<sup>[3]</sup>Passed away on June 14, 2008

# World Journal of Gastroenterology®

Weekly Established in October 1995

Volume 15 Number 9  
March 7, 2009

## Contents

### EDITORIAL

- 1025 Influence of genes, sex, age and environment on the onset of autoimmune hepatitis  
*Béland K, Lapierre P, Alvarez F*
- 1035 Update on autoimmune hepatitis  
*Teufel A, Galle PR, Kanzler S*

### TOPIC HIGHLIGHT

- 1042 Spontaneous bacterial peritonitis  
*Koulaouzidis A, Bhat S, Saeed AA*
- 1050 Role of upper endoscopy in diagnosing opportunistic infections in human immunodeficiency virus-infected patients  
*Werneck-Silva AL, Prado IB*

### ORIGINAL ARTICLES

- 1057 Omentum facilitates liver regeneration  
*Singh AK, Pancholi N, Patel J, Litbarg NO, Gudehithlu KP, Sethupathi P, Kraus M, Dunea G, Arruda JAL*
- 1065 Aminoguanidine impedes human pancreatic tumor growth and metastasis development in nude mice  
*Mohamad NA, Cricco GP, Sambuco LA, Croci M, Medina VA, Gutiérrez AS, Bergoc RM, Rivera ES, Martin GA*
- 1072 Suppression of matrix metalloproteinase-2 *via* RNA interference inhibits pancreatic carcinoma cell invasiveness and adhesion  
*Zhi YH, Song MM, Wang PL, Zhang T, Yin ZY*

### BRIEF ARTICLES

- 1079 Docosahexaenoic acid suppresses arachidonic acid-induced proliferation of LS-174T human colon carcinoma cells  
*Habbel P, Weylandt KH, Lichopoj K, Nowak J, Purschke M, Wang JD, He CW, Baumgart DC, Kang JX*
- 1085 Colonoscopic yield of colorectal neoplasia in daily clinical practice

## INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

## Abstract

The pathogenesis of autoimmune hepatitis (AIH) is complex. However, it is believed that a susceptible individual, owing to his genetic background, sex and age, can develop the disease following exposure to an environmental trigger. Autoimmune hepatitis does not follow a Mendelian pattern of inheritance; hence no single causative genetic locus has been identified. However, several genes, inside and outside the HLA locus, have been linked to an increased susceptibility to AIH. Epidemiological evidence also suggests that the sex and age of the patient plays a role in AIH pathogenesis as the disease onset occurs mainly in the two first decades of life and a higher disease incidence is observed in females. No environmental trigger has been identified, but several have been proposed, mainly viruses and xenobiotics. This article aims at reviewing the current knowledge on susceptibility factors leading to AIH and putative triggers, emphasizing fundamental mechanisms responsible for the break of liver immunological tolerance.

Béland K, Lapierre P, Alvarez F. Influence of genes, sex, age and environment on the onset of autoimmune hepatitis. *World J Gastroenterol* 2009; 15(9): 1025-1034 Available from: URL:

## INTRODUCTION

Autoimmune hepatitis (AIH) was described more than 50 years ago by Jan Gösta Waldenström and Henry George Kunkel<sup>[1]</sup> and patients were referred to as “Kunkel-Waldenström girls”. In 1959, following the observation by Ian Mackay of lupus erythematosus (LE) cells in AIH patients, the disease was referred to as “lupoid hepatitis” as it was believed to be a form of lupus erythematosus<sup>[1]</sup>. As knowledge of symptoms, natural course of disease, pathogenesis and treatment progressed, the name “chronic active hepatitis” was chosen and finally “autoimmune hepatitis” was adopted at the first meeting of the International Autoimmune Hepatitis Group.

It is now believed that this autoimmune disease results from the progressive destruction of the hepatic parenchyma through a loss of immune tolerance towards hepatocytes. While the origin of the immune system dysregulation is still unknown, recent fundamental and clinical research have shed some light on predisposing factors and immune mechanisms involved. The current hypothesis for AIH pathogenesis is that this immune dysregulation is a consequence of an environmental triggering event in a genetically predisposed individual of a particular sex and age (Figure 1).

## AUTOIMMUNE HEPATITIS: AN OVERVIEW

Autoimmune hepatitis is a disease with a chronic, but fluctuating course. Although primarily a female pediatric disease, autoimmune hepatitis is not limited to patients of a particular sex, age or ethnic group. Epidemiologic studies estimate the prevalence of AIH to be between 50 to 200 cases per million in Caucasian populations of Europe and North-America<sup>[2,3]</sup>. It is characterized by hypergammaglobulinemia, circulating autoantibodies, low levels of complement factor 4a (C4A) and a high prevalence of a HLA B8, DR3 and DR4 haplotype<sup>[4]</sup>. AIH clinical presentation can vary, from an acute to chronic hepatitis. Nonspecific symptoms include fatigue,

**Figure 1 Pathogenesis of autoimmune hepatitis (molecular mimicry hypothesis).** AIH can occur in an individual of a particular sex and age with a genetic background of susceptibility. To develop AIH, this individual must encounter an environmental trigger such as an infection or exposure to a xenobiotic. This will induce an immune response and secretion of pro-inflammatory molecules resulting in the elimination of the pathogen. However, this response may also lead to an immune cross-reactivity with liver proteins with an efficient activation of autoreactive cells leading to a break of immunological tolerance towards the liver.

**Table 1 Clinical and biochemical characteristics of type 1 and type 2 autoimmune hepatitis**

Characteristics	
Type 1 AIH	Anti-SMA, anti-ANA and/or anti-SLA Mean age of onset: 10 yr old Female:Male ratio 3:1 Higher incidence Frequently associated with IBD and sclerosing cholangitis
Type 2 AIH	Anti-LKM1 and/or anti-LC1 Mean age of onset: 6.5 yr old Female:Male ratio 9:1 Associated with HLA DR3, DR7 and DQB1*0201 More severe disease More likely to be resistant to treatment

anorexia and weight loss. Most AIH patients respond well to immunosuppressive treatments. The diagnosis of AIH is made according to a scoring system established by the International Autoimmune Hepatitis Group<sup>[4,5]</sup> which encompasses several clinical parameters and predisposing factors.

Liver histology in autoimmune hepatitis patients is usually characterized by portal and periportal inflammation (interface hepatitis) and lobular hepatitis. Approximately 50% of biopsies show some degree of bridging necrosis<sup>[4]</sup>. Infiltrates are mainly composed of a mononuclear cells with an abundance of plasma cells. Ten to twenty percents of liver biopsies also show multinucleated giant hepatocytes<sup>[4]</sup>. At diagnosis, portal fibrosis can be present ranging from an enlargement of the portal tract to cirrhosis.

Autoimmune hepatitis has been classified into two types according to circulating autoantibodies present in patients' sera. Type 1 AIH is characterized by the presence of anti-nuclear antibodies (ANA) and/or anti-smooth muscle antibodies (SMA) and/or anti-soluble liver antigen (SLA)<sup>[6,7]</sup>. Type 2 AIH patients are defined by the presence of circulating anti-liver-kidney microsome antibodies (LKM1) and/or anti-liver cytosol 1 antibodies (LC1)<sup>[8,9]</sup>. Anti-LKM1 antibodies recognize the cytochrome P4502D6 (CYP2D6)<sup>[10]</sup> and anti-LC1 antibodies

react against the formiminotransferase cyclodeaminase (FTCD)<sup>[9]</sup>. Both CYP2D6 and FTCD are mainly expressed by hepatocytes. The incidence ratio of type 1 to type 2 AIH is 1.5 to 2:1 in Europe and reaches 7:1 in North and South America and Japan<sup>[11]</sup>. Several clinical differences exist between type 1 and 2 AIH (Table 1). The mean age of onset is 10 years in type 1 AIH and 6.5 years in type 2 AIH, and the female to male ratio is higher in type 2 AIH<sup>[6,12]</sup>. Type 2 AIH patients frequently present a more severe disease course and are more likely to be resistant to treatment<sup>[13]</sup>. In addition, associated extrahepatic autoimmune diseases are different in type 1 and 2 AIH. For example, type 1 AIH is more frequently associated with inflammatory bowel diseases and sclerosing cholangitis, diseases that are never observed in type 2 AIH<sup>[6,12]</sup>.

## GENETIC SUSCEPTIBILITY

Autoimmune hepatitis does not follow a Mendelian pattern of inheritance and no single genetic locus has been identified as responsible for the disease. It is generally believed that one or more genes, acting alone or in concert, reduce or increase susceptibility to AIH.

The strongest association between genes and autoimmune hepatitis has been found at the human leukocyte antigen (HLA) locus on chromosome 6. Susceptibility alleles have been identified in several populations (Table 2). In North America and Europe, HLA-A1-B8, HLA-DRB1\*0301 and HLA-DRB1\*0401 (DR3 & DR4) have been associated with a susceptibility to AIH<sup>[14,15]</sup>. Through a linkage disequilibrium study in families of AIH patients, HLA-DRB1\*03 (DR3) and DRB1\*1301 (DR13) as well as HLA-DQB1\*0201 were found to be preferentially transmitted to patients compared to unaffected siblings in type 1 and type 2 AIH, respectively<sup>[16]</sup>. Another genetic study proposed that HLA-DR13 could be a risk factor in the absence of HLA-DR3 or HLA-DR4<sup>[17]</sup>. However, the size of the population studied did not allow reaching statistically significant conclusions. Hence this association needs confirmation.

Other HLA alleles have also been described as risk

Table 2 Specific susceptibility genes in type 1 and type 2 autoimmune hepatitis

Genes	Population	Type of AIH	Linkage disequilibrium	References
MHC genes				
HLA-A1-B8	North-America, Europe	1	Yes	[14, 15]
HLA-DRB1*0301	North-America, UK, Spain, Argentina	1 and 2	Yes	[14, 15, 25]
HLA-DRB1*0401	North-America, Europe		ND	[14, 15]
HLA-DRB1*0404	Mexico	1	ND	[18]
HLA-DRB1*0405	Argentina, Japan	1	-	[19, 20]
HLA-DRB1*1301	North-America, Europe, Brazil, Argentina	1	Yes	[16, 21]
HLA-DRB1-07	Germany, Brazil, UK	2	Yes	[23, 24]
HLA-DRB3*01	Brazil			[22, 23]
HLA-DQB1*0201	North-America, Europe	2	Yes	[16]
HLA-DQB1*0603	North-America, Europe	2	Yes	[16]
Non-MHC genes				
IgA	Europe	1		[28, 29]
C4A	Europe, North-America	1 and 2	Yes	[30, 31]
CTLA4	North-America, Europe	1	Yes	[35, 36]
Fas	Japan, North-America	1	ND	[37, 38]
Vitamin D receptor	Germany	1 and 2	ND	[39]
TNFA*2	North-America, UK	1	Yes	[43, 44]

ND: Non-determined.

factors for autoimmune hepatitis in other populations (Table 2). Among Mestizo Mexicans, HLA-DRB1\*0404 is predominant in adult AIH patients<sup>[18]</sup>. In Japan and Argentina, HLA-DRB1\*0405 has been associated with AIH<sup>[19,20]</sup> while in Brazil, HLA-DRB1\*1301 and DRB3\*01 are associated with the disease<sup>[19,21,22]</sup>. In type 2 autoimmune hepatitis, HLA-DRB1\*07 has been associated in German, Brazilian and British populations while HLA-DRB1\*03 was found as a risk factor in Spanish patients<sup>[23-25]</sup>. These differences in susceptibility alleles among various ethnic groups could be explained by the shared motif hypothesis which proposes that multiple alleles can encode for similar motifs within HLA class II. In 94% of type 1 AIH patients, susceptibility alleles encode the LLEQKR or LLEQRR motifs at position 67-72 of class II HLA<sup>[15,26]</sup>. In contrast, HLA-DB1\*1501, which is associated with a reduced risk to develop type 1 AIH, encodes for the ILEQAR motif<sup>[15,26]</sup>. Substitution of a lysine or arginine to alanine at position 71, which changes both polarity and charge, possibly modifying peptide binding and orientation in the MHC, could influence autoantigen presentation to T cell receptors (TCR).

HLA alleles have also been found to influence the autoantigenic humoral response. In a recent study, HLA-DQB1\*0201 was described as the main allele in association with susceptibility to type 2 AIH<sup>[27]</sup>. DQ2 is in linkage disequilibrium with DR3 or DR7, both associated with type 2 AIH. Interestingly, HLA-DRB1\*03 was found associated with type 2 AIH patients which show both LKM1 and LC1 antibodies in their sera, while HLA-DRB1\*07 was predominant amongst type 2 AIH patients, whose sole serological marker was anti-LKM1<sup>[27]</sup>. In addition, children carrying the HLA-DRB1\*07 allele developed a more restricted repertoire of anti-LKM1 epitopes compared to those carrying the HLA-DRB1\*03 allele<sup>[27]</sup>.

Other genes located at the HLA locus are linked with AIH susceptibility, such as the IgA and complement

factor 4A genes<sup>[12]</sup>. IgA deficiency is common in AIH patients. This deficiency is genetically linked to the MHC locus, especially with HLA susceptibility alleles such as HLA-DR1 and HLA-DR7<sup>[28,29]</sup>. Also, low levels of C4a are found in 69% of children with AIH<sup>[30]</sup>. Complement factor 4a (C4a) has also been linked with AIH pathogenesis since deletions in the C4A gene were found in patients who develop AIH at a younger age<sup>[31]</sup>.

Genes outside the HLA locus have also been linked with AIH using single nucleotide polymorphism (SNP) screening techniques. These genes encode proteins which influence either the innate or adaptive immune system. As in Graves' disease<sup>[32]</sup>, multiple sclerosis<sup>[33]</sup> and coeliac disease<sup>[34]</sup>, cytotoxic T-lymphocytes antigen 4 (CTLA-4) gene polymorphisms have been found in adult and children with type 1 AIH<sup>[35,36]</sup>. A linkage disequilibrium was also found in affected children compared to non-affected siblings<sup>[36]</sup>. A FAS gene promoter polymorphism (position -670) was found to influence susceptibility to AIH<sup>[37]</sup> and its progression, leading to a more aggressive disease with an early development of cirrhosis<sup>[38]</sup>. Recently, polymorphisms in the vitamin D receptor was shown to contribute to development of autoimmune liver diseases<sup>[39]</sup>. This receptor was found to have immunomodulatory functions such as macrophage and monocyte activation, inhibition of Th1 functions and prevention of dendritic cells differentiation<sup>[40-42]</sup>. Therefore, polymorphisms in the vitamin D receptor could influence the immune response towards autoantigens. Polymorphisms in the tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) gene (TNFA\*2) confers a susceptibility to AIH and influences the natural course of the disease. A G to A substitution at position -308 is believed to influence gene transcription and result in higher induced or constitutive levels of circulating TNF- $\alpha$ <sup>[43,44]</sup>. AIH patients who possess this polymorphism are prone to early disease development, are less likely to enter into remission and more prone to develop liver cirrhosis<sup>[44]</sup>.

Mutations in the autoimmune regulator gene (AIRE)

responsible for the development of Autoimmune Polyendocrinopathy-Candidiasis-Ectodermal Dystrophy (APECED) in patients can also lead to AIH in 10% to 20% of cases<sup>[45]</sup>. The AIRE gene encodes for a transcription factor involved in the thymic negative selection of lymphocytes. Thus, mutations that impair this function could cause multiple autoimmune manifestations. However, studies on known AIRE mutations in patients with autoimmune liver diseases showed that the AIRE gene does not play a major role in their pathogenesis<sup>[32,46]</sup>.

Genetic background influence on the development of an AIH has also been observed in an animal model of type 2 AIH<sup>[47]</sup>. Xenoimmunisation with plasmid DNA coding for type 2 human autoantigens was performed in three mouse strains which differ in their MHC and/or non-MHC genes<sup>[48]</sup>. C57BL/6 mice developed a severe AIH while 129/Sv mice, who share the same MHC alleles as with C57BL/6, but on a different non-MHC genetic background, had a mild AIH. In contrast, BALB/c mice, which differ in both MHC and non-MHC genetic background, did not develop AIH. These results highlight the importance of both MHC and non-MHC genes in the initiation and progression of an autoimmune response towards the liver after an environmental triggering event, xenoimmunisation in this case, occurs<sup>[48]</sup>.

## INFLUENCE OF SEX AND AGE ON AUTOIMMUNITY

Most autoimmune diseases show a striking sex difference in their incidence, women being affected more frequently than men<sup>[49]</sup>. Differences in incidence between women and men range from 20:1 in Sjogren's syndrome to 3:2 in multiple sclerosis<sup>[49]</sup>. Less frequently, the female to male ratio approaches 1:1, as in ulcerative colitis and diabetes<sup>[49]</sup>.

In AIH, the female to male ratio ranges from 3:1, in type 1, to 9:1, in type 2 AIH<sup>[11]</sup>. Sex differences in the immune response are also observed in other liver diseases. For example, men are more likely to become chronic carriers of hepatitis B than women<sup>[50]</sup>. In addition, several studies have investigated the effect of donor:recipient sex matching in the outcome of orthotopic liver transplantation (OLT) and have found that male to female grafts have the most, and female to male the least favourable, outcome, both in terms of patient and graft survival<sup>[51]</sup>.

This gender discrepancy could be the result of existing differences in basic immune responses between females and males. In fact, higher levels of antibodies and stronger T cell activation are observed in women after vaccination<sup>[52]</sup>. Women have higher absolute numbers of CD4<sup>+</sup> T-cells and produce higher levels of Th1 cytokines than men<sup>[53]</sup>. Interestingly, *in vitro* oestrogen increases Th1 cytokine production by T lymphocytes, while a decrease is observed in presence of androgen<sup>[54]</sup>.

Age also influences the incidence of several autoimmune diseases suggesting the role of hormones in the pathogenesis of these diseases. AIH is primarily

a pediatric disease; 40% of type 1 and 80% of type 2 AIH cases are diagnosed before the age of 18<sup>[6,12]</sup>. A second peak of incidence of AIH has also been reported in women after menopause<sup>[55]</sup>. The hormonal status of patients could be related to these prepubertal and post-menopausal peaks of incidence. In fact, sexual hormones are known to directly modulate immune responses and, by doing so, alter the development of autoimmune diseases. 17 $\beta$ -estradiol has been shown to suppress IL-2 secretion by T cells and inhibit IL-2 receptor expression in activated peripheral blood T cells<sup>[56]</sup>. *In vivo*, 17 $\beta$ -estradiol (E2) protects C57BL/6 mice from experimental autoimmune encephalomyelitis (EAE)<sup>[57]</sup>. However, 17 $\beta$ -estradiol was also shown to enhance susceptibility to experimental myasthenia gravis<sup>[58]</sup>, experimental autoimmune uveoretinitis<sup>[59]</sup> and lupus<sup>[60]</sup>. Therefore, the effects mediated by estradiol on autoimmunity are diverse and not fully understood. Male sex hormones also affect immune responses. Testosterone can directly affect CD4<sup>+</sup> T cells *via* androgen receptors and induce increased secretion of IL-10, an anti-inflammatory cytokine<sup>[61]</sup>. Testosterone was also found to protect female SJL mice from developing EAE<sup>[62]</sup>.

Hormonal status of AIH patients during pregnancy can also impact the disease course, with both improvement and exacerbations reported<sup>[63,64]</sup>. Patients who experience a remission of their disease during pregnancy generally have a disease flare-up after delivery<sup>[64]</sup>. In some cases, AIH is diagnosed in the first few months of pregnancy or post-partum<sup>[65]</sup>.

Currently, no pathological mechanism and/or direct hormonal effect can explain these observations. Although epidemiological studies show the impact of sex and age on AIH, more research will be needed to understand the interaction of sex, age and autoimmunity.

## ENVIRONMENTAL FACTORS

Environmental factors are thought to be the triggering event for the development of an AIH in genetically predisposed individuals of a particular sex and age. These environmental factors could be drugs, chemicals or viruses. They are believed to initiate the autoimmune response through several means: (1) non-specific activation of resting T cells; (2) modification or release of sequestered proteins; (3) cross-reactivity between virus and self-protein (molecular mimicry); and (4) modulation of gene expression.

### Non-specific activation of resting T cells

Non-specific activation of resting T cells has been reported after various virus infections, e.g. Epstein-Barr virus (EBV). It could be speculated that resting autoimmune T cells become activated and proliferate leading to an AIH development. EBV infection preceding the onset of AIH has been reported in some patients<sup>[66-69]</sup>. While this mechanism could be involved in AIH development, more evidence is needed to confirm its role in AIH pathogenesis.

Xenobiotics could also be a non-specific activator of lymphocytes, as observed in a murine model of

immune-mediated hepatic injury induced by injections of Concanavalin A (ConA)<sup>[70]</sup>. Concanavalin A is a lectin that stimulates the release of various cytokines by lymphocytes, mainly  $\text{INF-}\gamma$  and  $\text{TNF-}\alpha$ <sup>[71]</sup>. It can also directly stimulate T cells by binding to the MHC and induction of their proliferation<sup>[72]</sup>. This massive non-specific T cell activation results in hepatitis through a bystander effect mediated by  $\text{INF-}\gamma$  and  $\text{TNF-}\alpha$ <sup>[70,71]</sup>. Although this murine model does not rely on an autoimmune reaction against the liver *per se*, it has allowed a better understanding of how xenobiotics could lead to a T cell dependent autoimmune disease.

### **Modification or release of sequestered protein**

An ever growing list of drugs and chemicals has been linked with AIH development in humans. Among these, minocycline, a drug used to treat acne, has been frequently associated with liver autoimmunity<sup>[73-75]</sup>. Interestingly, when minocycline treatment is stopped, the AIH-like syndrome disappears. Herbal agents such as black cohosh<sup>[76]</sup>, a herbal medicine used to treat menopausal symptoms, and dai-saiko-to<sup>[77]</sup>, a herbal medicine used in Japan, have also been proposed as causative agents for AIH. Recently, a case report of 3 adults and meta-analysis of previous case reports has associated atorvastatin and simvastatin with AIH<sup>[78]</sup>. This report is significant since statins are amongst the most widely prescribed drugs. However, these patients were also genetically predisposed for AIH, being HLA-DR3, DR4 or DR7<sup>[78]</sup>. No mechanisms have been proposed to explain the autoimmune effects of these drugs and chemicals. Explanations may lie in the hepatotoxic effect of these chemicals, which could release autoantigens, up-regulate proteins expression (P450s, immunoregulatory proteins) or act as a hapten by modifying the hepatic protein, making them immunogenic.

In experimental models, potential mechanisms for xenobiotics resulting in an immune-mediated liver disease have been described. A model of primary biliary cirrhosis (PBC) in guinea pigs was developed by the injection of 6-bromohexanoate to mimic the lipoate moiety of PDC-E2, the main epitope recognized by anti-mitochondrial antibodies from sera of patients with PBC<sup>[79]</sup>. In this model, the disease becomes evident 18 mo after being exposed to 6-bromohexanoate. This may suggest that exposition to a xenobiotic and induction of a clinically apparent disease could be a long-term process, and should be taken into consideration in future cause-effect studies on xenobiotic exposition and AIH development.

Another mechanism which could explain the development of an AIH is that a hepatotropic viral infection could result in a release of sequestered autoantigens from hepatocytes within a pro-inflammatory environment. This would lead to an autoimmune reactivity towards hepatic antigens. Also, since hepatocytes can express the MHC class II molecule during the course of a clinical hepatitis<sup>[80]</sup>, a function normally reserved to antigen presenting cells (APC), they acquire the ability to specifically activate  $\text{CD4}^+$  T cells and induce an immune

response<sup>[80]</sup>. This hypothetical mechanism implies that hepatotropic viruses may trigger an autoimmune reactivity in a non-specific manner by giving activated immune cells access to autoantigens in a pro-inflammatory environment.

However, the liver is involved in the development of immunological tolerance towards oral antigens<sup>[81]</sup> and thus, has a tolerogenic immune environment resulting in poor immune cell activation and response. Experimental evidence shows that  $\text{CD4}^+$  T cells activated by hepatocytes are more likely to become  $\text{CD4}^+\text{Th2}$  cells and impair the  $\text{CD8}^+$  T cell response<sup>[82]</sup>. Some studies suggest that efficient immune responses are difficult to elaborate in the liver compared to lymph nodes<sup>[83]</sup>. Furthermore, work from Bowen *et al*<sup>[84]</sup> showed that specific T cells directed against a liver antigen are not properly activated if this antigen is uniquely expressed in the liver. A break of tolerance towards liver antigens could only be observed when the liver antigen was also expressed in the periphery<sup>[47,84,85]</sup>. In light of these results, both hepatotropic and non-hepatotropic viruses should be considered as potential triggering events leading to the development of an AIH, through release of autoantigens in a pro-inflammatory environment and/or by molecular mimicry between viruses and autoantigens.

### **Molecular mimicry**

In many autoimmune disorders, molecular mimicry between a virus and a self-protein has been hypothesized to be the key event leading to the disease. Molecular mimicry occurs when a virus protein sequence, structure or motif is shared with a self-protein. The immune system will mount a response against the virus but, in the process, will cross-react with a homologous self-protein. This immune cross-reactivity could evolve, under certain circumstances, into an autoimmune disease. This hypothesis has been proposed in several autoimmune disorders such as multiple sclerosis where homologies between several infectious agents and the myelin basic protein were found<sup>[86]</sup>.

In two animal models, molecular mimicry was proven to be a possible triggering mechanism for AIH. In the TTR-nucleoprotein (NP) transgenic mouse, which expresses the lymphocytic choriomeningitis virus (LCMV) NP under the control of a liver-specific promoter, DNA vaccination with a plasmid coding for the LCMV-NP led to a liver-specific immune response and a progressive destruction of the hepatic parenchyma<sup>[85]</sup>. In this case, a molecular identity between the self-protein and the injected antigen was the triggering factor for AIH development. In a model of type 2 AIH, DNA-vaccination of wild-type C57BL/6 mice with a plasmid coding for human type 2 autoantigens, CYP2D6 and FTCD, led to a break of immune tolerance towards the murine homologues of these proteins (the CYP2D9 and murine FTCD). While the initial immune response was directed against the foreign human proteins (CYP2D6 and FTCD), a molecular mimicry with murine homologous proteins led to the development of an autoimmune response against

**Table 3** Putative candidate viruses as triggering event in autoimmune hepatitis

Putative virus as AIH trigger event	Evidences	References
Hepatitis A virus	Case reports	[94-96]

Epstein-Barr virus	Case reports	[66-69]
Human herpes virus 6	Sequence similarities	[99]
Herpes simplex virus	Sequence similarities	[102]
	Cross-reactivity at B-cell level	[102]

the antigens. These mice developed anti-LKM1 and anti-LC1 autoantibodies and an AIH which shows striking similarities with human type 2 AIH<sup>[47]</sup>. This murine model of type 2 AIH proved that exposure to a foreign protein can break immunological tolerance against a hepatic self-protein and this, without prior liver damage. The fact that a hepatitis is not necessary to break the immunological tolerance towards liver antigens argues in favor of non-hepatotropic virus(es) being able to trigger AIH in humans.

In patients, links between specific viruses and an autoimmune disease are difficult to establish in part due to the hit-and-run effect. The triggering viral infection could have been cleared months or even years before clinical signs of an autoimmune disorder become apparent. The identification of a virus as a causative agent for AIH must therefore rely on epidemiological studies to establish links between a specific infection and the autoimmune disease. A major obstacle in the elaboration of these studies is the necessity of very large cohorts of patients. Since AIH is a disease of very low prevalence, these studies are very difficult, if not impossible, to perform. Therefore, current candidate viruses as putative causative agent for AIH result from published case reports and homologies between liver autoantigens and virus proteins (Table 3).

The hepatitis C virus (HCV) is probably the most studied infection present in AIH patients. Five to 10% of HCV infected patients show autoimmune features that are generally associated with AIH such as anti-LKM1, anti-LC1 and/or anti-SLA autoantibodies<sup>[87-89]</sup>. Purified anti-LKM1 antibodies from HCV-infected patients cross-reacted with the NS3 and NS5a purified proteins suggesting that CYP2D6 and those viral proteins shared similar structures<sup>[90]</sup>. A molecular mimicry at the B-cell level between a structural motif of CYP2D6 and HCV proteins could explain the production of anti-LKM1 antibodies in HCV-infected patients<sup>[90,91]</sup>. Another link between P450 and HCV was found at the T cell level by Kammer *et al*<sup>[92]</sup> who reported T cell cross-reactivity between P450 and the HCV core protein. Although HCV infection in some patients elicits autoimmune hepatitis-like immune responses through molecular mimicry mechanisms, HCV infection is not the triggering event in AIH patients. In fact, a study

showed that very few patients with AIH had specific antibodies against HCV suggesting that most of them had never encountered this virus<sup>[93]</sup>.

Other hepatitis-causing viruses such as hepatitis A and B viruses (HAV, HBV) have been proposed as triggers for AIH<sup>[94-98]</sup>. The Epstein-Barr virus (EBV), has been associated with AIH in several case reports and in a clinical follow-up of 13 patients<sup>[66-69]</sup>. These associations occurred in type 1 AIH patients; therefore, no molecular mimicry could be established since no specific autoantigens in type 1 AIH were identified. However, specific markers for these viral infections are not found in the majority of AIH patients.

In type 2 AIH, a putative molecular mimicry was found between two B cell epitopes of FTCD, the target of anti-LC1 autoantibodies, and sequences of the 101K antigenic virion protein and U50 protein from human herpes virus type 6 (HHV-6)<sup>[99]</sup>. Several homologies were also found between known epitopes of CYP2D6, targeted by anti-LKM1 antibodies, and proteins from HHV-6<sup>[99]</sup>. HHV-6 hepatotropism and its association with chronic and autoimmune hepatitis in children<sup>[100,101]</sup> makes this virus a plausible candidate for AIH onset.

A molecular mimicry has also been proposed between the main antigenic site of anti-LKM1 on CYP2D6 and herpes simplex virus (HSV-1) based on similarities between proteins sequences<sup>[102]</sup>. Cross-reactivity has been found between CYP2D6 and a HSV-1 protein using purified anti-LKM1 autoantibodies from an AIH patient<sup>[102]</sup>. However, in this study, 4 out of 20 patients had not encountered HSV-1 prior to the development of autoimmunity as determined by an antibody assay against HSV-1<sup>[102]</sup>. These data suggest that HSV-1 could be a trigger for the development of AIH in some patients, although this remains to be confirmed.

### **Modulation of gene expression: the role of the innate immune system in autoimmunity**

Environmental factors could trigger an autoimmune reaction by creating a pro-inflammatory immunological micro-environment in which autoantigens could be presented. Such a pro-inflammatory micro-environment could result from toll-like receptor (TLR) engagement. Members of the toll-like family of receptors are able to bind pathogen-associated molecular patterns (PAMP) present in most pathogens. By doing so, TLRs can induce a quick and efficient response against those pathogens through the up-regulation of key pro-inflammatory genes, such as type 1 interferons. When the liver undergoes an infection, TLR stimulation could result in the presentation of autoantigens in a pro-inflammatory environment which would result in an efficient activation of specific autoreactive cells.

The role of TLRs in autoimmune liver disease has been studied in PBC. It was shown that patients with PBC have higher levels of TLR3, TLR4 and TLR9 receptors in the liver<sup>[103,104]</sup>. *In vitro* stimulation of monocytes from PBC patients with several TLR-binding molecules resulted in higher levels of cytokine secretion<sup>[105]</sup>. PBMCs from PBC patients, when cultivated

with CpG, a TLR9 stimulator, secreted more IgM suggesting a role for TLR9 stimulation in the hyper-IgM observed in PBC patients<sup>[106]</sup>. Altogether, these studies suggest that TLRs could be involved in the pathogenesis of this autoimmune liver disease.

A break of immune tolerance towards the liver in a mouse model has been achieved by repeated CpG injections into a double-transgenic mouse expressing MHC class I molecule H-2K<sup>b</sup> exclusively on hepatocytes and having T cells bearing specific TCR for MHC H-2K<sup>b</sup><sup>[107]</sup>. CpG injections were sufficient to break immune tolerance and induce a transient AIH, which faded when CpG injections were stopped. These data suggest that TLR9 stimulation is sufficient to activate pre-existing autoreactive T cells and initiate an autoimmune response, but is not sufficient to induce a self-perpetuating autoimmune response. Recently, Lang *et al.*<sup>[108]</sup> were able to induce a liver inflammation by transferring liver-antigen specific CD8<sup>+</sup> T cells in combination with TLR9 and TLR3 stimulation. These results led to the speculation that the immunoprivileged status of the liver could be controlled by TLR signaling<sup>[108]</sup>. Altogether these data suggest that the innate immune system could be involved in the development of autoimmune processes in the liver possibly through expression up-regulation of pro-inflammatory genes.

## CONCLUSION

The pathogenesis of AIH is a complex process. Development of this disease requires a series of events (viral infection and/or chemical exposure) in a suitable environment (genetic background of susceptibility, female sex and young age) (Figure 1). Further research, both clinical and fundamental, will be needed before the pathogenesis of AIH is fully understood. A better comprehension of the disease would allow the development of specific immunotherapies with fewer side effects.

### Abstract

Autoimmune hepatitis (AIH) is a necroinflammatory liver disease of unknown etiology that occurs in children and adults of all ages. Characteristics are its autoimmune features, hyperglobulinemia (IgG), and the presence of circulating autoantibodies, as well as a response to immunosuppressant drugs. Current treatment consists of prednisone and azathioprine and in most patients this disease has become very treatable. Over the past 2 years, a couple of new insights into the genetic aspects, clinical course and treatment of AIH have been reported, which will be the focus of this review. In particular, we concentrate on genome-wide microsatellite analysis, a novel mouse model of AIH, the evaluation of a large AIH cohort for overlap syndromes, suggested novel criteria for the diagnosis of AIH, and the latest studies on treatment of AIH with budesonide and mycophenolate mofetil.

### INTRODUCTION

Autoimmune hepatitis (AIH) is a necroinflammatory liver disease of unknown etiology that occurs in children and adults of all ages<sup>[1]</sup>. Most patients are female. Characteristics of the disease are a fluctuating spontaneous course of activity, hyperglobulinemia (IgG), and the presence of circulating autoantibodies, as well as a response to immunosuppressant drugs. However, AIH shows considerable heterogeneity<sup>[1]</sup>. No single clinical or biochemical test proves the presence of AIH. An exception may be the presence of soluble liver antigen/liver-pancreas (SLA/LP) autoantibodies. In 1992, the International Autoimmune Hepatitis Group recommended a scoring system for the diagnosis of AIH to allow reliable diagnosis of the disease, and this was further updated in 1999<sup>[2]</sup>. The sensitivity of the scoring system for AIH ranges from 97% to 100%, and its specificity for excluding chronic hepatitis C ranges from 66% to 92%<sup>[2]</sup>. Besides, variant, overlapping, or mixed forms of AIH, it shares common features with other putative autoimmune liver diseases such as primary biliary cirrhosis and primary sclerosing cholangitis<sup>[3]</sup>. Although some patients do present with acute liver failure and may need liver transplantation<sup>[4]</sup>, the overall prognosis of AIH is mostly determined by response to corticosteroid therapy. Overall, long-term survival and average life expectancy are excellent and estimated to be comparable with those of the normal population<sup>[5]</sup>.

### IMMUNOPATHOGENESIS

Although the pathogenetic mechanism of the disease is still unknown, an underlying genetic predisposition has been suggested because of the fact that patients are predominantly female and the association of the disease with certain human leucocyte antigens (HLAs). HLA genes reside in the major histocompatibility complex (MHC), which is located on the short arm of chromosome 6. The MHC is a genetic system with extensive polymorphism. Although multiple genes are probably involved, HLA genes appear to play the dominant role in predisposition to AIH<sup>[6]</sup>. Particularly, HLA B8, DR3 and DR4 are found at a significantly higher frequency

in different populations with AIH<sup>[7,8]</sup>. The challenge is to investigate whether these findings help to better understand the etiology of AIH, predict its prognosis, or further improve its treatment.

## DIAGNOSIS

The presentation of AIH is very heterogeneous, and may be characterized by an undulating course with periods of decreased or increased activity; thus, clinical manifestations are variable, ranging from asymptomatic disease to severe icteric hepatitis, and even fulminant hepatic failure that requires liver transplantation, depending on the intensity of the autoimmune reaction<sup>[1]</sup>.

Patients may present with non-specific symptoms of varying severity, such as fatigue, lethargy, malaise, anorexia, nausea, abdominal pain, and itching. Arthralgia of the small joints is common. Physical examination may be without pathological findings, but may also reveal hepatomegaly, splenomegaly, jaundice, and signs and symptoms of chronic liver disease<sup>[1,9]</sup>. Many patients with acute presentation have histological evidence of chronic disease upon liver biopsy, which indicates that they probably have had subclinical disease for a long time (acute or chronic disease). Long periods of subclinical disease may also occur after presentation. In addition, diseases with an autoimmune background such as Hashimoto thyroiditis, ulcerative colitis, type 1 diabetes, rheumatoid arthritis, and celiac disease are more frequently found in patients with AIH<sup>[10]</sup>.

In general, hepatitis with elevation of aspartate aminotransferase (AST) and alanine aminotransferase leads to the diagnosis of AIH. In particular, viral and toxic hepatitis must be excluded. Some cases, however, are characterized by cholestasis, with high levels of conjugated bilirubin and alkaline phosphatase. In such circumstances, extrahepatic obstruction and cholestatic forms of viral hepatitis, drug-induced disease, primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), and variant syndromes must be considered.

One characteristic laboratory feature of AIH is elevation of serum globulins, in particular, gamma globulin, with a selective increase in IgG, which is generally 1.2-3.0 times higher than the upper level of normal. The characteristic circulating autoantibodies seen in AIH include antinuclear antibodies (ANAs), smooth-muscle antibody (SMAs), SLA/LP autoantibodies, and liver-kidney microsome (LKM) autoantibodies. In addition, perinuclear anti-neutrophil cytoplasmic antibodies and liver-cytosol type 1 antibodies are frequently encountered in patients with AIH. Antimitochondrial antibodies are sometimes present in patients with AIH<sup>[11,12]</sup>. In these patients, an overlap syndrome of AIH and PBC should be considered<sup>[3]</sup>. However, it should be noted that autoantibodies are found in various liver diseases, and their presence, by itself, is not diagnostic of AIH. With respect to the pathogenesis of AIH, there is little evidence that autoantibodies play a crucial role.

Since there is no single test proving the diagnosis of AIH (an exception could be SLA/LP autoantibodies), liver histology remains of central importance. As percutaneous liver biopsy frequently suffers from a

high rate of sampling error with respect to the staging of fibrosis and cirrhosis<sup>[13]</sup>, we frequently perform (mini)laparoscopy-guided liver biopsy in AIH patients, particularly at initial diagnosis.

The histological appearance of AIH is the same as that of chronic hepatitis of other etiology, and although certain changes are characteristic, no findings are specific for AIH. AIH is generally characterized by a mononuclear-cell infiltrate that invades the limiting plate (periportal infiltrate, also called piecemeal necrosis or interface hepatitis that progresses to lobular hepatitis). There may be an abundance of plasma cells, a finding that in the past has led to the use of the term "plasma-cell hepatitis". Eosinophils are frequently present. The portal lesion generally spares the biliary tree. Fibrosis is present in all but the mildest forms of AIH. In advanced disease, fibrosis is extensive, and with the distortion of the hepatic lobule and the appearance of regenerative nodules, it results in cirrhosis<sup>[14]</sup>.

## TREATMENT

If untreated, severe AIH has a very high mortality rate of up to 50% after 3-5 years of diagnosis<sup>[15]</sup>. Immunosuppressive therapy with corticosteroids, usually in combination with azathioprine is considered the gold standard to induce and maintain remission. Moreover, response to immunosuppressive therapy confirms the diagnosis of AIH<sup>[16]</sup>. The therapeutic goal should be complete normalization of transaminases because progression to liver cirrhosis may occur in patients with residual inflammatory activity within the liver. However, side effects of therapy must be taken into consideration. The magnitude of aminotransferase and gamma globulin elevations does not necessarily correlate with the histological extent of injury and provides little help with respect to the initiation of treatment.

Under immunosuppression, the vast majority of patients achieve complete remission<sup>[17]</sup>. In patients not sufficiently responding to immunosuppressive therapy, the diagnosis of AIH should be thoroughly reevaluated. In some patients an overlap syndrome of AIH with PBC or PSC can be a reason for insufficient response to immunosuppression, and addition of ursodeoxycholic acid may further improve laboratory results.

Although some patients remain in remission after drug treatment is withdrawn, most require long-term maintenance therapy. Even though there is only scarce evidence for how long maintenance therapy should be given, it has been proposed that patients should be in stable remission for at least 4 years before withdrawal of immunosuppressive therapy can be considered<sup>[17]</sup>. However, patients positive for LKM1 antibodies (type 2 AIH) should be treated with life-long immunosuppression, which can only be stopped in patients with ANA- and SMA-positive AIH (type 1 AIH). Since biochemical response and clinical remission do not necessarily mean that there is histological evidence of resolution of AIH, repeated liver biopsy should be performed, particularly if withdrawal of immunosuppressive therapy is planned.

In the very few patients that do not tolerate or have

significant side effects to standard therapy, alternative immunosuppressive therapies have been proposed, mainly on the basis of small series or case reports. Cyclosporine appeared to be effective in a group of adult patients who were corticosteroid-resistant<sup>[18]</sup>. A regimen of cyclosporine for 6 mo followed by the administration of prednisone and azathioprine was reported as successful in inducing remission in children<sup>[19]</sup>. Limited data are available concerning the use of tacrolimus<sup>[20]</sup>, methotrexate<sup>[21]</sup>, cyclophosphamide<sup>[22]</sup>, ursodiol<sup>[23]</sup> and mycophenolate mofetil (MMF)<sup>[24]</sup>. Data on a novel large study on budenodine in combination with azathioprine are discussed below<sup>[25]</sup>.

Although AIH primarily shows a chronic course with relapses under therapy (if immunosuppression is rapidly reduced), and particularly after discontinuation of immunosuppressive therapy, long-term prognosis is excellent, assuming close medical surveillance and/or treatment<sup>[5]</sup>. For some reason, the development of hepatocellular carcinoma is a very rare complication in patients with AIH, even though many patients have established liver cirrhosis at the time of diagnosis and patients are immunosuppressed. This fact might give further insight into the pathogenesis of liver carcinogenesis.

## **OVERLAP SYNDROMES-UPDATE 2008: SYSTEMATIC REVIEW REVEALS HIGH ASSOCIATION OF AIH WITH AUTOIMMUNE THYROIDITIS**

Although the pathogenetic mechanisms of autoimmune diseases in various organs remain unresolved, an accumulation of autoimmune diseases in individual patients has been observed. An overlap of AIH and PBC or PSC has been well documented. However, overlap with autoimmune diseases other than PBC or PSC has not yet been investigated in a large cohort. In a systematic review of our cohort of 278 patients with AIH, 111 (40%) were diagnosed with additional autoimmune diseases. Besides overlap syndromes with PBC and PSC, autoimmune thyroiditis was the most common concurrent disease, and was diagnosed in 28 patients (10%). Other concurrent autoimmune diseases comprised vitiligo (five patients) rheumatoid arthritis (five patients), Sjogren's syndrome (four patients) ulcerative colitis (four patients), conjunctivitis (four patients), celiac disease (three patients), systemic lupus erythematosus (two patients) type 1 diabetes (two patients), multiple sclerosis (two patients), polymyalgia rheumatica (two patients), and urticaria (two patients). One patient each was diagnosed with Crohn's disease, autoimmune gastritis, collagen colitis, hypophysitis and sarcoidosis. In conclusion, overlap with other autoimmune diseases is common in patients with AIH and mirrors the full range of known autoimmune diseases. Therefore, an extended diagnostic screening for accumulating autoimmune diseases seems reasonable in patients with AIH. In particular, monitoring for autoimmune thyroiditis must be considered mandatory as 10% of our patients with AIH developed such a condition<sup>[26]</sup>.

## **GENETIC BASIS OF AIH-UPDATE 2008: A GENOME-WIDE DNA MICROSATELLITE STUDY REVEALS MICROSATELLITE ASSOCIATIONS**

Although the pathogenesis of the disease is still unknown, an underlying genetic predisposition has been suggested because of the fact that patients are predominantly female, and the well-documented association of the disease with certain HLAs. It has been suggested that multiple individual genes are involved in the development of AIH, mostly based on the identification of single nucleotide polymorphisms<sup>[27-30]</sup>. However, until recently, a genome-wide search for the underlying genetic mechanisms has not been performed.

Yokosawa *et al*<sup>[31]</sup> investigated 400 polymorphic microsatellite markers in 81 patients with type 1 AIH. These markers covered the complete genome, with an average spacing of 10.8 cM. Of these, two markers, on chromosome 11 and 18, D11S902 and D18S464, respectively, were demonstrated to be significantly associated with AIH. An additional seven markers (D2S367, D6S309, D9S273, D11S1320, D16S423, D17S938 and D18S68) were designated as candidate susceptibility regions. Furthermore, a total of 17 markers were suggested to be relevant for resistance towards AIH. To further narrow down the genetic basis to individual genes within these microsatellite regions, a 500-kb perimeter of the D11S902 and D18S464 regions was screened for genes with a biological function that would fit into a potential pathogenetic mechanism of autoimmune liver disease. Several candidate genes such as PIK3C2A, ABCC8, KCNJ11 and VAPA were named to be involved in diverse cell functions that need to be further evaluated and investigated by means of molecular biology<sup>[31]</sup>. The genetic data were then integrated with clinical data on the course of the disease. However, no differences were seen in the clinical courses of patients with respect to their genetic background, mirrored by means of the identified microsatellite profile. The authors pointed out, that these differences in microsatellite profile were not observed in HLA-DR4-negative patients, a finding that needs to be further investigated and confirmed<sup>[31]</sup>.

## **MODELING AIH-UPDATE 2008: A NOVEL MOUSE MODEL OF AIH**

Mouse models of human diseases are of significant help in exploring the basic principles of disease development. However, modeling AIH in mice has been challenging. Concanavalin A (Con-A)-induced acute liver injury is considered to be a model of human AIH. Major criticisms of this model are that mice stimulated with Con A do not develop autoantibodies and that a single injection of Con A may induce rapid damage of liver cells, which culminates in lethal fulminant hepatitis, in contrast to the more chronic nature of AIH.

Kido *et al*<sup>[32]</sup> have now presented a new mouse model

of AIH based on an NTx- and PD-1 double knock out. By influencing the regulatory T cells (Tregs), these mice develop characteristics of AIH. Tregs are a specialized subpopulation of T cells. They function as suppressors of immune system activation, and maintain tolerance to autoantigens and immune system homeostasis. Tregs have been previously at the center of attention, as this T cell population has been demonstrated to be defective numerically and functionally in patients with AIH<sup>[33]</sup>.

A recently described mouse model of AIH provides improved modeling of the disease, as the mice develop ANAs as well as CD4+ and CD8+ T-cell infiltration<sup>[32]</sup>. Furthermore, on a histological level, these NTx-PD-1 double knock out mice develop a significant mononuclear cell infiltration and massive lobular necrosis, without bile duct destruction and fibrosis. This model certainly needs further evaluation, with respect to the underlying pathogenetic mechanisms, especially as it has been demonstrated that simply deleting Tregs is not sufficient for inducing AIH. Furthermore, PD-1 deficiency alone does not alter the suppressive activity of Tregs. Thus, the details of PD-1/Treg interaction may be of great interest in the further appreciation of this novel mouse model of AIH. Nevertheless, providing this novel mouse model of AIH, Kido *et al*<sup>[32]</sup> have certainly discovered a powerful tool for genetic research on the development of AIH and additional treatment options.

## DIAGNOSIS OF AIH-UPDATE 2008: SIMPLIFIED CRITERIA FOR THE EVALUATION OF AIH

Given the diverse clinical presentation of AIH, its diagnosis often remains challenging. To date, only SLA/LP autoantibodies are highly specific for the diagnosis of AIH<sup>[11]</sup>. However, they are only present in about 20% of patients. Currently, the diagnosis of AIH is made using the scoring system of The International Autoimmune Hepatitis Group. The scoring system has been demonstrated to be highly sensitive with a range from 97% to 100%, and its specificity for excluding chronic hepatitis C ranges from 66% to 92%<sup>[2]</sup>. However, handling of these criteria is rather laborious because they were primarily designed for scientific purposes.

Hennes *et al*<sup>[34]</sup> have now proposed shortened, easier-to-use criteria that consist of a set of only four relevant pieces of information. These clinical criteria are IgG, autoantibodies (ANA, SMA and SLA), histology, and exclusion of viral hepatitis. The novel shortened criteria have been demonstrated to either confirm or exclude the diagnosis of AIH with both positive and negative predictive values well over 90%.

In detail, the authors have proposed the following scoring system. Patients with IgG > 16 g/L, ANA and SMA > 1:40, and a compatible histology are assigned one point for each applicable criterion. Those with IgG > 18 g/L, ANA and SMA > 1:80, the presence of SLA/LP antibodies, histology compatible/typical for

**Table 1 Simplified criteria for the diagnosis of AIH by Hennes *et al*<sup>[35]</sup> (2008)**

Criteria	1 point	2 points
IgG	> 16 g/L	> 18 g/L
ANAs, SMAs	> 1:40	> 1:80
SLA autoantibodies		Positive
Histology typical for AIH		Positive
Viral hepatitis markers		Negative
6 points: AIH very likely		
8 points: AIH confirmed		

Patients with IgG > 16 g/L, ANA and SMA > 1:40, and a compatible histology are assigned one point for each applicable criteria. Patients with IgG > 18 g/L, ANA and SMA > 1:80, presence of SLA/LP antibodies, histology compatible/typical for AIH, and negative viral markers are assigned two points per applicable criterion. Six or more points made the diagnosis of AIH very likely, and seven or eight points confirmed the diagnosis of definite AIH.

AIH, and negative viral markers are assigned two points per applicable criterion. In summary, six or more points made the diagnosis of AIH very likely, and seven or eight points confirmed the diagnosis of definite AIH (Table 1).

These novel criteria for the diagnosis of AIH provide a valuable simplification for daily clinical practice. However, they should be further investigated and confirmed by independent prospective studies<sup>[34]</sup>.

## UPDATE 2008-ALTERNATIVE TREATMENT OF AIH WITH MMF

In most cases, patients with AIH can be treated successfully with prednisone, with or without azathioprine. However, a considerable number of patients with AIH, and in need of immunosuppressive treatment, tolerate azathioprine only poorly, or do not respond efficiently to treatment<sup>[1]</sup>. A smaller number of patients will even fail to respond to this conventional therapy<sup>[1]</sup>. As discussed above, several other therapies have been studied for their efficacy in AIH, but these studies were small or single case reports. However, MMF has demonstrated encouraging results in a few studies on small cohorts of patients with AIH. Thus, MMF has increasingly shifted into the center of attention as an alternative treatment option of AIH.

MMF inhibits purine synthesis by acting as an inhibitor of inosine monophosphate dehydrogenase. MMF treatment has been established successfully in many other conditions, such as rheumatoid arthritis or Crohn's disease. In addition, the drug has become routinely used in immunosuppressant regimens in patients who have undergone solid organ transplantation.

Triggered by a first case report in 1998<sup>[35]</sup>, several smaller studies have reported consecutively on successful treatment of AIH with MMF. Richardson *et al*<sup>[24]</sup> have reported on successful MMF treatment of seven patients. Five of these patients had normal transaminases after 3 mo treatment, as well as a significant reduction in steroid dose and hepatic activity index<sup>[24]</sup>. These findings were

further supported by a series of five Canadian patients who also benefited from transaminase normalization, a steroid sparing effect and histological remission<sup>[36]</sup>. Lately, Inductivo-Yu *et al*<sup>[37]</sup> and Chatur *et al*<sup>[38]</sup> have reported on an additional 31 patients with AIH being successfully treated with MMF. In addition to the benefits observed in the earlier case report series, Inductivo-Yu *et al*<sup>[37]</sup> have also documented that the inflammatory scores and Ishak fibrosis scores were decreased. These results have been further supported by observations from patients who had received a liver transplantation for AIH and required immunosuppressant therapy after transplantation. In these patients, MMF was also demonstrated to be part of the immunosuppressant regimen<sup>[39]</sup>.

In 2008, Hennes *et al*<sup>[40]</sup> reported the largest cohort to date of 36 patients treated with MMF. In contrast to earlier studies, they observed a much lower frequency of response to MMF treatment, as only 14 patients (39%) experienced remission, which was defined as AST less than twice the upper limit of normal. Twenty-two patients (61%) did not respond sufficiently to MMF. In a subset analysis, they further demonstrated that the response rate to MMF was dependent on the cause of treatment cessation of azathioprine. Most patients with prior non-response to azathioprine did not respond to MMF treatment either.

MMF certainly provides a valuable therapeutic option in patients with AIH. However, the latest and, so far, largest study by Hennes *et al*<sup>[40]</sup> suggests that less than half of all patients may benefit from MMF. Thus, MMF may be a valuable alternative to azathioprine but does not seem to be an option for the treatment of AIH after azathioprine non-response.

## TREATMENT OF AIH-UPDATE 2008: ESTABLISHING TREATMENT WITH BUDENOSIDE

Budesonide is a corticosteroid with the highest affinity for the glucocorticoid receptor when compared with other steroids. The drug has a high first pass metabolism, which results in a low incidence of systemic glucocorticoid-related adverse effects<sup>[41,42]</sup>. Budesonide has been demonstrated to be a highly efficient therapeutic option in the treatment of a wide range of diseases. Budesonide has been demonstrated to be a therapeutic option for inducing remission of Crohn's disease. It has been demonstrated to be less effective than conventional steroids, but also exhibited fewer adverse events and lower adrenal suppression<sup>[43]</sup>. Furthermore, the combination of budesonide and formoterol is an efficient alternative in asthma management in patients not adequately controlled by conventional regimens with short-acting  $\beta$ -adrenoceptor agonists<sup>[44]</sup>.

Given a high efficiency in several inflammatory diseases and fewer adverse effects, treatment of AIH with budesonide may highly beneficial if its efficiency were comparable to the conventional prednisolone. Over the past decade, several smaller studies have suggested

the efficacy of budesonide for remission induction<sup>[45]</sup>. However, one study failed to demonstrate such efficacy in AIH<sup>[46]</sup>.

Recently, Manns *et al*<sup>[47]</sup> have compared combined budesonide and azathioprine to standard prednisolone treatment of 208 patients with AIH. The primary end point of the study was complete remission without typical steroid adverse effects, defined as facial swelling, diabetes mellitus, acne, hirsutism, striae and glaucoma.

Budesonide treatment was initiated at 3 mg three times daily and was reduced to 3 mg twice daily when the patients reached clinical remission. Prednisolone was initiated at 40 mg/d and reduced to 10 mg/d in week 9. Azathioprine was administered to both groups at a dose of 1-2 mg/kg per day. In comparison between these two groups, significantly more patients in the budesonide group reached the predefined primary endpoint of biochemical remission without typical adverse effects of steroids (47% *vs* 18.4%,  $P < 0.00001$ ). Furthermore, for secondary endpoints, especially biochemical remission, budesonide was superior to prednisolone (60% *vs* 38.8%,  $P = 0.00128$ ). However, for the long-term results of normalization of bilirubin and IgG over a 6-mo period, budesonide was not superior to prednisolone, as 83% *versus* 89.3% of patients experienced normalization of bilirubin and 56.0% *vs* 62.1% normalization of IgG. Although these data seemed convincing at first sight, the studies have been discussed controversially with respect to the prednisolone dose. A potentially too-low dose of prednisolone was considered to be responsible for a very low 18.6% remission rate. These results seem poor compared to the approximately 90% remission in previous studies on AIH treatment.

In this first large study, budesonide has been proven to be an efficacious alternative to prednisone, with a highly beneficial adverse effect profile in patients with AIH. However, long-term results of budesonide treatment have yet to be collected and data on longer follow-up are expected soon<sup>[47]</sup>. Special attention needs to be given to the question of a comparable prednisolone dosage in the (control) conventionally treated patients.

## CONCLUSION

Over the past 2 years, substantial progress has been made in evaluating alternative treatment options for AIH. With respect to the pathophysiological changes that lead to the development of AIH, microsatellite studies have identified novel genomic regions that are involved in the development of the disease. Finally, the diagnosis of the disease may become easier if the novel shortened criteria for the diagnosis of AIH prove to be accurate in further studies.

## INTRODUCTION

It seems that all diseases or syndromes that comprise our routine differential diagnoses were, not so long ago, obscure clinical entities, at least until an astute clinician came across them. It was not any different for spontaneous bacterial peritonitis (SBP).

Although Laënnec's name had been connected with cirrhosis since the early 1800s, it was only much later that SBP was diagnosed as a separate entity. The papers of Kerr *et al*<sup>[1]</sup> and Conn<sup>[2]</sup>, which were published within a year of each other, describe the infection of ascitic fluid in the absence of a contiguous source of infection or an intra-abdominal inflammatory focus. Although similar reports had been published in the French literature since 1893, Conn<sup>[2]</sup> was the one who eventually coined the term (SBP) in his 1964 paper.

Since then, further research has made the once-feared disease (early reported mortality of 90%)<sup>[2]</sup> a treatable complication of decompensated cirrhosis<sup>[3]</sup>, albeit with a steady prevalence and high recurrence rate<sup>[4,5]</sup>. The plethora of publications has also led to national/international guidelines and recommendations over the last 10 years<sup>[5-11]</sup>.

## PATHOGENESIS

The importance of the liver as a bacterial filter is well established. However, it was Conn<sup>[2]</sup> who hypothesized that intestinal bacteria escaping into the blood stream cause prolonged bacteremia, and in turn, a

## Abstract

Since its initial description in 1964, research has transformed spontaneous bacterial peritonitis (SBP) from a feared disease (with reported mortality of 90%) to a treatable complication of decompensated cirrhosis, albeit with steady prevalence and a high recurrence rate. Bacterial translocation, the key mechanism in the pathogenesis of SBP, is only possible because of the concurrent failure of defensive mechanisms in cirrhosis. Variants of SBP should be treated. Leucocyte esterase reagent strips have managed to shorten the 'tap-to-shot' time, while future studies should look into their combined use with ascitic fluid pH. Third generation cephalosporins are the antibiotic of choice because they have a number of advantages. Renal dysfunction has been shown to be an independent predictor of mortality in patients with SBP. Albumin is felt to reduce the risk of renal impairment by improving effective intravascular volume, and by helping to bind pro-inflammatory molecules. Following a single episode of SBP, patients should have long-term antibiotic prophylaxis and be considered for liver transplantation.

© 2009 The WJG Press and Baishideng. All rights reserved.

greater chance of ascitic fluid invasion<sup>[3]</sup>. Other early reports have emphasized the possibility of abdominal paracentesis-induced SBP<sup>[1,3]</sup>, and certainly, prior to the use of stringent skin disinfection and protective clothing, the incidence of paracentesis-induced peritonitis would have been higher. The negative impact of this thinking created generations of clinicians who were hesitant and unsure about dealing with infective ascites. The persistence of researchers has helped to assuage concerns and has led to a more liberal and appropriate paracentesis protocol<sup>[12-14]</sup>.

Bacterial translocation (BT), the key mechanism in the pathogenesis of SBP, is only possible because of the concurrent failure of defensive mechanisms in cirrhosis<sup>[15-19]</sup>. Since the early 1990s, on-going research has confirmed the intensity of BT in cirrhotic rats<sup>[15-18,20,21]</sup>. Investigators have also demonstrated pronounced impairment of gastrointestinal tract motility in cirrhosis<sup>[22-24]</sup>. The disturbance of gut flora microecology that follows, in association with changes in the (ultra)structure of the gastrointestinal tract<sup>[25-27]</sup> and reduced local and humoral immunity paves the way for the relatively free flow of microorganisms and/or endotoxins to the mesenteric lymph nodes<sup>[25-27]</sup>.

## CLINICAL MANIFESTATIONS OF SBP

The clinical manifestations of SBP are subtle and require a high index of suspicion (Table 1). Previously, there was often delay in diagnosis, which led to considerable mortality and morbidity<sup>[28]</sup>.

SBP almost always occurs in large volume ascites, in patients with liver cirrhosis. Ascites of other causes or low volume rarely gives rise to SBP. Patients with cirrhosis usually have hypothermia; therefore, any temperature > 37.8°C should be investigated, unless it is clearly caused by flu-like symptoms. The necessary investigations are full blood count (FBC), urinalysis, ascitic fluid cell count, and ascites, blood and urine culture. Fever caused by SBP is differentiated from that of alcoholic hepatitis, in which the ascitic fluid neutrophil count is normal<sup>[28]</sup>. Alterations in mental status may be subtle and only apparent to someone close to the patient. A connect-the-number test, e.g. Reitan trail test, is preferable to testing serum ammonia levels<sup>[29]</sup>. Abdominal pain can be continuous and is different from tense ascites. Tenderness is a common feature. Paralytic ileus, hypotension and hypothermia are seen in advanced illness, where prognosis may be dire. Thirteen percent of patients have no signs or symptoms<sup>[28]</sup>. A 'diagnostic tap' should be performed in all patients with ascites admitted to hospital. SBP in outpatients with cirrhotic ascites is less frequent, occurs in patients with less advanced liver disease, and may have a better outcome than its counterpart in hospitalized patients<sup>[30]</sup>. A retrospective review of 916 outpatient AF samples from the United States showed that abnormal AF appearance had a sensitivity of 98.1% [(95% confidence interval (CI): 95.3%-99.5%)] and a specificity of 22.7%

Table 1 Symptoms and signs of ascitic fluid infection

Symptom or sign	Frequency (%)		
	SBP	Bacterascites	CNNA
Fever	68	57	50
Abdominal pain	49	32	72
Abdominal tenderness	39	32	44
Rebound	10	5	0

(95% CI: 19.4%-26.3%) in the detection of SBP<sup>[31]</sup>. For out- and inpatients, laboratory abnormalities such as leukocytosis, metabolic acidosis and azotemia, should prompt investigations for SBP, even in the absence of other clinical features.

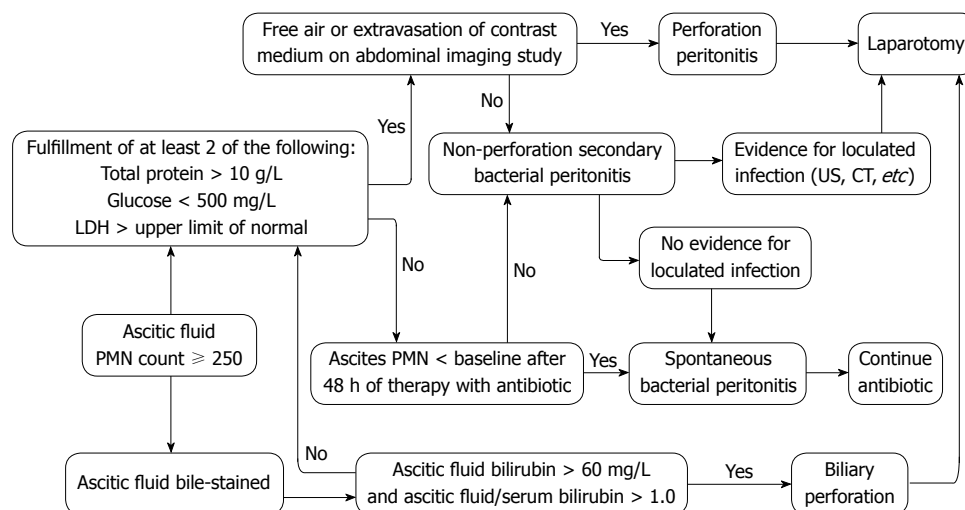

## TECHNIQUES AND LABORATORY DIAGNOSIS

The process of ascitic fluid analysis has come a long way. Inspections for color and transparency (as first evidence of infection) will probably always be carried out. Practice from this point forward, however, varies between regions and to a lesser extent, between hospitals. Over the last decade, it seems that a selective, possibly common-sense approach has started to prevail over the light-hearted dictum "send it (AF) for everything".

The diagnostic algorithm proposed by Runyon<sup>[28]</sup> (Figure 1) remains the most logical and cost-effective way to handle an abdominal paracentesis specimen, and we recommend that every gastrointestinal (GI) ward should have a laminated copy readily available in the doctors' office or protocol folder. Diagnostic paracentesis is now regarded as a safe procedure. Undoubtedly, there are complications inherent with the test, but the incidence rate of these is low<sup>[32-34]</sup>. The reported risks of diagnostic paracentesis include bleeding (hemoperitoneum or abdominal wall hematoma), visceral perforation, local infection at the site of paracentesis, or peritonitis. However, the most common complication is persistent leak. Post-procedural bleeding risk is very low, not only for diagnostic, but also for therapeutic taps<sup>[33-36]</sup>. Runyon has suggested that the practice of attempting to correct any coagulopathy prior to paracentesis is not cost-effective<sup>[28]</sup>. The use of trans-abdominal ultrasound (TUS) assists in a more accurate AF tap; therefore, it is an appealing alternative to the blind technique<sup>[37-39]</sup>.

The majority of the inpatient diagnostic AF taps are performed with a blind technique. The accepted area of preference is away from the midline, at the point of maximal dullness, and ideally in the left iliac fossa, two fingerbreadths medial and two ventral to the anterior superior iliac spine ("Runyon's spot")<sup>[28]</sup>. We advise that after two dry taps, TUS should be used to mark the best insertion spot. Equipment required for the tap comprises: 10-mL syringe; 1.5-inch, 22-gauge metal (or 18-gauge) needle; pack of sterile gloves and a galipot

**Figure 1** Algorithm for differentiating spontaneous from secondary bacterial peritonitis in patients with neutrocytic ascites (i.e. neutrophil count of 250 cells/mm<sup>3</sup> or greater) in the absence of hemorrhage into ascitic fluid, tuberculosis, peritoneal carcinomatosis, or pancreatitis. CT: Computed tomography; LDH: Lactate dehydrogenase; PMN: Polymorphonuclear neutrophil; US: Ultrasound (Reproduced with permission from Akriadias EA, Runyon BA: The value of an algorithm in differentiating spontaneous from secondary bacterial peritonitis. *Gastroenterology* 98: 127, 1990. Copyright 1990 by the American Gastroenterological Association).

with skin disinfectant<sup>[34,40]</sup>. Thirty milliliters of ascitic fluid should be aspirated and distributed between two blood culture bottles (aerobic and anaerobic, ideally 5-10 mL in each after replacement of the paracentesis green needle by a sterile one), a purple top tube and a brown top one for the necessary biochemistry.

The biochemical tests required for every ascitic fluid sample are for protein, albumin, glucose and lactate dehydrogenase, while other tests are graded between optional and unnecessary. Further expansion on AF biochemistry is beyond the scope of this review and the reader is advised to consult relevant textbooks/reviews<sup>[28]</sup>. Reference will only be made to AF tests used for the diagnosis of SBP.

A review of the laboratory diagnosis of SBP would not be complete without alluding to the most recent and practical change in protocol. Following aspiration of the AF sample, after inoculating the culture bottles and prior to splitting the rest of the sample into the purple- and brown-topped tubes, a small amount should be poured over a leukocyte esterase reagent strip (LERS) (any urine dipstick has the relevant reagent square), in order to detect any color change in the respective square. The colorimetric scale reference chart can be viewed on the side of the storage container. Results are obtained by direct optical comparison of the LERS with the scale, or, when available, by spectrophotometric analysis. Hepatologists, gastroenterologists and internists have developed an interest in this new addition (at least for AF analysis), especially as satisfactory sensitivity and specificity for SBP detection have been reported in small French and Spanish studies<sup>[41-43]</sup>. Further studies have been conducted worldwide<sup>[44-48]</sup>. However, initial enthusiasm and suggestions that LERSs may be used as the sole method of detection of AF infection have been tempered by the latest reports and two systematic reviews<sup>[49-51]</sup>. It appears that enthusiasm alone replaced structured, evidence-based approaches for LERSs in the presumptive diagnosis of SBP<sup>[50,51]</sup>.

In rural, remote and smaller hospitals and in developing countries, LERSs shrink the 'tap-to-shot' time

i.e. the time between paracentesis and first antibiotic dose, to only a few minutes. LERSs bear no resemblance to pH, lactate, lactoferrin or other difficult-to-measure infection indices. However, they are cheap and readily available. Moreover, no diagnosis is made in a clinical vacuum and in the right clinical context, the use of a single 'stat' dose prompted by a positive LERS can potentially lessen the burden of infection<sup>[51-53]</sup>.

Eventually, the AF sample will find its way to the bench of a busy clinical laboratory. It is known that in SBP, the number of polymorphonuclear neutrophils (PMNs) in the ascitic fluid is  $\geq 250/\text{mL}$ <sup>[6,28]</sup>. Despite numerous publications emphasizing the contrary<sup>[13,28,54,55]</sup>, many AF samples are prioritized inappropriately by clinical laboratories, giving rise to a significant delay in results. The manual count (performed by the traditional hematological method utilizing a microscope and Bucker chamber) is laborious and, in many instances, subjective. Angeloni *et al*<sup>[56]</sup> have produced clinical evidence that manual and automated PMN counting is equally efficient<sup>[57]</sup>. Cereto *et al*<sup>[58]</sup> have confirmed these results. Two years later, Link and colleagues (prompted by the statement of the International Ascites Club consensus document) examined the use of automated counters in detecting the total leucocyte count in ascitic fluid and diagnosing SBP<sup>[59]</sup>. It is surprising that such a crucial issue in expediting the diagnosis of SBP remained unaddressed for so long by many laboratories, which, despite the above evidence, continued to employ the old-fashioned manual technique over the automated one. At this point, it is necessary to highlight an important caveat when determining AF PMN count: an accurate PMN count may only be determined after non-traumatic paracentesis. If the tap is traumatic or the fluid is a priori hemorrhagic (red cells  $\geq 10\,000/\text{mL}$ ), the PMN count should be corrected as follows: subtract (from the measured PMN count) 1 PMN for every 250 red cells<sup>[7]</sup>.

Opinion is still divided on the issue of automated vs manual testing, but utilization of culture bottles in SBP diagnosis is now the well-established gold standard. SBP is a low-colony-count, monomicrobial infection of the

AF and, in this context, is very similar to bacteremia. The use of blood culture bottles can increase the yield of AF culture from 40% to > 80%<sup>[7]</sup>.

Although initially attractive<sup>[60]</sup>, pH testing of the AF, has now fallen into obscurity<sup>[28,34]</sup>. This is partly attributable to limited clinical accessibility and partly to increased investigator interest in newer measurements, i.e. procalcitonin and lactoferrin<sup>[4,60]</sup>. pH was last used in a clinical study in 1995<sup>[34]</sup>. In their systematic review, Wong *et al.*<sup>[34]</sup> have found that ascitic fluid pH  $\leq 7.35$  and blood-ascitic fluid odds ratio (OR)  $\geq 0.10$  had the highest diagnostic OR for SBP, and it may be reasonable to suggest a return to pH testing combined with LERSs as an appropriate means to diagnose SBP. The majority of urine dipsticks include a pH reagent square and the latest study on the subject has demonstrated that combination of LERSs with nitrite offers no additional benefit in SBP detection<sup>[48]</sup>. As far as we are aware, no study has investigated the combination of pH squares with LERSs. We can, however, envisage similar problems to those experienced by investigators in LERS studies occurring in this instance, namely, the lack of specificity of the reagents used for the usual pH values of AF (urine pH reference range is 6.75-7.5).

The use of procalcitonin should also be mentioned. Procalcitonin is the pro-hormone of calcitonin. It is synthesized in many different tissues of infected organs and has been hailed as a novel index of inflammation. Initial interest in its use in SBP<sup>[61]</sup> was eventually dampened by another study a year later<sup>[62]</sup>. Lactoferrin seems far more promising to serve as a rapid and reliable screening tool for SBP in patients with cirrhosis, and a recent study has suggested the need to develop an AF-specific dipstick<sup>[63]</sup>.

## SBP VARIANTS

Bacterascites (monomicrobial non-neutrocytic bacterascites) is the term used to describe the colonization of ascitic fluid by bacteria, in the absence of an inflammatory reaction in the bacterial fluid. By definition, the PMN count is  $< 250/\text{mm}^3$  and bacterial culture is positive, while the patient may present with symptoms and signs of infection. The natural course of bacterascites, if untreated, is variable. Diagnosis of bacterascites can only be made 2-3 d after initial paracentesis (the time necessary for culture growth), and a repeat ascitic tap is recommended on day 3. If the second sample has a PMN count  $> 250/\text{mm}^3$ , the current recommendation is to treat as for SBP. If the PMN count is  $< 250/\text{mm}^3$ , but the second set of cultures is positive, treat again as for SBP. If the PMN count is  $< 250/\text{mm}^3$  and the second set of cultures is negative, no further action is recommended<sup>[7,28]</sup>.

Culture-negative neutrocytic ascites is the term used to describe the clinical situation in which the ascitic PMN count is  $> 250/\text{mm}^3$  but fluid cultures fail to grow any bacteria. It is considered to represent the expected 20% failure rate of culture to isolate microorganisms,

Table 2 Pathogens in ascitic fluid infection

Micro-organism	Frequency (%)	
	SBP	Bacterascites
<i>Escherichia coli</i>	37	27
<i>Klebsiella pneumoniae</i>	17	11
<i>Pneumococci</i>	12	9
<i>Streptococcus viridans</i>	9	2
<i>Staphylococcus aureus</i>	0	7
Miscellaneous gram-negative	10	14
Miscellaneous gram-positive	14	30

Table 3 Costs of antibiotics used for spontaneous bacterial peritonitis

Route of administration	Antibiotic	Costs (£) <sup>1</sup> including VAT
Intravenous	Ciprofloxacin vial 400 mg	29.60 (per vial)
	Ciprofloxacin vial 200 mg	19.50 (per vial)
	Ofloxacin vial 200 mg	22.63 (per vial)
	Cefotaxime vial 1 g	0.94 (per vial)
	Ceftriaxone vial 1 g	0.91 (per vial)
	Augmentin <sup>2</sup> vial 1.2 g	1.35 (per vial)
Oral	Ciprofloxacin tabl 500 mg (10 tablets pack)	0.40 (4 p per tablet)
	Ciprofloxacin tabl 250 mg (20 tablets pack)	0.36 (1.8 p per tablet)
	Norfloxacin 400 mg (6 tablets pack)	2.30 (40 p per tablet)

VAT: Value added tax; <sup>1</sup>£1 approximately €1.45 and US\$2.00; <sup>2</sup>Amoxicillin-clavulanic acid. © 2007, BMJ publishing group, all rights reserved.

and it requires antibiotic treatment as if it were SBP. However, the term is now considered obsolete<sup>[28,55]</sup>.

## MANAGEMENT

Appropriate antibiotic therapy should achieve resolution of infection in most cases of SBP<sup>[64]</sup>. However, the management of SBP is complex and not just a matter of empirical therapy. Important issues include: (1) identification of the underlying organism; (2) choice of safe and appropriate antibiotics; (3) preservation of renal function and treatment of renal dysfunction; (4) duration of antibiotic therapy; and (5) subsequent antibiotic prophylaxis.

Whilst clarifying the diagnosis of SBP with paracentesis, an attempt should be made at identification of the underlying organism with inoculation of ascitic fluid into blood culture bottles. This vastly improves the identification of the responsible organism and, therefore, allows improved treatment of atypical or resistant organisms. Inoculation into blood culture bottles improves diagnostic yield from 40% to around 80%<sup>[65]</sup>. Simultaneous blood cultures should be taken as 50% of cases of SBP are associated with bacteremia<sup>[66]</sup>.

The common causative organisms of SBP are Gram-negative bacteria such as *Escherichia coli* and other coliforms such as *Klebsiella* spp. These account for at

least 50% of cases. Other causative organisms include pneumococci, streptococci and miscellaneous Gram-positive and -negative organisms<sup>[28,55,65,66]</sup> (Table 2).

Empirical therapy should not be delayed (beyond the first few minutes needed for LERS reading) while awaiting identification of the exact organism. Third generation cephalosporins are the antibiotic of choice as they have a number of advantages: (1) relatively safe and well tolerated; (2) broad spectrum activity; and (3) effectiveness, with many studies confirming high levels of SBP resolution.

Cefotaxime 2 g every 12 h is often used intravenously for at least 5 d<sup>[67-69]</sup>. A 5-d course of treatment has been shown to be equally effective as 10 d<sup>[70]</sup>. Other third generation cephalosporins (e.g. ceftriaxone) are felt to be equally effective<sup>[3,71-73]</sup>. Alternative antibiotic regimens include amoxycillin/clavulanic acid, fluoroquinolones or piperacillin/tazobactam<sup>[74-77]</sup> (Table 3). Regional resistance patterns should be accounted for with early communication with a microbiologist if necessary<sup>[11,77]</sup>. According to the International Ascites Club, it is important to perform a second tap 48 h after the start of therapy. If there is a less than a 25% drop in PMN count from baseline, a change of antibiotic should be considered<sup>[4,5]</sup>.

### Renal function

One third of patients with SBP will develop renal failure. The renal dysfunction is thought to occur as a result of a reduced effective circulating volume<sup>[7,78]</sup>. Renal dysfunction has been shown to be an independent predictor of mortality in patients with SBP<sup>[79]</sup>. Therefore, close attention to renal function and the avoidance of nephrotoxic medication is paramount. On the other hand, diuretic therapy and large-volume paracentesis should not be necessarily withheld (they potentially exacerbate the reduction in effective circulating volume and contribute to renal deterioration) if albumin is administered<sup>[80,81]</sup>. The benefit of human albumin solution for treating renal dysfunction has been studied in randomized controlled trials<sup>[82,83]</sup>. Albumin is thought to reduce the risk of renal impairment by improving effective intravascular volume and by helping to bind pro-inflammatory molecules<sup>[7,8,11]</sup>. Studies have shown an improvement in short-term survival and a reduction in renal impairment in patients with SBP treated with albumin. Although these studies have been subject to criticism<sup>[84,85]</sup>, most authors agree that infusion of 1.5 g/kg on day 1 and 1 g/kg on day 3 is beneficial in patients that have developed, or are developing renal dysfunction<sup>[7,61]</sup>. Patients with normal renal function are unlikely to benefit from albumin therapy.

### PROPHYLAXIS

Unfortunately, the long-term prognosis of patients with cirrhosis who have had a prior episode of SBP is poor. Mortality rates of 50%-70% have been reported at 1 year follow-up<sup>[7,11]</sup>. This is largely a result of the

advanced stage of liver cirrhosis in these patients, along with the associated complications<sup>[86]</sup>. The recurrence rate of SBP following a first episode is up to 70% at 1 year<sup>[7,86]</sup>. Given the high recurrence rate, it seems sensible to recommend prophylaxis to this group of patients and referral for transplant assessment. This therapy is backed up by evidence showing a reduction in recurrence of SBP from 68% to 20% in one study<sup>[87]</sup>.

Norfloxacin 400 mg/d or ciprofloxacin 500 mg/d orally appear to be the most studied and commonly recommended regimes<sup>[87-92]</sup>. Levofloxacin or antibiotic cycling may be used as an alternative<sup>[93-95]</sup>. There is debate over the use of antibiotics as primary prophylaxis against SBP. Some studies have shown reduced rates of SBP in selected patients deemed at high risk of developing SBP (those with low ascitic total protein)<sup>[79,91,96]</sup>. However, there are various criticisms of these studies, and at present, primary prophylaxis is not recommended. Further studies may help clarify this issue.

The last group of patients that are felt to benefit from antibiotic prophylaxis are those with known cirrhosis admitted with GI bleeding. Infection rates are high in this group regardless of whether they have ascites. The infection rates are also higher than those in patient with cirrhosis admitted for other reasons<sup>[61]</sup>. Several studies have shown a clear benefit from initiating antibiotic prophylaxis in this group<sup>[97-100]</sup>. Reductions in infection rate and mortality have been noted. Once again, the choice of antibiotic should be broad spectrum and guided by local policy; either oral norfloxacin or ciprofloxacin have been suggested<sup>[7,61]</sup>.

## INTRODUCTION

Highly active antiretroviral therapy (HAART) has dramatically reduced the incidence of opportunistic infections (OIs) in human immunodeficiency virus (HIV) disease. Different factors may be related to the decreasing prevalence of OI in the era of HAART. Besides restoring immune function<sup>[1]</sup>, antiretroviral protease inhibitors have been reported to have a direct inhibitory effect on the proteases of certain pathogens, including the aspartyl proteases of some parasites<sup>[2,3]</sup>.

Nevertheless, the gastrointestinal (GI) tract is still affected by OI in HIV-infected patients undergoing HAART, especially in those with severe immunosuppression<sup>[4]</sup>. Patients undergoing HAART may not have a sustained CD4 lymphocyte count increase for several reasons, including poor adherence to therapy, drug toxicity or interactions, acquisition of a drug-resistant strain of HIV, and/or the development of a discordant immunological response, which leads to low CD4 cell counts despite optimal suppression of plasma HIV viremia<sup>[5]</sup>. Whatever the reason, HIV-infected patients with a low CD4 cell count remain at high risk for OIs, including GI infections. Also, these patients may have an atypical presentation of OI, either early after the initiation of therapy or after prolonged treatment<sup>[6]</sup>. Hence, a CD4 count < 200 cells/mm<sup>3</sup> remains an important marker for those patients in whom OIs should be suspected as a cause of GI symptoms.

Nowadays, HAART-related GI adverse events have been recognized as a frequent cause of GI complaints<sup>[7]</sup>. When a physician is challenged with an HIV-infected patient with upper GI complaints undergoing HAART, his final diagnosis is usually unrelated to HIV-associated immunodeficiency. Therefore, careful evaluation is needed when considering GI symptoms in these patients, especially in those with advanced immunodeficiency.

## Abstract

Highly active antiretroviral therapy (HAART) has dramatically decreased opportunistic infections (OIs) in human immunodeficiency virus (HIV)-infected patients. However, gastrointestinal disease continues to account for a high proportion of presenting symptoms in these patients. Gastrointestinal symptoms in treated patients who respond to therapy are more likely to be the result of drug-induced complications than OI. Endoscopic evaluation of the gastrointestinal tract remains a cornerstone of diagnosis, especially in patients with advanced immunodeficiency, who are at risk for OI. The peripheral blood CD4 lymphocyte count helps to predict the risk of an OI, with the highest risk seen in HIV-infected patients with low CD4 count (< 200 cells/mm<sup>3</sup>). This review provides an update of the role of endoscopy in diagnosing OI in the upper gastrointestinal tract in HIV-infected patients in the era of HAART.

The tropism of many pathogens for the squamous mucosa of the esophagus (*Candida*, herpesviruses), as well as the appearance of new diseases (idiopathic esophageal ulceration) has established the upper GI tract as a common site for complications<sup>[8]</sup>. Upper endoscopy with mucosal biopsies is a standard part of the evaluation of upper GI symptoms in these cases, especially because the therapy will depend on the specific pathogen found. In this review, we discuss the role of endoscopy in diagnosing OIs in the upper GI tract, in the HAART era.

## ESOPHAGUS

HAART has changed the epidemiology of esophageal infections in HIV disease. Mönkemüller *et al*<sup>[9]</sup> have evaluated the prevalence of GI OI in symptomatic HIV-infected patients undergoing endoscopic procedures from 1995 to 1998. They observed that the prevalence of OI fell from 69% to 13% coincident with the use of HAART. The number of patients identified with esophageal candidiasis or cytomegalovirus (CMV) infection fell by 80%, while the prevalence of gastroesophageal reflux disease rose eight-fold. In another more recent study<sup>[4]</sup>, this same author observed GI OI in 9% of patients undergoing HAART. Those patients had a significantly decreased CD4 count (mean 23 cells/ $\mu$ L) despite HAART use.

There is not a close relationship between esophageal symptoms and OI. However, patients presenting with odynophagia are more prone to esophageal ulcers<sup>[10]</sup>. Biopsy is mandatory when finding esophageal ulcers upon endoscopy. Definitive differential diagnosis of esophageal ulcers can only be made by histological examination.

On the other hand, normal-appearing esophageal mucosa at endoscopy has a good correlation with the absence of OI. We have done a prospective study in a large cohort of dyspeptic and immunosuppressed HIV-infected patients ( $n = 1010$ ), who underwent endoscopy with esophageal biopsies in order to evaluate the presence of OI in a normal-appearing esophagus. A pathogen was found in normal-appearing esophageal mucosa in only one patient (0.09%)<sup>[11]</sup>. We concluded that it is not necessary to perform biopsies in normal-appearing esophageal mucosa, even in patients with advanced immunosuppression.

### *Candida* spp.

Despite the decreasing prevalence of OI, *Candida* spp. continue to be the most common cause of OI in the esophagus, followed by viral infection, especially CMV. Patients often present with dysphagia, but may also develop odynophagia and/or acute retrosternal chest pain. The presence of oral candidiasis (thrush) suggests candidal esophagitis. On the other hand, the absence of thrush *per se* does not exclude it. Some authors recommend empirical antifungal therapy for HIV-infected patients who present with dysphagia, postponing endoscopy for those individuals in whom symptoms persist<sup>[12]</sup>. This approach seems to be a safe,

efficacious, and cost-effective procedure.

At endoscopy, *Candida* esophagitis shows a characteristic superficial mucosal pattern: focal or confluent yellowish-white plaques that overlie an erythematous mucosa. It is seldom related to mucosal ulceration, which in general results from causes other than *Candida* infection<sup>[13]</sup>.

Endoscopy has also been used to grade the severity of *Candida* infection. We have analyzed the relationship between *Candida* esophagitis severity and peripheral blood CD4 cell count in a prospective study of a large cohort of adult HIV-infected patients ( $n = 261$ , mean CD4 cell count = 78.8 cells/ $\text{mm}^3$ ). Severity was graded I to IV<sup>[14]</sup> according to the extent of mucosal lesions. We have shown that the least severe disease (grade I) was related to the highest CD4 cell counts when compared to all others ( $P = 0.0003$ ). Meanwhile, the progression of disease severity from grade II to IV was not related to a corresponding decrease in CD4 cell counts. These findings suggest that even in immunosuppressed HIV-infected patients, immunological status may play a role in limiting *Candida* disease in initial grades, but seems to be irrelevant in the following progression of the infection<sup>[15]</sup>. Other mechanisms, such as the local epithelial defenses, may be involved with the development of these OIs in the GI mucosa.

### CMV

Patients that present with severe odynophagia or who fail empirical antifungal therapy usually have viral esophagitis or esophageal ulcers. These patients should be promptly referred for upper GI endoscopy, since they exhibit increased morbidity and may rapidly become malnourished<sup>[10]</sup>.

The most common virus detected is CMV, which may cause erosive esophagitis or deep esophageal ulcers. Upon endoscopy, CMV esophagitis appears frequently as small, well-circumscribed ulcerations, with a normal appearance of the intervening mucosa<sup>[16]</sup>. This appearance is similar to herpes esophagitis, but it is usually distinguishable from esophageal candidiasis. CMV ulcers are usually located in the middle or distal esophagus and are characteristically deep, with a halo of edema. This appearance is identical to the large idiopathic esophageal ulcerations associated with HIV infection<sup>[17]</sup>. The former ulcers are believed to be secondary to CMV-induced vasculitis, with ischemic injury of the endothelium. The CMV viral cytopathic effect is rarely identified in squamous epithelial cells alone, and thus, biopsies of the ulcer base should be carried out. The diagnostic feature of CMV with hematoxylin-eosin (H&E) staining is a central dense eosinophilic inclusion with a surrounding halo, which leads to an owl's eye nuclear inclusion appearance. It may also show basophilic granular cytoplasmic inclusions<sup>[18]</sup>.

### Herpes simplex virus (HSV)

HSV type 1 or 2 infection is associated with small, superficial, scattered or coalescent shallow ulcers with

exudate, which are separated by normal-appearing mucosa<sup>[17]</sup>. It has also been associated with deep ulcers. Biopsies should be done at the edge of the ulceration, as the HSV viral cytopathic effect is more reliably found in squamous cells. Histological analysis reveals typical Cowdry type-A intranuclear inclusion bodies<sup>[19]</sup>.

### **Mycobacterium**

Esophageal tuberculosis is rare and is associated with direct extension of the disease from adjacent mediastinal lymph nodes or lung foci. The middle third of the esophagus is the typical site of tuberculous involvement. It may exhibit different endoscopic appearances. In the first form, deep single or multiple ulcerations of various sizes form, with shallow smooth edges and a gray-white base, and the surrounding mucosa may contain small nodules or ulcerations. The second form is characterized by a hypertrophic or a granular-appearing lesion. This form may produce granulomatous fibrosis in the esophageal wall with stricture of the lumen. The third form consists of a protruding subepithelial mass. Fistulas may develop, and it may be bronchoesophageal as well as esophagoesophageal<sup>[20]</sup>. Biopsies should be taken from the edge of the lesions. Histological findings infrequently show acid-fast bacilli and caseating granulomas<sup>[17]</sup>.

### **Idiopathic ulceration**

Idiopathic ulceration may develop at the time of initial HIV infection or may occur long after the initial seroconversion period. Endoscopy usually shows a large single or multiple deep ulcers in the mid or lower esophagus, with transverse ridges visible in the base, which represent circular muscle bundles of the esophageal muscularis propria. The margins show variable degrees of inflammation, are often irregular, and overhang into the central ulceration. Evidence indicates that these ulcers are caused by HIV<sup>[20]</sup>. These lesions are negative on biopsy for known viral and fungal agents. Electron microscopy can be used to confirm the presence of HIV-like viral particles in these ulcers<sup>[21]</sup>.

## **STOMACH**

Symptoms of dyspepsia, such as epigastric pain, fullness, nausea and vomiting, are frequently reported by HIV-infected patients, mainly those undergoing HAART<sup>[7]</sup>. These symptoms may have different etiologies, including any adverse drug effects (HAART or others), the HIV disease itself, and GI infections. It is still unknown whether GI OI may cause dyspepsia as the main symptom.

Under normal conditions, most organisms cannot thrive in the acidic gastric environment. A decrease in gastric acidity has been described in HIV-infected patients<sup>[22]</sup>, possibly providing a more suitable environment for pathogen colonization. However, gastric OI seems to be an infrequent event even among HIV-infected patients<sup>[8]</sup>.

We have performed upper GI endoscopy with biopsies of the stomach and duodenum in a large cohort of HIV-infected patients ( $n = 528$ ) with dyspeptic symptoms undergoing HAART. We have shown a low prevalence (3.66%) of OI in these patients. It is noteworthy that the few cases of observed gastrointestinal OI were seen exclusively in HIV-infected patients with  $CD4 \leq 200$  cells/mm<sup>3</sup><sup>[23]</sup>.

In order to look for a correlation between OI and dyspeptic symptoms, we have performed another prospective study in a large cohort of HIV-infected patients ( $n = 690$ ) with advanced immunodeficiency ( $CD4 < 300$  cells/mm<sup>3</sup>; mean = 154.3 cells/mm<sup>3</sup>), despite HAART. We have compared the prevalence of GI OI in dyspeptic ( $n = 500$ ) versus non-dyspeptic ( $n = 190$ ) patients. All patients underwent upper digestive endoscopy with tissue biopsies from stomach and duodenum. Although GI OI was detected exclusively in the dyspeptic patient group, we could not demonstrate a relationship between GI OI and dyspepsia, since it occurred in low numbers (just 1.6% of patients)<sup>[24]</sup>.

Although not frequent, gastritis and/or gastric ulcers have been reported to be associated with some viral, helminthic, protozoan, and fungal pathogens<sup>[25-28]</sup>.

### **CMV**

Gastric CMV is the most common OI of the stomach<sup>[29]</sup>. It is commonly associated with non-specific symptoms such as epigastric pain, nausea and vomiting. Upon endoscopic examination, gastric CMV is usually associated with ulcerations, erosions and mucosal hemorrhage<sup>[25,30]</sup>, although it may be present in a normal-appearing mucosa<sup>[31]</sup>. Less commonly seen lesions are thickened edematous folds<sup>[32]</sup>, nodules<sup>[33]</sup>, and masses<sup>[34]</sup>. CMV targets endothelial cells, and related injuries often induce epithelial and interstitial necrosis that resembles ischemic damage<sup>[30]</sup>. The presence of cytomegalic cells in tissue biopsies stained by H&E is considered the gold standard for establishing a diagnosis of CMV GI disease. When the diagnosis is uncertain, additional immunohistochemical methods may be useful in confirming the presence of CMV<sup>[35]</sup>. However, the number of tissue samples appears to be especially important for diagnosing CMV. Goodgame *et al*<sup>[31]</sup> have reported that even when immunoperoxidase staining was used to make a diagnosis of CMV, after routine histology failed to demonstrate cytomegalic cells, a positive result seemed equally dependent on the number of biopsies as on routine histopathology. When histology involved multiple sections of 8-10 biopsies, the frequency of diagnosing CMV by histology was greater than by culture.

### **Schistosoma mansoni**

Gastric infection from *S. mansoni* is extremely rare, as this helminth usually infects the intestine and liver, which leads to portal hypertension<sup>[26]</sup>. In a large cohort of dyspeptic HIV-infected patients ( $n = 690$ ), we have shown gastric *S. mansoni* (gastric ulcer) in just one

patient<sup>[24]</sup>. Reported endoscopic findings are gastric ulcers<sup>[36]</sup> and pseudopolypoid lesions<sup>[26]</sup>. Tissue biopsies reveal ova of *S. mansoni* stained by H&E, accompanied by little or no inflammatory or fibroblastic response.

### **Cryptosporidium**

*Cryptosporidium* is a coccidian protozoan that more commonly affects the proximal small bowel. Gastric infection is considered a secondary localization. Parasites reach the stomach through duodenal backwash and localize mostly in the antrum because of its proximity<sup>[37]</sup>. There is no specific pathognomonic endoscopic appearance. Gastric hyperemia, edema and erosions, especially in the antrum, have all been reported<sup>[24,27]</sup>. Gastric cryptosporidiosis may also occur in normal-appearing mucosa<sup>[24]</sup>. Histological examination shows *Cryptosporidium* parasites mainly on epithelial cells covering gastric pits and stained by H&E<sup>[37]</sup>. Rivasi *et al.*<sup>[38]</sup> have demonstrated a close relationship between the intensity of *Cryptosporidium parvum* infection and the degree of histological alterations. They did not find, however, a clear correlation between the endoscopic and histological alteration types found<sup>[38]</sup>.

### **Strongyloides stercoralis**

*Str. stercoralis* larvae infect the duodenum and the first part of the jejunum; it is considered an opportunistic agent when found in the gastric mucosa. There are remarkably few reports of gastric strongyloidiasis in HIV-infected patients. Among these reports, gastric ulcers<sup>[39]</sup>, and edematous and thickened gastric folds have been reported<sup>[40]</sup>. Strongyloidiasis in normal-appearing gastric mucosa has also been reported by our group<sup>[24]</sup>. A true pathognomonic endoscopic finding does not exist, although a brownish mucosal discoloration of the gastric or duodenal mucosa is frequently observed<sup>[40]</sup>. The diagnosis is easily made by H&E tissue stained sections, identification of *Str. stercoralis* larvae and eggs, infiltration of eosinophilic cells into the lamina propria, and villous blunting.

### **Leishmania donovani**

A few cases of gastric localization of *L. donovani* have been reported in severely immunosuppressed HIV-infected patients. Endoscopy has shown gastric ulcers, erosions and a normal-appearing gastric mucosa as well<sup>[41,42]</sup>. Histological study has shown large macrophages, lymphoid cells and plasma cells infiltrating the lamina propria. Characteristically, macrophages are filled with round or oval nucleated complete microorganisms that contain kinetoplasts. Both the kinetoplasts and nuclei stain bright red with Giemsa staining and H&E<sup>[18]</sup>.

## **SMALL INTESTINE**

Chronic diarrhea is an important clinical problem in HIV-infected patients and is still a cause of morbidity and mortality in the HAART era<sup>[43]</sup>. Diarrhea in the

setting of HIV infection may have many causes; it may be a consequence of HAART<sup>[44]</sup>, the HIV infection itself or may result from any bacterial, viral or parasitic infection<sup>[45]</sup>.

Currently, HAART-induced diarrhea is the primary reason for the continually high prevalence of diarrhea in HIV-infected patients, especially with the use of protease inhibitors<sup>[46]</sup>. The likelihood of an opportunistic process is linked to the severity of immunodeficiency. Therefore, the search for a typical HIV-associated process should be undertaken based on risk stratification of the patient. Patients with CD4 counts of < 100 cells are most at risk for *Cryptosporidium*, *Microsporidium* and CMV disease<sup>[8]</sup>.

A consensus panel in 1999<sup>[47]</sup> recommended a stepwise approach to investigate diarrhea in HIV-infected patients at risk for OI: step 1, at least three sets of stool specimens for common enteric bacteria and parasites, including microsporidia and cryptosporidia; and step 2, colonic mucosal biopsies using flexible sigmoidoscopy or colonoscopy. Upper GI endoscopy with biopsy of the duodenum for light-microscopic examination, mycobacterial culture, and electron microscopy is considered the third recommendation if no pathogen is identified after performing steps 1 and 2. Duodenal aspirate seems to be of little value in the workup of these patients<sup>[48]</sup>.

### **Cryptosporidium**

*Cryptosporidium* is a protozoan that infects the small bowel mucosa and, in immunosuppressed persons, the large bowel and extraintestinal sites. Endoscopy may show fold thickening of the mucosa, with an erythematous and granular appearance that is most prominent in the duodenum<sup>[49]</sup>. In general, duodenal erosions or ulcers are not found. Histological study of duodenum samples shows a partial villus atrophy with crypt hypertrophy and increased chronic inflammatory cells, particularly eosinophils and plasma cells. The organisms are seen positioned along the brush border of the surface and crypt epithelium<sup>[37]</sup>.

### **Microsporidia**

Intestinal microsporidiosis is caused by *Enterocytozoon bienersi* and *Encephalitozoon intestinalis*. The diagnosis is frequently established by examination of three stool samples with chromotrope and chemofluorescent stains. There is not a typical endoscopic appearance. A small bowel biopsy, especially in the jejunum may show microsporidium organisms in villus enterocytes by different stains such as H&E, Giemsa, Warthin-Starry silver staining, or Chromotrope 2A<sup>[50,51]</sup>.

### **CMV**

Isolated lesions caused by CMV in the duodenum may result in severe GI bleeding<sup>[52]</sup>. Also, diffuse mucosal involvement of the duodenum and jejunum may lead to malabsorption. Rare manifestations of CMV infection include isolated ulcers that may cause perforation, terminal ileitis mimicking Crohn's disease<sup>[53]</sup>, and ileal

obstruction that results from a large inflammatory mass<sup>[54]</sup>.

### ***Mycobacterium avium* complex (MAC)**

MAC, commonly seen in the pre-HAART era, is now very rare and is most likely to be found in patients who first present with end-stage HIV infection. The most common site of MAC infection of the GI tract is the small bowel. The endoscopic appearance may mimic Whipple's disease with diffuse, scattered white nodules and plaques that may be yellow, white, yellow-whitish, or pink, located in the second portion of the duodenum. Therefore, it is often described as pseudo-Whipple disease<sup>[17]</sup>. Although nodular lesions are frequent, other endoscopic findings have also been described in the small bowel such as ulcerations, erythema, edema, friability, reduced mucosa vascular pattern, erosions, strictures and even normal-appearing mucosa<sup>[55]</sup>. Microscopically, the affected tissue is filled with large numbers of distended histiocytes that are packed with acid-fast organisms. Usually, granuloma formation or associated inflammatory response is minimal<sup>[56]</sup>.

### ***Mycobacterium tuberculosis***

*M. tuberculosis* bowel infection is also rare. It usually involves the small bowel and ileocecal region. It may be associated with granulomatous reactions that lead to ulcers, fistulas and even perforations. Upon endoscopy, ulcers have a cratered appearance with mass-like edges. Upon histology, there are few acid-fast bacilli and usually they do not form well-developed non-caseating granulomas in HIV-infected patients<sup>[57]</sup>.

### ***Histoplasma capsulatum***

Uncommonly, fungal organisms may cause disease in the small intestine in HIV-infected patients. *Histoplasma capsulatum* most commonly causes disease in the ileum, but may also cause disease in the jejunum. Ulcers are often found, but nodules, pseudopolyps or plaques caused by collections of infected macrophages have also been described<sup>[58]</sup>. Microscopic findings include lymphohistiocytic infiltration, infected macrophages within the lamina propria, and less commonly, granulomas<sup>[58]</sup>.

The role of upper GI endoscopy in the diagnosis of OI in HIV-infected patients with GI complaints without diarrhea is still more controversial. We have done endoscopy with duodenal biopsies in a large cohort ( $n = 690$ ) of HIV-infected patients that were severely immunosuppressed (mean CD4 count 154.3 cells/mm<sup>3</sup>), who were undergoing HAART and presented with GI complaints but without diarrhea, and we found a very low incidence of OI and non-opportunistic parasites in the tissue specimens (five patients, 1.0%). In 80% of these patients, the duodenum showed a normal-appearing mucosa upon endoscopy, which suggested the relevance of taking biopsies even from a normal-appearing mucosa when an OI diagnosis is suspected<sup>[24]</sup>. Our results seem to disagree with Olmos *et al*<sup>[59]</sup>. These

authors observed a low prevalence of OI in HIV-infected patients without diarrhea when the duodenal mucosa was normal. They suggested that biopsies should not be taken from normal duodenal mucosa in patients without diarrhea. Pathogens found in biopsies of normal duodenum in our study (*Cryptosporidium* and *Giardia*), however, should also be detectable in stool samples. One possible option is that more stool tests should be performed prior to pursuing endoscopy in these patients.

## **CONCLUSION**

Although there has been a decrease in the incidence of GI OI in the era of HAART, the gastroenterologist evaluating HIV-infected patients with GI symptoms should not discard this possibility. Since adverse events related to HAART are a frequent cause of GI complaints among HIV-infected patients, the approach for HIV-infected patient with CD4 counts  $> 200$  cells/mm<sup>3</sup> and upper GI complaints should parallel those of any other patient when immunodeficiency is not advanced. Patients with CD4  $\leq 200$  cells/mm<sup>3</sup>, however, should be referred earlier for upper GI endoscopy, in order to diagnose OI early, especially because many of these infections are now treatable. Different pathogens can result in similar endoscopic findings. To correctly diagnose OIs, multiple biopsy specimens may be necessary even from normal-appearing mucosa.

### Abstract

**AIM:** To investigate the mechanism of liver regeneration induced by fusing the omentum to a small traumatic injury created in the liver. We studied three groups of rats. In one group the rats were omentectomized; in another group the omentum was left *in situ* and was not activated, and in the third group the omentum was activated by polydextran particles.

**METHODS:** We pre-activated the omentum by injecting polydextran particles and then made a small wedge wound in the rat liver to allow the omentum to fuse to the wound. We monitored the regeneration of the liver by determining the ratio of liver weight/body weight, by histological evaluation (including immune staining for cytokeratin-19, an oval cell marker), and by testing for developmental gene activation using reverse transcription polymerase chain reaction (RT-PCR).

**RESULTS:** There was no liver regeneration in the omentectomized rats, nor was there significant regeneration when the omentum was not activated, even though in this instance the omentum had fused

with the liver. In contrast, the liver in the rats with the activated omentum expanded to a size 50% greater than the original, and there was histologically an interlying tissue between the wounded liver and the activated omentum in which bile ducts, containing cytokeratin-19 positive oval cells, extended from the wound edge. In this interlying tissue, oval cells were abundant and appeared to proliferate to form new liver tissue. In rats pre-treated with drugs that inhibited hepatocyte growth, liver proliferation was ongoing, indicating that regeneration of the liver was the result of oval cell expansion.

**CONCLUSION:** Activated omentum facilitates liver regeneration following injury by a mechanism that depends largely on oval cell proliferation.

### INTRODUCTION

The omentum has been called the “policeman of the abdomen” because after traumatic injury it migrates to the injured site, adheres to the wound, and promotes healing<sup>[1,2]</sup>. These properties have found clinical application where the omentum is surgically brought into contact with injured tissues such as ischemic heart, fractured bones, or injured spinal cord<sup>[3-6]</sup>. We have recently shown that introducing a foreign body into the peritoneal cavity further enhanced the healing power

of the omentum by causing it to expand, surround the foreign body, and transform itself from mostly fatty tissue to tissue abundant in progenitor cells and rich in growth and angiogenic factors (activated omentum)<sup>[7,8]</sup>.

Because liver regeneration can be brought about by resident stem cells (oval cells) even in the absence of hepatocyte multiplication<sup>[9,10]</sup>, we attempted to use the activated omentum to facilitate liver regeneration. The procedure involved removing a small wedge of tissue (traumatic injury) in rats and allowing the omentum to adhere to the wound in order to supply the liver with stem cells. We also studied two other groups of rats (controls); one in which the omentum was left in its native state (inactivated omentum), and the other in which the omentum was surgically removed (omentectomized), and focused on the cellular and developmental gene activation at the site of injury and omental adhesion.

## MATERIALS AND METHODS

### *Traumatic injury of the liver*

Animal experimentation was conducted according to the approval of the Institutional Animal Care and Use Committee (IACUC).

Under general anesthesia, male Sprague-Dawley rats (200-250 g) were laparotomized and the most anterior and prominent of the liver lobes lying in the middle of the abdominal cavity was exposed. Using a pair of fine scissors a small V-shaped cut was made in the lobe (3-4 mm on each side) and the wedge of liver was removed and later used as normal tissue for immunostaining and quantitative reverse transcription polymerase chain reaction (RT-PCR) (Figure 1). The rats were divided into three groups. In the activated omentum group, before the incision was sutured, 5 mL of polydextran particle slurry (Biogel P-60, 120  $\mu$ mol/L; Biorad Laboratories, Richmond, CA, USA) (1:1 in normal saline) was introduced into the abdominal cavity to activate the omentum. The inactivated omentum group underwent similar hepatic wedge injuries. However, polydextran slurry was not placed in the abdomen and, thus the omentum was not activated (inactivated omentum). The omentectomized group underwent similar hepatic wedge resections, in addition to an omentectomy. An omentectomy was performed by surgically excising the entire omentum from the lower curvature of the stomach.

The animals were maintained on normal rat chow and water *ad libitum* from three to twenty eight days. At the time of sacrifice, the livers were examined, wholly removed, and weighed. Liver mass was expressed conventionally as a percent ratio: liver weight/body weight. Pieces of the re-grown liver from the point of omental fusion, and at 0.5 cm and 1.0 cm away from the wound as well as portions from an uninjured lobe were collected for immunostaining and quantitative RT-PCR.

To test whether liver regeneration by omental intervention depended upon hepatocyte proliferation,

**Figure 1** The traumatic liver injury model used to induce regeneration. The wound was created in one of the lobes of rat liver by removing a wedge of tissue (3-4 mm on each side) with a pair of fine scissors. In rats with activated or unactivated omentum, the wound was filled with new liver tissue by day 7. On the other hand, in omentectomized rats the original wound edges as seen in the picture remained visible for up to 28 d. The horizontal black bar in the picture represents 3 mm.

rats were injected intraperitoneally daily for four days with 2-acetyl-amino-fluorene, which inhibits hepatocyte proliferation (2-AAF; 30 mg/kg dissolved in M400 polyethylene glycol (Avg. MW = 400); both chemicals were obtained from the Sigma Chemical Company, St Louis, MO, USA), followed by liver wounding and omental activation (at day 5 by intraperitoneal injection of polydextran), and further daily injections of 2-AAF for four days to inhibit expansion of hepatocytes. The rats were sacrificed 14 d after liver wounding and the livers were examined, wholly removed, and weighed.

### *Histological processing and immunostaining of the regenerated liver*

Pieces of normal and regenerated liver (including the omental attachment) were fixed for histology and immunostaining by immersion in Histochoice<sup>®</sup> (Amersco Inc., Solon, OH, USA). Following dehydration and paraffin embedment, tissues were sectioned (5  $\mu$ m thick) and stained with hematoxylin-eosin (HE) or Trichrome stain. Immunostaining was carried out by first pressure-cooking the sections for 10 min in a solution of BorgDecloaker<sup>®</sup> (Biocare Medical; Walnut Creek, CA, USA) for antigen enhancement. For immunofluorescent staining the sections were incubated with monoclonal (mouse) anti-rat cytokeratin-19 (Sigma Chem. Co., St Louis, MO, USA) followed by washing and re-incubating with fluorescein (FITC) labeled anti-mouse IgG antibody (Sigma Chem. Co., St Louis, MO, USA). The slides were washed and wet-mounted in glycerol-PBS. For immunoperoxidase staining, sections were sequentially incubated with monoclonal (mouse) anti-rat cytokeratin-19, anti-mouse IgG-biotin conjugate, avidin-horse radish peroxidase and finally developed with diaminobenzidine-H<sub>2</sub>O<sub>2</sub> (brown color) (Vector Laboratories, Inc., Burlingame, CA, USA). The slides were examined either by epifluorescent or light microscopy and digitally photographed (Nikon Inc., New York, NY, USA).

### Quantification of mRNA for selected developmental genes in regenerated liver by RT-PCR

Liver tissues at the point of omental attachment or wound edge (in omentectomized rats), at 0.5 and 1.0 cm away from the omental attachment, and from a remote uninjured lobe were tested for expression of developmental genes. The specific genes and their respective forward and reverse primer sequences are listed in Table 1. The liver tissue was cleared of the attached omental tissue and processed for total RNA extraction by Trizol using a RNA purification kit (Invitrogen, CA, USA). The RT-PCR procedure was carried out in one step using 3 µg of total tissue RNA and primers using the Invitrogen RT-PCR system (Invitrogen, CA, USA). The system uses Superscript II reverse transcriptase for first strand synthesis and *Taq* DNA polymerase for second strand cDNA synthesis and amplification (30 cycles). β-actin amplification was performed from the total RNA preparations (60 ng) as a control. The RT-PCR products were quantitated as the ratio of gene band density/β-actin band density by image analysis using MIPAV software (JAVA imaging software inspired by the National Institutes of Health).

### Statistical method

Quantitative data presented in Figures 2 to 6, which compare the differences between different groups, were analyzed by student's *t* test. The differences were considered significant when *P* < 0.05.

## RESULTS

### Fusion of the omentum to the wounded liver resulted in new liver growth

In all rats in which the liver was traumatically wounded and the omentum was intact, whether activated (*n* = 24) or inactivated (*n* = 12), there was fusion between the omentum and the wound edge of the liver, and the omentum remained attached to the injury site for up to

**Figure 2** Liver mass (as a ratio of body weight) at different times after injury and fusing of the activated omentum to the wound. The ratio of liver wt/body wt in normal rats was established to be 3.85% ± 0.07%. 'Omentx' are rats in which the omentum was removed before liver injury (*n* = 12) and 'inact oment' are rats in which the liver was injured, but the omentum was inactivated (*n* = 12). Liver regeneration following wounding and fusion of activated omentum was rapid, and by day 3 the liver grew to 110% of the original mass. The liver continued to grow, reaching a maximum size of 150% of the original mass by day 14, after which growth stopped (day 28, data not shown). Normal = 15 rats and there were 6 in each of the 3, 7, 14 and 28 d groups. <sup>a</sup>Denotes statistical difference from normal or 'omentx' or 'inact oment' groups at *P* < 0.05. <sup>b</sup>Denotes statistical difference from day 3 and day 7 groups at *P* < 0.05. With regard to 'omentx' and 'inact oment' groups, no differences were seen at days 3, 7, 14 and 28 compared to Normal (only day 14 data is shown in the figure; *n* = 3).

28 d. On gross inspection, by day 14 new tissue filled the resected wedge, and the location of the resection site was only identifiable by the omental attachment. In omentectomized rats (*n* = 12), there was an absence of omental attachment and of liver growth at the wound, making the wound edges noticeable until at least day 28 (Figure 1).

In rats with activated omentum, there was additional liver growth, especially in the wounded lobe at the point of omental attachment. There was also growth in other lobes which was suggested by alterations in the natural contours of the edges of the uninjured liver lobes. Figure 2 shows the liver mass (as a percent ratio to body

**Figure 3** Histology of the boundary between the growing edge of the liver and the activated omentum. A: Normal rat liver; B: 7 d after liver injury the liver and the omentum were separated by a wide and compact interlying tissue (400-600  $\mu\text{m}$ ). On one side of the interlying tissue (T) lay the omental tissue (OM) with the embedded polydextran gel particles and on the other side was the liver tissue (L). Occasionally, islands of liver tissue were observed in the interlying tissue (Figure 4G). The compactness and the width of the interlying tissue was maximal between 3 and 7 d after liver injury (B) which became thinner (100-150  $\mu\text{m}$ ) and looser by day 14 (C). By 28 d the interlying tissue was barely appreciable and looked like a tissue septum (picture not shown). Trichrome staining. The horizontal white bar in the pictures represents 100  $\mu\text{m}$ .

**Figure 4** Immunostaining of normal and regenerated rat liver (from activated omentum) for cytokeratin-19, a marker of oval cells. A: Normal or uninjured liver lobe showing widespread presence of oval cells in the lining of bile ducts lying around a central vein; B, D, E, G: Different areas of injured liver showing extensions of cytokeratin-19 positive bile ducts in the interlying tissue between the liver and the activated omentum; C: Tissue section shown in B stained with Trichrome to show the bile ducts lying in the interlying omental tissue; F: Occasionally, the growing edge of the liver lying in the interlying tissue was seen to be entirely covered with cytokeratin-19 positive cells; G: Islands of liver tissue, probably newly formed, were seen in the interlying tissue (white arrows; also seen in D); A, B, D-F were stained by immunofluorescence (green); G was stained by immunoperoxidase (brown). The horizontal white bar in F represents 100  $\mu\text{m}$  for all pictures.

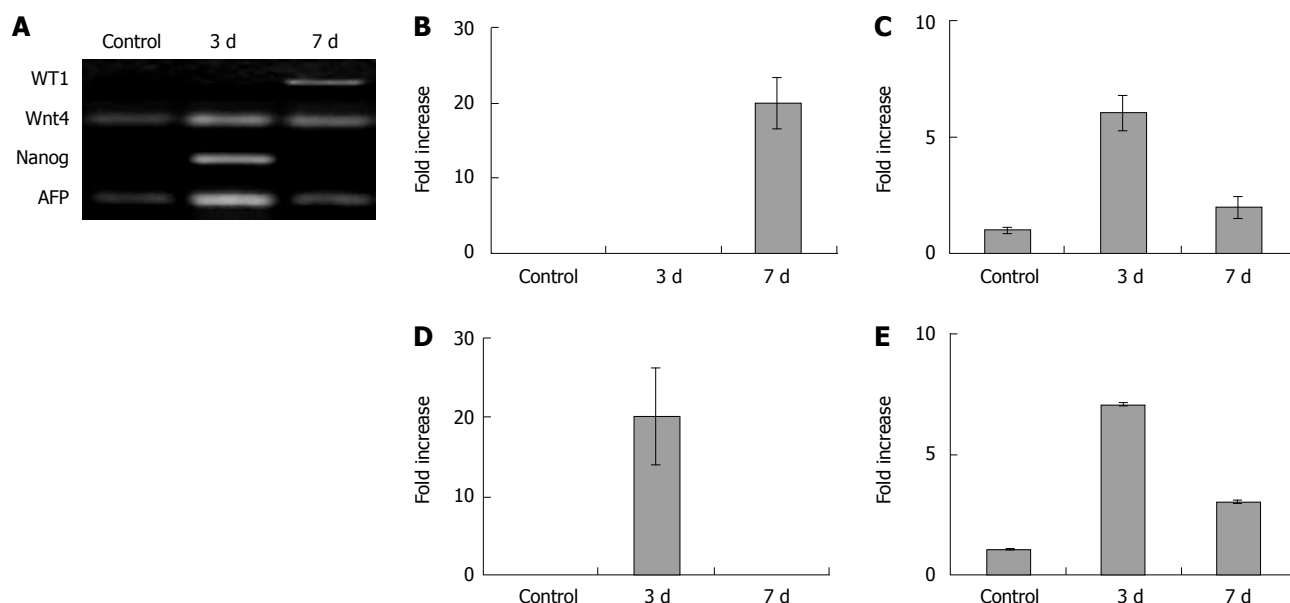

**Figure 5** Histology and cytokeratin-19 immune staining of the liver at the boundary between the growing edge of the liver and the inactivated omentum at day 3 or 7 after injury. A: Trichrome stained section showing the adherent omental tissue with a thinner interlying tissue (blue stained) than that seen in the activated omentum group (Figure 3 for comparison); B: Cytokeratin-19 positive bile ducts were seen in the interlying tissue (same section as A) although these were much less frequent than those seen in the activated omentum group (Figure 4 for comparison). The horizontal white bar in pictures represents 100  $\mu\text{m}$ .

weight) at different times after wounding and fusing of the omentum to the wound. The percent ratio in normal rats was established to be  $3.85 \pm 0.07$  [Normal ( $n = 15$ ); Figure 2]. In the activated omentum group, the liver grew to 110% of its original mass by day 3 (percent ratio:  $4.4 \pm 0.24$ ) and to a maximum size of 150% by day 14 (percent ratio:  $6.0 \pm 0.16$ ) ( $n = 6$  at days 3, 7, 14 and 28; Figure 2).

From day 14 to day 28, the liver did not grow any further, but remained enlarged (data not shown).

In rats with inactivated omentum, growth was observed at the site of omental fusion and filled the resected site with new tissue, however, the overall liver mass did not increase at any of the time points compared with the established normal liver mass [ $n = 3$

**Figure 6** Activation of developmental genes in the regenerated liver at the wound site at days 3 and 7 after injury and fusion of the activated omentum. The regenerating part of the liver (part of liver attached to the omentum) showed high expression levels (7 to 20-fold) of WT-1, Wnt-4, Nanog, AFP by RT-PCR (A) compared with normal rat adult liver tissue (control). Wnt-4 (C), Nanog (D), and AFP (E) were maximally activated at day 3, while WT-1 (B) showed maximal activation at day 7. Tissue from regenerated liver, from sites further away from the wound area (0.5 cm, 1.0 cm further away in the same lobe and from an uninjured lobe), showed reduced activation of WT-1, Wnt-4 and AFP genes (although higher in all cases compared with normal adult liver), suggesting that the regeneration stimulus 'rippled' throughout the liver from the wound area (data not shown).  $n = 3$  in each bar and the differences amongst the bars within each of the figures B, C, D, and E are statistically significant ( $P < 0.05$ ).

at days 3, 7, 14 and 28 (day 14 data shown in Figure 2)].

In omentectomized rats, the liver did not grow and the resection site remained visible up to day 28. The percent ratio of liver wt/body wt in this group was similar to that of normal rats at all time points [ $n = 3$  at days 3, 7, 14 and 28 (day 14 data shown in Figure 2)].

### Histology of the regenerated liver

In the activated omentum group, in which liver tissue grew to more than normal size, histological examination at the site of injury revealed normal hepatic architecture up to the point of omental fusion (Figure 3B). At the site of fusion there was a wide and compact band of interlying tissue between the omentum and the growing edge of the liver (Figure 3B). On one side of the interlying tissue lay the liver tissue and on the other side was the omental tissue with the embedded polydextran gel particles. The compactness and the width of the interlying tissue was maximal between 3 and 7 d after liver injury (400–600  $\mu\text{mol/L}$ ) (Figure 3B) and became thinner (100–150  $\mu\text{mol/L}$ ) and less compact by day 14 (Figure 3C). In the interlying tissue, small islands of liver tissue, probably newly formed, were seen (Figure 4G). By day 28 the interlying tissue was barely visible and appeared like a tissue septum (not shown).

In the inactivated omentum group in which liver growth was minimal, although the adherent omental tissue was clearly visible, a thinner interlying tissue than that seen in the activated omentum group was observed (Figure 5A). In the omentectomized group, the void left by the injury was visible at all time points. The injury site lacked omental attachment, but showed a layer of dead

tissue (approx. five cells thick) which sloughed off from the wound edge by day 14 (not shown).

### Immunostaining of the regenerated tissue for cytokeratin-19

Immunostaining of normal adult rat liver for cytokeratin-19, a well-known marker for bile ducts as well as oval cells (oval cells are presumed to be liver stem cells), showed the expected widespread presence of oval cells in the lining of bile ducts lying in the liver triads (Figure 4A). In the liver with or without omental attachment, cytokeratin-19 positive bile duct staining in the triads of the uninjured lobes was similar in intensity to that seen in the normal liver (not shown). In the liver tissue with activated omentum, remarkably, cytokeratin-19 positive bile ducts in the regenerated liver (day 3 or 7) extended into the interlying area between the liver and the omentum (Figure 4B–E). Occasionally, the growing edge of the liver at the interlying tissue was seen to be entirely covered with cytokeratin-19 positive cells (Figure 4F). Islands of liver tissue, probably newly formed, were present in the interlying tissue (Figure 4G).

In the inactivated omentum group, the interlying tissue attached to the wound edge also showed extensions of the cytokeratin-19 positive bile ducts (at days 3 and 7) (Figure 5B), although these were much less frequent than those seen in the activated omentum group. In omentectomized rats, the wound edge was devoid of omental attachment, and as expected no cytokeratin-19 positive bile ducts were seen outside the liver tissue (not shown).

### Expression of developmental genes in the liver tissue attached to the activated omentum

To further investigate if activated omentum fused to the injured liver triggered developmental events in the adult liver, we determined the expression levels of several important genes associated with (1) pluripotent embryonic stem cell activity (Nanog, Oct-4), (2) liver differentiation (WT1, Wnt-4, HNF-6) and (3) fetal liver synthetic activity ( $\alpha$ -fetoprotein; AFP) at days 3 and 7 after wounding using RT-PCR. Comparisons between normal rat adult liver and the regenerated liver attached to the activated omentum showed high expression levels (7-20 fold) of four of these genes (*WT-1*, *Wnt-4*, *Nanog*, *AFP*) in the regenerated liver tissue (Figure 6) (Oct-4 and HNF-6 levels were negative; not shown). *Wnt-4*, *Nanog*, and *AFP* were maximally activated at day 3, while *WT-1* showed maximal activation at day 7.

Regenerated liver tissue from sites further away from the injured area (0.5 cm and 1.0 cm away from the activated omentum in the same lobe, and tissue from an uninjured lobe), showed reduced expression of *WT-1*, *Wnt-4*, and *AFP* genes (although higher in all cases compared to normal adult liver (Nanog, Oct-4, AFP did not change), suggesting that the regeneration stimulus 'rippled' from the injured area further into the liver tissue (data not shown).

In contrast, in the inactivated omentum group (compared to normal adult liver) the expression level of *WT-1*, *Wnt-4* and *Nanog* increased to a much smaller degree than that observed in the activated omentum group at days 3 and 7 (*WT-1* by 1.5-fold, *Wnt-4* by 1.9-fold and *Nanog* by 1.2-fold), while *AFP* decreased by 0.8-fold ( $P < 0.05$  in all cases; no detectable changes were seen in Oct-4 and HNF-6).

In the omentectomized group, while the expression levels of *WT-1* and *Nanog* did not change, the levels of *Wnt-4*, Oct-4, *AFP* and HNF-6 decreased by 0.78-fold-undetectable levels compared with normal adult liver ( $P < 0.05$  in all cases).

### Omentum-assisted liver regeneration in rats treated with 2-AAF, a drug that blocks proliferation of hepatocytes

Because liver mass can increase due to either progenitor cell activation or hepatocyte multiplication, we performed the wedge wound experiment in a small group of rats in which hepatocyte multiplication was blocked by treatment with 2-AAF. This was performed to confirm that liver regeneration was *via* progenitor cells and not by hepatocyte expansion in our model. Fourteen days after wounding, 2-AAF treated rats showed complete healing of the wedge wound and increased the liver mass to 135% of the original mass [liver weight/body weight ratios:  $5.1 \pm 0.2$  in 2-AAF treated ( $n = 4$ ) *versus*  $3.85 \pm 0.07$  in normal controls ( $n = 15$ );  $P < 0.05$ ], confirming that omentum-assisted liver regeneration was not mediated by hepatocyte expansion, but by progenitor cell activation.

## DISCUSSION

For many years the omentum was believed to have

no specific function. During the course of the 19th century, however, several investigators recognized that it possessed healing properties. These were later exploited in a variety of surgical procedures designed to facilitate the healing of bone fractures, spinal cord injuries, and heart ischemia<sup>[1-6]</sup>. In previous studies we investigated this process and found that these properties can be enhanced by physically expanding the omentum with foreign particles. Under such conditions, the expanded omentum becomes rich in growth and angiogenic factors, and has abundant progenitor cells<sup>[7,8]</sup>. In a separate study we used this approach to generate new  $\beta$ -cells from the diabetic pancreas<sup>[11]</sup>.

Here we applied these findings in an attempt to regenerate liver tissue by creating a surgical wound and allowing the omentum to fuse with the wound. We studied groups of rats with (1) no omentum (omentectomized), (2) inactivated omentum, and (3) omentum pre-activated by foreign polydextran particles. We found no liver growth in omentectomized rats. In rats with inactivated omentum, the omentum fused with the injured site and although new growth was noted, this did not result in a significant increase in liver mass. However, in rats with activated omentum, following omental fusion, the liver grew to fill the wound and continued to grow, both at the wound site and globally, to a level 50% greater than the original mass. These findings suggest that the omentum plays an important role in bringing about growth and regeneration of the injured liver. The amount of liver growth induced by the omentum was proportional to the degree of omental activation, consistent with our previous observations that the concentration of growth factors and the number of progenitor cells in the omentum increase with increased activation<sup>[7,8]</sup>.

Clinicians have long known that the liver has the ability to regenerate. Experimentally, a 70% hepatectomy (either surgically or chemically) induces a form of liver regeneration in which growth is largely due to hepatocyte proliferation<sup>[9-13]</sup>. When hepatectomy is carried out following the administration of drugs which inhibit hepatocyte proliferation, the regeneration is mainly due to the expansion of oval cells<sup>[14-17]</sup>. In these various models, there is a massive loss of functional liver tissue, which then systemically triggers a cascade of cytokines (such as tumor necrosis factors- $\alpha$ , IL-6 and growth factors). In our model, the injury was so slight that regeneration would not occur unless the omentum was activated, as shown in our omentectomized control rats.

In further studies we attempted to understand the mechanism by which activation of the omentum causes liver regeneration. Histologically, at the fusion site between the activated omentum and the liver, we found a wide and compact interlying band of tissue into which tubular structures resembling bile ducts extended and proliferated. On staining, these structures were strongly positive for cytokeratin-19, a known marker for oval cells, believed to be liver progenitor cells<sup>[18-20]</sup>. At an early stage of regeneration the oval cells in the interlying tissue were seen near small islands of liver tissue; later these islands became integrated into the native liver, so

that the border between the native and the new liver could no longer be discerned in stained sections. Because proliferation of the progenitor oval cells took place in the omentum rather than in the liver, they may have had more room to proliferate and expand, accounting for the robust, supra normal liver growth.

Because liver tissue can also regenerate by hepatocyte proliferation we repeated our experiment in rats treated with 2-AAF, a drug commonly used to inhibit hepatocyte multiplication. Our finding that the activated omentum continued to exert its regenerative property in 2-AAF-treated rats by increasing the liver mass to 135% of the native mass, further suggested that the proliferation of progenitor oval cells rather than proliferation of hepatocytes was responsible for liver regeneration in our model.

As genes and proteins involved in liver development (Wnt-4, WT-1, HNF-6, AFP) may become re-activated during liver regeneration<sup>[15-17,21-23]</sup>, we tested these developmental genes and also Nanog and Oct-4, markers of early progenitor cells<sup>[24,25]</sup>, to see if they were altered in regenerating liver tissue. We found that many of these genes, silent in the adult liver, were highly up-regulated (7 to 20-fold) after fusion of the activated omentum. Nanog was up-regulated by 20-fold three days after omental fusion and returned to undetectable levels by day seven, suggesting the transient presence of early progenitor cells. Gene expression of Wnt-4 and AFP was highest at day 3 and decreased by day 7, in contrast to WT-1 which was unchanged at day 3 and highest at day 7. These findings are consistent with the transient activation of these transcription factors (WT-1 and Wnt-4) known to occur in liver re-modeling and differentiation<sup>[16,26,27]</sup>. HNF-6, a marker strongly associated with hepatocyte proliferation<sup>[28]</sup>, was unchanged, as also noted in a previous study of non-hepatocyte mediated (but progenitor cell mediated) liver regeneration<sup>[16]</sup>. This was not surprising because liver growth by omental fusion was *via* oval cells and not dependent on hepatocyte proliferation. Interestingly, we also found a few selected genes (*WT-1*, *Wnt-4* and *AFP*) to be activated in regions of the native liver 0.5 cm and 1.0 cm from the wound edge. The level of activation decreased as the distance from the wound edge increased, suggesting that a paracrine effect was exerted by the omentum. Importantly, we found lower activation levels of genes in the inactivated omentum group (1.2-1.9-fold), consistent with reduced liver growth seen in these rats. Furthermore, in omentectomized rats where there was no liver growth, a decrease in gene expression levels was observed compared with normal liver.

The present study is the first to demonstrate the unique role of the omentum in traumatic wound healing of the liver. We have shown previously that omental derived factors stimulate wound healing and can be upregulated by pre-activating the omentum. By bringing the omentum into close contact with injured liver we observed a vigorous regeneration of liver tissue. Although the liver is known to regenerate to the original size following a significant loss of hepatic

tissue, there are no reports of liver regeneration up to 150% of the original size as noted in our study. As both cytokeratin-19 positive cells and expression of developmental genes were increased, we postulate that both growth factors and stem cells are conveyed to the site of injury by omental fusion. It may be argued that bringing the omentum into contact with damaged organs after controlled deliberate wounding may have immediate clinical applicability. Also, the use of progenitor cells isolated from the activated omentum or of the growth factors secreted by these cells holds further promise of other exciting therapeutic possibilities.

## COMMENTS

### Background

Although the liver is a unique tissue that can regenerate after an acute injury, it has been a challenge to induce such regeneration after chronic liver disease. It is, therefore, important to study mechanisms of liver regeneration in order to devise new approaches for regeneration following damage by chronic disease. Although embryonic stem cells have the power to regenerate liver tissue, their use is hampered by ethical, political and safety concerns. In that regard, the use of adult stem cells derived from the patient's own tissue to regenerate the liver is free of such concerns and, therefore an alternative approach.

### Research frontiers

Stem cells have been derived from several adult organs such as bone marrow, skin, hair, kidney and dental pulp. Although these cells express stem cell markers and differentiate to other cell phenotypes in culture they seem to lack the potency to regenerate an organ *in vivo*. Identifying a source of adult stem cells that could regenerate liver or other organs would be an immense advantage.

### Innovations and breakthroughs

Singh and his colleagues devised a methodology to harness adult stem cells to regenerate the liver by first activating the omentum using a foreign body to increase its content of stem cells and growth factors. They then cut and removed a small piece of the liver tissue and let the activated omentum adhere to the wound in order to supply stem cells to the injured liver. They found that the liver of these rats with an activated omentum expanded to a size 50% greater than the original, an outcome never reported before. This approach represents an application of adult stem cells to regenerate an organ *in vivo*.

### Applications

This method of liver regeneration is novel and could be attempted in patients with liver failure in order to regenerate new liver tissue.

### Terminology

Activated omentum, which is central to this methodology of liver regeneration, was created by injecting polydextran particles (foreign body) into the abdominal cavity. As the omentum naturally grows to encapsulate the particles individually it expands 20-30 times its original size and has abundant stem cells and growth factors, which appear to be the basis of the regenerating power of the omentum.

### Peer review

Reviewers considered the use of the omentum to regenerate the liver as meritorious and interesting. Further they thought the paper was well written, results were clear, and the data supported the conclusions reached by the authors.

### Abstract

**AIM:** To study the action of aminoguanidine on pancreatic cancer xenografts in relation to cell proliferation, apoptosis, redox status and vascularization.

**METHODS:** Xenografts of PANC-1 cells were developed in nude mice. The animals were separated into two groups: control and aminoguanidine treated. Tumor growth, survival and appearance of metastases were determined *in vivo* in both groups. Tumors were excised and *ex vivo* histochemical studies were performed. Cell growth was assessed by Ki-67 expression. Apoptosis was studied by intratumoral expression of B cell lymphoma-2 protein (Bcl-2) family proteins and Terminal deoxynucleotidyl transferase biotin-dUTP Nick End Labeling (Tunel). Redox status was evaluated by the expression of endothelial nitric oxide synthase (eNOS), catalase, copper-zinc superoxide dismutase (CuZnSOD),

manganese superoxide dismutase (MnSOD) and glutathione peroxidase (GPx). Finally, vascularization was determined by Massons trichromic staining, and by VEGF and CD34 expression.

**RESULTS:** Tumor volumes after 32 d of treatment by aminoguanidine (AG) were significantly lower than in control mice ( $P < 0.01$ ). Median survival of AG mice was significantly greater than control animals ( $P < 0.01$ ). The appearance of both homolateral and contralateral palpable metastases was significantly delayed in AG group. Apoptotic cells, intratumoral vascularization (trichromic stain) and the expression of Ki-67, Bax, eNOS, CD34, VEGF, catalase, CuZnSOD and MnSOD were diminished in AG treated mice ( $P < 0.01$ ), while the expression of Bcl-2 and GPx did not change.

**CONCLUSION:** The antitumoral action of aminoguanidine is associated with decreased cell proliferation, reduced angiogenesis, and reduced expression of antioxidant enzymes.

### INTRODUCTION

Pancreatic cancer is an aggressive carcinoma usually diagnosed at an advanced stage and shows a median

survival time of only three months. Approximately half of the cases are metastatic at the time of diagnosis, while the remainder have locally advanced unresectable disease. To date, the only effective treatment is surgical therapy. Adjuvant chemo- and radiotherapy have not led to significant improvements in outcome<sup>[1]</sup>.

Nitric oxide synthase (NOS) produce nitric oxide (NO) by the oxidation of L-arginine. There are three known isoenzymes of NOS: two constitutive forms [neuronal NOS (nNOS) and endothelial NOS (eNOS)] and one inducible form, inducible NOS (iNOS). Constitutive isoforms nNOS and eNOS respond to a calcium influx with a transient release of NO<sup>[2]</sup>. On the other hand, iNOS always generates high quantities of NO over a prolonged period<sup>[3]</sup>. This isoform is not only expressed in activated macrophages, usually infiltrating tumors, but also in various types of malignant cells.

Nitric oxide is a highly diffusible, lipophilic free radical. Under certain pathological conditions, NO can combine with the superoxide anion (O<sub>2</sub><sup>-</sup>) to form peroxynitrite (ONOO<sup>-</sup>), a potent reactive nitric oxide species that nitrates tyrosine residues in proteins and induces DNA damage and lipid peroxidation, leading to cell damage and often cell death. NO in cancer exhibits both a cytotoxic and a cytoprotective effect according to its concentration within the tumor microenvironment. Low levels of NO produced by tumor cells themselves aid tumor progression, while the high level of NO produced by tumor adjacent macrophages function as a tumor suppressor agent through the induction of apoptosis<sup>[4-7]</sup>.

Aminoguanidine, a nucleophilic hydrazine compound first synthesized more than 100 years ago, is an irreversible inhibitor of iNOS, which also inhibits eNOS and nNOS at higher concentrations<sup>[8]</sup>. It has been shown *in vivo* to prevent disease states characterized by the pathological overproduction of NO, such as diabetic complications<sup>[9]</sup>, age-related arterial stiffening, cardiac hypertrophy<sup>[10]</sup> and also tumors (including cholangiocarcinoma<sup>[11]</sup> and gastric cancer<sup>[12]</sup>). These effects of AG are exerted by modulating proliferation<sup>[12]</sup>, apoptosis<sup>[12]</sup>, angiogenesis<sup>[12]</sup>, by the production of free radicals<sup>[12]</sup> and by preventing the formation of advanced glycation end products (AGEs)<sup>[13,14]</sup>.

The human pancreatic ductal carcinoma, PANC-1, cells express constitutive eNOS. However, though it is the most commonly tumor associated synthase isoform, PANC-1 cells do not express iNOS<sup>[15]</sup>.

Although the *in vitro* action of NOS inhibitors has been extensively studied, little research has been undertaken as regards their *in vivo* effects on cancer growth. Therefore, the aim of this work was to study the action of the NOS inhibitor AG in PANC-1 human pancreatic cancer xenografts in nude mice in relation to tumor growth, angiogenesis and the expression of antioxidant enzymes.

## MATERIALS AND METHODS

### Xenografts in nude mice

PANC-1 cells ( $7 \times 10^6$ ) were collected by centrifugation and resuspended in 100  $\mu$ L RPMI-1640 (GIBCO, Grand Island, New York, USA) to be inoculated in the dorsal

flank of each nude mouse (cepa N:NIH(S)-nu). When the tumors that developed reached a volume of 500 mm<sup>3</sup> they were excised, cut into 27 mm<sup>3</sup> pieces and grafted into the dorsal flank of another nude mouse. Xenografted mice were separated in four groups ( $n = 7$ ) and received daily doses of AG (aminoguanidine hydrochloride, Sigma, Saint Louis, Missouri, USA) of 1, 2 or 4 mg/mL in drinking water. *In vivo* treatments began when the graft volumes reached 100-150 mm<sup>3</sup>. The control group was left without treatment. Tumor size was measured with a caliper three times a week and volume was calculated as [(major diameter + minor diameter)/4]<sup>3</sup>  $\times \pi/3$ . Treatments lasted 32 d. Two-way ANOVA, Bonferroni post test and non linear fit of tumor growth data were carried out by GraphPad Prism version 5.00<sup>TM</sup>. All the experiments using mice were performed according to the NRC [National Research Council] Guide for the Care and Use of Laboratory Animals, 7th ed, Washington DC, National Academy Press, 1996.

### Survival

Mice bearing xenografts were divided into two groups ( $n = 7$ ), AG (2 mg/mL in drinking water) and control, and followed until spontaneous death. Kaplan-Meier survival curves, median survival time of each group and *P* value were obtained by GraphPad Prism<sup>TM</sup>. Development of palpable metastases was checked three times a week in both groups and the metastases were distinguished according to their location as either homolateral (those that appeared in the same flank as the xenograft) or contralateral (those that appeared in the opposite flank).

### Histochemistry

At the end of treatments, tumors were excised, fixed in 40 g/L formaldehyde in PBS (formalin), paraffin embedded and sliced into 3- $\mu$ m thick sections for: (1) Tunel, using TdT-FragEL DNA Fragmentation Detection Kit (Calbiochem, a brand of EMD Biosciences, La Jolla, California, USA) according to the manufacturer's instructions. 3,3'-Diaminobenzidine tablets (DAB; Sigma) were used for staining and methyl green for counterstaining; (2) Immunohistochemical detection using antibodies against Ki-67 (1/50, Dako Cytomation, Carpinteria, California, USA), PCNA (1/100, Dako Cytomation), Bcl-2 (1/50, Santa Cruz Biotechnology, Santa Cruz, California, USA), Bax (1/50, Santa Cruz Biotechnology), eNOS (1/30 Sigma), VEGF (1/20, R&D Systems, USA), catalase (1/50, Sigma), CuZnSOD (1/50, Calbiochem), MnSOD (1/50, Calbiochem) and GPx (1/125, Stressgen, Ann Arbor, Michigan, USA). The appropriate secondary HRP-conjugated antiserum was employed in each case. DAB tablets were used for staining and hematoxylin for counterstaining; (3) Tumor vascularization was assayed by means of Masson trichrome and CD34 (1/50, Santa Cruz Biotechnology) staining; and (4) hematoxylin and eosin staining of tumors and metastatic lymph nodes.

Microscopic observations were performed using an Axiolab Karl Zeiss microscope by two independent observers. Photographs were taken with a Canon Power

**Table 1** AG enlarges tumor volume doubling time (mean  $\pm$  SD)

Treatment	Doubling time (d)
Control	7.8 $\pm$ 0.3
AG 1 mg/mL	7.8 $\pm$ 0.3
AG 2 mg/mL	10.0 $\pm$ 0.5 <sup>a</sup>
AG 4 mg/mL	11.1 $\pm$ 0.7 <sup>a</sup>

Tumor volume doubling times were obtained by non linear fit of tumor growth rate (shown in Figure 1) to an exponential growth equation. <sup>a</sup> $P < 0.01$  vs control and AG 1 mg/mL, ANOVA one way with Bonferroni post test.

Shot G5 digital camera and processed with Remote Capture 2.7 software. Metastatic lymph nodes, Tunel, trichrome stain and CD34 of control mice were observed at 400  $\times$  and the remaining determinations at 630  $\times$ . Microscopic observations were done in ten random fields and graded as percent of positive cells. Positive nuclei were considered as positive cells for Tunel, Ki-67 and PCNA, whereas diffuse positive cytoplasm were considered as positive cells for cytoplasmic proteins. Non parametric Mann Whitney tests on the percent of positive cells in control and AG groups were performed by GraphPad Prism™. Peritumoral vascularity was assessed by screening trichrome stained sections at 50  $\times$  magnification to identify the largest vascular areas around the tumor. In these hot spots, individual vessel count was evaluated at 400  $\times$  magnification using an ocular grid. Intratumoral vascularity was evaluated on trichrome and CD34 stained slices, counting vessels inside the tumor at 400  $\times$  magnification in ten random fields (in the identified hot spots).

## RESULTS

### In vivo studies

**Tumor growth:** Animals were separated into four groups (control and 1, 2 and 4 mg/mL AG) to evaluate the effect of AG on tumor growth. Mice were treated for 32 d when grafts volume reached 100-150 mm<sup>3</sup>. Tumor volumes were determined three times a week and finally referred to the initial volume for each treatment (Figure 1). AG (2 and 4 mg/mL) treatment significantly diminished the tumor growth rate. Tumor volumes of mice treated with AG 2 and 4 mg/mL from day 28 of treatment on were significantly different from tumors of control animals ( $P < 0.01$  for AG 2 and 4 mg/mL vs control, two way ANOVA and Bonferroni post test).

In the same way, tumor volume doubling time of mice treated with AG 2 or 4 mg/mL was significantly greater than the other groups (Table 1;  $P < 0.01$  vs control and AG 1 mg/mL, Anova one way with Bonferroni post test).

**Tumor histology:** After excision of tumors, xenografts usually showed macroscopic infiltration of the dermis and abdominal muscular wall. Under microscopic observation, tumors presented undifferentiated adenocarcinoma cells, with high grade of atypia, marked anisokaryosis and anisocytosis. Multinucleated cells and atypical mitoses (often tri- and tetrapolar mitoses) were frequently observed.

**Figure 1** Antitumor effect of AG in PANC-1 xenografted mice. Tumor volumes were determined and referred to the initial volume for each treatment. <sup>a</sup> $P < 0.01$  for AG 2 and 4 mg/mL vs control, two way ANOVA and Bonferroni post test.

**Survival and metastases:** Two extra groups of PANC-1 xenografted animals (control and AG 2 mg/mL) were followed three times a week until spontaneous death. Kaplan-Meier survival curves (Figure 2A) were obtained for AG 2 mg/mL (dotted line) and control (solid line) groups. Median survival, i.e. the time at which survival percent equals 50%, of AG treated animals (95 d) was significantly greater than that of control mice (74 d;  $P < 0.01$  for AG vs control, log-rank test).

The same groups of animals were checked for the development of palpable metastases (concomitantly with survival studies) until the death of the animals. The total number of both homolateral and contralateral palpable metastases developed in each group ( $n = 7$  each group) was determined (Figure 2B). Appearance of metastases was significantly delayed in AG treated mice. The medians of appearance were 59 d for control homolateral metastases, 78 d for AG homolateral metastases and 92 d for AG contralateral metastases. The median for control contralateral metastases could not be determined since only two metastases appeared by the time of death. Curves were significantly different.

Also, the number of homolateral metastases per animal was lower in the AG group. The first control mouse died at 64 d; therefore, the mean number of metastases per animal at 63 d was obtained and compared for each of the four groups. Means, expressed as mean  $\pm$  SD, were significantly different. The number of homolateral metastases in the control ( $1.8 \pm 0.4$  per mouse) was significantly greater than in the other groups ( $0.3 \pm 0.3$  per mouse for control contralateral,  $0.1 \pm 0.1$  for AG homolateral and 0 for AG contralateral).

The metastases that developed were analyzed by microscopic observation after the mice died (Figure 3A). Both homolateral and contralateral metastases appeared mainly in the lymph nodes. The node architecture was only preserved in a few peripheral sections due to the considerable extent of tumor infiltration. Infiltrating tumor cells showed the same histological characteristics as xenograft neoplastic cells (Figure 3B). This finding confirms the metastatic character of the multiple masses found.

### Ex vivo studies

**Apoptosis and cell proliferation:** Cell proliferation

**Figure 2** Action of AG on survival and metastases in PANC-1 xenografted mice. A: Time of spontaneous death of mice was determined, Kaplan-Meier survival curves were plotted and median survival was calculated.  $P < 0.01$  for AG vs control, log-rank test; B: The development of palpable homolateral and contralateral metastases, which appeared mainly in lymph nodes, was checked until the death of the animals. Total number of metastases developed in both groups ( $n = 7$  each group) and medians of appearance were determined. Curves were compared by logrank test,  $P < 0.01$ .

in xenografts was evaluated through the expression of Ki-67<sup>[16]</sup> (Figure 3C and F). Apoptosis was studied in tumors by the TUNEL assay (Figure 3D and G) and by the expression of antiapoptotic protein Bcl-2 and proapoptotic Bax (Figure 3E and H).

Ki-67 expression, evaluated as percent of positive cells (mean  $\pm$  SD), was lower in tumors of AG treated mice than in the control group ( $19 \pm 11$  vs  $78 \pm 10$ ,  $P < 0.01$ , Mann Whitney test). Similar results were obtained by PCNA immunodetection, another proliferation marker.

The TUNEL test showed a lower proportion of apoptotic cells in grafts of animals which had received AG than the control group, ( $1 \pm 1$  vs  $5 \pm 1$ ,  $P < 0.01$ , Mann Whitney test), evaluated as percent of positive cells (mean  $\pm$  SD). In the same way, the expression of Bax, evaluated as percent of positive cells (mean  $\pm$  SD), was significantly lower in tumors of AG treated animals than in control animals ( $17 \pm 13$  vs  $88 \pm 11$ ,  $P < 0.01$ , Mann Whitney test). Lastly, Bcl-2 expression was not altered by AG treatment ( $20 \pm 10$  vs  $15 \pm 9$ , AG vs control). These results, therefore, indicate an antiapoptotic effect of AG in xenografts.

**Angiogenesis:** Angiogenesis is essential for the growth, invasion and metastasis of a tumor. eNOS has been shown to participate in tumor progression by promoting angiogenesis<sup>[17,18]</sup>. Vascular endothelial growth factor (VEGF), a potent endothelial cell mitogen and vascular permeability factor, is mainly implicated in tumor growth *via* the stimulation of NO production<sup>[6,18]</sup>. To evaluate

tumor angiogenesis in PANC-1 xenografts, eNOS and VEGF expressions were assayed, as well as intra and peritumoral vascularity (by the trichrome stain and CD34 expression; a marker of endothelial cells).

The expression of VEGF (Figure 3I and L) and eNOS (Figure 3J and M) was determined as percent of positive cells (mean  $\pm$  SD). Grafts of AG treated animals expressed lower levels of eNOS and VEGF than tumors of control mice ( $9 \pm 9$  vs  $75 \pm 9$ ,  $P < 0.01$  and  $25 \pm 17$  vs  $84 \pm 9$ ,  $P < 0.01$ , Mann Whitney test, respectively).

Vascularity evaluated by the trichromic stain (Figure 3N) in xenografts of untreated mice showed capillaries and medium size vessels in intratumoral areas, while medium and large size vessels were observed in peritumoral tissues. AG treatment did not modify peritumoral vascularity; however, a diminished level of intratumoral vascularity was detected. As shown in Figure 3K and N, the intratumoral observations were confirmed by CD34 staining ( $6 \pm 3$  vs  $21 \pm 6$ , AG vs control,  $P < 0.05$ , Mann Whitney test), indicating an antiangiogenic effect of AG.

**Expression of antioxidant enzymes:** Reactive oxygen species (ROS), reactive nitrogen species (RNS) and redox state modulate cell proliferation, apoptosis and angiogenesis. Cells defend themselves against ROS mainly by antioxidant enzymes. In this way, superoxide dismutases convert superoxide radicals into hydrogen peroxide, which is in turn scavenged by catalase and GPx. According to their intracellular distribution, cytosolic CuZnSOD protects against cytosolic superoxide, while mitochondrial MnSOD decomposes mitochondrial-generated superoxide<sup>[19]</sup>. The four antioxidant enzymes were assessed in PANC-1 xenografts. Tumors of AG treated mice showed a lower expression (evaluated as percent of positive cells; mean  $\pm$  SD) than grafts of control animals, for CuZnSOD ( $14 \pm 10$  vs  $80 \pm 15$ ), MnSOD ( $21 \pm 12$  vs  $77 \pm 17$ ) and catalase ( $9 \pm 6$  vs  $49 \pm 12$ ) ( $P < 0.01$ , Mann Whitney test). Meanwhile, GPx expression remained unchanged ( $70 \pm 11$  vs  $81 \pm 9$ , AG vs control).

## DISCUSSION

The effect of the NOS inhibitor aminoguanidine was studied in xenografts obtained by inoculation of PANC-1 human pancreatic ductal carcinoma cells into nude mice.

*In vivo* results showed an antitumor effect of AG, including suppression of tumor growth, enhanced survival, delayed appearance of metastases and a lower number of homolateral metastases per animal. Similarly, tumor development diminished in a hamster model of cholangiocarcinoma<sup>[11]</sup>. However, AG displayed an antimetastatic action on a model of inflammation-based murine fibrosarcoma progression, altering neither tumor incidence nor tumor growth<sup>[20]</sup>. Metastatic cell behavior could be positively or negatively regulated by nitric oxide, accordingly to iNOS and eNOS expression in endothelial cells, macrophages, stromal fibroblasts and cancer cells<sup>[21]</sup>. In an attempt to explain the observed

**Figure 3 Histopathology and immunohistochemistry of PANC-1 xenografted mice.** Formalin fixed paraffin embedded tissue sections of control mice were stained with HE. A: Metastatic lymph node ( $\times 400$ ); B: Xenografts ( $\times 630$ ). Immunohistochemistry in control and AG treated mice. Tissue sections were stained with DAB and counterstained with hematoxylin; C: Formalin fixed paraffin embedded tissue sections of control mice were stained with trichromic solution ( $\times 400$ ); D, G: Ki-67 ( $\times 630$ ); E, H: Tunel ( $\times 400$ ); F, I: Bax ( $\times 630$ ); J, M: VEGF ( $\times 630$ ); K, N: eNOS ( $\times 630$ ); L, O: CD34 in control ( $\times 400$ ) and AG treated ( $\times 630$ ) mice. Formalin fixed paraffin embedded tissue sections of control mice were stained with trichrome solution.

*in vivo* antitumor action of AG, multiple *ex vivo* experiments were performed.

Tissues, both normal or abnormal, grow mostly by increasing the number of cells. In turn, the cell number

of a given population is regulated by the balance between proliferation and death<sup>[22]</sup>. Altered indices of proliferation and/or apoptosis could explain the diminished tumor growth observed in AG treated mice xenografts. The

proliferation index, assessed by Ki-67 and PCNA expression, indicated that AG was antiproliferative in PANC-1 xenografts. Moreover, the apoptotic pathway state (evaluated by Bcl-2/Bax expression ratio) and apoptotic death (assayed by the TUNEL assay) revealed an antiapoptotic action of AG in pancreatic tumors. It has been hypothesized that Bcl-2 binds proapoptotic Bax to counteract its effects. Thus, the relative expression of Bcl-2 and Bax are involved in the regulation of the cell death program. In this sense, AG treatment enhanced the Bcl-2/Bax ratio while diminishing the rate of apoptosis. Therefore, AG did not lead to increased tumor cells apoptosis, but caused them not to proliferate.

Many articles support the proapoptotic action of NO associated with iNOS induction and high NO levels<sup>[5]</sup>, while others report a positive association between iNOS induction and tumor cell growth<sup>[11,23]</sup>. In a recent report<sup>[24]</sup>, the *in vivo* and *in vitro* inhibition of hepatocellular carcinoma growth by AG was associated with a proapoptotic effect of this drug. The cross-talk between NO and RAS/ERK and IKK/NF- $\kappa$ B pathways was determined to be crucial to this action. Conversely, our data show that the inhibition of PANC-1 xenografts' growth induced by AG is coupled to an antiapoptotic effect. It is well known that NO levels are quite different depending on the NOS isoform (eNOS or iNOS) involved in NO production. Although different NO concentrations regulate pathways related to either survival or cell death, the final effect on cell fate also depends on such factors as cell type, signaling pathways involved, genetic background and NO concentration in the microenvironment. Our *in vitro* experiments using PANC-1 cell line showed that the NO scavenger 2-phenyl-4,4,5,5-tetramethylimidazole-1-oxyl-3-oxide (PTIO) prevents cell proliferation (unpublished results). We have also demonstrated that activated ERK 1/2 down-modulation is related to the *in vitro* inhibition of the proliferation of PANC-1 cells<sup>[25]</sup>. Thus, even though a direct action of the low levels of NO produced by eNOS on this signal transduction pathway was not assessed in our work, it cannot be ruled out.

Another potential contribution to *in vivo* tumor growth might be determined by interactions with stroma. Fibroblasts and inflammatory cells express iNOS and NO is related to cytokines and growth factors secretion. The iNOS inhibition in stromal cells by AG treatment might modulate neoplastic cells' survival and death<sup>[26,27]</sup>. In addition, vascularity modulation is also involved in tumor growth. Locally, new blood vessel formation is essential for supplying oxygen and other nutrients to tumor cells and is one of the altered manifestations that dictate metastatic tumor growth. It is well known that the VEGF-mediated angiogenesis requires NO production *via* eNOS in endothelial cells. Growing evidence supports the hypothesis that reciprocal relations between NO and VEGF might contribute to drive angiogenesis in pathophysiological conditions, depending on the amount of produced NO<sup>[28]</sup>. Our results showed that AG reduced tumor vascularization and VEGF and eNOS expression in PANC-1 grafts. Small amounts of NO synthesized by eNOS are required for VEGF up-

regulation<sup>[28]</sup>. The low level of NO produced by the AG-inhibited eNOS enzyme might induce the down-modulation of VEGF. In turn, VEGF down-regulation might hinder eNOS up-regulation, consistent with the reduced eNOS expression detected in PANC-1 grafts. Therefore, the antiangiogenic action of AG could account for the reduced tumor growth rate, the lower rate of metastasis and the delay in its appearance.

Lastly, the expression of CuZnSOD, MnSOD and catalase antioxidant enzymes was diminished by AG. The same effect on these enzymes was observed in diabetic rats<sup>[29]</sup> and on superoxide dismutases in doxorubicin treated rats<sup>[30]</sup>. GPx activity was slightly decreased after AG treatment in a model of liver injury in rat<sup>[31]</sup>. Chronic treatment with AG might cause a disruption of the cellular redox balance due to its capacity to scavenge oxidant reactive species<sup>[32]</sup> and to inhibit NO synthesis. This could explain the reduced expression of antioxidant enzymes as a compensatory mechanism. Accordingly, our preliminary *in vitro* experiments in PANC-1 cells showed that hydrogen peroxide and NO intracellular levels were modified by AG, while cell proliferation was reduced. Cell cycle progression is modified by cellular redox status and the magnitude of its imbalance might lead to cell proliferation, differentiation, growth arrest, apoptosis or necrosis<sup>[33]</sup>. Different cell lines require the pro-oxidant status to persist beyond the G1-S restriction point in the cell cycle<sup>[34,35]</sup>. The AG driven impaired production of NO could hinder that oxidant level and, in turn, could prevent proliferation.

In conclusion, aminoguanidine, by exerting an antiapoptotic effect, shows an antitumoral action evidenced by a lower tumor volume at the end of treatment, a delayed appearance of palpable metastases and an extended life span. The antiproliferative action is associated with a lower intratumoral Ki-67 content, an antiangiogenic effect, a reduced NO production and reduced expression of antioxidant enzymes.

## COMMENTS

### Background

Pancreatic cancer is a devastating disease because of its high mortality rate. Chemotherapy alone or combined with radiotherapy are poor attempts to overcome the illness. In cancer, the free radical nitric oxide exhibits both a cytotoxic and a cytoprotective effect according to its concentration within the tumor microenvironment. Although the *in vitro* action of nitric oxide synthase inhibitors (such as aminoguanidine) has been extensively studied in tumor cells, little research has been undertaken as regards their *in vivo* effects on cancer growth.

### Research frontiers

Nitric oxide synthases catalyze the production of nitric oxide (NO), which, depending on its concentration, could act both as tumor promoter or suppressor. Compounds that modify expression and/or activity of these enzymes may be considered useful tools in cancer research.

### Innovations and breakthroughs

The nitric oxide synthase (NOS) inhibitor aminoguanidine, by exerting an antiapoptotic effect, shows an antitumoral action evidenced by a lower tumor volume at the end of treatment, a delayed appearance of palpable metastases and an extended life span. The antiproliferative action is associated with a lower expression of endothelial NOS (eNOS) and antioxidant enzymes.

### Applications

Chemoresistance is still the major problem of anticancer drug treatment of malignant diseases such as pancreatic carcinoma. Aminoguanidine could

provide an attractive line of investigation as a multi-modal avenue due to its different effects on tumor biology.

### Terminology

Nitric oxide is synthesized by a group of enzymes: the nitric oxide synthases. At least three isoforms have been described: eNOS, neuronal NOS (nNOS) and inducible NOS (iNOS). Most cancer cells express these enzymes and the NO produced is involved in biological processes associated with both survival and cell death.

### Peer review

In this work, the authors have studied the action of the nitric oxide synthase inhibitor aminoguanidine (AG) in PANC-1 cells xenografts in relation to cell proliferation, apoptosis, angiogenesis and redox status. Interestingly, authors indicate that AG has strong effects on tumor progression, through inhibiting growth, apoptosis, vascularization and metastasis. This study will be of great interest to the carcinogenesis field, particularly in the design of new therapeutic drugs for pancreatic cancer.

### Abstract

**AIM:** To investigate the inhibitory effects of RNA interference (RNAi) on expression of *matrix metalloproteinase-2* (MMP-2) gene and invasiveness and adhesion of human pancreatic cancer cell line, BxPC-3.

**METHODS:** RNAi was performed using the vector (pGPU6)-based small interference RNA (siRNA) plasmid gene silence system to specifically knock down MMP-2 expression in pancreatic cancer cell line, BxPC-3. Four groups of different specific target sequence in coding region of MMP-2 and one non-specific sequence were chosen to construct four experimental siRNA plasmids of pGPU6-1, pGPU6-2, pGPU6-3 and pGPU6-4, and one negative control siRNA plasmid of pGPU6 (-). MMP-2 expression was measured by reverse transcription polymerase chain reaction (RT-PCR) and Western blot. Cell proliferation and apoptosis were examined by methyl thiazolyl tetrazolium (MTT) and flow cytometry, respectively. The abilities of adhesion and invasion were detected by cell adhesion assay and cell invasion assay using Transwell chambers.

**RESULTS:** The expression of MMP-2 was inhibited and the inhibitory effects of different sequence varied. pGPU6-1 group had the most efficient inhibitory effect, followed by pGPU6-2 and pGPU6-3 groups.

Invasiveness and adhesion were more significantly reduced in pGPU6-1, pGPU6-2 and pGPU6-3 groups as compared with pGPU6 (-) and blank control groups. However, no difference concerning cell proliferation and apoptosis was observed after transfection between experiment groups and control groups.

**CONCLUSION:** RNAi against MMP-2 successfully inhibited the mRNA and protein expression of MMP-2 in the pancreatic cancer cell line, BxPC-3, leading to a potent suppression of tumor cell adhesion and invasion without affecting cell proliferation and apoptosis. These findings suggest that the RNAi approach towards MMP-2 may be an effective therapeutic strategy for the clinical management of pancreatic tumor.

Suppression of matrix metalloproteinase-2 *via* RNA interference inhibits pancreatic carcinoma cell invasiveness and adhesion. *World J Gastroenterol* 2009; 15(9): 1072-1078 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1072.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1072>

### INTRODUCTION

Pancreatic cancer is one of the most aggressive common tumors, most patients die within months as a result of rapid local spread of the tumor or metastatic dissemination<sup>[1]</sup>. The very poor prognosis may in part be attributed to the high invasive potential of this malignancy, and the invasion or metastasis of pancreatic cancer has been known to be a complex process involving many molecular mechanisms, of which proteolytic degradation of extracellular matrix (ECM) exerted by matrix metalloproteinases (MMPs) was

considered to be an essential step<sup>[2]</sup>. Some data suggest that MMP-2 is involved in pancreatic cancer invasion and metastasis, and a high level of MMP-2 has been found to correlate with poor prognosis in patients with pancreatic cancer<sup>[3]</sup>. Therefore, inhibition of MMP-2 may be of great value in both preventing pancreatic cancer and blocking metastasis of established tumors.

RNA interference (RNAi) is a conserved biologic response to double-stranded RNA that results in the sequence-specific silencing of target gene expression. As a kind of highly efficient, specific and relatively stable tool, RNAi technology has already been used to silence specific target gene expression<sup>[4]</sup>.

In this report, we used a vector-based MMP-2 siRNA expression system to suppress the expression of MMP-2 in pancreatic cancer cell line BxPC-3 and to evaluate its efficacy in the adhesion and invasion of pancreatic cancer cell. We found that specific down-regulation of MMP-2 by RNAi successfully inhibited the mRNA and protein expression of MMP-2, leading to significant inhibition of adhesion and invasion of pancreatic cancer cells without affecting cell proliferation and apoptosis. Thus, RNAi towards MMP-2 may be an effective therapeutic strategy for the treatment of patients with pancreatic cancer.

## MATERIALS AND METHODS

### Cell culture

Human pancreatic cancer cell line BxPC-3, obtained from Shanghai Institute of Biochemistry and Cell Biology, were maintained in Dulbecco Modified Eagle Medium (DMEM) containing 10% fetal calf serum (FCS; Hyclone Co., Ltd.) and were incubated in a humidified (37°C, 5% CO<sub>2</sub>) incubator, grown in 75-cm<sup>2</sup> culture flasks and passaged upon reaching 80% confluence.

### Construction of siRNA plasmids expression vector against MMP-2

We used the pGPU6 siRNA plasmid vector-based gene silence system to produce stable transfection, plasmid vector pGPU6 was purchased from Shanghai GenePharma Co., Ltd. Aiming at the sequence of MMP-2, four DNA chains with the following sense and antisense sequences were synthesized: no. 1, 5'-GGA GAGCTGCAACCTGTTTGT-3' (sense) and 5'-ACA AACAGGTTGCAGCTCTCC-3' (antisense); MMP-2 siRNA no. 2, 5'-GCTCCACCACCTACAACCTTTG-3' (sense) and 5'-CAAAGTTGTAGGTGGTGGAGC-3' (antisense); MMP-2 siRNA no. 3, 5'-GCAAACAGGA CATTGTATTG-3' (sense) and 5'-CAAATACAAT GTCTGTTTGC-3' (antisense); MMP-2 siRNA no. 4, 5'-GGAGATACAATGAGGTGAAGA-3' (sense) and 5'-TCITCACCTCATTGTATCTCC-3' (antisense). The target sequence of negative control group which is named pGPU6 (-) is 5'-GTCTCCGAACGTGTCACG T-3' (sense) and 5'-ACGTGACACGTTCCGAGAAT-3' (antisense), which has no homology with that of human beings or mice. The cancer cells without any plasmid were defined as blank control group. All DNA chains

were designed and synthesized by Shanghai GenePharma Co., Ltd., Shanghai, China. We contrived the structure of the DNA chains to be *Bam*HI + sense chain + loop + antisense chain + termination signal + *Eco*RI + *Hind*III. The four DNA chains were annealed and ligated into (*Bam*HI/*Eco*RI) sites of pGPU6 to generate the plasmid pGPU6/ MMP-2. The negative control plasmid pGPU6 (-) was constructed using the same procedure. As a result, four experimental groups of plasmids pGPU6-1, pGPU6-2, pGPU6-3, pGPU6-4, and negative control group plasmid pGPU6 (-) were generated. The plasmids were extracted and the accuracy of the constructs was confirmed by sequencing.

### Transfection of siRNA

BxPC-3 cells were seeded in a 24-well culture plate and divided into blank control group, pGPU6 (-) group and positive experimental groups (pGPU6-1, pGPU6-2, pGPU6-3 pGPU6-4). Each group contained 3 culture wells.  $2 \times 10^5$  cells were plated into each culture well 24 h before transfection, and cultured in a humidified (37°C, 5% CO<sub>2</sub>) incubator. BxPC-3 cells were stably transfected with pGPU6-1, pGPU6-2, pGPU6-3, pGPU6-4, or pGPU6 (-) in the presence of Lipofectamine 2000 (Invitrogen Co., Ltd.) following the manufacturer's instructions. No plasmid was introduced in the blank control plates; only Lipofectamine 2000 was used for the transfection in the blank control group. The cells were transfected with plasmid DNA (2 µg) and transfection reagent (4 µL) at a DNA: reagent ratio of 1:2, and then incubated at 37°C in a CO<sub>2</sub> incubator for 24 h prior to testing for gene expression.

### Expression of MMP-2 mRNA detected by reverse transcription polymerase chain reaction (RT-PCR)

Twenty-four hours after the transfection,  $5 \times 10^5$  cells were collected and total RNA was extracted using the Trizol reagent (Invitrogen Co., Ltd.) following the manufacturer's instructions. The concentration and purity of the total RNA were detected with ultraviolet spectrophotometer. Gluteraldehyde-3-phosphate dehydrogenase (GAPDH) was used as internal control. The primer sequences for the genes and expected product sizes were as follows: 5'-TG ATCTTGACCAGAATACCA-3' (sense), 5'-TGCCATAC TTCTGTGTCGCGGT-3' (antisense) for MMP-2 (731 bp), 5'-CCATGGAGAAGGCCGGGG-3' (sense), 5'-CAAA GTTGTCATGGATGACC-3' (antisense) for GAPDH (200 bp). The RT reaction was performed at 25°C for 10 min, then 37°C for 60 min. PCR amplification was performed under the following reaction conditions: 94°C for 30 s, 55°C (MMP-2) or 53°C (GAPDH) for 30 s, 72°C for 1 min, and a final extension at 72°C for 7 min. The amplification used 28 cycles for MMP-2, and 26 cycles for GAPDH. PCR products were analyzed by electrophoresis on 1% agarose gel and were visualized by ethidium bromide staining under ultraviolet light. The expression intensity of MMP-2 was denoted with the ratio of the photodensity of the RT-PCR products of MMP-2 to GAPDH. The inhibition ratio of MMP-2 expression was calculated with the following formula: inhibition ratio of MMP-2 expression = (1-the expression

intensity of MMP-2 in the experiment group/the expression intensity of MMP-2 in the blank or negative control group)  $\times 100\%$ .

### Cell lysis and Western blotting

Cells were collected 24 h after transfection, washed twice with phosphate buffered solution (PBS), and the supernatant was scraped off. Cell pellets were then lysed in iced bath for 30 min. The lysates were transferred to new tubes and centrifuged at 12000 r/min for 30 min at 4°C. Proteins were separated by 8% sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis and transferred to a hybond enhanced chemiluminescence (ECL) nitrocellulose membrane (Amersham Pharmacia Biotech, Germany). The membranes were blocked for 1 h in 3% bovine serum albumin (BSA) in PBS and then incubated with monoclonal antibodies recognizing MMP-2 or actin (Santa Cruz, USA). Second antibody incubations were carried out using peroxidase-conjugated goat anti-rabbit antibody, and reactive bands were detected by chemiluminescence. The expression levels of MMP-2 and actin protein were quantified by densitometry. The signal strength of each MMP-2 signal was normalized against the corresponding actin control. The inhibition ratio of MMP-2 expression was calculated with the following formula: inhibition ratio of MMP-2 expression = (1-the relative intensity of MMP-2 expression in the experiment group/the relative intensity of MMP-2 in the blank or negative control group)  $\times 100\%$ .

### Methyl thiazolyl tetrazolium (MTT) assay

Cell proliferation was assessed by using the MTT assay. Cells were collected 24 h after transfection, pancreatic cancer cells were plated at  $1 \times 10^4$  cells/well in 96-well plates in DMEM containing 10% FBS. Five duplicate wells were set up for each group. Blank control cells served as control. After 24, 48 and 72 h of incubation, 200  $\mu$ L of 5 mg/ $\mu$ L MTT solution (Sigma Co., Ltd.) in PBS was added to each well for 4 h. Absorbance of each well was measured on a microplate reader at a wave length of 492 nm.

### Flow cytometry

Flow cytometry was used to estimate the apoptosis. The harvested cells were washed with PBS, fixed with cold 75% ethanol at -20°C for 24 h, treated with 0.1 mL RNase A (Sigma Co., Ltd.) and then stained with propidium iodide (Sigma Co., Ltd.). Finally, cell cycle analysis was carried out using flow cytometer.

### Adhesion assay

Cells were collected 24 h after transfection. The cancer cells were trypsinized and seeded at  $1 \times 10^4$  cells/well in 96-well plates. Five duplicate wells were set up for each group. The cells were cultured for 60 min, and washed twice with PBS to remove the cells not adherent. The MTT assay as above was performed to assess A value of the adhesive cells. The inhibition ratio was calculated with the following formula: inhibition ratio = (1-A value of the experiment group/A value of the control group)  $\times 100\%$ .

**Table 1 Down-regulation of MMP-2 mRNA expression detected by RT-PCR**

Groups	Ratio of MMP-2 to GAPDH
Blank control	0.93 $\pm$ 0.02
pGPU6 (-)	0.91 $\pm$ 0.03
pGPU6-1	0.29 $\pm$ 0.02 <sup>b,d</sup>
pGPU6-2	0.33 $\pm$ 0.04 <sup>b,d</sup>
pGPU6-3	0.45 $\pm$ 0.03 <sup>b,d</sup>
pGPU6-4	0.88 $\pm$ 0.03 <sup>a,c</sup>

<sup>a</sup> $P > 0.05$  vs blank control,  $P = 0.057$ ; <sup>b</sup> $P < 0.05$  vs blank control; <sup>c</sup> $P > 0.05$  vs pGPU6 (-),  $P = 0.288$ ; <sup>d</sup> $P < 0.05$  vs pGPU6 (-).

### Cell invasion assay

Cell invasion assay was performed using Transwell chambers (Corning Co., Ltd.). After 24 h transfection,  $5 \times 10^5$  cells were suspended in 100  $\mu$ L serum-free medium and placed into the upper compartment of the Transwell chambers. The lower compartment of the chambers was filled with 200  $\mu$ L serum-containing medium and the cells were allowed to migrate for 24 h. After a 24-h incubation, cells on the lower surface of the filter were fixed in cold ethanol and stained with 0.5% crystal violet (CV) for 30 min, and 5 random fields were counted at 200  $\times$  magnification. Data represent the average cells of 5 fields were compared between the experimental groups and control group.

### Statistical analysis

All results were expressed as mean  $\pm$  SD. All statistical analyses were performed using one-way ANOVA.  $P < 0.05$  was considered significant.

## RESULTS

### Suppression of MMP-2 mRNA in human pancreatic cell by siRNA

Four MMP-2 siRNA-expressing plasmids (pGPU6-1, pGPU6-2, pGPU6-3 and pGPU6-4) and one negative plasmid pGPU6 (-) were constructed using the pGPU6 vectors. Twenty-four hours after the transfection, we observed significant inhibition of MMP-2 mRNA expression in the experimental groups (pGPU6-1, pGPU6-2 and pGPU6-3) compared with blank control and pGPU6 (-) group ( $P < 0.05$ ) whereas the slight inhibition was observed in pGPU6-4 cells ( $P > 0.05$ ) (Table 1). The inhibition ratio was 75.3% (pGPU6-1), 64.5% (pGPU6-2), 51.6% (pGPU6-3) with respect to blank control and 74.7% (pGPU6-1), 63.7% (pGPU6-2), 50.5% (pGPU6-3) compared to pGPU6 (-). The transfection with pGPU6 (-) had no significant inhibitory effect on the expression of MMP-2 mRNA compared to the blank group ( $P > 0.05$ ) (Figure 1).

### Significant down-regulation of MMP-2 protein expression by siRNA

The levels of MMP-2 protein in the total cell lysates were assessed by Western blot. Western blot analyses using the anti-MMP-2 antibody revealed significant

**Table 2** Down-regulation of MMP-2 protein expression detected by Western blot

Groups	Relative density
Blank control	0.86 ± 0.03
pGPU6 (-)	0.82 ± 0.02
pGPU6-1	0.18 ± 0.02 <sup>b,d</sup>
pGPU6-2	0.31 ± 0.04 <sup>b,d</sup>
pGPU6-3	0.41 ± 0.02 <sup>b,d</sup>
pGPU6-4	0.82 ± 0.03 <sup>a,c</sup>

<sup>a</sup> $P > 0.05$  vs blank control,  $P = 0.102$ ; <sup>b</sup> $P < 0.05$  vs blank control; <sup>c</sup> $P > 0.05$  vs pGPU6 (-),  $P = 0.885$ ; <sup>d</sup> $P < 0.05$  vs pGPU6 (-).

**Table 3** Effects of MMP-2 siRNA on tumor cell adhesion

Groups	A value
Blank control	0.35 ± 0.03
pGPU6 (-)	0.34 ± 0.04
pGPU6-1	0.13 ± 0.02 <sup>b,d</sup>
pGPU6-2	0.20 ± 0.01 <sup>b,d</sup>
pGPU6-3	0.26 ± 0.01 <sup>b,d</sup>
pGPU6-4	0.33 ± 0.02 <sup>a,c</sup>

<sup>a</sup> $P > 0.05$  vs blank control,  $P = 0.119$ ; <sup>b</sup> $P < 0.05$  vs blank control; <sup>c</sup> $P > 0.05$  vs pGPU6 (-),  $P = 0.274$ ; <sup>d</sup> $P < 0.05$  vs pGPU6 (-).

decreases in MMP-2 expression after transfection with siRNA in positive experimental groups (pGPU6-1, 2, 3) compared with blank control and pGPU6 (-) group ( $P < 0.05$ ). However, no change in MMP-2 expression was observed after transfection with siRNA in pGPU6-4 and pGPU6 (-) groups when compared with the blank control ( $P > 0.05$ ) (Table 2). Quantitative analysis of MMP-2 protein by densitometry revealed a decrease in protein expression with pGPU6-1 by 79.1%, pGPU6-2 by 64%, pGPU6-3 by 52.3% compared with blank control group and pGPU6-1 by 78%, pGPU6-2 by 62.2% and pGPU6-3 by 50.5% compared with pGPU6 (-) group (Figure 2).

#### Effects of MMP-2 siRNA on tumor cell proliferation

To address whether siRNA directed against MMP-2 has an inhibitory effect on pancreatic cancer cell proliferation, cell proliferation was assessed using the MTT assay. We found that treatment of pancreatic cancer with MMP-2 siRNA did not cause any significant inhibitory effect in tumor cell proliferation. And the pGPU6 (-) group did not significantly decrease tumor cell proliferation compared with blank control group ( $P > 0.05$ ) (Figure 3).

#### Effects of MMP-2 siRNA on tumor cell apoptosis

The effects of MMP-2 siRNA molecules on the induction of apoptosis in pancreatic cancer cells were inspected by flow cytometry. However, no discrepancy was observed after transfection with siRNA in positive experimental groups (pGPU6-1, 2, 3, 4) compared with blank control and pGPU6 (-) group ( $P > 0.05$ ). Besides, the pGPU6 (-) group did not significantly increase cell apoptosis compared with blank control group ( $P > 0.05$ ) (Figure 4).

**Figure 1** Down-regulation of MMP-2 mRNA expression detected by RT-PCR. Lane 1: Blank control; Lane 2: pGPU6 (-); Lane 3: pGPU6-1; Lane 4: pGPU6-2; Lane 5: pGPU6-3; Lane 6: pGPU6-4.**Figure 2** Down-regulation of MMP-2 protein expression detected by Western blot. Lane 1: Blank control; Lane 2: pGPU6 (-); Lane 3: pGPU6-1; Lane 4: pGPU6-2; Lane 5: pGPU6-3; Lane 6: pGPU6-4.**Figure 3** Effects of MMP-2 siRNA on tumor cell proliferation.

#### Effects of MMP-2 siRNA on tumor cell adhesion

Cell adhesion assay revealed significant decreases in cancer cell adhesion after transfection with siRNA in experimental groups (pGPU6-1, 2, 3) compared with blank control and pGPU6 (-) group ( $P < 0.05$ ). However, no change was observed after transfection with siRNA in pGPU6-4 and pGPU6 (-) groups when compared with the blank control ( $P > 0.05$ ) (Table 3). The inhibition ratio were 63.1% (pGPU6-1), 42.9% (pGPU6-2) and 25.6% (pGPU6-3) compared with the blank control, and 62.2% (pGPU6-1), 41.6% (pGPU6-2) and 23.9% (pGPU6-3) compared with pGPU6 (-) group.

#### Effects of MMP-2 siRNA on tumor cell invasion

Cell invasion was assessed using Transwell chambers. As shown in Table 4, for each 200 × field under microscope, the average migrated cell number of 5 fields of experimental groups (pGPU6-1, 2, 3) were observed to be significantly lower than the number of blank control and the pGPU6 (-) groups ( $P < 0.05$ ), which was not found in the pGPU6-4 group. In addition, there was

Figure 4 Effects of MMP-2 siRNA on tumor cell apoptosis. A: pGPU6-1; B: pGPU6-2; C: pGPU6-3; D: pGPU6-4; E: pGPU6 (-); F: Blank control.

Table 4 Effects of MMP-2 siRNA on tumor cell invasion

Groups	Invasive cell number
Blank control	180 ± 12
pGPU6 (-)	176 ± 8
pGPU6-1	42 ± 7 <sup>b,d</sup>
pGPU6-2	49 ± 9 <sup>b,d</sup>
pGPU6-3	58 ± 6 <sup>b,d</sup>
pGPU6-4	171 ± 10 <sup>a,c</sup>

<sup>a</sup> $P > 0.05$  vs blank control,  $P = 0.090$ ; <sup>b</sup> $P < 0.05$  vs blank control; <sup>c</sup> $P > 0.05$  vs pGPU6 (-),  $P = 0.328$ ; <sup>d</sup> $P < 0.05$  vs pGPU6 (-).

little difference between blank control and the pGPU6 (-) groups ( $P > 0.05$ ) (Figure 5).

## DISCUSSION

MMPs are a group of enzymes, which degrade the macromolecules of connective tissue, ECM and basement membrane. These enzymes are believed to play important roles in tumor metastasis, invasion and angiogenesis<sup>[5-7]</sup>. As a subgroup of MMPs, MMP-2 seems to play an important role in the progression of pancreatic cancer. Bramhall *et al*<sup>[8]</sup> found MMP-2 messenger RNA was the most commonly expressed MMP in pancreatic tumor specimens (93%), but was not seen in normal pancreas. Apparently, MMPs, particularly MMP-2 play an important role in the pathogenesis of pancreatic cancer. Consequently, a tumor therapy targeting MMP-2 would be particularly efficacious in the

treatment of pancreatic cancer. As a very potent tool, RNAi technology can generate a cellular knockdown of a desired gene utilizing a plasmid-based system that stably expresses siRNA molecules to target specific mRNAs for degradation<sup>[9,10]</sup>. In this study, we developed a siRNA sequence, when stably integrated into cellular DNA, which can selectively target MMP-2 expression. Our study demonstrated that RNAi against MMP-2 successfully inhibited the mRNA and protein expression of MMP-2 in the pancreatic cancer cell line BxPC-3. In contrast, MMP-2 expression was unchanged in the control groups. By using a stably integrating plasmid to express our siRNA molecule, we obtained at the most a 75% mRNA reduction and a 79% protein reduction in MMP-2 expression. Some studies are similar to our findings, which also draw a conclusion that MMP-2 mRNA and protein levels can be significantly inhibited by RNAi in solid tumors<sup>[11,12]</sup>.

On the basis of significant inhibitory effects of MMP-2 mRNA and protein, we investigated the effects of MMP-2 siRNA on tumor adhesion and invasion. We found that the MMP-2 siRNA not only suppressed the adhesion of the cancer cell, but also their ability to migrate and invade. Similar to our findings, Sun *et al*<sup>[13]</sup> also found that MMP-2 silencing by RNAi could inhibit invasion and growth of laryngeal cancer, and MMP-2 might be a potential target for gene therapy in laryngeal cancer. Moreover, a study *in vivo* showed that tumors implanted in MMP-2-deficient mice had decreased invasive properties, which further suggest that MMP-2 is important for pancreatic cancer invasion<sup>[14]</sup>.

**Figure 5** Cell invasion observed by CV stained ( $\times 200$ ). A: Blank control; B: pGPU6-1; C: pGPU6 (-); D: pGPU6-2; E: pGPU6-4; F: pGPU6-3.

The mechanism of MMP-2 involvement in the tumor invasion and metastasis is complex, some studies suggest that MMP-2 is associated with the degradation of type IV collagen which is the main component of basement membranes. Furthermore, Kim *et al.*<sup>[15]</sup> found that one additional mechanism by which MMP-2 was proposed to increase the local invasiveness was to facilitate angiogenesis. Interestingly, we got the suppressing effects of tumor cell adhesion and invasion by RNAi targeting the MMP-2 gene, but we did not find any significant change in tumor cell proliferation and apoptosis between the experimental groups and the control group. Some studies support our data showing that down-regulation of MMP-2 can inhibit cell invasion without affecting cell proliferation<sup>[16,17]</sup>. Based on these findings, we hypothesize that the ability of the pancreatic tumor cell adhesion and migration, but not the quantity of tumor cell proliferation, is the crucial factor for MMP-2 involved in pancreatic tumor cell invasion and metastasis. Some findings agreed with our hypothesis, which also observed a decrease in pancreatic cancer cell invasion through a reconstituted matrix in a dose dependent fashion without affecting cell proliferation *in vitro*<sup>[18,19]</sup>. Matrix metalloproteinases are enzymes responsible for extracellular matrix degradation, a critical component influencing metastatic potential of cancer. When endothelial cell MMP-2 gene is silenced, cell growth cycle will change correspondingly, which will be blocked in G1 stage. This may explain why MMP-2 gene affects only the ability of pancreatic cancer cells to modify the extracellular matrix to facilitate invasion and growth without affecting cell proliferation.

At time of diagnosis, 75%-85% of patients with pancreatic cancer can not accept resectable operation and conventional therapies which virtually are ineffective<sup>[20]</sup>. Therefore, there is clearly a need for new approaches to the treatment of this cancer. The over-

expression of MMP-2 in pancreatic tumor is a mark of poor prognosis with respect to disease progression as well as survival<sup>[21]</sup>. Our data has provided evidence that RNAi against MMP-2 successfully inhibited the mRNA and protein expression of MMP-2 in the pancreatic cancer cell line BxPC-3, leading to a potent suppression of tumor cell adhesion and invasion without affecting cell proliferation and apoptosis. These findings suggest that the RNAi approach towards MMP-2 may be an effective therapeutic strategy for the clinical management of pancreatic tumor. Although the leap to clinical practice remains elusive, gene therapy targeting MMP-2 is attractive and warrants further investigations.

## COMMENTS

### Background

Pancreatic carcinoma is an aggressive malignancy with an extremely poor prognosis. Most patients with pancreatic carcinoma have extremely poor prognosis, and the reason may in part be attributed to the high invasive potential of this malignancy leading to early metastasis. However, either invasion or metastasis of pancreatic carcinoma has been known to be a complex process involving molecular mechanisms. Activation of matrix metalloproteinase-2 (MMP-2) has been implicated in the progression, invasion, and metastasis of various cancers, but little information is available with regard to its role in pancreatic carcinoma with poor prognosis.

### Research frontiers

MMP-2 has an activity to degrade type IV collagen and is associated with invasion angiogenesis of malignant tumors. It seems that MMP-2 plays an important role in the progression of pancreatic carcinoma. In the area of pancreatic carcinoma gene therapy, one of the research hotspots is how to down-regulate MMP-2. As a kind of highly efficient, specific and relatively stable tool, RNA interference technology has already been used to silence specific target gene expression. Thus, RNA interference towards MMP-2 may be an effective therapeutic strategy for the treatment of patients with pancreatic cancer.

### Innovations and breakthroughs

A gene silencing system using the vector (pGPU6)-based small interference RNA (siRNA) plasmid has been established to specifically knock down MMP-2 expression in pancreatic cancer cells. MMP-2 expression was measured by

reverse transcription polymerase chain reaction (RT-PCR) and Western blot. Cell proliferation and apoptosis were examined by MTT and flow cytometry, respectively. The abilities of adhesion and invasion were detected by cell adhesion assay and cell invasion assay using Transwell chambers. RNA interference against MMP-2 successfully inhibited the mRNA and protein expression of MMP-2 in the pancreatic cancer cell line, BxPC-3, leading to a potent suppression of tumor cell adhesion and invasion without affecting cell proliferation and apoptosis.

### Applications

RNA interference towards MMP-2 may be an effective therapeutic strategy for the clinical management of pancreatic tumors. Although the leap to clinical practice remains elusive, gene therapy targeting MMP-2 is attractive and warrants further investigations.

### Terminology

The MMPs are a family of zinc-dependent endopeptidases. Their primary function is degradation of proteins in the extracellular matrix. RNA interference is a process of post-transcriptional gene silencing in which double-stranded RNA inhibits gene expression in a sequence dependent manner via degradation of the corresponding mRNA.

### Peer review

This is an interesting study. The invasiveness is usually related to cell growth. The manuscript is well written, but it needs explanation of the discrepancy in the study.

### Abstract

**AIM:** To investigate the impact of arachidonic acid (AA) and docosahexaenoic acid (DHA) and their combination on colon cancer cell growth.

**METHODS:** The LS-174T colon cancer cell line was used to study the role of the prostaglandin precursor AA and the omega-3 polyunsaturated fatty acid DHA on cell growth. Cell viability was assessed in XTT assays. For analysis of cell cycle and cell death, flow cytometry and DAPI staining were applied. Expression of cyclooxygenase-2 (COX-2), p21 and bcl-2 in cells incubated with AA or DHA was examined by real-time RT-PCR. Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) generation in the presence of AA and DHA was measured using a PGE<sub>2</sub>-ELISA.

**RESULTS:** AA increased cell growth, whereas DHA

reduced viability of LS 174T cells in a time- and dose-dependent manner. Furthermore, DHA down-regulated mRNA of bcl-2 and up-regulated p21. Interestingly, DHA was able to suppress AA-induced cell proliferation and significantly lowered AA-derived PGE<sub>2</sub> formation. DHA also down-regulated COX-2 expression. In addition to the effect on PGE<sub>2</sub> formation, DHA directly reduced PGE<sub>2</sub>-induced cell proliferation in a dose-dependent manner.

**CONCLUSION:** These results suggest that DHA can inhibit the pro-proliferative effect of abundant AA or PGE<sub>2</sub>.

Docosahexaenoic acid suppresses arachidonic acid-induced proliferation of LS-174T human colon carcinoma cells. *World J Gastroenterol* 2009; 15(9): 1079-1084 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1079.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1079>

### INTRODUCTION

Colon cancer is one of the leading causes of death in Western countries<sup>[1]</sup>. Increased levels of cyclooxygenase-2 (COX-2) were detected in 50% of colorectal adenomas and in up to 85% of colorectal cancers<sup>[2-4]</sup>. Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) is generated from the omega-6 polyunsaturated fatty acid (n-6 PUFA) arachidonic acid (AA) *via* action of the COX-1 and -2. Several studies have established PGE<sub>2</sub> as an important factor for proliferation of colon cancer cells *in vitro*<sup>[5-7]</sup>.

Regular Western diets are highly abundant in n-6 PUFAs<sup>[8]</sup>. Since AA is the precursor of PGE<sub>2</sub>, this may contribute to the high prevalence of colon cancer in the Western world<sup>[9]</sup>. In contrast, diets rich in omega-3 polyunsaturated fatty acids (n-3 PUFAs) such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), which are mainly found in fish oil, might reduce the risk of colon cancer development, and an inverse association of consumption of fish and colon cancer has been observed epidemiologically<sup>[10-12]</sup>. EPA was found to inhibit colon crypt cell proliferation *in vivo*<sup>[13]</sup>. A recent study has demonstrated an inverse association of the n-6/n-3 ratio with colon adenoma formation<sup>[14]</sup>. In an animal model system with increased amounts of endogenously synthesized n-3 PUFA (the fat-1 mouse), two studies have shown a protective effect against colon tumor development<sup>[15,16]</sup>.

*In vitro* studies in Caco-2 colon cancer cells with the n-3 PUFA DHA have demonstrated growth-inhibitory effects by induction of apoptosis<sup>[17-20]</sup>. Other results have shown that PGE<sub>2</sub> formation and vascular endothelial growth factor expression are suppressed, while apoptosis is induced by DHA and EPA in the HT-29 colon cancer cell line<sup>[21]</sup>. In contrast, several other studies in colon cancer cell lines have demonstrated that AA as well as DHA or EPA suppresses growth<sup>[22,23]</sup>. Other studies have found a pro-apoptotic effect of DHA and AA in HT-29 colon cancer cells<sup>[24,25]</sup> and in the A549 lung cancer cell line<sup>[26]</sup>. These *in vitro* observations have led to uncertainty regarding a differential role of n-3 and n-6 PUFA for growth of tumor cells. Furthermore, they do not address the effect of a changed n-3/n-6 ratio on cell proliferation.

In the present study, we used the LS-174T colon cancer cell line, for which a potent PGE<sub>2</sub>-triggered activation of proliferation has been demonstrated previously<sup>[6,27-29]</sup>, to test the effect of DHA co-incubation with AA or PGE<sub>2</sub> on cell growth, thereby mimicking a change in the ratio of n-3/n-6 fatty acids. We show that DHA suppressed cell growth, while AA increased proliferation, and that DHA co-incubation suppressed AA- and PGE<sub>2</sub>-induced cell growth.

## MATERIALS AND METHODS

### Cell culture

Cells were cultured in a saturated atmosphere of 5% CO<sub>2</sub> and 95% air at 37°C. LS-174T cells were grown in Dulbecco's modified Eagle's medium (Gibco, Carlsbad, CA, USA) without phenol red, which contained 10% heat-inactivated fetal bovine serum (FBS; HyClone, Logan, UT, USA), 2 mmol/L glutamine and 100 U/mL penicillin and 100 µg/mL streptomycin (Gibco, Carlsbad, CA, USA). Medium that contained PUFAs (NuchekPrep, Elysian, MN, USA) or PGE<sub>2</sub> (Caymanchem, Ann Arbor, MI, USA) was prepared with 2% FBS and 1 mg/mL fatty-acid-free bovine serum albumin (BSA). All chemicals used were bought from Sigma (St. Louis, MO, USA) except where stated otherwise.

**Figure 1 Effects of fatty acids on cellular viability.** A: Growth of LS-174T cells during incubation with different concentrations of fatty acids in the medium with 1 mg/mL BSA. Data points represent at least five independent experiments. <sup>a</sup>*P* < 0.05 versus control, <sup>b</sup>*P* < 0.001 versus control. B: Concentration-dependent effect of DHA and AA on growth of LS-174T colon cancer cells after 5 d incubation. Data points represent at least 13 independent experiments. <sup>a</sup>*P* < 0.01 versus control, <sup>b</sup>*P* < 0.001 versus control.

### Cell proliferation assay

Cell viability was determined by XTT (2,3-bis-(2-methoxy-4-nitro-5-sulphophenyl)-2H-tetrazolium-5-carboxanilide) assay according to the manufacturer's protocol (Invitrogen, Carlsbad, CA, USA). Briefly, 2500 LS-174T cells per well were seeded into a 96-well plate. After 24 h, medium was removed and replaced by medium that contained the appropriate concentration of respective PUFAs. In order to avoid unspecific toxic effects of free long-chain fatty acids, the maximum total fatty acid concentration used in the long-term incubation cell viability experiments was 100 µmol/L. Cell proliferation was assessed photometrically in dual wave length measurements at different time points after addition of activated XTT assay solution.

### Flow cytometry assays

For cell cycle analysis  $5 \times 10^5$  cells were plated in 10-cm dishes. After 24 h, medium was removed and replaced by 10 mL medium that contained PUFAs. Cells were harvested for flow cytometry after 72 h. For detection of the sub-G1 DNA fraction, cells were stained with 0.1 mg/mL propidium iodide, which contained 0.5 mg/mL RNase and 0.1% NP40 detergent. Afterwards, cells were analyzed on a FACSCalibur (Becton Dickinson, San Jose, CA,

**Figure 2** Effect of DHA and AA on cell cycle and apoptosis. A: Cell cycle analysis by flow cytometry. Induction of apoptosis is indicated by an increased pre-G1 fraction. Results represent five independent experiments. B: DAPI staining of LS-174T cells incubated with different concentrations of AA and DHA showed a clear increase of apoptotic bodies in cells incubated with DHA. C: RT-PCR demonstrated induction of bcl-2 expression by AA, while DHA suppressed bcl-2 mRNA expression. <sup>a</sup> $P < 0.01$  versus control.  $n = 3$  for each group. D: DHA induced transcription of p21, while AA did not alter p21 mRNA formation. <sup>a</sup> $P < 0.01$  versus control.  $n = 3$  for each group.

USA) flow cytometer.

#### 4',6'-diamidino-2-phenylindole (DAPI) staining

Cells were fixed using 2% paraformaldehyde and permeabilized with 0.1% Triton X 100. Cells were stained with DAPI solution and assessed for cell morphology and apoptotic bodies.

#### Semi-quantitative real-time RT-PCR

Total RNA was isolated from LS-174T cells using the RNeasy mini kit (Qiagen, Valencia, CA, USA), following the manufacturer's instructions. Reverse transcription of mRNA was performed using random primers (Promega, Madison, WI, USA) to generate cDNA. Real-time RT-PCR was carried out using Absolute QPCR SYBR Green Mix (ABgene, Rockford, IL, USA) in an ABI Prism 7000 Sequence detection system (Applied Biosystems, Foster City, CA, USA), following the manufacturer's protocol. Primers were designed with Primer Select 5.00 Software (DNASTAR Inc., Madison, WI, USA). Primer sequences were: COX-2for CGCTCAGCCATACAGCAAATCCTT, COX-2rev AATCCTGTCCGGGTACAATCGCA; p21for GTGGGGGCATCATCAAAACTT, p21rev ACCCCACCTTCCCCCTGCCTTCAC; bcl-2for

CATGCCAAGGGGAAACACCAGAA, bcl-2rev CACGGCCCCAGAGAAAGAAGAGG; GAPDHfor GGTGAAGGTCGGAGTCAAC, GAPDHrev CCATGGGTGGAATCATATTG.

#### PGE<sub>2</sub>-ELISA

For PGE<sub>2</sub> analysis, cells were treated with PUFAs, as described above. The PGE<sub>2</sub>-ELISA was then performed according to the manufacturer's protocol (R&D Systems, Minneapolis, MN, USA).

#### Statistical analysis

All results are presented as mean  $\pm$  SE, except where stated otherwise. Student's *t* test was used to evaluate the difference between two groups. RT-PCR was analyzed by using the  $2\Delta\Delta\text{Ct}$  method. Statistical significance was accepted at the level of  $P < 0.05$ , and Prism 4 for Windows Software (GraphPad, La Jolla, CA, USA) was used for calculations.

## RESULTS

### Opposing effects of AA and n-3 PUFA on colon cancer cell proliferation

LS-174T cells were treated with different concentrations

**Figure 3** DHA suppresses AA- and PGE<sub>2</sub>-induced proliferation. A: DHA inhibited AA-induced proliferation, <sup>a</sup> $P < 0.001$ . Results represent six independent experiments. B: PGE<sub>2</sub> formation was induced by AA treatment and was suppressed by concomitant DHA incubation, <sup>a</sup> $P < 0.001$ , <sup>b</sup> $P < 0.01$ . Results represent the mean of PGE<sub>2</sub> measurements from three independent samples. C: COX-2 transcription was activated by AA, but suppressed by DHA. <sup>c</sup> $P < 0.05$  versus control, <sup>b</sup> $P < 0.01$  versus control. Bars represent at least three experiments. D: DHA suppressed PGE<sub>2</sub>-induced cell proliferation, <sup>c</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ . Results represent five independent experiments.

of fatty acids bound to BSA. In XTT assays, DHA significantly diminished cell growth and viability in a time- and dose-dependent manner. At the same time, AA at identical concentrations was found to increase proliferation (Figure 1A and B).

In order to further explain the suppression of cell proliferation by DHA, we studied apoptosis by flow cytometry and DAPI staining. DHA increased the pre-G1 fraction (an indicator of apoptosis) in LS-174T cells, while the same concentrations of AA did not significantly alter the pre-G1 fraction compared to untreated cells (Figure 2A). DHA-induced apoptosis was further confirmed by DAPI staining (Figure 2B). We then investigated differential cellular gene expression by means of semi-quantitative RT-PCR. DHA significantly down-regulated anti-apoptotic bcl-2 mRNA, while in contrast, AA up-regulated bcl-2 (Figure 2C). In addition, DHA up-regulated the expression of p21, while AA did not alter the amount of p21 mRNA (Figure 2D).

#### Inhibition of AA- and PGE<sub>2</sub>-induced cell growth by DHA

LS-174T cells were treated with combinations of fatty acids bound to BSA and proliferation was assessed in

XTT assays. DHA co-incubation was able to reverse the proliferation associated with AA (Figure 3A). The anti-proliferative effect of DHA in the context of high AA concentrations was associated with a significant reduction of PGE<sub>2</sub> formation from AA (Figure 3B). This may have been caused by decreased presence of COX-2, as DHA incubation significantly reduced COX-2 gene expression in a dose-dependent manner (Figure 3C). However, the effect of DHA-associated growth inhibition was in part independent from a pure blocking effect on PGE<sub>2</sub>-formation, as co-incubation experiments with DHA and PGE<sub>2</sub> revealed that DHA also suppressed the PGE<sub>2</sub>-induced induction of proliferation (Figure 3D).

## DISCUSSION

As far as we are aware, our results demonstrate for the first time that DHA can directly suppress AA-induced colon cancer cell growth. Our data confirm that AA is a potent proliferative agent for colon cancer cells that are responsive to PGE<sub>2</sub>. In contrast, the n-3 PUFA DHA down-regulates anti-apoptotic factors, induces

apoptosis and decreases PGE<sub>2</sub> formation. This leads to a potent suppression of tumor cell growth by DHA. Our results confirm several previous studies that have shown that DHA is a potent suppressor of colon cancer cell proliferation and stimulates apoptosis<sup>[17-19,21,30]</sup>. However, previous studies have failed to address the differential effects of n-3 PUFA and n-6 PUFA, and of their combination, on cancer cell growth. In light of several studies that have demonstrated cancer cell growth inhibition by n-3 PUFA or n-6 PUFA<sup>[22,23,26]</sup>, our data help to clarify the issue of differential effects of n-6 and n-3 PUFAs on apoptosis and cell growth.

The most important result presented here is that the proliferation-stimulating effect of high concentrations of AA as a precursor of proliferation-stimulating lipid mediators (most notably PGE<sub>2</sub>) can be suppressed by increasing the DHA content of the cells. Indeed, DHA can also directly inhibit PGE<sub>2</sub>-induced proliferation in this context. Although our results are limited to an *in vitro* setup, they add evidence to the argument that the ratio of n-6/n-3 PUFA (and in particular the ratio of AA *versus* DHA) may be a critical determinant of proliferation and tumor growth in the colon, and that DHA supplementation can suppress tumor cell growth, even in the presence of high AA- and PGE<sub>2</sub>-levels.

## COMMENTS

### Background

Colon cancer is one of the leading causes of death in Western countries. It is known, that prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), generated from the omega-6 polyunsaturated fatty acid (n-6 PUFA) arachidonic acid (AA) is important in the tumorigenesis of colon cancer.

### Research frontiers

Several studies with the LS-174T colon cancer cell line have shown an important role of PGE<sub>2</sub> for tumor cell growth, but the effect of n-3 and n-6 PUFA has not been examined. Here, we used the LS-174T colon cancer cell line to study the role of the prostaglandin precursor AA and the omega-3 polyunsaturated fatty acid (n-3 PUFA) docosahexaenoic acid (DHA) on cell growth.

### Innovations and breakthroughs

The results presented here demonstrate that the n-3 PUFA DHA can directly suppress AA- as well as PGE<sub>2</sub>-induced colon cancer cell growth. The data add evidence to the argument that the ratio of n-6/n-3 PUFA (and in particular the ratio of AA *versus* DHA) may be a critical determinant of proliferation and tumor growth in the colon, and that DHA supplementation can suppress tumor cell growth even in the presence of high AA- and PGE<sub>2</sub>-levels.

### Applications

The results suggest that supplementation of DHA may be a powerful tool to counteract AA- and PGE<sub>2</sub>-promoted colon cancer cell growth that might be associated with the predominant Western diet.

### Terminology

PGE<sub>2</sub> is generated from the n-6 PUFA AA *via* action of cyclooxygenases 1 and 2. PGE<sub>2</sub> is important for proliferation of colon cancer cells *in vitro*. In contrast, diets rich in n-3 PUFAs, such as DHA and eicosapentaenoic acid, which are mainly found in fish oil, might reduce the risk of colon cancer development.

### Peer review

The authors show that addition of DHA to cell cultures decreased cell proliferation in a dose- and time-dependent manner. Overall, these studies establish the importance of the ratio of n-3 to n-6 PUFA and the beneficial effect of fish oil in neoplastic growth. Although this is a limited *in vitro* study, its implications are significant.

### Abstract

**AIM:** To assess the prevalence and location of advanced neoplasia in patients undergoing colonoscopy, and to compare the yield per indication.

**METHODS:** In a multicenter colonoscopy survey ( $n = 18$  hospitals) in the Amsterdam area (Northern Holland), data of all colonoscopies performed during a three month period in 2005 were analyzed. The location and the histological features of all colonic neoplasia were recorded. The prevalence and the distribution of

advanced colorectal neoplasia and differences in yield between indication clusters were evaluated. Advanced neoplasm was defined as adenoma  $> 10$  mm in size, with  $> 25\%$  villous features or with high-grade dysplasia or cancer.

**RESULTS:** A total of 4623 eligible patients underwent a total colonoscopy. The prevalence of advanced neoplasia was 13%, with 281 (6%) adenocarcinomas and 342 (7%) advanced adenomas. Sixty-seven percent and 33% of advanced neoplasia were located in the distal and proximal colon, respectively. Of all patients with right-sided advanced neoplasia ( $n = 228$ ), 51% had a normal distal colon, whereas 27% had a synchronous distal adenoma. Ten percent of all colonoscopies were performed in asymptomatic patients, 7% of whom had advanced neoplasia. In the respective procedure indication clusters, the prevalence of right-sided advanced neoplasia ranged from 11%-57%.

**CONCLUSION:** One out of every 7-8 colonoscopies yielded an advanced colorectal neoplasm. Colonoscopy is warranted for the evaluation of both symptomatic and asymptomatic patients.

### INTRODUCTION

Colorectal cancer (CRC) is the second leading cause of

cancer-related death in the Western world and the incidence in Asia is also rising<sup>[1,2]</sup>. In The Netherlands, 63 cases per 100 000 inhabitants were found in 2003, whereas the incidence in the United States was 52 cases per 100 000<sup>[3,4]</sup>. While several countries have already started nation-wide screening programs for colorectal cancer, in The Netherlands, the scale and mode of CRC screening are still being debated<sup>[5-8]</sup>. One issue is whether sigmoidoscopy or colonoscopy should be performed with particular emphasis on the potential differences in yield and spatial distribution of colorectal carcinomas and advanced adenomas. Before embarking on gradual implementation of any kind of endoscopic screening in The Netherlands, we need to understand the distribution of CRC as well as the high risk precursors within the colorectum. In recent advice to the government, the Health Council of The Netherlands acknowledged the importance of this issue, and indicated that additional research is required before commitment to a national screening program<sup>[6]</sup>. Although colonoscopy and sigmoidoscopy constitute a significant proportion of the endoscopic workload in daily clinical practice, the yield of pathology, except for highly selected populations, has not well been described<sup>[9]</sup>. In particular, international data are lacking real life incidence figures of both advanced and non-advanced colorectal neoplasia found in routine endoscopy programs. As a result, accurate data on CRC and its precursors obtained in this study could inform decisions in choosing a future screening modality and could facilitate future national research initiatives in the field of CRC.

Furthermore, in view of the relatively fixed endoscopic resources and the potential increase in endoscopic procedures related to a future CRC screening program, a clear insight into endoscopic utilization in daily clinical practice is mandatory. Colonoscopy is considered the gold standard for the evaluation of the symptomatic patient. However, indication clusters might predict the presence of advanced neoplasia located in the proximal or distal colon and, thus, might indicate whether a colonoscopy or a sigmoidoscopy is warranted. This insight might not only lead to changes in future manpower planning, but it might also lead to changes in endoscopic utilization depending on initial clinical indication, thereby potentially alleviating future endoscopic workload<sup>[10]</sup>.

In the present study, we evaluated the diagnostic yield in terms of advanced and non-advanced neoplasia in a large cohort of Dutch patients referred for lower gastrointestinal (GI) endoscopy. Within this study, our primary objective was to assess the prevalence and location of advanced colorectal neoplasia in all patients clinically referred for colonoscopy. A secondary objective was to compare the yield of proximally located advanced neoplasia *versus* distally located advanced neoplasia in several indication clusters in total colonoscopies.

## MATERIALS AND METHODS

### Study design

In this multicenter study, daily endoscopic clinical practice was prospectively monitored during a three month period

in 2005 in the province Northern Holland (Amsterdam area). All colonoscopies and sigmoidoscopies performed in this time interval were evaluated. The province Northern Holland, serving a total community of 2 599 103 inhabitants (www.cbs.nl) has 18 hospitals (2 academic hospitals and 16 general/teaching hospitals). All 18 hospitals participated in this study. The study protocol was approved by the central medical ethics review board of the VU University Medical Centre in Amsterdam.

Age, gender, procedure indications, and endoscopic findings were obtained from all patients referred for lower GI endoscopy. All hospitals were visited every two weeks and all lower GI endoscopy reports between September 1st 2005 and December 1st 2005 were evaluated.

### Study procedure and definitions

All examinations were performed by gastroenterologists, GI fellows, internists or colorectal surgeons. For the purpose of our analysis, the distal colon was defined as the rectum, sigmoid, and descending colon including the splenic flexure. The proximal colon was defined as the transverse colon, the ascending colon and the cecum, as assessed by the endoscopist. The percentage of complete colonoscopies was scored. Cecal intubation was considered a complete colonoscopy.

Indications for procedures were clustered in categories. In total, twelve clusters were defined as shown in Table 1. In many cases, more than one procedure indication was present. There was considerable overlap among the indications of abdominal pain (I), change in bowel habits (II), bloating (III), diarrhea (IV) and constipation (V). We defined an irritable bowel syndrome (IBS) cluster as including one or more of the above-mentioned symptoms (I-V), as has been described previously<sup>[7]</sup>. The IBS cluster excluded patients who underwent colonoscopy or sigmoidoscopy for surveillance of inflammatory bowel disease (IBD) or established IBD, weight loss, or GI bleeding [anemia/iron deficiency, positive fecal occult blood test (FOBT), hematochezia or melena].

All pathological and clinicopathological findings were categorized as indicating non-neoplastic mucosa (no polyps), hyperplastic polyps, adenomas with low-grade dysplasia, or advanced neoplasia. An advanced neoplasm was defined as an adenoma  $\geq 1.0$  cm, an adenoma with villous or tubulovillous architecture ( $\geq 25\%$  villous component), an adenoma with high-grade dysplasia, or cancer. Advanced adenoma was defined as an adenoma  $\geq 1.0$  cm, an adenoma with villous or tubulovillous architecture ( $\geq 25\%$  villous component) or an adenoma with high-grade dysplasia. Subsequently, the term advanced neoplasm was defined as comprising advanced adenomas and cancer, as has been described previously. A non-advanced neoplasm was defined as a hyperplastic polyp, an adenoma  $\leq 1.0$  cm with low-grade dysplasia or an adenoma  $\leq 1.0$  cm with  $\leq 25\%$  villous component of the architecture. Findings such as lipomas, lymphoid aggregates and inflammatory or juvenile polyps were categorized as indicating non-neoplastic mucosa. In the case of patients with more than one polyp in either the proximal or distal segment of the colon, the most

Table 1 Indication cluster definition

Indication cluster (n; %)	Consists of the following indications
G-I bleeding (696; 15)	Hematochezia and/or melena
Anemia (356; 8)	Any kind of anemia
CRC suspicion (204; 4)	Clinical and/or radiological suspicion CRC
Weight loss (101; 2)	Weight loss
Family history CRC <sup>1</sup> (447; 10)	Any family history of CRC or screening
IBS (969; 21)	Abdominal pain, change in bowel habits, bloating, diarrhea, constipation
IBD exacerbation (256; 6)	Clinical suspicion IBD and/or endoscopic evaluation of IBD exacerbation
CRC surveillance (454; 10)	Follow up after CRC
Polyp surveillance (583; 13)	Follow up after polypectomy
IBD surveillance (142; 3)	Surveillance for dysplasia in IBD
FAP/HNPCC surveillance (84; 2)	Screening and/or surveillance in FAP/HNPCC families
Other/non-specified (331; 7)	No indication mentioned, ileus and desufflation therapy, fecal incontinence, monitoring diverticulitis after treatment, tenesmus, endoscopic treatment radiation enteritis

<sup>1</sup>Known hereditary CRC syndromes like HNPCC, FAP or MYH-polypsis are excluded. Note 1: The number of patients included in both study objectives was 4623 patients; Note 2: Within the indication cluster, the numbers and percentages of patients are placed between brackets.

Table 2 Yield of advanced neoplasia per indication in all complete colonoscopies n (%)

Indication cluster	Right-sided advanced neoplasia	Left-sided advanced neoplasia	Synchronous left- and right-sided advanced neoplasia	Total number of patients with advanced neoplasia
G-I bleeding (n = 696)	19 (11)	146 (83)	11 (6)	176 (25)
Anemia (n = 356)	35 (57)	21 (34)	5 (8)	61 (17)
CRC suspicion (n = 204)	29 (33)	54 (61)	6 (7)	89 (44)

Family history CRC <sup>1</sup> (n = 447)	10 (30)	19 (58)	4 (12)	33 (7)
IBS (n = 969)	22 (26)	57 (66)	7 (8)	86 (9)
IBD exacerbation (n = 256)	1 (33)	2 (67)	0	3 (1)
CRC surveillance (n = 454)	11 (29)	23 (60)	4 (11)	38 (8)
Polyp surveillance (n = 583)	29 (41)	36 (51)	6 (8)	71 (12)
IBD surveillance (n = 142)	3 (43)	4 (57)	0	7 (5)
FAP/HNPCC surveillance (n = 84)	2 (25)	5 (63)	1 (13)	8 (10)
Other/Non-specified <sup>2</sup> (n = 331)	20 (48)	21 (50)	1 (2)	42 (13)
Total (n = 4623)	183 (29)	395 (63)	45 (7)	623 (13)

<sup>1</sup>Known hereditary CRC syndromes like HNPCC, FAP or MYH-polypsis are excluded; <sup>2</sup>Including no indication mentioned, ileus and desufflation therapy, fecal incontinence, monitoring diverticulitis after treatment, tenesmus and endoscopic treatment radiation enteritis. NB: Within the indication cluster, the numbers of patients are placed between brackets.

advanced lesion in this particular segment was included in the analysis. The size of the polyp was estimated either with the use of open-biopsy forceps or on the basis of clinical judgement.

Pathology specimens were evaluated by local pathologists, who classified polyps according to the criteria established by the World Health Organization<sup>[11]</sup>. Pathology reports were accessible through the national pathology data system (PALGA)<sup>[12]</sup>. The prevalence and location of advanced neoplasia were assessed for all colonoscopies and for each indication cluster separately. All sigmoidoscopies and incomplete colonoscopies were excluded, except for incomplete colonoscopies due to an obstructing CRC. Other exclusion criteria were colonoscopies with insufficient bowel cleansing and colonoscopies in patients with a known advanced neoplasm *in situ* (procedure indication is polypectomy or endoscopic re-evaluation of the anatomic position

of the tumor). In case a patient had undergone multiple colonoscopies, we only analyzed the examination in which the most advanced neoplastic lesion was found. In case a patient had a synchronous right-sided and left-sided advanced neoplasm, we only analyzed the most proximal lesion or we analyzed both synchronous lesions separately (Table 2).

### Statistical analysis

**Primary objective:** In all successful total colonoscopies, the prevalence and location of advanced colorectal neoplasia and the age and gender of patients were assessed.

**Secondary objective:** For each indication cluster separately, the prevalence and location of advanced colorectal neoplasia were assessed in all successful total colonoscopies.

For comparison of proportions, the Fisher's exact

**Table 3** Prevalence and distribution of advanced colorectal neoplasia in 4623 patients *n* (%)

Localization in the colo-rectum	CRC	Advanced adenoma	Advanced neoplasia <sup>1</sup>
Rectum	86 (31)	74 (22)	160 (26)
Sigmoid	77 (27)	131 (38)	208 (33)

<sup>1</sup>Advanced neoplasia was defined as an adenoma > 1.0 cm and/or > 25% of villous architecture and/or high-grade dysplasia or cancer; In two patients, two CRC's were found. In one case, both were located in the distal colon. In the other case, a distal and a proximal tumor was found; In 45 patients, both proximally and distally located advanced neoplasia were found.

test or chi-square test with Yates correction were used. Analyses were performed with SPSS for Windows software, version 12.0 (SPSS Inc., Chicago, Illinois).

## RESULTS

### General results

In total, 5652 colonoscopies and 3444 sigmoidoscopies were performed in 8636 patients during a three month period. Figure 1 shows an overview of the inclusion and exclusion criteria. After excluding all sigmoidoscopies (*n* = 3444), incomplete colonoscopies (*n* = 817), patients with insufficient bowel cleansing (*n* = 36), patients < 16 years (*n* = 2) and patients with a known advanced neoplasm *in situ* [procedure indication is polypectomy or endoscopic re-evaluation of anatomic position of the tumor (*n* = 85)], the total study cohort consisted of 4623 patients (mean age  $\pm$  SD 58.8  $\pm$  16 years, range 16-100 years). In 4 patients (0.1%), the age was not mentioned in the endoscopy report. Forty-seven percent and 53% of the patients were male and female, respectively (mean age for males 59.3  $\pm$  15 years, mean age for females 58.4  $\pm$  16 years, *P* = NS). In 0.1% of the patients (*n* = 4) gender was not mentioned in the endoscopy report. In 16% and 84% of the patients, endoscopies were performed in an academic hospital and general/teaching hospital, respectively. In all patients undergoing colonoscopy, the cecal intubation rate was 83%. In 14% of the cases, the cecum was not visualized and in 3% of the cases the issue was not accounted for in the colonoscopy report.

### Prevalence and location of advanced neoplasia

The prevalence and distribution of CRCs, advanced adenomas and advanced neoplasia are listed in Table 3. Furthermore, in all complete colonoscopies, three incident cases of carcinoid tumors, one anal carcinoma and three metastatic lesions of other primary tumors were detected. In patients with CRC (*n* = 281), 52% were males (mean age  $\pm$  SD 68.0  $\pm$  11 years) and 48% were females (mean age  $\pm$  SD 70.6  $\pm$  12 years) (*P* = NS). In patients with CRC, the tumor was located in the distal colon and

**Figure 1** Number of patients included in the primary and secondary study objectives (*n* = 4623).

**Figure 2** Yield of advanced neoplasia in different age categories (*n* = 4623). *P*-values for males compared to females.

proximal colon in 65% and 35% of cases, respectively. Of all patients with right-sided advanced neoplasia (i.e. advanced adenomas and/or cancer, *n* = 228), 51% had a normal appearing distal colon, whereas 49% had a synchronous distal polyp (41% advanced neoplasm, 14% small adenoma, 12% hyperplastic polyp and 33% non-specified polyp). Overall, 2.5% of the total study cohort had a proximally located advanced neoplasm without a synchronous distal polyp. Figure 2 illustrates the prevalence of advanced neoplasia in different age categories for males and females. Advanced neoplasia became more prevalent with increasing age. In 22% of the patients over 80 years an advanced neoplasm was found, compared to 5% of the patients under 50 years (*P* < 0.0001). Men were more likely than women to have advanced

neoplasia (15.6% for men *versus* 11.6% for women, odds ratio (OR) corrected for age is 1.4; 95% confidence interval (CI) 1.18 to 1.67;  $P < 0.0001$ ).

### **Yield of advanced neoplasia per indication**

The yield and distribution of advanced neoplasia are summarized per indication cluster in Table 2. Advanced neoplasia were found in 25% of patients who presented with GI bleeding. Moreover, in cases of a clinical or radiological suspicion of CRC, the yield of advanced neoplasia was 44%. In all of the procedure indication clusters, the prevalence of right-sided advanced neoplasia ranged from 11%-57%. In patients who presented with GI bleeding, predominantly left sided advanced neoplasia were found (83%). In contrast, in patients who presented with anemia mostly right-sided advanced neoplasias were encountered (57%,  $P < 0.001$ ). Advanced neoplasia were found in 7% of asymptomatic patients (10% of the total study cohort), who presented with a family history of CRC or with a CRC screening request. Finally, both left- and right-sided advanced neoplasias were found in 7% of all patients.

## **DISCUSSION**

This study included all procedures from patients clinically referred for colonoscopy in a three month period. In The Netherlands, all colonoscopies are performed in a hospital setting (academic, teaching or general hospitals). No other institutions, like private practices or doctor's offices, perform endoscopies. Our study includes all colonoscopies performed in Northern Holland, representing a large unselected sample of the population of The Netherlands. Therefore, our data accurately represent the entire lower GI endoscopic practice in Northern Holland which we regard to be representative for the whole of The Netherlands. This study cohort yielded 281 CRCs. However, all CRCs found using sigmoidoscopy ( $n = 95$ ) or during abdominal surgery without prior endoscopy ( $n = 38$ ), were excluded (data not shown in results section). Extrapolation of the total number of CRCs found to annual incidence figures would show a substantial increase in incidence of CRC compared to national/regional cancer registries (67 cases per 100 000 inhabitants compared to 63 cases per 100 000 inhabitants in 2003)<sup>[3]</sup>. In line with international data on the rising incidence of CRC, this finding would emphasize the importance of implementing a CRC screening program in The Netherlands to improve survival by diagnosing CRC or its precursors at an earlier stage<sup>[4,13]</sup>.

In this referral population, more than 13% of colonoscopies performed yielded an advanced neoplasm (CRC/advanced adenoma). Of all advanced neoplasia found, 33% were located in the proximal colon and 67% were located in the distal colon. Similar to other studies, we identified male sex and increasing age as independent risk factors of advanced neoplasia, either distally located or proximally located<sup>[14-17]</sup>. However, male sex adjusted for age and distal findings did not significantly increase the risk of advanced proximal neoplasia. As shown in

Figure 2, at least a 4-fold increase in prevalence of advanced neoplasia was observed in patients  $> 70$  years compared with those of  $< 50$  years. This age-related increase in prevalence of advanced neoplasia is in keeping with previous Western and Asian reports<sup>[18-20]</sup>. Unfortunately, the presence of a right-sided advanced neoplasm can not be adequately predicted by distal colonoscopic findings since 51% of proximally located advanced neoplasia had no distal polyps. If distal adenomas are considered sentinel lesions that warrant a complete colonoscopy, the percentage of detected proximally located advanced neoplasms would have been 27% if only sigmoidoscopy had been performed. However, in this study, a substantial proportion of distal polyps was not specified, which could be an important confounder (33% of all distal polyps in patients with proximally located advanced neoplasia). In accordance with other studies in which patients were referred for colonoscopy, no significant differences in the prevalence of proximally located advanced neoplasia with a normal appearing distal colon were found [prevalence of isolated, proximal advanced neoplasia in the United States (2.7%), Asia (2.2%) and The Netherlands (2.5%)]<sup>[17,21]</sup>. Moreover, compared to the Asian situation, no significantly different percentages were observed in terms of missed proximally located advanced neoplasia if only sigmoidoscopy had been carried out<sup>[17]</sup>.

When taking into account the different procedure indication clusters, the prevalence of proximally located advanced neoplasia ranged from 11%-57%. In patients who presented with GI bleeding, only 11% of advanced neoplasia were located in the proximal colon, while 83% were located in the distal colon ( $P < 0.001$ ). Six percent of the patients with GI bleeding had synchronous advanced neoplasia in both the distal and the proximal colon. Consequently, the majority of advanced neoplasia in patients with GI bleeding are found within reach of the sigmoidoscope. However, apart from GI bleeding, which is one of the most frequent procedure indications, right-sided advanced neoplasia is a common finding which cannot be ignored when considering the proper endoscopic procedure in clinical practice. Even in the IBS indication cluster, which has a low pretest likelihood ratio for advanced neoplasia<sup>[22,23]</sup>, similar percentages of right-sided advanced neoplasia were found compared to indications such as weight loss, family history of CRC, CRC surveillance and FAP/HNPCC surveillance ( $P = \text{N.S.}$ ). A change in bowel habits was included in the IBS indication cluster (Table 1) which may be responsible for the high yield of advanced neoplasia, particularly in patients  $> 50$  years. Surprisingly, there were hardly any referrals for colonoscopy based on a positive FOBT result ( $n < 10$ ), which is a frequent procedure indication in other studies<sup>[7]</sup>. In all probability, this is due to a lack of confidence in the FOBT as a diagnostic test in The Netherlands. We hypothesize that this finding might also reflect the Dutch lagging behind in CRC awareness and pre-screening activities compared to other European countries<sup>[24,25]</sup>.

In this accurate regional representation of Dutch

endoscopic practice, 10% of all colonoscopies in routine endoscopy programs were performed in asymptomatic patients. This ranged from an individual screening request without family history of CRC to a request because of a history of CRC in a 1st-3rd degree family relative. The diagnostic yield in terms of advanced neoplasia in this indication cluster was substantial (7%), and right-sided advanced neoplasms were frequently found (30%). Taking into account the yield of right-sided advanced neoplasia in each indication cluster, and in asymptomatic patients in particular, it can be argued whether these findings would be truly different in a CRC screening setting. To further elaborate on this conclusion, the majority of advanced colorectal adenomas and a proportion of early cancers are asymptomatic. These neoplasias are detected by chance during colonoscopy. Therefore, the topographic distribution and epidemiology of colorectal neoplasia, particularly advanced adenomas, found in this study should largely reflect the actual situation in The Netherlands where screening colonoscopy is non-existent. This also means that this study could not have been performed in a screening population only. However, because of the increasing attention to CRC screening, in both policy makers, medical doctors and the general population, a substantial number of endoscopies are performed in daily clinical practice in asymptomatic patients. To a certain extent, our asymptomatic patients are comparable to a screening population. Therefore, this study contains an informative mix of symptomatic and asymptomatic patients with a comparable distribution rate of advanced neoplasia.

Our findings should be interpreted taking into account several potential caveats in case of extrapolation to a screening setting. Firstly, in this study the majority of patients were symptomatic or in a surveillance program which may be accompanied by a higher likelihood of having colorectal neoplasia. In contrast to screening colonoscopy, in which age limits are restricted, the wide age range of our study population may have influenced the rate of advanced colorectal neoplasia. The Dutch Health Council, however, asked for such routine endoscopy data before implementing a CRC screening program. Secondly, histology reports were generated by local pathologists meaning that there was an inherent risk of inter-observer variability in characterization of the histological types and degrees of dysplasia of polyps<sup>[26,27]</sup>. Furthermore, in the total study cohort 331 patients had a non-specified polyp (7% of all patients and 18% of all colorectal neoplasms). Non-specification was mainly due to insufficient retrieval of snared polyps, lack of biopsies and poor quality of biopsy specimens. Although the percentage of advanced neoplasia that are missed because of non-specification remains elusive, the high number of non-specified polyps is rather worrisome for routine practice. Thirdly, polyp size is frequently misjudged by endoscopists<sup>[28]</sup>. In our study, no systematic size estimate was used and, therefore, an arbitrary cut-off value of 10 mm was used for discrimination of small and large polyps, leaving judgement of sizes to each endoscopist individually. Thus, due to the lack of predefined stand-

ardization, the proportion of truly advanced neoplasia may not be accurately reflected in this cohort.

Surprisingly, colonoscopy in daily clinical practice was incomplete in 17% of cases. Whether an incomplete colonoscopy was followed by a double-contrast barium enema or CT colonography to visualize the total colon is not known. Major contributors to cecal intubation failure were inflammation due to IBD or diverticulitis, extensive diverticular disease, stenosis/adhesions after abdominal surgery and large advanced adenomas. Undoubtedly, the miss rate of advanced neoplasia due to incomplete colonoscopies needs further clarification. Such low cecal intubation rates may frustrate future colonoscopy-based screening programs. Recently, simple measures have been proposed to optimise quality in colonoscopy<sup>[29,30]</sup>. These studies and this low cecal intubation rate underscore the importance of continuous quality control in terms of reporting and appropriate training.

In conclusion, this study is an exact representation of daily clinical practice, and as such provides relevant data on the performance of colonoscopy with respect to the detection of advanced neoplasia. Our data are mandatory for the future planning of CRC screening in The Netherlands. Although this referral population may have a higher pre-test likelihood for colorectal neoplasia, the distribution of these lesions throughout the colorectum may be the same. At present, 10% of all colonoscopies in routine endoscopy programs are performed in asymptomatic patients with a substantial yield of advanced neoplasia. Based on clinical indication, no significant changes in endoscopic utilization can be realized to alleviate endoscopic workload since substantial numbers of right-sided advanced neoplasia are found in each indication cluster. Extrapolation of our data indicates that sigmoidoscopy would miss 33% of advanced neoplasia. Hence, our data show that colonoscopy is warranted for the evaluation of both symptomatic and asymptomatic patients.

erlands; GH de Groot, MD, gastroenterologist, Rode Kruis Hospital, Beverwijk, The Netherlands; M Klemm-Kropp, MD, PhD, gastroenterologist, Westfries Gasthuis, Hoorn, The Netherlands; J Ph Kuyvenhoven, MD, PhD, gastroenterologist, Kennemer Gasthuis, Haarlem, The Netherlands.

## COMMENTS

### Background

Colorectal cancer (CRC) awareness accounts for an increasing number of colonoscopies performed in asymptomatic patients with a screening request or family history of CRC in The Netherlands. Before embarking on endoscopic screening, we need to understand the distribution of CRC as well as the high risk precursor lesions within the colorectum. International data are scarce regarding real life incidence figures of colorectal neoplasia found in routine endoscopy programs, evaluating both symptomatic and asymptomatic patients.

### Research frontiers

Knowledge of the incidence and distribution of CRC and high-risk precursor lesions in the colo-rectum in both symptomatic and asymptomatic patients, could tailor endoscopic utilization. Furthermore, it could facilitate making informed decisions in choosing a future screening modality and future national research initiatives in the field of CRC.

### Innovations and breakthroughs

The overall yield in advanced neoplasia was significantly higher in this study than in the Asian situation (13.5% vs 9.4%). In accordance with United States and Asian studies, in which patients were referred for colonoscopy, high percentages of proximally located advanced neoplasia with a normal appearing distal colon were found. Extrapolation of our data indicates that sigmoidoscopy would miss 33% of advanced neoplasia. The yield of advanced neoplasia in asymptomatic patients is substantial (7%). Although this referral population may have a higher pre-test likelihood of colorectal neoplasia compared to a screening population, the distribution of these lesions throughout the colorectum may be the same. In The Netherlands, where screening colonoscopy is non-existent, 10% of all colonoscopies in routine endoscopy programs are performed in asymptomatic patients.

### Applications

This study shows that colonoscopy has a high yield in detecting advanced colorectal neoplasia in daily clinical practice. Colonoscopy is warranted for the evaluation of both symptomatic and asymptomatic patients, since substantial numbers of right-sided advanced neoplasia are found in both patient groups. These data are mandatory for the future planning of CRC screening in The Netherlands.

### Terminology

Advanced colorectal adenoma is defined as an adenoma  $\geq 1.0$  cm, an adenoma with villous or tubulovillous architecture ( $\geq 25\%$  villous component) or an adenoma with high-grade dysplasia. Advanced colorectal neoplasm is defined as an adenoma  $\geq 1.0$  cm, an adenoma with tubulovillous or villous architecture ( $\geq 25\%$  villous component), an adenoma with high-grade dysplasia, or cancer. Subsequently, the term advanced colorectal neoplasm was defined as comprising advanced adenomas and cancer.

### Peer review

This is a useful study reporting the prevalence of colonic lesions in symptomatic and asymptomatic patients in a Dutch province containing 18 hospitals. The sample size is large, and it is fairly well written.

### Abstract

**AIM:** To investigate the histologic features of the liver in nonalcoholic fatty liver disease (NAFLD) cases according to the presence of metabolic syndrome or its individual components.

**METHODS:** We enrolled 81 patients (40 male, 41 female) who were diagnosed with fatty liver by ultrasonographic scan and fulfilled the inclusion criteria. First anamnesis, anthropometric, clinical, laboratory and imaging features of all participants were recorded and then liver biopsy was performed after gaining consent from patients. Diagnosis of metabolic syndrome was dependent on patients having 3 or more out of 5 risk criteria defined by the WHO. Biopsy specimens were assessed according to Brunt *et al*'s classification.

**RESULTS:** Sixty-nine of the 81 patients had nonalcoholic steatohepatitis (NASH), 11 had simple fatty liver and 1 had cirrhosis according to histologic evaluation. Comparisons were made between two groups of NASH patients, those with and without metabolic syndrome. We did not detect statistically significant differences in liver histology between NASH patients with and without metabolic syndrome.

**CONCLUSION:** NASH can progress without metabolic risk factors or the presence of metabolic syndrome.

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is common and has a spectrum of liver pathologies beginning with simple fatty liver and progressing to steatohepatitis, cirrhosis and liver failure<sup>[1,2]</sup>. NAFLD is frequently present along with the components of metabolic syndrome and, hence, is generally regarded as a manifestation of metabolic syndrome<sup>[3]</sup>. As insulin resistance (IR) is a main mechanism in the pathogenesis of metabolic syndrome, it is also thought to be an initiating factor in the process of NAFLD<sup>[4,5]</sup>. Nevertheless, some NAFLD cases did not fulfill all criteria of metabolic syndrome and did not display IR at the onset of disease according to the literature<sup>[6]</sup>. Certain recent studies revealed that all patients with NAFLD did not also have metabolic syndrome or its separate symptoms, including IR<sup>[6]</sup>.

In the present study, differences in liver histology according to the presence of metabolic syndrome or its individual components were investigated. We also explored the effect of IR on the development of NAFLD. The features of patients with an NAFLD-like clinical course, accompanying diseases, laboratory findings and histologic aspects, are able to provide remarkable clues into the etiopathogenesis of the disease. Although there were many common points and reported issues supporting the presence of metabolic disorder and its components in the etiology of NAFLD, some studies revealed that NAFLD could also progress in lean people, nondiabetics, males, adolescents and children<sup>[7,8]</sup>.

Certain articles in the literature have disclosed striking findings; for example, the frequency of IR in NAFLD patients varies from 47%-98% without diabetes also being present. Likewise the prevalence of metabolic syndrome in NAFLD patients was as low as 36% in some studies<sup>[6]</sup>. Furthermore, in different populations the prevalence of metabolic syndrome is about 22% and in NAFLD patients there was a subgroup who did not have IR<sup>[6]</sup>. We aimed to reveal whether there is a group of NAFLD patients without metabolic syndrome and IR or not. Recently, increasing number of studies on this topic are being presented. But more investigations are needed to attain convincing outcomes.

## MATERIALS AND METHODS

### Patients

This study consisted of 81 patients who were referred to Uludag University Gastroenterology Division. All 81 patients were diagnosed with fatty liver by ultrasonographic scan. After this complete clinical, anthropometric and laboratory assessments and liver biopsy were performed. Exclusion criteria included: alcohol consumption of > 20 g/d, pregnancy, positive tests indicating the presence of hepatitis B or C virus, autoimmune liver disease, hemochromatosis, Wilson's disease,  $\alpha$ -1 antitrypsin deficiency, primary biliary cirrhosis, primary sclerosing cholangitis and toxic liver disease.

### Laboratory studies

After taking a medical history, all cases underwent liver examination by ultrasonography and then clinical, anthropometric, complete blood count and biochemical assessments were performed. Biochemical evaluation consisted of assessment of alanine aminotransferase (ALT), aspartate aminotransferase (AST),  $\gamma$ -glutamyltransferase (GGT), alkaline phosphatase (ALP), bilirubin, albumin, high density lipoprotein (HDL)-cholesterol, triglycerides, glucose, and insulin levels and an oral glucose tolerance test (OGTT). Anthropometric parameters measured were height, weight, body mass index (BMI), waist and hip circumferences and waist/hip ratio values. Assessment of obesity was dependent on WHO criteria<sup>[9]</sup>. American Diabetes Association (ADA) criteria were used to define type 2 diabetes, impaired glucose intolerance, and impaired fasting glycemia<sup>[10]</sup>. Patients receiving oral antidiabetics or insulin therapy were accepted as diabetics. Hypertension was considered to be present when resting blood pressure was  $\geq 140/90$  mmHg or patients were receiving antihypertensive drug therapy. The homeostasis model assessment of IR (HOMA-IR) method was used to measure IR and patients were classified as 'insulin resistant' when HOMA-IR value was > 2.70. ALT levels 1.5 or more times higher than upper normal values indicated an elevation in ALT. The diagnosis of metabolic syndrome was made according to WHO criteria<sup>[10,11]</sup> (BMI  $\geq 30$  kg/m<sup>2</sup>, waist/hip circumference ratio > 0.90 in men and > 0.85 in women, fasting blood glucose  $\geq 1100$  mg/L, overt diabetes, presence of impaired glucose tolerance and/or IR,

triglycerides  $\geq 1500$  mg/L, HDL-cholesterol < 400 mg/L in men and < 500 mg/L in women, arterial blood pressure  $\geq 140/90$  mmHg and presence of microalbuminuria). Patients should have at least three of these criteria to be diagnosed with metabolic syndrome. The study was approved by the hospital ethics committee.

### Pathology

Liver biopsies were performed in 81 patients according to the severity of the clinical disease after the patients had given consent. All liver biopsy specimens were examined by a liver pathologist. Scoring of necroinflammation and fibrosis was performed using criteria devised by Brunt *et al*<sup>[12,13]</sup>. Nonalcoholic steatohepatitis (NASH) was diagnosed according to liver histology indicating steatosis (mild: < 33% of lobules, moderate: 33%-66% of lobules and severe: > 66% of lobules) with (1) ballooning degeneration of hepatocytes/mallory bodies; (2) necroinflammation (lobular or portal); (3) fibrosis (perisinusoidal, periportal and/or bridging) or cirrhosis.

### Statistical analysis

Due to the number of patients being small, statistical evaluation and *P* values were not available, as shown in all tables. Hence, features of patients were evaluated according to their percentage values.

## RESULTS

### Anthropometric, clinical and laboratory results

Eighty-one patients (40 male, 41 female) who were diagnosed as having fatty liver by ultrasonographic examination participated in this study at the Uludag University Gastroenterology Division. Only 8% of patients had slight and dull abdominal pain. The prevalence of hepatomegaly was 16% and 4% in NASH and simple fatty liver groups, respectively. All 81 patients underwent liver biopsy; 69 (35 male, 34 female) were diagnosed with NASH, 11 (4 male, 7 female) were diagnosed with simple fatty liver and 1 (male) was diagnosed with cirrhosis. First, we compared all cases with NASH and simple fatty liver to each other according to anthropometrical, clinical and laboratory data, including presence of IR and metabolic syndrome, but we did not find any significant difference between the 2 groups. For instance, numbers and proportions of IR and metabolic syndrome in NASH patients were 30 (43.4%) and 46 (66.7%) respectively and in simple fatty liver patients were 6 (54.5%), and 9 (81.8%) respectively. Then, the features of liver histology were examined in detail with regard to individual components of metabolic syndrome. As shown in Table 1, liver steatosis and necro-inflammation were evaluated with respect to individual parameters of metabolic syndrome. Because the numbers of cases in each section of Table 1 were too small, statistical assessments were not available and data analysis and interpretation were performed using percentage values. It seemed that the presence of individual risk factors did not affect the severity of steatosis and necroinflammation. Similarly, in Table 2 progression of liver fibrosis was

<sup>1</sup>(+): Present; (-): Absent. Presence of hypertriglyceridemia and insulin resistance seemed to increase the severity of steatosis and necroinflammation but these findings were not significant.

evaluated with respect to individual parameters of metabolic syndrome and again it seemed that individual metabolic risk factors did not initiate or advance liver fibrosis. In Table 3, dual combinations of risk factors were compared to grading and staging values of liver histology and there was no remarkable outcome. Finally, in Table 4 detailed histological parameters were evaluated according to the presence of metabolic syndrome. However, we did not determine any correlation between histological severity and the presence of metabolic syndrome.

When the distribution of risk factors and metabolic syndrome was examined in 11 simple fatty liver patients, the following results were found: central obesity 57%, hypertension 53%, diabetes 18.1%, hypertriglyceridemia 58%, low HDL level 57%. While 9 of these 11 patients had metabolic syndrome, the remaining 2 patients had only 2 risk factors for metabolic syndrome. The single cirrhotic patient was a 55-year-old male with metabolic syndrome who had obesity (also central obesity), diabetes and a low-HDL level.

### Histopathology

The important highlights of liver histology belonging to our 81 cases were investigated. Since the numbers of patients in each of the subgroups were too small, statistical assessments were not available and interpretations of histological findings in all tables were dependent on

percentage values. As shown in Table 1, liver steatosis and necroinflammation were evaluated in detail according to the individual presence of metabolic risk factors and there was no significant difference in the two groups. Similarly Table 2 showed that when liver fibrosis was studied with respect to the presence of individual risk factors there was no significant difference. In Tables 3 and 4, the presence of dual combinations of risk factors and the presence of defined metabolic syndrome, respectively, were compared to liver histology. Neither the presence of a dual combination of risk factors nor the presence of defined metabolic syndrome were found to be closely related with the severity of steatosis, necroinflammation and fibrosis. Interestingly, among 11 patients with simple fatty liver each patient had at least two metabolic risk factors. In the simple fatty liver group, the prevalence of defined metabolic syndrome was 81.8% which was higher than that in the NASH group. Finally, 1 patient who was diagnosed with cirrhosis according to liver histology had metabolic syndrome.

### DISCUSSION

The relationship between NAFLD and metabolic

Ob: Obesity; DM: Diabetes mellitus; Htg: Hypertriglyceridemia. Dual combination of risk factors did not seem to effect liver histology.

syndrome is well known. Certain metabolic disorders like obesity, diabetes, hypertriglyceridemia and hypertension frequently associate with NAFLD and are also components of metabolic syndrome<sup>[3,4,14]</sup>. Insulin resistance was thought to be a shared and basic metabolic disturbance in both these groups of diseases<sup>[15]</sup>. In the general population, the prevalence of NAFLD is 10%-24% while the prevalence of NASH is about 1%-5%<sup>[16]</sup>.

The association between NAFLD and metabolic syndrome gave rise to many studies on this subject. The prevalence of metabolic syndrome in NASH and simple fatty liver cases is 22.8%-88% according to the literature<sup>[14,17-20]</sup>. This suggests the relationship between NAFLD and metabolic syndrome is not a stable and constant feature. Moreover, the presence of IR was suggested to be a common and frequent finding in both NAFLD and metabolic syndrome in various studies<sup>[5,14,15,21]</sup>. Marchesini *et al*<sup>[17]</sup> revealed the prevalence of IR in NAFLD was 61%; but in certain recent studies, a low prevalence of IR in NAFLD was found<sup>[6,22,23]</sup>.

The influence of individual risk factors and defined metabolic syndrome on liver histology have become considerable and have inspired comprehensive studies. Marchesini *et al*<sup>[17]</sup> and Angelico *et al*<sup>[24]</sup> found a correlation between various degrees of liver steatosis (mild, moderate and severe) and BMI. According to studies by Willner *et al*<sup>[21]</sup>, Angulo *et al*<sup>[25]</sup> and Ratzliff *et al*<sup>[26]</sup> advanced obesity may be a risk factor for the development of liver fibrosis. But Xanthakos *et al*<sup>[27]</sup> stressed that in morbidly obese adolescents, severe NASH was uncommon and the presence of metabolic syndrome did not distinguish NASH from steatosis. We did not observe any connection between increased BMI and liver histology (steatosis and necroinflammation/fibrosis) in our NASH cases (Tables 1 and 2). Camilo Boza *et al*<sup>[28]</sup> did not find a significant association between BMI and histological changes; but in their study, high HOMA-IR values and ALT levels were the only independent predictors of NASH. Among our 69 cases with NASH, only 3 (4.34%) had normal body weight and among our simple fatty liver group (n = 11) only 1 (9.09%)

**Table 4** Liver histology according to the presence of metabolic syndrome in NASH cases (%)

Liver histology	Patients with NASH (n = 69)	
	With metabolic syndrome (n = 46, 66.6%)	Without metabolic syndrome (n = 23, 33.4%)

Cirrhosis	1 (2.12)	0 (0)

Evaluations were performed using percentage values. Presence of metabolic syndrome seemed to increase the severity of steatosis, necroinflammation and fibrosis in liver, but these results were not significant as well.

patient had normal body weight; there was no significant difference between these two groups. Diabetes and dyslipidemia (especially hypertriglyceridemia and low HDL level) were also considered to affect liver histology<sup>[29-31]</sup>. Risk factors for metabolic syndrome and defined metabolic syndrome was strongly considered to affect liver histology according to Marceau *et al*<sup>[32]</sup>.

But, still there are important and controversial points in the natural course of NAFLD. Which one has a precedence: liver steatosis or IR? Recently it was noticed that NAFLD could occur in nonobese, nondiabetic persons and even in infants and adolescents<sup>[7]</sup>. Some patients with NAFLD may not have metabolic risk factors initially and the components of metabolic syndrome may emerge during the course of the disease<sup>[24]</sup>. In these patients, after diagnosis of NAFLD the required time for genesis of metabolic disorders like hyperglycemia, hypertension and hyperlipidemia is not well known. Furthermore, not all NAFLD patients fulfill the criteria of metabolic syndrome according to the literature. Recently, certain studies showed that there have been lower prevalences of metabolic syndrome among NAFLD patients. For instance Moon *et al*<sup>[33]</sup> performed research to identify metabolic risk factors and clinical features for each stage of liver fibrosis in NAFLD patients and in their 25 study cases with NAFLD, only 14 patients (56%) had metabolic syndrome. They found no difference in the prevalence of metabolic syndrome between the simple steatosis and the NASH subgroups (5/10, 50% *vs* 9/15, 60%). In addition, there were no significant differences in the histological features of two separate NASH groups which were constituted according to the presence or absence of metabolic syndrome. Similarly, we detected some cases which did not have metabolic syndrome,

but had NASH (23 cases = 33.4% of all NASH cases). Conversely, some cases had metabolic syndrome, but were not diagnosed with NASH. The latter only had simple fatty liver (9 cases = 81.8% of all simply fatty liver cases). In our study, approximately 2/3 of the 69 NASH cases (66.6%) fit the criteria of metabolic syndrome and the remaining patients (33.4%) did not fit the full criteria of metabolic syndrome. These results suggest different causes of NASH other than metabolic syndrome should be searched for or that these NASH cases may represent patients in the early stages of metabolic syndrome. However, Kang *et al*<sup>[34]</sup> stated that a low proportion, 34% (31 of 91 patients), of NAFLD patients had metabolic syndrome, but these patients also had higher scores for steatosis and NASH activity.

Recent studies claimed that not only metabolic risk factors, but IR also could influence liver histology. Dixon *et al*<sup>[22]</sup> reported that HOMA-IR, ALT and arterial hypertension were independent predictors for NASH; but, they also found that 7.8% of their study patients had NASH even though they had normal AST and HOMA-IR values. Bahrami *et al*<sup>[35]</sup> found the rate of IR was only 54.7% in 53 patients with NASH. Similarly, Guidorizzi de Siqueira *et al*<sup>[23]</sup> determined the frequency of IR among NAFLD patients and described IR according to metabolic risk factors and histological findings. In their study, IR was detected in only 33% of NAFLD patients; but, there was a high frequency of IR in patients with advanced fibrosis, suggesting that IR may influence the prognosis of NAFLD. Sakurai *et al*<sup>[36]</sup> found that only steatosis was significantly and independently associated with elevated HOMA values; but there was no similar association with the grade or stage of NASH. However, we did not detect any connection between the presence of IR and liver histology. An interesting observation was expressed by Machado *et al*<sup>[6]</sup> who found that rates of IR in NAFLD patients ranged from 47% to 98% and only 36% of patients with NAFLD fulfilled three criteria of metabolic syndrome. The authors of this study designed it so that certain patients did not have IR at the onset of the study. The results of the study have been attributed to different factors. For instance, liver disease may precede IR or there may be a lack in sensitivity in the HOMA method.

In our study, NAFLD did not change histologically according to the presence of metabolic syndrome and its individual components. At the onset of NAFLD, metabolic disturbances may not be present, so patients with simple fatty liver should be followed for progression of metabolic disorders in the future.

## COMMENTS

### Background

Obesity, diabetes and hyperlipidemia are components of metabolic syndrome

and are frequently associated with nonalcoholic fatty liver disease (NAFLD). NAFLD consists of simple fatty liver and nonalcoholic steatohepatitis (NASH). The prognosis of NAFLD may worsen when there is an association with risk factors or metabolic syndrome. Insulin resistance (IR) is considered the common pathogenetic factor in both metabolic syndrome and NAFLD. We aimed to emphasize that NAFLD and NASH could progress not only in patients with metabolic risk factors, but also in nonobese healthy persons. Hence we investigated the histologic features of liver in NAFLD cases according to the presence of metabolic syndrome or its individual components.

### Research frontiers

In certain patients with NAFLD and NASH, the prevalence of metabolic syndrome was low and the influence of risk factors or metabolic syndrome on liver histology was not significant when compared to those without metabolic syndrome.

### Innovations and breakthroughs

It is important to be aware that it is not just NAFLD or NASH patients with metabolic syndrome who are at risk of advanced liver disease, but other NAFLD and NASH cases without metabolic syndrome may have severe liver disease. A new approach for these patients should be designed.

### Applications

For general public health, individuals diagnosed by ultrasonography scan as having fatty liver with or without risk factors and metabolic syndrome should be followed up closely for further serious complications and outcomes.

### Terminology

NAFLD and NASH may progress and worsen without metabolic syndrome (obesity, diabetes and hyperlipidemia) being present. In contrast to general opinion, the approach to individuals diagnosed with fatty liver by ultrasonographic examination should not be limited to the presence of metabolic syndrome. All patients with fatty liver should be advised about the hazardous outcomes of NAFLD.

### Peer review

This article is consistent and factual, and meets the aims of introducing NAFLD and NASH, advising patients to avoid their likely noxious outcomes and recommending clinical staff make the requisite inspections if there has been a diagnosis of NAFLD or NASH.

$\geq 3.1$ , the sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) in predicting variceal bleeding were 85%, 81%, 82%, 50%, and 96%, respectively. The score was prospectively validated in another set of 195 UGIB cases (46 variceal and 149 non-variceal bleeding). The PPV and NPV of a score  $\geq 3.1$  for variceal bleeding were 79% and 97%, respectively.

**CONCLUSION:** The UGIB Etiology Score, composed of 3 parameters, using a cutoff  $\geq 3.1$  accurately predicted variceal bleeding and may help to guide the choice of initial therapy for UGIB before endoscopy.

### Abstract

**AIM:** To identify clinical parameters, and develop an Upper Gastrointestinal Bleeding (UGIB) Etiology Score for predicting the types of UGIB and validate the score.

**METHODS:** Patients with UGIB who underwent endoscopy within 72 h were enrolled. Clinical and basic laboratory parameters were prospectively collected. Predictive factors for the types of UGIB were identified by univariate and multivariate analyses and were used to generate the UGIB Etiology Score. The best cutoff of the score was defined from the receiver operating curve and prospectively validated in another set of patients with UGIB.

**RESULTS:** Among 261 patients with UGIB, 47 (18%) had variceal and 214 (82%) had non-variceal bleeding. Univariate analysis identified 27 distinct parameters significantly associated with the types of UGIB. Logistic regression analysis identified only 3 independent factors for predicting variceal bleeding; previous diagnosis of cirrhosis or signs of chronic liver disease (OR 22.4, 95% CI 8.3-60.4,  $P < 0.001$ ), red vomitus (OR 4.6, 95% CI 1.8-11.9,  $P = 0.02$ ), and red nasogastric (NG) aspirate (OR 3.3, 95% CI 1.3-8.3,  $P = 0.011$ ). The UGIB Etiology Score was calculated from  $(3.1 \times \text{previous diagnosis of cirrhosis or signs of chronic liver disease}) + (1.5 \times \text{red vomitus}) + (1.2 \times \text{red NG aspirate})$ , when 1 and 0 are used for the presence and absence of each factor, respectively. Using a cutoff

### INTRODUCTION

Upper Gastrointestinal Bleeding (UGIB) is a common gastrointestinal emergency and carries a mortality rate of 5%-14%<sup>[1]</sup>. The causes of UGIB have been classified into variceal bleeding (esophageal and gastric varices) and non-variceal bleeding (peptic ulcer, erosive gastroduodenitis, reflux esophagitis, tumor, vascular ectasia, etc). Currently, emergency esophagogastroduodenoscopy (EGD) is the standard investigation of choice for active UGIB since it provides both diagnosis and treatment of UGIB<sup>[2-11]</sup>. However, in the real life situation, emergency EGD is seldom available in most hospitals due to the difficulty of setting up emergency services in non-official time, an insufficiency of well-

trained endoscopists and medical teams and lack of equipment. Thus, most patients are usually treated medically for a period of time before being referred for EGD at the centers with available facilities.

Some practice guidelines on non-variceal bleeding<sup>[5,6]</sup>, variceal bleeding<sup>[12,13]</sup> including Thai guidelines in 2004<sup>[14]</sup> recommend giving empirical treatments to patients with UGIB while waiting for EGD. If variceal bleeding is suspected, empirical treatment with vasoactive agents (e.g. somatostatin, octreotide, terlipressin, *etc*) is strongly recommended, since they can stop bleeding in up to 70%-80% of cases and a decrease in mortality has been shown with some agents (i.e. terlipressin)<sup>[12,13]</sup>. In contrast, for suspected non-variceal bleeding, empirical treatment with a high-dose proton pump inhibitor is recommended since it reduces the stigmata of recent hemorrhage<sup>[5,15,16]</sup>.

From a clinical viewpoint, to diagnose variceal bleeding precisely and to promptly administer vasoactive drugs to these patients, is crucial because variceal bleeding has a very high early mortality rate of up to 30% and up to 47%-74% of patients will have recurrent bleeding<sup>[12,13]</sup>. To predict which patients have variceal bleeding is not always easy. Some authors have suggested that the clinical signs of cirrhosis or portal hypertension<sup>[17-19]</sup>, painless hematemesis and bleeding with significant change in hemodynamics may indicate variceal bleeding. In contrast, nonsteroidal anti-inflammatory drug (NSAID) users, the presence of dyspepsia or coffee-ground NG aspirate have been suggested to favor non-variceal bleeding<sup>[18,19]</sup>. These suggestions are often expert opinions and have never been formally validated.

The aims of this study are to assess the clinical and basic laboratory parameters which may help differentiate variceal and non-variceal bleeding before performing EGD, to develop a model of the UGIB Etiology Score for predicting the cause of UGIB based on clinical parameters and to validate the accuracy of this suggested score.

## MATERIALS AND METHODS

All consecutive patients who presented with acute UGIB at Siriraj Hospital from June 2006 to December 2007 were prospectively enrolled into the study. Patients who presented in the initial period during June 2006 to December 2006 were included for score derivation purposes and patients who presented in the later period during May 2007 to December 2007 were included for score validation. The inclusion criteria were: 1. UGIB, defined by the presence of hematemesis, melena or hematochezia, and a positive NG tube aspiration for coffee-ground, black or bloody contents 2. EGD within 72 h after the onset of UGIB 3. Patients aged  $\geq 18$  years. An exclusion criterion was patients whose definite cause of UGIB was undetermined or inconclusive during EGD.

### Data collection

Data were collected by gastroenterology fellows at the

time of the patients' presentation. Patients' history included age, gender, appearance of vomitus, (red bloody, coffee-ground, clear), appearance of stool (red or maroon stool, melena, brown or yellow stool), presence of dyspepsia or abdominal pain, underlying cirrhosis, history of previous variceal or non-variceal bleeding within 1 year), comorbid diseases (e.g. acute or chronic kidney diseases, diabetes, hypertension, cardiac diseases, chronic lung diseases, and cerebrovascular diseases, *etc*), history of medications used within 4 wk (i.e. NSAIDS, aspirin, anticoagulants, corticosteroids and alcohol).

Physical examinations included blood pressure at presentation (presence of shock or BP < 90/60 mmHg), heart rate at presentation (presence of tachycardia, HR > 100 beats/min), degree of pallor (marked, mild/moderate, none), findings on NG tube aspiration (red blood, coffee-ground, clear), findings on rectal examination (red or maroon stool, melena, brownish to yellowish stool), the presence of any sign of chronic liver disease (spider angioma, palmar erythema, gynecomastia, testicular atrophy or parotid gland enlargement), epigastric tenderness, ascites, splenomegaly, and hepatic encephalopathy.

Laboratory data included hemoglobin, hematocrit, white blood cell count, platelet count, BUN, creatinine, prothrombin time, and a panel of liver chemistry tests.

### Esophagogastroduodenoscopy

EGD was performed within 72 h of admission in all cases. Causes of bleeding were classified into variceal (esophageal or gastric varices) and non-variceal (e.g. peptic ulcer, erosive gastroduodenitis, reflux esophagitis, tumor, vascular ectasia, *etc*).

### Statistical analysis

Statistical analysis was performed by using SPSS Program version 13.0. Univariate analysis for the associations between clinical parameters and the types of UGIB was carried out using the  $\chi^2$  test or Fisher's exact test for categorical variables and Student's *t*-test for continuous variable data.  $P < 0.05$  was considered statistically significant. Logistic regression analysis to identify independent parameters was performed and is presented with odds ratio and 95% confidence interval.

The UGIB Etiology Score was developed from the parameters derived from the multivariate analysis. The best cutoff of the score was chosen from the receiver operating curve (ROC) and the sensitivity and specificity for predicting the types of UGIB were calculated. The score was then tested in the validation group and the positive (PPV) and negative predictive value (NPV) were calculated.

The present study was approved by the Ethics Committee of Siriraj Hospital.

## RESULTS

There were 261 patients enrolled into the score derivation group, of which 214 patients (82%) had non-variceal

**Table 1** Univariate analysis of clinical parameters of patients with variceal and nonvariceal bleeding *n* (%)

Clinical parameter	Cause of UGIB		<i>P</i>

Coffee-ground or clear	19 (40)	176 (82)	

and 47 (18%) had variceal bleeding according to EGD findings. None had negative or inconclusive causes of UGIB by EGD. The causes of non-variceal bleeding were gastric ulcer (39%), duodenal ulcer (22%), both gastric and duodenal ulcer (9%), erosive gastroduodenitis (12%), GI malignancies (5%), Mallory-Weiss syndrome (3%), reflux esophagitis (2%) and miscellaneous (8%). The causes of variceal bleeding were esophageal varices (89%) and gastric varices (11%). Clinical characteristics and laboratory data of the 2 groups together with the univariate analysis of the associations between these factors and the causes of UGIB are shown in Tables 1 and 2.

### Clinical characteristics

Variceal bleeding occurred significantly more often than non-variceal bleeding in younger patients (mean age 52.7 *vs* 60.8 years). Patients with variceal bleeding commonly presented with red bloody vomitus (60% *vs* 18%), red NG aspirate (60% *vs* 18%), were often previously diagnosed with cirrhosis (36% *vs* 19%), often had signs of chronic liver disease (64% *vs* 15%), splenomegaly (32% *vs* 6%) and hepatic encephalopathy (15% *vs* 5%). Patients with non-variceal UGIB more commonly had comorbid diseases (62% *vs* 28%), a history of ulcerogenic drug use (53% *vs* 21%) and dyspeptic symptoms (21% *vs* 6%) as compared to those with variceal bleeding. Hemodynamic changes (hypotension or tachycardia) at presentation were not significantly different between patients with variceal and non-variceal bleeding.

Eighty-two patients were either previously diagnosed

**Table 2** Univariate analysis of laboratory findings of patients with variceal and nonvariceal UGIB *n* (%)

Laboratory findings	Causes of UGIB		<i>P</i>
	Variceal ( <i>n</i> = 47)	Nonvariceal ( <i>n</i> = 214)	
Hemoglobin, (g/dL)	8.6 ± 2.2	8.5 ± 2.6	0.731
Hematocrit, (%)	25.8 ± 6.3	25.9 ± 7.3	0.965

BUN (mg/dL)	31 ± 18	44 ± 29	0.003
Creatinine (mg/dL)	1.3 ± 0.7	1.6 ± 1.8	0.190
Albumin (g/L)	2.8 ± 0.7	3.2 ± 0.7	0.001
Globulin (g/L)	3.7 ± 0.9	3.2 ± 0.8	< 0.001
Albumin/globulin ratio < 1	38 (81)	83 (45)	< 0.001
Total bilirubin (mg/dL)	4.1 ± 5.8	2.3 ± 5.5	0.054
SGOT (U/L)	133 ± 187	62 ± 107	0.001
> 2 × UNL	25 (53)	36 (20)	< 0.001
SGPT (U/L)	62 ± 76	36 ± 50	0.003
> 2 × UNL	8 (21)	21 (12)	0.359
SGOT/SGPT > 1	43 (92)	132 (75)	0.025
Alkaline phosphatase (U/L)	158 ± 112	115 ± 105	0.015
Prothrombin time (s)	21 ± 11	16 ± 8	0.002
> 12.5 s	44 (94)	58 (29)	< 0.001

UNL: Upper normal limit.

with cirrhosis or had signs of chronic liver disease; however, only 40 (49%) of these patients had variceal bleeding.

### Laboratory findings

Patients with variceal bleeding had lower platelet counts, and albumin level, but more commonly had reverse albumin/globulin ratio (81% *vs* 45%), and higher mean AST and ALT levels (133 *vs* 62 U/L and 62 *vs* 36 U/L, respectively). Prolonged prothrombin time was found in 94% of patients with variceal bleeding as compared to 29% of patients with non-variceal bleeding.

### Multivariate analysis

Multivariate analysis was performed by a stepwise logistic regression analysis. Three factors were found to be independently associated with variceal bleeding; previous diagnosis of cirrhosis or signs of chronic liver disease (OR 22.4, 95% CI 8.3-60.4, *P* < 0.001), red vomitus (OR 4.6, 95% CI 1.8-11.9, *P* = 0.020) and red NG aspirate (OR 3.3, 95% CI 1.3-8.3, *P* = 0.011) as shown in Table 3.

### UGIB Etiology Score

Using the 3 independent factors, the formulation for calculating the UGIB Etiology Score was constructed for the prediction of variceal bleeding. The formulation was as follow:

UGIB Score = (3.1 × previous diagnosis of cirrhosis or the presence of signs of chronic liver disease) + (1.5 × presence of red vomitus) + (1.2 × presence of red NG aspirate).

To calculate the score, a previous diagnosis of cirrhosis or the presence of signs of chronic liver diseases was scored 1 if present and 0 if absent. Red vomitus was

**Table 3** Multivariate analysis showing independent factors associated with variceal bleeding

Parameter	Odds ratio	95% CI	P
Previous diagnosis of cirrhosis or signs of chronic liver disease	22.4	8.3-60.4	< 0.001
Red vomitus	4.6	1.8-11.9	0.020
Red NG aspirate	3.3	1.3-8.3	0.011

**Table 4** Clinical information of patients with variceal and nonvariceal bleeding in the validation group (mean  $\pm$  SD) *n* (%)

Clinical parameter	Cause of UGIB	
	Variceal ( <i>n</i> = 46)	Non-variceal ( <i>n</i> = 149)
Age (yr)	64.51 $\pm$ 16	56.43 $\pm$ 14
Male	31 (67)	76 (51)
Previous diagnosis of cirrhosis or signs of chronic liver disease	35 (76)	12 (8)
Red vomitus	33 (72)	27 (18)
Red NG aspirate	23 (50)	21 (14)

scored 1 if present and 0 if absent. Similarly, red NG aspirate was scored 1 if present and 0 if absent.

Using the receiver operating curve (ROC) in Figure 1, a cutoff  $\geq 3.1$  was chosen as the best cutoff for predicting variceal bleeding. The sensitivity, specificity, accuracy, PPV and NPV for variceal bleeding with this cutoff were 85%, 81%, 82%, 50% and 96%, respectively.

### Validation of the UGIB Etiology Score

The UGIB Etiology score was prospectively validated in another set of 195 patients with UGIB. Forty-six patients had variceal and 149 had non-variceal bleeding. None had negative or inconclusive etiologies of UGIB by EGD. The 3 clinical parameters are shown in Table 4. The PPV and NPV of the UGIB Etiology Score for predicting variceal bleeding in the validation group using the same cutoff of  $\geq 3.1$  were 79% and 97%, respectively.

## DISCUSSION

In the present study, the value of clinical and basic laboratory parameters for predicting the types of UGIB (variceal or non-variceal bleeding) was assessed before endoscopy. The present study differs considerably from other previously published studies on the use of clinical predictors in patients with UGIB, as most studies were aimed at predicting the risk of worst outcome or mortality from UGIB in order to triage patients for appropriate care. These studies similarly demonstrated that clinical parameters (e.g. hemodynamics<sup>[17,20-23]</sup>, comorbid illnesses<sup>[17,20-23]</sup>, NG aspirate<sup>[17,24,25]</sup>, endoscopic findings (stigmata of recent hemorrhage<sup>[17,21-23,26]</sup>, and the presence of varices<sup>[17,21-23]</sup>) were strongly associated with the worst outcome, the need for hospitalization or interventions. Multiple scoring systems in UGIB,

**Figure 1** Receiver operating curve of the UGIB Etiology Score. The best cutoff point is the score  $\geq 3.1$ .

e.g. the Rockall score<sup>[21]</sup>, Baylor bleeding score<sup>[22]</sup>, Blatchford score<sup>[20]</sup>, Cedars-Sinai score<sup>[23]</sup> and other scoring systems<sup>[27]</sup> including a scoring system in Thai patients<sup>[28]</sup> were also developed for these purposes. In contrast, the present study aimed to determine clinical parameters for use in a scoring system to predict the types of UGIB. Results of the present study may help physicians, particularly those in general practice, where emergency EGD is often unavailable, to decide on the type of empiric treatment more accurately, i.e. the use of pharmacological treatments and in some situations, the use of balloon tamponade in cases with a very high likelihood of severe variceal bleeding.

The present study demonstrated that variceal and non-variceal bleeding have many significant distinct features; but only 3 independent factors were able to predict variceal bleeding, i.e. previous diagnosis of cirrhosis or the signs of chronic liver disease, red vomitus, and red NG aspirate. Although these 3 factors are not new findings, our study clearly strengthened and demonstrated the power of these factors. Furthermore, some previously believed predictors, e.g. splenomegaly or thrombocytopenia (for variceal bleeding)<sup>[18,19]</sup> or the presence of dyspepsia (for non-variceal bleeding)<sup>[18,19]</sup> were found not to be useful due to rarity or weak associations. Other factors, particularly the severity of hemodynamic changes at presentation were also found to be an indistinguishable factor.

In the present study, the UGIB Etiology Score was developed from these 3 clinical parameters. Using a cutoff of  $\geq 3.1$ , the UGIB Score was shown to be accurate in predicting variceal bleeding with a sensitivity of 85% and a specificity of 81%. The strength of this study is the accuracy of this score which was validated in another set of patients and consistently gave good results. Although a PPV of 79% is not very high, a NPV of 97% for variceal bleeding is very appropriate in the setting of UGIB where variceal bleeding should never be missed. Therefore, a score  $< 3.1$  will help rule out variceal bleeding with confidence.

Since the cutoff of  $\geq 3.1$  reflected the presence of only one parameter, i.e. previous diagnosis of cirrhosis or the presence of signs of chronic liver disease this may be sufficient to predict variceal bleeding, it may be argued that considering only this parameter might be as accurate as calculating the UGIB Etiology Score. This is probably true; but, considering the other two parameters is also helpful because it increases the PPV of variceal bleeding to 86%-89% with the presence of another parameter and to 96% if all three parameters are present. The latter setting may help physicians to consider balloon tamponade<sup>[12,13,29]</sup> (which carries significant risks) in cases with severe unstable variceal bleeding when emergency EGD is unavailable or vasoactive agents fail.

Although there have been a few studies on UGIB in Thailand<sup>[28,30]</sup>, the present study is the largest prospective study on UGIB in Thailand. The prevalence of variceal bleeding in both study periods was 23%, which was slightly higher than the rate of 6%-14% in the literature<sup>[1]</sup> and might reflect the tertiary care setting of the present study. However, the present study demonstrated that patients with a history of previously diagnosed cirrhosis or the presence of signs of chronic liver disease had an approximately 50% chance of bleeding from varices. These findings are comparable to those from other studies which showed that 50%-60% of cirrhotic patients with UGIB would bleed from varices<sup>[1,31-33]</sup>. Nevertheless, the result of this study and the accuracy of the UGIB Etiology Score should be further validated in other hospitals, where the setting may be different.

In conclusion, the UGIB Etiology Score derived from 3 parameters, using a cutoff  $\geq 3.1$ , may be accurate enough to predict variceal causes of UGIB and may help in guiding the choice of initial therapy for UGIB before endoscopy.

## COMMENTS

### Background

Upper Gastrointestinal Bleeding (UGIB) is classified by etiology into variceal and non-variceal bleeding based on esophagogastroduodenoscopy (EGD) findings. Although emergency EGD is the standard investigation and treatment of UGIB, it is seldom available in most hospitals, particularly in the developing world. Patients are usually treated empirically for some time, while waiting for EGD, with vasoactive agents or acid suppressants based on the clinical suspicion of variceal or non-variceal bleeding, respectively. Therefore, the clinical prediction of which patients have variceal or non-variceal bleeding is critical.

### Research frontiers

Clinical prediction between variceal and non-variceal bleeding has not been extensively studied. Most suggestions have been based on opinions rather than evidence.

### Innovations and breakthroughs

The present study prospectively analyzed the clinical and basic laboratory data which were able to differentiate between variceal and non-variceal bleeding in a group of patients with UGIB. Only 3 independent factors were identified; previous diagnosis of cirrhosis or the presence of signs of chronic liver disease, red vomitus and red NG lavage. The UGIB Etiology Score was constructed and a score cut-off of 3.1 had a fair to good positive predictive value (PPV) but excellent negative predictive value (NPV) to rule out variceal bleeding. The accuracy of the score was also confirmed in another set of patients. The present study differs considerably from most other studies on scoring systems in UGIB which mostly aimed to identify high-risk patients with a poor outcome.

### Applications

The UGIB Etiology Score  $\geq 3.1$  had fair to good PPV for variceal bleeding;

thus, it can allow physicians to initiate vasoactive agents for variceal bleeding, while a score  $< 3.1$  helped to rule out variceal bleeding with confidence. The presence of all 3 factors or a score of 5.8 indicated variceal bleeding and may be enough for physicians to consider balloon tamponade if bleeding is severe, EGD is unavailable or vasoactive agents fail.

### Terminology

Variceal bleeding is UGIB caused by esophageal or gastric varices. Non-variceal bleeding is caused by any etiology of UGIB other than varices.

### Peer review

This is a nicely performed study aiming to develop and validate a scoring system for predicting variceal vs non-variceal bleeding. The steadily high NPV of the score makes the developed scoring system accurate in excluding variceal bleeding.

### Abstract

**AIM:** To investigate the changing pattern of different histological parameters occurring in the stomach tissue of *Helicobacter pylori* (*H pylori*) infected tribal populations and duodenal ulcer patients among ethnic Bengalis and correlation of the genotypes of *H pylori* with different histological parameters.

**METHODS:** One hundred and twelve adult individuals

were enrolled into this study between 2002 and 2004. Among them, 72 had clinical features of duodenal ulcer (DU) from ethnic Bengali population and 40 were asymptomatic ethnic tribals. Endoscopic gastric biopsy samples were processed for histology, genotyping and rapid urease test. Histologically, haematoxylin and eosin staining was applied to assess the pathomorphological changes and a modified Giemsa staining was used for better detection of *H pylori*. For intestinal metaplasia, special stainings, i.e. Alcian blue periodic acid-Schiff and high iron diamine-Alcian blue staining, were performed. PCR was performed on bacterial DNA to characterize the presence or absence of virulence-associated genes, like *cagA*, and distribution of different alleles of *vacA* and *iceA*.

**RESULTS:** Intraglandular neutrophil infiltration, a hallmark of activity of gastritis, was present in 34 (94%) of tribals (TRs) and 42 (84%) of DU individuals infected with *H pylori*. Lymphoid follicles and aggregates, which are important landmarks in *H pylori* infection, were positive amongst 15 (41%) of TRs and 20 (40%) of DU subjects. Atrophic changes were observed in 60% and 27.7%, respectively, among DU cases and tribals ( $P > 0.003$ ). Metaplastic changes were detected in low numbers in both groups. Moderate to severe density distribution of *H pylori* in the gastric mucosa was 63% among TRs, whereas it was 62% in DU subjects. There were no significant differences in the distribution of virulence-associated genes like *cagA*, *vacA* and *iceA* of *H pylori* strains carried by these two populations.

**CONCLUSION:** Our study showed almost similar distribution of inflammatory cells among asymptomatic tribals and DU Bengali patients. Interestingly, the tribal population are free from any clinical symptoms despite evidence of active histologic gastritis and infection with *H pylori* strains carrying similar virulence markers as of strains isolated from patients with DU. There was an increased cellular response, especially in terms of neutrophil infiltration, but much lower risk of developing atrophy and metaplastic changes among the tribal population.

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is of growing concern today because of its crucial role in the pathogenesis of chronic gastritis, peptic ulcer diseases and in the multi-step carcinogenic process of gastric cancer<sup>[1]</sup>. In developing countries, 70%-90% of the population carries *H. pylori* and develop persistent inflammation in their stomachs, which lasts for decades unless treated with antibiotics<sup>[2]</sup>. About 60%-95% of peptic ulcer diseases are thought to be idiopathic and it is now well established that *H. pylori* is the causative agent of nearly all of these cases in adults. In addition, almost all *H. pylori* infected individuals develop gastritis<sup>[3]</sup>. Severe gastritis is believed to be the denominator of peptic ulcer diseases and atrophic gastritis, which may lead to gastric cancer<sup>[4,5]</sup>. However, it is not clear why a few strains are associated with ulcer formation with relevant clinical symptoms, while others are not associated with any disease manifestation.

*H. pylori* is one of the most genetically diverse of bacterial species, with any given isolate easily distinguished from most others by DNA fingerprinting. Only one-half to two-thirds of US and European strains carry the *cag* pathogenicity island (*cag* PAI) and such strains are recovered preferentially from persons with overt disease. In contrast, nearly all-Asian strains carry the *cag* PAI, independent of disease status. Potentially more significant in terms of host interaction and evolution were the findings that East Asian and Western strains differ markedly in DNA sequence motifs in the *vacA* and *cagA* genes. We have previously reported that sequences of the *cagA* gene in Indian strains show a close match with ethnic European strains, but are distinct from East Asian strains. On the other hand, DNA sequence motifs of an informative middle region of *vacA* gene from Indian *H. pylori* strains are distinct both from European and East Asian strains. So, there are strong indications of significant geographic differences among strains<sup>[6,7]</sup>.

Moreover, gastric cancer is more prevalent in Japan and China than any other parts of the world and duodenal ulcer is more common in India as compared to

gastric ulcer. The distribution and the nature of gastritis are, thus, major determinants of clinical outcome of *H. pylori* infection. It is, therefore, important to understand the dynamics of gastritis associated with this infection in developing countries like India, where *H. pylori* infection is highly prevalent and *H. pylori* is acquired early in life. Surprisingly, even the healthy individuals in India carry the toxigenic *vacA* s1, *vacA* m1 alleles and *cag*-PAI<sup>[8]</sup>. However, previous reports do not indicate whether this lack of disease association with putative virulent *H. pylori* strains is due to a lesser bacterial load in gastric mucosa leading to insignificant level of epithelial injury.

Santhals and Oroans are two distinct ethnic tribal groups that had settled in the Birbhum district of West Bengal centuries ago<sup>[7]</sup>. They constitute less than 5% of the overall population of West Bengal (Census of India, 2001). Ethnically, Santhals are proto-Australoids and speak the Santhali dialect of the Austro-Asiatic language family, while the Oroans are ethnically Dravidian and speak the Khurukh dialect of the Dravidian linguistic family. That is, the two lineages to which they belong have been distinct for millennia. In contrast, the ethnic Bengalis have an Indo-European ancestry, and their Bengali language is derived from Sanskrit. Traditionally, both Santhals and Oroans have been hunters-gatherers, but most have now become settled as agriculturists. Nevertheless, they remain culturally and linguistically distinct from most of Indian society and rarely intermarry with people of other ethnicities. Their separation from mainstream Bengalis and other Indians during much of human history is reflected in genetic differences in autosomal and mitochondrial DNA markers. Our previous study<sup>[7]</sup> showed that the majority of these tribal communities are infected with *H. pylori*; but, interestingly, none of them shows any symptoms. On the other hand, duodenal ulcer, which is *H. pylori*-associated, is of particular importance in ethnic Bengali populations and is far more common than in most other geographic regions<sup>[9]</sup>.

These considerations and our interest in the dynamics of gastritis associated with this infection motivated the present study. We wanted to investigate the changing pattern of different histological parameters occurring in the stomach tissue of *H. pylori*-infected tribal populations and duodenal ulcer patients among ethnic Bengalis. Our aim was to get insights of the cause for the near absence of *H. pylori*-associated overt disease in these tribal populations and to correlate the *H. pylori* genotypes with the different histological findings.

## MATERIALS AND METHODS

A total of 112 adult mainstream Bengali and ethnic tribal individuals (72 Bengalis and 40 tribals) of both sexes (aged between 20-65 years) underwent a non-sedated upper gastrointestinal endoscopy (GIF XQ 30, Olympus optical company, Japan) under topical lignocaine anesthesia at the hospital of the Institute of Post Graduate Medical Education and Research,

Kolkata, India, throughout the years 2002-2004. Out of 72 suspected duodenal ulcer (DU) cases, the mean age of 43 males and 29 females was  $45 \pm 11.72$  and  $42.7 \pm 9.16$ , respectively. Among 40 tribals, the mean age of 24 males and 16 females was  $31.4 \pm 6.22$  and  $32.13 \pm 6.44$ , respectively. Seventy-two Bengali patients were chosen for endoscopy from individuals with abdominal pain seeking care at outpatient department as possible DU patients and for comparative analysis, 40 asymptomatic individuals from tribal (TR) population (Santhals and Orans) were recruited. A detailed history was taken, and a physical examination of each subject was carried out prior to endoscopy. The objectives of the study were explained to all. Informed consents were obtained from each individual under protocols approved by the institutional ethical committees of the Post-Graduate Medical Education and Research and National Institute of Cholera and Enteric Diseases, Kolkata, West Bengal, India. None of these asymptomatic individuals reported to have any gastro-duodenal discomfort. Exclusion criteria were: use of antibiotics, antihistamines and proton pump inhibitors during the three months prior to this study. From each participant, four biopsies were obtained, three from the antrum and one from the fundus. Of the three antral biopsy specimens, one was used for an in-house rapid urease test (RUT), one for culture and the third one, along with one biopsy from the fundus, was processed for histologic examination.

### Culture of *H pylori*

Biopsies for culture were taken in 1 mL of brucella broth (Difco) containing 15% glycerol and transported to the National Institute of Cholera and enteric Diseases in ice-cold condition. Biopsy samples in transport medium were vortexed vigorously for 2 min and 200  $\mu$ L of the broth were streaked on brain heart infusion (BHI) agar (Difco) enriched with 7% sheep blood, 0.4% IsovitaleX and *H pylori* selective supplement-Dent (Oxoid, Basingstoke, Hampshire, England). Plates were incubated at 37°C in double-gassed incubator, which maintains 10% CO<sub>2</sub>, 5% O<sub>2</sub> and 85% N<sub>2</sub> for 3-6 d. The organisms were identified by their typical colony morphology, appearance on Gram staining and positive reactions in urease, catalase and oxidase tests.

### Characterization of *H pylori* strains by PCR

A modification of the method of Murray and Thompson<sup>[10]</sup> was used for *H pylori* genomic DNA extraction. In brief, cells from a confluent lawn of bacterial culture on BHI agar plate were collected and resuspended in TE buffer (10 mmol/L Tris-HCl, 1 mmol/L EDTA, pH 8.0), treated with 10% SDS and freshly prepared proteinase K and incubated at 37°C for 1 h. After incubation, CTAB/NaCl (10% cetyl trimethyl ammonium bromide in 0.7 mol/L NaCl) was added and incubated at 65°C for 10 min. The aqueous phase was then treated with phenol-chloroform and DNA pellet was washed with 70% ethanol. The nucleic acid was suspended in TE and treated with RNase at 37°C for 30 min. Specific PCR was carried out in 20 mL volumes using 10 ng of DNA, 1 U of *Taq* polymerase (Promega, Madison, Wis.), 10 pmol of each primer per reaction, 0.25 mmol/L (each) deoxynucleoside triphosphate, and 2 to 3 mmol/L MgCl<sub>2</sub> in standard PCR buffer for 30 cycles generally under the following conditions: 94°C for 40 s, 55°C for 40 s, and 72°C for a time chosen based on the size of the expected fragment (1 min/kb). The primers are listed in Table 1.

### Histology

One biopsy from antrum and one from fundus of the stomach were fixed in 10% buffered formalin overnight, dehydrated in graded series of alcohol and xylene and were processed for paraffin embedding. Serial thin (3-4  $\mu$ m) sections were cut by Rotary microtome (Leica 2145, Germany) and stained with haematoxylin and eosin (H&E) stain to see the morphological changes. For better visualization of *H pylori*, modified Giemsa stain was done in all the cases along with H&E stain, as the sensitivity and specificity of this added stain exceeds 90%<sup>[11]</sup>.

The histologic changes and grading were done according to updated Sydney system<sup>[12]</sup>. All the biopsy specimens were number-coded and examined by a single pathologist who was unaware of the result of the other tests while examining the slides. *H pylori* in the biopsy specimens was looked for carefully and then the bacterial density was measured as it may have an impact on disease association and epidemiologic importance.

**Table 2** Histological changes of gastric mucosa among *H pylori* associated symptomatic duodenal ulcer (DU) and asymptomatic tribal (TR) individuals *n* (%)

	Symptomatic DU ( <i>n</i> = 50)	Asymptomatic TR ( <i>n</i> = 36)	<i>P</i> -values	OR (95% CI)
Neutrophil infiltration	42 (84)	34 (94.4)	0.124	3.24 (0.57-23.76)
Lymphoid follicle/aggregates	20 (40)	15 (41.7)	0.876	1.07 (0.41-2.80)
Atrophy	30 (60)	10 (27.7)	0.003 <sup>1</sup>	0.26 (0.10-2.67)
Metaplasia	7 (14)	3 (8.3)	0.325	0.56 (0.10-2.67)

<sup>1</sup>Indicates statistically significant *P*-value.

*H pylori* was measured in the modified Giemsa stained sections by counting the *H pylori* like organisms on the mucosal surface and in the foveolae<sup>[13]</sup>. In brief, bacterial density was measured by comparing the histologic presence of bacteria on the gastric surface epithelium using the visual analogue scale. Severe colonization was defined as the presence of large groups of organisms on the surface and upper pits of more than 2/3rd of the mucosal surface examined. Mild colonization was defined as individual organisms or small groups covering less than 1/3rd of the mucosal surface. Moderate colonization was between these two.

Chronic gastritis, activity, atrophy and *H pylori* density were scored as 0 (absent), 1 (mild), 2 (moderate) and 3 (severe). Intestinal metaplasia and lymphoid follicles/aggregates were graded as 0 (absent) or 1 (present). If antral and fundal biopsy sites showed different grades for any variable, the higher score was used. Intestinal metaplasia was classified as type 1, 11 or 111 by Alcian blue periodic acid-Schiff (AB-PAS) and high iron diamine-Alcian blue (HID-AB) staining.

## RESULTS

Among 112 individuals included in the study, 72 had clinical features of DU from ethnic Bengali population and 40 were asymptomatic ethnic tribals. In 50 out of 72 (69%) DU and 36 out of 40 (90%) TR subjects, evidence of *H pylori* infection was evaluated by three methods (RUT, histology and culture) and was included in further study. All of these subjects had evidence of chronic gastritis. A grade from 0 (absent) to 3 (severe) was assigned for five histological parameters, i.e. inflammation (chronic inflammatory cells), activity (neutrophils), glandular atrophy, intestinal metaplasia and *H pylori* density, and the grading was done according to the Sydney system<sup>[12]</sup>.

### Histology

Histologically active chronic gastritis was detected in 34 (94%) TRs and 42 (84%) DU patients (all from antral sites), whereas 30 TRs and 38 DU subjects showed evidence of chronic active gastritis from fundic sites. Intestinal metaplasia was detected in 3 (8.3%) TRs and 7 (14%) DU cases-all from antral sites of biopsy specimens (Table 2). No metaplastic changes were detected at fundic sites. For ease of the correlative analysis of the histological findings with genotypes, only antral biopsy specimens were evaluated further.

### Cellular infiltration and epithelial changes in gastric mucosa

Gastritis is characterized by lymphocytes, plasma cells and scattered polymorphonuclear leucocytes (PMNs) in gastric mucosa. Chronicity or persistent infection was a common feature in all of our study subjects. Chronic gastritis was evident histologically by the presence of inflammatory infiltrates, which was essentially made up of mononuclear cells like macrophages, lymphocytes and plasma cells. Intraglandular neutrophil infiltration, a hallmark of activity of gastritis was present in 34 (94%) of TRs and 42 (84%) of DU individuals infected with single strain of *H pylori*. Neutrophil infiltration inside glandular epithelium and in the lamina propria of a DU and a TR case are shown in Figure 1A and B, respectively.

Mucus depletion, derangement of normal cellular architecture and foveolar hyperplasia with erosion were noted among TRs; but, frank ulceration in the gastric surface mucosa was not detected. Among most of the DU cases, ulceration, haemorrhage with exudation, loss of surface epithelium at places and atrophic changes were the frequent findings.

### Lymphoid follicle/aggregates

Lymphoid follicles and aggregates were examined carefully as the positivity of this parameter is almost pathognomic of *H pylori* infection and the follicles/aggregates were positive amongst 15 (41%) of TRs and 20 (40%) of DU subjects. An almost comparable distribution pattern of lymphoid follicles/aggregates was present among DU patients and the tribal population. Mononuclear cells infiltration in the lamina propria with lymphoid follicle in a DU and lymphoid aggregate in a TR case has been represented in Figure 2A-B.

### Atrophy and metaplasia

Atrophic changes among 50 DU patients were detected in 30 (60%) cases, where mild form of atrophy was present in 18 (36%) and a moderate form of atrophy was found in 12 (24%). Among 36 asymptomatic TRs, atrophic changes were identified in 10 (27.7%), where 7 (19.4%) showed mild form of atrophy and 3 (8.3%) showed moderate form of atrophy. Although the incidence of active gastritis was quite high, especially among tribals, atrophy and metaplastic changes in the gastric mucosa were much rarer than in the urban DU patients. Metaplasia was recognized morphologically by the presence of goblet cells, absorptive cells and cells resembling colonocytes in the surface epithelium and

A: Metaplastic changes with goblet cells in glands (B) and surface epithelium of gastric mucosa (A)-DU (HE, × 200); B: Metaplastic cells replacing the normal gastric epithelium in glands (B) and surface mucosal epithelium (A)-TR (HE, × 200).

**Figure 2** Mononuclear cells, lymphoid follicles and aggregates in DU and TR. A: Arrow indicates mononuclear cells in lamina propria with a lymphoid follicle in DU (HE, × 200); B: Arrow indicates mononuclear cells in lamina propria with lymphoid aggregate in TR (HE, × 200).

glands of the gastric mucosa and (Type 1) or complete

type of intestinal metaplasia (Figure 3A-B) were detected in 3 TRs (8.3%) and 7 DU (14%) subjects (Table 2).

#### *H pylori* density

Moderate to severe density distribution of *H pylori* at the surface and in the pits of the gastric mucosa was found in 63% of TRs and in 62% of DU subjects.

#### Genotyping of *H pylori* strains

The presence or absence of the *cag* PAI was scored by PCR with specific primers using DNA extracted from cultured strains. As shown in Table 3, a 350-bp product indicative of the *cag* PAI was obtained with primers specific for the *cagA* gene from each of the 36 strains in tribal population. None yielded a 550-bp product expected of a *cag* empty site, which would indicate complete absence of the *cag* PAI. On the other hand, in the symptomatic Bengali population, all yielded band specific for *cagA* gene and three cases also produced a 550-bp product for *cag* PAI empty site indicating that these patients had mixed infections with both *cagA* positive and negative strains. The presence of potentially toxigenic *vacAs1* versus nontoxigenic *vacAs2* alleles at the 5' end of *vacA* was determined based on sizes of PCR products (259 bp versus 286 bp, respectively) generated with *vacAs* region-specific primers. All 36 tribal strains yielded a 259-bp fragment, indicating that they carried s1 alleles; no s2 alleles were found; but, in the Bengali population, three strains produced both s1 and s2 fragment whereas the rest produced a s1 fragment. The alleles of the

**Table 3** Genotypes of *H pylori* strains from duodenal ulcer (DU) and tribal (TR) subjects

Genotype	No. (%) of strain from	
	DU patients (n = 50)	TRs (n = 36)
<i>cagA</i> positive only	47 (94)	36 (100)
<i>cagA</i> negative only	1 (2)	0 (0)
Both <i>cagA</i> <sup>+</sup> and <i>cagA</i> <sup>-</sup>	2 (4)	0 (0)
<i>vacA</i> s1 only	47 (94)	36 (100)
<i>vacA</i> s2 only	1 (2)	0 (0)
<i>vacA</i> s1 and s2 mixed	2 (4)	0 (0)
<i>vacA</i> m1 only	31 (62)	26 (72.2)
<i>vacA</i> m2 only	17 (34)	7 (19.4)
<i>vacA</i> m1 and m2 mixed	2 (4)	3 (8.3)
<i>iceA</i> 1 only	29 (58)	15 (41.7)
<i>iceA</i> 2 only	18 (36)	14 (38.9)
<i>iceA</i> 1 and <i>iceA</i> 2 mixed	3 (6)	7 (19.4)

*vacA* middle(m) region, which determines the cell type specificity of the vacuolating cytotoxin action, were also studied by PCR. Products were obtained only with *vacA* m1 primers in 26 of 36 tribal strains, only with *vacA* m2 primers in seven strains and with both m1 and m2 primers in three strains, indicating a mixed infection. Among the 50 Bengali strains, 31 were positive for m1 while 17 strains had the m2 allele alone and the remaining two had both alleles. PCR was used to test for *iceA1*, which is virulence-associated in some populations, and the completely unrelated *iceA2* gene, which occupies the same chromosomal locus in strains lacking *iceA1*. The *iceA1* gene was found alone in 15 of 36 tribal cultures, *iceA2* was found alone in 14 strains, and a mixture of *iceA1* and *iceA2* alleles (again, indicating mixed infection) was found in seven tribal cultures (Table 3). Among strains isolated from Bengali DU patients, *iceA1* and *iceA2* were found in 29 and 18 cases, respectively whereas *iceA1-iceA2* mixed infections were found in 3 cases. Genotyping results from this study and sequence-based analysis from a previous study<sup>[7]</sup> clearly indicated that tribal strains are closely matched to those of mainstream Bengalis.

### Statistical analysis

$\chi^2$  test was employed to compare the histological parameters between symptomatic and asymptomatic subjects to know the status of few important histological parameters like neutrophil infiltration, lymphoid follicle/aggregates formation and atrophy and metaplastic changes. Neutrophil infiltration was almost three times higher in the asymptomatic tribal population compared to urban DU cases, although the difference was not statistically significant. Regarding the atrophic and metaplastic changes, DU subjects were 4 and 2 times at higher risk of developing further disease process than TRs. Atrophic changes among DU cases were statistically significant (Table 2). Genotyping of *H pylori* strains between DU and TRs were not found statistically significant (Table 3).

## DISCUSSION

*H pylori* infection is common in the Santhal and Oroan

ethnic minorities of West Bengal, whereas symptomatic individuals with *H pylori*-associated disease are rare in these populations, even though the genotypes of the strains they carry are similar to those for mainstream Bengalis. The near-universality of *H pylori* infection can be ascribed to relatively low levels of sanitation, hygiene and education, conditions that contribute to a high risk of infection and superinfection, even in adulthood. Hence, although both the tribal communities and Bengali urban population are infected with *H pylori* with similar genetic make-up, there is a distinct difference regarding the manifestation of the disease. This enigma was previously explained, mostly in Western countries, by reporting the association of certain virulence alleles (*vacAs1*, *cagA* and *iceA1*) with the *H pylori*-related disease where around 50% of the *H pylori* strains lack the *cagPAI*. However, this view needs to be reexamined since in the Asian context an overt disease association with these alleles does not exist<sup>[6-8]</sup>. The present study investigated the histologic findings observed in gastric mucosa of *H pylori*-infected asymptomatic TRs and urban DU subjects (which prevail only in Bengali population, but not in the tribal population) to understand the cause for near absence of *H pylori* associated overt disease in these tribal populations and correlation of the genotypes of *H pylori* with different histological parameters.

Bacterial density is directly related to inflammation in terms of neutrophil, lymphocytes and plasma cell infiltration of the gastric mucosa and we also noticed moderate to severe degree infiltration of the bacteria in the gastric mucosa<sup>[14-16]</sup>, where inflammatory cells were a marked feature. *H pylori*-positive biopsy samples were mostly inflamed with chronic superficial gastritis and the inflammatory cells were mononuclear cells with neutrophil infiltration in the epithelium. The amount of inflammation was highly variable, ranging from minimal infiltration in the lamina propria with intact glandular architecture to severe dense inflammation. Mononuclear cells, consisting mainly of macrophages, lymphocytes and plasma cells, were present to a variable degree in all the study cases, indicating a chronic infection among asymptomatic TRs as well as in DU patients. The presence of PMNs signifying 'a sign of activity' was more pronounced among the tribal population (94%) than DU patients (84%). It may be due to the host immune response against bacteria among tribals, which are stronger. Tribals are less exposed to environmental pollution and hazardous agents and as PMNs are the first line of defense against bacteria, increased cellularity and more active gastritis is well reflected in our study in *H pylori* infection.

A *H pylori* infection with a longer duration leads to loss of gastric glands and development of multifocal atrophic gastritis, which is often accompanied by intestinal metaplasia. In our study population, although the *H pylori*-associated gastritis as well as its activity is quite high among TRs, atrophic changes and the incidence of metaplasia were lower than in DU patients. One of the characteristics of *H pylori* infection is the growth of lymphoid follicles/aggregates. Here, 41% of

the biopsy specimens were positive for lymphoid follicles and aggregates in TRs and a comparable proportion (40%) was found among DU subjects, although we did not encounter any case associated with lymphoma. In a study conducted by Eidt and Stolte, lymphoid follicles or aggregates were detected in 54% of *H pylori* infected cases<sup>[17]</sup>, which is higher compared to our data.

It is now well accepted that peptic ulcer diseases have an etiologic link with *H pylori*; but, not every individual infected by this micro-organism develops the disease clinically<sup>[18,19]</sup>. The actual element responsible for the pathogenesis of *H pylori* is yet to be determined. The cytotoxin associated gene *cagA* has been related to ulcerogenicity<sup>[20]</sup>. The genes in the *cag* pathogenicity island are supposed to induce epithelial cells to release interleukin-8 production. This, together with other interleukins, attracts neutrophils, which migrate from capillaries through the lamina propria, and emerge between the epithelial cells. However, in our study, *cagA* was present in TRs as frequently as in DU. Consistent to this finding, polymorphonuclear activity was detected in 97% cases *cagA*-positive TRs, and 95% *cagA*-positive DU subjects, which was quite a high proportion. Correlating the histologic findings of gastritis with the genotypes, like *iceA*, or combination of *iceA*, *vacA* and *cagA*, no particular allelic mosaicism could be identified as responsible for neutrophil and mononuclear cell infiltration, formation of lymphoid follicles and aggregates, atrophic and metaplastic changes and the successive disease outcome. This is in consistent with the findings of few earlier reports<sup>[21,22]</sup>.

An apparent correlation has still to be detected between the different genetic features of *H pylori* strains and the histologic findings of the disease outcome. When the histological changes, such as the presence of neutrophil infiltration, the activity of gastritis, the mononuclear and lymphoid follicle/aggregate formation, the atrophy and the metaplastic changes, were evaluated with respect to the genotypes of the strains of *H pylori*, the differences between the Bengali ethnic duodenal ulcer patients and the tribal population were not statistically significant, except for the atrophy. However, a few observations in our study are interesting: (a) the almost similar distribution of inflammatory cells among asymptomatic TRs and DU cases; (b) the fact that, in spite of the evidence of active histologic gastritis, tribal groups were free from any clinical symptoms; (c) the increased cellular response, especially in terms of neutrophil infiltration, but much lower risk of developing atrophy and metaplastic changes among the tribal population.

Finally, the present study suggests that, on average, *H pylori* infections are less virulent in these ethnic minorities than in mainstream Indians. Such lack of virulence might be due to subtle features of bacterial strains or aspects of the human host environment. Thus, the bacterial genotype, host genetic factors and environmental factors, all may have important influence in the disease outcome of *H pylori* infected people. At least two reports of decreased virulence apparently being selected *in vivo* have appeared: one during human infection<sup>[23]</sup> and another during adaptation of human

strains to mice<sup>[24]</sup>. Lack of virulence might also reflect features of the host. One possibility entails concurrent infection with particular parasites that may down-regulate inflammatory responses to infection, as it has been documented in a mouse infection model<sup>[25]</sup>. Resistance to pathogenic effects of putatively virulent *H pylori* strains might also be determined by features of human host genotype<sup>[26-27]</sup>. It will be interesting to study why tribal groups are free from any clinical symptoms in spite of evidence of active histologic gastritis and also to identify the host factors that may provide immunity against the pathogenic effects of putatively virulent *H pylori* strains. Such kind of studies may uncover new genetic factor/factors that affect human infection, increase our understanding of bacterium-host interactions in colonization and disease, and provide new insights into the evolution of this diverse and globally distributed human pathogen.

## COMMENTS

### Background

*Helicobacter pylori* (*H pylori*) infection and duodenal ulcer disease is common among ethnic Bengali population in West Bengal, India. In contrast, although *H pylori* infection is equally or more common in the ethnic tribal minorities (Santhals and Orans) of West Bengal, symptomatic disease is extremely rare. This study addresses different histological parameters occurring in the stomach tissue of *H pylori*-infected tribal populations and duodenal ulcer patients among ethnic Bengalis for getting insights of the cause for the near-absence of *H pylori*-associated overt disease in these tribal populations and correlate the *H pylori* genotypes with different histological parameters.

### Research frontiers

Although both the tribal communities and Bengali urban population are infected with *H pylori* with similar genetic make-up, there is a distinct difference regarding the manifestation of the disease. When the histological changes, such as the presence of neutrophil infiltration, the activity of gastritis, the mononuclear and lymphoid follicle/aggregate formation, the atrophy and the metaplastic changes, were evaluated with respect to the genotypes of the strains of *H pylori*, the differences between the Bengali ethnic duodenal ulcer patients and the tribal population were not statistically significant, except for the atrophy.

### Innovations and breakthroughs

The most interesting observations in the study are: (1) the almost similar distribution of inflammatory cells among asymptomatic tribals and duodenal ulcer patients from Bengali population in Kolkata, (2) the fact that, in spite of evidence of active histologic gastritis, tribal groups were free from any clinical symptoms; and (3) the increased cellular response, especially in terms of neutrophil infiltration, but much lower risk of developing atrophy and metaplastic changes among the tribal population.

### Applications

The apparent lack of virulence in the tribal group might reflect features of the host. The study raised two important issues: (1) why are tribal groups free from any clinical symptoms, in spite of evidence of active histologic gastritis, and (2) the need to identify the host factors (in tribal patients) that may provide immunity against the pathogenic effects of putatively virulent *H pylori* strains. Such kind of studies may uncover new genetic factor/factors that affect human infection, increase our understanding of bacterium-host interactions in colonization and disease.

### Peer review

This article investigated the changing pattern of different histological parameters in the stomach tissue of *H pylori* infected populations. The paper is well written and their results are reliable.

function. These rats showed a significant decrease in liver GSH, as well as a significant increase in TNF- $\alpha$  and IL-10 concentrations. These results demonstrated that renal ischemia caused changes in liver histology, function, oxidative stress and inflammatory status, which led to a reduction in hepatic antioxidant capacity. With 30 min ischemia, the magnitude of these changes was less than those with 45 or 60 min ischemia.

**CONCLUSION:** A minimum of 45 min ischemia is needed to study the effects of renal injury on the liver as a remote organ.

### Abstract

**AIM:** To assess the hepatic changes after induction of different periods of renal ischemia.

**METHODS:** Rats were subjected to either sham operation or ischemia (30, 45 and 60 min) followed by 60 min reperfusion. Liver and renal functional indices were measured. Hepatic glutathione (GSH) and ferric reducing antioxidant power levels and the concentration of interleukin (IL)-10 and tumor necrosis factor (TNF- $\alpha$ ) were evaluated. Portions of liver and kidney tissues were fixed for histological evaluation.

**RESULTS:** Forty-five minutes renal ischemia followed by 60 min reperfusion caused significant changes in liver structure and a significant reduction in renal

### INTRODUCTION

Liver and kidney are both involved in the regulation of body homeostatic responses, metabolism and excretion of drugs and toxic products. Recent studies have suggested cross-talk between the liver and kidneys. Ischemia/reperfusion (I/R)-induced local response in kidney tissue has been well documented in a number of studies<sup>[1,2]</sup>. However, remote effects of renal I/R injury on the liver need further investigation. Renal injury associated with liver disease is an extensively encountered clinical problem of varied etiology and high mortality. I/R injury induces an inflammatory response, which results in the formation of reactive oxygen species (ROS) that augments local tissue damage or affects organs remote from the site of I/R. An important function of ROS is the regulation of cytokine gene expression<sup>[3]</sup>.

In 2002, Miyazawa *et al*<sup>[4]</sup> showed an influx of neutrophils and lymphocytes, not only in the clamped kidney, but also in the hepatic sinusoids concomitantly with liver dysfunction. These findings indicate that a systemic cellular immune response, including intermediate T cells, affects multiple organs during ischemic acute renal failure (ARF), which may play an important role in the development of multi-organ failure. Since the liver tissue represents one of the vascular beds into which ROS are delivered, it would be likely to manifest a number of toxic effects of these molecules. It has been suggested that dehydroepiandrosterone treatment has a beneficial effect on antioxidant defenses against hepatic injury after renal I/R in rabbits, possibly by augmenting glutathione (GSH) levels and lowering malondialdehyde (MDA) production<sup>[5]</sup>.

Kielar *et al*<sup>[6]</sup> have evaluated the extrarenal regulation of ARF. This regulation may be as a result of increased production of cytokines such as tumor necrosis factor (TNF)- $\alpha$  and growth factors such as hepatocyte growth factor (HGF) produced by extrarenal organs<sup>[7]</sup>. In addition, there is an inflammatory response to renal ischemia that results in secondary injury<sup>[8]</sup>. Further more, renal ischemia results in increased interleukin (IL)-6 mRNA expression<sup>[9]</sup>, renal production of IL-6, and expression of IL-10 receptors. IL-6 stimulates the production of IL-10 by the liver, which might ameliorate renal injury.

The question remaining is to what extent the renal damage affects the liver, although the liver function itself may enhance or reduce the extent of renal damage. It has been suggested that, while liver disease may alter the course of renal injury, exogenous administration of regulatory factors produced by extrarenal organs may play a therapeutic role in ARF<sup>[6,10]</sup>. Thus, the aim of the present study was to examine the effects of different periods of renal ischemia on rat liver function, histology, cytokine levels and antioxidant status.

## MATERIALS AND METHODS

### Surgical procedure

Twenty male Sprague-Dawley rats weighing 250–300 g were included in this study and randomly assigned into one of the four experimental groups ( $n = 5$ ): (1) sham-operated; (2) 30 min ischemia, 60 min reperfusion; (3) 45 min ischemia, 60 min reperfusion; and (4) 60 min ischemia, 60 min reperfusion.

Rats were placed on a warming pad and anesthetized with pentobarbital sodium (60 mg/kg ip, followed by 6 mg/kg per hour iv). Body temperature was maintained at  $37 \pm 1^\circ\text{C}$ . A tracheotomy was performed to facilitate free breathing. The right femoral artery was cannulated and connected to a pressure transducer for mean arterial pressure measurement. The tail vein was cannulated for infusion of 0.9% (9 g/L) NaCl solution. A midline laparotomy was performed and the renal arteries were carefully separated from around the tissues. After completion of the surgery, rats were allowed to stabilize for 30 min.

In the I/R groups, renal arteries were occluded by a non-traumatic micro-vascular clips for 30, 45 and 60 min, followed by 1 h reperfusion. Occlusion was approved visually by color change of the kidney to a paler shade and reperfusion by blushing. Sham-operated animals underwent identical surgical treatment, including isolation of both renal arteries. However, artery occlusion was not performed. At the end of the experimental procedure, serum was collected for determination of blood urea nitrogen (BUN) and creatinine. Kidney and liver tissues were removed and prepared for future analysis.

### Measurement of arterial blood pressure

Arterial blood pressure and heart rate were continuously monitored *via* a femoral artery cannula that was connected to a pressure transducer device. The transducer was connected to a PowerLab/4SP data acquisition system (AD Instruments).

### Biochemical assay

Blood concentration of creatinine, BUN, alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined by commercially available kits.

### Histological procedures

After formalin fixation (10% phosphate-buffered) and dehydration, paraffin-embedded renal and hepatic sections (4  $\mu\text{m}$ ) were stained by hematoxylin and eosin. Histopathology for all tissues was evaluated per section in at least 10 randomly selected non-overlapping fields at  $\times 400$  magnification of the sections. Kidney tissues were evaluated for the presence of congestion. Tubules were evaluated for the presence of degenerative changes (vacuolization), tubular dilatation, luminal debris and cast formation, and loss of brush borders from proximal tubules. Liver sections were evaluated for the presence of congestion, cellular degenerative changes, cytoplasmic vacuolization and leukocyte infiltration.

### Tissue homogenization

A portion of each liver was homogenized in KCl buffer (pH 7.4) for ferric reducing antioxidant power (FRAP) assay and in TCA for GSH assay. After centrifugation for 30 min, the supernatants were removed and subjected to analysis.

### GSH assay

Liver GSH was assayed according to the Tietz method. 5, 5'-Dithiobis 2-nitrobenzoic acid was used as a chromogen and the absorbance of the reduced chromogen was measured at 412 nm. The value for each sample was extracted from the standard curve.

### Measurement of ferric reducing ability of liver (FRAP)

FRAP assay was performed according to the method of Benzie and Strain (1996)<sup>[11]</sup>. Briefly, 50  $\mu\text{L}$  supernatant was added to 1.5 mL freshly prepared FRAP solution, and the absorbance was measured at 593 nm.

### Measurement of cytokine concentrations in liver tissues

TNF- $\alpha$  and IL-10 concentrations were measured in the liver of animals using an ELISA (Rat IL-10 and TNF- $\alpha$  ELISA kit, Diaclone A; Tepnel, Besancon, France). One hundred milligrams of tissue were homogenized in 1 mL PBS that contained antiproteases (0.1 mmol/L phenylmethylsulfonyl fluoride, 0.1 mmol/L benzethonium chloride, 10 mmol/L EDTA, 20 KI aprotinin A and 0.05% Tween 20). The samples were then centrifuged for 10 min at 3000 r/min and the supernatant was used for ELISA.

### Enzyme activities and Northern blot analysis

Total cellular RNA was extracted and hybridization was performed according to Church and Gilbert<sup>[12]</sup>. The expression of spermidine/spermine N-acetyl-transferase (SSAT) and collaborates with alternate reading frame (CARF), two mediators of tissue injury, in normal and experimental groups was evaluated.

### Statistical analysis

The results are given as mean  $\pm$  SE. Statistical analysis was performed by analysis of variance using a post-hoc Duncan test. The null hypothesis was rejected at the 0.05 level of significance. SPSS 11.0 software (Chicago, IL, USA) was used for data analysis.

## RESULTS

In all groups, the mean arterial pressure (MAP) during the experimental period was not significantly different from the basal value ( $110 \pm 9.8$  mmHg and  $109 \pm 10.3$ , respectively). Data on liver function tests are presented in Table 1.

### Effect of renal ischemia on serum biochemical parameters

BUN did not change after 30 min renal artery occlusion followed by 1 h reperfusion, but serum creatinine increased significantly compared to sham-operated animals ( $9.8 \pm 1.1$  mg/L *vs*  $5.5 \pm 1.5$  mg/L,  $P < 0.05$ ). Both 45 and 60 min ischemia followed by 1 h reperfusion resulted in significant increases in plasma creatinine ( $11.1 \pm 1.7$  mg/L and  $12.4 \pm 0.7$  mg/L *vs*  $5.5 \pm 1.5$  mg/L,  $P < 0.05$ ) and BUN ( $340 \pm 38.5$  mg/L and  $350 \pm 28.1$  mg/L *vs*  $237.5 \pm 11.0$  mg/L,  $P < 0.05$ ) compared to the sham-operated group (Figure 1).

### Effect of renal ischemia on liver oxidative parameters

The level of liver GSH did not change significantly after 30 min renal ischemia followed by 1 h reperfusion (Figure 2). Both 45 ( $19.5 \pm 2.7$   $\mu$ mol/g,  $P < 0.05$ ) and 60 min ( $25.86 \pm 1.71$   $\mu$ mol/g,  $P < 0.05$ ) ischemia followed by 1 h reperfusion caused a significant reduction in liver GSH compared to the sham-operated group ( $36.2 \pm 2.07$   $\mu$ mol/g,  $P < 0.05$ ). Figure 2 shows the level of FRAP in liver tissues. There were no significant differences between the groups.

Table 1 Data on liver function tests in different groups

Groups	AST (U/L)	ALT (U/L)
Sham-operated	263.7 $\pm$ 25.7	128 $\pm$ 27.5
30 min ischemia + 1 h reperfusion	275 $\pm$ 52.6	119 $\pm$ 20.8
45 min ischemia + 1 h reperfusion	459.7 $\pm$ 17.7 <sup>a</sup>	128 $\pm$ 15.5
60 min ischemia + 1 h reperfusion	491.5 $\pm$ 74.8 <sup>a</sup>	444.6 $\pm$ 198.6 <sup>a</sup>

<sup>a</sup> $P < 0.05$  compared to sham-operated group. The data are presented as mean  $\pm$  SE ( $n = 5$  in each group).

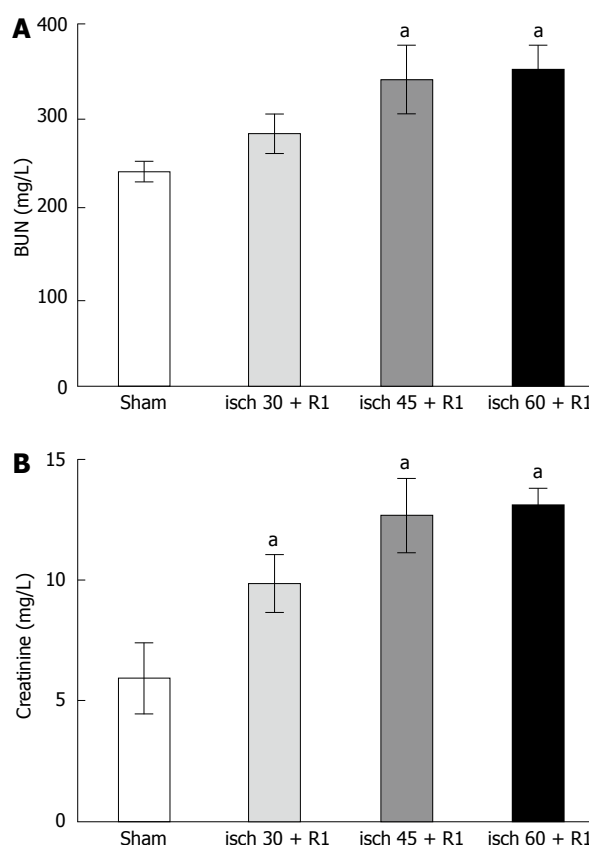

Figure 1 Alterations in renal function during different renal I/R periods. A: BUN; B: Plasma creatinine. The data are presented as mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs sham-operated group. All ischemic periods were followed by 1 h reperfusion.

### Effect of renal ischemia on liver TNF- $\alpha$

The level of liver TNF- $\alpha$  was increased significantly after 30 ( $466.9 \pm 71.7$  pg/100 mg,  $P < 0.05$ ), 45 ( $507.2 \pm 71.7$  pg/100 mg,  $P < 0.05$ ) and 60 min ( $718.6 \pm 68.8$  pg/100 mg,  $P < 0.05$ ) renal ischemia followed by 1 h reperfusion compared to the sham-operated group ( $210 \pm 16.6$  pg/100 mg). The increase in liver TNF- $\alpha$  following the induction of 60 min ischemia was significantly higher than the other ischemic periods.

### Effect of renal ischemia on liver IL-10

Renal ischemia (30, 45 and 60 min) followed by 1 h reperfusion resulted in a significant increase in liver IL-10 compared to that in the sham-operated group ( $121 \pm 34.5$  pg/100 mg,  $P < 0.05$ ). Induction of 60 min ischemia followed by 1 h reperfusion ( $667.8 \pm 34.5$  pg/100 mg,

**Figure 2 Alterations in liver GSH (A) and FRAP (B) during different renal I/R periods.** The data are presented as mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs sham-operated group; <sup>b</sup> $P < 0.05$  vs 30-min ischemia group. All ischemic periods were followed by 1 h reperfusion.

$P < 0.05$ ) showed a significant difference from the other groups (Figure 3).

#### Effect of renal ischemia on liver histology

Liver sections were evaluated for the presence of congestion, cellular degenerative changes, cytoplasmic vacuolization and leukocyte infiltration. The sections from the sham-operated rats displayed minimal/no changes. In the 30-min ischemia group, congestion was present, but much less than for the 45- or 60-min ischemic-reperfused group. There was no apparent evidence of cellular degenerative changes including cytoplasmic vacuolization. Leukocyte infiltration was almost absent in this group. Vacuolization was frequent in the 45-min ischemic-reperfused tissues. Irregularity, pale (atypical) nuclei, disintegrated cytoplasm, and infiltration of leukocytes were seen. Similar changes were observed in the 60-min ischemic-reperfused group (Figure 4).

#### Effect of renal ischemia on SSAT and CARF

RNA isolation and Northern hybridization were performed on some liver samples and the expression of SSAT was examined (Figure 5A). There was an increase in the 60-min renal ischemia compared with the control group, albeit by only about 35%, which was significant. The expression of CARF remained unchanged (Figure 5B).

**Figure 3 Alterations in liver TNF-α (A) and IL-10 (B) during different renal I/R periods.** The data are presented as mean  $\pm$  SE. <sup>a</sup> $P < 0.05$  vs sham-operated group; <sup>b</sup> $P < 0.05$  vs other groups. All ischemic periods were followed by 1 h reperfusion.

## DISCUSSION

Acute renal ischemic injury continues to be associated with a high mortality rate. Renal I/R injury occurs in many clinical situations, such as transplantation, partial nephrectomy, sepsis, hydronephrosis, or elective urological operations. Although most research in this area has focused on the renal response to this injury, recent work has suggested that renal injury affects and is also regulated by the extra-renal organs including the liver<sup>[15]</sup>. In the present study, the changes in hepatic function, histology, cytokine levels and antioxidant status were examined after induction of various periods of rat renal ischemic injury.

In 2002, Serteser *et al*<sup>[14]</sup> demonstrated some changes in hepatic TNF-α levels and oxidation products after renal I/R injury in mice. They have suggested that 30 min ischemia and 60 min reperfusion is sufficient to elicit remote effects of I/R injury. Their study was performed in mice, while we used rats in our study. This may explain why 30 min ischemia was less injurious compared to 45 and 60 min. In 2003, it was suggested that hepatic production of IL-10 and IL-1 receptor antagonists, in response to acute bile duct ligation, ameliorates ischemic ARF<sup>[15]</sup>. Hoke *et al*<sup>[16]</sup> in 2007 demonstrated that acute absence of kidney function results in pulmonary injury independent of renal ischemia, and highlighted the critical role of the kidney in the maintenance of serum

**Figure 4** Hematoxylin and eosin-stained sections of rat liver. A: Sham-operated group. B: I/R group, vacuolization was frequent in the 45 min ischemia-reperfused tissues. Irregularity, pale (atypical) nuclei, disintegrated cytoplasm, and infiltration of leukocytes were seen. C: Similar changes were observed in the 60 min ischemia-reperfused group ( $\times 400$ ).

cytokine balance and pulmonary homeostasis. In the present study, all three periods of ischemia caused an increase in hepatic TNF- $\alpha$  levels; but, the increase after 60 min was significantly higher than after 30 and 45 min ischemia. This means that, after 45 min ischemia, there are no irreversible changes, namely severe necrotic alterations.

In our study, as expected, I/R caused a reduction in renal function and structural alteration in an ischemia-time-dependent manner. Liver function was almost preserved after 30 min ischemia, partially reduced after 45 min, but showed a significant reduction in the 60-min ischemia group. This indicated that the liver underwent more prominent and severe damage in the 60-min group. Liver histology showed that, after 30 min ischemia, there was no apparent injury; but, 45 and 60 min ischemia elicited histological changes. The cytokines in the liver tissue were significantly increased after 30 and 45 ischemia; but, the increase after 60 min was very high and showed significant differences from the control and other ischemia groups. Although GSH showed a reduction in all of the experimental groups, the reduction in the 45- and 60-min groups was much higher than that in the 30-min ischemia group. The changes in GSH concentration suggested that ROS mediated the biomolecular alterations. On the other hand, FRAP showed a reduction after ischemia (although not significant). The rise in the 60-min group may have resulted from the contribution of uric acid to the overall

**Figure 5** Alterations in liver SSAT and CARF expression during 60 min renal ischemia followed by 1 h reperfusion. A: SSAT mRNA levels in the liver of renal ischemic samples were  $139 \pm 7\%$  vs the sham-operated group, after adjustment for RNA loading as determined by 18S rRNA.  $P < 0.05$  vs sham-operated group. B: CARF mRNA levels in the liver of renal ischemic samples were  $98\% \pm 8\%$  of levels in sham-operated group, after adjustment for RNA loading as determined by 18S rRNA.

concentration of FRAP, as reported previously<sup>[2]</sup>.

RNA isolation and Northern hybridization were also conducted on some liver samples. Total cellular RNA was extracted and hybridization was performed according to Church and Gilbert<sup>[12]</sup>. The expression of SSAT and CARE, two mediators of tissue injury, in normal and experimental groups was evaluated. The expression of SSAT was increased in the 60-min renal ischemia group compared with the controls. The expression of CARE remained unchanged. It is likely that SSAT is a more sensitive marker of injury than CARE.

These data clearly demonstrate that renal ischemia causes detrimental changes in liver histology, function, oxidative stress and inflammatory status, which leads to a reduction in hepatic antioxidant capacity. After 30 min ischemia, the magnitude of these changes is much less than after 45 or 60 min ischemia. A minimum of 45 min ischemia is needed to study the effects of renal injury on liver as a remote organ. Care should be taken to protect other organs remote from I/R sites, especially during renal surgery.

## COMMENTS

### Background

The effect of locally applied ischemia/reperfusion (I/R) injury to the kidney has been under investigation for many years. However, little is known about the changes in liver function and oxidative stress in renal I/R injury.

### Research frontiers

Renal injury associated with liver disease is an extensively encountered clinical problem of varied etiology and high mortality. Recent studies have suggested crosstalk between the liver and kidneys. I/R-induced local response in kidney tissue has been well documented in a number of studies. However, remote

effects of renal I/R injury on the liver need further investigation. The aim of the present study was to assess the hepatic changes after induction of different periods of renal ischemia.

### Innovations and breakthroughs

Rats were subjected to sham operation or ischemia (30, 45 and 60 min) followed by 60 min reperfusion. This study compared different ischemia times by the use of the following indices: hepatic glutathione and ferric reducing antioxidant power levels, and concentration of interleukin (IL)-10 and tumor necrosis factor- $\alpha$ .

### Applications

To study the effects of renal injury on liver as a remote organ, a minimum of 45 min ischemia is needed. Care should be taken to protect organs remote from I/R sites especially during renal surgery.

### Peer review

The authors describe the effects of different periods of rat renal ischemia on the liver in a rat model. They observed significant hepatic damage after at least 45-60 min of renal ischemia. This manuscript is well written and provides new information concerning the consequences of renal I/R injury on the liver.

### Abstract

**AIM:** To examine if dietary and socio-economic factors contribute to *Helicobacter pylori* (*H pylori*) re-infection.

**METHODS:** The population of patients consisted of subjects in whom *H pylori* infection had been successfully treated in the past. Patients were divided into two groups: I -examined group (111 persons with *H pylori* re-infection) and II -control group (175 persons who had not been re-infected). The respondents were interviewed retrospectively on their dietary habits and socio-economic factors.

**RESULTS:** A statistically significant lower frequency of fermented dairy products ( $P < 0.0001$ ), vegetables ( $P = 0.02$ ), and fruit ( $P = 0.008$ ) consumption was noted among patients with *H pylori* re-infection as compared to those who had not been re-infected.

**CONCLUSION:** High dietary intake of probiotic bacteria, mainly *Lactobacillus*, and antioxidants, mainly vitamin C (contained in fruit and vegetables), might decrease the risk of *H pylori* re-infection.

### INTRODUCTION

*Helicobacter pylori* (*H pylori*) infection exerts a decisive role in the pathogenesis of peptic ulcer disease and gastric cancer<sup>[1-3]</sup>. Epidemiological studies have shown that it is probably one of the most common bacterial infections throughout the world, involving 30% of the population living in developed countries and up to 80%-90% of the population in developing regions<sup>[4]</sup>. Poland, like most of the Eastern European countries, has an overall infection rate of 73% and an infection rate for the subjects over 25 years of age of 85%-95%<sup>[5]</sup>. Infection usually takes place in early childhood and youth; but, a proportion of the population becomes infected as adults<sup>[6-9]</sup>. Vectors of the bacteria are humans, by whom the infection is transmitted by oral-oral and faecal-oral routes<sup>[3,5]</sup>. The risk of infection is related mainly to socio-economic status<sup>[10-12]</sup>.

The important role of nutritional factors that might facilitate infection, such as low intake of antioxidants, mainly vitamin C, and high salt consumption, is also stressed<sup>[13,14]</sup>. Moreover, some research has shown that, in *in vitro* conditions, probiotic bacteria (especially *Lactobacillus*) might reduce the risk of *H pylori* infection<sup>[15-17]</sup>.

Owing to the wide implementation of eradication therapy, the recurrence of peptic ulcers has decreased significantly<sup>[18,19]</sup>. However, in some patients re-infection occurs and ulcers reappear. Re-infection affects ca. 1%-13% of patients annually, depending on the population studied<sup>[20-24]</sup>. It is believed that dietary and

socio-economic factors may contribute to the *H pylori* re-infection.

The aim of this study was to evaluate whether there are differences in dietary habits and lifestyle between subjects after effective eradication who were re-infected and patients who were not re-infected.

## MATERIALS AND METHODS

The study was carried out in 2002-2007 in a group of patients from the Provincial Gastroenterological Clinic of the Brodnowski Hospital in Warsaw who had ulcer disease or functional dyspepsia, and had been referred for endoscopic examination of the upper digestive tract. All the patients had been successfully treated for *H pylori* infection in the past and successful eradication after at least 6 wk after completion of the treatment was confirmed. The effectiveness of treatment was diagnosed by histology and a urease test (both negative) or urea breath test. Patients with neoplastic diseases were not included, along with persons with no confirmed eradication by the above mentioned methods and those who did not agree to take part in the research.

Patients were divided into two groups by *H pylori* status. One hundred and eleven patients were classified in group I (examined): persons with *H pylori* re-infection, and 175 patients were included in group II (control): persons not re-infected. The period following *H pylori* eradication ranged from 3 to 8 years. The mean time after the eradication treatment was similar for both groups: 5.2 years for group I and 5.6 years for group II.

Characteristics of both groups are presented in Table 1. Group I consisted of 47 women and 64 men aged 24-88. The control group included more women ( $n = 103$ ) than men ( $n = 72$ ). The range of age of the patients in this group was from 17 to 87 years old. No statistically significant differences between mean age and mean BMI between the groups were observed.

The status of *H pylori* was evaluated using the histological method and urease test (both positive) or urea breath test.

For all patients, a BMI value was calculated. An interview on dietary habits and socio-economic factors was performed by a dietician. The patients were interviewed retrospectively. A specially designed questionnaire was used. The first part of the questionnaire contained questions regarding the usual dietary habits during last year, while the second part referred to selected features relating to the patients' lifestyle. The questionnaire contained questions providing information, inter alia, on the applied diet, amounts, regularity and type of meals, frequency of consumption of products from various food groups, with particular attention paid to dairy products and fat, as well as salty products and dishes, along with additional salting. Consumption of products and dishes at least five times a week was regarded as frequent. For some products and dishes, the analysis covered moderate consumption with moderate frequency, i.e. twice to four times a week, and rare consumption, i.e. once a week or more seldom. For other products and dishes consumption frequency of up

	Group I HP (+)			Group II HP (-)		
	<i>n</i>	Mean	Range	<i>n</i>	Mean	Range
Age (yr)						
Women	47	63	24-88	103	62	17-87
Men	64	57	27-79	72	54	18-80
Total	111	60	24-88	175	58	17-87
BMI						
Women	47	24.8	16.3-32.5	103	24.8	15.6-48.9
Men	64	26.1	15.5-36.1	72	24.9	16.2-39.7
Total	111	25.5	15.5-36.1	175	24.9	15.6-48.9

to four times a week was regarded rare. The second part of the questionnaire contained questions referring to the patients' job and additional employment, stress exposure and smoking. Among the examined factors only those that had an impact on the occurrence of *H pylori* infection were selected and discussed. In the statistical analysis of the differences between studied groups, a  $\chi^2$  test was applied, assuming differences of statistical significance for  $P < 0.05$ .

## RESULTS

Dietary factors that are likely to have an impact on *H pylori* infection are presented in Table 2.

Most of the dietary factors analysed in both groups showed no significant differences. Both the patients who had been re-infected and patients from the control group said they ate meals regularly.

Statistically significant differences were noted in case of the frequency of eating dairy products ( $P < 0.0001$ ). The percentage of persons who often ate dairy products among patients with *H pylori* re-infection was much lower (41%) than in the control group (89%), and a higher proportion of the re-infected patients (32%) admitted to eating dairy products rarely, while in the control group this percentage was much lower (6%). A significant difference was also observed in the case of fermented milk drinks ( $P < 0.0001$ ). Less than half (43%) of the re-infected patients consumed these products frequently, while among non-infected persons-almost all (95%) did.

Most patients from both groups ate vegetables frequently (74% in the group re-infected and 87% in the control group); but, the differences in the frequency of the consumption of these products were statistically significant ( $P = 0.02$ ). The frequency of fruit consumption also showed differences; frequent consumption of these products was declared by fewer persons re-infected (58%) in comparison to the patients who were not re-infected (76%) ( $P = 0.008$ ).

Selected aspects relating to the lifestyle of examined patients are presented in Table 3.

Patients with *H pylori* re-infection did not vary significantly from the control group in terms of the analysed lifestyle factors. Most of the patients did not work professionally, but declared frequent tiredness and high stress exposure. In both groups, the majority did not smoke.

## DISCUSSION

The question of how to lower the risk of *H. pylori* re-infection is very important. This bacterium is the main cause of peptic ulcer disease (70%-90% of cases) and in 1% of infected persons, this leads to the development of gastric cancer<sup>[25]</sup>. Moreover, the treatment of *H. pylori* is difficult, requires a two-week application of at least three medicines (proton pump inhibitors and two antibiotics) simultaneously, proves successful in only 80%-90% of cases and is connected with the risk of adverse effects of therapy with antibiotics (15%-30% of the treated)<sup>[26,27]</sup>. In some patients, *H. pylori* re-infection occurs after eradication; but, factors responsible for this phenomenon have not yet been identified. It is presumed that these may be at least partly related to poor sanitary conditions and improper lifestyle, especially diet<sup>[12,28,29]</sup>.

In the present research, the dietary and some socio-economic factors after successful eradication of *H. pylori* infection were evaluated. The goal of this retrospective study was to point out potential differences in the dietary patterns of patients with *H. pylori* re-infection (group I) and in the control not-re-infected group (group II).

We showed a significant difference in the frequency of consumption of fermented dairy products containing probiotic bacteria, mainly *Lactobacillus*, between the group with *H. pylori* re-infection and the group without re-infection. This indicates that regular consumption of products containing probiotic bacteria might reduce the risk of *H. pylori* re-infection.

There is some evidence from *in vitro* and clinical research that can support this hypothesis. Numerous probiotic strains inhibit the growth or adhesion of *H. pylori* to epithelium cells in *in vitro* conditions. In

studies on animals infected with *H pylori*, it was also observed that probiotic bacteria lowered the intensity of inflammatory conditions in the stomach mucosa. Michetti *et al*<sup>[15]</sup> showed that the supernatant of a culture of *Lactobacillus johnsoni* La1 strain inhibited the growth of *H pylori* bacteria whether or not they were connected with epithelial cells. The supernatant was administered for 14 d to 20 volunteers infected with *H pylori* in a double-blind randomised study. The results of urea breath tests at the beginning and in the 6th week after the completion of the treatment were significantly lower than the initial results, which is most probably related to lowering the density of *H pylori* colonies. In a biopsy taken from the mucosa of the stomach, *H pylori* infection was still present<sup>[15]</sup>.

Aiba *et al*<sup>[30]</sup> showed that *L. salivarius* inhibited the growth of *H pylori* *in vitro*, and, in an animal model, reduced the inflammatory process in the mucosa of infected mice. No such phenomena were observed in the case of *L. casei* and *L. acidophilus*.

Coconnier *et al*<sup>[16]</sup> observed that supernatant from the *L. acidophilus* LB culture contains anti-bacterial substances produced by this strain, which reduced the viability of *H pylori* bacteria and inhibited its adhesion to human cells *in vitro* and *in vivo*. Sgouras *et al*<sup>[31]</sup> used *L. casei* Shirota cells *in vitro* and *in vivo* and noted that the cells (not the supernatant) lowered the activity of *H pylori* urease. In research carried out on mice, after the application of the above strain, the density of *H pylori* colonies decreased, along with the intensity of the inflammation of the mucosa of the stomach<sup>[31]</sup>.

Similar results were obtained in animal; for example, the density of colonisation of stomach mucosa by *H pylori* became lower, and inflammatory changes became smaller, after the administration of *L. rhamnosus*, *L. acidophilus* and *L. gasseri*<sup>[32,33]</sup>. Kabir *et al*<sup>[34]</sup> stated that administration of *L. salivarius* to mice infected with *H pylori* decreased the adhesion of pathogens to stomach mucosa cells.

So far, clinical tests have not been able to prove that use of probiotics leads to *H pylori* eradication<sup>[35,36]</sup>. Wendakoon *et al*<sup>[37]</sup> made an attempt to prove it in their study of patients with asymptomatic *H pylori* infection. The patients were given *L. acidophilus* and *L. casei* strains for 30 d, which inhibited *H pylori* growth *in vitro*; but, no eradication in any of the patients was observed.

Several clinical surveys showed that some strains of probiotic bacteria might increase the effectiveness of *H pylori* eradication. Canducci *et al*<sup>[38]</sup> noted higher *H pylori* eradication rate in patients who, in addition to triple therapy based on rabeprazole, clarithromycin and amoxicillin, were given a lyophilized and inactivated culture of *Lactobacillus acidophilus*. In a study by Sýkora *et al*<sup>[39]</sup> *H pylori*-positive children received the control treatment of omeprazole, amoxicillin and clarithromycin or the treatment consisted of the same antibiotics supplemented with fermented milk (trade name-Actimel) containing *L. casei* DN-114 001. Eradication success was significantly higher in the test group compared with the control group.

Application of probiotics during *H pylori* treatment might not only increase the eradication rate, but it might also decrease the adverse effects of antibiotic therapy. Park *et al*<sup>[40]</sup> showed that supplements containing probiotic bacteria strains, composed of *Bacillus subtilis* and *Streptococcus faecium*, enhanced the intention-to-treat eradication rate of *H pylori*, improved drug compliance and reduced side effects. Diarrhoea and overall side effects were more common in the group treated with antibiotics only in comparison to the group treated with antibiotics plus probiotics. De Bortoli *et al*<sup>[41]</sup> examined whether adding bovine lactoferrin and probiotics to the standard triple therapy for *H pylori* infection could improve the eradication rate and reduce side effects. The eradication rate was higher in more patients who underwent standard triple eradication therapy plus bovine lactoferrin and probiotics than in those who underwent standard therapy only. Moreover, fewer patients taking probiotics reported side effects. Improvement of the results of eradication therapy followed by the application of probiotics was also noted in Polish studies covering children with dyspeptic symptoms and confirmed *H pylori* infection<sup>[42]</sup>. In the group of children who were given probiotics (*L. acidophilus* and *L. rhamnosus*) in addition to standard therapy, not only was significantly higher eradication effectiveness demonstrated, but also a lower intensity of inflammation of the mucosa of the stomach and a lower rate of adverse effects of the therapy were noted.

The results of some studies do not confirm the positive impact of the use of probiotics on the eradication treatment ratio. No difference in eradication rate was observed in *H pylori*-positive patients receiving *L. reuteri* and a placebo<sup>[43]</sup>. Also Goldman *et al*<sup>[44]</sup>, in their study of children in Buenos Aires, found no significant differences in *H pylori* eradication rates between the group treated with triple therapy plus probiotic food (yogurt containing *Bifidobacterium animalis* and *Lactobacillus casei*) and the control group.

Although not all papers confirm the improvement of treatment results for *H pylori* infection upon simultaneous treatment with antibiotics and probiotics, the meta-analysis performed by Tong *et al*<sup>[45]</sup>, covering 14 randomized trials, suggests that supplementation with probiotics could be effective in increasing eradication rates of anti-*H pylori* therapy, and could be considered helpful for patients with previous eradication failure. Pooled *H pylori* eradication rates were 83.6% and 74.8% for patients with or without probiotics by intention-to-treat analysis. Furthermore, probiotics showed a positive impact on *H pylori* therapy-related side effects. The occurrence of total side effects was 24.7% and 38.5% for groups with or without probiotics.

Results found in most of the studies showed that the use of probiotics during eradication treatment was of benefit to patients. However, more large and well-designed studies of the use of probiotics in *H pylori* eradication treatment are necessary, including comparative and dose-ranging trials<sup>[46]</sup>.

We also demonstrated a significantly higher

consumption of fruit and vegetables among persons who were not re-infected. This is probably related to the consumption of a higher number of anti-oxidants, especially vitamin C. Vitamin C, which is highly concentrated in stomach mucosa and gastric juice and probably lowers the risk of gastric cancer and influences the course of *H. pylori* infection through a number of mechanisms<sup>[13,47]</sup>. It has a positive impact on the stimulation and activity of granulocytes, macrophages and lymphocytes and the production of immunoglobulins. The direct inhibitory impact of this vitamin on the growth of *H. pylori* is now being examined.

Jarosz *et al.*<sup>[13]</sup> showed that four weeks treatment of *H. pylori* infected patients with chronic gastritis with a high dose of vitamin C caused *H. pylori* eradication in 30% of cases. In those patients, a highly significant rise in gastric juice total vitamin C concentration was demonstrated, which persisted for at least four weeks after treatment. However, the mechanism whereby vitamin C treatment results in *H. pylori* eradication is unclear.

Ruiz *et al.*<sup>[48]</sup> found a causal association between *H. pylori* infection and low ascorbic acid levels in the gastric juice. Their findings supported two hypotheses that explain this phenomenon: increased oxidation and a decreased secretion of ascorbic acid.

The results obtained from the Third National Health and Nutrition Examination Survey showed that ascorbic acid might affect the risk of *H. pylori* infection<sup>[49]</sup>. In that survey, higher serum levels of ascorbic acid were associated with a decreased seroprevalence of *H. pylori* and of the presence of pathogenic *cagA*-positive strain of *H. pylori*.

The data of Park *et al.*<sup>[50]</sup> demonstrated that vitamin C levels in whole blood, plasma, and gastric juice and the gastric juice pH in Korean children were closely related to the severity of *H. pylori* infection and the histologic changes in the stomach. These data suggest that vitamin C may play a role in determining *H. pylori* infection and its progression. Thus, vitamin C supplementation might be an important tool for the management of *H. pylori* infection.

There were no differences between analysed lifestyle factors between patients with *H. pylori* re-infection and the control group. However, the results of some surveys indicate the influence of socioeconomic status on *H. pylori* infection<sup>[10-12]</sup>. Authors of a Polish study in Lodz observed a much higher prevalence of *H. pylori* infection in children from poor living conditions<sup>[10]</sup>. In adults from Lublin, the *H. pylori* infection was strongly affected by the lack of basic personal hygiene<sup>[12]</sup>. In the Czech Republic, the highest risk of *H. pylori* infection was found in children of mothers with basic or lower education, living in crowded accommodations, without access to running warm water, and residing in smaller towns<sup>[11]</sup>. Low education and heavy smoking were most strongly associated with prevalence of *H. pylori* infection in adults and adolescents. Smoking might also influence *H. pylori* eradication rates. For example, a Colombian study in patients who smoked found that *H. pylori* treatment was less effective<sup>[51]</sup>. Whereas data from Turkey supported the finding that personal

and environmental conditions in adults did not affect *H. pylori* infectivity<sup>[52]</sup>. Such factors as family income, living conditions, smoking, alcohol consumption and hygiene did not differ statistically between the *H. pylori* positive and negative subjects. Smoking, alcohol consumption, number of children and pets in the household were also not associated with *H. pylori* positivity among adolescents from Novosibirsk<sup>[53]</sup>.

We studied only a few lifestyle factors without taking into account living conditions, personal hygiene and educational level that could influence *H. pylori* re-infection. The lack of any relation between working, tiredness, stress exposure and *H. pylori* re-infection could be caused by the fact that the majority of studied patients were retired. In our study, smoking did not influence of *H. pylori* status, but not all surveys agree with our finding.

To summarise the results of some of the reviewed studies, the regular consumption of fermented milk products and fruit and vegetables might significantly reduce the risk of *H. pylori* re-infection and this effect could be used in the prevention of the infection among persons in whom *H. pylori* infection had been previously eradicated.

## COMMENTS

### Background

*Helicobacter pylori* (*H. pylori*) infection is the main cause of peptic ulcer disease (70%-90% of cases) and in 1% of infected persons, leads to the development of gastric cancer. The treatment of *H. pylori* infection is difficult and requires a two-week application of at least three medicines simultaneously. In some patients, *H. pylori* re-infection occurs after eradication; but, factors responsible for this phenomenon have not yet been identified. It is presumed that these might be at least partly related to poor sanitary conditions and improper lifestyle, especially diet.

### Research frontiers

*H. pylori* re-infection affects ca. 1%-13% of patients annually; therefore, it is very important to find out how to lower the risk of *H. pylori* re-infection. In this study, the dietary and some socio-economic factors after successful eradication of *H. pylori* infection were evaluated. The goal of this retrospective study was to point out potential differences in the dietary patterns of patients with *H. pylori* re-infection and in the control not-re-infected group.

### Innovations and breakthroughs

The majority of the studies concerned the influence of dietary patterns on *H. pylori* infection. The present research used a specially designed questionnaire to find out which factors lower the risk of *H. pylori* re-infection.

### Applications

The results suggest that the regular consumption of fermented milk products and fruit and vegetables might significantly reduce the risk of *H. pylori* re-infection and this effect could be used in the prevention of re-infection among persons in whom the infection had been previously eradicated. The results could also be helpful in preparation of dietary guidelines for patients after *H. pylori* eradication.

### Terminology

Antioxidant: An antioxidant is a molecule (especially vitamins and microelements) capable of neutralizing free radicals which damage cells; Eradication: Eradication is the elimination or destruction of a thing or group (in this article it is bacteria-*H. pylori*); Probiotics: Probiotics are live microorganisms which, when administered in adequate amounts, confer a health benefit on the host; Supernatant: Supernatant is a liquid remaining above the solid after chemical reaction.

### Peer review

The main aspects of the paper are adequate. The discussion is complete and deals with different thoughts that are currently controversial. In summary, this is a good retrospective analysis of factors probably related with *H. pylori* re-infection.

### INTRODUCTION

Intrahepatic cholestasis of pregnancy (ICP) is characterized by pruritis, jaundice and raised serum bile salts, which typically starting in the third trimester of pregnancy, resolve after delivery and recur in subsequent pregnancies<sup>[1]</sup>. It is associated with an increased incidence of fetal distress, premature delivery and stillbirth<sup>[2]</sup>.

ICP is thought to be caused by abnormal biliary transport, which may result from a number of factors, including hormonal, environmental and genetic. Recently it has been recognized that up to 15% of ICP may be associated with mutations in the MDR3 (*ABCB4*) gene<sup>[1]</sup>. The ATP binding cassette subfamily B, member 4 (*ABCB4*) gene codes for a protein responsible for the translocation of phosphatidylcholine (PC) from the inner to the outer leaflet of the canalicular membrane of the hepatocyte<sup>[3]</sup>. It is now becoming increasingly clear that disruption in the *ABCB4* gene can present a spectrum of clinical disorders ranging from ICP and low-phospholipid-associated cholestasis (LPAC), to progressive familial intrahepatic cholestasis type III (PFIC III), depending on the location of the new mutation<sup>[3]</sup>.

LPAC is a condition characterized by gallstones, high serum gamma glutamyl transferase (GGT), intrahepatic microlithiasis and recurrent biliary symptoms despite cholecystectomy<sup>[4]</sup>, while PFIC type III is characterized by chronic cholestasis that presents early in life, which often progresses to end-stage liver disease that requires liver transplantation<sup>[3]</sup>.

### CASE REPORT

We report a kindred of Anglo-Celtic descent, who present with features of ICP and gallstones (LPAC), and have been found to have a novel mutation in the *MDR3*

### Abstract

Pruritis with abnormal liver function tests is the classical presentation of intrahepatic cholestasis of pregnancy (ICP), a condition associated with significant fetal complications. Although the etiology of ICP is unclear in many cases, certain features of the clinical presentation should alert the practitioner to the possibility of an underlying metabolic defect, which may not only affect subsequent pregnancies, but may be an indicator of more serious subsequent liver disease. We report a kindred of Anglo-Celtic descent, among whom many members present with ICP, gallstones or cholestasis related to use of oral contraception. Genetic studies revealed a novel mutation in the *ABCB4* gene, which codes for a phospholipid transport protein. The clinical significance of this mutation and the importance of identifying such patients are discussed.

gene. The clinical aspects of the presentation that prompted further investigation are discussed.

The family (Figure 1) came to medical attention when the index case (case 1) was referred with persistently abnormal liver function tests following her second pregnancy. She was a 33-year-old healthy G2P2 who had pruritus, but no jaundice during her first pregnancy, and recovered. During the second pregnancy, she again developed pruritus at 32 wk gestation, associated with abnormal liver function tests (Figure 2). She received ursodeoxycholic acid supplements, but with only mild relief, and abnormalities in her liver function tests persisted. She delivered at 37 wk through induced labor because of worsening jaundice and gestational diabetes. Various investigations including serum ceruloplasmin, serum bile salts, alpha-1 antitrypsin assays and viral serology for hepatitis viruses were performed, and were all normal. Further questioning revealed several members of the family with similar symptoms (Table 1).

Case II was a 30-year-old, single, healthy, woman who developed pruritus and abnormal liver function tests after she commenced taking oral contraceptives (Figure 3).

Figure 2 Liver function tests of the index case with an MDR3 mutation.

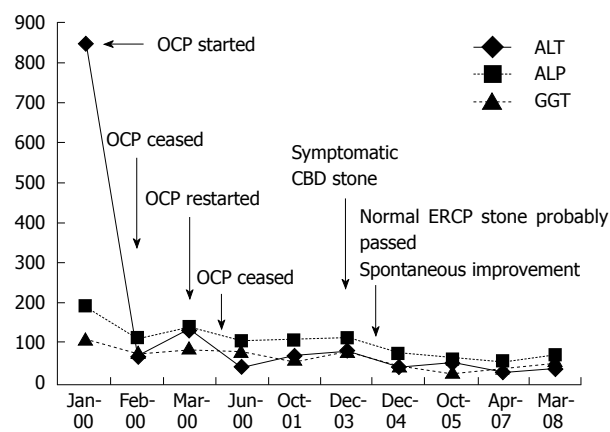

Figure 3 Liver function tests of case 2 with an MDR3 mutation.

These symptoms improved after discontinuation of contraceptives; however, they recurred when she recommenced the contraceptives. She had undergone a cholecystectomy at the age of 26 years following a prolonged history of episodic abdominal pain. Extensive investigations including viral serology, serum ceruloplasmin and copper levels, bile salt and alpha 1 antitrypsin assays for other causes of hepatitis were all normal. She was found to have a stone in her common bile duct upon ultrasound examination; but, subsequent endoscopic retrograde cholangiopancreatography was

normal. Her liver function tests started improving spontaneously, but never normalized.

Subsequently, a third sister (case III) was referred for persistently abnormal liver biochemistry that was detected incidentally during routine screening of liver biochemistry while she was taking anti-convulsant drugs for post-traumatic epilepsy. She had a cholecystectomy at the age of 17 years for gallstones. However, 4 years later, she had a severe head injury following which she developed post-traumatic epilepsy. She was treated with sodium valproate and her abnormal liver function tests were initially attributed to this drug. However, drug level monitoring revealed her anti-convulsants to be well within the therapeutic range. Further investigations including viral serology, copper studies and abdominal ultrasound were negative. She also had a liver biopsy that showed very mild chronic lobular inflammation.

Case IV had a cholecystectomy for gallstones associated with persistently abnormal liver function tests, and case V had cholestasis during both her pregnancies. Their mother had cholecystectomy for gallstones and also cholestasis during all her pregnancies.

Interestingly, their brother had normal liver function tests and was asymptomatic. A maternal grandmother had gallstones, but had not undergone cholecystectomy, and a maternal great grandmother died of a secondary liver cancer, the nature of which was uncertain. Two maternal cousins also had gallstones. There was no history suggestive of cholestatic disorders on their father's side. There was also a history of miscarriages in the family; the mother having had two and the index case and one of the sisters having had one each. The children of all the sisters are below 10 years of age and have not yet shown any features suggestive of cholestatic liver disease.

### DNA analysis

DNA of the index cases I and II was analyzed at the Academic Medical Centre, Amsterdam. Both the sisters were found to be positive for an 1102T > A mutation that converts phenylalanine at position 368 into isoleucine. This phenylalanine is highly conserved and the mutation has not been found in 150 control alleles. The mutation is located between the sixth transmembrane helix and the ATP-binding cassette, and is, therefore, likely to be of functional significance.

## DISCUSSION

Pruritus associated with abnormal liver function tests and raised bile acids during pregnancy are the classical presentation of ICP. As this syndrome carries a risk of premature delivery and sudden intrauterine fetal death, most practitioners commence ursodeoxycholic acid, which reduces pruritus, transaminases and probably prematurity, without adverse side effects<sup>[1,5]</sup>. If the pregnancy proceeds uneventfully, many practitioners do not pursue further follow-up or investigation to look for a cause of the ICP.

However, it is now apparent that, a significant minority of patients with ICP will have underlying

MDR3 mutations, which may predispose to further high-risk pregnancies and possibly serious liver disease later in life<sup>[3]</sup>. The percentage of patients with ICP caused by MDR3 mutations varies in different populations. In a recent Italian study, 7/96 (7.2%) women with ICP had MDR3 mutations identified while other studies have reported up to 15%<sup>[1]</sup>.

The current report highlights a number features in the history of a patient with presumed ICP, which should have alerted the practitioner to the possibility of an underlying mutation and the need for further investigation. Clues that could be readily obtained from the history included a cholestatic reaction to oral contraception, ICP in previous pregnancies and a strong family history of gallstones under the age of 40 years, and recurrence of symptoms after cholecystectomy<sup>[4]</sup>.

In our pedigree, the index case presented with typical ICP symptoms. However, it soon became apparent from the family history that most members had a history consistent with ICP during one or more pregnancies, and that all but one had gallstones at a young age. Whilst a high GGT level is observed in 30% patients with ICP, its presence increases the likelihood of an underlying MDR3 mutation<sup>[6]</sup>. Importantly, the first clue to the diagnosis and the reason for referral of our index case was that her obstetrician was concerned when GGT levels did not return to normal in the post-partum period.

The MDR3 (*ABCB4* transporter) is responsible for the translocation of PC from the inner to the outer leaflet of the canalicular membrane of hepatocytes. PC is extracted from the membrane by bile salts and then mixes with bile salts to form mixed micelles. These mixed micelles are known to solubilize cholesterol more efficiently than simple bile-salt micelles. On the other hand, the mixed micelles extract phospholipids less well from the membrane than simple bile-salt micelles and this protects the cells lining the biliary tree from membrane solubilization<sup>[3]</sup>. The rate of phospholipid secretion is an important factor in the prevention of gallstone formation and partial defects in phospholipid secretion may predispose to gallstone formation<sup>[4]</sup>.

Mutations in MDR3 in ICP have been described in multiple exons<sup>[7]</sup>. The mutation described in this report adds to an expanding group of mutations that have been shown to cause familial cholestatic syndromes including ICP. However, there is still little understanding of why and how various mutations in the *MDR3* gene produce different clinical syndromes.

Factors that occur during pregnancy, which might lead to the development of cholestasis in previously asymptomatic individuals with these disorders, include generalized impairment of bile formation in the third trimester<sup>[8]</sup> and the effects of sex hormones that are known to promote cholestasis, possibly by inhibition of the bile salt export pump. The administration of exogenous progesterone in the third trimester may also precipitate ICP.

This kindred is especially interesting as different members have presented with various features of the clinical spectrum of *ABCB4* transporter defects over

many years, before the significance of the family history was finally recognized. This highlights the importance of obtaining a family history in all patients with ICP. Even if a positive family history is not obtained, patients who present with abnormal liver tests during pregnancy should have follow-up testing to ensure the abnormality resolves post-partum. The possibility of a bile acid transport defect should be considered in all patients who have a family history of ICP or other symptoms suggestive of a familial cholestatic disorder. Of note, patients presenting with gallstones in young adulthood (under the age of 40 years) should be evaluated further, particularly if there is a suspicious family history. Early detection of such patients should ensure that there is adequate monitoring of subsequent pregnancies, early treatment with ursodeoxycholic acid, and that there is ongoing follow-up to detect and prevent the development of significant liver disease.

## INTRODUCTION

Screening for prostate cancer has become an important issue in recent years. Of all procedures used to diagnose prostate cancer, the gold standard is transrectal ultrasound (TRUS)-guided multiple biopsy of the prostate<sup>[1,2]</sup>. Complications from TRUS-guided prostate needle biopsy are occasionally encountered in the daily practice of urologists; the traditional spring-loaded device with a small-caliber needle used for the prostate biopsy is fast, safe, effective and associated with minimal complications, including self-limiting hematuria, hematospermia and pain<sup>[3-5]</sup>. Rare major complications include acute prostatitis, acute urinary retention, epididymitis, severe hematuria, sepsis, abscess formation, urinary tract infection, tumor tracking, vasovagal syncope, and significant rectal bleeding<sup>[3-7]</sup>. Most often, major and especially minor complications resolve with traditional conservative therapy<sup>[3,8]</sup>. Severe rectal bleeding is traditionally managed by the urologist, with rectum tamponade as the initial and simplest conservative method, or, when necessary, balloon compression by means of a transrectally inserted catheter<sup>[8]</sup>. Endoscopic intervention with injection of adrenaline and sclerosing solutions, thermocoagulation and band ligation have also been used successfully in some cases<sup>[9-13]</sup>. We describe, possibly for the first time, the use of endoclipping for the treatment of severe rectal bleeding following TRUS-guided prostate multiple biopsy.

## Abstract

Rectal bleeding is frequently seen in patients undergoing transrectal ultrasound (TRUS)-guided multiple biopsy of the prostate, but is usually mild and stops spontaneously. We report what is believed to be the first case of life-threatening rectal bleeding following this procedure, which was successfully treated by endoscopic intervention through placement of three clips on the sites of bleeding. This case emphasizes endoscopic intervention associated with endoclipping as a safe and effective method to achieve hemostasis in massive rectal bleeding after prostate biopsy. Additionally, current data on the complications of the TRUS-guided multiple biopsy of the prostate and the options for treating fulminant rectal bleeding, a consequence of this procedure, are described.

**Key words:** Prostate biopsy; Complications; Massive rectal bleeding; Endoscopic treatment; Endoclipping

## CASE REPORT

A healthy 59-year-old internist was found to have

**Figure 1** Endoscopic view showing oozing from biopsy sites in the anterior rectal wall.

**Figure 2** Hemostasis achieved after application of three clips.

prostate-specific antigen (PSA) at 5.8 ng/mL (normal < 3.5 ng/mL) during a screening test for prostate cancer. Laboratory data including platelet count, and prothrombin and bleeding times were normal. He underwent TRUS guided prostate multiple biopsy (18 cores) with a needle. Two hours later, he noticed rectal bleeding and thereafter he continued to pass a large volume of bright red blood through the rectum every 30 min. Manual compression and rectal tamponade with inflation of the balloon of an inserted urine catheter in the rectal cavity by his urologist failed to stop the bleeding. As a result of massive rectal bleeding that caused his hematocrit to drop from 45% to 28% and concomitant hemodynamic instability, he required hospitalization. Two packed red blood cell units were transfused and endoscopic consultation was requested. When transferred to our department, he was diaphoretic, with a pulse rate of 124 bpm and blood pressure of 100/70 mmHg. There was no history of hemorrhoidal disease. Urgent colonoscopy was performed without bowel preparation and revealed a rectal cavity full of fresh blood and clots, without a visible bleeding source. Vigorous washing and suction of the rectal cavity revealed two adjacent bleeding points in the anterior rectal wall, which corresponded to the sites of rectal wall injury caused by prostate multiple biopsy (Figure 1). Three endoclips (MH-858; Olympus, Tokyo, Japan) *via* an HX-6UR-1 applicator (Olympus) were applied to the bleeding lesions (Figure 2) and immediate hemostasis was achieved. The patient's condition was stabilized and 2 d later, he was discharged with an uneventful recovery.

## DISCUSSION

To the best of our knowledge, we report the first known severe rectal bleeding following TRUS-guided prostate biopsy, which was effectively managed by endoclipping.

There are two established techniques of prostate biopsy, including the more widely used transrectal technique, and the transperineal technique. Both techniques appear to be equally safe, although the transrectal technique is faster<sup>[14]</sup>. Currently, the preferred option for initial prostate biopsy is the transrectal procedure<sup>[15]</sup>. Nevertheless, concerns about the accuracy

of the standard sextant prostate biopsy for detecting prostate cancer have led to more cores being taken in each patient. This is not surprising, as mathematical models have shown that sextant biopsy misses 27% of tumors, and the probability of identifying a fixed volume of prostate cancer increases by taking more cores<sup>[16]</sup>. Results from clinical studies have shown that the sextant protocol for TRUS-guided prostate biopsy can miss cancer in 19%-31% of cases<sup>[17,18]</sup>. To overcome these diagnostic shortcomings, several extended biopsy policies have been advocated. Increasing the number of cores from six to eight, with extra cores targeted along the post-lateral margins of the gland, identifies up to 20% more tumors<sup>[19]</sup>, but even an eight-core biopsy may miss cancer, and others have advocated<sup>[16,18]</sup> more biopsies per gland<sup>[20-22]</sup>. However, trying to improve the diagnostic accuracy should not be at the expense of the increased complication rate that may accompany more core biopsies, particularly bleeding, as occurred in our patient, especially when the prostate and surrounding rectal tissue are supplied by a rich vascular bed that consists of branches of the inferior vesicular artery and the middle and inferior rectal arteries. Moreover, the venous plexus is also dense in the submucosal space of the region, particularly in patients with hemorrhoids. The total incidence of rectal bleeding is listed as 1.3%-58.6%, with a statistically significant positive correlation to the number of core samples obtained. In most cases, the rectal bleeding is slight without necessitating further therapeutic intervention<sup>[3,5]</sup>.

To overcome further the aforementioned diagnostic shortcomings, evaluation of the accuracy of TRUS-guided biopsies, by using combined magnetic resonance imaging (MRI) and magnetic resonance spectroscopic imaging (MRSI) in patients with persistently high PSA levels and negative TRUS-guided biopsy results, has revealed that MRI/MRSI have the potential to guide biopsies to tumor foci in these patients<sup>[23]</sup>. Overall, MRI and MRSI have accuracy similar to biopsy for intraprostatic localization of tumor and they are more accurate than biopsy in the prostate apex. Therefore, these imaging modalities may supplement biopsy results by increasing physician confidence when evaluating intraprostatic tumor location, which may be essential for planning disease-targeted therapy<sup>[24]</sup>. Our patient

did not accept further evaluation by these two imaging approaches.

In an extensive research of Medline using the key words rectal bleeding, prostate biopsy, hematochezia and rectal hemorrhage, we found seven publications that describe massive rectal bleeding occurring after transrectal biopsy, which required blood transfusion. In most of the cases, hemostasis was achieved with rectal tamponade by means of fleece tamponing, by urine balloon catheter inserted and inflated in the rectum by a condom filled with fluid in the rectal cavity, or after endoscopic intervention with injection of adrenaline or sclerosing solutions (polidocanol or pure ethanol), thermocoagulation and band ligation<sup>[9-13,25]</sup>. In our case, neither rectal tamponade nor manual compression of bleeding sites by a urologist succeeded in achieving hemostasis. Since the patient presented with hemodynamic instability (diaphoresis, tachycardia with drop of blood pressure), endoscopic consultation was requested. Having significant experience of endoclips for treatment of upper and lower gastrointestinal bleeding<sup>[26,27]</sup>, we proceeded with urgent endoscopy combined with placement of three clips at the sites of bleeding, which led to immediate hemostasis. We preferred endoclips instead of sclerosing solutions, despite the fact that the latter have been successfully used to achieve hemostasis in post-biopsy prostate bleeding<sup>[28,29]</sup>, because we were concerned about their risk of subsequent formation of deep ulceration. In contrast, the use of endocliping has been widely reported in gastrointestinal endoscopy, without complications<sup>[26,27]</sup>.

Argon plasma coagulation (APC) is a safe, well-tolerated treatment option in prostatic cancer patients with radiation-proctitis-induced hemorrhage, and historically, has been superior to Nd: YAG laser ablation<sup>[30]</sup>. Regarding the endoscopic treatment for initial hemostasis in upper and lower gastrointestinal bleeding, apart from the endoscopic hemostatic devices used, APC is an alternative hemostatic method<sup>[31,32]</sup>. Its potential therapeutic application in patients with severe rectal bleeding following TRUS-guided prostate biopsy remains to be elucidated.

In conclusion, our case emphasizes that urgent endoscopy allows accurate diagnosis and endocliping is a safe and effective therapy of massive rectal bleeding followed prostate biopsy.

## Abstract

Multivisceral surgical resection for cure was successfully performed in a 70-year-old man suffering from a primary hepatocellular carcinoma (HCC) associated with direct invasion to the stomach and pancreas. The patient presented with gastric outlet obstruction, upper abdominal pain and a history of chronic liver disease due to hepatitis B virus (HBV) infection. Upper gastrointestinal (GI) endoscopy revealed an infiltrating tumor protruding through the gastric wall and obliterating the lumen. Computer tomography (CT) and magnetic resonance imaging (MRI) scan demonstrated a 15-cm tumor in the left lateral segment of the liver with invasion to the stomach and pancreas. Alpha-fetoprotein (AFP) levels and liver function tests were normal. The patient underwent an *en bloc* left hepatectomy, total gastrectomy, distal pancreatectomy with splenectomy and radical lymphadenectomy. Pathology revealed a poorly differentiated, giant cell HCC involving the stomach and pancreas. Disease-free margins of resection were achieved. The patient's postoperative course was uneventful. Sixteen months after surgery, he has no

## INTRODUCTION

Hepatocellular carcinoma (HCC) is characterized by a soft consistency and extensive growth. These specific features of HCC mean that it rarely infiltrates the gastrointestinal (GI) tract directly. The incidence is reported to be 0.5% to 2% of clinical HCC cases<sup>[1,2]</sup>. Whether such an invasion causes massive hemorrhage or obstruction, a complete *en bloc* resection of these extensive HCCs can be safely performed using modern surgical techniques and sophisticated perioperative management. In this report, we describe a patient suffering from a giant, extra-hepatically growing HCC associated with direct invasion to the stomach and pancreas. The tumor was successfully extirpated with a multivisceral oncologic resection. A thorough review of the literature is also presented.

## CASE REPORT

A 70-year-old Caucasian male presented with signs of gastric outlet obstruction, upper abdominal pain and

**Figure 1** MRI scan demonstrates the presence of a large tumor, 15 cm in diameter, originating from the inferior surface of liver segments II and III. It is mainly solid with areas of tissue necrosis and shows direct invasion of stomach and pancreas.

a chronic hepatitis B virus (HBV) infection. Upper GI endoscopy revealed a large, infiltrating tumor protruding through the anterior wall of the body of the stomach and almost completely obliterating the gastric lumen. No esophageal varices were found. Total colonoscopy showed no abnormality. The computed tomography (CT) scan demonstrated the presence of chronic liver disease and a giant tumor of the left lobe. The magnetic resonance imaging (MRI) revealed a space-occupying lesion, 15 cm × 12 cm × 9.5 cm in size, originating from the inferior surface of segments II and III. It was mainly solid with areas of tissue necrosis, hemorrhage and cystic degeneration. A smooth fibrous capsule was covering part of its outer surface. The lesion showed extensive extrahepatic growth with invasion to the body and fundus of the stomach, as well as direct contact with the upper surface of the pancreas. A low grade HCC was suggested (Figure 1). Biochemical analysis on admission indicated that alpha-fetoprotein (AFP) level was 2.1 ng/mL (normal value, < 10 ng/mL) and CA19.9 level was 33.2 ng/mL (normal value < 34 ng/mL). Liver function test results were normal. The patient underwent an *en bloc* radiofrequency-assisted left hepatectomy using the RF Cooltip needle (Radionics, Valleylab, MA, USA) and vascular staplers (EndoGIA, Covidien Healthcare, USA), total gastrectomy, distal pancreatectomy with splenectomy, radical hepaticoduodenal, perigastric and celiac trunk lymphadenectomy, as well as cholecystectomy (Figure 2). Total operative time was 160 min and estimated blood loss was less than 200 mL. GI continuity was restored with a Roux-en-Y end-to-side esophago-jejunal reconstruction.

Pathology confirmed the presence of a poorly differentiated giant cell HCC developed in a liver cirrhosis. It was characterized by multinucleated giant cells and extensive areas of tissue necrosis (Figure 3). The tumor was invading the resected stomach and capsule of the body of pancreas and it was metastatic to 7 out of 54 resected lymph nodes. Disease-free margins of resection were achieved.

The patient had an uneventful course and was discharged on the 9th postoperative day. No adjuvant treat-

ment was given but close follow-up was suggested. Sixteen months after surgery, he is doing well with no evidence of locoregional recurrence or distant metastasis.

## DISCUSSION

Involvement of the GI tract by HCC is uncommon. In clinical HCC cases, the prevalence is 0.5% to 2% and in postmortem examination is discovered in about 10% of patients with HCC<sup>[2-4]</sup>. Chen *et al*<sup>[2]</sup>, who found GI tract invasion by HCC in 8 of 396 patients (2%), were the first to report GI tract involvement by HCC during the course of the disease. The mode of metastasis was presumed to be hematogenous spread in 2 patients (to the stomach in one and the jejunum in the other) and direct invasion in 5 patients (invasion to the stomach in one and of the duodenum in four), but was undetermined in the remaining patient, in whom the stomach was involved.

In the English language literature, 30 patients with direct GI tract invasion from HCC, including the present one, have been found in 12 case reports and 4 retrospective studies<sup>[5-10]</sup> (Table 1).

The most frequent initial symptom was melena, which was documented in 18 patients<sup>[11,12]</sup>. Hematemesis was recognized in only 6 of 23 patients in whom tumors

involved the upper GI tract. The history of hematemesis points out the site of tissue invasion and the amount of bleeding from the tumor. In those cases, massive varicose hemorrhage from portal hypertension should be considered as an alternative source of hematemesis. Endoscopic studies are essential to determine the source of bleeding. In 19 of the 29 patients, in whom HCC involved directly the upper GI tract; initial endoscopic assessment revealed an ulcerative hemorrhagic tumor protruding into the lumen of the stomach or duodenum.

The most common site of invasion was the duodenum, followed by the stomach and colon<sup>[13,14]</sup>. This is the first reported case of a direct invasion of both the stomach and pancreas from extrahepatically growing HCC that causes upper GI tract obstruction rather than hemorrhage.

The presumed mode of direct involvement to the GI tract is initiated by the adhesion of the serosal side of the adjacent organ with a bulky, exophytic tumor<sup>[2,6]</sup>. Some authors<sup>[6,8]</sup> have noted that in several patients with direct HCC invasion of the GI tract, the patient had received some form of regional therapy [transarterial chemoembolization (TACE), intra-arterial chemotherapy

(IA), either alone or in combination] because of unresectability and/or had experienced abdominal surgery. Accordingly, it was postulated that possible mechanisms underlying the direct GI tract involvement by HCC, other than as part of its natural course, may be TACE or IA chemotherapy-induced tumor necrosis, resulting in the promotion of subcapsular tumor adhesion to the GI serosa. Postoperative intraabdominal adhesions and scarring may account for the proximity of the GI tract to the tumor. Although no history of abdominal surgery or regional treatment was encountered, extensive necrosis found in the resected tumor specimen might partly explain its invading behavior in the presented case.

The median survival of patients who received curative surgery, nonsurgical treatment, and supportive therapy were 9.7, 3.0, and 1.2 mo, respectively<sup>[10,15]</sup>. The patients who had undergone oncologic surgery for cure survived for significantly longer compared to those receiving nonsurgical or supportive treatment, as strongly supported by the long disease-free survival of our patient. In light of the difficulty achieving relief of either bleeding or obstruction, surgical removal of such a tumor, together with involved structures, should be strongly considered.

Direct invasion of extrahepatically growing HCC to the GI tract is an unusual finding. Complete *en bloc* surgical resection of the tumor with negative margins may be the treatment of choice in order to control symptoms and to obtain oncologic cure in selected patients with an appropriate hepatic functional reserve.

### Abstract

Tumors of the minor papilla of the duodenum are quite rare. We successfully and safely treated an 18-mm adenoma of the minor papilla associated with pancreas divisum using endoscopic papillectomy. A 64-year-old man was admitted to our hospital for treatment of an asymptomatic mass in the minor papilla detected by upper gastrointestinal endoscopy. Endoscopic analysis showed an 18-mm, whitish, sessile mass, located in the duodenum proximal to a normal-appearing major papilla. Endoscopic retrograde pancreatography did not reveal the pancreatic duct. Magnetic resonance cholangiopancreatography showed a lack of the ventral pancreatic duct. We suspected this case was associated with pancreatic divisum; therefore, we performed endoscopic papillectomy of the minor papilla tumor. Subsequently, endoscopic pancreatic stent placement in the minor papilla was done to prevent drainage disturbance. The patient has been asymptomatic without recurrence of tumor or stenosis of the Santorini orifice upon endoscopic examination for the past 2 years.

### INTRODUCTION

Tumors arising in the region of the major duodenal papilla account for 5% of gastrointestinal (GI) neoplasms and 36% of resectable pancreaticoduodenal tumors<sup>[1]</sup>. Adenoma is a particularly common finding in patients with familial adenomatous polyposis (FAP). However, currently, adenomas that involve the papilla have been recognized increasingly often, even in the absence of FAP. With the development of endoscopic tools, the safety and the efficacy of endoscopic papillectomy has improved, and indications for endoscopic papillectomy have recently been expanded<sup>[2-5]</sup>. Recently, endoscopic papillectomy has been accepted as a viable alternative therapy to surgery in sporadic ampullary adenoma and has yielded high success and low recurrence rates<sup>[5,6]</sup>. However adenoma of the minor papilla has been reported in only a few cases<sup>[7-9]</sup>. We report a case of endoscopic treatment of sporadic adenoma of the minor papilla associated with pancreas divisum.

### CASE REPORT

A 64 year-old man was admitted to Ogaki Municipal Hospital for evaluation of an asymptomatic duodenal tumor that was found incidentally by X-ray examination of the stomach during a periodic health examination. The patient's medical history was otherwise unremarkable, and he had no family history of FAP. The laboratory findings were within normal limits, including tumor markers. Endoscopic analysis showed an 18-mm, whitish, elevated, slightly rough-surfaced mass, located in the descending duodenum proximal to

**Figure 1** Endoscopy showing an 18-mm, whitish, elevated, slightly rough-surfaced mass, located proximal to the major papilla.

**Figure 4** ERP was immediately performed *via* the minor papilla and it showed that the entire dorsal pancreatic ductal system was without communication with the ventral pancreatic duct.

**Figure 2** Hypotonic duodenography demonstrating a mass situated 15 mm proximal to the major papilla, which was raised highly from the duodenum.

**Figure 5** A pancreatic 5Fr stent was placed immediately after endoscopic papillectomy and coagulated the margin of the minor papilla tumor.

**Figure 3** EUS detected an 18 mm × 12 mm homogeneous, hypoechoic mass in the submucosal layer.

**Figure 6** Histopathological findings of the specimen showed tubular adenoma and the margin of the tumor was negative; however, a slight infiltration of the pancreatic duct system was revealed (HE stain, × 4).

a normal-appearing major papilla (Figure 1). Histological examination of forceps biopsy specimens from the mass revealed a tubular adenoma with moderate epithelial atypia. Hypotonic duodenography (double contrast radiographic study) demonstrated a mass situated 15 mm proximal to the major papilla, which was raised highly from the duodenum (Figure 2). Endoscopic retrograde pancreatography (ERP) (JF-230; Olympus, Tokyo, Japan) did not reveal the pancreatic duct upon initial examination.

Magnetic resonance cholangiopancreatography (MRCP) showed the entire dorsal pancreatic duct and the lack of a ventral pancreatic duct. We suspected this case was associated with pancreas divisum and that the tumor had arisen from the minor duodenal papilla. Endoscopic ultrasonography (EUS) (GF-UM240; Olympus) detected an 18 mm × 12 mm homogeneous,

hypoechoic mass in the submucosal layer (Figure 3). We further determined that the tumor was not invasive to the muscle layer. Endoscopic papillectomy of the minor papilla was performed after obtaining appropriate written informed consent. Submucosal injection of hypertonic saline-epinephrine (HSE) was carried out, and subsequently, snare excision was performed with polypectomy snare forceps. Following this, ERP was immediately performed *via* the minor papilla and it showed that the entire dorsal pancreatic ductal system was without communication with the ventral pancreatic duct (Figure 4). We placed a prophylactic pancreatic 5Fr stent (Figure 5) and endoscopic papillectomy was

performed successfully without any procedure-related complications. The resected specimen showed tubular adenoma with moderate epithelial atypia in the mucosal layer. However, the margin of the tumor was negative, with a slight infiltration of the pancreatic duct system (Figure 6). One week later, duodenoscopy was performed and no evidence of remaining tumor was seen, and the pancreatic stent was withdrawn. For the last 2 years, the patient has been asymptomatic without evidence of tumor recurrence or stenosis of the pancreatic duct orifice, based on endoscopic examinations performed every 6 mo.

## DISCUSSION

Endoscopic papillectomy of minor papilla tumors has been reported in only a few cases. Adenoma of the minor papilla associated with pancreas divisum is particularly rare and has been reported previously only once by Nakamura *et al*<sup>[8]</sup>. We think that duodenal and periampullary tumors occur in the general population, although patients with FAP invariably develop duodenal adenomas and have a risk of papillary carcinoma<sup>[10]</sup>. However, with the development of endoscopic tools and techniques, papillectomy has been accepted as a safe and feasible treatment for adenoma of the major papilla. It is important to diagnose tumor ductal infiltration correctly to determine endoscopic respectability by using intraductal ultrasonography (IDUS)<sup>[11]</sup>. In the present case, because ERP *via* the major and minor papilla was unsuccessful before the treatment of minor papillary tumors, we performed EUS before treatment and diagnosed the tumor as non-invasive to the muscle layer. EUS is a highly accurate and non-invasive modality for staging ampullary neoplasms and for evaluating ductal involvement by a tumor<sup>[12]</sup>. However, it is also essential to accurately diagnose tumors, adenoma or early cancer as not infiltrating Oddi's muscle layer. Therefore, we think it necessary to undertake IDUS before treatment of minor tumors of the papilla as frequently as possible.

In the present case, we injected HSE into the submucosal layer upon endoscopic papillectomy to reduce the risk of perforation. It is uncertain whether submucosal injections reduce the risk of perforation upon endoscopic papillectomy of a tumor of the major papilla. We think it safer to inject HSE into the submucosal layer upon endoscopic papillectomy of the tumor of the minor papilla. Many authors have reported the efficacy of pancreatic stents for decreasing both post-procedure pancreatitis and stenosis<sup>[13,14]</sup>. In the present case, the minor papilla drained all of the pancreatic juice flow from the dorsal pancreas. Therefore, we considered the placement of a pancreatic stent to be essential after endoscopic papillectomy of the minor papillary tumor.

We performed follow-up duodenoscopy and computed tomography at 3, 6, 12 and 18 mo later, and there was no evidence of tumor recurrence or

stenosis of the orifice of the Santorini duct for more than 2 years. Some authors have reported that long-standing pancreatic duct obstructions caused by relative stenosis of the minor duodenal papilla might be a factor promoting oncogenesis<sup>[15]</sup>. We will be performing a follow-up study of recurrence of minor papillary tumors and careful surveillance of the duodenum and pancreaticobiliary system.

## INTRODUCTION

Accessory spleen, a relatively common congenital defect, found in 10%-30% of patients at autopsy, is due to the fusion failure of the splenic anlage, which is located

in the dorsal mesogastrium<sup>[1-3]</sup>. The splenic hilus is the most common site of an accessory spleen followed by pancreatic tail. When an accessory spleen is located in the pancreas, it may mimic a hypervascular pancreatic tumor. Because an accessory spleen does not usually require treatment, accurate preoperative diagnosis is important. Here, we report an intrapancreatic accessory spleen and discuss its differential diagnosis and surgical management.

## CASE REPORT

A 51-year-old man without any abdominal discomfort or complaints had a health examination in our hospital in January 2008. Physical examination and laboratory data including peripheral blood counts, blood sugar and liver function tests were all unremarkable. Tumor markers, including CA19-9, CA125, carcino-embryonic antigen (CEA) and alpha-fetoprotein (AFP), were within the normal range. Abdominal sonography was performed, and a well-defined 4.2 cm × 5.2 cm focal lesion was noted in pancreatic tail. The echogenicity of the lesion was homogeneous and lower than that of the pancreatic parenchyma. On color Doppler sonography images, blood echo was observed in the lesion (Figure 1). Computed tomography (CT) confirmed the 4.0 cm × 5.1 cm mass in pancreatic tail (Figure 2). A nonfunctioning islet cell tumor or a solid pseudopapillary neoplasm of pancreatic tail was suspected on January 14, 2008, a laparotomic exploration was arranged to treat the lesion. After anesthesia, a left subcostal incision was performed and the well-defined mass was palpated in pancreatic tail. Because it was very close to the splenic hilus, excision of pancreatic tail and spleen was performed (Figure 3). An accessory spleen was confirmed by pathologic diagnosis (Figure 4).

## DISCUSSION

Accessory spleen is a congenital focus of healthy splenic tissue that is separated from the main body of spleen<sup>[1]</sup>. It results from the fusion failure of splenic anlage, which is located in the dorsal mesogastrium to fuse<sup>[2,3]</sup>. Accessory spleen, a relatively common congenital defect, is seen in 10%-30% of patients at autopsy<sup>[1,2,4]</sup>. Splenic hilus is the most common site of an accessory spleen followed by pancreatic tail. In an autopsy study of 3000 patients, 61 of 364 (17%) accessory spleens identified were found

**Figure 1** Transverse grayscale sonography image showing a homogeneous and isoechoic nodule (M) in pancreatic tail (arrow) near the spleen hilus with its echogenicity similar to that of the spleen (S).

**Figure 3** Excision of pancreatic tail and spleen with a well-defined lesion found in pancreatic tail.

**Figure 2** Axial CT image obtained in the portal venous phase showing an ovoid, well-enhanced nodule (AS) in pancreatic tail (arrow). The density of this lesion was higher than that of the pancreatic parenchyma and similar to that of the spleen (S). However, this finding is similar to that of pancreatic hypervascular tumors.

**Figure 4** An intrapancreatic accessory spleen confirmed by histological imaging (HE,  $\times 100$ ).

in pancreatic tail<sup>[5]</sup>. Although an accessory spleen usually appears as an isolated asymptomatic abnormality, it may have clinical significance in some situations. When an accessory spleen is located in the pancreas, it may mimic an islet cell tumor or a pseudopapillary neoplasm<sup>[6-8]</sup>. Because an accessory spleen does not usually require treatment, accurate preoperative diagnosis is important.

At present, the main preoperative diagnostic technique for intrapancreatic accessory spleen is radiological. On baseline sonography, intrapancreatic accessory spleens are well defined and round, ovoid or lobulated. The echogenicity of most intrapancreatic accessory spleens is low compared with pancreatic parenchyma. In all intrapancreatic accessory spleens, the echogenicity is homogeneous and identical to that of the main spleen. On color or power Doppler sonography images, blood supply to intrapancreatic accessory spleens from splenic artery or vein can be seen in some patients.

In recent years, contrast-enhanced ultrasound has been more frequently used to diagnose spleen abnormalities. Levovist is an ultrasound contrast agent containing air microbubbles. In the vascular phase, it increases signal intensities in both grey-scale and Doppler modes. In the delayed phase, also known as “hepatosplenic phase”, microbubbles are trapped almost exclusively by the hepatic and splenic parenchyma. By increasing the acoustic pressure, the

trapped microbubbles are disrupted and produce a non-correlated Doppler signal, which can be visualized as a strong transient enhancement. This method is also known as sonoscintigraphy, loss of correlation, stimulated acoustic emission and transient scattering<sup>[9]</sup>. Kim *et al.*<sup>[10]</sup> used this technique to study 6 patients with accessory spleen. In the vascular phase, the vascular pedicle was clearly visualized in 3 patients, including a patient with a suspected vascular pedicle on color Doppler sonography images. In the arterial phase, there was an inhomogeneous enhancement in 3 patients and a homogeneous enhancement in the other three patients. In all the 6 patients, the intrapancreatic accessory spleen became homogeneous in the portal phase, showing a dense and persistent enhancement for 3-5 min. In comparison with pancreatic parenchyma, the intrapancreatic accessory spleen appeared to be hyperechoic during all dynamic sonography phases. The echo enhancement of all intrapancreatic accessory spleens, however, was identical to that of the spleen in all phases.

Mortelé *et al.*<sup>[11]</sup> performed abdominal CT scans on 1000 consecutive patients. Of these patients, 156 (15.6%) had at least one accessory spleen, and 21 of these patients (13%) had more than one accessory spleen, with a maximum of three accessory spleens per patient, resulting in a total of 180 accessory spleens. Their anteroposterior diameter ranged 4-29 mm, with a mean of 11.9 mm. Their transverse diameter ranged 4-25 mm, with a mean of 11.6 mm. All accessory spleens were well defined, round in 141 patients (78.3%), ovoid in 27 (15%) and triangular in 12 (6.7%). The location of accessory spleens was variable. Most accessory spleens were located at the hilus of spleen. Intrapancreatic accessory spleens were seen in 2 patients. The findings suggest that most accessory spleens have a characteristic appearance on CT, and are well-defined, round masses that are smaller than 2 cm in diameter. Homogeneous enhancement on contrast-enhanced images is another important feature. However, in these case series, 32% of the accessory spleens were hypodense compared with the main spleen. Because all the accessory spleens were smaller than 1 cm in diameter, their attenuation may have been caused by partial volume effects. It is likely that, when thinner collimation (e.g.  $\leq 5$  mm) is used, accessory spleens appear similar to the spleen.

The most specific imaging method for diagnosing ectopic splenic tissue is nuclear scintigraphy using technetium-99m-labeled sulfur colloid or <sup>99m</sup>Tc-labeled heat-damaged RBCs. However, this technique offers far inferior anatomic resolution to CT or MRI, increasing likelihood of misdiagnosis<sup>[7]</sup>.

RES-specific contrast media are particles, such as superparamagnetic iron oxides, that are phagocytosed by the reticuloendothelial system (liver, spleen, lymph nodes, and bone marrow). Resovist-enhanced imaging can show an uptake of the contrast agent in normal splenic parenchyma because of its endothelial and Kupffer's cells. Negative enhancement or loss of signal

intensity of normal splenic parenchyma is delineated using T2-weighted images because of the more effective T2 shortening in these sequences<sup>[12]</sup>.

Endoscopic ultrasound (EUS)-guided fine-needle aspiration (FNA) biopsy is a very sensitive test, particularly for the evaluation of pancreatic lesions. Schreiner<sup>[13]</sup> and his colleagues reported three cases of intrapancreatic accessory spleen diagnosed by EUS-guided FNA, which revealed predominantly small lymphocytes with a subset of histiocytes, conspicuous eosinophils, and plasma cells. There was also characteristic CD8 positive immunostaining of endothelial cells in cell block sections.

In conclusion, when an asymptomatic intra-pancreatic mass is detected, the possibility of an accessory spleen should be considered. Although some radiological techniques are not widely used in clinics, well-defined round masses in pancreas should be considered accessory spleens, especially when its contrast-enhanced images are similar to those of the splenic parenchyma during all dynamic phases.

## Abstract

Congenital duodenal obstruction is rare in adulthood. An unusual presentation of this condition has led to difficult preoperative diagnosis. We present a case of proximal jejunal obstruction by a congenital band in an adult and review the literature.

## INTRODUCTION

Midgut malrotation is an anomaly of fetal intestinal rotation that usually presents in the first month of life. It is rare in adulthood. Congenital duodenal obstruction (atresia or stenosis) is associated with various congenital anomalies<sup>[1,2]</sup>. Midgut malrotation is a congenital anomaly referring to either lack of or incomplete rotation of the fetal intestines around the axis of the superior mesenteric artery during fetal development<sup>[3]</sup>. Most

patients present with bilious vomiting in the first month of life because of duodenal obstruction or a volvulus. The true incidence in adults is difficult to estimate because most patients remain asymptomatic and their conditions are, therefore, never diagnosed. A literature review by von Flüe *et al*<sup>[4]</sup> cites 40 cases from 1923 to 1992. Approximately 90% of patients with malrotation are diagnosed within the first year of life, of whom 80% are diagnosed within the first month of life<sup>[4]</sup>. Surgical therapy remains the mainstay of treatment regardless of age at presentation. The most commonly used approach is the Ladd procedure, which involves counterclockwise reduction of the volvulus if present, division of any coloduodenal bands, widening of the mesenteric base to prevent repeated volvulus, and prophylactic appendectomy<sup>[5]</sup>. We present a case of malrotation in an adult who presented with chronic abdominal pain.

## CASE REPORT

A 21-year-old woman was admitted to our hospital with a 15-year history of postprandial epigastric pain. Pain relieved after vomiting. The presentations since her teenage years with similar symptoms had failed to identify the cause of her pain. She had no changes in bowel habits, and no significant past medical history. On physical examination, the patient's vital signs were pulse 72, and regular, blood pressure 108/76, respirations 18, and temperature 36.8°C. She was a normally-developed and in no acute distress. Her abdomen was minimally distended on inspection. A succession splash was readily elicited. Normal bowel sounds were auscultated. She exhibited no peritoneal signs. She denied any history of disease and no history of abdominal surgery; her family history was negative for GI disease. She was on no current medications and denied alcohol or tobacco use. On admission, her rectal examination was normal, and her stool occult test was negative. Hemoglobin, white blood cell count, and basic chemical panel were all within normal values. Abdominal X-ray showed dilatation of the stomach and the proximal part of the duodenum. A computed abdominal tomography taken 6 mo before was normal. Upper gastrointestinal contrast studies showed the duodenum not crossing the lumbar spine. The entire small bowel was noted to be sequestered on the right side of the abdomen (Figure 1) Abdominal decompression was accomplished after placement of a nasogastric tube. The patient underwent

**Figure 1** Barium image from upper gastrointestinal series reveals duodenal obstruction, demonstrating high-grade stenosis of the fourth portion of the duodenum and extreme dilation of proximal duodenum (arrow).

**Figure 2** CT scan shows duodenum does not cross behind the superior mesenteric artery and the superior mesenteric vein, and extreme dilation of proximal duodenum (arrow).

aggressive fluid and electrolyte resuscitation, and parenteral nutrition was instituted for a suspected partial duodenal obstruction. On day 4 after admission to the hospital, the patient underwent abdominal exploration through a midline laparotomy, and was found to have a massively dilated stomach and proximal duodenum, and intestinal malrotation was confirmed. The small bowel and duodenum were on the right, with the transverse and descending colon positioned in the right upper quadrant. The duodenum was not posterior to the superior mesenteric artery, compressed between the peritoneal bands superiorly. Cecal bands attaching to the duodenum were immediately noted (Figure 2). The cecum was subsequently returned to the left abdomen. The appendix was not removed. The patient underwent the Ladd's procedure. Upon entering the abdomen, bands were lysed, and the duodenum and right colon were mobilized. Adhesions surrounding the superior mesenteric artery were also lysed (Figure 3). Postoperatively, the patient did well, tolerated a regular diet on postoperative day 4. The patient's postoperative course was uncomplicated. She was discharged from hospital on postoperative day 8. There were no complications with the surgery and the patient made a full and uneventful recovery and no recurrence was found after 4 mo of follow-up.

**Figure 3** One band running from the anti-mesenteric wall of proximal jejunum to cecum has been lysed (arrows) and no Treitz's ligament is found.

## DISCUSSION

The embryology of malrotation was described by Mall in 1898<sup>[6]</sup>. It was described in detail in 1923 by Dott. Intestinal malrotation was further classified by the specific embryologic abnormalities. Rotational abnormalities of the intestine occur when the normal embryologic rotation and fixation of the intestinal mesentery fail to take place<sup>[7]</sup>. Although the true incidence of intestinal rotation disorders is unknown, autopsy studies estimate that it may be as high as 1% of the total population<sup>[8]</sup>. Congenital anomalies of intestinal rotation are often seen in infants and children; however, they are uncommon in adults<sup>[9]</sup>. Yanez and Spitz<sup>[10]</sup> reported that only 50%-70% of patients actually present during the first 4 wk of life. In either event, there are a substantial number of discovered cases of malrotation that present after the neonatal period. In adults, it may cause chronic, but nebulous symptoms that are often difficult to diagnose. Adult presentation of malrotation is a difficult diagnosis because of the low incidence of the disorder. Patients with intestinal malrotation who were not diagnosed until adulthood may present with a variety of chronic symptoms, including nausea, vomiting, diarrhea, vague abdominal pain, early satiety and bloating, dyspepsia, and peptic or duodenal ulcer disease. Unfortunately, many patients never receive surgical referral and are instead labeled with functional or psychiatric disorders<sup>[11]</sup>. There may be a significant number of patients with malrotation who were undetected in the neonatal period either because they were asymptomatic, or because their symptoms were mild and misinterpreted. As these patients grow into adolescence and adulthood, they may continue to have misinterpreted symptoms, remain asymptomatic, or present with new onset of acute or chronic symptoms later in life, as did our patient. Adults, however, present with vague symptoms such as vomiting (bilious or non-bilious), weight loss, and recurrent or colicky abdominal pain (often postprandial)<sup>[10,12,13]</sup>. Intestinal obstruction, diarrhea, malabsorption, peritonitis, and septic shock also have been reported in the adult group<sup>[12]</sup>. Timing and frequency of the pain also can be variable<sup>[14]</sup>. It is these vague symptoms along with the relative rarity of adult

presentation of malrotation that often lead to a delay in diagnosis. In recent years, there has been increasing recognition of the various CT findings associated with malrotation in adults, leading to enhanced diagnostic accuracy<sup>[15]</sup>. In addition, the number of adults with malrotation misdiagnosed with non-abdominal (including psychiatric) pathology only reinforces the importance of obtaining routine imaging studies when the cause of chronic intermittent abdominal pain is unclear<sup>[16]</sup>. Generally, barium duodenography may still play an important role in the diagnosis of duodenal disorders. For the best management of duodenal diseases, barium studies in combination with cross-sectional imaging modalities may offer detailed evaluation of the duodenum and its surrounding organs. However, CT, US and MRI all provide excellent cross-sectional anatomic orientation, which allows accurate pre-operative evaluation<sup>[17]</sup>. Surgical therapy remains the mainstay of treatment regardless of age at presentation. For this reason, it is crucial that all surgeons operating on adult patients have firm knowledge of intestinal embryology and its anatomic variations. The most commonly used approach is the Ladd procedure, which involves counterclockwise reduction of the volvulus if present, division of any coloduodenal bands, widening of the mesenteric base to prevent repeated volvulus, and prophylactic appendectomy<sup>[5]</sup>. Although symptomatic malrotation after infancy requires prompt recognition and treatment, many patients with malrotation may remain asymptomatic into adulthood. Symptomatic or autopsy findings of malrotation were identified at a rate of 3 per 10 000 (0.03%) in a population-based birth defects study<sup>[18]</sup>. In 1996, a minimally invasive laparoscopic method was developed for performing Ladd's procedure in the case of malrotation without volvulus<sup>[19]</sup>.

### Abstract

In comparison to polyethylene glycol, lubiprostone offers other advantages and is increasingly being used as an adjunctive agent in diagnostic as well as management strategies not only in gastroenterology, but in other fields. For instance, lubiprostone exerts beneficial effects in cystic fibrosis tissues. It augments the chloride secretion in these cells by activating non-cystic fibrosis transmembrane regulator (CFTR) secretion of chloride by afflicted respiratory epithelia. Lubiprostone also seems to improve visualization of the gastrointestinal tract during procedures such as colonoscopy. This is especially true if the lubiprostone is administered prior to bowel cleansing with agents such as polyethylene glycol electrolyte (PEG-E). Lubiprostone also enhances and stimulates contraction in colonic as well as gastric muscles and may thus further contribute as a prokinetic agent. Besides these effects, lubiprostone also causes hyperpolarization in other tissues such as uterine muscle cells. This may prove to be of significant clinical benefit in the management of uterine pathologies in the near future.

Kapoor S. Lubiprostone: Clinical applications beyond constipation. *World J Gastroenterol* 2009; 15(9): 1147 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1147.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1147>

### TO THE EDITOR

I read with great interest the recent article by Moeser *et al*<sup>[1]</sup>. The authors have provided an interesting

comparison of lubiprostone and polyethylene glycol. In comparison with polyethylene glycol, lubiprostone offers other advantages and is increasingly being used as an adjunctive agent in diagnostic as well as management strategies not only in gastroenterology, but in other fields.

For instance, lubiprostone exerts beneficial effects in cystic fibrosis tissues. It augments the chloride secretion in these cells by activating non-cystic fibrosis transmembrane regulator (CFTR) secretion of chloride by afflicted respiratory epithelia<sup>[2]</sup>. Lubiprostone also seems to improve visualization of the gastrointestinal tract during procedures such as colonoscopy. This is especially true if the lubiprostone is administered prior to bowel cleansing with the agents such as polyethylene glycol electrolyte (PEG-E)<sup>[3]</sup>. Lubiprostone also enhances and stimulates contraction in colonic as well as gastric muscles and may, thus, further contribute as a prokinetic agent<sup>[4]</sup>. Besides these effects, lubiprostone also causes hyperpolarization in other tissues such as uterine muscle cells<sup>[5]</sup>. This may prove to be of significant clinical benefit in the management of uterine pathologies in the near future.

It is clear from the above examples that lubiprostone has an array of clinical features that may enhance its clinical application in gastroenterology. Further studies are needed to evaluate lubiprostone as an effective agent for the management of other diseases besides constipation.

## ACKNOWLEDGMENTS

# Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: Introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Leader Frontier: Comment on excitement and existing problems of core fields, and offer suggestions for the future research; (3) Topic Highlight: Experts in gastroenterology and hepatology to focus on certain individual hot topics and try to provide answers to the clinical questions on the topics; (4) Observation: Which updates the development of old and new questions, highlights unsolved questions, and provides strategies on how to solve the questions; (5) Guidelines for Basic Research: Which provides Guidelines for basic research; (6) Guidelines for Clinical Practice: Which provides guidelines for clinical diagnosis and treatment; (7) Review Articles: Summarize the representative progress in core scientific disciplines, comment on the research status, and make suggestions for the future work; (8) Original Articles: Originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: Briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: Report a rare or typical case; (11) Letters to the Editor: Discuss and make reply to the contributions published in *WJG*, or introduce and comment on a controversial issue of general interest; (12) Book Reviews: Introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: Guidelines or common understanding for gastroenterology and hepatology from international academic committee.

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The trial register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,  
Ocean International Center,  
No.62 Dongsihuan Zhonglu,  
Chaoyang District, Beijing 100025, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-59080039  
Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Contents

### EDITORIAL

- 1153 Islet transplantation and antioxidant management: A comprehensive review  
*Mohseni Salehi Monfared SS, Larijani B, Abdollahi M*

### TOPIC HIGHLIGHT

- 1162 Alcohol and liver  
*Osna NA*
- 1163 Nuclear effects of ethanol-induced proteasome inhibition in liver cells  
*Bardag-Gorce F*
- 1168 *In vitro* and *in vivo* models of acute alcohol exposure  
*Dolganiuc A, Szabo G*
- 1178 Autophagy and ethanol-induced liver injury  
*Donohue TM Jr*
- 1186 Is the iron regulatory hormone hepcidin a risk factor for alcoholic liver disease?  
*Harrison-Findik DD*
- 1194 Impact of asialoglycoprotein receptor deficiency on the development of liver injury  
*Lee SML, Casey CA, McVicker BL*
- 1201 Hepatitis C virus and ethanol alter antigen presentation in liver cells  
*Osna NA*
- 1209 Alcohol metabolites and lipopolysaccharide: Roles in the development and/or progression of alcoholic liver disease  
*Schaffert CS, Duryee MJ, Hunter CD, Hamilton BC 3rd, DeVeney AL, Huerter MM, Klassen LW, Thiele GM*
- 1219 Alcohol-induced protein hyperacetylation: Mechanisms and consequences  
*Shepard BD, Tuma PL*

### ORIGINAL ARTICLES

- 1231 Role of cathepsin B-mediated apoptosis in fulminant hepatic failure in mice  
*Yan BZ, Wang W, Chen LY, Bi MR, Lu YJ, Li BX, Yang BS*

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

Mohseni Salehi Monfared SS, Larijani B, Abdollahi M. Islet transplantation and antioxidant management: A comprehensive review. *World J Gastroenterol* 2009; 15(10): 1153-1161 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1153.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1153>

### Abstract

Islet transplantation as a promising treatment for type 1 diabetes has received widespread attention. Oxidative stress plays an essential role in cell injury during islet isolation and transplantation procedures. Antioxidants have been used in various studies to improve islet transplantation procedures. The present study reviews the role of oxidative stress and the benefits of antioxidants in islet transplantation procedures. The bibliographical databases Pubmed and Scopus were searched up to November 2008. All relevant human and animal *in-vivo* and *in-vitro* studies, which investigated antioxidants on islets, were included. Almost all the tested antioxidants used in the *in-vitro* studies enhanced islet viability and insulin secretion. Better control of blood glucose after transplantation was the major outcome of antioxidant therapy in all *in-vivo* studies. The data also indicated that antioxidants improved islet transplantation procedures. Although there is still insufficient evidence to draw definitive conclusions about the efficacy of individual supplements, the benefits of antioxidants in islet isolation procedures cannot be ignored.

### INTRODUCTION

Diabetes mellitus which is characterized by hyperglycemia has become an important disorder with major costs and complications worldwide. In a genetically susceptible person with an environmental trigger such as viruses and toxins, autoimmune destruction of  $\beta$  cells can occur causing type 1 diabetes usually in childhood and in young adults<sup>[1]</sup>. Type 2 diabetes usually results from dysfunction of  $\beta$  cells and peripheral insulin resistance. It is accepted that oxidative stress is increased in both type 1 and type 2 diabetes, and it has been shown in many studies that biochemical markers of oxidative stress are higher in tissue samples and in the pancreas of diabetic patients<sup>[2]</sup>. However, secondary complications comprising micro- and macro-vascular disorders which result in frequent amputation, end-stage renal failure, and blindness have motivated various investigators to identify new therapeutic approaches to cure diabetes. With this aim, whole pancreas transplantation was first carried out in 1966 by Kelly and Lillehei at the University of Minnesota and was then performed worldwide. Marked morbidity following pancreas transplantation prompted researchers to find other possible ways of curing this disease. As reviewed by Fontaine *et al*<sup>[3]</sup>, since 1974 when the first human islet transplantation was conducted by Sutherland and his colleagues, and then up to 1999, among approximately 1000 patients who received islet allotransplantations, most of the results were disappointing and only 10% remained insulin-independent for longer than one year.

In 1999, use of the Edmonton protocol with its steroid-free immunosuppressive regimen was an impressive leap in achieving insulin-independence after islet transplantation<sup>[4]</sup>. Although the Edmonton protocol

succeeded in achieving insulin-independence, two or more donors are still needed to achieve normoglycemia following islet transplantation.

## GREAT EFFORTS TO OPTIMIZE ISLET TRANSPLANTATION

Recent years, many studies have been carried out to optimize the Edmonton protocol to obtain the final goal of one-donor islet transplantation. Donor characteristics and pancreas procurement are the first steps. The quality of the donor pancreas depends largely on donor factors, such as age, body mass index, serum glucose levels, and hemodynamic stability<sup>[5]</sup>. In the procurement phase, improved surgical techniques such as *in-vivo* atraumatic dissection and *in-situ* separation have made sufficient advancements in minimizing warm ischemia before isolation. Moreover, using perfluorocarbon (PFC) and oxygen in the University of Wisconsin (UW) solution during cold ischemic preservation, which is identified as the Two layer method (TLM), has enhanced the final quality of islets<sup>[6]</sup>.

One of the most important areas of research in islet transplantation is the isolation procedure, which remains a major topic of islet transplant investigations. At present, the maximum rate of purified islets at leading centers is about 50% to 70%<sup>[7]</sup>. The largest reduction in islet yield occurs during the islet isolation phase. Below we will look in detail at the islet isolation phase, which has been the focus of a large number of studies.

Other efforts have focused on new approaches relating to the best site of transplantation, better revascularization of islet-grafts, visualization after engraftment, and further anti-rejection strategies which are not covered in this review. For the latest progress in these aspects of islet transplantation, readers are referred to two recently published review articles<sup>[8,9]</sup>.

## ISLET ISOLATION AND ROLE OF OXIDATIVE STRESS

Successful islet transplantation would enable patients to live without tedious multiple insulin injections and reduce the risk of hypoglycemia. As previously mentioned, the main restriction in this procedure is the loss of healthy islets at the end of the operation due to the inevitable prolonged time required for islet isolation. In the clinical setting, the isolated islets are transplanted immediately or within a few days after harvesting from donors. Isolated islets are avascular and are therefore ischemic from the time of isolation through to the period required for revascularization. Prolonged ischemia has profound deleterious effects on the islets, resulting in a significant loss of islet cells. Two major factors which are expected to cause potential cell damage include hypoxia and enzymatic/mechanical trauma related to the experimental procedures.

Reactive oxygen species (ROS) in physiological concentrations provide normal conditions to protect

cells, for instance they are important within white cells to allow effective defense against infection. Nevertheless, whenever ROS are accumulated in excess and for long periods they can destroy cells. Free radicals cause damage to cellular proteins, membrane lipids and nuclear nucleic acids. The only protective mechanism present in the body to protect cells against excessive free radicals is the antioxidant enzyme system. Catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GPx) are the main antioxidant enzymes. Hypoxia which occurs during the islet transplantation procedure initiates a cascade of biochemical reactions which results in the production of ROS causing necrosis and apoptosis *via* intracellular pathways.

Another important point which can lead to worsening of this condition is that  $\beta$  cells contain low levels of antioxidative enzymes such as CAT, SOD and GPx and thus they can only weakly defend against oxidative stress<sup>[10-12]</sup>. These findings have demonstrated the major destructive role of oxidative stress in islet transplantation and have encouraged investigators to use antioxidants during the isolation phase and the entire transplantation process to overcome the final lack of healthy islets.

Various strategies such as modifications in enzymatic digestion<sup>[13]</sup>, purification with iodixanol instead of ficoll<sup>[14]</sup>, incubation of purified islets in culture medium, genetic manipulation for overexpression<sup>[15,16]</sup> or silencing<sup>[17]</sup> of specific genes, employment of different anti-inflammatory or other supplements such as small intestinal submucosa<sup>[18]</sup> and serecin<sup>[19]</sup> have been considered in an attempt to increase islet quality and yield. In a previous publication we hypothesized that using phototherapy could improve islet function before transplantation<sup>[20]</sup>.

This review focuses on antioxidant management in islet transplantation procedures and evaluated both *in-vitro* and *in-vivo* studies.

## ANTIOXIDANT RECRUITMENT IN ISLET TRANSPLANTATION STUDIES

To perform a comprehensive survey and obtain all related studies we searched Pubmed and Scopus databases up to November 2008. Search terms were “antioxidant”, “islet”, “transplant” and “oxidative stress”. Individual antioxidants such as vitamin E or C were also searched with the term “islet”.

There were many studies in which various methods other than utilizing antioxidants were used to increase function and viability of islets which were not included in this review. Table 1 lists the various antioxidant agents which have been added to islets during the isolation procedure or to the culture medium. Table 2 shows the *in-vivo* studies.

### Metabolite and vitamin antioxidants

Vitamin E or tocopherol was the supplement most used to enhance the viability of islets. This lipid-soluble

Authors	Substance/Dose	Sample	Study design	Duration	Assessments
Campbell <i>et al</i> <sup>[21]</sup> , 2008	Sodium selenite (30 nmol/L)	Rat	Islets were incubated with/without Na <sub>2</sub> SeO <sub>3</sub>	72 h	Insulin content ↑ Insulin secretion ↑ Glucose-stimulated insulin secretion <sup>1</sup>
Kanitkar <i>et al</i> <sup>[22]</sup> , 2008	Curcumin (10 µmol/L)	Rat	Cryopreservation of islets with/without curcumin Assessments were performed after 24 h culture post-thawing	Cryopreserved	Intact islets ↑ ROS ↓ Insulin Secretion ↑ Expression of Hsp70 and HO-1 ↑
Thomas <i>et al</i> <sup>[23]</sup> , 2007	Peptide SS-31 (1 nmol/L)	Mice	SS-31 was added to all reagents which were used for islet isolation	Isolation procedure	Islet apoptosis ↓ Islet yield ↑
		Human	Islets were incubated in culture medium with without SS-31	72 h	Islet apoptosis ↓
Hara <i>et al</i> <sup>[24]</sup> , 2007	Epigallocatechin-3-gallate (EGCG) (36, 72, 360 µmol/L)	Rat	Islets cultured under normal or H/R condition with/without EGCG	48 h	Islet apoptosis ↓ LDH ↓ Insulin secretion ↑
Xiong <i>et al</i> <sup>[25]</sup> , 2006	Puerarin (10, 50, 100 µmol/L)	Rat	Islets cultured under normal or H <sub>2</sub> O <sub>2</sub> stress conditions with/without Puerarin	24 h	Islet apoptosis ↓, Islet viability ↑ CAT & SOD activity ↑, ROS ↓ Insulin secretion ↑
Marzorati <i>et al</i> <sup>[26]</sup> , 2006	Glutathione (1, 5, 10 mmol/L) Vitamin E (2 × 10 <sup>-5</sup> mmol/L) Ascorbic acid (0.3 mmol/L)	Human	Antioxidant agents were added to culture medium individually	48 h	Glutathione : CCL2/MCP-1 release ↓ Insulin secretion <sup>1</sup> Vitamin E: CCL2/MCP-1 release <sup>1</sup> Ascorbic acid: CCL2/MCP-1 release <sup>1</sup>
Amoli <i>et al</i> <sup>[27]</sup> , 2006	Curcumin (10, 20 µmol/L)	Rat	Curcumin was added to culture medium	18 h + 24 h	MCP-1 release ↓
Rao <i>et al</i> <sup>[28]</sup> , 2005	MCI - 186	Rat	Islets were treated with H <sub>2</sub> O <sub>2</sub> in the presence or absence of MCI-186	18 h	Cell death ↓
Avila <i>et al</i> <sup>[29]</sup> , 2005	L-glutamine (5 mmol/L)	Human	Pancreas were manually perfused through the main pancreatic duct with either the standard HBSS or with HBSS + L-glutamine	0 → 24 h	Islet yield ↑ Lipid peroxidation (MDA) ↓ Glutathione (GSH) ↑ Viability <sup>1</sup> Insulin secretion <sup>1</sup>
Brandhorst <i>et al</i> <sup>[30]</sup> , 2005	Free L-glutamine (2.5 & 5 mmol/L/L) Stable L-glutamine [NALG] (2.5 & 5 mmol/L)	Pig	Islets pretreated with free L-glutamine or NALG for 24 h and then stressed with H <sub>2</sub> O <sub>2</sub> , ETA or cytokine mix	24 h	Viability: L-glutamine ↑ NALG <sup>1</sup>
Giovagnoli <i>et al</i> <sup>[31]</sup> , 2005	Encapsulated enzymes (100 mg/35 mL)	NPCCs	NPCCs were co-cultured with/without entrapped enzymes	9 d	Viability ↑, Insulin secretion ↑ Insulin/DNA ratio ↑ mRNA expression of insulin and Glut-2 ↑
Bottino <i>et al</i> <sup>[32]</sup> , 2004	MnTDE (34 µmol/L)	Human	MnTDE was added as a supplement to culture or isolation medium	60 h	Islet yield ↑, Insulin secretion ↑ NF-κB DNA-binding ↓ IL6 & MCP-1 ↓, IL8 <sup>1</sup> PARP activation ↑
Arata <i>et al</i> <sup>[33]</sup> , 2004	Ascorbic Acid-2 Glucoside (AA2G) (100 µg/mL)	Human	Cryopreservation of islets with UW solution or AA2G + UW solution	Cryopreserved	Viability ↑ Insulin secretion ↑ Insulin gene expression ↑
Luca <i>et al</i> <sup>[34]</sup> , 2003	Free vitamin D3 (2 µmol/L) Encapsulated vitamin D3 (20 µmol/L)	Rat	Islets were treated with/without vitamin D3	9 d	Insulin secretion ↑
Hardikar <i>et al</i> <sup>[35]</sup> , 2001	Taurine (0.3 & 3 mmol/L)	Rat	Cryopreservation of islets with/without taurine	Cryopreserved	Viability ↑ Lipid peroxidation ↓
Luca <i>et al</i> <sup>[36]</sup> , 2000	Vitamin D3 Vitamin E	NPCCs	NPCC cells were treated with/without VitD3 & VitE during their maturation and differentiation process	16 d	Large & intact islets ↑ Insulin secretion ↑
Tajiri <i>et al</i> <sup>[37]</sup> , 1999	Vitamin E (50 µg/mL)	Rat	Islets were co-cultured with/without vitamin E	1 d	Insulin secretion ↑
Shewade <i>et al</i> <sup>[38]</sup> , 1999	Riboflavin	Rat	Inclusion of riboflavin in the cryopreserved medium	Cryopreserved	Viability ↑ Lipid peroxidation ↓ GSH ↑, Insulin secretion ↑
Jindal <i>et al</i> <sup>[39]</sup> , 1996	Zinc (20 µmol/L)	Rat	Preservation of islets in UW and Hanks solution with/without Zinc	1, 3, 6 d	Viability <sup>1</sup>

↑: Significant increase compared with non-treated group; ↓: Significant decrease compared with non-treated group; <sup>1</sup>No significance difference between groups. Hsp70: Heat shock protein 70; HO-1: Heme oxygenase-1; H/R: Hypoxia/Reoxygenation; LDH: Lactate dehydrogenase; CCL2/MCP-1: Monocyte chemoattractant protein 1; HBSS: Hanks balanced salt solution; NALG: N-acetyl-L-alanyl-L-glutamine; MDA: Malondialdehyde; MnTDE: Manganese (III) 5,10,15,20-tetrakis (1,3-diethyl-2-imidazolyl) porphyrin; NF-κB: Nuclear factor-κB; PARP: Poly (ADP-ribose) Polymerase indicative of ongoing cell damage and death; UW: University of Wisconsin; NPCCs: Neonatal pancreatic porcine cell clusters.

Table 2 *In-vivo* effects of antioxidants on pancreatic islets

Author	Substance/Dose	Sample	Procedure	Output
Thomas <i>et al</i> <sup>[23]</sup> , 2007	Peptide SS-31 (3 mg/kg)	Mice → Mice	Injection of SS-31 to donor mouse + adding SS-31 during islet isolation	Better glucose control after transplant
Avila <i>et al</i> <sup>[29]</sup> , 2005	L-glutamine (5 mmol/L)	Human → Rat	Transplantation of human islets which were treated before with/without intraductal L-glutamine to nude rats	Normoglycemia percentage ↑ (83% <i>vs</i> 26%) Time to reach normoglycemia ↓ (1.83 d <i>vs</i> 7.6 d)
Brown <i>et al</i> <sup>[40]</sup> , 2005	Pyruvate Vitamin E Vitamin C	Rat → Rat	Oral administration of pyruvate, vitamin E and vitamin C during perioperative period	Pyruvate enhanced engraftment & functionality of suboptimal islet mass Vitamin E and vitamin C failed to enhance
Olcott <i>et al</i> <sup>[41]</sup> , 2004	Salen-manganese [EUK-8] (100 mg/kg)	Mice → Mice	Daily treatment with/without EUK-8 (IP injection) to recipient NOD mice	Better glucose control until 20 d after transplant
Winter <i>et al</i> <sup>[42]</sup> , 2002	Vitamin A (500 µg) Ascorbic Acid (40 mg) Vitamin E (10.6 mg) Selenium (2 µg)	Rat → Rat	Oral antioxidants, 24 h prior to transplantation	Slight better glucose control
Bottino <i>et al</i> <sup>[43]</sup> , 2002	SOD mimetic compound (34 µmol/L)	Human → Mice	Culture of isolated islet in the presence of SOD mimetic for at least 2 h before transplantation	Better glucose control
Hardikar <i>et al</i> <sup>[35]</sup> , 2001	Taurine (0.3 & 3 mmol/L)	Rat → Mice	Transplantation of islets which were previously cryopreserved with/without taurine	No significant difference was observed
Tajiri <i>et al</i> <sup>[37]</sup> , 1999	Vitamin E (40 mg/kg)	Rat → Rat	Every other day IP injection of vitamin E to transplanted rats	Treatment for 2 not for 6 wk enhanced basal insulin release and arginine induced insulin release
Vajkoczy <i>et al</i> <sup>[44]</sup> , 1997	Vitamin E (150, 8000 mg/kg)	Rat → Rat	Oral vitamin E after xenograft	Reduction of xenograft leukocyte-endothelium interaction at day 6 Adequate development of functional capillary density
Gembal <i>et al</i> <sup>[45]</sup> , 1993	Allopurinol Vitamin E Chlorpromazine	Rat → Rat	Transplantation of islets which were pretreated with/without combination of allopurinol, alpha-tocopherol and chlorpromazine.	Better glucose control after 3 d

↑: Significant increase compared with non-treated group; ↓: Significant decrease compared with non-treated group.

vitamin protects membranes from oxidation by reacting with lipid radicals produced in the lipid peroxidation chain reaction<sup>[46]</sup>. Luca *et al*<sup>[36]</sup> and Tajiri *et al*<sup>[37]</sup> have shown that vitamin E can increase secretion of insulin from islets when added *in-vitro* to the culture medium. Likewise, when vitamin E was administered before, after, or during the transplantation period<sup>[37,42,44]</sup>, the islet transplantation outcome was better and glucose control was slightly superior compared with control groups. Another study demonstrated that digestion buffer which contained vitamin E, resulted in healthy isolated islets, however, this study was not designed to evaluate the effect of vitamin E and therefore a control group was absent. An investigation into the effect of a mixture of allopurinol, vitamin E and chlorpromazine on islet transplantation concluded that a combination of free radical scavengers, antioxidants and membrane stabilizing drugs may be used to increase the effectiveness of islet transplantation<sup>[45]</sup>.

In contrast to the above-mentioned positive effects of vitamin E, Brown and colleagues<sup>[40]</sup> showed that vitamin E and C could not enhance the function of rat engrafted islets; although the authors did not specify the dose which they applied. In a different study<sup>[26]</sup>, the use of vitamin E and ascorbic acid did not decrease the release of monocyte chemoattractant protein 1 (MCP-1)

from human islets. MCP-1 is a chemokine secreted from pancreatic islets to recruit the immune system and plays an important role in the clinical outcome of islet transplantation because of its proinflammatory property<sup>[47,48]</sup>. Nevertheless, this review did not assess the secretion of insulin or the viability of islets following the use of vitamin E, thus we can not conclude that islets may or may not benefit from vitamin E.

Ascorbic acid or vitamin C is a monosaccharide antioxidant. This water-soluble vitamin is a reducing agent and can neutralize oxygen species. This metabolite antioxidant in the form of ascorbic acid-2 glucoside (AA2G) supplies a stable form of vitamin C in the culture medium and cryopreservation solution and thus improves viability, secretion and expression of insulin in cryopreserved human islets<sup>[33]</sup>. In the study by Winter *et al*<sup>[42]</sup>, the combined administration of vitamin C and E, but not vitamin A and selenium, led to a significant improvement in functional islet graft survival, associated with augmented islet engraftment. In contrast, Brown *et al*<sup>[40]</sup> and Marzocchi *et al*<sup>[26]</sup> showed that the combination of vitamin E and C was unable to improve graft survival or decrease *in-vitro* MCP-1 release, respectively.

Glutathione (GSH), as a cysteine-containing peptide, is maintained in the reduced form by the enzyme glutathione reductase and in turn reduces other

metabolites and enzyme systems as well as reacting directly with oxidants in the cells. When GSH was added to culture medium, in contrast to vitamin E and C, it reduced MCP-1<sup>[26]</sup>. L-glutamine as a precursor of GSH was shown to increase islet yield when added intra-ductally during human pancreatic islet isolation. This study indicates that intra-cellular GSH levels can be increased by means of intra-ductal glutamine administration prior to the isolation procedure. Consequently, authors found lower cellular lipid peroxidation in islets isolated from glutamine-pre-treated pancreata, indicating less oxidative damage. Although they could not detect any differences in cell viability and islet function *in vitro*, the islets isolated from glutamine-pre-treated pancreata performed significantly better than controls after transplantation in diabetic nude mice<sup>[29]</sup>. Supporting this study, Brandhorst *et al.*<sup>[30]</sup> demonstrated that pig islet culture will significantly improve if L-glutamine is administered in an unbound (free) form compared with the stable compound N-acetyl-L-alanyl-L-glutamine (NALG).

Taurine (2-amino ethanesulfonic acid) an end-product of sulfur amino acid metabolism, is one of the most abundant free amino acids in the body. The membrane stabilizing, free radical scavenging, and osmoregulatory roles of taurine have been well documented<sup>[49,50]</sup>. In one study, taurine enhanced viability and reduced lipid peroxidation in cryopreserved islets. However, no significant difference was observed in the islet insulin content between groups following cryopreservation, and taurine could not enhance glucose control following transplantation of treated islets<sup>[55]</sup>.

1, 25 dihydroxyvitamin D3, the active form of vitamin D3 is a membrane antioxidant and can prevent lipid peroxidation at the cell membrane<sup>[51]</sup>. Luca and colleagues treated neonatal porcine cell clusters (NPCCs) with vitamin D3 at a certain time in their maturation and differentiation process. Insulin recovery showed that vitamin D3, unlike untreated controls, resulted in preservation of islet function for significantly long periods of time. Furthermore, this group exhibited sustained release vitamin D3 which entrapped vitamin D3 in microspheres. They showed that this form of vitamin D3 caused more insulin secretion compared with free vitamin D3 and both forms caused more insulin secretion than the untreated control group<sup>[34,36]</sup>.

Another study evaluated the benefit of 1, 25 dihydroxyvitamin D3 (1, 25 D3) on cytokine-induced human pancreatic islets. Addition of 1, 25 D3 significantly reduced nitrite release, IL-6 production and MHC class I expression which were not significantly different from controls. The authors suggested that vitamin D3 could affect this *via* reduction of cytotoxic challenges. Hence, it might play a role in the prevention of islet allograft rejection. However, more *in-vivo* studies are required to affirm this suggestion.

Riboflavin (vitamin B2) although it is not a pure antioxidant, has been used in one study<sup>[38]</sup>. The authors showed that inclusion of this vitamin in the cryopreservation medium could protect islets comparable to healthy fresh isolated islets.

### Trace elements

Selenium as an essential trace element plays an important role in the expression of some selenoproteins and selenoenzymes such as GPx. The antioxidative property of this element has been confirmed in many different cell types<sup>[52]</sup>. The insulin-mimetic effect of selenium has been found both *in-vitro* and *in-vivo*<sup>[53]</sup>. To ameliorate islet function, Campbell *et al.*<sup>[21]</sup> showed that sodium selenite could increase islet content and secretion but not glucose-stimulated insulin secretion in culture media. In the study by Winter, when a combination of vitamin E, C, A and selenium were administered orally to transplanted mice, no significant improvement in functional islet graft survival was seen when compared with mice administered only vitamin C and E.

Furthermore, selenium in the insulin-transferrin-selenium (ITS) compound is a commercially available media supplement for the culture of mammalian cells under serum-free or near serum-free conditions. In islet culture, when Fraga and colleagues used ITS supplement instead of FBS, ITS was capable of maintaining viable islets for up to two months<sup>[54]</sup>.

Zinc, another trace element antioxidant has a role in the storage, synthesis, and secretion of insulin in islet cells. In one study<sup>[39]</sup> when investigators added zinc to cold preservation UW and Hanks solution, no difference in islet viability was seen between the groups. The authors concluded that despite the integral role of zinc in islet metabolism, they were unable to find a beneficial role for zinc in cold storage solutions for the purposes of islet preservation.

Manganese as a trace element is a component of antioxidant enzymes and is used in new SOD mimetic compounds which will be discussed later.

### Herbs

Curcumin is a polyphenolic compound commonly found in the dietary spice turmeric<sup>[55,56]</sup>. Curcumin is an inhibitor of nuclear factor- $\kappa$ B (NF- $\kappa$ B) and has various biological activities such as anti inflammatory, antioxidant, antiseptic and anticancer effects<sup>[57,58]</sup>. In two different studies, curcumin was shown to decrease MCP-1 release from islets<sup>[27]</sup>, decrease generation of ROS, increase secretion of insulin, and present more intact islets<sup>[22]</sup>.

Puerarin, the main isoflavone glycoside found in the Chinese herb, Radix of Pueraria lobata (Willd) Ohwi, has been used for various medicinal purposes in traditional Chinese medicine. It has been shown that puerarin has antioxidant activities such as radical scavenging and increasing SOD activity as well as antihyperglycemic effects<sup>[59]</sup>. Xiong *et al.*<sup>[25]</sup> found that if islets pretreated with puerarin for 48 h were exposed to H<sub>2</sub>O<sub>2</sub>, this did not result in loss of islet viability. They showed that this protective effect resulted from inhibition of free radical generation. Puerarin was also found to increase CAT and SOD activities.

Epigallocatechin-3-gallate (EGCG) is the main ingredient found in green tea. Anticarcinogenic,

antioxidant, and antiangiogenic activities have been attributed to EGCG as a constituent of green tea<sup>[60]</sup>. In the study by Hara and colleagues, EGCG was shown to protect islets from hypoxia/reoxygenation injury. Insulin secretion was increased and apoptosis was inhibited by EGCG<sup>[24]</sup>.

### Enzymes and new antioxidants

Two forms of enzymes, encapsulated slow release SOD and CAT and SOD-mimetic compounds were shown to increase viability, islet yield, and to decrease the release of MCP-1 and IL-6 from islets.

Encapsulated SOD and CAT in Poly D, L-lactide-co-glycolide (PLGA) microspheres were analyzed with NPCC cells. These powerful antioxidizing agents were shown to significantly improve morphology, viability and function, as assessed by microscopy, molecular, biochemical and functional studies on the incubated NPCCs<sup>[31]</sup>.

**SOD mimetics:** There are four main classes of SOD mimetics including desferrioxamine, macrocyclics, salen compounds, and mesoporphyrins<sup>[61]</sup>. Two types of these compounds have been employed to possibly enhance islet survival by counteracting oxidative stress.

MnTDE is a manganese-porphyrin pentachloride, a synthetic porphyrin protein, which has been prepared as a SOD mimetic<sup>[62]</sup>. Synthetic probes with MnTDE (AEOL10113 or AEOL10150) were used in the culture medium of human islets to ameliorate islet yield and insulin secretion. When treated islets were transplanted into diabetic mice, glucose control was better than in the non-treated group<sup>[32,43]</sup>.

MnTMPyP Mn (III) tetrakis (1-methyl-4-pyridyl) porphyrin, is a composition of porphyrin SOD mimetics. MnTMPyP preserved islet viability upon exposure to a nitric oxide donor in culture medium<sup>[61]</sup>.

EUK-8 a salen compound SOD mimetic is one of a new class of synthetic salen-manganese compounds with SOD, peroxidase, and CAT activities. EUK-8 treatment prolonged the survival of islet allografts in newly diabetic non-obese diabetic (NOD) mice<sup>[41]</sup>.

Peptide SS-31 (D-Arg-2-, 6-dimethyltyrosine-Lys-Phe-NH<sub>2</sub>) is a novel peptide shown to target the inner mitochondrial membrane and prevent oxidative damage to cells. It has been shown to decrease islet apoptosis and increase islet yield<sup>[23]</sup>.

MCI-186 (3-methyl-1-phenyl-2-pyrazolin-5-one; Edaravone) is a new free radical scavenger produced for use in some clinical conditions. It is a strong scavenger of hydroxyl radicals and was shown to have benefits in myocarditis and cerebral infarction. MCI-186 prevented islet cell death dose-dependently when cells were treated with H<sub>2</sub>O<sub>2</sub><sup>[28]</sup>.

## DISCUSSION

Most studies on antioxidants and diabetes in the literature have evaluated the possible effects of antioxidants in preventing  $\beta$  cell glucose toxicity and

cytokine-mediated cell damage in the field of type 1 diabetes pathophysiology. The role of antioxidants in type 2 diabetes is still undetermined due to scientific conflict. Vitamin E and C, selenium and the majority of antioxidant trace elements, as well as herbs and drugs have been used or are being used to try to manage diabetes and its complications<sup>[2,63]</sup>. Moreover, there are, as seen in this review, few studies available which used antioxidants to improve islet transplantation outcome. However, a review of the existing studies indicates that many antioxidants are able to enhance cellular defense mechanisms against oxidative stress in islet cells. With deeper inspection of the presented studies, the effects of these drug compounds can be divided into two separate sub-categories.

The first sub-category concerns the direct antioxidant effects of drug compounds on islet viability (direct inactivation of free oxygen species). For instance, vitamin E and C were shown to increase viability of islets but they failed to decrease MCP-1 release from the cells. This shows that these vitamins do not act *via* inflammatory pathways. Enzyme antioxidants also promote islet yield and activity by direct inactivation of free radicals. The role of nitric oxide (NO) in early islet transplantation rejection should not be overlooked. NO was shown in experimental studies to harm islet cells in culture medium early after transplantation. N (G)-monomethyl-L-arginine (NMA) (a reversible inhibitor of NO synthase) prevented the dysfunction or destruction of cultured islets and markedly decreased the time needed to restore euglycemia after intraportal transplantation of islets in diabetic rats<sup>[64]</sup>. Direct antioxidants such as vitamin E and salen-manganese compounds can prevent NO and nitrite radicals as well as ROS<sup>[65,66]</sup> thus may play a protective role.

The second sub-category of effects concerns the action of these drug compounds on the modulation of beta cell apoptosis initiation and signaling. One potential ROS-dependent target molecule is the nuclear transcriptional factor NF- $\kappa$ B. It is now known that NF- $\kappa$ B is a key transcription factor involved in regulating proinflammatory cytokines, chemokines, adhesion molecules, and inflammatory enzymes. Some antioxidants block the effects of NF- $\kappa$ B including curcumin<sup>[22,27]</sup>, glutathione and MnTDE porphyrin<sup>[32]</sup> and have been shown to ameliorate islet yields by reducing MCP-1 release as a consequence of NF- $\kappa$ B blockade.

However, the two above-mentioned sub-categories may change following further investigations. Newer studies, especially those after 2004, have focused on the possible pathways by which antioxidants may improve the function of islets.

As previously stated, antioxidant enzymes are found in low levels in islets compared with other tissues. In addition, minimal amounts of GPx protein and mRNA expression as well as GPx activity in islets have been detected<sup>[67]</sup>, showing that GPx is low compared with SOD and CAT in islets. It is important to develop methods to increase islet survival and the number of islets during isolation and transplantation, thus

the suggestion of using antioxidants to improve islet transplantation is reasonable.

However, based on current data from *in-vitro* studies, we can conclude that the addition of an antioxidant during islet isolation procedures would result in better islet function. Furthermore, the overexpression of intracellular antioxidant enzymes and proteins<sup>[68]</sup>, as well as transgenic islets<sup>[15]</sup> has been found to improve the function of islets, which is in agreement with our conclusions.

Interestingly, all the *in-vivo* studies with the exception of one on taurine<sup>[35]</sup> showed better control of blood glucose using antioxidant supplementation mainly in the early stages of islet transplantation. However, similar to *in-vitro* studies, there was no significant advantage of any one antioxidant on glucose control following transplantation. Of course, the lack of human studies limits our conclusions regarding *in-vivo* research and necessitates further investigations to establish the benefits of antioxidants in human islet transplantation. Fortunately, there is sufficient evidence on the existence of oxidative stress in diabetes and the significant role of antioxidants in the reduction of diabetic complications<sup>[69-76]</sup>.

## CONCLUSION

The collective data reviewed here show that different antioxidants improve islet transplantation procedures both *in-vitro* and *in-vivo*. We recommend antioxidant supplementation in islet isolation protocols, however, there is still insufficient evidence to draw definitive conclusions about the efficacy of individual supplements and to support profitable antioxidant management *in-vivo* particularly in humans.

## FROM THE EDITOR

Liver is a primary site of ethanol metabolism, which makes this organ susceptible to alcohol-induced damage. Alcoholic liver disease (ALD) has many manifestations and complicated pathogenesis. In this Topic Highlight, we included the key reviews that characterize new findings about the mechanisms of ALD development and might be of strong interest for clinicians and researchers involved in liver alcohol studies.

Being the primary site of alcohol metabolism, liver is severely influenced by alcohol drinking. The combination of toxic effects of alcohol and numerous predisposing factors usually form the basis for ALD development. This disease has many manifestations, which are triggered by multiple pathogenic factors, causing progression in liver damage from steatosis to liver cirrhosis and hepatocarcinoma. The progression between various stages of ALD is driven by so-called "second hits", which trigger ALD development. In 2007, in *World Journal of Gastroenterology*, we published Topic Highlight: Alcohol liver injury: Pathological feature and models. There, we reviewed the role of alcohol in changes of iron metabolism, proteasome function, immune response, signaling mechanisms, transmethylation reactions, as well as apoptosis and mitochondrial damage. Current Topic Highlight is a logical continuation of the previous one, which further expands our understanding of the mechanisms of ALD progression and complexity of ALD pathogenesis, thereby providing important information for hepatologists about the modern directions in alcohol research.

### Abstract

Alcohol ingestion causes alteration in several cellular mechanisms, and leads to inflammation, apoptosis, immunological response defects, and fibrosis. These phenomena are associated with significant changes in the epigenetic mechanisms, and subsequently, to liver cell memory. The ubiquitin-proteasome pathway is one of the vital pathways in the cell that becomes dysfunctional as a result of chronic ethanol consumption. Inhibition of the proteasome activity in the nucleus causes changes in the turnover of transcriptional factors, histone modifying enzymes, and therefore, affects epigenetic mechanisms. Alcohol consumption has been associated with an increase in histone acetylation and a decrease in histone methylation, which leads to gene expression changes. DNA and histone modifications that result from ethanol-induced proteasome inhibition are key players in regulating gene expression, especially genes involved in the cell cycle, immunological responses, and metabolism of ethanol. The present review highlights the consequences of ethanol-induced proteasome inhibition in the nucleus of liver cells that are chronically exposed to ethanol.

### INTRODUCTION

Proteasomes of mammalian cells exhibit a complex heterogeneity. Different proteasome variants exist and perform subtle activities. The 20S proteasome catalytic core binds to different activators (19S, 11S and PA200), and the resulting complexes perform specific functions, such as ATP-ubiquitin proteolysis, immunological response, cell cycle regulation, nuclear factor (NF)  $\kappa$ B activation, response to hypoxia, and transcription<sup>[1]</sup>. Upon immune response, or interferon (IFN) $\gamma$  treatment, the three catalytic subunits,  $\beta$ 1,  $\beta$ 2 and  $\beta$ 5, are replaced by three different subunits, LMP2, LMP7 and MECL-1, respectively, which form the immunoproteasome<sup>[2]</sup>. Several chemical compounds, proteins and regulatory complexes, function as activators or inhibitors of the catalytic core 20S proteasome<sup>[3]</sup>. Some of them are termed gate-openers because they provoke the opening of the gate at the alpha-type subunits of the 20S proteasome<sup>[4]</sup>, and facilitate the access of designated proteins to be degraded to the catalytic chamber formed by the beta-type subunits. The best known of these activators are the regulatory complex 19S, which is involved in the ubiquitin-proteasome pathway (UPP), the PA28 $\alpha$ / $\beta$  and PA28 $\gamma$  complexes, which, among other functions, are important for the generation of epitope peptides presented to the major histocompatibility complex<sup>[5]</sup>, and PA200, which is implicated in DNA repair<sup>[6]</sup>. Recently, the hybrid form of the 26S proteasome, which contains both 19S and PA28 complexes associated at the two opposite sides of the 20S core particle, has also been characterized<sup>[7]</sup>, and other activators and proteins that modulate the proteasome activity are yet to be discovered.

As complex as is the UPP, it does not work alone. These regulatory complexes and proteasome interacting proteins (PIPs) complement the UPP to perform specific functions. Proteasome failure occurs in the liver cells because chronic ethanol exposure interferes with

the binding of the 20S catalytic core to its regulatory complex and to its PIPs. The 26S proteasome is responsible for the ATP-ubiquitin degradation of short-lived cellular proteins and the elimination of damaged and misfolded proteins, in addition to providing basic housekeeping functions<sup>[8-10]</sup>. Therefore, damaged and ubiquitinated proteins accumulate, causing protein aggregation, such as Mallory-Denk body (MDB) formation<sup>[11-13]</sup>, when, because of chronic ethanol ingestion, the 20S is unable to bind to the 19S to form the 26S proteasome, which leads to cell death and tissue damage<sup>[14]</sup>.

## PROTEASOMES AND TRANSCRIPTION

The UPP plays an important role in a variety of cellular functions, primarily *via* its proteolytic activity. However, recent studies have implicated this pathway in the direct regulation of specific transcriptional factors<sup>[15,16]</sup>. It is now believed that the proteolytic activity of the proteasome is critical in promoting the exchange of transcriptional factors on chromatin, and possibly facilitating multiple rounds of transcription initiation, hence controlling gene expression<sup>[17]</sup>. Proteasomes are also now widely accepted as being essential for promoting the exchange of transcriptional factors on chromatin<sup>[18,19]</sup>. A growing body of evidence demonstrates that the components of the UPP are directly, and mechanistically, involved in transcription and in regulating the gene expression of the DNA repair system<sup>[20,21]</sup>, cell cycle<sup>[22,23]</sup>, and chromatin modifying enzymes<sup>[17]</sup>. Although the role of the UPP in regulating many transcription factors, such as p53, NFκB and hypoxia-inducible factor 1  $\alpha$ , is well established, the role of the UPP in regulating epigenetic mechanisms has only recently been given attention<sup>[24]</sup>.

Ethanol-induced oxidative stress in nuclei is believed to damage DNA and proteins, thereby disrupting genomic integrity<sup>[25]</sup>. Oxidative stress has also been shown to cause adduct formation with lysine located in the N-terminal histone tails<sup>[26]</sup>. These lysine residues are the site of a number of post-translational modifications that regulate chromatin function. Therefore, chronic accumulation of oxidative stress adduct modifications may cause epigenetic changes, which may have important implications in terms of histone function and genomic integrity. Oxidatively damaged histones are degraded by a nuclear 20S proteasome in an ATP- and ubiquitin-independent manner<sup>[27]</sup>, which indicates that damaged histones accumulate when the activity of the proteasome is inhibited and causes alteration of the epigenetic mechanisms.

However, the effect of ethanol-induced proteasome inhibition in the nucleus, and thus in regulating gene expression, is still not well known. Inhibition of proteasome function has been widely reported in models of alcoholic liver disease (ALD)<sup>[28,29]</sup>, but how proteasome dysfunction may enhance hepatotoxicity is not well defined. It has been reported that chronic ethanol exposure leads to post-translational

modifications of the alpha type subunits of the 20S proteasome that constitute the opening of the gate to the catalytic chamber of the 20S proteasome<sup>[29]</sup>, thus blocking the opening of the gate and causing proteasome activity to decrease. Recently, proteasome activity has been measured in the isolated nuclei from liver cells of rats fed ethanol chronically, and the proteasome was found to be significantly inhibited (personal observation, manuscript submitted to *World Journal of Gastroenterology*, 2008). The inhibition of proteasome activity in the nucleus is therefore etiologically involved in the accumulation of damaged proteins in the nucleus, and in the deregulation of transcription.

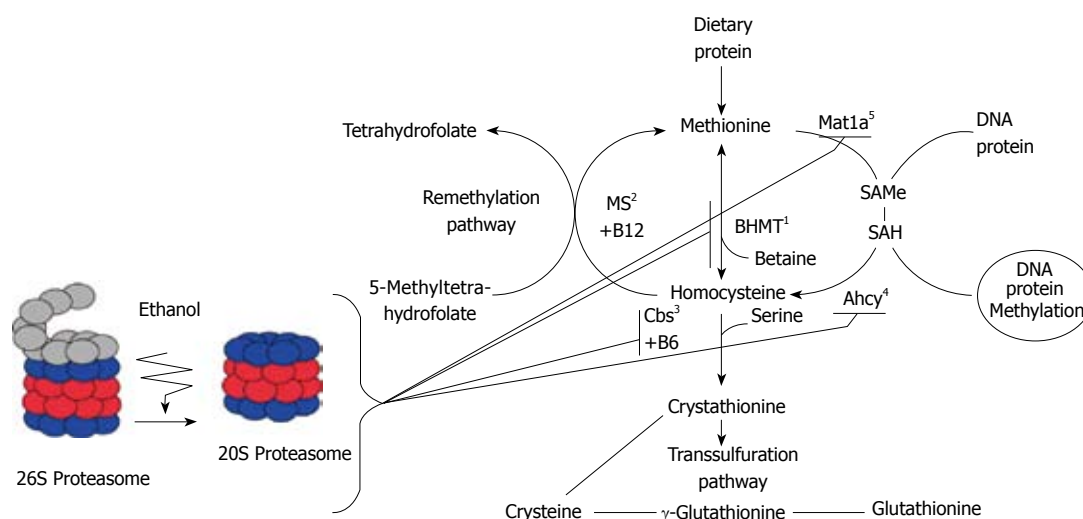

Thus, it seems reasonable to postulate that the nucleus should have a more important proteasomal activity than other cellular compartments. It is possible that proteasome inhibition, caused by chronic ethanol feeding in the nucleus, may be greater than the inhibition caused in the cytosolic compartment<sup>[29]</sup>.

## EPIGENETIC MECHANISMS AND PROTEASOME INHIBITION

Chronic ethanol exposure causes an alteration in liver cell memory by changing the epigenetic mechanisms, thus causing significant liver pathology that persists after ethanol withdrawal<sup>[30]</sup>. Dr. French's group has shown that cells forming MDBs have a memory of the exposure to the drug even four months after drug withdrawal<sup>[31]</sup>. This memory is primarily associated with histone modifications that are recovered when s-adenosylmethionine (SAME) is added to the drug-primed mouse diet<sup>[32]</sup>.

Epigenetic mechanisms are involved in development, phenotype determination and maintenance, aging, and cancer. These epigenetic mechanisms are based on histone modifications controlled by histone acetyltransferases (HATs) and histone methyltransferases, and by DNA methylation, controlled by a regulated balance between DNA methyltransferase and demethylase. These epigenetic events can change rapidly in response to changes in cell signaling, which are initiated by environmental influences, such as inflammation, metabolism, or toxic injury. These changes cause the genome to respond globally or in a restricted manner, depending on the nature of the signals generated. During these responses, the histone modifications themselves are rapidly changed as well<sup>[33]</sup>. The dynamics of this process are pervasive and extremely complex, which makes it difficult to connect the epigenetic responses to the final manifestations. The identification of key epigenetic changes, which are linked to alcohol liver injury, is of high interest and is at its very beginning. Histone modifying enzymes are the key target to regulate the histone modifications. Histone deacetylase (HDAC) inhibitors and demethylating agents are currently used in clinical trials to treat cancer. HDAC inhibitors, like trichostatin A, repress

**Figure 1** Illustration of methionine metabolism enzymes system and the effects of proteasome inhibition in the remethylation pathway. 1-BHMT: Betaine homocysteine Methyltransferase; 2-MS: Methionine synthase; 3-Cbs: Cystathionine beta-Synthase; 4-Ahcy: S'-adenosylhomocysteine transferase; 5-Mat1a: Methionine adenosyltransferase.

the expression of genes that induce growth arrest, cellular differentiation and apoptosis<sup>[34]</sup>. Likewise, DNA methyltransferase inhibitors, like 5-azacytidine (Aza), are being used in clinical trials to treat cancer. Aza, a potent inhibitor of Dnmt 1 and Dnmt3a (not Dnmt3b), induces demethylation and reactivation of silenced tumor suppressor genes<sup>[35]</sup>. Moreover, proteasome and HDAC inhibitors may be a prominent combination in future cancer therapy<sup>[36]</sup>, and specifically, in gastrointestinal cancer<sup>[37]</sup>.

## HISTONE MODIFICATIONS AND HISTONE MODIFYING ENZYMES

The nucleosome surface interacts with several histone modifying enzymes that are responsible for histone tail lysine or arginine modifications<sup>[38]</sup>, operating as part of a predictive and initiated epigenetic code that defines patterns of gene expression<sup>[39]</sup>. Histone modifications control the accessibility of DNA elements for transcription factors, which influences gene expression. These modifications control the recruitment of proteins involved in DNA methylation and affect chromatin structure and function<sup>[40]</sup>.

Histone modification alterations can change long-term effects on gene expression patterns by influencing chromatin structure throughout the cell cycle, and from one cell generation to the next<sup>[41]</sup>. For instance, trimethylation of H3K9me3 and depletion of acetylation leads to gene silencing, because H3K9me3 acts as a binding site for heterochromatin-forming protein HP1. In the nuclear extract from liver cells of rats fed ethanol chronically, H3K9me3 is decreased and H3K9 acetylation is increased<sup>[42,43]</sup>. These histone modifications are linked to DNA modifications and affect gene expression because DNA methylation is dependent on prior histone methylation<sup>[44-47]</sup>.

More epigenetic mechanisms still need to be elucidated with respect to alcoholism, particularly histone

modifications, such as methylation, phosphorylation and ubiquitinylation of lysine and arginine residues. The task will be to identify the modifications and the specific modifying enzymes that regulate gene expression and account for the cellular memory observed when ethanol is fed chronically<sup>[30]</sup>. For example, it has been reported that a global increase in histone H3 lysine 9 acetylation, histone H3 lysine 4 dimethylation and H3 lysine 27 trimethylation is found in the liver of rats fed ethanol chronically<sup>[48]</sup>, which correlates with an increase and a decrease, respectively, in transcriptionally active promoters. However, the genes linked to these changes are still to be identified. Microarray analysis has shown that hundreds of genes are up-regulated and hundreds are down-regulated when rats are fed ethanol for 1 mo, which indicates that ethanol causes several epigenetic changes that affect gene expression<sup>[25]</sup>. More specifically, gene expression of ALDH1a4<sup>[48]</sup> and ADH<sup>[49]</sup> are up-regulated, which suggests a change in the epigenetic events that regulate the expression of these genes in the liver of rats fed ethanol chronically. However, the linkage of ethanol-induced proteasome inhibition to the changes in the expression of these genes still needs to be determined. Data mining of microarray analysis of proteasome inhibition has shown that, similar to ethanol-treated rat liver, several genes are changed, which indicates an epigenetic phenomenon c proteasome inhibition<sup>[17,50]</sup>.

## PROTEASOME INHIBITION AND REMETHYLATION PATHWAY

The changes in gene expression in the remethylation pathway, particularly for the enzymes that regenerate SAMe, cause deregulation of cellular methylation, thus resulting in abnormal cellular methylation.

Hyperhomocysteinemia (HHcy) is a leading cause of liver injury in ALD. A lack of the activity of the enzymes responsible for homocysteine metabolism,

particularly cystathionine b-synthase (Cbs) or 5,10-methylenetetrahydrofolate reductase, results in severe forms of HHcy. Additionally, nutritional deficiencies in B vitamin cofactors required for homocysteine metabolism, including folic acid, vitamin B6 (pyridoxal phosphate), and/or B12 (methylcobalamin), can induce HHcy (Figure 1).

Proteasome inhibition is believed to be involved etiologically in the changes in gene expression of these enzymes responsible for the hepatic transmethylation reactions. Indeed, analyses performed on the livers of rats given PS-341 (bortezomib, Velcade®), a dipeptide boronic acid used to inhibit proteasome activity, and used today as an anticancer agent in human myeloma<sup>[51]</sup>, have shown down-regulation of gene expression for methionine metabolizing enzymes. Proteasome inhibition causes a decrease in methionine adenosyltransferase (MAT1a), in S-adenosylhomocysteine hydrolase gene expression, and a marked decrease in gene expression of betaine-homocysteine methyltransferase<sup>[50,52]</sup> and Cbs<sup>[53]</sup>, which affects cellular methylation. Rats fed ethanol chronically also exhibit a relatively low level of MAT1a, which is associated with low levels of SAME and faster growth<sup>[54]</sup>. These observations indicate that SAME is an attractive agent for both chemoprevention and treatment of alcohol associated liver cancer<sup>[54]</sup>.

Proteasome inhibition, induced by ethanol feeding, is associated with histone modifications, and is involved in the regulation of histone modifying enzymes, such as the HAT p300<sup>[42]</sup>. It is believed that proteasome inhibition affects gene expression, particularly genes of the transmethylation pathway, *via* an epigenetic mechanism that involves modified histone and transcriptional factors.

## CONCLUSION

Regulation of gene expression of the transmethylation pathway is one of the promising approaches to counteract proteasome inhibition effects. Investigating the changes in the remethylation pathway, particularly the enzymes that regenerate SAME, the major methyl group donor, is essential to identify the key enzyme that is changed by chronic ethanol exposure and proteasome inhibition.

## Abstract

Alcohol abuse is a global problem due to the financial burden on society and the healthcare system. While the harmful health effects of chronic alcohol abuse are well established, more recent data suggest that acute alcohol consumption also affects human wellbeing. Thus, there is a need for research models in order to fully understand the effect of acute alcohol abuse on different body systems and organs. The present manuscript summarizes the interdisciplinary advantages and disadvantages of currently available human and non-human models of acute alcohol abuse, and identifies their suitability for biomedical research.

## INTRODUCTION

Alcohol abuse is widely spread around the globe<sup>[1-9]</sup>.

Alcohol is the third leading cause of preventable death in the United States and the third leading cause of healthy years lost to death and disability in developed nations<sup>[9]</sup>. Humans use and abuse alcohol acutely or chronically, when alcohol consumption is frequent and dependence has developed<sup>[10]</sup>. Although significant progress was made in the area of alcohol research during the last decades, the pathogenesis of alcohol use and abuse is not fully understood. Further, most research was focused on alcoholism, which is an advanced stage of alcohol abuse, involving chronic alcohol consumption, alcohol dependence and severe health and social consequences<sup>[1-13]</sup>. Thus, research models are emergent in order to detail what drives human desire to consume alcohol, how the body responds to alcohol, and most important, what are the beneficial and harmful effects of acute alcohol consumption on the human body.

## ACUTE ALCOHOL ABUSE (AAA): HOW BIG THE PROBLEM REALLY IS?

In the USA, a “drink” is defined as an equivalent of 14 g alcohol, which equals roughly 1 shot [1.25 oz of 40% (80-proof) liquor], 1 (12 oz) beer (4.2 mL/L, Ethanol), or 1 (4 oz) glass of wine (12 mL/L, Ethanol)<sup>[14]</sup>. In other countries, the alcohol content of a serving is measured in “units”. One unit (about 25 mL of a 40% 80-proof liquor) contains 7.9 g of pure ethanol<sup>[8,15]</sup>. However, in many countries the “standard drink” is used to quantify alcohol intake. More importantly, the standard drink varies significantly from country to country, from 10 mL (7.9 g) of alcohol in the UK to as high as 25 mL (19.75 g) in Japan<sup>[16]</sup>. Current use includes at least one drink in the past 30 d; binge drinking is defined as five or more drinks on the same occasion within 2 h at least once in the past 30 d; and heavy use is defined as five or more drinks on the same occasion on at least 5 different days in the past 30 d<sup>[11-13]</sup>. The 0.08% blood alcohol level (BAL) is the legal limit for most states in the US and it is achieved with consumption of five or more drinks for an adult male and four or more drinks for an adult female<sup>[11-13]</sup>.

Traditionally medical research focuses on the mechanisms of chronic alcohol abuse; this is due to the significant financial burden that society encountered primarily from chronic alcohol abusers<sup>[1-13]</sup>. However, more recently acute alcohol abuse has emerged as a

Table 1 The characteristics of *in vitro* and *in vivo* models of AAA

AAA model	Advantages	Disadvantages	Area of research
<i>In vitro</i>	Low cost Technically easy to perform Large number of experimental groups Pure cell populations Single cell type or multi-cell type co-culture Strictly controlled settings yielding reproducible results	Limited alcohol metabolism Limited complexity at cellular and tissue levels Limited areas of research, not suitable for behavioral and social studies.	Behavioral and biomedical
<i>In vivo</i>	Availability of physiological routes of alcohol administration Complex interactions of all bodily organs and systems, including complex metabolism Controlled settings, caloric and composition controls Indications to individual and population variability	Ethical concerns High cost Limited information about the effect on one separate cell population.	All areas of research including biomedical, behavioral and social.

social problem<sup>[17]</sup>. The National Survey on Drug Use and Health (NSDUH) estimated that in the USA about 4.4 million persons had used alcohol for the first time in 2004, which lead to about 12000 “new recruits” per day; this was significantly greater than in 2002 (3.9 million) and 2003 (4.1 million). Most (86.9%) of the 4.4 million recent alcohol initiates were younger than 21 years of age at the time of encounter. More than one fifth (22.%) of people age 12 or older participated in binge drinking at least once in the 30 d prior to the survey in 2004<sup>[12]</sup>. Acute alcohol intake in the form of binge drinking in 2004 was highest for the 18- to 25-year-old age group compared with other age groups, with the peak rate occurring at age 21<sup>[1,5-7,11-13]</sup>. The statistics also show that illness and death among young adults primarily result from lifestyle choices and behaviors, including excessive alcohol use<sup>[18,19]</sup>.

### AAA: BIOMEDICAL IMPACT

The known biological effects of AAA include those of the central nervous system (CNS) and non-CNS origin. Alcohol use is characterized by symptoms of CNS intoxication, impaired brain activity, poor motor coordination, and behavioral changes<sup>[20,21]</sup>. AAA leads to impaired CNS activity due to alcohol's effect on synthesis<sup>[22]</sup>, release<sup>[23]</sup> and signaling<sup>[23,24]</sup> of neurotransmitters, including serotonin<sup>[25,26]</sup>, glutamate<sup>[27]</sup>, GABA<sup>[28]</sup>, endocannabinoids<sup>[29,30]</sup> and their receptors. AAA causes damage and functional impairment of the gastrointestinal (GI) tract, including luminal GI<sup>[31-38]</sup>, liver<sup>[39-55]</sup>, and pancreas<sup>[56-62]</sup>; it also affects the protein, carbohydrate, and fat metabolism<sup>[58,63-66]</sup>. AAA leads to insufficient immune system responses to infections; such deficiency was observed both in organ-specific<sup>[67-69]</sup> and systemic infections<sup>[70-72]</sup>. Acute alcohol intoxication impairs the ability of the host to counteract hemorrhagic shock<sup>[73]</sup>, augments corticosteroid release<sup>[74]</sup> and delays wound healing<sup>[75-78]</sup>, thus contributing to higher morbidity and mortality<sup>[79]</sup> and prolonged recovery from trauma<sup>[80]</sup>. The pathogenesis of AAA effects on human health is not fully understood.

### MODELS OF AAA

Research of acute alcohol consumption/abuse is entirely

based on models, due to their advantage of controlled settings. Currently there are *in vitro* and *in vivo* models of AAA; their characteristics are defined in Table 1. In contrast to chronic alcohol abuse, the research of AAA has not benefited from population studies due to recall bias<sup>[81-84]</sup>.

One important feature of AAA models is the definition of biologically meaningful levels of alcohol, either *in vitro* or *in vivo*, and their relationship to blood alcohol levels (BAL) in humans. This is an important requirement of the research models of AAA, because BAL can be detected as soon as minimal amounts of alcohol are ingested<sup>[85]</sup>, however measurable affects of alcohol on physiology and/or behavior is established at 0.08% or above this level, with individual variations depending on the species, metabolic particularities, age, gender and genetic background<sup>[86-97]</sup>. It is also important to identify that AAA models differ by their route of alcohol delivery to achieve alcohol intoxication, some of them being physiological, such as oral administration, while others being non-physiological, when ethanol is administered by parenteral routes. Nevertheless, current research shows that the BAL levels, rather than the route of alcohol administration play a major role in the establishment of the biological effects of alcohol<sup>[97]</sup>.

Thus, optimal AAA models should fulfill several criteria: (1) Define the length of alcohol exposure. *In vitro* the length of acute alcohol treatment is variable in diverse published experimental settings and range from seconds to hours; it is currently accepted that treatment with alcohol for up to 24 h is considered as an acute setting<sup>[98-106]</sup>. *In vivo* the consumption of alcohol in one setting implies that the entire dose of alcohol is consumed at once, while a ‘binge’ is defined by NIAAA as an excessive pattern of alcohol drinking that produces BAL greater than 0.08% within a 2-h period and may, or may not, be associated with dependence<sup>[11,12,17,18]</sup>. Thus any model using consumption of biologically active amounts of alcohol within 2 h is considered an acceptable model of AAA<sup>[81,107-121]</sup>. (2) Establish an exposure to an accurate concentration of ethanol. For *in vitro* studies the 10-100 mmol/L ethanol range is considered physiological, with 25 mmol/L ethanol being close to 0.08% BAL achieved *in vivo* after 4-5 drink equivalents<sup>[7,11,12,98-106]</sup>. For the *in vivo* studies an 0.08% BAL or above this level yields

signs of intoxication and it is employed in the majority of biomedical studies<sup>[107-121]</sup>. (3) Recruit individuals who are currently not and never have been alcohol abusers for *in vivo* studies and employ alcohol-naïve primary cells or cell lines for *in vitro* studies. Alcohol use habits of the study participants are usually determined by questionnaires<sup>[122]</sup>. Among most frequently used questionnaires are those that incorporate the AUDIT and CAGE tests<sup>[123-125]</sup>; the study parameters are usually permissive for males who had alcohol use of fewer than nine drinks/week, females < 6 drinks/week.

### IN VITRO AAA MODEL

The *in vitro* alcohol treatment model is based on supplementation of culture media with pure alcohol, usually 200-proof ethanol. Currently supplementation of cell culture with a wide variety of alcohol concentrations, ranging from 1 to 500 mmol/L, is reported in the bio-medical literature. One of the major concerns with the *in vitro* alcohol treatment using concentrations above 100 mmol/L is the direct cytotoxic effect of alcohol on cells<sup>[40,100]</sup>. At lower concentrations (< 100 mmol/L), alcohol changes the redox status of the cells and alters intercellular junctions<sup>[33,126]</sup>, increases the membrane fluidity of cells<sup>[127-129]</sup> and affects the composition of lipid rafts<sup>[106,130,131]</sup>, all of which may contribute to alcohol-mediated increase in transcellular and paracellular permeability<sup>[132,133]</sup> and thus affect cell function<sup>[106,130-134]</sup>. Alcohol also affects the expression of adhesion molecules<sup>[135]</sup>, which may be a concern when using adherent cell types due to possible cell detachment. Additional concerns arise from the possibility of modified *ex vivo* function of some primary cells, including hepatocytes, stellate cells and their precursors, due to limited *ex vivo* environment compared to *in vivo* conditions<sup>[136-138]</sup>.

From a technical point, the acute alcohol exposure of cells *in vitro* may be hampered by alcohol evaporation. To avoid the fluctuation of alcohol concentration due to evaporation, investigators used settings where ethanol was added into the culture media and the cell culture plates were maintained for the entire duration of stimulation in a microclimate chamber at 37°C with gas mixture and an alcohol atmosphere<sup>[139]</sup>. For example, if the desired alcohol concentration in the cell culture is 25 mmol/L, a Petri dish with 2 × the alcohol amount (50 mmol/L) was placed on the bottom of the chamber to ensure the saturation of the gas in the chamber; such conditions maintain the initial alcohol concentration ± 15% over a 24 h period<sup>[139]</sup>. However, depending on the scientific question of the study, the declining alcohol levels *in vitro* may be desired to mimic the alcohol elimination *in vivo*; in these situations the *in vitro* experiments are disadvantaged by the absence/limitation of alcohol metabolism<sup>[76,134]</sup>.

The *in vitro* AAA model offers the possibility of primary *in vitro* exposure of alcohol-naïve cells to alcohol alone or its combinations with diverse pharmacological or naturally-derived substances<sup>[24,28,31,35,36,42,55,68,71,72,96,103]</sup>,

but also the investigation of the effects of *in vivo* exposure to alcohol followed by *ex vivo* exposure to other stimulants<sup>[110,113,115]</sup> or *vice versa*. One other main characteristic of the *in vitro* AAA model is its simplicity, often considered as an advantage or disadvantage depending on the research goal. Most of the *in vitro* research involves culture of a single cell type<sup>[134,139-142]</sup> or co-culture of several cell types<sup>[143]</sup>; while such an approach brings forward the differential effect of alcohol on pure cell populations, and/or their intercellular interaction; it lacks the systemic alcohol metabolism and intercellular interactions. More recently significant efforts were invested in establishment of more complex *in vitro* systems, such as culture of cells in three dimensional systems<sup>[100]</sup>, organ slices<sup>[144]</sup> or organ explants<sup>[145]</sup>; while such systems are informative in the setting of chronic alcohol exposure to date there is no report of their use as an AAA model.

### IN VIVO AAA MODELS

The *in vivo* models of AAA are more informative compared to the *in vitro* model due to complex physiological impact of alcohol on all bodily organs and systems, but also due to the availability of systemic alcohol metabolism. Currently there are human and non-human models of AAA, and the later include use of invertebrates<sup>[146-147]</sup> and vertebrates<sup>[21,25,37,44,46,47,53,65,72,86,93,94,98,104,110,111]</sup>. The invertebrate models (*Drosophila melanogaster*<sup>[146,147]</sup>, *Caenorhabditis elegans*<sup>[105]</sup>) and those using lower vertebrates (Zebra fish *Danio rerio*)<sup>[98]</sup> are invaluable for research of the effect of alcohol on behavior, development and maintenance of memory, and on basic signaling mechanisms. These models offer the advantage of a well-defined genetic background, high-turnover rate of experiments due to short life cycle and relatively low-cost; in light of these advantages they constitute an excellent resource for research of signaling pathways and are highly desirable for their drug-screening capacity. On the downside, significant differences in the structure and function of organs and systems compared to humans limit the informative value of invertebrate and lower vertebrate models of AAA.

The vertebrate models are preferred to those using invertebrates due to closer resemblance of their bodily structure, function, and metabolism to that of humans. However, because of intrinsic differences between humans and other vertebrates, no single non-human model is perfect since none of the models can represent all features of the complex human trait, such as motivation for social occasional or binge alcohol consumption, development of alcohol dependence and establishment of the impact on health. Further, the controlled setting of research models may not be completely satisfactory for psychology and social research, since they may not fully reproduce the social component, the motivation and the spontaneity of alcohol abuse. However, research models are invaluable for the understanding of the effects of alcohol and its

mechanisms of action on hardwired bodily systems, including the brain and all other organs and systems.

## HUMAN MODELS OF AAA

Human alcohol intake in the experimental setting is the best available model of AAA, because it offers the advantage of the physiological route of alcohol consumption, the possibility to investigate human pathobiology and the availability of relatively large amounts of physiological bodily fluids for research. The disadvantages of human models of AAA include ethical concerns related to potential harmful health effects due to excessive or repeated intoxication, and the theoretical possibility of development of dependence or tolerance even after a one-time drinking session. Published models of human AAA are based on consumption of alcoholic beverages containing either distilled ethanol or wine; these models are physiological, as they involve alcohol drinking, and achieve a biologically meaningful BAL<sup>[87,92,107,110-113,115]</sup>. The majority of the reported *in vivo* models of human AAA strictly control for the amount of alcohol based on the constant volume of alcohol per kg body weight, includes placebo-treated age and gender matched controls. However, most of these studies design the consumption of the alcohol beverage during a 2 h period of time<sup>[92,107,110-113]</sup>, which based on recent NIAAA and NSDUH classification qualifies as binge drinking<sup>[11-13,17]</sup>. Thus the major disadvantage of the human models of AAA is that they (1) do not clearly distinguish between one-time and the binge alcohol consumption pattern, and, (2) for ethical reasons, do not allow longer binge sessions which are often observed in real-life and account for the majority of the heavy alcohol intake in young adults<sup>[5,7,11-13,17-19]</sup>.

To fulfill the requirement for an AAA model, the human studies usually include nonalcoholic individuals, who did not drink any alcohol at least 24 h prior to the study. Depending on the study design, some AAA human models require that the study participants did not take any medication, while others accept individuals taking moderate doses of anti-hypertensive medication and oral contraceptives<sup>[107,110]</sup>. The study participants are usually required to abstain from food for at least 6 h before alcohol consumption and are allowed free access to water and a light meal before or shortly after the study<sup>[107]</sup>. The human model of AAA is currently used for research in physiology<sup>[86,92,111,122]</sup>, hematology<sup>[107,128]</sup> and immunology<sup>[110,113,115]</sup>.

## CONSUMPTION OF DISTILLED ETHANOL MODEL

In this model the study individuals drink distilled alcohol (usually 80-proof vodka) in amounts of about 0.5-0.6 g/kg body weight, which is an equivalent of about 2 mL vodka/kg body weight in a standardized total volume of liquid (300-450 mL of water or orange juice)<sup>[92,107,110-113]</sup>.

## CONSUMPTION OF NON-DISTILLED ETHANOL MODEL

In this model the study individuals drink wine to an equivalent of a pre-determined amount of ethanol/kg BW (for example, Fehr *et al.*<sup>[107]</sup> reported use of 4.36 mL of red wine/kg of body weight as an equivalent of 0.5 g ethanol/kg BW to lead to a peak BAL of about 15 mmol/L in the first 2 h), while the control individuals are exposed to the same volume of fluid by mouth (usually water) per individual in a randomized way. The major disadvantage of this model is the use of controlled volumes of liquids that are not matched by calorie intake or by composition, which is technically challenging to achieve due to restricted availability of equivalent alcohol-free compounds. To bypass the bias concern some studies employ a cross-over approach, where each subject serves as its own control and repeats the study at least 2 wk after the first experiment with either alcohol or placebo consumption according to the cross-over design<sup>[107]</sup>.

## NON-HUMAN AAA MODELS

Among non-human vertebrates commonly involved in alcohol research are primates<sup>[90,91,148]</sup>, pigs<sup>[104,120]</sup>, dogs<sup>[114,121]</sup>, mice<sup>[70,72,74,86,89,96,109,118,119,141]</sup>, rats<sup>[88,94,108,149,150]</sup> and rabbits<sup>[132]</sup>. The rodent AAA models (mice and rats) are used most frequently due to their relatively well-defined genetic background and the availability of diverse genetic traits, including those coding for high or low alcohol consumption<sup>[88,89,96,109]</sup>. Most non-human AAA models currently in use<sup>[93,95]</sup> examine relative oral self-administration from a bottle containing alcohol versus one<sup>[86,94,108]</sup> or multiple bottles<sup>[119]</sup> containing water (preference drinking) or administration of alcohol against the will, either by physiological (by mouth using gavage)<sup>[54,71,72]</sup> or by non-physiological (parenteral)<sup>[67,68]</sup> routes. Voluntary consumption of alcohol may be an optimal animal model of AAA, due to physiological route and pattern of alcohol consumption. However, in the self-administration models it is not clear when or if the animals drink to pharmacologically significant levels because the drinking is episodic and often occurs over a 24-h period. Nevertheless, these models are invaluable for research of neurobiology of acute intoxication with alcohol and for establishment of mechanisms of addiction. The AAA models using administration of alcohol against-the-will bypass all the above-mentioned inconveniences of AAA models using voluntary consumption. Alcohol administered either by physiological (by mouth using gavage) or by non-physiological (parenteral) routes yields comparable physiological effects on the central nervous system and on organs/systems that are not affected directly by the route of alcohol administration, such as muscle and brain<sup>[97]</sup>. However, administration of alcohol per os is more physiological compared to administration via parenteral routes, yields meaningful levels of BAL and shows signs of acute alcohol intoxication<sup>[54,71,72,132,149]</sup>.

Table 2 The effect of acute alcohol abuse on GI system

GI segment	Effect of acute alcohol exposure
Oral cavity	Unknown
Esophagus	Low concentrations of alcohol (up to 5%) cause alterations in ion transports and affect the barrier function Concentrations of alcohol of 10% and above cause injury of mucosa Co-carcinogenic potency
Stomach	Motor dysfunction: decrease in lower esophageal sphincter pressure and amplitude Motor dysfunction: Inhibition of gastric emptying Mucosal damage, impaired barrier function, increased epithelial permeability Pro-inflammatory reaction: decreased gastric blood flow, vascular damage, polymorphonuclear neutrophils (PMN) dependent- and independent-mucosal damage Aggravation of <i>H pylori</i> infection
Intestine	Disruption of barrier function Epithelial apoptosis Enhanced bioavailability of some alcohol-soluble drugs and impaired absorption of key nutrients Increased paracellular intestinal permeability to toxins
Liver	Hepatocytes: Amplification of Fas-mediated hepatocyte death Generation of oxidative stress Hepatic mitochondrial dysfunction Increased free iron levels Imbalanced fatty acid metabolism Inhibition of IFN- $\alpha$ -induced antiviral response towards hepatotropic viruses including hepatitis C virus favors hepatitis C virus replication expression Induced histone H3 acetylation leading to increased gene expression in the liver Limited hepatic protein synthesis Arrest of liver regeneration early after partial hepatectomy and suppression of hepatic stimulator substance (HSS) activity by induction of liver cell cycle arrest Kupffer cells: Suppressed LPS-mediated priming for enhanced CC-chemokine release in vitro; up-regulated expression of CC-chemokine mRNA; primed the KC for enhanced RANTES release Desensitized HIV-1 gp120-induced CC-chemokine production Downregulates HIV-1 glycoprotein 120-induced KC and RANTES production Regulates production of reactive oxygen species Modulate the tolerance to LPS Stellate cells: Imbalanced redox potential owed to increased generation of reactive oxygen species upon GSH depletion
Pancreas	Stimulates islet blood flow, amplifies insulin secretion, induces hypoglycemia Lower baseline amylase output of acinar pancreatic cells, with the difference being significantly exacerbated by cerulein stimulation Interference with release of oxidized proteins in acinar cells Predisposes the pancreas to postprandial cholinergic stimulation that triggers cellular events leading to pancreatic inflammation Impaired apical exocytosis and redirected exocytosis to less efficient basolateral plasma membrane sites Augments elevated-[Ca <sup>2+</sup> ]-induced trypsin activation in pancreatic acinar zymogen granules, leading to premature activation of trypsin and tissue damage.

Among disadvantages of administration of alcohol per os are technical challenges, time consumption and high cost of the procedures. In contrast, alcohol administration by parenteral routes is relatively easy to perform technically and offers controlled settings (time, amount); on the downside, they may be less suitable for research of the effects of alcohol on organs/systems that are affected directly by the routes of alcohol administration. In this context, administration of alcohol by intraperitoneal route may be less suitable for research using peritoneal macrophages, or even liver and intestines, compared to other administration routes, such as intravenous or enteral. Further, some parenteral methods of alcohol administration are preferred over others, owing to differences in the level of technical difficulty of the procedure and the effect of alcohol on different cell types. For example, alcohol administration by intravenous route is known to affect the erythrocytes when present in high concentrations<sup>[128]</sup>. Thus alcohol administration by intravenous route is currently

limited to creating an acute alcohol exposure during treatment of alcohol withdrawal symptoms<sup>[151]</sup>, while administration by intraperitoneal injections is widely preferred in research settings.

Similar to human AAA models, the non-human *in vivo* models employ either distilled alcohol<sup>[53,67-72,74,89,90,96,109,116,119,121,132,135,141,152]</sup> or alcohol-containing beverages, such as wine<sup>[152,153]</sup> and beer<sup>[46]</sup>; the control groups are usually treated with alcohol-free caloric and composition equivalents. The vertebrate AAA models are widely used in research of biomedical effects of AAA, including brain<sup>[23-30,116]</sup>, gastrointestinal<sup>[38-44,46-48,64-66,154]</sup>, vascular<sup>[73,153]</sup>, muscle<sup>[97]</sup> and immune<sup>[68-72,74]</sup> systems.

## THE PARTICULARITIES OF AAA MODELS FOR RESEARCH IN GASTROENTEROLOGY

In contrast to the abundance of the literature about the

effects of chronic alcohol abuse on the gastrointestinal system, research of the effects of acute alcohol abuse on the gastrointestinal (GI) tract is limited to certain cell types, as outlined in Table 2.

Currently the state of scientific knowledge suggests a tight interplay between organs and systems. The GI system is dependent on blood circulation and systemic availability of metabolites, is closely governed by both the central and the autonomous nervous system<sup>[155,156]</sup> and contains a hallmark of resident and recruited immune cells<sup>[157,158]</sup>. Thus, it is conceivable that the direct effects of alcohol on either of these systems will indirectly affect the function of the gastrointestinal system; this area is currently largely unexplored.

From a technical point, the GI research may take advantage of both *in vitro* and *in vivo* AAA models; however some *in vivo* models, such as those using parenteral administration of alcohol by the intraperitoneal route, may be less suitable due to the non-physiological direct contact between high concentrations of alcohol and GI tissues.

Alcohol use/abuse is associated with acute life-threatening conditions, including acute alcoholic hepatitis<sup>[45]</sup> or acute pancreatitis<sup>[159]</sup>. The majority of these patients report acute alcohol abuse, which is often overlapping with withdrawal from or even discontinued chronic alcohol abuse, or it follows an episode of binge drinking<sup>[45,159]</sup>. As such, it is difficult to associate these diseases with the single-occasion AAA, yet they do not fit into the classic chronic alcohol abuse picture. This category of alcohol abuse, defined as “acute-on-chronic”, is in need of modeling for GI research.

In prospective, we currently lack in-depth knowledge in regards to the effects of acute alcohol abuse on different segments of the luminal GI tract, on liver functions, and on pancreas, including its endocrine and exocrine functions. Further, we do not know if acute alcohol consumption affects the GI stem cells and/or is involved in development of GI-derived tumors.

## INTRODUCTION

Lysosomes are the primary hydrolytic organelles of higher eukaryotic cells and have been appropriately named the cell's "digestive system". A large number of acid hydrolases inhabit these organelles. Together, these enzymes catalyze the breakdown of all forms of biopolymers, ranging from intracellular and extracellular proteins to storage carbohydrates (e.g. glycogen) to nucleic acids. Macromolecular catabolism takes place inside the lysosomal lumen at hydrogen ion concentrations that are 500-fold higher (pH about 4.7) than that in the cytoplasm (pH about 7.4)<sup>[1]</sup>. Maintenance of such an acidic lysosomal interior occurs through the continuous action of ATP-dependent proton transporters that reside on its membrane. Lysosomes exhibit morphological and functional plasticity; they undergo continuous change as they mature from larger primary vesicles that segregate and carry hydrolase precursors, to mature hydrolytic organelles that execute intracellular digestion. As the catabolic organelles for protein degradation, lysosomes differ from proteasomes in their size, their complexity, their intracellular locations and in the types of substrates they degrade. While proteasomes have essentially supplanted lysosomes as the primary system that degrades intracellular proteins in higher eukaryotes, the crucial task of breaking down protein substrates that are more difficult to digest, as well as hydrolyzing all other forms of polymeric substrates, is left to lysosomes. Certainly, compelling evidence of their importance is the existence of a number of human abnormalities known as lysosomal storage diseases, in which afflicted individuals possess genetically defective lysosomal hydrolases. Clinically, this group of diseases exhibits a spectrum of impaired function, from neurodegeneracy to premature death<sup>[2]</sup>. Furthermore, deficiencies in the pathways that participate in lysosome

## Abstract

The majority of ethanol metabolism occurs in the liver. Consequently, this organ sustains the greatest damage from ethanol abuse. Ethanol consumption disturbs the delicate balance of protein homeostasis in the liver, causing intracellular protein accumulation due to a disruption of hepatic protein catabolism. Evidence indicates that ethanol or its metabolism impairs trafficking events in the liver, including the process of macroautophagy, which is the engulfment and degradation of cytoplasmic constituents by the lysosomal system. Autophagy is an essential, ongoing cellular process that is highly regulated by nutrients, endocrine factors and signaling pathways. A great number of the genes and gene products that govern the autophagic response have been characterized and the major metabolic and signaling pathways that activate or suppress autophagy have been identified. This review describes the process of autophagy, its regulation and the possible mechanisms by which ethanol disrupts the process of autophagic degradation. The implications of autophagic suppression are discussed in relation to the pathogenesis of alcohol-induced liver injury.

biogenesis or that have a crucial function in supplying lysosomes with their substrates, can be lethal to the organism<sup>[3]</sup>. Studies in the mammalian liver have provided a great deal of our current understanding of the lysosomal pathway, as this organ is highly responsive to changes in nutrient supply<sup>[4,5]</sup>. The liver is also the predominant organ that metabolizes ethanol and liver injury is the principal clinical complication of alcohol abuse<sup>[6]</sup>. This review will focus on the process of autophagy, its role in normal hepatic function and its alteration due to ethanol consumption. A portion of this review will consider how ethanol disrupts protein catabolism, which is believed to have a significant role in liver injury. The reader will note the citation of other excellent reviews that have been published on the process of autophagy and/or lysosomal proteolysis<sup>[3,7-9]</sup>. The physiological and biomedical importance of autophagy is further underscored by the establishment of the international journal, *Autophagy*, the first issue of which was published in 2005.

## FEEDING THE LYSOSOMAL APPARATUS; HETEROPHAGY AND AUTOPHAGY

In order for lysosomes to be “fed”, substrates of high molecular weight must gain entry to the interior of the organelle through a membrane that is normally impermeable to large molecules. Such access is accomplished by a number of mechanisms, each involving the active participation of membranes. During heterophagy extracellular materials are imported into the cell by either receptor-mediated or fluid phase endocytosis or by bulk phagocytosis of larger particles, including whole cells such as bacteria and apoptotic cells. All these are accomplished by invagination of the plasma membrane, thereby transporting the membrane-enclosed material, via endosomes to their final destinations, which, in many (but not all) cases is degradation in lysosomes. Heterophagy has a critical function in the normal turnover of senescent plasma proteins and in adaptive immunity, the latter involving antigen presentation through the action of endosomal proteases by the MHC class II pathway<sup>[10]</sup>.

Autophagy is exclusively an intracellular lysosomal process, which literally means “self eating”. It was originally described in the 1950s and later systematically analyzed by the classical work of de Duve and Wattiaux in rat liver. Autophagy of intracellular proteins occurs by three distinct mechanisms: Macroautophagy is the vacuolar engulfment by membranes of large portions of cytoplasm and collateral organelles, forming a double membrane vesicle called an autophagosome or autophagic vacuole. The outer membrane of the autophagosome later fuses with existing lysosomes to form an autolysosome in which the contents are degraded. Microautophagy describes membrane uptake by existing lysosomes of smaller portions of cellular constituents by lysosomal membrane invagination followed by rapid hydrolysis of those molecules.

Chaperone-mediated autophagy (CMA) is the singular uptake and degradation by lysosomes of specific protein substrates bearing a recognizable peptide motif, KFERQ. The latter process is mediated by molecular chaperones, the most prominent of which is a cytoplasmic form of heat shock protein 70 (HSC 70), which recognizes and binds the peptide motif of the substrate protein<sup>[11,12]</sup>. The CMA substrate/chaperone complex then moves to the lysosome, where a specific receptor, the lysosome-associated membrane protein type-2A (LAMP-2A) recognizes and binds the complex; the substrate protein is then unfolded and translocated across the lysosome membrane and degraded in the lysosomal lumen. CMA is enhanced by oxidative stress, and, in addition to the proteasome, thereby serves a quality control function by degrading modified proteins. CMA also declines with age, largely due to the depletion of LAMP-2A. Recent studies have demonstrated that CMA can be restored in livers of aged mice that are transgenic for LAMP-2A. These animals, compared with their wild type littermates, showed improved cellular quality control and hepatic function<sup>[13]</sup>. While microautophagy and CMA are largely ongoing constitutive processes, macroautophagy is more highly regulated. In general, when the term autophagy is used here, it will be used synonymously with macroautophagy.

Autophagy is clearly important for survival of the organism, particularly in times of nutrient deprivation when degradation of macromolecular constituents becomes necessary to recycle essential carbon sources to maintain viability. Autophagy was initially characterized morphometrically and biochemically in rat liver, one of the most sensitive organs to changes in nutrient supply. An illustration of this is when rats are fasted for 48 h, they exhibit a 40% loss of liver protein and a significant loss of liver mass, both of which are rapidly restored to normal levels 12 h after food is replenished. These respective changes correlate with an induction of autophagy by fasting followed by its nutrient-induced suppression after refeeding<sup>[4,14,15]</sup>. A similar suppression of both autophagy as well as lysosome biogenesis was reported 24 h after partial hepatectomy in regenerating rat liver<sup>[16]</sup>. Thus, autophagy rapidly responds to these changes and is an important component of cell adaptation. In fact, the half-life of the autophagosome is less than 10 min<sup>[5]</sup>, which indicates that the molecular machinery required to form autophagic vacuoles is constitutive for rapid degradation of cellular constituents. Furthermore, like the proteasome, autophagy has a significant role in removing misfolded proteins from the hepatocyte. Such is the case in alpha-1-antitrypsin (A-1AT) deficiency, in which the cellular accumulation of the mutated unsecretable form of A-1AT, known as ATZ (the isoform most prone to aggregation), is directed to autophagic vacuoles for degradation<sup>[17]</sup>. Similarly, other aggregation-prone proteins are reported to have the same fate<sup>[18,19]</sup>. It was recently demonstrated that inhibition of proteasome activity by treatment of mice with bortezomib caused Mallory-Denk-(MD)-like body formation. Activation of autophagy with

rapamycin treatment prevented the formation of these inclusions, indicating that proteasome inhibition causes the formation of M-D like bodies in livers of susceptible mice, while autophagosomes prevent M-D body accumulation by resorbing and degrading these insoluble inclusions<sup>[20]</sup>. Thus, autophagy, not only functions in cell survival but also provides an additional line of cellular defense, the latter by removing aggregated, potentially toxic proteins, presumably resistant to degradation by the proteasome.

## REGULATION OF AUTOPHAGY

Hormonal and nutrient regulators of autophagy include food deprivation or glucagon treatment and both are reliable autophagy inducers. Conversely, treatment with growth factors such as insulin or amino acids are well-known methods of autophagic suppression. The molecular mechanisms by which these agents actually induce or suppress autophagy have been investigated more recently and this has led to investigations of the protein components and signaling mechanisms that regulate macroautophagy to form the autophagosome. To date, over 30 autophagy-related gene products (Atgs) are now known. There are extensive molecular interactions that occur between these gene products in the early stages of autophagosome formation. The most well known mechanism is that of the class I phosphoinositol-3-kinase (PI-3K) pathway, which initiates an upstream signaling cascade to regulate the activity of the mammalian target of rapamycin (mTOR), a kinase, which is a major regulatory anabolic protein, and a suppressor of autophagy. Activation of mTOR leads to inhibition of Atg1, a key signal in autophagy induction. If Atg1 is not inhibited by mTOR, it is free to recruit the autophagy proteins, Atg11, Atg13 and Atg17 to form a complex which signals the induction of autophagy. The cellular machinery that initiates the formation of the autophagosome occurs through the activation of Beclin-1 (Atg6), which interacts with the class III PI 3K pathway and complexes with Atg 14. A second complex involves the interaction of Atg12, Atg16, Atg5, and Atg 7 complex, which is critical for the recruitment of Atg8, (also known as LC31) to the phagophore, the isolation membrane at which the macroautophagic response is initiated and the precursor of the autophagosome. Autophagic induction leads to cleavage of Atg8 (LC3- I), which is covalently bound to phosphatidylethanolamine (PE) to form a distinct form of the protein, LC3- II. The latter is associated with and is a commonly used marker for autophagosome membranes. Atg8 is believed to be involved in autophagosome closure as well as its relative size to surround portions of the cytoplasm for degradation<sup>[21]</sup>. Eventual fusion of the autophagosome and the lysosome requires the participation of the LAMP-2 protein. Figure 1 depicts the major regulatory proteins and signaling factors in the autophagic response.

## ETHANOL CONSUMPTION AND THE HEPATIC AUTOPHAGIC/LYSOSOMAL SYSTEM

The majority of ethanol is metabolized in the liver and individuals who abuse alcohol by routinely drinking 50-60 g (about 4 to 5 drinks) of ethanol per day are at risk for developing alcoholic liver disease<sup>[6]</sup>. The pathogenesis of liver disease from alcohol abuse comes from the interaction of several factors, including the generation of oxidants and reactive metabolites from ethanol oxidation, which, in turn, causes other metabolic derangements. In addition, both acute and chronic ethanol administration cause enhanced formation of cytokines, especially TNF-alpha by hepatic Kupffer cells, which have a significant role in liver injury. This latter aspect is reviewed and described elsewhere<sup>[22-24]</sup>. Besides the development of fatty liver (steatosis), another early sign of excessive ethanol consumption is liver enlargement and protein accumulation, both of which are common findings in alcoholics and heavy drinkers. Baraona *et al*<sup>[25,26]</sup> originally described this in alcohol-fed rats. Later investigations sought to determine the origin of ethanol-elicited protein accumulation. They showed that chronic ethanol consumption slowed down the catabolism of long-lived proteins in rat liver<sup>[27]</sup> and also depressed hepatic protein synthesis<sup>[28]</sup>. Other studies confirmed that rats subjected to chronic ethanol feeding exhibited lower hepatic proteolysis than control rats. This was associated with reduced volume densities of autophagosomes and autolysosomes, as determined morphometrically<sup>[29]</sup>. Our later studies, using isolated lysosomes from chronically ethanol-fed rats also revealed a reduced capacity of these organelles for proteolysis of endogenous as well as exogenous (i.e. akin to CMA) substrates *in vitro*. Furthermore, there was an enhanced tendency of lysosomes from ethanol-fed rats to leak their contents, but the intact organelles still exhibited lower levels of cathepsins, B and L compared with those from pair-fed control rats. A later report showed that lysosomes from ethanol-fed rats exhibited altered sedimentation properties on density gradients. Pulse-chase analyses, using isolated hepatocytes demonstrated that the reduced lysosomal content of cathepsin L was the result of delayed trafficking of its nascent precursor and impaired processing to its mature catalytic form in cells from ethanol-fed rats<sup>[16,30,31]</sup>. Both flow cytometric and microscopy studies showed that vesicular movement and acidification of lysosomes in hepatocytes are both impeded after ethanol exposure<sup>[32,33]</sup>.

## MECHANISMS OF ETHANOL-ELICITED SUPPRESSION OF AUTOPHAGY

The exact mechanisms responsible for the aforementioned ethanol-induced changes in hepatic autophagy and lysosomal proteolysis are not clear but some cogent explanations have been advanced. One is that oxidants (e.g. peroxynitrite) and reactive species

**Figure 1 Interaction of gene products and pathways in the regulation of autophagy.** Growth factors and nutrients activate the Class I P13K proteins, which, in turn, signal, via the AKT pathway to activate mTOR. This leads to inhibition of ATG1 - the primary signal for autophagy. Nutrient deprivation or inhibition of mTOR by rapamycin allows ATG1 to recruit ATG11, ATG13 and ATG 17 to form a complex to initiate formation of the autophagosome. This is dependent on the formation of 2 complexes: ATG 6 (Beclin1) which interacts with the Class III P13K protein complexes with ATG14. Another complex involves ATG12, ATG16, ATG5 and ATG7. The latter complex recruits ATG8 (LC3). Upon induction of autophagy, cytosolic LC3-I (ATG8) is cleaved and lipidated to form LC3- II. LC3- II is a marker for the autophagosome membrane. Fusion between the autophagosome and the lysosome and subsequent breakdown of the contents of the autophagic vacuole requires LAMP2 protein. Reproduced in modified form with permission (Abcam, Inc.) <http://www.abcam.com/ps/pdf/cardiovascular/autophagic.pdf>.

(e.g. acetaldehyde and malondialdehyde-acetaldehyde)<sup>[34]</sup> derived from ethanol metabolism may impair autophagy, similar to that which occurs with the proteasome<sup>[35-37]</sup>. Some of the current evidence for this is circumstantial, but nevertheless compelling as there is evidence of lysosomal damage, as judged by enhanced lysosomal fragility, which could result from either altered lipid metabolism, oxidative stress or both<sup>[15]</sup>. By analogy, other instances of lysosome fragility by iron-induced oxidative stress are documented<sup>[38,39]</sup>. However, ethanol administration has little to no effect on the activities of lysosomal hydrolases<sup>[31]</sup> and, because a significant number of cathepsins rely on a reduced sulfhydryl group for their catalytic activity in their active centers, the alteration of lysosomal glutathione or cysteine content by ethanol seems unlikely. It is worth noting that lysosomes and proteasomes seem to exhibit differential sensitivity to ethanol levels in the serum. Animal experiments have revealed that proteasome activity declines in animals that have higher (i.e. > 40 mmol/L) serum ethanol concentrations<sup>[40]</sup>. The lysosomal system, on the other hand, appears to be impaired by lower serum ethanol levels, as recently reported in livers of

female ethanol-fed rats<sup>[41]</sup>.

Ethanol-induced suppression of autophagy may result from alterations in hepatic amino acid pool sizes, especially those of leucine, phenylalanine, methionine, histidine, tryptophan, glutamine, proline, and tyrosine, which have been deemed regulatory amino acids and suppressors of macroautophagy<sup>[5]</sup>. L-leucine appears to be one of the strongest autophagic suppressors in this group. It is noteworthy that reports indicate that chronic ethanol administration in rats increases the intrahepatic levels of leucine by 1.4 to 1.8-fold over paired controls<sup>[27,42]</sup>. Thus, the association of an ethanol-induced reduction in autophagy with higher levels of intrahepatic leucine may partially explain autophagic suppression in the ethanol-fed state. However, it remains to be conclusively demonstrated whether this association represents a causal relationship. It is also paradoxical that ethanol feeding results in higher levels of leucine during a slowdown in protein catabolism when one would expect the opposite situation. Still, leucine accumulation could reflect a reduced ability of the liver to synthesize proteins, which indeed occurs in ethanol-fed animals<sup>[42,43]</sup>.

A third likely mechanism of autophagic suppression

by ethanol is its well-documented ability to disrupt protein trafficking in the liver. Autophagy requires the action of cytoskeletal elements, including the microtubules and microfilaments. Both are necessary for autophagosome formation and their fusion with other vesicular bodies, as demonstrated by blockage of these processes with specific inhibitors, including nocadazole and vinblastine (microtubules) and the cytochalasins (microfilaments)<sup>[44,45]</sup>. Disruption of vesicular movement within the hepatocyte by ethanol treatment occurs by mechanisms that are independent of the molecular motors, dyenin and kinesin, although there is evidence for alterations in the protein, dynamin<sup>[32]</sup>. Trafficking of exogenous proteins into the hepatocyte by endocytosis<sup>[46,47]</sup> and the intracellular delivery of proteases to lysosomes<sup>[31]</sup> are both inhibited by ethanol consumption. Furthermore, the anti-secretory properties of ethanol in the liver are well documented. Studies with liver slices and cultured cells indicate that ethanol metabolism is required for disruption of these protein trafficking events<sup>[48-51]</sup>. *In vitro* investigations also revealed that acetaldehyde, the initial product of ethanol oxidation, inhibits the polymerization of tubulin to form microtubules, indicating that the reactive metabolite may impair protein trafficking by forming adducts with tubulin subunits, thereby blocking their polymerization into microtubules<sup>[52]</sup>. Further, the finding that acetaldehyde can undergo secondary reactions with malondialdehyde (MDA) to form more bulky substituents on proteins, known as malondialdehyde acetaldehyde adducts (MAA) with proteins, makes this mechanism of autophagic suppression an attractive hypothesis.

## ETHANOL-INDUCED ALTERATIONS IN CELLULAR SIGNALING: REGULATION OF AMP KINASE

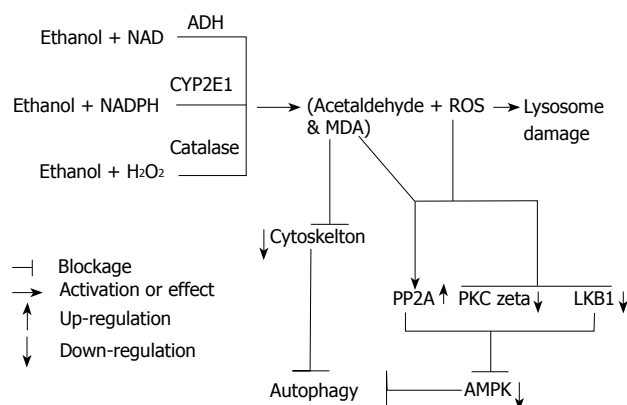

While the foregoing mechanisms of autophagic suppression by ethanol are plausible, it is likely that ethanol and/or its metabolites impact signaling events that govern the autophagic response. There have been significant advances in our understanding of these processes at the molecular level, as recently reviewed<sup>[3]</sup>. Because autophagy is an energy-dependent process and requires ATP<sup>[53]</sup>, it follows that ATP depletion naturally suppresses autophagy. Ethanol consumption has been reported to inhibit ATP production by mitochondria<sup>[54]</sup>, in part by enhancing oxidative modification and inactivation of proteins within these organelles<sup>[55]</sup>. However, others have reported an increased efficiency of mitochondrial oxidative phosphorylation in livers of ethanol-fed animals<sup>[56]</sup>. Thus, reduced ATP availability from mitochondria may not fully explain such downstream effects on autophagy. Adenosine monophosphate-activated protein kinase (AMPK) is a heterotrimeric protein that is, itself, activated by elevated ratios of AMP/ATP and is a significant regulator of a variety of metabolic and signal transduction pathways,

including autophagy. Elevated AMP/ATP ratios are indicators of low intracellular energy charge. Therefore, when AMP activates the AMPK it generally down-regulates energy requiring pathways and stimulates catabolic pathways. Interestingly, however, inhibition of AMPK also suppresses autophagy<sup>[57]</sup>. These findings are consistent with the suppression of autophagy by ethanol consumption, which significantly reduces AMPK activity in liver<sup>[58]</sup>. Such a decline in AMPK activity would, in turn cause the release of suppression of mTOR activity by AMPK<sup>[59]</sup>, thereby permitting mTOR to suppress proteolysis. Conversely, AMPK activation suppresses mTOR, thereby allowing autophagy to proceed. Recent work with cultured hepatoma cells determined that ethanol metabolism is required for suppression of AMPK phosphorylation. This occurs by an inactivation of two upstream kinases, LKB-1 and protein kinase C-zeta. Simultaneously, ethanol exposure activates protein phosphatase 2A (PP2A), which causes dephosphorylation (and inactivation) of AMPK<sup>[60]</sup>. The latter findings seem paradoxical, as AMPK is generally activated by reactive oxygen and nitrogen species<sup>[22,61]</sup>. Thus, while ethanol metabolism similarly generates oxidants and reactive species, including acetaldehyde, these molecules down-regulate upstream kinases and up-regulate the downstream phosphatase, PP2A, resulting in AMPK inactivation, which, in turn, can cause autophagic suppression. AMPK also has an important role in regulating lipid metabolism and AMPK suppression by ethanol allows activation of rate-limiting enzymes involved in lipid biosynthesis, which contribute to ethanol-induced fatty liver<sup>[62,63]</sup>. Figure 2 depicts the putative mechanisms of autophagic suppression.

## PATHOLOGICAL CONSEQUENCES OF AUTOPHAGIC SUPPRESSION

Protein accumulation due to ethanol-elicited decline in protein catabolism probably contributes to the formation of Mallory Denk (M-D) bodies in liver cells. These inclusions are prominent histological hallmarks of liver disease in alcoholics<sup>[64]</sup>. M-D bodies contain the cytokeratins 8 and 18 as well as ubiquitin, and p62, an adaptor protein. As pointed out earlier, M-D bodies comprise an aggresome, consisting of filamentous ubiquitylated misfolded proteins that are believed to represent a failed attempt by the proteasome to degrade them. Recent evidence indicates that autophagy can degrade these insoluble complexes<sup>[20]</sup>. However, clearance of such cellular debris is hampered by an ethanol-elicited suppression of autophagy, a situation that may have a perilous outcome if drinking continues.

In addition to the accumulation of potentially toxic proteins, ethanol also causes mitochondrial damage. Changes ranging from morphologically detectable mitochondrial swelling, to DNA fragmentation, to depolarization of the inner membrane, (commonly known as the mitochondrial permeability transition or MPT) to disruption of mitochondrial gene products

**Figure 2 Putative mechanisms of autophagy suppression by ethanol.** Ethanol metabolism by the three major pathways, alcohol dehydrogenase (ADH), cytochrome P450 2E1 (CYP2E1) and catalase generates acetaldehyde, which can undergo secondary reactions with malondialdehyde (MDA) to form MAA. In addition, reactive oxygen species (ROS) are generated by CYP2E1 catalysis. Reactive oxidants (ROS) may also contribute to lysosomal damage. The reactive aldehydes are known to form adducts with tubulin and other cytoskeletal elements to block trafficking and movement of autophagic vacuoles and their formation. The combined formation of ROS and acetaldehyde putatively cause upregulation of protein phosphatase 2A (PP2A) and a downregulation of LKB1 and PKC zeta. The latter changes cause inactivation of AMPK, which in turn suppresses autophagy due to up regulation of mTOR (not shown) as described in the text.

as well as decreases in glutathione occur in livers of ethanol-fed animals<sup>[55,65-72]</sup>. It is crucial that such damaged organelles be removed from the cell and there is evidence that selective engulfment of mitochondria (called mitophagy) into autophagic vacuoles occurs in cells as a quality control device<sup>[73-75]</sup>. Similarly, there appears to be rather selective autophagy of ER components (ER-phagy) as well as peroxisomes (pexophagy) in cells under conditions where there is an accumulation of these organelles<sup>[76,77]</sup>. It remains to be demonstrated whether such selective autophagy represents actual recognition of damaged organelles or simply occurs because of mass action due to their accumulation, however, reports show that the permeability transition may act as a signal for autophagic destruction of the mitochondrion<sup>[74]</sup>. While there is no firm evidence of ethanol-elicited suppression of mitophagy, the detection of increased numbers of damaged mitochondria in livers of ethanol-fed animals provides circumstantial evidence of mitophagy inhibition. In this regard it is also worth noting that mitochondrial damage also occurs by non-oxidative products of ethanol metabolism, namely fatty acid ethyl esters (FAEE). These condensation products between ethanol and fatty acids are generated enzymatically and have been shown to cause mitochondrial damage<sup>[78]</sup>. Thus a mechanism for ethanol-induced injury in nonhepatic tissue such as pancreas, heart and brain could occur by the generation of FAEE.

## CONCLUSION

This review has summarized the evidence for the ethanol-elicited suppression of autophagy as a mechanism by which liver cells can accumulate damaged

proteins and organelles. Suppression of proteolysis in general can be lethal to cells, as normal turnover is disrupted and the removal of potentially toxic proteins is prevented. As an organ that is sensitive to nutrients as well as toxins, the liver is highly active in autophagy. The inability to respond to depletion of nutrient supply in the alcoholic state is a potentially perilous condition. Still, while there have been numerous investigations of hepatic autophagy, the actual mechanism(s) by which ethanol may influence this process remain(s) to be conclusively determined. From this summary of results from our laboratory and from the literature, we hypothesize that ethanol consumption probably influences pathways upstream of the autophagic process, including inhibition of AMPK, but this awaits experimental confirmation. Finally, while this review has specifically focused on autophagy in hepatic tissue, a recent report indicates that ethanol exposure also slows autophagy in neural cells<sup>[79]</sup>, indicating that this effect of ethanol is not exclusively liver-specific. In conclusion, while autophagy has been recognized for decades as an indispensable means of macromolecular disposal, its roles in other cellular processes from differentiation to cell death are now being documented, thus rekindling new interest in this fascinating field of investigation.

## Abstract

Despite heavy consumption over a long period of time, only a small number of alcoholics develop alcoholic liver disease. This alludes to the possibility that other factors, besides alcohol, may be involved in the progression of the disease. Over the years, many such factors have indeed been identified, including iron. Despite being crucial for various important biological processes, iron can also be harmful due to its ability to catalyze Fenton chemistry. Alcohol and iron have been shown to interact synergistically to cause liver injury. Iron-mediated cell signaling has been reported to be involved in the pathogenesis of experimental alcoholic liver disease. Hepcidin is an iron-regulatory hormone synthesized by the liver, which plays a pivotal role in iron homeostasis. Both acute and chronic alcohol exposure suppress hepcidin expression in the liver. The sera of patients with alcoholic liver disease, particularly those exhibiting higher serum iron indices, have also been reported to display reduced prohepcidin levels. Alcohol-mediated oxidative stress is involved in the inhibition of hepcidin promoter activity and transcription in the liver. This in turn leads to an increase in intestinal iron transport and liver iron storage. Hepcidin is expressed primarily in hepatocytes. It is noteworthy that both hepatocytes and Kupffer cells are involved in the progression of alcoholic liver disease. However, the activation of Kupffer cells and TNF- $\alpha$  signaling has been reported not to be involved in the down-regulation of hepcidin expression by alcohol

in the liver. Alcohol acts within the parenchymal cells of the liver to suppress the synthesis of hepcidin. Due to its crucial role in the regulation of body iron stores, hepcidin may act as a secondary risk factor in the progression of alcoholic liver disease. The clarification of the mechanisms by which alcohol disrupts iron homeostasis will allow for further understanding of the pathogenesis of alcoholic liver disease.

## INTRODUCTION

Many eukaryotes require iron for critical biological processes<sup>[1,2]</sup>. However, excess iron is toxic, causing lipid peroxidation and oxidative stress<sup>[3]</sup>. Due to it being a “double edged sword”, iron uptake and transport must therefore be tightly regulated<sup>[4-7]</sup>. Hepcidin, a circulatory peptide synthesized by the liver, performs this important task by regulating iron transport in different parts of the body including duodenum, spleen and bone marrow<sup>[8,9]</sup>. Alcohol has been shown to suppress hepcidin expression in the liver leading to an increase in intestinal iron transport<sup>[10-15]</sup>. Both iron and alcohol act synergistically to cause liver injury. Disruption of hepcidin synthesis by alcohol may therefore be one of the “second hit” mechanisms leading to the progression of alcoholic liver disease.

## ALCOHOL-INDUCED DISTURBANCES IN IRON METABOLISM

Alcohol consumption has long been associated with

changes in iron homeostasis. The reported changes range from anemia to iron overload<sup>[16-22]</sup>. Blood loss is common in patients with alcoholic cirrhosis<sup>[23]</sup>. Anemia and iron deficiency can be due to gastrointestinal blood loss arising from the complications of alcohol abuse. Nutritional deficiencies, such as folate deficiency, can also be a common cause of anemia<sup>[24-27]</sup>. Megaloblastic and sideroblastic anemias, macrocytosis of alcoholism, elevated mean corpuscular volume, and iron deficiency have been reported to be common among hospitalized chronic alcoholics<sup>[23,27-30]</sup>. However, it has been demonstrated that anemia and megaloblastic and sideroblastic changes do not occur if an adequate diet is provided during chronic alcohol administration to human volunteers<sup>[25,31]</sup>. This has also been shown to be the case for relatively well-nourished alcoholics<sup>[25,26,32,33]</sup>. These findings therefore suggest that alcohol by itself does not induce iron deficiency or anemia.

In fact, wine has a high iron content and increases iron absorption<sup>[34]</sup>. Decreasing the alcohol content of red wine has been reported to significantly reduce the absorption of non-heme iron in human subjects<sup>[35]</sup>. Beer consumption has been suggested to have a more significant effect on serum ferritin levels than wine and spirits, both in males and females<sup>[18]</sup>. Alcohol consumption (up to 2 alcoholic drinks per day) has also been shown to exert a protective effect by reducing the risk for iron deficiency anemia in adult participants of the Third National Health and Nutrition Examination Survey<sup>[36]</sup>. On the other hand, heavy alcohol consumption (more than two alcoholic drinks per day) elevates the risk of iron overload<sup>[36]</sup>. In both male and female adolescents (aged 16-19 years), who participated in the First National Health and Nutrition Examination Survey, serum iron concentration was significantly related to drinking frequency<sup>[17]</sup>. Alcohol consumption was associated with elevated serum iron concentration in both male and female adolescents. Interestingly, male adolescents also exhibited increased transferrin saturation and hemoglobin concentration<sup>[17]</sup>. Drinking frequency was unrelated to dietary iron intake, poverty index or race<sup>[17]</sup>. A Danish population survey also reported a correlation between alcohol intake and elevated serum ferritin in healthy adult males and females (aged 30-60 years)<sup>[37]</sup>. African Americans who consume alcohol (4 drinks per day) exhibit a higher prevalence of ferroportin Q248H allele, which is implicated in iron accumulation, and alcohol has been suggested to contribute to higher body iron stores in this population<sup>[38]</sup>. Alcohol elevates iron absorption and patients with alcoholic cirrhosis often exhibit elevated liver iron content<sup>[39,40]</sup>. *In vivo* whole-body retention studies have demonstrated a two-fold increase in intestinal iron absorption in chronic alcoholics<sup>[41]</sup>. Alcoholic cirrhosis patients with higher liver iron content display increased mortality rates<sup>[42]</sup>. Experimental animal models of prolonged alcohol exposure also display increased liver iron deposition and hepatocellular injury<sup>[19,43]</sup>. In mild cases of alcoholic liver disease (ALD), iron has been reported to accumulate in hepatocytes<sup>[44]</sup>. However, in patients with advanced ALD, both parenchymal cells and Kupffer

cells exhibit iron staining<sup>[20]</sup>.

In some alcoholics, the elevated serum iron indices have been reported to significantly decrease within 2-6 wk of abstinence, suggesting a direct role for alcohol consumption<sup>[45]</sup>. However, the mechanisms by which alcohol disrupts iron metabolism are unclear. Recent studies indicate a role for hepcidin in this process.

## HEPCIDIN

The discovery of the circulating peptide hormone hepcidin has revolutionized our understanding of iron metabolism. Hepcidin sequence is highly conserved between species, from fish to mammals. Hepcidin was first isolated from human urine and serum as short cysteine-rich peptide forms<sup>[46,47]</sup>. Hepcidin is homologous to the members of the defensin family of antimicrobial peptides and has been reported to exhibit antimicrobial activity *in vitro*<sup>[46]</sup>. It is the studies with transgenic mice that have highlighted the importance of this protein in the regulation of iron metabolism. Namely, hepcidin knockout mice, deficient in the expression of hepcidin, develop severe iron overload, whereas mice overexpressing hepcidin display iron deficiency and anemia<sup>[48,49]</sup>. Moreover, the synthesis of hepcidin has also been shown to be responsive to the body iron levels. Iron overload state induces hepcidin synthesis whereas iron deficiency and anemia have the opposite effect<sup>[50,51]</sup>.

Liver is the main site of hepcidin synthesis in the body<sup>[50]</sup>. It is synthesized as an 84 amino acid precursor protein and is subsequently cleaved into the biologically active 25 amino acid peptide form<sup>[8,9,50,52]</sup>. In the liver, hepcidin is primarily expressed in the hepatocytes (Figure 1). Although to a much lesser extent, other cells of the liver and other organs also display hepcidin expression. The exciting discovery of the interaction between hepcidin and the iron exporter protein ferroportin was pivotal to our understanding of how hepcidin regulates iron metabolism<sup>[53,54]</sup>. The binding of hepcidin to ferroportin induces the internalization and degradation of the ferroportin protein, which in turn inhibits iron from being transported into the circulation. This is how hepcidin accomplishes the regulation of iron mobilization between distant locations (i.e. duodenum, bone marrow, reticuloendothelial macrophages) in the body (Figure 1)<sup>[8]</sup>.

The synthesis of hepcidin in the liver is modulated by numerous upstream regulators<sup>[1,2]</sup>. Transferrin receptor 2, the genetic hemochromatosis gene product, Hfe, and the juvenile hemochromatosis gene product, HJV, are positive regulators of hepcidin expression<sup>[55-62]</sup>. Mutations in these genes result in an increase in body iron stores (i.e. hemochromatosis) due to the down-regulation of hepcidin expression. Recently, a novel candidate TMPRSS6, a transmembrane serine protease also known as matriptase 2, has been identified. Interestingly, TMPRSS6 is the first identified negative regulator of liver hepcidin expression. In other words, TMPRSS6 keeps hepcidin expression under control in the liver<sup>[63,64]</sup>. Accordingly, patients expressing TMPRSS6 mutations exhibit iron-refractory iron deficiency anemia due to elevated hepcidin produc-

**Figure 1 The Iron regulatory hormone hepcidin.** Hepcidin is synthesized in the hepatocytes of the liver as an 84 amino acid precursor protein. It is subsequently cleaved into the 25 amino acid biologically active peptide form and is released into the circulation. Hepcidin plays a central role in the regulation of iron metabolism by inhibiting the release of iron from the enterocytes of the duodenum and from reticuloendothelial macrophages. Hepcidin blocks the export of iron from these cells by binding to the iron exporter protein, ferroportin, which induces the internalization and degradation of ferroportin protein. As a soluble mediator, hepcidin establishes the cross-talk between distant organs in the body in order to maintain iron homeostasis.

tion<sup>[63]</sup>. Moreover, the splicing defects in the TMPRSS6 gene lead to the mask phenotype, a recessive, chemically induced mutant mouse phenotype<sup>[64]</sup>. This phenotype results from the reduced absorption of dietary iron due to high levels of hepcidin expression<sup>[64]</sup>. However, the signaling mechanisms involved in these regulatory processes (negative or positive) are as yet unknown.

## KUPFFER CELLS, ALCOHOL AND HEPcidIN

Liver macrophages (Kupffer cells) also play a pivotal role in the progression of ALD. Alcoholics have elevated levels of lipopolysaccharide (LPS) in their circulation, which is believed to prime the macrophages leading to the release of proinflammatory cytokines, particularly TNF- $\alpha$ , and reactive oxygen species<sup>[65-67]</sup>. The importance of Kupffer cells in ALD has been demonstrated in studies where their depletion or inactivation blocked alcohol-induced symptoms, including inflammation, fatty liver and necrosis, in experimental animal models of chronic alcohol exposure<sup>[68,69]</sup>.

In advanced forms of ALD and in experimental animal models of ALD, besides parenchymal cells, Kupffer cells also exhibit iron accumulation<sup>[20,70,71]</sup>. Reticuloendothelial (RE) macrophages play a major role in iron trafficking and recycling to meet changes in the body's iron demand<sup>[72]</sup>. Like the parenchymal cells of the liver, the RE system also stores large amounts of iron bound to the storage protein, ferritin. RE macrophages acquire iron mainly by phagocytosing senescent red blood cells. However, macrophages also express the divalent metal transporter1 (DMT1), natural resistance associated macrophage protein1 (Nramp1), hemoglobin scavenger receptor (CD163) and transferrin receptor1 (TrfR1), all

**Figure 2 Hepcidin and alcohol.** Alcohol is metabolized by alcohol dehydrogenase (ADH) and cytochrome P4502E1 (CYP2E1) in the liver. Alcohol-induced oxidative stress leads to the suppression of hepcidin promoter activity and hepcidin transcription in the liver. The parenchymal, but not the non-parenchymal cells of the liver are involved in the regulation of hepcidin transcription by alcohol-induced oxidative stress. The activation of CYP2E1 or NADPH oxidase and changes in mitochondrial functions are involved in alcohol-induced oxidative stress in hepatocytes. The role of these pathways in the regulation of hepcidin transcription by alcohol requires further investigation.

of which are involved in iron uptake and transport<sup>[72-75]</sup>. The livers from experimental animal models of ALD and Japanese patients with ALD have been reported to exhibit significantly more TrfR1 mRNA or protein expression, respectively, compared to control animals or healthy human subjects<sup>[76,77]</sup>. Macrophages can take up transferrin-bound iron *in vitro*. However, a significant uptake of transferrin-bound iron by macrophages has not been observed *in vivo* in humans<sup>[72,78]</sup>. Although an increase in TrfR1 mRNA expression was observed in Kupffer cells of experimental animals, the increase in TrfR1 protein expression in Japanese patients with ALD was observed mainly in the hepatocytes<sup>[20,76,77]</sup>. It should also be noted that mice with disrupted TrfR1 gene, deficient in the global expression of TrfR1 receptor, display abnormalities only in erythropoiesis and neurologic development<sup>[79]</sup>. The Kupffer cells of rats exposed to chronic alcohol have also been shown to display an increase in mRNA levels of Hfe, the gene for genetic hemochromatosis<sup>[77]</sup>. Hfe gene product does not bind iron and is not directly involved in iron uptake. However, it is involved in the regulation of iron metabolism as shown by the fact that mice deficient in Hfe expression develop iron overload<sup>[80,81]</sup>. Hfe is believed to achieve this by modulating the expression and iron responsiveness of hepcidin in the liver<sup>[57,58,82]</sup>. On the other hand, the iron release from macrophages is regulated by the iron exporter protein ferroportin<sup>[83,84]</sup>. The multicopper ferroxidase, ceruloplasmin may also play a role in iron efflux in macrophages<sup>[85-87]</sup>. The Kupffer cells of animals subjected to alcohol exposure have been shown to display an increase in both ferroportin mRNA and protein,

indicative of increased iron export<sup>[77]</sup>. Of note, hepcidin binds to ferroportin and induces its internalization and degradation<sup>[53,54]</sup>. The increase in ferroportin expression in the Kupffer cells of these animals may be due to suppressed hepcidin expression. Alcohol has been shown to down-regulate hepcidin expression both in animal models of ALD and in patients with ALD<sup>[11-13]</sup>. However, Xiong *et al*<sup>[77]</sup> have reported no change in plasma pro-hepcidin levels and a decrease in hepcidin mRNA levels in Kupffer cells in their experimental model.

Iron has been reported to prime Kupffer cells for alcoholic liver injury in rats exposed to chronic intragastric alcohol infusion<sup>[70]</sup>. The proinflammatory cytokine TNF- $\alpha$  is a key player in alcohol-induced liver injury<sup>[88-90]</sup>. Iron has been shown to activate the transcription factor, NF- $\kappa$ B in hepatic macrophages and induce the synthesis and release of TNF- $\alpha$ <sup>[70,91]</sup>. Following erythrophagocytosis, Kupffer cells have been shown to display elevated levels of LPS-induced NF- $\kappa$ B activation<sup>[70]</sup>. Treatment of cultured Kupffer cells *in vitro* and *ex vivo* with iron chelators blocked both NF- $\kappa$ B activation and TNF- $\alpha$  synthesis<sup>[70,71]</sup>. Proinflammatory cytokines (IL-1, IL-6, TNF- $\alpha$ ) have been suggested to increase iron uptake into the monocytes of patients with rheumatoid arthritis<sup>[92]</sup>. It is therefore possible that alcohol and/or iron-induced release of TNF- $\alpha$  may serve as a feedback loop for further iron uptake into the Kupffer cells. On the other hand, Olynyk *et al*<sup>[93]</sup> have reported that deposition of iron in Kupffer cells impairs LPS-induced proinflammatory cytokine production in these cells. Xiong *et al*<sup>[77]</sup> have reported that the intracellular labile non-heme iron pool is involved in peroxynitrite or LPS-mediated activation of NF- $\kappa$ B and TNF- $\alpha$  release in Kupffer cells isolated from experimental animal models of chronic alcohol exposure. The intracellular labile iron pool is a transitory, free (non-ferritin-bound) pool of iron, which is chelatable by commonly used iron chelators. This pool of iron contributes to the generation of reactive oxygen species but its biological relevance is unclear<sup>[94]</sup>. Transient changes in the dynamics of the labile iron pool is not only affected by increased iron uptake but also by prooxidant chemicals, which induce the reductive release of iron from intracellular stores<sup>[95,96]</sup>. Xiong *et al*<sup>[77]</sup> have demonstrated that iron dextran treatment of cultured Kupffer cells *in vitro* does not affect the basal TNF- $\alpha$  release. Interestingly, Kupffer cells isolated from mice two weeks after iron dextran injection, exhibited significant increases in basal TNF- $\alpha$  release (independent of peroxynitrite or LPS stimulation). These findings suggest that either other cells in the liver (besides Kupffer cells) or yet unknown signals contribute to this process *in vivo*. It is also possible that the discrepancy between *in vitro* and *in vivo* iron loading regarding basal TNF- $\alpha$  release from Kupffer cells may not be due to iron (iron loading) *per se* but rather due to the differences in the level of oxidative stress.

The synthesis of hepcidin in the liver is mediated by several stimuli including iron and inflammation. Kupffer cells have been shown not to play a role in the regulation of hepcidin expression by iron *in vivo*<sup>[97,98]</sup>. The data in

the literature regarding the involvement of Kupffer cells in the regulation of liver hepcidin expression by inflammation is contradictory<sup>[97-99]</sup>. Montosi *et al*<sup>[97]</sup> have reported a role for Kupffer cells in the regulation of hepcidin expression by inflammation in mice. On the other hand, Lou *et al*<sup>[98]</sup> and Theurl *et al*<sup>[99]</sup> have demonstrated that the depletion of Kupffer cells in mice does not abrogate the up-regulation of liver hepcidin expression by LPS.

The role of Kupffer cell activation and TNF- $\alpha$  signaling in the regulation of hepcidin expression by alcohol *in vivo* has also been reported<sup>[100]</sup>. The inactivation of Kupffer cells by gadolinium chloride in rats paired with alcohol Lieber DeCarli diets for 6 wk or mice fed with ethanol in the drinking water for 1 wk did not reverse the alcohol-induced suppression of hepcidin expression in the liver<sup>[100]</sup>. Moreover, similar results were obtained when Kupffer cells were depleted by liposomes containing clodronate<sup>[100]</sup>. When phagocytosed by the Kupffer cells, clodronate released from the liposomes induces apoptosis and thereby depletes the Kupffer cell<sup>[101]</sup>. When co-cultured, Kupffer cells have been suggested to exert a negative effect on hepcidin synthesis in hepatocytes<sup>[99]</sup>. However, the depletion or inactivation of the Kupffer cells has been reported to not induce any significant changes in basal hepcidin expression levels in the livers of both control and alcohol-treated animals *in vivo*<sup>[100]</sup>. Interestingly, one week of ethanol treatment (in the drinking water) was sufficient to induce NF- $\kappa$ B activation and TNF- $\alpha$  and IL-6 release in mice, compared to control mice fed with plain water<sup>[100]</sup>. The neutralization of TNF- $\alpha$  inhibited the activation of NF- $\kappa$ B<sup>[100]</sup>. However, neither the neutralization of TNF- $\alpha$  nor the absence of TNF- $\alpha$  receptor I and II expression altered the effect of alcohol on hepcidin expression (i.e. down-regulation)<sup>[100]</sup>. These findings therefore strongly suggest that the activation of Kupffer cells and TNF- $\alpha$  signaling are not involved in the regulation of hepcidin expression by alcohol *in vivo*. These findings are also in agreement with Lou *et al*<sup>[98]</sup>, who demonstrated that Kupffer cells are not required for the regulation of liver hepcidin expression by LPS-induced inflammation.

The suppression of hepcidin synthesis in the liver by alcohol occurs very early (within days) following alcohol exposure and involves hepatocytes, but not Kupffer cells (Figure 2)<sup>[12,100]</sup>. It is noteworthy that hepatocytes are the main site of hepcidin synthesis in the liver<sup>[50]</sup>. Alcohol-induced oxidative stress in hepatocytes is one of the main mechanisms by which hepcidin expression in the liver is down-regulated by alcohol<sup>[12]</sup>. The decrease in liver hepcidin synthesis leads to an increase in intestinal iron transport and liver iron content<sup>[10-12]</sup>. Hence, alcohol dysregulates iron homeostasis by suppressing hepcidin expression in the liver. Although Kupffer cells are not involved in the initial stages of this process induced by alcohol, the increase in iron stores (due to low levels of hepcidin) will further activate Kupffer cells, and thereby lead to the release of proinflammatory cytokines. It is therefore possible that unlike LPS, the priming of Kupffer cells by iron<sup>[70]</sup> occurs in later stages of ALD and exacerbates the inflammatory processes by facilitating further

release of TNF- $\alpha$ , and thereby contributing to liver injury.

## ALCOHOL-INDUCED OXIDATIVE STRESS AND HEPCIDIN

Alcohol metabolism generates reactive oxygen species and lipid peroxidation products (malondialdehyde, 4-hydroxynonenal) during the oxidation of ethanol by alcohol dehydrogenase and cytochrome P4502E1 to form acetaldehyde. Serum thioredoxin levels are also an indicator of oxidative stress and they have been reported to be significantly higher in patients with ALD compared to healthy subjects<sup>[102]</sup>. Due to its capacity to take part in the Fenton reaction as a transition metal, iron itself induces the generation of reactive oxygen species (superoxide, hydroxyl iron), which subsequently damage cellular membranes *via* lipid peroxidation<sup>[3,103]</sup>. Iron and alcohol act as a deadly cocktail to exacerbate liver injury. Orally effective iron chelators have been reported to attenuate alcohol-induced hepatic lipid peroxidation in rats<sup>[104]</sup>.

Alcohol-induced oxidative stress is involved in the suppression of hepcidin promoter activity and hepcidin transcription in the liver *in vivo* by inhibiting the DNA-binding activity of the transcription factor, C/EBP  $\alpha$ <sup>[12]</sup>. Both Kupffer cells and hepatocytes are involved in alcohol-induced oxidative stress. However, a role for Kupffer cells in the regulation of hepcidin expression by alcohol in the liver has been excluded (Figure 2)<sup>[100]</sup>. This strongly suggests the involvement of hepatocytes in the regulation of hepcidin expression, and thereby iron metabolism by alcohol. Multiple pathways are involved in alcohol-induced oxidative stress in hepatocytes; redox state changes, the activation of CYP2E1 or NADPH oxidase and changes in mitochondrial functions<sup>[105-109]</sup>. Alcohol metabolism, which is accompanied by oxidation and reduction reactions, causes an imbalance in the redox state of the cell by generating excess NADH (reduced nicotinamide adenine dinucleotide). CYP2E1 enzyme, present in liver microsomes, has a high redox potential and is also metabolically active in the absence of alcohol<sup>[107]</sup>. It produces reactive oxygen species such as superoxide and hydrogen peroxide, which is increased by alcohol exposure leading to lipid peroxidation, oxidative stress and tissue injury. NADPH oxidase catalyzes the reduction of molecular oxygen to generate superoxide<sup>[110,111]</sup>. The liver expresses both phagocytic and non-phagocytic isoforms of NADPH oxidase<sup>[112,113]</sup>. Alcohol-induced liver pathology was not observed in mice with deficient NADPH oxidase activity suggesting a role for this enzyme in the progression of alcoholic liver disease<sup>[109]</sup>. Mitochondria play a key role both in iron biogenesis and alcohol metabolism<sup>[3,108,114]</sup>. Alcohol induces lesions in the proteins of the mitochondrial electron transport chain and decreases the rate of hepatic ATP synthesis<sup>[114-116]</sup>. This induces the transfer of unpaired electrons to molecular oxygen and elevates the production of reactive oxygen species. The involvement of

these changes in the regulation of hepcidin expression in hepatocytes by alcohol needs further investigation (Figure 2).

Several factors including iron, viral infection, endotoxin and reactive oxygen species have been implicated to act as second hit factors in the progression of alcoholic liver disease. Of note, hepcidin expression in the liver is regulated by iron, alcohol, hepatitis C viral proteins, inflammation, hypoxia and oxidative stress<sup>[10-12,48,100,117-120]</sup>. Nishina *et al*<sup>[119]</sup> have recently shown that hepatitis C viral protein-mediated oxidative stress suppresses hepcidin transcription by altering the activity of the transcription factor, C/EBP  $\alpha$ . These findings are in agreement with our previously published results demonstrating a role for alcohol-mediated oxidative stress in the inhibition of C/EBP  $\alpha$  activity and hepcidin transcription<sup>[11,12]</sup>. Hepcidin may therefore act as a potential second hit factor in the progression of alcoholic liver disease.

## CONCLUSION

Patients with alcoholic liver disease frequently display elevated iron stores. Recent reports by several groups strongly suggest that this may be a regulated mechanism rather than iron simply leaking out of injured intestinal cells. Hepcidin, an iron regulatory hormone synthesized in hepatocytes, plays a key role in the regulation of iron metabolism. Alcohol-mediated oxidative stress suppresses hepcidin expression in the liver leading to increased intestinal iron uptake and liver iron storage. Reduced hepcidin expression may be one of the mechanisms leading to elevated iron stores following alcohol exposure. Hepcidin may therefore act as a second hit in the progression of ALD. Both hepatocytes and Kupffer cells play a role in ALD. However, Kupffer cells have been reported to not be involved in the regulation of liver hepcidin expression by both acute and chronic alcohol exposure. Hepatocytes are the main site of alcohol metabolism in the liver leading to the generation of reactive oxygen species and the depletion of antioxidants. Alcohol-induced oxidative stress in hepatocytes is therefore one of the mechanisms leading to the suppression of hepcidin synthesis and thereby to iron overload, which in turn acts as a secondary risk factor in ALD. Accordingly, iron has been shown to prime Kupffer cells leading to the release of TNF- $\alpha$  in experimental animal models of ALD. The disruption of hepcidin synthesis and thereby iron metabolism by alcohol may have clinical relevance. Hepcidin therefore holds promise as an early diagnostic marker and as a candidate for therapeutic strategies for ALD.

## Abstract

The asialoglycoprotein (ASGP) receptor is a well-characterized hepatic receptor that is recycled *via* the common cellular process of receptor-mediated endocytosis (RME). The RME process plays an integral part in the proper trafficking and routing of receptors and ligands in the healthy cell. Thus, the mis-sorting or altered transport of proteins during RME is thought to play a role in several diseases associated with hepatocyte and liver dysfunction. Previously, we examined in detail alterations that occur in hepatocellular RME and associated receptor functions as a result of one particular liver injury, alcoholic liver disease (ALD). The studies revealed profound ethanol-mediated impairments to the ASGP receptor and the RME process, indicating the importance of this receptor and the maintenance of proper endocytic events in normal tissue. To further clarify these observations, studies were performed utilizing knockout mice (lacking a functional ASGP receptor) to which were administered several liver toxicants. In addition to alcohol, we examined the effects following administration of anti-Fas (CD95) antibody, carbon tetrachloride (CCl<sub>4</sub>) and lipopolysaccharide (LPS)/galactosamine. The results of these studies demonstrated that the knockout mice sustained enhanced liver injury in response to all of the treatments, as shown by increased indices of liver

damage, such as enhancement of serum enzyme levels, histopathological scores, as well as hepatocellular death. Overall, the work completed to date suggests a possible link between hepatic receptors and liver injury. In particular, adequate function and content of the ASGP receptor may provide protection against various toxin-mediated liver diseases.

## THE ASIALOGLYCOPROTEIN RECEPTOR AND ITS POTENTIAL ROLE IN LIVER INJURY

The asialoglycoprotein (ASGP) receptor, also termed the hepatic binding protein or the Ashwell receptor, was discovered nearly four decades ago by Ashwell and Morell, and was described as a hepatocellular surface carbohydrate that binds glycoproteins lacking terminal sialic acid residues (asialoglycoproteins)<sup>[1,2]</sup>. Subsequently, many studies have contributed to the detailed characterization of the ASGP receptor, describing its functional role in the binding, internalization and transport of a wide range of glycoproteins, which have exposed galactose or N-acetylgalactosamine residues, *via* the process of receptor-mediated endocytosis (RME)<sup>[3-6]</sup>. However, translating altered ASGP receptor function and its altered clearance of serum glycoproteins to disease states remains a topic of current

research efforts. This ongoing interest is fueled by the knowledge that the ASGP receptor can bind a variety of important plasma proteins that include transport proteins (i.e. transferrin)<sup>[7]</sup>, enzymes such as alkaline phosphatase<sup>[8]</sup>, immunoglobulins including IgA<sup>[9]</sup>, apoptotic hepatocytes<sup>[10,11]</sup>, fibronectin<sup>[12]</sup> and platelets<sup>[13]</sup>. Additionally, the expression of the ASGP receptor has been clinically correlated to the level of hepatic function that is lost during liver diseases related to cancer, viral hepatitis, and cirrhosis<sup>[14,15]</sup>. Overall, the quest to identify and understand the physiological role(s) of the ASGP receptor, and the consequences that may result from alterations in the function and/or expression of this abundant hepatocellular binding protein, continues.

In search of the physiological roles of the ASGP receptor, our lab initially concentrated on characterizing the role of the ASGP receptor and RME events during a serious and common form of liver injury, alcoholic liver disease (ALD). Alcoholism, and resultant ALD, are indeed significant biomedical problems. Specifically, recent data has noted that chronic liver disease and cirrhosis was the 12th leading cause of death in the United States in the year 2005, and that out of those deaths, approximately 47% of them were due to ALD<sup>[16]</sup>. Therefore, defining potential contributing mechanisms (such as altered protein trafficking and impaired hepatic receptor functions) may aid in the elucidation of potential therapeutic treatments for ALD. In that effort, our laboratory has extensively studied the RME process and parameters of the ASGP receptor following the administration of ethanol to rodents.

The ASGP receptor consists of major and minor subunits, which in the rat were identified as rat hepatic lectin (RHL) 1 and RHL 2/3, that have respective molecular weights of 42, 49 and 54 kDa<sup>[17]</sup>. The selective binding and uptake of terminal galactosyl bearing proteins requires the formation of hetero-oligomers between these major and minor forms, and that binding activity was calcium and pH dependent<sup>[2,5,18]</sup>. Also, the subcellular distribution of the receptor revealed that approximately one-third of the total ASGP receptor pool was associated with the plasma membrane located on the basolateral surface of the hepatocyte<sup>[19]</sup>. Additionally, it was shown that the total ASGP receptor population consisted of two functionally distinct receptor populations, designated State 1 and State 2, which were involved in the endocytosis and intracellular processing of ligands by different pathways<sup>[20-22]</sup>.

Utilizing these known properties, we studied the effects of ethanol on the ASGP receptor itself, as well as endocytic processes, using isolated hepatocytes, whole liver sections, and perfused livers obtained from rats voluntarily fed an ethanol containing diet over a time course of administration. In summary, differential effects were observed over the time course of treatment in the ability of ethanol and resultant metabolites to affect the ASGP receptor and RME events. Specifically, after early periods of ethanol feeding (1-2 wk), we found that the observed decrease in ligand binding capacity of the ASGP receptor could be attributed to inactivation and redistribution of the receptor<sup>[23]</sup>. However, after more

chronic ethanol administration (5-8 wk), the functional alterations of the receptor were found to be reflective of reductions in the content, synthesis, and mRNA expression of the receptor<sup>[23]</sup>. Also, it was determined that ethanol treatment caused equal inactivation of both State 1 and State 2 receptors, suggesting that ethanol may be unique compared to other agents (e.g. monensin, vanadate, and chloroquine) that are known to inflict post-translational modifications, such as acylation, selectively to just the State 2 population<sup>[24]</sup>. In other studies, it was revealed that the ASGP receptor was hyperphosphorylated over the time course of treatment, which could contribute to the aberrant activity of the receptor by disrupting the phosphorylation/dephosphorylation state associated with normal recycling of the receptor<sup>[25]</sup>. We were also able to demonstrate that the ASGP receptor is involved in the recognition and uptake of apoptotic cells and that this process was significantly altered in hepatocytes obtained from ethanol fed rats<sup>[11]</sup>. Overall, the results from these studies revealed that ethanol administration impairs multiple aspects of RME by the hepatic ASGP receptor, such that binding, internalization and degradation of ligands internalized by the receptor were found to be significantly altered. Additionally, it was shown that these defects are associated with alterations in the ASGP receptor's physiologically relevant role of clearing apoptotic cells. Taken together, our findings have important implications for the pathogenesis of alcoholic liver injury and potentially for other forms of liver diseases in which RME is profoundly affected. In more recent studies, a mouse model lacking the ASGP receptor was used to gain a better understanding of the associations that may exist between alterations in receptor function and the generation of pathological liver injury.

## THE ASGP RECEPTOR-DEFICIENT MOUSE MODEL

The ASGP receptor in mice is a hetero-oligomeric receptor composed of 2 subunits that are both required for its function. These subunits have been named murine hepatic lectin (MHL), with the major subunit called MHL-1 and the minor subunit called MHL-2<sup>[26]</sup>. ASGP receptor-deficient (RD) mice have a complete lack of the MHL-2 protein and were generated by homologous recombination with a gene replacement vector in embryonic stem cells<sup>[27]</sup>. MHL-2 appears to be required for the post-translational stability of MHL-1, as these mice have substantially reduced protein content of MHL-1, even though MHL-1 mRNA expression remains the same<sup>[27]</sup>. Although the MHL-1 protein is still detected in low levels in the RD mice, these levels are unable to induce a measurable clearance of 125I-labeled asialo-orosomucoid<sup>[27]</sup>. Despite lacking functional ASGP receptors, these knockout mice remain viable and fertile, and appear to have a normal lifespan. In addition, these mice do not display any obvious phenotypic abnormalities<sup>[27,28]</sup>.

As previously mentioned, we have found that chronic alcohol administration markedly decreased mRNA expression and content of the ASGP receptor

in rats prior to the appearance of pathology such as fibrosis<sup>[23,29]</sup>. Thus, it was felt that the RD mice might provide a powerful tool to examine the role of the ASGP receptor and help delineate pathways by which liver injury occurs in general, as well as during alcoholic liver injury. Currently, we are utilizing the knockout mouse model to examine the link between ASGP receptor function and liver injury, in the context of various models of toxic liver injury such as alcohol, anti-Fas, carbon tetrachloride (CCl<sub>4</sub>) and lipopolysaccharide (LPS)/galactosamine. In this report, we present a brief overview of our findings to date.

## MODELS OF LIVER INJURY AND THEIR EFFECTS ON ASGP RECEPTOR-DEFICIENT MICE

### Alcohol

Alcohol-induced liver injury has previously been found to be related to several events, including ethanol metabolism (*via* alcohol dehydrogenase<sup>[30-33]</sup>), generation of reactive oxygen species (*via* cytochrome isoforms such as CYP2E1<sup>[34-36]</sup>), interaction of other liver products (such as cytokines<sup>[37,38]</sup>) and the induction of apoptosis through the Fas death receptor system<sup>[39]</sup>. In the search for cellular signaling and mechanisms resulting as a consequence of these events, studies were performed that examined the effects of ethanol on hepatocellular protein trafficking, particularly the process of RME utilizing the hepatic ASGP receptor.

As mentioned previously, we examined the effects of ethanol administration using a rat model exclusively; the rats showed decreased ligand binding, internalization and degradation of several ligands including asialo-orosomucoid, which are processed by RME<sup>[4,23,40-43]</sup>. In order to assess the effect of ethanol administration on RME by the ASGP receptor using a mouse model, we obtained wild-type (WT) mice possessing abundant ASGP receptor activity and ASGP receptor-deficient (RD) mice lacking MHL-2 from the Jackson Laboratories (Bar Harbor, ME). The mice were fed a Lieber de-Carli liquid diet (with or without 5% by volume ethanol) for ten days<sup>[44]</sup>. When hepatocytes from these mice were incubated with 125I-ASOR (a representative ligand for the ASGP receptor), WT mice showed ethanol-induced alterations that were consistent with our observations for rats, with an approximately 50% decrease in ligand binding, internalization and degradation in isolated hepatocytes<sup>[4,23,44]</sup>. However, binding, internalization and degradation of the ligand by RD hepatocytes was negligible, regardless of diet<sup>[44]</sup>. In addition, the presence of apoptotic bodies was found to be approximately three-fold higher in the livers of RD mice compared to WT mice, irrespective of diet<sup>[44]</sup>. As a result of this work, it is hypothesized that a potential consequence of altered ASGP receptor function is impaired clearance of ethanol-generated apoptotic cells, resulting in the observed accumulation of apoptotic bodies. Furthermore, other work has shown that these bodies have the potential to promote a variety of responses

within the liver, such as the activation of Kupffer cells and the subsequent release of proinflammatory and profibrogenic substances, leading to the enhanced susceptibility to hepatocellular damage that is observed following ethanol administration<sup>[11,45]</sup>.

### Anti-Fas

Anti-Fas is an antibody that specifically recognizes and works as an agonist of the Fas antigen<sup>[46]</sup>. Fas is a member of the TNF receptor superfamily and is a key mediator of apoptosis<sup>[47]</sup>. This receptor is found in hepatocytes, cholangiocytes, sinusoidal endothelial cells, stellate cells and Kupffer cells<sup>[48]</sup>. Ligation of Fas results in the recruitment of adaptor proteins, such as Fas-associated death domain (FADD) and procaspase 8, to form the death-inducing signaling complex (DISC)<sup>[47]</sup>. Caspase 8 can then either directly or indirectly cleave procaspase 3 to mediate apoptosis<sup>[47]</sup>. A variety of studies have shown that the injection of anti-Fas into mice causes widespread apoptosis and ultimately results in focal hemorrhage and hepatocyte necrosis, making Fas injection a model for fulminant hepatic failure<sup>[46,49,50]</sup>.

From studies related to Fas-mediated cell death in our laboratory, we have shown that the metabolism of ethanol in WIF-B cells (hepatoma hybrid cells) was involved in enhanced Fas protein localization to the membrane, leading to increased activity of the upstream initiator caspases (caspase 2 and caspase 8) and the subsequent downstream activation of caspase 3<sup>[39]</sup>. As an extension to these studies, aimed to characterize the role of Fas-mediated death in injured hepatocytes, anti-Fas (0.1 or 0.2 µg/g body weight) was injected intraperitoneally into WT and RD mice, which were monitored for up to 48 h<sup>[51]</sup>. Receptor-deficient mice showed an enhancement of liver injury with higher aspartate transaminase (AST) and alanine transaminase (ALT) activities in the serum compared to the enzyme levels detected in WT mice<sup>[51]</sup>. Similarly, pathology showed that the RD mice had increased steatosis, inflammation and necrosis compared to the WT mice<sup>[51]</sup>. As expected, caspase 3 activities were found to be increased 5- to 6-fold in WT mice at 2 h and 16 h after anti-Fas injection, with caspase activities returning to baseline levels by 24 h<sup>[51]</sup>. However, the activity of caspase 3 remained elevated in the RD livers at all times following treatment and was significantly enhanced over the WT livers at 24 h and 48 h post anti-Fas injection<sup>[51]</sup>. Overall, the livers of the RD mice were found to be more susceptible than the livers of the WT mice to anti-Fas injection; showing greater apoptosis and increased ECM deposition of collagen and fibronectin<sup>[51]</sup>.

### Carbon tetrachloride

Another agent used to study liver injury is carbon tetrachloride (CCl<sub>4</sub>), which can cause liver damage through a number of mechanisms. Carbon tetrachloride is metabolized through the action of the mixed function cytochrome P450 system of the endoplasmic reticulum to form the trichloromethyl free radical (CCl<sub>3</sub>•), which can subsequently be converted to the trichloromethyl peroxy radical (CCl<sub>3</sub>OO•) in the presence of oxygen<sup>[52,53]</sup>.

These free radicals are highly reactive and can bind covalently to cellular macromolecules forming nucleic acid, protein and lipid adducts. When these radicals attack the polyunsaturated fatty acids of the cellular membranes, the fatty acid free radicals generated initiate autocatalytic lipid peroxidation, ultimately resulting in the loss of membrane integrity<sup>[52,53]</sup>. Carbon tetrachloride can also induce cellular hypomethylation, leading to inhibition of protein synthesis (possibly through ribosomal RNA hypomethylation) and defects in lipid and lipoprotein metabolism<sup>[53]</sup>. Finally, CCl<sub>4</sub> also affects hepatocellular calcium homeostasis, either by disrupting membrane integrity or by opening certain membrane calcium channels. High levels of Ca<sup>2+</sup> in the cell can then activate Ca<sup>2+</sup>-responsive enzymes such as proteases, endonucleases and phospholipases and lead to cell death *via* apoptosis and necrosis<sup>[52,53]</sup>. The consequences of CCl<sub>4</sub> toxicity include centrilobular steatosis, inflammation, apoptosis and necrosis<sup>[52-54]</sup>.

In our studies, WT and RD mice were injected with CCl<sub>4</sub> (1 mL/kg body weight) and monitored up to a week after injection<sup>[55]</sup>. Carbon tetrachloride injection caused greater liver injury in the RD mice, as evidenced by the RD mice having increased AST and ALT activities in the serum, compared to the WT mice 48 h post CCl<sub>4</sub> injection<sup>[55]</sup>. Histologically, centrilobular liver damage was observed in WT mice by 48 h after injection<sup>[55]</sup>. At this time point, RD mice had more severe damage, showing a greater number of neutrophilic inflammatory infiltrates<sup>[55]</sup>. In order to elucidate the mechanisms by which this damage is caused, malondialdehyde (MDA), deposition of  $\alpha$ -smooth muscle actin ( $\alpha$ -SMA) and the percentage of TUNEL-positive hepatocytes was measured<sup>[55]</sup>. Levels of MDA in the WT mice were not significantly increased throughout the course of the experiment<sup>[55]</sup>. In contrast, RD mice showed increased contents of MDA as early as 24 h post CCl<sub>4</sub> injection and these levels were maintained up to 48 h<sup>[55]</sup>.  $\alpha$ -SMA was increased significantly in both the WT and RD mice, with the RD mice having a more prolonged increase (between 48 h to 72 h) than the WT mice (only at 72 h)<sup>[55]</sup>. In addition,  $\alpha$ -SMA content was approximately 2-fold of that in the WT liver at 48 h, 96 h and 7 d following injection<sup>[55]</sup>. Finally, RD mice had significantly more TUNEL-positive hepatocytes than the WT mice at 48 h post injection (2.4-fold more)<sup>[55]</sup>. This suggests that the absence of functional ASGP receptor resulted in increased lipid peroxidation, perturbations in ECM turnover and increased apoptosis<sup>[55]</sup>.

### LPS/galactosamine

Lipopolysaccharide (endotoxin) and galactosamine can be used either alone or in combination with each other to cause liver injury in mice. The metabolism of galactosamine leads to hepatotoxicity by depleting uridine nucleotides and UDP-hexoses and concurrently increasing UDP-hexosamines, primarily in hepatocytes<sup>[56,57]</sup>. The depletion of uridine nucleotides (as mentioned above) results in an inhibition of RNA and protein synthesis<sup>[58]</sup>. It has also been suggested that metabolism of galactosamine results in an impaired biosynthesis of macromolecular cell

constituents<sup>[56]</sup>. This impairment leads to plasma membrane injury, which results in an influx of calcium ions and a commitment to cell death<sup>[58]</sup>. In rats, galactosamine leads to an inflammatory infiltrate of polymorphonuclear leukocytes and lymphocytes and foci of hepatocellular necrosis, resembling the effects of human viral hepatitis<sup>[57,59]</sup>.

Mice and rats are relatively resistant to the lethal effects of LPS<sup>[60]</sup>. Thus, LPS is injected in concert with galactosamine for a model of fulminant hepatitis<sup>[61]</sup>. It is thought that galactosamine-induced suppression of RNA synthesis leads to an increased tumor necrosis factor (TNF) production by macrophages, resulting in an increased susceptibility to LPS<sup>[60-62]</sup>. Tumor necrosis factor was proposed as the agent responsible for the lethality, because lethality was retained by substituting LPS with TNF and was inhibited by anti-TNF antibody<sup>[63,64]</sup>. Thus, in LPS/galactosamine injection, apoptosis induced by TNF occurs initially and is followed subsequently by necrosis<sup>[65]</sup>.

In our studies, a sub-lethal dose of LPS (50  $\mu$ g/kg body weight) combined with galactosamine (350 mg/kg body weight) was injected into WT and RD mice *via* the intraperitoneal route and the mice were monitored up to 4.5 h<sup>[66,67]</sup>. After LPS/galactosamine injection, WT mice maintained normal liver lobular architecture<sup>[66]</sup>. However, RD mice showed considerable liver injury with areas of portal inflammation, hepatocellular necrosis, increased inflammatory cell infiltration and hemorrhage<sup>[66]</sup>. These histological observations were further corroborated by the RD mice having increased serum AST and ALT activities at 4.5 h after LPS/galactosamine injection, which were not observed in the WT mice<sup>[66]</sup>. Also, RD mice showed increased apoptosis, having significantly enhanced caspase 3 activities and TUNEL-positive cells at 4.5 h post injection, whilst there were no changes measured in WT mice<sup>[66]</sup>. Additionally, the serum content of the pro-inflammatory cytokine interleukin 6 (IL-6) was increased in RD mice compared to WT mice at 3 and 4.5 h after LPS/galactosamine injection<sup>[67]</sup>. Overall, the results demonstrate that the RD mice are more susceptible to the development fulminant liver injury as a result of sub-lethal treatment with LPS/galactosamine<sup>[66,67]</sup>. Given that the induction of apoptosis is a consequence of LPS/galactosamine treatment, the enhanced susceptibility to liver damage observed in the RD mice may be related to the inability of hepatocytes to phagocytose and clear the dying apoptotic cells *via* the ASGP receptor.

## THE LINK BETWEEN FUNCTIONAL ASGP RECEPTOR AND LIVER INJURY

After the administration of the four toxicants mentioned above (alcohol, anti-Fas, CCl<sub>4</sub> and LPS/galactosamine), RD mice consistently sustained greater liver injury than WT mice, as evidenced by increased indices of liver damage (serum AST and ALT activities) and worse pathology (light microscopy). These four agents of liver injury cause damage through different biochemical pathways or signaling cascades. Therefore, it appears that proper functioning of the ASGP receptor may provide

universal protection against liver injury from these toxicants and possibly others. Although it is not known exactly how an adequately functioning receptor can protect the hepatocyte, the use of the knockout mice treated with these four toxicants highlight some of the possible mechanisms.

It appears that with all four toxicants, caspase 3 or TUNEL-positive cells are increased. Apoptosis is a highly regulated mode of cell death that helps to maintain tissue homeostasis in a healthy organ<sup>[68]</sup>. However, it appears that when apoptotic death factors are inappropriately expressed due to the introduction of pathological stimuli, such as the four toxicants, apoptosis becomes one of the common pathways by which liver injury is caused. Increased accumulation of apoptotic cells has been shown to occur during alcohol-induced liver injury in a variety of species, including humans, and is thought to play an important role in the progression of liver injury<sup>[69-75]</sup>. During the process of forming apoptotic cells, glycoconjugates on the cell surface losing their sialic acid masks the increase<sup>[10,76]</sup>. Since the ASGP receptor binds to desialylated proteins, the receptor recognizes and binds the altered glycans on apoptotic bodies, resulting in phagocytosis and efficient removal of the dying cells<sup>[11]</sup>. Thus, we speculate that the ASGP receptor exerts protection by removing apoptotic bodies in a timely fashion.

Another way that the ASGP receptor might be protective is through its role in regulating turnover of ECM. Anti-Fas and CCl<sub>4</sub> treatments lead to increased deposition of collagen, fibronectin or  $\alpha$ -SMA in the RD mice in comparison to the WT mice. The ASGP receptor has a direct link to cellular fibronectin clearance because cellular fibronectin displays terminal galactose residues, making it a ligand of the ASGP receptor<sup>[12]</sup>. Cellular fibronectin is one of the first ECM proteins that accumulates during fibrosis<sup>[77-79]</sup> and thus impairments of ASGP receptor function could lead to increased ECM deposition and hence lead to fibrosis and cirrhosis.

Two additional ways that liver injury could be mediated is through increased lipid peroxidation (MDA content) or by increased contents of pro-inflammatory cytokines, such as IL-6. At present, it is not known how ASGP receptor function is related to perturbations in levels of these two substances. In addition, there may be dysregulation of other asialoglycoproteins not examined at this point. The total absence of ASGP receptor function does not result in a measurable increase in the steady state concentrations of galactose-terminating glycoproteins in the plasma of knockout mice<sup>[28]</sup>. Thus, the ASGP receptor is unlikely to be involved in the normal turnover of serum glycoproteins. However, in toxicant-induced injuries, acute surges of asialoglycoproteins may overwhelm the alternative galactose recognition systems<sup>[28]</sup>. Thus, the ASGP receptor might function to prevent an acute increase in potentially harmful asialoglycoproteins. Altogether, the ASGP receptor knockout mouse model provides an excellent tool to elucidate the relationship between ASGP receptor function and liver injury.

**Table 1** Changes in ALT activity, TUNEL positive cells, AST activity, caspase 3 activity, collagen content, IL-6 content, MDA content and  $\alpha$ -SMA content in RD mice compared to WT mice

Challenge	RD mice compared to WT mice
Alcohol	Liver TUNEL-positive hepatocytes
Anti-Fas	Liver TUNEL-positive hepatocytes
	Serum ALT
	Serum AST
	Liver caspase 3 activity
	Collagen deposition in extracellular matrix
	Fibronectin deposition in the extracellular matrix
CCl <sub>4</sub>	Liver TUNEL-positive hepatocytes
	Serum ALT
	Serum AST
	Liver MDA content
	Liver $\alpha$ -SMA content
LPS/galactosamine	Liver TUNEL-positive hepatocytes
	Serum ALT
	Serum AST
	Liver caspase 3 activity
	Serum IL-6 content

ALT: Alanine transaminase; AST: Aspartate transaminase; IL-6: Interleukin 6; MDA: Malondialdehyde;  $\alpha$ -SMA:  $\alpha$ -smooth muscle actin; RD: Receptor-deficient; WT: Wild-type. The various conditions the mice were challenged with were alcohol (Lieber de-Carli ethanol diet for 7 d), anti-Fas (0.2  $\mu$ g/g body weight), CCl<sub>4</sub> (1 mL/kg body weight) and LPS/galactosamine (50  $\mu$ g LPS/kg body weight and 350 mg galactosamine/kg body weight).

## CONCLUSION

The ASGP receptor is an abundant hepatic receptor that recognizes desialylated ligands. After binding to its ligand, the receptor internalizes and facilitates transport of specific ligands by the process of receptor-mediated endocytosis. Previously, studies have shown that ASGP receptor function is impaired in disease states such as alcoholic liver disease. This gave us the impetus to examine if proper ASGP receptor function offers protection against liver injury or if defects in function occurred as a result of liver damage. To examine this, we utilized a knockout mouse model, which lacked functional ASGP receptor in comparison to wild-type animals in the context of various toxic challenges (alcohol, anti-Fas, CCl<sub>4</sub> and LPS/galactosamine). After all four challenges, the receptor-deficient mice consistently showed more liver injury than the wild-type animals (Table 1), proving that ASGP receptor function is protective. Thus, these studies highlight receptor-mediated endocytosis as a novel mechanism that may be involved in the induction of toxin-induced liver injury. At present, the precise nature of the specific ligands involved or the pathways that lead to further injury have not been determined. However, in the studies reviewed here, it is likely that impaired clearance of apoptotic bodies, perturbations in extracellular matrix deposition, oxidative stress, and cytokine dysregulation may play roles in the progression of disease. In the future, further clarification of the pathways by which liver injury occurs (including altered ASGP receptor-mediated endocytosis) will provide new therapeutic leads.

### Abstract

Alcoholic patients have a high incidence of hepatitis C virus (HCV) infection. Alcohol consumption enhances the severity of the HCV disease course and worsens the outcome of chronic hepatitis C. The accumulation of virally infected cells in the liver is related to the HCV-induced inability of the immune system to recognize infected cells and to develop the immune responses. This review covers the effects of HCV proteins and ethanol on major histocompatibility complex (MHC) class I - and class II-restricted antigen presentation. Here, we discuss the liver which functions as an immune privilege organ; factors, which affect cleavage and loading of antigenic peptides onto MHC class I and class II in hepatocytes and dendritic cells, and the modulating effects of ethanol and HCV on antigen presentation by liver cells. Altered antigen presentation in the liver limits the ability of the immune system to clear HCV and infected cells and contributes to disease progression. HCV by itself affects dendritic cell function, switching their cytokine profile to the suppressive phenotype of interleukin-10 (IL-10) and transforming growth factor beta (TGF $\beta$ ) predominance, preventing cell maturation and allostimulation capacity. The synergistic action of ethanol with HCV results in the suppression of MHC class II-restricted antigen presentation. In addition, ethanol metabolism and HCV proteins reduce proteasome function and interferon signaling, thereby suppressing the generation of peptides for MHC class I-restricted antigen presentation. Collectively, ethanol exposure further impairs antigen

presentation in HCV-infected liver cells, which may provide a partial explanation for exacerbations and the poor outcome of HCV infection in alcoholics.

### INTRODUCTION

In non-cytolytic viral infections, the immune system (and mainly T-lymphocytes) is necessary to clear the infected cells. The most specialized and effective homeostatic control is provided by cytotoxic T lymphocytes (CTLs) (CD8+ T-lymphocytes). For clonal expansion, CTLs need activating "help" from CD4+ T-lymphocytes, which, in turn, require recognition of viral antigens on professional antigen-presenting cells (APC), including dendritic cells (DC), macrophages and B-lymphocytes.

Recognition of antigens by T-lymphocytes depends upon the expression of the major histocompatibility complex (MHC) on the surface of APC. MHC molecules involved in antigen presentation include MHC class I, MHC class II and MHC-like CD1 molecules<sup>[1]</sup>. MHC class I molecules are expressed on the nuclear cells and load protease-generated peptides to CD8+ T-lymphocytes. MHC class II molecules are expressed on the surface of specialized APC and load peptides generated in the endocytic compartment to CD4+ T cells. CD1 molecules bind acyl chains, therefore allowing T cells to recognize fatty acids, glycolipids and lipopeptide antigens (self or foreign)<sup>[2]</sup>.

Hepatitis C virus (HCV) is an example of an intra-

cellularly persistent virus, which targets liver cells and is eliminated by immune cells<sup>[3,4]</sup>. In acute HCV infection, antigen presentation plays a pivotal role in the activation of immune response, while HCV protein-induced defects in antigen presentation lead to insufficient activation of the immune system, which controls the killing of infected hepatocytes<sup>[5]</sup>. Accumulation and persistence of virally infected cells provide a basis for the chronic course of HCV infection. The reduced clearance of virus and increased viral load usually observed in immunodeficient and in alcohol-consuming patients are associated with a high risk of hepatocarcinoma development<sup>[6,7]</sup>.

## LIVER AS AN IMMUNE PRIVILEGE ORGAN

Liver is considered an immunological organ<sup>[8]</sup>. Liver cells are involved in the clearance of foreign antigens, which come from the gastrointestinal tract. The physiological role of the liver is to face antigenic flow from the gastrointestinal tract and to respond to this intervention by activating the immune response. To escape immune activation, liver cells use a mechanism of immune tolerance, which prevents unnecessary immune-mediated damage of hepatocytes.

Some liver cells, such as liver dendritic, Kupffer, endothelial and stellate cells serve as antigen presenting cells<sup>[9]</sup>. Kupffer cells (KC) are the resident macrophage population, which act as incompetent antigen-presenters<sup>[10]</sup>. They produce IL-10, which down-regulates CD4+ T-cell activation<sup>[11,12]</sup>. Reactive oxygen species (ROS) production is an essential trigger of antigen presentation in KC, accompanied by induction of MHC class II and co-stimulatory molecule expression<sup>[13]</sup>. In contrast to KC, liver endothelial cells (LSEC) are known as potent APC that present antigens in a MHC class II-restricted manner to CD4+ T-cells<sup>[9]</sup>. The efficacy of their antigen presentation is comparable to DC<sup>[8]</sup>; however, IL-10 and TGF $\beta$  secreted by KC and LSEC as well as lipopolysaccharide (LPS), which comes with blood from the gastrointestinal tract, can down-regulate their antigen-presenting properties<sup>[14,15]</sup>. Both KC and LSEC express MHC antigens, costimulatory and adhesion molecules and produce IL-1 and IFN $\gamma$ , suggesting that these are relatively mature cells<sup>[16]</sup>. In contrast, liver DC are immature cells, which express MHC antigens on their surface, but express a relatively small amount of co-stimulatory molecules, which does not allow them to efficiently stimulate naïve T-cells<sup>[17]</sup>. Hepatic DC play an important role in the induction and regulation of immune responses, by interacting with CD4+, CD8+ lymphocytes and natural killers (NK) cells. These cells typically reside only around portal triads and like other DC, they capture, process and transport antigens to regional lymphoid tissues<sup>[16]</sup>. Two subpopulations of DC, myeloid and plasmocitoid cells are found in liver at a low density. Exposure of progenitor DC to IL-10 and TGF $\beta$  generates

suppressive and tolerogenic effects<sup>[18]</sup>. In the liver, they are resistant to DC maturation stimuli, such as IFN $\gamma$  and TNF $\alpha$ , while matrix proteins, such as collagen type 1, induces maturation<sup>[19]</sup>. However, even being tolerogenic in the liver, hepatic DC are the main professional liver APC, which can further migrate to lymphoid tissue to undergo maturation<sup>[20]</sup>. In addition to other liver cells, stellate cells have also recently been characterized as having antigen presentation properties<sup>[21]</sup>.

Almost 60% of liver cells are hepatocytes. Due to specific liver architecture, hepatocytes are exposed to a mixture of portal venous and hepatic arterial blood. Liver parenchyma is actively involved in immune response by expressing a variety of receptors. Because liver is a site of apoptotic CD8+ T-lymphocyte accumulation<sup>[22]</sup>, it raises the question whether liver cells, including hepatocytes, induce apoptosis in activated CD8+ T-lymphocytes, thereby promoting a tolerogenic response or they specifically attract apoptotic T-lymphocytes without causing T-lymphocyte death. Resting hepatocytes act as APC for MHC class I-restricted T-cells, while MHC class II and CD1 are not constitutively expressed on hepatocytes<sup>[23]</sup>. However, the role of hepatocytes as potent APC activating intrahepatic lymphocytes is contradictory. While some studies indicate that activation of naïve CD8+ T-lymphocytes does not happen in case the primary activation occurs within the liver, other studies suggest that the presentation of antigens in the liver showed no immunosuppressive effect on the activation of CD8+ T-cells and that hepatocytes are an excellent priming site for naïve CD8+ T-cells<sup>[24-26]</sup>.

## ANTIGEN PROCESSING AND PRESENTATION IN THE CONTEXT OF MHC CLASS I

Proteolysis is the first step in the antigen processing and presentation pathway. Peptide products are transported by transporters associated with antigen processing (TAP) to endoplasmic reticulum (ER), where they assemble in a trimolecular complex with  $\beta$ 2-microglobulin and the heavy chain of MHC. Assembly is facilitated by TAP and a number of chaperones and allows class I molecule to bind the peptide to achieve optimal MHC class I loading. These complexes are transported to the plasma membrane, where they interact with the T-cell receptor (TCR) of a T-lymphocyte. TAP has sequence preference and peptide-size limitation, which is matched to MHC class I. To be presented in a context of MHC class I, antigenic proteins undergo the processing to peptides and then the peptides are further cleaved, to fit into the MHC class I groove. Certain proteases participate in the cleavage of peptides for antigen presentation, and the major protease is proteasome.

For activation, CD8+ cells require presentation of MHC class I-peptide complexes on professional APC cells. Peptides can be generated from viral proteins sensitized by infected APC or from proteins originally synthesized by other infected "donor" cells (cross-priming, or cross presentation). Cross-priming can be carried by mo-

lecular chaperones and come from apoptotic cells<sup>[27]</sup>. In addition, it is suggested that these peptides are captured by the lysosomal compartment, with further trafficking to cytosol followed by proteasomal processing for MHC class I loading<sup>[28]</sup>. However, other authors question the role of proteasomal processing in the cross-presentation mechanism<sup>[29]</sup>.

## PROTEASOME, AMINOPEPTIDASES AND INTERFERON GAMMA-INDUCED GENERATION OF PEPTIDES FOR ANTIGEN PRESENTATION

Degradation of intracellular proteins into oligopeptides for antigen presentation is catalyzed by the proteasome<sup>[30]</sup>. This multicatalytic enzyme exists as a 26S particle, which is ATP-dependent and recognizes ubiquitinated polypeptides. Another form, the 20S proteasome, can degrade substrate proteins in an ubiquitin-independent manner. Both the 26S and 20S proteasome particles degrade antigenic proteins that may later be presented as peptides, depending on the properties of the protein. The chymotrypsin-like and the trypsin-like activities of the proteasome are related to antigen presentation due to their ability to cleave peptide bonds after hydrophobic and basic amino acids, respectively<sup>[30]</sup>. In cells treated with IFN $\gamma$ , proteasome particles acquire two novel MHC-encoded low molecular weight subunits, known as LMP-2 and LMP-7, and a third subunit, MECL-1, encoded by genes outside the MHC locus<sup>[31]</sup>. The acquisition of these three subunits converts the constitutive proteasome to the immunoproteasome and alters its peptidase activities for the generation of uniform sized 8-10-mer peptides<sup>[32]</sup>. The importance of immunoproteasome induction for antigen presentation has been confirmed using LMP-2 and LMP-7-knockout mice, which demonstrated impaired antigen presentation, reduced expression of MHC class I and poor CTL response to viral epitopes<sup>[33,34]</sup>. The immunoproteasome is responsible for cleavage of peptides at their C-termini<sup>[35]</sup>. However, some antigenic peptides have N-terminal extensions that are unable to bind to the MHC class I groove. Aminopeptidases, namely, cytosolic leucine aminopeptidase (LAP), finally trims the epitopes to 8-9 amino acid residues necessary to form the complexes with MHC class I<sup>[36]</sup>. This enzyme is also IFN $\gamma$ -inducible<sup>[37]</sup>. Trimmed peptides are transported to the endoplasmic reticulum (ER) by TAP. In the ER lumen, the peptide can be further trimmed by downstream endoplasmic reticulum aminopeptidase I (ERAP1)<sup>[38]</sup> to generate a stable complex with MHC class I heavy and light chains ( $\beta$ 2-microglobulin). These complexes, with the help of molecular chaperones, traffic to the cell surface to be recognized by CD8 $^{+}$  T-cells<sup>[39,40]</sup>. The immune system relies heavily on intracellular protein degradation to recognize a complex of surface MHC class I molecules with short peptide fragments of eight to nine amino acids<sup>[41]</sup>. Induction of CTLs is programmed by the spec-

trum of presented MHC class I-peptide complexes on the cell surface<sup>[42]</sup>.

## HCV, MHC CLASS I-RESTRICTED ANTIGEN PRESENTATION AND EFFECTS OF ETHANOL

The effects of HCV proteins on MHC class I-restricted antigen presentation are not widely studied and most of the findings are related to MHC class II-restricted antigen presentation. In HCV infected patients, associations between the human MHC and sustained virological response have been found, indicating that the various immunogenetic backgrounds of chronic hepatitis C patients are related to the differences in the course of the disease<sup>[43]</sup>.

Processing of CTL epitopes in HCV infected cells may be altered due to mutations generated by HCV, which interfere with the ability of the peptide to be cleaved by the proteasome<sup>[44]</sup>. Nevertheless, interferon alpha-mediated induction of immunoproteasome or aminopeptidase expression has been shown as a necessary step for CD8 $^{+}$  T-cell activation in acute HCV infected chimpanzees<sup>[45,46]</sup>. In addition to HCV-restricted mutations of viral proteins, proteasome activity is also modulated by HCV. Thus, proteasome activity in the nuclear compartment is up-regulated by PA28 $\gamma$  activator which forms a complex with HCV core protein<sup>[47]</sup>, while non-structural HCV protein, NS3, interacts with LMP-7, an immunoproteasome subunit, and reduces its activity, potentially providing a negative effect on the generation of peptides for antigen presentation<sup>[48]</sup>. Our previous studies on HCV core protein expressing Huh7 cells, which also express CYP2E1, revealed that core protein slightly enhances 20S proteasome activity, by 20S proteasome-core protein direct interactions and by induction of low CYP2E1-dependent oxidative stress<sup>[49]</sup>. However, this proteasome activation is reversed after ethanol exposure, where ethanol treatment considerably reduces proteasome function due to induction of high oxidative stress<sup>[49]</sup>. Indeed, the dependence of proteasome on the level of oxidative stress has been previously demonstrated<sup>[50,51]</sup>, and ethanol is known to suppress proteasome function in liver cells<sup>[52-55]</sup>. Ethanol-elicited suppression of proteasome activity in the liver ultimately results in reduced generation of antigenic peptides<sup>[56]</sup> and reduced MHC class I-restricted antigen presentation on hepatocytes (Osna *et al*, Hepatology, in press). Presentation of peptide-MHC class I complexes on virally infected hepatocytes (HCV, HBV infections, *etc*) as target cells is crucial for CTLs because when clonal expansion of CTLs is established, the next important restriction for elimination of infected cell is the availability of peptide-MHC class I complexes on the surface of target cells (hepatocytes), which are recognized by CTLs. Thus, even if CD8 $^{+}$  T-cells are activated by the presentation of HCV peptides on professional APC, the recognition of the peptide-MHC class I complexes on hepatocytes

(which are target cells for CTLs) may be limited under ethanol-induced oxidative stress.

## MHC CLASS II-RESTRICTED ANTIGEN PRESENTATION

Loading of MHC class II molecules with antigenic peptides requires the involvement of specialized APC, such as DC, B-lymphocytes and macrophages. Phagocytosis is the main way to capture antigenic proteins by DC or macrophages, while B-lymphocytes use the antigen specific B-cell receptors<sup>[57]</sup>. Antigens are digested into peptides (which are longer than those required for MHC class I-restricted antigen presentation) by proteases at endosome compartments. Cathepsins, intracellular acidic proteases, play a pivotal role in the processing of internalized antigens into class II-presentable T cell epitopes<sup>[58]</sup>. These peptidases play a dual role by generating the peptides or by destroying them. The coupling of peptides with MHC class II is controlled by chaperones and takes place in late endocytic vesicles<sup>[44]</sup>.

When pathogen-associated molecular patterns (PAMPs) on macrophages are recognized by innate immunity receptors (such as Toll-like (TLR)-, mannose-, Fc- and complement- receptors), they induce production of pro-inflammatory cytokines, namely, IFN $\gamma$  and colony-stimulating factor (GM-CSF). These cytokines increase the expression of MHC class II and co-stimulatory molecules in the cells. Chronic TLR signaling induced by LPS may impair MHC class II-restricted antigen presentation<sup>[59]</sup>. A large number of class II-bound proteins are derived from cytosolic proteins. Because the autophagy inhibitor has been shown to block the presentation of cytosolic peptides by MHC class II molecules, some authors discuss the role of autophagy in delivery of these cytosolic peptides to the endocytic route<sup>[60]</sup>.

After immature DC engulf pathogens, they undergo biochemical changes, such as secretion of TNF $\alpha$ , IL-6, IL-12, IL-10 and IFN $\alpha$  and expression of co-stimulatory molecules, including CD80, CD86 and CD40. These cells traffic to the nearest lymph node for presentation to T-lymphocytes. However, only mature DC can efficiently prime naïve T-lymphocytes, because only these cells generate MHC class II molecules, by redistribution of class II molecules and cathepsins to peptide-loading compartments and by enhancement of lysosomal acidification<sup>[61]</sup>. It is still unclear how the peptide-MHC class II complex is recruited to the cell surface from the endocytic compartment in DC. Human DC are subdivided into two big categories: myeloid DC and plasmacytoid DC. In addition to phenotypic differences, they express different TLRs and secrete a different spectrum of cytokines. Thus, myeloid DC express TLR3 and upon stimulation, produce IL-12p70, thereby promoting Th1 response, while plasmacytoid DC express TLR7 and TLR9 and secrete IFN $\alpha$ <sup>[62]</sup>. Therefore, myeloid DC cells are considered classic antigen presenters, while plasmacytoid DC have a limited ability to capture, process and load antigen onto MHC molecules<sup>[63]</sup>. Activation of DC

is positively regulated by IFN $\gamma$  and additional CD40 ligation; anti-inflammatory cytokines, such as IL-10, inhibit both IL-12 and IFN $\alpha$  expression, which results in pathogen survival<sup>[64]</sup>.

## MHC CLASS II-RESTRICTED ANTIGEN PRESENTATION, HCV AND ETHANOL

HCV infection affects DC function in many ways. Firstly, there is a decrease in the frequency of peripheral myeloid or plasmacytoid DC in chronically infected patients<sup>[65]</sup>. This may be, in part, related to an accumulation of intrahepatic DC in HCV infection, due to altered DC trafficking<sup>[66]</sup>. However, another study suggested that HCV directly targets mature cells because some HCV proteins (core, NS3 and NS5) induce apoptosis in DC<sup>[67]</sup>. Secondly, myeloid DC from chronic HCV patients have a decreased capacity to stimulate allogenic T-lymphocytes<sup>[68]</sup>. Furthermore, HCV core and E1 genes introduced in DC obtained from uninfected donors, lower their capacity to stimulate allogenic T-cell response<sup>[69]</sup>. In addition, core, NS3 and NS4 viral proteins were reported to influence the differentiation of DC from monocytes, due to IL-10 secretion<sup>[70]</sup>. The function of myeloid DC obtained from HCV patients is also decreased due to a reduced level of co-stimulatory molecules and down-regulated HLA-DR expression<sup>[5,68]</sup>. In addition, in chronic HCV patients, the production of IL-12 by DC is suppressed by HCV proteins, but can be restored by successful antiviral therapy<sup>[71]</sup>. Thirdly, the impairment of plasmacytoid DC function has been reported in HCV patients and reduced IFN $\alpha$  production upon DC stimulation with TLR ligands has also been observed<sup>[72]</sup>. This decrease in IFN $\alpha$  production can be attributed to monocyte-derived TNF $\alpha$  and IL-10<sup>[73]</sup>. Interestingly, the other studies did not demonstrate defective abilities in plasmacytoid DC to initiate immune response<sup>[74]</sup>, thereby questioning the altered presentation of HCV proteins by these cells to CD4+ cells.

The proposed mechanisms of ethanol-HCV interactions were summarized elsewhere<sup>[75]</sup>. Ethanol drastically enhances the negative effects of HCV on DC function. A possible reason for this is that alcohol stimulates HCV expression at HCV RNA and proteins levels, which is, in part, related to up-regulation of the Cox2 pathway<sup>[76]</sup>. Chronic ethanol feeding suppresses CD4+ T cell proliferation in response to antigens as well as CTL activity after DNA-based vaccine immunization with NS5 and HCV-expressing plasmids<sup>[77-79]</sup>. This CD4+T-cell response was restored by co-administration of IL-2-expressing plasmid, while the restoration of CTL activity required administration of GM-CSF<sup>[77,78]</sup>. Alcohol doubles the effects of HCV by decreasing expression of co-stimulatory molecule, B7, and IL-12 production, increasing IL-10 production and lowering allostimulatory capacity<sup>[80-82]</sup>. Furthermore, human studies demonstrated that ethanol affects the allostimulatory activity of resting and activated DC generated from peripheral blood mononuclear cells in the presence of cytokines<sup>[81]</sup>,

indicating that HCV infection impairs DC function, which is further exacerbated by ethanol. Recent studies performed on alcohol-fed mice, immunized with HCV DNA-based vaccine that induces immune response to NS5 HCV protein, demonstrated that ethanol exposure reduced the number of splenic DCs without altering endocytosis capacity. It also reduced the lymphoid DC population, as well as expression of co-stimulatory molecules, CD40 and CD86, altered cytokine profile (enhanced production of IL-1 and IL-10 and decreased secretion of IL-12, IFN $\gamma$  and IL-6)<sup>[83]</sup>. Finally, CTL response to NS5 was shown to be impaired, but was corrected by syngeneic transfer of control DC<sup>[83]</sup>.

## HCV, IFN SIGNALING AND ETHANOL

Antigen presentation is so tightly regulated by IFNs that it should be analyzed in the context of IFN signaling. The reported effects of HCV proteins on IFN signaling are quite controversial. Most studies revealed down-regulation of STAT1 phosphorylation in response to IFN $\alpha$ <sup>[84-86]</sup> attributed to SOCS3 activation by HCV core or NS5A proteins. In addition to that, NS3 protein plays a role in dissociation of the adaptor molecule, MAVS that disrupts the early activation of IFN $\beta$  signaling by the virus<sup>[87,88]</sup>. Subsequently, the disruption of STAT1 phosphorylation by the NS3/NS4 complex was documented<sup>[89]</sup>. In some studies, suppressed STAT1 phosphorylation was linked to either the ability of the core protein to specifically interact with the SH2 domain, preventing STAT1 hetero- or homodimerization<sup>[90]</sup> or to direct targeting of STAT1 with core protein and subjecting activated STAT1 to degradation by the proteasome<sup>[91]</sup>. The latter hypothesis is consistent with our recent findings that core protein activates proteasome function<sup>[49]</sup>. Core protein also inhibits the IFN-induced nuclear import of STAT1 and STAT2 and transcription of antiviral genes<sup>[92,93]</sup>. HCV proteins interfere with IFN $\alpha$  signaling related to the attachment of activated STAT1 to DNA. Methylation on arginine residues, which prevents the formation in STAT1-PIAS1 complexes, is altered in chronic hepatitis C patients<sup>[94,95]</sup>. Protective effects of the methylation regulators, S-adenosyl methionine and betaine, were shown to correct HCV-induced inhibition of IFN $\alpha$  signaling *in vitro*<sup>[96]</sup>. Interestingly, in other studies, core protein has been shown to activate interferon stimulated response element (ISRE) and gamma activated site (GAS) sequence promoters in the presence or absence of IFN $\alpha$  and  $\gamma$  and to stimulate INOS promoter, INOS protein induction as well as activation of IFN-inducible 2'5'-oligoadenylate synthetase (2'5'-OAS)<sup>[97,98]</sup>. Less is known about the interference of HCV with IFN $\gamma$ -induced signaling, which is up-regulated by core protein, due to enhanced IFN $\gamma$ R2 expression<sup>[99]</sup>. In a cell culture system, prolonged treatment with IFN $\gamma$  attenuated IFN $\alpha$ -signaling<sup>[100]</sup>. Acute ethanol treatment of hepatoma cells inhibited anti-viral actions of IFN against HCV replicon, induced serine STAT1 phosphorylation, but blocked tyrosine phosphorylation<sup>[101]</sup>. Recently, it has

**Figure 1 Alcohol (ethanol) reduces antigen presentation on HCV-infected liver cells.** HCV interferes with the capacity of professional antigen presenting cells (APC) to prime the immune response. Ethanol (EtOH) further dysregulates antigen presentation, suppressing both MHC class I-restricted antigen presentation on infected hepatocytes and MHC class II-restricted antigen presentation on APC.

been shown that alcohol metabolism induces increased replication of HCV and attenuates the antiviral effects of IFN<sup>[102]</sup>. However, the number of studies regarding the combined effects of ethanol and HCV proteins on IFN signaling is very limited.

## CONCLUSION

HCV alters antigen-presentation capacities of professional APC, thereby contributing to the persistence of virally infected cells. The most prominent effects were observed on MHC class II-restricted antigen presentation and DC functions. Ethanol potentiates the effects of HCV, providing further suppression of both MHC class I- and class II-restricted antigen presentation on DC, hepatocytes and others hepatic APC, which diminish CTL response. IFNs which support antigen presentation by activating APC and peptidases lose this property in the presence of HCV and alcohol, because HCV and alcohol, separately or in combination, reduce IFN signaling. This, in part, explains why alcohol consumption exacerbates the course, worsens the outcome and reduces the responsiveness to interferon alpha treatment in chronic HCV infection. The effects of alcohol (ethanol) on HCV-restricted antigen presentation are summarized in Figure 1.

### Abstract

The onset of alcoholic liver disease (ALD) is initiated by different cell types in the liver and a number of different factors including: products derived from ethanol-induced inflammation, ethanol metabolites, and the indirect reactions from those metabolites. Ethanol oxidation results in the production of metabolites that have been shown to bind and form protein adducts, and to increase inflammatory, fibrotic and cirrhotic responses. Lipopolysaccharide (LPS) has many deleterious effects and plays a significant role in a number of disease processes by increasing inflammatory cytokine release. In ALD, LPS is thought to be derived from a breakdown in the intestinal wall enabling LPS from resident gut bacterial cell walls to leak into the blood stream. The ability of adducts and LPS to independently stimulate the various cells of the liver provides for a two-hit mechanism by which various biological responses are induced and result in liver injury. Therefore, the purpose of this article is to evaluate the effects of a two-hit combination of ethanol metabolites and LPS on the cells of the liver to increase inflamma-

### INTRODUCTION

It has become increasingly clear that alcohol alone is not solely responsible for the initiation and/or progression of alcoholic liver disease (ALD). While alcohol consumption does increase fatty liver, lipid peroxidation, and reactive oxygen species (ROS), these insults are typically not enough to induce the onset of more severe forms of liver disease<sup>[1]</sup>. The "two-hit" proposal of ALD is of interest because inflammation caused by the metabolites of ethanol [ROS, aldehyde modified proteins or lipopolysaccharide (LPS)] increase the levels of cytokines/chemokines resulting in a deleterious positive feedback loop that propagates liver inflammation, infiltration of inflammatory cells<sup>[2,3]</sup>, and fibrosis. To support this, aldehyde modified proteins<sup>[4,5]</sup> and endotoxin (LPS)<sup>[6,7]</sup> have been detected in the serum and/or livers of patients with ALD. These substances have been shown to increase the release of TNF- $\alpha$ , interleukin-1 $\beta$ , and prostaglandin by Kupffer cells, sinusoidal endothelial cells and stellate cells. This release in turn promotes an influx of

inflammatory cells leading to an increase in cellular damage promoting the development of necrosis and eventually liver failure<sup>[8-11]</sup>. The purpose of this review was to more closely examine how a “two-hit” model of ethanol metabolism and LPS interaction affects resident liver cells in the progression and/or development of ALD. Many excellent reviews<sup>[12-14]</sup> exist concerning inflammatory cell activation and recruitment to the damaged liver during the development of ALD and therefore will not be discussed here<sup>[15-17]</sup>.

## ANIMAL MODELS OF ETHANOL AND LPS-INDUCED LIVER INJURY

Current animal models of ALD have provided many valuable findings<sup>[18]</sup>. However, in general, these models do not produce the type of end-stage liver failure observed in patients with ALD. To counter this, models have been developed that combine ethanol treatment strategies with an additional injury cofactor. One way of developing more overt injury (e.g. steatohepatitis and fibrosis) in order to mimic the human disease is to combine ethanol and LPS treatment. LPS is a component from the cell walls of bacteria found in the gut as normal flora. Typically, when gram-negative bacteria break down, LPS is released and removed by endothelial cells lining the blood vessels or Kupffer cells (KCs) in the liver. If the normal activity of the gut epithelium is disrupted, as has been shown to happen with acute or chronic ethanol ingestion, the LPS released from degrading bacteria can cross into the bloodstream<sup>[6,7,19]</sup>. Even though the exact mechanism of this is unknown, it is suggested that with chronic ethanol consumption, ethanol can damage the cells lining the interior of the intestine and increase the amount of LPS entering the blood stream. In addition, ethanol impairs KCs and prevents them from clearing LPS from the bloodstream<sup>[11,20]</sup>. When LPS enters into the bloodstream and moves to the liver, it activates KCs by interacting with the CD14 and Toll-like receptor 4 (TLR-4) molecules on the surface of the cell. This interaction causes a cascade which results in production of ROS and release of inflammatory cytokines (i.e. TNF- $\alpha$ , IL-1 $\beta$ , IL-6, IL-10), which in turn activates signaling cascades and causes injury to the primary liver cells, the hepatocytes<sup>[8,21]</sup>.

There have been a number of different approaches utilized to investigate the effects of ethanol consumption and LPS on ALD. The first hit from ethanol metabolism results in the production of ethanol metabolites (i.e. acetaldehyde and acetate). These metabolites increase redox state, steatosis, production of ROS, and lipid peroxidation. This in turn, increases other reactive aldehydes like malondialdehyde and 4-hydroxynonenal. These aldehydes can react with or adduct proteins to alter normal liver functions, induce cell death, and/or liver inflammation. This makes the liver more susceptible to a second hit, probably by LPS. The second hit perpetuates liver injury and fibrosis as a result of LPS-induced oxidative stress, cytokine release, and subsequent infiltration of immune cells<sup>[2]</sup>.

## Two-hit animal models

In a two-hit model of ALD described by Koteish *et al*<sup>[22]</sup>, C57BL-6 mice were maintained on diets containing 4 mL/L ethanol for five weeks. Pair-fed control mice were fed an identical volume of ethanol-free diet. At the end of the five weeks, the mice received one 10  $\mu$ g injection of LPS and sacrificed at 0.5, 1.5 and 6 h post-injection. Histological results showed that the livers from control pair-fed mice had features of apoptosis, but no inflammatory cell infiltrates or hemorrhage. In contrast, hepatocytes in the ethanol-fed mice showed fat accumulation, inflammatory cell infiltration, and hemorrhage.

Procaspase-3, procaspase-8, Jun N-terminal kinase (JNK), TNF- $\alpha$  and TNFR-1 are mediators of LPS-induced hepatotoxicity. Apoptosis in this model was evaluated by determining the levels of procaspase-3 and procaspase-8. Immunoblot analysis to examine procaspase-3 levels showed that the ethanol-fed mice exhibited a decreased content of procaspase-3 relative to the pair-fed mice before and after LPS injections. Evaluation of procaspase-8 showed that it was elevated in the ethanol-fed mice compared to the pair-fed mice.

Examination of JNK activity demonstrated an eight-fold increase 1.5 h after LPS exposure alone. In contrast, LPS had no effect on JNK activity in ethanol-fed mice. TNF- $\alpha$  can interact with TNFR-1 and initiate a signaling cascade that activates procaspase-3 and inducing apoptosis. The expressions of TNF- $\alpha$  and TNFR-1 were found to be steady between the ethanol-fed and control pair-fed mice. Cytokines (IL-10, IL-15 and IL-6) that inhibit TNF- $\alpha$  activity have been shown to prevent liver damage from LPS. These cytokines were up-regulated in both groups but to a greater extent in the ethanol-fed mice.

Thus, the Koteish mouse animal model provides an excellent way to set up a long-term study showing the interaction of ethanol and LPS. This model is beneficial as there is no surgery to perform and only one injection of LPS is administered at the end of the study.

In the von Montfort *et al*<sup>[23]</sup> model, four groups of C57BL-6J mice were given different treatments with epinephrine and ethanol. In the first group, 2 mg/kg per day of epinephrine was administered *via* an osmotic pump implanted in the dorsal area for five days. In previous studies this epinephrine dose had been shown to effectively mimic the effects of ethanol. The second group (controls) underwent sham surgery to mimic the implantation of the osmotic pump. The third group was injected with ethanol (6 g/kg per day) for three days. The last group was given a maltose/dextrin injection that was comparable calorifically to the ethanol injection. An injection of 10 mg/kg LPS was administered after the 5-d period and 24 h after the last ethanol dose, the mice were sacrificed at one, eight and 24 h later.

Histological results showed normal hepatocytes in the control animals and in the animals with the epinephrine pump/no LPS injection. Mice injected with LPS alone showed mild inflammation, whereas the mice receiving the epinephrine pump/LPS showed enhanced

liver damage. Importantly, the mice that were given ethanol/LPS showed dramatic liver damage. Plasma AST levels showed that the mice infused with epinephrine alone had no significant increase in plasma AST levels as compared with control mice. Animals treated with LPS only showed a progressive increase in AST with values approximately two-fold higher than the controls. Exposure of animals to epinephrine and ethanol with LPS exposure showed a significant increase in AST levels after LPS exposure by a factor of approximately four and six, respectively. The expression of pro-inflammatory genes, TNF- $\alpha$ , IL-6, and PAI-1 (plasminogen activator inhibitor 1) were analyzed by RT-PCR. In this part of the study, LPS alone stimulated all three genes as early as one hour after injection. Epinephrine pretreatment alone did not affect the expression of these genes, but paired with LPS showed an increased expression of all three genes. The induction of PAI-1 caused by LPS was significantly greater (two-fold) in the presence of epinephrine. The peak expression of TNF- $\alpha$  and IL-6, one hour after LPS exposure was not enhanced by epinephrine pre-exposure. However, these levels were significantly elevated when compared with the LPS alone group at the 8 h time point. Twenty-four hours after LPS injection, mRNA levels of all three returned to basal levels with no difference between the LPS and epinephrine/LPS groups.

Inflammation by LPS is not only enhanced by increased production of pro-inflammatory cytokines, but by impairing the expression of anti-inflammatory genes. Key anti-inflammatory genes such as IL-10, SOCS-1 and SOCS-3 were not significantly changed following epinephrine infusion alone, or in the sham-treated mice.

Curcumin (CMN) has been shown to exhibit anti-inflammatory, anti-bacterial, anti-oxidant properties, and reducing oxidative stress caused by ethanol. This animal model effectively shows how CMN pretreatment protects from LPS-induced liver damage. Kaur *et al.*<sup>[24]</sup> used CMN in a model where six groups of male Wistar rats were administered different treatments in conjunction with CMN. In these studies CMN was administered at different doses (5, 30, 60 mg/kg) in the presence or absence of LPS. Rats were sacrificed six hours after an LPS injection on the last day.

Serum alanine aminotransferase (ALT), serum aspartate aminotransferase (AST), and alkaline phosphatase (AP) were analyzed in all rats which showed a marked rise in serum levels, following LPS injection causing increased liver damage. LPS also caused a rise in serum bilirubin and a decrease in serum total protein compared to control rats. Treatment with CMN significantly decreased the elevated levels of AST, ALT, AP, and bilirubin in response to LPS challenge. Serum nitrite levels and lipid peroxidation were decreased, whereas hepatic GSH, reduced glutathione, and superoxide dismutase (SOD), were increased. Additionally, TNF- $\alpha$  and IL-6 cytokines increased in LPS-administered rats compared to normal rats. CMN administration for seven days ef-

fectively blocked the rise of TNF- $\alpha$  and IL-6 cytokines in the LPS-challenged rats. Histology results did not reveal any morphological alterations in the control group but did show marked morphological disruption in LPS-administered rats. Treatment with CMN attenuated these morphological changes.

In the Gustot *et al.*<sup>[25]</sup> animal model, C57BL-6J mice were fed a liquid ethanol diet adapted from the Lieber-DeCarli diet *ad libitum* for 10 d followed by an injection intraperitoneally with one of the following: 60 or 120  $\mu$ g lipoteichoic acid (LTA), 60 or 120  $\mu$ g peptidoglycan (PGN), 60 or 120  $\mu$ g polyinosine-polycytidylic acid (polyIC), 30 or 60  $\mu$ g LPS, 60  $\mu$ g flagellin or 60 or 120  $\mu$ g 7-allyl-8-oxoguanosine (loxoribine). Control mice were pair-fed with a control diet and injected with the same volume of saline solution after 10 d. Mice were sacrificed eight hours after injection.

The ethanol diet led to an increased liver weight compared to the control mice. Histology showed nearly 75% of hepatocytes in ethanol-fed mice exhibited steatosis. Compared to the control-fed mice, the ethanol-fed mice showed significant increase in serum (ALT) levels, and TNF- $\alpha$  mRNA expression. After 10 d, the expression of Toll-like receptors (TLR) 1, 2, 4, 6, 7, 8 and 9 was measured and found to have significant increases over control-fed mice. However, TLR3 and TLR5 were not statistically different in the two groups. To look at the role that endotoxin plays in liver damage in ethanol-fed mice, antibiotics were administered before the experiment began. Cultures from the ethanol-fed mice treated with antibiotics showed a clear decrease in gram-negative bacteria from the mice not treated with antibiotics prior to the start of the experiment. Addition of antibiotics reduced the severity of fatty liver, as shown by decreases in liver weight, serum ALT levels, and steatosis. An increase of lipid peroxidation products (e.g. malondialdehyde, 4-hydroxyaldenals) and a decrease of antioxidant levels (e.g. glutathione) demonstrated hepatic oxidative stress in the livers of ethanol-fed mice.

This animal model is effective because it provides a way to study ethanol consumption and LPS in a way that shows the importance of LPS in the liver for damage to occur. It is important to note that clinically, antibiotics have demonstrated some success in the treatment of ALD patients<sup>[26-28]</sup>.

The studies above used different approaches, but have shown very similar results when comparing the short-term and long-term effects of ethanol. Overall the short-term affects show that ethanol provides a protective affect from LPS by altering the expression of endotoxin receptors and intracellular signaling molecules<sup>[20]</sup>. In contrast, the long-term effect shows an increased sensitivity to LPS and ethanol resulting in liver damage. Clearly, while these models have helped in gaining new insights into the mechanisms of ALD, the development of new and innovative animal models are needed to better elucidate the development and/or progression of ALD.

## EFFECTS OF ETHANOL, METABOLITES, AND LPS *IN VITRO*

### Liver sinusoidal endothelial cells (SECs)

SECs are flattened, highly fenestrated, and lack a basement membrane. This leads to their common characterization as “sieve-like”. Scanning electron microscopy has shown healthy fenestrae are approximately 150 nm in diameter and make up 6%-8% of the sinusoidal surface. These cells are active filters, selectively moving liquids and solutes from the portal blood into the Space of Disse where they are exposed to parenchymal hepatocytes and lipid storage cells. SECs are also highly endocytotic using scavenger receptors (SRs) to clear the blood of many molecular waste products. They have much higher permeability than other capillaries, and there is constant bidirectional exchange between hepatic parenchyma and blood *via* SECs. The size of the molecules that can pass through SECs is only constrained by fenestral diameter<sup>[29]</sup>. These cells are the first line of defense against harmful molecules that could potentially damage the liver. There are many immunological functions of SECs. They have been shown to efficiently remove small (< 200 nm) molecules from the blood using innate immune mechanisms such as scavenger and mannose receptors<sup>[29,30]</sup>. They have also been shown to express MHC class II, and co-stimulatory molecules (CD40, CD80, and CD86). They also express intercellular adhesion molecules including CD54 and CD106, which attract immune cells during inflammation. This suggests that they are involved in antigen processing and presentation as well as leukocyte recruitment<sup>[30]</sup>.

Capillarization of the SECs occurs when they form basement membranes that have been shown to precede fibrosis<sup>[31]</sup>. Also, hepatic stellate cells (HSCs), when activated to their collagen producing form, induce fibrosis<sup>[32]</sup>. It has been shown *in vitro* that quiescent rat HSCs maintain their inactivity and active HSCs revert to quiescence when grown in co-culture with healthy, nitric oxide (NO) producing SECs in the presence of vascular endothelial growth factor (VEGF). However, this effect is not observed when HSCs are co-cultured with capillarized SECs or those not producing NO<sup>[33]</sup>.

There is also evidence that malondialdehyde and acetaldehyde-two ethanol metabolites-form an adduct (MAA) which modifies proteins such that they increase the expression of fibrotic molecules by SECs. One such molecule is fibronectin. Fibronectin is expressed following insult to the liver and is known to activate HSCs and induce fibrosis. After stimulation with MAA-modified bovine serum albumin (MAA-Alb), isolated rat SECs show significant increases over negative controls in expression of soluble fibronectin, cellular fibronectin, and of the EIIIA fibronectin variant (the form most closely associated with activation of HSCs)<sup>[34]</sup>. Incubation of MAA-Alb with isolated rat SECs for four hours has been shown to elicit increases in pro-inflammatory cytokines/chemokines: an eight-fold increase in TNF- $\alpha$ ; a two-fold increase in MCP-1; and a four-fold increase in MIP-2<sup>[8]</sup>. This increase in fibrotic molecules and pro-

inflammatory cytokines provides a potential mechanism by which damage to the liver is mediated by metabolites of ethanol adducted proteins.

Due to their participation in the clearance of LPS from the blood, SECs have mechanisms for the control of inflammatory, leukocyte-mediated response to LPS, while maintaining the population of SRs necessary for toxin and waste clearance. Upon initial contact with LPS, cultures of mouse hepatic SECs release and activate IL-6. This occurs without regard to the presence of TNF- $\alpha$  and requires functional TLR4. SEC responsiveness is decreased following repeated stimulation by LPS. This occurs *via* reduced nuclear translocation of transcriptionally active nuclear factor  $\kappa\beta$  (NF $\kappa\beta$ ). Importantly, repeated exposure to LPS diminishes SEC scavenger function but does not eliminate it. Initial exposure to LPS results in an increased expression of adhesion molecules on leukocytes including CD54, CD106, MCP-1, and IFN-inducible protein 10. None of the above are up-regulated in cultured SECs with previous LPS exposure, and in the case of CD54, this was shown to occur *via* reduced gene expression<sup>[35]</sup>.

Exposure to LPS *in vivo* has been shown to increase both the quantity of small (20 nm) latex beads and the maximum size (from 100 nm to 500 nm) of latex beads that can be ingested by mouse SECs. Increases were not seen in the rate of ingestion of 100 nm beads, which were the most aggressively ingested regardless of LPS stimulation. LPS was also shown to increase the uptake of both BSA (soluble protein) and dextran (soluble carbohydrate). These increases are attributed to LPS-induced actin remodeling by protein kinase C (PKC) and phosphoinositide 3-kinase (PI3-K) as indicated by increased expression of *src*-suppressed C kinase substrate (SseCKS) on the endothelial cells<sup>[36]</sup>.

### Two-hit model effects on SECs

Lining the portal veins of the liver, the SECs are the first line of defense against LPS derived from the gut<sup>[30]</sup>. Most of the attention in LPS clearance has been attributed to the KCs. However, it has been shown that SECs contribute to the regulation of LPS in the liver<sup>[30,35,36]</sup>. This regulation of LPS under normal physiological conditions is kept in check by both KC and SECs, which keep the amount of inflammation to a minimum. If LPS levels are increased due to other factors (i.e. alcohol or aldehyde modified proteins), then the potential for disruption of normal homeostasis exists. The fact that alcohol increases both gut permeability (increasing the LPS)<sup>[7]</sup> and aldehyde modified liver proteins<sup>[4]</sup>, provides a possible two-hit mechanism by which the liver could become damaged.

Chronic exposure to ethanol metabolites in the form of MAA-adducted albumin has been shown to alter the SEC response to LPS. In hepatic SECs isolated from rats, LPS-induced secretions of TNF- $\alpha$ , MCP-1, and MIP-2 all show at least two-fold increases in the presence of MAA modified albumin, but no increase in the presence of unmodified albumin. The TNF- $\alpha$

response is decreased by chronic ethanol consumption, but MCP-1 and MIP-2 responses are not<sup>[8]</sup>. The MAA-adduct has also been shown to bind to, and be degraded by, SECs *via* SRs on their surface<sup>[37]</sup>. It has also been shown that SECs have CD14 and TLR receptors, which are involved in the uptake of LPS<sup>[38,39]</sup>. The potential exists for both aldehyde modified proteins and LPS to bind their receptors simultaneously, increasing the normal release of pro-inflammatory factors that promote inflammation of immune cells to the liver.

While chronic ethanol consumption and LPS stimulation independently increase apoptosis of SECs (as measured by caspase-3 activity) in pre-ALD rat livers, the combination elicits no additional increases. However, data generated from this study did demonstrate that LPS treatment of animals increased the amount of malondialdehyde (MDA) in the hepatocytes. The increase in MDA provides additional substrate for the potential formation of MAA adducts. Therefore an increase in AA and MDA from alcohol metabolism and an increase in MDA from inflammation-induced cell damage could lead to increased MAA-adducted self cellular material and the subsequent initiation of an autoimmune disease<sup>[40]</sup>.

### KCs

KCs are the resident macrophages found in the liver. It is believed that KCs play an important role in the development of ALD<sup>[41]</sup>. When stimulated with LPS they become activated and release pro-inflammatory and fibrotic cytokines, along with ROS, which can contribute to liver injury<sup>[11]</sup>. Interestingly, it has been shown that circulating LPS concentrations are increased in the blood of alcoholics, and in rats fed alcohol intragastrically, due to the effects ethanol on increasing the permeability on the intestinal mucosa<sup>[42,43]</sup>. The circulating LPS derived from intestinal bacteria in turn activate KCs, which initiate their pro-fibrotic and pro-inflammatory effects. KCs can also be activated by interactions with proteins modified by reactive aldehydes associated with ethanol metabolism increasing oxidative stress due to [acetaldehyde (AA) and malondialdehyde (MDA)]. These modified proteins have been associated with ALD<sup>[44-47]</sup>. LPS may further sensitize KC interactions with aldehyde-modified proteins<sup>[8]</sup> and may actually be involved in their formation<sup>[48]</sup>.

Chronic ethanol does more than provide the KCs with LPS; it also directly affects their sensitivity to LPS. This section will examine the role that LPS activation of KCs plays in the development of ALD and whether ethanol directly affects KC responses to LPS. The role(s) of aldehyde modified proteins in KC activation and how LPS may affect KC sensitivity to stimulation by these modified proteins will also be examined.

Alcohol causes both tolerance and sensitization to KC activation by LPS<sup>[49-51]</sup>. Studies have shown that acute ethanol administration inactivates KCs probably due to ethanol's effects on calcium channels and their requirement for TNF- $\alpha$  release<sup>[52]</sup>. KCs isolated from rats two hours after ethanol treatment indeed lacked increased intracellular calcium normally observed when KCs are

treated with LPS. However, when KCs were isolated 24 h after the rats were treated with ethanol, the cells displayed their normal TNF- $\alpha$  production and histological changes upon LPS stimulation. These cells also displayed higher levels of the LPS binding receptor, CD14, which may explain their increased sensitivity to LPS. Treating the rats with antibiotics, which sterilizes the gut removing portal LPS, lowered CD14 expression on KCs isolated 24 h after the administration of ethanol, suggesting that gut derived LPS was the cause of the increased CD14 expression and resultant sensitivity to LPS<sup>[53]</sup>. From these studies it can be concluded that a single dose of ethanol can either sensitize KCs or induce tolerance to LPS based on timing.

### Two-hit model effects on KCs

As discussed above, chronic ethanol exposure seems to increase the sensitivity of KCs to LPS stimulation. One of the major cytokines released by KCs exposed to LPS is TNF- $\alpha$ , which plays a role in the development of ALD<sup>[41]</sup>. Use of anti TNF- $\alpha$  antibody has been shown to protect against ALD in certain animal models<sup>[54]</sup>. The role of TNF- $\alpha$  in ALD was also confirmed in studies using TNF- $\alpha$  receptor 1 knockout mouse. In these mice, the pathological changes associated with ethanol treatment were greatly diminished<sup>[55]</sup>. KCs may become extra sensitive to LPS and as a result increase their production of TNF- $\alpha$  when chronically exposed to ethanol. This increases CD14 expression and changes the signaling cascade molecules involved in LPS stimulation induced by ROS. These events change transcription factor binding to DNA and increase stability of mRNA involved in TNF- $\alpha$  production.

KCs stimulated by LPS also have effects on HSCs. Hepatic fibrosis is characterized by an over deposition of extracellular matrix components. HSCs are involved with the production of extracellular matrix (ECM) in the liver and during fibrogenesis they undergo a process of activation and proliferation leading to excess collagen synthesis<sup>[56]</sup>. LPS activated KCs have been shown to be capable of activating HSC *in vitro*, and levels of ECM production have been directly correlated to increased HSC proliferation<sup>[57]</sup>.

The *in vitro* effects that LPS-stimulated KCs have on HSCs may be similar to what is seen during *in vivo* fibrogenesis. Higher levels of LPS in the blood of chronic alcoholics may serve as the catalyst for KC activation and therefore may promote HSC activation and fibrogenesis. The production of TGF- $\beta$ 1 by LPS-stimulated KCs is one of the most significant steps in the activation of HSCs<sup>[57]</sup>.

Studies have indicated that the detection of acetaldehyde (AA), malondialdehyde (MDA), and AA MDA hybrid (MAA) modified proteins adducts, correlate with increased liver enzymes and liver damage<sup>[45,47,58]</sup>. Experiments have also demonstrated that administering gadolinium chloride with ethanol results in the decreased accumulation of MDA and especially AA protein adducts in the livers of rats chronically fed alcohol indicating a role for KCs in AA protein adduct formation<sup>[48]</sup>.

LPS stimulation of KCs and their ability to release

pro-inflammatory cytokines might also promote immune system recruitment and surveillance, which might help to promote an immune response to these modified proteins. Circulating antibodies to aldehyde-derived epitopes have been identified<sup>[59]</sup>. KCs might be involved in the actual presentation of these molecules to the immune cells and be stimulated by these adducted proteins to release pro-inflammatory cytokines. SRs found on their surfaces can bind MAA modified proteins and subsequent binding of these proteins leads to increased levels of TNF- $\alpha$ . When KCs are stimulated with low levels of LPS in addition to MAA modified albumin (MAA-Alb), TNF- $\alpha$  secretion increases six to eight fold. The levels of LPS used for co-stimulation were so low that LPS alone did not result in any TNF- $\alpha$  secretion<sup>[8]</sup>.

In summary, KCs are a key component in the development and/or progression of ALD. LPS is a potent activator of KCs, causing them to release cytokines such as TNF- $\alpha$  and TGF- $\beta$ 1, which have been indicated in the development of ALD. Acute administration of ethanol can lead to tolerance or sensitivity to LPS in isolated KCs, while chronic ethanol exposure usually induces a state of ethanol sensitivity marked by increased cytokine production. Cytokines produced by KCs stimulated by LPS can lead to proliferation and activation of HSCs resulting in ECM production. KCs might be involved in the formation of aldehyde protein adducts and these adducts might promote a pro-inflammatory response in KCs, especially in the presence of LPS.

### Stellate cells (HSCs)

HSCs undergo activation and proliferation when under the influence of acute and chronic liver injury events. Liver fibrosis and cirrhosis occur in the chronic stages of injury and represent activation of HSCs and secretion of matrix from these cells. Activation of HSCs also occurs in liver injury in acute stages where this damage is known to be able to resolve on its own<sup>[60]</sup>. Chronic liver injury events influenced by alcohol and LPS are of interest as they are associated with a constant hepatic insult that leads to life threatening complications with liver transplantation as the only viable option<sup>[60]</sup>. As HSCs are involved in the pathway of the wound healing of the liver, their association with alcohol and LPS is an important relationship to understand.

Metabolism of ethanol by the liver is an extremely oxidative event resulting in the development of acetaldehyde (AA). AA is further metabolized into acetate *via* the mitochondrial enzyme acetaldehyde dehydrogenase (ALDH)<sup>[61]</sup>. This is a slow reaction that allows for AA buildup over time when alcohol is consumed, and while ADH activity is not greatly influenced, CYP2E1 and other microsomal enzymes are greatly stimulated<sup>[61]</sup>. This buildup of AA has also been shown to form stable aldehyde adducts on proteins, which stimulate collagen synthesis, activate protein kinase C, and promote the release of chemokines MCP-1 and MIP-2<sup>[62-64]</sup>. Activation of HSCs increases the release of collagen and matrix proteins, which begin the fibrogenic response of wound healing<sup>[32,61]</sup>.

TGF $\beta$ 1 is the major profibrotic cytokine in the nor-

mal wound healing process. TGF $\beta$ 1 messenger expression in HSCs is elevated by ethanol and acetaldehyde, whereby collagen type I gene expression is up-regulated<sup>[32]</sup>. Indeed, mouse  $\alpha$ 2 (I) collagen promoter was shown to have greater activation in transient transfection experiments when TGF $\beta$ 1 and acetaldehyde were introduced in tandem, rather than alone, suggesting that TGF $\beta$ 1 could play a direct part in collagen I gene activation<sup>[65]</sup>.

### Two-hit model effects on stellate cells

In rodent models, using ethanol to induce substantial fibrotic liver injury is problematic regardless of the concentration or length of treatment. Therefore two-Hit models have been used in rodents with the hope to better emulate the fibrotic injury found in human disease states, using some secondary factor with ethanol. Degradation of ethanol increases oxidative stress within the hepatic system, generating free radicals, leading to further hepatic events such as endotoxemia. These events increase gut permeability allowing for more LPS release making LPS clearance more difficult<sup>[10,11,19]</sup>.

Karaa *et al*<sup>[66]</sup> looked for therapeutic agents that slow or possibly prevent ALD progression. S-adenosyl-L-methionine (SAME) has previously been shown to be a precursor in glutathione (GSH) synthesis in the transsulfuration pathway, which is an important hepatic antioxidant. The fact that chronic ethanol consumption greatly limits hepatic SAME storage, GSH synthesis, and increases gut permeability, allows LPS to act as a secondary agent in the two-hit model.

Karaa *et al*<sup>[66]</sup> examined how SAME acted as an anti-fibrotic agent by looking at liver fibrosis, HSC activation, and collagen deposition. This model used Lieber DiCarli liquid diet containing ethanol (or a calorie matched diet) concurrently with twice weekly LPS injections during an eight week period. Ethanol alone led to steatosis, some immune cell infiltration (mainly neutrophils), HSC activation, and increased hepatic collagen production. When LPS was introduced with ethanol, hepatic infiltration of neutrophils was increased as well as increased activation of HSCs and preferential pericellular collagen deposition. When SAME was introduced with LPS and chronic ethanol administration, the antioxidative properties of SAME were apparent. GSH stores depleted by ethanol were replenished and hepatic oxidative stress was reduced.

Quiroz *et al*<sup>[67]</sup> also looked at the effect of LPS on rat HSC (CFSC-2G) in relation to ethanol and AA. GSH, oxidized GSH (GSSG), IL-6, and collagen secretion were measured. The authors found that lipid peroxidation levels were increased in all experimental conditions versus controls (controls being HSCs with LPS, ethanol, or AA alone). MDA response to ethanol and acetaldehyde exposure did not show a significant change with LPS pretreatment. Experimental cells showed a 2.5 fold increase in GSSG content with LPS and ethanol, and a 5.5 fold increase with LPS and AA, with control values of GSH being much lower. Collagen content was also greatly enhanced with pretreatment of LPS, 120%

greater with ethanol and 209% greater with AA. TGF- $\beta$  secretion was similar to that of the controls, but IL-6 was greatly up-regulated<sup>[3]</sup>.

Pretreatment of LPS resulted in an increase of intracellular GSSG, leading to the formation of mixed disulfides with protein thiols, thus lowering the ability to fight oxidative stress induced hepatic injury<sup>[67]</sup>. The authors theorized that with the aforementioned change in GSH and GSSG levels, HSCs pretreated with LPS might also generate additional ROS. They also speculated that IL-6 not only promotes hepatocyte proliferation, but enhances collagen production by these activated HSCs. Therefore, "LPS pretreatment of HSC adds to the damage produced by ethanol and acetaldehyde by diminishing GSH content and increasing GSSG content, collagen, and IL-6 secretion"<sup>[67]</sup>.

### **Precision cut liver slices (PCLS)**

Precision cut liver slices (PCLS) may provide an alternative to other *in vitro* model systems using isolated liver cells to study the combined effects of ethanol and LPS. PCLS are representative of the whole liver and have recently been developed as an *in vitro* model of ethanol induced liver injury<sup>[68]</sup>. PCLS exhibit significant ethanol-induced damage in as little as 24 h. This model uses PCLS originating from Wistar rats, cultured in the presence or absence of 25 mmol/L ethanol in a roller system under 95% O<sub>2</sub><sup>[68]</sup>. Over a 96 h time period this model efficiently metabolizes ethanol, produces AA, develops a reduced redox state and fatty liver, and exhibits impaired albumin secretion. All of these phenomena are characteristics of early liver injury. Interestingly, in the presence of 4-methylpyrazole (4-MP), an inhibitor of ethanol metabolism, all of the ethanol-mediated effects are ameliorated or significantly reduced, indicating that the metabolites of ethanol are responsible. In addition, recent studies have shown that 25 mmol/L ethanol induces sustained production of IL-6, depletion of GSH, increased lipid peroxidation, and induction of fibrogenesis (increased expression of smooth muscle actin and deposition of collagen in sinusoidal areas). All these phenomena are inhibited by 4-MP, implicating ethanol metabolites. The production of IL-6, GSH depletion, and lipid peroxidation all precede the induction of fibrogenesis, suggesting that inflammation and production of reactive oxygen species are responsible.

PCLS have also been used to examine the effects of LPS on the liver<sup>[69,70]</sup>. LPS induced expression of TNF- $\alpha$ , IL-1 $\beta$ , IL-6 and IL-10 within 24 h of incubation. Consistent with other studies indicating TNF- $\alpha$  induces expression of other cytokines, TNF- $\alpha$  expression was maximal by five hours, whereas expression of the other cytokines was maximal by 16-24 h<sup>[69]</sup>. The authors attributed this to activation of KCs, but activation of SECs cannot be ruled out, as they also respond to LPS. Additionally, production of nitric oxide (NO) gradually increased after LPS treatment, starting at five hours after treatment, and continuing throughout the 24 h treatment period<sup>[70]</sup>. This increase was paralleled by an increase in inducible nitric oxide synthase (iNOS) expression in the hepatocytes. Inhibition of

TNF- $\alpha$  and IL-1 $\beta$  attenuated iNOS expression, indicating a paracrine effect by the cytokines induced by LPS treatment. Production of NO *in vivo* has been shown to have protective effects in inflammation and endotoxemia-induced hepatic injury<sup>[71]</sup>. Thus, these results might indicate a compensatory response by the PCLS to the inflammatory response induced by LPS treatment.

One previous study examined the combined effects of LPS and ethanol on PCLS cytotoxicity<sup>[72]</sup>. This study incubated PCLS in the absence or presence of 0.5%-8% ethanol and/or 0.1-100  $\mu$ g/mL LPS for up to 12 h. Ethanol at 1% or more exhibited a time- and dose-dependent hepatotoxicity by itself, whereas LPS had no appreciable effect. However, when combined, 2% ethanol and increasing concentrations of LPS exhibited additive effects on hepatotoxicity with 100  $\mu$ g/mL LPS inducing the most injury (70% viable) compared to 2% ethanol alone (90% viable) at 12 h. While these concentrations of both ethanol and LPS are extremely high, they do provide an upper limit for future studies to examine the combined effects of ethanol and LPS. In fact, preliminary data by this laboratory suggests that more physiological levels of ethanol (25 mmol/L) and LPS (10 ng) exhibit additive effects on inflammatory processes and induction of oxidative stress in PCLS.

## **CONCLUSION**

Studies into the pathogenesis of ALD have demonstrated that ethanol, LPS, and the metabolites of ethanol all may have a significant role in the development and/or progression of this disease. However, the data also strongly suggests that while each of these components are necessary, alone they are not sufficient to induce the pathogenesis of ALD. Indeed, it is becoming more apparent that combinations of one or more of these components must occur to induce ALD, which would suggest that at the very least a "two-hit" model is involved in the pathogenesis of ALD. Figure 1 shows a proposed hypothesis of the "two-hit" model of ALD.

Support for this concept can be found in some very simple observations. Acute (down-regulation) versus chronic (no effect) ethanol exposure decreases the response of KCs and SECs to LPS, which is thought to be a major co-factor in ALD. It has also been shown that on some cell types, multiple receptors (Scavenger Receptor A; SRA-1) are present and may bind LPS and degrade this ligand before it binds to TLR4. When the expression of these SRs is altered (ethanol inhibits degradation), LPS is now free to bind to CD14/TRL4 and initiate pro-inflammatory responses. It has also been shown that multiple ligands, ROS, aldehyde-modified proteins, and hyaluronan are involved in the development and/or progression of ALD. Therefore, depending upon which ligands were to bind to their appropriate receptors, then the response would be totally different than if only one of these ligands were to bind. Couple this with the fact that each cell type in the liver expresses different receptors, and it is easy to imagine that the interactions

**Figure 1** A proposed hypothesis of the two-hit model for the onset and/or progression of alcohol liver disease. A: The prolonged consumption of ethanol has been associated with an increase in gut permeability. Lipopolysaccharide (LPS) may leak out of the gut and into the blood stream, finding its way back to the liver. B: Meanwhile, the breakdown of alcohol and fats in the liver could modify cellular proteins with malondialdehyde and/or acetaldehyde and result in increased levels of these modified proteins. Receptors on endothelial cells (SECs) specific for LPS and aldehyde modified proteins might also be up-regulated. C: The various scavenger receptors bind LPS and/or aldehyde modified proteins circulating in the blood stream. D: Binding of these molecules causes an increased release of pro-inflammatory cytokines, which are dumped into the blood stream and into the liver through the Space of Disse. The release into the liver causes activation of kupffer cells, binding of LPS and modified proteins, and their release of more pro-inflammatory cytokines. E: The cytokine release from SECs and/or kupffer cells signals immune cells infiltrate into the liver and result in damage to the hepatocytes. F: Damage to the hepatocytes increases the amount of TGF- $\beta$  and other cytokines, causing the stellate cells and SECs to secrete pro-fibrogenic factors. These factors help to rebuild and remodel the liver parenchyma initiating the wound healing responses. Following repair of the liver, there is scarring and some irreparable damage, which can get better if the insults (LPS and modified proteins) are taken away. However, if alcohol consumption remains there becomes a point whenentence, preferably as two shorter sentences, to clarify this?

between the different cell types might change depending upon the receptors expressed. As discussed in this review, it is apparent that these interactions do occur and the development and/or progression of ALD is a complex interaction that may be investigated utilizing a “two hit” or “multiple hit” model.

### Abstract

Although the clinical manifestations of alcoholic liver disease are well-described, little is known about the molecular basis of liver injury. Recent studies have indicated that ethanol exposure induces global protein hyperacetylation. This reversible, post-translational modification on the  $\epsilon$ -amino groups of lysine residues has been shown to modulate multiple, diverse cellular processes ranging from transcriptional activation to microtubule stability. Thus, alcohol-induced protein hyperacetylation likely leads to major physiological consequences that contribute to alcohol-induced hepatotoxicity. Lysine acetylation is controlled by the activities of two opposing enzymes, histone acetyltransferases and histone deacetylases. Currently, efforts are aimed at determining which enzymes are responsible for the increased acetylation of specific substrates. However, the greater challenge will be to determine the physiological ramifications of protein hyperacetylation and how they might contribute to the progression of liver disease. In this review, we will first list and discuss the proteins known to be hyperacetylated in the presence of ethanol. We will then describe what is known about the mechanisms leading to increased protein acetylation and how hyperacetylation may perturb hepatic function.

### INTRODUCTION

The liver is the major site of ethanol metabolism and thus sustains the most injury from chronic alcohol consumption. In the hepatocyte cytosol, alcohol dehydrogenase (ADH) converts ethanol to acetaldehyde, a highly reactive intermediate. The acetaldehyde is further metabolized in mitochondria to acetate by acetaldehyde dehydrogenase (ALDH). Alcohol is also metabolized by the resident ER enzyme, cytochrome P450 2E1 (CYP 2E1). CYP 2E1-mediated ethanol metabolism not only leads to the formation of acetaldehyde, but also to the formation of oxygen and hydroxyethyl radicals that in turn promote the formation of other highly reactive intermediates<sup>[1]</sup>. All of these reactive metabolites can readily and covalently modify proteins, DNA and lipids<sup>[2-7]</sup>. More recently, it has become apparent that alcohol exposure induces protein covalent-modifications that are part of the natural repertoire. To date, these post-translational modifications include increased methylation, phosphorylation and acetylation<sup>[8-14]</sup>. In particular, numerous proteins have been identified that are hyperacetylated upon ethanol exposure, and this list is expanding rapidly. As for adduct formation, it is not clear how increased acetylation is related to the progression of alcohol-induced hepatotoxicity. In this review, we will first list and discuss hepatic proteins known to be hyperacetylated by ethanol exposure. We

will then describe our current understanding of the mechanisms and physiological consequences of protein hyperacetylation.

## ETHANOL-INDUCED LYSINE HYPERACETYLATION

For over 40 years it has been recognized that proteins can be acetylated and that the modification comes in two forms<sup>[15]</sup>. One is the irreversible, co-translational N-terminal acetylation of  $\alpha$ -amino groups of mainly serine and alanine, but also of threonine, methionine and glycine. The other form is the reversible, post-translational modification of  $\epsilon$ -amino groups on lysine residues located within a polypeptide<sup>[15,16]</sup>. The reversibility of lysine acetylation and its presence on an ever expanding list of nuclear and nonnuclear proteins have led some to postulate that it might rival phosphorylation in its ability to regulate cellular processes<sup>[16]</sup>. Thus, alcohol-induced protein hyperacetylation likely results in major physiological consequences that contribute to the progression of hepatotoxicity. In this section, we will first discuss individual hepatic proteins that are known to be hyperacetylated upon ethanol exposure (Table 1). We will then comment on recent work that implicates many more candidates for alcohol-induced lysine acetylation (Table 2).

### Histone H3

Histones were the first proteins known to be acetylated<sup>[15,16]</sup>, and histone H3 was the first protein known to be hyperacetylated after ethanol treatment. This effect has been observed in isolated hepatocytes and in rat liver after both acute and chronic ethanol exposure<sup>[8,17-21]</sup>. Although histone H3 encodes at least four acetylated lysines (lys 9, 14, 18 and 23), acetylation of lysine 9 is selectively increased after exposure to physiological ethanol concentrations<sup>[8]</sup>. Because histone H3 hyperacetylation was prevented by both 4-methylpyrazole (4-MP) and cyanamide, it was concluded that the modification requires alcohol metabolism and is likely mediated by the ethanol metabolite, acetate<sup>[8]</sup>. Interestingly, lysine 9 is also reversibly methylated, and in ethanol-treated hepatocytes, its methylation is decreased<sup>[9]</sup>. Furthermore, alcohol also induces hypermethylation of lysine 4 and phosphorylation of neighboring serine residues (ser 10 and ser 28)<sup>[10]</sup>. It will be important to consider all of these modifications as the functional consequences of histone H3 hyperacetylation are defined (see below).

### p53

p53 is a tumor suppressor that is mutated in over half of all human cancers. It is activated by DNA damage and functions to stop cell cycle progression. For over a decade it has been known that p53 is reversibly lysine acetylated, and that this modification promotes enhanced

<sup>1</sup>Our unpublished results.

DNA binding<sup>[15,16]</sup>. Very recently, p53 has been shown to be hyperacetylated upon chronic ethanol exposure in rat liver lysates<sup>[14]</sup>. Although multiple lysines are known to be acetylated, it is not yet known which residue(s) is hyperacetylated after ethanol consumption. Furthermore, it is not yet known whether hyperacetylation requires ethanol metabolism or whether it alters p53 DNA binding properties.

### Sterol response element binding protein-1c (SREBP-1c)

SREBPs are a family of transcription factors that regulate lipid and cholesterol synthesis. SREBP-1c is the major form expressed in liver and is known to activate numerous lipogenic enzymes. In rat hepatoma H4IIEC3 cells, ethanol treatment for 24 h led to a dose-dependent increase in SREBP-1c acetylation<sup>[12]</sup>. This result was confirmed in livers from ethanol-fed mice indicating it has physiologic importance. It is not yet known whether hyperacetylation requires ethanol metabolism nor is it known which lysine is hyperacetylated. However, more is known about the mechanism by which SREBP-1c is acetylated/deacetylated and how that relates to SREBP-1c function in gene regulation and lipogenesis (see below).

### Peroxisome proliferator-activated receptor $\gamma$ coactivator $\alpha$ (PGC-1 $\alpha$ )

The nuclear transcriptional coactivator, PGC-1 $\alpha$ , is a key regulator of hepatic glucose homeostasis and lipid metabolism<sup>[22]</sup>. It has also been implicated in regulating mitochondrial biogenesis and respiration<sup>[22]</sup>. PGC-1 $\alpha$  is known to be acetylated on many lysines,

and in general, acetylation is correlated with decreased transcriptional activity resulting in decreased expression of genes involved in mitochondrial fatty acid oxidation and gluconeogenesis. Thus, it is notable that PGC-1 $\alpha$  hyperacetylation is induced by ethanol consumption<sup>[12]</sup>. Currently, it is not known which lysine(s) is modified or whether PGC-1 $\alpha$  hyperacetylation requires ethanol metabolism. However, as for SREBP-1c, there is more known about some likely functional consequences of PGC-1 $\alpha$  hyperacetylation (see below).

### **Acetyl CoA synthetase 2 (AceCS2)**

A recent proteomic survey of mammalian cell proteins identified nearly 200 lysine-acetylated nuclear and nonnuclear proteins<sup>[23]</sup>. Remarkably, this survey further revealed that more than 20% of mitochondrial proteins were lysine-acetylated<sup>[23]</sup>. Thus, it is not surprising that the acetylation of AceCS2, an enzyme involved in lipid metabolism, is increased upon alcohol exposure, probably on lysine 635<sup>[13,24]</sup>. Acetylation of this residue correlates with decreased AceCS2 catalytic activity<sup>[25]</sup>, but whether its activity is decreased in ethanol-treated cells is not yet known. Interestingly, alcohol-induced acetylation of mitochondrial proteins, including AceCS2, was not observably altered in livers from CYP 2E1 knockout mice suggesting that the modification does not require CYP 2E1-mediated ethanol metabolism<sup>[13]</sup>. However, whether ethanol metabolism by ADH and ALDH is required for mitochondrial protein hyperacetylation is not yet known.

### **Tubulin**

Microtubules are one of the three major cytoskeletal systems of the cell. The polymer is made of repeating units of  $\alpha$ - and  $\beta$ -tubulin heterodimers that form protofilaments, which in turn assemble into hollow tubes consisting of 13 protofilaments arranged in parallel. Microtubules exist as both dynamic and stable polymers. The latter population is characterized by a longer half-life, resistance to microtubule poisons (e.g. cold and nocodazole) and by specific post-translational modifications on the  $\alpha$ -tubulin subunit<sup>[26]</sup>. These modifications include the removal of a carboxy-terminal tyrosine, polyglutamylation, polyglycylation and acetylation of lysine 40<sup>[26]</sup>. The functions of these modifications or whether they contribute to microtubule stability are still the subject of debate<sup>[27]</sup>. Recently, it was determined that chronic ethanol exposure enhanced  $\alpha$ -tubulin acetylation at lysine 40 in polarized WIF-B cells and livers from ethanol-fed rats<sup>[11]</sup>. Increased acetylation correlated to increased stability suggesting that tubulin acetylation might in fact enhance microtubule stability. In WIF-B cells, increased tubulin acetylation and stability displayed both ethanol time- and dose-dependence<sup>[11]</sup>. Furthermore, tubulin hyperacetylation and stability was prevented by 4-MP and potentiated by cyanamide indicating that ethanol metabolism was required for the effects<sup>[11]</sup>. Thus, unlike acetate-mediated histone H3 hyperacetylation, tubulin hyperacetylation and increased stability are likely mediated by acetaldehyde. This

disparity is likely to be due to the different mechanisms leading to enhanced acetylation of either substrate (see below).

### **The expanding list**

With the growing number of known acetylated proteins and the large number of modifying enzymes, it is likely that numerous hepatic proteins are hyperacetylated in ethanol-treated cells. We initiated a proteomics approach to identify other hyperacetylated proteins from cytosolic and total membrane fractions prepared from livers from control and ethanol-fed rats (manuscript in preparation). So far, about 40 nonnuclear proteins have been identified (but not yet confirmed), half of which were from the cytosolic fraction and half from the total membranes. Remarkably, all the hyperacetylated proteins in the latter fraction were from mitochondria and most were metabolic enzymes (Table 2). Seven of these mitochondrial proteins were also identified in the proteomic survey for acetylated lysines described above<sup>[23]</sup> partially confirming our result. Also consistent with this finding is a recent study where purified mitochondria from alcohol-fed rats were immunoblotted with anti-acetylated lysine antibodies<sup>[13]</sup>. Numerous immunoreactive species were observed (but not yet identified) suggesting massive mitochondrial protein hyperacetylation after ethanol exposure. Similarly, cytosolic fractions were highly hyperacetylated after ethanol exposure and the proteins identified varied widely in function, ranging from metabolic enzymes to proteins regulating oxidative stress to molecular chaperones. Efforts are currently underway to confirm the acetylation state of these proteins and to determine the functional consequences of their ethanol-induced hyperacetylation.

## **MECHANISMS OF ETHANOL-INDUCED LYSINE HYPERACETYLATION**

Protein acetylation results from the coordinated activities of acetyltransferases and deacetylases<sup>[15,16]</sup>. Histones were the first proteins known to be acetylated, and accordingly the modifying enzymes were initially named histone acetyltransferases (HATs) and histone deacetylases (HDACs). Although the list of acetylated proteins has since grown to include numerous nonhistone substrates, their names have remained. In this section, we will briefly describe the two classes of enzymes and whether they are expressed in the liver. We will also discuss what is known about how these HATs and HDACs may be responsible for the alcohol-induced increase in lysine acetylation.

### **HDACs**

To date, there are at least 18 known deacetylases that are categorized into four general classes based on sequence homology and cofactor/coenzyme dependence<sup>[28]</sup> (Table 3). Classes I, II and IV are closely related zinc-dependent enzymes whereas the class III HDACs are

Table 3 Deacetylases expressed in the liver

Class	Enzyme	In liver? (methods)	Location	Substrates	References

more distantly related, NAD<sup>+</sup>-dependent sirtuins<sup>[28,29]</sup>. Phylogenetic analysis of bacterial HDAC relatives indicates that the evolution of the class I, II and IV family members preceded the evolution of histones<sup>[29]</sup> suggesting that these HDACs have nonhistone substrates. This conclusion is consistent with the wide-range of mammalian HDAC substrates that have been identified (Table 3).

Mechanistically, classes I, II and IV all share a conserved catalytic core consisting of open  $\alpha/\beta$  folds and a tubular active site pocket in which a zinc ion sits. The poised zinc mediates the nucleophilic attack of water on the acetylated lysine substrate resulting in the formation of a tetrahedral oxyanion intermediate. The nitrogen on the intermediate is then primed to accept a proton resulting in a charge relay system between histidine, aspartate, and tyrosine that results in the formation of acetate and the deacetylated lysine<sup>[29-31]</sup>. This catalytic mechanism was deduced with the help of HDAC inhibitors that displace the zinc ion thereby disrupting the charge relay system. Many of these inhibitors are proving to be promising anti-cancer therapies. The most potent inhibitor, trichostatin A (TSA), is a near perfect fit for the HDAC active site and is often used in studies to confirm the affect of protein acetylation on function (see below)<sup>[32]</sup>.

The class I family members include HDACs 1, 2, 3 and 8 that are closely related to the yeast deacetylase, reduced potassium dependency 3 (RPD3)<sup>[32]</sup> (Table 3). They are all ubiquitously expressed (including in liver, Table 3), are found almost exclusively in the nucleus, are roughly the same length (370-480 aa) and encode one

deacetylase domain<sup>[29,30,32,33]</sup>. These four HDACs have all been shown to deacetylate histones as well as a variety of transcription factors and other nuclear proteins including STATs and Smads<sup>[29,30,32,33]</sup> (Table 3). Recent reports suggest that class I enzymes may function together in multiprotein complexes that bind and deacetylate transcription factors<sup>[29,30]</sup>. Future work is needed to understand how the deacetylase activities are specifically coordinated leading to changes in gene expression.

Class II enzymes are much more variable in size (700-1200 aa) and exhibit more tissue-specific expression patterns with only HDACs 4, 5, 6 and 10 identified in the liver (Table 3). Like for class I enzymes, known class II substrates are mainly nuclear transcription factors<sup>[28-30,32-34]</sup>. However, the class II deacetylases encode both nuclear import and export signals allowing them to shuttle between the nucleus and cytoplasm where they bind to location-specific substrates<sup>[30]</sup> (Figure 1, bottom panel). Although interactions between these enzymes and their substrates are thought to regulate their activity and location<sup>[29,30]</sup>, little is known how this process is regulated. The class II HDACs catalyze lysine deacetylation in much the same way as the class I enzymes but their active sites encode a glutamate instead of a glycine<sup>[29]</sup>. This larger side chain decreases active site size restricting substrate access thereby increasing enzyme specificity. Interestingly, HDAC6 and HDAC10 encode two deacetylase domains in tandem<sup>[28,34]</sup>. Whether the two sites deacetylate different substrates or whether both are needed for function is not yet clear<sup>[35-37]</sup>. Of particular interest to this review is HDAC6, the only exclusively cytosolic HDAC found in liver<sup>[38,39]</sup>. One

**Figure 1** Alcohol-induced defects in protein trafficking can be explained by increased microtubule acetylation and stability. Cargo internalized from the basolateral plasma membrane is delivered to the early endosome (EE) and sorted into at least four different pathways. They are recycled directly back to the plasma membrane (e.g. ASGP-R), delivered to the recycling endosome (RE) before recycling back to the plasma membrane (e.g. Tf-R), delivered to lysosomes (lys) (e.g. LY) or to the apical plasma membrane via the sub-apical compartment (SAC) (e.g. APN, pIgA-R and 5'NT). Albumin secretion is also indicated. In ethanol (EtOH) or TSA treated cells, albumin secretion and the internalization of APN, pIgA-R, Tf-R and ASGP-R is impaired whereas the fluid-phase delivery of LY to lysosomes or the raft/caveolae-mediated internalization of 5'NT and CTxB are not changed. In the lower hepatocyte, the various deacetylases and acetyltransferases that may play a role in the acetylation of nonnuclear proteins are indicated.

of its known substrates is  $\alpha$ -tubulin, one of the best characterized, nonnuclear, hyperacetylated proteins in ethanol exposed cells<sup>[11,39-42]</sup>.

Currently there is only one known class IV deacetylase, the recently identified HDAC11. As a result of its high sequence similarity to class I enzymes, HDAC11 is often considered a class I HDAC<sup>[30]</sup>. At present, little is known about HDAC11's substrates, expression patterns or subcellular distributions. HDAC11 has been shown to act in a complex with other HDACs, most notably HDAC6, suggesting that it may not be an independent lysine deacetylase<sup>[29]</sup>. Clearly, more work is needed on this class IV enzyme before we can understand its role in protein acetylation.

Unlike the three classes of zinc-dependent HDACs, class III deacetylases are referred to collectively as sirtuins. Sirtuin activity requires  $\text{NAD}^+$ , and thus each family member encodes a highly conserved, elongated catalytic core containing a Rossmann fold characteristic of  $\text{NAD}^+$ /NADH-binding proteins. Both the  $\text{NAD}^+$  and the acetylated lysine substrate bind to the "C pocket" which is located in the cleft between the Rossmann fold and a smaller, more variable domain containing a zinc ion. This binding results in a nucleophilic substitution reaction where the  $\text{NAD}^+$  and acetylated lysine substrate are converted to nicotinamide, a deacetylated lysine and a novel metabolite, 2'-O-acetyl-adenosine diphosphate ribose<sup>[31]</sup>. In total, there are seven known sirtuins that all

exhibit interesting expression patterns. SirT1 is a widely expressed, well characterized nuclear sirtuin whose long list of substrates includes transcription factors, histones, p53, and PGC-1 $\alpha$ <sup>[42-44]</sup> (Table 3). SirT6 and 7 are two other nuclear sirtuins, and all three have been found in the liver by RT-PCR<sup>[44,45]</sup>. SirT2 is the lone cytoplasmic sirtuin, and like its counterpart, HDAC6, its main substrate is  $\alpha$ -tubulin<sup>[46]</sup>. Although SirT2 was detected in liver homogenates by RT-PCR, the protein has not been detected at any level in liver lysates or WIF-B cells<sup>[39]</sup>. SirT3, 4 and 5 are all mitochondrial-specific sirtuins that are ubiquitously expressed (Figure 1, bottom panel). So far, only SirT3 and 5 have confirmed deacetylase activity<sup>[47,48]</sup>. Interestingly, recent reports suggest that SirT4 (and nuclear SirT6) are instead ADP ribosyltransferases that preferentially ADP-ribosylate acetylated substrates<sup>[49,50]</sup>. Further studies are needed to examine the effects of ethanol on this activity.

### HATs

To date, there are 17 families of HATs that have been grouped according to sequence homology. In general, the N and C terminal domains of the acetyltransferases are structurally and functionally diverse while the catalytic domain is highly conserved. All HAT active sites contain a structurally conserved loop- $\beta$  strand core domain that binds acetyl Co-A<sup>[51]</sup>. Also within this core domain is a glutamate that serves as a lysine docking site. The glutamate removes a proton from the docked lysine allowing acetyl transfer from acetyl CoA<sup>[51]</sup>. From the 17 families, three major groups have emerged: Gcn5/PCAF, p300/CBP and MYST (Table 4). Little is known about the mammalian members of the Gcn5/PCAF family, but in general these HATs have been detected in liver, reside in the nucleus and have mainly nuclear substrates. Only PCAF has been found to distribute to both the nucleus and cytoplasm<sup>[52-53]</sup> allowing for more varied substrates including histones, p53, and the actin binding protein, cortactin<sup>[56-58]</sup>. The p300/CBP family consists of p300 and CBP that are nearly structurally identical and are referred to interchangeably<sup>[57,58]</sup>. They also reside in the nucleus and are expressed in the liver. The least characterized MYST family consists of the mammalian enzymes, TIP60, HBO, MOZ, and MORF<sup>[57,58]</sup>. Although each of these HATs have been shown to acetylate histones H3 and H4, much still needs to be learned about other possible substrates and whether they function alone or in large multi-HAT complexes.

### General roles for HATs and HDACs in ethanol-induced protein acetylation

Changes in both HAT and HDAC expression have been correlated with global changes in protein acetylation. Thus, a simple explanation for ethanol-induced protein acetylation may be altered enzyme levels. The prediction is that either a decrease in HDAC expression or an increase in HAT levels will lead to increased protein acetylation. In addition, changes in enzyme activity or subcellular distribution may lead to hyperacetylation. For example, either a decrease in HDAC activity or a

loss of nuclear import could enhance nuclear protein acetylation. Additionally, the sirtuin deacetylases are NAD<sup>+</sup>-dependent enzymes. Because ethanol metabolism is NAD<sup>+</sup>-depleting, sirtuin activity may be impaired thereby leading to increased protein acetylation. Below, we summarize what is known about how alterations in HAT or HDAC activity/function contribute to ethanol-induced protein hyperacetylation.

### **Histone H3 hyperacetylation and p300**

At present, the mechanisms responsible for ethanol-induced hyperacetylation of histone H3 are not known, but recent studies have provided some clues. In livers of ethanol-fed rats, p300 protein levels were increased about 3 fold, which correlated with increases in overall nuclear HAT activity<sup>[17,18,21]</sup>. Acetate treatment also led to enhanced nuclear HAT activity and histone H3 hyperacetylation indicating ethanol metabolism is required for this modification<sup>[17]</sup>. Interestingly, the protein expression of the closely related p300 homologue, CBP, was not altered<sup>[18]</sup> indicating that ethanol-induced histone H3 acetylation may be specific to p300. These studies further suggest that these two HATs may not be completely interchangeable. To date, it is not known which (if any) HDAC is involved in histone H3 hyperacetylation in ethanol-treated cells. However, total nuclear HDAC activity was significantly decreased in ethanol-treated WIF-B cells, and that decreased activity correlated with increased histone H3 acetylation<sup>[39]</sup>. In contrast, total nuclear HDAC activity was not altered in ethanol-treated isolated hepatocytes where enhanced histone H3 acetylation was observed<sup>[17,21]</sup>. The reasons for these disparate results are not known but may be explained by differences in the cell systems used, acute vs. chronic alcohol-treatment, or differences in the deacetylase assay used. Further research is needed to elucidate this further.

### **SREBP-1c hyperacetylation and SirT1 and p300**

As for histone H3, the mechanisms responsible for ethanol-induced hyperacetylation of SREBP-1c are not known, but work has provided some hints. From studies performed in H4IIEC3 cells, overexpressing SirT1 and p300 were found to deacetylate or acetylate SREBP-1c,

respectively, confirming that SREBP-1c is a substrate for both enzymes<sup>[12]</sup>. Increasing ethanol concentrations enhanced p300-mediated SREBP acetylation in these cells while a concomitant decrease in SirT1 protein levels was observed<sup>[12,14]</sup>. Thus, SREBP-1c hyperacetylation was the result of changes in both types of modifying enzymes. As for SREBP-1c, PGC-1 $\alpha$  hyperacetylation was also correlated with decreased SirT1 protein expression<sup>[12,14]</sup>. At present, it is not known if changes in SirT1 or p300 activity levels correlate with changes in protein levels or whether SREBP-1c and PGC-1 $\alpha$  hyperacetylation requires ethanol metabolism. Future work is clearly needed to understand this fully.

### **Tubulin hyperacetylation and HDAC6**

Since the specific microtubule acetyltransferase has not yet been identified, studies thus far have focused on the known hepatic tubulin deacetylase, HDAC6 (Table 3). Although ethanol treatment did not alter HDAC6 subcellular distributions in polarized WIF-B cells, it led to a 25% decrease in HDAC6 protein levels<sup>[39]</sup>. HDAC6 binding to endogenous microtubules was also found to be significantly impaired by about 70% in ethanol-treated cells and this impairment partially required ethanol metabolism. Measuring HDAC6 tubulin deacetylase activity by two methods further revealed that ethanol did not impair HDAC6's ability to bind or deacetylate exogenous tubulin. This suggests that tubulin from ethanol-treated cells was modified, thereby preventing HDAC6 binding<sup>[39]</sup>.

Although decreased HDAC6 protein levels are a simple explanation for increased tubulin acetylation, it is likely that the impaired microtubule binding has more impact. HDAC6 is abundant in the liver<sup>[56,59]</sup> such that a 25% decrease in levels may not likely have profound effects on tubulin acetylation. Rather, the 70% impairment in HDAC6 binding to microtubules may have a more dramatic effect; much less of the available enzyme can bind its substrate leading to decreased deacetylation. At present, the nature of the alcohol-induced tubulin modification is not known, but there are some interesting possibilities. Both impaired HDAC6 binding to microtubules and alcohol-induced tubulin hyperacetylation require ethanol metabolism,

and from studies using 4-MP, both events are likely mediated by acetaldehyde<sup>[11,39]</sup>. Because this highly reactive ethanol metabolite can readily and covalently modify a highly reactive lysine in  $\alpha$ -tubulin *in vitro*<sup>[60]</sup>, one provocative possibility is that tubulin acetaldehyde adducts impede HDAC6 binding. Because decreased HDAC6 binding to microtubules was only partially prevented by 4-MP, it is also possible that other reactive ethanol metabolites form detrimental tubulin adducts. Future studies are needed to elucidate this and other details.

#### **Mitochondrial protein hyperacetylation and sirtuins**

The ever-expanding list of ethanol-induced hyperacetylated mitochondrial proteins is likely to generate much interest in the mitochondrial-specific sirtuins, but so far, only protein levels of SirT3 and 5 have been examined. Although SirT3 is considered the predominant mitochondrial deacetylase, its expression levels were not changed in livers from ethanol-fed rats<sup>[13]</sup>. In contrast, SirT5 protein levels were significantly decreased<sup>[61]</sup>. To date, nothing is known about the subcellular distributions, activities or substrate specificities of these deacetylases in ethanol-treated cells. Furthermore, virtually nothing is known about the HATs required for mitochondrial protein acetylation. Clearly, this is a fertile area of investigation for many researchers.

#### **Cytosolic protein hyperacetylation and nonnuclear HATs and HDACs**

Recent proteomics studies have revealed that many cytosolic proteins are hyperacetylated upon ethanol exposure (Table 2). At present, very little is known about the HATs or HDACs responsible for these modifications. However, attention is being turned to those modifying enzymes that are exclusively cytosolic (HDAC6) or those that shuttle between the nucleus and cytoplasm (PCAF, TIP60 and HDACs 5, 7, 9 and 10) (Figure 1, bottom panel). Not only will future studies likely provide a better understanding of alcohol-induced protein acetylation and the progression of hepatotoxicity, they will also undoubtedly identify new substrates for these enzymes. As for studies on the mitochondrial modifying enzymes, this area of research promises to be fruitful.

### **CONSEQUENCES OF ETHANOL-INDUCED LYSINE HYPERACETYLATION**

Although there is an ever-expanding list of proteins that are known to be hyperacetylated upon ethanol exposure, little is known about the functional consequences of this modification. In general, the added acetyl group likely neutralizes the positive charge on lysine while increasing the overall size and hydrophobicity of the side chain. Such changes may result in protein conformational changes that alter function, albeit to a much lesser extent than the addition of a large, highly

charged phosphoryl group. Also, lysine acetylation sites have been identified that overlap with nuclear localization signals<sup>[23]</sup> such that the modification may induce altered protein subcellular distributions. Not only can lysine residues be acetylated, they can also be methylated, sumoylated and ubiquitinated such that ethanol-induced hyperacetylation may displace other modifications further altering protein function. In fact, p300 acetylation has been shown to prevent its sumoylation thereby repressing its activity<sup>[62]</sup>. Clearly, mechanistic studies are required to not only understand the functional consequences of acetylation in the normal liver, but also how alcohol-induced hyperacetylation alters hepatic function in the alcoholic liver. In this section, we will describe some recent advances in our understanding of how ethanol-induced acetylation impairs hepatic function. Although it is too early for specific mechanistic details, the results provide an exciting framework for continued investigation.

#### **Histone H3 hyperacetylation alters transcriptional regulation**

Alcohol consumption has long been known to lead to changes in gene expression. Many genes are up-regulated including those encoding for enzymes involved in alcohol metabolism, lipogenesis and the regulation of oxidative stress<sup>[63,64]</sup>. Many genes are also down-regulated, but fewer seem to functionally group together<sup>[63,64]</sup>. The specific mechanisms responsible for changes in alcohol-induced gene expression are not well defined. Recent studies have been aimed at understanding the role of histone modifications in transcriptional regulation. The amino-termini of histones are characterized by at least six different modifications (acetylation, ubiquitinylation, methylation, phosphorylation, sumoylation and ADP-ribosylation) occurring on lysines, arginines, serines, threonines and histidines<sup>[65]</sup>. In general, these reversible modifications are thought to change the net negative charge of the amino-terminal domain leading to altered DNA binding and changes in gene expression<sup>[66]</sup>. Thus, the simple hypothesis is that alcohol-induced lysine 9 hyperacetylation will decrease the amino-terminal net negative charge thereby loosening histone H3 associations with DNA. The relaxed DNA becomes more accessible to the transcriptional machinery, leading to enhanced transcription.

This prediction was tested in ethanol-treated hepatocytes using a series of chromatin immunoprecipitations. In general, histone H3 with acetylated lysine 9 residues was found to be more highly associated with the promoters of genes known to be up-regulated by ethanol exposure (ADH and glutathione S-transferase)<sup>[9]</sup>, consistent with this hypothesis. Also consistent with this hypothesis is that histone H3 with methylated lysine 9 residues (this modification is associated with gene silencing) was more highly associated with promoters of genes known to be down-regulated by ethanol (L-serine dehydratase and CYP 2C11)<sup>[9]</sup>. Somewhat surprisingly, histone H3 containing methylated lysine 4 residues was found to be highly associated with ADH and glutathione

S-transferase promoters, not with promoters of down-regulated genes<sup>[9]</sup>. These associations suggest that lysine 4 hyperacetylation and lysine 4 methylation enhance gene expression while lysine 9 methylation represses transcription.

At present, the site-specific differences in promoter associations cannot be fully explained. One implication is that promoter regions are characterized by specific microenvironments that are differentially accessible to histone modifying enzymes and by extension, are differentially affected by ethanol exposure. In order to fully understand these site-specific differences, it will be necessary to fully account for all six possible histone H3 modifications and the modifying enzymes in control and ethanol-treated cells. Also, to determine how each modification or combination of modifications regulates gene expression, assays that directly monitor transcription activation (rather than promoter associations) will need to be developed. Furthermore, recent reports demonstrate that histone hyperacetylation may also lead to nucleosome instability allowing transcription at cryptic promoters resulting in aberrant gene product expression<sup>[67,68]</sup>. This emerging hypothesis must be considered as the transcriptional consequences of ethanol-induced histone acetylation as elucidated.

#### **Ethanol-induced acetylation of SREBP-1 and PGC-1 $\alpha$ leads to altered lipid metabolism**

One of the first clinical manifestations of alcohol consumption is the appearance of a fatty liver (steatosis). This is correlated with the up-regulation of many lipogenic enzymes that leads to the alcohol-induced synthesis of hepatic triglycerides and phospholipids<sup>[69]</sup>. An active area of steatosis research is aimed at identifying members of the transcriptional machinery that regulate gene expression of the enzymes involved in lipid metabolism. It has long been appreciated that SREBP-1 promotes the expression of many genes involved in lipogenesis that are up-regulated after alcohol consumption<sup>[69]</sup>. However, the exact mechanism by which SREBP-1 leads to enhanced expression is not well-defined. One emerging hypothesis is that SREBP-1 acetylation plays an important role. SREBP-1 is known to be acetylated in its DNA binding domain, and that when acetylated, DNA binding is enhanced. SREBP-1 is also known to be ubiquitinated on the same lysine residues leading to its proteosomal degradation<sup>[70]</sup>. Thus, in alcohol-treated hepatocytes the prediction is that hyperacetylation prevents SREBP-1 proteosomal degradation by displacing the ubiquitin while enhancing its DNA binding which leads to increased transcription of lipogenic enzymes.

A similar scenario is emerging for the transcriptional activator, PGC-1 $\alpha$ , but it is the deacetylated protein that up-regulates expression of genes regulating fatty acid  $\beta$ -oxidation<sup>[22]</sup>. Therefore in ethanol-treated hepatocytes, the prediction is that the hyperacetylated PGC-1 $\alpha$  will be inactive. Based on this prediction and the one for SREBP-1, a straightforward scenario emerges. Alcohol-induced SREBP-1 hyperacetylation enhances lipid

synthesis by activating lipogenic enzyme transcription while PGC-1 $\alpha$  hyperacetylation impairs lipid catabolism by inhibiting transcription of enzymes involved in fatty acid oxidation. The altered transcriptional activation in either case leads to hepatic fatty acid accumulation that likely contributes to development of steatosis. Because many other components of the transcriptional machinery are known to be acetylated (Tables 3 and 4), it is likely that alcohol-induced hyperacetylation will have far-reaching effects on hepatic gene expression.

#### **Ethanol-induced microtubule acetylation leads to impaired protein trafficking**

Because microtubules are central to multiple cellular processes, changes in their dynamics will likely alter hepatic function. An active area of research has been aimed at understanding the relationship between protein trafficking and alterations in microtubule dynamics. Not only is protein trafficking microtubule-dependent, the trafficking of many hepatic proteins is also impaired by ethanol<sup>[71-74]</sup>. Two transport pathways appear to be affected: transport of newly-synthesized secretory or membrane proteins from the Golgi to the basolateral membrane and receptor-mediated endocytosis from the sinusoidal surface (Figure 1). One attractive hypothesis is that the alcohol-induced defects in secretion and endocytosis can be explained by increased microtubule acetylation and stability.

To test this hypothesis, recent studies have examined the trafficking of selected proteins in WIF-B cells treated with ethanol or TSA, a potent inhibitor of HDAC6, the major tubulin deacetylase in liver and WIF-B cells<sup>[39]</sup> (Table 3). Importantly, TSA induces increased microtubule acetylation and stability to the same extent as ethanol<sup>[75]</sup>. As shown previously *in situ*, the endocytic trafficking of asialoglycoprotein-receptor (ASGP-R) was impaired in ethanol-treated WIF-B cells<sup>[75]</sup> (Figure 1). This impairment required ethanol metabolism and was likely mediated by acetaldehyde<sup>[75]</sup>. TSA also impaired ASGP-R endocytic trafficking, but to a lesser extent. Similarly, both ethanol and TSA impaired transcytosis of a single spanning apical resident, aminopeptidase (APN). For both ASGP-R and APN, and for both treatments, the block in trafficking was internalization from the basolateral membrane. Interestingly, no changes in transcytosis of the GPI-anchored protein, 5'nucleotidase (5'NT) (Figure 1), were observed suggesting that increased microtubule acetylation and stability differentially regulate internalization. It was further determined that albumin secretion was impaired in both ethanol- and TSA-treated cells<sup>[75]</sup> indicating that increased microtubule acetylation and stability also disrupt this transport step. Thus, increased microtubule acetylation and stability explain, in part, the alcohol-induced defects in membrane trafficking.

There is evidence that suggests that different microtubule populations (and/or their modifications) support specific protein transport steps<sup>[76]</sup>. Of particular interest are studies performed in WIF-B cells that used a novel microtubule depolymerizing drug, 201-F<sup>[77]</sup>. This

drug specifically depolymerizes dynamic microtubules leaving only stable, acetylated polymers behind. In 201-F-treated cells, both secretion and transcytosis were impaired<sup>[77]</sup>. Although the specific impaired transcytotic step was not identified, increased basolateral labeling of the apical proteins was observed. These results are remarkably consistent with the findings in ethanol or TSA treated cells where increased populations of stable microtubules were observed (presumably at the expense of dynamic microtubules) that correlated with impaired albumin secretion and basolateral internalization.

An unanswered question from these studies is why 5'NT distributions were not altered in treated cells. Furthermore, the internalization of cholera toxin B subunit (CTxB) (a known raft marker) was also not impaired by ethanol exposure (Figure 1). One possibility is that internalization mechanisms were differentially impaired by ethanol metabolism. There are at least three major internalization routes in mammalian cells: clathrin-mediated, caveolae/raft-mediated and non-clathrin/non-raft mediated<sup>[78]</sup> that are characterized by specific molecular players, cargoes and regulators. In general, the receptors that displayed impaired endocytosis in ethanol-treated hepatocytes *in situ* (ASGP-R, EGF-R, and to a lesser extent, insulin *via* its receptor)<sup>[71-73,79,80]</sup> and in WIF-B cells (ASGP-R, transferrin receptor (Tf-R) and polymeric IgA receptor (pIgA-R)<sup>[75]</sup> (Figure 1) are internalized *via* clathrin-mediated pathways. Interestingly, the non-clathrin/non-raft-mediated fluid phase uptake of Lucifer Yellow was not changed in livers of ethanol-fed rats or WIF-B cells suggesting this pathway is not affected by ethanol metabolism<sup>[81]</sup> (Figure 1). Thus, we propose that the molecular machinery that drives clathrin-mediated endocytosis is more prone to adduction (by acetaldehyde or other reactive metabolites) or covalent modification such that it is selectively impaired by alcohol treatment.

Another unanswered question from these studies is how the acetylation of lysine 40 specifically contributes to enhanced microtubule stability and trafficking defects. Although lysine 40 is thought to reside in the lumen of the microtubule<sup>[82]</sup>, it is possible that its acetylation may lead to altered tubulin conformation such that interactions with microtubule associated proteins and motors are altered. This hypothesis is supported by the findings that kinesin, dynein and dynactin preferentially bound acetylated microtubules in neuronal cells<sup>[83-85]</sup>. This is further supported by the finding that vesicles recovered from livers of ethanol-fed rats have decreased motility *in vitro*<sup>[86]</sup>. Clearly, further studies are needed to fully understand these results.

### **Mitochondrial dysfunction and protein hyperacetylation**

Despite the large number of mitochondrial proteins known to be acetylated, little is known about the functional consequences of the modification on mitochondrial function. So far, only glutamate dehydrogenase and AceCS2 activities have been related to their acetylation states, and in both cases, increased acetylation correlated with decreased activity<sup>[25]</sup>. Thus, the prediction is that in ethanol-treated hepatocytes,

the hyperacetylated enzymes would be inactivated leading to altered lipid metabolism that contributes to the development of steatosis as described above. Also, as described above, acetylation may function as an on/off switch for these and other mitochondrial metabolic enzymes such that alcohol-induced changes in this modification may have a large impact on hepatic metabolism.

However, recent results from knockout mice are not consistent with this conclusion<sup>[48]</sup>. Striking levels of mitochondrial protein acetylation were observed in livers from SirT3 knockout mice whereas mitochondrial acetylation in SirT4 or SirT5 knockout mice was not changed. This suggests that SirT3 is the predominant mitochondrial deacetylase. Despite the high levels of mitochondrial protein acetylation, there was no discernible phenotype in SirT3 knockout mice. Specifically in liver, there was no change in morphology, no change in mitochondrial numbers and metabolism was not altered suggesting hyperacetylation does not affect mitochondrial function<sup>[48]</sup>. However, it is possible that hyperacetylation is only detrimental under stressed conditions such that in the alcoholic liver, it leads to mitochondrial dysfunction.

This conclusion is consistent with a recent hypothesis that mitochondrial protein acetylation functions as a sensor for the overall cellular energy status<sup>[23]</sup>. Kim *et al*<sup>[23]</sup> suggest that acetyl-CoA and NAD<sup>+</sup> levels are the key indicators of energy status. Coincidentally, these two molecules serve as cofactors for HATs (acetyl-CoA) or sirtuins (NAD<sup>+</sup>). Furthermore, over 44% of mitochondrial dehydrogenases that require NAD<sup>+</sup> for activity are known to be acetylated. Thus, one possibility is that lysine acetylation serves as a feedback mechanism for the regulation of dehydrogenases. For example, under NAD<sup>+</sup>-depleting conditions, sirtuins are less active resulting in higher protein acetylation and dehydrogenase activities. In contrast, when acetyl-CoA levels are limiting, HATs are inactivated leading to decreased protein acetylation and increased dehydrogenase activities. Thus, in the alcoholic liver where NAD<sup>+</sup> is depleting, increased acetylation is predicted to correlate with impaired dehydrogenase activity and by extension, impaired mitochondrial function. Although it has been suggested that NAD<sup>+</sup> levels recover after prolonged ethanol exposure, the finding that hyperacetylation remains long after chronic ethanol withdrawal<sup>[13]</sup> suggests that this mechanism may have physiologic relevance. Clearly, this exciting hypothesis needs to be rigorously tested.

### **CONCLUSION**

Chronic alcohol consumption leads to the hyperacetylation of numerous hepatic nuclear and nonnuclear proteins. Although many interesting and provocative mechanisms have been proposed that describe how hyperacetylation contributes to alcohol-induced hepatotoxicity, future work is clearly needed to test these hypotheses. New therapeutic strategies for

treating patients with chronic liver disease may be aimed at reducing protein acetylation. Currently, specific SirT1 activators (e.g. resveratrol and SRT-501) are known to be well-tolerated in humans and are in clinical trials for treatment of various metabolic diseases including type 2 diabetes<sup>[87]</sup>. Furthermore, resveratrol has been shown to attenuate fatty liver in alcohol-exposed mice<sup>[88]</sup>. An exciting possibility is that this drug and other specific deacetylase activators or acetyltransferase inhibitors will be useful in treating alcoholic liver disease.

a maximum by 8 h. The expression of cathepsin B was significantly decreased in the protected group ( $P < 0.01$ ).

**CONCLUSION:** Cathepsin B plays an essential role in the pathogenesis of fulminant hepatic failure, and the cathepsin B inhibitor CA-074me can attenuate apoptosis and liver injury.

### Abstract

**AIM:** To investigate the pathogenic role of cathepsin B and the protective effect of a cathepsin B inhibitor (CA-074Me) in fulminant hepatic failure in mice.

**METHODS:** LPS/D-Gal N was injected into mice of the model group to induce fulminant hepatic failure; the protected group was administered CA-074me for 30 min before LPS/D-Gal N treatment; the normal group was given isochoric physiologic saline. Liver tissue histopathology was determined with HE at 2, 4, 6 and 8 h after Lps/D-Gal injection. Hepatocyte apoptosis was examined by TUNEL method. The expression of cathepsin B in liver tissues was investigated by immunohistochemistry, Western blot and RT-PCR.

**RESULTS:** Compared with the normal group, massive typical hepatocyte apoptosis occurred in the model group; the number of apoptotic cells reached a maximum 6 h after injection. The apoptosis index (AI) in the protected group was clearly reduced ( $30.4 \pm 2.8$  vs  $18.1 \pm 2.0$ ,  $P < 0.01$ ). Cathepsin B activity was markedly increased in drug-treated mice compared with the normal group ( $P < 0.01$ ). Incubation with LPS/D-Gal N at selected time points resulted in a time-dependent increase in cathepsin B activity, and reached

### INTRODUCTION

Fulminant hepatic failure is a rare, but severe, complication of acute hepatitis; it is associated with very high mortality. It has been reported that fulminant hepatic failure is an inflammatory process that causes the death of liver cells by necrosis or by triggering apoptosis<sup>[1-3]</sup>. Cathepsins are a family of proteolytic enzymes, many of which, including cathepsin B, are cysteine proteinases. Recent evidence suggests that cathepsin B contributes to cell apoptosis<sup>[4,5]</sup>. It is not known if cathepsin B-mediated hepatocyte apoptosis is involved in the pathogenesis of fulminant hepatic failure. The aim of the present study was to determine if fulminant hepatic failure contributes to a change in the expression of cathepsin B protein and mRNA. To ascertain its pathogenic role in hepatic failure, we examined the protective effect of a cathepsin B inhibitor, CA-074Me [N-(L-trans-propylcarbamyloxirane-2-carbonyl)-L-isoleucyl-L-proline] on fulminant hepatic failure in mice.

## MATERIALS AND METHODS

### Animals

Kunming mice (male, 18-20 g, 4 wk of age) were used. Animals were provided by the Animal Center of the First Clinical Hospital of Harbin Medical University. This study conformed to Harbin Medical University's guidelines for the care and use of laboratory animals.

### Experimental groups

Seventy-two mice were randomized to three groups (normal control, model and protected). Galactosamine (D-Gal N) 800 mg/kg and lipopolysaccharide (LPS) 100 µg/kg were injected into the abdominal cavity of mice of the model group; mice in the protected group were administered CA-074me (10 mg/kg) for 30 min before LPS/D-Gal N treatment; and the normal control group was given isochoric physiologic saline. Six mice in each group were killed 2, 4, 6 and 8 h after injection. The liver was cut into small pieces and snap-frozen in liquid nitrogen and stored at -70°C, or fixed in freshly prepared 4% paraformaldehyde in phosphate-buffered saline (PBS) at 4°C.

### Materials

Goat anti-mouse cathepsin B polyclonal IgG and P-conjugated secondary antibodies for immunoblotting were purchased from Santa Cruz Biotechnology Inc., USA; D-Gal N, LPS and CA-074me from Sigma (USA); TUNEL reagent kit from Zhong Shan Biotechnical Ltd (Beijing, China); immunohistochemical kit from Zymed (series SP kits); ABC reagent and DAB kits from Wuhan Boster Biological Technology Co, Ltd (Wuhan, China); Trizol kits from Invitrogen (USA); and the reverse transcription-polymerase chain reaction (RT-PCR) kit from Promega (USA). Primers were synthesized by Shanghai Sangon Biological Engineering Technology Co, Ltd (Shanghai, China).

### Histology and TUNEL assay

The liver was fixed in 4% paraformaldehyde for 48 h, and embedded in paraffin. Tissue sections were prepared with a microtome and placed on glass slides. Hematoxylin and eosin staining was done by standard methods. TUNEL assay was carried out with a commercially available kit according to the manufacturer's instructions. Hepatocyte apoptosis in liver sections was quantified by counting the number of TUNEL-positive cells in microscopic high-power fields.

### Immunohistochemistry

Sections were incubated with goat anti-mice cathepsin B, which was pre-diluted by the manufacturer for staining formalin-fixed paraffin-embedded tissues. After washing the sections exhaustively, they were incubated for 45 min with biotin-conjugated anti-goat IgG antibody, and then with horseradish peroxidase (HRP)-conjugated streptavidin. Negative control slides were incubated with non-immune immunoglobulin under identical conditions. Liver cell endochylema or nucleus containing

yellow granulation served as a positive control, followed by semi-quantitative analysis using Image-plus 6.0 software.

### RT-PCR

Total RNA was obtained from whole liver using trizol reagent. The RNA sample was reversely transcribed into cDNA according to manufacturer's instructions. The primers for the experiment were as follows: cathepsin B<sup>[6]</sup>, forward 5'-GAAGAAGCTGTGTGGCACTG-3', and reverse 5'-GTTCGGTCAGAAATGGCTTC-3' (yielding a 198-bp product); glyceraldehyde-3-phosphate dehydrogenase (GAPDH), forward 5'-CTGCACCACCAACTGCTTAG-3', and reverse 5'-GTCTGGGATGGAAATT GTGA-3' (660-bp). GAPDH was used as a control for RNA integrity. Thermal cycling conditions were 15 seconds at 96°C, 62°C for 20 s, and 1 min at 70°C. Amplification was stopped after 34 cycles. Ten microliters of PCR products were obtained in each group, and confirmed by gel electrophoresis (coloration by EB, Ethidium Bromide). Gel electrophoresis photographs were taken; the band of Cathepsin B PCR products on electrophoresis gel were quantified using a DNA sequencer equipped with Quantity-One analysis software.

### Western blotting

Samples were centrifuged at 10 000 × *g* for 20 min at 4°C to remove solid material. Supernatants were centrifuged at 100 000 × *g* for 1 h at 4°C. Cellular protein from each sample (50 µg) was mixed with sample buffer (0.25 mol/L Tris, pH 6.8, 8% SDS, 40% glycerol, 2.5% bromophenol blue, and 2% β-mercaptoethanol), heated for 3 min at 95°C, applied to a 12% acrylamide gel, separated by electrophoresis (SDS-polyacrylamide gel electrophoresis) and transferred to nitrocellulose membranes. Membranes were blocked with 5% non-fat milk in Tris-buffered saline containing 0.1% Tween 20 (TBST) for 1 h. Blots were incubated in cathepsin B polyclonal antibody at a dilution of 1: 200 for 2 h. After washed three times for 10 min with TBST, blots were incubated with HRP-conjugated anti-goat secondary antibody (1:5000) for 1 h. Following the secondary antibody incubations, blots were developed using an ECL-plus kit. Blots were visualized using the chemiluminescence detection system (Amersham Pharmaceuticals, Amersham, UK).

### Statistical analyses

Data represent at least four independent experiments, and were expressed as the mean ± SD (unless otherwise indicated). The difference was determined using two-way analyses of variance (ANOVA) following SNK. Data were analyzed by SPSS software. *P* < 0.05 was considered to be statistically significant.

## RESULTS

### Histopathology of liver tissue under light microscopy

Liver histopathology was used to assess if different

**Figure 1** Histopathology of liver tissue at 6 h (HE,  $\times 10$ ). A: Normal group; B: Model group; C: Protected group.

**Figure 2** Apoptosis in the model group and protected group measured by TUNEL assay.

groups had different effects on liver injury (Figure 1). Liver histology was normal in the control group. After treatment with D-Gal N and LPS for 6 h, massive

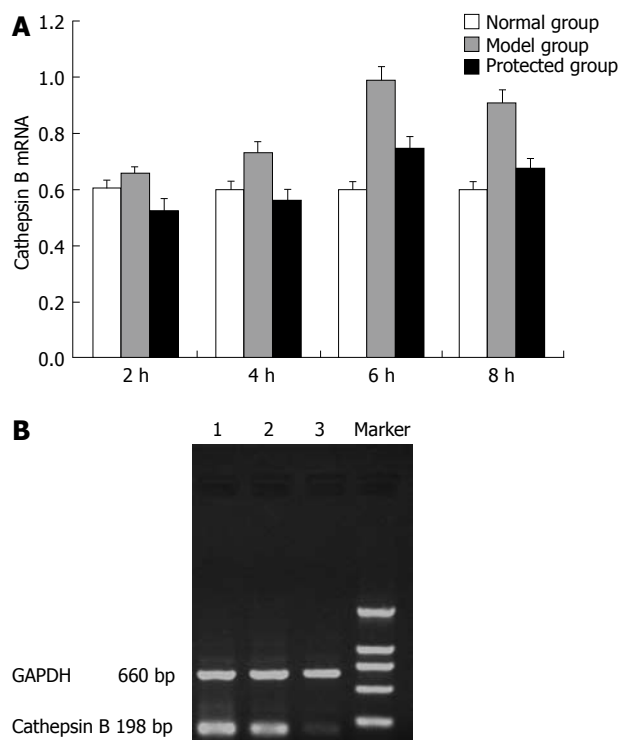

**Figure 3** Immunohistochemical analysis of cathepsin B at 8 h (HE,  $\times 10$ ). A: Normal group; B: Model group; C: Protected group.

hepatocyte apoptosis was detected in the model group; 8 h after injection, hepatocyte necrosis with massive infiltrates of neutrophils was widely spread. The protected group had far less apoptosis and necrosis, and little evidence of neutrophil accumulation, especially 6 and 8 h after injection.

#### TUNEL assay

Hepatocyte apoptosis was quantified using TUNEL assay (see Materials and Methods). None or few TUNEL-positive cells were observed in the normal group. In the model group, massive hepatocyte apoptosis occurred, and the number of apoptotic cells increased with time (Figure 2). The apoptosis index (AI) 2 h after injection of D-Gal N/LPS was  $(1.8 \pm 0.7)\%$ ,  $(7.8 \pm 1.5)\%$  at 4 h, and reached a climax at 6 h  $(30.4 \pm 2.8)\%$ . After 8-h treatment, AI was lower than that of 6 h, and reached  $(22.6 \pm 2.2)\%$  at 8 h. Compared with the model group, the apoptotic cells in the protected group were

**Figure 4** RT-PCR analysis of expression of cathepsin B mRNA in the normal, model and protected groups. A: Expression of cathepsin B mRNA in different groups; B: Images of agarose gel electrophoresis at 6 h; 1: Model group; 2: Protected group; 3: Normal group.

**Figure 5** Western blot analysis of expression of cathepsin B protein in the normal, model and protected groups. A: Expression of cathepsin B Protein in different groups; B: Expression of cathepsin B protein at 8 h; 1: Normal group; 2: Model group; 3: Protected group.

obviously reduced at the same time points, particularly at 6 h ( $18.1 \pm 2.0\%$ ) and 8 h ( $11.4 \pm 2.6\%$ ) ( $P < 0.01$ ).

#### Immunohistochemical analysis of cathepsin B

Immunohistochemistry for cathepsin B was done to confirm apoptosis (Figure 3). Strongly positive immunoreactivity for active cathepsin B was detected in mice injected with LPS/D-Gal N compared with

the normal group. After 6-h and 8-h treatment with LPS/D-Gal N, more expression of cathepsin B was found ( $0.251 \pm 0.010$  and  $0.280 \pm 0.011$ , respectively). At the same time points, cathepsin B was found to be significantly less expressed in mice of the protected group ( $0.202 \pm 0.008$  and  $0.241 \pm 0.011$ , respectively,  $P < 0.01$ ).

#### Expression of cathepsin B mRNA

Semi-quantitative RT-PCR was used to assess the expression of cathepsin B mRNA. Using densitometric analysis in comparison with the housekeeping gene GAPDH, we found that the expression of cathepsin B mRNA significantly increased after treatment of LPS/D-Gal N compared with the normal group ( $P < 0.01$ ). The expression of cathepsin B mRNA gradually increased 6 h and 8 h after injection with LPS/D-Gal N and reached a climax at 6 h. At the same time points, expression of cathepsin B mRNA in the protected group was significantly reduced compared with the model group, particularly at 6 h and 8 h (Figure 4).

#### Western blot analysis

Western blot analysis of cathepsin B protein expression is shown in Figure 5. A prominent band at a molecular size of about 27 kDa was detected, which represented the single-chain form of cathepsin B. Incubation with LPS/D-Gal N at selected time points resulted in a time-dependent increase in cathepsin B protein. The cathepsin B protein began to increase 2 h after treatment with LPS/D-Gal N and increased to maximum activity at 8 h compared with the normal group ( $P < 0.01$ ). Expression of cathepsin B was significantly decreased in the protected group, particularly at 8 h.

#### DISCUSSION

The traditional view is that hepatocyte necrosis is the main feature of fulminant hepatic failure, but increasing evidence implicates a dominant role for hepatocyte apoptosis in this pathogenesis<sup>[1,7]</sup>. The major objective of our study was to evaluate apoptosis-mediated fulminant hepatic failure in LPS/D-Gal N-induced liver injury.

Cathepsin B, a lysosomal cysteine protease, is a candidate for an apoptotic mediator originating from acidic vesicles. Cathepsin B is synthesized as a 38-kDa procathepsin B that undergoes sequential processing steps within lysosomes. First, a 30-kDa mature active form is generated by proteolytic cleavage<sup>[8]</sup>. Further processing involves removal of the NH<sub>2</sub>-terminal propeptide, cleavage of six residues from the COOH-terminus, and internal excision of residues 127 and 128 to generate a two-chain (a 27-kDa heavy chain and a 4-5-kDa light chain) form of the enzyme with inter-chain disulfide bonds. Pharmacologic inhibition of cathepsin B has been reported to block apoptosis induced by p53 and cytotoxic agents<sup>[9]</sup>. Recent evidence suggests that cathepsin B contributes to tumor necrosis factor- (TNF- $\alpha$ )-induced apoptosis *in vitro* and *in vivo*<sup>[10,11]</sup>. In cell culture systems, activation of caspase 8

is associated with the release of cathepsin B from acidic vesicles into the cytosol. In the cytosol, cathepsin B was found to induce mitochondrial release of cytochrome C<sup>[12,13]</sup> and activate caspase 9 and 3<sup>[14]</sup>. The importance of this pathway in TNF- $\alpha$ -mediated apoptosis *in vitro* was shown by demonstrating that hepatocytes isolated from cathepsin B knockout mice are resistant to TNF- $\alpha$ -induced apoptosis. More recently, some colleagues have demonstrated a dominant role for cathepsin B in TNF- $\alpha$ -mediated apoptosis. In a murine tumor cell line, caspase inhibition accentuated TNF- $\alpha$ -induced apoptosis by a cathepsin-B pathway. Inactivation of cathepsin B attenuates hepatocyte apoptosis and liver damage in liver reperfusion injury<sup>[15,16]</sup> and cholestasis injury<sup>[17]</sup>. CA-074me is a selective inhibitor of cathepsin B<sup>[18]</sup>; it is highly cell-permeant and can decrease the expression or activity of cathepsin B. During the early stages of pancreatitis, trypsinogen activation in the pancreas is mediated by cathepsin B, indicating that pharmacological interventions that inhibit cathepsin B may prove useful in preventing acute pancreatitis or reducing its severity<sup>[19]</sup>.

In summary, our studies suggested a role for cathepsin B in fulminant hepatic failure. Compared with the normal group, massive hepatocyte apoptosis occurred in the model group, and the number of apoptotic cells increased to a maximum at 6 h. Incubation for longer periods did not lead to further increase in apoptosis and instead resulted in an increase of cell necrosis. The apoptosis index in the protected group was obviously reduced. Consistent with these data, the activity of cathepsin B was markedly increased in drug-treated mice compared with the normal group. Incubation with LPS/D-Gal N for selected time points resulted in a time-dependent increase in cathepsin B activity, and reached a maximum at 8 h. Cathepsin B expression was significantly decreased in the protected group. Collectively, these data suggest that LPS/D-Gal N-mediated cathepsin B expression initiates hepatocyte apoptosis in fulminant hepatic failure. Inhibition of cathepsin B attenuates apoptosis and liver injury, supporting a link between cathepsin B and fulminant hepatic failure. Inhibition of hepatocyte apoptosis with CA-074me seems to be a feasible therapeutic option for fulminant hepatic failure.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Fulminant hepatic failure is a rare, but severe, complication of acute hepatitis; it is associated with very high mortality. The traditional view is that hepatocyte necrosis is the main feature of fulminant hepatic failure, but increasing evidence implicates a dominant role for hepatocyte apoptosis in this pathogenesis. Recent evidence suggests that cathepsin B contributes to cell apoptosis.

### Research frontiers

It is not known if cathepsin B-mediated hepatocyte apoptosis is involved in the pathogenesis of fulminant hepatic failure.

## Innovations and breakthroughs

The current study demonstrated that cathepsin B has an essential role in the pathogenesis of fulminant hepatic failure, and the cathepsin B inhibitor CA-074me could attenuate apoptosis and liver injury.

## Applications

Inhibition of cathepsin B attenuates apoptosis and liver injury, and CA-074me seems to be a viable therapeutic option for fulminant hepatic failure.

## Terminology

Cathepsin B, a lysosomal cysteine protease, is a candidate for an apoptotic mediator originating from acidic vesicles. CA-074me is a specific inhibitor of cathepsin B; it is highly cell-permeant and can decrease the expression or activity of cathepsin B.

## Peer review

This is a well-designed, most part well-written paper, with important new data on the pathogenesis of fulminant hepatic failure. Authors have shown that apoptosis is important in the development and that the process can be partially reversed by specific cathepsin-B inhibitor.

### Abstract

**AIM:** To determine the prevalence and clinical relevance of isolated antibodies to hepatitis B core antigen as the only marker of infection (“anti-HBc alone”) among human immunodeficiency virus (HIV) type-1 infected patients. Occult hepatitis B infection frequency was also evaluated.

**METHODS:** Three hundred and forty eight histories from 2388 HIV-positive patients were randomly reviewed. Patients with serological markers of hepatitis B virus (HBV) infection were classified into three groups: past hepatitis, “anti-HBc alone” and chronic hepatitis. Determination of DNA from HBV, and RNA and genotype from hepatitis C virus (HCV) were performed on “anti-HBc alone” patients.

**RESULTS:** One hundred and eighty seven (53.7%) HIV-positive patients had markers of HBV infection: 118 past infection (63.1%), 14 chronic hepatitis (7.5%) and 55 “anti-HBc alone” (29.4%). Younger age [2.3-fold higher per every 10 years younger; 95%

confidence intervals (CI) 1.33-4.00] and antibodies to HCV infection [odds ratio (OR) 2.87; 95% CI 1.10-7.48] were factors independently associated with the “anti-HBc alone” pattern. No differences in liver disease frequency were detected between both groups. Serum levels of anti-HBs were not associated with HCV infection (nor viral replication or HCV genotype), or with HIV replication or CD4 level. No “anti-HBc alone” patient tested positive for HBV DNA.

**CONCLUSION:** “Anti-HBc alone” prevalence in HIV-positive patients was similar to previously reported data and was associated with a younger age and with antibodies to HCV infection. In clinical practice, HBV DNA determination should be performed only in those patients with clinical or analytical signs of liver injury.

Clinical significance of “anti-HBc alone” in human immunodeficiency virus-positive patients. *World J Gastroenterol* 2009; 15(10): 1237-1241 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1237.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1237>

### INTRODUCTION

Infections by hepatitis B (HBV) and C (HCV) viruses are common in human immunodeficiency virus (HIV) infected patients, since nearly all these viruses share the same routes of transmission. HBV infection is present in between 49.2%-68% of HIV-positive patients<sup>[1-3]</sup> and there is evidence that co-infection can modify the natural history of HBV<sup>[4]</sup>, involves potential consequences on morbidity and mortality and has implications in management of both infections<sup>[5]</sup>. In fact, nowadays

HBV status is systematically and regularly assessed and systematic HBV vaccination is proposed in those patients without HBV markers.

Over recent years, numerous studies have been published about HBV-HIV co-infection, though some issues still remain unclear, such as clinical relevance and management of those patients with an isolated positive test for antibodies against hepatitis B core antigen (“anti-HBc alone” or defective immunological response)<sup>[6,7]</sup>. This serological pattern is the second most frequent serological profile of HBV infection, occurring in about 30% of HBV infected patients<sup>[1-3]</sup>.

One of the most controversial questions is about the frequency of occult hepatitis, i.e. HBV DNA positive markers without HBV surface antigen (HBsAg), among patient with a defective immunological response. Some authors consider the “anti-HBc alone” pattern to be a marker of occult HBV infection<sup>[1,3,8,9]</sup>, whereas others have not been able to demonstrate HBV DNA in the sera of these patients<sup>[10-13]</sup>.

This work was carried out to establish the prevalence and clinical significance of the “anti-HBc alone” pattern among HIV-positive patients. The frequency of HBV occult infection, determined by standard assays commonly used in routine clinical practice, was also determined.

## MATERIALS AND METHODS

Xeral-Cies University Hospital is a 700 bed Vigo University-affiliated Hospital which serves an urban population of about 400 000 inhabitants. From 2388 HIV-positive patients, who were followed-up in a specialised clinic of the hospital, 348 clinical histories were consecutively reviewed. Patients with some HBV markers were classified into three groups: chronic hepatitis [positive HBsAg and IgG anti-HBc, negative anti-HBs and IgM anti-HBc and positive or negative “e” antigen (HBeAg)]; past hepatitis (positive anti-HBs and IgG anti-HBc, negative HBsAg and IgM anti-HBc); and “anti-HBc alone” (positive IgG anti-HBc and negative HBsAg, anti-HBs, IgM anti-HBc and anti-HBe).

“Anti-HBc alone” patients were included only when a confirmatory test, performed two weeks later, showed a concurrent result. Patients that had been vaccinated against HBV were excluded.

In every “anti-HBc alone” patient and in those with past hepatitis epidemiologic characteristics (age, sex, risks conduct), co-morbidities (active infections, renal failure, diabetes, cancer, *etc*), antibodies against HCV, immunoglobulin levels and liver function tests were gathered. HCV RNA, HCV genotype and HIV viral load were tested and CD4 level was determined by flow cytometry. Also, abdominal imaging (ultrasound, CT, magnetic resonance) was performed to evaluate the presence of chronic liver disease (inhomogeneous hepatic texture or surface, rarefied hepatic central vein, an enlarged caudate lobe, splenomegaly or collateral veins)<sup>[14]</sup>. In every case, intake of antiretroviral therapy

active against HBV, such as lamivudine or tenofovir, was recorded. Changes in the serological response after introduction of antiretroviral therapy or after an immunological improvement were evaluated. When it was possible, serum was extracted to determine HBV DNA.

## Laboratory tests

HBs Ag, anti-HBe and anti-HBc were determined with 3rd generation microparticle enzyme immunoassays (MEIA) for qualitative detection of surface antigen, antibodies against “e antigen” and antibodies against “core antigen” of HBV [AxSYM HBsAg (V2) System, anti-HBe System y Core System. Abbott Laboratories, Chicago, IL, USA]. Anti-HBs was determined by 3rd generation MEIA for quantitative assessment of HBV surface antibodies (Abbott Laboratories, Chicago, IL, USA). Detection limits of the assay were 10-1000 IU/L. Serum HBV DNA levels were determined by an automated quantitative technique of molecular hybridization with genomic amplification; owned primers against the core region of the genome contained in a National “Reference Laboratory” were used. The lower detection limit of this assay was 10<sup>4</sup> copies/mL.

Antibodies against HCV were measured with 3rd generation MEIA to qualitatively determine this antibody (AxSYM HCV version 3.0 System. Abbott Laboratories, Chicago, IL, USA). Serum HCV RNA was quantified by molecular hybridization using a branched DNA technique [Versant HCV-RNA 3.0 (bDNA) - Bayer Diagnostics]. This assay has a lower detection limit of 3200 copies/mL. HCV genotype was determined by automatic sequencing with a fluorescent marker.

Antibodies against HIV-type 1, HIV-type 2 and p24 antigen were determined at the same time by 3rd generation MEIA (AxSYM HIV Ag/Ab Combo System. Abbott Laboratories, Chicago, IL, USA). Positive test results were confirmed by Western-Blot (NEW LAV-BLOT I Bio-Rad. France). HIV viral load was quantified by the Amplicor HIV-1 Monitor (Roche Diagnostics). The lower detection limit of this assay was 40 copies/mL.

The study was reviewed and approved by the Research Ethical Committee of Vigo Hospitality University Complex. All patients gave informed consent to participate in the study.

## Statistical analyses

Results were expressed as absolute values (percentage) and median (interquartile range, IQR) as appropriate. Baseline characteristics were compared by using  $\chi^2$  or Fisher exact test for categorical data and Mann-Whitney U test for continuous data.

When variables were significantly associated ( $P < 0.05$ ) with a defective pattern in the univariate analysis, a backward logistic regression analysis was conducted to identify those factors independently associated with “anti-HBc alone”.

**Table 1** Differences between HIV-positive patients with "anti-HBc alone" and past hepatitis B

	"anti-HBc alone" pattern (n = 55)	Past hepatitis B (n = 55)	P
Age, yr	38 (33-43)	45 (37-49)	0.001
Male, n (%)	38 (69.1)	38 (69.1)	1.000
Transmission mode n (%)			0.021
IDU	44 (80)	34 (61.8)	
Homosexual	4 (7.3)	15 (27.3)	
Heterosexual	7 (7.7)	6 (10.9)	
AST (IU/mL)	43 (23-65)	31 (22-47)	0.092
ALT (IU/mL)	39 (19-73)	29 (20-45)	0.301
Albumin (g/L)	42 (38.8-45.6)	43 (40.8-45.9)	0.261
Anti-HCV positive, n (%)	45 (81.8)	34 (61.8)	0.020
CDC C stage, n (%)	15 (27.3)	19 (34.5)	0.409
CD4 (cells/mm <sup>3</sup> )	434 (325-714)	459 (303-636)	0.740
HIV DNA < 50 copies/mL	25 (47.2)	32 (59.3)	0.210

IDU: Intravenous drug user; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase.

## RESULTS

From 348 clinical histories, 187 (53.7%) patients had positive tests against HBV; 118 past hepatitis (33.9%), 14 chronic hepatitis (4%), and 55 "anti-HBc alone" (15.8%). Among patients who had been infected by HBV, 29.4% developed an "anti-HBc alone" pattern and 63% showed a cured past infection. Fifty five patients with past hepatitis were randomly selected to be compared with "anti-HBc alone" patients. Epidemiologic characteristics of both groups are shown in Table 1.

The factors independently associated with a defective pattern were younger age [2.3-fold higher per every 10 years younger; 95% confidence intervals (CI) 1.33-4.00] and antibodies to HCV infection [odds ratio (OR) 2.87; 95% CI 1.10-7.48]. Intravenous drug users (IDU) were significantly more frequent in the "anti-HBc alone" group (80% *vs* 61.8%,  $P = 0.021$ ).

Liver function tests, CD4 levels, HIV viral load or AIDS stages were not significantly different between the two groups. Ultrasound signs of chronic liver disease were only present in HCV co-infected patients ( $P < 0.05$ ). Serum levels of anti-HBs were not associated with HCV infection (nor with viral replication or HCV genotype), and were not associated with HIV replication or CD4 level.

Serum HBV DNA was tested in 30 "anti-HBc alone" patients and no-one was positive. However, 10 patients were taking lamivudine or tenofovir when the tests were performed.

## DISCUSSION

In the present study, as in other studies<sup>[1-3]</sup>, a high prevalence of HBV infection (53.7%) among HIV infected patients was found. Although diverse frequencies in the "anti-HBc alone" pattern have been reported according to different geographic areas or

selected populations<sup>[15,16]</sup>, the frequency data among HIV patients (24.5-37.8%<sup>[1-3]</sup>) are fairly similar to data reported in this study (29.4%).

One of the independent factors related to the defective serological pattern was a younger age. This event has been previously reported in only one study<sup>[17]</sup>, in which a higher frequency of "anti-HBc alone" status was also found among women. Nevertheless, in our study the proportion of women in the "anti-HBc alone" group was the same as that in the past hepatitis group (30.9%).

The presence of HCV infection is another independent factor identified in our work which has been reported before<sup>[1,3,9,16,18]</sup>. A study showed that "anti-HBc alone" phenotype was significantly more frequent in HCV-viraemic than in HCV-recovered patients<sup>[18]</sup>. HCV replication could produce a down regulation in HBV replication, and this could be expressed as a defective serological pattern<sup>[7,18]</sup>.

IDU has also been reported previously as significantly more frequent in the "anti-HBc alone" group<sup>[19]</sup> and it has been related to a higher frequency of HCV, as IDU is one of the strongest risk factors for HCV infection.

This is the first study that evaluates liver disease by abdominal imaging scan and no statistically significant differences were found between "anti-HBc alone" patients and past hepatitis patients. In both groups, signs of liver disease were only demonstrated in patients co-infected with HCV.

Occult hepatitis prevalence data reported in "anti-HBs alone" HIV-positive patients varies greatly from 0% to 89.5%<sup>[1-3,9,12,17,20,21]</sup>. However, in those studies that have found viral replication, detected viral load was usually very low ( $< 10^3$  copies/mL)<sup>[3,20]</sup>. Ultra-sensitive PCR techniques ( $50-10^2$  copies/mL) were broadly used in those experimental studies, but are not available in daily clinical practice. In our study, no case of occult hepatitis was proved by standard assays commonly employed in routine clinical practice that can detect  $10^4$  copies/mL. Clinical relevance and management of this low viral replication is unclear because a higher incidence of hepatic damage was not found in these patients<sup>[16]</sup>. On the other hand, current therapeutic guidelines do not recommend starting treatment if the viral load is lower than  $10^4-10^5$  copies/mL<sup>[6,21-24]</sup>. More than 90% of doctors that attend HIV patients follow this practice<sup>[22]</sup>. However, the latest recommendations in HIV-positive patients with the "anti-HBc alone" pattern advise to test for HBV DNA in every patient<sup>[6,10,12,13,20]</sup>. We believe that HBV DNA testing should be performed only in those patients with an unexplained high level of alanine aminotransferase (ALT) or signs of liver disease.

The present study has some limitations. HBV DNA was not tested in every "anti-HBc alone" patient but non medical reasons prevented us from getting some serum specimens. Moreover, some tested patients were taking lamivudine or tenofovir. However, a study showed that the mean HBV load was similar among patients whether

or not they were treated with lamivudine, and that this was probably associated with an increasing number of resistance mutations<sup>[2]</sup>. Furthermore, in another study in which one case of occult hepatitis was demonstrated the patient was on lamivudine<sup>[11]</sup>. The present study displays a complete evaluation of HIV-positive patients with the “anti-HBc alone” pattern, since clinical, virological and radiological parameters have been considered in these patients.

In conclusion, in our population “anti-HBc alone” prevalence in HIV-positive subjects is similar to previously reported data and is associated with a younger age and with antibodies to HCV infection. After evaluating the results of the present study and others with similar results, HBV DNA determination should not be performed in every patient with the “anti-HBc alone” pattern, but only in those patients with unexplained clinical or analytical signs of liver injury.

## COMMENTS

### Background

Over recent years, numerous studies have been published about hepatitis B virus (HBV)-human immunodeficiency virus (HIV) co-infection, though some issues remain still unclear, such as clinical relevance and management of those patients with “anti-HBc alone” pattern or the frequency of occult hepatitis among patients with a defective immunological response. Some authors consider the “anti-HBc alone” pattern to be a marker of occult HBV infection, whereas others have not been able to demonstrate HBV DNA in the sera of these patients.

### Research frontiers

The authors studied the prevalence and clinical significance of the “anti-HBc alone” pattern among HIV-positive patients and the frequency of HBV occult infection, determined by standard assays commonly used in routine clinical practice.

### Innovations and breakthroughs

This is the first study that evaluates liver disease by abdominal imaging scan and no statistically significant differences were found between “anti-HBc alone” patients and past hepatitis patients. In both groups, signs of liver disease were only demonstrated in patients co-infected with hepatitis C virus (HCV). No single case of occult hepatitis was proved by standard assay commonly employed in routine clinical practice that can detect 10<sup>4</sup> copies/mL.

### Applications

Although the latest recommendations in HIV-positive patients with the “anti-HBc alone” pattern advise to test for HBV DNA in every patient, this and other studies show that viral load reported in these patients is usually low. Current therapeutic guidelines do not recommend starting treatment when viral load is lower than 10<sup>4</sup>-10<sup>5</sup> copies/mL. The authors believe that HBV DNA testing should be performed only in those patients with an unexplained high level of alanine aminotransferase (ALT) or signs of liver disease.

### Terminology

“Anti-HBc alone” pattern or defective immunological response: positive hepatitis B core antigen as the only marker of hepatitis B infection. Occult hepatitis B: HBV DNA positive without HBV surface antigen.

### Peer review

The “anti-HBc alone” pattern is very common among HIV-positive patients and it is not associated with liver injury. However this serological pattern can be associated with occult hepatitis B, usually with a very low viral load of HBV. The authors recommend testing DNA HBV only in those patients with the “anti-HBc alone” pattern and unexplained high levels of ALT or signs of liver disease.

### Abstract

**AIM:** To evaluate the prognostic factors for 5-year survival after local excision of rectal cancer, and to examine the therapeutic efficacy and surgical indications for this procedure.

**METHODS:** Clinical data, obtained from 106 local rectal cancer excisions performed between January 1980 and December 2005, were retrospectively analyzed. Survival analysis was performed using the Kaplan-Meier method, statistical comparisons were performed using the log-rank test, and multivariate analysis was performed using the Cox proportional hazards model.

**RESULTS:** Transanal, transsacral, and transvaginal excisions were performed in 92, 12, and 2 cases, respectively. The rate of complication, local recurrence, and 5-year survival was 6.6%, 17.0%, and 86.7%, respectively. Univariate analysis showed that T stage, vascular invasion, and local recurrence were related to the prognosis of the cases ( $P < 0.05$ ). Multivariate analysis showed that T stage [ $P = 0.011$ , 95% confidence interval (CI) = 1.194-3.878] and local recurrence ( $P = 0.022$ , 95% CI = 1.194-10.160) were the major prognostic factors for 5-year survival of cases after local excision of rectal cancer.

**CONCLUSION:** Local rectal cancer excision is associated with few complications, and suitable for stages Tis and T1 rectal cancer. Prevention of local

### INTRODUCTION

In China, unlike in Western countries, rectal cancer accounts for approximately 70% of colorectal cancers. Both abdominoperineal resection and anterior resection of rectal cancer can result in postoperative urinary impairment and sexual dysfunction, and the presence of a permanent colostomy significantly impacts the quality of life. With the advancement of imaging techniques, the accuracy of preoperative rectal cancer staging has increased dramatically, and the preservation of physical function in rectal cancer patients has become a very important aim of research. Local tumor excision preserves anal, urinary, and sexual function in patients with low rectal cancer. Some patients with early tumor have suitable indications for local tumor excision<sup>[1-5]</sup>. This study was to determine the prognostic factors for survival after local excision of rectal cancer.

### MATERIALS AND METHODS

#### Clinical data

This study included 106 low rectal cancer patients at the age of 26-81 years (60 males, 46 females, with a median age of 60 years) who underwent local tumor excision at our hospital between January 1980 and December 2005. The main symptom on presentation was rectal bleeding

(95 patients). Other symptoms included passage of mucus, altered bowel habits. Tumors were located at the anterior wall in 45 patients, posterior wall in 35 patients, and lateral wall in 21 patients, none located in 5 patients. The diameter of the tumor was  $\leq 3.0$  cm in 70.5% (80/106) patients and  $> 3.0$  cm in 17.9% (19/106) patients. Colonoscopy or barium enema was performed to exclude multiple primary tumors, while ultrasound, chest X-ray, or computed tomography (CT) was conducted to exclude distant metastases, thus a pathological diagnosis was made before operation.

### Treatment method

Transanal excision (TAE), transsacral excision (TSE), and transvaginal excision (TVE) were performed in 92, 12, and 2 patients, respectively. The margin was excised 1-2 cm from the tumor, and postoperative pathology reports indicated negative margins in all cases.

Four patients received preoperative radiotherapy and 41 patients underwent postoperative radiotherapy at the dose of 14-75 Gy (mean 53.5 Gy).

### Follow-up

Of the 106 patients, 104 received follow-up (by outpatient appointments, telephone, or mail), and the follow-up rate was 98.1%. Follow-up was performed between 11 mo and 20 years after operation, and the median follow-up time was 72 mo. During the follow-up period, 14 patients died. Of them, 9 died of tumor metastasis, 4 of other conditions, and 1 of a second primary esophageal cancer, respectively.

### Statistical analysis

SPSS 13.0 software was used for statistical processing. Survival analysis was performed using the Kaplan-Meier method, univariate analysis of prognostic factors was performed using the log-rank test, and multivariate analysis was performed using the Cox proportional hazards model.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Complications

The complication rate was 6.6% (7/106). Postoperative bleeding occurred in 1 case and wound breakdown was observed in 1 case after TSE. Four cases had anastomotic leakage after TAE, 1 of them was accompanied with bleeding. One case had rectovaginal fistulation after TVE. No death occurred during surgery.

### Local recurrence and related factors

Of the 106 patients, 18 (17%) had local recurrence 4-174 mo (mean 48.3 mo) after operation. The local recurrence rate for Tis-, T1-, and T2-stage tumors was 7.1%, 18.7%, and 20.8%, respectively ( $P = 0.331$ ), while the local recurrence rate for tumors with or without vascular invasion was 66.7% and 15.5%, respectively ( $P = 0.02$ ). Surgical treatment was reattempted for 12 patients after recurrence. Local excision was

performed in 5 patients. Of them, 1 died after 93 mo and the other 4 survived. Abdominoperineal resection was performed in 6 patients, and Park's procedure was performed in 1 patient. Of these 7 patients, 2 died after 36 and 40 mo, respectively, the other 5 survived. Distal metastases were present in 9 patients, who were then treated with chemotherapy, radiotherapy, or interventional therapy. Four T3 stage patients received preoperative radiotherapy, and local excision was performed after down staging. Tumors recurred in 2 patients with a recurrence rate of 50%.

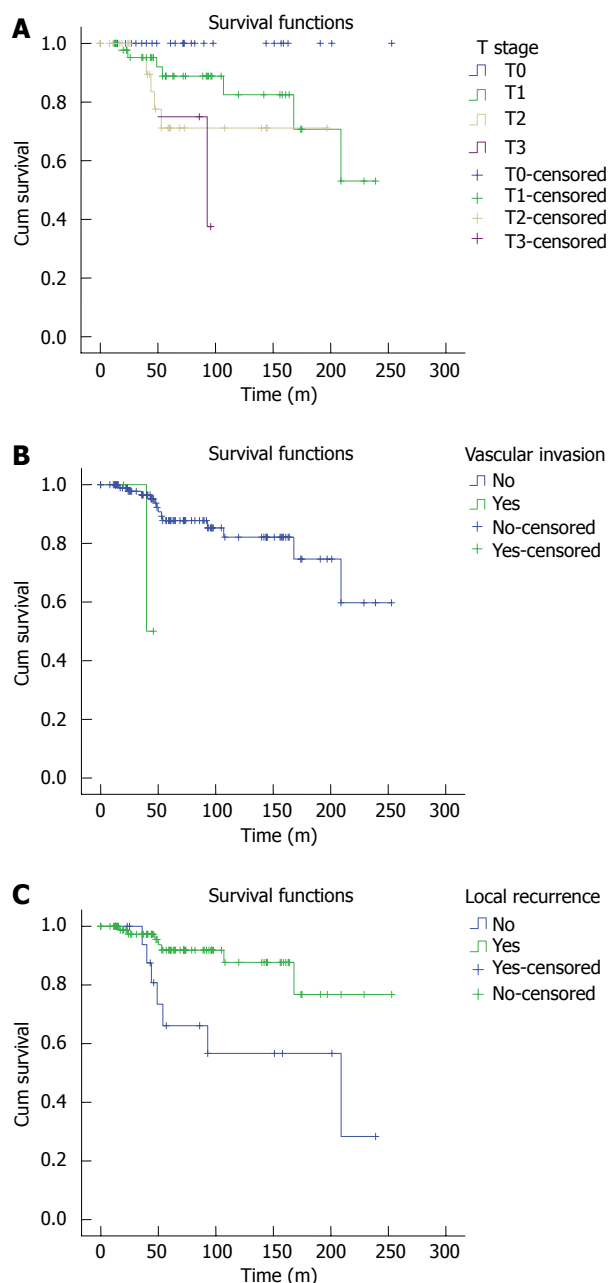

### Prognosis and influencing factors

The overall 5-year survival rate for our patients was 86.7%. The 5-year survival rate for Tis-, T1-, and T2-stage tumors was 100%, 88.8%, and 67.9%, respectively. Univariate analysis showed that infiltration depth, vascular invasion, and local recurrence were the prognostic factors for tumors ( $P < 0.05$ , Figure 1). Multivariate analysis showed that T stage [ $P = 0.011$ , OR = 2.152, 95% confidence interval (CI) = 1.194-3.878] and local recurrence ( $P = 0.022$ , OR = 3.483, 95% CI = 1.194-10.160) were the major prognostic factors for tumors.

## DISCUSSION

Although radical resection is an effective treatment for rectal cancer, it can lead to anal, urinary, and reproductive function impairment as well as surgical complications and death. Morson *et al*<sup>[6]</sup> have reported a 5-year survival rate of 82% in patients after local excision of early rectal cancer. Subsequent studies demonstrated that local excision of early stage low rectal cancer can produce a good outcome and preserve anal, urinary, and reproductive function<sup>[3,7-10]</sup>, but a higher local recurrence rate of tumor (5%-27%) has limited its wide application. Nevertheless, the 5-year survival rate after local tumor excision reported in the literature is 72%-95%<sup>[3,7-10]</sup>. In our study, the local recurrence rate was 17.0% and the 5-year survival rate was 86.7%, respectively, which are similar to the reported data<sup>[3,7-10]</sup>.

Risk factors affecting low rectal cancer prognosis after excision include the age and sex of patients, treatment methods, and vascular invasion and tumor stage. In our study, the age and sex of patients were unrelated to the prognosis of low rectal cancer. Vascular invasion and tumor stage affected rectal cancer recurrence and prognosis after local excision. Bouvet *et al*<sup>[11]</sup> found that T stage is the most important pathological factor for local rectal cancer recurrence after excision. In our patients, excision of Tis, T1, and T2 tumors was associated with the 5-year survival rate ( $P < 0.05$ ). The local recurrence and distant metastasis rates were significantly increased when the tumor was poorly differentiated, macroscopically ulcerative, or larger than 3.0 cm in diameter. However, because the number of patients was small in our study, the differences were not statistically significant. It was reported that rectal cancer patients also have a higher rate of lymphatic spread<sup>[12,13]</sup>, and therefore local excision should be recommended

**Figure 1** Survival curves for patients with different tumor T stages (A), different vascular invasions (B), and different local recurrence rates (C). The survival rate for the patients with T0 ( $n = 28$ ), T1 ( $n = 48$ ), T2 ( $n = 26$ ), T3 ( $n = 4$ ) varied significantly ( $P = 0.022$ ). Patients without vascular invasion ( $n = 103$ ) had a higher survival rate than those with vascular invasion. ( $n = 3$ ) ( $P = 0.01$ ). Patients without local recurrence ( $n = 88$ ) had a higher survival rate than those with local recurrence ( $n = 18$ ) ( $P = 0.005$ ).

with caution for such patients.

The excision method of local tumor may affect its prognosis. If R0 tumor excision is achieved, the surgical method used does not affect its local recurrence rate or the survival rate of patients. In our patients, all margins on pathological examination were negative. It was reported that if tumor margin is positive, the recurrence rate of tumor will be high and its prognosis is poor<sup>[14]</sup>. Therefore, if the margin is positive or borderline positive, the excision margins should be widened, otherwise, local tumor excision should be abandoned. Frozen section examination of margins during surgery

ensures margin negativity, which is essential for complete local tumor excision. It was reported that adjuvant chemotherapy and radiotherapy for tumor after local excision can reduce its local recurrence rate<sup>[15]</sup>. Our data show that radiotherapy was unrelated to local recurrence and prognosis of tumor, which may be due to the different indications for radiotherapy, and the standardized treatment modalities. It is generally believed that rectal cancer patients should undergo adjuvant chemotherapy and radiotherapy after local excision of T2 rectal tumor and poorly-differentiated or high-risk T1 rectal tumor<sup>[16]</sup>.

Salvage therapy is of great importance in the treatment of recurrent rectal tumor after local excision and can be performed when rectal wall involvement is significantly greater than extramural or pelvic cavity involvement. Therefore, the frequency of second surgery is higher in patients treated with local excision than in patients treated with radical resection. Mellgren *et al*<sup>[3]</sup> reported 17 cases (68%) of recurrent rectal cancer in the rectal wall and 8 cases (32%) of recurrent rectal cancer in extramural. Sengupta *et al*<sup>[4]</sup> found that 40%-100% of recurrent rectal cancer patients could be cured. Friel *et al*<sup>[17]</sup> used salvage therapy for 29 T1 or T2 tumor patients with recurrence after local excision (90% involving the rectal wall and 10% completely extramural), and found no residual tumor in 17 survivors after a mean follow-up time of 39 mo. Of the 18 patients with rectal tumor recurrence in our study, 12 were retreated surgically. Of the 5 patients treated with local excision, 1 died after 93 mo and 4 survived. In the 6 patients treated with abdominoperineal resection and 1 patient treated with Park's procedure, 2 died after 36 and 40 mo, respectively, and the other 5 survived, suggesting that salvage therapy is effective against early recurrent rectal cancer.

In rectal cancer patients who are unsuitable for or refuse abdominoperineal resection, local excision can be performed after the tumor is down staged<sup>[17]</sup>. Kim *et al*<sup>[18]</sup> showed that preoperative adjuvant therapy can effectively down stage T2 and T3 rectal cancer. In their study, 25 patients who were staged before operation by endorectal ultrasound (ERUS) received radiotherapy (45 Gy, 25 cycles) and chemotherapy (5-fluorouracil, 300 mg/m<sup>2</sup> per day, 5 d/week). Partial pathological response was achieved in 4 patients and complete response in 22 patients. In the 22 patients with complete-response, no recurrent rectal cancer occurred after local excision. In our 4 patients with preoperative stage T3 rectal cancer treated with local excision after chemotherapy, the cancer recurred in 2 cases with a recurrence rate of 50%. Since T3 and T4 tumors have a higher recurrent rate, they are unsuitable for local excision in patients who cannot tolerate or refuse abdominoperineal resection.

Local rectal cancer can be treated with a variety of methods, including TAE, TSE, TVE, and minimally invasive endoscopic transanal excision<sup>[19]</sup>. Irrespective of the surgical method, R0 excision is the most important procedure. TAE, a minimally invasive treatment modality, has few complications<sup>[20]</sup>. In our 92 patients, TAE had a low complication rate of 2.2%. Preoperative pelvic

CT and ultrasound examination can provide important information for surgical planning. Kwok *et al.*<sup>[21]</sup> analyzed data on the accuracy, sensitivity, and specificity of preoperative CT, magnetic resonance imaging (MRI), MRI-endorectal coil (MRI-ERC), and ERUS for rectal cancer staging, and found that the accuracy of CT, MRI, MRI-ERC, and ERUS is 80%, 74%, 81%, and 84%, respectively, with a higher accuracy for T1 tumors. At present, local excision is a generally accepted treatment modality for stage Tis and T1 rectal cancer. However, close follow-up is required. Early detection and salvage therapy can prolong the survival time of rectal cancer patients.

## COMMENTS

### Background

Both abdominoperineal resection and anterior resection of rectal cancer can result in postoperative urinary impairment and sexual dysfunction, and the presence of a permanent colostomy significantly impacts the quality of life. With the advancement of imaging techniques, the accuracy of preoperative rectal cancer staging has increased dramatically, and the preservation of physical function in rectal cancer patients has become a very important aim of research. Local tumor excision preserves anal, urinary, and sexual function in patients with low rectal cancer. Therapeutic efficacy and surgical indications for this procedure are controversial.

### Research frontiers

Some studies have demonstrated that local tumor excision of early stage low rectal cancer can produce a good outcome and preserve anal, urinary, and reproductive function. However, a higher local recurrence rate (5%-27%) of this procedure has limited its use in clinical practice. Nevertheless, the 5-year survival rate after local tumor excision is 72%-95%. Risk factors affecting low rectal cancer prognosis after local excision include age and sex of patients, treatment modalities, and vascular invasion and tumor stage.

### Innovations and breakthroughs

In this study, age and sex of the patients were unrelated to their prognosis. Vascular invasion and tumor stage affected rectal cancer recurrence and prognosis after local excision, and local recurrence and distance metastasis rates increased significantly when the tumor was poorly differentiated, macroscopically ulcerative, or larger than 3.0 cm in diameter. Therefore local excision should be recommended with caution for such patients. Frozen section examination of margins during surgery ensures margin negativity, which is essential for complete local tumor excision. Salvage therapy is of great importance in the treatment of recurrent rectal cancer after local excision.

### Applications

Local rectal cancer excision has few complications, and is suitable for stages Tis and T1 rectal cancer. Prevention of local recurrence, active postoperative follow-up, and salvage therapy can greatly increase the efficacy of local excision.

### Terminology

Local rectal cancer can be treated with a variety of methods including transanal excision (TAE), transsacral excision (TSE), transvaginal excision (TVE), transsphincter local excision, and minimally invasive endoscopic transanal excision.

### Peer review

The study is well designed and its results have confirmed the efficiency of different methods for rectal cancer and the discussion is reasonable.

### Abstract

**AIM:** To study the morphology and ontogeny of dendritic cells of Peyer's patches in rats at different development periods.

**METHODS:** The morphometric and flow cytometric analyses were performed to detect all the parameters of villous-crypts axis and the number of OX62<sup>+</sup>DC, OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC, and OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC in the small intestine in different groups of rats. The relationship between the parameters of villous-axis and the number of DC and DC subtype were analyzed.

**RESULTS:** All morphometric parameters changed significantly with the development of pups in the different age groups ( $F = 10.751, 12.374, 16.527, 5.291, 3.486; P = 0.000, 0.000, 0.000, 0.001, 0.015$ ). Villous height levels were unstable and increased from 115.24  $\mu\text{m}$  to 140.43  $\mu\text{m}$  as early as 3 wk postpartum. Villous area increased significantly between 5 and 7 wk postpartum, peaked up to 13817.60  $\mu\text{m}^2$  at 7 wk postpartum. Villous height and crypt depth ratios were relatively stable and increased significantly from  $2.80 \pm 1.01$  to  $4.54 \pm 1.56$ , 9-11 wk postpartum. The expression of OX62<sup>+</sup>DC increased from  $33.30\% \pm 5.80\%$  to  $80\% \pm 17.30\%$ , 3-11 wk postpartum ( $F =$

$5.536, P = 0.0013$ ). OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC subset levels detected in single-cell suspensions of rat total Peyer's patch dendritic cells (PP-DCs) increased significantly from  $30.73\% \pm 5.16\%$  to  $35.50\% \pm 4.08\%$ , 5-7 wk postpartum and from  $34.20\% \pm 1.35\%$  to  $43.60\% \pm 2.07\%$  9-11 wk postpartum ( $F = 7.216, P = 0.005$ ).

**CONCLUSION:** This study confirms the age-related changes in villous-crypt axis differentiation in the small intestine. Simultaneously, there are also development and maturation in rat PP-DCs phenotypic expression. Furthermore, the morphological changes of intestinal mucosa and the development of immune cells (especially DC) peaked at 9-11 wk postpartum, indicating that the intestinal mucosae reached a relatively mature state at 11 wk postpartum.

### INTRODUCTION

Different development periods have been suggested to play a role in controlling the development of gastrointestinal mucosal immune responses, which induce the intestinal mucosal immunity reflected differently over different development periods in children. As the lymphoid tissue is the primary site for the induction of mucosal immune responses. The morphometry of the villous-crypt axis in the small intestine reflects the function and adaptation of intestinal mucosal barriers. It was therefore of interest to investigate the potentially disparate phenotypic expression of dendritic cells (DCs) and the morphology of intestinal mucosa

found at different periods as a basis for determining the mechanisms that are apparently critical in intestinal mucosal immunity.

DCs were first identified in 1973 by Steinman and Cohn<sup>[1,2]</sup> and were found in two locations in the intestinal mucosa: the Peyer's patches (PPs) and lamina propria (LP). PP-DCs were isolated by Spalding in 1983<sup>[3]</sup>. It is now clear that PP-DCs may be unique in their ability to induce the differentiation of T cells that produce important cytokines such as IL-4 and IL-10 and other cytokines, including TGF- $\beta$ , which is important for B cell differentiation and bystander suppression after oral antigen feeding<sup>[4,5]</sup>. PP-DCs primarily perform two important tasks: (1) uptake of antigen after its transcytosis across the follicle-associated epithelium (FAE), which is mediated by immature DCs located largely in the subepithelial dome (SED); (2) T and B cell activation by mature DCs, which are found in the SED. T and B cells activated in PPs are "imprinted" and back to the gut due to the unique ability of PP-DCs to induce lymphocytes to regulate immunity<sup>[6-9]</sup>.

DC studies to date have been primarily carried out in mice *in vitro*. Little literature exists about rat DCs and of DCs *in vivo*, as current techniques for DC isolation are likely to induce phenotypic changes in DC. However, rats are of great value as experimental animals, especially in the field of nutrition. Additionally, some important findings about DC have been achieved through animal experiments. We therefore chose the rat model as the experimental object to detect the statement *in vivo*. In previous studies, DCs in mice had been divided into two subsets: CD8 $\alpha\alpha$ + and CD8 $\alpha\alpha$ -DC<sup>[10]</sup>. CD8 $\alpha\alpha$ + and CD8 $\alpha\alpha$ -DC preferentially activate T cells toward Th1 and Th2 differentiation, respectively<sup>[11]</sup>. CD8 $\alpha\alpha$ +DC constitutively cross-presents antigens to T cells, while CD8 $\alpha\alpha$ -DC does so upon their activation<sup>[12]</sup>. Kelsall *et al.*<sup>[13]</sup> also identified two distinct subsets of DCs in 6 to 8-wk-old murine PP. One population of DCs was positioned to capture antigens transported by overlying M cells, while the other subset activated native T cells to become effector cells. Recently, four different subsets of DCs have been described in mouse PPs<sup>[14,15]</sup>. Conversely, progress in the studies of rat DC is slow because of the relative shortage of reagents. CD11C, MHC-class II, and  $\alpha\epsilon$ -intergin (OX62 antigen) expression is routinely detected in rats to define DC in peripheral and lymphoid tissues.  $\alpha\epsilon$ -intergin expression is the strongest in mucosa-associated DC<sup>[16,17]</sup>. Additionally, as early as in 1980, rat DCs were subdivided on the basis of differential expression of CD4 and a member of the SIRP (signal inhibitory regulatory protein) family of molecules (detected by OX41)<sup>[18,19]</sup>. The existence of CD4<sup>-</sup>/SIRP<sup>-</sup> and CD4<sup>+</sup>/SIRP<sup>+</sup>DC subsets from the small intestine has recently been described<sup>[20]</sup>. Some reports<sup>[20]</sup> have shown that 12 to 16-wk-old rat intestinal and hepatic lymph DC is  $\alpha E_2$  intergin<sup>hi</sup> (OX-62) and includes two subsets: (1) signal regulatory protein  $\alpha$  (SIRP $\alpha$ )<sup>hi/low</sup> and (2) CD4<sup>hi/low</sup>, which most likely represents murine CD8 $\alpha\alpha$ -/+DC. In both lymph and the spleen, SIRP<sup>+</sup>/CD4<sup>+</sup> DCs are more potent than

SIRP<sup>-</sup>/CD4<sup>-</sup> DCs in the activation of allogeneic CD4<sup>+</sup> and CD8<sup>+</sup> T cells, naïve Ag-specific CD4<sup>+</sup> T cells *in vivo*, and sensitized Ag-specific CD4<sup>+</sup> T cells *in vitro*. To date, few studies have been conducted in rat PP-DCs at different development periods, our work focused on the morphometry of the villous-crypt axis in the small intestine as well as PP-DC differentiation and maturation in rats during ontogeny. Flow cytometry was used with emphasis laid on the implications of PP-DC interactions with intestinal mucosal immunity.

Our current study was to gain a better understanding of the expression and activation of PP-DCs in Sprague-Dawley rats. Single-cell suspension from the PP of the small bowel was isolated via collagenase A digestion. By collecting and manipulating these cells at 4°C, we maintained the cell activity. Using this model, we ascertained two phenotypically distinct subsets of PP-DC (both OX62<sup>+</sup>) that were distinguished by the existence or nonexistence of CD4 and SIRP coexpression. We also explored whether age-related development of DC ontogeny and morphological change occurred simultaneously. Our results demonstrate that morphological change is associated with DC ontogeny, suggesting that the intestinal mucosal immune system continuously changes as young rats mature.

## MATERIALS AND METHODS

### Animals

SD rats were purchased from the Shanghai Laboratory Animal Center, Chinese Academy of Sciences, Shanghai, China. Rats were held in plastic cages in temperature- and humidity-controlled animal quarters under a 12 h light/dark cycle and were fed a standard diet (rodent rat chow) *ad libitum* with free access to tap water. All procedures were approved by the Institutional Animal Care Committee.

### Reagents

Abs mouse anti-rat OX62:RPE, mouse anti-rat CD172a: FITC (OX41), and mouse anti-rat CD4:APC (Serotec) were purchased from Shanghai Jingmei Corporation.

### Tissue samples

SD rats were bred and maintained under specific pathogen-free conditions at Xinhua Hospital Affiliated to the Medical College, Shanghai Jiaotong University, Shanghai, China. Animals, aged 3 wk and weighing 52-58 g, were divided into 5 groups of equal size and approximately equal mean body weight (54 g), namely groups of 3, 5, 7, 9 and 11 wk. Rats were killed after a postpartum period of 21, 35, 49, 63 and 77 d. Abdominal cavities were opened by horizontal incision along the midsection and guts were excised. Central ileum tissue samples (0.5 cm) were taken. All PP tissue samples were taken from the small bowel.

### HE staining

Immediately after collection, ileum tissue samples were washed 3 times in cold phosphate buffered saline (PBS)

**Figure 1** Comparison of morphological changes of small intestinal mucosa (including villous height, villous width, villous area, crypt depth, and ratio of villous height to crypt depth) at different development periods in SD rats (HE,  $\times$  100). A: Group of 3 wk; B: Group of 5 wk; C: Group of 7 wk; D: Group of 9 wk; E: group of 11 wk.

and fixed for 48 h in 4% formalin solution. After fixation, specimens were dehydrated and embedded in paraffin. Sections from each sample were cut at a thickness of 4  $\mu\text{m}$  and stained with hematoxylin and eosin (HE).

#### Determination of staining results

Sections were examined under a light microscope. Villous height, villous width, and crypt depth in all tissues were determined using the image analysis system. Villous height was measured from the top of the villi to the Lamina muscularis mucosae. Villous width was defined as the distance from one crypt-villi junction to the next. The villous area (height  $\times$  width) was calculated out of these 2 parameters. PP areas in the ileum were imaged and measured in triplicate using a digital camera and software. PP outlines were performed by hand.

#### Flow cytometry

PP tissue samples were washed extensively 3 times in cold PBS. They were then cut into small segments and placed in cold PBS (4°C). After centrifugation at 800 rpm for 5 min at 4°C, the supernatant was removed and the remaining tissues were digested with 0.75 mg/mL collagenase A for 45 min at 37°C with periodic agitation.

Undigested stromal material was removed by passing over membrane filtration. Single-cell suspension was prepared and cells were incubated with mouse anti-rat OX62:RPE, mouse anti-rat CD172a:FITC (OX41) and mouse anti-rat CD4:APC for 30 min.

#### Statistical analysis

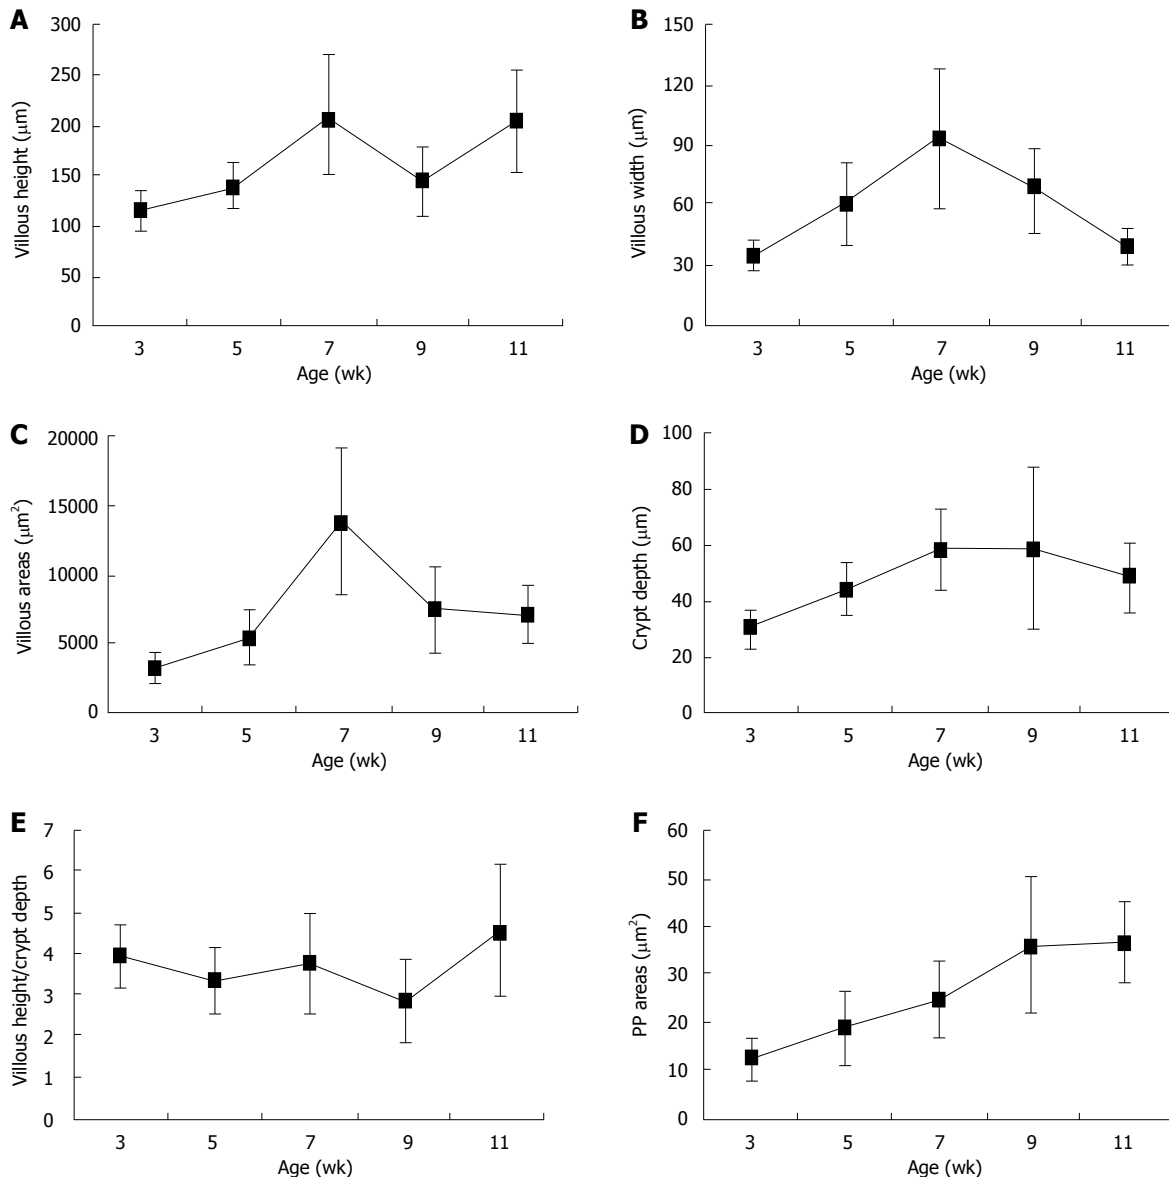

SPSS 11.0 statistical software was used for data analysis. Results were expressed as mean values with standard deviation (SD). Statistical analysis was completed using one-way ANOVA. Tukey's test was used to determine the significance of the difference between groups when the ANOVA test indicated a significant effect. *P* values of less than 0.05 were considered statistically significant.

## RESULTS

#### Morphological analysis of villous-crypt axis

The morphological parameters of the villous-crypt axis in the small intestine included villous height, villous width, villous areas, crypt depth, and the ratio of villous height to crypt depth. As shown in Table 1, Figure 1 and Figure 2A-E, all morphometric parameters changed significantly with the development of pups in

**Figure 2 Morphological analysis of villous-crypt axis: All morphological parameters matured as age increased.** The results were presented as mean  $\pm$  SD from 5 rats. A: Villous height increased at 3 wk postpartum, decreased 7 to 9 wk postpartum, and increased again after 9 wk postpartum; B: Villous width increased at 3 wk postpartum, peaked at 7 wk postpartum; C: Villous area increased significantly between 5 and 7 wk postpartum, peaked at 7 wk postpartum; D: Crypt depth increased from 3 to 7 wk postpartum and decreased slightly at 9 wk postpartum; E: Ratio of villous height to crypt depth were relatively stable and increased significantly from 9 to 11 wk postpartum; F: PP increased from 3 to 11 wk postpartum.

the different age groups ( $F = 10.751, 12.374, 16.527, 5.291, 3.486; P < 0.05$ ). Villous height was unstable and increased from  $115.24 \pm 21.82 \mu\text{m}$  to  $140.43 \pm 22.30 \mu\text{m}$  as early as 3 wk postpartum, decreased from  $210.71 \pm 59.47 \mu\text{m}$  to  $145.43 \pm 34.21 \mu\text{m}$  at 7-9 wk, and then increased again after 9 wk. Villous width increased from 3 wk postpartum, peaked at 7 wk up to  $93.06 \pm 35.03 \mu\text{m}$ , and decreased thereafter. Villous areas increased significantly between 5 wk and 7 wk postpartum from  $5451.92 \pm 2029.10 \mu\text{m}^2$  to  $13817.60 \pm 5236.52 \mu\text{m}^2$ , peaked at 7 wk, and decreased from then on, whereas few differences were found between 9 and 11 wk postpartum. Crypt depth increased from 3 wk to 7 wk postpartum, and decreased slightly at 9 wk. Few age-related differences were evident between 7 wk and 9 wk postpartum. Villous height and crypt depth ratio was

relatively stable and increased significantly from  $2.8 \pm 1.01$  to  $4.54 \pm 1.56$  at 9-11 wk postpartum.

#### Morphological analysis of PPs

PPs located in the small intestine showed a highly significant increase in size and number with age ( $P < 0.05$ ), and the degree of increase in different age groups varied from a few to a moderate number (from  $12.25 \pm 4.69 \mu\text{m}^2$  to  $37.12 \pm 8.20 \mu\text{m}^2$  at 3-11 wk postpartum) (Table 2, Figure 2F).

#### Ontogeny analysis of PP-DCs

Single-cell suspensions of the total PP-DCs in rats were identified by immunolabelling for OX62, which contained two populations distinguished by co-expression of CD4 and SIRP $\alpha$  or not. As shown in Table 3, Figures

Table 2 Changes of the areas of Peyer's patches (PP) at different development periods in SD rats (mean ± SD)

	3 wk	5 wk	7 wk	9 wk	11 wk	F	P
PP areas (μm <sup>2</sup> )	12.25 ± 4.69	18.91 ± 7.73	24.68 ± 7.73	36.13 ± 14.59	37.12 ± 8.20	7.474	0.000

Table 3 Changes in expression of OX62<sup>+</sup>DC, OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC and OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC subsets with development of SD rats (mean ± SD)

Age	3 wk	5 wk	7 wk	9 wk	11 wk	F	P
OX62 <sup>+</sup> DC/total cells in PP (%)	0.333 ± 0.058	0.367 ± 0.115	0.467 ± 0.153	0.533 ± 0.153	0.8 ± 0.173	5.536	0.013
OX62 <sup>+</sup> CD4 <sup>+</sup> SIRP <sup>+</sup> DC/OX62 <sup>+</sup> DC (%)	31.87 ± 1.99	30.73 ± 5.16	35.50 ± 4.08	34.20 ± 1.35	43.60 ± 2.07	7.216	0.005
OX62 <sup>+</sup> CD4 <sup>+</sup> SIRP <sup>+</sup> DC/OX62 <sup>+</sup> DC (%)	33.27 ± 5.71	25.33 ± 2.82	24.53 ± 2.64	28.97 ± 1.89	28.43 ± 1.94	3.242	0.060

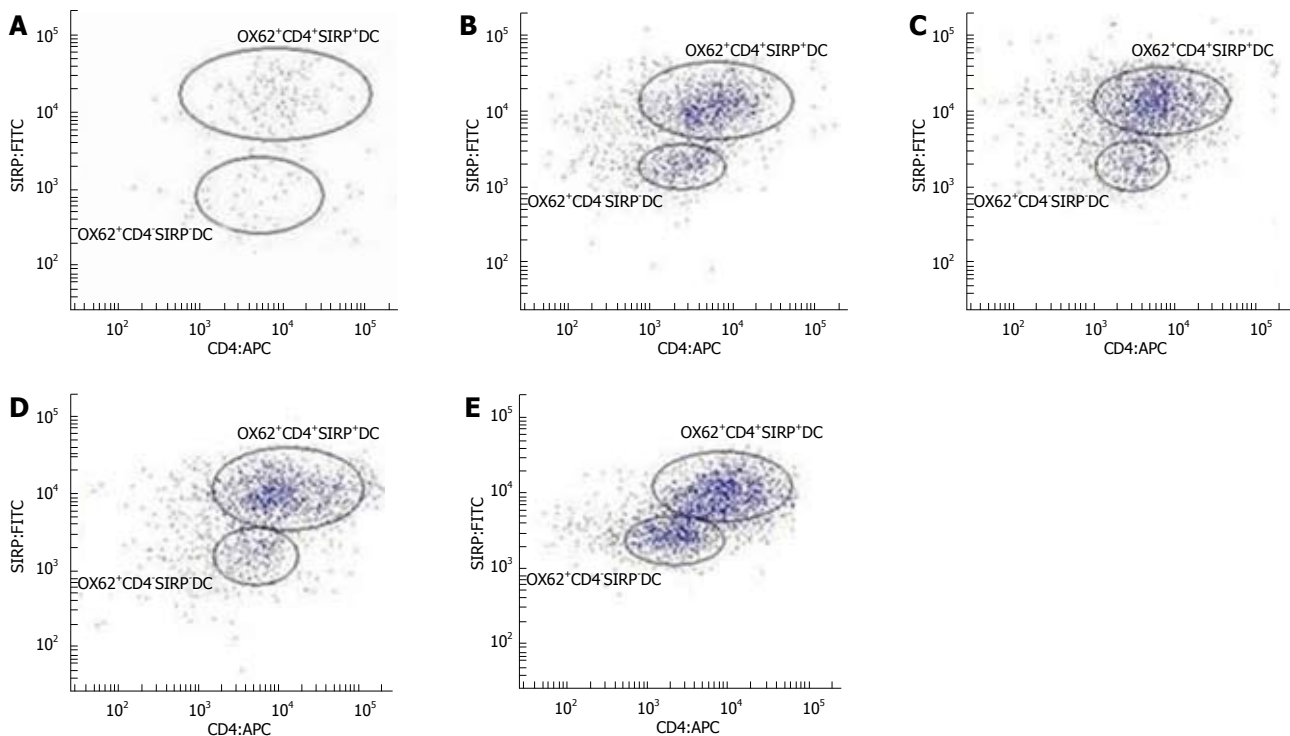

Figure 3 FCM of expression of OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC and OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC subsets at different development periods in SD rats. A: Group of 3 wk; B: Group of 5 wk; C: Group of 7 wk; D: Group of 9 wk; E: Group of 11 wk.

3 and 4, the expression of OX62<sup>+</sup>DC (i.e. the total PP-DC) increased from 33.3% ± 5.8% to 80% ± 17.3% at 3-11 wk postpartum. Moreover, age-related changes in total PP-DCs occurred as early as 3-5 wk postpartum and became more pronounced 9-11 wk postpartum. OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC subset levels detected in single-cell suspensions of rat total PP-DCs increased significantly from 30.73% ± 5.16% to 35.5% ± 4.08% at 3-5 wk postpartum and from 34.2% ± 1.35% to 43.6% ± 2.07% at 7-9 wk postpartum, whereas few age-related differences were found 9-11 wk postpartum. OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC levels varied in different age groups, whose trends were downward on the whole from 33.27% ± 5.71% to 28.43% ± 1.49% at 3-11 wk, although small fluctuations were observed 7-9 wk postpartum.

## DISCUSSION

PPs<sup>[21]</sup> are typical gut-associated lymphoid tissues located

along the small intestine wall and serve as the major sites for generation of immunity to intestinal antigens. PPs contain large amounts of immunocytes, of which DCs are the most potent antigen-presenting cell for activation of further immune response. Moreover, intestinal DC results in immune response to the intestinal mucosa, and therefore will not stimulate the immune response system. Thus, intestinal DC<sup>[22]</sup>, one of the best characters representing the maturation and activation of intestinal mucosal immunity, can exist in different levels of maturation and activation that are reflected in different ways, including antigen capture and process, effector cell activation, and cytokine networking.

It is well known that rats at 21-28 d, 28-60 d, and > 60 d postpartum approximate to the human weaning stage, childhood period, and adult period, respectively. Therefore, in our study we selected rats at the ages of 3, 5, 7, 9 and 11 wk postpartum to simulate the different human development periods. We found that DCs

**Figure 4** Flow cytometric analyses of OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup> and OX62<sup>+</sup>CD4<sup>-</sup>SIRP<sup>-</sup> PP DCs *in vivo* at 3, 5, 7, 9 and 11 wk postpartum. The results were presented as mean  $\pm$  SD from 5 rats. A: Significant growth occurred in different age groups for the number of OX62<sup>+</sup>DCs; B: Levels of OX62<sup>+</sup>CD4<sup>+</sup>OX41<sup>+</sup>DC subsets increased significantly at 3-5 wk postpartum and 7-9 wk postpartum; C: OX62<sup>+</sup>CD4<sup>-</sup>SIRP<sup>-</sup>DC levels declined on the whole, with small fluctuation from 7 to 9 wk postpartum.

isolated from single-cell suspensions of rat PP revealed OX62 expression and were subdivided based on the differential expression of CD4 and a member of the signal inhibitory regulatory protein (SIRP) family of molecules (detected by the OX41). These results concur with a previous study<sup>[17,20]</sup>. Trinite *et al*<sup>[23]</sup> have proposed that CD4 and SIRP expression levels may be related to DC developmental stages or reflect differential induction in response to the nature of the microenvironment and their expression is entirely tissue-specific and related to the function of DC in these tissues. DCs that coexpress CD4 and OX41, a member of the SIRP family, have functional properties typical of mature DCs. In contrast,

CD4<sup>+</sup>OX41<sup>+</sup>DCs are weak APCs for specific Ag, and in the allogeneic MLR survive poorly in cultures, contain large cytoplasmic inclusions, and are very strongly nonspecific esterase (NSE).

The current study revealed that development of the rat intestinal mucosa varies among different age groups, and the morphological parameters of the villous-crypt axis in the small intestine reflected proliferation and differentiation with age. Additionally, the total number of PP-DCs as well as the DC subpopulation trends varied significantly. Zaph *et al*<sup>[24]</sup> have also proposed that immune cells could promote the development of intestinal mucosa, and the mature immune system could promote the development of intestinal morphology. Our results therefore indicate that the development changes consisting of the proliferation and differentiation of intestinal morphology and the activation and maturity of intestinal immune cells (particularly DC) occurred simultaneously and not accidentally. The small intestine morphometric parameters and the total PP-DC increased with age and were more pronounced 9-11 wk postpartum, which indicates that the function of the intestinal mucosal barrier and mucosal immune system of rats gradually matured. The trend of CD4<sup>+</sup>SIRP<sup>+</sup> DC subpopulations was upward at the same time that CD4<sup>-</sup>SIRP<sup>-</sup> DC subpopulations were downward, which indicates that the immune system matured with age. The number of PP-DC subpopulations changed notably in the early post-weaning period (3-5 wk postpartum), which may be related to the change in diet from milk to solid feeding as well as intestinal adaptive adjustment induced by an increase in the number of antigens. All morphometric parameters detected in the small intestine increased promptly in rats aged 5-7 wk postpartum compared with rats at other age periods. It has been reported that the phenomenon of villous atrophy in mammals occurs after diet changes; this mechanism is related to a reduction in the rate of cell update and an increase in the rate of cell loss. Moreover, villous atrophy can also result in the intestinal immune function decline; therefore, we speculate that the phenomenon of delayed development of villous parameters may correspond to the diet change in the early post-weaning period (3-5 wk postpartum), which further impacted intestinal mucosal immune function in the late post-weaning period (5-11 wk postpartum). Finally, in the late post-weaning period, the development rate of PP-DCs decreased and the PP-DCs were in a relatively stable state. Additionally, the villous height/crypt depth ratio is a useful criterion for estimating digestive capacity in the small intestine<sup>[25]</sup>. Although a reduction in villous height occurred 7-11 wk postpartum, maintenance of the villous height/crypt depth ratio 7-11 wk postpartum suggested that a reduction in villous height was less deleterious when it was not accompanied by increased crypt depth. These results coincide with those of Montagne *et al*<sup>[25]</sup>.

In conclusion, results from the current study indicate that the intestinal mucosal immune system is continuously changing as young rats mature. This

study confirmed the age-related changes in villous-crypt axis proliferation and differentiation in the small intestine. Simultaneously, there are also developments and maturations in rat PP-DCs phenotypic expression. Furthermore, the morphological changes of intestinal mucosa and the development of immune cells (especially DC) peaked at 9-11 wk postpartum, indicating that the intestinal mucosae reached a relatively mature state at 11 wk postpartum. In the early weaning period, the number and the phenotypic expression of PP-DCs as well as the morphology changed rapidly due to ingestion of solid food, however, its mechanism requires further studies.

## COMMENTS

### Background

Recent evidences indicated that the different development period plays a role in controlling the development of gastrointestinal mucosal immunity. Peyer's patches (PPs) were the primary sites for the induction of mucosal immune responses. Dendritic cell (DC) populations play a major role in regulating gastrointestinal mucosal immune responses. The morphometry of the villous-crypt axis in the small intestine reflects the function and adaptation of intestinal mucosal barriers. It is therefore of interest to investigate the potentially disparate phenotypic expression of DC and the morphology of intestinal mucosa found in different periods.

### Research frontiers

PPs are typical gut-associated lymphoid tissues, which contain large amounts of immunocytes. The PP-DC can result in immune response to the intestinal mucosa, and therefore will not stimulate the immune response system. However, the study on DC was most thorough *in vitro* or in serum, because the techniques for DC isolation from mucosal lymphoid tissue such as PP are relatively rare. Therefore, this research investigated the PP-DCs and the morphology of intestinal mucosa at different periods as a basis for determining the mechanism by which it may initiate regulatory events that are apparently critical in intestinal mucosal immunity.

### Innovations and breakthrough

The authors evaluated, perhaps for the first time, the morphological and ontogeny of dendritic cells at different development periods. The analysis was carried out in 5 groups. As a result, all morphometric parameters (including villous height, villous width, villous areas, crypt depth, and villous height and crypt depth ratios) changed significantly with the development of pups at the different age groups ( $F = 10.751, 12.374, 16.527, 5.291, 3.486$ ;  $P < 0.05$ ). The OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC subset detected in single-cell suspensions of the rat total PP-DCs increased significantly at 3-11 wk postpartum, while the OX62<sup>+</sup>CD4<sup>+</sup>SIRP<sup>+</sup>DC levels varied in different age groups.

### Applications

This analysis of morphometric parameters and ontogeny of dendritic cells at different development periods may help further study the gastrointestinal mucosal immunity.

### Peer review

The measurement of morphometric parameters and ontogeny of immunity cells in gastrointestinal mucosa is useful for studies of gastrointestinal mucosal immunity. Although further studies are required, this study indicates the novel possibility for investigating the mucosal immunity cells in gastrointestinal.

### Abstract

**AIM:** To review the literature on capsule endoscopy (CE) for detecting esophageal varices using conventional esophagogastroduodenoscopy (EGD) as the standard.

**METHODS:** A strict literature search of studies comparing the yield of CE and EGD in patients diagnosed or suspected as having esophageal varices was conducted by both computer search and manual search. Data were extracted to estimate the pooled diagnostic sensitivity and specificity.

**RESULTS:** There were seven studies appropriate for meta-analysis in our study, involving 446 patients. The pooled sensitivity and specificity of CE for detecting esophageal varices were 85.8% and 80.5%, respectively. In subgroup analysis, the pooled sensitivity and specificity were 82.7% and 54.8% in screened patients, and 87.3% and 84.7% in the screened/patients under surveillance, respectively.

**CONCLUSION:** CE appears to have acceptable sensitivity and specificity in detecting esophageal varices. However, data are insufficient to determine the accurate diagnostic value of CE in the screen/surveillance of patients alone.

### INTRODUCTION

Variceal bleeding is a significant contributor to the morbidity and mortality associated with cirrhosis and portal hypertension. It has been estimated that up to 90% of patients with cirrhosis will ultimately develop esophageal varices<sup>[1]</sup>. Once the varices develop, the occurrence of subsequent variceal bleeding in the next 24 mo is 25%-35%, and the risk of the patient dying as a result of the index hemorrhage is up to 50%<sup>[2,3]</sup>. Esophagogastroduodenoscopy (EGD) is the most effective method of evaluating patients with portal hypertension and cirrhosis<sup>[4]</sup>. However, the procedure is unpleasant, and still associated with a small but potential risk of complications<sup>[5]</sup>. In addition, it is often carried out with the patients under sedation, which may bring additional complications in patients with cirrhosis<sup>[6]</sup>.

The PillCam ESO (Given Imaging, Israel) (esophageal capsule endoscopy, ECE) is a novel, wireless endoscope, similar in size to that of the standard PillCam small-bowel capsule endoscope (SBCE), which acquires video-images from both ends of the device during passage through the esophagus, and it has been approved by the United States Food and Drug Administration<sup>[7]</sup>. ECE provides a potentially less invasive diagnostic alternative in evaluating diseases of the esophagus such as esophageal varices, Barrett's esophagus, and gastroesophageal reflux disease (GERD)/erosive esophagitis<sup>[8-11]</sup>. Furthermore, Ramirez *et al*<sup>[12]</sup> attached a string to SBCE in the middle of the device which can allow the capsule to move up and down in the esophagus by swallowing the capsule and pulling the string. This

improvement can extend the retention time of CE in the esophagus and provide adequate information about esophageal details.

Recent years, a number of studies have been performed for evaluating CE in diagnosing esophageal disease, especially for Barrett's esophagus and esophageal varices, and the results varied<sup>[8-10]</sup>. If CE is a definitive diagnostic tool for esophageal varices, it is necessary to evaluate whether CE is sufficiently accurate for this purpose. In order to estimate the sensitivity and specificity of CE in the diagnosis of esophageal varices, a systematic review and meta-analysis of studies using CE for detecting esophageal varices with EGD as the standard was conducted.

## MATERIALS AND METHODS

### Study selection

A search in MEDLINE, EMBASE and ENBASE reviews (CDSR, ACP Journal Club, DARE, CCTR, CLCMR, CLHTA and CLEED) was conducted in May 2008. We did not confine our search to English language publications. Thorough literature retrieval for studies comparing CE and EGD for detecting esophageal varices in patients diagnosed or suspected as having esophageal varices was conducted along with a search of reference lists.

An additional search of abstracts presented at the proceedings of Digestive Disease Week (DDW) from 2004 to 2008 and international conference on CE through 2004 to 2007 was performed. If multiple updates of the same data were found, we selected only the most recent version or the most complete data for analysis. The search strategy employed is shown in Figure 1.

### Data extraction

Predefined criteria had to be met for the studies to be included. Studies comparing CE diagnostic accuracy in patients diagnosed or suspected as having esophageal varices with EGD as standard were included. CE frames were assessed by an investigator who was blinded to patient's EGD findings. The studies which met the following one or more criteria were excluded: (1) esophageal varices were detected by CE but were performed in obscure gastrointestinal bleeding patients or for assessment of small bowel diseases or in miscellaneous patients with esophageal diseases; (2) string CE was used to detect esophageal varices; and (3) studies with patient number less than 10.

The study parameters were extracted first independently and subsequently in consensus if there was a disagreement between the reviewers (Liao Z, Gao R) concerning the numeric value of a parameter. Data were extracted based on the previous reported standards. The absolute number of true-positive, false-positive, true-negative and false-negative was retrieved or calculated with Bayes theorem if values for sensitivity and specificity and predictive values were reported. These were also performed separately by the two

reviewers and subsequently checked for an agreement. The full text of papers (if available) of all relevant studies were obtained.

### Statistical analysis

Meta-analysis was undertaken using MetaDiSc statistical software (Meta-DiSc, version 1.4, Madrid, Spain) to estimate the overall sensitivity and specificity.  $\chi^2$  test was then performed to test for heterogeneity between studies, *P* value less than 0.1 was considered significant for heterogeneity. Wherever zero counts occurred for study data, a continuity correction of 0.5 was added to each value for that study. In order to define the calculation of sensitivity and specificity, fixed effect model was used when *P* value was more than 0.1 for heterogeneity test and random effect model used for *P* value was less than 0.1<sup>[13]</sup>.

## RESULTS

Eighty-one articles were selected through original searches in MEDLINE, EMBASE and ENBASE reviews (CDSR, ACP Journal Club, DARE, CCTR, CLCMR, CLHTA and CLEED) databases. Fifty-one articles were excluded after review of the titles and abstracts, leaving 30 articles for detailed evaluation by two independent reviewers. Of these, five met our inclusion criteria<sup>[10,14-17]</sup>. Two studies were identified by hand search in DDW 2008 meeting abstracts and reference lists respectively<sup>[18,19]</sup>. In total, seven studies, involving 446 patients were appropriate for meta-analysis. In the seven studies, CE type was PillCam ESO without string and they were all published in English. One study was performed in western Europe<sup>[14]</sup>, one in Australia<sup>[15]</sup>, two were international multi-center studies<sup>[10,17]</sup> and three in the USA<sup>[16,18,19]</sup>. The patient inclusion/exclusion criteria were all reported in these studies. All patients were for clinically indicated screening (suspected) or surveillance (diagnosed) of esophageal varices. EGD was performed after CE in the same day for most patients, and all patients in these studies served as their own controls. All endoscopists who assessed the CE images were blinded to the EGD diagnoses. CE transit time was variable from 134.5 s (median) to 251 s (Table 1).

Forrest plots for sensitivity and specificity are shown in Figures 2 and 3. Reported sensitivity ranged from 68.4% to 100% in the individual studies, while specificity ranged from 8.3% to 100%. The pooled estimate of sensitivity was 85.8% (95% CI: 80.5%-90.1%) and the pooled estimate of specificity was 80.5% (95% CI: 74.7%-85.5%). However, both estimates were subject to significant heterogeneity (*P* = 0.010 and *P* < 0.001, respectively). In the presence of such heterogeneity, pooled estimates should be interpreted with caution.

Studies included in our analysis were further classified into two subgroups: screening group and screening/surveillance group. There were four studies including 106 patients in the screening group, no heterogeneity (*P* = 0.166) was found for the analysis of sensitivity, and the pooled sensitivity was 82.7% (95% CI: 72.2%-90.4%),

Table 1 Summary of studies included for meta-analysis

Author and year of publication	Patients (screening)	Country	Article type	Study design	Setting	Patients inclusion/exclusion criteria reported	Two methods performed time	Transit time in esophagus
Lapalus, 2006	20 (20)	France	O	P, B	S	Yes	EGD after ECE on the same day	213 s
Eisen, 2006	32 (10)	International	O	P, B	3 centers	Yes	EGD after ECE on the same day	134.5 s (median)
Smith, 2007	15 (15)	Australia	A	NR, B	S	Yes	EGD within 1-2 h after ECE	NR
Groce, 2007	21 (21)	USA	A	P, B	S	Yes	EGD immediately after ECE	251 s

Figure 1 Search flow for Meta-analysis.

Figure 2 Pooled sensitivity of total studies included for meta-analysis.

Figure 3 Pooled specificity of total studies included for meta-analysis.

however, heterogeneity was found significant for specificity ( $P < 0.001$ ), the pooled result was 54.8% (95% CI: 36.0%-72.7%) (Figures 4 and 5). Both screened patients and patients under surveillance were included in the other three studies, involving 340 patients, and the detailed endoscopic results cannot be independently extracted for screen patients or surveillance patients. The pooled sensitivity was 87.3% (95% CI: 80.9%-92.2%) in a random effect model ( $P = 0.004$ ) and pooled specificity was 84.7% (95% CI: 78.8%-89.5%) in a fixed effect model ( $P = 0.789$ ). (Figures 6 and 7)

## DISCUSSION

Meta-analysis has been performed for SBCE in detecting small bowel disease comparing with other methods. It

is reported SBCE was superior when compared with push enteroscopy and small bowel barium radiography for OGIB ( $P < 0.00001$ )<sup>[20]</sup>. In detecting Crohn's disease, SBCE was also superior to small bowel barium radiography ( $P < 0.001$ ), colonoscopy with ileoscopy ( $P = 0.02$ ) and CT ( $P = 0.001$ )<sup>[21]</sup>. Furthermore, the yield of SBCE for small bowel diseases was similar to double-balloon enteroscopy in combination with oral and anal approaches<sup>[22]</sup>.

In the largest study performed in 11 centers (288 patients), the sensitivity and specificity were 88.0% and 84.4%, respectively, and ECE had good agreement with EGD<sup>[17]</sup>. The present meta-analysis indicates that CE appears to have acceptable sensitivity and specificity for esophageal varices with EGD as the standard. However, the limitations of these data need to be appreciated.

Figure 4 Pooled sensitivity of studies for screening patients.

Figure 5 Pooled specificity of studies for screening patients.

Figure 6 Pooled sensitivity of studies for screening/surveillance patients.

Figure 7 Pooled specificity of studies for screening/surveillance patients.

Firstly, because this new device has not been widely used for detecting esophageal varices, and the number of studies was small. Secondly, sample sizes of different studies were significantly different, ranging from 15 to 288 patients. So we considered the  $P$  value less than 0.1 as significant for heterogeneity in this analysis. At last, patients underwent CE including both screened patients and patients under surveillance, in 3 studies the detailed endoscopic results can not be extracted for these patients, and the accurate pooled diagnostic value of CE for patients under surveillance was not known.

There was considerable heterogeneity between the studies. In Pena's and Groce's studies, the sensitivity of ECE in detecting esophageal varices was only 68.4% and 77.8% respectively<sup>[16,18]</sup>. In Eisen's and Smith's studies, the sensitivity was both as high as 100%<sup>[10,15]</sup>. The diagnostic specificity of these seven studies varied significantly, the specificity was lowest in Jensen's study, only 8.3%, and the accuracy of capsule for detecting esophageal varices was modest<sup>[19]</sup>. However, in Lapalus's<sup>[14]</sup> and Pena's<sup>[16]</sup> studies, the specificity was both 100%. There was no heterogeneity in the analysis of sensitivity and specificity for the screening group and the screening/surveillance group, respectively. Although the sample was too small to undertake meta-regression to identify the cause of the heterogeneity, some potential reasons for heterogeneity may be identified. Except for the small sample size of most studies, the most possible causes for the existence of heterogeneity may be related to the experience of the endoscopists and the number of endoscopists who read the capsule images. Although the ECE investigators were all blinded to EGD findings, their experience was not described in detail. Only in Pena's study, the endoscopists were those with more than 5 years of experience in reading SBCE but no experience in reading ECE<sup>[16]</sup>. In two studies, ECE images were reviewed by two independent investigators<sup>[14,19]</sup>, and one investigator in an other five studies<sup>[10,19]</sup>.

The pooled sensitivity and specificity of the screening/surveillance group was higher than the screening group. The pooled data of screened patients

may be confused by Jensen's study, which had the largest number of patients in the screening studies and with a specificity of 8.3%<sup>[19]</sup>. In studies with screening/surveillance patients, the detailed results cannot be extracted, so the pooled data of surveillance patients cannot be obtained. One defect in the three studies was the percentages of screening or surveillance patients that were variable (Figure 1).

In summary, CE appears to have acceptable sensitivity and specificity in detecting esophageal varices, however, it seems inaccurate in screening patients based on the present data. There was insufficient data to determine the accurate diagnostic value of CE in patients under surveillance alone. Also, further researches with large numbers of patients are needed.

## COMMENTS

### Background

Capsule endoscopy (CE) has been reported to play an important role in detecting esophageal diseases, especially for esophageal varices. There are concerns about whether CE is sufficiently accurate for evaluating this disease.

### Research frontiers

Data concerning CE in detecting esophageal varices with esophagogastroduodenoscopy (EGD) results as the standard were derived from published original papers or conference abstracts. A meta-analysis was conducted to estimate the sensitivity and specificity of CE in diagnosis of esophageal varices.

### Innovations and breakthroughs

The current study demonstrated that CE appears to have acceptable sensitivity and specificity in detecting esophageal varices. However, it seems inaccurate in screening patients.

### Applications

The diagnostic accuracy of CE was low in screening patients in this study. Studies for further evaluating CE diagnostic accuracy in screening patients alone were needed.

### Terminology

Esophageal capsule endoscope (ECE) is a novel, wireless endoscope, similar in size to small-bowel capsule endoscope, which acquires video-images from both ends of the device during passage through the esophagus.

### Peer review

This meta-analysis was performed based on five peer reviewed papers and 2 in abstract form, involving about 500 patients. This study was well done, however, the missing rate of the small-sized varices is high and this tool is suitable for medium- and large-sized varices.

protein level was about 8.7-fold higher in SGC7901/VCR cells than that in SGC7901 cells, whereas the protein expression of PKC $\alpha$  was reduced by 78% in SGC7901/VCR/aPKC cells when compared with the SGC7901/VCR cells. SGC7901/VCR/aPKC cells had a 4.2-fold increase in DOX cytotoxicity, accompanied by a 1.7-fold increase of DOX accumulation in comparison with SGC7901/VCR cells.

**CONCLUSION:** PKC $\alpha$  positively regulates MDR in SGC7901 cells, and inhibition of PKC $\alpha$  can partially attenuate MDR in human gastric cancer cells.

Antisense expression of PKC $\alpha$  improved sensitivity of SGC7901/VCR cells to doxorubicin. *World J Gastroenterol* 2009; 15(10): 1259-1263 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1259.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1259>

### Abstract

**AIM:** To explore whether antisense blocking of protein kinase C alpha (PKC $\alpha$ ) would reverse multi-drug resistance (MDR) in the vincristine (VCR)-resistant human gastric cancer cell line SGC7901/VCR.

**METHODS:** SGC7901/VCR cells expressing antisense PKC $\alpha$ , SGC7901/VCR/aPKC, were established by transfection with a recombinant plasmid reversely inserted with PKC $\alpha$  cDNA. Empty vector (PCI-neo)-transfected cell clones, SGC7901/VCR/neo, served as the control. Western blot method was used to detect PKC $\alpha$  content in SGC7901, SGC7901/VCR, SGC7901/VCR/neo and SGC7901/VCR/aPKC cells, using PKC $\alpha$ -specific antibody. The sensitivity of SGC7901, SGC7901/VCR, SGC7901/VCR/neo and SGC7901/VCR/aPKC cells to doxorubicin (DOX) *in vitro* was determined by MTT assay. The uptake of DOX in these cells was detected with fluorescence spectrophotometer.

**RESULTS:** Western blot analysis showed that the PKC $\alpha$

### INTRODUCTION

Resistance of cancer cells to chemotherapeutic drugs is a major problem in clinical treatment of cancer. Multi-drug resistance (MDR) is the most important form of drug resistance characterized by decreased cellular sensitivity to a broad range of chemotherapeutic drugs, including anthracyclines, vinca alkaloids, epipodophyllotoxins, taxanes, antibiotics and some of the new topo- I inhibitors<sup>[1,2]</sup>. Classical MDR is mainly caused by overexpression of P-glycoprotein (Pgp), which is coded by the MDR1 gene and functions as an ATP-dependent drug-efflux membrane transporter that rapidly extrudes a variety of hydrophobic anticancer drugs from exerting cytotoxic effect<sup>[3,4]</sup>. Additionally, studies have shown that MDR is also accompanied by changes in the activity of protein kinase C (PKC).

Activation of PKC results in phosphorylation of Pgp and a decrease in drug accumulation, while inhibition of PKC can partially reverse the MDR phenotype<sup>[5,6]</sup>.

PKC comprises a family of at least 12 distinct serine/threonine kinase isoenzymes which are found in varying ratios in the cytosolic and membrane fractions of cells, depending on the type of issue and its physiological state<sup>[6,7]</sup>. The family of PKC is composed of three subclasses: classical, novel and atypical PKC, each having different isoforms. The members of the classical PKCs ( $\alpha$ ,  $\beta$  I,  $\beta$  II and  $\gamma$ ) bind phorbol esters and are  $\text{Ca}^{2+}$  dependent. The novel PKCs ( $\delta$ ,  $\epsilon$  and  $\eta$ ) do not depend on  $\text{Ca}^{2+}$  but bind phorbol esters. The third subfamily includes the atypical PKCs ( $\tau$ ,  $\zeta$ ,  $\lambda$  and  $\mu$ ), which do not bind to either  $\text{Ca}^{2+}$  or phorbol ester. It is likely that each isoform has a specific role in a given cell<sup>[5,7]</sup>. PKC regulates numerous cell processes including proliferation, apoptosis and differentiation by phosphorylating proteins in response to transmembrane signals from hormones, growth factors, neuro-transmitters and pharmacological agents<sup>[5]</sup>. Recently accumulated evidence indicated that PKC, especially classical PKC, plays a significant role in the formation of cancer MDR<sup>[5,6]</sup>. The isoenzymes of PKC possess distinct differences in localization in different cells, and research on distinct function of isoforms in cancer MDR has important significance<sup>[5,6]</sup>.

Among those isoforms of PKC, PKC $\alpha$  is likely to play a decisive role in maintaining MDR phenotypes in some cancer cells, and may therefore represent potential novel targets for the treatment of cancers<sup>[6,8-12]</sup>. In an effort to see whether down-regulation of a single isoform of PKC could affect drug resistance, vincristine (VCR)-resistant human gastric carcinoma cell line SGC7901/VCR was transfected with an expression vector containing the cDNA for PKC $\alpha$  in the antisense orientation, and their expression of PKC $\alpha$ , doxorubicin (DOX) sensitivity and DOX accumulation were determined.

## MATERIALS AND METHODS

### Materials

MTT and DOX were purchased from Sigma, VCR from the Twelfth Shanghai Pharmaceutical Product Factory, Lipofectamine 2000 from Invitrogen, nitrocellulose membranes and 3', 3'-diaminobenzidine (DAB) from Sigma, G418 and rabbit polyclonal anti-PKC $\alpha$  from Gibco-BRL. Plasmid pSP64-PKC $\alpha$  was kindly provided by Dr. PJ Parker (Imperial Cancer Foundation, England). The eukaryotic expression vector, plasmid PCI-neo, was kindly provided by Dr. Jun-Jie Xu (Institute of Microbiology and Epidemiology, Chinese Academy of Military Medical Sciences). The human gastric cancer cell line SGC7901, and its VCR-resistant counterpart SGC7901/VCR selected by stepwise exposure of parental SGC7901 cells to increasing concentrations of VCR, were purchased from Wuhan University Type Culture Collection (Wuhan, China).

### Cell culture

Both SGC7901 and SGC7901/VCR cells were grown in

RPMI-1640 medium supplemented with 10% fetal calf serum at 37°C in a humidified atmosphere of 5%  $\text{CO}_2$ . The SGC7901/VCR cells were cultured in the presence of 0.8  $\mu\text{mol/L}$  VCR and grown in drug-free medium 2 wk before the experiments.

### Plasmid construction

The full-length cDNA encoding PKC $\alpha$  cDNA (2.3 kb) was recovered from Sal I sites in pSP64-PKC $\alpha$  plasmid and subcloned into Sal I sites of PCI-neo plasmid. The recombinant plasmid with the PKC $\alpha$  cDNA in the antisense orientation was confirmed by BamH1 and/or Sal I restriction digestion, and designated PCI-neo-aPKC $\alpha$ .

### Cloning of cells transfected with antisense vector PCI-neo-aPKC $\alpha$

The process was performed as described by Wang *et al*<sup>[13]</sup>. Briefly, SGC7901/VCR cells were seeded in six-well plates to 70%-80% confluence. Empty vector PCI-neo and antisense vector PCI-neo-aPKC $\alpha$  were transfected into SGC7901/VCR cells *via* Lipofectamine 2000. The two kinds of transfected cells were named SGC7901/VCR/neo and SGC7901/VCR/aPKC respectively. After two days of transfection, cells were selected by culture medium containing G418 (400 mg/L) for 2 wk. The single clone was picked out using limiting dilution method and was expanded and maintained in medium containing 400 mg/L G418 until 1 wk prior to experiments.

### Western blot analysis

The whole cell lysates were extracted with lysis buffer containing 1% Triton-100, 50 mmol/L NaCl, 50 mmol/L sodium fluoride, 20 mmol/L Tris (pH 7.4), 1 mmol/L EDTA, 1 mmol/L EGTA, 1 mmol/L sodium vanadate, 0.2 mmol/L phenylmethylsulfonyl fluoride, and 0.5% NP40. An aliquot was taken for protein determination, and the remainder was mixed (1:1) with 2  $\times$  SDS sample buffer and boiled for 5 min. Samples were run on 10% SDS-PAGE and electrophoretically transferred to nitrocellulose membranes. After blocking, the membranes were incubated with rabbit polyclonal antibody against PKC $\alpha$  isoform at a dilution of 1:1000. Blots were washed three times with PBST to block nonspecific binding sites and incubated with secondary antiserum (goat anti-rabbit IgG conjugated to horseradish peroxidase) for 1 h at 37°C, then washed three times with 50 mmol/L Tris-HCl (pH 6.8). Color was developed with DAB as the substrate.

### Cytotoxicity assay

The cells in exponential growth were seeded in 96-well plates at a density of  $2 \times 10^4$  cells per well and 24 h later graded DOX (at the concentrations of 0, 0.01, 0.03, 0.1, 0.3, 1.0, 3.0, 10  $\mu\text{mol/L}$ ) were added, respectively. The total medium volume of each well was 200  $\mu\text{L}$ . Three days after drug addition, 10  $\mu\text{L}$  MTT (5.0 g/L in PBS) was added. After 4 h of incubation, supernatants were removed and replaced by 150  $\mu\text{L}$  DMSO. After formazan solubilization, the absorbance at 570 nm

**Figure 1** Restriction map of recombinant plasmid PCI-neo-aPKC $\alpha$ . Lane 1: PCI-neo digested with *Sal* I/*Eco*RI; Lane 2: PCI-neo-aPKC $\alpha$  digested with *Bam*HI; Lane 3: PCI-neo-aPKC $\alpha$  digested with *Sal* I; Lane 4: PCI-neo-aPKC $\alpha$  digested with *Bam*HI + *Sal* I; Lane M:  $\lambda$  DNA *Hind*III Marker.

was recorded using an automated microplate reader. IC<sub>50</sub> (concentration resulting in 50% inhibition of cell growth) values for DOX were calculated as 100% from plotted results using untreated cells.

### Intracellular DOX accumulation

The assay was performed as described by our previous report<sup>[2]</sup>. Briefly,  $1.0 \times 10^6$  cells were exposed to 4.0  $\mu$ mol/L DOX for 60 min. Following incubation, the cells were washed twice with ice-cold PBS, then suspended in 6.0 mL of 50% ethanol -0.3 mol/L hydrochloride, extracted for 2 h, centrifugated at  $100 \times g$  for 10 min, and the supernatant was collected. DOX-associated mean fluorescence intensity (MFI) was measured by fluorescence spectrophotometer at an excitation wavelength of 488 nm and an emission wavelength of 590 nm. The DOX standard solution ( $0.1$ - $1.0 \times 10^3$  nmol/L) was prepared, and a standard work curve with related quotient was constructed.

### Statistical analysis

Data were expressed as mean  $\pm$  SD. Student's *t* test was used to assess statistical significance of differences. *P* < 0.05 was considered statistically significant.

## RESULTS

### Establishment of SGC7901/VCR cells expressing antisense PKC $\alpha$

To construct the PKC $\alpha$  antisense expression plasmid, the full-length cDNA of PKC $\alpha$  (2.3 kb) recovered from *Sal* I sites in pSP64-PKC $\alpha$  plasmid was subcloned into *Sal* I sites of the eukaryotic expression vector PCI-neo (5.5 kb). A recombinant plasmid with PKC $\alpha$  cDNA in the antisense orientation was obtained and designated PCI-neo-aPKC $\alpha$ , which contains the neomycin resistance gene neo for drug selection. Two fragments were obtained by digesting PCI-neo-aPKC $\alpha$  with *Sal*I, one was PKC $\alpha$  cDNA fragment about 2.3 kb and the other was PCI-neo cDNA fragment about 5.5 kb (Figure 1). And the inserted fragment was verified by sequencing (data not shown).

**Figure 2** Western blot identification of PKC $\alpha$  protein in SGC7901, SGC7901/VCR, SGC7901/VCR/neo and SGC7901/VCR/aPKC cells. Lane M: Benchmark™ Marker; Lane 1: SGC7901 cells; Lane 2: SGC7901/VCR/aPKC cells; Lane 3: SGC7901/VCR/neo cells; Lane 4: SGC7901/VCR cells.

SGC7901/VCR cells were transfected with either PCI-neo or PCI-neo-aPKC $\alpha$ , respectively, and G418-resistant clones were isolated and amplified after G418 selection. Empty vector-transfected cell clones were named SGC7901/VCR/neo, which together with the parental cell line served as the controls for these experiments. Clones transfected with the PKC $\alpha$  antisense expression plasmid (PCI-neo-aPKC $\alpha$ ) were named SGC7901/VCR/aPKC.

Western blot analysis was performed to assess protein abundance of PKC $\alpha$  in SGC7901, SGC7901/VCR, SGC7901/VCR/aPKC and SGC7901/VCR/neo cells. As shown in Figure 2, the PKC $\alpha$  protein level was about 8.7-fold higher in SGC7901/VCR cells than that in SGC7901 cells. Transfection of SGC7901/VCR cells with the control vector did not alter PKC $\alpha$  expression, whereas the protein expression of PKC $\alpha$  was reduced by 78% in SGC7901/VCR/aPKC cells when compared with the SGC7901/VCR cells.

### Modulating effect of antisense expression of PkC $\alpha$ on MDR

Using the MTT assay, the *in vitro* cytotoxicity of DOX in SGC7901, SGC7901/VCR, SGC7901/VCR/neo and SGC7901/VCR/aPKC cells was examined. As shown in Table 1, SGC7901/VCR cells were 23.5 times more resistant to DOX in comparison with SGC7901 cells. The IC<sub>50</sub> in SGC7901/VCR/aPKC was 4.2-fold lower than that in SGC7901/VCR cells, indicating that antisense PkC $\alpha$  could partially reverse resistance to DOX in multi-drug resistant SGC7901 cells.

### Effect of antisense expression of protein kinase C $\alpha$ on intracellular accumulation of DOX in multi-drug resistant SGC7901 cells

DOX accumulation in SGC7901, SGC7901/VCR, SGC7901/VCR/neo cells and SGC7901/VCR/aPKC was measured by fluorescence spectrophotometry after incubation of cells with 4.0  $\mu$ mol/L DOX for 60 min. As shown in Figure 3, SGC7901/VCR cells accumulated 4.3-fold less DOX than SGC7901 cells, whereas SGC7901/VCR/aPKC cells showed 1.7-fold more drug retention than SGC7901/VCR cells.

**Table 1** Modulating effect of antisense expression of protein kinase C $\alpha$  on resistance to DOX in multi-drug resistant SGC7901 cells

Cell lines	IC <sub>50</sub> of DOX ( $\mu$ mol/L)	Resistance index (RI)
SGC7901	0.076 $\pm$ 0.0074	1.0
SGC7901/VCR	2.4 $\pm$ 0.14 <sup>b</sup>	31.6
SGC7901/VCR/neo	2.3 $\pm$ 0.19 <sup>b</sup>	30.3
SGC7901/VCR/aPKC	0.58 $\pm$ 0.076 <sup>b</sup>	7.6

<sup>b</sup>P < 0.01 vs IC<sub>50</sub> of SGC7901. The data are presented as mean  $\pm$  SD.

**Figure 3** Accumulation of intracellular DOX in SGC7901, SGC7901/VCR, SGC7901/VCR/neo and SGC7901/VCR/aPKC cells. Cells were incubated with 4.0  $\mu$ mol/L DOX for 60 min. Each point represents the mean  $\pm$  SD from three experiments. <sup>b</sup>P < 0.01 vs SGC7901/VCR cells.

## DISCUSSION

MDR to cancer treatment has been studied for more than 20 years. No useful method of reversing MDR suitable for clinical use has yet emerged from this large quantity of work. The reason could be complicated mechanisms involved. There are several ways for cancer cells to develop MDR<sup>[4]</sup>. The most investigated mechanisms with known clinical significance are: (1) activation of transmembrane proteins effluxing different chemical substances from the cells, in which Pgp is the best known efflux pump; (2) activation of the enzymes of the glutathione detoxification system; (3) alterations of the genes and the proteins involved in the control of apoptosis (especially p53 and Bcl-2)<sup>[10]</sup>. Recent studies have indicated a role for PKC in the regulation of the MDR phenotype. A number of studies have demonstrated that PKC activity was elevated in MDR-selected cell lines, and several PKC inhibitors are able to partially reverse MDR and inhibit Pgp phosphorylation<sup>[5,6]</sup>. Pgp is phosphorylated by PKC and that phosphorylation positively modulates its transport function<sup>[14]</sup>. The PKC family consists of at least 12 isoforms, and different isoforms of PKC possess distinct differences in expression and function in different MDR cells<sup>[12-15]</sup>. The elevated PKC activity level of the MDR cancer cells was frequently a result of increased PKC $\alpha$  expression in most cancers<sup>[8-12]</sup>, but in some cancers it was due to enhanced expression of other isoforms, such as PKC $\beta$  I, PKC $\gamma$  or PKC $\eta$ <sup>[15-18]</sup>.

SGC7901/VCR is an established VCR-resistant cell line selected by stepwise exposure of parental SGC7901 cells to increasing concentrations of VCR. Previous reports have proved that the SGC7901/VCR cells possess the characteristics of classical MDR with overexpression of Pgp, and the SGC7901/VCR cell line has been successfully used as an *in vitro* MDR reversal model by several study groups, including ours<sup>[19-23]</sup>. The recent report showed that the expression of PKC $\alpha$  was significantly higher in SGC7901/VCR cells than in SGC7901 cells, and there was no significant difference in the expression of PKC $\beta$  I, PKC $\beta$  II and PKC $\gamma$  between SGC7901/VCR and SGC7901 cells<sup>[10]</sup>.

In the present study, we observed that the expression of PKC $\alpha$  was significantly higher in SGC7901/VCR cells than in SGC7901 cells, which was consistent with the previous report by Han *et al*<sup>[10]</sup>. To investigate the possible effect of PKC $\alpha$  on MDR for chemotherapeutic drug in human gastric cancer cells, we established SGC7901/VCR cells stably expressing antisense PKC $\alpha$ . We demonstrated that down-regulation of the predominant PKC $\alpha$  isoform expressed in SGC7901/VCR cells by the expression of antisense PKC $\alpha$  led to greater DOX accumulation and partial reversal of resistance to DOX. These data support the thesis that MDR in this cell line is modulated, in part, by PKC $\alpha$ . These results suggest that a more effective means of reducing PKC $\alpha$  activity, possibly with RNA interference, might be a more efficient way of increasing drug sensitivity in this MDR cell line.

## COMMENTS

### Background

Protein kinase C (PKC) constitutes a family of closely related protein serine/threonine kinase which are sub-grouped into classical ( $\alpha$ ,  $\beta$  I,  $\beta$  II, and  $\gamma$ ), novel ( $\delta$ ,  $\epsilon$ ,  $\eta$ , and  $\theta$ ), and atypical ( $\iota$  and  $\zeta$ ) isoforms. The members of the PKC family are involved in the regulation of numerous cell processes including proliferation, apoptosis, and differentiation. It is likely that each isoform has a specific role in a given cell.

### Research frontiers

A recent study confirmed that PKC $\alpha$ , PKC $\beta$  I, PKC $\beta$  II and PKC $\gamma$  were expressed in both human gastric carcinoma cell line SGC7901 and vincristine (VCR)-resistant human gastric carcinoma cell line SGC7901/VCR, but the expression of PKC $\alpha$  was significantly higher in SGC7901/VCR cells than that in SGC7901 cells. There was no significant difference in the expression of PKC $\beta$  I, PKC $\beta$  II and PKC $\gamma$  between SGC7901/VCR cells and SGC7901 cells. In this report, the authors transfected SGC7901/VCR cells with an expression vector containing the cDNA for PKC $\alpha$  in the antisense orientation to see whether down-regulation of PKC $\alpha$  could affect drug resistance in SGC7901/VCR cells.

### Innovations and breakthroughs

In the present study the authors observed that down-regulation of the predominant PKC $\alpha$  isoform expressed in SGC7901/VCR cells by the expression of antisense PKC $\alpha$  led to greater doxorubicin accumulation and partial reversal of resistance to doxorubicin. These data support the thesis that MDR in this cell line is modulated in part by PKC $\alpha$ .

### Applications

This study provided a new target against MDR in human gastric carcinoma, suggesting that a more effective means of reducing PKC $\alpha$  activity, possibly with RNA interference, might be a more efficient way of increasing drug sensitivity in this MDR cell line.

### Peer review

The manuscript entitled "Antisense expression of PKC $\alpha$  improved sensitivity of SGC7901/VCR cells to doxorubicin" by Wu *et al* examines the effects of anti-

sense inhibition of PKC $\alpha$  expression on the MDR phenotype of gastric cancer cells. The authors used antisense technology to establish a derivative of the multi-drug/vincristine-resistant SGC7901-VCR cell line with reduced expression of PKC $\alpha$ . Using this isogenic pair of cell lines, the authors conclude that PKC $\alpha$  deficiency leads to increased intracellular accumulation of DOX and partially restores sensitivity to the drug, thus reversing the MDR phenotype.

## Abstract

Cannabis is a common drug of abuse that is associated with various long-term and short-term adverse effects. The nature of its association with vomiting after chronic abuse is obscure and is underrecognised by clinicians. In some patients this vomiting can take on a pattern similar to cyclic vomiting syndrome with a peculiar compulsive hot bathing pattern, which relieves intense feelings of nausea and accompanying symptoms. In this case report, we describe a twenty-two year-old-male with a history of chronic cannabis abuse presenting with recurrent vomiting, intense nausea and abdominal pain. In addition, the patient reported that the hot baths improved his symptoms during these episodes. Abstinence from cannabis led to resolution of the vomiting symptoms and abdominal pain. We conclude that in the setting of chronic cannabis abuse, patients presenting with chronic severe nausea and vomiting that can sometimes be accompanied by abdominal pain and compulsive hot bathing behaviour, in the absence of other obvious causes, a diagnosis of cannabinoid hyperemesis syndrome should be considered.

## INTRODUCTION

Cannabis has been used recreationally for millennia and is the third most commonly used drug after tobacco and alcohol<sup>[1,2]</sup>. Research into the neurobiology of the compound has led to the discovery of an endogenous cannabinoid system. The therapeutic potential of cannabinoids has been recognized and these compounds are utilized as anti-emetics<sup>[3-5]</sup>. Recently, a distinct syndrome in chronic cannabis abusers characterized by recurrent vomiting associated with abdominal pain and a tendency to take hot showers has been increasingly recognised. This clinical manifestation is paradoxical to the previously identified therapeutic role of cannabinoids as anti-emetics. We describe the case of a young male seeking repeated emergency room care with recurrent nausea and vomiting.

## CASE REPORT

A 22-year male presented with recurrent episodes of nausea, refractory vomiting, and colicky epigastric pain for one week. The symptoms were characterized by treatment-resistant nausea in the morning, continuous vomiting, and colicky epigastric abdominal pain. Each episode lasted 2 to 3 h and increased with food intake. He often had two or more episodes a day during the symptomatic period. He had been treated for the severe nausea and vomiting in the emergency room on two occasions in the preceding two months. He also reported having learned to help himself by taking a hot bath each time the symptoms appeared, which dramatically

improved his symptoms. This habit had become a compulsion for him for symptom relief with each episode of hyperemesis. On physical examination his mucous membranes were dry, his pulse rate was 102/min and blood pressure was 140/100 with positive orthostasis. The remainder of the physical examination was unremarkable. His complete blood count and comprehensive metabolic panel were unremarkable. In addition, serum amylase and lipase levels were within the normal range. His urine drug screen was positive for tetrahydrocannabinol (THC). Abdominal X-ray series and ultrasonography were within normal limits.

Oesophagogastroduodenoscopy revealed Grade 2 distal oesophagitis and hiatal hernia. On further interviewing, he admitted to consistent marijuana abuse for the past 6 years, often smoking cannabis every hour or two on a daily basis. The patient and his mother did not recall any significant past illnesses or recurrent vomiting when he was a child. He was treated with intravenous fluids with steady improvement in symptoms, and metoclopramide, pantoprazole and morphine for the abdominal pain. It was explained that marijuana was the cause of his symptoms and he was advised not to resume marijuana abuse. On subsequent follow-up, he had abstained from cannabis and remained symptom-free.

## DISCUSSION

Cannabis is one of the most commonly abused drugs worldwide. Over the past decade, marijuana has remained the most commonly used illicit substance with close to 50% of high school seniors admitting use at some time<sup>[1]</sup>. It is estimated that each year 2.6 million individuals in the USA become new users and most are younger than 19 years of age<sup>[6]</sup>.

The long-term and short-term toxicity of cannabis abuse is associated with pathological and behavioural effects. However, cannabis has also been suggested to have therapeutic properties with anticonvulsive, analgesic, antianxiety and anti-emetic activities. Cannabis has also been used to treat anorexia in patients with acquired immunodeficiency syndrome<sup>[3-5]</sup>. The actions of cannabis are mediated by specific cannabinoid receptors. The first of the cannabinoid receptors-CB-1-was identified in 1990 and this finding revolutionized the study of cannabinoid biology. Since then, a multitude of roles for the endogenous cannabinoid system has been proposed. A large number of endogenous cannabinoid neurotransmitters or endocannabinoids have been identified, and the CB-1 and CB-2 cannabinoid receptors have been characterized<sup>[7]</sup>. The CB-1 receptors exert a neuromodulatory role in the central nervous system and enteric plexus<sup>[8]</sup>. Cannabinoid type 2 receptors have an immunomodulatory effect and are located on tissues such as microglia<sup>[5]</sup>. The presence of other receptors, transporters, and enzymes responsible for the synthesis or metabolism of endocannabinoids are being recognised at an extraordinary pace. Cannabinoids have a wide variety of effects on the body systems and physiologic states (Table 1) due to their actions on the

**Table 1** Harmful effects of cannabinoids on body systems<sup>[1,6,7]</sup>

receptors as well as direct toxic effects.

The anti-emetic effect of cannabinoids is largely mediated by CB-1 receptors in the brain and the intestinal tract, although some of their effect may also be receptor-independent. However, in this report, we were presented with the paradoxical effect of hyperemesis in a susceptible chronic cannabis abuser. Such a paradoxical response has previously only been demonstrated following acute toxicity to an intravenous injection of crude marijuana extract<sup>[9]</sup>. Proposed mechanisms of cannabinoid hyperemesis include toxicity due to marijuana's long half-life, fat solubility, delayed gastric emptying, and thermoregulatory and autonomic disequilibrium *via* the limbic system<sup>[10]</sup>. Cannabinoids are known to impair peristalsis in a dose-dependent manner<sup>[11,12]</sup>, which can theoretically override the centrally mediated anti-emetic effects, thus leading to hyperemesis. It is not known why the hyperemesis syndrome surfaces after several years of cannabis abuse. The effects of cannabinoids on the functions of the thermoregulatory and autonomic mechanisms of the brain can lead to behavioural changes<sup>[10]</sup>. Such effects might be the underlying mechanism for the compulsive hot bathing behaviour. There is also a supposition that the syndrome could represent a type of cyclic vomiting. Cyclic vomiting syndrome (CVS) in adults is now very well recognized, and it has been proposed that marijuana contributes to CVS<sup>[13]</sup>. However, unlike the other forms of CVS, patients with cannabinoid hyperemesis are not likely to have a history of migraine or other psychosocial stressors and the peculiar behaviour of hot showers is

**Table 2 Clinical diagnosis of cannabinoid hyperemesis****Essential for diagnosis:**

History of regular cannabis use for years

**Major clinical features of syndrome**

Severe nausea and vomiting

Vomiting that recurs in a cyclic pattern over months

Resolution of symptoms after stopping cannabis use

**Supportive features**

Compulsive hot baths with symptom relief

Colicky abdominal pain

No evidence of gall bladder or pancreatic inflammation

unique to this syndrome.

Based on the published research and case reports<sup>[10,14-16]</sup>, we propose the set of clinical characteristics for the diagnosis of cannabinoid hyperemesis syndrome shown in Table 2. Allen *et al*<sup>[10]</sup> first noted this condition in a group of nineteen patients from Australia with chronic cannabis abuse and cyclical vomiting illness. An earlier case report by de Moore *et al*<sup>[17]</sup> described a chronic cannabis abuser with psychogenic vomiting, which was complicated by spontaneous pneumomediastinum. Subsequent reports have identified similar clinical presentations<sup>[7-9,18]</sup>. Given the high prevalence of chronic cannabis abuse worldwide and the paucity of reports in the literature, clinicians need to be more attentive to the clinical features of this underrecognised condition.

### Abstract

A liver tumor 35 mm in diameter was found incidentally in a 40-year-old woman who had no history of liver diseases or the use of oral contraceptives. Radiological diagnostics showed the typical findings of liver cell adenoma (LCA). Dynamic computed tomography revealed that the tumor showed a homogenous enhancement in the arterial phase and almost the same enhancement as the surrounding liver parenchyma in the delayed phase. The tumor was found to contain fat on magnetic resonance imaging. A benign fat containing liver tumor was suggested. However, radiological findings altered, which caused us to suspect that a well-differentiated hepatocellular carcinoma (HCC) containing fat was becoming dedifferentiated. Partial hepatectomy was performed and the pathological findings showed the typical findings of LCA. This case was an extremely rare LCA, which had no background of risk for LCA and developed the sequential alteration of the radiological findings to suspect well-differentiated HCC.

### INTRODUCTION

Liver cell adenoma (LCA) is a benign tumor of the liver parenchyma that is associated with the use of oral contraceptives or with glycogen-storage disease<sup>[1]</sup>. The occurrence of LCA in patients without such backgrounds is extremely rare<sup>[2]</sup>. We report a case of LCA found in a 40-year-old woman without a history of oral contraceptive use in which the sequential alteration of the radiological findings suggested well-differentiated hepatocellular carcinoma (HCC).

### CASE REPORT

In November 2006, a 40-year-old woman developed lower abdominal pain and was admitted to a hospital. The patient had no history of liver disease, alcohol consumption, oral contraceptive use, nor the use of any other medication. The family history of the patient was not noteworthy. The patient was diagnosed as having a left tubo-ovarian abscess and tubo-ovariectomy was performed. The resected ovary and oviduct showed the findings of endometriosis with bacterial infection, but there was no indication of neoplastic lesion. At this time, a space-occupying lesion (SOL) 35 mm in diameter was found in the liver by abdominal ultrasonography and computed tomography (CT). In the CT, the lesion in

**Figure 1** Magnetic resonance imaging (MRI). A: T1; B: T2; C: T2-SPIO; D: Plain; E: Arterial phase; F: Portal phase; G: Delayed phase; H: T1 in phase; I: T1 opposed phase.

the liver (segment 8) showed slight low density by plain examination and an enhancing effect by the contrast agent. In the magnetic resonance imaging (MRI), the SOL showed almost isointensity on T1 and slightly high intensity on T2 (Figure 1A-B). Superparamagnetic iron-oxide (SPIO)-MRI indicated that the SOL did not show most of the SPIO uptake (Figure 1C). On the gadolinium-enhanced T1, the SOL indicated a slight homogenous enhancement in the arterial phase, and almost the same enhancement as the surrounding liver parenchyma in the delayed phase (Figure 1D-G). The SOL showed almost isointensity on the in-phase-T1 and slightly low intensity on the opposed-phase-T1, which indicated that the SOL contained a fat component (Figure 1-H, 1-I). A capsule or scars were not detected in the SOL. A benign, fat containing tumor was suggested. The dynamic CT in March 2007 showed that the SOL had not changed in size (Figure 2). The SOL indicated low density by plain examination, showed a slight homogenous enhancing effect in the arterial phase, and, an enhancing effect that was slightly lower than the surrounding liver in the delayed phase (Figure 2). In the

dynamic CT after four months, the density of the SOL on plain examination was elevated and the enhancing effect in the arterial phase increased slightly, although the size and the form of the SOL did not show apparent changes (Figure 3). Because of the alteration of the findings in this CT, we suspected that the findings were suggestive of well-differentiated HCC. In August 2007, the patient was referred to our hospital for further examination and treatment. The physical examination of the patient showed no abnormal findings. The blood test indicated no abnormalities including liver related enzymes except slight iron deficiency anemia (Table 1). All the hepatitis virus markers were negative. There were no abnormal findings suggestive of autoimmune liver disease or metabolic liver disease including glycogen-storage disease. Hepatic arteriography was performed and the nodule presented with a slight tumor stain in the arterial phase and the hepatic parenchymal phase, and it did not show an apparent drainage vein (Figure 4). Positron emission tomography showed no difference in accumulation between the nodule and the surrounding hepatic parenchyma and no abnormal accumulation

suspicious of malignant tumors in other organs. No abnormal findings were found suggesting a primary tumor in other organs in whole-body CT. Digestive tract endoscopy showed no abnormal findings. Taken together, the above-mentioned findings suggested the

**Figure 5** Pathological findings. A: Hematoxylin and eosin staining, original magnification,  $\times 50$ ; B: Hematoxylin and eosin staining, original magnification,  $\times 200$ . Arrow: Myogenic artery.

possibility that the nodule was a well-differentiated HCC that was dedifferentiating. After receiving informed consent, partial hepatectomy was performed on August 28, 2007.

The pathological finding (Figure 5) revealed the following. Hepatocytes more lucent than that of the surrounding hepatic parenchyma had proliferated thickly in the nodule. Hepatocytes did not show severe cellular atypia. Exclusion of the surrounding hepatic parenchyma was apparent, but direct invasion to the surrounding was not seen. The nodule did not contain the portal tracts and bile ducts. Myogenic arteries, large lipid droplets, hemorrhage and degeneration were seen in the nodule. The surrounding hepatic parenchyma had no abnormal findings except fatty change with large lipid droplets around the nodule. Thus, we diagnosed the nodule as a LCA.

## DISCUSSION

LCA is considered a rare benign tumor of the liver and is distinguished from solitary tumors and adenomatosis<sup>[3,4]</sup>. LCA was a very rare tumor until an association with oral contraceptives was reported. Before 1954, only two cases were detected among 5000 autopsies in 36 years<sup>[5]</sup>. The association with oral contraceptives was thoroughly described in the 1970s<sup>[6,7]</sup>, and many cases of LCA have been reported since<sup>[8-10]</sup>.

Due to the progress of diagnostic imaging techniques, the typical findings of LCA have been identified<sup>[4,11]</sup>. A typical LCA shows low density or isodensity on plain

CT, presents a homogenous contrasting effect on arterial phase and does not show an apparent wash out on delayed phase. A typical LCA in MRI shows almost the same signal intensity as the surrounding parenchyma on T1 and T2 and shows high intensity on fat suppression T2. LCA may often present difficulties in a differential diagnosis with well-differentiated HCC and focal nodular hyperplasia<sup>[12-14]</sup>. The pathological findings of a typical LCA include the following<sup>[2,10,15-17]</sup>: (1) the tumor consists of hepatocytes with almost normal nuclei and cytoplasm presenting a homogenous increase, (2) and does not include the portal area and bile duct, (3) hepatocytes form hepatic cords, but sinusoids are pressed, and hepatic lobule structure is absent, (4) the tumor includes macrovesicular fatty changes, hemorrhage, degeneration, and myogenic arteries.

LCA can be divided into three categories: (1) LCA associated with oral administration of medicines including oral contraceptives and steroids<sup>[8-10]</sup>, (2) LCA developing as a complication of glycogen-storage diseases<sup>[18-20]</sup>, (3) adenomatosis<sup>[3,4,15]</sup>. Solitary LCAs are most frequently caused by oral contraceptives<sup>[7,21]</sup>. The occurrence of adenomatosis is unrelated to the use of oral contraceptives and the frequency of development is not related to sex<sup>[15]</sup>. It is reported that LCA occurs in patients of glycogen-storage disease type I<sup>[19]</sup>. In addition to oral contraceptives, oral administrations of such medications as clomiphene<sup>[22]</sup>, barbituric acid<sup>[23]</sup> or androgen<sup>[24,25]</sup> are reported as risk factors for LCA. Also, it is reported that LCAs associated with oral contraceptives show regression after discontinuing the drug<sup>[26,27]</sup>.

The main complications of LCA include tumor hemorrhage and malignant transformation. It is reported that hemorrhage is found in about one half of LCAs and can result in death<sup>[9,16,28]</sup>. Malignant transformation of LCA is considered to be rare. However, in several reported cases, LCA associated with glycogen-storage diseases and glucocorticosteroids developed HCC<sup>[29-32]</sup>. In another reported case, hepatocarcinogenesis occurred several years after discontinuation of oral contraceptives<sup>[32]</sup>.

Although LCA is a benign liver tumor, treatment is often conducted to avoid hemorrhage and malignant transformation<sup>[3,4]</sup>. Surgical treatments such as lobectomy<sup>[21,33]</sup>, enucleation<sup>[34]</sup> and liver transplantation<sup>[35]</sup> are performed for LCA. Percutaneous ethanol injection<sup>[20]</sup> and transcatheter arterial embolization<sup>[33]</sup> are established therapies for low invasive treatment of HCC, and were reported to be performed for LCA. However, precise pathological examination is not possible by these treatments. Since a definitive diagnosis of LCA by diagnostic imaging alone or by needle biopsy is difficult<sup>[11]</sup>, tumor resection is often the most suitable approach. Our case was found by chance during treatment of the endometriosis complicated with bacterial infection. The patient did not have a history of using oral contraceptives or glucocorticosteroids which are known risk factors for LCA. Nor did the patient have metabolic liver disease including glycogen-storage

disease. By MRI, the tumor was found to contain fat. In dynamic studies, the tumor showed a homogenous enhancement in the arterial phase and almost the same enhancement as the surrounding liver parenchyma in the delayed phase. These findings were typical for LCA. However, the tumor showed an elevation of the density on plain CT and an increase of the early enhancement in the arterial phase, which caused us to suspect that well-differentiated HCC containing fat was becoming dedifferentiated. Accordingly, hepatic resection was performed.

In a prospective study of 48 LCA cases reported by van der Windt *et al*<sup>[27]</sup>, serial observation was considered appropriate for tumors with the typical image findings of LCA if the diameter was less than 5 cm. Five of the 48 cases of LCA were resected because the radiological findings changed during serial observations and three of the five cases had well-differentiated HCC, while in the remaining two cases, it was difficult to distinguish between well-differentiated HCC and LCA pathologically. The present case showed the typical radiological findings for LCA and was 35 mm in diameter without an increasing tendency. However, diagnosis only by radiological findings is difficult in patients without a background supporting a diagnosis of LCA such as a history of receiving the above mentioned drugs or glycogen-storage disease. Resection of the tumor in the present case was therefore considered appropriate because of the risk of hemorrhage and possible malignant transformation.

### TO THE EDITOR

Intraductal papillary mucinous neoplasm (IPMN) is an increasingly reported entity, representing up to one third of all pancreatic cystic neoplasms<sup>[1]</sup>. IPMNs typically present with cystic dilatation of the pancreatic duct associated with mucin production and variable cellular atypia. Although extensive pancreatic calcification is generally considered to be a pathognomonic sign of chronic pancreatitis, it may also occur simultaneously with IPMN which may lead to diagnostic confusion<sup>[2,3]</sup>. We report a case of a patient who was initially diagnosed with chronic calcifying pancreatitis and was later shown to have an IPMN.

An 81-year-old man was referred to the gastroenterology clinic due to weight loss, diarrhea, and anemia. He did not drink any alcohol and got quit of smoking pipe 50 years ago. Medical history was unremarkable apart from chronic obstructive pulmonary disease and type 2 diabetes mellitus diagnosed one year prior to presentation. Laboratory tests revealed mild normocytic normochromic anemia with 11.3 g/L hemoglobin (reference 13.0-17.0 g/L) but essentially normal white cell and platelet counts as well as normal electrolytes, creatinine, albumin, liver function tests, amylase, endomysial antibodies, plasma protein electrophoresis, and thyroid function tests.

Esophagogastroduodenoscopy was normal. A CT-colonography showed normal colonic appearances but there was evidence of a grossly atrophic calcific pancreas with a dilated pancreatic duct. No mass lesion was seen. The patient did not have a history of acute pancreatitis, abdominal radiotherapy or trauma to the epigastric region. His serum calcium and triglycerides were normal. Fecal elastase was < 15 µg/g of stool (reference > 500 µg/g of stools). Therefore, exocrine pancreatic insufficiency due to idiopathic chronic calcifying pancreatitis was diagnosed and pancreatic enzyme substitution was started.

Despite some initial improvements, the patient reported further weight loss six months after initial

### Abstract

Intraductal papillary mucinous neoplasm (IPMN) is an increasingly reported entity. Extensive pancreatic calcification is generally thought to be a sign of chronic pancreatitis, but it may occur simultaneously with IPMN leading to diagnostic difficulties. We report a case of a patient initially diagnosed with chronic calcifying pancreatitis who was later shown to have a malignant IPMN. This case illustrates potential pitfalls in the diagnosis of IPMN in the case of extensive pancreatic calcification as well as clues that may lead the clinician to suspecting the diagnosis. The possible mechanisms of the relation between pancreatic calcification and IPMN are also reviewed.

**Figure 1** Abdominal computed tomography image showing gross pancreatic duct dilatation and extensive pancreatic calcification as well as bile duct dilatation. No distinct mass was seen.

**Figure 2** Endoscopic ultrasound revealing a dilated pancreatic duct (> 10 mm in diameter) with mural irregularities, calculi within the pancreatic duct, and an atrophic pancreas.

presentation. Laboratory testing showed that his alkaline phosphatase was 2629 IU/L (reference 95-320 IU/L), bilirubin was 42  $\mu$ mol/L (reference 3-17  $\mu$ mol/L), and alanine aminotransferase was 347 IU/L (reference 10-45 IU/L). A pancreatic protocol CT demonstrated gross pancreatic atrophy and calcification, dilated pancreatic as well as intrahepatic and common bile ducts. No mass lesion was seen (Figure 1). Endoscopic ultrasound confirmed these findings and also showed an enlarged heterogeneous pancreatic head with dilated side branches of the pancreatic duct as well as an area of hypoechogenicity, but did not show any distinct mass. The main pancreatic duct in the head was dilated with its diameter > 10 mm and with wall irregularities (Figure 2). Mucus extrusion from a protruding gaping major papilla was observed. Endoscopic retrograde cholangiopancreatography was attempted in which opacification of the main pancreatic duct showed multiple filling defects suggestive of intraductal mucin. Common bile duct cannulation failed and biliary drainage was achieved by means of a percutaneous transhepatic cholangiography. Carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA19-9) levels in mucin aspirated from the pancreatic duct were 24132 ng/mL and 60840 U/mL, respectively. On the basis of the imaging findings, the fact that mucus extrusion was observed from the papilla, and the high levels of CEA and CA 19-9 in pancreatic duct aspirates, a malignant IPMN was diagnosed. Due to his clinical condition, the patient was judged not to be a candidate for surgery and was offered palliative therapy.

Twelve to sixty percent of patients with IPMN have a history leading to a diagnosis of chronic pancreatitis<sup>[4,5]</sup> and roughly 2% of all diagnoses of chronic pancreatitis are associated with IPMN<sup>[5]</sup>. However, few reports of patients with concomitant calcifying pancreatitis and IPMN are available<sup>[2,3]</sup>. In a cohort study of 473 patients suffering from chronic pancreatitis, only 6 were found to have IPMN during follow-up but none had calcifications<sup>[5]</sup>. Of the 16 cases of patients with IPMN and pancreatic calcification published thus far, 8 had diffuse pancreatic calcification which did not involve the tumor itself in most of the cases<sup>[2,3]</sup>. The pathogenesis

of calcification in IPMN is unknown. Apart from the unlikely possibility that the two entities may occur coincidentally, it is possible that IPMN may be a complication of chronic calcifying pancreatitis, but no report of a patient with this condition developing IPMN in the course of the disease is available. It has also been proposed that IPMN may be responsible for pancreatic calcification due to chronic partial ductal obstruction by mucin plugs<sup>[2,3]</sup>. In any case, the concomitant presence of pancreatic cystic lesions, duct dilatation, and calcification should raise the suspicion of an IPMN. Particular care should be taken when diagnosing chronic pancreatitis in patients who do not present typical characteristics of the disease, namely age over 50 years, moderate alcohol intake, and non-smokers, which may be suggestive of IPMN<sup>[5]</sup>. In our case, the patient was 81 years of age and did not consume any alcohol as verified by the patient himself and his relatives.

Although CEA and CA 19-9 measurements are frequently performed during the diagnostic work-up of patients with pancreatic cystic lesions, it has been suggested that cyst fluid or pancreatic duct CEA or CA 19-9 is not helpful in the differentiation between benign and malignant IPMNs<sup>[6]</sup> but published data in the literature are not unanimous<sup>[7]</sup>. A CEA > 800 ng/mL has been reported to be helpful in differentiating mucinous cystadenocarcinomas from mucinous cystadenomas<sup>[8]</sup>. Although only 5/16 patients with concomitant calcifying pancreatitis and IPMN previously reported were shown to have a malignant lesion<sup>[2,3]</sup>, in the present case the fact that both CEA and CA 19-9 in the pancreatic duct aspirate were extremely high was felt to be highly suggestive of malignancy. A main pancreatic duct > 6 mm in diameter and protrusion of the papilla of Vater are also considered signs predicting malignancy<sup>[9]</sup>. Thus, endoscopic ultrasound is not just a technique to obtain fluid from cystic pancreatic lesions for tumor marker analysis, but it also provides invaluable morphological information on mural pancreatic duct irregularities, presence of solid lesions or septa in cysts. Compared to other imaging methods, it achieves the highest detail resolution.

In summary, concomitant presence of pancreatic

cystic lesions, duct dilatation, and calcification should raise the suspicion of an IPMN, especially when patients do not present typical characteristics of chronic pancreatitis, namely age over 50 years, moderate alcohol intake, and non-smokers. Inspection of the ampulla with a duodenoscope and aspiration of fluid from the pancreatic duct or endoscopic ultrasound-guided fine needle aspiration from a cystic pancreatic lesion for analysis of CEA and CA 19-9 may be useful in the diagnosis of such patients.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: Introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Leader Frontier: Comment on excitement and existing problems of core fields, and offer suggestions for the future research; (3) Topic Highlight: Experts in gastroenterology and hepatology to focus on certain individual hot topics and try to provide answers to the clinical questions on the topics; (4) Observation: Which updates the development of old and new questions, highlights unsolved questions, and provides strategies on how to solve the questions; (5) Guidelines for Basic Research: Which provides Guidelines for basic research; (6) Guidelines for Clinical Practice: Which provides guidelines for clinical diagnosis and treatment; (7) Review Articles: Summarize the representative progress in core scientific disciplines, comment on the research status, and make suggestions for the future work; (8) Original Articles: Originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: Briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: Report a rare or typical case; (11) Letters to the Editor: Discuss and make reply to the contributions published in *WJG*, or introduce and comment on a controversial issue of general interest; (12) Book Reviews: Introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: Guidelines or common understanding for gastroenterology and hepatology from international academic committee.

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The trial register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *ν* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

Postpyloric feeding is an important and promising alternative to parenteral nutrition. The indications for this kind of feeding are increasing and include a variety of clinical conditions, such as gastroparesis, acute pancreatitis, gastric outlet stenosis, hyperemesis (including gravida), recurrent aspiration, tracheoesophageal fistula and stenosis in gastroenterostomy. This review discusses the differences between pre- and postpyloric feeding, indications and contraindications, advantages and disadvantages, and provides an overview of the techniques of placement of various postpyloric devices.

### INTRODUCTION

According to both European and American guidelines for enteral and parenteral nutrition, enteral feeding is

the preferred method of nutritional support in patients who have a functioning gastrointestinal (GI) tract but cannot maintain an adequate oral intake<sup>[1,2]</sup>. Enteral nutrition prevents GI mucosal atrophy, keeps intestinal integrity and prevents bacterial translocation from the GI lumen to the rest of the body, by maintaining normal permeability of the GI mucosal barrier<sup>[3-6]</sup>. In addition, it is less expensive and has significantly fewer complications than parenteral nutrition<sup>[1,2]</sup>.

The enteral route traditionally delivered nutrition directly into the stomach *via* a nasogastric tube or gastrostomy (prepyloric feeding). The concept of postpyloric feeding has been developed over the past few decades and has become a part of the routine practice of nutritional teams in many countries. A wide variety of postpyloric nutrition devices are currently available, including different types of nasoduodenal and nasojejunal tubes and jejunostomies.

What are the differences between pre- and postpyloric feeding approaches? Why is the location of the tip of a nutritional device before or after the pylorus so important? The current review will discuss the major differences between these two methods of enteral nutrition in order to provide essential information for every nutritionist and gastroenterologist in making the right choice for every specific case. This review will provide a comprehensive overview of accepted indications and contraindications of postpyloric feeding, based on existing studies and guidelines. In addition, various devices for postpyloric feeding, as well as different techniques for their insertion, their advantages and disadvantages will be discussed.

### PHYSIOLOGICAL DIFFERENCES BETWEEN PRE- AND POSTPYLORIC FEEDING

There are several physiological differences between pre- and postpyloric feeding. The first major difference is a mechanical one. Postpyloric delivery of food significantly reduces the likelihood of aspiration/vomiting caused by gastroesophageal reflux, especially in the case of intrajejunal and not intraduodenal feeding. The second major difference is the neurohormonal effect of food that is supplied directly to the small intestine or the duodenum, compared to intragastric supply. It has different effects on pancreatico-biliary secretions and on small bowel and gallbladder motility. Ledebor *et al*<sup>[7]</sup> have demonstrated that intraduodenal feeding causes a stronger GI response than intragastric feeding. It stimulates gallbladder

Table 1 Differences between gastric and jejunal feeding

	Nasogastric tube	Nasojejunal tube
Indications	Anorexia, dysphagia, odynophagia	Gastroparesis, gastric outlet obstruction, recurrent aspirations, severe pancreatitis, hyperemesis gravidarum, proximal enteric fistula, postoperative anastomotic gastroenteric stenosis
Insertion technique	Easy access, no need for endoscopic or radiological study or medication	Needs endoscope or prokinetic agents
Costs	Much cheaper because: 1. low cost of the tube; 2. may be inserted by a nurse	More expensive because: 1. costly equipment; 2. requires insertion by physician
Physiology	More physiological, keep normal motility and hormonal profile	Less controlled motility and hormonal control. Less pancreatic stimulation if inserted after the Trietz ligament
Feeding mode	Bolus or continuous. Pump is not mandatory	Continuous only. Pump is mandatory in most cases
Risk of aspiration	High in patients with GER and swallowing impairments	Less frequent but not absolutely prevented
Clogging rate	Rare thanks to larger diameter of tube	Frequent

contractions, accelerates small bowel transit time, and increases cholecystokinin and pancreatic polypeptide release<sup>[7]</sup>. Intrajejunal feeding has a completely different effect<sup>[8,9]</sup>. The classic work in a canine model by Ragins *et al*<sup>[10]</sup> has demonstrated that jejunal feeding does not stimulate pancreatic secretion, as is seen in intragastric or intraduodenal delivery of food, which increases the volume and changes the content of pancreatic secretions. These results have been supported by animal and human studies on models of acute pancreatitis<sup>[11-14]</sup>.

Unfortunately, almost all these studies have focused on the influence of intrajejunal feeding on the pancreas and failed to address the intriguing issue of its impact on small bowel function. Data on the changes in the levels of relevant hormones and changes in the motor pattern of the small and large intestine are scarce.

Table 1 demonstrates differences between gastric and jejunal feeding.

## ACCESS ROUTES FOR POSTPYLORIC FEEDING

The access routes for postpyloric feeding include nasoduodenal and nasojejunal tubes and jejunostomy. Nasoenteric tubes may be placed manually or with endoscopic, radiological or surgical guidance. Nasoenteric tubes are a good choice for short-term feeding but have many drawbacks for long-term management. They tend to recoil into the stomach, become clogged, cause nasal pressure sores, and can be pushed out of place accidentally. As such, jejunostomy is the preferred option for long-term postpyloric feeding. Feeding by jejunostomy generally requires surgical placement, although endoscopic or fluoroscopic placement for jejunostomy has been successful in some medical centers with adequate experience<sup>[15,16]</sup>. In cases for which a surgical jejunostomy is considered, the benefits and tolerability of surgical jejunostomy and postpyloric feeding can be assessed by temporarily placing a nasojejunal tube or by inserting a jejunal extension of a percutaneous endoscopic gastrostomy-jejunostomy (PEG-J).

There are several kinds of nasoenteric tubes made from various materials (e.g. polyurethane and polyvinylchloride), that have different diameters (8-12 French), with and without guide wires, and with and

without weight at their tips. Unweighted tubes of smaller diameter (8 French) are used for endoscopic insertion to ensure a proper passage through a working channel of the endoscope. The length of a nasoenteric tube ranges from 140 cm to 220 cm.

Nasoduodenal tubes and duodenostomies have been in common use in the past, but cumulative experience has shown that the duodenal route is very problematic because of the tendency of a nasoduodenal tube to recoil back into the stomach, as well as the strong stimulatory effect of intraduodenal feeding on pancreatic secretions<sup>[7]</sup>. In addition, a feeding formula tends to flow to the stomach because of duodenogastric reflux<sup>[17-19]</sup>. Thus, intraduodenal feeding is contraindicated in the setting of recurrent aspiration and severe pancreatitis, which are the most common indications for postpyloric feeding. As a result, intraduodenal feeding is no longer routinely used in most medical centers and will not be discussed further.

## INDICATIONS FOR POSTPYLORIC FEEDING

There are several clinical situations in which postpyloric feeding is preferable to the intragastric route. One of the most common indications is gastroparesis that is not responsive to prokinetics<sup>[20,21]</sup>. This situation is most frequently encountered in the early postoperative setting or in critical care patients. Theoretically, postpyloric feeding would appear to be an attractive option in critically ill patients because of the frequently present problems of gastroparesis and aspirations<sup>[22-25]</sup>. It is, however, associated with significant cost and risks of nasojejunal tube insertion. It has been accepted widely in the past that every critically ill patient should be fed postpylorically, and this approach has been investigated in many studies and meta-analyses<sup>[26-29]</sup>. One of the most interesting of these was by Montejo *et al*<sup>[30]</sup>, who conducted a multicenter, prospective, randomized, single-blind study on 110 patients with similar characteristics who were randomized to be fed pre- or postpylorically. The authors concluded that the nutritional results were similar in both groups, and therefore, the routine use of a nasojejunal tube in critically ill patients is not justified. It may, however, have a role in selected patients with high gastric residuals on nasogastric feeding, or

with various conditions of the GI tract, such as severe pancreatitis. Boulton-Jones *et al*<sup>[31]</sup> have investigated postpyloric feeding in selected groups of 138 critically ill patients who suffered from burn injury, severe pancreatitis, sepsis, postoperative gastroparesis, and vomiting induced by bone marrow transplantation and chemotherapy. The results of that study demonstrated good nutritional results in all the patients. On the basis of these and additional studies that have been published since then, the current European and American guidelines for enteral and parenteral nutrition<sup>[1,2]</sup> support nasojejunal feeding only in selected groups of critically ill patients with one of indications mentioned in this section (i.e. gastroparesis, recurrent aspirations, severe hyperemesis, and severe acute pancreatitis).

Another common indication for postpyloric feeding is recurrent aspiration caused by severe gastroesophageal reflux disease (GERD) in bedridden patients<sup>[22,23]</sup>. One of the classic studies on this subject was by Montecalvo *et al*<sup>[22]</sup>. Thirty-eight patients were randomly assigned to feeding by nasogastric or nasojejunal tube. There were no documented aspirations in the postpyloric feeding group compared to two aspirations in the nasojejunal tube group. It is important to define whether episodes of aspiration are truly caused by GERD or are the result of disorders in swallowing.

Nasojejunal tube insertion has become routine practice in many hospitals in cases of severe pancreatitis. This kind of feeding enables the provision of enteral nutrition with less stimulation of pancreatic secretions and less exacerbation of inflammation in the pancreas. There are four phases of pancreatic secretions: (1) basal - very little pancreatic secretion during fasting; (2) cephalic - mildly increased secretion when the individual looks at food; (3) gastric - increased pancreatic secretion initiated by gastric distention with food and mediated by gastrin and acid; and (4) duodenal - extensive stimulation of pancreatic secretions initiated by the entry of chyme and acid into the duodenum, and mediated by secretin and cholecystokinin. The classic work of Ragins *et al*<sup>[10]</sup> in a canine model has demonstrated that intragastric or intraduodenal delivery of food increases the volume and changes the content of pancreatic secretions. In contrast, jejunal feeding does not stimulate pancreatic secretions<sup>[11,32]</sup>. Since it is very important to provide pancreatic rest during acute pancreatitis, the idea of intrajejunal feeding has become very attractive and it has been investigated in animal models of acute pancreatitis<sup>[33]</sup> and in several prospective randomized controlled human studies that have compared nasojejunal feeding with total parenteral nutrition (TPN)<sup>[12,13,34]</sup>. The consensus is that nasojejunal feeding has a good and even better clinical outcome and time of recovery from severe pancreatitis than those with TPN<sup>[32]</sup>. Moreover, TPN is more expensive and associated with more complications than intrajejunal feeding, giving further advantage to the latter. There have been only a few studies on the formula of choice for nasojejunal feeding in severe pancreatitis<sup>[35-37]</sup>. Most of these studies support polymeric formulas, but some show advantages for elemental or semi-elemental formulas. Polymeric formulas are preferred in most centers because of their lower cost.

A rare but important indication is a proximal enteric fistula. For example, if a fistula is located in the esophagus/stomach/duodenum (usually tracheo-esophageal fistula), a nasojejunal tube will supply food more distally and make it possible to provide food enterally as an alternative to parenteral nutrition.

A relatively newly defined indication is hyperemesis gravis. Parenteral nutrition had previously been indicated in some cases of severe hyperemesis gravis with significant weight loss. Two small studies have described the possibility of nasoenteric tube feeding in these women<sup>[38,39]</sup>. A pioneer study by Vaisman *et al*<sup>[40]</sup> has examined the feasibility and efficacy of nasojejunal feeding in 11 pregnant women with severe hyperemesis gravis that persisted despite in-hospital anti-emetic treatment. The nasojejunal feeding approach proved to be effective, reducing vomiting within the first 48 h, with complete resolution after 5 d in most of the women. More prospective studies are needed to validate this promising method.

Postpyloric feeding is the only route for enteral feeding in pyloric or duodenal outlet stenosis. This condition is common in malnourished oncological patients with gastric or pancreatic cancers who are waiting for definitive or palliative surgery, and who are required to improve their nutritional status prior to undergoing surgery.

Another common situation is the postoperative setting after Billroth II or Whipple procedures. Postoperative transient edema in a gastroenteric anastomosis might create a significant problem in gastric emptying. Temporary insertion of a nasojejunal tube below the anastomosis will provide an enteral feeding route for these patients until the edema resolves<sup>[41]</sup>. In some cases of difficult GI anastomosis, the preventive intraoperative insertion of a nasojejunal tube is recommended to enable early postoperative enteral feeding.

## CONTRAINDICATIONS FOR POSTPYLORIC FEEDING

The major contraindication for postpyloric feeding is an obstruction in different parts of the GI tract (esophagus, gastric outlet or intestine). An endoscopic nasojejunal tube or an endoscopic jejunostomy are contraindicated in some clinical scenarios because of the inability of inserting the gastroscope postpylorically, but surgical jejunostomy may still be indicated, as in the case of complete obstruction of the esophagus/stomach/duodenum. Endoscopic nasojejunal tube insertion may nevertheless be an option in some cases of partial obstruction of the upper GI tract because it is possible to push the tip of the tube far beyond the location of the endoscope, and the procedure might even be done blindly beyond a visible stricture. The feasibility of inserting an endoscopic nasojejunal tube depends on the degree of stenosis. Even a pinpoint passage that is sufficient for passage of a guide wire permits the insertion of a nasojejunal tube. Of course, surgical jejunostomy does not require any passage of an endoscope through the GI tract, which provides more

possibilities for applying this kind of technique.

The most important absolute contraindication for all kinds of postpyloric feeding is bowel obstruction or perforation/leakage. Therefore, exact information about the GI tract's mechanical problems, previous GI tract surgery, imaging of the GI tract and verification of GI tract patency must be obtained before postpyloric feeding can be considered.

Contraindications for jejunostomy, but not for a nasojeunal tube, are significant ascites, coagulopathy, peritoneal dialysis, and peritoneal metastasis. For endoscopic insertion of jejunostomy, there are additional contraindications, such as morbid obesity and the inability to transilluminate through the abdominal wall or to see a digital imprint.

## TECHNIQUES OF INSERTION

### Nasoenteric tube placement

Nasoenteric tubes may be placed by using manual (blind) techniques or with the aid of fluoroscopy or endoscopy<sup>[42]</sup>. Nasojeunal tubes for surgical patients may be placed during laparotomy. There are several manual techniques for nasojeunal tube placement. Usually, a nasoenteric tube (8-9 French) is inserted with a guide wire and a weighted tip is inserted into the stomach using the usual technique for nasogastric tube insertion. The patient is then asked to change his/her position to right lateral decubitus and the tube is pushed through the pylorus. The guide wire should be removed at the end of the procedure<sup>[43]</sup>. Several techniques have been developed to facilitate the passage of the tube through the pylorus, among them air insufflation of the stomach<sup>[44,45]</sup>, pH-sensor feeding tube guidance<sup>[46,47]</sup>, and prokinetic agents, such as intravenous erythromycin (250-500 mg)<sup>[48-51]</sup> or 10 mg metoclopramide<sup>[52-54]</sup>. For example, a very interesting randomized, double-blind, placebo-controlled study has been published by Griffith *et al*<sup>[51]</sup>. Thirty-six critical ill patients were randomized to receive a single bolus of intravenous erythromycin (500 mg) or saline before placement of 10-French feeding tubes, using a standardized active bedside protocol. The conclusion of the study was very impressive, with a 93% success rate in the erythromycin group *versus* 55% in the placebo group. In contrast, a study by Gharpure *et al*<sup>[50]</sup>, with a similar design, on a group of critically ill children demonstrated no clinical advantage with intravenous erythromycin (10 mg/kg) *versus* saline in facilitation of transpyloric passage of nasojeunal tubes.

There is no consensus on the best technique of manual insertion of a nasojeunal tube because of the great variety of success rates (30%-95%) reported in many studies carried out in different centers<sup>[44,46,48,52]</sup>. The advantage of weighted over unweighted tubes is uncertain<sup>[55]</sup>, although it is a widely accepted belief.

The nasojeunal feeding tube is commonly placed endoscopically, which allows placement under direct vision<sup>[56-59]</sup>. Its major disadvantage is the requirement of a complete gastroscopy, which increases the cost and duration of the procedure, the risks related to intravenous sedation, and the number of possible complications associated with gastroscopy, such as perforation and

dental injury. The high success rate of this procedure (93%-98%), however, makes it very attractive<sup>[56-59]</sup>. The technique is simple: after a gastroscope is placed deeply in the duodenum, a flexible unweighted 8-French nasojeunal tube with a guide wire is advanced through a working channel of the endoscope and pushed deep into the jejunum, beyond the tip of the endoscope during simultaneous withdrawal of the endoscope. When the procedure has been completed, the guide wire is removed and a feeding tube is passed from the mouth to the nose by means of a plastic device. Some centers also use a drag technique in which a suture is tied to the end of a feeding tube, which is then passed into the stomach *via* the nasopharynx. This suture is dragged with the endoscope snare or forceps from the stomach to the duodenum. Once the tube is in position, the suture is released and the endoscope is withdrawn. This procedure is less successful because the feeding tube frequently moves back into the stomach when the endoscope is removed.

A new technique of nasoenteric tube insertion has become very popular. It involves a transnasal thin endoscope that is inserted transnasally into the stomach and then into the duodenum<sup>[60-62]</sup>. A thin guide wire is inserted through a working channel while the endoscope is removed, after which a feeding tube is placed over the guide wire, which is then removed.

Fluoroscopic techniques of nasoenteric tube placement require skilled radiological support and exposure to radiation. In addition, they necessitate changes in the patient's position that may not be feasible for the critically ill. The success rate of radiological placement varies from 40% to 94%, depending on the local expertise of the staff in different medical centers<sup>[57,63-65]</sup>.

Whatever the technique that is used for nasojeunal tube placement, proper position of the nasoenteric feeding tubes must be verified radiographically before the feeding is initiated<sup>[66]</sup>. Clinicians should not rely on the accepted ways of checking nasogastric tube position, because it is impossible to adequately hear the entrance of air injected through the tube into the jejunum, and to distinguish its erroneous placement in the stomach/esophagus/lungs. In addition, air insufflation of the jejunum is unsafe.

### Jejunostomy placement

Most jejunostomies are placed at least 20 cm beyond the ligament of Treitz (a point of transition of the duodenum to the jejunum) because of the increased rate of complications of duodenostomy compared with jejunostomy. A jejunostomy may be inserted with endoscopic assistance (percutaneous endoscopic jejunostomy; PEJ) or surgically (surgical jejunostomy). A PEJ may be inserted indirectly *via* a previously placed gastrostomy (PEG-J)<sup>[16,67,68]</sup> or directly<sup>[15,69-71]</sup>.

For the placement of a PEG-J, a feeding tube long enough to pass beyond the pylorus is inserted through an existing PEG tube. The tip of the feeding tube is then grasped with the biopsy forceps of the endoscope and the tube is pushed as far as possible into the duodenum. Extra tubing length is left within the stomach to allow peristalsis to pull the tip of the feeding tube past the

ligament of Treitz. Although this procedure is simple, its major disadvantage is the tendency of the feeding tube to return back into the stomach during the withdrawal of the gastroscope. In addition, the feeding tube tends to dislodge from the outer gastrostomy.

An enteroscope or colonoscope should be placed into the proximal jejunum for direct PEJ placement<sup>[15,69-71]</sup>. One of the most common techniques<sup>[70]</sup> includes the insertion of a 19-gauge needle into the jejunal lumen at the site of the transillumination or a finger indentation marking the jejunal loop that is closest to the abdominal wall. The needle should be snared tightly, fixing the small bowel against the abdominal wall. The plastic sheath with stylet should then be inserted adjacent to the 19-gauge needle and snared by a wire loop that has been removed from the needle. An insertion wire should then be passed through the plastic sheath and grasped with a snare. The rest of the procedure is similar to the PEG's pull technique: the gastroscope together with a wire is pulled out through the duodenum, stomach, esophagus and mouth. The insertion wire is then secured to the loop at the end of the feeding tube with an internal jejunal bolster and the assembly is pulled through the mouth all the way to the duodenum. The tube is pulled through an incision in the abdominal wall, sufficiently tight to compress the jejunal wall against the anterior abdominal wall. Intrajejunal tube placement is then verified by a second gastroscopy. Finally, a skin disk is secured to the outside portion of the feeding tube to ensure the creation of a tract between the skin and jejunal lumen. It is important to avoid excess tension when approximating the jejunum to the abdominal wall, so as to prevent pressure sores of the skin or jejunal mucosa.

For patients in whom endoscopy is contraindicated, jejunal feeding tubes can be placed with radiological guidance<sup>[72]</sup>. Access is obtained at a previous gastrostomy site<sup>[73]</sup> or by direct jejunal punctures<sup>[74]</sup>. With this method, the stomach and the jejunum are insufflated with air *via* a nasogastric or nasojejunal tube, and the location of internal organs is identified by means of ultrasound or fluoroscopy to ensure that no organs lie between the jejunum and the abdominal wall. A needle is inserted through the abdominal wall into the jejunal lumen and a guide wire is inserted through the needle. The needle is removed, the tract is dilated, and a feeding tube is placed over the guide wire and secured.

Surgical placement of a jejunostomy can be performed by a needle catheter or by Witzel techniques. A needle catheter jejunostomy is placed during laparotomy for surgical patients who need short-term enteral support<sup>[75,76]</sup>. A purse-string suture is placed in the bowel wall, through which a large-bore needle is tunneled subserosally for several centimeters before entering the bowel lumen. A 5-, 7-, or 9-French feeding catheter with a flexible stylet is inserted through this needle and advanced distally into the bowel. The needle is removed and the purse string is tied. Next, a 3-5 cm Witzel tunnel is created in the abdominal wall proximal to the catheter insertion. A second large-bore needle is inserted through the abdominal wall and the feeding catheter and stylet are passed through the needle to the skin. The needle and stylet are then removed and the intestine is fastened to the anterior abdominal wall

to prevent leakage.

The Witzel jejunostomy is another open-surgery method. A tube is placed through an incision in the anterior abdominal wall and a tunneled incision is made in the jejunal wall. The adherence of jejunum to the abdominal wall is ensured by sutures<sup>[77]</sup>.

Some centers perform laparoscopic jejunostomy. Duh *et al*<sup>[78]</sup> have used this technique in 36 patients who could not undergo gastrostomy, with a good rate of success.

## COMPLICATIONS AND DISADVANTAGES OF POSTPYLORIC FEEDING

There are various complications of postpyloric feeding. Some of them are specific to a specific device (nasojejunal tube *versus* jejunostomy) and others are universal for all kinds of postpyloric feeding techniques. Tables 2 and 3 specify common and uncommon complications of nasojejunal and jejunostomy feedings. The common complications of nasojejunal tubes are as follows: failure of nasojejunal tube placement (the rate depends on the technique of insertion), displacement of the tube, clogging of the tube, mild transient epistaxis, nasal mucosal irritation, feeding-related diarrhea, abdominal cramping, and hyperglycemia<sup>[79]</sup>. The common complications of jejunostomy include pain and infection at the jejunostomy site, displacement of the jejunostomy, clogging, feeding-related diarrhea, abdominal cramping, hyperglycemia, transient pneumoperitoneum immediately after the insertion (in most cases, without any clinical significance), and leakage around the jejunostomy site<sup>[80,81]</sup>. It is essential to take into account any existing risks of intravenous sedation and gastroscopy as well as the risks of anesthesia and surgery. There is a possibility that the patient will experience abdominal cramping, hyperperistalsis and diarrhea whatever device is used for this kind of feeding. The considerable costs of postpyloric devices compared to prepyloric ones need to be taken into account as well<sup>[82]</sup>.

Although the list of possible complications is a long one, most of them might be successfully avoided by using proper techniques of placement and management of the post-pyloric devices. For example, a misplacement of a nasojejunal tube and subsequent aspiration may be detected and avoided by radiological verification of the tube's location before feeding is started<sup>[66]</sup>. The displacement of a nasojejunal tube may be prevented by proper fixation. Nasoenteric tubes tend to be blocked because they are usually longer and of finer bore. They are especially susceptible to being obstructed by crushed medications, viscous feeds and inadequate flushing. Therefore, these tubes should be flushed every 4-6 h, always before and after usage, and dense feeds and medications should be avoided. In the event of clogging, a tube can usually be unblocked by flushing it with hot water, coca-cola or pancreatic enzymes. The sudden influx of a hyperosmotic formula is likely to lead to abdominal cramping, hyperperistalsis and diarrhea since the jejunum relies on controlled delivery of isotonic substrates. An intrajejunal feeding is less physiological compared with an intragastric one. The ability of the

**Table 2 Potential complications of nasojejunal tube feeding**

Common (> 10%)
Failure of placement <sup>1</sup>
Displacement
Clogging of the tube
Mild transient epistaxis
Irritation of nasal, pharyngeal or esophageal areas
Feeding-related diarrhea
Abdominal cramping
Metabolic complication, such as hyperglycemia
Uncommon (< 10%)
Otitis media
Nasal mucosal pressure sores
Esophageal ulcers
Risks of intravenous sedation and gastroscopy
Sinusitis
Misplacement (pulmonary or intracranial intubation)
Dumping-like symptoms

<sup>1</sup>Depends on the technique of insertion.

stomach to distend and contain a large amount of food all at once is a great advantage compared to the limited distension capability of the jejunum. Some patients who are fed postpylorically may develop symptoms similar to dumping syndrome, i.e. faintness, palpitations, sweating, tachycardia, rebound hypoglycemia, and diarrhea. Therefore, intrajejunal feeding should always be carried out continuously by pump and not by boluses<sup>[42]</sup>. The recommended actions for cases of diarrhea are to exclude other possible causes, to decrease the rate of feeding, and to consider a change in formula to a less osmotic one and one that contains fibers.

## FORMULAS FOR POSTPYLORIC FEEDING

The mode of administration, the appropriate formula and the rate of administration are important features for successful postpyloric feeding. The preferable kind of formula has yet to be determined, and there are few studies that have addressed this issue<sup>[35,36,83,84]</sup>. Some of them advocate elemental and semi-elemental feeds and others support polymeric solutions. Lacking sufficient data, each medical center develops its own protocol.

Postpyloric feeds for children have traditionally been elemental or hydrolyzed and less viscous because of the narrow lumen of the tubes needed to pass the pylorus, although polymeric feeds have also been tolerated<sup>[85]</sup>. For adults, polymeric formulas are usually chosen except for patients with malabsorptive disorders or lymph duct problems.

As mentioned earlier, the sudden influx of a hyperosmotic feed is likely to lead to abdominal cramping, hyperperistalsis, diarrhea and symptoms similar to dumping syndrome, since the jejunum relies on a controlled delivery of isotonic substrates. It is worth repeating that postpyloric feeds should be administered continuously by pump. The initial rate of administration should be slow and increased gradually. Parenteral support is sometimes used as caloric intake is gradually increased until the target caloric intake has been reached.

**Table 3 Potential complications of jejunostomy feeding**

Common (> 10%)
Pain at the jejunostomy site
Skin infection of the jejunostomy site
Feeding-related diarrhea
Abdominal cramping
Clogging of tube
Transient pneumoperitoneum immediately after the insertion (but it has no clinical significance in most cases)
Metabolic complication, such as hyperglycemia
Displacement of jejunostomy
Leakage around the jejunostomy
Uncommon (< 10%)
Failure of placement
Misplacement
Gastric hemorrhage
Perforation of internal organs during the placement and peritonitis
Colocutaneous fistula
Persistent jejunocutaneous fistula after the removal of jejunostomy
Risks of intravenous sedation and gastroscopy or risks of anesthesia and surgery
Hemorrhage at jejunostomy site
Pressure sore due to skin disk of jejunostomy
Dumping-like symptoms

## CONCLUSION

The postpyloric route is a promising method of enteral feeding. In some cases, it is the only feasible way of maintaining enteral input and avoiding parenteral nutrition. Knowledge on the indications, contraindications, advantages and disadvantages and experience with the placement and replacement of different kinds of postpyloric devices should be an essential part of training of gastroenterologists and nutritionists. Further research on the physiological differences between intragastric and intra-jejunal food supply, including hormonal and enzymatic changes, is warranted.

## INTRODUCTION

Although metastatic tumours are the commonest malignant lesions affecting the liver, the incidence of 'primary' liver malignancies has significantly increased over the last 20 years. This is particularly true for hepatocellular carcinoma (HCC), which is globally the commonest liver primary, and for cholangiocarcinoma, the second commonest primary liver tumour<sup>[1]</sup>. HCC is now one of the commonest causes of cancer death worldwide and is the fifth most common cancer worldwide<sup>[2]</sup>. Cholangiocarcinoma accounts for 3% of all gastrointestinal cancers<sup>[3]</sup> but has increased relatively rapidly worldwide<sup>[4]</sup>. Mesenchymal liver tumours are rare, but include hepatic angiosarcoma and primary hepatic lymphoma.

Improvements in imaging technology have allowed exploitation of the dual blood supply of the liver by both the hepatic artery (25%-30%) and portal vein (70%-75%), and the fact that many benign lesions demonstrate characteristic contrast enhancement, due to their vascular supply. Imaging of the liver is often achieved in three distinct phases following intravenous contrast enhancement - the arterial phase, portal venous phase and a late phase.

For the purposes of this review, while we concentrate on the diagnosis and staging of both HCC and cholangiocarcinoma, we also discuss certain characteristics of benign liver lesions. We aim to highlight the advantages of each imaging technique, as well as underscoring potential pitfalls and limitations.

## Abstract

Improvements in imaging technology allow exploitation of the dual blood supply of the liver to aid in the identification and characterisation of both malignant and benign liver lesions. Imaging techniques available include contrast enhanced ultrasound, computed tomography and magnetic resonance imaging. This review discusses the application of several imaging techniques in the diagnosis and staging of both hepatocellular carcinoma and cholangiocarcinoma and outlines certain characteristics of benign liver lesions. The advantages of each imaging technique are highlighted, while underscoring the potential pitfalls and limitations of each imaging modality.

## IMAGING MODALITIES USED IN THE ASSESSMENT OF LIVER CANCER

### Ultrasound

B mode ultrasound (US) is often the first line investigation in liver disease and its use is outlined in the British Society of Gastroenterologist (BSG) guidelines for diagnosis of both HCC and cholangiocarcinoma in adults<sup>[5,6]</sup>.

**Contrast-enhanced ultrasound (CEUS):** Progress in both technical advances by ultrasound manufacturers and in the development of ultrasound contrast agents (UCAs) has allowed the role of UCAs to change from Doppler rescue agents to diagnostic agents, providing an assessment of contrast enhancement patterns of liver lesions in real-time.

UCAs used in diagnostic US are characterized by a microbubble structure, consisting of gas bubbles stabilized by a shell<sup>[7]</sup>. Current generation microbubbles are based on perfluorocarbons with a phospholipid membrane, providing low solubility and favorable resonance behavior at low acoustic pressures. Microbubble sizes typically range from 3 to 5  $\mu\text{m}$  and on intravenous injection remain in the vascular compartment for several minutes, being small enough to avoid filtration by the lungs and too large to enter the interstitial fluid. These compounds demonstrate strong non-linear harmonic responses when insonated with low acoustic pressure and generate specific signals without being destroyed when insonated at low mechanical index (MI), thus allowing continuous real-time imaging<sup>[7]</sup>.

UCAs act as blood pool agents allowing the definition and visualization of three overlapping vascular phases-the arterial phase, portal venous phase and late phase, which last until there is clearance of the UCA from the hepatic parenchyma. This late phase differs from the equilibrium phase of extracellular computed tomography (CT) and magnetic resonance imaging (MRI) agents and may reflect sinusoid pooling and reticulo-endothelial system (RES) or Kupffer cell uptake<sup>[8,9]</sup>.

Minor adverse effects of UCAs are reported in less than 5% of subjects and typically include transient discomfort at the injection site, taste aberrations and vasovagal attacks. UCAs are not nephrotoxic and it is not necessary to check renal function prior to their administration. The incidence of severe hypersensitivity or allergic reaction is lower than current X-ray contrast agents and comparable to that of MR contrast agents<sup>[10]</sup>.

### CT

The development of multidetector row helical computed tomography (MDCT), with its superior spatial and temporal resolution, has resulted in improved detection and characterization of focal liver lesions<sup>[11]</sup>. The acquisition of multiple data sets with each rotation of the x-ray tube in MDCT means the entire liver can be imaged in 10 s or less, compared with 25-30 s for single slice helical CT technology. The short time needed to image the liver allows multiple passes through the liver in different vascular phases following bolus

contrast injection and thin-section collimation produces volume data sets with isotropic or near-isotropic voxel dimensions, resulting in superior spatial resolution and the capability to display data in multiple planes.

With single-slice helical CT, a 'dual-phase' technique is commonly employed with image acquisition in the hepatic arterial-dominant phase and in the portal venous-dominant phase. The 'triple-phase' technique includes an early arterial phase, imaged 18-25 s following bolus injection of contrast<sup>[12]</sup>. Using multiplanar reconstructions, a 3D CT hepatic-mesenteric angiogram can be obtained.

Hypervascular liver lesions are best appreciated in the late arterial phase as they show maximal enhancement relative to the background liver parenchyma. In the portal venous-dominant phase there is maximal parenchymal enhancement with opacification of the hepatic veins. This phase is extended to include the entire abdomen and, depending on the clinical indication, the pelvis. A delayed or equilibrium phase performed 3-5 min following contrast administration may be helpful in further characterizing focal liver lesions.

### MRI

Although MRI is often viewed as the most sensitive and specific technique for evaluating the liver, this is probably debatable, given the recent revolution in multi-detector CT technology<sup>[13,14]</sup>. Nevertheless, lesion/liver contrast is higher for MRI than with CT and the flexibility and range of pulse sequences available in MRI provide a significant advantage over CT.

Hepatobiliary MRI uses several magnetic resonance pulse sequences, each of which produces images that provide unique information about the liver and the biliary tree. Most examinations include a T<sub>1</sub>-weighted in-phase/out-of-phase spoiled gradient echo sequence and one or more T<sub>2</sub>-weighted sequences. Combining these sequences with extracellular intravenous contrast agents, usually with a fat-saturated spoiled gradient echo sequence, also allows patterns of tumour enhancement to be determined. In addition, use of tissue-specific contrast agents such as super paramagnetic iron oxide, allows improved detection and characterisation of liver tumours<sup>[15-17]</sup>. Contraindications to MRI include pacemakers, implantable cardiac defibrillators, cochlear implants and metallic orbital foreign bodies.

**Intravenous MR contrast agents:** Categories of clinically available liver contrast agents include non-specific extracellular contrast; liver-specific categories of hepatocyte selective; RES-specific; and agents with combined early blood pool and late RES-specific properties.

Extracellular gadolinium chelates are used extensively for liver MRI. Following intravenous injection of a gadolinium-based agent, typically three phases of contrast enhancement are imaged: the arterial, portal venous phase and the equilibrium phase<sup>[15]</sup>. During the arterial phase, most of the liver does not enhance as the majority of the liver's blood supply is *via* the portal vein<sup>[15]</sup>. Enhancement patterns of liver lesions are similar

to those demonstrated on CEUS and contrast-enhanced CT. The equilibrium phase or delayed phase is useful for identifying late enhancement of liver lesions. In addition, washout of contrast from HCC and peripheral or heterogeneous washout from liver metastases are characteristic findings on delayed imaging<sup>[15]</sup>. Recent concern about nephrogenic systemic sclerosis in renal impairment following intravenous gadolinium may require modifications in imaging protocols<sup>[18,19]</sup>.

### **Liver-specific contrast agents**

**Hepatocyte-selective contrast agents:** Hepatocyte-selective contrast agents undergo uptake by hepatocytes and are eliminated through renal and biliary excretion<sup>[20]</sup>. All are T<sub>1</sub>-relaxation enhancing agents and increase the signal intensity in normal liver tissue and hepatocyte containing tumors. Non-hepatocyte containing tumors, such as hemangiomas and metastases, do not take up these agents and are rendered more conspicuous by the increase in signal of the background liver on delayed imaging. Agents such as Gd-BOPTA (Multihance) also exhibit early perfusional information, similar to gadolinium chelates.

**Reticuloendothelial agents:** Reticuloendothelial agents target the RES, particularly the liver and spleen and reflect the number of functioning macrophages<sup>[21]</sup>. Reticuloendothelial agents currently in clinical use include superparamagnetic iron oxide (SPIO) particles. SPIO particles act as a negative contrast agent and can be used alone or in combination with gadolinium<sup>[22,23]</sup>. Most liver tumors, whether benign or malignant are deficient in Kupffer cells and do not exhibit SPIO particle uptake<sup>[24,25]</sup>. Hence, most liver tumors appear relatively hyperintense, because the background liver darkens preferentially following SPIO administration. Combining gadolinium and SPIO-enhanced imaging in a 'dual contrast' MRI could be the most accurate technique for the detection of liver tumors<sup>[26]</sup>.

**Diffusion-weighted MRI:** Diffusion-weighted imaging (DWI) uses pulse sequence techniques that are sensitive to the very small scale motion of water protons at a microscopic level and improves the conspicuity of many hepatic and extrahepatic tumors<sup>[27]</sup>.

### **Positron emission tomography (PET)**

The advent of molecular imaging with PET has revolutionized the concept of functional imaging in the management of disease, particularly in the field of oncology, which accounts for 90% of PET applications. Imaging with PET rather than gamma camera SPECT radiopharmaceuticals allows higher spatial resolution and good image quality, with better detection of even small lesions<sup>[28]</sup>. PET has the advantage over cross-sectional anatomical imaging of providing whole body imaging, allowing the detection of multifocal and metastatic disease. There are many radiopharmaceuticals based on labeled short-lived positron emitters, of which, the most widely used is the fluorinated glucose derivative

<sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG). The use of other nuclear medicine techniques in the imaging of liver malignancy, e.g. colloid scintigraphy, has been rendered largely obsolete by improvements in other cross-sectional imaging techniques, principally MRI and US<sup>[29]</sup>.

## **HCC**

The majority of HCC cases develop in the cirrhotic liver. Cirrhosis is the strongest predisposing factor for HCC, with chronic viral hepatitis the commonest underlying etiological cause worldwide<sup>[30]</sup>. Curative resection, ablation or liver transplantation is possible if the tumor is detected at an early stage. Early detection of HCC is thus critical to achieve effective treatment and prolong survival<sup>[31]</sup>. However, it is often difficult to diagnose small HCCs, particularly in the presence of cirrhosis. In Europe, patients with chronic liver disease undergo regular surveillance, usually involving both alpha-fetoprotein (AFP) determination and conventional B-mode US examination of the liver<sup>[32]</sup>. Alpha-fetoprotein, the most commonly used serum tumor marker, is unfortunately not a dependable biomarker for diagnostic and prognostic purposes, having poor sensitivity, specificity, and positive predictive value, emphasizing the importance of high quality imaging techniques<sup>[33]</sup>.

Hepatocarcinogenesis is considered a multi-step process characterized by the development of a spectrum of nodules from benign regenerative nodules (RNs) and dysplastic nodules (DNs) to overt malignant HCC. Although conventional US can reveal the different types of nodules in cirrhosis, the ability to distinguish RNs from DN or malignant HCC is limited as this necessitates an understanding of hemodynamic changes: The vascular supply of RNs is similar to that of the liver parenchyma<sup>[34]</sup>, whereas DN demonstrate a more complex vascular supply with a degree of capillarization ranging from that similar to RNs to the arterial hypervascularization typical of HCC. Thus, a reduction of both portal vein and normal hepatic artery branches with a progressive increase in abnormal hepatic arteries are considered histological features of malignant transformation<sup>[34]</sup>. It is this process of tumor neoangiogenesis that gives rise to the characteristic appearances of HCC on several different contrast-enhanced imaging techniques (CEUS, contrast-enhanced CT and MR with gadolinium enhancement) and facilitates its differentiation from other benign causes of focal liver lesions.

In patients with liver cirrhosis, the diagnosis of HCC can be based on clinical, laboratory and imaging techniques with an accuracy of up to 99%<sup>[35]</sup>. If a mass detected on US is  $\geq 2$  cm in diameter, there is a greater than 95% chance that the lesion is HCC and biopsy is not indicated.

### **Characteristic appearances of HCC**

**Ultrasound:** HCC appearances on B-mode US are variable. Small lesions are usually hypoechoic, but larger le-

**Figure 1 HCC.** B-mode US demonstrates a heterogeneous hypoechoic solid liver lesion (arrow) in segment IV, confirmed to be HCC at histological examination. Note the background of an echogenic liver with an irregular surface.

**Figure 3 HCC.** Contrast enhanced CT demonstrates heterogeneous arterial phase enhancement of a focal liver lesion (arrow) adjacent to a low attenuation area representing a previous radiofrequency ablation site (arrowhead).

**Figure 2 HCC.** A: CEUS in the arterial phase (17 s following injection) demonstrates arterial phase enhancement of the solid lesion (corresponding grey scale image of the lesion is shown on the right hand side; software known as "twin view" which helps the sonologist track the lesion through the phases of enhancement). Note the "basket weave" pattern of angiogenic vessels with haphazard enhancement of this lesion; B: Twin view of the same segment IV lesion in the delayed phase (2 min 49 s following injection) of the same lesion as Figure 2A demonstrates contrast wash-out compared to the surrounding liver parenchyma which are features of a malignant lesion.

sions may demonstrate heterogeneous echotexture due to necrosis and fibrosis (Figure 1).

The most common feature of HCC using CEUS is the presence of early, intense and homogenous intra-tumoural enhancement (Figure 2A). Real-time imaging can demonstrate the 'basket pattern' of blood flow with peripheral vessels encircling and internally penetrating the tumor. After the arterial hyperenhancement, HCC show, 'wash-out', resulting in an isoechoic or hypoechoic

appearance in the portal-venous and delayed phase (Figure 2B). In most cases, this 'wash-out' is slower than with other malignant lesions, such as metastases. The degree of late-phase enhancement is determined by the degree of similarity of the nodule to normal liver parenchyma<sup>[36]</sup>. RNs usually have a hypoechoic or isoechoic appearance in the arterial phase and an isoechoic appearance in the portal and late phases<sup>[37]</sup>; and the detection of arterial hypervascularization reflects transformation to HCC. Some caution needs to be exercised, however, as up to 30% of HCCs, particularly the small, well-differentiated variety, may be isoechoic rather than hypoechoic on the late phase of imaging and thus be mistaken for a regenerative nodule or dysplastic nodule.

**CT:** On contrast-enhanced MDCT, the typical HCC demonstrates similar enhancement patterns to those seen on CEUS, with intense inhomogeneous enhancement seen in the hepatic arterial-dominant phase and contrast wash-out in the late portal venous phase<sup>[38]</sup> (Figure 3). A minority of HCCs are hypovascular tumors and do not demonstrate arterial enhancement, appearing as hypoattenuating lesions relative to the liver parenchyma on the portal venous-dominant phase.

HCC arising in the non-cirrhotic liver is often large, due to its long asymptomatic course and late presentation<sup>[39,40]</sup>. This contrasts with the multi-focal tumors more commonly found in patients with other forms of chronic liver disease. Large HCCs may demonstrate a number of characteristic appearances on MDCT which make differentiation from other causes of focal liver masses relatively straightforward. A mosaic appearance may be seen in large tumors, with fibrous septa separating areas of variable attenuation which represent internal regions of hemorrhage, necrosis, fatty degeneration and fibrosis. Characteristic satellite tumor nodules close to the margins of large tumors may be seen. Well-defined, lobulated margins and a distinct fibrous capsule are also features of large HCCs. The fibrous capsule has low attenuation on unenhanced images and does not enhance in the arterial phase but begins to enhance in the late portal venous phase. Retention of contrast within the capsule

**Figure 4 HCC.** T2-weighted gradient echo sequence shows a solid lesion in segment V (arrow) of the liver which is of intermediate signal hyperintensity compared to the surrounding liver parenchyma.

increases its conspicuity in the equilibrium phase. HCC has a propensity for early invasion of the portal venous system and biliary tree. The portal vein may be expanded by tumor thrombus that can be differentiated from bland tumor thrombus by the demonstration of arterial enhancement, either diffuse or streaky<sup>[41]</sup>.

A number of benign lesions, including hemangiomas, focal confluent fibrosis, peliosis, benign regenerative nodules and transient hepatic attenuation difference (THAD), can simulate small HCC lesions on CT, and an awareness of these lesions and their imaging characteristics is vital for the radiologist interpreting multi-phasic hepatic CT studies. THAD describes a focal increase in hepatic arterial flow that, in the context of cirrhosis, is most commonly due to arterial-portal shunting, but THAD can also result from intrahepatic thrombosis of hepatic or portal veins. The typical appearance of THAD is a peripheral, often wedge-shaped, area of arterial phase enhancement<sup>[42]</sup>. In a study of a large screening population with cirrhosis, Brancatelli and colleagues found an 8% false-positive rate upon comparison of pre-transplant CT studies with pathological examination of explanted livers<sup>[43]</sup>. Both hypo- and hyper-attenuating nodules were incorrectly diagnosed as HCC on CT but most of the lesions were small (< 1.5 cm diameter).

The use of both double arterial phase imaging and delayed phase imaging improve detection of HCC, particularly of small ( $\leq 2$  cm) nodules<sup>[44]</sup>. However, with radiation dose considerations in mind, most centers adopt a pragmatic approach in combining late arterial phase and portal venous phase imaging to evaluate HCC. Double arterial phase imaging is often reserved for patients who are candidates for surgical resection or chemoembolization, in whom accurate delineation of hepatic arterial anatomy is vital. The addition of an unenhanced phase does not improve detection of HCC in the cirrhotic liver<sup>[45]</sup>, but is used in some centres to differentiate high attenuation siderotic regenerative nodules from arterially-enhancing nodules. Delayed CT, following intra-arterial injection of iodized oil (Lipiodol®, Guerbet, Paris, France), may improve detection of HCC nodules and facilitate targeted biopsy due to the uptake and retention of contrast within the hypervascular tumor nodules<sup>[46,47]</sup>.

**Figure 5 HCC.** A: T1-weighted fat-suppressed sequence following gadolinium intravenous injection shows arterial phase enhancement of a focal liver lesion in segment IV (arrow); B: HCC: The same lesion as shown in Figure 5A becomes relatively less conspicuous on the portal phase images (arrow) as the surrounding liver parenchyma begins to enhance.

**MRI:** HCC can have a variable appearance on unenhanced T1-weighted images and typically shows increased signal on T2-weighted images<sup>[48]</sup> (Figure 4). Following gadolinium administration, HCC demonstrates characteristic early enhancement on arterial phase imaging<sup>[49]</sup> and washout on the delayed images - resulting in a hypointense lesion compared to the surrounding parenchyma<sup>[15]</sup> (Figure 5A and B).

Fibrolamellar HCC, a rare tumor found in young patients without a history of pre-existing liver disease, is usually seen as a large, well-circumscribed focal lesion with low signal intensity on T1-weighted MR images and high signal on T2-weighted images. There is usually early heterogeneous contrast enhancement and a central radiating scar is seen in 80% of cases, which is usually hypointense relative to the remainder of the tumor<sup>[50]</sup>.

Diffusion-weighted MRI may aid detection and characterization of focal liver lesions. Liver parenchyma is dark on DWI, whereas liver tumors (both benign and malignant) are depicted as high signal intensity masses<sup>[27,51-53]</sup>, although malignant liver tumors have lower apparent diffusion coefficients (ADCs) than benign cysts and hemangiomas<sup>[51,53]</sup>.

## PET

<sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG), the most widely used PET radiopharmaceutical in oncological imaging, can demonstrate the presence of malignant cells, because tumor cells utilize more glucose than normal

tissue. FDG is phosphorylated *via* hexokinase to FDG 6-phosphate, which has a much slower rate of dephosphorylation compared to glucose 6-phosphate, and is progressively trapped inside metabolically active cells. The rate of FDG trapping in the cell is therefore proportional to the rate of glycolysis. However, differentiated hepatocytes have a relatively high glucose-6-phosphatase activity which allows dephosphorylation of FDG and subsequent leakage of the tracer from cells. Trojan and colleagues reported a sensitivity of 50% in detecting HCC, with increased FDG uptake associated with moderate or poor differentiation, high serum levels of AFP and large tumor burden<sup>[54]</sup>. A study by Khan and colleagues demonstrated a similar sensitivity of 55%<sup>[55]</sup>. Therefore, <sup>18</sup>F-FDG is of very limited value in diagnosing HCC. This has led to the search for other PET tracers which may be used to screen for the presence of HCC. In a study by Ho and colleagues, dual imaging using <sup>11</sup>C-acetate and <sup>18</sup>F-FDG was assessed<sup>[56]</sup>. These authors found that the poorly differentiated HCCs were detected by <sup>18</sup>F-FDG and the well-differentiated HCCs were detected by <sup>11</sup>C-acetate, leading to a 100% sensitivity using both tracers. In addition, other liver malignancies such as cholangiocarcinomas and liver metastases did not demonstrate abnormal <sup>11</sup>C-acetate uptake, although focal nodular hyperplasia did show mild increased uptake.

### HCC detection

Despite technical improvements in all modalities used in the imaging of HCC, difficulties remain in detecting and characterizing small ( $\leq 2$  cm) lesions in the cirrhotic liver.

A recent prospective study comparing imaging findings with pathological examination of the explanted liver in a pre-transplant population, found that US, MRI and CT had similar sensitivities for HCC detection on a lesion-by-lesion basis, although US performed slightly better on a patient-by-patient basis<sup>[13]</sup>. All three modalities missed small lesions. PET failed to detect any of the pathologically proven HCC lesions.

Currently, B-mode US is recommended in the screening of patients at risk of HCC, including patients with hepatitis B and cirrhosis<sup>[5]</sup>. In experienced hands, B-mode US can detect 80%-95% of lesions 3-5 cm in diameter and has 60%-80% sensitivity in the detection of lesions of 1 cm<sup>[57,58]</sup>. CEUS can further improve the detection of lesions, even if  $< 2$  cm<sup>[59-62]</sup>, having the same sensitivity as helical CT<sup>[59]</sup>. Furthermore, the presence of 'washout' improves the specificity of CEUS in the detection of HCC by allowing the distinction from hemangiomas or hypervascular DNAs and pseudonodules that can mimic HCC due to the presence of homogeneous arterial enhancement. In cases of elevated AFP with no nodule visible on US, CT is recommended to investigate the possibility of infiltrative HCC.

In a prospective study comparing CT findings and pathological examination of the explanted liver in a large pre-transplant population with cirrhosis, CT detected tumor in only 44% of patients in whom HCC was found at pathological examination<sup>[63]</sup>. However, a variety of

CT protocols were used and if only triphasic helical CT (comprising non-contrast, hepatic arterial and portal venous phases) was considered, prospective tumor detection improved to 59%. This study employed single slice helical CT technology and current use of MDCT technology is likely to have improved tumor detection rate.

The sensitivity of MRI in the detection of HCC decreases in cases with advanced cirrhosis<sup>[14]</sup>, and the presence of ascites can generate significant artifacts. Additional difficulties can arise in distinguishing well-differentiated HCC from regenerative and DNAs<sup>[49]</sup>. Frequently, patients with cirrhosis have transient foci of enhancement on arterial phase imaging that cannot be visualized on any other pulse sequence<sup>[64,65]</sup>. While these are usually benign and likely to represent small arteriovenous shunts or dysplastic nodules, small HCCs can exhibit an identical appearance in up to 13%<sup>[66]</sup>. Although some advocate the use of SPIO contrast agents to improve sensitivity and specificity, this has had mixed results<sup>[13]</sup>. HCCs show variable enhancement with SPIO depending on the degree of differentiation and number of functioning Kupffer cells<sup>[15]</sup>, and often in the context of cirrhosis and small tumors ( $\leq 1.5$  cm) gadolinium enhanced imaging is preferred<sup>[67]</sup>. The combination of gadolinium and SPIO, however, provides a dual contrast assessment of HCC that is more effective than either contrast agent alone<sup>[22,68]</sup>. Given the rapid doubling time of most HCCs, close follow-up of cases with transient foci of enhancement may provide an additional strategy<sup>[69]</sup>.

### CHOLANGIOCARCINOMA

Cholangiocarcinomas are generally classified as intrahepatic, hilar or extrahepatic. Most cholangiocarcinomas, up to 60%, occur at the liver hilus<sup>[6]</sup>. Hilar and extrahepatic cholangiocarcinomas typically present with biliary duct obstruction. A multi-modality imaging approach, including endoscopic retrograde cholangiopancreatography (ERCP), US, CT, MRI and magnetic resonance cholangiopancreatography (MRCP), is used in patients with a suspected malignant cause for biliary obstruction.

Although the identification of a mass with B-mode US varies from 37% to 87%<sup>[70,71]</sup>, B-mode US is a highly sensitive method for confirming biliary duct dilatation, localization of the site of obstruction and excluding gallstones<sup>[72]</sup>. Peripheral cholangiocarcinomas can appear as a hyper- or hypoechoic mass similar to HCC, and distal lesions can present with intra- and extra-hepatic duct dilatation<sup>[73]</sup>. On CEUS, a cholangiocarcinoma can behave in the same way as a hypovascular metastasis and result in an area of hypoenhancement in the delayed phase following contrast administration.

Dual phase (arterial dominant and portal venous dominant) contrast-enhanced CT may be helpful in the assessment of cholangiocarcinoma. Small central tumors are often difficult to detect because of their size, infiltrating nature and iso- or subtle hypo-attenuation

**Figure 6 Cholangiocarcinoma.** Contrast enhanced CT in the portal venous-dominant phase demonstrates a poorly-enhancing central liver lesion. The hypodensity appears to follow some of the biliary radicals.

compared to adjacent liver parenchyma, and marked dilatation of the intrahepatic biliary tree may be the only evidence of disease on CT. Visualized central tumors are usually hypoattenuating masses that enhance poorly in the arterial and portal venous phases (Figure 6). Enhancement may be seen on delayed images, thought to be due to retention of contrast within the dense fibrous stroma<sup>[74]</sup>. The peripheral form of cholangiocarcinoma may appear as a nodular, hypoattenuating lesion surrounded by dilated biliary ducts. Previous studies have shown that CT tends to underestimate disease extent, accurately assessing tumor resectability in only 60% of patients in one study<sup>[75]</sup>. However, a more recent study by Aloia and colleagues showed that high resolution helical CT with 2.5 mm slice reconstructions correctly predicted tumor resectability in 17 of 18 patients who underwent laparotomy for cholangiocarcinoma<sup>[76]</sup>.

The appearance of intrahepatic cholangiocarcinoma on MRI is non-specific, typically appearing hypointense on T<sub>1</sub>-weighted and mildly hyperintense on T<sub>2</sub>-weighted sequences. More than 50% of patients will have satellite or remote intrahepatic tumor nodules<sup>[77]</sup>. Following gadolinium chelate contrast, peripheral enhancement can be seen initially and delayed equilibrium enhancement can show dense contrast retention adding to the detection and characterisation of these lesions<sup>[78]</sup>. A central scar may also be evident.

Extrahepatic cholangiocarcinomas have similar signal characteristics to intrahepatic tumors on MRI. The majority of extrahepatic cholangiocarcinomas show heterogeneous enhancement following gadolinium with a gradual increase to a peak on delayed imaging<sup>[79]</sup>. Peripheral early enhancement is rarely seen. Dynamic contrast-enhanced MRI is comparable to angiography in the assessment of the portal vasculature invasion in patients with cholangiocarcinoma<sup>[80]</sup>.

MRCP is the non-invasive imaging study of choice to investigate the biliary tree. MRCP has an excellent overall sensitivity and specificity for demonstrating the level and the presence of biliary obstruction, with slightly lower sensitivity for detecting stones or differentiating malignant from benign obstruction than ERCP<sup>[81]</sup>. Evaluation of

**Figure 7 Cholangiocarcinoma.** A: Contrast-enhanced T<sub>1</sub>-weighted magnetic resonance sequence shows irregular central liver mass (arrow) which enhances poorly in comparison to the adjacent liver parenchyma. There is intrahepatic bile duct dilatation and an external biliary drain (arrowheads); B: Maximum intensity projection image of the MRCP study of the same case as shown in Figure 7A demonstrates marked intrahepatic bile duct dilatation and abrupt cut-off at the liver hilum (due to obstructing tumour) (arrow) with non-visualisation of the extrahepatic ducts.

non-dilated biliary ducts, however, remains problematic as ductal distension is likely an important factor in visualizing subtle biliary abnormalities, particularly given the relatively limited spatial resolution of MRCP techniques.

Cholangiocarcinoma can present as a stenosing/sclerosing process resulting in ductal stricturing, usually with shouldered margins. Cholangiocarcinomas can also result in focal duct wall thickening or nodule formation or as an intraductal papillary lesion.

MRCP permits visualization of ductal irregularity and narrowing as well as intraluminal tumor extent, although bile duct involvement can be underestimated with MRCP<sup>[82]</sup>. Compared to ERCP, however, MRCP can more accurately determine the suprahilar tumor extension<sup>[82]</sup>. Furthermore, the combination of MRI and MRCP imaging allows the evaluation of the presence and size of extraluminal extension of the tumor and liver parenchyma invasion, leading to a greater accuracy in preoperative staging (Figure 7A and B).

There are few data regarding the use of <sup>18</sup>F-FDG PET in the diagnosis of cholangiocarcinomas. Anderson and colleagues reported a sensitivity of 85% for the nodular morphological type of cholangiocarcinoma but only 18% for the infiltrating type<sup>[83]</sup>. In addition, sensitivity for metastatic disease was 65%. All of these metastases were unsuspected on other imaging and led to a change

**Figure 8 Hepatic metastases.** Delayed phase CEUS (3 min 49 s following contrast injection) demonstrates two hypoechoic liver metastases following contrast washout with a residual peripheral rim of enhancement (arrows). Note that the adjacent image demonstrates that these lesions are echogenic on grey-scale and are poorly defined. The margins are better defined with contrast enhancement (right hand image).

**Figure 9 Hepatic metastases.** CEUS obtained in the arterial phase (17 s following contrast injection) demonstrates enhancement of a hypervascular liver metastasis from a colorectal primary tumor. It is the washout with peripheral rim enhancement in the delayed phase (see Figure 8) which helps confirm this to be a metastasis.

in management in all of the patients. Studies have shown that tumors of the tubular pathological type with high cell density and limited mucin production<sup>[84]</sup>, and peripheral<sup>[85]</sup>, nodular<sup>[83]</sup> lesions are better detected than hilar cholangiocarcinomas, infiltrating lesions and mucinous tumours. Dynamic <sup>18</sup>F-FDG PET may have a useful role in the detection of cholangiocarcinoma in patients with primary sclerosing cholangitis where other modalities such as CT, MRI and US are of limited value<sup>[86]</sup>.

## LIVER METASTASES

20%-25% of patients with known solid malignant tumors have hepatic metastases at the time of diagnosis. The incidence of solid benign liver tumors is around 20%<sup>[87]</sup>, thus in patients with known malignancy, 20%-25% of lesions under 2 cm are benign<sup>[88]</sup>. The most frequent benign lesion is hemangioma with a prevalence of 7%-21%, followed by focal nodular hyperplasia (FNH) with a prevalence of up to 3%<sup>[87]</sup>; other benign lesions are far rarer. Hence, imaging techniques of the liver in patients with malignancy not only require high sensitivity, but also the ability to reliably differentiate malignant from benign tumors.

CEUS improves the sensitivity of US in the detection of individual lesions by about 20% in comparison to baseline, with a resultant sensitivity of 82%-86%, comparable to contrast-enhanced CT and MRI with non-specific gadolinium chelates<sup>[89-92]</sup>. Although metastases show characteristic features in the three phases after contrast injection, the hypoenhancement of solid lesions or 'wash-out' in late phase is the key to distinguishing malignant from benign lesions. Benign lesions demonstrate sustained enhancement in the portal and late phases (Figure 8). The appearance of metastases in the arterial phase of enhancement depends on the extent of arterial perfusion. For example, the hypervascular metastases in neuroendocrine carcinomas demonstrate homogenous enhancement, whereas hypovascular metastases, commonly arising from breast, lung, colonic

or pancreatic primaries, may only demonstrate rim enhancement (Figure 9). For benign lesions, the arterial phase is of particular use in the further characterisation of the lesion: hemangiomas characteristically demonstrate peripheral nodular enhancement with gradual filling in of the lesion in the portal venous phase, whereas FNH may demonstrate the typical 'spoke-wheel' arterial pattern with centrifugal filling early in the arterial phase *via* a dominant filling artery<sup>[93]</sup>.

Pseudo liver tumors, such as focal fatty infiltration or focal fatty sparing, exhibit the same characteristics as the surrounding liver parenchyma and thus remain isoechoic to normal liver tissue<sup>[93]</sup>.

Appearances of hypovascular liver metastases on MDCT are similar to those seen on CEUS. Lesions are typically rounded and uniformly hypoattenuating on portal venous phase CT imaging. They may demonstrate peripheral rim enhancement on late arterial phase images<sup>[94]</sup>. Hypervascular hepatic metastases typically demonstrate homogeneous late arterial enhancement on MDCT although inhomogeneous enhancement may be seen due to areas of necrosis or hemorrhage<sup>[95]</sup>.

MRI typically demonstrates liver metastases as hypointense on T<sub>1</sub>-weighted images and hyperintense on T<sub>2</sub>-weighted images<sup>[48]</sup>. Most liver metastases show restricted water diffusion on DW images and therefore appear as hyperintense masses<sup>[52]</sup>. While it is generally accepted that CE MRI increases the sensitivity for detecting metastases, the sensitivity of unenhanced MRI for liver metastases being in the region of 70% compared to 90% following contrast enhancement and being comparable to, if not better than, CT<sup>[26]</sup>, there is some debate on which contrast agent to use<sup>[13]</sup>, and indeed, on whether detection rates remain comparable to CT with 64 plus multi-detector CT<sup>[13]</sup>.

SPIO-enhanced MRI can be most useful in patients with colorectal carcinoma when being considered for hepatic resection on the basis of limited metastatic disease<sup>[96]</sup>. In addition, combining gadolinium with SPIO provides advantages for the depiction of liver metastases: hypovascular metastases are better identified

on SPIO, whereas hypervascular metastases are better depicted and characterized with gadolinium<sup>[97]</sup>.

## TUMOUR STAGING

### HCC

Staging of HCC depends on several factors including location of the lesion, presence of satellite nodules, biliary extension and vascular invasion. CT and MR remain the imaging techniques of choice for evaluating the liver parenchyma and the presence or absence of distant spread, although CEUS may also be useful in the assessment of vascular invasion.

A lesion detected on US examination in the cirrhotic liver with a diameter  $\geq 2$  cm has a greater than 95% chance of representing an HCC in the presence of a raised serum AFP level. Current BSG guidelines recommend further imaging (CT or MRI) to assess local and distant disease extent and enable planning of suitable therapy<sup>[5,6]</sup>. Common sites of extrahepatic disease include the peritoneum, abdominal lymph nodes, lungs and bone, and staging CT examination should include the chest. If the AFP level is normal, a confident diagnosis can usually be established without the need for needle biopsy if characteristic CT or MRI appearances (arterial enhancement, late washout) are demonstrated. Biopsy should be reserved for lesions where imaging appearances are equivocal and AFP level normal.

Intra-operative US (IOUS) of the liver is being used with increasing frequency as an aid for surgical planning and provides real-time information that can affect the surgical decision-making<sup>[98,99]</sup>. IOUS has been shown to change the clinical management in up to 50% of patients undergoing hepatic resection for malignancy<sup>[100-102]</sup>, detecting more lesions than the pre-operative conventional B-mode US, CT or angiography<sup>[103]</sup>.

### Cholangiocarcinoma

In patients in whom a diagnosis of cholangiocarcinoma is suspected, current BSG guidelines<sup>[6]</sup> recommend MRI and MRCP as the optimal investigations to assess liver and biliary anatomy, local tumor extent (including duct and vascular involvement) and the presence of hepatic metastases. Invasive cholangiography (*via* either the endoscopic or percutaneous transhepatic routes) is usually reserved for tissue diagnosis and cases where therapeutic biliary decompression is required due to cholangitis. Endoscopic US may also be helpful in allowing visualization of the distal extrahepatic biliary tree, gallbladder, regional lymph nodes and vasculature as well as facilitating the use of fine needle aspiration or biopsy of lesions. Chest radiography is recommended to look for lung metastases and abdominal CT examination to screen for intra-abdominal metastatic disease if MRI has not been performed.

## CONCLUSION

Recent advances in imaging techniques, particularly in the development of CEUS, MDCT and MRI contrast

agents, have improved detection and characterization of focal liver lesions and enabled accurate staging and appropriate treatment planning in both hepatocellular carcinoma and cholangiocarcinoma. Challenges remain in imaging evaluation of the cirrhotic liver, particularly in the detection of small hepatocellular carcinomas and their differentiation from a number of benign liver pathologies.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the commonest cancers worldwide. It is a major health problem and its incidence is increasing<sup>[1]</sup>. The presence of cirrhosis of the liver is the major risk factor and worldwide this is largely due to chronic hepatitis C virus (HCV) and hepatitis B virus (HBV) infection. The diagnostic modalities, especially with respect to hepatic imaging, have improved in recent years. This, along with HCC surveillance in patients with cirrhosis, has led to the detection of HCC at an earlier stage, when curative therapy is likely to be more successful.

The major diagnostic techniques for HCC include serum markers, various imaging modalities and histological analysis.

## SERUM MARKERS FOR HCC

A number of serum markers have been proposed and several are currently used in commonplace clinical practice as a method for detecting HCC (Table 1).

### Alpha-1 fetoprotein (AFP)

Under physiological conditions, AFP is a fetal-specific glycoprotein with a molecular weight of around 70 kDa. It is synthesized primarily by the embryonic liver, by cells of the vitelline sac and by the fetal intestinal tract in the first trimester of pregnancy. The serum concentration of AFP declines rapidly after birth and its expression is repressed in adults. Pathologically, patients with chronic liver disease, particularly those associated with a high degree of hepatocyte regeneration, can express

## Abstract

Hepatocellular carcinoma (HCC) is one of the commonest cancers worldwide, particularly in parts of the developing world, and is increasing in incidence. This article reviews the current modalities employed for the diagnosis of HCC, including serum markers, radiological techniques and histological evaluation, and summarises international guidelines for the diagnostic approach to HCC.

Table 1 Serum markers for HCC

Alpha-1 fetoprotein
Lens culinaris agglutinin-reactive AFP (AFP-L3)
Des-gamma carboxyprothrombin (DCP)
$\alpha$ -L-Fucosidase
Glypican-3
Squamous cell carcinoma antigen (SCCA)
Golgi protein 73 (GP73)
Hepatocyte growth factor (HGF)
Transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1)
Vascular endothelial growth factor (VEGF)
Serum proteomics

AFP in the absence of cancer. Also, AFP is elevated in hepatocarcinogenesis, embryonic carcinomas<sup>[2-7]</sup> and in gastric<sup>[8]</sup> and lung cancer<sup>[9]</sup>.

AFP has been used as a serum marker for HCC for many years. It was first described by Abelev *et al*<sup>[10]</sup> in the 1960s. The first quantitative serum assays for AFP were established by Ruoshlati and Seppala<sup>[11]</sup>. AFP is not elevated in all patients with HCC. Some patients with cirrhosis and/or hepatic inflammation can have an elevated AFP, even without the presence of a tumor. The test had a sensitivity of 39%-65%, a specificity of 76%-94%, and a positive predictive value of 9%-50% for the presence of HCC in previously published studies<sup>[12]</sup>. The variation in sensitivity and specificity of AFP in the studies performed may be due to the diversity of patient populations examined, varying study designs and differing cut-off values for normality.

There is a debate in defining the AFP cut-off level for the diagnosis of HCC. An AFP value above 400-500 ng/mL has been considered to be diagnostic for HCC in patients with cirrhosis. However, such a cut-off value is problematic in absolute diagnostic terms, since high levels of this magnitude are not as common in the presence of smaller tumors (< 5 cm) and furthermore, only 30% of HCC patients have levels higher than 100 ng/mL in this context<sup>[3,13]</sup>.

A case-control study of 170 HCC patients and 170 matched patients with chronic liver disease was conducted in Italy. The authors defined an AFP level of 16 ng/mL as the threshold that maximized sensitivity and specificity for the diagnosis of HCC. Using an AFP level of 20 ng/mL (the upper normal range) as the cut-off yielded equivalent sensitivity (60.0% *vs* 62.4%) and specificity (90.6% *vs* 89.4%). The positive and negative predictive values were 85% and 70%, respectively. The positive predictive value increased to 100% for patients without chronic hepatitis B or hepatitis C infection<sup>[14]</sup>. However, up to 42% of patients with HCC present with serum AFP levels within normal values<sup>[3,15]</sup>.

In another study, conducted in 290 Chinese patients with chronic hepatitis B, 44 patients were found to have an elevated AFP (> 20 ng/mL)<sup>[16]</sup>. Of these, only six (14%) had HCC and the remaining 38 patients had an elevated AFP due to hepatitis B viral flares ( $n = 18$ ), or due to unknown causes ( $n = 20$ ). It is clear that using an AFP level of just above normal as a cut-off level gives a very low positive predictive value<sup>[17]</sup>. Moreover, patients

with chronic hepatitis B or C with reactivation were found to have AFP levels > 500 ng/mL<sup>[18]</sup>.

AFP seems to be of prognostic value at the time of tumor diagnosis. A high AFP concentration ( $\geq 400$  ng/mL) in HCC patients is associated with greater tumour size, bilobar involvement, portal vein invasion, and a lower median survival rate<sup>[7]</sup>. According to a recent study, patients with serum AFP greater than 1000 ng/mL have a higher incidence of vascular invasion (61%) compared to patients with an AFP level less than or equal to 1000 ng/mL (32%)<sup>[19]</sup>. This may relate to the finding that well-differentiated tumours express lower levels of AFP<sup>[20]</sup>.

In addition, AFP can be used as a marker for detecting tumour progression in patients with AFP-producing HCC. After treatment of the tumour, complete response is likely if the pre-treatment elevated AFP levels decline to and remain at normal levels during subsequent follow-up measurements. Reduction of AFP levels after palliative treatment, such as transarterial chemoembolization, usually indicates a favorable response to treatment. In addition, AFP is an excellent marker for detection of *de novo* HCC after treatment, if the new lesion is of the AFP-secreting variety<sup>[17]</sup>.

A large multicenter study, based on both retrospective and prospective data collection, was carried out by Farinati *et al*<sup>[21]</sup> over a consecutive series of more than 1000 HCC patients. Only 18% of the studied patients had an AFP level of > 400 ng/mL. Moreover, patients with high AFP had poor survival. In this study, AFP was not a sensitive marker to detect the presence of HCC. Also, the prognostic value of AFP is limited, but it is correlated with the overall survival in untreated patients, or in those treated by liver transplantation or locoregional therapies<sup>[21]</sup>.

### Lens culinaris agglutinin-reactive AFP

There are three different AFP variants, differing in their sugar chains (AFP-L1, AFP-L2, AFP-L3). AFP-L1, the non-LCA-bound fraction, is the main glycoform of AFP in the serum of patients with non-malignant chronic liver disease. In contrast, Lens culinaris-reactive AFP, also known as AFP-L3, is the main glycoform of AFP in the serum of HCC patients and it can be detected in approximately one third of patients with small HCC (< 3 cm), when cut-off values of 10% to 15% are used<sup>[22]</sup>. Its sensitivity and specificity ranges from 75% to 96.90% and 90% to 92%, respectively at the cut-off level of 15%<sup>[22-24]</sup>.

In a study conducted in HCC patients with lesions less than 2 cm in size, using a cut-off level of 10% was diagnostic for the presence of HCC. AFP-L3 was found to be associated with poorly differentiated and advanced HCC. Higher AFP-L3 levels were found in hypervascular HCC, compared to iso- or hypovascular HCC<sup>[25]</sup>. Elevated levels of AFP-L3 were associated with a shorter tumor doubling time in comparison with those with low levels of AFP-L3.

Moreover, AFP-L3 acts as a marker for clearance of HCC after treatment and as a predictor of recurrence as

failure to decline to the normal level indicates residual disease. Recurrence of HCC is expected when AFP-L3 levels increase to > 10% or rise after normalization with treatment<sup>[17]</sup>. Another study reported that AFP-L3 > 15% is a significant predictor for HCC recurrence<sup>[26]</sup>.

AFP-L3 levels were found to be related to progression from moderately differentiated to poorly differentiated tumors. HCC patients with AFP-L3 > 10% had a higher frequency of poorly differentiated tumors<sup>[27]</sup>. Thus, this biomarker may be able to predict advanced tumor stage and a worse prognosis.

It is reported that an AFP-L3 level of 15% or more is correlated with HCC-associated portal vein invasion<sup>[28]</sup>, both total serum AFP and AFP-L3 can be measured simultaneously<sup>[29]</sup>, and estimating the AFP-L3/AFP ratio is helpful in diagnosis and prognosis of HCC.

### ***Des-gamma carboxyprothrombin (DCP)***

DCP is an abnormal prothrombin protein that is found in the serum of patients with HCC and in patients with vitamin K-deficiency or on warfarin therapy. It is a “so-called” protein induced by vitamin K absence or antagonist- II (PIVKA- II)<sup>[29,30]</sup>.

DCP is produced as a result of an acquired defect in the post-translational carboxylation of the prothrombin precursor (the 10 glutamic acid residues at the N terminus) in malignant cells<sup>[31]</sup>. The reduced activity of gamma-carboxylase was attributed to defective gene expression in HCC patients<sup>[7]</sup>. A DCP level of 40 mAU/mL is commonly used as a cut-off level, at which the rate of early detection of small HCC is improved<sup>[17]</sup>. Serum DCP was found to have a sensitivity of 48% to 62%, a specificity of 81% to 98%, and a diagnostic accuracy of 59% to 84% in diagnosing HCC in several large case-controlled studies<sup>[7,32]</sup>.

DCP is a well-recognized tumor marker used for the diagnosis of HCC. Its diagnostic accuracy has been investigated in multiple studies, with conflicting results. DCP has been reported to be more sensitive and specific than AFP in the diagnosis of HCC, especially in Eastern Asian countries and in North America<sup>[3,7,33]</sup>. Conversely, in Europe, studies have not shown these results. These discrepant results were related not only to racial factors but also to different etiological factors in liver disease. Even with these results, the measurement of both markers is suggested to increase diagnostic efficacy<sup>[3]</sup>.

A recent study compared the performance characteristics of AFP, DCP and AFP-L3 in the diagnosis of HCC. DCP was significantly better than the other markers in differentiating HCC from cirrhosis, with a sensitivity of 86% and a specificity of 93%<sup>[34]</sup>. However, tumor size can affect the sensitivity and specificity of DCP in detecting HCC. According to a study by Nakamura and colleagues<sup>[35]</sup>, the efficacy of DCP was lower than that of AFP in the diagnosis of small HCC tumors, although higher than that of AFP for large tumors.

Multiple studies have shown that DCP can be a useful indicator of vascular invasion in HCC patients<sup>[27,28,36]</sup>. Moreover, it was found to be a helpful marker for

monitoring the effectiveness of treatment and the recurrence of HCC after treatment<sup>[17,37]</sup>.

### ***Alpha-L-fucosidase (AFU)***

AFU is a glycosidase found in all mammalian cell lysosomes and is concerned with the degradation of a variety of fucose-containing fucoglyco-conjugates<sup>[38]</sup>. The activity of this lysosomal enzyme is detectable in the sera of healthy subjects. Increased activities are found in patients with HCC compared to healthy individuals and patients with chronic liver disease. Using a cut-off value of 870 nmol/mL, the sensitivity and specificity was 81.7% and 70.7%, respectively. Simultaneous determination of both AFP and AFU can increase the sensitivity to 82.6%. AFU activity was correlated with tumor size in patients with HCC<sup>[7,39,40]</sup>. According to another study conducted in 884 Chinese subjects<sup>[41]</sup>, the AFU activity was significantly higher in HCC patients compared to patients with cirrhosis, chronic hepatitis, other malignant tumors, other diseases and healthy individuals. The sensitivity for AFU was 81.5% and the specificity was 85.4%. Furthermore, the persistently elevated AFU level in patients with cirrhosis adds to the detection of HCC at an earlier stage<sup>[7,22,38]</sup>, owing to elevated activity of AFU at least 6 mo before the detection of HCC by ultrasonography in 85% of patients<sup>[39]</sup>.

However, it should be noted that the prolonged storage of serum samples affects the enzyme activities over time<sup>[42]</sup>. Furthermore, AFU activity is not only elevated in primary HCC, but also in cases of colorectal cancer<sup>[43]</sup> and ovarian cancer<sup>[44]</sup>, in addition to some non-malignant extrahepatic diseases, such as diabetes, pancreatitis, and hypothyroidism<sup>[29]</sup>.

### ***Glypican-3 (GPC3)***

GPC3 is a cell-surface glycoprotein which is a member of the glypican family of glycosyl-phosphatidylinositol-anchored cell-surface heparin-sulfate proteoglycans<sup>[45]</sup>. GPC3 mRNA and protein are not detectable in normal tissues, except placenta and fetal liver, and they are expressed in the majority of HCCs<sup>[46,47]</sup>. Normally, GPC3 has a role in regulating cell proliferation and survival during embryonic development by modulating the activity of various growth factors. Also, it functions as a tumor suppressor<sup>[29,48,49]</sup>.

GPC3 was expressed in 72% of HCC tissues, while it was lacking in hepatocytes from normal liver and non-malignant hepatic diseases. In addition, GPC3 was detected in sera from 53% of HCC patients, and it was not detected in the serum of patients with chronic hepatitis, or healthy individuals. No correlation was found between GPC3 and total AFP levels in patients with HCC. However, simultaneous measurement of GPC3 and total AFP increased the sensitivity without affecting the specificity<sup>[50]</sup>.

Hippo and colleagues<sup>[51]</sup> found that serum levels of soluble GPC3 (sGPC3), the NH<sub>2</sub>-terminal portion of GPC3, were significantly higher in HCC patients, compared to patients with cirrhosis and healthy controls.

sGPC3 was better than AFP in detecting well- or moderately-differentiated HCC and the combination of both markers improved overall sensitivity from 50% to 72%<sup>[22,51]</sup>.

A recent study evaluated the level of GPC3 in 49 fine needle aspiration biopsies, using immunocytochemical staining. For the diagnosis of HCC in the cytological material, the sensitivity of GPC3 was 83.3%, the specificity 96%, and the positive predictive value and the negative predictive value were 95% and 85.7%, respectively. This high sensitivity and specificity enabled the delineation of HCC, distinct from other benign and malignant hepatic lesions, and from most metastatic lesions<sup>[52]</sup>. Recently, it has been suggested that GPC3 can induce oncogenesis through activation of the insulin-like growth factor II (IGF-II) signalling pathway<sup>[53]</sup>.

### **Squamous cell carcinoma antigen (SCCA)**

SCCA, a member of the serpin (serine protease inhibitor) family, is physiologically expressed in the skin and other squamous epithelial cells<sup>[54]</sup>. High levels have been reported in tissues of head and neck cancer and other epithelial cancers<sup>[55]</sup>. It has also been reported to be over-expressed in HCC tissue and in serum from patients with HCC<sup>[56]</sup>.

Giannelli and colleagues measured serum SCCA in three patient groups: 120 patients with HCC, 90 with cirrhosis, and 41 healthy subjects. SCCA levels were significantly elevated in HCC patients, compared to patients with cirrhosis only or normal subjects. The sensitivity and specificity for SCCA were 84% and 49%, respectively, at the optimum cut-off value of 0.37 ng/mL<sup>[56]</sup>. The authors suggested that combination of the SCCA (high sensitivity/low specificity) and AFP (low sensitivity/high specificity) markers may be beneficial. According to a recent study, SCCA was found to be expressed in pre-malignant dysplastic nodules as well as malignant lesions<sup>[57]</sup>.

It has been reported recently that both AFP and SCCA can react with the IgM class of immunoglobulins to form the immunocomplexes AFPIC and SCCAIC, respectively. Both of these can be detected in the serum of HCC patients<sup>[54,58,59]</sup>.

Between 2001 and 2005, 961 consecutive patients with HCC ( $n = 499$ ) and those with cirrhosis uncomplicated by malignancy ( $n = 462$ ) were studied in multiple centers in Italy and France<sup>[54]</sup>. AFP, SCCA, AFPIC and SCCAIC were measured using ELISA tests in all patients. SCCA levels were inversely correlated with tumor size. The combined use of AFPIC, SCCA and SCCAIC in patients with low levels of AFP ( $< 20$  IU/mL) detected 25.6% of HCCs (186/725). There was no correlation found between AFP and the other markers investigated. The authors suggested, perhaps optimistically, that each marker was related to a different aspect of HCC, so that the use of all of these markers in combination in clinical practice would provide a non-invasive and relatively simple

series of tests that could improve the accuracy of HCC diagnosis<sup>[54]</sup>. However, it is unlikely that this suggestion will be taken up widely, as many of these tests have restricted availability and there are cost implications that will need further evaluation.

### **Golgi protein 73 (GP73, also known as Golp2)**

GP73 is a resident Golgi-specific membrane protein expressed by biliary epithelial cells in normal liver. Hepatocyte expression of GP73 is up-regulated in patients with acute hepatitis, cirrhosis and HCC, while in published studies, there is no considerable difference in biliary epithelial cell expression of this marker<sup>[60,61]</sup>.

It has been reported that GP73 is superior to AFP for the detection of early HCC in patients with cirrhosis. According to a study of 352 patients, measurement of serum GP73 based on immunoblots revealed that HCC patients had significantly higher levels than patients with cirrhosis<sup>[62]</sup>. At the optimal cut-off (10 relative units), the sensitivity and specificity were 69% and 75%, respectively. For the diagnosis of early HCC, this marker had a significantly higher sensitivity (62%) than AFP (25%)<sup>[62]</sup>. Interestingly, serum GP73 levels were elevated in 57% of patients with HCC associated with normal AFP levels.

### **Hepatocyte growth factor (HGF)**

HGF is a multi-functional factor that is produced in various body organs and can affect mitogenesis, cell motility, matrix invasion, and epithelial carcinogenesis<sup>[29,63,64]</sup>. Increased HGF serum levels have been reported in patients with squamous cell carcinoma of the esophagus<sup>[65]</sup> and lymphomas, in addition to non-malignant diseases, such as aortic dissection, pulmonary thromboembolism<sup>[66]</sup>, coronary syndrome<sup>[67]</sup>, cerebral infarction<sup>[68]</sup> and sepsis<sup>[69,70]</sup>. In a prospective study, blood samples were collected from 99 patients with chronic hepatitis, cirrhosis, and HCC<sup>[71]</sup>. Serum HGF levels were significantly elevated in HCC patients compared to patients with cirrhosis or chronic hepatitis but no malignancy. All patients with a serum HGF concentration of greater than 0.6 ng/mL had HCC, irrespective of the AFP or DCP levels.

HGF has been used as a prognostic marker in HCC. Serum HGF levels greater than or equal to 1.0 ng/mL have been associated with poor survival in HCC patients<sup>[72]</sup>. A recent study conducted in HCC patients who underwent hepatic resection associated high HGF levels in peripheral and portal blood with adverse prognosis<sup>[73]</sup>. The authors postulated that HGF induces proliferation and invasiveness of HCC cells through expression of its receptor, the c-met receptor. Also, the persistent elevated level of serum HGF with intensive expression of c-met protein after partial hepatectomy were found to predict early tumor recurrence and metastasis<sup>[74]</sup>. This may be explained by the role of HGF in initiating proliferation of normal and malignant hepatocytes after partial hepatectomy.

**Transforming growth factor-beta 1 (TGF- $\beta$ 1)**

TGF- $\beta$ 1, a multifunctional factor, has a vital role in the regulation of growth and differentiation of normal and transformed cells, angiogenesis, extracellular matrix formation, immunosuppression and carcinogenesis<sup>[7,75]</sup>. It has been reported that TGF- $\beta$ 1 and TGF- $\beta$ 1 mRNA levels were significantly higher in the serum of patients with HCC compared to patients with non-malignant chronic liver diseases<sup>[7,75,76]</sup>. Using a cut-off level of 1.2  $\mu$ g/L for the diagnosis of HCC, the sensitivity was 89.5% and the specificity was 94%. Interestingly, expression of TGF- $\beta$ 1 in liver tissues was related to the degree of HCC differentiation. Hence, this biomarker might find a role as a prognostic marker in HCC. Simultaneous detection of TGF- $\beta$ 1 level and serum AFP yielded a higher detection rate of 97.4%<sup>[75]</sup>.

It has also been reported that TGF- $\beta$ 1 levels might increase in patients with cirrhosis, owing to decreased hepatic clearance in such patients. In addition, this biomarker is up-regulated in extra-hepatic tumors, wound healing, angiogenesis and fibrosis, indicating lack of disease-specificity<sup>[29,76]</sup>.

**Vascular endothelial growth factor (VEGF)**

VEGF is an endothelial cell mitogen that initiates and promotes neovascularization and endothelial cell proliferation, and it was initially identified as a vascular permeability factor. VEGF has a major effect in regulating angiogenesis, and its expression has been shown to correlate with carcinogenesis<sup>[7]</sup>. In a study by Poon and colleagues, conducted in 108 patients with HCC and 20 healthy controls<sup>[77]</sup>, serum VEGF levels in HCC patients were significantly higher, compared to control individuals, and was correlated with venous invasion and advanced tumour stage. In this study, a serum VEGF level of 245 pg/mL or more was associated with poor overall survival.

The expression of VEGF in HCC tissues was correlated with AFP, DCP tumor size and histological grade of the tumor<sup>[78]</sup>. Furthermore, this biomarker was related to invasiveness and metastasis of HCC<sup>[17,79]</sup>. The expression of VEGF in HCC patients with microscopic venous invasion was significantly higher than that in HCC patients without microscopic venous invasion<sup>[80]</sup>.

**Serum proteomics**

Recently, surface-enhanced laser desorption/ionization-time of flight mass spectrometry (SELDI-TOF) has been used to identify specific serum protein fragments. Paradis and colleagues conducted a SELDI-based study in 82 French patients and identified a six-peak panel that distinguished HCC and non-HCC patients in 90% of the cases<sup>[81]</sup>. The C-terminal fragment of vitronectin was identified as the highest discriminating peak. Identification of this fragment as a marker for HCC is possible, as it could be generated *in vitro* by cleavage of the intact vitronectin molecule by a metalloprotease<sup>[29]</sup>.

A more recent study compared the sensitivity and specificity of SELDI-TOF MS with AFP, AFP-L3,

and prothrombin induced by vitamin K absence-II (PIVKA-II) for the detection of established HCC<sup>[82]</sup>. For AFP, the sensitivity and specificity were 73% and 71%, respectively, using a cut-off level of 20 ng/mL. With AFP-L3, a cut-off level of 10% gave a sensitivity and specificity of 63% and 94%, respectively. Using the PIVKA-II cut-off of 125 mAU, the sensitivity and specificity were 84% and 69%, respectively. The sensitivity and specificity of SELDI-TOF MS were 79% and 86%, respectively. The authors concluded that SELDI-TOF MS analysis is more accurate than other conventional means of biomarker assessment in detecting small tumors.

**RADIOLOGICAL DIAGNOSIS OF HCC****(FIGURE 1)**

Imaging modalities employed in HCC diagnosis can be divided into two main groups: those routinely used such as ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI); and those that are more invasive, including iodized oil-CT, CT during hepatic arteriography (CTHA), CT arterial portography (CTAP) and conventional hepatic angiography<sup>[83]</sup>.

**Ultrasound scanning (US)**

Currently, US is the technique of choice for screening focal hepatic lesions. On US, lesions may appear hyperechoic, hypoechoic or show a 'target lesion' appearance, but none of these is specific<sup>[84,85]</sup>. Any mass detected on US in a cirrhotic liver is suspicious of HCC, particularly if it is > 1 cm in size. As a screening test, US has a sensitivity of 65%-80% and has a specificity of > 90%<sup>[84-86]</sup>. US permits the detection of smaller sized tumors (1 cm) in early carcinogenesis<sup>[3,13,87]</sup>. However, the detection of small HCC in a cirrhotic liver by US is much more difficult than the detection of metastases in a normal liver, owing to disturbed parenchymal architecture<sup>[88,89]</sup>.

The ultrasonographic characteristics of HCC depend on nodule characteristics and tumor size. Most small HCC nodules (less than 3 cm) are well defined, homogeneous and hypoechoic without posterior echo-enhancement. These features are non-specific and may be indifferent from the echo pattern of regeneration nodules in cirrhosis<sup>[88,89]</sup>. As the tumor grows in size, it becomes non-homogeneous and more hyperechoic or isoechoic, owing to fatty degeneration or coagulation necrosis. Alternatively, it may show a heterogeneous (mosaic) pattern with a star-shaped central hypoechoic area, owing to the presence of fibrous septae. There is another, less common type of nodular HCC that is homogeneous and diffusely hyperechoic, owing to fatty changes or dilated sinusoids. These features do not differ as the tumor grows<sup>[88]</sup>.

In addition, US can be used to assess the vascular structures and the presence of hilar adenopathies associated with advanced tumor stage<sup>[3]</sup>. The presence

**Figure 1** There is a large HCC in the left lobe of the liver with a pseudocapsule, hyper-enhancing on arterial phase and showing washout on late phases on MR and CEUS and is iso-intense in portal phases on CT and CEUS. The pseudo-capsule enhances in the portal phase on all modalities. A1: T<sub>2</sub> weighted scan showing slightly higher intensity HCC (arrow); A2: T<sub>1</sub> weighted scan shows same HCC which is iso-intense (arrow); B1: MultiHance enhanced T<sub>1</sub> weighted scan in the arterial phase showing enhancement of the HCC (arrow); B2: MultiHance enhanced T<sub>1</sub> weighted scan in the portal phase showing iso-enhancement of the HCC (arrow); B3: MultiHance enhanced T<sub>1</sub> weighted scan at 2 min showing contrast wash-out in the HCC (arrow); B4: MultiHance enhanced T<sub>1</sub> weighted scan at 40 min showing hypointense HCC (arrow); C1: Baseline ultrasound shows iso-echoic HCC (arrow); C2: SonoVue enhanced ultrasound shows hyper-enhancing HCC (arrow) in the arterial phase; C3: SonoVue enhanced ultrasound shows iso-enhancing HCC (arrow) in the portal phase with enhancement of the pseudocapsule; C4: SonoVue enhanced ultrasound shows wash-out of the HCC (arrow) in the late phase; D1: Contrast-enhanced CT scan shows enhancement of the HCC (arrow) in the arterial phase; D2: Contrast-enhanced CT scan shows iso-enhancement of the HCC (arrow) in the portal phase with enhancement of the pseudocapsule.

of intra-hepatic venous thrombosis, a mass protruding from the hepatic surface or a dilated intra-hepatic bile

duct offer indirect evidence that raise the suspicion of a liver tumor, even in the absence of a definite finding of

a liver mass on US<sup>[88]</sup>.

Tumor size has been found to affect the sensitivity of US in detecting HCC. Kim and colleagues (2001) assessed the performance of grey-scale US in pre-transplant patients. The sensitivity for HCC nodules greater than 2 cm was 38% and for lesions less than 2 cm, it was 30%<sup>[83]</sup>. Other studies showed the sensitivity for tumors smaller than 1 cm to be about 42%<sup>[3,90,91]</sup> compared to 95% for tumors of larger size<sup>[92]</sup>.

It has been found that US had low sensitivity and high specificity in detecting HCC and DN in patients with end-stage liver disease requiring liver transplantation<sup>[89]</sup>. According to a retrospective study of 200 patients with liver failure who underwent liver transplantation within 90 d of US scanning, correlating the US findings with explanted livers showed a sensitivity of 75% for large lesions (> 5 cm), but for small lesions (1-5 cm), the sensitivity ranged from 13.6 to 50%<sup>[93]</sup>.

### Colour Doppler US

Colour Doppler US gives an approximation of the mean velocity of blood flow within a vessel by color coding the flow and displaying it superimposed on the grey-scale image, while power Doppler assesses the amplitude of signals<sup>[89]</sup>. The diagnostic performance of US in the identification of tumor portal thrombosis in patients with HCC can be increased when combining Doppler with US: the sensitivity reaches up to 92% and the specificity virtually 100%. When US-Doppler reveals permeability of the portal system, portal thrombosis is ruled out and hepatic arteriography should be avoided<sup>[3,94]</sup>.

Patients with tumors treated with percutaneous ethanol injection may develop chemical thrombosis. Such benign thrombi can be differentiated from tumoral thrombosis using US Doppler, based on the presence of blood flow in the thrombus. The presence of a hepatofugal pulsatile flow inside the thrombus confirms the presence of tumoral invasion of portal vessels<sup>[3,95]</sup>.

### Contrast enhanced ultrasound (CEUS)

CEUS using non-linear imaging modes has been used to improve sonographic visualization of hepatic tumor vascularity<sup>[96,97]</sup>. CEUS can give information about the nature of liver lesions that are not characterized with baseline US, and every lesion detected during US surveillance in patients with chronic liver disease, or in patients with past history of malignancy<sup>[96,98]</sup>. CEUS is safe and well tolerated. The contrast study can be performed once a focal lesion is detected on standard US, providing immediate information about the vascular characteristics of the nodule<sup>[97]</sup>.

US contrast agents consist of microbubbles of low-solubility gas surrounded by a protein, lipid or polymer shell. The microbubbles are 1 to 10  $\mu\text{m}$ , which are too large to pass through the vascular endothelium and, as such, they are considered pure blood pool agents<sup>[99,100]</sup>. In the liver, the microbubbles dissolve several minutes later in the circulation leading to exhalation of the gas

and metabolism of the shell<sup>[99,101]</sup>. The microbubbles change their size when subjected to an US wave. On the other hand, soft tissues express minor changes. The bubbles are highly reflective, even when they are present in a small concentration. Furthermore, the expansion of these bubbles during the rarefaction phase exceeds their contraction during the pressure phase leading to the production of a returning signal (echo) that contains harmonics<sup>[99,102]</sup>.

The characterization of a hepatic lesion with microbubbles depends on all phases of contrast enhancement, i.e. the hepatic arterial phase (starting from 10-20 s after injection of contrast agent and lasting for about 10-15 s), portal venous phase (up to 120 s post-injection) and late parenchymal phase (up to 4-6 min after injection)<sup>[103]</sup>. The arterial phase helps in predicting the degree and pattern of vascularity, while the portal and late phases are helpful in determining the nature of a lesion, as most malignant lesions are hypo-enhancing in contrast with the benign lesions which are iso-or hyper-enhancing<sup>[103]</sup>.

The majority of HCCs are characterized by arterial phase enhancement and washout of the contrast during the late phase, so as to appear as a defect. However, well-differentiated HCCs may not show this washout. Moreover, it has been observed that the more differentiated a lesion, the more gradually it is likely to washout<sup>[99,103,104]</sup>. Recently, it was reported by Pompili and colleagues that CEUS and multidetector row CT have a similar sensitivity (up to 87%), unaffected by nodule size (< 2 cm *vs* 2-3 cm)<sup>[97]</sup>. Most hypervascular nodules (85.2%) were exactly identified by both methods, while CT was slightly more sensitive in detecting arterial vascularity. The authors concluded that CEUS is a dependable imaging tool for vascular characterization of small nodules (less than 2 cm) in patients with cirrhosis.

CEUS gives equivalent accuracy to CT and MRI in the characterisation of focal liver lesions<sup>[98]</sup> and is probably the best alternative when there are contraindications to CT or MRI<sup>[97]</sup>. However, the performance of CEUS compared with CT or MRI, is highly affected by operator skill and experience, patient-related factors, such as body habitus and cooperativeness, and tumor-related factors, such as nodule location. Also, it is inappropriate for panoramic detection and staging of HCC<sup>[97]</sup>.

### CT

Multiphasic helical CT (MPCT) is deemed the imaging technique of choice for the detection and staging of HCC<sup>[88,105,106]</sup>. MPCT includes four phases: pre-contrast, hepatic arterial, portal venous and delayed phases. A high-speed single detector spiral scanner is used to achieve the images. Images are obtained after contrast injection at a delay of 25 s (arterial phase), 70 s (portal venous phase) and 300 s (equilibrium phase). HCCs appear hypervascular during the hepatic arterial phase, owing to the fact that the hepatic artery provides the main blood supply, and it appears rather hypodense during the delayed phase, which is attributed to the early wash-out of contrast. It was found that delayed phase images can aid in the diagnosis of HCC in 14% of

patients<sup>[88,107]</sup>. Typically, HCC lesions are heterogeneous on CT and the appearance of satellite nodules around the lesion is characteristic<sup>[108]</sup>. Combining the hepatic arterial and portal venous phases improves the detection of small malignant tumors<sup>[88,109]</sup>.

It has been reported that the presence of intraluminal low attenuation with distension of the occluded venous segment would be indicative of tumor thrombus<sup>[88]</sup>. Tumor thrombosis can be differentiated from benign thrombosis during the arterial phase. Since tumor thrombosis enhances, such enhancement can be detected either as “diffuse”, which is typical of HCC, or as streaks of tumor vessels inside the thrombus<sup>[89,110]</sup>. Several studies have assessed the performance of spiral CT in the diagnosis of HCC. One study on 41 patients who underwent transplantation within 100 d of imaging, revealed a sensitivity and specificity for HCC of 80% and 96%, respectively<sup>[111]</sup>.

The diagnostic accuracy of CT is affected by technical factors, such as the injection of contrast, and intrinsic factors related to the tumor, such as tumor size and vascularity. It was reported that the diagnostic efficacy of CT is diminished in small tumors (less than 2 cm) owing to the hypo-vascularization of small-sized tumors<sup>[3,112,113]</sup>. The sensitivity of four phase CT in detecting HCC was up to 100% for tumors greater than 2 cm in size, 93% for tumors 1-2 cm in size, and for tumors less than 1 cm in size, it was 60%<sup>[114]</sup>.

Spiral CT is the standard imaging technique for detecting the response to loco-regional treatment of HCC<sup>[115]</sup>. It has been reported to be more effective than combining US scanning and AFP level estimation in the detection of early HCC recurrence after successful treatment<sup>[116]</sup>.

More recently, a study to evaluate the diagnostic efficacy of contrast-enhanced helical computed tomography (CECT) and CEUS has been conducted in patients with small hepatic nodules, previously detected by surveillance programs<sup>[117]</sup>. The sensitivity, specificity and diagnostic accuracy were 91.1%, 87.2%, and 89.3%, respectively, for CEUS. For CECT, the sensitivity, specificity and diagnostic accuracy were 80.4%, 97.0%, and 88.4%, respectively. The authors found no significant difference between CEUS and CECT in characterising small (1-2 cm) hepatic nodules.

### **Multidetector helical CT (MDCT)**

Recently, MDCT has allowed collection of early (18-28 s after injection of contrast) and late or so-called early parenchymal (35-45 s) arterial phase images. The early arterial images illustrate vessels optimally needed for treatment planning in patients who are likely to undergo surgery, while the late arterial phase images demonstrate the lesions better than the early arterial phase<sup>[118]</sup>. Evaluation of both early and late arterial phase images results in better sensitivity and positive predictive values<sup>[89,119]</sup>. MDCT with two arterial phases carry the risk of increased radiation exposure thus, limiting its use<sup>[89]</sup>. MDCT has been shown to have a higher sensitivity in the detection of HCC in cirrhotic liver, owing to the

high speed and flexibility leading to achievement of high quality, thin section imaging and three dimensional capabilities<sup>[108]</sup>. In addition, vascular tumors can appear hypodense, relative to liver parenchyma during the equilibrium phase (3-5 min post-injection). It is reported that tumors measuring less than 2 cm can be best detected in this phase, owing to the more rapid washout of contrast from the tumor than from the normal liver parenchyma<sup>[89,120]</sup>.

Recently, it was reported that MDCT scanning is useful in early detection and the effective treatment of small HCCs, especially during follow-up of patients with chronic hepatitis and cirrhosis. A study compared the efficiency of gadolinium-enhanced multiphase dynamic MRI with MDCT scanning in the detection of small HCC<sup>[121]</sup>. The detection rate of small HCC on MDCT was 97.5%-97.6% and it was 90.7%-94.7% on MRI, according to tumor size. For very small HCC  $\leq 1$  cm, the sensitivity of detection on MDCT was higher compared to MRI (90.0%-95.0% and 70.0%-85.0%, respectively). The authors concluded that MDCT scanning was better than MRI for early detection of small HCC during the follow-up of patients with chronic hepatitis and cirrhosis<sup>[121]</sup>.

### **MRI**

MRI has been used to improve detection and characterization of hepatic malignant lesions<sup>[3]</sup>. HCC appears hyper-intense on T<sub>2</sub>-weighted images with variable signal intensity on T<sub>1</sub>-weighted images. Usually, there is no signal drop-out on the in- and out-of-phase images, because of a low incidence of fatty change. With dynamic gadolinium-enhanced imaging, the lesion enhances in the arterial phase then becomes isointense in the portal phase then becomes hypo-intense in the delayed phase<sup>[88,122]</sup>.

MRI was found to be more accurate than CT or US in detecting HCC and estimating the actual tumor size<sup>[123]</sup>. Moreover, MRI was more effective than spiral CT in detecting HCC and dysplastic nodules in patients with cirrhotic liver. The sensitivity of MRI for characterising HCC was 61% while the sensitivity of CT was 52%<sup>[124]</sup>.

The sensitivity of MRI in detecting HCC depends on tumor size. It is about 95% in tumors larger than 2 cm, while in tumors less than 2 cm the sensitivity is reduced to 30%<sup>[125]</sup>. MRI is also very good at delineating the internal architecture of the tumor, the tumoral margins and intrahepatic vascular invasion<sup>[125]</sup>. Hence, MRI is deemed the best tool in differentiating HCC from hepatic hemangioma<sup>[3,13]</sup>. It has also been suggested that liver function may affect hepatic parenchymal signal intensity leading to the appearance of observed liver-to-lesion contrast on delayed images<sup>[89,126]</sup>.

### **Angiography**

Owing to the hypervascular nature of HCC, the arterial supply to the tumor is often dilated, tortuous, distorted and displaced. An intense tumor stain, vascular lakes and venous pools are commonly observed<sup>[88]</sup>. It is thought that the diagnostic efficacy of hepatic arteriography

**Table 2** EASL consensus diagnostic criteria for HCC (adapted from Bruix *et al.*<sup>[115]</sup>, 2001)

Cyto-histological criteria
Non-invasive criteria (restricted to patients with cirrhosis)
Radiological criteria: two coincident imaging techniques
Focal lesion > 2 cm with arterial hypervascularisation
Combined criteria: one imaging technique associated with elevated serum AFP levels
Focal lesion > 2 cm with arterial hypervascularisation
AFP levels > 400 ng/mL

is related to tumor size and vascularization<sup>[112]</sup>. The sensitivity, specificity and diagnostic accuracy of angiography in the detection of HCC smaller than 5 cm has been reported as 82%-93%, 73% and 89%, respectively. When tumor size was smaller than 2 cm, these values were reduced<sup>[3,127,128]</sup>. Currently, angiography is often used to delineate hepatic anatomy before resection or as guidance for transarterial chemoembolization of HCC lesions<sup>[108]</sup>.

### Histological diagnosis of HCC

Cytological examination of a suspected lesion can be achieved by fine needle aspiration biopsy (FNAB). FNAB diagnostic efficacy varies from 60% to 90% according to the size of the lesion, the diameter of the puncturing needle and level of operator training. The specificity and positive predictive value of this technique are from 90% to 100%. It is a safe technique with minimal risk of complications<sup>[3,13,129,130]</sup>.

Histopathological examination is considered the chief method for a sure diagnosis of HCC. It is mandatory to study non-tumoral liver tissue to exclude or to confirm the presence of liver cirrhosis, which affects the treatment modality<sup>[3,129]</sup>. Complications associated with liver biopsy are low with mortality rates of 0.006%-0.3%. The risk of tumor seeding along the needle tract has been estimated at up to 3%<sup>[108,131,140,144]</sup>.

A combination of the two pathological techniques can improve diagnostic performance<sup>[3,129]</sup>. One study reported that the sensitivity of cytological and histological examination was about 80% for each one separately. When combining the two methods, sensitivity reached 89%<sup>[132]</sup>.

Microscopically, HCC cells have an elevated nuclear to cytoplasmic ratio, trabecular architecture, atypical naked nuclei, and peripheral endothelial wrapping<sup>[108,133]</sup>. Pathological findings range from almost normal-appearing hepatocytes in well differentiated tumors to the largely anaplastic multinucleate giant cells in poorly differentiated HCC<sup>[108,134]</sup>.

### DIAGNOSTIC APPROACH

The European Association for the Study of the Liver (EASL) has formulated a consensus statement to regulate the diagnostic approach in HCC patients, based on histological and radiological criteria for identifying HCC in patients with cirrhosis. Recommendations were

**Table 3** Diagnostic criteria for HCC (adapted from Bruix *et al.*<sup>[85]</sup>, 2006)

Cyto-histological criteria
Non-invasive criteria (cirrhotic patients)
Focal lesion ≤ 2 cm. Two imaging techniques with arterial hypervascularisation and venous washout
Focal lesion > 2 cm. One imaging technique with arterial hypervascularisation and venous washout

considered based on the size of the lesion (Table 2)<sup>[115,135]</sup>.

HCC lesions of greater than 2 cm in diameter can be diagnosed non-invasively, based on radiographic criteria in patients with cirrhosis<sup>[115,135]</sup>. Detection of nodules with arterial hypervascularization in two imaging modalities, or in only a single imaging modality associated with an AFP level ≥ 400 ng/mL in the cirrhotic liver, is considered diagnostic of HCC. EASL recommended evaluating the vascularity of hepatic nodules using US, contrast-enhanced CT or MRI, with formal angiography used in cases of diagnostic uncertainty. Histological confirmation by biopsy was not mandatory owing to the excellent diagnostic accuracy of imaging criteria and the 10%-20% false-negative rate from histological samples<sup>[136-138]</sup>.

Focal hepatic lesions of less than 1 cm in size were found to be non-malignant in 50% of cases<sup>[135,141-143]</sup>. The EASL consensus statement recommended repeated ultrasound scanning every 3 mo until the lesion grows to 1 cm in diameter. Nodules from 1-2 cm in size are more likely to be HCC and pathological confirmation was recommended using fine-needle aspiration or biopsy or both for the diagnosis of these nodules. However, it carries a hazard for tumor seeding with a 30%-40% false-negative diagnostic rate<sup>[115,135,139]</sup>.

Recently, the American Association for the Study of Liver Disease (AASLD, 2005) issued guidelines which also proposed a diagnostic approach for HCC (Table 3). AFP of 200 ng/mL should lead to diagnostic suspicion of HCC requiring further investigation. In terms of imaging, nodules less than 1 cm in diameter should be repeatedly imaged for up to 2 years, due to uncertainty in the current diagnostic techniques in establishing a firm diagnosis. Nodules between 1 and 2 cm should be investigated with two dynamic imaging techniques such as CT scan, CE US or MRI<sup>[85]</sup>. If they show hypervascularity with washout in the portal venous phase, the lesion can be diagnosed as HCC. Nodules greater than 2 cm in size that reveal typical features of HCC on dynamic profile (arterial hypervascularity with wash-out in the early or delayed venous phase) can be diagnosed as HCC by using a single imaging modality. Histological diagnosis was recommended if the vascular pattern is not characteristic for HCC on imaging modalities, to establish the diagnosis<sup>[84,85]</sup>.

### CONCLUSION

The incidence of HCC is increasing around the world.

Although international consensus exists on a diagnostic pathway, there is no ideal screening modality. AFP serum level is the most commonly used serum test, while US is the most commonly used imaging test. Future research may delineate more specific and sensitive markers using proteomic or metabolomic approaches to screening blood or other biofluids such as urine.

## ACKNOWLEDGMENTS

We are grateful for support from the NIHR Biomedical Research Centre funding scheme. In addition, we are grateful to the following for their funding and support: AIE is funded by a scholarship from the Egyptian Government; SAK is supported by a grant from the Higher Education Funding Council for England (HEFCE); SDTR is funded by grants from the British Medical Research Council (MRC), London, United Kingdom; the British Engineering, Physics and Science Research Council (EPSRC), Swindon, United Kingdom; the Alan Morement Memorial Fund AMMF, Essex, United Kingdom; Broad Foundation, Los Angeles, United States; Pfizer Global Research and Development Inc, Sandwich, United Kingdom and GlaxoSmithKline, Ware, United Kingdom. We are grateful to Dr. I Jane Cox and Dr. Robert Edwards, Imperial College London for useful discussions.

### Abstract

Crohn's disease is a chronic inflammatory granulomatous process that usually involves different sites in the intestinal tract. Genetic and environmental factors are thought to play a role in its etiology and pathogenesis. The disorder has a heterogeneous clinical expression and data from tertiary care settings have documented its female predominance, occasional familial nature, and high rate of stricture formation and penetrating disease. It may appear from early childhood to late adulthood, although over 80% are currently diagnosed before age 40 years, usually with terminal ileal and colonic involvement. Several studies have now shown differences in phenotypic clinical expression depending on the initial age at diagnosis, with pediatric-onset disease being more severe and more extensive with more involvement of the upper gastrointestinal tract compared to adult-onset disease. In addition, long-term studies from these tertiary care settings have documented that the disorder may evolve with time into a more complex disease with stricture formation and penetrating disease complications (i.e. fistula and abscess). Although prolonged remission with no evidence of inflammatory disease may occur, discrete periods of symptomatic and active granulomatous inflammatory disease may re-appear over many decades. Long-term studies on the natural history have also suggested that discrete events (or agents) may precipitate this granulomatous inflammatory process.

### INTRODUCTION

Crohn's disease is a chronic inflammatory granulomatous disorder that usually involves different sites along the length of the intestinal tract. Genetic and environmental factors are believed to play a role in its etiology and pathogenesis. As Crohn's disease is very heterogeneous in its clinical expression, working groups at the World Congress of Gastroenterology, held initially in Vienna and later in Montreal, have developed an evolving classification scheme<sup>[1,2]</sup>. An important goal has been to enumerate different phenotypic characteristics so that more homogeneous subgroups can be explored. Application to a specialist care clinical database noted a female predominance, occasional familial nature, and a high rate of stricture formation and penetrating disease<sup>[3-5]</sup>.

The disorder seems to be life-long and may appear at almost any time from early childhood to late adulthood<sup>[1-3]</sup>. However, for most, the actual onset of the disease, or more precisely the age at diagnosis, is usually during the late teens and early twenties, and now, during the past two or three decades, over 80% of patients with Crohn's disease are diagnosed before the age of 40 years<sup>[3]</sup>. Moreover, the majority have involvement primarily of the ileum and colon, at least based on the most sensitive and modern imaging methods<sup>[1-3]</sup>. Finally, most specialists usually see late complicated disease, while early disease without stricture or fistula development may not be seen as often, particularly in specialist or tertiary-care centers.

### DISEASE ONSET AND AGE AT DIAGNOSIS

Clearly, an appreciation for the natural history of Crohn's disease must depend, not on the age at diagnosis

defined by these classifications, but the actual time of onset of the disorder. These are obviously very different. Symptoms that eventually lead the patient to specialist referral include diarrhea, abdominal pain and weight loss, but these are not always universally present. Occasionally, only a single symptom, possibly abdominal pain, may be evident. In some, detection of an unexpected ileal inflammatory process at laparotomy for suspected appendicitis may be the first presentation. For others, extra-intestinal findings (e.g. arthropathic process or a skin disorder, such as erythema nodosum) may be present without significant intestinal symptoms. In some, symptoms have often been present for variable periods of time, even months or years, before a diagnosis is established. Also, in these, an event (or possibly an infectious agent) that initiated this destructive inflammatory process may no longer be detectable, having long left the patient. Indeed, multiple events (or agents) can conceivably generate this insidious inflammatory cascade that causes clinical symptoms and the appearance of a common end-pathological change labeled Crohn's disease. Even hypothetical genetic, microbiological and immunological factors that permit ongoing progression of this frustrating clinical disorder still require elucidation.

## DISEASE LOCALIZATION, EXTENT AND BEHAVIOR

Most intriguing is the apparent predilection of the disease for the distal small intestine and proximal colon<sup>[3]</sup>. More extensive involvement of the small intestine and colon may occur<sup>[6]</sup>, and the old adage that Crohn's disease can potentially involve any site "from mouth to anus (and probably elsewhere in the case of "metastatic" disease)" still holds true. Moreover, genetic factors may play a role in localization of the disease to different intestinal sites<sup>[7,8]</sup>. Further information, however, is clearly required on basic luminal and intestinal factors that play a role in localization of the disorder to specific sites along the gastrointestinal tract. Crohn's disease can occasionally occur in the upper gastrointestinal tract, usually with disease elsewhere in the ileum, colon, or both. The disorder may also occur only in the upper gastrointestinal tract without disease involvement elsewhere, albeit rarely<sup>[2,3]</sup>. Also, extensive jejunoileal involvement, evaluated over the long-term, illustrates a special subgroup of Crohn's disease that historically responds poorly to medication, which often leads to surgical treatment and long-term nutritional support<sup>[6]</sup>. New and developing biological treatment paradigms largely focused on reducing numerical indices in ileocolonic disease may have little impact on this subgroup, unless the severity and extent of the inflammatory process can be reduced.

Crohn's disease is a chronic, persistent and destructive disorder with distinct forms of clinical behavior that may also, in part, be genetically-based<sup>[9,10]</sup>. It also seems progressive, although the rate of progression may be

altered or slowed, by the use of some therapy, such as steroids, antibiotics, or resective surgery, at least for a period of time. It appears that the disease begins as an inflammatory process that progressively develops over time to a more complex disease with stricture and fistula formation<sup>[11-13]</sup>. Once initiated, it is likely that numerous genetic and environmental factors play a role in regulating the rate of progression, but these are poorly understood. Moreover, the progression itself may not be linear but occur in a step-wise fashion with prolonged symptom-free periods over many decades<sup>[14]</sup>.

Crohn's disease may also initially present as an already advanced and clinically complex disease with extensive or multiple jejunoileal strictures<sup>[6]</sup>, sometimes even with free perforation of the small intestine, or alternatively, with large intra-abdominal inflammatory masses, sometimes with a deeply penetrating fistula (e.g. ileosigmoid fistula). In some, it has been hypothesized that recurrent disease may occur as a patterned clinical response, possibly related to specific genetic regulatory factors. For instance, recurrent stenotic events may result in a localized ileocecal resection, new erosions and ulcers in the neo-terminal ileum, and further stricture formation, recurrent obstructive symptoms and another resection<sup>[15]</sup>. Or, recurrent penetrating events with fistula and abscess formation may occur<sup>[15]</sup>. Classifying clinical behavior in Crohn's disease is difficult and may not be truly reflective of natural history as the rates of development of a complication, such as a stricture formation, may differ markedly, not only among patients, but even in the same patient during the disease course. Some may have either a rapidly progressive inflammatory process, or alternatively, a low grade sub-clinical process, possibly present for months, that suddenly becomes clinically expressed.

## AGE-RELATED PHENOTYPIC EXPRESSION

Early historical studies have suggested that the phenotypic clinical expression of Crohn's disease differs substantially, depending on the age of initial diagnosis<sup>[16-20]</sup>. This age-dependent phenotypic clinical expression probably reflects the dynamic nature of the disorder<sup>[21]</sup>. Disease developing earlier in children and adolescents tends to be much more severe, often resulting in significant disease complications, including strictures or fistulae, or both<sup>[22-25]</sup>. It is also more extensive, often involving multiple sites in the small and large intestine, with a higher frequency of involvement of the upper gastrointestinal tract<sup>[22-25]</sup>. Comparative studies also show significant differences in clinical expression for children and adults<sup>[21,22]</sup>, as well as the elderly<sup>[26]</sup>. Others have defined a difference in some immunoreactive characteristics of early-onset compared to late-onset Crohn's disease<sup>[27,28]</sup>. The hypothesis that a dysregulated immune response, likely affected by aging *per se* and leading to different phenotypic disease expressions of Crohn's disease, needs to be further elucidated.

## CLINICOPATHOLOGICAL CORRELATIONS

Clinical and pathological correlations have been explored during the long-term clinical course of Crohn's disease. Some early historical descriptions have tended to avoid the possible temporal sequence of progression of pathological lesions and have focused on their prognostic significance<sup>[29,30]</sup>. However, more recent studies of their chronological sequence have suggested early small ulcers or granulomas with ongoing progression to later sinuses and strictures complicating large ulcers<sup>[31]</sup>. Later studies have also confirmed that this granulomatous inflammation may be a histopathological marker for an early phase of the inflammatory process in Crohn's disease, at least prior to development of fibrotic strictures and fistulous tracts<sup>[31]</sup>. Granulomatous inflammatory change has been documented in multiple biopsy or surgically resected specimens obtained over many decades<sup>[14]</sup>. Often, long intervals of relatively symptom-free disease are also evident<sup>[14]</sup>. This temporal pattern may indicate multiple initiating events in Crohn's disease with different rates of progression, or alternatively, granulomas may reflect ongoing active inflammation, even as subclinical or asymptomatic disease.

These studies have also suggested a geographic change in Crohn's disease with extended periods of time<sup>[32]</sup>. For instance, granulomatous ileal involvement was defined many years after initial colonic disease, and gastroduodenal disease occurred after ileocolic resection. If there were a single event that initiated this granulomatous inflammatory process, then different tissues along the length of the gastrointestinal tract may develop a granulomatous response at different rates, or alternatively, there might be multiple or recurring initiating events. Different gastrointestinal sites may differ in sensitivity to a possible initiating event (or infectious agent). This could result from a site-specific differential in intestinal permeability or differing immunological responses along the length of the gastrointestinal tract<sup>[33,34]</sup>.

## HETEROGENEOUS DISEASE

Crohn's disease remains an intriguing disorder characterized by a granulomatous inflammatory process. The phenotypic clinical expression of Crohn's disease is clearly age-onset-dependent, as most children and adolescents suffer more severe, extensive and complicated disease than most adults and the elderly. If evaluated over a long period of time, the disease appears to be progressive, but only intermittently active, and at a rate that may be very heterogeneous, with some appearing to have prolonged periods of sub-clinical disease and others expressing complex disease with stricture formation and penetrating complications, even at the time of initial clinical presentation. Although the precise cause of Crohn's disease remains a mystery, an increasing appreciation for the long-term natural history of Crohn's disease may permit development of more effective treatment regimens.

### Abstract

In the last two decades, there has been substantial development in the diagnostic possibilities for examining the small intestine. Compared with computerized tomography, magnetic resonance imaging, capsule endoscopy and double-balloon endoscopy, ultrasonography has the advantage of being cheap, portable, flexible and user- and patient-friendly, while at the same time providing the clinician with image data of high temporal and spatial resolution. The method has limitations with penetration in obesity and with intestinal air impairing image quality. The flexibility ultrasonography offers the examiner also implies that a systematic approach during scanning is needed. This paper reviews the basic scanning techniques and new modalities such as contrast-enhanced ultrasound, elastography, strain rate imaging, hydrosonography, allergosonography, endoscopic sonography and nutritional imaging, and the literature on disease-specific findings in the small intestine. Some of these methods have shown clinical benefit, while others are under research and development to establish their role in the diagnostic repertoire. However, along with improved overall image quality of new ultrasound scanners, these methods

### INTRODUCTION

The small intestine is the most difficult part to examine of the gastrointestinal (GI) tract because of its length and tortuous course. The traditional investigations with small bowel enteroclysis and small bowel follow-through reveal information sparingly, and unfortunately involve radiation exposure of the patient. Although it is an organ that is spared from frequent disease, more precise and patient-friendly methods are needed. In the last three decades, new imaging techniques have been developed that have proven useful. Computerized tomography (CT), magnetic resonance imaging (MRI), wireless capsule endoscopy and double-balloon endoscopy are all relatively new additions to the diagnostic armamentarium.

Compared with these methods, transabdominal bowel sonography (TABS), has the advantage of being cheap, portable, flexible and user- and patient-friendly. There are challenges with depth penetration and intestinal air precluding optimal image quality, and the flexibility of ultrasonography (US) warrants a systematic approach by the examiner. However, the development of improved

scanner technology and high-resolution transducers has provided the clinician with image data of high temporal and spatial resolution, thus making it a useful tool in the diagnosis of small intestinal diseases<sup>[1-3]</sup>. This paper presents an overview of established US techniques for examining the small bowel and a description of new, promising scanning techniques.

When using US frequencies in the range of 7.5 to 14 MHz, the wall of the small intestine usually exhibits five different layers that correspond well to the histological layers. When looking at the mesenteric side of the intestine transabdominally, the first layer that is observed is the serosa/subserosa. It can be difficult to define exactly, as it is an interface echo between the surrounding structures (peritoneal wall/intestine/fat) and the serosa. The interface echo is thicker than the actual serosa and extends into the muscularis propria. Thus, the first layer that is clearly defined is echo-poor and corresponds to the muscularis propria. Next, is an echo-rich layer that corresponds to the submucosa, and an interface echo between the submucosa and the mucosa. Subsequently, there is an echo-poor layer followed by an echo-rich layer that corresponds to the mucosa and the interface echo between the mucosa and the luminal content. The wall layers as seen from the luminal side are described in the section on endoscopic sonography. The GI wall has a normal stratification if five US layers are visible, and there is loss of stratification if one or more US layers are missing<sup>[4,5]</sup>.

## BASIC SCANNING TECHNIQUES

### Preparations

The patient should be examined in the supine position and usually the examination requires no special preparation. Fasting for > 6 h, however, leads to smaller amounts of fluid and air in the intestine and reduces motility. The intake of fluids orally or through a feeding tube reduces the air content in the intestine and makes it easier to separate the lumen from the wall and different bowel loops from each other. Furthermore, the mesenteric wall of the intestine, which is often hidden behind pockets of air, can be more easily examined with these preparations<sup>[6]</sup>. Another technique for dealing with the problem of air is graded compression, for which the examiner uses the US transducer to squeeze the air away from the region of interest<sup>[7]</sup>.

### High frequency B-mode

It is recommended that the examiner starts performing a regular scan of the abdomen with a 3.5-5 MHz transducer. This might give additional information, a better overview, and larger lesions in the intestine can be imaged completely. For a detailed transabdominal examination of the small intestine, a curved or linear transducer with frequencies in the range 7.5-14 MHz should be used. If pathology is detected, wall thickness, stratification, luminal patency, degree of stenosis or dilatation, and motility pattern should be determined.

### Doppler modalities

Duplex scanning of the blood velocity in the superior mesenteric artery (SMA) provides several quantifiable parameters. The peak systolic (PV) and end diastolic velocity (EDV) can be used to calculate the resistive index (RI) = (PV-EDV)/PV, and the estimated mean velocity together with the inner diameter of the SMA is used to calculate the mean blood flow (MBF). The SMA is examined in the long axis. The best place to position the sample area is 2 cm after the SMA branches off from the aorta, and as it runs parallel to the aorta. The examiner should tilt the probe towards the epigastrium to obtain an angle < 60°. Intra- and interobserver agreements are good when the examiners are well trained<sup>[8]</sup>. Color and power Doppler gives information about the blood flow in smaller vessels that are difficult to find with duplex scanning. The information obtained from these images is qualitative. Triplex scanning can however be used for the estimation of RI in the GI wall.

## DISEASE-SPECIFIC FINDINGS

### Crohn's disease (CD)

CD is the most common reason for performing TABS of the small intestine. The typical US findings can be divided into bowel wall changes, focal reactions and complications of the disease. The wall changes are discontinuous and consist of wall thickening, ulcerations, infiltrations, flow alterations, and changes in stratification<sup>[9-11]</sup>. Around the bowel loops, enlarged lymph nodes and fatty infiltration of the mesentery can be found<sup>[12,13]</sup>. Several studies have also shown that complications such as fistulas, abscesses and stenosis with signs of obstruction can be found using TABS<sup>[14,15]</sup>.

The main finding in CD is a marked thickening of the intestinal wall of up to 15 mm. Fraquelli *et al*<sup>[16]</sup> have shown in a meta-analysis that, with a cut off of 3-mm, there was 88% sensitivity and 93% specificity for determining CD, while with a cut off of 4 mm, it was 75% and 97% respectively. The conclusion from this analysis should be that when used in primary diagnostics, 4 mm is a sensible lower limit, while in follow-up, a wall thickness > 3 mm should be considered as a sign of disease. Increased wall thickness is also associated with increased risk for surgery and for recurrence of disease after surgery<sup>[17,18]</sup>. Wall thickening is, however, not specific for CD and the final diagnosis should rest on endoscopic and histological findings if possible. In a thickened intestinal segment, loss of stratification is associated with inflammation, while retained stratification suggests fibrosis<sup>[11,19,20]</sup>.

CD is associated with hypervascularity of the bowel wall during active disease. This has been the rationale for performing Doppler studies of regional and local blood flow. Studies with duplex scanning have shown a correlation between disease activity, increased PV, MBF and decreased RI in the SMA<sup>[21-23]</sup>. Other studies looking at the difference in MBF, pulsatility index and RI before and after a meal have also found a significant

association<sup>[24,25]</sup>. Most of these studies have compared groups of less than 15 patients and have not been confirmed in larger studies. The measurements in the SMA are also be influenced by age, presence of atherosclerosis, and the length of the intestinal segment that is affected<sup>[26,27]</sup>. The most promising parameters, such as MBF, are difficult to assess and have found little use in clinical practice. Other studies have compared disease activity with semi-quantitative and quantitative estimates of vessel density in the GI wall with color and power Doppler. An association has been found in some studies<sup>[28,29]</sup>, but the results have been inconclusive in others<sup>[30,31]</sup>. The reason for these conflicting findings might be that the clinical assessment of disease activity with the CD activity index (CDAI) does not reflect vascularity. This theory might be supported by studies using US contrast in combination with power Doppler or harmonic imaging. Several studies have found the expected increase of contrast enhancement in patients with an elevated CDAI, but a subgroup of patients with contrast enhancement with low CDAI<sup>[32-34]</sup>. There is strong reason to believe that there is a correlation between vascularity and contrast intensity<sup>[35]</sup>. The hypervascularity in the GI wall of these patients may be a presentation of subclinical disease and it should be followed in prospective studies. There have been some recent studies with Doppler imaging that have investigated risk of relapse and treatment effects, which have indicated that detection of increased flow to and in the small intestine gives prognostic information<sup>[25,36]</sup>.

### Celiac disease

The associated findings of TABS are fluid-filled distended intestinal loops and continuous peristalsis in the small bowel segments during fasting<sup>[3,37-39]</sup>. Furthermore, a reduction in the number of mucosal folds in the jejunum and an increase in the ileum is another typical find<sup>[37,39]</sup>. Some authors have also found intermittent invaginations<sup>[37,38]</sup>. Less specific findings are free fluid, enlarged mesenteric lymph nodes, increased gall bladder size and a slight wall thickening. The studies performed have been mostly of an explorative nature, but in a prospective cohort study in patients with chronic diarrhea, iron deficiency or dyspepsia, dilated fluid-filled bowel loops were the most sensitive finding with a sensitivity of 92% and a specificity of 77%. In combination with increased gall bladder size, thickened small bowel wall (> 3 mm), increased fasting peristalsis, enlarged mesenteric lymph nodes and free abdominal fluid, the sensitivity was reduced to 33%, but specificity rose to 99%<sup>[3]</sup>. In untreated patients with celiac disease, increased peak velocity, mean velocity and MBF was found, while the RI was decreased as expected<sup>[40-42]</sup>. These findings disappeared with therapy<sup>[42]</sup> but reappeared after exposure to gluten<sup>[41]</sup>.

### Intussusception

In children with intussusception or intestinal invagination, the typical finding on TABS is a multilayered lesion with

concentric circles (onion sign) in the right fossa, when seen in the transversal plane. When the mesentery is involved, this forms an echo-rich crescent open towards the ante-mesenteric side. This is called the crescent in the donut sign. When seen longitudinally, the mesentery is seen as an echo-rich layer between two multilayered structures, the sandwich sign. Using these criteria, a sensitivity of nearly 100% and a specificity around 90% have been found in prospective studies<sup>[1,43]</sup>. TABS can also be used as guide in treatment procedures with hydrostatic reduction<sup>[44]</sup>. Color Doppler examination of children with intussusception shows that absence of flow in the wall of the invaginated intestine makes reduction more difficult, but does not necessarily mean the intestine is necrotic<sup>[45]</sup>.

In adults, TABS has proven useful as a primary diagnostic method, but since intestinal invagination is a rare cause of bowel obstruction in adults, it is often found by other means. The TABS appearance is similar to that in children, but there is often other pathology present that is the pathological lead point of the invagination<sup>[46,47]</sup>. As a result of the low number of incidents, there have been no prospective studies in the literature. Transient intestinal invaginations occur in children and adults, and mostly without symptoms. If there are no pathological lead points, the discovery is incidental, and if the intestinal segment is shorter than 3.5 cm, they are considered harmless<sup>[48,49]</sup>.

### Malignant tumors

Malignant tumors in the small intestine represent only 2% of GI cancers, and it is mainly the malignant tumors that are diagnosed as result of symptoms. The most frequent is adenocarcinoma (30%-50%), followed by carcinoids (25%-30%) and lymphoma (15%-20%)<sup>[50]</sup>. Less frequent are mesenchymal tumors of the GI tract, such as malignant GI stromal tumors and leiomyosarcomas<sup>[51]</sup>. The distribution in the small intestine is mainly duodenal adenocarcinoma, mesenchymal tumor in the jejunum, and lymphoma and carcinoids in the ileum<sup>[52]</sup>. As a result of the low number of patients, there have been few studies confirming the transabdominal echo characteristics of small bowel tumors. However, explorative studies and case series suggest some echo characteristics. Lymphoma is associated with target lesions caused by gross wall thickening with loss of stratification and sometimes aneurysmal dilatation of the intestine in the affected area<sup>[53,54]</sup>. Carcinoids have been shown to be intraluminal, oval and smoothly shaped. Furthermore they are echo-poor, and homogeneous, with an interruption of submucosa and a thickening of the adjacent muscularis propria<sup>[55]</sup>. Mesenchymal tumors appear as echo-poor, exophytic or dumbbell-shaped, with little contact with the bowel wall. If the bowel wall is involved, the submucosa is intact over the tumor and the muscularis propria adjacent to the tumor is unaffected. A typical feature might also be a peripheral, echo-rich or anechoic crescent-shaped area that represents necrosis<sup>[56]</sup>.

### Ischemic disease

In chronic ischemia of the small bowel, stenotic or occlusive lesions in the celiac and/or mesenteric arteries are found, and the patients typically have postprandial epigastric pain and weight loss. It is considered evidence of significant stenosis if duplex scanning of the celiac artery gives PV > 200 cm/s and EVD > 55 cm/s, and if the SMA PV is > 275-300 cm/s and EDV > 45 cm/s. If the patients have typical symptoms, it is indicative of ischemia, but still angiography must be performed for a definite diagnosis<sup>[57-59]</sup>. Duplex scanning is not the method of choice for diagnosing acute ischemia of the small bowel. If the ischemia has lasted a few hours, dilated bowel loops and a thickened bowel wall can be seen, but these signs are unspecific, and the examination is often made difficult by increasing amounts of intraluminal air. An arterial occlusion can be found, but the method is unlikely to show distal embolization and has not been studied with non-occlusive disease<sup>[60]</sup>.

## CONTRAST ENHANCED ULTRASOUND (CEUS)

Ultrasound contrast agents consist of micro-bubbles (1-7  $\mu\text{m}$ ), often made of a phospholipid shell with a gaseous content. They are given intravenously and excreted through the lungs. The use of CEUS has led to several new clinical applications<sup>[61]</sup>. As a result of their size, they stay in the circulation and because of their shape and gaseous content, they produce a non-linear, harmonic response that can be separated from the tissue signal using contrast harmonic US. When examining the intestine, it is preferable to use frequencies above 7.5 MHz, so that the different wall layers can be separated. Since there are fewer micro-bubbles that resonate at these high frequencies, higher contrast doses should be used. When a bolus of contrast is injected it will travel from the peripheral vein *via* the pulmonary bed and arteries before reaching capillaries in the intestinal wall. This lasts about 10-15 s and the moment contrast can be observed in the capillaries is the time of arrival. The concentration will continue to increase further as the contrast enters the capillaries and reaches its maximum concentration after approximately 30 s (Figure 1). This is the peak intensity, and the period leading up to this is called the arterial phase. In the intestine, it is followed by the venous phase in which the contrast has been distributed to the whole capillary bed and the concentration decreases as result of excretion of the contrast agent in the lungs<sup>[62]</sup>.

The simplest way of applying US contrast is to examine the intestinal wall 30 s after injection with power Doppler. This will enhance the Doppler signal, but also destroy all the micro-bubbles in the region of interest, which gives only a momentary flash of enhancement. Using contrast harmonic US with a low mechanical index (MI), the destruction of micro-bubbles is minimal and the arterial and venous phases can be observed continuously. The temporal dimension

to this examination gives quantifiable parameters that are independent of attenuation.

For quantification, there are currently two different methods (Figure 2). First, bolus tracking is a method in which the examiner simply injects a standard dose of contrast for a standardized injection time and registers the arterial and late phases. From the time intensity curve (TIC), time of arrival, peak intensity, time to peak and area under the curve can all be estimated. The problem with this method is that one needs to correct for attenuation, and the parameters are dependent on the injection speed and dose. Second, the burst replenishment method circumvents the problem of injection speed by giving a constant infusion of contrast agent. To observe how the capillary bed fills up in a region of interest, the micro-bubbles are simply destroyed by a burst of high-MI US, and then the replenishment is observed. Time to peak replenishment and the slope of increase are both quantifiable parameters that can be derived from a TIC. The burst replenishment method can however only provide indirect measurements of perfusion, while bolus-tracking potentially can be used for estimation of true perfusion when corrected for the arterial input function and attenuation.

## STRAIN IMAGING AND ELASTOGRAPHY

Occasionally an intestinal tumor or stenotic intestinal section in patients with CD can be palpated trans-abdominally. Palpation is informative since different tissues have different elastic properties. Elastography or strain imaging are US methods using this information by detecting the elasticity or stiffness of a tissue and providing a visual display<sup>[63-65]</sup>. The basis of every strain imaging technique is to measure tissue deformation caused by an external stimulus. The derivative of the tissue displacement is called strain, and can be calculated by cross-correlating the radio-frequency data before and after compression. The strain value in each point is color-coded and displayed in an elastogram. This elastogram can then be combined with the B-mode image to display the elastic properties of the tissue to the examiner through color information. Equipment using a quasi-static method of producing strain in the tissue through external compression with the US probe is now commercially available for clinical application<sup>[66]</sup>.

The quasi-static application of elastography of the small intestine represents special difficulties, as the pressure from the US transducer can cause several changes. When adding pressure, one not only deforms the GI wall, but also displaces the luminal content and the intestine itself. The intestinal content can be displaced using a preload, and in some areas, the small intestine can be fixed against the abdominal wall. The terminal ileum can be compressed against the psoas muscle in the right lower quadrant and this may prove useful in CD patients, who often have stenosis in this area<sup>[67]</sup>. To the best of our knowledge, there have been no human studies using the quasi-static method or other

**Figure 1 Stenosis of the terminal ileum in a patient with CD examined with ultrasound contrast.** The grey-toned images are the B-mode scouts while the brown-toned images portray the harmonic signals that are almost exclusively from micro-bubbles at a low MI. The right image shows the situation before contrast injection, while the left picture is taken at peak intensity.

**Figure 2 Stenosis of the terminal ileum in a patient with CD.** The right image shows a TIC using bolus tracking. The left image shows burst replenishment without constant infusion in the same patient. When the micro-bubbles are hit by ultrasound with a high MI, this causes them to burst, which produces high-intensity images (Burst). Quantifiable parameters such as time of arrival, peak intensity, time to peak, peak replenishment and time to peak replenishment are shown in the illustration.

**Figure 3 In vitro examination of a stenotic terminal ileum in a patient with CD.** The intestine has been cut open longitudinally and is resting on agar. The image was acquired with a 13-MHz linear probe (Hitachi Medical Systems Europe Holding AG, Zug, Switzerland) applied directly to the mucosa. The left image is an ordinary B-mode image showing the thickened GI wall ( $> 1$  cm *in vitro*) with the muscularis propria (MP), submucosa (SM), mucosa (M) and a thickened muscularis mucosa (MM). Towards the stenosis (S), the stratification is lost. In the right corresponding elastography image, there is a clear transition between the blue (hard) stenotic area and the red (soft) pre-stenotic area. The strain measured in region A and B (yellow circles) differ with a ratio of 3.77 (A: 0.27%; B: 1.02%; B/A: 3.77), which indicates a distinct difference in elasticity. Histology confirmed a fibrotic stenosis (Bar indicates 0.5 cm/unit).

elastography techniques transabdominally on the small intestine, but it has been applied with some success in the endosonographic detection of malignant lymph nodes<sup>[68,69]</sup>.

CD with stenotic obstruction is a potential application for elastography. We present two cases with stenosis of the terminal ileum. In one patient, the resection specimen was examined *ex vivo* (Figure 3), and in the other, the stenosis was examined transabdominally with elastography before surgery (Figure 4). In both patients, elastography indicated harder tissue in the stenotic area compared to the surrounding tissue. The

pathologist found a fibrotic stenosis in both surgical specimens.

## HYDROSONOGRAPHY

High-resolution transabdominal ultrasound for imaging the small intestine is often hampered by intestinal gas. The lumen of the small bowel is collapsed frequently and significant intraluminal pathology can be missed. Moreover, separation of different bowel loops can be difficult. Hydrosonography of the small intestine is a method in which an echo-poor contrast liquid is used

for distending the bowel and removing intestinal air, and thereby improving imaging. Most often, an isotonic polyethylene glycol (PEG) solution is used (e.g. Laxabon®). The PEG solution is indigestible and non-absorbable, therefore, it gives a predictable amount of luminal fluid and intestinal distension. In principle, any echo-poor fluid can be used. The amount of PEG solution used in different studies varies between 200 and 2000 mL. Oral intake of PEG solution (small intestine contrast ultrasonography) is the least invasive way of giving the contrast liquid, and probably the preferred method of most patients<sup>[70]</sup>. However, in patients having trouble drinking large amounts of PEG solution, a nasojejunal feeding tube can be used. The tube is placed at the duodenojejunal flexure by endoscopy, fluoroscopy or ultrasound guidance. These procedures are more time consuming than a regular transabdominal ultrasound examination, and the average examination may vary between 30 and 40 min (range 10-90 min). Examination time is very much dependent on the passage of contrast fluid to the terminal ileum. Sensitivity for diagnosing a suspected disorder in the small intestine in patients referred for a barium study varies as much as 64%-100%, while generally, a near 100% specificity is found<sup>[6,71-73]</sup>. In patients with known CD, the sensitivity for detecting a lesion in the small intestine varies between 96% and 100%<sup>[73-75]</sup>. Hydrosonography of the small intestine is safe. As opposed to enteroclysis and CT, the method can be used for examining the small intestine in patients in whom radiation should be avoided. Particularly, it is useful in the follow-up of patients with inflammatory bowel disease where repeated examinations often are necessary.

## ALLERGOSONOGRAPHY

Food hypersensitivity reactions, including GI reactions due to allergy against food items, can be visualized by advanced imaging and visualization modalities such as endosonography<sup>[76]</sup>, TABS and MRI. In Western countries, the rate of perceived food hypersensitivity is around 25% in the general population<sup>[77]</sup>. Conversely, a diagnosis of true food allergy in adults is confirmed in only 1%-4% of the cases. The difficulty is to diagnose the reactions, which occur by non-allergic mechanisms, or local reactions in the GI tract. They usually have negative allergic test results and when they reach the doctor, the symptoms are already gone. Therefore, a provocation test is often necessary to determine the reactions and symptoms.

Objective tests for diagnosing of food allergy are missing. In previous studies, double-blind placebo-controlled food challenge (DBPCFC) has been considered the gold standard for many years, but the latest literature has criticized the method because the procedure is labor-intensive and time-consuming, and the assessment is based on subjective symptoms such as abdominal discomfort and bloating<sup>[78]</sup>. In practice, therefore, the diagnosis is based on history and skin prick tests, and DBPCFC is seldom performed.

We have applied US to establish whether food hypersensitivity reactions can be objectively visualized. Not only mucosal swelling, but also luminal fluid can be visualized by TABS. Therefore, we wanted to explore the feasibility of using US to monitor the response of the intestine to direct luminal provocation in 32 patients with food hypersensitivity<sup>[79]</sup>. A nasoduodenal feeding tube was placed with its tip in the duodenum, aided by a gastroscope. The intestinal mucosa was challenged with the suspected food item dissolved in 10 mL water or saline given through the nasoduodenal tube over a 3-min period. Sonography was performed before (-5 min) and 5, 20, 30 and 60 min after the provocation. The following sonographic features were explored: wall thickness and diameter of the duodenal bulb, wall thickness and diameter of the pars descendens of the duodenum, wall thickness and diameter of the proximal jejunum, number of fluid-filled jejunal loops, air in the small intestine, and peristalsis of the small bowel. Sonographic changes were observed after challenge in 14 (44%) of the 32 patients. A positive sonographic response (increased wall thickness, diameter, peristalsis and/or luminal fluid) was significantly related to positive skin prick test ( $P = 0.008$ ) and positive DBPCFC ( $P = 0.03$ ). A significant correlation was found between provocation-induced symptoms and wall thickness of the duodenal bulb ( $r = 0.50$ ,  $P = 0.004$ ) or jejunum ( $r = 0.42$ ,  $P = 0.02$ ). Intra- and interobserver variation of the tracing procedure revealed low values.

Sonography appeared to be the most sensitive test applied, but the specificity of the new test is not yet known. Based on our findings, we conclude that responses of the proximal small intestines to direct provocation (swelling of the wall and exudation of fluid into the lumen) can be visualized by TABS, and that this new provocation test may become helpful in the evaluation of patients with food hypersensitivity.

## ENDOSCOPIC SONOGRAPHY

Intraluminal US (endosonography) is the common denomination of US examination using intracorporal transducers that are inserted under endoscopic guidance or blindly into the GI tract. Thus, the visceral wall and adjacent structures can be imaged in detail. Endoscopic US (EUS) has had an impact on the clinical management of several GI disorders and has become a valuable tool for investigating mucosal and deeper lesions of the GI wall, as well as biomechanical and motility abnormalities<sup>[80,81]</sup>.

The small intestine may be examined by relatively new endoscopic techniques such as wireless capsule endoscopy or double-balloon enteroscopy (DBE). DBE also allows therapeutic procedures to be performed and biopsies to be obtained. EUS of the duodenum and terminal ileum has been performed previously, but other parts of the small intestine have been regarded less accessible. However, when transducers are placed in the stomach or colon, it is possible to image loops and limited areas of the small intestine<sup>[82]</sup>.

The normal wall of the small intestine is thin and

**Figure 4** Elastography image acquired transabdominally in a patient with CD and stenosis of the terminal ileum. In the left image, the bowel wall is thickened without stratification and the anterior (A) and posterior (B) bowel wall is separated by luminal air (unmarked arrow). In the right elastography image, the stenotic area is colored blue relative to the surrounding tissue, which indicates that it is hard. The patient was operated upon and the histology confirmed a fibrotic stenosis. D1: 9.5 mm; D2: 8.8 mm; D3: 10.0 mm; D4: 13.0 mm.

**Figure 5** Illustration of EUS performed with an echoendoscope and an ultrasound miniprobe simultaneously. The echoendoscope can not pass a stenotic area which, however, can be further examined with a miniprobe. Lymph nodes are seen outside the GI wall.

**Figure 6** An ultrasound miniprobe (20 MHz) is placed in the ascending part of the partly water-filled jejunal lumen in a patient with CD. The layers of the wall are seen and also an erosion/superficial ulcer (b) can be observed. The edge of the lesion is indicated (a, c). A mucosal polypoid elevation is also seen (d).

folded and is displayed by high-frequency US as a layered structure usually consisting of a 5-layer structure but sometimes 3-9 layers are seen. When the visceral wall is imaged with an endoluminal transducer, the interface between the luminal content and mucosa accounts for the first, echo-rich layer. The rest of the mucosa appears as a second, echo-poor layer. The third, echo-rich layer usually includes the interface between the lamina propria and muscularis mucosae, the submucosa, and the interface at the border of the muscularis propria. In a five-layer structure, the rest of muscularis propria is imaged as an echo-poor fourth layer. The fifth, echo-

**Figure 7** Scan of the transpyloric area with velocity curve of gastric emptying episode (left) and duodenogastric reflux episode (right). Calibration bars indicate cm/s and 0.2 s on the y-axis and x-axis, respectively.

**Figure 8** VE of the ileum demonstrating stenosis of the intestinal lumen (arrow) (Rogalla *et al* [90]).

rich layer represents the outer wall delineation and is an interface echo at the serosal level<sup>[4,83]</sup>.

New and longer miniprobes that can be inserted through the working channel of enteroscopes are now available. These miniprobes may be helpful in the examination of small bowel lesions (e.g. CD, lymphoma, ischemic disease, subepithelial masses, tumors, strictures, stenoses and bleeding spots) when used in combination with DBE. Forward-viewing optic echoendoscopes can be combined with transendoscopic miniprobes, which allow endosonographic imaging with both instruments in the same procedure. Thus, imaging of stenotic areas not traversable for echoendoscopes, or other areas not accessible with echoendoscopes (e.g. parts of the jejunum) can be performed (Figure 5). Small bowel ulcers may exhibit a typical EUS pattern that consists of three separate elements: the ulcer crater, the echo-rich ulcer base, and frequently an echo-poor inflammation zone, which can extend beyond the thickness of the wall and more widely than the endoscopic changes (Figure 6). Enlarged vessels running into the ulcerated area can sometimes be demonstrated by EUS and may indicate an increased bleeding risk.

EUS has the potential to image biomechanical changes in all or individual GI wall layers as well as in the surrounding tissue. This information may improve our understanding of pathophysiological mechanisms of gut pathology. Several studies have been performed that combine miniprobe US with manometry to

describe the functional role of muscle layers of the GI wall. Recently, a multimodal device that combines bag distension, manometry, high frequency intraluminal US, laser Doppler flowmetry and symptom registration was applied to the esophagus, and demonstrated that these modalities can be used in combination without technical influence on each other<sup>[84]</sup>.

## NUTRITIONAL IMAGING

Nutritional imaging is US imaging to study the effects of nutrition such as fat, proteins and glucose on the function of the GI tract. Information concerning movement of luminal contents in humans can be obtained by fluoroscopy, scintigraphy, MRI, and impedance and duplex sonography. Studies based on scintigraphy and standard US of the stomach and duodenum indirectly measure overall rates of gastric emptying, but these methods do not have the temporal resolution to assess the rapid changes of transpyloric flow.

Hausken *et al*<sup>[85]</sup> have shown that using pulsed Doppler combined with real-time US (duplex sonography), it is possible to visualize antro-duodenal motility and transpyloric flow simultaneously. Antegrade and retrograde transpyloric flow is visualized using bidirectional velocity curves. Most contractions of the proximal duodenal bulb precede closure of the pylorus (and the terminal antrum), and duodenal bulb contraction is often accompanied by a short burst of duodenogastric reflux that occurs immediately before closure of the pylorus (Figure 7).

Patients with functional dyspepsia often experience early satiety and discomfort after a meal. Using duplex sonography, it is possible to relate timing of symptoms and early postprandial emptying in patients with functional dyspepsia<sup>[86]</sup>. Meal-related discomfort is experienced after commencement of transpyloric emptying. An inverse relationship has been found between the duration of the tasting period and symptom intensity, which suggests that the time allowed for duodenal tasting might be too short in patients with functional dyspepsia.

The effects of intraduodenal glucose, fat and protein on blood pressure, heart rate and SMA blood flow have been determined in healthy older subjects. Intraduodenal glucose, fat and protein decrease systolic BP in healthy older subjects, but the onset of the hypotensive response is earlier after glucose, and the effect of protein on SMA blood flow is less than that of the other nutrients<sup>[87]</sup>.

## ADVANCED COMPUTATIONAL VISUALIZATION

When a 3D volume data set of the small intestine is acquired using 3D US, CT or MRI, a diagnostic procedure known as virtual endoscopy (VE)<sup>[88]</sup> can be utilized. VE has been considered to be of interest for several years, mostly because of its potential to (at least

partially) substitute standard colonoscopic examinations (and the associated risks). Endoscopic views in the US examinations are nowadays incorporated into some medical workstations<sup>[89]</sup>.

While the colon is especially suitable for VE examinations since it is rather easy to inflate with air, and has a large diameter and a predictable position, the small intestine offer more of a challenge. Previous studies with liquid contrast and special procedures to minimize the presence of air have suggested that VE of the small intestine can be carried out<sup>[90,91]</sup>. Contrasting the interior of the small intestine enables segmentation and the diagnosis of certain pathologies using VE. Figure 8 shows an example of a diagnosis of intestinal stenosis using VE of the small intestine.

VE generally aims at examining all relevant parts of an inspected tubular structure, such as the colon or small intestine, or areas outside the GI tract, such as the bronchi or, in case of high precision scans, even thin vascular structures. The viewpoint navigation of a complex tubular shape can introduce an unnecessary burden on the examiner's side. Therefore, an advanced VE approach should compute and suggest a camera path along the tube's center line to the examiner. The examiner can then easily navigate throughout the entire structure, and if a more fine-tuned viewpoint is needed, detach from the pre-computed path and navigate in freehand mode. In most cases, the computation of the path is based on a skeletonization of segmented tubular structures<sup>[92]</sup>. The skeleton is a topological structure that is equidistant to the borders of given object. In medical imaging and visualization, it can be computed for particular organs using morphological operators or the distance transform.

### Selective visualization techniques

VE does not display the inspected tissue in its original color, and this information is acquired by optical endoscopy only. The advantage of VE, however, is the ability to see structures that are in close vicinity to the tube walls from outside. A tumor, for example, which develops on the outside wall of the examined structure, can be investigated in this way. Using semi-transparency for rendering the inspected organ walls can help with revealing external, potentially pathological structures. This can be achieved, for example, with a two-step first-hit ray-casting approach<sup>[93]</sup> or possibly with opacity peeling<sup>[94]</sup> and volume rendering. First-hit ray-casting usually stops ray traversal when a selected density value is reached and displays this boundary as an iso-surface. The two-step extension means that there are two locations where the viewing ray intersects the iso-surface. The inner one is represented with a semi-transparent surface, whereas the second, outer surface is fully opaque. In the case of opacity peeling, the ray traversal accumulates the optical representatives of the density values in the same way as the common direct volume rendering, i.e. using the over operator. The difference is that when the accumulation during the ray traversal reaches nearly

full opacity, the accumulation is reset to zero and ray traversal continues until the accumulation reaches full opacity again. This means that the second level of accumulation is shown. When selecting an appropriate transfer function, the tube wall can be peeled away to see structures behind the wall upon the examiner's request.

VE is essentially a computerized form of the optical screening approach that shares the same basic principles of pursuing a walk-through along the tubular structure. Alternatively, there are other new approaches that aim to present the whole structure in a single image. In some sense, this is analogous to representing the earth on a sphere and by a conformal map projection of the world into a 2D plane. One of these techniques, usually referred to as colon unfolding<sup>[95]</sup>, simulates a cut and a consecutive virtual opening of the tube, eventually flattening it into two dimensions. This technique requires high reconstruction quality during unfolding and good design for the cut (to not dissect a polyp structure, for example). The advantage of easing the complete visual inspection comes with a certain risk of deforming structures of interest, e.g. polyps, which may lead to errors in the interpretation. This issue can be addressed by another technique, originally developed for vascular investigation and recently applied for virtual colonoscopy<sup>[96]</sup>, known as curved planar reformation (CPR). The principle of CPR<sup>[97]</sup> is that a curved plane that includes the center line of the tubular structure cuts the tube in two halves. Then, both halves can be inspected separately or the plane can be rotated to redefine the cutting geometry. The center line that defines the plane can be estimated from the organ skeletonization<sup>[92]</sup>, for example. For particularly curved tubular structures, as in the case of the small intestine, the plane can be stretched or completely straightened to give a clear view on inside of the tube.

An alternative to the CPR technique is view-dependent section-view rendering such as the VesselGlyph focus + context technique<sup>[98]</sup>. To view the internal part of the walls, the section is cut starting at the center line, with opening towards the viewer. All these representations, for which all structures are visible on a single image, or the outside-in view is incorporated, can be effectively combined with endoscopy for easy navigation and better and faster diagnosis.

## CONCLUSION

In this review, we have presented different scanning techniques and US modalities for examining the small bowel. While TABS of the small intestine is standard in many tertiary centres for GI diseases around the world, some of the modalities reviewed here have not been implemented widely in clinical routine.

The strength of the US examination is high flexibility, repeatability, low patient risk and price, in combination with good spatial and excellent temporal resolution. If the initial US examination is not fully adequate, the operator has the opportunity to continue with more advanced methods, like CEUS or hydrosoneography.

However, further studies are needed to establish the methods' effectiveness at detecting small lesions in the small bowel. In patients in whom an invasive procedure is necessary, EUS with biopsy or even local resection is possible. Although the procedure is technically challenging, invasive and time-consuming, these factors are outweighed by the risk of an exploratory laparotomy or laparoscopy.

US can provide a wide range of physiological and pathophysiological parameters from the small bowel. Doppler techniques give information about the speed and direction of blood flow, and also provide indirect measurements of perfusion. The measurements can be difficult to reproduce and the perfusion estimates should be interpreted with care as detection of blood flow in small vessels is a great challenge. However, CEUS enhances the sensitivity of flow signal detection remarkably and enables calculation of true perfusion in a region of interest. This information is important in the characterization of small bowel tumors and lesions of CD.

Some of the techniques presented in this review have shown their potential in explorative studies, but need to be further tested to determine their ultimate clinical utility. Indeed, imaging of the small intestine is a great challenge to the clinician. In future, the clinician should be able to switch easily between the different modalities using the same scanner and with the help of improved visualization techniques, and have all relevant information presented simultaneously. Accordingly, the advance of multimodal and multiparametric imaging of the small intestine will enable better diagnostic performance and subsequently improved patient management.

of gluten sensitive enteropathy (GSE) detected by serology in a mass screening program; (2) sensitivity of antitransglutaminase (tTGA) and antiendomysium antibodies (EmA); and (3) adherence to gluten-free diet (GFD) and follow-up.

**METHODS:** One thousand, eight hundred and sixty-eight subjects recruited from an occupational health department underwent analysis for tTGA and EmA and, if positive, duodenal biopsy, DQ2/DQ8 genotyping, clinical feature recording, blood tests, and densitometry were performed. Since > 98% of individuals had tTGA < 2 U/mL, this value was established as the cut-off limit of normality and was considered positive when confirmed twice in the same sample. Adherence to a GFD and follow up were registered.

**RESULTS:** Twenty-six (1.39%) subjects had positive tTGA and/or EmA, and 21 underwent biopsy: six Marsh III (one IIIa, four IIIb, one IIIc), nine Marsh I and six Marsh 0 (frequency of GSE 1:125). The sensitivity of EmA for GSE was 46.6% (11.1% for Marsh I, 100% for Marsh III), while for tTGA, it was 93.3% (88.8% for Marsh I, 100% for Marsh III). All 15 patients with abnormal histology had clinical features related to GSE. Marsh I and III subjects had more abdominal pain than Marsh 0 ( $P = 0.029$ ), and a similar trend was observed for distension and diarrhea. No differences in the percentage of osteopenia were found between Marsh I and III ( $P = 0.608$ ). Adherence to follow-up was 69.2%. Of 15 GSE patients, 66.7% followed a GFD with 80% responding to it.

**CONCLUSION:** GSE in the general population is frequent and clinically relevant, irrespective of histological severity. tTGA is the marker of choice. Mass screening programs are useful in identifying patients who can benefit from GFD and follow-up.

Impact of mass screening for gluten-sensitive enteropathy in working population. *World J Gastroenterol* 2009; 15(11): 1331-1338 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1331.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1331>

## INTRODUCTION

Screening for celiac disease (CD) in the general population is still a controversial issue. Recent papers have reviewed the benefits and drawbacks of CD diagnosis in this situation<sup>[1]</sup>. CD is a highly prevalent disease (1:100 to 1:300) which fulfils some of the criteria favoring mass screening. That is, the availability of accurate and non-invasive diagnostic methods and an effective treatment (gluten-free diet: GFD) which restores health and prevents disease-associated complications<sup>[2]</sup>. The major concerns regarding mass screening are the reported lack of GFD adherence in asymptomatic patients detected in screening programs<sup>[3,4]</sup> and the limited available data on the cost-effectiveness of such an approach<sup>[5]</sup>. In addition, the benefits of early diagnosis in patients with mild disease, in terms of preventing late complications, are poorly understood<sup>[6]</sup>. In this sense, knowledge of the natural history of mild CD has been hampered by its imprecise definition in the medical literature, with frequent overlapping of the terms “mild enteropathy” (i.e. lymphocytic enteritis and partial atrophy) and “silent CD”. In fact, it was recently demonstrated that these terms may not be considered synonymous since gluten sensitive enteropathy (GSE) with preserved villous architecture may be symptomatically similar to patients with atrophy<sup>[7]</sup> showing a good response to a GFD<sup>[8,9]</sup>, and conversely, silent patients with atrophy do exist, and are at risk of subsequent severe complications<sup>[10]</sup>.

Occupational health departments provide care for the working population on environmental issues associated with work processes, but also help detect very frequent preventable diseases. In this setting, the aims of the present study were: (1) to assess the frequency and clinical relevance of GSE (both Marsh I and Marsh III) detected by serology in a mass screening program; (2) to compare the sensitivity of antitransglutaminase antibodies (tTGA) and antiendomysium antibodies (EmA) in detecting the whole spectrum of GSE (Marsh I to Marsh III); and (3) to assess the degree of adherence to a mass-screening program and the effectiveness of GFD.

## MATERIALS AND METHODS

### Subjects and study design

One thousand, eight hundred and sixty-eight individuals (1308 males, 560 females,  $36.6 \pm 0.5$  years) were recruited from the Occupational Work Surveillance Department in Catalonia, Northeastern Spain, between January 2004 and December 2005. None of the 1868

subjects included had previously been diagnosed with CD. After obtaining written informed consent, blood sampling for serum EmA and tTGA assay was carried out and clinical features for gastrointestinal and systemic symptoms, and associated diseases (yes/no questions) were obtained. HLA DQ2/DQ8 genetic study and duodenal biopsy were offered to those subjects positive for either EmA or tTGA. Furthermore, as previously described, a self-administered questionnaire of symptom severity using a visual analogue scale (VAS) ranging from 0 to 100 was recorded in these subjects<sup>[7,11]</sup>. The symptoms evaluated were diarrhea, abdominal pain, abdominal distension, flatulence and asthenia. Anemia and hypertransaminasemia, as well as abnormalities in bone mineral density (BMD), were also recorded. Subjects were considered to be symptomatic when they complained of at least one of the above-mentioned symptoms and/or had impaired blood test and/or densitometry. A symptom was considered to be present when it scored more than 20 points and was considered severe when it scored more than 50 points on the VAS.

### Antibody detection

Serum IgA-EmA was determined by indirect immunofluorescence (IFI) assay in serum samples at 1/5 dilution, as previously described<sup>[12]</sup>. Commercial sections of monkey distal oesophagus (BioMedical Diagnostics, France) were used as the IFI substrate.

IgA-class tTGA was analyzed in serum using a quantitative automated ELISA method by means of a commercially available detection kit (Varelisa Celikey™, Phadia AB, Freiburg, Germany) using recombinant human tTG as antigen<sup>[13]</sup>. Since > 98% of individuals had tTGA < 2 U/mL, this value was established as the cut-off limit of normality and was considered positive when confirmed twice in the same sample (recommended cut-off by the manufacturer > 8 U/mL). Total serum IgA was measured using rate nephelometry (BN II, Siemens Healthcare Diagnostics SL, Marburg, Germany). In cases of IgA deficiency, IgG-class EmA was measured.

When one or both serological markers were positive, an upper endoscopy with duodenal biopsy was proposed.

### Genetic markers

Standard techniques for DNA extraction, PCR amplification and product detection were used. To purify genomic DNA from whole blood, a commercial reagent Generation® Capture Column Kit (Gentra Systems, Minnesota, USA) was used. HLA-DQ2 (DQA1\*0501 and DQB1\*0201 alleles) and HLA-DQ8 (DQA1\*0301 and DQB1\*0302 alleles) genotyping was performed by PCR amplification using sequence specific primers (PCR-SSP)<sup>[14]</sup> on a GeneAmp PCR 2400 System (Applied Biosystems, Foster City, CA, USA). PCR products were detected by electrophoresis on 2% agarose gel and were visualized under UV light. Analysis of HLA-DQ8 haplotype was performed only on those patients with negative DQ2.

### Duodenal biopsy and diagnosis criteria for GSE

Four endoscopic biopsies from the 2nd-3rd portions of

the duodenum were processed by using hematoxylin/eosin staining and CD3 immunophenotyping, and were blindly evaluated by an expert gastrointestinal pathologist (A.S.). Histopathological findings were staged according to the Marsh criteria<sup>[15]</sup>, as revised by Rostami *et al.*<sup>[16]</sup>: 'Infiltrative' lesions with intraepithelial lymphocytosis are defined as Marsh type I, 'infiltrative/hyperplastic' lesions are defined as Marsh II, and 'partial (A), subtotal (B) and total (C) villous atrophy' as Marsh III. A cut-off of 25 intraepithelial lymphocytes (IELs)/100 epithelial cells was established to diagnose lymphocytic enteritis (LE)<sup>[17]</sup>. Other frequent causes of LE, such as parasites, NSAID ingestion, Crohn's disease and autoimmune diseases were ruled out<sup>[18]</sup>. *Helicobacter pylori* (*H. pylori*) infection was investigated by means of the urease test and histopathological assessment using hematoxylin/eosin staining of the gastric mucosa in all the cases.

The diagnosis of GSE was considered when some degree of histological abnormality was found and a good response to a GFD was demonstrated (see below) at least after one year of follow-up, according to AGA criteria<sup>[19]</sup>.

### Measurement of BMD

BMD was assessed in all patients showing some degree of histological abnormality (Marsh I to III), both at baseline and after GFD. T and Z-scores were measured in the lumbar spine and left femoral neck using a dual-energy X-ray absorptiometry (DXA) (Lunar DPX-aph, Madison, WI, USA). According to World Health Organization criteria, osteopenia is defined as a value of BMD between 1 SD and 2.5 SD below the average for young adults (T score -1 to -2.5), and osteoporosis is defined as a value of BMD more than 2.5 SD below the average value for young adults (T score < -2.5)<sup>[20]</sup>.

### Patient follow-up and response to GFD

GFD was recommended to all patients with villous atrophy and to all symptomatic LE patients, and adherence was recorded. To ensure the correct intake of a strict GFD, patients were referred to the Catalan Celiac Society ('Celiacs de Catalunya', Barcelona). Iron and/or calcium plus vitamin D supplements were prescribed when deficiencies or bone density impairment were detected. Clinical, histological, analytical and serological assessments were carried out in all patients who adhered to a GFD at least 1 year after starting the diet. In addition, a second densitometry assessment was carried out when the basal assessment was impaired. For the remaining individuals with positive tTGA at baseline, who were on a gluten-containing diet, clinical, analytical and serological assessments were requested, as a minimum. A patient was considered to have achieved a complete clinical response when all symptoms disappeared (VAS < 20 points) and when normalization of analytical and bone densitometry abnormalities occurred. A partial clinical response was defined as more than a 30-point reduction in the VAS score and/or a significant improvement but not normalization of analytical and bone densitometry abnormalities. A complete histological response was defined as a decrease from Marsh III to Marsh I or Marsh

0, and in Marsh I cases, a normalization in the IEL count or a reduction of at least 50% from the basal biopsy. An improvement in the degree of atrophy (i.e. from Marsh IIIc to Marsh IIIa) or a reduction in the IEL count from 25% to 50% of the basal biopsy in Marsh I cases, was considered a partial histological response.

In patients who did not accept a biopsy after GFD, negative serology was considered a criterion of at least partial response. Patients with LE and those with the lowest tTGA positive values were particularly encouraged to undergo histological retesting during follow-up.

### Statistical analysis

Categorical parameters were expressed as proportions, whereas continuous variables were expressed as both mean and standard error of the mean (SEM). Since intestinal biopsy was performed when EmA and/or tTGA were positive, the ratio of sensitivities of the two serological tests was calculated by an estimation of test sensitivity when disease confirmation was limited to positive results. Differences in sensitivities were assessed using a modified McNemar test as previously described<sup>[21]</sup>. Statistical comparisons for qualitative variables were made by an extension of Fisher's exact test for 2 × 3 contingency tables (Freeman-Halton test)<sup>[22]</sup>. One-way ANOVA and paired Student *t* test were used to compare quantitative variables. *P* < 0.05 was considered statistically significant. All statistical analyses were performed using the SPSS for Windows Statistical package (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Frequency of GSE and histological severity related to positive serology and genetic markers

Figure 1 represents a flow diagram of the evaluated patients. Twenty-six of the 1868 individuals (1.39%) had positive markers for CD (18 males, eight females, mean age 37.7 ± 11.0 years). Of the 26 patients with positive markers, seven were positive for both EmA and tTGA, one was positive only for EmA, and the remaining 18 were positive only for tTGA. Twenty-one of these 26 individuals (80.7%) underwent an intestinal biopsy, which disclosed the following histological findings: six Marsh III (one IIIa, four IIIb, one IIIc), nine Marsh I and six Marsh 0. Three Marsh I cases had *H. pylori* infection but the IEL count remained unchanged after 6 mo of eradication therapy. Thus, 0.80% of subjects initially tested had a biopsy proven lesion of the GSE spectrum (1:125) and 0.32% had villous atrophy (1:312). Values of tTGA related to the degree of mucosal damage are shown in Figure 2. All Marsh III patients were positive for both EmA and tTGA, and all Marsh I and 2 Marsh III patients had tTGA values higher than 2 U/mL but lower than the cut-off recommended by the manufacturer (8 U/mL).

The sensitivity of EmA for GSE diagnosis was 46.6% (11.1% for Marsh I and 100% for Marsh III), whereas the sensitivity of tTGA was 93.3% (88.8% for Marsh I and 100% for Marsh III) (*P* = 0.04). The sensitivity ratio demonstrated a two-fold sensitivity

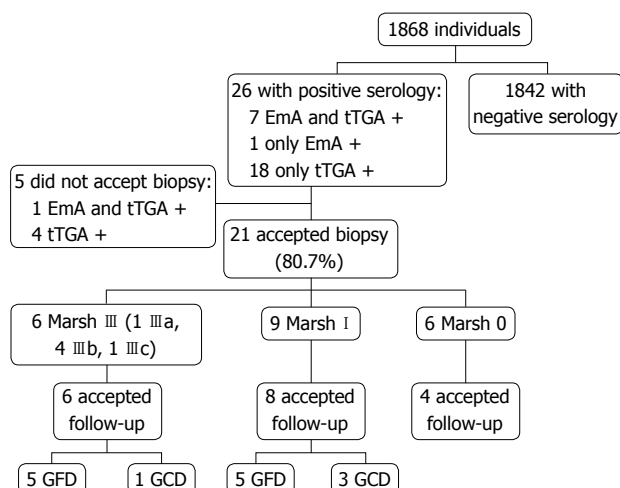

Figure 1 Flow diagram of recruited subjects. GCD: Gluten-containing diet.

Figure 2 Values of tTGA related to the degree of histological damage.

for tTGA compared with EmA to diagnose the whole spectrum of GSE (from Marsh I to III).

Thirteen of the 21 biopsied subjects (62%) were DQ2 +, 1 (4.7%) was DQ8 +, six had one allele of the DQ2 + (28.6%) (DQB1\*0201 in five subjects and DQA1\*0501 in one) and only one Marsh III (4.7%) was negative for both alleles of DQ2 and DQ8. A detailed description of the genetic markers related to the degree of histological damage is shown in Figure 3.

In five subjects with positive markers a biopsy was not performed, four because they did not accept the procedure and one patient could not be located [one was positive for both EmA (1/20) and tTGA (3.94 U/mL) and four were positive only for tTGA (2.21 to 5.10 U/mL)].

### Clinical characteristics of GSE related to the severity of intestinal damage

No significant differences were found in the percentage of autoimmune diseases ( $P = 0.415$ ), thyroid diseases ( $P = 0.632$ ), type 1 diabetes mellitus ( $P = 1$ ), previous anemia ( $P = 0.765$ ), diarrhea ( $P = 0.764$ ), abdominal pain ( $P = 1$ ), flatulence ( $P = 0.965$ ) or abdominal distension ( $P = 0.621$ ) between individuals, in the general working population, or in those with positive and negative serological markers.

All 15 subjects with abnormal histological findings had clinical features related to the disease. In one

Figure 3 HLA DQ2/8 related to the degree of histological damage.

Table 1 Frequencies of clinical manifestations related to the degree of histological severity

	Normal mucosa (Marsh 0) <i>n</i> = 6 (%)	LE (Marsh I) <i>n</i> = 9 (%)	Atrophy (Marsh III) <i>n</i> = 6 (%)	<i>P</i> value
Flatulence	4 (66.7)	6 (66.7)	4 (66.7)	1
Distension	2 (33.4)	7 (77.8)	4 (66.7)	0.282
Abdominal pain	0 (0.0)	6 (66.7)	4 (66.7)	0.029
Diarrhea	1 (16.7)	4 (44.5)	4 (66.7)	0.300
Asthenia	2 (33.4)	2 (22.3)	4 (66.7)	0.213
Anemia	0 (0)	0 (0)	1 (16.7)	0.571
Hypertransaminasemia	1 (16.7)	1 (11.9)	2 (33.3)	0.783

Statistical comparisons were made by an extension of Fisher's exact test (Freeman-Halton test).

Marsh III and two Marsh I patients, the only clinical feature was osteopenia (20%). The frequencies of clinical manifestations related to the degree of histological severity are described in Table 1. Subjects with Marsh I and Marsh III lesions had significantly more abdominal pain (66.7%) than those with normal mucosa (0%;  $P = 0.029$ ). A similar but non-significant trend was observed for distension and diarrhea, whereas asthenia was more often found in Marsh III patients. No differences were found for hypertransaminasemia and only one Marsh III patient had anemia. A progressive increase in the severity of most symptoms from Marsh 0 to Marsh III was observed when symptoms were assessed by means of a VAS (Table 2), reaching statistically significant differences for distension ( $P = 0.035$ ) and asthenia ( $P = 0.031$ ).

Moreover, severe abdominal pain (VAS > 50) was more frequent in Marsh I (33.4%) than in Marsh 0 (0%) and in Marsh III (16.7%) ( $P = 0.006$ ), while distension and asthenia were more frequent in Marsh III (66.7%) than in Marsh 0 (0%) and Marsh I (11.2%) ( $P = 0.001$  for both symptoms).

BMD was only assessed in those patients with abnormal biopsy. No significant differences in the percentage of osteopenia were found between Marsh I (55.6%) and III (33.4%) ( $P = 0.608$ ). There were no patients with osteoporosis.

### Follow-up after GFD

Eighteen of the 26 subjects with positive serology at

Figure 4 Evolution of the mean values of the VAS after GFD.

baseline accepted follow-up, disclosing a 69.2% adherence to the mass-screening program, with a mean follow-up of 28 months (range, 20 to 33). Of the 15 patients with histopathological lesions compatible with GSE, 10 followed a GFD (66.7%, five Marsh I and five Marsh III). Table 3 shows a detailed description of the patients who adhered to a GFD. Overall, nine of 10 patients (90%) (five Marsh III and four Marsh I) had a complete histological and/or serological response to a GFD. A dramatic clinical improvement was observed in both Marsh I and Marsh III patients; response was complete for two of the 10 patients (one Marsh III and one Marsh I) and partial for five (three Marsh III and two Marsh I). The main reason for Marsh I patients' adherence to GFD was the presence of osteopenia (four of five Marsh I patients). In contrast, osteopenia was only diagnosed in one Marsh I patient of the four who did not follow a GFD. No differences were found for either the number or the severity of symptoms between patients who followed a GFD and those who did not. At the end of follow-up, those patients who followed a GFD showed an improvement in the mean value of the VAS for all symptoms, and this was statistically significant for distension ( $P = 0.014$ ), flatulence ( $P = 0.028$ ) and abdominal pain ( $P = 0.007$ ) (Table 4). In Figure 4, evolution of the mean values of the VAS are shown separately for Marsh I and Marsh III.

Anemia and hypertransaminasemia reverted after GFD in those patients who had these conditions at basal evaluation. BMD normalized in two of the six patients with abnormal values at baseline. In the remaining cases, a trend for T score improvement in both the femoral neck (initial  $-0.74 \pm 0.22$ , final  $-0.69 \pm 0.18$ ;  $P = 0.144$ ) and lumbar spine (initial  $-1.27 \pm 0.30$ , final  $-1.09 \pm 0.30$ ;  $P = 0.068$ ) was observed.

Table 2 Relationship between the values of VAS and degree of histological damage

	Normal mucosa (Marsh 0) <i>n</i> = 6	LE (Marsh I) <i>n</i> = 9	Atrophy (Marsh III) <i>n</i> = 6	<i>P</i> value
Flatulence	36.6 ± 12.0 (0-60)	28.8 ± 8.2 (0-60)	36.6 ± 14.7 (0-80)	0.839
Distension	6.67 ± 4.2 (0-20)	28.8 ± 6.7 (0-60)	50.0 ± 16.9 (0-100)	0.035
Abdominal pain	0.0 ± 0.0 (0-20)	31.1 ± 10.0 (0-80)	26.6 ± 9.8 (0-60)	0.06
Diarrhea	8.33 ± 8.3 (0-50)	17.7 ± 9.1 (0-80)	30.0 ± 12.3 (0-80)	0.384
Asthenia	10.0 ± 6.8 (0-40)	11.1 ± 7.5 (0-60)	50.0 ± 16.9 (0-100)	0.031

Statistical comparisons were made by one-way ANOVA. Results are expressed as mean (SE) and range.

Eight additional patients with initial positive serology, who decided to follow a gluten-containing diet (one Marsh III, three Marsh I and four Marsh 0), accepted a clinical, serological and/or histological follow-up (Table 5). A progression from Marsh 0 to Marsh I was observed in one case and from Marsh I to Marsh III in another. This progression was accompanied by worsening of symptoms and an increase in tTGA values in the Marsh III patient. In the remaining cases with the exception of one, tTGA values diminished below 2 U/mL in the follow-up, although clinical symptoms remained unchanged.

## DISCUSSION

The frequency of biopsy proven CD with atrophy found in this study (1:312) is within the range previously described in our geographical area<sup>[23]</sup>. All Marsh III cases in our study had positive tTGA and EmA, confirming that both serological tests have a similar high sensitivity for diagnosing CD with villous atrophy<sup>[24]</sup>. However, it is well known that the sensitivity of serology sharply decreases in mild forms of GSE. Although not universally accepted, the recognition of Marsh I patients is important since a significant proportion of these patients have severe symptoms<sup>[7]</sup> and could benefit from a GFD. The observation that less than 2% of individuals in the general population have tTGA values higher than 2 U/mL prompted us to establish this value as the normal cut-off limit, instead of the 8 U/mL recommended by the manufacturer. This fact allowed us to identify two additional Marsh III and eight Marsh I patients by using tTGA alone, and it increased the sensitivity of this serological marker with respect to EmA at the expense of a greater number of diagnosed patients with mild enteropathy (88.8% versus 11.1% sensitivity in Marsh I for tTGA and EmA, respectively). With the combined use of EmA and tTGA the prevalence of biopsy proven GSE increased to 1:125.

A recently published study performed in Iran<sup>[25]</sup>, evaluating both Marsh I and Marsh III patients, found a similar number of GSE patients to that found in our study, with most Marsh I patients detected only

Table 3 Follow-up of patients who adhered to GFD

Asthenia	28 ± 12.3	12 ± 6.6	0.133

by positive tTGA and not with EmA. These results demonstrated, as did ours, the increased sensitivity of tTGA in detecting mild enteropathy. Unfortunately, the clinical characteristics of these patients and response to a GFD were not assessed in the Akbari *et al* study, raising some doubts about the reliability of the diagnosis of GSE in LE patients<sup>[26]</sup>. In fact, other causes of LE should be ruled out before considering the possibility of GSE diagnosis<sup>[18]</sup>.

Interestingly, despite the limitations of small sample size, the clinical features of Marsh I patients identified in the general working population duplicate those previously published in a group of first degree relatives of CD patients, confirming that Marsh I patients may be symptomatic similar to patients with atrophy<sup>[7]</sup>. Again, distension, abdominal pain and asthenia were the symptoms most consistently associated with GSE irrespective of the severity of the intestinal lesions, whereas non-significant differences were found for diarrhea and flatulence. In addition, as previously described, similar percentages of osteopenia were found in Marsh I and Marsh III patients, suggesting the

existence of a similar degree of calcium and/or vitamin D-impaired absorption. This study also demonstrated that the Marsh I patients detected in this mass-screening program, with low positive levels of tTGA, were true GSE patients with a gluten-dependent lesion and with a similar response to a GFD as those with Marsh III.

It is noticeable that tTGA values ranging from 2.6 to 3.9 U/mL were detected in six Marsh 0 individuals who could be considered false positives. However, a frequency higher than expected of DQ2/DQ8 positivity in these individuals, as well as the progression from Marsh 0 to Marsh I in one case, suggests that these individuals might have latent CD and therefore merit follow-up.

The genetic characteristics of the 21 individuals with available duodenal histology merit an additional comment. Sixty-two per cent and 4.7% were DQ2 and DQ8 positive, respectively, and 28.6% (five Marsh I and one Marsh 0) had only one allele of the DQ2 (DQB\*0201 in five cases and DQA1\*0501 in one more case). Thus, the percentage of DQ2 positivity in the present study was lower than that described for CD patients, among whom more than 90% express both DQ2 alleles<sup>[27]</sup>. However, it has been reported that in the majority of DQ2-negative CD patients (approximately 5%), one of the DQ2 alleles is present, generally DQB\*0201 and rarely DQA1\*0501<sup>[28]</sup>. Consistent with this, the DQ2 negative patients in the present study, most of them Marsh I, expressed only one allele of the DQ2, predominantly DQB\*0201. It may be speculated that the presence of only the  $\beta$  chain or  $\alpha$  chain of the DQ2 heterodimer, encoded by DQB\*0201 or DQA1\*0501, respectively, could impede the progression from mild enteropathy to atrophy in these subjects. Taking together all these data, individuals with tTGA values  $\geq 2$  U/mL

Table 5 Patients who accepted follow-up but did not adhere to GFD

detected in this study have, with a very high probability, some form of the GSE spectrum of conditions (from Marsh 0 to Marsh III).

The present study also shows that GSE patients in the general population may not be identified by clinical features, since a similar percentage of related CD symptoms was found in individuals with positive and negative markers. This fact explains why CD remains underdiagnosed in a high proportion of affected subjects and is an additional argument for mass-screening using other approaches, such as serology, irrespective of clinical symptoms. Unfortunately, serology had limitations due to its low sensitivity in detecting individuals with mild GSE. In addition, fluctuations from time to time in tTGA values may allow the identification of CD patients at some time points but not in others. In fact, most of the tTGA values in patients on a gluten-containing diet were negative in the follow-up.

Almost 70% of subjects with positive serology adhered to the follow-up program, which included GFD compliance or simple clinical, histological and serological surveillance. The reported degree of GFD adherence has been shown to vary greatly in different studies ranging from less than 10% (4) to 90%<sup>[29]</sup>, and is probably highly dependent on the patient-doctor relationship and confidence. In addition, the GFD adherence in this and other studies of CD detected by screening is similar to or better than that reported for other diseases, such as hypercholesterolemia or coronary heart disease<sup>[30]</sup>, in which specific diets or changes in lifestyle are required to prevent life-threatening complications.

It has been argued that the lack of adherence to a GFD in patients identified in screening programs is due to an absence of symptoms in these cases. We have demonstrated in the present study that, when systematically assessed, signs or symptoms related to GSE may be identified in all cases, taking into account that osteopenia was the only clinical feature detected in 20% of patients. Thus, the low GFD adherence due to an absence of potential benefit perceived by the

patient should never be used as an argument against the performance of mass screening for CD in the general population.

In conclusion, GSE in the general population is frequent and is clinically relevant, irrespective of the severity of the histological lesion. Mass screening programs are useful for identifying these patients in order to initiate either a GFD or close follow-up monitoring.

## COMMENTS

### Background

Screening for celiac disease (CD) in the general population is still a controversial issue. CD is a highly prevalent disease (1:100 to 1:300) that fulfils most of the criteria favoring mass screening. The benefits of early diagnosis in patients with mild disease, in terms of preventing late complications, are poorly understood.

### Research frontiers

In this study, the authors demonstrate that mass screening programs allow detection of CD cases with the whole gluten sensitive enteropathy (GSE) spectrum, which otherwise would have not been diagnosed, and that the adherence and response to a gluten-free diet (GFD) in these subjects was much better than that previously reported for other chronic diseases.

### Innovations and breakthroughs

This study shows unpublished information on GSE detected in the general population. It was demonstrated that Marsh I subjects detected by antitransglutaminase (tTGA) in this setting are as symptomatic as Marsh III and that they also respond equally to a GFD, reinforcing the final diagnosis of GSE in mild enteropathy.

### Applications

Understanding the evolution of GSE with mild enteropathy can help important decision-making, such as initiating a GFD in particular cases. Starting a GFD in symptomatic patients may prevent potential complications such as anemia and osteoporosis. The risk of lymphoma in mild GSE is at present unknown. A close follow-up of patients on a gluten-containing diet may help clarify this point.

### Terminology

GSE is characterized by a permanent intolerance to ingested gluten in susceptible individuals and leads to immunologically mediated inflammation of the small

intestine mucosa. Common histopathology findings range from mild enteropathy, which consists of an increase in intraepithelial lymphocytes (> 25 IEL/100 IELs) (Marsh I lesion), to 'classic' celiac disease with crypt hyperplasia and partial (Marsh IIIa), subtotal (Marsh IIIb) or total (Marsh IIIc) atrophy.

### Peer review

In this interesting retrospective study the power of screening tests for gluten sensitive enteropathy are critically evaluated in a cohort of 1868 patients. The authors conclude from their data that evaluation of tTGA is more essential in diagnosis of gluten sensitive enteropathy than EmA and histology. In order to select patients for gluten free diet and follow-up mass screening programs are proposed as useful. Statistical analyses are well. The manuscript is well-written and illustrated. The topic is of high interest for a readership interested in gastrointestinal diseases.

### Abstract

**AIM:** To investigate the antioxidant activity of chito-oligosaccharides (COSs) on pancreatic islet cells in diabetic rats induced by streptozotocin.

**METHODS:** The antioxidant effect of COSs on pancreatic islet cells was detected under optical microscopy and with colorimetric assay and gel electrophoresis. The activities of glutathione peroxidase and superoxide dismutase, total antioxidant capacity, and content of malondialdehyde in serum and tissue slices of pancreas were examined after 60 d to determine the effect of COSs in streptozotocin-induced diabetes in rats.

**RESULTS:** COSs can prohibit the apoptosis of pancreatic islet cells. All concentrations of COSs can improve the capability of total antioxidant capacity and activity of superoxide dismutase and decrease the content of malondialdehyde drastically. Morphological investigation in the pancreas showed that COSs have resulted in the reduction of islets, loss of pancreatic cells, and nuclear pyknosis of pancreatic cells.

**CONCLUSION:** COSs possess various biological activities and can be used in the treatment of diabetes mellitus.

### INTRODUCTION

Chitosan's properties allow it to rapidly clot blood, and it has recently gained approval in the USA for use in bandages and other hemostatic agents<sup>[1]</sup>. It has been further suggested that chitosan inhibits uptake of dietary lipids by increasing the thickness of the intestinal lumen boundary layer, a proposal again supported by numerous animal experiments that chito-oligosaccharides (COSs) possess various biological activities and can be used in diabetes treatment. Unlike high molecular weight chitosan, COSs, which are readily soluble in water due to their shorter chain and free amino groups in D-glucosamine units, and easily absorbed through the intestine, can quickly get into the blood flow and have versatile functional properties<sup>[2-4]</sup>.

Pancreatic beta-cell response to nutrient excess occurs by hypertrophy of existing  $\beta$  cells that increases insulin production and then formation of new  $\beta$  cells from progenitor cells. Failure of pancreatic  $\beta$  cells to adequately expand in settings of increased insulin demand ends up in hyperglycemia<sup>[5]</sup>. Streptozotocin (STZ) selectively kills insulin-secreting  $\beta$  cells, and is widely used to generate animal models of diabetes. Previous studies have suggested that streptozotocin toxicity results from its N-nitrosourea moiety releasing nitric oxide and possessing DNA alkylating activity. More recently, it has also been proposed that streptozotocin induces apoptosis by inhibiting O-GlcNAcase, an enzyme that, together with O-GlcNAc transferase, is important for dynamic

intracellular protein O-glycosylation<sup>[6]</sup>.

In the present study, soluble COSs with low molecular weight were prepared by enzymatic hydrolysis of chitosan with chitosanase. The purpose of this study was to examine the antioxidant effect of chito-oligosaccharides on pancreatic islet cells and pancreatic islets in rats with STZ-induced diabetes.

## MATERIALS AND METHODS

### Materials

Chitosan (90% deacetylated, Mr: 500 000) was purchased from Jinan Haidebei Marine Bioengineering Co., Ltd (Shangdong, China). Chito-oligosaccharides were prepared by enzymatic hydrolysis of chitosan with chitosanase. NIT-1 cell line was from Institute of Medicine, Ocean University of China. Male Wistar rats (200 ± 20 g) were from Laboratory Animal Centre, Institute of Medicine, Ocean University of China. STZ was from Sigma Chemical Co. Tissue-culture medium and reagents were from Gibco. All chemicals were purchased from Sigma Chemical unless otherwise stated.

### Cell culture

NIT-1 cell line, a widely used  $\beta$  cell line for insulin secretion studies, was established from non-obese diabetic (NOD) mice transgenic for the SV40 T antigen under control of the insulin promoter, and cultured in DMEM containing 10% FBS and antibiotics (100 IU/mL of penicillin and 100  $\mu$ g/mL of streptomycin). All cultures were kept at 37°C in 95% O<sub>2</sub> and 5% CO<sub>2</sub>. The medium was changed every 2 d.

### Effects of COSs on pancreatic $\beta$ cells exposed to STZ

**MTT assay:** COS was dissolved in Dulbecco's modified Eagle's medium (DMEM) without FBS and then diluted the medium to 10, 100, 500, 1000 and 2000 mg/L degrades. The structure and function of cultured pancreatic  $\beta$  cells were observed under inverted phase contrast microscope. MTT assay was used to estimate the cell viability. Pancreatic  $\beta$  cells were digested by 0.25% trypsin until appearance of unicellular suspension. Then, 100- $\mu$ L suspensions with the concentration of  $5.0 \times 10^4$  cells/mL were transplanted into 96-well plates. Each well had eight parallels. After incubating for 24 h, the medium was changed with COSs at different concentrations. Cells were divided into normal control group; positive control group with NIT-1 cells treated with STZ; and COS protective group with NIT-1 cells treated with different concentrations of COS for 0.5 h, and then cultured with 2 mmol/L STZ for 12 h. Cells were incubated with 0.5 mg/mL of MTT in the last 4 h of the culture period (48 h). The medium was then decanted, 200  $\mu$ L DMSO was added to the wells, and the absorbance was determined at 492 nm using an ELISA reader. The proliferation rate was calculated ( $PR = A/A_0 \times 100\%$ ).

**DNA gel electrophoresis:** Groups were divided as

described above. After treatment, DNA was extracted from the cultured cells, washed in Tris-HCl for 3 times, and 0.5 mL STE extraction buffer (0.5 mol/L NaCl, 100 mmol/L Tris-HCl, 10 mmol/L EDTA, 1% SDS, 100  $\mu$ g/mL protease K, pH = 8.0) was added, and the cells were re-suspended. The suspension was incubated in a water bath at 65°C for 30 min with occasional shaking, cooled to room temperature and incubated with chloroform/isoamylalcohol (24:1) for 10 min. After centrifugation at  $5600 \times g$  for 10 min, the supernatant was mixed with dehydrated alcohol and incubated at -20°C for 2 h. Then, the mixture was centrifuged at  $8600 \times g$  for 15 min. The DNA precipitation was washed with 70% ethanol twice and dissolved in sterilized TE (1 mol/L Tris-HCl, 0.1 mol/L EDTA, pH = 8.0). The DNA was examined in 1.2% agarose gel containing ethidium bromide (0.4  $\mu$ g/mL) for about 1 h at 5 V/cm. The gel was photographed under ultraviolet light (254 nm) using GDS-760 image-analysis system (UVP).

**Single cell gel electrophoresis (SCGE):** After treatment, cells were washed in DMEM without serum, resuspended in PBS to a concentration of  $2 \times 10^5$  cells/10  $\mu$ L, mixed with 1% Low Melting Agarose (LMA), spread on a slide coated with a layer of 0.5% Normal Melting Agarose and covered with another layer of LMA. Slides were immersed in lysis solution at 4°C for 1 h. After lysis, the slides were placed in a horizontal gel electrophoresis tank filled with fresh alkaline electrophoresis buffer (300 mmol/L NaOH, 1mmol/L Na<sub>2</sub>-EDTA, pH 13) and incubated in the solution for 20 min at 4°C. Electrophoresis (1 V/cm and 300 mA) was conducted at 4°C for 20 min, using a Bio-Rad 300 power supply. Once completed, the slides were washed 3 times with a neutralizing solution (0.4 mol/L Tris-HCl, pH = 7.5) and stained with ethidium bromide (5  $\mu$ g/mL). The slides were examined at 200  $\times$  magnification under a fluorescent microscope equipped with an excitation filter of 515-560 nm and a barrier filter of 590 nm. Twenty cells were selected randomly from each group as described above and analyzed by the Casp computerized image analysis system. To quantify the DNA damage, four different comet parameters were evaluated: tail length, tail DNA%, tail moment and olive tail moment.

### Antioxidant ability of COS on STZ-induced diabetic rats

Male Wistar rats were rendered diabetic by intraperitoneal injection of STZ at 65 mg/kg body weight. The rats whose fasting blood glucose level was above 11.11 mmol/L were used for experiments after 7 d. Then, the rats were randomly divided into metformin treatment group, positive control group and diabetes mellitus (DM) and COS treatment groups. Test samples were given intragastrically with gavage needle for 60 d. COS treatment groups were given COSs orally at the concentrations of 250, 500 and 1500 mg/kg body weight daily. Normal control group and DM group received an equal volume of distilled water, about 10 mL/kg body weight daily. The metformin treatment group was

given metformin at a concentration of 200 mg/kg body weight. After 60 d, blood samples were collected by orbital sinus puncture after lightly anesthetizing the rats with ether. Serum was separated from the blood samples by centrifugation (5000 r/min, 10 min) and the activity of glutathione peroxidase (GPH-PX) and superoxide dismutase (SOD), the capability of total antioxidant capacity (T-AOC) and the content of malondialdehyde (MDA) were measured. Pancreas pathologic changes were observed under microscope after the small lumps (3 mm) were fixed in 4% paraformaldehyde in 0.1 mol/L cacodylate buffer (pH 7.2), embedded in paraffin, and stained with hematoxylin-eosin.

### Statistical analysis

ANOVA was performed with Duncan's multiple range tests. SAS was used to compare the means (SAS Institute, Inc., Cary, NC, USA).  $P < 0.05$  was considered statistically significant

## RESULTS

COSs were prepared by enzymatic hydrolysis of chitosan. Components of the hydrolysis product were separated by Sephadex G-25 (Figure 1), and component 1 analyzed by TSK-GEL G3000PWXL had an average molecular weight of 1200 u, and a degree of deacetylation of 90% by the first derivative method of UV spectrometry.

The effect of COS on pancreatic islet cell viability was assessed by MTT assay (Figure 2). The degree of cell damage decreased with the increase of COS concentration (10-500 mg/L) and was significantly higher compared with the positive control group (Figure 3). The maximum protective effect on cell viability was achieved by 500 mg/L COS among the four samples (Figure 4).

Through DNA ladder (Figure 5) detection, we found that the injury degree of DNA fragmentation became more serious with the decrease in COS concentration (500-10 mg/L). As shown in Figure 5, the total DNA of the normal control group was a complete band and non-perceptible. An obvious DNA ladder could be seen in the positive control group treated with STZ. However, the DNA ladder disappeared with the increasing concentration of COS (10-500 mg/L). And the DNA ladder was more obviously decreased with 500 mg/L COS.

STZ can damage the DNA of the NIT-1 cells. The exposure to STZ produced significant DNA migration in the positive control group (Figure 6B). On the contrary, induction of DNA damage was rarely observed in the COS-treated group (500 mg/L) (Figure 6C). Similar differences in DNA damage between other COS groups (10-500 mg/L) and positive control group were observed after treatment with STZ. The concentration-dependent protective effect was found with COS at 10-500 mg/L, and the degree of DNA damage was decreased.

The results showed that exposure to STZ induced the breakage of DNA strands. COS can inhibit NIT-1

Figure 1 Chromatogram of COSs on Sephadex G-25 column.

Figure 2 Protective effect of COS on the damage of NIT-1 cells induced by STZ. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs STZ group.

Figure 3 Morphological photograph of the positive control group ( $\times 100$ ).

cell damage induced by STZ, and enhance the protective action of pancreatic  $\beta$  cells significantly (Table 1). All concentrations of COS could decrease the cells treated by STZ and had apparent dosage-dependent effects. The pretreatment of COS (500 mg/L) decreased the cells in tail length, tail DNA%, tail moment and olive tail moment significantly ( $P < 0.01$ ).

COSs at all concentrations improved the capability of T-AOC and activity of SOD and decreased the content of MDA in serum drastically (Table 2). The capability of T-AOC was enhanced and the content of MDA decreased

with COS in a dosage-dependent manner.

Morphological investigation of pancreas in the DM group showed a reduction of islets,  $\beta$  cell loss, and nuclear pyknosis of  $\beta$  cells to various degrees after 60 d of STZ injection (Figure 7B). While COSs of all concentrations could protect the pancreas against STZ, the morphological observation indicates that the cells treated with medium dosage (500 mg/kg) were most protected (Figure 7C), showing similar morphological features to those of the normal control group (Figure 7A).

## DISCUSSION

It has been observed that the radical scavenging properties of COSs are dependent on their DD and molecular weight. Based on the results obtained from studies carried out using electron spin trapping techniques, COSs with low molecular weight have been identified to have a higher potential to scavenge different radicals<sup>[7]</sup>. In addition, highly deacetylated (90%) COS is more preferable to scavenge DPPH, hydroxyl, superoxide and carbon-centered radicals<sup>[8]</sup>.

**Figure 5** COS protective effect on NIT-1 cell genomic DNA presented by DNA Ladder method. M: 200 bp Marker; A: Positive control group; B: Normal control group; C: 1000 mg/L COS treatment group; D: 500 mg/L COS treatment group; E: 100 mg/L COS treatment group; F: 10 mg/L COS treatment group.

Recently, several approaches have been taken to prepare COSs, among which the enzymatic preparation methods have attracted great interest due to safety concerns. New improvements have been introduced to enzymatic production. Properties of COSs, such as DP, DA, charge distribution and nature of chemical modification to the molecule, strongly influence their observed biological activities. Therefore, molecular weight is considered as a principal characteristic of COSs that highly correlates with their biological activities. We have successfully obtained COSs with a DP of 7-9 by enzymatic hydrolysis and investigated their effects on pancreatic cell protection and their antioxidant activity *in vivo* and *in vitro*.

Many studies have suggested that the apoptotic events are often induced by the accumulation of reactive oxygen species (ROS)<sup>[9]</sup>. The mechanisms of ROS damage to organisms mainly relate to the damage of DNA, especially the oxidative damage of mtDNA. The oxidative damage of mtDNA might cause some changes in the primary structure of DNA, such as base deletion,

**Figure 6** Photomicrograph of NIT-1 cells DNA migration in different experimental groups ( $\times 200$ ). A: Normal control group; B: Positive control group; C: COS treatment group.

modification and insertion mutagenesis, among which base deletion is most universal. ROS can also induce base deletion, base modification, single and double-strand breakage, and interstrand DNA cross links in nuclear DNA. Most damage in DNA primary structure is investigated by DNA ladder and SCGE methods. A model of chemically induced islet cell death *in vivo* and *in vitro* is the STZ mediated islet cell destruction. STZ is an alkylating agent that causes DNA strand breakage in rat pancreatic islet cells. Recent studies strengthen the hypothesis that the toxic effects of STZ are in part mediated by NO, which is generated during its metabolism.

Our studies found obvious damage to DNA in the process of apoptosis induced by 2 mmol/L STZ. In the positive group treated with STZ only, the total DNA was degraded into approximately 180-200 bp and its multiples and a typical DNA ladder appeared on the agarose gel after electrophoresis. However, it could not

**Figure 7** Photomicrograph of pancreas tissue slice in different experimental groups (HE  $\times 400$ ). A: Normal control group; B: Positive control group; C: COS treatment group.

be detected in apoptosis induced by STZ after treatment with different concentrations of COS. SCGE assay is a powerful technique for the detection of DNA damage at alkali-sensitive sites in eukaryotic cells. Also known as the “comet” assay, it is a rapid, simple and sensitive method to quantify DNA damage in a small number of cells. During electrophoresis under alkaline conditions, cells with damaged DNA display increased migration of DNA from the nucleus towards the anode. Broken DNA migrates farther in the electric field, and the cell resembles a “comet” with a brightly fluorescent head and a tail region, which increases as damage increases. Our study showed that the long-time exposure to STZ was capable of causing a significant increase in DNA damage. Conversely, no induction of DNA damage was observed in the COS-treated group (500 mg/L). Similar differences in DNA damage between other COS groups and positive control group were observed after treatment with STZ (2 mmol/L). The results indicate that COSs have

prominent protective effects on the DNA damage in NIT-1 cells induced by STZ, and can prohibit the apoptosis of NIT-1 cells induced by STZ.

There is an effective defense mechanism of antioxidation in organisms, including SOD, CAT and GPX, which can scavenge ROS effectively. Cells are in the normal condition when the balance is maintained between oxidation and antioxidation. Once the balance is disturbed, the function will be affected, leading to apoptosis. Scavengers of free radicals are preventive antioxidants. The presence of radical scavenging compounds can break the oxidative sequence at different levels. Therefore, there has been a growing interest in the identification of natural antioxidants from many natural sources to overcome the radical-mediated deleterious effects in biological systems. Many biological compounds, including carbohydrates, peptides and some phenolic compounds, have been identified as potent radical scavengers. It has been described in previous studies that COSs can cause a rapid increase in the anti-oxidant enzymes activity to scavenge reactive oxygen. Even though the precise mechanism of radical scavenging activity of COSs is not clear, it is often attributed to the reaction between the amino and hydroxyl groups attached to C-2, C-3 and C-6 positions of the pyranose ring and the unstable free radicals, to form stable macromolecule radicals. However, there are some discrepancies about hydroxyl radical scavenging activities of COSs and some of their derivatives. The latest studies have revealed that metal ion uptake ability of COSs has a great influence on their hydroxyl radical scavenging ability<sup>[10]</sup>. According to their results, hydroxyl radical scavenging potency of COSs is partly due to chelating ability of transition  $Fe^{2+}$ , molecular charge properties and proton donation *via* hydroxyl and amino groups. The uptake of metal ions by COSs can proceed through different mechanisms, including chelation *via* electron pairs of amino groups and ion exchange mechanisms of protonated amino groups<sup>[11]</sup>. Therefore, it further strengthens the effect of DD on radical scavenging which is directly correlated with protonation of amine groups. However, there is not much information about the relationship between ion chelation and antioxidant properties of COSs to date.

Our study showed that COSs of all concentrations improved the capability of T-AOC and activity of SOD and drastically decreased the content of MDA. Morphological investigation of the pancreas showed that COSs have significant effects on the reduction of islets, pancreatic cell loss and nuclear pyknosis of pancreatic cells, and can protect the pancreas against STZ. The possible mechanism of COSs' protective function in the pancreas is that they have strong *in vivo* antioxidative properties, so that they can scavenge directly the reactive free radicals such as hydroxyl radical and superoxide anion, and inhibit DNA damage, to protect pancreas against oxidative damage induced by STZ.

The highly increasing prevalence of obesity and type 2 DM in the general population makes non-alcoholic fatty liver disease (NAFLD) the most common diagnosis

in clinical practice<sup>[12]</sup>. Our study provided evidence for the protective effects of COSs in pancreatic  $\beta$ -cells against STZ *in vitro* and confirmed the usefulness of COSs in improving antioxidant ability and protecting the pancreas islet of STZ-induced diabetes in rats *in vivo*. These biological activities have considerable potential in DM and NAFLD.

## COMMENTS

### Background

Chitooligosaccharide (COS) possesses various biological activities and has been shown to be particularly useful in diabetes treatment. Several methods have been recently used to prepare COS, and enzymatic preparation methods capture a great interest due to their safety and non-toxicity.

### Research frontiers

Pancreatic  $\beta$  cells maintain the blood glucose concentration within a narrow range by modulating insulin secretion rate in response to the glucose levels in the blood. Proper insulin secretion requires the coordinated functioning of numerous  $\beta$  cells that form pancreatic islets. This coordination depends on a network of communication mechanisms whereby  $\beta$  cells interact with extracellular signals and adjacent cells *via* connexin channels. This study indicated that COSs improved the antioxidant ability and protection of the pancreas islet of streptozotocin (STZ)-induced diabetes in rats *in vivo*.

### Innovations and breakthroughs

Soluble COSs with lower molecular weight were prepared by enzymatic hydrolysis of chitosan with chitosanase. This study indicated that COSs could improve the antioxidant ability and protect the pancreas islet against STZ-induced diabetes in rats *in vivo*.

### Applications

This study indicated that COS could improve the antioxidant ability and protect the pancreas islets of STZ-induced diabetes in rats *in vivo*. These biological activities have considerable potential in diabetes mellitus treatment.

### Terminology

COS is a polycationic copolymer consisting of  $\beta$ -1, 4-linked 2-acetamido-D-glucose and  $\beta$ -1, 4-linked 2-amino-D-glucose units. COS obtained by hydrolysis or degradation of chitosan, is not only water-soluble but also more effective than chitosan. NIT-1 cell line, a widely used  $\beta$  cell line in insulin secretion studies, is established from non-obese diabetic mice transgenic for the SV40 T antigen under the control of insulin promoter.

### Abstract

**AIM:** To investigate the effects of curcumin on the expression of peroxisome proliferator-activated receptor $\delta$  (PPAR $\delta$ ) and related genes in HT-29 cells.

**METHODS:** HT-29 cells were treated with curcumin (0-80  $\mu$ mol/L) for 24 h. The effects of curcumin on the morphology of HT-29 cells were studied by Hoechst 33342 staining. The activity of caspase-3 was determined using DEVD-pNA as substrate. The levels of peroxisome PPAR $\delta$ , 14-3-3 $\epsilon$  and vascular endothelial growth factor (VEGF) in HT-29 cells were determined by Western blotting analysis and their mRNA expression was determined by real-time quantitative RT-PCR.

**RESULTS:** Treatment with 10-80  $\mu$ mol/L curcumin induced typical features of apoptosis and activated the caspase-3 in HT-29 cells. The expression of PPAR $\delta$ , 14-3-3 $\epsilon$  and VEGF was reduced and the activity of  $\beta$ -catenin/Tcf-4 signaling was inhibited by curcumin treatment.

**CONCLUSION:** Curcumin can induce apoptosis of HT-29 cells and down-regulate the expression of PPAR $\delta$ , 14-3-3 $\epsilon$  and VEGF in HT-29.

### INTRODUCTION

Peroxisome proliferator-activated receptors (PPARs) belong to the nuclear hormone receptor superfamily that enable the cell to respond to extracellular stimuli through transcriptional regulation of gene expression<sup>[1,2]</sup>. PPARs comprise three subtypes: PPAR $\alpha$ , PPAR $\delta$  and PPAR $\gamma$ . Many of the functions of PPARs are associated with pathways of lipid transport and metabolism<sup>[3-5]</sup>. Moreover, PPARs play important roles in cell replication, differentiation, tumorigenesis and apoptosis. For example, the expression of PPAR $\delta$  is elevated in human and rat colorectal cancer cells when compared with normal colon epithelial cells<sup>[6,7]</sup>. PPAR $\delta$  has also been implicated in the growth of other human cancers, including hepatocellular carcinoma, cholangiocarcinoma, breast cancer and prostate cancer<sup>[8,9]</sup>.

14-3-3 proteins are anti-apoptotic and anti-inflammatory molecules in cells, which include at least 7 isoforms ( $\beta$ ,  $\gamma$ ,  $\epsilon$ ,  $\eta$ ,  $\zeta$ ,  $\sigma$ ,  $\tau/\theta$ )<sup>[10]</sup>. 14-3-3 can bind phosphorylated Bad, sequester Bad in the cytosol, and inhibit cytochrome c release, caspase-3 activation, and the apoptosis of cells. PPAR $\delta$  can induce the expression of 14-3-3 $\epsilon$  protein. Elevated 14-3-3 $\epsilon$  augments Bad sequestration and prevents Bad-triggered apoptosis<sup>[10]</sup>. C/EBP $\beta$  protein is a mediator of PPAR $\delta$ -dependent 14-3-3 $\epsilon$  gene regulation in human endothelial cells. PPAR $\delta$  can regulate the expression of C/EBP $\beta$  protein, which can bind to the C/EBP response element located at -160/-151 of the 14-3-3 $\epsilon$  gene<sup>[11]</sup>. PPAR $\delta$  can directly bind to PPAR response elements located between -1426 and -1477 of the 14-3-3 $\epsilon$  promoter region, thereby activating 14-3-3 $\epsilon$  promoter activity and protein expression<sup>[10]</sup>. PPAR $\delta$  can also regulate the expression of vascular endothelial growth factor (VEGF), which can promote colon tumor epithelial cell survival<sup>[12,13]</sup>.

Curcumin is an important polyphenol extracted from the rhizomes of *Curcuma longa* L. Several studies have shown that curcumin exerts antioxidant, anti-inflammatory, anti-carcinogenic and chemopreventive activities on many tumor cells<sup>[14]</sup>. Curcumin can also down-regulate the activity of the  $\beta$ -catenin/Tcf signaling pathway<sup>[15,16]</sup>. Curcumin affects the expression of the target genes of  $\beta$ -catenin/Tcf signaling pathway, such as c-Myc, cyclin D1 and c-Jun. PPAR $\delta$  has been identified as another  $\beta$ -catenin/Tcf-regulated gene<sup>[6]</sup>. However, the effect of curcumin on the expression of PPAR $\delta$  remains unknown. In this study, we investigated the effects of curcumin on the expression of PPAR $\delta$  and related genes such as 14-3-3 $\epsilon$  and VEGF. The results showed that curcumin could inhibit the expression of PPAR $\delta$  and induce the down-regulation of the related genes, including 14-3-3 $\epsilon$  and VEGF.

## MATERIALS AND METHODS

### Reagents

RPMI-1640, fetal bovine serum (FBS), penicillin, streptomycin, and trypsin were purchased from GIBCO. Curcumin, sodium dodecylsulfate (SDS), phenylmethylsulfonylfluoride (PMSF), DNaseI and bovine serum albumin (BSA) were purchased from Sigma-Aldrich Co. (St. Louis, MO, USA). Anti-VEGF, anti-Tcf-4 and horseradish peroxidase-conjugated goat anti-rabbit antibodies were obtained from Epitomics. Anti-14-3-3 $\epsilon$ , anti-PPAR $\delta$  antibody and protein A/G plus-agarose were provided by Santa Cruz Biotechnology. Nitrocellulose membrane and the enhanced chemiluminescence (ECL) detection system were purchased from Amersham (USA). PrimeScript 1st strand cDNA Synthesis Kit and PCR Kit were from Takara, Japan. Caspase-3 assay kit and nuclear and cytoplasmic protein extraction kit were purchased from Beyotime Biotech, China. Other reagents used were of analytical grade and procured locally.

### Cell culture and treatment

The human colon cancer cell line HT-29 was obtained from the American Type Culture Collection (Manassas, VA, USA) and maintained in RPMI 1640, supplemented with 10% FBS, 100 U/mL penicillin and 100  $\mu$ g/mL streptomycin at 37°C in a humidified atmosphere of 5% CO<sub>2</sub> and 95% air. Upon reaching 70%-80% confluence, the cells were exposed to 0-80  $\mu$ mol/L curcumin for 24 h.

### Measurement of caspase-3 activities

Caspase-3 activities were measured as previously described<sup>[17]</sup>. Briefly, cells were lysed in a buffer containing 5 mmol/L Tris (pH 8), 20 mmol/L EDTA, and 0.5% Triton-X 100. Reaction mixture contained 20 mmol/L HEPES (pH 7.0), 10% glycerol, 2 mmol/L dithiothreitol, 50  $\mu$ g protein per condition, and 200  $\mu$ mol/L DEVD-pNA as substrate. After incubation for 24 h at 37°C, the absorbance in each well was measured at 405 nm with a microplate ELISA reader.

### Nuclear staining with Hoechst 33342

Chromatin condensation was detected by nuclear staining with Hoechst 33342<sup>[18]</sup>. After treatment with 0-80  $\mu$ mol/L curcumin for 24 h, cells were harvested and washed with PBS three times. Then, the cells were stained with 1  $\mu$ L of Hoechst 33342 (5 mg/mL, Sigma) in 1 mL basal medium and incubated at room temperature in the dark for 15 min. Stained cells were imaged under a fluorescent microscope using 350 nm stimulation and 460 nm emission.

### RNA extraction and real-time quantitative RT-PCR analysis

Total RNA was isolated using Trizol Isolation Reagent (Invitrogen, USA). RNA integrity was confirmed by denaturing agarose gel electrophoresis, and the concentration was quantified by measuring the optical density (OD) at 260 nm. One microgram total RNA was used for DNaseI treatment (Sigma) and subsequent cDNA synthesis. Reverse-transcription was performed with PrimeScript 1st Strand cDNA Synthesis Kit (Takara, Japan) according to the manufacturer's instructions. Real-time qPCR was performed on the ABI 7500 Real Time PCR System using SYBR Premix Ex Taq II (Takara, Japan) for analyzing expression of genes. Table 1 shows the primers used for real-time quantitative RT-PCR. The amplification reactions were performed under the following PCR conditions: one cycle at 95°C for 10 min, followed by 40 cycles of 95°C for 15 s, 59°C for 15 s and 72°C for 30 s. mRNA fold changes in target genes relative to the endogenous GAPDH control were calculated as suggested by Schmittgen *et al.*<sup>[19]</sup>. Each reaction was performed in triplicate.

### Western blotting

Western blotting analysis was done as previously described with minor modifications to detect the expressions of PPAR $\delta$ , 14-3-3 $\epsilon$ , and VEGF protein<sup>[20]</sup>. The total cellular protein and the nuclear protein were extracted according to the instructions of nuclear and cytoplasmic extraction reagents kit (Beyotime, Haimen, China). The lysates were used to estimate their protein content with BCA protein assay. Fifty micro-grams of protein from each sample was subjected to SDS-PAGE. After electrophoresis, proteins were electroblotted to a Hybond-C Extra nitrocellulose membrane (Amersham, USA). The membrane was blocked at room temperature with 5% non-fat dry milk in TBS containing 0.3% Tween (TBS-T). The membrane was washed three times with TBS-T and incubated overnight at 4°C with the primary antibody, anti-PPAR $\delta$  (1:500), anti-14-3-3 $\epsilon$  (1:2000), and anti-VEGF (1:1000), followed by 1 h incubation with a 1:5000 dilution of the appropriate horseradish-peroxidase-conjugated secondary antibody. After incubation, the membrane was washed with TBS-T for three times, the antigen-antibody complexes were visualized by enhanced chemiluminescence and exposure to X-ray film for 0.5 up to 30 min.

Table 1 Primers used for real-time quantitative RT-PCR

Apoptosis modulator	Forward primer (5'→3')	Reverse primer (5'→3')
PPAR $\delta$	GCAGGCTCTAGAATTCCATC	GTGCAGCCTTAGTACATGTC
VEGF	AGGAGGAGGGCAGAATCATCA	CTCGATTGGATGGCAGTAGCT
14-3-3 $\epsilon$	GAGCGATACGACGAAATGGT	CCTTGGACTCGCCAGTGTTAG
GAPDH	GGCAAATTC AACGGCACAGT	AGATGGTGATGGGCTTCCC

**Figure 1** Induction of apoptosis in HT-29 cells by curcumin. Fluorescence images of HT-29 cells using Hoechst 33258 staining showed curcumin induced typical apoptotic morphological changes. A: Control; B: HT-29 cells incubated with 20  $\mu$ mol/L curcumin; C: HT-29 cells incubated with 40  $\mu$ mol/L curcumin; D: HT-29 cells incubated with 60  $\mu$ mol/L curcumin.

### Immunoprecipitation

The immunoprecipitation was done as previously described with minor modifications<sup>[16]</sup>. The nuclear lysates containing 500  $\mu$ g protein were incubated with 5  $\mu$ g primary antibody overnight at 4°C. Fifty microliters of protein A/G plus-agarose (Santa Cruz Biotechnology) was added and the complex was incubated at 4°C overnight. The beads were washed three times with high salt buffer (1 mol/L Tris-HCl, pH 7.4, 0.50 mol/L NaCl, and 1% Nonidet P-40) and twice with lysis buffer to eliminate non-specific binding. The immunoprecipitated complexes were released with 2  $\times$  sample buffer for Western analysis.

### Transfection and luciferase assay

Transient transfection was performed using Eugene 6 Transfection Reagent (Roche) in accordance with the manufacturer's instructions. Briefly, HT-29 cells were seeded at a density of  $2 \times 10^5$  cells per well in six-well plates. After 24 h, cells were transfected with 0.5  $\mu$ g luciferase reporter constructs (TOPflash or FOPflash, respectively) and 0.5  $\mu$ g  $\beta$ -galactosidase gene. Three hours after transfection, the cells were treated with 0-80  $\mu$ mol/L curcumin and the incubation was continued for 24 h. Then, the cells were collected and resuspended in Luciferase Reporter Lysis Buffer (Promega, USA). The cell lysates were centrifuged and aliquots (70  $\mu$ L) of the supernatant were assayed for the activity of luciferase and galactosidase. Reporter activity was normalized for variations in transfection efficiency using  $\beta$ -galactosidase as an internal control. Experiments were performed three times independently.

### Statistical analysis

Results are presented as mean  $\pm$  SE. Comparisons

between multiple groups were performed using the one-way ANOVA followed by Dunnett's test. Differences were considered to be significant at  $P < 0.05$ .

## RESULTS

### Induction of HT-29 cell apoptosis by curcumin

Hoechst 33342 staining assay was performed to observe the effects of curcumin on cell nuclear morphology. As shown in Figure 1, the control cells displayed intact nuclear structure, while nuclei with chromatin condensation and formation of apoptotic bodies were seen in cells incubated with curcumin in a dose-dependent fashion (Figure 1A-D). Caspase-3 activation is an important marker of apoptosis, so we determined the activities of caspase-3 in HT-29 treated with curcumin for 12 or 24 h. Caspase-3 activities were highly elevated by curcumin at the concentration of 20-80  $\mu$ mol/L (Figure 2).

### Curcumin suppressed the expression of PPAR $\delta$

PPAR $\delta$  plays important roles in the growth and proliferation of many cancer cells<sup>[8]</sup>. PPAR $\delta$  has been identified as one of the down-streaming targets of the  $\beta$ -catenin/Tcf-4 pathway<sup>[6]</sup>. We studied whether curcumin affected the expression of PPAR $\delta$  in HT-29 cells. HT-29 cells were incubated with curcumin at different concentrations. PPAR $\delta$  gene expression at the mRNA level was detected by quantitative RT-PCR. The results showed that 40-80  $\mu$ mol/L of curcumin could significantly reduce the level of PPAR $\delta$  in HT-29 cells (Figure 3A). Whole-cell extracts were prepared and analyzed by Western blotting. Curcumin reduced the level of PPAR $\delta$  protein in a dose-dependent manner (Figure 3B).

**Figure 2** Caspase-3 activity was markedly increased by curcumin in a dose-dependent manner. Each bar denotes mean  $\pm$  SD ( $n = 3$ ). (<sup>a</sup> $P < 0.05$  vs control; <sup>b</sup> $P < 0.01$  vs control).

### Curcumin decreased the expression of 14-3-3 $\epsilon$ and VEGF

14-3-3 $\epsilon$  plays important roles in protecting cells from apoptosis<sup>[21]</sup>. It harbors three contiguous PPAR response elements (PPREs), which are the responsive promoter region of 14-3-3 $\epsilon$  activation. Deletion of PPREs abrogated PPAR $\delta$ -mediated 14-3-3 $\epsilon$  to PPAR $\delta$  up-regulation<sup>[10]</sup>. On the basis of this study, we hypothesized that curcumin could inhibit the expression of 14-3-3 $\epsilon$  in HT-29 cells. The real-time quantitative PCR showed that treatment with 60 and 80  $\mu$ mol/L curcumin for 24 h could markedly reduce the 14-3-3 $\epsilon$  mRNA level in HT-29 cells (Figure 4A). The Western blotting showed that curcumin treatment also inhibited the 14-3-3 $\epsilon$  protein expression at the concentration of 20-80  $\mu$ mol/L (Figure 4C).

VEGF can stimulate endothelial cell proliferation and prevents apoptosis in the endothelial cells of newly formed vessels<sup>[22]</sup>. VEGF has been identified as one of the potential targets of PPAR $\delta$  in colorectal cancer (CRC) cells<sup>[13]</sup>. We hypothesized that curcumin can decrease the expression of VEGF. The real-time quantitative RT-PCR showed that 40-80  $\mu$ mol/L of curcumin could significantly down-regulate the expression of VEGF (Figure 4B). Consistent with the VEGF mRNA level, VEGF protein was also decreased by curcumin at the concentrations of 20-80  $\mu$ mol/L (Figure 4D).

### Curcumin down-regulated $\beta$ -catenin/Tcf signaling pathway and inhibited $\beta$ -catenin associated with Tcf-4 in nuclei of HT-29 cells

The association of  $\beta$ -catenin with Tcf-4 is required for activation of  $\beta$ -catenin/Tcf signaling, so we determined the level of the  $\beta$ -catenin/Tcf-4 complex in the nucleus of HT-29 cells. We used anti-Tcf-4 antibody to co-immunoprecipitate the complex of Tcf-4 and  $\beta$ -catenin from nuclear extracts and determined the amount of  $\beta$ -catenin by immunoblotting. Curcumin markedly decreased the level of  $\beta$ -catenin/Tcf-4 complex (Figure 5A). However, the level of total  $\beta$ -catenin in the nucleus was not significantly affected by incubation of curcumin (Figure 5A). These results suggested that curcumin could inhibit  $\beta$ -catenin associated with Tcf-4 in the nucleus. Because PPAR $\delta$  is a target gene of  $\beta$ -catenin/Tcf-4, curcumin may decrease the expression of PPAR $\delta$  through

**Figure 3** Curcumin inhibits the expression of PPAR $\delta$  in HT-29 cells. A: Real-time quantitative RT-PCR indicated that curcumin markedly reduced the level of PPAR $\delta$  mRNA. Values are % reduction in PPAR $\delta$  mRNA fold changes caused by curcumin compared with cells without curcumin treatment. Values are mean  $\pm$  SD from three samples per group. GAPDH was used as an internal control; B: The effects of curcumin on the level of PPAR $\delta$  protein were determined by Western blotting.  $\beta$ -actin was used as an internal marker. (<sup>a</sup> $P < 0.05$  vs control; <sup>b</sup> $P < 0.01$  vs control).

blocking the  $\beta$ -catenin/Tcf-4 signaling pathway.

PPAR $\delta$  has been identified as a target of the  $\beta$ -catenin/Tcf signaling pathway<sup>[6]</sup>. We hypothesized that curcumin can inhibit the expression *via* the  $\beta$ -catenin/Tcf signaling pathway. We transfected HT-29 cells with either TOPflash or FOPflash. The cells were incubated with 0-80  $\mu$ mol/L curcumin for 24 h and the luciferase activity was determined. As a result, curcumin could decrease the transcriptional activity of  $\beta$ -catenin/Tcf-4 signaling pathway in HT-29 cells (Figure 5B).

## DISCUSSION

Curcumin can induce apoptosis of many cell lines. However, the mechanism is still unclear. In this study, we demonstrated that curcumin could induce the apoptosis of HT-29 cells and down-regulate the expression of PPAR $\delta$ , 14-3-3 $\epsilon$  and VEGF, which suggested that curcumin-induced apoptosis was attributed to the inhibition of the expression of PPAR $\delta$ , 14-3-3 $\epsilon$  or VEGF.

The PPARs are ligand-activated transcription factors that are members of the nuclear hormone receptor superfamily. PPARs form heterodimers with the retinoic X receptor and bind to DNA in correspondence to specific PPRE located in the promoter of target genes<sup>[23]</sup>. The PPAR subfamily includes PPAR $\alpha$ , PPAR $\delta$  (or  $\beta$ ) and PPAR $\gamma$ , which share extensive structural homology<sup>[23]</sup>. Studies have shown that PPAR $\alpha$  and PPAR $\gamma$  play important roles in such physiological processes as fatty acid metabolism, glucose metabolism, immunity, and cellular differentiation<sup>[24,25]</sup>. However, the physiological role of PPAR $\delta$  is less studied. Recently, PPAR $\delta$  has been found to be related to carcinogenesis<sup>[26,27]</sup>. Curcumin has been proved to inhibit the growth and differentiation of many cancer cell lines<sup>[28,29]</sup>. Administration of 30 mg/kg curcumin by intraperitoneal injection for 2 wk could

**Figure 4** The expression of 14-3-3 $\epsilon$  and VEGF is down-regulated by curcumin. Real-time quantitative RT-PCR showed that curcumin decreased the mRNA levels of 14-3-3 $\epsilon$  (A) and VEGF (B). Values are means  $\pm$  SD from three samples per group. GAPDH was used as an internal control for quantitative RT-PCR. Western blotting was performed to determine the effects of curcumin on the expression of 14-3-3 $\epsilon$  (C) and VEGF (D).  $\beta$ -actin was used as internal marker for Western blotting. (<sup>a</sup> $P$  < 0.05 vs control; <sup>b</sup> $P$  < 0.01 vs control).

**Figure 5** Curcumin inhibited  $\beta$ -catenin association with Tcf-4 and down-regulated the  $\beta$ -catenin/Tcf reporter activities in HT-29 cells. A: Immunoprecipitation and immunoblotting results showed that curcumin inhibited  $\beta$ -catenin associated with Tcf-4 but had no effects on the level of  $\beta$ -catenin in nucleus; B: Curcumin significantly reduced TOPflash luciferase activity but had no effect on the activity of FOPflash. Values represent means  $\pm$  SE of three independent experiments. (<sup>a</sup> $P$  < 0.05 vs control; <sup>b</sup> $P$  < 0.01 vs control).

significantly improve the expression of PPAR $\gamma$  in colonic tissues of rats<sup>[30]</sup>. To the best of our knowledge, the effects of curcumin on PPAR $\delta$  have not been investigated. In this study, we found that curcumin could inhibit the expression of PPAR $\delta$  in HT-29 cells. We hypothesize that there are two possible reasons. First, He *et al*<sup>[6]</sup> have identified PPAR $\delta$  as a  $\beta$ -catenin/Tcf-regulated gene. In this study, curcumin could inhibit the  $\beta$ -catenin associated with Tcf-4 and down-regulate the activity of the  $\beta$ -catenin/Tcf-4 signaling pathway, which is in agreement with the studies of Jaiswal *et al* and Park *et al*<sup>[15,16]</sup>. These studies indicate that curcumin may reduce the expression of PPAR $\delta$  by blocking the  $\beta$ -catenin/Tcf-4 signaling pathway. Second, PPAR $\delta$  can also be up-regulated by oncogenic K-Ras<sup>[31]</sup>,

suggesting that curcumin may reduce the expression of PPAR $\delta$  by other signaling pathways. We will further study the mechanism that curcumin inhibits the expression of PPAR $\delta$ .

14-3-3 are cytosolic proteins serving as a scaffold to interact with a large number of proteins<sup>[32]</sup>. They may protect cells from apoptosis through their binding and sequestering phosphorylated Bad in cytosol<sup>[21]</sup>. Seven isoforms of 14-3-3 proteins have been identified in mammalian cells<sup>[10]</sup>. It has been indicated that 14-3-3 $\epsilon$  is a target gene of PPAR $\delta$ , which can bind to the PPRE upstream of 14-3-3 $\epsilon$  promoter region<sup>[10]</sup>. We found that curcumin decreased the expression of 14-3-3 $\epsilon$  in HT-29 cells. To the best of our knowledge, curcumin-induced down-regulation of 14-3-3 $\epsilon$  has not reported previously.

VEGF is also up-regulated by the activation of PPAR $\delta$  in colon carcinoma cells<sup>[12]</sup>. Several studies have indicated that curcumin can down-regulate the expression of VEGF in different cell lines<sup>[33,34]</sup>. In the present study, we found that curcumin could inhibit the expression of VEGF in HT-29 cells. VEGF plays important roles in tumor angiogenesis<sup>[35]</sup>. Our results suggest curcumin may inhibit the angiogenesis of colorectal tumors.

In summary, our study shows that curcumin can suppress the expression of PPAR $\delta$  and the related genes such as 14-3-3 $\epsilon$  and VEGF in HT-29 cells. The reasons why curcumin inhibits the expression of PPAR $\delta$  and related protein are still unclear. Curcumin can down-regulate the activity of  $\beta$ -catenin/Tcf-4 signaling pathway, which suggests that curcumin may decrease the expression of PPAR $\delta$  by the inhibition of  $\beta$ -catenin/Tcf-4 signaling activity in HT-29 cells.

## COMMENTS

### Background

Colorectal cancer is one of the leading causes of death and is a major public health problem in Western countries. Peroxisome proliferator-activated

receptors (PPARs) play important roles in cell replication, differentiation, tumorigenesis, and apoptosis. The expression of PPAR $\delta$  is elevated in human and rat colorectal cancer cells when compared with normal colon epithelial cells.

### Research frontiers

Curcumin can affect the expression of the target genes of  $\beta$ -catenin/Tcf signaling pathway, such as c-Myc, cyclin D1, c-Jun, etc. PPAR $\delta$  has been identified as another  $\beta$ -catenin/Tcf-regulated gene. However, the effect of curcumin on the expression of PPAR $\delta$  remains unknown. In this study, the authors demonstrate that curcumin could affect the expression of PPAR $\delta$  and related genes such as 14-3-3 $\epsilon$  and vascular endothelial growth factor (VEGF).

### Innovations and breakthroughs

Recent studies have suggested the PPAR $\delta$  play important roles in colorectal carcinogenesis. It activates the expression of 14-3-3 $\epsilon$ , which can sequester the pro-apoptotic protein, Bad, to inhibit the apoptosis of cancer cells. It is the first report showing that the curcumin down-regulates the expression of PPAR $\delta$  and 14-3-3 $\epsilon$ .

### Applications

PPAR $\delta$  is found as a new target of curcumin to induce the apoptosis of HT-29 cells. New curcumin derivatives can be developed to efficiently inhibit the growth and differentiation of colorectal cancer cells by down-regulating the expression of PPAR $\delta$ .

### Terminology

Curcumin is an important polyphenol extracted from the rhizomes of *Curcuma longa* L. PPARs belong to the nuclear hormone receptor superfamily that enable the cell to respond to extracellular stimuli through transcriptional regulation of gene expression, including PPAR $\alpha$ , PPAR $\delta$ , and PPAR $\gamma$ . 14-3-3 proteins are anti-apoptotic and anti-inflammatory molecules in cells, which include at least seven isoforms ( $\beta$ ,  $\gamma$ ,  $\epsilon$ ,  $\eta$ ,  $\zeta$ ,  $\sigma$ ,  $\tau/\theta$ ). Elevated 14-3-3 $\epsilon$  augments Bad sequestration and prevents Bad-triggered apoptosis.

### Peer review

Curcumin can induce apoptosis of many cell lines. However, the mechanism is still unclear. In this study, the authors demonstrated that curcumin could induce the apoptosis of HT-29 cells and down-regulate the expression of PPAR $\delta$ , 14-3-3 $\epsilon$  and VEGF. More importantly, the authors showed that curcumin could markedly lower the level of  $\beta$ -catenin/Tcf-4 complex without affecting the level of total  $\beta$ -catenin in nucleus after incubation of curcumin. These results suggested that curcumin could inhibit  $\beta$ -catenin associated with Tcf-4 in nucleus.

Diagnosis of biliary strictures was modified in 20/29 and confirmed to be malignant in 10/23. Of the modified patients, no diagnosis was available in 17. Spyglass® demonstrated malignancy in 8/17 and non-malignancy in nine. Suspected pathology by imaging studies and abnormal LFT's was modified in 43/63 (66%). Staging of cholangiocarcinoma demonstrated multicentric cholangiocarcinoma in 2/3. There was no morbidity associated with the use of Spyglass®.

**CONCLUSION:** Spyglass Spyscope® is a first generation, single operator miniature endoscope that can evaluate and treat various biliary and pancreatic tract diseases.

### Abstract

**AIM:** To evaluate a new single-operator mini-endoscope, Spyglass®, for its performance, feasibility and safety in the management of pancreaticobiliary disease.

**METHODS:** In a multicenter retrospective analysis of patients undergoing intraductal endoscopy, we evaluated 128 patients (71 men, mean age 57.6 years). Indications were therapeutic (TX) in 72 (56%) and diagnostic (DX) in 56 (44%).

**RESULTS:** Peroral endoscopy was performed in 121 and percutaneous in seven. TX indications included CBD stones in 41, PD stones in six, and biliary strictures in 25. DX indications included abnormal LFT's in 15, abnormal imaging in 38 and cholangiocarcinoma staging in three. Visualization of the stone(s) was considered good in 31, fair in six, and poor in four. Advancement of the electrohydraulic lithotripsy probe was not possible in three patients and proper targeting of the lesion was partial in four patients. A holmium laser was used successfully in three patients. Ductal clearance was achieved in 37 patients after one procedure and in four patients after two procedures.

Management of pancreaticobiliary disease using a new intra-ductal endoscope: The Texas experience. *World J Gastroenterol* 2009; 15(11): 1353-1358 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1353.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1353>

### INTRODUCTION

Intraductal endoscopy is an integral part of the evaluation and therapy of patients with biliary and pancreatic diseases. The use of cholangiopancreatography was first described in the mid-1970s. The initial "baby" or "daughter" scopes were passed through the operating channel of the "mother" duodenoscope. These early endoscopes were not widely used due to cost, fragility, difficult maneuverability, limited optical resolution, and were easily damaged at the level of the duodenoscope elevator. In addition, these endoscopes required two trained endoscopists to operate. Due to these challenges,

the field of intraductal endoscopy did advance for several years<sup>[1,2]</sup>. Newer miniature endoscopes offer improved steering ability, durability, better optics and smaller size. These endoscopes have been increasingly used for diagnostic and therapeutic applications<sup>[3-5]</sup>. Spyglass Spyscope® (Boston Scientific, Natick, MA), is a new single-operator endoscope that has been recently introduced into the endoscopic arena<sup>[6]</sup>. It includes the Spyscope® which is 10 Fr in diameter, has a 4-way tip deflection and has a 1.2 mm working channel. It houses the Spyglass® optical fiber, an independent accessory channel and a separate channel for water irrigation.

We evaluated the Spyglass Spyscope® for its performance, feasibility and safety.

## MATERIALS AND METHODS

In this multicenter (three tertiary institutions; Houston, Dallas and San Antonio, TX) retrospective analysis, we evaluated 128 patients (71 males, 57 women, mean age 57.6 years) with various pancreatobiliary disorders (Table 1). Of the procedures to which the patients had been subjected, 56 (44%) were diagnostic and 72 were therapeutic (56%). Diagnostic indications included abnormal serum liver tests in 15, abnormal imaging studies in 38, and staging of cholangiocarcinoma in three. Therapeutic indications included choledocholithiasis in 41, pancreatic stones in six and biliary strictures in 25. The majority of procedures were performed per-orally (121), with the remaining seven performed percutaneously. All procedures were performed under monitored anesthesia, had prophylactic intravenous antibiotics, and the majority were performed on an outpatient basis. Most patients had a previous endoscopic retrograde cholangiopancreatography (ERCP), and had a previous biliary sphincterotomy. All procedures were performed by an experienced biliary endoscopist.

Abnormal imaging studies included computed tomography, magnetic resonance and endoscopic ultrasound. Therapeutic intervention was performed with electrohydraulic lithotripsy (EHL) and a holmium laser. Biopsies were obtained with the Spybite® as well as with standard biopsy forceps.

Spyglass Spyscope® procedure was performed by attaching the Spyglass Spyscope® to the duodenoscope, at the junction of the head and the shaft. The Spyscope® was introduced over a guide wire through the accessory channel. The Spyglass® was advanced through the Spyscope® just to its tip. The Spyglass Spyscope® apparatus was then advanced through the duodenoscope and then into either the bile duct or the pancreatic duct. The guide wire was then removed to facilitate Spyscope® tip deflection.

## RESULTS

### Diagnostic purposes

The main indication was determination of biological behavior of bile duct strictures (Table 2). The diagnosis of biliary strictures was modified in 20 of 29 patients. All 29 patients had a preoperative diagnosis of

Post-operative diagnosis malignant	9
Post-operative diagnosis benign	8

malignant bile duct stricture (three had established cholangiocarcinoma considered resectable in two, one stricture by MRCP, 25 strictures by ERC). Spyscope® endoscopy demonstrated malignancy (visualization, cytology and biopsy) in 11 of 20 patients. In three patients, Spyscope® endoscopy demonstrated stone related strictures (stones not seen by standard cholangiography), extrinsic compression of the distal bile duct in two, and scar-like tissue that appeared benign in four patients [all with Primary sclerosing cholangitis (PSC)]. Visual components of malignancy included exophytic lesions, ulcerations, and raised lesions. Biopsy alone showed malignant features in 6/11 patients. Cytology showed malignant features in 4/20 patients. In patients with abnormal liver tests, abnormal Spyscope® endoscopy findings included stones in two, anastomotic ulceration in two, intrahepatic duct ulcer in one, intrahepatic adenoma in one, and normal in nine. Of patients with abnormal imaging studies, Spyscope® endoscopy demonstrated supra-papillary polypoid lesions in two, intraductal extension of ampullary cancer in one, stones in two, anastomotic surgical material in three, villous adenoma in three, cholangiocarcinoma in one, and normal in 26 (including no mucosal abnormalities in four patients with choledochal cyst type I) (Figure 1A and B). Of the patients with cholangiocarcinoma, two had resectable disease. Spyscope® endoscopy demonstrated intrahepatic disease in two and confirmed localized disease in one.

Figure 2 Pancreatic use of Spyglass® with (A) fluoroscopic view of cannulation, (B) duodenoscope view, (C) Spyscope® views of pancreatic stone and stricture.

Table 3 Spyglass® evaluation of choledocholithiasis

Spyglass® evaluation of choledocholithiasis	Cases (n)
Indications for choledochoscopy	
Large choledocholithiasis	26
Mirizzi syndrome	1
Intrahepatic lithiasis	10
Lithiasis with bile duct strictures (also with intrahepatic lithiasis)	11 (7)
Maneuverability	
Intrahepatic peroral advancement without difficulty	8/10
Percutaneous advancement	6/6
Holmium laser usage	3/3
Poor targeting of lesion with EHL	4/41
EHL not advanced	3/41
Overall visualization	
Good	31
Fair	6
Poor	4

### Therapeutic purposes

Spyglass Spyscope® endoscopy was used in 41 patients for biliary stone disease (Table 3). In 35 patients, it was used per-orally, and percutaneously in six patients due to surgically modified anatomy. Indications for biliary therapy included large choledocholithiasis (26), Mirizzi syndrome (1), intrahepatic lithiasis (10), and lithiasis associated with bile duct strictures (11). Some of these indications pertain to the same patient (i.e. large stone and Mirizzi syndrome). EHL was used in 38 patients and a holmium laser in three

(Table 3). Lithotripsy was successful in 37/41 patients (Figure 1C). In five patients the EHL probe could not be advanced through the Spyscope® at the exit of the duodenoscope. In seven patients, the EHL probe could not be accommodated to fully target the stone. However, it produced enough fragmentation to remove the stone. Several factors were evaluated to assess feasibility, scope maneuverability, and technical success based on the ability to achieve ductal clearance of the Spyglass® system in the treatment of biliary disease. The initial assessment was based on the quality of visualization and related assessment of potential for intervention. Visualization (Table 3) was good in 31 (75.6%), fair in six (14.6%) and poor in four (12.9%). Maneuverability was superior if the guide wire was removed from the working channel. Percutaneous maneuverability was possible in 6/6 (100%) cases. The Spyscope® was advanced in the intrahepatics without difficulty in 8/10 (80%) patients. In 37/41 cases (87.1%) therapy for stones was completed by lithotripsy in one session (either by EHL or a holmium laser), and the remaining four patients required two sessions to achieve ductal clearance. A holmium laser was successfully used in three patients for stone destruction. Peroral use was easier than percutaneous. We noticed that the optical resolution of the Spyglass® deteriorated after ten uses. The best optical resolution was between uses one and seven.

### Management and treatment for pancreatic stone disease

Six patients had pancreatoscopy for stones related

to chronic pancreatitis (Figure 2). All patients had a pancreatic sphincterotomy and a biliary sphincterotomy. All patients had a stricture distal to the stone and all the stones were localized to the head of the pancreas. The stone size varied between 5-14 mm. Two of the six stones were cast-like and impacted. In all patients, EHL was used *via* Spyglass Spyscope®. All patients underwent stricture dilatation before lithotripsy. Maneuvering the Spyglass Spyscope® in these patients was difficult due to its size (10 Fr). Stone clearance was successful in three of six patients, with the remainder treated with stent therapy.

### **Biliopancreatic disease overall results**

Spyglass Spyscope® modified the preoperative diagnosis in 66% of the patients, prevented unnecessary surgery in two patients with cholangiocarcinoma, changed the diagnosis of malignant to benign disease in 45% of the patients with strictures, and provided successful therapy in 87% of the patients with stone disease. There was no morbidity or mortality associated with its use.

## **DISCUSSION**

Since the introduction of intraductal endoscopy in the 1970s, several iterations have occurred to optimize the diagnosis and therapy for biliary and pancreatic disorders.

Reported uses include patient demographics (including young children and elderly) to diagnose and treat biliary and pancreatic stones or masses, strictures due to malignancy, primary sclerosing cholangitis and post-orthotopic liver transplantation.

The Spyglass® system is a single-operator three-channel, catheter based mini-endoscope. The system uses the Spyscope®, which has four-way maneuverability, accepts a 3.4-mm diameter catheter with a separate irrigation port, a channel for the 0.77 mm Spyglass® optical probe, and a 1.2-mm accessory channel. The accessory channel can be used to take biopsies with the Spybite and introduce EHL or holmium laser fibers.

Chen and Pleskow recently reported the initial experience with Spyglass Spyscope® (Boston Scientific, Natick, MA), a new single-operator endoscope. They evaluated 35 patients with the majority of cases (27) to evaluate indeterminate filling defects or strictures<sup>[6]</sup>. PSC was the most common preoperative diagnosis present in 9/35 patients and 9/35 patients had common bile duct stones diagnosed by a pre- or peri-procedure, with EHL performed in five cases. The new endoscope had a 91% success rate for achieving either diagnostic or therapeutic endpoints, with a diagnosis by visual inspection yielding a 100% sensitivity and 77% specificity. When biopsies were performed, the overall sensitivity was 71% and 100% specificity for determining the behavior of a lesion. A low complication rate of 6% was reported with cholangitis seen in two patients, one requiring abscess drainage.

Chen reported an initial model system with Spyglass® that demonstrated improved targeting of lesions with improved steering ability compared to standard choledochoscopes<sup>[7]</sup>. A follow-up evaluation with 35 patients described the first experience using the

Spyglass® in patients with strictures, filling defects, choledocholithiasis, and gallbladder stent placements. Our experience with intraductal endoscopy using Spyglass® is one of the largest series to date and represents description of both diagnostic and therapeutic modalities. The use of Spyglass® resulted in management changes in two-thirds of patients and no complications occurred.

The primary indication for diagnostic intraductal endoscopy in the biliary tree is to evaluate strictures seen on abnormal imaging study or prior ERCP. The majority of these patients are either post-OLT or at risk for cholangiocarcinoma (i.e. patients with PSC or history of choledochal cyst). Several modalities such as methylene blue<sup>[8]</sup> and narrow band imaging<sup>[9]</sup> have been used to optimize diagnosis in patients with various bile duct disorders<sup>[6,7,10-12]</sup>, including liver transplant<sup>[5]</sup>, PSC, and cholangiocarcinoma<sup>[10,13-16]</sup>. Direct visualization and focused biopsy samples provide both endoscopic and pathological information to aid in diagnosis and treatment strategies. We described 29 patients who underwent Spyglass® to evaluate biliary strictures and the preoperative diagnosis was modified in 20 (68%) patients. All 29 patients had a preoperative diagnosis of malignant bile duct stricture, with 45% determined to be benign after Spyglass® evaluation. As with other intraductal endoscopes, bile duct stones were visualized in three Spyglass® cases, not seen on initial ERC.

Several reports detail the management of bile duct stones with standard choledochoscopy with EHL or laser therapies. Several authors have demonstrated the benefit of choledochoscopy in patients with filling defects or suspected choledocholithiasis by routine ERCP<sup>[5,17-20]</sup>. Siddiqui and colleagues reported 18 patients with suspected stones, with 14/18 treated with EHL and the remaining four patients had either benign epitheloid tumors, large-cell lymphoma and cholangiocarcinoma<sup>[5]</sup>. Arya *et al* described their experience of EHL in 111 patients<sup>[17]</sup>. The authors' primary use for choledochoscopy and EHL were stones larger than 2 cm, or those with associated stone-related strictures, with successful stone fragmentation in 89 of 93 patients (96%) and overall stone clearance in 85/94 patients (90%). Treatment failures were due to targeting problems and hard stones. In their experience, 76% received one EHL session, 14% with two sessions, and 10% with three or more sessions. Farrell *et al* used a modified single operator choledochoscopy system for treatment of stones, with 39 % of stones larger than 2 cm and 35% with stones above a stricture<sup>[19]</sup>. More than half (54%) of patients in this cohort had multiple stones visualized and treated with choledochoscopy and EHL. They determined that the location of the stone, presence of multiple stones, presence of a stricture and the size of the stone were predictive factors for success and need for multiple EHL sessions.

Our series of 41 patients with bile duct stones using the Spyglass® system demonstrated similar results, with 87.1% of patients with clearance after one EHL session and the remaining patients with a second session. As with

previous reports, difficulties in stone removal were related to passage of the EHL probe through the Spyscope® and targeting of the lesion with the EHL probe. We found that removal of the guide wire facilitated visualization and manipulation of the EHL probe.

Several authors have described experience with peroral pancreatoscopy to evaluate pancreatic lesions (intraductal papillary mucinous neoplasms, strictures and treatment of stones)<sup>[21-25]</sup>. We demonstrated the use of Spyglass® in six patients with adequate visualization of pancreatic stones, all with strictures distal to the stone. Half of the patients were successfully treated with EHL-directed therapy, with the remaining patients treated with stent-directed therapy. The outer diameter of the Spyscope® catheter and visibility limited better access in the presence of strictures.

## CONCLUSION

Choledochoscopy has been available to endoscopists for several years. It is of high value in the management of difficult biliary stones, biliary strictures, and determining the presence or absence of ductal disease. The same has been applied to pancreatoscopy, however only recently since the advent of small caliber mini-scopes. Spyglass® is a new intraductal scope that differs fundamentally from other existing miniscopes in its structure, its four-way steering ability, its separate irrigation channel, its ease of use and requirement for only one operator. Due to its different structure, the Spyscope® component is disposable and the Spyglass® optical probe is reusable. The innovative design and ease in use will create an increase in choledochoscopy by more endoscopists. The applications are likely to remain for therapy of difficult stone disease. However, its use will increase for staging of various biliary cancers as well as in the management of biliary tract disease in liver transplant patients. Likewise, the use of Spyglass® will increase in patients with various pancreatic disorders, but not at the same pace as biliary disease. Our findings in redefining two-thirds of patients with malignant disease may influence both biliary and pancreatic oncologic management.

Future studies are planned to evaluate therapeutic intervention with the Spyglass® and related intraductal endoscopes. Additionally, we anticipate further improvements in optical quality, smaller catheter size, and maneuverability. Advanced imaging modalities such as narrow band imaging and chromoendoscopy offer further improvement in diagnostic capabilities, which can be assessed in the treatment of patients with biliary and pancreatic disease. With an increase in use, of critical importance is the recognition of disease (both endoscopically and histologically) and terminology. Thus, we believe that there will be an increase in the literature reporting the use of Spyglass® in biliary and pancreatic disorders.

## COMMENTS

### Background

Intraductal endoscopy has been used for more than 30 years to evaluate and

treat disorders of the biliary and pancreatic ducts. Cholangiopancreatography allows direct visualization and permits focused biopsies and lithotripsy. Use was limited for several years due to cost, ease of breakage, difficult maneuverability, and limited optical resolution.

### Research frontiers

Spyglass Spyscope® (Boston Scientific, Natick, MA), is a new single-operator endoscope that can be used in the therapy of bilio-pancreatic disease. This intraductal endoscope is effective in the diagnosis of biliary strictures in patients with primary sclerosing cholangitis, orthotopic liver transplantation and cholangiocarcinoma. The Spyscope® can also be used in the management of biliary and pancreatic stones. The research hotspot is the significant improvement in cholangiopancreatography and the diversity of modalities that are demonstrated with the new endoscope.

### Innovations and breakthroughs

The main advantages of the Spyglass Spyscope® are that it requires only one endoscopist, it has four-way steering ability, and a separate irrigation channel. This endoscope allows directed biopsies, can be used percutaneously, and permits the use of electrohydraulic lithotripsy or a holmium laser for the treatment of biliary and pancreatic stones.

### Applications

This study demonstrates an effective new tool in the diagnosis and treatment of biliopancreatic disease using cholangiopancreatography.

### Terminology

Cholangiopancreatography is the direct endoscopic evaluation of the bile or pancreatic ducts.

### Peer review

The authors present a preliminary report of a new endoscope to directly evaluate the biliary and pancreatic ducts. Their promising results assessed the performance, feasibility and safety of the new endoscope. The new intra-ductal endoscope was useful for discriminating benign biliary strictures from malignancy.

### **Abstract**

**AIM:** To culture human pancreatic tissue obtained from small resection specimens as a pre-clinical model for examining virus-host interactions.

**METHODS:** Human pancreatic tissue samples (malignant and normal) were obtained from surgical specimens and processed immediately to tissue slices. Tissue slices were cultured *ex vivo* for 1-6 d in an incubator using 95% O<sub>2</sub>. Slices were subsequently analyzed for viability and morphology. In addition the slices were incubated with different viral vectors expressing the reporter genes *GFP* or *DsRed*. Expression of these reporter genes was measured at 72 h after infection.

**RESULTS:** With the Krumdieck tissue slicer, uniform slices could be generated from pancreatic tissue but only upon embedding the tissue in 3% low melting agarose. Immunohistological examination showed the presence of all pancreatic cell types. Pancreatic normal and cancer tissue slices could be cultured for up to 6 d, while retaining viability and a moderate to good morphology. Reporter gene expression indicated that the slices could be infected and transduced efficiently by adenoviral vectors and by adeno associated viral vectors, whereas transduction with lentiviral vectors was limited. For the adenoviral vector, the transduction seemed limited to the peripheral layers of the explants.

**CONCLUSION:** The presented system allows reproducible processing of minimal amounts of pancreatic tissue into slices uniform in size, suitable for pre-clinical evaluation of gene therapy vectors.

### **INTRODUCTION**

Pancreatic cancer is a devastating disease. The mortality rate of this cancer almost equals its incidence rate. Genetic alterations in pancreatic cancer, as reviewed by Saif *et al*<sup>[1]</sup>, result in an aggressive cancer that is resistant to medical intervention. Surgical resection of pancreatic adenocarcinoma remains the cornerstone of treatment but is only available for a small minority of patients.

Even after surgical intervention prognosis remains poor, since median and 5-year survival after resection are 7.5 mo and 8%, respectively<sup>[2]</sup>. A recent meta-analysis suggests that gemcitabine-based chemotherapy seems to improve overall survival of patients with advanced and metastatic disease to some extent<sup>[3]</sup>. However, even with this treatment the prognosis continues to be poor. New therapies, such as viral-vector-mediated gene therapy, are needed to improve the survival of patients with pancreatic cancer.

Adenoviral vectors are used most frequently in gene therapy strategies aimed to treat solid cancers. Important advantages of this vector are its capability to infect and transduce dividing and non-dividing cells and that it can be propagated to high titers. Initially, non-replicating adenoviral vectors were used to introduce expression of a cytotoxic or a pro-drug activating gene into cancer cells. This so-called suicide gene therapy approach did show efficacy in pre-clinical cancer models. However, in the subsequent phase 1 clinical trials, no therapeutic effect was observed due to limited spread of the viral vector in the tumors. To improve the efficacy and the spread, adenoviral vectors were developed that were able to replicate in cancer cells but not in normal cells. These conditional replicating adenoviral vectors (CRADs) replicate specifically, in tumor cells and kill them as result of their lytic cycle. Upon replication a large amount of virus progeny will be generated in a tumor and infect other cancer cells. In pre-clinical models, these CRADs were more efficient than the non-replicating vectors. At least six different CRADs have subsequently been evaluated in clinical trials but only a minority of these studies suggested that these vectors could be effective<sup>[4]</sup>. The first engineered oncolytic adenovirus that was implemented in a clinical setting was Onyx-015, which replicates specifically in p53-deficient tumor cells. Preclinical studies had shown that Onyx-015 efficiently kills human cancer cells in subcutaneous tumors in nude mice<sup>[5,6]</sup>. Subsequent clinical studies showed that ONYX lacked efficacy as a single anti-tumor agent<sup>[7]</sup>. Also, in phase I / II trials for pancreatic cancer, intra-tumoral injection of Onyx-015 lacked efficacy<sup>[8,9]</sup>. Further studies showed that for these replicating adenoviral vectors, the transduction of cancer cells *in vivo* also appeared to be the limiting factor in treating patients.

Low expression of the coxsackie- and adenovirus receptor (CAR), *via* which adenovirus normally enters cells, was subsequently shown to cause the poor transduction of pancreatic cancer *in vivo*<sup>[10]</sup>. To overcome this problem several strategies emerged to increase pancreatic cancer transduction by circumventing CAR-mediated entry<sup>[11]</sup>. Insertion of the Arg-Gly-Asp (RGD) peptide motif in the fiber knob of adenovirus, for instance, enhances infectivity of pancreatic tumors in a mouse model<sup>[12]</sup>. All such studies however rely on the use of human pancreatic cancer cells growing subcutaneously in a nude mouse model. The discrepancies in efficacy of novel treatments seen in these preclinical studies and in subsequent clinical trials demonstrates that this is not an ideal model. For instance, these mouse models do not

assess the cellular heterogeneity of solid tumors such as pancreatic cancers. In addition, they do not accumulate extracellular matrix, which occurs in human tumors. Finally, due to the lack of normal human pancreas cells, these models are not suitable for demonstrating increased tumor specificity of the retargeted adenoviral vector. Therefore new models are needed that more closely resemble the *in vivo* situation in patients. Tissue explants seem a good alternative in this respect. In these explants, the interaction between heterogeneous cell types comprising normal and tumor tissue is retained. In addition, these explants do contain extracellular matrix. Therefore, tissue explants seem a suitable model to study transduction efficiency in a setting more representative of the *in vivo* situation.

Several culture systems are available that allow the preservation of live pancreas tissue taken directly from patient specimens. Hoem *et al*<sup>[13]</sup> cultured normal exocrine pancreatic cells, derived from pancreaticoduodenectomy specimens, as spheroids for at least 6 wk. A similar method was used for culturing pancreatic adenocarcinomas<sup>[14]</sup>. Both groups manually dissected tumor specimens to small fragments or cubes. Manual dissection of fresh tissue, however, causes physical stress and generates fragments of variable size and shape. This will influence the transduction by viral vectors because it affects the viability of the tissue and surface/volume ratio. To generate tissue slices with a more consistent size and shape, we decided to use an automatic tissue slicer. These slicers are widely used to generate precision-cut organ slices for biotransformation research. Slices can be prepared from several organs including liver, lung, kidney, colon and intestine. They closely resemble the architecture of the original organ, which makes this technique a powerful instrument to perform toxicity and drug-metabolizing studies<sup>[15]</sup>. Recently, the ultra-thin slices also proved to be a representative model for *ex vivo* evaluation of the transduction efficiency of adenoviral vectors<sup>[16,17]</sup>.

Precision-cut slicing of human pancreatic tissue was never reported. The aim of the present study was to evaluate the use of slices to test adenoviral-vector-mediated gene therapy for pancreatic cancer. We performed tissue slicing and subsequent culture of human pancreatic tissue slices and examined viability and morphology over time of normal and malignant pancreatic explants. Since we show that patient explants derived from minimal amounts of tissue are viable for up to 6 d with preservation of morphology, these slices appear to be a good model for studying viral-vector-mediated gene therapy and also seem suitable for pre-clinical testing of novel drugs to treat pancreatic disease.

## MATERIALS AND METHODS

### Materials

MD4000 Krumdieck tissue slicer was from Alabama Research & Development, Munford, Alabama; L-glutamine, penicillin, streptomycin, amphotericin were from Cambrex Bio Science, Walkersville, Maryland;

insulin, transferrin and selenium solution, MEM vitamins and MEM amino acids were from Invitrogen; the Innova 4300 incubator was from New Brunswick Scientific Co, Edison, New Jersey; the NOVostar fluorometer was from BMG Lab Technologies, Offenburg, Germany; WST-1 assay was from Roche, Almere, Netherlands; mouse anti-GFP JL-8 was from Clontech, Palo Alto, CA. The Powervision system was from ImmunoLogic, Duiven, The Netherlands; the biotinylated rabbit anti-mouse immunoglobulins and streptavidin–horseradish peroxidase conjugate were from DAKO Netherlands.

## Methods

**Virus generation and propagation:** Plasmids encoding for E1-, E3-deleted adenovirus vectors were modified by using pAdHM15<sup>[18]</sup>. pAdHM15 was digested with *PI-Sce* and *Ceu-I* to insert the reporter genes enhanced green fluorescent protein (GFP) and DsRed under control of the CMV promoter<sup>[19]</sup>. Recombinant adenoviral vectors were generated by transfection of HEK 293 cells with *PacI*-linearized *Ad-GFP* and *Ad-dsRED*. Virus was purified and concentrated by performing two cesium chloride gradients according to standard protocols. Virus preparations were dialyzed two times against 1 L of PBS. After the second dialysis, glycerol was added to a final concentration of 10% (v/v) and virus preps were aliquoted, and stored at -80°C. The number of genomic copies was determined by quantitative real-time polymerase chain reaction by using the primers against hexon DNA<sup>[19]</sup>.

Lentivirus-CMV-*GFP* was constructed as described before, by transfection of 293T cells using a calcium phosphate method, concentrated by ultracentrifugation, and titrated on HeLa cells<sup>[20]</sup>. AAV2-CMV-*GFP* was constructed and titers were determined as described previously<sup>[21]</sup>.

**Primary tissue slices:** Fresh human pancreatic specimens were obtained from patients undergoing a pancreaticoduodenectomy for pancreatic head tumors (pancreatic cancer slices) and carcinomas of the bile duct or ampulla of Vater (normal pancreas slices). Tumor specimens were embedded in 3% low melting point agarose/PBS before cutting in the MD4000 Krumdieck tissue slicer, to produce slices with a thickness of approximately 250  $\mu\text{m}$  (estimated  $2.5 \times 10^5$  cells), while submerged in oxygenated ice-cold Krebs. Slices were incubated in 1 mL DMEM including L-glutamine (2 mmol/L), penicillin (100 U/mL), streptomycin (100  $\mu\text{g/mL}$ ) and amphotericin (Fungizone 2.5  $\mu\text{g/mL}$ ) with or without insulin, transferrin and selenium (ITS), and 20 mmol/L HEPES pH 7.4. After 1 h, medium was replaced and slices were infected with  $1 \times 10^8$  or  $5 \times 10^8$  genomic copies *Ad-GFP* and/or *Ad-DsRED*, or with  $1.0 \times 10^6$  transducing units of lentivirus-CMV-*GFP* or with  $1.2 \times 10^{10}$  genomic copies AAV-2-CMV-*GFP*. All experiments were performed in triplicate and were repeated at least three times.

Tissue culture plates were placed in an Innova 4300 incubator that was humidified and gassed with 95% O<sub>2</sub> and continuously shaken back and forth (90 times/min)

at 37°C. Virus was removed and medium was refreshed after 36 h. Slices were harvested at several time points and lysed overnight at 4°C in 60  $\mu\text{L}$  RIPA buffer (25 mmol/L Tris HCl pH 7.6, 150 mmol/L NaCl, 1% NP-40, 1% sodium deoxycholate, 0.1% SDS). After one round of freeze/thawing, cellular debris was removed by centrifugation. Total fluorescence of GFP and dsRED in supernatant was measured with a NOVostar fluorometer. The filter settings were as follows: GFP excitation at 485 nm, GFP emission at 520 nm, DsRed excitation at 550 nm, DsRed emission at 580 nm. Several slices were fixed in 4% paraformaldehyde.

**WST-1 and amylase secretion assay:** Viability of tissue explants was determined with the WST-1 assay according to the protocol of Roche. Amylase activity in culture medium was determined using an enzyme-based colorimetric assay on a P800 Modular Roche Diagnostics apparatus.

**Histology and immunohistology:** Tissue slices were fixed in 4% paraformaldehyde, embedded in paraplast and 7- $\mu\text{m}$  sections were made. Hematoxylin and eosin staining was performed according to standard protocols. Sections were assessed for viability and morphological characteristics. Paraffin-embedded sections were used for immunohistological detection of GFP as reported earlier<sup>[21]</sup>.

## RESULTS

### *Slicing procedure and culture conditions*

Several studies underline the relevance of tissue slice technology for experiments involving organ culture. Solid organs such as liver can be sliced directly with a tissue slicer. For human pancreas, this was not possible because it is too soft. We showed that this problem could be solved by embedding small (approximately 5 mm) pancreatic fragments in cylinders of 3% low melting agarose. The resulting core was solid enough for processing in a tissue slicer. Various slicing systems are available commercially.

Initially, we used the Brendel/Vitron tissue slicer. However, we found the pancreatic slices to vary significantly in viability, integrity and size. Therefore, these preparations contained a large percentage of tissue fragments not suitable for further experiments. Furthermore, operating this slicer requires both hands, which compromised the retention of aseptic conditions in the biosafety flow cabinet. Therefore, we switched to the fully automated Krumdieck tissue slicer. With this slicer, many more uniform slices with considerably less damage to the fragile pancreatic tissue were obtained.

The study of Wang *et al.*<sup>[14]</sup> suggests that supplement-enriched culture medium extends tissue survival. We therefore added ITS, amino acids and vitamins to the culture medium. The oxygen tension varies between culture systems reported<sup>[15]</sup>. We decided to gas the incubator with 95% O<sub>2</sub> to ascertain proper diffusion of oxygen to the inner cell layers.

**Figure 1** Histological staining of pancreatic tissue slices. Slices derived from normal pancreas and pancreatic cancer were cultured for 3 d. A, B: Normal pancreas of good viability; C: Normal pancreas of poor viability showing massive tissue slice necrosis; D: Poorly differentiated adenocarcinoma of good viability. Hematoxylin/eosin staining. Original magnification of all tissues (100 ×).

**Figure 2** Viability of pancreatic (cancer) slices cultured for 3 d. All slices were cultured for 3 d and then stained with hematoxylin/eosin. The morphology of normal pancreas ( $n = 10$ ) and pancreatic adenocarcinoma ( $n = 6$ ) was studied microscopically and scored by an experienced pathologist.

### Viability

To examine the quality over time of cultured pancreatic slices, we first assessed viability by histology. Parameters for viability included cell swelling, necrosis and nuclear pyknosis. We included slices from 10 normal pancreas specimens and six pancreatic adenocarcinomas for examination at 3 d after slicing. In normal pancreas, we were able to distinguish all cell types including exocrine cells, ductal cells, islets of Langerhans, and nerve cells. Figure 1A shows a normal pancreas tissue slice at day 3. We observed that a cell sheet consisting of squamous epithelial-like cells (Figure 1B) covered several tissue slices. Tissue slices of poor viability were characterized

by complete disappearance of viable cells (Figure 1C). Figure 1D shows poorly differentiated adenocarcinoma of good quality. Some pancreatic cancers were accompanied by stromal tissue consisting of fibroblasts and connective tissue. All 16 slices were scored for viability. For normal pancreas, 70% of the slices had moderate to good viability, while, for pancreatic cancer specimens, this was 57% (Figure 2). Not surprisingly, keeping the time between resection and start of tissue culture as short as possible improved the viability of the slices.

To examine the effect of medium formulation on the viability of the slices from normal human pancreas, we performed a WST-1 assay. Tissue slices were cultured either in normal culture medium or in medium supplemented with ITS, vitamins and amino acids. The WST-1 reaction was performed at day 0, 1, 3, 4 and 6. WST-1 measurements showed an increase in activity after 1 d of culture, which remained constant up to day 3 and then showed a gradual decline at day 4 and 6 (Figure 3A). Addition of ITS, vitamins and amino acids did not significantly improve viability of the tissue slices. After 6 d in culture, these slices were subsequently examined for morphology. Figure 3B and C shows a representative overview of normal pancreas of good viability, including Langerhans cells and nerve cells. We cultured two additional sets of normal pancreas slices for 6 d and performed histological staining. We noted moderate to good viability in one and moderate to poor quality, in the second. In slices with poor quality the deterioration of the tissue started in the peripheral cell layers. Even in these slices, moderate quality was maintained in

**Figure 3 Viability of human pancreas tissue slices cultured *ex-vivo* for up to 6 d.** A: Viability of explants cultured in 1 mL DMEM (black line) or in DMEM supplemented with ITS growth factors (dashed line) was determined at day 1, 3, 4 and 6 of culturing a WST assay. All data given as the means of at least five slices  $\pm$  SD; B: Normal pancreas with good viability at day 6; C: Normal pancreas of good viability at day 6 with Langerhans and nerve cells; D: Normal pancreas at day 6 with necrotic areas. Original magnification (100  $\times$ ).

**Figure 4 Amylase secretion by human pancreas tissue slices.** Human pancreatic cancer tissues were cultured *ex-vivo* for up to 3 d. Amount of amylase present in medium was determined using a colorimetric enzyme based assay. Data are the means  $\pm$  SD ( $n = 12$ ).

the center (Figure 3D). Based on these histological comparisons we concluded that pancreatic slices retain moderate to good morphology for at least 3 d in culture. The WST-1 conversion at day 6 and moderate to good morphology seen in several slices suggests that these cultured pancreatic tissue slices remain viable for even longer periods.

In addition to viability and morphology, we tested functionality of pancreas slices by determining amylase activity in the medium. Medium was analyzed during three consecutive days following explanting of tissue. As shown in Figure 4, amylase secretion is maximal at day 1 and declined below detection level at day 3. This secretion of amylase suggests that the slices are not just viable and retain the correct morphology, but that they are also functional at least up to day 2.

#### Transduction of slices with virus vectors

The possibility of culturing slices for up to 3 d renders

this system suitable for studying the transduction of pancreatic tissue by adenoviral vectors that require 48 to 72 h to reach maximal gene expression levels. We examined whether pancreatic tissue slices produce detectable levels of two different reporter proteins after transduction with adenoviral vectors. We chose to test the transduction in these slices with an adenovirus vector expressing GFP and with one expressing dsRed. Since both are Ad-5 vectors and will display their native tropism, we expect they should have overlapping transduction patterns. Figure 5A shows diffuse expression of GFP and DsRed upon transduction with these vectors, and as expected, the expression patterns of both reporter genes largely overlap. To quantify the expression levels of both reporter genes, the slices were lysed and used for fluorometric detection of GFP and ds-Red in the NOVOstar reader. Infection of normal pancreas and cancer tissues with  $1.0 \times 10^8$  and  $5.0 \times 10^8$  gc/slice, respectively, resulted in clearly detectable measurements of both reporter genes at 72 h after transduction (Figure 5B). Lower amounts of virus or measurements at earlier time points resulted in expression levels too low to measure accurately. As shown in Figure 5B, the expression of both reporter genes varies significantly between slices. These variations most likely reflect differences in viability, in size and in tissue composition between slices. Importantly, by dividing the remaining fluorescence values of GFP by DsRed we obtained an average GFP to DsRED ratio of 0.9. In addition to the overlapping expression pattern, this constant ratio between both reporter genes also indicates that one of these vectors can be used as internal control for slice quality. For instance, in case of co-transduction with a tropism modified vector, the GFP/DsRed ratio will reflect the improved transduction efficiency of the targeted vector in comparison to the wild type adenovirus.

The transduction of the slices by adenovirus is not

**Figure 5** Transduction of pancreatic tissue slices with different viral vectors. A: Normal human pancreatic tissue slices are incubated with  $1.0 \times 10^8$  Ad5.GFP and  $1.0 \times 10^8$  Ad5.dsRed. After 48 h presence of GFP and ds.Red was detected using a fluorescent microscope; B: Normal pancreas slices were infected with  $1.0 \times 10^8$  genomic copies per slice of Ad5.GFP and Ad5.dsRed, or  $1.2 \times 10^{10}$  viral genomes AAV2-GFP. At 48 h after infection slices were lysed, GFP and ds.Red were quantified using the Novostar; C: Pancreatic adenocarcinoma explants were transduced with Ad-GFP. At 72 h after virus addition expression of GFP was detected using an anti-GFP antibody and counterstained with hematoxylin; D: GFP expression in normal pancreas at 72 h after incubation with lentivirus-GFP.
