg/L)	2.902 $\pm$ 0.369	32.68 $\pm$ 4.962	11.26	2.315 $\pm$ 0.279	60.08 $\pm$ 4.93	25.95
Cisplatin (mg/L)	0.0527 $\pm$ 0.013	1.084 $\pm$ 0.0749	20.57	0.0483 $\pm$ 0.011	1.637 $\pm$ 0.172	33.89
Mitomycin (mg/L)	0.061 $\pm$ 0.017	1.085 $\pm$ 0.246	17.79	0.032 $\pm$ 0.013	0.644 $\pm$ 0.168	20.13
Vincristine (mg/L)	0.0093 $\pm$ 0.0035	0.086 $\pm$ 0.0098	9.25	0.006 $\pm$ 0.004	0.247 $\pm$ 0.023	41.16

Mean fluorescence intensity (MFI) of positively stained cells was determined.

### RNA extraction and quantitative real-time polymerase chain reactions (QRT-PCR)

ERK1 and ERK2 mRNA expression levels were measured by QRT-PCR. Total RNA was extracted using the TRIzol reagent (GIBCO BRL, Life Technologies Inc., Rockville, MD, USA) following the constructions of its manufacturer, and reverse transcribed to cDNA using the Gene Amp RNA PCR kit in a DNA thermal cycler (Bio-Rad). QRT-PCR was performed with SYBR green PCR master mix (Applied Biosystems, Foster City, CA, USA) in an ABI Prism 7700 real time PCR machine (Applied Biosystems).

The synthesized cDNA served as a template in a (25  $\mu$ L) reaction. A non-template control was included in all experiments. Primer sequences are as follows: ERK1 GenBank: NM\_002746 forward, 5'-TCAACAC CACCTGCGACCTT-3', and reverse, 5'-GCGTAGCC ACATACTCCGTCA-3'; ERK2 GenBank: NM\_002745 forward, 5'-GTTCCCAAATGCTGACTCCAA-3', and reverse, 5'-CTCGGGTCGTAATACTGCTCC-3';  $\beta$ -actin GenBank: NM\_001101 forward, 5'-TGACG TGGACATCCGCAAAG-3', and reverse, 5'-CTG-GAAGGTGGACAGCGAGG-3'.

QRT-PCR was performed at 94°C for 4 min, followed by 40 cycles at 94°C for 15 s, at 60°C for 25 s, and at 72°C for 25 s. Oligonucleotides and reagents for PCR assay were purchased from Qiagen GmbH, Hilden, Germany. Data were analyzed with the Sequence detector software (v1.9, Applied Biosystems). The mean Ct value for duplicate measurements was used to detect the expression of target gene with normalization to a housekeeping gene used as an internal control ( $\beta$ -actin) according to the  $2^{-\Delta Ct}$  formula.

### Western blot analysis

Protein was collected from cultured HepG2, SMMC7721, HepG2/ADM and SMMC7721/ADM cells and its concentration was measured (protein assay dye, Bio-Rad). Then, the protein was denatured in a LDS sample buffer for 5 min at 95°C, run on SDS-PAGE (NUPAGE, 4%-12% Bis-Tris, Invitrogen, Carlsbad, CA, USA) and blotted onto PVDF membranes (0.2  $\mu$ m, Invitrogen). Membranes were blocked with 5% dry milk in TBS-T (TBS containing 0.05% Tween 20) for 1 h at room temperature and incubated overnight at 4°C with antibodies against

ERK1, ERK2, or phospho-ERK1/2 (Thr202/Tyr204) (Cell Signaling Technology, Inc., Danvers, MA, USA). After incubation with the respective primary antibodies, the membranes were exposed to species-specific horseradish peroxidase-labeled secondary antibodies at room temperature, and developed using the ECL plus Western blotting reagent (GE Healthcare, Little Chalfont, UK) and Fuji Film LAS-1000 equipment (Fuji Film, Tokyo, Japan). Parallel membranes were incubated with 1:5000 rabbit monoclonal antibodies to GAPDH (Cell Signaling Technology, Inc.) and HRP-coupled rabbit anti-mouse secondary antibody. Primary and secondary antibody solutions were prepared in a PBS solution containing 2% bovine serum albumin and 0.1% Tween-20. After incubation with antibodies, the membranes were washed 3 times for 5 min in PBS containing 0.1% Tween-20. Calculation and statistics were performed using the ImageJ 1.37 software.

### Statistical analysis

Statistical analysis was performed using Student's *t*-test to compare the two groups and ANOVA was used with Dunnett's post-test for multiple comparisons when the three groups or more were compared. *P* < 0.05 was considered statistically significant. The results were expressed as mean  $\pm$  SE. Values were analyzed using the statistical package SPSS for Windows Ver.11.5 (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Determination of MDR

Each step of developing MDR HepG2/ADM and SMMC7721/ADM cells took 7-8 wk. MDR was maintained by culturing the cells with 0.2mg/L ADM. Cytotoxicity assay found that HepG2/ADM and SMMC7721/ADM were resistant not only to ADM but also to multiple anticancer drugs. Among them, fluorouracil (5-FU), cyclophosphamide (CTX), cisplatin (CDDP), mitomycin (MMC), and vincristine (VCR) were tested in our study. Their lethal dose (IC<sub>50</sub>) was significantly higher for HepG2/ADM and SMMC7721/ADM cells than for non-resistant parental cells (Figure 1 and Table 1).

### Cell cycle distribution

Cell cycle phase distribution was detected by flow cytometry to determine whether there is any difference in cell cycle kinetics between MDR HepG2/ADM and SMMC7721/

**Figure 1** Measurement of cellular sensitivity to anticancer drugs and parental cells. Cytotoxicity assay for adriamycin, fluorouracil, cyclophosphamide, tested cisplatin, mitomycin, and vincristine was performed to evaluate the IC<sub>50</sub> for HepG2 and HepG2/ADM cells (A), SMMC7721 and SMMC7721/ADM cells (B). Dose response curves were derived from five independent experiments using MTT assay. The data were shown as mean  $\pm$  SE.

**Table 2** Cell cycle distribution of parental and MDR HCC cells (mean  $\pm$  SD)

Cells ( <i>n</i> = 5)	G0/G1	S	G2/M
hepG2	65.08 $\pm$ 1.61	18.32 $\pm$ 1.37	16.58 $\pm$ 0.65
hepG2/ADM	62.44 $\pm$ 1.77 <sup>a</sup>	12.24 $\pm$ 1.21 <sup>b</sup>	25.36 $\pm$ 2.12 <sup>c</sup>
SMMC7721	71.12 $\pm$ 1.38	17.86 $\pm$ 1.91	11.02 $\pm$ 1.95
SMMC7721/ADM	67.8 $\pm$ 2.15 <sup>a</sup>	23.6 $\pm$ 0.93 <sup>b</sup>	8.62 $\pm$ 2.74 <sup>a</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01, <sup>c</sup>*P* < 0.001 vs control cells.

ADM cells and their parental cells. The percentage of HepG2/ADM and SMMC7721/ADM cells was significantly decreased at the G0/G1 phase and increased at the S phase or G2/M phase (Figure 2 and Table 2).

#### P-gp and MRP1 expression

Protein expression of P-gp and MRP1 in HepG2/ADM, SMMC7721/ADM and their parental cells was evaluated. P-gp expression was over 10-fold higher in HepG2/

**Table 3** P-gp and MRP1 expression in MDR and parental cells (mean  $\pm$  SD)

Cells ( <i>n</i> = 5)	P-gp (%)	MRP1 (%)
HepG2	0.88 $\pm$ 0.05	0.93 $\pm$ 0.15
HepG2/ADM	8.92 $\pm$ 0.22 <sup>a</sup>	0.9 $\pm$ 0.18
SMMC7721	1.74 $\pm$ 0.25	1.21 $\pm$ 0.35
SMMC7721/ADM	7.37 $\pm$ 0.26 <sup>a</sup>	0.79 $\pm$ 0.02

<sup>a</sup>*P* < 0.001 vs parental cells.

ADM cells than in HepG2 cells, and over 4-fold higher in SMMC7721/ADM cells than in SMMC7721 cells. However, the MRP1 expression was not significantly higher in HepG2/ADM and SMMC7721/ADM cells than in parental cells (Figure 3 and Table 3).

#### ERK1 and ERK2 mRNA expression

To examine the role of ERK signaling pathway in the development of MDR, ERK1 and ERK2 mRNA

**Figure 2 Cell cycle distributions in MDR and parental cells.** Cell cycle distributions of HepG2 (A), HepG2/ADM (B), SMMC7721 (C) and SMMC7721/ADM (D) cells were analyzed by flow cytometry as described in Materials and Methods.

**Figure 3 Expression of P-gp and MRP1 in MDR and parental cells.** Histograms showing that P-gp expression was over 10-fold higher in HepG2/ADM cells than in HepG2 cells, and over 4-fold higher in SMMC7721/ADM cells than in SMMC7721 cells, but MRP1 expression had no significant difference (A, D). Corresponding flow histograms for P-gp (B, E) and MRP1 (C, F) are presented. The results are shown as mean  $\pm$  SE ( $n = 5$ ). Statistical analyses comparing MDR cells with parental cells were performed using Student's *t*-test. <sup>b</sup> $P < 0.001$  vs SMMC7721 cells.

expression in parental and MDR cells was assessed, respectively (Figure 4). QRT-PCR analysis demonstrated that ERK1 and ERK2 mRNA expression was apparently higher in HepG2/ADM cells and significantly lower in SMMC7721/ADM cells.

#### Expression and phosphorylation of ERK1 and ERK2

The expression of ERK1, ERK2, p-ERK1 and p-ERK2 in HepG2/ADM, SMMC7721/ADM and their parental cells, was detected by Western blot analysis, respectively. The expression of ERK1 and ERK2 protein was

**Figure 4** ERK1 and ERK2 mRNA expression in MDR and parental cells. ERK1 and ERK2 mRNA levels were measured by QRT-PCR. A: HepG2/ADM and HepG2 cells; B: SMMC7721/ADM and SMMC7721 cells. Results were normalized by  $\beta$ -actin mRNA expression and compared with the levels in parental cells ( $n = 3$ ). The results are shown as mean  $\pm$  SE. Statistical analyses comparing MDR cells with parental cells were performed using Student's *t*-test. <sup>b</sup> $P < 0.01$  vs parental cells (data not shown).

markedly lower in SMMC7721/ADM cells than in their parental cells. However, the expression of ERK2 protein was significantly higher in SMMC7721/ADM cells than in their parental cells while the expression of ERK1 protein had no significant change in HepG2/ADM cells. The phosphorylation of ERK1 and ERK2 was markedly lower in HepG2/ADM and SMMC7721/ADM MDR cells than in their parental cells (Figure 5).

## DISCUSSION

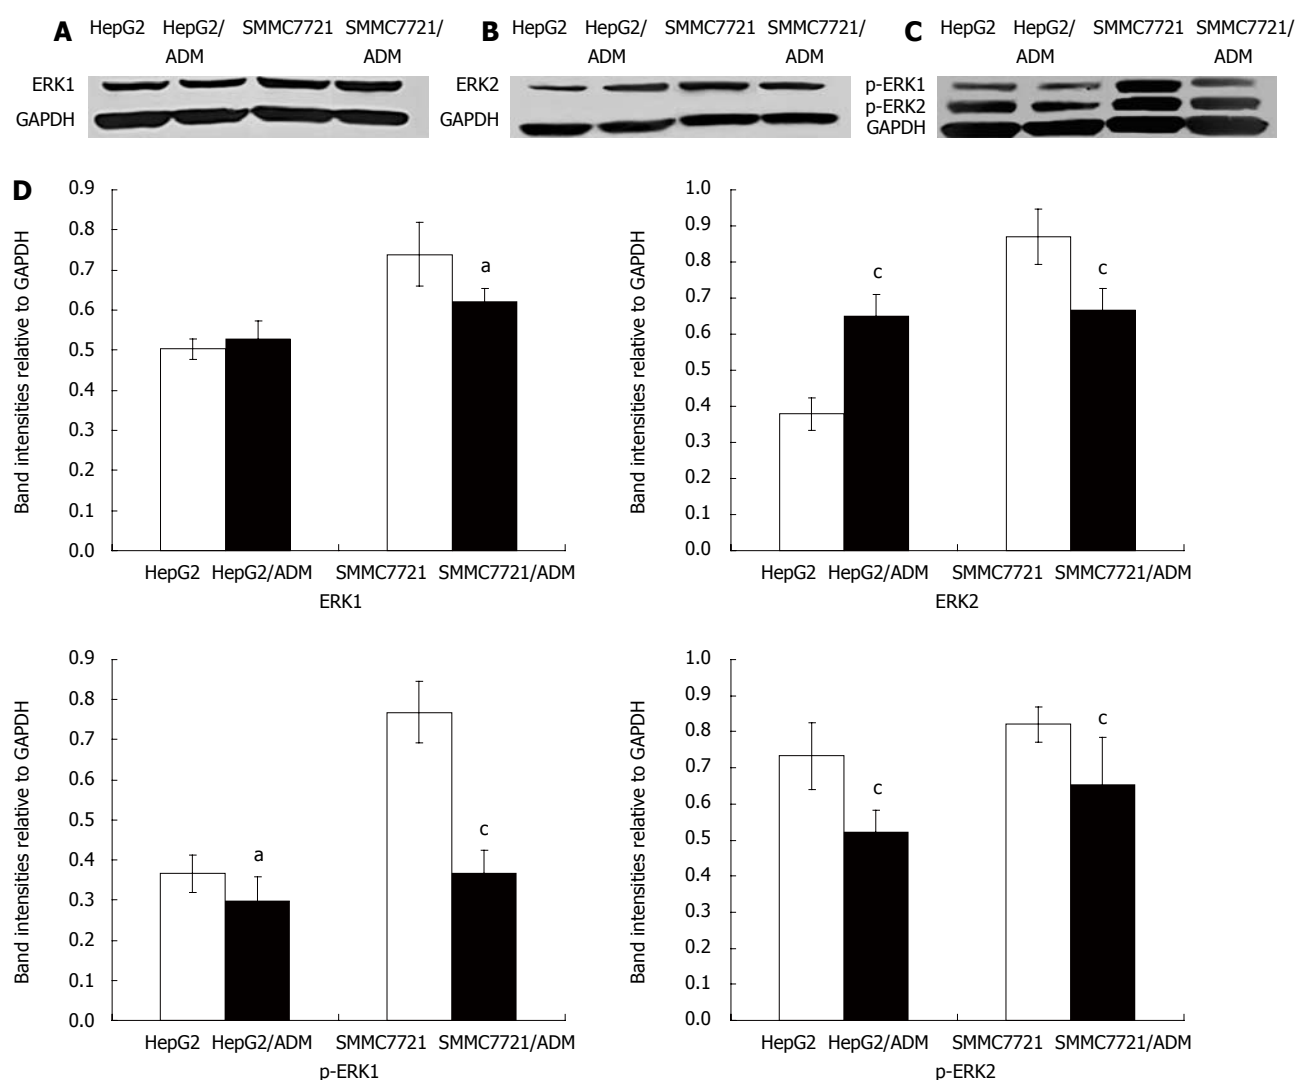

Multidrug resistant cancer cells may develop in patients upon prolonged treatment with anti-cancer drugs. MDR poses a great obstacle to chemotherapy for cancer because a higher dosage of drugs is needed to be administered to patients, which will cause severe adverse effects<sup>[18]</sup>. Most strategies developed to reverse MDR phenotype involve use of resistance modulators, which have the common ability to reverse the phenotype by inhibiting MDR transporter function<sup>[19,20]</sup>. A more efficient strategy to circumvent MDR is to down-regulate the expression of genes coding transporters. However, regulation of MDR-related gene expression is highly complex. For instance, such complexity is embodied in multiple transcription-regulatory elements in the 5' and 3' flanking sequences of the *mdr-1* gene, and numerous protein factors involved in transcription-regulatory processes in a cell type- and stimulus-dependent manner<sup>[21]</sup>. The mechanism underlying the expression of MDR-related genes has not yet been fully understood. Thus, the molecular mechanism and signal-transduction pathways involved in regulation of MDR-related genes should be further studied in order to overcome MDR and improve chemotherapeutic efficacy.

The ERK signaling pathway mediates a number of cellular processes, including cell differentiation, growth, survival, and apoptosis. Several growth factors stimulate a protein kinase cascade that sequentially activates Raf, MEK, and ERK1/2. The role of ERK pathway in the generation of MDR has received more consideration than before, and some specific blocking agents of

the ERK pathway have been found. Recent studies demonstrated that modulation of ERK activation may be a new method to reverse MDR<sup>[15,22]</sup>. However, whether ERK activation is positively or negatively correlated with MDR still remains controversial. Furthermore, the relationship between ERK activity and MDR of HCC is unknown. In this study, we found that ERK activity was down-regulated in MDR HCC Cells.

ADM is a chemotherapeutic agent principally used in treatment of solid tumors, including HCC<sup>[23]</sup>. Although ADM can work through various mechanisms, it is still not immune to the MDR phenotype, and consequently, development of resistance to ADM has been well-documented in a broad range of cell lines<sup>[24-26]</sup>. We established two MDR HCC cell lines, HepG2/ADM and SMMC7721/ADM. In this study, death of MDR cells with a lower drug resistance occurred at about 24-48 h after a higher concentration of ADM was added in the medium, and reached the peak at about 72 h. To recover the proliferation ability, the culture of remained adherent cells took at least 7-8 wk. The whole development of MDR HCC cell lines lasted ten months. The  $IC_{50}$  of anticancer drugs was much higher for HepG2/ADM and SMMC7721/ADM cells than for their parental cells, suggesting that the acquired MDR of HepG2/ADM and SMMC7721/ADM is reliable.

To elucidate the mechanism involved in the development of acquired MDR of HepG2/ADM and SMMC7721/ADM cells, cell cycle distribution and expression of MDR-related proteins (P-gp and MRP1) were analyzed by FCM. The percentage of MDR HepG2/ADM and SMMC7721/ADM cells was significantly decreased in the G0/G1 phase and increased in the S phase or G2/M phase than that of their parental cells, which probably contributes to the lower ability of cells to proliferate. Moreover, this kind of delayed cell cycle can result in cellular escape of cytotoxicity of cell cycle specific agents (e.g. vincristine, fluorouracil, *etc.*) and generate MDR<sup>[27,28]</sup>. P-gp and MRP1 are members of the ATP-binding cassette transporter proteins. Over-expression of ATP-binding cassette transporter proteins

**Figure 5** Expression and phosphorylation of ERK1 and ERK2 in MDR and parental cells. Western blot analysis of the ERK1 (A), ERK2 (B), p-ERK1 and p-ERK2 (C) expression in HepG2/ADM, SMMC7721/ADM as well as in HepG2 and SMMC7721 cells ( $n = 3$ ) was performed. The expression of ERK1 and ERK2 was markedly lower in SMMC7721/ADM cells than in parental cells. However, the ERK2 expression was markedly increased and the ERK1 expression had no significant change in HepG2/ADM cells. The phosphorylation of ERK1 and ERK2 was lower in MDR cells than in parental cells (D). The results are shown as mean  $\pm$  SE. Statistical analyses comparing MDR cells with parental cells were performed using Student's *t*-test. <sup>a</sup> $P < 0.05$ , <sup>c</sup> $P < 0.01$  vs parental cells (data not shown).

represents one of the major mechanisms that contribute to the MDR phenotype. Both P-gp and MRP1 function as a drug efflux pump that actively transports drugs from the inside to the outside of cells and causes a defect in the intracellular accumulation of drugs necessary for cancer cell killing. The results of our study show that P-gp was much higher in MDR HepG2/ADM and SMMC7721/ADM cells than in their parental cells, but the expression of MRP1 was low in both MDR and parental cells, indicating that MDR of HepG2/ADM and SMMC7721/ADM cells mainly attribute to the over-expression of P-gp but not MRP1. This phenomenon can partially be explained by the high expression of P-gp and low expression of MRP1 in liver tissue or HCC cell lines<sup>[29]</sup>.

ERK1 and ERK2, isozymes of ERK, are extensively expressed in cultured cell lines and mammalian tissues<sup>[30]</sup>. To answer the question of whether ERK1 and ERK2 are involved in P-gp-mediated MDR in HCC cells, we detected the expression of ERK1 and ERK2 mRNA

in parental and MDR cells, and the expression and phosphorylation (activity) of ERK1 and ERK2 protein. The results showed that the expression of ERK1 and ERK2 mRNA was increased in HepG2/ADM cells and decreased in SMMC7721/ADM cells. However, ERK1 protein expression had no significant change in HepG2/ADM cells. The phosphorylation of ERK1 and ERK2 was markedly decreased in HepG2/ADM and SMMC7721/ADM MDR cells, suggesting that ERK1 and ERK2 activity is down-regulated in P-gp-mediated MDR HCC cells. However, the decreased activity was not in accordance with mRNA and protein expression in HepG2/ADM cells. The expression of ERK1 and ERK2 protein was diverse, which may contribute to the augments on whether ERK activation is positively or negatively correlated with MDR.

In summary, MDR of HepG2/ADM and SMMC7721/ADM cells mainly attribute to the over-expression of P-gp but not MRP1. ERK1 and ERK2

activity is down-regulated in P-gp-mediated MDR HCC cells, providing new insights into the complicated regulatory mechanism of MDR phenotype. ERK1 and ERK2 might be potential drug targets for circumventing MDR HCC cells. *In vivo* studies are warranted to examine whether ERK1 and ERK2 have a clinical potential in modulating the MDR phenotype during HCC chemotherapy.

## COMMENTS

### Background

The development of multidrug resistance (MDR) to chemotherapeutic agents plays a major role in the failure of cancer therapy, including hepatocellular carcinoma (HCC). Recent studies have shown that modulation of extracellular signal-regulated kinase (ERK) activation may reverse MDR in prostatic, gastric and hematopoietic cancers. However, there is little evidence that ERK activity is related with MDR of HCC cells.

### Research frontiers

Multidrug resistant cancer cells may develop in patients upon prolonged treatment with anti-cancer drugs. Most strategies developed to reverse the MDR phenotype involve use of resistance modulators. A more efficient strategy to circumvent MDR is to down-regulate the expression of genes coding for transporters. Thus, to overcome MDR and improve chemotherapeutic efficacy, the molecular mechanism and signal-transduction pathway involved in the regulation of MDR-related genes should be further studied.

### Innovations and breakthroughs

In this study, the MDR of HepG2/ADM and SMMC7721/ADM cells could attribute to the over-expression of P-gp but not MRP1. ERK1 and ERK2 activity was down-regulated in P-gp-mediated MDR HCC cells, thus providing new insights into the complicated regulatory mechanism of MDR phenotype.

### Applications

ERK1 and ERK2 might be used as potential drugs targets for circumventing HCC MDR.

### Terminology

Multidrug resistance: an intrinsic or acquired cross-resistance to a variety of structurally and functionally unrelated drugs, which is almost constantly expressed in cancer and represents one of the major problems in cancer eradication by limiting the efficacy of chemotherapy, and resistance to therapy can result from decreased drug uptake, increased DNA repair or drug inactivation.

### Peer review

The authors examined the expression and phosphorylation of ERK1/2 in MDR HCC cell lines, and demonstrated that ERK1 and ERK2 activity was down-regulated in P-gp-mediated MDR HCC cells, indicating that ERK1 or ERK2 might be used as a potential drug target for circumventing MDR HCC cells.

### Abstract

**AIM:** To investigate the protective effects of melatonin on carbon tetrachloride (CCl<sub>4</sub>)-induced hepatic fibrosis in experimental rats.

**METHODS:** All rats were randomly divided into normal control group, model control group treated with CCl<sub>4</sub> for 12 wk, CCl<sub>4</sub> + NAC group treated with CCl<sub>4</sub> + NAC (100 mg/kg, i.p.) for 12 wk, CCl<sub>4</sub> + MEL-1 group treated with CCl<sub>4</sub> + melatonin (2.5 mg/kg) for 12 wk, CCl<sub>4</sub> + MEL-2 group treated with CCl<sub>4</sub> + melatonin (5.0 mg/kg) for 12 wk, and CCl<sub>4</sub> + MEL-3 group treated with CCl<sub>4</sub> + melatonin (10 mg/kg). Rats in the treatment groups were injected subcutaneously with sterile CCl<sub>4</sub> (3 mL/kg, body weight) in a ratio of 2:3 with olive oil twice a week. Rats in normal control group received hypodermic injection of olive oil at the same dose and frequency as those in treatment groups. At the end of experiment, rats in each group were anesthetized and sacrificed. Hematoxylin and eosin (HE) staining and Van Gieson staining were used to examine changes in liver pathology. Serum activities of alanine aminotransferase (ALT), aspartate aminotransferase (AST) and protein concentration were

measured with routine laboratory methods using an autoanalyzer. Hydroxyproline (HYP) content in liver and malondialdehyde (MDA) and glutathione peroxidase (GPx) levels in liver homogenates were assayed by spectrophotometry. Serum hyaluronic acid (HA), laminin (LN), and procollagen III N-terminal peptide (PⅢNP) were determined by radioimmunoassay.

**RESULTS:** Pathologic grading showed that the fibrogenesis was much less severe in CCl<sub>4</sub> + MEL3 group than in model control group ( $u = 2.172$ ,  $P < 0.05$ ), indicating that melatonin (10 mg/kg) can significantly ameliorate CCl<sub>4</sub>-induced hepatic fibrotic changes. The serum levels of ALT and AST were markedly lower in CCl<sub>4</sub> + MEL treatment groups (5, 10 mg/kg) than in model control group (ALT:  $286.23 \pm 121.91$  U/L *vs*  $201.15 \pm 101.16$  U/L and  $178.67 \pm 103.14$  U/L,  $P = 0.028$ ,  $P = 0.007$ ; AST:  $431.00 \pm 166.35$  U/L *vs*  $321.23 \pm 162.48$  U/L and  $292.42 \pm 126.23$  U/L,  $P = 0.043$ ,  $P = 0.013$ ). Similarly, the serum laminin (LN) and hyaluronic acid (HA) levels and hydroxyproline (HYP) contents in liver were significantly lower in CCl<sub>4</sub> + MEL-3 group (10 mg/kg) than in model control group (LN:  $45.89 \pm 11.71$   $\mu$ g/L *vs*  $55.26 \pm 12.30$   $\mu$ g/L,  $P = 0.012$ ; HA:  $135.71 \pm 76.03$   $\mu$ g/L *vs*  $201.10 \pm 68.46$   $\mu$ g/L,  $P = 0.020$ ; HYP:  $0.42 \pm 0.08$  mg/g tissue *vs*  $0.51 \pm 0.07$  mg/g tissue,  $P = 0.012$ ). Moreover, treatment with melatonin (5, 10 mg/kg) significantly reduced the MDA content and increased the GPx activity in liver homogenates compared with model control group (MDA:  $7.89 \pm 1.49$  nmol/mg prot *vs*  $6.29 \pm 1.42$  nmol/mg prot and  $6.25 \pm 2.27$  nmol/mg prot, respectively,  $P = 0.015$ ,  $P = 0.015$ ; GPx:  $49.13 \pm 8.72$  U/mg prot *vs*  $57.38 \pm 7.65$  U/mg prot and  $61.39 \pm 13.15$  U/mg prot, respectively,  $P = 0.035$ ,  $P = 0.003$ ).

**CONCLUSION:** Melatonin can ameliorate CCl<sub>4</sub>-induced hepatic fibrosis in rats. The protective effect of melatonin on hepatic fibrosis may be related to its antioxidant activities.

## INTRODUCTION

Hepatic fibrosis, a common pathological process of chronic hepatic disease, can lead to irreversible cirrhosis, and involves multiple cellular and molecular events that ultimately result in accumulation of collagen and extra cellular matrix protein in space of Disse. If treated properly at fibrosis stage, cirrhosis can be prevented<sup>[1]</sup>. However, no effective antifibrosis drugs are available at present. Several lines of evidence suggest that oxidative stress plays an important role in the etiopathogenesis of hepatic fibrosis<sup>[2,3]</sup>.

Melatonin (N-acetyl-5-methoxytryptamine), a secretory product of the pineal gland, is a powerful endogenous antioxidant, regulates circadian rhythms, sleep and immune system activity, behaves as a free radical scavenger<sup>[4]</sup>, eliminates oxygen free radicals and reactive intermediates<sup>[5-9]</sup>. Both *in vitro* and *in vivo* experiments have shown that melatonin can protect cells, tissues, and organs against oxidative damage induced by a variety of free-radical-generating agents and processes, such as safrrole, lipopolysaccharide (LPS), carbon tetrachloride (CCl<sub>4</sub>), ischemia-reperfusion, amyloid-protein, and ionizing radiation<sup>[10-12]</sup>. In addition, melatonin also has an indirect antioxidant effect by enhancing the levels of potential antioxidants such as glutathione peroxidase (GPx), superoxide dismutase (SOD), and glutathione (GSH)<sup>[10-12]</sup>. Recent studies showed that melatonin exerts its cytoprotective effects in various experimental models of acute liver injury and reduces fibroblast proliferation and collagen synthesis<sup>[12,13]</sup>, indicating that melatonin may have therapeutic effects on acute and chronic liver injury, through its antioxidant action.

The aim of our present study was to evaluate the possible antifibrotic effect of melatonin on a hepatic fibrosis model of rats. In addition, the antioxidant and anti-inflammatory properties of melatonin were investigated in rats with liver fibrosis.

## MATERIALS AND METHODS

### Drugs and materials

Crystalline melatonin was purchased from Sigma Chemical Company (St. Louis, MO, USA). The solvent used for melatonin was a mixture of ethanol (1%, v/v) and NaCl (0.9%). N-acetyl-L-cysteine (NAC) was purchased from Shanghai Sinopharm Chemical Reagent

Co. Ltd (Shanghai, China). Commercial kits used for determining malondialdehyde (MDA), glutathione peroxidase (GPx) and hydroxyproline (HYP) were obtained from Jiancheng Institute of Biotechnology (Nanjing, China). Commercial kits for radioimmunoassay of procollagen III N-terminal peptide (P<sub>III</sub>NP), laminin (LN), and hyaluronic acid (HA) were obtained from Beijing North Institute of Biological Technology (Beijing, China). Other commercial chemicals used in experiments were of analytical grade.

### Animal experiments and drug treatment

Male Sprague-Dawley rats, weighing 170-240 g at beginning of the study, purchased from Anli Experimental Animal Limited Company (Anhui, China), were kept at a constant temperature (22°C) in a 12-h light and dark cycle, with free access to food and water. All animals were treated humanely according to the National Guidelines for the Care of Animals in China. Rats were randomly divided into normal control group ( $n = 11$ ), model control group ( $n = 20$ ) treated with CCl<sub>4</sub> for 12 wk, CCl<sub>4</sub> + NAC group ( $n = 20$ ) treated with CCl<sub>4</sub> + NAC (100 mg/kg, i.p.) for 12 wk, CCl<sub>4</sub> + MEL-1 group ( $n = 20$ ) treated with CCl<sub>4</sub> + melatonin (2.5 mg/kg) for 12 wk, CCl<sub>4</sub> + MEL-2 group ( $n = 20$ ) treated with CCl<sub>4</sub> + melatonin (5.0 mg/kg) for 12 wk, and CCl<sub>4</sub> + MEL-3 group ( $n = 20$ ) treated with CCl<sub>4</sub> + melatonin (10 mg/kg) for 12 wk. Rats in treatment groups were injected subcutaneously with sterile CCl<sub>4</sub> (3 mL/kg of body weight) in a ratio of 2:3 with olive oil twice a week. Rats in normal control group received hypodermic injection of olive oil at the same dose and frequency as those in the treatment groups. At the beginning of CCl<sub>4</sub> injection, rats received intraperitoneal melatonin daily whereas rats that did not receive melatonin were given the same volume of vehicle (1% ethanol) at the same time point. After 12 wk, a laparotomy was performed and blood was drawn from the abdominal aorta under 3% pentobarbital sodium (1 mL/kg) anesthesia. The animals were then killed with their livers removed. Blood was collected into tubes and centrifuged. Serum was aspirated and stored at -80°C. Liver tissue was fixed in formalin for routine histological examination, or stored at -80°C until required.

### Histopathological examination

Liver tissue samples, fixed in 40 g/L paraformaldehyde and embedded in paraffin, were cut into 5-μm thick sections, which were stained with hematoxylin and eosin (HE) and Van Gieson (VG) according to the standard procedure. Van Gieson's method was used to detect collagen fibers. Hepatic fibrosis was divided into the following stages as previously described<sup>[14]</sup>: stage 0: no fibrosis; stage 1: expansion of portal tracts without linkage; stage 2: portal expansion with portal to portal linkage; stage 3: expansive portal to portal and focal portal to central linkage; and stage 4: cirrhosis. Two pathologists with no knowledge of liver sources examined the stained sections independently.

### Analysis of liver function

Serum activities of alanine aminotransferase (ALT), aspartate aminotransferase (AST) and protein concentration were measured with routine laboratory methods using an autoanalyzer (Hitachi Automatic Analyzer, Japan).

### Measurement of MDA and GPx levels in liver homogenates

Liver samples were thawed, weighed and homogenized (1:9 w:v) in 0.9% saline. The homogenates were centrifuged at  $1000 \times g$  for 10 min at 4°C and supernatant was taken for assay of MDA and GPx with a commercial kit (Jiancheng Institute of Biotechnology, Nanjing, China) following its manufacturer's instructions. MDA was assayed by measuring the levels of thiobarbituric acid reactive substances (TBARS) at 532 nm and expressed as nmol/mg protein. GPx assay was based on its ability to inhibit oxidation of oxyamine by the xanthine-xanthine oxidase system. Total protein concentration in liver homogenates was determined using the Coomassie blue method with bovine serum albumin as a standard.

### Detection of hydroxyproline content in liver

Total collagen content in fresh liver samples was determined by hydroxyproline assay. Hydroxyproline content was detected with a commercial hydroxyproline detection kit (Jiancheng Institute of Biotechnology, Nanjing, China) following its manufacturer's instructions.

### Measurement of serum HA, LN, and PIII NP levels

Serum HA, LN and PIII NP levels were measured by radioimmunoassay with a commercial kit according to its manufacturer's instructions (Beijing North Institute of Biological Technology, Beijing, China).

### Statistical analysis

Data were analyzed with SPSS software. Quantitative data were presented as mean  $\pm$  SD and analyzed by one way ANOVA analysis. Frequency data (pathologic grading of hepatic fibrosis) were analyzed by Ridit analysis.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Pathological changes

Degeneration, necrosis, infiltration of inflammatory cells, and collagen deposition were found in liver tissues of model control group, CCl<sub>4</sub> + NAC group and 3 melatonin treatment groups (Figure 1C-F). Liver tissue samples from rats in normal control group showed normal lobular architecture with central veins and radiating hepatic cords (Figure 1A and B). Formation of fibrotic septa encompassing regenerated hepatocytes was observed in liver tissue samples from rats in model group (Figure 1D). A large number of inflammatory cells infiltrated intra- and interlobular regions (Figure 1C). Statistical analysis revealed significant differences in pathologic grading between CCl<sub>4</sub> + MEL3 group

**Table 1** Pathologic grading of hepatic fibrosis in different groups

Group	Dose (mg/kg)	n	Pathologic grading of hepatic fibrosis					u value
			0	I	II	III	IV	
Normal	-	11	11	0	0	0	0	5.5681 <sup>b</sup>

	10	12	178.67 $\pm$ 103.14 <sup>bd</sup>	292.42 $\pm$ 126.23 <sup>bc</sup>	0.73 $\pm$ 0.07

ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; A: Albumin; G: Globulin. <sup>b</sup> $P < 0.01$  vs normal control group; <sup>c</sup> $P < 0.05$  vs model control group; <sup>d</sup> $P < 0.01$  vs model control group.

and model control group ( $P < 0.05$ ), indicating that fibrogenesis was much less severe in CCl<sub>4</sub> + MEL3 group than in model control group (Table 1, Figure 1C-F).

### Detection of liver function

The serum ALT and AST levels were significantly higher in experimental and model groups than in normal control group ( $P < 0.01$ ). The ALT and AST levels were significantly higher in model group than in CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups (5, 10 mg/kg) ( $P < 0.05$ ,  $P < 0.01$ ). Melatonin (5, 10 mg/kg) significantly decreased the elevated serum transaminase levels (Table 2), whereas no significant difference in the ratio of A/G was observed between model control group, CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups (Table 2).

### MDA content and GPx activity in liver homogenates

The MDA level was significantly higher while GPx activity was significantly lower in liver homogenates of CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups than in those of normal control group ( $P < 0.01$ ). The MDA level was significantly higher in model control group than in CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups (5, 10 mg/kg) ( $P < 0.05$ ). Melatonin (5, 10 mg/kg) significantly blocked the elevated MDA level. GPx activity was significantly lower in the model control group than in CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups (5, 10 mg/kg) ( $P < 0.05$ ,  $P < 0.01$ , Table 3).

### HYP contents in liver tissue

Hepatic fibrosis was quantified by measuring hepatic

**Figure 1 Pathological changes.** Light microscopy of liver tissue sections showing normal liver lobular architecture with central veins in the normal control group (HE staining,  $\times 200$ ) (A), no collagen deposition in liver of normal control group (VG staining,  $\times 200$ ) (B), degenerated and necrotic liver cells associated with inflammatory cells in model group (HE staining,  $\times 200$ ) (C), formation of fibrotic septa in model group (VG staining,  $\times 200$ ) (D), and pathological change in liver of  $\text{CCl}_4$  + melatonin (10 mg/kg) group was rather milder compared with the model group (HE staining,  $\times 200$ ; VG staining,  $\times 200$ ) (E, F).

**Table 3 MDA content and GPx activity in liver homogenates of different groups (mean  $\pm$  SD)**

Group	Dose (mg/kg)	<i>n</i>	MDA (noml/mg prot)	GPx (U/mg prot)
Normal	-	11	4.3 $\pm$ 1.87	80.68 $\pm$ 10.76
Model	-	13	7.89 $\pm$ 1.49 <sup>b</sup>	49.13 $\pm$ 8.72 <sup>b</sup>
NAC	100	12	6.29 $\pm$ 1.36 <sup>bc</sup>	64.68 $\pm$ 8.22 <sup>bd</sup>
MEL	2.5	11	6.84 $\pm$ 1.10 <sup>b</sup>	53.44 $\pm$ 9.35 <sup>b</sup>
	5	13	6.29 $\pm$ 1.42 <sup>bc</sup>	57.38 $\pm$ 7.65 <sup>bc</sup>
	10	12	6.25 $\pm$ 2.27 <sup>bc</sup>	61.39 $\pm$ 13.15 <sup>bd</sup>

MDA: Malondialdehyde; GPx: Glutathione peroxidase. <sup>b</sup> $P < 0.01$  vs normal control group; <sup>c</sup> $P < 0.05$  vs model control group; <sup>d</sup> $P < 0.01$  vs model control group.

hydroxyproline. The hydroxyproline content was significantly higher in model control,  $\text{CCl}_4$  + NAC and  $\text{CCl}_4$  + MEL groups than in normal control group ( $P < 0.01$ ), and significantly higher in model group than

in  $\text{CCl}_4$  + NAC and  $\text{CCl}_4$  + MEL groups (10 mg/kg) ( $P < 0.05$ ). Treatment with melatonin (10 mg/kg) or NAC reduced the hydroxyproline content in liver homogenates, and therefore prevented hepatic fibrosis induced by  $\text{CCl}_4$  (Figure 2).

#### Measurement of serum HA, LN, and PIII NP levels

The serum LN and HA levels were significantly higher in model control,  $\text{CCl}_4$  + NAC, and  $\text{CCl}_4$  + MEL groups than in normal control group ( $P < 0.05$ ,  $P < 0.01$ ), and significantly decreased after treatment with melatonin (10 mg/kg) ( $P < 0.05$ ). Treatment with NAC significantly reduced the serum HA level ( $P < 0.05$ ). The serum PIII NP level was significantly higher in model control,  $\text{CCl}_4$  + NAC and  $\text{CCl}_4$  + MEL groups than in normal control group ( $P < 0.05$ ). However, no significant difference was observed among the five groups (Table 4).

**Figure 2** Effect of melatonin on hydroxyproline content in liver of rats with fibrosis fibrotic induced by CCl<sub>4</sub>. <sup>a</sup>*P* < 0.05 vs model control group; <sup>b</sup>*P* < 0.01 vs normal control group.

## DISCUSSION

CCl<sub>4</sub> is widely used to induce hepatic fibrosis and cirrhosis in animal models. In this study, hepatic fibrosis was successfully induced by subcutaneous injection of sterile CCl<sub>4</sub> twice weekly for 12 wk. Through this hepatic fibrosis model, the effects of melatonin on hepatic fibrosis induced by CCl<sub>4</sub> in rats were examined.

N-acetylcysteine (NAC), a free radical scavenger, is a glutathione precursor which increases glutathione levels in hepatocytes<sup>[15,16]</sup>. Increased glutathione levels limit the production of reactive oxygen species (ROS) which can cause hepatocellular injury. NAC can also inhibit the proliferation of hepatic stellate cells<sup>[17]</sup>. Therefore, it was used as a positive control in this study.

It is well known that oxidative damage can induce hepatic fibrogenesis. ROS, such as H<sub>2</sub>O<sub>2</sub>, O<sub>2</sub><sup>-</sup>, and ·OH, are implicated in the development and pathological progress of hepatic fibrosis<sup>[18,19]</sup>. Free radicals and biomolecular reaction products promote phagocytic and myofibroblastic activities. Lipid peroxidation accelerates collagen synthesis by stimulating stellate cells<sup>[20]</sup>. It has been shown that melatonin is an effective antioxidant and a free radical scavenger. Due to its small size and high lipophilicity, melatonin can cross biological membranes easily and reach all compartments within the cell<sup>[21]</sup>, thus protecting DNA, proteins, and biological membrane lipids from the deleterious effects of free radicals<sup>[22]</sup>. It has been found that melatonin has a higher antioxidant

efficiency than vitamin E and GSH, which are known as powerful antioxidants<sup>[10]</sup>. The antioxidant properties of melatonin prevent acute liver injury induced by ischemia-reperfusion<sup>[23]</sup>, irradiation<sup>[24]</sup>, bile duct ligation<sup>[25-27]</sup>, and toxins<sup>[18,28,29]</sup>. Several lines of evidence suggest that melatonin plays an important role in regulation of collagen levels and inhibition of collagen accumulation. Ostrowska *et al*<sup>[30]</sup> showed that melatonin is negatively related with urine hydroxyproline levels in fasting rats. Cunnane *et al*<sup>[31]</sup> demonstrated that primary biliary cirrhosis is related with melatonin deficiency in pinealectomized rats. Tahan *et al*<sup>[12]</sup> reported that daily melatonin injection at pharmacological doses is effective against liver damage in a rat liver fibrosis model induced by a 14-d dimethylnitrosamine regimen. In the present study, liver injury was assessed with histological and biochemical parameters. The results suggest that melatonin could decrease the scores of hepatic fibrosis and serum ALT and AST levels in rats with hepatic injury caused by CCl<sub>4</sub>. Melatonin at a dose of 10 mg/kg was as effective as 100 mg/kg NAC in reducing serum ALT and AST levels, indicating that melatonin can protect liver and alleviate the progression of hepatic fibrosis. However, further study is needed on the liver function protective effect of melatonin in cirrhotic patients.

HA and LN are known to be good serum markers of hepatic fibrogenesis<sup>[32-34]</sup>. HYP in liver is an important index reflecting the degree of hepatic fibrosis and hepatic fibrosis can be quantified by measuring hepatic hydroxyproline<sup>[33,35]</sup>. In the present study, treatment with melatonin (10 mg/kg) could significantly reduce HA and LN in serum and HYP in liver. The decreased of hepatic hydroxyproline and serum LN and HA levels indicate that melatonin can inhibit collagen deposition in liver.

Oxidative stress plays an important role in the formation of hepatic fibrosis *via* increasing stellate cell activation and collagen synthesis. MDA is the main product of lipid peroxidation and its concentration is generally presented as the total level of lipid peroxidation products<sup>[36]</sup>. As an end product of lipid peroxidation, MDA can produce ozone, which reacts rapidly with cellular structures, generates hydrogen peroxide and other reactive oxygen species, leading to peroxidation and denaturation of membranes<sup>[37]</sup>. It has been shown that MDA can activate stellate cells that produce collagen. The results of this study suggest that treatment with melatonin (5, 10 mg/kg) could significantly block increased MDA, suggesting that melatonin decreases lipid peroxidation and plays an anti-oxidative role in hepatic fibrosis induced by CCl<sub>4</sub> in rats.

Melatonin is not only a direct antioxidant but also an indirect antioxidant through enhancement of antioxidant enzyme activities in liver<sup>[38]</sup>. It was reported that melatonin can reduce free radical damage by elevating GPx activation<sup>[11,39]</sup>. Montilla *et al*<sup>[25]</sup> reported that acute ligation of the bile duct is accompanied with decreased GSH levels both in plasma and in liver, as well as significantly reduced antioxidant enzyme activities. Treatment with melatonin is associated with a significant recovery of anti-oxidative enzymes such as

GPx<sup>[25]</sup>. Tahan *et al.*<sup>[12]</sup> found that melatonin can restore GPx activity in a rat liver fibrosis model induced by a 14-d dimethylnitrosamine regimen. In this study, the GPx activity was significantly lower in model control group than in CCl<sub>4</sub> + NAC and CCl<sub>4</sub> + MEL groups (5, 10 mg/kg), indicating that melatonin can protect liver against CCl<sub>4</sub>-induced hepatic fibrosis in rats, possibly through its direct and indirect antioxidant effects.

In conclusion, melatonin may have beneficial effects on hepatic fibrosis induced by CCl<sub>4</sub> in rats. The protective effect of melatonin on hepatic fibrosis may be related to its antioxidant activities.

The authors thank Dr. Shu-Jun Xia for his help in preparing this manuscript.

## COMMENTS

### Background

In China, the incidence of liver cirrhosis is still high. Liver cirrhosis results from fibrosis. If treated properly at fibrosis stage, cirrhosis can be prevented. However, no effective antifibrosis drugs are available at present. Several lines of evidences suggest that oxidative stress plays an important role in the etiopathogenesis of hepatic fibrosis. Melatonin can protect cells, tissues, and organs against oxidative damage induced by a variety of free-radical-generating agents and processes. The possible fibrosuppressant effect of melatonin on hepatic fibrosis was evaluated in this study. In addition, the antioxidant and anti-inflammatory properties of melatonin were investigated in rats with fibrosis.

### Research frontiers

Although the exact pathogenesis of hepatic fibrosis is still obscure, the role of free radicals and lipid peroxides in the development of hepatic fibrosis has attracted considerable attention. If treated properly at this stage, cirrhosis can be successfully prevented. However, it remains a problem to prevent hepatic fibrosis or to control its progression. Great efforts have been made to find safe and effective drugs. Recent experiments demonstrate that melatonin may have therapeutic effects on acute and chronic liver injury, possibly through its antioxidant activities.

### Innovations and breakthroughs

Melatonin may have beneficial effects on hepatic fibrosis induced by carbon tetrachloride in rats. The protective effect of melatonin may be related to its antioxidant activities.

### Applications

Melatonin can be used as an antifibrotic drug, protect liver cells against fibrosis and inhibits collagen fiber deposition in liver, thus providing a basis for further studies on its therapeutic effect on hepatic fibrosis.

### Terminology

Melatonin (N-acetyl-5-methoxytryptamine), a secretory product of the pineal gland, is a powerful endogenous antioxidant. It regulates circadian rhythms, sleep and immune system activity, behaves as a free radical scavenger, and eliminates oxygen free radicals and reactive intermediates.

### Peer review

This is a well-designed study describing the protective effect of melatonin on fibrosis induced by carbon tetrachloride. Methods are appropriate and results are consistent with the conclusion. The study is very interesting with a great amount of data, which corroborate the major conclusion.

### Abstract

**AIM:** To evaluate the incidence of contrast-induced nephropathy (CIN) in cirrhotic patients and to identify risk factors for the development of CIN.

**METHODS:** We performed a retrospective review of 216 consecutive patients with cirrhosis who underwent computed tomography (CT) with intravenous contrast at the University of Rochester between the years 2000-2005. We retrospectively examined factors associated with a high risk for CIN, defined as a decrease in creatinine clearance of 25% or greater within one week after receiving contrast.

**RESULTS:** Twenty-five percent of our patients developed CIN, and 74% of these patients had ascites seen on CT. Of the 75% of patients who did not develop CIN, only 46% had ascites. The presence of ascites was a significant risk factor for the development of CIN ( $P = 0.0009$ , OR 3.38, 95% CI 1.55-7.34) in multivariate analysis. Patient age, serum sodium, Model for End-stage Liver Disease score, diuretic use, and the presence of diabetes were not found to be significant risk factors for the development of CIN. Of the patients who developed CIN, 11% developed chronic renal insufficiency, defined as a creatinine clearance less than baseline for 6 wk.

**CONCLUSION:** Our results suggest that in hospitalized

### INTRODUCTION

Renal failure is associated with a high morbidity and mortality in patients with cirrhosis<sup>[1-4]</sup>. Cirrhotic patients may be particularly predisposed to renal failure because of intravascular volume depletion, hyperaldosteronism, and altered renal hemodynamics<sup>[5]</sup>. Furthermore, aggressive use of diuretics, repeated large volume paracenteses, and gastrointestinal bleeding often contribute to renal insufficiency in these patients<sup>[1,2]</sup>.

Contrast-induced nephropathy (CIN) is a common cause of renal failure, and is associated with substantial morbidity and mortality<sup>[6-9]</sup>. Multiple studies in the medical literature have estimated a risk of 2% in low-risk patients, rising to 50% in those with risk factors such as diabetes mellitus (DM), pre-existing renal disease, congestive heart failure, advanced age, anemia, and dehydration<sup>[10-15]</sup>.

Although cirrhosis has been suggested as a risk factor for CIN<sup>[13-17]</sup>, only two studies, to our knowledge, have specifically investigated this issue. A prospective study by Guevara *et al*<sup>[18]</sup> did not find an increased susceptibility to CIN in cirrhotic patients. Although this was a well-conducted study, it was conducted under idealized circumstances. Our goal was to conduct a study that may be more representative of the cirrhotic patients we encounter on a frequent basis<sup>[18]</sup>. The study by Najjar

*et al*<sup>[19]</sup> was a retrospective study which also did not find an increased prevalence of CIN in cirrhotics. However, the authors did not precisely define CIN, making it difficult to interpret the results of the study<sup>[15]</sup>. We believe that cirrhosis is a risk factor for the development of CIN, and we aimed to identify risk factors for the development of CIN. We thus performed a retrospective review of cirrhotics who received iodinated contrast during hospitalization for further analysis.

## MATERIALS AND METHODS

After approval by the University of Rochester's Institutional Review Board, we reviewed the charts of 347 patients with cirrhosis who underwent computed tomography (CT) with intravenous contrast during hospitalization at our institution between the years 2000-2005. Inclusion criteria consisted of the presence of cirrhosis, inpatient hospitalization, and the use of iodinated contrast for CT. Patients with pre-existing sepsis, known congestive heart failure, gastrointestinal bleeding, spontaneous bacterial peritonitis (SBP), and chronic kidney disease (CKD), defined as baseline Cr > 18 mg/L, were excluded from our study. Patients who received peri-contrast intravenous sodium chloride, sodium bicarbonate, N-acetylcysteine, as well as those whose diuretic therapy was held during the day of contrast exposure were also excluded from our study.

Clinical data that were reviewed included the Model for End-stage Liver Disease (MELD) score, use of diuretics, serum sodium, a documented diagnosis of diabetes mellitus (DM) in the medical record, and the presence of ascites seen on CT. The use of potentially nephrotoxic medications, such as angiotensin-converting enzyme inhibitors (ACE inhibitors), angiotensin receptor blockers (ARBs), nonsteroidal anti-inflammatory drugs (NSAIDs), and aspirin was documented. The age and race of each patient were also noted. Statistical analysis was performed by faculty of the Department of Biostatistics at the University of Rochester. Multivariate and univariate analyses were performed using logistic regression, and odds ratios were calculated.

All patients received 150 mL of iodinated contrast dye (iohexol, Omnipaque) intravenously per standard radiology protocol. Post-contrast creatinine was then reviewed and compared to baseline values. Serum creatinine on the day of contrast exposure was used to calculate the pre-contrast creatinine clearance (CrCl). Post-contrast CrCl was determined by the highest recorded creatinine value within one week after contrast exposure. The aim of this study was to evaluate the development of CIN, which we defined as a decrease in CrCl of 25% or greater, temporally associated with the use of contrast. CrCl was estimated using the Cockcroft-Gault equation. Patients who developed CIN were followed for 6 wk to assess the development of chronic renal insufficiency (CRI), defined as a CrCl less than baseline for 6 wk. The need for dialysis during this time period was also documented.

**Table 1** Demographic data of the 216 patients included in the study

Factor	Patients	Percentage
Mean age	53.2	N/A
> 65 YO	34	16
< 65 YO	182	84
Male	128	59
Female	88	41
Caucasian	158	73
African American	37	17
Hispanic	10	4
Asian	3	1
Unknown	8	5

**Table 2** Characteristics of patients who developed CIN (*n* = 53) vs those who did not develop CIN (*n* = 163)

Factor	Percent with CIN	Percent without CIN	P-value
Ascites	74	46	0.0009
MELD > 15	60	48	0.1774
Age > 65	9	18	0.2171
On diuretics	66	57	0.3200
Na ≥ 130	91	88	0.8449

**Table 3** Relationship of ascites to incidence of CIN

Factor	Patients	Percentage
Ascites	114	53
CIN	39	34
No CIN	75	66
No ascites	102	47
CIN	14	14
No CIN	88	86

Ascites was a significant risk factor for the development of CIN (*P* = 0.0009, OR 3.38, CI 1.55-7.34).

## RESULTS

A total of 216 patients met the inclusion criteria. 34 patients were greater than 65 years of age (16%). The mean age was 53.2 years. 158 patients were Caucasian, 37 were African American, 10 were Hispanic, and 3 were Asian (Table 1). The mean MELD score for all patients was 15.3.

A total of 53 (25%) patients developed CIN. Baseline characteristics of these patients included a mean MELD of 17, mean age of 51.9, and mean serum sodium of 134.7 mmol/L. In 36 of these patients (68%), renal insufficiency persisted for at least one week. A total of 39 (74%) of these patients had ascites (Table 2). Although 6 patients (11%) developed CRI, none of those patients required dialysis during our 6 wk review.

A total of 163 patients (75%) did not develop CIN. Their mean MELD score was 14.8, mean age was 53.6, and mean sodium was 135.8 mmol/L. Seventy-five of these patients (46%) had ascites seen on CT (Table 2).

The presence of ascites was a significant risk factor for the development of CIN (*P* = 0.0009, OR 3.38, 95% CI 1.55-7.34) in multivariate analyses (Table 3, Figure 1).

Figure 1 Percentage of patients experiencing CIN in the presence or absence of ascites ( $P = 0.0009$ ) or diabetes ( $P = 0.73$ ).

A total of 33 patients were on ACE inhibitors, ARBs, NSAIDs, or aspirin. Ascites remained a significant risk factor when these patients were excluded from this analysis ( $P = 0.0006$ , OR 3.98, 95% CI 1.83-8.69). Ascites was also a significant risk factor for the development of CRI, as 5/6 patients (83%) who developed CRI had ascites seen on CT scan. Age, serum sodium, and MELD score were not found to be significantly associated with a higher risk of CIN in multivariate analysis. Our analysis also did not show a significant association between the use of diuretics and an increased risk of CIN in patients with or without ascites (Figure 2).

In our study, the presence of DM was not a predisposing factor to CIN (Figure 1). A total of 66 diabetic patients were included in the analysis. The incidence of CIN was 18/66 (27%) in these patients, a nonsignificant difference compared to nondiabetics, where the incidence of CIN was 36/150 (24%). Among the total number of diabetic patients, three had evidence of mild kidney disease prior to the scan, defined as  $\text{Cr} > 15 \text{ mg/L}$ . Only one (33%) of these patients developed CIN.

## DISCUSSION

Intravenous contrast remains an important cause of acute renal failure in patients who receive CT scans. There is little data on whether the presence of cirrhosis serves as an important risk factor for the development of CIN.

We performed a large retrospective review at our institution of hospitalized cirrhotic patients who received intravenous contrast for CT imaging and found that there was a high rate of CIN. In multivariate analysis, the presence of ascites was a significant risk factor for the development of CIN, conferring over three times the risk compared to the absence of ascites. Factors such as MELD score, serum sodium, diuretic use, the presence of DM, and age failed to show a similar association.

The results of this study are dissimilar to those found in a prospective study by Guevara *et al.*<sup>[18]</sup>, who did not find an increased susceptibility to CIN in cirrhotic patients<sup>[18]</sup>. However, this study was limited by a relatively small sample size and diuretic therapy was withheld for

Figure 2 Percentage of patients experiencing CIN in relation to diuretic use and the presence of ascites.

at least 5 days prior to inclusion in the study. Our study included patients on diuretic therapy, and is therefore reflective of a broad range of cirrhotic patients.

A second retrospective study by Najjar *et al.*<sup>[19]</sup> comparing 72 cirrhotic patients receiving intravenous contrast with 72 non-cirrhotic controls, revealed the development of CIN in 2 patients with cirrhosis (2.8%) and in 1 patient in the control group (1.4%), a non-significant difference. The authors of this study concluded that cirrhosis may not be a risk factor for CIN. However, the results of this study should be interpreted with caution because the study does not clearly define CIN<sup>[19]</sup>. Without a precise definition of CIN, it is difficult to interpret the results of this study.

The exact mechanism by which iodinated contrast agents induce renal dysfunction is not entirely understood. The pathophysiology is complex, and a variety of factors act in concert to induce CIN. *In vitro* and animal studies suggest that damage secondary to iodinated contrast to the kidneys is likely mediated by a combination of toxic or obstructive injury to the renal tubules, ischemic injury by reactive oxygen species, and renal medullary hypoxia. The predominant factor is likely to be renal medullary hypoxia, in which adenosine, calcium, and endothelin bring about intrarenal vasoconstriction after contrast exposure<sup>[17,20-25]</sup>. Tubular toxicity is also thought to play a role in CIN through both direct nephrotoxicity and tubular obstruction. The generation of reactive oxygen species can cause toxic, ischemic, and immune-mediated direct nephrotoxicity<sup>[26-28]</sup>. Contrast dye increases urate excretion and leads to the deposition of Tamm-Horsfall proteins within the renal tubules, both of which can cause tubular obstruction<sup>[29-31]</sup>.

Factors such as age, serum sodium, MELD score, and diuretic use were not found to be associated with the development of CIN. It is surprising that there is no statistically significant relationship between diuretic use and CIN in our study. There are a fair number of studies suggesting that peri-contrast hydration can reduce the incidence of CIN<sup>[32-36]</sup>. Furthermore, prophylactic forced diuresis with furosemide has been shown to

augment the risks of CIN<sup>[32]</sup>. However, there are no data, to our knowledge, on the association between maintenance diuretic therapy and CIN. Although an increased frequency of CIN in the setting of diuretic use is biologically plausible, this relationship should be explored further before any conclusions can be made.

In our analysis, the presence of DM did not confer an increased risk of CIN. Although DM is considered to be a risk factor for CIN, the data on whether this relationship is present independent of underlying renal impairment are conflicting<sup>[7,8,37]</sup>. Only three patients with DM in our analysis had evidence of mild kidney disease before receiving contrast, and one of these developed CIN. Because our study was retrospective, we were unable to assess our patients for the presence of microalbuminuria or overt proteinuria. Furthermore, our exclusion criteria of heart failure and CKD may have excluded many diabetic patients with significant vascular disease. Our sample may thus have consisted of a higher proportion of patients with uncomplicated diabetes and therefore at a lower risk of CIN.

In those patients that developed CIN, a large proportion (68%) had CIN that persisted for at least one week. 11% of these patients developed CRI as a possible result of contrast exposure. Although none of these patients required dialysis, even transient elevations in creatinine without progression to dialysis have been associated with prolonged hospital stay, adverse cardiac events, and increased mortality<sup>[6-9]</sup>.

There have been multiple studies performed investigating whether certain prophylactic regimens may reduce the risk of CIN. These have included agents such as N-acetylcysteine, diuretics, dopamine, hemofiltration, as well as hydration with sodium chloride or sodium bicarbonate<sup>[38]</sup>. However, none of these have been performed in cirrhotic patients, and reviews of these trials have given discrepant results. Currently, only the use of low osmolality contrast medium at the lowest dose possible, in conjunction with saline hydration is recommended in a recent review article<sup>[17]</sup>.

The primary limitation of our study is the use of serum creatinine in determining the incidence of CIN. The assessment of renal function is notoriously difficult in patients with cirrhosis, and creatinine is likely a sub-optimal measure of renal function in these patients. Although we assessed CrCl rather than an absolute change in serum creatinine, studies suggest that creatinine-based formulas (e.g. Cockcroft-Gault, Modification of Diet in Renal Disease) can only provide a crude approximation of true glomerular filtration rate (GFR) in cirrhotics<sup>[38-40]</sup>. However, direct measurement of kidney function (e.g. inulin clearance) is impractical in large cohorts, and cystatin C-based equations (e.g. Larsson and Hoek) are also unable to accurately assess GFR in patients with cirrhosis<sup>[41]</sup>. Furthermore, the prognostic impact of serum creatinine in patients with cirrhosis is well-validated<sup>[5,42-45]</sup>, and its predictive value is reflected by its inclusion in the MELD score. Additionally, numerous studies have used either a 25%

rise in serum creatinine or a 25% decrease in estimated GFR to assess the development of CIN<sup>[7-9,11,12,34,38]</sup>. While not ideal, we feel that using a 25% decrease in CrCl is an adequate means of detecting clinically significant CIN.

Another important limitation of our study is that we defined CIN based solely upon the peak CrCl within one week after receiving contrast. Although patients with heart failure, SBP, sepsis, and CKD were excluded from the study, there are other causes of increases in serum creatinine in cirrhotic patients exposed to intravenous contrast (e.g. hepatorenal syndrome, large volume paracenteses). Fluctuations in serum creatinine are common in the inpatient setting, and often no discernable cause is found for these variations<sup>[46]</sup>. It is therefore possible that other factors may have contributed to alterations in CrCl in some of our patients. However, in hospitalized patients with no other apparent cause for a decline in renal function temporally associated with the administration of intravenous contrast, it is difficult to exclude CIN as a major contributing factor for this deterioration.

The retrospective nature of our study creates many limitations on our research, most notably the lack of a control group without intravenous contrast administration. The presence of a control group is particularly important when evaluating the incidence of CIN, as fluctuations in serum creatinine can have a multitude of causes. There are only two published studies, to our knowledge, that specifically compare the incidence of post-contrast renal dysfunction with the incidence of renal dysfunction in a control group of patients who did not receive intravenous contrast. Neither of these studies attributed a significant difference in the risk of renal failure to intravenous contrast, suggesting that the risk of CIN may be exaggerated. However, both of these studies were limited by a lack of randomization and a high threshold for the diagnosis of renal dysfunction (defined as a 50% increase in serum creatinine), and it is possible that differences in methodology may account for their findings<sup>[47,48]</sup>. Nonetheless, future studies assessing the risk of CIN in cirrhotic patients would be strengthened by the inclusion of a parallel control group<sup>[49,50]</sup>.

It is also important to note that although diuretic use did not have an independent association with the development of CIN, there may be an association that our retrospective analysis was not able to elucidate. Patients with ascites are the most likely to receive high doses of diuretic therapy. It is difficult to sub-classify patients on the aggressiveness of their diuretic therapy, and we were thus unable to differentiate between patients on minimal doses of diuretics and those receiving aggressive diuresis. It is possible that high doses of diuretics may be a significant contributing factor to the development of CIN in patients with ascites. In patients with ascites receiving large doses of diuretic therapy, our retrospective study was unable to differentiate whether the development of CIN was from volume depletion from diuretic use or whether ascites was an independent predisposing factor.

In conclusion, our large retrospective study of hospitalized cirrhotic patients revealed a high incidence of CIN, especially in patients with ascites. CIN was associated with a significant percentage of patients progressing to CRI as a likely result of contrast exposure. These results suggest that in hospitalized cirrhotic patients, especially those with ascites, the risk of CIN is substantial. Alternative imaging strategies should be considered, and post-contrast renal function should be meticulously followed. Prospective studies evaluating the risk of contrast-induced nephropathy in cirrhotic patients, with and without the presence of ascites, should be performed for further investigation.

## COMMENTS

### Background

Contrast-Induced Nephropathy (CIN) is associated with substantial morbidity and mortality, especially in patients with cirrhosis. It is therefore important to determine whether cirrhosis is a risk factor for CIN, as well as to investigate which, if any, cirrhotic patients are particularly prone to CIN.

### Research frontiers

The medical implications of CIN are substantial. As a result, there is a significant amount of research taking place on the identification of risk factors for CIN, as well as strategies to prevent its development. However, despite the vast amount of research on CIN, the data on the association between cirrhosis and CIN is scarce.

### Applications

The study results suggest that in hospitalized cirrhotic patients, especially those with ascites, the risk of CIN is substantial.

### Terminology

CIN: A decrease in CrCl of 25% or greater within one week after contrast exposure; Chronic Renal Insufficiency (CRI): a CrCl less than baseline for 6 wk; Chronic Kidney Disease (CKD): baseline Cr > 18 mg/L; Mild Kidney Disease: baseline Cr > 15 mg/L.

### Peer review

Lodhia *et al* report the findings of a retrospective study that measured the risk of CIN in patients with cirrhosis. They found that the incidence of CIN was increased and that ascites was an independent risk factor for CIN. This is a very interesting and well written study.

### Abstract

**AIM:** To study the association between Interleukin-1 (IL-1) and tumor necrosis factor (TNF)- $\alpha$  polymorphisms, infection by *Helicobacter pylori* (*H. pylori*) and the development of gastrointestinal diseases.

**METHODS:** Genomic DNA was extracted from the peripheral blood of 177 patients with various gastrointestinal diseases and from 100 healthy volunteers. The polymorphisms in IL-1 $\beta$  and TNF- $\alpha$  genes were analyzed using the polymerase chain reaction-restriction fragment length polymorphism method (PCR-

RFLP) and those from IL-1RN with PCR. The presence of infection due to *H. pylori* and the presence of the CagA toxin were detected by serology. The histopathological parameters in the gastric biopsies of the patients were according to the Sydney classification.

**RESULTS:** A comparison of the frequencies of the different polymorphisms studied among the patients and the control group demonstrated that the allele IL-1RN\*2 was more frequent among patients with gastric ulcers and adenocarcinoma. Carriers of the allele IL-1RN\*2 and those with reactive serology for anti-CagA IgG had a greater risk of developing peptic ulcer and gastric adenocarcinoma, as well as a higher degree of inflammation and neutrophilic activity in the gastric mucosa.

**CONCLUSION:** Our results indicate a positive association between IL-1RN gene polymorphism and infection by positive *H. pylori* CagA strains and the development of gastric ulcers and adenocarcinoma.

### INTRODUCTION

*Helicobacter pylori* (*H. pylori*) infection is the major cause of chronic superficial gastritis in humans, and is a hypochloridria etiological factor in the pathogenesis of peptic ulcer disease (PUD) and some forms of stomach

cancer<sup>[1]</sup>. However, most people harboring *H pylori* are asymptomatic, and only a few patients infected with this bacterium develop peptic ulcer or stomach cancer<sup>[2]</sup>. The variability of clinical manifestations is associated with various factors, such as environmental, genetic susceptibility of the host and bacterial virulence<sup>[1,2]</sup>.

One noteworthy factor for bacterial virulence is the CagA toxin, codified by the *cagA* gene, a marker for the Cag-PAI pathogenicity island<sup>[3]</sup>. Infection by *H pylori* cagA-positive strains cause an intense inflammatory process, with dense neutrophilic infiltrate in the gastric mucosa<sup>[2,3]</sup>. However, bacterial virulence factors alone are not sufficient for determining clinical evolution of the infection. While virulent strains are frequent in both patients with peptic ulcers and those with gastric carcinoma<sup>[2,3]</sup>, other factors in the host, mainly those that regulate immunological and inflammatory response may also contribute to a progression towards neoplasia<sup>[4]</sup>.

Genetic polymorphisms, particularly those that occur in the region promoting genes that codify inflammatory cytokines, have been associated with an increase in synthesis of those interleukins and have emerged as a hypochloridria determining factor for cancer susceptibility<sup>[4,5]</sup>.

Interleukin 1 beta (IL-1 $\beta$ ) is a hypochloridria initiator and amplifier of the immune response, and is also a potent inhibitor of stomach acid secretion<sup>[5,6]</sup>. The antagonist of the IL-1 (IL-1RN) receptor is an anti-inflammatory cytokine that competes for the IL-1 receptors, modulating the effect of IL-1 $\beta$ <sup>[7]</sup>. Studies carried out in Caucasian and Asian populations have demonstrated that polymorphisms in genes IL-1 $\beta$  and IL-1RN are associated with an increased risk of hypochloridria and gastric carcinoma<sup>[7-9]</sup>. Another important cytokine is TNF- $\alpha$ , the biallelic polymorphism in position -308 of the region promoting the gene codifying that cytokine, which has been associated with the development of gastric carcinoma in studies carried out in Caucasians<sup>[10,11]</sup>.

The objective of this study was to determine the frequency of polymorphisms in genes IL-1 $\beta$ , IL-1RN and TNF- $\alpha$  in patients from the state of Pará, in the northern region of Brazil, with various gastrointestinal diseases and in a control group. The relationship of these polymorphisms to infection by virulent strains of *H pylori* (CagA+) and to the histopathological characteristics of gastric tissue were also determined.

## MATERIALS AND METHODS

### Patient and control samples

Peripheral blood and gastric fragment samples were collected from 177 consecutive patients from the state of Pará-Brazil who had various gastrointestinal disturbances. Gastric fragment samples were obtained by the endoscopy service of the João de Barros Barreto University Hospital. For the control samples, peripheral blood was collected from 100 patients who were without

clinical or metabolic diseases and who were asymptomatic for gastrointestinal disturbances, and were thus not submitted to endoscopic examinations.

All patients and controls were enrolled in the study between September 2003 and September 2004 and were from the same socioeconomic level, and had similar cultural habits. All were natives of Pará state with the same ethnic background, approximately 50% Portuguese, 40% Amerindian and 10% African<sup>[12]</sup>. The study was approved by the Ethics Committee at João de Barros Barreto University Hospital.

### Detection of *H pylori* infection

In both patients and controls, the presence of the specific *H pylori* and CagA IgG antibodies in serum samples was determined. To detect *H pylori* antibodies the commercial HIK anti-*H pylori* EIA kit was used (Monobind, USA), and the Helicobacter P-120 EIA commercial kit (VIVA Diagnostica, Germany) was used to detect anti-CagA antibodies. Kits were used according to the manufacturers' technical descriptions.

### IL-1 $\beta$ , IL-1RN and TNF- $\alpha$ genotyping

Genomic DNA was extracted from total blood using a leukocyte lysis solution (100 mmol/L Tris-HCl, 20 mmol/L EDTA, 200 mmol/L NaCl, 1% dodecyl-sodium sulfate, 0.2%  $\beta$  mercaptoethanol) and was purified using the phenol-chloroform method<sup>[13]</sup>.

Polymorphisms of the IL-1 $\beta$  (-31, -511) and TNF- $\alpha$  (-308) genes were characterized using the polymerase chain reaction-restriction fragment length polymorphism method (PCR-RFLP). The volume for the PCR was 25  $\mu$ L, containing 0.5 mmol/L of each primer, 1 X PCR buffer, 1.5 mmol/L of MgCl<sub>2</sub>, 0.2 mmol/L of each nitrogenated base, 1.25 U of *Taq* DNA polymerase, 50 ng of DNA and sterile water.

To determine the polymorphism of the IL-1 $\beta$  gene in position -511, the PCR primers and conditions described by Wilkinson *et al*<sup>[14]</sup> were used. The PCR products were digested with *Ava*I overnight at 37°C and separated by electrophoresis in 2% agarose gel stained with ethidium bromide. Those presenting two bands were called CC (114 and 190 bp), those with three bands, CT (114, 190 and 304 bp) and those with a single band, TT (304 bp).

Polymorphism of the IL-1 $\beta$  gene in the -31 position was investigated using the primers described by El-Omar *et al*<sup>[7]</sup>. The conditions of the PCR were as follows: initial denaturation at 95°C for 2 min followed by 35 cycles of denaturation at 95°C for 1 min, annealing and extension for 1 min, and final extension at 72°C for 10 min. Annealing temperatures were set at 58°C for primers. Negative and positive controls were used in all reactions. To discriminate alleles, the PCR products were digested with *Alu*I overnight at 37°C and then separated by electrophoresis in 2% agarose gel stained with ethidium bromide. Those presenting a single band (235 bp) were called CC; those with three bands (98, 137 and 235 bp)

were called CT and TT was used for those with two bands (98 and 137 bp).

For genotyping polymorphism -308 in the TNF- $\alpha$  gene, the PCR primers and conditions as described by Wilson *et al.*<sup>[15]</sup> were used. The PCR products were digested with *Nco*I overnight at 37°C and separated by electrophoresis in 2% agarose gel stained with ethidium bromide.

The VNTR polymorphism at intron 2 of the IL-1RN gene was determined using the primers and conditions described by El-Omar *et al.*<sup>[7]</sup>. The PCR products were separated by electrophoresis in 2% agarose gel stained with ethidium bromide. They were named allele 1 = 442 bp (4 repeats), allele 2 = 270 bp (2 repeats), allele 3 = 528 bp (5 repeats), allele 4 = 356 bp (3 repeats), allele 5 = 614 bp (6 repeats).

### Histological evaluation

Biopsy specimens from the lesion and the adjacent area in each patient were obtained. The specimens were fixed in 10% buffered formalin solution, embedded in paraffin, cut into sequential 0.4- $\mu$ m sections, and stained with hematoxylin and eosin (HE). The histopathological parameters were graded (0-3) using the criteria described in the updated Sydney classification system<sup>[16]</sup> for analysis of chronic inflammation, polymorphonuclear activity, and intestinal metaplasia.

### Statistical analysis

Hardy-Weinberg equilibrium and heterogeneity among groups were tested using the Guo and Thompson<sup>[17]</sup> exact test. Maximum-likelihood haplotype frequencies were computed using an Expectation-Maximization (EM) algorithm<sup>[18,19]</sup>. Linkage disequilibrium was tested using a likelihood-ratio test<sup>[20]</sup>. All the aforementioned statistical procedures were carried out using Arlequin software<sup>[21]</sup>.

To compare the variables of sex, age, CagA status, *H. pylori* and genotype frequencies between patients and controls, the G test was utilized. The risks of carriers with different alleles developing gastric ulcers and adenogastric carcinoma, as well as having alterations in the gastric mucosa were calculated using the Odds ratio. The data were analyzed with BioEstat version 4.0 software<sup>[22]</sup>. Differences were considered statistically significant if *P* values were less than 0.05.

## RESULTS

### Clinical and demographic characteristics of patients and controls

One hundred and seventy-seven patients with various gastrointestinal pathologies were investigated; of these 80 (45%) had gastritis, 33 (19%) duodenal ulcer, 34 (19%) gastric ulcer and 30 (17%) had intestinal-type adenogastric carcinoma.

The epidemiological data of the two groups studied are described in Table 1. The patients had an average age of 45 years with ages ranging from 18 to 90 years. Subjects in the control group had an average age of

36 years, with ages ranging from 18 to 81 years. The patients with adenogastric carcinoma were older than those in the control group (Table 1).

The presence of IgG antibodies-*H. pylori* and CagA specific was greater in patients with gastrointestinal diseases than in the control group (Table 1). A comparison of the presence of anti-CagA antibodies IgG in patients with various gastrointestinal diseases demonstrated that patients with gastric ulcer (*G* = 6.330, *P* = 0.011), duodenal ulcer (*G* = 8.076, *P* = 0.004) and adenogastric carcinoma (*G* = 7.702, *P* = 0.005) had greater seroprevalence of this antibody than patients with gastritis. However, when we compared the frequency observed in patients with gastric ulcer with that in patients with duodenal ulcer (*G* = 0.007, *P* = 0.932) and with stomach cancer (*G* = 0.013, *P* = 0.908) no differences were observed. A similar observation was made when we compared patients with duodenal ulcer and those with cancer (*G* = 0.506, *P* = 0.476).

### IL-1 $\beta$ , IL-1RN and TNF- $\alpha$ polymorphisms

The polymorphisms studied were in the Hardy-Weinberg equilibrium for both the control group (IL-1 $\beta$ -31 *P* = 0.811; IL-1 $\beta$ -511 *P* = 0.902; IL-1RN *P* = 0.361; TNF- $\alpha$ -308 *P* = 0.363) and for patients with gastrointestinal diseases (IL-1 $\beta$ -31 *P* = 0.321; IL-1 $\beta$ -511 *P* = 0.791; IL-1RN *P* = 0.691; TNF- $\alpha$ -308 *P* = 0.552). An imbalance in linkage among alleles IL-1 $\beta$ -511T and IL-1 $\beta$ -31C (*P* > 10<sup>-5</sup>) was observed in both groups studied.

A comparison of the genotype frequencies of polymorphisms in genes IL-1 $\beta$  analyzed in this study with those from other studies carried out in different countries, demonstrated that the frequency of the alleles for polymorphisms IL-1 $\beta$ -31, IL-1 $\beta$ -511 in our population did not differ statistically from that described for Caucasians<sup>[7]</sup> and Asiatic populations<sup>[23]</sup>, and was

G Test: Our study *versus* other papers. <sup>1</sup>Queiroz *et al*<sup>[25]</sup> 2004; <sup>2</sup>El-Omar *et al*<sup>[7]</sup> 2000; <sup>3</sup>El-Omar *et al*<sup>[24]</sup> 2003; <sup>4</sup>Zeng *et al*<sup>[23]</sup> 2003; <sup>5</sup>Yea *et al*<sup>[11]</sup> 2001. NS: Not significant.

in an intermediate position compared to that found in those populations. In contrast, the polymorphisms of the IL-1RN genes differed from those described in Asiatic populations<sup>[11]</sup> and gene TNF- $\alpha$ -308 differed from descriptions in Caucasian populations<sup>[24]</sup> (Table 2). When we compared our data with those obtained in Minas Gerais<sup>[25]</sup>, we observed a difference in the frequency of the IL-1 $\beta$ -31 polymorphism, with the C allele being more frequent in our population than in the Minas Gerais population (Table 2).

In analyzing the distribution of the different genotypes among the patients and the control group we observed that the polymorphisms in genes IL-1 $\beta$ -31, IL-1 $\beta$ -511, TNF- $\alpha$ -308 did not differ. However, in relation to gene IL-1RN, we obtained a greater frequency of allele 2 carriers (IL-1RN\*2) among patients with adenogastric carcinoma and gastric ulcer than in the control group (Table 3).

A combined risk analysis of the different polymorphisms studied demonstrated that there was no synergism between those polymorphisms and the development of gastric ulcers and adenocarcinoma. Individuals carrying only a polymorphism in gene IL-1RN\*2 (OR = 3, *P* = 0.86) had a greater risk than individuals carrying polymorphisms in genes IL-31\*C and IL-1RN\*2 (OR = 1.2, *P* = 0.51) and the risk was similar to that for carriers of all the polymorphisms studied (OR = 3, *P* = 0.71).

In the association between the IL1-RN polymorphism and the presence of specific CagA antibodies, we found that carriers of allele IL-1RN\*2 who were reactive for anti-CagA IgG had a greater risk of developing gastric

ulcers and adenocarcinoma. This demonstrated an interaction between the presence of a virulent strain and allele IL-RN\*2 in the development of these diseases (Table 4).

The relationship between IL-1RN genotypes and anti-CagA antibodies with histopathological data demonstrated that carriers of allele IL-1RN\*2, who were seroreactive for CagA had high levels of inflammation and neutrophilic activity, with a heightened risk of developing intestinal metaplasia in the gastric mucosa (Table 5).

## DISCUSSION

The state of Pará has a high prevalence and incidence of gastrointestinal diseases, principally adenogastric carcinoma. In addition, an increased prevalence of *H pylori* infection has been observed among patients with gastrointestinal diseases<sup>[26,27]</sup>, with a predominance of virulent strains (*vacA*-s1b/m1/*cagA*-positive) that are associated with the development of both peptic ulcers and adenocarcinoma<sup>[28]</sup>.

The patients with adenogastric carcinoma were older than those in the control group. These patients had been developing progressive gastric cancer lesions for a long time<sup>[29]</sup>.

Some studies have demonstrated that polymorphisms in genes IL-1 $\beta$ , IL-1RN and TNF- $\alpha$ , together with *H pylori* infection are associated with an increased risk of developing stomach cancer<sup>[7,10,11]</sup>, therefore, to better understand the factors related to the high prevalence of stomach cancer in our region we analyzed the frequency of the genotypes of polymorphisms in genes IL-1 $\beta$ ,

IL-1RN and TNF- $\alpha$  and the presence of infection by CagA+ strains in patients with various gastrointestinal diseases and in a control group.

In this study, infection by virulent strains (CagA+) was greater in patients with peptic ulcers and adenocarcinoma than in patients with gastritis or in subjects in the control group. Similar results were found in a previous study carried out in Belém and other Brazilian states, where the presence of *H. pylori* CagA+ strains was associated with the development of peptic ulcers and adenocarcinoma<sup>[28,29]</sup>.

The frequency of polymorphisms in genes IL-1 $\beta$ -31 and IL-1 $\beta$ -511 in our study was similar to that described in Caucasian<sup>[7,24]</sup> and Asiatic populations<sup>[23,30]</sup>, whereas the frequency of polymorphisms in genes IL-1RN and TNF- $\alpha$ -308 was significantly different from that reported in Asiatic<sup>[23]</sup> and Caucasian<sup>[7,24]</sup> populations, respectively. The genetic composition of the Brazilian population is made up of a genetic mix of various ethnic groups, including Portuguese, Africans and Amerindians<sup>[12]</sup>. The differences and similarities between the allelic frequencies of the polymorphisms studied in our population with those of other ethnic groups are products of the genetic mix that has occurred in Brazil.

In comparing the frequencies of the polymorphisms studied in our population with those from another Brazilian study carried out in Belo Horizonte, Minas Gerais, located in the central-western region of the country, we observed differences in relation to IL-1 $\beta$ -31 polymorphism. In Brazil, several states show differences in ethnic background, and the populations in the Amazon region are the ones which have an important indigenous genetic component<sup>[12]</sup>, greater than that described for the Minas Gerais population<sup>[31]</sup>,

which may be reflected in the gene frequency of those polymorphisms.

An analysis of the genotypes of the polymorphisms in the patients and the control group demonstrated that IL-1RN\*2 carriers were more frequent among patients with gastric ulcers and adenocarcinoma. The IL-1Ra protein (codified by the IL-1RN gene) acts competitively to inhibit action by IL-1 $\beta$ <sup>[7]</sup>. Carriers of IL-1RN\*2 have higher levels of IL-1 $\beta$  in the gastric mucosa than those with IL-1RN1/1<sup>[32]</sup>, and thus have a more severe and prolonged immune response, which may lead to hypochloridria due to destruction of the gastric glands and to action by IL-1 $\beta$  that inhibits synthesis of chloridic acid by the parietal cells<sup>[6,7]</sup>. El-Omar *et al.*<sup>[7]</sup> have described an association between IL-1RN\*2 and hypochloridria, and both gastric ulcer and stomach cancer reduce the synthesis of chloridic acid. Other studies have also described the association between the IL-1RN\*2 polymorphisms and stomach cancer<sup>[23,24,33]</sup>. In Brazil, Rocha *et al.*<sup>[34]</sup> obtained similar results in relation to the association of allele IL-RN\*2 and an increased risk of developing stomach cancer, as well as the absence of an association between the IL-1 $\beta$ -31, TNF- $\alpha$ -308 polymorphisms and the risk of developing stomach cancer.

A combined analysis of the different polymorphisms demonstrated that there was no association between these polymorphisms and an increased risk of developing gastric ulcer or adenocarcinoma. In addition, we found an interaction between the presence of allele IL-RN\*2 and infection by CagA+ strains. This finding is important for our region, which has a high incidence of stomach cancer, high prevalence of infection by CagA+

strains and a high frequency of the IL-1RN\*2 allele. Reinforcing these data, our results have demonstrated that carriers of allele IL-1RN\*2 infected by CagA+ strains had a greater risk of developing an intense inflammatory process in the gastric mucosa, which confirms a synergistic action between the polymorphism of gene IL-1RN and another type of infecting strain. Other studies have also observed that both infection by virulent strains and gene IL-1RN polymorphism are important risk factors for gastric carcinogenesis<sup>[23,29,33]</sup>. In conclusion, our results suggest that bacterial virulence and genetic factors in the host act synergistically in the development of gastric ulcers and adenocarcinoma.

## COMMENTS

### Background

*Helicobacter pylori* (*H. pylori*) infection is associated with a broad spectrum of gastrointestinal disorders. However, most people harboring *H. pylori* are asymptomatic, and only a few patients infected with this bacterium develop peptic ulcer or stomach cancer. The variability of clinical manifestations is associated with various factors, such as environmental, genetic susceptibility of the host and bacterial virulence.

### Research frontiers

This study indicated a possible association between IL-1RN gene polymorphism and infection by positive *H. pylori* CagA strains and the development of gastric ulcers and adenocarcinoma.

### Innovations and breakthroughs

This study determined the frequency of polymorphisms in genes IL-1 $\beta$ , IL-1RN and TNF- $\alpha$  in patients with various gastrointestinal diseases from the state of Pará, in the Brazilian Amazon, and in a control group. The relationship of these polymorphisms to infection by virulent strains of *H. pylori* and to the histopathological characteristics of the gastric tissue were determined.

### Applications

This study may represent a future strategy for distinguishing patients with a risk of developing gastrointestinal diseases, such as gastric cancer.

### Terminology

The CagA toxin is a factor for bacterial virulence. The antagonist of the IL-1 (IL-1RN) receptor is an anti-inflammatory cytokine.

### Peer review

In this study, confirmatory new data on gene polymorphism in a Brazilian population and message is clearly shown.

rare in our experience, and are represented principally by carcinoid tumours and adenomas. Carcinoid tumours occurred in younger patients but were slightly more common in men than women. Tumours were not suspected clinically and were diagnosed incidentally in specimens submitted for acute appendicitis supporting the need for histological evaluation in all resection specimens.

## Abstract

**AIM:** To determine the prevalence, histologic types and clinical features of primary epithelial tumours of the vermiform appendix in a predominantly black population.

**METHODS:** All cases of primary tumours of the appendix identified by review of the histopathology records at the University of the West Indies between January 1987 and June 2007 were selected. Relevant pathologic and clinical data were extracted with supplementation from patient charts where available. Non-epithelial tumours were excluded. The total number of appendectomy specimens over the period was also ascertained.

**RESULTS:** Forty-two primary epithelial tumours were identified out of 6 824 appendectomies yielding a prevalence rate of approximately 0.62%. Well-differentiated neuroendocrine cell tumours (carcinoids, 47.6%) and benign non-endocrine cell tumours (adenomas, 45.2%) were most common with nearly equal frequency. The median age was 43 years, with no sex predilection. Carcinoid tumours occurred in younger patients (mean age 32 years), with a male-to-female ratio of 1.2:1. A clinical diagnosis of acute appendicitis was the most common reason for appendectomy (57.1%) and was histologically confirmed in 75% (18 of 24) of cases. In total, 16.7% of cases were diagnosed after incidental appendectomy.

**CONCLUSION:** Appendiceal epithelial tumours are

## INTRODUCTION

Primary appendiceal tumours are uncommon. They are often diagnosed incidentally after histopathological examination of the vermiform appendix submitted in the course of the management of another clinical diagnosis. This paper reviews the primary appendiceal tumours diagnosed at the University Hospital of the West Indies during the period from January 1987 to June 2007, and to our knowledge represents the first such analysis in a predominantly black population.

## MATERIALS AND METHODS

The surgical pathology records of the Department of Pathology at the University of the West Indies were retrospectively reviewed over the time period January 1987-June 2007 and all cases of primary neoplasms of the appendix were selected. Non-epithelial tumours were excluded from the study population because of diagnostic controversy in the absence of immunohistochemical

Table 1 Demographic data and histologic types

Tumour type	Age range (yr)	Mean age (yr)	Median age (yr)
Carcinoid	18-70	32 ± 20.3	35.8
Adenoma	29-87	59 ± 15.2	58.6
Adenocarcinoma	36-74	55 ± 19.0	55

evaluation. The parameters examined included patient age, sex, the clinical history, the surgical procedure, the gross description of the specimen submitted and the histopathological diagnosis. Patient charts were retrieved where possible, for additional clinical information. The total number of appendectomies over the time period was also ascertained.

## RESULTS

In the period under study, 6824 appendices were submitted for pathologic evaluation. Forty-two primary epithelial tumours of the appendix were identified, yielding a prevalence rate of approximately 0.62%.

The overall age range of patients was 18-87 years with a mean age of  $45.9 \pm 19.3$  years and a median age of 43 years. The male-to-female ratio for all tumours was 1:1. Table 1 illustrates the demographic data with respect to each tumour type.

Of the 42 epithelial tumours identified, 20 (47.6%) were carcinoids, including 1 insular and 3 goblet cell carcinoids. Of the 19 (45.2%) adenomas, we identified 15 villous adenomas, the majority of which (11, 26.2%) were morphologically mucinous cystadenomas, as well as 1 tubular and 3 tubulovillous adenomas. All 3 cases of adenocarcinoma were of the mucinous type. Interestingly no cases of serrated adenomas were found in the records.

Only in 3 cases of carcinoid and 1 case of mucinous cystadenocarcinoma was the lesion identified grossly. Measurements were recorded for 2 out of 3 cases of carcinoid measuring 1.3 and 1 cm in maximum dimension.

In 26 of the cases the clinical diagnosis was acute appendicitis, appendiceal abscess in 3, appendix mass, caecal carcinoma, primary peritonitis and an appendiceal tumour in 1 case each. In a further 7 cases, the vermiform appendix was removed incidentally. No clinical diagnosis was submitted in 2 cases.

Of the 42 cases, only 7 patient charts were retrievable; review of the clinical notes revealed aggressive behaviour in one case of carcinoid tumour (goblet cell variant) with hepatic metastases, in a 50-year-old female, who presented with perforated appendicitis. The tumour was not identified grossly in this case.

In 4 of 42 cases there were synchronous colonic neoplasms giving a prevalence rate of 9.5%. Two of these 4, were cases of solitary synchronous caecal carcinoma accompanying a mucinous cystadenoma of the appendix in 1 case and an adenocarcinoma of the appendix in the other. In the other 2 cases, there was a single case of a caecal carcinoma and 2 tubulovillous and 1 villous colonic adenomas coexistent with an appendiceal tubulovillous adenoma in a right hemicolectomy specimen. The other case was that of a caecal carcinoma and 2 tubulovillous colonic adenomas coexistent with a mucinous cys-

tenoma of the appendix in a right hemicolectomy specimen. The carcinoma was diagnosed pre-operatively in 3 of the cases with no pre-operative diagnosis proffered in the other case. In none of these 4 cases was an appendiceal tumour suspected, nor was there evidence of any inherited syndromes in any of the cases.

No metachronous colorectal lesions were diagnosed up to June 2007. This search was limited by the retrieval of only 7 patient charts.

Pseudomyxoma peritonei was rare, with 1 such case diagnosed in a patient with a mucinous cystadenoma. Acute appendicitis was found to complicate a neoplasm in 54.8% of cases. Incidental appendectomy contributed to 16.7% of the neoplasms diagnosed.

## DISCUSSION

Tumours of the appendix are uncommon. Our prevalence of 0.62% is comparable to the prevalence rate of 0.5%-0.9% found in other studies in New Zealand and the United Kingdom<sup>[1-3]</sup>. No published reports are available for other predominantly black populations. The clinical picture was most frequently that of acute appendicitis (24 of 42) with histologic confirmation in 75% of these cases. Of note, incidental appendectomy provided 7 cases (16.7%). This highlights the utility of routine histopathologic examination of appendiceal specimens because the diagnosis is often made without antecedent clinical suspicion and these diagnoses can potentially alter patient management<sup>[4]</sup>.

Importantly, the index of suspicion of appendiceal tumours should be raised in cases clinically suggestive of acute appendicitis in the middle aged and elderly, given the median age of 43 at diagnosis of these tumours in our experience.

Carcinoid tumours show epithelial and neuroendocrine differentiation, and may arise in many sites, but most commonly in the gastrointestinal tract<sup>[5]</sup>. These tumours frequently arise at the tip of the appendix<sup>[6]</sup> and are reportedly the most common tumours of the appendix<sup>[2,7]</sup>. Gaskin *et al*<sup>[8]</sup> in a previous study of carcinoids of the gastrointestinal tract from our institution reported that the appendix was the most common location with a similar mean age to that documented in this study. In our study, there were almost equal numbers of carcinoids and adenomas, but patients with carcinoids were younger than those with adenomas and adenocarcinomas. There is a paucity of literature with regards to neuroendocrine tumours in black populations, however, in one study the incidence of carcinoid tumours in all sites was found to be highest in African-American males<sup>[9]</sup>. Other studies, including those from the SEER data (1973-2001) report that appendiceal neuroendocrine tumours are more common in females<sup>[8,10,11]</sup>, in contrast to our data, which revealed a slight male predilection. This may be due in part to the small size of the study population.

While the overall behaviour of carcinoids is unpredictable, appendiceal carcinoids have an excellent prognosis<sup>[5,11]</sup>. Importantly, where lesions are identified in the gross assessment of the specimen, they should be measured. Appendectomy is appropriate for lesions

< 1 cm but for lesions over 2 cm in diameter there is a significant increase in metastatic spread and thus right hemicolectomy is required in such cases<sup>[3,6]</sup>. There remains controversy around what is the appropriate treatment for lesions between 1-2 cm. Authors have suggested that additional criteria be examined in such cases. These criteria include proliferation markers, mitotic activity, vascular and mesoappendiceal invasion<sup>[6,12]</sup>. Unfortunately, there was one case of an unmeasured grossly visible lesion in our review. This potentially exposed the patient to not receiving further surgery which may have been necessary.

After diagnosis of an epithelial non-endocrine neoplasm of the appendix, the entire colorectum should be examined for synchronous lesions<sup>[13,14]</sup>. In this series, appendiceal adenomas were associated with synchronous colonic tumours in 9.5% of cases, further underscoring the need for colorectal examination and surveillance post diagnosis of appendiceal adenoma. The relative unavailability of colonoscopy in our population over the period and the small sample size may be responsible for such a high rate when compared to Khan *et al*<sup>[14]</sup>. The absence of cases of serrated adenomas may reflect past alternative classification of these lesions, or a lack of reporter awareness or it may be highlighting a lesser contribution by the serrated pathway to colorectal carcinoma in our population. This area requires further study. Based on the available records, there were no cases of colorectal carcinoma syndromes with appendiceal involvement diagnosed during the period. Pseudomyxoma peritonei, a term best avoided for diagnostic purposes, was extremely rare.

## COMMENTS

### Background

Primary appendiceal tumours are uncommon. They are often diagnosed incidentally after histopathological examination of the vermiform appendix submitted in the course of the management of another clinical diagnosis. No previous research has been done in a predominantly black population to determine the prevalence or histologic types of primary epithelial tumours of the appendix.

### Research frontiers

Carcinoids (neuroendocrine tumours) are considered the most common primary appendiceal neoplasm and there is some evidence that African-American males have the highest incidence of carcinoids in all sites. However, several articles including the SEER database identified carcinoids more frequently in females. The roles of gender and ethnicity, if any, are unclear and require further investigation. The serrated pathway to colorectal carcinoma has been well described but the absence of such lesions in this study may reflect inappropriate classification or lack of reporter awareness. Further specific research into the serrated pathway to colorectal carcinoma in predominantly black populations is required.

### Innovations and breakthroughs

This and other articles have validated the use of routine histologic examination of appendectomy specimens given the frequency of diagnosis of incidental tumours which potentially require specific management. Generally carcinoid tumours portend a favourable prognosis but in some cases these tumours behave aggressively. Several criteria including proliferative markers, mitotic activity, vascular and mesoappendiceal invasion are being examined to determine their utility in predicting the behaviour of carcinoid tumours. The gross documentation of tumour size is important in determining if further management is required. While carcinoids are generally thought to be the most common tumour of the appendix, in this study an almost equal number of

adenomas were diagnosed. The published description of the sessile serrated adenoma and its recognition as a precursor to adenocarcinoma of the colon and rectum opened a new paradigm of research into colorectal carcinoma. It also highlighted that these lesions may have been previously misdiagnosed as hyperplastic polyps.

### Applications

Routine histopathological examination of appendectomy specimens is justified given the not infrequent incidental finding of appendiceal tumours. In cases of appendicitis in the elderly, the index of suspicion for epithelial tumours of the appendix should be raised. Moreover, once the diagnosis of an adenomatous lesion is made, colonoscopic examination of the entire large bowel is mandatory given the frequency of synchronous colorectal neoplasia in our population.

### Terminology

The term carcinoid refers to tumours which show epithelial, endocrine and neural characteristics which have been identified by light microscopic, ultrastructural and immunohistochemical means. The term serrated pathway of colorectal carcinoma refers to those lesions which arise from precursors with a peculiar hyperplastic morphology associated with architectural dysplasia but no cytologic abnormalities. These tumours have specific mutations which further distinguish them from the adenomatous and the hereditary nonpolyposis colorectal cancer (HNPCC) pathway.

### Peer review

This retrospective brief report is the first publication describing the prevalence and types of primary epithelial tumours of the appendix in a predominantly black population. It also describes the rate of synchronous neoplasia and highlights the need for routine histopathology. Thus, it is of reference value to the international scientific medical community.

### Abstract

**AIM:** To assess the adoption of Carbon dioxide (CO<sub>2</sub>) insufflation by endoscopists from various European countries, and its determinants.

**METHODS:** A survey was distributed to 580 endoscopists attending a live course on digestive endoscopy.

**RESULTS:** The response rate was 24.5%. Fewer than half the respondents (66/142, 46.5%) were aware of the fact that room air can be replaced by CO<sub>2</sub> for gut distension during endoscopy, and 4.2% of respondents were actually using CO<sub>2</sub> as the insufflation agent. Endoscopists aware of the possibility of CO<sub>2</sub> insufflation mentioned technical difficulties in implementing the system and the absence of significant advantages of CO<sub>2</sub> in comparison with room air as barriers to adoption in daily practice (84% and 49% of answers, respectively; two answers were permitted for this item).

**CONCLUSION:** Based on this survey, adoption of CO<sub>2</sub> insufflation during endoscopy seems to remain relatively exceptional. A majority of endoscopists were not aware of this possibility, while others were not aware of recent technical developments that facilitate CO<sub>2</sub> implementation in an endoscopy suite.

### INTRODUCTION

Use of Carbon dioxide (CO<sub>2</sub>) as the insufflating gas during colonoscopy was proposed in 1974 to decrease the explosion hazard associated with polypectomy<sup>[1]</sup>. As it appeared that there was less bloating and likely less pain after procedures using CO<sub>2</sub> for gut distension compared to air<sup>[2]</sup>, randomized controlled trials (RCTs) were performed to compare post-procedure pain when using CO<sub>2</sub> versus room air as the insufflation agent. The results of all of these RCTs were unambiguous, with significantly less pain reported after CO<sub>2</sub> colonoscopy<sup>[3-7]</sup>. For other endoscopic procedures also, CO<sub>2</sub> was found to be superior to air: (1) for double balloon enteroscopy, small bowel intubation is deeper<sup>[8]</sup>; (2) for endoscopic retrograde cholangio-pancreatography (ERCP), post-procedural pain is less<sup>[9,10]</sup>; and (3) for complex colorectal procedures (endoscopic submucosal dissection), fewer sedative drugs are required<sup>[11]</sup>. This is explained by the pathophysiology of gases: intestinal gases leave the body through alimentary orifices and exhaled air (gases can diffuse through the gut into splanchnic blood and subsequently pulmonary circulation). Experimental studies in live animals have shown that the clearance of gas from isolated bowel segments is much faster for CO<sub>2</sub> than nitrogen or oxygen (the two main components of air), and this by a factor of 160 and 12, respectively<sup>[12]</sup>. The most important reason for this is the higher solubility of CO<sub>2</sub> compared to other gases in water. Other factors that influence the diffusion of gases through the intestinal barrier are less significant

(e.g. gas tension gradient between the intestinal lumen and blood) or identical for all digestive gases (e.g. surface and thickness of the exchange membrane, and tissue perfusion)<sup>[13]</sup>.

Despite the high level of evidence supporting the use of CO<sub>2</sub> for gut distension during colonoscopy and other endoscopic procedures, this gas does not seem to be used in many endoscopy practices. We here report a survey that was performed in a large group of endoscopists to assess the use of CO<sub>2</sub> insufflation in daily endoscopy practice, including reasons for possible non-adoption.

## MATERIALS AND METHODS

### Survey design and administration

A questionnaire was developed by the authors for the study. Content validity of the survey was determined based on input by experts in the field and a review of the relevant literature. The final, two-page, 26-item, survey contained two parts: the first one addressed respondents' demographic characteristics and knowledge about the use of CO<sub>2</sub> as room air replacement during gastrointestinal endoscopy; and the second part was divided in two sections directed to endoscopists who, either did ("practitioners"), or did not ("non-practitioners") use CO<sub>2</sub>. Non-practitioners were asked for which reasons they did not use CO<sub>2</sub>, while practitioners were asked about their actual use of CO<sub>2</sub>.

The survey was performed during the 26th European Workshop on Gastroenterology and Endotherapy held in Brussels, Belgium, on 16-18 June 2008. Questionnaires were placed in cases distributed to course participants, and attendees were asked to deposit completed surveys in a dedicated box at the registration desk. Consent to participate in this study was inferred from voluntary completion of the survey. Efforts to increase response rates included two rehearsals by the course director (Deviere J), projection of a reminder slide during breaks, and collection of surveys by staff members who passed between rows of participants or were posted at the exits of the projection rooms. No gift or financial incentive was proposed to attendees.

### Statistical analysis

Results are expressed as mean  $\pm$  SD or as a percentage. Each response was included in the analysis, regardless of the completeness of the survey. In cases when not all survey respondents answered to an individual question, the number of respondents (i.e. the denominator for percentage calculations) is indicated.

## RESULTS

### Study population

Surveys were distributed to 580 medical doctors attending the course, and 142 of them completed the study (response rate, 24.5%). All of them answered all the demographic questions (Table 1). The respondents

**Table 1** Demographic characteristics of the 142 survey respondents (mean  $\pm$  SD)

Characteristics	n (%)
Male gender	109 (76.8)
Age (yr)	47.7 $\pm$ 9.1
Years in practice	17.5 $\pm$ 9.2
Country	
Belgium	25 (17.6)

had their endoscopy practice in 21 countries, but six of these (Belgium, Greece, Italy, France, Spain and Switzerland) made up two-thirds of the respondents. Main practices were roughly equally distributed between private practice, community hospitals and university hospitals. Sedation with propofol or general anesthesia was used for more than 50% of colonoscopies by about half the respondents.

### Answers to the survey

Fewer than half of the respondents (66/142, 46.5%) were aware that room air could be replaced by CO<sub>2</sub> for gut distension during endoscopy. Thirty-eight respondents (26.8%) had previously seen ( $n = 24$ ) or performed ( $n = 14$ ) an endoscopy procedure using CO<sub>2</sub>, with only six of them actually practicing this technique (adoption rate of the technique in the whole population, 4.2%). Fifty-eight (87.9%) of the 66 respondents who were aware of the technique also stated that all RCTs had shown that CO<sub>2</sub> insufflation decreased pain and gut distension compared to air insufflation. The proportions of survey respondents who correctly answered questions relating to various aspects of CO<sub>2</sub> use during endoscopy are shown in Figure 1.

One hundred and thirty endoscopists answered why they did not use CO<sub>2</sub>: 73 (56.1%) of them were not aware of this possibility, and those who were aware most often cited "technical difficulties in implementing the

**Figure 1 Percentages of correct answers (yes/no choice; correct answer was yes in all cases) to the following questions.** <sup>a</sup>CO<sub>2</sub> insufflation is not advised in patients with severe pulmonary diseases; <sup>b</sup>About 20% of patients still have pain 6 h after colonoscopy using air insufflation; <sup>c</sup>About 20% of patients need ≥ 2 d before they are able to return to their normal activities after screening colonoscopy; <sup>d</sup>Compared to air, CO<sub>2</sub> colonoscopy decreases the risk of bowel explosion; <sup>e</sup>Compared to air, CO<sub>2</sub> insufflation is better for ERCP and double balloon enteroscopy DBE.

system” and “advantages not significant enough for the patient” [ $n = 48$  (84%) and  $28$  (49%), respectively; two answers were permitted for this item]. Marginal answers included the risk of patient carbonarcosis ( $n = 6$ ) and of CO<sub>2</sub> inhalation by the endoscopy personnel ( $n = 4$ ).

Reasons that could motivate a change in their practice were stated by 127 endoscopists: a demonstration of the use of CO<sub>2</sub> [in a workshop ( $n = 61$ ; 48.0%) or in their endoscopy unit ( $n = 50$ ; 39.4%)], and proposal of a CO<sub>2</sub> insufflator as an option when buying a colonoscope ( $n = 44$ ; 34.6%) were the most frequently cited answers. Other answers were less frequent [5% higher reimbursement for CO<sub>2</sub> compared to air colonoscopy ( $n = 16$ ; 12.6%); virtual colonoscopy performed close to their practice using CO<sub>2</sub> insufflation ( $n = 9$ ; 7.1%)]. Four endoscopists reported that they had attempted implementing CO<sub>2</sub>, but that they had abandoned it because of costs.

Four endoscopists who were actually using CO<sub>2</sub> compared it with air colonoscopy. CO<sub>2</sub> was rated as similar to air in terms of ease of use, endoscopist comfort and patient comfort during colonoscopy, but better with respect to post-procedure patient comfort, and more expensive (all answers were identical, except for one endoscopist who rated CO<sub>2</sub> as better for patient comfort during colonoscopy).

## DISCUSSION

CO<sub>2</sub> was used for gut distension during endoscopy by < 5% of survey respondents, even though all RCTs performed since the description of the technique 35 years ago have shown that pain is lower with CO<sub>2</sub> compared to air<sup>[1,3-6,9,14]</sup>. Indeed, the adoption rate found in the present study was even lower than that reported 20 years ago in a survey of US hospitals in Illinois (13% for colonoscopy)<sup>[15]</sup>. A majority of endoscopists

were not aware at all of the possible use of CO<sub>2</sub> during endoscopy, while the remainder ignored recent practical developments (they cited technical difficulties in implementing CO<sub>2</sub> as the main factor limiting its adoption, even though CO<sub>2</sub> insufflators have become more widely available). The other major reason cited for not adopting CO<sub>2</sub> was that advantages for the patients were not sufficiently significant. This likely relates to a lack of information among endoscopists about post-colonoscopy patient inconvenience (only one-third of them knew that 20% of patients need ≥ 2 d before being able to return to their normal activities after screening colonoscopy)<sup>[16]</sup>.

Endoscopists currently pay more attention to patients' comfort; for example, polyethylene glycol is being replaced by sodium phosphate for bowel preparation before colonoscopy<sup>[17]</sup>. However, recent reports have shown that phosphate nephropathy may complicate bowel preparation using sodium phosphate, even after a single preparation<sup>[18]</sup>. Another example is the use of propofol for sedation in replacement of benzodiazepines<sup>[19]</sup>. CO<sub>2</sub> deals with the post-procedure phase of colonoscopy by reducing bloating and abdominal pain, the most frequent side effects of colonoscopy<sup>[16]</sup>. However, it remains to be demonstrated if the advantages conferred by CO<sub>2</sub> are sufficiently significant to improve patient acceptance of endoscopic procedures and cost-effectiveness (by reducing loss from normal activities after endoscopy). These two criteria, namely patient acceptance and cost-effectiveness, are of paramount importance for colorectal cancer screening as computed tomography (CT) colonography has been shown to be superior to colonoscopy for both of them<sup>[20,21]</sup>. Incidentally, one of the three CO<sub>2</sub> insufflators that are available for endoscopy was developed initially for gut distension during CT colonography, and radiologists use it increasingly often for reasons of safety and patient comfort (CO<sub>2</sub> is used in about half of CT colonographies)<sup>[22]</sup>. In our survey, the use of CO<sub>2</sub> for CT colonography was not perceived by endoscopists as an incentive to change their practice. As endoscopists become aware of the ease and benefits of CO<sub>2</sub> implementation in an endoscopy suite, the use of CO<sub>2</sub> may be the next logical step to minimize patient discomfort.

Most endoscopists reported that a demonstration (in their endoscopy unit or in a workshop) was likely to change their perception of CO<sub>2</sub> usefulness. This corroborates our previous observation that endoscopists' opinion may significantly change following a demonstration of a particular endoscopy technique<sup>[23]</sup>. However, it remains to be seen if intentions translate into actual changes, in particular, because CO<sub>2</sub> benefits are mainly observed after sedation reversal, when many patients are not evaluated by endoscopists.

From a practical standpoint, CO<sub>2</sub> is readily available in centers where laparoscopic surgery is performed (or it can be purchased from various distributors), and endoscopic CO<sub>2</sub> insufflators have recently become more

Table 2 Characteristics of CO<sub>2</sub> insufflators available for gut distension during endoscopy

	CO <sub>2</sub> -efficient	Olympus keymed ECR	Olympus UCR
Weight (kg)	9.0	26.0	4.9
Size (mm)	254 × 140 × 254	420 × 1049 × 539	130 × 156 × 334

FDA: Food and Drug Administration; NA: not available. <sup>1</sup>When the vent hole of the insufflation/irrigation valve is not occluded, CO<sub>2</sub> flow decreases from 3 L/min to a managed flow of 0.25 L/min, in order to preserve CO<sub>2</sub> reserves. None of the three models allows selecting between different intensities of CO<sub>2</sub> flow (in contrast with the selection of low/medium/high intensities of air flow with air insufflators).

widely available (Table 2). CO<sub>2</sub> insufflators are electrically powered devices that combine at the minimum a gas pressure regulator, a safety pressure valve to protect against over-insufflation, and connection tubes. When CO<sub>2</sub> is used, the regular air insufflation is inactivated (to prevent endoscopic insufflation with both gases), and endoscope manipulation is unchanged compared to using air for gut distension (CO<sub>2</sub> insufflation is obtained by placing the finger on the vent hole of the insufflation/irrigation valve, and lens cleaning is obtained by firmly pressing this valve). One may also switch from one gas to another during an endoscopic procedure. Contraindications to the use of CO<sub>2</sub> are limited to severe chronic obstructive pulmonary disease (if CO<sub>2</sub> is absorbed at a rate exceeding its respiratory elimination, this leads to CO<sub>2</sub> retention and pulmonary acidosis)<sup>[24]</sup>. Provided that this contraindication is observed, Brethauer *et al*<sup>[3]</sup> have shown that, although pCO<sub>2</sub> levels increase during colonoscopy and ERCP (due to the effect of sedative drugs), this increase is no more important with CO<sub>2</sub> than with air insufflation<sup>[4,9]</sup>.

Finally, the cost of an insufflator was cited as a limiting factor by endoscopists who attempted to implement the system. The cost of an insufflator ranges between 7000 and 7400 euros. The cost of CO<sub>2</sub> gas per colonoscopy is < 1 euro (renting a 2400-L CO<sub>2</sub> tank costs about 50 euros/year, and refilling it costs 25 euros; this volume is sufficient for 800 min of continuous insufflation; a mean of 8.3 L is used per colonoscopy procedure)<sup>[25]</sup>. The acquisition cost should be viewed in light of the multiple uses of these systems (e.g. colonoscopy, ERCP, double balloon enteroscopy) and ideally, from a societal perspective. Indeed, if cost calculations of screening colonoscopy took into account total time lost from work for patients undergoing the examination, as well as for the person accompanying the patient, this would increase the cost by about 50%<sup>[26]</sup>. A catalyst for CO<sub>2</sub> adoption by endoscopists could be the implementation of CO<sub>2</sub> insufflation capabilities into standard endoscopy processors, as additional costs would be hard to justify in the absence of specific reimbursement. The endoscope manufacturer that would

first take this step would have a competitive advantage.

Our study has several potential limitations, including selection bias and the relatively limited number of responders. However, survey respondents were distributed relatively evenly between different endoscopy practices, and an international audit with a larger panel of individual respondents than reported here is notably difficult to organize<sup>[27,28]</sup>.

In conclusion, the use of CO<sub>2</sub> for gut distension during endoscopy remains exceptional despite the results of numerous RCTs that have shown the superiority of this technique compared to air. A majority of endoscopists are unaware of this possibility, while those who are aware mostly think that CO<sub>2</sub> implementation in an endoscopy suite is technically difficult or presents few advantages. Greater availability of CO<sub>2</sub> insufflators, more widespread use of CO<sub>2</sub> in competing CT colonography, and better endoscopists' education have the potential to change this situation.

## COMMENTS

### Background

Carbon dioxide (CO<sub>2</sub>) is cleared much more rapidly than air from the bowel and randomized controlled trials have consistently shown that it is superior to air for several gastrointestinal endoscopy procedures. In particular, advantages were demonstrated for colonoscopy (less pain), endoscopic retrograde cholangiopancreatography (less pain), double balloon enteroscopy (deeper bowel intubation), and long, complex, therapeutic procedures (fewer sedative drugs).

### Research frontiers

Use of CO<sub>2</sub> is common for colon computed tomography but it does not seem to be widespread in endoscopy practice. Reasons for possible non-adoption of this gas are unknown.

### Innovations and breakthroughs

No data about the use of CO<sub>2</sub> by endoscopists have been available for > 20 years. Recently, CO<sub>2</sub> insufflators for endoscopy have become commercially available.

### Applications

As a majority of endoscopists were not aware of the possibility to use CO<sub>2</sub> as air replacement during endoscopy, specific endoscopists' education and implementation of CO<sub>2</sub> insufflation capabilities into standard endoscopy processors should be encouraged.

### Peer review

The cost of equipment required for CO<sub>2</sub> insufflation during endoscopy is the main barrier to adoption of this technique; it is actually around 7000 euros.

major quasispecies in each patient was performed using the MFOLD 3.2 program with Turner energies and selected constraints on base pairing.

**RESULTS:** Analysis of RNA secondary structure revealed that insertions in domain III altered Watson-Crick base pairing of stems and reduced molecular stability of RNA, which may ultimately reduce binding affinity to ribosomal proteins. Insertion mutations in domain III were statistically more prevalent in sustained viral response patients (SVR,  $n = 14$ ) as compared to breakthrough (BT,  $n = 5$ ) patients.

**CONCLUSION:** The influence of mutations within domain III on the response of HCV patients to combination therapy depends primarily on the position, but not the frequency, of these mutations within IRES domain III.

### Abstract

**AIM:** To investigate the effects of mutations in domain III of the hepatitis C virus (HCV) internal ribosome entry sequences (IRES) on the response of chronic HCV genotype 4a patients to interferon therapy.

**METHODS:** HCV RNA was extracted from 19 chronic HCV 4a patients receiving interferon/ribavirin therapy who showed dramatic differences in their response to combination therapy after initial viral clearance. IRES domain III was cloned and 15 clones for each patient were sequenced. The obtained sequences were aligned with genotype 4a prototype using the ClustalW program and mutations scored. Prediction of stem-loop secondary structure and thermodynamic stability of the

### INTRODUCTION

The hepatitis C virus (HCV) genome is a 9.5 Kb single stranded RNA molecule of positive polarity. It contains a single open reading frame flanked by 5' and 3' untranslated regions (UTR) of 341 and about 230 nucleotides, respectively<sup>[1]</sup>. Both the 5' and 3' UTRs contain conserved RNA structures essential for polyprotein translation and genome replication<sup>[2]</sup>. The 5'UTR is uncapped and contains the internal ribosomal

entry site (IRES) which contains highly conserved secondary and tertiary structures that are essential for proper binding and positioning of the viral RNA within the host cell's protein translation machinery<sup>[3,4]</sup>.

The only FDA approved medication for the treatment of HCV infection is the combination therapy of either standard or pegylated interferon and ribavirin<sup>[5]</sup>. However, only 28%-60% of HCV patients respond to the treatment, depending on the viral genotype<sup>[6,7]</sup>. Resistance to interferon therapy is believed to be controlled by host and viral factors<sup>[8]</sup>; a significant viral factor is the generation of different HCV quasispecies<sup>[9]</sup>. The critical role of 5'UTR in initiation of polyprotein translation requires the highest degree of conservation of this region. It contains four highly structured domains numbered I to IV; all are required for recruiting, positioning, and activating/regulating the host protein synthesis machinery<sup>[10]</sup>. Translation initiation in HCV starts by binding of the HCV IRES to the 40S subunit and assembly of this binary complex with eukaryotic initiation factor 3 (eIF3). The IRES-40S-eIF3 ternary complex combines with eIF2/GTP/initiator tRNA forming the 48S complex. Progression from 48S to 80S initiation complexes is a slow step during IRES-mediated initiation which may reflect a decrease or absence of factor activity or conformational rearrangements in the IRES leading to sub-unit joining<sup>[11]</sup>. The need for flexible rather than rigid binding allows the conformational rearrangement and subsequent efficient sub-unit joining leading to initiation of translation. Therefore low affinity binding of factors due to mutations in binding sites may be associated with more flexibility and efficient initiation of translation.

The 5'UTR can be divided into the 5' and 3' parts. The 5' part is near to a fully single stranded structure and includes domain I. The 3' part is highly structured and is essential for HCV IRES function. It folds into three additional domains II, III and IV. Domain II is a stem with several internal loops. Domain IV is a small hairpin which includes the AUG start codon. The pseudo knot joins domain II with domain III and is base-paired to the sequence directly upstream of domain IV.

The HCV IRES forms an extended structure that binds the 40S subunit by several synergetic interactions, and the domains involved in this binding have been determined by chemical and enzymatic foot-printing experiments<sup>[12]</sup>. The segment starting from nucleotide 141 to 279 which comprises domain III, the focus of the present study, is highly conserved at the primary nucleotide sequence as well as at secondary and tertiary structure levels. The basal part of domain III (including principally the pseudo knot and stem-loop III d) includes the elements of secondary structure that determine the binding of the IRES to the 40S subunit. Besides providing affinity for the 40S subunit, the basal part of domain III is thought to be required for correct positioning of the initiation codon in the decoding center of the 40S subunit, as indicated by "toe-printing" experiments<sup>[11]</sup>. The apical part of domain III binds eIF3 *via* stem-loop III b and the four-way junction and is required for 40S and eIF3 binding.

In the present study, the positional effect of mutations on the predicted secondary structure and thermodynamic stability of domain III was examined in 19 chronic HCV type 4a patients with initial virological response defined as undetectable viremia after 12 wk from start of treatment. Only 14 patients achieved sustained virological response (SVR) i.e. negative viremia 24 wk after end of treatment. In the remaining 5 patients who suffered virological breakthrough (BT), the predicted stem-loop structures and thermodynamic stability of domain III were compared in both pre- and post-treatment samples.

## MATERIALS AND METHODS

### HCV patients

Male or female patients ( $n = 19$ ; 18-60 years) with chronic active hepatitis C virus infection were included in this study. Patients were negative for HBsAg and HBsAb but positive for anti-HCV and HCV-RNA by RT-PCR. All had elevated ALT and AST levels and received combined therapy of pegylated IFN $\alpha$ -2b (100  $\mu$ g/wk) plus ribavirin (800-1000 mg/d). Patients had normal values for blood counts, other liver functions, auto immune markers, T3, T4 and TSH, renal functions, blood sugar and  $\alpha$ -fetoprotein. None of the patients had other causes of liver disease (e.g.  $\alpha$ 1 antitrypsin deficiency, Wilson's disease, alcoholic or decompensated liver disease, obesity-induced liver disease, drug-related liver disease), no CNS trauma, or active seizures, no ischemic cardiovascular disease within the last six months or hemochromatosis. None was co-infected with HBV or schistosomiasis.

### Cloning and sequencing of the HCV domain III

RNA extraction and reverse transcription-PCR of HCV RNA, using Qiagen single step RT-PCR kit (Qiagen, Inc., Chatsworth, CA, USA), were performed as described previously<sup>[13,14]</sup>. Amplification of 266 bp was performed in a single step using primer pair; forward (nt 47-68) 5'-GTGAGGAAGTACTGTCTTCACG-3' and reverse (nt 292-312) 5'-ACTCGCAAGCACCTATCAGG-3'. Cloning of amplified products was done with TA cloning kit (Invitrogen Co., Carlsbad, CA). Fifteen clones from each subject were sequenced using the TRUGENE HCV 5-NC genotyping kit, Visible Genetics, Inc. (Toronto, Ontario, Canada) in conjunction with the Open Gene DNA sequencing system. The insert DNA was sequenced by CLIP sequencing which allows both directions of the target amplicon to be sequenced simultaneously in the same tube using two different dye labeled primers (Cy5.0 and Cy5.5) for each reaction. This method provides sequence information for both positive and negative DNA strands from a single reaction. The obtained sequences were then aligned with genotype 4a prototype using the ClustalW program ([www.ch.embnet.org/software/ClustalW.html](http://www.ch.embnet.org/software/ClustalW.html)). Among the 15 domain III sequences obtained for each patient only one sequence was found in the majority of the clones, thus representing the major quasispecies of domain III in each patient.

The distribution of the observed mutations in different loops of domain III in sustained viral response (SVR) and breakthrough (BT) patients is shown. The majority of mutations (14/19) were simple substitutions whereas 5/19 were insertions. Most mutations were found in stem-loops IIIb and d. The effect of each mutation on the overall thermodynamic stability of the related domain is indicated. Decreased  $\Delta G$  means increased stability and vice versa. Pre-T: Pre-treatment; Post-T: Post-treatment.

Sequence diversities in each major quasispecies were compared with genotype 4a and various mutation types were scored.

### RNA secondary structure and thermodynamic stability

Prediction of stem-loop structure and thermodynamic stability of the major quasispecies in each patient was performed using the MFOLD 3.2 program with Turner energies and selected constraints on base pairing as indicated<sup>[15]</sup>. The program was run on EFN server: 1996-2008, Michael Zuker, Rensselaer Polytechnic Institute (<http://mfold.bioinfo.rpi.edu/cgi-bin/rna-form1.cgi>).

## RESULTS

### HCV Quasispecies and genotyping

The mean number of domain III quasispecies in pre-treatment samples of SVR and BT states was about 2 quasispecies per patient with no significant difference between both groups. The quasispecies complexity of domain III tripled in post-treatment samples of BT patients. All patients included in the study were genotyped as 4a except for one SVR patient infected with a hybrid 4a/1b genotype.

### Domain III sequence diversities in patient study groups

Different types of mutations were compared in both study groups with the prototype sequence of HCV 4a (Table 1). Insertion mutations in domain III were statistically more prevalent in SVR than BT patients. This is expected since insertions are known to dramatically alter the stem-loop structure by changing the Watson-Crick base pairing of stems, thus reducing molecular

stability of the RNA or binding affinity to ribosomal proteins. The percentage of transition mutations was statistically higher in pre-treatment samples of BT than SVR. There were no statistical differences in percentage of transversion mutations between the two patient groups.

### Distribution of mutations in different loops of domain III in SVR compared with BT patients

Alignment of domain III sequences derived from study patients revealed the presence of 19 point mutations scattered in stem-loops IIIa, b, c and d (Table 1). Percentage distribution of the identified mutations in different loops of domain III in SVR and BT patients is presented in Table 2. The majority of mutations, 14/19 (73.7 %), were simple substitutions while 5 (26.3%) were insertions. Substitutions included 42.8% transitions and 57.2% transversions. Most of the mutations (84.2%) were localized in 2 stem-loops; IIIb (nt 175-205) and III d (nt 254-275), with 42.1% of the mutations in each loop. The remaining 15.8% of mutations were located in junction IIIa, b, c (10.5%) and in loop IIIa (5.3%). The SVR patients contain specific mutations (Figure 1) that were not detected in either pre-treatment BT groups or post-treatment BT patients (Table 1). These SVR specific mutations comprise 42.1% (8/19) of the total number of mutations detected in the studied patient population (Table 1). Interestingly, approximately two thirds of SVR (5/8) specific mutations were located in loop IIIb and one third (3/8) in III d with only one exceptional mutational event (nt 243 in junction joining loops IIIa, b, c, d) that was detected outside loops IIIb and III d. These two stem-loop structures play critical roles in directing

**Table 2** Distribution of the 19 identified mutations in different loops of domain III in SVR and BT patients

Region	Responder (SVR; %)	BT pre treatment (%)	BT post treatment (%)
Stem-loop IIIa (156-171)	-	14.3	10
Stem-loop IIIb (172-227)	50	14.3	20
Stem-loop IIIc (228-238)	-	-	-
Stem-loop III d (253-279)	40	57.1	50
Junction joining stem-loop IIIa, b, c, & d (141-153) & (239-252)	10	14.3	20

Ten mutations, out of the 19 identified point mutations, are found in responders (SVR). Five of these mutations are found in loop IIIb, four in III d, and one in the junction. Seven mutations are found in the BT pre-treatment group (four in loop III d and one in each of loop IIIa, III b, and junction). Ten mutations were detected in BT post-treatment (five in III d, 2 in each of III b and the junction, and one in loop IIIa).

viral protein translation *via* recruiting and regulating ribosomal subunit proteins and cellular initiation factors for accurate positioning of HCV RNA in the translational machinery of the host cell. On the other hand, mutational events in pre-treatment samples of the BT patients were detected in almost all loop structures of domain III, mostly located in loop III d. Most notably loop III d mutations were associated with decreased  $\Delta G$  value (Table 1) indicating increased thermodynamic stability of the RNA structure, thus explaining resistance to therapy in the BT patient group. It is noteworthy that most of loop III b mutations in SVR were associated with increased  $\Delta G$  value, indicating decreased thermodynamic stability of the viral RNA, therefore contributing to the multifactorial eradication of viral RNA in the SVR patient group. When comparing the mutational events in pre-treatment BT patients with those observed post-treatment, the number of mutational events known to induce significant elevation in thermodynamic stability (i.e. decreased  $\Delta G$  in loop III d) did not increase after treatment in BT patients. These results suggest that domain III-associated factors of viral breakthrough are determined by genetic events in the HCV genome before start of treatment rather than being acquired as a result of stress induced by IFN $\alpha$  therapy.

**Prediction of thermodynamic stability and effect of mutations on the secondary structure**

Changes in the minimum free energy ( $\Delta G$ ) were detected for stem-loops IIIa, b, c and d spanning nucleotides 141 to 282. Predictive stability values were compared for genotype 1b (strain H77), genotype 4a (I.D. Y11604.1) and study samples derived from SVR and BT patients. The  $\Delta G$  value of genotype 1b was -53.6 kcal/mol; more stable than genotype 4a ( $\Delta G$  -47.0 kcal/mol) as illustrated in the secondary structure/thermodynamic stability prediction (Figures 2 and 3). As shown in Table 1, 31.5% of the mutations have no effect on the  $\Delta G$  value, 31.5% of the mutations were associated with increased  $\Delta G$  i.e. reduced stability of the secondary structure, while 37% of the mutations were associated with decreased  $\Delta G$  value

**Figure 1** Predicted secondary and tertiary structure of HCV IRES<sup>[23]</sup> with mutations observed in SVR patients shown.

i.e. increased stability of the RNA secondary structure. An interesting observation (Table 1 and Figure 1) is that mutations with no effect on  $\Delta G$  values were located in the apical part of domain III secondary structure (nt 186-243), spanning mostly the upper part of loop III b involved in eIF3 binding. On the other hand, those mutations affecting the stability parameters were localized in the basal part of domain III encompassing loops IIIa/b and III d. Most notably, IIIa/b (nt 158-199) mutations were associated with reduced stability and III d (nt 254-275) mutations were associated with increased stability of the RNA structure. Taken together, the data relating to minimum free energy in SVR and BT patients indicate that the levels of thermodynamic stability are not sufficient parameters to predict response to IFN $\alpha$  treatment and suggest that other parameters involving affinity of RNA binding to ribosomal subunits play important roles in determining response to treatment.

**DISCUSSION**

The pathway of HCV IRES-mediated initiation of translation is primarily dependent on RNA binding to several cellular proteins, of which ribosomal 40S subunit and eIF3 play pivotal roles in efficient translation of a polyprotein precursor<sup>[16]</sup>. Several foot-printing, toe-printing and UV cross linking assays have shown that domain III is the most active part in RNA-protein binding where it folds to form stem-loop structures for high affinity binding to host proteins<sup>[11,17-19]</sup>. Although genomic variability in HCV IRES was shown as one mechanism for escaping IFN $\alpha$  effects, there has been

**Figure 2** RNA secondary structure and thermodynamic stability of loops IIIa, b, c, & d from genotype 1b. The minimum free energy value ( $\Delta G$ ) was -53.6 kcal/mol.

controversy with regard to the predictive value of pre-treatment IRES genomic variations in determining later response to IFN $\alpha$ <sup>[20]</sup>. Although domain III harbors only 22% of the overall IRES mutations in a mixed genotype population<sup>[21]</sup>, IRES activity seems to depend more on the location of mutant nucleotides which play the most important roles in IRES activity.

We performed a focused study on domain III derived from patients infected exclusively with genotype 4a and presenting a dramatic difference in sustained response after initial viral disappearance. This approach allowed us to minimize quasispecies complexity (mean of 2 variants/patient) compared with 7 or more variants/patient in other studies<sup>[21]</sup> and to pinpoint a number of important genomic determinants of response to IFN $\alpha$ . Cloning of domain III and sequencing of 15 clones in each patient allowed us to identify the major variant (identical sequences in 12 clones or more) in each patient so that noise was reduced during extrapolation of the relationship between genomic variation and treatment outcome.

Disruption of base pairing in stem structure significantly inhibits IRES-dependent translation<sup>[22]</sup>. In our patient population insertion mutations in domain

**Figure 3** RNA secondary structure and thermodynamic stability of loops IIIa, b, c, & d from genotype 4a (prototype). The minimum free energy value ( $\Delta G$ ) was -47.6 kcal/mol.

III were statistically higher in SVR than in BT patients. These results are expected since insertions are known to dramatically alter the stem-loop structure by changing the Watson-Crick base pairing of stems, thus reducing molecular stability of the RNA or binding affinity to ribosomal proteins. The distributions of domain III mutations in SVR patients were distinct from those of the BT group in the present study. Of the total number of mutations, approximately 42% were exclusive to SVR patients; almost all were located in loops IIIb and IIId. These two stem-loop structures were implicated in initiation complex recruitment, positioning and regulation, where IIIb forms the core of high affinity binding with the 40S subunit<sup>[22]</sup> and recruits ribosomal elements involved in positioning of mRNA and tRNA<sup>[10]</sup>. Besides binding to eIF3, stem-loop IIIb interacts with a multisubunit initiation factor involved in subunit assembly and stability of ternary complex<sup>[22]</sup>.

This explanation cannot simply be taken to resolve mysteries of HCV IRES in light of the apparent controversy in loop IIIb genomic diversity. All of IIIb mutations detected exclusively in BT patients (pre- and post-treatment) were associated with increased thermodynamic stability, thus leading to viral persistence;

also most of III<sub>d</sub> mutations detected in SVR patients were again associated with increased stability of this RNA. The slow rate of ribosomal subunit transition compared to canonical translation<sup>[11]</sup> directs the attention towards the need for flexible rather than rigid binding which allows the conformational rearrangement and subsequent efficient subunit joining, leading to initiation of translation. Therefore mutations affecting binding affinity of factors regardless of thermodynamic stability of RNA structure may be associated with either more flexibility or rigidity which in turn regulates efficiency of translational initiation<sup>[11]</sup>. Taken together, the data regarding minimum free energy in SVR and BT patients indicate that the levels of thermodynamic stability are not sufficient parameters to predict response to IFN $\alpha$  treatment and suggest that other parameters involving affinity of RNA binding to ribosomal subunits play significant roles in determining response to treatment. The concept that mutations in BT patients appear only in post-treatment samples and are associated with no effect on RNA stability suggests that viral breakthrough is determined by mutations in domain III before start of treatment rather than being acquired during treatment. Alternatively, the roles of these mutations in viral persistence could be related to fine tuning of the flexibility of RNA structure for binding to cellular factors regardless of its stability. The former view is more plausible since the majority of III<sub>d</sub> mutations in pre-treatment were associated with increased RNA stability without change in the frequency of mutations post-treatment. An interesting observation in this study is that the A243G mutation in the III<sub>c</sub>/III<sub>d</sub> junction was detected both in SVR (5 times) and in pre-treatment BT (2 times) and was more detectable in post-treatment BT patients (4 times). Predictive folding however, revealed no effect of this mutation on the calculated thermodynamic stability. The role of nucleotide 243 in maintaining IRES structure was reported in HCV genotype 1b<sup>[21]</sup> and changes at this position were encountered in patients with viral stabilization. In genotype 1b, A243 pairs with U149, which is lacking in 4a, leading to altered pairing and explains the high rate of mutations at this position in our study population regardless of response to IFN $\alpha$ , thus making it more vulnerable to mutational event in genotype 4a.

In conclusion, the RNA structure of domain III in HCV IRES contains several important elements implicated in determining the response to IFN $\alpha$  treatment. The results presented herein demonstrate that domain III structure in SVR patients is different from BT patients. Thermodynamic stability of RNA secondary structure is a significant but not sufficient parameter for prediction of viral stabilization, or response to IFN $\alpha$ . Elements of binding to ribosomal subunit complexes require further studies to unravel the exact role of IRES in HCV stabilization and persistence.

## COMMENTS

### Background

The hepatitis C virus (HCV) is a major public health problem with about 200 million individuals currently infected with the virus (about 3% of the world's popula-

tion). So far, 11 genotypes and more than 70 subtypes have been identified. The only approved FDA treatment for chronic HCV infection is the combination therapy of pegylated interferon and ribavirin. The variable response of patients to therapy ranges between 28% and 60% and has been proposed to be affected by various host and viral factors. Investigating the effect of mutations within the HCV 5'UTR, the most conserved region in the viral genome, on response to therapy is important because this region is vital for initiation of viral polyprotein translation and the ability of HCV to replicate.

### Research frontiers

Although interferon and ribavirin are the only FDA approved drugs to treat HCV, they suffer from several drawbacks including severe side effects (including hematological abnormalities and neuropsychiatric symptoms), very high cost, and most importantly low therapeutic response. Consequently, factors that affect the response of HCV patients to therapy have to be addressed and results could be used for predicting response to therapy before initiation of treatment. Moreover, identification of viral factors that correlate with therapeutic response would contribute to other studies on viral and host factors. This could result in a global view and comprehensive understanding of how host and viral factors affect a patient's response to therapy.

### Innovations and breakthroughs

Recent reports, using clinical specimens or HCV replicon systems from different genotypes, have highlighted the effect of mutations in different domains of the viral genome (in particular the HCV 5'UTR) on patients' response to therapy. However, limited studies have been done on genotype 4a. In the present article, The authors focused mainly on genotype 4a which is the predominant genotype in Egypt; found in over 90% of all HCV-infected patients. They showed that the thermodynamic stability of the HCV 5'UTR region is different among responders (sustained viral clearance) and breakthrough patients (who suffer relapse at the end of treatment). Additionally, their results indicate that response to therapy is related mainly to the position of mutations but not their frequency. Finally, thermodynamic stability of IRES was shown to have a direct influence on the binding of the viral genome to the host proteins, which results in initiation of the translation of the viral polyprotein.

### Applications

The results of this study suggest that the presence of single nucleotide polymorphisms (SNPs) in certain positions had direct effect on the response of HCV patients to interferon therapy. Taking into consideration the positions of these mutations, different real-time PCR or other assays can be developed for detection of the SNPs to allow the prediction of the response to interferon therapy as a step for identification of patients who are more likely to respond to therapy.

### Terminology

5'UTR: non-coding region of HCV RNA; contains the internal ribosomal entry site (IRES); site of initiation of translation. IRES: (internal ribosomal entry site): a structure within the HCV RNA 5'UTR that binds directly to the ribosome to initiate translation. Cap-dependent translation: the mechanism of translation (protein synthesis) predominantly used for cellular proteins. Cap-independent translation: translation via an internal ribosomal entry site (IRES); the mechanism utilized by HCV. Eukaryotic initiation factors: cellular proteins involved in translation. SVR: sustained viral response; patients who show negative HCV PCR results after termination of therapy.

### Peer review

The authors present a sequence analysis study of HCV genotype 4a patients undergoing combination therapy. This study is of a substantial potential interest. In this work the authors propose that insertion mutations in domain III of the IRES region are more prevalent in sustained viral response patients compared with breakthrough patients and that such mutations may affect the ability of HCV virus to replicate by decreasing the thermodynamic stability of its RNA.

were carried out pertaining to the extracolonic lesions that were detected by CT colonography.

**RESULTS:** A total of 920 cases from 7 university hospitals were included, and 692 extracolonic findings were found in 532 (57.8%) patients. Of 692 extracolonic findings, 60 lesions (8.7%) were highly significant, 250 (36.1%) were of intermediate significance, and 382 (55.2%) were of low significance. CT colonography revealed fewer extracolonic findings in subjects who were without symptoms ( $P < 0.001$ ), younger ( $P < 0.001$ ), or who underwent CT colonography with no contrast enhancement ( $P = 0.005$ ). CT colonography with contrast enhancement showed higher cost-effectiveness in detecting highly significant extracolonic lesions in older subjects and in subjects with symptoms.

**CONCLUSION:** Most of the extracolonic findings detected using CT colonography were of less significant lesions. The role of CT colonography would be optimized if this procedure was performed with contrast enhancement in symptomatic older subjects.

### Abstract

**AIM:** To determine the frequency and characteristics of extracolonic lesions detected using computed tomographic (CT) colonography.

**METHODS:** The significance of extracolonic lesions was classified as high, intermediate, or low. Medical records were reviewed to establish whether further investigations

### INTRODUCTION

Computed tomographic (CT) colonography allows the visualization of extracolonic organs, thereby permitting

the detection of potentially significant pathologies beyond the colon<sup>[1]</sup>. Extracolonic lesions are found in 15%-85% of cases, with some being important lesions, such as extracolonic cancer or aortic aneurysm<sup>[2,3]</sup>. However, most of the extracolonic lesions are of minimal importance and lead to further investigations and possibly procedures, with the final diagnosis being simple benign pathology<sup>[2]</sup>. Thus, the evaluation and management of extracolonic findings have been found to lead to significant additional cost, and the feasibility and cost-effectiveness of CT colonography needs to be carefully evaluated<sup>[4]</sup>.

Since multi-section helical CT colonography was first introduced in 1998, improvements such as faster scanning, improved temporal resolution and reduced motion artifacts have been implemented<sup>[5]</sup>. However, multidetector CT colonography has been described as a sort of Pandora's box, releasing a cascade of diagnostic events with medicolegal, ethical and economic implications<sup>[6]</sup>. Therefore, it would be helpful to clinicians if there were defined strategies for the clinical approach toward the detection of highly significant extracolonic lesions.

To the best of our knowledge, there has been no large multicenter study on extracolonic findings of CT colonography among Koreans. We therefore performed a multicenter study to assess the frequency and characteristics of extracolonic lesions detected with the aid of CT colonography. In addition, we surveyed the factors related to the detection of highly significant extracolonic findings, and analyzed its cost-effectiveness to determine which factors would enhance the potential benefits of CT colonography examination.

## MATERIALS AND METHODS

### Subjects

The results of CT colonographies performed from January 2005 to December 2006 at the authors' seven university hospitals in Korea were reviewed. Those who were diagnosed as having a malignancy at the time of the CT colonography, those under the age of 16 years and those with ethnicity other than Korean were excluded from the study.

Types and scanning parameters of multidetector array CT colonography are summarized in Table 1. The subjects underwent standard bowel preparation, and a rectal catheter was inserted. Air was used to distend the colon to maximum subject tolerance. Scout image was taken to confirm the adequacy of distention before each examination. Images were taken from the diaphragm to the symphysis with the subject in the supine and prone positions during a breath hold. Medical records were reviewed to establish whether further investigation was carried out pertaining to the extracolonic lesions that were detected by CT colonography during 1 year follow up period. This retrospective study was approved by the institutional review boards which confirmed that the

study was in accordance with the ethical guidelines of the Helsinki Declaration.

### Classification of extracolonic lesions

Extracolonic lesions were divided into three categories, according to previous reports<sup>[7,8]</sup>. Highly significant lesions include those requiring immediate surgical therapy, medical intervention, and/or further investigation. Examples of highly significant extracolonic lesions include a solid organ mass, adrenal mass greater than 3 cm, aortic aneurysm greater than 3 cm, lymphadenopathy greater than 1 cm, cardiomegaly, pericardial effusion, fistula, abscess and small-bowel infarction.

Lesions of intermediate significance include conditions that do not require immediate therapy but would likely require further investigation, recognition, or therapy at a later time. Examples of such extracolonic lesions include calculi, intermediate cysts, pulmonary fibrosis, inguinal hernia, uterine myoma, endometriosis, pelvic fluid collection, liver cirrhosis, liver hemangioma and bile duct dilatation.

Lesions of low significance include benign conditions that do not require further medical therapy or additional work-up. Examples of such extracolonic lesions include calcifications, granulomas, diverticulosis, simple organ cysts, hernias, pleural thickening, benign prostatic hypertrophy, accessory spleen, benign bony lesion, fatty liver, and renal infarction.

### Statistical analyses

Differences between the groups were analyzed using the chi-square test and Student's *t*-test. The age was expressed as mean  $\pm$  SD (standard deviation) values. Cost effectiveness was calculated by cost needed for detecting one highly significant lesion (cost of CT colonography  $\times$  total number of CT colonography/number of subjects with highly significant extracolonic lesions). Regression analysis was performed to assess the related factors in detecting extracolonic lesions according to their significance. A probability value of  $P < 0.05$  was considered statistically significant.

## RESULTS

### Characteristics of the subjects

A total of 920 consecutive subjects (men/women = 535/385) were analyzed. Their mean age ( $\pm$  SD) was 57.3  $\pm$  12.8 (range, 34-87). Of these, 692 extracolonic findings were found in 532 (57.8%) subjects (Table 2). Of the 692 extracolonic findings, 60 (8.7%) were highly significant, 250 (36.1%) were of intermediate significance, and 382 (55.2%) were of low significance (Table 3). Data regarding the examination, age, and sex distribution of each group are summarized in Table 4.

Of 920 subjects, 764 and 156 subjects were examined by CT colonography with and without the aid of contrast enhancement, respectively. Extracolonic lesions were found in 459 of the 764 subjects (60.1%)

Table 1 Characteristics of the study population

Hospital	Number of the subjects	Type of CT colonography	kVp	mAs	Pitch	Slice thickness/reconstruction interval for extracolonic finding (mm)
A	278	Sensation 64; Siemens, Erlangen, Germany	120	70	1.5	3/3

C	152	Sensation 16; Siemens, Erlangen, Germany	120	30	1	5/5
D	135	Brilliance 40-channel MDCT, Phillips Medical System, Netherlands	120	160	1.176	0.5/0.9
E	92	LightSpeed 16; GE healthcare, Milwaukee, Wis	120	200	1.375	1.25/3.75
F	65	MX 8000 IDT 16, Phillips Eindhoven, Netherlands	120	200	1	2/1
G	41	Sensation 16; Siemens, Erlangen, Germany	120	30	1	5/5

Table 2 Results of 920 computed tomographic colonoscopy examinations *n* (%)

Number of extracolonic findings	Number of subjects
0	388 (42.2)
1	403 (43.8)
2	105 (11.4)
3	19 (2.1)
4	5 (0.5)

examined with contrast enhancement, but in only 73 of the 156 subjects (46.8%) examined without contrast enhancement ( $P = 0.005$ ).

### Factors related to the clinical significance of extracolonic findings

The mean age was lower in cases without extracolonic findings (Table 4). With regard to indications for CT colonography, gastrointestinal symptoms were more common in those in whom significant lesions were detected (Table 4). Regression analysis revealed that, older age ( $P < 0.001$ ), being female ( $P = 0.001$ ), presence of symptoms ( $P < 0.001$ ), and the use of contrast during CT colonography ( $P = 0.003$ ) were associated with detection of the more significant extracolonic lesions.

### Additional evaluation and management of extracolonic findings

Table 5 lists the additional tests performed in each group. It can be seen that, 81.7% of highly significant subjects received further treatment, while such treatment was received in only 20.8% and 2.9% of subjects of intermediate and low significance, respectively.

### Cost of finding a highly significant extracolonic lesion

Since each CT colonography procedure costs US \$ 190 (180000 won) in Korea, US \$ 2905 (2760000 won) was needed to detect each highly significant lesion in our study (i.e. cost of CT colonography  $\times$  total CT colonography cases/number of subjects with highly significant extracolonic lesions). The following factors were found to be associated with poor cost-effectiveness: patient age below 60 years, lack of symptoms and use of CT colonography without contrast enhancement (Figure 1).

## DISCUSSION

In this study, extracolonic lesions were found in 532

Table 3 Proportion of extracolonic lesions according to the clinical significance

Extracolonic findings	Number
Highly significant ( <i>n</i> = 60)	
Solid organ mass including malignancy	42 <sup>1</sup>
Cardiomegaly/pericardial effusion	5
Lymphadenopathy greater than 1 cm	3
Peritoneal carcinomatosis	3
Abscess	3
Aortic lesion	2
Small bowel obstruction	2
Intermediately significant ( <i>n</i> = 250)	
Benign solid organ lesion	141 <sup>2</sup>
Renal stone/hydronephrosis	28
Gall bladder stone/polyp/cholecystitis	22
Liver cirrhosis	13
Bile duct stone/dilatation/hemobilia	9
Small bowel inflammation	8
Vascular lesion (aortic stenosis, varix, etc)	6
Bronchiectasis/emphysema	5
Hepatosplenomegaly	5
Pleural effusion	3
Inguinal hernia	3
Ascites of unknown cause	3
Chronic pancreatitis	2
Mesenteric fat necrosis	1
Spinal stenosis with destruction	1
Lowly significant ( <i>n</i> = 382)	
Renal cyst	143
Hepatic cyst	114
Fatty liver	39
Vascular calcification/atherosclerosis	19
Chronic pulmonary disease/pleural thickening	16
Accessory spleen/splenic infarction	15
Hepatic calcification	10
Benign osteolytic lesion	8
Hiatal hernia	6
Benign prostatic hypertrophy	5
Colonic diverticulosis	4
Tiny pancreas cyst	1
Mesenteric calcification	1
Gallbladder sludge	1

<sup>1</sup>Liver 9, lung 9, stomach 7, pancreas 3, kidney 3, bladder 3, adrenal gland 2, small bowel 2, bone 1, bile duct 1, psoas muscle 1 and ovary 1. <sup>2</sup>Liver 46, kidney 30, uterus 19, ovary 13, lung 9, adrenal gland 8, lymph node 7, muscle 4, pancreas 3, spleen 1 and testis 1.

out of 920 subjects (57.8%), which is consistent with previous studies reporting incidences of between 33% and 85%<sup>[2-4,6,8,9]</sup>. A substantial proportion of these lesions were insignificant, which led to further unnecessary workup and, hence, additional cost. Highly significant extracolonic lesions were detected in the present study

**Table 4** Baseline characteristics according to the clinical significance of extracolonic lesions *n* (%)

	Highly significant lesion ( <i>n</i> = 60)	Intermediately significant lesion ( <i>n</i> = 250)	Lowly significant lesion ( <i>n</i> = 382)	No extracolonic lesion ( <i>n</i> = 388)	<i>P</i> -value

in only 60 of 920 subjects (6.5%), which is slightly lower than the incidences found in previous studies. This discrepancy might be due to differences in the study population (ours included only Koreans), the definition of highly significant lesion used and the CT colonography conditions used. In our study, a solid organ mass suspicious of malignancy was detected in 42 of 920 (4.6%) subjects. Considering that substantial numbers of subjects undergoing CT colonography are found to have clinically important extracolonic findings, this would have positive effects on health care by undergoing additional evaluations<sup>[10]</sup>. The cost of a CT colonography in Korea, i.e. US \$190 (180000 won), is only US \$ 53 (50000 won) more expensive than colonoscopy. Therefore, CT colonography might be more attractive in Korea, since is it less expensive when compared with US<sup>[11,12]</sup>. Several studies have reported

**Figure 1** Cost of detecting highly significant extracolonic lesions. Cost-effectiveness was assessed using the following calculation for each group. Poor cost-effectiveness in the detection of highly significant lesions was observed for subjects aged below 60 year-old (US \$ 3442), subjects without symptoms (US \$ 3737), and CT colonography performed without contrast enhancement (US \$ 4221).

on a prospective cost-benefit analysis of diagnostic CT colonography<sup>[10,13]</sup>. Some reported low clinical relevant disease in average-risk asymptomatic adults<sup>[14]</sup>, while others revealed higher proportion of colon cancers in subjects with colonic symptoms<sup>[13]</sup>. We further tried to identify the factors associated with the more effective use of CT colonography by analyzing the cost of detecting highly significant extracolonic lesions. As expected, the prevalence of significant extracolonic lesions was higher in older subjects and those with gastrointestinal symptoms. Since our results suggest that significant extracolonic lesions can be anticipated at a higher

frequency in this population than in an asymptomatic younger population, they also contribute toward a better understanding of the selection of subjects who would benefit more effectively from CT colonography.

Apart from age and clinical symptoms, contrast enhancement was found to be advantageous in identifying extracolonic lesions on CT colonography. This demonstrates that some important extracolonic lesions might have been overlooked in non-contrast enhanced cases. The inability of low-radiation dose CT colonography to accurately define lesions in other organs also raises important medico-legal considerations<sup>[2]</sup>. Based on our findings, age, the presence of gastrointestinal symptoms and the use of contrast enhancement must be taken into account when deciding when to use CT colonography in routine clinical practice.

In the present study, 221 of 250 (88.4%) subjects with extracolonic lesions of intermediate significance were referred for further investigations, of which 52 (20.8%) received treatment, while 65 of 382 (17.0%) subjects with extracolonic lesion of low significance were referred for further investigations, of which only 11 (2.9%) received treatment. Because symptomatic subjects were included in our study, CT colonography was performed as a diagnostic evaluation as well as a screening tool. This would explain why further investigations frequently followed CT colonography. Our results indicate that further investigations pertaining to extracolonic lesions, other than those of high significance, benefit only a few and result in additional and unnecessary cost as a result of unnecessary workups.

The limitation of our study is that there were some differences due to inhomogenous settings. Different participating institutions used such relevant differences in study protocols: Slice thickness varies between 0.5 and 5 mm and mAs varies between 30 and 200. The radiation dose was in the range of 1.7-8.8 mSv, with a median of 3.9 mSv. It was comparatively larger than simple X-ray or plain abdomen with approximately 0.1 mSv. For example, the hospitals D, E and F used almost standard dose contrast, while slice thickness were less than 1 mm for extracolonic lesions at the hospitals B, D and F. However, when considering that the proportions of normal extracolonic findings were highest in hospital F (54.5%) > A (48.2%) > C (47.3%) > D (30.2%) > E (28.8%) > B (15.4%) > G (13.6%), slice thickness and standard dose are not predictive factors of the presence of extracolonic lesions. Another limitation concerns the number of false positive and false negative results of the exam. Since study populations have not been followed up periodically, correct false positivity and negativity could not be evaluated. However, subjects diagnosed as having significant extracolonic lesions received full evaluation and treatment for their lesions. Accordingly, false positivity of significant extracolonic lesions was nearly zero.

In conclusion, most of the extracolonic lesions detected by CT colonography were of low significance, and resulted in additional costly investigations. However,

CT colonography may demonstrate asymptomatic malignant disease requiring immediate treatment in older subjects and among those with symptoms, particularly when performed with contrast enhancement. Based on these results, CT colonography should be performed with contrast enhancement in symptomatic older subjects.

## COMMENTS

### Background

Currently, computed tomographic (CT) colonography is widely used in the clinical field to visualize colon and extracolonic lesions. Extracolonic lesions occur in 15%-85% of cases, with some being important lesions, such as extracolonic cancer or aortic aneurysm. The utilization of CT colonography will increase in clinical field, and research for availability, detection rate and cost-effectiveness of CT colonography is necessary.

### Research frontiers

Early detection of extracolonic lesions is an aim of CT colonography. In particular, the detection of significant lesions is very important. However, the incidence rates of significant extracolonic lesions vary from country to country, and most reports relate to the Western population. This is the first study focusing on the Asian population, where the incidence rate of colorectal disease is lower than in the Western population.

### Innovations and breakthroughs

In recent reports, cost-effectiveness of CT colonography was calculated in US dollars, because most studies were carried out in the USA. However, the cost of CT colonography varies according to different countries. This study evaluated its cost-effectiveness taking into consideration the specific medical system of the country. In addition, optimal methods to detect significant extracolonic lesions were evaluated. This study showed that the selective use of CT colonoscopy (for symptomatic elderly and with contrast enhancement) shows a good cost-effectiveness.

### Applications

Use of CT colonography is currently rising due to its various functions. However, cost of CT colonography is comparatively high, and clinical availability is being evaluated. This study is helpful to clinicians to determine the best way to use the CT colonography for detecting highly significant extracolonic lesions.

### Terminology

Multi-section helical CT colonography was first introduced in 1998. There have many improvements such as faster scanning, improved temporal resolution, and reduced movement artifacts. Various approaches were tried to increase the effectiveness of CT colonography, and contrast enhancement is recommended as a good strategy if it is applied to an ideal case.

### Peer review

The authors examined the cost-effectiveness of CT colonography for various Korean patients, and proposed how to optimize the use of CT colonography. Considering the rising application of CT colonography to the medical field, this study will provide a good basis to guide its use.

## Abstract

**AIM:** To define the topography of mast cells and their numbers in cases of Hirschsprung's disease (HD) and non-HD, assess neural hypertrophy using imaging software and to study the relationship between mast cells and nerve fibers.

**METHODS:** HE stained sections of 32 cases of chronic constipation in the age group of 0-14 years were reviewed for ganglion cells. AChE staining was performed on frozen sections of colonic and rectal biopsies. Based on their findings cases were divided into HD and non-HD and mast cells stained by toluidine blue were evaluated. Image analysis by computerized software was applied to S-100 stained sections for assessment of neural hypertrophy.

**RESULTS:** Difference between number of mast cells in HD group (mean = 36.44) and in non-HD group (mean = 14.79) was statistically significant. Image analysis morphometry on S-100 stained sections served as a useful adjunct. The difference between number, size, and perimeter of the nerve fibers between HD and non-HD group was statistically significant.

**CONCLUSION:** Mast cells are significantly increased in HD and their base line values are much higher in

## INTRODUCTION

Constipation is a common presenting complaint in children attending the pediatric outpatient department<sup>[1]</sup>. Some 13%-15% cases of constipation are due to aganglionosis of bowel segment or Hirschsprung's disease (HD). HD is a serious disorder and can be fatal if left untreated. The disease is however, surgically correctable, underscoring the need to identify these cases.

HD has an incidence of 1 in 5000 neonates in Western literature and a male to female predominance of 4:1. Although there are no statistical figures available from India, a large number of studies in Indian literature suggest that the disorder is not uncommon in our country<sup>[2-4]</sup>.

Of late there has been a lot of interest in the role of mast cells (MC) in the pathogenesis of Hirschsprung's disease. Kobayashi *et al*<sup>[5]</sup> have found an increased number of mast cells in aganglionic bowel segments and in those with intestinal neuronal dysplasia. The exact role of mast cells in HD is not known. Therefore we undertook this study to evaluate the relationship between mast cells and nerve fibers in HD cases to shed some light on this issue. We have used image analysis morphometry to analyze nerve fibers stained with S-100 and correlated the findings with mast cell numbers.

There are only a couple of studies on mast cells in

HD in the literature<sup>[5-7]</sup>. There is however no study from India on mast cells in children with HD or constipation. As children in a developing country like India are more likely to be exposed to inflammatory stimuli like bacterial and viral antigens and pollutants/allergens as compared to their Western counterparts, an increase in mast cells was expected in the intestines. The cells were assessed in children with constipation, with an emphasis on HD, to ascertain their distribution in the colonic and rectal biopsies.

## MATERIALS AND METHODS

The study was conducted in the departments of Pathology and Surgery, University College of Medical Sciences and GTB Hospital, New Delhi.

### Selection criteria

Thirty two cases of chronic constipation (defined as decreased frequency of bowel movements “fewer than three each week” or a difficulty in defecation perceived by the parents as a problem that requires medication or manual intervention<sup>[1]</sup>) in the age group of 0-14 years were enrolled for the study. Cases of constipation due to local causes like anal fissure, anal stenosis and anterior perineal anus were excluded from the study.

The criterion used for diagnosis of HD in all of the HD cases was absence of ganglion cells upon evaluation of Haematoxylin & Eosin (HE) stained sections of colonic and rectal biopsies. Acetylcholinesterase (AChE) stain for the nerve fiber pattern was carried out in 12 cases. Based on the findings of HE and AChE they were divided into two groups: Group I - HD and Group II -non-HD. Group I -HD included 11 rectal biopsies and 7 resection specimens. Group II -non-HD included 14 rectal biopsies. Rectal biopsies obtained were rectal punch biopsies. Mucosa and submucosa was available for review in all the cases. Muscularis propria was available in resection specimens only.

Toluidine blue stain was performed on paraffin sections of all the cases to evaluate mast cells. Immunohistochemical stain for S-100 was also performed on 12 HD cases & 8 non-HD cases.

### Acetylcholinesterase stain

Ten micrometer thick sections cut on the cryostat were fixed by dipping in buffered formalin for 1-2 min, preserved by wrapping them in aluminium foil and stored at -20°C in a deep freezer till the time of staining. Stock solutions of various ingredients of incubation medium were kept at 4°C and the incubation medium was prepared just before staining. AChE stain was performed using modified Karnovsky and Roots method as described previously<sup>[8]</sup>. Incubation medium was prepared by mixing 0.1 mol/L sodium hydrogen maleate buffer 6.5 mL (pH 6.0), 0.1 mol/L sodium citrate 0.5 mL, 30 mmol/L copper sulphate 1.0 mL, 5 mmol/L potassium ferricyanide 1.0 mL, water 1.0 mL and acetylthiocholine iodide 5 mg. The sections were incubated at 37°C for 20 min in the incubation medium. Thereafter, the incubation medium

was drained off and re-incubation with rubanic acid solution was performed for 10 min. Rubanic acid solution was prepared by mixing absolute alcohol 10 mL, sodium acetate 6.55 g, rubanic acid 10 mg and distilled water 40 mL. Thereafter, the sections were counterstained with haematoxylin, dehydrated, cleared and mounted in DPX.

### Toluidine blue

Toluidine blue staining on paraffin sections was performed using a simple toluidine blue method that required incubation of sections in 1% aqueous solution of toluidine blue and mounting in a water based medium. Mast cells were counted in five successive high power fields ( $\times 400$ ) in the submucosa.

### S-100 Stain

Immunohistochemical stain for S-100 (Dako Corporation) was performed on HD (12 cases) and non-HD (8 cases) by the standard immunoperoxidase technique. The nerve fibers that stained positive for S-100 were counted in five high power fields ( $\times 400$ ) in the submucosa.

### Image analysis

Images of relevant areas in S-100 stained slides were captured using a digital camera. They were subsequently analyzed using the Scion image analysis software (www.scioncorp.com). The size and perimeter of the thickest nerve fiber in the submucosa was measured. The number, size and perimeter of nerve fibers were correlated with mast cell number in both the groups.

### Statistical analysis

Statistical analysis was performed by the chi-square and student *t*-test and correlation assessed by Pearson's correlation coefficient.

## RESULTS

A total of 32 cases of chronic constipation in children below 14 years were studied. Based on the findings of HE and AChE stained sections of colonic and rectal biopsies, they were divided into two groups: Group I - HD and Group II -non-HD. Group I -HD included 18 cases and Group II -non-HD included 14 cases.

The age of the patients ranged from 1 mo to 84 mo in the HD group (mean  $\pm$  2 SD = 26.78  $\pm$  36.72 mo). Maximum numbers of cases were found in the age group 36-47 mo in this group. In the non-HD group, age ranged from 6 d to 96 mo (mean  $\pm$  2 SD = 26.64  $\pm$  49.60 mo), maximum cases in this group being in the age group of 0-11 mo. Male to female ratio was 17:1 in the HD group and 4:3 in the non-HD group.

There was statistically no significant difference in the age distribution between the two groups ( $P = 0.8$ ). The difference in sex distribution between the two groups was statistically significant, the patient population in the HD group having a distinct male bias ( $P = 0.01$ ).

### Mast cells

The data obtained after evaluation for mast cells are

**Figure 1** Perineural and intraneural mast cells ( $\times 200$ ) are increased in HD patients (A) compared to non-HD patients (B). (Toluidine blue,  $\times 200$ ).

**Figure 2** Increased number of mast cells in perivascular distribution ( $\times 400$ ) in HD case (A) as compared to non-HD case (B) showing an occasional mast cell ( $\times 400$ ) only. (Toluidine blue).

**Figure 3** Hypertrophic nerve fibers in submucosa ( $\times 100$ ) in HD case (A) as compared to small and thin nerve fibers (black arrows,  $\times 100$ ) in non-HD case (B). (S-100).

**Figure 4** Hypertrophic nerve fiber in submucosa surrounded by mast cells. (S-100,  $\times 400$ ).

summarized in Table 1. There was a statistically significant difference in the number of MC between HD (mean  $\pm 2$  SD =  $36.44 \pm 36.02$ ) and non-HD (mean  $\pm 2$  SD =  $14.79$

$\pm 19.8$ ) ( $P = 0.0001$ ). The mast cells were distributed transmurally (An observation in resection specimens of HD cases. Statistical analysis could not be done due to small sample size) and were notably present around the nerve fibers (Figure 1) and perivascularly (Figure 2). The number of mast cells in HD as well as in non-HD cases was significantly higher than previous studies (Table 2).

#### S-100

S-100 immunohistochemistry was performed on 20 cases consisting of 12 HD and 8 non-HD cases (Table 3). The number of nerve fibers in the submucosa (Figure 3) of HD (mean  $\pm 2$  SD =  $11.17 \pm 6.18$ ) cases was higher than in non-HD (mean  $\pm 2$  SD =  $5.13 \pm 7.66$ ) cases. The difference between the two groups was statistically significant ( $P = 0.0001$ ). S-100 also stained the mast cells (Figure 4).

#### Image analysis

Size of the nerve fibers in HD group was mean  $\pm 2$  SD

**Table 1** Mast cells in Hirschsprung's disease (HD) and non-HD cases

HD cases				Non-HD cases

HD (mean  $\pm$  2 SD =  $36.44 \pm 36.02$ ) and non-HD (mean  $\pm$  2 SD =  $14.79 \pm 19.8$ ) [(HD vs non-HD)  $P = 0.0001$ ].

=  $57.18 \pm 24.86 \mu\text{m}$  and in non-HD group it was mean  $\pm$  2 SD =  $31.03 \pm 39.08 \mu\text{m}$ . The difference between the two was statistically significant ( $P = 0.0001$ ). The perimeter of nerve fiber in HD group was mean  $\pm$  2 SD =  $201.89 \pm 88.78 \mu\text{m}$  and in non-HD group was mean  $\pm$  2 SD =  $113.26 \pm 141.18 \mu\text{m}$ . This difference between the two groups was also statistically significant ( $P = 0.0001$ ) (Table 2).

### Mast cells and nerve fibers

We correlated each of the parameters obtained by image analysis morphometry of the nerve fibers with MC number. In the HD group it was observed that maximum correlation was seen with number of nerve fibers (correlation coefficient = 0.467). No correlation was seen with size of nerve fibers (correlation coefficient = -0.131) and some correlation was observed with the perimeter of nerve fibers (correlation coefficient = 0.274). In the non-HD group the respective values were 0.406, 0.304 and 0.157.

## DISCUSSION

Recently there has been a lot of interest in the role of mast cells in HD. Kobayashi *et al*<sup>[5]</sup> described an increased number of mast cells in the aganglionic segment of the colon in patients with HD. The number of these cells in transitional segments was significantly less compared with ganglionic segments in HD patients and controls. Similar findings were reported by Demirbilek *et al*<sup>[6]</sup>.

In the present study, mast cells were evaluated in rectal biopsies as well as in resected specimens from cases of HD and non-HD. Although the mast cells can be roughly estimated after HE staining, an exact count is obtained by

**Table 2** Comparison of mast cells in submucosa of HD and non-HD cases with previous studies

Mast cells per 5 hpf in submucosa		Kobayashi <i>et al</i> <sup>[5]</sup>	Demirbilek <i>et al</i> <sup>[6]</sup>	Present study
HD cases	Aganglionic segment	23.9 $\pm$ 6.6	18.2 $\pm$ 3.3	36.36 $\pm$ 39.58
	Ganglionic segment	8.5 $\pm$ 3.9	1.7 $\pm$ 0.4	38 $\pm$ 16.66
Non-HD cases		7.2 $\pm$ 3.4	5.4 $\pm$ 1.2	14.8 $\pm$ 5.3

Aganglionic segment (Kobayashi *et al* vs Present study,  $P = 0.0001$ ; Demirbilek *et al* vs Present study,  $P = 0.0001$ ); Ganglionic segment (Kobayashi *et al* vs Present study,  $P = 0.0001$ ; Demirbilek *et al* vs Present study,  $P = 0.0001$ ); Non HD cases (Kobayashi *et al* vs Present study,  $P = 0.0001$ ; Demirbilek *et al* vs Present study,  $P = 0.0001$ ).

special histochemical methods. Other authors<sup>[5]</sup> have used immunohistochemical detection of anti-MC antibody to demonstrate MC. In our study, these were studied by a simple and effective toluidine blue staining which requires a time as short as one minute incubation. A significant increase was noticed in the number of mast cells in HD as compared with the non-HD cases. The HD cases showed a transmural distribution of these cells as described in the previous two studies by Kobayashi *et al*<sup>[5]</sup> and Demirbilek *et al*<sup>[6]</sup>. However, in a recent study Hermanowicz *et al*<sup>[7]</sup> found them to be increased in the mucosa and lamina propria but the increase in mast cells in the submucosa, muscularis propria and serosa was not statistically significantly changed.

The mast cells were characteristically distributed around the nerves and blood vessels in addition to being randomly scattered. In our study the baseline number of the mast cells (i.e. number of mast cells in non-HD cases) was much higher than previous studies<sup>[5,6]</sup> (Table 2) and few mast cells were also seen in the ganglionic segment. This may be due to the response of the mast cells to infectious agents or allergens rather than their association with aganglionosis. An increased number of mast cells is also reported in various other gastrointestinal disorders such as acute appendicitis, ulcerative colitis, celiac disease and gluten enteropathy<sup>[9,10]</sup>. They are seen to be in apposition to the nerves<sup>[11]</sup> and are known to secrete substances like nerve growth factor<sup>[12]</sup>.

We also correlated each of the parameters obtained by image analysis morphometry of the nerve fibers with MC number. It was observed that maximum correlation was seen with number of nerve fibers (correlation coefficient = 0.467). No correlation was seen with size of nerve fibers and some correlation was observed with the perimeter of nerve fibers (correlation coefficient = 0.274). This correlation has not been shown in any previous study. This suggests that mast cells via their mediators may cause increased number of nerve fibers and affect size of nerve fibers to some extent. The interactive role of mast cells, their nerve growth factor secretion and neural hypertrophy as suggested by morphology is not explained by the studies to date.

**Table 3** Number, size and perimeter of nerve fibers in HD and non-HD cases

S. No.	HD cases					Non-HD cases				
	Age (mo)	Sex	No. of nerve fibers	Size of nerve fibers (μm)	Perimeter of nerve fibers (μm)	Age (mo)	Sex	No. of nerve fibers	Size of nerve fibers (μm)	Perimeter of nerve fibers (μm)
1	42	M	13	40.37	230.48	36	M	3	42.5	215.7
2	12	F	8	68.0	195.9	1	M	2	11.2	37.0
3	36	M	11	65.4	172.8	5	M	4	15.3	47.3
4	84	M	7	47.3	135.4	1	M	4	15.0	51.8
5	48	M	16	63.5	288.75	1	F	3	40.6	135.56
6	36	M	10	77.38	237.79	30	F	3	25.0	126.67
7	48	M	12	57.5	256.11	4	M	9	28.8	83.2
8	36	M	14	40.7	149.3	13	M	13	69.9	208.09
9	12	M	6	55.5	190.03					
10	24	M	11	47.6	184.08					
11	1	M	15	49.6	178.18					
12	60	M	11	73.4	203.9					

Number of nerve fibers (HD vs non-HD),  $P = 0.0001$ ; Size of nerve fibers (HD vs non-HD),  $P = 0.0001$ ; Perimeter of nerve fibers (HD vs non-HD),  $P = 0.0001$ .

The exact role of these cells in the pathogenesis of HD needs further research with focus on the enteric nervous system, its development and the role of MC in cases where ganglion cells are absent.

The neural hypertrophy in the colonic submucosa is associated with aganglionosis and is a surrogate marker for the disease. The thickness of submucosal nerve fibers has been measured by various authors in previous studies<sup>[13,14]</sup>. However, they have used less objective methods for measurement such as image graticules. In this study, we analyzed the status of the nerve fibers after S-100 immuno-staining and examination using an objective technique provided by image analysis software. The number, size and perimeter of the nerve fibers in the colonic submucosa of HD and non-HD cases were measured and results compared between HD and non-HD cases. The difference between the two groups was statistically significant for all the three parameters. Thus image analysis can be a useful adjunct to the available tools for the diagnosis of HD.

In conclusion, mast cells appear to have a significant role in the pathogenesis of Hirschsprung's disease. Their increased baseline number in Indian children may be a response to additional factors like allergens or antigenic components of infectious agents. The role of anti-mast cell reagents like sodium cromoglycate needs to be explored with regard to constipation in Indian children. The fact that Indian children with HD present at a later age is also significant and emphasizes the need for a different approach to disease in various geographical regions.

## COMMENTS

### Background

Hirschsprung's disease is an important cause of constipation in children. It is a serious disorder and can be fatal if left untreated. Recently, there has been a lot of interest in the role of mast cells in the pathogenesis of Hirschsprung's disease. A few studies have found increased number of mast cells in aganglionic bowel segments of Hirschsprung's disease cases. However the exact role of mast cells in Hirschsprung's disease is not known.

### Research frontiers

Mast cells are normally present in small numbers in various organs of the body.

They have been reported to be increased in a number of conditions other than Hirschsprung's disease. Regarding the role of mast cells in Hirschsprung's disease, the research hotspot is to elucidate the exact role played by them in the pathogenesis of Hirschsprung's disease and the relationship between mast cells and the neural hypertrophy observed in Hirschsprung's disease.

### Innovations and breakthroughs

Previous studies on the role of mast cells in the pathogenesis of Hirschsprung's disease have described an increased number of mast cells in the aganglionic segment in patients with Hirschsprung's disease. Apart from one article, other studies have found mast cells to be increased transmurally. In the present study a significant increase was also noticed in mast cells in Hirschsprung's disease. However their number was significantly higher than previous studies. This may be due to the response of the mast cells to infectious agents or allergens rather than their association with aganglionosis. The authors also performed image analysis morphometry and correlated each of the parameters obtained with mast cell number. It was observed that maximum correlation was seen with number of nerve fibers. No correlation was seen with size of nerve fibers and some correlation was observed with the perimeter of nerve fibers. This correlation has not been shown in any previous study. This suggests that mast cells via their mediators may cause increased number of nerve fibers and affect size of nerve fibers to some extent.

### Applications

The study suggests mast cells appear to have a significant role in the pathogenesis of Hirschsprung's disease. Whether this fact can be exploited to open novel therapeutic options in the management of this disease is something which needs to be looked at in the future.

### Terminology

Hirschsprung's disease is a congenital condition characterized by dilatation and hypertrophy of colon due to absence (aganglionosis) or marked reduction (hypoganglionosis) of ganglion cells of the myenteric plexus of the rectum and a varying but continuous length of colon above the rectum. Mast cells are connective tissue cells with cytoplasmic coarse metachromatic granules and their normal function is unknown.

### Peer review

This article only contributes minimal new information to the literature (morphometry or S-100 stained nerve fibers), but it reinforces the observation that mast cells are increased in patients with HD and reports this finding in Indian children for the first time.

### Abstract

**AIM:** To investigate the prognostic significance of phosphatase regenerating liver 3 (PRL-3) protein expression in gastric cancer.

**METHODS:** PRL-3 expression in paraffin-embedded tumor specimens from 293 patients with gastric cancer was studied retrospectively by immunohistochemistry. Monoclonal antibody specifically against PRL-3, 3B6, was obtained with hybridoma technique.

**RESULTS:** Positive PRL-3 expression was detected in 43.3% (127 of 293) of gastric cancer cases. High expression of PRL-3 was positively correlated with tumor size, depth of invasion, vascular/lymphatic invasion, lymph node metastasis, high TNM stage and tumor recurrence. Patients with positive PRL-3 expression had a significantly lower 5-year survival rate than those with negative expression (28.3% vs 51.9%,  $P < 0.0001$ ). Patients who received curative surgery, and with positive PRL-3 expression had a significant shorter overall survival and disease-free disadvantage over patients with negative expression (hazard ratio

of 16.7 and 16.6, respectively;  $P < 0.0001$  for both). Multivariate analysis revealed that PRL-3 expression was an independent prognostic indicator for overall and disease-free survival of gastric cancer patients, particularly for survival in TNM stage III patients.

**CONCLUSION:** PRL-3 expression is a new independent prognostic indicator to predict the potential of recurrence and survival in patients with gastric cancer at the time of tumor resection.

### INTRODUCTION

Gastric cancer (GC) is one of the most common malignancies in the world with a high incidence and death rate. In China, it remains the most frequent cancer and the second cancer-related cause of death with a high case fatality<sup>[1]</sup>. TNM staging system is used worldwide to predict prognosis and direct therapeutic decisions of patients with GC. The 5-year survival rate in patients with stage I GC is close to 90% and around 10% for patients with stage IV GC<sup>[2]</sup>. However, the prognoses of patients with stage II and III GC are more heterogeneous and less predictable by staging criteria. Therefore, finding molecular markers that are able to predict the potential of tumor recurrence and prognosis of patients is extremely important for appropriate individualized therapy. Phosphatase regenerating liver 3 (PRL-3) (also known as PTP4A3) belongs to a newly

discovered group of phosphatase regenerating liver family which is implicated in oncogenic and metastatic processes<sup>[3,4]</sup>. The PRL family represents a protein tyrosine phosphatase superfamily possessing a unique COOH-terminal prenylation motif and a protein tyrosine phosphatase-active site signature sequence CX5R<sup>[5,6]</sup>. Three PRLs (PRL-1, -2, and -3) are highly homologous with similar amino acid sequence of 76%-87%<sup>[7-9]</sup>. Recent reports found that PRL-3 was consistently expressed at higher level of metastasis in liver compared to normal colorectal epithelia and primary cancer tissues<sup>[10,11]</sup>. A growing body of evidence showed that an excess of PRL-3 phosphatase is a key alteration contributing to the acquisition of metastatic properties of the tumor cells. For example, nontumorigenic or low metastatic cell lines transfected with wild type PRL-3 displayed higher cell motility and invasiveness and could induce metastatic tumor formation in mice, while cells expressing catalytically inactive mutant PRL-3 significantly reduced the migratory capability<sup>[12,13]</sup>. Knockdown of endogenous PRL-3 in cancerous cells using small interfering RNA or phosphatase inhibitors can abrogate cell motility and the ability to form metastasis-like tumors in mice<sup>[12-15]</sup>. PRL-3 was further demonstrated to be a useful indicator for tumor recurrence and patient outcome in several human cancers including colorectal cancer and breast cancer<sup>[16-19]</sup>. In gastric cancer, PRL-3 was found to be highly expressed in tumor metastatic lymph nodes and closely associated with the peritoneal metastasis<sup>[20-23]</sup>, but the prognostic impact of PRL-3 expression in gastric cancer still remains to be further investigated.

In this study, we detected the expression of PRL-3 in GC tissue samples by immunohistochemistry using a PRL-3 specific monoclonal antibody 3B6 to investigate PRL-3 protein expression in GC tissues and whether PRL-3 could be applied as a prognostic indicator for GC to predict the potential of tumor recurrence and patient outcome.

## MATERIALS AND METHODS

### Patients

This retrospective study enrolled patients who underwent clinical surgery for primary gastric cancer at the Department of Surgery, Beijing Cancer Hospital, Peking University School of Oncology between July 1994 and December 2000. Patients with inadequate histologic specimens or missing clinical information were excluded. A total of 293 patients were finally included. There were 194 males and 99 females, with ages ranging from 25 to 82 (mean  $\pm$  SD, 58  $\pm$  17.1 years). Two hundred (68.3%) patients received curative resection (R0) with radical lymph node dissection; the remaining 93 (31.7%) patients with microscopic or macroscopic tumor residues were given palliative resection (R1/R2). Site distribution of the primary tumor was 153 at antrum, 52 at cardia or fundus, and 88 at corpus. Tumor size ranged from 5 to 120 mm (mean, 43.8 mm).

### Histology

Data were collected from clinical case report record and follow-up database. Tumor staging was based on the clinical evaluation and postoperative pathological reports. TNM staging was on the basis of the 1997 fifth edition of AJCC/UICC TNM staging criteria for gastric cancer<sup>[24]</sup>. The tumors were histologically classified according to the WHO classification criteria.

### Follow-up

None of these patients had received radiotherapy or chemotherapy preoperatively. All the patients were followed up at regular intervals of 6 mo after surgery until June 2006 with a minimum of five years. Tumor recurrence was clinically defined as the reappearance of tumor after curative surgery. The overall survival time was calculated from the date of surgery to the date of last visit or death and the disease-free survival time from the date of resection to relapse.

### Immunostaining of PRL-3

Tumor tissue specimens from the 293 patients were routinely fixed in 10% formalin and embedded with paraffin. Paraffin embedded tissue samples were cut into 4  $\mu$ m sections. The sections were put in an oven at 60°C for 5 h and cooled down overnight before they were deparaffinized in xylene. The sections were then dehydrated in a graded ethanol series, and treated with 3% hydrogen peroxide solution for 10 min to block endogenous peroxidase activity. Antigen retrieval was performed by microwaving the sections in 1 mmol/L EDTA (PH 8.0) for 15 min. PRL-3 monoclonal antibody 3B6 (a generous gift from Prof. Shou, Beijing Institute for Cancer Research, China)<sup>[25]</sup> was used as the primary antibody at a dilution of 1:100 overnight at 4°C. The Powervision two-step histostaining reagent PV-6002 (Dako, Glostrup, Denmark) was applied as the secondary antibody. The sections were visualized with diaminobenzidine and counterstained with hematoxylin. Each incubation step was followed by washing with phosphate-buffered saline. For negative control, the primary antibody was omitted from the reaction sequence. Sections of liver metastasis from colon cancer with known strong PRL-3 immunoreactivity were used as positive controls. The number of tumor cells with cytoplasm staining of PRL-3 was counted without knowledge of the clinicopathological data, and > 5% positive tumor cells were defined as positive PRL-3 expression<sup>[19]</sup>.

### Statistical analysis

Statistical analyses were performed with SAS 8.1 software. The  $\chi^2$  test was used to analyze the association between PRL-3 expression and clinicopathological features of GC. Cumulative survival rates and differences in survival curves were estimated by Kaplan-Meier method with the log-rank test. The effect of PRL-3 on survival was analyzed using the Cox proportional hazard regression model adjusted for clinical and histopathologic features. Two-sided *P* values

of less than 0.05 were considered to be statistically significant.

## RESULTS

### Patient outcome

Forty-two patients were classified as stage I, 52 as stage II, 99 as stage III and 100 as stage IV. A total of 194 cases were poorly differentiated, 69 cases were moderately differentiated and the remaining 30 cases were well differentiated.

The follow-up period for survivors ranged from 2 to 120 mo (median, 31 mo). The 5-year overall survival rate was 41.7% in the entire cohort of patients, 92.9% in stage I, 72.5% in stage II, 32.5% in stage III and 12.3% in stage IV patients. One hundred and five patients remained alive and disease-free, 15 patients were alive with disease. One hundred and seventy patients died

of GC, and 3 patients died of other causes. Among the 200 patients who received curative surgery, 23 patients had tumor recurrence with 3 in peritoneum, 3 in lymph node, 7 in liver, 3 in other organs (2 ovarian, 1 lung), 4 in multiple organs and 3 in remnant stomach.

### PRL-3 expression in GC and its relation with clinicopathological features

PRL-3 immunostaining was predominantly localized in the cytoplasm of normal or tumor epithelial cells. PRL-3 stained cells in normal epithelia were mainly observed in the neck of gastric glands (Figure 1). Among the 293 GC specimens analyzed, 127 (43.3%) tumors had positive PRL-3 expression. The rate of positive PRL-3 expression was significantly higher in stage III and IV than in stage I and II (48.7% vs 31.9%,  $P = 0.007$ ). High expression of PRL-3 was correlated closely with large tumor size, depth of invasion in gastric wall, lymph node metastasis, vascular/lymphatic invasion and recurrent frequency. No significant correlation was observed between PRL-3 expression and sex, age, distant metastasis, grade of differentiation and surgical curability (Table 1).

### Univariate survival analysis of prognostic impact of PRL-3 expression

Kaplan-Meier method with log-rank test revealed that patients with positive PRL-3 expression had a significantly lower cumulative 5-year overall survival rate than those with negative expression (28.3% vs 51.9%,  $P < 0.0001$ ). Among the 99 patients with stage III GC, those with positive PRL-3 expression had a lower survival rate than those with negative expression (18.6% vs 43.2%,  $P = 0.0004$ , Figure 2). Among the 200 patients who received curative surgery, patients whose tumor had positive PRL-3 expression had worse disease-free status and poorer overall survival (hazard ratio, 16.6 and 16.7 respectively;  $P < 0.0001$  for both) than those with negative expression (Figure 3). Among patients who received palliative resection or patients in stages other than stage III, PRL-3 showed no significant correlation with prognosis.

### Multivariate survival analysis of prognostic impact of PRL-3 expression

Multivariate analysis by extended Cox regression model revealed that PRL-3 expression remained an independent prognostic factor after adjusting for sex, age, tumor location, tumor size, depth of invasion, lymph node metastasis, distant metastasis, TNM staging, vascular/lymphatic invasion, and surgical curability. PRL-3 expression was a significantly independent prognostic factor for the overall survival of all 293 GC patients. For the 200 patients who received curative resection, PRL-3 expression was found to be an independent prognostic factor for both disease-free and overall survival. The results are shown in Table 2.

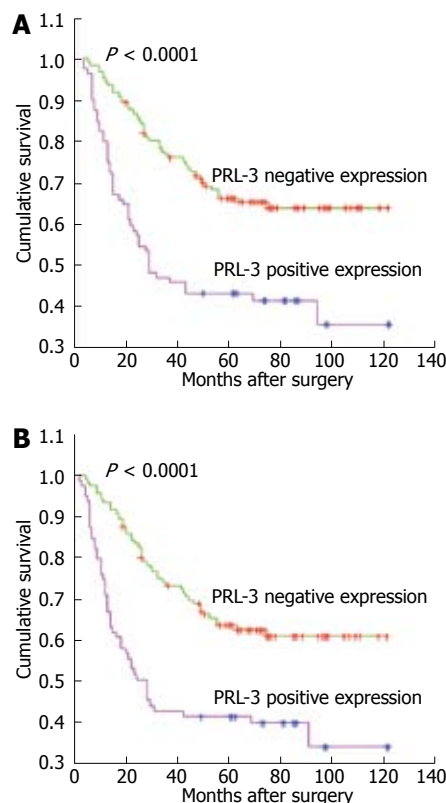

## DISCUSSION

In this study, we detected the protein expression

**Figure 1** Immunohistochemical staining. A: PRL-3 is negative or weak in adjacent (3 cm away from the tumor) normal gastric epithelial mucosa ( $\times 40$ ); B: In positive cases, PRL-3 expression in cancer cell cytoplasm is strong ( $\times 200$ ).

**Figure 3** Patients who underwent curative surgery. A: Overall survival; B: Disease-free survival. Significant differences were observed between the PRL-3 negative and positive groups.

**Figure 2** Overall survival curve. A: Entire cohort of 293 patients; B: Patients with stage III. Significant differences were observed between the two groups with PRL-3 negative and positive expression.

of PRL-3 in GC tissues using the highly specific monoclonal antibody 3B6 prepared by Peng *et al.* PRL-3

had higher rates of positive expression in advanced stages and PRL-3 expression was positively correlated with tumor size, depth of invasion, and lymph node metastasis vascular/lymphatic invasion at the time of surgery and recurrence. These results suggest that PRL-3 may play a crucial role in invasion, progression and metastasis of GC. The present analyses revealed that PRL-3 was an independent prognostic indicator for overall and disease-free survival of GC. Among patients with advanced TNM stages especially stage III, patients with positive PRL-3 expression have more frequent recurrence and poorer survival, adjuvant therapies such as radiotherapy and chemotherapy may be necessary after curative surgery. Evaluation of PRL-3 expression status may identify a subset of patients with GC who require more intensive treatment.

Miskad *et al.*<sup>[20]</sup> reported that PRL-3 was highly expressed in metastatic lymph nodes of GC and high expression of PRL-3 was closely associated with tumor stage. Wang *et al.*<sup>[21]</sup> found that the high expression of PRL-3 in lymph node metastases had a negative impact on the prognosis of patients with GC. Li *et al.*<sup>[22-23]</sup> reported that PRL-3 expression was correlated with peritoneal metastasis and poor prognosis in GC patients. The superiority of our study may be the use of antibody specifically against PRL-3 and the relatively extensive clinical data which facilitated the analysis from multiple angles. One limitation of our study is that the relatively small sample hindered the analysis in stage I and stage II patients.

PRL-3 expression, positive *vs* negative; T: Depth of invasion, T3-4 *vs* T1-2; N: Lymph node metastasis, present *vs* absent; D: Tumor size,  $\geq 5$  cm *vs* < 5 cm; S: Surgical curability, palliative *vs* curative.

Attributed to the high sequence similarity of three PRLs and the wide expression of PRL-1 and PRL-2 in normal tissues and cancer cell lines, commercial polyclonal antibody against PRL-3 used in previous studies could potentially cross-react with PRL-1 and PRL-2. Monoclonal antibody specifically reacting with PRL-3 is extremely important to exclude the interference of PRL-1 and PRL-2 and therefore allows us to accurately evaluate the prognostic implication of PRL-3 expression<sup>[25,26]</sup>. To prepare specific PRL-3 monoclonal antibody, Peng *et al*<sup>[25]</sup> obtained the monoclonal antibody 3B6 with hybridoma technique, and confirmed its specificity with ELISA and Western blotting assays. High specificity of the monoclonal antibody 3B6 against PRL-3 was demonstrated. The applicability of the monoclonal antibody has been further confirmed by two other studies investigating the prognostic impact of PRL-3 expression in colorectal cancer and breast cancer<sup>[16,19]</sup>.

PRL-3 has been confirmed to be an important metastatic instrumental molecule. Although the actual signal transduction pathways in which PRL-3 is implicated are largely unknown, Rho signaling pathway molecules which are regulators of motility and invasion have been identified as potential candidate targets of PRL-3. PRL-3 transfectants displayed altered extracellular matrix adhesive property and up-regulated integrin-mediated cell spreading efficiency<sup>[14,27]</sup>. Peng *et al*<sup>[28]</sup> recently found that PRL-3 activates the mitogen-associated protein kinase pathway by binding a cell membrane protein in cell migration and invasion. PRL-3 was also found to be associated with membrane structures including ruffles, protrusions, and some vacuolar-like membrane extensions which have been demonstrated to play a role in cell movement and invasion<sup>[29-31]</sup>. Besides, PRL-3 may be involved in triggering angiogenesis and establishing microvasculature *in vitro*<sup>[32-34]</sup>. These findings suggest that PRL-3 may be implicated with the key steps of tumor metastasis including tumor cell invasion and survival in circulation and vasculature formation.

In addition to its role in predicting tumor recurrence and prognosis, PRL-3 has a potential value of being a candidate for metastasis tailored therapies. Since primary tumors can be surgically resected, the metastatic tumors are the main cause responsible for a high case fatality. PRL-3 was highly expressed in tumor metastasis and

found to play a key role in tumor metastatic process<sup>[10-21]</sup>. PRL-3 may serve as a potential therapeutic target for cancer metastases. Inhibition of PRL activity might be carried out using phosphatase inhibitors targeting the consensus phosphatase motif, farnesyltransferase inhibitors, interference RNA or monoclonal antibody as well<sup>[9,35-37]</sup>. Recent progress in active recombinant PRL-3 production and findings on PRL-3 structure will undoubtedly facilitate the development of PRL-3 inhibitors<sup>[38-40]</sup>. Detection of PRL-3 expression would be able to provide supportive information for anti-cancer therapy.

In conclusion, PRL-3 is closely associated with tumor invasion and lymphatic metastasis and is identified as a new prognostic indicator to predict tumor recurrence and patient survival in GC.

## COMMENTS

### Background

It is established that phosphatase regenerating liver 3 (PRL-3) is consistently expressed in liver metastasis of colon cancer. A recent study reported that PRL-3 expression was related to peritoneal metastasis of stomach cancer.

### Research frontiers

In a few studies, the association of PRL-3 expression with prognosis of cancers was investigated and demonstrated that this is related to poor prognosis of breast and stomach cancer. The antibody used in many studies was commercial polyclonal antibody that could cross-react with PRL-1 and PRL-2.

### Innovations and breakthroughs

A recent study showed that PRL-3 was expressed in 70.4% of 637 GCs. PRL-3 expression was correlated with peritoneal metastasis. Patients with PRL-3 negative expression had a better survival rate than those with positive PRL-3 at all stages. In this study, PRL-3 was found to express in 43.3% (127/293) of primary tumor tissues of GC. PRL-3 protein expression was demonstrated to be an independent predictor for poor prognosis in GC. In addition, a specific monoclonal antibody to PRL-3 was used, allowing us to accurately evaluate the prognostic significance of PRL-3 expression in GC.

### Applications

Defection of PRL-3 protein expression in primary tumor tissues of GC might be helpful in identification of GC patients with poor prognosis who should receive more intensive treatment. In addition, PRL-3 may serve as a potential therapeutic target for GC.

### Terminology

PRL-3 (also known as PTP4A3) is a member of phosphate of regeneration liver (PRL) family including PRL-1, PRL-2 and PRL-3 which are implicated with oncogenic and metastatic processes of tumors. The excess of PRL-3 phosphates is an alteration contributing to the acquisition of metastatic properties of tumor cells. The monoclonal antibody 3B6 used in this study is a specific monoclonal antibody to PRL-3 generated by Peng *et al*, Beijing Institute for Cancer Research.

**Peer review**

The authors examined the expression of PRL-3 protein in primary tumor tissues of 293 cases of GC. It revealed that patients with negative PRL-3 expression had a higher 5-year survival rate than those with positive PRL-3 expression. PRL-3 is an independent prognostic indicator for GC. The findings are of clinical significance.

### Abstract

**AIM:** To evaluate the effect of intrahepatic transplantation of hepatic oval cells (HOC) on fulminant hepatic failure (FHF) in rats.

**METHODS:** HOC obtained from rats were labeled with green fluorescent protein (GFP) or 5, 6-carboxyfluorescein diacetate succinimidyl ester (CFDA-SE). Cell fluorescence was observed under fluorescent microscope at 6, 24, 48 and 72 h after labeling. CFDA-SE labeled HOC ( $5 \times 10^6$  cells each rat) were injected into livers of rats with FHF induced by D-galactosamine. Serum albumin (ALB), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and total bilirubin (TBil) levels were measured at different time points. Liver function of rats was examined on days 3, 7, 14 and 21 after HOC transplantation.

**RESULTS:** The positive rate of GFP and CFDA-SE labeled HOC was 10% and 90%, respectively, with no significant change in cell viabilities. The survival rate was higher in HOC transplantation group than in control group, especially 48 (9/15 vs 6/15) and 72 h (9/15 vs 4/15) after HOC transplantation. The serum ALT, AST and TBil levels were decreased while the serum Alb level was increased after HOC transplantation. Fluorescence became faded and diffused in liver tissues, suggesting that proliferation and differentiation occur in transplanted HOC.

### INTRODUCTION

Hepatic oval cells (HOC) are liver stem cells with a self-renewal capacity and a high proliferation potential<sup>[1]</sup>. Transplantation of HOC cultured *in vitro* can restore damaged liver function, thus providing more opportunities for patients with terminal-stage liver diseases<sup>[2,3]</sup>. In this study, we established a rat HOC proliferation model by feeding 2-acetylaminofluorene (2-AAF) and resecting 2/3 liver. HOC were isolated, purified and labeled with 5, 6-carboxyfluorescein diacetate succinimidyl ester (CFDA-SE), a fluorescence agent, before they were transplanted into the rats with fulminant hepatic failure (FHF). Then, we detected the fluorescence distribution in the recipient liver and a few laboratory indexes, trying to find the effect of HOC transplantation on FHF.

### MATERIALS AND METHODS

#### Animals and reagents

Wistar rats were provided by the Animal Experimental Center of the Radiation Institute, Chinese Academy of

Sciences (Beijing, China). 2-AAF was purchased from Sigma and D-galactosamine (D-GalN) was provided by Chongqing Medical University (Chongqing, China). *E. coli* strain harboring plasmids carrying the GFP gene, Pmax-GFP, was produced by Amaxa. Fugene HD transfection reagent was from Roche and CFDA-SE was from Molecular Probes.

### **Establishment of a rat HOC proliferation model**

Twenty healthy Wistar rats, weighing 180–220 g, received intra-gastric 2-AAF, 15 mg/kg per day, for 4 d. On day 5, the rats were anesthetized with 1% sodium pentobarbital and their left and middle liver lobes (about 2/3 of the liver volume) were resected. From day 6, the rats were given 2-AAF, 15 mg/kg per day, for additional 10 d to induce a rat HOC proliferation.

### **Isolation, cultivation and identification of HOC**

Hepatic cells were separated from the rat model by the improved *in situ* perfusion of Seglen collagenase<sup>[4]</sup>. HOC were purified from the separated hepatic cells by Percoll density gradient centrifugation and inoculated in a DMEM/F12 culture medium at a concentration of  $1 \times 10^6$ /mL. The cells were cultured at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>, and half of the medium was changed every two days. Cell morphology and expansion were regularly observed under an inverted microscope. The cells were passaged when necessary and observed under an electronic microscope. OV-6, AFP, ABL and PCNA, expressed on cells were tested by immunohistochemical assay.

### **Fugene HD-mediated transfection of HOC with the GFP gene**

HOC were transfected with Fugene HD transfection reagent following its manufacturer's instructions. Briefly, HOC at passage 1 were seeded onto 12-well plates at a density of  $2 \times 10^5$ /mL. One day later, transfection compounds at different ratios [transfection agent (μL): plasmid (μg) = 3:2, 4:2, 5:2, 6:2, 7:2 and 8:2] were added to the culture medium and shaken for 30 s at a low speed to ensure a homogeneous mixture. Then, the cells were incubated at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>. After 6, 12, 24, 48 and 72 h, samples were taken from three random sections in each well and observed under an inverted confocal microscope and 100 cells were counted. GFP expression in these cells was observed under a fluorescence microscope with the excitation wavelength at 488 nm and the emission wavelength at 507 nm. The transfection rate was calculated according to the following equation: transfection rate (%) = number of green fluorescent cells in dark field/number of cells in bright field. The cell proliferation was determined by 3-(4,5-dimethylthiazolyl)-2,5-diphenyltetrazolium bromide (MTT) colorimetry and growth curves were plotted.

### **HOC labeling by fluorochrome CFDA-SE**

Passage 1 HOC, reaching an approximate confluence of

80%, were adjusted to  $1 \times 10^6$ /mL in serum-free PBS with 5 μmol/L CFDA-SE and incubated at 37°C for 10 min. After the same volume of complete medium was added to terminate the staining, cells were separated by centrifugation and the staining was repeated three times before incubation. After 0, 6, 24 and 72 h, the cells were observed under a fluorescence microscope at 488 nm. Cell growth activity was also determined by MTT colorimetry and growth curves were plotted.

### **HOC transplantation for FHF in rats**

Thirty Wistar rats were intra-peritoneally injected with a 10% D-GalN solution at a dose of 1400 mg/kg to induce FHF. One day after FHF induction, rats were divided into transplantation group ( $n = 15$ ) and control group ( $n = 15$ ). Rats in HOC proliferation model were anaesthetized at the supine position, and a 1.5 cm incision was made at the middle of the upper abdomen to expose the liver. The number of fluorescence labeled HOC was adjusted to  $1 \times 10^7$ /mL for transplantation. Rats in the transplant group were injected with 0.5 mL CFDA-SE labeled HOC suspension in the left lobe of liver, while rats in the control group were given the same volume of culture medium. After 1, 2, 3, 5 and 7 d of transplantation, blood sample was taken from the rat tail and liver function was determined with an automatic biochemical analyzer. Albumin (ALB), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and total bilirubin (TBil) levels were measured. After 3, 7, 14 and 21 d, the animals were killed and their livers were removed for pathological examination. Frozen liver tissue around the injected site was cut into sections to observe the distribution of fluorescence labeled cells in the liver tissue under a fluorescent microscope.

### **Statistical methods**

All data were analyzed by SPSS 13.0. Two sets of sample means (mean ± SD) were compared by *t*-test and the percentages were compared by  $\chi^2$ -test.  $P < 0.05$  was considered statistically significant.

## **RESULTS**

### **HOC incubation**

The freshly separated rat HOC adhered to the wall after 12 h of incubation were spindle or polygonal in shape. After about 7 d, the cells grew into colonies. The HOC, 10 d after passage, grew into a single-layer flagstone which did not change 14 d after passage (Figure 1).

### **Morphological and phenotypic identification of the cells**

The expression of OV-6, AFP and ALB in HOC was detected by immunohistochemistry. Positive staining of OV-6 and AFP was detected in isolated HOC while no ALB expression was found in HOC. Electron microscopy showed short and tiny microvilli-like protuberances on the surface of HOC. The cell nuclei were oval with dispersed and homogenous nuclear chromatin, small nucleoli, little cytoplasm, great nucleus-cytoplasm ratio

Figure 1 HE stained HOC 10 h (A,  $\times 100$ ), 7 (B,  $\times 400$ ), 10 (C,  $\times 100$ ), and 14 d (D,  $\times 200$ ) after incubation.

Figure 2 Ultra-structure of rat HOC under electron microscope ( $\times 4000$ ).

and underdeveloped endoplasmic reticulum, mitochondria and ribosome (Figure 2), indicating that incubated HOC are primitive, naive and undifferentiated.

#### **HOC labeling**

Six hours after transfection with the GFP gene, a low GFP expression level in some HOC could be observed under a fluorescent microscope. The GFP gene was expressed both in nuclei and in cytoplasm. Its expression increased significantly after 24 h, reached its peak at 48 h and maintained till 72 h. A higher transfection efficiency (about 10.0%) could be achieved at a transfection reagent-plasmid ratio of 5:2. The fluorescent intensity of transfected cells was gradually reduced and disappeared after 5-7 generations. Green fluorescence could be

observed immediately after CFDA-SE labeling, with a labeling rate of 90%. The fluorescence intensity decreased slightly after 6 h and significantly after 24 h. However, the fluorescence intensity was almost the same at 72 h and 24 h (Figure 3).

#### **Liver functions and survival of FHF rats after HOC transplantation**

The rats in HOC transplantation group slightly restored their general conditions, food taking and movements 48 h after transplantation. On the contrary, the conditions of most rats in control group were further exacerbated. The serum ALB, AST, ALT and TBiL levels in rats of both groups are listed in Table 1. Death occurred in rats of both groups around 6 h after transplantation.

Figure 3 CFDA-SE stained HOC at 0 h (A,  $\times 200$ ), 6 h (B,  $\times 200$ ), 24 h (C,  $\times 100$ ), and 72 h (D,  $\times 100$ ).

Figure 4 Fluorescent microscopy showing colonies in control group (A), and 3 (B), 7 (C) and 14 d (D) after HOC transplantation ( $\times 100$ ).

However, no rat died in transplantation group 72 h after transplantation. The survival rate for rats in transplantation group and control group was 60% (9/15) and 26.7% (4/15), respectively.

#### **Fluorescent microscopy after HOC transplantation**

Green fluorescent cell colonies could be seen in sections of frozen rat liver tissue three days after transplantation. Most fluorescent colonies were located at the injection site with a strong fluorescent intensity. The fluorescent intensity decreased seven days after transplantation but the number of colonies increased with a wider distribution. No fluorescent cell was detected in the liver

sample 14 d after HOC transplantation and afterwards (Figure 4).

## **DISCUSSION**

The Solt-Farber model<sup>[4]</sup> is the most commonly used model for HOC proliferation, and has been used in studying the relationship between local disease and liver cancer or between nodules and liver cancer. Collagenase perfusion, proposed by Howard *et al.*<sup>[5]</sup> and improved by Berry and Seglen *et al.*<sup>[6,7]</sup>, is often used in detection of HOC separation. In this study, Solt-Farber model was used to detect HOC proliferation, and a large

amount of small proliferation focuses were found in portal area. The HOC were oval or oblong in shape, and their size was much smaller than that of hepatic cells (about 1/6-1/3 of the normal size). Moreover, immunohistochemical staining showed positive OV-6 and AFP expression, consistent with the traits of HOC. The positive PCNA staining showed that HOC were at their proliferating stage and that HOC proliferation in liver of adult rats could be induced by 2-AAF injection and 2/3 liver resection. After the proliferation model was established, suspended hepatic cells were prepared by two-step collagenase perfusion. The cells were purified by density gradient centrifugation and observed under an electron microscope. The purified cells were primitive, naive and undifferentiated. Immunohistochemical staining of OV-6 and AFP in the freshly separated cells was similar to that of proliferated cells in the model. The cells showed a certain proliferation capacity in culture and were heterogenous as previously reported<sup>[8-10]</sup>.

The therapeutic effect of HOC transplantation on FHF has been proved both in animal models and in clinical trials<sup>[11,12]</sup>. Matsusaka *et al*<sup>[13]</sup> transplanted hepatic cells with a large number of HOC into the spleen of rats, and found that hepatic cells can significantly proliferate compared to those without HOC. Yasui *et al*<sup>[14]</sup> transplanted HOC into the liver of Nagase rats (a family of rats with inherited serum albumin deficiency), and showed that the serum albumin level maintained high in these rats for 10 wk, indicating that HOC have differentiated into mature and functional hepatic cells. In this study, the rat FHF model was induced by D-GalN, into which rat HOC were transplanted. Biochemical assay showed the liver functions and pathological lesions of rats were slightly improved 48 h after transplantation. Moreover, the ALB and ALT levels were decreased in the following days, indicating that the transplanted HOC can survive in rats with FHF, and proliferate and differentiate to replace the damaged hepatic cells. The effect of HOC transplantation on FHF is related to the strong proliferation and differentiation of HOC into mature hepatic cells and biliary epithelial cells, which consequently benefit rat survival. In addition, liver failure elicits liver regeneration and up regulation of hepatocyte

growth factors. These cytokines, forming a suitable microenvironment, are necessary for the survival, growth and proliferation of transplanted HOC. Thus, newly regenerated hepatocytes compensate the damaged liver function, their robust activity may interact with adjacent cells and rescue some damaged liver cells with reversible pathologic lesions.

It is essential to appropriately label the transplanted cells to track their location and function in receptor. Both GFP and CFDA-SE are fluorescent labels for *in vivo* cell transplantation, but CFDA-SE showed superior properties in this study. CFDA-SE, a fluorescent dye, has been applied in various fields of immunology due to its stability and long duration. When cells divide, CFDA-SE is equally divided into two daughter cells, leading to an exponential decrease in fluorescence intensity with cell proliferation and division<sup>[15]</sup>. In this study, CFDA-SE labeled HOC were transplanted in rats with FHF. Seventy-two hours after transplantation, green fluorescent colonies could be observed in sections of frozen liver tissue. The fluorescence intensity was strong but the colonies were only found near the injection site. On day 7, the fluorescence intensity of the transplanted cells decreased but transplanted cells were widely distributed, indicating that HOC have proliferated and differentiated into hepatic cells. Therefore, multiple green fluorescent colonies could be observed.

In conclusion, labeled HOC transplantation exerts its effects on FHF by improving the serum levels of ALT, AST, and TBil. However, since fluorescence intensity of CFDA-SE decreases with cell division, it is still not the ideal label for cell transplantation. Further study is needed on the location and distribution of transplanted HOC.

## COMMENTS

### Background

Fulminant hepatic failure is a serious clinical disease and may threaten the life of patients. However, because of the damage of mass liver cells, the organ function is often irreversible due to the liver cell degeneration, swelling, or apoptosis. Thus, to supply new sources of functional liver cells is a valuable choice for these patients.

### Innovations and breakthroughs

The cultured hepatic oval cells (HOC) can provide cells for liver cell transplantation and even for biological artificial liver, thus solving the problem of liver donor shortage. In this study, a rat HOC proliferation model was established and the HOC were isolated, purified, labeled with CFDA-SE (a fluorescence agent), and transplanted into rats with fulminant hepatic failure (FHF). Then the authors detected the fluorescence distribution in the receptor liver to observe the role of HOC transplantation in FHF treatment.

### Applications

The study indicated that transplantation of hepatic oval cells was a potential therapeutic strategy for the treatment of fulminant hepatic failure.

### Terminology

HOC: liver stem cells with a self-renewal capacity and a high proliferative potential. FHF is usually defined as the severe impairment of hepatic functions in the absence of preexisting liver disease. 5,6-carboxyfluorescein diacetate succinimidyl ester (CFDA-SE): a fluorescence agent

### Peer review

The manuscript reports a therapeutic potential of transplantation of hepatic oval cells for fulminant hepatitis. Although liver transplantation is the most effective therapy for fulminant hepatitis at present, cell-based therapy could be an alternative treatment modality. The data presented are encouraging and promising.

### Abstract

**AIM:** To repair the partial esophagus defect with a chitosan stent, a new esophageal prosthesis made of pulmonary tissue with vascular pedicle.

**METHODS:** Fifteen Japanese big ear white rabbits were divided into experimental group ( $n = 10$ ) and control group ( $n = 5$ ). Esophagus defect in rabbits of experimental group was repaired using lung tissue flap with a chitosan tube stent, gross and histological appearance was observed at week 2, 4 and 8 after operation, and barium sulphate X-ray screen was performed at week 10 after operation. Esophagus defect of rabbits in control group was repaired using lung tissue flap with no chitosan tube stent, gross and histological appearance was observed at week 2, 4 and 8 after operation, and barium sulphate X-ray screen was performed at week 10 after operation.

**RESULTS:** In the experimental group, 6 rabbits survived for over two weeks, the lung tissue flap healed esophageal defection, and squamous metaplasia occurred on the surface of lung tissue flap. At week 10 after operation, barium sulphate examination found that barium was fluent through the esophagus with no stricture or back stream, the creeping was good. In the control group, 4 rabbits survived for two weeks, the lung tissue flap healed esophageal defection with fibrous tissue hyperplasia,

### INTRODUCTION

Esophagus disease is one of the common digestive tract diseases in our country. After excision, the esophagus needs to be reconstructed to restore the digestive tract continuity. At present, the commonly used esophagus reconstruction substitutes mainly include musculo-cutaneous flap with vessel peduncle<sup>[1]</sup>, platysma musculo-cutaneous flap<sup>[2,3]</sup>, periosteum intercostal muscle flap<sup>[4]</sup> and others<sup>[5-8]</sup> from stomach, colon and jejunum. Plastic tube, metallic pipe, teflon tube, silica gel tube, *etc*, are also used in reconstruction of artificial esophagus. However, their effects are not really ideal. The ideal substitute should be nontoxic, absorbable, without repulsive response and carcinogenicity, and easy to gain.

At present, various esophagus reconstruction techniques are available<sup>[9-11]</sup> and each has its own particular advantages and disadvantages. Irrespective of the kind of reconstruction, reducing scar formation and preventing stricture are still the key points. Different flaps from the lung tissue petal have been successfully applied in reconstruction of trachea<sup>[12]</sup>. Application of

lung tissue petal, inside lining metal and silica gel pipe stent in animals is also successful, but it is unable to overcome foreign matter response. In this study, we used inside lining metal, a new absorbable biological material-chitosan tube, to repair partial esophagus defect by preventing post-surgery stricture. Some questions concerning its application were discussed.

## MATERIALS AND METHODS

### *Experimental animals and main materials*

Fifteen healthy Japanese big ear white rabbits, weighing 3 kg, were provided by China Medical University Shengjing Hospital Animal Center. The rabbits were divided into experimental group ( $n = 10$ ) and control group ( $n = 5$ ). Chitosan tube stent, 15 mm long, 4 mm in inside diameter, was purchased from Shandong Province, China. Antiseptic glutaric dialdehydel were independently developed by the authors. TKR-200C micro-organism life-support machine was provided by Jiangxi Province, China. Rabbit surgery table, chest surgery instruments, infusion instruments, 20% urethane vein anesthetics, ketamine anaesthetics, 1% procaine, laryngoscope, 3.0-4.0 model trachea intubation were bought from Jiangxi Province, China. Tooth pad, medical adhesive plaster, digital camera (Sony, DSC-T10), and optical microscope (Olympics CH-20) were used in this study.

### *Experimental techniques*

Before surgery, rabbits did not receive any medicine. Twenty percent of urethane vein anesthetics (5 mL/kg) was injected into abdominal cavity. Three minutes after anesthesia, the breath of rabbits was slow and changed to shallow and abdominal breath with corneal reflex. Ketamine (1 mg/kg) was intramuscularly injected to reduce the pain. The anaesthetized rabbits were fixed on the operation table at a supine position, and the assistant pulled in the flank with the bandage to draw in the front tooth and lower jaw. The mouth was pulled open with 1% procaine spraying. The throat was superficially anaesthetized. The operator stood in the rabbit head side, set the laryngoscope from one side of mouth, pushed away the tongue from tip to root. Epiglottis was exposed behind the tongue root resembling the white soft bone. Sometimes, vocal cord could not be found, but air bubbles could be observed. The trachea was gently pulled in intubation. The air current in the trachea pipe could be heard. When the inspiration was sent in gently, rapid vertical insertion was performed. Trachea intubation and tooth pad were fixed 13 cm away from the front teeth. When the air exhaled from the trachea intubation could be felt with hands, the life-support machine connected with oxygen was adjusted to a low current capacity.

### *Surgery method*

The left side and barrier height of rabbit decubitus were exposed in the chest cavity, with the four limbs of rabbits fixed and the right flank prepared for

operation of the chest. The first step was to cut open pleural membrane. When lung collapse was observed, the rabbits were given machinery ventilation, and the breath frequency was adjusted to 30 times/min, and then adjusted according to the lung inflation. A stomach tube was inserted into esophagus to support it, and the center-section was searched for its dissociation, and slung with a spun yarn cloth strip. The excision of central esophagus was an esophagus wall, 3 mm in diameter, to make a animal model of partial esophagus wall damage. In the experimental group, a chitosan tube was placed in breakage of the esophagus and fixed with a needle. The esophagus was wrapped by the nearby lung tissue petal to form an encystation in the breakage place, and the edge of esophagus breakage was sutured continuously with a 3-0 silk suture. Then, the stomach tube was withdrawn to release the stress and return the esophagus. The control group did not need any inside lining chitosan tube. No chest internal hemorrhage and lung air leakage were found. Transition to ventilation was performed several times before the last needle was inserted into the pleural membrane. At end of the inspiration, pleural cavity was closed. The rabbits received fluid diet and anti-inflammation treatment, fresh milk and normal diet a week after operation.

### *Observation of target*

**Observation of ordinary circumstances:** Survival, feed, body weight, and complication were observed after operation.

**Observation of body:** If the experimental rabbits died in the observation period, prompt postmortem examination was performed to find the cause of death. The animals were killed at weeks 2, 4 and 8 after surgery, respectively. Scar formation and chitosan tube were observed.

**Observation of histology:** The surviving animals were executed at week 2, 4 and 8, respectively. The damaged patching lung tissue was stained with H&E. The growth of lung tissue petal was observed under optical microscope.

**Barium meal:** Ten weeks after operation, esophagus of survived rabbits was observed by barium meal to see whether the esophagus was unobstructed.

## RESULTS

### *Animal survival*

After operation, 6 animals in experimental group, and 4 animals in control group survived, respectively. Five animals and 1 animal died on the same day after operation, 1 animal died due to anesthesia 1 d after operation, 1 animal died of unhealed fistula on day 4 after operation, 1 animal died of infusion accident on day 7 after operation, and 1 animal died of malnutrition at week 2 after operation.

Figure 1 Lung tissue flap change in control group (A-C) and experiment group (D-F) after operation.

### Observation of ordinary circumstances

Five days after operation, animals in experimental and control groups could have oral diet. The animals were provided with a small amount of food 5 d after operation and normal diet 10 d after operation. During this period, no obvious feed barrier was observed in animals of the experimental group. Three weeks after operation, animals in the control group had a poor appetite. One week after operation, the body weight of all animals decreased about 1-2 kg. The body weight of animals in the control group was still lighter than before operation.

### Observation of body

Two weeks after operation, the esophagus damage was observed, the esophagus breakage edge and lung tissue petal were tightly united, accompanying dropsy. The chitosan tube could be touched under the substitute lung tissue petal and was soft, and the lumen surface had membranous contamination. Four weeks after operation, the damage was completely repaired, the suture was not absorbed. In the experimental group, the internal lumen surface of esophagus substitute was smooth, the blood circulation was rich, and the chitosan tube was partly decomposed. In the control group, the damage was red in color, hyperplasia was found around the damage, accompanying dropsy. In the experimental group, eight weeks after operation, the esophagus defect was covered by the white thick membranous substance. No dropsy, necrosis and ulcer, obvious stricture, or chitosan cast were found in the pipe wall. In the control group, scar

formation and hyperplasia were found on tissue petal surface (Figure 1).

Two weeks after operation, the lung structure of rabbits in experimental and control groups was observed. Pulmonary alveoli were withered and collapsed, and the denatured pulmonary alveolus cells were tumescent with acute inflammation response. Four weeks after operation, atypical pulmonary alveolus structure was observed in the experimental group. The inflammatory response was weakened accompanying a few neutral granular cells and lymphocytes, but no obvious fiber proliferation was observed. In the control group, the central pulmonary alveolus structure was atypical accompanying fiber cells and a few inflammatory cells. Eight weeks after operation, a large number of squamous epidermis cells were observed on the surface of lung tissue petal, and the chronic inflammatory response was significantly decreased in the experimental group. The control group had chronic inflammation response, accompanying obvious fiber proliferation but no superficial squamous metaplasia (Figure 2).

### Barium meal

Ten weeks after operation, esophagus barium test was performed. In the experimental group, barium meal went smoothly through the esophagus. No obvious stricture, reverse flow, anastomotic stoma leakage and expansion were observed in the esophagus. The creeping motion was good. Mild stricture was observed in control group. The anastomotic stoma was healed with expansion, and the barium meal went through smoothly with general creeping motion (Figure 3).

**Figure 2** Lung tissue flap change under optical microscope in control group (A-C) and experimental group (D-F) after operation (HE,  $\times 10$ ).

**Figure 3** Results of esophagus barium test in control group (A) and experimental group (B) ten weeks after operation.

## DISCUSSION

Esophagus excision and reconstruction are important in esophagus surgery. In recent years, biological substitutes have been extensively studied<sup>[13-21]</sup>. Zhi *et al*<sup>[13]</sup> reported that biological artificial esophagus can be used

to repair esophagus defect. In their study, esophagus substitution test was performed in 30 experimental dogs, showing that esophagus substitution can repair 93.3% of esophagus defects. Zhang *et al*<sup>[14-17]</sup> excised chest esophagus at the right chest flank of 30 Chinese hybrid dogs, and an 8 cm long biological artificial esophagus was used to reconstruct esophagus. At present, we still face the problems of fistula, stricture, and length of implants, which need further research. Based on the biological esophagus substitute, biodegradable and non-biodegradable materials have been developed for making artificial esophagus<sup>[18,19]</sup>. Meanwhile, the degradation speed of biodegradable material matches that of non-degradation material, which exerts the supporting function and prolongs the supporting time of biological materials, and finally regenerates esophagus to completely substitute the artificial esophagus. The project of digestion tube has made certain progress. However, its effect is unknown. Further study is needed on implantation and production of epithelial and muscle cells, gland and nerve plexus regeneration, scar reduction, speeding up repair and regeneration of

structure, *etc*<sup>[20]</sup>.

Dr. Shi first used lung tissue petal substitution to repair trachea defect successfully<sup>[21]</sup>, which is a new direction to repair esophagus defect with lung tissue petal and reconstruct esophagus. In the earlier experiment, we wrapped the damage spot using the lung tissue petal to make the artificial esophagus, in order to prevent stricture after repair of esophagus defect<sup>[22,23]</sup>. Based on previous experiment results, we chose a chitosan material to make absorbable tube stent to overcome the rejection, and further explored the feasibility of this new method. The blood circulation of lung tissue petal was good, which was confirmed by pathology and electron microscopy. The compatibility of repair material was good, thus avoiding foreign matter rejection and forming reliable scars of fibers. The lung tissue petal has certain ductility, and different lobes of the lungs can be selected to make different lengths of lung tissue petal. In brief, the selection of lung tissue petal is convenient, the compatibility is good and the blood circulation is rich, with a high scar formation ability and good anti-infectiousness, and good environment for esophagus epidermis.

Chitin is the only high polymer material with widespread biodegradation<sup>[24]</sup>. Acetyl-escaped product, also known as chitosan<sup>[25]</sup>, has the good biological compatibility with animal organs and cells, and degrades the low molecular oligosaccharide with no accumulation of products *in vivo* and no immunogenic ability. The tube we made of it is elastic and tough, slightly soft when it meets water, and can suppress inflammation response, prevent adhesion and scar formation in the breakage site. It was reported that chitosan membrane can prevent the adhesion to peritoneum and thus can be used in clinical practice<sup>[26]</sup>. It was also reported that chitosan can insert into nerve tube stent<sup>[27,28]</sup>. Chitosan tube stent is degraded gradually and absorbed *in vivo*, with no toxicity, stimulation and rejection. It has been shown that epidermis of the esophagus has certain degree of stricture but it is not serious enough to cause feed barrier in esophagus of dogs<sup>[29]</sup>. Long-term survival and delayed chronic inflammation have been achieved using metallic pipe and silica gel tube as an inner lining support, but foreign matter rejection occurs. We used chitosan as a support to prevent scar formation and stricture of esophagus by making use of its compatibility and degradability. When stricture is formed, chitosan tube is degraded *in vivo*, and its product is not toxic and has no side effects. Thus, it is worthy to be further studied. The most serious complication is fistula, which occurs 5-7 d after operation and is related with infection, anastomotic techniques and blood circulation, *etc*. Infection is the most important factor for the occurrence of complication, because esophagus patching is a pollutant. Since we performed the surgery under strict asepsis, we solved the problem. After operation, the rabbits in experimental group were fasted for 5 d, and then received venous transfusion and anti-inflammation treatment. Because the resistance of rabbits was lower than that of dogs, the mortality rate of rabbits was

30%. Since this study was to verify the new method and explore experimental conditions, a large sample size of slightly bigger animals, like dogs, pigs, *etc*, should be used in the study. We used big white rabbits to establish esophagus partial damage model, and repaired esophagus wall partial damage using chitosan tube with lung tissue petal as its inside lining. Based on results of this experiment, pigs and dogs and other bigger animals, may be further tested for the replacement of chitosan tube in the entire esophagus. Our experiment did not operate chest of rabbits. Compared with big animals, rabbits are docile, convenient, inexpensive, and easy to obtain. The choice of support is the key to the maintenance of unobstructed lumen, protection of the surface granulation tissue of lung from adhesion, formation of diverticulum and false passage. The metal lattice support is widely applied in treatment of esophagus stenosis, mainly because of its good support effect. Therefore, we used the chitosan tubular support, which functions as a support, reduces inflammation response, and can be absorbed and degraded by organisms, and can be used as a substitute of esophagus.

Further study involving smooth muscle, nerve plexus and gland regeneration is needed<sup>[30]</sup>. Creeping motion restoration, long esophagus reconstruction, *etc*, can be achieved in clinical practice.

## COMMENTS

### Background

At present, esophagus reconstruction techniques are available, but each of them has its advantages and disadvantages. Reducing scar formation and stricture is still the key to esophagus reconstruction.

### Research frontiers

In this study, chitosan tube was used as a support to prevent post-operation stricture.

### Innovations and breakthroughs

Trachea was reconstructed using chitosan and silica gel pipe stent. A chitosan material was used to make absorbable support tubes to overcome the rejection and prevent stricture of esophagus.

### Applications

Chitosan tubes provide a new surgery method for patients in whom substituting esophagus with cavity internal organs is impossible.

### Terminology

Lung tissue petal: A lung lobe closing the segment of trachea.

### Peer review

It is an interesting animal experiment about the use of chitosan stent with a lung tissue flap to repair esophageal perforation.

### Abstract

**AIM:** To observe the biotransformation process of a Chinese compound, aesculin, by human gut bacteria, and to identify its metabolites in rat urine.

**METHODS:** Representative human gut bacteria were collected from 20 healthy volunteers, and then utilized *in vitro* to biotransform aesculin under anaerobic conditions. At 0, 2, 4, 8, 12, 16, 24, 48 and 72 h post-incubation, 10 mL of culture medium was collected. Metabolites of aesculin were extracted 3 × from rat urine with methanol and analyzed by HPLC. For *in vivo* metabolite analysis, aesculetin (100 mg/kg) was administered to rats *via* stomach gavage, rat urine was collected from 6 to 48 h post-administration, and metabolite analysis was performed by LC/ESI-MS and MS/MS in the positive and negative modes.

**RESULTS:** Human gut bacteria could completely convert aesculin into aesculetin *in vitro*. The biotransformation process occurred from 8 to 24 h post-incubation, with its highest activity was seen from 8 to 12 h. The *in vitro* process was much slower than the *in vivo* process. In contrast to the *in vitro* model, six aesculetin metabolites were identified in rat urine, including 6-hydroxy-7-gluco-coumarin (M1), 6-hydroxy-7-sulf-coumarin (M2), 6, 7-di-gluco-coumarin (M3), 6-glc-7-gluco-coumarin (M4),

### INTRODUCTION

Aesculin, a 6, 7-dihydroxy derivative of coumarin with pleiotropic pharmacological and biochemical properties, has recently been analyzed for its biochemical activity<sup>[1]</sup>. Kaneko and colleagues<sup>[2]</sup> found that aesculetin and its 6-glycoside, aesculin, can inhibit oxidative DNA damage and formation of aberrant crypt foci and tumors. Furthermore, this compound shows an inhibitory effect on BOP-induced oxidative DNA damage and carcinogenesis in a hamster pancreatic tumor model<sup>[2]</sup>, as well as chemo-preventive<sup>[3]</sup> and anti-tumor activity on cancer<sup>[4]</sup>. Aesculin and aesculetin have strong antioxidative and photo-protective activities, by scavenging 1, 1-diphenyl-2-picrylhydrazyl (DPPH) radicals and superoxide anions from the xanthine/xanthine oxidase system and inhibiting oxidation of 5-(6-)-chloromethyl-2', 7'-dichlorodihydro-fluorescein diacetate<sup>[5]</sup>. Aesculetin increases apoptosis of 3T3-L1 adipocytes in a time- and

dose-dependent manner<sup>[6]</sup>, and inhibits cell growth and cell cycle progression by inducing G1 phase arrest in HL-60 leukaemia cells, which is a direct result of the inhibition of retinoblastoma protein phosphorylation<sup>[7]</sup>. Aesculetin also displays multiple immunomodulatory effects on murine lymphocytes and peritoneal macrophages in rat liver<sup>[8]</sup>, including anti-inflammatory activity, inhibition of lipoxygenase and tyrosinase activity, scavenge of hydroxyl radicals and suppressing lipid peroxidation.

However, the biotransformation progress of aesculin and its derivatives has not been completely determined, let alone their complex structure-activity relationships. Aesculetin is one of the simplest coumarins with two hydroxyl groups at carbons 6 and 7 that serve as targets for O-methylation or O-glycosylation. It has been reported that biotransformation of aesculetin with *E. coli* expressing O-methyltransferase (POMT-9) generates scopoletin, isoscapoletin, and scoparone<sup>[9]</sup>. The growth of *E. coli* is inhibited by aesculetin, but not by aesculin<sup>[10]</sup>. Hairy roots of medicinal morning glory (*Pharbitis nil*) show a potent glucosylation activity against aesculetin, especially at 7-hydroxyl group<sup>[11]</sup>. As one of the metabolites of caffeic acid oxidation, aesculetin observed in perfused rat liver may be responsible for its biological effects observed *in vivo*<sup>[12]</sup>. Aesculetin is a substrate of mushroom polyphenol oxidase and horseradish peroxidase enzyme resulting in the oxidization of aesculetin into its o-quinone<sup>[13]</sup>. Despite these accumulated data, we still do not fully understand the structural basis and dynamic pattern underlying the pleiotropic biological effects of aesculetin and there are few reports describing its derivatives or metabolites.

Therefore, in the present work, we analyzed the biotransformation process of aesculin in response to human gut microflora in a rat model, in order to identify its novel metabolites, which may enrich our understanding of the complicated structure-activity relationships between aesculin and its metabolites.

## MATERIALS AND METHODS

### Collection of representative human gut bacteria

Twenty healthy volunteers (10 males and 10 females) at the age of 20-24 years, were recruited from students of Chengdu University of Traditional Chinese Medicine. Their faeces were collected and intestinal flora was identified as normal with an automatic system of bacteria identification (BD, USA). Then, fecal samples were pooled. The bacterial concentration was adjusted to  $2 \times 10^7$  CFU/mL in culture medium, and 1 mL of aliquots was stored at -80°C until use.

### Preparation of anaerobic culture medium

Culture medium for anaerobic gut bacteria, GAM, was prepared according to the following formula: 3 g of soybean phytone, 10 g of peptone, 13.5 g digested blood serum powder, 5 g yeast extract, 2.2 g extractum carnis, 1.2 g beef liver extract, 3 g glucose, 5 g soluble starch, 2.5 g KH<sub>2</sub>PO<sub>4</sub>, 3 g NaCl, 0.3 g L-cysteine, 0.3 g sodiumthioglycollate, were added into 800 mL of dH<sub>2</sub>O. The pH was adjusted to 7.4 with 1 mol/L NaOH and the

final volume was adjusted to 1000 mL with dH<sub>2</sub>O. The medium was sterilized by autoclaving at 121°C for 20 min and stored at 4°C for further use.

### Chemicals

Aesculin (6-hydroxy, 7-glycoside coumarin), with an estimated purity of 98%, was purchased from Aldrich Chemical Co. (Milwaukee, WI). For the preparation of standard aesculin, 250 mg of aesculin was added to 25 mL of saline (0.9% NaCl solution) and dispensed into the solution by sonication. The mixture was then boiled for 10 min to dissolve aesculin. This stock solution of aesculin (10 mg/mL) was stored in the dark at -20°C until use.

Aesculetin (6, 7-dihydroxycoumarin) was also purchased from Aldrich Chemical Co. (Milwaukee, WI). The stock solution of aesculetin (10 mg/mL) was prepared as above and stored under the same condition for aesculin.

### Exposure of aesculin/aesculetin to human gut bacteria

Twenty millilitre of aesculin stock solution was added to 179 mL of GAM in a 500 mL glass flask, followed by addition of 1 mL of human gut bacteria. The final concentration of aesculin was 1 mg/mL. The mixture was incubated at 37°C in DY-II anaerobic incubator containing 80% N<sub>2</sub>, 10% CO<sub>2</sub>, and 10% H<sub>2</sub> (Yiwu Co. Ltd, Zhejiang Province, China). Ten mL of the solution was removed at 0, 2, 4, 8, 12, 16, 24, 48 and 72 h post-incubation, respectively, and 10 mL of methanol was then added to at each time point. The solutions were mixed well with hands for 5 min and the upper phase was transferred into a fresh flask. This extraction process was repeated two times and all the upper phase fractions were pooled for HPLC analysis.

The same protocol was employed to incubate aesculetin with human gut bacteria.

### HPLC analysis of cultured aesculin/aesculetin

**Preparation of control stock solution:** Methanol was used as a solvent to prepare the aesculin and aesculetin stock solutions. The final concentration of aesculin and aesculetin was 10.08 mg/mL and 6.120 mg/mL, respectively. The solutions were kept in the dark at 4°C for up to one week.

HPLC was performed on a Waters Separation Module 2695 at a detection wavelength of 340 nm, at a screen wavelength of 210-400 nm, at a flow rate of 1.0 mL/min, at a sample size of 10 µL, and at a column temperature of 25°C, with mobile phase A set at 5% acetic acid : methanol (78:22), mobile phase B at 5% acetic acid: methanol gradient elution (0-20 min, 80:20; 20-35 min, linearity changed from 80:20 to 40:60), and mobile phase C at 5% acetic acid: methanol gradient elution (0-20 min, 90:10; 20-35 min, linearity changed from 90:10 to 50:50), respectively.

### Preparation of urinary metabolites

Twelve adult SD rats (6 males and 6 females), weighing  $200 \pm 5.6$  g, were raised under specific pathogen-free conditions at the University Laboratory Animal Service

**Table 1** Quantitative biotransformation efficiency of human gut bacteria for aesculin

Incubation time (h)	0	2	4	8	12	16	24	48	72

**Figure 1** Biotransformation of aesculin by anaerobic human gut bacteria. The gut bacteria comprised 20 pooled fecal samples from healthy volunteers. Incubation was performed under anaerobic conditions (80% N<sub>2</sub>, 10% CO<sub>2</sub>, 10% H<sub>2</sub>) at 37°C for defined time periods. Ten millilitre of samples was collected at 0, 2, 4, 8, 12, 16, 24, 48 and 72 h, respectively post-incubation. Aesculin and metabolites were then extracted with methanol and analyzed by HPLC. The vertical axis shows the relative values for the concentration of aesculin and/or its metabolite. The horizontal axis indicates the HPLC overflow time.

Center of Chengdu University of Traditional Chinese Medicine, China. Each rat was raised in a solitary metabolic cage, with free access to normal food in a 12 h light and dark cycle. After adaptive nurture for one week, the aesculetin solution was administrated at a dosage of 100 mg per kilogram. Rat urine produced from 6 to 48 h after administration of aesculetin solution was collected for analysis. Five millilitre of urine sample from each rat was mixed for HPLC analysis.

#### Identification of aesculin metabolites in rat urine by LC/MS

Aesculin metabolites were identified in rat urine by XenoBiotic Laboratories, Inc., Plainsboro, NJ, USA. Control solutions of aesculetin and aesculin, and rat urine sample were analyzed by LC/ESI-MS and MS/MS in the positive and negative modes. The actual instrument conditions were modified to optimize chromatography and instrument sensitivity.

**HPLC:** HPLC System: Waters Separation Module 2695. Column: Ace 3, C18, 3  $\mu$ m, 150 mm  $\times$  4.6 mm; guard column: Ace 3, C18, 10  $\times$  3.2 mm; column temperature: 25°C; autosampler temperature: 4°C; mobile phase A: 0.4% HCOOH in H<sub>2</sub>O; mobile phase B: CAN.

**MS:** Mass spectrometer: Finnigan LCQ<sup>TM</sup> mass spectrometer. Data system: ThermoQuest Xcalibur Version 1.3; ionization mode: positive or negative electrospray ion modes [(+)/(-) ESI]; ion spray (IS): 4.5 kV; capillary temperature: 240°C; sheath gas flow: N<sub>2</sub>,

~80 units; auxiliary gas flow: N<sub>2</sub>, ~20 units; collision gas: helium.

## RESULTS

### Human gut bacteria converted aesculin into aesculetin

HPLC analysis revealed that our representative human gut bacteria degraded the glycoside of aesculin, thus completely converting it into aesculetin (Figure 1). The biotransformation process occurred between 8 and 24 h post-culture. After 24 h, aesculin was almost transferred into aesculetin. No other metabolite was observed, indicating that human gut bacteria cannot further modify aesculetin. No conversion of aesculin to aesculetin was observed in the absence of human gut bacteria 72 h after incubation (data not shown), indicating that human gut bacteria are a prerequisite for the biotransformation of aesculin.

The biotransformation efficiency of aesculin was quantitatively determined according to the following equation: Transformation ratio = (aesculetin concentration/178)/(aesculetin concentration/178 + aesculin concentration/340), where 178 represents the molecular weight of aesculetin and 340 represents the molecular weight of aesculin. Almost 80% of aesculin biotransformation occurred from 8 to 12 h post-incubation (Table 1).

The mixture of human gut bacteria did modify aesculetin under the same culture conditions (data not shown), indicating that human gut bacteria can only biotransform aesculin but not further modify its molecules.

### Identification of aesculetin metabolites in rat urine

Six metabolites of aesculin were detected in rat urine (Figure 2). The primary characteristics of each metabolite were obtained by CAD-MS/MS analysis (Figure 3). One or two hydrogens in these metabolites [6-hydroxy-7-glucoumarin (M1), 6-hydroxy-7-sulfocoumarin (M2), 6, 7-di-glucoumarin (M3), 6-glc-7-glucoumarin (M4), 6-O-methyl-7-glucoumarin (M5) and 6-O-methyl-7-sulfocoumarin (M6)] of the hydroxyl groups of aesculetin were modified by glucosylation, glycoside, sulfation, and/or methylation. In the present study, M2 and M6 were found to be novel aesculin metabolites compared with the reported data<sup>[1,2]</sup>.

Compared with the reference standards for aesculetin and aesculin, six aesculetin metabolites in rat urine were clearly observed on HPLC UV-chromatogram (Figure 4). The spectral data of aesculetin using LC/(+)ESI-MS and

**Figure 2 Summary of aesculetin metabolites identified in rat urine.** <sup>1</sup>The position(s) of methylation and/or conjugation(s) may be exchangeable on the two phenols.

**Figure 3 Proposed characteristic (-) CAD-MS/MS fragmentations for aesculetin metabolites.**

MS/MS are shown in Figure 5. By comparing the data, we could identify the substitution position of aesculetin metabolites in rat urine *in vivo*.

Unlike gut microflora, mammalian physiology could further modify aesculin and the pharmaceutical effects of aesculin might be a result of these metabolic modifications.

## DISCUSSION

Natural coumarins, widely distributed in plants, fungi and bacteria, have pleiotropic biological effects. Coumarins, made of fused benzene and  $\alpha$ -pyrone rings, have phenolic hydroxyl groups in their structures that can be easily replaced and/or modified, forming various metabolites or derivatives. Aesculin, one of the simplest

**Figure 4 HPLC UV-chromatograms of reference standards for aesculetin and aesculin (A), M2 isolated from rat urine (B), and a rat urine sample dosed with aesculetin with assignments of aesculetin urinary metabolites (C).**

coumarins known to have multiple pharmacological and biochemical activities, is an established inhibitor of lipoxygenase and cyclo-oxygenase and shows scavenging effects on ROS<sup>[13]</sup>. It has been reported that aesculetin has chemo-preventive and anti-tumor activities *in vivo* against cancer<sup>[15,14]</sup> and also induces apoptosis in several types of human cancer cells by diverse pathways<sup>[1,6,7,15,16]</sup>. Hence, it is a great challenge to determine the complex structure-activity relationships between aesculin/aesculetin and their metabolites. The aesculin metabolites in rat urine were identified both *in vitro* and *in vivo*.

The results of this study show that human gut bacteria could completely biotransform aesculin into aesculetin. About 80 % of aesculin was converted into aesculetin in less than 12 h post-incubation. The reason why the *in vitro* biotransformation speed of aesculin was so slow remains unclear. The universal time lag of our bacterial culture conditions might be a major reason, since human gut bacteria must first synthesize enough enzymes in order to adapt to any new environment. Since the starting concentration ( $10^5$  CFU/mL) of human gut bacteria was markedly lower than that of human gut flora (about  $10^{12}$  CFU/gram), some additional time is necessary for the exponent growth of seeded bacteria in order to reach the

Figure 5 Aesculetin LC/(+)ESI-MS and MS/MS spectral data.

maximum bacterial concentration in the culture medium. In addition, we only employed anaerobic gut bacteria for the biotransformation of aesculin, which should be somewhat slower than *in vivo* conditions, since both anaerobic and aerobic bacteria may be involved in the *in vivo* aesculin biotransformation process.

The results of aesculin transformation suggest a simple but vivid example of host-gut bacteria cooperation in the dynamic utilization and subsequent modification of xenobiotics. Human gut bacteria degrade the glycoside of aesculin to facilitate its absorption in intestine, then modification of aesculetin into various derivatives with the potential of having multiple biological activities, occurs in the host. It was reported that the distal human intestine represents an anaerobic bioreactor programmed with a large population of bacteria, providing us with genetic and metabolic attributes, including the ability to harvest otherwise inaccessible nutrients and to metabolize diverse xenobiotics<sup>[17-19]</sup>. Microbiome is still a largely under explored regulator of drug metabolism and bioavailability<sup>[17-19]</sup>. Our data present here provide additional evidence for the metabolism of aesculin by human gut microbiota.

In this study, two novel sulfated aesculetin metabolites were identified in rat urine, which might represent very interesting modifications of coumarins. As aesculetin has two hydroxyl groups at carbons 6 and 7, it can serve as targets for O-methylation or O-glycosylation. It has been reported that O-methylated products of

aesculetin are scopoletin (6-O-methyl aesculetin), isoscapoletin (7-O-methyl aesculetin), and scoparone (6, 7-O-dimethyl aesculetin), which possess antimicrobial, immunosuppressive, and hypolipidemic activities<sup>[7,9]</sup>. The hydroxyl groups of aesculetin, especially the 7-hydroxyl group, can also be glucosylated in plants such as hairy roots of medicinal morning glory<sup>[11]</sup>. In addition, mushroom polyphenol oxidase (PPO) and horseradish peroxidase (POD) can oxidize aesculetin and generate its o-quinone<sup>[13]</sup>. However, as far as we are know, no sulfated derivative of aesculetin has been identified. Indeed, sulfation is one of the most important modifications in many natural compounds. As their sulfate groups accumulate negative charges, sulfated coumarins can interact with certain molecular domains that usually have positive charges, resulting in compounds with anti-viral, anti-tumor and anti-oxidative effects<sup>[12]</sup>. Therefore, these novel derivatives identified in rat urine offer new evidence for the biological activities ascribed to aesculetin.

## COMMENTS

### Background

Aesculin and its metabolites have pleiotropic pharmacological and biochemical properties, such as antioxidative, photo-protective and multiple immunomodulatory effects. However, their biotransformation has not been extensively studied, let alone their complex structure-activity relationships.

### Research frontiers

To uncover the dynamic progress and identify the pharmacological metabolites of natural products is one of the hotspots in development of traditional Chinese herbal drugs.

### Innovations and breakthroughs

The biotransformation of aesculin was investigated in this study. Human gut bacteria could completely convert aesculin into aesculetin *in vitro*. Six aesculetin metabolites were identified in rat urine, 2 of which were first found. These novel sulfated aesculetin metabolites represent one of the most important modifications of coumarins. As their sulfate groups accumulate negative charges, sulfated coumarins can interact with certain molecular domains that usually have positive charges, resulting in compounds with anti-viral, anti-tumor and anti-oxidative effects. Therefore, these novel derivatives offer new evidence for the biological activities ascribed to aesculin.

### Applications

The results of this study can direct the development of anti-viral, anti-tumor and/or anti-oxidative natural herbal drugs, and display a useful design for retrieval of the complex biotransformation process of ceterin natural compounds.

### Terminology

LC/ESI-MS stands for Liquid chromatography-electrospray ion trap mass spectrometry; CFU indicates that colony forming units.

### Peer review

The authors studied the biotransformation of aesculin by gut bacteria in rats and showed that aesculin had a wide range of biological activities that may have important pharmaceutical applications. Hence, knowledge about its metabolism is essential for understanding its therapeutic effects. The findings are interesting. Aesculin was converted to aesculetin in an *in vitro* bacterial culture system and 6 aesculetin metabolites were identified in rat urine, 2 of which were first observed.

## INTRODUCTION

We report the first known case of both Noonan syndrome and Whipple's disease (WD) occurring in the same patient. Noonan syndrome is an autosomal dominant genetic disorder that causes abnormal development, originally labeled as the "male Turner syndrome." It affects at least 1 in 2500 male and female children and is thought to be due to a genetic mutation of *PTPN11* gene, first discovered in 2001. Signs and symptoms include webbing of the neck, changes in the sternum (pectus excavatum), facial abnormalities (low-set or abnormally shaped ears, ptosis, hypertelorism, epicanthal folds, antimongoloid palpebral slant, micrognathia), cubitus vulgaris, congenital heart disease (especially pulmonary stenosis, and/or atrial septal defect), and variable hearing loss. Mild mental retardation is present in approximately 25% of cases. WD is a rare systemic infection caused by a non-acid fast gram positive bacillus, *Tropheryma whippelii* (*T. whippelii*). Thus far fewer than 1000 reported cases have been described with an annual incidence of approximately 30 cases per year since 1980. In 1907, Whipple first reported this syndrome in an original case report. Invasion or uptake of the bacillus is widespread throughout the body, including the intestinal epithelium, macrophages, capillary and lymphatic endothelium, colon, liver, brain, heart, lung, synovium, kidney, bone marrow, and skin. Advancement in diagnosis has only recently occurred with the first successful culture of *T. whippelii* in the year 2000; nearly a full century after the disease entity was first described.

## Abstract

We report the first known case of both Noonan syndrome and Whipple's disease occurring in the same patient. A 36-year-old female with history of Noonan syndrome developed fatigue, anorexia, arthritis of the knees and hands with a diffuse hyperpigmented rash, night sweats, and an unintentional fifteen pound weight loss over 4 mo. Small bowel enteroscopy demonstrated mild edematous yellowish mucosa without friability. Random small bowel biopsies revealed extensive periodic acid-Schiff positive material within the foamy macrophages. She was treated with a 12 mo course of trimethoprim-sulfamethoxazole DS with clinical improvement to baseline status.

## CASE REPORT

A 36-year-old female with history of Noonan syndrome developed fatigue, anorexia, arthritis of the knees and hands with a diffuse rash, night sweats, and an

**Figure 1** Computerized tomography scan image displaying diffuse lymphadenopathy and small bowel wall thickening.

**Figure 2** A periodic acid-Schiff (PAS) stain showing extensive PAS positive material within the foamy macrophages (small intestinal biopsy).

unintentional fifteen pound weight loss over the past 4 mo. One year prior, she had an endoscopic workup performed for iron deficiency, which was significant for erosive esophagitis. Of note, ileal and duodenal biopsies were histologically normal. Prior to this consultation, she had recently seen a rheumatologist and was placed on prednisone and Plaquenil for arthritis thought to be of rheumatoid origin. She then developed an episode of acute right lower quadrant abdominal pain and an abdominal computerized tomography (CT) scan was ordered. This revealed lymphadenopathy and diffuse thickening of the small bowel (Figure 1). The patient was then referred for gastroenterological consultation at which time her chief complaints were fatigue, arthralgias, and anorexia. She denied abdominal pain, diarrhea, hematochezia, fevers, chills, nausea, or vomiting.

She was 5'2" feet tall and weighed 117 pounds. Physical examination was significant for arthritis of the knees and hands with mild diffuse hyperpigmented skin. Laboratory tests were significant for sedimentation rate of 33, hemoglobin 9.6, and a white blood cell count of 10.4 without a shift. At this time, concern for lymphoma warranted further investigation. Thus, enteroscopy was performed in May 2006. The only significant endoscopic findings were a mild edematous yellowish mucosa without friability in the

distal duodenum and jejunum. Random small bowel biopsies revealed intestinal mucosa in which the lamina propria was markedly expanded due to an infiltrate of histiocytic-appearing cells with foamy cytoplasm and a periodic acid-Schiff (PAS) stain showing extensive PAS positive material within the foamy macrophages; AFB stain was negative (Figure 2). These findings were consistent with a diagnosis of WD. Due to the patient's inability to psychologically tolerate intravenous therapy and an allergy to penicillin, she was placed on an oral regimen of trimethoprim-sulfamethoxazole double-strength twice daily for a 12 mo course.

At follow up in December 2006, she had a remarkable clinical improvement and returned to her baseline clinical status. That is, she had a marked improvement in weight and complete resolution of anemia, arthritis, rash, and bowel wall thickening and lymphadenopathy on CT scan.

## DISCUSSION

We report the first known case of both Noonan syndrome and WD occurring in the same patient. Noonan syndrome is an autosomal dominant genetic disorder that causes abnormal development, originally labeled as the "male Turner syndrome." It affects at least 1 in 2500 male and female children and is thought to be due to a genetic mutation of *PTPN11* gene, first discovered in 2001.

WD is a rare systemic infection caused by a non-acid fast gram positive bacillus, *T. whipplei*. Thus far, fewer than 1000 reported cases have been described<sup>[1]</sup>, with an annual incidence of approximately 30 cases per year since 1980. In postmortem studies, the frequency of the disease is less than 0.1%<sup>[2]</sup>. In 1907 Whipple first reported this syndrome in an original case report<sup>[3]</sup>. The ability to diagnose WD was advanced in 1949 with PAS staining which identified granules within macrophages that likely represented degenerating bacterial forms<sup>[4]</sup>. Invasion or uptake of the bacillus is widespread throughout the body, including the intestinal epithelium, macrophages, capillary and lymphatic endothelium, colon, liver, brain, heart, lung, synovium, kidney, bone marrow, and skin. The chronic, insidious nature of WD may at least be in part due to the long doubling time of 17 d. Advancement in diagnosis has only recently occurred with the first successful culture of *T. whipplei* in the year 2000; nearly a full century after the disease entity was first described. One year later, in 2001, the first phenotypic characterization of the Whipple bacillus occurred, resulting in the renaming of the bacterium to *T. whipplei*<sup>[5]</sup>.

Clinical manifestations include four cardinal findings: arthralgias, weight loss, diarrhea, and abdominal pain. Neurological involvement (dementia, supranuclear ophthalmoplegia, nystagmus, and myoclonus) has been recognized in up to 40% of patients, either as initial manifestations or during the course of the disease. Less common symptoms include fever and skin

hyperpigmentation. There may also be symptoms or signs related to cardiac disease (dyspnea, pericarditis, culture-negative endocarditis), pleuropulmonary disease (pleural effusions) or mucocutaneous disease.

Traditionally, the disease has been described in two stages: a prodromal stage and a much later steady-state stage. The time between these stages varies; however, it typically averages 6 years<sup>[6]</sup>. The prodromal stage is predominantly characterized by nonspecific symptoms including arthralgias and fatigue. More specific findings such as weight loss, diarrhea, and multi organ involvement occur in the steady state stage. Approximately 15% of patients with WD do not present with classic signs and symptoms of the disease; therefore, the diagnosis should be considered in a broad range of clinical scenarios<sup>[7,8]</sup>. Furthermore, immunosuppressed patients can display a more rapid progression of the disease<sup>[9,10]</sup>.

The clinical manifestations of the disease are believed to be caused by infiltration of *T. whipplei* into various tissues. The patient's immune system reacts by incorporating the bacteria into tissue macrophages. Serum studies typically have presented nonspecific findings, therefore biopsy of the appropriate tissue is essential for diagnosis. Tissue samples from the small bowel show expanded villi containing PAS staining macrophages. After the discovery of PAS staining in 1949, the detection of bacteria in macrophages in 1961 further contributed to our understanding of WD<sup>[4,11,12]</sup>. However, the only specific diagnostic tests for WD include determining the presence of *T. whipplei* DNA through molecular amplification of the 16S rRNA of *T. whipplei* by polymerase-chain-reaction (PCR) and cell culture of the organism<sup>[13-15]</sup>. Subsequently, this finding led to electron microscopy, which in turn led to DNA testing for *T. whipplei*. Most recently, in 2003 the full sequencing of two genomes from two different strains of *T. whipplei* has been reported<sup>[6,16,17]</sup>.

In conjunction with clinical signs and symptoms, endoscopy is an important diagnostic modality in WD. Endoscopic examination of the postbulbar region of the duodenum and jejunum includes findings consisting of pale yellow and shaggy mucosa alternating with eroded, erythematous, or mildly friable mucosa<sup>[18]</sup>. Several biopsy samples should be studied because the lesions can be sparse and focal<sup>[6]</sup>.

In the era before routine access to antibiotics, WD was a universally fatal disease. The discovery of antibiotics has resulted in antibiotics as the mainstay of therapy for WD. Treatment regimens are tailored for severity of disease, however, lack of well-controlled trials limits recommendations to reports of experience. The first reported efficacy of antibiotic treatment with chloramphenicol occurred in 1952<sup>[19]</sup>. With the progressive discovery of safer antibiotics, tetracycline at one time was the mainstay of therapy for many years. However, a comprehensive review by Keinath *et al*<sup>[20]</sup> subsequently revealed an overall relapse rate of 35% with

a high CNS relapse rate among patients treated primarily with tetracycline<sup>[21,22]</sup>. As a result, the current standard of therapy includes an initial phase of intravenous antibiotics known to penetrate the blood brain barrier followed by 12 mo of oral maintenance treatment. A typical course often includes ceftriaxone or penicillin for two weeks followed by trimethoprim-sulfamethoxazole double strength twice per day for one year. Depending on allergies to medications, antibiotics can be substituted as needed.

## Abstract

*Helicobacter pylori* (*H. pylori*), a gastric pathogen, is a major cause of chronic gastritis and peptic ulcer disease, and is an important risk factor for the development of gastric malignancies. Culture of the bacterium from gastric biopsy is essential for the determination of drug resistance of *H. pylori*. However, the isolation rates of *H. pylori* from infected individuals vary from 23.5% to 97% due to a number of factors such as biopsy preparation, cultural environment, medium and the method adopted. In the present case, we found that a prolonged incubation period of up to 19 d allowed successful isolation of *H. pylori* from a patient who received triple therapy that failed to eradicate the bacterium.

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is a gastric pathogen, which is present in approximately half of the world's population. It is a major cause of chronic gastritis and peptic ulcer disease, and is an important risk factor for the development of gastric malignancies<sup>[1-4]</sup>. Although accurate non-invasive methods such as the urea breath test, the stool antigen test, and serology are available, biopsy-based invasive techniques, including the rapid urease test, histology and culture, are required to confirm the infection. Moreover, culture of the bacterium from gastric biopsy is essential for the determination of drug resistance of *H. pylori* and thus for the subsequent treatment strategy after failed eradication therapy. However, the isolation rates of *H. pylori* from infected individuals vary from 23.5% to 97%<sup>[5,6]</sup> due to a number of factors, such as biopsy preparation, cultural environment, medium and the method adopted. The duration of incubation for isolation of *H. pylori* has been recommended to be 2 to 7 d. Here we reported our observation that a prolonged incubation period of up to 19 d allowed successful isolation of *H. pylori* from a patient who received triple therapy that failed to eradicate the bacterium.

## CASE REPORT

A patient (female, 59 years old) with an *H. pylori* positive duodenal ulcer received two consecutive trials of 7-d triple regimens in a regional hospital. The regimen consisted of Metronidazole, Clarithromycin, and Cimetidine. Four weeks after the second trial, the patient was still positive for a <sup>13</sup>C urea breath test. She then came to Beijing for a solution. To obtain the drug resistance profile of the *H. pylori* strain, the patient underwent an upper gastrointestinal endoscopy, and four biopsy specimens were taken from gastric antrum. The biopsies were placed directly into transport medium at room temperature and processed for culture within 2 h. Biopsy samples were smeared on *H. pylori* selective Dent Columbia agar plates (Oxoid Ltd., London, England) supplemented with 8% sheep blood (Hengzhaoxiang Science & Technology Co., Beijing), and incubated in a microaerophilic environment (5% O<sub>2</sub>, 10% CO<sub>2</sub>, and 85% N<sub>2</sub>) at 37°C. The plates were scheduled to be checked on days 3, 6, 8, and 10. However, there was no colony growing after 10 d. We decided to incubate the plates further, and check the plates every 3 d. On day 19, one suspected *H. pylori*-like colony appeared

on one of the plates. This colony was subcultured in non-selective 2 Columbia agar plates containing 8% sheep blood in the same environment mentioned above, for three days. The isolate was confirmed to be *H pylori* based on its typical colony morphology, negative Gram's stain, and positive urease, catalase, and oxidase tests.

The antimicrobial susceptibilities of the isolate to metronidazole, clarithromycin, amoxicillin, ampicillin, levofloxacin, and rifampicin were determined by the E-test (AB Biodisk, Solna, Sweden). Briefly, a bacterial suspension (2 McFarland standard) was prepared with brain heart infusion (Oxoid Ltd., London, England) containing 10% heat-treated serum<sup>[7]</sup>. After the bacterial suspension was swabbed onto the entire Columbia plates, sterile E-test strips impregnated with the above antibiotics were placed on the agar surface of corresponding plates. Minimal inhibitory concentration (MICs) were determined according to the manufacturer's instructions after three to four days of incubation. The isolate exhibited high-level resistance to metronidazole (MIC > 256 µg/mL) and clarithromycin (MIC > 48 µg/mL), but was susceptible to amoxicillin, ampicillin, levofloxacin, and rifampicin (all MIC < 0.016 µg/mL), which explained the failure of the triple regimens containing metronidazole and clarithromycin.

## DISCUSSION

Culture has been considered the "gold standard" in confirmation of the diagnosis of *H pylori* infection. Moreover, the isolation and identification of strains is important for the investigation of profiles of bacterial virulence and, particularly, drug resistance. Due to the gradually rising prevalence of *H pylori* resistance to many antibiotics commonly used in triple regimens, the determination of antibiotic susceptibility of individual isolates is of particular importance. However, primary isolation of *H pylori* from gastric biopsies is rather demanding, and is affected widely by the culture conditions in addition to the biopsy-related factors<sup>[8]</sup>. Our report also indicates that a prolonged incubation is necessary for some strains, especially those enduring hostile environment or a period of antibiotic force. It was reported that a longer incubation of 11 d is helpful for isolating *H pylori* strains from long-term-frozen specimens<sup>[9]</sup>, but this is the first report of the bacteria recovered after 19 d incubation. Indeed, the isolate requiring 19 d recovery later exhibited normal growth characteristics of *H pylori* strains when compared to another strain, NCTC11637, indicating its unusually long incubation requirement was a temporary predicament.

It has been demonstrated *in vitro* that *H pylori* cells can transform from a cultivatable spiral-shaped form to a non-cultivatable coccoid form, in which the recovery of the bacterium is very difficult by routine culture methods<sup>[10]</sup>. We would propose that during the period of eradication therapy, some organisms transform into the so-called "uncultivable form" with the propagation being stopped under the antimicrobial pressure in the local environment.

However, these organisms, which may have been selectively resistant to the used antimicrobials, survive, possibly with some suppressed metabolic activities<sup>[11]</sup>. Once released from the medication at the end of the trial, these organisms gradually restore their normal growing features after prolonged incubation in an optimal environment and eventually become cultivatable. Therefore, these "uncultivable form" organisms might contribute, at least partially, to treatment failures and the development of antimicrobial resistance. In the meantime, we suggest that a new *H pylori* culture after a first attempt to eradicate *H pylori* needs to be postponed, probably by four weeks or even longer. It is noticeable that the patient was positive for the <sup>13</sup>C urea breath test four weeks after completion of treatment, indicating that there are a number of organisms that are able to produce urease activities after release from antimicrobial pressure after four weeks. The coccoid *H pylori* can produce urease, though at a decreased level<sup>[12]</sup>, suggesting its potential pathogenicity.

### Abstract

In DNA-guided hepatitis B treatment, viral load is insufficient, and requires other viral markers for treatment of hepatitis B patients as in patients with acute exacerbation of chronic hepatitis B, end-stage renal disease on dialysis, human immunodeficiency virus co-infected patients. There are exceptions to this rule: a residual level hepatitis B virus (HBV) DNA at 24 wk predicts beneficial outcome and reduced resistance at 1 year. The genotypic viral resistance to antiviral agents and occult HBV infection can be determined by HBV-DNA levels.

### TO THE EDITOR

We read with interest the article “DNA-guided hepatitis B treatment: viral load is essential, but not sufficient” by Barcena Marugan *et al*<sup>[1]</sup>. We agree that viral load is

essential but requires other viral marker for treatment of hepatitis B patient.

Patients with exacerbation of chronic hepatitis B, requiring treatment, can be differentiated from acute hepatitis B based on hepatitis B virus (HBV) DNA<sup>[2]</sup>, but the sensitivity and specificity increase with addition of IgM anti-HBc. Low or undetectable DNA levels were seen in acute hepatitis<sup>[3]</sup>, whereas HBV DNA levels became detectable during reactivation of chronic hepatitis<sup>[4]</sup>. Kumar *et al*<sup>[5]</sup> in their study showed a low level of HBV DNA (< 0.5 pg/mL) in about 96% of patients with acute infection, as opposed to 13% in those with exacerbation of chronic hepatitis. The sensitivity and specificity of low levels of HBV DNA for identifying an acute infection are 96% and 86.6%, respectively, which increase to 100% and 97.9% respectively with high titers of IgM anti-HBc.

Tong *et al*<sup>[6]</sup> applied the four criteria (European Association for the Study of the Liver, a treatment algorithm by an independent panel of hepatologists in the United States, an Asian-Pacific consensus statement and the practice guidelines from the American Association for the study of liver disease) to treat 369 HBsAg-positive patients with antiviral therapy. Using these criteria for antiviral therapy as stated by the guidelines, only 20%-60% of hepatocellular carcinoma (HCC) patients and 27%-70% of patients who died of non-HCC were identified for antiviral therapy. If the criteria were broadened with baseline serum albumin 3.5 gm/dL or less or platelet counts of 130 000 mm<sup>3</sup> or less, 89%-100% of deaths from non-HCC liver-related complications and 96%-100% HCC patients would be identified for antiviral therapy.

In patients with end-stage renal disease on dialysis with HBV infection, it remains very difficult to predict the severity and outcome of liver disease based on the HBV-DNA level *per se*<sup>[7]</sup>. Liver biopsy appears to be the only definitive and reliable means to establish the activity of liver disease in patients on dialysis. It is recommended before starting antiviral therapy and undergoing kidney transplantation. Weisberg *et al*<sup>[8]</sup> have shown that the estimated 5-year survival rates in patients with end stage renal disease, chronic persistent hepatitis, chronic active hepatitis and chronic active hepatitis with cirrhosis due to hepatitis B are 97%, 86% and 55%, respectively.

In human immunodeficiency virus (HIV) infected patients with HBV, there is an increased risk of cirrhosis,

end-stage liver disease and death from liver disease, especially in patients with a low CD4 cell count or concomitant alcohol use<sup>[9]</sup>. The treatment of HBV patients co-infected with HIV depends on HBV-DNA levels, histological evidence of active and /or advanced disease (Metavir > A2 and/or  $\geq$  F2) and CD4 counts whether < or  $\geq$  500/mm<sup>3</sup>. So, HBV-DNA levels cannot be used alone in co-infected patients with HIV. A CD4 count < 500/mm<sup>3</sup> requires HAART regimen including tenofovir and lamivudine or emtricitabine. A CD4 count  $\geq$  500 mm<sup>3</sup> can be treated with entecavir, interferon or adefovir<sup>[10]</sup>.

HBV-DNA load is essential but not sufficient and has few exceptions. Keeffe *et al*<sup>[11]</sup> showed that complete virologic response (no detectable residual HBV DNA) at 24 wk in patients on anti-viral drugs, and the likelihood of HBeAg sero-conversion and maintenance of an undetectable level of HBV DNA are high, and resistance unlikely occurs. So the residual level HBV DNA at 24 wk can be used as a predictor of beneficial outcome and reduced resistance at 1 year.

The genotypic viral resistance to antiviral agents can be determined by  $\geq 1 \log_{10}$  IU/mL increase in serum HBV DNA. Virological breakthrough or secondary antiviral treatment failure is usually defined as reappearance or  $\geq 1 \log_{10}$  IU/mL increase after initial lack of detection or initial  $\geq 1 \log_{10}$  IU/mL reduction of serum HBV DNA<sup>[12]</sup>. Virological breakthrough is usually followed by biochemical response<sup>[13]</sup>. So, a change of serum HBV DNA can be an earliest predictor of viral resistance to antiviral agents. All patients commencing antiviral therapy should have quantitative HBV DNA measurements at baseline and three months after starting therapy<sup>[14]</sup>. It helps identify response and primary treatment failure in patients on lamivudine.

Occult HBV infection is defined as the detection of HBV-DNA in the serum or liver tissue of patients with negative hepatitis surface antigen<sup>[15]</sup>. Occult HBV infection has low HBV DNA levels less than 10000 in the serum and 0.01-0.1 copy per liver cell<sup>[16]</sup>. The likelihood of antiviral therapy benefit is low as most patients with occult HBV infection have very low levels of HBV DNA. Serum HBV DNA levels fluctuate in cryptic HBV carriers, repeating the HBV test over time is a useful tool in identifying the occult HBV status<sup>[17]</sup>.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: Introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Leader Frontier: Comment on excitement and existing problems of core fields, and offer suggestions for the future research; (3) Topic Highlight: Experts in gastroenterology and hepatology to focus on certain individual hot topics and try to provide answers to the clinical questions on the topics; (4) Observation: Which updates the development of old and new questions, highlights unsolved questions, and provides strategies on how to solve the questions; (5) Guidelines for Basic Research: Which provides Guidelines for basic research; (6) Guidelines for Clinical Practice: Which provides guidelines for clinical diagnosis and treatment; (7) Review Articles: Summarize the representative progress in core scientific disciplines, comment on the research status, and make suggestions for the future work; (8) Original Articles: Originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: Briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: Report a rare or typical case; (11) Letters to the Editor: Discuss and make reply to the contributions published in *WJG*, or introduce and comment on a controversial issue of general interest; (12) Book Reviews: Introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: Guidelines or common understanding for gastroenterology and hepatology from international academic committee.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The trial register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS AND DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho* I, *Kpn* I, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

This review focuses on the relationship between hepatitis C virus (HCV) infection and glucose metabolism derangements. Cross-sectional and longitudinal studies have shown that the chronic HCV infection is associated with an increased risk of developing insulin resistance (IR) and type 2 diabetes (T2D). The direct effect of HCV on the insulin signaling has been analyzed in experimental models. Although currently available data should be considered as preliminary, HCV seems to affect glucose metabolism *via* mechanisms that involve cellular pathways that have been implicated in the host innate immune response. IR and T2D not only accelerate the histological and clinical progression of chronic hepatitis C, but also reduce the early and sustained virological response to interferon- $\alpha$ -based therapy. Thus, a detailed knowledge of the mechanisms underlying the HCV-associated glucose metabolism derangements is warranted, in order to improve the clinical management of chronic hepatitis C patients.

### INTRODUCTION

Hepatitis C virus (HCV) infection is a frequent cause of acute and chronic hepatitis, and leads to the development of cirrhosis and hepatocellular carcinoma. It is estimated that about 150 to 200 million people have been in contact with HCV worldwide, and approximately 85% are chronically infected. The spectrum of severity of liver disease associated with HCV varies widely, as does the rate of progression towards the cirrhotic stage. The latter seems to depend on several, mostly host-related cofactors, such as age, sex, level of alcohol consumption, overweight, immune status and co-infections<sup>[1,2]</sup>. One of these cofactors is type 2 diabetes (T2D), which has been recognized to modify the course of hepatitis C even at the stage of insulin resistance (IR), a condition that precedes the development of T2D<sup>[3,4]</sup>. Although individuals may develop IR independently of HCV, a considerable amount of clinical and experimental data suggest that HCV contributes to its pathogenesis. This aspect is important, because IR seems not only to accelerate the course of chronic hepatitis C, but also to influence the response to antiviral therapy<sup>[5]</sup>. The scope of this review is to discuss the current level of evidence in favor of a causal association between HCV and T2D/IR, its clinical impact, and some directions for management.

### ASSOCIATION BETWEEN HCV AND T2D

T2D is a common complication of all liver diseases, independently of the etiology, especially at the advanced stage. However, clinical and experimental data suggest a direct role of HCV in the perturbation of glucose metabolism. The first observation that cirrhotic patients infected with HCV may present with T2D more often than patients with cirrhosis of other

etiology was reported in 1994 by Allison *et al*<sup>[6]</sup>. Most studies using a cross-sectional design and comparing the prevalence of T2D in a population of chronic hepatitis C patients with that of a comparator group have confirmed these preliminary observations<sup>[7-14]</sup>, with rare exceptions<sup>[15]</sup>. Comparator groups have included patients with chronic liver disease<sup>[7-9,12-14]</sup>, drug users<sup>[10]</sup> or human immunodeficiency virus (HIV) mono-infected patients<sup>[11]</sup>. It can be argued that, in these studies, the two populations of patients-i.e. HCV-infected and uninfected-may have differed by relevant risk factors for T2D, notably age, gender distribution and stage of liver disease. It is noteworthy that, in the HIV-co-infected cohorts studied by Visnegarwala *et al*<sup>[11]</sup>, the association between HCV and T2D was significant, as assessed by multivariate analysis, only among subjects < 50 years old. Similarly, in the study by Lecube *et al*<sup>[12]</sup>, glucose abnormalities, including impaired fasting glucose (IFG), were significantly more prevalent (i.e. about three-fold) among HCV-positive patients attending a liver unit, compared to HCV-negative patients, only when they were at a pre-cirrhotic stage. These observations suggest that HCV interferes with glucose metabolism independently of age and stage of liver disease. At a later, cirrhotic stage, however, multiple factors contributing to IR may prevail and partially or completely mask the HCV-related effect. Further evidence has come *via* case-control studies in which all cases were represented by HCV-infected individuals<sup>[16-24]</sup>, although in most cases, the prevalence of T2D among HCV-infected individuals compared to matched controls was, in general, lower than that seen in previous studies.

Several investigators have approached this issue from a different point of view, i.e. measuring the prevalence of HCV markers among populations of diabetic patients<sup>[8,15,25-33]</sup>. Most controlled studies have suggested a significant association, the proportion of HCV-positive persons among diabetics being two- to seven-fold compared to controls<sup>[8,15,29,32]</sup>. The prevalence of HCV markers among patients with T2D reported by uncontrolled studies was also claimed to be higher than that observed in the general population taken as a reference<sup>[25,27,30]</sup>. However, the study by Sotiropoulos *et al*<sup>[26]</sup> reported a rather low HCV prevalence (1.65%), especially if one considers that a field survey in the Greek general population gave a HCV seroprevalence of 1.25%<sup>[34]</sup>. Other controlled studies from Italy<sup>[28]</sup>, Nigeria<sup>[31]</sup> and Turkey<sup>[33]</sup> have failed to find an excess prevalence of HCV infection among patients with T2D. The data have therefore proven inconclusive. It has been suggested that patients with T2D are at risk of blood-borne infections *via* repeated use of finger stick devices. However, a single study from France, evaluating the prevalence of HCV antibodies in 259 patients with T2D seen during 1998 at a diabetic unit, has failed to confirm this hypothesis<sup>[35]</sup>. One cannot exclude that iatrogenic transmission of HCV among diabetic patients may however have been significant in previous decades.

The potential ascertainment bias that may occur in

clinic-based studies that target a specific disease group has been overcome in a vast (and hitherto unsurpassed) study conducted in the general population, the Third National Health and Nutrition Examination Survey (NANHES-III)<sup>[36]</sup>. This study, which included 9841 subjects aged  $\geq 20$  years, showed that persons who were anti-HCV-positive and aged  $\geq 40$  years had an odds ratio of 3.77 (95% CI: 1.80-7.87), after adjusting for sex, body mass index (BMI) and ethnicity, of having T2D compared to anti-HCV-negative individuals.

Thus, clinic-based studies and the general population-based NANHES-III study came to similar conclusions, which reinforce the hypothesis of a causal association between HCV infection and T2D. As a result of the cross-sectional nature of all these surveys, however, as hinted before, a temporal relationship between HCV infection and T2D cannot be established. This issue, i.e. did the HCV infection come before the occurrence of T2D or *vice versa*, has been addressed by longitudinal studies. A prospective, case-cohort study, performed in the United States, analyzed whether persons who developed T2D were more likely to have had precedent HCV infection when enrolled in a community-based cohort of 1084 persons aged 44-65 years (the Atherosclerosis Risk in Communities Study)<sup>[37]</sup>. The prevalence of HCV in this population was 0.8%. A total of 548 subjects developed *de novo* T2D over 9 years of follow-up. Prior to entry, subjects had been categorized as low-risk or high-risk for T2D based on age and BMI. Among those at high risk for T2D, persons with HCV infection were more than 11 times as likely as those without HCV infection to develop T2D (relative hazard, 11.58; 95% CI: 1.39-96.6). Among those at low risk, the incidence of T2D was not increased among HCV-infected subjects. The conclusion of this important survey was that pre-existing HCV infection may increase the incidence of T2D in persons with known risk factors. The second study<sup>[38]</sup>, a community-based cohort survey performed in southern Taiwan, enrolled 4958 persons aged  $\geq 40$  years, without T2D at entry. This study included 3486 seronegative persons, 812 anti-HCV-positive patients, 544 individuals with the hepatitis B surface antigen (HBsAg) and 116 with hepatitis B virus (HBV)/HCV co-infection. Over a follow-up of 7 years, 474 cases of incident T2D were recorded: overall, 14.3% of anti-HCV-positive, 7.5% of HBsAg-positive, and 8.6% of seronegative individuals developed T2D during the study. Compared to anti-HCV-negative individuals, anti-HCV-positive persons had a higher cumulative incidence of T2D ( $P < 0.0001$ ). By multivariate analysis, the fact of being anti-HCV-positive, co-infection with HBV and HCV, overweight, obesity, and increasing age were all significantly associated with T2D, while sex and alcohol consumption, among other factors, were not. Interestingly, when patients were stratified by age and BMI, the risk of developing T2D among anti-HCV-positive individuals increased when age decreased and BMI levels increased. This study concluded that HCV infection is an independent predictor of T2D. The risk

was higher in patients with elevated BMI, but, at variance with the previous study, seemed to decrease with age.

Thus, cross-sectional and longitudinal studies both seem to converge towards the same conclusion, i.e. there exists an excess T2D risk in HCV-infected persons compared to controls infected with HBV, which suggests a direct role of HCV in inducing derangement of glucose metabolism. A recent, large meta-analysis, the first of this kind, has reached the same conclusion<sup>[39]</sup>.

An additional, strong case in favor of an association between HCV and T2D comes from longitudinal studies performed in patients having received a liver or kidney transplant. T2D is a common complication of liver transplantation (LT). Apart from isolated negative reports<sup>[40]</sup>, there is accumulating evidence that HCV is a strong predictor of new-onset T2D after LT<sup>[41]</sup>. A first study from Toronto, Canada<sup>[42]</sup>, analyzed the prevalence of T2D among 278 LT recipients, whose indication for transplantation was liver failure caused by HCV (110 patients), HBV (53 patients) or cholestatic liver disease (115 patients). Multivariate analysis revealed that HCV-related cirrhosis ( $P = 0.002$ ), pre-LT T2D ( $P < 0.0001$ ) and male gender ( $P = 0.019$ ) were independent predictors of the presence of T2D 1 year after LT. The high prevalence of T2D persisted among HCV-positive persons, with 41% being diabetic at 5 years. This observation was subsequently confirmed by other studies. In a series from Harvard<sup>[42]</sup>, which compared 47 HCV-positive to 111 HCV-negative cases, HCV infection was an independent risk factor for the development of T2D after LT (hazard ratio 2.5,  $P = 0.001$ ). These data were repeatedly confirmed by later studies<sup>[43-49]</sup>, with one exception from the [University of California, Los Angeles (UCLA)] series, in which the lack of association may have been a consequence of the excess representation of HCV-positive patients<sup>[50]</sup>. Several predisposing factors were identified across the studies: impaired fasting glucose and a maximum lifetime BMI over 25 kg/m<sup>2</sup><sup>[49]</sup>, age and male gender<sup>[48]</sup>, serum HCV RNA level after LT<sup>[51]</sup>, and use of tacrolimus<sup>[45]</sup> or steroid boluses<sup>[43]</sup>. On the other hand, use of cyclosporine<sup>[49]</sup> and rapid discontinuation of steroids<sup>[52]</sup> seem to reduce the incidence of T2D among HCV-positive persons.

A similarly increased risk of T2D has been reported after kidney transplantation (KT). After two early reports, underlining a rather strong association between ongoing HCV infection and post-KT T2D<sup>[53,54]</sup>, a major retrospective analysis on 427 kidney recipients without T2D before KT<sup>[55]</sup> showed that, by multivariate logistic regression, HCV (adjusted OR 5.58; 95% CI: 2.63-11.83;  $P = 0.0001$ ), weight at transplantation (adjusted OR 1.028; 95% CI: 1.00-1.05;  $P = 0.001$ ), and tacrolimus (adjusted OR 2.85; 95% CI: 1.01-5.28;  $P = 0.047$ ) were associated with newly onset T2D after KT. In this study, a significant interaction ( $P = 0.0001$ ) was found between presence of HCV and use of tacrolimus, since in the HCV-positive group, T2D occurred more often in tacrolimus-treated than cyclosporine A-treated patients (57.8% *vs* 7.7%;  $P < 0.0001$ )<sup>[55]</sup>. Most subsequent studies

confirmed this robust association<sup>[56-63]</sup>, with some exceptions<sup>[21,64-66]</sup>. Thus, in a recent meta-analysis of 10 studies, the pooled relative risk for post-KT T2D was 2.73 (95% CI: 1.94-3.83)<sup>[67]</sup>. When only two large studies were considered, the pooled relative risk was still 1.36 (95% CI: 1.21-1.54). The existing publication bias did not change the results in a meaningful way, after a sensitivity analysis was performed<sup>[67]</sup>. In addition to ongoing HCV infection, risk factors for developing T2D after KT are family history of T2D<sup>[55,60]</sup>, age<sup>[57,59,61,62]</sup>, use of tacrolimus<sup>[55,59,60,62,63]</sup>, smoking<sup>[61]</sup>, overweight/obesity<sup>[62,63]</sup>, African-American ethnicity<sup>[62]</sup> and pre-transplantation impaired fasting glucose<sup>[63]</sup>. Thus, there exists a significant increase of the risk of post-KT T2D in HCV-positive recipients, especially in the first 2 mo after transplantation<sup>[57]</sup>. Since T2D and its complications are a leading cause of mortality after KT, it is easy to understand that every effort should be made to clear HCV with antiviral therapy in the pre-KT period, whenever this is feasible.

Thus, HCV and T2D are associated more than just by chance, suggesting that HCV may alter glucose homeostasis by its direct action, or *via* indirect mechanisms such as through cytokine stimulation (see below). The association between HCV infection and glucose abnormalities holds true if, instead of looking at the occurrence of overt T2D, one considers pre-diabetes conditions, such as impaired glucose tolerance (IGT) or IR. The latter is defined as a condition in which higher than normal insulin concentration are needed to achieve normal metabolic responses or, alternatively, normal insulin concentration are unable to achieve normal metabolic responses<sup>[68]</sup>. It has to be stated clearly, however, that it is not clear whether IR associated with HCV infection invariably evolves towards T2D in all infected persons, especially those without other risk factors of T2D. There is a clear need of longitudinal studies that may clarify this issue.

In a classical paper, Hui and collaborators<sup>[4]</sup> compared fasting levels of serum insulin, C-peptide and IR [measured as homeostasis assessment (HOMA) score] in 121 HCV patients with stage 0 or 1 liver fibrosis and 137 healthy volunteers matched by sex, BMI, and waist-to-hip ratio. Results showed that such HCV-infected persons, notwithstanding their early stage of liver disease, had higher levels of insulin, C peptide, and HOMA scores compared with controls. Besides, this study was the first to suggest that genotype 3 may have significantly lower HOMA scores than other genotypes (which were comparable when adjusted for the remaining independent predictors of IR). Thus, this work showed how HCV may induce IR irrespective of the stage of advancement of the underlying liver disease, an effect that seemed to be genotype specific. In a similar, more recent paper, Moucari *et al.*<sup>[69]</sup> analyzed 600 consecutive patients (500 with chronic hepatitis C and 100 controls with chronic hepatitis B). IR was less frequent in chronic hepatitis B than in matched chronic hepatitis C cases (5% *vs* 35%, respectively,  $P < 0.001$ ), again irrespective of the stage of liver disease (patients were divided

according to the presence or absence of liver cirrhosis). Furthermore, IR was associated with genotypes 1 and 4 and high serum HCV RNA levels, even suggesting a trend, among patients without features of the metabolic syndrome, between HCV replication level and HOMA score. These data further corroborated the hypothesis that HCV may have a direct involvement in glucose metabolism derangement. A correlation between HCV RNA levels and HOMA score has been reported also by other studies<sup>[70-72]</sup>, especially in genotype 1<sup>[71]</sup> or after adjustment for age, gender and visceral adipose tissue area<sup>[72]</sup>. These results are not, however, confirmed by all investigators. In a recent paper, Anty *et al*<sup>[73]</sup> reported that lean patients with non-3 genotypes had higher glycemia and lower adiponectin levels than controls, at closer look it was evident that, considering only the 52 patients with F0/F1, then the HOMA scores were comparable to those of 22 controls ( $1.7 \pm 1.6$  vs  $1.4 \pm 1.5$ ,  $P = \text{NS}$ ). Negative results have also been reported from Japan, where two studies failed to identify HCV infection as independent predictor of IR<sup>[14,74]</sup>. Thus, further work is warranted in this field, and, more importantly, a thorough analysis, at the population level, of HCV sequences that may be directly involved in stimulating IR. Furthermore, it is impossible to determine whether HCV replication is responsible for increased IR or whether HCV replication is favored by hyperinsulinemia, as suggested by some *in vitro* data<sup>[75]</sup>, and/or by the increased serum levels of free fatty acids<sup>[76]</sup> typically observed in IR and T2D<sup>[77]</sup>. Finally, the poor correlation between HCV RNA levels and HOMA score may also be caused by the fact that the overall level of IR also depends on the contribution from the adipose tissue and muscle, two extrahepatic compartments not infected by HCV.

Finally, if HCV is increasing the level of IR or predisposes to the development of glucose metabolism disturbances, including T2D, in high-risk individuals, then curing HCV should result in amelioration of the HOMA score and in a decreased incidence of T2D after the end of therapy. Kawaguchi *et al*<sup>[78]</sup>, in their study on 89 patients, showed that eradication of HCV improved the HOMA score and the intrahepatic expression of the insulin receptor substrate (IRS) 1 and 2, two cellular transducers of the insulin signal (see below). Similar results have been reported in a cohort of 181 genotype 4 patients from Egypt<sup>[79]</sup>. Regarding the incidence of glucose metabolism derangements after sustained virological response (SVR), Romero-Gómez *et al*<sup>[80]</sup> assessed the effect of SVR and other host and viral factors on the incidence of impaired fasting glucose and T2D in 1059 patients with chronic hepatitis C treated with pegylated interferon (IFN)- $\alpha$ 2a and ribavirin. Their data show that SVR reduces by half the incidence of T2D and/or IFG during a post-therapy follow-up of  $27 \pm 17$  mo (range, 9.3-67 mo). Similar data have been reported in 234 patients followed in Barcelona for at least 3 years after the end of therapy<sup>[81]</sup>. However, in a cohort of 202 patients with a significantly longer follow-

up (8.0 years, range 5-16)<sup>[82]</sup>, the benefit of SVR (if any) was not observed, even after adjustment for several baseline risk factors of T2D.

In conclusion, HCV seems to increase the risk of incident T2D in predisposed individuals. As a result, the association between HCV and T2D is more evident among patients who are older and have higher BMI. When measuring IR before T2D has occurred, some HCV-infected patients are clearly less insulin sensitive than controls, matched for risk factors of T2D and stage of liver disease. This effect is probably associated with specific HCV sequences and/or subtypes, and shows some dose-dependence, i.e. may be correlated with HCV replication level. Curing HCV seems to have beneficial effects on the level of insulin sensitivity, although this may not be the rule. In the next chapter we will analyze the potential mechanisms of interference with the insulin signaling brought about by HCV.

## MECHANISMS OF HCV INTERFERENCE WITH INSULIN SIGNALING

Experimental data are compatible with direct interference of HCV with the insulin signaling cascade. This was first suggested by a study in which liver specimens obtained from 42 non-obese, non-diabetic, HCV-infected individuals and 10 non-HCV-infected subjects matched for age and BMI were exposed *ex vivo* to insulin, and examined for the contents and phosphorylation/activation status of some insulin signaling molecules<sup>[83]</sup>. Insulin-stimulated IRS-1 tyrosine phosphorylation was decreased by two-fold in HCV-infected patients compared to non-HCV-infected ones, and this was paralleled by significant reductions in IRS-1/p85 phosphatidylinositol 3 (PI3)-kinase association, IRS-1-associated PI3-kinase enzymatic activity and insulin-stimulated Akt phosphorylation<sup>[83]</sup>. It was concluded that, in patients with chronic hepatitis C, direct interactions between HCV and insulin signaling components occur that may result in IR, which in turn, may progress to T2D in at-risk individuals. In the transgenic mouse model<sup>[84]</sup>, the core-encoding region of HCV is sufficient to induce IR. This effect was reversed by treatment with anti-tumor necrosis factor (TNF)-antibodies, which suggested an increased level of serine phosphorylation of IRS-1 as induced by TNF- $\alpha$ . Thus, the core protein may induce IR indirectly *via* stimulation of the secretion of TNF- $\alpha$ . However, *in vitro* models suggest otherwise, hinting at a direct interaction of the core protein with the insulin signaling pathway. An increased proteasomal degradation of the IRS-1 and -2 *via* the activation of the suppressor of cytokine signaling (SOCS)-3 has been reported after transient expression of the core protein<sup>[85]</sup>. Direct but genotype-specific mechanisms have been advocated in another study<sup>[86]</sup>, in which down-regulation of peroxisome proliferator-activated receptor- $\gamma$  (PPAR- $\gamma$ ) and up-regulation of SOCS-7 was observed in cells transfected with the core protein of genotype 3,

whereas the core protein of genotype 1b activated the mammalian target of rapamycin, findings that were confirmed by using agonists for PPAR- $\gamma$  (rosiglitazone) or short interfering RNAs for SOCS-7<sup>[87]</sup>. Among the indirect mechanisms, an increased endoplasmic reticulum stress has also been described that may lead to IR<sup>[87]</sup>. More recently, the role of c-Jun N-terminal kinase (JNK) has been emphasized<sup>[88]</sup>. The HCV core protein-mediated Ser (312) phosphorylation of IRS-1 was inhibited by a JNK inhibitor in an *in vitro* infection assay using cell-culture-grown HCV<sup>[88]</sup>.

Studies on chronically infected patients have suggested that increased oxidative stress and intrahepatic inflammation may also play a role. Mitsuyoshi *et al*<sup>[89]</sup> evaluated 203 chronic hepatitis C patients with HCV genotypes 1 or 2 infection. HOMA and serum levels of thioredoxin, a marker of oxidative stress, were significantly correlated with each other, even after adjustment for BMI. However, in the human model, the indirect role of inflammatory mediators, such as TNF- $\alpha$ , seems more likely, in keeping with the transgenic mouse model. In fact, in chronic hepatitis C patients, an increased intrahepatic TNF- $\alpha$  response, which results in IR and a higher risk of developing T2D, has been described<sup>[90,91]</sup>. Further work is necessary in this field, and the availability of genotype-specific replicon assays may pave the way to more in-depth mechanistic analyses.

## CLINICAL CONSEQUENCES OF IR/T2D IN CHRONIC HEPATITIS C

The clinical consequences of IR and T2D on chronic hepatitis C are dual: accelerated fibrogenesis and reduced response to IFN-based therapy. Since one of the most frequent consequences of IR/T2D on the liver is steatosis, many data can be inferred indirectly looking at past studies in which the impact of non-virus- and non-alcohol-induced fatty liver on fibrosis progression was evaluated<sup>[2]</sup>. In fact, in these cases, the most likely cause of fatty liver was IR, and this, rather than steatosis, seems to predict the stage of fibrosis and its progression over time<sup>[4]</sup>. More generally, accelerated liver fibrogenesis should be considered in the complex of the consequences of the metabolic syndrome on the liver. This view allows one to consider several pathogenetic mechanisms other than IR, such as oxidative stress, increased secretion of pro-inflammatory adipokines and cytokines, and the peculiar susceptibility to apoptosis that has been associated with steatosis. High serum glucose<sup>[92]</sup>, hyperinsulinemia<sup>[93]</sup> and IR<sup>[4,71,94-97]</sup> are all associated with increased fibrosis in chronic hepatitis C, and more rapid progression of hepatitis C in diabetics has been reported also after LT<sup>[98]</sup> and KT<sup>[99]</sup>. However, claiming that the sole pathogenetic mechanism that underlies accelerated fibrogenesis in patients with chronic hepatitis C and IR is the hyperglycemic/hyperinsulinemic state is an oversimplification. First, it is not unknown whether patients with virus-induced

IR alone, i.e. without the other components of the metabolic syndrome (especially in the absence of the visceral obesity and the inflammatory state associated with it), share the same risk of increased liver disease progression compared to patients with overt metabolic syndrome. Second, patients with central obesity have not only increased IR but also altered levels of a whole array of pro-inflammatory cytokines and adipokines, which may exert their unwanted effects on the liver and other extra-adipose tissues independently of the action of insulin. The relative contribution of these cytokines to liver fibrosis in chronic hepatitis C is starting to be unraveled, but it is far from being fully understood.

In non-alcoholic steatohepatitis, hyperglycemia/hyperinsulinemia may be directly stimulating hepatic stellate cells to produce connective tissue growth factor (CTGF), which leads to increased collagen fiber deposition<sup>[100]</sup>. Increased intrahepatic levels of CTGF have been reported to occur in chronic hepatitis C<sup>[101]</sup>. The reduction of IR consequent to body weight reduction and increased physical activity may lead to reduced fibrosis score over time and a diminished number of activate hepatic stellate cells<sup>[102]</sup>.

Several pro-inflammatory cytokines and adipokines may be involved in the pathogenesis of liver injury in chronic hepatitis C. However, their relative contribution is under debate. A large, careful study has evaluated the role of TNF- $\alpha$ , interleukin 6, leptin and adiponectin in the pathogenesis of HCV-associated liver injury<sup>[103]</sup>. Only TNF-levels seemed to correlate with severity of portal and periportal inflammation, but none of the cytokines considered in this study were correlated with liver fibrosis. Several other studies have failed to pinpoint a clear correlation between the severity of fibrosis and serum levels of leptin<sup>[94,104-106]</sup>, with only one positive report<sup>[107]</sup>. The role of adiponectin is quite controversial<sup>[103]</sup>. In addition, recent data have suggested a potential involvement of resistin in the pathogenesis of liver fibrosis<sup>[108]</sup>. However, these latter data await independent confirmation. Finally, increased liver cell apoptosis has been reported to be correlated with steatosis<sup>[109]</sup>. Hepatocyte apoptosis can be measured by caspase activity in serum<sup>[110]</sup>. In the presence of steatosis, apoptosis is correlated with activation of stellate cells and increased stage of fibrosis, in keeping with the hypothesis that a steatotic liver is more vulnerable to liver injury, and suggesting another mechanism of liver disease progression in patients with fatty liver and the metabolic syndrome<sup>[109]</sup>.

Increasing levels of IR are associated with reduced rates of initial virological response<sup>[111-113]</sup> as well as SVR in chronic hepatitis C patients treated with a combination of pegylated IFN- $\alpha$  and ribavirin<sup>[114-119]</sup>. This negative association has been reported not only in patients infected with the HCV genotype 1<sup>[114,116,119]</sup>, but also in those with the so-called “easy-to-treat” genotypes 2 and 3<sup>[118]</sup>. Furthermore, the negative impact of IR on the early response to anti-HCV therapy has been

recently confirmed among HIV-infected patients<sup>[120]</sup>. The molecular link between IR and lack of responsiveness to IFN- $\alpha$  seems to lie in the increased levels of SOCS-3 in the liver<sup>[117,121]</sup>. Interestingly, SOCS-3, as stated above, is not only promoting the proteasomal degradation of IRS-1, which leads to impaired insulin signaling and IR<sup>[85]</sup>, but, together with other members of the SOCS family, is also a negative regulator in the transduction of the IFN- $\alpha$  signaling<sup>[122]</sup>. Thus, it is not too unlikely that HCV may have developed, from the evolutionary standpoint, the ability to activate SOCS-3 or other members<sup>[86]</sup> of the SOCS family as a mechanism to inhibit the IFN- $\alpha$  signaling, one of the main arms of the host innate immune response, simultaneously impairing the insulin signaling. This view seems to be supported by the recent finding that HCV may also activate the protein phosphatase 2A, again with the dual effect of interfering with the insulin<sup>[87]</sup> and IFN- $\alpha$ <sup>[123]</sup> signaling pathways. Whether these mechanisms may be exploited pharmacologically, i.e. with drugs aimed at reducing IR while improving the responsiveness to IFN- $\alpha$ , remains to be fully explored (see below).

## PERSPECTIVES FOR CLINICAL MANAGEMENT

The treatment of IR and T2D in chronic hepatitis C patients has two goals, as far as the underlying liver disease is concerned: to reduce fibrogenesis (hence liver disease progression) and to increase the response to IFN-based therapy. As pointed out above, it is not known whether IR invariably increases liver fibrosis, i.e. in the context of the metabolic syndrome or in cases of purely virus-induced IR, without the remaining constellation of cytokine changes that accompany the metabolic syndrome. This distinction is important also when antiviral therapy has to be undertaken, because here therapy should be aimed at correcting IR based on the underlying molecular mechanisms, which may differ according to the viral genotype and the presence or absence of metabolic syndrome. At present, however, the approach that is being followed is rather empirical.

A single study<sup>[102]</sup> has analyzed the biochemical and histological consequences of a 3-mo program that comprises body weight reduction and increased physical activity. In 19 subjects with steatosis and chronic hepatitis C, the weight loss was paralleled by progressive reduction of serum alanine aminotransferase levels and of mean fasting insulin. In patients with paired liver biopsies, steatosis decreased, together with the fibrosis score and the number of activated stellate cells, despite the persistence of HCV. The authors concluded that weight reduction may provide an important adjunct management strategy for patients with chronic hepatitis C<sup>[102]</sup>. Lifestyle changes are the single most important measure to reduce the incidence of T2D in those at risk<sup>[124]</sup> and of the metabolic syndrome in patients with IGT<sup>[125]</sup>. Moreover, the metabolic syndrome may even

regress following such intervention<sup>[125]</sup>, more often than among patients treated with metformin. Therefore, lifestyle changes (weight reduction and increased physical activity) should constitute the mainstay of the clinical management of patients with chronic hepatitis C and initial glucose metabolism derangements (IR and IGT), with the aim of reducing their progression to overt T2D and possibly, their impact on liver fibrogenesis.

Alternatively, insulin sensitizing agents have been tested with the specific aim of improving the rate of response to IFN- $\alpha$ -based therapy. As said above, IR reduces the rate of response to antivirals in chronic hepatitis C. Thus, it was suggested that IR should be corrected in patients with chronic hepatitis C not responding to IFN- $\alpha$ -based treatment, in order to improve response upon re-treatment. The modalities of this intervention, however, have not been established. In addition, the optimal HOMA score to be reached has not been identified. The preliminary data from four independent studies<sup>[126-129]</sup> have not been encouraging. A first prospective, multicenter study aimed at investigating the efficacy and safety of the insulin sensitizer pioglitazone, 15 mg *qd*, added to pegylated IFN-2a, 180 g *qw*/ribavirin, 1000-1200 mg *qd* combination therapy in chronic hepatitis C patients who were previously non-responders to a pegylated IFN- $\alpha$ /ribavirin combination<sup>[126]</sup>. All patients had a baseline HOMA > 2, because this was the threshold that discriminated responders from non-responders in previous studies<sup>[114,118]</sup>. None of the first five patients enrolled into the trial had a sufficient virological response after 12 wk to warrant continuation of the trial, which was therefore prematurely terminated. Data from three additional trials have been presented at the 2008 meeting of the American Association for the Study of Liver Diseases. In an interim analysis of one of them, 30 mg *qd* pioglitazone was given for 4 wk as monotherapy, and then added for the first 4 wk of standard therapy of treatment-naïve, non-diabetic, chronic hepatitis C patients. The authors showed that the triple regimen that contained pioglitazone increased significantly the rate of virological response after 4 wk therapy, compared to pegylated IFN- $\alpha$ /ribavirin combination alone<sup>[127]</sup>. However, long-term data are awaited before any conclusion can be drawn, and some caution is required. In fact, in another randomized, double-blind, placebo-controlled study, adding pioglitazone 30 mg *qd* simultaneously to standard care increased the early and end-of-treatment virological response, but failed to increase the SVR<sup>[128]</sup>. Further data are needed before insulin sensitizers can be added to the panoply of drugs to treat hepatitis C.

Furthermore, the effects of PPAR agonists on serum lipids and their potential consequences on the HCV life cycle should be investigated in more detail. It is also unclear whether the treatment with the insulin sensitizer should be started at the same time as the antiviral retreatment or precede it, in order to start the pegylated IFN- $\alpha$ /ribavirin combination only when the HOMA

score has decreased to a level predictive of an increased SVR<sup>[114,118]</sup>. It is not clear whether the best approach is to use a PPAR agonist (and at what dose) or a biguanide such as metformin, whose mechanism of action is specifically directed against the hepatic AMP-activated protein kinase<sup>[130]</sup>. The final results of the TRIC-1 study<sup>[129]</sup> show that adding metformin to pegylated IFN- $\alpha$ /ribavirin combination afforded a marginal, non-significant gain as to the SVR rate, despite an increased rapid virological response after 4 wk of triple therapy. Thus, further clinical trials aimed at reducing the IR in chronic hepatitis C *via* different pharmacological interventions are warranted.

## CONCLUSION

HCV and IR/T2D are associated to an extent that cannot be merely explained by chance, which suggests that HCV interferes directly (through one or more of its proteins) and/or indirectly (by modulating the production of specific cytokines, like TNF- $\alpha$ ) with glucose metabolism. Independently of the mechanism, IR and T2D have important effects on the hepatitis C progression and response to antivirals, which warrants specific and effective measures to correct such metabolic anomalies. Although lifestyle interventions are certainly indicated in patients with chronic hepatitis C and the metabolic syndrome, in order to reduce the cardiovascular morbidity and mortality, it remains to be fully explored whether these measures will also have an impact on the underlying liver disease. Insulin sensitizers are currently being evaluated in clinical trials, but available data do not warrant their use in all chronic hepatitis C patients with IR, with the specific aim of increasing response to antivirals, at least outside of clinical trials.

### Abstract

We aimed to evaluate the efficacy of tricyclic antidepressants (TCAs) as a therapeutic option for irritable bowel syndrome (IBS) through meta-analysis of randomized controlled trials. For the years 1966 until September 2008, PubMed, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials were searched for double-blind, placebo-controlled trials investigating the efficacy of TCAs in the management of IBS. Seven randomized, placebo-controlled clinical trials met our criteria and were included in the meta-analysis. TCAs used in the treatment arm of these trials included amitriptyline, imipramine, desipramine, doxepin and trimipramine. The pooled relative risk for clinical improvement with TCA therapy was 1.93 (95% CI: 1.44 to 2.6,  $P < 0.0001$ ). Effect size of TCAs *versus* placebo for mean change in abdominal pain score among the two studies was -44.15 (95% CI: -53.27 to -35.04,  $P < 0.0001$ ). It is concluded that low dose TCAs exhibit clinically and statistically significant control of IBS symptoms.

### EPIDEMIOLOGY AND PATHOGENESIS OF IRRITABLE BOWEL SYNDROME (IBS)

IBS is a prevalent functional gastrointestinal (GI) disorder characterized by chronic or recurrent abdominal pain or discomfort associated with altered bowel habits<sup>[1]</sup>. Up to 20% of the North American population are affected by IBS<sup>[2]</sup>. A community-based study carried out in Birmingham, UK estimated the prevalence of IBS to be 10.5%<sup>[3]</sup>. IBS is commonly diagnosed between the ages of 15 and 45 years and affects women twice as often as men<sup>[3,4]</sup>. IBS places a significant burden on health economy in terms of using more health care services even for non-gastrointestinal symptoms comparing to general population<sup>[5]</sup>.

Environmental factors (psychological disturbances and stress), genetic links, recent infection, bacterial overgrowth, food intolerance, altered bowel motility and/or secretion, visceral hypersensitivity, altered central nervous system sensory processing, disturbed autonomic nervous system regulation, and serotonin dysregulation are all proposed as possible etiological factors for IBS<sup>[2-4,6,7]</sup>.

### MANAGEMENT OF IBS AND CURRENT PLACE OF TRICYCLIC ANTIDEPRESSANTS (TCAs)

In addition to non-pharmacological strategies such as diet and psychotherapy, various pharmacological agents are used for the management of IBS including bulking

agents, antidiarrheal agents, laxatives, antispasmodics, antidepressants, serotonergic agonists or antagonists, antibiotics and probiotics<sup>[8-12]</sup>. The rationale of using antidepressants in IBS is that these agents may alter pain perception by a central modulation of visceral afferents, treat comorbid psychologic symptoms, and alter GI transit. Different classes of antidepressants likely act by different combinations of mechanisms<sup>[1]</sup>. Two classes of antidepressants frequently used for the treatment of IBS are selective serotonin reuptake inhibitors (SSRIs) and TCAs. In a meta-analysis done in 2007<sup>[8]</sup>, the efficacy of SSRIs in IBS was reported. In the present paper, the efficacy of TCAs in IBS has been reviewed by meta-analysis of all randomized controlled trials.

## EVALUATION OF STUDIES

PubMed, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials were searched for studies investigated the efficacy of TCAs in IBS. Data were collected for the years 1966 to 2008 (up to September). The search terms were: “tricyclic antidepressants”, “amitriptyline”, “amoxapine”, “clomipramine”, “desipramine”, “dothiepin”, “doxepine”, “imipramine”, “prindole”, “lofepramine”, “nortriptyline”, “opipramol”, “protriptyline”, or “trimipramine” and “irritable bowel”, “functional bowel diseases” or “irritable colon”. Search was restricted to English literature. Reference lists of the retrieved articles were also reviewed for additional applicable studies.

All controlled trials investigating the efficacy of TCAs in patients with IBS were considered. “Global improvement of symptoms” and “adequate relief of pain and discomfort” were the key outcomes of interest for assessment of efficacy. We evaluated all published studies as well as abstracts presented at meetings. Three reviewers independently examined the title and abstract of each article to eliminate duplicates, reviews, case studies, and uncontrolled trials. Trials were disqualified if they were not placebo-controlled or their outcomes did not consider efficacy. Reviewers independently extracted data on patients’ characteristics, therapeutic regimens, dosage, trial duration, and outcome measures. Disagreements, if any, were resolved by consensus.

Jadad score, which evaluates studies based on their description of randomization, blinding, and dropouts (withdrawals), was used to assess the methodological quality of the trials<sup>[13]</sup>. The quality scale ranges from 0 to 5 points with a low quality report of score 2 or less and a high quality report of score at least 3.

Data from selected studies were extracted into 2 × 2 tables. All included studies were weighted and pooled. Data analysis was done using StatsDirect (2.7.2). Relative risk (RR) and 95% confidence intervals (95% CI) were calculated using Mantel-Haenszel and effect size (weighted mean difference) meta-analysis was performed using Mulrow-Oxman method. The Cochran *Q* test was used to test heterogeneity. The event rate in the experimental (intervention) group against the event rate

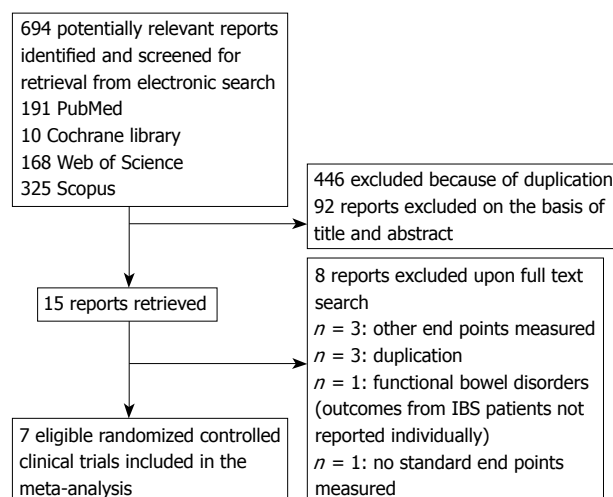

Figure 1 Flow diagram of the study selection process.

in the control group was calculated using L'Abbe plot as an aid to explore the heterogeneity of effect estimates. In case of homogeneity, fixed effect model was used for meta-analysis; otherwise random effect model was applied. In addition to Kendall's *t* test<sup>[14]</sup>, funnel plots were used as an indicator for publication bias<sup>[15]</sup>.

## FINDINGS

The electronic searches yielded 694 items; 191 from PubMed, 10 from Cochrane Central, 168 from Web of Science, and 325 from Scopus. Of these, 15 trials were scrutinized in full text and 7 trials<sup>[16-22]</sup> were included in the analysis (Figure 1). Of these 7 studies, 6<sup>[16-21]</sup> obtained a Jadad score of 3 or more and the remaining one<sup>[22]</sup> gained a Jadad score of 2 (Table 1). Regarding the Cochran *Q* test for heterogeneity, it was found that this study did not cause heterogeneity in our meta-analysis and thus, it was not excluded. Patients' characteristics, IBS subtype, TCA subclass, dosage, duration of treatment/follow up for each study are reported in Table 2. All subtypes of IBS (diarrhea-predominant, constipation-predominant and alternating) were incorporated in the included studies. This meta-analysis included 257 IBS patients randomized to receive either TCA or placebo. The efficacy of various TCAs has been investigated including amitriptyline (3 trials), imipramine (1 trial), desipramine (1 trial), doxepin (1 trial) and trimipramine (1 trial). Duration of treatment/follow up ranged between 4 and 12 wk. Definition of clinical response and mean change in abdominal pain score in each study are reported in Table 3.

Cochrane *Q* test suggested that the studies are homogeneous ( $P = 0.3284$ , Figure 2B) therefore, a fixed effect model was used for meta-analysis. Regression of normalized effect *versus* precision for all included studies for clinical response among TCAs *vs* placebo therapy was 2.40 (95% CI: -1.14 to 5.95,  $P = 0.14$ ). Funnel plot was suggestive of publication bias (Figure 2C); however, Kendall's *t* test was not indicative of such a bias ( $\tau = 0.05$ ,  $P > 0.9999$ ). Pooled RR for clinical response in 7 trials<sup>[16-22]</sup>

IBS: Irritable bowel syndrome; D: Diarrhoea predominant; Alt: Alternating; C: Constipation predominant; TCA: Tricyclic antidepressant.

Table 3 Response to treatment

Study	Definition of response	Response		Change in abdominal pain score (No. of patients)	
		TCA	Placebo	TCA	Placebo
Vahedi <i>et al</i> <sup>[16]</sup> , 2008	Complete loss of symptoms (total score = 0) at the end of the study or at least two scores with a decrease in the number of symptoms	17/25	10/25	-	-
Talley <i>et al</i> <sup>[17]</sup> , 2008	Adequate relief of IBS symptoms over 50% of the weeks	10/18	9/16	-45.3 ± 26.3 (18)	-7.4 ± 46.9 (16)
Morgan <i>et al</i> <sup>[18]</sup> , 2005	Improvement of IBS symptoms determined by patients	13/22	5/22	-	-
Rajagopalan <i>et al</i> <sup>[19]</sup> , 1998	Global well-being: patients were asked to estimate at the post-treatment interview how much better or worse they were on the whole (in percentage) as compared to the pretrial period	7/11	3/11	-	-
Vij <i>et al</i> <sup>[20]</sup> , 1991	Improvement of 50% or above in IBS symptoms	11/21	5/23	-	-
Greenbaum <i>et al</i> <sup>[21]</sup> , 1987	Global assessment of improvement	15/28	5/28	-58.96 ± 19.37 (28)	-13.93 ± 17.76 (28)
Tripathi <i>et al</i> <sup>[22]</sup> , 1983	Improvement of 50% or above in IBS symptoms	7/25	4/25	-	-

was 1.93 (95% CI: 1.34 to 2.6,  $P < 0.0001$ , Figure 2A).

Studies that considered abdominal pain score as an outcome showed homogeneity using Cochrane  $Q$  test ( $P = 0.61$ ). Regression of normalized effect *vs* precision for all included studies for mean change in abdominal pain score could not be calculated because of too few strata.

Using a fixed effect model, effect size of TCAs *versus* placebo for mean change in abdominal pain score among the two studies<sup>[17,21]</sup> was -44.15 (95% CI: -53.27 to -35.04,  $P < 0.0001$ , Figure 3).

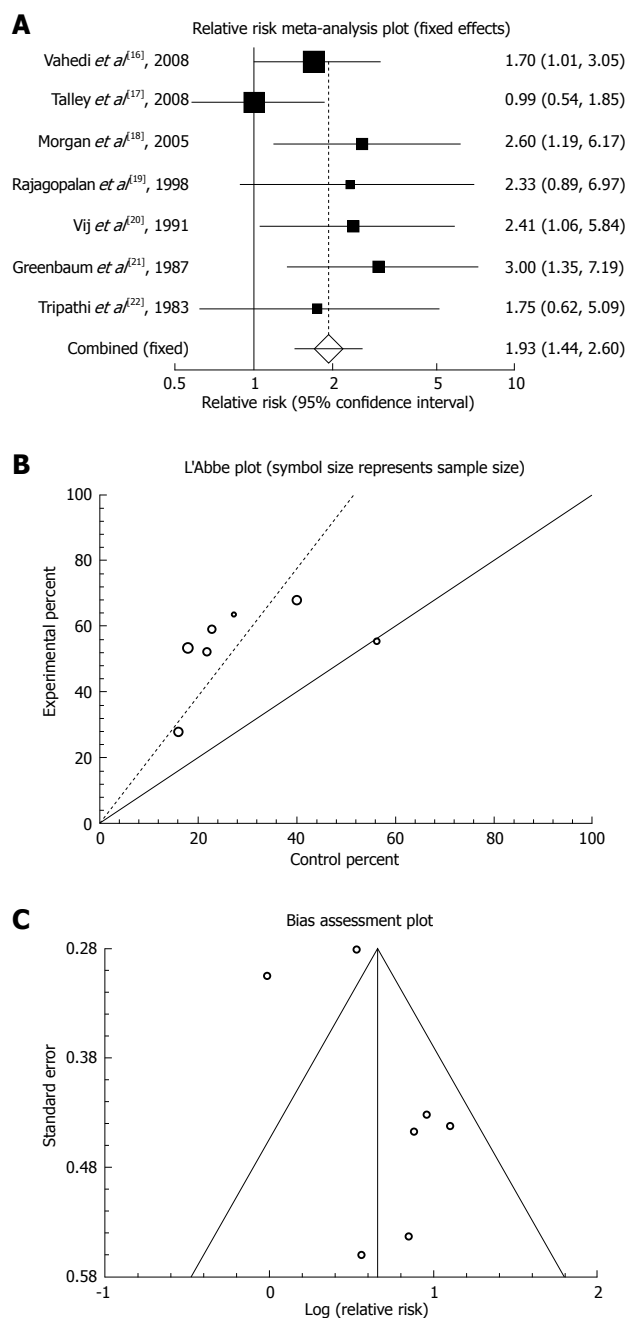

## DISCUSSION

Visceral hypersensitivity and dysregulation of central pain perception in the brain-gut axis is considered to play a pivotal role in the pathophysiology of IBS. IBS

patients have a lower sensory threshold to colonic and rectal balloon distention and electrical stimulation<sup>[23]</sup>; therefore, beneficial effects of antidepressants can be explained by partial increment in central pain threshold. Other mechanisms by which antidepressants might express their effect include anticholinergic effects, regulation of GI transit and peripheral antineuropathic effects<sup>[24,25]</sup>. The results from the current meta-analysis show that TCAs induce clinical response and reduce abdominal pain score in patients with IBS.

Other meta-analysis studies that considered the effects of antidepressants in functional gastrointestinal diseases have essential differences with the present study: O'Malley *et al*<sup>[26]</sup> pooled all functional diseases including IBS, functional dyspepsia, headache, fibromyalgia, and chronic fatigue. Jackson *et al*<sup>[27]</sup>

**Figure 2 Outcome of "clinical response" in the studies considering TCAs vs placebo therapy.** A: Individual and pooled relative risk; B: Heterogeneity indicators; C: Publication bias funnel plot.

included all the functional gastrointestinal disorders and found a statistically significant effect for TCAs (OR 4.2; 95% CI: 2.3 to 7.9). Quarero *et al*<sup>[8]</sup> included 4 studies for "global improvement of symptoms" and 2 studies for "abdominal pain" and demonstrated no benefit for antidepressants. Lesbros-Pantoflickova *et al*<sup>[28]</sup> demonstrated a favorable effect for antidepressants (OR 2.6; 95% CI: 1.9 to 3.5). Studies with visual analogue outcome<sup>[29]</sup> and functional dyspepsia patients were included in their analysis. None of these reviews meta-analyzed the newer evidence that has surfaced in the literature<sup>[16-18]</sup>.

Unfortunately, conduction of a randomized controlled trial in the field of antidepressants and IBS

**Figure 3 Pooled weighted mean difference for the outcome of "mean change in abdominal pain score" in the studies considering TCAs vs placebo.**

is challenging. High placebo response in IBS affects study trials and the stigma of antidepressants disturbs the compliance rate. Randomization is elusive as TCAs have immediate noticeable side effects for patients. As mentioned in Table 1, the majority of trials are of a medium quality. A well-designed trial has been conducted by Drossman *et al*<sup>[30]</sup> although not included in our study because of the recruitment of all functional bowel disorders. Drossman *et al*<sup>[30]</sup> conducted a large randomized 12-wk placebo-controlled trial evaluating the efficacy of desipramine in treating moderate to severe IBS (80% of the patients), functional constipation and functional chronic abdominal pain. Desipramine was shown to have statistically significant benefit over placebo in the per protocol analysis after non-compliant and drop-out patients were excluded (responder rate 73% *vs* 49%). 11% of the patients were proven to be non-adherent with non-detectable blood levels. This underlines the fact that previous studies might have underestimated the effect of antidepressants by the inclusion of non-adherent cases.

The choice of antidepressants in IBS patients remains controversial. Head to head trials comparing different classes or subclass formulations of antidepressants are lacking in the literature. In a recent meta-analysis<sup>[9]</sup>, we concluded that on current evidence, SSRIs do not improve abdominal pain, abdominal bloating or other IBS symptoms. Three studies have compared the effects of TCAs with SSRIs and all together they depict a non-conclusive picture<sup>[17,31,32]</sup>. Talley *et al*<sup>[17]</sup> compared imipramine with citalopram during a 12-wk trial. Clinical response was seen in 56% of imipramine group, 47% of citalopram group and 56% of placebo arm. Neither imipramine nor citalopram significantly improved global IBS endpoints over placebo. Forootan *et al*<sup>[31]</sup> compared the effects of nortriptyline, amitriptyline, and fluoxetine. The results demonstrated improvement of abdominal pain, flatulence, and general performance in all subgroups. Amitriptyline and nortriptyline improved frequency of defecation in both diarrhea- and constipation-predominant IBS, while fluoxetine improved GI transit of constipation- predominant IBS. Differential effects of amitriptyline and fluoxetine on

anorectal motility and visceral perception were assessed by Siproudhis *et al*<sup>[32]</sup> and the results demonstrated that both antidepressants similarly relax the internal anal sphincter, but only amitriptyline relaxed the external anal sphincter.

Generally, management of IBS requires lower doses of TCAs compared to doses used to treat depression; reflecting the fact that modulation of the brain-gut axis rather than treating concomitant depression is the target in IBS patients. Myren *et al*<sup>[29]</sup> in a large 8-wk trial demonstrated no dose-related response with various dosing regimens of trimipramine.

## CONCLUSION

This review has some limitations. Funnel plot is suggestive of publication bias with lack of negative small RCTs. However, a firm conclusion about bias is elusive to reach as the asymmetry of the funnel plot is minimal and Kendall's T is not suggestive of publication bias. In addition funnel plots can show asymmetry for various reasons other than publication bias<sup>[33]</sup>. Paucity of small negative or neutral studies has been brought to attention in other functional disorders<sup>[26]</sup> which might encompass IBS as well. Therefore, our pooled OR might be an overestimate of the true effect. Some other limitations that can be numbered for this meta-analysis are usage of various TCA formulations and doses, dissimilar duration of treatment, and different diagnostic criteria for IBS.

TCAs exhibit clinically and statistically significant control of IBS symptoms; however, given their abundant side effects they should be reserved for moderate to severe cases. Subjects should be started on subtherapeutic doses for depression and choice of drug should be tailored for each individual. We suggest using TCAs with the least anticholinergic effects (i.e. doxepin and desipramine) for elderly patients or constipation-predominant IBS and imipramine or amitriptyline for diarrhea-predominant IBS and patients with insomnia. Larger comparative trials with strict surveillance on compliance are needed to elaborate the role of antidepressants in standard practice.

In addition, new evidence suggests that IBS is very similar to IBD in pathogenesis but different in severity. Recent meta-analyses have indicated the benefit of antibiotics, probiotics, and anti-tumor necrosis factor agents<sup>[34-42]</sup> in IBD and thus the effects of these drugs on IBS remain to be elucidated in the future.

## Abstract

A new, hypervirulent strain of *Clostridium difficile*, called NAP1/BI/027, has been implicated in *C. difficile* outbreaks associated with increased morbidity and mortality since the early 2000s. The epidemic strain is resistant to fluoroquinolones *in vitro*, which was infrequent prior to 2001. The name of this strain reflects its characteristics, demonstrated by different typing methods: pulsed-field gel electrophoresis (NAP1), restriction endonuclease analysis (BI) and polymerase chain reaction (027). In 2004 and 2005, the US Centers for Disease Control and Prevention (CDC) emphasized that the risk of *C. difficile*-associated diarrhea (CDAD) is increased, not only by the usual factors, including antibiotic exposure, but also gastrointestinal surgery/manipulation, prolonged length of stay in a healthcare setting, serious underlying illness, immune-compromising conditions, and aging. Patients on proton pump inhibitors (PPIs) have an elevated risk, as do peripartum women and heart transplant recipients. Before 2002, toxic megacolon in *C. difficile*-associated colitis (CDAC), was rare, but its incidence has increased dramatically. Up to two-thirds of hospitalized patients may be infected with *C. difficile*. Asymptomatic carriers admitted to healthcare facilities can transmit the organism to other susceptible patients, thereby becoming vectors. Fulminant colitis is reported more frequently during outbreaks of *C. difficile* infection in patients with inflammatory bowel disease (IBD). *C. difficile* infection with IBD carries a higher mortality than without underlying IBD. This article

reviews the latest information on *C. difficile* infection, including presentation, vulnerable hosts and choice of antibiotics, alternative therapies, and probiotics and immunotherapy. We review contact precautions for patients with known or suspected *C. difficile*-associated disease. Healthcare institutions require accurate and rapid diagnosis for early detection of possible outbreaks, to initiate specific therapy and implement effective control measures. A comprehensive *C. difficile* infection control management rapid response team (RRT) is recommended for each health care facility. A communication network between RRTs is recommended, in coordination with each country's department of health. Our aim is to convey a comprehensive source of information and to guide healthcare professionals in the difficult decisions that they face when caring for these oftentimes very ill patients.

## INTRODUCTION

In our two previous reviews<sup>[1,2]</sup>, we joined those who have written about the new more virulent strain of *Clostridium difficile* that was described in December 2005 in the National Institutes of Health (NIH)/Center for Disease Control and Prevention (CDC) Morbidity and Mortality Weekly Report. This CDC report emphasized that, in the past, *C. difficile*-associated diarrhea (CDAD) usually affected hospital inpatients, but now was appearing in relatively healthy adults, including some

who had not even been exposed to a hospital setting.

Loo *et al.*<sup>[3]</sup> and McDonald *et al.*<sup>[4]</sup> have indicated that, not only is the rate of disease associated with *C. difficile* increasing, but a previously uncommon strain of *C. difficile* has been identified. This strain of *C. difficile*, which has variations in its toxin genes, is more resistant to fluoroquinolones than prior strains. This newer and more virulent organism has emerged as a cause of geographically dispersed outbreaks of antibiotic-associated diarrhea (AAD), specifically *C. difficile* diseases, CDAD and *C. difficile*-associated colitis (CDAC).

CDAD has also become a more severe disease, and more often has progressed to toxic megacolon (TM). More severe CDAC and CDAD have started to increase in incidence and severity. *C. difficile* also accounts for an increasing percentage of community-acquired diarrhea cases. Fluoroquinolones, especially C-8-methoxy fluoroquinolones, such as moxifloxacin and gatifloxacin, have been incriminated in CDAD epidemics in different health care facilities. This current review attempts to provide an update on this new virulent organism that causes very severe CDAD and CDAC, and emphasizes the importance of early recognition of its complications and its treatment.

Typing of bacterial outbreaks characterize *C. difficile* as a Gram-positive, anaerobic, spore-forming bacillus that is spread indirectly *via* the fecal-oral route through spores left on surfaces. It produces two cytotoxins, which bind to receptors on intestinal epithelial cells, leading to inflammation and diarrhea. The toxins loosen the junctions of the epithelial cells that line the colon, allowing for penetration between epithelial cells<sup>[5]</sup>. This begins a cascade of tissue-damaging inflammatory processes that involve the release of destructive leukotrienes and cytokines.

Colonization of *C. difficile* is facilitated by the disruption of normal intestinal flora as a result of antimicrobial therapy. The antibiotics most frequently implicated in CDAD are clindamycin, penicillins, cephalosporins and fluoroquinolones<sup>[6]</sup>.

There has been a dramatic increase in the frequency, severity and refractoriness of *C. difficile* as seen in multiple outbreaks, not only in North America, but around the world. These factors are attributed to this hypervirulent strain, NAP1/BI/027.

Bartlett documented that, over the first 5 years in which CDAD was acknowledged to exist, 1978 to 1983, the most common cause of CDAD was previous use of clindamycin<sup>[7]</sup>. The standard diagnostic test was a cytotoxin assay. Standard management was to withdraw the implicated antibiotic and treat with oral vancomycin. Most patients responded well, but 25% relapsed when vancomycin was withdrawn.

Over the next 20 years (1983-2003), the most commonly implicated antibiotics were the cephalosporins, which reflected their increased rates of use. Fluoroquinolones now are the major inducing agents, along with cephalosporins, a phenomenon which presumably reflects newly-acquired *in vitro* resistance and the escalating rates of use<sup>[8]</sup>.

Between 2003 and 2006, *C. difficile* has become more frequent, more severe, more refractory to standard therapy, and more likely to relapse than in previous years. This pattern has been seen throughout the United States, Canada and Europe, and is now attributed to a new strain of *C. difficile*, alternatively designated as BI, NAP1, or ribotype 027 toxinotype III (all synonymous terms). Although this strain had been isolated as far back as 1984, it has recently emerged as a public concern with the development of fluoroquinolone resistance in our current era of widespread fluoroquinolone use.

The emergence of this hypervirulent *C. difficile* strain has vastly altered the face of the disease, with increased nosocomial outbreaks and concomitant morbidity. In 2007, Blossom and McDonald<sup>[9]</sup> reported on the increasing incidence and severity of *C. difficile*-associated disease attributable to this hypervirulent strain. This strain produces increased levels of toxins A and B, as well as an extra toxin, known as 'binary toxin', which accounts for its increased toxicity. This previously uncommon strain now has become epidemic, and has been reported in populations that previously had been thought to be at low risk, including peripartum women and healthy persons living in the community. Individuals with low or undetectable levels of antibody against *C. difficile* toxins are more likely to develop diarrhea than those with detectable antibody against the toxin. Careful adherence to infection control policies is critical to the control of *C. difficile*, especially at nursing facilities, long-term care and rehabilitation facilities and hospitals, as well as in the community. CDAD primarily occurs in hospitals, where exposure to antimicrobial drugs (the major risk factor for CDAD) and environmental contamination by *C. difficile* spores are more common<sup>[10]</sup>.

Outbreaks of CDAD due to the new, highly-virulent strain of *C. difficile* have been recognized throughout European health care facilities, including 75 hospitals in England, 16 hospitals in the Netherlands, 13 healthcare facilities in Belgium, and nine healthcare facilities in France. In Germany, the first cases of the highly-virulent *C. difficile* strain, reported in 2007 and characterized as PCR ribotype 027, were associated with high mortality<sup>[11]</sup>. Larger outbreaks of *C. difficile* have been reported in northern France in particular<sup>[12]</sup>. These outbreaks are very difficult to control, and preliminary results from case-control studies indicate a correlation with the administration of fluoroquinolones and cephalosporins.

Seroprevalence increased in Denmark with increasing age in both 1990 and 1998. Unfortunately, the increase was about four times higher in 1998 than in 1990, which suggests a higher rate of exposure to *C. difficile* in the general Danish adult population<sup>[13]</sup>.

In Dublin, Ireland, *C. difficile* is a major cause of infectious diarrhea in hospitalized patients<sup>[14]</sup>. Between August 2003 and January 2004, there was an appreciable increase in the incidence of *C. difficile*-associated disease, peaking at 21 cases per 1000 patient admissions. Of the *C. difficile* isolates recovered, 85 (95%) were identical toxin A-negative and toxin B-positive strains, corresponding to

toxintype VIII and PCR ribotype 017. All clonal isolates were resistant to multiple antibiotics, including ofloxacin, ciprofloxacin, levofloxacin, moxifloxacin and gatifloxacin [minimum inhibitory concentrations (MICs) > 32 µg/mL] and erythromycin, clarithromycin and clindamycin (MICs > 256 µg/mL). Recurrent *C. difficile*-associated disease occurred in 26 (36%) of the patients. At least 10 of these 26 patients (14%) developed *C. difficile* colitis. The authors found that careful attention to improving infection control interventions was the most important means of controlling this nosocomial pathogen.

Reported mortality rates from *C. difficile*-associated disease in the United States increased from 5.7 per million population in 1999 to 23.7 per million in 2004. These increased rates also may be caused by the emergence of a highly virulent strain of *C. difficile*. *C. difficile* infection, according to Schroeder<sup>[15]</sup>, is now responsible for approximately 3 million cases of diarrhea and colitis annually in the United States, and has a mortality rate of 1%-2.5%. Zilberberg *et al*<sup>[16]</sup> have reviewed a sample of more than 36 million annual discharges from non-governmental US hospitals, and have concluded that 2.3% of the cases of *C. difficile*-related disease were fatal, amounting for roughly 5500 deaths. That was nearly double the percentage that resulted in death in 2000.

In Canada, Pépin *et al*<sup>[17,18]</sup> have documented that, since 2002, an epidemic of CDAD caused by the same hypervirulent strain previously found in the United States, the United Kingdom and the Netherlands, has spread to as many as 30 hospitals in Quebec. More than half (55%) of the patients with CDAD at the investigators' own hospital had received fluoroquinolones within the preceding 2 mo. Moreover, the excessive use of proton pump inhibitors might have facilitated this epidemic. This CDAD was associated with a very high case-fatality rate and with a 30-d mortality rate of 23.0% (37/161) compared with 7.0% (46/656) of matched control subjects ( $P < 0.001$ ). Twelve months after diagnosis, mortality was 37.3% (60/161) among patients with CDAD *vs* 20.6% (135/656) among controls ( $P < 0.001$ ), for a cumulative absolute attributable mortality of 16.7% [95% confidence interval (CI) 8.6%-25.2%]. Each case of nosocomial CDAD led, on average, to 10.7 additional hospital days. These investigators documented especially high attributable mortality among elderly patients with CDAD, mostly caused by this hypervirulent strain, which represents a dramatic change in the severity of this infection. Kuijper *et al*<sup>[19]</sup> have estimated that the financial impact of CDAD on the healthcare system is 5-15000 Euros/case in England and \$1.1 billion/year total expenditures in the USA. Assuming a European Union (EU) population of 457 million, the potential cost of CDAD in the EU can be estimated to be 3 billion Euros/year, and this is expected to almost double over the next four decades.

In Zimbabwe, *C. difficile* was isolated from 29.0% of 100 chicken feces samples and from 22.0% of 100 soil samples. Some of the *C. difficile* isolates from chickens (89.7%) and soil (95.5%) were toxigenic. All

of the isolates were resistant to cefotaxime, gentamicin, ciprofloxacin, norfloxacin and nalidixic acid. The results of this study suggest that broiler chickens sold at marketplaces can be an important source of *C. difficile*, and may infect humans through consumption<sup>[20]</sup>.

The incidence of CDAD in Singapore has remained relatively low, with isolates remaining susceptible to metronidazole and vancomycin<sup>[21]</sup>.

## CHARACTERISTICS OF AN INCREASINGLY PATHOGENIC *C. DIFFICILE*

The new, hypervirulent strain, NAP1/BI/027, has been implicated as the responsible pathogen in selected *C. difficile* outbreaks since the early 2000s. The epidemic strain is resistant to fluoroquinolones *in vitro*, a characteristic which was an infrequent observation in *C. difficile* strains prior to 2001. Five main characteristics of this strain contribute to the clinical and epidemiological observations. (1) The epidemic strain produces a binary toxin, an additional toxin that is not present in other *C. difficile* strains<sup>[22,23]</sup>. (2) Binary toxin is related to the iota-toxin found in *Clostridium perfringens*, and its role in *C. difficile* pathogenesis is not fully understood<sup>[24,25]</sup>. (3) The epidemic strain produces substantially larger quantities of toxins A and B *in vitro* than other *C. difficile* strains<sup>[26]</sup>. (4) Toxin production by an emerging strain of *C. difficile* has been associated with outbreaks of severe disease in North America and Europe<sup>[27]</sup>. The epidemic strain is toxinotype III; most other *C. difficile* strains are toxinotype 0<sup>[28]</sup>. Toxinotyping is based on analysis of the pathogenic locus (PaLoc) of the *C. difficile* genome, the region that includes the genes for toxin A (tcdA), toxin B (tcdB), and neighboring regulatory genes. (5) The epidemic strain has a partial deletion of tcdC, a gene in PaLoc that is responsible for down-regulation of toxin production<sup>[29]</sup>.

*C. difficile* produces at least two distinct toxins<sup>[30]</sup>. These have been labeled toxin A and toxin B. Although initially thought to have distinctive actions, both now appear to be cytotoxic and enteropathic. Previous animal experiments have suggested that only toxin A mediates diarrhea and enterocolitis, even though *C. difficile* releases two structurally similar exotoxins. But when toxin A-negative/toxin B-positive strains of *C. difficile* are isolated from patients with AAD and colitis, this indicated that toxin B also may also be pathogenic in humans. *C. difficile* toxin B, like toxin A, has been found to be a potent inflammatory enterotoxin in the human intestine<sup>[31]</sup>.

Both toxins disrupt the actin cytoskeleton of intestinal epithelial cells by uridine diphosphate-glucose dependent glycosylation of Rho and Ras proteins<sup>[32]</sup>. Stabler *et al*<sup>[33]</sup> have reported that toxin B from 027 strains may have a different binding capacity than their less-virulent counterparts and may, in addition to the mutated tcdC regulator, be responsible for the increased virulence of the 027 strains.

The most widely used laboratory assays for *C. difficile* infection involve toxin A and/or toxin B detection, and

both are usually detected if diarrhea is present. Atypical toxin variant strains that may cause symptoms have also been described in Asia<sup>[34]</sup>.

Kuijper *et al.*<sup>[19]</sup> have claimed that *C. difficile* has more than 150 PCR ribotypes and 24 toxinotypes, and has a PaLoc with genes that encode for enterotoxin A (tcdA) and cytotoxin B (tcdB). Genes for the binary toxin are located outside the PaLoc. The recently completed genome sequence of *C. difficile* 630 has revealed a large proportion (11%) of mobile genetic elements, mainly in the form of conjugative transposons.

Drudy *et al.*<sup>[35]</sup> have reported on several *C. difficile* outbreaks due to PCR ribotype 027 (PCR-027) associated with a mutation in *gyrA* that is associated with high-level resistance to fluoroquinolones. This strain type, which contains genes for the binary toxin, has an 18-bp deletion and a frameshift mutation in *tcdC*, which results in deregulated expression of toxins A and B. These strains can produce up to 16 times more toxin A and 23 times more toxin B *in vitro* than toxinotype 0 strains. The strain demonstrates universally high-level resistance to fluoroquinolones, in contrast to PCR 027 isolates that were collected before 2001. Mutations at the active site or the quinolone resistance determining region of DNA gyrase and topoisomerase IV have been associated with increased resistance to fluoroquinolones in several bacteria. In *Escherichia coli*, amino acid substitutions that occur at Ser-83 in *gyrA* have also been associated with fluoroquinolone resistance. Thus, the emergence of the hypervirulent NAP1/O27 *C. difficile* strain, also known as BI NAP1, has vastly altered the face of the disease, with increased nosocomial outbreaks and concomitant morbidity in countries worldwide.

In an epidemic of *C. difficile*-associated disease in the Canadian province of Quebec, Warny *et al.*<sup>[26]</sup> documented that the dominant strain produced higher amounts of toxins A and B than those produced by non-epidemic strains. The epidemic strain was characterized as toxinotype III, North American PFGE type 1, and PCR-ribotype 027 (NAP1/027). This strain carried the binary toxin gene *cdtB* and an 18-bp deletion in *tcdC*. The authors isolated this strain from 72 patients with *C. difficile*-associated disease. Peak median (IQR) toxin A and toxin B concentrations produced *in vitro* by NAP1/027 were 16 and 23 times higher, respectively, than those measured in isolates representing 12 different PFGE types, known as toxinotype 0 [toxin A, median 848 µg/L (IQR 504-1022) *vs* 54 µg/L (23-203); toxin B, 180 µg/L (137-210) *vs* 8 µg/L (5-25); *P* < 0.0001 for both toxins]. Thus, the severity of *C. difficile*-associated disease caused by NAP1/027 appears to be the result of hyper-production of toxins A and B. The dissemination of this strain across North America and Europe has led to dangerous changes in the epidemiology of *C. difficile*-associated disease.

A nationwide epidemiological study conducted in Korea has revealed that tcdA(-)tcdB(+) *C. difficile* strains already have spread extensively throughout the country. The use of enzyme immunoassays capable of detecting

TcdA and TcdB is strongly recommended for the diagnosis of CDAD in microbiology laboratories, in order to control the spread of the tcdA(-)tcdB(+) strains of *C. difficile*<sup>[36]</sup>. Sixty to 80% of *C. difficile* isolates in Korea have been reported to be toxigenic. Endoscopy, performed on 55/106 patients, revealed 29 with pseudomembranous colitis (PMC), five with colitis, 14 with other colon diseases, and seven normal colons. Among the 29 PMC cases, 21 (72.4%) were associated with tcdA-tcdB + strains (*P* = 0.0016). These results reveal the emergence of tcdA-tcdB+ *C. difficile* strains in Korea, and these variant strains could evoke a higher rate of PMC than tcdA + tcdB + strains<sup>[37]</sup>.

### Toxin damage

*C. difficile* toxin A elicits intestinal fluid secretion and neutrophil infiltration by both mast cell-dependent and -independent pathways, and substance P participates in both pathways<sup>[38]</sup>.

Extensive mitochondrial damage occurs within 15 min in cells exposed to toxin A. Diminished ATP concentrations and increased oxygen radicals contribute to cytotoxicity from this bacterial toxin<sup>[39]</sup>.

The toxins damage the tight junctions of the intestinal epithelium. Tight junctions are crucial determinants of barrier function in intestinal epithelia, and are regulated by Rho guanosine triphosphatase. Rho kinase (ROCK) is a downstream effector of Rho. ROCK inhibition in calcium switch assays has shown that ROCK is necessary for the assembly of tight and adherens junctions. ROCK also is critical for assembly of apical junctional proteins and F-actin cytoskeleton organization during junctional formation<sup>[40]</sup>.

### *C. difficile* toxicity and the immune response processes

*C. difficile* toxins A and B are glucosyltransferases, which catalyze the inactivation of Rho proteins. *C. difficile* toxins act *via* translocation into target cells, and do their damage through autocatalytic processes by inactivating low-molecular-mass GTP-binding proteins of the Rho GTPase family involved in cellular signaling. This leads to cytotoxicity, including depolymerization of the target cell's actin cytoskeleton. Thus, these toxins glycosylate members of the Rho GTPase family, and this GTPase inactivation leads to depolymerization of the cell's actin cytoskeleton and, ultimately, cell death<sup>[41]</sup>. In addition, the *C. difficile* toxins further damage the intestine's target cells by initiating massive cellular immune responses; i.e. neutrophilic infiltration with up-regulation and release of cytokines, such as interleukin (IL)-8, IL-6, IL-1β, leukotrienes B4 and interferon-γ.

Part of the mammalian immune response falls to the innate immune system called defensins and, specifically, human α-defensins produced by leukocytes, mucosal epithelial cells, and skin. Defensins, one of evolution's major groups of antibiotic peptides, have broad-spectrum antibiotic activity against Gram-positive and Gram-negative bacteria, fungi, and viruses<sup>[42-44]</sup>. Defensins are characterized by a conserved 6-cysteine array. Each cysteine has intra-molecular disulfide bonds

that are essential to protection against proteolysis<sup>[45]</sup>. Defensins also are known to contribute to wound healing, chemotaxis, and cytokine function<sup>[46,47]</sup>. Defensins are part of two major groups of antimicrobial peptides: defensins and cathelicidins. These groups of human defensins consist in part of alpha, beta and omega defensins, human neutrophil protein (HNP)-1, HNP-3, cathelicidin LL-37 and enteric human defensin (HD)-5. These peptides play a role in the innate immune response, by deactivating various microbial pathogens, as well as specific bacterial exotoxins.

The antibiotic activity of both HNPs and HD5 is well documented in host defenses against enteric pathogens<sup>[48,49]</sup>. HD5 and HD6 are produced and stored in Paneth cell secretory granules<sup>[50]</sup>, along with a variety of additional Paneth cell products demonstrated to have antimicrobial and immune activity<sup>[51-55]</sup>. The impact of defensins on *C. difficile* disease has been described by Giesemann *et al*<sup>[56]</sup> and others<sup>[57-60]</sup>.

Giesemann *et al*<sup>[56]</sup> have studied the effects of  $\alpha$ -defensin HNP-1, HNP-3, and enteric HD-5 on the activity of *C. difficile* toxins A and B. They found that the treatment of cells with human  $\alpha$ -defensins caused a loss of cytotoxicity of toxin B, but not of toxin A. In this study, only  $\alpha$ -defensins, but not  $\beta$ -defensin-1 or cathelicidin LL-37, inhibited toxin B-catalyzed *in vitro* glucosylation of Rho GTPases in a competitive manner. This indicates that human  $\alpha$ -defensins interact with high affinity for *C. difficile* toxin B. Defensins thereby provide a defense mechanism against clostridial glucosylating cytotoxins. At high concentrations, defensins (HNP-1  $\geq 2 \mu\text{mol/L}$ ) also cause high-molecular-mass aggregates of *C. difficile* toxins, thus further decreasing their toxic effects on target cells.

*C. difficile* has been found in approximately 3% of normal adults and up to 40% of hospitalized patients<sup>[7]</sup>. However, as Salzman emphasizes: "only about one third of patients harboring *C. difficile* develop colitis, whereas the rest remain asymptomatic<sup>[61]</sup>". Giesemann *et al*<sup>[56]</sup> have shown that  $\alpha$ -defensins inhibit *C. difficile* toxin B, which offers insight into the possibility of different inflammatory responses in patients who develop CDAC *versus* others who do not. Salzman feels that " $\alpha$ -defensins show an additional antitoxin activity, in which HD5 is more effective; i.e. the stimulation of toxin aggregation." Giesemann has shown that HD5, used at concentrations that normally can be found in the small intestine, is effective at causing aggregation of toxin B, thus effectively preventing the toxin's ability to enter cells and interact with its target. These findings suggest an additional mechanism of antitoxin activity by  $\alpha$ -defensin HD5.

This ability of HD5 to cause toxin B aggregation may provide an explanation for both the asymptomatic carriage of this pathogen and the frequency of patient relapse following antibiotic treatment, especially if the small intestine is a reservoir for *C. difficile* carriage in the gut. Salzman postulated that *C. difficile* is able to maintain colonization of the small intestine, but unable to cause colitis, because the high concentration of HD5 at this site neutralizes the secreted exotoxin.

In summary, Salzman feels that, in the small intestine, high concentrations of HD5 result in toxin B aggregation and therefore, the prevention of intoxication. While, in the large intestine, inadequate amounts of  $\alpha$ -defensin are present to aggregate or inhibit toxin B, resulting in epithelial intoxication, inflammation, and neutrophilic infiltration.

Usually, *C. difficile* that transits through the large bowel will be prevented from finding a niche by the normal colonic microbiota. Yet, if the microbial ecology of the colon is disrupted, perhaps through antibiotic treatment, *C. difficile* can colonize the large intestine. Salzman postulates that, under these conditions, HD5 concentration is reduced by diffusion and dilution; thus, *C. difficile* exotoxins become free to interact with colonic enterocytes, resulting in intoxication, inflammatory responses, and infectious colitis.

### The carrier state

Many patients are colonized with *C. difficile*, but have no symptoms. Perhaps *C. difficile* is harbored in the small intestine, where its toxic effects are well neutralized. Lawrence has claimed that about 20% of hospitalized adults are *C. difficile* carriers; and, in LTCFs, the carriage rate may approach 50%<sup>[62]</sup>. Although asymptomatic, these individuals shed pathogenic organisms and serve as a reservoir for environmental contamination. About 3% of healthy adults and 20%-40% of hospitalized patients are colonized with *C. difficile*, which in healthy persons is metabolically inactive in the spore form. Many patients have *C. difficile* as an asymptomatic organism in their intestine on hospital admission, and it only becomes a problem after they are treated with antibiotics, if, in fact, it ever induces symptoms. Exposure to antibiotics that disrupt the colonic microbial flora appears to be the most important risk factor for CDAD.

### Treatment of asymptomatic carriers

Asymptomatic colonized patients can act as a reservoir for the transmission of CDAD. Data, however, are limited regarding whether the treatment of these asymptomatic carriers leads to a decrease in the nosocomial transmission of *C. difficile*. Thirty asymptomatic *C. difficile* carriers were randomly assigned to one of three treatment groups: oral vancomycin 125 mg four times daily; metronidazole 500 mg orally twice daily; or placebo. Johnson *et al*<sup>[63]</sup> have found that nine of 10 patients receiving vancomycin became culture-negative during and immediately after treatment, compared to three of 10 receiving metronidazole and two of 10 receiving placebo. However, this decolonization was transient, as most patients became re-colonized within weeks. Thus, metronidazole does not appear to be effective for the treatment of asymptomatic carriers. In the setting of a hospital outbreak in which temporary elimination of the organism is felt necessary to reduce horizontal transmission, vancomycin may be a useful tool<sup>[63]</sup>.

Riggs *et al*<sup>[64]</sup> have reported on molecular typing of *C. difficile* performed on asymptomatic carriers using pulsed-field gel electrophoresis. They found that 35 (51%)

of 68 asymptomatic patients were carriers of toxigenic *C. difficile*, and 13 (37%) of these patients carried epidemic strains. They have also reported that 87% of isolates found in skin samples and 58% of isolates found in environmental samples were identical to concurrent isolates found in stool samples. Spores on the skin of asymptomatic patients were transferred easily to the investigators' hands, again accounting for spread to persons in contact. This might be an explanation for the McFarland *et al*<sup>[65]</sup> observation that nosocomial CDAD frequently is transmitted between hospitalized patients, and that the organism often is present on the hands of hospital personnel caring for such patients. Kyne *et al*<sup>[66]</sup> have studied prospectively *C. difficile* infections in hospitalized patients who were receiving antibiotics, and identified no evidence of immune protection against repeat colonization by *C. difficile*. However, after colonization, there is an association between a systemic anamnestic response to toxin A, as demonstrated by increased serum levels of IgG antibody against toxin A, and asymptomatic carriage of *C. difficile*.

## PRESENTATION OF *C. DIFFICILE* INFECTION

*C. difficile* infection causes diarrhea, often watery, rather than bloody, and it generally develops within 48-72 h of infection. In some, the symptoms may be delayed for 2-3 mo, usually after an antimicrobial agent has been administered. In some, only a single antibiotic tablet may lead to severe disease. Over time, the clinical spectrum has become better appreciated, with illness severity noted to be broad-ranging, from an asymptomatic carrier state (without detectable toxin) to severe and life-threatening pseudomembranous colitis with toxic megacolon<sup>[67]</sup>.

The clinician must be ever on the alert to make an early diagnosis of *C. difficile*-related disease in the setting of new-onset loose stools or symptoms of abdominal distension and/or leukocytosis, since unexplained leukocytosis in hospitalized patients, even in the absence of diarrhea, may reflect underlying *C. difficile* infection<sup>[68]</sup>. In a prospective study, Bulusu *et al*<sup>[69]</sup> found that, of 60 patients with unexplained leukocytosis (with a white blood cell count > 15000/ $\mu$ L), a positive stool *C. difficile* toxin was observed more frequently in cases than in controls (58% *versus* 12%, respectively). Age over 75 years and immunosuppression were associated with a poor outcome. Earlier surgical consultation is warranted in severe cases to consider potentially life-saving colectomy, as well as alterations in the hospital-based standard of care for prevention.

Usually, the disease affects the colon and, in many cases, is made evident by the presence of colonic pseudomembranes. However, in patients with underlying Crohn's or ulcerative colitis, pseudomembranous changes may not occur; therefore, typical endoscopic findings of *C. difficile* may not be present, and the colonic mucosa will reflect only the underlying inflammatory bowel disease.

*C. difficile* infection may present with an acute abdomen but either absent or mild diarrhea, as described by

Triadafilopoulos and Hallstone<sup>[70]</sup> in 1991. Plain abdominal radiographs revealed megacolon in these patients. This was combined with small and large bowel dilation in one who exhibited a volvulus-like pattern, and isolated small-bowel ileus in another. Diagnosis was revealed by emergency colonoscopy. All patients had positive results for *C. difficile*, and two tested positive for cytotoxicity. All were treated with IV metronidazole, resulting in the resolution of all symptoms and abdominal findings.

An unusual manifestation of CDAC was described in 1981 by Dansinger *et al*<sup>[71]</sup>. They reported that up to half of patients with indolent *C. difficile* infection develop manifestations of protein-losing enteropathy, including ascites, peripheral edema, and hypoalbuminemia. Inflammation of the bowel may allow leakage of albumin into the lumen, causing colonic loss of albumin with inadequate compensatory hepatic synthesis. As a result, serum albumin levels may drop below 20 g/L (20 g/L)<sup>[71,72]</sup>. Older patients may present with pedal edema, and be mistakenly diagnosed with CHF.

Rubin *et al*<sup>[73]</sup> studied patients who had developed a more aggressive form of CDAD *versus* those who developed milder disease. They found that 21 of 710 patients (3%) either required intensive care unit (ICU) admission or died as a result of their infection. The factors predisposing to the development of severe *C. difficile* colitis included concurrent malignancy, chronic obstructive pulmonary disease, immunosuppressive or anti-peristaltic medications, renal failure, and the administration of clindamycin ( $P < 0.05$  for all). Patients with severe *C. difficile* colitis were more likely to have abdominal pain, tenderness and distention, peritonitis, hemoconcentration (> 5 points), hypoalbuminemia (< 30 mg/L), and an elevated (> 25000) or suppressed (< 1500) white blood cell count ( $P < 0.05$  for all). Therefore, we must initiate aggressive diagnostic and therapeutic modalities in this patient group.

Extra-colonic features may occur in CDAD patients<sup>[74]</sup>. These include small bowel involvement in those patients with previous small bowel surgery, and visceral abscesses, primarily in the spleen, and less commonly in the pancreas. Other features include a reactive polyarticular arthritis, cellulitis, necrotizing fasciitis, osteomyelitis, and prosthetic device infections. Arthritis after *C. difficile* was further characterized by Birnbaum as being an asymmetric oligoarthritis<sup>[74]</sup>. *C. difficile* colitis has also been reported associated with intra abdominal hypertension and abdominal compartment syndrome<sup>[75]</sup>.

## POPULATIONS AT INCREASED RISK

In 2004 and 2005, the CDC emphasized that the risk of CDAD is increased in certain susceptible populations (Table 1).

### Drug exposure

Although the antibiotics most frequently implicated in predisposition to *C. difficile* infection are fluoroquinolones, clindamycin, cephalosporins and penicillins, virtually all

**Table 1** Populations at increased risk for *C. difficile*

Patients who take the following drugs
Antibiotics
Proton pump inhibitors
Valacyclovir
Patient characteristics
IBD
Serous underlying illness-comorbidities
Gastrointestinal surgery/manipulations
Advanced age
Immune-compromising conditions (post transplantation)
Peri-partum
Environment
Prolonged stay in health-care settings
Laboratory factors
Hypoalbuminemia
Low levels of anti-toxin and B antibodies

antibiotics, including metronidazole and vancomycin, can predispose to *C. difficile*. De Andrés *et al*<sup>[76]</sup> reported a case of *C. difficile* colitis associated with valacyclovir treatment.

The risk of CDAD in hospitalized patients receiving antibiotics may be compounded by co-existing disorders that require treatment with PPI therapy, which inhibits one's defenses against ingested bacteria by virtually eliminating gastric acid<sup>[77]</sup>. Dial *et al*<sup>[78]</sup> estimated an adjusted risk ratio for *C. difficile*-associated disease with the current use of PPIs as 2.9 (95% CI: 2.4-3.4); and with H2-receptor antagonists, the rate ratio was 2.0 (95% CI: 1.6-2.7). The authors also uncovered an elevated rate of CDAD in patients on non-steroidal anti-inflammatory drugs (rate ratio, 1.3; 95% CI: 1.2-1.5). Thus, the consumption of drugs other than antibiotics may put one at increased risk for community-acquired *C. difficile*.

PPI therapy is also associated with an increased risk of recurrent *C. difficile* colitis. Patients receiving PPIs have been found to be 4.17 times as likely to have recurrence as their counterparts not receiving them<sup>[79]</sup>. This relationship between PPI therapy and *C. difficile* was elucidated by Jump who found that the survival of vegetative *C. difficile* in gastric contents obtained from patients receiving PPIs was also increased at a pH of > 5<sup>[80]</sup>.

### Peripartum

The incidence of severe CDAD is increasing in peripartum women. A PubMed search identified 24 recorded cases of peripartum *C. difficile* infection. Most patients (91%) had received prophylactic antibiotics during delivery or for treatment of bacterial infections. Two cases without known risk factors were found, by polymerase chain reaction analysis, to be infected with an epidemic and hypervirulent *C. difficile* strain. These cases demonstrate the need for clinicians to consider *C. difficile* infection in pregnant and peripartum patients with diarrhea, even if they do not have the traditional risk factors for *C. difficile* infection, such as antibiotic use or concurrent hospitalizations<sup>[81]</sup>.

### Co-morbidities

The Agency for Healthcare Research and Quality

(AHRQ) is the lead US Federal agency charged with improving the quality, safety, efficiency, and effectiveness of health care. AHRQ data make clear that one of the challenges in accurately diagnosing CDAD is that it is not unusual for patients who acquire *C. difficile* to have multiple co-morbidities. Thus, multiple co-morbidities put patients at risk for *C. difficile* infection. AHRQ found that hospitalized patients with CDAD had over 10 diagnoses, *versus* six diagnoses among patients without CDAD<sup>[82]</sup>. According to recent AHRQ data, four out of the top 20 most common principle diagnoses observed with CDAD are infections (sepsis, pneumonia, urinary tract infection, and skin infection), where antibiotic use would be difficult to avoid<sup>[82]</sup>.

### Post-transplantation patients

Sixteen patients, representing an incidence rate of 0.16%, developed a *C. difficile* infection after total joint arthroplasty (TJA) at one institution. Those at risk for developing CDAD after TJA were patients with deteriorated physical status and those who had received more than one antibiotic postoperatively<sup>[83]</sup>.

In addition, *C. difficile* is now considered to be a significant cause of diarrhea in heart transplant recipients, and the post-transplantation period is now considered one of greater risk<sup>[84]</sup>. With *C. difficile* infection, CDAC prior to 2000 was a rare complication in this patient group; but 38 of the 43 reported cases of CDAC in these patients occurred after 2000. Therefore, *C. difficile* is now also one of the most common causes of diarrhea in patients who have undergone solid organ transplantation<sup>[85]</sup>. Another group of patients at increased risk are post orthotopic liver transplant patients. Testing for *C. difficile* toxins among orthotopic liver transplant patients with nosocomial diarrhea revealed that 63% of samples are toxin-positive<sup>[86]</sup>.

The development of life-threatening toxic megacolon secondary to CDAC now must be considered in solid organ recipients. Toxic megacolon was reported in five patients by Stelzmueller *et al*<sup>[85]</sup>.

### Post-surgery

The risk of *C. difficile* infection was 14.9 cases per 1000 surgical procedures among patients who received preoperative prophylaxis (PAP) during the period 2003-2005, which is a significant increase compared with 0.7 cases per 1000 surgical procedures during the period 1999-2002 ( $P < 0.001$ ). Independent risk factors associated with *C. difficile* infection in patients given PAP alone, were older age, the administration of cefoxitin (rather than cefazolin) alone or in combination with another drug, and the year of surgery. Thus, in the context of a large epidemic of *C. difficile* infection associated with the emergence of a novel strain of organism, 1.5% of patients who had received PAP as their sole antibiotic treatment developed *C. difficile* infection. In situations in which the only purpose of PAP is to prevent infrequent and relatively benign infections, the risks of PAP may outweigh its benefits, especially in elderly patients<sup>[87]</sup>.

Unfortunately, the incidence of *C. difficile* infection is increasing in US surgical patients even without PAP, and infection with *C. difficile* is most prevalent after emergency operations and among patients who have undergone intestinal tract resections<sup>[88]</sup>.

### **IBD as a risk factor for CDAC**

IBD patients are at greater risk than the general population for acquiring *C. difficile* infection<sup>[89]</sup>. Issa *et al*<sup>[90]</sup> performed a retrospective, observational study in IBD patients to evaluate the impact of *C. difficile*. They found that the rate of *C. difficile* infection had increased from 1.8% of IBD patients in 2004 to 4.6% in 2005 ( $P < 0.01$ ). The proportion of IBD patients within the total number of *C. difficile* infections at their institution increased from 7% in 2004 to 16% in 2005 ( $P < 0.01$ ). In 2005, IBD colonic involvement was found in the vast majority (91%) of *C. difficile*-infected patients, a clear majority (76%) had contracted infection as an outpatient, and antibiotic exposure was identified in 61% of IBD patients with *C. difficile* infection. Over the period 2004-2005, more than half of the infected IBD patients required hospitalization, and 20% required colectomy. Univariate and multivariate analyses identified maintenance immunomodulator use and colonic involvement as independent risk factors for *C. difficile* infection in IBD. The authors also reported a nationwide doubling in the rate of *C. difficile* infection among hospitalized UC patients between 1998 and 2004. The pathologic/endoscopic features of pseudomembranous colitis CDAC varies as a spectrum, with some patients exhibiting only mild inflammatory changes confined to the superficial epithelium, and typical pseudomembranes and crypt abscesses may not be present. The more severe cases demonstrate marked mucin secretion, and more intense inflammation. Intense necrosis of the full thickness of the mucosa, with a confluent pseudo-membrane, can become more prominent as disease severity increases.

The association between IBD and *C. difficile* may be due to a variety of factors, including antibiotic use for treatment of other gastrointestinal pathogens and frequent hospitalizations for the management of IBD flares. Many of these patients are taking immunosuppressive medications that may confer additional risk of *C. difficile* infection. *C. difficile*, and specifically its toxins, have been implicated as a risk factor for the exacerbation of the inflammatory process in up to 5% of patients with ulcerative colitis or Crohn's disease. A severe clinical course may result from *C. difficile* infection superimposed on IBD, including the precipitation of toxic colitis and toxic megacolon.

CDAC in patients with IBD carries a higher mortality than in patients with *C. difficile* without underlying IBD. On multivariate analysis, patients in the *C. difficile*-IBD group had a four times greater mortality than patients admitted to hospital for IBD alone (AOR = 4.7, 95% CI: 2.9 to 7.9) or *C. difficile* alone (AOR = 2.2, 95% CI: 1.4 to 3.4), and stayed in the hospital for 3 d longer (95% CI: 2.3 to 3.7 d). Significantly higher mortality, endoscopy and surgery rates were found in patients with ulcerative colitis compared

with Crohn's disease ( $P < 0.05$ ) who had associated *C. difficile*<sup>[91]</sup>. The median times from admission to a positive *C. difficile* test result for non-IBD was much longer than in Crohn's disease and ulcerative colitis patients (4.0, 0.8, and 0.5 d, respectively). *C. difficile* infections in IBD are confirmed predominantly within 48 h of admission, suggesting most were acquired before hospitalization. CDAD rates approximately doubled in Crohn's disease (9.5 to 22.3/1000 admissions) and tripled in ulcerative colitis (18.4 to 57.6/1000). Length of stay was similar among the groups. For all years combined, the adjusted odds ratios for CDAD in all IBD, Crohn's disease, and ulcerative colitis admissions were 2.9 (95% CI: 2.1-4.1), 2.1 (1.3-3.4), and 4.0 (2.4-6.6), respectively<sup>[92]</sup>.

Patients with severe *C. difficile* infection, especially IBD patients, require prompt diagnosis and management, since failure to diagnose the infection can lead to inappropriate treatment with glucocorticoids or immunosuppressive therapy. Furthermore, *C. difficile* may be difficult to distinguish from an IBD relapse, given the similar symptoms of diarrhea, abdominal pain, and low-grade fever. Thus, a high index of suspicion is required when evaluating IBD patients with apparent flares, especially those who recently have received antibiotics and/or have been hospitalized.

Thus, speedy diagnosis largely requires the use of laboratory tools, since endoscopy may not be helpful early, because IBD patients may not develop pseudomembranes. Given the underlying colonic pathology, patients with IBD who develop *C. difficile* colitis frequently require colectomy (20 percent in one series)<sup>[90]</sup>.

## **CLINICAL DIAGNOSIS**

Delays in both diagnosing and treating both initial and recurrent CDAD<sup>[93]</sup> are due to the fact that CDAD can mimic the more common 'benign' antibiotic-associated diarrhea that is not caused by *C. difficile*<sup>[94]</sup>. Thus, the diarrhea from *C. difficile* will be ascribed to other causes; e.g. food poisoning, viral infection, or other causes. *Klebsiella pneumoniae*, *Candida* species and *Staphylococcus aureus* have been identified as potential causative organisms in *C. difficile* negative AAD patients<sup>[95]</sup>.

Patients can be infected with this microorganism and may have no symptoms of colitis. They, therefore, may not be tested for *C. difficile* infection (see section on presentation). These asymptomatic carriers, who are admitted to healthcare facilities and hospitals, become vectors during outbreaks and can transmit the organism to other susceptible patients. Most cases of CDAD occur at 4-9 d after discontinuation of antibiotic therapy, according to Schroeder<sup>[15]</sup>; however, CDAD can occur up to 8 wk after the discontinuation of antibiotics.

### **Sigmoidoscopy/colonoscopy for the diagnosis of CDAD**

Lower endoscopy is a useful tool for the diagnosis of *C. difficile*. This is especially when: (1) there is a high level of clinical suspicion for *C. difficile*, despite a negative laboratory assay; (2) prompt *C. difficile* diagnosis is needed before laboratory results can be obtained; (3) *C. difficile*

infection fails to respond to antibiotic therapy; or (4) when there is an atypical disease presentation, and *C. difficile* is suspected, as with ileus, acute abdomen, leukocytosis or diarrhea.

Endoscopy is not indicated in patients with classic clinical findings and a positive stool toxin assay. Conversely, endoscopy may be contra-indicated, especially in the setting of fulminant colitis, due to the risk of perforation.

**Endoscopic findings:** Pseudomembranes are pathognomonic for CDAC, but are not found in all areas of the colon, even in severe cases; thus, findings may be patchy. Pseudomembranes may be absent in the rectosigmoid area, but may be visualized more proximally with colonoscopy. This is true in patients with co-existing IBD. Pseudomembranes are raised yellow or off-white plaques, up to 2 cm in diameter, which are randomly scattered over the colorectal mucosa with normal intervening mucosa, and that cannot be removed by lavage. The pseudomembranes form when *C. difficile* toxin-induced cytoskeleton disruption causes shallow ulcerations on the intestinal mucosal surface. It is postulated that ulcer formation allows for the release of serum proteins, mucus, and inflammatory cells, which appear grossly on the colorectal mucosal surface as pseudomembranes. Light and scanning electron microscopy after exposure to either of the *C. difficile* toxins reveal patchy damage and exfoliation of superficial epithelial cells, while crypt epithelium remains intact. Fluorescent microscopy of phalloidin-stained sections shows that both toxins cause the disruption and condensation of cellular F-actin<sup>[96]</sup>.

Other colonic mucosal findings include bowel-wall edema, erythema, friability, and inflammation, with or without pseudomembranes. This manifests on the abdominal CT scan as thickening of the colonic wall.

Colonoscopic findings among 16 patients with histologically-proven antibiotic-associated PMC or CDAC were described by Seppälä *et al*<sup>[97]</sup>. Pseudomembranes were found in only five of 16 (31%) patients by sigmoidoscopy, but were found in 11 of 13 patients (85%) in whom colonoscopy also was performed. These findings suggest the importance of colonoscopy in the early diagnosis of CDAC, because the typical endoscopic changes of pseudomembranes are limited to the colon above the rectosigmoid area in most patients. Consequently, colonoscopy should be performed, instead of sigmoidoscopy, at least in clinically suspected CDAC cases<sup>[98]</sup>.

### Complications of *C. difficile* colitis

*C. difficile* colitis is usually associated with a mild/moderate course, but may progress to fulminant colitis. Fulminant colitis develops in 3%-8% of patients. The manifestations of fulminant colitis typically include severe lower quadrant or diffuse abdominal pain, diarrhea, abdominal distention, fever, hypovolemia, lactic acidosis, and marked leukocytosis (up to 40 000 white blood cells/microL or higher). Diarrhea may be

less prominent in patients with prolonged ileus, due to pooling of secretions in the dilated, atonic colon. Other potential complications of fulminant colitis include toxic megacolon and bowel perforation<sup>[73]</sup>.

Toxic megacolon is a clinical diagnosis based upon the finding of colonic dilatation (> 7 cm in its greatest diameter) accompanied by severe systemic toxicity. Abdominal plain films also may demonstrate small-bowel dilatation, air-fluid levels (mimicking an intestinal obstruction or ischemia), and 'thumb printing' (scalloping of the bowel wall) due to submucosal edema. Toxic megacolon may be complicated by bowel perforation.

This latter complication presents with abdominal rigidity, involuntary guarding, diminished bowel sounds, rebound tenderness, and severe localized tenderness in the left or right lower quadrants. Abdominal radiographs may demonstrate free intra-abdominal air. Thus, patients with toxic megacolon must be followed with daily upright abdominal X-rays to ascertain if perforation has occurred. Patients with toxic megacolon should be evaluated for surgical resection. Once fulminant colitis is diagnosed, subtotal colectomy with ileostomy usually is required. In these patients who develop a marked leukocytosis or bacteremia, surgery is advisable, because the leukocytosis frequently precedes hypotension. The requirement for vasopressor therapy carries a poor prognosis, according to Shen *et al*<sup>[99]</sup>.

Lamontagne *et al*<sup>[100]</sup> has documented that emergency colectomy reduces mortality in patients with fulminant CDAD. The independent predictors of 30-d mortality in their study were leukocytosis  $\geq 50 \times 10^9/L$  (AOR, 18.6; 95% CI: 3.7-94.7); serum lactate  $\geq 5$  mmol/L (AOR, 12.4; 95% CI: 2.4-63.7); age  $\geq 75$  years (AOR, 6.5; 95% CI: 1.7-24.3); immunosuppression (AOR, 7.9; 95% CI: 2.3-27.2); and shock requiring vasopressor therapy (AOR, 3.4; 95% CI: 1.3-8.7). After adjusting for these confounders, patients who had an emergency colectomy were less likely to die than those treated medically. Colectomy also seemed more beneficial in patients 65 years or older; in those who were immune-competent; and those with leukocytosis  $\geq 20 \times 10^9/L$  or a serum lactate level between 2.2 and 4.9 mmol/L.

Small-bowel involvement with *C. difficile* enteritis is unusual<sup>[101]</sup>. Potential risk factors for small-bowel involvement with *C. difficile* enteritis include prior gastrointestinal surgery (including colonic resection) and advanced age<sup>[102]</sup>. Such patients may present with ileitis and high ileostomy output and may be at increased risk for fulminant disease.

Small-bowel involvement with *C. difficile* infection enteritis has been described increasingly since 2000. Usually, this occurs in patients with a history of a prior colectomy or total procto-colectomy for severe and extensive IBD. The ileal mucosa appears to be at increased risk for inflammatory disease in the specific subset of patients who have undergone a prior colectomy<sup>[67]</sup>. Serious post-colectomy concerns, like severe ileostomy dysfunction with high ileostomy volumes and marked diarrhea, have been known to occur after pan-procto-

colectomy and restorative ileo-anal pouch formation. They are almost always due to a non-*C. difficile* enteritis. This non-CDAD post colectomy enteritis can be life threatening; fortunately it is steroid/ immunosuppressive responsive, according to Gooding *et al*<sup>[103]</sup>. This picture can be mimicked by *C. difficile* infection.

Lundeen *et al*<sup>[104]</sup> reported that high ileostomy volumes may result from *C. difficile* enteritis in patients who have undergone colectomy for ulcerative colitis. All of the ileostomy output was positive for *C. difficile* toxins. These patients responded to metronidazole and/or vancomycin, in contrast to subjects with the former, non-CDAD entity.

Refractory or treatment-resistant pouchitis also may occur with *C. difficile* infection<sup>[105]</sup>. *C. difficile* infection involving ileal pouch-anal anastomosis is common, and occurs with or without the previous receipt of antibiotics<sup>[99]</sup>. Diagnosing recurrent *C. difficile* infection can be difficult in this group of patients, especially in the 20% without diarrhea.

### Laboratory confirmation

All health care facilities must develop rapid communication between the laboratory and the treating physician. At the Mayo Medical School, the time between electronic medical record reporting of a positive result for a test for *C. difficile* toxin in stool and the ordering of antimicrobial therapy was compared during consecutive periods when results were not telephoned ( $n = 274$ ) and when results were telephoned ( $n = 90$ ) to the clinical service<sup>[106]</sup>. The mean times to the ordering of antimicrobial therapy were 11.9 and 3.6 h, respectively ( $P < 0.001$ ). The clinical implications of this 8-h delay may be important, especially in patients with severe disease. Early recognition of CDAD caused by NAP1/027, followed by the initiation of rapid treatment, can help to prevent complications and further spread of the bacterium<sup>[107]</sup>.

Current laboratory testing lacks a single assay that is sensitive, specific, and rapid. Peterson *et al*<sup>[108]</sup> used clinical criteria that required at least three loose stools in one day, as part of the reference standard for a positive test result supporting CDAD (Table 2). They found that real-time PCR and anaerobic culture assays were significantly more sensitive than the enzyme immunoassay ( $P < 0.01$  to  $P < 0.05$ ). Real-time PCR has an assay turnaround time of  $< 4$  h, and is both more sensitive than, and as rapid as enzyme immunoassay. They feel that it is a feasible laboratory option to replace enzyme immunoassay for toxigenic *C. difficile* detection in clinical practice, as well as for use during the development of new therapeutic agents.

Tests for the presence of *C. difficile* and its toxins are imperfect, and false positives and false negatives are not uncommon. McFarland<sup>[30]</sup> found that false-negative results occur in 29%-56% of cases. False-negative results may occur when specimens are not promptly tested or not kept refrigerated until testing is performed. Also, there is a relatively high false-negative rate, due to the fact that 100-1000 pg of toxin must be present for an EIA test to be positive. Utilizing up to three serial EIA tests may increase the diagnostic yield by as much

Table 2 Laboratory diagnosis of *C. difficile*

Test	Sensitivity (%)	Specificity (%)	PPV	NPV

---

as 10 percent, if the initial test is negative. If CDAD is suspected, despite negative initial testing, submission of multiple specimens and verifying that the laboratory is testing for both the A and B toxins is mandatory (Table 3).

Enzyme immunoassays are labor-intensive tests, requiring several hours of technician time and an assay reader. The batching of specimens increases cost efficiency, but may delay the reporting of results, especially if tests are not done every day. Rapid enzyme immunoassay is more costly for each test performed but, for laboratories that process only occasional samples, it appears to provide prompt, reliable, and cost-effective results.

Enzyme immunoassay rapid cards have been evaluated, in terms of their ability to detect *C. difficile* toxins A and B. For one such card, the EIAPrem, the positive predictive value (PPV) was 75/85 samples (88.2%; CI: 79% to 94%) and the negative predictive value (NPV) was 360/361 samples (99.7%; CI: 98% to 99%). For a review of all card performances, see references<sup>[109-112]</sup>.

Killgore *et al*<sup>[113]</sup> compared the results of analyses done with seven *C. difficile* typing techniques: multi-locus variable-number tandem-repeat analysis (MLVA); amplified fragment length polymorphism; surface layer protein A gene sequence typing; PCR-ribotyping; restriction endonuclease analysis (REA); multi-locus sequence typing; and pulsed-field gel electrophoresis (PFGE). All techniques appeared to be capable of detecting outbreak strains; but only REA and MLVA exhibited sufficient discrimination to distinguish strains from different outbreaks.

### Rapid laboratory tests

Comparison of four enzyme immunoassays (Bartels Prima System *C. difficile* Toxin A EIA, Cambridge Biotech Cytoclone A+B EIA, Meridian Diagnostics Premier *C. difficile* Toxin A EIA, and TechLab *C. difficile* Tox-A Test EIA) found that, although enzyme immunoassays

were less sensitive than cytotoxin assay, they provide same-day results and may be useful in laboratories without tissue culture facilities<sup>[114]</sup>.

ELISA Toxin A+B is a reliable method with 100% specificity and sensitivity in the rapid diagnosis of *C. difficile*. Its results can be utilized until culture results are obtained. The specificity of the Toxin A latex test is 100%; however, its use alone as a primary rapid diagnostic test is not recommended, because of its low (30.7%) sensitivity. This was shown when all of the culture positive samples underwent testing by ELISA Toxin A+B method and were found to be 100% positive, but only four of these positive culture samples (30.7%) yielded positive results with the Toxin A latex test<sup>[115]</sup>.

Overall, the new-generation assays still are less sensitive than the cytotoxin assay; however, their advantages are that they provide same-day results; they can be used as a screening test; and they may be useful in laboratories without tissue-culture facilities. Results from a study by Vanpoucke *et al*<sup>[111]</sup> could not recommend one single assay over the other for the diagnosis of CDAD.

Therefore, the cytotoxin assay test (CYTA) is highly sensitive and specific, but it is difficult to perform, and results are not available for 24-48 h<sup>[15]</sup>. What further complicates efforts to determine if toxin was present on admission is that *C. difficile* toxin is very unstable. The toxin degrades at room temperature and may be undetectable within 2 h after collection of a stool specimen. Given the cost and complexity of culture and cytotoxicity assays, most laboratories rely on tests for toxin A detection only. Moreover, enzyme immunoassays generally are available at lower cost and provide more rapid results, usually within 4 h. Their sensitivity generally ranges from 60% to 90%, and specificity from 75% to 100%. Testing of a single diarrheal stool generally is sufficient to make the diagnosis of CDAD; but unfortunately, doing so misses a substantial proportion of cases. Therefore, testing only should be performed on three loose stool specimens.

The cytotoxin assay test, though the 'gold standard' for assaying *C. difficile* toxins A and B, is labor-intensive, requires tissue-cultured cells and an inverted microscope, and needs overnight incubation before results can be read.

## TREATMENT OF THE NEW VIRULENT STRAIN OF CDAD

Recent experience has not altered the principles of management for the individual patient, but it does serve to emphasize the need for: (1) recognition of clinical characteristics that indicate severe CDAD (Table 4); (2) early recognition of *C. difficile*; (3) improved methods to manage severe relapsing disease; and (4) greater attention to infection control and antibiotic restraint. Previously published *C. difficile* infection management is available: [Fekety "Guidelines for the diagnosis and management of *Clostridium difficile*-associated diarrhea and colitis" *Am J Gastroenterol*, 1997; 92(5): 739-750] and the CDC's own

The efficacy of metronidazole or vancomycin prophylaxis to prevent *C. difficile* infection in patients who are receiving other antimicrobials is unproven, and treatment with these agents is ineffective against *C. difficile* in asymptomatic carriers<sup>[116]</sup>.

The usual treatment for *C. difficile*-associated disease has been to stop antibiotics being given for other purposes and immediately start treatment with metronidazole or vancomycin. Patients who remain on antibiotics while undergoing treatment of CDAD have a high likelihood of treatment failure with metronidazole<sup>[117]</sup>.

In 1983, before the virulent *C. difficile* epidemics, metronidazole and vancomycin were shown to have equivalent efficacy and relapse rates, and to be tolerated to a similar extent by patients with *C. difficile*-related diarrhea and colitis, but metronidazole was considerably more economical. Metronidazole was favored because the pharmacy cost for the dosage used was \$387.48 to \$520.00 for vancomycin and \$11.84 for metronidazole<sup>[118]</sup>.

Findings from another study suggest that metronidazole and vancomycin are equally effective for the treatment of mild CDAD, but that vancomycin is superior for treating patients with severe CDAD. Among the patients with mild CDAD, treatment with metronidazole or vancomycin resulted in clinical cure in 90% and 98% of the patients, respectively ( $P = 0.36$ ). On the other hand, among the patients with severe CDAD, treatment with metronidazole or vancomycin resulted in clinical cure in 76% and 97% of the patients, respectively ( $P = 0.02$ ). Clinical symptoms recurred in 15% of the patients treated with metronidazole and 14% of those treated with vancomycin<sup>[119]</sup>.

In order to reduce vancomycin resistance, current guidelines still recommend the first-line use of

metronidazole over vancomycin. However, the new strain of *C. difficile* may not respond as well to treatment with metronidazole, despite the absence of laboratory evidence of metronidazole resistance.

Comparison of the clinical and microbiological effects of vancomycin and metronidazole reveal that vancomycin-treated patients are more likely to develop undetectable levels of *C. difficile* (adjusted hazard ratio, 3.99; 95% CI: 1.41-11.3;  $P = 0.009$ ) and to have resolution of diarrhea (adjusted hazard ratio, 4.17; 95% CI: 1.53-11.40;  $P = 0.005$ ) during the first 5 d of therapy<sup>[120]</sup>.

Recent studies demonstrate a high rate of failure of metronidazole, due either to infection with NAP-1 or to the presence, in hospitals, of older and sicker adults who previously have been treated with many broad-spectrum antibiotics. This raises the question as to what drug should be used as the initial therapy of *C. difficile* infection. The standard of care seems to be shifting towards using vancomycin first, if one is facing either a virulent organism or if risk factors for severe disease or several risk factors are present, like advanced age, immune deficiency, or pre-existing IBD (Table 4).

In addition, the cure rate seems to be significantly higher with vancomycin than metronidazole (97% *versus* 76%). In clinical practice, there is a shift toward using oral vancomycin as initial therapy for severe CDAD; and some clinicians are endorsing vancomycin as the preferred therapy for moderate to severe disease caused by this new epidemic strain. Currently, the treatment for hypervirulent *C. difficile* strains appears to be no different than for other *C. difficile* infections, and includes oral vancomycin<sup>[121]</sup>.

Failure with metronidazole treatment may be attributable to a slower and less consistent microbiological response than that with oral the next sentence is deleted because it is repeated exactly from a previous paragraph. Vancomycin-treated patients are more likely to develop undetectable levels of *C. difficile* (adjusted hazard ratio, 3.99; 95% CI: 1.41-11.3;  $P = 0.009$ ) and to have resolution of diarrhea (adjusted hazard ratio, 4.17; 95% CI: 1.53-11.40;  $P = 0.005$ ) during the first 5 d of therapy<sup>[120]</sup>.

Freeman *et al.*<sup>[122]</sup> found that duration of cytotoxin production by *C. difficile* ribotype 027 markedly exceeds that of ribotype 001. These findings may help to explain the increased severity of symptoms and higher case-fatality ratio associated with infections with *C. difficile* ribotype 027. The authors also found that sub-optimal gut concentrations of metronidazole, possibly due to inactivation by components of normal gut flora, are associated with continued toxin production. The persistence of *C. difficile* spores suggests that additional strategies to restore the normal colonic microflora also may be beneficial<sup>[123]</sup>. However we must take this paradigm change from metronidazole to vancomycin as initial therapy with caution. Pépin *et al.*<sup>[17,18]</sup> reported a large epidemic of CDAD in Quebec that included large numbers of patients with severe and complicated disease. They examined the relative efficacy of metronidazole and vancomycin in the wake of this hypervirulent strain. Pépin *et al.*<sup>[17,18]</sup> described a greater incidence of severe

Surgical evaluation for acute abdomen

complications associated with CDAD (defined as 30-d mortality, sepsis, toxic megacolon, emergent colectomy, or intestinal perforation) with the coincident emergence of NAP1/027 in Quebec in 2003. They observed an overall 79% decrease in progression to severe complicated CDAD in patients initially treated with vancomycin, rather than metronidazole, between 1991 and 2003. They also noted that marked leukocytosis or renal failure predicted a significant risk of complications and mortality. In 2004, this led to a change in guidelines in Quebec, which recommended that oral vancomycin be used as initial treatment in patients with these markers of severity. In some cases, rectal vancomycin (0.5-1 g dissolved in 1-2 L of isotonic saline) can be given as a single 60-min retention enema every 4-12 h. Rifaximin administered as a 'chaser', after control of acute *C. difficile* infection with a standard 10-14-d course of vancomycin, appeared to prevent recurrence in seven of eight patients, even though they were rifaximin resistant<sup>[124]</sup>.

An albumin level < 2.5 g/L and ICU stay are predictors of failure of metronidazole therapy for CDAD. These patients may benefit from oral vancomycin therapy at the outset<sup>[125]</sup>.

Regardless of what therapy is used, patients should be monitored carefully to ensure that they are responding to therapy, and not developing complications. If deterioration is suspected, or if the patient fits the criteria for very severe disease or is immunosuppressed or elderly, it may be wise to utilize vancomycin initially (Table 5). Our approach to patients with suspected or known *C. difficile* infection is based on the severity of their illness (Figures 1 and 2).

### Recurrent *C. difficile* infection

Twenty percent of *C. difficile* infection patients relapse, despite adequate therapy. Risk factors for relapse are presented in Table 6. Diagnosing recurrent *C. difficile* infection can be difficult, especially in the 20% without diarrhea. The usual treatment for recurrent *C. difficile* infection is a repeat course of metronidazole, unless the patient has severe disease. Tapered and pulsed dosing schedules of vancomycin have been investigated for the treatment of *C. difficile* infection that recurs after an initial course of vancomycin (Table 7). An example of an oral vancomycin taper schedule is as follows: 125 mg *qid* × 10-14 d; 125 mg *bid* × 7 d; 125 mg daily × 7 d; 125 mg once every 2 d × 8 d; and 125 mg once every 3 d × 15 d<sup>[126]</sup>. The treatment of recurrent *C. difficile* infection with various vancomycin daily doses (2 g/d, 1 g/d, and 500 mg/d) and administration schedules (daily vancomycin followed by tapered or pulsed dose

vancomycin therapy) was reported by McFarland *et al*<sup>[123]</sup>. They found that tapered and pulsed dosing schedules of vancomycin result in significantly better *C. difficile* infection cure rates than traditional vancomycin dosing.

Wenisch *et al*<sup>[127]</sup> conducted a prospective, randomized study to compare the efficacy of the oral drugs fusidic acid, metronidazole, vancomycin, and teicoplanin in the treatment of CDAD. Treatment resulted in clinical cure greater than 90% with all the agents: 94% vancomycin, 96% teicoplanin, 93% fusidic acid, and 94% metronidazole. However, recurrent clinical symptoms occurred in 16% of patients treated with vancomycin or metronidazole, 7% of those treated with teicoplanin, and 28% of those treated with fusidic acid. There was asymptomatic carriage of *C. difficile* toxin in 13% of patients treated with vancomycin, 16% with metronidazole, 4% with teicoplanin and 24% with fusidic acid. No adverse effects related to therapy were observed with vancomycin or teicoplanin. Considering the costs of treatment, their findings suggest that metronidazole is the drug of choice for CDAD, and that glycopeptides should be reserved for patients who cannot tolerate metronidazole or who do not respond to treatment with this drug.

### Probiotics

Studies on probiotics for *C. difficile* infection have been inconclusive and conflicting, with respect to treatment benefit. Nonetheless, the use of probiotics is becoming more widespread.

Pillai and Nelson conducted a meta-analysis to assess the potential therapeutic effects of probiotics for *C. difficile* infection<sup>[128]</sup>. Randomized, prospective studies (1966-2007) using probiotics alone or in conjunction with conventional antibiotics for the treatment of documented *C. difficile* colitis were eligible for inclusion. Ultimately, four studies met the inclusion criteria and were included in the review. The four studies examined the use of probiotics

**Figure 1** Approach to patients with suspected *C. difficile* infection.**Figure 2** Initial therapeutic approach to patients with *C. difficile* infection.

in conjunction with conventional antibiotics (vancomycin or metronidazole) for the treatment of recurrence or the initial episode of *C. difficile* colitis in adults. All of the studies were small and had methodological issues. A statistically-significant benefit of probiotics combined with antibiotics was detected in only one study. The authors concluded that, overall, there is insufficient evidence to recommend probiotic therapy as an adjunct to antibiotic therapy for *C. difficile* colitis. There also is no evidence to support the use of probiotics alone in the treatment of *C. difficile* colitis.

In 1994, McFarland *et al*<sup>[129]</sup> reported that patients receiving *Saccharomyces boulardii* were significantly less likely than patients receiving placebo to experience a recurrence of *C. difficile* diarrhea (RR 0.59; 95% CI: 0.35 to 0.98). Consequently, in a later meta-analysis, he compared the efficacy of probiotics for the prevention of AAD and the treatment of CDAD. Across 25 randomized controlled trials (RCTs), probiotics significantly reduced the relative risk of AAD (RR 0.43, 95% CI: 0.31 to 0.58,  $P < 0.001$ )<sup>[130]</sup>. Across six randomized trials, probiotics had significant efficacy for CDAD (RR 0.59, 95% CI: 0.41 to 0.85,  $P = 0.005$ ).

This time, McFarland *et al*<sup>[129]</sup> concluded that a variety of different types of probiotic show promise as effective therapies for these two diseases. Again using meta-analysis, three types of probiotics (*S. boulardii*, *Lactobacillus rhamnosus* GG, and probiotic mixtures) were found to significantly reduce the development of AAD. Only *S. boulardii* was effective for CDAD.

Treatment of recurrent *C. difficile* infection with high-dose vancomycin plus *S. boulardii* is the only treatment

combination that has been evaluated in a prospective, randomized, controlled trial and found to generate a significant trend toward reduced recurrent *C. difficile* infection<sup>[131]</sup>. *Lactobacillus* spp. have been evaluated for use in recurrent *C. difficile* infection, but data on regimens containing these organisms are poorly derived and conflicting. Fungemia with its administration has been reported in immunocompromised hosts. Therefore, its use is not appropriate in this group<sup>[132]</sup>.

### **Fecal bacteriotherapy especially for relapsing (recurrent) CDAD**

Relapse of *C. difficile* occurs in 10%-25% of patients treated with metronidazole or vancomycin. Furthermore, multiple relapses may occur in the same patient. An alternative approach to patients with recurrent CDAD involves the administration of the entire fecal flora from a healthy individual, which is referred to as fecal bacteriotherapy. Borody *et al*<sup>[133]</sup> reviewed 84 fecal transplantation therapies for severe cases of relapsing, or recurrent *C. difficile* infection (*via* various routes of administration). They found that 80% resulted in a good clinical response, resolution, or cure<sup>[133]</sup>. A review of eight reports on the infusion of feces or fecal bacteria revealed an optimistic cure rate, without recurrence in most patients<sup>[134]</sup>. In a study involving 18 patients treated with healthy donor stools *via* a nasogastric tube, 15 patients were recurrence-free at 90 d (two died of unrelated causes and one experienced recurrence)<sup>[135]</sup>. The patients described in these reports<sup>[133,136-144]</sup> included those with symptomatic relapse after receiving multiple courses of antibiotics; e.g. vancomycin, and/or metronidazole, and/or rifampicin together with cholestyramine. Case series have suggested a clinical benefit of fecal bacteriotherapy in patients with severe or recurrent CDAD who have failed to respond to standard approaches. Although the data are limited to case series, fecal bacteriotherapy has been used successfully to treat relapsing *C. difficile* infection. The precise mechanisms for the benefits of fecal bacteriotherapy are unclear. The reappearance of *Bacteroides* species after treatment suggests that *Bacteroides* species may be involved in the restoration of the presumably antibiotic-damaged flora in the colon.

Successful treatment with two or more fecal enemas has been described in other reports, according to Borody, Leis, & Gerald Pang (www.Up-to-date.com2008), involving a total of 23 patients with PMC who were refractory to antibiotic therapy, or who had experienced multiple relapses. In one study of 16 patients with severe, refractory disease treated over an 18-year period, 13 responded dramatically with decreases in diarrhea, temperature and leukocytosis. In a report describing nine patients, the single administration of a fecal enema (5-10 gm homogenized stool in pasteurized cow's milk) was effective in seven. In another case report, according to Borody, Leis, & Gerald Pang (www.Up-to-date.com), the one-time administration of bacteriotherapy was effective when 500 mL of fecal infusion in saline was delivered throughout the colon *via* a colonoscope. The authors hypothesized that the greater area of re-colonization by

fecal bacteria created a greater capacity to inhibit spore formation proximal to the splenic flexure. The use of the colonoscope to deliver fecal bacteria has an added theoretical advantage of permitting delivery of the active flora components to the distal small bowel, where *C. difficile* can reside. In addition, the colonoscope may permit the proximal delivery of flora in patients with a dilated colon, although colonoscopy must be performed extremely cautiously in this setting, because of the risk of perforation. One of the current authors (JSB) has utilized this modality with similar results.

Aas *et al*<sup>[135]</sup> reported on 18 subjects who received donor stool by nasogastric tube for recurrent *C. difficile* infection over a 9-year period at a single institution. During the period between the initial diagnosis of *C. difficile* colitis and the stool treatments, the 18 subjects received a total of 64 courses of antimicrobials (range, 2-7 courses; median, three courses). During the first 90 d after receipt of treatment with stool, two patients died of unrelated illnesses. Only one of the 16 survivors experienced a single recurrence of *C. difficile* colitis over the 90-d follow-up. No adverse effects associated with stool treatment were observed. Patients with recurrent *C. difficile* colitis may benefit from the introduction of stool from healthy donors *via* a nasogastric tube.

Lund-Tønnesen *et al*<sup>[140]</sup> reported on 18 patients with CDAD who were given homologous feces from one healthy donor. In 17 patients, feces were instilled *via* a colonoscope, and in one patient *via* a gastric stoma. Fifteen patients were clinically cured, and no relapses were observed; however, it is important to note that three patients with severe colitis did not respond to the treatment.

In recalcitrant, recurrent *C. difficile* infection, one should attempt initially to use probiotics that have been shown to be effective in published studies. Subsequently, in patients who remain seriously ill from recurrent *C. difficile* infection, fecal bacteriotherapy may be used when other approaches have been unsuccessful<sup>[133,145]</sup>. The above-mentioned study by Lund-Tønnesen *et al*<sup>[140]</sup>, in which three patients with severe colitis did not respond to the treatment, while only the remaining less-severely ill patients were clinically cured, and no relapses were observed may indicate that this may serve as rescue therapy for patients with recurrent *C. difficile*. But its role in patients with severe *C. difficile* infection remains unproven.

**Suggested protocol for fecal bacteriotherapy:** Barody's protocol is as follows. (a) Donor stool and blood are screened for pathogens and viruses before infusion. CBC, serological testing for hepatitis A, B, and C; HIV-1 and HIV-2 and syphilis, stool culture for enteric bacterial pathogens, and light microscopy examination of stool sample for parasites and ova are performed. (b) The donor is clinically well, with the passage of normal, daily stools, and has had no intake of antibiotics for the last 6 mo. (c) The donor should not be a close relative, living in the same household such as a husband or child, theoretically to avoid use of flora from a silent carrier

of the same pathogen. (d) The recipient is evaluated for HIV and hepatitis markers to avoid future questions about transmission. (e) Oral vancomycin (500 mg twice daily for 7 d) is administered, and then followed by a single oral lavage with 3-4 L of polyethylene glycol with electrolyte purgative (such as GoLYTELY). (f) Although the lavage is skipped in patients too ill to tolerate it, vancomycin pretreatment is used, whenever possible. (g) 200-300 gm of donor stool suspended in 200-300 mL of sterile normal saline (homogenized briefly in a kitchen blender to a liquid consistency) is administered *via* an enema within 10 min of preparation, and this is repeated daily for 5 d. (h) Initial infusion may be filtered and infused *via* colonoscopy, preferably into the terminal ileum to address known ileal presence of *C. difficile*. (i) At least five consecutive days of rectal enemas are administered, using donor stools. (j) The enema should be retained for at least 6 h (loperamide pretreatment may help), followed by a high-fiber meal and overall diet. (k) Although some patients are unable to retain the enema initially for prolonged periods, it appears that coating of the mucosa by the infusate is adequate. (l) Adverse effects have been transient and mild, and have consisted primarily of abdominal gurgling, gas and borborygmi-expected post-enema symptoms. Recurrence has not been observed with follow-up of 1-3 years in most patients, even though a number of patients subsequently have required antibiotics for unrelated infections.

In summary, patients who develop a second episode of *C. difficile* infection after successful treatment of the first episode may be at increased risk for developing complications. Although different drugs and regimens have been used, vancomycin may be the best option; and the combination of high-dose vancomycin plus *S. boulardii* is the only treatment combination that has been evaluated in a prospective, randomized, controlled trial to demonstrate a significant trend toward reduced recurrent *C. difficile* infection. Fecal bacteriotherapy seems promising and is undergoing further testing at this time

## NEWER ALTERNATIVE THERAPIES

Other therapeutic options for CDAD are being developed, and drugs used for other infections are being studied as alternatives to metronidazole and vancomycin.

Nitazoxanide, a nitrothiazolide and metabolic precursor of tizoxanide, has broad-spectrum activity against helminths and protozoa, as well as bacterial enteric pathogens, including *C. difficile*. It is marketed in the US and has been widely used throughout the world to treat parasitic diseases of the gastrointestinal tract; several million children have been treated with this drug over the past decade. Nitazoxanide is a US FDA approved drug that is used as an anti-protozoal agent for oral administration in pediatric patients, aged 1-11 years, with diarrhea. The drug acts by interfering with anaerobic metabolic pathways, and it has been shown to have excellent *in vitro* activity against *C. difficile*. An ongoing double-blind study comparing metronidazole with nitazoxanide for *C. difficile* infection involved the treatment

of 16 patients. The response rate for nitazoxanide was recently shown to be comparable to metronidazole for CDAD treatment in a prospective, randomized, double-blinded clinical trial<sup>[146-148]</sup>. It is associated with fewer side effects than metronidazole, which should improve compliance.

Tinidazole is a structural analogue of metronidazole, with similar bioavailability (100%) and fewer drug-related adverse effects, but similar *in vitro* activity against *C. difficile*<sup>[149,150]</sup>.

OPT-80, previously known as tiacumicin B, and with the proposed name difimicin, is a novel 18-membered macrocycle antibiotic. It has little or no systemic absorption after oral administration, and a narrow activity spectrum against Gram-positive aerobic and anaerobic bacteria, and has tested well in patients with *C. difficile* infection<sup>[151,152]</sup>.

Rifalazil and rifaximin are rifamycin derivatives. Rifalazil is an orally-absorbed systemic antibiotic with a broad spectrum of activity that has been shown to prevent and treat CDAD recurrence in a hamster model. Rifaximin, a non-systemic antibiotic approved by the US FDA for travelers' diarrhea, currently is under evaluation for the treatment of CDAD<sup>[153,154]</sup>.

In unresponsive cases (e.g. those who have had no improvement after 3 d on metronidazole), one should add oral vancomycin, 500 g four times daily and intracolonic vancomycin (500 mg of IV vancomycin in 100 mL of normal saline per rectal Foley catheter, clamping for 60 min, repeating every 6 h). In addition, if there is an ileus, metronidazole can be given intravenously. While there is still no significant experience with nitazoxanide or rifaximin, these would be reasonable choices. As well, Pullman *et al*<sup>[155]</sup> report that ramoplanin, a poorly-absorbed glycolipodepsipeptide that has been evaluated for the prevention of vancomycin-resistant enterococci, has good *in vitro* activity against *C. difficile*.

Teicoplanin may be a good choice, because some empirical evidence suggests that it is better than vancomycin for bacteriologic cure. It has borderline superior effectiveness in terms of symptomatic cure, but it is not readily available in the United States.

Therefore, in addition to nitazoxanide, bacitracin, teicoplanin, and fusidic acid, agents that have published efficacy, are several drugs, like rifaximin and PAR-101, which currently are under investigation. Other therapies, including polymers that bind *C. difficile* toxin, monoclonal antibodies to toxins, and preventative measures like toxoid vaccines, also are under study.

### A role for monoclonal antibodies?

Taylor *et al*<sup>[156]</sup> examined the safety and pharmacokinetics of a novel neutralizing human monoclonal antibody against *C. difficile* toxin A (CDA1) in 30 healthy adults whose median age was 27.5 years. While there were no serious adverse events related to its use, 21 of 30 reported non-serious adverse events were possibly related to CDA1. These included transient blood pressure changes requiring no treatment, nasal congestion, headache, abdominal cramps, nausea, and self-limited diarrhea. The authors concluded that, at least in healthy subjects, the

administration of CDA1 as a single intravenous infusion is safe and well tolerated.

### Anion-binding resins

The importance of toxin production in the pathophysiology of *C. difficile* diarrhea has prompted consideration of anion-binding resins as a possible alternative to antimicrobial therapy. An advantage of resin therapy is that the bowel flora is not altered, as occurs with antibiotics (e.g. vancomycin or metronidazole), which may allow for more rapid reconstitution of normal colonic flora. Anion-exchange resins bind vancomycin as well as toxins; thus, the resin must be taken at least 2 h or 3 h apart from the vancomycin. Suggested regimens are colestipol (5 g every 12 h) or cholestyramine (4 g three or four times daily) for 1-2 wk, usually in conjunction with vancomycin.

Tolvamer, a novel toxin-binding polymer, has been developed to ameliorate *C. difficile*-associated disease without adversely affecting normal flora. Tolvamer has been tested for its ability to neutralize clostridial toxins produced by the epidemic BI/027 strains, thereby preventing toxin-mediated tissue culture cell rounding. The titers of toxin-containing *C. difficile* culture supernatants were determined using confluent cell monolayers, and then the supernatants were used in assays containing dilutions of tolvamer to determine the lowest concentration of drug that prevented  $\geq 90\%$  cytotoxicity. Tolvamer neutralized toxins in the supernatants of all *C. difficile* strains tested. Specific antibodies against the large clostridial toxins TcdA and TcdB also neutralized the cytopathic effect, suggesting that tolvamer specifically neutralizes these toxins, and that the binary toxin (whose genes are carried by the BI/027 strains) is not a significant source of cytopathology against tissue culture cells *in vitro*<sup>[157]</sup>.

However, tolvamer is not FDA approved or commercially available, to date. Castanospermine has been identified as an inhibitor of the Rho/Ras-glucosylating *Clostridium sordellii* lethal toxin and *C. difficile* toxin B. Microinjection of castanospermine into embryonic bovine lung cells prevents the cytotoxic effects of toxins. The inhibitor binds in a conformation that brings its four hydroxyl groups and its N atom almost exactly into the positions of the four hydroxyls and the ring oxygen of the glucosyl moiety of UDP-glucose, respectively<sup>[158]</sup>. It is in its early stage of development.

### Vaccination

Testing the feasibility of active vaccination against *C. difficile* and its toxins in high-risk individuals currently is ongoing<sup>[159]</sup>. *C. difficile* toxoid vaccine has induced immune responses to toxins A and B in patients with CDAD, and has been associated with resolution of recurrent diarrhea. This parenteral *C. difficile* vaccine, which contains toxoid A and toxoid B, has been reported to be safe and immunogenic in healthy volunteers. Three patients with multiple episodes of recurrent CDAD were vaccinated. Two of the three exhibited an increase in serum IgG antitoxin A antibodies (three- and four-fold

increases), and in serum IgG antitoxin B antibodies (52 and 20-fold). Both individuals also developed cytotoxin-neutralizing activity against toxins A and B. Prior to vaccination, the subjects had required nearly continuous treatment with oral vancomycin for 7, 9, and 22 mo, respectively, to treat recurrent episodes of CDAD. After vaccination, all three subjects discontinued treatment with oral vancomycin without any further recurrence. Thus, *C. difficile* toxoid vaccine induced immune responses to toxins A and B in patients with CDAD, and was associated with resolution of recurrent diarrhea.

Vaccination with a partially-purified preparation of inactivated toxins A and B is also undergoing current study. Several studies have shown that the humoral immune response of the host to *C. difficile* toxins A and B influences the clinical course of CDAD, as well as the risk of relapse<sup>[160-162]</sup>.

Another vaccine, containing toxoids A and B, has been shown to induce adequate antibody responses in healthy volunteers<sup>[163]</sup>. The efficacy of this vaccine subsequently was evaluated in an open-label study involving three patients with recurrent *C. difficile* colitis<sup>[159]</sup>. Following four intramuscular inoculations over an 8-wk period, all three patients discontinued antibiotic treatment without further recurrence over 6 mo of follow-up.

### Immunoglobulin therapies

A retrospective review was performed on 264 *C. difficile* toxin-positive patients (November 2003-January 2005), which documented 14 patients with severe, refractory, recurrent *C. difficile* diarrhea who were treated with intravenous immunoglobulin (Flebogamma, 150-400 mg/kg)<sup>[164]</sup>. Patients received a median of three (range, 1-5 g/L) courses of vancomycin or metronidazole before receiving intravenous immunoglobulin. All had hypoalbuminemia (median, 22 g/L; range, 18-33 g/L) and raised C-reactive protein (median, 47 mg/L; range, 25-255 g/L) at the time of infusion. The median white cell count was  $15.3 \times 10^9$ /L (range, 4-24 g/L). Eight patients had evidence of pancolitis on abdominal imaging, suggesting severe *C. difficile* diarrhea. All patients tolerated intravenous immunoglobulin without side effects. Nine (64%) responded with bowel habits normalizing in a median of 10 (range, 2-26) d; one patient received two doses. One patient had a partial response from two doses, but died 2 mo later after a recurrence. Thus, intravenous immunoglobulin may be effective for severe, refractory, or recurrent *C. difficile* diarrhea after failed conventional treatment.

### Surgery

In patients with *C. difficile* colitis, a progressive, systemic inflammatory state may develop that is unresponsive to medical therapy; some cases ultimately will progress to colectomy or death. *C. difficile* colitis is a significant and increasingly common cause of death. Surgical treatment of *C. difficile* colitis has a high death rate once the fulminant expression of the disease is present<sup>[165]</sup>. These authors reviewed 2334 hospitalized patients with *C. difficile* colitis from January 1989 to December 2000.

In the setting of CDAD before the predominance of the hypervirulent strain, 64 patients died or underwent colectomy for pathology-proven *C. difficile* colitis. Unfortunately, those patients who underwent colectomy for *C. difficile* colitis had an overall death rate of 57%. Significant predictors of death after colectomy were preoperative vasopressor requirements and older age.

Fulminant *C. difficile* colitis is associated with a high mortality rate. As in the former study, Hall *et al*<sup>[166]</sup> found that the development of a vasopressor requirement and the need for intubation are ominous signs which should lead to rapid surgical intervention. From 1998 to 2006, they studied a total of 3237 consecutive patients with *C. difficile* cytotoxin-positive stool samples. Commonly referenced indicators for surgical intervention were gathered on the day of surgery. The preoperative characteristics of patients surviving subtotal colectomy were compared with those who did not survive. They found that 36 patients underwent colectomy. Twenty-three patients (64%) were discharged from the hospital alive. Preoperative intubation and vasopressor requirement were risk factors for in-hospital mortality (OR: 7.15; 95% CI: 1.28-39.8 and OR: 6.0; 95% CI: 1.08-33, respectively). Patients who had a recent surgical procedure experienced a lower in-hospital mortality rate (OR: 0.11; 95% CI: 0.02-0.52).

In the setting of CDAD due to the hypervirulent strain, some patients have progressed from severe disease to death in less than 48 h. Emergency colectomy has prevented mortality in some patients with fulminant CDAD. The decision to perform an emergency colectomy remains largely empirical<sup>[100]</sup>. In a retrospective observational cohort study of 165 cases of CDAD, among those patients who required ICU admission or prolongation of ICU stay between January 2003 and June 2005 at two tertiary care hospitals in Quebec, 53% died within 30 d of ICU admission, and almost half (44%) within 48 h of ICU admission. The independent predictors of 30-d mortality were: leukocytosis  $\geq 50 \times 10^9/L$  (AOR: 18.6; 95% CI: 3.7-94.7), lactate  $\geq 5$  mmol/L (AOR: 12.4; 95% CI: 2.4-63.7), age  $\geq 75$  years (AOR: 6.5; 95% CI: 1.7-24.3), immunosuppression (AOR: 7.9; 95% CI: 2.3-27.2) and shock requiring vasopressors (AOR: 3.4; 95% CI: 1.3-8.7). After adjustment for these confounders, patients who had an emergency colectomy were less likely to die (AOR: 0.22; 95% CI: 0.07-0.67,  $P = 0.008$ ) than those treated medically. Surgical intervention is indicated in the setting of peritoneal signs, severe ileus, or toxic megacolon; but colectomy also seems more beneficial in patients aged 65 years or older, in the immune competent, and in those with a leukocytosis  $\geq 20 \times 10^9/L$  or serum lactate between 2.2 and 4.9 mmol/L.

The standard of care for patients undergoing emergency surgical intervention for CDAD is a total colectomy (with preservation of the rectum) and ileostomy, since primary anastomosis is not feasible acutely due to the pancolitis associated with severe disease. However, after colonic inflammation has subsided,

Table 8 Indications for emergency colectomy

Based upon
30-d mortality
Leukocytosis $\geq 20 \times 10^9/L$
Lactate $\geq 5$ mmol/L
Age $\geq 75$ yr

closure of the ileostomy and ileorectal anastomosis can be performed (Table 8).

## CONCLUSION

CDAD has increased in frequency and severity throughout North America and Europe over the last several years, largely due to the emergence of the NAP1 epidemic strain. This transformation of a formerly mild disease into one that can cause severe morbidity and mortality within a few days has challenged the entire approach to this suddenly serious infection. Institutions require accurate and rapid diagnostics for early detection of cases and possible outbreaks, in order to initiate specific therapy and implement early and effective infection control<sup>[167]</sup>.

Aggressive diagnostic and therapeutic interventions are warranted in the setting of *C. difficile* infection. Bedside sigmoidoscopy or colonoscopy may be performed to make a presumptive diagnosis of *C. difficile* infection, by evaluating for the presence of pseudomembranes. Given the risk of perforation, care should be taken to introduce minimal amounts of air to avoid exacerbating ileus or distention. The choice of initial drug therapy depends on severity of illness, co-morbidities, and strain suspicion. Prompt surgical consultation is warranted to assess the requirement for colectomy<sup>[100]</sup>.

*C. difficile* infection is a global problem. A comprehensive *C. difficile* infection control management rapid response team (RRT) is recommended for each health care facility throughout the world. A communications network between RRTs also is recommended, in coordination with each country's Department of Health. It is only through the implementation of the new approaches to its diagnosis, therapy and presentation that we can help to reduce the morbidity and mortality caused by this infection.

## ADDENDUM I

### Contact precautions: For patients with known or suspected *C. difficile*-associated disease

We must address environmental reservoirs to help to limit transmission. *C. difficile* has been cultured not only from patient bathrooms and bedpans, but from stethoscopes, blood pressure cuffs, and hospital furniture.

The initial step is identifying possible *C. difficile* patients, especially in long-term care facilities (LTCFs). Quinn *et al.*<sup>[168]</sup> determined that only 111 facilities (42.2%) had a protocol to identify residents with *C. difficile* infection, and most (77.5%) did not test for *C. difficile* unless a resident had severe diarrhea. Only 58.5% of the facilities placed residents with *C. difficile* infection in private rooms, and 60.9% cohorted residents infected with *C. difficile* with other residents with *C. difficile* colonization or infection. Only 66 facilities (25.1%) had a program to control the use of antimicrobial agents.

Findings suggest that asymptomatic carriers of epidemic and non-epidemic *C. difficile* strains have the potential to contribute significantly to disease transmission in long-term care facilities. Thirty-five (51%) of 68 asymptomatic patients were carriers of toxigenic *C. difficile*, and 13 (37%) of these patients carried epidemic strains. Compared with non-carriers, asymptomatic carriers had higher percentages of skin (61% *vs* 19%;  $P = 0.001$ ) and environmental contamination (59% *vs* 24%;  $P = 0.004$ ). Eighty-seven percent of isolates found in skin samples and 58% of isolates found in environmental samples were identical to concurrent isolates found in stool samples. Spores on the skin of asymptomatic patients were transferred easily to investigators' hands. Previous *C. difficile*-associated disease ( $P < 0.001$ ) and previous antibiotic use ( $P = 0.017$ ) were associated with asymptomatic carriage, and the combination of these two variables was predictive of asymptomatic carriage (sensitivity, 77%; specificity, 58%; PPV, 66%; NPV, 70%)<sup>[64]</sup>.

In a prospective study of 27 patients with *C. difficile*-associated disease, it was found that *C. difficile* frequently contaminated multiple skin sites, including groin, chest, abdomen, forearms, and hands, and was easily acquired on investigators' hands. Skin contamination often persisted on patients' chest and abdomen after resolution of diarrhea. Thus, skin contact of the patient by a health-care worker is a means of *C. difficile* transmission<sup>[169]</sup>.

It is important to emphasize that asymptomatic fecal excretion of *C. difficile* is transient in most patients, and treatment with metronidazole is not effective. Although treatment with vancomycin is temporarily effective in asymptomatic carriers, it is also associated with a significantly higher rate of *C. difficile* carriage 2 mo after treatment and, therefore, is not recommended<sup>[63]</sup>.

An increase in hospital-acquired *C. difficile* infection rate was found at the University of Pittsburgh Medical Center. A comprehensive *C. difficile* infection control 'bundle' was implemented by hospital personnel to control the outbreak of *C. difficile* infection. This *C. difficile* infection control bundle consisted of education, increased and early case-finding, expanded infection-control measures, the development of a *C. difficile* infection management team, and antimicrobial management. Process measures, antimicrobial usage, and hospital-acquired *C. difficile* infection rates were analyzed, and *C. difficile* infection isolates were typed. The rates of compliance with hand hygiene and isolation were 75% and 68%, respectively.

The *C. difficile* infection management team evaluated a mean 31 patients per month (11% were evaluated for moderate or severe disease). The use of antimicrobial

therapy associated with increased *C. difficile* infection risk decreased by 41% during the period 2003-2005. The aggregate rate of *C. difficile* infection during the period 2001-2006 decreased to 4.8 infections per 1000 HDs; and, by 2006, it had decreased to 3.0 infections per 1000 HDs, a rate reduction of 71%. During the period 2000-2001, the proportion of severe *C. difficile* infection cases peaked at 9.4% (37 of 393 *C. difficile* infections were severe); this rate decreased to 3.1% in 2002 and further decreased to 1.0% in 2006, a 78% overall reduction. In 2005, 13% of *C. difficile* isolates were type BI (20% were hospital acquired), which represented a significant reduction from 2001. These authors concluded that the outbreak of *C. difficile* infection with the BI strain in hospital was controlled after implementing this infection control 'bundle'. Thus, early identification, coupled with appropriate control measures, reduces the rate of *C. difficile* infection and the frequency of adverse events. However, it requires a multipronged approach.

**Methods of contact precautions and control:** (1) Place patients with *C. difficile* in private rooms. (2) If private rooms are not available, place these patients in rooms with other patients who have *C. difficile*-associated disease. (3) Perform hand hygiene procedures preferably using soap and water-not alcohol. To reduce the transmission of *C. difficile* spores, environmental disinfection with 10% sodium hypochlorite and hand-washing with soap and water can be effective at removing the spores from hands and surfaces.

Strict antiseptic procedures should be followed by health care workers in contact with the patient, and these procedures should include the use of disposable gloves, and a mask and gown. Because alcohol is ineffective at killing *C. difficile* spores, health care workers must frequently wash their hands with soap and water, rather than with alcohol-based waterless hand sanitizers, especially when caring for CDAD patients. Patient-care equipment (e.g. blood-pressure cuffs, stethoscopes and thermometers) should either be used only for the infected patient or cleaned well before they are used with another patient.

Enhanced environmental cleaning following a regular schedule with dilute bleach should be used to eliminate *C. difficile* spores from all patient contact surface areas. These spores may remain on infected surface areas for months or even years.

In addition, note the ability of the vegetative form of *C. difficile* to survive on moist surfaces. On dry surfaces, vegetative *C. difficile* cells die rapidly, whereas they remained viable for up to 6 h on moist surfaces in room air. This illustrates the importance of washing and drying room surfaces when cleaning contaminated rooms.

A very important method of controlling outbreaks of *C. difficile*-associated disease should be restricting the use of antimicrobial agents that have been implicated as risk factors for the disease, as recommended by Gerding *et al.*<sup>[116]</sup>. Davey *et al.*<sup>[170]</sup> documented that interventions to improve antibiotic prescribing practices to hospital inpatients can be successful, and that they can reduce antimicrobial resistance and the rates of hospital-acquired infections.

### Control of fluoroquinolone use

Effective surveillance of antibiotic-resistant bacteria and CDAD must be intensified in every healthcare setting, but especially in long-term care and rehabilitation facilities. All these facilities must have easy laboratory access for prompt and active surveillance culturing and *C. difficile* cyto-toxin testing, for both A and B, at the earliest indication of any infection or CDAD. In addition, Furuno *et al*<sup>[171]</sup> advise that those patients at higher risk for carriage of antibiotic-resistant bacteria should be identified early for active surveillance targeting-culturing for methicillin-resistant *S. aureus* (MRSA) and vancomycin-resistant enterococci (VRE); e.g. patients who report having had antibiotics or prior hospital admissions within the past year. The authors found that this was very cost-effective, saving a projected \$19 000-\$26 000 relative to non-directed hospital wide screening for resistant organisms (MRSA and VRE), during the 8-mo study period at their tertiary care facility. They also found that there often is a significant delay between the onset of CDAD symptoms and the full implementation of CDC contact precautions.

## ADDENDUM II

Note that current Proper Hand Hygiene techniques for *C. difficile* differ from previous 2002 CDC Guidelines for hand hygiene in health-care settings, which were as follows.

IV.A.1. During the delivery of healthcare, avoid unnecessary touching of surfaces in close proximity to the patient to prevent both contamination of clean hands from environmental surfaces and transmission of pathogens from contaminated hands to surfaces.

IV.A.2. When hands are visibly dirty, contaminated with proteinaceous material, or visibly soiled with blood or body fluids, wash hands with either a non-antimicrobial soap and water or an antimicrobial soap and water.

IV.A.4. Wash hands with non-antimicrobial soap and water or with antimicrobial soap and water if contact with spores (e.g. *C. difficile* or *Bacillus anthracis*) is likely to have occurred. The physical action of washing and rinsing hands under such circumstances is recommended, because alcohols, chlorhexidine, iodophors, and other antiseptic agents have poor activity against spores.

Alcohol-containing hand disinfection products were recommended over soap and water in the control of most organisms of epidemiological importance<sup>[172]</sup>. Alcohol, however, does not eradicate *C. difficile* spores, maintain both Bettin *et al*<sup>[173]</sup> and Boyce *et al*<sup>[174]</sup>. Thus, what hand cleaning method to use in the presence of *C. difficile* infection is controversial. Papers conflict on the subject of alcohol eradicating *C. difficile* spores.

There even has been concern that the widespread use of alcohol-based hand sanitizers (instead of hand washing) has played a role in recent *C. difficile* outbreaks. Furthermore, because soap and water hand hygiene requires more time than alcohol-based hand hygiene, there is concern that alcohol-based hand hygiene may decrease overall effective hand hygiene compliance.

These concerns remain unproven. Overall CDAD rates have tended to decrease or remain the same after the introduction and increased use of alcohol-based sanitizers as the primary mode of hand hygiene<sup>[175,176]</sup>. There is a lack of rigorous evidence, however, linking specific hand hygiene interventions with the prevention of health care associated infections (HCAIs). The varied nature of the interventions used and the diverse factors affecting the acquisition of HCAIs make it difficult to show any specific effect of hand hygiene alone. The most frequent methodologies currently used in this research area have been before-and-after observational studies without a control comparison group<sup>[177]</sup>. However, the CDC recommends soap and water hand hygiene when caring for patients with CDAD.

In summary, if a facility is experiencing a *C. difficile* outbreak, it is prudent to emphasize that health care workers should frequently wash their hands with soap and water, in addition to using an alcohol-based hand sanitizer<sup>[178]</sup>.

The 2008 recommendations have been ambivalent, as seen below.

If your institution experiences an outbreak of *C. difficile*, consider using only soap and water for hand hygiene when caring for patients with *C. difficile*-associated disease; alcohol-based hand rubs are not as effective against spore-forming bacteria.

Current (Reviewed 3/08) CDC hand hygiene guidelines, available at <http://www.cdc.gov/handhygiene/> [7A] Accredited organizations are required to provide health care workers with a readily accessible alcohol-based hand rub product (CDC recommendations 8 C&D). However, use of an alcohol-based hand rub cleaner by any individual health care worker is not required. If you choose not to use it, then soap and water should be used instead.

In addition, use gloves when entering patients' rooms and during patient care; use gowns if soiling of clothes is likely; dedicate equipment, whenever possible.

Implement an environmental cleaning and disinfection strategy. Ensure adequate cleaning and disinfection of environmental surfaces and reusable devices, especially items likely to be contaminated with feces and surfaces that are touched frequently. Use an Environmental Protection Agency (EPA)-registered hypochlorite-based disinfectant for environmental surface disinfection after cleaning, in accordance with label instructions; generic sources of hypochlorite (e.g. household chlorine bleach) also may be appropriately diluted and used. Follow the manufacturer's instructions for the disinfection of endoscopes and other devices. Infection control practices in long-term care and home health settings are similar to those practices taken in traditional health-care settings.

How to clean and disinfect surfaces and devices according to the CDC's evidence-based guidelines for the prevention of CDAD (as reported at [http://www.cdc.gov/ncidod/dhqp/id\\_CdiffFAQ\\_HCP.html](http://www.cdc.gov/ncidod/dhqp/id_CdiffFAQ_HCP.html)). (1) Surfaces should be kept clean, and body substance spills should be managed promptly, as outlined in the CDC's 'Guidelines for Environmental Infection Control in Health-Care Facilities'. (2) Hospital cleaning products can be used for

routine cleaning. (3) Hypochlorite-based disinfectants have been used with some success for environmental surface disinfection in those patient-care areas where surveillance and epidemiology indicate ongoing transmission of *C. difficile*. (4) Consult the aforementioned guidelines for the use conditions for generic sources of hypochlorite-based products (e.g. household chlorine bleach) for disinfection of environmental surfaces. Note: EPA-registered hospital disinfectants are recommended for general use, whenever possible, in patient-care areas. At present, there are no EPA-registered products with specific claims for inactivating *C. difficile* spores, but there are a number of registered products that contain hypochlorite.

If an EPA-registered proprietary hypochlorite product is used, consult the label instructions for proper and safe use conditions. The literature supports the role of environmental disinfection with unbuffered hypochlorite solutions (diluted 1:10)<sup>[179]</sup>.

Fawley *et al.*<sup>[180]</sup> studied the differences between the activity of various cleaning agents and germicides against *C. difficile* spores and the potential for some of these products to promote sporulation. When used at recommended working concentrations, only chlorine-based germicides were able to deactivate *C. difficile* spores. *C. difficile* epidemic strains had a greater sporulation rate than non-epidemic strains. The mean sporulation rate, expressed as the proportion of a cell population that is in spore form, was 13% for all strains not exposed to any cleaning agent or germicide, and it was significantly increased by exposure to cleaning agents or germicides containing detergent alone (34%), a combination of detergent and hypochlorite (24%), or hydrogen peroxide (33%). By contrast, the mean sporulation rate did not change substantially after exposure to germicides that contain either a combination of detergent and dichloroisocyanurate (9%) or dichloroisocyanurate alone (15%).

A study by White *et al.*<sup>[181]</sup> revealed that all floor cleaning methods reduce the overall microbial load, though high counts and bacterial pathogens occasionally persist despite cleaning. Spray cleaning yielded marginally better results than traditional mopping and vacuuming. Wet scrubbing significantly reduced levels of coagulase-positive staphylococci ( $P = 0.03$ ), which, in combination with routine methods, produced an effect that persisted for at least a week. Any sudden change in CDAD incidence in any medical institution should be reported immediately to public health officials.

The use of copper surfaces within the clinical environment and the application of a germination solution in infection control procedures may offer a novel way by which to eliminate *C. difficile* from contaminated surfaces and reducing CDAD<sup>[182]</sup>.

Three novel copper-based biocidal formulations, but not their components (copper sulfate and inorganic binders), were found by Gant *et al.*<sup>[183]</sup> to have potent activity against organisms highly relevant to healthcare-associated infections, and all were active against *C. difficile* spores. This biocidal activity was not achieved by copper sulfate or the inorganic binders used in the formulations.

Table 9 Strength of recommendation and quality of evidence

Category/grade	Definition
Strength of recommendation	
A	Good evidence to support a recommendation for use
B	Moderate evidence to support a recommendation for use
C	Poor evidence to support a recommendation
Quality of evidence	
I	Evidence from $\geq 1$ properly randomized, controlled trial
II	Evidence from $\geq 1$ well-designed clinical trial, without randomization; from cohort or case-control analytic studies (preferably from $> 1$ center); from multiple time series; or from dramatic results from uncontrolled experiments
III	Evidence from opinions of respected authorities, based on clinical experience, descriptive studies, or reports of expert committees

Adapted from Canadian Task Force on the Periodic Health Examination. *Can Med Assoc J* 1979; 121(9): 1193-1254.

All three copper-based formulations completely decontaminated UMF cloths containing MRSA, ACCB or *C. difficile* spores, suggesting that any of these copper-based formulations could be highly beneficial in the healthcare environment. None of the three copper-based formulations or copper sulfate was cytotoxic to human epithelial cells, up to concentrations of 100-200 ppm.

### ADDENDUM III

*C. difficile* infection rates are rising (Figures 3 and 4). The most recent guidelines on *C. difficile* infection based on the strength of recommendations and quality of evidence were issued on 9 October 2008. This was issued as part of the latest updated guidelines for hospital acquired infections by the American Hospital Association, the Joint Commission on Accreditation of Health Organizations, the Infectious Diseases Society of America, the Society for Healthcare Epidemiology of America, and the Association for Professionals in Infection Control and Epidemiology in-"A Compendium of Strategies to Prevent Healthcare-Associated Infections in Acute Care Hospitals." *Infect Control Hosp Epidemiol* 2008; 29: S12-S21 (Authors-Yokoe, Mermel, Anderson, Arias, Burstin, Calfee, Coffin, Dubberke, Fraser, Gerding, Griffin, Gross, Kaye, Klompas, Lo, Marschall, Nicolle, Pegues, Perl).

#### (I) Basic practices for prevention and monitoring of *C. difficile* infection

Recommended for all acute care hospitals using strength of recommendations and quality of evidence from Table 9.

**A. Components of a *C. difficile* infection prevention program:** (1) Use contact precautions for infected patients, with a single-patient room preferred (A-II for hand hygiene, A-I for gloves, B-III for gowns, and B-III for single-patient room). (2) Ensure cleaning and disinfection of equipment and the environment (B-III

**Figure 3 Trends in hospital stays associated with *C. difficile*-associated disease, 1993-2005.** (From Elixhauser and Jhung<sup>[82]</sup>) shows the trend in CDAD from 1993 through 2005. During the 8-year period from 1993 until 2001, the total number of hospital discharges with CDAD increased from approximately 85 700 to 148 900 per year, 74% increase. However, during the following 4-year period, from 2001 to 2005, the rate of increase for CDAD escalated, when the numbers of cases more than doubled to 301 200 (a 102 percent increase in 4 years). There were a total of 2 037 900 hospital discharges with CDAD over this 12-year period.

**Figure 4 Discharge rate for *C. difficile*-associated disease, per 10 000 hospital discharges, 1993-2005.** (From Elixhauser and Jhung<sup>[82]</sup>) shows the number of CDAD discharges per 10 000 hospital discharges from 1993 through 2005. The findings are similar to those of the previous figure. From 1993 to 2001, the rate of CDAD per 10 000 discharges increased by 60% while the rate of increase from 2001 to 2005 was considerably steeper, 92%. Thus, the recent sharp rise in CDAD was not attributable solely to an increase in the number of hospital discharges.

for equipment and B-II for the environment). (3) Implement a laboratory-based alert system to provide immediate notification to infection prevention and control personnel and clinical personnel about patients with newly diagnosed *C. difficile* infection (B-III). (4) Conduct *C. difficile* infection surveillance and analyze and report *C. difficile* infection data (B-III). (5) Educate healthcare personnel, housekeeping personnel, and hospital administration about *C. difficile* infection (B-III). (6) Educate patients and their families about *C. difficile* infection, as appropriate (B-III). (7) Measure compliance with CDC or World Health Organization hand-hygiene and contact precaution recommendations (B-III).

## (II) Special approaches for the prevention of *C. difficile* infection

Perform a *C. difficile* infection risk assessment. These special approaches are recommended for use in locations and/or populations within the hospital for which outcome data and/or risk assessment suggest lack of effective control despite implementation of basic practices.

**A. Approaches to minimize *C. difficile* transmission by healthcare personnel:** (1) Intensify the assessment of compliance with process measures (B-III). (2) Perform hand hygiene with soap and water as the preferred method

before exiting the room of a patient with *C. difficile* infection (B-III). (3) Place patients with diarrhea under contact precautions while *C. difficile* test results are pending (B-III). (4) Prolong the duration of contact precautions after the patient becomes asymptomatic until hospital discharge (B-III).

**B. Approaches to minimize *C. difficile* infection transmission from the environment:** (1) Assess the adequacy of room cleaning (B-III). (2) Use sodium hypochlorite (bleach)-containing cleaning agents for environmental cleaning. Implement a system to coordinate with the housekeeping department if it is determined that sodium hypochlorite is needed for environmental disinfection (B-II).

**C. Approaches to reduce the risk of *C. difficile* infection acquisition:** Initiate an antimicrobial stewardship program (A-II).

## (III) Approaches that should not be considered a routine part of *C. difficile* infection prevention

(1) Do not test patients without signs or symptoms of *C. difficile* infection for *C. difficile* (B-II). (2) Do not repeat *C. difficile* testing at the end of successful therapy for a patient recently treated for *C. difficile* infection (B-III).

## ADDENDUM IV

### *C. difficile* infection as a unique infectious problem

In the US, The Deficit Reduction Act of 2005 (P.L. 109-171) requires the Centers for Medicare & Medicaid Services (CMS), the US federal agency which administers Medicare, Medicaid, and the State Children's Health Insurance Program to deny the assignment of a case to a higher DRG (payment to a health care facility) based on the occurrence of one of a selected number of hospital-acquired conditions, if that condition was acquired during the hospitalization. This rule is named CMS-1390-P: Medicare Program; Proposed Changes to the Hospital Inpatient Prospective Payment Systems and Fiscal Year 2009 Rate - Provisions on Preventable Hospital-Acquired Conditions Including Infections. The US Congress requires CMS to select conditions that are high cost, high volume, or both; assigned to a higher paying DRG when present as a secondary diagnosis; and reasonably preventable through the application of evidence-based guidelines.

In its original ruling, CMS had proposed adding nine hospital-acquired conditions, including *C. difficile* to the list of hospital acquired infections for which it proposed to deny payment. This would have taken effect on 1 October 2008. In July 2008, however, in response to an April 2008 letter sent by all three of the US major gastroenterology organizations, CMS, in a final rule setting policies and payment rates for the hospital setting, decided not to add *C. difficile* to the list of 'Hospital-Acquired Conditions for Which It Will Deny Payment'.

The gastroenterology organizations in its April 2008 letter to CMS focused on the last criterion necessary for 'non-reimbursement'-reasonably preventable through the application of evidence-based guidelines.

US gastroenterology organizations, in the letter to CMS, made much about the alleged fact that alcohol-based products are effective against the majority of microorganisms other than (i.e. not for) *C. difficile*, with the statement that "Alcohol-based products, in compliance with CDC guidelines, have played a significant role in potentially complicating efforts to avoid the spread of CDAD."

"Indeed", stated the letter, quoting Shen *et al*<sup>[184]</sup> "the proportion of all hand hygiene episodes performed with soap and water dropped from 90% to 15%, three years after the introduction of alcohol hand gels in one U.S. teaching hospital". The letter continued by stating "that the trade-off of higher overall compliance against more focused use of soap and water is one that CMS must consider given that 'CDC guidelines have played a significant role in potentially complicating efforts to avoid the spread of CDAD'. "In conclusion", ended the letter to CMS, "the ACG, AGA and ASGE urge CMS not to add *C. difficile* to its list of hospital-acquired conditions for which additional payment as a complicating condition would not be available. We strongly believe that the disease is not reasonably preventable. Adding it to the list would create a very expensive and unworkable situation for CMS, hospitals,

physicians and patients."

However, as we have seen in our above review of *C. difficile* infection, the fact is that the hand washing issue is controversial and basically not objectively ascertained with good RCTs. Nevertheless, one can agree that hand washing at least may be superior secondary to the mechanical shedding of *C. difficile* spores with vigorous hand washing.

One can agree with the arguments against adding *C. difficile* infection to the list of non-reimbursable hospital services because of its variable incubation period. Complicating the accurate diagnosis of CDAD is that, while symptoms typically occur within 48 h of infection, patients infected in the hospital with *C. difficile* usually become infected within 3 wk of admission. However, the onset of symptoms can be delayed by 2-3 mo<sup>[30]</sup>. Also, although most cases of CDAD occur on days 4-9 of antibiotic therapy<sup>[15]</sup>, the subsequent diagnosis of CDAD is not always possible upon admission to the hospital, due to a variable incubation period. Therefore, one can agree that it is not reasonable to hold an inpatient hospital liable for a condition acquired in a different setting, one which is not even always detectable upon the patient's admission into their setting.

The CMS accepted these arguments against including *C. difficile* infection in those nosocomial infections that are not reimbursable. However, that still does not alleviate the responsibility of each healthcare facility to make aggressive attempts to counteract this problem. One can look to successful efforts made by others.

The University of Pittsburgh Medical Center developed a program, as mentioned in our review, consisting of education, increased early case finding, expanded infection-control measures, development of a *C. difficile* infection management team, and microbial management. The aggregate rate of *C. difficile* infection decreased from 7.2 infections per 1000 (9.4 during a peak) hospital discharges to 4.8 infections per 1000 hospital discharges, and later, was 3.0 infections per 1000 hospital discharges. The rates of compliance with hand hygiene and isolation were 75% and 68%, respectively<sup>[185]</sup>.

### Abstract

Prior studies have suggested that the incidence of some neoplastic disorders, particularly malignant lymphoma and small intestinal adenocarcinoma, are increased in celiac disease. Earlier studies from the United Kingdom have also suggested a link between celiac disease and esophageal carcinoma, although this has not been confirmed in North America. The risk of other gastrointestinal cancers seems to be limited. Gastric cancer does not appear to be detected more frequently, although direct endoscopic visualization of the upper gastrointestinal tract is now very common in patients with celiac disease. Colon cancer also appears to be limited in celiac disease, even in patients first diagnosed with celiac disease late in life. This has led to the hypothesis that untreated celiac disease may be protective, possibly owing to impaired absorption of fat or fat-soluble agents, including hydrocarbons and putative co-carcinogens implicated in the pathogenesis of colon cancer, which may be poorly absorbed and rapidly excreted.

### INTRODUCTION

Malignant disease is a serious concern in celiac disease<sup>[1]</sup> and recently has been reviewed in detail<sup>[2,3]</sup>. Some patients may even present with lymphoma<sup>[4,5]</sup> or a small-intestinal adenocarcinoma<sup>[6]</sup>, and the celiac disease is only detected later. In others, malignancy, particularly lymphoma, complicates the clinical course of well established celiac disease, but may be especially difficult to diagnose<sup>[7]</sup>. The precise risk of malignant disease in adult celiac disease is difficult to evaluate, but about 8%-10% with severe biopsy changes develop lymphoma<sup>[8]</sup>, and this figure has remained remarkably constant over several years<sup>[9]</sup>. Age of first diagnosis of celiac disease seems to be a critical factor. In those first diagnosed late in life (and presumably, initiating a protective gluten-free diet much later), detection of lymphoma may be much higher<sup>[8]</sup>.

Mechanisms involved in development of malignant disease in celiac disease require elucidation. Significantly, however, the small-intestinal mucosa that is involved, with changes caused by celiac disease, may still pathologically respond to a gluten-free diet, even after lymphoma is detected<sup>[4,5]</sup>. There are likely to be many potential confounding variables that alter the pathogenesis of lymphoma in a celiac population and influence risk measurements for various malignancies in different populations. These include genetic, geographic, infectious, and other epidemiological factors. Finally, the duration of gluten restriction and the degree of compliance with the gluten-free diet are specific factors that may be difficult to measure precisely, but seem crucial to malignant change in celiac disease.

### DIAGNOSTIC DIFFICULTIES

Most lymphomas are detected in the small intestine, usually the jejunum, but ileal localization may also occur<sup>[2]</sup>. Gastric or colonic lymphoma also occurs<sup>[2]</sup>. Lymphomas are usually ulcerating lesions, or stenosing and obstructing tumors<sup>[3]</sup>. Occasionally, the lymphoma may be multifocal or diffuse and localized only in the mucosa<sup>[5]</sup>. Often, concomitant nodal involvement is present<sup>[2]</sup>. The diagnosis may be especially difficult if small-intestinal (including duodenal) erosions and ulcers are present, as neoplastic cells may be more difficult to identify pathologically if significant superimposed inflammatory changes are present<sup>[4]</sup>. In some, benign

ulcers may lead to a mistaken diagnosis of Crohn's disease or a label of "ulcerative jejunoileitis"<sup>[4]</sup>. Some of these ulcers may contain frankly neoplastic lymphoma cells. Free perforation of the small intestine is a condition that should lead the clinician to a high level of suspicion of lymphoma in a patient with known or suspected celiac disease<sup>[10]</sup>. Even if there is a very high degree of suspicion, lymphoma may be notoriously difficult to diagnose, despite multiple endoscopic or suction small-intestinal biopsies<sup>[7]</sup>. In some patients that eventually prove to have lymphoma, even full thickness biopsies of the small intestine may not yield a definitive pathological diagnosis, especially if only mucosal disease is present. Additional tissue may be helpful for immunohistochemical labeling or PCR may be helpful in showing an altered binding pattern of antigen expression or a monoclonal cell population.

## TYPES OF LYMPHOMA

Lymphoma may be classified based on pathological and immunophenotypical features. B-cell and T-cell lymphomas both occur in celiac disease. However, detection of a T-cell type more often leads to suspicion of underlying celiac disease. Primary intestinal T-cell lymphoma is recognized under the WHO classification as enteropathy-associated T-cell lymphoma (ETL or EATL). They are very uncommon and represent an estimated 5% of all gastrointestinal lymphomas<sup>[3,11]</sup>. Previously, these were thought to be histiocytic in origin (and labeled malignant histiocytosis) but their origin now appears to be from T cells, specifically intra-epithelial lymphocytes<sup>[3,11]</sup>. In celiac disease (without lymphoma), the intra-epithelial lymphocytes express the following antigens (among others): surface CD3 and CD8. In a subset of patients that seem clinically refractory to a gluten-free diet, intra-epithelial lymphocytes have a different form of T-cell phenotypic expression: CD3 shows intra-cytoplasmic expression while CD8 expression is absent. Some believe this may reflect a specific form of refractory celiac disease (type 2) with a poor prognosis and a possible precursor lesion for the development of lymphoma<sup>[12-15]</sup>.

Even lymphomas with T-cell immunophenotypic features have been detected in extra-intestinal sites, which complicates the clinical course of celiac disease. These may be very rare and include lymphoma diffusely involving the liver and spleen (i.e. hepatosplenic type T-cell lymphoma) without evidence of small-intestinal involvement<sup>[16]</sup>, or lymphoma in other embryologically related or gut-derived sites, such as the thyroid gland or broncho-pulmonary and pleural sites<sup>[17]</sup>.

Recent studies have also provided evidence for an increased risk of other lymphoma types. In a pathological review of tumor materials from celiac disease patients, there was an apparent aggregation of autoimmune disorders, female sex and B-cell lymphoma<sup>[18]</sup>. More than double the risk for B-cell lymphoma was recorded, with

the most common type classified as a diffuse large B-cell lymphoma. In the same study, T-cell lymphomas had an approximately 50-fold risk along with a poorer prognosis (reflected in mean survival time after diagnosis and 5-year survival rate)<sup>[18]</sup>.

Recent studies have also evaluated risk of lymphoma in celiac disease. While the risk of lymphoma in celiac disease, especially of the T-cell type, is increased, the risk appears not to be as significant. The relative risk has been estimated to be close to 3 and likely is lower in clinically silent disease<sup>[19]</sup>.

## OTHER GASTROINTESTINAL CANCER

Also intriguing are studies related to malignant disease elsewhere in the gastrointestinal tract. Small-bowel adenocarcinoma is increased in celiac disease. Normally, this is a rare tumor. Some have suggested that this carcinoma may be related to an adenoma-carcinoma sequence<sup>[2]</sup>, but the risk of duodenal adenoma may not be increased in celiac disease<sup>[20]</sup>. Most patients appear to present with proximal small-intestinal localization, usually with small-bowel obstruction or bleeding. If complete surgical resection of a small-intestinal adenocarcinoma can be accomplished, the prognosis is better than if lymphoma is present<sup>[21]</sup>.

Some European studies have shown that there may be an increased risk of esophageal and pharyngeal carcinoma<sup>[1,22]</sup>. However, these findings have not been confirmed in America. In one report<sup>[8]</sup>, only a single terminal hypopharyngeal squamous cell carcinoma was detected in a celiac disease patient with lymphoma. No esophageal or gastric cancer was detected, despite repeated endoscopic studies during the course of diagnosis and treatment of celiac disease. Interestingly, however, Barrett's esophagus, a known precursor lesion of esophageal adenocarcinoma was frequently detected<sup>[8]</sup>. It may be that exposure to different environmental factors in different geographic areas or other confounding variables are important in cancer etiology and pathogenesis in celiac disease.

In a population-based cohort of celiac disease patients, overall colorectal cancer risk was marginally increased, owing to an increased risk in the ascending and transverse colon<sup>[23]</sup>, but not in dermatitis herpetiformis<sup>[23]</sup>. However, others have noted that colorectal cancer may not be increased<sup>[9]</sup>, especially in celiac disease patients with a diagnosis established late in life<sup>[9]</sup>. Possibly, untreated celiac disease is protective; dietary fat or fat soluble agents, including hydrocarbons or other putative co-carcinogens, may be implicated in the pathogenesis of colon cancer if poorly absorbed and rapidly excreted. Alternatively, immunological changes (e.g. increased intraepithelial lymphocytosis) in celiac disease may inhibit the development of epithelial malignancies at other gastrointestinal sites. Additional studies are needed to further clarify this information for celiac disease patients.

## TREATMENT

Treatment of lymphoma associated with celiac disease to date has not substantially differed from lymphoma in the absence of celiac disease, and generally involves a combination of surgical treatment, radiation and chemotherapy. Most believe that the best treatment results occur in those diagnosed early<sup>[24]</sup>. Biological agents are also being evaluated.

In newly diagnosed lymphoma patients with chronic diarrhea and weight loss, underlying celiac disease should be excluded, preferably prior to lymphoma treatment (since both radiation and chemotherapy may structurally alter the small intestine), because concomitant recognition of celiac disease may have important nutritional implications.

### Abstract

Capsule endoscopy (CE) is a simple, safe, non-invasive, reliable technique, well accepted and tolerated by the patients, which allows complete exploration of the small intestine. The advent of CE in 2000 has dramatically changed the diagnosis and management of many diseases of the small intestine, such as obscure gastrointestinal bleeding, Crohn's disease, small bowel tumors, polyposis syndromes, *etc.* CE has become the gold standard for the diagnosis of most diseases of the small bowel. Lately this technique has also been used for esophageal and colonic diseases.

### INTRODUCTION

A few years ago, the assessment of small bowel pathology was a major dilemma, especially when it came to the management of obscure gastrointestinal bleeding. Evaluation of the patients was frequently unsatisfactory because of the inability to completely visualize the small bowel mucosa with the available endoscopic and

radiological techniques. Capsule endoscopy (CE) was launched at the beginning of this millennium and since then has had a very important impact on managing obscure gastrointestinal bleeding and many other small bowel diseases.

### CAPSULE ENDOSCOPY

Until a few years ago, the small bowel was an organ which was very difficult to explore with the available endoscopic, radiological and nuclear medicine techniques. In routine practice, only the last few centimeters of the ileum were accessible to retrograde visualization by ileocolonoscopy. Exploration from the proximal side by push, sonde or intraoperative enteroscopy were invasive procedures that did not always allow us to visualize the lesions in the small bowel<sup>[1]</sup>. Sonde enteroscopy had been abandoned in the 90's because it was a tedious technique (long duration of the procedure) and it had several technical limitations. Push enteroscopy is limited by the depth of insertion of the scope and is poorly tolerated. Intraoperative enteroscopy is the most effective of these techniques, but it is the most invasive with a significant percentage of adverse side effects<sup>[2]</sup>.

With wireless CE we can provide a simple, safe, non-invasive, reliable procedure, well accepted and tolerated by the patient, which has revolutionized the study of the small bowel. This technique evaluates endoscopically, with high resolution images, the whole small bowel, avoiding any sedation, surgery or radiation exposure<sup>[2]</sup>.

Currently, CE is recommended as a third stage examination, after negative gastroscopy and colonoscopy in patients with obscure gastrointestinal bleeding. Also many studies have established, with a growing body of evidence, that this technique is cost-effective in other clinical situations, such as detection of small bowel lesions in Crohn's disease in patients in which other methods have failed to provide a diagnosis, non steroidal anti-inflammatory drug enteropathies, celiac disease, small bowel polyposis syndromes and small bowel tumors<sup>[2]</sup>. Other possible indications are HIV patients with gastrointestinal symptoms<sup>[3]</sup>, malabsorptive syndromes other than celiac disease<sup>[4]</sup>, Henoch-Schonlein purpura<sup>[5]</sup>, patients with small bowel transplants<sup>[6]</sup> and with intestinal graft *versus* host disease, particularly in monitoring the response to immunosuppressive therapy<sup>[7]</sup>.

The acquired knowledge of the wide range of lesions that can be found in the small bowel, encouraged the

implementation of some diagnostic and therapeutic techniques, such as double balloon enteroscopy, MRI-enteroclysis and CT-enteroclysis<sup>[2]</sup>.

The capsule endoscope is a disposable, small, swallowable, wireless, miniature camera which allows us to get a direct visualization of the gastrointestinal mucosa<sup>[8]</sup>. The initial capsule endoscope was developed by Given Imaging (Yoqneam, Israel) and approved in Europe by the European Medicines Agency and in the United States by the Food and Drug Administration in 2001<sup>[8]</sup>. This technique is available in over 4500 gastrointestinal centers throughout the world.

The capsule which measures only 11 mm × 26 mm and weighs 3.7 g, holds a metal oxide semiconductor imaging-chip video camera, 6 white light-emitting diode illumination sources, 2 silver-oxide batteries and a radio telemetry transmitter. The image field is 140 degrees, magnification is × 8 and the depth of view is 1 to 30 mm<sup>[9,10]</sup>.

Before the capsule is swallowed, 8 skin antennas are taped to the patient's anterior abdominal wall and connected to the hard drive. After an overnight fast, the patient swallows the capsule with a few sips of water, then the capsule is passively moved along by peristalsis. Two hours after ingestion, the patient is allowed to drink, while eating is allowed after 4 h. During the procedure the patient may carry on with his daily activities<sup>[11]</sup>.

The camera is activated by removal of the capsule from its magnetic holder and takes 2 images per second and transmits these by means of radio frequency to a sensor array placed on the patient's abdomen and from here to a recording device in a belt that the patient wears for the duration of the battery life (8 h). The use of the real time viewer may shorten procedures, as the patient can be disconnected once the cecum is visualized<sup>[11]</sup>.

After those 8 h, the sensor array and recorded data are removed and the recorded images are downloaded to the computer. It takes on average 40-60 min to read these images<sup>[3,12]</sup> and since it is very time-consuming, one possible cost-effective strategy could be the use of expert nurse endoscopists to select images. Some studies have shown that highly motivated nurses and gastrointestinal residents trained to read CE can detect clinically significant lesions at a similar rate to physicians<sup>[13-15]</sup>. Since its development, additional support systems have been added to the software to assist the reader, such as localization capability, suspected blood indicator, a multiviewing feature and quick view modality<sup>[3]</sup>.

The capsule is excreted with the feces, usually within 24 to 48 h<sup>[16]</sup>. CE is usually performed as an outpatient procedure. The presence of intestinal contents or a motility disorder may cause the incomplete visualization of the intestinal mucosa. Several studies have examined the possibilities of improving bowel cleanliness and shortening transit time by means of different medications and different fasting periods. Nevertheless, small bowel preparation is still a controversial issue<sup>[6]</sup>. We have participated in a prospective multicenter randomized trial which has shown that bowel preparation with different laxatives does not improve the visualization of the small intestine<sup>[17]</sup>.

The main contraindication to performing CE is the suspicion or knowledge of an obstruction in the gastrointestinal tract.

The retention of the device is the main complication of the procedure and is defined when CE remains in the digestive tract for a minimum of 2 wk<sup>[18]</sup>. The frequency of this problem varies, depending mostly on the clinical indication for CE, and ranges from 0% in healthy subjects, to 1.5% in patients with obscure gastrointestinal bleeding, to 5% in patients with suspected Crohn's disease<sup>[6]</sup> and to 21% in patients with intestinal obstruction<sup>[3]</sup>. At present CE has some technical limitations: it cannot be used to obtain biopsy specimens or for endoscopic treatment and it cannot be controlled remotely<sup>[8]</sup>. CE has also some clinical limitations which are problems in sizing and locating small bowel lesions<sup>[2]</sup>, a possible false-negative CE result, due to the fact that the global miss rate is about 11%, ranging from 0.5% for ulcerative lesions to 18.9% for neoplastic disease and the fact that sometimes we can get findings of uncertain relevance in healthy subjects<sup>[8]</sup>. Another drawback is that in almost 20% of procedures the capsule does not reach the cecum while it is active<sup>[11]</sup>.

Since its development, more than 650 000 capsules have been swallowed worldwide<sup>[19]</sup> and more than 1000 peer-reviewed publications have appeared in the medical literature. The most important gastrointestinal societies have published guidelines about its use (ASGE<sup>[20]</sup>, ESGE<sup>[21]</sup>, BSG<sup>[22]</sup>).

In latter years, breakthrough developments in CE technology have enabled the direct visualization of the upper<sup>[23,24]</sup> and lower segments<sup>[25,26]</sup> of the gut using specifically designed capsules.

In recent issues of this journal we have coordinated the publication of several papers, some covering the latest advances in this field, presenting the use of CE in diagnosis of gastrointestinal bleeding<sup>[27]</sup>, inflammatory bowel disease<sup>[28]</sup>, celiac disease<sup>[29]</sup>, neoplastic disease<sup>[30]</sup>, non-steroidal anti-inflammatory drugs-enteropathy and rare intestinal diseases<sup>[31]</sup>, and also its use in pediatric patients<sup>[32]</sup>. Others studied the value of intestinal preparation before CE<sup>[33]</sup>, CE use in the colon<sup>[34]</sup> and esophagus<sup>[35]</sup>, and the Patency and Agile<sup>[36]</sup> capsules, and finally another paper was about the future of the CE<sup>[37]</sup>.

I wish to emphasize here that we have been very successful in convincing some of the most important groups working in this area to write the above-mentioned papers.

### Abstract

**AIM:** To evaluate the ability of endoscopic ultrasound (EUS) elastography to distinguish benign from malignant pancreatic masses and lymph nodes.

**METHODS:** A multicenter study was conducted and included 222 patients who underwent EUS examination with assessment of a pancreatic mass ( $n = 121$ ) or lymph node ( $n = 101$ ). The classification as benign

or malignant, based on the real time elastography pattern, was compared with the classification based on the B-mode EUS images and with the final diagnosis obtained by EUS-guided fine needle aspiration (EUS-FNA) and/or by surgical pathology. An interobserver study was performed.

**RESULTS:** The sensitivity and specificity of EUS elastography to differentiate benign from malignant pancreatic lesions are 92.3% and 80.0%, respectively, compared to 92.3% and 68.9%, respectively, for the conventional B-mode images. The sensitivity and specificity of EUS elastography to differentiate benign from malignant lymph nodes was 91.8% and 82.5%, respectively, compared to 78.6% and 50.0%, respectively, for the B-mode images. The kappa coefficient was 0.785 for the pancreatic masses and 0.657 for the lymph nodes.

**CONCLUSION:** EUS elastography is superior compared to conventional B-mode imaging and appears to be able to distinguish benign from malignant pancreatic masses and lymph nodes with a high sensitivity, specificity and accuracy. It might be reserved as a second line examination to help characterise pancreatic masses after negative EUS-FNA and might increase the yield of EUS-FNA for lymph nodes.

## INTRODUCTION

A major limitation of endoscopic ultrasound (EUS) examination is its limited capacity to determine the exact nature of a lesion. Differential diagnosis between benign and malignant lymph nodes and focal pancreatic masses based on the EUS appearance is difficult and frequently requires EUS-guided fine needle aspiration (EUS-FNA) for confirmation of malignancy<sup>[1-4]</sup>.

Elastography has recently been presented as a novel technique that can be applied during ultrasound (US) examination to assess and measure tissue elasticity. Knowing that malignant tissues are generally harder than normal surrounding tissue, elastography might provide interesting clinical information to help distinguish benign from malignant tissue based on their specific tissue consistency. Clinical research has shown promising results in differentiating between benign and malignant tissue in the thyroid gland<sup>[5]</sup>, breast<sup>[6-8]</sup>, prostate<sup>[9,10]</sup> and to assess liver fibrosis<sup>[11-14]</sup>. Recently, elastography has also been introduced during EUS examination<sup>[15-19]</sup>. The current study is a continuation of previous research<sup>[15]</sup> to validate the potential role of elastography in distinguishing benign from malignant lymph nodes and focal pancreatic lesions in a large retrospective trial. The aim of this multicenter study was to classify lymph nodes and pancreatic masses during EUS examination as benign or malignant based on the real time (qualitative) elastography patterns and to compare the results with a classification based on the conventional B-mode EUS images and with the final diagnosis obtained by EUS-FNA and/or by surgical pathology.

## MATERIALS AND METHODS

### *Patients, procedure and examination technique*

Every patient ( $n = 222$ ) who underwent EUS examination with evaluation of a pancreatic mass ( $n = 121$ ) or lymph nodes ( $n = 101$ ), between October 2006 and February 2007, was included. The study was conducted in seven different centers throughout Europe. Only one lesion per patient was examined and by one single endoscopist per center. Each center started the study after six months experience of EUS elastography. The EUS examinations were performed with conventional linear EUS probes (Pentax EG38-UT and EG38-70UTK, Hamburg, Germany). The examined lesion was first classified as benign or malignant based on the conventional B-mode images. Subsequently, elastography was carried out in real time using a commercially available module incorporated into the Hitachi EUB-8500 system (Hitachi Medical Systems Europe, Zug, Switzerland). The technology measures the degree of tissue deformation after compression as an indicator for the stiffness of tissue. This compression during EUS examination is naturally obtained by arterial pulsations and respiratory movements. Detailed reviews on the technical aspects of elastography have been previously published<sup>[15,20,21]</sup>. The sample area was adjusted to the region of interest and the suitability of the elastographic signal was indicated

by a numeric scale within the image. Tissue elasticity was shown superimposed on the conventional B-mode EUS image by colors reflective of stiffness. Hard tissue areas were marked with blue, intermediate areas with green, medium soft areas with yellow and soft areas with red. Elastographic and B-mode images were displayed simultaneously side by side. The complete spectrum from blue to red was applied to each elastographic image and represented the graduation of relative elasticity within the sample area. Elastographic images were interpreted during the examination and a 60 s video loop was recorded for an interobserver study. After assessing the elastographic images, EUS-FNA was performed in all cases for clinical reasons using a 22-gauge needle (Wilson-Cook Medical, Winston-Salem, North Carolina). The technique of EUS-FNA is described elsewhere<sup>[22]</sup>. In all participating centers, the specimen were examined using the monolayer cytology technique<sup>[23]</sup>. An on-site pathologist was present in only four centers during the examination. In the remaining centers, the endoscopist assessed the sample to ensure sufficient tissue was obtained based on the presence of tissue filaments in the conservation solution and repeat punctures were performed if necessary. The pathologist was blinded to the elastography results. The final diagnosis was based on histology obtained by EUS-FNA and surgical specimen when available. If EUS-FNA was found to be negative (after at least one repeat examination), a 12 mo clinical and imaging follow-up was carried out in the absence of surgical specimens. The following parameters were recorded in a protocol: the classification as benign or malignant based on the B-mode images, the elastography score based on the elastographic pattern and the classification as benign or malignant based on this pattern and the final result based on histology.

### *Scoring system*

The elastographic images were scored according to elastographic patterns based on previous research<sup>[15]</sup>: a score equal to 1 was assigned when the image showed a homogenous soft tissue area (green) corresponding to normal tissue (Figure 1), a score equal to 2 when the image indicated heterogenous soft tissue (green, yellow, and red) corresponding to fibrosis or inflammatory tissue (Figure 2A and B), a score equal to 3 when the image displayed mixed colors or a honeycombed elastography pattern indicative of mixed hard and soft tissue making the interpretation difficult (Figure 3), a score equal to 4 when the image displayed a small soft (green) central area surrounded by mainly hard (blue) tissue corresponding to a malignant hypervascularized lesion (Figure 4) and a score equal to 5 was assigned to lesions representing mainly hard (blue) tissue with areas of heterogeneous soft tissue (green, red) representing zones of necrosis in an advanced malignant lesions (Figure 5). For the study purpose and to facilitate the use in clinical practice, we subsequently classified an elastography score equal to 1 and 2 as: (A) representing normal tissue or a benign

Figure 1 Elastographic image showing homogenous soft tissue corresponding to normal tissue.

Figure 3 Elastographic image showing mixed hard and soft tissue ("honeycombed pattern") making the interpretation difficult.

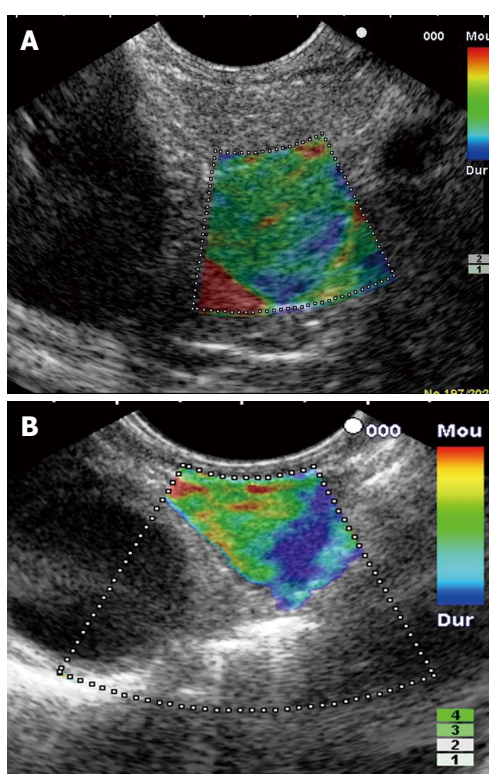

Figure 2 Elastographic image. A: Heterogenous soft tissue corresponding to fibrosis (benign nodule in patient who had an acute pancreatitis 2 mo before); B: Heterogenous soft tissue corresponding to inflammatory tissue (benign lymph node).

tumor; a score equal to 4 and 5 was classified as (C) representing a malignant lesion; and a score equal to 3 was classified as (B) which represented tissue difficult to classify as benign or malignant based on the elastographic pattern. However a score equal to (B) was considered as malignant for statistical analysis (Figure 6).

### Statistical analysis

The results are presented as means plus or minus standard deviation or as medians with ranges, depending on the data distribution. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were calculated as appropriate.

Figure 4 Elastographic image showing mainly hard tissue with a small soft central area corresponding to a malignant hypervascularized lesion (pancreatic neuroendocrine tumor).

Figure 5 Elastographic image showing mainly hard tissue with areas of heterogenous soft tissue corresponding to an advanced malignant lesion with necrotic areas (pancreatic adenocarcinoma).

An interobserver study was performed on a statistically representative and blinded selection of 30 videos (15 of a pancreatic mass and 15 of a lymph node). These videos were each evaluated by five endoscopists experienced in EUS and elastography. The elastographic images were scored with a whole number from 1 to 5 using the previous described criteria, constituting an ordered variable. The agreement between two different examiners was measured by an adapted kappa coefficient. The

Figure 6 Elastography score.

Figure 7 Pancreatic masses: elastography score and final histology.

interobserver study also evaluated the agreement between two examiners to classify the examined tissue as benign or malignant. The result is a binary variable (“malignant” or “benign”). The results being “inconclusive” were considered as missing data for the calculation of the agreement. This agreement was measured by the Cohen kappa coefficient.

## RESULTS

### Pancreatic masses

One hundred and twenty-one patients (77 M and 44 F, mean age 63 years) underwent EUS examination with elastography for evaluation of a pancreatic mass (mean diameter 29.5 mm, range 7-80 mm). The masses were located in the pancreatic head ( $n = 48$ ), isthmus ( $n = 17$ ), body ( $n = 29$ ), tail ( $n = 13$ ) and uncinate process ( $n = 14$ ). No complications occurred during the study. The final histological assessment was based on the FNA results in 82 cases and on surgical pathology in 39 cases. The final diagnosis of the pancreatic masses included pancreatic adenocarcinoma ( $n = 72$ ), malignant endocrine tumor ( $n = 16$ ), benign endocrine tumor ( $n = 2$ ), benign chronic pancreatitis related nodules ( $n = 28$ ) and pancreatic metastasis ( $n = 3$ ) (Figure 7). The elastographic images were interpreted as benign (score 1 + 2 = A) in 31 cases, indeterminate (score 3 = B) in 19 cases and malignant (score 4 + 5 = C) in 71 cases. Considering the “indeterminate” result equal to score (B) as malignant, the calculated sensitivity, specificity, positive and negative predictive values of EUS elastography to differentiate benign from malignant pancreatic masses were, respectively, 92.3%, 80.0%, 93.3% and 77.4% with a global accuracy of this new technology of 89.2%. The

**Table 1** Pancreatic masses: classification as benign or malignant based on EUS elastography, conventional B-mode imaging and the final diagnosis based on histology

		Histology	
		Malignant (n)	Benign (n)
Elastography/ conventional B-mode	Malignant	84/85	6/27
	Benign	7/7	24/2

Elastography: sensitivity =  $84/91 = 92.3\%$ , specificity =  $24/30 = 80\%$ , accuracy =  $108/121 = 89.2\%$ ; Conventional B-mode: sensitivity =  $85/92 = 92.3\%$ , specificity =  $2/29 = 68.9\%$ , accuracy =  $87/121 = 71.9\%$ .

calculated sensitivity, specificity, positive and negative predictive values of conventional B-mode images to differentiate benign from malignant pancreatic masses were, respectively, 92.3%, 68.9%, 75.8% and 22.2% with an accuracy of 71.9% (Table 1).

### Lymph nodes

One hundred and one patients (56 M and 45 F, mean age 61.1 years) underwent EUS examination of a lymph node for staging of lung cancer ( $n = 25$ ), oesophageal carcinoma ( $n = 25$ ), gastric cancer ( $n = 13$ ), pancreatic cancer ( $n = 13$ ), for suspicion of lymph node relapse of kidney cancer ( $n = 2$ ) and of breast cancer ( $n = 8$ ). EUS examination was also performed for evaluation of isolated lymph nodes ( $n = 15$ ). Lymph nodes (mean diameter 20.1 mm, range 7-50 mm) were located in the mediastinum ( $n = 51$ ), in the cervical area ( $n = 4$ ), in the celiac or mesenteric area ( $n = 44$ ), and in the perirectal space ( $n = 2$ ). No complications occurred during the study. The final histological assessment was based on FNA and classified the lymph nodes as malignant in 57 cases, including metastasis of an adenocarcinoma ( $n = 35$ ), metastasis of a squamous cell carcinoma ( $n = 13$ ), metastasis of an endocrine tumor ( $n = 3$ ), metastasis of a melanoma ( $n = 1$ ), lymphomas ( $n = 5$ ), and benign in 44 cases (including three cases of sarcoidosis) (Figure 8). The elastographic images were interpreted as benign (score 1 + 2 = A) in 38 cases, indeterminate (score 3 = B) in 10 cases and malignant (score 4 + 5 = C) in 53 cases. Considering the “indeterminate” result equal to score (B) as malignant, the calculated sensitivity, specificity, positive and negative predictive values were, respectively, 91.8%, 82.5%, 88.8% and 86.8% with a global accuracy of this new technology of 88.1%. The calculated sensitivity, specificity, positive and negative predictive values for the conventional B-mode images were respectively 78.6%, 50.0%, 70.5% and 60.6% with an accuracy of 67.3% (Table 2).

### Inter-observer study

The kappa coefficient of the sonoelastography score for pancreatic masses was 0.524, for the lymph nodes 0.519, and 0.520 for all cases confound.

The kappa coefficient for the differentiation between benign and malignant tissue was 0.785 for the pancreatic masses, 0.657 for the lymph nodes and 0.725 for all cases confound.

Figure 8 Lymph nodes: elastography score and final histology.

Table 2 Lymph nodes: classification as benign or malignant based on EUS elastography, conventional B-mode imaging and the final diagnosis based on histology

		Histology	
		Malignant (n)	Benign (n)
Elastography/ conventional B-mode	Malignant	51/48	2/20
	Benign	10/13	38/20

Elastography: sensitivity =  $51/61 = 83.6\%$ , specificity =  $38/40 = 95\%$ , accuracy =  $89/101 = 88.1\%$ ; Conventional B-mode: sensitivity =  $48/61 = 78.6\%$ , specificity =  $20/40 = 50\%$ , accuracy =  $68/101 = 67.3\%$ .

## DISCUSSION

The aim of this multicenter study was to evaluate the ability of EUS elastography to distinguish benign from malignant focal pancreatic masses and lymph nodes and to compare the results with the conventional B-mode images and final histology.

Our study shows that EUS elastography has high sensitivity, specificity and accuracy and a much higher specificity than conventional B-mode images to differentiate between benign and malignant focal pancreatic lesions. Using our current scoring system, 15.7% of the cases still obtain an elastography score equal to 3 indicating tissue difficult to classify as benign or malignant. However, 84% of these cases with an elastography score equal to 3 turned out to be malignant and we believe that the soft tissue parts of these focal lesions on elastography represent necrotic areas in an adenocarcinoma ( $n = 15$ ) or a hypervascularised area in an endocrine tumor ( $n = 1$ ). Hence, an elastography score equal to 3 should be considered as malignant, in our opinion.

There were seven false negative cases (five adenocarcinoma and two neuroendocrine tumors) that may be explained in a similar way: the presence of abundant necrotic or vascular tissue resulted in an elastographic pattern mainly consisting of soft tissue. By contrast, the false positive cases in our study ( $n = 6$ ) might represent patients with (early) chronic pancreatitis having areas of hard fibrotic nodules. Unfortunately, lack of surgical specimens in these patients cannot confirm

this hypothesis. However, in a recent publication by Janssen *et al.*<sup>[16]</sup>, the elastographic patterns of the normal pancreas and the pancreas affected by inflammatory or focal disease were studied. They concluded that elastography does not distinguish between chronic pancreatitis and tumors because of their similar fibrous structure. This implies that EUS elastography will not be able to help target suspicious lesions and improve the rather low accuracy of EUS-FNA in patients with chronic pancreatitis.

In distinguishing benign from malignant focal pancreatic lesions, EUS elastography does not replace tissue confirmation and we believe that EUS elastography should not be used as a first line examination in the evaluation of focal pancreatic lesions. However, when facing (repeated) negative EUS-FNA or technical problems in performing EUS-FNA, the interpretation of the EUS elastographic images could help orientate the diagnosis and influence the decision making for surgery when the lesion is suspicious on elastography, or justify a follow-up when the elastographic images are in favour of a benign lesion.

Our data also shows that EUS elastography has high sensitivity, specificity and accuracy in distinguishing benign from malignant lymph nodes and seems to be superior to conventional B-mode images. Whether the false negative and false positive cases in this study are due to the presence of necrotic and fibrotic areas in lymph nodes, respectively, is less certain. Our results confirm comparable results obtained by Săftoiu *et al.*<sup>[18]</sup> using similar elastography pattern criteria to differentiate benign from malignant lymph nodes in 42 patients with a reported sensitivity, specificity and accuracy of, respectively, 91.7%, 94.4% and 92.86%. The role of EUS elastography to distinguish benign from malignant lymph nodes should be considered as complementary to other imaging techniques rather than a replacement for tissue confirmation. Based on a high PPV, EUS elastography might help in selecting more suspicious lymph nodes for tissue sampling, especially in patients presenting multiple lymph nodes, such as in oesophageal or lung cancer. Based on a high NPV, it might be used to reduce the number of unnecessary biopsies. As for focal pancreatic lesions, EUS elastography might offer an alternative for differential diagnosis in the case of negative EUS-FNA of a lymph node, as well as in situations where EUS-FNA is not possible (technical problems, interposed malignant tissue or interposed vascular structure).

The current results are different from the results obtained during our previous research<sup>[15]</sup>. In this previous study, EUS elastography was shown to have a sensitivity of 100% and specificities of 67% and 50% for diagnosing malignant pancreatic masses and lymph nodes, respectively. Although false positive results in both study groups were reported, it should be recalled that the number of benign lesions in the previous study was relatively small.

For both pancreatic masses and lymph nodes, EUS elastography might also help in guiding the puncture in a non necrotic part of the suspicious lesion when necrotic

tissue is present, as in advanced cancer.

One of the main criticisms of EUS elastography is the variability of the elastographic images and the difficulty of interpretation<sup>[19]</sup>. However, our interobserver study showed a satisfying interobserver concordance for the differentiation between benign and malignant pancreatic masses and lymph nodes ( $\kappa = 0.725$ ).

In the absence of pathologic assesment of surgical specimens, we considered the EUS-FNA result as a gold standard. Although the specificity of EUS-FNA is close to 100%<sup>[24-28]</sup>, it has the potential to miss micro-invasion of malignancy into lymph nodes or to give false negative results for a necrotic pancreatic lesion. However, we consider it as representative of daily practice, particularly when it is combined with an adequate clinical and imaging follow-up period.

To overcome the difficulty in classifying the EUS elastography score equal to 3 or (B) as benign or malignant, we are currently evaluating the next generation of elastography software. This new software provides a quantitative histogram analysis of the elastographic images and has already proven to be useful in the evaluation of lymph nodes<sup>[18]</sup>.

The potential role of EUS elastography to help detect and differentiate submucosal tumors as well as any other solid masses situated nearby the gastrointestinal tract has still to be evaluated. The exact role of EUS elastography in patients manifesting symptoms suggestive of chronic pancreatitis with equivocal EUS (3 features or fewer) has still to be validated<sup>[29]</sup>.

EUS elastography is a new application in the field of the endosonography and seems to be able to differentiate benign from malignant lymph nodes and pancreatic lesions with a high sensitivity, specificity and accuracy. EUS elastography is superior compared to conventional B-mode imaging and the interobserver reproducibility is satisfying. The goal is not to replace tissue confirmation. Instead, the information obtained by EUS elastography should be considered as complementary to the conventional EUS imaging. It should be reserved as a second line examination to orientate further decision making after repeat negative EUS-FNA for pancreatic lesions. It may increase the yield of FNA and reduce the number of unnecessary biopsies when assessing lymph nodes. However, further research is necessary to improve our current elastography scoring system. The second generation of elastography software providing quantitative analysis of tissue elasticity might be able to increase the accuracy of this technique.

## COMMENTS

### Background

Elastography has recently been presented as a novel technique that can be applied during ultrasound examination to assess and measure tissue elasticity. Clinical research has shown promising results in differentiating between benign and malignant tissue in the thyroid gland, breast, prostate and to assess liver fibrosis.

### Research frontiers

endoscopic ultrasound (EUS) elastography is a new application in the field of the endosonography and seems to be able to differentiate benign from

malignant lymph nodes and pancreatic lesions with a high sensitivity, specificity and accuracy. EUS elastography is superior compared to conventional B-mode imaging and the interobserver reproducibility is satisfying.

### Innovations and breakthroughs

In distinguishing benign from malignant focal pancreatic lesions, EUS elastography does not replace tissue confirmation and should not be used as a first line examination in the evaluation of focal pancreatic lesions. However, when facing (repeated) negative EUS-guided fine needle aspiration (EUS-FNA) or technical problems to perform EUS-FNA, the interpretation of the EUS elastographic images could help orientate the diagnosis and influence the decision making for surgery when the lesion is suspicious on elastography, or justify a follow-up when the elastographic images are in favour of a benign lesion.

### Applications

The goal is not to replace tissue confirmation. Instead, the information obtained by EUS elastography should be considered as complementary to the conventional EUS imaging. It should be reserved as a second line examination to orientate further decision making after repeat negative EUS-FNA for pancreatic lesions. It might increase the yield of FNA and reduce the number of unnecessary biopsies when assessing lymph nodes.

### Peer review

The importance of the research and the significance of the research contents are high. Presentation and readability of the manuscript is highly acceptable.

### Abstract

**AIM:** To assess the efficacy and safety of mycophenolate mofetil (MMF) prospectively in inflammatory bowel disease (IBD) patients intolerant or refractory to conventional medical therapy.

**METHODS:** Crohn's disease (CD) or ulcerative colitis/IBD unclassified (UC/IBDU) patients intolerant or refractory to conventional medical therapy received MMF (500-2000 mg *bid*). Clinical response was assessed by the Harvey Bradshaw index (HBI) or colitis activity index (CAI) after 2, 6 and 12 mo of therapy, as were steroid usage and adverse effects.

**RESULTS:** Fourteen patients (9 CD/5 UC/IBDU; 8M/6F; mean age 50.4 years, range 28-67 years) were treated and prospectively assessed for their response to oral MMF. Of the 11 patients who were not in remission on commencing MMF, 7/11 (63.6%) achieved remission by 8 wk. All 3 patients in remission on commencing MMF maintained their remission. Ten patients were still on MMF at 6 mo with 9/14 (64.3%) in remission, while of 12 patients followed for 12 mo, 8 were in remission without dose escalation (66.7%). Three patients were withdrawn from the MMF due to drug intolerance. There were no serious adverse events attributed due to the medication.

**CONCLUSION:** MMF demonstrated efficacy in the management of difficult IBD. MMF appeared safe, well tolerated and efficacious for both short and long-term

### INTRODUCTION

The natural history of both forms of the inflammatory bowel diseases (IBDs), Crohn's disease (CD) and ulcerative colitis (UC), is characterized by a lifelong course of remissions and relapses and a proportion of these patients are steroid refractory or develop steroid dependence requiring maintenance immunosuppression. The most commonly used immunomodulatory medications are azathioprine (AZA), or its metabolite 6-mercaptopurine (6MP). Approximately 10% of patients, however, will be intolerant of these drugs, resulting in their withdrawal and the need for an alternative immunomodulator<sup>[1]</sup>. Up to 50% of CD and 20% of UC patients will also develop a severe acute episode of their disease requiring hospitalization<sup>[2]</sup> and almost half of these patients will require rescue therapy or surgery<sup>[2,3]</sup>. In severe steroid refractory UC, remission may be achieved through the use of cyclosporine or infliximab, but despite continued maintenance therapy for these patients with AZA/6MP, over 65% will relapse by 12 mo and 30% will require colectomy<sup>[4]</sup>. Thus, despite the advent of new biological agents, used in combination with AZA/6MP, efficacy is not universal so the need for other immunomodulatory medications remains imperative.

Mycophenolate mofetil (MMF) is a powerful

immunosuppressant primarily indicated for prevention of solid organ transplantation rejection. It is an anti-metabolite with pharmacodynamic properties similar to AZA. MMF appears to be very safe and efficacious for this indication and is used as a first-line anti-rejection drug in many transplant centers. More recently, however, this immunosuppressant has been employed in the management of difficult IBD cases<sup>[5,6]</sup>. Its efficacy has primarily been assessed in small, uncontrolled case series with only a few small randomized trials<sup>[7-9]</sup>. They indicate that MMF may be effective in IBD, but its role is controversial. The problem arises primarily from observations that despite clinical remission and response achieved early in the course of treatment, a large proportion of patients ultimately flare and require biological agents or surgery. There is also a suggestion that the MMF dose needs to be increased over time in order to maintain an effect and some studies also suggest non-superiority of MMF to conventional immunosuppressants such as AZA<sup>[10,11]</sup>.

Most of the early studies on MMF were undertaken in patients with chronic active CD who failed, or were intolerant to, AZA, and demonstrated good efficacy<sup>[7,9]</sup>. These findings, however, were not supported by later studies, with either a low response or high relapse rate<sup>[5,8,12]</sup>. The rate of treatment discontinuation due to side effects was also high<sup>[6,12,13]</sup> and studies comparing MMF to AZA yielded conflicting and inconsistent results<sup>[7,10]</sup>. In one study MMF was identified to be more likely to be effective in AZA intolerant, rather than refractory patients, and was not inferior to AZA in the management of UC for the induction or maintenance of remission at 6 mo<sup>[11]</sup>. Another study with longer term outcomes evaluating MMF in a cohort of AZA resistant/intolerant patients, however, observed that although MMF was initially effective, relapses were common<sup>[14]</sup>.

This study presents our experience in the use of MMF in the treatment of IBD patients in the short and long term. We prospectively assessed the efficacy of MMF in both the induction and maintenance of remission in patients who were intolerant of AZA/6MP and had previously failed courses of either methotrexate (MTX), antibiotics and/or infliximab. We particularly examined the need for dose escalation over time in patients who initially responded to the MMF as this has been a criticism of its long-term efficacy.

## MATERIALS AND METHODS

All subjects were patients at the Centre for Inflammatory Bowel Diseases, Fremantle Hospital, which is a specialist IBD unit in a 450 bed tertiary institution that services the southern metropolitan region of Perth, Australia. Patients with IBD were classified as CD or ulcerative colitis/IBD unclassified (UC/IBDU) according to the "Montreal Classification" (a modification of the Vienna Classification). The diagnosis of IBD had to be definite, and was made in accordance with previously established criteria based upon clinical, endoscopic, histopathological

and radiological findings. The diagnoses of CD or UC/IBDU were exclusive of infective enterocolitis (excluded by stool microscopy and culture, bacterial and amoebic serology, acid-fast staining of biopsies and mycobacterial cultures), Behcet's disease and microscopic colitis. Patient demographics, disease status, infusion number, response and remission rates and adverse effects were recorded.

All patients were treated between Jan 2003 and July 2008. Patients treated with MMF received between 500 mg and 2000 mg twice a day with the dose optimized to maintain the white cell count (WCC) between  $4$  and  $6 \times 10^9/L$ , neutrophil count  $> 2.0 \times 10^9/L$  and lymphocyte count at or just below the normal range of  $1.1 \times 10^9/L$  without side effects. A clinical response to the MMF in CD patients was determined by a reduction in the Harvey Bradshaw index (HBI) of greater than or equal to 3, with a remission defined as a HBI less than 5 off steroids. A clinical response to the MMF in the UC/IBDU patients was defined as a reduction of 4 or more points in the colitis activity index (CAI) and remission was considered to be CAI of less than or equal to 4 off steroids. The response and remission rates after 8 wk of therapy and long-term response to treatment with MMF were assessed.

Serious adverse effects (SAE) were analyzed. Serious adverse effects are defined as any adverse drug experience occurring that results in death, life-threatening adverse event, persistent or significant disability/incapacity, required in-patient hospitalization, or prolonged hospitalization or congenital anomaly or birth defect.

## RESULTS

The primary indications for treatment were either steroid refractoriness, or dependence, and allergy, or intolerance, to AZA/6MP therapy. Patients were steroid dependant if they were unable to be withdrawn from steroids without a disease flare and patients were steroid refractory if they continued to suffer active inflammation whilst on steroids of 20 mg or greater per day. All patients with active disease were considered for treatment with MMF only after demonstrating failure of disease control or steroid dependency. Two CD and 1 UC/IBDU patients were in clinical remission at the time of commencing the MMF. One of these patients suffered from severe psoriasis in addition to her CD and was changed to MMF in consultation with the dermatologists in an attempt to control both the psoriasis and the CD. The second patient had undergone 3 terminal ileal resections with recurrent severe ileal inflammation occurring within 1 to 2 years after each surgery, but was allergic to AZA/6MP, while MTX and infliximab were ineffective. The third patient required 6MP to maintain remission, but was intolerant of this medication due to severe alopecia.

### Patient demographics

Fourteen patients (9 male, 5 female) were treated with MMF during the study period (Table 1). The ages at time of commencing the MMF ranged from 28-67 years (mean age  $50.4 \pm 12.9$  years). Nine patients suffered from CD

**Table 1** Demographics of the IBD patients using the Montreal classification

	CD patients <i>n</i> = 9	UC/IBDU patients <i>n</i> = 5
Gender: male	57.1% (8/14)	57.1% (8/14)
Age at diagnosis		
Mean $\pm$ SE (range)	38.6 $\pm$ 13.3 yr (19-54)	44.0 $\pm$ 12.7 yr (30-63)
A1- $\leq$ 16	0% (0/9)	0% (0/5)
A2-17-40	44.4% (4/9)	40% (2/5)
A3- > 40	55.6% (5/9)	60% (3/5)
Disease duration		
Mean (range)	10.4 yr (1-26)	9.8 yr (1-28)
Crohn's disease		
L1-terminal ileum	22.2% (2/9)	
L2-colon	33.3% (3/9)	
L3-ileocolonic	44.4% (4/9)	
L4-upper GI	11.1% (1/9)	
P-perianal	22.2% (2/9)	
B1-inflammatory	44.4% (4/9)	
B2-stricturing	33.3% (3/9)	
B3-perforating	22.2% (2/9)	
Ulcerative colitis/IBDU		
E1-proctitis		20% (1/5)
E2-left sided		40% (2/5)
E3-extensive		40% (2/5)
Raised CRP	55.6% (5/9)	80.0% (4/5)

and 5 had UC/IBDU. Of the CD patients, 77.8% (7/9) suffered from colonic inflammation, 22.2% (2/9) had ileal involvement alone, 11.1% (1/9) had jejunal CD, and 22.2% (2/9) suffered from perianal disease. Of the UC/IBDU patients, 2 had extensive colitis, while 2 suffered left-sided colitis and 1 patient had proctitis. The age of diagnosis was lower in the CD patients (mean  $38.6 \pm 13.3$  years, range 19-54 years) compared to the UC/IBDU patients (mean  $44.0 \pm 12.7$  years, range 30-63 years), but this was not statistically significant. Both the CD and UC/IBDU patient groups had similar disease duration at the time of the MMF therapy (mean 10.4 years and 9.8 years respectively). Four (44.5%) of the CD patients had previously undergone at least one surgery (1 subtotal colectomy, 2 small bowel resections and 1 total colectomy and ileal surgery). C-reactive protein (CRP) levels were also elevated in 5 of the 9 CD patients and 4 of 5 UC/IBDU patients prior to commencement of the MMF.

### Current and previous medical therapy

Conventional therapies had been tried in all patients (Table 2). Surgical options had been discussed in detail and were considered to be either medically inappropriate at that stage, or were declined by the patient. Of the 9 CD patients, 88.9% (8/9) were on 5-aminosalicylic acid (5ASA) and 77.8% (7/9) were dependent on, or intolerant to, oral steroids. Antibiotic therapy with metronidazole and ciprofloxacin had been tried and was unsuccessful in 44.4% (4/9) of CD patients. All but 1 (88.9%) of the CD patients were allergic or intolerant to the use of AZA/6MP (drug fevers, severe vomiting requiring hospitalization, severe alopecia and hepatotoxicity). MTX was ineffective in 33.3% (3/9) with 44.4% (4/9) intolerant to, or refusing to take, this medication. Infliximab was ineffective and not continued

**Table 2** Medications taken by study patients at time of the commencement of MMF therapy

	CD patients <i>n</i> = 9	UC/IBDU patients <i>n</i> = 5
5-ASA		
Current	88.9% (8/9)	100% (5/5)
Steroids		
Current	55.5% (5/9)	100% (5/5)
Intolerant	22.2% (2/9)	0%
AZA/6MP		
Intolerant	88.8% (8/9)	100% (5/5)
Methotrexate		
Ineffective	33.3% (3/9)	N/A
Intolerant	11.1% (1/9)	
Refused	33.3% (3/9)	
Antibiotics		
Ineffective	33.3% (3/9)	N/A
Intolerant	11.1% (1/9)	
Infliximab		
Current	0%	0%
Ineffective	44.4% (4/9)	40% (2/5)
Intolerant	22.2% (2/9)	0%

N/A: Not applicable.

**Table 3** Response and remission rates at 8 wk and CRP levels with MMF therapy

	CD patients <i>n</i> = 9	UC/IBDU patients <i>n</i> = 5
Remission	66.7% (6/9)	80% (4/5)
Response	66.7% (6/9)	80% (4/5)
Intolerant	22.2% (2/9)	20% (1/5)
Ineffective	11.1% (1/9)	0% (0/5)
Raised CRP		
In responders	0% (0/6)	0% (4/5)
In non responders	33.3% (1/3)	100% (1/1)

in 44.4% (4/9) and 22.2% (2/9) were intolerant to its use (anaphylaxis and serum sickness).

Of the UC/IBDU patients, all were currently on both 5ASA and oral steroid therapy. All of these patients were intolerant to AZA/6MP therapy, while infliximab had been tried and was ineffective in 2 patients.

### Efficacy at 8 wk

After 8 wk of MMF therapy, 63.6% (7/11) of patients (3 CD and 4 UC/IBDU) who were not in remission at commencement of MMF responded and went into remission, while 71.4% (10/14) went into remission or maintained clinical remission (Tables 3 and 4) as determined either by the HBI or CAI. The 2 patients who had AZA/6MP ceased and MMF commenced due to concurrent severe psoriasis and severe alopecia, maintained their disease remission. The other CD patient who was placed on MMF to prevent post-surgical recurrence was still in remission. All patients in remission at 8 wk also had normal CRP levels. Three of the 14 patients (2 CD and 1 UC/IBDU) were intolerant to MMF and took the medication for 1 mo or less. In only 1 patient was MMF ineffective after 8 wk of therapy, with the patient undergoing surgery 6 mo after commencing the MMF. The surgical pathology

Table 4 Individual patient data of disease extent, age at treatment, duration of MMF therapy and response

	Sex	Diagnosis	Age at diagnosis	Age at MMF	Indication for MMF	Disease extent	Duration of MMF (mo)	Response after 8 wk	Steroids continued at 8 wk
1	M	CD	27	28	Steroid dependant	Pancolitis	30	Remission	Ceased
2	M	CD	54	55	Steroid dependant	L Sided colitis/fistula	12	Remission	Ceased
3	F	CD	50	67	Severe Psoriasis	Ileocolonic disease	48	Remission	N/A
4	M	CD	41	41	Steroid dependant	Ileocolonic disease	12	Remission	Ceased
5	M	CD	53	63	Recurrent TI resections	Recurrent ileal disease	15	Remission	N/A
6	F	CD	32	58	Steroid intolerant	Colectomy/2x TI resection/ recurrent ileal disease	< 1	Intolerant	Continued
7	F	CD	19	28	Steroid dependant	Subtotal colectomy/recurrent ileal disease/fistula	< 1	Intolerant	Continued
8	M	CD	21	48	Steroid dependant	Ileal disease	6	Ineffective	Surgery
9	F	UC/IBDU	43	50	Steroid dependant	Pancolitis	12	Remission	Ceased
10	M	UC/IBDU	31	33	Steroid dependant	L Sided colitis	9	Remission	Ceased
11	M	UC/IBDU	53	64	Steroid dependant	L Sided colitis	22	Remission	Ceased
12	F	CD	50	50	Recurrent flares	Pancolitis	12	Remission	Ceased
13	M	UC/IBDU	63	63	Steroid dependant	Pancolitis	8	Remission	Ceased
14	F	UC/IBDU	30	58	Steroid dependant	Subtotal colectomy/proctitis	< 1	Intolerant	Continued

demonstrated chronic active inflammation and fibrosis of the previous ileocolonic anastomosis.

#### Efficacy at 6 mo

Of the 10 patients on MMF who responded or were in remission at 8 wk, all were still on MMF at 6 mo. Only one patient suffered a disease flare in that 6-mo period. This patient flared 10 wk after commencing the MMF and required further steroids and a single dose of infliximab to induce remission, but continued on the MMF with subsequent successful withdrawal of the steroids and no further need for infliximab therapy. None of the other patients required an increase in their dose of MMF over the 6-mo period in order to maintain their remission. The patient who was on the MMF for recurrent inflammation following previous terminal ileal resections for uncontrolled CD inflammation underwent a colonoscopy at 6 mo, which demonstrated no ileal or colonic CD inflammation.

#### Efficacy at 12 mo

Ten patients (Table 4) had been on MMF for more than 6 mo (mean  $18.1 \pm 12.1$  mo, max 48 mo) with 8 patients taking MMF for 12 mo or more. Of the 10 patients, 1 flared at 8 mo and was withdrawn from MMF due to lack of efficacy. One of the patients died 12 mo after commencing the MMF from an unrelated cause while in remission from his CD. One patient who flared after 30 mo of MMF was withdrawn and commenced on adalimumab with good effect. A total of 12 patients were followed for 12 mo or more and of these 8 were in remission (66.7%). All the 8 patients on MMF maintained their remission without the need for dose escalation.

#### Adverse effects

There was one serious adverse event (SAE) in this patient cohort. This patient died from decompensated alcoholic liver disease. He had previously denied any significant alcohol consumption on numerous occasions

and had been on a stable dose of MMF for over 10 mo. The patient presented to hospital jaundiced with ascites and blood results consistent with an acute hepatitis. The MMF was ceased and the patient was subsequently diagnosed with acute severe alcohol-induced hepatitis. His condition deteriorated over a 2-wk period and he died from liver failure. This SAE was considered to be 'unlikely related' to the MMF use. Adverse events that resulted in cessation of the medication occurred in 3 (21.4%) patients (2 CD and 1 UC/IBDU). These were GI disturbances (nausea and vomiting) and severe headaches. There were no other adverse events that required modification of the MMF dose.

## DISCUSSION

The treatment of refractory IBD has always been one of the most challenging aspects in the clinical practice of luminal gastroenterology. MTX has been the primary alternative therapy for CD patients who are treatment refractory or intolerant to AZA/6MP. Although MTX has demonstrated efficacy in CD, the rate of adverse events at the higher doses often required to achieve clinical response/remissions has limited its use<sup>[15]</sup>. At low doses, however, MTX is often ineffective<sup>[15]</sup> and definitely less effective than AZA/6MP<sup>[16]</sup> with longer-term studies demonstrating a frequent loss of efficacy over time<sup>[17]</sup>. A systematic review of 5 trials identified only one large randomized trial that recommended high dose parenteral MTX to induce clinical remission<sup>[18]</sup>. The remaining studies using oral forms have disappointing results<sup>[15]</sup> and because of its route of administration MTX is not acceptable to many patients. Despite some evidence justifying the use of MTX in UC<sup>[19]</sup>, and fistulising CD<sup>[20]</sup>, data remains limited and confined to retrospective chart reviews. AZA/6MP, therefore, has been the mainstay of immunosuppressive maintenance therapy in IBD. The use of MMF has, therefore, been proposed as an alternative immunosuppressive therapy for patients who either are refractory or intolerant to AZA/6MP.

The aim of our study was to prospectively evaluate the short and long-term efficacy and safety of MMF in patients who were either steroid refractory, or dependent, as well as intolerant or allergic to AZA/6MP therapy. We also wanted to examine the need for dose escalation of MMF over time as this has been suggested as a problem with the use of MMF by some studies<sup>[13]</sup>. As with many of the other published data on MMF, ours was a small cohort of IBD patients with open-label use of MMF. Our patients, however, were assessed at numerous time points and were followed for over a year. The patients in our cohort were also medication resistant, with two thirds failing anti-TNF- $\alpha$  therapy, suggesting a more difficult-to-treat population of patients compared to some other studies. Despite this the results were encouraging. Overall the response rate observed was 71% of patients achieving or maintaining a complete clinical remission after 8 wk of therapy. Excluding the 3 patients who were in remission and off steroids at the time of commencing the MMF, the response/remission rates were still 63.6% at 8 wk. These findings are in contrast with current literature, which reports short-term response rates of only between 25%-40%<sup>[8,13,14]</sup>.

A proportion of MMF-treatment failures in previous studies have been attributed to discontinuation secondary to significant adverse effects. In our study MMF was generally well tolerated, but discontinuation of the MMF secondary to adverse effects was still 21.4%, similar to the 30% observed in other studies. This does not explain the difference, however, in the overall response rates and the reasons behind the difference remains unclear. Relapses over time have also been previously reported as common<sup>[8,13,14]</sup>. Early relapse in our cohort, however, was not commonly observed and even after 12 mo of MMF therapy, 57.1% (8/14) of our IBD patients were still in remission. Of particular note is the lack of dose escalation required over time in our patients responding to MMF. None of the 8 patients on MMF in remission at 12 mo had their dose of MMF increased in the previous 6 mo.

In our experience, the efficacy of MMF appears to differ in some aspects to the published data. Our data demonstrate that MMF can be efficacious and well tolerated in treating refractory IBD patients who are intolerant to AZA/6MP. Problems of lack of long-term efficacy and early disease flare as well as the need for dose escalation over time did not eventuate. Our findings support the use of MMF in the management algorithm of resistant IBD, but its role needs further clarification in larger randomized, double-blind studies comparing it to conventional immunosuppressants. Long-term efficacy would appear to be demonstrated in our study and our current experience suggests that MMF can and should be considered in patients who have failed conventional immunosuppressive therapy.

## COMMENTS

### Background

Treatment for patients with inflammatory bowel disease (IBD) refractory, or intolerant, to conventional immunosuppressive therapy such as azathioprine/6-

mercaptopurine and methotrexate is difficult. The advent of biological therapies has alleviated this problem to a certain degree but there are still a proportion of patients who fail to respond to them or develop drug reactions. The need for alternative effective immunosuppressive agents in the management of IBD are thus required.

### Research frontiers

This study aimed to further define the role of mycophenolate mofetil (MMF) in the treatment of inflammatory bowel disease. The use of this immunosuppressant has been studied in patients refractory, or intolerant, to conventional treatments and results have varied with some studies showing a lack of efficacy or high rates of adverse events. The authors describe a single center experience in the use of MMF for difficult-to-treat IBD patients.

### Innovations and breakthroughs

In contrast to previous reports the study identified MMF to be a safe and efficacious choice in the treatment of difficult IBD and found that the agent to be well tolerated and the response to be sustained. The reported clinical remission rates also seem to be higher than those in previous studies.

### Applications

The findings of study supported the use of MMF in the treatment of patients with IBD who are refractory or intolerant to conventional therapies such as azathioprine/6-MP or methotrexate.

### Terminology

Inflammatory bowel disease is a group of chronic diseases involving the gastrointestinal tract particularly in the small and large bowel. It is divided into 2 groups: Crohn's disease and ulcerative colitis. Crohn's disease is characterized by transmural rather than superficial mucosal inflammation and often presents as a discontinuous disease involving the small or large intestine, or both. Ulcerative colitis/IBD unclassified is the Montreal classification of patients with IBD but without the features needed to diagnose Crohn's disease.

### Peer review

The authors examined the use of mycophenolate mofetil in the treatment of inflammatory bowel disease and found it to be a good alternative immunomodulator in those with IBD who have either failed or become intolerant to conventional therapy. The presence of a good response in those who previously failed biological agents suggests a possible role of MMF in the management of this subgroup of patients as well.

### Abstract

**AIM:** To assess the efficacy of allopurinol to prevent hyperamylasemia and pancreatitis after endoscopic retrograde cholangiopancreatography (PEP).

**METHODS:** One hundred and seventy patients were enrolled and randomized to two groups: a study group ( $n = 85$ ) who received 300 mg of oral allopurinol at 15 h and 3 h before endoscopic retrograde cholangiopancreatography (ERCP) and a control group ( $n = 85$ ) receiving an oral placebo at the same times. Main Outcome Measurements included serum amylase levels and the number severity of the episodes of

pancreatitis. Serum amylase levels were classified as normal ( $< 150$  IU/L) or hyperamylasemia ( $> 151$  IU/L). Episodes of PEP were classified following Ranson's criteria and CT severity index.

**RESULTS:** Gender distribution was similar between groups. Mean age was  $53.5 \pm 18.9$  years for study group and  $52.8 \pm 19.8$  years for controls. Also, the distribution of benign pathology was similar between groups. Hyperamylasemia was more common in the control group ( $P = 0.003$ ). Mild PEP developed in two patients from the study group (2.3%) and eight (9.4%) from control group ( $P = 0.04$ ), seven episodes were observed in high-risk patients of the control group (25%) and one in the allopurinol group (3.3%,  $P = 0.02$ ). Risk factors for PEP were precut sphincterotomy ( $P = 0.02$ ), pancreatic duct manipulation ( $P = 0.002$ ) and multiple procedures ( $P = 0.000$ ). There were no deaths or side effects.

**CONCLUSION:** Oral allopurinol before ERCP decreased the incidences of hyperamylasemia and pancreatitis in patients submitted to high-risk procedures.

## INTRODUCTION

Pancreatitis is the most common complication of endoscopic retrograde cholangiopancreatography (ERCP)<sup>[1-4]</sup>, with the reported incidence ranging from 1.8% to 7.2% in most prospective series<sup>[5-9]</sup>. However, the reported incidence can be up to 30%, depending on the criteria used to diagnose pancreatitis, the type and duration of patient follow-up and the type of case mix<sup>[10]</sup>. More commonly, hyperamylasemia occurs in up to 30% of patients undergoing ERCP<sup>[11]</sup>.

The generally accepted criteria for the diagnosis of post-ERCP pancreatitis (PEP) were proposed in 1991 during a consensus workshop. These criteria include the new onset of pancreatic-type abdominal pain associated with at least a threefold increase in serum amylase or lipase occurring within 24 h after an ERCP. The pain symptoms need to be severe enough to require admission to a hospital or to extend the length of stay of patients who are already hospitalized<sup>[12]</sup>. Most of the episodes of acute pancreatitis are catalogued as mild. However, based on the presence of organ failure or local complications, acute severe pancreatitis occurs after 0.3% to 0.6% of ERCP procedures<sup>[10,13,14]</sup>.

Numerous attempts have been made to find a pharmacologic agent that could be used to reduce the incidence and severity of PEP. An ideal agent should be highly effective in reducing PEP, safe for the patient, well tolerated, relatively affordable and not require a prolonged administration time. Unfortunately, nearly all of the agents investigated have fallen short of these goals, but several agents have shown some promise<sup>[15,16]</sup>. An early step in the pathogenesis of acute pancreatitis is capillary endothelial injury manifested by an increase in capillary permeability<sup>[17,18]</sup>. Subsequent research has suggested that this capillary injury might be mediated by oxygen-derived free radicals<sup>[19-21]</sup>. Xanthine oxidase catalyzes the conversion of hypoxanthine to xanthine, which generates an oxygen-derived free radical. This catalyst is commonly derived from a ubiquitous inactive precursor, xanthine dehydrogenase, which is present in the pancreas and the intestinal mucosa. Xanthine dehydrogenase is converted to xanthine oxidase by the proteolytic cleavage of a peptide fragment. These findings have prompted attempts at the prevention of pancreatitis by treatment with free radical scavengers (e.g. superoxide dismutase, dimethyl sulfoxide or catalase), protease inhibitors (e.g. gabexate) or xanthine oxidase inhibitors (e.g. allopurinol)<sup>[22-25]</sup>.

The efficacy of oral allopurinol to reduce PEP has been investigated in an *in vivo* animal model<sup>[26]</sup>. Pretreatment was not only associated with a significant (sixfold) reduction in the incidence of pancreatitis, but when pancreatitis did occur it was less severe. Other animal models using pretreatment with allopurinol have demonstrated a significant reduction in the progression of histological pancreatic injury and in the severity of experimental pancreatitis in dog and rat models<sup>[27-29]</sup>. These findings in animals supported the need for human studies on the utility of allopurinol pretreatment to reduce the incidence of hyperamylasemia and PEP.

One randomized clinical trial has reported positive clinical results<sup>[30]</sup>, whereas three have reported negative outcomes<sup>[31-33]</sup>. Given the findings of these published clinical results, the beneficial animal data and the practical benefits of allopurinol's potential use for prevention of hyperamylasemia and PEP, we designed a randomized clinical trial to compare the rates of these symptoms seen with treatment using either allopurinol or a placebo.

## MATERIALS AND METHODS

### *Trial design and patient selection*

This was a randomized clinical trial carried out in patients who underwent ERCP within a six-month period (July through December 2007) at the Endoscopy and Gastroenterology Departments of the High Specialty Medical Unit, Specialties Hospital of the Western National Medical Center of the Mexican Institute of Social Security. From the 300 candidates for ERCP, only 170 met the trial criteria. Patients needed to be over 18 years old and undergoing ERCP due to suspected bile duct obstruction with intact papilla of Vater. No patients were enrolled in the study if they had clinically evident acute pancreatitis or hyperamylasemia ( $> 150$  IU/L) before the procedure or if they had ingested nonsteroid anti-inflammatory drugs (NSAIDs) within a week prior to assessment. Patients submitted to diagnostic, therapeutic or failed ERCP 12 mo before the inclusion in the study were not admitted nor were those who had undergone previous endoscopic or surgical sphincterotomy. Patients were also excluded if they were being treated with anticoagulants or platelet antiagregants, such as acetyl salicylic acid and placitaxel or with a prothrombin time with a difference of  $> 5$  s against the blind sample taken no earlier than 72 h before the study. We also eliminated patients who were allergic or hypersensitive to allopurinol or hydrosoluble contrast solutions or those with active hemorrhages of peptic origin. Additional exclusion criteria included a hemoglobin level of less than 8 g/dL; a platelet count of less than  $60 \times 10^9$ /L; relative neutropenia (absolute neutrophil count  $< 2.0 \times 10^9$ /L); significant renal dysfunction (serum creatinine level,  $> 200$   $\mu$ mol/L); decompensated cirrhosis; a known or suspected pregnancy or presence of lactation; current or recent use of allopurinol (within 48 h); current use of drugs with a known interaction with allopurinol, including cyclophosphamide, chlorpropamide, azathioprine/mercaptopurines, or probenecid and an inability to swallow or absorb oral medication.

### *Main outcome measurements*

We included 170 patients in this study. Randomization was performed at the Department of Gastrointestinal Endoscopy by using computer-generated random numbers. Allopurinol and the placebo were similar in presentation and packed in appropriate containers with the identification code. The drug or placebo was only administered after informed consent was obtained. Eighty-five patients were randomly assigned to the study

group receiving 600 mg of allopurinol divided in two oral doses before the procedure (300 mg at 15 h and 300 mg at 3 h before ERCP) and 85 patients were assigned to the control group receiving two doses of an oral placebo at the same time. Blood samples were drawn from all patients to determine serum amylase levels before the procedure and 2 h later and classified as normal level ( $< 150$  IU/L); or hyperamylasemia ( $> 151$  IU/L). If the amylase serum level was  $> 151$  IU/L and there was no evidence of acute pancreatitis (abdominal pain, nausea or vomiting), patients were started on a liquid diet and discharged 8 h to 24 h after the endoscopic procedure. If the serum amylase was above 600 UI/L or three times above the normal value and the patient had a sharp pain irradiating to the back and nausea or vomiting, the diagnosis of PEP was established in the absence of radiological evidence of a pneumoperitoneum or emphysema in the retroperitoneal space through a plain radiologic examination of the abdomen or CT scan. These patients were managed in the hospital with fasting, hydration with crystalloid solutions, antiemetics (metoclopramide) and analgesics. Pancreatitis episodes were classified according to Ranson's prognostic criteria and CT severity index<sup>[34]</sup>.

Details concerning the endoscopic procedure, specifying the difficulty for cannulation, number of pancreatic duct injections, sphincterotomies, characteristics of the bile duct, presence of choledocolithiasis, as well as defining whether the procedure was diagnostic or therapeutic (endoprosthesis placement or stone extraction). Patients were classified as low-risk for the development PEP or those male and older than 50 years old, when the procedure was diagnostic or therapeutic with sphincterotomy, biliary or pancreatic stenting and stone extraction or presence of chronic pancreatitis. Otherwise, patients were considered as high-risk for the development of PEP in the case of female gender and younger than 50 years old, those submitted to pancreatic duct manipulation or precut sphincterotomy, multiple endoscopic procedures, difficult or failed cannulation and patients with suspected sphincter of Oddi dysfunction<sup>[10,16]</sup>. Other complications such as perforation, bleeding and infection, were recorded.

### Statistical analysis

The results are shown as percentages and as means with standard deviations. Statistical inference was tested using chi-squared or Fisher's exact test for qualitative variables, while Student's *t* test was used for quantitative variables. To explore the risk factors, the relative risks and 95% confidence intervals were estimated.  $P < 0.05$  was considered statistically significant. Finally, the reduction in absolute risk (ARR), the reduction in relative risk (RRR) and number needed to treat (NNT) were analyzed to estimate factors needed to prevent an episode of pancreatitis.

### Ethical considerations

The research protocol was reviewed and approved by the Research and Ethics Committees of our Institution. All patients signed informed consent forms before

taking part in the study. The study was financed with funds from the Department of Gastroenterology, Gastrointestinal Endoscopy and the Medical Research Unit in Clinical Epidemiology of the Medical Center.

## RESULTS

The patients participating in the trial comprised 70 men (41.2%) and 100 women (58.8%). The study group had 36 men and 49 women; in the control group there were 34 men and 51 women. The average age for the study group was  $53.5 \pm 18.9$  years and for the control group it was  $52.8 \pm 19.8$  years. Basal amylase levels were  $50.8 \pm 19.3$  U/dL for the study group and  $46.9 \pm 16.1$  U/dL for the control group.

A benign diagnosis for both groups was reported in 108 patients (63.5%): 54 in the study group and 54 in the control group. Malignant diseases were diagnosed in 17 and 20 cases respectively (21.8%). Normal cholangiography was determined in eight and five cases respectively (7.6%) and difficult or failed ERCP occurred in six patients in each group (7%). The diagnoses reached are shown in Table 1. No significant statistical differences were found between groups, and there were no differences in the procedural details described in Table 2. Twenty-three patients developed hyperamylasemia ( $> 151$  IU/L), five (5.8%) from the study group and eighteen (21.1%) from the control group ( $P = 0.003$ ). Ten patients developed pancreatitis, two from the study group (2.3%) and eight from the control group (9.4%;  $P = 0.04$ ). In all cases amylase levels were above 600 IU/L (range 771 to 8886 IU/L). These patients were classified according to Ranson's criteria at admission and at 48 h by CT Severity index as having mild pancreatitis (less than 3 positive signs and Balthazar's A an B without necrosis, severity index of 0 to 1 points). They were handled conservatively and all did well. All patients were discharged within three days of starting the treatment.

The analysis of the risk factors for the development of PEP revealed that Gender ( $P = 0.52$ , RR, 0.83, CI 95% 0.24-3.1), age [younger or older than 50 years old ( $P = 0.31$ , RR, 0.38, CI 95% 0.04-3.12)] and etiology ( $P = 0.18$ , RR, 0.77, CI 95% 0.46-1.29) were not statistically different between groups. When sphincterotomy or biliary stenting was performed, no risk of developing acute pancreatitis was observed ( $P = 0.31$ , RR, 0.38, CI 95% 0.04-3.12). Otherwise, we observed a marked tendency to favor the development of acute pancreatitis if precut sphincterotomy was performed ( $P = 0.022$ , RR, 4.9, CI 95% 1.3-18.19), if there was instrumentation of the pancreatic duct ( $P = 0.002$ , RR 9.3, CI 95% 1.91-45.4) or if multiple endoscopic procedures such as pre-cut sphincterotomy plus pancreatic duct manipulation plus biliary stenting during the same ERCP were performed, ( $P = 0.000$ , RR 14.8, CI 95% 3.0-73.06). PEP was observed in eight patients submitted to high-risk procedures (Table 2), one (3.3%) corresponded in the allopurinol group and seven (25%) patients for the control group ( $P = 0.02$ ). In contrast, two episodes of PEP were observed in patients submitted to low-risk procedures, one (1.8%) from the allopurinol group and one (1.7%) from the control group ( $P = 0.70$ ).

We found an ARR of 21.7%, with an RRR of 86.8% and an NNT of 4.6 patients submitted to high-risk ERCP procedures to avoid a clinically evident episode of pancreatitis. Major complications were observed in four patients (two from each group) consisting of mild to moderate bleeding which required blood transfusion and resolved without surgical intervention and one perforation was observed in a patient of the study group

treated surgically without complications or mortality. No adverse events were recorded with the use of allopurinol or the placebo.

## DISCUSSION

Xanthine oxidase (XO) was first discovered in milk over a century ago and in rat serum nearly 70 years ago<sup>[35,36]</sup>. This enzyme is now known to be present in many different tissues and in a wide range of species from bacteria to humans<sup>[37,38]</sup>. It is a cytosolic metalloflavoprotein that is predominantly responsible for the oxidation of endogenous purines and exogenous ethanol<sup>[39-41]</sup>. Granger and colleagues demonstrated that XO was an important source of the oxidative stress associated with ischemia and reperfusion<sup>[38]</sup>. This enzyme has since been implicated in the pathogenesis of a wide spectrum of diseases<sup>[42]</sup>, and it is thought to be the most important source of oxygen-derived free radicals and cell damage during reoxygenation of hypoxic tissues and pancreatitis<sup>[40-44]</sup>. A number of studies in animal models conducted during the past two decades have highlighted the potential benefit of XO inhibition in a range of clinical settings. Thus, clinical studies have shown that it is safe and effective for the treatment of gout and tumor-lysis syndrome (a life-threatening constellation of metabolic abnormalities resulting from spontaneous or treatment-related tumor necrosis or fulminant apoptosis) and to reduce complications such as postoperative arrhythmias, myocardial infarction and associated mortality after cardiovascular surgery<sup>[39]</sup>.

Allopurinol has high oral bioavailability (80%-90%), a rapid onset of action (peak circulating level reached in 0.5-2 h) and a 70% hepatic transformation to a long-lasting active metabolite (oxypurinol, with a half-life of 15 h)<sup>[39]</sup>. These pharmacokinetic attributes mean a single oral dose of allopurinol before ERCP could conceivably prevent PEP, because the drug targets those changes that contribute to the initial triggering of pancreatitis<sup>[42,43]</sup>. Allopurinol is also an inexpensive generic drug with an excellent safety record and is not included in the catalog of drugs inducing pancreatitis<sup>[45]</sup>.

Four randomized clinical trials have been published in full to date (Table 3): a negative study from Budzyńska *et al*<sup>[31]</sup> ( $n = 300$ ), a positive study from Greece<sup>[30]</sup> ( $n = 250$ ), a negative study from the USA<sup>[32]</sup> ( $n = 701$ ) and the most recent study published by Romagnuolo *et al*<sup>[33]</sup>, from Canada ( $n = 586$ ) with negative results. In the present study, we demonstrated that the use of allopurinol led to a significant reduction in the incidence of hyperamylasemia (5.8% *vs* 21.1% in placebo-treated controls,  $P = 0.003$ ) and acute pancreatitis (2.3% *vs* 9.4%,  $P = 0.04$ ). According to the particular patient's conditions, type of endoscopic procedure or multiple procedures, patients were divided as low and high risk for the development of PEP. The incidence was similar between patients submitted to low-risk procedures. In contrast, the difference was statistically significant in high-risk procedures, favoring the use of allopurinol (incidence 3.3% in the study group *versus* 25%

Table 3 Summary of randomized trials using allopurinol to prevent post-ERCP pancreatitis

Study (year), SC vs MC, country	n	Dose, mg	Allopurinol vs placebo PEP rates	Percentage high risk <sup>1</sup>	Comment
Budzyńska <i>et al</i> <sup>[31]</sup> (2001) SC, Poland	300	400 <sup>2</sup>	12.1% vs 7.9%; 12 vs 8	0	3-arm study, with third arm (n = 100) given prednisone
Kastinelos <i>et al</i> <sup>[30]</sup> (2005) SC, Greece	250	1200 <sup>3</sup>	3.2% vs 17.8%; 4 vs 21	0	2 patients with suspected SOD
Mosler <i>et al</i> <sup>[32]</sup> (2005) MC, USA	701	900 <sup>4</sup>	13.0% vs 12.1%; 46 vs 42	70.2	4% absolute benefit in high-risk patients; 4% absolute harm in average risk
Romagnuolo <i>et al</i> <sup>[33]</sup> (2008) MC, Canada	586	300 <sup>5</sup>	5.5% vs 4.1%; 16 vs 12	11.3	Harm in average risk patients; benefit in high-risk patients
Current study (2009) SC, Mexico	170	600 <sup>6</sup>	2.3% vs 9.4%; 2 vs 8	34.1	21.7% absolute benefit in patients with high-risk procedures favoring allopurinol, no difference in low-risk procedures
Raw pooled	2007 (1008 vs 999)	-	7.9% vs 9.1%; 80 vs 91	-	1.2% difference (95% CI, 3.2% to 2.0%)

<sup>1</sup>As defined in this protocol, namely sphincter manometry and/or pancreatic therapy. Other higher-risk cases (e.g. precut sphincterotomy or suspected SOD) were not considered; <sup>2</sup>200 mg 15 h before, 200 mg 3 h before; <sup>3</sup>600 mg 15 h before, 600 mg 3 h before; <sup>4</sup>600 mg 4 h before, 300 mg 1 h before; <sup>5</sup>300 mg 1 h before; <sup>6</sup>300 mg 15 h before, 300 mg 1 h before; SC: Single centre; MC: Multicenter.

in the control group,  $P = 0.02$ ). Fortunately, all episodes of acute pancreatitis were catalogued as mild and there were no deaths.

There was variability in the doses used in the previous studies and in the baseline rates of PEP in the control (placebo) groups (some of which are out of the usual range reported), but these differences do not appear to completely explain the heterogeneity in the results. There remains a possibility for a threshold effect or a minimally effective dose for allopurinol, given that the positive study<sup>[30]</sup> used the highest dose (1200 mg); however, there does not seem to be a clear dose-response relationship as the larger negative studies<sup>[31-33]</sup> used different lower doses (300, 400 and 900 mg; Table 3). The four earlier studies all checked formally or informally for interactions, presenting the active treatment and placebo PEP rates in different subgroups. None found significant interactions between diagnostic and therapeutic procedures. The most detailed analyses of this type were found in the studies by Mosler *et al*<sup>[32]</sup> and Romagnuolo *et al*<sup>[33]</sup>. Both demonstrated a benefit in the reduction of the episodes of acute pancreatitis as well as the severity when analyzing high-risk patients or those requiring sphincter of Oddi manometry or planned pancreatic therapy. Mosler *et al*<sup>[32]</sup> demonstrated that allopurinol reduced the incidence of PEP from 27% to 23% in the high-risk group (4% absolute risk reduction) and also reduced harm (8% versus 12% PEP) in the non-high-risk group (Table 3). Romagnuolo *et al*<sup>[33]</sup> found that, for non-high-risk patients, the crude rate of PEP was 5.4% in the allopurinol group and 1.5% in the placebo group ( $P = 0.017$  favoring the placebo, indicating harm associated with allopurinol), whereas in the high-risk group the PEP rates were 6.3% in the allopurinol group and 23% in the placebo group ( $P = 0.050$  favoring allopurinol). It is also necessary to note that more patients in the allopurinol group (44% vs 34%  $P = 0.02$ ) required pancreatic duct injection as well as more injections (two versus one,  $P = 0.01$ ). However, confounding was not confirmed statistically, and correcting for pancreatic injection in a stratified model still showed a nonsignificant trend toward harm for allopurinol in the non-high-risk subgroup. If

allopurinol is truly harmful for non-high-risk patients undergoing ERCP (the adjusted subgroup OR was not significant), the mechanism responsible is unclear. It could be the result of an idiosyncratic reaction to the medicine itself; one study did suggest that medications with a history of inducing pancreatitis could increase the risk of PEP<sup>[46]</sup>.

Budzyńska *et al*<sup>[31]</sup>, also included primarily non-high-risk patients and showed a higher rate of PEP with allopurinol. In contrast, the patients in the study by Kastinelos *et al*<sup>[30]</sup> were also primarily non-high-risk patients and yet the study showed a significant benefit for allopurinol. In our results, using 600 mg of allopurinol we observed a significant reduction in the episodes of mild acute pancreatitis (2.3% vs 9.4,  $P = 0.04$ ), but the difference was attributed to a beneficial effect of allopurinol in patients submitted to high-risk procedures, since in low-risk procedures the difference was not statistically significant.

The debate still continues. In a recent meta-analysis just published in September, 2008, Bai *et al*<sup>[47]</sup> concluded that allopurinol may not be useful to prevent PEP. However, they recognized the limitations of their meta-analysis since it was a study-level analysis and the authors denoted the difficulties in stratifying high-risk patients and high-risk procedures because this information was not available in reviewed trials<sup>[30-33,47]</sup>. To overcome the limitations, they recommended the design of multicenter trials with appropriate numbers of high-risk patients and high-risk procedures.

In conclusion, extensive evidence supports a beneficial effect of allopurinol in the prevention and severity of experimental pancreatitis. Clinical evidence supports a favorable effect of oral allopurinol in the prevention of PEP in patients submitted to high-risk procedures. Our results establish a reduction of the incidence of asymptomatic hyperamylasemia and PEP, particularly in patients submitted to high-risk procedures. More clinical trials with different dosification and patient selection are required to definitively determine any positive or deleterious effect of oral allopurinol in the prevention of PEP.

## COMMENTS

### Background

Endoscopic retrograde cholangiopancreatography (ERCP) is a widely applied method for the diagnosis and treatment of pancreatobiliary disease. Post-ERCP pancreatitis is the most common postoperative complication of ERCP and its prevention has become an urgent clinical challenge.

### Research frontiers

ERCP is an indispensable method for the diagnosis and treatment of pancreatobiliary disease, and pancreatitis is the most common postoperative complication of it. There are some studies on drugs for preventing post-ERCP pancreatitis, but their results remain debatable. Therefore, most endoscopy centers do not give patients a conventional chemoprophylaxis.

### Innovations and breakthroughs

This trial revealed that oral allopurinol 300 mg 15 and 3 h (600 mg) before ERCP could reduce pancreatitis and hyperamylasemia.

### Applications

Oral allopurinol 300 mg 15 and 3 h (600 mg) before ERCP can prevent post-ERCP pancreatitis. Compared with other drugs, oral allopurinol is inexpensive, convenient and has very few side-effects, and can be used as a protective drug for preventing post-ERCP pancreatitis.

### Peer review

This paper is interesting since aiming to demonstrate the effect, and possible effectiveness, of allopurinol on the occurrence of post ERCP acute pancreatitis. The design is well organized and the conclusion is that this drug has a preventive effect on post ERCP - hyperamylasemia and pancreatitis, especially in high risk patients.

## Abstract

**AIM:** To identify the stochastic autoregressive integrated moving average (ARIMA) model for short term forecasting of hepatitis C virus (HCV) seropositivity among volunteer blood donors in Karachi, Pakistan.

**METHODS:** Ninety-six months (1998-2005) data on HCV seropositive cases ( $1000^{-1} \times \text{month}^{-1}$ ) among male volunteer blood donors tested at four major blood banks in Karachi, Pakistan were subjected to ARIMA modeling. Subsequently, a fitted ARIMA model was used to forecast HCV seropositive donors for 91-96 mo to contrast with observed series of the same months. To assess the forecast accuracy, the mean absolute error rate (%) between the observed and predicted HCV seroprevalence was calculated. Finally, a fitted ARIMA model was used for short-term forecasts beyond the observed series.

**RESULTS:** The goodness-of-fit test of the optimum ARIMA (2,1,7) model showed non-significant autocorrelations in the residuals of the model. The forecasts by ARIMA for 91-96 mo closely followed the pattern of observed series for the same months, with mean monthly absolute forecast errors (%) over 6 mo of 6.5%. The short-term forecasts beyond the observed

series adequately captured the pattern in the data and showed increasing tendency of HCV seropositivity with a mean  $\pm$  SD HCV seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) of  $24.3 \pm 1.4$  over the forecast interval.

**CONCLUSION:** To curtail HCV spread, public health authorities need to educate communities and health care providers about HCV transmission routes based on known HCV epidemiology in Pakistan and its neighboring countries. Future research may focus on factors associated with hyperendemic levels of HCV infection.

## INTRODUCTION

Hepatitis C virus (HCV) infection poses a major public health problem in developing countries, including Pakistan. However, the results of prevalence studies have shown variable estimates in select groups including 1.8% to 3.0% in volunteer blood donors<sup>[1,2]</sup> and 16% to 20.5% in familial contacts of infected patients<sup>[3,4]</sup>. A community-based study in Hafizabad, Punjab, found a 6.5% HCV seroprevalence<sup>[5]</sup>. Using these estimates, Pakistan has been grouped into intermediate category with respect to burden of HCV infection<sup>[6]</sup>. Several routes have been implicated for nosocomial and community acquired

HCV infection including unsafe injections, recycling of used syringes, inadequate sterilization of surgical and dental equipment, and facial shaving by barbers<sup>[2,7]</sup>.

Public health authorities in Pakistan intermittently run educational campaigns in electronic and print media to create awareness in the general population to halt HCV spread. However, in the absence of adequate HCV surveillance, the true impact of the HCV control efforts remains uncertain. Volunteer blood donors are generally considered to be the healthier segment of any community and the proportions of HCV seropositivity among them may be considered to mirror the situation in the general population<sup>[8]</sup>. We have previously reported a significant increase in HCV seroprevalence among volunteer blood donors over the past several years using data from two blood banks<sup>[2]</sup>. However, there is need to expand this HCV surveillance network countrywide to obtain more reliable and representative estimates.

Recently, mathematical models have been used to project the future HCV prevalence among intravenous drug users<sup>[9]</sup>, and its impact on the future development of HCV related morbidity and mortality<sup>[10]</sup>. Modeling and forecasting HCV seropositivity among volunteer blood donors in Pakistan, and perhaps in other neighboring countries, might provide useful information for allocating resources, and re-shaping and planning future control activities<sup>[11]</sup>. This study aimed to develop a univariate time series model for HCV seropositivity ( $1000^{-1} \times \text{month}^{-1}$ ) among volunteer blood donors attending four large blood banks. Specifically, the objective of this study was to identify the stochastic autoregressive integrated moving average (ARIMA) model for short term forecasting of HCV seropositivity ( $1000^{-1} \times \text{month}^{-1}$ ) among volunteer blood donors in Karachi, Pakistan.

## MATERIALS AND METHODS

### Setting

This study was conducted in Karachi-the largest cosmopolitan city and the hub of economic activity of Pakistan. It has an estimated population of 9.3 million, accounting for approximately 10% of the total population of the country. Forty three percent of the city's population is under the age of 15 years. The population of Karachi comprises several ethnic groups defined by mother tongue, including predominantly Urdu, Sindhi, Punjabi, Pushto, and Balochi. The healthcare facilities for the population include several small and tertiary care hospitals, both in the private and public sector.

### Data

Eight-year (1998-2005) data on monthly aggregates of number of donors attending four large blood banks (blood bank I-IV) in Karachi were available for this study. These blood banks receive blood donations only from non-remunerated volunteer blood donors. Blood bank I is part of a tertiary care hospital in the private sector and receives blood donations as replacements

from friends and relatives of inpatients requiring blood transfusions. Blood banks II-IV belong to non-governmental organizations and cater for the needs of those in Karachi who need blood transfusions, including the patients with leukemia, hemophilia, thalassemia and other blood related diseases. Blood banks II-IV also receive blood donations from volunteers on an exchange basis. Prior to blood donation, each blood donor is subjected to screening for known risk factors for transfusion transmissible infections. All the blood banks follow similar criteria to receive blood donations and exclude potential donors who admit known risk factors of transfusion transmissible infections or any medical or non-medical condition associated with high risk (e.g. use of narcotic drugs, history of jaundice in the past 5 years and recent hospitalization). All four blood banks in the study use commercially available enzyme-linked immunosorbant assay kits and results are interpreted according to the manufacturer's instructions.

As noted earlier, blood donations between January 1998 and December 2005 by men aged 18-64 years were included in this evaluation. HCV serological results of consecutive blood donations from these blood banks were available from variable starting dates depending on the completed records, to assess the proportions of HCV seropositive donors.

### Analytic approach

We used methods developed by Box and Jenkins to build an ARIMA time series model<sup>[12]</sup>. This model-building process is designed to take advantage of associations in the sequentially lagged relationships that usually exist in data collected periodically. The general form of the ARIMA model was

$$\Delta^d z_t = \Phi_1 z_{t-1} + \dots + \Phi_p z_{t-p} + a_t - \theta_1 a_{t-1} - \dots - \theta_q a_{t-q}$$

where:

$\Delta^d z_t$  = differenced series i.e.  $z_t - z_{t-1}$

$z_t$  = set of possible observations on the time-sequenced random variable

$a_t$  = random shock term at time  $t$

$\Phi_1 \dots \Phi_p$  = autoregressive parameters of order  $p$

$\theta_1 \dots \theta_q$  = moving average parameters of order  $q$

The series was subjected to Box-Cox transformation<sup>[13]</sup>. The transformed series was then differenced at the non-seasonal level and mean corrected to induce stationarity. Sample autocorrelation and partial autocorrelation functions were used to identify the ARIMA model of the appropriate order. Estimates of the model's parameters were obtained by the maximum likelihood method. Diagnostic checking included residual analysis and the Akaike Information Criterion was used to compare goodness-of-fit among ARIMA models. The final model was a result of several iterations of the identification, estimation, and checking process, and met the conventional criteria for the adequacy of the model<sup>[14]</sup>.

### Assessment of forecast accuracy

The last 6 observations in the data set were used for validation of the forecast accuracy of the ARIMA

**Figure 1** Hepatitis C virus seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) among volunteer male blood donors in Karachi, Pakistan 1998-2005. A: Observed data along with forecasts; B: Transformed series.

**Table 1** Hepatitis C virus seroprevalence ( $1000^{-1} \times \text{year}^{-1}$ ) among male volunteer blood donors at four large blood banks in Karachi (1998- 2005)

Yr	Mean	SD	95% CI for mean		Minimum	Maximum
			Lower limit	Upper limit		
1998	13.8	1.5	12.8	14.7	12	16
1999	16.3	2.2	14.8	17.7	13	21
2000	18.5	2.2	17.1	19.9	15	22
2001	19.8	2.0	18.6	21.1	16	22
2002	19.9	3.0	18.0	21.8	15	26
2003	20.3	3.2	18.2	22.3	16	27
2004	29.3	2.6	27.6	30.9	25	33
2005	24.8	2.1	23.4	26.1	21	27
Total	20.3	5.1	19.3	21.3	12	33

$F = 47.9$ ;  $df = 7, 88$ ;  $P < 0.001$ .

model. The fitted ARIMA model was used to forecast the HCV seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) for 91-96 mo (June 2005 to December 2005) to contrast with the observed series of the same months. The average forecast error at prediction interval of  $m$  months ( $\bar{\epsilon}_m$ ) was calculated as:

$$(\bar{\epsilon}_m) = \left[ \sum_{i=1}^6 (y_{t+m} - \hat{y}_{t+m}) / 6 \right]^{1/2}$$

Where  $y_{t+m}$  and  $\hat{y}_{t+m}$  denote the observed and forecast values for month  $t + m$ . Finally, the fitted ARIMA model was used for short term (January 2006 to June 2006) forecasts along with their 95% confidence limits beyond the observed series.

## RESULTS

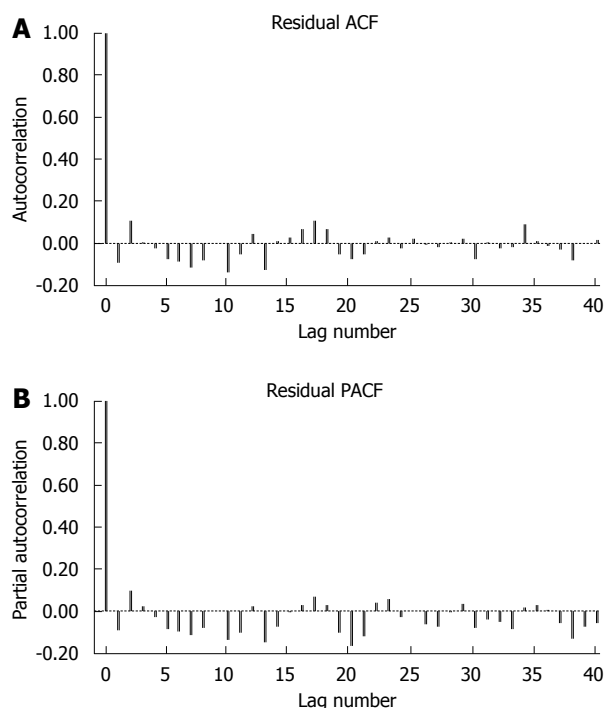

### Descriptive analysis

The crude HCV seropositivity ( $1000^{-1}$ ) among the male volunteer blood donors during the study period was 20.3 (12792/630134). The mean prevalence ( $1000^{-1} \times \text{month}^{-1}$ ) was 18.3 [95% confidence interval (CI): 16.8-19.9]. There was no statistically significant difference in HCV seropositivity ( $1000^{-1}$ ) across various months of the years ( $F = 0.201$ ;  $P = 0.997$ ) (data not shown). However, a substantial variation in HCV seroprevalence ( $1000^{-1}$ ) was observed across different calendar years ( $F = 47.895$ ;  $P < 0.001$ ) (Table 1). The observed and transformed series are presented in Figure 1.

### ARIMA model

The parameters' estimates for the optimum ARIMA (2,1,7) model for the series of monthly HCV seropositive donors ( $1000^{-1}$ ) are shown in Table 2. The autocorrelation and partial autocorrelation functions of the residuals showed good-fit (Figure 2). The residual plots showed small variations around the zero mean. None of these residuals had its magnitude larger than twice the standard deviation. Residuals' autocorrelations were not significantly different from zero as a set and had constant variance, thus confirming the adequacy of the model (Ljung-Box statistic = 20.4;  $P = 0.433$ ).

The forecasts by the ARIMA (2,1,7) model for 91-96 mo (June 2005 to December 2005) using the

**Figure 2** Residual plots for the final ARIMA (2,1,7) model of HCV seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) among male volunteer blood donors in Karachi, Pakistan 1998-2005. A: Autocorrelation function; B: Partial autocorrelation function.

observed series of months 1-90, closely followed the pattern of observed series for the same months (Figure 1), with mean  $\pm$  SD and maximum monthly absolute forecast errors (%) over 6 mo interval being  $6.5\% \pm 3.4\%$  and  $10\%$ , respectively. Furthermore, the short term (January 2006 to June 2006) forecasts beyond the observed series adequately captured the pattern in the data (Figure 1) and showed evidence of increasing tendency of HCV seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) with the mean  $\pm$  SD as  $24.3 \pm 1.4$  over the forecast interval.

## DISCUSSION

Epidemiological surveillance of communicable diseases is one of the more traditional public health activities. Time series analysis of surveillance data on prevalence and/or incidence of various infections may be helpful in developing hypotheses to explain and anticipate the dynamics of the observed phenomena and subsequently in the establishment of a quality control system and re-allocation of resources<sup>[15,16]</sup>. This method is an ecologic approach and takes advantage of the strong association in the sequentially lagged relationship that usually exists in the data collected periodically<sup>[17]</sup>.

During the study period, the overall HCV seroprevalence ( $1000^{-1}$ ) in volunteer blood donors was 20.3, which falls in the range of 14.9 to 38.9 known for first time blood donors in other developing countries. However, HCV seroprevalence ( $1000^{-1}$ ) in this study was much higher than the 2.1 reported for developed countries<sup>[18]</sup>. The low HCV seroprevalence in resource-

**Table 2** Autoregressive integrated moving average model (2,1,7) of hepatitis C virus seroprevalence ( $1000^{-1} \times \text{month}^{-1}$ ) among male volunteer donors in Karachi, Pakistan, (January 1998-December 2005)

Parameters	Estimate	Standard error	t-ratio
Autoregressive parameter ( $\Phi$ )

Moving average parameter ( $\theta$ )			
$\theta_2$	-0.59	0.18	3.3
$\theta_3$	0.49	0.15	3.3
$\theta_4$	-0.80	0.11	7.3
$\theta_6$	0.74	0.21	3.5
$\theta_7$	-0.37	0.17	2.2

White noise variance = 9.74; Ljung-Box Q statistic = 20.4 ( $P = 0.433$ ).

rich countries is attributed to safe blood transfusion, whereas, in poor regions of the world, several million people acquire HCV infection each year as a result of contaminated transfusions and the re-use of infected medical devices<sup>[18,19]</sup>. Therefore, public health practices adopted by the developed countries need to be strictly enforced in less developed countries to break the chain of transmission of HCV and other blood-borne pathogens.

Monitoring of HCV seropositivity among volunteer blood donors may provide clues about the effectiveness of control efforts of public health authorities and future trend of the proportion of HCV infected donors in Pakistan. In this paper, we used the ARIMA model on a time series of HCV seropositivity ( $1000^{-1}$ ) collected monthly over a period of 96 mo on asymptomatic male volunteer blood donors from four major blood banks in Karachi. The forecasts made in a prospective manner over six months demonstrated increasing tendency of HCV seropositivity among the blood donors in this cosmopolitan city. Such a predicted increase in HCV seropositivity might result from inconsistent and naïve HCV control efforts on the part of public health officials in Pakistan. Therapeutic injections in a health-care setting have consistently been shown as a strong risk factor for HCV infection in Pakistan<sup>[2,7,20,21]</sup>, and if concerted efforts by the public health authorities are not made, might continue to contribute to the increasing load of HCV infection in this and similar settings in the region. An increasing trend among first time US blood donors of 50 to 59 years of age from 1995 to 2002 has been demonstrated<sup>[22]</sup>. According to the authors, teenage children and young adults in 1960, and 1970s might have experimented with drug injection and were infected with HCV. These people entered into the 50 to 59 years age group during 1995 to 2002. However, in other age groups of donors in the same study and two other studies from US<sup>[23,24]</sup>, and from other developed countries (France<sup>[25,26]</sup> and Spain<sup>[27]</sup>) have shown a decreasing trend of residual risk of HCV infection in blood donors. According to these investigators different factors could have played a role in this reduction, for instance, increased awareness about the factors associated with increased risk of HCV infection, voluntary deferral by potential high risk

donors, improvement in donor recruitment, and /or an overall decrease in HCV infection level in the general population. Such factors need to be evaluated in our population in future studies.

Results from our previous study<sup>[2]</sup>, and those predicted by ARIMA model for 6 mo beyond the observed data exhibited a slightly increasing tendency of HCV seropositivity among male volunteer blood donors over the forecast period. This increasing pattern of HCV seroprevalence among these asymptomatic male volunteer donors merits further investigation of factors contributing to HCV seroprevalence in this population, which is thought to be a mirror image of the situation in the general population.

Some limitations of this study need to be taken into account when interpreting the results. Our HCV seroprevalence estimates are based on ELISA, which has sensitivity of more than 95%. However, these results do not reflect possible HCV infections that do not produce detectable seropositivity during the window period of HCV infection. The exact proportion of these HCV infected, but HCV seronegative, is not known, however, it has been argued that this figure must be very small given the use of current sero-assays<sup>[28]</sup>. Our HCV seroprevalence estimates in male volunteer donor population were based on data from a limited number of blood banks; we do not know whether they reflect the national average. The blood banks that participated in this study however, account for a substantial proportion of donations made annually in Karachi. These centers are located in large metropolitan areas where the prevalence and/or incidence of HCV may be higher than the national figures. Therefore, we think we are justified in making generalizations from our data. In conclusion, in the absence of comprehensive HCV surveillance in the general population in Pakistan and perhaps in other neighboring countries, further monitoring of HCV seropositivity in blood donors and the investigation of factors associated with hyperendemic HCV infection using multivariate ARIMA models might further expand our understanding about HCV epidemiology in this region. Furthermore, effective screening of all blood donors for HCV infection at all blood banks should be seriously considered, because one single HCV infected regular blood donor could transmit the infection to several recipients.

## ACKNOWLEDGMENTS

We gratefully acknowledge the support provided by the administration and staff of the participating blood banks and the Department of Community Health Sciences, Aga Khan University, Karachi, Pakistan in the conduct of this study.

## COMMENTS

### Background

Less developed countries such as Pakistan generally lack effective surveillance systems for communicable diseases. In this study, the authors used the Box-Jenkins approach to fit an autoregressive integrated moving average (ARIMA)

model that might be used to monitor and predict trends in hepatitis C virus (HCV) seroprevalence in the general population using volunteer blood donors as a sentinel group. This information may be helpful to facilitate early public health responses to minimize HCV related morbidity and mortality.

### Research frontiers

Developed countries have been able to control the HCV transmission in the general population by public health measures. However, such initiatives are practiced at sub-optimal level in resource-constrained countries. This problem is further compounded by the absence of effective surveillance of communicable diseases including blood-borne pathogens. Therefore, alternative methods to monitor and predict the burden of such infections are needed for rational allocation of resources.

### Innovations and breakthroughs

This is the first application of an ARIMA model to monitor and predict the HCV seroprevalence in volunteer blood donors at multiple blood banks. Such data on infections with HCV and other blood-borne pathogens may mirror the situation in a setting that lacks an effective surveillance system for these infections.

### Application

The fitted ARIMA model could be used for sentinel surveillance of blood-borne infections in volunteer blood donors. Therefore, the estimates for current and predicted future burden of these infections could be used by public health authorities for making rational policy decisions for control and prevention of HCV and other blood-borne pathogens in resource-constrained countries including Pakistan.

### Peer review

The authors describe an effective model to predict HCV seropositivity in Pakistan.

### Abstract

**AIM:** To compare the efficacy of pentoxifylline and prednisolone in the treatment of severe alcoholic hepatitis, and to evaluate the role of different liver function scores in predicting prognosis.

**METHODS:** Sixty-eight patients with severe alcoholic hepatitis (Maddrey score  $\geq 32$ ) received pentoxifylline ( $n = 34$ , group I) or prednisolone ( $n = 34$ , group II) for 28 d in a randomized double-blind controlled study, and subsequently in an open study (with a tapering dose of prednisolone) for a total of 3 mo, and were followed up over a period of 12 mo.

**RESULTS:** Twelve patients in group II died at the end of 3 mo in contrast to five patients in group I. The probability of dying at the end of 3 mo was higher in group II as compared to group I (35.29% *vs* 14.71%,  $P = 0.04$ ; log rank test). Six patients in group II developed hepatorenal syndrome as compared to none in group I. Pentoxifylline was associated with a significantly lower model for end-stage liver disease (MELD) score at the end of 28 d of therapy ( $15.53 \pm 3.63$  *vs*  $17.78 \pm 4.56$ ,  $P = 0.04$ ). Higher baseline Maddrey score was associated with increased mortality.

**CONCLUSION:** Reduced mortality, improved risk-benefit

### INTRODUCTION

Severe alcoholic hepatitis is an acute or acute-on-chronic hepatic inflammatory response syndrome, which is part of the spectrum of diseases that result from alcohol-induced liver injury, ranging from the most common asymptomatic fatty liver to fulminant hepatitis and cirrhosis in the long term. However, it is difficult to predict the clinical response in an individual patient, as only a minority of individuals consuming large amounts of alcohol develop alcoholic hepatitis<sup>[1,2]</sup>. The importance of acute alcoholic hepatitis lies in its significant morbidity and mortality, with a reported in-hospital mortality as high as 44%<sup>[3]</sup>. Large amounts of alcohol with binge drinking, malnutrition, and female sex, are some of the factors associated with more severe disease<sup>[4]</sup>. The presence of coexisting hepatitis C has been found to be associated with worse prognosis<sup>[5]</sup>. Recent studies have shown that impaired immune response, endoplasmic reticulum stress, mitochondrial dysfunction, and free-radical injury induced by alcohol and its acetaldehyde adduct metabolites, Kupffer cell activation and cytokine production, have an important role in accentuating the hepatocyte injury and disease

precipitation<sup>[6,7]</sup>. Serum level of cytokines such as tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)-1, IL-6 and IL-8 are elevated in acute alcoholic hepatitis<sup>[8]</sup>. Studies have shown a linear relationship between TNF- $\alpha$  receptors and mortality from acute alcoholic hepatitis<sup>[9]</sup>.

Maddrey discriminant function (DF) has commonly been used in estimating mortality among patients with acute alcoholic hepatitis, with an elevated DF ( $> 32$ ) indicating an increased likelihood of death, and conversely, a low DF suggesting a generally favorable prognosis<sup>[10,11]</sup>. Recently, model for end-stage liver disease (MELD) score and glasgow alcoholic hepatitis score (GAHS) have also gained interest as predictors of disease outcome in patients with severe acute alcoholic hepatitis<sup>[12,13]</sup>.

Although prednisolone is used widely and considered the standard treatment for severe acute alcoholic hepatitis with DF score  $\geq 32$ , it is not free of adverse effects and has had its share of controversies<sup>[14]</sup>. Recently, pentoxifylline, a non-specific phosphodiesterase inhibitor, with combined anti-inflammatory (TNF- $\alpha$  inhibition) and antifibrogenic properties, has been found to be useful in patients with acute alcoholic hepatitis with DF  $\geq 32$ <sup>[15-17]</sup>. The beneficial effects are believed to occur through various mechanisms such as inhibition of phosphodiesterases, increased cAMP levels and down-regulation of TNF- $\alpha$ , IL-1, IL-6, transforming growth factor-beta (TGF- $\beta$ ), interferon-gamma (IFN- $\gamma$ ), stellate cell activation and procollagen- I mRNA expression<sup>[18]</sup>.

Although many individual studies are available on the efficacy of pentoxifylline and prednisolone in the treatment of severe alcoholic hepatitis, as far as we are aware, no study has compared the two drugs head to head in a randomized controlled study.

The present study compared the efficacy of pentoxifylline and prednisolone in the management of severe alcoholic hepatitis (DF  $\geq 32$ ), and their immediate and short-term outcomes. Also, we evaluated the GAHS and MELD score in patients with severe alcoholic hepatitis and compared them to traditional scores like DF and Child's score.

## MATERIALS AND METHODS

One hundred and fifty-eight chronic alcoholic patients attending the liver clinic, outpatient department or the emergency medical services of the Medical College and Hospitals Calcutta were initially considered. The study was carried out from July 2006 to September 2008. The patients were initially examined clinically, evaluated, and subsequently were admitted for the duration of the study. The study protocol was approved by the institutional ethical committee. All the patients underwent investigations for liver chemistry (liver function tests, prothrombin time), complete hemogram, random blood sugar level, urea, creatinine, electrolytes, viral markers such as hepatitis B surface antigen (HBsAg), anti-hepatitis C virus (HCV) antibody, hepatitis A virus IgM, hepatitis E virus IgM, serum ceruloplasmin, 24-h urinary copper (as and when required), and antinuclear antibody, upper gastrointestinal endoscopy, and Doppler abdominal

ultrasound, as and when required. Patients were included who had a history of chronic alcohol intake of more than 50 g/d<sup>[19]</sup> with clinical and biochemical features of severe alcoholic hepatitis [Maddrey DF  $\geq 32$  and aspartate aminotransferase: alanine aminotransferase (AST: ALT)  $> 2:1$ , with absolute values of AST  $< 500$  IU/L and ALT  $< 200$  IU/L]. Patients with any other potential etiology of liver injury (acute or chronic viral hepatitis, autoimmune liver disease, Wilson's disease) even in the background of chronic alcohol intake were excluded from the study. Also, patients with a history of abstinence from alcohol in the last month, or who were positive for human immunodeficiency virus antibodies were excluded. Patients with infection, sepsis or spontaneous bacterial peritonitis, gastrointestinal bleeding, hepatorenal syndrome, acute pancreatitis or any other severe associated disease (uncontrolled diabetes, hypertension, heart failure, pulmonary disease or malignancy) at the time of inclusion or in the previous 3 mo were also excluded.

MELD score, GAHS and Child's score were calculated for all the patients who were included in the study. Only those patients were considered for final study who gave a prior informed written consent for pharmacotherapy.

The included patients were then divided into two groups by a computer-generated randomization table: group I, patients receiving pentoxifylline, and group II, patients receiving prednisolone. The pharmacotherapy (pentoxifylline or prednisolone) was started within a week of admission.

Patients in group I received pentoxifylline (Trental tablets, Sanofi Aventis, Mumbai, India) at a dose of 400 mg thrice daily orally and a placebo tablet in the place of prednisolone for the first 4 wk. Patients in group II received prednisolone tablet (Wysolone, Wreath, Mumbai, India) at a dose of 40 mg once daily for 4 wk and a placebo tablet taken thrice daily in place of pentoxifylline for the same duration. During the study, concomitant treatments with salicylates, nonsteroidal anti-inflammatory drugs, budesonide, anti-TNF $\alpha$  agents, vitamin E, s-adenosyl methionine or ursodeoxycholic acid were not allowed. The investigators who allocated the patients to the groups, administered the drugs and collected the clinical and laboratory data, as well the statisticians, were all blinded regarding the nature of the pharmacotherapy. All the patients were admitted in the wards of the Department of Medicine, Medical College and Hospitals, Calcutta for the initial period of 4 wk. All investigations such as liver function tests, prothrombin time, electrolytes, renal profile and abdominal ultrasound were repeated after the initial 4 wk of pharmacotherapy. After the initial 4 wk, the study was opened and the patients allocated to the different groups were revealed. After 4 wk of initial therapy, the dose of prednisolone in group II was tapered by 5 mg/wk over a period of 7 wk and then stopped. Patients in group I (pentoxifylline) who tolerated the drug well, continued to receive the medication at the same dose for the next 8 wk, and then stopped.

Only those patients who were clinically stable at the end of 4 wk were discharged and later followed-up in the

liver clinic. All the patients were counseled for strict alcohol abstinence at the time of discharge from the hospital.

The patients were reviewed at least once a month in the liver clinic. During follow-up, all the patients were examined clinically, and asked about drug compliance, intake of alcohol or potential drug adverse effects. Liver function tests, prothrombin time, renal function test, electrolytes, and abdominal ultrasound were performed as and when required. Maddrey DF, MELD, GAHS and Child's scores were calculated for all the patients during follow-up. Patients who had any alcohol intake in the follow-up period were excluded thereafter from the study.

### Statistical analysis

Student's *t* test was used for analysis of continuous variables, Fisher's exact test for binary variables, and the  $\chi^2$  test was used for categorical variables. All results of continuous variables are expressed as mean  $\pm$  SD. Survival curves were estimated according to the Kaplan-Meier method and were compared using the log-rank test. Survival comparisons between groups were performed on an intent-to-treat basis. Results were considered statistically significant at  $P < 0.05$ .

## RESULTS

Of the 158 patients initially evaluated, 74 who fulfilled the inclusion criteria without any other potential etiology of liver injury or severe co-morbid states were considered. Two patients refused consent for the study and another two patients refused to be admitted for the duration of the study. Seventy patients who fulfilled the inclusion and exclusion criteria and who gave informed written consent were randomized and divided into two groups: group I (pentoxifylline) had 34 patients, and group II (prednisolone) had 36 patients. The total duration of follow-up was 12 mo, with the patients being examined and evaluated in the liver clinic on a monthly basis. Two patients in group II withdrew voluntarily from the study and were excluded.

A total of 68 patients, 34 in each group, were considered for the final analysis. The baseline clinical and biochemical parameters of the patients receiving pentoxifylline or prednisolone are elaborated in Table 1, and were found to be comparable.

In group I, pentoxifylline therapy had to be stopped prematurely (within 3 mo) in five patients because of the development of life-threatening complications, all of whom unfortunately succumbed to the disease. Two patients expired following massive gastrointestinal bleeding. Two patients were lost to progressive hepatic encephalopathy and one patient died of sepsis, not responding to conservative management. Out of the five patients lost, two patients succumbed in the first 4 wk and three expired between 4 wk and 3 mo of therapy.

In group II, prednisolone therapy was stopped prematurely (within 3 mo) in 13 patients because of development of life-threatening complications. Two patients developed sepsis and both of them died of septic

shock. Two patients had upper gastrointestinal bleed and succumbed to hemodynamic failure. One patient developed acute pancreatitis 26 d after inclusion; prednisolone was stopped and the patient responded to conservative management who has been doing well till the end of this study. Six patients died of hepatorenal Syndrome, not responding to conservative management. This is in sharp contrast to Group-I where none of the included patients developed hepatorenal Syndrome. One patient died of progressive hepatic encephalopathy and the cause of death could not be determined in one of the patients. Out of the total of 12 patients who expired in group II, seven succumbed in the first 4 wk and five more were lost between 4 wk and 3 mo of therapy. The cause of death and the complication profile are shown in Tables 2 and 3. The mortality was significantly higher among patients receiving prednisolone (35.29%) as compared to 14.71% among those receiving pentoxifylline, as elaborated by Kaplan-Meier analysis shown in Figure 1 ( $P = 0.04$ ).

Thirty-two patients in group I and 27 in group II were evaluated in the liver clinic at the end of 4 wk. The study was opened at this point in time and the allotment

All values are expressed as mean ± SD. *P* < 0.05 considered statistically significant.

of patients to the different groups was revealed. The investigations done at the baseline were repeated, and the patients were re-admitted if deemed necessary. The patients were followed-up on a monthly basis and the investigations were repeated at the end of 3 mo, 6 mo and 1 year. The patients did relatively well beyond 3 mo of follow-up, and no more patients succumbed to the disease. In group I (pentoxifylline), one patient resumed alcohol consumption and another was lost to follow-up after 5 mo, and they were excluded from further analysis. In group II (prednisolone), two patients resumed alcohol consumption, after 8 and 10 mo of follow-up, respectively, and both were excluded from further analysis.

The morbidity/complication profiles among the two groups were comparable (Table 3). Nausea followed by vomiting and dyspepsia were the most common adverse

**Figure 1** Survival curves (Kaplan-Meier life table analysis) of patients receiving pentoxifylline (group I) as compared to patients receiving prednisolone (group II), at the end of 3 mo of therapy.

effects encountered in both groups. Patients receiving pentoxifylline more frequently complained of nausea and vomiting, whereas dyspepsia was more common among those receiving prednisolone. Recurrent hepatic encephalopathy was only seen in group I (pentoxifylline), while oral thrush, worsening of ascites, impaired glucose tolerance, delayed wound healing and deep vein thrombosis were seen only in group II (Table 3). On follow-up, recurrent encephalopathy was observed among five patients in group- I (pentoxifylline) in contrast to none in group II. The summary of the trial and its design is shown in Figure 2.

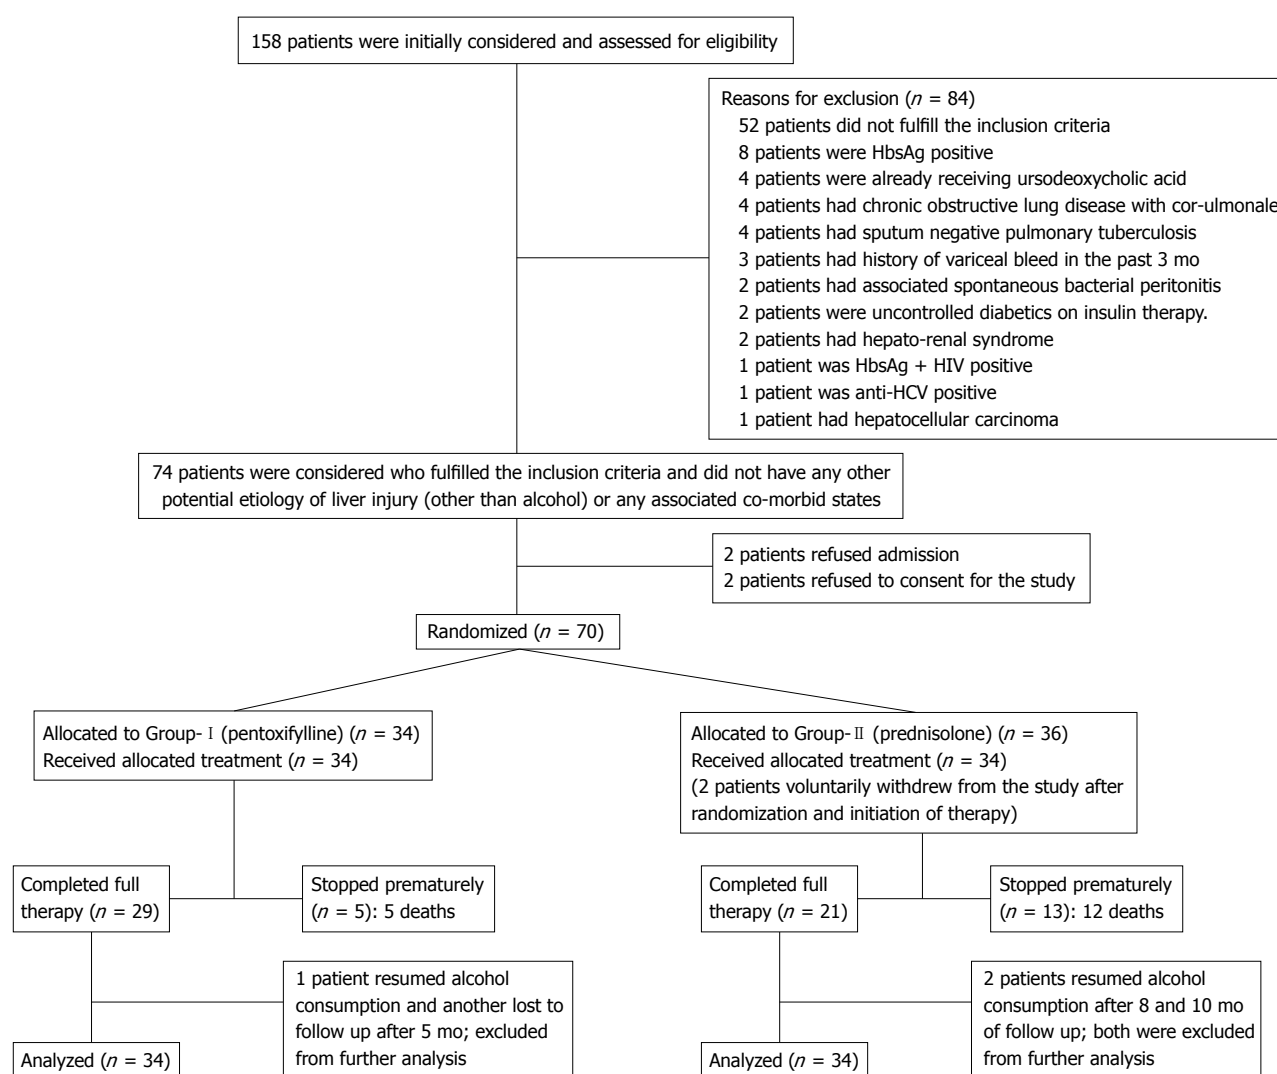

Table 4 shows the baseline profile of patients who succumbed to various complications as compared to those surviving at the end of the study. It shows that baseline Maddrey DF score and international normalized ratio (INR) was significantly higher among patients who succumbed to the disease as compared to those who survived (*P* = 0.038 and 0.049 respectively; Table 4). The baseline MELD score, GAHS and Child's score was not significantly different among the patients who expired as compared to those who survived (Table 4).

Table 5 shows the progression of GAHS, MELD, Child's and Maddrey DF score in the patients over 12 mo. The fall in Maddrey DF score and GAHS was comparable among the patients receiving pentoxifylline

or prednisolone. MELD score was observed to be significantly lower among the patients receiving

pentoxifylline at the end of 4 wk, as compared to those receiving prednisolone.

## DISCUSSION

The pathogenesis of alcohol-induced liver injury has not yet been clearly elucidated. Oxidative and nitrosative stress are believed to have a key role in the pathogenesis of alcoholic liver disease, and greater emphasis has been given to the role of cytochrome P450 2E1 in mitochondrial stress and disruption<sup>[20]</sup>. Altered signaling pathways and involvement of extrahepatic mediators such as adiponectin may also have a key role<sup>[20]</sup>. Augmented TNF- $\alpha$  production by macrophages and Kupffer cells and signaling *via* the p55 TNF receptor have been shown to be critical in the development of steatosis and hepatitis following chronic alcohol intake<sup>[21]</sup>. Pentoxifylline, a non-specific phosphodiesterase inhibitor, with combined anti-inflammatory and antifibrogenic properties, has been shown to block the activation of hepatic stellate cells in culture<sup>[22]</sup>. It also has inhibitory effects on basic mechanisms of fibrogenesis such as cell proliferation and extracellular matrix synthesis<sup>[23]</sup>. Pentoxifylline has an added advantage of fewer adverse effects, such as gastrointestinal bleeding and renal shutdown, as compared to steroids. In the present study, none of the patients developed hepatorenal syndrome in the pentoxifylline group as compared to six in the prednisolone group. The MELD score in the pentoxifylline group was found to be significantly lower at the end of 4 wk of therapy (Table 5), as compared to the prednisolone group, confirming the renoprotective effects of pentoxifylline (as serum creatinine is a component of MELD score). Also gastrointestinal bleeding occurred more frequently in the prednisolone group as compared to the pentoxifylline group (Table 3).

The most important observation was the significantly reduced mortality among patients in the pentoxifylline group (14.71%) as compared to those receiving prednisolone (35.29%,  $P = 0.04$ , Figure 1). This reduced mortality in the pentoxifylline group was observed in spite of the increased occurrence of recurrent encephalopathy among patients in the pentoxifylline group. The patients with recurrent attacks of encephalopathy responded well to conservative management. This reduced mortality among patients in the pentoxifylline group can at least in part be explained by the renoprotective effects of pentoxifylline and the lower occurrence of gastrointestinal bleeding. In spite of the increased occurrence of nausea, and to a lesser extent vomiting, among patients in the pentoxifylline group, they were not severe enough to warrant stoppage of therapy. Also, with time, the occurrence of these complications was reduced (Table 3). Oral thrush, impaired glucose tolerance, poor wound healing, deep venous thrombosis and pancreatitis were some of the significant problems faced by the patients in the prednisolone group (Table 3).

Retrospectively, on analyzing the different liver function scores at the time of inclusion, only a higher Maddrey DF score was associated with the occurrence of increased mortality among patients with severe alcoholic hepatitis (Table 4). Thus Maddrey DF score remains the score of choice in determining prognosis

of patients with severe alcoholic hepatitis, even after the advent of newer scores like MELD and GAHS.

One of the limitations of this study is the absence of evidence of histological improvement and survival among patients receiving pentoxifylline or prednisolone, because of the lack of availability of transjugular liver biopsy. Also the assessment of immunological and inflammatory status (e.g. TNF- $\alpha$ ) of the patients was not possible. Nevertheless, a reduced mortality and more advantageous risk-benefit profile of pentoxifylline compared with prednisolone in patients with severe alcoholic hepatitis suggest that pentoxifylline is at least equivalent to prednisolone in the treatment of severe alcoholic hepatitis. However, further studies with a larger cohort of patients is warranted to decide if pentoxifylline is actually superior to the traditional drug prednisolone in the treatment of severe alcoholic hepatitis.

## COMMENTS

### Background

Severe alcoholic hepatitis is an acute, potential life-threatening manifestation of alcohol-induced liver injury, and forms part of the spectrum of liver disease, ranging from asymptomatic fatty liver to cirrhosis. The importance of severe alcoholic hepatitis lies in its significant morbidity and mortality, with a reported in-hospital mortality as high as 44%. Prednisolone has been used widely and is considered the standard treatment for severe acute alcoholic hepatitis with maddrey discriminant function (DF) score  $\geq 32$ . However, it is not free of adverse effects and has had its share of controversies.

### Research frontiers

Various other drugs have been tried in the treatment of alcoholic hepatitis, such as antioxidants, colchicines, calcium channel inhibitors, propylthiouracil and d-penicillamine, without much success. Augmented tumor necrosis factor (TNF)- $\alpha$  production by macrophages and Kupffer cells plays an important role in the pathogenesis of severe alcoholic hepatitis. However, infliximab, a human-mouse chimeric antibody to TNF- $\alpha$ , when used with prednisolone, has been found to be associated with severe infections, and is thus potentially harmful. The challenge is to find a drug whose efficacy is not only comparable to that of the standard drug prednisolone, but also safe and easy to administer over long periods of time.

### Innovations and breakthroughs

Recently, pentoxifylline, a non-specific phosphodiesterase inhibitor, with anti-inflammatory (TNF- $\alpha$  inhibition) and antifibrogenic properties has been found to be useful in patients with severe alcoholic hepatitis. The idea was to evaluate the efficacy of pentoxifylline and compare it to the standard drug prednisolone in the treatment of severe alcoholic hepatitis in a randomized controlled study, and to study the immediate and short term outcomes. Significantly reduced mortality, a more advantageous risk-benefit profile, and renoprotective effects of pentoxifylline compared with prednisolone in patients with severe alcoholic hepatitis may be considered as a breakthrough.

### Applications

The authors found that pentoxifylline was tolerated well in the treatment of severe alcoholic hepatitis, and was associated with significantly lower mortality, significantly lower model for end-stage liver disease (MELD) score at the end of 4 wk, and absence of hepatorenal syndrome. This should encourage the use of pentoxifylline in the treatment of severe alcoholic hepatitis. However, long-term prospective studies with a larger cohort of patients are needed to decide if pentoxifylline is actually superior to the traditional drug prednisolone in the treatment of severe alcoholic hepatitis.

### Terminology

MELD score is a measure of the severity of liver dysfunction and has been recently used in the assessment of patients with severe alcoholic hepatitis. However Maddrey DF score remains the standard for the assessment of patients with severe alcoholic hepatitis.

### Peer review

The experiments were planned and executed well and the manuscript is well written.

### Abstract

**AIM:** To investigate *in vitro* effects of propofol, midazolam and dexmedetomidine, which are commonly used anaesthetic or sedatives, on spontaneous contractions of the ileum both in normal rats and those exposed to hyperdynamic peritonitis.

**METHODS:** Spontaneous contractions of isolated ileum muscle segments from sham operated rats and those exposed to peritonitis, were studied *in vitro*. The amplitude and the frequency of spontaneous contractions of ileum muscle segments were studied after adding dexmedetomidine, propofol, and midazolam to the organ bath in a cumulative manner.

**RESULTS:** Both amplitude ( $85.2 \pm 6.6$  vs  $47.4 \pm 7.1$ ) and frequency ( $32.8 \pm 4.6$  vs  $20.2 \pm 3.9$ ) of spontaneous contractions in ileum smooth muscle segments were decreased significantly in the peritonitis group compared to the control group ( $P < 0.05$ ). Dexmedetomidine significantly increased the amplitude of spontaneous contractions ( $85.2 \pm 6.6$  vs  $152.0 \pm 5.4$ ,  $P < 0.05$ ) whereas, propofol ( $85.2 \pm 6.6$  vs  $49.6 \pm 4.8$ ,  $P < 0.05$ ) and midazolam ( $85.2 \pm 6.6$  vs  $39.2 \pm 4.5$ ,  $P < 0.05$ ) decreased it in both control and peritonitis groups. The frequency of spontaneous contractions were significantly decreased by propofol

in both control ( $32.8 \pm 4.6$  vs  $18.2 \pm 3.4$ ,  $P < 0.05$ ) and peritonitis groups ( $20.2 \pm 3.9$  vs  $11.6 \pm 3.2$ ,  $P < 0.05$ ). Dexmedetomidine and midazolam did not cause significant changes in the number of spontaneous contractions in both control and the peritonitis groups ( $P > 0.05$ ).

**CONCLUSION:** Propofol, midazolam and dexmedetomidine have various *in vitro* effects on spontaneous contractions of the rat ileum. While dexmedetomidine augments the spontaneous contraction of the rat ileum, propofol attenuates it. However, the effects of these compounds were parallel in both control and peritonitis groups.

### INTRODUCTION

Dysmotility of the gastrointestinal tract is a major complication in critically ill patients in intensive care units. Most of the time, this dysmotility manifests itself as inhibition of gastrointestinal motility, and rarely as hypermotility<sup>[1]</sup>. Hypomotility can cause a functional, nonmechanical obstruction, most commonly an adynamic ileus. Impaired motility in critically ill patients can be caused by intestinal ischemia, electrolyte imbalances, peritoneal injury, abdominal surgery, lower-lobe pneumonia, pancreatitis, cholecystitis, intraabdominal abscesses, and medications (opiates, dopamine, diltiazem, verapamil, and anticholinergics)<sup>[2]</sup>. Sedatives such as propofol and midazolam further inhibit delayed intestinal transit in critically ill patients

in a dose dependent manner. The delay may cause complications such as intolerance to enteral feeding and overgrowth of bacteria in the gastrointestinal tract resulting in increase the incidence of aspiration pneumonitis<sup>[3]</sup>.

Abdominal sepsis or peritonitis is also a major cause of morbidity and mortality in surgical intensive care units. Gastrointestinal dysmotility commonly accompany peritonitis and those patients suffering peritonitis are also exposed to the additive effects of sedatives or anesthetics in surgical intensive care units. Koyluoglu *et al*<sup>[4]</sup> recently demonstrated that peritonitis induced a decrease in the amplitude and frequency of spontaneous contractions of ileum and jejunum segments from rats. Therefore, it is preferable to use a sedative or an anaesthetic that has few inhibitory effects on gastrointestinal transit in patients with peritonitis. However, there has been little study on this topic in the literature. In the present study, we aimed to investigate *in vitro* effects of propofol, midazolam and dexmedetomidine on spontaneous contractions of the ileum both in normal rats and those are exposed to hyperdynamic peritonitis.

## MATERIALS AND METHODS

### Animal preparation

Sixteen male Wistar albino rats each weighing approximately 280 g were used in this study. The study was approved by the ethics committee of Cumhuriyet University School of Medicine. Cecal ligation and puncture were used as the peritonitis model<sup>[5]</sup>. Animals were divided into two groups. The first group consisted of sham surgical controls that underwent the same procedure as the peritonitis group, such that laparotomy was performed under anesthesia, with manipulation of the cecum, but cecum ligation and puncture were not performed. Rats in the second group underwent cecal puncture and ligation as previously described by Martin *et al*<sup>[5]</sup>. Animals were anesthetized with intramuscular injections of 3 mg/kg xylazine (Rompun®, Bayer, Istanbul, Turkey) and 90 mg/kg ketamine (Ketalar®, Pfizer, Istanbul, Turkey), following which, laparotomy was performed *via* a 2 cm midline incision and the cecum was exposed. The cecum was ligated using 4/0 silk suture material just below the ileocecal valve, so that intestinal continuity was maintained. Then, the cecum was punctured using an 18-gauge needle in three locations, 1 cm apart, on the antimesenteric surface of the cecum, and cecum was gently compressed until feces were extruded. The cecum was replaced into the peritoneal cavity and the abdomen was then closed. When the animals were alert, they were transferred to single housing cages where they were left with ad libitum food and water. We then observed the rats in a recovery cage for 24 h.

A summary of the experimental treatments is presented below: Groups: Group I ( $n = 8$ ): Sham surgical controls; Group II ( $n = 8$ ): Peritonitis group.

At the second laparotomy, 24 h later, the rats were killed by cervical dislocation. The abdomen was opened with a midline incision and the ileum was removed and placed in previously aerated (95% O<sub>2</sub> and 5% CO<sub>2</sub>) Krebs-bicarbonate solution (composition in mmol/L: NaCl, 120; KCl, 4.6; CaCl<sub>2</sub>, 2.5; MgCl<sub>2</sub>, 1.2; NaHCO<sub>3</sub>, 22; NaH<sub>2</sub>PO<sub>4</sub> and glucose 11.5). Whole full-thickness segments of ileum were placed in circular direction in a 10 mL tissue baths, filled with pre-aerated Krebs-bicarbonate solution (KBS) at 37°C. The upper end of the preparation was tied to an isometric transducer (Grass FT 03, Quincy, MA, USA) and preloaded with 1-1.5 g. Tissues were allowed to equilibrate for 30 min.

### *In vitro* muscle contractility studies

Muscle segments from each group were contracted with 80 mmol/L KCl to ensure that they worked properly at the beginning and end of each experiment.

At the beginning of each experiment, 80 mmol/L KCl was added to the organ bath, and the contraction was considered as reference response. Subsequently, the amplitude of spontaneous contractions of the isolated ileum muscle segments were calculated as a percentage of the contraction induced by KCl (80 mmol/L) from both control and peritonitis groups. Changes in the frequency (number/min.) of spontaneous contractions were expressed as the number of contractions for 10 min intervals.

Following the KCl response, smooth muscle segments were allowed to equilibrate for 30 min before addition of cumulative doses of propofol ( $10^{-8}$ - $10^{-4}$  mol/L), midazolam ( $10^{-8}$ - $10^{-4}$  mol/L) and dexmedetomidine ( $10^{-8}$ - $10^{-4}$  mol/L). Amplitudes of the contractions induced by these compounds from both control and peritonitis groups were calculated as the percentage of the initial spontaneous contractions. Changes in the frequency of spontaneous contractions were expressed as the number of spontaneous contractions for 10 min after drug application. Isometric tensions were recorded on a Grass model 79 E polygraph. All experiments were performed in duplicate.

### Drugs

The following compounds were used: Propofol (2,6diisopropylphenol®, Aldrich Chemicals Co., USA), Midazolam (Midazolam hydrochloride®, Sigma, St Louis, USA), Dexmedetomidine (Abbot Laboratories, Abbot Park, IL, USA). All drugs were dissolved in distilled water. All drugs were freshly prepared on the day of the experiment.

### Data analysis

All data are expressed as mean  $\pm$  SD. Statistical comparisons between groups were performed using general linear models of analysis of variance (ANOVA) followed by the Newman-Keuls test and a *t* test when appropriate and *P*-values of less than 0.05 were considered to be statistically significant.

**Figure 1** KCl (80 mmol/L) induced contractions of isolated ileum muscle segments in control and peritonitis groups. No statistical difference was observed between groups ( $P > 0.05$ ).

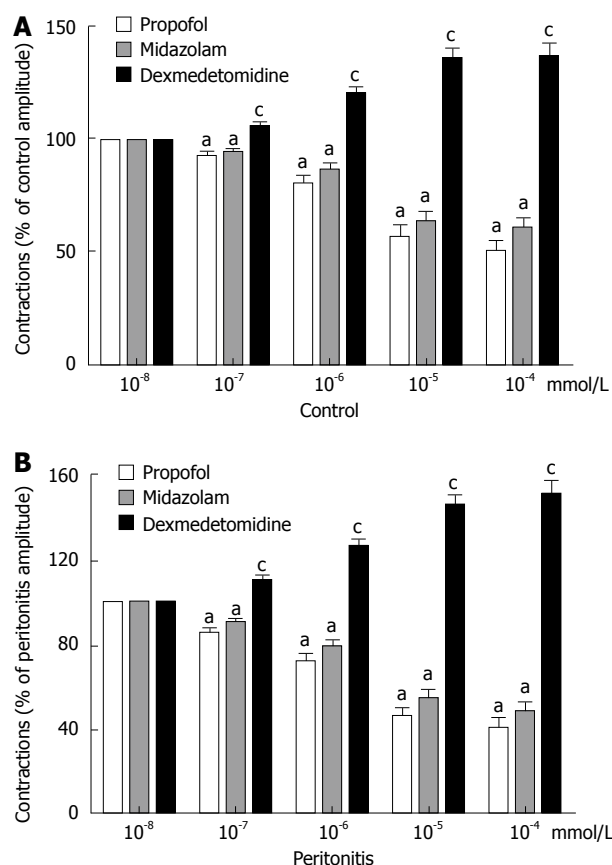

**Figure 2** Changes in the spontaneous contractions of the isolated ileum muscle segments. A: Amplitudes were calculated as a percentage of the contraction induced by KCl (80 mmol/L) from both control and peritonitis groups; B: Frequencies were expressed as the number of contractions for 10 min from both control and peritonitis groups. ( $^aP < 0.05$  vs control group; analysis of variance followed by Newman-Keuls test).

## RESULTS

Contractions induced by 80 mmol/L KCl were not significantly different between the peritonitis group and the control group in isolated ileum smooth muscle segments which indicated that muscle segments from both groups worked properly (Figure 1).

The mean amplitude of the spontaneous contractions was  $85.2 \pm 6.6$  in the control and  $47.4 \pm 7.1$  in the peritonitis group, respectively. The number of spontaneous contractions obtained in 10 min in the

**Figure 3** Amplitudes of the contractions induced by anaesthetic agents. A: Control group; B: Peritonitis group; both were calculated as the percentage of the initial contractions. ( $^aP < 0.05$  vs initial contractions,  $^cP < 0.05$  vs propofol and midazolam; analysis of variance followed by Newman-Keuls test).

peritonitis group was  $32.8 \pm 4.6$  and  $20.2 \pm 3.9$  in the control group. Both the amplitude and the frequency of spontaneous contractions of ileum smooth muscle segments were decreased significantly in the peritonitis group compared to the control group ( $P < 0.05$ ), (Figure 2A and B).

The amplitudes of spontaneous contractions of ileum muscle segments were studied after adding dexmedetomidine, propofol, and midazolam to the organ bath. Dexmedetomidine ( $10^{-8}$ - $10^{-4}$  mol/L) significantly increased the amplitude of spontaneous contractions starting from  $10^{-7}$  mol/L in isolated ileum muscle segments, in both the control and peritonitis groups, in a concentration-dependent manner. Propofol ( $10^{-8}$ - $10^{-4}$  mol/L) and midazolam ( $10^{-8}$ - $10^{-4}$  mol/L) decreased the amplitude of spontaneous contractions starting from  $10^{-7}$  mol/L as the molar concentrations of these drugs were increased ( $P < 0.05$ ). However, there was no statistical difference between the decreasing effects of propofol and midazolam ( $P > 0.05$ ), (Figure 3A and B), (Tables 1 and 2).

The frequency of spontaneous contractions of the ileum segments were significantly decreased by cumulative doses of propofol ( $10^{-8}$ - $10^{-4}$  mol/L) in both the control and peritonitis groups ( $P < 0.05$ ). Dexmedetomidine ( $10^{-8}$ - $10^{-4}$  mol/L) and midazolam ( $10^{-8}$ - $10^{-4}$  mol/L) did not cause a significant change in the number of spontaneous

Dexmedetomidine	Increased	No significant change

**Figure 4** Changes in the frequency of spontaneous contractions. A: Control group; B: Peritonitis group. Both were expressed as the number of contractions for 10 min. (<sup>a</sup>*P* < 0.05 *vs* initial contractions; analysis of variance followed by Newman-Keuls test).

contractions of the isolated ileum muscle segments in both the control and peritonitis groups (*P* > 0.05) (Figure 4A and B) (Tables 1 and 2).

## DISCUSSION

The first finding of our study is that peritonitis altered the spontaneous activity of the rat ileum by decreasing both the amplitude and the frequency of the contractions in accordance with the previous study reported recently by Koyluoglu *et al*<sup>[4]</sup>. The main findings are that dexmedetomidine, a selective  $\alpha_2$ -adrenergic agonist, increased the amplitude, midazolam decreased the amplitude and propofol decreased both the amplitude and frequency of the spontaneous contractions in rat ileum in a concentration-dependent manner in both the control and peritonitis groups. Liu *et al*<sup>[6]</sup> reported that the  $\alpha_2$ -adrenoceptors inhibited neurogenic contractions of the rat ileum. Dexmedetomidine inhibited peristalsis in the guinea pig small intestine *in vitro* in a concentration dependent manner<sup>[7]</sup>. Dexmedetomidine strongly inhibited intestinal transit in the rat, however this inhibition was less potent than morphine<sup>[8]</sup>. However, in our study, dexmedetomidine, when applied in a concentration dependent manner significantly increased the amplitude but did not change the frequency of spontaneous contractions in the rat ileum *in vitro* both in the control and peritonitis groups. Our result seems to contradict previous reports. However, similarly to our results, Karaman *et al*<sup>[9]</sup> showed that dexmedetomidine *in vitro* caused a significant increase in the amplitude and frequency of spontaneous contractions in rat myometrium in a dose-dependent manner. The augmenting effect of this agent on spontaneous contractions needs to be investigated further.

Lee *et al*<sup>[10]</sup> demonstrated that propofol has an *in vitro* inhibitory effect on spontaneous contractile activity and causes acetylcholine induced contractions of human gastric and colonic smooth muscles at clinically relevant concentrations. It was demonstrated in a previous study that propofol, at concentrations of  $10^{-7}$  and  $10^{-6}$  mol/L, potentiated the guinea pig ileum contractile responses to  $\gamma$ -aminobutyric acid (GABA), but only at the lower dose range of applied GABA; at a concentration of  $10^{-5}$  mol/L, it inhibited the contractile effect over the entire dose range of applied GABA<sup>[11]</sup>. In the present study, propofol decreased both amplitude and frequency of contractions of rat ileum muscle segments in the control and peritonitis groups. Previous studies have reported the relaxant effects of propofol on other smooth muscle tissues such as vascular<sup>[12]</sup> and uterine smooth muscles<sup>[13]</sup>. The action of propofol involves a positive modulation of the inhibitory function of the neurotransmitter GABA through GABA A receptors<sup>[14]</sup>. Jensen *et al*<sup>[15]</sup> evaluated the influences of propofol, nitrous oxide and isoflurane and found that recovery and postoperative bowel function were not influenced by the anaesthetic technique after major gastrointestinal surgery. However, it might be different in case of a critically ill patient with peritonitis in an intensive care unit. The combined inhibitory effects of peritonitis and propofol might further slow intestinal transit and lead to an adynamic ileus.

Like other benzodiazepines, midazolam acts on the benzodiazepine binding site of GABA A receptors. When bound, it enhances the binding of GABA to the GABA A receptor, resulting in inhibitory effects on the central nervous system<sup>[16]</sup>. Castedal *et al*<sup>[17]</sup> reported in their manometric study that midazolam had relatively few effects on small bowel motility. In the present study, midazolam decreased the amplitude but caused very little change in the frequency of ileum contractions. Midazolam is often used for intravenous conscious sedation in endoscopic retrograde cholangiopancreatography (ERCP). Midazolam significantly altered the mobility of the sphincter of Oddi and caused a significant reduction in basal pressure of the sphincter of Oddi but did not affect the phasic frequency<sup>[18]</sup>.

In conclusion, dexmedetomidine, midazolam and propofol have various *in vitro* effects on spontaneous contractions of the rat ileum. While dexmedetomidine augments the spontaneous contraction of the rat ileum, propofol attenuates it. The effects of these agents were parallel in both control and peritonitis groups. The clinical implications of these findings need to be tested in surgical intensive care units, which might help in choosing the most appropriate drug for the sedation of patients with peritonitis.

## COMMENTS

### Background

Gastrointestinal dysmotility commonly accompanies peritonitis and those patients suffering peritonitis are also exposed to the additive effects of sedatives or anaesthetics in surgical intensive care units. Therefore, it is preferable to use a sedative or an anaesthetic that has few inhibitory effects on gastrointestinal transit in the patients with peritonitis. The *in vitro* effects of propofol, midazolam and dexmedetomidine, which are commonly used anaesthetic or sedatives, are worth investigating for that purpose.

### Research frontiers

The first finding of the study is that peritonitis altered the spontaneous activity of the rat ileum by decreasing both the amplitude and the frequency of the contractions. The main findings are that dexmedetomidine increased the amplitude, midazolam decreased the amplitude and propofol decreased both the amplitude and frequency of the spontaneous contractions of the rat ileum in a concentration-dependent manner in both the control and peritonitis groups.

### Innovations and breakthroughs

In this study, the *in vitro* effects of dexmedetomidine, midazolam and propofol on spontaneous contractions of ileum muscle in rats exposed to peritonitis were demonstrated.

### Applications

These findings will aid the selective use of sedatives or anaesthetics that have fewer inhibitory effects on gastrointestinal transit in patients with peritonitis.

### Peer review

The authors of the present study have compared the acute effects of different sedatives or anaesthetics on the spontaneous contractions in the ileum of sham-operated rats and rats with peritonitis. The amplitude and the frequency of the spontaneous contractions were affected to a different extent by the respective sedatives. This study was well performed.

### Abstract

**AIM:** To compare the treatment modalities for patients with massive pancreaticojejunal anastomotic hemorrhage after pancreatoduodenectomy (PDT).

**METHODS:** A retrospective study was undertaken to compare the outcomes of two major treatment modalities: transcatheter arterial embolization (TAE) and open surgical hemostasis. Seventeen patients with acute massive hemorrhage after PDT were recruited in this study. A comparison of two treatment modalities was based upon the clinicopathological characteristics and hospitalization stay, complications, and patient prognosis of the patients after surgery.

**RESULTS:** Of the 11 patients with massive hemorrhage after PDT treated with TAE, one died after discontinuing treatment, the other 10 stopped bleeding completely without recurrence of hemorrhage. All the 10 patients recovered well and were discharged, with a mean hospital stay of 10.45 d after hemostasis. The patients who underwent TAE had a re-operation rate of 18.2% and a mortality rate of 9.1%. Among the six patients who received open surgical hemostasis, two underwent another round of open surgical hemostasis. The mortality was 50%, and the recurrence of hemorrhage was 16.67%, with a mean hospital stay of 39.5 d.

**CONCLUSION:** TAE is a safe and effective treatment

### INTRODUCTION

Massive pancreaticojejunal anastomotic hemorrhage is the second most common complication of pancreatoduodenectomy (PDT). Blind open surgical hemostasis, however, poses additional risks and complications, which can be prevented by transcatheter arterial embolization (TAE). The present study was to evaluate the effectiveness of TAE and open surgical hemostasis. Between June 2005 and August 2008, a total of 308 patients underwent PDT in our hospital. Of these patients, 17 had massive pancreaticojejunal anastomotic hemorrhage following PDT. In this retrospective study, we summarized our clinical experiences with these patients in order to compare the safety and efficacy of TAE and open surgical hemostasis. The results may help determine the therapeutic approaches to massive pancreaticojejunal anastomotic hemorrhage after PDT.

### MATERIALS AND METHODS

#### Patient information

A total of 17 subjects were enrolled in our study, including 13 men and five women, aged 42-68 years (mean  $60 \pm 2.45$  years). There were 10 cases of lower

common bile duct carcinoma, three cases of pancreatic head carcinoma and four cases of ampullary carcinoma. Obstructive jaundice was found in 12 patients. A catheter was inserted into the pancreatic duct in four cases, pancreatic duct exterior drainage was placed in two cases, and T-tube external drainage was placed in six cases, respectively. No T-tube or pancreatic duct drainage was placed in the remaining five patients. Post-surgical hemorrhage occurred in 10 cases from the gastroduodenal artery, from the posterior edge of the pancreatic stump in one case, and from the inferior pancreaticoduodenal artery in one case. Patients with upper gastrointestinal hemorrhage after PDT could be divided into early- and late-stage groups depending on the occurrence of hemorrhage within 5 d after PDT<sup>[1]</sup>. In our study, there were two cases of early-stage hemorrhage and 15 cases of late-stage hemorrhage. Pancreatic leakage was confirmed in five cases. One patient withdrew from the study because his family gave up the treatment. All patients enrolled in this study signed the informed consent.

#### **Inclusion criteria**

Patients who were diagnosed as lower common bile duct cancer, pancreatic head cancer, or digestive tract tumors such as ampullary carcinoma, with the need of pancreatoduodenectomy. Modified Child procedures were adopted in each patient, were included in this study. Digestive tract reconstruction was performed in order of pancreas-intestine, bile duct-intestine and stomach-intestine. An internal support tube was placed in the pancreatic duct and a cross-section of the pancreas was sutured to stop bleeding. Patients with massive pancreaticojejunal anastomotic hemorrhage after PDT and specific criteria are listed below.

#### **Exclusion criteria**

Patients not meeting the above diagnostic criteria or with accompanying mental disorders or severe primary diseases in cardiovascular, liver, kidney and hematopoietic systems, or those giving up treatment and withdrawing from the study were excluded, except for women in pregnancy or breast-feeding, or those going to be pregnant.

#### **Diagnosis of massive pancreaticojejunal anastomotic hemorrhage after PDT**

In our study, a modified Child's procedure was adopted for all subjects, namely digestive tract reconstruction was performed in order of pancreas-intestine, bile duct-intestine and stomach-intestine. An internal support tube was placed in the pancreatic duct and a cross-section of the pancreas was sutured to stop bleeding as previously described<sup>[2-4]</sup>. The diagnosis of massive pancreaticojejunal anastomotic hemorrhage after PDT was based on the literature<sup>[3]</sup>. The main diagnostic criteria for patients in our study were as follows. (1) Hemorrhage occurred within 1 mo of PDT (the last hemorrhage in our study occurred on day 23 post-surgery) and the presence of a

massive hemorrhage impacting vital signs was confirmed by angiography or gastroscopy (subjects whose origin of hemorrhage could not be found by angiography or those with acute ulcer hemorrhage were confirmed by gastroscopy). (2) Massive hemorrhage manifested as fresh blood effusing suddenly from the abdominal drainage tube or T-tube, or massive hematemesis or blood drainage from the gastric tube (> 200 mL). (3) Patients experienced hypovolemic shock accompanying a simultaneous decrease in hemoglobin (hemoglobin decreased more than 30 g/L in 24 h). Massive pancreaticojejunal anastomotic hemorrhage after PDT was diagnosed when the patients had hemorrhage and any other manifestations.

#### **Treatment of massive hemorrhage**

**TAE:** Of the 11 patients treated with TAE, eight underwent hepatic artery embolization, two underwent embolization of hepatic artery proper, and one refused any treatment upon initiating TAE. Hemorrhage was stopped in six cases after a single embolization procedure. Two patients underwent TAE twice for hemostasis (Figure 1). Emergency arteriography showed that the two patients had pancreatic stump artery bleeding into the jejunum. Hepatic artery was embolized during the first TAE, but recurrence of bleeding was found 4 h later. Arteriography showed that the pancreatic stump artery bled again, and microcoils embolizing the hepatic artery were displaced into the right hepatic artery. TAE was performed again with the common hepatic artery embolized using five microcoils, which stopped postoperative hemorrhage. Arteriography showed no obvious origin of hemorrhage in patient 3 during the first TAE. However, 7 h later, the patient received another arteriogram because of recurrence of bleeding. Duodenal stump bleeding was detected, and the common hepatic artery was then embolized to stop the hemorrhage. Arteriography revealed a crude edge on hepatic artery in patient 5, and the bleeding was stopped after embolization of the hepatic artery. A "vascular pool" image was observed in the inferior pancreaticoduodenal artery of patient 6, which was considered the origin of bleeding stopped by embolizing the common hepatic artery.

Complications such as hepatophyma and spleen necrosis may occur after TAE. In this study, patient 2 suffered from fever 2 mo after operation, with its peak at 39°C. Hepatophyma larger than 5 cm in diameter was seen in the right liver lobe. The patient recovered after paracentesis and anti-infective therapy. No such complications were found in the other patients.

**Open surgery:** A total of six patients received direct open surgical hemostasis for their hemorrhage.

## **RESULTS**

#### **Efficacy of TAE**

A total of 11 cases of massive hemorrhage after PDT

**Figure 1** Images from patient 2 (treated using TAE). A: Angiogram of the gastroduodenal stump bleeding before the first embolization. Arrow: Angiogram of the gastroduodenal stump bleeding; B: Angiogram of the gastroduodenal stump, which stopped bleeding after the first TAE. Arrow: Angiogram of the gastroduodenal stump); C: Angiogram of the stump prior to the second embolization. Angiography indicates that microcoils have entered the hepatic artery, causing renewed bleeding from the stump. Arrows: The second angiogram of the gastroduodenal stump bleeding; D: After the second embolization, angiography confirmed that the bleeding was stopped. Arrow: Angiogram of the gastroduodenal stump.

**Table 1** Overview of 11 patients with massive hemorrhage after PDT treated with TAE

Case	Time until bleeding	Symptom	Bleeding site	Embolization site	TAE	Hospital stay	Complications after TAE	Prognosis
1	21	T-tube bleeding	Pancreatic stump artery	Proper hepatic artery	1	9	High TB	Good
2	23	T-tube bleeding, hematemesis	Gastroduodenal stump	Common hepatic artery	2	14	High TB	Good
3	12	Double catheterization cannula, T-tube bleeding	Gastroduodenal stump	Common hepatic artery	2	14	High TB	Good
4	14	Hematemesis	Gastroduodenal stump	Common hepatic artery	1	5	Hyperpyrexia, pyemia	Dead
5	3	Double catheterization cannula bleeding	Proper hepatic artery	Proper hepatic artery	1	11	None	Good
6	5	Double catheterization cannula bleeding	Inferior pancreaticoduodenal artery	Common hepatic artery	1	8	High TB	Good
7	7	Single lumen cannula bleeding	Gastroduodenal Stump	Common hepatic artery	1	7	None	Good
8	9	Hematemesis	Gastroduodenal stump	Common hepatic artery	1	11	High TB	Good
9	10	Hematemesis	Gastroduodenal stump	Common hepatic artery	1	13	High TB	Good
10	7	Double catheterization cannula bleeding	Gastroduodenal stump	Common hepatic artery	1	13	High TB	Good
11	8	Double catheterization cannula bleeding	Gastroduodenal stump	Common hepatic artery	1	10	None	Good

TB: Total bilirubin.

underwent TAE which completely stopped their bleeding, except for one patient who died after refusing further treatment. Bleeding was stopped in eight patients after a single TAE procedure and in two patients after two treatments with TAE. All 10 patients recovered well and were discharged.

Total bilirubin (TB) exceeded the ULN level in seven out of the 10 patients and was as high as 178  $\mu\text{mol/L}$  in patient 2 after TAE, who was discharged with a full recovery of liver function after treatment. Patient 4 experienced a fever at 39.5°C after TAE and his TB level was 140  $\mu\text{mol/L}$ . Blood bacterial culture showed pyemia, and this patient abandoned treatment 5 d after TAE, and died 7 d after discharge. The other patients had a good prognosis after anti-infective and supportive treatment. Recurrence of hemorrhage was not found during a follow-up period of 2 mo and all 10 patients reported having an acceptable quality of life. The mean hospital stay was 10.45 d after hemostasis. Patients requiring a second operation accounted for 18.2%, and the overall mortality rate was 9.1% (Table 1).

### Efficacy of open surgery

Six patients underwent a second open surgical hemostasis for hemorrhage. Patients 1, 3 and 6 recovered and were discharged. However, patient 6 received an additional open surgical hemostasis, and patient 2 received emergency open surgical hemostasis again because of rebleeding 5 and 9 d after surgery, respectively. Patient 2 died of multiple organ failure. Liver and renal failure was observed in patients 4 and 5 after surgery. Both patients abandoned treatment, and one of them died 1 wk after discharge. The other patients had a good prognosis after anti-infective and supportive treatment. The mortality rate for patients undergoing open surgery was 50%, the recurrence rate of hemorrhage was 16.67%, and the mean hospital stay was 39.5 d (Table 2).

## DISCUSSION

Pancreatojejunal and choledochojejunal anastomotic internal drainage can effectively prevent biliary and pancreatic leakage. PDT is a common abdominal

Table 2 Overview of six patients with massive hemorrhage after PDT treated with open surgical hemostasis

Case	Time until bleeding	Symptom	Bleeding site	Hemostasis surgeries	Duration of hospital stay after hemostasis	Complications after surgery	Prognosis
1	17	T-tube bleeding	Gastroduodenal stump	1	59	None	Good
2	9	T-tube bleeding, hematemesis	Gastroduodenal stump	2	32	Multiple organ failure	Dead
3	10	T-tube bleeding	Gastroduodenal stump	1	63	None	Good
4	11	Hematemesis	Gastroduodenal stump	1	16	Liver failure	Dead
5	8	T-tube bleeding	Gastroduodenal stump	1	13	Renal failure	Dead
6	8	T-tube, pancreatic duct bleeding	Gastroduodenal stump	2	54	None	Good

operation. However, it is associated with the most common complications of hemorrhage and pancreatic leakage, with a relatively high risk<sup>[5]</sup>. The incidence of postoperative massive hemorrhage is 7.5%-12.4%. From June 2005 to August 2008, we performed 308 PDT, and massive pancreaticojejunal anastomotic hemorrhage occurred in 16 patients, accounting for 5.2% of its overall incidence rate, which is slightly lower than the reported rate<sup>[6]</sup>. Massive hemorrhage after PDT is difficult to stop, and if it is not stopped immediately, the mortality rate can be as high as 30%-58%<sup>[7,8]</sup>. Massive pancreaticojejunal anastomotic hemorrhage after PDT, mainly from the gastroduodenal stump, is often caused by transudatory digestive juices or corrosion of peripheral tissues by local fluid infection. Corrosion of the anastomotic vicinal vessels is especially common. In the present study, pancreatic leakage was confirmed in five of the 16 patients, and the number of leukocytes was increased before bleeding in six of them, and the number of WBC was  $20.5 \times 10^9/L$  in one patient. In addition, four of the six patients had a fever. Gastroduodenal arterial bleeding was detected by DSA in five of our patients, suggesting that it is particularly important to prevent intra-abdominal infection after PDT. Abdominal CT and B-ultrasound should be regularly performed to monitor the fever or blood pressure of such patients, to ensure that seroperitoneum is not compromised. If there is any indication of infection, puncture and drainage should be carried out to prevent further infection. During the surgery, arteries should be ligated twice or transfixed, with longer suturing ends as appropriate<sup>[9]</sup>.

Pancreaticojejunal anastomotic hemorrhage after PDT is difficult to treat. TAE with or without surgery might be a more effective procedure to stop bleeding. Since PDT may produce significant surgical trauma, and the site of hemorrhage is often difficult to locate, blind open surgical exploration often ends in failure. In addition, postoperative complications such as pancreatic leakage and intra-abdominal infection can result in more severe consequences than those caused by hemorrhage. Thus, better treatment modalities are needed for pancreaticojejunal hemorrhage after PDT. In our study, six patients underwent open surgical hemostasis again after PDT, and two of them received additional open surgical hemostasis because of recurrence of bleeding, which can be explained as follows. Namely, their overall poor condition following two major operations may have hindered recovery; the exact site of bleeding could

not be accurately located during the first operation for hemorrhage; intra-abdominal organ edema such as pancreatic edema was common and pancreatic leakage and intra-abdominal infections were not completely controlled. One patient with an intra-abdominal infection died of multiple organ failure. Liver or renal failure was also found in two patients after surgery. Both patients abandoned treatment, and one of them died 1 wk after discharge. Overall, the mortality rate for open surgery was 50%, the recurrence rate of bleeding was 16.67%, and the mean hospital stay was 39.5 d, suggesting that the prognosis of patients undergoing TAE is rather poor.

However, TAE can prevent re-operation risk and complications. In our study, 18.2% patients had a second TAE with a mortality of only 0.9%. In addition, the mean hospital stay after TAE was 10.45 d. Angiography should be performed as soon as hemorrhage is diagnosed to locate the site of bleeding. Then, embolization can be performed to stop hemorrhage<sup>[4,5]</sup>.

Angiography can diagnose hemorrhage and evaluate the efficacy of its treatment.

Angiography can locate the site of bleeding. TAE after PDT is needed for successful treatment of hemorrhage, and cooperation between surgeons is necessary to maximize the therapeutic efficacy and minimize the risk of TAE.

Since patients will be transported and allergy testing of contrast medium will be carried out during TAE, preoperative and intraoperative anti-hemorrhagic shock should be prevented. Any change in vital signs should be monitored while performing TAE. Larger microcoils should be selected for TAE because the common hepatic artery is large with a high-pressure blood flow.

After TAE, patients should be closely observed, and the outcome of hemostasis should be confirmed by arteriography. Patients without recurrence of bleeding can be sent to the intensive care unit for observation. The site of bleeding was found in eight of our 10 patients who underwent TAE. No recurrence of bleeding was observed at first in the other two patients who required additional surgery, which may have resulted from their poor condition (unresolved shock and low blood pressure), leading to reduced bleeding despite. Spastic contraction of blood vessels and/or obstruction of vessels or blood clots may have prevented accurate angiography. It was reported that gastroduodenal arterial stump bleeding is one of the main sources of pancreaticojejunal anastomotic hemorrhage after PDT<sup>[10]</sup>. If pancreaticojejunal

anastomotic hemorrhage is suspected but not dealt with, massive hemorrhage may occur. Common hepatic arterial embolization may be a better choice of treatment.

Nevertheless, we found that common hepatic artery embolization with TAE was likely to result in liver injury, which was manifested as elevated TB and aminotransferase level. In our study, TB level was higher in five patients than in normal controls after TAE, and the aminotransferase level was three-fold higher in four patients than in normal controls. However, if not accompanied with liver disease, liver failure rarely occurs after TAE. We provided supportive treatment for patients with liver injury by increasing the oxygen flow and concentration, extending oxygen absorption time, maintaining a high oxygen pressure and 100% oxygen saturation, and improving liver support. We also provided low-dose hormone therapy with prostaglandin E, growth hormone, and hepatocyte growth factor to increase the liver blood flow and promote liver cell regeneration. The patients received additional supportive treatment with plasma and human serum albumin when necessary.

In summary, TAE, which can avoid reoperation and complications of surgery, is an effective and safe treatment modality for acute postoperative hemorrhage after PDT. However, TAE may damage liver function due to hepatic artery embolization. Angiography can locate the site of bleeding, and if there are indications for surgery, TAE should be performed in time.

## COMMENTS

### Background

Massive pancreaticojejunal anastomotic hemorrhage after pancreaticoduodenectomy (PDT) is the second most common severe complication, only next to pancreaticojejunal anastomotic dehiscence. Blind open surgical hemostasis has more surgical risks and complications. However, transcatheter arterial embolization (TAE) can prevent reoperation risk and complications.

### Research frontiers

An internal support tube was placed in the pancreatic duct and a cross-section of pancreas was sutured to stop bleeding. If the bleeding site was located by selective angiography, embolization could be performed to stop bleeding.

## Applications

TAE is an effective and safe treatment modality for acute hemorrhage after PDT. Vasography should be performed in time to locate the site of bleeding. TAE can also prevent reoperation risk and complications.

## Peer review

The authors showed that TAE was an effective and safe treatment modality for acute hemorrhage after PDT. The initial observations are interesting.

### Abstract

**AIM:** To explore the feasibility of passage of bone-marrow-derived liver stem cells (BDLSCs) in culture systems that contain cholestatic serum.

**METHODS:** Whole bone marrow cells of rats were purified with conditioning selection media that contained 50 mL/L cholestatic serum. The selected BDLSCs were grown in a proliferating culture system and a differentiating culture system. The culture systems contained factors that stimulated the proliferation and differentiation of BDLSCs. Each passage of the proliferated stem cells was subjected to flow cytometry to detect stem cell markers. The morphology and phenotypic markers of BDLSCs were characterized using immunohistochemistry, reverse transcription polymerase chain reaction (RT-PCR) and electron microscopy. The metabolic functions of differentiated cells were also determined by glycogen staining and urea assay.

**RESULTS:** The conditioning selection medium isolated BDLSCs directly from cultured bone marrow cells. The selected BDLSCs could be proliferated for six passages and maintained stable markers in our proliferating system. When the culture system was changed to a differentiating system, hepatocyte-like colony-forming

units (H-CFUs) were formed. H-CFUs expressed markers of embryonic hepatocytes (alpha-fetoprotein, albumin and cytokeratin 8/18), biliary cells (cytokeratin 19), hepatocyte functional proteins (transferrin and cytochrome P450-2b1), and hepatocyte nuclear factors 1 $\alpha$  and -3 $\beta$ ). They also had glycogen storage and urea synthesis functions, two of the critical features of hepatocytes.

**CONCLUSION:** BDLSCs can be selected directly from bone marrow cells, and pure BDLSCs can be proliferated for six passages. The differentiated cells have hepatocyte-like phenotypes and functions. BDLSCs represent a new method to provide a readily available alternate source of cells for clinical hepatocyte therapy.

### INTRODUCTION

About a decade ago, many reports highlighted the broad developmental potential of bone-marrow-derived stem cells<sup>[1]</sup>. This gave new hope for cell therapy using autologous bone marrow cells, which has few ethical problems and has been applied to severe liver diseases<sup>[2]</sup>. However, little progress has been made in recent years because of the difficulties of selection and proliferation of this specific cell population<sup>[3]</sup>. It is necessary to find a new way to isolate and purify bone-marrow-derived liver stem cells (BDLSCs). Following the principle that cells in culture can survive only when they become accommodated to the surrounding environment, we developed a culture system to isolate BDLSCs from

bone marrow cells. Within this system, only BDLSCs could survive, while the other bone marrow cells could not<sup>[4]</sup>. This method could provide pure BDLSCs, but still could not harvest large numbers of cells, and the efficiency of differentiation was insufficient for therapeutic application. Here, we developed a proliferating culture system to passage BDLSCs and a differentiating system to yield hepatocyte-like cells, by modified culture environments.

## MATERIALS AND METHODS

### **Selection, proliferation and differentiation of BDLSCs**

#### **Preparation of conditioning selection medium:**

Common bile duct ligation and transection were carried out under general (ether) anesthesia in Sprague-Dawley rats weighing 200-250 g to induce cholestasis. After 10 d, whole blood was collected from each rat, and serum was separated. Cholestatic serum (50 mL/L) was added to Dulbecco's Modified Eagle's Medium (DMEM; Gibco) that contained 20 mmol/L HEPES (Sigma),  $10^{-7}$  mol/L dexamethasone (Sigma), and antibiotics, to act as the conditioning selection medium (See our previous study)<sup>[4]</sup>.

**Culture of bone marrow cells:** Rat bone marrow cells were obtained by flushing the femurs. About  $3 \times 10^8$  bone marrow cells were retrieved from one rat. Bone marrow cells were suspended in DMEM and plated at a density of  $1 \times 10^9$  cells/L onto culture dishes. DMEM enriched with 100 mL/L fetal bovine serum (FBS; HyClone), 20 mmol/L HEPES,  $10^{-7}$  mol/L dexamethasone, and antibiotics was used. Dishes were placed in a humidified incubator containing 50 mL/L CO<sub>2</sub> and 950 mL/L O<sub>2</sub> at 37°C.

**Selection and passage of liver stem cells:** Three days after culture, the medium and suspended cells were discarded and replaced by conditioning selection medium. Pure liver stem cells were selected by this medium. The cells were then proliferated with a new proliferating culture system, which contained 5% cholestatic serum, 10% FBS (Gibco), 10 mmol/L nicotinamide (Sigma), 1 mmol/L 2-phosphate ascorbic (Sigma), 1 mg/mL galactose (Sigma), 30 µg/mL praline (Sigma), insulin/transferrin/selenite mixture (Gibco), 10 ng/mL epidermal growth factor (EGF; Pepro Tech) and 10 ng/mL hepatocyte growth factor (HGF; Pepro Tech). When the cells developed into the proliferating stage, 10 ng/mL leukocyte inhibitory factor (LIF; Cytolab) was added to inhibit the differentiation of the cells. Passaging was carried out when the cells overlapped in the plate.

**Differentiation of liver stem cells:** Each passage of the stem cells was cultured in the differentiating system (i.e. the above culture system containing 20 ng/mL EGF, 25 ng/mL HGF, 1% DMSO (Sigma) and 20 ng/mL interleukin (IL)-3 (Pepro Tech), and LIF was discarded at this time. Differentiated cells were harvested.

### **Growth curve of passaged BDLSCs**

The passaged BDLSCs were digested and re-cultured on 24-well dishes at a concentration of  $1 \times 10^7$ /L. The mean number of cells in every three wells were counted daily for 8 d. The cell growth curve was then drawn according to these numbers.

### **Flow cytometry detection of the stability of stem cell markers of cell passages**

After each passage, the stem cells and the differentiated cells were digested to prepare single-cell suspensions. The cell surface markers beta-2 microglobulin (β<sub>2m</sub>), Thy-1, CD34, Flt-3, c-kit and IL-3R were detected with cytometry. Each marker was detected six times in every passage, and mean values were determined. The stability of stem cell surface marker expression was determined, and the expression before and after differentiation was compared.

### **Morphological and phenotypic markers of differentiated cells**

**Immunohistochemistry:** Stem cells of each passage were cultured in the differentiating system in six-well dishes with cover glasses. When hepatocyte-like cells came into being, cover glasses and the differentiated BDLSCs were removed and fixed for immunohistochemistry. The primary antibodies were goat anti-rat albumin, alpha-fetoprotein (AFP), and cytokeratin -8/18 (CK8/18) polyclonal antibodies. (see our previous study)<sup>[4]</sup>.

**Electron microscopy:** Culture dishes of differentiated cells were washed with PBS, and fixed in glutaraldehyde for 48 h. After fixation, cells were curetted and centrifuged to form aggregates. After post-fixation in osmium tetroxide, cells were dehydrated in graded alcohols and embedded in low-viscosity epoxy resin. Ultrathin sections were stained with uranyl acetate and lead citrate and viewed under an electron microscope (see our previous study)<sup>[4]</sup>.

**Reverse transcription polymerase chain reaction (RT-PCR):** Total RNA was extracted from the differentiated cells and mRNA transcription of hepatocyte nuclear factor (HNF)-1α, HNF-3β, CK18, CK19, albumin, AFP, transthyretin (TTR) and cytochrome P450-2b1 (CYP2b1) were detected by RT-PCR (see our previous study)<sup>[4]</sup>.

### **Function tests of differentiated cells**

Periodic acid-Schiff (PAS) staining for glycogen and urea assay of the differentiated cells were also conducted to confirm their hepatocyte-like function (see our previous study)<sup>[4]</sup>.

### **Statistical analysis**

Data were presented as mean ± SD. All the data were analyzed using the SPSS statistical package 13.0. Differences in means were tested by the unpaired Student's *t* test. All tests were considered statistically significant at *P* < 0.05.

## RESULTS

### Morphological evidence of BDLSC differentiation

During the first 3 d, many colonies appeared in the conditioning cholestatic serum. These colonies were composed of small, undifferentiated cells in the center, and epithelioid cells at the periphery (Figure 1A). After replacing with the proliferating system, the colonies enlarged, and the cells proliferated rapidly in about 4 d (Figure 1B). With the addition of LIF, mature differentiation was inhibited, and colonies of small round cells with large nuclei, little endochylema and high nuclear-to-cytoplasmic ratio appeared (Figure 1C). The colonies maintained the ability of proliferation and passage was required in 5-7 d. The original aim of six passages could be achieved. After six passages, however, the proliferation was difficult to maintain and fibroblast-like cells appeared. After replacing with the differentiating system, hepatocyte-like colony-forming units (H-CFUs) started to appear. The H-CFUs were composed of small, undifferentiated cells in the center, and large cells with regular multilateral contours, low nuclear-to-cytoplasmic ratio, and single round nuclei at the periphery. The differentiated cells formed cords or trabeculae that resembled the hepatocyte cords in hepatic lobules (Figure 1D).

### Growth curve of passaged BDLSCs

The curve showed that the number of cells increased as the culture time passed, and rapid proliferation appeared from day 2 to day 5 (Figure 2).

### Flow cytometry detecting stability of stem cell markers of cell passage

Flow cytometry detecting the cell surface markers of

**Figure 2** Cell growth curve of passaged BDLSC.

each passage showed that the undifferentiating cells were relatively stable  $\beta_2m^{low}/Thy-1^+/CD34^{low}/c-kit^+$  cells. The markers changed after differentiation, with significant differences ( $P < 0.05$ ) in all of the detected markers except CD34 (Figures 3 and 4).

### Phenotypic markers of differentiated cells

The differentiated cells from each passage were analyzed for biochemical evidence of hepatocytic differentiation, in order to confirm their characteristics. Just as in our previous study<sup>[4]</sup>, immunohistochemistry was performed on differentiated cells grown on cover glasses to determine the presence of albumin, AFP and CK8/18, the characteristic proteins expressed during hepatocyte development, which revealed diffuse cytoplasmic staining for these proteins. RT-PCR further confirmed the hepatocytic characteristics of differentiated cells as the results showed that there were mRNA transcripts of HNF-1 $\alpha$ , HNF-3 $\beta$ , albumin, AFP, CK-18, CK-19, TTR,

**Figure 3** Differences of stem cell markers before and after differentiation by flow cytometry. Red curves: Negative control, M1: Negative part, M2: Positive part.

and CYP2b1, all of which were hepatocyte specific.

Ultrastructurally, the differentiated cells were rich in endoplasmic reticulum and ribosomes and contained abundant ellipsoid mitochondria, which were typical features of adult hepatocytes.

#### Function tests of differentiated cells

We also found glycogen storage in the cytoplasm of hepatocyte-like differentiated cells by PAS staining, and urea production and secretion by urea assay of the culture medium<sup>[4]</sup>.

Figure 4 Expression of stem cell markers before and after differentiation.

## DISCUSSION

Bone-marrow-derived stem cells are able to transdifferentiate into hepatic cells as shown in cross-sex and cross-strain bone marrow and whole liver transplantation experiments<sup>[5]</sup>. Great interest has been aroused in the identification and isolation of BDLSCs<sup>[6]</sup>. However, the characteristic surface markers of BDLSCs and their pedigrees in the derivation of bone marrow stem cells remain obscure<sup>[7]</sup>. It is difficult to identify and sort particular cells by immunological methods, such as fluorescence-activated and magnetic-activated cell sorting<sup>[8,9]</sup>. Furthermore, the sorting of stem cells with complicated surface markers is difficult<sup>[10]</sup>. We developed a conditioning culture system to solve this problem. Within such a system, only BDLSCs could survive, while other cells could not, therefore, it was possible to purify these specific stem cells<sup>[4]</sup>.

However, the passage of BDLSCs is still a challenge, which has hindered the proliferation of the cells. No report of successful passage has been published. In our experiments, we found that the key to passage of the stem cells was to isolate purified stem cells. We were able to harvest pure BDLSC colonies with our selection system. After that, a proliferating system that contained all the nutrients required for the proliferation of liver stem cells was introduced to culture the cells<sup>[11,12]</sup>. This system contained all the known conditions required for the proliferation of oval cells<sup>[13]</sup>, with low concentrations of HGF and EGF and a mixture of FBS and cholestatic serum, so as to maintain the characteristics of the liver stem cells. At the same time, for stem cell proliferation, differentiation must be prevented. We therefore provided LIF, a factor known as a strong inhibitor of stem cell differentiation<sup>[14]</sup>. When replaced with the proliferating system on day 4, rapid proliferation occurred and the cells maintained their undifferentiated state, under the action of LIF. To harvest the differentiated cells, LIF must be discarded, and the concentration of EGF and HGF must be higher. Under the conditions that contained the differentiating factors, hepatocyte-like cells appeared from each passage of the stem cells. The morphology and phenotypic markers manifested in the differentiated cells were similar to those of liver stem cells. These cells

expressed markers of embryonic hepatocytes (AFP, albumin and CK18), biliary cells (CK19), hepatocyte functional proteins (ITR and CYP2b1), and hepatocyte nuclear factors (HNF-1 $\alpha$  and HNF-3 $\beta$ ). To confirm that the differentiated cells had functional characteristics of hepatocytes, we tested the glycogen and urea synthesis functions of the cells, and demonstrated that the cells possessed hepatocyte-like functions. These all proved that each passage of the stem cells can differentiate into hepatocyte-like cells. We also detected the stability of each passage of the stem cells with flow cytometry, and the results showed that the proliferation was stable. In addition, the increase in  $\beta 2m$  expression on the differentiated cells demonstrated their maturation because  $\beta 2m$  is only expressed on mature cells. However, we had difficulty in maintaining the proliferation after six passages. The emergence of fibroblast-like cells became inevitable. The explanation might be that the proliferation of adult stem cells, unlike tumor cells, was limited, and that new factors or a network similar to the liver tissue were required for further proliferation.

In conclusion, we demonstrated that BDLSCs could be selected from whole bone marrow cells using conditioning medium. The stem cells could also be proliferated for six passages and differentiated into hepatocyte-like cells. These methods not only provide a new and effective method for the isolation and purification of extrahepatic liver stem cells, but also provide a readily available alternate source of cells for clinical hepatocyte therapy.

## COMMENTS

### Background

Bone-marrow-derived liver stem cells (BDLSCs) were once a hot topic in the field of stem cell research because of their important therapeutic implications, but little progress has been made in recent years because of the difficulty of isolation and proliferation of this special cell population. The authors developed a culture system to isolate BDLSCs from bone marrow cells, from which they could culture pure BDLSCs *in vitro*. However, the passage of BDLSCs is still a challenge, which has hindered the proliferation of the cells.

### Research frontiers

Great interests has been aroused in the identification and isolation of liver stem cells from bone marrow cells. Several subsets of bone marrow cells have been found to have the potential to differentiate into hepatocytes, but no report of successful passage has been published.

### Innovations and breakthroughs

This study provided a new method for BDLSC isolation and proliferation. With a careful designed culture system, BDLSCs can be purified *in vitro* and be passaged, which brings new hope to the clinical use of bone-marrow-derived stem cells.

### Applications

BDLSCs can be selected directly from bone marrow cells, and pure BDLSCs can also be proliferated for six passages. The differentiated cells have hepatocyte-like phenotypes and functions. BDLSCs represent a new method to provide a readily available alternate source of cells for clinical hepatocyte therapy.

### Peer review

In this study, the authors used their original method to retrieve cells that are possibly BDLSCs. Then, they used fluorescence-activated cell sorting to determine the cells' characteristics before and after differentiation. This is an interesting and potentially important study, which suggests that bone-marrow-derived cells can be stimulated to expand and then differentiate into hepatocyte-like cells, which may possibly be used to treat liver disease.

### Abstract

**AIM:** The association of hepatitis C virus (HCV) infection with type II mixed cryoglobulinemia is well established, but the role of HCV in B-cell lymphoma remains controversial. In patients with HCV infection, B-cell clonal expansions have been detected in peripheral blood and bone marrow, and a high prevalence of B-cell non-Hodgkin's lymphomas has been documented. Liver biopsies in chronic HCV infection frequently show portal lymphoid infiltrates with features of B follicles, whose clonality has not yet been investigated. The object of this study was to determine the frequency of liver-infiltrating monoclonal B-cells in 40 patients with HCV infection.

**METHODS:** Eight hundred and forty-eight patients were studied prospectively, including 40 HCV-positive patients and 808 patients with chronic hepatitis B virus (HBV) infection. Immunohistochemical study for B- and T-cell markers was performed on the paraffin-embedded liver tissue sections. The clonality of lymphoid B-cells was tested using a

polymerase chain reaction (PCR) approach designed to identify immunoglobulin heavy chain gene (*IgH*) rearrangements.

**RESULTS:** Liver-infiltrating monoclonal B-cells were detected in the liver for 4 (10%) of 40 HCV-positive patients but were present in only 3 (0.37%) of 808 liver biopsy specimens with chronic HBV infection. Chi-square testing showed that the monoclonal B-cells infiltration in the liver was more frequent in the HCV-infected patients ( $P = 0.000$ ). A clonal *IgH* rearrangement was detected in 5 (71.4%) of 7 liver biopsy specimens with monoclonal B-cells infiltration. In 2 of 5 patients with both a clonal B-cell expansion and monoclonal B-cells infiltration in the liver, a definite B-cell malignancy was finally diagnosed.

**CONCLUSION:** Liver-infiltrating monoclonal B-cells are detected in the liver of patients with chronic HCV and HBV infection. A high percentage of patients with monoclonal B-cells infiltration and B-cell clonality in the liver were finally diagnosed as having a definite B-cell malignancy.

### INTRODUCTION

The relationship between lymphoproliferative disorders and infectious agents has been recognised and studied for many decades. A causative association between

hepatitis C virus (HCV) and non-Hodgkin's lymphoma (NHL) was postulated relatively recently and has been the subject both of intense investigation and of some debate<sup>[1-5]</sup>. On the strength of epidemiological data, emerging biological investigations and clinical observations, HCV appears to be involved in the pathogenesis of at least a proportion of patients with NHL<sup>[6-7]</sup>. This hypothesis is supported by the evidence that HCV is not only hepatotropic, but also a lymphotropic virus<sup>[8]</sup>. *In vitro*, HCV is able to replicate in human T-cell lines<sup>[9]</sup> and in normal peripheral blood mononuclear cells from healthy subjects<sup>[10]</sup>. Moreover, viral genomic sequences have been found in T- and B-cell populations, as well as in monocyte-derived cells from peripheral blood and liver tissue in patients with HCV-related chronic hepatitis<sup>[10-12]</sup>. Most studies on HCV-associated B-cell proliferations have focused on peripheral blood and bone marrow lymphocytes. During HCV infection, liver tissue is frequently characterized by prominent lymphoid aggregates in portal tracts that show histological and immunophenotypical features of B follicles<sup>[13-14]</sup>. The nature of these aggregates has not yet been investigated in detail; in particular, the clonality of B-cells within lymphoid infiltrates in the liver of HCV-infected patients has not been analyzed at the molecular level. In the present study, we analyzed the frequency of liver-infiltrating monoclonal B-cells from the paraffin-embedded liver biopsies of 40 patients with HCV infection. In 7 patients with monoclonal B-cells infiltration in the liver who were followed up, B-cell clonality was tested using a polymerase chain reaction (PCR) approach designed to identify immunoglobulin heavy chain gene (*IgH*) rearrangements.

## MATERIALS AND METHODS

### Ethics

All patients were notified of the risk of the liver puncturation and provided informed written consent.

### Selection of cases

From June 2003 to December 2005, 848 patients were enrolled in a prospective study and were followed up as outpatients at the Department of Infectious Disease at our NanFang Hospital. In 40 HCV-positive patients (anti-HCV antibody and HCV RNA positive), anti-hepatitis B virus (HBV) and anti-human immunodeficiency virus antibodies were negative. The patients had not received anti-HCV therapy for at least 6 mo. For each patient, a sample of liver biopsy was performed. A control group, consisting of 808 HBV-infected patients with other non-immune chronic liver diseases, was followed up at the same department. All the patients were diagnosed as having chronic hepatitis according to the criteria formulated by the Chinese Society of Infectious disease and Parasitology and Chinese Society of Hepatology, Chinese Medical Association.

### Immunohistochemical characterization of lymphoid aggregates

The 848 liver biopsies contained 7 monoclonal B-cell infiltrations. The composition of the 7 infiltration cell specimens was investigated by immunohistochemistry, using antibodies against B-cell (L26/CD20) markers, following the streptavidin-biotin-complex immunoperoxidase technique.

### Polymerase chain reaction of *IgH* rearrangements

The DNA from the 7 monoclonal B-cells infiltration liver specimens successfully amplified for the  $\beta$ -actin gene was then subjected to clonality assessment by PCR amplification of rearranged *IgH* genes. After heating for 10 min at 95°C, 2  $\mu$ L from each sample was added to the PCR mixture containing 50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.3), 25 pmol/L of each primer, 200  $\mu$ mol/L of each dNTP, 1.25 units of *Taq* polymerase, and 4.5 mmol/L MgCl<sub>2</sub> in a final volume of 50  $\mu$ L.

We amplified the hypervariable complementary region (CDR-II and CDR-III), included between the third and joining regions (FR-III and JH) of *IgH* genes, with a 5'-primer homologous to the FR-III region, and JH as 3'-primers, using a seminested protocol. The primers were FR3, CTGTGACACGGCCGTGTATTACTG; JH, AACTGCAGAGGAGACGGTGACC. The first PCR cycle consisted of denaturation of the sample DNA at 93°C for five minutes, annealing of the primers at 55°C for one minute, then extension of the DNA at 73°C for two minutes. Each experiment was duplicated and accompanied by a negative control containing no template DNA. Ten microlitres of the PCR products were analyzed by electrophoresis on 3% agarose gels, stained by ethidium bromide, and viewed under UV light.

### The histologic features of liver biopsy specimens were analyzed

Liver biopsy specimens (> 10 mm in length) were fixed, paraffin-embedded, and stained with hematoxylin-eosin-saffron, and Warthin-Starry stained for collagen. For each liver biopsy specimen, a stage of fibrosis and a grade of activity were established according to the criteria formulated by the Chinese Society of Infectious Disease and Parasitology and Chinese Society of Hepatology, Chinese Medical Association.

### Data analysis

Categorical variables were compared by chi-square testing, and continuous variables were compared by the two-sided Student *t* test.

## RESULTS

Among the 848 patients prospectively included in this study, 40 were HCV-positive (anti-HCV antibody

**Figure 1** Histological appearances of a B-cell lymphoma, best classified as a marginal zone lymphoma involving the liver. A, B: Low power view of liver core biopsy shows chronic hepatitis and marked portal lymphoid infiltrates. C: High power view of liver core biopsy shows a monotonous portal lymphoid infiltrate composed of small lymphocytes with moderate amount of clear cytoplasm (so-called monocytoid appearance). Note that the infiltrate does not involve the biliary epithelium. D: CD20 immunostain shows that virtually all of the lymphoid cells are B-cells.

**Table 1** Baseline characteristics of patients with, and those without, chronic HCV infection

Characteristic	HCV positive (n = 40)	HCV negative (n = 808)	P
Age, (mean $\pm$ SD, yr)	50 $\pm$ 14	51 $\pm$ 15	> 0.05
Male	28/40	550/808	> 0.05
ALT, (mean $\pm$ SD, upper limit of normal value)	136 $\pm$ 7.8	132 $\pm$ 6.9	> 0.05
Liver histologic activity			
None or mild (G0-G1)	7/40	142/808	> 0.05
Moderate or severe (G2-G4)	33/40	666/808	> 0.05
Liver histologic fibrosis			
None or portal fibrosis (S0-S1)	8/40	17/808	> 0.05
Few or many septa or cirrhosis (S2-S4)	32/40	791/808	> 0.05

Yes	4/40	3/808	0.000

and HCV RNA positive), and 808 were HBV-infected patients. The main characteristics of patients with, and those without, chronic HCV infection are detailed in Table 1.

The histological appearance of a B-cell lymphoma is shown in Figure 1.

A clonal B-cell expansion was detected in 5 (71.4%) of 7 of the livers with monoclonal B-cells infiltration. In 2 of 5 patients with both a clonal B-cell expansion and monoclonal B-cells infiltration in the liver, a definite B-cell malignancy was finally diagnosed.

## DISCUSSION

In this study, we addressed the question of whether

lymphoid aggregates in the liver of patients with chronic hepatitis C are clonal B-cell proliferations.

Seven of the 848 patients have monoclonal B-cells infiltrating in the livers, including 4 of 40 chronic HCV-infected patients and 3 of 808 chronic HBV-infected patients. Five of the 7 patients with monoclonal B-cells infiltration showed a single band, suggesting that they were formed by a single B-cell clone. We were able to observe progression in patients who continued to be followed up after the end of this study. Lymphoma developed in 2 HCV-infected patients out of 5 patients who had monoclonal B-cells infiltration and B-cell proliferation in the liver.

Although epidemiological data link HCV infection and NHL, the pathobiological processes leading to clonal B-cell expansion and subsequent malignant transformation are only recently becoming better understood. CD81 has emerged as a potentially key mediator of B-cell/HCV interaction, in light of the finding that CD81 can bind to at least two sites on the HCV envelope protein, E2. CD81/E2 interaction does not apparently promote viral entry into B-cells; however, B-cells with specific anti-HCV surface immunoglobulins can simultaneously interact with viral E2 protein *via* CD81, resulting in dual activation signals leading to B-cell proliferation. Furthermore, clonal immunoglobulin gene rearrangements from HCV-positive lymphomas often share a similar restricted gene segment usage pattern, as seen in B-cells from patients with mixed cryoglobulinemia, and also show somatic hypermutation, emphasising the link between chronic viral antigenic stimulation and NHL pathogenesis<sup>[15-20]</sup>.

A multistep process has also been documented in a lymphoproliferative disorder in an HCV-infected patient, in whom the bcl-2 translocation was followed by myc translocation during the clinical progression of the disease<sup>[21]</sup>. However, the wide spectrum of lymphomas that have been described in patients with HCV infection, ranging from lymphoplasmacytoid<sup>[2]</sup>, to MALT-type<sup>[22]</sup>, to

follicle-centre cell lymphomas<sup>[23]</sup>, seem to indicate that more heterogeneous and complex processes are probably involved in the lymphomagenesis associated with HCV.

In conclusion, in patients with chronic HCV infection, the presence of a B-cell clonality and monoclonal B-cells infiltration in the liver may be useful for detecting patients at high risk for developing malignant lymphoproliferative disease. The importance of B-cell clonality analysis in the course of chronic HCV disease needs to be further evaluated, as do the indications for, and the efficacy of, antiviral treatment in patients at risk for B-cell malignancy.

## COMMENTS

### Background

The association of hepatitis C virus (HCV) infection with type II mixed cryoglobulinemia is well established, but the role of HCV in B-cell lymphoma remains controversial. The incidence of B-cell lymphoma is currently rising in line with the progression of hepatitis C though the cause of this increase is largely unknown.

### Research frontiers

Investigating the clonality of B-cells in the liver by analyzing the *IgH* gene rearrangement has been shown to correlate the development of B-cell lymphoma with HCV-infected patients. Liver biopsies in chronic hepatitis C frequently show portal lymphoid infiltrates with features of B follicles, whose clonality has not yet been investigated. In this study, the authors demonstrate that the clonality of B-cells in the liver may represent a low-grade lymphoma.

### Innovations and breakthroughs

Recent reports have highlighted the importance of antiviral treatment in the HCV-infected patient with B-cell clonality in the liver. This is the first study to analyze the association of monoclonal B-cells infiltration in the liver with the B-cell clonality. Furthermore, our follow up study showed that the lymphoma developed more frequently in the patients who had monoclonal B-cells infiltration and B-cell proliferation in liver.

### Applications

The presence of a B-cell clonality and monoclonal B-cells infiltration in the liver may be useful for detecting patients at high risk for developing malignant lymphoproliferative disease. The study results suggest a strategy for antiviral treatment in patients at risk for B-cell malignancy.

### Terminology

Polymerase chain reaction (PCR) amplification is a method currently in widespread use for detection of clonal *IgH* rearrangements. In PCR, rearranged DNA is amplified with a series of consensus primers that are complementary to sequences of variable regions; framework 1, framework 2, and framework 3 and to joining regions of the *IgH* gene.

### Peer review

The authors investigate the association of HCV infection and liver B-cell clonality in a prospective clinical trial. Liver biopsy specimens from 40 HCV-positive patients were analyzed, and specimens from hepatitis B virus (HBV)-positive patients served as a control. This is the first study to describe B-cell clonality in the liver of HCV-infected patients, and the results of their study are of interest.

## Abstract

Liver transplantation has been reported in the literature as an extreme intervention in cases of severe and complicated hepatic trauma. The main indications for liver transplant in such cases were uncontrollable bleeding and postoperative hepatic insufficiency. We here describe four cases of orthotopic liver transplantation after penetrating or blunt liver trauma. The indications were liver failure, extended liver necrosis, liver gangrene and multiple episodes of gastrointestinal bleeding related to portal hypertension, respectively. One patient died due to postoperative cerebral edema. The other three patients recovered well and remain on immunosuppression. Liver transplantation should be considered as a saving procedure in severe hepatic trauma, when all other treatment modalities fail.

## INTRODUCTION

The liver is the most commonly injured abdominal organ, despite its protected location under the rib cage. The therapeutic options for the management of both blunt and penetrating hepatic trauma include a range of operative and non-operative treatment modalities<sup>[1-3]</sup>. Currently available methods for the management of hepatic trauma include observation, laparotomy with direct suturing, perihepatic gauze packing, application of fibrin tissue glue, mesh hepatorrhaphy, limited debridement resection and partial lobectomy. Extensive surgical techniques, such as formal hepatectomy or total hepatectomy with liver replacement, have been documented only in selected patients<sup>[4,5]</sup>. The surgical aim is control of hemorrhage, preservation of sufficient hepatic function and prevention of secondary complications. Liver transplantation has a limited, though very important, role in specific life threatening cases, when all the above mentioned methods fail to control bleeding or when liver failure ensues. We here describe our experience over the course of 11 years (1996 through 2007) with four cases of severe hepatic trauma requiring liver transplantation.

## CASE REPORT

### Case 1

A 25-year-old Caucasian male presented with hypovolemic shock to the Trauma Center due to a gunshot wound to the abdomen. The patient was severely acidotic, requiring intense fluid resuscitation. His Glasgow Coma Scale (GCS) score was 9/15 upon admission. The patient was initially managed according to the "advanced trauma life support" (ATLS) guidelines and very shortly thereafter was transferred to the operating theatre, due to signs of active bleeding. During an exploratory laparotomy, a trajectory wound affecting segments VII and VIII of the liver was documented, with active bleeding. A Pringle manoeuvre was initially used

along with repair of liver injury. The abdomen was then packed. On the first postoperative day the patient remained unstable and acidotic with further bleeding from the liver surface requiring re-exploration. Right hepatic artery ligation and packing were performed and the patient was transferred to the intensive care unit with a plan for a possible right hepatectomy. Liver and renal functions, however, deteriorated progressively, with persistent acidosis, prolonged prothrombin time, low fibrinogen level and acute renal failure. The patient was placed on the transplant list and two days later underwent an orthotopic liver transplant. A portal and systemic veno-venous bypass was utilized. During re-exploration of the abdomen, the native liver appeared necrotic; mass clamping of the hilum following by supra and infra-hepatic vena cava clamping was performed. The donor liver was implanted using a conventional method for the inferior vena cava. Postoperatively, the patient remained unstable, with progressive lactic acidosis, liver dysfunction and cerebral edema. Cerebral edema was managed with direct monitoring of intracranial pressure (ICP) and drainage of cerebrospinal fluid when decompression was necessary. Despite the above treatment and the complete support in the intensive care unit (ICU), with elevation of the patient's head by 25 degrees and maintenance of cerebral perfusion pressure by supporting systemic arterial pressure, reducing central venous pressure and avoiding agitation, the patient's condition gradually deteriorated and he died on the eleventh post-operative day.

#### Case 2

A 68-year-old white female developed a subcapsular hematoma of the right lobe of the liver due to blunt abdominal trauma. A right liver lobectomy was performed in another institution because of hematoma expansion. Liver function, however, continued to deteriorate after surgery. The patient was referred for further evaluation. GCS was 15/15 upon admission. Doppler ultrasound revealed main portal vein thrombosis. An exploratory laparotomy was performed to attempt portal vein thrombectomy through the right portal vein stump, but this was unsuccessful. The common bile duct was also found to be partially necrotic and external bile drain placement was performed. Due to postoperative liver failure, the patient was listed as a status 1 candidate for liver transplant. Transplantation was performed two days later using a veno-venous bypass, with caval reconstruction in a piggyback fashion. The patient recovered after prolonged hospitalization and remains on immunosuppression with tacrolimus and mycophenolate mophetil ten years after transplantation.

#### Case 3

A 58-year-old white female suffered a gunshot wound to the abdomen which resulted in a penetrating right lobe liver injury and a through-and-through injury of the duodenum. Suture ligation with packing and duodenal repair performed in another institution, were adequate to control initial bleeding. However, over the course of the

following two years she experienced multiple episodes of cholangitis due to biliary strictures and she required a choledoco-duodenostomy. Additionally, she went on to develop an arterio-venous fistula between the right hepatic artery and the right portal vein, which resulted in the development of significant portal hypertension. She experienced multiple episodes of gastrointestinal bleeding related to secondary biliary cirrhosis and the portal hypertension. An attempt to embolize the arterio-venous fistula failed and orthotopic liver transplantation was then considered. Her GCS score was 15/15. The native liver was cirrhotic with partial main portal vein thrombosis and a dilated hepatic artery. Under veno-venous bypass, a piggyback technique was used for the caval dissection and the recipient portal vein was thrombectomized. The spleno-portal junction was used for venous reconstruction. Due to intra-operative injury to the duodenum during the dissection, a Billroth II gastrojejunostomy was performed and a Roux-en-Y hepatico-jejunostomy was created for bile duct reconstruction. The patient recovered after an uneventful postoperative course. Explant pathology revealed cirrhotic liver with periportal abscess formation. Six months later, the patient developed cholestasis and hepatic artery thrombosis. He underwent re-transplantation and is alive and well 11 years later.

#### Case 4

A 35-year-old female was admitted to the casualty department with a gunshot injury. She presented in hypovolemic shock. Her GCS score upon admission was 9/15. After initial management according to ATLS guidelines she underwent exploratory laparotomy and segment II and III penetrating liver injuries with concomitant portal vein laceration were discovered. Longitudinal venorrhaphy of the portal vein, along with liver packing was performed without liver resection. She was then taken to angiography for embolization of the left hepatic artery. Two months later she developed liver gangrene with hepatic artery pseudo-aneurysm. Although septic, the patient was not excluded from evaluation for liver transplant due to the fact that the liver was primarily the source of infection. After removal of the native liver, the patient's hemodynamic status markedly improved. During transplant, the liver was fragile and the hilar structures were impossible to identify. The hilum was mass clamped and the structures isolated in a serial fashion after hepatectomy. The portal vein was dissected free to the confluence with the splenic vein because of the associated fibrosis and the native hepatic artery was suture ligated after removal of the pseudo-aneurysm. Transplant was performed in a piggyback fashion using a supra-celiac jump graft for the arterial inflow. The patient was discharged on postoperative trauma day 85 and is currently doing well at home nine years after transplantation.

## DISCUSSION

The overall mortality of hepatic trauma has declined

Table 1 Liver injury scale (AAST)

Grade		Description
I	Hematoma	Subcapsular, < 10% surface area
	Laceration	Capsular tear, < 1 cm parenchymal depth
II	Hematoma	Subcapsular, 10%-50% surface area: intraparenchymal, < 10 cm in diameter
	Laceration	1-3 cm parenchymal depth, < 10 cm in length
III	Hematoma	Subcapsular, > 50% surface area or expanding; ruptured subcapsular or intraparenchymal hematoma > 10 cm or expanding
	Laceration	> 3 cm parenchymal depth
IV	Laceration	Parenchymal disruption involving 25%-75% of hepatic lobe or 1-3 Couinaud's segments within a single lobe
V	Laceration	Parenchymal disruption involving > 75% of hepatic lobe or > 3 Couinaud's segments within a single lobe
	Vascular	Juxtahepatic venous injuries; i.e. retrohepatic vena cava/central major hepatic veins
VI	Vascular	Hepatic avulsion

Table 2 Type of injury, operations performed and patient outcome

Patient	Age	Injury	Primary operation	Indication for OLT	Re-transplant	Outcome
1	25	Gun shot wound right lobe	Packing, hepatic artery ligation	Acute liver failure	No	Died (cerebral edema)
2	68	Blunt trauma subcapsular hematoma right lobe	R lobectomy, failed portal vein thrombectomy	Portal thrombosis progressive liver failure	No	Discharged POD 45
3	58	Gun-shot wound right lobe, A-V fistula	Hepatorrhaphy, duodenal repair, embolization	Portal hypertension (A-V fistula), left portal vein thrombosis	Yes	Alive at 11 yr
4	35	Gun-shot wound left lateral lobe, hepatic artery pseudoaneurysm	Packing, embolization	Liver gangrene	No	Discharged POD 85

from 60% in the first half of the last century to approximately 6% today<sup>[6]</sup>. As many as 90% of patients with liver trauma are non-surgically managed with a remarkably high success rate, with only 10% requiring surgical intervention. The American Association for the Surgery of Trauma classified liver trauma degree and reported a liver injury scale (Table 1)<sup>[7]</sup>. The need for orthotopic liver transplantation (OLT) after liver trauma is clearly restricted. However, since the mortality rate of severe and complicated hepatic injuries remains significantly high, reaching 46% for grade IV and 80% for grade V hepatic injury<sup>[8,9]</sup>, OLT must be taken under consideration when all other methods to achieve hemostasis have failed or cannot be applied.

The indications for liver transplantation in the setting of severe and complicated liver trauma, reported in the literature are: (1) uncontrollable bleeding despite repeated previous surgical interventions; (2) postoperative evolution towards hepatic insufficiency (acute or progressive); (3) injuries of the portal vein that cannot be reconstructed<sup>[4,5,9-13]</sup>. In our series, the indications for OLT were the following: portal hypertension due to portal thrombosis and arterio-venous shunt; liver failure from massive injury; and portal thrombosis and liver gangrene with pseudo-aneurysm formation (Table 2). Sepsis was not an absolute contraindication in our study provided that the source of infection was limited to the liver. The above indications, such as fulminate liver failure without irreversible brain injury or extra hepatic sepsis, can also be used as criteria for prompt referral.

Esquivel<sup>[12]</sup> first reported the use of liver transplantation in two patients with progressive hepatic failure and uncontrollable bleeding. Ringe *et al.*<sup>[4]</sup> proposed a two-stage procedure (total hepatectomy and subsequent liver transplantation) in cases of severe hepatic trauma,

when all other conventional methods failed to control bleeding. In reviewing the literature between 1987 and 2005, we found 13 reported cases of patients who underwent OLT for the management of severe and life threatening hepatic trauma<sup>[4,5,10-14]</sup>. All of them had severe (grade IV or V) hepatic trauma according to the organ injury scale of the American Association for the Surgery of Trauma<sup>[7]</sup>, and were hemodynamically unstable upon admission.

Furthermore, all patients in these studies had undergone a primary or even secondary operation to control bleeding, before they were finally referred to a transplant center. All our patients had also been managed with more conservative surgical procedures to control bleeding prior to referral for OLT. In our cohort OLT was partly planned due to complications related to the initial surgical management in addition to the severity of the initial liver injury.

To our knowledge, this is the largest series from a single center reported so far. The postoperative mortality rate was 25% and involves a patient with significant hemodynamic instability. In agreement with previous reports, we feel that OLT might be contraindicated when patients do not show any signs of hemodynamic stabilization despite intensive medical support. In such cases, rapid clinical deterioration follows the transplant surgery, leading to multi organ failure and death<sup>[15]</sup>.

Although liver transplantation can be life saving in selective cases with severe liver injury, the lack of immediately available liver grafts combined with the inability to keep a patient in an anhepatic state, are the main causes of why such a few cases have been reported. Patients have to be listed as status 1 and donors with expanded criteria may also be accepted (size mismatch or steatotic livers). Reduced liver grafts have also been used

in the literature but primary non-function is possible<sup>[4]</sup>.

Preexisting sepsis and associated organ injuries are usual contraindications of liver transplantation for the management of severe hepatic trauma<sup>[16]</sup>. Bowel perforation with peritonitis, severe pancreatic trauma and loss of a large portion of the abdominal wall increase the mortality rate and preclude liver transplantation. A severe closed head injury with associated cerebral edema is also an absolute contraindication for orthotopic liver transplantation<sup>[17]</sup>. However, localized sepsis in the liver is a relative contraindication, since the septic focus can be eradicated by the transplant itself<sup>[10]</sup>.

It is worth noting that from a technical point of view: (1) veno-venous bypass is favored due to absence of portal hypertension; (2) mass clamping of the hilum is advocated in situations of difficult dissection or need for rapid liver removal and (3) a piggyback technique is facilitated by the absence of pre-existing portal hypertension. *Ex situ* liver surgery with subsequent auto-transplantation has been reported for the management of otherwise unresectable hepatobiliary malignancies, with good results<sup>[18,19]</sup>. It could be a viable alternative option for severe liver trauma, especially if a liver graft is not immediately available. In our series *ex vivo* liver repair was not performed. Patients with lethal injuries to the liver can survive only if they are referred to a transplantation center promptly as documented by our experience.

Liver transplantation is an acceptable surgical method for management of patients with severe traumatic liver injury, under the previously mentioned life-threatening conditions. Further reports are awaited, in order to support and expand the application of OLT in such devastating cases.

### INTRODUCTION

Guillain-Barré syndrome (GBS) is an acute polyradiculoneuropathy presenting, in its classical form, as a rapidly evolving symmetric and ascending motor paralysis with hypotonia and areflexia accompanied by an albuminocytologic cerebrospinal fluid with elevated protein level. In over two-third of cases, an infection precedes the onset of neuropathy by 1 to 3 wk. Cytomegalovirus and Epstein-Barr virus account for a large proportion of virus-triggered cases. There are also many reports linking acute hepatitis A, B, and C, with GBS. Hepatitis E is a frequent cause of acute hepatitis in Asia, the Middle East, North Africa and South or Central America. Locally acquired hepatitis E in individuals who have not travelled to endemic areas is, however, becoming an emerging problem in European countries<sup>[1,2]</sup>. We report a case of Guillain-Barré syndrome in a patient sporadically contaminated in a Western country. This is the third report of GBS in a patient with hepatitis E<sup>[3,4]</sup>, and the first occurring in a patient sporadically contaminated in a Western country. This is the first time, to our knowledge, that ganglioside molecular mimicry is suggested in the pathogenesis of GBS-associated with a hepatotropic virus.

### CASE REPORT

A 66-year-old male general practitioner who worked in an urban area consulted due to an acute elevation of liver function tests (AST: 1062 IU/L, ALT: 1813 IU/L,  $\gamma$ -GT: 90 IU/L). Serum bilirubin and alkaline phosphatases were normal. The liver tests had been carried out during a routine check-up and the patient was completely asymptomatic at presentation. Three months prior to consultation his blood tests were normal. The patient had not recently received any hepatotoxic or neurotoxic drugs or vaccinations, and had not travelled abroad during the last year.

### Abstract

Guillain-Barré syndrome (GBS) is often triggered by a preceding bacterial or viral infection. Occasionally, it has been observed in association with acute hepatitis A, B and C, and three cases have been previously described in India in which GBS was associated with acute hepatitis E. A molecular mimicry mechanism is supposed to be involved in the pathogenesis of GBS triggered by infectious agents, although the nature of the shared epitopes has not been characterized in most instances, including that in the case of hepatotropic viruses. We report a case of GBS following acute hepatitis E in a European individual. The presence of antiganglioside GM2 antibodies in this patient suggested molecular mimicry involving ganglioside GM2 in the pathogenesis of GBS associated with hepatitis E.

A few days later, the patient developed neurological symptoms, beginning with progressive loss of strength in both legs and paraesthesia of the lower limbs, mainly in the evening. Ataxia and neuropathic pain appeared a few days later. These symptoms led the patient to be hospitalized in the neurology department of our institution.

On physical examination, the patient was afebrile. Blood pressure was normal. Examination of heart, lungs and abdomen was unremarkable. There were no features of chronic liver disease and no signs of encephalopathy. The neurological examination showed a stance and gait ataxia with Romberg's sign and distal hypopallesthesia. Symmetric hyporeflexia in the upper limbs and areflexia in the lower limbs were associated with a severe proximal weakness prominent in the lower limbs.

Routine blood examination showed an AST of 68 IU/L, ALT of 443 IU/L and  $\gamma$ -GT of 94 IU/L. Renal function, electrolytes, glucose, and haematologic values were normal.

Cerebrospinal fluid analysis showed a major increase in protein concentration at 1722 mg/L, associated with a high level of immunoglobulin G, without an increased number of leucocytes. Electrophysiological examinations of the lower limbs demonstrated an acute demyelinating polyradiculoneuropathy.

These findings were consistent with a diagnosis of GBS. Of note, serum antiganglioside antibodies GM2 IgM were positive (Dotzen ganglio profile Ab IgG and IgM by Zentech®). Other antiganglioside antibodies were negative (GM1, GM3, GD1A and GD1B, GD3, GQ1B, GT1A and GT1B). Antibodies to Purkinje cells, to neurons and to myelin were negative. Sulfatide antibodies were negative.

A serological study showed IgM antibodies to hepatitis E (two assays were used: HEV IgM ELISA by Genelabs, with a sensitivity of 93% and a specificity of 99%; and Recomblot HEV IgM by Mikrogen, with a sensitivity of 85.7% and a specificity of 100% in non endemic regions<sup>[5]</sup>).

Hepatitis B surface antigen, antibodies to hepatitis C, IgM anti-HAV were absent. The following serological tests were also negative: antibodies to HIV, Varicella-Zoster virus and cytomegalovirus. Serology for campylobacter was negative. IgG were positive, with negative IgM, for Epstein-Barré virus, adenovirus and herpesvirus.

A diagnosis of GBS associated with acute hepatitis E was made. Intravenous immunoglobulins were given at a dose of 0.4 g/kg per day for five days. This treatment significantly improved the patient's neurological condition with progressive recovery of walking perimeter and a reduction in neuropathic pain. Liver enzymes completely normalized. Four months later, a near-complete neurological recovery was noted.

## DISCUSSION

Hepatitis E has become an emerging cause of acute hepatitis in western countries<sup>[1,2]</sup>. In most cases, acute

hepatitis E in these regions is of autochthonous origin<sup>[6]</sup>. The most frequent risk factors for hepatitis E, reported in a French survey, were water consumption from a personal water supply, uncooked shellfish consumption, and the recent acquisition of a pet pig<sup>[7]</sup>. None of these risk factors were present in our patient. It is possible that the contamination was related to the patient's profession as a general practitioner. It has been shown that the clinical evolution of hepatitis E can be different in patients infected sporadically compared with patients infected in endemic areas. In autochthonous cases, the mean age is higher and the prognosis is more severe with a higher rate of fulminant liver failure<sup>[8]</sup>.

Guillain-Barré syndrome is clinically defined as an acute inflammatory demyelinating polyradiculoneuropathy causing limb weakness<sup>[9]</sup>. Paralysis of muscles develops acutely over a period of days, but can take up to 4-6 wk. In most patients, after a brief plateau, improvement begins with a gradual resolution of paralysis which lasts from weeks to months. The syndrome is considered to be an autoimmune disease triggered by a preceding bacterial or viral infection. The most commonly identified triggering agents are *Campylobacter jejuni*, followed by cytomegalovirus, Epstein-Barr virus, and mycoplasma pneumonia. HIV, shigella, clostridium, haemophilus influenza, as well as hepatitis A, B and C were also identified as triggering agents<sup>[10]</sup>. In our case, the temporal association between acute hepatitis E and GBS strongly suggested a relation between both disorders.

The mechanism by which infection can trigger GBS is not completely understood. It is thought that the immune system mistakenly attacks myelin or axons by a molecular mimicry mechanism (in which the host generates an immune response against an infectious organism that shares epitopes with the host's peripheral nerves)<sup>[11]</sup>. The nature of the epitope, although still uncertain, is likely to be a glycolipid. The most attractive candidate targets are gangliosides, which are present in nodal and internodal membranes of nerve fibres<sup>[12]</sup>. Ganglioside antibodies may perturb nerve conduction and, in a complement-dependant fashion, disrupt the molecular topography of nodal and paranodal proteins and induce motor axonal degeneration<sup>[13]</sup>. It is postulated that infected cells can produce ganglioside-like epitopes that trigger the immune response. This mechanism of molecular mimicry has been observed for *Campylobacter jejuni* with the implication of several gangliosides (GM1, GD1B, and GQ1B)<sup>[14]</sup>. The implication of antiganglioside GM2 antibodies in the pathogenesis of GBS related to CMV has been described<sup>[15]</sup>. It has been demonstrated that CMV-infected fibroblasts express ganglioside-like epitopes that specifically recognize anti-GM2 antibodies<sup>[16]</sup>. These results suggest that, in CMV-infected GBS patients, infected cells with CMV can express epitopes inducing an immune response against gangliosides.

For GBS related to hepatitis A, B, C, or E, no homologous epitopes to a component of the peripheral nerves have been described to date. We report the first

description of the presence of antiganglioside GM2 antibodies in GBS associated with a hepatotropic virus, suggesting possible molecular mimicry involving gangliosides. This possible relationship should be further documented in the very rare cases of GBS associated with viral hepatitis to confirm the mechanism.

## Abstract

Schistosomal appendicitis is very rare in developed countries like the USA, Europe, and Japan. The author reviewed 311 pathologic archival specimens of vermiform appendix over the past 10 years. One case of schistosomal appendicitis was recognized. Therefore, the incidence of this disease was 0.32% in all appendices surgically resected in our hospital. The patient was a 41-year-old woman presenting with lower abdominal pain. She was a sailor traveling to many countries including endemic areas. Physical examination, laboratory data, and imaging modalities suggested an acute appendicitis, and appendectomy was performed under the diagnosis of ordinary appendicitis. Histologically, numerous schistosomal eggs were present in the vasculatures throughout the appendiceal walls. Some of the eggs were calcified. Stromal foreign body reaction was also recognized. The appendicitis was phlegmonous consisting of severe infiltrations of neutrophils and eosinophils. Acute serositis was also noted. Examination of feces revealed numerous eggs of *Schistosoma mansoni*. Clinicians should be aware of schistosomal appendicitis.

## INTRODUCTION

Schistosomiasis is caused by *Schistosoma mansoni* or *Schistosoma japonica*, and is a disease of waterborne trematode infestation. Schistosomal appendicitis is very rare in developed countries like the USA, Europe, and Japan<sup>[1-5]</sup>. However, it is prevalent in endemic areas such as Africa and South Asia<sup>[1-5]</sup>. In Japan, Yamanashi and Fukuoka prefectures are endemic areas. However, the incidence and pathological features of schistosomal appendicitis are not known. Therefore, the author herein reports the incidence and pathological features of this disease in Japan.

## CASE REPORT

The author re-examined 311 pathologic archival specimens of vermiform appendix over the past 10 years. Of these specimens, one case of schistosomal appendicitis was recognized. Therefore, the incidence of this disease was 0.32% of all appendices surgically resected in our hospital. The specimen was from a 41-year-old woman, who was a sailor traveling to many countries including endemic areas, who had complained of lower abdominal pain. Physical examination was suggestive of acute appendicitis. Blood laboratory data showed leukocytosis. Imaging modalities including CT indicated an appendiceal swelling. An appendectomy was performed under the clinical diagnosis of ordinary appendicitis.

Histologically, numerous schistosomal eggs were present in the vasculatures throughout the appendiceal walls (Figure 1A). This finding was unexpected. Some of the eggs were calcified (Figure 1B). Stromal foreign body reaction was also recognized (Figure 1B). Severe infiltrations of neutrophils and eosinophils were recognized (Figure 1C). Acute serositis was also noted (Figure 1A). Examination of feces revealed numerous eggs of *Schistosoma mansoni*. The involvement of other organs was unclear.

## DISCUSSION

Schistosomiasis is a waterborne parasitic disease caused by *Schistosoma mansoni* and *Schistosoma japonica*. This

**Figure 1** Histologic findings of schistosomal appendicitis. A: Low power view of the appendiceal walls in schistosomal appendicitis. Acute inflammation is recognized throughout the walls. Schistosomal eggs are seen in the mucosa and muscular layer. The serosa shows acute serositis (right). HE,  $\times 40$ ; B: Schistosomal eggs in the mucosa. Foreign body granulomatous reaction is recognized. Some eggs show calcification. HE,  $\times 200$ ; C: Schistosomal eggs in the subserosa. The eggs were located within vasculatures. Severe infiltrations of neutrophils and hemorrhage are recognized. HE,  $\times 200$ .

disease is endemic and particularly prevalent in Africa and South Asia<sup>[1-5]</sup>. Our hospital is located in a non-endemic area. Schistosomiasis is a disease of intestine and liver, where the parasite resides and produces eggs in the vasculatures.

The incidence of schistosomal appendicitis is unclear in Japan. The present study revealed that the incidence was 0.32% of all vermiform appendices resected.

The present case is pathologically typical of schistosomal appendicitis, and feces examination strongly supported the diagnosis. Clinically, schistosomal appendicitis was not considered, and clinicians were first informed after pathologic examination. The present patient was a sailor traveling to many countries including endemic areas. Thus, clinicians should be aware of schistosomal appendicitis.

It is uncertain whether schistosomiasis of the vermiform appendix induces acute appendicitis<sup>[1]</sup>. However, it is now thought that appendiceal schistosomiasis may cause acute appendicitis. This may be due to ischemic changes caused by egg emboli. This situation may diminish mucosal immunity, thus leading to bacterial infection.

In endemic areas like Nigeria, Badmos *et al*<sup>[4]</sup> reported that appendices with schistosomiasis were present in 35/843 (4.2%) of surgically resected cases. Of these 35 positive cases, 23 (65.7%) were associated with acute appendicitis, while the remaining 12 cases (34.3%) were not associated with inflammation. Thus,

the presence of the parasite does not always give rise to acute appendicitis. In developed countries like the USA, Nandipati *et al*<sup>[5]</sup> reported that schistosomal appendicitis was found in 3/1690 (0.2%) of surgically resected cases. All three cases were African Americans<sup>[5]</sup>. Thus, in developed countries, schistosomal appendicitis is preferentially found in travelers or in an endemic area population.

In summary, the incidence of schistosomal appendicitis is 0.34% in Japan. The present patient with this disease was a sailor traveling to many countries. Thus, clinicians should be aware of schistosomal appendicitis.

### Abstract

Of patients with severe exacerbation of chronic hepatitis B accompanied by jaundice and coagulopathy, 20%-30% have a fatal outcome. In this report, we describe 2 cases of severe exacerbation of chronic hepatitis B with jaundice and coagulopathy who were successfully treated with a combination of entecavir and corticosteroid. In both cases, rapid reductions in serum hepatitis B virus (HBV)-DNA levels were observed, and corticosteroid was stopped after serum HBV-DNA levels became undetectable. Entecavir treatment was continued. Generally, entecavir treatment reduced serum HBV-DNA levels rapidly, although the improvement in liver function was delayed by a few weeks. During this time lag, liver cell injury continued and the disease progressed. Corticosteroid suppressed the excessive host immune response and was useful for stopping progressive deterioration. A combination of entecavir and early-phase corticosteroid may be a useful treatment in severe exacerbation of chronic hepatitis B.

### INTRODUCTION

An estimated 400 million people worldwide have chronic hepatitis B virus (HBV) infection, and more than 500 000 people die every year from complications of HBV-related chronic liver disease<sup>[1]</sup>. In patients chronically infected with HBV, acute exacerbations are clinically important because they can have severe or even fatal consequences<sup>[2]</sup>. An estimated 10%-30% of hepatitis B carriers experience acute exacerbation each year<sup>[3]</sup>. Hepatitis B e antigen (HBeAg) seroconversion and mortality occur in 2.7% and 0.7% of patients with acute exacerbation, respectively<sup>[4]</sup>. On the other hand, mortality occurs in 20%-30% of cases with severe exacerbation accompanied by jaundice and coagulopathy<sup>[5,6]</sup>.

In the past decade, lamivudine (LMV) has revolutionized the treatment of chronic hepatitis B. Treatment with LMV significantly decreases the rate of hepatic decompensation and prevents the development of hepatocellular carcinoma<sup>[7]</sup>. On the other hand, LMV monotherapy confers no significant protection against rapid progression to hepatic failure in severe exacerbation of chronic hepatitis B, although LMV results in long-term benefits<sup>[5]</sup>. Furthermore, viral resistance, which is usually followed by a loss of clinical response, a rise in aminotransferase levels and worsening of hepatic histology, is related to mutations in the tyrosine-methionine-aspartate-aspartate (YMDD) motif which

occurs in 70%-80% of patients treated continuously for 4-5 years<sup>[8]</sup>. Recently, the early introduction of high-dose corticosteroid was reported to improve the short-term prognosis of patients with severe exacerbation of chronic hepatitis B<sup>[9]</sup>.

In this report, we describe 2 cases with severe exacerbation of chronic hepatitis B successfully treated with a combination of entecavir (ETV) and corticosteroid.

## CASE REPORT

### Case 1

A 33-year-old Japanese man was admitted to our hospital with general fatigue. He had been diagnosed as a carrier of HBV but had never received treatment. His family history included chronic hepatitis B in his late mother, who had died of severe exacerbation of the disease. On physical examination at admission, he was conscious and the bulbar conjunctiva was not icteric. Neither ascites nor pretibial edema was noted. Laboratory data on admission were as follows: bilirubin, 19 mg/L; aspartate aminotransferase, 698 IU/L; alanine aminotransferase, 756 IU/L; albumin, 33 g/L; and prothrombin activity, 47.7%. He was positive for both hepatitis B surface antigen (HBsAg) and HBeAg, and his serum HBV-DNA level measured by real-time quantitative polymerase chain reaction (TaqMan PCR, Roche Diagnostics) was 2.6 LGE/mL. He was diagnosed with severe exacerbation of chronic hepatitis B, and oral ETV treatment (0.5 mg/d) was initiated. On his fifth day of hospitalization, prednisolone (30 mg/d) was added. At 6 wk, his serum transaminase level was normal, after which the dose of prednisolone was tapered. At 12 wk, his serum HBV-DNA level was 3.3 LGE/mL and prednisolone was stopped. Since then, his transaminase level has remained normal (Figure 1).

### Case 2

A 44-year-old Japanese woman was admitted to our hospital with general fatigue and anorexia. She had been diagnosed as a carrier of HBV but had never received treatment. Her family history included a father who was a carrier of HBV. On physical examination at admission, she was conscious and her bulbar conjunctiva was icteric. Neither ascites nor pretibial edema was noted. Laboratory data on admission were as follows: bilirubin, 96 mg/L; aspartate aminotransferase, 1389 IU/L; alanine aminotransferase, 573 IU/L; albumin, 31 g/L; and prothrombin activity, 22.7%. She was positive for both HBsAg and HBeAg, and her serum HBV-DNA level measured by transcription-mediated amplification assay (Roche Diagnostics) was 5.3 LGE/mL. She was diagnosed with severe exacerbation of chronic hepatitis B. A combination treatment of oral ETV (0.5 mg/d) and intravenous methylprednisolone (250 mg/d) was immediately started. On her sixth day of hospitalization, intravenous methylprednisolone was changed to oral prednisolone (50 mg/d). At 8 wk, her serum transaminase level was normal and her serum bilirubin levels and prothrombin activity were improved to

**Figure 1 Patient clinical course.** ALT: Alanine aminotransferase; PT: Prothrombin activity; T. Bil: Total bilirubin; HBV DNA: Hepatitis B virus DNA. At 6 wk, his serum transaminase level was normalized. At 12 wk, his serum HBV-DNA level became 3.3 LGE/mL and prednisolone was stopped.

**Figure 2 Patient clinical course.** ALT: Alanine aminotransferase; PT: Prothrombin activity; T. Bil: Total bilirubin; HBV DNA: Hepatitis B virus DNA. At 8 wk, her serum transaminase level was normalized. At 15 wk, her serum HBV-DNA level became undetectable and the prednisolone was stopped.

68.8% and 29 mg/L, respectively. Subsequently, the dose of prednisolone was tapered. At 15 wk, her serum HBV-DNA level became undetectable and prednisolone was stopped. One year later, her ETV treatment has continued, and her serum HBV-DNA level has continued to be undetectable (Figure 2).

## DISCUSSION

ETV suppresses HBV replication significantly better than LMV. The mean reduction in serum HBV-DNA levels from baseline to week 48 is reported to be 6.9 log in HBeAg-positive patients and 5.0 log in HBeAg-

negative patients<sup>[10,11]</sup>. Furthermore, ETV shows a lower frequency of virologic rebound (2% in the first year of drug administration) compared with LMV. Thus, ETV is considered a first-choice therapy for patients with chronic hepatitis B not previously treated with a nucleoside analogue. However, for patients with severe exacerbation of chronic hepatitis B, treatment during the first 2 wk determines their prognosis<sup>[9]</sup>. The liver cell injury caused by HBV infection is mediated mainly by the response of CD8+ cytotoxic T lymphocytes to small epitopes of HBV proteins, especially the hepatitis B core antigen, present on the surface of liver cells<sup>[12]</sup>. ETV treatment reduces serum HBV-DNA levels rapidly, although the improvement in liver function is delayed by a few weeks. During this time lag, liver cell injury continues and the disease progresses. Corticosteroid suppresses the excessive host immune response and is useful for stopping progressive deterioration. On the other hand, patients not treated with any antiviral drugs show a subsequent rebound increase in serum transaminase levels 4 to 10 wk after withdrawal of corticosteroid<sup>[13]</sup>. Thus, we consider that a combination of ETV and early-phase corticosteroid may be reasonable for improving prognosis in severe exacerbation of chronic hepatitis B.

Corticosteroid has been reported to directly stimulate HBV replication through specific glucocorticoid receptors in the HBV genome in cultured human hepatoma cells<sup>[14]</sup>. Clinically, immunosuppressive treatment has been indicated to have a potentiating effect on HBV replication in patients with chronic active hepatitis B<sup>[15]</sup>. Furthermore, corticosteroid has been reported to delay the normalization of serum transaminase levels<sup>[16]</sup>. However, in this study, both our patients showed rapid reductions in serum HBV-DNA levels despite corticosteroid treatment. We consider that this may be attributable to the antiviral effect of ETV, which may be strong enough to overcome HBV replication activated by corticosteroid treatment.

In this study, 0.5 mg/kg or more of prednisolone was administered daily. When the patient showed a trend toward remission in serum transaminase levels, the dose of prednisolone was tapered. After serum HBV-DNA level became undetectable, prednisolone was stopped. In Japan, ETV is administered at a dose of 0.5 mg daily in order to treat chronic HBV infection in accordance with Japanese national health insurance rules. However, further study is required in order to confirm adequate doses of prednisolone and ETV in severe exacerbation of chronic hepatitis B.

In conclusion, the combination treatment of ETV and corticosteroid may improve the prognosis in severe exacerbation of chronic hepatitis B. However, this is a case report; prospective studies of large study populations are needed in order to confirm the effectiveness of this combination treatment.

### Abstract

Neoplastic needle track seeding following percutaneous radiofrequency ablation (RFA) of secondary liver tumors is exceedingly rare. Reports on cutaneous tumor seeding after percutaneous RFA for colorectal liver metastasis are even rarer in the literature. Here we report a case of a 46-year-old female who developed an ulcerating skin lesion along the needle track of a previous percutaneous RFA site around 6 mo after the procedure. The previous RFA was performed by the LeVeen® needle for a secondary liver tumor from a primary rectal cancer. The diagnosis of secondary skin metastasis was confirmed by fine needle aspiration cytology. The lesion was successfully treated with wide local excision. We believe that tumor seeding after percutaneous RFA in our patient was possibly related to its unfavorable subcapsular location and the use of an expansion-type needle. Hence, prophylactic ablation of the needle track should be performed whenever possible. Otherwise, alternative routes of tumor ablation such as laparoscopic or open RFA should be considered.

### INTRODUCTION

Radiofrequency ablation (RFA) is a well established local ablative treatment for primary or secondary hepatic neoplasms. Despite a relatively low complication rate, the percutaneous application of RFA carries a potential risk of needle track seeding. As reported by a recent systematic review<sup>[1]</sup>, the seeding risk after percutaneous RFA for hepatocellular carcinoma (HCC) is around 0.6%. However, such a seeding risk in secondary liver tumors is less well defined. Reports on tumor seeding after percutaneous RFA for colorectal liver metastasis are rare. The following report illustrates a patient with cutaneous tumor seeding after percutaneous RFA for a small colorectal liver metastasis.

### CASE REPORT

A 46-year-old female, who had no other major medical illness, was referred to our unit for stage IV rectal cancer with liver metastasis after receiving laparoscopic anterior resection of the primary rectal tumor in the private sector. Preoperative staging computed tomography (CT) of the abdomen showed no distant metastasis. The operation for the primary rectal tumor was uneventful. However, a suspicious liver lesion was incidentally found on the surface of the liver intra-operatively and was biopsied. Histopathology revealed a T3N2 well-differentiated adenocarcinoma of the rectum and a metastatic adenocarcinoma of the liver. A postoperative re-staging CT scan identified a 1.7 cm solitary subcapsular liver metastasis at segment 4 of the liver (Figure 1). A

Figure 2 Percutaneous radiofrequency ablation by LeVeen® needle.

subsequent positron emission tomography scan excluded additional distant metastasis. Unfortunately, the patient refused curative hepatic resection. Hence, a single session of CT-guided percutaneous RFA of the liver lesion using a 3 cm 17-gauge LeVeen® needle electrode (Super-slim, Boston Scientific, United States) with a single puncture was performed (Figure 2). Thermal ablation of the needle tract was not done in this case. She was subsequently put on a complete course of oxaliplatin-based chemotherapy.

Six months after RFA, she presented with a 2 cm ulcerating skin nodule at the previous RFA puncture site (Figure 3). Fine needle aspiration cytology of the nodule confirmed a metastatic adenocarcinoma of primary colorectal origin. At the same time, a CT scan revealed multiple simultaneous recurrences at the left liver. Left hepatectomy for the liver lesions and wide local excision of the cutaneous tumor were performed. Multiple suspicious peritoneal deposits were incidentally identified intra-operatively and they were all resected. Final histopathology revealed metastatic disease in the

Figure 3 Ulcerating skin nodule. A: Cutaneous neoplastic seeding 6 mo after RFA. B: A closer view.

liver, skin and peritoneum. She then received further courses of palliative chemotherapy in view of likely recurrence. In the subsequent follow-up period, no cutaneous recurrence was identified at the RFA needle track. However, she developed progressive disease with lung metastasis and carcinomatosis. The patient finally died around 5 mo after the second operation.

## DISCUSSION

Neoplastic seeding is an uncommon but well-recognized complication following percutaneous diagnostic and therapeutic procedures for primary liver cancer. For diagnostic percutaneous biopsy, the risk of neoplastic seeding was approximately 2.2%<sup>[1]</sup>. As for therapeutic RFA of HCC, initial results from a small-scale Spanish study suggested an alarmingly high risk of 12.5%<sup>[2]</sup>. A recent large-scale multicenter study by Livraghi *et al*<sup>[3]</sup> in contrast identified a substantially lower risk of only 0.9%. As highlighted by a recent systematic review<sup>[1]</sup>, such a seeding risk for HCC was definitely lower with

an overall median risk of only 0.6%. For secondary liver tumors, objective evidence on the seeding risk following percutaneous RFA is lacking. In the English literature, there were only two related case reports identified<sup>[4,5]</sup> (Table 1).

Several associated risk factors have been identified for neoplastic seeding following RFA for HCC, notably subcapsular tumor location<sup>[2,6]</sup>, poor tumor differentiation grade<sup>[2]</sup>, multiple RFA sessions<sup>[6]</sup>, multiple electrode placements<sup>[6]</sup> and history of previous biopsy<sup>[6]</sup>. In an Italian study by Latteri *et al*<sup>[7]</sup>, the risk of neoplastic seeding after open RFA was virtually zero but the risk was as high as 1.4% after percutaneous RFA. Remarkably, most of these identified factors were based on seeding risk for HCC. As for our patient, tumor seeding in the RFA needle track was possibly related to its unfavorable subcapsular location and the use of an expansion-type electrode. The previous use of laparoscopic biopsy in such a subcapsular tumor was probably a major detrimental factor related to its peritoneal dissemination. Nevertheless, potential risk factors of neoplastic seeding solely for secondary liver tumors were still undefined. To evaluate the seeding risk, a larger-scale prospective cohort study for secondary liver tumors is required. However, these sorts of studies are practically difficult to conduct because of the rare occurrence.

To prevent neoplastic seeding, some investigators advocated the application of thermocoagulative ablation along the needle track while withdrawing the RFA needle<sup>[8]</sup>. However, this ablative technique may not be technically feasible in cases of subcapsular lesions as in our case. With regard to treatment, surgical excision with a wide margin seems to be the most justifiable option. Alternatively, different novel techniques had been described. Shibata *et al*<sup>[9]</sup> successfully treated a chest wall neoplastic seeding from HCC by transarterial embolization of the feeding vessel. Espinoza *et al*<sup>[10]</sup> suggested the use of RFA again for ablating the metastatic seeding tract as treatment.

To conclude, despite its rare occurrence, needle track seeding is a real hazard following percutaneous RFA for secondary liver tumors. Prophylactic ablation of the

needle track should be performed whenever possible for high risk patients. Otherwise, alternative routes of tumor ablation like laparoscopic or open RFA should be considered.

### Abstract

Arterioportal fistula (APF) is a rare cause of portal hypertension and may lead to death. APF can be congenital, post-traumatic, iatrogenic (transhepatic intervention or biopsy) or related to ruptured hepatic artery aneurysms. Congenital APF is a rare condition even in children. In this case report, we describe a 73-year-old woman diagnosed as APF by ultrasonography, computed tomography, and hepatic artery selective arteriography. The fistula was embolized twice but failed, and she still suffered from alimentary tract hemorrhage. Then, selective arteriography of the hepatic artery was performed again and venae coronariae ventriculi and short gastric vein were embolized. During the 2-year follow-up, the patient remained asymptomatic. We therefore argue that embolization of venae coronariae ventriculi and short gastric vein may be an effective treatment modality for intrahepatic APF with severe upper gastrointestinal bleeding.

### INTRODUCTION

Arterioportal fistula (APF) is a rare cause of portal hypertension and may lead to death. APF can be congenital, post-traumatic, iatrogenic (transhepatic intervention or biopsy) or related to ruptured hepatic artery aneurysms. Congenital APF is a rare condition in children. To date, only 18 cases of congenital intrahepatic APF have been reported<sup>[1]</sup>. Most of them were found in their infancy, in which the oldest one was a 13-year-old boy<sup>[1]</sup>. We report here the incidental findings of a large and solitary congenital APF in a 73-year-old woman. Digital subtraction angiography revealed a stubby fistular vessel between the left hepatic artery and portal vein of the patient. Transcatheter closure of APF was performed three times using multiple coils.

### CASE REPORT

A 73-year-old woman was admitted to our hospital with complaints of ascites, splenomegaly, abdominal distension and pain. She had been asymptomatic before and denied any medication history as well as history of cirrhosis and hepatic neoplasms, blunt or penetrating trauma, percutaneous liver biopsy, transhepatic cholangiography, gastrectomy and biliary surgery. Her mother and aunt died of ascites and gastrointestinal bleeding in their thirties, about 60 years ago. There was no history of chronic hepatic disease in her family.

A recent physical examination revealed ascites, splenomegaly, and a subcutaneous varicose vein in the abdominal wall. Her laboratory results are listed in Table 1.

Values for other biochemical tests were within the normal ranges. All viral markers for hepatitis including

Table 1 Laboratory results

Item	Results

Platelet count	$131 \times 10^9/L$
Prothrombin time	14 s (normal value: 9.8-15.0 s)
Serum ALT	37 IU/L (normal value: 3-40 IU/L)
Serum AST	62 IU/L (normal value: 3-40 IU/L)
Serum GGT	102 IU/L (normal value: 0-54 IU/L)
Serum ALP	141 IU/L (normal value: 30-115 IU/L)
Total bilirubin	10 $\mu\text{mol/L}$ (normal value < 22 $\mu\text{mol/L}$ )
Direct bilirubin	4 $\mu\text{mol/L}$ (normal value < 7 $\mu\text{mol/L}$ )
Albumin	39.7 g/L

hepatitis A-E viruses, autoantibodies (antinuclear, anti-mitochondrial, anti-smooth-muscle, anti-liver-kidney microsomal enzymes, anti-soluble liver antigen, and anti-mitochondrial antibody) were also negative. Serum alpha-fetoprotein level was normal. Upper gastrointestinal endoscopy revealed non-bleeding esophageal and fundus varices, but mild portal hypertensive gastropathy.

Real-time sonography of the liver demonstrated an anechoic lesion in continuity with a normal width of the left portal vein (LPV) branch, which was assumed to be an intrahepatic APF. Reverse flow in the left portal vein was observed on color Doppler sonography (Figure 1), and high-velocity flow at 1.31 m/s (Figure 2) was observed on spectral Doppler sonography. The distal portion of the LPV showed no enlargement but turbulent flow. The left hepatic artery branch was dilated, with a diameter of 5 mm. Color speckling (mosaic pattern), present in hepatic tissues adjacent to the aneurysmal lesion, was considered a typical sign of arteriovenous fistula.

Contrast-enhanced computed tomography (CT) also confirmed the diagnosis of intrahepatic APF. A high density of the LPV was observed with a CT value of 220.6 Hounsfield units (HU) (Figure 3A) at the arterial phase, and a CT value of 159.7 HU (Figure 3B) at the portal venous phase, close to the CT values of 226.2 HU (Figure 3A) and 168.0 HU (Figure 3B), respectively, for the abdominal aorta at the same phase.

After a comprehensive analysis, a diagnosis of portal hypertension secondary to hepatic portal fistula was established.

Selective digital subtraction angiography of the hepatic artery was performed, which revealed a large left hepatic artery-left portal vein fistula (Figure 4A). The aneurysmal lesion was embolized, and angiography CT and sonography showed no shunt after operation (Figure 4B).

Three months after operation, the patients had severe upper gastrointestinal bleeding from esophageal and fundus varices. She received another transcatheter closure, with no recurrence of bleeding. She underwent somatostatin infusion and conservative treatment but hemorrhage recurred 1 mo later. She refused any surgical intervention. Selective arteriography of the hepatic

Figure 2 PW Doppler sonography of the portal vein aneurysm showing a high speed blood flow at 1.31 m/s in the aneurysm.

artery was performed again with her venae coronariae ventriculi and short gastric vein embolized (Figure 5A and B). During the 2-year follow-up, the patient remained asymptomatic.

## DISCUSSION

Congenital APF is a rare cause of severe portal hypertension, with challenging diagnostic and therapeutic implications<sup>[2,3]</sup>. Upon physical examination, a characteristic bruit can be heard over the right upper quadrant. Liver function tests are usually normal. Radiologic evaluation of APF is usually performed with color Doppler ultrasonography (US), helical CT, and magnetic resonance imaging. Arterial and direct portography as well as splenoportography may also be used. Doppler ultrasound is the best way in making the decisive diagnosis and helpful in the subsequent evaluation of these patients<sup>[4,5]</sup>. Angiography is the most useful test because it can not only identify multiple APFs but also be therapeutic. These APFs are mostly intrahepatic and represent 12% of the cases developmental intrahepatic shunts<sup>[3]</sup>. The presence of a patent ductus venosus is protective in the initial postnatal period. Symptoms usually develop after 1 mo of age, and these children are often investigated for generalized abdominal findings and are later noted to

**Figure 5** Angiography showing collateral circulation in fistula after embolism (A) and no more shunt after embolism (B).

develop symptoms related to portal hypertension<sup>[2,3]</sup>. APF often presents in conjunction with major gastrointestinal tract bleeding and should be differentiated between small peripheral intrahepatic APF (type 1) and large central APF (type 2), whereas diffuse congenital intrahepatic APF that is difficult to manage is defined as typed 3<sup>[6]</sup>. A few cases of congenital fistula from the hepatic artery to the

portal vein have been reported<sup>[4]</sup>, but this abnormality is not a common cause of portal hypertension. Increased blood flow in the portal system is considered to be the cause of hyperkinetic portal hypertension in patients with hepatoportal arteriovenous fistula. Arterioportal venous fistula can be treated with percutaneous arterial occlusion<sup>[7]</sup>. Ligation of the hepatic artery has been proved

to be successful in reported cases<sup>[8]</sup>. Recently, transcatheter arterial embolization has been attempted as the first choice, because of its low invasiveness and success in some cases. Recanalization of the embolized artery in some cases has also been reported<sup>[9,10]</sup>. Therefore, some of the cases can undergo hepatic resection, including fistula.

To date, in the literature, the oldest congenital APF case was a 13-year-old child<sup>[1]</sup>. We report here a 73-year-old woman. This patient had no history of cirrhosis and hepatic neoplasms, blunt or penetrating trauma, percutaneous liver biopsy, transhepatic cholangiography, gastrectomy, and biliary surgery, and was finally diagnosed having a congenital APF. Initially, the APF was demonstrated by contrast-enhanced CT and the fistula was subsequently identified by color Doppler imaging and angiography. The case was classified as type 3.

No more shunt was found after coil occlusion. Notably, esophageal varices and ascites disappeared after embolization. However, color Doppler sonography still displayed the shunt 3 mo after operation.

The aneurysmal lesion was embolized twice, but transcatheter closure did not work well. After undergoing embolization twice, she suffered alimentary tract hemorrhage again, suggesting that transcatheter closure is not so effective against a large APF. The reason why embolization failed was because of too much collateral circulation. The purpose of embolizing the venae coronariae ventriculi and short gastric vein is to cut off the collateral circulation, because it can effectively control hemostasis. Since it cannot cure the disease, the treatment modality is radical surgery.

In conclusion, this case suggests that interventional radiology plays an important role in the treatment of congenital APF with severe upper gastrointestinal bleeding caused by esophageal and fundus varices.

Liver function test, abdomen ultrasonography and gastroscopy should be performed regularly during the follow-up.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27, 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: Introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Leader Frontier: Comment on excitement and existing problems of core fields, and offer suggestions for the future research; (3) Topic Highlight: Experts in gastroenterology and hepatology to focus on certain individual hot topics and try to provide answers to the clinical questions on the topics; (4) Observation: Which updates the development of old and new questions, highlights unsolved questions, and provides strategies on how to solve the questions; (5) Guidelines for Basic Research: Which provides Guidelines for basic research; (6) Guidelines for Clinical Practice: Which provides guidelines for clinical diagnosis and treatment; (7) Review Articles: Summarize the representative progress in core scientific disciplines, comment on the research status, and make suggestions for the future work; (8) Original Articles: Originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: Briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: Report a rare or typical case; (11) Letters to the Editor: Discuss and make reply to the contributions published in *WJG*, or introduce and comment on a controversial issue of general interest; (12) Book Reviews: Introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: Guidelines or common understanding for gastroenterology and hepatology from international academic committee.

ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Electronic journal (list all authors)

- 15 Morse SS. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) =  $8.6 \pm 24.5$   $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### INTRODUCTION

Genomic studies have demonstrated that many portions of the human genome do not encode conventional protein-coding genes but encode biologically active non-coding RNA species<sup>[1]</sup>. With the development of small RNA interface techniques over the past decade, it becomes clear that many small RNA molecules could regulate gene and protein expression. One class of such small non-coding RNAs is microRNAs (miRNAs), a group of regulatory RNAs of 19-22 nucleotides involved in control of gene expression at the post-transcriptional level<sup>[2]</sup>. Recent studies suggest that miRNAs are involved in regulating cell fate (cell death and proliferation), initiation and progression of human cancer, developmental timing, and inflammatory responses<sup>[3-6]</sup>. Modulation of miRNA expression *in vitro* as well as *in vivo* has revealed an important role of miRNAs in liver functions. In this review, we appraise the recent findings on miRNAs in liver physiology and disease. We will also discuss the development and use of miRNA antagonists (antagomirs) to target miRNAs *in vivo*, which may translate into novel therapeutic strategies for liver disease in the future.

### Abstract

MicroRNAs (miRNAs) are an emerging class of highly conserved non-coding small RNAs that regulate gene expression at the post-transcriptional level. It is now clear that miRNAs can potentially regulate every aspect of cellular activity, including differentiation and development, metabolism, proliferation, apoptotic cell death, viral infection and tumorigenesis. Recent studies provide clear evidence that miRNAs are abundant in the liver and modulate a diverse spectrum of liver functions. Deregulation of miRNA expression may be a key pathogenetic factor in many liver diseases including viral hepatitis, hepatocellular cancer and polycystic liver diseases. A clearer understanding of the mechanisms involved in miRNA deregulation will offer new diagnostic and therapeutic strategies to treat liver diseases. Moreover, better understanding of miRNA regulation and identification of tissue-specific miRNA targets employing transgenic/knockout models and/or modulating oligonucleotides will improve our knowledge of liver physiology and diseases.

### miRNAs ARE REGULATORY NON-CODING SMALL RNAs IMPORTANT TO POST-TRANSCRIPTIONAL GENE REGULATION

miRNAs are endogenous, single-stranded RNA molecules consisting of approximately 22 non-coding nucleotides that regulate target genes<sup>[2,3]</sup>. miRNA molecules have been identified in over 80 species including those encoded by viral genomes. There are approximately 500-1000 different mammalian miRNA genes; a complete list and details about the nomenclature of the miRNAs can be viewed at Sanger mirBase 10.1 (<http://microrna.sanger.ac.uk/sequences/>)<sup>[7]</sup>. Up to 600 miRNAs have been identified in humans<sup>[2,3]</sup>.

Most miRNAs are generated by RNA polymerase

**Figure 1** miRNA biogenesis and function in animal cells. Animal genomes have specific genes that encode miRNAs. Primary miRNA transcripts (pri-miRNAs) are processed into precursor miRNA (pre-miRNAs) stem-loops of approximately 60 nucleotides in length by the nuclear RNase III enzyme Drosha. These pre-miRNAs are transported to the cytoplasm via exportin-5 and are further processed by the ribonuclease Dicer. Mature miRNAs are then incorporated in the RNA-induced silencing complex (RISC) and interfere with the regulation of mRNA translation by targeting mRNAs resulting in mRNA degradation or translational repression.

as long primary transcripts (pri-miRNAs) that form a stem-loop structure<sup>[8-11]</sup>. In the nucleus, pri-miRNAs are processed into 70-100 nucleotide-long hairpin pre-miRNAs by the RNase III Drosha. These pre-miRNAs are then exported into the cytoplasm by exportin-5<sup>[11]</sup>. They are then further processed by another RNase III, Dicer. The resultant approximately 22-nucleotide RNA duplexes contain the mature miRNA and the passenger miRNA strand<sup>[12,13]</sup>. The mature miRNA can be incorporated into the so-called RNA-induced silencing complex (RISC). This miRNA-mRNA interaction either blocks translation initiation, induces the endonucleolytic cleavage of the target mRNA, or both (Figure 1)<sup>[12-14]</sup>. In mammal cells, the sequence of the miRNAs loaded in the complex targets the RISC to specific binding sites in the 3'-untranslated region (UTR) of mRNA transcripts. Each mRNA can be regulated by several miRNAs, and one miRNA can recognize several targets<sup>[12,13,15]</sup>. Intriguingly, miRNAs may also lead to an upregulation of gene expression<sup>[16]</sup>. However, the exact mechanism is currently unknown but may be the result of direct effects, such as chromatin remodeling, or indirect effects, e.g. suppression of transcriptional repressors. It is believed that expression of 30% of human genes may be regulated by miRNAs<sup>[17]</sup>.

## miRNAs ARE ABUNDANT AND FINELY REGULATED IN THE LIVER

One of the first clues of the existence of miRNAs in mammals came from studies on genetic alterations in liver tumors. An unusual transcript, named hcr, was described

and characterized as liver-specific, essentially non-coding, specifically nuclear, and processed by endonucleases in one of woodchuck liver tumors investigated in 1989<sup>[18]</sup>. Later on, the hcr transcript was found to encompass the so-called "pri-miRNA" for miR-122<sup>[19]</sup>. miRNA-122 was later described as a liver specific miRNA and has been reported in mouse, woodchuck and human livers, in human primary hepatocytes, and in cultured liver derived cells<sup>[19,20]</sup>. Besides miR-122, many other miRNAs, such as miR-1, miR-16, miR-27b, miR-30d, miR-126, miR-133, miR-143, and the *let-7* family, are also abundantly expressed in adult liver tissue. While miR-122 appears as the most highly expressed miRNA in adult liver, miR-92a and miR-483 seem to be more specifically expressed in the fetal liver (Table 1)<sup>[21]</sup>. Thus, the liver displays a differential miRNA expression profile during its development.

The liver contains many cell types including parenchymal cells (i.e. hepatocytes) and "non-parenchymal cells" which include endothelial cells, stellate cells, lymphoid cells, and biliary epithelial cells (cholangiocytes). Each cell type may have completely distinct miRNA expression profiles. However, miRNA expression profile in those cell types, in particular from humans, is not fully tested yet. Current understanding is limited to available human cell lines. For example, a distinct expression profile of miRNAs has been identified in H69 cells, a cell line of SV40 transformed human cholangiocytes<sup>[22,23]</sup>.

The molecular mechanisms underlying transcriptional regulation of miRNA genes in the liver remain largely unknown. Hepatocyte nuclear factor 1 $\alpha$  (HNF-1 $\alpha$ ) is a hepatocyte-enriched transcription factor. Manipulation of HNF-1 $\alpha$  function through RNA interference causes reciprocal changes in miR-107 expression and thus, may be involved in the regulation of miR-107 transcription in the liver<sup>[24]</sup>. The myocyte enhancer factor-2 transcription factor can increase the expression of miR-1-2 and miR-133a-1<sup>[25]</sup>. The transcription factor Myc can up-regulate the expression of miR17-92 cluster and down-regulate several other miRNAs in tumorigenesis<sup>[26]</sup>. However, whether these transcription factors are also involved in the transcriptional regulation of those miRNAs in the liver is unclear. In addition, decrease of *let-7* family expression in human cholangiocytes in response to microbial stimulation appears to be nuclear factor (NF)- $\kappa$ B-dependent<sup>[23]</sup>. On the other hand, the functional expression of transcription factors can also be regulated by miRNAs, as it has recently been shown for signal transducer and activator of transcription 3 (STAT-3)<sup>[22]</sup>.

## miRNAs MAY BE KEY PLAYERS IN THE REGULATION OF LIVER FUNCTIONS

For a comprehensive understanding of miRNA function and potential therapeutic use in liver physiology and disease, identification and validation of miRNA targets are of fundamental importance. Several bioinformatic methods have been developed to predict miRNA targets<sup>[7]</sup>. Arora and Simpson adapted the 'ranked ratio

Table 1 Repertoire of miRNAs in human liver

The minus sign is used to indicate very low to undetectable levels and one plus to three pluses indicate a gradual expression from low levels to very high levels. The slash stands for the miRNAs that were not assayed. This figure is modified from Girard *et al*<sup>[21]</sup> with the permission of the authors and the publisher.

(RR)’ described by Yu *et al*<sup>[27]</sup> and predicted the genes that are potentially targeted miRNAs in the liver<sup>[28]</sup>. This RR value is an indicator of the distribution of miRNA target genes within a single mRNA population. A high RR indicates low expression in a greater proportion of target genes and is, therefore, indicative of miRNA expression in that tissue. The RR values for all miRNAs were calculated for the miRNAs in the liver<sup>[28]</sup> and are shown in Figure 2. Clearly, many mRNAs could be the targets for miRNAs in the liver.

Validation of those potential targets for each miRNA requires experimental studies both *in vitro* and *in vivo*.

Figure 2 Prediction of targets by miRNAs in the liver. The miRNAs are ordered by RR values (upper-axis). The higher values reflect lower expression of predicted target genes and are, therefore, indicative of miRNA activity. The numbers of genes predicted to be targeted by each miRNA (lower-axis) are indicated by the grey line. This figure is reprinted from Arora and Simpson<sup>[28]</sup> with the permission of the authors and the publisher.

Several groups have tested the overall importance of miR-122 in the regulation of metabolism in the liver<sup>[29,30]</sup>. Through an antisense strategy to knock down miR-122, Esau *et al*<sup>[30]</sup> observed that several genes which regulate lipid metabolism, specifically the key enzyme phosphomevalonate kinase, were down-regulated. Remarkably, silencing miR-122 in high-fat fed mice resulted in a significant reduction of hepatic steatosis, which was associated with reduced cholesterol synthesis rates and stimulation of hepatic fatty-acid oxidation<sup>[30]</sup>. Functional inhibition of miR-122 by an “antagomir” resulted in increased expression of several hundred genes including those that are normally repressed in hepatocytes<sup>[29]</sup>. In addition, Chang *et al*<sup>[20]</sup> identified a binding site for miR-122 in the 3'-UTR of the cationic amino acid transporter (CAT-1) mRNA using the Lewis-based miRNA targets approach<sup>[31]</sup>. Consistently, an inversed pattern of expression of CAT-1 and miR-122 was noted at all stages of liver development. Interestingly, miR-122-induced inhibition through the CAT-1 3'-UTR was efficiently relieved upon amino acid starvation, which validates CAT-1 as a target of miR-122<sup>[32]</sup>.

Several groups, including ourselves, have recently tested the role of miRNAs in the regulation of biliary epithelial immunity in the liver. Human cholangiocytes express *let-7* family members, miRNAs with complementarity to TLR4 mRNA. *let-7* regulates TLR4 expression *via* post-transcriptional suppression in cultured human cholangiocytes. Infection of cholangiocytes with *Cryptosporidium parvum* (*C. parvum*), a parasite that causes intestinal and biliary disease, results in decreased expression of primary *let-7i* and mature *let-7* in a MyD88/NF- $\kappa$ B-dependent manner. The decreased *let-7* expression is associated with *C. parvum*-induced up-regulation of TLR4 in infected cells<sup>[23]</sup>. miRNAs may also be involved in cholangiocyte responses to pro-inflammatory cytokines, such as interferon-gamma (IFN- $\gamma$ ), and actively participate in the regulation of biliary inflammatory response in the liver. Specifically, miR-513 regulates B7-H1 translation and mediates IFN- $\gamma$ -induced B7-H1 expression in human cholangiocytes. B7-H1 (CD274, PD-L1) is a member of the B7 family of costimulatory molecules and plays a critical immunoregulatory role in cell-mediated immune responses. Resting human cholangiocytes express B7-H1 mRNA, but not B7-H1 protein. IFN- $\gamma$  induces B7-H1 protein expression and alters miRNA expression profile in cholangiocytes. Of those IFN- $\gamma$ -down-regulated miRNAs, miR-513 has complementarity to the 3'-UTR of B7-H1 and targeting of miR-513 to B7-H1 mRNA results in translational repression, but not B7-H1 mRNA degradation<sup>[33]</sup>.

## miRNAS AND LIVER DISEASES

### miRNAs and viral hepatitis

Genes encoding miRNAs have also been found in viruses and viral miRNAs have a regulatory effect on their protein-coding genes<sup>[34]</sup>. This regulatory effect may be beneficiary to the virus toward maintaining its replication, latency and evading the host immune

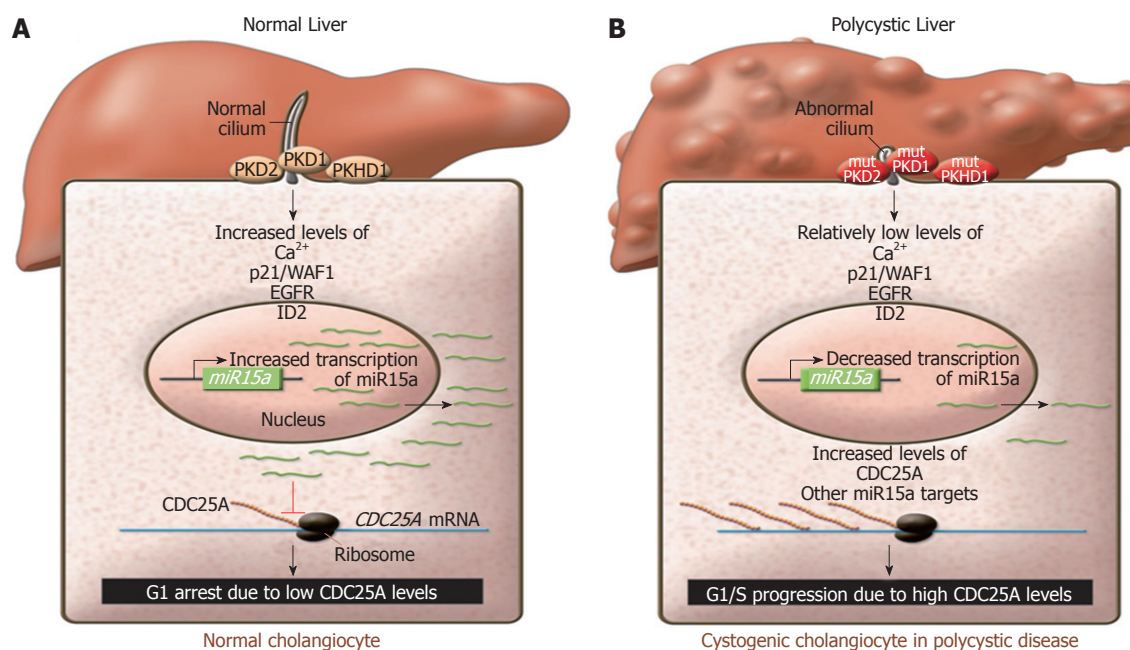

system. Wu and colleagues analyzed the miRNA-encoding potential of the hepatitis B virus (HBV). Using computational approaches, the authors found that HBV putatively encodes only one candidate pre-miRNA. One viral mRNA was found to be targeted by the viral miRNA when they searched the target from viral mRNAs. Thus, HBV has evolved to use viral miRNAs as a means to regulate its own gene expression<sup>[35]</sup>.

miRNAs from the host cells may play a role in building up direct or indirect effect in regulating viral genes<sup>[34,36,37]</sup>. Hepatitis C virus (HCV) is an enveloped RNA virus of the *Flavivirus* family, which is capable of causing both acute and chronic hepatitis in humans by infecting liver cells. miRNA-122 has been reported to facilitate the replication of HCV, targeting the viral 5' non-coding region<sup>[38]</sup>. Indeed, HCV RNA can replicate in Huh 7 cells, which express miR-122, but not in HepG2 cells, which do not express miR-122. Silencing of miR-122 in hepatocytes resulted in a marked loss of replicating RNAs from HCV<sup>[38]</sup>. A putative miR-122 binding site in the 50-end of HCV genome was identified, suggesting a direct role of miR-122 in HCV replication<sup>[38]</sup>. An indirect effect of miR-122 inhibition on HCV regulation *via* the up-regulation of the cytoprotective enzyme heme-oxygenase 1 (HO-1) and the converse down-regulation of HO-1 repressor Bach1 was also characterized<sup>[21]</sup>. In addition, HCV replication is associated with an increase in expression of cholesterol biosynthesis genes that are regulated by miR-122<sup>[39]</sup>.

On the other hand, Pedersen *et al*<sup>[40]</sup> demonstrated IFN-mediated modulation of the expression of numerous cellular miRNAs in the treatment of hepatocytes infected with HCV. Expression of a total of 30 cellular miRNAs in hepatocytes was influenced by IFN- $\alpha/\beta$  or IFN- $\gamma$ . Specifically, eight of the miRNAs (miR-1, miR-30, miR-128, miR-196, miR-296, miR-351, miR-431 and miR-448), having nearly perfect complementarity in their seed sequences with HCV RNA genomes, were up-regulated. Importantly, these miRNAs are capable of inhibiting HCV replication and infection. This has opened the door to our understanding of novel host-defense mechanisms that exist in mammalian cells as well as the antiviral mechanisms employed by interferon.

### miRNAs and human hepatocellular cancer (HCC)

Several studies have shown that specific miRNAs are aberrantly expressed in malignant HCC cells or tissues compared to non-malignant hepatocytes or tissue<sup>[41-47]</sup>. Selected miRNAs such as miR-21, miR-224, miR-34a, miR-221/222, miR-106a, and miR-203 are up-regulated in HCC compared to benign hepatocellular tumors such as adenomas or focal nodular hyperplasia. Certain miRNAs have been noted to be decreased in HCC compared to non-tumoral tissue, such as miR-122a, miR-422b, miR-145, and miR-199a. Murakami *et al*<sup>[48]</sup> showed a correlation between miR-222, miR-106a, miR-92, miR-17-5p, miR-20, and miR-18 and the degree of differentiation suggesting an involvement of specific miRNAs in the progression of the disease. Interestingly, the altered expression of some miRNAs was associated

**Figure 3 Model of miR15a function in hepatic cystogenesis.** A: In normal cholangiocytes, ciliary signaling activates intracellular signaling pathways resulting in miR15a expression and CDC25A repression. Decreased levels of CDC25A then lead to G1 arrest, preventing cyst formation; B: In cholangiocytes of polycystic liver, miR15a level is reduced as a result of mutation of molecules important to the ciliary signaling. Reduction of miR15a results in elevated Cdc25A level, increased cell proliferation, and cyst growth. This figure is reprinted from Chu and Friedman<sup>[49]</sup> with the permission of the authors and the publisher.

with distinctive risk factors, such as miR-96 with hepatitis B virus infection and miR-126\* with alcohol use. Further investigations suggested the highly deregulated miR-223 and miR-222 could unequivocally distinguish HCC from adjacent non-tumoral liver, irrespective of viral association<sup>[46]</sup>. In HCC patients with hepatitis C and liver cirrhosis, miR-122, miR-100, and miR-10a were overexpressed, whereas miR-198 and miR-145 were up to five-fold down-regulated in hepatic tumors compared to normal liver parenchyma<sup>[47]</sup>.

Alteration of expression profile in HCC for some miRNAs may be the consequence of malignant transformation. For other miRNAs, they may play a role in the transformation process. miRNA-122 was reported to be significantly and specifically down-regulated in HCC in humans as well as in rodents<sup>[41,42]</sup>. Amongst the putative target genes of miR-122 that can be predicted using computational tools, at least three are of interest in tumorigenesis: the gene for N-Myc, which is frequently rearranged in woodchuck liver tumors by woodchuck hepatitis virus<sup>[43]</sup>, the gene referred to as “down-regulated in liver malignancy”<sup>[44]</sup>, and the gene for cyclin G1<sup>[45]</sup>. In fact, miR-122 was shown to modulate cyclin G1 expression in HCC-derived cell lines, and an inverse correlation between miR-122a and cyclin G1 expression in primary liver carcinomas was further observed<sup>[45]</sup>. These studies suggest an influence of the down-regulation of miR-122 and the converse expression of cyclin G1 in hepatocarcinogenesis<sup>[21]</sup>.

### miRNAs and polycystic liver diseases

The polycystic liver and kidney diseases are a family of disorders with heterogeneous etiologies. Autosomal dominant polycystic kidney disease (ADPKD) is

associated with renal and liver cystogenesis that clinically manifests in adulthood, often leading to dialysis and renal transplantation. It is caused by mutations in either of two genes, *PKD1* and *PKD2*, which code for polycystin 1 and polycystin 2, respectively<sup>[49]</sup>. Autosomal recessive polycystic kidney disease (ARPKD) can present in neonates with massive renal cysts, causing respiratory failure secondary to abdominal competition that subsequently leads to infant demise, although milder forms can present later in life. Proposed mechanisms of disease include ciliary dysfunction, excess cell proliferation, and altered cell-cell or cell-matrix interactions.

Lee and colleagues provide data to support a novel mechanism for cystogenesis involving miRNA. They demonstrate that levels of the miRNA miR15a are decreased in livers of patients with ARPKD and ADPKD, respectively, and congenital hepatic fibrosis as well as in the *PKC* rat model of ARPKD. This results in increased expression of the cell-cycle regulator Cdc25A, which is a direct target of miR15a, and increased cellular proliferation and cystogenesis *in vitro*. As a whole, the findings indicate that changes in miRNA expression contribute to the phenotypic changes found in cystic liver disease (Figure 3)<sup>[49,50]</sup>.

## miRNAs FOR THE DIAGNOSIS OF LIVER DISEASES

miRNAs could be of diagnostic significance for many liver diseases but current literature has been focused on tumors in the liver. Hepatocellular tumors comprise diverse benign and malignant neoplasms. Although the phenotypes can be broadly distinguished histologically or immunologically, these tumors can vary widely

in their clinical behavior and prognosis. The use of miRNA-based classifications that correlate with etiology, pathogenetic changes, or malignant tendency will enhance molecular diagnosis and enable further definition of these phenotypes. In turn, this may yield clinically useful predictive markers of tumor behavior, as well as identify individual genetic and molecular contributors to tumorigenesis<sup>[51,52]</sup>. Thus, miRNA profiling studies could be used for defining clinical phenotypes, as well as providing potentially useful molecular diagnostic markers.

Impairments in miRNA functioning seen in cancerogenesis can be used for determination of miRNA expression for diagnostics of tumor origin. Each type of cancer is characterized by a certain profile of miRNA expression<sup>[52]</sup>. For example, the miRNA expression profiles in malignant hepatocytes differ from those of malignant cholangiocytes. Cluster analysis of miRNA expression profiles in tumors accurately determines not only type of the tissue (e.g. epithelium or hemopoietic system), but also discriminates tumors within the same type of tissue; this may reflect mechanism of transformation<sup>[53]</sup>. Obviously, evaluation of miRNA profiles can be used for prognosis of the development of tumors<sup>[54-56]</sup>. Such an approach for tumor diagnostics is very promising. However, it is not widely employed yet due to inadequately developed technology, lack of standards, requirements of very high purity of RNA samples, and not always reproducible results.

## miRNAS AS THERAPEUTIC TARGETS FOR LIVER DISEASES

Development of miRNA/RNAi-based therapeutics requires several critical experimental steps, which include: (1) miRNA profiling of disease versus healthy tissue; (2) functional analysis of dysregulated miRNAs; and (3) *in vivo* studies with the use of different RNAi-based therapeutic methods to dysregulate miRNAs<sup>[57]</sup>. The success of such strategies for gene therapy will provide clinicians with a larger repertoire that includes miRNA-therapeutic agents. For example, chemically engineered oligonucleotides, termed 'antagomirs', have recently been developed and proven to be efficient and specific silencers of endogenous miRNAs in mice<sup>[29]</sup>. The silencing effect was considerably sustained over time probably because of a long half-life of endogenous miRNAs<sup>[12]</sup>. In addition, induction of stable loss-of-function phenotypes for specific miRNAs by lentiviral-mediated antagomir expression has recently been described<sup>[58]</sup>.

Over the past several years, strategies based on targeting HBV, and to a lesser extent HCV, by both synthetic and expressed activators of the RNAi pathway have proved efficient to inhibit viral replication both *in vitro* and *in vivo*<sup>[59,60]</sup>. The recent study by Pedersen *et al*<sup>[40]</sup> provided great insights into validating sequence-predicted targets of cellular miRNAs within the HCV genome. miRNA-122 antagomir can down-regulate expression of several adult-liver genes<sup>[29]</sup>, providing

the potential to generate a new attractive expandable cell source for hepatocyte transplantation that would feature stem/progenitor cell phenotype. In addition, the effect of miR-122 antagomir in high-fat fed mice may be of therapeutic potential to reduce hepatic steatosis<sup>[29]</sup>.

The important breakthrough in the field of hepatocarcinogenesis came from the accurate correlation of alterations in miRNAs with tumor proliferation and differentiation. So far, there have been very limited insights into this characterization. Recent studies by Meng *et al*<sup>[22,61]</sup> suggest a role for miRNAs in the influence of interleukin-6 in malignant cholangiocytes. MicroRNA-141, which showed strong overexpression in malignant cholangiocytes, was specifically localized in 12p, a region of known chromosomal aberration in biliary tract cancers<sup>[42]</sup>. Inhibition of miR-21 sensitized the response of cholangiocarcinoma cell lines to chemotherapy<sup>[42]</sup>. This observation gives rise to significant hope that miR-21 could serve as a biomarker for drug response in cholangiocarcinoma.

## CONCLUSION

Study of miRNAs flourished during the decade after their discovery. It is now clear that miRNAs can potentially regulate every aspect of cellular activity, from differentiation and proliferation to apoptosis, and also modulate a large range of physiological processes from developmental timing to organogenesis<sup>[1-6]</sup>. miRNAs also modulate a diverse spectrum of liver functions with developmental, (patho) physiological, and clinical implications. In the near future, the distinctive signature patterns of miRNA expression associated with liver cancer should allow classification of different stages in tumor progression<sup>[21]</sup>. Further, creating artificial miRNAs with salutary effects by promoting the expression of beneficial gene products (e.g. tumor-suppressor proteins) or targeting viral genomes (e.g. molecules designed to specifically target HCV-genome sequences) may become part of our patient management and complement chemotherapy and antiviral treatments. Overall, unraveling the regulatory circuits of miRNAs in the liver is a great challenge, but may provide attractive targets for mechanism-based treatment of liver diseases.

## Abstract

Exocrine pancreatic insufficiency caused by chronic pancreatitis results from various factors which regulate digestion and absorption of nutrients. Pancreatic function has been extensively studied over the last 40 years, even if some aspects of secretion and gastrointestinal adaptation are not completely understood. The main clinical manifestations of exocrine pancreatic insufficiency are fat malabsorption, known as steatorrhea, which consists of fecal excretion of more than 6 g of fat per day, weight loss, abdominal discomfort and abdominal swelling sensation. Fat malabsorption also results in a deficit of fat-soluble vitamins (A, D, E and K) with consequent clinical manifestations. The relationships between pancreatic maldigestion, intestinal ecology and intestinal inflammation have not received particular attention, even if in clinical practice these mechanisms may be responsible for the low efficacy of pancreatic extracts in abolishing steatorrhea in some patients. The best treatments for pancreatic maldigestion should be re-evaluated, taking into account not only the correction of pancreatic insufficiency using pancreatic extracts and the best duodenal pH to permit optimal efficacy of these extracts, but we also need to consider other therapeutic approaches including the decontamination of intestinal lumen, supplementation of bile acids and, probably, the use of probiotics which may attenuate intestinal inflammation in chronic pancreatitis patients.

## INTRODUCTION

Exocrine pancreatic insufficiency caused by chronic pancreatitis results from various factors which regulate digestion and absorption of nutrients. Pancreatic function has been extensively studied over the last 40 years, even if some aspects of secretion and gastrointestinal adaptation are not completely understood. The pancreatic gland normally secretes more than 2 L of juice per day which is composed of water, bicarbonates and enzymes<sup>[1]</sup>; protein secretion per gram of pancreatic tissue is elevated more than that of any other organ<sup>[2]</sup>, and more than 85% of the protein content is composed of enzymes which are able to digest lipids, proteins and carbohydrates<sup>[3]</sup>. The pancreas normally produces more enzymes than are necessary for food digestion<sup>[1]</sup>, and normal digestion is guaranteed up to a loss of 95% of pancreatic secretory capacity<sup>[4]</sup>. Recently, it has been demonstrated that gastric lipase can compensate pancreatic lipase even if it is not capable of complete lipolytic activity<sup>[5]</sup>. Enzyme degradation in the intestinal lumen is the main factor controlling nutrient absorption. The activity of pancreatic enzymes progressively decreases during their progression in the intestinal lumen: 60% of active trypsin and chymotrypsin are present in the jejunum, whereas only 20% of these enzymes are present in the ileum; on the other hand, amylases and lipases are more stable<sup>[6-8]</sup>. There are various explanations for the loss of enzymatic activity during progression in the intestinal lumen, including proteolytic degradation (chymotrypsin is the main lipase degradation factor)<sup>[9]</sup>, lipase acid inactivation (lipase is particularly sensitive to acid inactivation)<sup>[10]</sup>, and the brief half-life of some

enzymes, particularly lipase<sup>[11]</sup>. This is the reason why, in patients with exocrine pancreatic insufficiency, fat maldigestion is more severe than that of carbohydrates and proteins. In addition to an optimal concentration of biliary acids and colipases in the intestinal lumen, good fat digestion requires an adequate blending of nutrients with the pancreatic juice and optimal intestinal motility. In pathological conditions, such as chronic pancreatitis, there is a deficit in bicarbonate production; a low duodenal pH determines biliary acid precipitation and the remaining lipase activity worsens. Finally, other causes of malabsorption may be an accelerated gastric emptying and a lower intestinal transit time<sup>[12,13]</sup>.

## CLINICAL MANIFESTATIONS AND DIAGNOSIS OF EXOCRINE PANCREATIC INSUFFICIENCY

The main clinical manifestations of exocrine pancreatic insufficiency are fat malabsorption, known as steatorrhea, which consists of fecal excretion of more than 6 g of fat per day, weight loss, abdominal discomfort and abdominal swelling sensation. Fat malabsorption also results in a deficit of fat-soluble vitamins (A, D, E and K) with consequent clinical manifestations. The diagnosis of exocrine pancreatic insufficiency is based on these clinical symptoms and signs observed with direct and indirect tests. Some of these tests can be used to determine the degree of insufficiency which is usually classified as mild, moderate or severe. The most sensitive test is the secretin-cholecystokinin (CCK) or secretin-cerulein test; this test has a double-lumen tube capable of separately draining the gastric juice and the pancreatic juice. The test starts with pancreatic stimulation by secretin which produces the hydro-electrolyte pancreatic secretion and CCK or cerulein, which can stimulate enzymatic secretion. This test is highly sensitive and specific<sup>[14]</sup> but is invasive, lengthy and expensive; moreover, it is only possible in patients with a normal gastrointestinal tract, and it is not useful in patients with an altered digestive anatomy. At present, fecal chymotrypsin and elastase 1 are more frequently used to diagnose exocrine pancreatic insufficiency<sup>[15]</sup>. In particular, the determination of elastase 1 is more sensitive and specific than chymotrypsin determination. The advantage of these tests is that they can be used in patients who have undergone surgery involving the gastrointestinal tract, but they can not reveal a mild degree of exocrine pancreatic insufficiency<sup>[15,16]</sup>. A cholesteryl-octanoate breath test is rarely used because of its high cost and possible interference with metabolic and pulmonary diseases<sup>[17]</sup>. Fecal fat determination is useful in monitoring lipid malabsorption therapy. Pancreatic exocrine evaluation during magnetic resonance cholangiopancreatography with secretin administration is still under study and the results of the published studies seem to be promising<sup>[18-20]</sup>.

## MALDIGESTION, INTESTINAL ECOLOGY AND INTESTINAL INFLAMMATION

The relationships between pancreatic maldigestion, intestinal ecology and intestinal inflammation have not received particular attention, even if in clinical practice these mechanisms may be responsible for the low efficacy of pancreatic extracts to abolish steatorrhea in some patients.

One mechanism which has been hypothesized between maldigestion and intestinal alterations relates to bacterial overgrowth in the small intestine; bacterial overgrowth is often seen in experimental models of exocrine pancreatic insufficiency<sup>[21]</sup>. Furthermore, bacterial overgrowth has been observed in dogs with naturally occurring exocrine pancreatic insufficiency<sup>[22]</sup>. The presence of bacterial overgrowth in human exocrine pancreatic insufficiency has been studied using non-invasive breath tests based on <sup>14</sup>C-cholyglycine<sup>[23]</sup>, <sup>14</sup>C-xylose<sup>[24]</sup>, glucose<sup>[25,26]</sup> or by intubation followed by culture of intestinal aspirates<sup>[27]</sup>. These studies indicated that bacterial overgrowth complicates 25%-50% of patients with exocrine pancreatic insufficiency, and it was suggested that bacterial overgrowth might either contribute to diarrhea or account for the persistence of diarrhea in patients with exocrine pancreatic insufficiency who receive adequate pancreatic enzyme supplementation. Furthermore, bacterial overgrowth might give rise to bile acid malabsorption and changes in intestinal permeability<sup>[28]</sup>.

However, Madsen *et al*<sup>[29]</sup> found no bacterial overgrowth in any of their patients with exocrine pancreatic insufficiency, and these findings seem to conflict with previous observations seen in both humans and animals. In fact, in the study based on intestinal culture<sup>[27]</sup>, it was observed that bacterial overgrowth occurred in 50% of patients with severe pancreatic insufficiency who were not receiving enzyme replacement therapy, and studies in dogs indicated that bacterial overgrowth from ligation of the pancreatic duct can be reversed by bovine pancreatic extract replacement therapy; thus these results indicate that pancreatic enzymes might have an important influence on small-intestinal bacterial flora<sup>[21]</sup>. Since all the patients studied by Madsen had oral enzyme supplementation, it is possible that enzyme substitution treatment normalized the luminal conditions of the small intestine, which otherwise would have facilitated bacterial overgrowth.

In a previous study, a wide range of bile salt malabsorption was observed in patients with exocrine pancreatic insufficiency secondary to alcoholic pancreatitis<sup>[30]</sup>. Moreover, these data suggested that intraluminal factors, rather than a primary defect in the ileal mucosa, were responsible for bile salt malabsorption. The fecal loss of bile salts in their patients was markedly reduced by oral administration of pancreatic enzymes, indicating an important role for pancreatic enzymes in bile acid absorption. It has been postulated from studies performed *in vitro* that a lack

of pancreatic enzymes causes generalized maldigestion, which in turn may be responsible for persistent bile salt binding to maldigested protein, carbohydrate, or fiber in these patients<sup>[31]</sup>. It is conceivable, therefore, that in patients with untreated pancreatic insufficiency, an exceeding low concentration of intraluminal pancreatic enzymes during the postprandial period gives rise to persistent binding of bile acids to undigested dietary components, resulting in bile acid malabsorption.

Low intraluminal pH in the upper small intestine might be another important factor in the pathogenesis of fecal loss of bile acids in pancreatic insufficiency. Thus, bile acid malabsorption in patients with chronic pancreatitis and exocrine dysfunction does not occur until bicarbonate output is below a certain level<sup>[32]</sup>, and cimetidine has been shown to reduce pH-induced precipitation of bile acids, thereby improving the micelle concentration of bile salts in the duodenum<sup>[33]</sup>. Moreover, food residues seem to absorb more bile salts at pH values less than 6.0<sup>[34]</sup>.

The study by Madsen<sup>[29]</sup> also evaluated intestinal permeability in exocrine pancreatic insufficiency due to chronic pancreatitis in adult patients; these authors found that patients receiving enzyme replacement therapy had reduced urinary excretion of mannitol. The exact character of the underlying epithelial impairment was at that time not obvious, as the pathways for permeation of both smaller molecules such as mannitol and larger molecules are not yet known. It is possible that larger pores located in the crypts of intestinal epithelium permit absorption of larger molecules, while smaller molecules pass through both these pores and smaller pores located in the villi<sup>[35,36]</sup>. According to this hypothesis, it is suggested that a defect localized in the villi of the intestinal epithelium may exist. It is possible, however, that more pronounced disturbances in intestinal permeability would have been revealed, if urine excretion of the test substances had been properly corrected for variations in the small-intestinal transit rate<sup>[37]</sup>. Since bacterial overgrowth which often gives rise to defects in intestinal permeability was not found in any of our patients, it is suggested that pancreatic disease *per se* and not enzyme supplementation therapy caused the permeability defect. In a recent study, we evaluated fecal calprotectin in a total of 90 subjects; 22.2% with chronic pancreatitis, 16.7% with pancreatic cancer, 6.7% with chronic non-pathological pancreatic hyperenzymemia, 17.8% with non-pancreatic diseases and 25.6% with no detectable diseases<sup>[38]</sup>. Calprotectin is a cytoplasmic antimicrobial component prominent in granulocytes, monocytes, and macrophages. It accounts for approximately 60% of the total protein in the cytosol. The release of calprotectin is most likely a consequence of cell disruption and death<sup>[39]</sup> and is stable in stools for more than 7 d at varying temperatures, as well as being resistant to proteolysis even after transportation and storage<sup>[40]</sup>. Calprotectin can inhibit bacterial proliferation both as a component of the innate immune response and through its iron-binding capacity<sup>[41]</sup>. Fecal calprotectin determination has been demonstrated to

be useful in diagnosing various inflammatory diseases of the gastrointestinal tract<sup>[42-46]</sup>. We found that patients with chronic pancreatitis had abnormally high fecal calprotectin concentrations in 55% of cases and most of these patients (40%) had pancreatic insufficiency<sup>[38]</sup>. It is possible that, in these patients, pancreatic insufficiency may determine an alteration in intestinal ecology, and in intestinal inflammation. In the population studied, multivariate analysis showed that patients with abnormally low fecal elastase had more than a five-fold risk of increased fecal calprotectin suggesting that, in patients with pancreatic disease, the determination of fecal calprotectin may be useful in evaluating the possible presence of intestinal inflammation which may worsen the intestinal absorption of nutrients. Thus, our data further support the hypothesis that pancreatic insufficiency may cause intestinal inflammation probably due to a modification in intestinal ecology.

## CONCLUSION

Pancreatic extracts are the basic treatment for pancreatic insufficiency. However, we need to explore the possibility that other drugs used to treat pancreatic insufficiency such as proton pump inhibitors or H<sub>2</sub>-blockers should be administered to our patients in order to modify the duodenal pH and to permit optimal efficacy of pancreatic extracts. Furthermore, we need to explore the possibility that other therapeutic approaches including the decontamination of intestinal lumen, supplementation of bile acids and the use of probiotics may attenuate intestinal inflammation permitting optimal efficacy of pancreatic extracts as well as the control of clinical signs and symptoms of pancreatic insufficiency.

### Abstract

Several studies have characterized the cellular and molecular mechanisms of hepatocyte injury caused by the retention of hydrophobic bile acids (BAs) in cholestatic diseases. BAs may disrupt cell membranes through their detergent action on lipid components and can promote the generation of reactive oxygen species that, in turn, oxidatively modify lipids, proteins, and nucleic acids, and eventually cause hepatocyte necrosis and apoptosis. Several pathways are involved in triggering hepatocyte apoptosis. Toxic BAs can activate hepatocyte death receptors directly and induce oxidative damage, thereby causing mitochondrial dysfunction, and induce endoplasmic reticulum stress. When these compounds are taken up and accumulate inside biliary cells, they can also cause apoptosis. Regarding extrahepatic tissues, the accumulation of BAs in the systemic circulation may contribute to endothelial injury in the kidney and lungs. In gastrointestinal cells, BAs may behave as cancer promoters through an indirect mechanism involving

oxidative stress and DNA damage, as well as acting as selection agents for apoptosis-resistant cells. The accumulation of BAs may have also deleterious effects on placental and fetal cells. However, other BAs, such as ursodeoxycholic acid, have been shown to modulate BA-induced injury in hepatocytes. The major beneficial effects of treatment with ursodeoxycholic acid are protection against cytotoxicity due to more toxic BAs; the stimulation of hepatobiliary secretion; antioxidant activity, due in part to an enhancement in glutathione levels; and the inhibition of liver cell apoptosis. Other natural BAs or their derivatives, such as choly-N-methylglycine or cholylysarcosine, have also aroused pharmacological interest owing to their protective properties.

### INTRODUCTION

Bile acids (BAs) are the major organic solutes in bile, and are involved in several important functions in the liver and the intestine. However, the retention of hydrophobic BAs in pathophysiological conditions, such as cholestatic diseases, is believed to play an important role in liver injury by inducing apoptosis or necrosis of hepatocytes<sup>[1]</sup>. Primary BAs are directly synthesized from cholesterol by hepatocytes, by the addition of hydroxyl groups and the oxidation of its side chain to form a more water soluble end product. The hydroxylation is always on one side of the molecule resulting in an amphipathic molecule. In humans, the most abundant BA species are the primary BAs cholic acid (CA) and chenodeoxycholic acid (CDCA) (Figure 1), and the secondary BAs deoxycholic acid (DCA) and

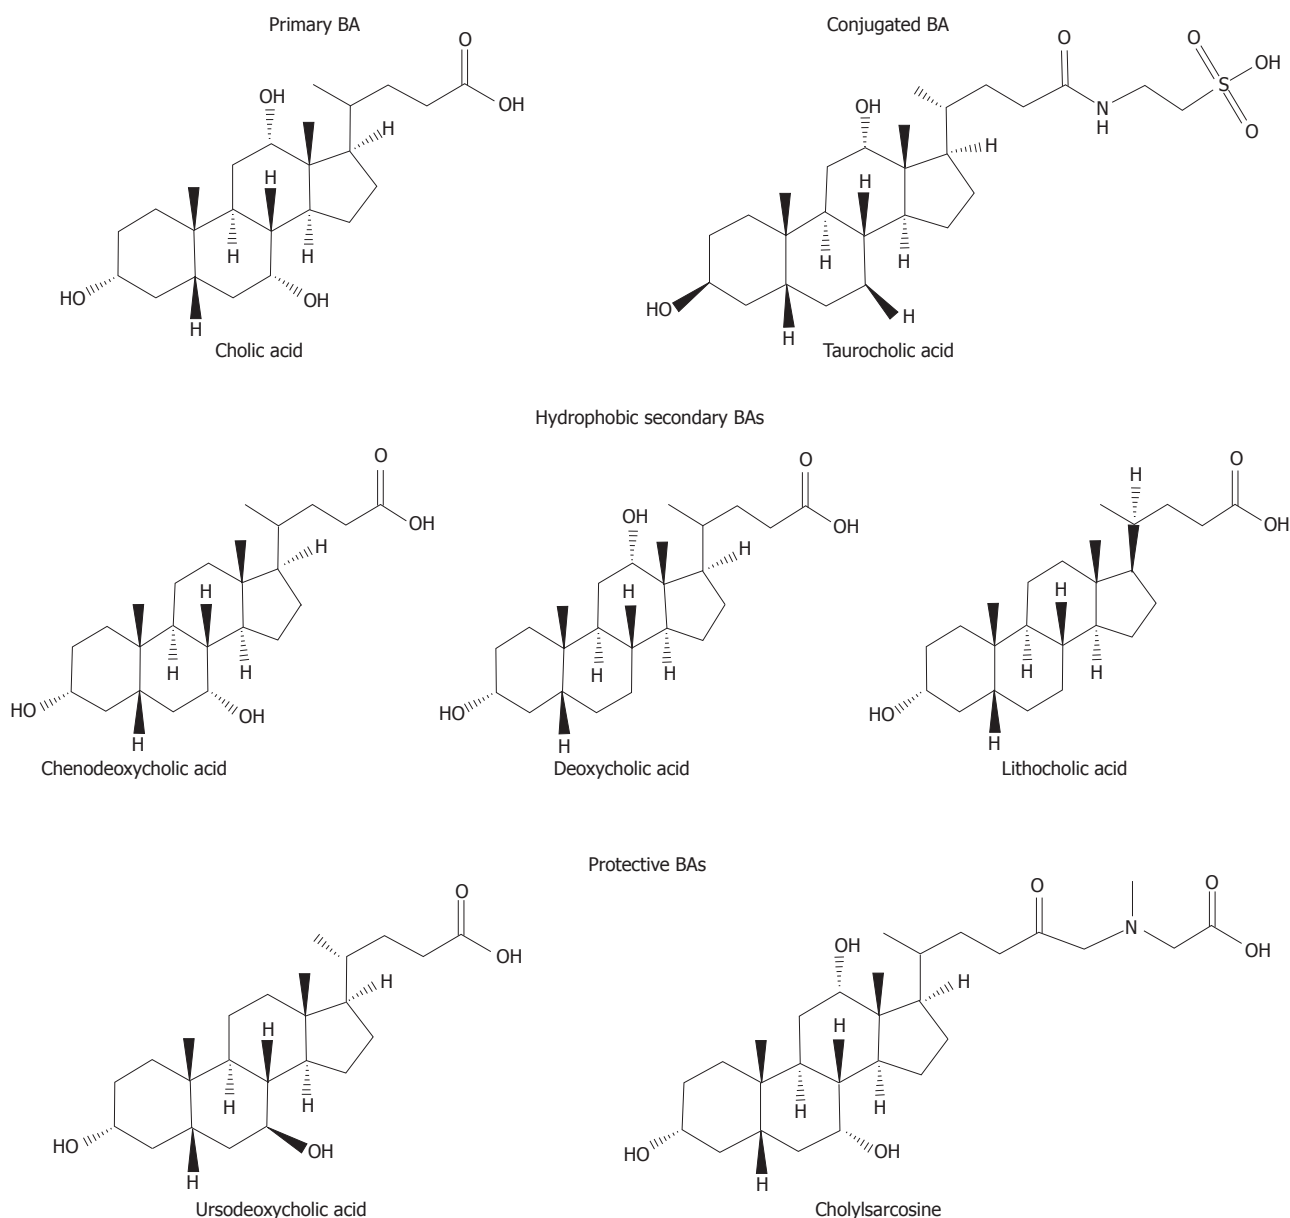

Figure 1 Molecular structures of different potentially toxic or protective natural bile acids and synthetic bile acid analogues.

lithocholic acid (LCA) (Figure 1), generated in the intestine by bacterial biotransformation of CA and CDCA, respectively. Small amounts of other secondary BAs such as ursodeoxycholic acid (UDCA; Figure 1), currently used in the treatment of cholestatic liver diseases, are also present in the human BA pool<sup>[2,3]</sup>.

BA hydrophobicity is an important determinant of the toxicity and protection of BAs, two biological properties of these compounds which will be reviewed in this manuscript. BA hydrophobicity depends on the number, position and orientation of the hydroxyl groups, as well as amidation at the C-24 position. Regarding the magnitude of hydrophobicity of BAs the order would be UDCA < CA < CDCA < DCA < LCA<sup>[4]</sup>. Before being secreted into bile, most BA molecules are conjugated with glycine or taurine (Figure 1) within hepatocytes to more hydrophilic amidated forms. Under normal conditions, the amount of BAs undergoing further biotransformations to dianionic

glucuronidated or sulfated derivatives is negligible, although these may become important in cholestasis<sup>[5]</sup>.

## BILE-ACID-INDUCED HEPATOCYTE INJURY

The retention and accumulation of hydrophobic BAs, such as CDCA and DCA, inside hepatocytes during cholestasis have long been implicated as a major cause of liver damage in this disease<sup>[1]</sup>. Experimentally, hydrophobic BAs are known to induce injury to isolated hepatocytes<sup>[6]</sup>, cultured hepatocytes<sup>[7]</sup>, and whole liver<sup>[8]</sup>, but the mechanisms involved in this toxicity are not fully understood. In animal models<sup>[9]</sup> and human cholestatic disorders<sup>[10]</sup>, hepatocyte swelling and the intracellular accumulation of bile pigments have been reported to occur. Moreover, swelling, pleomorphism and abnormal cristae have also been reported in

mitochondria from cholestatic hepatocytes<sup>[11]</sup>. This injury to parenchymal cells, which occurs early on in the course of cholestasis, can be responsible for many of the subsequent inflammatory and fibrinogenic responses of non-parenchymal cells. Thus, altered hepatocytes may release molecules, including growth factors, cytokines, chemokines and lipid peroxide products, able to amplify the inflammatory response, stimulate fibrogenesis by hepatic stellate cells, or directly injure other nearby cells<sup>[12]</sup>.

Several mechanisms may account for the cytotoxicity associated with the most hydrophobic BAs in cholestatic liver diseases<sup>[1]</sup>. BAs could disrupt cell membranes through their detergent action on lipid components<sup>[13]</sup> and promote the generation of reactive oxygen species (ROS) that, in turn, oxidatively modify lipids, proteins, and nucleic acids, and eventually cause hepatocyte apoptosis<sup>[14]</sup>. Additionally, they can activate Kupffer cells to generate ROS, which may further contribute to the liver cell insult<sup>[15]</sup>.

## BILE-ACID-INDUCED OXIDATIVE STRESS

Several studies have suggested that oxidative stress may play an important role in the pathogenesis of hepatic injury during cholestasis in rats<sup>[16]</sup> and humans<sup>[17]</sup>. Thus, the antioxidant  $\alpha$ -tocopherol is able to reduce both hydrophobic BA-induced ROS generation and injury to hepatocytes *in vitro*<sup>[18]</sup> and *in vivo*<sup>[8]</sup>. Hepatic mitochondria have been proposed as a major source of the oxidative stress induced by these BAs. In this respect, it has been demonstrated that hepatic mitochondria undergo lipid peroxidation during experimental cholestasis and BA toxicity in rats<sup>[8,16]</sup>. Hydrophobic BAs impair respiration and electron transport in hepatic mitochondria. These compounds decrease the activities of several enzyme complexes involved in the electron transport chain, such as complexes I, III and IV, whereas complex II is not affected in isolated rat liver mitochondria<sup>[19]</sup>. Moreover, toxic BAs decrease the mitochondrial membrane potential developed upon succinate energization<sup>[20]</sup>. These compounds decrease state three and enhance state four respiration in mitochondria<sup>[20]</sup>. The decrease in state three respiration is probably related to an inhibitory action of these compounds on the phosphorylation system, although by means of a mechanism that has yet to be defined. The reported stimulation of state four by hydrophobic BAs is associated with an enhanced permeability of mitochondria to protons<sup>[20]</sup>. The observed uncoupling may be the consequence of several interactions of these compounds with the structure of mitochondria. These BAs induced membrane permeability to protons, either by acting as protonophores or by disruption of the structural organization of membrane components. Hydrophobic BAs can stimulate the generation of ROS in rat hepatic mitochondria and hepatocytes<sup>[18,21]</sup> as well as in human hepatic mitochondria<sup>[22]</sup>. Intracellular ROS generation by mitochondria appears to be an early event in hydrophobic BA-induced hepatocyte

toxicity<sup>[21]</sup>. As occurs in cholestatic rats, this can lead to a depletion of antioxidant defences, including total hepatic and mitochondrial glutathione contents, and the concentrations of substances involved in electron transport, such as ubiquinone-9 and ubiquinone-10<sup>[23]</sup>.

Hydrophobic BAs can induce the mitochondrial permeability transition (MPT)<sup>[22,24,25]</sup>, a critical intracellular event that triggers both the apoptotic and necrotic forms of cell death in hepatocytes<sup>[26]</sup>. MPT involves a rapid increase in the permeability of the mitochondrial membrane to low-molecular-weight solutes, caused by the opening of a channel composed of the adenine nucleotide translocator of the inner membrane, the voltage-dependent anion channel of the outer membrane, and mitochondrial cyclophilin D<sup>[26]</sup>. Induction of MPT is associated with mitochondrial swelling, collapse of the mitochondrial membrane potential, reduced oxidative phosphorylation, rupture of the outer mitochondrial membrane, cytochrome c release, and generation of ROS<sup>[26]</sup>. Hydrophobic BA-induced MPT has been associated with mitochondrial ROS generation in rat hepatocytes<sup>[27]</sup> and in isolated mitochondria<sup>[14]</sup>. An elevation of the cytosolic free calcium concentration induced by hydrophobic BAs<sup>[28]</sup> may also be an important permissive factor that allows oxidant stress to open the permeability pore.

## BILE-ACID-INDUCED CELL DEATH PATHWAYS

BA accumulation within the hepatocyte can result in cell injury and death through two mechanisms; lower BA concentrations induce hepatocellular apoptosis<sup>[25,29-31]</sup>, whereas higher concentrations induce necrosis<sup>[7,21]</sup>. Both types of cell death seem to play a role in cholestatic liver injury, although the contribution of each is controversial. The role of apoptosis in cholestatic injury has been demonstrated<sup>[32]</sup>. However, in certain models of BA toxicity in the mouse, it has been reported that hepatocyte necrosis is the predominant form of cell death<sup>[33]</sup>.

Interestingly, at the level of apoptosis induction, cytotoxicity of BAs does not always correlate with their hydrophobicity, which is not the case in necrosis. Apoptosis induction is indeed dependent on the BA, its concentration, or its conjugation state<sup>[29]</sup>.

### Necrosis

In rat hepatocytes, cellular necrosis is characterized by cell swelling and disruption of the intracellular and plasma membranes. BA-induced lethal hepatocellular injury has been attributed to direct membrane damage due to the detergent-like properties of hydrophobic BAs<sup>[13]</sup>, as well as to depletion of ATP, ion dysregulation, mitochondrial and cellular swelling, plasma membrane failure, and cell lysis, releasing intracellular contents<sup>[6]</sup>. In the liver of humans with cholestatic disorders, the histological features of hepatocyte necrosis, such as massive swelling of hepatocytes containing accumulated bile and elevated serum hepatocellular aminotransferase

**Figure 2** Intracellular mechanisms of bile acid-induced hepatocyte apoptosis. In this schema, further transduction after activation of death receptors and formation of the DISC, direct mitochondrial toxicity and ER stress are implicated.

enzymes, have been observed<sup>[10]</sup>. Antioxidants have been shown to prevent hepatocellular necrosis and reduce oxidant stress in isolated hepatocytes exposed to hydrophobic BAs<sup>[18,21]</sup> and to inhibit the dissipation of mitochondrial membrane potential<sup>[14]</sup>. Thus, it has been proposed that MPT induction by ROS generated in hepatocyte mitochondria<sup>[27]</sup> is a critical event promoting BA-induced hepatocyte necrosis. In contrast to BA-induced apoptosis, only high concentrations of BAs are able to induce hepatocyte necrosis<sup>[7,21]</sup>. The generation of ROS can result from a direct detergent effect of BAs on membrane enzymes, such as phospholipase A<sub>2</sub>, which upon activation release arachidonic acid. Mitochondrial damage due to BAs can arise from several causes, including the endogenous generation of arachidonic acid<sup>[34]</sup>.

### Apoptosis

The impairment of apoptosis in hepatocytes and bile duct epithelial cells has been implicated in the pathogenesis of many liver diseases<sup>[32]</sup>. It is well known that hydrophobic BAs can induce apoptosis by activating the death receptor or extrinsic pathway<sup>[35,36]</sup>, and through the mitochondrial or intrinsic pathway<sup>[25,27,30]</sup> (Figure 2). More recently, it has been demonstrated that hydrophobic BAs can also induce apoptosis in hepatocytes by causing endoplasmic reticulum (ER) stress (Figure 2). In contrast to BA-induced cell necrosis, apoptosis is characterized by the maintenance of cellular ATP content<sup>[29]</sup>.

**Extrinsic pathway of apoptosis:** BA-associated hepatocyte apoptosis has been shown to occur through the death receptors Fas<sup>[35]</sup> and TRAIL-R2. In contrast, BAs do not appear to enhance tumor necrosis factor (TNF)- $\alpha$ /TNF-R1 cytotoxicity<sup>[36]</sup>. Toxic BAs cause cell death, partly due to the activation of a protease cascade. The proximal signaling protease caspase 8 appears to be activated by toxic BAs in a Fas-receptor-dependent manner. After caspase 8 activation, cathepsin B activity also increases. Inhibition of either protease attenuates apoptosis *in vitro*, suggesting that they both play a critical role in BA-induced apoptosis<sup>[35]</sup>. Moreover, toxic BAs can induce Fas aggregation on the plasma membrane *via* a Fas-ligand-independent mechanism<sup>[37]</sup>. These compounds appear to promote Fas activation by altering the cellular trafficking of this death receptor. The shuttling of Fas and the resulting apoptosis can be inhibited by Golgi-disrupting agents and microtubule poisons. By inference, a Golgi-associated and microtubule-dependent pathway appears to be involved in the trafficking of Fas to the cell surface during BA cytotoxicity<sup>[38]</sup>.

Oxidative stress has been implicated in the stimulation of Fas translocation induced by BAs. It has been demonstrated that BA-induced oxidative stress may trigger the activation of c-Jun-N-terminal kinases (JNKs) and protein kinase C (PKC). These are responsible for activating the epidermal growth factor receptor (EGFR), which associates with Fas in a JNK-dependent manner. The resulting phosphorylation of Fas induces its mobilization to the plasma membrane<sup>[39]</sup>.

The increased density of Fas on the cell surface also sensitizes hepatocytes to cell death induced by Fas agonists<sup>[38]</sup>. Thus, toxic BAs also promote Fas-ligand-dependent hepatocyte apoptosis.

After death receptor activation and death-inducing signaling complex (DISC) formation, caspase 8 is activated and the pro-apoptotic protein Bid is cleaved and translocated to the mitochondria, which results in opening of the MPT pore, and the release of cytochrome c and other proapoptotic intermembrane space small molecules. Cytosolic cytochrome c leads to the binding of apoptosis activating factor-1 (APAF 1) with procaspase 9, resulting in the activation of caspase 9. A caspase cascade is then initiated and, finally, activation of the effector caspases, which leads to irreversible hepatocyte death<sup>[40]</sup>.

The death receptor TRAIL-R2 has been also suggested to be involved in the apoptosis induced by BA. Enhanced expression and oligomerization of this death receptor has been described in glycochenodeoxycholic acid (GCDCA)-induced apoptosis in Fas-deficient cell lines<sup>[36]</sup>.

**Intrinsic pathway of apoptosis:** BAs are able also to induce apoptosis through the mitochondrial or intrinsic pathway, in which intracellular stress causes mitochondrial dysfunction and the subsequent release of proapoptotic factors<sup>[25,27,30]</sup>. As mentioned above, BAs can directly induce the generation of ROS by mitochondria<sup>[18,21]</sup> and mitochondrial membrane potential depolarization<sup>[27,30,31]</sup> in rat hepatocytes. MPT induction in apoptosis induced by several BAs has also been demonstrated<sup>[24,25]</sup>. Antioxidants prevented GCDCA-induced apoptosis in rat hepatocytes through a mechanism involving the MPT<sup>[25]</sup>. It has also been demonstrated that DCA-triggered apoptosis, involved in decreased mitochondrial membrane potential and alterations in Bax subcellular distribution, exhibits increased mitochondrial-associated Bax protein levels<sup>[31]</sup>. These results suggest that BA-induced MPT is the initial event, and the initial cytochrome c release stimulates Bax translocation to the mitochondria, accomplishing further cytochrome c release<sup>[31]</sup>. *In vivo* studies show that 3 d after bile-duct-ligation, Bax expression is increased but then decreases over time. Bax translocation to the mitochondria and cytochrome c release are also found in these conditions<sup>[41]</sup>.

Mitochondrial dysfunction can also occur in death-receptor-mediated apoptosis, especially the so called “type II cells”, such as hepatocytes. Mitochondrial cytochrome c release is (Fas-associated death domain) FADD/caspase 8-dependent during the death receptor-mediated apoptosis of type II cells<sup>[42]</sup>.

**ER stress-induced apoptosis:** More recently, it has been demonstrated that hydrophobic BAs can also induce apoptosis in hepatocytes through another intracellular pathway of cell death involving ER stress. Thus, GCDCA induces ER stress which, in turn, induces apoptotic signalling in a time-dependent manner in isolated rat hepatocytes. This BA caused  $\text{Ca}^{2+}$  release

from ER, which in turn induced extracellular  $\text{Ca}^{2+}$  influx followed by the activation of calpain and caspase-12. In this study it is suggested that ER stress induced by GCDCA may trigger the activation of both ER mediated apoptosis and mitochondria-mediated apoptosis in isolated rat hepatocytes by cross-talk between ER and mitochondria using calcium ions as signal substances<sup>[43,44]</sup>. Recent studies have suggested that ER stress might be involved in hepatocyte cell death caused by cholestasis or BAs<sup>[45,46]</sup>. It has been demonstrated that cholestasis induces ER stress mediated by CHOP, a key component in ER stress mediated apoptosis, and triggers hepatocyte cell death. Moreover, CHOP deficiency attenuates this cell death and subsequent liver fibrosis. The results demonstrate an essential role of CHOP in development of liver fibrosis due to cholestatic liver damage<sup>[46]</sup>.

## BILE-ACID-INDUCED DAMAGE IN THE PLASMA MEMBRANE

In hepatocytes, high concentrations of BAs can cause damage to the basolateral membrane, cell organelle membranes, and because they are more concentrated in bile, these compounds might be particularly harmful to the outside layer of the canalicular membrane. Hydrophobic BA-induced structural and functional injury of hepatocyte membranes plays an important role in the pathogenesis of cholestatic liver diseases in humans<sup>[47]</sup>. Conjugated-BAs are more hydrophilic and not usually cytotoxic until their concentrations approach their critical micellar concentration<sup>[48]</sup>. The effect of BAs on cell membranes is induced by binding to the membrane components<sup>[49]</sup>. The authors carried out experiments using large unilamellar vesicles and showed that at very low BA concentrations, BA/lipid aggregates are formed in the outer membrane monolayer, with a size and BA-binding strength that depended on the species of BA and lipids involved. As BA concentrations increased, binding to membranes also rose until a certain threshold was reached and the BA-membrane interaction then resulted in the formation of transient membrane holes<sup>[49]</sup>, which caused the disruption of plasma membrane integrity and subsequently lysis of hepatocytes<sup>[1]</sup>. The efficiency of BAs to solubilise membrane lipids, such as phospholipids, cholesterol or fatty acids, is generally enhanced with increasing BA hydrophobicity<sup>[1,13]</sup>. CDCA and DCA have critical micellar concentrations lower than that of CA; therefore at any given concentration they are more cytotoxic<sup>[48]</sup>. In the hepatocyte, when the concentration of hydrophobic BAs exceeds the binding capacity of the cytosolic proteins, these compounds possibly damage organelle membranes, especially in the case of mitochondria, which leads to mitochondrial damage and ultimately to apoptosis or necrosis<sup>[48]</sup>.

The amount of BAs present in bile as monomers depends on their degree of association with phospholipids and cholesterol to form mixed micelles. Such mixed micelles are formed at concentration

values well below cytotoxic levels, which accounts for the lack of BA-induced injury in the biliary system and small intestine under physiological circumstances. In *Mdr2*-knockout mice and patients lacking the canalicular phosphatidylcholine transporter MDR3 (*Mdr2* in rodents), phospholipid secretion is markedly impaired, leading to an increase in the concentration of monomeric BAs, which causes damage to biliary epithelial cells<sup>[48]</sup>.

## BILE-ACID-INDUCED INJURY IN OTHER CELL TYPES

### *Biliary cells*

In addition to the cytoprotective role of biliary phospholipids against the detergent activity of BAs, other mechanisms prevent cell damage, necrosis and apoptosis in the biliary epithelium even through this is exposed to high concentrations of these compounds. In immortalized mouse cholangiocytes it has been demonstrated that hydrophobic BAs cause apoptosis when they are taken up and accumulate inside the cell. This is, in part, inhibited by the activity of Mrp3, an export pump able to reduce intracellular BA concentrations<sup>[50]</sup>. However, when the accumulation of hydrophobic BAs occurs in chronic or subchronic cholestasis, this triggers cholangiocyte proliferation<sup>[51]</sup>. This stimulation capacity has been observed both in normal cholangiocytes and in cholangiocarcinoma cells<sup>[52,53]</sup>. Hydrophobic BA-induced cholangiocellular proliferation occurs by transactivation of EGFR<sup>[37,54]</sup>, which stimulates a phosphatidylinositol 3-kinase-dependent pathway<sup>[55]</sup>.

### *Gastrointestinal cells*

In humans, an increased incidence of cancer of the laryngopharyngeal tract, esophagus, stomach, pancreas, small intestine and colon is associated with high levels of hydrophobic BAs<sup>[34]</sup>. DCA has been proposed to be a cancer promoter in these organs<sup>[56]</sup>. These BAs cause DNA damage in several human colon cancer cell lines<sup>[57,58]</sup>, probably through an indirect mechanism involving the induction of oxidative stress and the production of ROS. Repeated DNA damage is likely to increase the mutation rate in several genes, including those coding for tumour suppressor factors and oncogenes. Moreover, hydrophobic BAs may behave as selection agents for apoptosis-resistant cells. The subpopulation of cells with a reduced apoptosis capability may be selected to survive and proliferate versus the more fragile normal cells. Indeed, long-term exposure of a human colonic epithelial cell line to sublethal concentrations of DCA has been reported to result in the selection of a population of cells partially resistant to DCA-induced apoptosis<sup>[59]</sup>.

### *Kidney and lung cells*

Regarding extrahepatic tissues, BA accumulation in the systemic circulation may contribute to endothelial

injury in the kidney and lungs<sup>[60]</sup>. Hydrophobic BAs cause oxidative damage to tubular cell membranes by stimulating the generation of ROS from mitochondria, as well as promoting their release from neutrophils and macrophages. Oxidative stress can promote the formation of a variety of vasoactive mediators including endothelin-1, cysteinyl leukotrienes, F2-isoprostanes and endogenous products of lipid peroxidation. These mediators can affect renal function directly by causing renal vasoconstriction or by decreasing the coefficient of glomerular capillary ultrafiltration, and thus reducing the glomerular filtration rate. Collectively, these factors contribute to the onset of renal failure in patients with biliary obstruction<sup>[61]</sup>. Disturbances in the biochemical functions of the kidney glomeruli and tubules have been reported in patients with intrahepatic cholestasis during pregnancy<sup>[62]</sup>.

BAs may reach the lung accidentally by aspiration of gastrointestinal contents or by direct uptake from blood. Bile aspiration produces a severe chemical pneumonitis in a porcine lung model<sup>[63]</sup> and intratracheally injected BAs have been shown to produce severe pulmonary edema in rabbits<sup>[64]</sup>. When intratracheal instillation of taurocholic acid (TCA, Figure 1) in rabbits was studied, microscopic evidence of widespread atelectasis, the pooling of eosinophilic substances in the intra-alveolar spaces, and the formation of hyaline membranes were found. The authors speculated that surfactant activity might be inhibited by BAs<sup>[65]</sup>.

### *Placental and fetal cells*

The accumulation of BAs may also have deleterious effects on the fetal-placental unit. The excretion of BAs produced by the fetus is performed by the placenta and the maternal liver, therefore impairment in biliary excretion may lead to the accumulation of BAs, in particular in the fetal liver-placenta-maternal liver trio<sup>[66]</sup>. An interesting issue that has recently been addressed is how this accumulation of BAs can affect fetal and placental tissues. In cholestatic pregnant rats, hydrophobic BA accumulation induces impairment of the placental antioxidant system and oxidative damage. These alterations are accompanied by enhanced activation of the mitochondrial pathway of apoptosis<sup>[67]</sup>. Moreover, the accumulation of hydrophobic BAs in the fetal compartment also causes marked oxidative damage and apoptosis in the fetal liver<sup>[68]</sup>. This is evidenced by enhanced lipid peroxidation and protein carbonylation, a pro-apoptotic imbalance in the Bax- $\alpha$ /Bcl-2 ratio, caspase-3 activation, and DNA fragmentation. Different sensitivities to BAs have been reported in fetal and maternal hepatocytes in short-term primary culture<sup>[69]</sup>. Although the basal production of ROS by fetal hepatocytes has been found to be higher than by maternal hepatocytes, ROS production is higher in maternal hepatocytes in response to exposure to relatively high concentrations of GCDCA<sup>[69]</sup>.

BA accumulation can cause other complications in extrahepatic fetal tissues. TCA (Figure 1) impairs neonatal rat cardiomyocyte function by altering calcium

dynamics and impairing the function of gap junctions in these cells, resulting in dysrhythmia. This has been proposed as a mechanism for intrauterine fetal death in obstetric cholestasis<sup>[70]</sup>. Recently, it has been reported that BAs can induce lung injury in newborn infants because these compounds are detectable in the bronchoalveolar lavage fluid of newborns from mothers with intrahepatic cholestasis during pregnancy affected by respiratory distress syndrome. Elevated serum BA levels in these infants can reach the lung after uptake from the circulation. These findings support the concept of a role of BA in the etiopathogenesis of some types of pneumonia<sup>[71]</sup>.

## BILE-ACID-INDUCED CELL PROTECTION

### **UDCA: protective effects and mechanisms of action**

UDCA (Figure 1) and its taurine-conjugated derivative, tauroursodeoxycholic acid (TUDCA) are hydrophilic BAs that have become highly popular owing to their low toxicity and efficiency in the treatment of several cholestatic liver diseases, such as cholelithiasis, primary biliary cirrhosis, primary sclerosing cholangitis, cystic fibrosis and intrahepatic cholestasis of pregnancy<sup>[2,3]</sup>. These BAs may be also useful to protect organs other than the liver, such as the brain<sup>[72]</sup> or placenta<sup>[67,73-75]</sup>.

UDCA is a major primary BA in some species of bears<sup>[76]</sup>. In fact, for centuries dried bear bile has been used in traditional Chinese medicine as a remedy for liver disorders<sup>[76]</sup>. In humans, UDCA is considered as a minor secondary BA because it is formed by 7 $\beta$ -epimerization of CDCA in the gut by intestinal bacteria. The abundance of UDCA in the total BA pool is less than 3%<sup>[77]</sup>. Despite its clinical efficacy, the precise mechanism by which UDCA improves liver function during cholestasis is still under study. It is considered that the choleretic effect of UDCA, together with its ability to cause a marked shift in the composition of the BA pool towards hydrophilicity, accounts for the beneficial properties of UDCA in the treatment of liver disorders<sup>[2,78]</sup>. Moreover, it has recently become evident that UDCA and TUDCA are capable of exerting direct protective effects at the cellular and molecular level, including the stabilization of hepatocyte membranes, the enhancement of defences against oxidative stress and the inhibition of apoptosis induced by several agents<sup>[2]</sup>. Other proposed mechanisms of action for UDCA, such as the immunomodulation and stimulation of bile secretion by hepatocytes and bile duct epithelial cells, may also contribute to the cytoprotective effects of this hydrophilic BA<sup>[78]</sup>. Nevertheless, the predominant mechanism of action of UDCA may vary, depending on the pathophysiology of the underlying liver disease.

**Protection against oxidative stress:** UDCA has shown to play an important role in the prevention of the oxidative injury induced by several agents, either through a direct antioxidant effect or an increase in antioxidant defences. The enhancement of glutathione levels, which has been demonstrated using isolated rat

hepatocytes<sup>[79]</sup> and rats with bile-duct-ligation-induced secondary biliary cirrhosis<sup>[80]</sup>, can be included among the beneficial effects of UDCA treatment, and may be due to a higher expression of the enzymes involved in glutathione synthesis. In this sense, an enhancement of  $\gamma$ -glutamylcysteine synthetase at the transcriptional level has been found in isolated rat hepatocytes treated with UDCA, which allows these cells to be more resistant to cadmium- or hydrogen-peroxide-induced oxidative injury<sup>[79]</sup>. UDCA treatment of chronic bile-duct-ligated rats also leads to an up-regulation of  $\gamma$ -glutamylcysteine synthetase and prevents the marked increase in the production of mitochondrial peroxide and of hydroxynonenal-protein adducts observed during chronic cholestasis<sup>[80]</sup>. The activity of methionine S-adenosyltransferase, another enzyme involved in glutathione (GSH) biosynthesis, has also been found to be increased by UDCA in rat livers<sup>[81]</sup>.

Pre-treatment of hepatocytes with UDCA also increases the amount of thiol-containing proteins such as metallothioneins, which efficiently scavenge hydroxyl radicals (OH $\cdot$ ), the most highly reactive ROS<sup>[79]</sup>. In human hepatoblastoma HepG2 cells, UDCA has been shown to be able to activate the metallothionein IIA promoter<sup>[82]</sup>.

During rat development, there is an excessive mitochondrial response to pro-oxidant stimuli, together with less well developed antioxidant protection mechanisms. This may account for the particularly high sensitivity of the foetal liver to lipid peroxidation<sup>[83]</sup>. In rats, obstructive cholestasis during pregnancy (OCP) increases the degree of lipid peroxidation and protein carbonylation in placenta<sup>[67]</sup> and in foetal liver<sup>[68]</sup>. Treatment of rats with UDCA during pregnancy prevents oxidative injury in the placenta<sup>[67]</sup> and foetal liver<sup>[68]</sup>. The drop in the activities of the enzymes involved in the mechanisms of resistance against oxidative stress, such as catalase, glutathione peroxidase and glutathione-S-transferase<sup>[67]</sup>, increases GSH content and the GSH/glutathione disulfide ratio. The impairment in liver structure and function in 4-wk-old pups born from rats with OCP is also partially prevented if the mothers are treated with UDCA<sup>[75]</sup>.

Hydrophobic BAs stimulate Kupffer cells, increasing their capacity to generate ROS, which in turn attack nucleic acids, thiol proteins or membrane lipids, causing lipid peroxidation. UDCA can block hydrophobic-BA-induced cellular phenomena, therefore, it could also antagonise macrophage activation by hydrophobic BAs to blunt their capacity to generate ROS<sup>[15]</sup>.

UDCA has direct antioxidant properties, which are evident at therapeutically relevant drug concentrations and are especially relevant against Fe<sup>3+</sup>- and OH $\cdot$ -induced oxidative damage<sup>[84]</sup>. The OH $\cdot$ -scavenging efficiency of UDCA appears remarkable, considering that its rate constant for reactions with this radical species is about 10-fold higher than that of the typical pharmacological scavenger (mannitol) and of the physiological scavengers glucose and histidine<sup>[84]</sup>. Thus, together with the high therapeutic concentrations of UDCA reached in

human bile, the drug could readily act as an effective OH<sup>•</sup> scavenger, especially in the biliary milieu<sup>[84]</sup>. It is therefore possible that UDCA could act not only as a site-specific OH<sup>•</sup> scavenger, but also as an antioxidant against iron (IV)-induced oxidative damage.

**Inhibition of apoptosis:** UDCA and TUDCA have been shown to prevent *in vitro* apoptosis induced by several agents in both hepatic and non-hepatic cells<sup>[27]</sup>. In rats with OCP, UDCA also prevents apoptosis in the placenta<sup>[67]</sup> and fetal liver<sup>[68]</sup>. In patients with primary biliary cirrhosis treated with UDCA, this drug shows a potential effect in reducing nuclear DNA fragmentation in biliary epithelial cells<sup>[85]</sup>. It has been suggested that UDCA could function as a therapeutic agent in the treatment of neurodegenerative disorders associated with increased levels of apoptosis<sup>[72]</sup>. Indeed, UDCA is neuroprotective in pharmacological and transgenic animal models of Huntington's disease<sup>[86]</sup>; it inhibits unconjugated bilirubin-induced apoptosis in both glial and neuronal rat cells in culture<sup>[87]</sup>, improves graft survival in Parkinsonian rats<sup>[86]</sup>, and protects against neurological injury after acute ischemic and hemorrhagic stroke<sup>[86]</sup>. The ability of UDCA to prevent apoptosis induced by a wide variety of compounds, such as hydrophobic BAs, ethanol, transforming growth factor beta 1 (TGFβ1), Fas ligand, and okadaic acid, suggests a mechanism that is common to each of the different apoptotic pathways<sup>[27]</sup>. A possible explanation for this ubiquitous antiapoptotic effect of UDCA seems to involve a blockage of mitochondrial dysfunction, mitochondria having a role as integrators of apoptosis signalling pathways<sup>[24,30]</sup>. UDCA is involved in both short- and long-term mechanisms in the prevention of the MPT responsible for hepatocyte cell death<sup>[24,30]</sup>. UDCA is able to reduce BA-induced disruption of the mitochondrial membrane potential, ROS production, and Bax protein abundance in mitochondria<sup>[30]</sup>. UDCA treatment also prevents the marked decrease in cardiolipin levels, which modulate apoptotic processes by inhibiting the MPT of damaged and primarily apoptotic hepatocytes during biliary cirrhosis induced by chronic cholestasis in rats<sup>[88]</sup>. Additionally, UDCA prevents the release of cytochrome c from mitochondria to the cytoplasm after mitochondrial injury and the subsequent cytosolic caspase activation and cleavage of the nuclear enzyme poly(ADP-ribose) polymerase<sup>[31]</sup>.

Nevertheless, the mechanisms by which UDCA prevents cell death involve molecular targets other than mitochondria, such as the ER. In an ER stress model in the liver-derived cell line Huh7, it has been shown that stress in this organelle activates caspase-12 and triggers apoptosis without the involvement of mitochondria<sup>[89]</sup>. TUDCA is able to abolish the typical morphological changes of ER stress preceding apoptosis, including activation of caspase-3 and -7, DNA fragmentation, and cleavage of poly(ADP-ribose) polymerase. TUDCA also blocks one of the calcium-mediated apoptotic pathways by a reduction in calcium efflux and the inhibition of

caspase-12 activation<sup>[89]</sup>.

Apoptosis can be inhibited, not only by blocking pro-apoptotic pathways, but also by promoting survival signals, including the cAMP, Akt, nuclear factor kappaB (NF-κB), mitogen-activated protein kinases (MAPK), and phosphatidylinositol 3-kinase (PI3K) signalling pathways<sup>[90,91]</sup>. The antiapoptotic effect of TUDCA against hydrophobic BA-induced apoptosis in rat hepatocytes is independent of caspase-8 inhibition, but results from the activation of the p38 MAPK, extracellular signal regulated-kinase (ERK) MAPK, and PI3K survival pathways<sup>[91]</sup>. UDCA stimulates the activation of the intracellular MAPK pathway through the activation of the epidermal growth factor receptor (EGFR)<sup>[90]</sup>. TGFβ1-induced hepatocyte apoptosis is associated with the activation of E2F transcription factors and p53 stabilization through its inhibitor Mdm-2. UDCA interferes in the E2F-1 transcriptional activation of apoptosis, thus modulating p53 stabilization, NF-κB activation, and the expression of Bcl-2 family members<sup>[92]</sup>, through a mechanism that appears to involve nuclear glucocorticoid and mineralocorticoid receptors<sup>[93]</sup>.

**Stimulation of bile flow and detoxification of cholephilic compounds:** The impairment of bile formation in cholestasis results in the accumulation of potentially toxic BAs and other biliary constituents in the liver, which can result in necrosis, apoptosis, fibrosis, and ultimately liver cirrhosis<sup>[94]</sup>. UDCA stimulates the biliary excretion of BAs and other cholephilic organic anions, even in situations of impaired bile secretion, such as primary biliary cirrhosis and primary sclerosing cholangitis, two disorders in which the effects of UDCA have mostly been studied<sup>[3]</sup>. In patients with these diseases, UDCA treatment decreases the serum levels of bilirubin and the accumulation of hydrophobic BAs<sup>[95]</sup>, probably due to stimulation of the expression of the export pumps involved in the detoxification process of cholephilic organic compounds by hepatocytes<sup>[96]</sup>, which are down-regulated in cholestatic liver diseases<sup>[94,96]</sup>.

Transient latent cholestasis in young rats born from mothers with OCP has been reported<sup>[97]</sup>. UDCA treatment of rats with OCP has long-term beneficial effects on their offspring by partially preventing the congenital impairment in hepatobiliary function of the pups that affects their biliary lipid secretion<sup>[73]</sup>. UDCA also has a beneficial effect on BA transport mechanisms in placentas from patients with intrahepatic cholestasis of pregnancy<sup>[73]</sup> and rats with OCP<sup>[74]</sup>. UDCA partially prevents OCP-induced impairment in the placenta-maternal liver tandem excretory pathway, by preserving trophoblast structure and function<sup>[74]</sup>.

In rodents fed for several weeks with diets supplemented with CA, CDCA and LCA, a down-regulation of the expression of xenobiotic-metabolizing enzymes, such as hepatic glutathione S-transferase in mice<sup>[98]</sup> and intestinal UDP-glucuronyltransferase in rats<sup>[99]</sup>, has been found. The prevention by UDCA of the decrease in the activity of phase-II-metabolizing

enzymes by hydrophobic BAs helps to maintain detoxification processes of cholephilic compounds<sup>[98,99]</sup>.

The secretory capacity of hepatocytes is mainly determined by the number and activity of carrier proteins in the apical membrane. In mouse liver, UDCA stimulates the gene expression of both the canalicular bile salt export pump (Bsep) and the canalicular multidrug resistance associated protein 2 (Mrp2)<sup>[100]</sup>. UDCA also stimulates the alternative basolateral ATP-binding cassette proteins Mrp3<sup>[101]</sup> and Mrp4<sup>[102]</sup>, which represent a compensatory overflow system under cholestatic conditions when the function of canalicular export pumps is impaired. UDCA also stimulates murine renal (Mrp2 and Mrp4) and intestinal (Mrp2 and Mrp3) efflux transport proteins, resulting in an increased overall elimination capacity for potentially toxic biliary compounds<sup>[101,102]</sup>.

Besides the long-term effects of UDCA on the regulation of gene transcription, post-transcriptional events such as increased targeting of transport proteins to the canalicular membrane *via* stimulation of vesicular exocytosis, can be accounted for by the increased expression of hepatobiliary transporters under treatment with UDCA or its conjugated derivatives<sup>[78]</sup>. Calcium<sup>-</sup><sup>[103]</sup>, protein kinase C (PKC)<sup>-</sup><sup>[104]</sup> and MAPK-dependent mechanisms<sup>[105]</sup> mediate the enhancement of the secretory capacity of cholestatic hepatocytes by TUDCA. Indeed, TUDCA favors the insertion of rat Mrp2 into apical membranes *via* PKC-dependent mechanisms<sup>[104]</sup>. Furthermore, p38 MAPK signalling pathways are involved in the enhanced insertion of both rat Bsep<sup>[105]</sup> and human BSEP<sup>[106]</sup> into the canalicular membrane of hepatocytes by TUDCA. Since the Golgi apparatus may serve as a BSEP pool and since p38 MAPK regulates BSEP trafficking from the Golgi apparatus to the plasma membrane, the activation of p38 MAPK by TUDCA can recruit Golgi-associated BSEP and insert it into the canalicular membrane<sup>[106]</sup>.

Besides the up-regulation of synthesis, apical targeting and insertion, direct activation of key canalicular transporters through modification of their phosphorylation status may contribute to the anticholestatic action of UDCA. This has been shown for mouse Bsep, whose transport capacity is increased by TUDCA *via* PKC $\alpha$ -mediated phosphorylation<sup>[107]</sup>.

**Protection of cholangiocytes against toxic effects of hydrophobic BAs:** The enrichment of bile with UDCA contributes to the prevention of toxic effects of more hydrophobic BAs, because this compound renders bile more hydrophilic, modifying the structure and composition of mixed phospholipid-rich micelles<sup>[108]</sup>. In addition, UDCA and its conjugates exert a direct effect on membranes by stabilizing their structure. This effect appears to be due to the incorporation of UDCA into the non-polar domain of the lipid bilayer and of its conjugates, into the interface<sup>[109]</sup>.

An experimental model in which the *in vivo* effects of UDCA on the protection of cholangiocytes have been studied is the *Mdr2*-knockout mouse. These

animals lack the ability to secrete phospholipids into bile and develop a chronic cholangitis resembling human chronic cholestatic liver disease<sup>[110]</sup>. The feeding of mice with UDCA or TUDCA decreases the degree of cholangiocellular injury, portal inflammation, and ductular proliferation<sup>[110]</sup>. 24-norursodeoxycholic acid seems to be superior to UDCA in the treatment of cholangitis in *Mdr2*-knockout mice<sup>[111]</sup>. Similar beneficial effects of UDCA have been found in bile-duct-ligated rats<sup>[112]</sup>. Likewise, in patients with primary cholestatic liver diseases under treatment with UDCA, the inflammatory reaction around bile ducts has been reported to be less severe<sup>[113]</sup>.

In addition to stabilizing cell membranes, other molecular mechanisms responsible for the protective effects of UDCA on cholangiocytes have been described recently. BAs are taken up by cholangiocytes mainly *via* the apical sodium-dependent BA transporter (ASBT). The accumulation of BAs in chronic cholestasis triggers cholangiocyte proliferation and secretion through a PI3K-dependent pathway<sup>[55]</sup>. UDCA and TUDCA reduce ASBT expression in cholangiocytes isolated from bile-duct-ligated rats, and they inhibit cellular growth and secretion<sup>[114]</sup> through Ca<sup>2+</sup>- and PKC $\alpha$ -dependent mechanisms<sup>[115]</sup>. TUDCA also inhibits the growth of the cholangiocarcinoma cell line Mz-ChA-1 through a signal-transduction pathway involving MAPK p42/44 and PKC $\alpha$ , which suggests that this compound may be a candidate for the treatment of cholangiocarcinoma<sup>[116]</sup>.

**Immunomodulation:** The immunomodulatory mechanism of action of UDCA accounts for the beneficial properties of treatment with this BA against several autoimmune liver diseases, such as primary biliary cirrhosis and chronic viral hepatitis. Among the *in vitro* experimental evidence of the immunomodulatory activity of UDCA reported is its ability to decrease the secretion of interleukins 2 and 4, TNF- $\alpha$  and interferon- $\gamma$  from activated T lymphocytes, and immunoglobulin production from B lymphocytes<sup>[117]</sup>. The suppression of cytokine and immunoglobulin production and T-cell-mediated cytotoxicity in mice by the treatment not only with UDCA<sup>[118]</sup> but also with CDCA<sup>[119]</sup> has been observed. In patients with primary biliary cirrhosis, the administration of UDCA down-regulates the expression of abnormal major histocompatibility complex (MHC) class I molecules in periportal hepatocytes, whereas the expression of abnormal MHC class II molecules in bile-duct epithelial cells does not change<sup>[120]</sup>. However, UDCA suppresses the interferon- $\gamma$ -mediated induction of MHC class II gene expression *via* the glucocorticoid-receptor-mediated pathway<sup>[121]</sup>.

#### **Protective effects of other bile acids**

Other natural BA molecules or their derivatives have also aroused pharmacological interest owing to their protective properties. Besides the efficiency of CDCA in cholesterol cholecystolithiasis<sup>[122]</sup> and cerebrotendinous xanthomatosis<sup>[48,123]</sup>, BA replacement therapy with a

mixture of this BA together with CA is used in the treatment of inborn errors of BA biosynthesis involving the A ring<sup>[48]</sup>. This treatment suppresses the synthesis of cytotoxic BA precursors and restores the input of primary BAs into the enterohepatic circulation<sup>[48]</sup>. Cholyl-N-methylglycine or cholylsarcosine (Figure 1) is a synthetic BA analog that has been shown to prevent the severe fat malabsorption seen in patients with short-bowel syndrome due to a BA deficiency, which leads to impaired micellar solubilization in the proximal intestine<sup>[124]</sup>.

## CONCLUSION

Rapid advances in the understanding of the cellular and molecular pathophysiology of BAs have led to a better knowledge of hepatocyte injury caused by the retention of hydrophobic BAs in cholestatic diseases. These BAs can damage cell membranes and promote the generation of ROS, and eventually cause necrosis and apoptosis. Hydrophobic BAs can also trigger hepatocyte apoptosis by the activation of death receptors, through the mitochondrial pathways, and by the induction of ER stress. The accumulation of hydrophobic BAs in the systemic circulation may have also deleterious effects on extrahepatic tissues such as kidney, lung, placenta, and foetal cells.

UDCA is a hydrophilic BA useful for the treatment of cholestatic liver diseases by its ability to modulate hydrophobic-BA-induced injury in hepatocytes. Underlying mechanisms of their beneficial effects are only now being clarified, and include protection against cytotoxicity due to more toxic BAs, stimulation of bile secretion, immunomodulation, protection against oxidative stress, and the inhibition of apoptosis. Other natural BAs or their derivatives, such as CA, CDCA and cholylsarcosine, have also aroused pharmacological interest owing to their protective properties in several diseases.

## ACKNOWLEDGMENTS

We thank Dr. JJG Marin for critical reading of the manuscript and N Skinner for the revision of the English spelling, grammar and style of the manuscript.

### Abstract

While lifestyle modifications are currently used as first-line treatment for subjects with gastroesophageal reflux disease (GERD), the pathogenetic role of lifestyle factors and consequently, the efficacy of lifestyle measures is controversial. Our aim was to systematically review the pathogenetic link between overweight/obesity, dietary habits, physical activity and GERD, and the beneficial effect of specific recommended changes, by means of the available literature from the 1999 to the present. Obesity, in particular, abdominal obesity, plays a key role in determining GERD symptoms and complications through mechanical and metabolic effects. Controlled weight loss (by diet or surgery) is effective in improving GERD symptoms. No definitive data exist regarding the role of diet and, in particular, of specific foods or drinks, in influencing GERD clinical manifestations. Moderate physical activity seems to be beneficial for GERD, while vigorous activity may be dangerous in predisposed individuals. In conclusion, being obese/overweight and GERD-specific symptoms and endoscopic features are related, and weight loss significantly improves GERD clinical-endoscopic manifestations. The role of dietary behavior, mainly in terms of specific dietary components, remains controversial. Mild routine physical activity in association with diet modifications, i.e. a diet rich in fiber and low in fat, is advisable in preventing reflux symptoms.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) is defined as an abnormal reflux of the gastric contents into the esophagus at least once a week, leading to symptoms, such as heartburn and/or acid regurgitation, and/or esophageal mucosal damage, which may also provoke long-term complications, such as Barrett's esophagus<sup>[1,2]</sup>. GERD represents a common disorder, particularly in the Western world (about 10%-20% in Western countries and under 5% in Asia) and its prevalence appears to be increasing<sup>[3,4]</sup>. The incidence rate, reported by two longitudinal studies<sup>[5,6]</sup>, was 4.5 and 5.4/1000 people per year, respectively.

GERD is a multifactorial disease in which anatomical and functional factors both play a pathogenetic role. The main pathogenetic mechanism of GERD is considered to be transient lower esophageal sphincter relaxation (TLESR)<sup>[7]</sup> which may account for the majority of reflux episodes, in patients with esophagitis and in those with non-erosive reflux disease (NERD). An increased number of TLESR episodes, combined or not with an impaired LES basal tone or with gastric or esophageal motor dysfunction, may lead to GERD, but the underlying causes of these functional disorders are still partially unknown<sup>[2]</sup>.

However, the role of genetic factors was suggested by twin studies<sup>[8,9]</sup> wherein heritability accounted for 31%-43% of the likelihood of reflux disease, which suggests that genetic and environmental factors both

play an important role. Among the environmental factors, lifestyle factors, in particular being overweight/obese, incorrect dietary habits, the lack of regular physical activity and smoking have frequently been suggested to be possible GERD risk factors. However, the exact pathogenetic role of these factors is still under debate and the beneficial effect of specific recommended changes in lifestyle habits is also controversial<sup>[10]</sup>.

A comprehensive search of the literature (Medline/PubMed databases 1999-June 2008, using the following keywords singly and in different combinations: GERD, food intake, food questionnaire, energy intake, motor activity, exercise, obesity, abdominal obesity) was carried out and the evidence available was critically reviewed.

## RELATIONSHIP BETWEEN OVERWEIGHT/OBESITY AND GERD

The observation of a consensual increase in the frequency of obesity and GERD<sup>[7,11,12]</sup> in Western countries has suggested a possible pathogenetic link between these two diseases, and it has generated great interest in elucidating the mechanisms demonstrating this association. However, although the relationship between GERD and obesity has been the subject of several studies, conflicting results have been obtained.

In a meta-analysis of epidemiological studies regarding the association between obesity and GERD-related disorders, it was found<sup>[13]</sup> that being overweight (BMI, 25-30 kg/m<sup>2</sup>) and being obese (BMI, > 30 kg/m<sup>2</sup>) were associated with GERD symptoms (OR, 1.43; 95% CI, 1.158-1.774 and OR, 1.94; 95% CI, 1.468-2.566, respectively), erosive esophagitis (OR, 1.76; 95% CI, 1.156-2.677 in overweight subjects) and esophageal adenocarcinoma (OR, 1.52; 95% CI, 1.147-2.009 and OR, 2.78; 95% CI, 1.850-4.164, respectively). A cross-sectional study on 206 consecutive patients not on acid-suppressing medications who underwent 24-h pH measurement showed<sup>[3]</sup> a significant ( $P < 0.005$ ) association between a BMI > 30, a high waist circumference and acid reflux episodes. An additional meta-analysis of clinical studies on the relationship between obesity and reflux symptoms, esophagitis or GERD-related hospitalization documented a positive association between BMI (OR, 1.57; 95% CI, 1.36-1.80 in overweight and OR, 2.15; 95% CI, 1.89-2.45 in obese subjects) and GERD in studies carried out in the USA, but the results were heterogeneous in those carried out in Europe<sup>[14]</sup>.

Different explanations have been proposed in order to interpret these geographical differences. In fact, the relationship between BMI and the percentage of body fat differs between ethnic groups<sup>[15]</sup>.

Since there are probably multiple pathogenetic mechanisms of GERD (TLESR, esophageal and gastric motor function, and gastric secretion), it is possible that not all of them are related to, or influenced by, the presence of obesity<sup>[16]</sup>. Furthermore, different definitions of GERD (endoscopic, symptom reports by self-administered or validated questionnaires) have

been utilized in the different studies, as well as different measures of obesity (BMI, central adiposity).

## RELATIONSHIP BETWEEN BEING OVERWEIGHT/OBESITY AND GERD: SUGGESTED PATHOGENETIC MECHANISMS

The exact pathophysiological mechanisms that demonstrate the association/relationship between being overweight/obese and GERD have not been fully identified, but some hypotheses have been suggested.

It has long been hypothesized<sup>[17-20]</sup> that visceral adiposity, expressed by an increased abdominal waist circumference, could be associated with increased intra-abdominal pressure which would, in turn, promote GERD by increasing intragastric pressure (IGP).

Using high-resolution manometry, it was found<sup>[17]</sup> that IGP as well as the gastroesophageal pressure gradient (GEPG), during expiration and inspiration, was significantly higher ( $P < 0.0001$ ) in obese and overweight patients, as compared to those with a normal BMI. This showed an IGP increase of 0.3 mmHg per unit of increase in BMI and the association was stronger in men than in women. Similar results were obtained in a recent retrospective analysis<sup>[18]</sup> in patients with typical GERD symptoms who underwent pH-monitoring and esophageal manometry. By means of multiple regression analysis, an increase of BMI was independently associated with IGP and with an increase of GEPG during inspiration; furthermore, BMI, IGP and GEPG were strong independent predictors of hiatal hernia, and IGP and GEPG were not independently associated with abnormal acid exposure or esophagitis.

A further pathogenetic mechanism has been suggested by Pandolfino *et al*<sup>[17]</sup> who observed that obesity was associated with a separation between LES and the extrinsic crural diaphragm, a disruption which could predispose obese subjects to hiatal hernia. It is known that hiatal hernia is commonly associated with symptomatic GERD, and patients with abnormal esophageal acid exposure have a significantly higher prevalence of hiatal hernia<sup>[21,22]</sup>. Furthermore, in patients with hiatal hernia, esophagitis or abdominal low distal esophageal pH are more common than in those without hiatal hernia<sup>[23]</sup>. In a retrospective case-control study on 1389 patients, obesity was found to represent an independent risk factor for hiatal hernia<sup>[24]</sup>. Therefore, it is possible that obesity, through alteration of normal IGP and separation between LES and the extrinsic crural diaphragm, predisposes to hiatal hernia and consequently, to GERD.

Another plausible mechanism for the association between obesity and GERD is represented by slower esophageal acid clearance, as shown by Quiroga *et al*<sup>[25]</sup> in a case-control study using esophageal manometry in normal weight and obese patients with GERD and in healthy subjects. All subjects with GERD showed altered

Table 1 Association between being overweight/obese and GERD-related symptoms

esophageal motility and obese patients also had impaired esophageal acid clearance.

In obese patients, other esophageal motor abnormalities, such as hypotensive LES pressure, nutcracker esophagus and non-specific motility disorders<sup>[26-29]</sup> have been observed.

However, the most important reflux mechanism in obese subjects seems to be TLESR<sup>[7]</sup>. The main stimulus for generating TLESR episodes is gastric distension, which leads to intense stimulation of both stretch and tension mechanoreceptors in the proximal stomach<sup>[30,31]</sup>. In fact, in a recent study<sup>[32]</sup>, three groups of subjects without GERD (28 obese, 28 overweight and 28 normal) underwent BMI measurements, upper endoscopy, manometry and pH recordings for both the fasting and the postprandial period and were given a symptom questionnaire. During the 2-h postprandial period, both overweight and obese individuals showed a significantly ( $P < 0.001$ ) higher rate of TLESR episodes, and a higher proportion of TLESR episodes accompanied by acid reflux and total acid exposure than normal weight subjects. A direct correlation between increasing BMI, an increased number of TLESR episodes, and an increased number of TLESR episodes associated with acid reflux was identified. Therefore, it seems that obese subjects have a higher postprandial IGP, which provokes more postprandial TLESR episodes.

Another mechanism by which obesity can cause GERD is related to the visceral component of abdominal obesity. In fact, visceral fat is metabolically active<sup>[33]</sup> and it has been associated with low serum levels of protective cytokines, such as adiponectin, and high levels of inflammatory cytokines, such as tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)-1 $\beta$  and IL-6. An increase in these inflammatory cytokines in patients with erosive esophagitis and Barrett's esophagus has also been observed<sup>[34]</sup>.

In conclusion, although conflicting and non-definitive results exist, it is likely that GERD and obesity are in some way linked; in particular, abdominal obesity seems to play a key role in determining GERD symptoms and complications through mechanical and metabolic effects. Consistent with this evidence, it is

possible to hypothesize that GERD may be a curable condition through the control of body weight and, in particular, by reducing abdominal obesity.

## OBESITY AND GERD-RELATED SYMPTOMS

Different studies have analyzed the possible relationship between obesity and GERD by evaluating the clinical manifestation of the disease since reflux symptoms (mainly, heartburn and acid regurgitation) represent the main target for diagnostic evaluation and treatment in GERD patients. However, the factors responsible for the generation of symptoms, in normal or overweight subjects, have not been clearly identified.

Sensitization of esophageal chemoreceptors, either directly by intermittent exposure to refluxed acid or indirectly through esophagitis-associated inflammatory mediators, is thought to be one of the most important mechanisms responsible for symptom generation in GERD<sup>[35,36]</sup>.

Several authors have evaluated the relationship between obesity and the symptoms of GERD, both to confirm the association between obesity and GERD and to find potential risk factors for symptom generation (Table 1). In all the studies available, only typical GERD symptoms (i.e. heartburn and regurgitation) have been taken into account, with the use of interviews or structured questionnaires.

In a large cross-sectional study<sup>[37]</sup> on abdominal obesity, GERD symptoms and ethnicity performed on 80 110 members of a health organization, it was found that increased abdominal diameter, adjusted for BMI, was an independent risk factor for reflux symptoms (OR, 1.85; 95% CI, 1.55-2.21) in the white population but not among blacks and Asians, and this aspect was not influenced by gender.

A recent large cohort study in 10 545 women reported a significant ( $P < 0.001$ ) dose-dependent relationship between increasing BMI and frequent reflux symptoms; this relationship was present even in the normal range of BMI<sup>[38]</sup>.

Two large population studies<sup>[39,40]</sup> and a case-control study<sup>[41]</sup> have found a positive association between BMI and reflux symptoms. The same results were previously obtained in a large population-based study carried out in Norway<sup>[42]</sup>; the authors found a stronger association among women, especially premenopausally, and that the use of hormone therapy strengthened the association, which suggested that estrogens may play an important role in the etiology of reflux disease. Another recent study<sup>[43]</sup> performed in Sweden on a large number of twins, confirmed that BMI seems to be a risk factor for GERD symptoms in monozygotic twins.

However, the association between obesity and GERD symptoms was not confirmed in subjects with benign esophageal disease<sup>[44]</sup>. Furthermore, a cohort study from New Zealand found no association between BMI and reflux symptoms<sup>[45]</sup> but, as its authors noted, the cohort consisted of young adults, and GERD symptoms do not usually appear until middle age. The same results were produced by a nationwide case-control study in Sweden<sup>[46]</sup> and by a recent population-based epidemiological study in Italy<sup>[47]</sup>.

No data are available yet about the possible correlation between obesity and atypical GERD symptoms.

In conclusion, although further studies are probably needed, most of the available evidence suggests a relationship between obesity, mainly abdominal obesity, and GERD-related typical symptoms.

## OBESITY AND REFLUX ESOPHAGITIS

Endoscopic investigation, alone or combined with information regarding specific symptoms obtained by means of structured questionnaires, has been carried out in order to evaluate the possible correlation between GERD-related disorders, such as esophagitis, and obesity (Table 2).

The above mentioned meta-analysis by Hampel *et al*<sup>[13]</sup> has documented the association between a BMI  $\geq 25$  kg/m<sup>2</sup> and erosive esophagitis. This association was confirmed by Nocon *et al*<sup>[40]</sup> using a symptomatic questionnaire and upper endoscopy in 6215 patients and by Kim *et al*<sup>[48]</sup> who observed, in 27319 subjects, an association between an increasing BMI and abnormal endoscopic findings, such as erosive gastritis, gastric

ulcer, duodenal ulcer (OR, 1.31; 95% CI, 1.22-1.40;  $P < 0.0001$  for overweight subjects; OR, 1.40; 95% CI, 1.14-1.72;  $P < 0.001$  for obese patients) and reflux esophagitis (OR, 1.61; 95% CI, 1.42-1.83;  $P < 0.001$  for overweight subjects, OR, 2.23; 95% CI, 1.59-3.11;  $P < 0.001$  for obese patients). In a long-term follow-up study (median 18.5 years) on 12349 subjects<sup>[49]</sup>, increased hospitalization rates for esophagitis and hiatal hernia were documented in patients with a BMI  $> 25$  kg/m<sup>2</sup>. Other population-based studies<sup>[50,51]</sup> have also confirmed the correlation between obesity, mainly abdominal obesity, and erosive esophagitis.

Furthermore, an association between the metabolic syndrome and reflux esophagitis has recently been documented<sup>[52]</sup> in a cross-sectional case-control study on 7078 subjects. In particular, it was observed that, among the single components of the metabolic syndrome, abdominal obesity (in particular visceral fat) and elevated serum triglycerides represented independent risk factors for reflux esophagitis (OR, 1.60; 95% CI, 1.03-2.48). Furthermore, it has been demonstrated that only visceral adipose tissue, evaluated by cross-sectional computed tomography, was an independent risk factor for reflux esophagitis. This tissue, in fact, is recognized to be metabolically active and it has been associated with elevated serum levels of pro-inflammatory adipokines (IL-6, TNF- $\alpha$  and adiponectin), compounds which may play a role in GERD development<sup>[53,54]</sup>. It seems that visceral adipose tissue plays a key role in increasing lipolysis and free fatty acid, leading to insulin resistance, which is considered the major pathophysiological factor for the development of the metabolic syndrome<sup>[33,55-57]</sup>. It has been suggested that these substances might alter the LES pressure or affect the esophageal clearance of refluxate<sup>[52]</sup>.

However, the association between BMI and esophagitis has not been confirmed in a recent Japanese prospective study<sup>[58]</sup>, as well as in an epidemiological survey<sup>[47]</sup> and a multicenter Italian observational study<sup>[59]</sup>. The different percentages of body fat in different ethnic groups may represent a possible explanation for these different results<sup>[15]</sup>.

In conclusion, as occurs for specific GERD symptoms, most of the evidence available also suggests a positive correlation for the association between being

overweight/obese and GERD-related morphological lesions.

## WEIGHT CHANGES AND GERD-RELATED SYMPTOMS

The observed relationship between weight gain and an increase in GERD-related symptoms<sup>[60,61]</sup>, as well as that between weight reduction and a decrease in GERD-related symptoms<sup>[62-64]</sup>, represents additional evidence of the close relationship between obesity and GERD. However, results from studies of weight loss for the control of GERD-related symptoms in obese subjects are not conclusive<sup>[65]</sup>.

In an uncontrolled study on selected patients with a BMI > 25 kg/m<sup>2</sup>, Fraser-Moodie *et al*<sup>[64]</sup> found that weight loss, induced by general dietary advice, had a beneficial effect on GERD symptoms, as evaluated by a structured questionnaire. Different results were obtained<sup>[66,67]</sup> in obese patients with reflux disease who were on a very-low-calorie diet, in which no reduction in reflux symptoms or changes in reflux episodes measured by 24 h pH-monitoring were documented. However, these studies have presented important limitations since they included patients with hiatal hernia, which represents an irreversible condition that contributes to the occurrence of GERD despite the weight loss, and they were carried out on very small numbers of patients, 20 and 15, respectively.

The effect of weight loss induced by endoscopic or surgical procedures has been evaluated. A significant reduction in esophageal acid exposure was documented during weight loss induced by an intragastric balloon<sup>[62,63]</sup> in a randomized, double-blind, sham-controlled study. An improvement in GERD symptoms was also found after weight loss induced by bariatric surgery<sup>[68]</sup>. In particular, the Roux-en-Y gastric bypass seems to represent the surgical procedure that is most effective in improving GERD symptoms in obese subjects<sup>[68-72]</sup>. Roux-en-Y gastric bypass may be successful at reducing GERD symptoms by diverting bile away from the esophagus<sup>[68,73]</sup>, eliminating acid production in the gastric pouch<sup>[73]</sup>, and reducing the volume of acid refluxate<sup>[70]</sup>. This hypothesis is supported by the observation of rapid symptom improvement after the surgical procedure; long-term symptom improvement is likely to be the result of weight loss<sup>[68]</sup>.

Studies evaluating other types of bariatric surgery, such as laparoscopic gastric banding or vertical banded gastroplasty, have produced conflicting results<sup>[26,74-78]</sup>. In particular, laparoscopic adjustable gastric banding has no, or minimal, effect on GERD-related symptoms but, over time, symptoms increase toward baseline or beyond. This effect is likely caused by slippage of the band distally, which results in more stomach above the band. Therefore, the impact of laparoscopic adjustable gastric banding on GERD is independent of weight loss; instead, it is the direct anatomical alteration of the band that impacts on GERD symptoms<sup>[65]</sup>.

However, these studies are still limited by small sample sizes, lack of randomization, failure to use control groups, use of retrospective data and inconsistent timing of postoperative re-evaluation. Furthermore, it has yet to be clarified whether the surgical technique itself, and/or weight loss, represents the mechanism of action for symptom improvement.

In obese subjects undergoing weight loss, the effect of changes in meal composition on reflux symptoms has also been investigated<sup>[79,80]</sup>, although in small studies. In a study on eight obese volunteers, a lower carbohydrate diet reduced reflux symptoms and reflux episodes, which was evaluated by means of 24-h pH monitoring<sup>[79]</sup>. A higher frequency of reflux symptoms with a high-fat diet as compared to a low-fat diet has also been demonstrated<sup>[80]</sup>, using four different calorie/fat composition diets, in 15 patients with GERD. Furthermore, esophageal acid exposure was higher with the high-calorie diet as compared to the low-calorie diet.

Together, these data indicate an effective role for weight loss in improving GERD symptoms as well as the effect of differing meal compositions on reflux disease.

## DIET AND GERD

It is a common belief that some foods may induce or worsen GERD symptoms; in fact, in daily clinical practice, this belief leads to advising patients to avoid the suspect foods<sup>[81]</sup>. Furthermore, since GERD symptoms are most commonly reported postprandially, the role of diet components in inducing symptoms has been suggested. However, different and conflicting results exist in the literature for identifying the most "refluxogenic" foods (Table 3).

Old experimental and clinical studies have shown a decrease in LES pressure and an increase in esophageal acid exposure in response to the ingestion of food rich in fats, chocolate and carminatives<sup>[82-85]</sup>. Nebel *et al*<sup>[86]</sup> have demonstrated that fried foods, spicy foods and alcohol are the most common precipitating factors of heartburn; however, this study had no control group and did not quantify the intake of dietary items.

In order to elucidate the association of different nutrients with the risk for GERD, El-Serag *et al*<sup>[87]</sup> carried out a cross-sectional study on 915 employers, using a dietary questionnaire to estimate the average food consumption over the previous year, and a GERD questionnaire together with an upper endoscopy for assessing GERD severity. A positive association between high fat intake, and GERD symptoms and erosive esophagitis was observed, while a high-fiber diet seemed to reduce reflux symptoms. However, the effects of fat on GERD symptoms and erosive esophagitis were dependent on BMI since this is statistically significant only in overweight individuals. Furthermore, a higher daily intake of fats and proteins was observed in those participants with erosive esophagitis.

More recently, Shapiro *et al*<sup>[88]</sup> observed in 58 subjects with typical heartburn symptoms that increased consumption of cholesterol, saturated fatty acids and an

higher percentage of calories from fats was significantly associated with an increased likelihood of having reflux events. The role of fats in symptom generation has been confirmed by some<sup>[89-91]</sup>, but not by others<sup>[41,49,92,93]</sup>. Ruhl *et al*<sup>[49]</sup> failed to document an association between dietary fat intake and erosive esophagitis and reflux symptoms,

although higher reflux disease hospitalization rates were associated with an increased BMI. These results are consistent with those produced by Nandurkar *et al*<sup>[41]</sup>, who analyzed potential risk factors for reflux among 211 community subjects and concluded that only BMI, and not diet, may influence symptomatic GERD.

Also Pehl *et al*<sup>[92]</sup> did not find differences in reflux parameters comparing a high-fat meal with a low-fat meal; similar results were obtained by Colombo *et al*<sup>[93]</sup>, although they found that a caloric load increased esophageal acid exposure.

Furthermore, none of the dietary items evaluated (i.e. vegetables, fruits, fish, meat, rice, milk, grilled and fried food), including alcohol, was associated with the risk of GERD symptoms in the above-mentioned monozygotic co-twin study based on the Swedish Twin Registry<sup>[43]</sup>, which investigated lifestyle factors that potentially cause GERD.

Considering the recommended advice of controlling alcohol drinking and reducing, or avoiding, coffee to prevent GERD symptoms<sup>[81,94]</sup>, several studies investigated the role of alcohol and coffee in GERD. While some authors have suggested that alcohol is an independent risk factor for GERD-related symptoms<sup>[95-98]</sup>, others have not found such a relationship<sup>[99-102]</sup>. In their study about the lifestyle habits and GERD symptoms of the participants in two consecutive public health surveys in Norway (> 40000 people), Nilsson *et al*<sup>[99]</sup> did not find that alcohol, coffee or tea were risk factors for reflux-related symptoms. Shapiro *et al*<sup>[88]</sup> not only confirmed these results, but also documented that alcohol was associated with a reduced perception of intra-esophageal acid reflux events.

Despite the observation that the intraesophageal infusion of coffee in patients with acid sensitivity may induce heartburn<sup>[103]</sup>, two large epidemiological studies have found no association between coffee drinking and GERD<sup>[96,101]</sup>. Boekema *et al*<sup>[104]</sup> have found that coffee does not alter postprandial acid reflux time or the number of acid reflux episodes, and others<sup>[41]</sup> have noted that coffee consumption is lower in subjects with reflux symptoms. However, the latter result might reflect avoidance of coffee by those who suffer from reflux because the beverage aggravates symptoms.

Furthermore, in their recent study of twins, Zheng *et al*<sup>[43]</sup> have found that coffee intake might be a protective factor for GERD symptoms in men, but not in women. The authors have suggested that the differences observed might be caused by sex differences regarding caffeine metabolism. In fact, it has been demonstrated that the conversion of caffeine to paraxanthine, which accounts for 84% of the primary degradation of caffeine in humans<sup>[105]</sup>, is markedly inhibited by exogenous estrogen in women taking oral contraceptives<sup>[106]</sup> or in postmenopausal women on hormone replacement therapy<sup>[107]</sup>. Given the conflicting data reported, the relationship between coffee and GERD remains unclear; as a consequence, there is insufficient evidence to support the routine recommendation of avoiding such beverages for patients with GERD.

In conclusion, no definitive data exist regarding the role of diet and, in particular, of specific foods or drinks, in GERD clinical manifestations. Despite the insufficient evidence to support an association between dietary behavior and GERD, some dietary interventions continue to be recommended as first-line therapy<sup>[81]</sup>. Larger prospective controlled trials are required to

conclusively recommend dietary modifications in the treatment of GERD.

## SMOKING AND GERD

Population-based and epidemiological studies have suggested that tobacco smoking may represent a risk factor for GERD<sup>[9,39,108-113]</sup>. Studies using specific questionnaires have reported that smoking is significantly associated with GERD-related symptoms (OR, 1.35; 95% CI, 1.01-1.82)<sup>[114-116]</sup>. Furthermore, a recent monozygotic co-twin study<sup>[43]</sup> has provided compelling evidence that tobacco smoking increases the risk for the occurrence of frequent GERD symptoms, and a case-control study<sup>[99]</sup> on 3153 patients with severe GERD-related symptoms has shown that the duration of smoking was associated with increasing reflux symptoms (OR, 1.7; 95% CI, 1.5-1.9 in subjects who had smoked for > 20 years). Different mechanisms have been suggested to justify the association between smoking and GERD. Cigarette smoking can reduce the LES pressure<sup>[117-119]</sup> and decrease salivary bicarbonate secretion, thus reducing the physiological neutralizing effect of saliva on intraesophageal acid and prolonging acid clearance<sup>[120,121]</sup>. Furthermore, abrupt increases in intra-abdominal pressure, as occur during coughing or deep inspiration, have been associated with reflux symptoms in smokers<sup>[122]</sup>. However, studies that have examined acid perfusion using the Bernstein test or esophageal pH<sup>[123-125]</sup> have reported that smokers compared to non-smokers do not show an increased esophageal acid exposure time, despite having more "reflux episodes"<sup>[126]</sup>. Furthermore, two old case-control studies evaluating, on very small samples, the effect of smoke cessation on GERD outcomes<sup>[126,127]</sup> were unable to document an improvement in GERD symptoms after the cessation of tobacco use.

## PHYSICAL ACTIVITY AND GERD

Since previous investigations have demonstrated that strenuous exercise may induce GERD<sup>[128-130]</sup> and that GERD symptoms are common among athletes<sup>[131]</sup>, it has been suggested that physical activity represents another risk factor for GERD. However, available evidence indicates that a positive association between exercise and GERD is present in vigorous, but not in moderate, exercise<sup>[41,132,133]</sup>. In fact, Clark *et al*<sup>[134]</sup> have reported that running, cycling and weight lifting increase GERD in asymptomatic volunteers. Furthermore, these authors have found that specific types of exercise are more likely to induce reflux symptoms, with running and resistance exercises being more refluxogenic than cycling.

Similar results have been obtained by Peters<sup>[135]</sup>, in addition, this author has found increased reflux using high-carbohydrate sport drinks with respect to water, which demonstrates a possible role of sport drinks in facilitating reflux symptoms. Therefore, it seems that a hierarchy of exercises in inducing reflux symptoms exists<sup>[134]</sup>. However, there is no general agreement with respect to the mechanism by which vigorous exercise

**Table 4** Physical activity and GERD-related clinical manifestations

Author	Year	Country	Study design	Population size	Method of data collection	Association/Effect
Vigorous/agonistic exercise						
Clark <i>et al</i> <sup>[134]</sup>	1989	USA	Crossover	12 asymptomatic volunteers	pH-monitoring, 1 h exercise period (bicycling, running and weight routine)	Yes

induces reflux. Exercise may alter esophageal motility and worsen symptoms of the upper gastrointestinal tract<sup>[136]</sup>. Clark *et al*<sup>[134]</sup> have speculated that “body agitation” may be important in inducing reflux. Soffer *et al*<sup>[137]</sup> have focused on a decreased duration, amplitude and frequency of esophageal contractions with increasing exercise intensity. This suggestion has not been confirmed by Choi *et al*<sup>[138]</sup> who reported increased frequency, but not duration or amplitude, of peristaltic contractions. Furthermore, Pandolfino *et al*<sup>[129]</sup> have suggested that the anatomical compromise of the esophagogastric junction, as a consequence of frequent abdominal straining associated with strenuous exercise, may predispose to exercise-induced reflux. Other studies have suggested that GERD may be increased in athletes because of a decreased gastrointestinal blood flow, alterations of hormone secretion, changes in the motor function of the esophagus and the ventricle, and constrained body position during exercise<sup>[139]</sup>.

All these studies suggest that a specific physical activity, i.e. an agonistic activity, plays a possible pathogenetic role in inducing GERD symptoms. However, these results should not be extended to normal physical activity, which has been demonstrated to have a protective effect against GERD<sup>[99]</sup> (Table 4). In particular, in a large population-based study<sup>[99]</sup>, a protective effect of physical activity was observed, documenting a correlation between the number of exercise sessions lasting at least 30 min and a decreased risk of GERD symptoms (OR, 0.5; 95% CI, 0.4-0.7). Therefore, a mechanism of an exercise-strengthened antireflux barrier, possibly constituted by striated muscle was suggested. The same results were produced by Nocon *et al*<sup>[39]</sup>, who have also found that subjects with typical GERD symptoms are physically less active than those without symptoms.

Furthermore, in their monozygotic co-twin study, Zheng *et al*<sup>[43]</sup> have provided evidence that physical activity at work increases the risk of GERD symptoms, whereas physical activity at leisure time decreases this risk. The authors have suggested that physical activity at work might be linked with postprandial exercise, which has been found to be a risk factor for the development of GERD symptoms<sup>[140]</sup>. Indeed, physical exercise at leisure time is predominantly performed at times without a feeling of stomach fullness and is, therefore, most unlikely to be a reflux-provoking postprandial exercise<sup>[140]</sup>.

In conclusion, the relationship between exercise and GERD is also controversial. It may be a consequence of differences in the populations studied (age, race), evaluation of exercise (short-term, long-term), assessment of physical activity (different questionnaires) and diagnosis of the disease (symptom scale or pH-metry). However, mild routine physical activity in association with diet modifications, i.e. a diet rich in fiber and poor in fat, seems to be advisable to prevent reflux symptoms.

## CONCLUSION

There is sufficient evidence to support the relationship between being obese/overweight and GERD, expressed as specific symptoms and endoscopic features. Furthermore, available evidence suggests that controlled weight loss (by diet or surgery) is able to induce a significant improvement in GERD symptoms and/or in GERD clinical-endoscopic manifestations. Definitive data still do not exist regarding the association between dietary behavior, mainly in terms of specific dietary components and GERD manifestations. Moderate

physical activity seems beneficial, while vigorous activity may be dangerous in predisposed individuals. However, owing to the evidence that incorrect dietary habits and the absence of regular physical activity represent important risk factors for the development of the so-called “non-communicable diseases”<sup>[141]</sup>, lifestyle changes are recommended in patients with or at high risk for GERD. According to the recent proposal by a panel of international experts of a new algorithm for GERD management<sup>[142]</sup>, life-style factors (i.e. meal size and timing, not lying down after a meal or lying down where the head is in a non-elevated position, not smoking, not consuming alcohol, not eating heavily spiced or fatty food and having a physically active life) are important instruments for the overall management of GERD. Additional clinical studies are required.

### INTRODUCTION

Reactive oxygen species (ROS) are molecules or ions formed by the incomplete one-electron reduction of oxygen. These reactive oxygen intermediates include singlet oxygen, superoxides, peroxides, hydroxyl radical, and hypochlorous acid. They contribute to the microbicidal activity of phagocytes, regulation of signal transduction and gene expression, and induce oxidative damage to nucleic acids, proteins, and lipids. Peroxidation by ROS alters the amounts of unsaturated fatty acids and proteins in the cell membrane and thus affects membrane fluidity. In addition, with aging, humans tend to show an increased affectability of lipid peroxides caused by ROS<sup>[1]</sup>. Recent research has indicated that ROS also play a critical role in the energy dysfunction of mitochondria caused by ethanol-induced gastric mucosa injury<sup>[2]</sup>. In addition, oxidative damage caused by ROS and other free radicals is involved in a number of pathological conditions including cancer. Data presented herein is consistent with this opinion. Yagoda *et al*<sup>[3]</sup> found erastin interacted with voltage-dependent anion channel proteins to induce mitochondrial dysfunction, release of oxidative species and, ultimately, non-apoptotic, oxidative cell death. This process has a degree of selectivity for cells with activated Ras-Raf-MEK signaling. ROS production also involves the induction of autophagy, which contributes to caspase-independent macrophage cell death<sup>[4]</sup>. ROS, produced in the redox cycle, contribute to p53 mutations, which are dominated by G-to-T transversions. These mutations are suppressed by ROS attenuators<sup>[5,6]</sup>. The mutations of p53, a well characterized tumor suppressor, are believed to relate to carcinogenesis. Since oxidative stress comprehensively

### Abstract

Reactive oxygen species (ROS) are molecules or ions formed by the incomplete one-electron reduction of oxygen. Of interest, it seems that ROS manifest dual roles, cancer promoting or cancer suppressing, in tumorigenesis. ROS participate simultaneously in two signaling pathways that have inverse functions in tumorigenesis, Ras-Raf-MEK1/2-ERK1/2 signaling and the p38 mitogen-activated protein kinases (MAPK) pathway. It is well known that Ras-Raf-MEK1/2-ERK1/2 signaling is related to oncogenesis, while the p38 MAPK pathway contributes to cancer suppression, which involves oncogene-induced senescence, inflammation-induced cellular senescence, replicative senescence, contact inhibition and DNA-damage responses. Thus, ROS may not be an absolute carcinogenic factor or cancer suppressor. The purpose of the present review is to discuss the dual roles of ROS in the pathogenesis of cancer, and the signaling pathway mediating their role in tumorigenesis.

**Key words:** p38 mitogen-activated protein kinases; Reactive oxygen species; Signal transduction; Tumorigenesis

damages cells and tissues, it is reasonable that factors which induce ROS would contribute to the occurrence and development of tumors, while antioxidant agents that scavenge ROS may inhibit this process. To the best of our knowledge, the former inference is consistent with previous reports<sup>[7,8]</sup>, however, there is little supportive evidence for the latter<sup>[9,10]</sup>. Vitamins C and E, two reducing agents and antioxidants, show no additional benefit in the chemoprevention of gastric cancer<sup>[11,12]</sup>. Inadequate dose, heterogeneous research, poor compliance and multiple effects of antioxidants may lead to this paradox. Is there anything more to be elucidated on this subject?

## REGULATION OF ROS PRODUCTION BY RAS

Oxidative stress and Ras activation lead to the production of ROS<sup>[13]</sup>. Introduction of ROS by Ras may occur at the transcription level. GATA-6 is a component of the specific protein-DNA complexes at the nicotinamide adenine dinucleotide phosphate oxidase (Nox) 1 promoter, and is able to trans-activate the Nox1 promoter. GATA-6 is phosphorylated at serine residues by MEK-activated extracellular signal-regulated kinase (ERK), which enhances GATA-6 DNA binding. The site-directed mutation of the consensus ERK phosphorylation site (PYS(120)P to PYA(120)P) of GATA-6 abolishes its trans-activation activity, suppressing the growth of CaCo-2 cells. By MEK-ERK-dependent phosphorylation of GATA-6, oncogenic Ras signaling enhances the transcription of Nox1<sup>[14]</sup>. A regulatory subunit, Rac, of the NADPH oxidase complex also involves the regulation of ROS<sup>[15]</sup>. Other factors that regulate the production of ROS will not be discussed here.

## ROS INVOLVE TUMORIGENESIS THAT RELATES TO THE RAS-RAF-MEK-ERK PATHWAY

Growth factors, cellular stress, and  $\gamma$  radiation stimulate oncogenic Ras-Raf-MEK signaling, which plays a crucial role in tumorigenesis. As an important mediator of physiological and pathological signal-transduction pathways, ROS is also involved in Ras-Raf-MEK signaling (Figure 1). The functions of ROS in tumorigenesis relating to this pathway include the following. (1) In cells with activated Ras-Raf-MEK signaling, released ROS cause non-apoptotic, oxidative cell death, as previously mentioned<sup>[3]</sup>, and the Ras-ERK pathway is critical in mediating protection against apoptotic cell death induced by increased oxidative stress<sup>[16]</sup>. (2) The activity of the ROS-generating enzyme Nox1 is required for vascular endothelial growth factor (VEGF), a potent stimulator of tumor angiogenesis. However, if extracellular signal-regulated kinase (ERK)-dependent phosphorylation of the transcription factor

**Figure 1** Roles of ROS in the Ras-Raf-MEK-ERK signaling and p38 pathway (Modified from Ref. 31, with permission).

Sp1 and Sp1 binding to a VEGF promoter is inhibited, this activity does not occur. Nox1 mediates oncogenic Ras-induced upregulation of VEGF and angiogenesis by activating Sp1 through Ras-ERK-dependent phosphorylation of Sp1<sup>[8]</sup>. (3) Ras (p19) interaction with p73 $\beta$ , a structural and functional homolog of p53, amplifies p73 $\beta$ -induced apoptotic signaling responses including Bax mitochondrial translocation, cytochrome c release, increased production of ROS and loss of mitochondrial transmembrane potential. After taxol treatment, endogenous expression of Ras and p73 $\beta$  significantly increase, and taxol-enhanced endogenous p73 $\beta$  transcriptional activities are further amplified by p19, which markedly increases cellular apoptosis in the p53-null SAOS2 cancer cell line<sup>[17]</sup>. (4) In human U937 monocytes, hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) evokes Ca<sup>2+</sup> influx through TRPM2 to activate Ca<sup>2+</sup>-dependent tyrosine kinase Pyk2 and amplify ERK signaling *via* Ras GTPase. TRPM2 Ca<sup>2+</sup> influx controls the ROS-induced signaling cascade responsible for chemokine production, which aggravates inflammation<sup>[18]</sup>.

In contrast, the released ROS have complicated effects on Ras-Raf-MEK signaling, which may occur on several levels (Figure 1). ROS directly enhance the activation of Ras<sup>[19]</sup>, and augment ERK1/2<sup>[20]</sup>. Melatonin, a natural antioxidant, inhibits the activation of Ras in H4IIE hepatoma cells<sup>[21]</sup>. Generation of ROS is required for Ras transformation phenotypes including anchorage-independent growth, morphological transformation, and tumorigenesis<sup>[22]</sup>. In diabetes-related angiogenesis of the retina, activation of H-Ras and its downstream signaling pathway may be under the control of superoxide, and H-Ras activation in diabetes can be prevented by inhibiting superoxide accumulation<sup>[23]</sup>. H<sub>2</sub>O<sub>2</sub> activates H-Ras and its downstream signaling pathway, including Raf-1 and phosphorylation of p38 MAP kinase. Inhibition of superoxide significantly attenuates glucose-induced activation of H-Ras, Raf-1 and p38 MAP kinase<sup>[23]</sup>. PI3K is a mediator in the

E-Ras-PI3K-Akt signaling pathway, which leads to tumor-like properties in embryonic stem cells. AKR1C2 and AKR1C3 mediated prostaglandin D(2) metabolism augments the PI3K/Akt proliferative signaling pathway in human prostate cancer cells<sup>[24]</sup>. Activated Ras is usually associated with cancer, but it also produces paradoxical premature senescence in primary cells by inducing ROS followed by the accumulation of tumor suppressors p53 and p16<sup>INK4A</sup><sup>[25]</sup>.

## ROS INVOLVE TUMOR SUPPRESSION VIA THE P38 PATHWAY

Oncogenic Ras sequentially activates MEK, p38 and two p38 downstream kinases, MAPK-activated protein kinase2 (MK2) and p38 regulated/activated protein kinase (PRAK), which in turn suppress Ras-induced cell proliferation by blocking activation of Jun N-terminal kinase (JNK). Increased intracellular levels of ROS, induced by the Ras-Raf-MEK-ERK signaling cascade, may mediate the activation of the p38 pathway and act as an intermediate signal between the MEK-ERK and MKK3/6-p38 pathways (Figure 1). On the one hand, the activation of p38 mitogen-activated protein kinase (MAPK) is a prerequisite for ROS-mediated functions such as apoptotic cell death in cancer cells<sup>[26]</sup>, and adrenal steroidogenesis<sup>[27]</sup>. On the other hand, inhibiting or scavenging ROS may attenuate the activation of p38-dependent pathways<sup>[28,29]</sup>. Since Ras induces the production of ROS and the latter activates p38, a conclusion can be derived theoretically that the inhibition of Ras may weaken the tension of p38. This inference is supported by research which involved H4IIE hepatoma cells<sup>[21]</sup>. However, in some cases, it is not certain that increased intracellular ROS should enhance the activation of p38<sup>[30]</sup>. The p38 MAPK pathway negatively regulates cell proliferation and tumorigenesis. The involvement of the p38 pathway in the regulation of cellular processes that directly contribute to tumor suppression includes oncogene-induced senescence (OIS), replicative senescence, contact inhibition and DNA-damage responses, which have been discussed in detail<sup>[31]</sup>. Recently, we found that p38 also plays an important role in inflammation-induced cellular senescence<sup>[32]</sup>, which is believed to be a process related to tumor suppression. Several reports have shown that ROS mediate OIS *via* p38-dependent pathways<sup>[33-35]</sup>. The accumulation of intracellular ROS induced by oncogenic Ras is ERK-dependent during the activation of p38 and the induction of senescence. After sensing the oxidative stress induced by activated Ras, p38 directs cells to undergo apoptosis<sup>[36]</sup>. Human cancer cell lines with high ROS levels display enhanced tumorigenicity and impaired p38 $\alpha$  activation by ROS. p38 $\alpha$  has also been reported to antagonize oncogenic transformation induced by activated N-Ras in murine fibroblasts<sup>[37]</sup> and by activated K-Ras in colon cancer cell lines<sup>[38]</sup>. Activated components of the p38 pathway phosphorylate multiple residues on p53, including Ser33 and Ser46 (by p38),

Ser37 (by PRAK), and possibly others, leading to increased transcriptional activity of p53 and induction of a transcriptional target of p53 and p21<sup>WAF1</sup><sup>[31]</sup>. Through an unknown mechanism, activated p38 also induces the expression of p16<sup>INK4A</sup> and p14/p19<sup>ARF</sup>, which, together with the p53-p21<sup>WAF1</sup> cascade, cause premature senescence that serves as a tumor-suppressing defense mechanism both in cell culture and *in vivo*<sup>[31]</sup>. Ras also involves senescence, in which Seladin-1 acts as a key mediator of oxidative stress<sup>[39]</sup>. Seladin-1 has previously been implicated in Alzheimer's disease and cholesterol metabolism. Following oncogenic and oxidative stress, Seladin-1 binds to the p53 amino terminus and displaces E3 ubiquitin ligase Mdm2 from p53, thus resulting in p53 accumulation. Ablation of Seladin-1 causes the bypass of Ras-induced senescence in rodent and human fibroblasts, and allows Ras to transform these cells. Wild-type Seladin-1, but not mutants that disrupt its association with either p53 or Mdm2, suppresses the transformed phenotype. The same mutants are also inactive in directing the p53-dependent oxidative stress response<sup>[39]</sup>. p38 related replicative senescence, contact inhibition and DNA-damage responses will not be discussed here, refer to Ref. 31.

## ROS INVOLVE APOPTOSIS THAT RELATES TO THE P38 PATHWAY

Numerous researchers have shown that ROS relate to apoptosis that is processed through the mitochondrial pathway, which depends on the activation of p38 (Figure 2)<sup>[40-44]</sup>. Apoptosis signal-regulating kinase 1 (ASK1) is an evolutionarily conserved mitogen-activated protein 3-kinase that activates both JNK and p38 MAPK, which may also be triggered by ROS<sup>[45-49]</sup>. However, activation of MAPKs (JNK, p38, ERK) is differentially regulated by cleavage size (40 kDa and 36 kDa) of mammalian sterile 20-like kinase 1, which is controlled by caspase-7 and -3<sup>[50]</sup>. ASK1-induced and ROS-dependent activation of MAPKs is crucial for apoptosis<sup>[43,51]</sup>, and for TLR4-mediated mammalian innate immunity<sup>[52]</sup>. In the case of oxidative stress, a positive feedback may form in the ASK1-p38-TNF- $\alpha$  pathway, which enhances ROS-mediated apoptosis (Figure 2). Ask1 activates both JNK and p38 MAPK, then the activated p38 translocates into the nucleus and stimulates the expression of MK2. After moving out of the nucleus, MK2 increases TNF- $\alpha$  production. On the other hand, enhanced TNF- $\alpha$  and ROS activate ASK1 activity<sup>[46]</sup>, which leads to the activation of JNK. JNK abrogates Bcl-2, which is believed to be a protector away from mitochondria-related apoptosis, although Bcl-2 may manifest opposing phenotypes in text of interacting with other proteins<sup>[53]</sup>. In addition, this positive feedback is required for ROS-mediated apoptosis (Figure 2). Functional analyses have revealed that the initial ROS-independent activations of JNK, Bax, and caspase-3 are not sufficient for cell death, and thus, should be re-activated by ROS in order to kill the cells<sup>[54]</sup>. ROS do

Figure 2 ROS-mediated apoptosis.

not simply mediate the lethal action of  $\gamma$  radiation, but actually amplify it by forming a feedback loop between a downstream effector (caspase) and the upstream initiation signals leading to the activation of JNK. This role of ROS appears to allow Bcl-2 to block the signaling events, which are initially induced upstream<sup>[54]</sup>. p38 $\alpha$  MAPK contributes to the further activation of p53, which also leads to a positive feedback loop, p38 $\alpha$  MAPK/p53. The p53/ROS/p38 $\alpha$  MAPK cascade is essential for cisplatin-induced cell death in HCT116 cells, and the subsequent p38 $\alpha$ /p53 positive feedback loop strongly enhances the initial p53 activation<sup>[55]</sup>. Of interest, p38 may stimulate indirectly the production of ROS *via* p53. Glioma pathogenesis-related protein 1 (GLIPR1), a novel p53 target gene, is down-regulated by methylation in prostate cancer and has p53-dependent and -independent pro-apoptotic activities in tumor cells. Overexpression of GLIPR1 in cancer cells leads to suppression of colony growth and induction of apoptosis. Mechanistic analysis indicates that GLIPR1 up-regulation increases the production of ROS, leading to apoptosis through activation of the JNK signaling cascade<sup>[56]</sup>. However, in p38-related apoptosis that is independent of ROS generation, JNK seems to execute a reverse function. Inhibition of JNK by SP600125 significantly enhanced apoptosis<sup>[57]</sup>.

*Via* regulation of MAPKs, the protein kinase C (PKC) $\delta$ -mediated pathway also involves ROS related apoptosis. As a tentative stimulator of p38, JNK1/2 and MEK/ERK signaling<sup>[58]</sup>, PKC $\delta$  regulates cell apoptosis and survival in diverse cellular systems. Knock down of PKC $\delta$  suppresses p38 MAPK phosphorylation. *Via* p38 MAPK, activated PKC $\delta$

regulates the phosphorylation of heat shock protein (HSP) 27. Attenuated phosphorylation of HSP27 correlates with tumor progression in patients with hepatic cell cancer<sup>[59]</sup>. PKC $\delta$  translocates to different subcellular sites in response to apoptotic stimuli. The localization of PKC $\delta$  differentially affects the activation of downstream signaling pathways. PKC $\delta$ -cytosol increases the phosphorylation of p38, whereas PKC $\delta$ -nucleus increases c-JNK phosphorylation. Moreover, p38 phosphorylation plays a role in the apoptotic effect of PKC $\delta$ -cyto, whereas c-JNK activation mediates the apoptotic effect of PKC $\delta$ -Nuc<sup>[60]</sup>. Recent evidence has shown that calcium/calmodulin (Ca<sup>2+</sup>/CaM)-dependent protein kinase II (CaMK II) activity is also enhanced by pro-oxidant conditions. CaMK II is activated by angiotensin II-induced oxidation, leading to apoptosis in cardiomyocytes both *in vitro* and *in vivo* (Figure 2)<sup>[61]</sup>.

Besides apoptosis, ROS also relate to proliferation. In mice lacking Nrf2 transcription factor, oxidative stress-mediated activation of p38, Akt kinase and downstream targets is impaired, resulting in enhanced death and delayed proliferation of hepatocytes<sup>[62]</sup>. p38 MAPK, p53, and p21 also act as molecular mediators on the way from increased ROS levels to the observed growth arrest<sup>[63]</sup>.

## CONCLUSION

Besides their well-known roles, recent studies have demonstrated additional functions of ROS in tumorigenesis. However, the evidence comes from studies performed in cell culture, in addition to data from human tumors. In addition, these cell lines are generally kept in room air, whereas hyperoxic oxygen levels may favor enhanced ROS formation, which is well known. The relevance of ROS in all these events *in vivo*, especially in humans, is not clear. ROS seem to have dual roles in tumorigenesis, cancer promoting and cancer suppressing. ROS participate in both Ras-Raf-MEK1/2-ERK1/2 signaling and the p38 MAPK pathway. However, these two pathways may have inverse functions in tumorigenesis. The former is related to cancer promotion, whereas the latter is associated with a variety of cellular responses such as OIS, replicative senescence, contact inhibition and DNA-damage responses. Thus, regarding ROS as an absolute "carcinogenic factor" or "cancer suppressor" seems to be inappropriate. It seems that more extensive investigations are needed to determine the integrity of ROS in human cancer development. Two aspects of research remain to be carried out in the future. Firstly, we should determine whether ROS directly mediate the Ras-Raf-MEK1/2-ERK1/2 and p38 MAPK signaling pathways, or whether other mediators are needed. Secondly, the definite shunting mechanism, which controls the steering from triggering Ras-Raf-MEK1/2-ERK1/2 signaling to triggering p38 MAPK signaling and *vice versa*, should be determined. The relationship between ROS and p38-pathway-mediated OIS is of particular interest because several reports indicate that part of the OIS pathway is intact at least in certain cancer cells, and that senescence

responses improve the outcome of chemotherapy. Drugs which artificially trigger senescence in tumor cells will thus improve cancer treatment<sup>[31]</sup>. Studies on the shunting mechanism would facilitate research on the roles of ROS in tumorigenesis, and could shed light on drug discovery.

### Abstract

**AIM:** To develop a method of labeling and micro-dissecting mouse Kupffer cells within an extraordinarily short period of time using laser capture microdissection (LCM).

**METHODS:** Tissues are complex structures comprised of a heterogeneous population of interconnected cells. LCM offers a method of isolating a single cell type from specific regions of a tissue section. LCM is an essential approach used in conjunction with molecular analysis to study the functional interaction of cells in their native tissue environment. The process of labeling and acquiring cells by LCM prior to mRNA isolation can be elaborate, thereby subjecting the RNA to considerable degradation. Kupffer cell labeling is achieved by

injecting India ink intravenously, thus circumventing the need for *in vitro* staining. The significance of this novel approach was validated using a cholestatic liver injury model.

**RESULTS:** mRNA extracted from the microdissected cell population displayed marked increases in colony-stimulating factor-1 receptor and Kupffer cell receptor message expression, which demonstrated Kupffer cell enrichment. Gene expression by Kupffer cells derived from bile-duct-ligated, *versus* sham-operated, mice was compared. Microarray analysis revealed a significant (2.5-fold, *q* value < 10) change in 493 genes. Based on this fold-change and a standardized PubMed search, 10 genes were identified that were relevant to the ability of Kupffer cells to suppress liver injury.

**CONCLUSION:** The methodology outlined herein provides an approach to isolating high quality RNA from Kupffer cells, without altering the tissue integrity.

### INTRODUCTION

Kupffer cells, resident tissue macrophages that line the liver sinusoids, play a key role in modulating inflammation in a number of experimental models

of liver injury<sup>[1]</sup>. Since Kupffer cells represent only a small portion of the entire liver cell population, greatly outnumbered by the parenchymal cells, Kupffer cell isolation faces major technical obstacles. Initial Kupffer cell preparations were heavily contaminated with other cell types or, if sufficiently purified, were only a small fraction of the total cell number and therefore not truly representative. Preparation improved drastically with the introduction of techniques that involved perfusion of the liver with collagenase and pronase<sup>[2]</sup>.

After enzymatic digestion of the liver, the non-parenchymal liver cells are purified by density gradient centrifugation or centrifugal elutriation<sup>[3]</sup>. Neither of these methods is able to separate Kupffer cells from other non-parenchymal cell types since cell size and density exhibit considerable overlap<sup>[4]</sup>. Furthermore, Kupffer cell purification can be achieved by adherence to plastic<sup>[5]</sup>, or positive selection using specific antibodies and magnetic beads<sup>[6]</sup>.

Laser capture microdissection (LCM) circumvents many of the limitations inherent in conventional isolation methods. LCM was created at the National Institutes of Health, Bethesda, MD, USA and further developed by Arcturus Engineering, Inc., Mountain View, CA, USA<sup>[7]</sup>. The principals of LCM entail overlaying the tissue section with a transparent ethylene vinylacetate thermoplastic film. At the point of interest, the film is melted onto the tissue surface with a laser integrated with the microscope optics and then removed, capturing sample areas as small as 3–5  $\mu\text{m}$  from intact tissue sections<sup>[8]</sup>.

For the analysis of gene expression, an important challenge for LCM remains the specific and rapid labeling of the target cell population, thus minimizing the degradation of RNA. In this regard, classic immunohistochemical staining methods for visualizing Kupffer cells are not generally applicable. In the present study, a well-established and efficient method using India ink to label Kupffer cells *in vivo* was described<sup>[9]</sup>. Kupffer cells are mainly located in the periportal areas, where they have ready access to pathogens and particulate antigens entering the liver with portal-venous blood<sup>[10,11]</sup>. In contrast to liver sinusoidal endothelial cells (LSECs), which mainly ingest soluble materials *via* pinocytosis, Kupffer cells take up particulate material *via* phagocytosis<sup>[12]</sup>. It is relevant to note, therefore, that while colloidal gold  $\leq 100$  nm diameter particle size is internalized almost exclusively by LSECs, colloidal carbon is taken up primarily by Kupffer cells. This apparent contradiction is explained by the fact that blood platelets bind carbon and the platelet-carbon complexes are subsequently phagocytosed by Kupffer cells<sup>[9]</sup>. Importantly, the phagocytic capacity of Kupffer cells is not altered by the ingestion of these complexes<sup>[13]</sup>.

The ability to isolate carbon-labeled Kupffer cells from intact tissue sections using LCM offers an attractive approach to studying gene expression under diverse conditions. The aim of this study was to validate this approach and to apply it to an animal model of cholestatic liver injury.

## MATERIALS AND METHODS

### Animals

Wild-type female, C57BL/6J mice were purchased from The Jackson Laboratories (Bar Harbor, ME, USA) and used at 8–12 wk of age. The animals were treated in accordance with NIH publications entitled “Principles for Use of Animals” and “Guide for the Care and Use of Laboratory Animals.” The mice were housed in well-ventilated rooms maintained at 22°C and an alternating 12-h light and dark cycle; food and water were provided *ad libitum*.

### Common bile duct ligation

Ligation of the common bile duct was performed as previously described<sup>[6]</sup>. The abdomen of mice under deep anesthesia was disinfected with 70% ethanol. A midline upper abdominal incision was made and the abdominal wall was retracted. The common bile duct was identified, isolated and double-ligated with #4-0 braided silk sutures and divided in between. The fascia and skin of the midline abdominal incision were closed with #6-0 braided silk sutures. Control mice underwent sham operations in which the common bile duct was exposed, but not ligated.

### Kupffer cell staining

Frozen, 6- $\mu\text{m}$  thick liver sections were cut with a cryostat (Leica, Wetzlar, Germany). Slides were warmed to room temperature for 30 min, fixed by immersion in ice cold acetone (4°C) for 5 min, and air dried for 30 min. After rinsing the slides three times in PBS to remove the tissue freezing matrix, non-specific binding was blocked with 5% normal rabbit serum and 1% BSA for 60 min. This step was followed by 15 min of avidin blocking and 15 min of biotin blocking (Vector Laboratories, Burlingame, CA, USA). After each step, the slides were rinsed in PBS. The slides were stained first with a 1/10 dilution of rat IgG<sub>2a</sub> anti-mouse F4/80 (a pan-specific macrophage marker; eBioscience, San Diego, CA, USA) monoclonal antibody for 60 min. Subsequently, the slides were washed three times for 10 min with PBS and then incubated for 45 min on a shaker with a 1/50 dilution of biotinylated goat anti-rat polyclonal antibody (Vector Laboratories). After rinsing the slides, pre-diluted streptavidin-Cy3 (Invitrogen, Carlsbad, CA, USA) was applied to the tissue sections and incubated for 30 min; the slides were then dried and mounted with Fluoromount-G (SouthernBiotech, Birmingham, AL, USA). All the steps were performed at room temperature.

### Processing of the liver tissue and LCM

Mice were inoculated *iv* *via* the tail vein with 200  $\mu\text{L}$  India ink diluted 1:100 in saline 1 d prior to surgery. Immediately following euthanasia, the livers were perfused *in situ* with 20 mL Hank's buffered salt solution to eliminate blood cells, and dissected. Tissue wedges were flash frozen in Tissue-Tek<sup>®</sup> Optimum Cutting Temperature<sup>™</sup> (OCT) compound and stored at -80°C.

**Figure 1** India-ink-positive cells revealed in tissue section overlaid with xylene. A non-stained liver section derived from a mouse inoculated iv with India ink was not mounted (A), or was overlaid with xylene (B).

**Figure 2** Carbon particles co-localize with ingested fluorescent latex beads and macrophages stained immunohistochemically. A-C: Kupffer cells lining the liver sinusoids were identified by the presence of carbon particles in mice inoculated iv with India ink. Fluorescent latex beads mixed with India ink co-localized with the carbon particles. D-F: A carbon-particle-containing liver section was stained sequentially with streptavidin-conjugated anti-pan macrophage marker F4/80 and biotin-Cy3, and visualized by fluorescence microscopy. An accumulation of carbon particles stained intensely with F4/80 (white arrows), whereas single carbon spots (black arrows) were not stained with F4/80.

Cryostat sections (6  $\mu$ m) were prepared under RNase-free conditions at  $-20^{\circ}\text{C}$ , fixed immediately in acetone for 2 min at  $4^{\circ}\text{C}$ , dehydrated by sequential immersion for 30 s in 75%, 95% and 100% ethanol, immersed for 2 min in xylene, and then air dried. For each cutting session, new blades, single use staining jars, and fresh (RNase free) solutions were used.

LCM was performed using an AutoPix Automated

Laser Capture Microdissection System equipped with an infrared diode laser according to the protocols and methods provided by the manufacturer (Arcturus Engineering, Santa Clara, CA, USA). Air-dried slides were placed under the microscope of the LCM system and one drop of xylene was applied to visualize the carbon-containing Kupffer cells (Figure 1). A static image was taken and, after the xylene evaporated,

the liver sections were overlaid with thermoplastic membranes mounted on transparent, CapSure Macro LCM Caps (Arcturus). The carbon-labeled (Kupffer) cells were captured by laser activation (12–15  $\mu\text{m}$  laser spot size, 60–80 mW power, 3.0 ms duration) and focal melting of the membrane. At least 300 cells were captured on each cap, and three different caps (equivalent to approximately 1000 cells) were prepared for each sample.

### **RNA extraction and purification**

Cells captured on thermoplastic membranes were immersed in Lysis Buffer (RLT) (Qiagen Inc., Valencia, CA, USA). Subsequently, the RNA was extracted, purified using an RNeasy Micro Kit (Qiagen), and quantified using Lab-on-Chip technology (Agilent Technologies, Palo Alto, CA, USA). Intact 18S and 28S rRNA confirmed the integrity of the RNA extracted. RNA representative of cells constituting the whole liver was extracted from an entire (scraped) tissue section.

### **RNA amplification and cRNA labeling**

Purified total RNA obtained from the microdissected cells was subjected to 1.5 rounds of linear amplification using T7 bacteriophage RNA-polymerase-driven *in vitro* transcription, with materials and protocol provided in the RiboAmp<sup>TM</sup> HS RNA Amplification Kit (KIT0205; Arcturus). The final amplification and labeling of dsDNA product was performed using the Enzo BioArray HighYield RNA Transcript Labeling Kit (Enzo Life Sciences, Framingdale, NY, USA).

### **Microarray hybridization**

Microarray analysis was performed using the GeneChip Mouse Genome<sup>®</sup> 430 2.0 array and the recommended instruments (GeneChip Scanner 3000), with reagents and protocols provided by the supplier (Affymetrix, Santa Clara, CA, USA). This GeneChip covers the transcribed mouse genome on a single array with 45 000 probe sets that analyze the expression level of over 39 000 transcripts.

### **Bioinformatics and data mining**

Each group consisted of three samples; each sample was pooled from three sets of captured material derived from individual, sham-operated or bile-duct-ligated mice. The expression signals were normalized using the standardization and normalization of microarray data (SNOMAD) program<sup>[14]</sup>. Concordantly absent expression signals were removed from analysis. A *t* test was used to perform paired comparisons of the gene expression levels between sham-operated and bile-duct-ligated animals. A 5% false discovery rate (FDR) correction controlled for multiple comparisons. The *q* value of a test measured the minimum FDR rate incurred when calling that test significant. *q* values were computed from the unadjusted *P* values, using the Q-VALUE program written by Storey and Tibshirani<sup>[15]</sup>. Significant, differentially expressed genes were grouped into functional categories using the GenMAPP 2 (<http://www.GenMAPP.org>) and MAPPFinder

programs by integrating the annotations of the Gene Ontology Project (<ftp://ftp.geneontology.org/go/gene-associations>)<sup>[16,17]</sup>.

### **Quantitative real-time reverse-transcriptase polymerase chain reaction (RT-PCR)**

Purified RNA extracted from microdissected Kupffer cells was treated with DNase (10 U DNase I/ $\mu\text{g}$  total RNA) and reverse transcribed with Sensiscript Reverse Transcriptase according to the protocols provided by the supplier (Qiagen). Quantitative gene expression analysis was performed using the MX4000 Multiplex Quantitation QPLR System (Stratagene, La Jolla, CA, USA) and SYBR green technology. QuantiTect SYBR Green PCR Master Mix (12.5  $\mu\text{L}$ ; Qiagen) was mixed in 96-well optical plates with an equal volume of RNase-free water that contained 0.6  $\mu\text{mol/L}$  of the forward and reverse primers, and cDNA corresponding to 70 ng of total RNA input. The plates were heated for 2 min at 50°C, and then 15 min at 95°C to activate the HotStart *Taq* DNA polymerase. Subsequently, 45 cycles consisting of 30 s at 95°C followed by 1 min at 55°C and 30 s at 72°C were run. To verify the generation of single PCR products, melting curves were constructed by heating the samples to 95°C with a ramp time of 20 min at the end of the run. 18S rRNA was used as the housekeeping standard. The threshold cycle (i.e. the number of PCR cycles required in order for the fluorescent signal to reach a fixed intensity) was determined and the number of RNA copies was calculated from standard curves. The mean mRNA copies/ $10^5$  18S rRNA copies  $\pm$  SD for samples derived from three mice treated comparably was reported. The PCR primers listed in Table 1 were designed using Primer3 software (Whitehead Institute, Cambridge, MA, USA) and purchased from Qiagen.

### **Statistical analysis**

The results were analyzed using the SigmaStat statistics program (Jandel Scientific, San Rafael, CA, USA). Individual means were compared using a non-paired Student's *t* test or a Mann-Whitney rank sum test. Data derived from three or more groups were compared by one-way analysis of variance (ANOVA) followed by a Tukey test, to identify the groups that differed significantly ( $P < 0.05$ ).

## **RESULTS**

### **Carbon particles co-localize with fluorescent latex beads and anti-F4/80 staining**

LCM and analysis of the genes expressed by a specific cell type in a heterogeneous population (i.e. Kupffer cells among other hepatic cells in the study reported here) depends upon the rapid identification of those cells. The intravenous inoculation of India ink and subsequent ingestion of carbon particles by Kupffer cells provides a well-documented means of rapidly labeling Kupffer cells *in vivo* for laser capture. At 18 h or more post-inoculation of India ink, the livers were perfused *in situ* with a balanced salt solution, dissected, and frozen at

-80°C, and 6-μm liver sections were prepared from representative tissue wedges. The carbon particles were visualized microscopically by overlaying the sections with xylene (Figure 1). To ensure the particles were phagocytosed by Kupffer cells, mice were injected simultaneously with India ink and fluorescent latex beads (Sigma-Aldrich Chemical Co., St. Louis, MO, USA), which are often used to track and label Kupffer cells *in vivo*. Using conventional light and UV light to visualize fluorescent emissions, two images were made with a confocal microscope, and both images were merged using Adobe Photoshop. As shown in Figure 2A-C, the carbon particles and fluorescent latex beads co-localized. The liver sections were also stained with a streptavidin-conjugated antibody specific for F4/80, a surface marker expressed by macrophages including Kupffer cells, and biotinylated Cy3 was used to visualize antibody binding. Confocal images of the carbon particles and bound antibody were merged and found to co-localize as well (Figure 2D-F). Notably, areas with an accumulation of carbon particles stained intensely with F4/80 (white arrows), whereas single carbon spots (black arrows) were not stained with F4/80. This observation was considered when selecting areas for LCM.

#### LCM of carbon-positive areas enriches for Kupffer cell receptor (KCR) and colony-stimulating factor-1 receptor (CSF-1R) mRNA

Labeling Kupffer cells with India ink *in vivo* prior to liver dissection negates *in vitro* staining prior to LCM. This drastically reduced the time between tissue sectioning and actually capturing the cells (approximately 15 min elapsed time) (Figure 3). To ascertain that material was captured, tissue sections and caps were examined by conventional microscopy. A liver section with carbon particles overlaid with xylene is shown in Figure 4A; the red-crossed-through circles show the location of carbon-positive areas on the static image obtained with the LCM system. After microdissection, the same section displayed gaps where the captured areas were removed (Figure 4B). Captured material on caps before RNA extraction with lysis buffer is shown in Figure 4C. Overlaying the cap with water revealed carbon particles associated with this material (Figure 4D).

The RNA was extracted from the captured material

**Figure 3 Experimental timeline.** Schematic outline of the experimental approach used to isolate Kupffer cells labeled *in vivo* with carbon. Notably, the elapsed time between liver dissection, sectioning and LCM of carbon-labeled Kupffer cells was only about 11 min.

on caps, and the quality and quantity were assessed using a bioanalyzer and Lab-on-Chip technology (Agilent Technologies). Degradation appeared only slight relative to the RNA extracted from an entire tissue section scraped from a slide (Figure 5). Indeed, the quality of RNA obtained by LCM proved to be high and the quantity sufficient for subsequent analyses by real-time RT-PCR and microarray analysis. The amount of RNA isolated ranged from 100 to 1000 pg per 1000 Kupffer cells captured.

The carbon-labeled material obtained by LCM was significantly enriched in KCRs and CSF-1R RNA transcripts relative to the transcripts determined in the

**Figure 4** Images documenting LCM of carbon-labeled Kupffer cells. tissue scrape (Figure 6). This further substantiates the association of carbon with and preferential dissection of Kupffer cells by LCM in accordance with our previous findings<sup>[6]</sup>.

#### **Comparison of microarray data generated from Kupffer cells dissected from sham-operated and from bile-duct-ligated mice**

Kupffer cells play a vital role in suppressing tissue damage that occurs in a mouse model of cholestatic liver injury. To identify the genes involved, groups of mice inoculated iv with India ink 18 h previously underwent bile-duct ligation or sham operation. The livers were dissected at 6 h post-surgery and sectioned; the carbon-labeled cells were obtained by LCM; the RNA was extracted, purified and amplified; and DNA microarray analysis was performed using the GeneChip Mouse Genome<sup>®</sup> 430 2.0 array. A total of 493 genes were found to be more than 2.5-fold up- or down-regulated ( $q$  value < 10) when the microarray data from bile-duct-ligated and sham-operated animals were compared. Interestingly, most of the genes that exhibited significant change were involved in cell growth and maintenance (Table 2: Gene ontology). Sixteen of the genes identified were highly up-regulated or down-regulated (> 5-fold change with a  $q$  value < 0.5), and the focus of further analyses. Our primary interest in evaluating these genes was to ascertain their role in maintaining the integrity of the liver during periods of cholestasis. Therefore, the 16 highly up- or down-regulated genes were subjected to a standardized PubMed search (<http://www.ncbi.nlm.nih.gov/sites/entrez>) with terms related to our model (Table 3). Abstracts dating back 15 years were reviewed and the publications relevant to our model were selected

**Table 2** Significantly up- or down-regulated genes ontology

	Number	Percentage (%)

(articles of interest). Based upon this search algorithm, the number of genes of interest was further reduced to 10 (Table 4). Three of these genes, i.e. 3-hydroxy-3-methylglutaryl-coenzyme A synthase 1 (HM GCS1), lipocalin 2, and hemopoietic cell kinase (Hck), were of particular interest in light of the role of Kupffer cells in abrogating cholestatic liver injury.

## **DISCUSSION**

Non-specific phagocytosis of particles taken up in the liver is mediated primarily by Kupffer cells. Kupffer cells constitute 20%-30% of the non-parenchymal cells of

**Table 4** Overview of function, source and involvement of the 10 genes identified by Pubmed-search: Degree of up- or down-regulation

Gene	Fold change	Biological function	Primary cell source	Involvement	Reference
Acetyl-Coenzyme A synthetase 2	9.61	Mitochondrial matrix enzyme involved in CoA ligation	Mitochondrial matrix	Activation during fasting	[50,51]
HM GCS1	5.81	Cholesterol biosynthesis		Inhibition induces apoptosis, up-regulation involved in liver regeneration	[25,26]
RBP4	5.76	An α2-globulin that transports vitamin A from the liver	Parenchymal liver cells, little in Kupffer cells	Known marker for hepatocellular necrosis	[22,23]
Inter-alpha trypsin inhibitor, heavy chain 2	5.46	Plasma protease inhibitor	Kupffer cells	Endothelial growth factor	[27-29]
Lipocalin 2	5.35	Iron-siderophore-binding protein	Macrophages, neutrophils	Suppression of inflammation, tissue involution, apoptosis, differentiation of myeloid cells	[31-40]
Hck	-5.67	Protein-tyrosine kinase	Granulocytes, monocytes	Mitogenesis, differentiation, survival, migration	[41-44]
Leucine-rich repeat-containing 5	-6.26	Interaction with cellular G-proteins		Enzyme inhibition, cell adhesion, cellular trafficking, proliferation and activation of lymphocytes and monocytes	[45,52]
Myristoylated alanine rich protein kinase C substrate	-7.14	Substrate of protein kinase C		Intracellular signaling, brain development, cellular migration and adhesion, phagocyte activation, phagocytosis	[46,47,53-55]
Heterogeneous nuclear ribonucleoprotein A/B (SCAN-KRAB-) zinc finger gene 1	-7.94	Chromatin-associated RNA-binding protein	Ubiquitous	RNA handling, proliferation arrest	[56,57]
	-9.05	Protein interaction domain	Ubiquitous	Cell survival, differentiation	[48,49]

the liver, where they reside within the sinusoidal vascular space, predominantly in the periportal area. Here, they

are perfectly situated to clear endotoxins from the blood, and to phagocytose microorganisms and debris. For

**Figure 5** High quality RNA is extracted from material obtained by LCM. RNA size and quality were analyzed with the Agilent 2100 Bioanalyzer. A, B: Profiles of total RNA extracted from scrapes of the entire liver section (A) and from laser-captured cells (B); C: Electrophoresis gel of the same RNA.

**Figure 6** Kupffer-cell-specific mRNA transcripts are enriched in the laser-captured material. Carbon-labelled cells or total liver section scrapes were obtained from three mice; Kupffer cell receptor and CSF-1 receptor mRNA transcripts were quantified by real-time RT-PCR. <sup>a</sup>Significantly more than extracted from total tissue scrapes ( $P < 0.005$ ; non-paired Student  $t$  test).

example, latex particles inoculated *iv* distinguish a latex-labeled Kupffer cell population that does not change over a 3-mo period, substantiating the relatively long life span of these resident tissue macrophages<sup>[18]</sup>. While endothelial cells lining the blood vessels internalize soluble materials *via* pinocytosis, Kupffer cells generally ingest particulate matter, e.g. colloidal carbon, *via* phagocytosis. The restricted ability to internalize carbon particles was used herein to label and subsequently dissect Kupffer cells by LCM. The specificity of

this approach is demonstrated by co-localization of the particles with fluorescent latex beads inoculated simultaneously *iv*, and with anti-F4/80-stained hepatic macrophages (Figure 2). The specificity is further documented by the elevated levels of macrophage-associated RNA transcripts (i.e. CSF-1R and KCR messages) extracted from the carbon-labeled material obtained by LCM, relative to those levels extracted from whole liver sections.

Unlike the majority of cells that constitute the mononuclear phagocyte system, Kupffer cells synthesize interleukin (IL)-10 (an anti-inflammatory cytokine) when exposed to lipopolysaccharide (LPS), rather than proinflammatory cytokines such as IL-12 and IL-18<sup>[19]</sup>. This finding suggests that Kupffer cells, which are continuously exposed to LPS derived from the intestines *via* the hepatic portal vein, generally impose an immunosuppressive effect on the hepatic environment. In this regard, it is relevant to note that the ingestion of endotoxin and debris occurs coincidentally with the ability of Kupffer cells to induce tolerance<sup>[20]</sup>. Moreover, in addition to tolerance, our studies involving a mouse model of cholestasis indicate that Kupffer cells play a general role in suppressing inflammation and liver injury<sup>[6]</sup>.

Differentiating Kupffer cells from non-resident macrophages, which infiltrate the liver during periods of chronic inflammation, and which may or may not display similar effector functions, represents a major challenge in characterizing the activity of Kupffer cells. The relatively short time period between bile-duct ligation and liver dissection enabled the specific identification and isolation of carbon-labeled Kupffer cells in the study reported here. Whether this approach permits the differentiation of Kupffer cells from inflammatory macrophages recruited to cholestatic livers 2-3 d after biliary obstruction is a matter of ongoing investigations in our laboratory.

LCM allows the isolation of tissue sections as small as 8-10  $\mu\text{m}$ <sup>[8]</sup> and avoids procedures such as collagenase digestion that, conceivably, can alter the gene expression profile of Kupffer cells. Since no staining is necessary,

sections derived from the livers of sham-operated and bile-duct-ligated mice could be processed and subsequently dissected within an extremely short period of time. Moreover, while the effects of histological staining on the integrity of RNA are well documented<sup>[21]</sup>, the quality of RNA obtained using our approach proved to be high and the quantity sufficient enough for subsequent analyses (Figure 5).

Microarray analysis comparing Kupffer cells derived from bile-duct-ligated versus sham-operated mice revealed a total of 493 genes that were differentially expressed (2.5-fold,  $q$  value < 10). In an effort to restrict further analysis to genes specifically relevant to Kupffer cells and their response to cholestasis, those genes that were up- or down-regulated more than five-fold were subjected to a standardized PubMed search (Table 3), and 10 genes of interest were selected (Table 4). Notably, the expression of four of these genes [retinol binding protein 4 (RBP4), inter-alpha trypsin inhibitor heavy chain 2, lipocalin 2, and Hck] was previously described in Kupffer cells or cells of the mononuclear phagocyte lineage. Of these, only RBP4 appears more common in hepatocytes than in Kupffer cells<sup>[22]</sup>. RBP4 is often up-regulated in response to hepatocellular necrosis<sup>[23]</sup> and thus, its expression in Kupffer cells may derive readily from the ingestion of apoptotic hepatocytes<sup>[24]</sup>. Two of the other up-regulated genes are involved in tissue regeneration: HMGCS1 is critical for hepatocyte regeneration after partial hepatectomy<sup>[25,26]</sup>, and inter-alpha trypsin inhibitor, a plasma protease inhibitor, promotes endothelial cell growth<sup>[27-29]</sup>.

In addition to promoting tissue regeneration and cell growth, Kupffer cells may induce apoptosis by infiltrating inflammatory cells (e.g. neutrophils) and thus, suppress their contribution to cholestatic liver injury<sup>[30]</sup>. In this regard, lipocalin 2, the product of one of the up-regulated genes expressed by Kupffer cells present in cholestatic livers induces apoptosis by leukocytes, but not other cell types<sup>[31-34]</sup>. Moreover, lipocalin has been implicated in myeloid cell differentiation and innate host defenses to bacterial infections<sup>[35-40]</sup>.

In contrast to the genes discussed immediately above, five genes expressed by Kupffer cells were significantly down-regulated in response to cholestasis. Hck, a member of the highly conserved sarcoma family of protein-tyrosine kinases that is preferentially expressed by cells of the myeloid lineage, influences cell migration, adhesion, differentiation and survival<sup>[41-44]</sup>. Secondly, leucine-rich repeat containing protein 5 promotes the proliferation and/or activation of lymphocytes and monocytes<sup>[45]</sup>. Thirdly, myristoylated alanine-rich C kinase substrate (a substrate of protein kinase C contained in large amounts in macrophages) has been implicated in phagocyte activation, endocytosis, exocytosis, phagocytosis, and mobility<sup>[46,47]</sup>. Finally, the SCAN domain is a highly conserved motif found near the N terminus of C(2)H(2) zinc finger transcription factors. Some family members play a role in the transcriptional regulation of genes involved in cell differentiation and survival<sup>[48,49]</sup>.

In summary, LCM offers an effective approach to analyzing gene expression by Kupffer cells without altering liver integrity. Pre-labeling the cells with carbon *in vivo* renders further staining procedures unnecessary and allows the isolation of sufficient amounts of intact RNA. Thus, the contributions of Kupffer cells to various models of liver injury can be delineated. In this regard, using DNA microarray analysis, we identified 16 genes expressed by Kupffer cells that were highly up- or down-regulated following bile-duct ligation in a mouse model of cholestatic liver injury. A standard PubMed search conducted using terms relevant to the model determined 10 of these genes to be of specific interest and germane to the role of Kupffer cells in suppressing tissue damage. These genes are the subject of ongoing investigation in our laboratory.

## ACKNOWLEDGMENTS

The authors thank Dr. Patricia Meitner (Pathology Research, Rhode Island Hospital, directed by Dr. Murray Resnick) for her aid and technical expertise with LCM and Karl Simkevitch for his support with the microarray hybridization.

## COMMENTS

### Background

Kupffer cells, resident tissue macrophages that line the liver sinusoids, play a key role in modulating intrahepatic inflammation. Since Kupffer cells represent only a small portion of the entire liver cell population, greatly outnumbered by the parenchymal cells, Kupffer cell isolation faces major technical obstacles. Laser capture microdissection (LCM) offers a method of isolating a single cell type from specific regions of a tissue section. LCM is an essential approach used in conjunction with molecular analysis to study the functional interaction of cells in their native tissue environment.

### Research frontiers

LCM circumvents many of the limitations inherent in conventional isolation methods. LCM was created at the National Institutes of Health (Bethesda, MD, USA) and further developed by Arcturus Engineering (Mountain View, CA USA). The principles of LCM entail overlaying the tissue section with a transparent ethylene vinylacetate thermoplastic film. At the point of interest, the film is melted onto the tissue surface with a laser integrated with the microscope optics and then removed, capturing sample areas as small as 3-5  $\mu$ m from intact tissue sections.

### Innovations and breakthroughs

Described herein is a method of labeling and microdissecting mouse Kupffer cells within an extraordinarily short period of time. Kupffer cell labeling is achieved by injecting India ink intravenously, thus circumventing the need for *in vitro* staining. This method provides an approach to isolating high quality RNA from Kupffer cells without altering the tissue integrity.

### Applications

The ability to isolate carbon-labeled Kupffer cells from intact tissue sections using LCM offers an attractive approach to studying gene expression under diverse conditions. Thus, the specific contributions of Kupffer cells to various models of liver injury can be delineated.

### Terminology

LCM permits under direct microscopic visualization rapid isolation of selected cell populations from a tissue section. A transparent thermoplastic film is applied to the surface of the tissue section, and a laser pulse then specifically activates the film above the cells of interest. The film is melted onto the tissue surface and then removed, capturing the pre-selected cells. Kupffer cells are resident tissue macrophages that line the liver sinusoids. Here, they are perfectly situated to clear endotoxins from the blood, and to phagocytose microorganisms and debris. Kupffer cells play a key role in modulating inflammation in the liver.

## Peer review

In the current study, a new method of isolating Kupffer cells is presented based upon labeling the cells with India ink inoculated iv and microdissection of the carbon-labeled cells by laser capture. The study is well-controlled with regard to the specificity of staining of Kupffer cells with India ink. The method was further validated in a model of cholestasis.

**RESULTS:** AhR expression was significantly increased in GC tissues and GC cell lines. IHC results indicated that the levels of AhR expression gradually increased, with the lowest levels in CSG, followed by CAG, IM, AH and GC. AhR expression and nuclear translocation were significantly higher in GC than in precancerous tissues. TCDD inhibited proliferation of AGS cells *via* induction of growth arrest at the G1-S phase.

**CONCLUSION:** AhR plays an important role in gastric carcinogenesis. AhR may be a potential therapeutic target for GC treatment.

### Abstract

**AIM:** To determine the functional significance of aryl hydrocarbon receptor (AhR) in gastric carcinogenesis, and to explore the possible role of AhR in gastric cancer (GC) treatment.

**METHODS:** RT-PCR, real-time PCR, and Western blotting were performed to detect AhR expression in 39 GC tissues and five GC cell lines. AhR protein was detected by immunohistochemistry (IHC) in 190 samples: 30 chronic superficial gastritis (CSG), 30 chronic atrophic gastritis (CAG), 30 intestinal metaplasia (IM), 30 atypical hyperplasia (AH), and 70 GC. The AhR agonist tetrachlorodibenzo-para-dioxin (TCDD) was used to treat AGS cells. MTT assay and flow cytometric analysis were performed to measure the viability, cell cycle and apoptosis of AGS cells.

### INTRODUCTION

Gastric cancer (GC) is the fourth most common malignancy and the second most frequent cause of cancer-related death in the world. It is often diagnosed at advanced stages when treatment options are limited, leading to a poor prognosis<sup>[1]</sup>. The development of human GC is a multi-step process where normal mucosa progresses to chronic gastritis, precancerous lesions (including gastric atrophy, intestinal metaplasia, dysplasia), and invasive cancer<sup>[2,3]</sup>. The carcinogenesis of GC involves numerous genetic and epigenetic alterations, as well as many environmental risk factors<sup>[4]</sup>. Environmental pollutants such as polycyclic aromatic hydrocarbons (PAHs) and halogenated hydrocarbons (HAHs) are well-known carcinogens that play important roles in GC development<sup>[5,6]</sup>. The toxic effects of PAHs and HAHs are mediated by a conserved signaling

pathway that binds and activates the aryl hydrocarbon receptor (AhR)<sup>[7]</sup>.

AhR is a ligand-activated transcription factor of the basic helix-loop-helix/Per-Arnt-Sim family. PAHs and HAHs are exogenous AhR ligands, among which 2,3,7,8-tetrachlorodibenzo-para-dioxin (TCDD) is the most potent<sup>[8]</sup>. The ligand-AhR complex is translocated to the nucleus and heterodimerizes with the AhR nuclear translocator. The complex binds to the cognate enhancer sequence and subsequently activates downstream gene expression. AhR regulates genes that code for xenobiotic metabolizing enzymes, such as cytochrome P450 1A1 (CYP1A1), cytochrome P450 1B1 (CYP1B1), and growth-regulatory proteins<sup>[9]</sup>. Inappropriately modified expression, and/or abnormally sustained expression of critical genes by the xenobiotic-activated AhR leads to various toxicities which were observed in exposed organisms: teratogenicity, immunotoxicity, tumor promotion, as well as various metabolic dysfunctions<sup>[10,11]</sup>.

Many studies in recent years have demonstrated a close relationship between AhR and mammary gland tumorigenesis<sup>[12,13]</sup>. AhR gene polymorphisms have been linked to an increased risk of lung and breast cancers<sup>[14,15]</sup>. Increased expression of AhR has been reported in lung, breast, and pancreatic cancers in humans<sup>[9,12,16]</sup>. Studies also suggest that constitutively active AhR may promote hepatocarcinogenesis in mice<sup>[17]</sup>. On the other hand, more and more studies have indicated that AhR-mediated responses are anti-proliferative in some cell types and that AhR might function as a potential target for cancer treatment<sup>[16,18]</sup>. However, the role of AhR in gastric tumorigenesis is still unclear. Andersson *et al*<sup>[19-21]</sup> reported that constitutively active AhR could induce stomach tumors and mediate down-regulation of osteopontin gene expression in a mouse model. In our previous study, we found increased expression of AhR in two human GC cell lines (RF1 and RF48) using microarray analysis<sup>[22]</sup>. A recent study suggested that concurrent expression of AhR and CYP1A1 is correlated with GC development<sup>[23]</sup>.

The aim of our current study was to further determine the functional significance of AhR in gastric carcinogenesis, and to explore the potential role of AhR as a therapeutic target for GC treatment.

## MATERIALS AND METHODS

### Tissue specimens

Tissues of chronic superficial gastritis (CSG), chronic atrophic gastritis (CAG), intestinal metaplasia (IM) and atypical hyperplasia (AH) were obtained from 120 patients undergoing upper gastrointestinal endoscopy. Tissues of gastric tumors and their corresponding adjacent non-tumor tissues were collected from 70 GC patients who underwent GC surgery. Written, informed consent was obtained from all patients before sample collection. None of the GC patients had received preoperative chemotherapy or radiotherapy. Tissue samples were fixed in 10% neutralized formalin and embedded in paraffin for histological processing or

**Table 1 Clinical and histological characteristics of the study population**

Histology type	Patient number	Gender		Age (yr) mean $\pm$ SD
		Male	Female	
CSG	30	20	10	50.47 $\pm$ 11.63
CAG	30	12	18	53.27 $\pm$ 16.36
IM	30	16	14	52.38 $\pm$ 10.26
AH	30	15	15	55.67 $\pm$ 16.88
GC	70	37	33	56.59 $\pm$ 13.24
i-GC	32	17	15	57.27 $\pm$ 14.56
d-GC	38	20	18	55.91 $\pm$ 11.62

CSG: Chronic superficial gastritis; CAG: Chronic atrophic gastritis; IM: Intestinal metaplasia; AH: Atypical hyperplasia; GC: Gastric cancer; i-GC: Intestinal-type gastric cancer; d-GC: Diffused-type gastric cancer.

snap-frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  for RT-PCR and Western blot analysis. All tissue specimens were histologically verified by a pathologist. Chronic gastritis specimens were classified according to the updated Sydney System<sup>[24]</sup>. GCs were classified according to the WHO classification<sup>[25]</sup> and Lauren's classification<sup>[26]</sup>. The clinical and histological characteristics of the study population are shown in Table 1. The study was approved by the Ethics Committee of the university hospital.

### GC cell lines

Five GC cell lines- MKN28, MKN45, AGS, NCI N-87 (N87), and KATO III-were obtained from the Riken Cell Bank (Tsukuba, Japan) and the American Type Culture Collection (ATCC, Rockville, MD, USA). All five cell lines were maintained in RPMI-1640 medium (Hyclone, USA) supplemented with 2 mmol/L glutamine, 100 mL/L fetal bovine serum (Hyclone, USA),  $1 \times 10^5$  U/L of penicillin, and 0.1 g/L of gentamycin. The cellular environment was maintained at 50 mL/L  $\text{CO}_2$  and  $37^{\circ}\text{C}$ . Cells were harvested from the exponential growth phase and total RNA and protein were prepared as described below.

### RNA isolation, RT-PCR and real-time PCR

Gastric tissue specimens and cell pellets were homogenized with an ultrasound homogenizer. Total RNA in cells and tissues was extracted using the Qiagen RNeasy Mini Kit (Qiagen, Germany) according to the manufacturer's instructions. cDNA was synthesized with 1  $\mu\text{g}$  total RNA using reverse transcriptase, ReverTra Ace<sup>TM</sup> (Toyobo Co., Osaka, Japan) under the following conditions:  $30^{\circ}\text{C}$  for 10 min,  $42^{\circ}\text{C}$  for 20 min,  $99^{\circ}\text{C}$  for 5 min, and  $4^{\circ}\text{C}$  for 5 min. PCR of cDNA was carried out in a reaction mixture (30  $\mu\text{L}$ ) containing 2  $\mu\text{L}$  of template cDNA, 2.5 mmol/L  $\text{MgCl}_2$ , 200  $\mu\text{mol/L}$  dNTPs, 0.3  $\mu\text{mol/L}$  primer 1 and 2, and 1 U of Taq DNA polymerase (New England Biolabs, China). Amplification was performed using the following conditions:  $94^{\circ}\text{C}$  for 5 min, followed by 25-32 cycles (denaturation for 45 s at  $94^{\circ}\text{C}$ , annealing for 30 s, and extension for 30 s at  $72^{\circ}\text{C}$ ), and then  $72^{\circ}\text{C}$  for 7 min. Details of primers, annealing temperature, amplification cycles, and

**Table 2** Primer sequences and PCR amplification conditions

Gene	Primers (5'→3')	Annealing temperature (°C)	Cycles	Product size (bp)
AhR	S: ACTCCACTTCAGCC-ACCATC A: ATGGGACTCGGCAC-AATAAA	55	25	204
CYP1A1	S: CCATGTCGGCCAC-GGAGTT A: ACAGTGCCAGGTG-CGGGT	59	32	174
β-actin	S: CTCGCTGTCCAC-CTTCCA A: GCTGTCACCTTCA-CCGTT	52	30	256

S: Sense primer; A: Antisense primer.

PCR product size for each gene are listed in Table 2. The PCR products were electrophoresed on 15 g/L agarose gel, stained with ethidium bromide, and visualized with an UV transilluminator. The positive rate of mRNA expression was calculated. mRNA expression levels of AhR were further detected by quantitative real-time PCR with beta-actin as the internal reference, using the Stratagene MX3000P system (Stratagene, USA). cDNA was mixed with SYBR Green QPCR master mix (Stratagene) and primers. The thermal cycling comprised of an initial step at 95°C for 10 min, then 40 intermediate cycles (95°C for 30 s, 55°C for 30 s, and 72°C for 30 s), and one final cycle (95°C for 1 min, 55°C for 30 s, and 95°C for 30 s). Real-time PCR was performed using AhR primers (5'-TACCCTGGACTTGCCTCTGC-3' and 5'-TGAAGCCAGTCAGCACCTC-3'), and beta-actin primers (5'-TCATGAAGTGTGACGTGGACATC-3' and 5'-CAGGAGGAGCAATGATCTTGATCT-3'). Relative quantitation was calculated using the comparative threshold cycle ( $C_T$ ) method.  $C_T$  indicates the fractional cycle number at which the amount of amplified target genes reaches a fixed threshold within the linear phase of gene amplification, and is inversely related to the abundance of mRNA transcripts in the initial sample. Mean  $C_T$  of duplicate measurements was used to calculate  $\Delta C_T$  as the difference in  $C_T$  for target and internal reference ( $\beta$ -actin) genes.  $\Delta C_T$  for each sample was compared to the corresponding  $\Delta C_T$  of the experiment control and expressed as  $\Delta\Delta C_T$ . Relative quantitation was expressed as fold changes of the gene of interest compared to the experimental control according to the formula  $2^{-\Delta\Delta C_T}$ : fold change =  $2^{-\Delta\Delta C_T}$ .

### Western blot analysis

Gastric tissue specimens and cell pellets were homogenized in a lysis buffer containing 20 mmol/L HEPES, 1 mmol/L EGTA, 50 mmol/L  $\beta$ -glycerophosphate, 2 mmol/L sodium orthovanadate, 100 mL/L glycerol, 10 mL/L Triton X-100, 1 mmol/L DTT, and 1  $\times$  Protease Inhibitor Cocktail (Roche, Mannheim, Germany). The lysate was centrifuged at 13000 g and 4°C for 10 min.

The supernatant was the total cell lysate. Protein concentration was measured using the BCA protein assay kit (Pierce Chemical Co., Rockford, IL, USA). Thirty micrograms of protein was loaded per lane, separated by 100 g/L SDS-PAGE, and transferred onto equilibrated polyvinylidene difluoride membrane by electroblotting. Membranes were blocked with TBS-T buffer containing 50 g/L non-fat dry milk. AhR, CYP1A1, and beta-actin were detected for 2 h using antibodies against AhR (SC-5579, Santa Cruz Biotechnology, USA, working dilution 1:150), CYP 1A1 (AB1258, Chemicon International, USA, working dilution 1:500), and beta-actin (4970, Cell Signaling Technology, USA, working dilution 1:1000). After secondary antibody incubation (working dilution 1:2000), enhanced chemiluminescence (Pierce Biotechnology, Inc., USA) was determined by exposure to x-ray film. Band intensities in Western blotting were quantified using Quantity One imaging analysis software. Band intensities of AhR and CYP 1A1 were normalized with corresponding band intensities of beta-actin. Data was reported as mean  $\pm$  SD.

### Immunohistochemistry

Paraffin sections (4  $\mu$ m thickness) were dewaxed in xylene and rehydrated in graded alcohols. Antigen retrieval was performed by heating the sections for 10 min at 100°C in 0.01 mol/L citrate buffer (pH 6.0). Endogenous peroxidase activity was quenched with 30 mL/L  $H_2O_2$  for 15 min and non-specific staining was reduced using a blocking serum for 10 min. The sections were then incubated with rabbit anti-human AhR antibodies (SC-5579, Santa Cruz Biotechnology, working dilution 1:100) overnight at 4°C. The next day, a two-step detection method (EnVision™ Detection Kit, Gene Tech Company Limited, China) was used according to the manufacturer's instructions. Briefly, after incubation with primary antibodies the tissues were incubated with the ChemMate™ EnVision™/HRP for 30 min at room temperature. The reaction was visualized using the CheMate™ DAB plus Chromogen. Hematoxylin was used as a counterstain. Negative controls were carried out using a similar process, however, the first antibodies were omitted.

A scoring system with two categories was used to evaluate the immunohistochemical results<sup>[27]</sup>. Category A documented the number of immunoreactive cells: 0 (< 5%), 1 (5%-25%), 2 (26%-50%), 3 (51%-75%), and 4 (> 75%). Category B documented the intensity of the immunostaining: 0 (no immunostaining), 1 (weak), 2 (moderate), and 3 (strong). A final score was calculated by adding the individual scores for each category. The staining results were measured semi-quantitatively based on the final combined score: 0 (score less than 2), 1+ (score range from 2 to 3), 2+ (score range from 4 to 5), and 3+ (score range from 6 to 7). Immunostaining was assessed by an experienced histopathologist who was blinded to the clinical data of the patients.

### Treatment of cells

TCDD and resveratrol were purchased from Sigma

Chemical Company (Bellefonte, PA, USA). Cells were plated on 60 mm diameter plates (for RNA preparation) and 100 mm diameter plates (for cytosolic preparation) at 80%-90% confluence in RPMI-1640. After incubating for 24 h, one group of cells was treated with TCDD at different concentrations (0, 0.01, 0.1, 1, 10, 100 nmol/L) for 24 h. A second group was also treated for an additional 24 h with TCDD (1 nmol/L) plus resveratrol (0, 1, 5, 10, 20  $\mu$ mol/L). Another group was treated with TCDD (1 nmol/L) for different time intervals (0, 1, 6, 24, 48, 72 h), respectively. All drugs were dissolved in dimethyl sulfoxide (DMSO). Control cells received 1 mL/L DMSO only.

### MTT Assay

A total of  $1 \times 10^4$  trypsin-dispersed cells in 0.1 mL culture medium were seeded into each well of a 96-well plate and cultured for 24 h. Next, the cells were incubated with medium alone or with medium plus TCDD at different concentrations (0, 0.01, 0.1, 1, 10, 100 nmol/L) for another 12, 24 or 48 h. Then, 20  $\mu$ L of MTT (5 g/L, Sigma) was added to each well and the incubation was continued for 4 h at 37°C. Finally, the culture medium was removed and 200  $\mu$ L of DMSO was added to each well. The absorbance was determined with an ELISA reader at 490 nm. The cell viability percentage was calculated as: Viability percentage (%) = (Absorption value of TCDD treatment group) / (Absorption value of control group)  $\times$  100%

### Flow cytometric analysis

For flow cytometric analysis, AGS cells were plated on 60-mm diameter culture plates and treated with TCDD at different concentration (0.01, 0.1, 1, 10, 100 nmol/L) for 48 h. The control contained 1 mL/L DMSO only. Prior to harvesting, the cells were washed twice with 0.01 mol/L PBS, trypsinized, and pelleted. The cells were then fixed with ice-cold 700 mL/L ethanol at 4°C overnight. Finally, the cells were washed twice with PBS and dyed with propidium iodide (PI). The DNA content was analyzed with a flow cytometer (Beckman-Coulter, USA). The cell cycle and apoptosis of AGS cells were analyzed using MULTICYCLE and winMDI2.9 software (Phoenix, AZ, USA). The final data was reported as the mean  $\pm$  SD for each of the three independent experiments.

### Statistical analysis

All quantitative data were expressed as mean  $\pm$  SD and analyzed using Student *t*-tests. Immunohistochemical results were analysed using the Kruskal-Wallis test and the Mann-Whitney test. The differences in positive rates were evaluated by Fisher's exact test. All statistical analyses were carried out using the SPSS statistical software package (version 11.0, SPSS Inc.).  $P < 0.05$  was considered statistically significant.

## RESULTS

### Expression of AhR in gastric cancer and pre-malignant tissues

RT-PCR and Western blotting were performed to

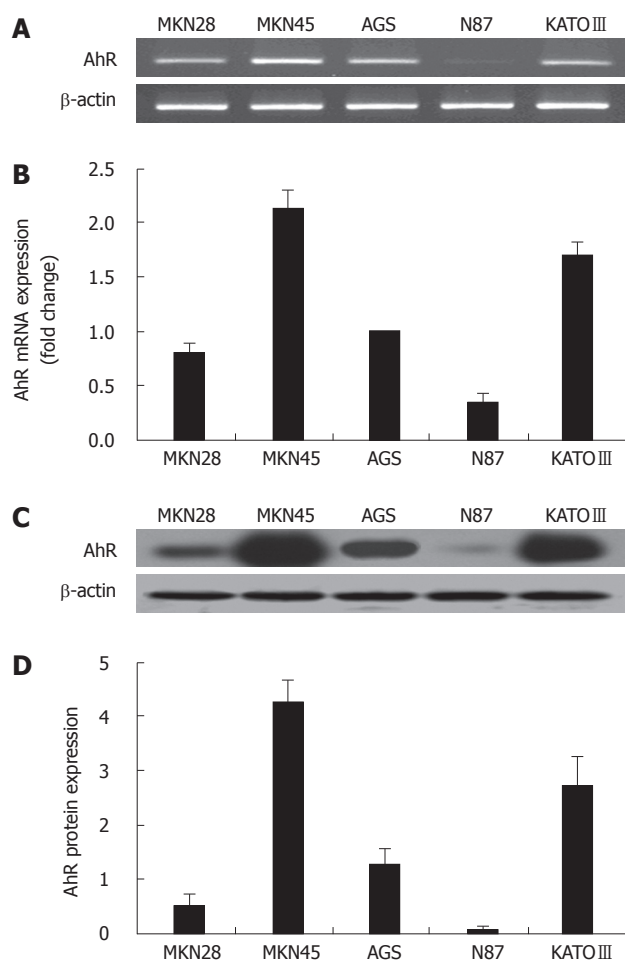

**Figure 1** AhR mRNA and protein expression in GC tissues (T) and their corresponding adjacent non-cancerous tissues (N). A: AhR mRNA was detected by RT-PCR; B: AhR mRNA was detected by real-time PCR; C and D: AhR protein expression was detected by Western blotting and band intensities of AhR were normalized with corresponding band intensities of  $\beta$ -actin. A and C represent three cases; B and D summarize the overall mRNA and protein expression levels of AhR in all 39 cases.
