analyze AhR mRNA and protein expression in 39 GC tissues and their corresponding adjacent non-cancerous tissues. Five GC cell lines (MKN28, MKN45, AGS, N87, and KATO III) were also analyzed. Compared with non-cancerous tissues both AhR mRNA and protein expression were significantly increased in cancer tissues. The AhR mRNA positive rate was significantly higher in GC tissues compared with their corresponding adjacent non-cancerous tissues (92.31%, 36/39 *vs* 66.67%, 26/39,  $\chi^2 = 7.863$ ;  $P = 0.005$ ). Quantitative real-time PCR and Western blotting results indicated that both AhR mRNA (Figure 1A and B) and protein levels (Figure 1C and D) in cancer tissues were significantly higher than levels in corresponding adjacent non-cancerous tissues ( $P < 0.01$ ). AhR expression was high in MKN28, MKN45, AGS and KATO III cells, but very weak in N87 cells (Figure 2A-D). The five GC cell lines were derived from different sources: MKN45 and AGS were derived from poorly differentiated primary carcinoma of the stomach; MKN28 was derived from a moderately differentiated primary gastric carcinoma; N-87 was derived from a liver metastasis of a well-differentiated carcinoma; KATO-III was derived from metastasis of gastric carcinoma. Tumor stage did not appear to correlate with the level of AhR expression.

Expression of AhR was further detected by

**Figure 2** AhR mRNA and protein expression in five GC cell lines. A: AhR mRNA was detected by RT-PCR; B: AhR mRNA was detected by real-time PCR, AhR mRNA of AGS cells was used as the experimental control to calculate the fold changes; C and D: AhR protein expression was detected by Western blotting and band intensities of AhR were normalized with corresponding band intensities of beta-actin.

immunohistochemistry in 190 GC and pre-malignant gastric tissues: 30 CSG, 30 CAG, 30 IM, 30 AH, and 70 GC. Among the 70 GC patients, 38 suffered from Lauren diffuse type and 32 had intestinal type GC<sup>[25]</sup>. There were no significant differences in gender or age in the different groups in this study population ( $P = 0.095$ ) (Table 1). Strong nuclear expression and weak cytoplasmic distribution of AhR were observed in epithelial cells of both GC and pre-malignant tissues. Interestingly, AhR expression was also found in some stroma cells of both GC and pre-malignant tissues (Figure 3). The levels of AhR expression gradually increased, with the lowest levels in CSG, followed by CAG, IM, AH and GC (Table 3). Considering the fact that AhR needs to move into the nucleus to trigger expression of its target gene, evaluation of nuclear translocation of AhR may be of more importance than assessing the overall AhR expression in both the nucleus and cytoplasm. Therefore, we further calculated nuclear expression of AhR in GC and pre-malignant tissues. As with overall AhR expression, nuclear translocation of AhR also showed an increasing trend, with the lowest expression in CSG, followed by CAG,

**Table 3** Expression of AhR in gastric cancer and pre-malignant tissues

IM, AH and GC (Table 4). Both AhR expression and nuclear translocation were significantly higher in GC than in precancerous tissues. There were no significant differences in AhR expression and nuclear translocation between diffuse type (d-GC) and intestinal type gastric cancers (i-GC) (Tables 3 and 4).

#### Effects of AhR signal pathway activation in AGS GC cell line

To investigate the potential role of the AhR signal pathway in gastric carcinogenesis, we first treated the GC cell line AGS with a specific AhR agonist, TCDD. CYP1A1, a classic target gene of AhR, was utilized as the indicator of AhR signal pathway activation. Although a baseline level of CYP1A1 expression was observed in AGS cells, RT-PCR and Western blot analysis showed that both CYP1A1 mRNA and protein expression in AGS cells were increased in a dose- and time-dependent manner following TCDD treatment (Figure 4A-D). After TCDD treatment, while CYP1A1 protein expression increased, AhR protein in the total cell lysates gradually decreased (Figure 4C and D). To further confirm the activation of the AhR signal pathway in gastric carcinogenesis, we treated AGS cells with a specific AhR antagonist, resveratrol<sup>[28,29]</sup>. Controls included AGS cells treated with DMSO only. Experimental samples included AGS cells treated with resveratrol (10  $\mu\text{mol/L}$ ) only or TCDD (1  $\text{nmol/L}$ ) plus different concentrations of resveratrol (0, 1, 5, 10, 20  $\mu\text{mol/L}$ ), respectively for 24 h (Figure 5). In concordance with previous results, treatment of AGS cells with 1  $\text{nmol/L}$  TCDD caused a

**Figure 3** Immunohistochemical staining of AhR in gastric tissues. A: CSG; B: CAG; C: IM; D: AH; E: i-GC; F: d-GC (Original magnification  $\times 400$  and  $\times 200$ ). Strong nuclear expression and weak cytoplasmic distribution of AhR were observed in epithelial cells and some stroma cells of both GC and pre-malignant tissues.

**Figure 4** AhR and CYP1A1 expression in AGS cells after TCDD treatment. A and B: RT-PCR; C and D: Western blotting. Treatment of AGS cells with specific AhR agonist TCDD resulted in a dose- (A and C) and time-dependent (B and D) induction of CYP1A1 expression. The results shown are representative of three independent experiments.

remarkable increase in CYP1A1 expression. However, this TCDD-induced CYP1A1 expression was partially reversed by resveratrol in a dose-dependent manner (Figure 5A and B).

Effects of AhR activation by TCDD on the

proliferation, cell cycle and apoptosis of AGS cells were further analyzed by MTT assay and flow cytometry. MTT assay demonstrated that the viability of AGS cells was significantly decreased in a dose- and time-dependent manner after TCDD treatment (Figure 6). Flow cytometric analysis demonstrated that TCDD caused a dose-dependent alteration in the cell cycle distribution of AGS cells 48 h after treatment. TCDD increased the proportion of cells in the G1 phase and correspondingly decreased the proportion in the S phase of the cell cycle. The proportion of cells in the G2 phase showed no significant change after TCDD treatment (Table 5, Figure 7). However, apoptosis of AGS cells was unable to be detected in this assay (Table 6, Figure 8). Thus, these results suggest that TCDD inhibits proliferation of AGS cells via induction of growth arrest at the G1-S phase.

## DISCUSSION

AhR is an evolutionarily conserved ligand-activated transcription factor bound and activated by ubiquitous environmental pollutants. Historically, AhR has been studied for its transcriptional regulation of genes encoding xenobiotic metabolizing enzymes such as cytochrome P450 enzymes, which metabolize many of these chemicals into mutagenic and toxic intermediates. Therefore, it has been suggested that AhR may play a role in oncogenic processes, especially those initiated by environmental carcinogens<sup>[11-13]</sup>. Environmental carcinogens such as PAHs and HAHs are well-known exogenous AhR ligands that play important roles in GC<sup>[5,6]</sup>. In addition to synthetic and environmental chemicals, numerous naturally occurring dietary and endogenous AhR ligands have also been identified

**Figure 5** Inhibition of TCDD-induced CYP1A1 mRNA and protein expression by resveratrol. A: CYP1A1 protein was detected by Western blotting; B: CYP1A1 mRNA was detected by RT-PCR. The results shown are representative of three independent experiments. Treatment of AGS cells with 1 nmol/L TCDD caused a remarkable increase in CYP1A1 expression. This TCDD-induced CYP1A1 expression was partially reversed by resveratrol in a dose-dependent manner.

**Figure 6** Viability of AGS cells after TCDD treatment was assessed by MTT assay. Viability of AGS cells was significantly decreased in a dose-dependent manner after TCDD treatment.

recently<sup>[8,10]</sup>. Since gastric epithelium may be constantly exposed to both exogenous and endogenous AhR ligands, it would be of significance to shed light on the essential role of AhR in gastric tumorigenesis. Andersson *et al.*<sup>[19-21]</sup> first suggested that constitutively activated AhR could induce stomach tumors in a transgenic mouse model. In our previous study, we found increased expression of AhR in two human GC cell lines (RF1 and RF48) using microarray analysis<sup>[22]</sup>. A recent study by Ma *et al.*<sup>[23]</sup> reported that concurrent expression of AhR and CYP1A1 is correlated with GC development. However, the role of AhR in human gastric tumorigenesis is still unclear.

In the current study, we first detected AhR mRNA and protein expression in 39 GC tissues and five GC cell lines using RT-PCR and Western blot analysis. Compared with their corresponding adjacent non-cancerous tissues, both AhR mRNA and protein expression were significantly increased in cancer tissues. Moreover, significantly different AhR levels in GC

cell lines from different derivations suggest that AhR expression may not be correlated with tumor stage. Since the development of human GC is a multi-step process, we further detected the expression and distribution of AhR using immunohistochemistry in a series of GC and pre-malignant gastric tissues. Ma *et al.*<sup>[23]</sup> performed similar examinations in their study. However, their study included only 39 GC tissues, 17 pre-malignant tissues, and six non-cancerous mucosa samples which were detected using immunohistochemistry. In addition, atypical hyperplasia, the most important pre-malignant histology type, was not included in their study. The small sample size in that study may not accurately reflect the real expression pattern of AhR in GC and pre-malignant tissues. In our study, we included a larger sample size and included 30 atypical hyperplasia tissues. Similar to the findings of Ma *et al.*<sup>[23]</sup>, our data also demonstrated a close correlation of AhR with tumor formation via enhanced expression levels and frequent nuclear translocation from pre-malignant lesions to GC. Significantly increased nuclear translocation of AhR was found even early in AH (Table 4). There were no significant differences in AhR expression and nuclear translocation between i-GC and d-GC. Our findings suggest that activation of AhR signaling may be an early event in gastric carcinogenesis. Interestingly, besides strong expression of AhR in epithelial cells, AhR expression was also found in some stroma cells of both GC and pre-malignant tissues. Trombino *et al.*<sup>[30]</sup> reported similar findings in their study of mammary tumorigenesis. Using a rat model of PAH-induced mammary tumorigenesis, they demonstrated that AhR expression levels were significantly elevated in PAH-induced mammary tumors as well as in stroma elements surrounding these tumors. Since stroma

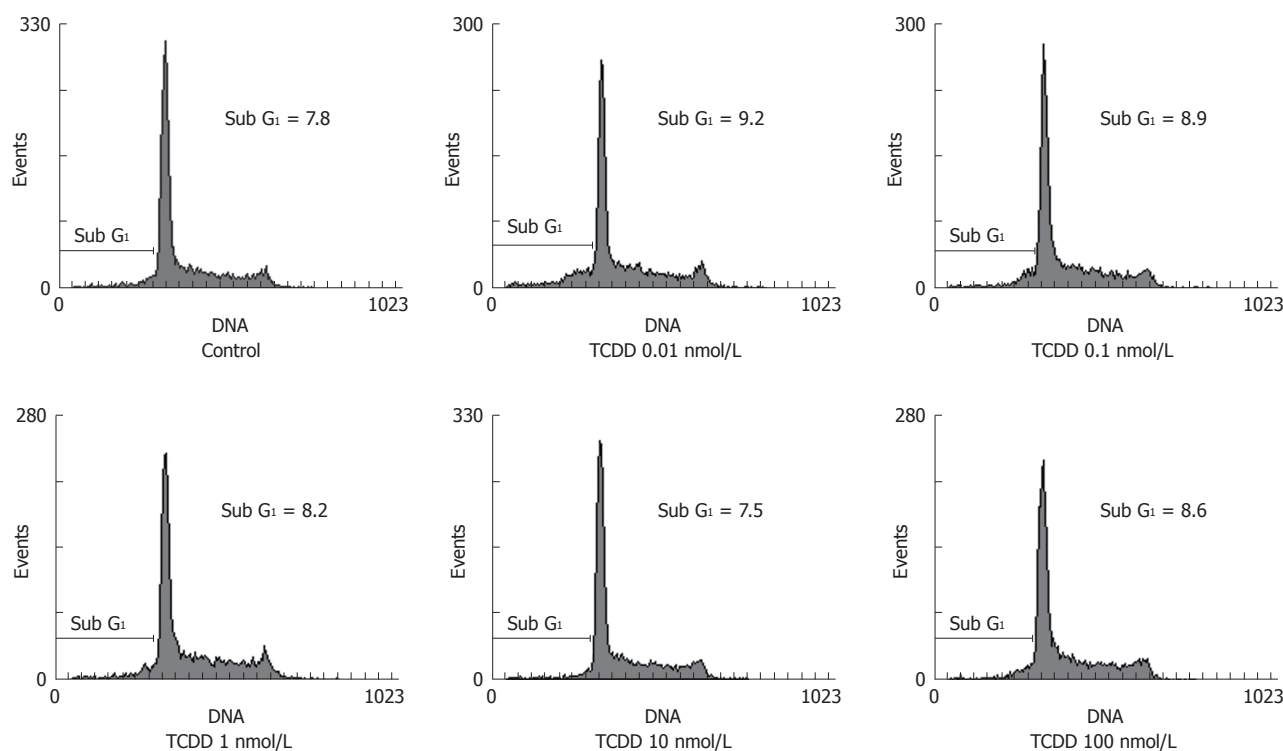

**Figure 7** The effect of TCDD on AGS cell cycle distribution. AGS cells were treated with different concentrations of TCDD and subjected to flow cytometric analysis. The percentage of each phase is indicated in each panel. The results shown are representative of three independent experiments.

elements play important roles in maintaining the microenvironment and regulating growth of epithelial cells, expression of AhR in stroma cells may have a bearing on malignant transformation of gastric epithelial cells.

To further investigate the potential role of the AhR signal pathway in gastric carcinogenesis, we treated GC cell line AGS with the most potent AhR agonist, TCDD, and chose CYP1A1, a classic target gene of AhR, as the indicator of AhR signal pathway activation. Although both CYP1A1 and CYP1B1 are classic target genes of AhR, cell-specific expression of these two genes have been reported previously<sup>[30-32]</sup>. Over-expression of CYP1A1, but not CYP1B1 in GC has been reported by Ma *et al*<sup>[23]</sup> and Zhang *et al*<sup>[33]</sup>. Baseline levels of CYP1A1 expression were also observed in AGS cells in the present study. However, expression of CYP1A1 was significantly increased in a dose- and time-dependent manner after TCDD treatment, indicating the activation of AhR. Interestingly, while CYP1A1 protein expression increased, AhR protein in the total cell lysates gradually decreased (Figure 4C and D). Similar phenomena have

been reported by several other groups<sup>[34-36]</sup>. Recent studies have demonstrated that the down-regulation of AhR following ligand binding is ubiquitin mediated and occurs *via* the 26S proteasome pathway following nuclear export of AhR. The degradation of AhR is the endpoint and would be one of the key factors controlling gene regulations by the AhR signal pathway<sup>[37]</sup>. To confirm the activation of the AhR signal pathway by TCDD, we treated AGS cells with a specific AhR antagonist, resveratrol. Previous studies suggested that resveratrol can regulate the transcription of AhR targeted genes by preventing AhR from binding to the enhancer sequences of the gene promoter<sup>[28,29]</sup>. Our results showed that TCDD-induced CYP1A1 expression was partially reversed by resveratrol in a dose-dependent manner. The incomplete reversal of CYP1A1 expression by resveratrol may be due to the fact that AhR is not the only regulator of CYP1A1 transcription<sup>[38,39]</sup>. Taken together, these results suggest that the AhR signal pathway could be activated in GC cells and that abnormal activation of the AhR signal pathway may be involved in gastric carcinogenesis.

**Figure 8** The effect of TCDD on apoptosis of AGS cells. AGS cells were treated with different concentrations of TCDD and subjected to flow cytometric analysis. Cellular apoptosis was evaluated by fragmented DNA (sub-G<sub>1</sub>) analysis using winMDI2.9. The results shown are representative of three independent experiments.

Since AhR is significantly up-regulated in GC and may be involved in the early stage of gastric carcinogenesis, regulation of the AhR pathway may have a potential role in the treatment of GC. Interestingly, our MTT assay demonstrated that the viability of AGS cells was significantly decreased in a dose- and time-dependent manner after TCDD treatment. Further flow cytometric analysis indicated that TCDD inhibited growth of AGS cells *via* induction of growth arrest at the G<sub>1</sub>-S phase. As far as we know, this is the first report suggesting an inhibitory role of AhR agonists on human GC cell growth. Similar results have been reported in the treatment of pancreatic cancer and mammary tumors by AhR agonists<sup>[16,18,40]</sup>. However, previous studies by Andersson *et al.*<sup>[19,20]</sup> showed that constitutively active AhR may result in significant proliferation in the parietal/chief cell region of glandular gastric mucosa in transgenic mice. These contradictory outcomes indicate that AhR appears to contribute to processes in both cell cycle arrest as well as cell proliferation. Recent studies on the cellular signal pathway may partly explain this complex phenomenon. As an evolutionarily conserved transcription factor, outside its well-characterized role in the induction of xenobiotic metabolizing enzymes, AhR also functions as a modulator of cellular signaling pathways. By interacting with different signal pathway effectors, AhR activation may result in completely different effects on cell growth<sup>[12,13]</sup>. Our present findings on the inhibitory effect of TCDD on GC cell growth suggest that AhR may be a potential therapeutic target for gastric cancer.

## ACKNOWLEDGMENTS

This study was accepted and presented orally at the 15th United European Gastroenterology Week (UEGW 2007) in Paris, in October 2007. The authors thank Dr. Robert Wong for his improvements to the English in the manuscript.

## COMMENTS

### Background

The carcinogenesis of gastric cancer (GC) involves numerous genetic and epigenetic alterations, as well as many environmental risk factors. Environmental pollutants such as polycyclic aromatic hydrocarbons (PAHs) and halogenated hydrocarbons (HAHs) are well-known carcinogens that play important roles in GC development. The toxic effects of PAHs and HAHs are mediated by a conserved signaling pathway that binds and activates the aryl hydrocarbon receptor (AhR).

### Research frontiers

AhR is a ligand-activated transcription factor and can mediate the carcinogenic and other toxic effects of a variety of environmental pollutants. Many studies in recent years have demonstrated a close relationship between AhR and tumorigenesis. However, the role of AhR in gastric tumorigenesis is still unclear. In this study, the authors demonstrate a close correlation of AhR with GC formation and the potential role of AhR as a therapeutic target for GC treatment.

### Innovations and breakthroughs

AhR functions as a modulator of cellular signaling pathways. By interacting with different signal pathway effectors, AhR activation may result in completely different effects on cell growth. This is the first report suggesting an inhibitory role of AhR agonists on human GC cell growth. Furthermore, the present findings suggest that AhR may be a potential therapeutic target for GC.

### Applications

By understanding how cell growth of human GC is influenced by AhR activation, this study may represent a future strategy for therapeutic intervention in the treatment of patients with GC.

### Terminology

AhR is a ligand-activated transcription factor of the basic helix-loop-helix/Per-

Arnt-Sim family. As an evolutionarily conserved transcription factor, outside its well-characterized role in the induction of xenobiotic metabolizing enzymes, AhR also functions as a modulator of cellular signaling pathways.

### Peer review

The authors investigated the functional significance of AhR in gastric carcinogenesis. This paper is interesting and written well.

### Abstract

**AIM:** To investigate the effect of Bu-Zhong-Yi-Qi-Tang (Decoction for Reinforcing Middle Jiao and Replenishing Qi) on deficiency of N-glycan/nitric oxide (NO) and islet damage induced by injecting two medium doses of streptozotocin (STZ).

**METHODS:** Diabetes was induced by intraperitoneal injection of STZ at 55 mg/kg on day 1 and day 8. Islet damage was evaluated using a scoring system. Nitrite, nitrate,  $\alpha$ -mannosidase and amylase activities were measured by colorimetry. N-glycan patterns of amylase were determined with lectin [ConA, pisum sativum agglutinin (PSA), peanut agglutinin (PNA), and lens culinaris agglutinin (LCA)] affinity precipitation method.

**RESULTS:** Severe islet necrosis and mild islet atrophy were observed in diabetic rats. The number and size of islets, the activities of  $\alpha$ -mannosidase, amylase and nitrite were decreased, while the binding of PNA and LCA to amylase was increased. All of which were improved after treatment with Bu-Zhong-Yi-Qi-Tang. Islet damage was significantly correlated with nitrite, nitrate,  $\alpha$ -mannosidase, amylase and the binding of LCA, PNA, and PSA to amylase.

**CONCLUSION:** STZ-induced islet damage is related to N-glycan deficiency in proteins by blocking  $\alpha$ -mannosidase activity and no deficiency, accumulation of unfolded proteins, and endoplasmic reticulum stress and activation of cellular signals, all of which are improved after treatment with Bu-Zhong-Yi-Qi-Tang.

Liu XQ, Wu L, Guo XJ. Effect of Bu-Zhong-Yi-Qi-Tang on deficiency of N-glycan/nitric oxide and islet damage induced by streptozotocin in diabetic rats. *World J Gastroenterol* 2009; 15(14): 1730-1737 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1730.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1730>

### INTRODUCTION

N-glycan plays an important role in the quality control (QC) of glycoprotein folding both in endoplasmic reticulum (ER) lumen and in ER-associated degradation (ERAD) of proteins by cytosolic proteasomes<sup>[1]</sup>. Alpha-mannosidase, a key enzyme converting precursor high-mannose-type N-glycans to matured complex-type structures, contributes to the establishment of an equitable glycoprotein quality control standard, by which the efficiency of Asn-linked glycoprotein conformational maturation results in dislocation of misfolded glycoproteins into the cytosol, where proteins are degraded in proteasomes and maintain the homeostasis of ER<sup>[2]</sup>.

The unfolded protein response (UPR) is a conserved cellular response designed to alleviate damage and promote survival of cells experiencing stress by either shutting down translation to reduce the protein flow into ER, or by up-regulating molecules that protect cells or clear misfolded proteins from the ER, thus alleviating ER stress. Nitric oxide (NO) is a known activator of the

UPR<sup>[3-5]</sup>, and NO-induced UPR activation may function to assist in the recovery of  $\beta$ -cells from NO-mediated damage, which is associated with enhanced expression of heat shock proteins and chaperones that assist in protein folding.

Islet  $\beta$  cells have a well-developed ER and secrete a large amount of insulin and glycoproteins. Islet  $\beta$  cells may be at risk of developing ER stress and increase misfolded glycoproteins. Inability to clear misfolded proteins causes early accumulation of unfolded proteins, and ER stress and activation of cellular signals lead to cell death, thus resulting in loss of  $\beta$  cell secretion potential and diabetes.

Xiong *et al.*<sup>[6]</sup> showed that the pathogenesis of diabetes is closely correlated to Pixu (insufficiency of the spleen), a major pathogenic factor for diabetes syndrome. Pixu is therefore considered in the treatment of diabetes. Diabetes mellitus is caused by Pixu, when diabetes progresses, deficiency of Yin and dryness-heat exist simultaneously, and when diabetes prolongs, deficiency of Yin becomes the key pathogenesis, finally resulting in impaired Yin and Yang<sup>[7]</sup>.

The levels of nitrite and nitrate are significantly decreased in stimulated crude whole saliva of diabetic patients with Pixu<sup>[8]</sup>. Bu-Zhong-Yi-Qi-Tang, a traditional Chinese medicine, tonifies qi, strengthens the stomach and spleen, and increases sunken Yang qi. It is prescribed mainly for Pixu by improving the deficiency of spleen and stomach qi. It was reported that the lower levels of nitrite, nitrate, and peroxynitrite in gastric mucosa of rats with Pixu can return to normal after treatment with Bu-Zhong-Yi-Qi-Tang<sup>[9]</sup>.

This study was to examine the effect of Bu-Zhong-Yi-Qi-Tang on deficiency of N-glycan/NO and islets damage in rats with diabetes mellitus induced by streptozotocin (STZ).

## MATERIALS AND METHODS

### Ethics

This study was approved by Guangdong Science and Technology Committee and Guangdong Management Committee for Medical Experimental Animals.

### General procedure

Sprague-Dawley rats were obtained from the Laboratory Animal Research Center of Guangzhou University of Traditional Chinese Medicine. The animals were housed in a plastic cage in an air-conditioned room at  $20 \pm 2^\circ\text{C}$  with a humidity of  $58\% \pm 5\%$  in a 12-h light and dark cycle, with free access to standard rat food and tap water. The rats were divided into normal control, and diabetic model groups after 1 wk.

### Diabetic model

A diabetic model of rats was established by intraperitoneal injection of STZ at 55 mg/kg on day 1 and day 8. The rats were bred for 4 wk. Blood was sampled from the tail vein and blood glucose was determined with the one touch ultra blood glucose monitoring system (LifeScan,

Inc. Milpitas, CA, USA). Animals with their non-fasting blood glucose less than 16.65 mmol/L were excluded from the study. The rats were divided into diabetics groups and Bu-Zhong-Yi-Qi-Tang treatment group.

### Preparation and administration of Bu-Zhong-Yi-Qi-Tang

Bu-Zhong-Yi-Qi-Tang was made of *Radix Astragali*, *Codonopsis pilosula*, *Glycyrrhiza uralensis* f. *isch*, *Rhizoma Atractylodis Macrocephalae*, *Radix Angelicae Sinensis*, *Rhizoma Cimicifugae Foetidae*, *Radix Bupleuri Chinensis*, and *Pericarpium Citri Reticulatae*, which were put into a 20-fold volume of distilled water, decocted from  $80^\circ\text{C}$  to  $100^\circ\text{C}$ , filtered and concentrated at  $40^\circ\text{C}$ - $80^\circ\text{C}$ , and stored in a refrigerator until use. Bu-Zhong-Yi-Qi-Tang was administered by gavage, 8 g/kg per day for 4 wk.

### Samples

At the end of treatment, the animals were killed by exsanguination from the carotid artery. Blood samples were taken immediately and centrifuged at 3000 r/min for 5 min. Serum was separated for the measurement of nitrite, nitrate,  $\alpha$ -mannosidase and amylase activities, and determination of the N-glycan patterns of amylase. The pancreas was removed from each rat and dissected longitudinally. One half was dried and homogenized. Supernatant was removed for the measurement of nitrite, nitrate,  $\alpha$ -mannosidase and amylase activities, and determination of the N-glycan patterns of amylase. The other half was fixed in Bouin's solution for 24 h. The pancreatic tissue, embedded in paraffin wax, was cut into 3-4- $\mu\text{m}$ -thick sections which were stained with hematoxylin and eosin (HE) for histopathological examination.

### Histopathological examination of pancreatic islet damage

Bouin's-solution-fixed pancreatic tissue was cut into eight sections (approximately 1 mm  $\times$  1 mm  $\times$  1 mm). Four sections were randomly selected, stained with HE, and observed under a microscope with a digital camera (C170 D425, Olympus Imaging Corp). Digital micrographs were analyzed for estimating the number, size, necrosis and atrophy of islets and insulinitis by two observers unaware of the status and/or treatment modalities.

The number of islets was calculated as previously described<sup>[10]</sup> with some minor modifications and graded as 0, no visible islets; 1, < 5 islets; 2, 6-10 islets; 3, 11-20 islets; 4, > 20 islets.

The size of islets was measured as previously described<sup>[11]</sup> with some minor modifications and graded as 1, 1-40 cells per section; 2, 41-100 cells per section; 3, 101-200 cells per section; 4, 201-400 cells per section; 5, > 400 cells per section.

Insulinitis was evaluated by examining at least 10 islets from each treatment group and graded as 0, no mononuclear cell infiltration; 1, very mild mononuclear cell infiltration in and around the islets; 2, mild cell infiltration in and around the islets; 3, moderate cell infiltration in and around the islets; 4, marked cell infiltration observed as the structure of islets was

destroyed. Pancreas was graded for insulinitis according to the most severely involved islets in each pancreas.

Necrosis of islets was graded as 0, no islet necrosis; 1, very mild islet necrosis; 2, mild islet necrosis; 3, moderate islet necrosis; 4, marked islets necrosis.

Atrophy of islets was graded as 0, no islet atrophy; 1, very mild islet atrophy; 2, mild islet atrophy; 3, moderate islet atrophy; 4, marked islet atrophy.

#### **Determination of nitrite and nitrate in serum and pancreas tissue**

Pancreatic tissue was homogenized, supernatant and serum were initially deproteinized with Somogyi reagent<sup>[12]</sup> (using 2.0 mL 55 mmol/L NaOH followed by 2.0 mL 75 mmol/L ZnSO<sub>4</sub>). After centrifugation, aliquots of supernatant were mixed with an equal volume of Griess reagent<sup>[13]</sup>. The absorbance was measured at 546 nm. Nitrite level was measured using 120  $\mu$ mol/L sodium nitrite solution diluted to 10  $\mu$ mol/L intermediate dissolution. Results were expressed as  $\mu$ mol/L per gram wet tissue, and serum nitrite was expressed as  $\mu$ mol/L.

Pancreatic tissue was homogenized, supernatant and serum were initially deproteinized with Somogyi reagent<sup>[12]</sup> (using 2.0 mL 55 mmol/L NaOH followed by 2.0 mL 75 mmol/L ZnSO<sub>4</sub>). After centrifugation, excess nitrite was eliminated with 10 mg/mL ammonium sulfamate and acidified with 1 mol/L hydrochloric acid which prevented interference with hydroxide or carbonate. Aliquots of supernatant nitrate were determined by dual-wavelength ultraviolet spectrophotometry<sup>[14,15]</sup>. Nitrate absorbance was calculated by subtracting the absorbance at 275 nm for background correction from the absorbance at 220 nm. Nitrate level was measured using 120  $\mu$ mol/L standard sodium nitrate solution diluted to 10  $\mu$ mol/L intermediate dissolution. Results were expressed as  $\mu$ mol/L per gram wet tissue, and serum nitrate was expressed as  $\mu$ mol/L.

#### **Determination of $\alpha$ -mannosidase activity in serum and pancreas tissue**

The animals were killed by exsanguination from the carotid artery. Blood samples were taken immediately. The serum was stored at -18°C. Pancreas was removed, fragmented and stored at -20°C until required. Extracts from pancreatic tissue were prepared by homogenization in 0.05 mol/L sodium phosphate (pH 6.5) containing 5 mmol/L MgCl<sub>2</sub> and 0.1% Triton X-100 (a DY89-1 tissue homogenizer) at 4°C. Tissue homogenate was centrifuged at 16000 r/min for 30 min. Clear supernatant and serum were used to determine the enzyme activity. The level of  $\alpha$ -mannosidase was measured by spectrophotometry as previously described<sup>[16]</sup> with some minor modifications. Fifty microliters of supernatant (or serum) was added to 50  $\mu$ L 4 mmol/L p-nitrophenyl- $\alpha$ -D-mannopyranoside substrate (Fluka, Bucks, Switzerland) in 0.1 mol/L sodium acetate-acetic acid buffer (pH 5.8). Reaction mixtures were incubated at 37°C for 60 min. The reaction was terminated by adding

3 mL glycine-sodium hydroxide (0.1 mol/L, pH 10.14). The amount of liberated p-nitrophenol was determined by spectrophotometry at 405 nm. One international unit of enzyme was defined as the amount required for catalyzing the release of 1  $\mu$ mol p-nitrophenol from p-nitrophenyl- $\alpha$ -D-mannopyranoside substrate per hour at 37°C under the conditions described above. Tissue enzyme activities were expressed as U/g wet tissue, and serum enzyme activities were expressed as U/mL serum.

#### **Determination of amylase activity and binding of lectin to amylase in serum and pancreas tissue**

Extracts from pancreatic tissue were prepared by homogenization in 9 g/L NaCl (a DY89-1 tissue homogenizer) at 4°C. Tissue homogenate was centrifuged at 16000 r/min for 30 min. Clear supernatant and serum were used to determine the amylase activity and binding of lectin to amylase. Amylase N-glycan patterns were analyzed with lectin [ConA, pisum sativum agglutinin (PSA), peanut agglutinin (PNA), lens culinaris agglutinin (LCA)] affinity precipitation method. The precipitation procedure was performed as previously described<sup>[17,18]</sup>. The clear supernatant and serum were mixed with 400  $\mu$ L of an aqueous solution of ConA, PSA, PNA, LCA (5 g/L in distilled water). The mixture was incubated for 30 min at 37°C and centrifuged at 2000 r/min for 15 min. Without disturbing the precipitate, we removed the supernatant and measured its amylase activity. Binding of lectin to amylase was calculated by subtracting the corrected value from the total amylase activity. ConA, PSA, PNA, LCA were purchased from Sigma (St. Louis, MO, USA).

#### **Statistical analysis**

All data were presented as mean  $\pm$  SD. Statistical significance was calculated using unpaired Student's *t* test. The correlation coefficient between islet histomorphometry and nitrite, nitrate, binding of lectin to amylase, activity of  $\alpha$ -mannosidase and amylase was calculated. *P* < 0.05 was considered statistically significant. All analyses were performed using Excel 2003.

## **RESULTS**

#### **Body weight and blood glucose level**

The body weight of normal rats increased over the 12 wk experimental period. However, diabetic rats lost 22.1% of their body weight within 12 wk, the non-fasting blood glucose level increased from 16.62 mmol/L to 31.63 mmol/L 4 wk after injection of STZ, and remained significantly elevated for 8 wk thereafter.

#### **Histopathological changes in pancreatic islets**

Relatively well documented pancreatic islets and tightly arranged islet cells were observed in the normal control group. Severe islet necrosis and mild islet atrophy were detected in the diabetic group, and improved after treatment with Bu-Zhong-Yi-Qi-Tang compared to the diabetic group (Figure 1). Histomorphometrical analysis

**Figure 1** Histological profiles for pancreatic islets in normal rats (A), diabetic rats (B), Bu-Zhong-Yi-Qi-Tang-treated rats (C). Relatively well documented pancreatic islets and tightly arranged islet cells were observed in normal rats. Severe necrosis and mild atrophy of islets were found in diabetic rats, which were improved after treatment with Bu-Zhong-Yi-Qi-Tang. Stained sections showing islet morphology in sections stained with HE. The left region: Low-power magnification view; Middle region: Middle-power magnification view; Right region: High-power magnification view.

### Activity of $\alpha$ -mannosidase and amylase in serum and pancreas tissue

The activity of  $\alpha$ -mannosidase and amylase in pancreas tissue in the diabetic group was significantly lower than that in the normal control group. However, the serum  $\alpha$ -mannosidase activity was not significantly different between the two groups. The activity of  $\alpha$ -mannosidase and amylase in pancreas tissue was significantly increased in the Bu-Zhong-Yi-Qi-Tang treatment group compared to the diabetic group (Table 3).

### Binding of lectin to amylase in serum and pancreas tissue

Binding of LCA, and PNA to serum amylase and binding of LCA to pancreas amylase in the diabetic group were significantly higher than those in the normal control group, while the binding of ConA and PSA to amylase was not significantly different between the two groups. After treatment with Bu-Zhong-Yi-Qi-Tang, the binding of ConA, PNA and LCA to amylase was significantly lower than that in the diabetic group (Tables 4 and 5).

### Correlation between the number, size, necrosis and atrophy of islets and the activity of $\alpha$ -mannosidase, amylase, nitrite, nitrate, and binding of lectin to amylase

The number, size, necrosis and atrophy of islets were significantly correlated with the activity of nitrite, nitrate,  $\alpha$ -mannosidase, amylase and binding of LCA, PNA, and PSA to amylase (Table 6).

## DISCUSSION

In the present study, severe necrosis and mild atrophy of islets were observed in diabetic rats. The number and size of islets. The activity of  $\alpha$ -mannosidase and amylase were decreased, and the binding of PNA and LCA to amylase were increased. All of which were improved after treatment with Bu-Zhong-Yi-Qi-Tang.

Islet damage was found to be related to the levels of nitrite, nitrate,  $\alpha$ -mannosidase and amylase, and the binding of LCA, PNA and PSA to amylase.

Trimannosyl oligosaccharide is a unique moiety recognized by concanavalin A lectin (ConA) for high affinity and extended site binding. ConA primarily binds to the outer trimannosyl region of high mannose and bisected hybrid-type glycopeptides rather than to the central trimannosyl region of complex glycopeptides<sup>[19]</sup>. Fucosyl residues in the outer chain moieties have a shielding effect on the neighboring  $\alpha$ -mannosyl residues and can eliminate this type of interaction<sup>[20]</sup>. PNA is a lectin with a high binding affinity for galactose-galactosamine disaccharide<sup>[21]</sup>. NeuAc caps the galactose-terminated chains<sup>[22]</sup>. Like ConA, LCA is able to bind (or not bind) to the same glycopeptides. LCA additionally requires the fucosyl- N-glycan-asparaginyl core for high-affinity binding. The presence of a core fucose residue greatly enhances recognition of N-linked sugar chains by LCA. Exposure of terminal N-acetylglucosamine (GlcNAc) residues to glycopeptides can enhance the binding of glycopeptide to LCA<sup>[23]</sup>. Like ConA, PSA is able to bind (or not bind) to the same glycopeptides. PSA

The activity of amylase in pancreas tissue	43	0.428 <sup>b</sup>	0.639 <sup>b</sup>	-0.314 <sup>a</sup>	-0.631 <sup>b</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01, test of significance of correlation coefficient.

additionally requires the fucosyl-N-glycan-asparaginyl core for high affinity binding. The presence of a core fucose residue greatly enhances recognition of N-linked sugar chains by PSA. Exposure of terminal mannose residues to glycopeptides can enhance the binding of glycopeptide to PSA<sup>[23]</sup>.

These findings indicate that N-glycan processing is deficient in diabetic rats. Amylase core-fucosylate, high-mannose-type, hybrid-type sugar chains are increased while terminal sialic acid and fucose on the sugar chain are decreased, thus resulting in exposure of terminal galactose and GlcNAc residues to PNA and LCA.

N-glycan plays an important role in the quality control of glycoprotein folding in lumen and ERAD of proteins by cytosolic proteasomes<sup>[1]</sup>. Alpha-mannosidase, a key enzyme converting precursor high-mannose-type N-glycan to matured complex-type structure, contributes to the establishment of an equitable glycoprotein quality control standard, by which the efficiency of Asn-linked glycoprotein conformational maturation results in dislocation of misfolded glycoproteins into the cytosol where proteins are degraded in the proteasome and maintain the homeostasis of ER<sup>[2]</sup>.

Lin *et al*<sup>[24]</sup> cultured neurons derived from embryonic chicken brains with tunicamycin (TM), an inhibitor of N-linked glycosylation, and found that the light neurons resembled necrotic cells, but the dense neurons exhibited distinct morphological features of necrosis and apoptosis, indicating that TM has an irreversible toxicity to the neurons and a different mechanism underlying neuron death.

Finnie *et al*<sup>[25]</sup> showed that cultured rat hepatocytes exposed to TM have degenerative changes characterized by marked cytoplasmic lipid accumulation and dilatation of cisternae of rough ER or necrosis.

Shi *et al*<sup>[26,27]</sup> reported that inhibition of 6A8 alpha-mannosidase causes oncosis-like death of BJAB cells with no apoptotic bodies, annexin-V staining DNA fragmentation assay cannot show any evidence of apoptosis in these cells. However, binding of ConA

to the cells transduced with the antisense 6A8 DNA is increased, but ConA-binding to the cells transduced with the sense 6A8 DNA is decreased.

The UPR is a conserved cellular response designed to alleviate damage and promote survival of cells experiencing stress by either shutting down translation to reduce the protein flow into the ER or by up-regulating molecules that protect cells or clear misfolded proteins from the ER and alleviate stress. NO, a known activator of UPR<sup>[3-5]</sup>, may function to assist in the recovery of  $\beta$ -cells from NO-mediated damage, which is associated with enhanced expression of heat shock proteins and chaperones that assist in protein folding.

Islet  $\beta$  cells have a well-developed ER, reflecting their role in secreting a large amount of insulin and glycoproteins. Islet  $\beta$  cells may be at risk for ER stress. Inability to clear misfolded proteins causes accumulation of unfolded proteins, ER stress and activation of cellular signals, leading to cell death, loss of  $\beta$  cell secretion potential, and diabetes.

These findings indicate that STZ induces islet damage, which might be related to the N-glycan processing deficiency of proteins. Blocking of  $\alpha$ -mannosidase activity and NO deficiency can easily cause accumulation of unfolded proteins, ER stress and activation of cellular signals leading to cell death.

Diabetes (Xiaoke) was firstly recorded in the Yellow Emperor's Canon of Medicine (722-221 B.C.), a classic medical book, in which Xiaozhong (polyorexia) and Xiaodan (diabetes) are used to describe diabetes. It points out that the etiologic factors excess fat and sugar, and imbalance of emotion. The General Treatise on the Etiology and Symptomology (618-907 AD) say that diabetes patients often suffer from carbuncle and deep-root carbuncle. The Medical Secrets of an Official (670-755 AD) describes that urine of patients with diabetes is sweet, indicating that glucose can be found in the urine of diabetes patients early.

It has been shown that the pathogenesis of diabetes is closely related to Pixu<sup>[6]</sup>, a major pathogenic factor

for diabetes syndromes. Improving Pixu is therefore appropriate in the treatment of diabetes. In this study, the nitrite and nitrate levels were significantly decreased in diabetic rats, which is consistent with the reported findings in patients with Pixu<sup>[8]</sup>.

Bu-Zhong-Yi-Qi-Tang, a traditional Chinese medicine, tonifies qi, strengthens the stomach and spleen, and increases sunken Yang qi, and is prescribed mainly for the deficiency of spleen and stomach qi in the treatment of Pixu. It was reported that the levels of nitrite, nitrate, and peroxynitrite in gastric mucosa are lower in Pixu rats, and return to normal after treatment with Bu-Zhong-Yi-Qi-Tang<sup>[9]</sup>.

In conclusion, Bu-Zhong-Yi-Qi-Tang can improve these abnormal conditions of diabetic rats by increasing the levels of nitric oxide and mannosidase activation, promoting N-glycosylation of proteins, assisting in the quality control of glycoprotein folding in ER lumen, and preventing accumulation of unfolded proteins, ER stress, activation of cellular signals.

## COMMENTS

### Background

N-glycans,  $\alpha$ -mannosidase and nitric oxide (NO) play an important role in the quality control of glycoprotein folding in endoplasmic reticulum (ER) lumen, promote ER homeostasis and prevent ER-stress-related cell damage. There is evidence that ER stress plays a role in the pathogenesis of diabetes, contributing to loss of pancreatic beta-cells and insulin resistance. However, little attention has been paid to islet damage associated with the deficiency of N-glycan/nitric oxide in diabetes mellitus patients. It has been shown that the pathogenesis of diabetes is closely related to Pixu, a major pathogenic factor for diabetes syndromes. Improving Pixu is therefore appropriate in the treatment of diabetes. Bu-Zhong-Yi-Qi-Tang, a traditional Chinese decoction, is prescribed mainly for Pixu. However, little attention has been paid to its activity in islet damage and related mode of action in patients with diabetes.

### Research frontiers

N-glycans,  $\alpha$ -mannosidase and NO play an important role in the quality control of glycoprotein folding in ER lumen, promote ER homeostasis and prevent ER-stress-related cell damage. There is evidence that ER stress plays a role in the pathogenesis of diabetes, contributing to loss of pancreatic beta-cells and insulin resistance. The results of this study indicate that streptozotocin induces islet damage, which might be related to the N-glycan processing deficiency of proteins. Blocking of  $\alpha$ -mannosidase activity and nitric NO easily causes accumulation of unfolded proteins, ER stress and activation of cellular signals leading to cell death. Bu-Zhong-Yi-Qi-Tang could improve these abnormal conditions of diabetic rats by increasing the levels of NO and mannosidase activity, promoting N-glycosylation of proteins, assisting in quality control of glycoprotein folding in ER lumen, and preventing accumulation of unfolded proteins, ER stress, activation of cellular signals leading to cell death.

### Terminology

Bu-Zhong-Yi-Qi-Tang: a traditional Chinese medicine, consisting of *Radix Astragali*, *Codonopsis pilosula*, *Glycyrrhiza uralensis* f. *isch*, *Rhizoma Atractylodis Macrocephalae*, *Radix Angelicae Sinensis*, *Rhizoma Cimicifugae Foetidae*, *Radix Bupleuri Chinensis*, *Pericarpium Citri Reticulatae*, is prescribed mainly for deficiency of spleen and stomach qi in treatment of Pixu. Streptozotocin (STZ): 2-deoxy-2-(3-methyl-3-nitrosourea)-1-D-glucopyranose, is actively transported into pancreatic  $\beta$  cells via the Glut-2 glucose transporter. Alpha-mannosidase: a key enzyme converting precursor high-mannose-type N-glycans to matured complex-type structure, contributes to the establishment of an equitable glycoprotein quality control standard, by which the efficiency of Asn-linked glycoprotein conformational maturation results in dislocation of misfolded glycoproteins into the cytosol, where proteins are degraded in proteasome and maintain the homeostasis of ER.

### Peer review

This is a good descriptive study. Experiments were well designed and the data

contained novelty. The authors investigate the deficiency of N-glycan/nitric oxide in diabetic rats, and evaluated the effects of Bu-Zhong-Yi-Qi-Tang on diabetics, showing that STZ can induce islet damage, which might be related to the N-glycan processing deficiency of proteins. Blocking of  $\alpha$ -mannosidase activity and nitric oxide deficiency could easily cause accumulation of unfolded proteins, ER stress and activation of cellular signals leading to cell death. Bu-Zhong-Yi-Qi-Tang was found to be effective against these abnormal conditions.

### Abstract

**AIM:** To investigate the expression of  $\alpha$ -fetoprotein (AFP), a cancer-associated fetal glycoprotein, and its involvement during rat colon development.

**METHODS:** Colons from Sprague-Dawley rat fetuses, young and adult (8 wk old) animals were used in this study. Expression levels of AFP in colons of different development stage were detected by reverse-transcriptase PCR (RT-PCR) and Western blotting. To identify the cell location of AFP in the developing rat colons, double-immunofluorescent staining was performed using antibodies to specific cell markers and AFP, respectively.

**RESULTS:** The highest levels of AFP mRNA were detected in colons of rats at embryonic day 18.5 (e18.5). Compared to e18.5 d, the AFP expression was significantly decreased during rat development [85% for e20.5,  $P < 0.05$ , 58% for postnatal day 0.5 (P0.5),  $P < 0.05$ , 37% for P7,  $P < 0.05$ , 24% for P14,  $P < 0.05$ , and 11% for P21,  $P < 0.05$ ] and undetected in adult rats. Only the 72-kDa isoform of AFP was detected by Western blotting, the expression pattern was similar to AFP mRNA and conformed to the results of mRNA expression. The AFP positive staining was identical to different distribution patterns in fetuses, young and adult animals and positive staining for both AFP and vimentin was overlapped in mesenchymal cells at each stage tested.

**CONCLUSION:** This study has for the first time

### INTRODUCTION

The mammalian gut epithelium is a highly organized and dynamic system that requires continuous, controlled proliferation and differentiation throughout life. Identification of the growth factors controlling these processes is crucial since the molecular mechanisms regulating organogenesis are often the same as those necessary for repair following injury. Furthermore, mis-regulations of embryonic signaling pathways are often associated with neoplastic diseases.

We assumed that accurate transcriptional profiles over gut development interval could provide fundamental information about underlying mechanisms, and characterized candidate regulators of cell interactions and mucosal differentiation. This resource also can be applied to address long-standing questions about reactivation of fetal genes in cancer.

A number of transcription factors, growth factors, and their receptors have been found to be expressed in the gastrointestinal epithelium or mesenchyme. However, little is known about their specific functions in gastrointestinal development. For those factors where a mutation has been generated by gene targeting,

gastrointestinal development either proceeds normally<sup>[1-3]</sup> or the embryos die too early to allow assessment of the gene functions in gut development<sup>[4,5]</sup>.

Mammalian  $\alpha$ -fetoprotein (AFP) is a single-chain glycoprotein with molecular mass ranging from 66 to 72 kDa and 3%-5% carbohydrate (glycan) content. This protein, which expresses at high levels in the fetal liver and yolk sac, constitutes 0.1% of the total mRNA in the fetal gut<sup>[6]</sup>. At birth, AFP mRNA declines precipitously in both liver and gut to levels that are barely detectable<sup>[7]</sup>. The gut development during late gestation and early neonatal period is accompanied by changes in the synthesis of AFP<sup>[8]</sup>, and abundance declines significantly during gut development. In this case, AFP is considered as an important growth factor with a specific function in gastrointestinal development.

The ontogeny of AFP gene expression has been examined in the fetal and adult mouse gastrointestinal tract<sup>[9]</sup> to understand the basis of the ontogeny of AFP transcription in the gut and its regulatory elements. However, little is known about the expression pattern of AFP genes or its involvement during rat colon development.

## MATERIALS AND METHODS

### *Specimens*

Colons from Sprague-Dawley rat fetuses embryonic day 18.5 (e18.5 and e20.5 gestation), young (0 d and 1, 2 and 3 wk old) and adult (8 wk old) animals were used in this study. Five rats were used at each age stage. The embryonic age was determined according to Kaufman<sup>[10]</sup>. Mating was performed by housing a male and a female rat together in the same cage overnight. The presence of a vaginal plug was determined the next morning (0.5 d gestation). Rats were housed in plastic cages in an air-conditioned and light controlled room at  $24 \pm 2^\circ\text{C}$  and  $60\% \pm 5\%$  humidity. The study protocol was approved by the Nanjing Medical University Animal Care and Use Committee.

### *Reverse-transcriptase PCR (RT-PCR)*

Total RNA was extracted from tissues at each time point with TRIZOL reagent (Invitrogen Life Technologies, Burlington, Ontario, Canada), according to the manufacturer's instructions. The quality of the RNA was verified by agarose gel electrophoresis using ethidium bromide staining. For each PCR, 2  $\mu\text{g}$  DNA-free total RNA with oligo (deoxythymidine) primers and reverse transcriptase were used. PCR was performed in 50- $\mu\text{L}$  reactions containing 2.5 ng cDNA, 1  $\mu\text{L}$  each primer pair, and 25  $\mu\text{L}$  Premix Taq (TaKaRa, CA, USA). PCR was carried out in a T-gradient Biometra PCR thermal cycler (Montreal Biotech Inc., Kirkland, Quebec, Canada) to determine the annealing temperature for each pair of primers<sup>[11]</sup>. The AFP primer pairs used were: 5'-GCTGAACCCAGAGTACTGCAC-3' (forward), and 5'-GACACGTC GTAGATGAACGTG-3' (reverse). Amplification reactions were carried out for 30 cycles at  $94^\circ\text{C}$  for 30 s,  $58.4^\circ\text{C}$  for 30 s and at  $72^\circ\text{C}$  for 1 min.

The amplified products were 443 bp and analyzed on 1% agarose gels and visualized by ethidium bromide staining. Controls omitting RT cDNA or DNA polymerase showed no reaction bands. The data were normalized by 18S RNA.

### *Western blot analysis*

The tissues were homogenized in a lysis buffer containing 50 mmol/L Tris-HCl (pH 7.5), 150 mmol/L NaCl, 5 mmol/L EDTA, 10 mmol/L NaF, 1 mmol/L sodium orthovanadate, 1% Triton X-100, 0.5% sodium deoxycholate, 1 mmol/L phenylmethylsulfonyl fluoride and Complete Protease Inhibitor Cocktail (Roche, Mannheim, Germany). The lysate was then centrifuged at  $12000 \times g$  for 25 min at  $4^\circ\text{C}$ . The total protein concentration of each sample was analyzed by BCA Protein Assay Kit (Pierce, Rockford, IL, USA). An equal amount of protein samples, 60  $\mu\text{g}$ , from each specimen was boiled in  $3 \times$  loading buffer (10 mmol/L Tris-HCl, pH 6.8 including 3% SDS, 5%  $\beta$ -mercaptoethanol, 20% glycerol and 0.6% bromophenol blue) for 3 min and separated by 12.5% SDS-PAGE and transferred to nitrocellulose membranes (Bio-Rad, Hercules, CA, USA). After transfer, membranes were blocked with 5% fat-free milk in Tris-buffered saline plus 0.05% Tween 20 (TBS-T) overnight at  $4^\circ\text{C}$ . The membranes were then incubated with the primary antibody (sc-8108, an affinity purified goat polyclonal antibody raised against a peptide mapping at the C-terminus of AFP, diluted 1:500; Santa Cruz, Biotechnology CA, USA) for 2 h at room temperature. After washing in TBS-T three times, the membranes were incubated with the peroxidase-linked rabbit anti-goat IgG conjugates (Santa Cruz Biotechnology) for 1 h at room temperature. At the end, they were washed again in TBS-T, incubated in enhanced chemiluminescence reagents (Pierce) for 2 min, and exposed to X-Omat BT film (Eastman Kodak, Rochester, NY, USA). Signal intensity was quantified using a Bio-Rad image analysis system and the results were normalized to band intensities at e18.5. Loading controls of presumably and constantly expressed proteins such as  $\beta$ -actin were used; however, their variability and increase in development precluded their use<sup>[12]</sup>. For negative controls, the primary antibody was omitted.

### *Double fluorescence immunohistochemistry*

Tissues were fixed in 4% paraformaldehyde overnight at  $4^\circ\text{C}$  followed by a standard protocol of dehydration and paraffin embedding, and 5- $\mu\text{m}$  sections were cut. The paraffin sections were deparaffinized in xylene and rehydrated in graded ethanol and distilled water. The non-specific binding sites were blocked in 1% bovine serum albumin (BSA) for 30 min. For AFP and vimentin double immunofluorescence, the goat anti-AFP primary polyclonal antibody was applied and revealed using fluorescein isothiocyanate (FITC)-labeled rabbit anti-goat IgG (1:400, sc-2777; Santa Cruz Biotechnology). Mouse anti-vimentin primary monoclonal antibody (1:1000, CBL202; Chemicon International, Inc. Temecula, CA,

USA) was then applied and revealed by rhodamine-labeled anti-mouse IgG (1:400, AP192C; Chemicon International, Inc.). Sections were placed in gel aqueous mounting medium (G0918; Sigma, St. Louis, MO, USA) with a cover glass and were examined under an Olympus BX51 microscope (Olympus Optical, Tokyo, Japan). Controls were treated by omitting the primary or secondary antibody. No staining was observed under the negative control conditions. Images were taken at a magnification  $\times 200$ .

### Statistical analysis

All experiments were done in triplicate. Analysis of the experimental data was carried out using PDQuest 7.0 software (Bio-Rad Laboratories) and one-way analysis of variance and paired *t* test were used. Data are presented as mean  $\pm$  SD. *P* < 0.05 was considered statistically significant.

## RESULTS

### Temporal expression of AFP in the developing rat colons

We carried out RT-PCR and Western blotting to detect the expression of AFP using samples extracted from the colons of fetal e18.5 and e20.5, postnatal day 0 (P0), P7, P14 and P21 and adult rats. As shown in Figure 1, the highest levels of AFP mRNA were detected in colons of rats at e18.5. The AFP mRNA levels in colons declined steadily during rat development and were undetected in adult rats (*P* < 0.05) (Figure 1). The level of AFP mRNA in e20.5 colon was significantly decreased compared with that in e18.5 colon. AFP mRNA in P0 colon was lower than those in e20.5 colon (*P* < 0.05), and AFP mRNA in P7 colon was also lower than in P0 (*P* < 0.05). There was no difference in the levels of AFP mRNA between P14 and P21. The AFP protein had four isoforms: 72, 60, 48 and 37 kDa. In our study, only the 72-kDa isoform of AFP was detected in rat colon (Figure 2A). From the results of the densitometric quantification (Figure 2B), it was seen that the total AFP was the highest at e18.5, after which expression decreased steadily, being the lowest in the adult colons. This result was similar to those of AFP mRNA expression.

### Regional and temporal localization of AFP in the developing rat colons

In e18.5 fetus, the colonic mucosa was lined by a stratified epithelium and AFP positive staining was detected in the epithelium and mesenchymal tissue (Figure 3A). In e20.5 fetus, the epithelium has transformed into a simple columnar one. The AFP positive cells located at the bottom of crypt-like structure and the number of positive cells decreased markedly at this time (Figure 4A). After birth, positive cells were scattered on the epithelium during the first 7 d (Figure 4B). By P14 and P21, when the adult crypt structure replaced the villi, positive cells became largely restricted to the base of the crypts, no positive staining of AFP in the adult colonic epithelium was observed (Figure 3C and D).

**Figure 1** Expression of AFP mRNA using RT-PCR analysis in the developing rat colons as indicated in lanes e18.5, e20.5, P0, P7, P14, P21 and adult rats. The position of molecular weight markers is indicated on the left. A: The highest levels of AFP mRNA were detected in colons of rats at e18.5 and declined steadily during rat development and were undetected in adult rats; B: Results are indicated in percentages above the e18.5 value and are representative of three independent experiments. <sup>a</sup>*P* < 0.05 vs e18.5, e20.5 and P0, respectively.

**Figure 2** Expression of AFP protein using Western blot analysis in the developing rat colons as indicated in lanes e18.5, e20.5, P0, P7, P14, P21 and adult rats. A: Western blot analysis using AFP (C-19), an affinity purified goat polyclonal antibody against a peptide mapping at the C-terminus of AFP, revealed a 72-kDa isoform. The highest levels of AFP protein were detected in colons of rats at e18.5 and declined steadily during rat development and were undetected in adult rats. B: Results are indicated in percentage above the e18.5 value and are representative of three independent experiments. <sup>a</sup>*P* < 0.05 vs e18.5, e20.5 and P0, respectively.

### Cells localization of AFP in the developing rat colons

The pattern of AFP-expressing cells and mesenchymal cells were very similar, which suggested a relationship between them. To identify the cells, an antibody against vimentin, which has been used as a marker for the mesenchymal cells, was used. Double-immunofluorescent staining for the vimentin and AFP showed a complete

**Figure 3** Immunofluorescence localization of AFP in the developing rat colons. A: In e18.5, AFP positive staining can be detected in the epithelium and mesenchymal tissues; B: At P0, positive cells were located at the base of the crypts and scattered on the epithelium; C, D: Only a few positive cells restricted to the base of the crypts between 14 and 21 d, and no positive cells can be detected in adult rat colons. ( $\times 200$ ).

**Figure 4** Immunofluorescence localization of AFP and vimentin in the developing rat colons. Labeling by the AFP antibody was detected with an FITC (green)-labeled secondary antibody. Labeling of vimentin was detected with a rhodamine- (red)-labeled secondary antibody on the same section. The overlap of AFP (green) and vimentin (red) labeling appeared orange in color. Double-labeling revealed complete localization of AFP and vimentin in the same colon cells at both e20.5 and P7. A: e20.5; B: P7.

overlap between the AFP positive cells and the antibody staining for vimentin at each stage tested (Figure 4A and B).

## DISCUSSION

AFP is known to be associated with the successful completion of term pregnancies in mammals and even minute amounts of AFP may still be necessary during human pregnancy<sup>[13]</sup>. The capability of both up and down modulation of growth and differentiation as a dose-dependent function of AFP has been demonstrated in a multitude of cell types including placental, ovarian, uterine, lymphoid, epidermal, endothelial, testicular, breast, and liver<sup>[14-18]</sup>. The rat colon undergoes rapid growth and differentiation during the last few days of gestation and the first 2 wk after birth<sup>[19-22]</sup>. This maturation process is accompanied by changes in the composition of AFP, which indicates that AFP might be involved in many aspects of colon development. Liu *et al*<sup>[23]</sup> studied the changes of the protein levels of AFP in rat pancreas during development also by Western blot analysis and immunohistochemistry. Their results have demonstrated that the expression of AFP protein in the rat pancreas was increased in e18.5 rats and down-regulated after birth. They found a the similar possibility to ours, that the pancreatic cells, which went through dramatic growth, differentiation and proliferation, result from the dynamic expression of AFP in the various developmental stages<sup>[23]</sup>.

The genetic variants of rat AFP mRNA consist of sizes ranging from 2.2 to 1.35 kb, representing translated proteins ranging from 72 kDa down to 37 kDa, respectively<sup>[24]</sup>. The smaller AFP isoforms are found to be truncated from the amino-terminal end. Molecular variants of AFP expressed in liver have long been reported in biomedical studies. All isoforms of the 72-kDa, 60-kDa and 48-kDa AFP protein may be involved in different aspects of liver cell behavior<sup>[25,26]</sup>. Using a polyclonal antibody against a peptide mapping at the C terminus of AFP<sup>[27-29]</sup>, we found that only the 72-kDa isoform in the developing rat colons was detected by Western blotting. These results indicate that the 72-kDa isoform of AFP, with the highest expression in embryonic and regenerated liver, may also play an important role in colon cell proliferation and organ maturation.

Tyner *et al*<sup>[9]</sup> have reported that AFP is expressed in a subset of enteroendocrine cells expressing chromogranin A, which suggested that they could be of enteroendocrine origin. AFP is a soluble glycoprotein that is able to bind many ligands including fatty acids, metals, steroids (estrogens), thyroxine, and tryptophan<sup>[6,30]</sup>. The identity of the cells that express AFP in the colon cells was tested by double antibody staining with antibodies to chromogranin A (an enteroendocrine cell marker), cytokeratin (a epithelial cell marker), proliferating cell nuclear antigen (a proliferative cell marker) and vimentin (a mesenchymal cell marker and AFP) at each stage in rat development, respectively (data

not shown). Only an overlap of positive staining of AFP and vimentin was found in the same cell, indicating that AFP is indeed expressed and produced in mesenchymal cells. Liu *et al*<sup>[23]</sup> reported that, in rat developing pancreas, AFP was also co-expressed with the vimentin, which was similar to our results. These results demonstrated that mesenchymal cell-derived AFP can act as a potent paracrine regulator of colon cell proliferation and organ maturation. The epithelial-mesenchymal interactions play an essential role in the control of gastrointestinal epithelial growth and differentiation not only in fetal stages, but also in adults<sup>[31,32]</sup>, but the mechanism has not been fully understood. Characterization of AFP expression in mesenchymal cells may help us discern a function in the gastrointestinal tract.

Cancer cells display immature features and dysregulated gene expression, with attenuation of tumor suppressors and aberrant expression of genes that are inactive in normal adult tissues. Since many down-regulated genes during development are re-expressed in tumors, understanding their respective cellular roles can provide information about both development and cancer biology. Despite some recent advances<sup>[33]</sup>, the extent of embryonic gene expression by tumor cells and the significance of this phenomenon are still unknown. AFP is one such gene and is reactivated in human tumors of the same fetal origin. Further studies are necessary to identify elements in the AFP gene that contribute to its expression. Numerous data support the hypothesis that AFP repression is a part of a global scheme of liver differentiation prematurely activated by glucocorticoids<sup>[34]</sup>. The involvement of glucocorticoids in AFP expression in the gut remains an open question. Studies are now in progress in our laboratory using animal and tissue culture models.

In summary, our present study has, for the first time, demonstrated that AFP is localized to the mesenchyme in rat colon from the embryo to the weaning stage (up to 21 d after birth) by immunofluorescence, and presents a 72-kDa isoform in the developing rat colon by Western blotting. The dynamic expression of AFP in the various developmental stages of the colon indicates that AFP might be involved in many aspects of colon development. The exact function of AFP in colon development remains to be determined.

## COMMENTS

### Background

Mammalian  $\alpha$ -fetoprotein (AFP) is a single-chain glycoprotein, developmentally down-regulated and re-expressed in tumors. The authors assumed that its accurate profiles over gut developmental interval could provide fundamental information about underlying mechanisms. This resource also can be applied to address longstanding questions about reactivation of fetal genes in cancer.

### Innovations and breakthroughs

This study demonstrated that AFP presented a 72-kDa isoform and localized to the mesenchyme in the developing rat colon. The expression of AFP in the various developmental stages is dynamical. AFP might be involved in many aspects of colon development.

### Applications

This animal model is a useful tool for the studies of gastrointestinal mucosal

proliferation and differentiation mechanism *in vivo*. The authors will identify elements in the AFP gene that contribute to its expression.

### Terminology

AFP is a single-chain glycoprotein with molecular mass ranging from 66 to 72 kDa and a 3%-5% carbohydrate (glycan) content.

### Peer review

The study investigated the expression of AFP and its involvement during rat colon development. It was well designed and conducted adequately.

### Abstract

**AIM:** To investigate the anti-angiogenic and anti-tumor activities of recombinant vascular basement membrane-derived multifunctional peptide (rVBMDMP) in hepatocellular carcinoma (HCC).

**METHODS:** HepG2, Bel-7402, Hep-3B, HUVE-12 and L-02 cell lines were cultured *in vitro* and the inhibitory effect of rVBMDMP on proliferation of cells was detected by MTT assay. The *in vivo* antitumor efficacy of rVBMDMP on HCC was assessed by HepG2 xenografts in nude mice. Distribution of rVBMDMP, mechanism by which the growth of HepG2 xenografts is inhibited, and microvessel area were observed by proliferating cell nuclear antigen (PCNA) and CD31 immunohistochemistry.

**RESULTS:** MTT assay showed that rVBMDMP markedly inhibited the proliferation of human HCC (HepG2, Bel-7402, Hep-3B) cells and human umbilical

vein endothelial (HUVE-12) cells in a dose-dependent manner, with little effect on the growth of L-02 cells. When the IC<sub>50</sub> was 4.68, 7.65, 8.96, 11.65 and 64.82  $\mu\text{mol/L}$ , respectively, the potency of rVBMDMP to HepG2 cells was similar to 5-fluorouracil (5-FU) with an IC<sub>50</sub> of 4.59  $\mu\text{mol/L}$ . The selective index of cytotoxicity to HepG2 cells of rVBMDMP was 13.8 (64.82/4.68), which was higher than that of 5-FU [SI was 1.9 (8.94/4.59)]. The VEGF-targeted recombinant humanized monoclonal antibody bevacizumab (100 mg/L) did not affect the proliferation of HepG2, Bel-7402, Hep-3B and L-02 cells, but the growth inhibitory rate of bevacizumab (100 mg/L) to HUVE-12 cells was  $87.6\% \pm 8.2\%$ . Alternis diebus intraperitoneal injection of rVBMDMP suppressed the growth of HepG2 xenografts in a dose-dependent manner. rVBMDMP (1, 3, 10 mg/kg) decreased the tumor weight by 12.6%, 55.9% and 79.7%, respectively, compared with the vehicle control. Immunohistochemical staining of rVBMDMP showed that the positive area rates ( $2.2\% \pm 0.73\%$ ,  $4.5\% \pm 1.3\%$  and  $11.5\% \pm 3.8\%$ ) in rVBMDMP treated group (1, 3, 10 mg/kg) were significantly higher than that ( $0.13\% \pm 0.04\%$ ) in the control group ( $P < 0.01$ ). The positive area rates ( $19.0\% \pm 5.7\%$ ,  $12.2\% \pm 3.5\%$  and  $5.2\% \pm 1.6\%$ ) of PCNA in rVBMDMP treated group (1, 3, 10 mg/kg) were significantly lower than that ( $29.5\% \pm 9.4\%$ ) in the control group ( $P < 0.05$ ). rVBMDMP at doses of 1, 3 and 10 mg/kg significantly reduced the tumor microvessel area levels ( $0.26\% \pm 0.07\%$ ,  $0.12\% \pm 0.03\%$  and  $0.05\% \pm 0.01\%$  vs  $0.45\% \pm 0.15\%$ ) in HepG2 xenografts ( $P < 0.01$ ), as assessed by CD31 staining.

**CONCLUSION:** rVBMDMP has effective and unique anti-tumor properties, and is a promising candidate for the development of anti-tumor drugs.

## INTRODUCTION

Hepatocellular carcinoma (HCC), the fifth most common cancer in the world, is responsible for over 600 000 deaths annually<sup>[1]</sup>. The majority of patients with HCC die within 1 year after the diagnosis. Unfortunately, HCC is often diagnosed at its late stage when potentially curative therapies are least effective. For such patients, medical treatment modalities, including chemotherapy, chemoembolization, ablation, and proton beam therapy, remain disappointing. Most patients show recurrent HCC that rapidly progresses to its advanced stage with vascular invasion and multiple intrahepatic metastases and their 5-year survival rate is only 7%<sup>[2]</sup>. Patients with surgically resectable localized HCC have a better prognosis, but their 5-year survival rate is only 15%-39%<sup>[3]</sup>, showing that new therapies for this aggressive disease are urgently needed.

Angiogenesis plays a critical role in the development of HCC. Antiangiogenesis therapy, which inhibits blood vessel formation, may be a promising treatment modality for HCC, because HCC depends on a rich blood supply<sup>[4]</sup>.

Tumstatin, a 28-kDa (244 amino acids) peptide fragment derived from the NC1 domain of  $\alpha 3$  chain of type IV collagen, is an endogenous angiogenesis inhibitor, and has two binding sites for  $\alpha v\beta 3$  integrin. One is in the N-terminal region of the molecule consisting of amino acids 74-98, which is associated with the anti-angiogenic property. The other is in the C-terminal region consisting of amino acids 185-203, which is associated with the antitumor activity<sup>[5-7]</sup>. The peptide fragment of tumstatin consisting of amino acids 74-98 binds to both endothelial and melanoma cells, but only inhibits the proliferation of endothelial cells. However, the anti-tumor activity of amino acids 185-203 is not realized until this peptide region is exposed by truncation, a requirement not essential for the anti-angiogenic activity of amino acids 74-98<sup>[5]</sup>.

By targeting proliferating tumor cells and endothelial cells in a previous study<sup>[8]</sup>, we have constructed a fusion gene of the human IgG3 upper hinge region with two tumstatin-derived specific sequences, which exhibit anti-proliferation and anti-angiogenic activities. The human IgG3 upper hinge region is composed of 11 amino acids, and has a good flexibility, thus not affecting the spatial conformations of the connected peptides. The fusion sequence is named vascular basement membrane-derived multifunctional peptide (VBMDMP)<sup>[9]</sup>. Recombinant

VBMDMP (rVBMDMP) can significantly inhibit tumor growth and metastasis in a mouse lung carcinoma model<sup>[10]</sup>. Moreover, rVBMDMP selectively inhibits the proliferation of endothelial and human colon cancer cells, as well as induces apoptosis of endothelial cells *in vitro* and suppresses the growth of human colon cancer xenografts in Balb/c-nude mice<sup>[11]</sup>. However, whether rVBMDMP inhibits tumor growth and angiogenesis of human HCC xenografts in a nude mouse model is unknown.

In the present study, we showed that rVBMDMP selectively inhibited the proliferation of HCC cells, using *in vitro* models of tumor growth, and also potently inhibited tumor neoangiogenesis of HepG2 xenografts in a nude mouse model, suggesting that rVBMDMP can be used as a potential agent in the treatment of human HCC.

## MATERIALS AND METHODS

### Cell culture and reagents

HepG2, Bel-7402, Hep-3B, HUVE-12 and L-02 cell lines, were purchased from the China Center for Type Culture Collection (CCTCC), were cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum, 100 U/mL penicillin and 100  $\mu$ g/mL streptomycin (Life Technologies) in an incubator containing 50 mL/L CO<sub>2</sub> at 37°C. rVBMDMP was over-expressed in *Escherichia coli* with pGEX-4T-1-VBMDMP and purified as previously described<sup>[10]</sup> with a purity of over 95%. Synthetic peptide CNYYSNSYSFWLASLNPER (amino acid 185-203 of tumstatin, T4 peptide) and its rabbit polyclonal antibody were provided by Xi'an Huacheng Biotechnology Co., Ltd (China). Bevacizumab was purchased from Roche (Avastin®, Basel, Switzerland). Mouse monoclonal antibodies against proliferating cell nuclear antigen (PCNA) and CD31, as well as peroxidase-conjugated goat anti-mouse IgG and goat anti-rabbit IgG were purchased from Santa Cruz Biotechnology, Inc (Santa Cruz, CA, USA).

### MTT assay

Cells were seeded in a 96-well plate at a density of 1000 cells/well as described previously<sup>[12]</sup>. Different concentrations of drugs were added to each well and cultured for 48 h, followed by incubation with 0.5 g/L MTT for 4 h. The supernatant was removed after centrifugation. Finally, 100  $\mu$ L DMSO was added and the absorbance at 570 nm wavelength ( $A_{570}$ ) was measured with an enzyme-labeling instrument (ELX-800 type). Relative cell proliferation inhibition rate (IR) = (1-average  $A_{570}$  of the experimental group/average  $A_{570}$  of the control group)  $\times$  100%. The IR was analyzed using the CalcuSyn program to determine the IC<sub>50</sub>.

### Tumor xenograft experiments

Balb/c-nude female mice (Vital River Laboratory Animal Technology Co., Ltd), used in *in vivo* study, were housed in a sterile room at Institute of Cancer Research, University of South China, with free access to food and water.

Tumors were generated by harvesting HepG2 cells

from mid-log phase cultures using 0.25% trypsin (Life Technologies). Cells were resuspended in PBS to a final cell count of  $2.5 \times 10^7/\text{mL}$ . A cell suspension (0.2 mL) was subcutaneously injected into the back of each mouse. The mice received a total of 10 injections of 1, 3, and 10 mg/kg body weight rVBMDMP (i.p) every other day when their average tumor volume reached 200 mm<sup>3</sup>.

Tumor dimensions and body weight were recorded every 5 d from the beginning of treatment. Tumor length and width were measured using a Vernier caliper, and tumor volume was calculated as described previously<sup>[13]</sup>. Upon termination of treatment, the mice were weighed and sacrificed, and their tumors were excised. The mean tumor weight per group was calculated. The ratio of the mean of the treated tumor weight to the mean of vehicle control tumor weight  $\times 100$  was subtracted from 100% to give the tumor growth inhibition rate for each group.

### Immunohistochemical staining and quantification

Immunohistochemical staining of paraffin tumor tissue sections was done with rabbit polyclonal anti-T4 peptide antibody (Xi'an Huacheng Biotechnology) at a dilution of 1:50 using the DAB system from DAKO (Carpinteria, CA, USA) according to the manufacturer's instructions.

The tumor tissue sections were viewed at  $\times 100$  magnification and images were captured with a digital camera (Diagnostic Instruments, Inc., Sterling Heights, MI, USA), and analyzed under four fields, excluding peripheral connective tissue and necrotic regions. The total tissue area in each section was 2.576 mm<sup>2</sup>. Areas of rVBMDMP, PCNA or CD31-positive objects were quantified using ImagePro Plus version 3.0 (Media Cybernetics, Silver Spring, MD, USA). Percentage of microvessel area (MVA) in each field was calculated as (area of CD31-positive objects/measured tissue area)  $\times 100$ . Percentage of rVBMDMP or PCNA-positive staining in each field was calculated as (area of rVBMDMP or PCNA-positive objects/measured tissue area)  $\times 100$ . Mean values of MVA- or VBMDMP or PCNA-positive area in each group were calculated from six tumor tissue samples.

### Statistical analysis

Experimental data in each group were expressed as mean  $\pm$  SD. Analysis of variance was performed with SPSS software for Windows 15.0 using one way ANOVA and pairwise comparison with Student's *t* test. *P* < 0.05 was considered statistically significant.

## RESULTS

### Effects of rVBMDMP on proliferation of HCC, endothelial cells (ECs) and L-02 cell lines

MTT assay showed that rVBMDMP markedly inhibited the proliferation of human HCC (HepG2, Bel-7402, Hep-3B) cells and human umbilical vein endothelial (HUVE-12) cells in a dose-dependent manner, with

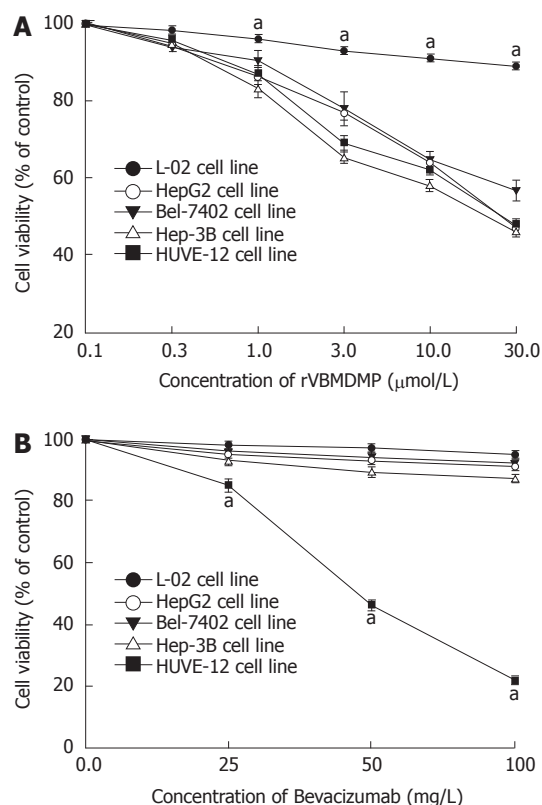

Figure 1 Proliferation of HCC (A) and ECs (B) selectively inhibited by rVBMDMP (mean  $\pm$  SD, *n* = 9). <sup>a</sup>*P* < 0.05 vs other cells.

Figure 2 Robust efficacy of rVBMDMP against HepG2 xenografts in nude mice (mean  $\pm$  SD, *n* = 6). <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs NS.

little effect on the growth of L-02 cells (Figure 1A). When the IC<sub>50</sub> was 4.68, 7.65, 8.96, 11.65 and 64.82 μmol/L, respectively, the potency of rVBMDMP to HepG2 cells was similar to that of 5-FU with an IC<sub>50</sub> of 4.59 μmol/L. The selective index of cytotoxicity to HepG2 cells of rVBMDMP was 13.8 (64.82/4.68), which was higher than that of 5-FU with a SI of 1.9 (8.94/4.59). Bevacizumab (100 mg/L) did not affect the proliferation of HepG2, Bel-7402, Hep-3B and L-02 cells, but its growth inhibitory rate for HUVE-12 cells was 87.6%  $\pm$  8.2% (Figure 1B).

### In vivo efficacy of rVBMDMP against HepG2 xenografts

rVBMDMP inhibited the growth of implanted HepG2 tumor xenografts in nude mice in a dose-dependent

**Figure 3** Accumulation of rVBMDMP in HepG2 xenografts in nude mice after treatment. A: NS; B: 20 mg/kg of 5-FU; C: 10 mg/kg of rVBMDMP; D: Quantification of rVBMDMP-positive areas in HepG2 xenografts. The data are expressed as mean  $\pm$  SD ( $n = 6$ ). <sup>a</sup> $P < 0.05$  vs NS.

**Figure 4** Expression of PCNA in HepG2 xenografts in nude mice after treatment. A: NS; B: 20 mg/kg of 5-FU; C: 10 mg/kg of rVBMDMP; D: Quantification of PCNA-positive areas in HepG2 tumors. The data are expressed as mean  $\pm$  SD ( $n = 6$ ). <sup>a</sup> $P < 0.05$  vs NS.

manner (Figure 2). Different doses of rVBMDMP (1, 3, 10 mg/kg) decreased the tumor weight by 12.6%, 55.9% and 79.7%, respectively, compared with the vehicle control.

#### Distribution of rVBMDMP in HepG2 xenografts

Immunohistochemical staining of rVBMDMP showed that the positive area rates ( $2.2\% \pm 0.73\%$ ,  $4.5\% \pm$

$1.3\%$  and  $11.5\% \pm 3.8\%$ ) were significantly higher in rVBMDMP treated group (1, 3, 10 mg/kg) than that ( $0.13\% \pm 0.04\%$ ) in the control group ( $P < 0.01$ , Figure 3), indicating that rVBMDMP can accumulate in HepG2 xenografts nude mice.

#### PCNA expression in HepG2 xenografts

After intraperitoneal injection of rVBMDMP every other

**Figure 5** Microvessel density of HepG2 xenografts in nude mice after treatment. A: NS; B: 20 mg/kg of 5-FU; C: 10 mg/kg of rVBMDMP; D: Quantification of microvessel density (CD31 staining) positive areas in HepG2 xenografts in nude mice. The data are expressed as mean  $\pm$  SD ( $n = 6$ ). <sup>a</sup> $P < 0.05$  vs NS.

day, the positive area rates ( $19.0\% \pm 5.7\%$ ,  $12.2\% \pm 3.5\%$  and  $5.2\% \pm 1.6\%$ ) of PCNA in rVBMDMP treated group (1, 3, 10 mg/kg) were significantly lower than that in the control group ( $29.5\% \pm 9.4\%$ ) ( $P < 0.05$ , Figure 4), suggesting that rVBMDMP inhibits the proliferation of tumor cells in HepG2 xenografts in nude mice.

#### Effect of rVBMDMP on angiogenesis of HepG2 xenografts

The tumor MVA rates ( $0.26\% \pm 0.07\%$ ,  $0.12\% \pm 0.03\%$  and  $0.05\% \pm 0.01\%$ ) were significantly lower in the HepG2 xenografts of the rVBMDMP-treated group assessed by CD31 staining (1, 3 and 10 mg/kg) than that ( $0.45\% \pm 0.15\%$ ) in the control group ( $P < 0.01$ , Figure 5), demonstrating that rVBMDMP inhibits angiogenesis of HepG2 xenografts in nude mice.

## DISCUSSION

It was recently reported that angiogenesis inhibitors may not work well in monotherapy<sup>[14,15]</sup>. In contrast, studies conducted in preclinical tumor models showed that angiogenesis inhibitors in combination with cytotoxic chemotherapeutic agents or radiation therapy produce additive or synergistic anti-tumor activities<sup>[12,16,17]</sup>. The positive effects of combined chemotherapy with angiogenesis inhibitors have been reported<sup>[18-22]</sup>, suggesting that the combination therapy of a cytotoxic agent and an angiogenesis inhibitor may be a fruitful topic in future clinical research<sup>[23,24]</sup>.

In this report, rVBMDMP inhibited the proliferation of human HCC cells selectively *in vitro*. Our previously research also showed that rVBMDMP could inhibit the proliferation of colon cancer cells, but have no effect on the proliferation of normal cells<sup>[11]</sup>, suggesting that

rVBMDMP can maintain the selective anti-tumor activity of tumstatin amino acids 185-203 fragment, which is consistent with the previously reported findings<sup>[23]</sup>. The specific inhibitory effect of rVBMDMP on the proliferation of tumor cells strongly suggests that rVBMDMP functions *via* a tumor-specific cell surface protein or its receptor.

Tumor neoangiogenesis has recently been recognized as an important factor in defining subsets of cancer patients with a poor outcome<sup>[25-27]</sup>. A number of angiogenesis inhibitors, discovered in recent years, can inhibit tumor growth by targeting proliferating and migrating ECs. Targeting ECs supports growth of tumor rather than tumor cells directly, which is particularly promising because these ECs are genetically stable and do not develop drug resistance. In this study, rVBMDMP suppressed reduplication in human endothelial HUVE-12 cells, like bevacizumab. By immunostaining of CD31 in tumor tissues, we found that rVBMDMP significantly decreased the microvessel density of human HCC xenografts in a mouse model. It was reported that rVBMDMP can significantly inhibit the proliferation of endothelial cells, blood vessel formation, and tumor growth in *in vitro* and *in vivo* models of angiogenesis, as well as induce EC-specific apoptosis<sup>[11]</sup>. These anti-angiogenic properties of rVBMDMP, coupled with its anti-tumor activities, strongly indicate that rVBMDMP acts as a novel inhibitor of angiogenesis and tumor growth.

Since the proliferation velocity of ECs is higher in tumor tissue than in normal tissue, angiogenesis inhibitors may be accumulated in tumor<sup>[28]</sup>. Our results show that rVBMDMP was significantly accumulated in human HCC xenografts in a mouse model, indicating

that rVBMDMP is selectively distributed in tumor tissue.

Maeshima *et al.*<sup>[5]</sup> demonstrated that tumstatin amino acids 185-203 fragment does not show anti-tumor activity until the peptide region is exposed to truncation, which is not required for the anti-angiogenic activity of tumstatin amino acids 74-98 fragment. A shorter fragment comprising seven N-terminal residues 185-191 (CNYYSNS) shares the same inhibitory profile. The three-dimensional structures of CNYYSNS and tumstatin amino acids 185-203 fragment show a  $\beta$ -turn at the YYSNS (188-191) sequence level, which is crucial for its biological activity<sup>[29]</sup>. In our study, analysis of the structures of rVBMDMP using the AntheProt software indicated that both ends of the IgG3 upper hinge region sequence were a rarefaction structure, suggesting that rVBMDMP acts as a potent and specific agent against tumor progression<sup>[11]</sup>.

It has been shown that  $\alpha_v\beta_3$  integrin is a putative receptor of tumstatin<sup>[30,31]</sup>. Tumstatin fails to suppress neovascularization of Matrigel plugs in  $\beta$  integrin-deficient mice, and tumors in  $\beta$  integrin-deficient mice grow much faster than tumors in wild-type mice<sup>[30,31]</sup>, strongly suggesting that tumstatin acts via  $\alpha_v\beta_3$  integrin as a negative regulator of angiogenesis. We speculate that the anti-tumor activity of rVBMDMP might also be mediated by  $\alpha_v\beta_3$  integrin<sup>[32]</sup>.

In conclusion, rVBMDMP is a novel inhibitor of angiogenesis and tumor growth. Targeting both endothelial and tumor cells can enhance the efficacy of anti-tumor therapy. The mechanism of its action requires further investigation.

## COMMENTS

### Background

Tumstatin, a 28-kDa (244 amino acids) peptide fragment, derived from the NC1 domain of  $\alpha 3$  chain of type IV collagen, is an endogenous angiogenesis inhibitor. Tumstatin has two binding sites for  $\alpha_v\beta_3$  integrin. One is in the N-terminal region of the molecule consisting of amino acids 74-98, which is associated with the anti-angiogenic property. The other is in the C-terminal region consisting of amino acids 185-203, which is associated with the antitumor activity. However, the anti-tumor activity of amino acids 185-203 is not realized until this peptide region is exposed to truncation, a requirement not essential for the anti-angiogenic activity of amino acids 74-98.

### Research frontiers

Angiogenesis plays a critical role in the development of hepatocellular carcinoma (HCC). Antiangiogenesis therapy, which inhibits blood vessel formation, may be promising treatment modality for HCC, because HCC depends on a rich blood supply. The strategy of targeting both proliferating tumor and endothelial cells can improve the effectiveness of therapy for HCC.

### Innovations and breakthroughs

It was recently reported that rVBMDMP significantly inhibits tumor growth and metastasis in a mouse lung carcinoma model and selectively inhibits the proliferation of endothelial and human colon cancer cells. In this study, recombinant vascular basement membrane-derived multifunctional peptide (rVBMDMP) selectively inhibited the proliferation of HCC cells in *in vitro* and *in vivo* models of tumor growth. Furthermore, our *in vivo* studies suggested that rVBMDMP was significantly accumulated in human HCC xenografts and potentially inhibited tumor neoangiogenesis in HepG2 xenografts in nude mice.

### Applications

rVBMDMP is a novel inhibitor of angiogenesis and tumor growth. Targeting both endothelial and tumor cells can enhance the efficacy of anti-tumor therapy and can be used as a treatment modality for HCC.

## Terminology

VBMDMP is a fusion gene in the human IgG3 upper hinge region with two tumstatin-derived specific sequences (amino acids 74-98 and amino acids 185-203), which exhibits anti-proliferation and anti-angiogenic activities. Recombinant VBMDMP (rVBMDMP) is produced as a recombinant molecule in *E. coli*.

## Peer review

The authors demonstrated that rVBMDMP selectively inhibited the proliferation of HCC cells, and was significantly accumulated in human HCC xenografts, and potentially inhibited tumor neoangiogenesis in HepG2 xenografts in a nude mouse model by examining the effects of rVBMDMP on tumor growth and angiogenesis of HCC *in vitro* and *in vivo*. The results are interesting and may represent the strategy of targeting both proliferating tumor and endothelial cells, and provide a new treatment modality for HCC.

affect the cell cycle, but induced apoptosis. PE significantly decreased  $\Delta\Psi_m$  at 0.25, 0.5 and 1 mmol/L, respectively, suggesting that PE induces cell apoptosis by decreasing the mitochondrial transmembrane potential. The Bcl-2 expression level induced by different concentrations of PE was lower than that in control groups. However, the Bax expression level induced by PE was higher than that in the control group. Meanwhile, PE increased the caspase-3 expression in a dose- and time-dependent manner.

**CONCLUSION:** Exogenous PE induces apoptosis of human hepatoma HepG2 cells *via* the bcl-2/bax pathway.

### Abstract

**AIM:** To investigate the signaling pathways implicated in phosphatidylethanolamine (PE)-induced apoptosis of human hepatoma HepG2 cells.

**METHODS:** Inhibitory effects of PE on human hepatoma HepG2 cells were detected by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Cell cycle, apoptosis and mitochondrial transmembrane potential ( $\Delta\Psi_m$ ) were analyzed by flow cytometry. Immunocytochemical assay and Western blotting were used to examine Bcl-2, Bax and caspase-3 protein levels in HepG2 cells treated with PE.

**RESULTS:** PE inhibited the growth of HepG2 cells in a dose- and time- dependent manner. It did not

### INTRODUCTION

Phospholipids, including phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylserine (PS) and sphingomyelin (SM), are the dominant lipid constituents of the membranes of animal cells, in which they are distributed in an asymmetrical fashion and act as the matrix for the support and organization of different membrane proteins<sup>[1]</sup>. In addition to this structural role, many individual phospholipid constituents are known to be involved in specific signaling functions necessary for cells to respond to external stimuli<sup>[2-4]</sup>.

Some studies have provided evidence that membrane

phospholipid asymmetry is disturbed in one of the early stages of apoptosis<sup>[5-7]</sup>. Specifically, a translocation of PS and PE from the internal to external surface of the plasma membrane appears to be a fundamental mechanism through which apoptotic cells are recognized and eliminated by phagocytic macrophages<sup>[8-10]</sup>. PS and PE externalization could arise either through inactivation of aminophospholipid translocase (APTL), whose normal function maintains the asymmetric distribution of PS and PE in cells<sup>[11,12]</sup> or by accelerating reversal of movement of the phospholipid. Inhibition of APTL could induce apoptosis of central nervous system (CNS)-derived HN2-5 and HOG cells, activating caspase-3, indicating that abnormal distribution of cell membrane phospholipid can induce apoptosis<sup>[13]</sup>. PS externalization is a characteristic feature of the apoptotic cells. It has been shown that the externalized PS serves as a marker for detecting the apoptotic cells, and PE exposed to the cell surface forms lipid rafts with PS during apoptosis<sup>[14]</sup>.

It was recently reported that overexpression of Raf kinase inhibitor protein (RKIP), a member of the phosphatidylethanolamine-binding protein (PEBP) family, can inhibit the Raf-ERK1/2 pathway<sup>[15]</sup>. However, the effects of PE on cell proliferation or apoptosis remain unclear. Our results in this study suggest that exogenous PE induces apoptosis of human hepatoma HepG2 cells *via* the bcl-2/bax pathway.

## MATERIALS AND METHODS

### Materials and agents

RPMI-1640 medium and fetal calf serum were purchased from GIBCO (Canada). PE, MTT and propidium iodide (PI) were purchased from Sigma. Annexin V-FITC apoptosis detection kit was from BD Biosciences (USA). Monoclonal antibodies were obtained from Cell Signaling Technology (USA).

### Cell culture

Human hepatoma cell line HepG2 was obtained from Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences (Shanghai, China). SMMC7721, HEK293 and HeLa cells were provided by Molecular Biology Center of the First Affiliated Hospital, Xi'an Jiaotong University. HepG2 cells ( $5.0 \times 10^4$  cells/mL) were cultured in RPMI-1640 supplemented with 100 mL/L fetal bovine serum, containing 2.0 mmol/L glutamine and 20  $\mu$ g penicillin-streptomycin/mL in 50 mL/L CO<sub>2</sub> at 37°C, and allowed to adhere for 24 h. The experiments were divided into four groups: control group, 0.25 mmol/L PE, 0.5 mmol/L PE, and 1 mmol/L PE treatment groups.

### MTT assay for cell viability

HepG2 cells ( $2 \times 10^4$  cells/well) were seeded onto 96-well plates and incubated with test substances for an indicated time at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>. Then, 20  $\mu$ L MTT solution (5 g/L) was added into each well and incubated for another 4 h. Supernatants

were removed and formazan crystals were dissolved in 200  $\mu$ L dimethylsulfoxide. Finally, optical density was determined at 490 nm by POLARstar + OPTIMA (BMG Labtechnologies, Germany).

### Cell cycle analysis by flow cytometry

DNA content per duplicate was analyzed by flow cytometry (BD Biosciences). Adherent cells were harvested by brief trypsinization, and washed with PBS, fixed in 700 mL/L ethanol, stained with 20  $\mu$ g/mL PI containing 20  $\mu$ g/mL RNase (DNase free) for 30 min, and analyzed by flow cytometry. The number of cells at the G0/G1, S, and G2/M phases was calculated.

### Detection of HepG2 cell apoptosis by annexin-V/PI staining

HepG2 cells were treated with PE at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub> for 48 h, then harvested and washed twice with PBS. The cells were labeled by incubation with 5  $\mu$ L FITC-annexin V and 10  $\mu$ L PI at 250  $\mu$ g/mL for 10 min in the dark at room temperature. The cells were washed with PBS again and examined by flow cytometry. Apoptosis was routinely quantified by counting the number of cells stained with FITC-labeled annexin V.

### $\Delta\Psi_m$ examination

HepG2 cells ( $1 \times 10^6$ /mL) were washed twice with PBS, incubated with rhodamine 123 (10  $\mu$ g/mL) at 37°C for 30 min, then washed with PBS and analyzed by flow cytometry.

### Immunocytochemical assay

HepG2 cells were grown on glass culture slides coated with poly-lysine in a 24-well plate and treated with PE. Slides with cells were fixed in 40 mg/L paraformaldehyde for 20 min, and then incubated with monoclonal antibody (anti-Bcl-2, anti-Bax, anti-caspase-3), which was labeled with FITC-conjugated goat anti-rabbit IgG. Positive-staining-area percentages were calculated under SP2 confocal microscope (Leica, Germany). Additionally, fluorescence intensity in 20 positive cells was evaluated.

### Western blotting

HepG2 cells were plated at  $5 \times 10^4$  cells/tissue culture dish in six-well plates with RPMI-1640. After exposure to the inhibitor at different concentrations, the cells were washed with PBS and subsequently lysed in 200  $\mu$ L of a lysis buffer containing 150 mmol/L NaCl, 50 mmol/L Tris-HCl (pH 8.0), 0.1 mg/L sodium azide, 10 mL/L NP-40, 1 mmol/L phenylmethylsulfonyl fluoride. Insoluble material was removed by microcentrifugation at 13000 r/min for 15 min at 4°C. Cell lysates (80  $\mu$ g of protein/lane) were subjected to electrophoresis on 100 mg/L SDS-PAGE. The proteins were transferred to a polyvinylidene difluoride membrane (NEN Life Science Products, Boston, MA, USA).

**Figure 1** Effect of exogenous PE on the growth and apoptosis of human hepatoma HepG2 cells. A: Control group; B: 0.25 mmol/L PE; C: 0.5 mmol/L PE; D: 1 mmol/L PE; E: 48 h after treatment, inhibition of cell growth shown by MTT assay; F: Cell cycle in human hepatoma HepG2 cells shown by PI staining 24 h after PE treatment, with data showing the cell percentages at G1/G0, S and G2 phases; G: Apoptosis of human hepatoma HepG2 cells shown by annexin- V/PI staining 24 h after PE treatment, with data showing the percentages of non-affected, early and late apoptotic cells and necrosis. The results are given as mean  $\pm$  SD from three experiments.

After blocked with Tris-buffered saline containing 10 mmol/L Tris-HCl (pH 8.0), 150 mmol/L NaCl, 0.5 mL/L Tween 20, 10 mg/L bovine serum albumin, the membrane was incubated with different monoclonal antibodies (R&D Systems) and anti-glyceraldehyde-3-phosphate dehydrogenase, respectively. For chemiluminescence detection, WB membranes were incubated in the dark with ECL (Amersham) which is a luminol-based enhanced chemiluminescence substrate for horseradish peroxidase. The luminescent signal was recorded and quantified with the Syngene G box (Syngene, UK) which consists of a high-performance CCD videocamera with focus stabilized optics, in a mini darkroom enclosure. The instrument is linked to a computer that controls the instrument and handles the data. The luminescent signal is detected by the CCD camera and transmitted to the controller unit and the data are sent to the computer for analysis and documentation.

### Statistical analysis

All data were expressed as mean  $\pm$  SD and analyzed by

SPSS 11.0 software. Analysis of data was performed using *t* test. *P* < 0.05 was considered statistically significant.

## RESULTS

### PE inhibited growth of HepG2 cells

The growth of SMMC7721, HEK293, HeLa and HepG2 cells was detected by MTT assay at different time points after treatment with PE at different concentrations. The results showed that PE inhibited the growth of these cells as well as normal cells (HEK293), suggesting that the inhibition is non-specific (Table 1). HepG2 cells were chosen in our study.

Polygon or fusiform HepG2 cells were observed in the control group with intact and distinct peripheria (Figure 1A), but round HepG2 cells were found in the PE treatment groups with ambiguous peripheria (Figure 1C and D). PE inhibited the growth of HepG2 cells in a dose-and-time dependent manner (Figure 1E). PE did not affect the cell cycle (Figure 1F), but induced apoptosis (Figure 1G).

**Figure 2** Effects of exogenous PE on the  $\Delta\Psi_m$  of human hepatoma HepG2 cells. A: Control group; B, C, D: Groups treated with 0.25, 0.5 and 1 mmol/L PE at 24 h; E: Flow cytometry analysis of cells with  $\Delta\Psi_m$  collapse in human hepatoma HepG2 cells shown by rhodamine staining at 24 h. The results are given as mean  $\pm$  SD from three repeat experiments.  $^bP < 0.01$  vs control group.

#### Effect of PE on $\Delta\Psi_m$ of HepG2 cells

The uptake of rhodamine123, a lipophilic fluorescent dye absorbed by mitochondria, is positively correlated with  $\Delta\Psi_m$ . The descent of rhodamine can reflect the collapse of  $\Delta\Psi_m$ <sup>[16]</sup>. In order to determine the effect of PE on  $\Delta\Psi_m$ , the uptake of rhodamine was detected by flow cytometry. PE significantly decreased the  $\Delta\Psi_m$  at 0.5 mmol/L and 1 mmol/L (Figure 2C-E), suggesting that PE induces cell apoptosis by decreasing the  $\Delta\Psi_m$ .

#### PE induced apoptosis of Bcl-2/Bax in HepG2 cells

Bcl-2 and Bax are involved in the maintenance of mitochondria membrane stability<sup>[17,18]</sup>. Immunocytochemical assay showed that Bcl-2 expression in HepG2 cells was significantly suppressed 24 h after treatment with

PE, showing a negative correlation with the PE dosage (Figure 3A-E), while Bax expression was significantly increased 24 h after treatment with PE, showing a positive correlation with the PE dosage (Figure 4A-E). The results of Western blotting and immunocytochemical assay were similar. The Bcl-2 expression level was lower in different PE treatment groups than in the control group at different time points (Figure 3F). However, the Bax expression level was higher in different PE treatment groups than in the control group (Figure 4F).

#### Involvement of caspase-3 in HepG2 cell apoptosis induced by PE

Caspase-3, a key regulatory protease from which many signaling pathways merge for the execution of apoptosis, participates in apoptosis induced by bcl-2/bax, p38 and JAK-STAT<sup>[19,20]</sup>. We detected the caspase-3 expression in HepG2 cells after treatment with PE. Immunocytochemical assay showed that caspase-3 expression was significantly increased, showing a positive correlation with the PE dosage 24 h after treatment (Figure 5A-E). The caspase-3 expression level was higher in PE treatment groups than in the control group (Figure 5F). However, PE increased the caspase-3 expression in a dose- and time-dependent manner (Figure 5F).

## DISCUSSION

PE is an important phospholipid component, which is involved in the formation of membrane asymmetry. PE locates at the intracellular leaflet of normal cell membranes, and is exposed to the cell surface during apoptosis. It has been shown that externalization of PE is a signal of early apoptosis<sup>[21]</sup>. However, the effect of PE on cell apoptosis remains unclear.

In this study, PE inhibited the growth of HepG2 cells (Figure 1A-E) in a dose-dependent manner. Because the cell cycle and apoptosis are involved in the regulation of cell growth, they were detected with a flow cytometer 24 h after treatment with PE in our study. PE did not significantly affect the cell cycle (Figure 1F), but induced apoptosis of HepG2 cells (Figure 1G), suggesting that PE induces apoptosis by inhibiting the growth of HepG2 cells.

At the early stage of cell apoptosis,  $\Delta\Psi_m$  was decreased before chromatin condensation and DNA fragmentation. It was recently reported that mitochondrial dysfunction is essential to the apoptotic pathway, and loss of  $\Delta\Psi_m$  may be an early event in the apoptotic process<sup>[22]</sup>. Reduced  $\Delta\Psi_m$  induces cytochrome C release from the mitochondria, and causes apoptosis<sup>[23-25]</sup>. In this study, 0.5 and 1 mmol/L of PE significantly decreased the  $\Delta\Psi_m$  (Figure 2C-E), suggesting that PE induces apoptosis of HepG2 cells *via* the mitochondrial pathway. Loss of  $\Delta\Psi_m$  was found to be closely associated with the expression of Bcl-2 and Bax. It is generally thought that the expression of Bax increases following death stimulation, and then translocates at the mitochondria to induce cytochrome

C release<sup>[26,27]</sup>. It is also known that Bax undergoes post-translational modification during apoptosis of HepG2 cells in response to various stimuli with interferon alpha and chemotherapeutic drugs, and the cleaved form of Bax is a potent inducer of apoptosis<sup>[28-30]</sup>. Anti-apoptotic Bcl-2 inhibits the pro-apoptotic function of Bax. In the present study, PE up-regulated the expression of Bax and down-regulated the expression of Bcl-2 in HepG2 cells in a dose-and time-dependent manner. Bax expression was observed 12 and 24 h after treatment with 0.5 and 1 mmol/L PE (Figure 4E). The expression of Bax was negatively correlated with decreased  $\Delta\Psi_m$ , suggesting that increased Bax expression may be involved in the decreased  $\Delta\Psi_m$ . Increased Bax/Bcl-2 proportion will lead to release of cytochrome C from the mitochondria, thus inducing cell apoptosis<sup>[31]</sup>. Experiments *in vitro* have proved that PE plays a key role in cytochrome C transmembrane transport in liposomes composed of acid-phospholipid and neutrophospholipid<sup>[32]</sup>. When the amount of the PE in PA/PE/PC system is increased, cytochrome C transmembrane

transport increases in liposome<sup>[32]</sup>.

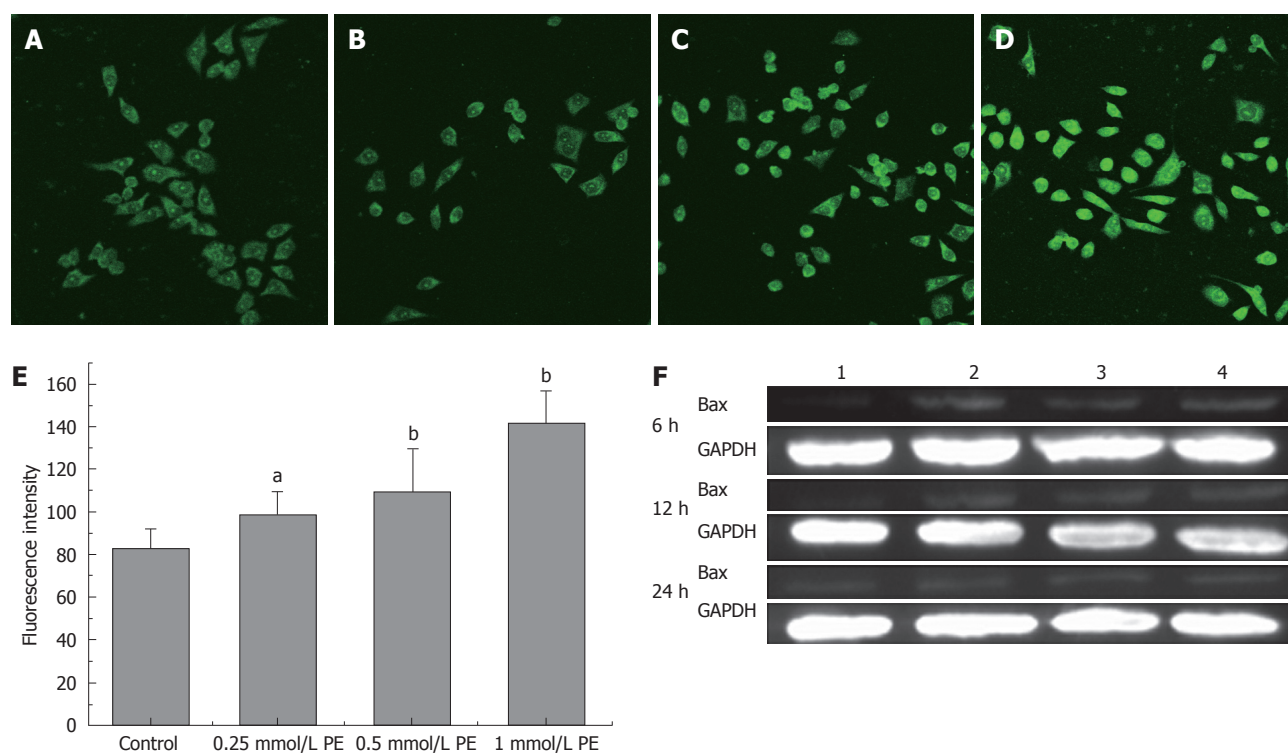

Caspases are cystein proteases that play a key role in cascade activation during apoptosis induced by many stimuli<sup>[33-36]</sup>. Activation of initiator of caspases (procaspases 8-10) leads to proteolytic activation of downstream effector caspases (caspase-3, -6, -7). The activation of caspase-3 is a common event in two major pathways, death receptor and mitochondrial pathways<sup>[37-40]</sup>. In the present study, we proved that PE up-regulated caspase-3 expression in a dose-dependent manner, suggesting that exogenous PE induces apoptosis of human hepatoma HepG2 cells *via* the bcl-2/bax pathway.

## COMMENTS

### Background

Phosphatidylethanolamine (PE) is one of the dominant lipid constituents in the membranes of animal cells in which it is distributed in an asymmetrical fashion. Many individual phospholipid constituents are known to be involved in specific signaling functions necessary for cells to respond to external stimuli, but the specific signaling function of PE is largely unknown.

### Research frontiers

Translocation of phosphatidylserine (PS) and PE from the internal to external surface of plasma membrane appears to be a fundamental mechanism underlying apoptotic cells. Aminophospholipid translocase involving the

asymmetric distribution of PE in cells was inhibited to induce apoptosis in our study, implying that PE externalization leads to apoptosis. The authors of this paper demonstrated that exogenous PE could induce apoptosis of human hepatoma HepG2 cells.

### Innovations and breakthroughs

PS externalization is a typical feature of apoptotic cells. It has been shown that externalized PS serves as a marker for detecting apoptotic cells. PE exposed to the cell surface forms lipid rafts with PS during apoptosis. This is the first study to report that the bcl-2/bax pathway is involved in PE-induced apoptosis of HepG2 cells.

### Applications

PE is a dominant component of liposome. This study revealed the mechanism of liposome cytotoxicity to cells.

### Peer review

In the present work, the authors showed that PE, one of the important phospholipid components in cell membrane, inhibited the growth of HepG2 cells by inducing apoptosis, but did not change the cell cycle. Furthermore, PE down-regulated Bcl-2 expression, and up-regulated Bax expression in HepG2 cells, induced  $\Delta\Psi_m$  collapse, and increased the caspase-3 expression level. Therefore, exogenous PE could induce apoptosis of human hepatoma HepG2 cells via the bcl-2/bax pathway. So it is an interesting work.

### Abstract

**AIM:** To prospectively investigate the effectiveness and patient's tolerance of two low-cost bowel cleansing preparation protocols based on magnesium citrate only or the combination of magnesium citrate and senna.

**METHODS:** A total of 342 patients who were referred for colonoscopy underwent a colon cleansing protocol with magnesium citrate alone ( $n = 160$ ) or magnesium citrate and senna granules ( $n = 182$ ). The colonoscopist rated the overall efficacy of colon cleansing using an established score on a 4-point scale. Patients were questioned before undergoing colonoscopy for side effects and symptoms during bowel preparation.

**RESULTS:** The percentage of procedures rescheduled because of insufficient colon cleansing was 7% in the magnesium citrate group and 4% in the magnesium citrate/senna group ( $P = 0.44$ ). Adequate visualization of the colonic mucosa was rated superior under the citramag/senna regimen ( $P = 0.004$ ). Both regimens were well tolerated, and did not significantly differ in the occurrence of nausea, bloating or headache.

### INTRODUCTION

Good bowel preparation is mandatory for optimal intraluminal visualization during colonoscopy. Inadequate bowel cleansing has a negative impact on completion rate<sup>[1]</sup> and polyp detection rate<sup>[1,2]</sup>. It also increases procedure time<sup>[1,3]</sup> and difficulty<sup>[1]</sup>, and it may affect the procedure safety profile<sup>[4]</sup>. All these factors negatively affect therapeutic efficiency and diagnostic accuracy and increase colonoscopy costs<sup>[5]</sup>.

Magnesium citrate is an osmotic saline agent that increases intraluminal volume resulting in a secondary increase of intestinal motility<sup>[6]</sup>. According to a prospective study of colonoscopy practice in 68 hospitals in the UK, magnesium salts are used as bowel cleansing agents in 36.8% of colonoscopies<sup>[7]</sup>. Magnesium citrate must be used cautiously in patients with impaired renal function.

Senna, an anthraquinone derivative, is a stimulant laxative stimulating intestinal motility<sup>[8]</sup>. Senna has been reported to be a useful adjunct to polyethylene glycol

(PEG) colonoscopy preparation regimens<sup>[9,10]</sup>. However, the role of senna as a potential adjunct of magnesium citrate for bowel preparation is yet to be explored.

In two prospective clinical audits, we compared the colon cleansing efficacy and patient tolerability of two colon preparation regimens for adults undergoing colonoscopy: (a) magnesium citrate; and (b) magnesium citrate combined with senna granules.

## MATERIALS AND METHODS

### Patients

A total of 345 consecutive adult out patients referred to the endoscopy unit of the John Radcliffe hospital for colonoscopy on routine clinical indications were prospectively invited to participate. Exclusion criteria were ileus or suspected bowel obstruction, significant gastroparesis or gastric outlet obstruction, toxic colitis or megacolon, pregnancy, or lactation. Patients included were referred mainly due to alarm symptoms such as altered bowel habit in patients > 45 years of age, blood per rectum, iron-deficiency anaemia, unintentional weight loss, and/or other symptoms suggestive of malignant disease. No patient refused to participate. Patients who could not be sedated for colonoscopy were excluded from further evaluation. All patients gave informed consent before participation.

From July to November 2006, we prospectively audited the performance of the large bowel cleansing with magnesium citrate (citramag-only group). The colon preparation protocol with magnesium citrate and senna (citramag/senna group) was audited from August 2007 to January 2008.

### Bowel preparation regimens

All patients were asked to refrain from taking iron tablets 7 d prior to colonoscopy and any medications reducing gastrointestinal motility, e.g. loperamide, 4 d before colonoscopy, but continued all other medications. Two days before colonoscopy, all patients were instructed to eat a low-fiber diet such as white fish, chicken, white bread, eggs, cheese, or potato without skins. High-fiber kinds of food such as red meat, fruit, or vegetables, were to be avoided and patients were advised to consume plenty of fluids. On the day before colonoscopy patients, were instructed to have a low-fiber breakfast. Following that, patients were instructed not to eat any solid food until after colonoscopy and to consume plenty of clear fluids. On the day before colonoscopy at 5:00 pm, patients were instructed to dissolve one sachet of citramag in 200 mL of hot water, which was to be consumed half an hour later when cool. One sachet contains 11.6 g magnesium carbonate and 17.8 g anhydrous citric acid. At 7:00 pm, the patients were instructed to dissolve half of the second sachet of citramag in 100 mL of water and consume it once cooled. Patients were instructed to drink clear fluids (at least a cupful every 30 min) throughout the day and evening before colonoscopy. On the day of colonoscopy, at 6:00-7:00 am in the case of a morning appointment

or at 9:00-10:00 am in the case of an afternoon appointment, patients were instructed to consume the other half of a sachet of citramag as described above.

Patients in the citramag-only group underwent colonoscopy after bowel cleansing as described above (two sachets of citramag). Patients in the citramag/senna group were instructed to follow the above instructions but they were also asked to consume one sachet of senna in a cup of warm water and consume it at 2:00 pm on the day before colonoscopy (two sachets of citramag and one sachet of senna).

### Colonoscopy

In order to eliminate interobserver variability, all colonoscopies were performed by the same experienced endoscopist who was, however, not blinded as to the cleansing regimen used. The colonoscopist rated the overall cleansing of the bowel on a 4-point Likert scale as in previous studies<sup>[11-13]</sup>: 1 = "unacceptable" (large amounts of solid and semisolid fecal residue requiring additional cleansing resulting in rebooking); 2 = "poor" (enough feces or fluid to prevent a completely reliable examination); 3 = "satisfactory" (small amounts of feces or fluid not interfering with the exam); 4 = "good" (no more than small bits of adherent feces/fluid). For the primary efficacy variable, scores of 3 and 4 were considered "adequate" and scores of 1 or 2 were considered "inadequate".

### Symptom score

Prior to colonoscopy, patients were asked to describe their tolerance to the cleansing protocol. Symptoms of nausea, vomiting, bloating, abdominal pain/discomfort, and headache were documented. Patients were asked to rate their symptom severity on a 5-point Likert scale as in previous bowel cleansing studies<sup>[12-14]</sup>: 1 = "none"; 2 = "mild"; 3 = "moderate"; 4 = "severe"; and 5 = "extreme". Any adverse event reported during bowel cleansing and/or during the procedure and/or during stay in the recovery room after the procedure was also recorded.

### Statistics analysis

Data are shown as mean and standard deviation or as median and ranges, as appropriate. The  $\chi^2$  test was used for comparisons between categorical variables and the Student's *t* test was used for comparisons between quantitative variables. All tests were two-tailed and conducted at a 5% significance level.

## RESULTS

Overall, 345 patients underwent colonoscopy. Three patients in the citramag-only group could not be sedated for colonoscopy and were excluded from further evaluation. Data analysis was based on 160 patients who underwent colonoscopy after using the citramag bowel cleansing regimen and on 182 patients who performed bowel preparation for colonoscopy according to the combined citramag/senna regimen. Demographic and

**Table 1** Demographic and clinical data

	Citramag-only ( <i>n</i> = 160)	Citramag/senna ( <i>n</i> = 182)
Male/female	76/84	97/85
Age	60 ± 13	58 ± 14
History of bowel resection	6	9
Sedation		
Fentanyl iv (µg)	75 (0-200)	75 (0-200)
Midazolam iv (mg)	4 (0-10)	4 (0-10)
Polyp detection rate	37 (23.1%)	63 (34.6%) <sup>1</sup>
Colorectal cancer	17	16
Completion rate	86% (adjusted 92%)	92% (adjusted 97%) <sup>2</sup>

Data are presented as mean and standard deviation or *n* and percentage as appropriate. <sup>1</sup>*P* < 0.03, <sup>2</sup>*P* = 0.07.

**Table 2** Quality of colon cleansing as evaluated by the endoscopist *n* (%)

	Citramag-only ( <i>n</i> = 160)	Citramag/senna ( <i>n</i> = 182)
Good	20 (12.5)	41 (22.5)
Satisfactory	88 (55.0)	107 (58.8)
Poor	41 (25.6)	26 (14.3)
Unacceptable	11 (6.9)	8 (4.4)

clinical data of the patients are given in Table 1. The two groups did not differ regarding age, gender, previous history of colorectal surgery, caecal intubation rate, and sedation required (Table 1).

### **Patients following the citramag-only bowel cleansing regimen**

In six of 160 patients (3.8%) using the citramag only cleansing protocol, bowel preparation was so poor with solid fecal residues that the procedure was abandoned in the rectosigmoid, and we did not attempt further insertion. In five other patients the cecum was reached but the view was unacceptable due to fecal residues, especially on the right side. Therefore, a repeat colonoscopy was indicated in these patients as well. Totally, 11/160 (6.9%) of the patients had to be rebooked for colonoscopy or virtual colonoscopy because of insufficient bowel cleansing after the citramag regimen.

Complete colonoscopy with visualization of the cecum was reached in 137/160 colonoscopies (86%). Adjustment for tumor strictures (4), cancellation of the procedure due to poor bowel preparation (6) or severity of colitis (1) raised the completion rate to 92% (137/149).

### **Patients following the citramag and senna bowel cleansing regimen**

Five out of 182 patients (2.7%) were not examined further than the rectosigmoid because of insufficient bowel cleansing after taking the senna protocol, and three had to be rebooked because of insufficient views despite intubation of the cecum. Thus, eight of 182 patients (4.4%) had unacceptable bowel cleansing under the senna/citramag regimen.

The unadjusted completion rate for cecal intubation

was 92%. Adjustment for tumor strictures<sup>[4]</sup> and exclusion of procedures abandoned in the rectosigmoid due to poor bowel preparation<sup>[5]</sup> resulted in a completion rate of 97%.

Table 2 shows the quality of colon cleansing results for the two regimens used in the current study as assessed by the endoscopist. The combined citramag/senna regimen proved superior in bowel cleansing as it achieved “adequate” colon visualization (quality of colon cleansing rated as “good” or “satisfactory” in 148/182 (81.3%) compared to 108/160 (67.5%) colonoscopies using the citramag protocol (*P* = 0.004; Table 3). The colonic polyp detection rate was higher in the citramag/senna group compared to the citramag-only group (*P* < 0.03; Table 1).

### **Side effects and tolerability**

Both protocols were well tolerated. None of the side effects observed were categorized as extreme, and five patients reported severe side effects during bowel preparation. The two bowel cleansing regimens did not significantly differ in the occurrence and intensity of nausea, vomiting, bloating or headache (Table 3). Abdominal cramps occurred more often in the citramag/senna group (*P* < 0.003; Table 3). Two patients reported “severe” abdominal pain/cramps both of whom had a stricturing tumor in the rectosigmoid.

## **DISCUSSION**

According to our findings, the overall cleansing results were superior using the combination of senna compared to the citramag-only regimen. Although we did not perform a segmental evaluation of colon cleansing, the general impression was that particularly the right colon was better visualized in the citramag/senna group, while in the citramag-only group the cecum and ascending colon were often still covered in sticky solid fecal layers. Having reviewed the relevant bibliography and to the best of our knowledge, the current study is the first to evaluate the efficiency of senna as an adjunct to magnesium citrate for large bowel preparation prior to colonoscopy.

The rationale for using an osmotic agent such as magnesium citrate, together with a stimulant laxative such as senna for colonoscopy preparation, is that increased fluid bowel content produced by the osmotic agent may be more readily evacuated upon bowel stimulation by the stimulant agent<sup>[15]</sup>. Previous studies have shown that the combination of PEG with stimulant bisacodyl allows for less volume of PEG to be used for colonic cleansing<sup>[14,16]</sup>. Furthermore, the adjunctive use of senna with PEG has been shown to improve the quality of bowel preparation<sup>[9]</sup> and to reduce the amount of PEG required for colonic cleansing<sup>[10]</sup>. Similarly, we could demonstrate that the combination of senna with magnesium citrate was associated with improved quality in bowel preparation as assessed by a single experienced endoscopist. Although no cost-effectiveness analysis was undertaken, considering the relatively low price of senna<sup>[13]</sup> and that bowel preparation has been reported

**Table 3** Proportions of patients with side effects reported under bowel cleansing using citramag only or the combination of senna and citramag

Side effect	Treatment group	None (%)	Mild (%)	Moderate (%)	Severe (%)	Extreme (%)	P-value <sup>1</sup>
Nausea	Citramag	83.5	7.9	7.9	0.7	0	NS
	Citramag/senna	76.5	10.3	12.6	0.6	0	
Vomiting	Citramag	94.8	2.6	2.6	0	0	NS
	Citramag/senna	92.6	3.4	4	0	0	
Bloating	Citramag	88.1	5.3	6.6	0	0	NS
	Citramag/senna	81.7	7.4	10.3	0.6	0	
Abdominal pain	Citramag	90.1	6	3.9	0	0	P < 0.0003
	Citramag/senna	70.8	16	12	1.2	0	
Headache	Citramag	95.4	3.9	0.7	0	0	NS
	Citramag/senna	93.7	3.4	2.9	0	0	

<sup>1</sup>P-value (significant at the 0.05 level) was obtained using a  $\chi^2$ -test to compare the frequency of side effects in treatment groups.

to have an impact on colonoscopy costs<sup>[5]</sup>, our results suggest that it may be a useful adjunct to magnesium citrate for outpatient colonoscopy preparation.

Bowel preparation was well tolerated in both the magnesium citrate-only and the magnesium citrate/senna group with no self-reported “extreme” symptoms during preparation in any one group. The prevalence of gastrointestinal symptoms did not differ between the two groups with the exception of an about three times increased frequency of abdominal pain noted in the magnesium citrate/senna group which, however, did not seem to affect compliance. No serious adverse events were recorded in either preparation group. Nevertheless it must be noted that no monitoring of laboratory values and electrolytes was performed, which is a limitation of the current study.

Although the majority of patients enrolled had alarm symptoms suggestive of colonic neoplasia (which may explain the relatively high polyp detection rate in both patient groups), our aim was not specifically to explore the potential role of the addition of senna to magnesium citrate in polyp detection. However, more colonic polyps were found in the group receiving bowel preparation with the addition of senna to magnesium citrate, which is in accordance with previous studies showing that the detection of polyps is dependent on bowel cleansing quality<sup>[1,2]</sup>.

There are certain limitations to the evaluation of the present audits. Although it was conducted in a prospective manner, no placebo was used and the endoscopist was not blinded to the patient group that was colonoscoped. Second, the scales used for the assessment of bowel cleansing and patient symptom severity were not previously validated. Third, no segmental assessment of bowel cleansing quality was performed, and finally, no monitoring of electrolyte levels was performed. As all consecutive patients underwent the same bowel preparation protocol during the audit periods, we can consider the allocation of the bowel cleansing regimen a block randomization.

In conclusion, the addition of senna to bowel preparation protocol with magnesium citrate significantly improves the cleansing outcome. It produces no major side effects but abdominal pains occur more often.

Senna might be a useful adjunct to magnesium citrate for colonoscopy preparation.

## COMMENTS

### Background

Adequate colon preparation is essential for the quality of colonoscopy. The completion and polyp detection rate as well as the complication risk and the duration of the colonoscopy are strongly affected by poor bowel cleansing.

### Innovations and breakthroughs

As far as we know, this is the first study to evaluate the efficacy of senna as an adjunct to magnesium citrate for large bowel preparation prior to colonoscopy. Our findings demonstrate that the addition of senna to the bowel cleansing protocol with magnesium citrate significantly improves the cleansing outcome, but also increases the occurrence of side effects such as (mild) abdominal pains and discomfort.

### Applications

Our study results suggest that senna can be used as a helpful adjunct to a cleansing protocol based on magnesium citrate and will increase the efficacy of the bowel preparation before colonoscopy.

### Terminology

Magnesium citrate acts as an osmotic laxative which is often used for bowel preparation; senna is a stimulative agent increasing peristaltic movement.

### Peer review

This interesting study evaluates how the addition of senna alters the cleansing outcome and the occurrence of side effects under a bowel preparation protocol based on magnesium citrate. The results suggest that senna might be a helpful adjunct to standard bowel preparation protocols.

### Abstract

**AIM:** To evaluate the association between gastroesophageal reflux diseases (GERD) and coronary heart diseases.

**METHODS:** One thousand nine hundred and seventy consecutive patients who attended our hospital were enrolled. All of the patients who first attend our hospital were asked to respond to the F-scale questionnaire regardless of their chief complaints. All patients had a careful history taken, and resting echocardiography (ECG) was performed by physicians if the diagnostic necessity arose. Patients with ECG signs of coronary artery ischemia were defined as ST-segment depression based on the Minnesota code.

**RESULTS:** Among 712 patients (36%) with GERD, ECG was performed in 171 (24%), and ischemic changes were detected in eight (5%). Four (50%) of these patients with abnormal findings upon ECG had no chest symptoms such as chest pain, chest oppression, or palpitations. These patients (0.6%; 4/712) were thought to have non-GERD heartburn, which may be related to ischemic heart disease. Of 281 patients who underwent ECG and did not have GERD symptoms, 20 (7%) had abnormal findings upon ECG. In patients with GERD symptoms and ECG signs of coronary artery ischemia, the prevalence of linked angina was considered to be 0.4% (8/1970 patients).

### INTRODUCTION

Chest pain often precedes echocardiographic coronary angiography, electrocardiography (ECG), and scintigraphy for the diagnosis of angina. Many patients presenting to a hospital emergency room for chest pain turn out not to have coronary artery disease (CAD)<sup>[1]</sup>. According to data from a large university, 81%-86% of patients evaluated in an emergency room for acute chest pain did not have coronary ischemia<sup>[2,3]</sup>. It is well known that non-cardiac chest pain is closely related to gastroesophageal reflux diseases (GERD)<sup>[4,5]</sup>. Similarly, erosive esophagitis is not found in some patients with persistent GERD symptoms. Although GERD symptoms affect 10%-30% of the population in Western countries<sup>[6]</sup>, endoscopic esophagitis is less prevalent, and is reported to occur in up to 2% of individuals<sup>[7-8]</sup>. Only one-third of GERD patients have endoscopic positive findings, while others have no obvious mucosal breaks, even though GERD symptoms are present<sup>[9]</sup>. Chest pain of esophageal origin can be difficult to distinguish from that caused

by cardiac ischemia because the distal esophagus and the heart share a common afferent vagal supply, and GERD can cause episodes of non-cardiac chest pain that resemble ischemic cardiac pain<sup>[10,11]</sup>. It is possible that GERD may be misclassified as angina pectoris and vice versa in clinical practice. The aim of this study was to evaluate the association between GERD and coronary heart disease and to clarify the presence of non-GERD heartburn.

## MATERIALS AND METHODS

### Ethics

The study was carried out in accordance with the Declaration of Helsinki, and approved by the ethical committee at Toho University.

### Patients

Between October 2005 and May 2006, 1970 consecutive patients (934 men and 1036 women with a mean age of 43 years) who first attended the Outpatient Department of General Medicine and Emergency Care of Toho University Omori Hospital were enrolled. Informed consent was obtained from all the patients. None of the patients had a history of use of proton pump inhibitors, H<sub>2</sub>-receptor antagonists, antibiotics, steroids, or nonsteroidal anti-inflammatory drugs for a period of at least 2 mo before the investigation. Patients who had a previous history of partial gastrectomy were also excluded from the study.

### Questionnaire

All of the patients who attended our hospital were asked to respond to the F-scale questionnaire regardless of their chief complaints. The questionnaire is a self-report instrument, written in a simple and easy-to-understand language, which contained 12 questions. As reported previously by Kusano *et al.*<sup>[12]</sup>, the following definitions were used to identify symptoms in the F-scale: (1) "Do you get heartburn?"; (2) "Is your stomach bloated?"; (3) "Does your stomach ever feel heavy after meals?"; (4) "Do you sometimes subconsciously rub your chest with your hand?"; (5) "Do you ever feel sick after meals?"; (6) "Do you get heartburn after meals?"; (7) "Do you have an unusual sensation in your throat?"; (8) "Do you feel full while eating meals?"; (9) "Do some things get stuck when you swallow?"; (10) "Do you get bitter liquid coming up into your throat?"; (11) "Do you belch a lot?"; and (12) "Do you get heartburn if you bend over?". Symptoms frequency was measured on the following scale: 0, never; 1, occasionally; 2, sometimes; 3, often; and 4, always. A score of more than 7 points, was considered positive for GERD.

### Electrocardiogram

All patients had a careful history taken, and resting ECG was performed by physicians if diagnostic necessity arose. Patients with ECG signs of coronary artery ischemia were defined as having ST-segment depression based on the Minnesota code<sup>[13]</sup>.

Table 1 Characteristics of study participants

Cardiogram	Abnormal	Normal	P
No. of patients	456	1514	
Age (yr)	48.2 ± 17.6 (16-91)	40.7 ± 15.7 (15-93)	< 0.001
Male/female	231/225	703/811	< 0.05
Hypertension	49/407	84/1430	< 0.001
Diabetes	36/420	45/1469	< 0.001
Hyperlipidemia	79/377	146/1473	< 0.001
Current smoker	156/300	488/1026	NS

Table 2 Relationship between GERD symptoms and ECG abnormalities

Cardiogram	Abnormal	Normal
GERD (+)	8	166
GERD (-)	20	261

### Statistical analysis

All values are expressed as means ± SD. Comparisons of groups were made using Student's *t* test or chi-square tests as appropriate. *P* < 0.05 was considered statistically significant.

## RESULTS

Overall, ECG was performed in 456 patients (23%, ECG group). The remaining 1514 patients were defined as controls. Patients in the ECG group were significantly older and the male to female ratio was significantly higher than in controls (Table 1). The prevalence of hypertension, diabetes mellitus, and hyperlipidemia was also significantly higher in the ECG group. There was no difference in the proportion of current smokers between the two groups.

Among 712 patients (36%) with GERD, ECG was performed in 171 patients (24%) and ischemic changes were detected in eight patients (5%). Four (50%) of these patients with abnormal findings upon ECG had no chest symptoms such as chest pain, chest oppression, or palpitations. These patients (0.6%; 4/712) were thought to have non-GERD heartburn, which may be related to ischemic heart disease. Of 281 patients who underwent ECG and did not have GERD symptoms, 20 (7%) had abnormal findings upon ECG (Table 2). No significant differences in the prevalence of ischemic changes were found between patients who underwent ECG and those who did not. As shown in Table 3, an exercise thallium test was performed in 12 GERD patients, of whom, one had ischemic coronary artery disease that was proven angiographically. In patients with GERD symptoms and ECG signs of coronary artery ischemia, the prevalence of linked angina, was considered to be 0.4% (8/1970 patients) (Figure 1). In contrast, patient with angina not related to GERD was found in 20 (1.0%).

## DISCUSSION

Screening asymptomatic patients is an area of

**Table 3** Number of patients undergoing additional cardiological tests

	GERD (+) <i>n</i> = 171		GERD (-) <i>n</i> = 285	
	Abnormal findings (+)	Abnormal findings (-)	Abnormal findings (+)	Abnormal findings (-)
ECG	8	163	20	265
Exercised thallium test	2	10	5	13
Cardioangiography	1	0	4	3

considerable interest because silent CAD is an important cause of premature death; many of these patients have three-vessel CAD or left main coronary artery stenosis<sup>[14]</sup>. Little is known, however, about the effects of intervention on asymptomatic disease, and screening strategies for asymptomatic CAD have been difficult to justify. Of patients with a low pre-test probability of CAD, only about 20% with a positive exercise test will have angiographically verified CAD<sup>[15]</sup>. Little evidence exists currently to support doing resting ECGs<sup>[16]</sup> or exercise tests<sup>[17]</sup> in patients without clinical evidence of CAD or cardiovascular risk factors.

When coronary arteries appear normal upon angiography, particularly when there is no other cardiac disorder or objective evidence of ischemia, a diagnosis of non-cardiac chest pain is made. In that particular study<sup>[18]</sup>, cardiac mortality was 0.09% and coronary event rate was 0.65% per year, but 81% of patients had chest pain after 9 years follow-up. The clinician often is faced with the problem of a patient with comparatively mild coronary disease but persistent severe symptoms despite anti-anginal drugs. This subset of patients presents a difficult clinical problem because both the patient and physician usually perceive the pain to be of cardiac origin. It is probable that many of these patients have coexisting coronary disease and a symptomatic esophageal disorder. Symptoms of chest pain are a major source of concern for patients and physicians alike because they can sometimes be the harbinger of acute life-threatening events. However, many patients who describe chest pain that sounds identical to the type associated with significant cardiac disease can actually be free of such disease. After appropriate evaluations, about 40% of patients admitted for potential acute coronary syndromes turn out not to have CAD<sup>[19,20]</sup>. A study at the Emergency Room Assessment of Sestamibi for Evaluating Chest Pain Trial (ERASE trial), and a second study at a large hospital center in Philadelphia, showed that 81%-86% of all patients presenting to the emergency department with chest pain did not have a final diagnosis of cardiac ischemia<sup>[3,21]</sup>. Thus, differentiation between cardiac- and esophageal-origin chest pain is especially difficult since both organs have overlapping sensory pathways: Th1-Th4 for the heart and C8-TH10 for the esophagus. Moreover, they have autonomic nerve reflex, the so-called vagal visceral reflex function between the heart and organs of the gastrointestinal tract<sup>[22]</sup>.

Direct mechanical effects between the esophagus

**Figure 1** Prevalence of linked angina based on symptoms.

and the heart are thought to be compression of the left atrium by a huge hiatus hernia or extrinsic esophageal compression by cardiac enlargement. Other than these direct effects, a neural reflex, mediated by the vagus nerve, exists that allows changes in esophageal function to affect cardiac physiology<sup>[22]</sup>. Atrial tachycardia can be triggered by swallowing and belching, although the precise neural mechanism remains unclear<sup>[23]</sup>. Furthermore, bradycardia occurs in most people during balloon inflation within the esophagus and this may be blocked by atropine<sup>[24]</sup>. It has been suggested that esophageal dysfunction can itself trigger myocardial-ischemia-linked angina<sup>[25]</sup>. Smith *et al*<sup>[25]</sup> have coined the term “linked angina”, which implies that gastrointestinal factors bring on attacks of genuine angina in patients with established CAD. They have explained this on the basis of cardiovascular changes, although gastroesophageal acid reflux may equally explain the phenomenon. Instillation of acid into the esophagus has been shown to significantly reduce the exertional angina threshold at which angina occurs or can provoke angina with ischemic ECG changes<sup>[26]</sup>. A previous animal study has demonstrated the reduced coronary flow caused by distension of the stomach that does not occur after vagal section or after the administration of atropine. This suggests that reflex coronary vasoconstriction is initiated by vagal irritation in the gastrointestinal tract<sup>[27]</sup>. Mellow *et al*<sup>[28]</sup> have demonstrated that acid perfusion of the esophagus results in reduced coronary blood flow in patients with proven CAD. It should be emphasized that 67% of patients felt chest pain and two-thirds of them developed ischemic ST-segment changes upon ECG. Dobrzycki *et al*<sup>[29]</sup> have also reported that GERD patients have a larger total ischemic burden and higher incidence of ST depression. Thus, spontaneous GER may have a role to play in the causation of or provocation of cardiac chest pain. Linked angina can be defined as that induced by GER. However, most patients with asymptomatic angina or symptoms, that do not reach the threshold required to define disease, do not refer to a hospital. Therefore, the present study was designed in the Department of General Medicine to evaluate the association between GERD and coronary heart disease in the general population because general

practice registers offer the best means of sampling the general population<sup>[30]</sup>. We hypothesized that the prevalence of CAD in GERD patients who were referred for the first time to the gastroenterology outpatient clinic because of heartburn may be substantial.

The present study revealed a small number of patients with abnormal ECG findings but without chest symptoms such as chest pain, chest oppression, or palpitations. This suggests that the extra-esophageal condition causes GERD symptoms and that angina may be misclassified as GERD. Such patients are often treated with proton pump inhibitors and chest pain disappears, which suggests that CAD may be overlooked. The results may therefore have clinical relevance, as it has been reported in a previous population-based, nested case-control study that patients with GERD have an increased risk of angina pectoris in the year after GERD diagnosis<sup>[31]</sup>. Actually, the incidence of reflux esophagitis is increasing as the population grows older, which makes it likely that such disease may be present in patients with CAD<sup>[32]</sup>. Physicians have to be concerned about missing clinically important CAD while evaluating patients for GERD symptoms.

## COMMENTS

### Background

Screening asymptomatic patients is an area of considerable interest because silent coronary artery disease (CAD) is an important cause of premature death, although many patients presenting to a hospital emergency room for chest pain turn out not to have CAD. It is well known that non-cardiac chest pain is closely related to gastroesophageal reflux diseases (GERD) and GERD symptoms affect 10%-30% of the population. Little is known, however, about the prevalence of linked angina, which is defined as angina induced by GER.

### Research frontiers

In patients with GERD symptoms and echocardiography signs of coronary artery ischemia, prevalence of linked angina, was considered to be 0.4% (8/1970 patients). The prevalence may be increased when more sensitive tests such as angiography are used for diagnosis of angina.

### Innovations and breakthroughs

Recent reports have highlighted the association between non-cardiac chest pain and GERD because both organs have overlapping sensory pathways. However, there have been few reports that GERD symptoms may be caused by ischemic heart disease. The present study is believed to be the first to evaluate the presence of non-GERD heartburn. GERD symptoms induced by coronary artery ischemia, so-called linked angina, certainly exist.

### Applications

The study results suggest that an extra-esophageal condition causes GERD symptoms and that angina may be misclassified as GERD. Since patients with GERD have an increased risk of angina pectoris in the year after GERD diagnosis, physicians have to be concerned about missing clinically important CAD while evaluating patients for GERD symptoms.

### Terminology

Linked angina is defined as angina induced by GER. GERD symptoms typically include heartburn and regurgitation. GERD is diagnosed according to symptoms regardless of the presence of endoscopically proven esophagitis.

### Peer review

The authors examined the prevalence of linked angina. The results suggest the possibility that GERD patients also have coronary heart disease.

### Abstract

The occurrence of leiomyoma of the rectum is uncommon. Most of these lesions are clinically silent and are found incidentally during laparotomy or endoscopic procedures for unrelated conditions. Symptomatic leiomyomas of the rectum are encountered less frequently, with only sporadic reports in the literature. We describe a case of a leiomyoma of the rectum presenting as recurrent lower gastrointestinal hemorrhage and secondary anemia.

### INTRODUCTION

Smooth muscle tumors may occur throughout the entire gastrointestinal tract, but are rarely seen in the colon and rectum. Most of these lesions are clinically silent and are found incidentally during laparotomy or endoscopic procedures for unrelated conditions. Symptomatic leiomyomas (LMs) of the rectum are encountered less frequently, with only sporadic reports in the literature. We describe a case of LM of the rectum, presenting as recurrent lower gastrointestinal hemorrhage and secondary anemia.

### CASE REPORT

A 55-year-old woman presented to our unit complaining of recurrent rectal bleeding and secondary sideropenic anemia. Colonoscopy revealed the presence of a polypoid, submucous, ulcerated lesion in its vertex (2 cm from the anal margin) (Figure 1).

An endoanal ultrasound scan showed a mass located in the anterior wall of the rectum, approximately 7 cm in size, with no infiltration of perirectal fat (Figure 2). A biopsy was made and the pathological study showed a proliferation of fusiform, elongated spindle cells arranged in fascicles. The nuclei were elongated and cigar-shaped, and there was minimal nuclear pleomorphism. No mitotic figures were seen (Figure 3). Immunohistochemistry was positive for smooth muscle actin (SMA) and desmin and negative for CD117.

With a preoperative diagnosis of rectal LM, the mass was removed by local excision with preservation of the rectum. The patient is currently in the 12th mo of follow-up, and has no signs or symptoms of relapse.

### DISCUSSION

Primary LMs present most commonly in the female genital tract and as skin lesions. This tumor is seldom encountered in the gastrointestinal tract. The most common localization is the stomach, followed by the small intestine. The colon, rectum and esophagus are less likely sites. LM of the anorectal region represent 3% of all gastrointestinal LM, and less than 0.1% of rectal tumors<sup>[1-6]</sup>.

Most reported LMs are sessile intraluminal or intramural tumors. They can also present as pedunculated extra luminal mass of the colon<sup>[7]</sup>. LM often remain asymptomatic until they have reached a fairly large size. The clinical manifestations of these smooth muscle

Figure 1 Endoscopic view of a polypoid, submucous, ulcerated lesion in its vertex.

Figure 2 Endoanal ultrasound scan showing a mass located in the anterior wall of the rectum.

tumors depend on the location, size and direction of tumor growth. They include intestinal obstruction, hemorrhage, and perforation into the peritoneal cavity.

Intraluminal lesions can be detected earlier because of the earlier presentation of symptoms. Many of these tumors are discovered incidentally on routine endoscopic examination of the large bowel. Endoscopically, these tumors can present as pedunculated intramural or intraluminal polyps, and they may look like the more usual adenomas. Complementary investigation, such as with computed tomography, endoscopic ultrasonography, and magnetic resonance imaging, strongly corroborates the diagnosis. Endorectal ultrasound can help to define the extent of disease and may be a useful adjunct in deciding about the appropriate surgical procedure<sup>[8]</sup>.

The biological behavior of smooth muscle tumors varies from benign to locally aggressive and highly malignant. The biological behavior may not be reflected by the histology, as even benign-looking smooth muscle tumors may metastasize. Thus, a combination of site, tumor size, histological appearance and mitotic count give the best prediction of behavior<sup>[9]</sup>.

LM should be separated from gastro-intestinal stromal tumors (GISTs). LMs are positive for actin and desmin and negative for CD34 and CD117 (KIT), and

Figure 3 Microscopic findings showing a proliferation of fusiform, elongated spindle cells arranged in fascicles.

GISTs have the opposite pattern<sup>[10]</sup>. Surgical excision is the treatment of choice for most LMs. Snare polypectomy is an adequate treatment, but large LMs are believed to be best treated by surgical resection, because conventional colonoscopic resection of large and deep-seeded tumors poses a high risk of perforation<sup>[11]</sup>. Ensuring the complete removal and follow-up are necessary precautions for tumors with any atypia or mitotic activity.

## Abstract

A 48-year-old female with severe ulcerative colitis refractory to conventional therapy was referred to our facility for management. The patient showed extensive ulcerative colitis since the age of 20 years and had failed therapy with 5-aminosalicylic acid agents and azathioprine. The disease remained active despite treatment with steroids and cyclosporine. The clinical and endoscopic parameters were consistent with severe disease. Infectious precipitants were ruled out. Given the severity of the disease and in order to avoid a colectomy, we started the patient on infliximab therapy. A dramatic clinical and endoscopic response was observed and she remained in remission at the end of a 1-year follow-up period. We discuss findings in the literature regarding the use of infliximab therapy in patients with ulcerative colitis who have failed steroids and cyclosporine.

## INTRODUCTION

Infliximab is a monoclonal antibody against tumor necrosis factor alpha (TNF- $\alpha$ ) used in the treatment of Crohn's disease and ulcerative colitis. It has demonstrated efficacy in patients with moderate to severe ulcerative colitis, as well as in those with severe disease who have failed intravenous (IV) steroids<sup>[1]</sup>. According to historical data, patients with severe disease who fail IV steroids have a risk of colectomy of up to 60%. Currently, there are three therapeutic options: cyclosporine, infliximab and colectomy<sup>[2]</sup>. Such patients are often treated empirically with cyclosporine or infliximab. If the patient fails to respond to either, colectomy is typically performed. Using infliximab to treat patients who have failed steroids and cyclosporine is controversial, since the risk of opportunistic infection is considered to be high. We report a case in which infliximab was safely introduced and successfully used in a patient with severe ulcerative colitis who would otherwise have undergone colectomy.

## CASE REPORT

A 48-year-old female with ulcerative colitis presented to our facility for the management of refractory disease. She had extensive ulcerative colitis since the age of 20 years and had a number of flares requiring IV and oral (PO) steroids, having failed 5-aminosalicylic acid agents. In the prior 6 mo, the patient had been treated with azathioprine at 2 mg/kg per day and both IV and subsequent PO cyclosporine (8 mg/kg per day). She was referred for further management as she was passing in excess of six stools per day, as well as presenting bloody diarrhea and abdominal pain. She had severe anemia, with repeated need for blood transfusions. Sigmoidoscopy confirmed active ulcerative colitis (Figures 1 and 2). This clinical spectrum was despite current therapy with cyclosporine and azathioprine.

At the time of presentation, her blood pressure was 160/100 mmHg, with a pulse rate of 150 bpm, and an intense generalized abdominal pain. She had a white blood cell count of  $161\,000/\text{mm}^3$ , hematocrit of 13%, hemoglobin of 5.0 g/dL, erythrocyte sedimentation rate of 130 mm in the first hour, C-reactive protein of  $> 5\text{ mg/dL}$ , iron of 10 mg/dL, albumin of 2 g/dL, and alpha 1-acid glycoprotein of 230 mg/dL. A colonoscopy revealed severe ulcerative colitis extending from the rectum (Figure 1). Biopsies confirmed chronic active colitis.

Figure 1 Rectal view during treatment with azathioprine.

Figure 3 Colonoscopy: Rectal view after 18 mo of treatment with infliximab.

Figure 2 Colonoscopy: Sigmoid view during treatment with azathioprine.

Figure 4 Colonoscopy: Sigmoid view after 18 mo of treatment with infliximab.

Table 1 Laboratory test results by treatment regimen

	Azathioprine	Cyclosporine	Infliximab (after 18 mo of treatment)
Hemoglobin, g/dL	5.0	8.0	13.0
Hematocrit (%)	13	19	40
Erythrocyte sedimentation rate, mm in the first hour	130	230	7
Albumin, g/dL	2	2.5	3.5
Iron, mg/dL	10	15	55
$\alpha$ -1 glycoprotein, mg/dL	230	245	< 100
C-reactive protein, mg/dL	> 5	> 5	< 5

After 18 mo of infliximab treatment, the patient was in remission, with one stool per day and no abdominal pain. A repeat colonoscopy demonstrated marked endoscopic improvement (Figures 3 and 4). There was a dramatic improvement in the overall nutritional status of the patient and in the serum levels of all parameters, as shown in Tables 1 and 2. She remained in remission on maintenance infliximab and azathioprine at the last assessment.

## DISCUSSION

Refractory ulcerative colitis is currently defined as an inadequate response to conventional treatment. In cases of ulcerative colitis, the symptoms used to determine whether an individual is refractory to treatment include

Table 2 Mayo scale score for ulcerative colitis by treatment regimen

	Azathioprine	Cyclosporine	Infliximab
Frequency of evacuations	3	3	0
Rectal bleeding	3	3	0
Endoscopic findings	3	3	0
Overall medical evaluation	3	3	0

fever, diarrhea three or more times per day, bleeding, and fecal urgency<sup>[3]</sup>. Immunomodulators, such as azathioprine, have been used as adjuvant therapy in patients with ulcerative colitis who are classified as non-responders to oral steroids, the recommended initial dose being 2 mg/kg per day, which can be gradually increased if a satisfactory response is not achieved<sup>[4]</sup>.

Cyclosporine has been used in refractory patients, as well as in patients classified as non-responders, who typically present extensive or severe colitis. For such patients, treatment with cyclosporine appears to control the disease in approximately 90% of cases<sup>[5-8]</sup>. In the present case, the patient did not exhibit a sustained response to cyclosporine, and there was recurrence within 1 mo, at which point infliximab was initiated.

Infliximab, a chimeric monoclonal antibody to TNF- $\alpha$ , was originally believed to bind biologically active TNF- $\alpha$  freely present in the lamina propria and expressed on inflammatory cells. However, it soon became clear that this binding phenomenon had to be

followed by complement binding and activation, leading to apoptosis of the activated inflammatory TNF- $\alpha$ -bearing cells, as well as inducing apoptosis of T cells<sup>[9-11]</sup>.

In two large-scale studies, designated Active Ulcerative Colitis Trial 1 and Active Ulcerative Colitis Trial 2, patients with ulcerative colitis were treated with infliximab, together with corticosteroids or the 6-mercaptopurin/azathioprine combination, and were monitored/evaluated using the Mayo scale<sup>[12,13]</sup>. The authors found that the rate of remission was higher in patients treated with infliximab than in those receiving placebo.

Currently, the use of infliximab in patients with ulcerative colitis is recommended for those with corticosteroid dependence, refractory pouchitis and pouchitis in the maintenance phase, although there is still controversy regarding the appropriate duration of treatment<sup>[14,15]</sup>. Treating patients with infliximab after failing steroids and cyclosporine is controversial, as one study reported a serious adverse event rate of 15%, due to opportunistic infections<sup>[16-18]</sup>. In the case described here, we opted to maintain the infliximab, taking into account the quality of life that could be sustained without surgical intervention. The patient remained under treatment with infliximab every 8 wk for 2 years, at a dose of 5 mg/kg without adverse events and recurrence of the symptoms.

the small bowel appeared to be associated with the cancer development. Previous reports suggest the risk of SBA in patients with CD is higher than in the overall population. Since early diagnosis is extremely difficult in these cases, novel techniques, such as PET/CT and DBE, may be expected to help in making a preoperative diagnosis of the development of SBA in CD.

## Abstract

Small bowel adenocarcinoma (SBA) in patients with Crohn's disease (CD) is quite rare, difficult to diagnose without surgery, and has a poor prognosis. Here, we report a 48-year-old man with SBA and a 21-year history of CD who was diagnosed by a combination of positron emission tomography/computed tomography (PET/CT) and double-balloon enteroscopy (DBE). Since the age of 27 years, the patient had been treated for ileal CD and was referred to our hospital with persistent melena. Multiple hepatic tumors were found by CT. PET/CT detected an accumulation spot in the small bowel. DBE revealed an ulcerative tumor in the ileum about 100 cm from the ileocecal valve. An endoscopic forceps biopsy specimen showed poorly differentiated adenocarcinoma. There were some longitudinal ulcer scars near the tumor, and the chronic inflammation in

## INTRODUCTION

Previous studies have documented that patients with inflammatory bowel disease (IBD) are at increased risk of developing colorectal and intestinal cancer<sup>[1-6]</sup>. However, because of its rarity, there is limited data on the precise cancer risk of small bowel adenocarcinoma (SBA) in patients with Crohn's disease (CD). To date, recommendations for screening and surveillance have been supported by very limited data<sup>[7]</sup>. Even in extensive colitis, a recent report found that colonoscopy surveillance may not improve survival<sup>[8]</sup>, and other tools are needed to detect cancer development in the early stages. Here, we report a patient with a 21-year history of CD who developed a SBA that was detected by 18F-fluorodeoxyglucose (FDG) positron emission

tomography/computed tomography (PET/CT) and double-balloon enteroscopy (DBE) without conventional intestinal examinations.

## CASE REPORT

A 48-year-old man who was diagnosed with ileal CD as a 27-year-old was referred to our hospital with persistent melena. His family history was negative for this disease. He had no evidence of gluten intolerance. He had been treated with 5-aminosalicylates (5-ASAs) combined with an elemental-diet (ED) therapy and had several hospitalizations for temporary melena in the past two decades. He had not agreed to have an intestinal examination at regular intervals. In January 2007, he was examined by abdominal CT due to persistent melena for 1 year, and multiple metastatic tumors were discovered in the liver (Figure 1A). Blood tests showed a slight anemia (Hb 11.8 g/dL), but he was negative for inflammatory factors. The serum carcinoembryonic antigen (CEA) was elevated (31.6 ng/mL; normal range, < 2.5 ng/mL), and wall thickening in part of the ileum was detected by CT (Figure 1B). PET/CT showed accumulations in the multiple hepatic tumors and the wall thickening of the ileum (Figure 2). DBE showed an ulcerative tumor in the ileum about 100 cm away from the ileocecal valve (Figure 3A). There were some longitudinal ulcer scars near the tumor (Figure 3B). An endoscopic forceps biopsy specimen showed microscopically poorly-differentiated adenocarcinoma (Figure 4A and B). Immunohistochemistry of the tumor cells was negative for p58 and positive for  $\beta$ -catenin (Figure 4C and D). Accordingly, he was diagnosed with SBA with hepatic metastases. Although he was treated by chemotherapy with S-1 and cisplatin (CDDP), there was no effective response. He died 4 mo after the diagnosis because of liver failure due to progression of the hepatic metastases.

## DISCUSSION

Primary SBA is rare and the incidence is reported to be 1 to 5% of all gastrointestinal tract malignancies<sup>[9,10]</sup>, and the most important known risk factor for this malignant tumor is previous CD<sup>[5,11]</sup>. SBA in CD was reported for the first time by Ginzburg in 1956<sup>[12]</sup>. The risk for SBA is reportedly higher in patients with CD than in the overall population. Recent meta-analysis revealed the relative risk of SBA in patients with CD as 28.4 (95% CI, 14.5-55.7)<sup>[13]</sup> to 33.2 (95% CI, 15.9-60.9)<sup>[14]</sup>. In clinical settings, SBA in CD is difficult to diagnose, and most previous cases were diagnosed after surgery without suspicion of malignancy. Therefore, novel tools are needed to detect and survey the development of this cancer. In our case, we were able to diagnose SBA non-surgically by a novel approach using PET/CT and DBE.

Based on previous reports, Dossett *et al*<sup>[3]</sup> summarized the 154 cases of SBA in CD reported in Europe and America. SBA in CD occurred more frequently in males than females (M:F ratio of 2.4:1). The age at diagnosis

**Figure 1** CT findings. A: Abdominal CT showed the multiple hepatic tumors with ring enhancement; B: Wall thickening of a part of the small bowel (arrow).

**Figure 2** PET/CT findings. A: Wall thickening of a part of ileum (arrow). B: PET/CT showed <sup>18</sup>F-FDG accumulation in the site of wall thickening of ileum (arrow).

ranged from 21 to 86 years (mean age, 51.3), and the average duration of CD was 24.5 years (0-45 years)<sup>[3]</sup>. SBA in CD was observed at a younger age<sup>[11]</sup> as compared

**Figure 3** DBE findings. A: DBE showed ulcerative mass located in the ileum at about 100 cm away from ileocecal valve; B: Some longitudinal ulcer scars near the tumor.

with *de novo* cancers that were found in 60-69-year-olds<sup>[15]</sup>. Tumors were found in the ileum at a rate of 75%. The presence of previously bypassed segments of the intestine was 20.3%. Obstruction was the most common manifestation (76%), whereas hemorrhage, fistula, and perforation were observed in 3.9%, 3.9%, and 5.4% of cases, respectively. The majority of diagnoses were made at the time of operation (35.4%) or postoperatively (61.5%). Only 3.1% of the cases could be diagnosed preoperatively. Survival rates after 1 and 2 years were 49.6% and 27%, respectively<sup>[3]</sup>.

In the present case, there were some longitudinal ulcer scars near the tumor, suggesting that chronic inflammation is associated with the development of SBA. Because it is well known that a combination of immunohistochemically strong p53 expression and absent or weak  $\beta$ -catenin expression in ulcerative colitis (UC) patients is evidence for colitis-associated dysplastic lesions<sup>[16]</sup>, we examined the immunohistochemical characteristics of the tumor<sup>[17]</sup>. In this case, there was no detectable p53 expression, but strong  $\beta$ -catenin expression. Chemotherapy and radiation for SBA have produced disappointing results, and only a few studies have evaluated chemotherapy for unresectable SBA in CD<sup>[18]</sup>. There have been no controlled studies recommending an effective treatment regimen. Although we treated this patient by systemic chemotherapy with S-1 and CDDP in agreement with the patient, the therapy was not effective and did not seem to prolong the survival time.

**Figure 4** Histopathological findings of the biopsy specimen showed poorly differentiated adenocarcinoma. A: HE ( $\times 100$ ), B: HE ( $\times 400$ ), C: Immunohistochemical staining using  $\beta$ -catenin antibody ( $\times 100$ ), D: Immunohistochemical staining using p53 antibody ( $\times 100$ ).

There are several previous reports of long-standing risk factors for SBA, including onset of the disease before the age of 30 years, presence of a bypassed segment, chronic active course with stricture and fistulas, male gender, and smoking<sup>[1-3,5,11,19-21]</sup>. Corticosteroid and

azathioprine therapy to treat CD are also considered potential risk factors. However, 5-ASAs prevent the development of intestinal adenocarcinoma in IBD<sup>[1,22-25]</sup>. There is also a theoretical risk for an increased rate of malignancies due to antagonism of TNF- $\alpha$ , but to date, there is no clear proof of such an effect<sup>[26,27]</sup>.

Recommendations for screening and surveillance of SBA in CD have been supported by only very limited data<sup>[8]</sup>. The overall risk of colorectal cancer for UC patients is estimated to be 3.7% (95% CI, 3.2%-4.2%); 2% at 10 years, 8% at 20 years, and 18% at 30 years<sup>[28]</sup>, whereas reported cancer in CD is 0.63%-3.1%<sup>[29]</sup>. Although diagnostic investigations using conventional modalities such as small bowel series, double-contrast enteroclysis, and upper and lower gastrointestinal endoscopies have been performed on patients with a high cancer risk, a recent report found that colonoscopy surveillance may not improve survival even in studying extensive colitis, thus other tools are needed to detect cancer development<sup>[8]</sup>. CT and MRI are now considered the common imaging modality of choice for abdominal malignancy. Endoscopy of the small intestine, especially capsule endoscopy and DBE, are promising new diagnostic tools<sup>[30]</sup>. Capsule endoscopy is not invasive, but has a risk of retention for patients with CD who have a stenosis in the intestinal tract<sup>[31,32]</sup>. DBE is a new endoscopic method that provides complete visualization, the ability to biopsy the small bowel, and provides diagnostic and therapeutic information<sup>[33]</sup>.

In this case, PET/CT was effective for the discovery of a small bowel tumor at the initial examination. Although the localization of lesions may not be completely accurate, PET/CT provides accurately fused morphological and functional imaging within a single examination. Today, PET imaging has a high sensitivity for detecting colorectal cancer (CRC) and is superior to conventional CT staging when CRC patients are assessed for local and distant metastases<sup>[34,35]</sup>. PET/CT also offers a better non-invasive tool for identifying and localizing active intestinal inflammation in patients with CD<sup>[36]</sup>. Although PET/CT is not able to replace conventional studies due to its high cost, it may be useful when conventional studies cannot be performed or are not completed in CD patients. In this case, the tumor was detected at an advanced stage with multiple liver metastases. Although it is still uncertain whether combining PET/CT and DBE will enable us to make an early diagnosis for SBA, this case certainly indicates the possibility of combining PET/CT and DBE without conventional modalities, such as a small bowel series, to detect a primary malignant tumor of the small bowel without surgery. One strategy to monitor high-risk patients might be to perform PET/CT at an initial examination, and then conduct a DBE examination for the patient who has abnormal regions suspected as being malignant.

The recent development of innovative imaging techniques involving PET/CT and DBE has opened a new area in the exploration of the small bowel in CD patients. Each of these techniques is characterized by

its own profile of favorable and unfavorable features<sup>[30]</sup>. Future clinical studies are expected to demonstrate strategies to monitor SBA in CD patients.

### Abstract

We report the successful treatment of multiple lung metastases after hepatic resection for hepatocellular carcinoma (HCC) with combined docetaxel, cisplatin (CDDP), and enteric-coated tegafur/uracil (UFT-E). A 68-year-old man was diagnosed with multiple lung metastases of HCC 7 mo after partial hepatectomy for HCC. Oral UFT-E was given daily and docetaxel and CDDP were given intra-arterially (administered just before the bronchial arteries) every 2 wk *via* a subcutaneous injection port. One month after starting chemotherapy, levels of tumor marker, protein induced by vitamin K absence II (PIVKA-II), decreased rapidly, and after a further month, chest X-ray and computed tomography revealed the complete disappearance of multiple liver metastases. Two years after the combined chemotherapy, HCC recurred in the liver and was treated but no pulmonary recurrence occurred. In the absence of a standardized highly effective therapy, this combined chemotherapy with docetaxel, CDDP and UFT-E may be an attractive option for multiple lung metastases of HCC.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is the sixth most common cancer worldwide<sup>[1]</sup>. Prognosis has been improved by careful follow-up of the high-risk patient, progress in diagnostic techniques, and combined modality therapy such as surgery, chemotherapy including transarterial chemoembolization (TACE), percutaneous ethanol injection therapy, and radiofrequency ablation. While recurrence of HCC is generally intrahepatic, long-term therapy increases the risk of extrahepatic metastases, and more than 50% of these occur in the lung<sup>[2,3]</sup>. While the most effective therapy for lung metastasis is surgical resection<sup>[4-7]</sup>, Kawamura *et al*<sup>[5]</sup> reported that only 2.6% of patients with lung metastases can undergo this type of surgery. Most patients are not deemed suitable because of multiple lung metastases, uncontrolled intra-hepatic HCCs, and deterioration in liver function. Since the prognosis of extrahepatic tumors is poor, options are limited to palliation for many people. Most people will be forced to depend on the few available chemotherapy protocols suitable for this situation; there is no standardized effective chemotherapy regime. A recent pilot study found that S-1, a novel oral dihydropyridine dehydrogenase

(DPD) inhibitor, and interferon-alpha (IFN- $\alpha$ ) were associated with objective response in three of 12 patients with lung metastasis of HCC<sup>[8]</sup>. Accumulation of such reports may lead to a standard therapy being confirmed in the future. Ishikawa *et al*<sup>[9]</sup> previously reported combined chemotherapy with docetaxel, combined docetaxel, cisplatin (CDDP) and enteric-coated tegafur/uracil (UFT-E) for lung metastases of HCC. This chemotherapy regime was effective for lung metastases of HCC but not for the primary hepatic lesion; however, the reasons for this difference remain unknown. We report a case in which multiple lung metastases of HCC were completely resolved by modified combined chemotherapy with docetaxel, CDDP and UFT-E.

## CASE REPORT

A 68-year-old man diagnosed with multiple lung metastases of HCC was admitted to Saiseikai-Niigata Daini Hospital in February 2006. He had undergone right hepatic lobectomy to remove three hepatocellular carcinomas (6 cm, 5 cm and 4 cm in diameter) 7 mo before the admission. Pathological diagnosis was moderately differentiated HCC, and clinical stage at the time of surgery was stage IVa according to the TNM classification. Tests for hepatitis B and C viral markers were all negative, but examination of the resected liver indicated cirrhosis, possibly caused by alcohol. Liver function test disclosed the following values: alanine aminotransferase 137 IU/L, alkaline phosphatase 503 IU/L, serum albumin 4.4 g/dL, and PT-INR 1.19 (Child-Pugh class A). While there was no elevation of tumor marker alpha-fetoprotein (4.3 ng/mL), protein induced by vitamin K absence II (PIVKA-II) was markedly elevated at 6280 mAU/L. Chest X-ray and computed tomography (CT) showed at least 50 metastases spread diffusely throughout the lungs (Figure 1). Since no treatment guidelines were available, we modified the combined chemotherapy with docetaxel, CDDP and UFT-E reported by Ishikawa *et al*<sup>[9]</sup> after obtaining informed consent. First, 400 mg/d of oral UFT-E was started. We then placed an intra-arterial catheter that delivered medication into the aorta just before the bronchial arteries, and docetaxel (80 mg/body initially, followed by 40 mg/body) and CDDP (50 mg/body initially, followed by 20 mg/body) were administered every 2 wk *via* a subcutaneous injection port (Figure 2). This was performed on an outpatient basis from the third injection. The serum level of PIVKA-II decreased 1 mo after starting chemotherapy and normalized after 4 mo. Two months after starting chemotherapy, chest X-ray and CT showed complete disappearance of the lung metastases (Figure 1). Adverse events during the therapy were grade 3 leukocytopenia (minimum white blood cell count was 2500/ $\mu$ L), grade 2 fatigue and anorexia, and grade 1 alopecia according to Common Terminology Criteria for Adverse Events v3.0 (CTCAE). Therapy was stopped after the fourth administration and only UFT-E was continued, in accordance with the patient's wishes. This was also stopped 5 mo after starting chemotherapy, when chest X-ray and CT remained

**Figure 1** Chest X-ray and CT images before and after chemotherapy (A-H). Seven months before the chemotherapy, huge multiple HCCs were apparent in the right lobe of the liver (A, B). On admission before chemotherapy, multiple lung metastases were seen in the bilateral lung fields (C, D). Two months after starting chemotherapy, the multiple lung metastases had disappeared completely (E, F). Five months after starting chemotherapy, the tumors had not recurred (G, H).

negative. Approximately 2 years after hepatic surgery, HCC reappeared in the liver and was treated with TACE; however, lung metastasis did not recur. The patient remains well and is being followed-up as an outpatient.

## DISCUSSION

The most effective therapy for lung metastasis of HCC is thought to be pulmonary resection<sup>[4-7]</sup>, and this has been reported to prolong life in some cases<sup>[10]</sup>. However, the present patient was unsuitable for pulmonary resection because of multiple lung metastases. Reports of chemotherapy for lung metastasis of HCC are rare and most are case reports, indicating the absence of a highly effective standard therapy. Nonetheless, the literature contains reports of successful treatment of lung metastasis of HCC using tegafur/uracil<sup>[11]</sup>, 5-fluorouracil (5-FU) + IFN<sup>[12]</sup>, and 5-FU + CDDP + IFN<sup>[13]</sup>. Moreover, a pilot study of S-1 and IFN- $\alpha$  in patients with pulmonary metastases of HCC showed that three of 12 patients responded objectively<sup>[8]</sup>. There is also a report of the complete disappearance of multiple lung metastases with combined chemotherapy with docetaxel, CDDP and UFT-E<sup>[9]</sup>. In the present case, multiple lung metastases also disappeared in response to modified

**Figure 2** Clinical course of this patient. First, 400 mg/d of oral UFT-E was started. We then placed an intra-arterial catheter that delivered medication into the aorta just before the bronchial arteries, and docetaxel (80 mg/body initially, followed by 40 mg/body) and CDDP (50 mg/body initially, followed by 20 mg/body) were administered every 2 wk via a subcutaneous injection port. Levels of PIVKA-II, a tumor marker, decreased rapidly 1 mo after starting chemotherapy; levels continued to fall to normal and were maintained.

combined chemotherapy with docetaxel, CDDP, and UFT-E, suggesting that the effects of this combined chemotherapy are reproducible. We chose to modify the original intravenous combined chemotherapy including the docetaxel dose (original recommended dose was 60 mg/m<sup>2</sup> of docetaxel, 80 mg/m<sup>2</sup> of CDDP on day 1 and 400 mg/m<sup>2</sup> per day of tegafur/uracil in consideration of adverse effects<sup>[9]</sup>. This original dose was determined by modifying the regime for advanced lung cancer<sup>[14]</sup>) since two patients who received this could not be treated effectively because of adverse events attributed to docetaxel (personal communication). To reduce the adverse events and increase treatment efficacy, we used an intra-arterial catheter that delivered medication to just before the bronchial arteries. In this way, docetaxel and CDDP could be administered in high concentration to the lung.

The precise mechanisms underlying the effectiveness of this therapy for lung metastasis of HCC are not known. It has been reported previously that the growth inhibition of hepatoma cells induced by docetaxel was mediated through G2/M-phase arrest, caspase activation and DNA fragmentation<sup>[15]</sup>. It is uncertain whether a single drug is sufficient, whether combinations of these agents are necessary, or whether docetaxel is the key drug. Furthermore, we do not know whether repeated doses or administration *via* the intra-arterial route improved the outcome for this patient. Further study is needed into the tumor characteristics of lung metastasis and immune responses in patients such as this one. While many issues must be resolved, this report is the second to document the effectiveness of combined chemotherapy with docetaxel, CDDP and UFT-E for lung metastasis of HCCs. This suggests that the present regime could be useful in this situation, as no highly effective standard therapy has been reported.

## Abstract

Gastric teratoma (GT) is a seldom seen congenital abnormality. GT always occurs in children. The greater curvature and posterior wall of the stomach are the most common sites involving GT. We diagnosed a case of GT located on the inferior wall of the cardiac orifice in a 20-year-old man. To the best of our knowledge, this is the first case of GT located on the wall of the cardiac orifice in an adult in the English literature. We report this unusual case as an addition to this rare disease usually found in children. Computed tomography combined with endoscopic ultrasonography can be selected to diagnose GT.

## INTRODUCTION

Gastric teratoma (GT) is a seldom seen congenital abnormality. It has been reported in the world literature that GT always occurs in children<sup>[1,2]</sup>, and an increasing mass in the epigastric region is the main sign of GT<sup>[1,3,4]</sup>. Only six cases of GT in adults were reported in Medline<sup>[5-8]</sup> between 1922 and 2007. Yoon *et al*<sup>[9]</sup> reported the second case of GT in a child in Korea in 2000. GT is usually located on the posterior wall or greater curvature of the stomach<sup>[3,7]</sup>. To the best of our knowledge, this is the first report of GT located on the wall of the cardiac orifice in an adult in the English literature. Calcifications in the cystic-solid mass may be features of GT on computed tomography (CT)<sup>[3,4,10]</sup>. Endoscopic ultrasonography (EUS) may help to correctly diagnose GT before surgery.

## CASE REPORT

The patient was a 20-year-old man. Due to slight pain and distention of the upper abdomen of 3 mo duration, he was admitted to our hospital. Physical examination was carried out and no mass was found in the epigastrium. The level of serum alpha-fetoprotein (AFP) was normal. CT showed a spherical mass on the inferior wall of the cardiac orifice of the stomach. The mass was about 4.8 cm × 5.2 cm, and there was no clear border between the mass and the wall of the stomach. The density of the mass was uneven. High-density and low-density substances were found in the mass (Figure 1). EUS demonstrated a giant mass on the inferior wall of the cardiac orifice. The mucosa of the mass was normal (Figure 2), and there was a lobulated polyp near the mass. The five-layer structure of the stomach was clearly manifested in the mass on ultrasonography (Figure 2). The mass had formed from the outer layer of the stomach. The mass was completely excised with a partial gastrectomy and the digestive tract was rebuilt. Macroscopically, the mass was about 5.0 cm × 5.3 cm × 2.3 cm, and was derived from the inferior wall of the cardiac orifice (Figure 3A). The mass contained small cystic tissue and a large solid area. Microscopically, the tumor was resected completely in one piece with a tumor cell-free margin. Cartilage, squamous cells and respiratory epithelium were observed in the mass (Figure 3B-F). No immature tissue was observed in the mass. The diagnosis of a primary mature GT derived from the cardiac orifice was established. The syndromes

Table 1 Five reported cases of GT in Medline between 1922 and 2007

Author (yr)	Age (yr)	Signs and symptoms	Location	Type	Size
Eustermann <i>et al</i> <sup>[6]</sup> 1922	31	?	Posterior wall	Mature	7 cm × 6 cm × 5 cm
Fadeeva <i>et al</i> <sup>[12]</sup> 1960	25	?	Anterior wall	Mature	4 cm × 3 cm
Gray <i>et al</i> <sup>[8]</sup> 1964	40	?	Lesser curvature	Mature	7 cm × 6 cm
Matsukuma <i>et al</i> <sup>[5]</sup> 1995	83	Tarry stool and anemia	Lesser curvature	Immature	12 cm × 10 cm × 6 cm
Joo <i>et al</i> <sup>[7]</sup> 1999	27	Fever, pain and vomiting	Greater curvature	Mature	9.5 cm × 7.5 cm × 5 cm

Note: Five patients were all male. Complete resection of the tumor was carried out in all patients and all patients recovered.

**Figure 1** Axial CT shows a large soft tissue mass located on the inferior wall of the cardiac orifice of the stomach. The border of the mass is clear and the mass is from the stomach. The density of the mass is uneven. Low density (white arrow) indicates cystic tissue and the high density (black arrow) indicates calcifications.

in this patient disappeared within 1 wk after surgery. In the 10-mo follow-up period, the patient was well without abdominal discomfort.

## DISCUSSION

Teratoma usually occurs in the gonads (mainly between the age of 6 mo and 15 years), the sacrococcygeal region (mainly in infants)<sup>[1,2]</sup>, and in the retroperitoneum, cranium or mediastinum<sup>[5]</sup>. Teratoma derived from the stomach is very rare, and was first reported by Eustermann and Sentry in 1922<sup>[6]</sup>. Up to 2002, only 107 cases of GT had been reported in the English literature<sup>[1]</sup>. Surprisingly, GT always occurs in male children, especially around the age of 1 year<sup>[1-3,5,11]</sup>. GT in an adult is unusual. To the best of our knowledge, there were just six cases of GT in adults reported in MEDLINE between 1922 and 2007, and five of these cases are listed in Table 1<sup>[5-8,12]</sup>. GT is commonly located on the greater curvature and the posterior wall of the stomach<sup>[3,7]</sup>. In the five cases listed in Table 1, two cases originated from the lesser curvature, and three cases from the posterior wall, anterior wall and the greater curvature, respectively. To the best of our knowledge, we report the seventh case of GT in an adult in the English literature and the first case originating from the cardiac orifice. Partly because of the rarity of GT in adults, the preoperative diagnosis of GT is difficult for surgeons<sup>[7]</sup>.

**Figure 2** EUS was used to diagnose the gastric teratoma. A: A spherical mass was noted on the inferior wall of the cardiac orifice, and the mass mucosa was normal; B: The heterogeneous mass was formed from the outer layer and the five-layer structure of the stomach in the mass was clearly detected (white arrow).

Typical radiographic findings of GT<sup>[3,4,10]</sup>, such as calcifications, uneven density of the tumor and an intratumoral solid area with mixed cysts, were predominant in our case (Figure 1). EUS was first used to diagnose GT. A mass from the inferior wall of the cardiac orifice was observed. EUS demonstrated a heterogeneous mass from the outer layer of the stomach, and the five layers of the stomach were clearly detected (Figure 2). The echo pattern in the mass and the mass from the outer layer of the stomach were different from those of other common submucosal tumors, such as lipoma, myogenic tumor and lymphangioma. The use of EUS alone cannot help to diagnose GT qualitatively, but could provide useful information for preoperative diagnosis.

Cartilage, squamous cells and respiratory epithelium were found histologically (Figure 3F). According to pathological criteria, cartilage, squamous cells and respiratory epithelium in the mass are interesting

**Figure 3** GT was pathologically examined under macroscopy and microscopy. A: The mass was about 5.0 cm × 5.3 cm × 2.3 cm, and it derived from the inferior wall of the cardiac orifice; B: Photomicrograph of an area composed respiratory epithelium and cartilage without immature teratoma components (HE, × 20); C, D: The cartilage (C) and the respiratory epithelium (D) were amplified (HE, × 100); E: The three layers, mucous layer, submucous membrane, and muscular layer, of the wall of the stomach were clear. The tissue of GT was derived from the muscular layer of the stomach (HE, × 20); F: The Squamous cell was amplified (HE, × 100).

histological features of teratoma. The diagnosis of GT from the cardiac orifice was therefore exclusively established. Complete resection is an effective method to treat both benign and malignant GT. Compared to traditional surgery, laparoscopic surgery has many advantages, and has been used to treat teratomas<sup>[13]</sup>, and will be used to treat GT in the future. AFP is a good indicator of the recurrence of malignant GT<sup>[1,3,11]</sup>. Subsequent chemotherapy might be required when the level of AFP is high after surgery.

In conclusion, GT is rare and always occurs in infancy or childhood. The greater curvature and the posterior wall of the stomach are the most common sites involving GT. GT involving the cardiac orifice in an adult is seldom seen. To the best of our knowledge, this is the first report involving GT on the cardiac orifice in the English literature. EUS is helpful in diagnosing GT.

### Abstract

There is a growing number of case reports of hepatotoxicity from the widely marketed weight-loss supplement Hydroxycut, which contains the botanical ingredient *Garcinia cambogia*. These case reports may substantially undercount the true magnitude of harm. Based on the past experience with harmful dietary supplements, US regulators should assume the more precautionary approach favored by Canada and Europe. Lacking effective adverse event surveillance for supplements, or the requirements to prove safety prior to coming to the market, case reports such as those summarized here assume added importance.

### TO THE EDITOR

Dara *et al*<sup>[1]</sup> report on a case series of two patients with hepatotoxicity associated with the weight-loss

supplement Hydroxycut, so named because it contains potentially hepatotoxic hydroxycitric acid derived from the tropical fruit *Garcinia cambogia*<sup>[1]</sup>. Two earlier case reports in 2005 were also referenced<sup>[2]</sup>. To this count should be added two additional case reports of hepatotoxicity associated with Hydroxycut<sup>[3,4]</sup>. An estimated 15% of the US population uses dietary supplements for weight loss<sup>[5]</sup>, and Hydroxycut is the top selling product in this class and market, with roughly a million units sold per year<sup>[6]</sup>. With such wide usage, these six cases may underestimate the true incidence of hepatotoxicity by several degrees of magnitude.

Each case report has similarities both in reported liver screening abnormalities and symptoms reported by patients, all of whom were otherwise healthy and experienced normalized hepatic function once they stopped taking the supplement. Table 1 synthesizes key laboratory findings and reported symptoms.

Poor regulation of dietary supplements in the US has been noted by consumer advocates, researchers and policymakers<sup>[7-10]</sup>. US manufacturers of dietary supplements are not required to conduct trials establishing safety or efficacy prior to marketing; only provide a copy of their label for the Food and Drug Administration (FDA) to review<sup>[7,9,11]</sup>. Ingredients do not need to be considered “generally regarded as safe” as pharmaceuticals or food additives do, and the FDA must prove that a supplement is harmful before taking regulatory action<sup>[9,11]</sup>. This means consumers in effect become unwitting subjects in a large scale post-marketing trial of a product’s safety. Unfortunately, the FDA does a generally poor job of post-marketing monitoring of adverse events from supplements, only receiving reports of an estimated 1% of such events<sup>[11]</sup>. A recent search of FDA’s adverse events surveillance database for “Hydroxycut”, “hydroxycitric acid”, “*Garcinia cambogia*”, or “SuperCitrimax” (the proprietary blend of *Garcinia cambogia* used in Hydroxycut) yielded no reports<sup>[12]</sup>. Furthermore, the nation’s poison control centers, which receive far more supplement adverse event reports than the FDA, lack the necessary coordination to act in a surveillance role<sup>[11]</sup>. Supplement manufacturers may not be forthcoming with information about emerging health risks from their products. The makers of the weight-loss supplement Metabolife 356, for example, withheld over 14000 reports they had received over 5 years documenting serious adverse events associated with

their ephedra-containing product, including myocardial infarction, stroke, seizure and death<sup>[7]</sup>. (Though not legally mandated to report serious adverse events until 2007<sup>[9,11]</sup>, failure to act on such reports suggests an ethical lapse.) To be fair, the FDA has taken action to protect the public health from dangerous supplements, banning ephedra in 2004 due to its cardiac risk<sup>[13]</sup>. Formerly a common ingredient in numerous weight-loss supplements, ephedra was banned only after 155 deaths were associated with its use<sup>[14]</sup>. In contrast, regulators in Canada, the UK and Europe appear to take a more precautionary approach. The supplement kava-kava was banned in Canada in 2002 after 29 cases of hepatotoxicity were associated with its use<sup>[15]</sup>, and in the UK and Europe the following year after some 40 more cases were reported<sup>[16]</sup>. In the US, the FDA has issued a consumer advisory about possible hepatotoxicity associated with kava-kava use, but has not banned the substance<sup>[17]</sup>.

Faced with the aforementioned difficulties ensuring the safety of widely used dietary supplements, reliable and transparent case reports such as those cited above assume added importance. They may also underscore the need for US regulators to adopt the more precautionary post-marketing practices of their European and Canadian counterparts. Authorities should also exercise their responsibilities to the public's health by being empowered to practise more stringent and evidenced-based regulation of these products, many of whom could be considered pharmaceuticals due to their clear pharmacological effects and potent risks<sup>[9]</sup>.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27, 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week  
<http://www.apdwcongress.org/2009/index.shtml>

October 7-11, 2009  
Boston Park Plaza Hotel and Towers, Boston, MA, United States  
Frontiers in Basic Cancer Research

October 13-16, 2009  
Hyatt Regency Mission Bay Spa and Marina, San Diego, CA, United States  
Advances in Breast Cancer Research: Genetics, Biology, and Clinical Applications

October 20-24, 2009  
Versailles, France  
Fifth International Conference on Tumor Microenvironment: Progression, Therapy, and Prevention

October 30-November 3, 2009  
Boston, MA, United States  
The Liver Meeting

November 15-19, 2009  
John B. Hynes Veterans Memorial Convention Center, Boston, MA, United States  
AACR-NCI-EORTC Molecular Targets and Cancer Therapeutics

November 21-25, 2009  
London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,  
Ocean International Center,  
No.62 Dongsihuan Zhonglu,  
Chaoyang District, Beijing 100025, China  
E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)  
<http://www.wjgnet.com>  
Telephone: +86-10-59080039  
Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee. EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### INTRODUCTION

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

### Abstract

There have been rapid developments in gastroenterology (GE) over the last decade. Up until the late 1980s, GE-training was incorporated in Internal Medicine training. The introduction of endoscopy has necessitated the need for additional training. Around the world different national boards have developed their own curricula which will be discussed in this paper. Emphasis will be placed on the curriculum recently introduced in The Netherlands. The internal medicine component has become a two-year requirement (Common Trunk) and the duration of training in GE has been extended to four years. Because of the growing complexity of GE, there are now four subspecialties: Interventional Endoscopy, Neuromotility, Oncology and Hepatology that trainees can choose from. These subspecialties each have predefined specific requirements. The World Gastroenterology Organization has drawn up a standard curriculum which can be of help to the boards in different countries. The curriculum emphasizes the knowledge and skill components. The curriculum also defines the training recommendations, the requirements of training facilities and competence evaluation of fellows and facilities, while less is said about research, finance and the number of gastroenterologists required. In the coming decades the curriculum will need to be revised continuously. Personalization of the curriculum will be the next challenge for the years to come.

### INTRODUCTION

Since the late 1960s, there have been rapid developments in the field of gastroenterology (GE). Up until the late 1980s, GE was considered a subspecialty of internal medicine, along with other subspecialties such as cardiology, pulmonology and rheumatology. However, since then, GE has become more complex, with advancements in both diagnostic and management procedures, and now incorporates hepatology. In this fast moving field, it is challenging to develop a comprehensive GE training program to enable gastroenterologists to become competent in all aspects of GE by the completion of their training program. In earlier years, one to two years of GE training was incorporated into Internal Medicine. Today, gastroenterologists have less exposure to general medicine, with more emphasis placed on GE. Endoscopy has completely revolutionized GE. In 1961, Basil Hirschowitz published the first description of flexible endoscopy of the stomach and duodenal bulb - a gastroduodenoscopy<sup>[1]</sup>.

In many hospitals, endoscopy was first introduced by performing gastroduodenoscopies in an all-purpose room. Due to the rapid development in endoscopy, it was necessary to implement training requirements. In the last decade, many national boards of GE developed their own curriculum handbook<sup>[2,3]</sup>.

Because of the world wide need to standardize procedures, we will attempt to give an overview of the different approaches to training. Our focus has been on the first world. However, developing areas, where access to high-quality training in GE is sometimes problematic, have some guidelines that are worth considering. We will also discuss the curricula of a number of countries, with emphasis on The Netherlands. Recently, the World Gastroenterology Organization (WGO) published a

document about the basic standards of a GE training program, which will be reviewed and discussed<sup>[4]</sup>.

## GENERAL

In Europe, as in many other parts of the world, GE was considered a subspecialty of internal medicine. This was and still is hampering the development of GE in advanced care and skills, especially in rapidly developing fields such as hepatology, interventional endoscopy, motility, GE-oncology and -immunology.

In the 1970s and 1980s, the majority of gastroenterologists were trained as internists, with a fellowship of one to two years in GE. In general, the fellowship focused on 'on-the-job' training in an endoscopy unit, which was necessary due to the extensive workload in the different countries by either colorectal cancer screening programs or the enormous amount of people with chronic hepatitis and other GE infections in developing countries. High-quality training in GE has been a secondary consideration and unfortunately, in most countries, a two-year fellowship in endoscopy is still the recognised standard (Table 1).

Since hepatology has been incorporated into GE, additional training seems mandatory. The duration of specific training in GE in the late 1980s and early 1990s was extended from two to three years. Recently, in some countries, including The Netherlands and the USA, GE training has been increased to four years. Training in internal medicine has now been limited to a Common Trunk. The Common Trunk is a two to three year basic training in internal medicine; similar to cardiology and pulmonology.

### United States of America

Four American GE-related societies have joined together to develop the GE curriculum. Together, they have structured the American GE Core Curriculum. Their first document was published in 1996, and thereafter an updated edition has been released every five years<sup>[2]</sup>. A detailed description of requirements in seventeen GE fields is given in the latest release, the third edition (2007). GE trainees are required to select a subspecialty<sup>[5,6]</sup>.

### United Kingdom

The British Society of Gastroenterology developed their National Training Program in a similar manner. They emphasized a comprehensive, well structured program that encourages flexibility in content and duration. The core curriculum offers various options of training in specialised fields, such as hepatology, advanced endoscopy and research<sup>[3]</sup>.

The Joint Advisory Group on GE Endoscopy (JAG) developed their programs in the late 1990s in UK. Interestingly, it defines standards of endoscopy training which are not specific to a medical specialty. JAG developed and organizes endoscopy training. This organization is responsible for the accreditation of endoscopic units and the certification of trainees. They developed the criteria for accreditation of

endoscopies: colonoscopy, endoscopic retrograde cholangiopancreatography (ERCP), data of cumulative life and year time number of procedures, complication thresholds and cecal intubation percentages *etc*<sup>[7]</sup>.

### Global standardization

Unfortunately, there is no global standardization. In contrast to these high-quality training programs, many countries have no detailed training guidelines and only specify the duration of training. The duration of basic training in internal medicine prior to training in GE varies from one to six years<sup>[8]</sup>. The duration of training in GE varies from one to four years. It is also variable as to whether there are entrance examinations, or examinations on completion of the curriculum. The European Union, a Free Labour Market, has not standardized their training in GE (Table 1).

The implementation of high-quality training in GE remains problematic. Boards such as the United European Gastroenterology Federation and the WGO should regularly collaborate and present their recommendations at the American, Pacific and World Digestive Disease Weeks. The WGO Training Centers in the developing world should focus on preventing the loss of skills from their countries, therefore lessening the impact of these losses on digestive health care in Asia, Africa and South America<sup>[9]</sup>.

## THE DUTCH MODEL FOR TRAINING IN GE

### Common Trunk

The Dutch Gastro and Hepatology Board concluded that high-quality training in GE could not be accomplished within a three year period. A working committee developed a new curriculum<sup>[10]</sup>. In 2002, the working committee extended GE training from 3 to 4 years, with two years of Internal Medicine as a Common Trunk. This Common Trunk may be completed at either a university hospital or a general hospital. At least 12 mo should be completed in a ward of internal medicine during this Common Trunk period<sup>[11]</sup>. Optional training periods can be completed in intensive care, emergency medicine, oncology or cardiology. The Board of Internal Medicine is responsible for this Common Trunk period. During the four years of training in GE, fellows may train for two years in a general hospital. Requirements include a six months rotation in the GE ward and two and a half years in outpatient care and endoscopy.

### Subspecialisation

In the fourth so called final year of training, the fellow can choose from the subspecialties as accredited by the Board. These include interventional endoscopy, neuromotility, oncology or hepatology. All the subspecialties require research, preferably resulting in the publication of at least one article in a peer-reviewed journal and, if possible, a PhD-thesis. International courses and conferences should be attended, such as the American Society of Clinical Oncology, the American Association for the Study of Liver Disease *etc*.

Table 1 Different curricula

	Duration (yr)		Minimal numbers of endoscopy					Exam		Protocols	English protocols
	Internal medicine	GE	Gastro	Colo	Abdominal			Entrance	Final		
					ERCP	Echo	EUS				
Austria	6	2	Nt	Nt	Nt	Nt	Nt	Nt	Nt	Nt	Nt
Canada	4	2	100	200	200	0	200	No	Yes	Yes	Yes
UK	2.5	2.5	200/yr	100/yr	No	No	No	Yes	No	Yes	Yes
Finland	3	3	Nt	Nt	Nt	Nt	Nt	Yes	No	No	No
Hungary	Nt	2-3	Nt	Nt	Nt	Nt	Nt	Oral	No	No	No
Iran	4	2	> 400	100-150	40-60	No	No	Yes	Yes	No	No
Italy	1	3	300	100	No	300	No	Yes	Yes	Nt	Nt
NL	2	4	300	200	100	No	100	No	No	Yes	No
Romania	2	3	> 150	100	No	No	No	Yes	Yes	No	No
South Africa	4	2	500	75	50	No	No	Yes	No	No	No

No: Not required; Nt: Not known.

### Hepatology

Training in hepatology has been well defined. During the 12 mo of subspecialisation, the fellow needs to complete at least four months liver transplant training in a certified transplantation unit. Beside these four months, the fellow must attend at least two out-patient clinics a week for four to six months and consultations in the clinics. Skills like the endoscopic treatment of esophageal varices and paracentesis are components of this subspecialisation. In some university clinics, abdominal ultrasonography will be included.

### Motility

Motility, as a subspecialty, incorporates outpatient clinic and laboratory skills in motility and neurogastroenterology, such as 24-h pH measurements. Like the other subspecialties, an article should be written and an abstract presented at an international neurogastroenterology conference.

### Oncology

Oncology training should be carried out in a hospital where at least two gastroenterologists in the team are specialised in oncology. Added emphasis is placed on interventions and rare tumors, beside the knowledge of screening and primary prevention. Special interventions like endoscopic ultrasound (EUS) must be done on a regular basis. In addition, specific fellowships in related specialties are a part of the training. The fellow is required to work for at least one month in a multidisciplinary setting. This setting should include oncologists, radiotherapeutics, pathologists and clinical geneticists. All the main surgical procedures, for example sigmoid resection and esophagogastrectomy should be observed. Interventional endoscopy is a primary skill required in the oncology subspecialisation.

### Interventional endoscopy

Another subspecialisation is interventional endoscopy. The unit where the fellow works in this sixth year should do at least 250 ERCP and 250 EUS procedures a year, as well as a minimum of 5000 endoscopies a year. During this fellowship, the candidate should perform at least 100

ERCP and 100 EUS procedures of the esophagus, and another 100 EUS procedures of the pancreas/duodenum. Experience can also be gained in endoscopic procedures for Zenker diverticulum, and in double balloon enteroscopy and endomucosal resection of the esophagus.

### Trainees

The duration of this new curriculum is thus six years on a full-time basis, with a minimum of 38 h of work and 10 h of teaching a week. Training in GE is an ongoing dynamic process and the program should be individualized if possible for each fellow. Fellows are required to keep a portfolio, so that their progress and accomplishments can be evaluated. This portfolio must include numbers of (interventional) endoscopies done, 360-degree interviews, evaluations of skills, short clinical observations, direct observations during clinical rounds, saved files of oral lectures given during courses, conferences and published articles. Management is a major part of daily practice after becoming a medical doctor (MD). This skill is slowly introduced into the program.

### WGO

The WGO Education & Training Committee formulated a document outlining the standards of GE training<sup>[4]</sup>. The WGO reviewed the composition of programs in a number of countries. They reviewed both comprehensive curricula in the USA and UK as well as curricula in developing countries, which have a number of shortcomings.

### Curriculum

The WGO curriculum includes recommendations on training standards and accreditations of institutions (Table 2). After completion of this curriculum, an MD will be a generalist in GE. Local facilities will dictate what the fellow is exposed to. Fellows may be able to include abdominal ultrasonography and/or EUS in their portfolio. In some countries, ERCP is not included in the curriculum as it is done by radiologists or surgeons. In the former Soviet-Union, endoscopy was considered a specialty independent of GE. These endoscopists are also performing bronchoscopies<sup>[12]</sup>.

**Table 2** Standard curriculum

Knowledge
Anatomy, histology, molecular biology, embryology and development of the GI tract
Physiology and pathophysiology
Pharmacology
Epidemiology
Nutrition, metabolism and endocrinology
Diagnose and evaluate patients
Timely surgery and other therapeutic interventions
Cost-effective management
Prevention
Complications and disinfection of endoscopy procedures
Educator of chronic patients and support family
Bioethics
Conduct, write and publish research
Skills
Professional principles: behavior, commitment highest standard, responsive
Effectively and efficiently
Lead multidisciplinary teams
Maintain skills in general medicine
Appropriate communications
Information-science resources
Interpret laboratory data
Interpret radiographic data
Endoscopic skills

### Training

The recommendation of the WGO is to complete three years of internal medicine (Common Trunk), before fellows enter GE. The standard training includes both knowledge and skill components that must be fulfilled (Table 2). The WGO proposes a minimum number of each procedure that must be completed by the fellow. This is in contrast with higher numbers required in the UK, The Netherlands and the USA (Tables 3 and 4). The WGO differentiates between level I and level II endoscopists. These endoscopists have different skills. Level II includes ERCP, stenting of the esophagus and colon, diagnostic laparoscopy and EUS. Techniques that are still being developed for clinical practice like natural orifice transluminal endoscopic surgery (NOTES) have not yet been included. We suggest that Level I endoscopists should also have defined training in hepatology, oncology and motility. Although we do recognise that training in endoscopy level I might be sufficient for some developing environments.

### Outpatient clinic, clinic and endoscopy

These three components form the foundation of the training required to become an all-round gastroenterologist. The WGO advises that 150 new patient contacts must be seen a year. They do not however, define how these outpatient contacts should be structured. We suggest that at least one outpatient clinic session is attended by a fellow each week.

### Trainees and trainers

WGO suggests that attitudes, experience in patient and non-patient care as well as management skills should be more precisely defined by the different societies. The

**Table 3** Endoscopic skills level I

	Numbers			
	WGO	UK	NL	USA
Esophagoduodenoscopies	100	> 200	300	130
Esophagoduodenoscopies therapeutic interventions	-	> 30	25	-
Treatment of non-variceal bleeding	20/10 active	-	-	25
Treatment of variceal bleeding	15/5 active	-	-	20
Esophageal dilation	15	-	-	20

Liver biopsy	20	-	-	-
Paracentesis	50	-	-	-
Foreign body removal	-	-	-	-
Videocapsule endoscopy	-	-	-	25

WGO states that at least three years of training in GE is required. During this time, fellows should be present in the GE training unit for at least 33 to 44 h a week. Part-time fellows who work fewer hours are required to amend the time period of their training accordingly. The most efficient and reliable manner in which to hand over patient details to doctors starting the next work shift is not detailed in the guidelines. This is a challenge for both full and part-time fellows. Such a curriculum could not be implemented if the training period for internal medicine remains at four to five years.

Training institutes require a number of components in order to deliver a comprehensive curriculum. The training team should require a ratio of one trainer to one and a half trainees. At least one trainer should be a hepatologist. Training for endoscopic procedures is graded and staged, and involves the progression from observation, to working under supervision and finally performing procedures independently. The trainer should have at least five years experience as a gastroenterologist. He or she should be a role model, participating in all gastroenterology activities including research meetings, scientific societies *etc.*

### Competency evaluation

The competence of the fellow is based on the various areas of expertise that are evaluated. A wide variety of evaluation methods are recognised around the world. These include direct observations, patient based exams, portfolios and final assessments. The WGO committee has not initiated guidelines regarding entrance and final exams. In some countries, candidates are accepted into training programs based upon results of an entrance exam. These examinations usually comprise a multiple choice format; but some centers also require clinical assessment examinations.

Table 4 Endoscopic skills level II

	Numbers			
	WGO	UK	NL	USA
ERCP	-	> 200	100	200
Sphincterotomy	-	-	25	-
Stone extraction	-	-	-	-

Complications	-	< 5%	-	-
Satisfactory completion of intended therapeutic procedure	-	> 80%	-	-
Diagnostic laparoscopy	-	-	-	-
EUS	-	-	100	150

### Research

The WGO has not, as yet, incorporated research training, despite the recognition that there has been a significant decline in the number of physicians-scientists in GE<sup>[8,13]</sup>.

In order to increase the trainees devoted to research, it is advocated to increase medical student research, and improve mentoring and funding for GE-fellows. Unfortunately, there are no available data in this regard. Training in GE should offer research opportunities with an emphasis on intestine, liver or pancreas. Up until now, the limited time in the GE curriculum hampers the participation in research. An alternative is to identify talent and increase interest among undergraduates and develop and integrate a formal undergraduate GE research program in medical school<sup>[14-16]</sup>. In The Netherlands, and especially in our department, we encourage students to complete a two year GE research program prior to entering the Common Trunk of internal medicine. Involvement in these programs unquestionably strengthens the physician-scientist pool of the future. Such programs are comparatively inexpensive as the students are a relatively inexpensive investment as they have not yet been formally trained in GE. Clinicians with scientific training will be valuable members of university and general hospitals.

### Public health

Public health care is not specifically highlighted in the WGO curriculum. Education and global standardization, is, however, emphasized in the training program. The WGO documents the importance of preventative medicine, for example colorectal carcinoma screening and viral hepatitis prevention; but no protocols are given in this regard. Going forward, further emphasis should be placed on the anagement of these public health issues.

### Finance and requirements of gastroenterologists

The burden of disease is markedly different between developing and developed countries. Thus, the numbers of gastroenterologists required and their expertise will vary. This issue has not been addressed. The reasons for this are multifactorial<sup>[17]</sup>. By way of illustration, intestinal infectious disease was the fifth leading cause of death

in South Africa, a developing country, in 2006. In The Netherlands, a developed country, diarrhoeal disease does not feature in the 10 most common causes of mortality. Colon and rectal cancer were the seventh leading cause of death in 2006<sup>[18,19]</sup>. Recently, Everhart *et al*<sup>[20]</sup> showed an increase of 35% in medical care for digestive diseases in the United States between 1998 and 2004.

The WGO committee does not give a recommendation for the numbers of gastroenterologists required in different countries. In South Africa, there is only one gastroenterologist per one million inhabitants; while in the USA there is one gastroenterologist per twenty thousand inhabitants. Similarly, there are no recommendations regarding the number of doctors required to carry out colorectal cancer screening programs. We should mention the shortage of skills in sub-Saharan Africa, for example there are no doctors performing ERCP in Nigeria.

The committee also does not outline the financial implications of new curricula<sup>[21]</sup>.

### Maintenance certification

The WGO curriculum is written to formulate a standard GE training program. Learning is on a continuum following certification, and the quality thereof is of importance. Less is known about maintaining this certification or re-validation thereof. Although many countries like the US have their own continuing medical education program, there is no proper data regarding the number of endoscopies required to maintain a licence. In The Netherlands 200 h training in five years is required and at least 100 colonoscopies, 200 gastroduodenoscopies and 30 ERCPs should be done per year. This continuing certification should be defined and evaluated in the near future.

## CONCLUSION

Reviewing all recently published papers on the subject, a new trend in training of GE fellows has been identified. In the last ten years, GE has emerged as a leading branch of internal medicine. The developments seen over this period are expected to continue, ensuring exponential growth in the discipline for years to come. A new curriculum will, therefore, need to be revised on a continuing basis. It is envisaged that GE will become more sub-specialised, although more generalised skills will also be necessary to ensure a complete service delivery in a number of areas, especially in developing countries. In the curricula written so far, little is mentioned about part-time contracts, continuing certification or special public health needs. The daily transition is something which has to be learned. Beside the part-time issues, it may also be possible to develop a flexible training program, where the length of the training is dependent on the skills of the trainee. The personalization of the curriculum for GE is the next major challenge in the curriculum, which will develop the GE in the coming years.

## Abstract

5-aminosalicylate (5-ASA) agents remain the mainstay treatment in ulcerative colitis (UC). A number of oral 5-ASA agents are commercially available, including azobond pro-drugs, as well as delayed- and controlled-release forms of mesalazine. However, poor adherence due to frequent daily dosing and a large number of tablets has been shown to be an important barrier to successful management of patients with UC. Recently, new, once-daily formulations of mesalazine, including the unique multi-matrix delivery system and mesalazine granules, were proven to be efficacious in inducing and maintaining remission in mild-to-moderate UC, with a good safety profile comparable to that of other oral mesalazine formulations. In addition, they offer the advantage of a low pill burden and might contribute to increased long-term compliance and treatment success in clinical practice. This editorial summarizes the available literature on the short- and medium-term efficacy and safety of the new once-daily mesalazine formulations.

## INTRODUCTION

The pathogenesis of ulcerative colitis (UC) has only been partly elucidated. Inflammatory bowel disease (IBD) is a multifactorial entity with both genetic and environmental factors contributing to disease pathogenesis<sup>[1]</sup>. Worldwide, the incidence rates for UC vary from 0.5 to 24.5 per 100 000 person-years<sup>[2]</sup>. Recent reports from China and Korea also present an increase in patient numbers<sup>[3]</sup>. The classical presentation is that of rectal bleeding and diarrhea, with other symptoms such as urgency, tenesmus, and abdominal cramping also being common. The disease might be limited to the rectum or extend proximally to include the entire colon and is characterized by a remission-relapse course in most patients.

5-aminosalicylic acid (5-ASA) remains the mainstay treatment in mild to moderate UC<sup>[4]</sup>. In left-sided and extensive cases, a combination of oral and topical mesalazine appears to be more effective than either alone; however, this is probably not a simple dose-response effect, as higher topical 5-ASA doses do not improve efficacy<sup>[5]</sup>. A number of oral 5-ASA agents are commercially available, including azo-bond prodrugs, such as sulfasalazine, olsalazine and balsalazide, and delayed- and controlled-release forms of mesalazine. Overall, the safety profile of oral 5-ASA agents is favorable and similar to that of a placebo in large clinical trials<sup>[6]</sup>. In addition, the use of sulfasalazine is mainly limited by its side effects (including nausea, vomiting, abdominal pain, fever, skin rash, agranulocytosis, neutropenia, male infertility, folate deficiency, neuropathy, autoimmune hemolysis, and, rarely, nephrotoxicity, hepatotoxicity or pancreatitis) and the high rate of intolerance (up to 20%). Somewhat in contrast, although mild side effects are more common with sulfasalazine, some of the more severe side effects, for example pancreatitis, are more common with mesalazine (OR: 7.0), with interstitial nephritis being exclusively described for mesalazine<sup>[7]</sup>. Conclusions from this study, however, were criticized due to incomplete data collected through spontaneous reporting. Interestingly,

in a recent review by the Cochrane group, mesalazine was not superior compared to sulfasalazine for inducing response or remission (OR = 0.83, 95% CI: 0.60-1.13)<sup>[6]</sup>, but was better tolerated.

Much emphasis has been placed on the manner in which different delivery systems may influence response to 5-ASAs; however, evidence in clinical practice for variability in efficacy is rather weak. Delivery systems can be divided into azo-compounds, controlled release, pH-dependent (either pH 6 or 7) and composite (pH-dependent combined with controlled release)<sup>[8]</sup>. In addition, the effectiveness of oral therapy relies on good compliance, which may be adversely affected by frequent daily dosing and a large number of tablets. Recent studies have shown that poor adherence has been an important barrier to the successful management of patients with UC. Only 40% to 60% of the patients who are newly diagnosed or have longstanding disease are adherent to therapy<sup>[9,10]</sup>. Hence, once-daily oral formulations of 5-ASA are likely to be a better therapeutic option in clinical practice, partly due to improved adherence. Furthermore, when assessing remission and response rates, one must be aware that the placebo group rates may vary anywhere from 0 to 40% according to the definition used for response and remission. In a recent review<sup>[11]</sup>, a significant heterogeneity was reported among studies using different criteria [e.g. UC Disease Activity Index (UC-DAI), Rachmilewitz]. Thus, the direct comparison of studies using different criteria is difficult to interpret.

A new, oral delayed-release formulation of mesalazine utilizing Multi Matrix System (MMX) technology (hereafter referred to as MMX mesalazine) was recently approved in the US for the induction and maintenance of remission in patients with active, mild-to-moderate ulcerative colitis<sup>[12]</sup>. It is a high dose (mesalazine 1.2 g/tablet), delayed-release form that permits once-daily administration. The MMX technology involves incorporating mesalazine into a lipophilic matrix, which itself is dispersed within a hydrophilic matrix, to delay and prolong dissolution. A gastro-resistant polymer film prevents initial drug release until exposed to a pH < 7; thus, the film coat normally starts to dissolve only in the terminal ileum. The hydrophilic matrix is then exposed to intestinal fluids and swells, resulting in the formation of a viscous gel mass with a slow and gradual release of mesalazine throughout the length of the colon. This editorial will focus on the efficacy and tolerability of the new, once-daily mesalazine formulations.

## EFFICACY AND SAFETY OF THE MMX MESALAZINE IN INDUCTION AND MAINTENANCE OF REMISSION

First, a preliminary randomized, double-blind, double-dummy clinical study compared the efficacy of MMX mesalazine *versus* topical mesalazine in 79 patients with active, left-sided, mild-to-moderate UC<sup>[13]</sup>. Comparable

clinical remission rates were achieved; 60% of the patients in the MMX mesalazine group and 50% of the patients in the enema group were in clinical remission at the end of week eight. Endoscopic remission rates were also not significantly different. Overall compliance was 97% for oral administration and 87.5% for the enema. In a subsequent Phase II, randomized, double-blind, dose-ranging study, D'Haens *et al*<sup>[14]</sup> evaluated three different doses of MMX mesalazine (1.2, 2.4, and 4.8 g/d) given once daily for the induction of remission in 38 patients with mild-to-moderate UC in an eight week trial. Remission at the end of week eight was defined as a UC-DAI score of 1 or less, a score of 0 for rectal bleeding and stool frequency, and at least a 1-point reduction in sigmoidoscopy scores from baseline. Remission was achieved in 0% (0/12), 30.8% (4/13), and 18% (2/11) of the patients receiving MMX mesalazine 1.2, 2.4, and 4.8 g/d, respectively, with no statistically significant differences ( $P = 0.13$ ). Improvements in physician's global assessment (PGA), stool frequency, and rectal bleeding were similar in all treatment arms.

The FDA's approval of MMX mesalazine (SPD476, Mezavant<sup>TM</sup>, Lialda<sup>TM</sup>) was based on the two randomized, double-blind, placebo-controlled Phase III trials<sup>[15,16]</sup>. The first trial investigated the efficacy of MMX mesalazine 1.2 g twice daily and 4.8 g once-daily compared with the placebo for eight weeks, for the induction of remission in 280 patients with mild-to-moderate UC. The primary endpoint was endoscopic and clinical remission at week eight, defined as a modified UC-DAI  $\leq 1$  with a subscore of 0 for rectal bleeding and stool frequency, a combined PGA and sigmoidoscopy score of  $\leq 1$ , a sigmoidoscopy score reduction of  $\geq 1$  from baseline, and no mucosal friability. Secondary endpoints included clinical improvement (reduction in modified UC-DAI scores from baseline of  $\geq 3$  points) and clinical remission (scores of 0 for stool frequency and rectal bleeding). At the end of week eight, both MMX mesalazine groups achieved statistically significant clinical and endoscopic remission compared with the placebo (34.1% and 29.2% *vs* 12.9%, 2.4 g/d and 4.8 g/d *vs* placebo,  $P < 0.001$  and  $P = 0.009$ , respectively). A statistically significant proportion of patients receiving either dose of MMX mesalazine achieved clinical improvement and clinical remission (37.5%, 32.6% *vs* 18.8%,  $P < 0.05$ ) compared with the placebo. The median time to initial clinical remission (lasting  $\geq 3$  consecutive days) was 43 and 44 d for the 2.4 g/d and 4.8 g/d MMX mesalazine groups, respectively; in contrast it was not reached for the placebo.

In the second Phase III double-blind, placebo-controlled, multicenter clinical trial, Kamm *et al*<sup>[16]</sup> randomized 343 patients with active, mild-to-moderate UC to receive MMX mesalazine 2.4 g once daily, MMX mesalazine 4.8 g once daily, placebo, or a delayed-release mesalazine (Asacol<sup>TM</sup>) 800 mg, 3 times daily. The Asacol group served as a reference arm in the study. Due to the study's double-dummy design, all patients received 4 tablets and 2 capsules in the morning, 2 capsules at

lunch time, and 2 capsules in the evening. Significantly more patients achieved clinical and endoscopic remission at week eight in the MMX mesalazine groups compared with the placebo group (40.5% and 41.2% *vs* 22.1% with 2.4 g/d, 4.8 g/d *vs* placebo;  $P = 0.01$  and  $P = 0.007$ ). In contrast, the Asacol group demonstrated only a trend for improvement (32.6% *vs* 22.1%,  $P = 0.124$ ). MMX mesalazine was not directly compared with Asacol. Interestingly, endoscopic remission rates (69% for MMX 2.4 g/d, 77.6% for MMX 4.8 g/d, 61.6% for Asacol, and 46.5% for the placebo) exceeded clinical remission rates for both active treatment and placebo groups and were much better than previously reported for 5-ASA.

In a combined analysis<sup>[17]</sup> of the two trials, data from 517 patients were analyzed. Eight-week remission rates were 37.2% and 35.1% in the MMX mesalazine 2.4 g/d and 4.8 g/d groups, respectively, *versus* 17.5% in the placebo group ( $P < 0.001$ , for both). The respective rates for clinical improvement were 58%, 62%, and 33%. The eight-week, complete mucosal healing rates were 32% in both MMX mesalazine groups compared with 16% in the placebo group. In an intent-to-treat analysis, the median time to resolution of symptoms (stool frequency and rectal bleeding) was 25, 26, and 44 d, respectively<sup>[18]</sup>. The median time to resolution of rectal bleeding was seven, eight, and 16 d, while the median time to normalization of stool frequency was 19, 20, and 34 d.

In a subsequent analysis<sup>[19]</sup>, the authors stratified the data according to disease extent, severity, gender and prior 5-ASA use. The percentage of patients in clinical and endoscopic remission was not different according to disease extent and severity and among patients who did not previously receive low-dose 5-ASA. Among patients transferring directly from prior low-dose oral 5-aminosalicylic acid, MMX mesalazine 4.8 g/d was significantly ( $P = 0.018$ ) more effective than the placebo in inducing clinical and endoscopic remission. Efficacy over the placebo did not reach significance in patients transferring directly to MMX mesalazine 2.4 g/d. Interestingly, remission rates were higher in females in both active treatment groups and placebo groups (44.8% for MMX 2.4 g/d, 41.4% for MMX 4.8 g/d, and 20.7% for the placebo) compared to males (29.4%, 28.7%, and 14.3%,  $P = 0.008$ ). Nevertheless, in a logistic regression analysis, the authors excluded the gender effect. It is not clear, however, which other possible confounding variables were included in the analysis.

If patients were not in remission after an eight-week treatment with either MMX mesalazine 2.4 g once daily, MMX mesalazine 4.8 g once daily, placebo, or a delayed-release mesalazine (Asacol<sup>TM</sup>) 800 mg 3-times-daily, patients were offered an open-label extension treatment with 4.8 g MMX mesalazine for another eight weeks<sup>[20]</sup>. Out of the 304 patients who entered the extension study, 59.5% of patients achieved remission at the end of the extension treatment irrespective of prior therapy. Normal mucosal appearance was seen at sigmoidoscopy in 42.4% of the patients at the end of the extension study *vs* 3.3% prior to the extension phase.

Upon completion of the remission induction

trials, eligible patients could enter a Phase III open-label extension study to evaluate the long-term efficacy and safety of MMX mesalazine in the maintenance of remission. Patients who were not in remission at the end of the original induction trial were offered an additional eight-week open label MMX mesalazine 4.8 g/d treatment administered twice daily<sup>[21]</sup>. Those who were in remission at either eight or 16 wk were then randomized to MMX mesalazine 2.4 g/d given once or twice daily for 12 mo. Two-hundred-twenty-five and 234 patients were randomized into the two treatment groups. At the end of the 12-mo follow-up, 67.8% and 72.3% of the patients were strictly defined to have clinical and endoscopic remission in the per-protocol population. 88.7% and 92.5% of the patients were not considered to have relapsed based on the physician's clinical assessment and the need for alternative therapy. These data are comparable to other mesalazine agents, with reported remission rates of 60%-70% after 6-12 mo of maintenance therapy<sup>[22]</sup>.

In a post-hoc analysis<sup>[23]</sup>, the authors did not find differences in the relapse rate according to the initial treatment; relapse rates at 12 mo were 6.3%, 10.8%, and 5.6% for patients initially treated with MMX mesalazine 2.4 g/d, 4.8 g/d or Asacol 2.4 g/d, respectively. No significant differences were found in remission rates in a similar sub-group analysis in patients with baseline mild or moderate (71% *vs* 64%) and left-sided or extensive (67% *vs* 65%) ulcerative colitis. Similarly, relapse rates were independent of previous relapse history, although there was a trend for increased frequency of relapses in patients with a higher number of prior relapses ( $< 3$  prior relapses: 70.1% *vs*  $\geq 3$  prior relapses: 59.8%). In contrast, the degree of initial mucosal inflammation (mild: 68.6%, moderate: 68.1%, and severe: 43.3%) and time needed to induce remission (remission at week eight: 75.8% *vs* remission at week 16: 55.9%) were significantly associated with decreased remission rates at 12 mo<sup>[21,24,25]</sup>.

In a subsequent Italian multicenter study<sup>[26]</sup>, the authors preliminarily reported on the efficacy of once-daily 2.4 g MMX mesalazine *vs* 2.4 g delayed-release mesalazine (Asacol<sup>TM</sup>) maintenance therapy taken twice daily in 323 mild-to-moderate patients with left-sided ulcerative colitis in clinical remission without mucosal friability. At 12 mo, 30.8% *vs* 43.2% of the patients relapsed in the two groups in a per-protocol analysis, resulting in an 11.3% difference in long-term remission rates in favor of the once-daily treatment (95% CI: -0.01-22.7).

MMX mesalazine was generally well tolerated in all controlled clinical trials, with most adverse events being of mild or moderate severity. Of the 434 MMX mesalazine recipients evaluated for safety in the four published controlled trials<sup>[13-21]</sup>, only two patients had serious adverse events that were considered treatment-related; both included pancreatitis caused by hypersensitivity to mesalazine. There was no evidence of a dose-response relationship with MMX mesalazine for any tolerability parameter in either trial.

Table 1 Efficacy of the MMX mesalazine formulations for induction and maintenance of remission in mild-to-moderate UC

Study	Phase	Patient number (n)	Dosing regimen (g/d)	Duration	Remission rates (%)	
					Treatment	Placebo

			Granules 1.5 <i>tid</i>		68.8
			Salofalk®		

<sup>a</sup>*P* < 0.05, *od* vs *bid*.

The most common treatment-related adverse events were headache, flatulence, and abdominal pain. Severe events were more common in the placebo recipients (6.1%) than in patients receiving MMX mesalazine 2.4 or 4.8 g/d (1.1% and 2.2%), and mostly consisted of gastrointestinal events related to the underlying disease.

The efficacies of the new MMX mesalazine formulations for the induction of remission in mild-to-moderate UC are summarized in Table 1.

## THERAPEUTIC EFFICACY AND SAFETY OF OTHER ONCE-DAILY MESALAZINE FORMULATIONS

Another once-daily preparation (SalofalkR granules) also proved to be efficacious in inducing remission in mild-to-moderate active ulcerative colitis in a double-blind, randomized, Phase III clinical trial, termed SAG-26<sup>[27]</sup>. Three-hundred-eighty patients were randomized to receive 3 g/d mesalazine granules either once daily (OD) or three times per day (TID). At week eight, treatment groups achieved comparable clinical (as defined by a CAI ≤ 4 at the final/withdrawal visit, 3 g OD: 79.1% vs TID: 75.7%)

with comparable endoscopic (71% vs 70%) remission and histological remission (35% vs 41%) rates. OD treatment was more effective in patients with proctosigmoiditis (86% vs 73%, *P* = 0.02); but, efficacy was not different according to baseline severity and disease duration.

In a combined analysis of three Phase III clinical trials (SAG2, SAG15, and SAG26)<sup>[28]</sup>, the efficacy of the 3 g/d mesalazine (Salofalk granules) treatment was not affected by gender, duration since first symptom, disease location or disease duration (new vs established disease). In contrast, significantly lower remission rates were achieved in patients with moderate disease (66% vs 89%, *P* = 0.0009) and in patients relapsing on 5-ASA maintenance therapy (67% vs 82%, *P* < 0.0001).

The once-daily maintenance treatment was also shown not to be inferior for the mesalazine, 3 g Salofalk granules in a double-blind, double-dummy, randomized, controlled, dose-ranging study<sup>[29]</sup>. Six-hundred-forty-seven patients who have achieved clinical (CAI ≤ 4) and endoscopic remission (EI ≤ 3) within 12 wk from baseline were randomized to 3 g once daily, 1.5 g once daily, and 1.5 g three-times-daily mesalazine treatment. At 12 mo, 74.7%, 60.8%, and 68.8% of patients were in clinical remission pointing toward a statistically

significant superiority of the once-daily 3 g treatment group. All treatment groups showed excellent safety profiles and there were no indications for increased risk in patients treated once daily or with the higher dose.

The use of once-daily treatment for maintenance of remission is further supported by a recent randomized, multicentre, investigator-blinded study of 362 patients who were randomised to receive mesalazine granules (PentasaR) 2 g once daily or 1 g twice daily. It showed an 11.9% greater remission rate at one year (73.8% *vs* 63.6%, respectively) in the single daily dose group<sup>[30]</sup>. The 95% CI values for the treatment difference (1.4%-22.5%,  $P = 0.024$ ) in intent to treat analysis were completely above the non-inferiority limit of -10.0 and did not cross 0. Therefore, once-daily administration of the drug proved to be superior to twice-daily treatment. Normal mucosa was found in 49.3% and 46.2% of the patients with once-daily or twice-daily treatment and there was a trend toward less friability in the once-daily group (9.7% *vs* 15.9%). In addition, subjects undergoing once-daily treatment had a lower likelihood of rectal bleeding (20.4% *vs* 29.3%) and also increased rates of normal stool frequency (81.5% *vs* 61.7%) at 12 mo. Patient questionnaires showed significantly greater self-reported compliance ( $P < 0.05$ ) and acceptability ( $P < 0.001$ ) in the once-daily group. High compliance rates were reported for the once-daily MMX mesalazine<sup>[17]</sup>; therefore, the effect is likely to be generic rather than compound-specific. The efficacy of the other new mesalazine formulations for the maintenance therapy in mild-to-moderate UC is summarized in Table 2.

## CONCLUSION

MMX mesalazine and the newly developed mesalazine granules were all shown to be efficacious in inducing and maintaining remission in mild-to-moderate UC in large clinical trials. However, existing data are insufficient to make a comparison between new and “conventional” 5-ASA formulations. Short-term evaluation reveals that the new formulations are at least as effective as other oral 5-ASA formulations. Recently, MMX mesalazine has been approved in the US for the induction of remission in adult patients with active, mild-to-moderate ulcerative colitis. In Europe, it is indicated for both induction and maintenance of remission. The safety profile is favorable and comparable to that of other mesalazine formulations. In addition, new mesalazine formulations offer a simplified dose regime, resulting in presumably improved long-term compliance that can be considered an important advantage in the management of UC patients. This is of great importance in everyday clinical practice, because only 40% to 60% of the patients who are newly diagnosed or have longstanding disease are adherent to therapy. While patients at all stages of UC are affected by non-adherence, those in symptomatic remission are particularly at risk of poor adherence, often taking less than 70% of their prescribed medication, with non-adherent patients being more likely to relapse. Therefore, improving adherence to therapy has become

one of the most important goals of patient management. However, once-daily administration was never tested for conventional 5-ASAs. Furthermore, ulcerative colitis patients (except proctitis) are at an increased risk for colorectal cancer<sup>[31,32]</sup>, and according to a recent meta-analysis<sup>[33]</sup>, the incidence of colon cancer is approximately 50% lower in aminosalicilate users. Thus, improved compliance might further contribute to decreasing the likelihood of the colorectal cancer burden in UC.

### Abstract

Nitazoxanide, the first thiazolide, was originally developed for the treatment of *Cryptosporidium parvum*. More recently, antiviral activity of nitazoxanide against hepatitis B virus (HBV) and hepatitis C virus was recognized in *in vitro* systems. These basic studies led to phase II clinical trials that demonstrated the safety and efficacy of nitazoxanide in combination with peginterferon, with or without ribavirin, in the treatment of chronic hepatitis C genotype 4. The sustained virologic response rate was 79% and 80% in two studies, which was higher than the response rate of 50% with the standard of care with peginterferon plus ribavirin. In very preliminary studies of patients with chronic hepatitis B, nitazoxanide suppressed serum HBV DNA and led to loss of hepatitis B e antigen in the majority of patients and hepatitis B surface antigen in approximately a quarter of patients. Randomized controlled studies of naive and nonresponder patients with chronic hepatitis C genotype 1 are underway, new second generation and controlled release thiazolides are being developed, and future studies of patients with chronic hepatitis B are planned.

### INTRODUCTION

Nitazoxanide (Alinia<sup>®</sup>, Romark Laboratories, L.C., Tampa, FL, USA), the first thiazolide, was licensed in the USA for the treatment of *Cryptosporidium parvum* and *Giardia lamblia* in immunocompetent adults and children in 2002<sup>[1]</sup>. A number of emerging basic and clinical studies support an additional role of nitazoxanide in the treatment of chronic hepatitis C virus (HCV) and chronic hepatitis B virus (HBV) infection. This brief review summarizes current data from emerging phase II studies related to this new potential use of nitazoxanide combined with peginterferon and ribavirin for the treatment of chronic hepatitis C and very preliminary experiences with nitazoxanide for the treatment of chronic hepatitis B.

### ANTIVIRAL MECHANISM OF ACTION OF NITAZOXANIDE

The antiviral mechanism of action of nitazoxanide is different from the mechanism of action in protozoa and anaerobic bacteria *via* direct inhibition against the pyruvate-ferrodoxin oxidoreductase reaction<sup>[1]</sup>, and appears in recent studies to involve activation of the protein kinase activated by double-stranded RNA (PKR), an interferon-induced mediator of the cellular antiviral response<sup>[2]</sup>. The activation of PKR results in phosphorylation of its substrate, eukaryotic initiation factor 2 alpha (eIF2 $\alpha$ ). Nitazoxanide, thus, represents a new class of small molecules that modulate host antiviral pathways. By targeting a host function, the barrier to development of

antiviral resistance is significantly higher than for drugs directly targeting a viral function.

## IN VITRO ACTIVITY OF NITAZOXANIDE AGAINST HBV AND HCV

After nitazoxanide was serendipitously suspected as active against viral hepatitis in patients with acquired immune deficiency syndrome (AIDS) treated with nitazoxanide for *Cryptosporidium*, the antiviral activities of nitazoxanide and its metabolite, tizoxanide, were confirmed in standard antiviral assays *in vitro*<sup>[3,4]</sup>. Both nitazoxanide and tizoxanide are potent inhibitors of HBV, and in combination with other antiviral agents such as lamivudine or adefovir, show synergistic effects. Nitazoxanide and tizoxanide are also effective against HBV-resistant mutants to lamivudine and adefovir. Additionally, both nitazoxanide and tizoxanide are potent inhibitors of HCV in genotype 1a- and 1b-derived replicon cells and genotype 2a cell culture models, and synergistic effects are observed when tizoxanide is combined with interferon<sup>[3]</sup>. Three days of pretreatment of the HCV replicon model with nitazoxanide sensitizes the virus to the effects of subsequent treatment with interferon, providing support to the clinical studies underway using a nitazoxanide lead-in phase prior to combination therapy.

## LACK OF DIRECT ANTIVIRAL RESISTANCE TO NITAZOXANIDE

Studies were carried out in HCV replicons exposed to increasing concentrations of nitazoxanide or tizoxanide over 24 wk in an attempt to produce resistance to nitazoxanide and tizoxanide<sup>[5]</sup>. This serial passage did not reduce the susceptibility of HCV replicons to interferon, ribavirin, or 2'-C-methyl-cytidine, indicating that nitazoxanide and tizoxanide do not induce resistance to these agents.

## TREATMENT OF CHRONIC HEPATITIS C

### Completed studies

Romark made the decision to initially focus on the potential treatment of chronic hepatitis C with nitazoxanide. Three phase II studies of nitazoxanide for the treatment of chronic hepatitis C have been completed and communicated in publications or presentations at national and international meetings<sup>[6-8]</sup>. The first study was a randomized, double-blind, placebo-controlled study of the treatment of chronic hepatitis C with nitazoxanide 500 mg twice daily in 50 adult patients with chronic hepatitis C infected with genotype 4<sup>[6]</sup>. Seven of 23 patients (30%) had a virologic end-of-treatment response (ETR) with undetectable virus, and a sustained virologic response (SVR) with undetectable virus 24 wk after the completion of treatment was observed in 4 of 23 patients (17%). All responders had low serum HCV RNA levels less than 400 000 IU/mL. This study was the first use of nitazoxanide in patients with chronic hepatitis C and for

a longer time period than for its use for cryptosporidiosis and giardiasis, and the drug was well tolerated with the same number of mild gastrointestinal adverse events in the treated and placebo groups.

A second randomized, double-blind, placebo-controlled study (STEALTH C-1) evaluated the effects of nitazoxanide plus peginterferon alfa-2a (dual regimen) or nitazoxanide plus peginterferon alfa-2a and ribavirin (triple regimen) *versus* the standard of care (SOC) with peginterferon alfa-2a and ribavirin in 96 treatment-naïve patients with chronic hepatitis C infected with genotype 4<sup>[7]</sup>. Nitazoxanide 500 mg twice daily was administered over a 12-wk lead-in followed by an additional 36 wk in combination with peginterferon alfa-2a 180 µg weekly with or without ribavirin 1000-1200 mg daily. The SOC group received the same doses of peginterferon alfa-2a and ribavirin for 48 wk. A rapid virologic response (RVR; undetectable serum HCV RNA after 4 wk of combination therapy) occurred in 38%, 54%, and 64% of patients receiving the SOC, dual regimen and triple regimen, respectively ( $P = 0.048$ , SOC *vs* triple regimen). A complete early virologic response (cEVR; undetectable serum HCV RNA at week 12 of combination therapy) occurred in 70, 68 and 86% of the SOC, dual regimen and triple regimen, respectively. The SVR rates at 24 wk post-treatment were 50%, 61% and 79%, respectively, demonstrating a 29% difference between the SOC and the triple regimen with nitazoxanide ( $P = 0.023$ ).

A third open label study was carried out in 44 patients; 40 were infected with genotype 4, and 3 were infected with genotype 1, and 1 infected with genotype 2<sup>[8]</sup>. This study evaluated a shorter 4-wk lead-in phase with nitazoxanide 500 mg twice daily followed by 36 wk of treatment with a combination of nitazoxanide with peginterferon alfa-2a 180 µg weekly without ribavirin, and the results were compared with the historical results from the STEALTH C-1 study. The RVR, cEVR, and SVR rates were 59%, 82% and 80%, respectively, and the SVR rate of 80% in this study was significantly higher than the historical SVR rate of 50% in the SOC group ( $P = 0.006$ ). The 3 patients infected with genotype 1 and the single patient infected with genotype 2 all had an SVR. The SVR rate of 80% raises the possibility using nitazoxanide in place of ribavirin, which requires further study.

In both this study and the STEALTH C-1 study, the administration of nitazoxanide in combination with peginterferon, with or without ribavirin, was associated with a low relapse rates (3 of 38 in the current study; and 3 of 20 patients receiving dual therapy and 1 of 23 patients receiving triple therapy, compared with 10 of 30 patients in the SOC arm in the STEALTH C-1 study). These low relapse rates, with or without ribavirin, suggest the possibility that nitazoxanide might play a similar role as ribavirin in reducing the relapse rate and be a possible substitute for ribavirin in combination with peginterferon for the treatment of chronic hepatitis C.

The results of these preliminary studies in Egypt in patients predominantly infected with genotype 4 were met with considerable interest in the hepatology community; but, studies conducted in the United States and the

response to nitazoxanide in combination with the SOC in patients with genotype 1 were recognized as the next steps required to confirm these initial interesting findings.

### Ongoing studies

A phase II randomized, double-blind, placebo-controlled study with of nitazoxanide or placebo monotherapy (2:1 randomization) over a 4-wk lead-in phase followed by nitazoxanide or placebo in combination with peginterferon alfa-2a plus ribavirin is currently underway in 112 naive patients infected with genotype 1 at 13 USA study sites. The preliminary results of the early virologic responses will be communicated in early 2009.

A second phase II, randomized, double-blind, placebo controlled study of nitazoxanide with peginterferon and ribavirin is being conducted in 10 USA sites in 64 patients who are prior nonresponders to peginterferon and ribavirin. Preliminary results from this study will also be communicated in 2009.

### CONTROLLED RELEASE TABLET

Studies have recently been initiated to study the pharmacokinetics, viral kinetics, and tolerability of a controlled release tablet of nitazoxanide in adult healthy volunteers as well as a phase II study in patients with chronic hepatitis C<sup>[9]</sup>. The new nitazoxanide controlled release tablet contains 675 mg of the drug, and kinetics has been evaluated using either 675 mg or 1350 mg twice daily for 7 d in a phase I study. The pharmacokinetics profile is substantially improved compared to the standard tablet, with higher blood levels and an increased area under the curve of approximately 70%.

In a subsequent randomized, controlled trial, 40 treatment-naïve patients with chronic hepatitis C genotype 4 have been allocated to receive either 675 mg or 1350 mg or placebo twice daily for 4 wk followed by the same regimen plus the addition of peginterferon alfa-2a 180 µg weekly and ribavirin 1000 or 1200 mg daily based on body weight. An early interim analysis has shown that the mean reduction in serum HCV RNA from baseline to week 8 (after 4 wk of combination therapy) were 5.45, 5.25, and 2.75 in the high-dose, low-dose and placebo groups, respectively<sup>[9]</sup>. Nitazoxanide was well tolerated without gastrointestinal toxicity.

### TREATMENT OF CHRONIC HEPATITIS B

Nitazoxanide alone has shown preliminary evidence of efficacy in the treatment of chronic hepatitis B over a one year course of therapy<sup>[10]</sup>. Nitazoxanide 500 mg twice daily resulted in a decrease in serum HBV DNA in all of 4 HBeAg-positive patients, with undetectable HBV DNA in 2 of 4 patients, loss of HBeAg in 3 patients, and loss of HBsAg in one patient. Seven of 8 HBeAg-negative patients treated with nitazoxanide 500 mg twice daily had undetectable HBV DNA and 2 had loss of HBsAg. Additionally, nitazoxanide monotherapy in one case and nitazoxanide plus adefovir in another case resulted in undetectable HBV DNA, loss of HBeAg and loss of

HBsAg<sup>[11]</sup>. These preliminary studies showed a higher rate of HBsAg loss than any currently licensed therapy for chronic hepatitis B. The similar mechanism of action of interferon and nitazoxanide suggest that stand-alone nitazoxanide therapy or nitazoxanide in concert with nucleos(t)ide analogs have the potential to increase loss of HBsAg, which is the ultimate end-point of therapy. A formal phase II study is being planned for 2009.

### SECOND GENERATION THIAZOLIDES

Newer thiazolidine analogs have been identified with higher specific activity against HBV and HCV. The objective of this search for alternative thiazolidines is to identify compounds that do not have antiparasitic or antibacterial activity *via* direct inhibition against the pyruvate-ferredoxin oxidoreductase reaction and increased antiviral activity. There are several lead compounds that have undergone preliminary study in experimental replicon models and have the potential to move into clinical trial.

### CONCLUSION

Nitazoxanide shows significant activity against HBV and HCV, both in cell culture models as well as in patients with chronic hepatitis B and C. The HCV antiviral mechanism of action has been elucidated to involve up-regulation of PKR and eIF2α phosphorylation, which enhances natural cellular antiviral mechanisms without induction of antiviral resistance. Second generation molecules in controlled release formulations are in development. Interim results of the American phase II trial involving treatment of naïve and nonresponder patients with chronic hepatitis C infected with genotype 1 will be reported in early 2009. The thiazolidines have a very favorable toxicity profile with a very low incidence of mild gastrointestinal side effects.

There are many future potential uses of nitazoxanide in treatment regimens for chronic hepatitis C. Nitazoxanide might allow reduction in the duration of a standard peginterferon-based regimen, as the results in the phase II studies of patients with genotype 4 were achieved with 36 wk of combination therapy versus the usual 48 wk used in the current SOC. Further studies using even shorter duration of combination therapy, i.e. 24 wk, are warranted. It is also possible that the interferon-like mechanism of action of nitazoxanide will allow use of a reduced dose of peginterferon in combination treatment regimens. The findings of high SVR rates with nitazoxanide in combination with peginterferon without ribavirin require confirmation, but raise the possibility that nitazoxanide might be used in the place of ribavirin and avoid the substantial hematologic and other side effects of this drug. Finally, nitazoxanide might be used with a reduced dose of peginterferon or even without peginterferon in combination with a protease inhibitor and/or polymerase inhibitor as part of an all-oral cocktail for treatment of chronic hepatitis C, avoiding the need for injectable interferon with all of its side effects.

### Abstract

The clinical implications of non-alcoholic fatty liver diseases (NAFLD) derive from their potential to progress to fibrosis and cirrhosis. Inappropriate dietary fat intake, excessive intake of soft drinks, insulin resistance and increased oxidative stress results in increased free fatty acid delivery to the liver and increased hepatic triglyceride (TG) accumulation. An olive oil-rich diet decreases accumulation of TGs in the liver, improves postprandial TGs, glucose and glucagon-like peptide-1 responses in insulin-resistant subjects, and upregulates glucose transporter-2 expression in the liver. The principal mechanisms include: decreased nuclear factor-kappaB activation, decreased low-density lipoprotein oxidation, and improved insulin resistance by reduced production of inflammatory cytokines (tumor necrosis factor, interleukin-6) and improvement of jun N-terminal kinase-mediated phosphorylation of insulin receptor substrate-1. The beneficial effect of the Mediterranean diet is derived from monounsaturated fatty acids, mainly from olive oil. In this review, we describe the dietary sources of the monounsaturated fatty acids, the composition of olive oil, dietary fats and their relationship to insulin resistance and postprandial lipid and glucose responses in non-alcoholic steatohepatitis, clinical and experimental studies that assess the relationship between olive oil and NAFLD, and the mechanism by which olive oil ameliorates fatty liver, and we discuss future perspectives.

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) occur in 10%-24% of the general population<sup>[1]</sup>. The potential to progress to fibrosis (20%-40%), cirrhosis (30%) and hepatocellular carcinoma<sup>[1-3]</sup> makes these conditions clinically important. Obesity, diabetes, hyperlipidemia, and the intake of soft drink beverages are risk factors frequently associated with NAFLD<sup>[4,5]</sup>.

The pathogenesis of NASH includes insulin resistance, increased inflammation, tumor necrosis factor (TNF)- $\alpha$ , interleukin (IL)-6 and increased oxidative stress<sup>[6]</sup>. The etiologic mechanism of NAFLD includes increased influx of free fatty acids (FFAs) to the liver from dietary triglycerides (TGs) and from FFAs that are released from adipocytes during fasting, reduced FFA  $\beta$ -oxidation, reduced hepatic secretion of TG-rich very low density lipoprotein (VLDL), and increased lipid peroxidation<sup>[6]</sup>. An impaired postprandial TG response has been recently reported in patients with NASH and may play a pathophysiologic role by favoring TG accumulation in the liver<sup>[7]</sup>.

Diet and nutrition, in particular the amount and type of fat intake, has been linked to insulin resistance, an increased risk of developing type 2 diabetes and impaired postprandial lipid metabolism<sup>[8,9]</sup>. In addition, animal models and human studies suggest that dietary factors can affect fatty infiltration and lipid peroxidation in various types of liver disease including NAFLD<sup>[10,11]</sup>. More recently, increased ingestion of soft drinks was found to be linked to NAFLD<sup>[5]</sup>. Although few studies of the effects of different diets on NAFLD have been performed in humans, a Mediterranean diet has been proposed for the prevention of metabolic syndrome, hypertension and cardiovascular disease<sup>[12]</sup>. The major

part of its beneficial effect is a high supply of energy coming from monounsaturated fatty acids (MUFAs), mainly from olive oil. The principle fatty acid esters present in normal liver are palmitate (16:0) and oleate (18:1 n-9). In patients with alcoholic fatty liver, the proportion of linoleate (C18:2 n-6) and linolenic acid (C18:3 n-3) decreases and the proportion of oleate (C18:1 n-9) increases compared with diabetics with fatty liver and control subjects who underwent liver biopsies<sup>[13]</sup>.

In this review, we describe dietary habits and their relationship to insulin resistance and postprandial glucose and TG levels in NASH, the mechanism by which olive oil ameliorates fatty liver, experimental and clinical studies of olive oil and NAFLD, and future perspectives.

## COMPOSITION OF OLIVE OIL

Each 100 g of olive oil contains the following fatty acids: MUFA 73.7 g (n-9 oleic acid 18:1); saturated fatty acids (SFA) 13.5 g (16:0 palmitic acid); polyunsaturated fatty acids (PUFA) 7.9 g (n-6 linoleic acid 18:2, and n-3 alpha-linolenic acid 18:3)<sup>[14]</sup>.

MUFAs include palmitic (C16:1), oleic (C18:1), elaidic (C18:1) and ventic acids (C18:1). The most abundant MUFA in the diet is oleic acid (C18:1 n-9)<sup>[15]</sup>. In Mediterranean countries, the main source of MUFA is olive oil (74 g/100 g). Other oil sources of MUFAs are canola (59 g/100 g), peanut (46 g/100 g), sunflower (32 g/100 g), corn (29 g/100 g), soybean (24 g/100 g) and safflower oils (14 g/100 g)<sup>[16]</sup>. Additionally, new oil variants, rich in oleic acid have been developed including high-oleic acid sunflower oil (84 g/100 g) and high oleic acid safflower oil (74 g/100 g)<sup>[17]</sup>. In addition to a high MUFA content, virgin (unrefined) olive oil contains a significant amount of antioxidants and  $\alpha$ -tocopherol and phytochemicals. However, when refined or heated, olive oil loses these natural compounds<sup>[18]</sup>.

Olive oil is graded according to its acidity. Extra virgin olive oil, the first pressed oil, having maximum free acidity, contains an abundance of squalene and phenolic antioxidants including simple phenols (hydroxytyrosol, tyrosol), aldehydic secoiridoids, flavonoids and lignans (acetoxypinoresinol, pinoresinol). Interestingly, it contains significantly higher concentrations of phenolic antioxidants and squalene than refined virgin and seed oils. In addition, seed oils, which contain very low amounts of squalene, have none of the phenolic antioxidants that are present in virgin and refined olive oils<sup>[19]</sup>. The exact composition of olive oil depends not only on the growth conditions in the year preceding the harvest, but also on the degree of ripeness of the fruit and the technical processing (cold pressing, refining)<sup>[20]</sup>.

## PATHOPHYSIOLOGY OF NAFLD, DIETARY FAT AND HEPATIC LIPIDS

### Fat metabolism in fatty liver

Excessive inappropriate dietary fat intake combined with peripheral insulin resistance, continued TG hydrolysis

*via* lipoprotein lipase and other genetic alterations in key lipid metabolic pathways results in increased blood FFA concentration<sup>[21]</sup> leading to excessive muscle fat accumulation and increased liver concentration of TG and cholesterol esters. High blood TG concentration in the form of VLDL tends to accompany this condition and induces cholesterol ester transfer protein activity, resulting in an increased transfer of TG from VLDL to high density lipoprotein (HDL) and a subsequent increase in HDL clearance and decreased HDL concentration<sup>[21]</sup>.

### Insulin resistance in fatty liver

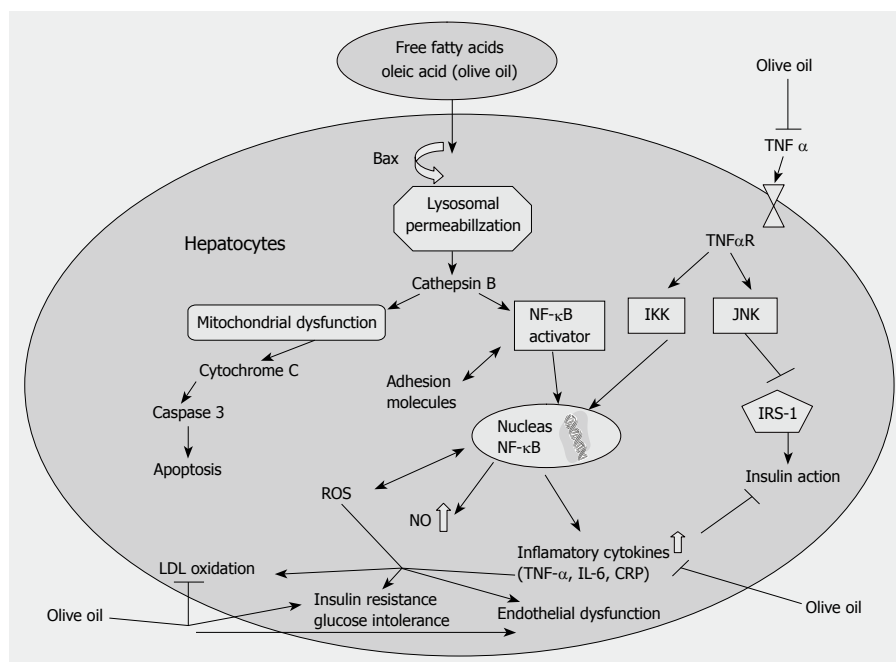

Peripheral insulin resistance affects carbohydrate and fat metabolism causing TG accumulation in the liver. Resistance to insulin stimulation of glucose uptake *via* glucose transporter-4 by skeletal muscle and adipose tissue, in conjunction with the inhibition of lipolysis in adipose tissue by insulin, diverts glucose to the liver where the insulin continues to stimulate de novo lipogenesis and increase the flux of fatty acids from adipose tissue to the liver<sup>[6,22]</sup>. As a result, the liver TG concentration increases. It is unclear how impairment in lipid export *via* VLDL secretion,  $\beta$ -oxidation of FFAs, or other metabolic pathways result in an inability to maintain fat balance, which leads to the development of fatty liver<sup>[22]</sup>.

### Fat induces hepatic insulin resistance

The mechanism underlying fat-induced hepatic insulin resistance is not understood. Recent evidence points to an accumulation of fat metabolites (IL-6, TNF- $\alpha$ ) that activate various signal transduction pathways, such as serine/threonine kinases, i.e. protein kinase-C (PKC), c-JUN NH2-terminal kinase-1, (JNK) and inhibitor of kappa B kinase, as a key event in the pathway of fat-induced hepatic insulin resistance. Downstream effects include: nuclear factor-kappaB (NF- $\kappa$ B) and activator protein-1 translocation to the nucleus resulting in increased production of inflammatory cytokines which inhibit insulin action<sup>[6,23]</sup> (Figure 1). Under conditions of insulin resistance, excess lipid metabolites such as diacylglycerol can cause insulin resistance by activating PKC which binds to the insulin receptor and inhibits its tyrosine kinase activity. The activation of PKC may also interfere with the ability of insulin to phosphorylate insulin receptor substrate-2<sup>[24]</sup>.

### Relationships among dietary habits, insulin resistance, postprandial lipemia and fatty liver

In the setting of excessive dietary fat intake, high levels of FFAs are delivered to the liver. Hepatocyte stimulation by FFAs leads to the intracellular translocation of Bax to the lysosome. Lysosomal permeability is increased, leading to release of cathepsin B. The presence of cathepsin B in the cytosol causes NF- $\kappa$ B translocation into the nucleus with increased production and release of TNF- $\alpha$  which inhibits insulin action. Cathepsin B also induces mitochondrial dysfunction leading to hepatocyte apoptosis and progression from fatty liver to

**Figure 1 Molecular mechanism of the benefit of oleic acid in NAFLD.** Increased levels of TNF- $\alpha$  leads to activation of stress-related protein kinases (IKK $\beta$ , JNK) which induce NF- $\kappa$ B translocation to the nucleus, resulting in increased production of inflammatory cytokines and reduced insulin sensitivity. Insulin sensitivity is further impaired by JNK-mediated phosphorylation of IRS-1. In the postprandial setting or after excessive inappropriate dietary intake, free fatty acids are delivered to the liver, taken up and accumulated in hepatocytes. This leads to the intracellular translocation of Bax to the lysosomes which leads to increased cathepsin B. This causes NF- $\kappa$ B translocation to the nucleus with increased production and release of TNF- $\alpha$  and increased insulin resistance. Cathepsin B also causes mitochondrial dysfunction leading to hepatocyte apoptosis and progression to NASH. The role of olive oil in decreasing NF- $\kappa$ B activation, decreasing LDL oxidation and in improving insulin resistance is illustrated.

steatohepatitis (Figure 1)<sup>[25]</sup>.

An impaired postprandial TG response has been reported in patients with NASH. This may promote the infiltration of fat into the liver by increasing TG uptake in the postprandial period<sup>[26]</sup>. Enhanced lipogenesis appears as a prominent abnormality of hepatic fatty metabolism in subjects with NASH; the contribution of hepatic lipogenesis to TG secretion was 3  $\times$  higher in patients with NAFLD as compared to healthy controls<sup>[27]</sup>. NASH patients had significantly higher overnight fasting glucose or FFAs than controls, as well as higher saturated and monounsaturated levels in both studied lipid fractions, mainly due to an increase in palmitate, palmitoleate and oleic acids<sup>[28]</sup>. NASH patients showed depletion of PUFAs (n-3 and n-6) in liver triglycerols. This results from defective PUFA desaturation or from a higher lipid peroxidation<sup>[28]</sup>. The diet of NAFLD patients who were free of hyperlipidemia, diabetes and obesity was richer in saturated fat and poorer in PUFAs<sup>[29]</sup>. Finally, a MUFA-rich diet improves postprandial glucose, lipid and glyp-1 responses in insulin-resistant subjects. Ingestion of an olive oil-based breakfast decreased postprandial glucose and insulin levels<sup>[30]</sup>.

## DIETARY MUFAs AND NAFLD: HUMAN STUDIES

The beneficial effect of MUFAs such as those found in olive oil, nuts and avocados, on risk of cardiovascular disease and on lipid profile has been studied<sup>[31]</sup>. Dietary MUFA (oleic acid) decreased oxidized LDL<sup>[32,33]</sup>, LDL cholesterol and TG concentration without the concomitant decrease in HDL<sup>[34,35]</sup>. Additionally, replacement of carbohydrate and saturated fat with MUFAs led to a reduction in glucose and blood pressure and to an increase in HDL in patients with diabetes<sup>[36]</sup>. A MUFA-rich diet (40% of energy as

fat), also decreased VLDL cholesterol and VLDL triglycerol and was more acceptable to patients with non insulin-dependent diabetes mellitus (NIDDM) than was a higher carbohydrate diet (28% of energy as fat)<sup>[37]</sup>. A meta-analysis of studies in individuals with diabetes showed that a high fat diet with 22%-33% of the energy from MUFAs resulted in lower plasma total cholesterol, VLDL, and TG levels than did a low fat, high carbohydrate (49%-60% energy) diet<sup>[38]</sup>. Therefore, an increase in intake of MUFAs, particularly as a replacement for SFA and as a higher proportion in the diet, instead of carbohydrate, may be beneficial for NAFLD patients. It has been demonstrated that consumption of MUFAs decreases blood TGs by increasing fatty acid oxidation through activation of peroxisome proliferator-activated receptor (PPAR) $\alpha$  or by reducing the activation of sterol regulatory element binding protein (SREBP) and inhibiting lipogenesis. Dietary MUFAs activate PPAR $\alpha$  and PPAR $\gamma$ , increasing lipid oxidation, and decreasing insulin resistance leading to a reduction in hepatic steatosis<sup>[39]</sup>.

NAFLD, hypertension and hypertriglyceridemia are major components of metabolic syndrome. Four clinical studies have documented the beneficial effect of MUFAs in decreasing blood pressure<sup>[40-43]</sup>. Moreover, another 6 dietary trials assessing the effect of MUFA intake on blood pressure showed beneficial effects<sup>[44]</sup>. Although there are some inconsistencies in these studies, MUFA from olive oil in the context of the Mediterranean diet, plays a role in the primary prevention of NAFLD.

## DIETARY MUFAs AND NAFLD: ANIMAL STUDIES

Recently, the authors evaluated the effect of different types of dietary fats on the hepatic lipid content and oxidative stress parameters in the livers of rats with

**Table 1** Effect of olive oil on percentage of fatty acids in rat liver

Fatty acid components	Control	MCDD	MCDD + olive oil

Enrichment of a MCDD by olive oil increases the oleic acid, long chain PUFA n6:n3 ratio, and arachidonic acid percentages in the rat livers. Data from reference 39.

experimental NAFLD<sup>[45]</sup>. The study demonstrated that olive oil decreases the accumulation of TGs in the liver of rats. Severe fatty liver was seen in methionine-choline deficient diet (MCDD), MCDD + fish oil and in MCDD + butter fat groups, but not in the MCDD + olive oil group. The hepatic TG increase in the MCDD + olive oil group was blunted by 30% compared with the MCDD group. The serum TG increase was 10% lower in the MCDD + olive oil group compared with the MCDD group. In comparison with the control group, the long chain PUFA n6:n3 ratio increased in the MCDD + olive oil group by 345-fold (Table 1). Olive oil improved insulin resistance, increased the release of TG from the liver and decreased the flux of FFAs from peripheral adipose tissue back to the liver<sup>[45]</sup>. A study from Spain showed that treatment with a balanced diet rich in olive oil contributed to the recovery of the liver from hepatic steatosis<sup>[46]</sup>. This was achieved by decreasing activation of hepatic stellate cells by MUFAs, which are less susceptible to lipid peroxidation compared to PUFAs. Moreover, previous studies carried out in fibrotic rats showed that olive oil, in contrast to polyunsaturated oils, could protect against the development of fibrosis<sup>[47]</sup>. In animal studies, saturated fat significantly increased insulin resistance, long and short chain omega-3 fatty acids improved it, and the effect of MUFAs and omega-6 polyunsaturated acids ranged somewhere between the two<sup>[48]</sup>. In humans, shifting from a diet rich in SFA to one rich in MUFAs improved insulin sensitivity in healthy people<sup>[49]</sup>. A MUFA-rich diet prevented central body fat distribution, improved insulin sensitivity and increased postprandial adiponectin expression compared to a carbohydrate-rich diet (with similar caloric intake) in insulin-resistant subjects<sup>[50]</sup>. Furthermore, fasting plasma leptin fell during a MUFA-rich diet and has been associated with improved insulin action<sup>[51]</sup>. Weight maintenance with a MUFA-rich diet improved homeostasis model assessment (HOMA) and fasting pro-insulin levels in insulin-resistant subjects. Ingestion of a virgin olive

**Table 2** Mechanisms of action of olive oil on fatty liver

Mechanism	Component involved
Anti-inflammatory and immunomodulatory effects	Oleic acid
Anti-oxidants:	Phenolic compounds
Decrease lipid peroxidation	Oleic acid
Decrease oxidative DNA damage	Phenolic compounds: hydroxytyrosol, oleuropein, caffeic acid, o-coumaric acid, vanillic acid, and 3,4-dihydroxyphenylethanol (3,4-DHPEA).
Modulation of transduction pathways:	Oleic acid
Decreases arachidonic acid	Phenolic compounds: protocatechuic acid
Inhibits lipooxygenase	Hydroxytyrosol
Inhibits HMG-CoA reductase	Squalene
Decreases RAS activation	Squalene
Regulation of gene expression in liver regeneration:	Oleic acid
(Oleic acid inhibits $\delta 6$ -desaturase which decreases PGE2 and inhibits liver regeneration)	Minor compounds
Change in membrane fluidity and membrane peroxidation (estrogen modulator, regulates G protein)	Oleic acid
	Lignans

oil-based breakfast decreased postprandial glucose, triacylglycerol, and insulin concentrations, and increased HDL cholesterol and glucagon-like peptide-1 (GLP-1) concentrations as compared with a carbohydrate-rich diet<sup>[50,52]</sup>. The Mediterranean diet elicits a less prothrombotic environment by modifying different hemostatic components, such as platelet aggregation, fibrinogen, Von Willebrand factor, plasma factor VII, tissue factor and plasminogen activator inhibitor type 1 plasma levels. The postprandial increase in activated factor VII is reduced by the intake of virgin olive oil in comparison with saturated fat<sup>[53]</sup>.

## THE SPECIAL MECHANISM OF OLIVE OIL

Olive oil has traditionally been the principal oil of the Mediterranean diet. The MUFA diet prevents central body fat accumulation and decreases postprandial adiponectin expression induced by a carbohydrate-rich diet in insulin-resistant subjects<sup>[50,54]</sup>. Mechanistic studies show a direct beneficial role for olive oil in improving plasma lipids in the treatment of metabolic syndrome<sup>[44]</sup>. Unrefined or virgin olive oil has bioactive compounds with beneficial antioxidants action (Table 2)<sup>[48]</sup>. Oleocanthal, a component found in extra virgin olive oil, is a natural anti-inflammatory compound that has a potency and profile strikingly similar to that of ibuprofen<sup>[55]</sup>. The exact mechanism through which MUFAs and olive oil could modify hepatic TG content is not clear. Oleic acid from cooking oil was associated with lower insulin resistance in the general population<sup>[56]</sup>. An olive oil-enriched diet contributes to redistribution of body fat and modifies the lipolytic efficiency of fat cells<sup>[57]</sup>. Furthermore, n-9 fatty acids may regulate gene expression related to peripheral insulin sensitivity<sup>[58]</sup>,

increased endothelial vasoreactivity<sup>[59]</sup>, up-regulation of uncoupling protein mRNA in adipose tissue and muscle<sup>[60]</sup>, and expression of upregulates glucose transporter-2 in the liver<sup>[61]</sup>. Oleic acid decreases the expression of genes involved in hepatic gluconeogenesis and lipogenesis and SREBP in Zucker fatty rats<sup>[62]</sup>. Additional effects of olive oil beyond its MUFA composition relate to its polyphenols. Polyphenols present in olive oil, such as oleuropin, hydroxytyrosol, tyrosol and caffeic acid, have an important antioxidant and anti-inflammatory effect<sup>[63,64]</sup>. In rat leukocytes, these molecules have been shown to inhibit leukotriene B4 generation at the 5-lipoxygenase level and to reduce the generation of reactive oxygen species<sup>[65]</sup>. Moreover, a diet rich in olive oil improves endothelial function compared with a high carbohydrate diet or a high linoleic acid diet<sup>[66,67]</sup>. Finally, the consumption of olive oil as a single item or within a Mediterranean diet showed a significant inverse association with TNF- $\alpha$  and vascular cell adhesion molecule-1 serum levels<sup>[68]</sup>, and improved glycemic tolerance through increased secretion of GLP-1<sup>[69]</sup>. Moreover, an oleic acid-rich Mediterranean type diet may reduce the risk of atherosclerosis by decreasing the number of chylomicron remnant particles as compared to a linoleic acid-enriched diet<sup>[70]</sup>. The principal mechanisms of action of olive oil are a decrease in NF- $\kappa$ B activation, a decrease in LDL oxidation and an improvement in insulin resistance (Figure 1).

## CONCLUSION

Dietary fat content modifies liver fat in overweight non diabetic subjects<sup>[71]</sup>. NAFLD patients have a higher postprandial TG response and an increased production of large VLDL after an oral fat load compared with controls, despite normal fasting blood lipid concentration, which suggests that the metabolism of dietary fat is impaired in these individuals<sup>[72]</sup>. Decreasing total fat consumption and shifting to MUFAs found in olive oil (20%-40% of total energy) or n-3 PUFAs found in fish oil (2 g/d) could lead to a decrease in postprandial lipidemia and steatosis<sup>[73]</sup>. Further studies in humans are needed to ascertain whether the consumption of olive oil may be helpful in NAFLD patients.

### Abstract

**AIM:** To investigate the inhibitory effect of acetylshikonin on human gastric carcinoma cell line SGC-7901 and its mechanism.

**METHODS:** MTT assay was used to assess the inhibitory effect of acetylshikonin on proliferation of SGC-7901 cells. Apoptosis-inducing effect was determined by flow cytometry and terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end-labeling with Hoechst staining. Expression of mRNA and protein in Bcl-2 and Bax was analyzed by reverse transcription-polymerase chain reaction and Western blot. Antitumor effect of acetylshikonin on a mouse SGC-7901 model was also determined.

**RESULTS:** Forty-eight hours after treatment with acetylshikonin, MTT assay showed that acetylshikonin inhibited the proliferation of SGC-7901 cells in a dose-dependent manner. The half maximal inhibitory concentration of acetylshikonin to SGC-7901 cells was  $0.428 \pm 0.07$  mg/L. Cell shrinkage, nuclear pyknosis and chromatin condensation, which are the characteristics of cell apoptosis, were observed in treated SGC-7901 cells and the percentage of apoptosis increased in a dose-dependent manner. Acetylshikonin down-regulated the expression of Bcl-2 and up-regulated the expression of Bax in the treated SGC-7901 cells compared with the controls. The experiment *in vivo*

showed that 0.5, 1, and 2 mg/kg of acetylshikonin significantly inhibited the growth of tumor in the mouse SGC-7901 model, with an inhibitory rate of 25.00%-55.76%.

**CONCLUSION:** Acetylshikonin inhibits the growth of SGC-7901 cells *in vitro* and *in vivo* by inducing cell apoptosis.

### INTRODUCTION

Although advances have been made in clinical medicine, no effective treatment modalities are available for patients with advanced or metastatic tumors<sup>[1]</sup>. Gastric cancer is one of the most common malignant tumors worldwide, and its incidence and mortality rank first in China<sup>[2,3]</sup>. At present, gastric cancer patients have certain clinical responses to chemotherapy or radiation therapy, but they cannot tolerate it well<sup>[4,5]</sup>. Therefore, it is absolutely necessary to explore drugs capable of preventing and treating gastric cancer and other malignancies.

Chemotherapy is one of the main treatment modalities for advanced cancer<sup>[6]</sup>. It has been shown that acetylshikonin, one of the shikonin derivatives, is effective against sterilized and infected wounds<sup>[7,8]</sup>. It has been demonstrated that acetylshikonin can inhibit tumor-induced cutaneous angiogenesis<sup>[9]</sup> and has obvious antitumor effects on S180 sarcoma model<sup>[10]</sup>. However, little is known about the effect of acetylshikonin on gastric cancer *in vitro*, especially *in vivo*. This study was to evaluate the ability of acetylshikonin to inhibit cell proliferation and induce apoptosis of human gastric cancer SGC-7901 cells. Our results demonstrate

that acetylshikonin could induce apoptosis by down-regulating Bcl-2 and up-regulating Bax in SGC-7901 cells. Significant antitumor effects of acetylshikonin could also be observed in a SGC-7901 tumor xenograft model of nude mice.

## MATERIALS AND METHODS

### Cell line and reagents

Human gastric carcinoma cell line SGC-7901 was obtained from the Institute of Materia Medica, North Sichuan Medical College (Nanchong, China). The cells were cultured in RPMI 1640 (Gibco, Grand Island, NY, USA) supplemented with 10% fetal bovine serum (Minhai Bioengineering Co., Lanzhou, China), and maintained at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>. Acetylshikonin was obtained from Huakang Pharmaceutical Company (Deyang, China). Cyclophosphamide was provided by Hengrui Pharmaceutical Company (Jiangsu, China). MTT was purchased from Sigma Chemical Company (St. Louis, MO, USA).

### Cell viability assay

Effect of acetylshikonin on the viability of SGC-7901 cells was detected by MTT assay<sup>[11]</sup>. Cells were plated in a 96-well plate ( $5 \times 10^3$  cells/well) for 24 h, and then treated with different concentrations of acetylshikonin (0.05, 0.1, 0.2, 0.4, 0.8, 1.6, 3.2, 6.4 mg/L). Tetrazolium dye, 3-(4, 5-dimethylthiazol-2)-2, 5-diphenyl-2H-tetrazolium bromide (MTT; Sigma; 5 mg/mL in PBS) was added to the medium for 4 h, and measured by spectrophotometry after 15 min at room temperature. Optical density (OD) which reflects the viable cell population in each well was determined.

### Terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end-labeling (TUNEL) assay and cell morphology assessment

For apoptosis studies, cells were plated on glass cover slips. Samples were assessed 24 h after plated for the detection of TUNEL-positivity (brown cellular nuclei appeared) using an *in situ* cell death detection kit (Roche Diagnostic Corp., USA). Apoptotic rates of cells were also determined with Hoechst staining and cells showing condensed chromatin were defined as apoptotic<sup>[12]</sup>. Percentage of apoptotic cells in each sample was counted under microscope and averaged over 10 fields (80-100 cells each).

### Flow cytometry

Cells were harvested and pelleted at  $1000 \times g$  for 5 min, then fixed in 70% ethanol and washed with cold PBS. After suspended in 1 mL propidium iodide solution (50 µg/mL), 0.1% (w/v) sodium citrate, and 0.1% Triton X-100. Cells were incubated at 4°C in the dark for at least 15 min and analyzed with a flow cytometer (FACS, Beckman Coulter, USA) to determine the number of cells at each cell cycle and cell apoptosis rate as previously described<sup>[11]</sup>.

### Western blot analysis

Expression of apoptosis-related proteins (Bcl-2 and

Bax) was analyzed by Western blotting as previously described<sup>[11]</sup>. In brief, the cells were lysed in a lysis buffer at 4°C by sonication. Lysates were centrifuged at 15000 r/min for 15 min at 4°C. Proteins were separated on SDS-PAGE, transferred to nitrocellulose filters and incubated with antibodies against Bcl-2, Bax and actin, respectively. The membrane, were incubated with peroxidase-conjugated secondary antibodies, and detected with an enhanced chemiluminescence reagent.

### Expression of Bcl-2 and Bax mRNA

Expression of Bcl-2 and Bax was semi-quantitatively detected by reverse transcription-polymerase chain reaction (RT-PCR). Total RNA was isolated from the cells using the TRIzol reagent (Gibco) and reverse transcribed with the SuperScript first-strand synthesis system (Invitrogen) according to the manufacturer's instructions. Sequences of the primers used for RT-PCR are listed in Table 1. PCR for Bcl-2 was performed at 94°C for 3 min, followed by 30 cycles at 94°C for 30 s, at 70°C for 30 s, at 72°C for 45 s and a final extension at 72°C for 7 min. PCR for Bax was performed at 95°C for 3 min, followed by 30 cycles at 95°C for 30 s, at 57°C for 30 s, at 72°C for 1 min, and a final extension at 72°C for 7 min. PCR products were separated on 10 g/L agarose gel stained with ethidium bromide and observed under ultraviolet light.

### In vivo anti-tumor activity

Seven-week old male nude mice (supplied by Experimental Animal Center, West China Center of Medical Sciences, Sichuan University, China) were inoculated subcutaneously with transplanted human SGC-7901 gastric carcinoma cell line ( $5 \times 10^6$  cells per mouse). Tumors were allowed to develop to about 75 mm × 75 mm × 75 mm. Thirty mice were randomized into 6 groups ( $n = 5$ ). Mice in 3 acetylshikonin treatment groups received 0.5, 1 and 2 mg/kg acetylshikonin suspended in castor oil; mice in the castor oil group received an equal volume of castor oil; mice in control group received an equal volume of normal saline (NS), once a day for 15 consecutive days. Mice in the positive control group received cyclophosphamide (60 mg/kg) only on the first day. The animals were sacrificed and their tumors removed and weighed immediately. Tumor inhibitory rate was calculated according to the following formula: tumor inhibitory rate (%) =  $1 - (W_{\text{treated}}/W_{\text{control}}) \times 100\%$ <sup>[11]</sup>.

### Immunohistochemical staining

Thirty tumor tissue samples were fixed in 10% buffered formalin and embedded in paraffin. Tumor tissue was cut into 4-µm thick sections. The sections were stained as previously described<sup>[13]</sup>. Expressions of Bax, Bcl-2 and Caspase 3 were observed under an inverted phase contrast microscope. Photos were taken and analyzed by Image pro plus, and the integrated optical density (IOD) was calculated.

### Statistical analysis

Data were expressed as mean ± SD. Statistical analysis was performed using Student's *t* test and chi-square test.  $P < 0.05$  was considered statistically significant.

Table 1 Sequence of primers used in our study

	Product size	Sense primer	Anti-sense primer
Bax	311 bp	5'GCGTCCACCCAAGAAGCTGAG3'	5'ACCACCCTGGTCTTGGATCC3'
Bcl-2	280 bp	5'TGTGGCCTTCTTTGAGTTCG3'	5'TCACTTGTGGCTCAGATAGG3'

Table 2 Effect of acetylshikonin on cell-cycle phase distribution and apoptotic ratios of SGC-7901 cells *in vitro* (mean  $\pm$  SD)

Concentration (mg/L)	Cell cycle phase distribution (%)			Apoptotic index (%)		
	G <sub>0</sub> /G <sub>1</sub>	S	G <sub>2</sub> /M	Hoechst	TUNEL	FACScan
0	53.73 $\pm$ 4.61	36.29 $\pm$ 7.32	9.98 $\pm$ 2.35	5.76 $\pm$ 0.58	5.34 $\pm$ 0.64	6.15 $\pm$ 0.75
0.2	54.82 $\pm$ 4.12	33.45 $\pm$ 6.05	11.73 $\pm$ 3.90	11.05 $\pm$ 2.10 <sup>a</sup>	11.56 $\pm$ 1.62 <sup>a</sup>	10.13 $\pm$ 1.69 <sup>a</sup>
0.4	56.92 $\pm$ 5.04	30.15 $\pm$ 5.84	12.93 $\pm$ 5.32	28.76 $\pm$ 3.55 <sup>b</sup>	30.89 $\pm$ 2.35 <sup>b</sup>	25.40 $\pm$ 2.46 <sup>b</sup>
0.8	57.12 $\pm$ 2.94	28.58 $\pm$ 5.21	14.30 $\pm$ 4.79 <sup>a</sup>	52.25 $\pm$ 6.16 <sup>b</sup>	56.33 $\pm$ 5.78 <sup>b</sup>	48.73 $\pm$ 6.55 <sup>b</sup>

Different concentrations of acetylshikonin were added to SGC-7901 cell culture for 24 h, cell-cycle phase distribution and apoptotic ratios were then analyzed by FACScan flow cytometry and TUNEL assay with Hoechst staining. Each experiment was independently performed three times. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

Figure 1 Effect of acetylshikonin on proliferation of SGC-7901 cells *in vitro*. SGC-7901 cells were treated with various concentrations of acetylshikonin for 48 h. Tumor growth inhibitory rate was determined by MTT assay.

## RESULTS

### Effect of acetylshikonin on the growth of SGC-7901 cells *in vitro*

The SGC-7901 cells were treated with various concentrations of acetylshikonin for 48 h and cell viability was determined by MTT assay. Acetylshikonin inhibited the growth of gastric cancer cells in a dose-dependent manner (Figure 1). Cell growth was suppressed by 33.7%, 39.3% and 45.5% 48 h after treatment with 0.2, 0.4 and 0.8 mg/L acetylshikonin, respectively. The inhibitory rate of 3.2 mg/L acetylshikonin for tumor cell growth was over 90%. The half maximal inhibitory concentration (IC<sub>50</sub>) of acetylshikonin for SGC-7901 cells was 0.428 mg/L.

### Acetylshikonin induced apoptosis of SGC-7901 cells

Twenty-four hours after exposure to acetylshikonin, SGC-7901 cells began to show morphologic features of apoptosis and some cells rounded up off the plate, exhibiting a smaller and circular shape. Cell cycle analysis revealed that the number of cells was different at the G<sub>2</sub>/M phase after exposure to 0.2 and 0.4 mg/L acetylshikonin, but significantly decreased at the G<sub>2</sub>/M phase after exposure to 0.8 mg/L acetylshikonin. Hoechst assay showed nuclear condensation, DNA

fragmentation and perinuclear apoptotic bodies after treatment with 0.2 mg/L acetylshikonin, indicating that acetylshikonin induces apoptosis in a dose-dependent manner (Table 2).

### Acetylshikonin regulated the expression of Bcl-2 and Bax proteins

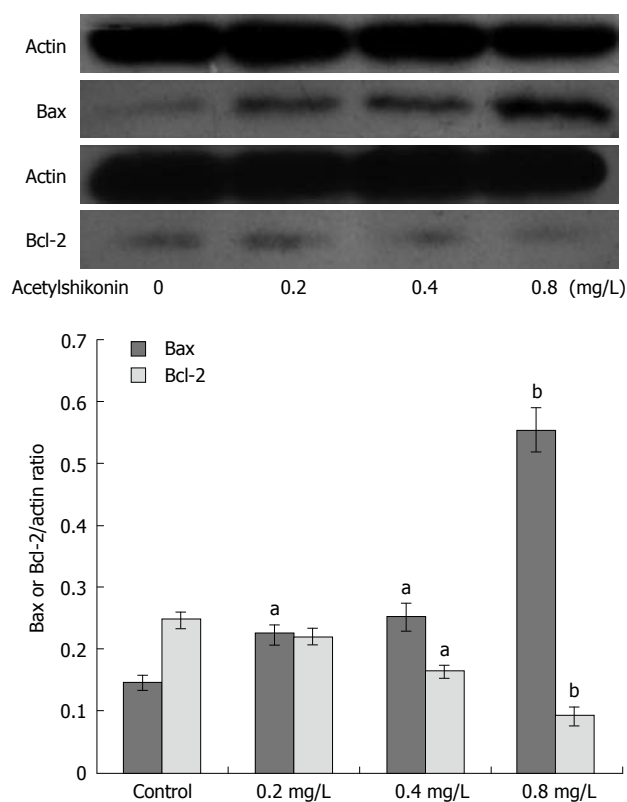

Western blot assay showed that acetylshikonin could induce or inhibit the expression of Bcl-2 and Bax. Twenty-four hours after treatment with indicated concentrations of acetylshikonin, the expression of Bax was markedly increased, while that of Bcl-2 had a trend to decrease. The Bax/Bcl-2 protein ratio was also elevated remarkably. The expression of actin remained unchanged (Figure 2).

### Acetylshikonin regulated the expression of Bcl-2 and Bax mRNA

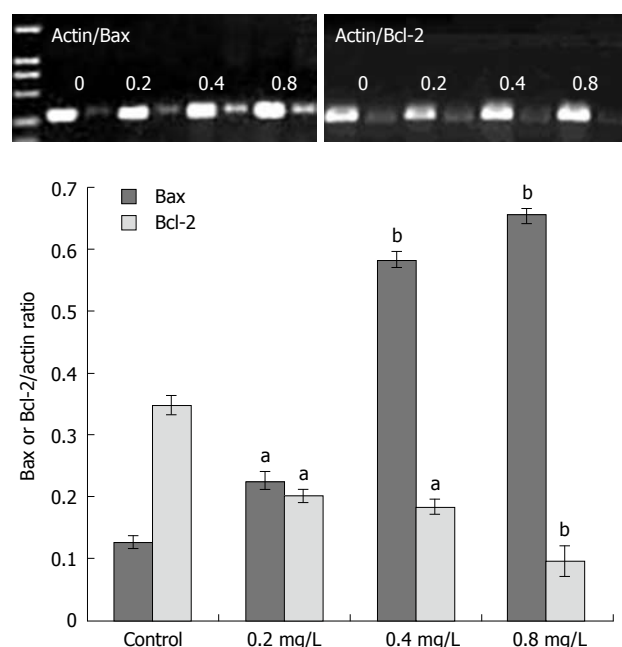

The expression of Bcl-2 and Bax was semi-quantitatively detected with  $\beta$ -actin as an internal standard. Acetylshikonin inhibited the expression of Bcl-2 in SGC-7901 cells in a dose-dependent manner. However, the expression of Bax mRNA increased with the concentration of acetylshikonin used (Figure 3).

### Effect of acetylshikonin on inoculated tumors in mice

To determine whether acetylshikonin inhibits tumor growth *in vivo*, an equal number of SGC-7901 cells were injected into the right flanks of nude mice. Tumor growth was notably inhibited in mice after treatment with acetylshikonin (Figure 4). The inhibitory rate of tumor growth in 3 acetylshikonin groups and cyclophosphamide group was 55.76%, 39.42%, 25.00% and 58.65%, respectively. In addition, no toxicity judged by parallel monitoring of body weight was observed in acetylshikonin-treated mice. Immunohistochemistry data showed that the IOD value for Bcl-2 was  $19.26 \pm 2.15$  in the negative control group and  $11.59 \pm 1.04$  in the 2 mg/kg acetylshikonin group (Figure 5). However, the expression of Bax and Caspase 3 was markedly higher in 3 acetylshikonin groups than in negative control group.

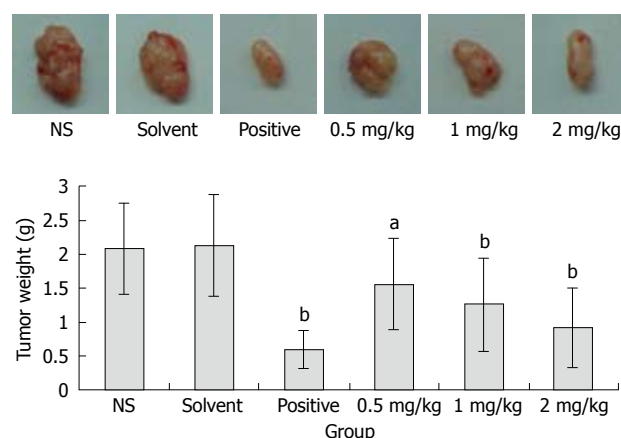

**Figure 2** Effect of acetylshikonin on expression of Bcl-2 and Bax in SGC-7901 cells. Lower panel: Ratios of protein quantitation of Bcl-2 or Bax to actin. Each experiment was independently performed three times. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

**Figure 3** Effect of acetylshikonin on Bcl-2 and Bax mRNA expression levels in SGC-7901 cells. Lower panel: Ratios of mRNA quantitation of Bcl-2 or Bax to actin. Each experiment was independently performed three times. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

## DISCUSSION

Shikonin, isolated from roots of the medicinal herb *Lithospermum erythrorhizon* Siebold Zucc<sup>[14]</sup>, is

**Figure 4** Anti-tumor effects of acetylshikonin *in vivo*. Representative tumors from each group were shown. Lower panel: Average tumor weight of sacrificed animals. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

**Figure 5** Effect of acetylshikonin on expression of Bax, Bcl-2 and Caspase-3 in SGC-7901 tumor tissues. Tumor tissue sections showed strong Bax/Caspase-3 cytoplasmic staining and weak Bcl-2 cytoplasmic staining of tumor cells in acetylshikonin treatment groups, as well as the integrated optical density (IOD) for the expression of Bax, Bcl-2 and Caspase-3 in SGC-7901 cells. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

a Chinese herbal medicine with various biological activities, including anti-microbial, anti-fungal, anti-HIV, anti-inflammatory, anti-tumor, and wound-healing activities<sup>[15-17]</sup>. However, its toxicity has limited it as a therapeutic agent<sup>[14,17]</sup>. Acetylshikonin, one of the shikonin derivatives, has been shown to possess anti-cancer activity<sup>[9,10]</sup> with less toxicity<sup>[18]</sup>, which has made acetylshikonin a promising anti-tumor agent. However, its effects on gastric cancer cells have not been reported.

In the present study, acetylshikonin suppressed the proliferation of SGC-7901 cells *in vitro*, and inhibited tumor growth in a SGC-7901 tumor xenograft model of nude mice. Generally, tumorigenesis and tumor progression are strongly associated with abnormal apoptosis. It has been shown that shikonin and its derivatives induce apoptosis of tumor cells<sup>[16,19,20]</sup>. Our data demonstrate that acetylshikonin could also induce apoptosis of SGC-7901 cells with typical apoptotic alterations, including morphological changes and positive TUNEL assay, DNA fragmentation and apoptotic

sub-G1 peak.

Apoptosis is a complex process regulated by a variety of factors<sup>[21,22]</sup>. Members of the Bcl-2 family are the important regulators in the apoptotic pathway with individual members that promote or suppress apoptosis. As an anti-apoptotic protein, Bcl-2 confers a negative control in the pathway of cellular suicide machinery, whereas Bax, a Bcl-2-homologous protein, promotes cell death by competing with Bcl-2<sup>[23,24]</sup>. To explore whether apoptosis-related genes contribute to the inhibitory effect of acetylshikonin on SGC-7901 cells, the relative Bcl-2 and Bax expression levels induced by acetylshikonin were determined in this study. We found that acetylshikonin decreased the Bcl-2 expression while increased the Bax expression in a dose-dependent manner. Moreover, acetylshikonin up-regulated the expression level of Caspase 3 *in vivo*. Taken together, the reduced Bcl-2/Bax ratio, activating Caspases and cell apoptosis ultimately<sup>[24]</sup>, might serve as a mechanism of acetylshikonin underlying apoptosis of SGC-7901 cells.

In conclusion, acetylshikonin has significant antitumor effects both *in vitro* and *in vivo* by inducing apoptosis of SGC-7901 cells involved in down-regulation of Bcl-2 expression and up-regulation of Bax expression. Acetylshikonin can be used as a potent and selective agent in the treatment of human gastric adenocarcinoma.

## COMMENTS

### Background

Patients with gastric cancer have certain clinical responses to chemotherapy or radiation therapy, but they cannot tolerate it. Therefore, it is absolutely necessary to explore drugs capable of preventing and treating gastric cancer and other malignancies.

### Research frontiers

Previous studies on shikonin, a chemical derived from a Chinese medicinal herb, have shown that shikonin has anti-tumor effects although it is toxic. Acetylshikonin, an acetyl derivative, has less toxicity and suppresses the growth of sarcomas. However, little is known about its effect on gastric cancer *in vitro*, especially *in vivo*.

### Innovations and breakthroughs

The study demonstrated that acetylshikonin could exert significant effects on SGC-7901 cells both *in vitro* and *in vivo* by inducing cell apoptosis.

### Applications

Acetylshikonin can be used as a potent and selective agent in treatment of human gastric adenocarcinoma.

### Terminology

Apoptosis: A type of cell death, in which cells use a specialized cellular machinery to kill themselves, as well as a cell suicide mechanism enabling metazoans to control the cell number and eliminate them.

### Peer review

The study analyzed the effect of acetylshikonin, derived from a Chinese medicinal herb, on gastric cancer cell line SGC-7901 *in vivo*, which is an interesting finding.

### Abstract

**AIM:** To evaluate the therapeutic effects of a probiotic supplement (*Clostridium butyricum*, CGMCC0313) in a chemically-induced rat model of experimental colitis.

**METHODS:** An experimental ulcerative colitis model was established by rectal injection of oxazolone into the colon of 40 Wistar rats randomly divided into four groups. The positive control group was sacrificed 3 d after colitis onset. The remaining groups were fed daily with either 2 mL of *C. butyricum* ( $2.3 \times 10^{11}$  CFU/L), 2 mL of mesalamine (100 g/L), or 1 mL of sodium butyrate (50 mmol/L) for 21 d. The animals' body weight, behavior, and bowel movements were recorded weekly. After sacrifice, visual and microscopic observations of pathological changes of colon tissue were made, body weight and wet colon mass index were measured and recorded, and serum levels of interleukin-23 (IL-23) and TNF- $\alpha$  were measured using ELISA. Expression of calcitonin gene-related peptide in colon tissue was measured by RT-PCR. Finally, changes in rat intestinal microflora status were measured in all groups.

**RESULTS:** We found that treatment with *C. butyricum*

lowered the serum levels of both IL-23 and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) with similar or even better efficiency than that of mesalamine or sodium butyrate. The rat intestinal flora appeared to recover more quickly in the group treated with *C. butyricum* than in the mesalamine and sodium butyrate groups. Finally, we found that the expression level of calcitonin gene related peptide was elevated in colon tissue in the sodium butyrate treated group but not in the *C. butyricum* or mesalamine treated groups, indicating a sensitization of colon following sodium butyrate treatment.

**CONCLUSION:** In our experimental colitis model, treatment with *C. butyricum* CGMCC0313, a probiotic supplement, is at least as efficient as treatment with mesalamine.

Therapeutic effects of *Clostridium butyricum* on experimental colitis induced by oxazolone in rats. *World J Gastroenterol* 2009; 15(15): 1821-1828 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1821.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1821>

### INTRODUCTION

Inflammatory bowel disease (IBD) includes ulcerative colitis (UC) and Crohn's disease (CD). The incidence rate of ulcerative colitis increases annually in China<sup>[1,2]</sup>. A number of recent studies have been published that focus on the role of cellular inflammatory factors and related immune mechanisms during the onset and progression of IBD. Furthermore, animal experiments show that inflammation of the bowel can be induced by dysbiosis

of, or immune tolerance deficiencies related to, the intestinal microbiological flora<sup>[3,4]</sup>.

Steroid hormones, immunosuppressive agents or salicylic acid derivatives are used to treat IBD with modest results and often with serious side effects. Several recent studies, however, on the microecological therapy of UC using *Clostridium butyricum* preparations show promising results and have been drawing some attention in the biomedical research community<sup>[5-9]</sup>. Sodium butyrate, although it is a confirmed anti-inflammatory agent for the treatment of experimental colitis<sup>[10-14]</sup>, can cause non-inflammatory colonic hypersensitivity<sup>[15]</sup>. Calcitonin gene related peptide (CGRP) may increase organ sensitivity, and sensory afferents are implicated in peritoneal irritation of organs involved in inflammation<sup>[16-18]</sup>.

Based on animal experiments and clinical applications, we found that treatment of ulcerative colitis with *C. butyricum*, CGMCC0313.1 live bacterium, gives good results both in animal and human ulcerative colitis<sup>[19-22]</sup>; but, the mechanisms are not yet fully understood. As a part of our effort to elucidate the therapeutic mechanisms of *C. butyricum* CGMCC0313.1, we used an oxazolone induced rat model of experimental colitis to measure the effect of intrarectally administered *C. butyricum* CGMCC0313.1 and two treatment controls on a set of UC relevant parameters.

Oxazolone is a chemical allergen and a sensitizing agent. Using oxazolone to induce colitis in rat constitutes a more satisfactory animal model of UC with a high degree of similarity to the histopathological characteristics and distribution of inflammation described in human UC<sup>[23,24]</sup>.

Thus, we compared *C. butyricum* CGMCC0313.1 with sodium butyrate and mesalamine (5-aminosalicylic acid, one of the standard prescriptions for ulcerative colitis) to measure each compound's effects on the repair of intestinal walls, on serum concentrations of interleukin-23 (IL-23) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), on the level of CGRP-mRNA in rat colon tissue, and restoration of the balance of the intestinal microflora.

## MATERIALS AND METHODS

Wistar SPF (specific-pathogen free) rats with body weight of 160-180 g were purchased from the Experimental Animal Center of Qingdao Institute for Drug Control, China. Oxazolone was purchased from Alfa Aesar (Great Britain). Mesalamine was purchased from Adepha Drug Group (France). Sodium butyrate was purchased from Sigma-Aldrich Chemical Company (St. Louis, Missouri, USA). *C. butyricum*, CGMCC0313.1 powder or capsules, were kindly provided by East Sea Pharmaceutical Co. Ltd, Shandong, China. Trizol was purchased from Invitrogen (USA). The transcription kit was purchased from Promega (USA). Primers were synthesized by Shanghai Biological Engineering Co., China. The EasyTek PCR Amplifier Kit was obtained from Shanghai Biological Engineering Co., China. The IL-23 ELISA Kit and TNF- $\alpha$  Kit was purchased from Wuhan Boster Biological Engineering Co. Ltd, China.

## Establishing an animal model of experimental colitis

Our model was based on a method previously described by Lamprecht *et al*<sup>[25]</sup> and modified by us. Briefly, we used 40 animals for testing. A 2 cm  $\times$  2 cm area on the back of each animal was shaved to expose the skin. Using a cotton ball, 300  $\mu$ L Oxazolone (5% in absolute alcohol) was applied topically on the exposed area to induce an allergic reaction. After 5 and 7 d, 450  $\mu$ L of 5% oxazolone in a 50% ethanol solution, was injected using 1 mm diameter rubber tubing inserted into the colon through the rectum to about 8 cm proximal to the anal verge. To ensure even distribution of the oxazolone solution throughout the entire colon and cecum, the animals were kept in a vertical position for 45 s by holding them up by their tails after injections.

## Groups and treatment

After the induction of colitis, the 40 treated animals were randomly divided into four groups. Thus, 10 animals belonged to the positive control (PC) group and received no treatment (three of these animals died during the study). Ten animals were assigned to the positive drug control (mesalamine, MA) group and received mesalamine treatment (two animals died during the study). Ten animals receiving probiotic treatment with *C. butyricum* CGMCC0313.1 (*C. butyricum*), were part of the probiotic (PB) group. Finally, 10 animals received treatment with sodium butyrate (two of these animals died during the study). A group of eight animals were kept as negative (NC) controls and received no oxazolone, nor any drug treatments. All animals in the mesalamine, probiotic and sodium butyrate groups were treated for 21 d, once per day, by feeding with either 2 mL of *C. butyricum* ( $2.3 \times 10^{11}$  CFU/L), 2 mL of mesalamine (100 g/L), or 1 mL of sodium butyrate (50 mmol/L) *via* an orogastric tube. During the test period, animal behavior, bowel movements, and body weight was observed and recorded once per week. After 21 d of treatment, all animals were sacrificed by decapitation. The colons were cut longitudinally then cleaned with physiological saline. Excess water was removed with filtration paper before measuring the colon wet mass. Index of wet colon mass = colon wet mass (g)/body weight (kg). The colon tissue was subsequently perfused with a 10% formalin solution, gradually dehydrated with ethanol, embedded in paraffin and sliced into 5  $\mu$ m sections. The sections were wet mounted on glass slides and subjected to hematoxylin-eosin staining. Pathological changes in the animal tissues were identified under light microscope.

## Measurement of IL-23 and TNF- $\alpha$ in rat serum

Blood was collected after decapitation and incubated overnight at 4°C. Serum was recovered after centrifugation and aliquoted. The aliquots were stored at -20°C for later tests. The serum levels IL-23 and TNF- $\alpha$  were measured using ELISA kits strictly following the manufacturer's instructions.

## Extraction of total RNA from colon tissue

Colon tissue (100 mg) was ground to powder in liquid

nitrogen and 1 mL Trizol was added. After thorough mixing, the suspension was transferred into 1.5 mL Eppendorf tubes, kept in a -20°C freezer for 1-2 h, then stored in liquid nitrogen for later use.

Frozen 1.5 mL Eppendorf tubes were taken out from the liquid nitrogen and allowed to warm to room temperature for 5 min. Chloroform (200 µL) was added and the mixture was shaken for 20 s, incubated for 5 min at room temperature and spun for 15 min at 4°C and 10 000 r/min. Isopropanol (500 µL) was thoroughly mixed into the supernatant recovered after centrifugation. The solution was incubated for 10 min at room temperature and spun for 10 min at 4°C 10 000 r/min. The supernatant was discarded and the pellet was washed once in 75% ethanol and allowed to air dry for 10 min at room temperature. Finally, the pellet was dissolved in 30 µL DEPC-water. Three 5 µL samples were taken from the solution; one for OD measurement (20 × dilution), one for RNA content analysis, and one for agarose gel electrophoresis. The rest of the solution was stored in liquid nitrogen.

#### Confirmation of CGRP expression using RT-PCR

cDNA was prepared using the AMV reverse transcriptase reaction. Reverse transcription solution contained 4 µL 25 mmol/L MgCl<sub>2</sub>, 2 µL 10 × PCR buffer, 2 µL dNTP, 0.5 µL recombinant RNasin, 0.7 µL AMV reverse transcriptase, and 1 µL dT oligo solution. RNA (3 µg) was added in each 20 µL reaction mixture. Reaction parameters were as follows: pre-denaturation for at 70°C 10 min; elongation at 42°C for 15 min; denaturation at 95°C for 5 min, and hold at 4°C for 5 min. Products were stored at -20°C.

PCR reaction mixtures (50 µL) were prepared containing 15 µL ddH<sub>2</sub>O, 25 µL 2 × PCR buffer, 1 µL MgCl<sub>2</sub>, 3 µL cDNA, and 3 µL of each primer (final concentration: 1 µmol/L) before mixing and spinning briefly.

For CGRP, the PCR reaction conditions were as follows: initialization at 94°C for 5 min followed by 35 cycles of denaturation at 94°C for 30 s, annealing for 45 s at 56°C, and extension for 45 s at 72°C. The final extension was 10 min at 72°C. For β-actin, the same process was used, except the annealing temperature was adjusted to 50°C. After completion of the PCR-protocols, 5 µL of the reaction mixture was analyzed with agarose gel electrophoresis (1.5%). The bands were visualized under UV light.

The sequences of the primers were CGRP (sense AGGTCGGGAGGTGTGGTGAA and anti sense ATCCGCTTGAGGTTTAGCAGAG) and β-actin (sense ATCATGTTTGAGACCTTCAAC and antisense CATCTCTTGCTCGAAGTCCA).

#### Analysis of intestinal flora

Feces samples were collected under sterile conditions directly from the rat's rectum before and after induction of colitis and after the treatments were given. After weighing, the freshly collected feces was suspended in physiological saline (10 × w/v) and mixed well. Aliquots (100 µL) of the mixtures were spread evenly on selective

medium surfaces. After incubating 48 h at 37°C (aerobic bacteria) or 72 h at 37°C (anaerobic bacteria) live bacteria was counted (CFU/g). Intestinal content was cultured separately on EMB, BBL, MRS, LEVY, and FS media.

#### Data and statistical analysis

All data were given as mean ± SD. Data were analyzed in SPSS11.5, using one-way ANOVA to perform the comparisons among groups, then using least significant difference test (LSD-*t*) to perform the multi-comparisons among means, *P* < 0.05 was considered a significant difference.

## RESULTS

#### Lower body weight, loose or bloody stool, and higher index of wet colon mass in rat colitis induced with oxazolone

The body weight decreased dramatically in the positive control group compared to the negative control group. The treatment groups also showed body weight loss; but, it was not as dramatic as the positive control group (Table 1). During the initiation phase of the UC model, most rats in the experimental group had loose, greasy or watery, sometimes bloody stools. Stools became normal in all treatment groups. Thus, the clinical symptoms of UC obviously improved upon treatment in this animal model. The wet colon mass index in the mesalamine group, the *C. butyricum* group and sodium butyrate group was clearly lower than the positive control wet colon mass index (*P* < 0.05) (Table 1).

#### Pathological changes in oxazolone-induced experimental colitis in rats

Animals in the positive control group were sacrificed three days after the experimental model was successfully established. Most pathological changes were found in the middle and lower part of colon with hyperemia and dropsy in the distal colon. Pathological changes were continuously distributed throughout the affected parts of the colon. Microscopic inspection of the tissues under light revealed abscissions of the mucous membrane epithelial cells, erosion of the mucous membrane and ulcer formation. We also noticed a decrease in the number of goblet cells and a disappearance or atrophy of the intestinal glands. Inflammation was located in or beneath the mucous membrane, although, in some cases, the muscle layers also appeared to be affected. Tissues were infiltrated mainly by lymphocytes, oxyphilic cells and plasmocytes; and less with neutrophil granulocytes. After treatment, the hyperemia-like characteristic of the mucous membrane improved, the swelling receded and the erosion healed. A few small ulcers were still discernible under microscopy, but the inflammatory cell infiltration, when apparent, consisted mainly of lymphocytes and acidophilic granular cells (Figure 1).

#### Serum levels of IL-23 and TNF-α in rat experimental colitis induced with oxazolone

The serum levels of IL-23 and TNF-α in the positive

**Table 1** Effects on body weight and wet colon mass index in rat colitis induced with oxazolone (mean  $\pm$  SD)

Group	n	Dose	Body weight (g)	Wet colon mass index (g/kg)
NC	8	N/A	191.3 $\pm$ 24.2	5.3 $\pm$ 1.2
PC	7	N/A	149.0 $\pm$ 15.9 <sup>d</sup>	9.1 $\pm$ 2.5 <sup>d</sup>
PB	10	2.3 $\times$ 10 <sup>11</sup> CFU/L	175.9 $\pm$ 43.2	6.7 $\pm$ 1.3 <sup>a</sup>
MA	8	100 g/L	179.8 $\pm$ 18.4	6.9 $\pm$ 2.3
SB	8	0.05 mol/L	175.8 $\pm$ 23.0	6.5 $\pm$ 1.6 <sup>a</sup>

<sup>a</sup> $P$  < 0.05 vs positive control; <sup>d</sup> $P$  < 0.01 vs negative control; NC: Negative control; PC: Positive control; PB: Probiotic (*C. butyricum*); MA: Mesalamine; SB: Sodium butyrate.

control group was remarkably higher than the negative control group ( $P$  < 0.05, Table 2). After treatment, rat serum levels of IL-23 in *C. butyricum*, mesalamine and sodium butyrate groups became much lower than the positive control ( $P$  < 0.01). The levels of TNF- $\alpha$  in the *C. butyricum* group was clearly lower than the positive control, while there was no significant difference in the mesalamine and sodium butyrate groups (Table 2).

#### Sodium butyrate treatment increases CGRP expression levels

CGRP expression levels in the negative control, positive control, *C. butyricum* and mesalamine groups were weak, whereas the expression of CGRP in the sodium butyrate group was remarkably enhanced (Figure 2).

#### Effect on intestinal flora of rats with oxazolone-induced experimental colitis

In normal rats, intestinal *Colibacter*, *Bifidobacterium*, *Acidobacterium*, *Fusobacterium*, and *Clostridium* grew well (Table 3). After UC was established in this animal model, the number of intestinal *Bifidobacterium* and *Acidobacterium* in the positive control group decreased in

**Table 2** IL-23 and TNF- $\alpha$  levels in rat serum in oxazolone-induced experimental colitis

Group (n = 7)	Dose	IL-23 (ng/L)	TNF- $\alpha$ (ng/L)
NC	N/A	5.75 $\pm$ 2.51	15.93 $\pm$ 11.36

comparison to the negative control ( $P$  < 0.01), whereas the number of *Colibacter*, *Fusobacterium* and *Clostridium* increased ( $P$  < 0.01). After treatment with *C. butyricum*, mesalamine or sodium butyrate, the amount of intestinal *Bifidobacterium* and *Acidobacterium* increased relative to the positive control, whereas the number of *Colibacter*, *Fusobacterium* and *Clostridium* decreased ( $P$  < 0.01 and  $P$  < 0.05). Compared with the *C. butyricum* group, the amount of *Colibacter* increased ( $P$  < 0.01 and  $P$  < 0.05), and the number of *Acidobacterium* clearly decreased (all  $P$  < 0.01) in the mesalamine and sodium butyrate groups. The amount of *Clostridium* in the mesalamine group was significantly lower than in the other groups ( $P$  < 0.01). The remaining bacterial groups showed no significant differences between the treatment groups (Table 3).

## DISCUSSION

In our rat model of experimental colitis, the inflammatory disease is induced by intrarectal administration of oxazolone. Symptoms of inflammation of the distal rat colon included reddening and swelling of the mucous membrane. The continuously distributed pathological

**Figure 2** Effect on CGRP expression in treated or untreated rat experimental colitis induced with oxazolone. M: MW marker; 1: Negative control; 2: Positive control; 3: *C. butyricum*; 4: Mesalamine; 5: Sodium butyrate.

changes included the loss of epithelia cells, erosion of the epithelial mucous layer, ulcers, a decrease in the number of goblet cells and a decrease in gland density. The inflammation appeared to be located in or beneath the epithelial mucous layer, although in some cases the muscle layer showed infiltration of inflammatory cells. The wet colon mass index increased in the positive control group, as did the serum concentrations of cellular inflammation markers IL-23 and TNF- $\alpha$ .

After treatment with *C. butyricum*, mesalamine or sodium butyrate, the swelling and reddening of the colonic mucous membrane improved. The mucous membrane was almost healed, and the wet colon mass index decreased significantly. The serum content of IL-23 and TNF- $\alpha$  was remarkably decreased, almost back to the normal levels, and the balance of intestinal flora was restored.

IL-23 is a cellular factor, a new member of the IL-12 family. Similar to IL-12, it is a heterodimer, sharing the p40 subunit with IL-12. The p40 and p19 subunits form a covalently linked heterodimer *via* a disulfide bond. In addition to the interleukin receptor subunit 12R $\beta$ 1 shared with IL-12, IL-23 has its own special receptor subunit IL23R. Activated dendritic cells, macrophages, T cells and blast cells all generate large amounts of p19 mRNA with Th1 cells expressing more p19 than Th2 cells. Among these cell types, only activated dendritic cells and macrophages produce both the p40<sup>[26]</sup> and p19 required for the formation of IL-23, which is then secreted by these cells. Thus, human and rat IL-23 is mainly produced by activated dendritic cells<sup>[27]</sup>. IL-23 can induce mononuclear cells and macrophages to express

inflammatory factors IL-1, IL-6 and TNF- $\alpha$ <sup>[28,29]</sup>. A recent study indicated that IL-23 is a necessary factor for the induction of chronic congenital or immune-modulated bowel diseases<sup>[30]</sup>. Hue *et al*<sup>[31]</sup> demonstrated that Th17 cells play a key role in mediating chronic spontaneous inflammation reactions, and that IL-23, but not IL-12, is essential for the induction of chronic bowel diseases. Together with IL-1, IL-23 can directly stimulate T helper cells to form Th17 competent cells that secrete IL-17. Interleukin 17 can enhance tissue inflammation reactions with the associated immune responses.

Several recent studies confirm a link between the IL-23 receptor IL23R and inflammatory bowel disease, both in Crohn's disease and ulcerative colitis patients<sup>[32-37]</sup>. In our model, the serum levels of IL-23 rose significantly in the oxazolone treated animals, while the IL-23 levels dropped after treatment with mesalamine, *C. butyricum* or sodium butyrate. The decrease in serum IL-23 was greater in the group treated with *C. butyricum* than in both the mesalamine group and the sodium butyrate group.

TNF- $\alpha$  is mainly a product of macrophages that can induce widespread immune responses in many cell types. TNF- $\alpha$  can induce production of IEC prostaglandin and increase the expression of inner epithelial adherent molecule-1 further by promoting inflammation. It can also stimulate production of extracellular proteases and matrix metalloproteinases from fiber cell promotion. These proteases can degrade the matrix of the mucous membrane causing epithelial cell abscissions<sup>[38]</sup>. Furthermore, TNF- $\alpha$  can increase the permeability of the intestinal epithelium by decreasing the expression of transmembrane core proteins associated with tight junctions<sup>[39]</sup>. This is an important early pathological change in the mucous membrane in both IBS and IBD. Araki *et al*<sup>[9]</sup> found that feeding *C. butyricum* can reduce intestinal mucous membrane wounds and the frequency of bloody diarrhea in rat-UC induced with dextran sodium sulfate (DSS). Also, Lu *et al*<sup>[40]</sup> found a positive correlation between the severity of disease and the levels of IL-6 and TNF- $\alpha$  in patients with active ulcerative colitis during their clinical trials. Wan *et al*<sup>[21]</sup> demonstrated that the expression of TNF- $\alpha$  rose remarkably before and clearly dropped after *C. butyricum* treatment in a rat-UC model induced by immunological challenge using colonic mucosal membrane protein. They also found that the treatment effects were better when *C. butyricum* was combined with mesalamine than

mesalamine alone. Our data indicate that the serum concentrations of TNF- $\alpha$  were significantly increased in the oxazolone-treated animals when compared with the negative control group. After treatment with a *C. butyricum* preparation, the TNF- $\alpha$  level decreased. Mesalamine and sodium butyrate had similar, but lesser effects on the TNF- $\alpha$  levels in our study.

Calcitonin Gene-Related Peptide (CGRP) consists of 37 amino acids and is widely distributed throughout the central nervous system (CNS), particularly in the accessory nerves, with a high concentration in the dorsal root ganglia (DRG) of the spinal cord. Retrograde labeling and IP Western blots confirmed that primary spinal afferent innervations of the mouse colon wall to a high degree are CGRP containing neuritic fibers<sup>[41]</sup>. Some studies indicate that CGRP is involved in the induction of peritoneal irritation by promoting release and suppressing the degradation of substance P, thus enhancing the prevalence of substance P<sup>[18,19]</sup>. About 50% of the CGRP containing dendritic cells also contain neurokinin, and CGRP can increase organ hypersensitivity by adjusting the expression of neurokinin 1 receptors in the primary synaptic cell bodies of the spinal cord<sup>[20]</sup>. In our study, we found no increase in the CGRP expression levels in the groups treated with mesalamine or *C. butyricum*, whereas we found a significant increase of the CGRP expression level in the sodium butyrate group. This indicates that *C. butyricum* or mesalamine treatment did not increase organ hypersensitivity, whereas sodium butyrate treatment, although it appears to be a treatment for colitis induced with oxazolone, might also cause organ hypersensitivity. This is in agreement with data published by Xing *et al*<sup>[42]</sup> indicating that sodium butyrate can increase the CGRP expression in spinal cord neurons in a dose dependent manner.

According to our data, treatment with *C. butyricum* leads to the recovery of the balance of the intestinal microflora of the experimental animals (Table 3). Daron Zhang *et al*<sup>[43]</sup> gave *C. butyricum* to patients suffering from irritable bowel syndrome. They found that *C. butyricum* suppresses the proliferation of putrefactive and pathogenic bacteria, while it promotes the proliferation of intestinal *Bifidobacterium* and *Acidobacterium* and other beneficial microbes. The amount of beneficial microbes was significantly increased in mouse feces after treatment with *C. butyricum*<sup>[44]</sup>. *C. butyricum* has been shown to suppress intestinal enterohemorrhagic *Escherichia coli*, *Shigella dysenteriae*, *Cholera salmonella*, and *Cholera bacillus in vitro*<sup>[45]</sup>. Our data shows that the counts of intestinal *Bifidobacterium* and *Acidobacterium* rose dramatically and almost returned to normal after the treatment with live *C. butyricum*. The prevalence of the conditional disease germs *Colibacter*, *Fusobacterium* and *Clostridium* increased after the induction of colitis, and dropped significantly after treatment. Our data also indicate that the *C. butyricum* preparation used in our study had a better effect than mesalamine and sodium butyrate on the restoration of intestinal microbe balances, especially at decreasing intestinal bacillus counts and increasing *Acidobacterium* and

*Clostridium* (Table 3).

Thus, in our experimental model of UC, treatment with live *C. butyricum* CGMCC313.1 had a similar or better effect than both mesalamine and sodium butyrate, both on the levels of the inflammatory effectors monitored in this study (IL-23 and TNF- $\alpha$ ) and on restoring the balance of the intestinal microflora. The general idea that probiotics based on carefully selected microbes constitute a treatment for UC worthy of consideration is supported by results from clinical trials. Thus, a recent meta-analysis of the results from six published clinical trials concluded that probiotic treatment may reduce UC relapses better than placebo and equivalently to mesalamine treatment<sup>[46]</sup>. During our study on experimental colitis in rats, we found that treatment with a probiotic containing one well-characterized microorganism promoted the repair of the colon mucosa and recovery of intestinal flora. Thus, probiotics must continue to be a target for investigation both as a potential treatment for active UC and for the management of UC to prevent relapse.

## ACKNOWLEDGMENTS

We thank Ms. Kai Ding for her help with the preparation of this manuscript.

## COMMENTS

### Background

Ulcerative colitis is a chronic condition characterized by recurring episodes of intestinal inflammation that affect individuals throughout life. Ulcerative colitis and Crohn's disease, a related disorder, are together called Inflammatory Bowel Disease.

### Research frontiers

No effective cure is known for ulcerative colitis. Patients are usually treated with anti-inflammatory drugs, sometimes in combination with antibiotics to relieve symptoms. Treatment with food containing live microorganisms (probiotics) may, according to some recent clinical trials, improve symptoms, possibly with fewer side effects than conventional treatment.

### Innovations and breakthroughs

This study showed that treatment with a microorganism, *Clostridium butyricum* CGMCC0313.1, can facilitate healing and repair of the intestinal wall in rats suffering from experimental colitis induced with a haptenizing agent. Interestingly, both *C. butyricum* and mesalamine, the control drug, lowered the serum levels of the inflammatory cytokines IL-23 and TNF- $\alpha$ , but the rat intestinal flora appeared to recover faster in the animals treated with the microorganism than in those treated with mesalamine.

### Applications

By understanding how probiotic treatment alleviates the symptoms of experimental (ulcerative) colitis, new avenues for research into treatment of inflammatory bowel diseases will open. Our study demonstrates that, in our experimental model of ulcerative colitis, *C. butyricum* acts as an anti-inflammatory agent drug rather than just assisting in the recovery of the intestinal flora. Identifying bacterial strains with these properties might lead to novel treatments of ulcerative colitis and other inflammatory disorders of the colon and rectum.

### Peer review

This is a fine study comparing the anti-inflammatory efficacy of *C. butyricum*, mesalamine and sodium butyrate on oxazolone-induced colitis in rats.

TP significantly attenuated the paracetamol-induced hepatic injury and dramatically reduced the mortality of paracetamol-treated mice. Furthermore, TP reduced CYP2E1 and CYP1A2 expression at both protein and mRNA levels in a dose-dependent manner.

**CONCLUSION:** TP possess potential hepatoprotective properties and can suppress CYP450 expression.

### Abstract

**AIM:** To investigate the hepatoprotective activity of tea polyphenols (TP) and its relation with cytochrome P450 (CYP450) expression in mice.

**METHODS:** Hepatic CYP450 and CYPb<sub>5</sub> levels were measured by UV-spectrophotometry in mice 2 d after intraperitoneal TP (25, 50 and 100 mg/kg per day). Then the mice were intragastrically pre-treated with TP (100, 200 and 400 mg/kg per day) for six days before paracetamol (1000 mg/kg) was given. Their acute mortality was compared with that of control mice. The mice were pre-treated with TP (100, 200, and 400 mg/kg per day) for five days before paracetamol (500 mg/kg) was given. Hepatic CYP2E1 and CYP1A2 protein and mRNA expression levels were evaluated by Western blotting, immunohistochemical staining and transcriptase-polymerase chain reaction.

**RESULTS:** The hepatic CYP450 and CYPb<sub>5</sub> levels in mice of TP-treated groups (100, 200 and 400 mg/kg per day) were decreased in a dose-dependent manner compared with those in the negative control mice.

### INTRODUCTION

Tea has been consumed in China to promote health and longevity since 3000 B.C. It is now a popular beverage all over the world. Tea polyphenols (TP) are a large and diverse class of compounds extracted from tea. The major compounds of TP are picatechin (EC), epigallocatechin (EGC), epicatechin gallate (ECG) and epigallocatechin-3-gallate (EGCG). Recent studies indicate that TP can prevent oxidative stress-related diseases, including cancer, cardiovascular and degenerative diseases and have other bioactive properties<sup>[1-4]</sup>.

In recent years, the interest in understanding the metabolic benefits of TP has been increasing. Liver is the main organ responsible for the metabolism of TP. Liu *et al*<sup>[5]</sup> reported that TP can markedly increase cytochrome P450 (CYP450) activity in rats. However, the effect of TP on CYP450 activity remains controversial<sup>[6,7]</sup>.

Until now, no one could give a clear explanation of the different results. CYP450 enzymes play a pivotal role not only in the metabolism of xenobiotics, but also in the biosynthesis and catabolism of endogenous substrates, such as vitamins, fatty acids, hormones and prostaglandins<sup>[8]</sup>. Alteration in hepatic CYP450 enzyme expression would affect the pharmacokinetic profiles of clinically used drugs. Furthermore, both induction and suppression of several CYP450s may lead to cellular oxidative stress and tissue injury in response to xenobiotics<sup>[9]</sup>.

Paracetamol, one of the most widely used hepatotoxic drugs, is safe at therapeutic doses, but causes liver failure in overdoses<sup>[10,11]</sup>. When a normal dose is used, paracetamol is extensively metabolized by conjugation with sulphate and glucuronic acid. A small fraction of the drug is subjected to oxidation reactions catalyzed by CYP450 enzymes in the liver, resulting in generation of N-acetyl-p-benzo-quinoneimine (NAPQI), a highly electrophilic metabolite that triggers ensuing liver damage. Exposure to high doses of paracetamol increases the NAPQI level. Normally, toxic oxidation metabolites generated in the liver are converted into non-toxic metabolites excreted in urine via conjugation with glutathione (GSH) containing sulphhydryl groups. However, high doses of paracetamol limit the ability of GSH to detoxify NAPQI, and result in the consumption of liver GSH stores<sup>[12,13]</sup>. It was reported that oxidative stress constitutes a major mechanism underlying the pathogenesis of paracetamol-induced liver damage<sup>[14,15]</sup>.

There are three families of CYP450 isoforms, CYP1, CYP2, and CYP3, which are mainly involved in the biotransformation of xenobiotics<sup>[16]</sup>. It has been shown that CYP2E1, CYP1A2, and intracellular GSH play an important role in the hepatotoxicity induced by paracetamol<sup>[17-19]</sup>. The present study was to investigate the hepatoprotective activity of TP and its relation with CYP450 expression in mice.

## MATERIALS AND METHODS

### Animal treatment

TP obtained from Wuyuan Tea Plantation (Jiangxi Province, China) with a purity of > 98% containing 63.84% of EGCG and 7.30% of ECG were decaffeinated. Kunming male mice, weighing 18-22 g, provided by Experimental Animal Center of Dalian Medical University, were used in the study. The mice were randomly divided into high, medium, low TP dose groups, positive and negative control groups ( $n = 10$ ). The mice in low, medium and high dose TP groups were intraperitoneally injected with 25, 50 and 100 mg/kg of TP per day for two days. The mice in positive control group were given 50 mg/kg chloramphenicol one hour before they were killed. The mice in the negative control group were given the same volume of saline solution for two days. On day 3, all the mice were killed by decapitation, with their livers removed immediately and cleaned with a cold saline solution. Specimens were stored at -80°C for preparation of liver microsomes.

Male mice in each group received intragastric TP at the dose of 100, 200, and 400 mg/kg, once a day for six days. The mice in positive control group were given 900 mg/kg N-acetylcysteine, once a day. The mice in negative control group were given the same volume of a saline solution. All the mice were given 1000 mg/kg paracetamol one hour later and the acute mortality of mice in both groups was recorded 72 h after paracetamol was given.

Male mice in each group received intragastric TP at the dose of 100, 200, and 400 mg/kg, once a day for five days. The mice in model and negative control groups were given the same volume of a saline solution. The mice were given 500 mg/kg paracetamol one hour later, except for the mice in negative control group. All the mice were killed by decapitation 24 h later with their livers removed immediately and cleaned with a cold saline solution. Specimens were fixed in formalin for histological examination or snap-frozen in liquid nitrogen and stored at -80°C for protein and RNA extraction.

### Preparation of liver microsomes

Liver microsomes extracted from frozen samples were prepared as previously described<sup>[20]</sup>. Microsomal protein level was measured as previously described<sup>[21]</sup> with bovine serum albumin as a standard.

### Measurement of microsome enzyme levels

The levels of CYP450 and CYPb<sub>5</sub> were measured as previously described<sup>[22]</sup>.

### Western blot assay

Aliquots (80 µg) of liver microsomes from each sample were loaded onto each lane of 10% SDS-PAGE gel electrophoresis and electroblotted onto nitrocellulose membranes (Millipore, Bedford, MA). The membranes were probed with rabbit antibody against mice CYP2E1 (Boster Biological Technology Co., Ltd, Wuhan, China) at a dilution of 1:400 or CYP1A2 (Santa Cruz Biotechnology, Inc., California, USA) at a dilution of 1:500 and peroxidase-conjugated affinitypure goat anti-rabbit IgG (Zhongshan Golden Bridge Biotechnology Co., Ltd, Beijing, China) according to the manufacturer's constructions. The signals were visualized with a DAB assay kit (Zhongshan Golden Bridge Biotechnology Co., Ltd, Beijing, China) and analyzed with Quantity One software.

### Histology and immunohistochemical assay

All specimens embedded in paraffin were cut into 4-µm thick serial sections. The specimens were mounted on slides and deparaffinized with graded concentrations of xylene and ethanol, and stained with hematoxylin and eosin (HE). For immunohistochemical staining, all sections were immersed in 3% H<sub>2</sub>O<sub>2</sub> for 15 min at room temperature to block the endogenous peroxidase activity. To stain with CYP2E1 and CYP1A2, the sections were predigested with 0.4% proteinase K for 5 min at 37°C. The sections were then incubated with 10% normal goat serum for 15 min to reduce the nonspecific background

staining and reacted with polyclonal rabbit anti-mouse antibody (Ab) at 4°C overnight. The working dilution of Abs used for examining mouse CYP2E1 and CYP1A2 in the liver was diluted at 1:100 and 1:50. After rinsing with phosphate-buffered saline (pH 7.4), the sections were incubated with biotinylated anti-rabbit immunoglobulin secondary Abs at room temperature for 30 min. Horseradish peroxidase labeled streptomycin-avidin complex was used to detect the second antibody. Finally, the sections were counterstained with hematoxylin before examination under a light microscope. The brown or dark brown stained cells were considered positive cells.

### Reverse transcription-polymerase chain reaction (RT-PCR) assay

Total RNA was extracted from liver tissue with the TRIquick reagent (Solarbio Science & Technology CO., Ltd, Beijing, China). RNA purity was assessed by the optical densities at 260 nm and 280 nm, and the integrity was verified by electrophoresis on a 1% agarose gel containing 0.5  $\mu$ g/mL of ethidium bromide. Reverse transcription was conducted for 30 min at 42°C from 500 ng of purified RNA in 10  $\mu$ L of reserve transcriptions system reaction mixture using AMV reverse transcriptase (TaKaRa, Japan), followed by 30 cycles of PCR (denaturation at 94°C for 30 s, annealing at 56°C for 30 s, and extension at 72°C for 1 min). The amplified products were electrophoresed on a 1.5% agarose gel using 100 bp DNA ladder markers (TaKaRa, Japan) as a standard to determine the molecular size and visualized with ethidium bromide staining. Images of the ethidium bromide-stained agarose gel were acquired with a Gel Doc EQ system and quantified using Quantity One software. The sequences of oligonucleotide primers are provided in Table 1.

### Statistical analysis

Data were calculated separately and expressed as mean

Table 3 Effect of TP on mortality induced by paracetamol in mice

Group (n = 10)	Dose (mg/kg)	Death (n)	Death rate (%)	Protection rate (%)
Negative control		9	90	10
Positive control		2	20	80
TP				
Low	100	7	70	30
Medium	200	4	40	60

## RESULTS

### Effect of TP on CYP450 and CYPb<sub>5</sub> levels

Two days after peritoneal injection of TP, the CYP450 and CYPb<sub>5</sub> levels in livers of mice were measured. The CYP450 and CYPb<sub>5</sub> levels were significantly lower in the high, medium and low dose TP groups than in the negative control group (*P* < 0.01), indicating that TP can reduce the CYP450 and CYPb<sub>5</sub> levels in liver of mice. The CYP450 level was higher in the medium and low dose groups than in the positive control group (*P* < 0.01); but, it was not significantly different between the high dose and positive control groups (*P* > 0.05). The CYPb<sub>5</sub> level was markedly different in the low dose group (*P* < 0.01); but it, was not significantly different in the high and medium dose groups (*P* > 0.05) compared the positive control group, indicating that TP can suppress both CYP450 and CYPb<sub>5</sub> in mice in a dose-dependent manner (Table 2).

**Figure 2** Changes of HE staining in liver tissue of mice 24 h after paracetamol administration ( $\times 100$ ) in control group with a normal central lobular region (A), model group with some central lobular hepatocyte necrosis and microvesicular fatty change (B), low TP dose group (C), medium TP dose group (D) and high TP dose group (E). The pathological change of liver was much milder in different TP dose groups than in model group.

#### **Effect of TP on mortality of paracetamol-treated mice**

We examined the effect of TP on mortality of paracetamol-treated mice. The mortality rate of mice in the negative control group, low, medium and high dose TP groups was 90%, 70%, 40% and 20%, respectively, indicating that TP can significantly reduce the mortality of paracetamol-treated mice. The effect of high dose TP on mortality of paracetamol-treated mice was not different from that of mice in the positive control group (Table 3).

#### **Western blot analysis**

Western blot showed strong positive CYP2E1 signals in the control and model groups. The expression of CYP2E1 in the low dose group was not significantly different from that in the control and model groups. However, TP significantly decreased the CYP2E1 expression level in the medium and high dose groups in a dose-dependent manner (Figure 1). The expression of CYP1A2 and CYP2E1 protein was similar in the liver microsomes (Data not shown).

#### **Histology analysis**

Liver tissues from the control group showed a normal lobular architecture with central veins and radiating hepatic cords (Figure 2A). However, liver tissues from the model group showed formation of more fibrous tissues extending into the hepatic lobules, leading to their complete separation. A large number of inflammatory cells infiltrated the intralobular and interlobular regions. The liver structure was in disorder and there were more necrotic and fatty degenerated liver cells than in the controls (Figure 2B). In the three TP treatment groups, however, hepatocyte degeneration, necrosis and infiltration of inflammatory cells were all apparently ameliorated (Figure 2C-E). Compared with the model

group, the liver condition in TP treatment groups was significantly improved in a dose-dependent manner.

#### **Immunohistochemical analysis of liver CYP2E1 and CYP1A2**

The expression of CYP2E1 showed a deep brown immunostaining. No difference was found in the expression of CYP2E1 between the control and model groups. However, in medium and high dose groups, TP significantly suppressed the CYP2E1 expression in a dose-dependent manner (Figure 3A).

The expression level of CYP1A2 (showing a deep brown immunostaining) was markedly lower in the low, medium and high dose TP groups than in the control and model groups (Figure 3B).

#### **Expression levels of CYP2E1 and CYP1A2 mRNA**

The expression levels of CYP2E1, CYP1A2 and GAPDH cDNAs in the mouse liver were assayed by RT-PCR (Figure 4A), and the ratio of CYP2E1 and CYP1A2/ GAPDH cDNAs was calculated (Figure 4B). TP significantly inhibited the CYP2E1 mRNA expression in medium and high dose groups ( $P < 0.01$ ), compared to the control and model groups ( $P > 0.05$ ). The expression of CYP1A2 mRNA was reduced in all TP groups compared with the control and model groups ( $P < 0.05$ ), indicating that TP can suppress the expression of CYP2E1 and CYP1A2 mRNA in a dose-dependent manner.

## **DISCUSSION**

Hepatic drug metabolizing enzyme is called mixed-function oxidase or monooxygenase containing many enzymes including phase I enzymes such as

**Figure 3** Immunohistochemical staining showing expression of CYP2E1 (A) and CYP1A2 (B) in liver tissue of mice 24 h after paracetamol administration ( $\times 400$ ) in control group (a), model group (b), low TP dose group (c), medium TP dose group (d) and high TP dose group (e). The brown or dark brown stained cells were considered positive.

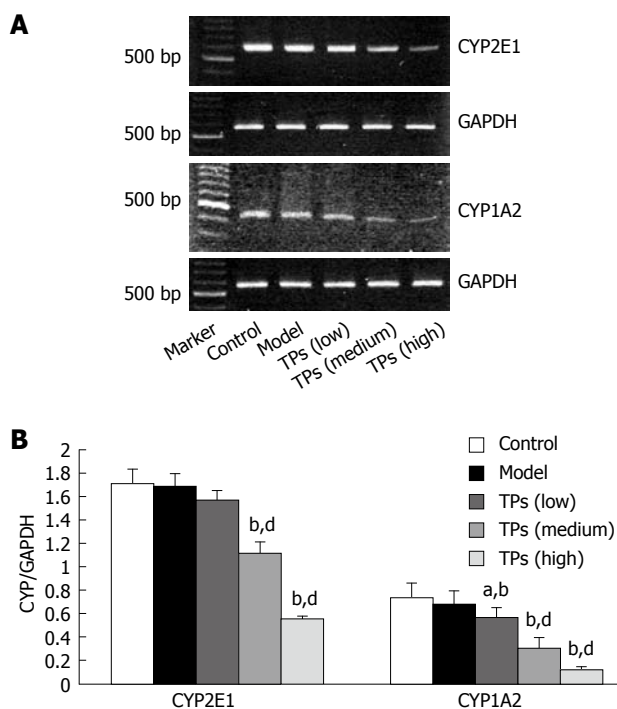

CYP450 and CYPb<sub>s</sub>, *etc*, and plays a prominent role in the metabolism of many pharmaceutical agents and activation or deactivation of potential carcinogens. Acquiring metabolic information and determining the effect of chemicals on hepatic drug metabolizing enzymes are important in developing clinically safe and efficient medications<sup>[23]</sup>.

TP have various pharmacological effects on cancer, cardiovascular and degenerative diseases and have other bioactive properties<sup>[1-4]</sup>. In this experiment, TP significantly suppressed the CYP450 and CYPb<sub>s</sub> levels in liver of mice, suggesting that TP can restrain the activity of drug metabolizing enzymes.

In the present study, 100, 200 and 400 mg/kg TP could reduce the mortality of mice after treatment with paracetamol (Table 2). The immunohistochemical study

showed that TP markedly alleviated paracetamol- induced hepatotoxicity, thus improving alterations in liver tissue pathology. Especially marked hepatoprotective effects of TP were observed in the high dose TP group with its diffuse hemorrhage and necrosis changed into focal hemorrhage and necrosis (Figure 2) compared to the model group that received a single dose of 500 mg/kg paracetamol, indicating that TP can protect liver of mice against paracetamol injury, which is consistent with the reported data<sup>[24]</sup>.

It was reported that many mechanisms are involved in paracetamol hepatotoxicity<sup>[25]</sup>, showing that the toxicity is mediated by CYP450 metabolism of paracetamol to NAPQI which covalently binds to critical proteins leading to inactivation of these proteins, especially after GSH depletion. CYP2E1 is usually assumed to be the

**Figure 4** RT-PCR analysis of mRNA for CYP2E1 and CYP1A2 expression in liver tissue of mice showing representative bands of each group (A) and normalized densitometric ratio of CYP2E and CYP1A2 to GAPDH (B). <sup>a</sup> $P < 0.05$  vs model group; <sup>b</sup> $P < 0.01$  vs control group; <sup>d</sup> $P < 0.01$  vs model group.

most active CYP450 in catalyzing the metabolism of paracetamol to hepatotoxic NAPQI<sup>[15,18]</sup>. Studies with knockout mice showed that CYP2E1 and CYP1A2 play an important role in the metabolism of paracetamol<sup>[26,27]</sup>. To confirm whether the protective effects of TP on liver are correlated with the inhibition of CYP2E1 and CYP1A2, we investigated the effect of TP on the expression of CYP2E1 and CYP1A2 mRNA and protein.

In the present study, 200 mg/kg and 400 mg/kg TP significantly down-regulated the CYP2E1 expression either at gene level (Figure 4) or at protein level (Figures 1 and 3) as shown by RT-PCR, Western blot and immunohistochemistry. The effects of TP on the expression of CYP1A2 and CYP2E1 gene and protein were similar. It was reported that the CYP1A2 level in increased in rats after drinking a 2% solution of green or black tea<sup>[28]</sup>. Caffeine, a component of tea, is responsible for the induction of CYP1A2<sup>[29]</sup>. In our study, however, different doses of TP (100, 200 and 400 mg/kg) significantly suppressed the expression of CYP1A2 protein and mRNA, partly because TP used in our experiment did not contain caffeine.

The above findings indicate that the dose-dependent liver-protective effects of TP are likely related to the suppression of CYP2E1 and CYP1A2 expression, which reduces NAPQI associated with the paracetamol hepatotoxicity, and effectively protects liver against paracetamol hepatotoxicity.

In conclusion, TP restrain the activity of drug metabolizing enzymes, CYP450 and CYPb<sub>s</sub>, and protect liver against paracetamol-induced injury. The protective

effects of TP are associated with the expression of CYP2E1 and CYP1A2 gene and protein.

## COMMENTS

### Background

Paracetamol is one of the most widely used hepatotoxic drugs, which is safe at therapeutic doses, but causes liver failure at overdoses. High doses of paracetamol limit the ability of glutathione (GSH) to detoxify N-acetyl-p-benzoquinonimine (NAPQI), and results in consumption of liver GSH stores. There are three families of cytochrome P450 (CYP450) isoforms, CYP1, CYP2, and CYP3, which are mainly involved in the biotransformation of xenobiotics. It has been shown that CYP2E1, CYP1A2 and intracellular GSH play an important role in paracetamol-induced hepatotoxicity. Tea polyphenols (TP) are a large and diverse class of compounds extracted from tea. Liver is the main organ responsible for the metabolism of TP. Some work has been done in the field of TP modulation or interaction with drug metabolizing enzymes. However, until now, no one could give a clear explanation for this.

### Research frontiers

TP are a large and diverse class of compounds extracted from tea. Liver is the main organ responsible for the metabolism of TP. Some work has been done in the field of TP modulation or interaction with drug metabolizing enzymes. However, until now, no one could give a clear explanation for this. The research hotspot is to investigate the effects of TP on CYP450 and CYPb<sub>s</sub> expression in livers of male mice. Whether the protective effect of TP on paracetamol-induced hepatotoxicity in mice is related with their effect on CYP450 was studied.

### Innovations and breakthroughs

The protective effect of TP on paracetamol-induced hepatotoxicity was found to be related with their effect on CYP450.

### Applications

TP possess potential hepatoprotective properties, which are closely related with their suppressive effect on CYP450 expression.

### Terminology

Paracetamol-induced hepatotoxicity: When a normal dose is used, paracetamol is metabolized extensively by conjugation with sulphate and glucuronic acid. A small fraction of paracetamol is subjected to oxidation reactions catalyzed by CYP450 enzymes in the liver, resulting in generation of NAPQI, a highly electrophilic metabolite that triggers the ensuing liver damage.

### Peer review

This is a good descriptive study in which the authors gave a clear explanation of the effect of TP on the expression of CYP450, CYP2E1 and CYP1A2 in liver of mice at both protein and mRNA levels. The interesting results suggest that TP can significantly attenuate paracetamol-induced hepatic injury, which is closely related with their suppressive effect on CYP450 expression.

The three false positive PET/CT findings comprised chronic inflammation of mediastinal lymph nodes ( $n = 2$ ) and anastomosis inflammation ( $n = 1$ ). PET/CT demonstrated distant metastasis in 10 patients.  $^{18}\text{F}$ -FDG PET/CT imaging-guided salvage treatment in nine patients was performed. Treatment regimens were changed in 12 (60%) patients after introducing  $^{18}\text{F}$ -FDG PET/CT into their conventional post-treatment follow-up program.

**CONCLUSION:** Whole body  $^{18}\text{F}$ -FDG PET/CT is effective in detecting relapse of esophageal cancer after surgical resection and radiotherapy. It could also have important clinical impact on the management of esophageal cancer, influencing both clinical restaging and salvage treatment of patients.

### Abstract

**AIM:** To evaluate the clinical usefulness of  $^{18}\text{F}$ -fluorodeoxyglucose positron emission and computed tomography ( $^{18}\text{F}$ -FDG PET/CT) in restaging of esophageal cancer after surgical resection and radiotherapy.

**METHODS:** Between January 2007 and Aug 2008, twenty histopathologically diagnosed esophageal cancer patients underwent 25 PET/CT scans (three patients had two scans and one patient had three scans) for restaging after surgical resection and radiotherapy. The standard reference for tumor recurrence was histopathologic confirmation or clinical follow-up for at least ten months after  $^{18}\text{F}$ -FDG PET/CT examinations.

**RESULTS:** Tumor recurrence was confirmed histopathologically in seven of the 20 patients (35%) and by clinical and radiological follow-up in 13 (65%).  $^{18}\text{F}$ -FDG PET/CT was positive in 14 patients (68.4%) and negative in six (31.6%).  $^{18}\text{F}$ -FDG PET/CT was true positive in 11 patients, false positive in three and true negative in six. Overall, the accuracy of  $^{18}\text{F}$ -FDG PET/CT was 85%, negative predictive value (NPV) was 100%, and positive predictive value (PPV) was 78.6%.

### INTRODUCTION

Esophageal cancer is one of the least studied and deadliest cancers worldwide and one of the 10 most prevalent cancers worldwide and has an unfavorable prognosis among digestive tract malignancies<sup>[1,2]</sup>. The management of esophageal cancer has evolved from surgery alone to definitive and preoperative chemotherapy-radiation therapy. The best option for curative treatment for patients with esophageal cancer is radical surgery; however, the long-term survival is only 25%<sup>[3]</sup>. Postoperative tumor recurrence is not uncommon

in patients undergoing curative resection for esophageal cancer and can be categorized as either locoregional (locoregional lymph node metastases, anastomotic recurrence) or distant (hematogenous metastases, pleural or peritoneal seeding). Lymph node recurrence and hematogenous metastasis to solid organs (commonly to the lung) are the usual patterns of recurrence<sup>[4,5]</sup>.

<sup>18</sup>F-fluorodeoxyglucose positron emission tomography (<sup>18</sup>F-FDG PET) and, particularly, <sup>18</sup>F-FDG positron emission and computed tomography (<sup>18</sup>F-FDG PET/CT) are widely accepted imaging methods in the management of a wide variety of cancers<sup>[6]</sup>. In the initial staging of esophageal cancer, a preoperative PET scan may be useful in detecting additional cases of metastatic disease before costly and toxic definitive therapy<sup>[7]</sup>. Currently, <sup>18</sup>F-FDG PET and PET/CT also seem to be the best available tool for neoadjuvant therapy response assessment in esophageal cancer<sup>[8,9]</sup>. However, the utility and limitation of <sup>18</sup>F-FDG PET/CT in patients with esophageal cancer treated by surgical resection and post operation radiation is not clear. In this study, we aimed to analyze the value of <sup>18</sup>F-FDG PET/CT scans in the follow up of patients with esophageal cancer treated with combined surgical treatment and radiotherapy management.

## MATERIALS AND METHODS

### Patients

A retrospective review of our electronic database of 20 patients with esophageal cancer after surgical resection and following radiotherapy (15 males and 5 female; age range, 39-68 years; mean age, 55.1 years) imaged by <sup>18</sup>F-FDG PET/CT between January 2007 and Aug 2008 was performed to select and analyze <sup>18</sup>F-FDG PET/CT scans findings of patients with or without clinically and/or radiologically suspicious findings for restaging. Twenty patients had undergone 25 PET/CT scans (three patients had two scans and one patient had three scans). The standard reference for tumor recurrence consisted of histopathological confirmation or clinical follow-up for at least ten months after <sup>18</sup>F-FDG PET/CT.

### <sup>18</sup>F-FDG PET/CT technique

The patients were asked to fast for at least 4 h before undergoing <sup>18</sup>F-FDG PET/CT. Their blood glucose levels were within the normal range (70-120 mg/dL) prior to intravenous injection of <sup>18</sup>F-FDG. The patients received an intravenous injection of 370-666 MBq (10-18 mCi) of <sup>18</sup>F-FDG. Data acquisition by an integrated PET/CT system (Discovery STE; GE Medical Systems, Milwaukee, WI, USA) was performed within 60 min after injection. The procedure for data acquisition was as follows: CT scanning was performed first, from the head to the pelvic floor, with 110 kV, 110 mA, a tube rotation time of 0.5 s, a 3.3-mm section thickness, which was matched to the PET section thickness. Immediately after CT scanning, a PET emission scan that covered the identical transverse field of view was obtained. Acquisition time was three minutes per table position. PET image data sets were reconstructed iteratively by

Table 1 Patient characteristics

Clinical characteristics	Data
Mean age (yr)	55.1 (39-68)
Gender	
Males	15
Females	5
Mean time after treatment to PET/CT exam	1 mo-5 yr; mean 20 mo
Mean follow-up time after PET/CT exam	1 mo-18 mo; mean 11 mo

applying the CT data for attenuation correction, and coregistered images were displayed on a workstation.

### Definitive diagnoses of positive and negative findings

Reviewer 1 and reviewer 2, who were aware of other clinical or imaging information, read the <sup>18</sup>F-FDG PET/CT images on a high-resolution computer screen. The reviewers reached a consensus in cases of discrepancy. Reviewer 1 had 20 years of experience in both nuclear medicine and radiology, and reviewer 2 had 5 years of experience in both nuclear medicine and radiology. On the basis of knowledge of the normal biodistribution of FDG, lesions were identified as foci with increased tracer accumulation relative to that in comparable normal contralateral structures and surrounding soft tissues. The lesions were qualitatively graded as definitely or probably abnormal (i.e. representing tumors) if the accumulation of FDG was markedly to moderately increased. Diffuse mildly increased activity or no increased activity (in the case of an abnormality identified on CT for which no corresponding abnormality was present on PET) was considered normal or as benign disease. Quantification of the tumor metabolic activity was obtained using the Standardized Uptake Value (SUV) normalized to body weight. mean  $\pm$  SD of maximum-pixel SUV (SUVmax) of the lesions were calculated.

## RESULTS

The characteristics of the patients are summarized in Table 1. For suspected recurrent esophageal cancer, the mean patient age was 55.1 years with a tendency of male gender distribution (75%). <sup>18</sup>F-FDG PET/CT was positive in 14 patients (68.4%) and negative in six (31.6%). When correlated with final diagnosis, which was confirmed by histopathological evidence of tumor recurrence in seven of the 20 patients (35%) and by clinical and radiological follow-up in 13 (65%), <sup>18</sup>F-FDG PET/CT was true positive in 11 patients (Table 2, Figures 1 and 2), false positive in three and true negative in six. The three false positive PET/CT findings were chronic inflammation of mediastinal lymph nodes ( $n = 2$ ) and anastomosis inflammation ( $n = 1$ ) (Figure 3), which were confirmed by at least 11 mo of clinical and radiological follow-up. There were no false negatives in our group. Overall, the accuracy of <sup>18</sup>F-FDG PET/CT was 85%, negative predictive value (NPV) was 100%, and positive predictive value (PPV) was 78.6%.

Notably, <sup>18</sup>F-FDG PET/CT demonstrated true positive distant metastasis in 90.9% (10/11) patients.

Table 2 PET/CT findings in 11 patients with true positive PET/CT scans

No.	PET/CT findings	SUV max	Further treatment plan	Interval time
1	Retroperitoneal lymph nodes	4.5	Surgical resection of metastases	5 yr
2	Retroperitoneal lymph nodes	6.5	Local radiotherapy	1yr
	Lung metastasis	1.6	Chemotherapy	
3	Mediastinal lymph nodes	5.2	Chemotherapy	13 mo
4	Supraclavicular lymph nodes	3.3	Local radiotherapy	11 mo
5	Retroperitoneal lymph nodes	6.0	Local radiotherapy	2 mo
6	Supraclavicular lymph nodes	8.4	Chemotherapy	11 mo
	Retroperitoneal lymph nodes	3.6

7	Retroperitoneal lymph nodes	12.1	Chemotherapy	14 mo
	Liver metastasis	14.0	RF-ablation	
8	Liver metastasis	8.4	RF-ablation	16 mo
	Supraclavicular lymph nodes	3.6	Chemotherapy	
	Retroperitoneal lymph nodes	10.6		
9	Supraclavicular lymph nodes	3.2	Local radiotherapy	1 mo
10	Supraclavicular lymph nodes	6.7		1 mo
	Osseous metastasis	5.3		
	Peritoneal carcinomatosis	7.9		
11	Anastomosis recurrence	7.1	Stent implant	5 mo
	Retroperitoneal lymph nodes	8.5	Chemotherapy	

RF-ablation: Radiofrequency-ablation.

**Figure 1** A 56-year-old woman who had esophageal cancer resection 5 years ago. PET/CT displayed multi-retroperitoneal lymph node recurrence (arrows in A and B). The patient accepted retroperitoneal lymph node resection, which was later verified as esophageal cancer metastasis by histopathology. PET/CT Follow-up 10 mo after her second operation demonstrated no new recurrent lesions (C, D).

Except for 45.5% (5/11) patients who suffered from supraclavicular lymph nodes metastasis, the remaining 54.5% (6/11) patients were asymptomatic, with no evidence of relapse disease. These remaining patients underwent further PET/CT scans as part of routine post-operative surveillance.  $^{18}\text{F}$ -FDG PET/CT imaging-guided salvage treatment (surgical resections of

metastasis lesions, additional radiotherapy, chemotherapy, and radiofrequency ablation of hepatic metastatic tumors) in 10 patients was performed within two weeks after the  $^{18}\text{F}$ -FDG PET/CT scan. Clinical decisions of treatment were changed in 12 (60%) patients after introducing  $^{18}\text{F}$ -FDG PET/CT into their conventional post-treatment follow-up program.

In our study, 90.9% (10/11) cases of recurrence after curative resection occurred within 16 mo and 9.1% (1/11) occurred within 5 years, respectively, after the initial resection. A high percentage of first failures presented as supraclavicular lymph nodes and retroperitoneal lymph nodes metastases.

## DISCUSSION

Surgery is still the main treatment option for esophageal cancer; however, long-term survival has remained poor, even when a curative operation is performed<sup>[10]</sup>. Despite increasingly extended radical esophagectomy for esophageal cancer, many patients continue to experience relapse of the disease<sup>[11]</sup>. About one half of the patients develop recurrent disease within three years after the operation, and most of them develop mediastinal lymph node, liver, bone, or lung metastasis<sup>[12]</sup>. Anastomotic recurrence is a major reason of late mortality following esophago-gastrectomy for carcinoma of the esophagus and esophago-gastric junction, using either the Ivor Lewis approach with intra-thoracic anastomosis<sup>[13]</sup>. However, neoplastic recurrence was most common at the supraclavicular lymph nodes and retroperitoneal lymph nodes (81.8%; 9/11); only one patient suffered from mediastinal lymph nodes recurrence and one patient suffered from anastomotic recurrence in our study results. Cooper *et al*<sup>[14]</sup> reported that concurrent postoperative chemotherapy and radiotherapy significantly improved the rates of local and regional

**Figure 2** A 62-year-old woman had esophageal cancer resection. She underwent three PET/CT scans (1.5, 4.5 and 11 mo after treatment, respectively) as part of routine post-operative surveillance. The first PET/CT imaging (1.5 mo) revealed hypermetabolic activity in the anastomosis and supraclavicular lymph nodes (arrows, A, B). The second PET/CT imaging (4.5 mo) showed decreasing of hypermetabolic activity at anastomosis and supraclavicular lymph nodes (arrows, C, D). The third PET/CT imaging (11 mo) showed no abnormal FDG uptake at anastomosis, but revealed new focal hypermetabolic activity at left supraclavicular lymph nodes (arrows, E, F). Inflammation of lymph nodes and anastomosis at the first and second PET/CT scan were confirmed by the third PET/CT examination. New relapse at the left supraclavicular lymph nodes was later verified by biopsy.

control and disease-free survival among high-risk patients with resected head and neck cancer. All of our patients accepted postoperative radiotherapy, which may be beneficial in the control of mediastinum recurrence.

It was reported that PET/CT using the radiolabeled glucose analog,  $^{18}\text{F}$ -FDG, was valuable in detecting recurrence of esophageal cancer, particularly when anatomic imaging modalities have presented equivocal interpretations<sup>[15]</sup>.  $^{18}\text{F}$ -FDG PET/CT is a metabolic imaging technique where the scope covers the whole body (from the skull to the lower limbs). Major advantages

**Figure 3** A 40-year-old asymptomatic man who had esophageal cancer resection 30 mo ago underwent PET/CT as part of routine post-operative surveillance. The first PET/CT revealed hypermetabolic activity at the anastomosis (arrows, A, B) 5 mo after treatment. The second PET/CT showed hypermetabolic activity at the anastomosis (arrows, C, D) 30 mo after treatment. The final diagnosis by endoscopic biopsy was anastomotic inflammation.

of  $^{18}\text{F}$ -FDG PET/CT are the ability to perform full body examinations, the potential to detect locoregionally recurrence and distant metastatic lesions in one single examination, and the possibility of distinguishing new

active disease from scar or necrotic tissue<sup>[16,17]</sup>. However, conventional CT and magnetic resonance imaging (MRI) examinations only cover local regions of the body. The current study is the first that specifically focused on the utility of <sup>18</sup>F-FDG PET/CT imaging for whole body diagnosis and staging of recurrent esophageal cancer after curative resection and postoperative radiotherapy. Our preliminary results suggest that <sup>18</sup>F-FDG PET/CT provides a highly sensitive diagnosis of recurrent disease, both for locoregionally recurrence and distant metastasis.

Whether earlier diagnosis of recurrent esophageal cancer would improve patient survival has not yet been reported<sup>[18,19]</sup>. The possibility of a survival benefit, however, can be deduced indirectly from results obtained in our previous study with early detection of recurrence in asymptomatic post-operation patients with gastric cancer, indicating a survival benefit of nine months<sup>[20]</sup>. The available therapeutic modalities in recurrent esophageal cancer are radical re-resection, palliative resection and bypass, laser thermocoagulation, stenting, chemotherapy, brachytherapy, and radiotherapy, alone or in combination<sup>[21,22]</sup>. The choice of a specific therapeutic modality depends on the extent of the recurrence. Patients with metastatic esophageal cancer have a median survival time of six months<sup>[23,24]</sup>. However, one patient who suffered from retroperitoneal lymph node recurrence around the pancreas accepted retroperitoneal lymph node resection and partial excision of the pancreas. The patient remained in a good condition over a 10-mo follow-up period.

The prognosis of patients with post-operative loco-regional recurrence of esophageal cancer is poor. However, long-term survival might be expected by definitive radiotherapy for the patients with small-size tumors and with a good performance status<sup>[25]</sup>. Raoul *et al*<sup>[26]</sup> reported the survival rates of patients with postoperative recurrence treated with chemoradiotherapy to be 47.1% at one year, 17.1% at two years and 4.3% at three years. Although the average follow-up time of this group of patients is only 11 mo, our study results of nine patients also indicated that <sup>18</sup>F-FDG PET/CT-guided salvage therapy and earlier diagnosis of recurrent esophageal cancer might improve patient survival. PET/CT also has advantages in individualized treatment for patients. Morphological imaging with CT or MRI after radiofrequency ablation of malignant liver tumors is hampered by rim-like enhancement in the ablation margin, making the identification of residual or local recurrent tumors in the ablation zone difficult<sup>[27,28]</sup>. In our study, three patients with hepatic metastatic tumors from esophageal cancer accepted radiofrequency-ablation of metastatic lesions. <sup>18</sup>F-FDG PET/CT proved to be more accurate in morphological imaging with CT or MRI when making radiofrequency-ablation plans and assessing the liver for residual tumors after radiofrequency-ablation.

A noteworthy finding in the current study is the high incidence [21.4%; (3/14)] of false-positive <sup>18</sup>F-FDG PET/CT findings at the mediastinal lymph nodes ( $n = 2$ ) and anastomotic inflammation ( $n = 1$ ). False-

positive FDG uptake at inflammatory lesions is widely known and remains a major problem in the diagnosis of oncologic patients<sup>[29,30]</sup>. Three other patients had high-moderate uptake at the mediastinal lymph nodes. The FDG uptake in the three patients probably reflected a normal inflammatory healing process after operation and radiation. In our experience, the presence of the stomach in the thoracic cavity after the operation induces focal atelectasis and lung inflammation in many of patients after treatment, which might be also contribute to the increasing FDG uptake in mediastinal lymph nodes.

PET scans for response assessment should also be timed correctly<sup>[31,32]</sup>. Treatment with surgical resection and radiation often results in temporary inflammatory changes that may show up positive on a PET/CT scan when there is no real disease. These changes take some time to subside<sup>[33,34]</sup>. In our experience, it is recommended that PET/CT scans be performed only after at least two weeks of chemotherapy and five-six weeks of radiation for the true picture to emerge. Thus, the sophisticated surgical procedures used in esophagectomy and radiation treatment after operation can result in anatomical and functional changes. Clinicians at PET/CT centers must understand how these procedures can affect imaging data and be familiar with the appearances of postoperative anatomical changes, complications, and tumor recurrence, to ensure accurate evaluation of affected patients.

In conclusion, <sup>18</sup>F-FDG PET/CT has the potential to be a highly sensitive diagnostic tool for accurate whole-body staging of asymptomatic and symptomatic recurrent esophageal cancer. <sup>18</sup>F-FDG PET/CT-guided salvage treatment to the early recurrent lesion might improve patient survival in a considerable proportion of patients. Due to the false-positive findings based on <sup>18</sup>F-FDG accumulation in areas of inflammation, interpretation of <sup>18</sup>F-FDG PET/CT results is optimized by understanding the diagnostic limitations and pitfalls that may be encountered, together with knowledge of the natural history of esophageal cancer and the staging and treatment options available.

## COMMENTS

### Background

The incidence of esophageal cancer has steadily increased over the past three decades. The best option for curative treatment for patients with esophageal cancer is radical surgery, with a long-term survival of only 25%. Postoperative tumor recurrence is not uncommon in patients undergoing curative resection for esophageal cancer. The outcome of esophagectomy could be improved by optimal diagnostic strategies leading to adequate guided salvage treatment. In this study, we aimed to analyze the value of <sup>18</sup>F-fluorodeoxyglucose positron emission and computed tomography (<sup>18</sup>F-FDG PET/CT) scans in the follow up of patients with esophageal cancer treated with combined surgical treatment and radiotherapy management.

### Research frontiers

<sup>18</sup>F-FDG PET and, particularly, <sup>18</sup>F-FDG PET/CT are widely accepted imaging methods in the management of a wide variety of cancers. However, the utility and limitation of <sup>18</sup>F-FDG PET/CT in patients with esophageal cancer treated by surgical resection and post operation radiation is not clear.

### Innovations and breakthroughs

Whole body <sup>18</sup>F-FDG PET/CT was effective in detecting relapse in esophageal

cancer after surgical resection and radiotherapy and also had important clinical impacts on the management of esophageal cancer; influencing both clinical restaging and salvage treatment of patients.

### Applications

This has the potential to be a powerful technology for restaging of esophageal cancer after surgical resection and radiotherapy.

### Peer review

This manuscript can be presented as an initial report and is an interesting article about the application of PET-CT to restaging of esophageal cancer after surgical resection and radiotherapy.

### Abstract

**AIM:** To prospectively evaluate the short and long term clinical impact of selective transarterial chemoembolization (TACE) on liver function in patients with hepatocellular carcinoma (HCC). To assess side effects in relation to treatments. To analyze the overall survival and HCC progression free survival probability.

**METHODS:** One hundred and seventeen cirrhotic patients with HCC were enrolled. Baseline liver function included Child-Pugh score and serum levels of alanine-aminotransferase (ALT), prothrombin time (PT) and bilirubin. According to Cancer Liver Italian Program (CLIP) and Barcelona Clinic Liver Cancer (BCLC)

staging systems, 71 patients were eligible for TACE; 32 had previously received treatment for HCC. No significant differences in liver function were observed between previously treated and not treated patients. TACE was performed by selective catheterization of the arteries nourishing the lesions. While hospitalized, patients underwent clinical, hematologic and ultrasonographic assessments. One month after TACE a CT scan was performed to assess tumor response. A second TACE was performed "on demand". Liver function tests were checked in all patients every four months.

**RESULTS:** After first TACE, the mean Child-Pugh score increased from a mean baseline  $5.62 \pm 1.12$  to  $6.11 \pm 1.57$  at discharge time ( $P < 0.0001$ ), decreasing after four months to  $5.81 \pm 0.73$  (not significant). ALT, PT and bilirubin significantly ( $P < 0.0001$ ) increased 24 h after TACE and progressively decreased until discharge. After the second TACE, variations in Child-Pugh score, ALT, PT and bilirubin were comparable to that described after the first TACE. No major complications were observed. The mean follow-up was  $14.7 \pm 6.3$  mo (median: 16 mo). Only one patient died. No other patient experienced important long term worsening of clinical status. The overall survival probability at twenty-four months was 98.18% with a correspondent HCC progression free survival probability of 69%.

**CONCLUSION:** Selective TACE may produce significant, but transitory increases in ALT values, with no major impact on liver function and Child-Pugh score. Preservation of liver function is achievable also in patients previously treated with other therapeutic modalities and in patients undergoing multiple TACE cycles. Liver function can remain stable in the long-term, with optimal medium term survival. This result can be achieved through rigorous patient selection on the basis of tumour characteristics and clinical conditions.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the sixth most common neoplasm in the world<sup>[1]</sup> and its incidence is increasing worldwide<sup>[2]</sup>. Overall, HCC is associated with liver cirrhosis in 80% of cases and it is the leading cause of death among cirrhotic patients<sup>[3]</sup>.

The treatment of patients with HCC has evolved in the last few years. However, curative treatments such as liver resection, liver transplantation or percutaneous ablation [percutaneous ethanol injection (PEI) and radiofrequency ablation (RF)] are applicable in only 30%-40% of cases<sup>[4]</sup>. Since transarterial chemoembolization (TACE) was introduced as a palliative treatment in patients with unresectable HCC, it has become one of the most common forms of interventional therapy<sup>[5]</sup>. Recently, it has been demonstrated that TACE improves survival compared with best supportive care in meta-analyses of randomized trials<sup>[6,7]</sup> and in two individual clinical trials<sup>[8,9]</sup>.

Nowadays TACE is often performed by selective catheterization of the hepatic segmental arteries nourishing the HCC lesions, to limit as much as possible the injury to the surrounding non tumorous liver as reported in previous studies<sup>[10-12]</sup>. However, although selective TACE is currently widely used, to our knowledge there are no reported extensive data from large series on both short and long term effects of this treatment on liver function. Because the optimal number of sessions is not known<sup>[13]</sup>, it is debatable if repeated courses of selective TACE may progressively impair liver function and if they are well tolerated or are limited by major side effects.

On this basis, in the present study, we prospectively evaluated the short and long term impact of selective TACE on liver function in a consecutive series of patients with liver cirrhosis and HCC. Side effects in relation to treatments were also assessed. Furthermore, we analyzed the overall survival and HCC progression free survival probability.

## MATERIALS AND METHODS

### Patients and HCC diagnosis

From September 1st 2006 to August 31st 2008, at a

**Table 1** Patients' demographic characteristics and etiology of liver cirrhosis *n* (%)

	Patients
Patients number	117
Gender	
Male	81 (69.2)
Female	36 (30.8)
Age (yr)	
mean $\pm$ SD	69 $\pm$ 7.8
Range	43-85
Causes of cirrhosis	
HBV (hepatitis B)	9 (7.7)
HBV and NAFLD	5 (4.3)
HBV and alcohol abuse	1 (0.09)
HCV (hepatitis C)	59 (50.4)
HCV and NAFLD	16 (13.7)

Alcohol abuse	8 (6.8)
Alcohol abuse and overweight	8 (6.8)
Sarcoidosis	1 (0.09)

NAFLD: Non-alcoholic fatty liver disease.

single center, we prospectively evaluated 117 consecutive patients with liver cirrhosis and HCC. Patients' demographic characteristics and etiology of liver cirrhosis are reported in Table 1.

HCC diagnosis was established by means of alpha-fetoprotein (AFP) assay, abdominal ultrasound examination and cross-sectional imaging, including at least one multiphase contrast-enhanced spiral or multidetector CT (CT; Hi Speed CT/I or light speed plus, GE Medical Systems, Milwaukee, USA). Extrahepatic metastases were ruled out by chest X-ray and bone scintigraphy. The HCC Tumor-Node-Metastasis (TNM) stages for our patients were: 44 (37.6%) patients T1 N0 M0, 40 (34.1%) patients T2 N0 M0, 32 (27.3%) patients T4 N0 M0, 1 (0.8%) patient T4 N0 M1.

Baseline evaluation of liver function included determination of the Child-Pugh score and serum levels of alanine-aminotransferase (ALT), prothrombin time (PT) and bilirubin.

The Child-Pugh class of disease was A (score 5-6) in 71 patients, B (score 7-9) in 26, and C (score 11-15) in 20.

We also stratified patients according to the staging system for HCC of Cancer Liver Italian Program (CLIP)<sup>[14]</sup>: it combines Child-Pugh staging with tumor criteria (tumor morphology, portal invasion and AFP levels). The CLIP score stratification of our patients is described in Figure 1.

According to the Barcelona Clinic Liver Cancer (BCLC) staging system<sup>[15]</sup>, which assesses tumor characteristics and liver function to generate a treatment algorithm, 13 patients were suitable for curative treatments (resection, liver transplant, PEI/RF) and 33 patients had advanced (i.e. portal invasion) or terminal stage HCC suitable only for symptomatic treatments. The remaining 71 patients were considered eligible for TACE. In this group mean HCC size was  $39.8 \pm 14.1$  mm.

We further stratified the patients suitable for TACE in two subgroups according to whether or not they had positive anamnesis for previous treatments for

Figure 1 Stratification of HCC patients according to CLIP score.

HCC. Thirty-two out of 71 patients (45%) had received treatment for HCC (TACE in 15, liver resection in 4, PEI/RF in 3 cases) before coming to our center. In these pretreated patients, the mean time between the first diagnosis of HCC and inclusion in our study was  $16.7 \pm 22.4$  mo. No significant differences in Child-Pugh and CLIP scores were observed between previously and not previously treated patients (Table 2).

### TACE protocol

Informed consent was obtained from all patients after the nature and the purpose of TACE had been fully explained. Digital subtraction angiography (DSA; Multistar, Siemens, Erlangen, Germany) was performed in all patients immediately before TACE.

TACE was performed by selective catheterization of the hepatic segmental arteries nourishing the lesions, using either 5-F catheters (Simmons 1 and Cobra; Mallinckrodt, St Louis, USA or Hydrophilic Simmons 1 and Cobra; Terumo, Tokyo, Japan) or 3-F coaxial microcatheters (Tracker 18; Vascular Access System, Target, St José, USA; SP Catheter; Terumo). A mixture of iodised oil (Lipiodol UltraFluid; Laboratories Guerbet, Aulnay-sous-Bois, France) and epirubicin hydrochloride (Farmorubicina; Farmitalia Carlo Erba, Milan, Italy) was injected, followed by selective arterial embolization using gelatin sponge particles (Spongostan Standard; Johnson and Johnson Medical Limited, Gargrave, Skipton, UK).

The amount of administered Lipiodol (10-30 mL) and anticancer drug (40-100 mg) was decided on the basis of number, location and diameter of lesions.

### Follow-up

After TACE procedure, the patients recovered with about 20 h bed rest. After this time, compression of the femoral artery, used as an access for administration of medication, was removed. Every 2 h during the first 6 h patients underwent clinical examination (abdominal evaluation and measurements of pulse rate, arterial blood pressure and body temperature).

A routine hematologic check was performed in all patients the morning after TACE and at discharge time,

Table 2 Child-Pugh and CLIP score in 71 patients eligible for TACE at enrollment (mean  $\pm$  SD)

	Not pretreated patients	Previously treated patients
Number of patients	39	32
Child-Pugh score	$5.82 \pm 0.82$	$5.4 \pm 1.2$
CLIP score	$1.12 \pm 0.82$	$0.86 \pm 0.83$

usually 5-7 d after the procedure. If severe abdominal pain or fever persisted during hospitalization, patients underwent abdominal ultrasonography to help exclude complications. One month after TACE a CT scan of the liver was performed to assess tumor response. TACE was repeated "on demand", if there was no tumor response, insufficient tumor response or progressive disease.

Tumor response to TACE was evaluated according to World Health Organization (WHO) criteria (complete response (CR): complete disappearance of all known disease and no new lesions; partial response (PR): at least 50% reduction in total tumor load of all measurable lesions; stable disease (ST): does not qualify for CR/PR or progressive disease; progressive disease (PD): at least 25% increase in size of one or more measurable lesions or the appearance of new lesions) modified according to the EASL amendments that take into account the reduction in viable tumor volume due to TACE-induced necrosis<sup>[16]</sup>.

Liver function tests were checked in all patients every four months in order to evaluate hepatic functional reserve.

### Statistical analysis

Descriptive statistics (mean  $\pm$  SD) were provided when appropriate. Parametric data were tested with Student's paired *t*-test. Overall survival and HCC progression free survival curves were determined by the Kaplan-Meier method. A two sided *P* value of less 0.05 was considered statistically significant. Statistical analysis was performed with SAS software (SAS Institute, Cary, NC).

## RESULTS

Ninety-eight TACE procedures were performed in 71 patients (mean number of treatments per patient  $1.4 \pm 0.61$ ). After first TACE, the mean Child-Pugh score increased from a mean baseline  $5.62 \pm 1.12$  to  $6.11 \pm 1.57$  at discharge time ( $P < 0.0001$ ), decreasing after four months to  $5.81 \pm 0.73$  (not significant).

ALT, PT and bilirubin significantly ( $P < 0.0001$ ) increased 24 h after TACE and then progressively decreased until discharge (Figure 2). After the second TACE cycle, variation of Child-Pugh scores (mean procedural value of  $5.71 \pm 0.78$ , discharge value to  $5.9 \pm 1.07$ ,  $P = 0.056$  not significant) and of ALT, PT and bilirubin were comparable to that described after the first TACE cycle.

No major complications were observed in our series of patients after TACE. After the first TACE cycle, post chemoembolization syndrome occurred in 23 (32.4%) patients, whereas 4 (5.6%) patients developed

Figure 2 Variations of ALT, PT and bilirubin after the first TACE (71 patients).

Figure 3 Overall survival probability according to Kaplan-Meier analysis.

acute cholecystitis and 2 (2.8%) patients presented with hematomas at the site of the femoral artery used as an access for administration of medication.

Following a second TACE cycle (22 patients), 5 (22.7%) patients experienced post chemoembolization syndrome, 1 (4.5%) patient presented with acute cholecystitis and 1 (4.5%) case showed mild ascites. After both the first or second TACE, side effects were successfully managed with medical therapy. When comparing patients according to whether or not they had positive anamnesis for previous treatments for HCC, we did not find significant differences in the modifications of pre- and post-TACE Child-Pugh scores.

Six months after chemoembolization in 57 (80%) out of 71 patients, the mean tumor size had not changed. In the remaining 14 (20%) patients, mean tumor size was  $44.8 \pm 17.7$  mm. The mean follow-up was  $14.7 \pm 6.3$  mo (median 16 mo). At the end of the follow-up, 49 (69%) of the treated patients presented with a CR; 21 (29.57%) patients had a PR; only 1 (1.4%) patient had progression of the tumor that involved more than 50% of the liver, with rapidly progressive worsening of clinical condition and appearance of bone metastasis. No other patient with class A disease was reclassified as having a class B disease, and no other patient with class B disease was reclassified as having class C disease after either the first

Figure 4 HCC progression free survival probability according to Kaplan-Meier analysis.

or the second TACE.

On follow-up, despite slight fluctuations in Child-Pugh score, no other patient experienced important long term worsening of clinical status and there was no progression of HCC that could modify CLIP or BCLC.

The overall survival probability at 24 mo was 98.18% (Figure 3) with a correspondent HCC progression free survival probability of 69% (Figure 4).

## DISCUSSION

Our single center study prospectively evaluated a large cohort of patients with liver cirrhosis and HCC to assess the short and long term clinical impact of selective TACE on liver function.

TACE is the most widely used treatment in patients with HCC who are considered unsuitable candidates for surgery and/or ablative therapies<sup>[17,18]</sup> and, recently, it has been shown to improve survival compared with best supportive care. The proper selection of candidates for TACE appears to be a key point. Even if a consensus has not yet been reached, the best candidates for TACE seem to be asymptomatic patients with preserved liver functions without vascular invasion or extrahepatic tumor spread<sup>[19]</sup>. In fact, the benefits of the procedure should not be offset by treatment-induced liver damage. Thus, to minimize the injury to nontumoral liver tissue, TACE is often performed by selective (or superselective) catheterization of the hepatic segmental or subsegmental arteries nourishing the tumor.

Although the possible impairment of liver function is a critical point when assessing TACE feasibility, only a few studies (which are not recent) were adequately reported, evaluating the effects of non-selective TACE on hepatic function<sup>[20-23]</sup>. Furthermore, to the best of our knowledge, there are no extensive published data on the short and long term clinical impact of selective TACE in HCC patients.

Attempts to improve the classification and prognostic prediction of HCC are still evolving and there is no agreement on the best staging system that can be recommended worldwide<sup>[24]</sup>. For this reason, in our study patients suitable for TACE were selected using Child-

Pugh, TNM, CLIP and BCLC staging systems. In this series, we had not only naive HCC patients: at the time of enrollment, about half of our patients had previously been treated for HCC. In our patients, after either first or second TACE, at discharge time, the increase in Child-Pugh score approached significance in comparison with baseline scores, without important variations in the patients' clinical status.

We observed a statistically significant increase in ALT, PT and bilirubin 24 h after treatment. Interestingly, ALT values increased the most, when compared to PT and bilirubin. This phenomenon could be the expression of selective treatment that enables sufficient tumor necrosis without impairing liver function.

TACE was well tolerated by all patients, with no major complication observed in this series. As already known, the most frequent side effects were post-chemoembolization syndrome often associated with temporarily increased liver enzymes. The post-chemoembolization syndrome, which can have widely variable manifestations, consists usually of fever, abdominal pain, nausea, vomiting and leucocytosis: often it requires only patient monitoring and pain control, but it can prolong the hospitalization period<sup>[25]</sup>.

As an institutional policy, we usually discharged patients 5-7 d after the procedure even if no major side effects occurred. This is in contrast with other authors who discharged patients 48-72 h after TACE<sup>[26,27]</sup>. Indeed we believe that this approach enables early diagnosis and treatment of possible clinical complications that could become symptomatic even a few days after treatment.

Considering the long-term follow-up, only slight and clinically negligible impairment of liver function was observed in our patients, with only one case of rapid HCC progression.

Liver function remained substantially stable independent of whether patients had undergone previous treatments or were treated by repeated TACE. In our study TACE was repeated "on demand", when there was evidence of insufficient tumor response, tumor recurrence or disease progression. According to our data, this type of treatment schedule may help preserving liver function and can be well tolerated in elderly patients, often suffering from co-morbidities, as well as in patients previously treated with other therapeutic techniques. TACE repeated at a fixed time, until the planned number of courses has been reached, may cause progressive liver atrophy and vascular damage<sup>[28]</sup>. The decision to repeat TACE should be based not only on tumor response or progression, but also on patients' clinical conditions and tolerance, which have to be assessed before each new course.

Recently, it has been demonstrated that TACE improves survival compared with best supportive care in patients with unresectable HCC. Indeed, our 2 years cumulative survival probability was 98%, which compares favorably with previous studies. We believe that this good clinical result may be related to the strict criteria applied in the selection of patients who may benefit from TACE. To this purpose, different staging systems should be used, to determine tumor characteristics and underlying liver disease, as these factors impact patient survival and

treatment options.

In conclusion, our prospective study demonstrates that TACE may produce a significant, but transitory increase in ALT values, with no major impact on liver function and Child-Pugh scores, as an expression of treatment selectivity and tolerability. Preservation of liver function is achievable in patients previously treated with other therapeutic modalities as well as in patients undergoing multiple TACE cycles. Moreover, liver function can remain stable in the long-term, with optimal medium term survival. However, this result can be achieved only through rigorous patient selection, on the basis of tumor characteristics and clinical conditions.

At this time, further studies are warranted to consider the clinical impact of new methods of chemoembolization using drug-eluting particles, which could allow larger tumor necrosis with reduced systemic effects.

## COMMENTS

### Background

Since transarterial chemoembolization (TACE) was introduced as a palliative treatment in patients with unresectable hepatocellular carcinoma (HCC), it has become one of the most common forms of interventional therapy. However, although selective TACE is currently widely used, up to now there are no reported extensive data from large series on both short and long term effects of this treatment on liver function. It is debatable whether repeated courses of selective TACE progressively impair liver function and if they are well tolerated or are limited by major side effects.

### Research frontiers

In the area of treatment of HCC, selective TACE is one of the most common forms of interventional therapy. In this field, the research hotspot is how to reduce TACE-related morbidity and how to improve overall survival and HCC progression free survival.

### Applications

The study results suggest the proper selection of candidates for TACE using different staging systems and careful clinical management after the procedure. TACE repeated "on demand" may help preserving liver function and can be well tolerated in elderly patients as well as in patients previously treated with other therapeutic techniques.

### Terminology

Selective TACE: it is a transarterial chemoembolization performed by a selective catheterization of the hepatic segmental arteries nourishing the HCC lesions, to limit as far as possible the injury to the surrounding non tumorous liver; TACE "on demand": it is a transarterial chemoembolization repeated not at a fixed time but in cases of absent or insufficient tumor response or progressive disease.

### Peer review

This is a very interesting manuscript that describes the efficacy of selective transarterial chemoembolization in patients with non-operable hepatocellular carcinoma. The procedure was associated with minimal complications or alteration of liver function. The excellent long-term results, when considering tumor progression and survival, could be achieved only through rigorous patient selection, on the basis of tumor characteristics and clinical conditions.

was 35.6%. The other genotypes nearby C/T-13910 and associated with lactase activity were not present in the study population. The consumption of milk among people with the non-persistent genotype tended to be lower than among the lactose tolerant subjects, but was not statistically significant.

**CONCLUSION:** An investigation of the lactase persistent genotype in a northern Russian population has not been performed before. The genotype did not affect the consumption of milk products in this population which could be explained by low consumption of milk products among the entire study population.

### Abstract

**AIM:** To estimate the prevalence of the lactase non-persistent genotype (C/C-13910) in a northern Russian population in accordance with ethnicity, and to evaluate self-reported milk consumption depending on lactase activity.

**METHODS:** Blood samples for genotyping lactase activity, defining the C/T-13910 variant by polymerase chain reaction, and direct sequencing were taken from 231 medical students of Russian origin aged 17-26 years. We analyzed milk product consumption by questionnaire which was specially designed for the estimation of milk consumption and abdominal complaints.

**RESULTS:** We found that the prevalence of the C/C-13190 genotype in the northern Russian population

### INTRODUCTION

The prevalence of adult-type hypolactasia (primary lactose malabsorption, lactase non-persistence) varies considerably between different races and populations<sup>[1,2]</sup>. Inheritance of primary lactose malabsorption is controlled by a single recessive autosomal gene<sup>[3]</sup>.

Simoons<sup>[4]</sup> and McCracken<sup>[5]</sup> suggested the cultural historical hypothesis to explain the differences in prevalence of hypolactasia. Hence, people with lactase persistence could survive better because they could use all nutrients in milk without having diarrhea. It is possible that they had more children than subjects

with hypolactasia. The idea of the calcium absorption hypothesis was proposed by Flatz<sup>[6]</sup>, who suggested that as lactose is a stimulant of calcium absorption, people who consume milk have less rickets, pelvic deformities and more children. This was genetic selection to the benefit of lactase persistence.

Several laboratory methods are used in the diagnosis of hypolactasia. Previously the prevalence of hypolactasia was detected by a lactose tolerance test (LTT) or a lactose tolerance test with ethanol (LTTE)<sup>[7,8]</sup>. The “gold standard” which can be used as a reference method is the direct determination of lactase activity in the small intestinal mucosa, taken by biopsy; however, the invasiveness of the test does not allow its use in everyday practice and screening<sup>[7]</sup>. In 2002 the genetic variant associated with adult-type hypolactasia, a one base polymorphism C/T-13910 (rs 4988234) upstream of the lactase coding gene on chromosome 2 was identified. The C/T-13910 variant is located in the OCT-1 binding site and acts as an enhancer<sup>[9]</sup>. The variant is inherited recessively so that the C-13910 allele in a homozygous form (the C/C-13910 genotype) is always associated with adult-type hypolactasia and the T-13910 allele (C/T and T/T-13910 genotypes) with persistent lactase activity<sup>[10]</sup>. The specificity of the genetic test is 100% with a sensitivity of 93% in subjects older than 12 years<sup>[11]</sup>. In addition, several other suggested variants (C/G-13907, T/C-13913, T/G-13915 and G/C-14010) nearby the C/T-13910 variant were identified in African and Middle Eastern populations<sup>[12-14]</sup>. Of these variants, 13915 T/G and 14010 G/C are associated with lactase persistence<sup>[12,14]</sup>.

Data on the prevalence of hypolactasia from studies performed in the territories of Russia are available. The prevalence of lactase malabsorption among Russians has been found to vary from 13% to 57% according to different authors and the different methods used<sup>[15-17]</sup>. Many studies were carried out in other populations living in the territories of Russia and the prevalence of lactose malabsorption among them was between 11% and 94%<sup>[16-20]</sup>.

Genotyping has been used in only two Russian studies<sup>[21,22]</sup> which showed that the prevalence of hypolactasia among Russians living in the central part ranged from 36% to 50% and depended on the area of residence<sup>[22]</sup>.

The main hypothesis of the current study was that people with the C/C-13910 genotype will avoid using milk or their milk consumption will be less compared to those with the lactase persistent genotype.

The objective was to estimate the prevalence of the lactase non-persistent genotype in a northern Russian population of students from the Medical University of Archangelsk. We determined the frequency of the C/T-13910 variants in accordance with ethnicity and estimated self-reported milk consumption and its relationship to the C/T-13910 genotypes.

## MATERIALS AND METHODS

### Study group

The study was performed in collaboration with the

Department of Family Medicine, Northern State Medical University (NSMU), Archangelsk, Russia, the Department of Medical Genetics, University of Helsinki and the Department of General Practice, University of Tampere. The study was approved by the Ethics Committee of NSMU (No. 08/06 from 29.11.2006). Medical students from different faculties aged 17 to 26 years were enrolled into the investigation. All subjects gave written informed consent and completed a questionnaire on their personal data, self-reported health status, milk consumption habits, ethnicity and their place of birth as well as their parents' and grandparents' place of birth. Blood samples were taken from 241 students. Of these, 231 reported their origin as Russian; but, according to the origins of grandparents (at least three out of four grandparents) only 149 were considered to have Russian ethnicity. Of the others, 61 did not report the data on grandparents and these subjects were classified as “missing information” on ethnicity. Twenty one students who reported their origin as Russian had at least 2 grandparents with another origin mostly Ukrainian, but also Byelorussians, Komi, Mordvinian and others. Final analysis of the prevalence of the C/C-13910 genotype was based on one of three subgroups: Russians, the group with missing data on grandparents and the mixed origin group (Table 1). We included students who were chosen by random methods from four main faculties of the university in the investigation. Randomization in our study was done according to standard rules. The NSMU has 16 faculties and each of them has 10 to 12 groups of students. We took every third group of students according to an official list from every fourth faculty. As a result we received 176 students chosen by a random method. The remaining 65 were taken at an annual medical review. Although that sample was not random, there was no selection because every student who attended medical review during a certain time (while we were collecting the material) was taken. Age and sex do not affect gene frequency.

The number of students and the selection process are presented in Figure 1. The majority of students (155 of 231) who participated in the study were born in the Archangelsk region, the others were born in different regions of north-west Russia (Figure 2).

### Questionnaire

We used the questionnaire designed by Sahi<sup>[3]</sup> with some modifications in the present study. Milk consumption was estimated using questions about milk and sour milk consumption. For comparison, we divided all subjects into two groups (Table 2). The first group consisted of students who were consumers of milk regardless of amount (answer “Yes” in Table 2) and the second group consisted of those who never consumed milk (answer “No” in Table 2).

### Analyses of genotype

DNA was amplified by polymerase chain reaction (PCR). We used Taq polymerase (Dynazyme, Finnzymes, Espoo, Finland) with the conditions described elsewhere. The

used forward primer was 5'-CCTCGTTAATACCCACT GACCTA-3' and the reverse primer was 5'-GTCACCTT GATATGATGAGAGCA-3' which covered about 400 bp regions on both sides of the C/T-13910 variant. The PCR product was verified by 1.5% agarose gel electrophoresis (with ethidium bromide). The PCR products were purified using shrimp alkaline phosphatase (USB) and exonuclease I (New England Biolabs) at 37°C for 60 min and at 80°C for 15 min.

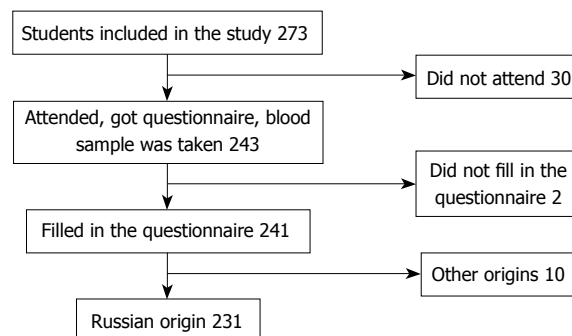

During sequencing, BigDye 3.1 terminator (Applied Biosystems) was used according to the manufacturer's instructions. Sequencing conditions were as follows: 96°C for 1 min, then 25 cycles at 96°C for 10 s, 55°C for 5 s and 60°C for 4 min. The sequencing reaction followed purification by Millipore Multiscreen plates (Millipore, USA) with Sephadex G-50 Superfine sepharose (Amersham Biosciences, Sweden), electrophoresis using the ABI 3730 DNA Analyzer (Applied Biosystems) and base calling by Sequencing Analysis 5.2 software (Applied Biosystems). The obtained sequence was analyzed using Sequencher 4.6. software (Gene Codes, USA)<sup>[23]</sup>.

### Statistical analyses

The Chi-square test was used to test the difference between groups of genotype in milk consumption.  $P < 0.05$  was considered statistically significant.

## RESULTS

The prevalence of the C/C-genotype was found to be 35.6% among young Russian people who were born and lived in north-west Russia (Table 1). None of the previously identified other variants (C/G-13907, T/C-13913, T/G-13915 and G/C-14010) were present in the study population.

**Figure 1** Steps in the data collection process.**Figure 2** Study group by region of birth place in north-west Russia.

The frequency of milk consumption varied among the milk consumers; however, the majority of subjects consumed 1-2 glasses per week or less and only 5 persons of 231 consumed 3 or more glasses per week. The same pattern was found for the consumption of sour milk. Only 3 persons in the entire study population consumed 3 or more glasses of sour milk per week.

Among subjects with lactase non-persistence (C/C-13910 genotype) more than half (63.1%) did not consume milk at all compared with those with the C/T-13910 variant (49.6%). The differences in milk consumption between lactose persistent subjects (C/T and T/T variants together) and those with hypolactasia (C/C-13910 genotype) was not statistically significant ( $P = 0.094$ ).

The consumption of sour milk did not have a significant effect within the group of “non-consumers”; but, subjects with the C/T- and the T/T -variants consumed sour milk relatively more often than subjects with the C/C-13910 genotype (59.3%, 64.7% and 48.8%, respectively). The sour milk consumption among lactose non-persistent subjects (C/C-variant) and lactase persistent subjects (C/T- and T/T- variant together) was not statistically significant ( $P = 0.084$ ).

All 5 persons who consumed milk products in

relatively greater amounts (3 and more glasses per week) had the lactase persistent genotype.

We estimated the gastrointestinal symptoms among subjects with lactase persistent and non-persistent genotypes. However, differences in the frequencies of symptoms were not statistically significant.

## DISCUSSION

The prevalence of adult-type hypolactasia among Russians is in accordance with previous investigations and varies from 13% to at least 50%<sup>[15-17,21,22]</sup>. The majority of previous studies were performed using the lactose tolerance test, and only two of the recent studies performed in Russia<sup>[21,22]</sup>, used the same direct genotyping we used in the present investigation. However, these researchers studied the frequency of the lactase persistent/non-persistent genotype among other populations living in the territories of Russia, but did not estimate the milk consumption.

Genetic testing is a direct method of diagnosing adult-type hypolactasia, and is not confounded by environmental factors which may affect the results of the other tests. Therefore the results of this study specify the actual prevalence of adult-type hypolactasia in Russia. An investigation into the lactose persistent genotype among a northern Russian population has not been performed before.

Since the variants (C/G-13907, T/C-13913, T/G-13915 and G/C-14010) nearby C/T-13910 were previously associated with lactase activity in southern parts of the world and were not present in this study, it is possible that these variants are not responsible for the regulation of lactase activity in north-west Russia. This is in agreement with results obtained from other countries in northern Europe<sup>[23,24]</sup>.

More than half of the study subjects did not drink milk and almost 45% did not drink sour milk at all. The great majority of "milk-consumers" drank very small quantities of milk, 1-2 glasses or less per week. Apparently, this is a habitual feature of the subjects in the study population and it did not depend on genotype. However, those five persons who drank the most milk had the lactase persistent genotype. Our data on the consumption of sour milk confirmed the results of previous studies which showed that people with lactose intolerance are more able to tolerate fermented milk because lactose in these products is reduced by 30%-40%<sup>[25]</sup>.

It is well-known that people with lactase non-persistence can consume small quantities of milk without any problems<sup>[26]</sup>. The results of our study strengthen this theory, even though we did not reach statistical significance in milk product consumption between the lactase persistent and non-persistent subjects. In summary, genotype does not affect the consumption of milk products in a northern Russian population which can be explained by low consumption of milk products among the entire study population.

## ACKNOWLEDGMENTS

We thank Timo Sahi for the questionnaire and help in designing the study.

## COMMENTS

### Background

The prevalence of adult-type hypolactasia (primary lactose malabsorption, lactase non-persistence) varies considerably between different races and populations. Data on the prevalence of hypolactasia from previous studies performed in the territories of Russia are limited especially for northern Russian populations. Moreover, the majority of these studies were performed using other methods. The inheritance of primary lactose malabsorption is controlled by a single recessive autosomal gene and genotyping allows us to determine the true prevalence of the lactase persistent/non-persistent gene. Thus, the prevalence of adult-type hypolactasia among the current population becomes obvious. The hypothesis that the lactase non-persistent genotype can affect milk and sour milk consumption has not been tested before in a northern Russian population.

### Research frontiers

This was the first time that genotyping of the lactase persistent gene was performed in a population from north-west Russia and an estimation of milk products consumption according to genotype was performed.

### Innovations and breakthroughs

In previous studies, the prevalence of lactase malabsorption among Russians has been found to vary between 13% and 57% according to different authors and the different methods used. Many studies were carried out in other populations living in the territories of Russia where there was great variation in the prevalence of lactose malabsorption, from 11% to 94%. Genotyping has a specificity of 100% and a sensitivity of 93%. Genetic methods have been used before in only two Russian studies which showed the prevalence of hypolactasia among Russians living in the central part to range from 36% to 50% depending on the area of residence. An estimation of the lactase non-persistent genotype affecting milk and dairy milk product consumption in a northern Russian population has not been done before.

### Applications

The study results suggest that the prevalence of the lactase non-persistent genotype in a northern Russian population is 35.6% which is more than that in northern Europe and less than that in southern Europe. This prevalence confirms the historical hypothesis of lactase malabsorption. However, the genotype does not affect milk and sour milk consumption among northern Russians which could be a result of relatively low milk product consumption among the entire study population.

### Terminology

Hypolactasia means very low activity of lactase in the jejunal mucosa; Lactose malabsorption describes poor lactose hydrolyzing capacity; Adult-type hypolactasia (primary lactose malabsorption, lactase non-persistence) - primary type of hypolactasia which is controlled by a single recessive autosomal gene; CC-13910 genotype defines lactase non-persistence; CT-13910, TT-13910 genotypes define lactase persistence.

### Peer review

This manuscript has potential for contribution regarding genetic subtypes and milk intolerance.

### Abstract

**AIM:** To study the incidence and survival rate of stomach cancer (SC) and its associated factors in a high risk population in Chile.

**METHODS:** The population-based cancer registry of Valdivia, included in the International Agency for Research on Cancer system, covers 356 396 residents of Valdivia Province, Southern Chile. We studied all SC cases entered in this Registry during 1998-2002 (529 cases). Population data came from the Chilean census (2002). Standardized incidence rates per 100 000 inhabitants (SIR) using the world population, cumulative risk of developing cancer before age 75, and rate ratios by sex, age, ethnicity and social factors were estimated. Relative survival (Ederer II method) and age-standardized estimates (Brenner method) were calculated. Specific survival rates (Kaplan-Meier) were measured at 3 and 5 years and survival curves were analyzed with the Logrank and Breslow tests. Survival was studied in relation to demographics, clinical presentation, laboratory results and medical management of the cases. Those variables significantly

associated with survival were later included in a Cox multivariate model.

**RESULTS:** Between 1998 and 2002, 529 primary gastric cancers occurred in Valdivia (crude incidence rate 29.2 per 100 000 inhabitants). Most cases were male (69.0%), residents of urban areas (57.5%) and Hispanic (83.2%), with a low education level (84.5% < 8 school years). SC SIR was higher in men than women (40.8 and 14.8 respectively,  $P < 0.001$ ), risk factors were low education RR 4.4 (95% CI: 2.9-6.8) and 1.6, (95% CI: 1.1-2.1) for women and men respectively and Mapuche ethnicity only significant for women (RR 2.2, 95% CI: 1.2-3.7). Of all cases, 76.4% were histologically confirmed, 11.5% had a death certificate only (DCO), 56.1% were TNM stage IV; 445 cases (84.1%) were eligible for survival analysis, all completed five years follow-up; 42 remained alive, 392 died of SC and 11 died from other causes. Specific 5-year survival, excluding cases with DCO, was 10.6% (95% CI: 7.7-13.5); 5-year relative survival rate was 12.3% (95% CI: 9.1-16.1), men 10.9% (95% CI: 7.4-15.2) and women 16.1% (95% CI: 9.5-24.5). Five-year specific survival was higher for patients aged < 55 years (17.3%), with intestinal type of cancer (14.6%), without metastasis (22.2%), tumor size < 4 cm (60.0%), without lymphatic invasion (77.1%), only involvement of the mucous membrane (100%). Statistically significant independent prognostic factors were: TNM staging, diffuse type, metastasis, supraclavicular adenopathy, palpable tumor, and hepatitis or ascites.

**CONCLUSION:** Social determinants are the main risk factors for SC, but not for survival. An advanced clinical stage at consultation is the main cause of poor SC survival.

## INTRODUCTION

In 2002, stomach cancer (SC) was the fourth most common cancer in the world, with 900 937 cases and 700 349 deaths. Two-thirds of these occurred in developing countries<sup>[1]</sup>. The high risk zones encompass Asia, Eastern Europe, and the Andean region of South America, all of diverse geographical characteristics<sup>[2]</sup>. Chile, a representative of the Andean Region, presents an SC average mortality rate per 100 000 in 1990-2005 of 25.1 for men and 13.2 for women<sup>[1]</sup>. This high SC mortality has not changed in the last 20 years<sup>[3]</sup>. The existence of a population-based Cancer Registry in Valdivia<sup>[4]</sup> gave us the opportunity to measure SC incidence and survival in a middle developing country. The Cancer Registry of Valdivia was initiated in 1982 and encompasses the inhabitants of an area of 18 429 square kilometres in Southern Chile; the data are included in the International Agency for Research on Cancer (IARC) cancer reports in 5 continents<sup>[4]</sup>. The aims of this study were to measure SC incidence and risk factors and to assess SC survival.

## MATERIALS AND METHODS

### Cancer registry of Valdivia

The cancer registry of Valdivia covers a population of 356 396 people, and encompasses a systematic review of records in private and public clinical centers, hospitals and laboratories, and death certificates to identify every cancer case or cancer death occurring among residents of the Valdivia area. To guarantee complete case-ascertainment, it includes various national databases of particular cancers, death certificates and hospital records to identify residents of Valdivia who may have been diagnosed in other regions. This allows near 100% case ascertainment verification in the catchment area.

### Cases

The subjects in the study were the 535 SC cases residents of Valdivia, identified in the Cancer Registry of Valdivia between the years 1998 and 2002. Of these, 6 cases were deemed non-eligible due to lack of information, leaving 529 subjects eligible for the study (98.9% of the total cases). In calculating the survival rate, 18 cases were excluded because they had a history of a previous cancer, apart from non-melanoma skin cancer; and 66 were excluded because the only information came from a death certificate or autopsy, leaving 445 cases (84.1%) to estimate SC survival. Deaths occurring within 30 d of a surgery with curative intention (3 cases) were considered deaths from other causes<sup>[5]</sup>. Deaths from other causes were included, but censored.

### Incidence and risk factors of stomach cancer

Standardized incidence rates, using the world population,

cumulative risk of developing cancer before the age of 75 and rate ratios were estimated according to the methodology proposed by the IARC<sup>[6]</sup>. Population data were obtained from the National Institute of Statistics and the Chilean census of 2002<sup>[7-9]</sup>. The risk of developing SC was estimated by sex, age, ethnicity (considering anyone with at least one Mapuche surname to be Mapuche, and the rest of the population to be Hispanic/European), education level (0-8 years and more than 8 years of education), urban or rural residency.

### Survival analysis

Relative survival was calculated following the Ederer II method<sup>[10]</sup> and age-standardized estimates were calculated using the approach proposed by Brenner *et al*<sup>[11]</sup>. Specific survival rates were measured at 3 and 5 years using the Kaplan-Maier method and survival curves for selected characteristics were compared using the Logrank and Breslow tests<sup>[12]</sup>. Those variables significantly associated with survival were later included in a Cox multivariate model<sup>[12]</sup>. Survival was studied in relation to demographics, clinical presentation, laboratory results and medical management of the cases. The characteristics of the tumor registered were: morphology according to the Lauren classification<sup>[13]</sup>, size measured at its largest diameter, location in the stomach (fundus, body or antrum or all the stomach) and invasion of the gastric wall. Stage of the tumor was based on TNM classification system<sup>[14]</sup>. The intervals between the onset of symptoms, the diagnosis and definitive treatment were determined.

## RESULTS

### Incidence of gastric cancer

Between 1998 and 2002, 529 primary gastric cancers were detected amongst the residents of Valdivia (crude incidence rate 29.2 per 100 000 inhabitants). The majority of cases were men (69.0%), residents of urban areas (57.5%), had a low education level (84.5% had 8 or less years of schooling) and were predominantly of Hispanic origin (83.2%) (Table 1). Age of cases ranged from 27 to 94 years, being significantly lower in men than women with mean age of 66.8 years [95% confidence intervals (CI): 65.5-68.1] and 70.4 years (95% CI: 68.2-72.6), respectively. Relative risk (RR) of SC was higher among men, particularly at age 55-64 years. Mapuche ethnicity was a significant risk factor only for women (RR 2.2, 95% CI: 1.2-3.7), and low education status was a stronger risk factor for women than for men: RR 4.4, (95% CI: 2.9-6.8) and 1.6, (95% CI: 1.1-2.1), respectively; the highest differential of risk between men and women was found among cases with more than 8 years of education (RR = 7.5,  $P < 0.001$ ) (Table 1).

### Clinical characteristics of the cases

Weight loss and epigastric pain were the most common symptoms in patients at diagnosis, and both symptoms were significantly more common in males than females (Table 2). Signs considered to indicate poor prognosis:

Table 1 SIR of stomach cancer by selected characteristics, Valdivia, Chile, 1998-2002

<sup>a</sup>Significant risk factors between characteristics groups; RR: Relative risk.

palpable epigastric mass, ascites or supraclavicular adenopathy, each were present in less than 15% of cases; only a palpable epigastric mass was significantly more common among females (Table 2). The main detection source was histology; only 11.5% of cases were identified by their death certificate only. The latter cases were significantly older: in those over 80, 45.5% and 15.1% were confirmed by death certificate only and histology, respectively ( $P < 0.001$ ); there was also a higher proportion of women (22.6% versus 6.6%,  $P < 0.001$ ) in this group.

In the majority of cases, the time interval between the beginning of symptoms and diagnosis was more than 3 mo. Early diagnoses were more frequent among men (Table 2). The main diagnostic procedures were gastric endoscopy and gastric biopsy (Table 2). At diagnosis only 5.5% of cases were in Stage I or II of the TNM classification; these earlier stages were more frequent among women (7.3%) than men (4.7%) (Table 2). The three most common histological types of SC both in men and women were: tubular adenocarcinoma (36%), undefined adenocarcinoma (20.2%) and signet ring cell carcinoma (18.7%) (Table 2). The fundus was the most frequent localization of the SC (29.9%) and the tumor location was not determined in a third of the cases. Information about tobacco or alcohol consumption was available for 65.4% and 63.9% of cases, respectively; tobacco use was declared by 51.4% of men and 29.1% of women ( $P < 0.001$ ), and alcohol consumption was declared by 73.6% of men and 31.3% of women ( $P < 0.001$ ) (Table 2).

### Five years survival

Follow-up of the 445 cases included in the survival analysis was concluded on December 31st 2007, with 100% of the cases included in the 5-year analysis; only 42 cases remained alive, 392 cases had died of SC and 11 died from other causes. Specific survival at 5 years, including cases with a death certificate only, was

9.6% (95% CI: 6.9-12.3), excluding cases with a death certificate only, the survival was 10.6% (95% CI: 7.7-13.5); lower in men 9.8%, (95% CI: 6.5-13.1) than in women 12.9% (95% CI: 6.7-19.1). The 5-year relative survival rate, adjusted for the life expectancy of the population, was 12.3% (95% CI: 9.1-16.1), increasing the difference in survival of men 10.9% (95% CI: 7.4-15.2) and women 16.1% (95% CI: 9.5-24.5).

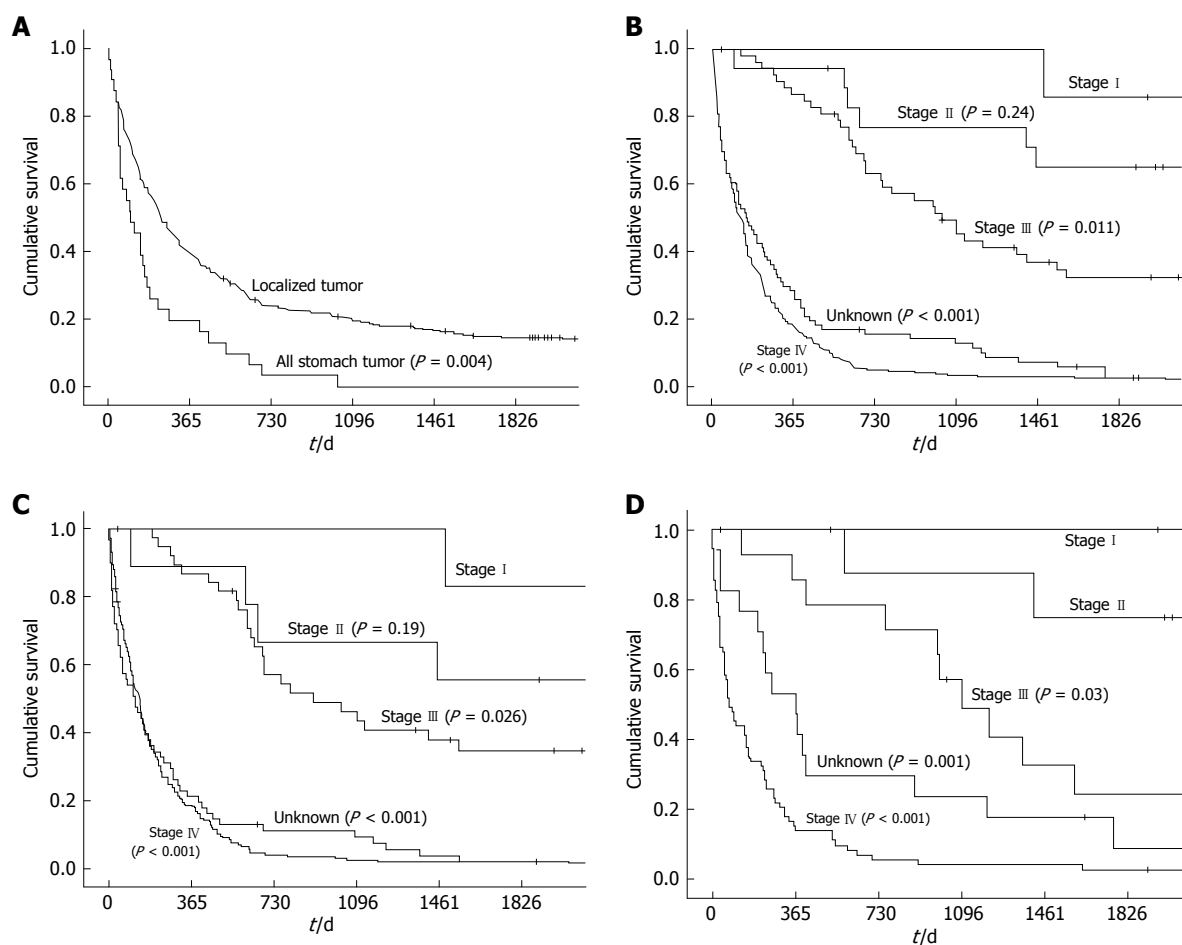

In univariate analysis, the significant factors for greater than 5 years survival were: younger age; Hispanic/European ethnicity; urban residency; lack of some clinical markers (supraclavicular adenopathy, palpable mass, ascites, or vomiting); gastrectomy; intestinal histological type; localized tumor (Figure 1A); size less than 4 cm, limited to the mucosa, without lymphatic invasion or metastasis; TNM stage 1 (Table 3). Tumors with proximal and distal localization had the same TNM distribution. However, tumors localized in the body had better 5-year survival than those localized to the fundus or in all the stomach, 23.0% vs 11.4% ( $P = 0.049$ ) and 0% ( $P < 0.001$ ), respectively; there was no statistical difference in survival between tumor location in the body and antrum (23.0% and 14.8%,  $P = 0.16$ , respectively).

The cumulative survival curve of Stage I SC was significantly higher than Stage III, Stage IV or unknown stage (Figure 1B), and was similar in men and women (Figure 1C and D).

### Multivariate survival analysis

The multivariate models only included cases with sufficient clinical data (271 cases, 69%). All cases (445) had "unknown staging" more frequently than the cases included in the multivariate models (17.8% and 8.9% respectively,  $P = 0.001$ ) while their 5-year survival was lower (10.6% vs 14.1%  $P = 0.002$ ). Nevertheless, all cases were similar to those included in the multivariate analysis with regard to socio-demographics and to the variables associated with survival in the univariate analysis (listed in Table 3).

**Figure 1** Stomach cancer-specific survival in Valdivia 1998-2005. A: Tumor location; B: TNM stage classification; C: Men by TNM; D: Women by TNM.

In the multivariate analysis, only 6 variables maintained their statistical significance as independent prognostic factors (Table 4). TNM staging was the strongest prognostic variable, the risk of dying in the following year was 23 times higher with stage IV compared with stage I. Other factors of poor prognosis were: diffuse type, presence of metastasis, supraclavicular adenopathy, a palpable tumor and hepatitis or ascites (Table 4).

## DISCUSSION

We confirmed that Chile, in particular southern Chile, where Valdivia is located, has one of the highest risks of stomach cancer reported, particularly among men (SIR 40.8 per 100 000 inhabitants). This population has many factors that have been associated with SC such as poverty, a high rural population (32%), poor sanitary conditions in 43% of houses<sup>[15]</sup>, high prevalence of smokers (37.4%), high alcohol consumption (alcohol dependence in the Chilean population varies from 7.2% to 14.1% among low and high socioeconomic groups and from 5.0% to 17.6% among females and males respectively)<sup>[16]</sup>; low daily consumption of fruits and vegetables (32.1%)<sup>[17]</sup>; and high prevalence of *Helicobacter pylori* (*H. pylori*) infection, especially among young people<sup>[18]</sup>.

We could not demonstrate an independent effect of race in the incidence of SC among men; but, for women,

Mapuche ancestry was a significant risk factor (RR: 2.2, 95% CI: 1.2-3.7). Similarly low schooling was a stronger risk factor among women (RR: 4.4 and 1.6 for women and men, respectively) and the highest male/female ratio of 7.5 occurred among people with greater schooling, suggesting that behavioral or environmental factors preferentially protect women of Hispanic origin and with more years of education. In the 2003 National Health Survey of Chile, more educated women had significantly better nutritional indicators than men of high or low educational level and women of low educational level, with body mass index of 25.0 *vs* 27.8, 26.1 and 28.0, respectively<sup>[19]</sup>. This better nutritional status is associated with a higher intake of fruits and vegetables among these women, a protective factor for gastric cancer<sup>[20]</sup>. Also, the 2006 Quality of Life National Survey showed that women added salt to the meals before eating less frequently than men (8.5% and 10.9%, respectively)<sup>[17]</sup>. In the population, as well as in our series, smoking and alcohol consumption were less frequent in women than men. Interaction of smoking and drinking has been demonstrated to play a role in SC<sup>[21]</sup>. Plus, in Chile, *H. pylori* infection was also 10% lower among women than men<sup>[18]</sup>. These environmental factors may interact with susceptibility factors, such as alcohol dehydrogenase polymorphisms<sup>[22-24]</sup>, to explain the predominance among men and also the higher frequency of this cancer in the

<sup>1</sup>Includes 3 cases diagnosed based on a biopsy of metastasis; <sup>2</sup>Time between first symptoms and diagnosis.

Mapuche areas of southern Chile<sup>[18]</sup>.

In this population-based study only 10.6% of SC survived the 5-year period following the detection of SC. When cases detected by death certificate only were included, the 5-year survival dropped to 9.6% (95% CI: 6.9-12.3). Previous studies based on cases detected at the hospital, reported higher survival rates of 12% to 48.9%<sup>[25-27]</sup>, probably due to a selection bias created at hospital admission, when cases in the advanced stages of the disease who will not benefit from medical care are referred to palliative care units. The mean age of SC in our series was similar to that reported by European population-based cancer registries<sup>[28,29]</sup>, and was 10 years

greater than the mean age reported in hospital-based survival studies. The 5-year relative survival rate, adjusted for the life expectancy of the population, was 12.3%, half that reported in population registries in North America<sup>[30]</sup> and Europe<sup>[31]</sup>, where the survival rates are between 20.1% and 25.6%. Main risk factors of this poor survival were either clinical (palpable tumor, ascites, hepatitis) or related to the tumor characteristics (stage, histological type, metastasis, nodes); there were no significant social determinants of survival. This underlines the relevance of the advanced stage at consultation of most cases. When a gastrectomy with the intention to cure was undertaken the 5-year specific

survival was 38.6%, which is comparable to reports from Europe and North America in either population-based or hospital-based registries: 45% in Spain<sup>[32]</sup>, 46.1% in Japan<sup>[33]</sup>, 29.7% in Florence<sup>[29]</sup> and 32.6% in Côte d'Or<sup>[34]</sup>. We found that the stage of the disease was the main prognostic factor for survival as has been reported by others<sup>[26,27,32,33]</sup>. Thus, in our population the high incidence of SC was aggravated by a very late diagnosis of the disease. 11.5% of cases were never recognized by the medical system and were discovered based on death certificates, while another 20% of cases were inoperable at their first medical consultation. Only 5.5% of cases were found in stages I or II at the moment of diagnosis, lower than what has been reported in other population-based cancer registries in places with no screening programs such as Florence (36.7% of cases in stages I or II)<sup>[29]</sup> and Changle, China (30.9% in stages I or II)<sup>[35]</sup>; in Florence, where methods are the same as those in our study, a higher 5-year relative survival was reported than in our series (22.7%, 95% CI: 20.5%-24.9% and 12.3%, 95% CI: 9.1-16.1, respectively). Most cases presenting at

earlier stages, stage I or II, were under age 54 in men and under age 68 in women, suggesting that in men the disease is initiated earlier or evolves faster (data not presented in the tables). Time elapsed between the onset of symptoms and medical attention, 8.4 mo, was twice as high as that reported in La Coruña, Spain<sup>[32]</sup>. Most cases (55%), exceeded the current Chilean standard of less than 45 d between first consultation and diagnosis, and 44% of operated cases exceeded the 30 d interval between diagnosis and treatment. Thus late consultation and slow medical management contributed to the high mortality of SC in this series.

In our series, there were 0.7 proximal tumors for each distal tumor, half of that described in industrialized countries such as the USA 1.46<sup>[36]</sup> or Canada 1.5<sup>[37]</sup>. Distal cancers, the majority in our series, are mostly associated with *H pylori* and poverty, and have a somewhat better prognosis than proximal cancers, so that the biological characteristics of the tumor did not provide a plausible explanation for our poor survival rates.

Screening of SC based on endoscopy and radiography has been shown to reduce the mortality rate in Japan<sup>[38]</sup> but not in Chile<sup>[39,40]</sup>. In mid 2006, a nationwide screening program was initiated in Chile, offering endoscopic examination to patients over 40 years with dyspeptic symptoms. The usefulness of symptoms as selection criteria for endoscopy has recently been discussed by Maconi<sup>[41]</sup> because symptoms of early stage SC are highly nonspecific while warning symptoms, such as a palpable abdominal mass, represent an advanced stage of the disease. Others are proposing a combination of serological tests to screen for gastric atrophy, *Helicobacter*<sup>[42]</sup> plus alcohol dehydrogenase<sup>[24]</sup>, followed by gastroscopy of cases that screen positive. Such a strategy would allow screening of a broad population in a short time to be followed by more invasive techniques in a much smaller group, estimated as 12% in Chile<sup>[42]</sup>.

SC has a high incidence rate and a poor prognosis in the province of Valdivia. Main factors associated with poor survival were delays in obtaining medical care: time taken to seek medical care, time to be diagnosed and time to receive medical treatment; once medical care was obtained survival was comparable to other series. Current efforts to shorten these times with greater use of gastric endoscopy may improve this situation.

## COMMENTS

### Background

Stomach cancer (SC) has been the main cancer killer in the Chilean population since the 1950s. Despite important socioeconomic development of the country and improvements in health indicators, SC mortality has not decreased. To date, there are no population-based studies of SC incidence and survival in Chile which would illuminate the causes behind the high SC mortality, particularly among men. The cancer registry of Valdivia is currently the only population-based cancer registry in Chile included in the International Agency for Research on Cancer reports and is one of 10 cancer registries in Latin America. This is the first report of SC survival in the Chilean population.

### Research frontiers

There have been few studies of the real magnitude of the SC problem and the characteristics of the patients who survive or die from this cancer.

### Innovations and breakthroughs

The most innovative product is the exact measurement of the incidence and survival of SC using the most up-to-date statistical methods which provide data which is easily comparable among populations.

### Applications

This report represents a baseline of the SC situation in Valdivia and will permit evaluation of future interventions aimed to control SC. The methods presented here can be used to analyze any other cancer covered by a cancer registry.

### Terminology

Incidence rate: calculated from the new occurrences of primary SC in the whole area divided by its population in the study period. Standardized incidence rate: the incidence rate adjusted by the age structure of a theoretical population, the world population, to permit direct comparisons between populations of diverse age structure. Specific survival rate: the number of cancer cases that are alive at the end of the study period divided by the person-time of cases over the period at risk of dying of SC. Relative survival rate: the specific survival rate adjusted by the life expectancy of the baseline population.

### Peer review

This report presents invaluable data on SC incidence and SC survival in an area at high risk of SC in a middle developing country of Latin America. It provides information about the clinical presentation of SC cases, their socio-demographic characteristics and risk factors and prognostic factors of survival. The results indicate that a late stage at diagnoses is by far the principal explanatory factor of poor survival of SC in the area.

### Abstract

**AIM:** To investigate the aspects of liver histology in patients with non-alcoholic steatohepatitis (NASH) who had normal aminotransferase levels.

**METHODS:** Thirty-four patients diagnosed with liver steatosis by ultrasonographic examination participated in the study. We compared all non-alcoholic fatty liver disease and NASH cases, according to aminotransferase level, aspartate aminotransferase (AST)/alanine aminotransferase (ALT) ratio and presence of metabolic syndrome.

**RESULTS:** Sixteen of 25 patients with high aminotransferase levels were diagnosed with NASH and nine with simple fatty liver according to liver histology. Among the nine patients with normal aminotransferase levels, seven had NASH and two had simple fatty liver. The patients with normal and high liver enzyme levels had almost the same prevalence of NASH and metabolic syndrome. Liver histology did not reveal any difference according to aminotransferase levels and AST/ALT ratio.

**CONCLUSION:** Aminotransferase levels and AST/ALT ratio do not seem to be reliable predictors for NASH. Despite numerous non-invasive biomarkers, all patients with fatty liver should undergo liver biopsy.

### INTRODUCTION

Non-alcoholic fatty liver disease (NAFLD) is a common liver pathology that begins from simple steatosis and then progresses to steatohepatitis and ends with cirrhosis or liver failure<sup>[1,2]</sup>. While simple steatosis is accepted as a benign state, steatohepatitis, because of elevated liver enzymes [alanine aminotransferase (ALT) and aspartate aminotransferase (AST)] and certain metabolic abnormalities such as diabetes, obesity, dyslipidemia, hypertension and insulin resistance is assessed as a serious condition<sup>[3-6]</sup>. Nevertheless, according to the literature, some non-alcoholic steatohepatitis (NASH) patients can have normal aminotransferase levels or conversely some patients with high liver enzymes may not have steatohepatitis<sup>[7]</sup>. It has emerged that some NAFLD patients may not fulfill all criteria concerned with metabolic syndrome and do not have insulin resistance<sup>[8]</sup>. Some studies have revealed that NAFLD can progress in the absence of metabolic disorders, as defined also in lean and non-diabetic patients, males and children<sup>[9]</sup>. We aimed to show that NASH can occur without an increase in liver enzyme levels and that there may not be progression of NASH in fatty liver patients with high liver enzymes. More attention has been paid to these issues in recent years; but, further research especially related to large populations should be performed.

### MATERIALS AND METHODS

#### Study design and patients

In the present retrospective study, we aimed to establish

the presence of patients with normal liver enzymes who were diagnosed histologically with NASH, to compare NAFLD and NASH patients according to liver enzyme levels, and to establish whether histological aspects of NAFLD differ with liver enzyme levels. This study included 34 patients who attended the Gastroenterology Division of Uludag University. The patients were diagnosed with liver steatosis by ultrasonography and complete clinical, anthropometric and laboratory evaluations and liver biopsies were performed. Exclusion criteria were as follows: alcohol consumption of  $\geq 20$  g/d, pregnancy, presence of hepatitis B and C infection, autoimmune liver diseases, hemochromatosis, Wilson's disease,  $\alpha$ -1 antitrypsin deficiency, toxic liver diseases, primary biliary cirrhosis, primary sclerosing cholangitis, respectively.

### Laboratory studies

Anthropometric, clinical and laboratory features of all NAFLD cases with both high and normal liver enzyme levels were recorded. Anthropometric parameters consisted of height, weight, body mass index (BMI), waist and hip circumferences and waist/hip ratio. Overweight and obesity were defined as BMI  $\geq 25$  kg/m<sup>2</sup> and  $\geq 30$  kg/m<sup>2</sup>, respectively. Biochemical assessments included ALT, AST,  $\gamma$ -glutamyltransferase (GGT), alkaline phosphatase (ALP), bilirubin, albumin, high-density lipoprotein (HDL)-cholesterol, triglycerides, glucose, insulin levels and oral glucose tolerance test (OGTT). The diagnosis of type 2 diabetes, impaired glucose intolerance (IGT), impaired fasting glycemia were dependent on American Diabetes Association (ADA) criteria and patients taking oral antidiabetics or insulin therapy were accepted as having diabetes. The cut-off values of ALT and AST were 0-43 and 0-40 IU/L, respectively. Resting blood pressure  $\geq 140/90$  mmHg or treatment with antihypertensive drugs indicated hypertension. Cut-off levels of hypertriglyceridemia and low HDL-cholesterol status were  $\geq 150$  mg/dL and  $\leq 40$  mg/dL, respectively. Lipid-lowering drug therapy indicated dyslipidemia. Fasting insulin level was 6-27  $\mu$ U/mL and presence of insulin resistance was defined when homeostasis model assessment of insulin resistance (HOMA-IR) value was  $\geq 2.70$ . Description of metabolic syndrome was made according to World Health Organization criteria (BMI  $\geq 30$  kg/m<sup>2</sup>, increased waist/hip ratio of  $> 0.90$  in men and  $> 0.85$  in women, fasting blood glucose  $\geq 110$  mg/dL, presence of IGT, HOMA-IR  $\geq 2.70$ , triglycerides  $\geq 150$  mg/dL, HDL-cholesterol  $\leq 40$  mg/dL in men and  $\leq 50$  mg/dL in women, arterial blood pressure  $\geq 140/90$  mmHg and microalbuminuria)<sup>[10]</sup>. At least three of these criteria were required to diagnose the metabolic syndrome. Liver biopsy was performed according to the severity of the clinical features and permission from the patients. The study was approved by the hospital ethics committee.

### Histological assessment

All liver biopsy specimens were evaluated by a liver pathologist according to the criteria of Brunt *et al*<sup>[11]</sup>. NASH was diagnosed according to the criteria as

presented below: steatosis (mild, moderate and severe) and two of the three features: (1) necro-inflammation with mononuclear cells and/or polymorphonuclear leukocytes, (2) ballooning degeneration of hepatocytes and (3) perisinusoidal and/or bridging fibrosis.

### Statistical analysis

Statistical analysis was performed by using the SPSS statistical software version 15.0 for Windows.  $P < 0.05$  was considered to indicate statistical significance. According to the data distribution, independent  $t$ -test and Mann-Whitney test were used to compare continuous variables related to the case groups. Pearson's Chi-square test and Fischer's absolute Chi-square test were used to compare categorical variables.

## RESULTS

The features of 34 patients (12 male, 22 female) with liver steatosis who attended the Gastroenterology Division of Uludag University were investigated. Slight and blunt abdominal pain were present in 77.7% of patients with elevated liver enzymes and in 64.0% of patients with normal liver enzymes. The prevalence of hepatomegaly was 44.4% and 28% in the high liver enzyme and normal liver enzyme group, respectively. All 34 patients underwent liver biopsy according to their clinical and laboratory aspects. Twenty-five patients had elevated and the remaining nine had normal liver enzyme levels. Sixteen of 25 patients with high liver enzymes were diagnosed with NASH and nine of 25 as simple fatty liver with respect to liver histology. When we analyzed the nine patients with normal ALT levels, seven were diagnosed with NASH and two with simple fatty liver according to liver histology.

Anthropometric, clinical and laboratory results of all NAFLD patients according to high and normal liver enzyme groups are presented in Table 1. The patients with high and normal aminotransferase levels had almost same prevalence of NASH (77.7% *versus* 64.0%). Only the proportion of patients with hypertriglyceridemia in the normal liver enzyme group was significantly higher than in the group with elevated liver enzyme. However according to the Table 1, the number and proportions of the other metabolic risk factors in high and normal liver enzyme levels groups did not differ. Moreover, a comparison was performed between the elevated and normal aminotransferase level groups in NASH patients and there were no significant differences (Table 2). The prevalence of metabolic syndrome was similar in NASH patients both with elevated or normal aminotransferase levels.

There were seven patients with normal aminotransferase levels who were diagnosed with NASH. Six of these were female (mean age: 52.8 years) and one was male. Five of the female patients were obese (average BMI: 31 kg/m<sup>2</sup>) and one was morbidly obese (BMI: 49.3 kg/m<sup>2</sup>). All six female patients had metabolic syndrome (five of whom had three risk factors and one had four risk factors). Two of the six female

NASH	7 (77.7)	16 (64.0)	> 0.05
Metabolic syndrome	8 (88.8)	19 (76)	> 0.05

<sup>1</sup>Data expressed as median (minimum-maximum); BMI: Body mass index; HDL: High-density lipoprotein; ALP: Alkaline phosphatase; GGT: Gamma glutamyl transpeptidase. Only the prevalence of hyperglyceridemia in NAFLD patients with normal liver enzyme levels was higher than in those with elevated liver enzyme.

patients had overt diabetes, two had impaired glucose tolerance and the remaining two had normal OGTT results. Two female patients who were non-diabetic had insulin resistance determined by HOMA test. Three female patients had hypertension and five had hypertriglyceridemia. The male patient with NASH was 46 years old with central obesity (BMI: 30.5 kg/m<sup>2</sup>). He also had insulin resistance (HOMA-IR:3.46), but had no other risk factors such as diabetes, hypertriglyceridemia, hypertension and microalbuminuria; therefore he was not diagnosed with metabolic syndrome.

In Table 3, the findings of all NASH patients according to the presence of metabolic syndrome are presented and evaluated. According to Table 3, average age, the prevalences of female gender, hypertension, low-HDL level and hypertriglyceridemia were significantly higher in patients with metabolic syndrome than those in patients without metabolic syndrome. Interestingly, among the 18 NASH patients with metabolic syndrome twelve had elevated and six had normal liver enzyme levels as stated at Table 2. Similarly, among the 5 NASH patients without metabolic syndrome, there were four

<sup>1</sup>Data expressed as median (minimum-maximum); BMI: Body mass index; HDL: High-density lipoprotein; ALP: Alkaline phosphatase; GGT: Gamma glutamyl transpeptidase. There was no difference between the features of NASH patients with high and normal aminotransferase levels.

patients with elevated and one with normal liver enzyme levels. But these results were not statistically significant. In addition, the proportion of patients with obesity was similar in both the elevated and normal liver enzyme groups with metabolic syndrome.

Table 4 represents the features of liver histology in all NAFLD patients according to liver enzyme levels. In Table 4, patients with elevated liver enzyme levels seemed to have more severe liver histology than those with normal liver enzyme levels, but this was not statistically significant.

Liver histology in patients with normal liver enzyme levels (1 male and 8 female patients) was described in detail below. Histologically defined NASH was present in one male and six female patients. Among six female patients, four had mild, one had moderate and one had severe necroinflammation, and fibrosis (stage 1) was detected only in two patients. In one male patient with NASH, the features of liver histology consisted of moderate steatosis and necroinflammation, but no fibrosis. Simple fatty liver was detected in two female patients in the normal liver enzyme group and one had mild and the other had moderate steatosis.

Table 5 shows the features of liver histology in all NAFLD patients according to AST/ALT ratio

**Table 3** Features of NASH patients with high and normal aminotransferase levels according to the presence of metabolic syndrome *n* (%)

<sup>1</sup>Data expressed as median (minimum-maximum); BMI: Body mass index; HDL: High-density lipoprotein; ALP: Alkaline phosphatase; GGT: Gamma glutamyl transpeptidase. There were significant differences between NASH cases with or without metabolic syndrome according to average age, gender and the presence of hypertension, low-HDL level and hypertriglyceridemia.

values. However, there were no statistically significant differences between patient groups according to AST/ALT ratio. Table 6 compares patients with NASH and without NASH according to anthropometric, clinical and laboratory features; and only the prevalence of obesity was significantly different between these two groups.

## DISCUSSION

An increase in ALT value is regarded as a parameter for the diagnosis of NASH. The criteria for establishing a diagnosis of NASH are elevated aminotransferases (ALT and AST), histological features resembling to those in alcoholic steatohepatitis and exclusion of other liver diseases<sup>[2-4]</sup>. However, anthropometric, clinical and histological aspects of NASH with normal ALT levels have not been investigated extensively. In this retrospective study, we aimed to describe the anthropometric, clinical and histological features of NASH patients with normal ALT values and to compare these with NASH cases that had elevated ALT levels.

There have been many studies on normal ranges for serum ALT levels. The new cut-off values for upper limits of serum ALT levels are now proposed as 30 U/L for men and 19 U/L for women<sup>[12]</sup>. Amarapurkar *et al*<sup>[13]</sup> have expressed that after excluding other liver disorders, normal ALT may not exclude severe liver diseases and, hence, liver biopsy may be necessary

**Table 4** Liver histology according to the level of liver enzymes in all NAFLD cases *n* (%)

Liver histology	All NAFLD patients	
	Patients with normal aminotransferase levels ( <i>n</i> = 9)	Patients with elevated aminotransferase levels ( <i>n</i> = 25)
Steatosis		
Mild	5 (55.5)	12 (48.0)
Moderate	3 (33.3)	7 (28.0)
Severe	1 (11.2)	6 (24.0)
Necroinflammation		
Absent	2 (22.2)	9 (36.0)
Mild	4 (44.4)	3 (12.0)
Moderate	2 (22.2)	10 (40.0)
Severe	1 (11.2)	3 (12.0)
Fibrosis

Due to the small number of patients statistical evaluation and *P* values were not available. There were no significant differences between patient groups according to AST/ALT ratio.

to detect the seriousness of liver diseases. Likewise, Kunde *et al*<sup>[14]</sup> have stated that the diagnostic use for ALT to determine NASH was insufficient in their study. Fracanzani *et al*<sup>[15]</sup> have expressed the view that normal ALT is not a reliable criterion to exclude patients from liver biopsy. Mofrad *et al* have found that histological features of NAFLD may progress in persons with normal ALT values and the liver histology in these persons is not very different from that in patients with high ALT levels and in addition having a low or normal ALT level is not a reliable indicator against the presence of steatohepatitis<sup>[7]</sup>. Sorrentino *et al*<sup>[16]</sup> have detected that

liver enzyme levels are not reliable markers of NASH. However, Chen *et al.*<sup>[17]</sup> have determined that elevated serum ALT level may be associated with NAFLD but it is not a reliable parameter for metabolic risk factors. Furthermore, Amarapurka *et al.*<sup>[18]</sup> have added that high levels of transaminases are non-specific and may not indicate the progression of NASH. Therefore, liver biopsy is necessary in grading and staging of NASH to predict disease progression. Lizardi-Cervera *et al.*<sup>[19]</sup> have also revealed that the number of patients with NASH was not increased with high levels of AST. Sebastiani *et al.*<sup>[20]</sup> have revealed that the usefulness of non-invasive biomarkers is very restricted in general practice.

In our study, the patients were comparable with respect to age, gender, anthropometric features, imaging aspects and laboratory findings. Interestingly, in NAFLD patients only the prevalence of hypertriglyceridemia in normal liver enzyme group was higher than those with elevated liver enzyme. All other clinical, histological and laboratory findings of patients with normal ALT were no different from those with elevated ALT in the NAFLD group. Moreover, the prevalence of NASH in NAFLD patients with elevated and normal aminotransferase (ALT) levels was similar. These findings suppose that NASH can progress without an increase in ALT levels and this

raises the suspicion that this parameter may not be a reliable marker of NASH. In the present study patients with elevated and normal ALT levels in the NASH group had no significant differences, including the prevalence of metabolic syndrome and insulin resistance. These results suggest that cases with normal aminotransferase levels can also have steatohepatitis and metabolic syndrome and not only simple fatty liver and, hence, a liver biopsy is not an incorrect approach for these patients. We found that the histopathological features of the liver were more severe in NASH patients with high liver enzyme levels than in those with normal liver enzyme levels; but, the difference was not statistically significant.

We compared the NASH patients according to the presence of metabolic syndrome; we did not detect any difference according to liver enzyme levels. Consequently, in our opinion, liver biopsy for cases diagnosed with fatty liver by imaging methods may be beneficial even if they have normal aminotransferase levels.

## COMMENTS

### Background

Nowadays certain non-alcoholic steatohepatitis (NASH) cases are detected without an elevation in liver enzyme levels. To make a distinction between NASH and simple fatty liver the approach for all non-alcoholic fatty liver disease (NAFLD) patients should be assessed again regarding the utility and reliability of noninvasive biochemical and imaging modalities as opposed to liver biopsy which still remains the gold standard.

### Research frontiers

It was almost impossible formerly to recognize the prognosis of fatty liver, and certain fatty liver patients with elevated liver enzymes may not have NASH. To avoid serious outcomes of NASH such as cirrhosis, hepatocellular carcinoma and liver failure, and to detect these complications early, the accurate and definitive diagnosis of NASH, and protective measures, life style modification and appropriate treatment are essential.

### Innovations and breakthroughs

The authors demonstrated that anthropometric, clinical, laboratory and imaging features of NAFLD patients including certain noninvasive markers may not reflect or always be in agreement with the histological aspects of liver biopsy in NASH. The importance and accuracy of liver histopathology should not be disregarded.

### Applications

After initial evaluation and discrimination of NAFLD patients by anthropometrical, clinical, laboratory and imaging studies, liver biopsy which is the gold standard should be considered and performed when available.

### Terminology

While simple fatty liver is only an accumulation of triglycerides in liver and is accepted to be a benign condition, it is not definitely known which patients will keep their stationary state or which patient and when will progress to steatohepatitis. NASH indicates necroinflammation and fibrosis in liver and may progress to cirrhosis, hepatocellular carcinoma and liver failure.

### Peer review

This article is useful for the purpose of evaluating and establishing principles for the best approach in patients with NAFLD.

to increase with the degree of fat deposition in the pancreas on sonography. In a multivariate logistic regression analysis, HOMA-IR, visceral fat, and ALT level were independently related to fatty pancreas after adjustment for age, body mass index, and lipid profile. The incidence of metabolic syndrome in the fatty pancreas group was significantly higher than in the control group, and the numbers of metabolic syndrome parameters were significantly higher in the fatty pancreas group ( $P < 0.05$ ).

**CONCLUSION:** Sonographic fatty pancreas showed higher insulin resistance, visceral fat area, triglyceride, and ALT levels than normal pancreases. Fatty pancreas also showed a strong correlation with metabolic syndrome.

### Abstract

**AIM:** To investigate the clinical implications of lipid deposition in the pancreas (fatty pancreas).

**METHODS:** The subjects of this study were 293 patients who had undergone abdominal computed tomography (CT) and sonography. Fatty pancreas was diagnosed by sonographic findings and subdivided into mild, moderate, and severe fatty pancreas groups comparing to the retroperitoneal fat echogenicity.

**RESULTS:** Fatty pancreas was associated with higher levels for visceral fat, waist circumference, aspartate aminotransferase (AST), alanine aminotransferase (ALT), total cholesterol, triglyceride, high density lipoprotein, free fatty acid,  $\gamma$ -GTP, insulin, and the homeostasis model assessment of insulin resistance (HOMA-IR) than the control group ( $P < 0.05$ ). HOMA-IR, visceral fat, triglyceride, and ALT also tended

### INTRODUCTION

It has been reported that increases in triglyceride and free fatty acids causes ectopic fat deposition in the liver, heart, muscles, and pancreas. This is called steatosis and is known to be related to obesity and/or insulin resistance<sup>[1]</sup>. In particular, steatosis in the liver (or fatty liver) refers to fat deposition in hepatocytes, and its pathophysiology, diagnostic criteria, clinical implications are already well known. However, few studies have been done on lipid deposition in the pancreas (fatty pancreas) and its clinical implications.

A recent animal study reported that lipid deposition in pancreas islet cells due to a high fat/high glucose diet could damage pancreatic beta cells and make them hyperglycemic<sup>[1]</sup>. However, another study reported that there was no histological evidence of the existence of steatosis in the human pancreas and no reports have clearly demonstrated that the increase of pancreas echogenicity implied steatosis of the pancreas or fat deposition<sup>[2]</sup>. Autopsy studies reported pathologic findings of pancreatic steatosis in interlobular septa rather than in pancreas acinar cells<sup>[3-5]</sup>, and fat deposition related to aging<sup>[6,7]</sup>. According to an animal study, pancreatic steatosis caused anomalies of pancreas islet cells leading to hyperglycemia<sup>[8-10]</sup>. Some authors suggested that pancreas islet cell damage that occurs in pancreatic steatosis is accompanied by hyperlipidemia and this plays an important part in the generation of type 2 diabetes<sup>[11]</sup>. Gullo *et al*<sup>[12]</sup> suggested that hypercholesterolemia causes fat deposition in the pancreas and this change is related to hyperamylasemia. In this study we investigated the clinical implications of fatty pancreas and the correlation between insulin resistance and metabolic syndrome.

## MATERIALS AND METHODS

### Patients

The subjects of this study were adults who visited an obesity clinic and for whom doctors performed physical examinations and took their medical histories. Those who had diabetes, pancreatic disease, thyroid disease, renal disease, liver disease, and who drank alcohol over 40 g daily for male and 20 g daily for female were excluded from the subjects. Among them, 293 people who underwent abdomen sonography and/or fat measurement CT for evaluation of abdominal fat distribution were chosen as the subjects. Daily alcohol intake, past history, and other general characteristics of the subjects were collected through questionnaires.

### Clinical and biochemical parameters

We measured the height and body weight of subjects in light clothing to calculate the Body Mass Index ( $BMI = kg/m^2$ ). For waist circumference, we used a tape measure and measured in the middle part between the lowest rib and the iliac crest of the pelvis, horizontal to the ground with the subject in an upright position. Blood samples were test for liver functions, fasting glucose, HbA1c, insulin, total cholesterol, triglyceride, high density lipoprotein, and low density lipoprotein, after fasting for 12 h.

### Abdomen sonography and diagnostic criteria of fatty pancreas

All subjects received tests with the same sonograph (Envisor HD, Phillips, Bothell USA) using a convex 5-2 MHz transducer by one radiologist to minimize biases by different testers. The increase of echogenicity of the pancreatic body over the kidney echogenicity was

classified as fatty pancreas, and in other cases as non-fatty pancreas. As the pancreas could not be compared with the kidney in the same window, the radiologist compared pancreatic echogenicity with kidney echogenicity using the difference between liver and kidney echogenicity and liver and pancreas echogenicity. Fatty pancreas was subdivided into four stages: control group (non-fatty pancreas), where the pancreas echogenicity was similar to the kidney parenchymal echogenicity; light fatty pancreas, where the pancreas echogenicity was higher than the kidney echogenicity, but very much lower than the retroperitoneal fat echogenicity; severely fatty pancreas, where the pancreas echogenicity was higher than the kidney echogenicity, but a little lower than the retroperitoneal fat echogenicity; and highly fatty pancreas, where the pancreas echogenicity was similar to the retroperitoneal fat echogenicity.

### Fat distribution and computed tomography

Abdomen visceral fat, subcutaneous fat, total fat, and thigh muscle fat areas were measured. A 16-channel multiplex abdominal CT system (General Electric Medical Systems, Milwaukee, USA) was used and measurements were made at the location of the umbilicus and middle part of the thigh. The embedded computer was used for calculations. Hounsfield units (HU) were measured at five different parts of the pancreas (head, neck, body, tail, and uncinate process) and three different parts of the spleen. The differences between the mean values of them were determined. If this difference was -5 or lower, it was classified into the fatty pancreas group and the rest were classified into the non-fatty pancreas group.

### Evaluation of insulin resistance

Insulin concentration was measured using a chemiluminescent immunoassay (Immulite 2000, Diagnostic Products Corp., Los Angeles, CA; CV, < 7%). The measure of insulin resistance was obtained using the HOMA-IR (Homeostasis model assessment-insulin resistance), and the calculation formula shown below:  $HOMA-IR: [Fasting\ blood\ sugar\ (mmol/L) \times Fasting\ insulin\ (\mu U/mL) / 22.5]$ <sup>[13]</sup>.

### Definition of metabolic syndrome

The criteria for metabolic syndrome diagnosis followed the NCEP-Adult Treatment Panel III (ATP III), and the visceral obesity was defined by substituting it with the standard waist circumference in the Asia-Pacific Region. Diagnostic criteria were defined as when three or more items of the following were met: visceral obesity (waist circumference  $\geq 90$  cm for males, or waist circumference  $\geq 80$  cm for females), increased triglyceride ( $\geq 150$  mg/dL), decreased HDL ( $< 40$  mg/dL for males,  $< 50$  mg/dL for females), hypertension ( $\geq 130/85$  mmHg), and fasting glucose ( $\geq 110$  mg/dL).

### Statistical analysis

For statistical analysis, the SPSS for Windows (version

11.0; SPSS, Chicago, Ill) was used. The Student's *t*-test was used for comparison between the two groups according to the existence or non-existence of fatty pancreas; the  $\chi^2$  test for relationship between fatty pancreas and metabolic syndrome; the multiple logistic analysis was used for analysis of independent correlation factors related to fatty pancreas; and the ANOVA test was used to compare the four groups according to the severity of fatty pancreas.

## RESULTS

### Clinical characteristics of fatty pancreas

The mean age of 293 subjects was  $44.9 \pm 9.5$  years. There were 133 males (45.4%) and 160 females (54.6%). Among them, 180 (61.4%) were diagnosed as having fatty pancreas from the abdomen sonography; 93 males (51.7%) and 87 females (48.3%). The subjects were divided into the fatty pancreas group and the non-fatty pancreas group for comparison of clinical characteristics. In the fatty pancreas group to compared non-fatty pancreas group, the mean body mass index ( $26.5 \pm 3.1$  kg/m<sup>2</sup> *vs*  $24.4 \pm 3.2$  kg/m<sup>2</sup>,  $P < 0.001$ ), waist circumference ( $88.9 \pm 8.5$  *vs*  $82.1 \pm 9.3$ ,  $P < 0.001$ ), and visceral fat ( $10767 \pm 4260$  *vs*  $7462 \pm 3244$ ,  $P < 0.001$ ) were statistically higher. The aspartate aminotransferase (AST) ( $30.2 \pm 20.7$  *vs*  $23.8 \pm 11.1$ ,  $P = 0.001$ ), alanine aminotransferase (ALT) ( $40.3 \pm 32.2$  *vs*  $25.0 \pm 23.0$ ,  $P < 0.001$ ), total cholesterol ( $205.2 \pm 35.2$  *vs*  $192.9 \pm 36.4$ ,  $P = 0.005$ ), triglyceride ( $159.8 \pm 92.5$  *vs*  $119.6 \pm 70.3$ ,  $P < 0.001$ ), high density lipoprotein cholesterol ( $47.7 \pm 10.6$  *vs*  $51.9 \pm 10.1$ ,  $P = 0.001$ ),  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -GGT) ( $46.5 \pm 43.0$  *vs*  $29.9 \pm 29.9$ ,  $P < 0.001$ ), fasting insulin concentration ( $6.8 \pm 3.6$  *vs*  $5.4 \pm 2.1$ ,  $P < 0.001$ ), and homeostasis model assessment of insulin resistance (HOMA-IR) ( $3.2 \pm 2.1$  *vs*  $2.3 \pm 1.0$ ,  $P < 0.001$ ), free fatty acid ( $767.9 \pm 324.9$  *vs*  $639.3 \pm 287.6$ ,  $P = 0.001$ ) also showed significant differences between the two groups ( $P < 0.05$ ). However, age, fasting glucose, low-density lipoprotein, and cholesterol concentration did not show any differences (Table 1).

### Factors related to fatty pancreas

To analyze the factors related to fatty pancreas, we conducted a multiple logistic analysis for variables, which were found to have significant relationships with fatty pancreas from the univariate analysis. The multiple logistic analysis was conducted by adding variables in three steps. In the first stage, Model I, age, sex, HOMA-IR, and fasting glucose were used as the independent variables and fatty pancreas as the dependent variable. In Model II, triglyceride and free fatty acid, which were already known to be related to fatty liver, were added to Model I. In Model III, abdominal visceral fat, subcutaneous fat area, and thigh muscle fat area were added to Model II to evaluate the body fat distribution. The multiple logistic analysis found that HOMA-IR had a strong correlation with fatty pancreas, even after correction of age and sex, and this did not change even after correction for triglycerides, cholesterol and free

Table 1 Clinical and laboratory characteristics of study groups

	Non-fatty pancreas (n = 113)	Fatty pancreas (n = 180)	P-value
Age (yr)	44.4 $\pm$ 9.7	45.4 $\pm$ 8.5	NS

$P < 0.05$  by *t*-test; NS: Not significant; BMI: Body mass index; WC: Waist circumference; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; FBS: Fasting blood sugar; TC: Total cholesterol; TG: Triglyceride; HDL: High density lipoprotein cholesterol; LDL: Low density lipoprotein cholesterol;  $\gamma$ -GT: Gamma glutamyl transpeptidase; FFA: Free fatty acid.

Table 2 Multivariate logistic regression analysis for the fatty pancreas

Model		Odds ratio (95% CI)	P-value
Model 1	Age (yr)	1.025 (0.999-1.051)	0.059
	Sex (male/female)	0.397 (1.474-4.311)	0.001
	Fasting glucose (mg/dL)	0.998 (0.987-1.010)	0.747
	HOMA-IR	2.319 (1.431-3.757)	0.001
Model 2	Model 1		
	(HOMA-IR)	1.761 (1.041-2.978)	0.035
	+		
	TC (mg/dL)	1.005 (0.998-1.013)	0.184
	TG (mg/dL)	1.004 (1.000-1.008)	0.060
Model 3	FFA (mg/dL)	1.000 (0.999-1.001)	0.409
	Model 2		
	(HOMA-IR)	0.990 (0.533-1.839)	0.973
	+		
	BMI (kg/m <sup>2</sup> )	1.137 (0.965-1.339)	0.125
	Visceral fat	1.000 (1.000-1.000)	0.006
	Subcutaneous fat	1.000 (1.000-1.000)	0.932
	Thigh fat	1.000 (1.000-1.000)	0.214

Model 1: HOMA-IR and fasting glucose were adjusted for age, sex; Model 2: In addition to Model I, HOMA-IR and fasting glucose were adjusted for lipid profiles (TC, TG, FFA); Model 3: In addition to Model II, HOMA-IR and fasting glucose were adjusted for BMI and fat distribution factors (abdominal visceral fat area, abdominal subcutaneous fat area, thigh fat area).  $P < 0.05$  was considered to be significant throughout the analysis.

fatty acid. However, after correction with the visceral fat area, the visceral fat showed the strongest correlation with fatty pancreas; but, HOMA-IR did not show a significant correlation (Table 2).

### Relationship between fatty pancreas and metabolic syndrome

An analysis of 104 subjects who showed metabolic syndrome based on ATP III criteria found fatty pancreas in the sonography of 80 (76.9%) patients, which was

**Figure 1** Four echogenicity grades of fatty pancreas. A and B: Non-fatty pancreas, pancreatic echogenicity is equal to renal cortical echogenicity; C: Mild fatty pancreas, pancreatic echogenicity is definitely lower than retroperitoneal fat; D: Moderate fatty pancreas, pancreatic echogenicity is slightly lower than retroperitoneal fat; E: Severe fatty pancreas, pancreatic echogenicity is equal to retroperitoneal fat.

**Table 3** Prevalence of metabolic syndrome and metabolic components in the fatty pancreas

	Non-fatty pancreas	Fatty pancreas	<sup>1</sup> P-value
Metabolic syndrome	24 (23.1%)	80 (76.9%)	< 0.001
Number <sup>2</sup>	1.4 ± 1.2	2.3 ± 1.4	< 0.001

<sup>1</sup>P < 0.05 by chi-square ( $\chi^2$ ) test; <sup>2</sup>Number: Number of metabolic components.

a significantly higher proportion of the fatty pancreas group ( $P < 0.001$ ). Furthermore, the number of metabolic syndrome parameters (waist circumference, HDL, triglyceride, fasting glucose, blood pressure) in the fatty pancreas group ( $2.3 \pm 1.4$ ) was statistically significantly higher than that of the non-fatty pancreas group ( $1.4 \pm 1.2$ ) ( $P < 0.001$ ) (Table 3).

#### Comparison of characteristics according to fatty pancreas by sonography

Among the 180 subjects who showed fatty pancreas, 90 patients were found to have mild fatty pancreas, 68 moderate fatty pancreas, and 22 severe fatty pancreas. The four groups, including the control group of non-fatty pancreas, were compared. We analyzed the correlation between HOMA-IR, visceral fat, triglyceride, and ALT, which were found to be related to fatty pancreas by multivariate multiple logistic analysis and the degree of fatty pancreas. HOMA-IR, visceral fat, triglyceride, and ALT tended to increase with the degree of fat deposition in the pancreas on sonography (Figure 1; Table 4).

#### Comparison of fatty pancreas by sonography and abdominal CT

To determine correlations between metabolic parameters and fatty pancreas appearing on CT finding pancreas

**Table 4** Univariate correlation between ultrasonographic severity of fatty pancreas and several metabolic parameters

Ultrasonographic severity of fatty pancreas ( $\gamma$ )	P-value
HOMA-IR	0.250
Visceral fat	0.396
TG (mg/dL)	0.245
ALT (IU/L)	0.276

$\gamma$ : Correlation coefficient.

and those found by sonography, the difference between the average Hounsfield Units (HU) from mean pancreas HU to mean spleen HU was calculated. If the difference was -5 or lower the subjects were classified into the fatty pancreas group on CT finding, and others were classified into the non-fatty pancreas group. A comparison of metabolic syndrome factors and body measurement factors found no difference in visceral fat, lipid profile, and liver chemistry between the two groups, based on CT findings.

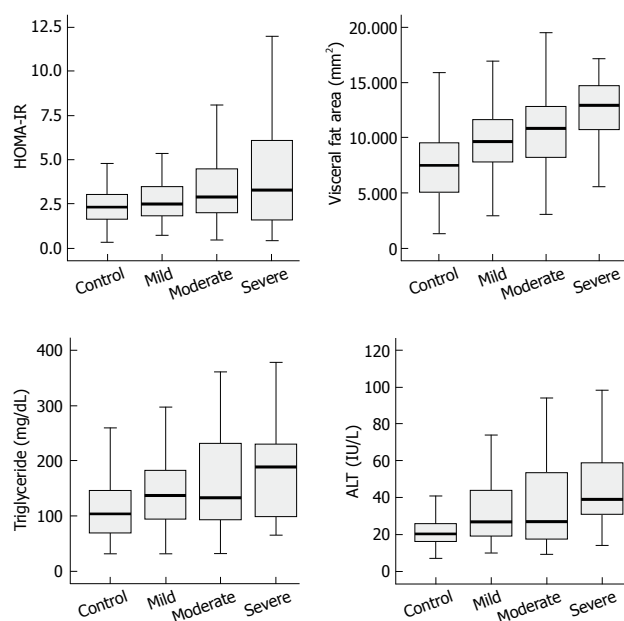

#### Frequency of concurrent fatty liver and fatty pancreas

The total number of fatty pancreas or fatty liver patients was 184. Concurrence of fatty pancreas and fatty liver on sonography was found in 125 subjects (67.9%); fatty pancreas with normal liver was found in 55 (29.9%) and fatty liver without fatty pancreas was only found in four (2.2%) patients. In other words, among 180 fatty liver patients, 125 subjects also had fatty pancreases (96.8%), and the negative predictive value of fatty liver in normal pancreas was 96.4%.

## DISCUSSION

The pathophysiology and diagnostic criteria for steatosis

**Figure 2** Values of HOMA-IR, visceral fat, triglyceride and ALT in four echogenicity grades of fatty pancreas.  $P < 0.05$ , by ANOVA based on Tukey's multiple comparison test.

in liver or fatty liver are already established. Pancreas echogenicity in abdomen sonography is known to be determined by peripancreatic fat deposition rather than pancreatic parenchymal deposition<sup>[6]</sup>, and it was reported that this correlated with age and subcutaneous fat<sup>[14]</sup>. However, there have been few studies on lipid deposition in the pancreas and its clinical implications.

Sonography has been widely used as a tool for evaluation of fat deposition in the pancreas, and the pancreas echogenicity has been traditionally compared with liver echogenicity<sup>[7,14]</sup>. However, this does not seem to be a good method, because the liver is metabolically very active and its echogenicity exhibits high variance<sup>[15,16]</sup>. The concurrence of fatty pancreas and fatty liver on sonography was very high in our data (67.9%). Therefore, liver echogenicity was not a good reference value for diagnosis of fatty pancreas. In contrast, spleen and kidney are known to be metabolically less variable than liver. Therefore, the authors compared the pancreas echogenicity with kidney parenchymal echogenicity, unlike prior studies. This seems to be a reasonable method because the kidney is metabolically more stable than the liver, although it is difficult to compare both the pancreas and the kidney in the same window.

We performed a multiple logistic regression analysis that corrected for age, sex, and serum lipid and found that insulin resistance was independently related to the existence of fatty pancreas in various models. Subjects with fatty pancreas showed strong association with frequency of metabolic syndrome, and fatty pancreas correlated with a number of the parameters of metabolic syndrome, including insulin resistance. However, after adjusting for factors related to body fat distribution, particularly visceral fat, the strong association with insulin resistance disappeared. The reason for this seems to be that visceral fat is a much stronger relational

factor and influenced the relationship between fatty pancreas and insulin resistance. This suggests that fatty pancreas is a risk factor for metabolic syndrome or another manifestation of metabolic syndrome, such as the previously reported correlations of nonalcoholic fatty liver disease with obesity, insulin resistance, and metabolic syndrome<sup>[17,18]</sup>.

Furthermore, this study subdivided fatty pancreas by the degree of pancreas echogenicity, and compared it with HOMA-IR, visceral fat, triglyceride, and ALT. The correlation coefficients were 0.250, 0.396, 0.245, and 0.276, respectively ( $P < 0.001$ ), demonstrating statistically significant correlation with fatty pancreas severity (Figure 2). A comparative analysis with various other factors is needed with a greater number of subjects.

This study found that HOMA-IR, an insulin resistance marker, had an independently significant correlation with fatty pancreas; but, there were no differences in fasting blood sugar between the two groups. The reason for this seems to be that diabetes was excluded from the selection conditions for subjects.

To compare the echogenicity on sonography with objective Hounsfield units on CT, this study conducted mean pancreas and spleen HU, and analyzed the clinical meaning of fatty pancreas using by CT imaging. However, unlike sonography, no statistical difference in clinical and biochemical parameters could be found. It seems that fat deposition in the pancreas shows different patterns from that in the liver. There is a report that fat deposition was markedly increased in pancreas islet cells of people aged over 60 years<sup>[19]</sup>, and an animal study demonstrated lipid deposition in pancreas islet cells induced by a high fat/high sucrose diet<sup>[1]</sup>. On the other hand, another study claimed that fat deposition in the human pancreas does not occur in the parenchymal cells of the pancreas, but is only limited to interstitial stroma<sup>[20]</sup>. Some researchers insist that steatosis in the pancreas or fat deposition in pancreatic cells does not exist in humans<sup>[12]</sup>. However, according to some studies that contained pathological observations on the human pancreas<sup>[3-5]</sup>, fat deposition in the human pancreas appears to occur mainly in interlobular septa, rather than in cells. However, it is difficult to arrive at clear conclusions due to the difficulty of tissue collection from the pancreas, which limits histological proof. The results of the subgroup analysis, which investigated the relationship of degree of fatty pancreas with CT, seems to be due to such characteristics of fat deposition in the pancreas. In other words, because pancreas fat deposition mainly occurs in interlobular septa, the CT images of pancreas show severe non-homogenous patterns with big differences in Hounsfield Units depending on the part measured. Consequently, for CT judgment of pancreas fat deposition it is more appropriate to evaluate the degree of irregular lobulated contour by fat deposition in interlobular septa rather than by Hounsfield Units<sup>[6,20,21]</sup>. Therefore, sonography seems to be the more useful imaging technique for judgment of pancreas fat deposition, and a comparison with MRI, which is known to be excellent in judgment of fat deposition, is needed.

Evaluation of pancreas by abdominal sonography is introduced as a screening tool for diagnosis of pancreatic disease by many authors because of its significant accuracy, cost-effectiveness, and few side effects<sup>[22]</sup>. Therefore, evaluating pancreas echogenicity during abdominal sonography, which is frequently used in health examinations, is expected to play a part as another indicator for screening for metabolic syndrome and insulin resistance.

This study does suffer from a few limitations. Firstly, the fatty pancreas group ( $n = 180$ ) was larger than the non-fatty pancreas group ( $n = 113$ ), because it was a retrospective study of limited subjects of a single medical center. Secondly, the hyperinsulinemic euglycemic clamp technique, which is known to be the most accurate evaluation method of insulin resistance, was not used and this needs to be incorporated into future studies. Thirdly, the degree of fatty pancreas was not well defined, and there might be problems with inter-observer agreement among ultrasonographers when grading different levels of pancreas echogenicity.

An interesting finding of this study is that in a majority of cases (67.9%), fatty pancreas and fatty liver were found concurrently on sonography, and most fatty liver patients (96.9%) also showed fatty pancreas. Although the positive predictive value of fatty liver in fatty pancreas was 69.4%, the negative predictive value of fatty liver in normal pancreas was 96.4%. This implies that fatty pancreas could be used as the initial indicator of 'ectopic fat deposition' and as an early marker of insulin resistance, which is a key element of fatty liver and/or metabolic syndrome. More studies will be necessary on the role of fatty pancreas as an early marker of ectopic fat deposition or insulin resistance.

This is the first study that evaluated pancreatic steatosis using sonography and the clinical factors related to it, including its relations with insulin resistance and metabolic syndrome. Additional studies are needed to investigate the actual progress of fatty pancreas into metabolic diseases.

## COMMENTS

### Background

Pathophysiology, diagnostic criteria, and clinical implications of steatosis in liver or fatty liver are already well known. However, there are few studies on the lipid deposition in pancreas (fatty pancreas) and its clinical implications. The authors evaluated the clinical implications of fatty pancreas.

### Research frontiers

In particular, steatosis in liver or fatty liver refers to fat deposition in hepatocyte, and its pathophysiology, diagnostic criteria, clinical implications are already well known. However, researches on lipid deposition in pancreas (fatty pancreas) and its clinical implications are still insufficient.

### Innovations and breakthroughs

Insulin resistance, visceral fat, triglyceride, and alanine aminotransferase (ALT) tended to increase with the degree of fat deposition in the pancreas on sonography. In a multivariate logistic regression analysis, insulin resistance, visceral fat, and ALT level were independently related to fatty pancreas after adjustment for age, body mass index, and lipid profile. Incidence of metabolic syndrome in the fatty pancreas group was significantly higher than in the control group.

## Applications

A majority of cases (67.9%) of fatty pancreas and fatty liver were found concurrently on sonography. Although positive predictive value of fatty liver in fatty pancreas was 69.4%, the negative predictive value of fatty liver in normal pancreas was 96.4%. This implies the possibility of fatty pancreas as the initial indicator of 'ectopic fat deposition' and as an early marker of insulin resistance, which is a key element of fatty liver and/or metabolic syndrome.

## Terminology

The increase in echogenicity of pancreatic body over the kidney echogenicity was classified as fatty pancreas. Fatty pancreas was subdivided into four stages: control group (non-fatty pancreas), where pancreas echogenicity was similar to kidney parenchymal echogenicity; light fatty pancreas, where the pancreas echogenicity was higher than kidney echogenicity, but very much lower than the retroperitoneal fat echogenicity; severely fatty pancreas, where the pancreas echogenicity was higher than kidney echogenicity, but a little lower than the retroperitoneal fat echogenicity; and highly fatty pancreas, where the pancreas echogenicity was similar to the retroperitoneal fat echogenicity.

## Peer review

This study contains useful information on a difficult topic to study; i.e. fatty pancreas. The authors also speculate on a possible relationship between metabolic syndrome and fatty pancreas and/or fatty liver.

### Abstract

**AIM:** To study the behavior as well as optimal treatment of gallbladder sarcomatoid carcinoma, we reviewed the results of treatment of gallbladder sarcomatoid carcinoma from Chang Gung Memorial Hospital.

**METHODS:** From 1987 to 2005, six patients were diagnosed with gallbladder sarcomatoid carcinoma and treated at our institution. Tumor staging was based on 2002 revised tumor-node-metastasis (TNM) staging for gall bladder cancer from the American Joint Committee on Cancer. The clinical presentation, laboratory data and preoperative workup were reviewed retrospectively.

**RESULTS:** Five patients were female and one was male. The age ranged from 51 to 66 years (median, 58 years). Surgical procedures included three curative resections, two palliative resections and one biopsy. There were two surgical complications (33.3%) and one case of surgical mortality (16.7%). The follow-up time ranged from 30 d to 5 mo. The median survival was 2.5 mo. The prognosis was extremely poor, even after curative resection and postoperative chemotherapy.

**CONCLUSION:** The prognosis of gallbladder sarcomatoid carcinoma was not dependent on TNM stage and was always dismal. The clinicopathological features were different from those of gall bladder cancer.

### INTRODUCTION

Primary gallbladder carcinoma is the fifth most common gastrointestinal tract malignancy and the most common malignancy in the biliary tract<sup>[1,2]</sup>. Despite improvements in imaging modalities and therapeutic facilities, the prognosis of gallbladder carcinoma is still poor. Tumors that possess epithelial and mesenchymal components are so-called sarcomatoid carcinomas. Gallbladder sarcomatoid carcinoma is a rare and atypical subset of gallbladder carcinoma, and only 44 cases have been described in the English-language literature worldwide<sup>[3-18]</sup>. All of these have been case reports and have little information about the clinical behavior and optimal treatment of these tumors. In order to define the behavior and prognosis of gallbladder sarcomatoid carcinoma, we reviewed retrospectively the data of six patients from Chang Gung Memorial Hospital (Taoyuan, Taiwan).

### MATERIALS AND METHODS

From 1987 to 2005, six patients were diagnosed with gallbladder sarcomatoid carcinoma and treated at our institution. The histology was confirmed in all patients by tissues taken from either surgical or biopsy specimens. In total, there were 141 patients diagnosed with gallbladder cancer who received surgical treatment during this period. Among them were 124 with adenocarcinoma (87.9%), eight with adenosquamous carcinoma (5.7%), six with sarcomatoid carcinoma (4.3%), two with squamous cell carcinoma (1.4%), and

**Table 1** Clinical features, operative methods and survival of six patients with gallbladder sarcomatoid carcinoma

	Age/sex	Jaundice	Operative method	Pathological staging	Chemotherapy	Survival
Case 1	51/F	No	Curative resection	T3N1M0 (II b)	Yes	3 mo
Case 2	66/M	Yes	Palliative	T4NxM0 (IV)	No	2 mo
Case 3	60/F	No	Palliative resection	T3N0M0 (II a)	No	2 mo
Case 4	65/F	No	Curative resection	T3N1M0 (II b)	No	20 d <sup>1</sup>
Case 5	56/F	No	Curative resection	T2N1M0 (II b)	Yes	5 mo
Case 6	53/F	Yes	Palliative resection	T3N1M1 (IV)	Yes	5 mo

one with neuroendocrine carcinoma (0.7%). Tumor staging was based on the 2002 revised tumor-node-metastasis (TNM) staging for gallbladder cancer from the American Joint Committee on Cancer (AJCC)<sup>[19]</sup>. The clinical presentation, laboratory data and preoperative workup, including abdominal sonography, computerized tomography (CT), magnetic resonance imaging (MRI) and endoscopic retrograde cholangiopancreatography (ERCP) were reviewed retrospectively. Extensive surgery was defined as cholecystectomy combined with one or more of the following procedures: liver resection of the involved gallbladder fossa, common hepatic artery lymph nodes and hepatic proper artery lymph nodes, and resection of the extrahepatic bile duct, or other organs invaded by tumor directly. Cholecystectomy was defined as cholecystectomy alone without other extensive surgical procedures. Palliative surgery included cholecystectomy, drainage of biliary obstruction or biopsy of tumor only.

## RESULTS

Five patients were female and one was male. The age ranged from 51 to 66 years (median, 58 years). Table 1 displays the clinical features, operative methods and survival of the six patients with gallbladder sarcomatoid carcinoma. Abdominal pain (83%) was the most frequent complaint in these patients, and two (33.3%) were found to have jaundice. No patient had anemia. Except in patients with jaundice, the liver function tests were all normal. Carcinoembryonic antigen (CEA) level was elevated in one patient and carbohydrate antigen 19-9 (CA19-9) level was elevated in two patients. Five patients were diagnosed with gallbladder cancer preoperatively and one was diagnosed with gallstones with chronic cholecystitis. All six patients underwent surgical procedures, including three curative resections and three palliative procedures. Four patients underwent extensive surgery, including three cholecystectomies with partial resection of the gallbladder bed of the liver, and one cholecystectomy with right hemicolectomy for direct tumor invasion of the hepatic flexure of the colon. One patient underwent laparoscopic cholecystectomy only, after preoperative diagnosis with gallstones and chronic cholecystitis. The remaining patient received laparotomy and biopsy of the tumor only as a result of peritoneal seeding during operation. There were two surgical complications (33.3%) including one

postoperative hematoma and one case of postoperative sepsis caused by bile leakage. One case of surgical mortality (16.7%) was encountered after bile leakage. Three patients received fluorouracil-based chemotherapy postoperatively. Pathological staging was one stage II a, three II b, and two stage IV.

The follow-up time ranged from 30 d to 5 mo. Except for the case of surgical mortality, all patients died within 5 mo from tumor recurrence or disease progression. The median survival was 2.5 mo. The prognosis was extremely poor even, after curative resection with or without postoperative chemotherapy.

## DISCUSSION

The most common histological type of gallbladder cancer is adenocarcinoma, and sarcomatoid carcinoma is extremely rare<sup>[2-18]</sup>. Chao *et al.*<sup>[11]</sup> have reported the incidence of sarcomatoid carcinoma from gallbladder cancer as 4.1%. It has been described that sarcomatoid carcinoma arises from totipotent stromal stem cells<sup>[8]</sup> and is composed of epithelial and mesenchymal components that contain undifferentiated spindle or stellate cells<sup>[3,4,6,8,9,11,14-18]</sup>. The cancer was first reported by Landsteiner in 1907, and until now, only 44 cases have been reported in the English-language literature, with an age range of 45-91 years<sup>[2-18]</sup>. However, in our review, patient age was limited to the sixth and seventh decades of life. At our institution, the female-to-male ratio for gallbladder cancer was about 2:1, which was similar to the ratio for gallbladder sarcomatoid carcinoma reported in the literature<sup>[1,2,4]</sup>. In the present study, the female-to-male ratio was 5:1.

Patients with gallbladder sarcomatoid carcinoma usually present with abdominal pain, jaundice, nausea, and poor oral intake, and some may present with a palpable abdominal mass and weight loss. Symptoms may persist from several days to years. Liver function tests are normal, except in patients with obstructive jaundice caused by tumor invasion of the biliary tract<sup>[3-18]</sup>. Most cases have been reported to have normal CEA and CA19-9 levels, and in our series, the CEA level was elevated in one case and CA19-9 level was elevated in two cases. Mass lesions can be identified by abdominal sonography and CT. Sonographic studies have shown an echogenic mass, with or without areas of necrosis occupying the gallbladder lumen, and the wall may be diffuse, localized or irregular. The

**Figure 1** Survival curve of adenocarcinoma and sarcomatoid carcinoma of the gallbladder (excluding stage I, biopsy only and surgical mortality patients).

characteristics of gallbladder sarcomatoid carcinoma are similar to those of adenocarcinoma of the gallbladder, and it is difficult to distinguish between these two tumors. However, if there is speckled calcification within the tumor upon CT, gallbladder carcinoma with calcification, calcified gallstones, porcelain gallbladder and ossifying sarcomatoid carcinoma should be the in differential diagnosis of the tumor<sup>[6,13,16]</sup>. Other associated findings, including gallstones, liver invasion or metastasis, retroperitoneal organ invasion or lymph node enlargement along the hepatoduodenal ligament, can be identified by CT. In our series, five patients (83.3%) were diagnosed preoperatively with gallbladder cancer, and the remaining one was diagnosed with a 1.5-cm gallstone.

T and N stages are important prognostic factors in gallbladder cancer<sup>[20]</sup>. However, there are no prognostic factors determined in gallbladder sarcomatoid carcinoma. Surgery is suggested as the only recognized treatment for gallbladder sarcomatoid carcinoma; either radiotherapy or chemotherapy has no benefit on survival<sup>[8]</sup>. However, even after curative extensive surgery with combined gallbladder/liver bed resection or combined resection of involved organs, many patients die shortly after surgery from recurrence or metastasis. After excluding stage I gallbladder adenocarcinoma, biopsy only and surgical mortality patients, the survival rate for gallbladder sarcomatoid carcinoma and stage II-IV gallbladder adenocarcinoma is shown in Figure 1. One-year survival rate for gallbladder sarcomatoid carcinoma *vs* adenocarcinoma was 0% *vs* 38.2%  $\pm$  5.57% ( $\chi^2$ ,  $P < 0.05$ ). Among the 44 cases reviewed in the literature, the mean survival time was 2 mo and only two patients have survived for  $> 1$  year<sup>[11,12]</sup>. In our series, the median survival time was 2.5 mo and the longest survival was only 5 mo. Apart from the one case of surgical mortality, all patients died from cancer recurrence or disease progression.

In conclusion, better survival of gallbladder cancer was seen in patients with early-stage disease. However, the prognosis of gallbladder sarcomatoid carcinoma was not dependent on TNM stage, and was always dismal. The

clinicopathological features were different from those of gallbladder cancer, and will be necessary to accumulate additional reports of such patients to clarify these issues.

## COMMENTS

### Background

Gallbladder cancer is the most common malignancy in the biliary tract. Sarcomatoid carcinoma of the gallbladder is a rare and atypical subset of gallbladder carcinoma, and only 44 cases have been described in the English-language literature worldwide.

### Research frontiers

Little information about the clinical behavior and optimal treatment of these tumors has been reported. In this study, the authors retrospectively reviewed clinical presentation and treatment results of six patients from Chang Gung Memorial Hospital Taoyuan, Taiwan.

### Innovations and breakthroughs

Only case reports have been described before. This is believed to be the first series of patients diagnosed with gallbladder sarcomatoid carcinoma in a single institution.

### Applications

Tumor staging was based on the 2002 revised tumor-node-metastasis (TNM) staging for gallbladder cancer from the American Joint Committee on Cancer. The clinical presentation, laboratory data and preoperative imaging workup were reviewed. Surgical procedures, postoperative chemotherapy and survival rate after treatment were discussed by the authors.

### Terminology

Sarcomatoid carcinoma arises from totipotent stromal stem cells, and is composed of epithelial and mesenchymal components that contain undifferentiated spindle or stellate cells.

### Peer review

The authors emphasized that the prognosis of gallbladder sarcomatoid carcinoma was not dependent on TNM stage, and was always dismal. The clinicopathological features are different from those of gallbladder adenocarcinoma.

### Abstract

**AIM:** To review percutaneous transhepatic portal venoplasty and stenting (PTPVS) for portal vein anastomotic stenosis (PVAS) after liver transplantation (LT).

**METHODS:** From April 2004 to June 2008, 16 of 18 consecutive patients (11 male and 5 female; aged 17-66 years, mean age 40.4 years) underwent PTPVS for PVAS. PVAS occurred 2-10 mo after LT (mean 5.0 mo). Three asymptomatic patients were detected on routine screening color Doppler ultrasonography (CDUS). Fifteen patients who also had typical clinical signs of portal hypertension (PHT) were identified by contrast-enhanced computerized tomography (CT) or magnetic resonance imaging. All procedures were performed under local anesthesia. If there was a PVAS < 75%, the portal pressure was measured. Portal venoplasty was performed with an undersized balloon and slowly inflated. All stents were deployed immediately following the predilation. Follow-ups, including clinical course, stenosis recurrence and stent patency which were evaluated by CDUS and CT, were performed.

**RESULTS:** Technical success was achieved in all patients. No procedure-related complications occurred. Liver function was normalized gradually and the symptoms of PHT also improved following PTPVS. In 2 of 3 asymptomatic patients, portal venoplasty and stenting were not performed because of pressure gradients < 5 mmHg. They were observed with

periodic CDUS or CT. PTPVS was performed in 16 patients. In 2 patients, the mean pressure gradients decreased from 15.5 mmHg to 3.0 mmHg. In the remaining 14 patients, a pressure gradient was not obtained because of > 75% stenosis and typical clinical signs of PHT. In a 51-year-old woman, who suffered from massive ascites and severe bilateral lower limb edema after secondary LT, PVAS complicated hepatic vein stenosis and inferior vena cava (IVC) stenosis. Before PTPVS, a self-expandable and a balloon-expandable metallic stent were deployed in the IVC and right hepatic vein respectively. The ascites and edema resolved gradually after treatment. The portosystemic collateral vessels resulting from PHT were visualized in 14 patients. Gastroesophageal varices became invisible on poststenting portography in 9 patients. In a 28-year-old man with hepatic encephalopathy, a pre-existing meso-caval shunt was detected due to visualization of IVC on portography. After stenting, contrast agents flowed mainly into IVC *via* the shunt and little flowed into the portal vein. A covered stent was deployed into the superior mesenteric vein to occlude the shunt. Portal hepatopetal flow was restored and the IVC became invisible. The patient recovered from hepatic encephalopathy. A balloon-expandable Palmaz stent was deployed into hepatic artery for anastomotic stenosis before PTPVS. Percutaneous transhepatic internal-external biliary drainage was performed in 2 patients with obstructive jaundice. Portal venous patency was maintained for 3.3-56.6 mo (mean 33.0 mo) and all patients remained asymptomatic.

**CONCLUSION:** With technical refinements, early detection and prompt treatment of complications, and advances in immunotherapy, excellent results can be achieved in LT.

liver transplantation. *World J Gastroenterol* 2009; 15(15): 1880-1885 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1880.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1880>

## INTRODUCTION

Liver transplantation is an important option in the management of end-stage liver disease, severe acute liver failure and some metabolic liver disorders. Postoperative vascular complications have been well documented. The incidence of portal venous complications following liver transplantation is considered to be relatively uncommon in comparison with hepatic arterial complications, yet they can be potentially devastating and lead to graft loss. In the past, portal venous complications were managed with surgical treatments such as thrombectomy, anastomosis revision or retransplantation. However, surgical management of these complications has been limited by technical difficulties due to postsurgical fibrosis and limitations in the length of the involved venous structures<sup>[1]</sup>. Percutaneous interventional procedures have gained worldwide acceptance for alleviating the symptoms of portal hypertension and preserving the graft, due to their minimal invasiveness as well as low complication and high success rates<sup>[2]</sup>. In this study, we retrospectively reviewed 16 cases that received percutaneous transhepatic portal venoplasty and stenting (PTPVS).

## MATERIALS AND METHODS

### Patients

From April 2004 to June 2008, 16 of 18 consecutive patients (11 male and 5 female; aged 17-66 years, mean age 40.4 years) underwent PTPVS for portal vein anastomotic stenosis (PVAS) after liver transplantation (LT). Nine patients were from other hospitals. One patient had a living donor LT; another patient received a second graft. The right branch of the portal vein of the donor was anastomosed to the main portal vein of the recipient by end-to-end anastomosis in the living donor LT; all other reconstructions of the portal vein were performed by standard end-to-end anastomosis of the recipient and donor portal vein. PVAS occurred 2-10 mo after LT (mean 5.0 mo).

Three of 18 patients were asymptomatic and were detected on routine screening color Doppler ultrasonography (CDUS). Seven patients presented with increased liver function tests; two patients complicated with obstructive jaundice. Fifteen patients presented the typical clinical signs of portal hypertension (PHT), which included variceal bleeding ( $n = 7$ ), ascites ( $n = 5$ ), and splenomegaly ( $n = 4$ ) with or without thrombocytopenia. The 15 symptomatic patients also were identified by other noninvasive imaging examinations.

The initial diagnosis of PVAS was based on CDUS in all 18 patients, and 15 of 18 patients also underwent

contrast-enhanced computerized tomography (CT) or magnetic resonance imaging (MRI) to confirm the stenosis. The criteria of CDUS for the detection of PVAS were as follows: > 50% narrowing of the stenotic segment compared with the main portal venous diameter in adults or to a diameter < 2.5 mm in children on gray-scale imaging; the presence of an acceleration of flow at the stenosis or a poststenotic jet flow or scarcity flow of the intrahepatic portal vein on Doppler US<sup>[1,3,4]</sup>. The criterion for PVAS on CT or MRI was > 50% narrowing of the main portal venous diameter with or without poststenotic dilatation<sup>[5]</sup>.

### Procedures

Informed consent was obtained from each patient. Our institutional review committee did not have to give approval for this retrospective study. All procedures were performed *via* a right-sided intercostal approach under local anesthesia. The transplanted liver was punctured with a 22-gauge Chiba needle (Neff Percutaneous Access Set, NPAS-100-RH-NT; COOK Co., USA) under fluoroscopic guidance, and the needle was targeted to the peripheral branch of the portal vein. After confirming puncture of the intrahepatic portal vein with a test dose injection of contrast media, a 0.018-inch nitinol guidewire (NPAS; COOK, USA) was advanced into the main portal vein. The needle was exchanged for a 4.0-French coaxial dilator and 6.0-French sheath (NPAS; COOK, USA) combination included in the introducer system over the guidewire, then the 0.018-inch guidewire was exchanged for a 0.035-inch hydrophilic coating guidewire (Terumo Co., Japan), and then a 7.0-French vascular sheath (Terumo, Japan) was inserted over the guidewire into the portal vein. Initial portography was obtained with a 5.0-French catheter (KMP; COOK, USA or Cobra; Terumo, Japan). If there was an anastomotic stenosis < 75%, the portal pressure was measured at the postanastomotic main portal vein or at the level of the hepatic hilar portal bifurcation. A disposable pressure transducer system (Utah Medical Products, USA) was used for measuring portal pressure. The catheter was guided by the 0.035-inch guidewire through the stenotic segment. Portography including the splenic vein and superior mesenteric vein was obtained (Figure 1A) and the preanastomotic portal pressure was also measured. The criteria for definite diagnosis of PVAS were as follows: stenosis > 50% of the main portal venous diameter<sup>[6]</sup> and a pressure gradient across the stenosis > 5 mmHg<sup>[3,7,8]</sup>.

Portal vein anastomotic venoplasty was performed with a percutaneous transluminal angioplasty balloon dilatation catheter (Powerflex P3; Cordis, Johnson & Johnson Co., USA or Synergy; Boston Scientific Co., USA). The balloon had a smaller diameter than that of the allograft portal vein. Balloon pressure was slowly and gradually elevated using an inflation syringe (Basix Compak; Merit Medical Systems Co., USA) within a pressure limit of 10-atm until the balloon's waist was effaced (Figure 1B). Postvenoplasty portography was repeated to assess the results (Figure 1C). A self-

**Figure 1 Procedure of percutaneous transhepatic portal venoplasty and stenting.** A: Percutaneous transhepatic portography revealed a severe anastomotic stenosis and gastroesophageal varices; B: Portal venoplasty was performed with an undersized balloon and the balloon was slowly inflated; C: Postvenoplasty portography showed a residual stenosis, but gastroesophageal varices became almost invisible; D: Poststenting portography visualized portal venous patency and inflow had recovered completely.

expandable metallic stent (SMART Control; Cordis, USA) was deployed to cover the stenosis with minimal angulation between the portal vein and the stent. The stent had the same or 1-2 mm larger diameter than that of the allograft portal vein. Poststenting portography (Figure 1D) and the pressure gradient were obtained repeatedly to assess the results. If the deployed stent showed an hourglass deformity of  $> 50\%$  of its normal diameter, balloon postdilatation was performed. If a satisfactory result had been achieved, the catheter was removed and the puncture tract was embolized with compressed gelfoam bars through the cut vascular sheath.

No intravenous or systemic heparinization was used. Poststenting anticoagulation was achieved by oral administration of aspirin enteric-coated tablets (Bayaspirin, Bayer S.p.A., Italy) 100 mg/d for at least 6 mo.

Technical success, complications, clinical signs and symptoms, laboratory values including the liver function test and the imaging surveillance results after PTPVS were documented. Technical success of the procedure was defined as  $< 30\%$  residual stenosis being observed on portography with the absence of varices or collateral circulation<sup>[3]</sup>. Follow-up, including clinical course, stenosis recurrence and stent patency which were evaluated by CDUS and CT, were performed.

## RESULTS

Technical success of PTPVS was achieved in all 16 patients. No procedure-related complications occurred. In these patients, liver function was normalized gradually and clinical manifestations related to PHT were improved following PTPVS.

In three asymptomatic patients, a Yashiro type catheter (Terumo, Japan) was introduced into the splenic artery or superior mesenteric artery *via* a right femoral artery approach and indirect portography was obtained to confirm the diagnosis of PVAS. More than 50% stenosis of portal vein anastomosis was further demonstrated using percutaneous transhepatic portography, but portal venoplasty and stenting were not performed in two patients because pressure gradients across the stenosis were  $< 5$  mmHg. They were observed with periodic CDUS or CT. Portal venoplasty (using 8-10 mm diameter and 40 mm length balloons) and stenting (using 10-12 mm diameter and 40-60 mm length stents) was performed in 16 patients. In 2 patients, the mean initial pressure gradient across the stenosis was 15.5 mmHg and then it decreased to 3.0 mmHg after PTPVS. In the remaining 14 patients, a pressure gradient was not obtained because of  $> 75\%$  stenosis and typical clinical signs of PHT.

In a 51-year-old woman, who suffered from massive ascites and severe bilateral lower limb edema after secondary LT, CDUS and CT detected PVAS complicated by hepatic vein stenosis and inferior vena cava stenosis. These venous stenoses were identified by indirect portography, percutaneous transhepatic hepatic venography and inferior vena cavography. First, a self-expandable metallic stent (COOK-Z, GZV-30-75; COOK, USA) was placed in the inferior vena cava *via* a right femoral vein approach. Second, a balloon-expandable metallic stent (IntraStent, SPM16-26-08-B; ev3 Co., USA) was deployed in the right hepatic vein *via* an intercostal transhepatic route. Last, PTPVS was performed. The ascites and edema resolved gradually after treatment.

**Figure 2** A 28-year-old man with a pre-existing meso-caval shunt. A: Initial portography revealed an almost occlusive anastomosis; B: Portography detected a pre-existing meso-caval shunt due to visualization of the inferior vena cava; C: After stenting, the contrast agents flowed mainly into the inferior vena cava via the shunt and little flowed into the portal vein; D: A covered stent was deployed into the superior mesenteric vein to occlude the shunt. Portal hepatopetal flow was restored and the inferior vena cava became invisible.

The portosystemic collateral vessels resulting from PHT were visualized by initial portography in 14 patients. Gastroesophageal varices became invisible on poststenting portography in 9 patients. To avoid variceal bleeding, the residual gastroesophageal flow was obstructed with platinum embolization coils (Tornado, MWCE-35-8/4-5-Tornado; COOK, USA) in 2 remaining patients. No further procedure was performed for anorectal varices and pre-existing splenorenal shunt because the abnormal flow became reduced after stenting.

In a 28-year-old man with hepatic encephalopathy, a pre-existing meso-caval shunt was detected due to visualization of the IVC on initial portography (Figure 2A and B). A meso-caval shunt was performed due to refractory massive ascites and recurrent variceal bleeding before LT. After stenting, it was seen that the contrast agents flowed mainly into the IVC *via* the shunt and little flowed into the portal vein (Figure 2C). To maintain adequate hepatoportal perfusion pressure and to avoid thrombosis in the portal stent or liver failure, a covered stent (Wallgraft Endoprosthesis; Boston Scientific, USA) with a 10 mm diameter and a 50 mm length was deployed into the superior mesenteric vein to occlude the shunt. Once more portography revealed that portal hepatopetal flow was restored and the IVC became invisible (Figure 2D). The patient felt abdominal pain after the procedure, but the symptom subsided a week later. The patient recovered from hepatic encephalopathy.

A balloon-expandable Palmaz stent (Genesis PG1840PMW; Cordis, USA) was deployed into the hepatic artery *via* a right femoral artery route for anastomotic stenosis 2 mo before PTPVS. Percutaneous transhepatic internal-external biliary drainages were performed with a biliary drainage catheter (Ultrathane MAC-LOC, ULT8.5-38-40-P-32S-CLB-RH; COOK, USA) in 2 patients complicated with obstructive jaundice.

The follow-up results of CDUS in all 16 patients and CT scan in 6 patients revealed portal venous patency was maintained for 3.3-56.6 mo (mean 33.0 mo).

These patients remained asymptomatic at the time this manuscript was completed.

## DISCUSSION

### Portal venoplasty and stenting

The rate of portal venous complications after LT, which include primary portal vein anastomotic stenosis or portal vein thrombosis, has been reported to be below 3%<sup>[9-11]</sup>. However, in children with reduced-size LT and living donor LT, the incidence of portal venous stenosis or thrombosis is higher than in adults with deceased donor transplantation, because the donor portal segment is relatively short, and due to interposition grafts and size mismatch of the portal vein diameter between donors and recipients. Factors that increased the risk of portal venous complications were pre-existing vein thrombosis or hypoplasia and large portocaval collaterals<sup>[12]</sup>.

Since the first report of portal venous angioplasty and stent placement through a transhepatic approach after LT by Olcott *et al*<sup>[13]</sup> in 1990, percutaneous transhepatic interventional procedures have gained worldwide acceptance for treatment of these complications following LT, due to their minimal invasiveness as well as low complication and high success rates<sup>[2,14]</sup>. Nonetheless, the reported recurrence rate has been relatively high, i.e. 28.6%-36.8%, following balloon angioplasty alone<sup>[3,6,7]</sup>.

Stents have usually been used to treat recurrent and elastic portal venous stenoses following balloon angioplasty, as this procedure has several potential complications<sup>[3,6,7]</sup>. Nevertheless, Ko *et al*<sup>[4]</sup> preferred to perform primary stent placement rather than balloon angioplasty in the early posttransplantation period (less than 1 mo). In our study, all stents were deployed immediately following balloon angioplasty for two reasons. First, balloon predilation can reduce the incidence of stent displacement (most jump forward) during stent deployment, especially when the stenosis is severe. Second, direct venoplasty and stenting can recover the normal portal flow once and for all, because repeat percutaneous transhepatic portal venoplasty may lead to puncture injuries in the transplanted

liver and increase the incidence of procedure-related complications, such as intrahepatic pseudoaneurysm, arteriovenous fistulas, subcapsular hematoma, bleeding through the puncture tract of the graft, or portal venous thrombosis<sup>[2-4,6,7]</sup>.

The luminal area is proportional to the square of the radius; flow is proportional to the fourth power of the radius. Thus, any small improvement is magnified. Intimal damage can lead to platelet aggregation that can in turn lead to short-term occlusion or long-term restenosis. Therefore, any intimal tears should be avoided at all costs, even to the extent of accepting a less visually appealing angiographic result. Slow and gradual inflation of the balloon during angioplasty results in fewer large intimal tears, flaps, and dissections than the more commonly used method of “blow it up, let it down”<sup>[15]</sup>. In our study, portal venoplasty was performed with an undersized balloon and the balloon was slowly and gradually inflated. Although portal vein thrombosis or stent-edge stenosis may occur, the follow-up results revealed portal venous patency was maintained for a mean 33.0 mo.

Although the etiology of anastomotic stenosis was unclear in our patients, it suggested fibrosis or intimal hyperplasia, which retained an hourglass deformity on the deployed stent.

### Role of imaging examination

It is important to detect vascular complications after liver transplantation, because most stenoses or thromboses are frequently treatable with interventional procedures; but, if left untreated, many vascular complications may progress to graft failure. However, compared with biliary obstructions, early portal venous stenosis is difficult to detect from clinical signs and symptoms alone. Furthermore, sometimes the portal venous anastomotic site cannot be seen with ultrasonography because of intestinal artifacts. In such a case, other noninvasive cross-sectional imaging modalities, CT and MRI, may be valuable.

Ultrasonography is often used to screen for vascular abnormalities, including hepatic arterial stenosis and thrombosis, and the less common stenoses or thromboses of the portal vein, hepatic veins, and inferior vena cava. Precise anatomy of the vascular abnormalities is often better determined on CT or MRI, especially when a focal stenosis occurs in the distal IVC, or in the hepatic artery proximal to the porta hepatis where it is difficult to image directly by ultrasonography. CT and MRI give detailed imaging, while ultrasonography tends to give more physiologic data. CT and MRI can provide a more comprehensive evaluation of the transplanted liver; reveal abnormalities of vascular structure; and depict bile ducts, liver parenchyma, and extrahepatic tissues. Moreover, CT angiography and MR angiography can be used to evaluate the extent and degree of the portosystemic collateral vessels resulting from PHT. Magnetic resonance cholangiopancreatography can be valuable to detect focal biliary abnormalities; however,

percutaneous transhepatic cholangiography remains the gold standard for biliary complications<sup>[16]</sup>.

When a patient is asymptomatic, indirect portography is a recommended option to identify a portal venous stenosis, as this procedure has a relatively lower incidence of procedure-related complications and no puncture injuries to the graft. When there is a requirement for measurement of portal pressure gradients across a stenosis or further interventional procedures, percutaneous transhepatic portography is necessary.

Portal venography with measurement of pressure gradient across the stenosis remains the most reliable examination<sup>[16]</sup>; but, the procedure is an invasive one. Although some reports have considered a transstenotic pressure gradient of > 5 mmHg as abnormal<sup>[7,8,17]</sup>, no standard guidelines for a significant pressure gradient have yet been established. Park *et al*<sup>[3]</sup> believed that the pressure gradient is not directly correlated with the clinical results, and mentioned that portal venoplasty might not be so helpful for patients whose clinical symptoms are possibly related with graft dysfunction and not with the stenosis. The treatment is valuable if patients have symptoms related to portal venous inflow abnormality or PHT even though the pressure gradient is not significant<sup>[4]</sup>. In patients who do not have evidence of PHT, and have normal hepatic function, stenoses may be observed for progression with periodic ultrasound. Moreover, in patients with PHT, the potential contribution of underlying hepatic parenchymal disease (rejection or recurrent hepatitis) must be considered. However, if portal venous stenosis is suspected as being a significant contributor to PHT, therapeutic intervention is necessary.

Negative findings on serial CDUS and the absence of clinical symptoms during the follow-up period might prompt us to regard these patients as not having any hemodynamically significant vascular abnormalities.

In conclusion, percutaneous transhepatic portal venoplasty and stenting for anastomotic stenosis after liver transplantation is a safe and effective procedure for alleviating the signs and symptoms of portal hypertension and preserving the graft. With technical refinements, early detection and prompt treatment of complications, and advances in immunotherapy, excellent results can be achieved in liver transplantation.

## COMMENTS

### Background

Portal vein anastomotic stenosis after liver transplantation is an uncommon vascular complication that may result in graft loss if not promptly treated. In the past, portal venous complications were managed with surgical treatments such as thrombectomy, anastomosis revision or retransplantation. However, surgical management of these complications has been limited by technical difficulties due to postsurgical fibrosis and limitations in the length of the involved venous structures. Percutaneous interventional procedures have gained worldwide acceptance for alleviating the symptoms of portal hypertension and preserving the graft, due to their minimal invasiveness as well as low complication and high success rates.

### Research frontiers

The reported recurrence rate has been relatively high, i.e. 28.6%-36.8%, following balloon angioplasty alone. Stents have usually been used to treat

recurrent and elastic portal venous stenoses following balloon angioplasty, as this procedure has several potential complications. Nevertheless, Ko *et al* preferred to perform primary stent placement rather than balloon angioplasty in the early posttransplantation period (< 1 mo).

### Innovations and breakthroughs

In this study, all stents were deployed immediately following balloon angioplasty for two reasons. First, balloon predilation can reduce the incidence of stent displacement during its deployment. Second, direct venoplasty and stenting can recover normal portal flow once and for all, because repeat percutaneous transhepatic portal venoplasty may lead to puncture injuries to the transplanted liver and increase the incidence of procedure-related complications. Intimal damage can lead to platelet aggregation that can in turn lead to short-term occlusion or long-term restenosis. Slow and gradual inflation of the balloon during angioplasty results in fewer large intimal tears, flaps, and dissections than the more commonly used method of "blow it up, let it down." In this study, portal venoplasty was performed with an undersized balloon and the balloon was slowly and gradually inflated. Although portal vein thrombosis or stent-edge stenosis may occur, the follow-up results revealed portal venous patency was maintained for a mean of 33.0 mo. The treatment is valuable if patients have symptoms related to portal venous inflow abnormality or portal hypertension even though the pressure gradient is not significant.

### Applications

Percutaneous transhepatic portal venoplasty and stenting (PTPVS) could be used for portal anastomotic stenosis after liver transplantation to alleviate the signs and symptoms of portal hypertension and preserve the graft.

### Peer review

PTPVS for anastomotic stenosis after liver transplantation is a safe and effective procedure for alleviating the signs and symptoms of portal hypertension and preserving the graft. The results are encouraging and suggest that the method of undersized balloon and slow and gradual inflation can reduce intimal damage and keep the portal venous patency for a mean of 33.0 mo after stenting.

### Abstract

**AIM:** To investigate the risk factors for gallstone disease in the general population of Chengdu, China.

**METHODS:** This study was conducted at the West China Hospital. Subjects who received a physical examination at this hospital between January and December 2007 were included. Body mass index, blood pressure, fasting plasma glucose, serum lipid and lipoproteins concentrations were analyzed. Gallstone disease was diagnosed by ultrasound or on the basis of a history of cholecystectomy because of gallstone disease. Unconditional logistic regression analysis was used to investigate the risk factors for gallstone disease, and the Chi-square test was used to analyze differences in the incidence of metabolic disorders between subjects with and without gallstone disease.

**RESULTS:** A total of 3573 people were included, 10.7% (384/3573) of whom had gallstone diseases. Multiple logistic regression analysis indicated that the incidence of gallstone disease in subjects aged 40-64 or  $\geq 65$  years was significantly different from that in those aged 18-39 years ( $P < 0.05$ ); the incidence was higher in women than in men ( $P < 0.05$ ). In men,

### INTRODUCTION

Gallstone disease is prevalent worldwide; however, its prevalence varies by region. In Western countries, the prevalence of gallstone disease reportedly ranges from approximately 7.9% in men to 16.6% in women<sup>[1]</sup>. In Asians it ranges from approximately 3% to 15%, is nearly non-existent (less than 5%) in Africans<sup>[2,3]</sup>, and ranges from 4.21% to 11% in China<sup>[4]</sup>. The prevalence of gallstone disease is also high in some ethnic groups, e.g. 73% in Pima Indian women; 29.5% and 64.1% of American Indian men and women, respectively; and 8.9% and 26.7% of Mexican American men and women, respectively<sup>[1,5,6]</sup>. From a medical economic perspective, gallstone disease is the most common reason for hospitalization and creates a high burden in the United States<sup>[7]</sup> and other Western countries<sup>[8]</sup>. Many recent studies have shown that gallstone disease is related to age, sex, and metabolic disorders, such as obesity, dyslipidemia (hypertriglyceridemia), and type 2 diabetes<sup>[9-11]</sup>. The pathogenesis of gallstone disease is suggested to be multifactorial and probably develops from complex interactions between many genetic and

environmental factors<sup>[12,13]</sup>.

Because of an increase in the Westernization of dietary habits and a decrease in physical activity, the prevalence of gallstone disease has increased in the Chinese population in recent years. From a public health standpoint, it is not only important to study the background prevalence of gallstone disease regionally, but to also explore the demographic and biological markers related to the development of gallstone disease. Meanwhile, gallstone disease can result in serious outcomes, such as acute gallstone pancreatitis and gallbladder cancer. If we can predict which factors contribute to the development of gallstone disease, we can prevent it by controlling these factors. The present study was designed to explore the potential risk factors for gallstone disease and to improve the understanding of the overall pathogenesis of this disease.

## MATERIALS AND METHODS

### Data resource and data collection

This study was conducted at the physical examination center of West-China Hospital at Sichuan University. This hospital provides medical care mainly for middle- and high-income individuals from Chengdu City and the surrounding metropolitan areas. Our sample population consisted of consecutive subjects who were referred to the physical examination center by their companies as an annual requirement. Data collection, including age, sex, demographic data, history of systemic diseases and gastrointestinal surgery, and a complete physical examination were done by the doctors at the physical examination center. Ultrasonography of the abdomen was conducted by ultrasonographers using a scanner equipped with a 3.5-MHz transducer (Philips Medical Systems, Bothell, USA). Blood samples were drawn *via* venipuncture from the study participants, after they had fasted overnight, by clinical nurses for laboratory examination. Fasting plasma glucose (FPG), triglyceride, total cholesterol, high-density-lipoprotein cholesterol (HDL-C), and low-density-lipoprotein cholesterol (LDL-C) concentrations were measured using Hitachi Modular analyze system (Roche Modular DPP, Hitachi Ltd, Tokyo, Japan).

### Diagnosis criteria

Gallstone disease was defined as the presence of strong intraluminal echoes that were gravity-dependent or that attenuated ultrasound transmission (acoustic shadowing) during abdominal ultrasonography or as a history of cholecystectomy because of gallstone disease.

Obesity was defined as a body mass index (BMI)  $\geq 25$  kg/m<sup>2</sup> in both men and women according to the redefined World Health Organization criteria for the Asia Pacific Region<sup>[14]</sup>. High blood pressure was defined as a systolic blood pressure (SBP)  $\geq 140$  mmHg or a diastolic blood pressure (DBP)  $\geq 90$  mmHg or a history of hypertension. Subjects with an FPG  $\geq 1260$  mg/L and/or a history of diabetes were considered to have diabetes mellitus (DM). Hypertriglyceridemia was defined as a

$\geq 1550$ mg/L	24/144	16.7	1.71	1.09-2.68

triglyceride concentration  $\geq 1500$  mg/L. Low HDL-C was defined as an HDL-C level < 350 mg/L in men or < 390 mg/L in women. Hypercholesterolemia was defined as a total cholesterol level  $\geq 2200$  mg/L. High LDL-C was defined as an LDL-C level  $\geq 1550$  mg/L.

### Statistical analysis

Categorical data are presented as the number of cases and percentages. Statistical analysis was performed using SPSS software (SPSS Inc., Chicago, IL). Odds ratios (ORs) were calculated with the variables coded in a multivariate form. Pearson's Chi-square or Fisher's exact tests were used for categorical variables. Multiple logistic regression analysis was performed to investigate the independent factors associated with gallstone disease. In all cases, tests of significance were 2-tailed,  $P < 0.05$  indicated statistical significance.

## RESULTS

A total of 3573 subjects undergoing an annual health examination from January to December 2007 were included: 1825 men and 1748 women. The prevalence of gallstone disease among the study subjects was 10.7% (384/3573): 9.9% in men and 11.6% in women. The results of univariate analysis of individual factors and their association with gallstone disease among the 3573 subjects are shown in Table 1. The factors significantly

**Table 2** Multivariate logistic regression analysis for gallstone disease

Variables	OR	95% CI	P
Female sex	1.70	1.35-2.15	< 0.001
Age (yr)			
40 to 64	2.44	1.88-3.17	< 0.001
≥ 65	5.83	4.02-8.44	< 0.001
FBG ≥ 1260 mg/L	2.12	1.31-3.43	0.002
Triglycerides ≥ 1500 mg/L	1.67	1.31-2.13	< 0.001

The dependent variable was the presence or absence of gallstone disease. The covariates included sex, age of 40-64 and ≥ 65 years, BMI ≥ 25.0 kg/m<sup>2</sup>, high blood pressure (SBP ≥ 40 mmHg or DBP ≥ 90 mmHg or a history of hypertension), an FPG level between 1100 and 1260 mg/L and ≥ 1260 mg/L, a triglyceride level ≥ 1500 mg/L, an HDL level ≥ 350 mg/L in men or ≥ 390 mg/L in women, a total cholesterol level ≥ 2200 mg/L, and an LDL level ≥ 1550 mg/L.

associated with gallstone disease were an age of 40-64 years and an age ≥ 65 years, a BMI ≥ 25.0 kg/m<sup>2</sup>, high blood pressure, an FPG level between 1100 and 1260 mg/L, an FPG level ≥ 1260 mg/L, a triglyceride level ≥ 1500 mg/L, a total cholesterol level ≥ 2200 mg/L, and an LDL level ≥ 1550 mg/L ( $P < 0.05$ ). In contrast, a low HDL-C level was inversely associated with gallstone disease ( $P < 0.05$ ). As shown in Table 1, the prevalence of gallstone disease for each metabolic disorder was 14.1% for obesity, 18.0% for hypertension, 30.2% for DM, 15.8% for hypertriglyceridemia, and 10.4% for a low HDL-C level.

In order to identify the risk factors, we further performed a multivariate logistic regression analysis (backward stepping); the results are shown in Table 2. Women aged 40-64 years and ≥ 65 years, with an FPG level ≥ 1260 mg/L, and a triglyceride level ≥ 1500 mg/L were positively correlated with gallstone disease.

The incidence of metabolic disorders in the groups with and without gallstone disease is shown in Table 3. Obesity, hypertension, DM, hypertriglyceridemia, a low HDL-C level, and hypercholesterolemia were found in 26.8%, 29.9%, 7.6%, 46.4%, 6.8%, and 10.7% of subjects with gallstone disease, respectively. In the group without gallstone disease, the incidences of obesity, hypertension, DM, hypertriglyceridemia, a low HDL-C level, and hypercholesterolemia were 19.7%, 16.5%, 2.1%, 29.8%, 3.4%, and 6.6%, respectively. The incidences of all metabolic disorders were higher in the group with gallstone disease than in the group without gallstone disease ( $P < 0.01$ ).

The results of univariate analysis of metabolic factors and their association with gallstone disease in different sexes are shown in Table 4. In men, the factors significantly associated with gallstone disease were high blood pressure, an FPG level between 1100 and 1260 mg/L, an FPG level ≥ 1260 mg/L, and a triglyceride level ≥ 1500 mg/L ( $P < 0.05$ ). In women, the factors significantly associated with gallstone disease were a BMI ≥ 25.0 kg/m<sup>2</sup>, high blood pressure, an FPG level between 1100 and 1260 mg/L, an FPG level ≥ 1260 mg/L, a triglyceride level ≥ 1500 mg/L, a total

cholesterol level ≥ 2200 mg/L, and an LDL-C level ≥ 1550 mg/L ( $P < 0.05$ ). A low HDL-C level was inversely associated with gallstone disease only in women ( $P < 0.05$ ).

To control the covariates simultaneously, multivariate logistic regression analysis (backward stepping) was performed (Table 5). The analysis revealed that an FPG level ≥ 1260 mg/L was a significant independent predictor of gallstone disease in men ( $P = 0.005$ ) and a BMI ≥ 25.0 kg/m<sup>2</sup> and a triglyceride level ≥ 1500 mg/L were predictors of gallstone disease in women ( $P < 0.05$ ).

## DISCUSSION

One of the important benefits of early screening for gallstone disease is that ultrasonography can detect asymptomatic cases, which results in early treatment and the prevention of serious outcomes such as acute gallstone pancreatitis and gallbladder cancer<sup>[15]</sup>. However, few reports on the prevalence and possible etiology of gallstone disease have been published in China. In the present study, gallstone disease appeared to be common in the test population, i.e. an estimated 10.7% of the test population in Chengdu, China, had gallstone disease. The reported prevalence of gallstone disease is approximately 3.6% in Japan and 4.3%-5.0% in Taiwan<sup>[16-18]</sup>. The apparently higher prevalence rate in our study may have been due to the Westernized lifestyle of our patients, who were of middle-to-high income class. Another possible reason for such differences has been related to the fact that this was a hospital-based study which was unlikely the population study that could represent the general population.

The present study, in accordance with reports from Western countries and other regions of Asia, showed that an older age is a significant risk factor for gallstone disease<sup>[16,18,19]</sup>. In contrast, gallstone disease is virtually absent in children and adolescents aged 8-19 years<sup>[20]</sup>. Long-term exposure to many risk factors, as is true for the elderly, may increase the risk of gallstone disease. At the same time, sedentary activity, which is greater in the elderly than in younger populations, may also increase the risk of gallstone disease<sup>[21,22]</sup>. Furthermore, gallstone disease is also an acquired disease influenced by chronic environmental factors plus an aging effect<sup>[23]</sup>.

In concordance with the findings of previous studies, female sex was also a major risk factor for gallstone disease in the present study. The commonly perceived opinion that women are at greater risk of developing gallstone disease than men may largely be due to extraneous risk factors, such as pregnancy and sex hormones. The number of pregnancies is the main one related to the high rates of gallstone disease in women. Sex hormones are most likely to be responsible for the increased risk. Estrogen increases biliary cholesterol secretion causing cholesterol super saturation of bile. Thus, hormone replacement therapy in postmenopausal women has been described to be associated with an increased risk for gallstone disease<sup>[24,25]</sup>. Some studies have also shown a relation between oral contraceptive use and a high prevalence of gallstone disease<sup>[26,27]</sup>.

**Table 3** Prevalence of metabolic disorders in the subjects with and without gallstone disease *n* (%)

Metabolic disorders	Gallstone disease	No gallstone disease	$\chi^2$	<i>P</i>
Obesity	103/384 (26.8)	629/3189 (19.7)	10.603	0.001
Hypertension	115/384 (29.9)	525/3189 (16.5)	42.387	< 0.001
Diabetes mellitus	29/384 (7.6)	67/3189 (2.1)	40.550	< 0.001
Hypertriglyceridemia	178/384 (46.4)	950/3189 (29.8)	43.529	< 0.001
Low HDL-C	26/384 (6.8)	107/3189 (3.4)	11.157	0.001
Hypercholesterolemia	41/384 (10.7)	209/3189 (6.6)	8.954	0.003

**Table 5** Multivariate logistic regression analysis for gallstone disease in gender

Variables	Men		Women	
	OR	95% CI	OR	95% CI
BMI ≥ 25.0 kg/m <sup>2</sup>	-		1.59	1.01-2.50 ( <i>P</i> = 0.046)
FBG ≥ 1260 mg/L	2.30	1.28-4.12 ( <i>P</i> = 0.005)	-	
Triglyceride ≥ 1500 mg/L	1.37	0.99-1.90 ( <i>P</i> = 0.057)	2.17	1.54-3.07 ( <i>P</i> < 0.001)

The dependent variable was the presence or absence of gallstone disease. The covariates included a BMI ≥ 25.0 kg/m<sup>2</sup>, high blood pressure (SBP ≥ 140 mmHg or DBP ≥ 90 mmHg or a history of hypertension), an FPG level between 1100 and 1260 mg/L and ≥ 1260 mg/L, a triglyceride level ≥ 1500 mg/L, a low HDL level (men: ≥ 350 mg/L; women: ≥ 390 mg/L), and a total cholesterol level ≥ 2200 mg/L.

Previous population studies have reported inconsistent associations of DM with gallstone disease. A study in Rome showed that DM was associated with an increased risk of gallstone disease in men and women separately<sup>[28]</sup>. A study of Hispanic Americans found a positive association between DM and self-reported gallstone disease in women, but not in men<sup>[26]</sup>. A study in Italy failed to find any relation between DM and gallstone disease in men and women combined<sup>[29]</sup>. The present analyses showed a positive association between DM

and gallstone disease in men, but not in women. The mechanism underlying the relation of DM with gallstone disease may be fasting hyperinsulinemia, which can overly activate the rate-limiting enzyme for cholesterol synthesis<sup>[30]</sup> and finally leads to cholesterol saturation in the bile. Reduced motility of the gallbladder in persons with diabetes is another possible explanation<sup>[31,32]</sup>.

In our study, obesity only showed a positive association with gallstone disease in women. Previous studies have found disparate findings for BMI or relative weight in men with gallstone disease<sup>[29,33,34]</sup>. However, three population screening surveys using ultrasonography failed to find a positive association between BMI and gallstone disease in men in Italy, Denmark, and the United States<sup>[26,35,36]</sup>, whereas all three showed a positive association in women. The discrepant findings for BMI in men with gallstone disease have not been fully explained. A possible reason for these findings may be that BMI is not a suitable standard of obesity in men. Waist-to-hip ratio may be a better measure of obesity. The mechanism responsible for the increased risk of gallstone disease in obese persons may be the increase in bile saturation that results from an increase in the biliary secretion of cholesterol, which likely depends on the higher synthesis rate of cholesterol in obese persons<sup>[23]</sup>.

The present study showed that hypertriglyceridemia was a risk factor for gallstone disease only in women.

However, high total cholesterol, low HDL-C, and high LDL-C levels were negatively associated with the risk of gallstone disease in both men and women. The present finding is different from that of previous studies, which noted a positive relation between hypertriglyceridemia and gallstone disease<sup>[36]</sup>. However, a cross-sectional study in Denmark failed to find a significant association between gallstone disease and plasma lipid levels (including triglyceride, total cholesterol, HDL-C, and LDL-C)<sup>[37]</sup>. Further studies are needed to clarify whether elevated levels of plasma lipids are independent risk factors for gallstone disease.

A major limitation of the present study was the potential self-selection bias due to the hospital-based study design, which resulted in a sample that was not representative of the general population in western China. However, we believe that our findings are useful as background data for future studies of the epidemiology of gallstone disease in China. Second, our measurements were inadequate. Some factors that might play an important role in gallstone disease development, such as oral contraceptive use and waist-to-hip ratio, were not collected in detail. Third, measurement error and different pathogenicities may have occurred, because the measurements were only made at one time point. Therefore, future studies need to determine whether these factors affect the results of our study.

In conclusion, older age, and female sex are associated with the prevalence of gallstone disease in both men and women. Obesity and hypertriglyceridemia were positively associated with gallstone disease in women, but not in men, whereas DM (FPG  $\geq$  1260 mg/L) was positively associated with gallstone disease only in men.

## COMMENTS

### Background

Gallstone disease is one of the most prevalent gastrointestinal diseases with a substantial burden to health care systems. Because the pathogenesis of gallstone disease is still not well defined and strategies for prevention and efficient non-surgical therapies are missing, further studies are required. Many researchers have shown that gallstone disease is related to age, sex, and metabolic disorders, such as obesity, dyslipidemia (hypertriglyceridemia), and type 2 diabetes. However, the findings concerning metabolic disorders and gallstone disease are disparate in different regions and ethnicity.

### Research frontiers

There are a cluster of metabolic syndromes which includes obesity, glucose intolerance, increased low-density-lipoprotein cholesterol, triacylglycerol, diminished high-density-lipoprotein cholesterol and hypertension. The number of gallstone patients is increasing with a high prevalence of metabolic syndrome.

### Innovations and breakthroughs

This study confirmed that age and sex are positive risk factors for gallstone disease; but, the association between metabolic disorders and gallstone disease is different for men and women. Furthermore, the study complemented the background prevalence of gallstone disease in Chengdu, China.

### Applications

The results of this paper can guide clinicians to target high-risk groups for related inspection and early treatment. Furthermore, preventive strategies can be identified and planned according to these results.

### Terminology

Gallstone disease, formally known as cholelithiasis, occurs when gallstones formed in the bile duct, which are abnormal masses of a solid mixture of cholesterol crystals, mucin, and calcium bilirubinate proteins. It is asymptomatic

in most patients. Sometimes it can cause dyspepsia and other gastrointestinal symptoms or biliary colic or Mirizzi syndrome.

### Peer review

This paper provides information about the incidence and risk factors of gallstone disease in China. The results of this study can give information for further research to explore the pathogenesis of gallstone disease and the role of metabolic syndrome in the process of gallstone formation.

### Abstract

**AIM:** To evaluate hepatic recurrence and prognostic factors for survival in patients with surgically resected hilar cholangiocarcinoma in a single institution over the last 13 years.

**METHODS:** From 1994 to 2007, all patients with hilar cholangiocarcinoma referred to a surgical clinic were evaluated. Demographic data, tumor characteristics, and outcome were analyzed retrospectively. Outcome was compared in patients who underwent additional liver resection with resection of the tumor.

**RESULTS:** Of the 69 patients submitted to laparotomy for tumor resection, curative resection ( $R_0$  resection) was performed in 40 patients, and palliative resection in 29. Thirty-one patients had only duct resection, and 38 patients had combined duct resection with liver resection including 34 total or part caudate lobes. Curative rates with the combined hepatectomy were significantly improved compared with those without additional hepatectomy (27/38 vs 13/31;  $\chi^2 = 5.94$ ,  $P < 0.05$ ). Concomitant liver resection was associated with a decreased incidence of initial recurrence in liver one year after surgery (11/38 vs 23/31;  $\chi^2 = 13.98$ ,  $P < 0.01$ ). The 3-year survival rate after  $R_0$  resection was 30.7% and was 10.5% for palliative resection.  $R_0$  resection improved the 3-year survival rate (30.7% vs 10.5%;  $\chi^2 = 12.47$ ,  $P < 0.01$ ).

### INTRODUCTION

The surgical treatment of hilar cholangiocarcinoma has changed completely in recent decades, before 1980 the majority of patients were not resected, and in a few cases local excision of the tumor was performed with low radicality and poor long-term outcome. Since 1980, indications for resection have progressively improved and liver resection has been associated with bile duct resection in order to increase radicality and achieve better survival results<sup>[1-5]</sup>. In contrast to reports from 2 or 3 decades ago, today most patients with hilar cholangiocarcinoma are diagnosed pre-mortem. The most important factor affecting prognosis is resectability of the tumor. Patients who undergo resection with curative intent have 3-year survival rates as high as 50% and 5-year survival rates between 10% and 44%. Significant determinants of improved prognosis in patients undergoing curative resection include well-differentiated tumors, absence of lymph node metastases, absence of direct tumor extension into the liver, papillary histology, serum bilirubin at presentation of less than 9 mg/dL, and a near-normal or normal performance status. Palliative resection, surgical bypass procedures, and various types of intubation and drainage procedures are associated with 3-year survival rates from 0% to 4%<sup>[6-8]</sup>.

The prognosis of patients with hilar cholangiocarcinoma is poor, and the survival rate reported so far describes a very limited life expectancy, < 3 mo if no treatment is offered. Although radical hilar tumor is a formidable challenge for surgeons, endoscopic transpapillary and/or percutaneous transhepatic biliary drainage offers the best survival<sup>[9-11]</sup>.

Local resection seems to have a very narrow role because of its poor results compared with those of hepatectomy associated with bile duct resection. We have tried to address the above-mentioned issues in this systematic retrospective analysis of the literature.

## MATERIALS AND METHODS

### Data selection

Long-term follow-up of patients with hilar cholangiocarcinoma undergoing surgical resection was performed by retrospective analysis. The study included 69 unselected consecutive patients whose tumor resection was attainable (46 males and 23 females with a mean age of 58 years) during treatment for hilar cholangiocarcinoma from 1994 to 2007 in the Department of General Surgery, at First Affiliated Hospital, Fujian Medical University. Data acquisition was based on hospital records. Furthermore, follow-up data were obtained by telephone contact with relatives of the patients. In order to evaluate the life expectancy of patients with hilar cholangiocarcinoma, follow-up analysis was performed from the time the patient received his or her first treatment until death. Negative margins of bile duct at final pathologic reports had R<sub>0</sub> resection, otherwise positive margins had palliative resection.

### Bismuth classification and treatment strategies

The biliary stricture location was classified in relation to the confluence of hepatic ducts as described by Bismuth-Corlette. Bismuth stage was assessed by endoscopic retrograde cholangiography, endoscopic retrograde cholangioscopy, percutaneous transhepatic cholangiography and/or percutaneous transhepatic cholangioscopy. 3D images provided accurate information on the relationship between hilar cholangiocarcinoma and adjacent vessels. This technique is a powerful new tool for improving the proportion of potentially curative resections<sup>[12]</sup>. In addition, selected patients underwent computed tomography (CT-scan), magnetic resonance imaging (MRI), or magnetic resonance cholangiopancreatography (MRCP). The final diagnosis was made by surgical specimens in addition to resection of the extrahepatic bile ducts with complete porta hepatis and lymphadenectomy. An en bloc resection of the right or left hepatic lobe and caudate lobe was performed in many patients. Biliary-enteric construction was completed with a single hepaticojejunostomy to the bile duct using a Roux-en-Y limb.

### Statistical analysis

All data were analyzed with SPSS 15.0 statistical package.

**Table 1** Pathologic characteristics and serum bilirubin level in patients

Number of patients	Lymph node metastases	Extension in liver parenchyma	Invasion of nervous tissue	Serum bilirubin (μmol/L)
Curative resection	11	17	20	267 ± 158
Palliative resection	8	13	19	280 ± 161

There were no significant differences between the data of the two groups (Curative resection *vs* palliative resection,  $P > 0.05$ ).

Cumulative overall survival rate was calculated by the Kaplan-Meier method using the log rank test. Intergroup comparisons of hepatic recurrence rate and survival rate were analyzed using the  $\chi^2$  test. Significance was accepted with 95% confidence.

## RESULTS

### Characteristics of patients

A total of 69 consecutive patients underwent surgical resection for malignant hilar bile duct tumors during 1994-2007. The characteristics of the patients entered into this study included a mean age of  $58 \pm 10.5$  years. Of the 69 patients at the time of final diagnosis, 10 were diagnosed as Bismuth stage I, 23 were diagnosed as Bismuth stage II, 35 as Bismuth stage III, and 1 as Bismuth stage IV. All the patients presented with jaundice and almost complete obstruction of the common and left or right hepatic duct. Pathologic characteristics and serum bilirubin levels of the patients are shown in Table 1.

### Surgical treatment

We performed 31 local resections including the extrahepatic bile duct, gallbladder, and regional node-bearing tissue. From 2004, a resection usually included the caudate lobe and was performed in 8 cases for Bismuth stage I and II. In patients who did not have prior extensive abdominal surgery, and who demonstrated evidence of direct tumor extension into the right or left lobes of the liver Bismuth stage III, surgery was performed in addition to liver resection in 22 patients, which encompassed an en bloc extended left or right hepatectomy including 15 caudate lobes. In all, 40 patients with negative margins of the bile duct at final pathologic reports had radical resection with complete tumor removal. The other 29 patients had palliative resection. Radical resection rates combined with hepatectomy significantly improved curative rates compared with those without additional hepatectomy ( $27/38$  *vs*  $13/31$ ;  $\chi^2 = 5.94$ ,  $P < 0.05$ ). The surgical treatment of the patients is shown in Table 2.

### Liver tumor recurrence and survival rate of patients

Two patients with additional liver resection died within 30 d of surgery, and only one patient without liver resection died. Three patients had liver recurrence one year after operation in the 12 patients who had resection

Table 2 Surgical treatment of Bismuth stage

Number of patients	Without hepatectomy	Addition of hepatectomy	
		Caudate lobe	Without caudate lobe
Bismuth I	7	2	1
Bismuth II	11	10	2
Bismuth III	13	15	7
Bismuth IV	0	1	0

Radical resection rates combined with hepatectomy significantly improved curative rates compared with those without additional hepatectomy (27/38 vs 13/31;  $\chi^2 = 5.94$ ,  $P < 0.05$ ).

**Figure 1** Kaplan-Meier estimate for survival depending on R<sub>0</sub>/palliative resection. The three-year survival rate after R<sub>0</sub> resection was 30.7% and was 10.5% for palliative resection, R<sub>0</sub> resection improved the 3-year survival rate (30.7% vs 10.5%;  $\chi^2 = 12.47$ ,  $P < 0.01$ ).

including the caudate lobe for Bismuth stage I and II, otherwise, there were 11 liver recurrences within one year of surgery in 18 patients without resection of the liver lobe for Bismuth stage I and II. Concomitant liver resection was associated with a decreased incidence of initial recurrence in the liver one year after surgery (11/38 vs 23/31;  $\chi^2 = 13.98$ ,  $P < 0.01$ ) compared with those without liver resection. R<sub>0</sub> resection improved 3-year survival rates (30.7% vs 10.5%;  $\chi^2 = 12.47$ ,  $P < 0.01$ ). The Kaplan-Meier estimates for survival depending on R<sub>0</sub>/palliative resection are shown in Figure 1.

## DISCUSSION

Cholangiocarcinoma at the liver hilum, or Klatskin tumor, is the most common type of bile duct cancer. It is often unresectable owing to regional extension into the liver, surrounding lymphatics, and, most notably, hilar vascular structures<sup>[13]</sup>. It can occur against the background of primary sclerosing cholangitis with its associated liver disease, and may elude detection until an advanced stage<sup>[14]</sup>. Chemotherapy, as well as radiation or photodynamic therapy, yield negligible response rates, and do not favorably impact either local control or long-term survival. Effective adjuvant agents are still lacking. For unresectable cholangiocarcinoma, chemotherapy-impregnated biliary stents and photodynamic therapy have been used<sup>[15,16]</sup>.

The only effective treatment for hilar cholangio-

carcinoma is major surgery<sup>[17]</sup>. Surgeons have pushed the technical envelope to achieve negative margins. In patients with hilar cholangiocarcinoma, concomitant hepatic resection is associated with improved median disease-specific and disease-free survival, and decreased hepatic recurrence<sup>[18]</sup>. Today, extended biliary-hepatic resections together with vascular resections/reconstructions are being performed. Survival rates, however, have still not exceeded 40%<sup>[19]</sup>. In our research the 3-year survival rates after R<sub>0</sub> resection were 30.7%, considerably more than the 10.5% achieved after palliative resection. After all, it is not uncommon to find skip lesions above and below the primary cancer. Despite negative frozen sections of margins at the time of index resection, surgeons will occasionally be left to deal with positive margins at final pathologic reports. This is an insidious cancer, prone to submucosal spread, and especially when it is well differentiated it can be difficult to realize<sup>[20]</sup>. Frozen section analysis of the proximal bile duct margin is misleading in 9% of patients. Among patients who are determined to have negative duct margins intraoperatively, only 60% will have margins adequately wide enough to be associated with an improvement in disease-specific survival<sup>[21]</sup>. Therefore in our research negative margins of bile duct at final pathologic reports had R<sub>0</sub> resection, otherwise positive margins had palliative resection, and then Bismuth stage II became Bismuth stage III for the final diagnosis. The resection must encompass the bile duct and areas of the liver at risk of involvement by direct tumor extension as well as the lymph nodes draining the region. Because cholangiocarcinoma is known to spread along the wall of the bile ducts and because the caudate lobe is a frequent site of tumor recurrence following extrahepatic duct resection, surgeons perform a resection that includes the caudate lobe. However, from 2004 in our research, a resection including the caudate lobe was carried out in 8 cases for Bismuth stage I and II, because of the small number of patients the results were not enough to show that liver recurrence within one year of surgery was related to resection of the liver lobe for Bismuth stage I and II. Major hepatectomy can improve the outcome of hilar cholangiocarcinoma. Compared with nonoperative treatment or R<sub>0</sub> hepatectomy, R<sub>1</sub> resection in patients with no other risk factors can offer long-term survival<sup>[22]</sup>. If evidence of direct tumor extension into both the right and left lobes of the liver is demonstrated, no further surgery is performed. In contrast, tumor extension into only the right or the left lobe that can be encompassed by an en bloc extended left or right hepatectomy is not a contraindication to proceed with resection. In cases where the hilar cholangiocarcinoma extends directly into the right or left bile duct, we performed an en bloc extended right or left hepatectomy.

Combining extended right or left hepatectomy is recommended when preoperative imaging suggests extension above the hilum to either side. Furthermore, CT liver volume estimates can guide resection strategy, even to include preoperative selective portal vein embolization to induce remnant hypertrophy. Others describe how

radical vascular resections can be attempted to achieve wide tumor clearance. Resection increases survival, but carries the risk of significant morbidity and mortality<sup>[23-26]</sup>. In our research of 69 patients submitted to laparotomy for tumor resection, R<sub>0</sub> resection was performed in 40 patients, and palliative resection in 29. 31 patients had only duct resection, 38 patients had combined duct resection with liver resection including 28 total or part caudate lobes. R<sub>0</sub> resection rates combined with hepatectomy significantly improved the recurrence rate compared with those without additional hepatectomy. Concomitant liver resection was associated with a decreased incidence of initial recurrence in the liver one year after surgery. The 3-year survival rate after R<sub>0</sub> resection was 30.7% and was 10.5% after palliative resection. R<sub>0</sub> resection, thus, improved the 3-year survival rate.

A transhepatic approach may be useful when performing extensive hilar bile duct resection for bile duct stricture of biliary disease at the hepatic hilus, especially in high-risk patients who are unfit for major hepatectomy as well as in those with benign bile duct stricture and low-grade malignancy<sup>[27]</sup>. In highly selected patients with advanced hilar cholangiocellular carcinoma, a high hilar resection is technically safe and oncologically justifiable. In combination with our new technique of sheath-to-enteric anastomosis, patients benefit considerably from the preservation of liver parenchyma with low postoperative morbidity and very short in-hospital stay<sup>[28]</sup>. Excellent survival rates without any in-hospital deaths have been demonstrated following right trisectionectomy with caudate lobectomy. This procedure may be an effective surgical technique which can be executed to achieve low mortality rate and high pathological curability for hilar cholangiocarcinomas, with the exception of Bismuth type III (b)<sup>[29]</sup>.

In patients with hilar cholangiocarcinoma, local resection is not an adequate treatment for hilar cholangiocarcinoma involving the bile duct confluence; associated liver resection should be recommended. In Bismuth-Corlette type I and II hilar cholangiocarcinoma, survival benefits with the association of biliary and liver resection have been reported. Concomitant hepatic resection is associated with improved rates of radical resection, decreased hepatic recurrence, and longer survival. Therefore, hepatectomy especially including the caudate lobe combined with bile duct resection should be considered standard treatment to cure hilar cholangiocarcinoma. The surgical approach to Bismuth type I and II hilar cholangiocarcinomas should be determined according to cholangiographic tumor type. For nodular and infiltrating tumors, right hepatectomy is essential; for papillary tumors, bile duct resection with or without limited hepatectomy is adequate<sup>[30]</sup>.

resection is good and has a high 5-year survival rate. In contrast to reports from 2 or 3 decades ago, today most patients with hilar cholangiocarcinoma are diagnosed preoperatively. The most important factor affecting prognosis is resectability of the tumor; however, the surgical prognosis is poor even when local tumor resection is performed. Local resection seems to have a very narrow role. Thus, finding a surgical approach for the treatment of hilar cholangiocarcinoma is essential.

### Research frontiers

In patients with hilar cholangiocarcinoma, local resection is not an adequate treatment for hilar cholangiocarcinoma involving the bile duct confluence; associated liver resection should be recommended. In Bismuth-Corlette type I and II hilar cholangiocarcinoma, survival benefits with the association of biliary and liver resection have been reported. Concomitant hepatic resection is associated with improved rates of radical resection, and decreased hepatic recurrence. Therefore, the surgical approach to hilar cholangiocarcinomas should be determined according to cholangiographic tumor type.

### Innovations and breakthroughs

Of the 69 patients submitted to laparotomy for tumor resection, curative resection was performed in 40 patients, and palliative resection in 29. Thirty-one patients had only duct resection, and 38 patients had duct resection combined with liver resection including 34 total or part caudate lobes. Curative rates with the combined hepatectomy significantly improved compared with those without additional hepatectomy. Concomitant liver resection was associated with a decreased incidence of initial recurrence in the liver one year after surgery, and curative resection improved 3-year survival rates.

### Applications

The study results suggest that hepatectomy, especially including the caudate lobe combined with bile duct resection should be considered standard treatment to cure hilar cholangiocarcinoma.

### Peer review

Concomitant liver resection was associated with improved curative and survival rates and decreased hepatic recurrence. The content of the paper has merit since this cancer has a poor prognosis and is still a challenge for surgeons and clinicians.

### **Abstract**

We report the case of a 21-year-old man who was noted to have pneumomediastinum during an admission for an acute flare of ulcerative colitis. At that time, he was on maintenance treatment with azathioprine at a dose of 1.25 mg/kg per day, and had not received supplementary steroids for 9 mo. He had never received anti-tumor necrosis factor (TNF) $\alpha$  therapy. Shortly after apparently effective treatment with intravenous steroids and an increased dose of azathioprine, he developed worsening colitic and new respiratory symptoms, and was diagnosed with *Pneumocystis jiroveci* (*carinii*) pneumonia (PCP). Pneumomediastinum is rare in immunocompetent hosts, but is a recognized complication of PCP in human immunodeficiency virus (HIV) patients, although our patient's HIV test was negative. Treatment of PCP with co-trimoxazole resulted in resolution of both respiratory and gastrointestinal symptoms, without the need to increase the steroid dose. There is increasing vigilance for opportunistic infections in patients with inflammatory bowel disease following the advent of anti-TNF $\alpha$  therapy. This case emphasizes the importance of considering the possibility of such infections in all patients with inflammatory bowel disease, irrespective of the immunosuppressants they receive, and highlights the potential of steroid-responsive opportunistic infections to mimic worsening colitic symptoms in patients with ulcerative colitis.

### **INTRODUCTION**

*Pneumocystis jiroveci* (*carinii*) is a unicellular fungus that is found in the respiratory tracts of many mammals, including humans. The organism was first described in 1909 by Chagas<sup>[1]</sup> and later by Delanoë<sup>[2]</sup> who ultimately named the organism. Years later, Jirovec's group isolated the organism from humans<sup>[3]</sup>, and the organism was subsequently renamed after him. *P. jiroveci* (*carinii*) pneumonia (PCP) is the most common opportunistic infection in human immunodeficiency virus (HIV)-infected patients and, by definition, constitutes an acquired immunodeficiency syndrome (AIDS)-defining illness. In our hospital, which serves a population of 450 000, the incidence of PCP is approximately 12 per year. The majority of these are in patients following either solid organ, or bone marrow transplantation. Recently, there has been increased awareness and reporting of PCP and other opportunistic infections in patients with inflammatory bowel disease and other inflammatory conditions. This has been attributed to the increased use of anti-tumor necrosis factor (TNF) $\alpha$  therapy<sup>[4-8]</sup>, but may reflect the increased surveillance for such infections in this group of patients. We report a case that highlights the importance of considering opportunistic infection in any immunosuppressed

patients with inflammatory bowel disease, who present with unusual symptoms and signs, including those of worsening disease activity.

## CASE REPORT

A 21-year-old Caucasian man presented in June 2005 age 18 years with 7 d of bloody diarrhea and abdominal discomfort. He reported a similar, but less severe, self-limiting episode 2 mo earlier. He had never smoked tobacco. On admission he had a temperature of 38°C and a pulse of 90 bpm. Admission laboratory tests included hemoglobin 7.5 g/dL (normal range 13.0-18.0 g/dL), mean corpuscular volume 69.4 fl (normal range 82-98 fl), C-reactive protein (CRP) 188 mg/L (normal range < 3 mg/L), and negative stool cultures. Flexible sigmoidoscopy demonstrated erythematous mucosa with a mucopurulent exudate and confluent ulceration, which continued beyond the extent of the examination. A diagnosis of acute severe ulcerative colitis was made and he was commenced on intravenous and rectal steroids. Histology subsequently confirmed distorted crypt architecture with cryptitis, micro-abscesses and increased inflammatory cells in the lamina propria. He responded well to intensive therapy and by day 3 his stool frequency had fallen to 3/d and CRP to 34 mg/L. He was discharged on day 7 with a reducing course of oral prednisolone and mesalazine (Asacol™ 800 mg *bid*). He was reluctant to use topical therapy. His symptoms relapsed once the prednisolone was reduced below 15 mg/d, and thus azathioprine was introduced in September 2005. He was commenced at 25 mg/d, increasing by 25 mg fortnightly to a maximum dose of 150 mg/d (2 mg/kg). Thiopurine methyl-transferase (TPMT) activity level was 51 nmol 6-MTG/g Hb per hour (normal range 25-55 nmol 6-MTG/g Hb per hour). He had one minor further flare of his disease, but subsequently entered clinical remission using mesalazine 800 mg *bid* and azathioprine 150 mg/d. Twelve months later, a routine blood test demonstrated a low total white blood cell count of  $2.2 \times 10^9/L$  (normal range  $3.8-10.6 \times 10^9/L$ ), with a neutrophil count of  $1.34 \times 10^9/L$  (normal range  $1.8-6.5 \times 10^9/L$ ) and a lymphocyte count of  $0.4 \times 10^9/L$  (normal range  $1.1-3.5 \times 10^9/L$ ). These results were confirmed on a repeat sample. He was advised to reduce azathioprine dose to 100 mg/d, and these cell counts recovered.

Our patient then travelled to Australia to participate in a cricket tour and for the next 3 mo he remained well and his blood monitoring was satisfactory. However, in February 2008, whilst on tour, he had an acute flare of his colitis, which required hospital admission. Admission blood tests demonstrated CRP 121 mg/L, hemoglobin  $9.0 \times 10^9/L$  and total white blood cell count  $4.2 \times 10^9/L$ . He underwent flexible sigmoidoscopy, which showed a large anal fissure and severe colitis, with extensive mucosal loss to the splenic flexure. A chest X-ray on admission demonstrated pneumomediastinum, but no cause was identified following a barium swallow and subsequent computed tomography (CT) scan of

Figure 1 CT scan demonstrating parenchymal abnormalities caused by PCP.

his thorax, abdomen and pelvis. He was treated with intravenous and rectal hydrocortisone and azathioprine was increased to 150 mg/d. His symptoms resolved and he was discharged, returning to the UK on a reducing course of steroids and azathioprine.

On arrival back in the UK, his colitis rapidly relapsed and he was re-admitted to hospital. On admission, he was passing six bloody liquid stools per day. Blood tests demonstrated hemoglobin 9.9 g/dL, total white blood cell count  $2.0 \times 10^9/L$ , neutrophil count  $1.60 \times 10^9/L$ , lymphocyte count  $0.22 \times 10^9/L$  and CRP 61 mg/L. An abdominal X-ray did not show evidence of colonic dilatation. He was recommenced on intravenous hydrocortisone and azathioprine was stopped in view of the leukopenia. After 48 h, his stool frequency and urgency had much improved, his CRP fell to 11 mg/L and total white cell count increased to  $2.8 \times 10^9/L$  (lymphocyte count  $0.39 \times 10^9/L$ , neutrophil count  $2.2 \times 10^9/L$ ). However, on converting to oral steroids on day 3, CRP rose to 146 mg/L and he became febrile. He was noted to have a dry cough, and reported breathlessness on exertion, which on direct questioning he admitted had been present immediately prior to leaving Australia. No abnormal chest signs were elicited, but his oxygen saturation was noted to be 95% at rest (on room air), falling to 90% on exertion. A chest X-ray was normal, but he was clearly at risk of opportunistic infection because of his recent leukopenia and long history of immunosuppression, and was also at risk of thromboembolic disease in view of his recent long-haul flight and active colitis. A CT pulmonary angiogram with full lung views did not show pulmonary emboli, but demonstrated bilateral, small-volume hilar lymphadenopathy (8 mm) and widespread patchy ground glass changes in both lungs, with more confluent consolidation within the basal segments (Figure 1). Bronchoalveolar lavage washings were positive for *P. jirovecii* (*carinii*) on immunofluorescence. An HIV test was negative. The patient was commenced on a 2-wk course of intravenous co-trimoxazole (2.4 g *qds*) and was maintained on a reducing course of oral steroids (prednisolone 40 mg/d) and high dose oral mesalazine (Asacol™ 2.4 g *bid*). His respiratory and gastrointestinal symptoms improved and his inflammatory markers and white cell count normalized within 5 d. He was discharged

at 14 d with a further week of oral co-trimoxazole. Three days later he was re-admitted with a severe blanching rash on his trunk and limbs and worsening diarrhea. A drug reaction to co-trimoxazole was suspected and he was switched to oral clindamycin (600 mg *tds*) and primaquine (30 mg/d), with slow resolution of the rash and improvement in his stool frequency. Blood tests for cytomegalovirus serology and polymerase chain reaction were negative. He was discharged and remains under close follow up. He had no recurrence of his respiratory symptoms and his colitis remains in clinical remission on high dose oral and rectal mesalazine.

## DISCUSSION

We report the case of a 21-year-old Caucasian man, naïve to anti-TNF $\alpha$  therapy, who presented with PCP following treatment with azathioprine and steroids for ulcerative colitis. Azathioprine is a commonly used immunosuppressive agent. It acts by inhibiting purine synthesis by disrupting normal purine incorporation into ribonucleic acids. It is a pro-drug, which is converted in the body to the active metabolites 6-mercaptopurine and 6-thioinosinic acid. Its recognized side effects include hepatitis, pancreatitis and bone marrow suppression. The incidence of these side effects relates in part to the activity of a genetically moderated enzyme involved in the metabolism of thiopurine compounds including 6-mercaptopurine. This enzyme is thiopurine methyltransferase (TPMT). TPMT activity assays are thus used to identify patients with deficient and low activity (approximate 8.5% population), who are at increased risk of bone marrow toxicity from thiopurine drugs, enabling dose adjustments or avoidance. In 2007, in the Royal Devon and Exeter Hospital, 104 patients with inflammatory bowel disease were commenced on azathioprine. In our department, this is the first case of PCP in a patient with inflammatory bowel disease who was naïve of anti-TNF $\alpha$  therapy. In this case, the patient's TPMT was normal (51 nmoL 6-MTG/g Hb per hour). From relatively early in the disease course, he was noted to have steroid-dependent disease, and 9 mo following diagnosis, was commenced on 2 mg/kg azathioprine. This dose was tolerated well initially with no evidence of agranulocytosis, pancreatitis or abnormal liver function on regular blood tests. However, after 1 year of receiving this dose, a routine blood test showed leukopenia, which was confirmed on a repeat sample. The dose was, therefore, reduced to 100 mg/d and the leukopenia resolved. Three months later, he had a further acute flare of his ulcerative colitis whilst in Australia and his azathioprine dose was increased to 150 mg/d (2 mg/kg per day). On returning to the UK, he was subsequently admitted because of symptom recurrence and was noted to be leukopenic, at which point his azathioprine was stopped. In total, this patient received azathioprine for 2 years and 6 mo, with a maximum dose of 2 mg/kg. He became leukopenic on two occasions, the second corresponding with the onset of his respiratory symptoms.

Steroids have been the cornerstone of the treatment

of acute ulcerative colitis since Truelove and Witts first reported their pioneering trial results in 1955<sup>[9]</sup>. Steroid use has, however, been associated with PCP in HIV-negative patients<sup>[10]</sup>. Since being diagnosed with ulcerative colitis, this patient received two courses of oral steroids, which were prolonged (12 mo and 8 mo) because of symptom recurrence on weaning the dose. However, he had not received any steroids for 9 mo prior to his admission in Australia. During this admission, he received 5 d of intravenous steroids and he received a further 2 d on returning to the UK. These were the first courses of intravenous steroids that he had received since the initial course that was used at diagnosis. Interestingly, adjunctive steroid use in the treatment of PCP has been shown to reduce the incidence of death and respiratory failure associated with severe infection<sup>[11,12]</sup>. This patient developed respiratory symptoms immediately prior to his return to the UK and we hypothesize that his initial improvement with high dose intravenous steroids and subsequent deterioration on lower dose oral steroids, was to the result of partial treatment of PCP by steroids. It is also noteworthy that his colitis symptoms and elevated inflammatory markers improved significantly once his PCP was treated with intravenous co-trimoxazole, without any need to increase his steroid dose. We, therefore, conclude that both the symptoms and blood test abnormalities were likely to have been caused by PCP, rather than active colitis *per se*. This case demonstrates the potential of steroid-responsive opportunistic infections to mimic worsening colitis symptoms in patients with ulcerative colitis. It is, therefore, important to consider opportunistic infection in immunosuppressed patients with inflammatory bowel disease, whose inflammatory markers appear disproportionate to the severity of the disease activity.

It is difficult to be sure exactly when this patient contracted PCP. It is noteworthy that pneumomediastinum was recognised on a chest X-ray shortly after he was admitted in Australia, before the introduction of intravenous steroids. Pneumomediastinum is the presence of extra-alveolar air in the mediastinum, which is thought to arise from free air leaking from ruptured alveoli. Historically, the incidence of spontaneous pneumomediastinum has been reported to be 1 in 32896<sup>[13]</sup>. However, in HIV infection, spontaneous pneumomediastinum has been well described in association with PCP<sup>[14-17]</sup>. Indeed, in one series, the incidence was reported to be as high as 9.5% of cases<sup>[17]</sup>. If our patient had contracted PCP prior to his admission in Australia, it is likely to have occurred at a time when he was taking 100 mg/d azathioprine without supplementary steroids.

The advent of anti-TNF $\alpha$  therapy has resulted in improved disease control in many patients with inflammatory bowel disease. Unfortunately, it has also resulted in an increase in the reported number of patients with inflammatory bowel disease who present with opportunistic infections<sup>[4-6]</sup>. This has resulted in increased vigilance for such infections in this group of patients. In the case described, the patient is likely to

have developed PCP either as a result of treatment with 100 mg azathioprine (1.25 mg/kg per day) or following a 5-d course of intravenous steroids and 2 mg/kg azathioprine. The presence of pneumomediastinum, a recognised complication of PCP, before he was exposed to intravenous steroids would appear to make the former possibility more likely. He had not received steroids for 9 mo prior to this admission, and at no stage did he receive rescue therapy. During the 6 mo that preceded this admission, he was maintained on a stable dose of azathioprine (100 mg/d) and was not leukopenic. He never received anti-TNF $\alpha$  therapy. With the trend towards increasing use of early immunomodulation, this degree of immunosuppression would not, we believe, be considered excessive nor particularly likely to cause an otherwise fit 21-year-old man to develop PCP. However, this case highlights the importance of considering such diagnoses in any patients with inflammatory bowel disease who are immunosuppressed, irrespective of which agents they may have received.

### Abstract

Primary non-Hodgkin's lymphoma of the esophagus is a rare disease. A case of primary isolated non-Hodgkin's lymphoma of the esophagus in a 77-year-old man without acquired immunodeficiency syndrome is presented. We describe the clinical features and the imaging findings (barium swallow, endoscopic ultrasonography and CT) of a biopsy proven B-cell lymphoma with diffuse transmural involvement of the esophagus wall, which was discovered incidentally. We also briefly review the literature.

### INTRODUCTION

Although lymphomas are malignant neoplasms which are usually confined to the lymph nodes, one fifth of lymphomas present with extranodal localization<sup>[1]</sup>. The esophagus is an uncommon localization accounting for less than 1% of patients with lymphoma and is usually seen secondary to mediastinal nodes or gastric lymphoma<sup>[2,3]</sup>. Isolated primary lymphoma of the esophagus is exceptionally rare, and when seen, is usually the non-Hodgkin's type<sup>[4]</sup>.

The imaging findings of esophageal lymphoma have shown a diverse spectrum of abnormalities, similar to those of lymphoma elsewhere in the gastrointestinal tract. We present a distinctly rare case of primary diffuse non-Hodgkin's lymphoma of the esophagus with a unique, to our knowledge, endoscopic ultrasonographic appearance, of a mainly hyperechoic mass.

### CASE REPORT

A 77-year old man was admitted because of paroxysmal atrial fibrillation and epigastric pain. His physical examination was normal without clinical evidence of lymph node enlargement or hepatomegaly. Complete blood cell count and routine serum chemistry levels were also normal. A double-contrast barium swallow showed enlargement of the mucosal folds and mild dilatation of the esophageal lumen below the level of the aortic arch (Figure 1); the stomach and duodenum were normal. Chest CT showed extensive thickening of the esophagus wall extending from the middle to the lower portion, without enlargement of mediastinal lymph nodes (Figure 2). CT of the abdomen and pelvis were negative.

Endoscopic ultrasonography (EUS) was performed in order to evaluate the esophageal wall thickening. EUS showed a transmural wall thickening along the middle and lower portion of the esophagus with a heterogeneous, mainly hyperechoic mass confined to the sub-mucosal layer, without erosions or ulcers. There was

**Figure 1** Double-contrast barium swallow, showing enlargement of the mucosal folds and mild dilation of the esophageal lumen below the level of the aortic arch.

**Figure 2** CT of the chest shows marked thickening of the wall of the esophagus from the aortic arch to the gastrointestinal junction. There was no enlargement of the mediastinal or hilar lymph nodes.

no enlargement of adjacent lymph nodes (Figure 3).

Endoscopy showed excessive rigid folds extending 20-30 cm from the incisors, along the length of the middle and lower esophagus. The stomach and duodenum were normal. Biopsy of the lesion was performed. Histologic examination revealed the presence of a B-cell non-Hodgkin's lymphoma (Figure 4A-C).

Bone marrow biopsy specimens showed no evidence of lymphoma; hence, the patient was diagnosed as isolated B-cell lymphoma with diffuse primary involvement of the esophagus.

## DISCUSSION

The gastrointestinal tract is the most common extranodal site of non-Hodgkin's lymphoma accounting for 5%-20% of all cases<sup>[1,5,6]</sup>. Non-Hodgkin's lymphoma of the esophagus is an extremely uncommon localization of non-Hodgkin's disease, accounting for less than 1% of patients with lymphoma and occurs more often in the distal esophagus<sup>[1,4,7]</sup>. In a review of the literature, Okerbloom *et al*<sup>[8]</sup> found only 4 primary lymphomas of the esophagus in a large series of 1235 cases of non-Hodgkin's lymphoma, representing an incidence of 0.3%. Freeman *et al*<sup>[11]</sup>, in another large series found only 3 esophageal lymphomas. Taal *et al*<sup>[9]</sup> found 37 cases of esophageal non-Hodgkin's lymphoma and only two were primary lymphomas. Isolated primary lymphoma of the esophagus without an extra-esophageal location is very rare and only about 20 cases have been described in the

**Figure 3** Endoscopic ultrasonography shows a transmurally thickening of the esophageal wall and a heterogeneous, mainly hyperechoic, submucosal lesion. A: Thoracic aorta, B: Water-filled balloon, T: Tumor.

literature<sup>[10,11]</sup>.

Although lymphoma of the esophagus is often asymptomatic, most patients present with dysphagia. Other less common clinical manifestations of esophageal lymphoma are odynophagia, fever and weight loss<sup>[12-15]</sup>. Although this disease is extremely rare, it should be considered in the differential diagnosis of patients with acquired immunodeficiency syndrome presenting with dysphagia and weight loss. In our case, the patient complained of epigastric pain. This symptom is nonspecific and should be differentiated from other esophageal or gastric diseases. Our patient had no fever, dysphagia or odynophagia and he was not immunocompromised. Furthermore, our patient fulfilled all Dawson's criteria to identify primary gastrointestinal lymphoma, such as, no palpable superficial lymphadenopathy, no enlargement of mediastinal or hilar lymph nodes and no splenic involvement<sup>[16]</sup>.

Previously described cases have reported a variety of radiographic appearances for primary esophageal lymphoma. The most common include polypoid masses with or without erosions, stricture with ulceration mimicking esophageal cancer, thickening of the mucosal folds producing a varicoid appearance, narrowed distal segments (achalasia-like appearance), or submucosal nodules<sup>[5,12,17,18]</sup>. Given such a diverse spectrum of radiographic appearance, EUS and CT must be performed and biopsy of the esophageal wall are needed in order to confirm the diagnosis.

In our case double-contrast esophagography showed diffuse mucosal fold thickening, without luminal narrowing, suggesting an intramural, benign lesion. CT revealed the precise extent of the lesion, involving the middle and lower third of the esophagus and the absence of mediastinal lymph nodes. With the clinical application of EUS, great progress has been made in the diagnostic accuracy of structural abnormalities and depth of invasion in various gastrointestinal diseases, including lymphoma<sup>[19]</sup>. EUS provides more accurate information on the involvement of the wall layers by such an intrinsic process. In our case, all layers were thickened, but not disrupted. Furthermore, a submucosal-located heterogeneous, mainly hyperechoic mass was imaged,

**Figure 4** Histologic examination shows the presence of a B-cell non-Hodgkin's lymphoma (A) infiltration of the esophageal mucosa by lymphoplasmotoid cells; (B) expression of CD20 antigen by lymphoid cells; (C) Ki-67 antigen (index of proliferation) in lymphoma cells.

which had gradually elevated margins.

In a previous study esophageal lymphoma was described to involve the whole length of the esophagus<sup>[20]</sup>. However, in this study, EUS showed lymphomatous involvement of the gastrointestinal wall to produce a typical hypo-echogenic transmural thickening. To our knowledge, our case of primary diffuse esophageal lymphoma is the first described in the literature to have a mainly hyperechoic appearance on EUS.

Given the non-specific clinical and radiological appearances, endoscopic biopsy of the lesion was necessary. Endoscopy showed extensive rigid folds without erosions and biopsy was performed. Pathologic evaluation of the endoscopic biopsy showed a B-cell non-Hodgkin's lymphoma. The treatment of esophageal lymphoma depends on the histological tumor type and its initial location. Because of the extent of the lesion, our patient was treated with chemotherapy and showed clinical improvement. The chemotherapy regimen was a combination of chemotherapeutic agents. The cycle was repeated every 28 d. The patient received six cycles and achieved complete remission (CT scan of thorax and barium swallow did not reveal any residual lesion).

In summary, esophageal lymphomatous involvement should be considered in the differential diagnosis of immunocompetent patients presenting with epigastric pain. A transmural, mainly hyperechoic, diffuse thickening of the esophageal wall in the EUS is another possible appearance of gastrointestinal lymphoma.

of varices are the distal esophagus, stomach, and rectum, although varices may develop at any level of the gastrointestinal tract below the esophagus. In this infrequent site of varices, development of acute bleeding may be profuse, but very hard to detect and treat. Endoscopic diagnosis is impossible to achieve with a standard endoscope, and mesenteric angiography often gives a negative result. Recently, a novel endoscopic technique involving a single balloon assisted enteroscopy has emerged. In this report, we showed that the injection of a sclerosant solution in bleeding varices of the deep small intestine can be accomplished using a freehand technique *via* the single-balloon enteroscopy.

## Abstract

We report a case of acute uncontrolled gastrointestinal bleeding in a patient with liver cirrhosis. The upper and lower endoscopy were negative for bleeding lesions. We decided to perform the examination of the small bowel using single-balloon enteroscopy. The lower enteroscopy revealed signs of bleeding from varices of the ileum. In this report, we showed that the injection of a sclerosant solution can be accomplished using a freehand technique *via* the single balloon enteroscopy.

## INTRODUCTION

Variceal bleeding occurs in 25 to 40 percent of patients with cirrhosis and each episode of active variceal bleeding is associated with a high percentage of mortality (up to 30%). The most common sites for development

## CASE REPORT

A 58-year-old woman with HBV-related cirrhosis was transferred to our unit for acute uncontrolled gastrointestinal bleeding. The woman was on beta-blocker therapy for primary prophylaxis against variceal bleeding because of F3-grade oesophageal varices. The upper and lower endoscopy performed upon admission were negative for bleeding lesions. We, therefore, decided to complete the examination of the small bowel using single-balloon enteroscopy. Upper enteroscopy was negative until approximately two meters below the Treitz ligament. The lower enteroscopy, about 1.5 meters from the ileo-cecal junction, revealed signs of recent bleeding from varices of the ileum (Figure 1). On this evidence, sclerotherapy with cyanoacrylate was performed (Figure 2). Bleeding stopped and the patient underwent placement of a trans-jugular intrahepatic portosystemic stent shunt (TIPS).

## DISCUSSION

A major cause of cirrhosis-related morbidity and mortality is the development of variceal bleeding due to portal hypertension. Variceal bleeding occurs in 25 to 40 percent of patients with cirrhosis<sup>[1]</sup> and each episode of active variceal bleeding is associated with a high percentage of mortality (up to 30%)<sup>[2,3]</sup>. The most common sites for development of varices are the distal oesophagus, stomach, and rectum, although varices may develop at any level of the gastrointestinal tract below the oesophagus. In this infrequent site of varices, development of acute bleeding may be profuse, but

Figure 1 Varices in the ileum with signs of recent bleeding.

Figure 2 Varices after cyanoacrylate injection.

very hard to detect and treat. Endoscopic diagnosis is impossible to achieve with a standard endoscope, and mesenteric angiography often gives a negative results. Consequently TIPS placement<sup>[4,5]</sup> or major surgery<sup>[6]</sup> are the treatment of choice to resolve the bleeding. Reports showed that ectopic varices can re-bleed despite a reduction of the porto-systemic pressure gradient to  $\leq 12$  mmHg or by 25%-50% of the baseline<sup>[7]</sup>; otherwise careful patient selection is vital to a successful outcome, as patients with severe liver dysfunction tend to die post-TIPS despite a functioning shunt. All patients who require TIPS for treatment of complications of cirrhosis should be referred for consideration of liver transplant.

Recently, a novel endoscopic technique involving a single balloon assisted enteroscopy has emerged<sup>[8]</sup>. This enteroscopy system consists of a high-resolution endoscope with a latex-free balloon attached at the tip of the silicon over the tube. The balloon is inflated and deflated with air from a pressure controlled pump system. The scope is threaded into the small bowel with

push-pull movements under fluoroscopy control. This is not easy to perform, but can safely examine the deep small intestine with the possibility of both diagnostic and therapeutic approaches during bleeding from varices developed in the small bowel<sup>[9]</sup>. Endoscopic therapy is currently the treatment of choice for active variceal bleeding (sclerotherapy and variceal band ligation), but with a standard endoscope only upper and lower variceal bleeding can be treated<sup>[10]</sup>. In this report, we showed that the injection of a sclerosant solution in bleeding varices of the deep small intestine can be accomplished using a freehand technique *via* the single-balloon enteroscopy. This novel technique may be used alone or with other treatments of active variceal bleeding, such as TIPS placement. Unfortunately, the difficulty and length of the procedure restricts the use of enteroscopy to referral centers with expert endoscopists.

### INTRODUCTION

Hepatobiliary cystadenoma is an uncommon lesion, which is mainly seen in females. No more than 10 male cases were reported in the world literature prior to 2005<sup>[1]</sup>. It is difficult to make an accurate diagnosis of hepatobiliary cystadenoma before surgery. We recently treated a male with a preoperative diagnosis of hepatobiliary cystadenoma. We, in this paper, report this case to elucidate its clinical presentation, preoperative evaluation and treatment. To the best of our knowledge, such a case with obvious convex papillate has very rarely been reported in the literature.

### CASE REPORT

A 35-year-old man was admitted because of a multilocular cyst in his liver detected by computerized tomography (CT) during the course of health examination 2 wk ago. His past medical history was unremarkable. Physical examination was negative at admission. Laboratory tests were within normal limits, serology for hepatitis B infection was negative, and serum carcinoembryonic antigen (CEA), carbohydrate antigen (CA) 19-9 and alpha-fetoprotein (AFP) levels were normal. CT showed an area measuring 11 cm × 9 cm in which multiple density areas were grouped together. The internal septations and convex papillate were visible, and enhanced after intravenous administration of contrast medium (Figure 1).

Abdominal magnetic resonance imaging (MRI) revealed a large cystic tumor measuring approximately 10 cm in diameter originating from the left liver lobe. On T1-weighted images (T1WI), low signal intensity was apparent within the cystic spaces. On corresponding T2-weighted images (T2WI), the tumor was characterized by a medium-high intensity signal clearly delineated from the surrounding liver tissue with internal septal

### Abstract

Hepatobiliary cystadenoma is an uncommon lesion that is most often found in middle-aged women and difficult to diagnose preoperatively. Here, we report a case of giant hepatobiliary cystadenoma in a male patient with obvious convex papillate. On the basis of imaging examinations, the patient was diagnosed as hepatobiliary cystadenoma prior to operation. Left hepatectomy was performed and the patient was symptom-free during a 6-mo follow-up period, suggesting that imaging examination is the major diagnostic method of hepatobiliary cystadenoma, and operation is its best treatment modality.

structures separating the fluid-filled spaces (Figure 2). On the basis of these findings, the patient was diagnosed with a hepatobiliary cystadenoma.

Left hepatectomy was performed (Figure 3A). On gross examination, the resected specimen showed a multilocular cystic lesion with a solid part measuring 12 cm × 9 cm × 9 cm (Figure 3B). The cyst contained mucinous fluid with no connection to the bile duct. CT and MRI showed papillary projections inside the cyst.

Histological examination revealed the cystic wall, most of which was lined with a single layer of columnar and cuboidal cells. The cells were not pleomorphic (Figure 4A). The epithelium showed strong and diffuse cytoplasmic staining with antibodies to CK7, CK8, CK18, and CK19 (Figure 4B), but was negative for AFP,

CEA and CK20. Ki-67 labeling index was lower than 5%. A final diagnosis of hepatobiliary cystadenoma was established.

The patient was discharged on day 9 after surgery. No evidence of recurrence was found during the 6-mo follow-up period.

## DISCUSSION

Hepatobiliary cystadenoma is rare neoplasm that arises in the liver, or less frequently in the extrahepatic biliary system, accounting for less than 5% of all cystic neoplasms found in the liver<sup>[2]</sup>. However, it is believed to be premalignant. Because its rarity and cystic aspect are similar to other cystic liver lesions<sup>[3]</sup>, diagnosis is often delayed and may result in inaccurate treatment modalities, such as aspiration, thus further causing unnecessary morbidity and mortality<sup>[4]</sup>. Sometimes, a two-stage operation is needed, due to misdiagnosis of the disease<sup>[5]</sup>.

The lesion is mainly seen in females and more than 80% of the reported patients are over 30 years of age<sup>[2]</sup>. Our patient was a male. No more than 10 male cases were reported in the world literature prior to 2005<sup>[1]</sup>. This lesion is usually located in the right lobe of liver<sup>[6]</sup>. However, all the cases reported by Lewin were found in the left lobe of liver<sup>[7]</sup>. In our patient, the lesion was also located in the left lobe of liver.

Clinical manifestations of the tumor are non-specific. The chief complaints are usually an abdominal mass, abdominal pain and distension. When the tumor compresses the porta hepatis or the extrahepatic bile duct, obstructive jaundice may occur<sup>[8]</sup>. Nevertheless, some patients are asymptomatic and discovered incidentally at imaging examination, like ours. Thus, clinical manifestations are considered less reliable in the diagnosis of hepatobiliary cystadenoma.

Laboratory results are normal in most patients with hepatobiliary cystadenoma, though serum liver enzyme levels may be mildly elevated occasionally. Serum alpha-fetoprotein and CEA levels are usually within the normal range. It was recently reported that CA 19-9 may be elevated in the cystic fluid and contributes to the diagnosis of hepatobiliary cystadenoma before operation; but, carcinomatosis may occur following cyst

**Figure 3** A large cystic hepatobiliary cystadenoma in the left hepatic lobe (A) and a multilocular hepatobiliary cystadenoma with papillary projections (B) observed during and after operation.

**Figure 4** Locules were lined by simple columnar-to-cuboidal epithelium with no nuclear atypia (HE,  $\times 100$ ) (A), and CK7 strongly and diffusely stained cystadenomas (immunostaining,  $\times 400$ ) (B). Similar results were also observed with CK8, CK18 and CK19 staining.

aspiration or biopsy<sup>[9]</sup>. It has been shown that serum CA 19-9 level can be used as a parameter of tumor activity during follow-up after resection<sup>[10]</sup>. In another high CA 19-9 level may be related to focal dysplasia of epithelial cells<sup>[11]</sup>. For this reason, the presence of elevated CA 19-9 level cannot be considered a significant parameter for the discrimination between malignant and benign hepatic tumors.

Imaging examination is the key to the diagnosis of hepatobiliary papillary cystadenoma. Preoperative imaging examination, particularly CT and MRI, plays an important role in recognizing and characterizing the disease. Patients are often incidentally diagnosed by imaging examination. The typical CT features of cystadenoma are usually a well-defined mass with low-density and internal septa. Its fibrous capsule and internal septations are often visible and help distinguish the lesion from a simple cyst. The convex papillate can be seen on the septation, although it is more common in cystadenocarcinoma. Bile duct dilatation commonly results from extrinsic compression. Calcifications along the wall and internal septum are uncommon. Unilocular lesions have been reported<sup>[12,13]</sup>, and are often incorrectly diagnosed as a simple cyst, thus resulting in inadequate therapy<sup>[2]</sup>. Contrast CT demonstrates enhanced internal septations and mural nodules. MRI may improve tissue characterization because of its high contrast resolution. Signal intensity may vary depending on the property of cyst fluid<sup>[13,14]</sup>. On T1WI, the signal intensity may increase with protein concentration. The signal intensity of serous fluid and bile is low. In rare cases, the intensity of serous cystic

content can be raised by intracystic hemorrhage and fluid-fluid level can be present<sup>[3]</sup>. On T2WI, septations with low signal intensity are better visualized in contrast to the high signal intensity of cystic fluid. Kubo *et al*<sup>[15]</sup> reported that monitoring changes in radiological appearance of the tumor may be useful for the differential diagnosis of cystadenoma and cystadenocarcinoma. Endoscopic retrograde cholangiopancreatography (ERCP), even if rarely employed, may show a cystic cavity communicating with the biliary tree<sup>[4]</sup>.

According to their histology, cystadenoma is classified into two subgroups: cystadenoma with and without mesenchymal stroma. Hepatobiliary cystadenoma without mesenchymal stroma can cause malignant alterations, to which our case belongs. The prognosis of patients, especially male patients with hepatobiliary cystadenoma is poor<sup>[16]</sup>. Because of its malignant potential, natural history of progressive enlargement and recurrence after partial excision<sup>[17]</sup>, total excision of the cyst with a wide margin ( $> 2$  cm) of normal liver tissue is widely supported.

In summary, our experience demonstrates that imaging examination contributes to the diagnosis of hepatobiliary cystadenoma before operation. Complete excision is its best treatment modality.

## INTRODUCTION

Imatinib mesylate (IM) is a small molecule inhibitor of tyrosine kinase that has been evaluated for efficacy in the treatment of gastrointestinal stromal tumors (GISTs)<sup>[1]</sup>. The role of IM neoadjuvant therapy has been discussed<sup>[2]</sup> and explored in many clinical trials, since it may potentially offer benefits in the treatment of rectal malignant GIST. The most obvious benefit is to increase the likelihood of complete gross resection of the tumor, and, as a result, the likelihood to minimize the sacrifice of normal tissue avoiding a radical excision. In this report, we describe the case of a patient with rectal malignant GIST who was successfully treated with IM neoadjuvant and followed up 57 mo with a disease-free survival.

## CASE REPORT

A 72-year-old man presented at the hospital with a 6-mo history of intermittent melena, mild lower abdominal discomfort and intussusception. At the time of admission, his complete blood count (CBC) revealed anemia with a low hemoglobin concentration of 75 g/L. An abdominal ultrasound and a computerized tomography (CT) scan of the abdomen and pelvis revealed a solitary irregular and low-density mass of 7 cm × 6 cm in the rectum, extending from the anterior rectal wall into the prostate. The urinary bladder was compressed anteriorly and tightly attached. X-ray showed no intra-abdominal lymphadenopathy or liver metastases (Figure 1) or any lung abnormality. Then, colonoscopy and ultrasound endoscopy revealed a submucous mass in the rectum without any visible mucosal abnormality or intraluminal blood. The mass was localized at about 6.5 cm from the anal verge. However, the histological examination of

## Abstract

Surgical treatments including radical resection and local excision remain the main treatment for primary rectal gastrointestinal stromal tumors (GISTs). However, since patients with high-grade rectal GISTs have a higher risk of tumor recurrence and a shorter life expectancy, neoadjuvant treatment is necessary. In this case report, the efficacy of imatinib mesylate (IM) as a neoadjuvant therapy was assessed in an old man with malignant rectal GIST. The patient received IM preoperative treatment for a short period of one and a half months; at the end of the IM treatment, computed tomography scanning showed a markedly reduced tumor size and cystic changes of the tissue. At that time, a function sphincter-sparing surgery was performed. The histological examination of the resected specimen detected no tumor cells, but residual blood vessels and scattered inflammatory lymphocytes. After surgery, the patient has been followed up without additional IM treatment and remained disease-free for 57 mo. This case indicates that IM neoadjuvant therapy can dramatically improve the prognosis of rectal malignant GIST.

**Key words:** Gastrointestinal stromal tumor; Imatinib mesylate; Neoadjuvant

**Figure 1** CT scan image at pelvic showing a large low-density lesion arising from the rectum.

the rectal biopsy, performed three times at other two hospitals, revealed a normal tissue with a mild infiltrate of inflammatory cells. A provisional diagnosis of rectal GIST was suspected by the CT scan.

The patient was admitted at the hospital and transfused with 3 units of packed red blood cells. Considering the patient's age, the tumor localization and size and its relationship with the neighbouring organs, a definitive histopathological diagnosis was mandatory in order to adopt appropriate treatment. To do so, a rectal subserosa fine-needle deep biopsy was successfully obtained under the guidance of ultrasound endoscopy. Histologically, spindle cells were detected in one of five sections of the tissue biopsy. The cells exhibited moderate to severe atypia and active mitoses, with a total of six mitotic figures in two high-power fields (Figure 2A). Immunohistochemistry showed strong and diffuse staining for CD117 (Figure 2B) and CD34, but proved negative for all other differentiation markers such as  $\alpha$ -SMA, MSA, desmin, S-100 protein, and HMB45. Based on the histopathological exam, the final diagnosis of a high grade malignant GIST was made. There was in sufficient tumor tissue to examine the genetic mutations for the c-kit and PDGFR $\alpha$  genes.

Because of the size and the localization of the lesion, both surgical intervention and the possibility of IM neoadjuvant were recommended to the patient and his family members. All declined radical excision and consented to IM neoadjuvant. The patient received IM therapy with a single dose of 400 mg administered daily for one and a half months, and was followed up by CT scans of the chest, abdomen and pelvis to monitor the outcome. The tumor dramatically shrunk to 5 cm after one month, and then developed complete cystic changes and sharp demarcation with respect to neighbouring organs after another half a month, when an exploratory laparotomy was carried out, followed by a segmental colectomy resection. The surgery was performed more easily than we would have anticipated for a similar case without IM therapy. Due to a delayed postoperative recovery, the patient was discharged one week later. Visual observation of the resected tissue found a grayish tumor of 4 cm  $\times$  3.5 cm  $\times$  3 cm in the muscularis propria (Figure 2C). Histopathology examination

revealed that the tumor had completely responded to IM neoadjuvant since there was no viable tumour cells found in the extirpated specimen (Figure 2D). Satisfied with the histopathologic results, the patient declined continuous IM adjuvant therapy. He has been followed up and his disease free survival is currently at 57 mo after the combined therapy: no signs of recurrence or relapse of the tumor have occurred so far.

## DISCUSSION

GISTs are the most common mesenchymal tumors of the gastrointestinal tract, most frequently found in the stomach (60%) and the small intestine (30%). The incidence of the rectal GIST is low (4%)<sup>[3,4]</sup>. Although abdominoperineal resections of large sized GISTs are not sufficient to prevent the highly frequent recurrence of the tumor<sup>[5]</sup>, surgical treatments, including radical resection and local excision, remain the main treatment for primary rectal GISTs. However, for rectal GISTs, its rarity makes it difficult to assess the role of the extension of the surgical resection of the tumor.

IM selectively inhibits the enzymatic activity of tyrosine kinases, such as ABL, PDGFR, and KIT. Its development was a landmark event in the history of cancer therapy. With IM adjuvant treatment, approximately 60%-80% of patients with recurrent or metastatic GISTs achieve a partial response or stable disease; but, complete response induced by IM is rare. The lack of complete response in many patients with partial response may be due to the drug resistance developed with a prolonged treatment. In fact, studies showed that half of the patients no longer respond to IM after approximately two years of continuous treatment<sup>[6-8]</sup>, and the likelihood of developing IM resistance is proportional to the size of residual viable GIST. Therefore, alternative and more efficient therapies for primary GISTs are required in the IM era. Currently, a potential paradigm shift in the management of GISTs has been proposed and explored, and whether IM neoadjuvant can improve outcome has been broadly evaluated.

Until now, the evaluation criteria for IM neoadjuvant therapy have not been well defined. GISTs comprise a wide range of biological behaviors, including benign, borderline and malignant variants<sup>[9]</sup>. Surgery remains the treatment of choice for benign and borderline GISTs. Preoperative diagnosis is the most critical criterion for selecting the appropriate therapy. Most alimentary tract diseases can be initially diagnosed by endoscopy, imaging and other methods; pathologic examination of tissue specimens is the most valuable final confirmation of the diagnosis. GISTs are submucous tumors with the surface covered with normal mucosa. A common problem for the diagnosis of GISTs is that conventional endoscopic biopsies using forceps are often unsuccessful in sampling submucosal mass, because they are too superficial and only obtain biopsy samples of the mucosal tissue. EUS-guided aspiration or core biopsy for submucosal tumors had a success rate of 60%-70% in the earlier studies,

**Figure 2** Different images of the rectal tumor. A: Histopathological microphotograph of biopsy tissue showing spindle-shaped cells with obvious atypia and active mitoses (HE, × 200); B: Envision immunohistochemical stained tumor cells showing strong and diffuse positive staining for CD117 (HE, × 200); C: Macroscopic image of the resected tissue showing a submucosal tumor grayish and uniformly soft tissue texture, measuring 4 cm × 3.5 cm × 3 cm in size; D: Histological examination of the resected tissue showing no residual tumor cells, except for blood vessels and scattered lymphocytes (HE, × 200).

but this rate is now gradually reaching 80%-90%, which is significantly higher than that of a simple endoscopic biopsy<sup>[10-12]</sup>. The usefulness of biopsy in diagnosis can be enhanced by immunohistochemical staining on aspirates or tissues for tumor-specific markers such as CD117 and CD34, which are crucial for a diagnosis of GISTs<sup>[13]</sup>. Severe nuclear atypia and active mitotic figures indicating malignancy can help the decision in favor of a neoadjuvant therapy. For this reason, four biopsies were obtained from our patient to confirm the diagnosis before starting the therapy.

IM neoadjuvant therapy for primary GISTs has been reported<sup>[14-18]</sup>. Among the reports, there are five gastric and one intestinal GISTs, where the tumor mass size made it unresectable, two primary rectal GISTs<sup>[19,20]</sup>, and one recurrent rectal GIST where the abdominoperineal resection of the rectum could not be done<sup>[21]</sup>. Sparing surgery with preservation of the anal sphincter was possible in all of the three rectal GIST cases reported previously as well as in our case. In the case reported by Lo *et al*<sup>[19]</sup>, residual tumor cells were found 2.5 mo after IM therapy. In another case, reported by Shah *et al*<sup>[20]</sup>, no data are available concerning any residual tumor 6.5 mo after IM neoadjuvant therapy. One recurrent rectal case, reported by Salazar *et al*<sup>[21]</sup>, showed complete histopathological response 12 mo after IM therapy. In our case, the patient achieved complete response after only one and half months of IM neoadjuvant therapy. To our knowledge, this is the shortest time to achieve complete response by IM therapy. Since the patient declined

postoperatively IM adjuvant treatment, he was then closely followed up. The patient has been asymptomatic and disease-free since then, i.e. 57 mo after the combined treatment. It is reasonable to speculate that the 57 mo disease-free survival from the combined treatment is largely due to the preoperative IM therapy.

Recently, Andtbacka *et al*<sup>[22]</sup> compared the outcomes of preoperative IM therapy combined with surgery with locally advanced and metastatic GISTs among 46 patients, including 11 with locally advanced primary tumors and 35 with metastatic tumors. Complete surgical resection after IM neoadjuvant was accomplished in all of the advanced primary tumors, but only 31.4% (11/35) of the metastatic tumors. Based on these results, IM neoadjuvant combined with surgery can be considered as more effective for patients with primary GISTs.

Based on our prior experience and the findings from this case, we believe that the approach of IM neoadjuvant treatment combined with surgery should offer the patient a longer event-free and overall survival.

## Abstract

Some aspects related with the use of furazolidone as a rescue therapy for *Helicobacter pylori* (*H. pylori*) infection should be remarked, especially regarding its potential oncologic risk. The inclusion of furazolidone in a treatment regimen for *H. pylori* infection is, at least, controversial, and it does not appear to be safe.

## TO THE EDITOR

We have read with great interest the study performed in Brazil by Felga *et al*<sup>[1]</sup> on the efficacy and safety of a 'rescue' therapy to cure *Helicobacter pylori* (*H. pylori*) infection. Briefly, following a quadruple therapy including PPI, bismuth salts, amoxicillin and furazolidone, a 68.8% eradication rate was achieved, a side-effect incidence of 31.4% was observed, and treatment interruption occurred in 3 (6.7%) out of

45 controlled patients. The authors concluded that 'it is an effective, cheap and safe option for salvage therapy'. We have some concerns about these conclusions. First, in the manuscript, the eradication rate was calculated only at 'per protocol' analysis (68.8%; 31 of 45). However, by calculating the success rate at 'intention to treat' analysis (all the 51 treated patients), the eradication rate was as low as 60.8%. Therefore, this quadruple therapy would not appear so 'effective' as declared. Indeed, it has been found that a simpler, levofloxacin-amoxicillin triple therapy achieved a higher eradication rate as a second-line therapy or even 'rescue' therapy<sup>[2,3]</sup>. The reported side-effect incidence (31.4%) was much higher than that observed following furazolidone-free therapies, which was lower than 10% with an interruption rate as low as 0.003%-0.007% in thousands of patients<sup>[4]</sup>. This observation suggests that treatment with furazolidone is not so 'safe' as declared. Last but not the least, some crucial ethical concerns arise with the use of furazolidone. This is an antibiotic used in the 1980s for parasitic infections and some studies described its use in human subjects to treat *H. pylori* infection. However, different studies were published that raised several concerns about this agent and its potential for causing tumors<sup>[5,6]</sup>. Moreover, the company that made the agent in the United States (Roberts Pharmaceuticals) was sold to Shire Pharmaceuticals and the FDA withdrew its approval for furazolidone in March 2005. The drug was ordered to be removed even from animals as an antibiotic by the FDA in 2002. The FDA has subsequently sued companies that illegally imported the drug from Mexico for use in animals. Simultaneously, the European Medicinal Agency (EMA; the equivalent of the FDA in the European Union) banned the drug in Europe. Although the drug continues to be available in some developing countries such as Iran, Pakistan, India, Mexico and Brazil, a number of public and press campaigns from concerned individuals have urged governments to ban the drug in those countries. Therefore, can we consider a therapy including furazolidone to be 'safe' as the authors declared? Although it has been stated that study was approved by the Ethical Committee, were patients informed of possible genotoxic and carcinogenic effects for which furazolidone is not currently approved by both FDA and EMA?

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

# World Journal of Gastroenterology®

Weekly Established in October 1995

Volume 15 Number 16  
April 28, 2009

## Contents

### EDITORIAL

- 1921 Surgical treatment of anal stenosis  
*Brisinda G, Vanella S, Cadeddu F, Marniga G, Mazzeo P, Brandara F, Maria G*
- 1929 Measurement of serum paraoxonase-1 activity in the evaluation of liver function  
*Camps J, Marsillach J, Joven J*

### TOPIC HIGHLIGHT

- 1934 Five years' experience with capsule endoscopy in a single center  
*Kav T, Bayraktar Y*

### ORIGINAL ARTICLES

- 1943 Effects and mechanisms of silibinin on human hepatocellular carcinoma xenografts in nude mice  
*Cui W, Gu F, Hu KQ*
- 1951 Histological and biochemical alterations in early-stage lobar ischemia-reperfusion in rat liver  
*Arab HA, Sasani F, Rafiee MH, Fatemi A, Javaheri A*
- 1958 Rocket "*Eruca sativa*": A salad herb with potential gastric anti-ulcer activity  
*Alqasoumi S, Al-Sohaibani M, Al-Howiriny T, Al-Yahya M, Rafatullah S*
- 1966 *In vitro* and *in vivo* suppression of hepatocellular carcinoma growth by midkine-antisense oligonucleotide-loaded nanoparticles  
*Dai LC, Yao X, Wang X, Niu SQ, Zhou LF, Fu FF, Yang SX, Ping JL*

### BRIEF ARTICLES

- 1973 Colonoscopic polypectomy in anticoagulated patients  
*Friedland S, Sedehi D, Soetikno R*
- 1977 Effect of dephytinization on bioavailability of iron, calcium and zinc from infant cereals assessed in the Caco-2 cell model  
*Frontela C, Scarino ML, Ferruzza S, Ros G, Martínez C*
- 1985 Intussusception in adults: Clinical characteristics, diagnosis and operative strategies  
*Yakan S, Caliskan C, Makay O, Denecli AG, Korkut MA*
- 1990 Computer simulation of flow and mixing at the duodenal stump after gastric resection  
*Filipovic N, Cvetkovic A, Isailovic V, Matovic Z, Rosic M, Kojic M*

**INTRODUCTION**

*World Journal of Gastroenterology* is an international, open-access, peer-reviewed, and multi-disciplinary weekly journal that serves gastroenterologists and hepatologists. The biggest advantage of the open access model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the values of the readers, the authors and the society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

**EDITORS FOR THIS ISSUE**

**Responsible Assistant Editor:** *Xiao-Fang Lin*  
**Responsible Electronic Editor:** *Wen-Hua Ma*  
**Proofing Editor-in-Chief:** *Lian-Sheng Ma*

**Responsible Science Editor:** *Lai-Fu Li*  
**Proofing Editorial Office Director:** *Jian-Xia Cheng*

**NAME OF JOURNAL**

*World Journal of Gastroenterology*

**RESPONSIBLE INSTITUTION**

Department of Science and Technology of Shanxi Province

**SPONSOR**

Taiyuan Research and Treatment Center for Digestive Diseases, 77 Shuangta Xijie, Taiyuan 030001, Shanxi Province, China

**EDITING**

Editorial Board of *World Journal of Gastroenterology*, Room 903, Building D, Ocean International Center, No.62 Dongsihuan Zhonglu, Chaoyang District, Beijing 100025, China

### Abstract

Anal stenosis is a rare but serious complication of anorectal surgery, most commonly seen after hemorrhoidectomy. Anal stenosis represents a technical challenge in terms of surgical management. A Medline search of studies relevant to the management of anal stenosis was undertaken. The etiology, pathophysiology and classification of anal stenosis were reviewed. An overview of surgical and non-surgical therapeutic options was developed. Ninety percent of anal stenosis is caused by overzealous hemorrhoidectomy. Treatment, both medical and surgical, should be modulated based on stenosis severity. Mild stenosis can be managed conservatively with stool softeners or fiber supplements. Sphincterotomy may be quite adequate for a patient with a mild degree of narrowing. For more severe stenosis, a formal anoplasty should be performed to treat the loss of anal canal tissue. Anal stenosis may be anatomic or functional. Anal stricture is most often a preventable complication. Many techniques have been used for the treatment of anal stenosis with variable healing rates. It is extremely difficult to interpret the results of the various anaplastic procedures described in the literature as prospective trials have not been performed. However, almost any approach will at least improve patient symptoms.

### INTRODUCTION

Anal stenosis is an uncommon disabling condition<sup>[1-5]</sup>. It is a narrowing of the anal canal. This narrowing may result from a true anatomic stricture or a muscular and functional stenosis. In anatomic anal stenosis, the normal pliable anoderm, to a varying extent, is replaced with restrictive cicatrized tissue. Stenosis produces a morphologic alteration of the anal canal and a consequent reduction of the region's functionality, leading to difficult or painful bowel movements<sup>[6-8]</sup>.

Anal stenosis is a serious complication of anorectal surgery. Stenosis can complicate a radical amputative hemorrhoidectomy in 5%-10% of cases<sup>[9-14]</sup>, particularly those in which large areas of anoderm and hemorrhoidal rectal mucosa from the lining of the anal canal is denuded, but can also occur after other anorectal surgical procedures.

Treatment, both medical and surgical, should be modulated based on stenosis severity<sup>[4,15]</sup>. Mild stenosis can be managed conservatively with stool softeners or fiber supplements. Daily digital or mechanical anal dilatations may be used. Sphincterotomy may be quite adequate for a patient with a mild degree of narrowing. For more severe anal stenosis, a formal anoplasty should be performed to treat the loss of anal canal tissue. Several techniques have been described for the treatment of moderate to severe stenosis refractory to non-operative management. In the literature, several studies have been conducted on anal stenosis treatment, but there is not yet universal consent on the anaplastic procedure to use. This review examines some of the evidence concerning the surgical treatment of anal stenosis.

## ETIOLOGY AND PATHOPHYSIOLOGY

Stenosis may be caused by an intrinsic or extrinsic pathologic process of the anorectum. Anal stenosis may follow almost any condition that causes scarring of the anoderm. The causes of anal stenosis include surgery of the anal canal, trauma, inflammatory bowel disease, radiation therapy, venereal disease, tuberculosis, and chronic laxative abuse. We focus on the treatment of postsurgical anal stenosis.

Ninety percent of anal stenosis is caused by overzealous hemorrhoidectomy<sup>[16]</sup>. Removal of large areas of anoderm and hemorrhoidal rectal mucosa, without sparing of adequate muco-cutaneous bridges, leads to scarring and a progressive chronic stricture. The surgical procedure influences the incidence of anal stenosis, particularly after "Whitehead hemorrhoidectomy" because, later, surgeons misinterpreted Whitehead's description and anchored the mucosa to the anal verge (Whitehead deformity)<sup>[14,17-19]</sup>. After Milligan-Morgan and stapled rectal mucosectomy (SRM), stenosis is less frequent. In a study of 1107 patients treated with stapled hemorrhoidectomy, 164 of 1107 patients registered a complication: anal stenosis was observed in only 0.8% of cases<sup>[19]</sup>. Stenoses caused by SRM are presumably rectal stenoses, since the causing event was a resection of rectal mucosa. The stenosis rate following stapled mucosectomy generally ranges from 0.8%-5.0%. The calculated actuarial one-year stenosis rate is 6%, which is higher than the above-mentioned published stenosis rates.

In addition, anal fissure surgery can lead to anal stenosis, if an internal sphincterotomy is not performed. Stenosis may follow anterior resection of the rectum, if complicated by anastomotic dehiscence. Inflammatory bowel diseases may cause anal stenosis, particularly Crohn's disease. These stenoses are characterized by a transmural scarred inflammatory process. Patients with anal fissure or who abuse paraffin laxatives may develop a disuse stenosis. Radiotherapy treatment for pelvic tumors (i.e. uterine carcinoma, prostatic carcinoma, *etc.*) promotes anal stenosis formation. Also sepsis, ischemia from occlusion of lower mesenteric artery or upper rectal artery, AIDS, venereal lymphogranuloma, gonorrhea, amoebiasis and anorectal congenital disease may lead to anal stenosis. Finally, chronic abuse of ergotamine tartrate for the treatment of migraine headache attack may lead to anorectal stricture<sup>[20]</sup>.

In the natural anatomic configuration, the anal canal is an upside down funnel, where its diameter is lower than the diameter of the anal verge. Physiologically, during evacuation, the internal sphincter relaxes and dilates to the cutaneous side, where the diameter is greater, to allow the regular passage of stool. On this subject, it is important to distinguish acute from chronic anal stenosis. Acute anal stenosis is determined by a severe and sudden spasm of persistent pain (i.e. in the anal fissure). These spasms are dynamic and reversible. In this case, the ano-rectal passage is cylindrical. Chronic anal stenosis, occurs secondary to surgical procedures, infections and fibrosis, and spasms are adynamic and irreversible<sup>[3,4]</sup>.

Thus, the anal canal progressively reduces its diameter. In patients who use laxatives improperly, physiologic regular dilatation is abolished. Gradual and irreversible fibrosis occurs in the sub-cutaneous space of the anal canal with a pathologic funnel-shaped configuration in which the diameter of the anal canal is greater than the diameter of the anal verge.

## DIAGNOSIS

Diagnosis of this condition is straightforward. The patient usually reports difficult or painful bowel movements. The patient may also have rectal bleeding and narrow stools. The fear of fecal impaction or pain usually causes the patient to rely on daily laxatives or enemas. Suspicion of anal stenosis is heightened by a history of hemorrhoidectomy, Crohn's disease, or excessive laxative use.

Physical examination confirms the diagnosis. Visual examination of the anal canal and perianal skin, along with a digital rectal examination, is usually suffice to establish the presence of anal stenosis. Occasionally the patient is too anxious or the anal canal too painful to allow an adequate examination. In this situation, anesthesia is needed to perform a proper examination of the anal canal. The anesthetic abolishes the spasm associated with an acute fissure but will not produce an increased luminal diameter in a patient with a true stenosis. Anorectal manometry is an objective method for assessing anal musculature tone, rectal compliance, anorectal sensation, and verifying the integrity of the rectoanal inhibitory reflex. Several methods are available for obtaining this information. No single method is universally accepted and manometric data from different institutions are difficult to compare. Manometry has been widely used to document sphincter function prior to procedures, such as lateral internal sphincterotomy, which may affect continence.

It is important to ascertain the cause of the stricture in order to determine proper therapy; a malignant disease must be treated by excision or resection, and anal Crohn's disease is an absolute contraindication to anoplasty<sup>[4]</sup>.

## CLASSIFICATION AND TOPOGRAPHY

When planning treatment of anal stenosis, it is useful to categorize the severity of the stenosis. Anatomic anal stenosis may be classified on the grounds of stricture severity, its structure and the level of involvement in the anal canal. On the basis of severity, Milsom and Mazier<sup>[6]</sup> distinguished mild (tight anal canal can be examined by a well-lubricated index finger or a medium Hill-Ferguson retractor), moderate (forceful dilatation is required to insert either the index finger or a medium Hill-Ferguson retractor), and severe anal stenosis (neither the little finger nor a small Hill-Ferguson retractor can be inserted unless a forceful dilatation is employed). Furthermore, stenosis may be diaphragmatic (after inflammatory bowel disease, characterized by a thin strip of constrict-

tor tissue), ring-like or anular (after surgical or traumatic lesions, of length less than 2 cm), and tubular (length more than 2 cm). On the basis of the anal canal levels, stenosis may also be distinguished as low stenosis (distal anal canal at least 0.5 cm below the dentate line, 65% of patients), middle (0.5 cm proximal to 0.5 cm distal to the dentate line, 18.5%), high (proximal to 0.5 cm above the dentate line, 8.5%), and diffuse (all anal canal, 6.5% of cases)<sup>[6]</sup>.

## TREATMENT

The best treatment of postsurgical anal stenosis is prevention. Adequate anorectal surgery reduces the incidence of anal stenosis<sup>[3,16]</sup>. It is essential to treat tissues delicately and not to draw them. Also it is important to use absorbable sutures and minimal resection of tissues. Khubchandani<sup>[3]</sup> condemned the use of manual dilatation under anesthesia for the non-operative treatment of mild to moderate stenosis because the resultant hematoma in the sphincter apparatus may cause fibrosis and progressive stenosis. In Milligan-Morgan hemorrhoidectomy, internal sphincterotomy, if necessary, associated with preservation of adequate muco-cutaneous bridges, prevents anal stenosis. However, if anal stenosis is present, treatment should be modulated based on severity, cause and localization<sup>[6]</sup>.

Non-operative treatment is recommended for mild stenosis and for initial care of moderate stenosis. Also, with severe stenosis, conservative treatment can lead to good results, however, surgery is always necessary. The use of stool softeners and fiber supplements with adequate gain of fluids is the basis of non-operative treatment. This gradual and natural dilation is very effective in most patients. Anal dilatation is another important part of this treatment. Anal dilation can be performed daily both digitally or with any of a number of graduated mechanical dilators. Patients are instructed to sit down on the toilet, bear down, and gradually insert the smallest dilator with ample lubrication. If the patient can persist with the dilations on a regular basis, the result is usually excellent. Many patients do not tolerate this procedure. On the other hand, a dilator may tear the canal. In fact, a complication from the use of dilators may itself precipitate the need for surgical intervention. However, it would be a rare circumstance when mild stenosis would require surgery<sup>[4]</sup>.

Moreover, if the patient remained symptomatic with the usual measures, it is important to be certain that anal stenosis is indeed the cause of the patient's complaints; particularly in the postoperative patient, anal fissure must be ruled out as a possible source of the problem. If stenosis is refractory to non-operative management, surgery represents the last solution. However, a long course of conservative, medical management is indicated in the treatment of mild anal stenosis before resorting to a surgical approach.

Many different surgical techniques have been described for the management of moderate to severe anal stenosis. Moderate stenosis is generally treated initially in

the same fashion as mild stenosis. Fiber supplementation is initiated and dilations are carried out if necessary. Furthermore, partial lateral internal sphincterotomy may be quite adequate for a patient with a mild degree of narrowing. This technique is simple and safe and use is limited to functional stenosis. It is important that the sphincterotomy is done in the open fashion so that the associated scarred anoderm is divided at the same time to allow full release of the scar. The resulting wound is then left open and allowed to heal by secondary intent. This provides relief of the partial obstruction and pain caused by the stenosis, but the relief will be short-lived without appropriate medical management. The importance of a high-fiber diet and fiber supplements must be emphasized to the patient and instituted immediately after surgery. Although the results have been reported as excellent<sup>[21,22]</sup>, it is difficult to interpret whether the patients had significant narrowing or spasm associated with the anal fissure.

For more severe anal stenosis, a formal anoplasty should be performed to treat the loss of anal canal tissue. Various types of flaps have been described for anal stenosis which allow delivery of the more pliable anoderm into the anal canal to replace the scarred lining at that level. A lateral internal sphincterotomy is also usually necessary at the time of anoplasty.

### Lateral mucosal advancement flap

This is a modification of Martin's anoplasty (Figure 1A)<sup>[1,23,24]</sup>. A midlevel stenosis is corrected by excision of the scar tissue. An undermining of the proximal rectal and anal mucosa through a transverse incision at the dentate line is performed. An internal sphincterotomy is performed if a functional component is present. The resulting flap is advanced to the distal edge of the internal sphincter near the anal verge. The vascular supply is maintained through the submucosal plexuses. The external part of the wound is left open to minimize ectropion formation.

### Y-V advancement flap

This procedure is performed in the gynaecological prone position. It is important to administer adequate antibiotic therapy (cephazoline and metronidazole) at the time of surgery. A mechanical bowel preparation is usually done the day before surgery. After anal dilatation with a medium Hill-Ferguson retractor, the initial incision overlying the area of stricture is the vertical limb of the Y (Figure 1B). This incision is extended on the perianal skin in two directions for creating a V flap. Incisions are carried proximally for 5 to 8 cm. The V flap is incised with fatty subdermal tissue, providing an adequate blood supply. The resulting V advancement flap is sutured into the vertical limb of the Y incision in the anal canal with the internal apex of the triangular flap sutured to the internal sphincter and to rectal mucosa (dentate line) with interrupted long-term absorbable sutures<sup>[5,20,23,25-30]</sup>. This flap can be done in the posterior midline or in either lateral position. It can also be done bilaterally if needed to relieve the stenosis. Postsurgical management consists of fiber supplements and pain control. Sitz baths can also

**Figure 1** Operative procedure for the surgical treatment of anal stenosis. A: Martin's anoplasty; B: Y-V advancement flap; C: V-Y advancement flap; D: Diamond-shaped flap; E: House-shaped flap; F: U-shaped flap; G: Rotational S-flap.

be instituted to assist with local hygiene. In the post-operative period, a constipating regimen is recommended for 2 d. Antibiotic therapy is usually continued for 7 d. This technique is simple and quite useful for stenosis associated with an anal fissure. However, if more than 25% of the circumference of the anal canal needs to be covered, another anaplastic procedure is indicated<sup>[4]</sup>.

#### **V-Y advancement flap**

This procedure is an alternative to Y-V anoplasty. The base of the triangular V flap is sutured to the dentate line (Figure 1C). In addition, the underlying vascular pedicle is contained in the subcutaneous fat. Thus, it is necessary to preserve fatty subcutaneous tissue with wide mobilization to maintain flap viability. The skin is then closed behind the V at the external portion of the perineum to push the V into the anal canal and widen the stenotic area<sup>[31]</sup>.

#### **Diamond-shaped flap**

After adequate mechanical bowel preparation and antibiotic therapy in the pre-operative period, this procedure is performed in the gynaecological prone position. To avoid bleeding, epinephrine can be used. On the basis of stenosis severity, one or two flaps can be created. The scar tissue is incised leaving a diamond-shaped defect (Figure 1D). A diamond-shaped flap is designed so that it will cover the intra-anal portion of the defect<sup>[5,23,29]</sup>. The preparation of the flap is a crucial step in the procedure: the flap should be well mobilized to reduce tension and to provide enough blood supply to preserve the underlying vascular pedicle.

#### **House flap**

After the use of stool softeners in the pre-operative period, enema is performed on the day of surgery. This technique is performed in the gynaecological prone position. If stenosis is extended from the dentate line to perianal skin, a house flap is recommended (Figure 1E). With the use of a Hill-Ferguson retractor, a longitudinal incision is made toward the perianal skin, from the dentate line to the end of the stenosis. The length of incision corresponds to the length of the flap wall. Proximal and distal transverse incisions are centered on the longitudinal incision. The flap is then designed in the shape of a house with the base oriented proximally. The width of the base of the house is designed to match the transverse incisions and hence the width of the mucosal defect to be replaced. It is necessary to preserve the subcutaneous vascular pedicle<sup>[2,7,26,31,32]</sup>. The flap is then easily advanced into the anal canal and sutured. This procedure offers two advantages: (1) the creation of a wide flap increases the anal canal diameter along its length, (2) the technique allows primary closure of the donor site.

#### **U flap**

This procedure is used for the treatment of anal stenosis associated with mucosal ectropion. A U-shaped incision is made in the adjacent perianal skin (Figure 1F). Mobilization and suture of the flap are the same as for diamond-shaped anoplasty. The donor site is left open, and covered with fatty gauzes.

#### **C flap**

This procedure is performed in the lithotomy position.

Table 1 Anoplasty for anal stenosis

Procedures	Indications	Advantages/Disadvantages
Partial lateral internal sphincterotomy	Functional stenosis; mild and low stricture in the anal canal	This technique is simple and safe. Use is limited to functional stenosis
Mucosal advancement flap	Middle or high localized stricture	Ectropion formation if the flap is sutured at the anal verge
Y-V advancement flap	Low and localized stricture below the dentate line	Proximal part of the flap is very narrow and will not allow for a significant widening of the stricture above the dentate line. Also, the tip of the V within the anal canal is subject to ischemic necrosis from lack of mobilization, tension of the flap or loss of vascularization
V-Y advancement flap	Mild to severe stricture at the dentate line. Middle or high localized strictures, associated with mucosal ectropion	The tip of the V is subject to ischemic necrosis
Diamond flap	Moderate to severe long stricture, localized or circumferential stricture above the dentate line, associated with mucosal ectropion	A diamond-shaped flap is designed so that it will cover the intra-anal portion of the defect. The flap is mobilized with minimal undermining to preserve the integrity of the subcutaneous vascular pedicle
House flap	Moderate to severe long stricture, localized or circumferential or diffuse, and stricture above the dentate line, associated with mucosal ectropion	It allows primary closure of the donor site and increases anal canal diameter along its length. Because of the wide base, it avoids the pitfall of having a narrow apex present inside the anal canal that may become ischemic
U flap	Moderate to severe stricture, localized or circumferential, associated with mucosal ectropion	This technique is particularly useful when there is need to excise a significant area of ectropion. The donor site is left open
C flap	Moderate to severe stricture, localized or circumferential, associated with mucosal ectropion	The donor site is left open
Rotational S flap	High severe stricture, circumferential or diffuse, associated with mucosal ectropion	It provides for adequate blood supply, avoids tension, and can be performed bilaterally if necessary for coverage of large areas of skin. Complex technique: high morbidity and longer hospital stay

With the use of a small Hill-Ferguson retractor, a radial lateral incision is made from the dentate line to the anal verge. Then a C-shaped incision is made in the perianal skin starting from the distal point of radial incision. Preparation of a C flap should guarantee an adequate blood supply.

### Rotational S-flap

The S-plasty is best used for the treatment of Bowen's disease or Paget's disease, where a large amount of skin has to be excised and new skin rotated into the area<sup>[29,33]</sup>. The S-plasty does not open a stricture as well as the advancement flap. In the gynaecological prone position, after scar tissue has been excised, a full-thickness S-shaped flap is made in the perianal skin, with the size of the base as great as its length, starting from the dentate line for approximately 8 cm to 10 cm. The flap is then rotated and sutured to the normal mucosa (Figure 1G).

### Internal pudendal flap anoplasty

A solitary case report has been reported where extensive coverage was required concomitant with excision of Paget's disease of the anal canal<sup>[34]</sup>.

### Foreskin anoplasty

This interesting operation has been described for the treatment of mucosal ectropion. The procedure uses the foreskin (suitable prepuce) to provide a full-thickness skin graft to the anal canal. Since the initial report by Freeman with six children in 1984<sup>[35]</sup>, no further publications have been noted.

### Choice of procedure

The choice of an adequate procedure is related to the

extent and severity of the stenosis (Table 1) as it may involve the skin, transitional zone to the dentate line, anal canal, or all of these. Y-V anoplasty is not used in the treatment of stricture above the dentate line. V-Y anoplasty has been used in the treatment of severe low anal stenosis with good results.

Various types of anoplasties with adjacent tissue transfer flaps have been devised to relieve anal stenosis. All of these flaps share the concept of an island of anoderm that is incised completely around its circumference. A significant advantage of these flaps over the Y-V anoplasty is that there is significantly greater mobility of the flap, so it can be advanced well into the anal canal. The diamond flap, House flap, and island flap have all been reported to yield excellent results<sup>[3-8,10,15,19,20,22-32,34-44]</sup>. The type of flap to be used is based on the surgeon's familiarity and choice as well as the patient's anatomy and the availability of adequate perianal skin for use in the various flaps. For any of these flaps, the preoperative preparation is the same as for the Y-V flap. A partial lateral internal sphincterotomy is often required as well. Once the flap is fully mobilized, it can be advanced into the anal canal and sutured in place with interrupted long-term absorbable sutures. Similar to the Y-V flap, these flaps can be done in any location and can be done bilaterally if needed.

The House flap is recommended if stenosis extends from the dentate line to perianal skin, allowing primary closure of the donor site and an increase in anal canal diameter along its length. U flap anoplasty is used for the treatment of anal stenosis associated with mucosal ectropion. If less than 50% of the anal circumference is involved, an advancement flap should suffice; however, if 50% or more of the anal canal needs to be recon-

structed, a rotational flap of skin should be considered, as it is necessary to cover a large area providing adequate blood supply and avoiding tension.

### Postoperative care

Single and limited flaps may be performed in the outpatient setting. For the simplest procedures, patients are started on a high-fiber diet, bulk laxatives and mineral oil for a short time in the postoperative period. Sitz baths and showers are recommended for comfort and hygiene. Flaps with multiple and extensive dissection or reconstruction will require hospital admission. These extensive procedures may require bowel confinement for 3 d to 5 d after which a high-fiber diet is initiated.

### Complications

In the literature, various complications have been reported after anoplasty. These include flap necrosis from loss of vascular supply, infection or local sepsis, suture dehiscence from excessive suture line tension, failure to correct the stenosis, donor site problems, sloughing of the flap, ischemic contracture of the edge of the flap, pruritus, urinary tract infection subsequent to *Clostridium difficile* enterocolitis only in a few cases, fecal incontinence, constipation without stenosis, urinary retention, restenosis and ectropion if the flap is advanced too far and sutured at the anal verge<sup>[4-7,10,15,19,20,22,23,25,26,31,32,34,36-39,41,42,44]</sup>.

## COMMENTS

Anal stenosis, although rare, is one of the most feared and disabling complications of anorectal surgery. It has been documented that hemorrhoidectomy is the most frequent cause, but stenosis may be a consequence of other causes. Several operative techniques to treat hemorrhoids have been described. Milligan-Morgan's open hemorrhoidectomy is most commonly used; other procedures, such as Ferguson's closed hemorrhoidectomy and Parks' submucosal hemorrhoidectomy, are technically more complex. We feel that the surgeon's choice of technique is primarily based on personal experience and technical training, and only a competently performed technique produces satisfying results: hemorrhoidectomy needs skilled operators. If technical guidelines are rigorously followed, the feared complications associated with surgical procedures, such as anal stricture and sphincteric injuries, are largely reduced.

Furthermore, anal stenosis became a focus of interest after the introduction of SRM. Anorectal stenosis is not a specific problem of SRM but is a considerable problem after all anal interventions. In a direct comparison in prospective randomized trials there was no significant difference in stenosis rate between conventional hemorrhoidectomy and SRM. Nevertheless, a substantial rate of stenoses was observed following conventional hemorrhoidectomy, and probably the highest stenosis rate was described after Whitehead hemorrhoidectomy. One potential mechanism that might cause stenosis following SRM is ring dehiscence followed by submucous inflammation. Another theoretical cause is that the

stapled ring is placed too deep in the anal canal and that the squamous skin cells react by scarring and shrinking. One major aspect of the potential risk of developing a stenosis is the distance to the anal verge. A full thickness excision of the rectal wall is another potential cause for stenosis after SRM.

A number of corrective surgical procedures have been designed aiming to bring a healthy lining to the narrowed portion of the anal canal. Since more complex techniques, such as S-plasty, have now been abandoned due to high morbidity and longer hospital stay, easier techniques are still being performed with good results (Table 2). The ideal procedure should be simple, should lead to no or minimal early and late morbidity, and should restore anal function with a good long-term outcome.

Each of the surgical techniques described can be performed safely and have been used with variable healing rates. It is extremely difficult to interpret the results of the various anaplastic procedures in the literature for the obvious reason that prospective trials have not been performed. There are no controlled studies on the advantages and disadvantages of the various anaplastic maneuvers; however, almost any approach will at least improve symptoms in the patient. Oh and Zinberg<sup>[41]</sup> used C anoplasty in 12 patients with anal stenosis (10 by previous hemorrhoidectomy, 1 by fistulectomy and 1 by fissurectomy), and 11 patients obtained satisfactory results with a total healing rate of 91%. Khubchandani<sup>[3]</sup> published a study in which 53 patients underwent mucosal advancement flap anoplasty with a healing rate of 94%. Similar results have been reported in a total of 33 patients treated with Y-V anoplasty in two studies<sup>[23,28]</sup>. A total healing rate of 100% was obtained using diamond flap anoplasty in a total of 23 patients affected by anal stricture and mucosal ectropion. The healing rate was 91.5% in 53 patients who suffered from anal stenosis and ectropion treated with island flap anoplasty<sup>[29,39]</sup>.

Aitola and coworkers<sup>[25]</sup> conducted a retrospective study in 10 patients who had undergone Y-V anoplasty combined with internal sphincterotomy between 1991 and 1995. After a median follow up period of 12 mo, all but one patient improved. Six patients had good results, three had fair results and in one the result was poor. This patient later developed a restenosis. Total healing rate was 60% with improvement rate of 30%. In a recent study<sup>[5]</sup>, a Y-V anoplasty was performed in 29 cases and a diamond flap anoplasty in the remaining 13 cases. At 2 years follow-up, all patients who underwent diamond flap anoplasty had complete resolution of the stenosis (healing rate 100%). Among 29 patients who underwent Y-V anoplasty, 26 (90%) judged their clinical results as excellent while 3 patients (10%) required periodical use of anal dilators. Those three patients had post-operative complications (two suture dehiscence and one ischemic contracture of the edge of the flap).

Rakhmanine and colleagues<sup>[24]</sup> published a study in which 95 patients underwent lateral mucosal advancement anoplasty. Mean follow up was 50 mo. Only 63% of patients had undergone previous surgery: 35 patients

Nr: Not reported. <sup>1</sup>No sphincterotomies were done; <sup>2</sup>Not all patients underwent sphincterotomy, and some of the procedures were for anal ectropion; <sup>3</sup>Depending on the degree of stenosis, patients initially underwent either unilateral (62%) or bilateral (38%) anoplasty. Thirteen patients with a follow up of less than 6 mo were excluded from the analysis for restenosis.

had had hemorrhoidectomy, 10 operations for anal fissure, 4 for fistula, 1 transversal excision of a neoplasm and 10 other operations. The overall complication rate was 3% (one abscess and two seepage of liquid stool).

## CONCLUSION

Anal stenosis is most often a preventable complication. A well-performed hemorrhoidectomy is the best preventative measure. Anoplasty should be part of the armamentarium of colorectal surgeons for treating severe anal stenosis. The anatomic configuration of the anorectum and perianal region is very complex and knowledge of this area is essential before performing any surgical procedure. Most post-anoplasty complications can be avoided by respecting the rectal wall anatomy in the execution of surgical procedures. The preparation of flaps is important for treatment success. In all cases, in fact, it is necessary to preserve as much sub-cutaneous fat as possible with wide mobilization, and to maintain viability and to avoid excessive suture line tension. In addition, it is important to treat tissues delicately and not to draw them, to use absorbable sutures and perform minimal tissue resection.

### Abstract

Paraoxonase-1 (PON1) is an esterase and lactonase synthesized by the liver and found in the circulation associated with high-density lipoproteins. The physiological function of PON1 seems to be to degrade specific oxidized cholesteryl esters and oxidized phospholipids in lipoproteins and cell membranes. PON1 is, therefore, an antioxidant enzyme. Alterations in circulating PON1 levels have been reported in a variety of diseases involving oxidative stress including chronic liver diseases. Measurement of serum PON1 activity has been proposed as a potential test for the evaluation of liver function. However, this measurement is still restricted to research and has not been extensively applied in routine clinical chemistry laboratories. The reason for this restriction is due to the problem that the substrate commonly used for PON1 measurement, paraoxon, is toxic and unstable. The recent development of new assays with non-toxic substrates makes this proposal closer to a practical development. The present editorial summarizes PON1 biochemistry and function, its involvement with chronic liver impairment, and some aspects related to the measurement of PON1 activity in circulation.

### INTRODUCTION

The paraoxonase (PON) enzyme family comprises 3 members, PON1, PON2 and PON3, whose genes are located adjacent to each other on chromosome 7q21-22<sup>[1]</sup>. In humans, PON1 and PON3 are mainly found in the circulation bound to high-density lipoproteins (HDL)<sup>[2]</sup>. Conversely, PON2 is an intracellular enzyme<sup>[3]</sup>. Their physiological roles have not been completely ascertained. PON1 has esterase and lactonase activities<sup>[4]</sup> and is involved in protection against xenobiotic toxicity<sup>[5]</sup>. PON2 and PON3 have only lactonase activity<sup>[6]</sup>. All the PONs are able to reduce low density lipoprotein (LDL) oxidation<sup>[7]</sup>, while PON2 reduces cellular oxidative stress and prevents apoptosis in vascular endothelial cells<sup>[8]</sup>. PON1 is the best known among these enzymes. Alterations in circulating PON1 levels have been reported in a variety of diseases involving oxidative stress. These include cardiovascular disease, Alzheimer's disease, chronic renal failure, HIV-infection, metabolic syndrome, and chronic liver impairment<sup>[9]</sup>. As such, increased knowledge of the physiological significance of PON1 and its involvement in human pathology would be of critical importance in the years to come. In the present article we review fundamental concepts regarding PON1 biochemistry and function, and the relationships with chronic liver diseases. We also discuss the possible application of its measurement in serum for an improved evaluation of hepatic function.

### PON1 IS AN ANTIOXIDANT ENZYME

The first approximation to the physiological role of PON1 was suggested by Mackness *et al*<sup>[10]</sup>. The authors investigated the protection against copper-induced LDL oxidation *in vitro* provided by purified PON1. They observed that this enzyme prevents the generation of

lipoperoxides during the process of LDL oxidation. Further studies from this and other groups reached the conclusion that PON1 protects LDL and HDL from lipid peroxidation by degrading specific oxidized cholesteryl esters and specific oxidized phospholipids contained in oxidized lipoproteins<sup>[11-13]</sup>. PON1 is, in turn, inactivated by oxidized lipids. This was shown by Aviram *et al*<sup>[14]</sup>, who demonstrated that the incubation of PON1 *in vitro* with oxidized palmitoyl arachidonoyl phosphatidylcholine, lysophosphatidylcholine, and oxidized cholesteryl arachidonate, inactivated PON1 activity, as well as did oxidized LDL. Cysteine-284 was required for this effect of oxidized lipids on PON1 because, in recombinant PON1 in which this amino acid had an induced mutation, no inactivation was observed. A further article from the same group showed that, under oxidative stress, PON1 may be inactivated by  $\gamma$ -glutathionylation, a redox regulatory mechanism characterized by the formation of a mixed disulfide between a protein thiol (i.e. cysteine-284) and oxidized glutathione<sup>[15]</sup>.

Identifying the native function of PON1 has, for a long time, been hampered by confusion with respect to the structure and mechanism-of-action of this enzyme. Several studies established the primordial function of PON1 as that of a lipolactonase<sup>[16-18]</sup> which subsequently evolved new substrate specificities. These studies also established that the preferred substrates of PON1 are 5- and 6-membered ring lactones, typically with aliphatic side-chains<sup>[19]</sup>. A model has been proposed to link lactonase activity and the degradation of lipid peroxides<sup>[20]</sup> by which oxidized lipids containing hydroxyl groups at the 5'-position could be lactonized by PON1 to yield lysophosphatidylcholine and  $\delta$ -valerolactone products. As such, according to this hypothesis, the PON1 ability to degrade lipid peroxides is secondary to its lipolactonase activity.

## PON1 IS ESSENTIALLY SYNTHESIZED BY THE LIVER

PON1 is found mainly in serum and in the liver. Northern blot analysis performed in human and rabbit tissues detected *PON1* mRNA only in the liver, although reverse transcriptase PCR (RT-PCR) studies in mice identified *PON1* mRNA in liver, kidney, heart, brain, intestine, and lung<sup>[1]</sup>. It seems highly likely that the liver is the main source of serum PON1 since it is the organ with the highest *PON1* gene expression, and where an important percentage of HDL is synthesized and secreted into the circulation. Over the last 15 years, there have been several attempts to purify hepatic PON1 to homogeneity with the aim of comparing its properties with those of the serum enzyme. This task is complicated by the hepatic PON1 being an enzyme associated with membrane vesicles derived from the endoplasmic reticulum<sup>[21]</sup>.

In 1993, the first method for the partial purification of rat liver PON1 was published<sup>[22]</sup>. Essentially, the process consisted of the preparation of microsomes, solubilization with Triton X-100, adsorption on to hydroxyapatite, and chromatography with DEAE-52

cellulose to yield a 77-fold purified product. Later, Huang *et al*<sup>[23]</sup> isolated PON1 from mouse hepatic microsomes, and Rodrigo *et al*<sup>[24]</sup> in 1997, purified rat liver PON1 to homogeneity. They achieved a 415-fold purified product by using hydroxyapatite adsorption followed by three chromatography steps including DEAE-Sephacrose, affinity chromatography, and Mono Q HR fast-performance liquid chromatography. The N-terminal sequence and two internal sequences of the purified protein were similar to those of rabbit and human PON1 of serum and mouse liver PON1. Subsequent studies with rat and human liver PON1 demonstrated many biochemical characteristics in common with those of serum PON1. These included optimum pH, substrate affinity ( $K_M$ ), kinetic constants, heat inactivation, and calcium requirement<sup>[25]</sup>; all of which strongly suggested a high degree of identity between both enzymes.

What is the true role of hepatic PON1? If HDL-bound serum PON1 is an antioxidant enzyme, it may not seem illogical to infer that a similar function could apply to intracellular PON1. Indeed, liver microsomes are the major sites for the catabolism of xenobiotic compounds, in the course of which process an increased production of free radical species is observed. Rodrigo *et al*<sup>[26]</sup> observed PON1 protein expression mainly in the hepatocytes from the centrolobular region, thus supporting the hypothesis of intrahepatic PON1 participation in oxidative by-product inactivation.

## OXIDATIVE STRESS AND CHRONIC LIVER IMPAIRMENT

Increased oxidative stress and inflammation play a fundamental role in the onset and development of liver diseases. The most important causes of chronic liver disease are alcohol abuse, obesity, and hepatitis C virus infection.

Alcoholic liver disease (ALD) comprises a broad spectrum of hepatic alterations ranging from steatosis and minimal injury to advanced fibrosis and cirrhosis<sup>[27]</sup>. The involvement of oxidative injury in ethanol toxicity has emerged from reports showing that alcohol-fed animals and patients with ALD present with a high content of lipid peroxidation products in their livers and in the circulation<sup>[28]</sup>. Oxidative stress associated with ethanol intake comes mainly from reactive oxygen species (ROS) generated by the mitochondrial respiratory chain and cytochrome P4502E1 from hepatocytes, and the NADPH oxidase from Kupffer cells and recruited macrophages<sup>[29]</sup>. The impairment of mitochondrial lipid oxidation is one of the mechanisms responsible for hepatic fat accumulation<sup>[30]</sup>. Pan *et al*<sup>[31]</sup> reported that lipid peroxidation reduces hepatic lipoprotein secretion by enhancing the degradation of newly synthesized apolipoproteins and this effect, together with alterations in lipoprotein glycosylation in the Golgi apparatus<sup>[28]</sup>, might contribute to microvesicular steatosis. Further evidence suggests that alcohol-induced oxidative stress interferes with the regulation of lipid synthesis by the peroxisome proliferator-activated receptor- $\alpha$  and the sterol

regulatory element binding protein 1<sup>[32]</sup>. The possible role of oxidative stress in promoting an inflammatory reaction in ALD has emerged from the observation that ethanol-induced lipid peroxidation increases the hepatic production of cytokines, growth factors, and collagen<sup>[33-35]</sup>.

Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are hepatic lesions which appear frequently in obese and diabetic individuals despite the fact that they may not have a history of alcohol abuse. These lesions resemble those of ALD, and are characterized by steatosis, hepatocyte hydropic degeneration, and inflammatory infiltrates. In addition, alterations in mitochondrial shape and function, and varying degrees of fibrosis are usually found<sup>[36]</sup>. NAFLD is an emerging lesion in modern societies, and will become more prevalent in the future, as it is associated with insulin resistance, metabolic syndrome, diabetes, and obesity. Oxidative stress plays a pivotal role in the evolution of "benign" steatosis to the more severe NASH. Several studies have shown that mitochondria in patients with NASH are abnormal from both the morphological and the functional points of view and, as in ALD, alterations in the fatty acid  $\beta$ -oxidation promote increased free radical production and lipid peroxidation<sup>[36]</sup>. The consequences of oxidative stress in NASH would be similar to those of ALD, with altered lipoprotein synthesis and secretion, an inflammatory reaction, and fibrosis.

Hepatitis C virus (HCV) is a major cause of viral hepatitis. In the USA, about 4 million people are infected, and 35 000 new HCV cases are estimated to occur every year<sup>[37]</sup>. The infection by this virus frequently does not resolve, and about 80% of the infected individuals become chronic carriers who may then progress to the most severe forms of liver impairment, as cirrhosis or hepatocellular carcinoma. Lipid peroxidation products, aldehydes as 4-hydroxynonenal, and 8-hydroxyguanosine (a marker of oxidative DNA damage) are elevated in HCV infection<sup>[38]</sup>. The increased oxidative stress may be explained by chronic inflammation and the generation of free radicals by Kupffer cells and recruited macrophages. The NS3 protein of HCV has been found to activate Nox 2 protein from macrophages, leading to increased generation of ROS that can exert oxidative stress to the nearby cells<sup>[39]</sup>. Furthermore, studies have indicated that HCV can directly induce oxidative stress in hepatocytes. HCV core gene expression has been associated with increased ROS, decreased reduced glutathione content, and increased thioredoxin in parenchymal cells. Recent studies showed that HCV core proteins bind to the outer mitochondrial membrane resulting in mitochondrial dysfunction by  $\text{Ca}^{2+}$  accumulation. These alterations would inhibit electron transport and promote ROS production<sup>[37]</sup>. Another HCV protein, NS5A, has also been reported to increase free radical production by Huh7 cells<sup>[40]</sup>. As in ALD and NASH, increased oxidative stress would produce a multifactorial reaction involving the synthesis of pro-inflammatory and pro-fibrogenetic cytokines and chemokines.

Therefore, it seems evident that chronic liver diseases share common biochemical alterations irrespective

of their etiology. They are all accompanied by an increased oxidative stress secondary to mitochondrial abnormalities, promoting changes in lipid and lipoprotein metabolism, fat accumulation, an exacerbation of the inflammatory reaction due to increased cytokine synthesis, and extracellular matrix deposition.

## THE MEASUREMENT OF SERUM PON1 ACTIVITY

There are no standardized methods for measuring PON1 esterase activity. The most widely used method is the hydrolysis of paraoxon. However, this method is not free of drawbacks, because paraoxon is very unstable and extremely toxic. The solution to the former problem is to prepare the reagent immediately before use. The solution to the latter problem requires that the stock solutions be handled in an air-extraction cupboard and the operator to take appropriate safety precautions such as wearing masks and gloves to protect against accidental contact or inhalation of the toxic fumes. Recent significant advances in the search for reliable PON1 lactonase activity assays may facilitate the measurement in a routine clinical chemistry laboratory setting. A new serum test based on this capacity of PON1, and employing 5-thiobutyl butyrolactone (TBBL) as a substrate, was recently proposed<sup>[41,42]</sup>. TBBL is a synthetic chromogenic lactone that resembles the natural lipolactone substrate of PON1. The method enables PON1 activity to be measured using a more 'physiological-like' substrate.

## SERUM PON1 ACTIVITY IN CHRONIC LIVER IMPAIRMENT

In chronic liver diseases, oxidative stress influences the pathophysiological changes leading to liver cirrhosis and to hepatocellular carcinoma. Since PON1 exerts a protective effect against oxidative stress, it is logical to find an association between this enzyme and liver impairment. Ferre *et al.*<sup>[43]</sup> observed, in rats with carbon tetrachloride-induced fibrosis, that an inhibition of hepatic PON1 activity was an early biochemical change related to increased lipid peroxidation and liver damage. They investigated the relationships between hepatic microsomal PON1 activity, lipid peroxidation and the progress of the disease in this experimental model. They found that PON1 activity decreased while lipid peroxidation increased in carbon tetrachloride-administered rats while the addition of zinc, which possesses antioxidant and anti-fibrogenetic properties, was associated with enhanced PON1 activity and a normalization of lipid peroxidation. This study suggested that PON1 activity may be involved in the defence against free radical production in liver organelles.

Pioneer studies in the 1970's observed for the first time a significant decrease in serum PON1 activity in small groups of patients with liver cirrhosis<sup>[44,45]</sup>. This results were confirmed by Ferre *et al.*<sup>[46,47]</sup> in a wider series of patients with various degrees of chronic liver damage. These latter studies noted a significant decrease of serum

PON1 activity in patients with chronic hepatitis, and an even greater decrease in cirrhotic patients, compared to a control group. In alcoholic patients, the effects of alcohol intake on serum PON1 levels depend on the degree of liver dysfunction. In a study conducted in chronic alcohol abusers, subjects were classified into several sub-groups according to their degree of liver disease. The results demonstrated that serum PON1 activity was decreased in alcoholic patients, and that the magnitude of the alteration was related to the degree of liver damage<sup>[48]</sup>. These findings differ from those described in normal volunteers reporting moderate alcohol consumption, and in whom serum PON1 activity and HDL cholesterol were found to be slightly increased<sup>[49]</sup>. Changes in serum PON1 activity has also been studied in relation to outcomes of liver transplantation in patients with severe liver disease<sup>[50]</sup>. The serum PON1 activity was low, but tended to increase, in liver transplanted patients when the hepatic arteries had become blocked. Since PON1 activity is closely related to the recovery of liver function, its measurement could provide more accurate information on the success, or otherwise, of the liver transplant.

Serum PON1 measurement has been proposed as an useful test for the evaluation of the degree of liver impairment. Clinical diagnosis of chronic liver impairment and/or liver fibrosis is currently conducted *via* the invasive procedure of needle biopsy followed by histological evaluation. This procedure has important drawbacks, including a significant mortality rate (1/10000-1/1000), sampling error, and subjectivity. Therefore, the development of non-invasive tests for the diagnosis of liver disease and the extent of the disease is an important goal of current research. Unfortunately, most of the individual laboratory tests to assess liver impairment have low specificity and sensitivity and, hence, the standard approach is to perform a battery of several tests followed by an algorithmic evaluation of the results. It is for this reason that several years ago, Ferre *et al*<sup>[46]</sup> proposed the addition of serum PON1 paraoxonase activity measurement as a biomarker of liver impairment. Serum PON1 measurement has an important feature in that the measured value is inversely related to the degree of liver derangement i.e. it decreases while most of the standard laboratory test values increase with the extent of the disease. Thus, PON1 measurement makes an additional contribution in improving current algorithms, and the ratios between tests. These authors estimated, by multiple logistic regression analysis, that the addition of paraoxonase measurement to a battery of standard liver function tests increased the overall sensitivity up to  $\geq 90\%$ , while keeping the specificity close to 100%. However, the measurement of this enzyme is, to-date, restricted to research laboratories and has not been extensively applied as yet in routine clinical chemistry laboratories, due to the problems associated with the use of paraoxon as a substrate. These drawbacks preclude full automation of PON1 measurement and, as such, can rarely be justified for inclusion in panels of standard biochemical tests. The recent development of new assays, such as the TBBL lactonase assay, makes this proposal closer to practical development. The TBBL assay has been

shown to be equivalent to the paraoxon assay in terms of diagnostic accuracy<sup>[42]</sup>, but with better safety of the TBBL substrate for the laboratory worker, and makes the lactonase measurement a strong candidate for inclusion into routine clinical laboratory testing of liver impairment, or for the study of other diseases involving oxidative stress.

## CONCLUSION

Research into paraoxonases has flourished over the last 10 years. It seems now evident that PON1 is a lactonase with the ability to degrade lipid peroxides in lipoproteins and in cells, and that plays a protective role against oxidative stress and inflammation, which are key processes involved in the pathophysiology of chronic liver diseases. In the years to come, more reliable, practical, and accurate methods to measure PON activity and concentration will become available and these will facilitate more research in this field, and also enable the addition of PON measurement to the battery of routine analyses in clinical chemistry laboratories.

## Abstract

Capsule endoscopy (CE) is a novel technology that facilitates highly effective and noninvasive imaging of the small bowel. Although its efficacy in the evaluation of obscure gastrointestinal bleeding (OGIB) has been proven in several trials, data on uses of CE in different small bowel diseases are rapidly accumulating in the literature, and it has been found to be superior to alternative diagnostic tools in a range of such diseases. Based on literature evidence, CE is recommended as a first-line investigation for OGIB after negative bi-directional endoscopy. CE has gained an important role in the diagnosis and follow-up of Crohn's disease and celiac disease and in the surveillance of small bowel tumors and polyps in selected patients. Capsule retention is the major complication, with a frequency of 1%-2%. The purpose of this review was to discuss the procedure, indications, contraindications and adverse effects associated with CE. We also review and share our five-year experience with CE in various small bowel diseases. The recently developed balloon-assisted enteroscopies have both diagnostic and therapeutic capability. At the present time, CE and balloon-assisted enteroscopies are complementary techniques in the diagnosis and management of small bowel diseases.

## INTRODUCTION

Examination of the small bowel (SB) has been considered a challenge for several anatomical (i.e. distance from external orifices, length) and physiological (i.e. active peristalsis) reasons. Conventional techniques of endoscopy are limited by length while radiologic examinations, such as barium studies, are insensitive for the evaluation of pathology in the SB. An ingestible miniature camera device capable of obtaining images of the whole small intestine was developed due to a need for the exploration of this "final frontier". Video capsule endoscopy (CE) is a breakthrough in medical history for noninvasive imaging of the entire small intestine<sup>[1-3]</sup>. It was first introduced in 2000, and since then more than 700 studies have been published, which is indicative of its ease and the widespread acceptance of this new diagnostic tool<sup>[4]</sup>. According to reports by Given Imaging, more than 650 000 CEs have been performed, representing an increase in the utilization of this technology of approximately 15% over the previous year<sup>[5]</sup>. Problems with reimbursement, physician training, time requirements for interpretation and lack of therapeutic capability limit the further widespread use of this technology.

A wide range of uses for CE has been reported in the literature, but the majority of the studies have aimed to evaluate the cause of obscure gastrointestinal bleeding (OGIB). Recent studies showed the superiority of CE over conventional methods, but passive features such as inability to insufflate the bowel and to biopsy and lack of therapeutic capability have generated a debate on its advantages<sup>[6-14]</sup>. Newly developed balloon assisted enteroscopes are also available and have the potential to outscore CE in terms of diagnostic indications and therapeutic applications.

The purpose of this article was to review and share our institution's results using small bowel CE, with special reference to the existing literature.

## PROCEDURE

### Technical features of the capsule

The Given M2A (Given Imaging, Yoqneam, Israel) video CE is a pill-shaped wireless device with a slippery coating for easy ingestion and measures 11 mm × 26 mm. It is composed of a white light-emitting diode as light source, lens, imaging chip, batteries and a radio transmitter with internal antenna. The image field is 140 degrees and magnification is × 8<sup>[4]</sup>. Once swallowed, the capsule moves thorough the intestine *via* peristalsis and is excreted in the stool. The camera takes two images per second as it sweeps the intestine and transmits these to eight lead sensor arrays, arranged in a specific manner and taped to the anterior abdominal wall, connected to a recording device in the belt for the duration of the battery life, which is 6-8 h. Once the study is completed, the recording device and sensor arrays are removed and the images (50 000-60 000 images total) are downloaded to a computer with reporting and processing of images and data (Rapid, Given Imaging) software that displays the video images on a computer monitor. This software includes a localizing system, blood detector and some features to assist the interpreter. The suspected blood indicator is quite good at detecting active bleeding, but is not so useful at detecting other lesions and does not replace careful examination of the CE. It is recommended that patients avoid magnetic fields such as magnetic resonance imaging (MRI), and metal detectors until the capsule is excreted in the stool, which usually occurs in 24-48 h.

### Bowel preparation

Pre-procedure bowel preparation is a controversial issue. Some favor the bowel preps and prokinetics. Incomplete SB transit during the examination occurs in about 20% of patients<sup>[6]</sup>; however, according to data from the international conference on capsule endoscopy, it was suggested that there was no need for routine use of bowel preparations<sup>[11]</sup>. We performed CE in an ambulatory outpatient setting, but there were some inpatients. All of the patients undergoing CE examination had bowel preparations before the procedure. Each patient was administered 3 L of polyethylene-glycol solution for bowel cleansing. Patients fasted overnight for at least 12 h before taking the capsule. After ingestion of the capsule, patients were allowed to drink clear liquids after 2 h and eat a light meal after 4 h and were observed for 8 h at the study site.

## INDICATIONS

Capsule endoscopy is mainly indicated for the evaluation of SB diseases, particularly for the diagnosis of OGIB. CE can be used in a variety of conditions including Crohn's disease (CD), malabsorption, chronic diarrhea, evaluation

Table 1 Indications and contraindications of capsule endoscopy

Indications	Contraindications
Small bowel	Absolute
Obscure gastrointestinal bleeding	Bowel obstruction
Overt GI bleeding	Extensive and active Crohn's
Occult (positive FOBT)	Disease ± strictures
Evaluation of iron deficiency anemia	Intestinal pseudo-obstruction
Crohn's disease	Young children (< 10 years)
Suspected Crohn's disease	Relative
Indeterminate colitis	Cardiac pacemakers
Assessment of mucosal healing	Implanted electromedical
Determine post-operative recurrence	Devices
Abdominal pain	Dysphagia
Graft-versus-host disease	Previous abdominal surgery
Surveillance of polyposis syndromes	Pregnancy
Celiac disease	Diverticulosis
Suspected small bowel tumors	
Follow-up of small intestine transplantation	
Evaluation of abnormal small bowel imaging	
Evaluation of drug induced injury	
Esophagus	
Barrett esophagus	
Esophagitis	
Variceal evaluation	

of refractory iron deficiency anemia, abdominal pain, polyposis syndromes, celiac disease, and detection of SB tumors. Graft versus host disease (GVHD) and follow-up of small intestine transplantation are rare indications, but our experience thus far did not include such patients. CE with high frame rate (PillCam Eso, Given Imaging) can be used for esophageal disorders, such as noninvasive evaluation of esophageal varices, esophagitis and Barrett's esophagus<sup>[11]</sup>. Table 1 shows the indications and contraindications for Capsule Endoscopy.

We reviewed our database in a retrospective evaluation of the characteristics and findings of patients who underwent CE examination between 2003 and 2008. All patients had upper and lower GI endoscopies before the CE study. There was no clinical sign of intestinal obstruction, but patients with suspected CD had radiologic examinations to exclude obstruction. A total of 120 CE examinations were performed from 2003 to 2008 for various indications. The average patient age was 47.7 ± 18.2 (min: 13 - max: 97), 45 were female (37.5%) and 75 male (62.5%). The CE completely evaluated the entire SB in 89 patients (74.2%). Indications for CE were OGIB (57.5% of cases), diarrhea (15%), abdominal pain (5.8%), other indications such as known CD, and surveillance for polyposis syndromes. CE study was normal without any finding in 22.5% of patients. We did not use CE for esophageal disorders and there were no findings suggestive of esophageal diseases.

### OGIB

Gastrointestinal bleeding is a common problem encountered by gastroenterologists during clinical practice. Proximal and distal bleeding sites are mostly identified by means of endoscopy and colonoscopy. The bleeding

**Figure 1** VCE images of lesions found in patients with obscure-overt GI bleeding. A: Multiple angiodysplasias in the jejunum; B: A jejunal mass with active bleeding; C: An ileal ulcer in a patient with newly diagnosed Crohn's disease. VCE images of small bowel polyps; D: Benign lymphoid hyperplasia located diffusely through the GI tract in a patient with CVID; E: A jejunal polyp in a patient with peutz-jeghers disease; F: Multiple small polyps in the ileum in the same patient depicted in Figure 1 E.

source is not identified in 3%-5% of cases despite the utilization of multiple studies<sup>[15,16]</sup>. OGIB is defined as bleeding from an unidentified source that persists and recurs after a negative endoscopy examination<sup>[16,17]</sup>.

Obscure GI bleeding is the most common indication for CE examination. CE has a high diagnostic yield in OGIB, which may lead to early diagnosis and revision of the management strategy. CE facilitates effective decision-making regarding subsequent investigations and treatments<sup>[4]</sup>.

Diagnostic yield of CE for OGIB varied between 31% and 91%<sup>[9,17-31]</sup>. Lema and Ruano-Ravina<sup>[32]</sup> reviewed the published studies of CE for OGIB and reported that sensitivity ranged from 79% to 95% and specificity from 75% to 100%. The positive predictive value (PPV) varied from 94% to 100% and the negative predictive value (NPV) from 80% to 100%. CE led to a change in therapeutic management in 9%-77% of patients. A recent study by Albert *et al*<sup>[33]</sup> reported that CE detected the bleeding source in 76.8% of patients.

The diagnostic yield of CE in OGIB depends on the type of bleeding. Pennazio *et al*<sup>[17]</sup> found that the highest yield of CE was in patients with active bleeding (92.3%) compared to those with obscure occult bleeding (44.2%). Researchers observed a reverse relationship between findings and time after last bleeding episode. The longer the time from last bleed, the lower the diagnostic yield. Do the lesions discovered by CE have any bleeding potential or clinical importance in terms

of management change? Saurin *et al*<sup>[18]</sup> showed that CE detects more lesions, but only half of them have true bleeding potential.

Several studies examined the diagnostic role of CE in OGIB and mostly compared the diagnostic yield of CE to other diagnostic modalities. CE is superior to other techniques in diagnosing the source of bleeding. The yield for CE is 63% and 67% compared with 28% for push enteroscopy (PE) and 8% for barium study<sup>[34]</sup>.

Obscure GI bleeding was the most common (57.5% of cases) indication for CE study in our cohort. SB ulcerations were found in 25.8% of patients. Angiodysplasias were present in 12.5% of cases (Figure 1A). Active bleeding was observed in 8.3% of patients. Figure 1B shows a jejunal mass, which was found to be adenocarcinoma, with active bleeding. Diagnostic yield of CE for OGIB was 72.5% in our series. We have been performing single balloon enteroscopy (SBE) (Olympus; Tokyo, Japan) and a few patients underwent both CE and SBE. CE revealed angiodysplasias in two patients with OGIB who were treated with argon plasma coagulation during SBE examination. Balloon assisted enteroscopy and CE should be used as complementary studies. It is advisable to use CE to detect lesions and direct enteroscopy for the therapeutic interventions.

### Crohn's disease

Crohn's disease is a chronic inflammatory disease that can involve any part of the GI system, and disease is

confined to the SB in about one-third of the patients. There is no single test to diagnose CD completely, so CD diagnosis can be established with a combination of clinical, endoscopic and histological findings. Most imaging studies lack sensitivity to identify early changes, and endoscopy does not allow total examination of the bowel. CE is able to identify mucosal changes before other technologies. It has a valuable role in the evaluation of the SB in patients with suspected or known CD. The use of CE in the diagnosis of small bowel CD has been examined in several studies. Triester *et al*<sup>[35]</sup> compared the yield of CE with other modalities in patients with suspected small bowel CD. Diagnostic yield of CE was 63% compared with 23% for barium radiography. When compared with ileocolonoscopy, CE had a higher yield (61% *vs* 46%). Compared with PE, CE had a 38% higher yield, and when compared with CT enterography, the yield of CE was 69% to 30%. Due to its high diagnostic yield, CE will have a very important place in the diagnostic workup of patients with CD, but more studies are needed to make such suggestions. Triester *et al*<sup>[35]</sup> reported in their meta analysis that there was no statistical significance in the incremental yield between CE and other diagnostic modalities in patients suspected of having CD. However, there was a significant difference in yield of CE over alternative methods in patients with known CD who were being evaluated for SB recurrence<sup>[35]</sup>. Yield of CE is low when performed in patients with abdominal pain alone; when other criteria are added, this yield is increased<sup>[34]</sup>.

Capsule endoscopy can be used for the assessment of mucosal healing after treatment. The only limitation of CE is its inability to offer biopsy for histological examination. A scoring system has been proposed to evaluate CD on the basis of CE findings of villous structure, ulceration and stenosis. Each variable is assessed by size and extent of the change<sup>[36]</sup>; however, further studies are needed to clarify the helpfulness of this system. The score provides a common language to quantify mucosal changes associated with any inflammatory process. The index does not diagnose or measure a disease, it measures mucosal change. In addition, this scoring index does not have the discriminatory ability to differentiate between illnesses. This index could be helpful in determining mucosal healing after therapy in CD<sup>[34]</sup>. Mucosal breaks and aphthous ulcers or erosions are also seen in asymptomatic healthy volunteers. Since non-steroidal antiinflammatory drugs (NSAIDs) may cause ulcerations resembling those of CD, patients should be advised to stop such drugs at least one month before the CE examination<sup>[10]</sup>. It is difficult to differentiate these findings with the presence of CD.

Mucosal ulcerations were the most common finding in our patient series, determined in almost one out of four patients. CD was the third most common indication for CE study (6.7% of patients). Patients with CD had severe ulcerations and two patients had strictures

that resulted in regional transit abnormality. However, no capsule retention occurred in this group. Moreover, CE changed the management strategy in 10% of patients with a new diagnosis of CD. Another interesting finding was that 37.5% of the patients diagnosed as suspected CD did not have complete examination. Nonspecific jejunoileitis and NSAID-induced erosions were observed in 6.7% of patients. Figure 1C shows a mucosal ulceration.

### Celiac disease

Celiac disease is an immune-mediated disease characterized by chronic SB inflammation that may result in mucosal atrophy, malabsorption and related clinical manifestations. Diagnosis is based on the combination of serologic, endoscopic and typical histological changes of the SB biopsy in clinically suspected patients. Its prevalence is around 1% in the United States. There are four endoscopic changes suggestive of villous atrophy: loss of mucosal folds, mosaic mucosal pattern, scalloping of the duodenal folds and nodularity of the mucosa<sup>[37]</sup>. It is no surprise that CE provides high resolution images that contain such changes. Rondonotti<sup>[38]</sup> evaluated 43 patients with signs or symptoms suggestive of celiac disease and positive serological markers. Patients underwent both CE and upper GI endoscopy. Characteristic histological changes were observed in 32 patients. Using this as a gold standard, 87.5% of patients were diagnosed by CE. Mucosal changes beyond the duodenum were detected in 18 (66.6%) patients and in 3 (11.1%) patients the whole SB was affected.

Another newly published study, searching for celiac disease in older adults, also showed that duodenal mucosa was normal in appearance on CE in 71% of patients, but classic abnormalities of celiac disease were present distally<sup>[39]</sup>.

Overall, CE can detect endoscopic markers of celiac disease. In addition, CE seems to be able to recognize the extent of disease and may be a tool for follow-up. CE has a high sensitivity (range, 70%-95.2%), specificity (range, 63.6%-100%) and high PPV and NPV (96.5%-100% and 71.4%-88.9%, respectively)<sup>[38,40-43]</sup>. When an atrophic pattern is detected by CE, the patient has a high probability of having celiac disease<sup>[37]</sup>. CE has also been reported to be able to demonstrate diseases such as adenocarcinoma, lymphoma or ulcerative jejunoileitis, which may complicate the course of celiac disease. A limitation is that CE is able to detect Marsh III lesions, which are associated with clear mucosal abnormalities, but may not distinguish between Marsh I and II lesions<sup>[37]</sup>. At present, CE is an alternative to endoscopy with biopsy in patients with suspected celiac disease who do not consent to the conventional methods.

Chronic diarrhea was the second most common indication for CE study in our series. Half of these patients did not have any condition that may cause diarrhea. Lymphoid hyperplasia and nodularity were observed in 6.7% of patients. Lymphoid hyperplasia due to common variable immune deficiency was detected in three pa-

tients. Celiac disease was investigated in only one patient but CE examination was completely normal. One patient with iron deficiency anemia had mucosal atrophy on CE examination and was diagnosed as having celiac disease. Figure 1D shows benign lymphoid nodular hyperplasia in a CVID patient.

### Small bowel tumors and polyps

Capsule endoscopy is a major advance in the diagnosis of SB tumors. Before the introduction of CE, malignant neoplasms of the SB were often diagnosed at a later stage of the disease, mostly during the work-up of obstructive symptoms. Diagnosis is delayed because conventional imaging techniques fail to detect small neoplasms in almost half of the patients. SB tumors are a rare disease, accounting for 1%-3% of all primary GI tumors. SB mass lesions are responsible for OGIB in up to 10% of patients<sup>[44-48]</sup>. Early clinical studies of CE have reported a frequency of SB tumors ranging between 6% and 9%<sup>[49-54]</sup>. This has led to an idea that CE doubled the rate of diagnosing SB tumors. However, a recent multicenter European study showed that the frequency of SB tumors was 2.4% and the most common indication for CE was OGIB<sup>[55,56]</sup>. SB tumors appear as masses or polyps in most patients and ulcer or stenoses in a minority of patients. It is not possible to distinguish the type of tumor based only on CE pictures. Most of the tumors reside in the mid SB<sup>[56]</sup>.

Capsule endoscopy is also useful for the surveillance of polyps in patients with inherited GI polyposis syndromes (familial adenomatous polyposis and Peutz-Jeghers syndrome), who are at increased risk of developing polyps in the SB. Several studies comparing the yield of CE to other imaging modalities in patients with polyposis syndromes have shown that CE is accurate in the detection of polyps. The same studies also emphasized that CE is not reliable for sizing and determining localization of polyps<sup>[57-60]</sup>. The duodenum is a potential blind point of CE because the capsule passes quickly with tumble and results in inadequate examination. Wong *et al*<sup>[61]</sup> reported that CE underestimated the total number of polyps and did not reliably detect larger polyps in that portion.

In our series, SB masses were diagnosed in 4.2% of patients who had tumor resection, and two patients had benign tumors. CE examination was done in only one patient with Peutz-Jeghers disease. CE revealed a few proximal jejunal polyps measuring < 2 cm (Figure 1E and F). Subsequent enteroscopy showed multiple jejunal polyps with diameters up to 8 cm. CE definitely has a potential for use in patients with polyposis syndromes, but more studies are needed.

### Other indications

Abdominal pain is one of the most common symptoms of patients referred to the gastroenterologist. Use of CE for the evaluation of abdominal pain is debated. Although some serious causes are identified in such patients, CE is mostly unyielding. If patients with other signs and symptoms of inflammation were selected, than

the diagnostic yield was considerably higher<sup>[62]</sup>.

Capsule endoscopy may be helpful in the diagnosis of the following diseases: surveillance for NSAID side effects, Henoch-Schönlein purpura, indeterminate colitis, protein losing enteropathy, intestinal lymphangiectasia, Meckel's diverticulum, follow-up of SB transplantation, GVHD, and bowel changes in refractory pouchitis<sup>[1-10,62]</sup>.

## COMPLICATIONS, LIMITATIONS AND SAFETY ISSUES OF CAPSULE ENDOSCOPY

Capsule endoscopy is a safe and well-tolerated procedure for patients, with very low complication rates. Contraindications to CE include the presence of intestinal obstruction, fistulas and strictures. Swallowing abnormalities and esophageal stricture are other contraindications for the procedure. Capsule retention is the major complication of CE. Retention is defined as the indefinite presence of a capsule in the SB. This is different from slow transit, incomplete transit or regional transit abnormalities. In these cases, the capsule stays in the ileum but ultimately passes *via* peristalsis. Retention can cause symptoms of SB obstruction that in turn lead to need for endoscopic or surgical removal of the capsule<sup>[63,64]</sup>.

Retention risk is high in patients with known CD, NSAID stricture, radiation enteritis and SB tumors. The capsule retention rate ranges from 0% to 13%. The rate of retention in patients with OGIB is 5% and in suspected CD 1.4%, and it can be as high as 8% in patients with known CD. Interestingly, no capsule retention was reported in healthy volunteers. The overall frequency of capsule retention is usually 1%-2%<sup>[10,63,64]</sup>. A negative SB series does not prevent capsule impaction<sup>[17]</sup>. It is advisable to perform abdominal radiographs within two weeks to identify capsule retention if the capsule did not enter the colon. Therapeutic intervention can be instituted anytime unless the patient becomes symptomatic<sup>[4]</sup>.

The patency capsule (Agile Patency System, Given Imaging Ltd; Yoqneam, Israel) has been developed for the detection of high-risk patients before the procedure. This capsule is identical to the video capsule, with the same dimensions, and is made of lactulose and 5% barium, which make the capsule radiopaque and it dissolves spontaneously after 40 h. The capsule has a radiofrequency identification tag that enables easy detection by a special handheld device. In a recent study that included patients with known strictures, no CE retention occurred if the patency capsule passed safely<sup>[65]</sup>. Although there are promising data on patency capsule use before CE, it is still not definitive to predict capsule retention based on results of barium studies or patency capsule.

Another theoretic risk is electromagnetic interference with implantable medical devices, pacemakers, *etc.* In a small series of patients, no adverse cardiac effect or

image distortion due to interference was noted. Large sample sized studies are needed to confirm the safety of capsule in this context<sup>[66]</sup>.

Reading the procedure is a time-consuming process and reading time is another limitation of this procedure. The optimal review rate is 15 images/s and it takes over 1 h to read a full 8-h procedure<sup>[62]</sup>. The reliable interpretation of the CE procedure requires experienced readers (experience of reading at least 20 studies).

Another clinical problem is sizing and locating SB lesions, since location and size are important findings for subsequent management. CE underestimates the number of SB polyps and does not reliably detect large polyps<sup>[61]</sup>. Technical problems related to the battery and failure of image downloading are also reported. The overall rate of technical failure is around 9%<sup>[10]</sup>. Incomplete study occurs due to delayed gastric emptying, previous SB surgery, hospitalization and poor bowel cleansing. A gastric transit time longer than 45 min was identified as a risk factor<sup>[67]</sup>. Reported incompleteness rates vary between 0% and 50%, approximately 20% to 30% in most studies<sup>[67]</sup>. Effect of prokinetic drugs on completion rates is uncertain. Real time viewers of CE may help to identify prolonged gastric stay and in such case, endoscopy can be done to push the CE into the SB.

The overall miss rate of CE is about 11%, ranging between 0.5% for ulcerative disease and 18.9% for neoplastic disease. Of course, this rate is much lower than conventional examinations<sup>[47]</sup>. Inability to take biopsy or perform any therapeutic procedure is also a limitation of the CE, which makes balloon assisted enteroscopies a good choice for a number of indications.

In our patient cohort, the most common cause for an incomplete examination was premature battery failure in 20 patients (16.7%), followed by technical problems, of the capsule itself, in seven patients (5.8%). No complication related to the CE procedure was observed. There was no capsule retention event. Two patients' studies showed regional transit abnormality. One was due to severe CD with stricture, and the other patient had an ileal adenocarcinoma that was diagnosed after operation for ileal perforation. Although there was a temporal relation of perforation to CE study (2 d after the study), no capsule was detected in the preoperative radiograms and CE was not the likely cause of perforation. There was no patient with an implantable cardio defibrillator or pacemaker among our cohort, but it seems safe to use the capsule in these patients. Based on our data, we can say CE is a safe procedure. Placing the capsule directly in the duodenum by means of dedicated devices or endoscopy may lower the incomplete examination rate. However, by doing so, we can miss esophageal and gastric disorders in which CE is also informative. Therefore, if selective placement of the capsule is preferred, the proximal GI tract should be carefully re-examined. Higher capture rate and longer battery life could resolve these obstacles.

## OTHER TYPES OF CAPSULE ENDOSCOPE

The Olympus Endo Capsule (Olympus; Tokyo, Japan) has been in the Turkish market for a while, but there is not yet sufficient experience with its use. It differs from the PillCam by having a high resolution image chip and an external real time viewer. There are additional SB capsule systems that are not currently available in Turkey. One is from China, the OMOM pill (Jinshan Science and Technology; Chongqing, China) and there is also a Korean model (MicroCam, Intromedic; Seoul, Korea)<sup>[68,69]</sup>. Both the capsule endoscopes are similar to the PillCam in terms of battery life, dimensions, field of view and picture intervals. The first trials of the MiRo capsule and OMOM capsule were published in 2008 but they were without FDA approval. The MiRo capsule uses a novel telemetry technology known as "electric-field propagation", which uses the human body as a conductive medium for data transmission. A pair of gold plates coated on the surface of the capsule acts as a transmitter. This is claimed to be superior in terms of battery life since the CE has few power-consuming components. Bang *et al.*<sup>[68]</sup> used this new capsule in 45 healthy adults and it produced good image quality and capture rates. This capsule may also be used for the colon due to the long battery life. The first trial of the OMOM CE revealed comparable results to the PillCam. The authors express the cost advantage over other CEs, which could affect the choice of CE systems because of reimbursement problems<sup>[69]</sup>. PillCam SB2 and EndoCapsule have real time viewer capability that may shorten the examination once the cecum is seen. PillCam ESO was specially designed for investigation of esophageal disorders. It may be an accurate noninvasive method for detection of esophageal varices and portal hypertensive gastropathy, but it may not be suitable as a screening tool for Barrett's esophagus<sup>[12]</sup>. PillCam COLON is bigger than the standard PillCam SB capsule (11 mm × 31 mm). It was developed for detection of colonic neoplasia. It is a promising tool but further studies and improvements are needed before its regular use<sup>[70]</sup>.

In summary, capsule endoscopy is a new diagnostic modality for the diagnosis and management of GI disorders. It is a simple and well-tolerated procedure. Capsule retention is the major complication. Care must be taken in patients with symptoms suggesting partial obstruction and CD. SB series and computerized tomography enteroclysis before CE may reveal stenosis. The newly developed patency capsule may be an alternative for detection of stenoses.

The value of CE in patients with OGIB appears to be high and is supported by high yields in the literature. CD and celiac disease appear to be areas where use of CE would be helpful. There may also be an indication for CE in CD surveillance and follow-up. The diagnostic role of CE extends beyond the SB. PillCam ESO and COLON showed promising outcomes in diagnosing esophageal and colonic diseases. More

research is needed to explore the feasibility of CE in these contexts.

Blind spots of CE such as the duodenum should be examined by a second look endoscopy before the CE procedure, especially in patients with OGIB. After negative endoscopic examinations, CE should be recommended as a first-line investigation over balloon assisted enteroscopies in view of its noninvasiveness, higher probability of visualizing the entire small intestine and the similar diagnostic yield of both investigations. Such an approach may decrease the time between diagnosis and intervention. A second look CE may reveal more findings in up to 35% of patients who had prior nondiagnostic CE.

## CONCLUSION

The newly announced CEs would fire up the competition for new innovations and possible cost reductions, making possible the widespread use of this technology. Improvement in capsule design for better luminal visualization by coupling with a second backward camera, higher frame rates for viewing and longer battery life will definitely overcome the blind spots resulting in complete and detailed examination of the whole GI tract from the mouth to anus with just one capsule, as the capsule named M2A has denoted.

### Abstract

**AIM:** To investigate the *in vivo* effects and mechanisms of silibinin on the growth of hepatocellular carcinoma (HCC) xenografts in nude mice.

**METHODS:** Nude mice bearing HuH7 xenografts were used to assess the anti-HCC effects and mechanisms of silibinin.

**RESULTS:** Silibinin resulted in a potent dose-dependent reduction of HuH7 xenografts in association with a significant decrease in Ki-67 and  $\alpha$ -fetoprotein production, nuclear NF- $\kappa$ B content, polo-like kinase 1, Rb phosphorylation, and E2F1/DP1 complex, but increased p27/CDK4 complex and checkpoint kinase 1 expression, suggesting that the *in vivo* effects of silibinin are mediated by inhibiting G1-S transition of the cell cycle. Silibinin-induced apoptosis of HuH7 xenografts was associated with inhibited survivin phosphorylation. Silibinin-reduced growth of HuH7 xenografts was associated with decreased p-ERK, increased PTEN expression and the activity of silibinin was correlated with decreased p-Akt production, indicating involvement of PTEN/PI3K/Akt and ERK pathways in its *in vivo* anti-HCC effects. Silibinin-reduced growth of HuH7 xenografts was also associated with a significant increase in AC-H3 and AC-H4 expression and the production of superoxide dismutase (SOD)-1.

### INTRODUCTION

Hepatocellular carcinoma (HCC) represents approximately 6% of all human cancers<sup>[1,2]</sup>. The global incidence of HCC has risen significantly in the past 2 decades<sup>[2]</sup>, and prognosis of HCC is usually poor<sup>[3]</sup>. Limited treatment options and the poor prognosis of HCC emphasize the importance of developing an effective chemoprevention for this disease.

Milk thistle (*Silybum marianum*) is a popular dietary supplement that has been reported to be safe, well-tolerated, and protects the liver from drug or alcohol-related injury<sup>[4]</sup>. Silibinin, the major biologically active compound of milk thistle is a polyphenolic flavonoid, and a strong antioxidant and radical scavenger<sup>[5-7]</sup>. Studies have demonstrated the inhibitory effects of silibinin on multiple cancer cell lines, including prostate, lung, colon, skin, and bladder cancers<sup>[8-16]</sup>. Recently, we and Varghese *et al*<sup>[17]</sup> reported the *in vitro* anti-HCC effects of silibinin<sup>[18]</sup>, however, additional studies are needed to further determine its *in vivo* inhibitory effects and mechanisms on the growth of human HCC. Clearly, nude mice bearing human hepatoma xenografts represent a suitable model for such a study<sup>[19,20]</sup>.

Plasma  $\alpha$ -fetoprotein (AFP) has been used as a

clinical marker in the diagnosis and monitoring of HCC<sup>[21-23]</sup>. We demonstrated that silibinin reduces AFP production and secretion from human hepatoma cells, but the AFP value in monitoring the *in vivo* anti-HCC effects of silibinin has not yet been tested.

Hepatocarcinogenesis is a complicated process that alters cell cycle progression and apoptosis. This may be mediated by altering signal transduction through cell cycle modulators, phosphatase and tensin homolog deleted on chromosome ten (PTEN), phosphatidylinositol 3'-kinase (PI3K) and Akt (PTEN/PI3K/Akt) pathways<sup>[24-30]</sup>, and histone acetylation<sup>[31-33]</sup>. p-Rb, p21, and p27 are molecules that are involved in cell cycle regulation<sup>[17]</sup>. Nuclear factor (NF)- $\kappa$ B activation stimulates G1 to S phase progression and transcription of a wide variety of genes that are involved in cell proliferation<sup>[34,35]</sup>. Checkpoint kinase 1 (Chk1) and polo-like kinase 1 (Plk1) are the up-stream molecules. Chk1 controls cell cycle progression and inhibits mitosis<sup>[36]</sup>. Plk1 has long been recognized as a potential target for cancer therapy. Inhibition of Plk1 function may increase anti-tumor activity *in vivo*<sup>[37]</sup>. It is unclear whether these pathways are involved in silibinin-mediated anti-HCC effects.

Studies have also indicated that signals related to reactive oxygen species (ROS) may play important roles in the development of HCC<sup>[38]</sup>. The cellular levels of ROS are regulated by the antioxidant defense systems, that is, the enzymatic activities of superoxide dismutase (SOD), catalase, glutathione peroxidase, and glutathione reductase<sup>[39]</sup>. Altered expression of SOD has been associated with the development and differentiation of HCC<sup>[40,41]</sup>. Silymarin significantly increased suppressed SOD activity in patients with chronic alcoholic liver disease<sup>[42]</sup>. However, it is unclear whether silibinin-reduced growth of HCC cells is mediated by enhanced expression of SOD.

In the present study, we demonstrated that silibinin can effectively inhibit growth of HuH7 xenografts, a human HCC cell line, in nude mice and examined the related mechanisms.

## MATERIALS AND METHODS

### Reagents

The cell culture media were the same, as previously reported<sup>[19,20]</sup>. Anti-activated caspase-3 antibody was purchased from Sigma Chemical Co. (St. Louis, MO, USA). The antibodies against human Ki-67, AFP, p-Rb, E2F1, DP1, CD1, CDK4, p21 and p27, active caspase-9, phosphorylated-AktThr308, PTEN, AC-histone3 and AC-histone4, survivin phosphorylation (p-survivin), Plk1, Chk1, and  $\beta$ -actin were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). The NF- $\kappa$ B assay kit was from Panomics, Inc. (Redwood City, CA, USA).

### Cell culture

HuH7 cells, a human HCC cell line, were cultured in DMEM with 10% FBS, as previously reported<sup>[17,19,20]</sup>, and used to establish HCC xenografts in nude mice as described below.

### Development and treatment of nude mice bearing HuH7 xenografts

After subcutaneous inoculation of  $5 \times 10^6/0.25$  mL of HuH7 cells<sup>[19,20]</sup>, the mice were randomized to 3 groups, 10 mice in each group, respectively. The control group received daily gavage of a vehicle solution. The other 2 groups received silibinin at a dose of 80 mg/kg per day and 160 mg/kg per day, respectively, started 24 h after inoculation. The silibinin dose was adjusted weekly based on changes in body weight. Tumor volumes were recorded weekly and the experiment lasted for 5 wk. At the end of the experiments, xenograft tumors were measured, isolated, and weighted after euthanasia. Blood specimens were collected from the tail vein and plasma was used to quantify AFP. Three HCC xenograft specimens which were closest to the mean volume were taken from each group. Three hundred milligram of tumor tissue from each xenograft was homogenized with lysing buffer. After centrifuging, the clarified supernatants were stored in -80°C and used for the experiments described below.

### Quantification of plasma and tissue AFP levels

The plasma AFP level was quantified using an enzyme immunoassay (EIA) kit as previously reported<sup>[20]</sup>. A standard curve was obtained using the manufacturer's internal control and was used to calculate plasma AFP levels.

### Analysis of apoptosis

Apoptosis was quantified using an EIA kit, as previously reported<sup>[19,20]</sup>. The degree of apoptosis was expressed based on the ratios of absorbance of the treated *vs* control xenograft tissue specimens.

### Immunoprecipitation and Western blotting analysis

The supernatants of xenograft lysates were used to detect Ki-67, p21, p27, E2F1, CDK4, p-Rb, activated caspase-3 and caspase-9, PTEN, AC-H3, AC-H4, p-Akt, p-survivin and p-ERK, Plk1, Chk1, and SOD1. To determine whether silibinin could affect binding of p21 and p27 with CDK4, and binding of DP1 with E2F1, an immunoprecipitation technique was used.  $\beta$ -actin was used as an internal control. The relative amount of each protein was quantified by digitally scanning its hybridizing bands, and the optical density of the scanned Western blotting results, as previously reported<sup>[19,20]</sup>.

### PTEN activity assay

PTEN protein was immunoprecipitated with 10  $\mu$ L of rabbit anti-human antibodies at 4°C overnight, followed by the addition of 25  $\mu$ L of anti-rabbit IgG-conjugated agarose beads at 4°C for 2 h. The phosphatase reaction was performed using the PTEN activity assay kit in accordance with the manufacturer's instructions<sup>[19,20]</sup>.

### NF- $\kappa$ B assay

NF- $\kappa$ B was quantified using an enzyme-linked immunosorbent assay (ELISA) kit according to the manufacturer's instructions. Briefly, after incubation

**Table 1** Silibinin reduced the frequency and volume of HuH7 xenografts in nude mice

Groups	Treatment	Tumor frequency (%)	Tumor volume (cm <sup>3</sup> )
Group 1	Placebo	100	4.0 ± 0.9
Group 2	80 mg/kg per day	50 <sup>a</sup>	2.1 ± 0.3 <sup>a</sup>
Group 3	160 mg/kg per day	30 <sup>a</sup>	0.6 ± 0.2 <sup>a</sup>

<sup>a</sup>*P* < 0.05 vs Group 1, *n* = 10/group.

for 1 h with 10 μL of the sample solution at room temperature the sample was washed 3 times, NF-κB p50 antibody (1:1000) was added and incubated for another hour at room temperature, followed by anti-rabbit HRP antibody (1:1000) and substrate reaction. The *A* absorbance at 450 nm was recorded.

### Statistical analysis

The descriptive statistics are provided with mean ± SD. *t*-test was used to assess the effect (i.e. mean differences) of silibinin treatment on AFP production, apoptosis, as well as the scanning data of Western blots. *P* < 0.05 was considered statistically significant.

## RESULTS

### Silibinin reduced the frequency and volume of HuH7 xenograft growth

As shown in Table 1, silibinin treatment significantly reduced the frequency and volume of HuH7 xenografts in a dose-dependent fashion. The frequency of HuH7 xenografts was reduced by 50% in the group treated with silibinin 80 mg/kg per day and by 70% in the group treated with 160 mg/kg per day. The mean reduction in HuH7 xenograft volume was 48% in the group treated with silibinin 80 mg/kg per day and was 85% in the group treated with 160 mg/kg per day. The silibinin-reduced frequency and volume of HuH7 xenografts was associated with a significant decrease in Ki-67 expression (Figure 1A). These findings demonstrated that silibinin produced a significant *in vivo* inhibition of HCC growth through a reduction in HCC cell proliferation.

### Silibinin-reduced growth of HCC xenografts was associated with decreased AFP production and secretion

Consistent with our previous *in vitro* report<sup>[17]</sup>, we found that silibinin treatment significantly reduced AFP levels in both xenograft tissue and plasma obtained from the mice (Figure 2A and B). This indicated that silibinin-reduced HuH7 xenograft growth was associated with decreased production of AFP in xenograft tissue and secretion of AFP into blood circulation.

### Effects of silibinin on cell cycle progression

Uncontrolled progression of the cell cycle promotes multiplication of cancer cells. We have reported the inhibitory effects of silibinin on p-Rb formation *in vitro*<sup>[17]</sup>. In the present study, we demonstrated that silibinin

**Figure 1** Effects of silibinin on proliferation and cell cycle progression in HuH7 xenograft tissue specimens. A: Silibinin inhibited Ki-67 expression; B: Silibinin inhibited Rb phosphorylation; C: Silibinin inhibited E2F1/DP1 complex formation; D: Silibinin increased p27/CDK4 complex formation; E: Silibinin inhibited Plk1 expression; F: Silibinin increased Chk1 expression; G: β-actin as internal control; H: Silibinin inhibited nuclear NF-κB content. <sup>a</sup>*P* < 0.05; <sup>b</sup>*P* < 0.01 vs control.

resulted in a significant and dose-dependent inhibition of p-Rb production (Figure 1B), which was associated with decreased E2F1/DP1 complex formation in HuH7 xenograft tissue (Figure 1C).

By binding to the cyclin/CDK complexes, cyclin dependent kinase inhibitors, such as p21 and p27, halt uncontrolled cell proliferation. P21/CDK4 and p27/CDK4 complexes are involved in the transition from G1 into S phase. Consistent with our *in vitro* report<sup>[17]</sup>, silibinin treatment significantly and dose-dependently increased p27/CDK4 complex (Figure 1D), but did not affect p21/CDK4 complex formation (data not shown) in HuH7 xenograft tissue. To further determine whether silibinin could also alter the levels of up-stream molecules that control cell cycle progression, the changes in Plk1, Chk1 and nuclear NF-κB were determined. As shown in Figure 1E-H, silibinin increased Chk1 expression, but inhibited Plk1 expression and nuclear NF-κB level.

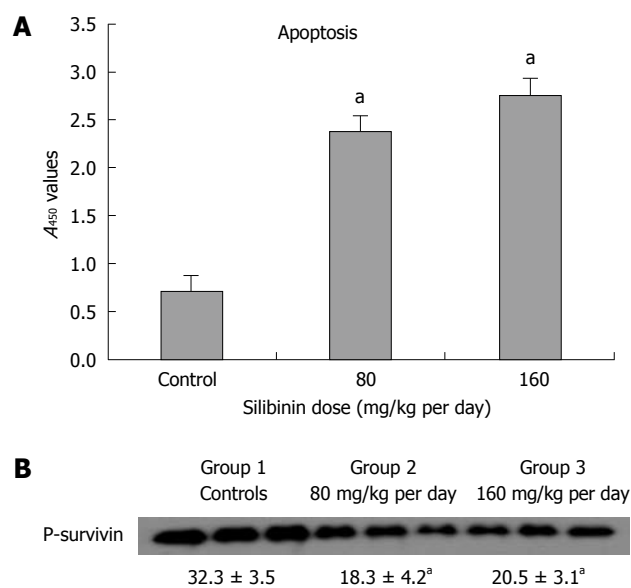

**Figure 2** Effects of silibinin on AFP production and secretion. A: Silibinin reduced AFP production; B: Silibinin reduced AFP secretion. <sup>a</sup>*P* < 0.05; <sup>b</sup>*P* < 0.01 vs control.

### Silibinin-reduced HuH7 xenograft growth was associated with increased apoptosis and reduced survivin phosphorylation

Apoptosis is another important mechanism that controls cancer cell growth. We previously reported that silibinin promotes HuH7 cell apoptosis *in vitro*<sup>[17]</sup>. In the present study, we examined apoptosis in HuH7 xenograft tissue specimens. As showed in Figure 3A, we observed that silibinin significantly increased apoptosis in HuH7 xenograft tissue. To further define the mechanisms involved in the apoptosis pathway, activated caspase-3 and 9, Bcl-2, and p-survivin expression were assessed. We demonstrated that silibinin treatment significantly inhibited p-survivin (Figure 3B), as previously reported in the *in vitro* system<sup>[17]</sup>. However, inconsistent with our previous *in vitro* findings, silibinin did not affect production of activated caspase 3 and 9, or Bcl-2 (data not shown).

### In vivo effects of silibinin on p-Akt and P-ERK pathways

P-Akt and p-ERK pathways are involved in modulating cancer development and growth<sup>[24-30]</sup>. Our previous study indicated that silibinin increased PTEN activity and reduced p-Akt expression *in vitro*<sup>[17]</sup>. In the present study, we found that significantly reduced p-Akt production was only seen in HuH7 xenograft tissue treated with silibinin at a dose of 160 mg/kg per day, but not 80 mg/kg per day (Figure 4A). However, silibinin-

**Figure 3** Effects of silibinin on apoptosis in HuH7 xenograft tissue. A: Silibinin induced apoptosis; B: Silibinin inhibited survivin phosphorylation. <sup>a</sup>*P* < 0.05 vs control.

**Figure 4** Effects of silibinin on P-Akt and P-ERK pathways in HuH7 xenograft tissue. A: Silibinin inhibited p-Akt expression; B: Silibinin increased PTEN expression; C: Silibinin inhibited P-ERK expression; D: β-actin as internal control; E: Silibinin increased PTEN activity. <sup>a</sup>*P* < 0.05; <sup>b</sup>*P* < 0.01 vs control.

reduced HuH7 xenograft growth was associated with a silibinin dose-dependent increase in PTEN production (Figure 4B) and its activity (Figure 4E). In addition, silibinin-reduced HuH7 xenograft growth was also dose-dependently associated with a decrease in p-ERK (Figure 4C).

**Figure 5** Effects of silibinin on AC-H3, AC-H4, and SOD1 in HuH7 xenograft tissue. A: Silibinin increased AC-H3 expression; B: Silibinin increased AC-H4 expression; C: Silibinin increased SOD1 expression in HuH7 xenograft tissue; D:  $\beta$ -actin as internal control. <sup>a</sup> $P < 0.05$  vs control.

### *In vivo* effects of silibinin on histone acetylation

Histone acetylation plays an important role in controlling cell proliferation and cell cycle progression<sup>[31-33]</sup>. Our previous *in vitro* results indicated silibinin increases AC-H3 and AC-H4<sup>[17]</sup>. In the present study, we found that silibinin-reduced HuH7 xenograft growth was associated with significantly increased AC-H3 and AC-H4 production (Figure 5A and B). These results further confirmed the *in vivo* effects of silibinin on AC-H3 and AC-H4 production, indicating their potential role in HCC growth.

### *In vivo* effects of silibinin on SOD1 expression

SOD1 is one of the most important enzymes in reducing ROS levels. It was reported that SOD1 may play a role in the effects of silymarin on alcoholic-induced liver injury<sup>[42]</sup>. We demonstrated that silibinin-reduced growth of HuH7 xenografts was associated with a significant and dose-dependent increase in SOD1 production in the xenograft tissue (Figure 5C). Our results indicate a possible mechanistic role of SOD1 in silibinin-reduced growth of HuH7 xenografts.

## DISCUSSION

HCC is one of the most common malignancies globally. A rise in incidence, limited treatment options, and poor prognosis of this disease emphasize the importance of developing effective chemoprevention for this disease. Silibinin is the major biologically active compound of milk thistle which has been reported to be safe and well-tolerated, and protects the liver from drug or alcohol-related injury<sup>[5-7]</sup>. Recently, the potent *in vitro* anti-HCC effects of silibinin have been demonstrated<sup>[15,17]</sup>, which have provided us with a rationale to further define the *in vivo* effects and mechanisms of silibinin on HCC growth.

In the present study, we examined the *in vivo* effects and mechanisms of silibinin on HCC growth using the nude mouse model bearing human HCC xenografts following inoculation of HuH7 cells<sup>[19,20]</sup>. We demonstrated that silibinin treatment resulted in a

significant dose dependent decrease in both frequency and mean volume of HuH7 xenograft growth. Our previous data recently reported the *in vivo* anti-HCC effects of silymarin<sup>[43]</sup>. The silibinin dose used in our study was lower than that of silymarin<sup>[43]</sup>. The fact that silibinin is a purified bioactive component from silymarin may explain why silibinin at the lower dose can achieve a potent anti-HCC effect. The anti-HCC effects of silibinin were associated with a significant reduction in Ki-67 expression, a biomarker of cell proliferation. These findings were consistent with our previous *in vitro* results and those of Varghese *et al.*<sup>[17]</sup>, and were further supported by the recent reported effects of silibinin on colorectal cancer<sup>[14,17]</sup>. Thus, our data suggest that silibinin-reduced *in vivo* growth of human HCC xenografts is associated with down regulation of cell proliferation.

Plasma AFP has been widely used as a noninvasive biomarker for HCC<sup>[21-23]</sup>. As we previously reported in the cell culture system, it was demonstrated that silibinin treatment resulted in a significant decrease in xenograft production and plasma levels of AFP which was correlated with growth inhibition of HCC xenografts. Since AFP overexpression has been associated with uncontrolled growth of HCC, our data provided additional *in vivo* evidence that silibinin-reduced growth of human HCC is associated with down regulation of cell proliferation. These findings also indicate the potential value of using plasma AFP as a non-invasive biomarker to determine the *in vivo* anti-HCC effects of silibinin.

Uncontrolled G1-S progression results in continued proliferation with potential malignant transformation and carcinogenesis. Increased E2F1/DP1 complex promotes cell cycle progression. Our results indicated that silibinin could significantly inhibit E2F1/DP1 complex formation in association with inhibition of HCC xenograft growth. Consistent with these findings, we also demonstrated that silibinin significantly decreased p-Rb expression, an important modulator that induces E2F1/DP1 formation.

P21 and p27 inhibit cell cycle progression by forming p21/CDK4 or p27/CDK4 complexes. Consistent with our previous *in vitro* report<sup>[17]</sup>, we demonstrated that silibinin significantly increased p27/CDK4 complexes in HuH7 xenograft tissue. Similar effects of silibinin were previously reported in a skin carcinogenesis model. In contrast to the *in vitro* data<sup>[17]</sup>, silibinin did not enhance p21/CDK4 complex formation in HuH7 xenograft tissue.

Chk1 is a critical enzyme in DNA damage-induced G2/M arrest, and blocks mitosis by phosphorylating Cdc25C and has been proposed as a novel tumor suppressor<sup>[36]</sup>. Both Plk1 and NF- $\kappa$ B promote cell cycle progression. NF- $\kappa$ B mediates activation of cyclin D1 gene transcription, induces cell cycle progression and inhibits cell apoptosis<sup>[34]</sup>. Inhibition of NF- $\kappa$ B activation induced an early G1 cell cycle arrest in primary rat hepatocytes<sup>[35]</sup>. In human cells, Plk1 has

been implicated in the regulation of different processes, including mitotic entry, spindle formation, and plays a role at multiple points during the restart of the cell cycle following DNA damage<sup>[37]</sup>. Our results demonstrated that silibinin at 80 mg/kg and 160 mg/kg significantly reduced Plk1 expression and the level of nuclear NF- $\kappa$ B. The higher dose of silibinin (160 mg/kg) also increased Chk1 expression. Taken together, our data indicate that silibinin reduced *in vivo* HCC xenograft growth by decreasing HCC cell proliferation and cell cycle progression which was mediated by inhibiting translocation of NF- $\kappa$ B to the nucleus, Plk1, p-Rb expression, E2F1/DP1, and increasing Chk1 expression and formation of the p27/CDK4 complex.

Increasing cell apoptosis is another important step that inhibits tumor growth<sup>[44]</sup>. We demonstrated that silibinin promotes *in vivo* apoptosis in HuH7 xenografts, which reconfirmed the previous *in vitro* findings<sup>[17,18]</sup>. Survivin is an apoptosis inhibitor that is overexpressed in most cancers in a cell cycle-dependent manner. P-survivin is necessary for cancer cell viability<sup>[45]</sup>. Our results demonstrated that silibinin inhibited p-survivin in association with increased apoptosis in HuH7 xenograft tissue. These results reconfirmed our previous *in vitro* findings<sup>[17]</sup> and indicated the important role of the survivin-mediated decrease in apoptosis in HCC growth.

We reported that silibinin-enhanced apoptosis of cultured HuH7 cells was associated with increased production of activated caspase 3 and 9, however, these changes were not reproducible in HuH7 xenograft tissue. Additionally, silibinin seemed not to alter Bcl-2 expression, another modulator of apoptosis, in HuH7 xenograft tissue. These data indicated that a discrepancy of silibinin-mediated apoptosis signaling may occur in these two systems.

Studies have indicated the important roles of PTEN/PI3K/Akt and ERK signaling in carcinogenesis and cancer progression<sup>[24-30,46]</sup>. Phosphorylation of Akt results in its activation, which promotes cell cycle progression by phosphorylating several other key proteins<sup>[47-51]</sup>. PTEN is an up-stream molecule that inhibits p-Akt. We found that silibinin significantly increased PTEN expression and activity that was further associated with reduced p-Akt production in HCC xenograft tissue. These results indicate a possible pathogenic role of the PTEN/PI3K/p-Akt pathway in HCC growth that may also serve as an important silibinin target. Increased p-ERK activates transcription of the mitogenic and cell regulatory genes and promotes oncogenesis<sup>[46]</sup>. P-ERK was reportedly increased in HCC<sup>[52]</sup>, suggesting its involvement in HCC development. A previous *in vitro* study reported that silibinin can inhibit ERK phosphorylation in human osteosarcoma<sup>[53]</sup>. In the present study, we found silibinin-reduced HuH7 xenograft growth was also associated with a significant inhibition of p-ERK production. These results are also in agreement with an effect on colorectal cancer reported by Singh *et al*<sup>[14]</sup>. The results revealed that the p-ERK pathway is likely involved in silibinin-reduced HCC growth, another possible novel

target of HCC chemoprevention and therapy in future research.

Histone acetylation has been reported to be involved in cell proliferation, differentiation, and cell cycle regulation. A decrease in acetylation status in the cells is associated with carcinogenesis<sup>[31-33]</sup>. Our results demonstrated that silibinin significantly increased AC-H3 and AC-H4 expression, suggesting that increased histone acetylation may mediate silibinin-reduced HCC growth.

ROS stress has been associated with the development of HCC. SOD is one of the important enzymes in reducing ROS levels. Altered expression of SOD has been associated with the development and differentiation of HCC. Although the effects of silibinin on SOD were reported in patients with alcoholic liver disease<sup>[42]</sup>, it is unknown whether the same mechanism has any role in the anti-HCC effects of silibinin. We demonstrated that silibinin-reduced growth of HuH7 xenografts was associated with a significant increase in the production of SOD1 in the xenograft tissue of nude mice. This was particularly evident when a higher dose of silibinin was used. Thus, our results indicate a possible mechanistic role of SOD1 in silibinin-reduced growth of HuH7 xenografts.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is one of the most common malignancies. Silibinin has been reported to be safe, well-tolerated, and protects the liver from drug or alcohol-related injury. A recent demonstration of the potent *in vitro* anti-HCC effects of silibinin has provided us with a rationale to further assess the *in vivo* effects of silibinin on HCC growth. The present study examined the *in vivo* effects and mechanisms of silibinin on HCC growth using a nude mouse model bearing HuH7 (a human HCC cell line) xenografts.

### Research frontiers

The search for safe and well-tolerated chemopreventive agents is one of the significant research frontiers in HCC chemoprevention. Many studies have demonstrated that silibinin can effectively inhibit the growth of various types of tumor cells, however, little is known about the *in vivo* effects and mechanisms of silibinin on HCC growth.

### Innovations and breakthroughs

Previous study demonstrated that silibinin can inhibit HCC cell growth *in vitro*. In the present study, we confirmed that silibinin can effectively inhibit growth of human HCC xenografts in mice by affecting cell cycle progression, apoptosis, and several other pathways.

### Applications

These results provide a rationale to further pre-clinical investigations which may result in clinical trials assessing the application of silibinin in HCC chemoprevention.

### Terminology

Xenografts: Tissue or organs from an individual of one species inoculated, transplanted into or grafted onto an organism of another species, genus, or family. Chemoprevention: The use of chemical compounds to intervene in the early stage of carcinogenesis and thereby reverse tumor formation.

### Peer review

This is a well-designed and very interesting study, methods are appropriated and results are consistent with the conclusions.

### Abstract

**AIM:** To investigate the structural and biochemical changes in the early stage of reperfusion in the rat livers exposed to lobar ischemia-reperfusion (IR).

**METHODS:** The median and left lobes of the liver were subjected to 60 min ischemia followed by 5, 10, 30, 45, 60 and 120 min reperfusion. Blood samples were taken at different time intervals to test enzyme activities and biochemical alterations induced by reperfusion. At the end of each reperfusion period, the animals were killed by euthanasia and tissue samples were taken for histological examination and immunohistochemistry.

**RESULTS:** Cell vacuolation, bleb formation and focal hepatitis were the most important changes occur during ischemia. While some changes including bleb formation were removed during reperfusion, other alterations including portal hepatitis, inflammation and the induction of apoptosis were seen during this stage. The occurrence of apoptosis, as demonstrated by apoptotic cells and bodies, was the most important histological change during reperfusion. The severity of apoptosis was dependent on the time of reperfusion, and by increasing the time of reperfusion,

the numbers of apoptotic bodies was significantly enhanced. The amounts of lactate dehydrogenase, alanine aminotransferase, aspartate aminotransferase, creatinine and urea were significantly increased in serum obtained from animals exposed to hepatic IR.

**CONCLUSION:** Inflammation and subsequent apoptotic cell death were the most important changes in early-stage hepatic reperfusion injury, and the number of apoptotic bodies increased with time of reperfusion.

Histological and biochemical alterations in early-stage lobar ischemia-reperfusion in rat liver. *World J Gastroenterol* 2009; 15(16): 1951-1957 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1951.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1951>

### INTRODUCTION

Reperfusion of a previously ischemic tissue is associated with additional injury that leads to structural and functional alterations in many organs including the liver. The hepatic injury that occurs during reperfusion has been shown to be the major problem associated with stroke, shock, cirrhosis, liver surgery and transplantation<sup>[1-4]</sup>. The mechanisms of reperfusion-induced pathological and functional alterations are under intensive investigation, but the results of different studies are controversial. Some studies suggest that the reintroduction of oxygen to the ischemic (hypoxic) tissues stimulates the production of reactive oxygen species (ROS), which contribute to cell damage. Others have argued that the liver tissues are basically resistant to the oxidative stress followed by ischemia-reperfusion (IR)<sup>[5-7]</sup>. However, many studies have shown that the ischemic livers undergo moderate<sup>[8,9]</sup> to severe structural and functional alterations by IR<sup>[10,11]</sup>.

It has been shown that the injury induced during

reperfusion has a biphasic pattern that consists of an early stage that starts upon reoxygenation and a delayed phase. The early stage is associated with hepatocellular damage during 2-6 h after reperfusion (reoxygenation), and the delayed phase occurs 18-24 h after reperfusion and is accompanied with a massive neutrophil infiltration<sup>[12-15]</sup>. The injury in early stage (acute phase) is mediated by ROS, but the damage in the delayed stage (subacute phase) is associated with the inflammatory responses mediated by neutrophil activity. It is thought that ROS formation during reperfusion induces a cascade of cellular events that eventually leads to hepatocellular injury, including inflammation, necrosis, and/or apoptosis<sup>[16-19]</sup>. However, the detailed mechanisms of cell death and the structural alterations induced during different stages of reperfusion injury are not yet completely determined. Some studies have reported that the morphological changes induced by reperfusion are predominantly limited to non-parenchymal cells<sup>[20-23]</sup>, whereas others have shown that some changes are seen in parenchymal cells<sup>[8,24]</sup>.

While necrosis has been shown to be the cause of hepatic IR injury, many studies have shown that programmed cell death or apoptosis is the cause of cell death during liver reperfusion after long-term ischemia<sup>[20,25,26]</sup>. However, the role of apoptosis as the main cause of the injury and the level of morphological changes induced by this type of cell death have not been determined in detail.

The present study was designed to characterize the features of the injury induced in the early stage of reperfusion in rat liver. The ischemia was established by a lobar model and the ischemic liver was exposed to different reperfusion times. The hepatic alterations were assessed by both histological and biochemical observations.

## MATERIALS AND METHODS

### Animals and experimental groups

Female Sprague-Dawley rats weighing 230-280 g were used in all experiments. The animals were group-housed with a 12-h light-dark cycle and fed a standard laboratory diet. All experiments were performed according to the standard procedures outlined by our institutional guidelines. Rats were fasted overnight for at least 16 h prior to the experiments, but access to water was uninterrupted.

A group of four animals were subjected to 60 min lobar ischemia only. They were sacrificed at the end of this period and then liver tissue samples were taken for histology and immunohistochemistry (IHC). Seven groups of animals underwent 60 min ischemia followed by 5, 10, 15, 30, 54, 60 or 120 min reperfusion. A sham-operated group was selected for each test groups as a control.

### In vivo (lobar) models of IR

This term refers to the model in which the ischemia is induced in the anesthetized animals through application of a vascular clamp simultaneously to branches of the hepatic portal vein, hepatic artery and bile duct. The

reperfusion is commenced by removal of the clamp, thus restoring normal blood flow. Anesthesia was induced by a single intraperitoneal (i.p.) injection of ketamine (80 mg/kg) plus xylazine (10 mg/kg). After injection of 300 U of heparin *via* the femoral vein, the right jugular veins were catheterized by polyethylene tubing for blood sampling and infusion of normal saline solution to replace the removed blood. After laparotomy, the median and left lobes of the liver were removed from the abdominal cavity. Then, *in vivo* lobar ischemia was induced by clamping the left branches of the hepatic portal vein, hepatic artery and bile duct with a microvascular occlusion clip for a period of 60 min. This, caused occlusion of all blood vessels supplying the median and left lobes of the liver, which is reported to produce approximately 70% (partial) liver ischemia<sup>[27]</sup>. Upon release of the clamp, reperfusion was commenced and the blood flow was continued for different times as described above. Control (sham-operated) groups underwent the same surgical procedure, except that the blood supply to the liver lobes was not interrupted.

### Biochemical assays

Blood samples were taken at different times before ischemia, during ischemia and after reperfusion. The plasma was separated by centrifuging the blood, which was kept in the freezer until analysis. The release of lactate dehydrogenase (LDH), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) enzymes, as well as the level of glucose, urea and creatinine were measured by a Hitachi 747 analyzer (Boehringer Mannheim).

### Histological examination

Small pieces of liver were taken from both left and median hepatic lobes. Parts of samples were fixed in 10% formalin for light microscopy. Paraffin embedded sections of 5- $\mu$ m thickness were stained with hematoxylin and eosin and/or periodic acid-Schiff. The remaining samples were fixed with 3% glutaraldehyde/4% paraformaldehyde in 0.1 mmol/L sodium cacodylate buffer for electron microscopy. They were transferred into sodium cacodylate buffer on the following day and then stored at 4°C until processing.

### IHC

IHC was carried out to detect the presence of apoptosis protease-activating factor 1 (APAF-1) as a marker of apoptosis induction in tissue samples. Serial embedded sections were prepared from formalin-fixed samples, which were cut at a thickness of 3  $\mu$ m and dried at 37°C overnight. IHC was performed by the avidin-biotin complex (ABC) procedure, including heat-induced epitope-retrieval and enzymatic antigen-retrieval procedures. Incubation with the primary antibody (NCL-APAF-1; Novocastra; 1:100 dilutions) was carried out in a moist chamber at 37°C for 1 h. Negative controls were treated identically, with the primary antibody omitted; positive controls consisted of normal hepatic tissue.

**Table 1** Data analysis of different biochemical tests obtained from livers subjected to 60 min ischemia followed by 30-120 min reperfusion

Time of sampling	Glucose ( $\mu\text{g/dL}$ )	Urea ( $\mu\text{g/dL}$ )	Creatinine ( $\mu\text{g/dL}$ )	AST (IU/L)	ALT (IU/L)	LDH (IU/L)
Before ischemia	261.33 $\pm$ 36.16 <i>n</i> = 5	17.66 $\pm$ 2.88 <i>n</i> = 5	0.55 $\pm$ 0.058 <i>n</i> = 5	54.82 $\pm$ 19.82 <i>n</i> = 5	78.2 $\pm$ 24.3 <i>n</i> = 5	153.75 $\pm$ 0.11 <i>n</i> = 16
During ischemia	189.66 $\pm$ 18.8 <i>n</i> = 5	18.33 $\pm$ 1.2 <i>n</i> = 5	0.57 $\pm$ 0.075 <i>n</i> = 7	12.74 $\pm$ 9.51 <i>n</i> = 5	18.19 $\pm$ 4.39 <i>n</i> = 5	39.69 $\pm$ 8.58 <i>n</i> = 16
After reperfusion	160.83 $\pm$ 10.63 <i>n</i> = 14	26.50 $\pm$ 1.66 <i>n</i> = 14	2.62 $\pm$ 1.29 <i>n</i> = 13	61.58 $\pm$ 9.12 <i>n</i> = 10	142.28 $\pm$ 30.94 <i>n</i> = 7	200.52 $\pm$ 60.52 <i>n</i> = 23

The values are expressed as the mean  $\pm$  SE taken from at least 12 samples in test.

**Table 2** Comparison of data obtained from biochemical analysis of blood samples taken from the animals exposed to 60 min ischemia followed by different times of reperfusion

Sampling phase	<i>P</i> -value					
	Glucose	Urea	Creatinine	AST	ALT	LDH
Before ischemia/ during ischemia	0.38	0.72	0.79	0.043	0.049	0.034
Before ischemia/ after reperfusion	0.31	0.05 <sup>a</sup>	0.006 <sup>a</sup>	0.08	0.043 <sup>a</sup>	0.008 <sup>a</sup>
During ischemia/ after reperfusion	0.17	0.05 <sup>a</sup>	0.05 <sup>a</sup>	0.08	0.005 <sup>a</sup>	0.014 <sup>a</sup>

<sup>a</sup>*P* < 0.05.

### Statistical analysis

Data from biochemical assays are expressed as the mean  $\pm$  SD obtained from at least four experiments in each group. They were analyzed by ANOVA using the SPSS program and the significance of the differences between groups were tested by Tukey's post-hoc test, with *P* < 0.05 considered statistically significant. Pathological changes in both untreated and treated groups were scored semi-quantitatively from + (mild) to ++++ (severe).

## RESULTS

### Biochemical changes induced by reperfusion injury

There were significant changes in enzyme release and blood urea and creatinine level in the animals exposed to hepatic IR, compared to the controls. The data obtained from analysis of biochemical assays are summarized in Table 1, and comparison of the results at different times of reperfusion is shown in Table 2. As seen in the tables, while enzyme release was significantly reduced during ischemia (*P* < 0.05), the level of glucose, creatinine and urea did not change in the blood of animals exposed to lobar hepatic ischemia. However, plasma level of LDH, AST, creatinine and urea was significantly increased during reperfusion (Table 2).

### Morphological findings

The histological changes induced by IR were examined, based on portal inflammation, focal inflammation, sinusoidal congestion, cytoplasmic vacuolation, bleb formation, apoptotic cells and apoptotic bodies production. The liver samples from the sham-operated group did not show significant histological alterations,

**Figure 1** Zone 3 cytoplasmic vacuolation and hepatocyte bleb formation in the liver subjected to 60 min ischemia only. A: The white arrow shows cytoplasmic vacuolation and the black arrows show the cytoplasmic blebs formation with light microscopy; B: The arrows shows the cytoplasmic blebs with electron microscopy.

similar to those of the non-operated control group. Changes observed in the liver exposed to lobar ischemia alone were limited to mild to moderate focal hepatitis, sinusoidal congestion, vacuolation and bleb formation (Figure 1).

During reperfusion, whilst some changes including blebbing of hepatocytes were improved, induction of portal hepatitis and mild apoptosis were added at 5 min of reperfusion. By increasing the time of reperfusion, the induction of portal and local hepatitis were reduced, but the amount of apoptosis was moderately increased, so that at 30 min reperfusion, the presence of apoptotic cells but not apoptotic bodies was the most important change in the majority of tissue samples (Figure 2A). Sixty minutes ischemia followed by 45 or 60 min reperfusion caused an increased amount of apoptosis

**Figure 2** Histological changes in the livers exposed to 60 min lobar ischemia followed by different times of reperfusion. A: Nuclear pyknosis (P), nuclear fragmentation (F) and cytoplasmic vacuolation in the liver exposed to 60 min ischemia followed by 30 min reperfusion; B: Apoptotic bodies (A.B) and nuclear fragmentation (F) in the liver exposed to 60 min ischemia followed by 60 min reperfusion; C: Nuclear fragmentation (F), apoptotic cell (A.C) and apoptotic bodies (A.B) in the liver exposed to 60 min ischemia followed by 120 min reperfusion.

with phagocytic apoptotic bodies and sinusoidal congestion (Figure 2B). However, in the livers that underwent ischemia and 60 or 120 min reperfusion, phagocytic apoptotic bodies were seen in most tissue samples (Figures 2C and 3). To organize different groups exposed to different reperfusion times, they were classified into three durations: short time, 5 and 10 min; middle time, 30, 45 and 60 min; and long time (120 min). Statistical analysis of the histological alterations and the severity of hepatic changes in the liver subjected to 60 min ischemia followed by short, middle and long times of reperfusion in comparison with the changes induced by 60 min ischemia only are summarized in Figure 4.

The occurrence of apoptosis was confirmed by

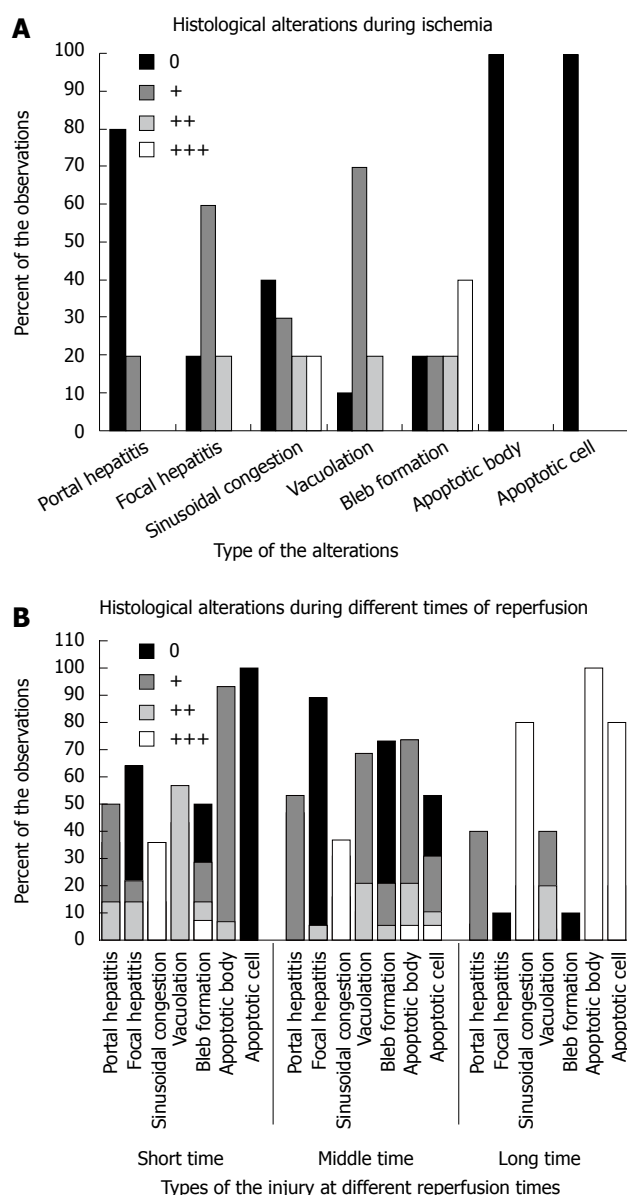

**Figure 3** Apoptotic bodies of an endothelial origin apoptotic cell phagocytosed by a hepatocyte in the liver exposed to 60 min ischemia followed by 60 min reperfusion.

IHC, in which the expression of APAF-1 was positive in the stained sections of livers exposed to IR, and the presence of apoptosis and/or apoptotic bodies was seen by light and electron microscopy (Figure 5A). Representative staining patterns for APAF-1 expression showed that the occurrence of apoptosis was limited to the pericentral area (Figure 5B). The presence of cells labeled with brown color indicated that the expression of APAF-1 was increased during 5-15 min of reperfusion. This showed that the occurrence of apoptosis occurred upon the initiation of reperfusion. However, during 30-60 min of reperfusion, the presence of cells with a brown-colored cytoplasm was accompanied with apoptotic bodies in which, when reperfusion time was increased (120 min), the number of apoptotic bodies also increased (Figure 5B).

## DISCUSSION

In the present study, an *in vivo* lobar (partial) model of rat liver IR injury was established by clamping the vessels to the left lateral and median hepatic lobes, which account for 70% of the rat liver mass. This hepatic insult is similar to the clinical situation when the liver is rendered ischemic during total vascular exclusion for liver resection<sup>[28]</sup>. We tried to illustrate the pathological profile of the liver exposed to 60 min ischemia followed by different periods of 5, 10, 30, 45, 60 and 120 min reperfusion. It was found that cell vacuolation, bleb formation and focal hepatitis were the most important changes induced by *in vivo* lobar ischemia in rat liver. However, during reperfusion, not only some changes including bleb formation was reduced, but some other alterations including portal hepatitis, inflammation and the induction of apoptosis, occurred. It appears that the occurrence of apoptosis, as demonstrated by the formation of apoptotic cells and bodies, is the most important histological change during the early stage of reperfusion. The severity of apoptosis was dependent on the time of reperfusion, so that by increasing the time of reperfusion, the number of apoptotic bodies was significantly enhanced. To accompany these changes,

**Figure 4** A summary of statistical analysis of histological alterations in the livers exposed to ischemia or ischemia-reperfusion. A: Hepatic changes in the liver exposed to 60 min lobar ischemia only; B: Changes in the liver subjected to 60 min ischemia followed by short, middle and long times of reperfusion in which: 0= Normal or no changes, +: Mild injury, ++: Moderate injury, +++: Severe injury;  $0 < A.C./A.B \leq 2 = +$ ,  $2 < A.C./A.B \leq 5 = ++$ ,  $5 < A.C./A.B = +++$ .

the serum level of LDH, ALT, creatinine and urea was significantly increased in rats exposed to hepatic IR, which indicates the induction of cell injury in the liver and other organs, including the kidneys.

Hepatic IR injury is a common pathological phenomenon that may be induced after severe liver trauma, extensive hepatic lobe excision, liver transplantation, and shock. By initiation of reperfusion injury, a series of functional, humoral and structural alterations occur in the liver tissues that directly influence the prognosis of patients<sup>[3-5,9]</sup>. The mechanisms by which the reperfusion injury induces pathological and functional alterations and the methods of intervention have been under intensive investigation. However, the detailed

**Figure 5** Confirmation of apoptosis by IHC assay in the staining sections of livers exposed to ischemia-reperfusion and the presence of apoptosis cells and/or apoptotic bodies. A: Representative staining patterns for APAF-1 positive, illustrating the occurrence of apoptosis in the sections of the liver exposed to 60 min ischemia followed by long time of reperfusion; B: APAF-1 positive staining that shows the high level of apoptosis incidence in the pericentral area of the liver exposed to 60 min ischemia followed by long time of reperfusion.

pathological mechanisms of liver injury induced by this phenomenon are complex and not yet fully understood. Different *in vivo* and *in vitro* models have been used to establish the pathological process of hepatic IR injury, such as the liver transplantation model, the partial warm or cold IR model, and the total hepatic IR model<sup>[6,28-30]</sup>.

There is evidence that the pathogenesis of reperfusion injury involves a series of events, including Kupffer cell activation, cytokine release, neutrophil activation, increased expression of adhesion molecules, sinusoidal endothelial cell death, and hepatocyte injury<sup>[15,19,31-33]</sup>. Among these, the inflammatory process and activation of Kupffer cells, which result in the release of excessive quantities of cytokines and ROS formation, play a major role<sup>[4,17]</sup>. The inflammatory aspect of the injury includes cellular and humoral components. A growing body of evidence, primarily from animal models of IR and preliminary human studies, has revealed that the inflammatory mechanisms may play a major role in the pathogenesis of the injury induced by reperfusion. It has been shown that hepatocyte injury followed by reperfusion is partly dependent on Kupffer cell activation and production of inflammatory mediators. This occurs in a biphasic pattern that consists of acute-phase (ROS-mediated) and subacute-phase (neutrophil-mediated) damage<sup>[8,19,20,24]</sup>.

Our findings strongly suggest the occurrence of inflammation and the subsequent cell death by apoptosis as an important morphological change observed in the early stage (acute phase) of reperfusion. It is proposed that in the early stage of hepatic reperfusion injury, these inflammatory reactions and the different stress processes that follow may result in the activation of the apoptotic pathway mediated by mitochondria. This may lead to an increased number of apoptotic cells and apoptotic body formation, which is associated with a reduction in the total number of parenchymal cells, thus damaging the hepatic tissues and resulting in liver dysfunction<sup>[20,27]</sup>.

The role of apoptosis as a cell death mechanism in reperfusion injury has been shown by some studies previously<sup>[20,34,35]</sup>. Although other alterations including hepatocyte blebbing, sinusoidal congestion, and portal and focal hepatitis were shown have been seen in liver histology, the integrity and organizational arrangement of the hepatic acinus remains intact. This suggests that the liver parenchyma is able to resist against these types of insults<sup>[9]</sup>. This has been confirmed with further studies that have demonstrated that parenchymal cells are not susceptible to damage under some conditions of ischemia-reperfusion IR<sup>[21-23]</sup>.

In the present study, the occurrence of apoptosis was confirmed by IHC of the liver for APAF-1 expression. Positive APAF-1 staining in most sections of liver exposed to IR confirmed the role of apoptosis as the main cause of cell death in early-stage hepatic reperfusion injury. APAF-1 has been identified as a key protein that plays an essential role in the induction of apoptosis in different mammalian cells. In response to apoptotic stimuli, such as ROS, Ca<sup>2+</sup> and cytokines released by reperfusion, APAF-1 binds to cytochrome c and procaspase 9, to yield a complex entitled the apoptosome. Activation of procaspase 9 through an autocatalytic process initiates a cascade of downstream effector caspases, which finally leads to mitochondrial apoptosis. The mitochondrial/cytochrome c apoptotic pathway and the expression of APAF-1 have attracted close attention of researchers to determine the induction of apoptosis<sup>[36-39]</sup>. Using IHC, we found that the occurrence of apoptosis was started in the initial phase of reperfusion, and it was completed as the reperfusion time increased. This was shown by the abundance of apoptotic bodies phagocytosed by macrophages or neighboring hepatocytes during long periods of reperfusion. Increased expression of APAF-1 in zone 3 of the liver indicated the greater susceptibility of this area of the liver to reperfusion injury.

In conclusion, we showed that inflammation and apoptosis were the major histological alterations induced by early-stage reperfusion injury in the liver exposed to lobar ischemia. It appears that apoptosis is the most important histological change induced in the early stage of hepatic reperfusion injury, during which the number of apoptotic bodies was increased with the time of reperfusion.

chancellor for research and technology for a grant to support this work.

## COMMENTS

### Background

Reperfusion of a previously ischemic tissue is associated with additional injury that leads to structural and functional alterations in many organs, including the liver. The mechanisms of reperfusion-induced pathological and functional alterations are under intensive investigation, but the results of different studies are controversial.

### Research frontiers

The injury induced during reperfusion evolves in a biphasic pattern that consists of an early stage that starts with reoxygenation and a delayed phase. The early stage is associated with hepatocellular damage at 2-6 h after reperfusion, and the delayed phase occurs at 18-24 h after reperfusion, and is accompanied by massive neutrophil infiltration. The injury in the early stage is mediated by reactive oxygen species (ROS), but the damage in the delayed stage is associated with the inflammatory responses mediated by neutrophil activity. It is thought that ROS formation during reperfusion induces a cascade of cellular events that eventually leads to hepatocellular injury. However, the detailed mechanisms of cell death and the structural alterations induced during different stages of reperfusion injury are not yet completely understood.

### Innovations and breakthroughs

In the present study, the authors demonstrated that the occurrence of inflammation and the subsequent cell death by apoptosis were the most important changes in the early stage of hepatic reperfusion injury.

### Applications

By characterizing the feature of the injury induced in the early stage of reperfusion, this study may represent a future strategy for therapeutic intervention of reperfusion injury induced under different conditions, such as stroke, shock, cirrhosis, liver surgery and transplantation.

### Terminology

Lobar ischemia refers to the model in which the ischemia is induced in the anesthetized animals through application of a vascular clamp simultaneously to branches of the hepatic portal vein, hepatic artery and bile duct.

### Peer review

The authors examined the effects of 60 min lobar ischemia followed by different periods of 5, 10, 30, 45, 60 and 120 min reperfusion. It was found that the occurrence of apoptosis, as demonstrated by apoptotic cells and bodies, was the most important histological change during reperfusion. The severity of apoptosis was dependent on the time of reperfusion, such that by increasing the time of reperfusion, the number of apoptotic bodies was significantly enhanced.

hypothermic restraint stress. The anti-ulcer effect was further confirmed histologically. On the other hand, the extract significantly replenished GWM and NP-SH levels, as well as the MDA level significantly reduced by extract pretreatment.

**CONCLUSION:** Rocket extract possesses anti-secretory, cytoprotective, and anti-ulcer activities against experimentally-induced gastric lesions. The anti-ulcer effect is possibly through prostaglandin-mediated activity and/or through its anti-secretory and antioxidant properties.

### Abstract

**AIM:** To validate gastric anti-ulcer properties of Rocket "*Eruca sativa*" on experimentally-induced gastric secretion and ulceration in albino rats.

**METHODS:** Gastric acid secretion studies were undertaken using pylorus-ligated rats. Gastric lesions in the rats were induced by noxious chemicals including ethanol, strong alkalis, indomethacin and hypothermic restraint stress. The levels of gastric wall mucus (GWM), nonprotein sulfhydryls (NP-SH) and malondialdehyde (MDA) were also measured in the glandular stomach of rats following ethanol administration. The gastric tissue was also examined histologically. The extract was used in two doses (250 and 500 mg/kg body weight) in all experiments.

**RESULTS:** In pylorus-ligated Shay rats, the ethanolic extract of Rocket "*Eruca sativa* L." (EER) significantly and dose-dependently reduced the basal gastric acid secretion, titratable acidity and ruminal ulceration. Rocket extract significantly attenuated gastric ulceration induced by necrotizing agents (80% ethanol, 0.2 mol/L NaOH, 25% NaCl), indomethacin and

### INTRODUCTION

Gastric ulcer is an illness that affects a considerable number of people worldwide. The etiological factors of this disorder include: stress, smoking, nutritional deficiencies, infections, frequent and indiscriminate use of nonsteroidal anti-inflammatory drugs (NSAIDs)<sup>[1]</sup>. The pathogenesis of gastroduodenal ulcers are influenced by various aggressive and defensive factors, such as mucus secretion, mucosal barrier, acid-pepsin secretion, blood flow, cellular regeneration and endogenous protective agents (prostaglandins and epidermal growth factor)<sup>[2]</sup>. Although the introduction of proton-pump inhibitors to the classic anti-ulcer therapy had revolutionized treatment of peptic ulcers and other gastrointestinal disorders, but there is still no complete cure for this disease. It has been shown that long term use of these drugs leads to various adverse

and side effects. Relapses of the malady, ineffectiveness of different drug regimens and even resistance to drugs are emerging<sup>[3]</sup>. Thus, there is an urgent requirement to identify more effective and safe anti-ulcer agents. During the past few decades, a widespread search has been launched to identify new anti-ulcer therapies from natural sources. Herbs, medicinal plants, spices, vegetables and crude drug substances are considered to be a potential source to combat various diseases including gastric ulcer. In the scientific literature, a large number of medicinal plants with gastric anti-ulcer potential have been reported<sup>[4-8]</sup>. In recent years, Rocket "*Eruca sativa* L." (EER), a member of the Brassicaceae family, has gained greater importance as a salad vegetable and spice, especially among Middle Eastern populations and Europeans<sup>[9]</sup>. It is believed that plants belonging to the Brassicaceae family possess diversified medicinal and therapeutic properties including inhibition of tumorigenesis<sup>[10]</sup>, anti-ulcer<sup>[11]</sup>, and hepatoprotective<sup>[12]</sup> activities. Rocket, locally known as Jarjeer, is used in salads, by local herbal practitioners and in Unani medicine, and is used as a diuretic, stimulant, and in the treatment of stomach disorders and scurvy<sup>[13]</sup>. The seeds and tender leaves are known in Arabian countries to increase sexual desire and are considered to be an aphrodisiac. It is also used as a carminative and to alleviate abdominal discomfort and improve digestion. It has been reported that the rocket seed ethanolic extract possesses potent antioxidant and renal protective and diuretic activities<sup>[14-16]</sup>. Phytochemical studies of rocket leaves and seeds have revealed the presence of glucosinolates<sup>[17,18]</sup>. Weckerle *et al*<sup>[19]</sup> isolated and identified three new quercetins from *Eruca sativa* leaves. In view of the acclaimed medicinal value of rocket in Unani, Ayurvedic and Arab traditional medicine as well as its diversified therapeutic uses, we have undertaken the present study to evaluate the anti-ulcerogenic property of EER in different ulcer models in rats.

## MATERIALS AND METHODS

### *Plant material and preparation of extract*

Fresh *Eruca sativa* leaves were purchased from a local vegetable market in Riyadh, and the identity of these leaves was confirmed by an expert taxonomist of the Department of Pharmacognosy, where a voucher specimen (No. 8208) of the plant has been kept in the Herbarium of the College of Pharmacy, KSU, Riyadh. Shade-dried, coarsely pulverized rocket leaves were placed in a glass percolator with ethanol and were allowed to stand at room temperature for about 72 h. The percolate was collected and dried under reduced pressure in vacuo. The extract obtained was later used and dissolved in distilled water for evaluation of anti-ulcer activity.

### *Animals and dosing*

Albino Wistar rats of either sex, approximately the same age, weighing 150 to 200 g and fed on a diet of standard chow were used in this study. They were randomly

divided into experimental groups of 6 rats each. Aqueous solutions of ulcerogens and EER were freshly prepared before administration. EER at doses of 250 and 500 mg/kg were given orally in the anti-ulcer studies and intraperitoneally for gastric secretion evaluation. The rats were sacrificed, and the stomachs removed and opened along the greater curvature. After washing with saline, the gastric lesions were quantified by a person unaware of the treatments. The animal study protocol was approved by the Research and Ethics Committee of the Experimental Animal Care Society, College of Pharmacy, King Saud University, Riyadh, Saudi Arabia.

### *Pylorus-ligated rats*

Rats were fasted for 36 h with access to water *ad libitum* before pylorus ligation under ether anesthesia was carried out. Care was taken not to cause bleeding or to occlude blood vessels<sup>[20]</sup>. EER was administered intraperitoneally immediately after pylorus ligation (Shay). The rats were sacrificed at 6 h after pylorus ligation. The stomachs were removed, the contents were collected, volumes measured, centrifuged and analyzed for titratable acidity against 0.01 mol/L NaOH at pH 7.

### *Gastric lesions induced by necrotizing agents (cytoprotection)*

Each rat was administered 1 mL of a necrotizing agent (80% ethanol, 0.2 mol/L NaOH or 25% NaCl). Rocket extract was given 30 min before the administration of necrotizing agents. One hour after the administration of ethanol and the alkalis, the rats were sacrificed and examined for stomach lesions. The scoring of stomach lesions was as follows: Patchy lesions of the stomach induced by ethanol were scored according to the method described by Robert *et al*<sup>[21]</sup> using the following scale: 0 = normal mucosa; 1 = hyperemic mucosa or up to 3 small patches; 2 = from 4 to 10 small patches; 3 = more than 10 small or up to 3 medium-sized patches; 4 = from 4 to 6 medium-sized patches; 5 = more than 6 medium-sized or up to 3 large patches; 6 = from 4 to 6 large patches; 7 = from 7 to 10 large patches; 8 = more than 10 large patches or extensive necrotic zones. "small" was defined as up to 2 mm across (max. diameter), "medium-sized" between 2 and 4 mm across and "large" more than 4 mm across.

### *Gastric lesions induced by indomethacin*

Indomethacin was suspended in 1.0% carboxymethylcellulose (CMC) in water (6 mg/mL) and administered orally to the 36 h fasted rats at a dose of 30 mg/kg body weight. Control rats were treated similarly with an equivalent amount of vehicle<sup>[22]</sup>. The rocket extract was given 30 min prior to indomethacin administration at a dose of 250 and 500 mg/kg. The animals were sacrificed 6 h after treatment. The stomachs were excised, rinsed with normal saline and examined for ulceration.

### *Hypothermic restraint stress-induced ulcers*

The method described by Senay *et al*<sup>[23]</sup> was adopted

with slight modifications. Animals were fasted for 36 h but had access to water *ad libitum*. Thirty minutes after the oral administration of EER (250 and 500 mg/kg), the rats were immobilized in restraint cages and placed inside a ventilated refrigerator maintained at  $3 \pm 1^\circ\text{C}$  for 3 h. The animals were then sacrificed and the stomachs were excised. They were examined for ulceration and the severity of intraluminal bleeding according to the following arbitrary scale described by Chiu *et al*<sup>[24]</sup>. 0 = no blood detectable; 1 = thin blood follows the rugae; 2 = thick blood follows the rugae; 3 = thick blood follows the rugae with blood clots in certain areas and 4 = extensive covering of the whole gastric mucosal surface with thick blood.

#### Determination of gastric wall mucus (GWM)

Gastric wall mucus was determined according to the modified procedure of Crone *et al*<sup>[25]</sup>. The glandular segment of the stomach was separated from the rumen of the stomach, weighed, and transferred immediately to 10 mL of 0.1% w/v Alcian blue solution (in 0.16 mmol/L sucrose solution buffered with 0.05 mL sodium acetate at pH 5). Tissue was stained for 2 h in Alcian blue, and excess dye was removed by two successive rinses with 10 mL of 0.25 mmol/L sucrose, firstly after 15 min and then after 45 min. Dye complexed with the gastric wall mucus was extracted with 10 mL of 0.5 mmol/L magnesium chloride which was intermittently shaken for 1 min at 30 min intervals for 2 h. Four milliliters of blue extract were then vigorously shaken with an equal volume of diethyl ether. The resulting emulsion was centrifuged at 4000 r/min for 10 min and the absorbance of the aqueous layer was recorded at 580 nm. The quantity of Alcian blue extracted per gram of wet glandular tissue was then calculated.

#### Estimation of non-protein sulfhydryls (NP-SH)

Gastric mucosal non-protein sulfhydryls were measured according to the method of Sedlak and Lindsay<sup>[26]</sup>. The glandular part of the stomach was homogenized in ice-cold 0.02 mmol/L ethylenediaminetetraacetic acid (EDTA). Aliquots of 5 mL of the homogenates were mixed in 15 mL test tubes with 4 mL of distilled water and 1 mL of 50% trichloroacetic acid (TCA). The tubes were shaken intermittently for 10 min and centrifuged at 3000 r/min. Two milliliters of supernatant were mixed with 4 mL of 0.4 mol/L Tris buffer at pH 8.9. 0.1 mL of 5,5'-dithio-bis(2-nitrobenzoic acid) (DTNB) was added and the sample was shaken. The absorbance was measured within 5 min of DTNB addition at 412 nm against a reagent blank.

#### Determination of malondialdehyde (MDA)

The method reported by Utley *et al*<sup>[27]</sup> was followed. The animals were killed 1 h after ethanol administration. The stomachs were removed and each was homogenized in 0.15 mol/L KCl (at  $4^\circ\text{C}$ ) in a Potter-Elvehjem type C homogenizer to give a 10% w/v homogenate. Aliquots

of homogenate 1 mL in volume were incubated at  $37^\circ\text{C}$  for 3 h in a metabolic shaker. Then 1 mL of 10% aqueous TCA was added and mixed. The mixture was then centrifuged at 800 g for 10 min. One milliliter of the supernatant was removed and mixed with 1 mL of 0.67% w-thiobarbituric acid in water and placed in a boiling water bath for 10 min. The mixture was cooled and diluted with 1 mL distilled water. The absorbance of the solution was then read at 535 nm. The content of malondialdehyde (nmol/g wet tissue) (index of the magnitude of lipid peroxidation) was then calculated, by reference to a standard curve of malondialdehyde solution.

#### Histopathological evaluation

Gastric tissue samples were fixed in neutral buffered formalin for 24 h. Sections of gastric tissue were histopathologically examined to study the ulcerogenic and/or anti-ulcerogenic activity of EER. The tissues were fixed in 10% buffered formalin and processed using a VIP tissue processor. The processed tissues were embedded in paraffin blocks and sections about 5  $\mu\text{m}$  thick were cut using an American optical rotary microtome. These sections were stained with haematoxylin and eosin using routine procedures<sup>[28]</sup>. The slides were examined microscopically for pathomorphological changes such as congestion, hemorrhage, edema, and erosions using an arbitrary scale for severity assessment of these changes.

#### Statistical analysis

Values in tables and figures are given as mean  $\pm$  SE. Data were analyzed by using one-way analysis of variance (ANOVA) followed by Student's *t*-test.

## RESULTS

#### Effect of EER on gastric secretions in 6 h pylorus-ligated rats

When the rats were subjected to pylorus ligation for 6 h, a considerable amount of basal gastric acid secretion was noted ( $10.83 \pm 1.16$  mL) in the control group. In the same control group, the titratable acidity was found to be  $196.57 \pm 15.50$  mEq/L and the ulcer index was recorded as  $2.33 \pm 1.5$ . EER at both doses (250 and 500 mg/kg) significantly reduced gastric acid secretion, titratable acidity and ulcer formation ( $6.33 \pm 1.63$  mL,  $4.16 \pm 1.16$  mL  $P < 0.05$ ,  $P < 0.01$ ;  $132.77 \pm 17.43$ ,  $55.55 \pm 10.46$  mEq/L  $P < 0.05$ ,  $P < 0.001$ ,  $0.66 \pm 0.51$ ,  $0.50 \pm 0.54$ ,  $P < 0.05$ ,  $P < 0.05$ ), respectively (Table 1).

#### Effect of EER on necrotizing agents-induced gastric lesions

The treatment of rats with 80% ethanol, 0.2 mol/L NaOH and 25% NaCl produced extensive gastric lesions in the glandular mucosa of the stomach in all the control rats. The ulcer index was  $6.00 \pm 0.89$ ,  $6.66 \pm 1.36$  and  $6.66 \pm 0.51$ , respectively in control rats 1 h after administration of the necrotizing agents. Pretreatment of rats with EER at doses of 250 mg/kg (ulcer index in 80% ethanol, 0.2 mol/L

**Table 1** Effects of EER on gastric secretion, acidity and gastric lesion index in pylorus-ligated shay rats (mean  $\pm$  SE)

Group serial	Treatment	Dose (mg/kg, i.g.)	Volume of gastric content (mL)	Titratable acidity (mEq/L)	Ulcer index
1	Control (distilled water)	-	10.83 $\pm$ 1.16	196.57 $\pm$ 15.50	2.33 $\pm$ 1.50
2	EER	250	6.33 $\pm$ 1.63 <sup>a</sup>	132.77 $\pm$ 17.43 <sup>a</sup>	0.66 $\pm$ 0.51 <sup>a</sup>
3	EER	500	4.16 $\pm$ 1.16 <sup>b</sup>	55.55 $\pm$ 10.46 <sup>d</sup>	0.50 $\pm$ 0.54 <sup>a</sup>

Six rats were used in each group. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>d</sup> $P < 0.001$  vs control (distilled water) group, Student's *t*-test.

**Table 2** Effect of EER on gastric lesions induced by necrotizing agents (mean  $\pm$  SE)

Group serial	Treatment	Dose (mg/kg, i.g.)	Ulcer index		
			80% EtOH	0.2 mol/L NaOH	25% NaCl
1	Control (distilled water)	-	6.00 $\pm$ 0.89	6.66 $\pm$ 1.36	6.66 $\pm$ 0.51
2	EER	250	2.00 $\pm$ 0.89 <sup>b</sup>	2.66 $\pm$ 1.21 <sup>a</sup>	2.83 $\pm$ 0.98 <sup>b</sup>
3	EER	500	1.66 $\pm$ 1.03 <sup>b</sup>	1.50 $\pm$ 0.54 <sup>b</sup>	2.16 $\pm$ 0.75 <sup>d</sup>

Six rats were used in each group. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>d</sup> $P < 0.001$  vs control (distilled water) group, Student's *t*-test.

**Table 3** Effect of EER on indomethacin-induced gastric mucosal lesions (mean  $\pm$  SE)

Group serial	Treatment	Animals (n)	Dose (mg/kg, i.g.)	Ulcer Index
1	Control (indomethacin only)	6	-	44.50 $\pm$ 5.82
2	EER	6	250	25.50 $\pm$ 6.88
3	EER	6	500	13.50 $\pm$ 4.84 <sup>b</sup>

Six rats were used in each group. <sup>b</sup> $P < 0.01$  vs control (indomethacin only) group, Student's *t*-test.

NaOH and 25% NaCl = 2.00  $\pm$  0.89,  $P < 0.01$ , 2.66  $\pm$  1.21,  $P < 0.05$  and 2.83  $\pm$  0.98,  $P < 0.001$ ; 500 mg/kg (ulcer index = 1.66  $\pm$  1.03,  $P < 0.01$ , 1.50  $\pm$  0.54,  $P < 0.01$  and 2.16  $\pm$  0.75,  $P < 0.001$ ), respectively, significantly inhibited the formation of gastric lesions as shown in Table 2.

#### Effect of EER on gastric lesions induced by indomethacin

The oral administration of indomethacin induced marked damage in the rat glandular stomach. EER at the 500 mg/kg dose significantly prevented the development of gastric lesions in the rat stomach ( $P < 0.01$ ), however, no significant preventive effect of EER at the 250 mg/kg dose, in indomethacin-treated rats was observed (Table 3).

#### Effect of EER on hypothermic restraint stress-induced gastric mucosal lesions

Table 4 shows that EER at a dose of 500 mg/kg body weight significantly inhibited intraluminal bleeding and ulcer formation induced by hypothermic restraint stress ( $P < 0.05$ ). Although the intraluminal bleeding and ulcer index was reduced at a dose of 250 mg/kg body weight, this reduction was not found to be statistically significant.

#### Effect of EER on ethanol-induced changes in gastric wall mucus (GWM)

Rats treated with ethanol showed a significant decrease

**Table 4** Effect of EER on hypothermic restraint stress-induced intraluminal bleeding and gastric lesions in rats (mean  $\pm$  SE)

Group serial	Treatment	Dose (mg/kg, i.g.)	Intraluminal bleeding score	Gastric lesion ulcer index
1	Control (distilled water)	-	2.60 $\pm$ 0.50	24.00 $\pm$ 3.24
2	EER	250	1.20 $\pm$ 0.83	15.20 $\pm$ 3.96
3	EER	500	0.83 $\pm$ 0.40 <sup>a</sup>	7.66 $\pm$ 6.12 <sup>a</sup>

Six rats were used in each group. <sup>a</sup> $P < 0.05$  vs control (distilled water) group, Student's *t*-test.

in the Alcian blue binding capacity of gastric wall mucus (148.41  $\pm$  18.81  $\mu$ g/g of tissue,  $P < 0.001$ ) as compared to control (normal) rats (426.73  $\pm$  39.15  $\mu$ g/g). Pretreatment of rats with EER at doses of 250 mg/kg (263.87  $\pm$  32.65  $\mu$ g/g,  $P < 0.05$ ) and 500 mg/kg (313.90  $\pm$  24.30  $\mu$ g/g,  $P < 0.001$ ) significantly enhanced the Alcian blue binding capacity of gastric mucosa (Figure 1).

#### Effect of EER on ethanol-induced depletion of gastric mucosal NP-SH

The level of NP-SH in the gastric mucosa of control rats was 5.26  $\pm$  0.63 mmol/g of tissue, which was significantly decreased to 2.38  $\pm$  0.33 mmol/g ( $P < 0.001$ ) following the administration of 80% ethanol. Pretreatment of rats with EER at both doses (250 and 500 mg/kg) significantly replenished the ethanol-induced depletion of NP-SH (3.63  $\pm$  0.22,  $P < 0.001$ ; 4.53  $\pm$  0.56,  $P < 0.01$ ), respectively (Figure 2).

#### Effect of EER on ethanol-induced increase in MDA

As depicted in Figure 3, MDA levels in the gastric mucosa used as an index of lipid peroxidation were significantly higher in the ethanol only treated group than in the untreated control group (7.09  $\pm$  0.60  $\mu$ mol/g of tissue; 2.77  $\pm$  0.19  $\mu$ mol/g of tissue), respectively. EER at both doses (250 and 500 mg/kg) significantly

**Figure 1** Effect of EER on the changes in gastric wall mucus induced by 80% ethanol.

**Figure 2** Effect of EER on NP-SH concentration in gastric ulcer induced by 80% ethanol.

**Figure 3** Effect of EER on MDA concentration in gastric ulcer induced by 80% ethanol.

decreased the MDA content ( $4.55 \pm 0.66 \mu\text{mol/g}$  and  $3.58 \pm 0.49 \mu\text{mol/g}$ ), respectively.

#### Effect of EER on histopathological evaluation

Histopathological studies (Figure 4) further confirmed that pretreatment with rocket extract prevented ethanol-

**Figure 4** Light micrographs showing the effect of EER on ethanol-induced gastric lesions of rats. A: Normal mucosa; B: Ethanol-induced gastric mucosal congestion and necrosis; C: Pretreatment of rats with EER 250 mg/kg; D: Pretreatment of rats with EER 500 mg/kg.

induced necrosis in the superficial layers of the gastric mucosa with congestion.

#### DISCUSSION

The results of this study show that the ethanolic extract

of Rocket possesses significant anti-secretory, anti-ulcer and cytoprotective properties in rats. Pretreatment with EER produced a dose-dependent decrease in the volume of basal gastric secretion, titratable acidity and lesions in pylorus-ligated Shay rats. It has been reported that anti-secretory agents such as histamine H<sub>2</sub>-receptor antagonists ameliorate the decrease in gastric mucosal blood flow caused by factors that disturb the gastric mucosa such as NSAIDs and ethanol<sup>[29]</sup>. Gastric acid is an important factor in the genesis of ulceration in pylorus-ligated rats<sup>[20]</sup>. The activation of the vagus-vagal reflux by stimulation of pressure receptors in the antral gastric mucosa in the hypersecretion model of pylorus ligation is believed to increase gastric acid secretion<sup>[30]</sup>. Since EER markedly inhibited gastric acid secretion and ruminal ulcers in pylorus-ligated rats, this observed effect could be related, at least in part, to the ability of EER to reduce gastric acid secretion. It is now accepted that gastric acid secretion plays an important role in the progression from an erosive mucus layer to a gastric lesion. On the other hand, substances which have the ability to suppress gastric acid secretion, such as proton pump inhibitors and histamine H<sub>2</sub>-receptor antagonists are believed to accelerate the healing process of the gastric lesions or inhibit the formation of mucosal injury<sup>[31]</sup>. Rocket extract was found to offer the gastric mucosa, a statistically significant and dose-dependent protection against ulceration caused by various necrotizing agents including ethanol and strong alkalis. Ethanol-induced gastric ulcers have been widely used in the evaluation of gastroprotective activity. Ethanol is metabolized in the body and releases superoxide anion and hydroperoxy free radicals. It has been found that oxygen-derived free radicals are implicated in the mechanism of acute and chronic ulceration in the stomach<sup>[32]</sup>. The genesis of ethanol-induced gastric lesions is of multifactorial origin with a decrease in gastric mucus, and is associated with the significant production of free radicals leading to increased lipid peroxidation which in turn causes damage to cells and cell membranes<sup>[33]</sup>. The cytoprotective effect of EER may be related to its ability to prevent gastric acid secretion and/or enhance the mucosal defensive factors such as prostaglandins and decrease lipid peroxidation<sup>[34]</sup>. Treatment of rats with indomethacin, a non-selective cyclooxygenase inhibitor is known to induce gastric damage through multiple mechanisms which include suppression of prostaglandin generation, overproduction of leukotrienes, acting as a topical irritant and by reducing the local blood-flow<sup>[35]</sup>. Rats pretreated with EER produced significant protection in this model. It is possible that an enhanced level of gastric mucus, generating prostaglandins and inhibiting leukotriene may contribute to the gastroprotective effect of rocket extract.

Hypothermic-restraint stress ulcers have been used as an experimental model in the evaluation of anti-ulcer activity in rats due to data reproducibility<sup>[36]</sup>. Disturbances of gastric mucosal microcirculation, enhancement of acid secretion and reduction in mucus production are mediated by histamine release and abnormal gastric motility<sup>[37]</sup>. It is also reported that

free radicals may play a major role in stress-induced gastric injury<sup>[38]</sup>. Stress is reported to inactivate mucosal prostaglandin syntheses by accumulating hydrogen peroxide, a prostaglandin biosynthesis inhibitor, which also causes reactive oxygen species (ROS) generation<sup>[39]</sup>. In addition, a positive correlation has been reported between the level of gastric mucosal lipid peroxidation products, a marker of oxidative stress, and stomach damage in cold restraint-stressed rats<sup>[40]</sup>. The protective efficacy against cold restraint-stress may be due to the antioxidant activities of EER, as an antioxidant activity was reported earlier in *Eruca sativa*<sup>[14]</sup>, this together with its antisecretagogue potential, thereby strengthens the animals physiological capabilities to decrease stress ulcers.

Our results revealed that the rocket ethanol extract significantly protected gastric mucosa against the depletion of gastric wall mucus. The mucus gel adhering to the gastric mucosal surface protects the underlying epithelium against acid<sup>[41,42]</sup>, pepsin<sup>[43]</sup> and necrotizing agents such as ethanol and indomethacin<sup>[11]</sup>. Gastric wall mucus however, plays a more important role in the defense of the gastric mucosa against chemical or mechanical aggression than the soluble mucus in the lumen of the stomach<sup>[44]</sup>. The gastric mucus coat is thought to be important in facilitating the repair of the damaged gastric epithelium<sup>[45]</sup>. It seems likely that the cytoprotective activity of EER could result, at least in part, from interaction with the adhering gastric mucus layer.

Sulfhydryl compounds in living organisms plays a central role in the maintenance of gastric integrity, particularly when ROS are involved in the pathogenesis of tissue damage<sup>[46]</sup>. A significant decrease in gastric NP-SH following ethanol administration indicated massive generation of oxygen derived free radicals (ODFR). Our findings are in agreement with earlier reports showing depletion of sulfhydryls in ethanol-induced gastric lesions<sup>[3,47]</sup>. Treatment of rats with glutathione depletors has been shown to significantly potentiate ulcerogen-induced gastric mucosal injury<sup>[48]</sup>, whereas an increase in mucosal NP-SH exerts a gastroprotective effect<sup>[49]</sup>. Our observations clearly point towards the mediation of sulfhydryls in EER gastric mucosal protection.

Furthermore, the extract also showed significant inhibition of lipid peroxidation. The generation of MDA from lipids that react with thiobarbituric acid was found to be inhibited by the EER. Thus, it appears that the antioxidant property of the rocket extract may possibly counteract oxidative damage caused by alcohol toxicity. The observed anti-ulcerogenic activity may be due to its antioxidant effects and appears to strengthen the mucosal barrier, which is the first line of defense against endogenous and exogenous ulcerogenic agents.

The preliminary phytochemical screening of rocket revealed the presence of flavonoids, sterols and/or triterpenes. Moreover, quercetin and its derivatives were also reported in rocket leaves. Previous studies have shown that flavonoids may be related to the anti-ulcer activity<sup>[50]</sup>, and play a major role in the mechanism of

gastroprotection<sup>[51,52]</sup>. In addition to flavonoids, other constituents in rocket such as sterol and/or triterpenes are known for their antioxidant activities, which may contribute to some of the anti-ulcer mechanisms<sup>[53]</sup>.

In conclusion, the data obtained confirm the traditional indications for this salad herb and present a new therapeutic option for the treatment of gastric ailments. The exact mechanism(s) underlying this anti-ulcerogenic effect remain unknown, but the extract contains substances, which might increase endogenous prostaglandins and mucus synthesis through its potent antioxidant activity. Furthermore, the anti-secretory mechanism can not, however, be dismissed.

## COMMENTS

### Background

Gastric ulcer is an illness that affects a considerable number of people worldwide. The etiological factors of this disorder include: stress, smoking, nutritional deficiencies, infections, frequent and indiscriminate use of nonsteroidal anti-inflammatory drugs (NSAIDs). Herbs, medicinal plants, spices, vegetables and crude drug substances are considered to be a potential source to combat various diseases including gastric ulcer. In the scientific literature, a large number of medicinal plants with gastric anti-ulcer potential have been reported.

### Research frontiers

Although the introduction of proton-pump inhibitors to the classic anti-ulcer therapy has revolutionized treatment of peptic ulcers and other gastrointestinal disorders, there is still no complete cure for this disease. It has been shown that long term use of these drugs leads to various adverse and side effects. Relapses of the malady, ineffectiveness of different drug regimens and even resistance to drugs are emerging. Thus, there is an urgent requirement to identify more effective and safe anti-ulcer agents. During the past few decades, a widespread search has been launched to identify new anti-ulcer therapies from natural sources.

### Terminology

The anti-secretory, cytoprotective and antioxidant properties of the rocket extract caused an inhibition of chemically and stress-induced gastric ulceration in rats.

### Peer review

The authors examined an ethanolic extract of rocket "*Eruca sativa* L." for its claimed beneficial effects on gastrointestinal disorders. The results are interesting and may provide a better understanding and give a clue for further investigations and innovations for an effective and safe phytotherapy for peptic ulcer disease.

### **Abstract**

**AIM:** To synthesize antisense oligonucleotides (ASODNs) of midkine (MK), package the ASODNs with nanoparticles, and to inhibit hepatocellular carcinoma (HCC) growth using these nanoparticles.

**METHODS:** HepG2 cell proliferation was analyzed *in vitro* using the 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2Htetrazolium, inner salt assay. The *in vivo* activity of nanoparticles delivering the MK-ASODNs was analyzed by histopathological and immunohistochemical staining and quantitative real time polymerase chain reaction (PCR).

**RESULTS:** The *in vitro* proliferation of HepG2 cells was significantly inhibited by the nanoparticles packaged with MK-ASODNs (NANO-ASODNs). Furthermore, the NANO-ASODNs significantly inhibited the growth of HCC in the mouse model.

**CONCLUSION:** NANO-ASODNs can significantly suppress the growth of HCC *in vitro* and *in vivo*.

### **INTRODUCTION**

Hepatocellular carcinoma (HCC), a primary malignancy of the liver, is one of the most common tumors worldwide. The mortality rate from HCC is the third highest worldwide for any cancer-related diseases, and since the 1990s, HCC has been the cause of the second highest mortality rate due to cancer in China<sup>[1]</sup>. Globally, the 5-year survival rate of HCC is less than 5% and 598 000 HCC patients die each year<sup>[2]</sup>, mainly because no satisfactory treatment is available and chemotherapy has been extremely ineffective. Recent insights into the biology of HCC suggest that certain pathways and molecular alterations are likely to play essential roles in HCC development by promoting cell growth and survival. Growth factors and the downstream signaling factors are often overexpressed in tumors and will become the targets of diagnosis or treatment.

Midkine (MK), a heparin-binding growth factor or cytokine, has been reported to be generally overexpressed in malignant tumors<sup>[3-5]</sup>, whereas in normal adult tissues, MK levels are low or undetectable<sup>[6-10]</sup>. MK exhibits several cancer-related activities, including fibrinolytic, anti-apoptotic, mitogenic, transforming, angiogenic and chemotactic functions. The antisense oligonucleotide (ASODN) that targets MK has been reported to suppress the growth of tumors in nude mice<sup>[11,12]</sup>. Additionally,

siRNA or an ASODN that targets MK inhibits neointima formation<sup>[13]</sup> and renal injury after ischemia<sup>[14]</sup>. MK has been suggested to play an important role in carcinogenesis, thus MK can serve as a novel tumor marker or therapeutic target.

At present, the delivery tools of siRNAs or ASODNs are ineffective and toxic. Although lentiviral technology is a proven tool in the laboratory setting, it has several adverse effects, such as toxic immune responses and genetic alterations. Therefore, in the present study, we have used the systemic delivery of nanoparticles incorporated with MK-ASODNs (NANO-ASODNs). This delivery approach is a much safer and more effective alternative to viral therapy for the treatment of tumors, such as HCC. NANO-ASODNs have been found to play an important role in the suppression of HCC growth *in vitro* and *in vivo*, and provide insights into their future clinical application to tumor therapy.

## MATERIALS AND METHODS

### ASODN synthesis

Antisense phosphorothioate oligonucleotide MK-ASODN (5'-CCCCGGGCGCCCTTCTTCA-3') targeting 108-127 base positions of MK mRNA was synthesized by an Applied Biosystems Model 391 DNA synthesizer (Amersham, Piscataway, NJ, USA) and purified by HPLC (Waters Delta Prep 4000, Milford, MA, USA) using a SOURCE 15Q column (Amersham). In our previous study<sup>[15]</sup>, this antisense sequence has been identified to be the most effective sequence for the down-regulation of MK. Consequently, this sequence was synthesized and applied in this study.

### Nanoparticles liposome packaging

Acyl-chloride-cholesterol 2.25 g was dissolved in 5 mL anhydrous chloroform and transferred to a 25-mL three-necked flask. Two milliliters of N', N'-dimethylethanediamine was dissolved into another 5 mL of anhydrous chloroform. The solution was added to the acyl-chloride-cholesterol solution at a constant temperature of 0°C. After dropwise addition, the chloroform was removed by reduction vaporization and the product was purified three times by recrystallization with dehydrated alcohol, and finally eluted with dehydrated alcohol. Following recrystallization, the product was dehydrated by vacuum dehydration for 12 h and the white DC-Chol was obtained. This target product was confirmed by thin-layer chromatography and <sup>1</sup>H-NMR exosynonim analysis. Ten milligrams of DC-Chol and 8 mg of dioleophosphatidyl-ethanolamine were dissolved into chloroform and transferred into a pear shape. The shape was filled with nitrogen gas on a rotary evaporation instrument. Organic solvent was removed by reduction vaporization at a constant temperature of 40°C, until an even lipid film formed on the shape wall. Fifteen milliliter chloroform and 6 mL PBS (pH 7.4) were added into the shape to produce a water-in-oil emulsion adjuvant, using water-bath ultrasound. Chloroform was removed by reduction vaporization on a rotary evaporation instrument to produce a proteoliposome suspension. The suspension

was filled with nitrogen gas, made up to a volume of 10 mL with PBS, shattered using a transducer-ultrasound (1 s ultrasound with 2 s breaks for 150 times, with a work rate of 200 W) and filtered using a 0.1-μm polycarbonate membrane five times using a minitruder. Nanometer liposomes were finally produced. One milliliter of the stock solution (5% manicol) was stored at -70°C for more than 3 h before vacuum dehydration. The shape and size of the nanometer liposomes were detected by transmission electron microscopy (TEM) and dynamic light scattering.

### Cell culture and transduction assay

Human liver HCC cell line HepG2 (HepG2 cells were purchased from the Chinese Academy of Medical Sciences, Beijing, China) were cultured in Dulbecco's Modified Eagle's Medium (DMEM) (Invitrogen Corporation, Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (FBS; GIBCO BRL, Grand Island, NY, USA), 100 U/mL penicillin and 100 μg/mL streptomycin at 37°C and 5% CO<sub>2</sub>. Cells ( $3 \times 10^3$ ) were seeded in each well of a 96-well microtiter plate and allowed to attach overnight. ASODNs and NANO-ASODNs with different concentrations were added to the cells at different time points. Furthermore, the transduction rate of NANO-ASODNs was analyzed using a confocal microscope (Leica, Heidelberg, Germany).

### Cell proliferation assay

NANO-ASODNs with concentrations of 0.1, 0.2, 0.4 and 0.6 μmol/L were added into the HepG2 cell cultures. ASODNs (0.6 μmol/L) transfected into the cells with Lipofectin (Invitrogen), following the manufacturer's instructions, acted as a positive control. Free nanoparticles were added as a negative control. The effects of ASODNs on cellular viability were measured by an MTS [3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium, inner salt] assay. After 48 h of incubation following transfection, 20 μL MTS (Sigma, St Louis, MO, USA) was added to each well and incubated at 37°C for 2 h. The absorbance values were determined at 490 nm using a MR600 microplate reader (Wallac 1420 Multilable counter; Wallac, Turku, Finland).

### In vivo tumor studies

Athymic nude mice (BALB/c-nu/nu females, 6-8 wk old) were purchased from the Academy of Military Medical Science (Beijing, China) and housed in a controlled environment at 22°C on a 12 h light/12 h dark cycle. Animals were maintained in accordance with the NIH Guide for the Care and Use of Laboratory Animals. The *in situ* HCC models were established as described previously<sup>[16]</sup>. Three days after the *in situ* HCC models were established, mice were randomly divided into six groups and each experimental group consisted of eight mice. The mice were intravenously injected with PBS (negative control group), 5-fluoro-2, 4 (<sup>1</sup>H, <sup>3</sup>H) pyrimidinedione (5-FU, positive control group) at 10 mg/kg per day and free nanoparticles as a second positive control group. 25, 50 and 100 mg/kg per day of NANO-ASODNs or

free ASODNs were injected into the mice for 20 d. The distribution of NANO-ASODNs was detected with the *in vivo* imaging systems (ICE-FM-1024B, LumazoneFM). Briefly, mice were anesthetized and FAM-NANO-ASODNs or Free ASODNs were intravenously injected through the tail vein. Images were obtained using the YAP-(S) PET scanner (ISE) at 0, 30, 60 and 90 min after injection. The data were acquired in list mode from 256 views over an angle range of 360 degrees. Images were reconstructed using an iterative reconstruction algorithm that provided transaxial, coronal and sagittal slices. At the end of the second *in vivo* imaging study, animals were sacrificed and tumors were removed for radioactivity counting. The body weights of the animals were recorded weekly. Two days after the intravenous injections were completed, mice were sacrificed and the tumors were removed and weighed. Tumor sizes were monitored with calipers; the tumor volume ( $V$ ,  $\text{mm}^3$ ) was calculated as:  $V = \text{length} \times \text{width} \times \text{depth} / 2$ . The percentage of tumor growth inhibition was calculated as: Inhibitory rate =  $(W_{\text{control}} - W_{\text{treat}}) / W_{\text{control}} \times 100\%$ . The blood of the mice was taken for routine blood tests and the  $\alpha$  fetoprotein (AFP) test. The tissues of livers and tumors were taken for hematoxylin and eosin (HE) staining and histological examination.

### Animal HCC model

The virgin female BALB/c mice used in this experiment were obtained from the Academy of Military Medical Science (Beijing, China). All animal experiments were carried out according to the standards of animal care as outlined in the NIH guide for the Care and Use of Laboratory Animals. The human HCC tumor model was described previously<sup>[17]</sup>. Briefly, the HCM-Y89 tumor derived from a surgical specimen of HCC was cut into 1 mm  $\times$  1 mm  $\times$  1 mm pieces, and implanted into the liver of mice. Twenty days later, the mice treated with or without drugs were killed. The tumors were removed and fixed in neutral buffered 10% formalin, processed by standard methods, embedded in paraffin and sectioned and stained with HE. The HCC model maintains various important features similar to clinical liver cancer patients, including local growth, regional invasion, lymph nodes and pulmonary metastasis, peritoneal seeding with bloody ascites, and secretion of AFP in the recipient animals<sup>[17]</sup>.

### Histopathological and immunohistochemical analysis

The liver and tumor specimens were fixed and frozen in Tissue Freezing Medium (Triangle Biomedical Sciences, Durham, NC, USA). Five-micrometer sections were cut and stained with HE for histopathological analysis. The immunohistochemical demonstration of anti-MK protein binding was achieved with a rabbit polyclonal anti-MK antibody and an LSAB 2 kit, with visualization of the binding using 3,3'-diaminobenzidine tetrahydrochloride. Staining intensities were classified according to the proportions of positive cells as: negative, none; slightly positive, 50%; positive, 50%-90%; and strongly positive, > 90%. The specificity of the binding was confirmed by negative control staining using a rabbit non-immune serum rather than the primary antibody.

### RNA isolation and real-time polymerase chain reaction (PCR)

Total cellular RNA from cell cultures and tissues isolated from the livers and the tumors of mice were extracted using the RNeasy kit according to the manufacturer's protocol. cDNA of the tissue was synthesized from 5  $\mu\text{g}$  of total RNA using a reverse transcription kit. Subsequently, the first strand of cDNA was used as a PCR template. Aliquots of 1  $\mu\text{L}$  of 10-fold diluted cDNA solutions were subjected to PCR in a 20- $\mu\text{L}$  reaction mixture (2  $\mu\text{L}$  PCR buffer; 2  $\mu\text{L}$  dNTP mix; 0.1  $\mu\text{L}$  Taq DNA polymerase; 0.2  $\mu\text{L}$  primers; 14.7  $\mu\text{L}$  autoclaved, distilled water). The primers were as follows: MK, sense primer: 5'-CTCCGCGGTTCGCCAAAAAGAAAGA-3'; anti-sense primer: 5'-CCCCCATCACACGCACCCCA GTT-3'. GAPDH, sense primer: 5'-GGAGCCAAAAG GGTTCATCATCT-3'; anti-sense primer: 5'-AGGGGCC ATCCACAGTCTTCT-3'. PCR was conducted using a SYBR Premix ExTaqTM kit (TakaRa, Dalian, China) with the following conditions: pre-heating at 95°C for 2 min, 40 cycles of 30 s denaturation at 94°C, a 20 s annealing at 56°C, and a 40-s extension at 72°C.

### Statistical analysis

All parameters were analyzed by analysis of variance. Analysis of variance and Student's *t* test were used to compare each post operative result of each level among all groups. A minimum level of 0.05 was chosen.

## RESULTS

### Generation of nanoparticles

The produced nanometer liposomes were used to package the MK-ASODNs using a ratio of 1.8  $\mu\text{L}$  of the nanometer liposomes to 1  $\mu\text{g}$  MK-ASODNs (Figure 1A). The nanoparticles packaged with MK-ASODNs were stained with 1% uranyl acetate and examined with an electron microscope. The size of the micelles was determined with a Zetasizer 5000 (Malvern Instruments, Malvern, Worcestershire, UK). The morphology of the nanoparticles packaged with MK-ASODNs was examined using dynamic light scattering and TEM (Figure 1B).

### Inhibition of growth of HCC *in vitro*

In order to determine the transduction of NANO-ASODNs, the ASODNs were conjugated with FAM and the rate of transduction under the confocal microscope at different time points was observed. Figure 2A shows that the NANO-ASODNs were effectively transduced into the HepG2 cells at the indicated times (6, 12 and 18 h). Since the NANO-ASODNs readily enter into the cells, we wanted to know whether they could decrease expression of MK in HepG2 cells. Figure 2B shows that the NANO-ASODNs (0.1, 0.2, 0.4 and 0.8  $\mu\text{g}/\text{mL}$ ) could significantly down-regulate the MK mRNA levels (Figure 2B). The MTS assay was used to analyze the effect of NANO-ASODNs on HCC cell proliferation. Figure 2C shows that the inhibition rates ranged from 20% to 80%, which correlated with the ASODNs concentrations.

**Figure 1** Nano-assembly of MK-ASODNs and nanoliposomes and characterization of NANO-ASODNs. A: Schematic illustration of the self-assembly of MK-ASODN and nanoliposomes; B: TEM image of the empty nanoliposomes stained with 1% uranyl acetate; C, D: TEM image of the NANO-ASODNs.

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 *vs* control (PBS).

### Inhibition of growth of HCC *in vivo*

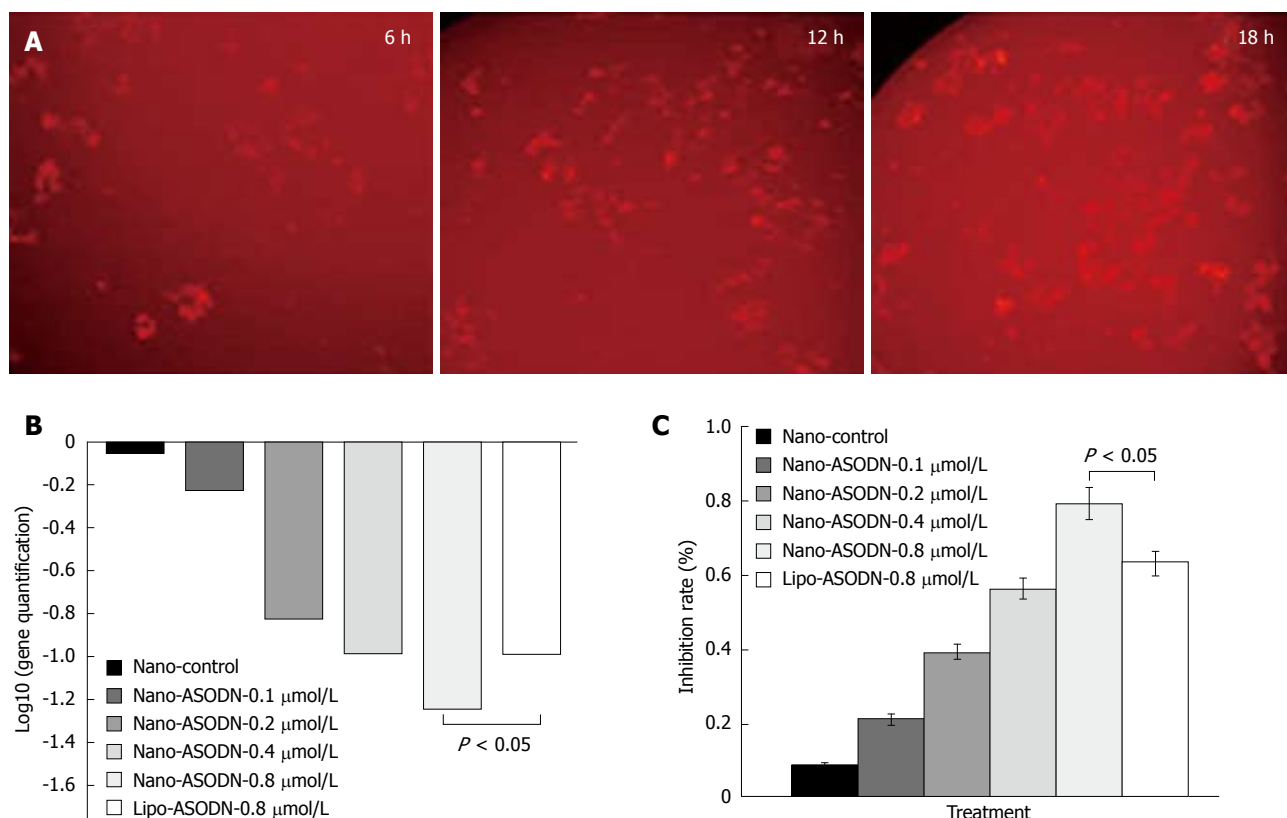

NANO-ASODNs mainly target the liver. In the present study, we used an *in situ* mouse HCC model to evaluate the antitumor activity of NANO-ASODNs. Figure 3 shows that NANO-ASODNs mainly targeted the liver after injection through the tail vein. We also found that the concentration of the NANO-ASODNs reached a peak 90 min after the injection, and then slowly decreased.

**Effects of NANO-ASODNs treatment on *in situ* HCC xenograft growth:** After establishing the mouse HCC model for 2 d, PBS, free nanoparticles, 10 mg/kg per day 5-FU, various doses of NANO-ASODNs or ASODNs (25, 50 and 100 mg/kg per day) were administered through the tail vein for 20 d. The tumors were removed after sacrificing the mice. The tumors were measured and weighed. Table 1 and Figure 4 show the final tumor volumes and weights after 20 d of treatment. The results showed that the tumor volumes decreased in both free ASODNs and NANO-ASODNs treated groups compared with the PBS control group (*P* < 0.01).

Additionally, the effect of NANO-ASODNs on tumor growth inhibition was superior to the free ASODNs (*P* < 0.05). Moreover, the effect of NANO-ASODNs on inhibiting tumor proliferation was dose-dependent (Table 1). In addition, the NANO-ASODNs treatment also resulted in a significant inhibition of tumor weight compared with the PBS- and free-nanoparticle-treated mice. In contrast to the PBS group, it had the highest inhibitory efficacy for the tumor weight which was 81.77% and 10 mg/kg 5-FU had an inhibitory efficacy of 48.96%; however, for the free nanoparticles treatment, the inhibitory rate was only 17.18% (*P* < 0.01) (Table 1).

**Histopathological analysis:** The morphology of the tumors treated by NANO-ASODNs, ASODNs, 5-FU and PBS were evaluated by HE staining. The tumors were excised at the endpoint of the treatment of each protocol. Figure 5 shows the representative sections of the tumors from each experimental group. The tumors from the mice treated with NANO-ASODNs, ASODNs and 5-FU showed a marked increase in the necrotic

**Figure 2** Transduction and function of NANO-ASODNs *in vitro*. A: 0.2 μmol/L FAM-conjugated NANO-ASODNs transduced into HepG2 cells. The results were observed under a confocal microscope at indicted times of 6, 12 and 18 h; B: NANO-ASODNs down-regulated expression of MK mRNA; C: The proliferation of HepG2 cells was significantly inhibited by NANO-ASODNs.

**Figure 3** NANO-ASODNs target the liver. The kinetic results of the NANO-ASODNs were observed through *in vivo* imaging systems at indicated times after NANO-ASODNs were injected through the tail vein. A: Free ASODNs did not concentrate within the liver and these ASODNs disappeared quickly; B: NANO-ASODNs were found to mainly target the liver (the arrow represents the NANO-ASODNs).

area compared with the PBS-treated animals. This result suggests that the NANO-ASODNs, ASODNs and 5-FU treatment induced HCC necrosis *in vivo*.

**Inhibition of plasma AFP secretion:** AFP is often expressed in high levels in fetal liver, the gastrointestinal tract and the yolk sack, but AFP is transcriptionally down-regulated after birth and frequently re-expressed in HCC. Therefore, it is often used as an indicator of HCC<sup>[18]</sup>. In this experiment, we used radioimmunoassay to detect serum AFP concentrations at the endpoint of the treatment. Table 1 shows that NANO-ASODNs at the dose of 100, 50 and 25 mg/kg per day significantly

**Figure 4** Morphological changes of HCC following treatment with NANO-ASODNs. The volume of HCC decreased significantly following treatment with 100, 50 and 25 mg/kg per day of NANO-ASODNs for 20 d. MK-ASODNs were the positive control. The PBS or free nanoparticles represent the negative controls.

decreased AFP secretion compared with the ASODNs or control groups. This result suggests that there were fewer liver tumor cells in the NANO-ASODNs-treated mice and this treatment reduced circulating AFP.

**Systemic toxicity of NANO-ASODNs:** Drug treatment of cancer is usually associated with terrible side effects, which result in severe reduction of white blood cell counts or weight loss. In order to evaluate the toxicity of the NANO-ASODNs, we compared the systemic toxicity

**Figure 5 Histopathological analysis.**

A: Tissue sections of the tumors from *in situ* xenograft HCC; B: Tissue sections of the tumors from nanoparticles; C: Tissue sections of the tumors from 5-FU (10 mg/kg per day); D: Tissue sections of the tumors treated with ASODNs 50 mg/kg per day; E-G: Tissue sections of tumors treated with NANO-ASODNs 100, 50 and 25 mg/kg per day of NANO-ASODN treated tumors, respectively; H: Tissue sections of the tumors treated with 5-FU (10 mg/kg per day) and 50 mg/kg per day of NANO-ASODNs. Regions showing an increase of necrosis and fibrosis were observed in the 5-FU or ASODN treatment groups (C-H,  $\times 200$ ) compared with the free nanoparticles and untreated groups (A and B,  $\times 200$ ).

of free ASODNs, 5-FU and NANO-ASODNs. Mice without tumors were administered a dose of 10 mg/kg per day ASODNs, 5-FU and NANO-ASODNs, and PBS as the control. The body weight was subsequently monitored. The results showed that the mean body weight decrease of the NANO-ASODNs group was not significantly different compared with the ASODNs or PBS groups ( $P > 0.05$ ). However, the decrease in the weight of ASODN- and 5-FU-treated mice was more significant (data not shown). In addition, no inflammatory infiltrate was observed surrounding the solid tumor after treatment with different concentrations of the NANO-ASODNs (data not shown).

All the above studies suggest that nanoparticles packaged with ASODNs were safer than free ASODNs or chemical drugs.

## DISCUSSION

MK is a heparin-binding growth factor identified as a product of a retinoic acid response gene<sup>[19,20]</sup>. MK is overexpressed in a wide range of human carcinomas and believed to contribute to tumorigenesis and tumor progression. HCC is the most common primary liver malignancy, with a rising incidence worldwide. At present, although surgery and chemotherapy are effective in patients with localized tumors, the prognosis of patients with advanced or metastatic tumors is not ideal. Therefore, novel treatment approaches for the cancer are urgently needed. Recently, HCC tumor cells were found to overexpress MK. In our previous studies, ASODNs that target MK were demonstrated to play an important role in anti-tumor functions<sup>[15,16]</sup>. However, the anti-tumor effect was not satisfactory and found to be toxic because of the absence of smart and safer delivery tools. At present, the strategies that have been adopted to improve the uptake of various nucleic-acid-based therapeutic agents are microinjection, passive diffusion, endocytosis (i.e. receptor

mediated endocytosis, fluid phase pinocytosis, adsorptive endocytosis) and artificially enhanced uptake (i.e. using delivery vectors like liposomes, micro- or nanoparticles or dendrimers)<sup>[21,22]</sup>.

In the present study, we used more effective and less toxic nanoparticle liposomes that have previously been used effectively to deliver siRNA for the treatment of lymphoma and ovarian cancer, as well as colorectal carcinoma. Liposomes, the first nanotechnology to benefit cancer patients, are continuing to evolve as tools for delivering potentially useful therapies for the treatment against tumors. In this study, MK-ASODNs incorporated into nanoliposomes have been used effectively *in vivo*. Evidence from these experiments showed that nanoliposomes packaged with MK-ASODNs could suppress HCC growth both *in vitro* and *in vivo*. In addition, the data also indicated that nanoliposomes could effectively deliver MK-ASODNs and showed less systematic toxicity. Consequently, nanoliposomes incorporated with MK-ASODNs should represent an effective and less toxic approach for treatment of HCC, and potentially, other tumor types.

In summary, our results suggest that nanoliposomes packaged with MK-ASODNs can increase the therapeutic effect of MK-ASODNs, both *in vivo* and *in vitro*, for the treatment of HCC. The combination of nanoliposomes and MK-ASODNs showed a more effective and less toxic tool for therapy against HCC and should provide a novel strategy for cancer treatment.

## COMMENTS

### Background

Midkine (MK) is a 13-kDa protein with a heparin-binding growth factor function. MK has been found to play important roles in carcinogenesis, including mitogenic, anti-apoptotic, transforming, fibrinolytic, chemotactic and angiogenic cancer-related activities.

### Research frontiers

MK plays an important role in tumor development and progression.

Nanoliposomes packaged with MK-antisense oligonucleotides (ASODNs) can inhibit growth of hepatocellular carcinoma (HCC), both *in vitro* and *in vivo*, and potentially represents a significant clinical benefit.

### Innovations and breakthroughs

In this study, nanoliposomes effectively delivered MK-ASODNs *in vitro* and *in vivo* with low toxicity. Additionally nanoliposomes packaged with MK-ASODNs inhibited proliferation of HepG2 cells and the growth of HCC xenografts.

### Applications

In this study, the authors addressed the potential therapeutic effect of nanoliposomes packaged with MK-ASODNs on the suppression of HCC growth. Significant inhibition of HCC growth was achieved using the nanoliposomes packaged with MK-ASODN. This observation indicates that the nanoliposomes packaged with MK-ASODN are an effective anti-tumor agent.

### Terminology

MK is a growth protein, which is overexpressed in HCC and promotes the growth of tumors. Nanoparticles represent powerful delivery tools, which can effectively deliver drugs or molecules into cells.

### Peer review

The authors studied the growth inhibition of HCC *in vitro* and *in vivo* with nanoparticles delivering MK-ASODNs. MK-ASODNs have been shown to inhibit the growth of HCC. They found that the proliferation of HepG2 cells was significantly inhibited in the presence of different concentrations of nanoparticles packaged with MK-ASODNs (NANO-ASODNs). Furthermore, in the HCC mouse model, the NANO-ASODNs mainly accumulated in the liver and significantly inhibited the growth of the HCC tumors.

### Abstract

**AIM:** To review our experience performing polypectomy in anticoagulated patients without interruption of anticoagulation.

**METHODS:** Retrospective chart review at the Veterans Affairs Palo Alto Health Care System. Two hundred and twenty five polypectomies were performed in 123 patients. Patients followed a standardized protocol that included stopping warfarin for 36 h to avoid supratherapeutic anticoagulation from the bowel preparation. Patients with lesions larger than 1 cm were generally rescheduled for polypectomy off warfarin. Endoscopic clips were routinely applied prophylactically.

**RESULTS:** One patient (0.8%, 95% CI: 0.1%-4.5%) developed major post-polypectomy bleeding that required transfusion. Two others (1.6%, 95% CI: 0.5%-5.7%) had self-limited hematochezia at home and did not seek medical attention. The average polyp size was  $5.1 \pm 2.2$  mm.

**CONCLUSION:** Polypectomy can be performed in therapeutically anticoagulated patients with lesions up to 1 cm in size with an acceptable bleeding rate.

### INTRODUCTION

Current guidelines for the management of anticoagulants during colonoscopic polypectomy recommend that clotting parameters should be normalized at the time of the procedure<sup>[1,2]</sup>. These guidelines are based largely on expert opinion: polypectomy is considered to be a high risk procedure, and the risk of temporary discontinuation of anticoagulants was previously considered low<sup>[3-5]</sup>. However, recent data suggest that the risk of thromboembolic events is significant when anticoagulants are discontinued for endoscopic and other procedures: the risk of stroke was 1% in a study of 987 patients with atrial fibrillation undergoing 1137 endoscopic procedures, and the risk of thromboembolic events was 0.7% in a study of 1293 warfarin interruptions in 1024 patients<sup>[6,7]</sup>.

One strategy that may decrease this risk by shortening the period of subtherapeutic anticoagulation, is to use intravenous heparin or subcutaneous low-molecular-weight heparin in the perioperative period, rather than simply holding warfarin for several days before and resuming warfarin after the procedure<sup>[8,9]</sup>. An alternative strategy to decrease the thromboembolic risk is to perform polypectomy on lesions up to 1 cm in size while patients remain anticoagulated. In 2007, we reported a series of 41 polypectomies performed in 21 patients with an average international normalized ratio (INR) of 2.3 (range 1.4-4.9)<sup>[10]</sup>. The patients were maintained on warfarin until 36 h before the procedure; the medication was held for 36 h in order to avoid supratherapeutic anticoagulation as a result of dietary restriction during colonoscopy preparation. Endoscopic clipping was performed prophylactically immediately after polypectomy. There were no episodes of post-polypectomy bleeding in that small case series. In this study we report our experience of performing polypectomy in a significantly larger number of patients who were anticoagulated.

## MATERIALS AND METHODS

We reviewed available data from all anticoagulated patients from July 2004 to May 2008 who underwent colonoscopy at the Veterans Affairs Palo Alto Health Care System. Informed consent for the procedure was obtained from all patients, including discussion of the potentially high risk of bleeding due to anticoagulation. Institutional review board approval was obtained for retrospective data analysis. Our clinical protocol, which was followed by all patients, was to continue warfarin until 36 h before the procedure, when a clear liquid diet was initiated in preparation for the procedure. Warfarin was not taken while patients were on a clear liquid diet in order to avoid supratherapeutic anticoagulation during this period of potentially low vitamin K intake. In the first 21 patients, as reported in our original case series, INR was measured on the day of the procedure<sup>[10]</sup>. Subsequently, INR was no longer routinely measured. Colonoscopic polypectomy was generally only performed on polyps up to 1 cm in size (the size was estimated by comparison to a fully opened 1 cm snare), and patients with larger lesions were rescheduled at a later date with cessation of anticoagulation. On five occasions, lesions larger than 10 mm were removed and these patients were also included in the series. Immediately after polypectomy, one or more endoclips were placed prophylactically to close the polypectomy defect. Following the procedure, warfarin anticoagulation was continued on the patient's standard schedule. Follow-up was available on all patients *via* telephone and/or clinic visits.

## RESULTS

Two hundred and twenty five polypectomies were performed in 123 patients (Table 1). The most common indications for colonoscopy were screening, history of polyps, iron-deficiency anemia, hematochezia and occult bleeding. The most common indications for warfarin therapy were atrial fibrillation, history of thromboembolism and mechanical heart valves. Characteristics of resected polyps are described in Table 2. The average diameter of resected polyps was  $5.1 \pm 2.2$  mm, with a range of 2-15 mm. Most of the polyps were removed by cold snare (snare removal without cautery or submucosal saline injection) or by snare with cautery following submucosal saline injection. Seventy percent of the resected polyps were neoplastic, consisting mainly of tubular adenomas. Twenty percent of the resected polyps were non-neoplastic. Ten percent of the specimens were lost.

One patient (0.8%, 95% CI: 0.1%-4.5%) developed major post-polypectomy bleeding. He was a 79-year-old man with atrial fibrillation, dilated cardiomyopathy, emphysema and a history of alcohol abuse who had 6 mm, 8 mm and 12 mm tubular adenomas removed. The smallest polyp was removed by cold snare and the larger two were removed by snare with cautery after saline injection. A subsequent upper endoscopy on the same day as the colonoscopy demonstrated

Table 1 Patient characteristics

Patient characteristics	Number or percentage
Number of patients	123
Average age (range)	68.4 $\pm$ 9 (49-90) yr
Male, female	122, 1
Indication for procedure	Screening (48%) History of polyps (24%) Iron def anemia (9%) Hematochezia (7%) Occult-blood positive stool (7%) Other (5%)
Indication for warfarin	Atrial fibrillation (65%) Thromboembolism (16%) Mechanical valve (9%) Other indications (13%)

Table 2 Polypectomy characteristics

Polyp characteristics	Number or percentage
Number of polyps	225
Polyps per patient	1.8
Average polyp size (mm)	5.1 $\pm$ 2.2
Range of polyp size (mm)	2-15
Polypectomy method	Cold snare (48%) Snare/cautery after saline injection (30%) Snare/cautery, no saline injection (16%) Cold biopsy (4%) Cold snare after saline injection (1%)
Polyp histology	Neoplastic (70%) Non-neoplastic (20%) Lost specimen (10%)

portal hypertensive gastropathy. On post-procedure day 4, he developed hematochezia. He was admitted to a local hospital and received 2 units of packed red blood cells. Repeat colonoscopy was not performed, and the bleeding resolved without further treatment. Two patients (1.6%, 95% CI: 0.5%-5.7%) had self-limited hematochezia at home and did not seek medical attention; these were classified as minor bleeding complications. No thromboembolic events were observed.

## DISCUSSION

Current practice guidelines for the management of anticoagulation during colonoscopy are largely based on expert opinion. According to current guidelines, colonoscopy with or without biopsy can be performed in anticoagulated patients, but polypectomy is considered a high risk procedure for which anticoagulation must be temporarily discontinued in order to achieve normalization of coagulation function at the time of the polypectomy. The risk of withholding warfarin for several days has generally been estimated based on extrapolation from the annual incidence of thromboembolic events in patients with various clinical conditions who do not receive anticoagulants. However, more recent data suggest that actual observed thromboembolic complication rates in patients who have interruption of anticoagulation for endoscopic

procedures are higher than the theoretical predictions; this may be due to a rebound increase in clotting factors in this setting<sup>[6-7,11]</sup>.

Post-polypectomy bleeding is a relatively common complication of colonoscopic polypectomy, with a reported incidence of approximately 0.3%-2% that depends on multiple factors including lesion size<sup>[12,13]</sup>. A multivariate regression analysis suggested that anticoagulation increases this risk<sup>[14]</sup>. Post-polypectomy bleeding is generally divided into two types: immediate bleeding following the polypectomy, and delayed bleeding that can occur up to 2-3 wk following the procedure. Immediate bleeding is familiar to therapeutic endoscopists, as it is particularly common following endoscopic mucosal resection of large lesions<sup>[15]</sup>. In this situation, it is generally treated very effectively by methods such as clip application<sup>[15-17]</sup>. In contrast, delayed bleeding typically occurs when the patient is already at home and is therefore a significant concern when polypectomy is undertaken in patients who require anticoagulation. Even when current guidelines are followed and warfarin is held in anticipation of polypectomy, it is quite possible that the patient will be therapeutically anticoagulated at the time that delayed bleeding occurs several days after the procedure. The major issues with performing polypectomy while patients are anticoagulated are therefore as follows: will there be difficulty in controlling any immediate bleeding, will there be a significantly increased risk of delayed bleeding, and are the bleeding risks outweighed by the risk of thromboembolic events that could occur if anticoagulation was interrupted? This study systematically evaluated the risks associated with performing polypectomy while patients were anticoagulated.

Our study demonstrated that polypectomy of lesions up to approximately 1 cm in size can be performed with relative safety in anticoagulated patients. Because we anticipated some degree of immediate bleeding, our uniform practice was to immediately apply endoscopic clips to the polypectomy sites rather than observing the site and waiting to see if bleeding developed. With this strategy, we did not observe any extraordinary episodes of immediate bleeding that could not be controlled with clip application. There was only 1 episode of major delayed bleeding out of 123 patients and 225 polypectomies, a major bleeding rate of 0.8% (CI: 0.1%-4.5%). There were no thromboembolic events, although follow-up was often performed by telephone and typically did not include a neurological exam. The complication profile observed in this study suggests that the strategy of removing small lesions up to 1 cm in size may compare favorably with the standard practice of discontinuation of warfarin for elective procedures, where two major recent studies found thromboembolic rates of 0.7% and 1%<sup>[6,7]</sup>.

It must be emphasized that in our patients warfarin was withheld for approximately 36 h in order to avoid supratherapeutic anticoagulation due to dietary restriction and possibly other factors relating to bowel

preparation. We previously published our experience with the first 21 patients in our series, in whom INR was routinely measured before the procedure<sup>[10]</sup>. In those patients the average INR at the time of colonoscopy was 2.3. Following this experience, we stopped routine measurement of INR before colonoscopy as this involved significant logistical difficulty. The polypectomy techniques utilized in our series varied, with cold snare, standard snare with cautery and inject & cut mucosectomy comprising the majority of polypectomies. Although our data suggest that all three techniques may be safe, our current preference is to perform cold snare in lesions smaller than 5 mm and to perform submucosal injection for larger lesions in which cautery is used in order to minimize potential injury to the bowel wall. In addition, prophylactic clipping was performed immediately at all polypectomy sites. While there is no data to demonstrate the efficacy of clipping in this circumstance, and a randomized study of clipping in average-risk patients demonstrated no benefit, we felt compelled to perform clipping because of the absence of data in anticoagulated patients<sup>[18]</sup>. The drawbacks of clipping include additional endoscopy time, clip cost, and in our case also the practice of immediate clipping before specimen retrieval may have contributed to a relatively large fraction, 10%, of lost specimens.

Limitations of our study include the retrospective, single center design. It is possible that the bleeding rate could be higher in different patient populations, with alternative polypectomy techniques, and/or with less experience in clip placement. Anecdotally, we have observed that endoscopists in our unit apply significantly less cautery during polypectomy than many of our colleagues and it is possible that this will influence delayed bleeding rates due to cautery ulcers. An additional limitation is the absence of INR measurements on patients after the first 21 in the series. However, there were no changes in our colonoscopy preparation during the study period so we expect that the INR levels in subsequent patients would have been similar.

Our study suggests that a reasonable strategy for screening and surveillance colonoscopy in anticoagulated patients may be to perform the procedure while patients are anticoagulated. Small polyps can be removed with a relatively low risk of bleeding. The proportion of patients with lesions larger than 1 cm is relatively low in most clinical settings, so only a relatively small number of patients would undergo a repeat colonoscopy with normalization of coagulation parameters to resect these larger lesions<sup>[19,20]</sup>. A more refined strategy, which would be ideal, would be to develop a highly predictive algorithm to determine which patients are likely to harbor a lesion larger than 1 cm and proceed directly to colonoscopy with interruption of anticoagulation only in these select patients. This strategy could potentially resolve a dilemma facing endoscopists and patients who follow current American Society for Gastrointestinal Endoscopy guidelines: whether to perform screening/surveillance colonoscopy while patients are anticoagulated and repeat

the procedure off anticoagulation in the large number of patients who have small polyps, or to risk thromboembolic complications by normalizing coagulation parameters even in screening/surveillance colonoscopies where potentially no polyps may be found.

A recent survey of endoscopists in the United Kingdom demonstrated a wide variation in the management of anticoagulants for colonoscopy, with 49% of responding physicians routinely stopping anticoagulants and 37% routinely continuing anticoagulants<sup>[21]</sup>. This wide variation in practice suggests that the management of anticoagulants is a significant clinical dilemma. A prospective randomized trial would be the ideal method to resolve this dilemma, and by demonstrating that polypectomy of small lesions can be performed with relative safety, our series demonstrated that it would be reasonable to prospectively compare a strategy of anticoagulant interruption to one of colonoscopy in anticoagulated patients where small polyps can be removed at the discretion of the endoscopist.

## COMMENTS

### Background

Current guidelines recommend discontinuation of anticoagulation prior to colonoscopic polypectomy. However, small colon polyps are exceedingly common and the risk of significant complications from anticoagulant interruption may outweigh the benefit in these patients.

### Research frontiers

In this study, the authors report their experience with resection of small colon polyps up to 1 cm in diameter without interruption of anticoagulation.

### Innovations and breakthroughs

The authors report that the bleeding risk is very low (0.8%) when small polyps are removed in this setting. This suggests that it is reasonable to perform polypectomy without interruption of anticoagulation.

### Applications

Patients who are on chronic anticoagulation and are undergoing screening colonoscopy can be considered for colonoscopy without interruption of anticoagulation, and if small polyps are found then polypectomy can be considered.

### Terminology

Polyps are growths in the colon that are often precancerous. During colonoscopy, the colon is examined for polyps using an endoscope. Polyps are usually removed using a variety of instruments during colonoscopy. Bleeding is a relatively common complication of polyp removal, so there is widespread concern about performing polyp removal in patients who are taking anticoagulants.

### Peer review

The authors performed a retrospective review that demonstrated that the risk of post-polypectomy bleeding is low in patients with small polyps who are anticoagulated. A comparison to published risk estimates for anticoagulant interruption suggests that it may be favorable to perform polypectomy in this setting rather than interrupting anticoagulation.

uptake showed a significant increase ( $P < 0.05$ ) after removing phytate from most of the samples analyzed. A positive relationship ( $P < 0.05$ ) between mineral solubility and the cell uptake and transport efficiencies was observed.

**CONCLUSION:** Removing phytate from infant cereals had a beneficial effect on iron and zinc bioavailability when infant cereals were reconstituted with water. Since in developing countries cereal-based complementary foods for infants are usually consumed mixed with water, exogenous phytase additions could improve the nutritional value of this weaning food.

### Abstract

**AIM:** To test the effect of the dephytinization of three different commercial infant cereals on iron, calcium, and zinc bioavailability by estimating the uptake, retention, and transport by Caco-2 cells.

**METHODS:** Both dephytinized (by adding an exogenous phytase) and non-dephytinized infant cereals were digested using an *in vitro* digestion protocol adapted to the gastrointestinal conditions of infants younger than 6 mo. Mineral cell retention, transport, and uptake from infant cereals were measured using the soluble fraction of the simulated digestion and the Caco-2 cells.

**RESULTS:** Dephytinization of infant cereals significantly increased ( $P < 0.05$ ) the cell uptake efficiency (from 0.66%-6.05% to 3.93%-13%), retention (from 6.04%-16.68% to 14.75%-20.14%) and transport efficiency (from 0.14%-2.21% to 1.47%-6.02%), of iron, and the uptake efficiency (from 5.0%-35.4% to 7.3%-41.6%) and retention (from 4.05%-20.53% to 14.45%-61.3%) of zinc, whereas calcium only cell

Effect of dephytinization on bioavailability of iron, calcium and zinc from infant cereals assessed in the Caco-2 cell model. *World J Gastroenterol* 2009; 15(16): 1977-1984 Available from: URL: <http://www.wjgnet.com/1007-9327/15/1977.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.1977>

### INTRODUCTION

Insufficient mineral intake during infancy is responsible for many diseases which can not only influence immediate health, but may also have an adverse impact on adult health. Anaemia, rickets, osteoporosis, and immune diseases are caused by a deficiency of iron, calcium and/or zinc<sup>[1]</sup>. An adequate intake of these minerals is important for meeting infant nutritional needs<sup>[2]</sup>. Cereals are considered a rich plant source of carbohydrate, proteins, vitamins, and minerals, and are therefore usually introduced to an infant's diet between the ages of 4 and 6 mo. However, cereals are also rich in phytate, which can decrease the bioavailability of critical nutrients such as iron, calcium, and zinc because of its high ability to chelate and precipitate minerals<sup>[3,4]</sup>. Dephytinization by adding an

exogenous phytase or by activating the naturally occurring plant phytases has been proposed as a sustainable strategy for reducing mineral deficiency by increasing mineral bioavailability in infant complementary cereal-based foods<sup>[5]</sup>. An estimate of mineral bioavailability from infant cereals is important because not only must the absolute amounts of minerals be increased in the edible portions of foods, but they must also be in forms bioavailable to infants. Bioavailability should preferably be determined by *in vivo* testing, however, these studies could also be based on preliminary *in vitro* methods<sup>[6]</sup>. Caco-2 cells are human intestinal adenocarcinoma cells exhibiting biochemical and morphological characteristics of small intestinal absorptive enterocytes, and together with a simulation of gastrointestinal digestion, have been used widely for mineral bioavailability studies<sup>[7-9]</sup>. Caco-2 cells grown on microporous supports, allow the measurement of mineral uptake and transport across cell monolayers, improving the estimation of bioavailability by *in vitro* methods used until now (solubility and dialysis)<sup>[10,11]</sup>. In western countries, infants are usually fed with infant cereals reconstituted with follow-on formula; nevertheless in developing countries, where mineral deficiencies are particularly frequent, cereal-based complementary foods destined to infants are usually consumed mixed with water<sup>[12]</sup>. Given the importance of an adequate intake of minerals during infancy, the purpose of the current investigation was to study the effect of dephytinization on iron, calcium and zinc solubility, retention, transport, and uptake by Caco-2 cells from infant cereals when reconstituted with water, with the aim of obtaining data on mineral bioavailability from infant cereals with this kind of reconstitution.

## MATERIALS AND METHODS

### Chemicals

Enzymes and bile salts were purchased from Sigma Chemical Co. (St. Louis, MO): pepsin (porcine, catalogue no. P-7000), pancreatin (porcine, catalogue no. P-1750), and bile extract (porcine, catalogue no. B-8756). Pepsin solution was prepared by dissolving 1.6 g of pepsin in 10 mL of 0.1 mol/L HCl. Pancreatin-bile extract solution was prepared by dissolving 0.2 g of pancreatin and 1.25 g of bile extract in 50 mL of 0.1 mol/L NaHCO<sub>3</sub>. Millipore Milli-Q distilled-deionized water (Millipore Ibérica S.A., Barcelona, Spain) was used throughout the experiments. Cell culture media, antibiotics (penicillin and streptomycin), glucose, 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES), 2-(N-morpholino) ethanesulfonic acid (MES), and Hank's Balanced Salt Solution (HBSS) were obtained from Gibco BRL Life Technologies (Paisley, Scotland).

### Inositol phosphate content

Inositol phosphates were determined by HPLC using a Merck Hitachi chromatograph [pump L-7100, refraction index (RI)-detector L-7490, and L-7350 column oven] according to the method of Lehrfeld<sup>[13]</sup>. Inositol phosphates were extracted from the different samples with 0.5 mol/L HCl at room temperature for 2 h. Because

of the high binding capacity of inositol pentaphosphate (IP<sub>5</sub>) and inositol hexaphosphate (IP<sub>6</sub>) to minerals, we consider the sum of IP<sub>5</sub> and IP<sub>6</sub> to determine phytate content<sup>[4,13]</sup>. The molar ratios of phytate to iron, calcium, and zinc were calculated as the millimoles of phytate present in the sample divided by the millimoles of iron, calcium, and zinc present in the sample, respectively. To find the phytate × (Ca/Zn) molar ratio, the total amount of Ca (mmol) in 100 g of infant cereal was multiplied by the phytate/Zn molar ratio.

### Samples

Both commercial and dephytinized infant cereals were dried in an oven at 120°C overnight to obtain the dry weight, and were then milled. Infant cereals were reconstituted according to the recommendations of the manufacturer: 200 mL of water was mixed with 35 g of infant cereal. The infant cereals were dephytinized using an exogenous phytase from *Aspergillus oryzae* (EC 3.1.3.26 from Stern-Enzym GmbH & Co. KG, Ahrensburg, Germany, 2500 PU/g). The phytase was added to the aqueous slurry at a concentration of 3.2 U/g of sample and incubated at pH 5.5 with stirring at 55°C for 20 min. The dephytinized samples were dried in an oven at 120°C overnight to obtain the dry weight, and then ground in an electrical mill to a fine powder similar to that of commercial infant cereals. Dephytinization was checked by HPLC<sup>[13]</sup>.

### Caco-2 cells

Caco-2 cells were obtained from the European Collection of Cell Cultures (ECACC; number 86010202, Salisbury, UK) and used in assays at passages 28-55. For iron, calcium, and zinc uptake assays, cells were seeded onto polycarbonate membrane chamber inserts (24 mm diameter, 0.4 µm pore size; Transwell, Costar Corp.) at a density of 50 000 cells/cm<sup>2</sup> and allowed to differentiate on filters for 21 d. During this period, cells were maintained in minimum essential medium (MEM) with 10% v/v heat-inactivated fetal bovine serum (FBS), 1% v/v nonessential amino acids, 1% v/v L-glutamine and 1% antibiotic solution (penicillin-streptomycin) at 37°C in an incubator with 5% CO<sub>2</sub>, 95% air atmosphere and 95% relative humidity. The medium was changed every 2 d. During the cell differentiation period, monolayer formation and tight junction maturation and sealing were assessed by measuring the passage of phenol red across the monolayer according to Ferruzza *et al*<sup>[14]</sup>. Briefly, following three washes of cell monolayers with phosphate-buffered saline (PBS), 0.5 mL of 1 mmol/L phenol red was added in the apical compartment, whereas 1 mL of PBS was added in the basolateral compartment. After 1 h of incubation at 37°C, 0.9 mL of basolateral medium was collected, treated with 0.1 mL of 0.1 mol/L NaOH, and read at 560 nm using a molecular absorption spectrophotometer (UV-Vis, U-200, Hitachi Ltd. Tokyo, Japan) to determine the phenol red concentration. The passage of phenol red was expressed as apparent permeability (P<sub>app</sub>) and obtained from the following formula:  $P_{app} = C_t \times V_{BL} / \Delta t \times C_0 \times A$ , where V<sub>BL</sub> is the volume of the basolateral compartment

( $\text{cm}^3$ ),  $A$  is the filter area ( $\text{cm}^2$ ),  $\Delta t$  is the time interval (s),  $C_t$  is the phenol red concentration in the basolateral compartment at the end of time interval, and  $C_0$  is the phenol red concentration in the apical compartment at time zero. Apparent permeability of monolayers at the end of differentiation period was  $1.71 \times 10^{-5} \text{ cm/s}$ , indicating that tight junctions were functionally mature<sup>[14]</sup>. The experiments were conducted on day 21 from seeding. Microscopic examination of the cultures revealed that confluence was reached after 3–4 d of growth. Cell viability 3 h after the addition of the soluble fraction was assessed by trypan blue exclusion and was typically 85%–95%.

### *In vitro* gastrointestinal digestion

Gastrointestinal digestion was applied to infant cereals, whether or not dephytinized, and reconstituted with deionized distilled water using the *in vitro* method described by Miller *et al.*<sup>[15]</sup> with modifications aimed at reducing the amounts of the enzymes used because the gastrointestinal tract in the early stages of life is not yet fully developed<sup>[16,17]</sup>. The method consisted of two phases: gastric and intestinal. Prior to the gastric stage, the pH of 17.5 g of each infant cereal homogenized with 100 mL of deionized-distilled water was lowered to pH 4 with 6 mol/L HCl. Then, 3 g of pepsin solution was added, and the sample was incubated in a shaking water bath at 37°C and 120 strokes/min for 2 h to allow pepsin digestion. The digest was then maintained in ice for 10 min to stop pepsin digestion. For intestinal digestion, the pH of the gastric digests was raised to 5.0 by dropwise addition of  $\text{NaHCO}_3$  1 mol/L. Then a freshly prepared pancreatin-bile solution sufficient to provide 0.005 g of pancreatin and 0.03 g of bile salts/g of sample was added, and incubation was continued for 2 h. To stop intestinal digestion, the sample was kept for 10 min in an ice bath. Then the pH was adjusted to 7.2 by dropwise addition of 0.5 mol/L NaOH. The intestinal digest was heated for 4 min at 100°C to inhibit the sample proteases and then cooled by an ice bath. The gastrointestinal digest were centrifuged at  $9187 \times g$  for 30 min at 4°C. The supernatant fraction was filtered through a centrifugal filter devices with a 30000 MW cut-off (Millipore Corporation Bedford, MA 01730, USA) and then centrifuged at  $4000 \times g$  for 90 min at 4°C using a Sorvall centrifuge (Model RC5C, with SS-34 rotor; Sorvall instruments, DuPont, Mississauga, ON, Canada). Prior to addition of the soluble fraction to the cells, glucose (5 mmol/L final concentration), HEPES (50 mmol/L final concentration), and MES (30 mmol/L final concentration) (pH 6.5–6.9) were added to make the soluble fraction similar to the culture media; and finally, water was added to adjust the osmolarity to  $310 \pm 10 \text{ mOsm/kg}$  (Freezing point osmometer 030, Berlin, Germany) according to Ekmekcioglu<sup>[18]</sup>. Then the supernatants (soluble fraction) were analyzed for mineral content and used in cell uptake assays.

### Uptake, retention and transport experiments

The soluble fraction obtained from gastrointestinal digestion was used to carry out uptake, retention, and

**Figure 1** TEER values of Caco-2 monolayers incubated in the presence of digested infant cereals.

transport experiments with Caco-2 cells because it is more similar to the *in vivo* digests<sup>[19]</sup>. Before each experiment growth medium was removed and apical and basolateral cell surfaces of the monolayers were washed three times with phosphate-buffered saline (PBS) at 37°C. One millilitre of soluble fractions was added to the apical chamber and 1.5 mL of HBSS (pH 7.4) was added to the basal chamber of each cell monolayer. After incubation, the apical samples were collected, and the monolayers were carefully washed three times with 1 mL ice-cold HBSS to remove any nonspecific-bound mineral and residual soluble fractions. Cells on filters were lysed by the addition of 0.5 mL of deionized water to each well, and then harvested; HBSS in basal chamber also was removed. Total mineral content was measured in the apical solutions, cell monolayer, and basal solutions.

### Assessment of cell monolayer integrity during experiments

To investigate possible adverse effects of infant cereal components or digestive enzymes from the supernatants on Caco-2 cells, the integrity of the monolayer was assessed by measuring the transepithelial electrical resistance (TEER) according to the method of Okada *et al.*<sup>[20]</sup>. At the end of differentiation period control, monolayers used for experiments had a resistance higher than  $900 \Omega \cdot \text{cm}^2$  (Figure 1). During the uptake, retention, and transport experiments measurements of TEER were taken every 30 min. Background resistance was determined by measuring across a filter without cells in Hank's Balanced Salt Solution (HBSS). Monolayers with resistances  $< 500 \Omega \cdot \text{cm}^2$  were discarded.

### Iron, calcium, and zinc determination

To estimate mineral bioavailability, iron, calcium, and zinc contents in the sample (before digestion), soluble fraction (apical solution), blank (HBSS), basal solution and in cell homogenates were determined by flame atomic absorption spectrophotometry (AAS; Perkin-Elmer, mod. 3100 Norwalk, U.S.A) according Perales *et al.*<sup>[10]</sup> with slight modifications; dry organic matter destruction (450°C) was applied prior to analysis. An amount of lanthanum chloride sufficient to obtain a final content of 0.1% was added to eliminate phosphate

**Table 1** Mineral content (per 100 g), phytate (IP<sub>5</sub> + IP<sub>6</sub>) content (per 100 g) and molar ratios of phytate to iron, calcium and zinc, and phytate × calcium/zinc of commercial infant cereals

Infant cereal	Fe (mg)	Ca (mg)	Zn (mg)	Phytate (mg)	Phytate/Fe	Phytate/Ca	Phytate/Zn	Phytate × Ca/Zn
Eight cereals-honey	8.3 ± 0.4	137.3 ± 5.6	0.6 ± 0.3	319.6 ± 3.1	3.8	0.16	53.1	182.3
Rice cream	8.8 ± 0.1	283.1 ± 27.7	1.2 ± 0.2	167.1 ± 27.5	1.6	0.11	14.4	101.9
Multicereals	8.7 ± 0.2	174.4 ± 21.0	1.5 ± 0.4	143.5 ± 10.6	1.4	0.07	9.8	42.7
Gluten-free cereals	7.5 ± 1.0	154.4 ± 38.9	1.0 ± 0.3	299.8 ± 16.9	3.5	0.18	31.8	122.7

interferences in the calcium determination. To dissolve the ashes, 2 mL of concentrated HCl (sp gr = 1.19) was added, and the vessel was covered with a watch glass and gently warmed (70-75°C) for 4 h, leaving about 1 mL of liquid at the end of heating. The solution was then transferred to a 10 mL volumetric flask, and the volume was completed with water. Solubility percentages were determined as follows: solubility % =  $100 \times S/C$ , where S = soluble mineral content (μg of mineral/g of sample), and C = total mineral content of the sample (μg of mineral/g of sample). Differences between the mineral content of the monolayer incubated with soluble mineral fraction and the content of monolayer not exposed (retention blank) yielded an estimation of the cellular retention (micrograms) of minerals. Transport (T) was evaluated by the difference between the mineral amount in basal chamber solutions of treated samples and HBSS. The following calculation was used for retention percentages: retention % =  $100 \times R/C$ , where R = mineral retention (μg of mineral/well), and C = mineral soluble added (μg). Transport percentages were calculated as follows: transport % =  $100 \times T/C$ , where T = cellular transport (μg of mineral/well), and C = mineral soluble added (μg/well). The differences between the mineral content of cells cultures incubated with samples or HBSS (blank) gave an estimation of the cellular uptake (cell retention plus transport) of these mineral elements. Uptake percentage values were calculated as the percentage of the mineral applied to the Caco-2 cell monolayer which was taken up by the cells and results were used as a measure of mineral availability. Due to the differences among samples in terms of the solubility of minerals after *in vitro* digestion, mineral transport and uptake were normalized for solubility as follows: % transport efficiency = (% solubility × % transport)/100, % uptake efficiency = (% solubility × % uptake)/100.

#### Quality control of the iron, calcium, and zinc analyses

The absence of matrix interferences in AAS determination of Fe and Ca in the samples was checked by the addition's method. Community Bureau of reference material CRM-189 (wholemeal flour) (Brussels, Belgium) was used as a control to test the method for accuracy. For Fe, Ca and Zn, the measured mean values were 66.9 μg/g, 519 μg/g and 54.9 μg/g, respectively, which were in accordance with the certified range of  $68.3 \pm 1.9$  μg/g for Fe, 520 μg/g (standard deviation non-certified) for Ca and  $56.5 \pm 1.7$  μg/g for Zn. The detection limit was determined to be 0.6 mg/L. The method was shown to

be linear ( $r \geq 0.998$ ) over the range 1-5 mg/L for both Fe ( $y = 2.86 \times 10^{-3} + 4.76 \times 10^{-2} X$ ) and Ca ( $y = 2.67 \times 10^{-3} + 5.24 \times 10^{-2} X$ ).

#### Statistical analysis

Results are reported as mean ± SD of five experiments. After testing for normality and equal variances, the mean solubility, retention, transport efficiency, and uptake efficiency percentages of Fe, Ca, and Zn from infant cereals, whether or not dephytinized, were compared by one-way analysis of variance (ANOVA) including the Tukey post-test in the data treatment to determine significant differences among means ( $P < 0.05$ ). A Pearson correlation analysis was performed to investigate the possible correlation between phytate content; Fe, Ca, and Zn contents; mineral solubility (%); retention (%); uptake (%); and transport (%) by Caco-2 cells. Values of  $P < 0.05$  were considered significant. All statistical analyses were performed with the Statistical Package for the Social Sciences (version 14.0; SPSS).

## RESULTS

#### Inositol phosphate content

Molar ratios of phytate (IP<sub>5</sub> + IP<sub>6</sub>) to iron, phytate to calcium and phytate to zinc, as well as the phytate × (Ca/Zn) molar ratio, are shown in Table 1. For iron, values ranged from 1.4 to 3.8; for calcium, from 0.07 to 0.18; and for zinc, 42.7 to 182.3.

#### Uptake, retention and transport experiments

The results obtained in the iron retention, transport, and uptake assays by Caco-2 from infant cereals are summarized in Table 2. The iron retention percentage and transport and uptake efficiencies of eight cereals-honey, Multicereals and Gluten-free cereals after dephytinization were significantly higher ( $P < 0.05$ ) than that of commercial infant cereals. The iron solubility percentage was higher from eight cereals-honey and Multicereals after dephytinization; conversely the solubility percentage of commercial rice cream was higher than that of the same sample after phytase treatment. Total iron content of each infant cereal before and after phytase treatment was equal.

Table 3 shows the results obtained for calcium cell retention, transport, and uptake assays by Caco-2 cells. Calcium uptake efficiency percentage was higher from infant cereals analyzed after phytase treatment with the exception of eight cereals honey; however, results were significant ( $P < 0.05$ ) only for Gluten-free cereals.

After phytase treatment, this infant cereal showed that solubility and transport efficiency percentages of calcium increased significantly as well. From samples not dephytinized, significant highest solubility and retention percentages of calcium were observed for eight cereals-honey, and highest solubility and transport efficiency percentages for multicereals. Total calcium content of each infant cereal before and after phytase treatment was equal.

As shown in Table 4, the effect of dephytinization caused an increase (*P* < 0.05) in retention and uptake efficiency percentages of zinc in most of samples analyzed. Rice cream showed an increase in solubility, transport, and uptake efficiencies percentages after phytase treatment. Significant differences on the solubility percentage of zinc were observed for Gluten-free cereals and rice cream between samples, whether or not dephytinized. Total zinc content of each infant

cereal before and after phytase treatment was equal.

With significant values at *P* < 0.05, a negative correlation between phytate content and retention percentages of iron and zinc (*r* = -0.730 and *r* = -0.538) and iron transport (*r* = -0.507), and uptake efficiency (*r* = -0.519) percentages were found. Calcium content showed a negative correlation with transport efficiency percentage of iron (*r* = -0.426) and with uptake efficiency percentage of zinc (*r* = -0.855). Mineral solubility percentage showed for each mineral analyzed (Fe, Ca, and Zn) a positive correlation with transport efficiency percentage (*r* = 0.735, *r* = 0.912, *r* = 0.732, respectively) and with uptake efficiency percentage (*r* = 0.794, *r* = 0.923, *r* = 0.838, respectively).

## DISCUSSION

Fe, Ca, and Zn contents of infant cereals analyzed were

in accordance with recommendations of the European Economic Community (Directive 2006/125)<sup>[21]</sup>. In the present study, the values found for the phytate (IP<sub>5</sub> + IP<sub>6</sub>) to iron molar ratios were higher than 1.4. Although the critical ratio (capable of compromising bioavailability) has not yet been well established, according to Hurrell<sup>[5,12]</sup>, values obtained in infant cereals of this study have the potential to compromise iron bioavailability. It is interesting to note the very low phytate to calcium molar ratio for all infant cereals analyzed; apparently phytate could not compromise Ca availability since the critical value for which the absorption of calcium is compromised has been reported to be  $> 0.24$ <sup>[4]</sup>. Three of the four infant cereals analyzed showed a phytate to zinc molar ratio above 12, a value implicated in interference with zinc bioavailability in humans<sup>[22,23]</sup>. The infant cereal named eight cereals-honey showed phytate  $\times$  calcium/zinc molar ratios above the critical value within the range of 150-200, which have been associated with a decrease in zinc bioavailability.

It has been reported that removing phytate increases iron bioavailability in the Caco-2 cell *in vitro* model<sup>[24,25]</sup>. Since iron solubility, iron retention, transport efficiency, and uptake efficiency percentages can be used as bioavailability predictors<sup>[8,26,27]</sup>, our results showed that three of the four infant cereals analyzed after phytase treatment increased iron bioavailability. The source of iron used for the enrichment of infant cereals (elemental iron) plays an important role in iron solubility<sup>[28]</sup>; in this regard, values found in our study were lower than those reported by other authors<sup>[29,30]</sup> for the same element, probably due to the phytate content or fiber components from cereals, the different pH conditions applied for the assays<sup>[29]</sup>, or the previously reported the inhibitory effect of calcium on iron availability<sup>[10]</sup> since infant cereals used in this study were calcium-enriched. Differences in iron bioavailability parameters between dephytinized infant cereals could indicate that other components of infant cereals can also decrease iron bioavailability; in this regard, it has been reported that some dietary fiber components can bind mineral ions decreasing their bioavailability<sup>[30,31]</sup>. Commercial infant cereal (Multicereals) showed the highest values of iron bioavailability parameter measures which can be justified because of its lower molar ratio of phytate to iron, compared to eight cereals-honey, rice cream and Gluten-free cereals.

It should be noted that the positive correlation observed between iron solubility with cell transport and uptake efficiencies percentages found in our study is in agreement with Bergqvist *et al*<sup>[26]</sup>, studying iron absorption from carrot juice, and with Proulx and Reddy<sup>[32]</sup> studying iron bioavailability of maize, both using Caco-2 cells. Meanwhile, it has been reported by other authors<sup>[27,33]</sup> that solubility and bioavailability by Caco-2 cells did not show parallel trends.

In our study, a lack of significant effect of dephytinization on calcium bioavailability parameters by Caco-2 cells was found in most of the infant cereals

analyzed, although a great variability was observed. The inhibitory effect of phytate on calcium bioavailability has been reported<sup>[34-36]</sup> but only for high ratios. Our observation could be explained by the binding of calcium phytate to the membrane of Caco-2 cells. In this regard, Phyllippy<sup>[36]</sup> reported that Caco-2 cells may not be useful for studying the effects of inositol phosphates on the calcium uptake by cells. Calcium solubility from eight cereals-honey and Multicereals decreased after phytase treatment whereas Gluten-free cereals showed a higher calcium solubility after phytase treatment. Since it has been reported that calcium solubility depends on the phytate to calcium molar ratio<sup>[34]</sup> the low ratio Ca: phytate ratio ( $\leq 0.18$ ) of all infant cereals analyzed could explain the lack of effect of phytase on calcium solubility. In fact, only Gluten-free cereals (the sample with the highest phytate/Ca molar ratio) showed a significant increase in transport and uptake efficiencies after dephytinization.

Percentages of soluble zinc did not show significant differences before and after dephytinization for most of the samples analyzed. Zn solubility percentages obtained ( $< 37.8\%$  for commercial infant cereals;  $< 46.9\%$  for dephytinized infant cereals) were lower than values obtained by Cámara *et al*<sup>[27]</sup> in school meals, and by Lyon<sup>[37]</sup> in cereal products. The same trend was observed in a previous analysis in our laboratory studying infant cereals<sup>[38]</sup>, since a lack of phytase effect on zinc solubility was found for most of the samples studied; moreover, Kayode *et al*<sup>[39]</sup> observed similar results studying opaque sorghum beer. Probably, as reported Perales *et al*<sup>[10]</sup>, the calcium added as enrichment to infant cereals that are not Zn-fortified exerted a negative effect on Zn solubility.

However, when bioavailability was evaluated in Caco-2 cells, all infant cereals analyzed showed an increase in the Zn uptake efficiency percentage after phytase treatment. Values obtained for Multicereals, rice cream and Gluten-free cereals were significant ( $P < 0.05$ ). Eight cereals-honey, Multicereals and Gluten-free cereals presented a higher percentage of zinc retention after phytase treatment with respect to the same infant cereal not dephytinized. The retention and uptake efficiencies of zinc data obtained in our study clearly demonstrate that phytate impaired bioavailability, since significant differences were found between samples dephytinized and not dephytinized. The inhibitory effect of phytate on Zn bioavailability by Caco-2 cells has been previously reported<sup>[40,41]</sup>.

In conclusion, dephytinization of infant cereals by an exogenous phytase resulted in increasing bioavailability parameters of iron and zinc measured in a Caco-2 cell line. However, for calcium, a lack of effect of dephytinization of infant cereals on bioavailability by Caco-2 cells was found in our study.

## ACKNOWLEDGMENTS

We appreciate the technical help of Dr. Y Sambuy. We acknowledge SternEnzym for kindly providing samples

of phytase for experiments. We also thank Hero España SA for providing the samples.

## COMMENTS

### Background

An adequate intake of minerals is particularly important for infants in the first year of life. Although breast-feeding is considered the natural and preferred method for infant feeding, after the 6th mo of age cereals are introduced to supplement breast milk. Given the importance of an adequate nutrition during infancy, a better knowledge of the gastrointestinal conditions of infants and its effects on food components affecting intestinal absorption of minerals are essential.

### Research frontiers

The research hotspot is the study and improvement of mineral bioavailability from cereal foods with a different matrix under gastrointestinal conditions of infants and to obtain major knowledge about intestinal absorption of iron, calcium and zinc using the Caco-2 cell line.

### Innovations and Breakthroughs

Low absorption of minerals from infant foods is considered to be a factor in the aetiology of mineral deficiencies in infants. Gastrointestinal conditions (pH and digestive enzymes) are keys in mineral absorption. Data indicate that the Caco-2 cell line is a useful tool to study iron and zinc absorption and simultaneously to characterize the effect of some food components on mineral intestinal absorption.

### Applications

Better knowledge of intestinal mineral absorption process and interactions with dietary factors at a gastrointestinal level would be helpful to develop infant foods with improved mineral availability.

### Terminology

Phytic acid: (my-inositol hexaphosphoric acid), a dietary factor found principally in cereals and legumes which is a potent inhibitor of mineral absorption owing to its strong ability to bind multivalent metal ions. Mineral bioavailability: the proportion of minerals that can be absorbed and used for physiological purposes.

### Peer review

This is a descriptive study that shows the effect of dephytinization on the bioavailability of iron, calcium and zinc in different commercial infant cereals using the *in vitro* Caco-2 cell model. The manuscript is easy to understand and in general terms well written. The work described is well done.

## Abstract

**AIM:** To evaluate 20 adults with intussusception and to clarify the cause, clinical features, diagnosis, and management of this uncommon entity.

**METHODS:** A retrospective review of patients aged > 18 years with a diagnosis of intestinal intussusception between 2000 and 2008. Patients with rectal prolapse, prolapse of or around an ostomy and gastroenterostomy intussusception were excluded.

**RESULTS:** There were 20 cases of adult intussusception. Mean age was 47.7 years. Abdominal pain, nausea, and vomiting were the most common symptoms. The majority of intussusceptions were in the small intestine (85%). There were three (15%) cases of colonic intussusception. Enteric intussusception consisted of five jejunojejunal cases, nine ileoileal, and four cases of ileocecal invagination. Among enteric intussusceptions, 14 were secondary to a benign process, and in one of these, the malignant cause was secondary to metastatic lung adenocarcinoma. All colonic lesions were malignant. All cases were treated surgically.

**CONCLUSION:** Adult intussusception is an unusual and challenging condition and is a preoperative diagnostic problem. Treatment usually requires resection of the involved bowel segment. Reduction can be attempted in small-bowel intussusception if the segment involved

## INTRODUCTION

Intestinal invagination or intussusception is the leading cause of intestinal obstruction in children, but in adults it accounts for only 5% of all intussusceptions, and 0.003%-0.02% of all adult hospital admissions. In contrast to childhood intussusception, which is idiopathic in 90% of cases, adult intussusception has a demonstrable lead point, which is a well-definable pathological abnormality in 70%-90% of cases<sup>[1-3]</sup>.

The presentation of pediatric intussusception often is acute with sudden onset of intermittent colicky pain, vomiting, and bloody mucoid stools, and the presence of a palpable mass. In contrast, the adult entity may present with acute, subacute, or chronic non-specific symptoms<sup>[4]</sup>. Therefore, the initial diagnosis often is missed or delayed and may only be established when the patient is on the operating table. Most surgeons accept that adult intussusception requires surgical resection because the majority of patients have intraluminal lesions. However, the extent of resection and whether the intussusception should be reduced remains controversial<sup>[5]</sup>.

Therefore in this paper, we report our experience in an attempt to clarify the cause, clinical features, diagnosis, and management of this uncommon entity.

## MATERIALS AND METHODS

The clinical, operative, and pathological records of 20 adult patients (> 18 years of age) with a diagnosis of intussusception, surgically treated between 2000 and 2008 were reviewed retrospectively. Patients with rectal prolapse, prolapse of or around an ostomy and gastroenterostomy intussusception were excluded.

Intussusception was classified as enteric or colonic. When the pathologic lead point was located in the small bowel, including jejunojejunal, ileoileal and ileocolic intussusceptions, it was classified as enteric. Colonic intussusception included ileocecal-colic, colocolonic, sigmoidorectal, and appendicocolic intussusception. Ileocolic and ileocecal-colic intussusception was distinguished by the site of the pathological lead point. When the lead point was at the ileum, intussusception was classified as ileocolic, whereas when the lead point was at the ileocecal valve, it was classified as ileocecal-colic.

## RESULTS

### Demographics

A total of 20 patients were identified who had a diagnosis of intussusception and were older than 18 years of age. The average age of the patients was 47.7 years, with a range of 21 to 75 years. Nine (45%) were male and 11 (55%) were female.

### Clinical manifestations

Pain was the most common presenting complaint and was present in 17 patients (85%). Nausea, vomiting, constipation, rectal bleeding, and diarrhea were other symptoms. Table 1 shows the symptoms and signs. A palpable mass was found in only one patient (5%). The mean duration of symptoms was 7.9 d (range, 1 d to 3 mo). Six patients (30%) had acute symptoms (< 4 d), five (25%) had subacute symptoms (4-14 d), and nine (45%) had chronic symptoms (> 14 d).

### Preoperative diagnostic studies

Plain abdominal X-rays were first obtained in patients with acute symptoms, which revealed air-fluid levels that suggested intestinal obstruction in five patients (25%). It was normal in the other 15 patients (75%).

Intussusception was a preoperative diagnosis in 14 patients (70%). Six patients (30%) who were diagnosed with intussusception in the operating room showed serious signs of bowel strangulation and were not diagnosed preoperatively because they were transferred to the operating room without further radiological evaluation. Abdominal computed tomography (CT) scan was performed in 12 patients, of whom 10 (83.3%) were diagnosed with intussusception. The finding on CT was an in-homogeneous soft-tissue mass that was target- or sausage-shaped (Figure 1). Three patients underwent colonoscopy, and intussusception was confirmed in two. A small-bowel series were performed in three patients. Two patients in diagnostic studies had findings

Table 1 Symptoms and signs of intussusception

Symptoms and signs	n (%)
Pain	17 (85)
Nausea	15 (75)
Vomiting	14 (70)
Constipation	3 (15)
Rectal bleeding	1 (5)
Diarrhea	1 (5)
Abdominal mass	1 (5)
Fever	1 (5)

Figure 1 Abdominal CT scan showing an in-homogeneous soft tissue mass that is target or sausage-shaped in a jejunojejunal intussusception (white arrow).

suspicious of intussusception caused by obstruction with polyps or tumors.

### Location

The majority of intussusceptions were enteric (17/20 or 85%) (Table 2). There were three (15%) cases of colonic intussusception. Five cases of enteric intussusception were jejunojejunal (Figure 2A), nine were ileoileal, and four had ileocecal invagination detected.

### Pathology

The pathological cause of intussusception was identified in 18 (90%) cases (Table 2). Benign pathology was seen in 14 cases (77.8%) and malignancy in four (22.2%). Among enteric intussusception, 14 cases were secondary to a benign process, including submucosal lipoma, Peutz Jeghers polyps, inflammatory fibroid polyp, intussuscepting Meckel diverticulum, fibroid polyp (Figure 2B), and congenital band adhesions. One malignant case was secondary to metastatic lung adenocarcinoma. All colonic intussusceptions resulted from a malignant lesion. The causes of colonic intussusception were secondary to primary adenocarcinoma in two cases and primary colonic lymphoma in one. No colorectal or rectorectal intussusception was identified in this study.

### Treatment and consequences

All patients underwent operative treatment (Table 2). No hydrostatic reduction was attempted in any case. The choice of procedure was determined by the location, size, and cause of the intussusception and the viability

Table 2 Location, treatment and pathology

No. of patients	Age	Gender	Location of the lesion	Preoperative diagnosis	Surgical treatment	Pathology
1	33	M	Enteric (jejunojejunal)	+ (small bowel series)	Reduction + enterotomy + polypectomy	Peutz-Jeghers (hamartomatous polyp)
2	49	F	Enteric (ileocecal)	+ (CT)	Right hemicolectomy	Ileal lipoma
3	60	F	Enteric (ileoileal)	- (Urgent)	Reduction + segmental ileal resection	Inflammatory fibroid polyp
4	30	F	Enteric (ileocecal)	+ (CT)	Reduction + segmental ileal resection	Fibrous polyp
5	63	M	Colonic (colocolic)	+ (colonoscopy)	Near total colectomy + ileorectal anastomosis	Lenfoma
6	56	F	Enteric (ileocecal)	+ (CT)	Right hemicolectomy	Inflammatory fibroid polyp
7	21	F	Enteric (jejunojejunal)	+ (CT)	Reduction + segmental jejunal resection + enterotomy + polypectomy	Peutz-Jeghers (hamartomatous polyp)
8	36	M	Enteric (ileoileal)	- (Urgent)	Reduction	Idiopathic
9	75	M	Colonic (colocolic)	+ (colonoscopy)	Left hemicolectomy	Adeno CA
10	25	M	Enteric (ileoileal)	- (Urgent)	Reduction	Congenital band
11	60	M	Enteric (ileoileal)	+ (CT)	Reduction + segmental ileal resection	Ileal lipoma
12	28	F	Enteric (jejunojejunal)	- (Urgent)	Reduction + segmental jejunal resection	Inflammatory fibroid polyp
13	48	M	Enteric (jejunojejunal)	+ (CT)	Reduction + segmental jejunal resection	Idiopathic
14	55	F	Enteric (ileoileal)	+ (CT)	Reduction + segmental ileal resection	Ileal lipoma
15	62	F	Enteric (ileoileal)	+ (CT)	Reduction + segmental ileal resection	Inflammatory fibroid polyp
16	26	M	Enteric (jejunojejunal)	+ (small bowel series)	Reduction + enterotomy + polypectomy	Peutz-Jeghers (hamartomatous polyp)
17	48	F	Enteric (ileoileal)	- (Urgent)	Reduction + diverticulectomy	Meckel's diverticulum
18	72	M	Colonic (colocolic)	+ (CT)	Left hemicolectomy	Adeno CA
19	56	F	Enteric (ileoileal)	+ (CT)	Reduction + segmental ileal resection	Metastatic Adeno CA
20	51	F	Enteric (ileoileal)	- (Urgent)	Reduction + diverticulectomy	Meckel's diverticulum

**Figure 2** Operative picture. A: Jejunojejunal intussusception; B: The fibroid lesion that acted as a lead point for ileocecal intussusception.

of the bowel. All 20 patients underwent laparotomy. En bloc resection (without reduction) was performed in five patients (25%), four of whom underwent right or left hemicolectomy, and one, subtotal colectomy and ileorectal anastomosis because of suspicion of malignancy. Reduction of the intussuscepted bowel was performed on the remaining 15 patients (75%). Among these, segmental resection was performed in nine, two of whom underwent diverticulectomy, two, enterotomy and polypectomy, and one, congenital band excision.

Postoperative complications occurred in four of 20 patients (20%): superficial wound infection in two (10%), pneumonia in one (5%), and severe sepsis in one (5%). There were no anastomotic leaks or intra-abdominal abscesses. There was one perioperative death (5%), which was secondary to severe sepsis complicated by multiple organ failure 6 d after the operation.

## DISCUSSION

Adult intussusception is an uncommon clinical entity encountered by surgeons. The exact mechanism is unknown, and it is believed that any lesion in the bowel wall or irritant within the lumen that alters normal peristaltic activity is able to initiate invagination<sup>[2,6]</sup>. Ingested food and the subsequent peristaltic activity of the bowel produce an area of constriction above the stimulus and relaxation below, thus telescoping the lead point (intussusceptum) through the distal bowel lumen (intussusciens)<sup>[1,2]</sup>. The most common locations are at the junctions between freely moving segments and retroperitoneally or adhesioneally fixed segments<sup>[6,7]</sup>.

About 90% of occurrences in adults have a lead point, a well-definable pathological abnormality. In general, the majority of lead points in the small intestine

consist of benign lesions, such as benign neoplasms, inflammatory lesions, Meckel's diverticuli, appendix, adhesions, and intestinal tubes. Malignant lesions (either primary or metastatic) account for up to 30% of cases of intussusception in the small intestine<sup>[2,5]</sup>. On the other hand, intussusception occurring in the large bowel is more likely to have a malignant etiology and represents up to 66% of the cases<sup>[2,5,6,8]</sup>. In our study malignant etiology was detected in all cases of colonic intussusception.

The clinical presentation in adult intussusception is often chronic, and most patients present with non-specific symptoms that are suggestive of intestinal obstruction. Abdominal pain is the most common symptom followed by vomiting and nausea<sup>[1,2]</sup>. Abdominal masses are palpable in 24%-42% of patients, and identification of a shifting mass or one that is palpable only when symptoms are present is suggestive of intussusception or volvulus<sup>[1,2,5]</sup>. In our series, an abdominal mass was only palpable in one patient (5%).

The symptoms in cases of adult intussusception are so non-specific that a clinical diagnosis beyond bowel obstruction is rarely made before surgery.

Several imaging techniques may help to precisely identify the causative lesion preoperatively. Plain abdominal X-rays are typically the first diagnostic tool and show signs of intestinal obstruction, and may provide information regarding the site of obstruction<sup>[8,9]</sup>. Contrast studies can help to identify the site and cause of the intussusception, particularly in more chronic cases. Upper gastrointestinal series may show a "stacked coins" or "coiled spring" appearance<sup>[8]</sup>. Barium enema examination may be useful in patients with colonic or ileocolic intussusception in which a "cup-shaped" filling defect is a characteristic finding<sup>[8]</sup>. Barium studies are obviously contraindicated if there is the possibility of bowel perforation or ischemia.

Colonoscopy is also a useful tool for evaluating intussusception, especially when the presenting symptoms indicate a large bowel obstruction<sup>[2,10,11]</sup>. It may not be advisable to perform endoscopic biopsy or polypectomy in those individuals with long-term symptoms because of the high risk of perforation, which is more likely to happen in the phase of chronic tissue ischemia, and perhaps necrosis because of vascular compromise in intussusception<sup>[12]</sup>.

In our series, three patients underwent colonoscopy, and intussusception was confirmed in two (66.6%). A small-bowel series were performed in three patients. Two (66.6%) patients in diagnostic studies had findings suspicious of intussusception because of obstruction with polyps or tumors.

Ultrasonography has been used to evaluate suspected intussusception. The classic features include the "target and doughnut sign" on transverse view and the "pseudokidney sign" in longitudinal view. The major disadvantage of ultrasound is masking by gas-filled loops of bowel, and operator dependency<sup>[10,11,13,14]</sup>.

In recent years, CT has become the first imaging method performed, after plain abdominal X-rays, in the evaluation of patients with non-specific abdominal

complaints. The characteristics of intussusception on CT are an early "target mass" with enveloped, excentrically located areas of low density. Later, a layering effect occurs as a result of longitudinal compression and venous congestion in the intussusceptum<sup>[15]</sup>. Abdominal CT has been reported to be the most useful tool for diagnosis of intestinal intussusception and is superior to other contrast studies, ultrasonography, or endoscopy<sup>[15-18]</sup>. The reported diagnostic accuracy of CT scans was 58%-100%, especially in recent series<sup>[1,4,6,16,19]</sup>. The diagnosis of intussusception was based on CT findings in the majority of our cases (10/12); two were based on colonoscopy and two on a small-bowel series. The accuracy was 83.3% for CT, 66.6% for colonoscopy, and 66.6% for small-bowel series. The preoperative diagnostic accuracy was 70% in our series.

Although few reports have described magnetic resonance imaging (MRI) of adult intussusception, the general imaging characteristics of intussusception on MRI are similar to those on CT<sup>[18,20]</sup>, but fast MR examination, unlike CT, is not technically limited by the presence of previously administered barium for small bowel series<sup>[21]</sup>.

The optimal management of adult intussusception remains controversial. Most of the debate focuses on the issue of primary en bloc resection versus initial reduction, followed by a more limited resection<sup>[1,2,19,22]</sup>. Proponents of primary resection cite the high incidence of underlying malignancy, especially in colonic lesions, which mandates en bloc resection. Furthermore, the inability to differentiate malignant from benign etiology preoperatively or intraoperatively also dictates that small bowel intussusception be resected without reduction. The reduction of an intussusception secondary to a malignant lead point is potentially detrimental, as there is the theoretic risk of intraluminal seeding and venous embolization in regions of ulcerated mucosa. Other drawbacks include the increased risk of anastomotic complications (the bowel wall may be weakened during manipulation) and the potential for bowel perforation<sup>[1,5,6,23,24]</sup>.

On the other hand, some authors have recommended a selective approach to resection, taking into consideration the site of intussusception, which influences the type of pathology<sup>[2,25]</sup>. They advocate resection of all colonic lesions but a more selective approach for small bowel pathology, as the lower malignancy rate for small bowel intussusception makes the argument for initial resection less convincing.

Recently, minimally invasive techniques have been applied to the treatment of small or large bowel obstructions, specifically to the diagnosis and treatment of adult intussusception. There are several case reports about laparoscopic small bowel resection because of intussusception<sup>[26,27]</sup>. The choice of using a laparoscopic or open approach depends on the clinical condition of the patient, the location and extent of intussusception, the possibility of underlying disease, and the availability of surgeons with sufficient laparoscopic expertise<sup>[28,29]</sup>. In the present study, we did not use laparoscopy for diagnosis or treatment.

In conclusion, intussusception in adults is a rare entity and diagnosis may be challenging because of non-specific symptoms. Surgeons should be familiar with the various treatment options, because the real cause of the intussusception often is accurately diagnosed by laparotomy. CT is the most useful imaging modality in the diagnosis of intussusception. Treatment usually requires resection of the involved bowel segment. Reduction can be attempted in small-bowel intussusception if the segment involved is viable or malignancy is not suspected; however, a more careful approach is recommended in colonic intussusception because of a significantly higher chance of malignancy.

## COMMENTS

### Background

Intestinal intussusception in adults is a rare entity and there is an ongoing controversy regarding the optimal management of this problem. Most surgeons accept that adult intussusception requires surgical resection because the majority of patients have intraluminal lesions. However, the extent of resection and whether the intussusception should be reduced remains controversial.

### Research frontiers

Authors aimed to evaluate their experience with 20 adult intussusception cases and to clarify the cause, clinical features, diagnosis, and management of this uncommon entity.

### Applications

The present study was retrospective; however, it highlights the clinical features in adult intussusception and may guide surgeons who encounter this problem.

### Terminology

Intussusception occurs when a segment of bowel and its mesentery (intussusceptum) invaginates the downstream lumen of the same loop of bowel (intussusciens). Sliding within the bowel is propelled by intestinal peristalsis and may lead to intestinal obstruction and ischemia.

### Peer review

This is an interesting retrospective study with excellent figures. Although the authors do not show any case with laparoscopic approach, the general statement should be more positive and oriented towards the practice in 2009.

### Abstract

**AIM:** To investigate the flow and mixing at the duodenal stump after gastric resection, a computer simulation was implemented.

**METHODS:** Using the finite element method, two different Billroth II procedure cases (A and B) were modeled. Case A was defined with a shorter and almost straight duodenal section, while case B has a much longer and curved duodenal section. Velocity, pressure and food concentration distribution were determined and the numerical results were compared with experimental observations.

**RESULTS:** The pressure distribution obtained by numerical simulation was in the range of the recorded experimental results. Case A had a more favorable pressure distribution in comparison with case B. However, case B had better performance in terms of food transport because of more continual food

### INTRODUCTION

The duodenum is a short, complex and functionally highly specialized part of the small intestine. It has many motor, sensitive and secretory functions. Transit of chyme through the duodenum is a very complicated process (which includes intestinal peristalsis, gastric emptying, and pyloric sphincter tone) and is regulated by many neurological and hormone-dependent feedback mechanisms<sup>[1-6]</sup>.

Two layers of smooth muscle cells (inner-longitudinal and internal-circumferential), as well as two neurological intramural networks (*Auerbach's* and *Meisner's* complexes), are responsible for gastroduodenal peristalsis. Electrical activity of the smooth muscle cell syncytium of the duodenum and in other parts of the gastrointestinal tract is represented by two basic types of electrical waves: slow waves and the spikes. Slow waves represent basic electrical activity and they are caused by activity of the Na-K pump. When the resting membrane potential become less negative than -40 mV, the spikes appear on the top of slow waves with a frequency of 1-10 Hz,

**Figure 1** Normal physiological gastric outlet, pylorus, and superior duodenum.

and cause smooth muscle contraction. The number of duodenal contractions is about 12/min<sup>[7]</sup>. Several new investigations suggest that slow waves and spikes are regulated and spread through different cell networks<sup>[8]</sup>.

The pylorus shown in Figure 1 comprises a collection of tissue structures that connect the antrum to the duodenum. Its luminal diameter is controlled by a sphincter muscle complex that sets resistance to the bulk gastric effluent, through regulation of the pyloric orifice tone. During gastric digestion, the proximal and distal pyloric muscle loops occlude the pyloric lumen, preventing premature discharge of unprocessed material into the duodenum. Once the stomach has completed its task of breaking down large solid agglomerates into smaller particles, the pylorus relaxes and peristaltic contractions in the antrum begin to force chyme distally. At this point, antral contraction waves approach the pyloric orifice and, along with the sphincter complex and mucosal folds, cause steady constriction of the pyloric lumen. Chyme continues to be forcibly transported through this lumen until it is fully occluded, a process thought to induce an effluent jet into the superior duodenum<sup>[9]</sup>. Dysfunction of the duodenum can occur as a result of many disorders of gastric emptying and dyspeptic complaints, which demonstrates the vital role of the duodenum<sup>[10]</sup>. This role becomes especially apparent in surgical interventions on the gastroduodenum<sup>[11]</sup>.

A large number of studies have investigated the intact gastrointestinal tract anatomically<sup>[12-14]</sup>, but there have been relatively few studies on the consequences of cutting muscles, nerves and other important anatomical structures of the gastroduodenum. These are unavoidable during surgical interventions, with disturbance of many fine, highly sophisticated feedback systems. These undesirable conditions lead to negative feedback mechanisms<sup>[15,16]</sup> that cause changes in physiological processes with respect to the preoperative state<sup>[17,18]</sup>.

To date, it seems that insufficient attention has been paid to how the geometry and flow conditions affect the gastroduodenal system after distal gastric resection. There are various types of reconstruction

**Figure 2** Schematic representation of reconstruction of gastrointestinal continuity after gastric resection. A: Normal anatomy of gastroduodenal region with resection lines; B: Billroth II antiperistaltic anastomosis.

of gastrointestinal continuity after gastric resection. In studying the treatment of gastric cancer, Devin reported in 1968 about 300 types of reconstruction after surgery of the gastroduodenal region<sup>[19]</sup>. During recent years, a few types have become more frequent. The first and most physiological variant is a state in which continuity of the gastrointestinal tract is reconstructed with anastomosis between the gastric stump and the duodenum; this procedure is called Billroth I gastric resection (gastroduodenal anastomosis). The other type of reconstruction is the Billroth II operation, which is shown in Figure 2, in which the anastomosis is located between the gastric stump and a loop of jejunum (gastrojejunal anastomosis, gut to side), and this type of intervention is the subject of our study. Anastomosis may include the entire circumference of the gastric stump (today it is a rarely used technique because of many unwanted consequences) or just a part of the circumference when a smaller diameter anastomosis is created. This is a better method of adaptation of the gastric stump and jejunal loop-the Hoffmeister-Finsterer modification. The length of the proximal jejunal loop is variable and depends on anatomical variations (e.g. length of the mesentery of the small intestine, and adhesions), as well as surgeons' ability. The jejunal loop conducts duodenal juice toward the gastric stump and the rest of the intestine. There is a hypothesis that increased intraluminal pressure in the afferent loop is the dominant cause of duodenal suture

dehiscence (caused by the length of afferent jejunal loop, narrow gastrojejunostomy, etc.<sup>[20-22]</sup>). The distal or efferent loop is the part of the duodenum that is downstream of the anastomosis, and it conducts duodenal and gastric stump content distally to the small intestine. The anastomosis is antecolic when the jejunal loop is positioned in front of the transverse colon, or the jejunal loop may be brought up posteriorly through an opening made in the transverse mesocolon (retrocolic anastomosis). Adequate position, shape and diameter of the anastomosis facilitate gastric emptying. The orientation of the jejunal loop may be two-fold, isoperistaltic, when the stomach and jejunum have the same peristalsis direction, and antiperistaltic, when the stomach and afferent loop of the jejunum have the opposite direction of peristalsis.

There are other methods of gastrointestinal tract reconstruction after gastric resection, and one of these is called Roux en Y gastrojejunostomy, in which the small bowel is cut distal to the ligament of Treitz, and the anastomosis is created between the distal limb of the jejunum and remaining gastric tissue (or esophagus in cases of total gastrectomy). The proximal limb of the jejunum is positioned downstream to the jejunum at a distance of about 45 cm, where a termino-lateral end-to-side anastomosis is created<sup>[23,24]</sup>.

In gastrointestinal tract reconstruction, the small bowel is not prepared to receive acidic content from the stomach, especially when duodenal juice is not present to neutralize it<sup>[25]</sup>. Suture dehiscence with postoperative peritonitis can occur as a complication after surgical intervention. Duodenal stump blowout is considered to be a serious postoperative complication, because of its high mortality rate<sup>[26,27]</sup>. Suture dehiscence after surgical intervention in the gastroduodenal region has been the subject of many investigations, but still many pathological mechanisms involved in this surgical problem remain unclear<sup>[28]</sup>.

This study offers a new approach to this problem. Using finite element analysis with computer modeling and clinical experiments, we attempted to determine physiological constants relevant to the above-mentioned surgical complication. In order to achieve this goal, we computed flow and mixing in the duodenal junction after distal gastric surgical resection and a Billroth II procedure.

## MATERIALS AND METHODS

A prospective, randomized, placebo-controlled, multicenter study was performed on patients treated with Billroth II Hofmeister-Finsterer subtotal gastrectomy. Our task was to investigate and quantify the effects of increased intraluminal pressure in the duodenal stump on disruption of the duodenal suture.

### Subjects

Measurements were performed on five patients after Billroth II Hofmeister-Finsterer surgical intervention. The indication for surgery was a malignant gastric

**Figure 3** Schematic representation of the manometry equipment positioned in a patient during pressure measurement.

process in three cases and ulcer disease in two. Patients with no significant co-morbidity were chosen for the study. Each patient gave written consent to our investigation. No complications were observed, and no complaints were made by these patients in relation to our actions for the purpose of this study.

### Manometry equipment

We created hardware and software equipment for measurement of pressure in the duodenal stump after distal gastric resection. The manometry assembly consisted of a Miller-Abbott tube, connecting catheters with control valves, transducers, analog-to-digital (AD) converter, and a computer with appropriate software. A Miller-Abbott tube 3.7 m in length, with an outer diameter of 5 mm, was placed in the duodenum after the operation (Figure 3). The volume of the balloon on top of the Miller-Abbott tube was 30 mL and the balloon expanded under pressure. The length of the balloon was 7 cm. The proximal end of the two-lumen tube was divided in two channels: one that connected the balloon with the measurement assembly of catheters, transducers, AD converter and personal computer; and the other used for aspiration of the duodenal stump. Distilled water was injected manually through the first channel into the balloon positioned in the duodenal stump. Data were recorded by an in-house developed software and stored to disk for later analysis. The measuring system was mobile and could be used outside the laboratory.

### Protocol

The balloon of the Miller-Abbott tube was positioned at the duodenal bulb with minimum air insufflation, followed by direct visual control. The duodenum and anterior wall of the gastrojejunal anastomosis were sutured after appropriate placing of the balloon. The entire procedure lasted 3-5 min and did not have any influence on the operative procedure itself. The final location of the catheter was documented by checking X-rays before starting measurements and again before removal. Catheter migration from the duodenum was not observed. However, duodenal motility activity was noticed in two cases.

**Figure 4 Computer simulation of pressure measurement inside duodenum bulb. A:** Schematic representation of the computational model of balloon pressure measurement inside the duodenum. Geometry of the model (a); 3D model view (b); **B:** Distribution of solid deformation (wall displacement) at the maximum pressure measurement (a); Fluid pressure distribution inside the duodenum (b).

**Figure 5 Geometry and finite element mesh of two selected cases.** Case A showed a straight duodenal part with shorter length. Case B had a much longer and curved duodenal section.

After the catheter was positioned and each subject was at rest for at least 24 h, all measurements were performed on patients in the supine position. Data files were recorded for each patient during seven postoperative days, starting 24 h after intervention. Data files consisted of pressure measurements over time. Prostigmine was used to stimulate bowel peristaltic movements. Every measurement lasted about 30 min. All external impacts that could cause some changes in duodenal intraluminal pressure were recorded in diagram form, as contractions of the anterior abdominal wall, cough, patient movements and administration of prostigmine.

Patients were discharged from the clinic after 10 d.

They continue to be under observation and come to follow-up clinical examinations.

Details about the calculation of pressure inside the duodenal bulb using finite element fluid-solid analysis are as follows.

#### Computer simulation of pressure measurement inside duodenum bulb:

We modeled balloon measurement of duodenal intraluminal pressure by using a finite element method<sup>[29,30]</sup>. The balloon and the duodenal walls were discretized by 2D solid finite elements, while 2D fluid elements were used for the fluid domain (Figure 4A). A simplified axi-symmetric model was adopted. The thickness of the balloon wall was 0.05 cm and the outer wall was 0.2 cm. The length of the balloon was 7.0 cm, with a distance from the outer wall of 2.0 cm. Fluid density was taken as 1 g/cm<sup>3</sup>, dynamic viscosity  $\mu$  was 1000 cP, Young's elasticity modulus  $E$  was 1 MPa. Fluid and solid domains had common boundaries at the interfaces on the balloon wall and duodenal wall. Air pressure was applied to the balloon wall, which caused flow of the fluid surrounding the balloon. The air pressure  $p_1$  inside the balloon was measured, and the fluid pressure  $p_2$  between the balloon and duodenal wall was calculated. The balloon deformed as a result of the difference between the air and fluid pressures. The deformed walls and fluid pressure distribution inside the duodenum are shown in Figure 4B. They corresponded to a maximum inlet balloon pressure of 2000 Pa (15 mmHg). The maximum balloon displacement was 0.4 cm, and the maximum

fluid pressure within the duodenum was around 338 Pa (2.54 mmHg), which was in the physiological range.

### Computational analysis

Computational analysis aimed to examine two different Billroth II antiperistaltic anastomosis cases. Case A represents gastric resection with a shorter and straight part of the duodenum, while case B, has a much longer and curved duodenal section. The geometry with finite element mesh for both cases is shown in Figure 5.

A viscous incompressible fluid flow was considered here as the model for the transit of chyme. This flow is governed by the Navier-Stokes equations and continuity equation that can be written as<sup>[30]</sup>:

$$\rho \left( \frac{\partial v_i}{\partial t} + v_j \frac{\partial v_i}{\partial x_j} \right) = -\frac{\partial p}{\partial x_i} + \mu \left( \frac{\partial^2 v_i}{\partial x_j \partial x_j} + \frac{\partial^2 v_j}{\partial x_j \partial x_i} \right) \quad (1)$$

$$\frac{\partial v_i}{\partial x_i} = 0 \quad (2)$$

where  $v_i$  is the chyme velocity in direction  $x_i$  (the coordinate axes are  $x_1 \equiv x$  and  $x_2 \equiv y$ ),  $\rho$  is the fluid density,  $p$  is pressure,  $\mu$  is the dynamic viscosity; and summation is implied on the repeated (dummy) indices,  $i, j = 1, 2$ . The first equation represents balance of linear momentum, while equation (2) expresses incompressibility condition.

To take into account mass transport of food, we used the additional transport equation. The assumption is that the concentration of food does not affect the gastric fluid flow (i.e. a diluted mixture is considered). The food mass transport process is governed by the convection-diffusion equation,

$$\frac{\partial c}{\partial t} + v_x \frac{\partial c}{\partial x} + v_y \frac{\partial c}{\partial y} = D \left( \frac{\partial^2 c}{\partial x^2} + \frac{\partial^2 c}{\partial y^2} \right) \quad (3)$$

where  $c$  denotes the food concentration;  $v_x, v_y$  are the gastric velocity components in the coordinate system  $x, y$ ; and  $D$  is the diffusion coefficient, assumed constant, of the transported food.

The code was validated using the analytical solution for shear stress and velocities through a straight tube<sup>[29,30]</sup>. The finite element equations were solved with respect to velocities after the pressure was eliminated by a so-called penalty procedure. The solution was obtained by use of an incremental-iterative approach and implicit integration scheme over time. The system of algebraic equations of balance for a finite element, and for a time step and equilibrium iteration " $m$ ", can be written as:

$$\begin{bmatrix} \frac{1}{\Delta t} \mathbf{M}_v + {}^{t+\Delta t} \mathbf{K}_{vv}^{(m-1)} + {}^{t+\Delta t} \mathbf{K}_{vw}^{(m-1)} & \mathbf{0} \\ {}^{t+\Delta t} \mathbf{K}_{wv}^{(m-1)} + {}^{t+\Delta t} \mathbf{J}_{vv}^{(m-1)} + \mathbf{K}_{iv} & \mathbf{0} \\ {}^{t+\Delta t} \mathbf{K}_{cv}^{(m-1)} & \frac{1}{\Delta t} \mathbf{M}_c + {}^{t+\Delta t} \mathbf{K}_{cc}^{(m-1)} + {}^{t+\Delta t} \mathbf{J}_{cc}^{(m-1)} \end{bmatrix} \begin{Bmatrix} \Delta \mathbf{v}^{(m)} \\ \Delta \mathbf{c}^{(m)} \end{Bmatrix} = \begin{Bmatrix} {}^{t+\Delta t} \hat{\mathbf{F}}^{(m-1)} \\ {}^{t+\Delta t} \mathbf{F}_c^{(m-1)} \end{Bmatrix} \quad (4)$$

where the detailed expressions for the matrices and vectors can be found elsewhere (e.g.<sup>[29-31]</sup>).

Figure 6 Geometry and boundary conditions for a Billroth II Hoffmeister-Finsterer operation.

## RESULTS

We here present typical results obtained by computer modeling and by our experimental investigation.

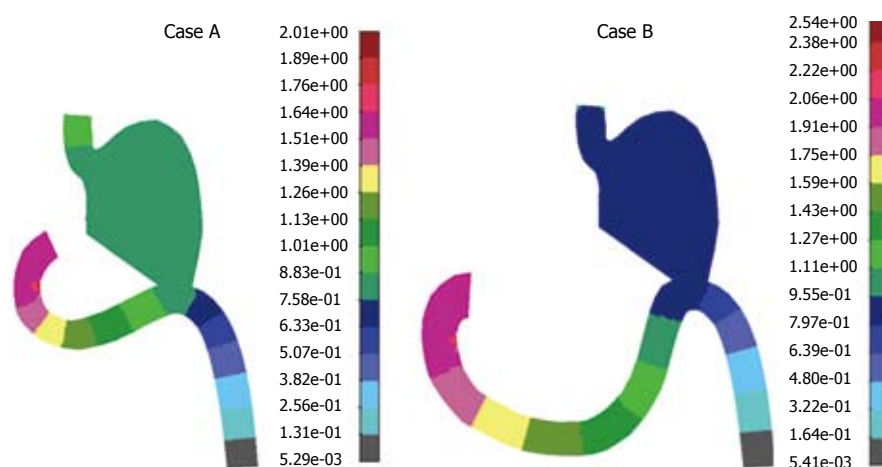

To examine different flow conditions, a few cases were considered within a simple 2D model. The steady state inflow conditions were imposed by specifying inlet fluxes at two different locations: gastric inlet with  $Q_1 = 2.2$  (l/d) and duodenum inlet with  $Q_2 = 2.0$  (l/d), as shown in Figure 6. These two flow conditions corresponded to a postoperative period of 3-4 d after distal gastric resection. Fluid density was taken as  $1 \text{ g/cm}^3$  and dynamic viscosity  $\mu$  was 1000 cP. For the convective-diffusion equation (3), boundary conditions were prescribed by the inlet food concentration  $c_0 = 1.0 \text{ (g/cm}^3\text{)}$ .

For the prescribed flow conditions at the inlets, steady state velocity distributions for both cases are shown in Figure 7. It can be seen that maximum velocity occurred at the inlet duodenal section, which was dominant during steady state flow conditions, such that fluid was moving distal to the remainder of the small intestine. Also, a maximum pressure (shown in Figure 8) was found near the pyloric section in the duodenal zone where the gastric resection was performed. Case B showed a higher pressure in comparison to case A, which was expected because of the longer section of duodenum in case B. This directly implies possible complications for case B because the risk of undesirable duodenal stump blowout was higher.

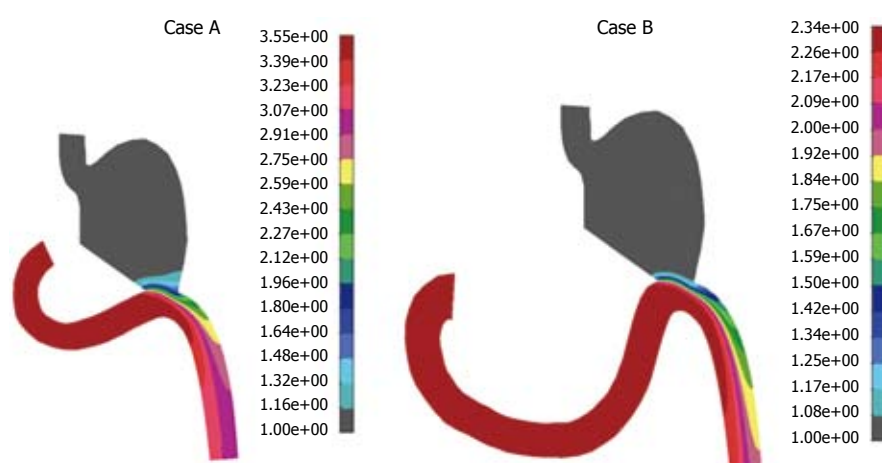

Mixing effect during postoperative period was examined by using mass transport analysis coupled with Navier-stokes equations. The influence of the diffusivity coefficient on the mass transport was investigated. Some authors<sup>[8]</sup> have suggested a negligible diffusivity which means that mass species simply advect along the fluid streamlines. Mass concentration distribution for the diffusion coefficient  $D = 2.0 \times 10^{-3} \text{ cm}^2/\text{s}$  for both cases A and B is presented in Figure 9. It can be seen from Figure 9 that maximal food concentration was located in the duodenal zone for both cases, which means that the food stays in this zone if the diffusion coefficient  $D$  is  $2.0 \times 10^{-3} \text{ cm}^2/\text{s}$ . If the coefficient of diffusion is four times larger, at  $8.0 \times 10^{-3} \text{ cm}^2/\text{s}$ , mass concentration distribution is

**Figure 7** Velocity distribution for the steady state flow conditions [in (cm/s)].

**Figure 8** Pressure distribution for the steady state flow conditions [in (mmHg)].

**Figure 9** Mass concentration [in (g/cm<sup>3</sup>)] distribution for the diffusion coefficient  $D = 2.0e-3$  cm<sup>2</sup>/s.

different (Figure 10). Obviously, for the higher diffusivity coefficient (according to our analysis,  $D = 8.e-3$  cm<sup>2</sup>/s) mass transport of food will go smoothly to the rest of gastrointestinal system, which is a desirable outcome. This effect of diffusivity is expected since diffusion enhances mass transport. There is also a difference in these two cases A and B, when the diffusivity is higher. It can be seen from Figure 9 that in case B, the duodenum section looked empty, while in case A there was approximately uniform mass distribution. This was probably the effect of the duodenal section. Therefore, the conditions in case B were better for the patient. A

lower diffusivity coefficient  $D$  caused a more dominant convective term in equation (3), which resulted in food accumulation in the duodenal section. This is clearly shown in Figure 9, in which cases A and B had maximum food concentration in the duodenal zones. This means that a patient after this surgical procedure may have food accumulation in the duodenal zone, which is not desirable.

We tested cases A and B for  $D > 8.e-3$  cm<sup>2</sup>/s (data not shown), for which computational analysis indicated a slightly better performance in the gastroduodenal connection for case A, for which more food passed

**Figure 11** Pressure measurement of Miller-Abbott (MA) tube and connecting catheter in the duodenum at 3 d after gastric resection.

through the duodenal zone.

A measurement technique described in the Methods section and Appendix was implemented in order to measure pressure inside the duodenum a few days after surgical intervention. Patients agreed that this measurement technique could be used at 3-4 d after gastric resection. Among five patients, there was one with duodenal stump leakage, and one died from a non-surgical complication (pulmonary embolism). The contractile events associated with pressure changes were detected and recorded with our in-house software. We recorded pressure changes every 0.1 s. The pressure range shown in Figure 11 for the air inside the balloon was around 15 mmHg, while the fluid pressure inside the duodenum was between 3.5 and 4.5 mmHg (which was in the physiological range<sup>[32]</sup>). Also, numerical simulations (Figure 8) for cases A and B showed similar pressure distributions (around 2.5 mmHg).

## DISCUSSION

The rate of postoperative gastric resection complication seems to be primarily influenced by increased duodenal pressure. Localization and extent of the malignant process, suture material, surgical technique, presence of potentially pathogenic microorganisms colonizing the digestive tract, and tissue quality, also may play a role in

the pathogenesis of this complication<sup>[33,34]</sup>. In this study, we focused on numerical simulation of two different Billroth II antiperistaltic anastomosis cases, with a slightly different geometrical connection of the duodenal and gastric parts during gastric resection. Numerical solutions of velocity and pressure distribution for both cases gave similar results. As expected, the maximum pressure was localized in the duodenal suture area and it was in the range of experimental pressure measurements obtained by using a Miller-Abbott tube and connecting catheter. Case B showed higher pressures, which was the result of the longer duodenal section.

Additional transport analysis showed that the food distribution in the gastric and duodenal connection zone varied depending on the diffusivity coefficient. The results of this analysis implied that case B was more favorable with respect to food transport because of continual food distribution and an empty duodenal section. Therefore, the longer duodenal section in case B provides conditions for food not to stay within the duodenal zone.

Experimental results have shown that intraluminal duodenal stump pressure after gastric resection was higher by an order of magnitude with respect to the pre-operative state. Comparison of models with different lengths of afferent loops showed that the afferent loop syndrome was an important factor in postoperative complications.

By changing input parameters of our interactive computational model (fluid parameters, model geometry), we can improve prediction of the potential *in vivo* events. Also, it is possible to obtain insight into possible outcomes of different types of surgical reconstruction of the digestive tract after operations on the gastroduodenal region. This may include variations of the same surgical intervention, related to surgeons' ability or the specific anatomy of a single patient.

The practical aim of this study was to provide an insight into the physical conditions within the duodenal stump after gastric resection, in relation to the pathogenesis of duodenal stump blowout, and the implications for the surgical technique itself.

New, more comprehensive computational models may first include duodenal pressure quantification,

which causes disruption of the duodenal stump closure. Such models will require determination of shear stress and pressure distribution at the inner surface of the duodenal stump, as well as the stress-strain state within the duodenal wall, especially in the suture area. The stress-strain state and the critical state at the point of disruption depend on tissue quality and tissue material characteristics. Furthermore, these sophisticated models need to establish a correlation between duodenal flow and the wall dynamics of contractions, in order to quantify critical levels of increased intraluminal duodenal pressure.

## COMMENTS

### Background

A malignant process and ulcer disease in the gastric distal section are the main causes for surgical intervention, which has become a standard procedure over recent years. Duodenal stump dehiscence after gastric resection occurs relatively rarely, but is of particular importance because it is associated with a high rate of mortality. A computer simulation can provide better understanding of this process.

### Innovations and breakthroughs

Computer simulation offers better insight into fluid flow, mass transport and pressure distribution in the duodenal section before and after surgical intervention.

### Applications

This computer simulation study can be applied to new follow-up studies that will help clinicians with diagnosis and treatment.

### Terminology

Computer simulation and a finite element method solve a large number of equations in which physical laws such as fluid flow and mass transport are solved with differential partial equations. This methodology has been well known in industrial applications over several decades, and recently, it has been used for biological systems. Many questions regarding parameters in this computational study are still unknown and future computer simulation will try to answer these.

### Peer review

The title describes well the manuscript. The introduction is clear. The description of the materials and methods is clear. The results are reported well. The discussion is well organized. The references are well reported. The tables and figures are clear.

### Abstract

**AIM:** To evaluate the efficacy of transjugular intrahepatic portosystemic shunts (TIPSs) after liver transplantation (LT).

**METHODS:** Between November 1996 and December 2005, 10 patients with severe recurrent hepatitis C virus infection ( $n = 4$ ), ductopenic rejection ( $n = 5$ ) or portal vein thrombosis ( $n = 1$ ) were included in this analysis. Eleven TIPSs (one patient underwent two TIPS procedures) were placed for management of therapy-refractory ascites ( $n = 7$ ), hydrothorax ( $n = 2$ ) or bleeding from colonic varices ( $n = 1$ ). The median time interval between LT and TIPS placement was 15 (4-158) mo.

**RESULTS:** TIPS placement was successful in all patients. The mean portosystemic pressure gradient was reduced from 12.5 to 8.7 mmHg. Complete and partial remission could be achieved in 43% and 29% of patients with ascites. Both patients with hydrothorax did not respond to TIPS. No recurrent bleeding was

seen in the patient with colonic varices. Nine of 10 patients died during the study period. Only one of two patients, who underwent retransplantation after the TIPS procedure, survived. The median survival period after TIPS placement was 3.3 (range 0.4-20) mo. The majority of patients died from sepsis with multiorgan failure.

**CONCLUSION:** Indications for TIPS and technical performance in LT patients correspond to those in non-transplanted patients. At least partial control of therapy-refractory ascites and variceal bleeding could be achieved in most patients. Nevertheless, survival rates were disappointing, most probably because of the advanced stages of liver disease at the time of TIPS placement and the high risk of sepsis as a consequence of immunosuppression.

### INTRODUCTION

Since the first attempts were made over 30 years ago, placement of transjugular intrahepatic portosystemic shunts (TIPSs) has become an established procedure in patients with complications of portal hypertension<sup>[1]</sup>. The two main indications for TIPS are therapy-refractory ascites and variceal bleeding unresponsive to endoscopic treatment<sup>[2-7]</sup>. In many patients with these complications,

TIPS is used as a bridge to liver transplantation (LT). In contrast, there is rather limited experience with the use of TIPS following LT. One reason is the rare occurrence of portal hypertension after LT. The causes of portal hypertension in such patients can be impaired venous outflow, recurrence of the underlying liver disease, size mismatch between donor and recipient organs and/or vessels<sup>[8,9]</sup>, or increased vascular resistance as a consequence of repeated rejection episodes<sup>[10]</sup>. This might result in the development of ascites, hepatic hydrothorax or variceal bleeding comparable to the non-grafted population. Therapeutic options for these conditions are basically the same, including TIPS. The placement of a TIPS can be rendered more difficult by the altered anatomy after transplantation. Furthermore, patients undergoing chronic immunosuppression are at higher risk of infection.

Only few data have been published on TIPS after LT and its role in LT recipients is largely undefined. The aim of our retrospective analysis was to critically scrutinize the indications, efficacy and safety of TIPS placement in liver recipients at our center.

## MATERIALS AND METHODS

Between November 1996 and December 2005, a total of 11 TIPSs were placed in 10 liver recipients at Innsbruck Medical University Hospital, which represents 5% of all 217 TIPS procedures carried out during this time period. One of the patients received a TIPS before and after retransplantation. The mean age of the six male and four female patients was 56.8 (37-71) years. The underlying liver diseases were hepatitis C virus (HCV) cirrhosis ( $n = 4$ ), alcoholic liver disease ( $n = 2$ ), primary biliary cirrhosis ( $n = 2$ ), hemochromatosis ( $n = 1$ ) and autoimmune hepatitis ( $n = 1$ ).

Patients underwent full-sized deceased donor LT, three of them using a piggyback technique, and the remaining patients by replacement of the retrohepatic vena cava. The mean time interval between LT and TIPS was 29.7 mo (range: 3.8-158 mo). In four patients, recurrent HCV cirrhosis was present at the time of TIPS implantation, five had ductopenic rejection, and one had portal vein thrombosis.

Therapy-refractory ascites was the indication for TIPS in seven patients, resistant hydrothorax in two, and bleeding from colonic varices in one. Ascites and hydrothorax were assessed by ultrasound and chest X-ray, respectively.

All four patients with recurrent HCV presented with decompensated cirrhosis at the time of TIPS implantation. One patient was in Child-Turcotte-Pugh class B and three were in class C. The median model for end-stage liver disease (MELD) score for all patients was 20 (12-35).

The TIPS procedure used for LT recipients did not differ from that for non-transplanted patients, as described previously<sup>[6,7]</sup>.

The immunosuppressive regimen at the time of the TIPS procedure consisted of calcineurin inhibitors,

alone ( $n = 1$ ) or in combination with steroids ( $n = 2$ ), mycophenolate mofetil (MMF;  $n = 3$ ), or an mTOR-inhibitor ( $n = 1$ ). An mTOR-inhibitor was used with MMF in one patient or with low-dose steroids in three patients.

Variables were compared using Student's *t* test, and  $P < 0.05$  was considered statistically significant. Kaplan-Meier plots were calculated using SPSS 15.0 statistical software (SPSS Inc., Chicago, IL, USA).

## RESULTS

TIPS were placed in all patients without any procedural complications. One patient with pre-existing atrial fibrillation developed cardiac failure during the procedure but responded to specific treatment.

The mean portosystemic pressure gradient was reduced from 12.5 (8-22) mmHg to 8.7 (5-14) mmHg after the procedure. Although pressure gradients below 12 mmHg were found in three patients with refractory ascites and one with hydrothorax, the TIPS procedure was continued, with the aim of further decreasing the final pressure gradients (around 5 mmHg), in order to improve the clinical condition.

Regarding patients with refractory ascites, complete resolution of ascites was achieved in three and a partial response in two patients, whereas no response was seen in two others. TIPS failed to improve the condition in both patients with hydrothorax. After TIPS implantation, no more bleeding was seen in the patient who suffered from colonic variceal hemorrhage.

Seven out of 10 patients developed TIPS-related hepatic encephalopathy, which necessitated TIPS reduction in two patients with a later closure in another. In the other patients, encephalopathy was successfully treated with standard medical therapy. One patient developed TIPS dysfunction, which was corrected by dilatation.

Only one patient in our cohort, who underwent retransplantation, survived long-term. All other patients died, mainly from sepsis associated with multiorgan failure. The median survival time of all patients was 3.3 mo (range 0.4-20 mo; Figure 1).

The course of all 10 patients is summarized in Table 1. Although TIPS was able to reduce ascites in patients 1 and 2, both died at 1 and 3 mo after TIPS placement because of HCV recurrence, with sepsis and multiorgan failure. Both patients presented with a high MELD score of 22 and 26, respectively.

The third patient with therapy-refractory ascites first responded well to TIPS. Four months later, however, she developed massive bleeding in the upper gastrointestinal tract and lungs because of severe coagulopathy, secondary to graft failure associated with ductopenic rejection, and died.

No improvement in ascites was seen in the fourth patient. Eight months after TIPS implantation, the patient underwent retransplantation for recurrent HCV cirrhosis. A few months after retransplantation, he again developed a rapidly progressive HCV recurrence, with

Table 1 Summary of clinical data and outcomes

Patient no.	Age, sex	Cause of liver disease	Transplant pathology before TIPS	Indication for TIPS	MELD score at TIPS	CPC at TIPS	Time from transplantation to TIPS (mo)	Encephalopathy-post-TIPS	Follow-up after TIPS
1	71, F	Hepatitis C	HCV recurrence	Ascites	22	C	15	Yes	Died 1 mo
2	59, M	Hepatitis C	HCV recurrence	Ascites	26	C	16	Yes	Died 3 mo
3	37, F	Primary biliary cirrhosis	Vanishing bile duct syndrome	Ascites	18	B	4	Yes	Died 4 mo
4	56, M	Hepatitis C	HCV recurrence	Ascites	15	C	158	Yes	ReLT 8 mo, died after ReLT, see below
	59, M	Hepatitis C	HCV recurrence	Ascites	13	C	18	Yes	TIPS reduction day 11 and 16; died at 2 mo
5	52, M	Fatty liver cirrhosis	Vanishing bile duct syndrome	Ascites	35	C	10	No	ReLT 3 mo; alive 32 mo
6	51, F	Hepatitis C	HCV recurrence	Ascites	19	B	61	No	Died 3 mo
7	71, M	Primary biliary cirrhosis	Thrombosis of the portal vein at the anastomosis	Ascites	12		4	No	TIPS revision 3 mo; died 12 mo
8	62, M	Hemochromatosis	Vanishing bile duct syndrome	Hydrothorax	21	C	17	Yes	Died 1.5 mo
9	68, M	Fatty liver cirrhosis	Vanishing bile duct syndrome	Hydrothorax/Ascites	30	B	11	Yes	Died 11 d
10	38, F	Autoimmune hepatitis	Vanishing bile duct syndrome + thrombosis of the portal vein	Bleeding	<sup>1</sup>	B	8	Yes	TIPS reduction 2.5 mo; died 19 mo

<sup>1</sup>MELD score calculation not possible due to incomplete laboratory data. ReLT: Liver retransplantation.

Figure 1 Kaplan-Meier plot of patients' overall survival after TIPS implantation.

massive ascites that was resistant to diuretic therapy. Therefore, 18 mo after retransplantation, a TIPS was placed again. Eleven days after placement, a reduction in the TIPS, with subsequent complete closure was necessary because of severe hepatic encephalopathy. The patient died 2 mo after the second shunt placement from sepsis with multiorgan failure.

In the fifth patient, TIPS implantation resulted in complete resolution of ascites. Three months after TIPS placement, the patient developed ductopenic rejection in association with renal failure, and underwent combined liver and kidney transplantation. Thirty-two months later, the patient is doing well with stable graft function.

The sixth patient with TIPS placement for ascites did not respond to the procedure and died 3 mo later from HCV recurrence.

Ascites further deteriorated in patient seven after TIPS placement. Shunt occlusion was suspected and the patient was given another TIPS 3 mo later, which

led to a reduction of portosystemic pressure from 19 to 12 mmHg, and disappearance of ascites. The patient, however, died 1 year after TIPS insertion from cholangitis secondary to multiple ischemic-type intrahepatic biliary strictures.

TIPS placement did not result in any improvement in the two patients with hydrothorax (patients 8 and 9). One of them died at 6 wk and the other at 11 d after TIPS, as a result of sepsis.

The patient with colonic bleeding as indication for TIPS placement developed severe encephalopathy at 2.5 mo after the procedure, which required a reduction in TIPS. The portal pressure increased from 5 to 9 mmHg, and encephalopathy improved thereafter. Although there was no recurrence of bleeding, the patient died 19 mo after TIPS because of chronic rejection.

## DISCUSSION

TIPS is an established therapeutic modality for the management of complications of portal hypertension, in particular, therapy-refractory ascites or pleural effusion, as well as variceal bleeding resistant to endoscopic treatment. However, there is much less experience with TIPS after LT<sup>[11-15]</sup>. Although the indications for TIPS should be essentially the same as in patients without LT, certain specific points need to be considered.

At our center, the indications for TIPS placement did not differ between the transplant and non-transplant patients, with therapy-refractory ascites being the main indication also in LT recipients. Therapy-refractory hydrothorax and variceal bleeding, not manageable by endoscopic means, were less frequent indications. Our analysis showed that, in principle, TIPS was technically feasible in patients with portal hypertensive

complications after LT, and was efficacious in the majority of patients. Complete resolution was achieved in three out of eight patients, and a partial response in two further patients with therapy-refractory ascites. In addition, severe variceal hemorrhage in one patient did not recur after TIPS. No improvement, however, was seen in both patients with severe hepatic hydrothorax. Similar response rates have been reported in four previously published series, including a small study of 6-12 patients<sup>[11-14]</sup>. In these studies, improvement or complete resolution of ascites was achieved in 50%-90% of patients, and only two out of 10 patients with variceal hemorrhage experience recurrent bleeding.

The success rate of TIPS placement for managing ascites and variceal bleeding in LT was comparable with that in non-transplanted patients at our department. In the present cohort, complete resolution or significant reduction in the amount of ascites was achieved in about 70% of patients, and recurrence of bleeding was prevented in about 77% of patients (data not shown).

With an average survival of 3.3 mo, the survival in our series was extremely poor. This might mainly have been the result of the advanced stage of liver disease and the already poor prognosis of our patients at the time of TIPS placement, and not by the intervention itself. TIPS should serve as a bridge to a possible liver retransplantation. As we had only little experience with TIPS in LT recipients, this intervention was indicated with great caution. As a consequence, TIPS was placed in LT patients as the last therapeutic option, after all conservative modalities had failed. Several studies have shown that survival rates of TIPS patients with advanced disease are markedly poorer than those in earlier stages of liver disease<sup>[4,16,17]</sup>. In fact, almost all of our patients presented with an advanced stage of graft dysfunction and high MELD scores (median score of 20). The MELD score was originally developed for patients undergoing TIPS<sup>[18]</sup>, and then slightly modified to predict survival of patients with liver cirrhosis in general<sup>[19]</sup>. In our analysis, there was a trend towards a higher MELD score being associated with poor survival. The correlation was not statistically significant, most probably as a result of the small number of patients.

It is well known that the natural course of recurrent HCV infection is more aggressive and leads more rapidly to cirrhosis of the allograft and graft failure than HCV infections in non-transplanted patients. Subsequently, the long-term outcome of HCV-positive patients after LT is worse compared to those with other indications for transplantation<sup>[20-23]</sup>. It has been shown that the prognosis of HCV patients is poor after decompensation, with a median survival of less than 1 year<sup>[20]</sup>. All of our four patients with recurrent hepatitis C infection presented with decompensated cirrhosis (Child-Pugh stage B or C and MELD scores between 13 and 26).

Chronic rejection with progressive loss of bile ducts inevitably leads to irreversible loss of the allograft<sup>[24]</sup>, with liver retransplantation rates of 50%-90%<sup>[25,26]</sup>. Prognosis is especially poor in patients with bilirubin values > 10 mg/dL<sup>[27]</sup>. In our study, all three patients with chronic

rejection presented with a bilirubin above this level.

Therefore, an advanced stage of graft dysfunction caused by recurrent HCV cirrhosis and chronic ductopenic rejection might have been responsible for the poor survival rate in our patients. In addition, the number of liver retransplantations, the only potentially curative therapy for these patients, was lower in our series compared to other studies. Only two of our patients underwent liver retransplantation, whereas the retransplantation rate was 50% in the largest series of Amesur and co-workers<sup>[13]</sup>. Three of our patients died while being on the waiting list for a second LT, which suggests that retransplantation should be considered as early as possible when graft decompensation occurs.

The most frequent cause of death ( $n = 5$ ) in our cohort was sepsis associated with multiorgan failure. Thus, two interacting factors were responsible for the frequency of sepsis in our patients. Patients with impaired liver function or recurrent cirrhosis frequently develop bacterial infections, which lead to death in 30%-50% of cases<sup>[28,29]</sup>. The risk of infection is further increased by chronic immunosuppression. Therefore, we recommend prophylactic antimicrobial therapy following TIPS placement.

The altered anatomy of the hepatic vessels that results from LT should be kept in mind before the TIPS procedure. The two most frequently used techniques are the replacement of the retrohepatic vena cava and the piggyback-type of transplantation. Previous studies have shown that there are no difficulties in TIPS placement with either of these procedures. In contrast, in patients with cava-cava liver transplantation, probing for the hepatic and portal veins in the recipient's organ might be difficult<sup>[11-14]</sup>. No technical problems were encountered in our series, in which, three had undergone the piggyback-type of transplantation and the remaining patients had replacement of the retrohepatic vena cava. This indicates that the anatomical situation in these patients creates no problems for the TIPS procedure.

Only one patient (10%) developed dysfunction of the TIPS, which was managed successfully by TIPS dilatation. In contrast, the rate of TIPS revision in our non-transplanted patients was markedly higher at 35% ( $P = 0.059$ ). This low rate of TIPS dysfunction in the LT group might be attributed to the fact that immunosuppressive therapy can lead to reduced intima proliferation<sup>[11]</sup>, but can also be ascribed to the very short survival of these patients.

Noticeable in our LT recipients was a low pre-interventional mean portosystemic pressure gradient of 12.5 mmHg, which suggests that ascites and hydrothorax post-transplant may not be as well-correlated with portal pressure as in the pre-transplant phase. Other factors beside the portosystemic pressure gradient, such as renal function, may play a major role in the efficacy of TIPS in LT transplant recipients. Chronic renal dysfunction is a common complication in transplant recipients, especially if calcineurin inhibitors are used<sup>[30]</sup>. In our cohort, both patients with hepatic hydrothorax presented with markedly impaired renal function (glomerular filtration

rate < 20 and 45 mL/min per 1.73 m<sup>2</sup>, respectively), which may explain their non response to TIPS treatment, although the postinterventional pressure gradients could be successfully lowered to 10 and 5 mmHg, respectively.

In the ascites group, only three of seven patients showed normal renal function, and in two of these, complete resolution of ascites was achieved. No statistically significant correlation was found between the reduction of the portal pressure gradient and response to TIPS.

Hepatic encephalopathy developed in 70% of our patients. A similar rate of encephalopathy was also described in a previous study, and is markedly higher than the incidence reported for non-transplant TIPS recipients<sup>[4,11]</sup>. We could not find a relation between final pressure gradients and the development of encephalopathy. Mild pre-existing hepatic encephalopathy was found in two patients, and in both, a deterioration of encephalopathy was noticed after TIPS creation. Therefore, we conclude that the main reasons for the high occurrence of hepatic encephalopathy in this cohort might be the advanced stage of disease in these patients, as well as the potentially neurotoxic effects of immunosuppressive drugs, in particular the calcineurin inhibitors.

In summary, our study showed that the TIPS procedure in LT recipients was feasible without technical difficulties. Indications for TIPS seemed not to differ from those of the non-transplanted TIPS group. The TIPS procedure was efficacious in the management of therapy-refractory ascites and severe variceal bleeding unresponsive to endoscopy, in the majority of patients. TIPS did not appear to be useful in patients with hepatic hydrothorax. However, the outcome was very disappointing. The low survival rate shows that, in LT patients with an already advanced stage of graft dysfunction, TIPS does not improve prognosis. Similar to the recent work of Kim and co-workers<sup>[15]</sup>, we conclude that TIPS may not be useful in most transplant patients with an advanced graft disease. It may have its place in treating some vascular problems after LT. Otherwise retransplantation remains the only possibility to improve the survival of patients with portal hypertensive complications after LT.

## COMMENTS

### Background

Transjugular intrahepatic portosystemic shunt (TIPS) is a well-established therapeutic procedure in patients suffering from complications of portal hypertension, such as ascites or variceal bleeding. In rare cases, portal hypertension develops in liver transplant (LT) recipients. The use of TIPS in this special patient cohort has been discussed in the literature, but only few cases have been reported so far.

### Research frontiers

In this study, the authors report a series of TIPS placements in 10 LT recipients

because of ascites, hydrothorax and variceal bleeding. In the majority of patients, at least a partial response could be achieved, however, the outcome of these patients was poor with a median survival of 3.3 mo.

### Innovations and breakthroughs

Portal hypertension is a rare but severe complication after LT and leads to graft loss in the majority of patients. The pathophysiology is not well understood and the best therapeutic modality for these patients remains to be defined. TIPS placement has been discussed. This paper shows that TIPS placement is not efficacious in this cohort.

### Applications

Results from this study will help to refine the post-transplant care of patients and should encourage physicians to consider retransplantation as the only effective treatment in LT patients with portal hypertensive complications.

### Terminology

TIPS is an interventional technique for the creation of an intrahepatic decompressive shunt between a branch of the portal vein and the main hepatic vein, using expandable metallic stents. This leads to a decrease in portosystemic pressure gradient and has become an established therapy for patients with therapy-refractory ascites and unresponsive variceal bleeding.

### Peer review

This is a well written report on a single institution's experience on the use of TIPS after LT for the treatment of portal hypertension recurrence related complications. Although the series is small, the paper gives a clear message to the readers about a selected topic in liver transplantation.

there were fewer patients in the treatment group than placebo group who required opioid infusion within the first 24 h (60% vs 37%,  $P = 0.053$ ).

**CONCLUSION:** Perioperative administration of parecoxib provided no significant effect on postoperative pain relief after laparoscopic cholecystectomy. However, preoperative infusion 20 mg parecoxib could significantly reduce the postoperative opioid consumption.

Efficacy of perioperative parecoxib injection on postoperative pain relief after laparoscopic cholecystectomy: A prospective, randomized study. *World J Gastroenterol* 2009; 15(16): 2005-2008 Available from: URL: <http://www.wjgnet.com/1007-9327/15/2005.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.2005>

### Abstract

**AIM:** To determine the efficacy of perioperative parecoxib injection on postoperative pain relief after laparoscopic cholecystectomy.

**METHODS:** A prospective, double-blind, randomized, placebo-controlled study was conducted on 70 patients who underwent elective laparoscopic cholecystectomy under general anesthesia at Siriraj Hospital, Bangkok, from January 2006 to December 2007. Patients were randomized to receive either 20 mg parecoxib infusion 30 min before induction of anesthesia and at 12 h after the first dose (treatment group), or normal saline infusion, in the same schedule, as a placebo (control group). The degree of the postoperative pain was assessed every 3 h in the first 24 h after surgery, and then every 12 h the following day, using a visual analog scale. The consumption of analgesics was also recorded.

**RESULTS:** There were 40 patients in the treatment group, and 30 patients in the control group. The pain scores at each time point, and analgesic consumption did not differ between the two groups. However,

### INTRODUCTION

Preemptive analgesia has become a popular adjunct to conventional postoperative pain control. The concept of preemptive analgesia is based on the hypothesis that the most effective way to eliminate or reduce postoperative pain is to prevent nociceptive input from afferent stimuli to the central nervous system so that central nervous system hyperexcitability does not occur<sup>[1]</sup>. Clinically, this strategy predicts not only less pain during the initial postoperative period but also a reduced intensity of pain during the days after the procedure<sup>[2]</sup>. A variety of preoperative or preemptive analgesic regimens have been used such as intravenous administration of opioids or non-steroidal anti-inflammatory drugs (NSAIDs), local anesthetic infiltration, nerve block, and epidural block<sup>[3]</sup>.

Recent research indicates that cyclooxygenase-2 (COX-2) inhibitors, a selective class of NSAIDs, could

play an important role in perioperative pain management by reducing the inflammatory response in the periphery, modulating nociceptors, and attenuating central sensitization<sup>[4]</sup>. The COX-2 inhibitors provide effective pain control, in addition to a lesser degree of platelet dysfunction and gastrointestinal toxicity compared to nonselective NSAIDs. Reuben *et al*<sup>[5]</sup> reported that patients receiving perioperative oral COX-2 inhibitors experienced less postoperative pain, required fewer analgesic drugs, and had a greater range of motion after total knee arthroplasty than those receiving placebo.

The injectable COX-2 inhibitor, parecoxib, could play an important role in pain control in the perioperative and immediate postoperative period, especially in those who cannot take an oral analgesic such as a patient about to undergo intraabdominal surgery under general anesthesia. Laparoscopic cholecystectomy is the most common laparoscopic procedure performed in a general surgical unit worldwide, and accounts for about two-thirds of total laparoscopic operations in the authors' unit. However, the efficacy of perioperative parecoxib injection on postoperative pain relief after laparoscopic cholecystectomy remains controversial<sup>[6-11]</sup>.

The aim of this study was to determine the efficacy of perioperative parecoxib injection on postoperative pain relief after laparoscopic cholecystectomy in a university hospital.

## MATERIALS AND METHODS

After obtaining approval from our Institutional Ethics Committee, a prospective double-blind, randomized, controlled study was conducted at the Department of Surgery, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, involving 70 consecutive ASA class I-III patients who underwent elective laparoscopic cholecystectomy from January 2006 to December 2007. All patients gave written informed consent.

Patients were excluded from the study for one of the following reasons: age under 18, hypersensitivity to NSAIDs, or conversion to open cholecystectomy. Patients were randomized into one of two groups by opening a sealed envelope in the operating theater: the treatment group received 20 mg parecoxib infusion 30 min before induction of anesthesia and at 12 h after the first dose; the control group received normal saline infusion as a placebo in a similar time schedule. All patients underwent laparoscopic cholecystectomy under a balanced general anesthetic technique, using fentanyl for premedication and during the intraoperative period. The procedures were performed by an experienced laparoscopist.

The degree of the postoperative pain was assessed every 3 h in the first 24 h after surgery and then every 12 h the following day, using a visual analog scale (0 = no pain, 10 = worst possible pain), by nursing staff who were unaware of the perioperative intervention. A standard postoperative analgesic regimen was administered to all patients. This consisted of intravenous pethidine 1 mg/kg prn for patients with a pain score = 5, every 3 h during the first 24 h after the operation, or until oral analgesics could be taken. The consumption of analgesics was also recorded.

**Table 1** Comparison of patients' characteristics, indication for surgery and operative details between treatment group and control group (mean  $\pm$  SD) *n* (%)

	Treatment group ( <i>n</i> = 40)	Control group ( <i>n</i> = 30)	<i>P</i> -value
Age (yr)	57.6 $\pm$ 12.7	56.2 $\pm$ 15.1	0.67
Female	25 (63)	16 (53)	0.44
Co-morbid diseases	24 (60)	15 (50)	0.41
Indication for surgery			0.26
Symptomatic gallstone	28 (70)	23 (77)	
Common bile duct stone	6 (15)	6 (20)	
Gallstone induced pancreatitis	6 (15)	1 (3)	
Operative time (min)	63.7 $\pm$ 36.9	58.1 $\pm$ 31.5	0.51

**Figure 1** Average visual pain score (0 = no pain, 10 = worst possible pain) at 3, 6, 9, 12, 15, 18, 21 and 24 h after surgery in the treatment group and control group.

All data were prepared and compiled using SPSS software. Mean and SD were assessed. The Kolmogorov-Smirnov test was used to test for the pattern of data distribution. The student's unpaired *t*-test was used to compare data between the two groups when the data were in a normal distribution pattern. The Mann-Whitney *U* test was used to compare data between the two groups when the data were in a non-normal distribution. *P* < 0.05 was considered statistically significant.

## RESULTS

There were 40 patients in the treatment group, and 30 patients in the control group. The patient's characteristics, indication for surgery and operative details between the treatment group and control group were well matched (Table 1). The pain scores at each time point did not significantly differ between the two groups (Figure 1). However, there were fewer patients in the treatment group than in the placebo group who required opioid infusion within the first 24 h (60% *vs* 37%, *P* = 0.053).

## DISCUSSION

Parecoxib, the first injectable COX-2 inhibitor, was

introduced into clinical practice in 2001. It was found that preoperative administration of parecoxib was more effective than postoperative administration for postoperative pain relief in patients undergoing elective general surgical procedures such as appendectomy, open cholecystectomy and hernioplasty<sup>[12]</sup>. Parecoxib can be injected intravenously or intramuscularly with good patient tolerance. The lack of platelet inhibition allows COX-2 inhibitors such as parecoxib to be administered preoperatively. Parecoxib is now increasingly used in ambulatory or day-case surgery because it reduces opioid consumption, improves pain scores, and results in earlier hospital discharge and return to normal function<sup>[13]</sup>.

In the present study, perioperative administration of parecoxib provided no significant effect on postoperative pain relief after laparoscopic cholecystectomy. One possible explanation for our observation is that administration of a total of 40 mg parecoxib is not an optimal dose for perioperative pain control. Puolakka *et al*<sup>[8]</sup> found that a single dose of 80 mg parecoxib resulted in the least pain intensity after laparoscopic cholecystectomy compared with 40 mg parecoxib or placebo. However, preoperative infusion of 40 mg parecoxib could significantly reduce the postoperative opioid requirement, and the incidence of opioid-related adverse effects if oral COX-2 inhibitors have been taken in the early postoperative period<sup>[9]</sup>. There is evidence that the administration of preoperative intravenous parecoxib followed by oral COX-2 inhibitors after laparoscopic cholecystectomy resulted in a shorter length of stay in the postoperative anesthesia care unit, a better quality of postoperative recovery, and a faster return to normal activity, with greater patient satisfaction<sup>[10]</sup>.

It is also possible that pain after laparoscopic cholecystectomy has several components such as incisional and visceral pain; the latter type of pain seems to be more resistant to the analgesic effect of NSAIDs<sup>[8]</sup>. Therefore, systemic administration of COX-2 inhibitors alone is relatively ineffective. Several investigators have suggested that intraperitoneal administration of local anesthetics could improve postoperative pain control by means of attenuation of the visceral pain. Jabbour-Khoury *et al*<sup>[14]</sup> reported that intraperitoneal spray of an aliquot of bupivacaine and NSAIDs, or intraperitoneal spray of local anesthetics following by intravenous NSAIDs resulted in significantly lower abdominal pain scores and incidence of vomiting after laparoscopic cholecystectomy, compared to the non-treatment group. Meanwhile, Elhakim *et al*<sup>[15]</sup> revealed that a combination of intraperitoneal lidocaine and tenoxicam provided better analgesia on movement, and faster return of bowel function compared with intraperitoneal lidocaine and intravenous tenoxicam after laparoscopic cholecystectomy<sup>[15]</sup>.

In conclusion, perioperative administration of intravenous parecoxib provided no significant effect on postoperative pain relief after laparoscopic cholecystectomy. However, preoperative infusion of 20 mg parecoxib could significantly reduce the postoperative opioid consumption.

## COMMENTS

### Background

Preemptive analgesia has become a popular adjunct to conventional postoperative pain control. The concept is based on the hypothesis that the most effective way to reduce postoperative pain is to prevent nociceptive input from afferent stimuli to the central nervous system so that central nervous system hyperexcitability does not occur.

### Research frontiers

The injectable Cyclooxygenase-2 (COX-2) inhibitor, parecoxib, could play an important role in perioperative pain control and is increasingly used in day-case surgery because it reduces opioid consumption, improves pain scores, and results in earlier discharge and return to normal function.

### Innovations and breakthroughs

This study determined the efficacy of perioperative 20 mg parecoxib injection on postoperative pain relief after laparoscopic cholecystectomy.

### Applications

Perioperative administration of intravenous 20 mg parecoxib provided no significant effect on postoperative pain relief, but could significantly reduce the postoperative opioid consumption after laparoscopic cholecystectomy.

### Terminology

COX-2 inhibitors, a selective class of non-steroidal anti-inflammatory drugs (NSAIDs), could play an important role in perioperative pain management by reducing the inflammatory response in the periphery, modulating nociceptors, and attenuating central sensitization. The COX-2 inhibitors provide effective pain control, in addition to a lesser degree of platelet dysfunction and gastrointestinal toxicity compared to nonselective NSAIDs.

### Peer review

This is a well written manuscript with concise data. The concept of perioperative COX-2 infusion can make GI surgeons pay much attention.

### Abstract

**AIM:** To investigate the effect of Lianshu preparation on lipopolysaccharide (LPS)-induced diarrhea in rats.

**METHODS:** A diarrhea model was established in Sprague Dawley rats *via* injection of 1 mL of 30 mg/kg LPS. A total of 40 rats were randomly divided into normal group, LPS group, LPS + Lianshu group, LPS + berberine group ( $n = 10$  in each group). Their intestinal mucosal barrier and frequency of diarrhea were observed. Levels of glucose, serum  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Cl}^-$  and hematocrit, plasma nitrogen monoxide (NO), diamine oxidase (DAO), and D (-)-lactate were measured. The number of IgA+ plasma cells in small intestine was detected and SIgA levels in the intestinal fluid were measured. The antipyretic activity of Lianshu preparation in rats was evaluated using Brewer's yeast-induced pyrexia (10 mL/kg of 20% aqueous suspension). Acetaminophen (250 mg/kg, intragastric administration, *bid*) was used as a standard drug for comparison. Temperature was recorded 1 h before and 6 h after Brewer's yeast injection. Finally, small intestinal

transmission in mice treated with Lianshu was detected after intraperitoneal injection of methyl prostigmin (2 mg/kg). Atropine (10 g/kg) was used as a control. The ink content in intestine was determined and the total length of intestine was measured.

**RESULTS:** The frequency of diarrhea was higher in LPS group than in LPS + Lianshu group and LPS + berberine group ( $36.70 \pm 5.23$  vs  $28.50 \pm 4.06$  and  $32.70 \pm 9.30$  respectively,  $P < 0.01$ ), and lower in LPS + Lianshu group than in LPS + berberine group ( $P = 0.03$ ). The levels of  $\text{Na}^+$ , glucose,  $\text{Cl}^-$ ,  $\text{K}^+$  were significantly lower in LPS + Lianshu group than in LPS + berberine group ( $140.35 \pm 3.19$  mmol/L vs  $131.99 \pm 4.86$  mmol/L,  $8.49 \pm 1.84$  mmol/L vs  $6.54 \pm 2.30$  mmol/L,  $106.29 \pm 4.41$  mmol/L vs  $102.5 \pm 1.39$  mmol/L,  $5.08 \pm 0.66$  mmol/L vs  $4.32 \pm 0.62$  mmol/L respectively,  $P < 0.05$ ). The level of hematocrit was lower in LPS + Lianshu group than in LPS + berberine group ( $0.50\% \pm 0.07\%$  vs  $0.59\% \pm 0.10\%$  respectively,  $P < 0.05$ ). The plasma levels of NO, DAO and D (-)-lactate were higher in LPS group than in normal group ( $79.74 \pm 7.39$   $\mu\text{mol/L}$  vs  $24.94 \pm 3.38$   $\mu\text{mol/L}$ ,  $2.48 \pm 0.42$   $\mu\text{g/mL}$  vs  $0.82 \pm 0.33$   $\mu\text{g/mL}$ ,  $5.63 \pm 0.85$   $\mu\text{g/mL}$  vs  $2.01 \pm 0.32$   $\mu\text{g/mL}$  respectively,  $P < 0.01$ ), and lower in LPS + Lianshu group than in LPS + berberine group ( $48.59 \pm 4.70$   $\mu\text{mol/L}$  vs  $51.56 \pm 8.38$   $\mu\text{mol/L}$ ,  $1.43 \pm 0.53$   $\mu\text{mol/mL}$  vs  $1.81 \pm 0.42$   $\mu\text{mol/mL}$ ,  $4.00 \pm 0.54$   $\mu\text{g/mL}$  vs  $4.88 \pm 0.77$   $\mu\text{g/mL}$  respectively,  $P < 0.05$ ). The morphology of the intestinal mucosa showed destroyed villi in LPS group and atrophied intestinal mucosa in other groups. The pathological intestinal mucosal changes were less in LPS + Lianshu group than in LPS group. The number of IgA+ plasma cells and amount of SIgA were higher in LPS + Lianshu group than in LPS group ( $1.16 \pm 0.19/\mu\text{m}^2$  vs  $1.09 \pm 0.28/\mu\text{m}^2$ ,  $P = 0.026$ ;  $0.59 \pm 0.12$  mg/L vs  $0.15 \pm 0.19$  mg/L respectively,  $P = 0.000$ ). Lianshu had counteractive effects on yeast-induced pyrexia and enterokinesia in rats.

**CONCLUSION:** Lianshu preparation has therapeutic effects on LPS-induced diarrhea and enterokinesia in rats.

Effect of Lianshu preparation on lipopolysaccharide-induced diarrhea in rats. *World J Gastroenterol* 2009; 15(16): 2009-2015 Available from: URL: <http://www.wjgnet.com/1007-9327/15/2009.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.2009>

## INTRODUCTION

Infectious diarrhea is often caused by Gram-negative bacteria such as *Escherichia coli*. These organisms contain lipopolysaccharide (LPS). Antibiotics developed in the 1940s have saved millions of people's life. However, because of the widespread and inappropriate use of antibiotics, some bacterial strains become antibiotic-resistant. Antibiotic-resistant bacteria and side effects of antibiotics severely threaten the general welfare and health of people. Folk herbal drugs have been extensively studied in recent years for the treatment of acute diarrhea. This study was to investigate the effect of Lianshu preparation on LPS-induced diarrhea in rats.

## MATERIALS AND METHODS

### Animals

Eighty adult female and male Sprague-Dawley rats, weighing 230-280 g (Experimental Animal Breeding Center, Fudan University), and thirty 5-wk-old female and male Kunming mice, weighing 18-20 g, were used in this study following the guidelines of the Animal Care Committee of Institute of Chinese Medicine, Tongji University. The animals were housed at  $22 \pm 2^\circ\text{C}$  with a humidity of  $55\% \pm 5\%$  in a 12-h light/dark cycle for at least 1 wk prior to use, with free access to laboratory chow and tap water.

### Lianshu preparation

*Coptis chinensis*, *atractylodis*, *pulsatillae* and *portulacae*, provided by Leiyunshang Company, were treated twice at  $100^\circ\text{C}$  for 2 h, divided into 1:5:5:5 proportions, then treated at  $100^\circ\text{C}$  for 1 h, filtered and concentrated to a relative density of 1.25 ( $60^\circ\text{C}$ ), and finally, desiccated. The effective constituents of Lianshu preparation were determined by Ley's Company (Shanghai, China). Lipopolysaccharide from *Escherichia coli* serotype 0128: B12 was purchased from Sigma Aldrich (St Louis, MO, USA). Nitrogen monoxide (NO) assay kit was provided by Jiancheng Bionic Research Center (Nanjing, China). Diamine oxidase (DAO) standard preparation, O-dianisidine, horseradish peroxidase, 1,5-pentanediamine-di-hydrochloride, D-lactate standard preparation, NAD- aminoacetic acid, and D-lactic dehydrogenase were purchased from Sigma Aldrich (St Louis, MO, USA). Anti-rat IgA mAb was purchased

from Santa Crus Company (USA) and SIgA assay kit was purchased from Bethyl Labs Inc. (USA).

### Detection of inhibitory effect of Lianshu preparation on LPS-induced diarrhea in rats

Rats were randomly divided into normal group, LPS group, LPS + Lianshu group, LPS + berberine group ( $n = 10$  in each group). Before exposure to LPS, rats in normal and LPS groups were treated with distilled water, rats in LPS + Lianshu group were given Lianshu preparation (1.8 g/kg), rats in LPS + berberine group received berberine (0.2 g/kg) twice a day for 3 d. The rats were allowed to have water alone for 12 h. One hour after the last administration of drugs, rats in all groups apart from those in the normal group were treated with LPS (30 mg/kg).

### Detection of diarrhea frequency before specimen collection

After treated with LPS, rats in each cage had a filter paper couch. Filter paper was changed once an hour for 4 h. The frequency of diarrhea was determined by counting the number of feces deposits on the filter paper.

### Measurement of erythrocrit, blood glucose, and serum $\text{Na}^+$ , $\text{K}^+$ , $\text{Cl}^-$ levels

Four hours later, 8 mL of blood was drawn from the abdominal aorta of each rat after anesthetized with 10 mg/kg intraperitoneal pentobarbital. Of the 8 mL blood, 2 mL was treated with heparin for erythrocrit analysis, 2 mL was centrifuged at  $3000 \times g$  for 15 min at  $4^\circ\text{C}$ . Blood glucose and serum  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Cl}^-$  levels were measured.

### Measurement of plasma NO, DAO and D (-)-lactate levels

Four milliliters of blood was centrifuged at  $3000 \times g$  for 15 min at  $4^\circ\text{C}$ . Plasma was collected to measure NO at 550 nm as previously described<sup>[1]</sup>. DAO and D (-)-lactate levels were measured by spectrophotometry at 436 nm<sup>[2]</sup> and enzyme-linked ultraviolet spectrophotometry<sup>[3]</sup>, respectively. The absorbance at 340 nm was recorded.

### Observation of morphologic changes in intestinal mucosa

After humane killing, a 5-cm long section of ileum 10 cm below the Treitz ligament was removed, dissected longitudinally, fixed in 100 mL/L formalin, embedded in paraffin, stained with hematoxylin and eosin, and observed under a light microscope.

### Detection of IgA+ plasma cells in rat small intestine

ABC immunohistochemistry staining of tissue paraffin sections was performed. The brown stained IgA + plasma cells were detected and analyzed using medical image analysis software (Taimeng Technology Co. Chengdu, China).

### Determination of SIgA in small intestine

A small intestine segment about 5 cm long, 15 cm

Table 1 Serum electrolyte levels in different groups (mean  $\pm$  SD)

Figure 1 Frequency of diarrhea in different groups. <sup>a</sup> $P < 0.01$  vs normal group; <sup>b</sup> $P < 0.01$  vs LPS group; <sup>c</sup> $P < 0.05$  vs LPS + Lianshu group.

below the Treitz ligament, was removed. Intestinal fluid was collected by passing 5 mL PBS and 0.02% sodium into the small intestine. The first intestinal washing removed 85%-90% of total IgA, and the variability of samples was less than 5%. The washed out material was centrifuged at  $3000 \times g$  for 10 min at 4°C. The supernatant was harvested and stored at -70°C. Total IgA was determined by ELISA.

#### Assay of antipyretic activity of Lianshu preparation

Antipyretic activity of Lianshu preparation in rats was evaluated using Brewer's yeast-induced pyrexia. Forty rats were divided into 4 groups. Rats in control group were given sodium chloride (2 mL) and rats in experimental groups were given Lianshu preparation (1.8 g/kg), twice a day before yeast was injected. Acetaminophen (250 mg/kg, *bid*) was used as a standard drug to compare the antipyretic action of Lianshu preparation. One hour after the last administration of drugs, fever was induced by hypodermic injection of a 20% suspension of 10 mL/kg Brewer's yeast and rectal temperature was recorded 1 h before and 6 h after injection of Brewer's yeast. The antipyretic activity of Lianshu preparation in rats was assayed.

#### Detection of effect of Lianshu preparation on small intestine transmission in mice

Thirty Kunming mice, after 12 h fasting, were divided into sodium chloride group, Lianshu preparation group and atropine group ( $n = 10$ ). Mice in the sodium chloride group received 0.5 mL sodium chloride by intragastric administration, twice a day for 1 d. Mice in the Lianshu preparation group received 1.8 g/kg Lianshu preparation,

twice a day for 1 d. Mice in the atropine treatment group received 10 g/kg intraperitoneal atropine, twice a day for 1 d. All mice were given 2 mg/kg methyl prostigmin followed by 0.1 mL ink after 10 min, and killed by cervical vertebral dislocation with their belly cut open to collect intestines. The effect of Lianshu preparation on small intestinal transmission in mice was detected.

#### Statistical analysis

Data were expressed as mean  $\pm$  SE and analyzed by analysis of variance and Student-Newman-Keuls test.  $P < 0.05$  was considered statistically significant.

## RESULTS

#### General health of rats

No diarrhea and loose stools occurred in rats of the normal group. The fur of rats was smooth and the rats were active. Rats in the other groups that received LPS drank more water and had loose stools. The fur of rats was fluffy, and the rats were affected by lassitude. The respiration of rats was rapid.

#### Frequency of diarrhea after injection of LPS

The frequency of diarrhea in LPS group, LPS + Lianshu group and LPS + berberine group was increased compared to normal group ( $36.70 \pm 5.23$ ,  $28.50 \pm 4.06$ ,  $32.70 \pm 9.30$  vs  $12.40 \pm 3.20$  respectively,  $P < 0.01$ ), significantly increased in LPS + Lianshu group and LPS + berberine group compared with normal group ( $P < 0.01$ ), and decreased in LPS + Lianshu group compared with LPS + berberine group ( $P = 0.03$ ) (Figure 1).

#### Glucose, serum electrolyte and hematocrit levels in rats

The levels of glucose,  $\text{Na}^+$ ,  $\text{Cl}^-$ , and  $\text{K}^+$  were significantly lower in LPS + Lianshu group than in LPS + berberine group ( $140.35 \pm 3.19$  mmol/L vs  $131.99 \pm 4.86$  mmol/L,  $8.49 \pm 1.84$  mmol/L vs  $6.54 \pm 2.30$  mmol/L,  $106.29 \pm 4.41$  mmol/L vs  $102.5 \pm 1.39$  mmol/L,  $5.08 \pm 0.66$  mmol/L vs  $4.32 \pm 0.62$  mmol/L respectively,  $P < 0.05$ ), while the hematocrit level was lower in LPS + Lianshu group than in LPS + berberine group ( $0.50\% \pm 0.07\%$  vs  $0.59\% \pm 0.10\%$ ,  $P < 0.05$ , Table 1, Figure 2).

#### Plasma NO and DAO levels in rats

The plasma NO and DAO levels were higher in LPS group than in normal group ( $P < 0.01$ ) and lower in LPS + Lianshu group than in LPS + berberine group ( $P < 0.05$ , Table 2).

**Figure 2 Hematocrit in different groups.** <sup>b</sup>*P* < 0.01 vs normal group; <sup>c</sup>*P* < 0.01 vs LPS group; <sup>e</sup>*P* < 0.05 vs LPS + Lianshu group.

**Figure 3 Comparison of plasma D (-)-lactate in different groups.** <sup>a</sup>*P* < 0.01 vs normal group; <sup>b</sup>*P* < 0.01 vs LPS group; <sup>c</sup>*P* < 0.05 vs LPS + Lianshu group.

### Plasma D (-)-lactate levels in rats

Plasma D (-)-lactate level was higher in LPS group, LPS + Lianshu group and LPS + berberine group than in normal group ( $5.36 \pm 0.85$ ,  $4.00 \pm 0.54$ ,  $4.88 \pm 0.77$  vs  $2.01 \pm 0.32$  respectively, *P* < 0.01), and lower in LPS + Lianshu group, LPS + berberine group than in LPS group and LPS + berberine group (*P* < 0.01, Figure 3).

### Morphological changes in intestinal mucosa

The villi of intestinal mucosa maintained their integrity and the shape of epithelial cells remained unchanged in the normal group. The villi were destroyed in the LPS group. Intestinal mucosal atrophy and inflammatory reaction were detectable in the other groups (Figure 4).

### Staining and number of IgA+ plasma cells in intestinal mucosa

IgA+ cells, round or elliptical in shape, were distributed in the intestinal villi, lamina propria and intestinal glands. The endochylema was stained brown (Figure 5).

### Number of IgA+ cells and SIgA in intestinal fluid

The number of IgA+ cells and amount of SIgA in intestinal fluid were less in LPS group than in normal group (*P* < 0.01) and higher in LPS + Lianshu

**Table 2 Plasma NO and DAO levels in different groups (mean  $\pm$  SD)**

Group	NO ( $\mu$ mol/L)	DAO ( $\mu$ mol/mL)
Normal	24.94 $\pm$ 3.38	0.82 $\pm$ 0.33
LPS	79.74 $\pm$ 7.39 <sup>b</sup>	2.48 $\pm$ 0.42 <sup>b</sup>
LPS + Lianshu	48.59 $\pm$ 4.70 <sup>b,d</sup>	1.43 $\pm$ 0.53 <sup>b,d</sup>
LPS + berberine	51.56 $\pm$ 8.38 <sup>b,d,f</sup>	1.81 $\pm$ 0.42 <sup>b,d,e</sup>

<sup>b</sup>*P* < 0.01 vs normal group; <sup>d</sup>*P* < 0.01 vs LPS group; <sup>e</sup>*P* < 0.05, <sup>f</sup>*P* < 0.01 vs LPS + Lianshu group.

**Table 3 Number of IgA+ cells and SIgA in intestinal fluid of different groups (mean  $\pm$  SD)**

Group	IgA+ cells (/μm <sup>2</sup> )	SIgA (mg/L)
Normal	0.94 $\pm$ 0.21	0.50 $\pm$ 0.09
LPS	0.73 $\pm$ 0.22 <sup>a</sup>	0.22 $\pm$ 0.66 <sup>b</sup>
LPS + Lianshu	1.16 $\pm$ 0.19 <sup>b,d</sup>	0.59 $\pm$ 0.12 <sup>d</sup>
LPS + berberine	1.09 $\pm$ 0.28 <sup>a,d,e</sup>	0.15 $\pm$ 0.19 <sup>b,c,e</sup>

<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs normal group; <sup>c</sup>*P* < 0.05, <sup>d</sup>*P* < 0.01 vs LPS group; <sup>e</sup>*P* < 0.05 vs LPS + Lianshu group.

group than in LPS + berberine group (*P* = 0.05, Table 3).

### Counteractive effect of Lianshu preparation on yeast-induced pyrexia in rats

The temperature of rats in yeast group and sodium chloride group was similar 1 h after treatment with Lianshu preparation and higher in yeast group than in sodium chloride group 2-5 h after treatment with Lianshu preparation (*P* < 0.05). The temperature was not significantly changed in yeast + Lianshu group compared to yeast group 1 h or 2 h after treatment with Lianshu preparation. The temperature in yeast + Lianshu group decreased 3 h after treatment with Lianshu preparation (*P* = 0.025), and was almost identical to that in the normal group 4 h after treatment with Lianshu preparation. The temperature was lower in yeast + acetaminophen group than in the sodium chloride group 2 h after treatment with Lianshu preparation. Yeast + acetaminophen exhibited their effect 1 h earlier than yeast + Lianshu preparation (Table 4).

### Counteractive effect of neostigmine on enterokinesia in mice

The rate of small intestinal peristalsis for mice after treatment with Lianshu preparation and atropine was different from that in mice after treatment with sodium chloride ( $55.20\% \pm 10.16\%$  and  $39.96\% \pm 8.57\%$  vs  $65.10\% \pm 10.93\%$  respectively, *P* < 0.05, Figure 6).

## DISCUSSION

A group of Japanese workers reported that parenteral LPS can lead to proliferation of gastrointestinal luminal bacteria in mice<sup>[4]</sup>. Subsequent work established that this enhancement of bacterial growth is secondary to

**Figure 4** Optical microscopic observation of ileum mucosa of rats (HE, × 100). A: Normal group; B: LPS group; C: LPS + Lianshu group; D: LPS + berberine group.

fluid exudation, since the growth of bacteria could be suppressed by enteral unabsorbable antibiotics like neomycin<sup>[5]</sup>. Subcutaneous LPS from Gram-negative bacteria induces intestinal diarrhea characterized by destruction of the intestinal mucosa barricade<sup>[6-9]</sup>.

In the present study, the frequency of diarrhea and gastrointestinal transit (GIT) were detected, and the levels of NO, DAO and D (-)-lactate were measured in mice after treatment with intraperitoneal LPS. Lianshu

preparation could effectively prevent diarrhea by inhibiting enterokinesia. Generally, NO can protect and repair gastrointestinal mucosa. Endogenous NO has therapeutic effects on hypoxia, inflammation and damage. However, excess NO is probably one of the most important mediators that induce blood poisoning, septic shock and multi-organ dysfunction<sup>[10]</sup>. When stimulated by LPS, NO is excessively expressed and induces multi-organ functional lesions in stomach and intestine<sup>[11-13]</sup>.

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs normal group; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs yeast group.

**Figure 6** Counteractive effects of neostigmine on enterokinesia of mice. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs sodium chloride group; <sup>d</sup> $P < 0.01$  vs Lianshu group.

In this study, Lianshu preparation prevented enteritis necroticans by inhibiting the production of excess NO. DAO is an ideal index of intestinal mucosal structure and function. The activity of DAO is closely related with villi, nucleic acid and protein synthesis in mucosal cells. When intestinal mucosal epidermis is damaged, DAO is released into blood, indicating that DAO in blood reflects the destruction of the intestinal mucosal epithelial cell layer and intestinal mucosa barricade<sup>[14,15]</sup>. In our study, DAO was localized mostly in the epithelial cell layer of mucous membrane as previously described<sup>[16]</sup>, and Lianshu preparation could effectively decrease DAO induced by LPS. However, its mechanism of action remains unclear. In addition, the function of the intestinal mucosa barricade could also be evaluated by measuring D (-)-lactate in plasma<sup>[17-19]</sup>. D (-)-lactate is a product of bacterial metabolism and schizolysis. However, mammals cannot produce D (-)-lactate<sup>[20]</sup>. D (-)-lactate cumulation in plasma reflects membrane permeability and barrier function of the intestinal mucosa<sup>[21,22]</sup>. In our study, Lianshu preparation could reduce D (-)-lactate in plasma ( $P < 0.01$ ) by protecting the barrier function of the intestinal mucosal and suppressing the overgrowth of harmful bacteria in the intestinal tract.

IgA is the main immunoglobulin in the mucosal immune system<sup>[23]</sup>. Polymeric IgA antibodies produced by plasma cells in the lamina propria of the intestinal tract bind to polymeric immunoglobulin receptors at the base of the epithelium. The complex of IgA and polymeric immunoglobulin receptors undergoes endocytosis and vesicular transport to the apical surface of enterocytes, and is secreted into the lumen. Generally,

plasma cells are derived from B cells. It was reported that B cells are able to switch from IgM expression to IgA expression by Th2 cytokine activity in Peyer's patches of the lamina propria and mesenteric lymph nodes, and then return to lamina propria of the intestinal tract *via* systemic circulation<sup>[24-26]</sup>. LPS, a mouse B-cell mitogen, induces B cell multiplication<sup>[26]</sup> and differentiation into plasma cells. LPS also activates macrophages to promote the production of cytokines such as interleukin (IL)-1, IL-6 and nitric oxide, which might regulate immunoglobulin production. Therefore IgA inhibits diarrhea caused by viruses<sup>[27-29]</sup>. Moreover, LPS might activate IgA production in the intestine<sup>[30]</sup>. However, in our study, the number of IgA+ cells and SIgA in the intestinal fluid was less in the LPS group than in normal group, and greater in the LPS + Lianshu group than in the LPS group, suggesting that high dose LPS leads to severe destruction of intestinal mucosa.

## ACKNOWLEDGMENTS

The authors thank Dr. Wan-Ju Liu for his assistance with manuscript preparation.

## COMMENTS

### Background

Infectious diarrhea is often caused by Gram-negative bacteria such as *Escherichia coli*. These organisms contain lipopolysaccharide (LPS). It is the important task of modern medicines to control infectious diarrhea. Antibiotics developed in the 1940s have saved millions of people's lives. However, because of the widespread and inappropriate use of antibiotics, some bacterial strains become antibiotic-resistant. Folk herbal drugs have been studied for the treatment of acute diarrhea.

### Research frontiers

The method to treat diarrhea is mainly to kill bacteria or viruses. Lianshu preparation could destroy bacteria, prevent diarrhea, and protect the intestinal mucosa.

### Innovations and breakthroughs

Lianshu preparation, comprised of non-antibiotic botanic components, has been used in the treatment of infectious diarrhea with a satisfactory effect. Lianshu preparation could effectively prevent diarrhea, relieve electrolyte disturbances and protect immune barriers. Its effect is better than berberine. In addition, Lianshu preparation has counteractive effects on pyrexia.

### Applications

Lianshu preparation can be used as a natural medicine in treatment of infectious diarrhea with pyrexia. Chinese herbal drugs are effective against both chronic and acute diseases.

### Peer review

The authors confirmed, in their study, that Lianshu preparation was effective against LPS-induced diarrhea, its effect was better than berberine, suggesting that it can be used as a natural medicine in treatment of infectious diarrhea.

### Abstract

**AIM:** To investigate the ezrin expression in normal colorectal mucosa and colorectal cancer tissues, and study the correlation between ezrin expression in colorectal cancer tissues and tumor invasion and metastasis.

**METHODS:** Eighty paraffin-embedded cancer tissue samples were selected from primary colorectal adenocarcinoma. Twenty-eight patients had well-differentiated, 22 had moderately differentiated and 30 had poorly differentiated adenocarcinoma. Forty-five patients and 35 patients had lymph node metastasis. Forty-five patients were of Dukes A to B stage, and 35 were of C to D stage. Another 22 paraffin-embedded tissue blocks of normal colorectal epithelium (> 5 cm away from the edge of the tumor) were selected as the control group. All patients with colorectal cancer were treated surgically and diagnosed histologically, without preoperative chemotherapy or radiotherapy. The immunohistochemistry was used to detect the ezrin expression in paraffin-embedded normal colorectal mucosa tissues and colorectal cancer tissue samples.

**RESULTS:** Ezrin expression in colorectal cancer was significantly higher than in normal colorectal mucosa (75.00% vs 9.09%,  $P < 0.01$ ), and there was a close relationship between ezrin expression and the degree of tumor differentiation, lymph node metastasis and

### INTRODUCTION

Ezrin belongs to the ezrin/radixin/moesin (ERM) protein family, which act as membrane organizers and linkers between the plasma membrane and cytoskeleton<sup>[1,2]</sup>. Ezrin is mainly expressed on the cell surface to maintain the polarity of endothelial cells<sup>[3]</sup>. Recent studies have found that, through regulating adhesion molecules and signal transduction pathways, ezrin is involved in cell-cell and cell-matrix interactions, and might play an important role in the process of tumor cell invasion and metastasis<sup>[4]</sup>. Overexpression of ezrin protein is correlated with the metastatic potential of several cancers<sup>[5-8]</sup>, and a high level of ezrin protein expression can induce conversion of a variety of cell lines, as well as abnormal hyperplasia<sup>[9]</sup>. Tumor cell lines with stronger metastatic abilities are usually accompanied by overexpression of ezrin<sup>[10]</sup>. Through testing the expression of ezrin protein in normal colonic mucosa

and colorectal cancer tissues, we aimed to establish the relationship between ezrin expression and clinical parameters, evaluate its molecular action mechanisms in the process of colorectal cancer carcinogenesis, invasion and metastasis, and provide the evidence for clinical prognosis and suitable adjuvant therapy.

## MATERIALS AND METHODS

### Patients and their pathological samples

The immunohistochemistry was performed in paraffin-embedded tissue samples. Eighty colorectal adenocarcinoma patients diagnosed by postoperative pathology were investigated. There were 44 male and 36 female patients, whose ages ranged from 31 to 80 years, with an average age of 55.5 years. Histologically, 28 patients had well-differentiated, 22 had moderately differentiated, and 30 had poorly differentiated adenocarcinoma. Forty-five patients were without and 35 patients had lymph node metastasis. Forty-five patients were of Dukes A to B stage, and 35 were of C to D stage. Another 22 paraffin-embedded tissue blocks of normal colorectal epithelium (> 5 cm away from the edge of the tumor) was the control group.

### Drugs and reagents

Mouse anti-human ezrin mAb was purchased from Fujian Maixin Biotechnology Development Co. Ltd, and SP kit DAB from Beijing Zhong Shan Jinqiao Biotechnology Development Co. Ltd. Experiments were performed following the instructions of the manufacturers. PBS (0.01 mmol/L) was used to replace the first antibody as a negative control, while the normal colorectal mucosa was a positive control.

### Result judgment

Each stained slide was assessed and given a score according to the classification standard of Mathew *et al*<sup>[11]</sup>: score 0, no expression; score 1, < 50% of cells staining positive expression or less; score 2, ≥ 50% of cells staining positive expression. Score 0-1 was recorded as negative, and score 2 recorded as positive.

### Statistical analyses

SPSS for Windows version 11.0 was used for statistical analyses. The  $\chi^2$  test was used in the analysis of the relationship between ezrin and colorectal cancer clinicopathological parameters.  $P \leq 0.05$  was considered as a significant difference.

## RESULTS

The positive expression of ezrin in colorectal cancer was significantly higher than that in normal colorectal mucosa (Figure 1A-E). The positive rate of ezrin protein in normal colorectal mucosa was 9.09% (2/22) and 75.00% (60/80) in colorectal cancer tissues. There were significant differences between the two groups (75.00% *vs* 9.09%,  $P < 0.01$ ), as shown in Table 1.

Table 1 Ezrin expression in different colorectal tissues *n* (%)

Group	<i>n</i>	Positive expression (%)
Normal colorectal mucosa	22	2 (9.09) <sup>b</sup>
Colorectal cancer tissues	80	60 (75.00)

<sup>b</sup> $P < 0.01$  *vs* colorectal cancer tissues.

Table 2 Relationship between ezrin expression in colorectal cancer tissues and clinicopathological parameters *n* (%)

Clinicopathological parameters	<i>n</i>	Ezrin positive expression (%)
Well-differentiated	28	14 (50.00) <sup>b</sup>
Moderately and poorly differentiated	52	46 (88.46)
Lymph node metastasis	35	33 (94.28) <sup>d</sup>
Without lymph node metastasis	45	27 (51.11)
Dukes A to B stage	45	27 (51.11) <sup>e</sup>
Dukes C to D stage	35	33 (94.28)

There was a close relationship between ezrin expression and the degree of tumor differentiation, lymph node metastasis and Dukes stage. There were significant differences between the well-differentiated and the moderately and poorly differentiated groups (<sup>b</sup> $P < 0.01$ ); lymph node metastasis group *vs* group without lymph node metastasis (<sup>d</sup> $P < 0.01$ ); Dukes A to B stage *vs* Dukes C to D stage (<sup>e</sup> $P < 0.01$ ).

### Relationship between ezrin expression in colorectal cancer tissues and clinicopathological parameters

There was a close relationship between ezrin expression and the degree of tumor differentiation, lymph node metastasis and Dukes stage (88.46% *vs* 50.00%,  $P < 0.01$ ; 94.28% *vs* 51.11%,  $P < 0.01$ ; 94.28% *vs* 51.11%,  $P < 0.01$ ), as shown in Table 2.

## DISCUSSION

Ezrin protein expression in specific cell membrane regions is mainly involved in the connection between the epithelial cell cytoskeleton and the cell membrane, through membrane surface signaling molecules and some transmembrane signal transduction pathway. It participates in the regulation of cell survival, adhesion, proliferation and migration processes. Recent studies have found that ezrin protein may play an important role in the tumorigenesis, development, invasion and metastasis process, probably through regulating adhesion molecules and participating in cell signal transduction, and other channels in the tumor<sup>[12-17]</sup>. Ezrin protein is an indispensable factor for tumor cell metastasis of osteosarcoma<sup>[18]</sup>, breast cancer<sup>[19]</sup>, nasopharyngeal carcinoma<sup>[20]</sup>, and prostate cancer<sup>[21]</sup>. In addition, in malignant tumor tissues, there are also changes in subcellular localization of ezrin expression. Moilanen *et al*<sup>[22]</sup> found that ezrin expression in normal ovarian epithelial cells is a kind of cell polarity expression, and that ezrin expression in malignant ovarian tumor cells is more diffusive, with a different degree of tumor cell differentiation, and the location and intensity of ezrin expression in cells is quite different. Therefore, we speculate that ezrin subcellular localization in normal

**Figure 1 Ezrin expression (HE, × 400).** A: Normal colorectal mucosa; B: Well-differentiated adenocarcinoma; C: Poorly differentiated adenocarcinoma; D: Adenocarcinoma without lymph node metastasis; E: Adenocarcinoma with lymph node metastasis.

cells forms the foundation of various physiological functions and cell structure. Abnormal ezrin expression or distribution will also lead to abnormal cell structure and physiological function, and accordingly, these abnormal changes participate in the occurrence, development, invasion and metastasis of malignant tumors.

The role of ezrin in tumor progression is very important and deserves much attention. Recent studies have found that ezrin is a key factor in Fas-mediated apoptosis<sup>[23]</sup>, in the P-gp1-mediated multidrug resistance of cancers, and in cannibalism of metastatic tumors<sup>[24]</sup>. The active ezrin C-terminal is connected with the actin cytoskeleton, and the N-terminal is connected with cell adhesion molecules such as E-cadherin, and CD44<sup>[25,26]</sup>, etc. Ezrin participates in regulating cell-cell and cell-extracellular matrix adhesion, thus influencing tumor cell invasion and other biological behavior<sup>[27-30]</sup>. CD44 is a cellular membrane receptor which can specially recognize hyaluronic acid and collagen, and regulate cell-cell and cell-extracellular matrix adhesion. Some studies have found that ezrin, CD44 and CD44 variants could make up a compound that is co-expressed in the tumor cells<sup>[1]</sup>. Pujuguet *et al*<sup>[31]</sup> have found that ezrin can regulate E-cadherin expression in the cell membrane through Rho protein, thereby regulating cell adhesion. At the same time, ezrin also has regulating function in the E-cadherin membrane localization, and activated ezrin can make the E-cadherin protein aggregate in the cell, thereby undermining the cell-to-cell contact and intercellular adhesive ability, and the overexpression of ezrin in the tissues also has the same function of weakening the intercellular adhesion<sup>[32]</sup>. Through activation of RhoA and the MAPK pathway, ezrin can promote the cell adhesion plaque formation, thereby promoting the adhesive function between the tumor cells and other cells, as well as stoma cells<sup>[33]</sup>. Therefore, we believe, through participation in the formation of the cell adhesion plaque, cytoskeletal connections and cell surface compounds assembly, and other biological functions, ezrin protein mediates and regulates cell-cell and cell-extracellular matrix adhesion, and is also involved in the malignant tumor invasion and metastasis process. This study showed that, the overexpression of ezrin in colorectal cancer tissues may

be involved in cancer invasion and metastasis. The studies on the correlation between ezrin protein and cancer might help us further reveal the tumor invasion and metastasis mechanism, and find the targets for inhibiting tumor metastasis, or indicators that forecasts the prognosis of patients with tumors.

## COMMENTS

### Background

Ezrin belongs to the ezrin/radixin/moesin (ERM) protein family, which act as membrane organizers and linkers between the plasma membrane and cytoskeleton. Ample evidence has indicated that ezrin is regarded as a metastatic determinant and a key component in tumor progression and metastasis; however, its role in the process of colorectal cancer growth and metastasis is not clearly understood.

### Research frontiers

Recent studies have found that a high level of ezrin protein expression can induce a variety of cell line conversions, as well as abnormal hyperplasia. Ezrin is a key factor in Fas-mediated apoptosis, the P-gp1-mediated multidrug resistance of cancers, and cannibalism of metastatic tumors.

### Applications

This preliminary study about ezrin in colorectal cancer growth and metastasis may pave the way for further clinical studies on colorectal cancer dissemination and metastasis.

### Terminology

Ezrin belongs to the ERM protein family, which are expressed in specific cell membrane regions, and acts as membrane organizers and linkers between the plasma membrane and epithelial cell cytoskeleton.

### Peer review

This study is interesting, and discusses the ezrin expression in normal colorectal mucosa and colorectal cancer tissues, and the clinical relevance of ezrin expression to tumor invasion and metastasis. The study was carefully performed and the data and conclusions drawn are sound.

more cases with DNMT1 overexpression in HCC with HBV (42.85%) than in HCC without HBV (28.57%). However, no significant difference in DNMT1 expression was found in HBV-positive and HBV-negative cases in the Chinese HCC group. There was a trend that DNMT1 RNA expression increased more in HCC cell lines than in pericarcinoma cell lines and normal liver cell lines. In addition, we inhibited DNMT1 using siRNA in the SMMC-7721 HCC cell line and found depletion of DNMT1 suppressed cells growth independent of expression of proliferating cell nuclear antigen (PCNA), even in HCC cell lines where DNMT1 was stably decreased.

**CONCLUSION:** The findings implied that DNMT1 plays a key role in HBV-related hepatocellular tumorigenesis. Depletion of DNMT1 mediates growth suppression in SMMC-7721 cells.

### Abstract

**AIM:** To explore the relationship between DNA methyltransferase 1 (DNMT1) and hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) and its biological significance in primary HCC.

**METHODS:** We carried out an immunohistochemical examination of DNMT1 in both HCC and paired non-neoplastic liver tissues from Chinese subjects. DNMT1 mRNA was further examined in HCC cell lines by real-time PCR. We inhibited DNMT1 using siRNA and detected the effect of depletion of DNMT1 on cell proliferation ability and cell apoptosis in the HCC cell line SMMC-7721.

**RESULTS:** DNMT1 protein expression was increased in HCCs compared to histologically normal non-neoplastic liver tissues and the incidence of DNMT1 immunoreactivity in HCCs correlated significantly with poor tumor differentiation ( $P = 0.014$ ). There were

### INTRODUCTION

DNA methylation plays an important role in transcriptional regulation, chromatin remodeling and genomic stability<sup>[1-3]</sup>. It is catalyzed in mammalian cells by a family of highly related DNA methyltransferases (DNMTs) that use S-adenosylmethionine as the methyl donor<sup>[4]</sup>. Alteration of DNA methylation is one of the most consistent epigenetic changes in human cancers and is involved even in the early and precancerous

stages of human carcinogenesis<sup>[5,6]</sup>. Overexpression of DNMT1 has been detected in several human cancers<sup>[7-11]</sup> and showed a relatively significant correlation with tumorigenesis, but not in hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC). HCC is a devastating disease with a very poor prognosis, and is the fourth or fifth largest cause of cancer-related death worldwide<sup>[12,13]</sup>. More than 85% of Chinese HCC patients have HBV infection history. Data on hepatocarcinogenesis in other countries showed that DNMT1 mRNA and protein expression were significantly higher in HCCs<sup>[14,15]</sup>. Therefore, DNMT1 may play an important role during hepatocarcinogenesis. However, the relationship between HBV infection and DNMT1 in HCC has still to be elucidated, especially in Chinese subjects. In the present study, we examined the expression of DNMT1 both in HBV-related HCC cases and cell lines from Chinese subjects. DNMT1 expression was significantly increased both in tumor tissues and HCC cell lines compared with corresponding controls. To further investigate and evaluate the possibility of DNMT1 knockdown strategies for cancer therapy, we inhibited DNMT1 using siRNA and examined the cell growth and cell proliferation ability in the HCC cell line SMMC-7721.

## MATERIALS AND METHODS

### Tissue specimens

We selected 42 cases of surgically resected livers from the surgical pathology files of the Department of Pathology at The Qidong County Hospital, China. The patients' clinicopathologic features are shown in Table 1. All the HCC samples were diagnosed by a single pathologist and appropriate consent was obtained. Paired samples of primary HCC and matched non-cancerous normal tissues were obtained from each patient. The pathological classification of HCC tissues was carried out and the stage of each HCC was determined according to criteria. Histological examination of noncancerous liver tissues from HCC patients revealed no remarkable findings. Thirty-five cases were associated with HBV infection, and 7 cases were negative for HBV.

### Cell lines

Nine human cell lines were cultured for the study. Human hepatocellular carcinoma cell lines (BEL-7402, BEL-7404, BEL-7405, QGY-7703, QGY-7701, SMMC-7721), an immortalized human hepatocellular normal cell line (HL-7702) or a pericarcinoma (QSG-7701) cell line were cultured in RPMI-1640 (Life Technologies, Inc., Rockville, MD) containing 10% new born bovine serum in 5% CO<sub>2</sub> incubation at 37°C.

### Preparing a vector-based siRNA construct for DNMT1

siRNAs targeting DNMT1 were designed and prepared as described previously<sup>[16]</sup>. The siRNA sequences against DNMT1 were designed as sense and antisense oligonucleotides corresponding to nucleotide position 2620-2638 of human DNMT1 (GenBank accession No. NM001379.1). The siRNA sequence and scramble

sequence were sub-cloned into the pSUPER-EGFP vector (gift from Dr. Dianqing Wu), which was identified by *Hind*III (TAKARA) and *Bgl*II (TAKARA), to be the DNMT1 siRNA construct named pMT1, with sMT1 as a control.

### Transfection of DNMT1 RNAi construct to hepatocellular carcinoma cell line SMMC-7721

The human HCC cell line SMMC-7721 (No. TCHu13 Cell Bank Shanghai, China) was cultured in RPMI-1640 containing 10% new born bovine serum in 5% CO<sub>2</sub> incubation at 37°C. Cells were transfected with 1.5 µg of DNMT1 siRNA (pMT1) construct or sMT1 using transfectamine<sup>TM</sup> 2000 reagent (Invitrogen), and selected with 0.4 mg/mL genetincin (Life Technologies). SMMC-7721 cells were transfected with pMT1 and named 7721-MT1 cell lines or transfected with sMT1 and named 7721-sMT1 as a control.

### Immunohistochemistry

Four micrometre thick sections of formalin-fixed, paraffin embedded tissue specimens from all 42 patients were deparaffinized and dehydrated. For antigen retrieval, the sections were heated for 10 min at 120°C in an autoclave, and nonspecific reactions were blocked with 5% normal horse serum. All sections were incubated with specific primary antibodies that recognized DNMT1 (goat polyclonal antibody, dilution 1:500; Santa Cruz Biotechnology, Santa Cruz, CA). We previously confirmed the specificity of the goat anti-human DNMT1 polyclonal antibody by Western blotting analysis: an immunoreactive band of 193.5 kDa, corresponding to the molecular mass of DNMT1, was detected in human cancer cells, but no nonspecific bands were detected with this antibody<sup>[16]</sup>. All primary antibody incubations were conducted at 4°C overnight and were followed by incubation with biotinylated secondary antibodies (anti-goat IgG, anti-mouse IgG, dilution 1:200; QIAGEN Laboratories) at room temperature for 30 min. The sections were then treated with Vectastain Elite ABC reagent (Vector Laboratories). All sections were counterstained with hematoxylin. For negative

control preparations, the primary antibody was omitted from the reaction sequence.

### Real time PCR to detect mRNAs of DNMT1

Total RNA was purified from a normal liver cell line, a cell line established from pericarcinoma tissue and HCC cell lines with TRIzol (Invitrogen). The first-strand cDNA was synthesized from 2 µg total RNA using Oligo (dT) 18 primer and SuperScript II reverse transcription kit (Life Technologies). A PCR reaction was performed in a 50 µL volume with 5U polymerase (TAKARA) and cDNA samples equivalent to 1 ng of RNA. SYBR green with 20000 dilutions was included in each reaction for relative quantification in the ABI 7300 sequence detection system (Applied Biosystems). To normalize the input load of cDNA among samples, *β-actin* was quantified and used as an endogenous standard. The relative level of expression of each *DNMT1* among different cell lines was then calculated accordingly (ABI PRISM 7300 Sequence Detection System, USA). The primers used for PCR were as follows: *DNMT1*: sense primer, 5'-CCGAGTTGGTGATGGTGTGATC-3'; antisense primer, 5'-AGGTTGATGTCTGCGTGCTAGC-3'. *β-actin*: 5'-AAAGACCTGTACGCCAACAC-3'; antisense primer, 5'-GTCATACTCCTGCTTGCTGAT-3'. *PDCD4*: sense primer 5'-TGGATGAAAGGGCATTTGAGA-3'; antisense primer, 5'-AGCCTTCCCCTCCAATGCTA-3'.

### Western blotting analysis

Cells were grown and harvested at 80%-85% confluency, and cellular proteins were extracted with lysis buffer containing 0.5% NP-40, 150 mmol/L NaCl, and 1 mmol/L EDTA in 50 mmol/L Tris-HCl at pH 7.5, supplemented with a protease inhibitor cocktail (Sigma Chemical Co., St. Louis, MO). The protein concentration of each extract was quantified by BCA assay (Pierce, Rockford, IL). Two to forty microliter of total protein was electrophoresed on 7%-15% SDS-polyacrylamide gel and transferred to polyvinylidene fluoride membranes (PVDF, Amersham) electrophoretically. After blocking with 5% nonfat dry milk and 0.1% Tween 20 in Tris-buffered saline, membranes were incubated with goat anti-DNMT1 (Santa Cruz Biotechnology), proliferating cell nuclear antigen (PCNA) (mouse monoclonal antibody, dilution 1:200, Lexington, KY) or mouse monoclonal anti-actin (Sigma) antibodies. The membranes were then developed with peroxidase-labeled antibodies (Amersham Pharmacia, Piscataway, NJ) by Super Signal chemiluminescence substrate (Pierce, Rockford, IL). Actin protein levels were used as a control for equal protein loading.

### In vitro analysis of cell growth

Cell proliferation of transiently transfected SMMC-7721 cells was measured by trypan blue dye cell count assay. Cells were cultured in triplicate in 12-well plates at a concentration of  $3 \times 10^4$  cells per well. Cells were collected at 1, 3, 5 and 7 d and exposed to trypan blue (Sigma), and nonviable cells took up the dye. Both viable

(unstained) and nonviable (stained) cells were counted, and the relative survival rate (%) of each siRNA treatment was then calculated.

### Flow cytometric (FCM) analysis

Stably transfected SMMC 7721 cells were washed, resuspended in staining buffer, and examined by ApoAlert Annexin V Apoptosis kit (BD Biosciences) and PI according to the manufacturer's instructions. Stained cells were analyzed by FACS (FACScalibur, BD Biosciences).

## RESULTS

### Immunohistochemical analysis of DNMT1 in pericancerous liver tissues and HCCs

Immunoreactivity for DNMT1 was detected in the nuclei and cytoplasm, but not in the cell membranes, of cancer cells (Figure 1). To discriminate definitely positive cases from cases with a leaky background level signal, if more than 30% of the cells in a tissue sample exhibited nuclear and cytoplasm staining the sample was considered to show positive immunoreactivity. Nuclear and cytoplasmic DNMT1 immunoreactivity was detected and overexpressed in 40.48% of patients. The incidence of DNMT1 immunoreactivity in carcinoma correlated significantly with poor tumor differentiation (Table 2,  $P = 0.014$ ,  $\chi^2$  test). The incidence of DNMT1 immunoreactivity was significantly higher in HCCs than in pericancerous liver tissues. DNMT1 protein overexpression was not significantly associated with other parameters relating to cancer aggressiveness, such as the depth of invasion, vascular involvement, or lymph node metastasis. In HBV-related HCC cases, 70% had different degrees of hepatocirrhosis. To investigate whether there was an HBV-induced increase in DNMT1 expression in HCC, we evaluated the relationship between HBV infection and up-regulated DNMT1. There was higher expression of DNMT1 in HCC with HBV than in HCC without HBV. However, there was no significant correlation between the incidence of DNMT1 immunoreactivity in HCCs and the patients' viral status (HBs-Ag-positive, HBs-Ag-negative) by statistical analysis.

### Expression of DNMT1 in nine cell lines

In order to determine whether the expression of DNMT1 was different between HCC cell lines and normal hepatocellular cell lines which were cultured under the same conditions, real-time RT-PCR was carried out in ABI 7300. DNMT1 was increased more in most HCC cell lines, especially in BEL-7405, BEL-7402 and SMMC-7721, than in a normal cell line and a pericarcinoma cell line. There were a trend that *DNMT1* increased more in HCC cell lines than in a normal liver cell line and a pericarcinoma cell line. In contrast to the low expression level of DNMT1 in the pericarcinoma cell line, the levels of DNMT1 in most HCC cell lines were increased more than 2-fold (Figure 2).

**Figure 1** DNMT1 expression was analyzed in pericancerous liver tissues and HCCs by immunohistochemistry (x 100). A: The expression of DNMT1 was detected in cirrhotic noncancerous liver tissue obtained from HCC patients; B: The expression of DNMT1 was detected in well differentiated HCC; C: The expression of DNMT1 was detected in poorly differentiated HCC. The arrow is to show DNMT1 antibody staining in cell nuclei.

### Decrease in DNMT1 suppresses growth of human hepatocellular carcinoma cells *in vitro*

We analyzed the proliferation ability of SMMC-7721 cells transfected with DNMT1 siRNA constructs and its control by FCM and trypan blue assay. The resulting RNA interference had a negative effect on SMMC-7721 growth (Figure 3). This growth suppression was noticeable two days after transfection, and the effect was more prominent in DNMT1 knockdown cells than at seven days after transfection (Figure 3A). For the determination of DNMT1 protein expression in construct pMT1 transiently transfected SMMC 7721 cells,  $\beta$ -actin was employed for adjustment of DNMT1 expression data to protein content. PCNA, an established cell proliferation marker and the DNA replication factor to which DNMT1 binds, was employed to evaluate cell proliferation. Comparison with PCNA expression levels

**Figure 2** DNMT1 mRNA expression levels analysis in HCC cell lines by quantitative real-time PCR. DNMT1 mRNA expression levels were normalized according to the  $\beta$ -actin mRNA level of the same cell line. DNMT1 was increased more in most hepatocellular carcinoma cell lines, especially in BEL-7402, BEL-7405 and SMMC-7721, than in the normal cell line HL-7702 and pericarcinoma cell line QSG-7701.

**Figure 3** Inhibition of DNMT1 affects cell growth in HCC cell lines. Expression of endogenous DNMT1 protein in 7721-MT1 cells transfected with DNMT1 RNAi construct were decreased more than 80%. A: The SMMC-7721 cells were transfected transiently with DNMT1 siRNA and analyzed for their survival by trypan blue staining assay. The assays were performed in triplicates and the data are the mean  $\pm$  SE; B: Western blotting analysis of DNMT1 expression in cells transfected transiently with DNMT1 siRNA for 1, 3, 5, 7 d; C: The SMMC-7721 cells were transfected stably with DNMT1 siRNA for 2 mo and the inhibition of DNMT1 and expression of PCNA were evaluated.

revealed that the changes in DNMT1 expression were independent of the cell proliferation status (Figure 3B). The data showed that DNMT1 levels started to decrease on day 3 and was maintained until seven days after transfection with cell growth inhibition. However, there were no significant changes in PCNA expression, even in a stably decreased DNMT1 HCC cell line (Figure 3C).

### DNMT1 knockdown induced cell apoptosis in SMMC-7721 cell line

Cell apoptosis detection was performed by flow cytometric analysis as described above. The data from

**Table 2** Relationship between DNMT1 and pathological change in patients with HCC *n* (%),  $\chi^2$  test

	Subtotal	DNMT1 expression ( <i>P/OR</i> : up-regulated/normal + down-regulated)			<i>P</i>	OR (95% CI)

**Figure 4** Knock-down DNMT1 induces cell apoptosis in HCC cell lines. A: The SMMC-7721 cells were transfected stably with DNMT1 siRNA for 2 mo and apoptosis was detected by FACS; B: Knock-down DNMT1 induced apoptosis gene PDCD4 expression in 7721-MT1 cell line compared with control cell line by quantitative real-time PCR. <sup>a</sup>Show the significant difference between 7721-pMT1 and control.

the present study indicated that DNMT1 knockdown induced cell apoptosis. The apoptotic rate increased from  $8.78\% \pm 0.44\%$  to  $14.24\% \pm 0.12\%$ . These results indicated that DNMT1 knockdown may induce HCC cell apoptosis (Figure 4). The apoptosis gene *PDCD4* was induced by DNMT1 siRNA in SMMC-7721.

## DISCUSSION

HCC is well known to develop through the stages

of dysplasia and early HCC in a background of chronic liver diseases, including chronic hepatitis and liver cirrhosis. Increased DNMT1 mRNA expression has been reported in a number of human cancers<sup>[17-19]</sup>. DNMT1 may play an important role during hepatocarcinogenesis even at the precancerous stage<sup>[9,20]</sup>. Although DNMT1 expression and its role were evaluated in different populations, information from Chinese subjects was still unclear. HCC is one of the most lethal and prevalent cancers in China, where HBV is one of the main attributable risk factors<sup>[4,21]</sup>. To study the significance of aberrant DNMT1 expression during hepatocarcinogenesis in a Chinese population, we used an immunohistochemical technique to directly evaluate DNMT1 protein expression in noncancerous liver tissues and HCCs, and real-time PCR to evaluate DNMT1 expression in HCC cell lines and a normal liver cell line.

After all tumors were analyzed, HBV infection was present in 83.3% of the samples, indicating that our study cohort is representative of the subset of HCC arising from HBV infection, which is the most considerable risk factor for HCC in studied cases. In the present study, more than 80% of nonneoplastic liver tissues with either chronic hepatitis or liver cirrhosis showed variable nuclear and cytoplasm immunopositivity for DNMT1. DNMT1 immunoreactivity was certainly detected in HCCs, as it was in other cancers<sup>[22-24]</sup>. DNMT1 overexpression was detected in 40.48% of the patients and the incidence of DNMT1 immunoreactivity was significantly higher in HCC than in pericancerous liver tissues. Specifically, the incidence of DNMT1 immunoreactivity in HCCs correlated significantly with poor tumor differentiation. The above evidence indicates that increased DNMT1 protein expression may play a role in the malignant progression of HCCs in Chinese subjects. Alternatively, in virus-associated cancers, viral proteins have been shown to disturb the host DNA methylation system by up-regulating DNMT activities, thereby increasing tumor susceptibility<sup>[25]</sup>.

Park *et al.*<sup>[26]</sup> showed that HBx promoted specific regional hypermethylation of tumor suppressor genes and genome-wide hypomethylation by transcriptional regulation of DNMTs. HBx expression elevates overall intracellular DNMT activity by inducing DNMT1 and DNMT3A. HBx promotes epigenetic abnormalities by modulating the expression of DNMTs immediately after HBV infection, thus epigenetically accelerating hepatocarcinogenesis. In this study, we evaluated DNMT1 expression in HBV-positive cases and HBV-negative cases. No significant relationship was found between HBV infection and DNMT1 up-regulation. These data suggested there is a different mechanism of HBV affected by DNMTs expression in diverse ethnic populations although additional studies with larger sample sizes are required to confirm our findings.

According to the results of both immuno-histochemistry and real time RT-PCR, progressive increases in DNMT1 expression may be accompanied by hepatocarcinogenesis from the precancerous stage to the malignant progression of HCC. Immunohistochemical analysis of DNMT1 in biopsy specimens obtained for diagnostic purposes and/or surgically resected materials may show that DNMT1 is a biologic predictor of both HCC recurrence and poor prognosis in HCC patients. To address whether DNMT1 overexpression plays an important role in hepatocellular carcinogenesis in Chinese subjects and to evaluate DNMT1 knockdown strategies for cancer therapy, it is necessary to deplete DNMT1 in the HCC. To avoid the problem of DNMT1 siRNA not being sufficient to inhibit cell growth due to the short-term inhibition of DNMT1 expression, we employed the RNAi technique to knockdown DNMT1 expression in an HCC cell line and assessed tumor cell growth in transiently transfected and stably expressed DNMT1 siRNA cell lines, respectively. Fortunately, we observed that depletion of DNA methyltransferase 1 mediates growth suppression in the HCC cell line SMMC-7721. In order to explore whether this inhibition of DNA replication reflects a distinct alteration in cell cycle kinetics, similar to the DNA damage checkpoints that trigger arrest at distinct phases of the cell cycle<sup>[27]</sup>, we detected PCNA in the treated cells, and found there were no significant changes in PCNA expression in treated cells and controls. However, DNMT1 knockdown inhibited cell growth and induced cell apoptosis in the SMMC-7721 cell line. With a view to the results of cDNA microarray<sup>[16]</sup>, PDCD4, an over-expression apoptosis gene, may contribute to the apoptosis rate in SMMC-7721 cells treated by siRNA. PDCD4 is a proapoptotic molecule involved in TGF-beta1-induced apoptosis in human HCC cells, and a possible tumor suppressor in hepatocarcinogenesis<sup>[28-30]</sup>. These results provide a rationale for the development of a DNMT1-targeted strategy as an effective epigenetic cancer therapy.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) is the fourth or fifth largest cause of cancer-

related death worldwide. The aberration of DNA methylation (DNMT), which is catalyzed by DNA methyltransferases, is common in HCC. DNMT1 is the main and maintenance methyltransferase in mammals. DNMT1 may play an important role during hepatocarcinogenesis. However, the relationship between abnormal DNMT1 expression and hepatocellular carcinogenesis is still to be elucidated, especially in a Chinese population.

### Research frontiers

Overexpression of DNMTs is a common event in nearly all malignancies, and DNMT1 may play an important role during hepatocarcinogenesis. In the present study, the authors demonstrated that the overexpression of DNMT1 is correlated significantly with poor tumor differentiation in HCC. Inhibition of DNMT1 through siRNA affected the proliferation ability of an HCC cell line.

### Innovations and breakthroughs

Recently, most reports focus on the overexpression of DNMT1 and DNA methylation in tumors. However, abnormal expression of DNMT1 may be involved in tumorigenesis, especially in HBV-related HCC. RNA interference is a direct and efficient way to suppress the target gene in a gene function study. This is the first study to report that inhibition of DNMT1 via RNAi suppressed cell proliferation and induced cell apoptosis in an HCC cell line.

### Applications

This study implied that DNMT1 maybe considered as a target for HCC therapy. The study also gives a general and better understanding of tumor cell biology and the potential epigenetic mechanism of hepatocellular carcinogenesis.

### Terminology

DNMTs are crucial components of DNA methylation. DNMT1 is the major and best-known DNMT in somatic cells. DNMT1 overexpression correlated significantly with poorer tumor differentiation, but not with the phenotype of the cancer cells, in several tumors. DNMT1 protein might have a more direct and immediate effect on the state of cellular growth and transformation.

### Peer review

The manuscript by Hong *et al* shows an increased expression of DNMT1 in hepatocellular carcinoma tissue samples and cell lines compared to controls. The increase was correlated with the degree of differentiation. Knockdown of DNMT1 expression in HCC cell lines decreased the number of cells at the end of the experiment. This did not correlate with decreased proliferating cell nuclear antigen (PCNA) expression but was associated with an increase in apoptosis and the expression of apoptosis-related gene PDCD4. For the most part the data is convincing and the experiments are well carried out.

### Abstract

**AIM:** To investigate the incidence of incidental gastrointestinal stromal tumor (GIST) and its etiopathogenesis.

**METHODS:** From January 1, 2000 to December 31, 2007, 13804 cases of gastrointestinal epithelial malignant tumor (EMT) and 521 cases of pancreatic adenocarcinoma (PAC) were successfully treated with surgery at the Department of General Surgery and the Department of Thoracic Surgery, West China Hospital, Sichuan University, China. The clinical and pathologic data of 311 cases of primary GIST, including 257 cases with clinical GIST and 54 cases of incidental GIST were analyzed.

**RESULTS:** Of the 311 patients, 54 had incidental GIST, accounting for 17.4%. Of these tumors, 27 were found in 1.13% patients with esophageal squamous cell carcinoma (ESCC), 22 in 0.53% patients with gastric adenocarcinoma (GAC), 2 in 0.38% patients with PAC, 2 in 0.03% patients with colorectal adenocarcinoma, and 1 in one patient with GAC accompanying ESCC, respectively. Patients with incidental GIST presented symptoms indistinguishable from those with EMT. All incidental GIST lesions were small in size, and the majority had a low mitotic activity while only 1.9% (5/257) of clinical GIST lesions had a high risk.

### INTRODUCTION

Gastrointestinal stromal tumor (GIST) is the most common mesenchymal tumor of gastrointestinal (GI) tract, probably arising from precursor interstitial cells of Cajal. Significant advances have been made in symptomatic GIST in the last two decades<sup>[1,2]</sup>. However, little is known about the incidental GIST detected during examinations or surgery for other reasons. Its clinicopathologic characteristics are unclear. Many cases of synchronous or asynchronous GIST with other tumors have been reported as single cases<sup>[3-6]</sup>. We discovered 54 cases of incidental GIST during surgery for epithelial malignant tumor (EMT). This study was to investigate the incidence of incidental GIST and its etiopathogenesis.

### MATERIALS AND METHODS

#### Patients

From January 1, 2000 to December 31, 2007, 13804 cases of gastrointestinal EMT and 521 cases of pancreatic adenocarcinoma (PAC) were successfully treated with surgery at the Department of General

Table 1 Location of 54 incidental GIST lesions and their corresponding EMT

EMT	Patients (n)	Median age	Gender (M/F)	Incidental GIST site (No. of patients)

GIST: Gastrointestinal stromal tumor; EMT: Epithelial malignant tumor; GAC: Gastric adenocarcinoma; ESCC: Esophageal squamous cell carcinoma; CRA: Colorectal adenocarcinoma; PAC: Pancreatic adenocarcinoma.

Surgery and the Department of Thoracic Surgery, West China Hospital, Sichuan University, China. Gastrointestinal EMT cases included 2382 cases of esophageal squamous cell carcinoma (ESCC), 35 cases of esophageal adenocarcinoma (EAC), 4168 cases of gastric adenocarcinoma (GAC), 329 cases of small intestinal adenocarcinoma (SAC), and 6890 cases of colorectal adenocarcinoma (CRA). During this period, 311 cases of primary GIST (121 females, 190 males) were identified in our center, including 257 cases of clinical GIST and 54 cases of incidental GIST.

### Methods

Hospital records of patients with incidental GIST were reviewed. Each patient was followed up by telephone or mail. Histopathologic features of primary GIST were evaluated by two experienced pathologists, blinded to their respective findings and patient outcomes, at the Department of Pathology, West China Hospital. The largest diameter of tumor was recorded. In patients with multiple GIST lesions, only the largest GIST lesion was included in pathological analysis. The risk category for GIST was defined by assessing the tumor size and mitotic count following the consensus guidelines of the National Institutes of Health-(NIH-NCI) workshop<sup>[7]</sup>. In addition to the assessment of CD117 in tumor cells, reactions with CD34, SMA, and S-100 proteins were also studied. Immunohistochemical examination of these proteins was performed on tumor tissues embedded in paraffin with DAKO (Glostrup, Denmark) antibodies according to the manufacturer's instructions.

### Statistical analysis

Categorical variables were compared by  $\chi^2$  test or by Fisher's exact test where applicable. Survival analysis was performed using the Kaplan-Meier method.  $P < 0.05$  was considered statistically significant. Statistical analysis was performed using SPSS version 13.0 (SPSS Inc., Chicago, IL, USA).

## RESULTS

Of the 311 patients, 54 had incidental GIST, accounting for 17.4%. Among these tumors, 27 were found in 1.13% patients with ESCC, 22 in 0.53% patients with GAC, 2 in 0.38% patients with PAC, 2 in 0.03% patients with CAC, and 1 in one patient with GAC accompanying ESCC,

respectively.

The median age of the 54 cases of incidental GIST was 63 years (range, 44-79 years). Interestingly, 48 of them (88.9%) were males, and 6 (11.1%) were females ( $P < 0.001$ ). The patients presented symptoms of EMT without specific clinical manifestations indicative of GIST. Among the 54 patients, only a submucous lesion in gastric fundus, 2.5 cm in diameter, was preoperatively detected in 1 patient with GAC by gastroscopy, and a single-lesion was postoperatively detected in 4 patients by specimen examination. A total of 58 incidental GIST lesions were discovered in the 54 patients, including 51 single-lesions, 2 double-lesions, and 1 triple-lesion. A total of 90.7% incidental GIST lesions occurred in stomach, 3.6% in esophagus, 1.9% in terminal ileum, 1.9% in colon and 1.9% in omentum, respectively. The most common sites were the gastric fundus and body. In our series, 4 cases with a unique coexistence style (esophageal GIST + ESCC: 2, gastric GIST + ESCC + GAC: 1, colonic GIST + CRA: 1) have not been reported previously. The location of 54 incidental GIST lesions and their corresponding EMT lesions are shown in Table 1.

Of the incidental GIST lesions, 37 (68.5%) were of spindle-cell morphology, 9 (16.7%) epithelioid morphology, and 8 (14.8%) a mixed histological type. Immunohistochemical staining showed that 50 cases (92.6%) and 52 cases (96.3%) of incidental GIST were positive for CD117 and CD34, respectively. None of them was proven to have a metastasis of GIST, while 29 cases were confirmed with metastasis derived from EMT. Incidental GIST was small in size. The majority (90.7%) had a low mitotic activity and a very low risk, while only 1.9% cases of clinical GIST had a very low risk ( $P < 0.001$ ), and 38.5% had a high risk with a marked mitotic activity (Table 2).

All the GAC patients received radical excision (distal gastrectomy for 3, proximal gastrectomy for 2, total gastrectomy for 12, esophagogastrectomy for 5). All the ESCC patients including the patient with triple tumors underwent esophagogastrectomy. The two PAC patients underwent duodenopancreatectomy and distal pancreatectomy, respectively, with local gastrectomy. Right and left hemicolectomy was performed for the two CRA patients, respectively. Thirty-four out of the 54 patients received either adjuvant chemotherapy and/or radiotherapy after operation. None of them received oral Imatinib mesylate (Glivec) treatment. On September

Table 2 Distribution of gender, age, tumor site, tumor size, and risk in 311 patients with GIST

GIST	Patients (n)	Gender (M/F)	Median age in yr (range)	Tumor site (No. of patients)	Tumor size (cm)			Risk patients, n (%)
					Median	Mean	Range

Risk was determined as previously described<sup>[7]</sup>. VL: Very low risk; L: Low risk; Int: Intermediate risk; H: High risk.

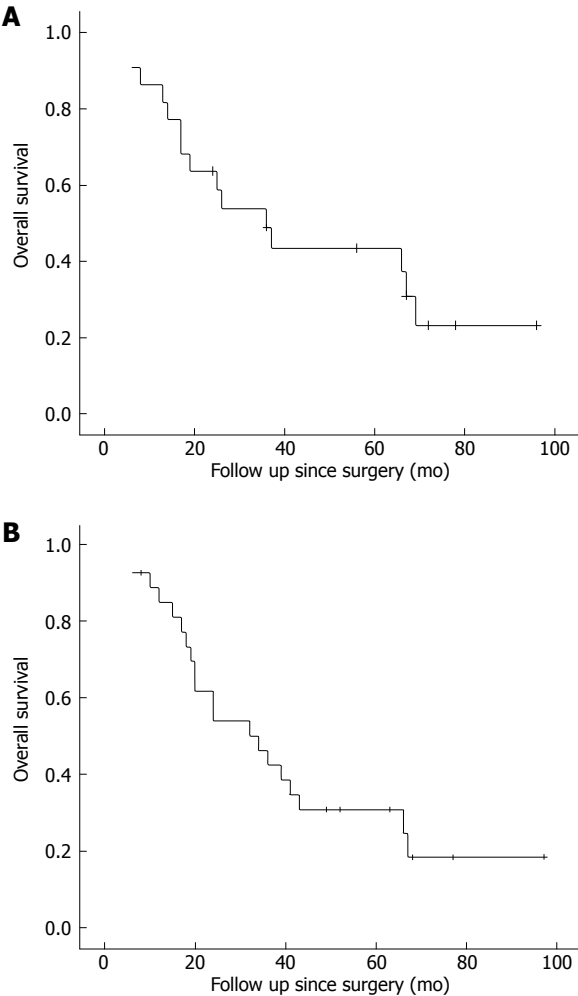

Figure 1 Kaplan-Meier survival curves. A: 22 patients with GIST accompanying GAC; B: 27 patients with GIST accompanying ESCC.

1, 2008, four of the patients were alive while 50 died of recurrence or distal metastasis of other malignancies. The remaining two patients died of other causes. Recurrent GIST was not found during the survival period of all dead patients, and the follow-up time of the remaining four. The overall 5-year survival rate of the 22 patients with GAC and incidental GIST was 31.8%, with a median survival time of 36 mo (Figure 1A). The 5-year survival rate of the 27 patients with ESCC and incidental GIST was 22.2%, with a median survival time of 32 mo (Figure 1B). The average survival time of the

two PAC and two CRA patients was 26 mo and 52 mo, respectively, and the survival time of the patients with triple tumors was 47 mo.

DISCUSSION

In our series, incidental GIST occurred simultaneously with EMT in 17.4% (54/311) of the GIST patients, which is higher than the reported incidence (14%)<sup>[8]</sup>. However, assessment of the actual incidence of incidental GIST with EMT is difficult, because the data are only based on patients who have been surgically treated, whereas EMT patients managed with non-surgical measures are unaccounted for. Moreover, during examination or surgery, identification of GIST is incidental rather than intentional, and many lesions are missed as a result.

Notably, in addition to those with EMT, many synchronous and asynchronous cases of GIST with non-epithelial tumors have been reported, such as osteosarcoma, Burkitt’s lymphoma, plasmocytoma, neuroblastoma, somatostatinoma, chronic lymphatic leukemia, lipoma and ectopic pancreas<sup>[4,9-13]</sup>. Synchronous incidental GIST and non-tumorous diseases have been reported, such as ulcerative colitis, Meckel’s diverticulum, rapidly progressive glomerulonephritis, HIV carriers, and Crohn’s disease<sup>[5,14-17]</sup>. Sanchez *et al*<sup>[18]</sup> reported that incidental gastric GIST is found in 0.8% of patients undergoing laparoscopic Roux-en-Y gastric bypass surgery for obesity. Kawanowa *et al*<sup>[19]</sup> showed that microscopic GIST can be found in 35% of stomach- resected patients with gastric cancer. It has been shown that microscopic GIST can be found in 10% of patients undergoing surgery for esophageal carcinoma<sup>[20]</sup>. Especially, incidental GIST has also been detected in 0.2% of all autopsies, accounting for 10% of all patients with primary GIST<sup>[21]</sup>. These findings suggest that incidental GIST may occur synchronously with other diseases more frequently than expected, and the incidence of incidental GIST might be much higher than that of clinical GIST.

Particular attention has been paid to clinical GIST because of its striking symptoms such as gastrointestinal bleeding, pain, dyspepsia, abdominal mass and obstruction<sup>[22,23]</sup>. On the contrary, incidental GIST may emerge asymptotically, and even if symptomatically, the symptoms may often be vague and nonspecific<sup>[18]</sup>. In our study, all the 54 patients presented symptoms

indistinguishable from those of EMT, which might have been overlooked because of the progressing symptoms of EMT such as severe dysphagia, weight loss, abdominal pain and anemia. The size of incidental GIST was small, and the majority (90.7%) of them had a very low risk. Also, only a few reports are available on incidental GIST with a high risk<sup>[21,24,25]</sup>. In this study, only 1.9% of clinical GIST lesions had a very low risk, and 38.5% had a high risk, indicating that GIST is malignant. Perhaps, incidental GIST might have emerged later than EMT, or their development may have been depressed by EMT through mechanisms which are yet to be studied.

Generally, the preoperative detection rate of incidental tumors is very low. In this study, except for two patients with PAC, the other patients received endoscopic examinations preoperatively, yet only one GIST lesion was found. Difficulty in detecting the lesion might be attributed to its small size and intramural location. Incidental GIST, if detected at CT or MRI, is often mistaken for metastatic lymph nodes derived from EMT. Therefore, radiological examination is minimally helpful for its diagnosis. As a result, the endoscopist and surgeon should take the major responsibility of detecting incidental GIST. Incidental GIST occurs most commonly in stomach, esophagus, small bowel, colon and omentum. Consistent with the reported findings<sup>[19]</sup>, incidental GIST was observed in gastric fundus and body in the present study. Careful assessment of the hotspot (i.e. the upper portion of stomach) is important for both endoscopist and surgeon.

Interestingly, we found that there was a significant difference of the incidence of incidental GIST in male and female patients. Because of the unclear pathogenesis of incidental GIST, we cannot explain this finding. Further studies are needed on the gene expression in primary tumor cells from male and female patients and signal transduction may also provide us with some clues to this question.

In the absence of prospective control studies, whether resection of incidental GIST lesions helps to improve the quality of life and/or the survival rate of EMT patients remains unclear. There are two major concerns for incidental GIST if missed during operation for other tumors. First, residual GIST lesions may progress to invasive disease and cause intestinal obstruction and/or life-threatening gastrointestinal hemorrhage because the malignant potential is unpredictable based on gross appearance alone. Second, a residual incidental GIST may be mistaken for the relapse or metastasis of a previously removed neoplasm, which may result in inappropriate treatment of patients in follow-up after operation. Therefore, an en bloc resection with other tumors or an additional local resection with adequate margins has been recommended by surgeons<sup>[6,18,25]</sup>. Making surgeons aware of this will help to correct surgical procedures, and ultimately improve the quality of life and avoid inappropriate treatment of patients during follow-up after operation.

Common carcinogenic agents, which result in a simultaneous proliferation of different cell lines (epithelial

and stromal cells), may be involved in the development of incidental GIST as a mere coincidence. In this study, males with primary GIST were more likely to have a synchronous tumor than females ( $P < 0.001$ ). Synchronous tumors may have a high prevalence in males. Simultaneous neoplastic proliferation of epithelial and stromal cells might be stimulated by the same carcinogenic factors, such as *Helicobacter pylori* infections, germline mutations, and exposure to ionizing radiation<sup>[6,24,26,27]</sup>. To clarify possible common carcinogenic agents against synchronous tumors, further studies are needed.

In conclusion, incidental GIST coexists with EMT at a higher incidence than expected. Surgeons are advised to be alert against possible primary GIST accompanying other tumors.

## ACKNOWLEDGMENTS

The authors thank Dr. Ping Yu and Jing Gong for their expert analysis of the lesions, and Dr. Jun-Ping Xin for his assistance with the manuscript revision.

## COMMENTS

### Background

Gastrointestinal stromal tumor (GIST) is one of the most common tumors in gastrointestinal (GI) tract, probably arising from precursor cells that serve as a pacemaker to trigger gut contraction. It may exist alone with clinical manifestations or coexist with other diseases. The former is usually diagnosed by its clinical presentations and called clinical GIST, while the latter is usually found during examination or surgery for other diseases and called incidental GIST.

### Research frontiers

Clinical GIST has been extensively studied in the past twenty years. Many cases of GIST existing alone or coexisting with other diseases have been reported, but GIST coexisting with other GI tumors has only been reported as single cases. It is necessary to conduct a comprehensive study with a large sample size to determine its incidence and features.

### Innovations and breakthroughs

For the first time, the authors report an extensive study on incidental GIST coexisting with other GI tumors. This study revealed some important and interesting information regarding incidental GIST coexisting with other GI tumors. Firstly, they found that incidental GIST coexisted most frequently with esophageal and gastric tumor (1.13% and 0.53% respectively), and least with colorectal tumor (0.03%). Secondly, the majority of clinical GISTs had a moderate or a high risk. In contrast, the majority of incidental GISTs had a very low risk. Thirdly, the incidence of incidental GIST was significantly higher in male than in female patients (88.9% vs 11.1%). Finally, this study also provided the statistics for age, survival time and prognosis of studied patients and outlined the other features of incidental GIST, such as the number of lesions, lesion location and cellular morphology, etc.

### Applications

The incidence of incidental GIST coexisting with other GI tumors is much higher than expected. However, without specific manifestations, preoperative detection of incidental GIST is difficult. Residual GIST lesions may progress to invasive diseases, cause intestinal obstruction and/or life-threatening gastrointestinal hemorrhage. In addition, residual incidental GIST may be mistaken for the relapse or metastasis of previously removed tumors, resulting in inappropriate treatment of patients during follow-up after operation. A careful inspection for GIST is highly recommended during surgery for GI tumors.

### Terminology

GIST is one of the tumors in the GI tract, probably arising from precursor cells that serve as a pacemaker to trigger gut contraction. GI epithelial malignant tumor (EMT) refers to a tumor arising from the surface cells of the GI tract.

### Peer review

This article is the first report to present the incidence of incidental GIST accompanying gastrointestinal EMT. In this study, the authors evaluated the

incidental GIST and its clinical significances. The title of the paper reflects the major contents of the article. The abstract gives a clear delineation of the research background. Results and discussion are well organized. The conclusion is reliable and valuable.

### Abstract

**AIM:** To investigate the effects of 5-Fluorouracil (5-FU) on modulation of pro-inflammatory and anti-inflammatory cytokines in acute pancreatitis and the mechanism of it in the treatment of acute pancreatitis.

**METHODS:** Male Sprague Dawley rats were assigned to 3 Groups: Group A, sham operated rats as controls ( $n = 7$ ); Group B, acute pancreatitis induced by ductal injection with 5% sodium cholate at a volume of 1.0 mL/kg without any other treatment; Group C, after the pancreatitis was induced as in Group B, the rats were injected intravenously with 5-FU 40 mg/kg. The animals in Groups B and C were killed at 2, 6 and 24 h after operation ( $n = 7$ ), and blood samples were taken for measurement of tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interleukin-1 (IL-1), interleukin-6 (IL-6) (by bioassay), and interleukin-10 (IL-10), transforming growth factor- $\beta$  (TGF- $\beta$ ) (by ELISA). The wet weight of pancreatic tissue, serum amylase levels and white blood cells were also measured.

**RESULTS:** Four rats in Group B and one in Group C died after pancreatitis was induced. Both pro-inflammatory cytokines (TNF- $\alpha$ , IL-1, IL-6) at the 2 and 6 h period and the anti-inflammatory cytokines (IL-10, TGF- $\beta$ ) at 24 h increased significantly ( $P < 0.05$ ) in rats of Group B. After treatment with 5-FU, TNF- $\alpha$ , IL-1, and

IL-6 in serum of rats of Group C were inhibited at 2 and 6 h after operation ( $P < 0.05$ ), and IL-10, TGF- $\beta$  were inhibited at 24 h compared to Group B ( $P < 0.05$ ). Obvious improvements in the severity of the acute pancreatitis, including the amylase levels, wet weight of pancreatic tissue and neutrophil counts, were also observed after treatment with 5-FU.

**CONCLUSION:** 5-FU is an anti-metabolic and immunosuppressive agent which can minimize the abnormal immune cytokine response and relieve the pathophysiological disorders associated with experimental acute pancreatitis.

Effect of 5-FU on modulation of disarrangement of immune-associated cytokines in experimental acute pancreatitis. *World J Gastroenterol* 2009; 15(16): 2032-2037 Available from: URL: <http://www.wjgnet.com/1007-9327/15/2032.asp> DOI: <http://dx.doi.org/10.3748/wjg.15.2032>

### INTRODUCTION

5-Fluorouracil (5-FU) has been used in the treatment of acute pancreatitis both experimentally and clinically since 1970<sup>[1-3]</sup>. Several animal experiments of pancreatitis treated with 5-FU have shown very promising results, especially for a decrease in amylase and trypsin levels and improvement of survival rates<sup>[1,2]</sup>. It has been reported that prolongation of pancreatic allograft survival and protection from pancreatitis in dog pancreas allografts occur after pretreatment with 5-FU<sup>[4]</sup>. A prospective controlled clinical study was carried out in 1983, which showed that treatment with 5-FU was of some benefit in the modulation of clinical pancreatitis<sup>[5]</sup>. Clinical studies conducted in Russia documented that both the mortality and the length of hospital stay were reduced after treatment with 5-FU<sup>[6-8]</sup>. In China, administration of 5-FU

has been considered as an adjuvant therapy of acute pancreatitis. More than one thousand patients with acute pancreatitis have received the treatment of 5-FU each year in China, with many reports showing some beneficial results<sup>[9-12]</sup>. While there are many studies focusing on clinical observation of 5-FU treatment, research involving the mechanisms is sparse, but many investigators felt that the effect of 5-FU treatment for pancreatitis was derived from inhibiting the activities of pancreatic enzymes<sup>[1-3,5,9,10]</sup>. Recently, it has been increasingly clear that disarrangement of the immune system during acute pancreatitis is the determining factor in the pathophysiological process<sup>[13-19]</sup>. Considering that abnormal inflammation-associated cytokines (pro- and anti-inflammatory cytokines) present a primary index of disarrangement of immune function during acute pancreatitis<sup>[20-24]</sup>, we designed this animal experiment to investigate the inhibiting effect of 5-FU on the inflammatory cytokines (TNF- $\alpha$ , IL-1, IL-6) and anti-inflammatory cytokines (IL-10, TGF- $\beta$ ) in acute pancreatitis and the relationship between the level of cytokines in serum and degree of acute pancreatitis.

## MATERIALS AND METHODS

### Materials

Sodium cholate was purchased from Sigma. Rat TGF- $\beta$  and IL-10 EIA kits were purchased from R & D Co., USA. Reagents and instruments for measurement of TNF- $\alpha$ , IL-1, IL-6 were supplied by the Immunology Department, Medical Center, Sichuan University. Sprague Dawley (SD) rats were purchased from the Experimental Animal Center, Sichuan University, China.

### Animals and pancreatitis model

SD rats (male, 10-12 wk-old, weighing 200-250 g) were fasted but allowed to drink water freely for 16 h before the experiment. They were allocated randomly into three Groups: Group A ( $n = 7$ ), sham operation, with the same laparotomy under general anesthesia as Group B and sham intubation of the cholo-pancreatic duct but without any drug injection. These rats were killed 2 h later. In Group B, the acute pancreatitis Group, SD rats were injected with 5% sodium cholate into the cholo-pancreatic duct at a volume of 1.0 mL/kg using a mid-line laparotomy under general anesthesia and strict aseptic conditions to establish acute pancreatitis; Group C, acute pancreatitis with treatment of 5-FU. After pancreatitis was induced as in Group B, the rats were injected intravenously 40 min later with 5-FU 40 mg/kg. (This dosage is equal to 10-15 mg/kg in humans based on body surface). All the animals in Groups B and C were resuscitated post-operatively with 0.9% sodium chloride, subcutaneously at 6 mL/kg per hour. The surviving animals in Groups B and C were killed at 2, 6 and 24 h after operation ( $n = 7$ ). Blood samples were taken for measurement of TNF- $\alpha$ , IL-1, IL-6, IL-10, and TGF- $\beta$ . The wet weight of pancreatic tissue (the index of pancreatic edema), serum amylase levels and

the total and differential count of leukocytes, were also measured and recorded.

All the measurements of cytokines were done in the Department of Immunology, Medical Center, Sichuan University. IL-1, IL-6 and TNF- $\alpha$  were measured by bioassay according to Lederer, Kimura and Heo's methods<sup>[25-27]</sup>. IL-10 and TGF- $\beta$  were measured by EIA according to the manufacturer's instructions. Amylase and white blood cells levels were tested by the Clinical Laboratory, Medical Center, Sichuan University.

### Statistical analysis

We used the analysis of variance for continuous variables to detect variation among Groups with the same time (version 9.0 SAS Institute, Inc, Cary, NC). Statistical significance was regarded as  $P < 0.05$ . All reported  $P$  values are 2 sided. Continuous variables were described as mean  $\pm$  SD unless stated.

## RESULTS

There were 4 deaths in Group B at the 4, 6, 8, 15 h time points after pancreatitis was induced, and one rat died in Group C at 12 h.

In Group A, TNF- $\alpha$ , IL-1, IL-6, IL-10, and TGF- $\beta$  in the serum of rats were detected as basic concentrations because of tissue injury resulting from sham operation. After acute pancreatitis was induced in Group B, the concentrations of pre-inflammatory cytokines such as TNF- $\alpha$ , IL-1 and IL-6 in the serum of rats increased rapidly. At the 2, 6, and 24 h periods, TNF- $\alpha$ , IL-1, IL-6 in Group B and Group C were significantly higher than that of Group A ( $P < 0.05$ ). After pancreatitis was treated with 5-FU, the concentrations of IL-1 and IL-6 in serum of rats in Group C were significantly lower than those of Group B at 2, 6 h periods after operation ( $P < 0.05$ ). At 6 h after operation the concentration of TNF- $\alpha$  in serum of Group C was also lower than that of Group B ( $P < 0.05$ ). But at the time point 24 h, TNF- $\alpha$ , IL-1, IL-6 in Groups B and C still maintained a higher level and there was no significant difference between these two Group (Table 1). We presume that this is due to 5-FU being quickly catabolised in the body so that its regulating action disappeared swiftly and was not maintained up to 24 h. Serum IL-10 and TGF- $\beta$  were significant higher in Group B and Group C than in Group A at the 24 h period ( $P < 0.05$ ). At 24 h after operation, compared to Group B, the concentrations of IL-10 and TGF- $\beta$  in serum in rats of Group C were decreased significantly ( $P < 0.05$ ) (Table 2). When we collected the samples of pancreas after rats were sacrificed, we found that samples of pancreas in Group C were more obviously swollen and congested than those of Groups A and B. Since some doctors have investigated histopathological change of pancreas in detail in similar animal experiments with 5-FU, here we only chose the wet weight of pancreas (index of pancreatic edema) and serum amylase as indexes of severity of acute pancreatitis. In the control Group, the weight of pancreatic tissue was  $0.5 \pm 0.09$  g. At 2, 6, 24 h

<sup>1</sup>Compared to sham operation Group (Group A),  $P < 0.05$ ; <sup>2</sup>Compared to pancreatitis Group (Group B),  $P < 0.05$ .

after acute pancreatitis being induced, the wet weights of pancreatic tissue in Group B were  $1.63 \pm 0.54$  g,  $1.85 \pm 0.25$  g and  $1.53 \pm 0.13$  g, respectively; but at 2, 6, 24 h after treatment with 5-FU in Group C, the wet weights of pancreatic tissue were  $0.87 \pm 0.22$  g,  $0.58 \pm 0.24$  g and  $0.88 \pm 0.13$  g, respectively. There was a significant difference between the acute pancreatitis Group (Group B) and the treatment with 5-FU Group (Group C) at all time periods ( $P < 0.05$ ). In the control Group, the concentration of serum amylase was  $374.2 \pm 92.84$  U/L. At 24 h after operation, the concentration of serum amylase was  $1817.25 \pm 459.35$  U/L, but after treatment with 5-FU the concentration was  $797.4 \pm 225.9$  U/L at the same time period. The concentration of serum amylase in the acute pancreatitis Group (Group B) was higher than that in the treatment with 5-FU Group (Group C), and it reached statistical significance ( $P < 0.05$ ). In the control Group, leukocyte count in the peripheral blood of the rats was  $(6.59 \pm 2.59) \times 10^9$ /L. At 24 h after experiment, the leukocyte counts in the Groups A and B were  $(6.93 \pm 0.67) \times 10^9$ /L and  $(6.1 \pm 1.44) \times 10^9$ /L respectively and there was no significant difference between the two Groups. Percentage of neutrophils in rats in Group A was  $0.35\% \pm 0.09\%$ . In Group B, the percentage of neutrophils was increased significantly at each time period. After treatment of 5-FU, the percentage of neutrophils in Group C decreased compared to Group B, but it did not reach statistical significance until after the 2 h period (Table 3).

## DISCUSSION

More and more studies have been reported to support the theory that the severity of acute pancreatitis largely depends on the degree of secondary disarrangement of inflammatory mediators<sup>[13-16]</sup>. Damage caused by trypsin at the initial stage of acute pancreatitis is an event that triggers the systemic inflammatory response syndrome (SIRS)<sup>[28]</sup>. The pathological process of SIRS results in the clinical manifestation and damage to other distant organs in acute pancreatitis<sup>[29,30]</sup>. If SIRS persists and anti-inflammatory cytokines are not adequate to suppress this response, SIRS may lead to clinical sepsis and the multiple organ dysfunction syndrome, which could account for one of the main causes of death in severe pancreatitis<sup>[31,32]</sup>. Along with the production and release of large amounts of pro-inflammatory cytokines in acute pancreatitis, anti-inflammatory cytokines (IL-10, TGF-β, IL-4, IL-13) and other immunosuppressive factors (PGE2, glucocorticosteroids) start to be synthesized and released. This process could be helpful to restrain SIRS and restore the balance between the inflammatory and anti-inflammatory responses. However, when the anti-inflammatory cytokines and other immunosuppressive factors became predominant in severe acute pancreatitis, these mediators will inhibit the immunity against pathogens, especially inhibiting the cellular immune function, and this will result in the so-called compensatory anti-inflammatory response syndrome (CARS), a secondary immunological deficiency syndrome<sup>[33-36]</sup>. CARS seems to be related to the systemic infection and pancreatic abscess which develop during severe acute pancreatitis<sup>[37-39]</sup>. In the present experiment, after pancreatitis was induced in animals in Group B, pro-inflammatory cytokines such as TNF-α, IL-1 and IL-6, increased promptly, and 24 h later, the anti-inflammatory cytokines IL-10 and TGF-β increased sequentially. These results indicate that there is a pro-inflammatory process (SIRS) followed by an anti-inflammatory process in acute pancreatitis. It is thus suggested that the strategy for acute pancreatitis should not only include modulation of SIRS, but also prevention of CARS.

With this knowledge, the mechanism of treatment of

acute pancreatitis with 5-FU should be evaluated further. Previously, it was thought that inhibition of exocrine secretion of the pancreas was a fundamental mechanism of treatment of acute pancreatitis with 5-FU<sup>[1,2,9]</sup>. 5-FU traditionally is classified as an anti-metabolic agent. 5-FU is a derivant of pyrimidine, and interferes with the synthesis of DNA and RNA both in normal cells and tumor cells. 5-FU also inhibits the synthesis of protein. Essentially, 5-FU can serve as a proteinase inhibitor and exert general action throughout the whole process of acute pancreatitis. 5-FU decreases the synthesis and secretion of pancreatic enzymes. Thus, it can alleviate the damage to pancreatic tissues by auto-digestion at the initial stage. This function has been confirmed previously<sup>[1-4]</sup>. Results from the present experiment provide evidence that 5-FU can reduce inflammation-associated cytokines. We also presume that 5-FU inhibits proteinases produced by leukocytes, which is thought a powerful factor in development of MODS. In this study, after the treatment of acute pancreatitis with 5-FU, the activity of inflammation-related cytokines was inhibited. Meanwhile, the level of serum amylase and the weight of pancreatic tissue, factors that reflect the severity of pancreatic injury and pathological lesions, were improved significantly. This indicated that 5-FU could improve the severity of acute pancreatitis by means of modulation of disarrangement of inflammation.

We cannot recommend that 5-FU could be a definite therapy for acute pancreatitis based only on the results of this experiment. We know that there is much difference between animal experiments and clinical practice with regard to results of medical research. Deterioration of acute pancreatitis is never due to simple inflammatory processes, many factors may be involved including secondary infection, derangement of blood circulation, even genetic predisposition so that clinical effects of 5-FU on acute pancreatitis need to be validated by large scale, prospective controlled studies. But we do think that 5-FU may be a candidate for treatment of SIRS based on results of this experiment. After the immunopathogenesis of sepsis following surgical disease was elucidated, many biological products were introduced for use against the pre-inflammatory cytokines<sup>[40-43]</sup> and the prevention of SIRS, such as anti-endotoxin antibodies<sup>[44]</sup>, anti-TNF- $\alpha$  antibodies<sup>[45,46]</sup>, IL-1 receptor antagonists<sup>[47-49]</sup> and monoclonal anti-interleukin 8 antibody<sup>[50]</sup>. None of these interventions have been shown to improve the prognosis of sepsis, possibly because many patients were already in a state in which anti-inflammatory responses dominated<sup>[51,52]</sup>. Because inflammation plays an important role in the defense against pathogenic microbes and reparation of injured tissue, there is a possibility of infection becoming lethal by excessive anti-inflammatory therapy. In our study, elevated TGF- $\beta$  and IL-10 levels in an animal model of acute pancreatitis predicted the potential tendency of immunodepression. We think that the decrease of both pro-inflammatory cytokines in addition to the decrease of anti-inflammatory cytokines after treatment with 5-FU may offer a rational strategy for treatment of SIRS. As observed above, 5-FU has multiple

actions and biphasic regulation for the disarrangement of immunity in acute pancreatitis. Compared with the effect of single inflammatory cytokine blockers, treatment with 5-FU for SIRS and CARS in surgical disease may be the more effective method. Moreover, immunoregulation with 5-FU displayed in this experiment opens a new possible pathway towards the search for therapy of surgical systemic inflammatory response syndrome.

## COMMENTS

### Background

5-Fluorouracil (5-FU) has been used in the treatment of acute pancreatitis both experimentally and clinically since 1970, but the mechanisms of the therapeutic effect of 5-FU are not clear, and it has been considered an adjuvant therapy of acute pancreatitis. Recently, it has been increasingly clear that disarrangement of the immune system during acute pancreatitis is the determining factor in the pathophysiologic process. Abnormal inflammation-associated cytokines (pro- and anti-inflammatory cytokines) present a primary index of disarrangement of immune function during acute pancreatitis and lead to sepsis. Sepsis revealed as self-destructive inflammatory reaction remains a puzzle worldwide with respect to its pathological mechanism and corresponding preventive and therapeutic strategies for the clinicians.

### Research frontiers

The hotspots of sepsis therapy research have focused on the modification of the inflammatory factors existing in sepsis, ever since the basis of sepsis injuries were revealed as self-destructive inflammatory reactions. Although with some frustrations, research is still focused on the immune regulation.

### Innovations and breakthroughs

The authors designed an acute pancreatitis animal model to investigate the inhibiting effect of 5-FU on the inflammatory cytokines (TNF- $\alpha$ , IL-1, IL-6) and anti-inflammatory cytokines (IL-10, TGF- $\beta$ ) in acute pancreatitis and the relationship between the level of cytokines in serum and degree of acute pancreatitis. The experiments obtained encouraging results that the 5-FU, as an immunosuppressive agent, could be effective because of its regulation of immunity. Previously it was thought that inhibition of exocrine secretion of pancreas was a fundamental mechanism of treatment of acute pancreatitis with 5-FU. This trial reveals the immunoregulatory effect of 5-FU in the therapy of acute pancreatitis. The majority of research in the last 20 years on sepsis focused on the blocking agents of inflammatory factors, which failed in clinical trials. According to their trial, 5-FU has multiple actions and biphasic regulation for disarrangement of immunity in acute pancreatitis. Compared with the effects of single inflammatory cytokine blockers, treatment with 5-FU for SIRS and CARS in surgical disease may be the more effective method.

### Applications

This trial reveals the potential of 5-FU treatment against acute pancreatitis and sepsis in the clinic. 5-FU is cheaper and safer as a typical immunosuppressive agent, and has been a familiar therapy compared to new medicines.

### Terminology

5-FU is one of the first pyrimidine antagonists to be synthesized as an antineoplastic; 5-FU *in vivo* is transformed enzymatically into 5-fluoro-2'-deoxyuridine-5'-monophosphate (FdUMP), which covalently binds and inhibits thymidylate synthase (TS) and interferes with the synthesis of nucleic acids and prevents the cell from making DNA. Another bio-transformed form of 5-FU, 5-fluorouridine-5'-triphosphate (FUTP), also incorporates itself into RNA and disrupts biological activity of RNA and protein. Systemic inflammatory response syndrome (SIRS) is the self-destructive, severe systemically inflammatory reaction of the body responding to invasion of pathogen, trauma or ischemia.

### Peer review

This is an innovative study in which authors analyze the regulative effect of 5-FU on inflammatory reaction in rats. The results are encouraging and suggest that 5-FU is a potential therapeutic substance that could be used in acute pancreatitis, and sepsis caused by other etiological factor.

## Abstract

Although plasma cell infiltration is not rare in autopsy of patients with multiple myeloma (MM), it is very rarely detected in living patients. This is because MM rarely causes significant liver dysfunction that requires further evaluation. A 49-year-old man presented with acute renal failure and was diagnosed with kappa light chain MM stage II B. Thalidomide and dexamethasone were initiated. The patient developed a continuous increase in bilirubin that led to severe cholestasis. A liver biopsy revealed plasma cell infiltration. He then rapidly progressed to liver failure and died. Treatment options are limited in MM with significant liver dysfunction. Despite new drug therapies in MM, those patients with rapidly progressive liver failure appear to have a dismal outcome.

## INTRODUCTION

Plasma cell infiltration of the liver can be detected in up to 45% of patients with multiple myeloma (MM) at autopsy<sup>[1-2]</sup>. However, only rare cases have been reported of massive plasma cell infiltration of the liver that leads to non-obstructive cholestasis with progression to liver failure<sup>[3-10]</sup>. Here, we report a patient with MM with biopsy-proven plasma cell involvement of the liver. The patient died of rapidly progressive liver failure despite treatment for MM.

## CASE REPORT

A 49-year-old black man presented with acute renal failure with a serum creatinine of 13 mg/dL. He was found to have circulating plasma cells in the blood and was diagnosed with kappa light chain MM by a bone marrow biopsy, which revealed 90% plasma cells with kappa light chain restriction. Free kappa light chains were noted in the serum. Cytogenetics of the bone marrow plasma cells revealed an abnormal hypodiploid clone with deletions of chromosomes 4, 13, 16, 17 and 21. A skeletal survey was negative for lytic bone lesions. The serum hemoglobin was 10 g/dL and the serum calcium was normal. Liver enzymes were normal at presentation. The physical examination was remarkable only for cachexia. Therapy with thalidomide (200 mg/d) and high dose dexamethasone (40 mg on days 1-4, 7-11, 14-17 and 21-24) was initiated. After receiving three cycles over a 3-mo period, the patient had clearance of circulating plasma cells on the peripheral blood smear but no response on repeat bone marrow biopsy. His therapy was switched to bortezomib.

One month after the initiation of thalidomide and dexamethasone, he started developing a gradual increase in total and direct bilirubin from a normal baseline. Right-upper-quadrant ultrasound revealed an enlarged liver with a largest dimension of 23 cm; however, no mass lesions were noted. The parenchymal echogenicity was within normal limits. Abdominal computed tomography performed with oral and IV contrast agents revealed a diffusely enlarged liver with no mass lesions and no evidence of intra- or extrahepatic ductal dilatation. After three cycles of thalidomide and dexamethasone therapy, the total bilirubin had increased to 3.9 mg/dL.

One week after switching to bortezomib, the patient

**Figure 1** HE liver biopsy showing massive plasma cell infiltration (HE).

**Figure 2** Positive kappa light chain stain on liver biopsy.

**Figure 3** Positive CD138 (syndecan-1), a plasma cell marker. CD138 is expressed on plasma cells, including the malignant plasma cells of MM and some lymphomas.

was admitted to the hospital for further evaluation after the total bilirubin acutely increased to 9.4 mg/dL. The remainder of the liver function tests revealed aspartate aminotransferase of 41 U/L, alanine aminotransferase of 38 IU/L, lactate dehydrogenase of 306 IU/L, and gamma-glutamyltransferase of 286 IU/L. The direct bilirubin was 5.8 mg/dL. The physical examination was remarkable for frank jaundice and hepatomegaly. A repeat ultrasound of the abdomen showed significant liver enlargement up to 26 cm over a period of 2 mo with no evidence of biliary obstruction. A hepatobiliary imino-diacetic acid scan revealed delayed hepatic uptake consistent with severe

hepatocellular dysfunction. Hepatitis serology for hepatitis A/B/C, and antinuclear and antineutrophil cytoplasmic antibodies was negative. Cytomegalovirus serology was also negative. A transjugular liver biopsy was performed to rule out drug toxicity. It demonstrated massive infiltration of the liver parenchyma with plasma cells (Figure 1). The immunological profile of the liver biopsy revealed diffuse kappa light chain restriction that was similar to that in the bone marrow biopsy, which supported the diagnosis of MM with hepatic infiltration (Figures 2 and 3). Flow cytometry of the liver biopsy revealed plasma cells with CD38/CD138 co-expression and kappa light chain restriction. No evidence of amyloidosis was evident on immunostaining. During his 2 wk of hospitalization, the patient rapidly developed hepatic failure, characterized by coagulopathy, hyperbilirubinemia, encephalopathy and ascites. He was discharged to hospice care and expired 1 wk later.

## DISCUSSION

Pathologic liver involvement in patients with MM has been reported in up to 45% of patients<sup>[1,2]</sup>. An autopsy series of 128 cases with MM done by Perez-Soler *et al*<sup>[3]</sup> showed diffuse infiltration of the liver by plasma cells in 10 of 21 patients with liver tissue involvement. Thomas *et al*<sup>[4]</sup> reviewed 64 cases of MM, including autopsy reports and prior medical records; 58% of patients had hepatomegaly, defined as percussible dullness of more than 12 cm or a liver edge palpable 4 cm below the right costal margin, and 25% had splenomegaly. Jaundice was reported in nine patients (14%) and serum bilirubin values ranged from 3.2 to 17.3 mg/dL. Only six patients (9%) had a completely normal liver on pathological examination, while 40% had plasma cell involvement of the liver in the form of plasmacytoma or diffuse sinusoidal infiltration. Both these two autopsy series excluded cases with plasma cell leukemia<sup>[3,4]</sup>.

The histological pattern of liver involvement in MM can be in the form of light chain deposition disease, extramedullary plasmacytoma, amyloidosis, or a diffuse infiltrative pattern. Massive liver involvement can be either from tumor-forming plasmacytomas or diffuse sinusoidal flooding<sup>[4]</sup>. The latter can consist of sinusoidal flooding by plasma cells of varying degrees of differentiation with little or no propensity to destroy liver parenchyma<sup>[5]</sup>. Some of these patients may present with non-obstructive jaundice and show elevations in alkaline phosphatase from plasma cell infiltration, as did our patient<sup>[3]</sup>. Only two prior cases of severe cholestasis associated with hepatic failure have been reported<sup>[6,7]</sup>. Radiographic imaging is unable to detect this diffuse infiltrative pattern and a liver biopsy is essential to make a diagnosis.

Plasmacytomas (nodular forming pathology) are less common. This entity can be detected radiographically as space-occupying lesions in the liver or in the head of the pancreas, and may be associated with biliary obstruction<sup>[8-10]</sup>.

Amyloidosis manifested as tissue deposition of clonal light-chain fibrils is seen in 15% of the general MM patient population. Liver involvement has been reported

in MM patients as well as those with primary systemic amyloidosis<sup>[11]</sup>. Elevation in alkaline phosphatase is more common and liver enzymes are often normal or mildly elevated. Obstructive jaundice occurs rarely and only a few cases have been reported, with some associated with hepatic failure<sup>[12-18]</sup>.

The clinical significance of liver involvement in MM is uncertain. Treatment of MM with hepatic involvement requires systemic therapy. Successful treatment with combination chemotherapy or steroids alone has been reported<sup>[6,19,20]</sup>. Talamo *et al*<sup>[21]</sup> have reviewed the medical records of 24 patients with MM involvement of the gastrointestinal (GI) system as documented by tissue biopsy, 11 of whom had hepatic involvement. GI involvement at the time of initial diagnosis of MM was less common than later in the disease course.

The treatment of MM patients with significant liver dysfunction is challenging because of the inability to deliver most chemotherapeutic agents in the setting of liver failure. Substantial dose reductions are required to administer anthracyclines and vincristine in the setting of liver failure. Steroids, and the newer agents thalidomide and bortezomib have been administered in these settings, although thalidomide has been cited in a single case report as causing fulminant hepatic dysfunction, and liver toxicity has been reported rarely with bortezomib<sup>[22,23]</sup>.

Stem cell transplantation (SCT) is now the standard first-line therapy for myeloma patients who respond to chemotherapy. Patients are analyzed to evaluate the role of treatment with high-dose chemotherapy with autologous or allogeneic SCT, and its impact on survival<sup>[21]</sup>. It has been found that GI involvement is common during relapse after SCT. Plasmablastic morphology was common (Bartl grade III) in 29% of cases with GI involvement. Monosomy 13, which is one of the most powerful negative prognostic factors, was observed in 46% of the cases, while it is present in 15% of the general MM patient population. SCT is effective in inducing remissions but relapse is common.

In conclusion, there are no classical clinical manifestations of liver infiltration in MM. The initial presentation can be subtle, but then very rapidly progressive, as in our case. The number of clinically reported cases of liver involvement with MM is small, therefore, it is difficult to ascertain the prognosis of this clinical presentation of the disease or its response to therapy. We suspect that the prognosis is poor because of the limited number of chemotherapeutic agents that can be administered to patients with severe liver dysfunction. The optimal approach in managing these cases can only be standardized after studying a larger number of patients.

### INTRODUCTION

Tumor obstruction of the cystic duct is a known risk factor for the development of cholecystitis following biliary stent placement. Percutaneous cholecystostomy is an effective treatment for such cholecystitis<sup>[1,2]</sup>. However, recurrent cholecystitis or retractable symptoms may be troublesome. Recently, chemical ablation of the gallbladder has been shown to be effective in patients at high risk for complications after surgery<sup>[3]</sup>. Absolute alcohol or 95% ethanol causes necrosis and fibrosis in the gallbladder epithelium, which reduces the gallbladder to a shrunken fibrous remnant<sup>[4]</sup>.

However, until now there have been few human studies of which sclerosants are safe and feasible, and for how long the sclerosant has to be in contact with the mucosa.

In this report, we describe the successful chemical ablation of the gallbladder in a patient who developed intractable cholecystitis with obstruction of the cystic duct, after undergoing palliative stenting for the management of a malignant biliary obstruction.

### CASE REPORT

An 82-year-old woman presented with gradually aggravated right upper-abdominal pain after undergoing biliary stent implantation for the palliative management of a cholangiocarcinoma 2 wk previously. Upon presentation, clinical examination revealed severe tenderness of the right upper abdomen without rebound tenderness. Laboratory tests revealed the following: white blood cell count,  $14.380 \times 10^9/L$  (normal  $4.0-10.8 \times 10^9/L$ ); total bilirubin, 5.4 g/dL (normal 0.1-1.0 g/dL); aspartate aminotransferase, 118 IU/L (normal < 40 IU/L); alanine aminotransferase, 118 IU/L (normal < 40 IU/L); alkaline phosphatase, 118 IU/L (normal 39-117 IU/L); and carbohydrate antigen 19-9, 98 U/mL (normal <

### Abstract

Chemical ablation of the gallbladder is effective in patients at high risk of complications after surgery. Percutaneous gallbladder drainage is an effective treatment for cholecystitis; however, when the drain tube cannot be removed because of recurrent symptoms, retaining it can cause problems. An 82-year-old woman presented with cholecystitis and cholangitis caused by biliary stent occlusion and suspected tumor invasion of the cystic duct. We present successful chemical ablation of the gallbladder using pure alcohol, through a percutaneous gallbladder drainage tube, in a patient who developed intractable cholecystitis with obstruction of the cystic duct after receiving a biliary stent. Our results suggest that chemical ablation therapy is an effective alternative to surgical therapy for intractable cholecystitis.

**Figure 1** Abdominal CT scan revealing a markedly enlarged and distended gallbladder with a thickened wall.

**Figure 2** Cholangiographic findings. A: Endoscopic retrograde cholangiopancreatography showed a severe irregular segmental stricture at the mid-CBD, without visualization of the cystic duct; B: A covered metal stent, 60 mm in length, was implanted in the narrowed CBD.

34 U/mL). Abdominal computed tomography (CT) revealed a markedly enlarged and distended gallbladder with a thickened wall (Figure 1). Clinically, both cholecystitis and cholangitis were suspected, based on CT and laboratory data. Following decompression of the gallbladder via percutaneous cholecystostomy, endoscopy using a duodenoscope (TJF 240; Olympus, Tokyo, Japan) was performed, which showed a completely occluded plastic biliary stent. The occluded stent was subsequently removed. Cholangiography showed a severe irregular segmental stricture at the mid common bile duct (CBD), without visualization of the cystic duct, a finding that indicated cystic duct occlusion caused by tumor invasion (Figure 2A).

For the management of cholecystitis and malignant stricture, the percutaneous drainage tube was left in place and a covered metal biliary stent (Niti-S; Taewoong Medical Co., Ltd., Seoul, Korea), 60 mm in length, was implanted through the peroral route (Figure 2B). Seven days later, the percutaneous cholecystostomy was draining less than 50 mL/d; therefore, removal of the drain tube was attempted. However, the patient complained of recurrent abdominal pain and discomfort whenever the drain tube was closed, and the amount of fluid draining continued at a rate of > 40 mL/d. Consequently, removal of the drain tube failed. As a result of the patient's advanced age and her refusal of palliative cholecystectomy, medical ablation of the

**Figure 3** Chemical ablation therapy. A: Before chemical ablation of the gallbladder, the gallbladder volume was measured by infusing contrast medium through the drain tube; the contrast medium did not pass into the CBD; B: Three weeks later (after a total of three chemical ablation sessions), cholecystography showed a marked collapse in the lumen of the gallbladder.

gallbladder was considered to be a good option for treating the symptoms and to allow the removal of the percutaneous drain tube.

After informed consent from the patient and approval by the ethics committee of our hospital, 99% absolute ethanol was used as a sclerosant for chemical ablation of the gallbladder. The volume of the gallbladder was measured by filling it with contrast medium, followed by aspiration (Figure 3A). Absolute ethanol, 1-2 mL less than the volume of the gallbladder, was infused into the gallbladder through the drain tube. Initially, a total of 55 mL of ethanol was infused and the drainage tube was closed. Then, the patient changed positions every 10 min for a total of 30 min, and the sclerosant was drained. Cholecystography was performed 1 wk after the first chemical ablation, and it showed a decrease in the size of the gallbladder. The same method was repeated twice more in weekly sessions with 40 and 25 mL of ethanol, respectively. During the final week, a small amount of bright yellow fluid (< 10 mL/d) was draining, and cholecystography showed a marked collapse in the lumen of the gallbladder (Figure 3B). During each procedure, the patient's vital signs were closely monitored. The patient had no abdominal pain or other complications related to the procedure. The cholecystostomy drain tube was removed, and there were no complications in the following 8 wk, during which she remained under outpatient observation.

## DISCUSSION

Endoscopic insertion of biliary stents is a well-established palliative treatment for obstructive jaundice caused by unresectable malignant disease<sup>[5-7]</sup>. As a result of increased use, complications such as cholangitis, cholecystitis, pancreatitis, stent migration, and stent occlusion are being reported increasingly<sup>[8]</sup>. In particular, cholecystitis has been reported in 1.9%-12% of stent insertion cases<sup>[9,10]</sup>. For several reasons, obstruction of the cystic duct by a tumor is a risk factor for the development of cholecystitis following biliary stent placement<sup>[2]</sup>.

Although cholecystectomy is a safe and effective treatment in patients with cholecystitis, the morbidity

and mortality of this operation increases considerably in the elderly and unfit patients who often have concomitant diseases. Percutaneous gallbladder drainage or aspiration, transpapillary gallbladder drainage, and endoscopic-ultrasound-guided gallbladder drainage have been reported for the management of cholecystitis after stent placement or for cystic duct invasion by a tumor<sup>[1,2,11]</sup>. However, in cases such as those reported here, when the drain tube cannot be removed because of recurrent symptoms, retaining it causes problems for the patient, and its experimental removal may cause other complications.

Chemical ablation of the gallbladder may be a useful alternative to cholecystectomy in high-risk patients or in those who refuse surgery. Recently, experimental studies on chemical ablation of the gallbladder *in vitro* and *in vivo* have demonstrated that many sclerosants, including 95% ethanol, 3% sodium tetradecyl sulfate, 5% tetracycline, and 5% trifluoroacetic acid, ablate gallbladder mucosa<sup>[3,12-14]</sup>. Oh *et al*<sup>[15]</sup> used 99.9% ethanol for the chemical ablation of cystic tumors of the pancreas. Xu *et al*<sup>[3]</sup> reported that minicholecystostomy followed by chemical ablation of the gallbladder was safe and effective. In that study, 95% ethanol was in contact with the gallbladder mucosa for 30 min every 4 h, for a total of eight times after occlusion of the cystic duct. A suitable chemical for gallbladder mucosal ablation must be safe, effective, and require brief contact time with the mucosa. However, there have been few human studies to determine which sclerosants are feasible and the duration for which the sclerosant must be in contact with the mucosa. Some studies have reported complications, including mucocele, gallbladder hydrops, abscess formation, and perforation; however, there have been no serious, life-threatening complications<sup>[3,4,12-14]</sup>.

In our case, we used absolute ethanol as a chemical sclerosant. In animal and human studies, alcohol has been found to be safe and has resulted in few complications; however, it requires more treatments of longer duration than other sclerosants. More studies are needed to determine which sclerosants are suitable, how often they need to be applied and at what interval, and the contact duration required for chemical ablation. Absolute ethanol is a safe sclerosant and procedure-related complications did not develop during the procedure or follow-up period. Especially in the case of cystic duct obstruction by tumors, this method is easy and feasible, and is not affected by the presence of additional biliary stents. However, if the cystic duct is patent, the use of chemical agents is restricted and another approach is necessary.

In summary, following development of cholecystitis after stent placement, with tumor obstruction of the cystic duct, or in patients with recurring symptoms,

chemical ablation using absolute ethanol may be an alternative to percutaneous cholecystostomy or surgical cholecystectomy. Further investigation of this technique and the identification of suitable sclerosants are necessary, and long-term follow-up should be conducted.

## Meetings

### Events Calendar 2009

January 12-15, 2009  
Hyatt Regency San Francisco, San Francisco, CA  
Mouse Models of Cancer

January 21-24, 2009  
Westin San Diego Hotel, San Diego, CA  
Advances in Prostate Cancer Research

February 3-6, 2009  
Carefree Resort and Villas, Carefree, AZ (Greater Phoenix Area)  
Second AACR Conference  
The Science of Cancer Health Disparities in Racial/Ethnic Minorities and the Medically Underserved

February 7-10, 2009  
Hyatt Regency Boston, Boston, MA  
Translation of the Cancer Genome

February 8-11, 2009  
Westin New Orleans Canal Place, New Orleans, LA  
Chemistry in Cancer Research: A Vital Partnership in Cancer Drug Discovery and Development

February 13-16, 2009  
Hong Kong Convention and Exhibition Centre, Hong Kong, China  
19th Conference of the APASL  
<http://www.apasl2009hongkong.org/en/home.aspx>

February 27-28, 2009  
Orlando, Florida  
AGAI/AASLD/ASGE/ACG Training Directors' Workshop

February 27-Mar 1, 2009  
Vienna, Austria  
EASL/AASLD Monothematic: Nuclear Receptors and Liver Disease  
[www.easl.ch/vienna2009](http://www.easl.ch/vienna2009)

March 13-14, 2009  
Phoenix, Arizona  
AGAI/AASLD Academic Skills Workshop

March 20-24, 2009  
Marriott Wardman Park Hotel  
Washington, DC  
13th International Symposium on Viral Hepatitis and Liver Disease

March 23-26, 2009  
Glasgow, Scotland  
British Society of Gastroenterology (BSG) Annual Meeting  
Email: [bsg@mailbox.ulcc.ac.uk](mailto:bsg@mailbox.ulcc.ac.uk)

April 8-9, 2009  
Silver Spring, Maryland  
2009 Hepatotoxicity Special Interest Group Meeting

April 18-22, 2009  
Colorado Convention Center, Denver, CO  
AACR 100th Annual Meeting 2009

April 22-26, 2009  
Copenhagen, Denmark  
the 44th Annual Meeting of the European Association for the Study of the Liver (EASL)  
<http://www.easl.ch/>

May 17-20, 2009  
Denver, Colorado, USA  
Digestive Disease Week 2009

May 29-June 2, 2009  
Orange County Convention Center  
Orlando, Florida  
45th ASCO Annual Meeting  
[www.asco.org/annualmeeting](http://www.asco.org/annualmeeting)

May 30, 2009  
Chicago, Illinois  
Endpoints Workshop: NASH

May 30-June 4, 2009  
McCormick Place, Chicago, IL  
DDW 2009  
<http://www.ddw.org>

June 17-19, 2009  
North Bethesda, MD  
Accelerating Anticancer Agent Development

June 20-26, 2009  
Flims, Switzerland  
Methods in Clinical Cancer Research (Europe)

June 24-27, 2009  
Barcelona, Spain  
ESMO Conference: 11th World Congress on Gastrointestinal Cancer  
[www.worldgicancer.com](http://www.worldgicancer.com)

June 25-28, 2009  
Beijing International Convention Center (BICC), Beijing, China  
World Conference on Interventional Oncology  
<http://www.chinamed.com.cn/wcio2009/>

July 5-12, 2009  
Snowmass, CO, United States  
Pathobiology of Cancer: The Edward A. Smuckler Memorial Workshop

July 17-24, 2009  
Aspen, CO, United States  
Molecular Biology in Clinical Oncology

August 1-7, 2009  
Vail Marriott Mountain Resort, Vail, CO, United States  
Methods in Clinical Cancer Research

August 14-16, 2009  
Bell Harbor Conference Center, Seattle, Washington, United States  
Practical Solutions for Successful Management  
<http://www.asge.org/index.aspx?id=5040>

September 23-26, 2009  
Beijing International Convention Center (BICC), Beijing, China  
19th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists (IASGO)  
<http://iasgo2009.org/en/index.shtml>

September 27-30, 2009  
Taipei, China  
Asian Pacific Digestive Week  
<http://www.apdwcongress.org/2009/index.shtml>

October 7-11, 2009  
Boston Park Plaza Hotel and Towers, Boston, MA, United States  
Frontiers in Basic Cancer Research

October 13-16, 2009  
Hyatt Regency Mission Bay Spa and Marina, San Diego, CA, United States  
Advances in Breast Cancer Research: Genetics, Biology, and Clinical Applications

October 20-24, 2009  
Versailles, France  
Fifth International Conference on Tumor Microenvironment: Progression, Therapy, and Prevention

October 30-November 3, 2009  
Boston, MA, United States  
The Liver Meeting

November 15-19, 2009  
John B. Hynes Veterans Memorial Convention Center, Boston, MA, United States  
AACR-NCI-EORTC Molecular Targets and Cancer Therapeutics

November 21-25, 2009  
London, UK  
Gastro 2009 UEGW/World Congress of Gastroenterology  
[www.gastro2009.org](http://www.gastro2009.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (World J Gastroenterol ISSN 1007-9327 CN 14-1219/R) is a weekly open-access (OA) peer-reviewed journal supported by an editorial board consisting of 1179 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of the value of the readers can be comprehended in two ways. First, the journal publishes articles that can be directly read or downloaded free of charge at any time, which attracts more readers. Second, the readers can apply the knowledge in clinical practice without delay after reading and understanding the information in their fields. In addition, the readers are encouraged to propose new ideas based on those of the authors, or to provide viewpoints that are different from those of the authors. Such discussions or debates among different schools of thought will definitely boost advancements and developments in the fields. Maximization of the value of the authors refers to the fact that these journals provide a platform that promotes the speed of propagation and communication to a maximum extent. This is also what the authors really need. Maximization of the value of the society refers to the maximal extent of the social influences and impacts produced by the high quality original articles published in the journal. This is also the main purpose of many journals around the world.

The major task of *WJG* is to rapidly report the most recent results in basic and clinical research on gastroenterology, hepatology, endoscopy and gastrointestinal surgery fields, specifically including autoimmune, cholestatic and biliary disease, esophageal, gastric and duodenal disorders, cirrhosis and its complications, celiac disease, dyspepsia, gastroesophageal reflux disease, esophageal and stomach cancers, carcinoma of the colon and rectum, gastrointestinal bleeding, gastrointestinal infection, intestinal inflammation, intestinal microflora and immunity, irritable bowel syndrome; liver biology/pathobiology, liver failure, growth and cancer; liver failure/cirrhosis/portal hypertension, liver fibrosis; *Helicobacter pylori*, hepatitis B and C virus, hepatology elsewhere; pancreatic disorders, pancreas and biliary tract disease, pancreatic cancer; transplantation, genetics, epidemiology, microbiology and inflammatory disorders, molecular and cell biology, nutrition; geriatric gastroenterology, pediatric gastroenterology, steatohepatitis and metabolic liver disease; diagnosis and screening, endoscopy, imaging and advanced technology.

The columns in the issues of *WJG* will be adjusted in 2009, which will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Articles: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Articles: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice in gastroenterology and hepatology.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press and Baishideng

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgments, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Baishideng, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine, and we encourage all potential contributors to register with it. However, in the event that other registers become available, you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the corresponding author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com/wjg>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of

supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... etc. It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, etc., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, etc., in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]}</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum numbers can be found at: <http://www.wjgnet.com/wjg/help/14.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first

mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No.62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision.

(1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/10.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/9.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put online. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
