## Contents

Weekly Volume 16 Number 1 January 7, 2010

### EDITORIAL

- 1 Hepatocyte cryopreservation: Is it time to change the strategy?  
*Stéphenne X, Najimi M, Sokal EM*

### OBSERVATION

- 15 Limitations in assessment of mucosal healing in inflammatory bowel disease  
*Freeman HJ*

### ORIGINAL ARTICLE

- 21 Loss of CD103<sup>+</sup> intestinal dendritic cells during colonic inflammation  
*Strauch UG, Grunwald N, Obermeier F, Gürster S, Rath HC*
- 30 Antibiotics and probiotics in chronic pouchitis: A comparative proteomic approach  
*Turroni S, Vitali B, Candela M, Gionchetti P, Rizzello F, Campieri M, Brigidi P*
- 42 Is there an association between *Helicobacter pylori* in the inlet patch and globus sensation?  
*Alagozlu H, Simsek Z, Unal S, Cindoruk M, Dumlu S, Dursun A*
- 48 Atrial natriuretic peptide signal pathway upregulated in stomach of streptozotocin-induced diabetic mice  
*Qiu ZX, Mei B, Wu YS, Huang X, Wang ZY, Han YF, Lu HL, Kim YC, Xu WX*

### BRIEF ARTICLE

- 56 Double balloon enteroscopy in children: Diagnosis, treatment, and safety  
*Thomson M, Venkatesh K, Elmalik K, van der Veer W, Jacobs M*
- 63 Z-line examination by the PillCam™ SB: Prospective comparison of three ingestion protocols  
*Fernandez-Urien I, Borobio E, Elizalde I, Irisarri R, Vila JJ, Urman JM, Jimenez J*
- 69 Systematic review of randomised controlled trials: Probiotics for functional constipation  
*Chmielewska A, Szajewska H*
- 76 Incidental findings at MRI-enterography in patients with suspected or known Crohn's disease  
*Jensen MD, Nathan T, Kjeldsen J, Rafaelsen SR*

- 83 Association of autoimmune type atrophic corpus gastritis with *Helicobacter pylori* infection  
*Veijola LI, Oksanen AM, Sipponen PI, Rautelin HIK*
- 89 On-treatment predictions of success in peg-interferon/ribavirin treatment using a novel formula  
*Saito H, Ebinuma H, Ojiro K, Wakabayashi K, Inoue M, Tada S, Hibi T*
- 98 Reoperation for early postoperative complications after gastric cancer surgery in a Chinese hospital  
*Sah BK, Chen MM, Yan M, Zhu ZG*
- 104 Electro-acupuncture to prevent prolonged postoperative ileus: A randomized clinical trial  
*Meng ZQ, Garcia MK, Chiang JS, Peng HT, Shi YQ, Fu J, Liu LM, Liao ZX, Zhang Y, Bei WY, Thornton B, Palmer JL, McQuade J, Cohen L*
- 112 Silencing Fas-associated phosphatase 1 expression enhances efficiency of chemotherapy for colon carcinoma with oxaliplatin  
*Xiao ZY, Wu W, Eagleton N, Chen HQ, Shao J, Teng H, Liu TH, Jiang ZM, Yao HR*

**CASE REPORT**

- 119 Malignant schwannoma of the pancreas involving transversal colon treated with *en-bloc* resection  
*Stojanovic MP, Radojkovic M, Jeremic LM, Zlatic AV, Stanojevic GZ, Jovanovic MA, Kostov MS, Katic VP*
- 123 Successful endoscopic sclerotherapy for cholecystojejunostomy variceal bleeding in a patient with pancreatic head cancer  
*Hsu YC, Yen HH, Chen YY, Soon MS*
- 126 Ileum perforation due to delayed operation in obturator hernia: A case report and review of literatures  
*Zhang H, Cong JC, Chen CS*
- 131 Biliary cystadenocarcinoma diagnosed with real-time contrast-enhanced ultrasonography: Report of a case with diagnostic features  
*Ren XL, Yan RL, Yu XH, Zheng Y, Liu JE, Hou XB, Zuo SY, Fu XY, Chang H, Lu JH*

**LETTERS TO THE EDITOR** 136

- A dynamic model of once-daily 5-aminosalicylic acid predicts clinical efficacy  
*Parakkal D, Ehrenpreis ED, Thorpe MP, Putt KS, Hannon B*

**ACKNOWLEDGMENTS** I-II Acknowledgments to reviewers of *World Journal of Gastroenterology*

**APPENDIX** I Meetings  
 I-IV Instructions to authors

**AIM AND SCOPE**

*World Journal of Gastroenterology (WJG)*, print ISSN 1007-9327, DOI: 10.3748 is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**FLYLEAF** I-VII Editorial Board

**EDITORS FOR THIS ISSUE**

**Responsible Assistant Editor:** *Xiao-Fang Liu*  
**Responsible Electronic Editor:** *Wen-Hua Ma*  
**Proofing Editor-in-Chief:** *Lian-Sheng Ma*

**Responsible Science Editor:** *Lin Tian*  
**Proofing Editorial Office Director:** *Jian-Xia Cheng*

**NAME OF JOURNAL**  
*World Journal of Gastroenterology*

**LAUNCH DATE**  
 October 1, 1995

**RESPONSIBLE INSTITUTION**  
 Department of Science and Technology of Shanxi Province

**SPONSOR**  
 Taiyuan Research and Treatment Center for Digestive Diseases, 77 Shuangta Xijie, Taiyuan 030001, Shanxi Province, China

### Abstract

Liver cell transplantation presents clinical benefit in patients with inborn errors of metabolism as an alternative, or at least as a bridge, to orthotopic liver transplantation. The success of such a therapeutic approach remains limited by the quality of the transplanted cells. Cryopreservation remains the best option for long-term storage of hepatocytes, providing a permanent and sufficient cell supply. However, isolated adult hepatocytes are poorly resistant to such a process, with a significant alteration both at the morphological and functional levels. Hence, the aim of the current review is to discuss the state of the art regarding widely-used hepatocyte cryopreservation protocols, as well as the assays performed to analyse the post-thawing cell quality both *in vitro* and *in vivo*. The majority of studies agree upon the poor quality and efficiency of cryopreserved/thawed hepatocytes as compared to freshly isolated hepatocytes. Intracellular ice formation or exposure to hyperosmotic solutions

remains the main phenomenon of cryopreservation process, and its effects on cell quality and cell death induction will be discussed. The increased knowledge and understanding of the cryopreservation process will lead to research strategies to improve the viability and the quality of the cell suspensions after thawing. Such strategies, such as vitrification, will be discussed with respect to their potential to significantly improve the quality of cell suspensions dedicated to liver cell-based therapies.

### INTRODUCTION

Liver cell transplantation (LCT) is able to correct inborn errors of liver metabolism by supplying viable and functional hepatocytes<sup>[1-5]</sup>. This innovative therapeutic approach is currently accepted as a bridge to transplantation during the waiting time for a graft. The efficacy of

this alternative treatment varies according to the etiology of the disease and remains principally dependent on the quality of the initial liver cell suspension used.

The current great challenge of LCT is the constant availability of the cell suspension. Besides sterility, the cell suspension should present high viability and metabolic activity levels. If freshly isolated cells can be ready to use 5-8 h after the treatment of the organ, data of sterility tests are rarely available before transplantation. Nevertheless, most of the quality control tests performed and documented in the literature reveal a good quality profile of freshly isolated cells, both *in vitro* and *in vivo* after transplantation. However, their availability remains significantly limited by ongoing organ shortages. Furthermore, even if freshly isolated cells could be transplanted the same day, we are limited by the quantity of cells that can be infused in one single session. Extensive research based on two different strategies has been developed to efficiently store the isolated liver cells: cold preservation, which could happen during the first 24 h post-isolation and cryostorage. This later strategy remains the sole practical method for the long-term storage of hepatocytes and leads to (1) the development of a readily available cell bank, even in emergency cases, such as metabolic decompensation; (2) the use of fully analysed cell suspensions, including bacterial and viral safety assays; and (3) an efficient planning of future transplantation. In 1999 an “international panel of experts” recognized that “research should continue to improve the liver cell cryopreservation procedures”<sup>[6]</sup>. Ten years later, only a few cryopreservation protocol improvements have been documented, and hepatocyte post-thawing quality remains poor.

The aim of this review is to discuss current developments regarding the major cryopreservation/thawing (C/T) protocols used in the field. Pre-C/T management of the cell suspension and post-thawing *in vitro* and *in vivo* analyses will be discussed and reviewed. Understanding the biophysical properties of the cryopreservation protocol might supply key and useful information to build efficient strategies. Intracellular ice formation (IIF) or exposure to hyperosmotic solutions, which remain the major C/T damages initiators will be reviewed in detail, regarding their effects on the decrease or loss of cell function, and on cell damages and cell death. Finally, technological developments, such as vitrification, which avoids the crystalline state, or encapsulation, which confers mechanical protection, are currently considered to be exciting new perspectives for the improvement of the cell suspension quality dedicated to clinical LCT.

## PRE-CRYOPRESERVATION/THAWING CRITICAL FACTORS

### **Donor organ and isolation step**

An initial high quality cell suspension after isolation remains essential prior to cryopreservation. Indeed, key factors that compromise the quality of the isolated hepatocytes include high liver fat content, prolonged warm

ischemia and/or storage of the organ<sup>[6]</sup>.

Liver cell isolation is mainly performed using the two-step collagenase perfusion protocol. At 37°C, the first solution, which contains a calcium chelating agent, is perfused to weaken the intercellular junctions of liver cells by removing extracellular calcium ions. The second solution contains collagenase and calcium, essential for the collagenase activity, and disaggregates the extracellular compartment to easily release both non-parenchymal and parenchymal cell fractions. The isolated hepatocyte suspension is obtained after mechanical dissociation, filtration and low speed centrifugation<sup>[7]</sup>.

Isolation is thus the first cause of cell trauma, probably due to oxidative stress, as demonstrated in ischemia/reperfusion of the liver, with impaired mitochondrial functions, consequent intracellular adenosine triphosphate (ATP) depletion (personal unpublished data), and production of reactive oxygen species, leading to hepatocyte death. Addition of anti-oxidant molecules to the isolation medium, such as curcumin, ameliorates the post-isolation quality in terms of metabolic activity and plating. However, such compounds did not show any beneficial effect after cryopreservation/thawing<sup>[8]</sup>.

Detachment from the extracellular matrix has also been shown to promote apoptosis, called anoikis (loss of adhesion molecule). This early cell death could not be totally reversed after *in vitro* culture of hepatocytes because cells already engaged in this process will die in the hours following the isolation procedure<sup>[9,10]</sup>. Anoikis is possibly a consequence of the recently described isolation oxidative stress. In conclusion, cell damage, due to the isolation process itself, is already evidenced prior to C/T. However, if plated, the cells have the opportunity in culture to recover and maintain a good metabolic activity.

### **Post-isolation management of the cell suspension**

**Suspension pre-culture:** To allow the hepatocytes to recover from the isolation stress and improve their quality post-isolation, authors proposed culturing (no attachment culture conditions) freshly isolated hepatocytes prior to C/T. Cold (4°C) or warm (37°C) non-attached, stirred, culture conditions (bio-artificial liver) were developed to avoid later addition deleterious detachment of plated cells. Using pig hepatocytes, Darr *et al.*<sup>[11,12]</sup> demonstrated that 24 h pre-culture in a spinner bioreactor at 37°C leads to a detectable increase in albumin production after C/T as compared to non pre-cultured hepatocytes. This beneficial effect decreased after 48 h of pre-culture, showing that the recovery of cell quality post-thawing remains difficult. Indeed, non-attached culture conditions might, over time, lead to additional cell damage. Furthermore, albumin production levels remained markedly lower following cryopreservation as compared to freshly isolated cells, even with 24 h pre-incubation. The utility of pre-culture was confirmed by Gómez-Lechón *et al.*<sup>[13]</sup> who demonstrated that high post-thawing quality hepatocytes of other species (rat, dog and human hepatocytes) were possible using non-attached pre-culture. Criteria such as viability, adaptation of hepatocytes

to culture, drug-metabolizing capability and cytochrome P450 (CYP) activity were assessed. The influence of a non-supplemented pre-culture step on hepatocyte quality was not confirmed by data published by Lloyd *et al.*<sup>[14]</sup> with pig hepatocytes cultured in a bioartificial liver.

**Pre-incubation with antioxidants:** ATP cellular boosters or antioxidants have been proposed to supplement pre-incubation medium and to potentialize the beneficial effects of pre-culture. Several pre-culture conditions, type of ATP booster and culture at 4°C or 37°C, were evaluated by Terry *et al.*<sup>[15,16]</sup>. Two hours hyperosmotic glucose 100-300 mmol/L pre-incubation has been shown to improve the viability and attachment efficiency of rat hepatocytes, as well as the viability of human hepatocytes post-thawing. Fructose 100-300 mmol/L pre-incubation also improved the viability and attachment efficiency of rat hepatocytes. On human hepatocytes, fructose improved their attachment efficiency, but not their viability. Pre-incubation with the anti-oxidant alpha-lipoic acid at 0.5-5 mmol/L improved the viability and attachment efficiency of both rat and human hepatocytes. The beneficial effects of this pre-treatment (at lower concentration: 15 mmol/L glucose for 30 min at 37°C) in human hepatocytes were demonstrated by Silva *et al.*<sup>[17]</sup>. They found that the response of CYP enzymes to typical inducers was significantly improved in the pre-incubated rat and human hepatocytes. The pre-incubated hepatocytes showed a significantly higher plating efficiency compared with hepatocytes cryopreserved without pre-incubation. Finally, Gómez-Lechón *et al.*<sup>[18]</sup> recently demonstrated that the optimal preservation of isolated cells (cell viability, attaching capacity, and functionality, particularly GSH and glycogen levels, as well as drug-metabolizing cytochrome P450 enzymes) was found in media supplemented with 2 mmol/L N-acetyl-cystein (anti-oxidant molecule) and 15 mmol/L glucose, confirming the importance of anti-oxidant protection after isolation.

In conclusion, based on the literature and on our experience, we believe that liver cell isolation represents an important oxidative stress, potentially controlled by the addition of anti-oxidants to the isolation media and/or by non-attached time-limited culture in an anti-oxidant supplemented medium. Quality of cells prior to C/T is therefore increased. However, all the damage related to C/T is not avoided by these pre-C/T steps. Furthermore, in clinical settings, pre-culture adaptation is difficult.

## STANDARDISED HEPATOCYTE CRYOPRESERVATION/THAWING PROTOCOL: STATE OF THE ART

After isolation and related oxidative stress, the obtained cell population is re-suspended in cryopreservation media and distributed at specific concentrations in special freezing vials. The hepatocytes are then ready for the cooling process and storage in liquid nitrogen. In this

chapter, we will review the literature data for liver cell freezing solution as well the documented cooling and thawing process.

### Concentration of hepatocytes and type of vials

In most studies, the hepatocyte concentration varied from  $10^6$  to  $10^7$  cells/mL<sup>[19]</sup>. In this range, Lloyd *et al.*<sup>[14]</sup> did not find any significant superiority of cell concentrations investigated, when evaluating porcine hepatocytes after thawing. This was confirmed by analyzing, hepatocyte attachment, lactate dehydrogenase (LDH) leakage, bilirubin conjugation, and CYP3A4 activity. However, De Loecker *et al.*<sup>[20,21]</sup> revealed that a decreased cell density of rat hepatocytes correlated with an increased post-thawing viability, as estimated by viability trypan blue exclusion assay. These data suggest that higher cell densities might increase membrane-membrane contacts and subsequent cell damage. Therefore, unless high cell density will save space and is useful for the development of cell banks, cryopreservation at a low cell density (less than  $10^7$ /cell) is recommended.

Besides cell density, type and volume of vials used for liquid nitrogen storage might also influence post-thawing cell quality; however, few data are available in the literature. Based on the trypan blue exclusion test, cytochrome activity, and tetrazolium inner salt assays, bags of 50 mL seem to give better quality pig hepatocytes, post-thawing, than bags of 100 mL<sup>[22]</sup>.

The lack of recently published data on the concentration of hepatocytes is considered as a minor point for reaching the best post-thawing quality.

We also confirm that, in our hands, in several different volumed vials (from 2 to 100 mL) and varying cell densities, cell density does not influence post-thawing cell quality.

### Freezing solution

**Cryopreservation medium:** University of Wisconsin solution (UW) is the gold standard cryopreservation medium for isolated hepatocytes. It was originally developed as a cold storage solution for transplant organs. The principal cryoprotectants of the UW solution are Lactobionate (100 mmol/L), a large molecular weight anion impermeable to most membranes and supposed to suppress hypothermia-induced cell swelling, and Raffinose (30 mmol/L), which allows additional osmotic support<sup>[23]</sup>. Dexamethasone, another compound in UW solution, is used to stabilise cell membranes<sup>[24]</sup>.

The superior beneficial effect of UW solution was demonstrated by comparing UW to three other freezing media [all were supplemented with 12% dimethylsulfoxide (DMSO)], Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum and commercial solutions, Cell Banker 1 and Cell Banker 2. Parameters including viability, plating efficiency, LDH release, ammonia removal test, and lentiviral gene transfer were shown to be highly maintained in hepatocytes cryopreserved with UW solution<sup>[25]</sup>.

The effectiveness of UW solution as a cryoprotectant

agent suggests that metabolic, as well as ultrastructural, factors might be important in the effective cryopreservation of isolated hepatocytes<sup>[26]</sup>. However, UW solution also has limitations, principally its cost and, as demonstrated in the “Parameters for the evaluation of hepatocytes quality after cryopreservation/thawing” paragraph, its incomplete cell protection.

HypoThermosol (HTS), a recently developed freezing solution, is a dextran-based intracellular-type solution. It is used as the carrier solution of the freezing medium. Freshly isolated rat hepatocytes cryopreserved in HTS supplemented with 10% DMSO have been shown to present high viability levels, good long-term maintenance of hepatospecific functions, and good quality response to cytokine challenge at the post-thawing level compared to other supplemented culture media<sup>[27]</sup>. Further studies confirmed the utility of HTS, allowing a decrease in the DMSO levels within the cryopreservation solution. However, no data comparing UW to HTS are available in the literature<sup>[28,29]</sup>.

**Cryoprotectants:** Cryoprotectants are essential components of freezing solutions. Two classes of cryoprotectants are described, those that permeate the cell membrane (DMSO, Glycerol) and those that do not such as polymers (Dextran), oligosaccharides (Trehalose), and sugars (Glucose, sucrose or fructose).

DMSO is an important polar permeating aprotic solvent which is less toxic than other members of this class. The use of DMSO in medicine dates from around 1963, when an University of Oregon Medical School team discovered it could penetrate the skin and other membranes without damaging them and could carry other compounds into a biological system. It is able to enter cells and reduce injury by moderating the increase in solute concentration during freezing. In most studies, DMSO is the ideal cryoprotectant, notably giving the best plating efficiency<sup>[27,30,37]</sup>. Classically, a final concentration of 10% DMSO is described in many protocols, with some exceptions, although higher levels are potentially toxic due to high osmolarity<sup>[38]</sup>. The rate of addition of the cryoprotectant also appears important to the outcome of cryopreservation. Freezing must be commenced as soon as possible after addition of the cryoprotectant to reduce the possibility of toxicity at ambient temperatures. Hence, DMSO should be added at 4°C, as toxicity of DMSO was demonstrated at 25°C or 37°C. Some authors proposed adding permeating cryoprotectants slowly to the cell suspension to avoid damages related to osmotic shock and cellular dehydration<sup>[35,39]</sup>. However, this seems to be a minor point<sup>[38]</sup>.

The use of oligosaccharides with higher molecular weights resulted in greatest improvement in viability. Their combination with DMSO has been shown to allow efficient hepatocyte cryopreservation. Both rat and human hepatocytes exhibit significantly higher viability (as estimated by trypan blue exclusion assay) than hepatocytes previously cryopreserved without oligosaccharides. Moreover, attachment and survival rates in plastic dishes of rat

hepatocytes were greater after freezing in the presence of di-, tri-, and tetrasaccharides. Such plating amelioration was not confirmed with human hepatocytes<sup>[40]</sup>. Metabolic activity was also evaluated after cryopreservation with oligosaccharides. When trehalose was combined with DMSO for the cryopreservation of human hepatocytes, a significant increase in total protein level and secretion of albumin was observed after thawing, as well as decreased levels of aspartate aminotransferase<sup>[41]</sup>.

Those works were inspired from data demonstrating the influence of trehalose on cell quality on bull sperm<sup>[42,43]</sup>. Similarly, several authors recommended adding sucrose to the cryopreservation medium, with or without trehalose, to ameliorate the quality of the cells after thawing. This allows the concentration of DMSO to be decreased while ameliorating the quality of cells. However, it was evaluated on hematopoietic stem cells and fetal liver hematopoietic stem/progenitor cells<sup>[44,45]</sup>, not on hepatocytes.

The beneficial role of a non-metabolizable glucose derivative as a cryoprotectant that mimicked the natural cryoprotective adaptations observed in freeze-tolerant frogs was also investigated. Primary rat hepatocytes were loaded with 3-O-methyl glucose (3OMG) through endogenous glucose transporters without evident toxicity and cryopreserved according to a controlled rate freezer program down to -80°C before storage in liquid nitrogen. In this study, hepatocytes cryopreserved with a relatively small amount of intracellular 3OMG (< 0.2 mol/L) showed high post-thaw viability and maintained long-term hepatospecific functions, including synthesis, metabolism, and detoxification. Metabolite uptake and secretion rates were also largely preserved in the cryopreserved hepatocytes, showing that 3OMG must be considered as an interesting cryoprotectant<sup>[46]</sup>.

An interesting report proposed that wheat protein extracts permitted long-term storage and recovery of large quantities of healthy cells that maintain high hepatospecific functions, *via* an osmotic modulation effect<sup>[47]</sup>. In post-thawing culture, the morphology of hepatocytes cryopreserved with wheat protein extracts was similar to that of fresh cells. Furthermore, hepatospecific functions, such as albumin secretion and biotransformation of ammonium to urea, were well maintained during four-days post-plating. Inductions of CYP1A1 and CYP2B in hepatocytes cryopreserved with wheat extracts were similar to those in fresh hepatocytes. Additional data confirmed the utility of wheat extracts as efficient, non-toxic, economic natural cryoprotectants, superior to DMSO, which has limitations due to potential cellular toxicity<sup>[47-49]</sup>.

Finally, human application does not tolerate the use of animal origin products because of possible zoonosis contamination and/or immune response to animal proteins<sup>[50]</sup>. Fetal calf serum (FCS) or human albumin, are classical ingredients of the cryopreservation solution, in a proportion of 10% to 90 %. No significant differences in classical viability or drug metabolizing enzyme activities were noted while varying the percentage of serum for (human, pig, and rat) hepatocyte cryopreservation in most

Table 1 Summary of freeze-rate comparison studies

Species	Cryoprotectant	Freeze rate	Storage temperature	Ref.
Human	DMSO	-1°C/min	-80°C	[55]
Rat	DMSO	-1°C/min to -38°C (with cooling shock) then liquid nitrogen	Liquid nitrogen	[61]
Dog, monkey, human	DMSO	-1.9°C/min from 4°C to -30°C, then -30°C from -30°C to -150°C	Liquid nitrogen	[57]
Rat	DMSO	-38°C/min	Liquid nitrogen	[59]
		-2°C/min		
		Slow variable		
		Optimized variable rate		
Human	DMSO	-1.9°C/min from 4°C to -30°C, then -30°C from -30°C to -150°C	Liquid nitrogen	[51]
Rat	DMSO	Cooling in 10 min down to 0°C, 8 min at 0°C, in 4 min down to -8°C, in 0.1 min down to -28°C, in 2 min down to -33°C, in 2 min up to -28°C, in 16 min down to -60°C, in 4 min down to -100°C (variable rate)	Liquid nitrogen	[60]
Human	DMSO	Variable rate	Liquid nitrogen	[6]
Dog, monkey, human	DMSO	-1.9°C/min from 4°C to -30°C, then -30°C from -30°C to -150°C	Liquid nitrogen	[58]
Rat	DMSO	Variable rate	Liquid nitrogen	[59]
Pig	DMSO	Optimized <sup>[59]</sup>	Liquid nitrogen	[22]
		Modified variable		

DMSO: Dimethylsulfoxide.

of the published studies<sup>[26,30,33,36,51-53]</sup>. We think that a minimal concentration of serum is required for optimal cryopreservation, even if some authors have also successfully cryopreserved porcine hepatocytes without serum. They showed that, after thawing, in appropriate conditions and without serum, the addition of conditioned medium derived from hepatic non-parenchymal cells improved attachment and function of hepatocytes (urea production and CYP activity)<sup>[54]</sup>.

In conclusion, UW solution remains the best and most studied freezing medium and must be supplemented with a permeating cryoprotectant; DMSO remains the gold standard. The addition of a non-permeating cryoprotectant to this solution must also be considered.

### Cooling process

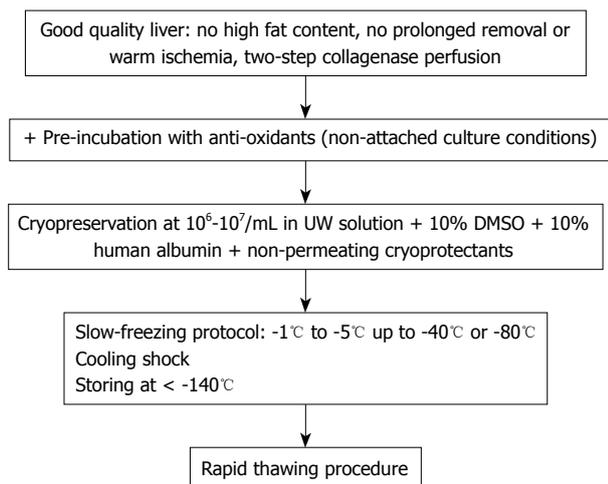

Slow freezing protocols are considered to be the best strategy for cryopreserving mature isolated hepatocytes. All the protocols described in this paragraph were developed using DMSO as the cryoprotectant. First protocols included the use of an isopropranolol cooler device, placed in a -80°C freezer, giving a constant temperature decrease of -1°C/min down to -70°C or -80°C, before storing in liquid nitrogen<sup>[55]</sup>. Other slow freezing protocols are described in the literature, varying from -1°C/min to -5°C/min up to -40°C or -80°C, before storing at -196°C<sup>[56]</sup>. A decrease in temperature at -1.9°C/min from 4 to -30°C and then -30°C/min from -30°C to -150°C was also adopted by many authors<sup>[51,57,58]</sup>. More specific protocols were developed by Diener *et al* and by Hengstler *et al*<sup>[39,59,60]</sup>. Several cooling process protocols, where the temperatures of the vial and of the cryopreserving solution were controlled, were tested on rat hepatocytes. Firstly, shock freezing in liquid nitrogen dramatically decreased cell viability, despite the presence of 10% DMSO. Secondly, a slow freezing protocol with -2°C/min led to much better recovered viability than a cooling rate of -38°C/min. While using the slow freezing protocol, the authors determined that the cell suspension becomes

supercooled around -20°C. Indeed, when crystallisation starts, the latent heat of fusion is released and the cell sample is warmed. This heat release may be deleterious; therefore, a freezing program with shock cooling was developed. Analysis of post-thawing viability did not show significant differences of hepatocyte viability (86% viability *vs* 79% according to the slow linear protocol). The same cooling shock can be obtained by clamping the vials, with forceps cooled in liquid nitrogen<sup>[61]</sup>. However, studies from Lloyd *et al*<sup>[14]</sup> (measuring LDH release, cell return, attachment, and biochemical assays) and from our team<sup>[62]</sup> did not show any difference between computer-controlled freeze rate (without frozen shock), the Nalgene propan-2-ol device or simply using -20°C and -80°C freezers.

Storage of hepatocytes at -20°C or -80°C remains deleterious for cells functions as several proteases might be active at those temperatures. At -130°C, no chemical reaction can occur as there is no more thermal energy. Furthermore, at this temperature, no water, which is at the vitreous or crystalline state, is present at the liquid state. Therefore, -140/-150°C is the minimum acceptable temperature for long-term storage of cryopreserved hepatocytes<sup>[6,34,57,63]</sup>. At -140°C (the vapour phase of liquid nitrogen) or -196°C (the liquid phase of liquid nitrogen), cells can be stored for long periods<sup>[6,34,51,57]</sup>. A summary of freeze rate comparison studies is presented in Table 1. The passage of water from one state to another, IIF, is the critical point that might modulate the cell quality. The limitations of these cooling processes will be discussed later in the IIF paragraph.

### Thawing procedure

The critical point of this procedure is to avoid the deleterious phenomenon, IIF. Rapid thawing at 37°C to minimize cellular damage due to reformation of intracellular ice will significantly enhance cell viability. As for cooling, a slow dilution of the cryoprotectant at 4°C is recommended, to avoid osmotic shock and the toxicity

**Figure 1 Standardized cryopreservation protocol.** UW: University of Wisconsin solution; DMSO: Dimethylsulfoxide.

of the cryoprotectant<sup>[38]</sup>.

The standardized cryopreservation/thawing protocol is summarized in Figure 1.

## PARAMETERS FOR EVALUATING HEPATOCYTE QUALITY AFTER CRYOPRESERVATION/THAWING

The aim of this paragraph is to review the principal assays that may help to standardize the post-thawing evaluation step process.

The viability assays (Trypan blue exclusion test, LDH release, mitochondrial functions and necrotic/apoptotic markers) are important quality markers. Most of the “metabolic” assays investigate only some specific hepatocyte functions, notably drug metabolizing enzymes activities, essential for drug industry application; but also the hepatocytes’ capacity to plate to collagen coated dishes. Other assays should be developed to allow a rapid evaluation of LCT-related critical parameters.

### Viability assays

Necrosis was first described to occur following C/T<sup>[31]</sup>, whereby intracellular organelles, most notably the mitochondria, and the entire cell swell and rupture (cell lysis). This phenomenon begins with an impairment of the cell’s ability to maintain homeostasis, leading to an influx of water and extra-cellular ions. Due to the breakdown of the plasma membrane, the cytoplasmic contents, including lysosomal enzymes, are released into the extracellular fluid. This can be tested by LDH release from the cytoplasm to the extracellular medium and reflects cell membrane integrity. However, we found that LDH release was unaffected after C/T of both human and mice hepatocytes and does not adequately assess viability after C/T<sup>[62]</sup>.

Apoptosis, a programmed cell death which has been well characterized, both at the morphological and biochemical levels, was also described following C/T. Annexin V staining, *in situ* TUNEL assay combined with

confocal laser scanning microscopy, or deoxyribonucleic acid (DNA) fragmentation are the most popular apoptosis assays<sup>[28,31,64]</sup>. These assays should be carefully interpreted if performed *in vitro* or *in vivo*.

The mitochondrion is a key player in the initiation of apoptosis and recent studies highlighted its role in C/T-induced cellular damage<sup>[65]</sup>. Disruption of mitochondrial membrane potential ( $\Delta\Psi$ ) was reported following C/T, which is followed, within hours after thawing, by cytochrome c extra-mitochondrial release, caspase-3 activation, and DNA fragmentation. Addition of caspase inhibitors (IDN-1965 or ZVAD-fmk) to the medium during cryopreservation and static culture rescued cells from apoptosis and was associated with increased phase 1 and phase 2 metabolism<sup>[64,66]</sup>.

As mitochondria are the major source of reactive oxygen species (ROS), induction of apoptosis by oxidative stress was also proposed to be involved in the impairment of hepatocytes after C/T<sup>[67,68]</sup>. In fact, the combination of antioxidant medium containing a caspase inhibitor allowed significant improvements in viability and function in treated rat hepatocytes<sup>[68]</sup>. Similarly, other authors proposed the addition of S-adenosylmethionine to the cryopreservation medium, to avoid glutathione and viability decrease during cold preservation or cryopreservation in liquid nitrogen<sup>[69]</sup>. Finally, C/T decreased mitochondria-related cellular respiration and oxygen consumption rate. This effect was evidenced on oligomycin (ATP synthase inhibitor)-sensitive respiration, suggesting that it could result from alteration of a mitochondrial process linked to ATP synthesis, rather than an intrinsic modification of mitochondrial membrane proton permeability (leak). In permeabilized hepatocytes, a marked impairment of mitochondrial oxidative phosphorylation following C/T was observed in *in situ* mitochondria with substrates for complex 1, under basal mitochondrial respiratory rate. Interestingly, the inhibition of basal mitochondrial respiration was not revealed with complex 2 substrates<sup>[62]</sup>. The respiratory-chain complex 1 is one of the largest known membrane protein complexes, and is also the major source of mitochondrial ROS<sup>[70,71]</sup>. Thus, specific alterations of complex 1 subunit(s), which comprise the hydrophilic domain containing the redox centres of the enzyme, and/or deregulation of ROS production leading to oxidative stress, could constitute one of the start-points of the C/T-induced damage. This could explain the oxygen consumption and  $\Delta\Psi$  decrease, leading to ATP depletion and later cytochrome c release. The intracellular ATP concentration, which is an indirect mitochondrial marker, is probably the easiest and most rapidly measurable parameter for detecting early cellular damages related to cryo-storage.

Detailed information regarding cryopreserved hepatocyte death *in situ* after transplantation remains poorly investigated in LCT *in vivo* models.

### Plating

Attachment of isolated hepatocytes *in vitro* (collagen coated dishes) is widely used for the evaluation of their quality. The low plating efficiency is often documented

in cryopreserved cells. This remains a major problem because engraftment of the transplanted hepatocytes in the recipient liver parenchyma is also dependent on the proteins involved in extracellular matrix adhesion mechanisms<sup>[17,23,25,63,72]</sup>. Structural membrane damage observed after cryopreservation might contribute to such alterations. Recently, it was demonstrated that the process of cryopreservation leads to down-regulation of cell adhesion at the gene and the protein level ( $\beta$ 1-integrin and E-cadherin, amongst others)<sup>[73]</sup>. This is relevant and probably begins to explain the observed low plating efficiency. Another team was able to demonstrate that when hepatocytes are cryopreserved with wheat extracts instead of DMSO, there was a clear protective effect against loss of  $\beta$ 1-integrin, E-cadherin, and  $\beta$ -catenin<sup>[74]</sup>. We must also recognize the high plating variability from one liver to another.

### Hepato-specific functions

Conjugation and secretion of biliary acids seems to be maintained following C/T of human hepatocytes. The uptake of taurocholate in cryopreserved hepatocytes of was found to range from 10% to 200% of that observed in freshly isolated cells immediately after thawing at 37°C<sup>[75]</sup>.

The characterization of freshly isolated and C/T monkey hepatocytes demonstrated the maintenance of various hepato-specific functions, but at a low level. The ability to synthesize proteins, glucose, and glucose-6 phosphatase activity was decreased after deep-freeze storage<sup>[30]</sup>. Concerning protein synthesis, data from the literature show that this important hepatic function is often impaired in hepatocytes after C/T. De Loecker *et al.*<sup>[61]</sup> demonstrated that cryopreserved human hepatocytes albumin production was reduced to half that of freshly isolated hepatocytes. Glycogen synthesis in cryopreserved porcine hepatocytes was reduced by about 30% after 24 h of culture and about 47% after 48 h of culture compared to freshly isolated hepatocytes. Reduced basal levels of glycogen and of glycogen synthesis could be explained by an increased energy demand in cryopreserved hepatocytes to repair damage caused by cryopreservation. Glycogenolysis was reduced to about 50% in cryopreserved hepatocytes and gluconeogenesis to about 40% of the glucose production in freshly isolated hepatocytes at day 1 and 2 post-thawing. Incubation with glucagon (90 min) increased the glucose production from glycogenolysis and gluconeogenesis in both freshly isolated and cryopreserved hepatocytes<sup>[76]</sup>.

Urea production also seems to be reduced following C/T, according the majority of the papers<sup>[30]</sup>.

There is no apparent significant change in drug metabolizing enzyme activities between freshly isolated and cryopreserved hepatocytes for the major drug-metabolizing pathways. The cryopreservation of human hepatocytes isolated from 17 donors was shown not to alter their capability to metabolize substrates for the major CYP isoforms (CYP1A2, CYP2A6, CYP2C9, CYP2C19, CYP2D6, and CYP3A4), as well as the phase II enzymes UDP glucuronyltransferase, and 7-HC sulfation for sulfotransferase<sup>[77]</sup>.

Steinberg *et al.*<sup>[78]</sup> showed that phase I drug-metabolizing enzyme activities analyzed in cryopreserved human, rat, and mouse hepatocytes were very similar to those of freshly isolated hepatocytes; while phase II enzyme activities were affected by cryopreservation.

Other studies show better stability of drug metabolizing activities in monkey than in rodent hepatocytes. After thawing, Phase I and Phase II activities (CYP, ethoxycoumarin-O-deethylase, aldrin epoxidase, epoxide hydrolase, glutathione transferase, glutathione reductase, and glutathione peroxidase) were well preserved<sup>[79]</sup>. The decrease in the activity of phase II enzymes, documented in several studies, might be related to the loss of the corresponding cofactors; however, the hypothesis of physical cell alteration is not excluded<sup>[78]</sup>. The cytosolic enzymes, notably glutathione S-transferase, are more exposed to intracellular ice formation and related C/T damages, even if some mechanical protection can be given by microsomal membranes<sup>[55]</sup>.

Finally, if thawed hepatocytes cultures are sensitive to CYP inducers (rifampicin, rifabutin, phenobarbital, omeprazole, and  $\beta$ -naphthoflavone) the induced activity remains lower as compared to freshly isolated cells, with an increased delay induction time<sup>[6,17,60,80-83]</sup>. This is summarized in Table 2.

In conclusion, the standardized “literature based” C/T protocols have limitations, as demonstrated by the collected data in the last four paragraphs. If some progress were made in the assessment of specific hepatic functions, then the true effects of pre-C/T incubation with anti-oxidants or the addition of non-permeating cryoprotectants to the freezing solution on the poor quality of hepatocyte post-C/T could be properly tested. Finally, cell death, probably not a reversible mechanism following C/T, is initiated due to mitochondrial impairment. ATP concentration evaluation, as a mitochondrial operation marker, is a crucial test to evaluate the quality of C/T cells.

## INTRA-CELLULAR ICE FORMATION: THE START POINT OF THE OBSERVED CELL DAMAGE?

Post-thawing cell quality remains poor. How can we explain the observed damages? The passage from a liquid stage of the intracellular and extracellular water, to a crystalline state probably holds the key to understanding C/T damages. In the cryopreservation of cells or tissues, each system has its specific optimal cooling rate, showing a decreased survival at both too low (slow cooling damage) and too high cooling rates (fast cooling damage). During freezing, the transition phase of water leads to a decrease of the extracellular water content. Water can pass through the plasma membrane, which will in turn lead to water efflux and cell dehydration. Slow cooling damage has been attributed to such phenomena as the increase in the external and internal solute (salt) concentration, the small size of the

Table 2 *In vitro* evaluation of post-thawing quality of hepatocytes

Hepatocyte <i>in vitro</i> model	Cryopreservation protocol	Parameters evaluated: impairment following C/T	Parameters evaluated: no impairment following C/T	Ref.
Rat and human	Pre-incubation -20°C, -70°C, liquid nitrogen	Plating	CYP induction	[17]
Porcine	Slow freezing protocol up to -80°C	Trypan blue exclusion test Plating Ammonia clearance		[23]
Rat	Slow freezing protocol up to -80°C	Trypan blue exclusion test Plating Ammonia clearance		[25]
Human	20% DMSO, 40% FCS Slow freezing protocol	Trypan blue exclusion test Plating LDH release MTT	ATP Urea synthesis	[63]
Porcine	Freezing boxes or slow freezing protocol	CYP	Plating	[72]
Rat and mouse	Slow freezing protocol	Glycogen synthesis Glycogenolysis Gluconeogenesis Plating Uptake of neutral red Protein synthesis		[41]

C/T: Cryopreservation/thawing; FCS: Fetal calf serum; LDH: Lactate dehydrogenase; MTT: 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H tetrazolium bromide; CYP: Cytochrome P450.

channels of unfrozen solution, or the mechanical stress of cell shrinkage and destabilisation of membranes and proteins at low water potential. At high cooling rates, the intracellular dehydration (by water efflux) cannot keep pace with the extracellular dehydration (by phase transition of water). As a consequence, higher cooling rates result in higher levels of intra-cellular supercooling, higher trans-membrane differences in osmotic pressure and solute concentrations, and higher rates of water efflux through the membrane. This fast cooling damage seems to be due particularly to IIF<sup>[84-89]</sup>.

We recently demonstrated that cryopreservation at -20°C for 20 min followed by rapid thawing induced a dramatic drop of ATP levels in cryopreserved/thawed hepatocytes, correlated with a decreased oxygen consumption rate and altered mitochondrial complex 1 activity (personal unpublished data).

These results suggest that during the cryopreserva-

tion damage, complex 1 impairment occurred early in the cryopreservation process by mechanical alteration of mitochondria due to IIF or exposure to hyperosmotic solutions. However, IIF might also occur during the thawing process.

## CRYOPRESERVED/THAWD HEPATOCYTES FOR LIVER CELL TRANSPLANTATION

### Animal

According to the data available in the literature, the ability of cryopreserved/thawed hepatocytes to engraft and to repopulate the recipient liver is not definitively demonstrated. In the eighties, Fuller *et al.*<sup>[90]</sup> described that fewer cryopreserved (slow freezing protocol in DMSO) autologous hepatocytes cells were detected one month

post-transplantation in the recipient liver as compared to freshly isolated cells. David *et al*<sup>[91]</sup> in Nagase albuminemic transplanted rats, found few clusters of C/T cells three months post-transplantation as compared to freshly isolated hepatocytes, with no significant production of albumin. Dunn *et al*<sup>[92]</sup> showed in a Dalmatian dog model that sequential intrasplenic LCT can provide a significant but transient, 22 d, correction of urinary uric acid excretion that was similar with either freshly isolated or C/T (slow freezing protocol in DMSO, post-thawing viability around 60%) hepatocytes. The protocol of Papalois *et al*<sup>[93]</sup> has demonstrated that cryopreserved pig hepatocytes, at -20°C without cryoprotective medium in Hank's solution, have adequate viability (around 60%) after one month of storage to support hepatic function in animals with severe acute liver failure by hepatoproliferative factors produced by the hepatocytes engrafted in the spleen.

Besides metabolic supply, intrasplenic transplantation of C/T hepatocytes (at -80°C in UW and DMSO) in rats pre-treated with D-galactosamine improved survival to 60% after seven days (as compared to 100% obtained using freshly isolated hepatocytes)<sup>[23]</sup>.

However, in a transgene-induced liver disease model, an environment that is permissive for clonal expansion of donor cell populations, C/T hepatocytes (stored up to 32 mo in liquid nitrogen) have been shown to possess clonal replicative potential identical to that of freshly isolated hepatocytes. C/T hepatocytes constituting 0.1% of the total adult hepatocyte number in the recipient could repopulate a mean of 32% of recipient liver parenchyma<sup>[94]</sup>. Furthermore, transplantation of woodchuck hepatocytes into the liver of urokinase-type plasminogen activator/recombination activation gene-2 mice demonstrated that cryopreserved (slow freezing protocol in DMSO, viability up to 70%-80%) cells, retained the ability to divide and to repopulate a xenogenic liver three months post-transplantation. Notably, *in vivo* susceptibility to infection with woodchuck hepatitis B virus and the proliferative capacity of frozen/thawed woodchuck hepatocytes in recipient mice were identical to those observed by transplanting freshly isolated hepatocytes<sup>[95]</sup>.

The efficiency of C/T (slow freezing protocol in DMSO and HTS, post-thawing viability around 60%) for human hepatocytes was also evaluated in an animal NOD/SCID mice model. Cho *et al*<sup>[96]</sup> demonstrated that transplanted cryopreserved human liver cells engrafted in the peritoneal cavity as well as the liver, retained hepatic function (glycogen storage and Glucose-6 phosphatase activity) and proliferated in response to liver injury by carbon tetrachloride. This effect was greater two hours and three days post-transplantation as compared to 7, 14 and 40 d post-transplantation, suggesting some loss of transplanted cells at later times.

Based on the above data, we may conclude that C/T hepatocytes, in a favourable environment, are transiently able to maintain hepatocyte function *in vivo*, engraft the liver and proliferate at low levels, as compared to freshly isolated cells.

## Human

**Metabolic diseases:** Immediate and medium term metabolic efficacies, decrease of the ammonia levels and urea synthesis were observed in our hands in two urea cycle disorder patients using C/T hepatocytes<sup>[97,98]</sup>. This was correlated, in one case, with effective demonstration of engraftment up to one year after cell infusion, using Fluorescence *In Situ* Hybridization (FISH) for the Y chromosome. This four year-old arginosuccinate-lyase deficiency girl was transplanted with C/T cells and underwent a first liver biopsy after infusion of C/T male hepatocytes, which showed a XX/XXYY chimerism, with 4.7% Y-positive cells. This cell lineage was further described on several post-transplant biopsies, reaching more than 10% of the recipient cells, while she received additional fresh and C/T hepatocyte infusions. At King's College Hospital, one patient with an inherited factor VII deficiency was entirely transplanted with C/T hepatocytes, which led to a transient reduction to 20 percent of the requirements for factor VII therapy<sup>[99]</sup>. To our knowledge, all other published case reports used an infusion protocol at least partially comprising freshly isolated hepatocytes, preventing any conclusion regarding the respective efficiency of C/T *vs* freshly isolated cells.

In conclusion, as in animal models and based on few reported data, C/T hepatocytes seem able to transiently support deficient hepatocyte function, justifying their use to stabilise metabolically unstable patients while waiting for a liver graft.

## PERSPECTIVES ON HEPATOCYTE CRYOPRESERVATION

In this final section, we will analyze and discuss several ways to ameliorate the C/T protocols. We think that these new techniques applicable to C/T protocols are the best hopes for changing the future of cryopreservation/thawing.

### New hepatocyte culture configurations

**Encapsulation-*in vitro*, *in vivo*:** Encapsulation, by conferring a mechanical protection, was investigated with success for hepatocyte cryopreservation protocols.

Firstly, and before considering LCT, several *in vitro* studies showed that encapsulation of freshly isolated hepatocytes in specially designed multi-component capsules (alginate, cellulose sulphate, and poly (methylene-guanidine) hydrochloride) retained their specific functions (transaminase activity, urea synthesis and protein secretion) over the first days of culture. Furthermore, most detoxifying enzymes were also expressed (in cryopreserved alginate-entrapped hepatocytes) at levels close to those in unfrozen encapsulated hepatocytes<sup>[100]</sup>. Long-term, up to 120 d of cryopreservation, preservation of drug metabolism and transport activities was demonstrated using microencapsulated rat hepatocytes<sup>[101]</sup>. Moreover, cold-induced apoptosis in hepatocytes can be significantly reduced following their entrapment within alginate gel beads, as demonstrated by measurement of

caspase-3-like activity<sup>[102]</sup>. Finally, cryomicroscopy studies showed that the alginate microencapsulation technique protected the hepatocytes from physical damage caused by the growth of extracellular ice crystals<sup>[103]</sup>.

How can we adapt the encapsulation of cells to the LCT protocol? In 1993, in the Gunn rat model, the authors proposed intraperitoneal transplantation of cryopreserved alginate-encapsulated hepatocytes, allowing significantly reduced hyperbilirubinemia, as well as freshly isolated encapsulated hepatocytes, up to 28 d following transplantation<sup>[104]</sup>. In a severe liver failure model, two-stage 95% hepatectomy, with xenogenic hepatocytes and without immunosuppression, the authors demonstrated the utility of intrasplenic encapsulated hepatocytes<sup>[105]</sup>.

Intraperitoneal transplantation of cryopreserved or fresh encapsulated rat hepatocytes significantly increased the survival rate to 66% and 80% in the ALF model (acetaminophen administration and 30% hepatectomy). Intraperitoneal transplantation of cryopreserved or fresh encapsulated immortalized hepatocytes improved survival, in this model, to 50% and 55%, respectively. Histopathology revealed that encapsulated hepatocytes were viable, but for a limited period (up to two weeks post-transplantation)<sup>[106]</sup>. Recently, Baldini *et al.*<sup>[107]</sup> showed the retention of biological activity and significant viability of porcine encapsulated hepatocytes transplanted intraperitoneally in rats without immunosuppression, confirming the utility of encapsulation to avoid rejection. Moreover, Aoki *et al.*<sup>[108]</sup> demonstrated that poly-L-lysine entrapped cryopreserved human hepatocytes survived and expressed albumin in rat spleen after transplantation. Finally, Mei *et al.*<sup>[109]</sup> confirmed these data by showing an increased rate of survival in a mouse model of fulminant hepatic failure after xenogenic transplantation of pig hepatocytes.

In conclusion, cryopreservation of encapsulated hepatocytes is a promising tool for the establishment of banks for the supply and storage of hepatocytes, by mechanically conferring protection. However, the main problem of this technique remains the adaptation to LCT, the problem of injection site and adaptation to the treatment indication (size of capsule pore). Furthermore, this can be only be proposed for ALF or metabolic unstable patients, as the efficacy of the transplantation remains time-limited. Repeated injections must therefore be considered. The time-limited effect is notably due to the hepatocyte de-differentiation, observed with freshly isolated or C/T cells, in this kind of configuration. New projects must evaluate the utility of co-encapsulation of hepatocytes with mesenchymal bone marrow cells or pancreatic islets, as a new type of feeder cells to avoid de-differentiation.

### Vitrification

Vitrification (from the Latin, vitreus, glassy) is essentially the solidification of a supercooled liquid by adjusting the composition (high concentration of cryoprotectant) and cooling rate (fast freezing protocol) such that the crystal phase is avoided. The process involves a progressive and marked increase in viscosity during cooling and

prevention of ice nucleation and growth. The system is stabilized in the glassy state as translational molecular motion is essentially halted. Vitrification eliminates the biologically damaging effects associated with freezing. No appreciable degradation occurs over time in living matter trapped within a vitreous matrix. Vitrification is potentially applicable to all biologic systems. As the major problem with the current protocols remains IIF, alternatives such as vitrifying hepatocytes are an interesting strategy for attaining the best post-thawing cell quality. Vitrification of precision cut-slices, tissue engineered pancreatic substitute, jugular veins/vessels constructs, and embryonic kidneys has already been performed, allowing the absence of ice into the vitrified samples and an excellent post-thawing quality and/or viability<sup>[110-115]</sup>.

Classically, tissues (vessels constructs and embryonic kidneys) are vitrified at cooling rates of  $> 40^{\circ}\text{C}/\text{min}$  in a specific solution, comprising DMSO, formamide and 1,2-propanediol in EuroCollins solution (VS55) or a polyethylene formulation consisting of propanediol, DMSO and polyethyleneglycol 400<sup>[110,113]</sup>. Best viability results were obtained with the VS55 solution. To obtain cooling rates of  $> 40^{\circ}\text{C}$ , tissues contained in vials, are cooled to  $-100^{\circ}\text{C}$  in an isopentane bath (conductive cooling, freezing point  $-160^{\circ}\text{C}$ ) placed in a  $-135^{\circ}\text{C}$  freezer, removed from the 2-methylbutane bath and vitrified to  $-120^{\circ}\text{C}$  in the  $-135^{\circ}\text{C}$  freezer (convective cooling).

Re-warming is performed under controlled conditions, and the chemicals removed in a stepwise manner. However de-vitrification might occur during warming from the vitrified state. To prevent de-vitrification, the vitrified material must be warmed uniformly as fast as possible [slowly re-warmed to  $-100^{\circ}\text{C}$  using convection followed by rapid re-warming achieved by placing the vial in a DMSO/H<sub>2</sub>O mixture at room temperature ( $225^{\circ}\text{C}/\text{min}$ )] so that ice does not have the opportunity to form in significant quantities.

Vitrification of encapsulated hepatocytes in M or G-collagen was recently proposed as an alternative freezing protocol<sup>[116]</sup>. Wu *et al.*<sup>[117]</sup> proposed a rapid stepwise introduction of microencapsulated hepatocytes to vitrification solution (40 % v/v ethylene glycol, 0.6 mol/L sucrose in the medium) and their direct immersion in liquid nitrogen. Using this technique, they obtained 100% retention of hepatocyte functions, correlated with excellent viability, and no detectable damage to the microcapsules. If vitrification was also proposed as successful cryopreservation protocol for isolated cells, as has been done for human amnion derived mesenchymal stem cells<sup>[118]</sup>; however, vitrification of non-encapsulated hepatocytes has not yet been studied. Therefore, further investigations are needed to confirm the potential of vitrification for LCT protocols.

### CONCLUSION

Using current protocols, C/T of hepatocytes induces cell alteration. *In vitro* functions of C/T hepatocytes remain poorer than those of freshly isolated hepatocytes, while

the efficacy *in vivo* seems to be time-limited, both in animal models and in humans. Hepatocyte mitochondria are very sensitive to C/T, with marked complex 1 activity impairment following thawing. This leads to low intracellular ATP concentration, an excellent and easily obtaining post C/T viability marker. Related cytochrome c release induces cell death within hours by apoptosis.

The IIF or exposure to hyperosmotic solutions are probably the start point of the observed damage. New adapted cryopreservation protocols have therefore to be urgently developed. Interesting perspectives such as vitrification, to avoid the crystalline state, with or without encapsulation, conferring a mechanical protection, must be validated in the future, while considering the problem of their clinical translation.

### Abstract

An emerging parameter to define the effectiveness of new therapeutic agents in clinical trials, and by extension, for use in day-to-day clinical practice has been labeled mucosal healing. It has been hypothesized that complete healing of the intestinal mucosa in inflammatory bowel diseases should result in reduced disease complications, reduced hospitalization and reduced surgical treatment. By implication, the natural history of inflammatory bowel disease might then be altered. Measurement of mucosal healing, however, is largely observational, requiring repeated invasive endoscopic examinations, sometimes with mucosal biopsies. Other indirect imaging methods may play a role in this assessment along with other surrogate markers, including intestinal permeability. These measurements may have significant limitations that prohibit precise correlation with symptom-based disease activity indices in clinical trials. This likely reflects the dynamic nature of this evolving and individualized inflammatory process that tends to be focused, but not limited, to the mucosa of the intestinal tract.

### INTRODUCTION

Ulcerative colitis and Crohn's disease are inflammatory bowel disorders; both with no known cause. Curative treatment is still needed. As such, management has focused largely on ameliorating symptoms, and reducing hospitalization and the need for surgical treatment. In clinical trials, reductions of symptom-related numerical endpoints have been used [e.g. the Crohn's Disease Activity Index (CDAI)] as evidence of treatment effectiveness and their possible role in translation to clinical practice has been discussed previously<sup>[1-5]</sup>. Another treatment goal for these diseases is improving quality of life, based upon any means that this parameter might be clinically defined or measured. Now, an emerging measurement to define the effectiveness of new therapeutic agents in clinical trials, and by extension, for use in day-to-day clinical practice has been popularly labeled "mucosal healing".

In practical terms, the assessment of mucosal healing is based largely on observational evaluation, which requires the use of repeated endoscopic studies before and after a defined treatment period, sometimes in conjunction with histological examination of mucosal biopsies, or other more indirect imaging methods, other surrogate markers or miscellaneous methods, such as measurements of intestinal permeability. Logically, however, but not yet conclusively shown, complete healing of the intestinal mucosa should result over the long term in

reduced disease complications, hospitalization and surgical treatment. This proposed hypothesis further suggests that, if mucosal healing can be induced by treatment, then hopefully, the natural course and history of the disease in an individual patient might be modified, and by implication, improved. For example, in a Norwegian study<sup>[6]</sup>, Crohn's disease or ulcerative colitis first diagnosed between 1990 and 1994 (before the use of biological agents) were examined endoscopically for up to 5 years. Mucosal healing after 1 year of treatment was reported in almost 50% of 495 treated patients that could be followed. Mucosal healing also appeared to predict reduced subsequent disease activity and a decreased need for active treatment in ulcerative colitis, but not Crohn's disease. Of note, the study also has demonstrated that other environmental factors may play an important role in mucosal healing (e.g. smoking, level of education).

## ENDOSCOPIC INDICES

Earlier historical studies from Europe remain very important. These have shown considerable variability in endoscopic changes detected by experienced observers caring for patients with inflammatory bowel disease<sup>[7]</sup>. Moreover, the correlation between the patient's clinical status and endoscopic (and histopathological) changes in the colorectal mucosa was limited<sup>[8]</sup>. Later, using more modern measurements of disease activity (e.g. CDAI), there was a poor correlation between colonoscopic (or histological) findings and indices of disease activity, which implies that these were not reliable measures of disease severity or extent<sup>[9]</sup>. Similar results have been published by French investigators in a prospective evaluation of ileocolonic and colonic Crohn's disease<sup>[10]</sup>. In a later study<sup>[11]</sup>, however, specific lesions were identified for evaluation that included: erythema, superficial and deep ulceration, stenoses and pseudopolypoid changes. Then, an index was calculated (Crohn's Disease Endoscopic Index of Severity; CDEIS), based on the percentage of involvement of different ileocolonic segments, for use in clinical trials of new therapeutic agents. A good correlation with lesion severity was reported with positive inter-observer agreement, but these investigators were very experienced and well trained for their study<sup>[11]</sup>. In routine day-to-day clinical practice, however, the reproducibility of this measurement seemed to be less helpful. As a result, other simplified endoscopic activity measures were proposed and applied in some clinical trials for Crohn's disease<sup>[12]</sup> and ulcerative colitis<sup>[13,14]</sup>. A detailed and excellent review of treatment indices, including endoscopic endpoints used in inflammatory bowel disease, specifically ulcerative colitis, has appeared elsewhere<sup>[15]</sup>.

Definition of mucosal ulcers or erosions (or their apparent complete absence as a marker of mucosal healing) has been viewed by some clinicians with skepticism, given the highly fluid and dynamic nature of the inflammatory process in inflammatory bowel disease. Also, other factors may influence endoscopic evalua-

tion, particularly for inflammatory bowel disease and its treatment (e.g. bowel preparation effects on the inflamed intestinal mucosa may differ from non-inflamed mucosa). In addition, the depth or extent of small-intestinal penetration at the time of visualization during ileocolonoscopy may not be well defined in some studies. For example, capsule endoscopy has demonstrated mucosal erosions or ulcerations distributed throughout the small intestine in Crohn's disease that are not appreciated well by other imaging modalities, including routine ileocolonoscopy<sup>[16]</sup>. Finally, a recent prospective evaluation in Crohn's disease confirmed that clinical response of the patient seemed to correlate poorly with capsule evaluation of the surface mucosa for assessment of healing<sup>[17]</sup>.

Similarly, for ulcerative colitis, few well validated and well accepted endoscopic criteria for endoscopic mucosal healing have been evaluated for clinical trials. A large degree of overlap is evident within historical definitions of mild, moderate and severe endoscopic changes and, the degree of intra- and inter-observer error has been validated poorly in clinical trials, especially in multicenter studies with multiple observers involved in the evaluation of oral, intravenous or topical treatment regimens. In contrast, some studies have reported good inter-observer agreement for some, but not all endoscopic changes in ulcerative colitis, with experienced<sup>[18]</sup> as well as well-trained observers<sup>[19]</sup>.

## HISTOPATHOLOGICAL EVALUATION

In theory, microscopic definition of the mucosa provides precise evaluation of mucosal healing in response to treatment. However, this microscopic evaluation is not only dependent on endoscopic (or macroscopic) evaluation (for selection of the biopsy site), but is also prone to the impact of pathological inter- and intra-observer error. In Crohn's disease, this may be an especially significant problem owing to the focal or segmental nature of the inflammatory process. Even in ulcerative colitis, a disorder often characterized as a continuous inflammatory process, there may be a non-uniform pattern of mucosal healing. Little information is available on the temporal resolution of the inflammatory process, but it not likely to be uniform.

Moreover, the evaluation of the depth of inflammation may also be crucial to precise monitoring of treatment response. In Crohn's disease, this transmural dimension makes complete histopathological definition virtually impossible because endoscopic biopsies provide only mucosa for pathological evaluation. After treatment, this transmural pattern in Crohn's disease may be especially difficult to evaluate since medications may not affect the inflammatory process in a consistent or uniform fashion. Even with ulcerative colitis, a process thought to demonstrate a more continuous and mucosally based pattern of inflammation, variability in the histopathological severity within the colonic mucosa occurs. More precise studies are still needed that define the

mucosal response to different forms of injury and the healing response to different forms of treatment.

## OTHER IMAGING METHODS

Invasive imaging studies, particularly repeated endoscopic studies, are normally not appealing to patients, and potentially, although rare, can still result in a procedure-related complication. Indeed, complications in patients with active inflammatory disease may exceed reported rates in otherwise healthy individuals undergoing screening procedures, and have been studied or reported poorly, particularly from treatment trials of new agents. Other less invasive approaches have often also been used in clinical practice, especially for repeated evaluations to assess the effects of therapy. These include imaging methods, such as computerized tomography (CT) and magnetic resonance imaging (MRI), usually with complete enterography. As with older barium imaging, however, there may be some inherent limitations. For example, these more modern imaging methods still have difficulty differentiating the inflammatory component of an intestinal stricture from its more established fibrotic component. CT may correlate with endoscopic evaluation for detection of ileal disease, but substantially increased radiation exposure results with repeated studies<sup>[20,21]</sup>. While both CT and MRI have limitations, multi-detector spiral CT enteroclysis may be more sensitive than MR enteroclysis for suspected bowel disease. In contrast, pelvic MRI has emerged as a standard for evaluation of perianal inflammatory disease or sepsis, particularly for fistula assessment and treatment<sup>[22]</sup>. Further correlation of these imaging modalities with other measures of intestinal healing are still needed.

## OTHER NONINVASIVE METHODS

A number of surrogate markers have been promoted, including leukocytosis, thrombocytosis and C-reactive protein levels<sup>[23,24]</sup>, but these are more clearly systemic rather than intestinal markers of the inflammatory process. Some of these markers also have been correlated with other indices. Other luminal markers, such as fecal lactoferrin or calprotectin<sup>[25]</sup>, along with functional permeability measurements are available, and may provide a potentially important option for evaluation of healing, but need further evaluation.

## TREATMENT ASSESSMENT

### Placebo response and remission

In patients with inflammatory bowel disease, spontaneous clinical improvement or remission without treatment may occur. As a result, randomized placebo-controlled trials are done to determine if the investigative agent is superior to placebo treatment. Both patient and investigator are blinded to obviate bias. Placebo-based trials usually produce a positive effect even with placebo, in

part, because of repetitive attention provided by caregivers to the trial subject. The placebo response is known to be powerful and, in a meta-analysis of placebo rates for inflammatory bowel disease clinical trials, rates up to 40% have been noted<sup>[26]</sup>. A superimposed issue in a clinical trial is the need to provide a proven form of therapy (while also testing the trial treatment). As a result, the placebo may, by necessity, be a standard therapy, not an inert treatment, while the treatment may include the standard therapy plus the trial treatment. For some medications, it may be difficult to hide the treatment because of known systemic effects (e.g. sulphasalazine or steroids). As noted elsewhere<sup>[26]</sup>, placebo remission rates may also be influenced by trial length, number of study visits, use of strict remission definitions and enrollment favoring patients with more active disease.

### Historical steroid studies

Early clinical trials with steroids have noted reduced clinical symptoms and improved appearances of the colonic mucosa<sup>[27,28]</sup>. Later trials with steroids have shifted the emphasis to the persistence of inflammatory changes, even though reduced symptoms were evident<sup>[29,30]</sup>. Unfortunately, the longer term role, if any, of steroids in mucosal healing and curbing the inflammatory process is understood poorly. In clinical practice, physicians limit the duration and dosage of systemic corticosteroids and taper these rapidly within weeks. This may not permit sufficient time for steroids to cause complete restitution of the mucosal surface. In a pooled treatment analysis of a first-pass metabolized steroid, budesonide, mucosal healing was reported to be limited in Crohn's disease after 1 year<sup>[31]</sup>. Budesonide, however, differs substantially in its chemical structure, metabolism and other properties from other steroids, therefore, generalization to other steroids may be premature. Some have hypothesized that steroids *per se* might be potentially deleterious to the mucosal healing process<sup>[32]</sup>, but there is no evidence to support this view. It is possible that the observed healing effects of steroids only reflect the clinical tendency to minimize duration and dosage of systemic steroids because of fear of potential side effects.

### Studies with other agents

Other agents used to treat inflammatory bowel disease, recently summarized in detail elsewhere for ulcerative colitis<sup>[33]</sup>, also have been reported to cause endoscopic mucosal healing. These include 5-aminosalicylates, including a modernized formulation MMX mesalazine<sup>[34,35]</sup>, immunosuppressant agents in Crohn's disease, such as azathioprine and methotrexate<sup>[36-40]</sup>, antibiotics<sup>[41,42]</sup>, and even prolonged courses of anti-mycobacterial treatment in Crohn's disease<sup>[43]</sup>. Similarly, biological agents are now being evaluated and mucosal healing has been reported as an important endpoint of treatment in the clinical trials<sup>[44-46]</sup>. Most of these studies, along with initial reports of other biological agents, have been conducted over only limited time frames, relative to the

natural duration of the disease, so positive and negative effects over the long term are not evident. In a recent report from a cohort in a treatment trial that has compared infliximab and azathioprine to conventional therapy with steroids, complete mucosal healing, defined as a simple endoscopic score<sup>[12]</sup> of 0 after 2 years of treatment predicted a sustained remission 3 and 4 years after therapy in > 70% of patients, compared to almost 30% of those with endoscopic lesions<sup>[47]</sup>. Of note, the authors also have concluded that achieving mucosal healing (defined by endoscopy) was the sole determining predicting factor and not the treatment *per se*.

## FUTURE DIRECTIONS

A number of issues need to be addressed carefully in the near future. Therapeutic trials of differing pharmacological and biological agents in inflammatory bowel disease have shown that mucosal healing may occur with most of the traditional drugs, as well as the emerging biological agents, to a greater or lesser degree, but correlation with the patient's symptoms or other measures of disease activity appear to be limited. The current technology to assess mucosal healing in clinical trials and clinical practice remains limited, tends to be observational, and is not ideal because it does not evaluate transmural inflammation precisely, only the luminal surface mucosa. Repeated invasive endoscopic evaluations may not be optimal, particularly since these are largely one-dimensional. Possibly, this will be improved with the future evolution of confocal endoscopy. The inflammatory process is not a static target and the measured impact of one or the other agent may reflect, in part, this fluidity of the inflammatory process *per se*. As a result, assessing the longer-term effects of old and emerging agents is needed urgently, but may also prove to be particularly challenging. Genome-wide expression differences have been defined using endoscopic pinch biopsies in both ulcerative colitis and Crohn's disease<sup>[48]</sup>. These ultimately may provide a means for selecting individuals with either ulcerative colitis or Crohn's disease that might be managed optimally with a specific therapy, because multiple genes appear to be involved<sup>[49]</sup>. New studies have appeared employing microarray technology in animal and human colitis, which have increased our understanding of the basic inflammatory process, along with possible mediators that might be regulated<sup>[50-53]</sup>. Indeed, very recent genome-wide association studies in ulcerative colitis have identified new susceptibility loci that suggest that changes in the integrity of the mucosal barrier are important in pathogenesis<sup>[54]</sup>. By recognizing the limitations of current methodology used in clinical trials to assess mucosal healing, the modern day clinician will still have to rely on his or her clinical evaluation and best judgment whenever a new treatment paradigm is contemplated, or a change or cessation in therapy is indicated. Fortunately, however, emerging gene-based technology is likely to lead to better end points for more precise assessment of available treatments.

### Abstract

**AIM:** To investigate possible differences in dendritic cells (DC) within intestinal tissue of mice before and after induction of colitis.

**METHODS:** Mucosal DC derived from intestinal tissue, as well as from mesenteric lymph nodes and spleen, were analyzed by fluorescence activated cell sorting (FACS) analysis. Supernatants of these cells were analyzed for secretion of different pro- and anti-inflammatory cytokines. Immunohistochemistry and immunofluorescence were performed on cryosections of mucosal tissue derived from animals with colitis as well as from healthy mice.

**RESULTS:** It was shown that DC derived from healthy intestinal lamina propria (LP) represented an immature phenotype as characterized by low-level expression of costimulatory cytokines. In contrast to DC from spleen and mesenteric lymph nodes (MLN) that secreted pro-inflammatory cytokines, LP-DC produced high levels of the anti-inflammatory cytokine IL-10. After induction of mu-

rine colitis in a CD4<sup>+</sup>CD62L<sup>+</sup> transfer model or in chronic Dextran sulfate sodium-colitis, a marked increase of activated CD80<sup>+</sup> DC could be observed within the inflamed colonic tissue. Interestingly, in contrast to splenic DC, a significant population of DC within MLN and colonic LP expressed the mucosal integrin CD103 which was lost during colitis.

**CONCLUSION:** The constitutive secretion of anti-inflammatory cytokines by immature DC within the intestinal LP might regulate the homeostatic balance between mucosal immunity and tolerance. CD103<sup>+</sup> DC could mediate this important function.

Loss of CD103<sup>+</sup> intestinal dendritic cells during colonic inflammation. *World J Gastroenterol* 2010; 16(1): 21-29 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i1/21.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i1.21>

### INTRODUCTION

The intestinal mucosa is continuously challenged by innocuous antigens and potentially harmful pathogens. Therefore, the local immune system has to mount an efficient response towards pathogenic bacteria but must keep the immunological balance during exposure to commensal antigens. Dendritic cells (DC) are most likely

involved within this dual functionality. However, so far only limited data are available regarding intestinal DC (reviewed in<sup>[1,2]</sup>). Mucosal DC are not only found within Peyer's patches (PP) and mesenteric lymph nodes (MLN) but are also located within smaller isolated lymphoid follicles and within the lamina propria, distributed throughout the wall of the small and large intestine<sup>[3-5]</sup>. Unusual phenotypic subsets of DC have been described within MLN and PP<sup>[6-9]</sup> that preferentially stimulate antigen-specific CD4<sup>+</sup> T cells to produce IL-10 and/or TGF- $\beta$ <sup>[9,10]</sup>. This cytokine pattern is similar to that of TR<sub>1</sub> or TH<sub>3</sub> regulatory T cells which have been identified in gut-associated lymphoid tissue of mice fed tolerogenic doses of proteins, and are thought to play an important role in oral tolerance<sup>[11]</sup>.

Considerably more is known about DC in PP and MLN than about DC within the lamina propria of the gut. However, these cells are ideally situated to pick up any material that is transported between or through epithelial cells and have been shown to sample luminal antigens directly by sending dendrites outside the epithelium<sup>[12]</sup>. It is thought that DC as mobile cells migrate to MLN after antigen-uptake and interact with naïve T cells mainly within lymphatic organs, rather than in the mucosa itself. This rapid and constitutive trafficking of DC from lamina propria to MLN is increased by the presence of inflammatory stimuli<sup>[13]</sup>. As shown recently, interaction of mucosal DC with T cells generates gut-tropic CD8<sup>+</sup> effector T cells that express CCR9 and  $\alpha$  $\beta$ <sup>[14]</sup>. Additionally, DC expressing the mucosal integrin CD103 promote the development of regulatory Foxp3<sup>+</sup> T cells through a TGF- $\beta$  and retinoic acid-dependent mechanism<sup>[15]</sup>. Together, these findings indicate that lamina propria DC (LP-DC) might be more important for the surveillance of the intestinal milieu and the shaping of intestinal immune responses than previously thought.

Animal model systems of colitis have been used extensively in an effort to determine possible mechanisms that contribute to the initiation and perpetuation of colitis in humans<sup>[16]</sup>. One model in particular which has been well characterized involves the transfer of CD4<sup>+</sup>CD45RB<sup>hi</sup> T cells. Here, transfer of naïve (CD4<sup>+</sup>CD45RB<sup>hi</sup> or CD4<sup>+</sup>CD62L<sup>+</sup>) T cells into immunodeficient SCID mice induces chronic intestinal inflammation<sup>[17,18]</sup>. Key factors that drive the pathogenic TH<sub>1</sub>-biased mucosal T cell responses within this model are still unknown<sup>[19]</sup>. However, as described for various other experimental colitis models<sup>[20-25]</sup>, antigen presentation of bacterial antigens plays a role, as only mild colitis develops when lymphocytes are transferred into animals with a restricted enteric flora and no intestinal inflammation is observed after transfer into germ-free mice<sup>[26]</sup>. Additionally, intestinal bacterial antigens and their presentation were shown to be crucial for the generation and expansion of regulatory T cells in a healthy individual<sup>[18]</sup>, and disruption of the interaction of mucosal DC with activated T lymphocytes by administration of a receptor-blocking antibody against OX40L was shown to ameliorate colitis<sup>[27]</sup>. Overall, the data indicate that antigen presentation, presumably *via* mucosal DC, plays a role in the pathogenesis of chronic intestinal inflammation. However, the properties of these

cells during intestinal inflammation are only beginning to be explored.

The aim of our study was to investigate differences between intestinal DC populations under healthy conditions and after induction of colitis.

## MATERIALS AND METHODS

### Mice

Balb/c mice and *scid* mice (C.B.-17 SCID) (H2<sup>d</sup>) were obtained from Charles River (Germany). Animals were housed under conventional animal facility conditions and were generally used at 6-8 wk of age weighing 20-22 g. The animal studies were approved by the local institutional Review Board.

### Monoclonal antibodies

The following experimental monoclonal antibodies (mAbs) were purchased from BD Pharmingen (Heidelberg, Germany): anti-CD8, anti-MHC-II, anti-B220, anti-CD11b, anti-CD3, anti-CD11c, anti-CD80, anti-CD86, anti-CD40, anti-CD103 ( $\alpha$ E $\beta$ 7), anti-CD16/CD32. Directly PE- or FITC-conjugated mAbs were used for FACS analysis. For immunofluorescent staining directly FITC-conjugated anti-CD103 mAb was used in addition to Alexa 546-conjugated tyramide (Invitrogen, Germany).

### Isolation of primary dendritic cells

DC were isolated from spleen, MLN and intestinal lamina propria by enzymatic digestion of tissue using collagenase I (Worthington, UK), hyaluronidase and DNase I (both from Sigma-Aldrich, Germany) followed by immunomagnetic selection with anti-CD11c coated microbeads (Miltenyi Biotech, Germany). For intestinal DC, mononuclear lamina propria cells were isolated from digested tissue as described previously<sup>[28]</sup>, followed by enrichment of CD11c<sup>+</sup> DC using microbeads. Purity was generally > 85%. Routinely, isolated cells were stained for contaminating T cells and B cells, however virtually no cells could be detected by FACS analysis in the DC preparations.

### Colitis models

We adapted a previously described transfer model that resembles the CD4<sup>+</sup>CD45RB<sup>high</sup> model and uses the expression of L-selectin (CD62L) to select for naïve splenic T lymphocytes<sup>[18]</sup>. Briefly, CD4<sup>+</sup> T cells were purified from spleen mononuclear cells of healthy mice by negative depletion of other cell types using anti-CD8, anti-MHC-II, anti-B220 and anti-CD11b mAbs and anti-rat-IgG immunomagnetic microbeads (Miltenyi Biotech, Bergisch Gladbach, Germany). The resulting CD4<sup>+</sup> lymphocytes were separated further into CD62L<sup>+</sup> and CD62L<sup>-</sup> T cells by CD62L-conjugated microbeads (Miltenyi Biotech). Recipient SCID mice were reconstituted with  $0.25 \times 10^6$  CD4<sup>+</sup>CD62L<sup>+</sup> lymphocytes in 200  $\mu$ L of sterile PBS by intraperitoneal injection. Colitis activity was monitored by changes in weight over time and by histological analysis.

For chronic DSS-colitis, dextran sodium sulfate

(DSS; MW 40000) was purchased from ICN (Eschwege, Germany) and intestinal inflammation was induced by feeding 3% DSS over 7 d followed by a period of 10 d of water without DSS. Mice received 4 cycles of DSS treatment and animals were sacrificed on day 8 after completion of the 4th cycle<sup>[29]</sup>.

### Cytokine ELISA

Dendritic cells from different organs were isolated as described above and  $2 \times 10^5$  cells/well were incubated in 200  $\mu$ L complete medium (RPMI-1640, 10% FCS, 100 U/mL penicillin, 100  $\mu$ g/mL streptomycin, all from GIBCO-BRL, Eggenstein, Germany; and  $3 \times 10^{-5}$  mol/L  $\beta$ -mercaptoethanol, Sigma) for 24 h. Cells were partly stimulated with 5  $\mu$ g/mL CpG-ODN (Metabion, Martinsried, Germany) or with 1  $\mu$ g/mL *Salmonella typhimurium*-derived lipopolysaccharide (LPS) (Sigma, Deisenhofen, Germany). Cytokine levels were measured in the supernatant by ELISA (all from Endogene, Woburn, MA, USA), according to the manufacturer's instructions.

### FACS analysis

Samples were analyzed using two-color staining as described previously<sup>[18]</sup>. Briefly, isolated DC were preincubated with 20  $\mu$ g/mL of anti-CD16/CD32 and 10% FCS to block Fc-Receptors and stained with both FITC- and PE-conjugated mAbs. The cells were washed and analyzed by FACS using an EPICS-XL MCL Coulter.

### Immunohistochemistry and immunofluorescence

Tissue samples were snap-frozen in liquid nitrogen, embedded in OCT resin and 5 to 10- $\mu$ m cryostat-sections cut. For immunohistochemistry, primary antibody application was followed by biotinylated polyclonal anti-rat IgG or anti-hamster IgG (both Dianova, Germany) as secondary antibody. Tissue was stained using the ABC (avidin/biotin complex)-immunoperoxidase kit according to the manufacturer's instructions (Vector Laboratories) and developed with AEC. Sections were counterstained with hematoxylin. For immunofluorescence, sections were incubated with APC-conjugated anti-CD11c and with FITC-labeled anti-CD103 mAbs. The anti-CD11c mAb was visualized by applying horseradish peroxidase-labeled streptavidin followed by Alexa 546-conjugated tyramide, according to the manufacturer's recommendations (Invitrogen, Germany). Slides were counterstained with DAPI.

### Statistical analysis

Statistical analysis was performed using the two-tailed Mann-Whitney *U* test. Differences were considered statistically significant when  $P < 0.05$ .

## RESULTS

### **DC within the healthy intestinal lamina propria show an immature phenotype and produce constitutively the anti-inflammatory cytokine IL-10**

CD11c<sup>+</sup> DC are found within the lamina propria (LP) of

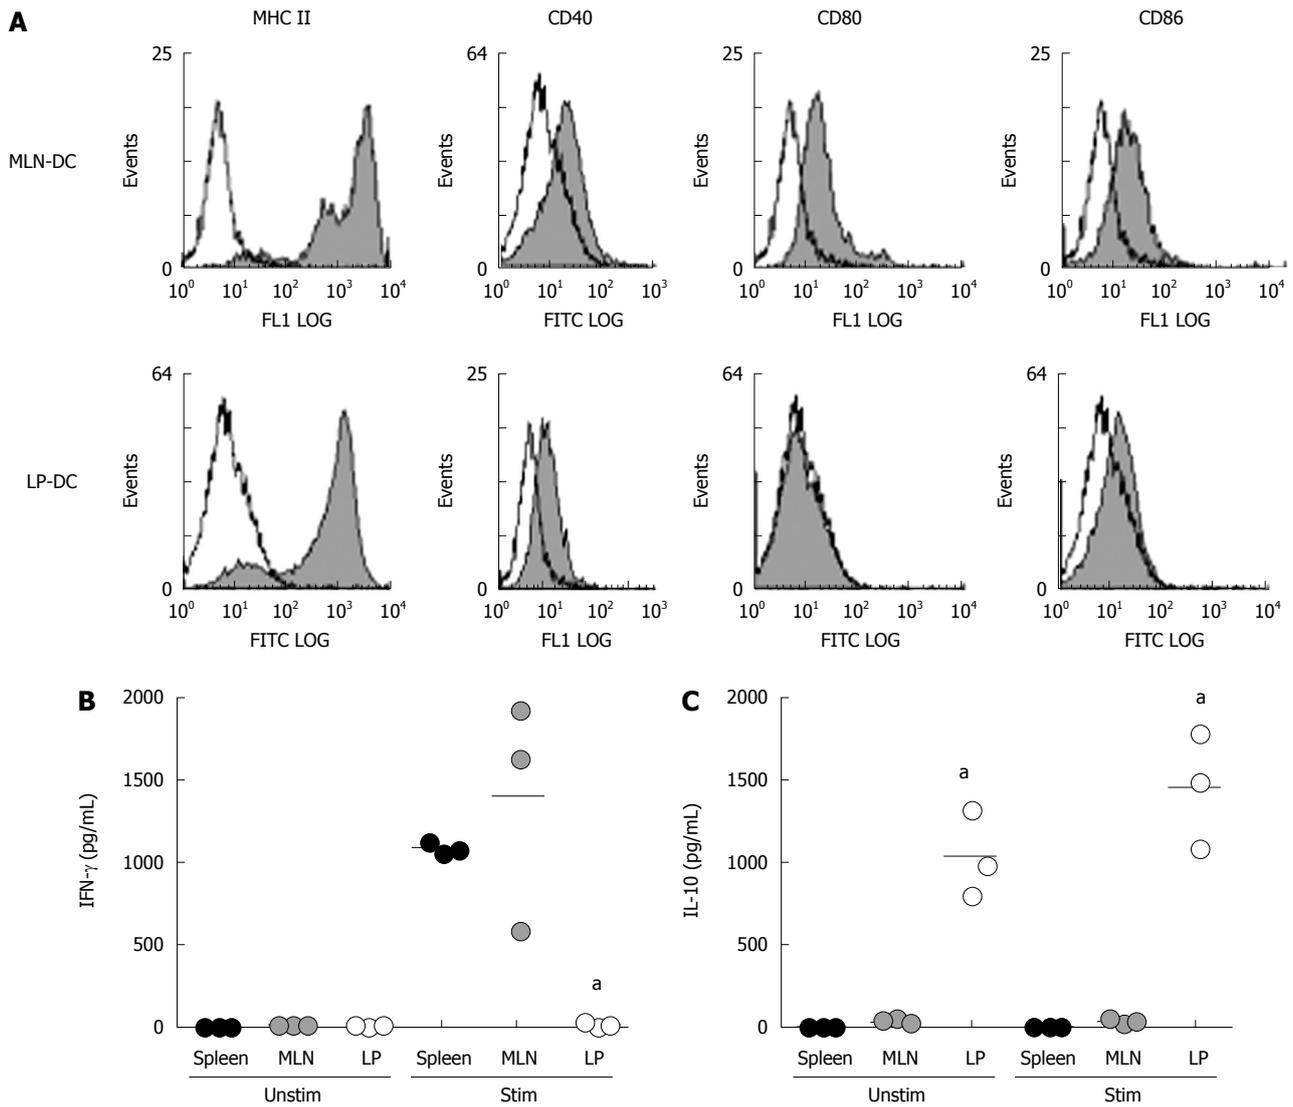

the small and large intestine of healthy mice. Whereas a dense network of cells underlining the epithelium can be detected by immunohistochemistry within the mucosa of the small intestine, only a few scattered cells are found within the colonic LP. To compare the phenotype of DC derived from colonic LP and mesenteric lymph nodes (MLN), CD11c<sup>+</sup> DC were isolated from intestinal tissue and MLN of healthy mice. As demonstrated in Figure 1A, no significant levels of costimulatory molecules (CD40, CD80 and CD86) could be detected on the cell surface of freshly isolated DC from the intestinal LP or MLN. This suggests that DC within mucosal tissues demonstrate a rather immature phenotype as compared to splenic DC which show low levels of costimulatory molecules (data not shown). Additionally, isolated primary DC were incubated either unstimulated or in the presence of CpG and secretion of cytokines was detected by ELISA. As shown, MLN-DC and splenic DC differed markedly from LP-DC with regard to their cytokine profile. Unstimulated MLN-DC or splenic DC did not secrete significant amounts of pro- or anti-inflammatory cytokines, however, LP-DC dramatically produced 30-fold higher levels of the anti-inflammatory cytokine IL-10 (MLN-DC:  $35.4 \pm 5.0$ ; splenic-DC:  $12.8 \pm 0.7$ , LP-DC:  $1035 \pm 270$  pg/mL,  $P = 0.0235$ , Figure 1B). In contrast, large amounts of IFN- $\gamma$  and IL-12 were secreted by MLN-DC and splenic-DC after stimulation with CpG, whereas LP-DC did not produce significant amounts of proinflammatory cytokines (MLN-DC:  $1398 \pm 407$ , splenic-DC:  $1087 \pm 30$ , LP-DC:  $24 \pm 11$  pg/mL,  $P = 0.0009$ ). The differences seen were independent from the stimulatory agent used as similar results were detected by using LPS to stimulate primary DC.

### **Diffuse infiltration of intestinal lamina propria with CD11c<sup>+</sup> DC during colitis**

As shown in Figure 2A, CD11c<sup>+</sup> DC were diffusely distributed throughout the non-inflamed colonic LP and were rarely detected in the submucosa. Chronic colitis was either induced by adoptive transfer of splenic CD4<sup>+</sup>CD62L<sup>+</sup> T lymphocytes from donor mice into immunodeficient SCID recipients or by cyclic administration of DSS in the drinking water of animals<sup>[18,29]</sup>. As analyzed by immunohistochemistry using an anti-CD11c antibody in both models of colitis, a dramatic increase in numbers of CD11c<sup>+</sup> DC could be detected within the inflamed mucosa of the colon of mice (Figure 2B). MLN of mice with colitis showed a slight increase in the number of DC (Figure 2C and D), whereas no changes in infiltrating DC were seen in Peyer's patches and the spleen (data not shown).

### **Infiltrating LP-DC in inflamed colonic tissue show a mature phenotype with high expression of CD80 cells and secretion of the regulatory cytokine IFN- $\alpha$ is decreased**

As shown above, mucosal DC in healthy tissue are immature. To investigate whether infiltrating CD11c<sup>+</sup> DC within the inflamed colon show an activated phenotype,

**Figure 1 Phenotypic and functional analysis of DC derived from MLN and LP of healthy mice.** A: Primary DC were isolated from MLN (MLN-DC) and colonic LP (LP-DC) of healthy mice. CD11c<sup>+</sup> DC were stained with FITC-conjugated mAbs for expression of MHC-class II and the costimulatory molecules CD40, CD80 and CD86; B: Isolated DC from spleen, MLN and LP were incubated for 24 h in complete medium partly stimulated with 5  $\mu$ g/mL CpG (5 wells per situation). Cytokine levels were measured within the supernatant by ELISA. <sup>a</sup>*P* < 0.05. Data presented are representative of three independent experiments.

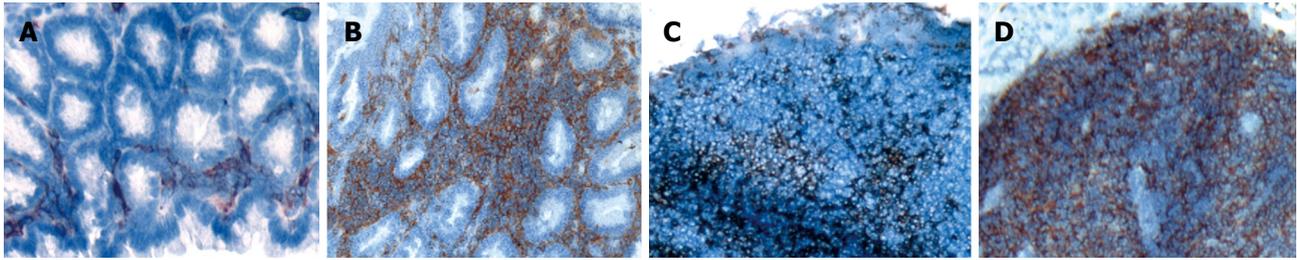

tissue sections were stained for the expression of costimulatory molecules. As demonstrated in Figure 3A, we were able to detect dramatically increased numbers of CD80<sup>+</sup> DC within the colonic LP as compared to healthy mucosa. On the other hand, no significant numbers of CD40<sup>+</sup> and CD86<sup>+</sup> cells were detected. We confirmed the results by FACS analysis after isolation of primary DC from inflamed tissue, demonstrating that LP-DC indeed showed increased cell-surface levels of CD80, whereas no difference in expression of CD40 and CD86 could be observed (Figure 3B).

To investigate whether the cytokine profile of isolated DC from different tissues was changed in animals with colitis we measured the cytokine secretion of primary DC. Secretion of IL-10 by LP-DC was reduced to only 27% of the amount secreted by LP-DC from healthy intestine (colitic LP-DC: 277  $\pm$  27, healthy LP-DC: 1035  $\pm$  270 pg/mL) (data not shown). Additionally,

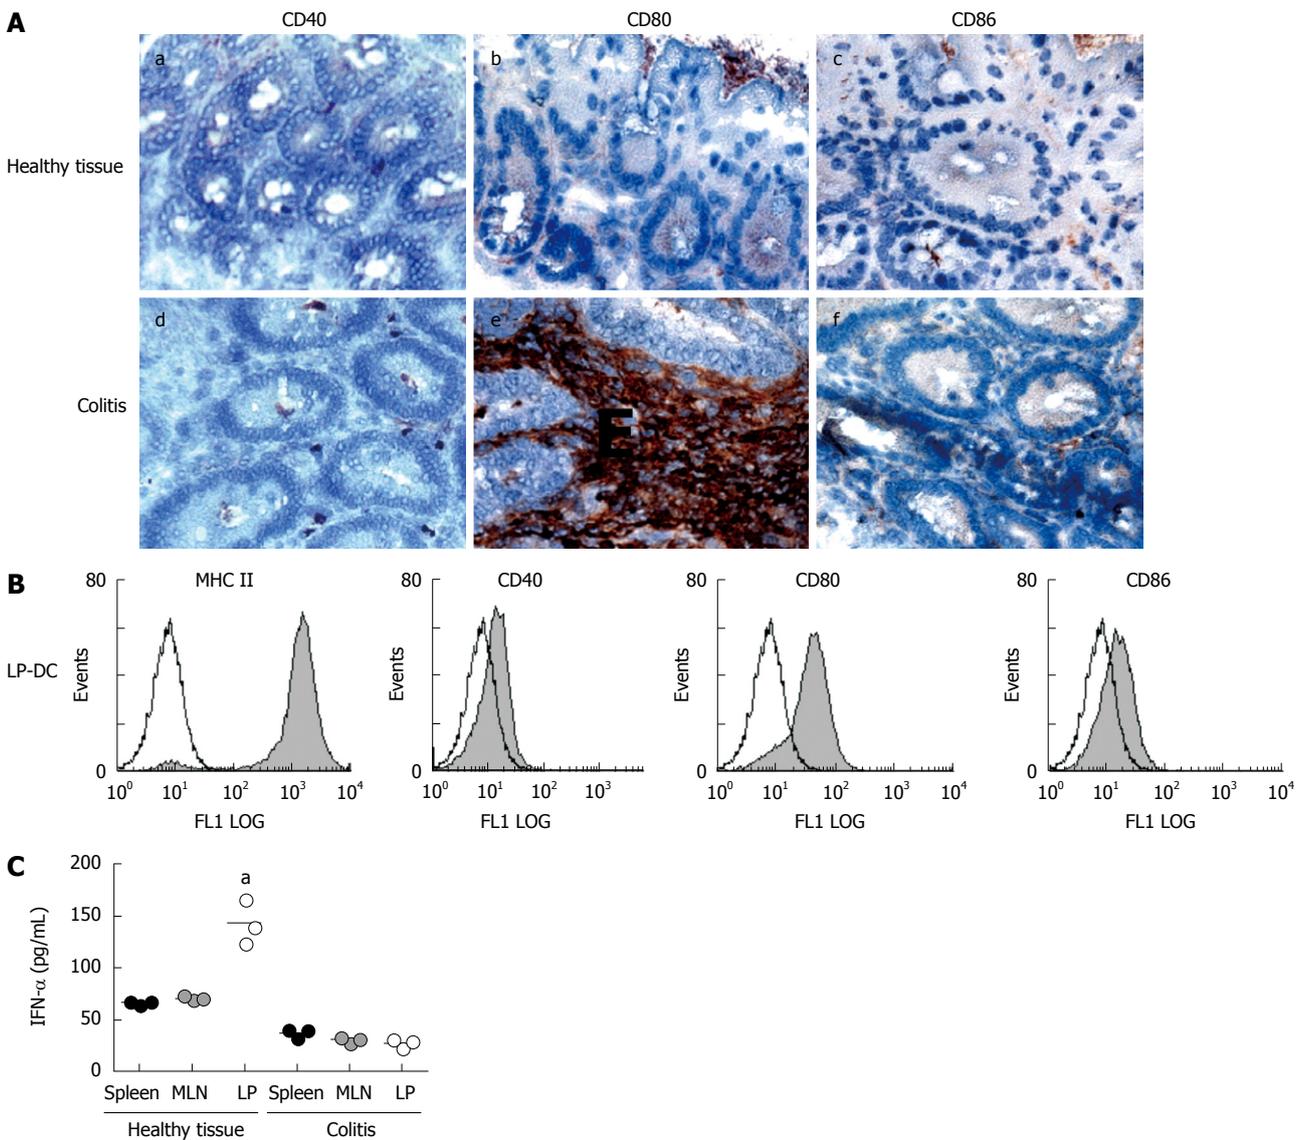

whereas LP-DC from normal colon did not secrete any proinflammatory cytokines as demonstrated above, DC from inflamed intestine were able to produce significant amounts of IFN- $\gamma$  (397  $\pm$  163 pg/mL) and TNF- $\alpha$  (650  $\pm$  91 pg/mL) (data not shown). Furthermore, IFN- $\alpha$ , a cytokine attributed to plasmacytoid DC with regulatory function, was secreted to a greater extent by LP-DC from healthy mice as compared to splenic or MLN-DC which produced distinctly lower amounts of this cytokines (LP-DC: 143  $\pm$  12, MLN-DC: 71  $\pm$  2, splenic-DC: 67  $\pm$  2 pg/mL, *P* = 0.0242). However, during colitis, production of IFN- $\alpha$  by LP-DC was significantly reduced to 19.6% (Figure 3C, colitic LP-DC: 28  $\pm$  4 pg/mL, *P* = 0.0111).

**Numbers of CD103<sup>+</sup> intestinal DC are dramatically reduced in colitic mice**

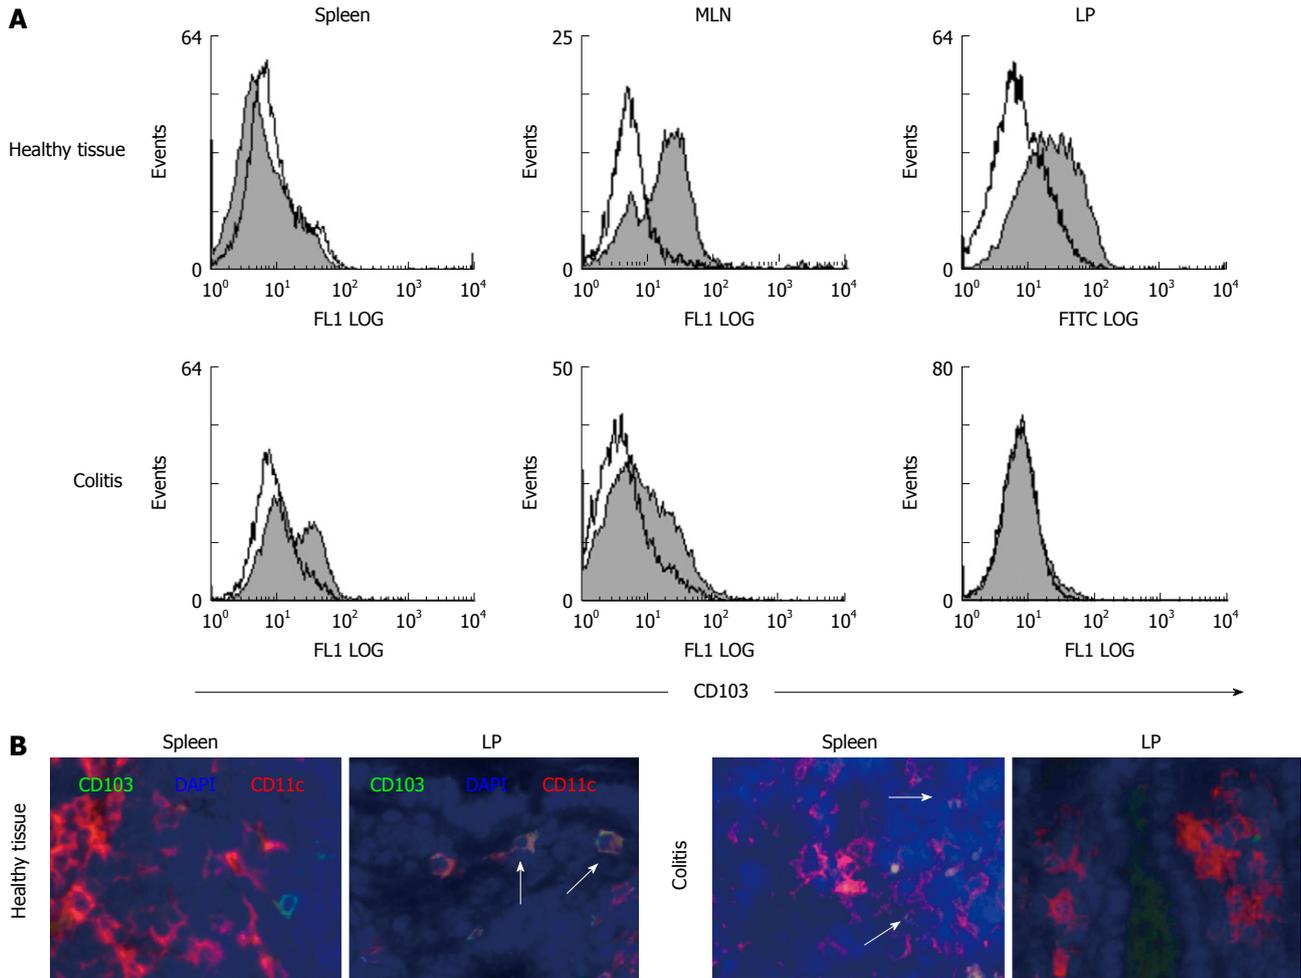

The mucosal integrin  $\alpha$ E $\beta$ 7 (CD103) is expressed on the cell surface of intraepithelial lymphocytes and mediates

**Figure 2 Inflammation induces infiltration of colonic LP and MLN with CD11c<sup>+</sup> DC.** Tissue was harvested from colonic LP (A/B) and MLN (C/D) of healthy animals (A/C) and mice with colitis (B/D). Immunohistochemistry was performed using an anti-CD11c<sup>+</sup> antibody to stain for intestinal DC. Staining with isotype control revealed no background staining (data not shown). Representative sections from 5 mice per group are shown (magnification 100 ×). Staining was performed on tissue derived from colitic animals with transfer colitis as well as chronic DSS colitis and revealed similar results. Sections shown within this figure are derived from animals with transfer colitis.

**Figure 3 Intestinal DC are activated after induction of colitis.** A: Tissue was harvested from LP of healthy animals and from mice with colitis. Immunohistochemistry was performed with antibodies against the following costimulatory molecules: CD40 (a/d), CD80 (b/e), CD86 (c/f). Representative sections are shown (magnification 100 ×). Experiments were performed from 5 animals each group. Sections shown within this figure are derived from animals with transfer colitis, however staining was also performed on tissues derived from colitic animals with chronic DSS colitis and revealed similar results; B: LP-DC were isolated from inflamed intestinal tissue and FACS analysis was performed. CD11c<sup>+</sup> DC were stained with FITC-conjugated mAbs for expression of MHC-class II and the costimulatory molecules CD40, CD80 and CD86. Data presented are representative of three independent experiments performed with cells derived from animals with transfer colitis. Similar results were generated in the DSS colitis model; C: Primary DC were isolated from different tissues (spleen, MLN, colonic LP) of healthy animals and mice with colitis. Isolated DC were incubated for 24 h in complete medium and levels of IFN-α were measured within the supernatants by ELISA (5 wells per situation). \**P* < 0.05. Data presented are from one of three independent experiments performed with cells derived from animals with transfer colitis. Similar results were generated in the DSS colitis model.

**Figure 4** CD103<sup>+</sup> DC are found in mucosal tissues of healthy mice and are lost during colitis. **A:** Primary DC were isolated from different tissues (spleen, MLN, colonic LP) of healthy animals and mice with colitis. FACS analysis was performed after staining of CD11c<sup>+</sup> DC with FITC-conjugated mAb against CD103, the integrin  $\alpha\epsilon\beta7$ . Data presented are representative of three independent experiments that were carried out with cells derived from animals with transfer colitis. Similar results were generated in the DSS colitis model; **B:** Tissue was harvested from spleen and LP of healthy animals and mice with colitis. Immunofluorescence was performed using an anti-CD11c<sup>+</sup> mAb to stain for intestinal DC and an anti-CD103 mAb to recognize the integrin  $\alpha\epsilon\beta7$ . DAPI was used to visualize nuclei. Images show overlays of CD103 (green), CD11c (red) and DAPI (blue). DC coexpressing CD103 appear yellow (indicated by arrows). Representative sections from 5 mice per group are shown (magnification 100  $\times$ ). Staining was performed on tissue derived from colitic animals with transfer colitis as well as chronic DSS colitis and revealed similar results. Sections shown within this figure are derived from animals with transfer colitis.

adhesion to epithelial cells *via* binding to E-cadherin<sup>[30]</sup>. Recently, it was shown that expression of CD103 characterizes an important subset of regulatory T cells<sup>[31]</sup>. Additionally, CD103<sup>+</sup> mucosal DC were suggested to play an important role for the generation of Foxp3<sup>+</sup> T lymphocytes within the gut<sup>[15]</sup>. As this integrin seems to play a role in regulatory immunological functions, especially in mucosal sites, we wanted to investigate whether CD103<sup>+</sup> intestinal DC change during intestinal inflammation. As demonstrated in Figure 4, freshly isolated DC from healthy spleen did not contain a significant population of CD103<sup>+</sup> DC. However, this was very different in mucosal sites of healthy animals. Here, a large subpopulation of MLN-DC expressed the integrin  $\alpha\epsilon\beta7$  and even more strikingly, almost all LP-DC showed at least low levels of CD103 expression on the cell surface, demonstrating that LP-DC from healthy mucosa did not only differ dramatically in their cytokine secretion potential but also in their phenotype from DC

at peripheral sites. However, when we looked for CD103 expression on DC isolated from animals with colitis we observed a dramatic loss of this population in mucosal tissues. Within the chronically inflamed colonic LP, no CD103<sup>+</sup> DC were seen as demonstrated by FACS analysis, and numbers of integrin-positive DC in MLN were dramatically reduced. In contrast, we detected a significant subpopulation of CD103<sup>+</sup> DC within the spleen of colitic animals (Figure 4).

## DISCUSSION

Antigen-presenting cells are the key to maintaining the immunological balance between active immune responses and tolerance within the intestine and DC are most likely to participate importantly in this immunological homeostasis within the gut. However, data has recently started to be available regarding intestinal DC in normal and inflamed colon. Comparing DC populations from

different tissues we were able to demonstrate that mucosal DC represent an immature phenotype as characterized by the absence of CD40, CD80 and CD86 expression. Whereas CD80 was found in low levels on the cell surface of MLN-DC, the molecule was absent on LP-DC, indicating that LP-DC represent an even more immature phenotype than MLN-DC. It is thought that DC can be divided into tolerogenic immature and immunogenic mature differentiation stages<sup>[32]</sup>, as tolerance is mediated by partial- or semi-matured DC, whereas only full DC maturation is immunogenic<sup>[1,2,33]</sup>. Therefore, our observation of phenotypically immature (or semi-mature) LP-DC within the healthy gut supports the hypothesis that intestinal DC, which sample antigens without being fully activated, induce tolerance against antigens of the regular gut flora. Additionally, we were able to show that DC from spleen and MLN secrete proinflammatory cytokines such as IFN- $\gamma$  and IL-12 in response to the different strong inflammatory stimuli, CpG and LPS. In contrast, intestinal-derived CD11c<sup>+</sup> DC constitutively produced high levels of the anti-inflammatory cytokine IL-10 and did not release significant amounts of proinflammatory mediators after stimulation. As shown previously, pulmonary DC - situated within a mucosa that is similar to the intestine exposed to antigens - produce IL-10 in response to inhalative antigens and induce the development of regulatory T cells<sup>[34]</sup>. Therefore, it can be speculated that constitutive production of the anti-inflammatory cytokine IL-10 by LP-DC is also critical for the generation of regulatory T cells and the maintenance of tolerance towards luminal antigens within the normal gut.

However, during intestinal inflammation the cellular composition within the colonic lamina propria changes. As shown, gut inflammation in different murine models of colitis was accompanied by a marked infiltration of the colonic mucosa by CD11c<sup>+</sup> DC. LP-DC derived from the inflamed mucosa expressed high levels of CD80, a cell surface molecule thought to be involved with induction of TH<sub>1</sub> responses<sup>[35,36]</sup>, and cells resembled a phenotype of mature activated DC. Additionally, these cells produced dramatically lower levels of IL-10 and INF- $\alpha$ , cytokines necessary for anti-inflammatory responses<sup>[37]</sup>. Our observation is in concordance with a recent study that also demonstrated expansion of colonic LP-DC during murine colitis<sup>[5,38]</sup> and other data that showed up-regulated expression of activation markers on DC in diseased mucosal tissues from patients with inflammatory bowel disease<sup>[39]</sup>. It is likely that the infiltration of the intestinal mucosa with mature DC during intestinal inflammation leads to a continuous activation of T lymphocytes and a sustained overproduction of proinflammatory mediators within the lamina propria, which perpetuates colitis.

Additionally, we were able to show that LP-DC from normal colonic mucosa and MLN-DC contain a significant subpopulation of CD103<sup>+</sup> ( $\alpha\text{E}\beta\text{7}$ ) DC, whereas splenic-DC were negative for the mucosal adhesion molecule. This observation suggests the localization of specific DC subpopulations within the intestinal lamina

propria. So far, it is known that intraepithelial lymphocytes express the integrin  $\alpha\text{E}\beta\text{7}$  which interacts with epithelial E-cadherin and is thought to mediate localization of T cells within the epithelial layer<sup>[30]</sup>. Additionally, it seems to characterize a specific subgroup of lymphocytes with regulatory function<sup>[31]</sup> and a recent study was able to show that CD103<sup>+</sup> DC promote expression of the gut-homing receptor CCR9 on T cells<sup>[14,40]</sup>, as well as generation of Foxp3<sup>+</sup> T lymphocytes with TGF- $\beta$  and retinoic-acid as cofactors<sup>[15]</sup>. Because in our study almost all intestinal LP-DC within the healthy mucosa express this integrin and show a tolerogenic phenotype and function, we hypothesize that CD103 mediates homing for tolerogenic DC into the intestinal mucosa or enables as adhesion molecule the crosstalk with other lamina propria cells, thereby influencing the balance between effector and regulatory T cell activity in the intestine. As we were not able to identify the CD103<sup>+</sup> LP-DC during colitis when tolerance is lost, this subgroup of DC could help to maintain the immunological balance within the normal intestinal mucosa. Surprisingly, during inflammation, CD103<sup>+</sup> DC were found within the spleen, suggesting that intestinal CD103<sup>+</sup> DC might migrate to systemic lymphatic tissues.

Overall, our results indicate that the specific localization of particular CD103<sup>+</sup> DC subpopulations within the intestinal mucosa may be an important mechanism of the immune system to determine between active immune responses and tolerance towards luminal antigens. Additionally, the constitutive secretion of anti-inflammatory cytokines by intestinal DC might regulate the homeostatic balance under healthy conditions. After induction of colitis, loss of CD103<sup>+</sup> intestinal DC and infiltration of mature DC that express the costimulatory molecule CD80 within the colonic mucosa would lead to a dysregulation of this balance. Antigen presentation *via* activated DC could be involved in the onset or/and chronification of colitis. Interrupting the activation of intestinal DC *in vivo* and promoting the preservation of presumably tolerogenic CD103<sup>+</sup> DC within the colonic mucosa may be key approaches to control the pathogenesis of inflammatory bowel disease.

## COMMENTS

### Background

Within the gut mucosa the immune system has the task of distinguishing between commensal bacteria and foreign antigens, to maintain tolerance or to mount an inflammatory response. Dendritic cells are very important for this process. However, even if in the last few years some important insights have been made, much still is unknown about these cells, especially about the changes they undergo during intestinal inflammation.

### Research frontiers

Previous data indicate that antigen presentation, presumably *via* mucosal dendritic cells, plays a role in the pathogenesis of chronic intestinal inflammation. However, the properties of these cells during intestinal inflammation are only beginning to be explored.

### Innovations and breakthroughs

Dendritic cells in normal intestinal lamina propria showed an immature phenotype and produced high levels of the anti-inflammatory cytokine IL-10 whereas

dendritic cells in the spleen and local lymph nodes secreted the proinflammatory cytokine IFN- $\gamma$ . Furthermore, the studies in mouse models of colitis showed that the development of colitis was associated with a marked increase of activated dendritic cells within the inflamed colonic tissue and the loss of CD103<sup>+</sup> dendritic cells in the colonic mucosa and local lymph nodes but not in spleen, suggesting that CD103<sup>+</sup> dendritic cells could play important roles in the regulation of homeostatic balance between mucosal immunity and tolerance in the gastrointestinal tract.

### Applications

Overall, these results indicate that the specific localization of particular CD103<sup>+</sup> dendritic cell subpopulations within the intestinal mucosa may be an important mechanism of the immune system in determining between active immune response and tolerance towards luminal antigens. Additionally, the constitutive secretion of anti-inflammatory cytokines by intestinal DC might regulate the homeostatic balance under healthy conditions. Interrupting the activation of intestinal dendritic cells *in vivo* and promoting the preservation of presumably tolerogenic CD103<sup>+</sup> dendritic cells within the colonic mucosa may be key approaches to control the pathogenesis of inflammatory bowel disease.

### Peer review

This is a well prepared manuscript and the experiments described were well designed, controlled and executed. The loss of CD103<sup>+</sup> CD11c<sup>+</sup> DCs in progression of colitis is a unique and novel finding which seems to coincide with other groups' findings relating to regulatory T cells. Overall the results could contribute to our understanding of the immunopathogenesis of human inflammatory bowel diseases.

### Abstract

**AIM:** To profile protein expression in mucosal biopsies from patients with chronic refractory pouchitis following antibiotic or probiotic treatment, using a comparative proteomic approach.

**METHODS:** Two-dimensional polyacrylamide gel electrophoresis and matrix-assisted laser desorption/ionization-time of flight mass spectrometry were used to characterize the changes related to antibiotic therapy in the protein expression profiles of biopsy samples from patients with chronic refractory pouchitis. The same proteomic approach was applied to identify differentially expressed proteins in the non-inflamed pouch before and after probiotic administration.

**RESULTS:** In the first set of 2D gels, 26 different proteins with at least 2-fold changes in their expression levels between the pouchitis condition and antibiotic-

induced remission were identified. In the second set of analysis, the comparison between mucosal biopsy proteomes in the normal and probiotic-treated pouch resulted in 17 significantly differently expressed proteins. Of these, 8 exhibited the same pattern of deregulation as in the pouchitis/pouch remission group.

**CONCLUSION:** For the first time, 2D protein maps of mucosal biopsies from patients with ileal pouch-anal anastomosis were provided, and differentially expressed proteins following antibiotic/probiotic treatment were identified.

### INTRODUCTION

Total proctocolectomy with ileal J-pouch-anal anastomosis (IPAA) is the surgical treatment of choice for patients with refractory ulcerative colitis (UC) or UC with dysplasia. Although the surgery generally cures UC and has been shown to result in a significant improvement of health-related quality of life, complications can occur after IPAA<sup>[1]</sup>.

The most common long-term complication is pouchitis, an idiopathic inflammatory disease of the ileal reservoir. The reported incidence of pouchitis is variable, largely because of differences in the type and duration of follow-up. However, studies have shown that as many as 15%-46% of patients with UC develop at least 1 episode of pouchitis within 5 years after surgery<sup>[2]</sup>.

Clinically, pouchitis is characterized by variable symptoms, including increased stool frequency and fluidity, abdominal cramping, pelvic discomfort, bleeding, tenesmus, fever and weight loss, and extra-intestinal manifestations in more severe cases<sup>[3]</sup>. For an unequivocal diagnosis, endoscopic examination and histologic investigation are mandatory<sup>[4]</sup>. Pouchitis Disease Activity Index (PDAI) is the most commonly used diagnostic instrument and represents an objective and reproducible scoring system for pouchitis<sup>[5]</sup>. Active pouchitis is defined as a score  $\geq 7$  and remission is defined as a score  $< 7$ .

The etiology and pathophysiology of pouchitis are still poorly understood. However, the fact that pouchitis almost exclusively occurs in patients with underlying UC and that it generally responds to antibacterial therapy suggests a role for the gut microbiota and a genetic predisposition<sup>[6]</sup>.

The disease activity of pouchitis can be defined as remission, mild-moderate or severe based primarily on symptoms. Duration can be classified as acute ( $< 4$  wk) or chronic ( $\geq 4$  wk). Disease pattern can be infrequent (1-2 acute episodes), relapsing ( $\geq 3$  acute episodes) or chronic (a treatment-responsive form requiring maintenance therapy or a treatment-resistant form). Approximately 10%-15% of patients with pouchitis experience a chronic pouchitis, either treatment-responsive or treatment-refractory, and some of them require surgical excision or exclusion of the pouch because of impairment of reservoir function and poor quality of life<sup>[7]</sup>.

Treatment of pouchitis is largely empirical. Broad-spectrum antibiotics have been widely used and represent the mainstay of treatment. Small randomized trials have shown that both metronidazole and ciprofloxacin, alone, sequentially or in combination, are effective in reducing the PDAI score and achieving a significant improvement in clinical symptoms and endoscopic and histologic findings. However, metronidazole is poorly tolerated and treatment with systemically active antibiotics is not ideal from the perspective of the development of antibiotic resistance. In addition, in chronic pouchitis antibiotic-induced remission periods are often short and the condition is complicated by frequent relapses<sup>[8]</sup>.

Recently, several studies have suggested that altering the microbiota in the pouch by administering probiotic bacteria can be effective in maintaining remission and reducing the incidence of flare-ups in chronic pouchitis<sup>[9,10]</sup>. Moreover, the efficacy of probiotic therapy as prophylaxis to delay the first onset of pouchitis after pouch surgery, has been demonstrated<sup>[11,12]</sup>.

Comparative proteomic analysis represents an effective tool to identify proteins critical for functional pathways in normal cells and phenotype changes that

occur during disease development. Since biological and functional output of cells is governed primarily by proteins, the applications of proteomic technologies are beginning to have a profound impact on understanding of the molecular mechanisms underlying several disease processes, which, in turn, will help to reduce disease-related morbidity and mortality. However, despite their extensive use in proteomic profiling of gene expression in various diseases, the applications of such technologies in inflammatory bowel diseases are still in their infancy<sup>[13]</sup> and, so far, no proteomic study has been reported in IPAA research.

In the present study, we apply 2-dimensional polyacrylamide gel electrophoresis (2D-PAGE) and matrix-assisted laser desorption/ionization-time of flight mass spectrometry (MALDI-TOF MS) to define the differential protein displays of mucosal biopsy samples from patients with chronic refractory pouchitis before and after antibiotic treatment. The same proteomic approach has also been applied to identify specific changes in protein expression in the non-inflamed *vs* probiotic-administered pouch in order to provide a picture of the intestinal mucosa protein modulation by probiotics.

## MATERIALS AND METHODS

### *Patients and biopsy collection*

Six patients who underwent restorative proctocolectomy with IPAA were recruited for this study and routinely followed up by the Department of Internal Medicine and Gastroenterology, University of Bologna, Polyclinic S. Orsola. Patients were included if they had a chronic refractory pouchitis, defined as no response to at least 4 wk of standard antibiotic therapies (ciprofloxacin 1 g twice daily (*bid*) or metronidazole 400 mg 3 times daily). They were divided in 2 groups according to PDAI score at study entry and treatment received. In the first group, 3 patients with PDAI  $\geq 7$  were orally administered with a combination of metronidazole (500 mg *bid*) and ciprofloxacin (500 mg *bid*) for 1 mo. The second group, including the other 3 patients with chronic refractory pouchitis but with a total PDAI  $< 7$  at study entry, received VSL#3 (VSL pharmaceuticals Inc., Ft. Lauderdale, FL, USA) 2 packets *bid* for 3 mo. VSL#3 contains 450 billion viable lyophilized bacteria per packet, comprised of 4 strains of lactobacilli (*Lactobacillus acidophilus*, *L. casei*, *L. delbrueckii* subsp. *bulgaricus* and *L. plantarum*), 3 strains of bifidobacteria (*Bifidobacterium breve*, *B. infantis* and *B. longum*) and one strain of *Streptococcus thermophilus*. Mucosal biopsies were collected during pouch endoscopy before and after antibiotic/probiotic therapy.

All samples were immediately snap frozen in liquid nitrogen. The institutional ethics committee approved all protocols and all enrolled subjects gave their informed consent.

### *Protein extraction*

Frozen mucosal biopsies (about 10-20 mg) were washed in 200  $\mu$ L of cold low salt washing buffer (3 mmol/L

KCl, 1.5 mmol/L KH<sub>2</sub>PO<sub>4</sub>, 68 mmol/L NaCl, 9 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, with Complete Protease Inhibitor (Roche Molecular Biochemicals, Mannheim, Germany). After centrifugation at 13000 r/min for 2 min, tissue samples were homogenized in 1 mL of lysis solution (0.11 mol/L DTT, 0.11 mol/L CHAPS, 8 mol/L urea, 2 mol/L thiourea, 35 mmol/L Tris and Complete Protease Inhibitor) using an Ultra-Turrax<sup>®</sup> homogenizer (IKA Labortechnik, Staufen, Germany). Protein extraction was performed as previously described<sup>[14]</sup>. Total protein concentration of the cell extract was calculated using the PlusOne 2D Quant Kit<sup>™</sup> (GE Healthcare, Uppsala, Sweden). The protein extract preparation was immediately used or aliquoted and frozen at -20°C.

## 2D-PAGE

Samples containing 100 µg of protein were diluted to 250 µL with rehydration solution (8 mol/L urea, 2% CHAPS, 10 mmol/L DTT, 2% (v/v) ampholine, pH 3.5-9.5 (GE Healthcare) and trace bromophenol blue) and applied to Immobiline DryStrips (13 cm, pH 3-10, GE Healthcare) for 12 h rehydration at 50 V. Isoelectric focusing was performed using IPGphor apparatus (GE Healthcare) to give a total of 19 kVh. IPG strips were then reduced and alkylated<sup>[15]</sup> prior to loading onto 15% acrylamide separating gels (20 cm long, 1 mm thickness). Electrophoresis was performed at 250 V for 7 h using Protean II xi Cell (Bio-Rad, Hercules, CA, USA). Protein spots were visualized with a MS-compatible silver-staining procedure<sup>[16]</sup>.

## Image analysis

Protein patterns in the gels were recorded as digitalized images using a GS-800 imaging densitometer (Bio-Rad). Spot detection, matching and the examination of differentially expressed proteins were performed by PDQuest v6.2 software (Bio-Rad). Three technical replicates were made per patient and condition and formed 1 replicate group with average normalized spot intensities. The comparison was carried out for each patient before and after antibiotic/probiotic therapy. Proteins that showed at least 2 times enhanced/decreased expression were selected for identification along with a few spots that showed a similar expression pattern in all 2D gels.

## Protein identification

Protein spots with conserved expression levels throughout the gels in all patients and conditions were identified. Two identification methods were employed: comparison of our reference proteome map with Swiss-2D PAGE (<http://www.expasy.ch/ch2d/>) and other published 2D proteome patterns<sup>[17-21]</sup> obtained under very similar experimental conditions, and MALDI-TOF MS analysis. Since both methods provided the same identification result for each spot, we used the gel matching method to identify the differentially expressed proteins in pouchitis/antibiotic-induced remission and normal pouch/

probiotic-treated pouch groups. When gel matching produced an unreliable and doubtful identification, because of excessive deviations in *pI* and *M<sub>r</sub>* values across gels, MALDI-TOF MS was employed.

Protein spots were manually excised from 2D gels, washed and in-gel digested as previously reported<sup>[22]</sup>. Crude digests were concentrated and desalted using mC18 ZipTips (Millipore, Bedford, MA, USA). Peptide extracts were mixed on the MALDI-TOF target (Applied Biosystems, Foster City, CA, USA) with an equal matrix volume of 5 mg/mL  $\alpha$ -cyano-4-hydroxycinnamic acid (Sigma-Aldrich, St. Louis, MO, USA) saturated with 50% acetonitrile/0.2% trifluoroacetic acid, and analyzed using a Voyager-DE Pro Biospectrometry Workstation (Applied Biosystems). All mass spectra were obtained in a reflectron mode, with an accelerating voltage of 20 kV and a delayed extraction of 40 ns. Internal mass calibration with peptides arising from trypsin autolysis was performed. Peptide masses were searched against Swiss-Prot, TrEMBL and NCBI non-redundant protein databases using ProFound (<http://prowl.rockefeller.edu/prowl-cgi/profound.exe>) and Aldente (<http://expasy.org/tools/aldente>) programs. Search parameters were set to allow up to one missed tryptic cleavage and a peptide mass tolerance of 50 ppm. Only protein hits with a significant probability score calculated by software and at least 3 matching peptide masses were considered.

## Statistical analysis

Statistical analysis of protein expression was performed using the Student's *t*-test carried out with SigmaStat v3.5 software (Systat Software, Point Richmond, CA, USA). A *P* value < 0.05 was considered as statistically significant. Bibliometric analysis for co-citation was performed using Biblosphere Pathway Edition from Genomatix (Genomatix Software, Munich, Germany).

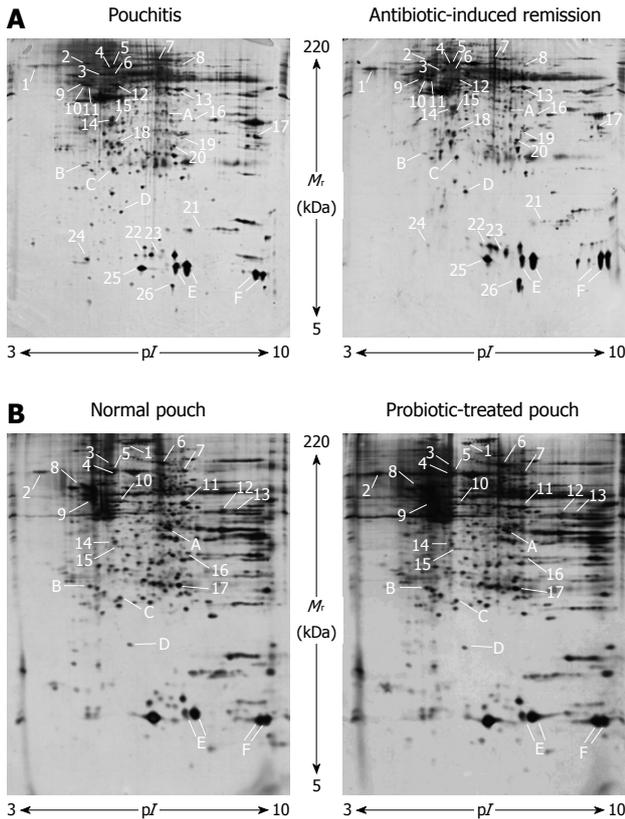

## RESULTS

### Clinical outcome of antibiotic/probiotic treatment

All the enrolled subjects completed the study. In the first group of patients, after 1 mo of antibiotic therapy, clinical and endoscopic remission was achieved with a significant decrease in both PDAI and median stool frequency (data not shown). In the second group, no episodes of active pouchitis were recorded during the probiotic administration. Both treatments were well tolerated and no side effects were recorded.

### Antibiotic administration-related effects on mucosal biopsy proteome in pouchitis

An example of 2D gels obtained from mucosal biopsies in pouchitis and pouch remission is provided in Figure 1A. Approximately 1200 protein spots per gel were detected within a *pI* range of 3-10 and a *M<sub>r</sub>* range of 5-220 kDa. The resolution of the polypeptides showed better quality in the low molecular mass area and toward the acidic side of the gels whereas increased streaking and precipitation,

**Figure 1** Representative 2D gel maps of the mucosal biopsy proteomes from a patient with chronic refractory pouchitis before (left) and after (right) antibiotic therapy (A) and from a subject with a non-inflamed pouch before (left) and after (right) probiotic administration (B). Proteins showing altered expression identified by gel matching and MALDI-TOF MS analysis are numbered and reported in Table 1. Identified spots with conserved expression levels in all patients and conditions are marked by letters and shown in Table 2.

a well known phenomenon observed in 2D-PAGE, were visible on the basic side.

For each patient, 2D patterns of mucosal biopsies collected before and after antibiotic administration were compared by PDQuest. Because of the high intrinsic variability among individuals, a stringent criterion was applied whereby only those proteins with at least 2 times increased or decreased expression and deregulation in the same way in all patients were considered. Out of 40 differentially expressed protein spots, 26 (65%) were identified, of which 15 were upregulated and 11 downregulated in antibiotic-induced remission of pouchitis (Figure 1A and Table 1). In addition, 6 protein spots with a similar expression pattern in all 2D gels were selected and identified (Figure 1 and Table 2).

The altered proteins were classified in terms of their subcellular location and biological function by information from Swiss-Prot, HPRD (Human Protein Reference Database, <http://www.humanproteinpedia.org>), and COGs (Cluster of Orthologous Groups of proteins, <http://www.ncbi.nlm.nih.gov/COG/>) (Figure 2A). The majority of the identified proteins were located in the cytoplasm (38%), mitochondria (27%) and endoplasmic reticulum (11%). Twenty-seven percent of

the altered proteins play a key role in post-translational modifications and protein turnover as chaperones, 15% are involved in energy production and conversion, and 11% are related to lipid transport and metabolism.

The results of a histogram data analysis carried out on the spot quantity values determined by PDQuest are displayed in Figure 3 together with representative gel images for each protein spot in each patient and clinical condition. A statistically significant increased expression in pouch remission was detected for tubulin  $\beta$ -2C chain (TUBB), ATP synthase subunit  $\beta$  (ATP5B) and calponin-2 (CNN2) in all patients, whereas calreticulin (CALR), 60 kDa heat shock protein (HSP60), heat shock cognate 71 kDa protein (HSPA8), and intestinal (FABP2) and liver fatty acid-binding proteins (FABP1) expression patterns showed an increase with statistical significance in only 1 or 2 out of the 3 patients enrolled. For ileal lipid binding protein (FABP6) and electron transfer flavoprotein subunit  $\alpha$  (ETF $\alpha$ ), *P* values of 0.07 and 0.06, respectively, near the threshold of significance were obtained. Among downregulated protein spots after antibiotic treatment, statistical significance was achieved in all patients for thioredoxin domain-containing protein 5 (TXNDC5), type I cytoskeletal keratin 20 (KRT20) and cathepsin D (CTSD). Pyruvate dehydrogenase E1 component subunit  $\beta$  (PDHB) showed a statistically significant decreased expression in only 1 patient.

#### **Probiotic administration-related effects on mucosal biopsy proteome in non-inflamed pouch**

Representative 2D gels obtained from mucosal biopsies in normal pouch and after probiotic therapy are shown in Figure 1B, confirming the protein maps reported in Figure 1A in terms of number, *M<sub>r</sub>* and *pI* of the spots.

For each of the 3 subjects enrolled, the comparison of the 2D patterns of non-inflamed mucosal biopsies before and after VSL#3 administration was performed by PDQuest as reported above. Seventeen spots, which represented 75% of total proteins recognized as differentially expressed, were identified, of which 7 were upregulated and 10 were downregulated in the probiotic-treated pouch (Figure 1B and Table 1). In addition, it was possible to identify 6 protein spots that showed a similar expression pattern in all 2D gels (Figure 1 and Table 2).

Pie charts representing the subcellular location and the functional distribution of the probiotic administration-altered proteins are reported in Figure 2B. The majority of the identified proteins were in the cytoplasm (41%), mitochondria (35%) and endoplasmic reticulum (12%). The functional classification indicated that 29% play a key role in energy production and conversion, 17% are related to post-translational modifications and protein turnover as chaperones and 12% are involved in carbohydrate transport and metabolism.

The spot quantity values determined by PDQuest are shown in the form of a histogram in Figure 4 together with representative gel images for each protein spot in each subject and condition. A statistically significant increased

<sup>1</sup>A: RNA processing and modification. For other abbreviations see Table 1; <sup>2</sup>For each protein spot, the gel matching identification method was also employed. Spots A, B and D were identified by comparison with published 2D proteome patterns<sup>[17,18]</sup>; spots C, E and F by comparison with Swiss-2D PAGE.

**Figure 2** Pie charts representing the distribution of the differentially expressed proteins from pouchitis/pouch remission (A) and normal pouch/probiotic-treated pouch (B) group comparison, according to their subcellular location and biological function. ER: Endoplasmic reticulum.

**Figure 3** Protein expression histograms of the 26 differentially expressed protein spots between pouchitis (dark grey) and antibiotic-induced remission (light grey). Each bar represents the average spot quantity determined from 3 technical replicates for each patient condition by PDQuest. Representative gel images are displayed on top of each graph. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P = 0.06$  for ETFA and  $P = 0.07$  for FABP2 and FABP6.

expression after 3 mo of probiotic administration was detected for HSPA8 and PDHB in all the subjects enrolled.  $P$  values of 0.06, near the threshold of significance, were obtained for vinculin (VCL) and phosphoenolpyruvate carboxykinase (PCK2) in 3 and 2 patients, respectively. Among protein spots with downregulated expression levels after VSL#3 therapy, statistical significance was achieved in all patients for KRT20 and in only 1 for TXNDC5.

### Bibliometric analysis

On the basis of literature co-citation from NCBI PubMed, a protein-protein network tree using the data-mining program Bibliosphere software was generated. As shown in Figure 5, the network tree was compiled of 28 different proteins forming 2 network clusters. Group 1 consisted of 26 highly interrelated proteins including ATP5B, carbonic anhydrase I (CA1) and II (CA2), creatine kinase (CKMT1B),  $\alpha$ -enolase (ENO1), PCK2, PDHB and triosephosphate isomerase (TPI1), associated with energy, carbohydrate and amino acid metabolism, as well as glycolysis/gluconeogenesis, oxidative phosphorylation and electron transport chain. The second group was formed by 2 linear co-cited proteins, NADH-ubiquinone oxidoreductase 75 kDa subunit (NDUFS1) and cytochrome b-c1 complex subunit 2 (UQCRC2), related to energy production and conversion. The residual 5 detected proteins, S-adenosylmethionine decarboxylase (AMD1), CNN2, tubulin  $\alpha$ -1A chain (TUBA1A), TUBB and TXNDC5 were completely disconnected from the network tree.

## DISCUSSION

In this study, we provided for the first time 2D protein maps of mucosal biopsy samples collected during pouch endoscopy in patients who underwent IPAA.

The comparison between mucosal biopsy proteomes in pouchitis and in antibiotic-induced remission enabled the identification of 26 different proteins with at least 2-fold changes in their expression levels. Statistical significance was achieved for ATP5B, CNN2, CTSD, KRT20, TUBB and TXNDC5. In addition, a statistically significant altered expression pattern was obtained for CALR, HSP60, HSPA8, FABP1, FABP2 and PDHB in 1 or 2 of the 3 patients enrolled.

Among the identified mitochondrial proteins, ATP5B, ETFA and PCK2 directly participate in the process of energy production. The decrease of their expression levels in the inflamed pouch suggests the decline of mitochondrial function with pouchitis onset. This assumption is consistent with a previous hypothesis that chronic intestinal inflammation represents an energy-deficiency disease with alterations in the oxidative metabolism of the epithelial cells<sup>[23]</sup>. Moreover, the low expression of FABP1, FABP2 and FABP6, involved in enhancing the uptake of fatty acids into cells and facilitating their transport to intracellular organelles, could reinforce the speculation that pouchitis-diseased enterocytes do not perform  $\beta$ -oxidation/oxidative phosphorylation owing to a lack of normal supply of fatty acids<sup>[24]</sup>. Combined with these results, the overexpression of ENO1 found in the inflamed pouch may reflect a shift toward anaerobic

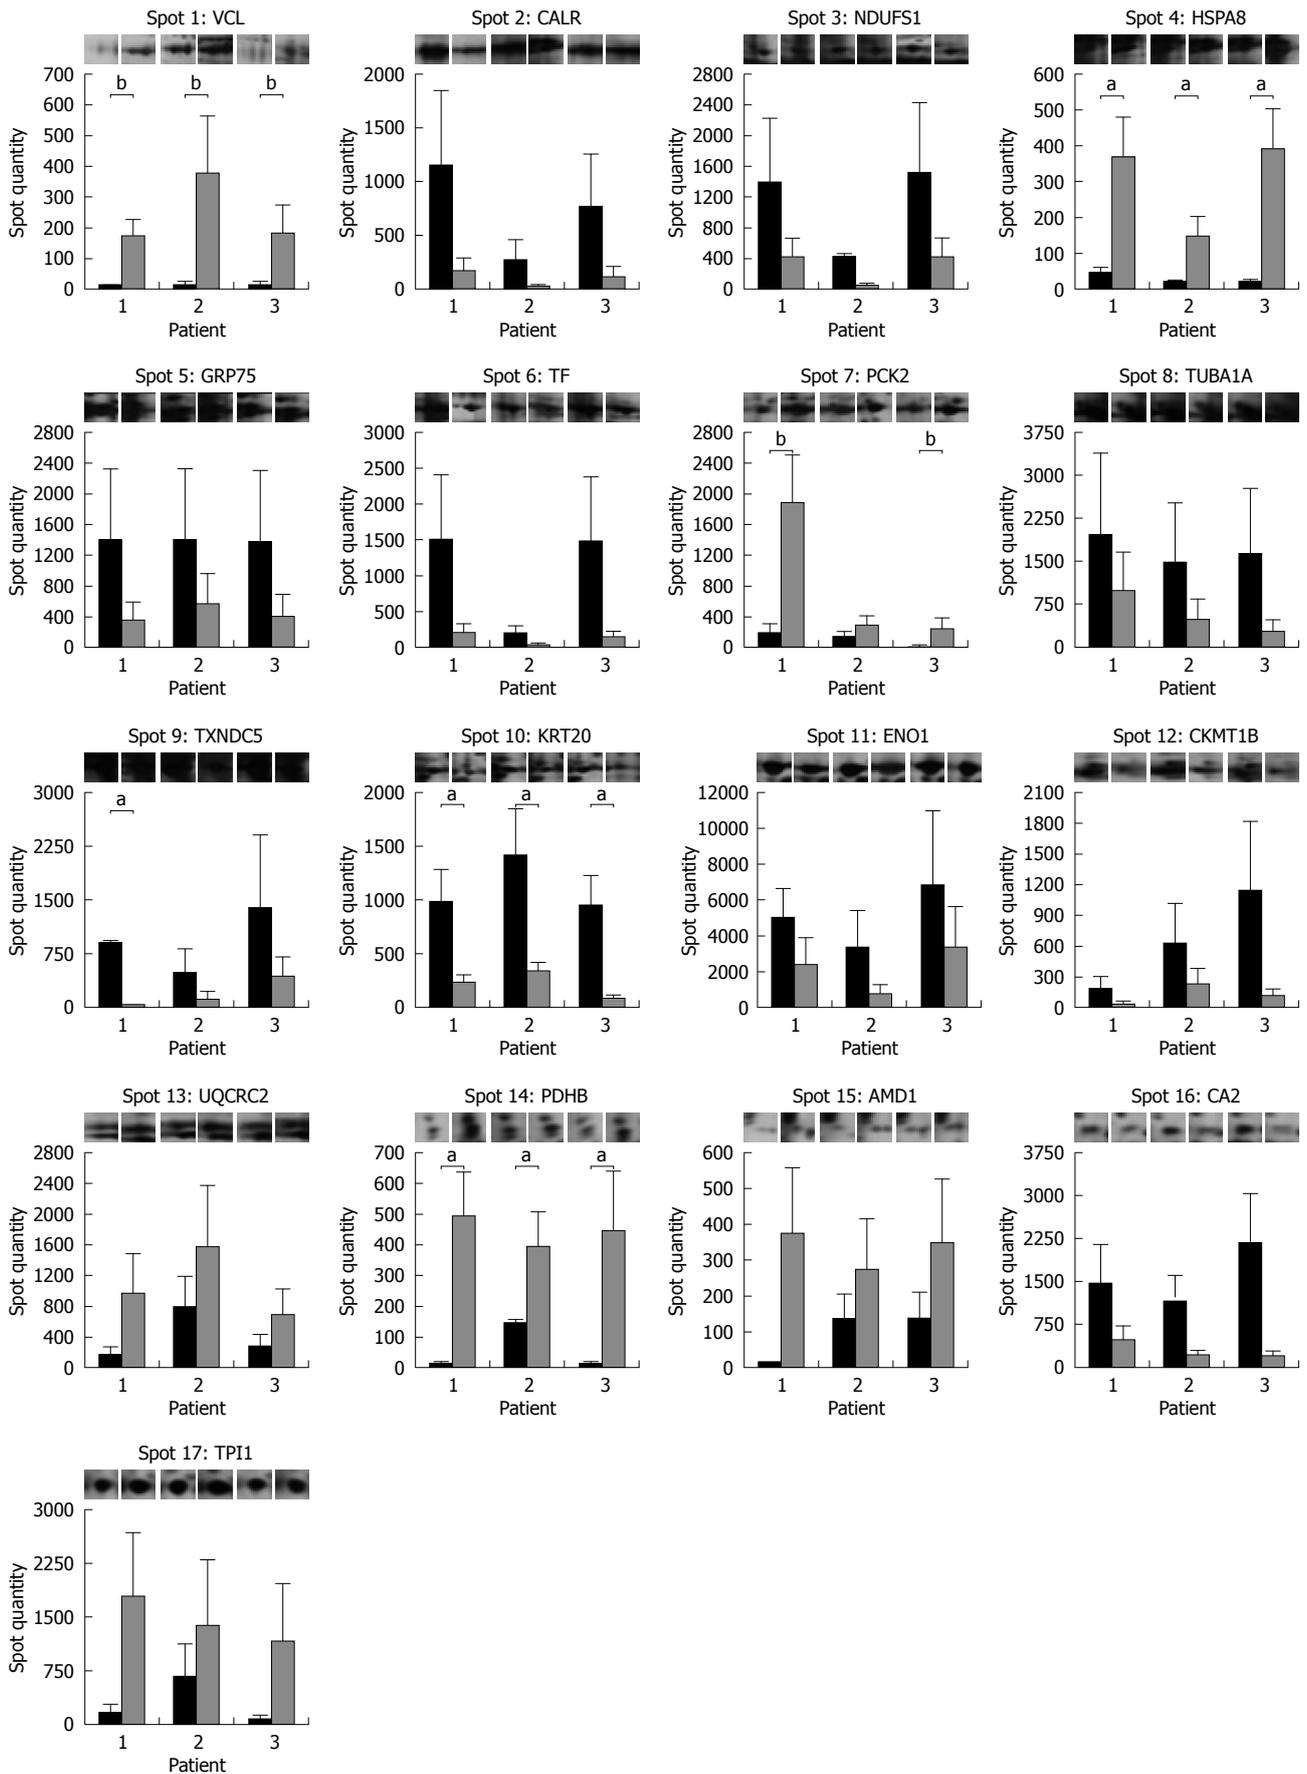

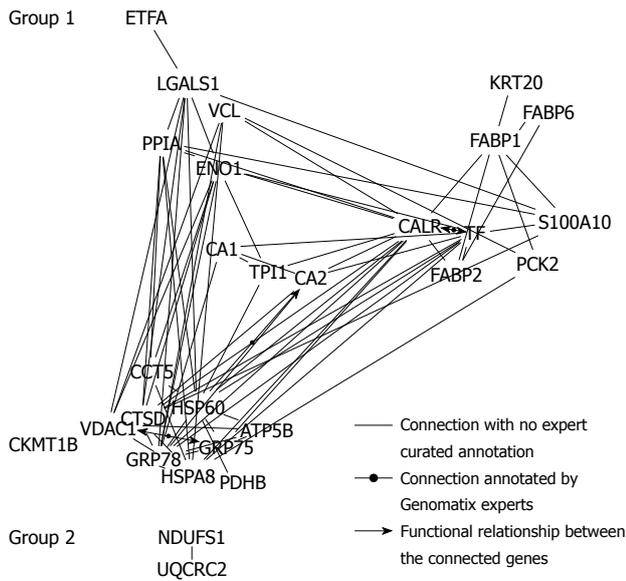

Figure 4 Protein expression histograms of the 17 differentially expressed protein spots in non-inflamed pouch before (dark grey) and after (light grey) probiotic treatment. Each bar represents the average spot quantity determined from 3 technical replicates for each subject condition by PDQuest. Representative gel images are displayed on top of each graph. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P = 0.06$  for VCL and PCK2.

**Figure 5 Bibliometric data analysis.** Protein-protein network tree generation using the data-mining program Bibliosphere software.

glycolysis to overcome the decreased ATP formation by a dysfunctional oxidative phosphorylation<sup>[21]</sup>.

The hypothesis of cellular stress and hypoxic conditions in chronically inflamed tissues is supported by the induction of several chaperone proteins, including 75 (GRP75) and 78 kDa glucose-related proteins (GRP78), TXNDC5, voltage-dependent anion-selective channel protein 1 (VDAC1), CTSD and peptidyl-prolyl cis-trans isomerase A (PPIA)<sup>[25-27]</sup>. In addition, we detected a statistically significant altered expression pattern for TUBB, KRT20 and CNN2, suggesting changes in cytoskeletal architecture with potential alterations in signal transduction and cellular transcription profiles<sup>[27,28]</sup>.

Next, we compared mucosal biopsy proteomes in the normal pouch before and after probiotic administration and we identified 17 different proteins with significant changes in their expression levels. Interestingly, 8 of the differentially expressed proteins exhibited the same pattern of deregulation as in the pouchitis/pouch remission group. Indeed, both antibiotic and probiotic therapy resulted in downregulation of GRP75, serotransferrin (TF), TXNDC5, KRT20, ENO1 and in upregulation of HSPA8, PCK2 and AMD1, suggesting profound structural and metabolic alterations in enterocytes. In particular, TXNDC5 is a newly identified member of the thio-redoxin family of endoplasmic reticulum proteins<sup>[29]</sup>, and it has been proposed as a promising biomarker for cancer diagnosis<sup>[30]</sup>. Because of its important role in redox regulation<sup>[31]</sup>, the altered expression profile of TXNDC5 in IPAA may be related to the increased oxidative stress with significantly lower plasma concentrations of lipophilic antioxidants and higher free radical activity measured in patients with restorative proctocolectomy compared to normal subjects<sup>[32]</sup>. Furthermore, for KRT20 and ENO1, widely applied as diagnostic markers for colon adenocarcinomas and many other tumors<sup>[33,34]</sup>,

as well as for PCK2 and AMD1 a differential protein profile in inflammatory bowel disease has been already reported<sup>[21,35,36]</sup>.

In addition to these results, in the VSL#3-treated pouch we found a statistically significant upregulation of VCL and an altered expression pattern for TUBA1A, supporting the assumption of a positive modulation exerted by probiotics at cytoskeleton level for cell morphology and integrity<sup>[37,38]</sup>. In addition, the dysregulated expression levels of NDUFS1, CKMT1B, UQCRC2, PDHB, CA2 and TPI1, directly involved in energy metabolism, strengthen the hypothesis of significant changes in the metabolic profiles of the host associated with probiotic administration<sup>[39,40]</sup>. Nonetheless, although the manipulation of the ubiquitin/proteasome pathway and the ability to intervene with the complex host system of detoxification of potentially harmful xenobiotics and endobiotic compounds may account for some of the cytoprotective effects of probiotics<sup>[37,41,42]</sup>, we did not find any significant change in glutathione S-transferase P (GSTP1) and ubiquitin-conjugating enzyme E2 N (UBE2N) protein expression levels.

The bibliometric data analysis including all the 33 differentially regulated proteins from the pouchitis/pouch remission and non-inflamed/probiotic-treated pouch group comparison generated a complex network with 26 highly interrelated proteins. As expected, the majority of clustered proteins were associated with glycolysis/gluconeogenesis, oxidative phosphorylation and electron transfer chain pathways.

In conclusion, the identified proteins, both upregulated and downregulated, may be involved in pouchitis pathophysiology and participate in disease onset or in maintenance of the non-inflamed pouch.

## COMMENTS

### Background

Restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) is the procedure of choice for complicated ulcerative colitis. In the long-term, up to 50% of patients develop pouchitis, an idiopathic inflammatory disease of the ileal reservoir. The management of pouchitis is largely empirical and only few small placebo-controlled clinical trials have been conducted. Although antibiotics represent the mainstay of treatment, probiotics have recently gained more attention as an effective therapeutic option for pouchitis management.

### Research frontiers

The etiology and pathophysiology of pouchitis are still not entirely clear but the bulk of the evidence points towards an abnormal mucosal immune response to altered microbiota patterns. By investigating the dynamic nature of protein expression, cellular and subcellular distribution, posttranslational modifications and protein-protein interaction networks, proteomic technologies could play a major role in unraveling the mystery of immunopathogenic mechanisms of pouchitis and in discovering novel biomarkers for disease activity, diagnosis and prognosis.

### Innovations and breakthroughs

The current study is the first proteomic study to be reported in IPAA research. The authors provided the 2D protein maps of mucosal biopsy samples collected during pouch endoscopy in patients with chronic refractory pouchitis. The changes in the protein expression profiles following antibiotic or probiotic treatment were characterized.

### Applications

The identified proteins, upregulated or downregulated following antibiotic/

probiotic treatment, may be involved in pouchitis pathophysiology and participate in disease onset or in maintenance of the non-inflamed pouch. Future work will be focused in validating the list of proteins identified in larger patient cohorts.

### Peer review

The results are well described and interesting, although the number of patients is a bit on the small side. Even though this manuscript does not give a clear understanding to the mechanistic differences, the results may aid other scientists in making a follow-up study.

**Peer reviewers:** Dr. Gert De Hertogh, Morphology and Molecular Pathology, University Hospitals KULeuven, Minderbroedersstraat 12, Leuven 3000, Belgium; Qin Su, Professor, Department of Pathology, Cancer Hospital and Cancer Institute, Chinese Academy of Medical Sciences and Peking Medical College, PO Box 2258, Beijing 100021, China

### Abstract

**AIM:** To determine the association between *Helicobacter pylori* (*H. pylori*) and globus sensation (GS) in the patients with cervical inlet patch.

**METHODS:** Sixty-eight patients with esophageal inlet patches were identified from 6760 consecutive patients undergoing upper gastrointestinal endoscopy prospectively. In these 68 patients with cervical inlet patches, symptoms of globus sensation (lump in the throat), hoarseness, sore throat, frequent clearing of the throat, cough, dysphagia, odynophagia of at least 3 mo duration was questioned prior to endoscopy.

**RESULTS:** Cervical heterotopic gastric mucosa (CHGM) was found in 68 of 6760 patients. The endoscopic prevalence of CHGM was determined to be 1%. *H. pylori* was identified in 16 (23.5%) of 68 patients with inlet patch. 53 patients were classified as CHGM II. This group included 48 patients with globus sensation, 4 patients with chronic cough and 1 patient with hoarseness. All the patients who were *H. pylori* (+) in cervical inlet patches had globus sensation.

Alagozlu H, Simsek Z, Unal S, Cindoruk M, Dumlu S, Dursun A. Is there an association between *Helicobacter pylori* in the inlet patch and globus sensation? *World J Gastroenterol* 2010; 16(1): 42-47 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i1/42.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i1.42>

### INTRODUCTION

Islands of heterotopic gastric mucosa are found throughout the gastrointestinal tract, the most common site being the cervical esophagus. Cervical heterotopic gastric mucosa (CHGM) or cervical inlet patches are commonly seen during withdrawal of the gastroscope. Patients with CHGM have various laryngeal and oropharyngeal symptoms, ranging from asymptomatic to protracted symptoms such as globus sensation and chronic cough due to acid secretion from the inlet patch<sup>[1-4]</sup>.

Globus sensation (GS) is caused mainly by cervical disturbances. The usual complaint in patients with globus sensation or globus pharyngeus is the sensation of a ball or lump in the throat, generally not accompanied

by dysphagia. Globus sensation is felt medially deep in the throat during dry swallowing (empty swallow), and almost never while drinking or eating. It is not painful, and there is no obstruction of food<sup>[2,3]</sup>.

*Helicobacter pylori* (*H. pylori*) produces chronic inflammation in the CHGM (as in non-ulcer dyspepsia). *H. pylori* infection plays a role in altered gastric perception in non-ulcer dyspepsia. *H. pylori* in CHGM may cause altered cervical perception such as globus sensation. In this prospective study, we aimed to determine the association between *H. pylori* and globus sensation in patients with CHGM.

## MATERIALS AND METHODS

### Subjects

Over a one-year period, between 2005 and 2006, the number of patients with cervical inlet patches from a total of 6760 consecutive patients undergoing upper gastrointestinal endoscopy at the Hospital of the Gazi University in Ankara, Turkey were identified. Patients were referred for endoscopy for a variety of reasons, primarily for evaluation of dyspepsia. In these patients, symptoms of globus sensation (lump in the throat), hoarseness, sore throat, frequent clearing of the throat, cough, dysphagia and odynophagia of at least 3 mo duration were questioned prior to endoscopy.

The investigation conformed to the principles outlined in the Declaration of Helsinki. Informed consent was obtained from all subjects and the study was approved by the ethical review committee of Gazi University in Ankara, Turkey.

### Esophagogastroduodenoscopy

After an overnight fast, a routine esophagogastroduodenoscopy was performed with a standard endoscope using topical anesthesia with or without conscious sedation, depending on patient preference. Conscious sedation was performed with midazolam (2-5 mg). During all procedures the esophagus was carefully surveyed and special attention was paid to the area of the upper esophageal sphincter. This region was best examined when slowly withdrawing the endoscope, with repeated short inflations while rotating the instrument.

Heterotopic gastric mucosa was defined as patches covered with salmon-red mucosa distinguishable from surrounding greyish-pearly colored esophageal mucosa by well-defined margins (Figure 1). The size of the patches was determined by the top span of the fully open biopsy forceps. In all subjects, the distance between the patch and the frontal incisor was recorded and the patch size measured under the guidance of the open biopsy forceps.

### pH monitoring

pH monitoring was performed in our laboratory in the patients with inlet patch. A 2.1-mm diameter dual-electrode antimony pH catheter (pHersaflex ambulatory

catheter, MMS) was placed transnasally after an overnight fast. Recording sites were fixed on the catheter, with a distance of 15 cm to measure proximal and distal pH. The distal electrode was placed 5 cm above the manometrically defined lower esophageal sphincter. The proximal electrode was placed at 16-21 cm, which corresponded approximately with the endoscopic finding of inlet patches. The pH values from both intraesophageal electrodes were recorded continuously on an ambulatory Mark III Digitrapper (Synectics Medical Inc.). Abnormal distal esophageal reflux and proximal reflux were defined as the percentage of esophageal total acid exposure (pH < 4) of  $\geq 4.2\%$  and  $\geq 1\%$ , respectively<sup>[5]</sup>.

### Biopsies

A minimum of two biopsies were obtained from the CHGM (Figure 2) and antral gastric mucosa. The samples were taken using large cup and side-opening forceps. Pathology and/or the rapid urease test were performed to determine the presence of *H. pylori* in all patients (Figure 3). The presence of *H. pylori* was identified using hematoxylin-eosin, cresyl violet, giemsa and silver stain.

### Statistical analysis

All statistical analyses were carried out using the Statistical Package for Social Sciences (SPSS) 13.0 software for Windows XP. Categorical variables were compared with the chi-squared test or Fisher's exact test, and continuous variables were compared using Student's *t*-test and univariate analysis. A *P* value of less than 0.05 was considered to be statistically significant.

## RESULTS

### Prevalence, demographic characteristics

CHGM patches were found in 68 of 6760 patients (3173 female, 3587 male). The endoscopic prevalence of CHGM was determined to be 1%. Demographic characteristics of the patients with and without patches are shown in Table 1. The female/male ratio was 1.12 in the 68 patients with patches and 0.88 in those without. There was no significant difference between the mean age of the patients with CHGM with and without *H. pylori* (*P* > 0.05). Female patients with inlet patches had higher colonization of *H. pylori* than male patients (*P* < 0.05).

### Size, number, symptoms, pH monitoring

The size of the inlet patches varied between 5 and 32 mm and occupied between 10% and 30% of the circumference. Five patients had "double" patches. Symptoms are shown in Tables 1 and 2. Five patients had distal reflux and 1 patient had both proximal and distal reflux. There were no patients with only proximal reflux. The other patients were normal.

### Histological characteristics

***H. pylori*:** *H. pylori* was identified in the CHGM in

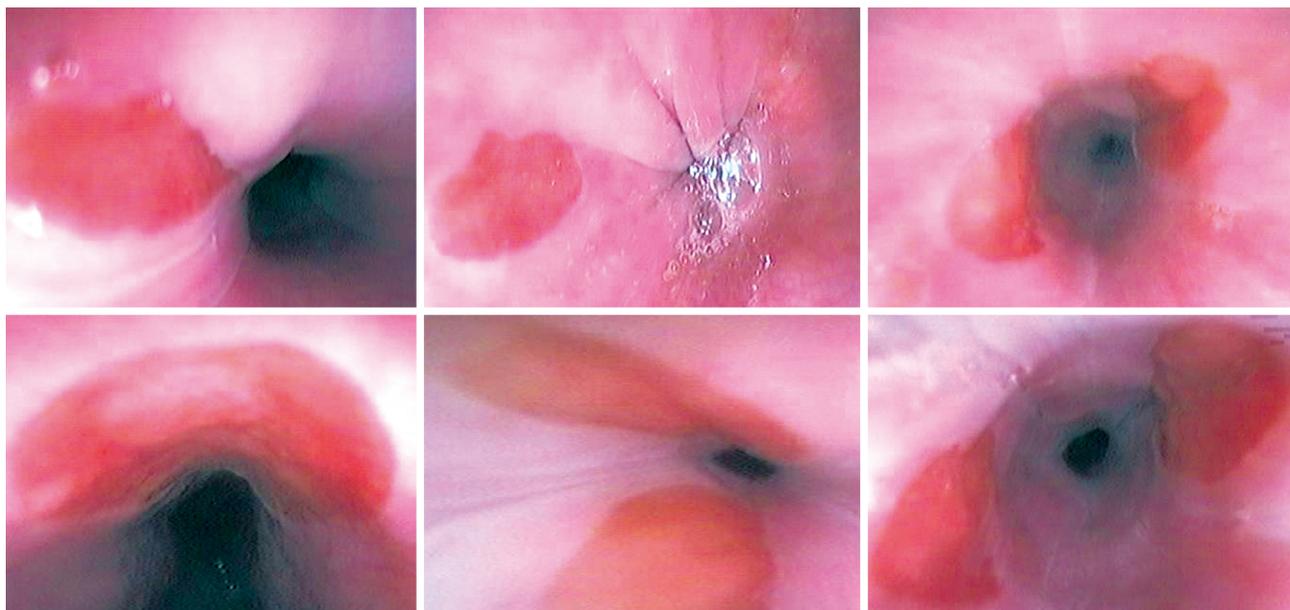

Figure 1 Various endoscopic images of inlet patches (single or double).

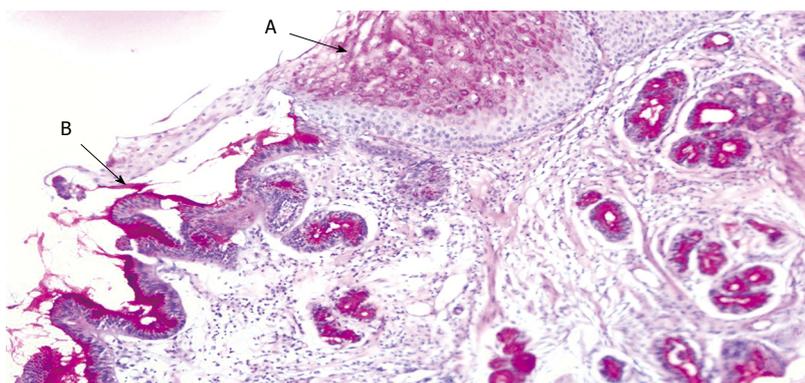

Figure 2 Biopsies. A shows heterotopic gastric mucosa, B shows squamous epithelium.

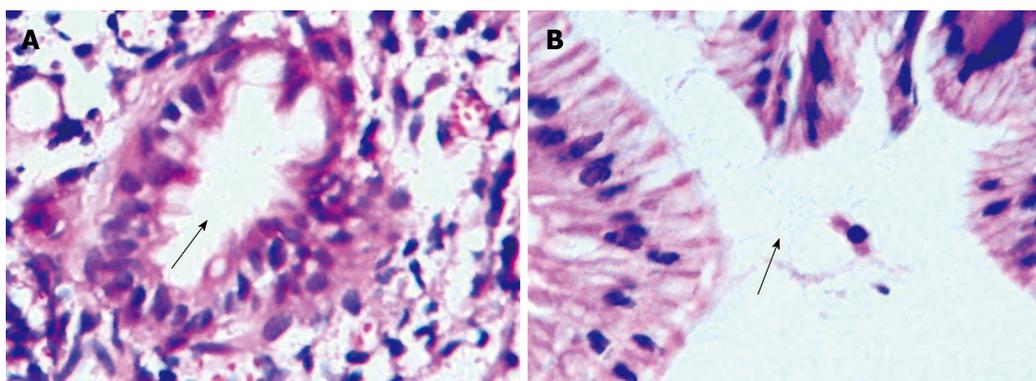

Figure 3 The presence of *Hp* bacilli in heterotopic gastric mucosa with HE stain ( $\times 1000$ ). A: Few *Hp* bacilli (arrow); B: *Hp* colonization (arrow).

23.5% of patients (16/68) (Table 3) and gastric *H. pylori* infection was positive in all (16/16) of these patients (Table 4, Figure 3). Colonization of *H. pylori* was most common in fundic-type mucosa (81.2%). All the patients who were *H. pylori* (+) in the cervical inlet patches had globus sensation ( $P < 0.05$ ).

**Mucosal type:** In the inlet patch, fundic-type mucosa was the most common histologic type (44/68), followed

by antral-type mucosa (15/68) (Table 3). Eight specimens of the inlet patch contained only foveolar epithelium and were therefore considered too superficial to be classified. In one patient, mucosal type was unremarkable because one specimen had complete replacement of the underlying mucosa with intestinal metaplasia.

**Intestinal metaplasia:** Intestinal metaplasia was identified in the inlet patch in seven patients (10.3%). One pa-

CHGM: Cervical heterotopic gastric mucosa; GS: Globus sensation; Cough: Together with clearing of the throat.

tient had complete replacement of the underlying mucosa with intestinal metaplasia. Both *H. pylori* and intestinal metaplasia were observed in the inlet patch mucosa in one patient. In the remaining five patients, intestinal metaplasia was present, but no *H. pylori*. The type of mucosa was evaluated in these patients; three had antral-type and three fundic-type.

### Associated lesions

Endoscopic esophagitis (7 patients), duodenal ulcer (3 patients), hiatal hernia (9 patients) and endoscopic Barrett's esophagus (9 patients) accompanied CHGM.

### Clinicopathologic classification

Clinicopathologic classification was performed according to the classification reported by von Rahden *et al*<sup>[1]</sup> in patients with CHGM. (1) Asymptomatic carriers of esophageal CHGM were classified as CHGM I. Twelve patients were classified with CHGM I in our study. (2) Symptomatic individuals with esophageal CHGM complaining of globus sensation, cough, hoarseness or "extraesophageal manifestations" were classified as CHGM II without morphologic changes. Fifty-three patients were classified with CHGM II. This group included 48 patients with globus sensation, 4 patients with chronic cough and 1 patient with hoarseness. There were 48 (70.5%) patients with globus sensation out of the 68 patients with CHGM II. Symptoms of globus sensation were obvious attractive in these patients. (3) A smaller group of patients with additional morphologic changes (inlet patch complicati-

ons) were classified as CHGM III. This group included one patient with ulcer and polyp in the inlet patch. (4) If dysplasia was present, this was classified as CHGM IV. None of the patients belonged to this category. (5) If the diagnosis was invasive cancer and originated within the inlet patch, this was classified as CHGM V. One patient who had adenocarcinoma in the CHGM was classified as CHGM V.

## DISCUSSION

The usual endoscopic appearance of CHGM is a salmon-rose-colored mucosal patch with a sharp border or edge in the upper esophagus. The patches vary in diameter from 1 to 20 mm or more. Inlet patches are recognized endoscopically as 1 or 2 patches mostly in the lateral walls between the level of the cartilage and the fifth tracheal ring, and are seen as sharply demarcated, salmon-rose-colored oval or round patches.

The prevalence of CHGM varied between 0.29% and 2.27% in one prospective study<sup>[6]</sup>. Akbayir *et al*<sup>[7]</sup> reported a prevalence of 1.67% and Tang *et al*<sup>[8]</sup> reported a prevalence of 1.1%. In our prospective study, over a period of 1 year, 68 cases (1%) of CHGM were documented and confirmed by histology.

Microscopically, gastric mucosa containing either

cardiac, antral and potentially acid-secreting fundic mucosa can be found. In general, CHGM is uniformly of the fundic-type, containing both parietal and chief cells. Less frequently, histopathologic examination of CHGM shows an “antral pattern”, defined by the absence of chief cells and only a few parietal cells<sup>[1,8,9]</sup>. In our series, fundic-type mucosa was found in 44 of 68 patients examined histologically.

*H. pylori* is a well known pathogenic micro-organism responsible for chronic inflammation. Ectopic gastric mucosa of the inlet patch is an ideal location for *H. pylori* colonization<sup>[10]</sup>. Borhan-Manesh *et al*<sup>[11]</sup> found *H. pylori* in the inlet patch in 35% of patients in a subset with gastric *H. pylori*. Among our 68 patients with inflamed inlet patches, 16 were positive for *H. pylori* (23.5%), and all of these 16 patients also had *H. pylori* in the antrum. Coinfection of *H. pylori* in the inlet patch and gastric antrum has also been reported by others<sup>[10]</sup>. Since the infection by *H. pylori* is through the oral route, inlet patches may be important sites of *H. pylori* infection in the upper gastrointestinal tract because of its more proximal location. The inlet patches may function as reservoirs for *H. pylori*. Inlet patch colonization by *H. pylori* can occur during ingestion of food, and the presence of gastric *H. pylori* may play a role in the development of inlet patches. We searched but did not find any follow-up studies on antibiotic therapy for *H. pylori* and its impact on infection of inlet patches in the literature. We believe that the elimination of *H. pylori* in both the inlet patch and antrum is very important in the treatment of patients with coinfection.

In this study, the female/male ratio in the *H. pylori* (+) CHGM group was higher than that in the *H. pylori* (-) CHGM group. Females had higher inlet patch colonization with *H. pylori* than males ( $P < 0.05$ ). The mechanism of *H. pylori* colonization in the inlet patch is unclear.

A clinicopathological classification of CHGM as proposed by von Rahden *et al*<sup>[1]</sup> was carried out on all 68 patients, 53 of whom were classified as CHGM II; 48 had globus sensation, 4 had cough, one had hoarseness. Theoretically, laryngeal and oropharyngeal symptoms should be common due to acid secretion from the inlet patch. Several studies have reported cases of esophageal inlet patch presenting with various laryngeal and oropharyngeal symptoms, ranging from asymptomatic to protracted symptoms such as chronic cough and globus sensation<sup>[4,12-14]</sup>. In addition, CHGM can cause stricture, ulcer, perforation, web or polyp in the esophagus because of its capability to secrete acid<sup>[15,16]</sup>. In our two patients with CHGM III, one had a hyperplastic polyp and one had an ulcer.

There are also reports that CHGM is associated with an increased risk for Barrett's esophagus, suggesting a possible link. Traditionally, Barrett's esophagus is considered a distinct entity from esophageal inlet patch. Barrett's esophagus is an acquired precancerous lesion and the cell origin probably involves multipotential undifferentiated cells. Inlet patch is considered to be congenital. Up to half of all patients with cervical inlet patch have concurrent Bar-

rett's esophagus in some reports<sup>[17]</sup>. They have the same mucin core protein expression and cytokeratin pattern, suggesting a pathogenetic link between these two diseases<sup>[18]</sup>. Similarly, in the current study, the presence of CHGM in the upper esophagus was common and closely related to Barrett's esophagus (13.2%) compared with those without inlet patches ( $P < 0.05$ ). Gastro-esophageal diseases in patients with cervical inlet patch was not statistically significant when compared with those without patches ( $P > 0.05$ ). We speculated that the acid secretion from the inlet patches did not contribute to the pathogenesis of Barrett's esophagus. However, the patients with inlet patches were inherently predisposed to developing columnar metaplasia in the distal esophagus.

The usual complaint in GS is that of a ball or lump in the throat generally not accompanied by dysphagia. This sensation is often more pronounced when taking an “empty swallow”. In our study, all the patients with *H. pylori* in cervical inlet patches had globus sensation.

CHGM should be looked for, particularly in patients with GS. *H. pylori* positivity in the CHGM correlated with GS symptoms in our study. There were no reports on a link between *H. pylori* positivity in patients with CHGM and “globus sensation” or “globus pharyngeus” in our review of the English literature. Therefore, we were not able to compare our data.

*H. pylori* infection plays a role in causing symptoms in patients fulfilling the criteria for non-ulcer dyspepsia. There is agreement that *H. pylori* infection causes changes in gastric physiology. In addition, *H. pylori* infection plays a role in altered gastric perception in non-ulcer dyspepsia. We speculate that the disturbances in globus sensation are like non-ulcer dyspepsia. *H. pylori* produces chronic inflammation in the CHGM (as in non-ulcer dyspepsia). It could be speculated that globus sensation is a non-ulcer dyspepsia of CHGM. *H. pylori* is a potential cause of GS in patients with CHGM.

There are no follow-up studies on antibiotic therapy for *H. pylori* and its impact on infection of inlet patches in the literature. Additional studies are needed to understand the fundamental mechanisms leading to globus sensation in CHGM. These patients might benefit from *H. pylori* eradication therapy to alleviate this potentially aggravating factor. Based on these important findings, we expect to see more studies on inlet patches in the near future.

## COMMENTS

### Background

Cervical heterotopic gastric mucosa (CHGM) or cervical inlet patches are commonly seen on the cervical esophagus during withdrawal of the gastro-scope. Patients with inlet patches have various laryngeal and oropharyngeal symptoms, ranging from asymptomatic to protracted symptoms such as globus sensation and chronic cough due to acid secretion from the inlet patch. Globus sensation has a largely unknown etiology.

### Research frontiers

All the patients who were *Helicobacter pylori* (*H. pylori*) (+) in the cervical inlet patches had globus sensation. *H. pylori* produces chronic inflammation in the CHGM (as in non-ulcer dyspepsia). It could be speculated that globus sensa-

tion is a non-ulcer dyspepsia of CHGM. *H. pylori* is a potential cause of GS in patients with CHGM.

### Innovations and breakthroughs

The authors showed a causal association between *H. pylori* infection and the symptoms of globus sensation in these patients. Inlet patches may function as reservoirs for *H. pylori*. Inlet patch colonization by *H. pylori* can occur during ingestion of food and the presence of gastric *H. pylori* might play a role in the development of inlet patches.

### Applications

Patients might benefit from *H. pylori* eradication therapy to alleviate this potentially aggravating factor. Based on these important findings, we expect to see more studies on inlet patches in the near future.

### Terminology

CHGM in the cervical esophagus appears to result from incomplete replacement of the original columnar epithelium by stratified squamous epithelium in the embryonic period. Islands of heterotopic gastric mucosa are found throughout the gastrointestinal tract, the most common site being the cervical esophagus. Macroscopically, visible islands of CHGM, referred as "inlet patches" are often detected during endoscopic examination.

### Peer review

The manuscript presented interesting data on heterotopic gastric mucosa on the cervical esophagus. They proved the link between presence of inlet patch and globus sensation in these patients. Interestingly, they showed a causal association between *H. pylori* infection and the symptom of globus sensation in these patients.

### Abstract

**AIM:** To investigate atrial natriuretic peptide (ANP) secretion from gastric mucosa and the relationship between the ANP/natriuretic peptide receptor type A (NPR-A) pathway and diabetic gastroparesis.

**METHODS:** Male imprinting control region (ICR) mice (4 wk old) were divided into two groups: control mice, and streptozotocin-induced diabetic mice. Eight weeks after injection, spontaneous gastric contraction was recorded by using physiography in control and streptozotocin-induced diabetic mice. The ANP-positive cells in gastric mucosa and among dispersed gastric epithelial cells were detected by using immunohistochemistry and flow cytometry, respectively. ANP and natriuretic

peptide receptor type A (NPR-A) gene expression in gastric tissue was observed by using the reverse transcriptase polymerase chain reaction.

**RESULTS:** The frequency of spontaneous gastric contraction was reduced from  $12.9 \pm 0.8$  cycles/min in the control group to  $8.4 \pm 0.6$  cycles/min in the diabetic mice ( $n = 8$ ,  $P < 0.05$ ). However, the amplitude of contraction was not significantly affected in the diabetic group. The depletion of interstitial cells of Cajal in the gastric muscle layer was observed in the diabetic mice. ANP-positive cells were distributed in the gastric mucosal layer and the density index of ANP-positive cells was increased from  $20.9 \pm 2.2$  cells/field in control mice to  $51.8 \pm 2.9$  cells/field in diabetic mice ( $n = 8$ ,  $P < 0.05$ ). The percentage of ANP-positive cells among the dispersed gastric epithelial cells was increased from  $10.0\% \pm 0.9\%$  in the control mice to  $41.2\% \pm 1.0\%$  in the diabetic mice ( $n = 3$ ,  $P < 0.05$ ). ANP and NPR-A genes were both expressed in mouse stomach, and the expression was significantly increased in the diabetic mice.

**CONCLUSION:** These results suggest that the ANP/NPR-A signaling pathway is upregulated in streptozotocin-induced diabetic mice, and contributes to the development of diabetic gastroparesis.

## INTRODUCTION

Gastroparesis is a chronic complication of diabetes, also called delayed gastric emptying, occurs in > 50% of patients with long-standing diabetes<sup>[1]</sup>. Symptoms of gastroparesis include heartburn, pain in the upper abdomen, vomiting, nausea, and early feeling of fullness, but the worst effect of gastroparesis is that it can make diabetes worse by making blood glucose control more difficult<sup>[2]</sup>. Besides, there are deterioration in glycemic control and incapacitating symptoms such as malnutrition, water and electrolyte imbalance, and aspiration. However, the pathophysiology of diabetic gastropathy and gastroparesis, such as the mechanism of impaired fundic, pyloric relaxation and impaired electrical pacemaking, are still not established<sup>[3,4]</sup>. It is generally believed that diabetic gastropathy and gastroparesis may be caused by visceral autonomic neuropathy, hyperglycemia, and degeneration of smooth muscle. Hyperglycemia itself can cause antral hypomotility, gastric dysrhythmia, and delayed gastric emptying in some patients<sup>[5]</sup>. Several physiological studies have reported that dysfunction of gastric smooth muscle in diabetes is associated with neural factors and intracellular signaling pathways<sup>[6,7]</sup>.

Atrial natriuretic peptide (ANP) was isolated from the atrium by de Bold *et al.*<sup>[8]</sup> in 1981. From then on, brain natriuretic peptide (BNP), C-type natriuretic peptide (CNP), dendroapsis natriuretic peptide (DNP), micrurus natriuretic peptide (MNP), and ventricular natriuretic peptide (VNP) have been found in succession. Three types of single transmembrane natriuretic peptide receptors (NPRs) for ANP, BNP and CNP have been identified<sup>[9,10]</sup>, namely, NPR type A (NPR-A), type B (NPR-B), and type C (NPR-C). NPR-A and NPR-B have the membrane-bound particulate guanylate cyclase (pGC), which can catalyze the formation of cGMP from GTP<sup>[8-11]</sup>. NPR-A preferentially binds to ANP and BNP, but has a low affinity for CNP. NPR-B has a much higher affinity for CNP than either ANP or BNP<sup>[12]</sup>. Besides the heart, ANP is also distributed in other organs, for example, ANP can be secreted by gastric mucosa<sup>[13-15]</sup>. It is well known that ANP and other family members exert natriuretic-diuretic effects, vasorelaxation, and other functions including: decreasing blood pressure, and controlling electrolyte homeostasis. Some studies have demonstrated that the natriuretic peptide family plays an inhibitory role in regulating gastrointestinal motility, for example, in the chicken rectum<sup>[3]</sup>, rat tenia coli<sup>[16]</sup> and guinea-pig cecum<sup>[17]</sup>.

Our previous study also indicated that CNP relaxes gastric circular and longitudinal smooth muscles in human, rat and guinea-pig stomach, and NPRs are distributed in rat gastric smooth muscle layer<sup>[18-20]</sup>. Recently, we have also reported that the CNP-induced

relaxation and the production of cGMP of gastric smooth muscle are potentiated in streptozotocin (STZ)-induced diabetic rats. As well as the activity of pGC, the expression of *NPR-B* gene in gastric smooth muscle is upregulated in STZ-induced diabetic rats<sup>[21]</sup>. These results suggest that the CNP/(NPR-B)/pGC/cGMP signaling pathway is involved in the pathogenesis of diabetes. Our previous studies have confirmed that ANP-synthesizing cells exist in different regions of the gastric mucosa in rats<sup>[15]</sup>, therefore, ANP can be considered an endogenous natriuretic peptide of gastric mucosa. However, it is not clear whether the ANP/NPR-A signaling pathway is involved in the pathogenesis of diabetic gastroparesis.

In the present study, we investigated the relationship between the ANP signaling pathway and STZ-induced diabetic gastroparesis to confirm whether ANP contributes to the development of gastroparesis. The present study focused on whether the amount of ANP secretion from gastric mucosa was enhanced and the expression of the *NPR-A* gene in gastric smooth muscle was upregulated in a mouse model of STZ-induced diabetic gastroparesis.

## MATERIALS AND METHODS

### Drugs

STZ, TRIzol Reagent and chemicals were purchased from Sigma. C-kit antibody, ANP antibody and pronase were purchased from Santa Cruz Biotechnology and Roche. Other chemicals were purchased from Sangon Biological Company.

### STZ-induced diabetic mouse model

Male imprinting control region (ICR) mice (4 wk old) were purchased from the Experimental Animal Center of Shanghai Jiaotong University School of Medicine. A total of 80 mice were divided into two groups: control group and STZ-induced diabetic group. STZ-induced diabetes was created as follows: the mice were fasted overnight and intraperitoneally administered STZ solution (Sigma-Aldrich, St. Louis, MO, USA). STZ was diluted in 0.1 mol/L citrate buffer (pH = 4.0) and used at a dose of 200 mg/kg. Control mice were intraperitoneally administered with the same volume of 0.1 mol/L citrate buffer. The glucose concentration of blood was determined with One-touch Apparatus (Johnson & Johnson Medical Company). STZ-induced diabetic mice were confirmed by measuring glucose concentration from tail blood after fasting, and diabetes was defined when the blood glucose level was > 16 mmol/L. All experimental protocols included in this study were approved by the local Animal Care Committee and conformed to the Guide for the Care and Use of Laboratory Animals published by the Science and Technology Commission of P.R.C. (STCC Publication No. 2, revised 1988).

### Gastric motility in mouse intact stomach

Eight weeks after treatment with STZ, the animals

were euthanized by lethal dose of intraperitoneal pentobarbital sodium (50 mg/kg). The abdomen of each mouse was opened along the midline, and the intact stomach was removed and placed in pre-oxygenated Krebs solution (containing in 118.1 mmol/L NaCl, 4.7 mmol/L KCl, 1.0 mmol/L KH<sub>2</sub>PO<sub>4</sub>, 1.0 mmol/L MgSO<sub>4</sub>, 25.0 mmol/L NaHCO<sub>3</sub>, 2.5 mmol/L CaCl<sub>2</sub>, and 11.1 mmol/L glucose), which was equilibrated with 95% oxygen and 5% CO<sub>2</sub>. The connective tissue was removed and the pylorus was connected to a pressure transducer (Chengdu Equipment Factory, China) with a thin glass tubule, and the gastric cardia was tied with thin string. The stomach was incubated in a 15-mL organ bath filled with Krebs solution and gassed with 95% O<sub>2</sub> and 5% CO<sub>2</sub> at 37°C. The sensitivity of the pressure transducer was adjusted to an appropriate value and we recorded gastric motility by using the SMUP-E biological signal processing system (Chengdu Equipment Factory). The stomach was allowed to incubate for at least 60 min before the experiments were started, and we eliminated error by injecting an equal volume of Krebs solution into the stomach.

### Immunohistochemistry

The mice were euthanized by lethal dose of intraperitoneal pentobarbital sodium (50 mg/kg), the stomach was removed and washed with saline, and then fixed in 4% paraformaldehyde (4°C, 24 h). The fixed tissue was washed with running water (room temperature, 2 h), immersed with 95% and 100% alcohol (room temperature, 2 × 2 h), xylene (2 × 20 min) and paraffin (68.5°C, 30/40/50 min). Sections of 6 μm thickness were cut and deparaffinized in xylene (4 × 30 min). The specimens were hydrated in graded concentrations of ethanol, and washed three times in PBS, and incubated in the blocking reagent for 30 min. The samples were incubated with polyclonal antibody against c-Kit protein (sc-5535; Santa Cruz Biotechnology, Santa Cruz, CA, USA; 1:100 dilution). c-Kit protein was used as a marker of interstitial cells of Cajal (ICCs)<sup>[22,23]</sup> and with polyclonal antibody against ANP (sc-20158; Santa Cruz Biotechnology; 1:100 dilution) for 24 h at 4°C, followed by 3 h incubation in Rho-anti-rabbit and horseradish peroxidase-anti-rabbit second antibody, respectively. The negative control group was omitted by incubating with primary antibody against ANP. The slice was visualized and photographed under a fluorescence microscope (Olympus IX71, Tokyo, Japan).

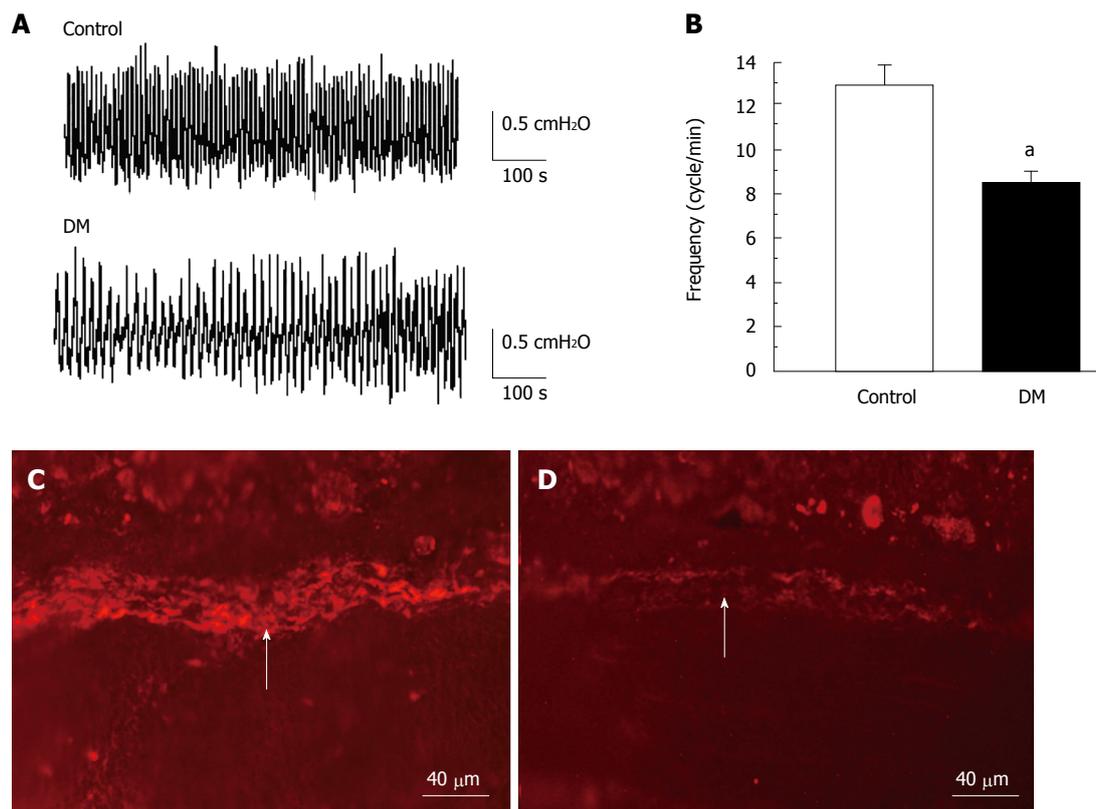

### Flow cytometry analysis of gastric epithelial cell

Eight weeks after injection with STZ, the mice were euthanized by lethal dose of intraperitoneal pentobarbital sodium (50 mg/kg). The stomach was removed and washed with saline. After the stomachs were inverted to make mucosal-side-out stomachs, the stomachs were rinsed with saline, and pronase solution was injected into the stomach. The pronase was diluted into 1 mg/mL with MA solution (0.5 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, 1 mmol/L Na<sub>2</sub>HPO<sub>4</sub>, 20 mmol/L NaHCO<sub>3</sub>, 80 mmol/L NaCl,

5 mmol/L KCl, 50 mmol/L HEPES, 11 mmol/L glucose, 20 g/L BSA, 2 mmol/L EDTA; pH = 7.4). The stomach sacks were incubated in the oxygenated MA solution for 3 × 30 min, at 37°C equilibrated with 95% oxygen and 5% CO<sub>2</sub>, followed by gently stirring for 1 h in MB solution (0.5 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, 1 mmol/L Na<sub>2</sub>HPO<sub>4</sub>, 20 mmol/L NaHCO<sub>3</sub>, 80 mmol/L NaCl, 5 mmol/L KCl, 50 mmol/L HEPES, 11 mmol/L glucose, 10 g/L BSA, 1 mmol/L CaCl<sub>2</sub>, 1.5 mmol/L MgCl<sub>2</sub>; pH = 7.4). MB solution that contained the gastric mucosal cells was collected, and filtered through a 200-mesh cellular sieve. The solution sample was centrifuged at 1500 × g for 5 min. The centrifuged sample was re-suspended with MC solution (0.5 mmol/L NaH<sub>2</sub>PO<sub>4</sub>, 1 mmol/L Na<sub>2</sub>HPO<sub>4</sub>, 20 mmol/L NaHCO<sub>3</sub>, 80 mmol/L NaCl, 5 mmol/L KCl, 50 mmol/L HEPES, 11 mmol/L glucose, 1 mmol/L CaCl<sub>2</sub>, 1.5 mmol/L MgCl<sub>2</sub>, 1 mmol/L dithiothreitol; pH = 7.4) and centrifuged at 1500 × g for 5 min again. The density of the cell suspension was adjusted to 3 × 10<sup>6</sup>/mL. The cells were fixed with 75% cold alcohol (-20°C, 24 h), and washed with PBS, followed by 0.2% Triton X-100 for 10 min. The antigen was blocked by 10% goat serum diluted in PBS, and incubated with antibody against ANP (sc-20158; Santa Cruz Biotechnology; 1:50 dilution) overnight at 4°C. The cells were stained with FITC-conjugated goat anti-rabbit IgG and examined by flow cytometry (Becton Dickinson). Using Cellquest software, 10<sup>4</sup> cells were analyzed per sample.

### Reverse transcriptase polymerase chain reaction (RT-PCR) analysis of ANP, and NPR-A gene expression

The whole gastric tissue was quickly removed from the mouse. Total RNA was isolated from the tissue as recommended by the manufacturer of TRIzol Reagent (Sigma). RNA concentration was determined by absorbance reading at 260/280 nm. Reverse transcription was performed with a volume of 20 μL mixture that contained 11 μL mRNA, and 1 μL oligo dt<sub>18</sub>, which was incubated at 70°C for 5 min, and 4 μL 5 × reaction buffer, 2 μL dNTP, 1 μL RNase inhibitor, 1 μL M-MLV RT was added to the mixture, followed by incubation at 42°C for 1 h. The enzyme was inactivated by heating at 70°C for 10 min. cDNA samples were used for analyzing specific cDNA of ANP and NPR-A. One microliter of cDNA was added to 19 μL PCR reaction mixture that contained: 7 μL nuclease-free water, 10 μL 2 × reaction buffer, 1 μL sense primer, and 1 μL anti-sense primer. The following conditions were used for PCR amplification: for GAPDH, 95°C for 4 min; 95°C for 30 s; followed by 40 cycles at 52.9°C for 1 min; 72°C for 30 s; 72°C for 7 min; for ANP, 40 cycles at 54.6°C for 30 s; for NPR-A, 60°C for 30 s. RT-PCR was performed on an iCycler™ Thermal Cycler (Bio-Rad, Hercules, CA, USA) using the Access RT-PCR System (Promega, Madison, WI, USA). Specific primers for murine GAPDH, ANP and NPR-A were synthesized by Sangon Biological Company (Shanghai, China). The primer sequences were as follows: GAPDH (sense) 5'TCAACGGCACAGTCAAGG3', GAPDH (antisense) 5'ACCAGTGGATGCAGGGAT3'; ANP

**Figure 1** Comparison of gastric contractility and expression of ICCs in normal and STZ-induced diabetic mice. A: Representative traces of spontaneous gastric contraction in control and STZ-induced diabetic mice; B: Summary of amplitudes and frequencies of gastric motility in control and STZ-induced diabetic groups ( $n = 8$ ;  $^aP < 0.05$  vs control group); C and D: Expression of c-Kit-positive cells in the muscle layer. Arrow indicates the positive staining area. Expression of c-Kit was more obvious in STZ-induced diabetic mice than in the normal controls. Scale bar = 40  $\mu\text{m}$ .

(sense) 5'TCCTTCTCCATCACCCTG3', ANP (antisense) 5'CCTAGAGCACTGCCGTCT3'; NPRA (sense) 5'AGACGATGGGCAGGATAG3', NPRA (antisense) 5'GGATGTCAGGAGGTGGGT3'. The PCR products were size-fractionated by 1% agarose gel electrophoresis, and visualized under ultraviolet light with 0.5% ethidium bromide staining. GAPDH, ANP and NPR-A cDNAs were quantified by Gel Doc XR System and Quantity One software (Bio-Rad). Gene expression for ANP and NPR-A was normalized to that for GAPDH.

### Statistical analysis

The data was expressed as the mean  $\pm$  SE. We evaluated differences between the treatment groups using Student's *t* test. Differences were considered to be significant at  $P < 0.05$ . The density index referred to the number of ANP-positive cell per field of vision.

## RESULTS

### Change in plasma glucose concentration

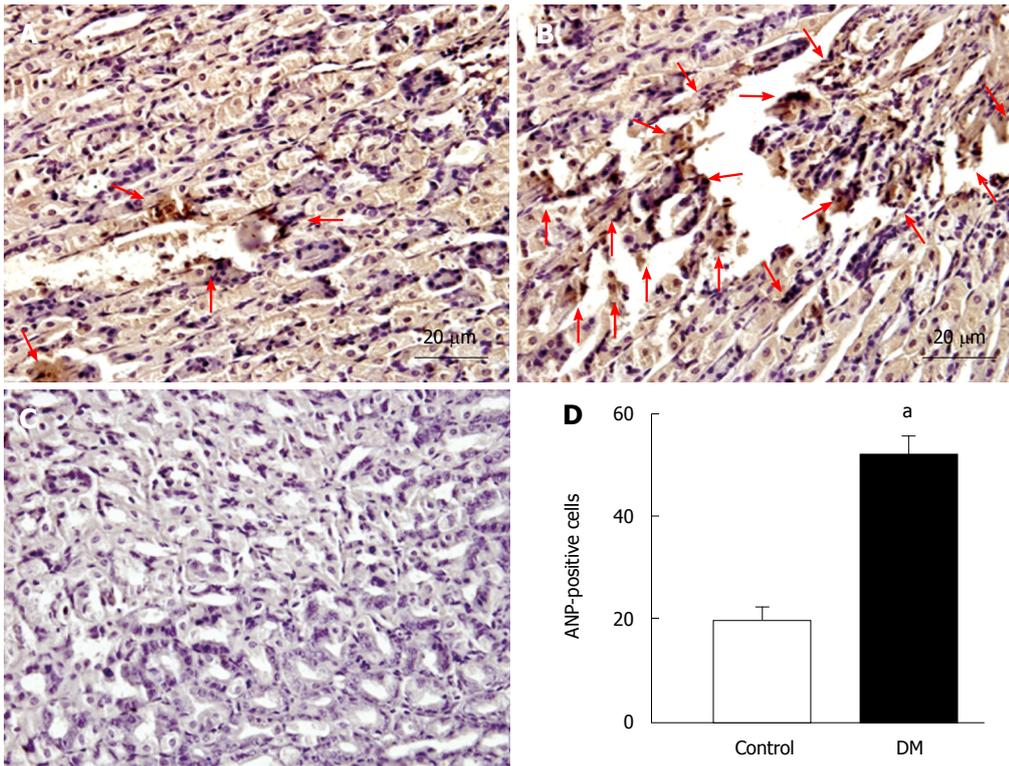

We detected changes in blood glucose concentration. Mice were used at 8 wk after injection of STZ. At the time of the study, most STZ-treated mice exhibited hyperglycemia; their average blood glucose concentration was  $26.7 \pm 1.3$  mmol/L ( $n = 32$ ), which was significantly higher than that of the non-diabetic control mice ( $6.9 \pm 0.6$  mmol/L,  $n = 32$ ;  $P < 0.01$ ).

### Gastric motility and ICC expression in STZ-induced diabetic mice

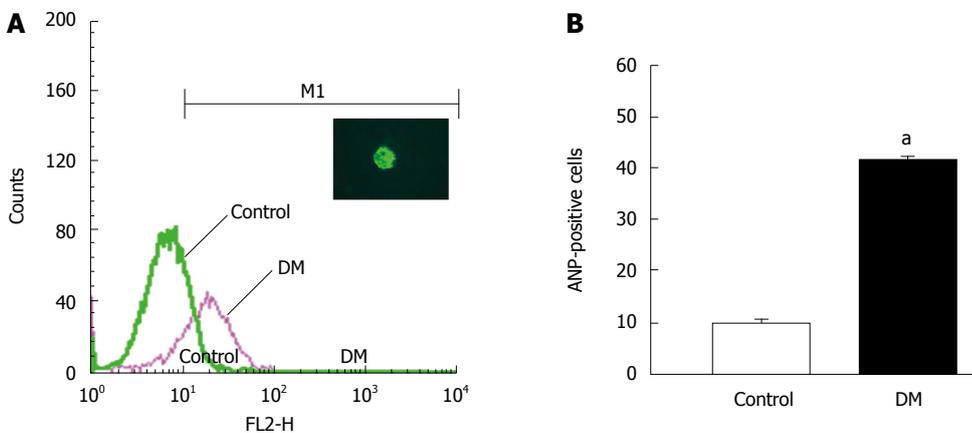

To determine whether diabetic gastropathy occurred, the amplitude and frequency of spontaneous gastric contraction were observed in normal and STZ-induced diabetic mice. The frequency of spontaneous gastric contraction decreased significantly from  $12.9 \pm 0.8$  cycles/min in the control group to  $8.4 \pm 0.6$  cycles/min in diabetic mice ( $n = 8$ ,  $P < 0.05$ ; Figure 1A and B). However, the amplitude of contraction was not changed in the diabetic group. Spontaneous rhythmic contraction of gastrointestinal smooth muscle is triggered by ICCs, which are also mediators of neuromuscular transmission in the gastrointestinal tract. Depletion of ICCs contributes to dysfunction of gastrointestinal motility in patients and animal models<sup>[24]</sup>. ICCs distributed in the gastric smooth muscle layer were observed by immunohistochemistry. c-Kit protein, an ICC marker, was detected in the inter-muscular layer of normal and diabetic mice (Figure 1C and D), but the expression was significantly decreased in the diabetic group ( $n = 6$ ; Figure 1D). The results suggested that the STZ-induced diabetic mice exhibited gastric dysfunction, and the reduced frequency of gastric motility in diabetic mice might have been related to ICC depletion.

### ANP secretion from gastric mucosa

Besides the heart, the ANP family is also distributed in other organs, and some studies have found that ANP

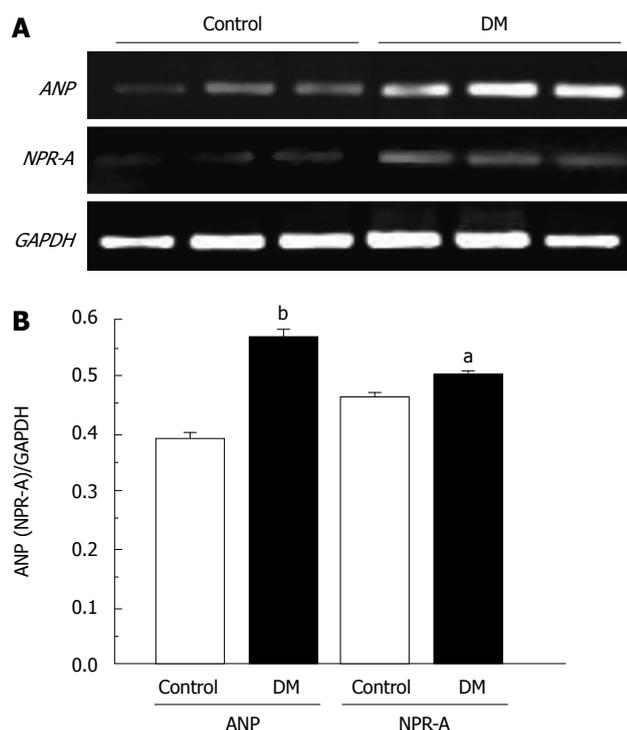

**Figure 2** Immunohistochemical analysis of atrial natriuretic peptide (ANP) in mouse gastric tissue. The photographs show ANP expression in gastric mucosa in the control group (A), STZ-induced diabetic group (B), and negative control group (C); The paranuclear cytoplasmic stained cells that display an intense dark brown color were ANP-positive-staining cells in the mucosa. The red arrows indicate ANP-positive cells; B shows that the number of ANP-positive cells increased in the STZ-induced diabetic group; D shows the density index that referred to the number of ANP-positive cells per field of vision ( $n = 8$ ,  $^aP < 0.05$  vs control group). Scale bar = 20  $\mu\text{m}$ .

**Figure 3** Flow cytometric analysis of ANP-positive cells among gastric mucosal cells. The percentage of ANP-positive cells was determined by flow cytometry with FITC-conjugated goat anti-rabbit IgG. A: Relative fluorescence intensity of gastric mucosal cells in the control and diabetic groups. M1 indicates the proportions of ANP-positive cells that displayed positive FITC labeling. The inserted fluorescent image is a single ANP-positive cell that had a positive fluorescent signal in its cytoplasm ( $\times 400$ ); B: ANP-positive cells among the gastric mucosal cells ( $10^4$  cells per sample) in control and STZ-induced diabetic mice ( $n = 3$ ,  $^aP < 0.05$  vs control).

can be secreted from gastric mucosa<sup>[13-15]</sup>. To determine whether ANP secretion from gastric mucosa is enhanced in STZ-induced diabetic mice, ANP-positive cells in the gastric mucosa were observed in the control (Figure 2A) and STZ-induced diabetic (Figure 2B) mice. The number of ANP-positive cells was increased significantly in the gastric mucosa of diabetic mice, and the density index was enhanced from  $20.9 \pm 2.2$  cells/field of vision in the controls to  $51.8 \pm 2.9$  cells/field of vision in the diabetic

group ( $n = 8$ ,  $P < 0.05$ ; Figure 2D). We further analyzed the number of ANP-positive cells in gastric epithelial cells by flow cytometry. The relative fluorescence intensity of the diabetic group was higher than that of the control group (Figure 3A). The number of ANP-positive cells was increased significantly in the diabetic group. The percentage of ANP-positive cells among dispersed epithelial cells was enhanced from  $10.0\% \pm 0.9\%$  in the control group to  $41.2\% \pm 1.0\%$  in the

**Figure 4** RT-PCR of gastric *ANP* and *NPR-A* genes in control and STZ-induced diabetic mice. A: Results of agarose gel electrophoresis, including *ANP*, *NPR-A* and *GAPDH* genes. The density signal was normalized to that of *GAPDH*. The mean value of the density was obtained from three separate experiments; B: Expression of *ANP* and *NPR-A* genes was increased in STZ-induced diabetic mice ( $n = 3$ ;  $^*P < 0.05$ ,  $^bP < 0.01$  vs control).

diabetic group ( $n = 3$ ,  $P < 0.05$ ; Figure 3B). The results suggested that ANP secretion from gastric mucosa was potentiated in the stomach of STZ-induced diabetic mice.

#### Expression of ANP and NPR-A gene

The number of ANP-positive cells was increased in the STZ-induced diabetic group, therefore, we investigated whether *ANP* and *NPR-A* gene expression was also increased. *ANP* and *NPR-A* gene expression was observed in gastric tissue by RT-PCR. *ANP* and *NPR-A* gene expression was increased in the diabetic group ( $n = 3$ ; Figure 4A). The signal was normalized to that of *GAPDH*. The ratio of *ANP*/*GAPDH* and *NPR-A*/*GAPDH* was  $0.54 \pm 0.02$  and  $0.5 \pm 0.01$  and  $0.39 \pm 0.01$  and  $0.46 \pm 0.02$  in the STZ-induced diabetic and control group, respectively ( $n = 3$ ,  $P < 0.05$  and  $P < 0.01$ ; Figure 4B).

## DISCUSSION

Diabetic gastroparesis is defined as slow gastric emptying in the absence of mechanical obstruction, and constipation is considered to be the most significant clinical manifestation. It occurs in 30%-60% of diabetic patients observed at tertiary referral centers<sup>[25]</sup>. Many investigators view these changes as the consequences of irreversible autonomic neuropathy, which affects the

vagus and sympathetic nerves primarily<sup>[2,5]</sup>. However, the cause of gastroparesis is multifactorial and also involves enteric neurons, mucosal endocrine cells, smooth muscle cells and ICCs<sup>[4]</sup>. The main conclusion drawn from the present study is that the ANP/NPR-A signaling pathway is upregulated and may contribute to the development of gastroparesis in STZ-induced diabetic mice, and then lead to gastric motility dysfunction.

In non-obese diabetic (NOD) mice, a well-established model of human type I diabetes mellitus, gastric emptying of solids is delayed after 6-8 wk of untreated diabetes<sup>[23]</sup>. In the present study, we established an STZ-induced diabetic model and gastric motility was observed *in vitro* after 8 wk of untreated diabetes. The frequency of spontaneous contraction in the STZ-induced diabetic group was decreased significantly, however, the amplitude of contraction was not significantly different between these two groups. The results suggest that diabetic gastropathy mostly exhibits slow rhythm and turbulence, however, the amplitude of spontaneous contraction is not affected significantly in the early stage of diabetes. ICCs play a key role in gastric motility, and damage to the ICC networks may contribute to the development of gastropathy and gastroparesis<sup>[26]</sup>. In the present study, we confirmed whether the number of ICCs in the gastric smooth muscle layer was changed, by using immunohistochemistry in the STZ-induced diabetic mice. c-Kit expression in the muscle layer was observed in normal and diabetic mice, however, c-Kit expression was decreased in diabetic mice. The results suggest that gastric dysfunction in STZ-induced diabetic mice may be related to ICC depletion.

Atrial myocytes are the main source of ANP, but ANP is also found in other tissues, such as the gastrointestinal tract<sup>[27]</sup>. ANP and its receptor NPR-A have been detected in the gastric antrum<sup>[28]</sup>. NPR-A has the same membrane-bound guanylate cyclase activity as NPR-B, which catalyzes the formation of cGMP from GTP<sup>[9,10]</sup>. Some studies have demonstrated that ANP has an inhibitory effect on the regulation of gastrointestinal motility; for example, in chicken rectum<sup>[16]</sup>, rat tenia coli<sup>[17]</sup> and guinea-pig cecum<sup>[3]</sup>. Our previous study also has indicated that NPs relax gastric circular and longitudinal smooth muscles in human, rat and guinea-pig stomach, and NPRs are distributed in the rat gastric smooth muscle layer<sup>[18,19]</sup>. Another previous study has indicated that ANP release is augmented in the atrium of STZ-induced diabetic rats<sup>[29]</sup>. Recently, we have found that the expression of NPR-B gene is increased and NP-dependent guanylate cyclase/cGMP signaling is upregulated in STZ-induced diabetic rats<sup>[20,21]</sup>. ANP is also secreted from the gastric mucosa<sup>[15]</sup>, therefore, ANP can be considered endogenous to the gastric mucosa. However, the relationship between the ANP/NPR-A signaling pathway and STZ-induced diabetic gastroparesis is not clear. In the present study, we confirmed that the expression of ANP in gastric mucosa was increased significantly in STZ-induced diabetic mice. We demonstrated that the percentage of ANP-positive

cells was also enhanced significantly among the dispersed gastric epithelial cells, and the expression of the *ANP* gene in gastric tissue was upregulated in STZ-induced diabetic mice. These results suggest that ANP secretion from gastric mucosa is increased significantly in STZ-induced diabetes. The amount of ANP secretion is increased in diabetic mice, therefore, we investigated whether expression of NPR-A in the stomach was upregulated in STZ-induced diabetic mice. We demonstrated that expression of the *NPR-A* gene was also increased significantly in gastric tissue of diabetic mice. The results suggest that the ANP/NPR-A signaling pathway is upregulated in the stomach of STZ-induced diabetic mice.

Our previous study has demonstrated that the CNP/NPR-B signaling pathway is upregulated in STZ-induced diabetic rats<sup>[20,21]</sup>, while the present study indicates that the ANP/NPR-A signaling pathway is also upregulated in STZ-induced diabetic mice. Previous studies have indicated that diabetes may also affect expression of the *ANP* gene; for example, *ANP* gene expression in heart and kidney are increased in STZ-induced diabetic rats<sup>[11,30]</sup> and plasma concentration of pro-ANP is increased in comparison with control rats<sup>[31]</sup>. Christoffersen *et al.*<sup>[32]</sup> also have reported that diabetic mice show an increase in *NPR-B* gene expression in the heart, and have suggested that increased NPR-B signaling affects development of diabetic cardiomyopathy. The NP/NPR signaling pathway has an inhibitory effect on gastrointestinal motility, therefore, upregulation of this signaling pathway may be involved in development of gastroparesis in STZ-induced diabetic mice.

In summary, gastroenteropathy causes considerable morbidity in patients with diabetes mellitus and it has become a major healthcare burden. Current treatments are mainly symptomatic and frequently ineffective. Development of new therapeutic options is hampered because of poor understanding of the underlying pathological mechanisms. Our study demonstrates that the ANP/NPR-A signaling pathway is upregulated. The results suggest that ANP/NPR-A signaling is involved in the development of gastroparesis in STZ-induced diabetic mice.

## COMMENTS

### Background

Gastroparesis is a gastrointestinal complication of diabetes, which is also called delayed gastric emptying. The mechanism of gastroparesis is not clear, but a recent study has reported that the C-type natriuretic peptide-natriuretic peptide receptor B (CNP/NPR-B) pathway is upregulated in the stomach of diabetic rats. Atrial natriuretic peptide (ANP) has an inhibitory effect on motility of the gastrointestinal tract, but whether secretion of ANP is increased in the stomach of diabetic mice has not been reported.

### Research frontiers

NPs are located in several organs besides the heart. Recently, the authors have found that ANP and its receptor (NPR-A) are also present in the mouse stomach, and the CNP/cGMP pathway in diabetic gastroparesis was investigated in STZ-induced diabetic rats. This study was designed to investigate whether ANP secretion is altered in the stomach of STZ-induced diabetic mice.

### Innovations and breakthroughs

ANP with an inhibitory effect on gastrointestinal motility is present in the

stomach, and previous studies have focused on the relationship between the CNP/NPR-B pathway and gastric motility. This is believed to be the first study to investigate ANP secretion and NPR-A in the stomach of STZ-induced diabetic mice. The results suggest that ANP secretion and expression of NPR-A mRNA are both increased in the stomach of STZ-induced diabetic mice. This may be involved in stomach motility dysfunction in STZ-induced diabetic mice.

### Applications

The dysfunction of stomach motility that occurs in diabetic gastroparesis may be related to ANP secretion and upregulation of NPR-A. This may contribute to the treatment and preventive intervention of diabetic gastroparesis in the future.

### Terminology

Gastroparesis also called delayed gastric emptying, and usually occurs in diabetes. Symptoms of gastroparesis include heartburn, pain in the upper abdomen, vomiting, nausea, and early feeling of fullness.

### Peer review

This study deals with questions about the mechanisms involved in gastroparesis in diabetes.

### Abstract

**AIM:** To assess the feasibility and utility of double balloon enteroscopy (DBE) in the management of small bowel diseases in children.

**METHODS:** Fourteen patients (10 males) with a median age of 12.9 years (range 8.1-16.7) underwent DBE; 5 for Peutz-Jeghers syndrome (PJ syndrome), 2 for chronic abdominal pain, 4 for obscure gastrointestinal (GI) bleeding, 2 with angiomatous malformations (1 blue rubber bleb nevus syndrome) having persistent GI bleeding, and 1 with Cowden's syndrome with multiple polyps and previous intussusception. Eleven procedures were performed under general anesthesia and 3 with deep sedation.

**RESULTS:** The entire small bowel was examined in 6 patients, and a length between 200 cm and 320 cm distal to pylorus in the remaining 8. Seven patients had both antegrade (trans-oral) and retrograde (trans-anal and *via* ileostomy) examinations. One patient underwent DBE with planned laparoscopic assistance.

The remaining 6 had trans-oral examination only. The median examination time was 118 min (range 95-195). No complications were encountered. Polyps were detected and successfully removed in all 5 patients with PJ syndrome, in a patient with tubulo-villous adenoma of the duodenum, in a patient with significant anemia and occult bleeding, and in a patient with Cowden's syndrome. A diagnosis was made in a patient with multiple angiomata not amenable to endotherapy, and in 1 with a discrete angioma which was treated with argon plasma coagulation. The source of bleeding was identified in a further patient with varices. DBE was normal or revealed minor mucosal friability in the remaining 3 patients. Hence a diagnostic yield of 11/14 with therapeutic success in 9/14 was achieved.

**CONCLUSION:** Double balloon enteroscopy can be a useful diagnostic and therapeutic tool for small bowel disease in children, allowing endo-therapeutic intervention beyond the reach of the conventional endoscope.

### INTRODUCTION

The advent of flexible fiberoptic endoscopes transformed

the diagnosis and management of gastrointestinal (GI) disorders in adults and children, allowing direct visualization with targeted mucosal biopsies. Furthermore, endo-therapeutic procedures have now been possible throughout the upper GI tract and ileo-colon. However, the small bowel distal to the ligament of Trietz is inaccessible to conventional GI endoscopes. Recently, push enteroscopy, allowing the therapeutic endoscopist access up to 70-100 cm beyond the pylorus<sup>[1-4]</sup>, intra-operative enteroscopy techniques which are relatively invasive<sup>[5,6]</sup>, and wireless video capsule endoscopy (WCE) which affords excellent diagnostic yield combined with lack of morbidity but is non-therapeutic<sup>[7-9]</sup>, have been performed.

Double balloon enteroscopy (DBE) is a more recent modality which enables high resolution endoscopic imaging of the entire small bowel, allowing interventional endo-therapy (e.g. non-variceal hemostasis, snare polypectomy and pneumatic balloon stricture dilatation)<sup>[10-12]</sup>. It is clear that this technology could allow treatment of lesions, possibly identified by WCE or other less invasive investigations such as magnetic resonance imaging (MRI) enteroclysis, in parts of the small bowel inaccessible to standard endoscopy, and hence may preclude the need for formal surgical approaches in such children. We present the first pediatric-only experience of DBE, although 2 predominantly adult series have included a few children with an age range up to 20 years and no specification as to those under 16 years<sup>[13,14]</sup>.

## MATERIALS AND METHODS

We prospectively collected the following data on all consecutively enrolled children between January 2004 and December 2007. All had undergone upper endoscopy, ileo-colonoscopy, and most had had WCE. Various imaging techniques had been employed but none had undergone virtual CT. The double balloon enteroscopy system (Fujinon; Fujinon Inc., Japan) (Figure 1) consists of a high resolution video endoscope (EN-450P5/20) with a flexible over-tube (TS-12140), as well described elsewhere. The enteroscope has a working length of 200 cm and an outer diameter of 8.5 mm. The flexible over-tube has a length of 140 cm and outer diameter of 12 mm. Two enteroscopes are available, currently with 2.2 mm and 2.8 mm working channels, allowing therapeutic intervention. The enteroscopes and over-tube have balloons fitted at the distal tip of each, which are sequentially inflated and deflated with air from a pressure controlled pump system with a maximum inflatable pressure of 45 mmHg.

Specifics of the procedure are not provided here as these have been well documented elsewhere and do not differ in pediatric practice compared to that in adults. Patients received bowel preparation as for colonoscopy in anticipation of a trans-anal approach. For bowel preparation, Senokot 1-2 mg/kg (max 30 mg) and sodium picosulphate 2.5-10 g (depending on age) were given on the evening prior to the day of procedure with sodium picosulphate repeated on the morning of the procedure.

The new double balloon enteroscopy (DBE) system features the following components  
An EN-450P5/20 video endoscope  
A 400 (VP-402, XL-402) processor  
A TS-12140 overtube  
BS-1 balloons  
A PB-10 balloon controller

Figure 1 Double balloon enteroscopy system configuration.

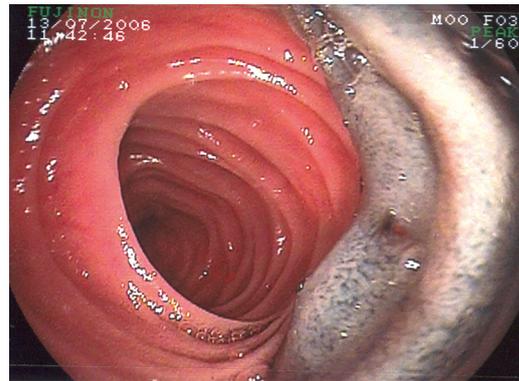

Figure 2 Double balloon tattoo.

The preference was for general anesthesia but moderate conscious sedation was employed in the older patients in one centre. If the terminal ileum (TI) was not reached then the most distal part of the small bowel negotiated was "tattooed" in the sub-mucosal plane with an endo-needle (Figure 2). The DBE could then be repeated *via* the trans-anal route and retrograde movement from the TI proximally was attempted to attain the marked area. No external compression, fluoroscopy, or other aides were necessary or useful in aiding intubation. No anti-spasmodics were employed, and air rather than carbon dioxide was insufflated. If lesions were encountered it was usual practice to treat as they were encountered rather than on withdrawal in case the lesions were not then found again. Potential adverse events such as pancreatitis, perforation, or bowel damage due to traction or torsion around the mesentery have been reported in the adult literature. Two of the authors (Thomson M and Jacobs M) performed all of the DBE having attained competence in DBE in adult patients first. Training and learning curves for this procedure are, it is estimated by the procedurists, similar to that encountered in ileo-colonoscopy, and clearly it is not yet apparent in pediatric practice how many DBE procedures are necessary in order to attain a high degree of competence.

## Patients

Fourteen patients (10 males), median age 12.9 years (range 8.1-16.7), median weight 39.6 kg (range 24.1-67.3)

**Table 1** Investigations performed on patients prior to DBE

1	WCE: ?small sessile polyp in mid-small bowel
2	Intra-operative enteroscopy with polypectomy MRI enteroclysis: normal
3	OGD: polyps in stomach and duodenum MRI: 3 big polyps in small bowel
4	WCE: multiple polyps in mid-small bowel
5	WCE: possible polyp in ileum
6	WCE: ?polyps seen in small bowel, ?intermittent intussusception Colonoscopy: polyp in rectum
7	WCE: normal, Abdominal Ultrasound: enlarged spleen
8	WCE: no source of bleeding
9	OGD, WCE: lymphonodular hyperplasia in duodenum of little clinical significance
10	OGD, WCE: no positive findings
11	OGD, ileo-colonoscopy, WCE: multiple blue rubber bleb nevus lesions throughout bowel
12	WCE: angioma in small bowel
13	WCE: polyp in mid-small bowel
14	WCE: multiple polyps seen throughout the small bowel including a lymphangitic polyp

DBE: Double balloon enteroscopy; WCE: Wireless video capsule endoscopy; OGD: Gastroduodenoscopy.

underwent DBE. Indications: patients 1-5 for Peutz-Jeghers syndrome (PJS); patients 6-7 for recurrent abdominal pain; patients 8, 9, 10 and 13 for obscure GI bleeding. Patients 11 and 12 had, respectively; blue rubber bleb nevus syndrome and an angioma identified by WCE, and had transfusion-dependent persistent GI bleeding. Patient 14 had Cowden's syndrome with previous episode of intussusceptions. Thirteen patients had undergone WCE and 1 MRI enteroclysis (Table 1).

Eleven patients received general anesthesia and 3 procedures were performed under sedation with fentanyl and midazolam. Thirteen patients had trans-oral DBE, of whom 6 patients also had trans-anal, and 1 patient had trans-stomal DBE through an ileostomy. One patient underwent intra-operative DBE.

## RESULTS

The results of this investigation suggest that DBE is both useful and feasible in children with small bowel disease. The entire small bowel was examined in 6 patients, either trans-oral alone or with both trans-oral and trans-anal DBE. When TI was not attained, trans-oral progression was assessed as approximately 200 to 320 cm beyond the pylorus (Table 2), based on the assumption that each set of maneuvers to advance the enteroscope traversed around 30 cm of bowel with diminishing distance the more attempts at advancement were made. No fluoroscopy was used hence these estimates of distance attained are presumptive. The median examination time was 118 min (range 95-195). No complications of DBE were encountered, and mild post-procedure abdominal discomfort, as occurs secondary to bowel insufflation in some ileo-colonoscopies, was temporary and controlled easily with simple analgesia.

Patients 1-5 were known to have PJS. Patient 1 had not undergone WCE, and both trans-oral and trans-anal DBE allowed the whole small bowel to be visualized. No polyps were found in the small bowel; however a rectal polyp was resected which confirmed PJS on histology. Patient 2 had undergone previous intra-operative enteroscopy with polypectomy, and DBE revealed a presumably new small polyp in the jejunum which was removed. Patient 3 underwent laparoscopic-assisted DBE and 7 polyps were removed. The postoperative period was complicated by pelvic abscess requiring surgical drainage, but no intestinal perforation had occurred, hence the reason for the laparoscopic complication was unclear. Patient 4 had multiple sessile polyps in the jejunum and patient 5 had one PJS polyp removed from the mid jejunum. It is therefore suggested that PJS patients undergo WCE prior to DBE and if no polyps are found, then no DBE should take place.

Patients 6 and 7 had recurrent abdominal pain as the main presenting complaint with multiple negative investigations. Patient 6 had a family history of PJS and WCE had suggested a polyp in the mid-ileum. However, trans-oral (200 cm post-pylorus) and trans-anal (35 cm proximal to ileo-cecal valve) DBE failed to identify a polyp. Patient 7 presented with recurrent abdominal pain over 3.5 years (repeated upper GI endoscopy and ileocolonoscopy were inconclusive), and WCE had suggested proximal jejunal polyps. Trans-oral DBE demonstrated thickened folds in the proximal jejunum, which on histology proved to be a tubulo-villous adenoma. Surveillance enteroscopy after 1 year identified progression to intra-mucosal carcinoma. Surgical excision of the affected bowel and pancreas has proved curative. Clearly, this finding is very uncommon and the literature does not suggest an incidence in this age group. Of course, it is not suggested that all patients with recurrent abdominal pain undergo DBE. Clear clinical indication and warning signs such as a family history of polyp syndromes, in spite of negative WCE, are reasonable pointers towards DBE.

Patients 8-13 were investigated for GI bleeding. Patient 8 was transfusion-dependent and DBE was non-contributory since esophago-gastric varices were identified which could also have been identified and treated by standard upper GI endoscopy, although prior to transfer to our unit this procedure had not identified the varices. Mid-small bowel varices were not found at DBE. Patient 9 was investigated for obscure GI bleeding and trans-oral DBE did not reveal a bleeding site. Subsequently a Meckel's scan, initially negative, was repeated, found to be positive and surgical resection occurred. Had trans-anal DBE been performed this may have identified the Meckel's diverticulum, but this was not attempted due to a technical failure of the system and remains conjectural. The technical failure was due to the distal balloon bursting and is not considered as a dangerous adverse event.

Patient 10 had intestinal aganglionosis, an ileostomy and a gastrostomy, and presented with a 3-year history

Table 2 Details of indications, approach and findings in patients undergoing DBE

Patient No.	Age/Sex	Indication	Approach	Complete /incomplete	Findings
1	13/M	PJS	Oral + anal	Complete	Rectal polyp
2	12/M	PJS	Oral	320 cm <sup>1</sup>	Small polyp in jejunum
3	16/M	PJS	Intra-operative	Complete	3 small polyps removed endoscopically and 3 large polyps removed surgically
4	11/M	PJS	Oral	250 cm <sup>1</sup>	Multiple polyps in mid-small bowel
5	9/M	PJS	Oral	Incomplete	Mid-small bowel polyp
6	10/F	Chronic abdominal pain	Oral + anal	Up to 200 cm <sup>1</sup> trans-orally, 35 cm TI proximal to ICV trans-anally	Normal
7	16/M	Chronic abdominal pain with family history of colorectal carcinoma	Oral + anal	Complete	Tubulo-villous adenoma in duodenum; Lymphoid aggregates in ileum
8	11/M	Upper GI bleeds/possible vascular malformation	Oral	300 cm <sup>1</sup>	Grade 1 esophageal varices; no source found in small bowel
9	16/M	Occult bleeding	Oral	200 cm <sup>1</sup>	No source found
10	8/M	Occult bleeding	Oral + <i>via</i> ileal stoma	Complete	Increased friable mucosa throughout the small bowel
11	12/F	Blue rubber bleb syndrome with persistent GI bleeding	Oral + anal	200 <sup>1</sup> cm trans-orally, 50 cm proximal to ICV trans-anally	Numerous angiomas throughout small bowel not amenable to therapy
12	9/F	Angioma	Oral	Incomplete	Angioma identified: APC applied
13	16/M	Occult bleeding with significant anemia	Oral + anal	Complete	Polyp 40 cm from TI: removed
14	12/F	Cowden's syndrome	Oral + anal	Complete	Multiple polyps: 2 snare polypectomies; Meckel's diverticulum found

<sup>1</sup>Post-pylorus distance achieved. PJS: Peutz-Jeghers syndrome; ICV: ileo-caecal valve; APC: Argon plasma coagulation.

of transfusion-dependent obscure GI bleeding. DBE identified very friable small bowel mucosa with contact bleeding, but no histological diagnosis was concluded with normal biopsies obtained. Patient 11 had transfusion-dependent recurrent GI bleeding due to multiple lesions consistent with blue rubber bleb nevus syndrome, identified in the colon at colonoscopy, and throughout the small bowel at DBE (Figure 3). Argon plasma coagulation (APC) was used in order to ablate some of the lesions and transfusion requirement diminished. The extensive nature of the lesions precluded definitive surgery and further DBE is planned, but has not occurred to date, therefore post-APC images are not available. However, transfusion dependency in both patients 10 and 11 had ceased.

Patient 12 had angioma detected in the mid-small bowel on WCE. This was identified with DBE, and APC was applied. Patient 13 presented with occult bleeding and significant anemia, and a polyp was detected in the small bowel on WCE. At DBE, a 4 mm polypoid structure was found (Figure 4A) and removed (Figure 4B). Patient 14 had Cowden's syndrome with a history of intussusception. DBE revealed presence of multiple sessile polyps and polypectomies were performed on 2 polyps. Incidentally, a Meckel's diverticulum was found (Figure 5) in this patient.

No patients referred and considered for DBE were rejected, i.e. there seems no reason not to consider this minimally invasive approach. No complications occurred in the 13 patients who had DBE alone without intra-operative assistance. Significant post-procedure abdominal pain was not encountered, and only paracetamol was needed to counter minor abdominal discomfort, except

in the individual who had undergone laparoscopy. All patients were in-patients although it is anticipated that day case procedures are viable. No evidence of pancreatitis, perforation or bowel damage was encountered, and the intra-abdominal abscess could have been the result of a micro-perforation rather than bowel damage due to the laparoscope, although the authors consider this unlikely. All patients were allowed home with no evidence of significant complications or discomfort within 24 h of the DBE being performed. All of those who did not undergo polypectomy were allowed home on the same day as the procedure. The longest duration at 195 min has to be considered as a long endoscopic procedure, but this has to be counter-balanced by the relative lack of invasiveness of the technique.

## DISCUSSION

Flexible GI endoscopy is sufficient for diagnostic and therapeutic procedures in the vast majority of pediatric cases, and in adult patients with obscure GI bleeding this procedure is known to determine the source in up to 90% of cases. However, in the small number of cases where the pathology is confined to the small bowel beyond the reach of conventional endoscopy, WCE and DBE have been recently employed. In our series the entire small bowel was examined in 6/14 patients in whom trans-oral and trans-anal approaches were combined. One cannot claim that DBE diagnosed the disease in this series of patients, but it can be considered that it had a very important role in treatment. In all patients with PJ syndrome polyps were detected. Prior to the advent of these technologies, modalities such

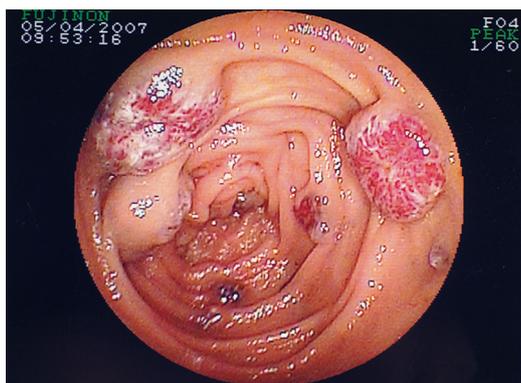

Figure 3 Multiple angiomas in small bowel.

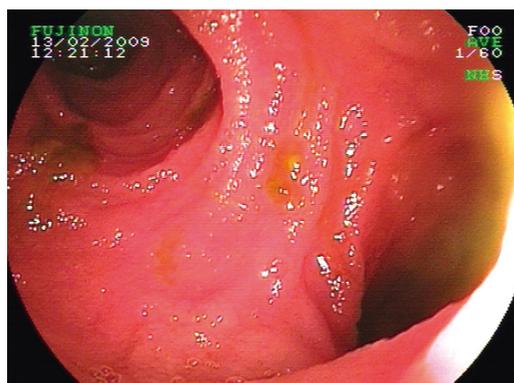

Figure 5 Meckel's diverticulum.

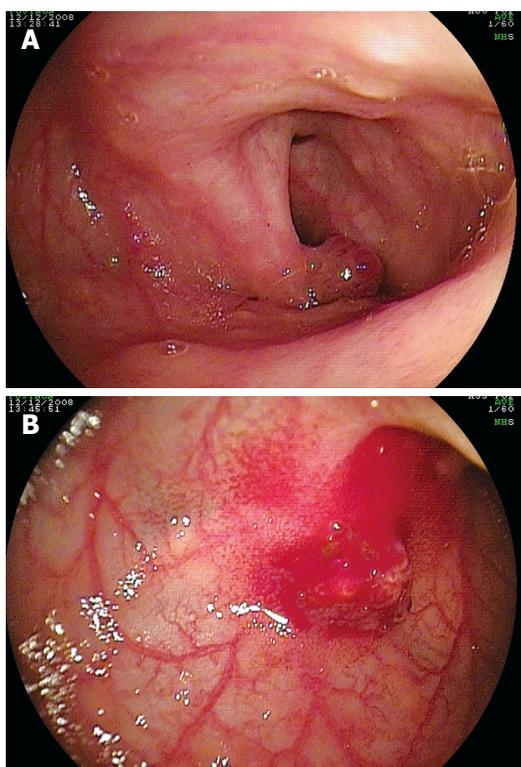

Figure 4 Polyp detected (A) and removed (B).

as push enteroscopy (PE) have had limited pediatric exposure due to safety concerns. In children, 80% of all mucosal lesions identified and biopsied by PE, and 20% of therapeutic procedures performed, were beyond the reach of a standard GI endoscope<sup>[13]</sup>. Small bowel series, angiography, scintigraphy and enteroclysis have been used with variable results in the evaluation of adult patients with obscure GI bleeding<sup>[15,16]</sup>. WCE has recently attained the position of investigation of first choice for such diagnoses, while intra-operative enteroscopy, despite its invasive quality, has been the mainstay in the subsequent treatment of obscure GI bleeding in children and adults<sup>[5,17,18]</sup>.

Wireless capsule endoscopy (WCE) has been compared favorably with intra-operative enteroscopy for

the diagnosis of obscure bleeding in adults, with 95% sensitivity and 75% specificity<sup>[19]</sup>. WCE has been found to be diagnostically superior to PE<sup>[20,21]</sup> and barium follow through/CT scan in obscure GI bleeding, and has been recently evaluated in children<sup>[22]</sup>. WCE is, however, non-therapeutic by its nature, and since the imperative in pediatric gastroenterology is the drive to diagnosis by mucosal histology, this is a shortcoming of WCE.

Trans-oral and, if necessary, subsequent trans-anal DBE allow therapeutic interventions such as polypectomy, hemostasis, balloon dilatation and placement of stents for the whole of the small bowel<sup>[23]</sup>. In a prospective comparative study between WCE and DBE in patients with obscure GI bleeding, the diagnostic rate was 80% for WCE and 60% for DBE; however, 51% of the patients had therapeutic intervention using argon plasma, underlining the therapeutic utility of DBE<sup>[24]</sup>. In a recent large retrospective analysis of 152 patients undergoing DBE for obscure GI bleeding in adults, 75% had the potential source of bleeding detected and, for 83% of patients, management was changed as a direct result of DBE<sup>[25]</sup>. Yamamoto has described full small intestinal examination in 86% of adults using DBE<sup>[23]</sup>. DBE in this series of children had a diagnostic yield of 11/14, and therapeutic success in 9/14 was achieved. Clearly if a regional or national small bowel diagnostic and therapeutic centre is contemplated then the duality of WCE and DBE is mandatory to achieve the goals of diagnosis and treatment without operative intervention, which should be the goal of a pediatric endoscopic centre of excellence. Hence, with the results of our prospective DBE study a case could be made for the discontinuation of push enteroscopy in the investigation and treatment of children with suspected small bowel pathology.

Complications have been reported in the literature with DBE, including intestinal perforation<sup>[26,27]</sup>, pancreatitis<sup>[28]</sup> and paralytic ileus<sup>[29]</sup>. However, the only complication in our group of children occurred secondary to surgical intervention in the child who underwent intra-operative DBE.

Training remains an issue with no clear resolution attempted by this small series which included only two

experienced endoscopists.

In conclusion, double balloon enteroscopy is a useful diagnostic and therapeutic tool for the investigation of small bowel disease. It is useful in conjunction with WCE for optimizing diagnostic potential in the small bowel and offering a therapeutic option. It is also of benefit in situations where diagnosis has not been reached by other investigative modalities, and particularly in those lesions amenable for therapeutic intervention endoscopically, but not reachable by the conventional endoscope.

## COMMENTS

### Background

The small bowel distal to the ligament of Trietz is inaccessible to conventional gastrointestinal (GI) endoscopes. Several techniques such as push enteroscopy, intra-operative enteroscopy techniques and wireless video capsule endoscopy have been developed. All these procedures have some limitations. Double balloon enteroscopy (DBE) is a recently developed tool which enables high resolution endoscopic imaging of the entire small bowel and allows interventional endo-therapy.

### Research frontiers

Small bowel is a particular area of the GI tract difficult to be imaged completely by conventional endoscope. DBE enables high resolution endoscopic imaging of the entire small bowel. In addition to diagnosis, DBE permits interventional endo-therapy.

### Innovations and breakthroughs

DBE has found application in the investigation of obscure GI bleeding in adults. This is the first study to assess the usefulness, safety and diagnostic potential of DBE in children.

### Applications

DBE is a valuable diagnostic and therapeutic tool for the investigation of small bowel disease both in adults and in children. DBE is useful in conjunction with other investigative modalities in optimizing diagnostic potential in the small bowel and offering a therapeutic option.

### Peer review

This is a good introductory study on DBE in children.

### Abstract

**AIM:** To evaluate the Z-line visualization by the PillCam™ SB2 using three different ingestion protocols.

**METHODS:** Ninety consecutive patients undergoing small bowel capsule endoscopy (SBCE) between January and May 2008 were included in the study. They swallowed the capsule in the standing (Group A = 30), supine (Group B = 30) and right supine positions (Group C = 30). Baseline patient characteristics, difficulties in capsule ingestion, esophageal transit times (ETT) and Z-line visualization were noted.

**RESULTS:** No significant differences were found between the groups with regard to baseline patient characteristics, ingestion difficulties and complete SB examinations ( $P > 0.05$ ). At least 1 frame of the Z-line was detected in 15.8%, 46.7% and 90% of patients in groups A, B and C, respectively ( $P < 0.001$ ). The average number of Z-line images was  $0.21 \pm 0.53$ ,  $3.23 \pm 6.59$  and  $5.53 \pm 7.55$  and the mean % of the Z-line

detected was 71.3, 25.1 and 8.3, in groups A, B and C, respectively (both  $P < 0.001$ ). ETT times were longer in the supine group followed by the right supine and the standing groups (median of 237 s vs 64 s and 39 s, respectively;  $P < 0.001$ ).

**CONCLUSION:** Z-line visualization in patients undergoing SBCE can be accurately achieved in most cases when the capsule is swallowed in the right supine position.

### INTRODUCTION

Small bowel examination has recently become possible because of emerging procedures such as capsule endoscopy. As demonstrated by previous studies, capsule endoscopy is an accurate, easy and safe method which allows examination of the entire small bowel in most cases<sup>[1-3]</sup>. Moreover, capsule endoscopy has been demonstrated to be more effective than small bowel follow-through and push-enteroscopy for small bowel exami-

nation<sup>[4-8]</sup>. Nevertheless, images and lesions outside the small bowel (i.e. esophagus, stomach and colon) can also be detected by the capsule<sup>[9-11]</sup>. These images or lesions are sometimes missed by conventional endoscopy<sup>[12,13]</sup> which means that non-small bowel segments of capsule videos should be carefully reviewed by physicians. As the small bowel capsule is usually swallowed in the standing position, the esophageal transit time becomes very short resulting in few images taken in the esophagus. Recent advances in capsule designs have demonstrated that an accurate examination of the esophagus is feasible<sup>[14-18]</sup>. In fact, the esophageal capsule is swallowed by the patient in the supine or right supine positions in order to increase esophageal transit time allowing the capsule to take more images in the esophagus. However, the esophageal capsule battery lasts 20 min on average, which means that only upper gastrointestinal segments, usually including the esophagus and stomach, can be examined. Since the small bowel capsule has longer battery time, the esophagus in addition to the stomach, small bowel and colon, could be explored. Whether esophageal mucosa can be accurately explored by the small bowel capsule in the supine and right supine positions has not been previously studied. The aims of this study were to evaluate and compare the Z-line visualization by the PillCam™ SB in patients undergoing small bowel capsule endoscopy using three different ingestion protocols: standing, supine and right supine positions.

## MATERIALS AND METHODS

### Patients

This study was conducted at a single hospital between January and May 2008. All patients who were not contraindicated to undergo capsule endoscopy, despite procedure indications, were suitable for inclusion in the study. Exclusion criteria were: age < 18 years, swallow and or esophageal motility disorders and previous prokinetic drugs administration. Patients were randomized, by means of computer-generated random numbers, to swallow the capsule in one of the three different positions: standing (Group A), supine (Group B) and right supine position (Group C).

### Capsule endoscopy

All capsule procedures were performed with the PillCam™ SB2 (Given Imaging Ltd; Yoqneam, Israel). Two CE-experienced gastroenterologists (Fernandez-Urien I and Borobio E) reviewed the videos helped by the latest version of the program RAPID® 5.1.

### Ingestion protocols

All patients underwent capsule endoscopy after an 8-h fast. Prokinetics, laxatives or simethicone were not used, and all patients were asked to drink 100 mL of water before capsule ingestion in order to clear the esophagus of secretions. They were also kindly asked not to talk during the ingestion procedure.

**Standing position (Figure 1A):** Patients from Group A were asked to swallow the capsule in the standing position with a small amount of water if required (no more than 20 mL).

**Supine position (Figure 1B):** Patients from Group B were asked to swallow the capsule in the supine position with a small amount of water if required (no more than 20 mL). They remained in this position for two min and then they were raised to an inclination of 30 degrees for 2 min and 60 degrees for additional 1 min in order to facilitate the transit of the capsule through the esophagus. Then, all patients were asked to drink a small sip of water (10 mL), allowed to sit upright and then asked again to drink 10 mL of water (in order to ensure complete esophageal examinations).

**Right supine position (Figure 1C):** Patients from Group C were asked to swallow the capsule in the right supine position with a small amount of water if required (no more than 20 mL). They remained in this position for 7 min and then were asked to drink small sips of water (10 mL) every 30 s helped by a flexible straw in order to ensure that the capsule reached the distal part of the esophagus. After that, all patients were allowed to sit upright and asked to drink 10 mL of water (in order to ensure complete esophageal examinations).

### Variables analyzed

Baseline patient characteristics, difficulties in capsule ingestion, esophageal transit times (from mouth to stomach) and Z-line visualization were prospectively noted. Difficulties in capsule ingestion were classified as follows: easy when the capsule was swallowed before 1 min and without nausea, difficult when the capsule was swallowed after 1 min and/or with nausea, and impossible when the capsule was not swallowed by the patient. The Z-line visualization was measured on screen using a 4-quadrant scale (Figure 2).

### Sample size

Sample size estimation is not possible in the absence of data regarding the incidence of Z-line visualization with the PillCam™ SB2 ingested in the supine and right supine positions. However, assuming an incidence of Z-line visualization of 10% in the standing position, 35% in the supine position and 70% in the right supine position, 30 patients would be required in each group to detect significant differences (with  $\alpha$  level set at 0.05 and  $\beta$  at 95%).

### Statistical analysis

Data from quantitative variables which did not follow a Gaussian distribution are presented as median and interquartile range (IQR) and compared using the Kruskal-Wallis and the Mann-Whitney tests. Those data from quantitative variables which followed a Gaussian distribution are presented as mean and standard deviation

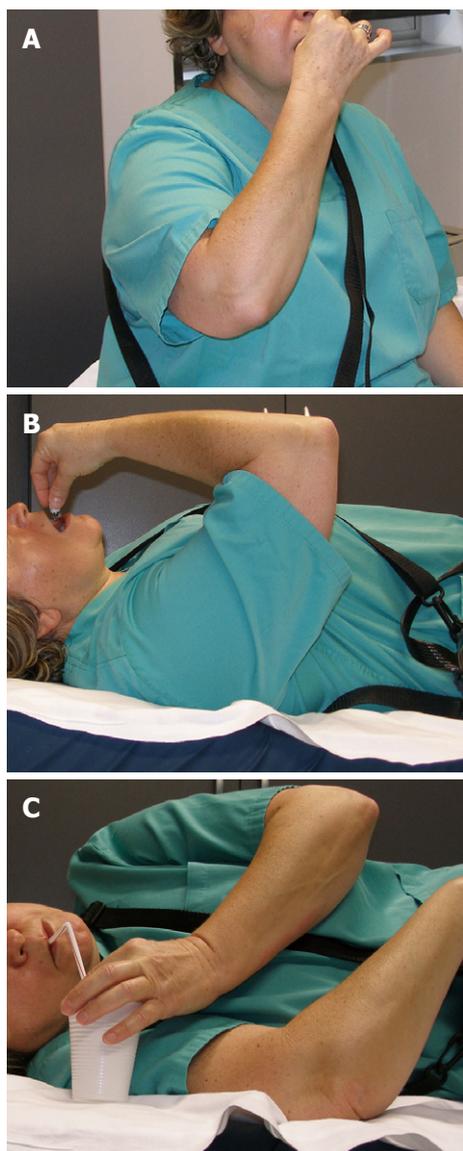

Figure 1 Capsule ingestion in the standing position (A: group A), supine position (B: group B) and right supine position (C: group C).

analysis was performed with SPSS version 15.0 (SPSS Inc; Chicago, Ill, USA). Values of  $P < 0.05$  were considered to be statistically significant.

## RESULTS

### Baseline patient characteristics

Baseline patient characteristics are shown in Table 1. There were no statistically significant differences in age, gender, body mass index (BMI), procedure indication and outpatient setting between groups A, B and C ( $P > 0.05$ ).

### Capsule ingestion

Capsule ingestion was possible in all patients (results of capsule ingestion are summarized in Table 2). Capsule ingestion was easy in more than 90% of the patients in all positions. No significant differences were observed between groups A, B and C ( $P > 0.05$ ).

### Esophageal transit time

Esophageal transit times were significantly longer in the supine group followed by the right supine and the standing groups [median (IQR) of 237 s (80-474), 64 s (40-108) and 39 s (24-55), respectively;  $P < 0.001$ ]. Post-hoc comparisons showed that the differences group by group were also statistically significant ( $P < 0.05$ ) (Table 3).

### Z-line visualization

Table 4 shows the results concerning Z-line visualization in the standing, supine and right supine positions. At least one image of the Z-line was detected by the capsule in 15.8%, 37.3% and 90% of patients when the capsule was swallowed in the standing, supine and right supine positions, respectively ( $P < 0.001$ ). Post-hoc comparisons showed that the differences found group by group were also significant ( $P < 0.05$ ). The Z-line was detected by the

Mean frames	0.21 ± 0.53	3.23 ± 6.59	5.53 ± 7.55	0.017 <sup>2</sup>
Standing vs supine		Standing vs right supine	Supine vs right supine	
% patients	$P = 0.027^3$	$P < 0.001^3$	$P < 0.001^3$	(-)
Mean % Z-line	NS <sup>4</sup>	$P < 0.001^4$	$P < 0.001^4$	(-)
Mean frames	NS <sup>4</sup>	$P = 0.002^4$	NS <sup>4</sup>	(-)

<sup>1</sup>Pearson-Fischer  $\chi^2$  test; <sup>2</sup>ANOVA test; <sup>3</sup>Pearson-Fischer  $\chi^2$  test; <sup>4</sup>Tamhane test (post-hoc comparisons).

capsule in  $5.5 \pm 7.5$ ,  $3.2 \pm 6.5$  and  $0.2 \pm 0.5$  frames per procedure in the right supine, supine and standing groups. Although these differences were significant ( $P < 0.05$ ), post-hoc comparisons showed that only the differences between the standing and the right supine groups were significant ( $P < 0.05$ ). The mean % of Z-line detected by the capsule was 71.3% in the right supine group, 25.1% in the supine group and 8.6% in the standing group. These differences were also significant ( $P < 0.001$ ) but post-hoc comparisons group by group demonstrated that the differences between the standing and the supine group were not significant ( $P > 0.05$ ).

### Complete small bowel examinations

The cecum was reached by the capsule in 89.5%, 86.2% and 96.7% of cases in the standing, supine and right supine positions, respectively. These differences were not statistically significant ( $P > 0.05$ ).

## DISCUSSION

Wireless capsule endoscopy has opened a new era for small bowel examination. In fact, more than 500 000 capsule procedures have been performed worldwide. Capsule endoscopy offers excellent images of the small bowel but also from the esophagus, stomach and colon in most cases. As demonstrated by some previous studies<sup>[12,13]</sup>, non-small bowel lesions detected by capsule endoscopy are sometimes missed by conventional endoscopy which means that non-small bowel segments of capsule videos should be carefully reviewed by physicians. However, esophageal examination with the PillCam™ SB has been demonstrated not to be feasible in the standing position<sup>[19]</sup> but possible in the supine and

right supine positions as shown with the PillCam™ ESO capsule<sup>[14-18]</sup>. Esophageal images taken by the capsule when it is swallowed in the standing position are not usually enough in terms of number and quality. Since the first small bowel examinations, capsule endoscopy has been performed in the standing position in most institutions and the reason for this seems to be simple, to reach the duodenum as soon as possible to ensure complete small bowel examinations. Currently, the rate of complete examinations is up to 80% in published series<sup>[20]</sup> and it depends on factors such as previous abdominal surgery, patient hospitalization and diabetes. Although there are no references in the literature, it seems that capsule ingestion in the standing position does not improve the rate of complete examinations. Moreover, there is a recent study which concludes that the right supine position after capsule ingestion improves the rate of complete examinations<sup>[21]</sup>. Thus, there are no specific reasons to perform small bowel capsule endoscopy in the standing position.

The main objective of our study which was to analyze the Z-line visualization with the PillCam™ SB in the supine and right supine positions has not been previously analyzed. This new modality of the small bowel capsule endoscopy procedure could optimize the capsule resources without affecting small bowel examinations and patients' tolerability. In fact, we did not find significant differences in the rate of complete small bowel examinations and patients' swallowing difficulties despite their positions during capsule ingestion. Capsule ingestion in the right supine position was significantly more effective for Z-line visualization than the standing and supine positions. On the one hand, our results showed that the Z-line was detected in most patients who swallowed the capsule in the right position. On the other hand, the frequency and the quality of Z-line images taken by the capsule were greater in the right supine position than in the standing and supine positions. Although in some patients it was not completely visualized by the capsule in the right supine position, the Z-line was detected more than 5 times per procedure on average. Therefore, it seems reasonable to affirm that the Z-line was almost completely visualized in most cases. These results are consistent with those previously obtained by esophageal capsule endoscopy<sup>[22,23]</sup>.

Surprisingly, esophageal transit times which were significantly longer in the supine group did not affect the Z-line visualization. More time in the esophagus did not mean more and better images from the Z-line. A reasonable explanation for this may be the position of the His angle at the gastroesophageal junction. While the capsule remains too long in the mid and distal esophagus but far away from the Z-line when is swallowed in the supine position, it rapidly reaches the distal esophagus but is kept by the His angle over the Z-line for several seconds in the right supine position. Therefore, the right supine position seems to be anatomically optimal for Z-line examination. Moreover, a previous study by Gralnek *et al.*<sup>[22]</sup> in healthy volunteers using the PillCam™ ESO, tested

several ingestion procedures including standing, supine, right supine and left supine positions, concluding that the right supine position was the best approach to explore the distal esophagus.

Several studies have previously evaluated the feasibility of capsule endoscopy in the evaluation of the esophagus, however, the majority of them employed the PillCam™ ESO. The PillCam ESO and the ESO2 offer excellent images of more than 75% of the Z-line in most patients<sup>[22,23]</sup>. However, to our knowledge, there is only one study which has evaluated the role of the small bowel capsule for esophageal examinations<sup>[19]</sup>. In that study, an adequate assessment of the Z-line (50% and 100% of the circumference) was achieved in 10.4% and 0% of patients in the standing position and in 12.5% and 37.5% of patients in the supine position. Therefore, the authors concluded that esophageal examinations using small bowel capsule endoscopy was not feasible. Our results in patients who swallowed the capsule in the standing and supine positions are consistent with those obtained in that study, however, those authors did not include the right supine position as an additional comparative arm.

In this situation, the main question is: should all patients undergoing capsule endoscopy, despite indications, swallow the capsule in the right supine position? The answer is probably yes, because this alternative is easy to perform, is not uncomfortable for the patient, is not time consuming for physicians and the most importantly, it offers excellent images of the Z-line in most cases. However, the PillCam™ SB has to demonstrate that it is accurate in detecting esophageal lesions such as gastroesophageal reflux disease (GERD) lesions or varices. Other capsule prototypes such as the PillCam ESO capsule have demonstrated a high diagnostic accuracy for detecting GERD lesions, Barrett's esophagus and esophageal varices<sup>[14-16]</sup>. Nevertheless, it has to be taken into account that this capsule prototype takes 14 images per second and the PillCam SB, only 2 per second. Therefore, future studies in patients with suspected esophageal diseases should be performed. If favourable results are obtained, then this alternative should be used in all capsule procedures including small bowel, colon and of course, esophageal examinations.

## COMMENTS

### Background

Capsule endoscopy has become a very important tool for small bowel examination. However, images from other parts of the gastrointestinal (GI) tract, can also be detected by the capsule. These images or lesions are sometimes missed by conventional endoscopy, which means that images from the esophagus, stomach and colon should be carefully reviewed.

### Research frontiers

Esophageal examination is not feasible if the capsule is ingested in the standing position as shown by previous studies. With recent prototypes designed for esophageal examination, new ingestion protocols have been evaluated. The supine and right supine positions have been demonstrated to be good positions to achieve a good esophageal examination. Whether the small bowel capsule is capable of examining the esophagus in these positions has not been previously studied.

### Innovations and breakthroughs

This study demonstrates that the PillCam SB can accurately explore the Z-line when it is ingested in the supine and right supine positions.

### Applications

Esophageal examination could be of interest in those patients who undergo capsule endoscopy of the small bowel. Missed lesions in the esophagus by conventional endoscopy could be detected by the capsule if it is ingested in the right supine position.

### Peer review

This study demonstrate that Z-line examination is those patients undergoing small bowel capsule endoscopy is feasible if the capsule is ingested in the right supine position.

Lcr35, but not *L. rhamnosus* GG, showed a beneficial effect.

**CONCLUSION:** Until more data are available, we believe the use of probiotics for the treatment of constipation condition should be considered investigational.

### Abstract

**AIM:** To systematically evaluate and update evidence on the efficacy and safety of probiotic supplementation for the treatment of constipation.

**METHODS:** The MEDLINE, EMBASE, CINAHL, and Cochrane Library databases were searched in May 2009 for randomised controlled trials (RCTs) performed in paediatric or adult populations related to the study aim.

**RESULTS:** We included five RCTs with a total of 377 subjects (194 in the experimental group and 183 in the control group). The participants were adults (three RCTs,  $n = 266$ ) and children (two RCTs,  $n = 111$ ) with constipation. In adults, data suggests a favourable effect of treatment with *Bifidobacterium lactis* DN-173010, *Lactobacillus casei* Shirota, and *Escherichia coli* Nissle 1917 on defecation frequency and stool consistency. In children, *L. casei rhamnosus*

### INTRODUCTION

Constipation is a common condition affecting children and adults<sup>[1,2]</sup>. In the vast majority of cases, no underlying organic cause is found and functional constipation is diagnosed<sup>[3,4]</sup>. The standard treatment consists of disimpaction and the administration of laxatives to achieve a normal bowel habit of passing a soft stool without pain. Even though traditional treatment is well established and safe, for many patients it does not provide satisfying improvement, prompting interest in other therapeutic strategies<sup>[5]</sup>.

Currently, probiotics, defined as live microorganisms which when administered in adequate amounts confer a health benefit on the host<sup>[6]</sup>, are increasingly being used in the management of constipation. Those most widely studied are organisms within the genera *Bifidobacterium*

and *Lactobacillus*. There are several reasons why probiotics might have therapeutic potential for the treatment of constipation. Firstly, there are data demonstrating differences in the intestinal microbiota between healthy individuals and patients with chronic constipation<sup>[7,8]</sup>. The key features are an increased number of clostridia and bifidobacteria, with different species of clostridia and enterobacteriaceae being frequently isolated. A number of key questions remain to be answered, principally, what is the origin of this dysbiosis? Is dysbiosis a secondary manifestation of constipation, or is it a factor contributing to constipation? Secondly, studies involving the administration of *B. lactis* DN-173 010 have shown improved colonic transit times, both in a healthy population<sup>[9]</sup> and in constipated patients<sup>[10]</sup>. Finally, probiotics lower the pH in the colon. This reduction in pH is due to the bacterial production of short-chain fatty acids (butyric acid, propionic acid, and lactic acid). A lower pH enhances peristalsis in the colon<sup>[8]</sup> and, subsequently, might decrease the colonic transit time.

In view of the uncertainty regarding the use of probiotics for the treatment of constipation, we decided to systematically review and update data from randomised controlled trials (RCTs) on the efficacy and safety of using probiotics for the treatment of constipation in both paediatric and adult populations. If the probiotics were effective, another aim was to determine what strain(s) of probiotic microorganisms is the most effective.

## MATERIALS AND METHODS

The guidelines from the Cochrane Collaboration for undertaking and reporting the results of this systematic review were followed<sup>[11]</sup>. Briefly, we searched three electronic bibliographic databases (MEDLINE, EMBASE, and CINAHL) and the Cochrane Library. Every database was searched from inception to May 2009. Additionally, the reference lists from identified studies and key review articles assessing the effects of probiotics on the treatment of constipation were searched. While no language restrictions were applied, in practice the search was restricted to English-language papers, papers written in languages known to the reviewers, or those with English-language abstracts. The review was restricted to RCTs only carried out in paediatric or adult populations. Participants in the experimental groups received any well-defined probiotic at any dosage regimen for at least several days; those in the control group received placebo or no intervention. The search strategy included the use of a validated filter for identifying RCTs, which was combined with a topic-specific search strategy. In brief, the search terms were: *constipation AND probiotic\**, *Lactobacillus*, *L. GG*, *L. acidophilus*, *L. rhamnosus*, *L. plantarum*, *L. casei*, *L. gasseri*, *L. reuteri*, *L. lactis*, *Bifidobacterium*, *B. breve*, *B. longum*, *B. infantis*, *B. adolescentis*, *B. lactis*, *Bacillus*, *Clostridium butyricum*, *Streptococcus thermophilus*, *Escherichia coli*, *Propionibacterium freundensreichii*, *Enterococcus SF68*,

*Enterococcus faecalis*, *Saccharomyces boulardii*, and *VSL#3*. The primary clinical outcome measure was treatment success (as defined by the investigators). In addition, a priori it was decided to extract other data reported by the investigators if clinically relevant to the current review and/or adverse effects. All of the published studies that met our eligibility criteria were assessed for methodological quality, with the following strategies associated with good-quality studies: adequate generation of allocation sequences; concealment of allocation; blinding of investigators, participants, outcome assessors, and data analysts; intention-to-treat analysis (yes or no); and comprehensive follow-up ( $\geq 80\%$ ).

Data extraction was performed using standard data-extraction forms. For dichotomous outcomes, the total number of participants and the number of participants who experienced the event were extracted. For continuous outcomes, the total number of participants and the means and standard deviations were extracted. If feasible, the data were entered into Review Manager (RevMan) (Computer program. Version 5.0. Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2007) for analysis.

## Statistical methods

As the studies we identified were not sufficiently similar and of sufficient quality we did not perform a meta-analysis. The binary measure for individual studies is reported as the risk ratio (RR) between the experimental and control groups with 95% confidence intervals (95% CI). The mean difference (MD) between the treatment and control groups was selected to represent the difference in continuous outcomes (with 95% CI).

A priori defined subgroup analyses were planned based on factors that could potentially influence the magnitude of the treatment effect, such as the probiotic strain or study population (children, adults); however, these analyses were not performed due to the limited data available.

## RESULTS

By means of our systematic search, we identified six trials<sup>[12-17]</sup>. One was a protocol of an ongoing study<sup>[15]</sup>, so it was not included. Thus, eventually five trials, including a total of 377 subjects (194 in the experimental group and 183 in the control group), met our predefined inclusion criteria. The characteristics of the included studies are presented in Table 1. The list of excluded trials ( $n = 22$ ) is available upon request. The most usual reason for exclusion of a study was that the study was not randomised, the study was carried out in healthy volunteers, or the intervention was treatment with a symbiotic, not a probiotic alone. In addition, some studies were published in Japanese with no English abstract, and thus, were not accessible to the reviewers, even for initial screening.

All of the trials were full peer-reviewed publications.

Table 1 Characteristics of included trials

Study ID	Probiotic	Design	Allocation concealment/ Blinding/Intention-to-treat analysis/Description of withdrawals or dropouts	Exp/cont (age, yr)	Definition of constipation	Duration of intervention	Intervention (daily dose)	Placebo
Studies in adults								
Mollenbrink <i>et al</i> <sup>[13]</sup> 1994 (Germany)	<i>E. coli</i> Nissle 1917	RCT, crossover	Unclear/Yes/No/Yes	35/35 (18-60)	< 2 BM per week	4 + 4 wk	25 × 10 <sup>9</sup> CFU	Placebo
Koebnick <i>et al</i> <sup>[12]</sup> 2003 (Germany)	<i>L. casei</i> Shirota	RCT, parallel	Unclear/Yes/Yes/Yes	35/35 (18-70)	Not provided	4 wk	6.5 × 10 <sup>9</sup> CFU, probiotic beverage	Placebo
Yang <i>et al</i> <sup>[14]</sup> 2008 (China)	<i>B. lactis</i> DN-173 010	RCT, parallel	Unclear/No/Yes/Yes	63/63 (25-65, only women)	< 3 BM per week; increased stool hardness; non-organic constipation and habitual constipation	2 wk	Fermented milk containing 1.25 × 10 <sup>10</sup> CFU of probiotic plus yoghurt strains	Placebo (acidified milk without any fermenters or probiotics)
Studies in children								
Banaszkiewicz <i>et al</i> <sup>[17]</sup> 2005 (Poland)	<i>L. rhamnosus</i> GG	RCT, parallel (computer-generated randomisation list)	Yes/Yes/Yes/Yes	43/41 (2-16)	< 3 BM per week during 14 days for at least 12 wk	12 wk	Lactulose plus LGG 2 × 10 <sup>9</sup> CFU	Lactulose plus placebo
Bu <i>et al</i> <sup>[16]</sup> 2007 (Taiwan)	<i>L. casei rhamnosus</i> Lcr35	RCT, parallel (computer-generated randomisation list)	Yes/Yes/Yes/Yes	18/9 (< 10)	< 3 BM per week for > 2 mo plus at least one of the criteria: anal fissures with bleeding due to constipation, faecal soiling, or passage of large and hard stool	4 wk	8 × 10 <sup>8</sup> CFU	Placebo (starch)

RCT: Randomised controlled trials; CFU: Colony-forming units; BM: Bowel movements.

Four of the included studies were RCTs with a parallel design, and the remaining included RCT had a crossover design. All were placebo-controlled trials. The participants were adults (three RCTs,  $n = 266$ ) and children (two RCTs,  $n = 111$ ) with constipation defined as stated in Table 2. The following different probiotic strains were tested: *Bifidobacterium lactis* DN-173010, *E. coli* Nissle 1917, *Lactobacillus casei rhamnosus* Lcr35, *L. casei* Shirota, and *L. rhamnosus* GG. One RCT assessed the effectiveness of using *L. rhamnosus* GG as an adjunct to lactulose therapy compared with treatment with lactulose alone<sup>[17]</sup>. The durations of the interventions in the parallel-design studies were two weeks in one study, four weeks in two studies, and 12 wk in one study. The duration of the intervention in the crossover design study was eight weeks. The doses of the probiotic used ranged from 8 × 10<sup>8</sup> to 25 × 10<sup>9</sup> colony-forming units (CFU)/d.

The methodological quality of the trials varied. While all were randomised trials, the randomisation method was described and adequate in only two RCTs<sup>[16,17]</sup>. Except for one study<sup>[14]</sup>, double blinding was applied in the remaining RCTs. An adequate description of the intention-to-

treat analysis was provided in all but one study<sup>[13]</sup>. The withdrawals and dropouts were described adequately in all of the studies, and all included an adequate number (i.e. ≥ 80%) of participants in the final analysis.

### Study description

**RCTs in adults:** The study by Mollenbrink and Bruck-schen<sup>[13]</sup> was a single-centre, randomised, double-blind, crossover trial that investigated the efficacy of treating 70 constipated patients with *E. coli* Nissle 1917 or placebo. After four weeks of treatment, there was a significant difference in the mean number of stools per week in the *E. coli* group compared with the placebo group (4.9 ± 1.5 *vs* 2.6 ± 1.0, respectively, MD 2.3 stools per week, 95% CI 1.7 to 2.9), which also remained significant at eight weeks (6 ± 1.3 *vs* 1.9 ± 1.5, respectively, MD 4.1, 95% CI 3.2 to 5). This study also revealed a significant difference between the probiotic and the control group in the incidence of hard stools (2/34 *vs* 16/30, respectively, RR 0.1, 95% CI 0.03 to 0.4). Both the effectiveness and tolerance of the treatment, as assessed both by a physician and the patients, were significantly better in

<sup>1</sup>Mean values are presented for the experimental group and control group, respectively; <sup>2</sup>Comparisons of experimental and control group. NS: Not significant.

those in the *E. coli* group. The authors concluded that *E. coli* Nissle 1917 is successful in the therapy of idiopathic chronic constipation.

The study by Koebnick *et al*<sup>[12]</sup> was a single-centre, double-blind, placebo-controlled, randomised trial involving 70 patients with symptoms of chronic constipation. All of the patients received either a probiotic beverage containing *L. casei* Shirota or placebo for four weeks. Patients completed a questionnaire related to their gastrointestinal symptoms, well-being, and stool habits, and underwent a medical examination weekly. The severity of constipation, flatulence, and bloating was divided into four categories (severe, moderately severe, mild, and no symptoms). Compared to the placebo group, those randomised to the *L. casei* Shirota group experienced a significant improvement

in the self-reported severity of constipation and stool consistency. That is, they experienced significant reductions in the occurrence of moderate and severe constipation (*P* < 0.001), the degree of constipation (*P* = 0.003), and the occurrence of hard stools (*P* < 0.001), and increased their defecation frequency (*P* = 0.004). However, the occurrence and degree of flatulence or bloating sensation did not significantly differ between the groups.

In the most recent study, Yang *et al*<sup>[14]</sup> administered a fermented milk product containing *B. lactis* DN-173 010 and some yoghurt strains (*S. thermophilus* and *L. bulgaricus* (1.2 × 10<sup>9</sup> CFU/pot 100 g) (experimental group) or an acidified milk containing non-living bacteria but no *B. lactis* DN-173 010 or yoghurt strains (control group) for two weeks to constipated women. Comparison of the experi-

mental group with the control group revealed a significantly higher stool frequency after one week of product administration ( $3.5 \pm 1.5$  vs  $2.5 \pm 0.9$ , respectively, MD 1.0 stool per week, 95% CI 0.6 to 1.4) and at two weeks ( $4.1 \pm 1.7$  vs  $2.6 \pm 1.0$ , respectively, MD 1.5 stool per week, 95% CI 0.7 to 1.6). The extent of defecation difficulty was assessed as 0-3 point defecation condition scores. In brief, 0 points indicates normal defecation, while 3 points indicates often abdominal pain or anal burning sensation to influence defecation. (Table 2 for complete categorisation of defecation condition scores). Both at one and two weeks after product consumption, there was a significant improvement in the defecation condition scores in the experimental group compared with the control group:  $1.1 \pm 0.9$  vs  $1.6 \pm 1.1$ , respectively (MD -0.5, 95% CI -0.85 to -0.18) at 1 wk and  $0.8 \pm 1.0$  vs  $1.6 \pm 1.1$ , respectively (MD -0.79, 95% CI -1.14 to -0.44) at 2 wk. The stool consistency score was determined according to the Bristol Stool Scale. In brief, 0 points indicates stools like a sausage or a snake, smooth and soft, while 2 points indicates separating hard lumps, like fruit kernel (difficult discharge) (Table 2). The stool consistency scores were significantly improved in the *B. lactis* DN-173010 group compared to the control group at 1 wk ( $1.0 \pm 0.8$  vs  $1.4 \pm 1.0$ , respectively, MD -0.4, 95% CI -0.73 to -0.12) and at 2 wk ( $0.6 \pm 0.8$  vs  $1.3 \pm 1.0$ , respectively, MD -0.7, 95% CI -1 to -0.4). There were no significant differences between groups in food intake and safety parameters. The researchers concluded that the administration of a fermented milk product containing *B. lactis* DN-173010 has a beneficial effect on stool frequency, defecation conditions, and stool consistency in adult women with constipation.

**RCTs in children:** Only two RCTs have addressed the use of probiotics in the treatment of constipation in children. In the study by *Banaszkiewicz* and *Szujewska*<sup>17</sup>, 84 children (aged: 2-16 years) with constipation (< 3 spontaneous bowel movements per week for at least 12 wk) were enrolled in a double-blind, randomised, placebo-controlled trial in which they received 1 mL/kg per day of 70% lactulose plus  $10^9$  CFU of *L. rhamnosus* GG (experimental group,  $n = 43$ ) or a lactulose-containing placebo (control group,  $n = 41$ ) orally twice daily for 12 wk. The primary outcome measure was treatment success; all analyses were performed on an intention-to-treat basis. Treatment success was defined as  $\geq 3$  spontaneous bowel movements per week with no episodes of faecal soiling. Treatment success was similar in the control and experimental groups at 12 wk [28/41 (68%) vs 31/43 (72%), respectively;  $P = 0.7$ ] and at 24 wk [27/41 (65%) vs 27/43 (64%), respectively;  $P = 1.0$ ]. The groups also did not differ in their mean number of spontaneous bowel movements per week or episodes of faecal soiling per week at four, eight, and 12 wk. Adverse events and overall tolerance did not differ between groups. It was concluded that *L. rhamnosus* GG, as dosed in this study, was not an effective adjunct to lactulose in treating constipation in children.

The study by *Bu et al*<sup>16</sup> evaluated the effect of treating children with chronic constipation with *L. casei rhamnosus* Lcr35 compared to magnesium oxide (MgO) or placebo; however, only the latter comparison is valid for this systematic review. For those treated with the probiotic ( $n = 18$ ) compared with placebo ( $n = 9$ ), the trial showed an increase in the treatment success defined as  $\geq 3$  spontaneous defecations per week with no episodes of faecal soiling (14/18 vs 1/9, respectively, RR 7, 95% CI 1.1 to 45), an increase in the defecation frequency (times/d) ( $0.57 \pm 0.17$  vs  $0.37 \pm 0.10$ , respectively, MD 0.2, 95% CI 0.1 to 0.3), a reduction in abdominal pain (frequency) ( $1.9 \pm 1.6$  vs  $6.7 \pm 3.3$ , respectively, MD -4.8, 95% CI -6.6 to -3), a reduction in the use of glycerin enemas during the four weeks of therapy (frequency) ( $1.6 \pm 1.9$  vs  $4.0 \pm 2.1$ , respectively, MD -2.4, 95% CI -4 to -0.8), and a decrease in the percentage of hard stools in the total number of defecations ( $22.4 \pm 14.7$  vs  $75.5 \pm 6.1$ , respectively, MD -53%, 95% CI -63 to -43). However, there was no difference between groups in the use of lactulose or the number of episodes of faecal soiling. No change in appetite was observed. However, the sample size was too small to draw any meaningful conclusion.

#### Adverse events

The probiotics were well tolerated, and no adverse events associated with this supplementation were reported in any of the trials.

## DISCUSSION

### Principal findings

The objective of this review was to provide some resolution to the uncertainty regarding the use of probiotics for the treatment of functional constipation in paediatric and adult populations. The main finding of the review is that there is very limited evidence available from controlled trials to evaluate with certainty the effect of probiotic administration on constipation. Data published to date suggest that adults with constipation might benefit from ingestion of *B. lactis* DN-173010, *L. casei* Shirota, and *E. coli* Nissle 1917, which were shown to increase defecation frequency and improve stool consistency. However, in some cases, even if there was a significant difference in results, their clinical relevance is unclear. For example, compared with placebo, *B. lactis* DN-173010 increased only by one the number of stools per week. In children, the administration of *L. rhamnosus* GG was not effective, while the administration of *L. casei rhamnosus* Lcr35 augmented the number of stools and reduced the number of hard stools. Again, although the results were statistically significant, the overall effects were clinically modest. All of the conclusions are based on single studies, some of which had a very small number of participants and methodological limitations; thus, the conclusions should be interpreted with great caution. Repeat studies with the probiotic strains that have been proven effective are needed. A paucity of data did not allow us to con-

clude whether any particular probiotic is more effective than another.

### Previous reports

Previously, one systematic review<sup>[18]</sup>, co-authored by one of the authors of the current review, aimed at determining the effect of probiotics on constipation was performed. This systematic review, published in 2005 (search date: January 2004), identified two RCTs with a total of 140 adult participants. It was concluded that the administration of two probiotic strains (*E. coli* Nissle 1917, *L. casei* Shirota) significantly improved stool frequency and consistency, with no difference in the degree of bloating or flatulence; no adverse effects were reported. Our updated results include results from more RCTs, thus, more precisely define the effects of using probiotics for the treatment of constipation.

Evidence from non-RCTs suggests that at least some probiotics may be effective. For example, in children with constipation defined according to the Rome III criteria, the administration of *Bifidobacteria* (*B. bifidum*, *B. infantis*, and *B. longum*) and *Lactobacilli* (*L. casei*, *L. plantarum*, and *L. rhamnosus*) to 20 children aged 4-16 years resulted in an increased frequency of bowel movements, a decreased number of faecal incontinence episodes, and reduced abdominal pain, although there was no change in stool consistency<sup>[19]</sup>. In adults, preliminary data from a non-RCT revealed that the administration of *L. rhamnosus* and *Propionibacterium freudenreichii* resulted in a small, but significant, increase in defecation frequency<sup>[20]</sup>. However, this result was only true if the probiotics were administered together and not if only a single strain was given.

### Mechanism of action

Mechanisms by which probiotics might work in the treatment of constipation have been briefly discussed in the Introduction section. Clearly, they are not well understood. Perhaps the best mechanism documented is the mechanism by which *B. animalis* DN-173 010 exerts its effects. In healthy subjects, several RCTs have evaluated the effect of *B. animalis* DN-173 010 on colonic transit times. One double-blind RCT conducted in 72 healthy adults (aged 21-42 years) used radio-opaque pellets to measure colonic transit times. This study revealed a statistically significant reduction in the total colonic transit time of 21% (men:  $P < 0.03$ , women:  $P < 0.05$ ) and a reduction in the sigmoid transit time of 39% ( $P = 0.02$ ), particularly in women, with probiotic treatment. However, the beneficial effect was limited to the subjects who received living *B. animalis* DN-173 010 and was not observed in those who received heat-treated *B. animalis* DN-173 010<sup>[21]</sup>. Another double-blind RCT performed in 36 healthy women (aged 18-45 years) revealed significantly shorter total colonic and sigmoid colonic transit times ( $P < 0.05$ ) following ingestion of 375 g/d of a fermented milk containing yoghurt cultures plus *B. animalis* DN-173 010 for 10 d, compared with

the transit times observed with ingestion of the control probiotic-free product<sup>[22]</sup>. Two further non-blinded RCTs were carried out in healthy elderly subjects who were divided into groups according to their different baseline colonic transit times. Both studies demonstrated a reduction in transit times in all of the groups compared with baseline with consumption of fermented milk containing *B. animalis* DN-173 010<sup>[23,24]</sup>. Further studies are needed to confirm these findings.

### Strengths and limitations

The advantage of any systematic review is the low risk of subjective data selection. Study searches, assessment, and data synthesis were all based on predefined criteria and were performed with the use of well-established repetitive tools by two reviewers independently. Nevertheless, our analysis has some limitations. First, we cannot fully exclude publication bias, i.e. publication or non-publication of data depending on the results, with negative findings being less likely to be published irrespective of the methodological quality. As studies involving the administration of probiotics are often supported by the manufacturers, the possibility remains that negative results remain unpublished. No sufficiently effective strategy of identifying such studies has been developed. Second, even though no language limitation was imposed, in practice it was not feasible to assess data from reports written in Japanese. Third, any systematic review is only as good as the constituent studies. Only some of the trials included in our analysis seemed methodologically sound. Potential limitations included unclear or inadequate allocation concealment, no intention-to-treat analysis, and no blinding. Fourth, some trials included a small sample size. Finally, the effects of probiotics are strain specific as well as population specific. While a systematic review or a meta-analysis on probiotics does provide valid information, caution should be exercised in not over interpreting the results of a meta-analysis, particularly when all probiotics have been evaluated together.

### Safety issues

In general, the safety profile of probiotics seems to be good. In the included trials, no adverse effects were noted. The safety issue is important, as based on the available literature there is concern that the use of probiotics in at-risk populations may result in harmful events. Most complications have occurred in immunocompromised subjects or in patients with other life-threatening illnesses, who were managed in intensive care units and treated with probiotics.

In summary, this systematic review demonstrates that the data published to date do not yet provide sufficient scientific evidence to support a general recommendation about the use of probiotics in the treatment of functional constipation. Until such data are available, we believe that the use of probiotics for this condition should be considered investigational. Also, we believe that our demonstration of clinical uncertainty about this issue is

an important finding. As pointed out by Alderson and Roberts<sup>[25]</sup>, clinical uncertainty is a prerequisite for the large-scale RCTs needed to evaluate the influence of such interventions; it also helps to clarify available treatment options and stimulate new and better research.

## COMMENTS

### Background

Probiotics are increasingly being used in pediatric population. However, there is still uncertainty regarding the use of probiotics for the treatment of constipation.

### Research frontiers

Until more data are available, the use of probiotics for the treatment of constipation condition should be considered investigational. The large-scale RCTs are needed to evaluate the effect of specific probiotic strain(s) for the treatment of constipation.

### Innovations and breakthroughs

The updated results include results from more RCTs; thus, more precisely define the effects of using probiotics for the treatment of constipation.

### Applications

Until such data are available, the use of probiotics for this condition should be considered investigational.

### Peer review

This manuscript describes a systematic review of randomised controlled trials that evaluated the efficiency of probiotics in the treatment of functional constipation.

### Abstract

**AIM:** To determine the frequency and clinical impact of incidental findings detected with magnetic resonance imaging (MRI)-enterography in patients with suspected or known Crohn's disease (CD).

**METHODS:** Incidental findings were defined as unexpected lesions outside the small intestine, not previously known or suspected at the time of referral, and not related to inflammatory bowel disease. Through a systematic review of medical charts we analyzed the clinical impact of incidental findings, and compared the MRI findings with subsequent diagnostic procedures.

**RESULTS:** A total of 283 patients were included in the analysis, and MRI detected active CD in 31%, fistula in 1.4% and abscess in 0.7%. Extra-intestinal findings not

related to CD were recorded in 72 patients (25%), of which 58 patients (20%) had 74 previously unknown lesions. Important or incompletely characterized findings were detected in 17 patients (6.0%). Incidental findings led to 12 further interventions in 9 patients (3.2%) revealing previously unknown pathological conditions in 5 (1.8%). One patient (0.4%) underwent surgery and one patient was diagnosed with a malignant disease. MRI detected incidental colonic lesions in 16 patients of which additional work-up in 4 revealed normal anatomy. Two patients (0.7%) benefitted from the additional examinations, whereas incidental findings led to unnecessary examinations in 9 (3.2%).

**CONCLUSION:** In a minority of patients with suspected or known CD, important incidental findings are diagnosed at MRI-enterography. However, a substantial number of patients experience unnecessary morbidity because of additional examinations of benign or normal conditions.

### INTRODUCTION

In recent years magnetic resonance imaging (MRI) has been increasingly used for the assessment of small

bowel Crohn's disease (CD). MRI has a high diagnostic accuracy<sup>[1,12]</sup> and reproducibility<sup>[12]</sup>, both with enteroclysis and the oral contrast method (enterography), for evaluating CD. Unlike conventional enteroclysis, MRI enables visualization of disease extension beyond the intestinal wall, i.e. abscesses and fistulas. In comparison with enteroclysis, MRI detects additional extra-intestinal lesions in 24%-58% of patients<sup>[1,3]</sup>. However, some extra-intestinal findings are unexpected and not related to CD, and are often referred to as incidental findings. The ability to detect incidental findings presents a clinical dilemma. On one hand, modern imaging techniques may detect early extra-intestinal malignant disease or disease requiring clinical intervention, thereby reducing morbidity and mortality. On the other hand, incidental findings may lead to further diagnostic work-up or surgery of benign lesions causing increased morbidity.

Only one previous study has analyzed the frequency of incidental findings in MRI-enteroclysis. Herfarth *et al.*<sup>[13]</sup> found extra-intestinal lesions in 57% of 710 patients with suspected or known inflammatory bowel disease. Lesions of major clinical importance were detected in 12% of patients, of which the majority consisted of extra-intestinal manifestations of CD (abscesses). Findings were classified as tumor, metastasis or mass in 1.3% of patients. Ajaj *et al.*<sup>[14]</sup> performed MRI-colonography in 375 patients with suspected colonic diseases and detected extra-colonic lesions in 69%, with 12% requiring additional examinations. Approximately half of the extra-colonic lesions were previously unknown. These results emphasize that extra-intestinal findings are common when performing MRI of the abdomen. A significant proportion of incidental findings are clinically important and have an impact on clinical decision-making. However, these studies did not include the results of subsequent diagnostic work-up to reveal the benefit from detection of incidental findings.

The purpose of this study was to determine the frequency and clinical impact of incidental findings detected at MRI-enterography in patients with known or suspected CD.

## MATERIALS AND METHODS

This retrospective study was conducted in the Department of Radiology, Vejle Hospital part of Lillebaelt Hospital, Denmark. The Department introduced MRI-enterography in December 2003, and a study period from December 2003 to November 2007 was chosen, allowing a minimum of 1 year follow-up after MRI. All MRI-enterographies performed in the study period were identified in the hospital's computerized radiology information system, and radiology reports were printed out. Through a systematic review of medical charts we analyzed the clinical impact of incidental findings and compared the MRI findings with subsequent diagnostic procedures. All reports were reviewed independently by the first author.

### Criteria for inclusion and exclusion

MRI-enterographies performed in patients with suspected

or known CD having symptoms consistent with disease activity or complications were included in the study. The subsequent analysis focused on incidental findings defined as unexpected findings outside the small intestine not previously known or suspected at the time of referral and not related to inflammatory bowel disease. Hence, extra-intestinal manifestations of CD (abscesses and fistulas) were not regarded as incidental findings.

Examinations performed on indications other than CD, repeated MRI-enterographies, and examination failures because of technical malfunctions or patient discomfort were excluded. In order to minimize selection bias, the study population was restricted to patients with no previous MRI-enterographies. The likelihood of previously unknown findings outside the small intestine is substantially reduced in repeated scans during a short study period. Therefore, in cases of 2 or more examinations performed, only the first MRI scan was included.

A total 354 patients underwent MRI-enterography. Twenty-nine scans were performed on indications other than inflammatory bowel disease, and additionally 2 scans were excluded because of failure to perform the examination. Both patients were unwilling to ingest the enteral contrast. A total of 40 scans in 29 patients were excluded because of repeated MRI-enterographies in the study period. Hence, a total of 283 MRI-enterography examinations in 283 patients were included in the analysis.

A clinical impact was defined as one or more subsequent interventions, i.e. additional diagnostic work-up, medical and/or surgical treatment, solely caused by the incidental finding at MRI-enterography. The clinical impact was assessed by analyzing the number of patients with subsequent clinical interventions, and the number and type of interventions performed in each patient. Incidental findings were classified as true or false positive on the basis of the diagnostic work-up and as beneficial or unnecessary for the patient. Data were collected from radiological reports, medical charts, laboratory data and the results of subsequent diagnostic procedures. Information was collected from the hospital's computerized medical charts and radiology information system. In patients referred from other hospitals, referrals and medical charts were collected from the department in charge of treatment.

### Ethics

The study was approved by the local ethics committee of Southern Denmark and the Danish Data Protection Agency. In a few patients diagnostic work-up was performed at other hospitals, and prior to collecting these data, patients gave informed consent.

### Imaging technique

Scans were carried out with an Intera 1.5T MRI system with a 5 element Syn-body coil (Philips Medical Systems, Eindhoven, The Netherlands). The evening before the examination, patients were instructed to eat a light meal

Table 1 Indications and results of 283 MRI investigations of the small intestine

Clinical indication for MRI		<i>n</i>	Total
Suspected CD	Diagnostic MRI in patients with suspected CD not confirmed at endoscopy	156	156
Known CD	Extension of newly diagnosed CD detected at endoscopy	17	
	Evaluation of disease activity and extension or suspected complications of known CD	110	127
Total			283
Results of MRI-enterographies	CD in the small intestine	87	31%
	Stenosis	38	13%
	Entero-enteric fistula	4	1.4%
	Intra-abdominal abscess	2	0.7%
	Suspected IBD in the colon	35	12%

MRI: Magnetic resonance imaging; CD: Crohn's disease; IBD: Inflammatory bowel disease.

and fast overnight. They were allowed to drink water prior to the examination. Patients received 1000 mL water mixed with psyllium husk fiber ingested gradually over one hour. Patients were examined in the supine position. The protocol contained the sequences Cor T1 (TR/TE, 7/3.4; flip angle 15; slice thickness 4 mm; 208 matrix; FOV 375), Cor T2 (B-FFE; TR/TE, 4.1/2.0 ms; flip angle, 60; slice thickness 5 mm; 224 matrix; FOV 400), Cor SPIR (TR/TE, 3000/125 ms; flip angle 90; slice thickness 7 mm; 256 matrix; FOV 400) and axial T1W (TR/TE, 7/3.4; flip angle 15; slice thickness 4 mm; 208 matrix; FOV 375) with discontinuous breath-hold before and after contrast. Gadodiamide 0.1 mmol/kg (GE Healthcare, Medical Diagnostics, Oslo, Norway) was given intravenously, and hyoscinebutylbromide 20 mg (Buscopan, Boehringer Ingelheim, Basel, Switzerland) was administered to reduce peristalsis during the procedure. All images were evaluated using an Impax PACS workstation (Agfa, Mortsel, Belgium) with 2 Coronis monitors (1600 × 1200 pixels) (Megapixels Diagnostic Display System, Barco, Kortrijk, Belgium). Radiologists performing the studies were all specialist doctors with experience in abdominal MRI techniques.

### Classification of scans

MRI-enterographies were classified according to the most important incidental finding. Lesions were assessed as proposed by Zalis *et al*<sup>[15]</sup> for computed tomography (CT) colonography. E0 is an examination in which technical factors severely limit evaluation, e.g. because of artifacts. E1 denotes a normal examination or variants in anatomy that are not expected to affect the patient's health status. E2 refers to examinations with clinically unimportant extra-intestinal findings. E3 denotes incompletely characterized findings that are likely to be benign and E4 refers to examinations with potentially important extra-intestinal findings. Classification of scans was performed by the first author on the basis of the radiological reports and prior to analyzing the clinical impact of incidental findings. The co-authors subsequently evaluated the classification of incidental findings, and agreement was attained. Incidental findings located in the colon were analyzed separately.

### Statistical analysis

Data were analyzed using descriptive statistics. Difference in means was calculated using the Wilcoxon rank-sum test and *P*-values less than 0.05 were considered significant.

## RESULTS

Of the 283 patients included in the study, 193 (68%) were female. The mean age of the study population was 38.7 years (range 9.9-84.9 years). The indication for MRI was suspected CD in 156, and newly diagnosed or known CD in 127. MRI examinations revealed active CD in 31%, fistula in 1.4%, and abscess in 0.7% of patients (Table 1). There was no difference in mean age between patients with known and suspected CD (*P* = 0.9).

### Extra-intestinal incidental findings

Extra-intestinal findings were recorded in 72 patients, of which 58 patients (20%) had previously unknown findings. Forty-one scans were classified E2, 11 were E3, and 5 were E4. In 225 scans no or previously known extra-intestinal lesions were recorded. In one examination the radiologist suspected multi-cystic ovaries, but evaluation of extra-intestinal organs was significantly compromised. The examination was classified E0, even though the finding led to further diagnostic work-up.

Seventy four incidental findings were detected in 58 patients (Table 2). In 43 patients only one finding was recorded, 14 patients had 2 findings, and 3 findings were recorded in one patient. The most frequent findings were benign cysts in the kidneys, ovaries and liver requiring no further work-up (*n* = 39). In 12 patients (4.2%) incompletely characterized extra-intestinal findings (E3) were detected. Of these, 2 patients had a large bladder suggesting previously unknown lower urinary tract disease, and one scan revealed a large hepatic cyst with a diameter of 15 cm displacing the right kidney. Potentially important findings (E4) were recorded in 5 patients (1.8%). Three patients had an undetermined mass or a cystic lesion in conjunction to the ovaries and pelvis wall, and further work-up was recommended. One scan revealed a focal hepatic lesion (atypical hemangioma), and one patient was diagnosed with an abdominal aortic

**Table 2** Previously unknown extra-intestinal findings in 58 patients

		<b>Finding</b>	<b>n</b>
E0	Female genitals	Suspected multi-cystic ovaries	1
E2	Liver	Hepatic cysts	3
		Gallstones	7
Kidney		Renal cysts	19
		Renal anatomical variants	3
		Reduced kidney size	1
		Metallic artifact in the kidney	1
Female genitals		Leiomyomas in the uterus	4
		Ovarian cysts	14
Miscellaneous		Atrophy of the abdominal musculature after surgery	1
		Small amounts of free abdominal fluid	3
			56
E3	Liver	Large hepatic cyst with displacement of the right kidney	1
		Urinary tract	Bilateral nephropathy with reduced kidney size <sup>1</sup>
Female genitals		Large bladder	2
		Free fluid in the pelvis and suspected leiomyoma of the uterus	1
Miscellaneous		Two lobulated and cystic lesions in the pelvis	1
		Splenomegaly	1
E4		Ascites	1
		Bilateral hip joint effusion	1
		Lymphadenopathy in the mesentery	1
		Spondylosis and spinal stenosis	1
			12
E4		Focal hepatic lesion (atypical hepatic hemangioma)	1
		Unexplained mass in conjunction to the ovaries	3
		Abdominal aortic aneurysm	1
			5
Total			74

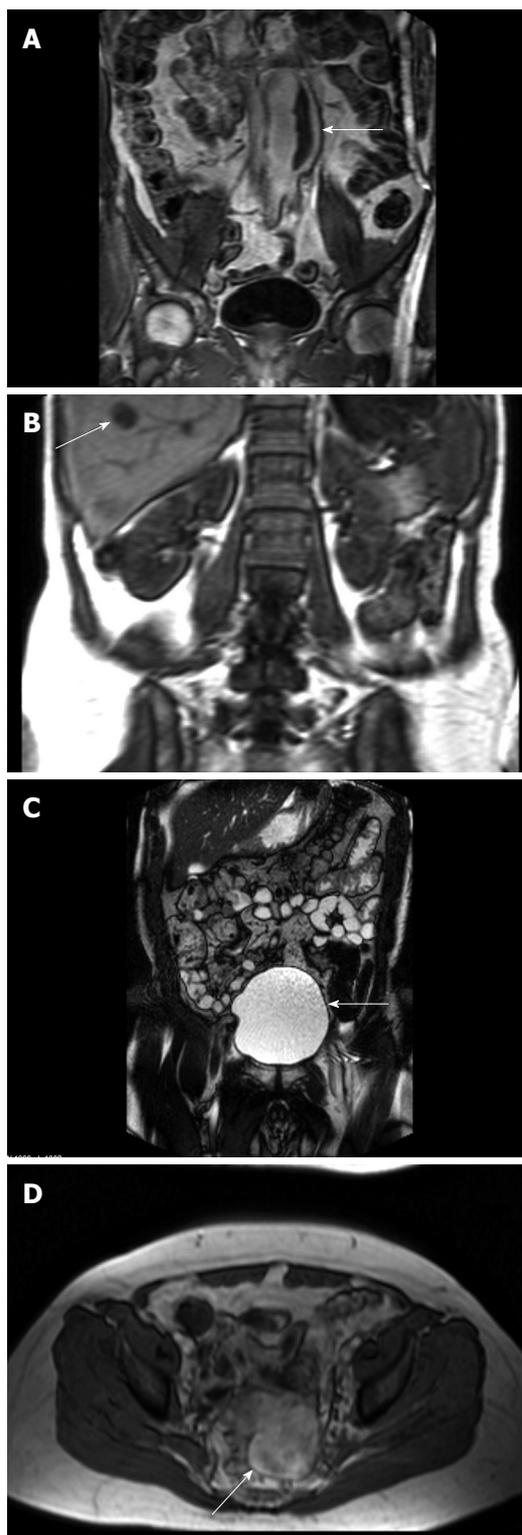

<sup>1</sup>Both patients had a normal S-creatinine at the time of MRI-enterography with intravenous contrast.

aneurysm (Figure 1).

Significantly more scans were classified E3 and E4 in patients with suspected CD (15 out of 156) than known CD (one out of 127) suggesting that incidental findings necessitating further diagnostic work-up are more common in this group of patients ( $P = 0.001$ ). Except for bilateral hip joint effusion, all E3 and E4 findings were detected in patients with suspected CD, and one patient had 2 E3 findings (Table 2).

### Clinical impact of extra-intestinal findings

Extra-intestinal findings resulted in 12 clinical interventions in 9 patients (3.2%). The interventions consisted of ultrasound examination in one, ultrasound-guided biopsy in one, contrast-enhanced ultrasound and biopsy in one, CT-scan in one, gynecological examination including transvaginal ultrasound in 5, surgery in one and biochemical tests in one (Table 3). Succeeding work-up resulted in 5 true positive extra-intestinal findings and 3 false positive findings. One patient with bilateral hip joint effusion failed to attend the follow-up ultrasound examination.

**Figure 1** Incidental findings at MRI-enterography. A: Abdominal aortic aneurysm (arrow). CT scans confirmed the aneurysm and ruled out rupture; B: Atypical hepatic hemangioma (arrow). The results of ultrasound-guided biopsy were benign; C: Large bladder leading to diagnostic work-up and diagnosis of prostate cancer (arrow); D: A lesion with a diameter of 6 cm in the small pelvis (arrow) was confirmed with transvaginal ultrasound. Surgery showed a torquated leiomyoma in the top of the uterus.

In a patient with suspected CD, MRI showed an enlarged bladder. The patient was referred for fur-

**Table 3** Previously unknown extra-intestinal findings leading to further examinations and the result of diagnostic work-up

	Extra-intestinal finding	Clinical intervention	Result of diagnostic work-up
5 true positive findings	Abdominal aortic aneurysm (E4)	CT-scan of the aorta	Abdominal aortic aneurism without rupture
	Focal hepatic lesion (E4)	Contrast-enhanced US and biopsy (atypical hemangioma)	Hemangioma
	Two unexplained masses in conjunction to the ovaries (E4)	GE and transvaginal US Surgery	Leiomyomas
	Free fluid in the pelvis and suspected leiomyoma of the uterus (E3)	GE and transvaginal US	Leiomyoma
	Large bladder (E3)	Transrectal US and biopsy Abdominal CT scan Biochemistry (PSA)	Prostate cancer
3 false positive findings	4.5 cm cystic lesion with an excrescens associated with the cyst wall (E4)	GE and transvaginal US	Normal
	2.9 cm solid lesion in the pelvis and displacement of the uterus (E4)	GE and transvaginal US	Normal
	Multicystic ovaries (E0)	GE and transvaginal US	Normal
Results not available	Bilateral hip joint effusion (E3)	Referred for US examination	The patient did not attend the examination

US: Ultrasound; GE: Gynecological examination; PSA: Prostate-specific antigen; CT: Computed tomography.

**Table 4** Sixteen incidental findings located in the colon and their clinical impact

Finding	n	Clinical intervention	Result of diagnostic work-up
Suspected benign neoplasia (3 cm large polyp)	1	Colonoscopy and CT-colonography	Normal
Coprostasis	7	-	-
Indeterminate thickening of the cecum mucosa	2	Colonoscopy	Normal
Displacement of the cecum	3	-	-
Diverticulosis	2	-	-
Suspected malignant neoplasia	1	Colonoscopy and abdominal CT scan	Normal

ther urological examinations, and was subsequently diagnosed with a previously unknown prostate cancer. In another patient, MRI revealed a 6 cm wide and 9 cm long abdominal aortic aneurysm. CT scan of the aorta confirmed the aneurysm, and ruled out rupture. Five patients diagnosed with one or more lesions associated with the female genitals had further diagnostic work-up. In one patient, MRI showed a 6 cm large lesion in the small pelvis, and the finding was confirmed with transvaginal ultrasound. The patient underwent surgery, which showed a 5 cm × 4 cm × 5 cm torquated leiomyoma in the top of the uterus and 2 smaller leiomyomas in the anterior wall of the uterus. The surgeon performed a hysterectomy.

#### Incidental findings in the colon

MRI revealed incidental findings located in the colon and not related to inflammatory bowel disease in 16 patients (5.7%, Table 4), of whom 5 also had an extra-intestinal finding (E2 in all). In 12 patients, colonic findings were of minor or no clinical relevance. Four patients underwent additional examinations because of mucosal changes not characteristic of inflammatory bowel disease. The examinations revealed no pathological conditions.

## DISCUSSION

Few studies have dealt with incidental findings in abdominal MRI. In a recent retrospective study, Herfarth *et al.*<sup>[13]</sup> analyzed extra-intestinal findings in MRI-enteroclysis. In 710 patients with suspected or known inflammatory bowel disease 57% had extra-intestinal lesions and 12% of the observed lesions were of major clinical importance. In 5 patients (0.7%) extra-intestinal findings were suspicious of previously unknown malignant disease. However, findings of major importance were mainly abscesses related to CD, and comparison with the present study is difficult because of different study designs.

Extensive work has been done on extra-intestinal findings in CT-colonography. Results are summarized in a comprehensive review from 2005 including 17 studies. In total 40% of patients were recorded to have extra-colonic abnormalities, 14% had further diagnostic work-up and extra-colonic cancers were detected in 2.7%<sup>[16]</sup>. The cancer detection rate was reported in 5 studies and varied from 0.4% to 4.6% with the highest rates in the elderly.

In the present study, MRI-enterography revealed incidental findings located outside the small intestine and not related to CD in 25% of patients resulting in additional examinations in 5%. Additional investigations

confirmed abnormal lesions in 1.8%, and one patient had a malignant disease. Two patients benefitted from the additional examinations (aortic aneurysm and prostate cancer), whereas incidental findings led to unnecessary examinations in 9 patients. Detection of extra-intestinal manifestations of CD was rare (1.8%).

Incompletely characterized or clinically important findings were more common in patients with suspected than known CD, suggesting that findings necessitating additional work-up are more frequent in this group of patients. Because of the retrospective nature of this study, and the small number of patients referred for additional examinations, it was not possible to elucidate further on this assumption or whether incidental findings could explain the patients' symptoms. A prospective study would clarify this issue.

Comparing studies can be troublesome because of differences in population characteristics, classification systems, examination protocols and study designs. In the present study we used an MRI technique with intravenous contrast in a young population with a low risk of malignant disease. Compared to the study by Ajaj *et al.*<sup>[14]</sup> we detected fewer extra-intestinal lesions, and the frequency of malignant disease was much higher when performing MRI-colonography. In an overall comparison with CT studies we also found a lower frequency of extra-intestinal findings and a lower rate of additional work-up. These discrepancies probably arise from differences in age, prior morbidity and the risk of malignant disease in the study populations.

MRI-enterography is a relatively new modality for evaluating CD in the small intestine. Ileo-colonoscopy, CT-enterography, capsule endoscopy, abdominal ultrasound and small bowel enteroscopy are alternative examinations. Choosing between modalities relies on several factors. Primarily a modality with a high sensitivity and specificity for luminal abnormalities as well as pathology in the bowel wall and extra-intestinal manifestations of CD is essential. Also other aspects of the investigations should be considered: risk of complications (aspiration, capsule retention, radiation exposure, *etc.*), patient discomfort, complexity of the examinations, accessibility, costs, and finally the impact of incidental findings. In the present study, the detection rate of clinically significant lesions outside the small intestine was low. In contrast, incidental findings led to unnecessary examinations in a substantial number of patients. Hence, in comparison with other modalities the detection rate of important incidental lesions was too low to be an argument in itself for performing MRI-enterography in patients with suspected or known CD.

Our study was limited by its retrospective design. Radiological reports were not performed with the focus on incidental findings, and underestimation of clinically unimportant findings are likely. The study population contained a preponderance of women (ratio 2:1), which is reflected by the frequency of incidental findings in the female genitalia. The second most common finding was ovarian cysts, and lesions in the female genitals were

common in all classification groups. It is well established that CD is more common in females (1.2-1.5:1) and in specialized centers for inflammatory bowel diseases the prevalence of women with irritable bowel syndrome is up to 4 times as high as that of men<sup>[17,18]</sup>.

In conclusion, incidental findings were common in patients with known and suspected CD having MRI for evaluation of small intestinal disease. Additional examinations revealed important disease in only a minority of patients. However, a substantial number of patients experienced unnecessary morbidity because of the additional examinations of benign or normal conditions. The detection rate of important incidental lesions not related to CD was too low to be an argument in itself for performing MRI-enterography in this group of patients.

## COMMENTS

### Background

Magnetic resonance imaging (MRI) is increasingly used in the assessment of small bowel Crohn's disease (CD). Unlike conventional radiology, MRI enables visualization of disease extension beyond the intestinal wall, i.e. abscesses and fistulas. However, some extra-intestinal findings are unexpected and without relation to CD (incidental findings).

### Research frontiers

Only a few studies have described the clinical impact of incidental findings in abdominal MRI. Lesions may represent important diseases and benefit patients, but may also cause unnecessary morbidity because of the diagnostic work-up of benign lesions.

### Innovations and breakthroughs

In 2 recent studies using abdominal MRI techniques, extra-intestinal lesions of major clinical importance were common. However, these studies did not include the results of subsequent diagnostic work-up to reveal the benefit from detection of these findings. In the present study, incidental findings were common in patients having MRI for evaluation of small bowel CD. Additional examinations revealed important disease in a minority of patients. However, a substantial number of patients experienced unnecessary morbidity arising from the additional examinations of benign or normal conditions.

### Applications

Several modalities for diagnosing small bowel CD are available. The present study emphasized that the detection rate of important incidental lesions was too low to be an argument in itself for performing MRI-enterography in this group of patients.

### Peer review

Jensen *et al* gave a nice and clear description of the research background, materials, methods, results and conclusions. Significant points have been presented and compared with data from prior research. Used methods are advanced, and detailed descriptions are provided allowing other investigators to reproduce or validate them. The statistical methods are appropriate. From the presented results, sufficient data can be drawn. In discussion, valuable conclusions are provided. References are appropriate and relevant. Tables and figures reflect the major findings of the study.

atrophy, as demonstrated by histology and serum markers, and no evidence for an ongoing *H. pylori* infection, eight showed *H. pylori* antibodies by immunoblotting. All eight had elevated PCA and 4/8 also had IF antibodies. Of the six immunoblot-negative patients with severe corpus atrophy, PCA and IF antibodies were detected in four. Among the patients with low to moderate grade atrophic gastritis (all except one with an ongoing *H. pylori* infection), serum markers for gastric atrophy and autoimmunity were seldom detected. However, one *H. pylori* negative patient with mild atrophic gastritis had PCA and IF antibodies suggestive of a pre-atrophic autoimmune gastritis.

**CONCLUSION:** Signs of *H. pylori* infection in autoimmune gastritis, and positive autoimmune serum markers in *H. pylori* gastritis suggest an etiological role for *H. pylori* in autoimmune gastritis.

### Abstract

**AIM:** To study the association between *Helicobacter pylori* (*H. pylori*) infection and autoimmune type atrophic gastritis.

**METHODS:** Twenty-three patients with different grades of atrophic gastritis were analysed using enzyme immunoassay-based serology, immunoblot-based serology, and histology to reveal a past or a present *H. pylori* infection. In addition, serum markers for gastric atrophy (pepsinogen I, pepsinogen I/II and gastrin) and autoimmunity [parietal cell antibodies (PCA), and intrinsic factor (IF), antibodies] were determined.

**RESULTS:** Of the 14 patients with severe gastric

### INTRODUCTION

Autoimmune type corpus gastritis, formerly named type

A gastritis, is severe atrophy of gastric corpus associated with hypochlorhydria<sup>[1]</sup>. Even without total gastric atrophy, many of these patients have an inability to absorb vitamin B12 from food<sup>[2]</sup>. Generally, 15%-20% of vitamin B12 malabsorption in elderly patients is due to pernicious anaemia, as defined as deficiency of intrinsic factor (IF)<sup>[3]</sup>. Over 90% of patients with pernicious anaemia have parietal cell antibodies (PCA) and 50%-70% have elevated IF antibodies<sup>[1]</sup>. The autoantigen for PCA is H+/K+-adenosine triphosphatase, the proton pump<sup>[4]</sup>.

In patients with *Helicobacter pylori* (*H. pylori*) infection, superficial gastritis proceeds to atrophic gastritis in about half of the patients<sup>[5]</sup>. Although this type of atrophic gastritis, which is associated with intestinal metaplasia, mainly involves the antrum, it can proceed to the corpus or affect the mucosa focally, *viz.* multifocal atrophic gastritis. Advanced atrophy develops over many years and *H. pylori* disappears from the gastric mucosa. In some patients, the antral intestinal metaplasia disappears and PCA appears; thus, the disease resembles classic autoimmune gastritis<sup>[6]</sup>. Gastric H+/K+-ATPase is also the major autoantigen in chronic *H. pylori* induced atrophic gastritis in corpus mucosa<sup>[7]</sup>.

In *H. pylori* induced atrophic gastritis, the activated CD4+ Th1 cells infiltrating the gastric mucosa cross-recognize the epitopes of the gastric parietal cell proton pump and various *H. pylori* proteins<sup>[8,9]</sup>. It is not known if *H. pylori* is the initiating factor in activating Th1 cells, which leads to inflammation and apoptosis, or is only a coincidental bystander<sup>[10]</sup>. If the classic autoimmune type gastric atrophy is an end-stage of *H. pylori* induced gastric autoimmunity with atrophic gastritis, the prevalence of pernicious anaemia should decrease with declining prevalence of *H. pylori*. It is not known if vitamin B12 malabsorption in the late stages of gastric atrophy could be restored or prevented if *H. pylori* were eradicated earlier<sup>[11-14]</sup>.

In the present study we investigated the signs of a previous *H. pylori* infection in patients with different grades of atrophic gastritis to assess the proportion of gastric atrophy not associated with *H. pylori* infection.

## MATERIALS AND METHODS

All patients with an earlier gastroscopy reprint available and who had undergone a gastroscopy for clinical indications at Herttoniemi Hospital during 2004 and 2005<sup>[15]</sup> were included in the present study if their follow-up histology indicated they had atrophic gastritis. Twenty-three of the 38 patients with different grades of atrophic gastritis had a blood sample available and were included in the study. The median age was 65 years and 18 were females.

The Ethics Committee of the Hospital District of Helsinki and Uusimaa approved the study and all the participants gave their written informed consent.

### Histology

Two biopsies from each of the antrum and the corpus

were taken during gastroscopy and stained with haematoxylin-eosin, Alcian blue (pH 2.5)-periodic acid Schiff, and modified Giemsa stains. All the samples were examined by one pathologist who was unaware of the identity of the samples. The samples were assessed according to the updated Sydney system<sup>[16]</sup>.

### Serum tests

*H. pylori* antibodies were detected by an enzyme immunoassay (EIA) and by immunoblotting. Serum samples were taken after gastroscopy and stored (-20°C) until analyzed for IgG antibodies to *H. pylori* using a locally validated in-house EIA with high sensitivity and specificity<sup>[17]</sup>. Immunoblotting was performed by MP Diagnostics Helico blot 2.1 (MP Biomedicals, Singapore). The interpretation criteria for an *H. pylori* seropositive sample, according to the manufacturer, were: (1) fulfilling the criteria for CagA positivity; (2) the presence of any bands at 89 kDa, 37 kDa, or 35 kDa; or (3) the presence of both the bands at 30 kDa and 19.5 kDa. The criteria for CagA positivity were the presence of 116 kDa CagA band (a) in combination with current infection marker CIM; (b) in combination of the 30 kDa (UreA) and 19.5 kDa bands; or (c) in combination of at least one of the following bands 89 kDa (VacA), 37 kDa, or 35 kDa.

PCA were measured by Varelisa (Pharmacia Diagnostics, Freiburg, Germany) using H+/K+-ATPase as an antigen. According to the manufacturer's instructions, values > 15 U/mL were interpreted as positive but equivocal values (10-15 U/mL) were interpreted negative as well as values < 10 U/mL.

Serum IF antibodies of the blocking type were measured routinely with the haemoglobin charcoal adsorption assay. The cut off value used was 2 U/L.

Serum pepsinogen I and II and gastrin-17 levels were investigated with Gastropanel (Biohit PLC Diagnostics, Helsinki, Finland). The reference ranges were 30-120 µg/L for pepsinogen I, 3-10 µg/L for pepsinogen II, 3-20 for pepsinogen I / II, and 2-10 pmol/L for gastrin-17.

### Statistical analysis

The differences between the groups were tested using two-tailed Fisher's exact test and the data were analysed using GraphPad software (QuickCalcs online calculators for scientists [www.graphpad.com](http://www.graphpad.com)). *P* values < 0.5 were considered significant.

## RESULTS

Of the 23 patients included in the study, 14 had severe gastric atrophy according both to histology and the serum markers, and the remaining nine patients had mild to moderate atrophic gastritis. The patients with severe atrophy were slightly younger (median age 64 years) than the other patients (median age 70 years). None of the patients with severe atrophy had either *H. pylori* in histology or elevated *H. pylori* antibodies in the EIA

Table 1 Histological and serum findings in patients with mild to moderate ( $n = 9$ ) and severe ( $n = 14$ ) atrophic changes in the corpus

Findings	Number of patients with atrophic corpus gastritis						P-value
	Grade 1 or 2			Grade 3			
	IB+ ( $n = 8$ )	IB- ( $n = 1$ )	Total	IB+ ( $n = 8$ )	IB- ( $n = 6$ )	Total

<sup>1</sup>In-house EIA positive  $\geq 700$ ; <sup>2</sup>Parietal cell antibodies PCA elevated  $> 15$ ; <sup>3</sup>Intrinsic factor IF elevated  $> 2$ ; <sup>4</sup>Pepsinogen I low  $< 30$ ; <sup>5</sup>Pepsinogen II elevated  $> 10$ ; <sup>6</sup>Pepsinogen I / II low  $< 3$ ; <sup>7</sup>Gastrin 17 elevated  $> 10$ . EIA: Enzyme immunoassay; *H. pylori*: *Helicobacter pylori*; PCA: Parietal cell antibodies; IF: Intrinsic factor; NS: Not significant; IB+: Immunoblot positive; IB-: Immunoblot negative. P-value: Total (grade 1 or 2) vs total (grade 3).

(Table 1); one patient had had a successful *H. pylori* eradication therapy 7 years earlier. Of the nine patients with mild to moderate atrophic gastritis, two had had a successful eradication therapy (4 mo and 6 mo earlier, respectively) and four had an ongoing infection shown in histology; seven had elevated *H. pylori* antibodies in the EIA (Table 1). All patients, except one with moderate atrophic gastritis, had chronic gastritis in the corpus, whereas the antrum was significantly less often affected in patients with severe atrophy compared to those with mild and moderate atrophic changes ( $P = 0.04$ , Fisher's exact test, Table 1). Antral intestinal metaplasia was not found in any of the patients with severe atrophy.

Serum markers for gastric autoimmunity were only rarely detected in patients with mild to moderate atrophic gastritis (PCA in three patients and IF antibodies in one patient, Table 1). In contrast, all 14 patients with severe atrophy had either elevated PCA or IF antibodies, six patients having both antibodies elevated. Furthermore, the levels of elevated PCA and IF antibodies were higher in patients with severe atrophy (eight of 12 patients with elevated PCA had a PCA titre over 100, and the mean IF antibody titre in eight patients with an elevated value was 8.7) compared to patients with only mild to moderate atrophic changes (only one of the three patients with elevated PCA had a PCA titre over 100 and the IF antibody titre in the only patient with an elevated value was 2.1).

*H. pylori* antibodies could be demonstrated by immunoblotting in 8/9 patients with mild to moderate atrophic gastritis and in 8/14 patients with severe gastric atrophy (Table 1). Patients with severe atrophy and a positive immunoblot result did not significantly differ from those with severe atrophy and negative immunoblot results as far as age, sex, histological findings, and serum results were concerned (Table 1). Although six patients with severe atrophy showed negative immunoblot results

(according to the criteria of the manufacturer) four of them had a positive CagA band in the immunoblot; thus, only two patients showed no evidence of previous *H. pylori* infection. In addition, one patient with mild atrophic gastritis had no evidence (not even a CagA band) for ongoing or previous *H. pylori* infection (Table 1). This particular patient showed clearly elevated PCA ( $> 100$  U/mL) and slightly elevated IF antibodies (2.1 U/L).

## DISCUSSION

In our study, of the 14 patients having autoimmune type atrophic gastritis (severe gastric atrophy with elevated PCA and/or IF antibodies) only two had no signs of previous *H. pylori* infection. In addition, all except one of the patients with mild to moderate atrophic corpus gastritis had an ongoing *H. pylori* infection or signs of previous infection. The *H. pylori* negative patient with minor atrophic changes in the gastric corpus had elevated PCA and IF antibodies; whether this particular patient goes on to develop severe gastric atrophy of autoimmune type remains to be shown. To the best of our knowledge, she is the first patient described in the literature as having preatrophic autoimmune gastritis with elevated serum markers of pernicious anaemia and no signs of *H. pylori* infection, despite being investigated with both invasive and non-invasive methods: antrum and corpus histology in two gastroscopies with a 5.4 years interval and negative EIA serology and immunoblotting, including CagA.

In severe gastric atrophy, the exclusion of previous *H. pylori* infection is controversial, as the sensitivity of histology is low<sup>[18]</sup>, and many of the EIA based serological tests are poorly validated<sup>[19]</sup>. In *H. pylori* gastritis, the antibodies in EIA serology decline below the cut-off values along with advanced atrophy<sup>[20]</sup>, as

well as after eradication therapy<sup>[21]</sup>; thus, the previous *H. pylori* infection cannot be deduced by negative EIA serology. Immunoblotting with CagA antibodies can give positive results for years after the disappearance of *H. pylori*<sup>[22,23]</sup>, but all *H. pylori* strains are not CagA positive. Discrepancies in CagA seropositivity yielded by immunoblotting in patients with severe gastric atrophy<sup>[24,25]</sup> may derive from the different sensitivities of the immunoblotting methods used<sup>[26]</sup>.

Studies of patients with preatrophic autoimmune type of corpus gastritis are rare. In a population-based study, all 12 patients with autoimmune type atrophic gastritis (diffuse lymphocytic infiltration of the entire lamina propria in the corpus mucosa) without severe gastric atrophy showed *H. pylori* in histology or serology<sup>[27]</sup>. In the same study, of the 28 individuals with severe autoimmune type gastric atrophy six were *H. pylori* positive in histology and another 13 were positive in serology (altogether 68% positive for *H. pylori*). Considering the moderately high prevalence (2.8% in the Kalixanda study<sup>[27]</sup>) of the autoimmune type of gastric atrophy in general, the description in the literature of patients with *H. pylori* negative autoimmune type gastritis in preatrophic stage is rare.

Uibo described a 17-year-old female with no signs of gastritis and *H. pylori* in histology developing atrophic gastritis during a 12-year follow-up<sup>[28]</sup>. However, the exclusion of *H. pylori* infection in this case was based only on histology, and the childhood infection rate in this population cohort was nearly 100%. Kuipers described two patients who were negative for *H. pylori* and without gastritis at first visit, who then developed atrophic gastritis (one developed also intestinal metaplasia and pernicious anaemia) during more than 10 years of follow-up<sup>[29]</sup>. However, although in this study the *H. pylori* infection was assessed with serology and histology at the first visit, in cases of discrepant results, histology was considered predominant over serology unless atrophic mucosa was observed. Whether these two patients had positive serology at the first visit was not mentioned. In the study of Segni *et al.*<sup>[30]</sup> of children with juvenile autoimmune thyroid disease, of the 18 children with elevated PCA who underwent gastroscopy, two children with hypergastrinaemia had *H. pylori* negative preatrophic gastritis, as shown by histology and EIA serology. Immunoblotting was not studied and follow-up has not been published. In the study of adult patients with Sjögren's syndrome, there was no difference in the prevalence of *H. pylori* infection, antigastric antibodies, or gastric histology between patients and controls, but after successful eradication therapy for *H. pylori*, the lymphocytic infiltration and atrophy in patients with Sjögren's syndrome, contrary to the controls, did not improve<sup>[31]</sup>. In addition, patients with Sjögren's syndrome who were positive for antigastric antibodies all had *H. pylori* infection and they more often had atrophic gastritis than the controls. In conclusion, from the previous studies, patients with autoimmune type atrophic gastritis without

*H. pylori* infection might rarely exist, but at the moment a study showing preatrophic gastritis proceeding to total gastric atrophy without *H. pylori* infection is lacking. This is in accordance with our results; as the patient having preatrophic gastritis without signs of *H. pylori* infection did not proceed to total gastric atrophy during 5 years of follow-up.

Several studies suggest that autoimmune atrophic corpus gastritis is associated with *H. pylori* infection in the majority of cases. In one study, two-thirds of patients with atrophic corpus gastritis had evidence of *H. pylori* infection, when assessed with histology and serology<sup>[32]</sup>. In another study, 62% of the patients with pernicious anaemia and severe atrophic corpus gastritis had positive *H. pylori* serology<sup>[33]</sup>. In one further study, patients with atrophic corpus gastritis were negative for *H. pylori* in histology and in EIA-serology, but positive when studied by immunoblotting<sup>[25]</sup>. In another study of atrophic corpus gastritis, among 111 patients with negative *H. pylori* EIA serology, 95.5% were positive in immunoblotting<sup>[34]</sup>. In a study of 10 patients with severe atrophic corpus gastritis, all were *H. pylori* negative in histology and in EIA-serology, and only one was positive in immunoblotting<sup>[24]</sup>. However, in this particular study, the immunoblotting method used to measure CagA antibodies was less sensitive than EIA-serology in detecting an ongoing *H. pylori* infection. In the present study, all except three patients had a positive CagA band on the immunoblot, including all EIA-serology positive patients. We have studied the sensitivity and specificity of this particular immunoblotting method previously, with good results<sup>[23]</sup>. However, not even the immunoblotting method used in our present study can rule out a previous *H. pylori* infection with 100% certainty, as all *H. pylori* strains are not CagA positive. On the other hand, the common occurrence of *H. pylori* antibodies in patients with autoimmune type of atrophic gastritis could be a random effect, as the *H. pylori* infection rate has been nearly 100% in populations now presenting as the peak age group of autoimmune gastritis. This could also be one explanation why *H. pylori* prevalence studied by immunoblotting in patients with serological markers of autoimmune type gastritis (PCA and IF antibodies) was no different from patients with no such markers in our study.

Thus, it still remains to be shown if *H. pylori* infection is crucial for the development of autoimmune type atrophic gastritis. However, bacterial infections might be important in autoimmune processes, as recently suggested by Torchinsky *et al.*<sup>[35]</sup>. In this *in vitro* study, phagocytosis of immune cells infected with bacteria and undergoing apoptosis promoted Th17 cell differentiation, the cell type having a potential role in autoimmunity. Thus, it is tempting to speculate that cells in the gastric mucosa infected with *H. pylori* could trigger an autoimmune response.

In conclusion, atrophic corpus gastritis, including

autoimmune type severe atrophy with vitamin B12 malabsorption, is associated with a longstanding *H. pylori* infection in most cases. There is an urgent need for population-based studies to assess the effect of *H. pylori* eradication on the development of vitamin B12 malabsorption.

## ACKNOWLEDGMENTS

Our deepest appreciation goes to the late Pirjo Kosunen for her skilful and assiduous assistance. We also thank Biohit PLC.Diagnostics for providing laboratory tests for pepsinogens and gastrin-17.

## COMMENTS

### Background

Autoimmune type atrophic gastritis is a severe gastric atrophy associated with pernicious anaemia with lifelong substitution therapy with vitamin B12. Longstanding *Helicobacter pylori* (*H. pylori*) infection proceeds in about 50% of patients to atrophic gastritis. *H. pylori* infection is much more prevalent than autoimmune type gastritis, and the association of these two conditions is possible without a causal relationship.

### Research frontiers

Previous studies have shown that *H. pylori* shares several epitopes with the proton pump, and the  $\beta$ -subunit of this pump is the causative antigen in autoimmune gastritis. In animal models, the passive transfer of these antibodies does not cause disease, but CD4+ T-cells are responsible for the gastritis. Recently, it has been shown that bacterial infection can modify the immune response in the direction seen in autoimmune diseases, i.e. Th17 cell differentiation, thus linking infection and autoimmunity.

### Innovations and breakthroughs

It is difficult to differentiate severe end stage *H. pylori* atrophic gastritis and autoimmune type gastric atrophy, because the autoimmune serum markers appear in *H. pylori* gastritis with increasing grade of atrophy, as shown in previous studies and confirmed in our study. The preatrophic stage of autoimmune type gastritis without *H. pylori* infection is an unknown entity. Several patients with autoimmune type gastric atrophy have signs of a previous *H. pylori* infection when studied with sensitive methods and remain positive for years, as shown in this study.

### Applications

If *H. pylori* initiates the apoptosis that leads to gastric atrophy and vitamin B12 deficiency, eradication of the bacteria before the development of severe atrophic changes should abolish the development of pernicious anaemia and the need of lifelong vitamin B12 substitution therapy.

### Peer review

This is a very interesting paper and asks quite an important question as to whether there is an association between *H. pylori* infection and autoimmune type atrophic gastritis. This work could be accepted after revision.

### Abstract

**AIM:** To predict treatment success using only simple clinical data from peg-interferon plus ribavirin therapy for chronic hepatitis C.

**METHODS:** We analyzed the clinical data of 176 patients with chronic hepatitis and hepatitis C virus genotype 1 who received 48 wk standard therapy, derived a predictive formula to assess a sustained virological response of the individual patient using a logistic regression model and confirmed the validity of this formula. The formula was constructed using data from the first 100 patients enrolled and validated using data from the remaining 76 patients.

**RESULTS:** Sustained virological response was obtained in 83 (47.2%) of the patients and we derived formulae to predict sustained virological response at pretreatment and weeks 4, 12 and 24. The likelihood of sustained virological response could be predicted effectively by

the formulae at weeks 4, 12 and 24 (the area under the curve of the receiver operating characteristic: 0.821, 0.802, and 0.891, respectively), but not at baseline (0.570). The formula at week 48 was also constructed and validation by test data achieved good prediction with 0.871 of the area under the curve of the receiver operating characteristic. Prediction by this formula was always superior to that by viral kinetics.

**CONCLUSION:** These results suggested that our formula combined with viral kinetics provides a clear direction of therapy for each patient and enables the best tailored treatment.

### INTRODUCTION

Persistent hepatitis C virus (HCV) infection is the major chronic liver disease in Japan, and pegylated interferon- $\alpha$  (PEG-IFN) plus ribavirin (RBV) therapy is the current mainstay of treatment. The goal of treatment is a sustained virological response (SVR), which is defined as undetectable serum HCV RNA, according to a polymerase

chain reaction-based assay, 6 mo after the cessation of therapy<sup>[1]</sup>. Patients who achieve SVR gain the benefits of regression of fibrosis, decreased incidence of hepatocellular carcinoma, and reduced morbidity and mortality. The genotype of HCV affects treatment efficacy and HCV RNA levels (viral load) also may have an effect. Only a small percentage of patients infected with HCV genotype 1b and high viral load achieved SVR with conventional IFN therapy for 6 mo<sup>[2]</sup>. Patients infected with HCV genotype 1 should receive 48 wk of PEG-IFN plus RBV, while 24 wk of treatment is recommended for patients with HCV genotype 2<sup>[3,4]</sup>. When PEG-IFN plus RBV is administered in this manner, around 50% of patients infected with HCV genotype 1 achieve SVR<sup>[5]</sup>, which is a great improvement over the SVR associated with 24 wk conventional IFN- $\alpha$  therapy.

The likelihood of treatment success may also be predicted by viral kinetics on therapy as well as circulating core antigen and immune parameters<sup>[6,7]</sup>. In particular, recent studies have shown that SVR can be predicted by a rapid virological response (RVR), which is defined as an undetectable level of HCV RNA at 4 wk of treatment<sup>[8]</sup>, and an early virological response (EVR), which is defined as either an undetectable level of HCV RNA or a drop in HCV RNA levels of at least 2 log<sub>10</sub>IU/mL after 12 wk of treatment<sup>[9]</sup>.

Nevertheless, the current dosing regimens for PEG-IFN plus RBV could potentially under-treat some patients<sup>[10]</sup> and additional measurements of viral response are needed to facilitate individualization of therapy. Among predictive factors already reported<sup>[11-15]</sup>, many are not readily available from daily clinical assessment, because they require genomic analyses and/or advanced experimental methods. There is increasing evidence to support extending the duration of treatment beyond 48 wk for patients with an HCV genotype 1 infection who display a slow virological response, which is defined by HCV RNA levels > 50 IU/mL at week 12 but undetectable at week 24. Several trials suggested that 72 wk of treatment with PEG-IFN plus RBV results in a better SVR rate than the same treatment for 48 wk<sup>[16-18]</sup>. However, it is difficult to accurately determine whether the individual should have their therapy extended at week 48, because the predictive value of a slow virological response may be insufficient alone. It would be very valuable to have a more accurate predictive marker of SVR at week 48, derived from clinically available measurements.

In this study, to try to make better prediction of patients who would or would not respond to 48 wk of PEG-IFN plus RBV therapy, we analyzed the clinical data of patients with chronic hepatitis C who received 48 wk of therapy, derived a predictive formula to assess the likelihood of an SVR for each individual patient using a logistic regression model and confirmed the validity of this formula.

## MATERIALS AND METHODS

The study was approved by the Ethics Committee of the

Keio University, School of Medicine, and was performed in accordance with the internationally accepted ethical standards for human experimentation. The study was conducted by the Keio Association for the Study of Liver Diseases (KASLD). All patients received explanations of the purpose and protocol of the study and written informed consent was obtained from each patient.

### Patients

One hundred and seventy-six patients with chronic hepatitis C infected with HCV genotype 1b were enrolled prospectively and received PEG-IFN plus RBV therapy from December 2004 to May 2007. All patients had HCV RNA levels  $\geq$  100 KIU/mL, measured by a quantitative polymerase chain reaction (PCR) assay (COBAS HCV AmpliCor MONITOR<sup>TM</sup>, sensitivity 500 IU/mL; Roche Diagnostic Systems, Inc., Tokyo, Japan). Pregnant women and women of childbearing potential, nursing mothers, male patients whose partner could have become pregnant, and those with anemia (hemoglobin concentration of 10 g/dL or less), leucopenia (1500 cells/ $\mu$ L or less), thrombocytopenia (80 000 cells/ $\mu$ L or less), severe dysfunction of organs other than the liver (these exclusion criteria are included in the instruction of the drug and provided by the manufacturer), infection with hepatitis B virus or human immunodeficiency virus, autoimmune hepatitis, primary biliary cirrhosis, and liver dysfunction caused by other etiologies were excluded. Some patients did not undergo a liver biopsy because not all of the centers could perform biopsies. All patients were treated for 48 wk and were followed for 24 wk after cessation of treatment. The formula was derived using data from the first 100 patients enrolled as selection data and validated using data from the additional 76 patients as test data. In this way it was possible to analyze the predictive accuracy and validity of the constructed formula.

### Treatment and data collection

PEG-IFN- $\alpha$ 2b (Schering-Plough K.K., Osaka, Japan) was administered weekly in doses adjusted for body weight according to the manufacturer's recommendations in Japan (45 kg or less, 60  $\mu$ g; 46-60 kg, 80  $\mu$ g; 61-75 kg, 100  $\mu$ g; 76-90 kg, 120  $\mu$ g; 91 kg or more, 150  $\mu$ g). Similarly, RBV (Schering-Plough K.K.) was given in daily doses adjusted to body weight according to manufacturer's instructions (60 kg or less, 600 mg/d; 61-80 kg, 800 mg/d; 81 kg or more, 1000 mg/d). Serum levels of HCV RNA were quantified and, when the level was below 500 IU/mL, HCV RNA was measured with the COBAS HCV Amplification and Detection version 2.0, sensitivity 50 IU/mL, Roche Diagnostic Systems). Blood cell counts and chemistry were analyzed at the beginning of treatment and every 4 wk thereafter. A questionnaire was used to review demographic data (gender, age, weight, height), previous treatment, histologic activity grade, and fibrosis stage, dose of PEG-IFN, dose of RBV, presence of diabetes, HCV RNA levels, SVR, white blood cell

counts (WBC), neutrophil counts (NC), red cell counts (RBC), hemoglobin levels (Hb), platelet counts (PLT), serum aspartate aminotransferase levels (AST), and serum alanine aminotransferase levels (ALT).

### Statistical analysis

The Mann-Whitney *U*-test was used to analyze continuous variables. Chi-squared and Fisher's exact tests were used for analysis of categorical data. One of our goals was to predict SVR using only simple clinical data, so a database was created containing the following basic information: for all patients, baseline age, sex, body weight (kg), height (cm), dose of PEG-IFN ( $\mu\text{g}/\text{kg}$ ), dose of RBV ( $\text{mg}/\text{kg}$ ), HCV RNA levels (KIU/mL), SVR (+/-), WBC ( $/\mu\text{L}$ ), NC ( $/\mu\text{L}$ ), RBC ( $/\mu\text{L}$ ), Hb (g/dL), PLT ( $/\mu\text{L}$ ), AST (IU/L), and ALT (IU/L). Statistical analyses were performed using the Statistical Package of Services Solutions (SPSS; SPSS Inc., Chicago, IL, USA) software, version 11.0. First, factors that differed significantly between SVR and non-SVR groups were identified at every time point by univariate analyses. The independent discriminative value of markers for predicting SVR was then assessed by logistic regression analysis. The third step was to construct a formula that combined independent factors. The best index for discrimination was the logistic regression function that combined the most discriminatory independent factors. The predictive formula was logically constructed by following basal formula:

$$1/p = 1 + \exp [-(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_r X_r)]$$

Diagnostic values of indices and isolated factors were assessed by sensitivity, specificity, positive and negative predictive values (PPV and NPV), and receiver operating characteristic (ROC) curves.

## RESULTS

### Patient profile

Of the 176 patients, 101 (59.8%) were men and the median age was 56 years (18-77), which is greater than has been reported from Western countries. The median values of body weight and BMI were 61 kg (41.2-90.5) and 22.8 (15.7-32.0), respectively, which are lower than has been reported from Western countries. These conditions are characteristic of recent trends in Japanese patients; older and less obese patients. Ninety-four patients (66.2%) were treatment naïve and the median value of HCV RNA was 2165 KIU/mL (130 to > 5000). The pretreatment median values were as follows; RBC 464 cells/ $\mu\text{L}$ , Hb 14.4 g/dL, PLT  $165 \times 10^3$  cells/ $\mu\text{L}$ , WBC 4775 cells/ $\mu\text{L}$ , NC 2549 cells/ $\mu\text{L}$ , AST 51 IU/L, and ALT 63 IU/L.

### Response rate and factors associated with svR

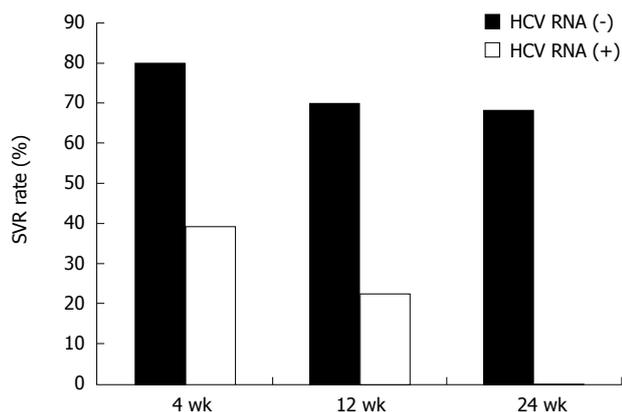

SVR was obtained in 83 (47.2%) patients and in 54 (54%) of the first 100 patients (selection data) enrolled in this study (Table 1). Of the 83, 43 were male; 60.6% of the male patients achieved SVR and there was a statistically significant gender difference ( $P = 0.020$ ). The median

SVR: Sustained virological response; BMI: Body mass index; RBC: Red blood cell count; Hb: Hemoglobin; PLT: Platelet count; WBC: White blood count; NC: Neutrophil count; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; PEG-IFN dose (48 wk): Total dose of PEG-IFN at 48 wk ( $\mu\text{g}/\text{kg}$  per wk); RBV dose (48 wk): Total dose of RBV at 48 wk ( $\text{mg}/\text{kg}$  per day).

age was significantly lower in the SVR group. There was no difference in body weight and BMI between the SVR group and non-SVR group for the patients used for selection data. The pretreatment HCV RNA level did not differ significantly between the SVR and non-SVR groups, while pretreatment RBC, Hb, PLT and ALT levels differed between the groups. The average cumulative dose of RBV administered up to the time point indicated was always much greater in the SVR group than in

**Figure 1** Sustained virological response rates (%) of the patients during peg-interferon plus ribavirin therapy for chronic hepatitis C at week 4 (4 wk), week 12 (12 wk) and week 24 (24 wk). HCV RNA (-) means patients whose serum HCV RNA became undetectable at the time point indicated. HCV RNA (+) means patients whose serum HCV RNA was not cleared at the indicated time point.

the non-SVR group. The average cumulative dosage of PEG-IFN differed between the groups at week 48.

Among the first 100 patients, serum HCV RNA decreased 1 log or more at week 4 in 67 (67.0%) and became undetectable in 31 (RVR, 31.0%). SVR was attained in 25 of the 31 RVR patients (80.6%). Likewise, a complete EVR was attained in 66 patients, among whom 46 (69.7%) finally achieved SVR. SVR was achieved in 52 of 76 patients (68.4%) whose serum HCV RNA had disappeared by week 24. SVR also was achieved in patients whose serum HCV RNA had not disappeared until week 12. SVR was attained in 39.3%, 22.6% and 0% of patients who failed to achieve RVR, complete EVR and HCV RNA negativity at week 24, respectively (Figure 1). From these data, PPV and NPV determined by viral kinetics at week 4 were 80.6% and 60.7%, respectively. PPV at weeks 12 and 24 were 68.7% and 68.4% respectively, and NPV were 77.4% and 100%, respectively.

#### Multivariate analysis for contributing factors to achieve SVR

Multivariate analysis was performed to determine the factors contributing to SVR. Analysis was made pretreatment and at weeks 4, 12 and 24. Factors available from pretreatment until at the time point were all included, and those calculated as  $P < 0.1$  by univariate analysis at each time point were analyzed using the logistic regression method. A statistical difference was found in gender, age, RBC, Hb, PLT and log (ALT 0 wk: ALT levels at week 0) at pretreatment by univariate analysis. The independent factor contributing to SVR was RBC ( $P = 0.024$ ) at pretreatment. Among significant factors found by univariate analysis at week 4, log (ALT 0 wk) ( $P = 0.015$ ), RVR (4 wk) ( $P = 0.0049$ ), and log (AST 4 wk) ( $P = 0.042$ ) were independent factors by multivariate analysis. Similarly, log (ALT 0 wk) ( $P = 0.0076$ ), EVR ( $P = 0.0083$ ), WBC (4 wk) ( $P = 0.035$ ), and average cumulative RBV dose ( $P = 0.045$ ) were significant factors at week 12. Independent

**Table 2** Logistic regression analysis of independent predictive factors for sustained virological response

Variables	Odds ratio	95% CI	P value
At pretreatment			
RBC ( $\times 10^4$ ) (0 wk)	1.011	1.002-1.021	0.024
PLT ( $\times 10^3$ ) (0 wk)	1.085	0.986-1.193	0.095
log (ALT 0 wk)	3.509	0.727-16.934	0.118
At week 4			
Age	0.941	0.885-1.000	0.051
log (ALT 0 wk)	27.090	1.891-388.001	0.015
RVR +/-	6.543	1.766-24.243	0.0049
log (AST 0 wk)	0.036	0.001-0.886	0.042
At week 12			
log (ALT 0 wk)	39.331	2.648-584.144	0.0076
RVR +/-	3.015	0.694-13.100	0.141
EVR +/-	8.340	1.728-40.265	0.0083
WBC (4 wk)	1.001	1.000-1.002	0.035
log (AST 12 wk)	0.049	0.002-1.037	0.053
RBV dose (12 wk)	1.519	1.010-2.284	0.045
At week 24			
log (ALT 0 wk)	68.688	3.669 to < 999.999	0.0047
RVR +/-	3.329	0.819-13.529	0.093
EVR +/-	31.775	2.840-355.460	0.0050
WBC (4 wk)	1.001	1.000-1.002	0.044
log (AST 12 wk)	0.036	0.001-0.918	0.044
RBV dose (12 wk)	1.607	1.021-2.528	0.040

contributing factors at week 24 were log (ALT 0 wk) ( $P = 0.0047$ ), HCV RNA (-/+) (24 wk) ( $P = 0.005$ ), WBC (4 wk) ( $P = 0.044$ ), log (AST 12 wk) ( $P = 0.044$ ) and average cumulative RBV dose (12 wk) ( $P = 0.040$ ) (Table 2). It was intriguing in addition to RVR and EVR that baseline ALT level (log) always affected SVR prediction from pretreatment until week 24.

#### Predictive formulae of svr by logistic regression analysis

According to the method of logistic regression analysis, we derived four formulae to predict SVR of patients receiving 48-wk PEG-IFN plus RBV treatment in our cohort from significant factors selected by multivariate analysis at pretreatment and week 4, week 12 and week 24 as shown in Table 2. These formulae are as follows:

Pretreatment:  $1/p = 1 + \exp \{-[-8.8065 - 0.0114 \times \text{RBC} (\times 10^4) \text{ 0 wk} + 0.0812 \times \text{PLT} (\times 10^4) \text{ 0 wk} + 1.2552 \times \log (\text{ALT 0 wk})]\}$

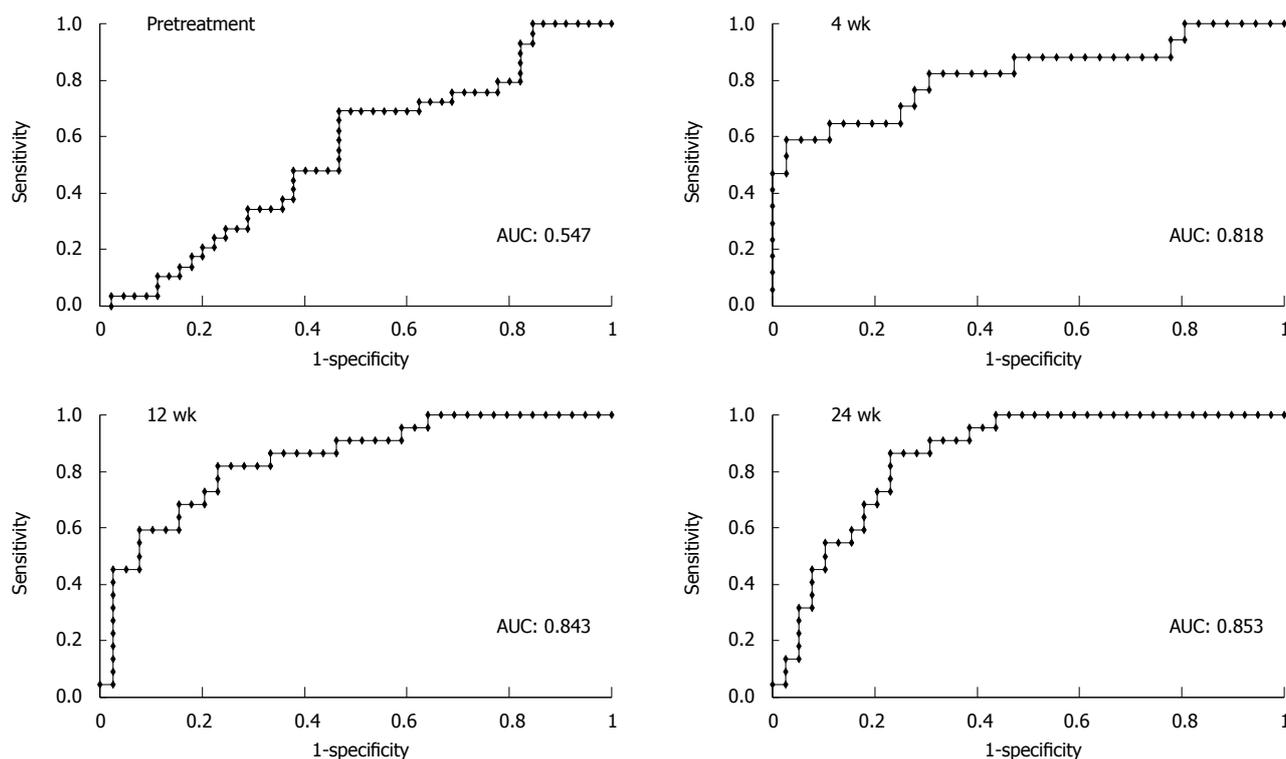

At week 4:  $1/p = 1 + \exp \{-[-1.8839 - 0.00607 \times \text{Age} + 3.2992 \times \log (\text{ALT 0 wk}) + 1.8784 \times \text{RVR} - 3.3364 \times \log (\text{AST 4 wk})]\}$

At week 12:  $1/p = 1 + \exp \{-[-11.5278 + 3.672 \times \log (\text{ALT 0 wk}) + 1.1036 \times \text{RVR} + 2.1211 \times \text{EVR} + 0.000837 \times \text{WBC 4 wk} - 3.0134 \times \log (\text{AST 12 wk}) + 0.418 \times \text{RBV dose 12 wk}]\}$

At week 24:  $1/p = 1 + \exp \{-[-14.5754 + 4.2296 \times \log (\text{ALT 0 wk}) + 1.2028 \times \text{RVR} + 3.4587 \times \text{HCV RNA 24 wk} + 0.0009 \times \text{WBC 4 wk} - 3.3224 \times \log (\text{AST 12 wk}) + 0.4741 \times \text{RBV dose 12 wk}]\}$

HCV RNA (-): 1, (+): 0.

ROC curve analysis was conducted to evaluate the accuracy of each prediction using both selection data and test data. The area under the curve of the ROCs

**Figure 2** Receiver operating characteristic (ROC) curves and the area under curve (AUC) of the predictive values made by the formulae during peg-interferon plus ribavirin therapy for chronic hepatitis C at week 4, 8, 12 and 24.

(AUCs) of multiple logistic regression analyses using selection data ( $n = 100$ ) at pretreatment and at weeks 4, 12 and 24 were 0.710, 0.828, 0.889, and 0.933, respectively. The predictive value at pretreatment was insufficient, but those after weeks 4, 12 and 24 were satisfactory.

The validity of the predictive formulae was evaluated further using test data ( $n = 76$ ). The AUCs of logistic regression analyses using test data were 0.547, 0.818, 0.843, and 0.853 at pretreatment and weeks 4, 12 and 24, respectively (Figure 2). Unlike prediction by viral kinetics, our formula is always applicable to all patients and the final predictive value is fairly high according to the ROC analysis, as described above. The median calculated values for patients who ultimately attained SVR were 0.545, 0.661, 0.589 and 0.656, at pretreatment and weeks 4, 12 and 24, respectively, and these values were always significantly higher than those of non-SVR cases (Table 3). The statistical difference of predictive values between SVR and non-SVR patients increased with the duration of therapy.

#### Prediction at week 48

It has been suggested that the prolongation of treatment is effective for patients who do not achieve HCV RNA negativity at week 12. There are also patients who achieve RVR and/or EVR but whose serum HCV RNA reappears after cessation of the treatment. We evaluated whether we can select such patients for whom treatment should be lengthened to 72 wk, using the same procedure as for on-treatment prediction of SVR with 48 wk of treatment. The predictive formula at week 48

**Table 3** The median predictive values for sustained virological response (SVR) rates calculated using our formulae at pretreatment and weeks 4, 12 and 24

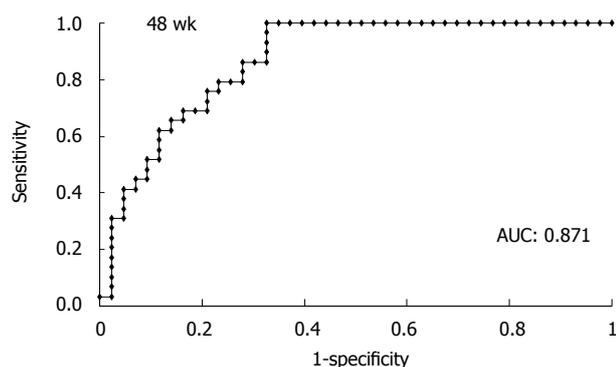

Median (range)	Patients who attained SVR	Patients with non-SVR	P value
Pretreatment	0.545 (0.286-0.926)	0.507 (0.108-0.945)	0.514
At week 4	0.661 (0.139-0.998)	0.251 (0.056-0.688)	0.000
At week 12	0.589 (0.079-0.994)	0.146 (0.001-0.952)	0.000
At week 24	0.656 (0.038-0.996)	0.026 (0.000-0.949)	0.000

The values were compared between patients who attained SVR and those who did not.

was constructed from the data of the 100 patients used for selection data. This formula included the parameter whether HCV RNA disappeared during therapy. When HCV RNA disappeared at week 4, 8, 12 and 24, each value, such as 4, 8, 12 and 24, was inserted into the formula. For non-SVR cases, 100 was inserted into the formula. The formula was determined as follows:

$$1/p = 1 + \exp \{-[-4.9107 - 0.0079 \times \text{Time of HCV RNA negative (wk)} + 0.1477 \times \text{PLT 0 wk} + 3.4941 \times \log(\text{ALT 0 wk}) - 1.7018 \times \log(\text{AST 12 wk})]\}$$

The ROC curve obtained from the test data of 76 patients is shown in Figure 3. The AUC derived from the test data ( $n = 76$ ) by logistic regression analysis was 0.871, suggesting that patients who can stop treatment at week 48 are predicted accurately by this formula. The median calculated value of patients who attained SVR was 0.775 (0.237-0.999) and that of patients who did not achieve

**Figure 3** Receiver operating characteristic (ROC) curves of the predictive values calculated by the formula from data up to 48 wk of peg-interferon plus ribavirin therapy for chronic hepatitis C.

SVR was 0.004 (0-0.966,  $P < 0.00001$ ). PPVs and NPVs calculated by the formula with various cut-off points are shown in Table 4. When we set the cut-off point at 0.2, NPV was 100% and 28 patients were included in this category.

There were 10 patients who relapsed after attaining complete EVR in 76 patients (4 cases achieved negativity of HCV RNA at week 8 and others achieved at week 12), and two of them could be pointed out as non-SVR by our calculation if the cut-off point was set at 0.5 (the value of one predicted person was 0.129 and another was 0.421).

## DISCUSSION

We propose here a method using formulae for the prediction of SVR in patients with chronic hepatitis C treated for 48 wk with PEG-IFN plus RBV. The predictive potential was very high when judged by AUC analysis, which was more than 0.8 from week 4. In particular, the validity at week 24 was more than 0.85 of AUC. The simplest method of prediction of SVR may be viral kinetics and a response-based on-treatment prediction, such as RVR and EVR, which are the outcomes of totally integrated viral and host factors. The PPV of the formulae were better at weeks 12 and 24 than the prediction with viral kinetics, and the NPV of the formulae were better at weeks 4 and 12. Evaluation of the formulae using data from the test patients revealed a very high AUC value of more than 0.85. These results suggest that formulae based on simple clinical data are superior to prediction by viral kinetics. These formulae, however, cannot be permanent, and may vary among different groups of patients, so should be re-evaluated or re-constructed, even for our series when the number of patients has increased. The most important outcome of this study is that we can predict SVR of our patients accurately with 48-wk PEG-IFN plus RBV therapy using only "simple" clinical data. Individual tailoring of treatment duration may be an option in the future to reduce relapse rates in HCV type 1-infected patients. The concept that

**Table 4** Positive and negative predictive values calculated by the formula constructed with data at week 48

Cut-off point	PPV (%)	NPV (%)	<i>P</i> value
0.2	65.9	100	< 0.00001
0.3	66.7	96.7	< 0.00001
0.4	66.7	86.1	< 0.00001
0.5	68.8	82.5	0.000013
0.6	71.4	79.5	0.000024
0.7	77.3	76.0	0.000048
0.8	80.0	70.2	0.00074

The calculated value was applied to the cut-off points and the numbers of patients with sustained virological response were evaluated.

extension of treatment duration can reduce relapse rates should be adopted only for a limited proportion of type 1-infected patients because the possibility of SVR may be very low in those whose serum HCV RNA remains positive at week 24. The patients who will benefit most from prolongation of therapy include those whose serum HCV RNA is positive at week 12 but negative at week 24, including even patients with RVR and EVR. The formulae we suggest might be helpful for such patients who are expected to achieve SVR but did not do so. For those individuals, our method based on logistic regression analysis will show a clear direction of therapy in each case and enable the best tailored treatment. Further prospective studies should be performed to determine whether this approach really increases the SVR rate by selection of patients and extension of treatment duration up to week 72.

RVR may be valuable for determining treatment duration but is not sufficient for predicting the response to treatment<sup>[8]</sup>. When SVR is predicted by RVR, the confirmed SVR rate within whole patients may be low. In the study of Yu *et al.*<sup>[19]</sup>, SVR was achieved in 42 of 100 patients, and all the patients who attained RVR achieved SVR. However, SVR was also attained in patients who did not attain RVR, and another 30 SVR patients who were not included in the RVR group. If 100% of patients with RVR attain SVR, the final prediction of SVR at this point (week 4) is 53.2%. In the study of Jensen *et al.*<sup>[20]</sup>, 95 of 374 (25.4%) genotype 1 patients attained RVR. The SVR rate of these 95 patients was 82% compared to 20.8% among the 374 treated subjects. The PPV of EVR for SVR is estimated to be less robust, less than 70%, and the validity may decrease more when we predict SVR by RVR only. We could predict SVR patients with 57.9% if the cut-off point was set at 0.5, and with 64.7% if that was set at 0.6 at week 4. The potent SVR of patients who did not achieve RVR could be predicted by our formula and the combination with viral kinetics may further improve predictive value.

Ferenci *et al.*<sup>[21]</sup> investigated response-guided treatment based on RVR and 78.8% of HCV genotype 1 patients with RVR attained SVR. Around 20% of patients with RVR failed to achieve SVR in their study. The SVR rate of patients with a complete EVR is around 80% and that

of patients without an EVR is around 15%. Therefore, there are several unfortunate patients with RVR and EVR but in whom serum HCV RNA reappears after the cessation of treatment. On the other hand, it may be difficult to attain SVR for patients whose serum HCV RNA does not disappear until after week 24 (late responders), even if they are treated for more than 48 wk with PEG-IFN plus RBV. Recent studies suggested that the extension of treatment to 72 wk would help to achieve SVR in such “unfortunate” patients, who should have responded well to the 48 wk therapy. It is not realistic that all patients who attain RVR and EVR should receive 72 wk therapy to ensure SVR. Our method of deriving a formula, predicting success or failure of response to 48 wk treatment, may serve as a good compass to identify patients who require extended treatment to achieve SVR. Of course, further prospective study is necessary and there has been no evidence that prolongation of therapy really decreases relapse rate. However, using the formula of week 48, we could predict patients who will benefit from an additional 24 wk of treatment and achieve an SVR. In fact, we could recognise 2 of 10 EVR patients as non-SVR by our formula and they would be rescued if they receive additional 24 wk therapy.

Perhaps the rule of stopping the treatment of patients with a decrease of less than  $2 \log_{10}$  in HCV RNA level within the initial 12 wk of therapy should be reconsidered because the high NPV of this rule (98%-100%) could be confirmed only for the 48 wk treatment group and not for the 72 wk group. As seen in our series, Japanese patients with chronic hepatitis C are older and have thinner physiques than those in Western countries. Because the time of infection was approximately 60 years ago<sup>[22]</sup>, and much earlier than elsewhere in the world, patients of an older age require treatment with PEG-IFN plus RBV<sup>[23]</sup>. However, these patients easily become anemic, probably because of their older age combined with their physical characteristics<sup>[24]</sup>, and the adherence to RBV, which may be critical for attaining SVR, is usually low. An RBV dosage of 1000-1200 mg/d is administered rarely in Japanese studies. The higher dose of PEG-IFN and RBV in 48 wk therapy suggested by Fried *et al.*<sup>[25]</sup>, who studied patients with a mean age of approximately 47, is almost impossible in Japan. When older patients opt for PEG-IFN plus RBV therapy, it is a “one-chance-treatment” and they always endure patiently the side effects of therapy but rarely agree to re-treatment after the cessation of therapy. Therefore, the on-treatment prediction of SVR is very important for older patients and, if the probability of success is reasonable, they would choose prolongation of the therapy. In this case, our formula is a very useful tool to decide whether the patient should receive additional therapy at week 48.

Many factors affecting the SVR rate have been reported, including viral- and host-related factors. Among the viral factors, amino acid substitutions in the interferon sensitivity determining region (ISDR) located in HCV nonstructural region 5A<sup>[11]</sup> and the core region (71st and 90th codons)<sup>[12]</sup> are well established. We also reported

amino acid substitutions in the RNA-dependent RNA polymerase (NS5B) region from our cohort study<sup>[16,27]</sup>. On the other hand, host factors, such as pretreatment intrahepatic CD8+ cell count<sup>[28]</sup>, the T-helper type 1 and 2 (Th1/Th2) ratio<sup>[13,29,30]</sup> and T-helper activity<sup>[31]</sup>, have also been demonstrated. Other factors, such as metabolic and diabetic factors, have been implicated in the efficacy of IFN therapy<sup>[32]</sup>. RBV plasma concentration at week 4<sup>[14]</sup> and a new index, named accordion index<sup>[33]</sup>, have also been proposed. These significant viral and host factors, except for the metabolic factors, are difficult to examine and daily clinical assessment is not practical. Shirakawa *et al.*<sup>[15]</sup> published an excellent report recently on the classification of patients according to their responsiveness to PEG-IFN plus RBV therapy. They predicted SVR successfully with pretreatment data, but the prediction included particular determinations, such as ISDR sequences and Th1/Th2 ratios, which are not easily available in clinics and are uneconomical. In contrast to their report, the formulae proposed in this study involve factors included among readily available data, and moreover, the validity was very high, especially at weeks 24 and 48.

In conclusion, our predictive formula, which is easily constructed in every institution with simple clinical data, would offer better prediction of SVR and non-SVR than the prediction by viral kinetics. Further study including extended protocol (72 wk treatment) and analysis with other measurement of HCV RNA, such as real-time PCR, should be evaluated in the future.

## ACKNOWLEDGMENTS

We would like to thank to Dr. Kyong-Mi Chang (GI Division, University of Pennsylvania) for her kind advice in the manuscript preparation. The study was conducted by the Keio Association for the Study of Liver Diseases (KASLD), the multicenter clinical study group, and we thank the following doctors who provided the data for the sake of KASLD; Tsuchimoto K, Kumagai N, Tsunematsu S (Kitasato Institute Hospital), Yokomori H, Kaneko F (Kitasato Institute Medical Center), Zeki S, Nakashita M (Keiyu Hospital), Inagaki Y, Masuda T (Nihon Kohkan Hospital), Komatsu H, Hara Y (Yokohama Citizen Hospital), Yoshida T, Watanabe N (Social Security Saitama Hospital), Morishita T, Nishida J, Kishikawa H (Toyko Dental Collage Ichikawa General Hospital), Horie Y, Umeda R (Eiju Hospital), Nishimura K (Tokyo Denryoku Hospital), Tanaka S, Takahashi M, Kaneko H (National Hospital Tokyo Medical Center), Yoshioka M and Itoh T (Social Security Minami-Tama Hospital).

## COMMENTS

### Background

The likelihood of treatment success of 48 wk peg-interferon (PEG-IFN) plus ribavirin (RBV) therapy for chronic hepatitis C may be predicted by viral kinetics on therapy. In particular, recent studies have shown that sustained virological response (SVR) can be predicted by a rapid virological response (RVR), and

an early virological response (EVR). Nevertheless, the current dosing regimens could potentially under-treat some patients and additional measurement of viral response is needed to facilitate individualization of therapy. Among predictive factors already reported, many are not readily available from daily clinical assessment, because they require genomic analyses and/or advanced experimental methods.

### Research frontiers

It is difficult to accurately determine whether the individual should have their therapy extended at week 48, because the predictive value of a slow virological response may be insufficient alone. It would be very valuable to have a more accurate predictive marker of SVR at week 48, derived from clinically available measurements. According to the method of logistic regression analysis, the authors of this study derived formulae to predict SVR of patients receiving 48 wk PEG-IFN plus RBV treatment in their cohort from significant factors selected by multivariate analysis at pretreatment and weeks 4, week 12 and week 24.

### Innovations and breakthroughs

The most important outcome of this study is that it is possible to predict SVR accurately with 48 wk PEG-IFN plus RBV therapy by formulae using only "simple" clinical data.

### Applications

This study may enable the best tailored treatment especially for patients with a high expectation of sustained virological response with 48 wk peg-interferon and ribavirin therapy for chronic hepatitis C but whose responses relapse. Prospective studies informed by this method will be of considerable value.

### Terminology

RVR is defined as an undetectable level of HCV RNA at 4 wk of treatment, and EVR is defined as either an undetectable level of HCV RNA or a drop in HCV RNA levels of at least 2 log<sub>10</sub> IU/mL after 12 wk of treatment. Recent studies reported that these on-treatment viral kinetics are useful for prediction of SVR.

### Peer review

Conclusively, establishing a new predictive formula to assess the likelihood of a SVR of the individual patient chronically infected with HCV is very important.

### Abstract

**AIM:** To investigate the occurrence of postoperative complications of gastric cancer surgery, and analyze the potential causes of reoperation for early postoperative complications.

**METHODS:** A total of 1639 patients who underwent radical or palliative gastrectomies for gastric cancer were included in the study. The study endpoint was the analysis of postoperative complications in inpatients.

**RESULTS:** About 31% of patients had early postoperative complications, and complications of infection occurred most frequently. Intra-abdominal hemorrhage and anastomotic leak were the main causes of reoperation, which accounted for about 2.2%. Mortality was 11.1% in the reoperation group, but was only 0.8% in other patients. The duration of postoperative stay in hospital was significantly longer and the total expenditure was markedly higher in the patients who underwent reoperation ( $P < 0.001$ ). There was no significant association of any available factors in this study with the high rate of reoperation.

### INTRODUCTION

Though the occurrence of postoperative complications and mortality rate after surgery for gastric cancer have significantly decreased over the past years, they are still considered high<sup>[1,2]</sup>. Radical gastrectomy with D2 lymph node dissection is widely accepted, but the extent of lymph node dissection is controversial among different centers<sup>[3-10]</sup>. It is well accepted that the extent of surgery (particularly aggressive dissection of the lymph nodes) does not extend the overall survival, and postoperative complications were significantly related to the extent of surgery, particularly the extent of lymph node dissection. This was proved by Japanese surgeons who conducted several clinical randomized controlled trials (RCTs)<sup>[5,9-11]</sup>. Sasako *et al*<sup>[9]</sup> conducted a RCT in 24 hospitals in Japan to compare D2 lymphadenectomy alone with D2 lymphadenectomy plus para-aortic nodal dissection

(PAND) in patients undergoing gastrectomy for curable gastric cancer. They concluded that compared with D2 lymphadenectomy alone, D2 lymphadenectomy plus PAND does not improve the survival in curable gastric cancer; extended D2 lymphadenectomy plus PAND should not be performed to treat curable stage T2b, T3, or T4 gastric cancer; and that D2 gastrectomy is associated with the low mortality and reasonable survival of the patients.

Many researchers at leading centers for gastric cancer, including those in Korea and China, have indicated that combined resection of other organs is not of long-term benefit and it significantly increased the prevalence of postoperative complications and mortality<sup>[3,4,11-13]</sup>. The occurrence rates of postoperative complications in the spleen-preservation group and splenectomy group were 11.6% and 29.3%, respectively. There was a higher frequency of pleural effusion, intra-abdominal abscess, and pancreatitis in splenectomized patients. A higher recurrence was observed in the splenectomy group (40.4%) compared with the spleen-preservation group (25.1%). The mean survival time was 72.0 mo in the spleen-preservation group compared with 56.7 mo in the splenectomy group<sup>[13]</sup>. Investigation of early postoperative complications would therefore be beneficial to optimize the extent of gastric cancer surgery.

Reoperation after routine surgery, particularly after gastric cancer surgery, increases the overall burden for both the surgical ward and the patients. We therefore investigated the factors causing reoperation and their effects on the recovery of patients who undergo surgery for gastric cancer.

## MATERIALS AND METHODS

A total of 1639 patients who underwent radical or palliative gastrectomies for gastric cancer in five consecutive years were included in the study (Table 1). Data were collected directly by comprehensive review of the original records of all patients. Sixty-seven patients with missing data and 13 patients who underwent emergency surgery were excluded from the analysis. Exclusion criteria were disease other than gastric cancer, and any type of palliative surgery (including exploratory laparotomy and gastrojejunal anastomosis) other than gastrectomy. The median age of the patients was 59 years (range, 17-93 years). The ratio of male and female patients was approximately 7:3.

Patients with early and resectable advanced gastric cancer underwent radical surgery (gastrectomies with D2 lymphadenectomy). Patients with late-stage gastric cancer underwent palliative gastrectomy. Most patients were diagnosed to be in stage III. The tumor invaded the serosa or adjacent structures in 38.1% of patients which was classified as pT3, and in 11.4% of patients classified as pT4 (Table 1). With respect to combined organ resection, 19 splenectomies, 14 partial pancreatectomies with splenectomy, 14 partial colectomies, two partial colectomies with splenectomy, seven partial hepatectomies (lobectomy),

<sup>1</sup>Including recurrent gastric cancer; <sup>2</sup>Oesophago-gastric anastomosis.

one total hysterectomy and one partial pancreatectomy were carried out in 58 patients (Table 1). About 25% of the patients underwent total gastrectomy. Billroth I, typical Roux-en-Y, and Billroth reverse (esophagogastric anastomosis) were the preferred methods for anastomosis after distal gastrectomy, total gastrectomy and proximal partial gastrectomy. Above 85% patients underwent surgery by senior surgeons with experience of 20-30 years. The minimal working experience of the surgeons was > 15 years. No surgical fellow or surgeons-in-training was allowed to perform the surgery independently. All the patients were managed by senior attendants under direct supervision of the surgeons.

The endpoint was analysis of postoperative complications and postoperative mortality in inpatients. Complications were recorded according to the definitions stated in the Physiological and Operative Severity Score for the Enumeration of Mortality and Morbidity (POSSUM)<sup>[14]</sup>. As there are many complications that are not covered by its definitions, an undefined complication was therefore

recorded as “innominate” and the details were provided in separate tables. Severities of all complications were stratified according to Rui Jin Hospital Classification of Complications<sup>[15]</sup>.

We also audited the overall expenditure in US dollars (\$) of patients during their stay in hospital and compared it between the reoperation group and non-reoperation group.

### Statistical analysis

The statistical analysis was done using the Statistical Package for Social Science (SPSS) version 13.0 for Windows (SPSS, Incorporated, Chicago, IL, USA). Non-parametric methods were used to test the data without normal distribution.  $P < 0.05$  was considered significant.

## RESULTS

About 31% of patients had different types of complications according to POSSUM criteria. The prevalence of individual complications was not equal to the total number of complications. Multiple complications were possible in a single patient (Table 2). Postoperative infection was the most common complication. The occurrence of anastomotic leak was about 2%, and postoperative mortality was only 1%.

There were numerous innominate complications (Table 3), most of which were accompanied by complications described in POSSUM. Most patients had pleural effusion or/and seroperitoneum, most of which were accompanied by low fever but pathological diagnosis of infection could not be confirmed. A substantial number of patients had persistent fever or recurring fever of unknown origin. About 5% of patients had persistent nausea or vomiting caused by gastroplegia or enteroplegia, anastomosis edema, or ileus. Some patients were clinically suspected to have a minor leak but there was no sufficient objective evidence to support this finding. Although these patients were managed by conservative treatment (mainly NPO, intravenous antibiotics, and total parenteral nutrition), they still increased the burden on the surgical ward. Complications were rare such as pancreatic fistula, chyle leak, and bleeding at the anastomosis site.

Innominate complications were recorded empirically and merged to calculate different levels of complication type according to the Rui Jin Hospital Classification of Complications<sup>[15]</sup>. Most complications were minor (11.0%) or moderate (15.2%), only 8.3 % of patients had severe complications.

Patients were categorized into three levels according to the length of postoperative stay in hospital. About 75% of patients were discharged in good condition in less than 15 d after uneventful recovery and removal of sutures, 19.7% of patients discharged within 16-30 d and only 6% of patients stayed in hospital for more than a month.

There was a significant difference in the occurrence rate of overall complications between partial and total gastrectomy with radical lymphadenectomy, but no significant difference between partial and total gastrectomy with palliative lymphadenectomy was observed (Table 4).

Pancreatitis	22	1.3
Central vein catheter infection	14	0.9
Anastomosis site or upper GI bleeding	10	0.6
Chyle leak	8	0.5
Pancreatic fistula	6	0.4

The occurrence of complications of infection (including deep infection, pulmonary infection), system failure, and mortality was significantly higher in total gastrectomy with radical lymphadenectomy. After stratification of patients into partial and total gastrectomy groups, we noted no significant difference in complication occurrence between radical lymphadenectomy and palliative lymphadenectomy (Table 5).

Thirty-six patients underwent reoperation for different causes, with intra-abdominal hemorrhage and anastomotic leak as the main causes (Table 6). There was no significant difference in physiological score (PS;  $P = 0.382$ ) and operative severity score (OSS;  $P = 0.849$ ) between patients in the reoperation group and the non-reoperation group. Median values of PS and OSS in the reoperation group were 14.5 (range, 12-25) and 18 (range, 16-24) respectively, whereas they were 15 (range, 12-38) and 18 (range, 11-28) in the non-reoperation group. Mortality was significantly higher in patients who underwent reoperation ( $P < 0.001$ ), being 11.1% in the reoperation group but only 0.8% in

Respiratory	4 (11.11)	10 (0.62)
Cardiac	2 (5.55)	9 (0.56)
Hypotension	1 (0.03)	9 (0.56)
Deep venous thrombosis	0	3 (0.18)
Pancreatitis	0	1 (0.06)
Anastomosis site bleeding	0	1 (0.06)

underwent partial gastrectomy (Table 7).

Except for four patients with wound dehiscence who were discharged within one month, the other 32 patients were treated in hospital for more than one month. The length of postoperative stay was significantly longer in patients who underwent reoperation ( $P < 0.001$ ). The mean duration of postoperative stay was 44.6 d (standard deviation, SD = 29.41 d) in patients with reoperation, but was only 14.6 d (SD = 8.09 d) in other patients.

Reoperation caused a significant economic burden for patients. There was a significant difference in the total expenditure between groups of patients with or without reoperation ( $P < 0.001$ ). The median expenditure in patients with reoperation was 7946.36 \$ (SD = 8930.38 \$) but it was only 3238.32 \$ (SD = 4404.63 \$) in other patients.

Univariate analysis of the data revealed no significant association of any available factors in this study with the higher rate of reoperation, including age, hypertension,

anemia, hypoalbuminemia, hyperglycemia, type of gastrectomy, combined organ resection, type of anastomosis, surgeon's experience (number of operations performed), tumor stage.

## DISCUSSION

In the surgical approach for early and selective advanced gastric cancer, gastrectomy with D2 lymphadenectomy is justified<sup>[6,16-19]</sup>. The procedure of surgery, particularly the extent of lymphadenectomy for gastric cancer, varies among individual centers. The occurrence of postoperative complications was higher in inexperienced hands, and there was a considerable difference in early surgical outcomes among centers<sup>[3,20]</sup>. Postoperative complications were inversely correlated with the number of patients undergoing treatment in a surgical unit<sup>[21]</sup>; similar results were published for patients undergoing surgery for gastric cancer<sup>[15]</sup>. Overall survival rate was higher at specialized centers. It was therefore stressed in many articles that gastric cancer surgery was safe at specialized centers<sup>[3,6,22,23]</sup>.

The postoperative complications at our institution were in the acceptable range because most patients had a smooth recovery and postoperative mortality was not high. Overall surgical outcome was acceptable because of the occurrence rate of complications was below the moderate level. Postoperative infection was the commonest complication. There are several complications (e.g. gastroplegia or enteroplegia, suspicious anastomotic leak, pleural effusion) which are not covered by POSSUM. These complications cannot be ignored because they have a big impact on the overall burden (patient-related and economic) of our hospital. A substantial number of patients had persistent fever without a clear diagnosis; appropriate investigation was necessary to find the cause. Further investigation was required to classify or define the diagnosis of sub-clinical anastomotic leak. The Ruijin Hospital Classification of Complication, stratifies complications to different levels according to the severity of the disease, and is a validated classification<sup>[2,15]</sup>. We suggest that other hospitals use this classification for assessment of surgical outcome.

Reoperation was in the acceptable range as compared with a recent report from the Korean Institute, and the mortality caused by reoperation was low<sup>[24]</sup>. Most reoperations were carried out for intra-abdominal hemorrhage, which may be related to the experience of surgeons and necessitates additional efforts to examine the easily missed bleeding sites (particularly anastomosis sites). The four cases of rupture of the abdominal wall may be attributed to the poor surgical technique because these patients had their linea alba closed by an interrupted silk suture. We did not observe this complication in patients with linea alba closed by a continuous absorbable suture. Anastomotic leak was followed by intra-abdominal infection which often caused peripancreatic abscess, and eventually pancreatic fistulas in some cases. Improvement of surgical

technique is therefore crucial to lower the occurrence of intra-abdominal hemorrhage and anastomotic leak.

In conclusion, although the overall occurrence of postoperative complications was high after gastric cancer surgery, the occurrence rate of severe complications and mortality were low. Reoperation after gastric cancer surgery significantly increases the mortality and overall burden of the surgical unit. As the gastric cancer surgery is considered as a routine surgery, it is important to control the postoperative complications. Univariate analysis of the data revealed no significant association of any available factors in this study with the high rate of reoperation; however, more prospective studies are required to explore the potential risk factors for the higher rate of reoperation after gastric cancer surgery.

## COMMENTS

### Background

Though the occurrence of postoperative complications and mortality after surgery for gastric cancer have significantly decreased over the past years, they are still considered high. It was well accepted that the extent of surgery does not extend the overall survival and that postoperative complications were significantly related to the extent of surgery. Therefore, surgical extent should be seriously considered and postoperative complications should not be ignored.

### Innovations and breakthroughs

The postoperative complication is highly variable among different centers. However, surprisingly there are very few reports on this issue, especially from Chinese surgical centers. This study was conducted at a leading center for gastric cancer surgery in China, and analyzed a large cohort of patients for a long period. It provides the details on the occurrence of postoperative complications and analyzed its impact on patients and surgical ward. The finding of this study certainly provides very useful reference to the surgeons working in this field.

### Applications

The better understanding about the occurrence of different types of the postoperative complications and its underlying causes may help surgeons reduce the postoperative complications and upgrade the quality of surgical treatment.

### Terminology

"POSSUM" is an internationally accepted scoring system which is applied for the evaluation of surgical treatment. "Rui Jin Hospital Classification of the complications" is a novel system which stratifies all the complications in three different levels and provides objective idea about the severity of complications.

### Peer review

The article has some very good information and is worthy of publication.

### Abstract

**AIM:** To examine whether acupuncture can prevent prolonged postoperative ileus (PPOI) after intraperitoneal surgery for colon cancer.

**METHODS:** Ninety patients were recruited from the Fudan University Cancer Hospital, Shanghai, China. After surgery, patients were randomized to receive acupuncture (once daily, starting on postoperative day 1, for up to six consecutive days) or usual care. PPOI was defined as an inability to pass flatus or have a bowel movement by 96 h after surgery. The main outcomes were time to first flatus, time to first bowel movement, and electrogastroenterography. Secondary outcomes were quality of life (QOL) measures, including pain, nausea, insomnia, abdominal distension/fullness, and sense of well-being.

**RESULTS:** No significant differences in PPOI on day 4 ( $P = 0.71$ ) or QOL measures were found between the groups. There were also no group differences when the data were analyzed by examining those whose PPOI had resolved by day 5 ( $P = 0.69$ ) or day 6 ( $P = 0.88$ ). No adverse events related to acupuncture were reported.

**CONCLUSION:** Acupuncture did not prevent PPOI and

was not useful for treating PPOI once it had developed in this population.

## INTRODUCTION

Bowel dysfunction following abdominal surgery is common and usually temporary, lasting no more than 3 d; however, if patients are unable to tolerate an oral diet, pass flatus, or have a bowel movement by postoperative day 4, they are considered to have prolonged postoperative ileus (PPOI). PPOI is uncomfortable for patients and potentially dangerous. The collection of gas and secretions related to PPOI causes pain and discomfort with bloating, distention, and often emesis<sup>[1]</sup>. Delayed gastric emptying also increases the risk of aspiration in patients during the early postoperative period. Patients with PPOI cannot be discharged from the hospital until the ileus has resolved. Few published studies have estimated the cost of PPOI, but expenses related to longer hospital stays, nursing care, laboratory/diagnostic testing, and interventional treatments are likely to be considerable.

Current treatment for postoperative ileus in China is primarily supportive and includes nasogastric suction, intravenous fluids, parenteral nutrition, and gradual ambulation with simple exercises. However, a variety of preventive interventions<sup>[2-6]</sup> for PPOI, such as preoperative carbohydrate loading, wrapping patients in warm blankets in the operating room, chewing gum, and rocking in a rocking chair postoperatively to stimulate gastrointestinal function, have been mentioned in the literature. Further research is needed, however, to evaluate the efficacy of these approaches. Two studies published by Sculati and colleagues have concluded that a preoperative bran-enriched diet (lasting 8-10 d) may help prevent PPOI<sup>[7,8]</sup>, but this is often not practical for patients undergoing gastrointestinal surgery.

Although prevention and treatment of PPOI with various pharmacologic agents has been explored for several years, success has been limited<sup>[9-17]</sup>. Alternatives

to systemic opioid analgesia, such as thoracic epidural analgesia<sup>[18]</sup> and non-opioid analgesics such as ketorolac tromethamine<sup>[10,11]</sup>, have been shown to shorten the duration of PPOI when compared with opioids, but non-opioid analgesia does not adequately control pain in all patients<sup>[10,11]</sup>. The combined use of a local anesthetic for chemical sympathectomy and sparing amounts of narcotic for improved pain control has been proposed, but there is no clear guidance as to which combination best promotes bowel motility while maintaining adequate pain control<sup>[17]</sup>.

A 2008 Cochrane review of the use of prokinetic agents in PPOI has concluded that there was no evidence to support the use of erythromycin, and insufficient evidence for cisapride, cholecystokinin-like drugs such as cerulein, and dopamine antagonists such as metoclopramide, propranolol and vasopressin<sup>[19]</sup>. Neostigmine rapidly decompresses the colon and has shown some potential in PPOI; however, side effects such as bradycardia, bronchospasm, and increased risk of anastomotic dehiscence are of major concern<sup>[17,20]</sup>. Lubiprostone, a bicyclic fatty acid that acts as a chloride channel opener and thereby increases intestinal water secretion, has been shown to be effective in constipation<sup>[21]</sup> and is currently being investigated in PPOI<sup>[16]</sup>.

Narcotic receptor antagonists represent another major class of drugs studied in the treatment of PPOI. Naloxone, for example, is limited by its central nervous system effects and potential to reverse analgesia<sup>[17]</sup>. Methylnaltrexone, a quaternary derivative of naltrexone that does not cross the blood-brain barrier, has shown some efficacy in opioid-induced constipation<sup>[22,23]</sup>, but preliminary results from two trials in PPOI showed no benefit over placebo<sup>[24]</sup>. In May 2008, alvimopan, a selective mu-receptor antagonist, was the first drug to receive United States Food and Drug Administration (FDA) approval specifically for the treatment of PPOI after showing benefit in several phase III trials<sup>[25,26]</sup>. However, there are concerns about the cost-benefit ratio of this drug, given that it shows only a modest reduction in hospital stay (7-15 h) and costs nearly \$1000/treatment cycle<sup>[27,28]</sup>.

Some research has suggested that traditional Chinese herbal medicines can also help bowel motility<sup>[29,30]</sup>. For example, *saussura cappa* and the formula *Liu Jun Zi Tang* have been associated with improved stomach and intestinal emptying time and increased plasma motilin levels<sup>[29,31]</sup>. Although herbal medicine shows some benefit for gastrointestinal motility, abdominal surgery patients generally cannot have anything by mouth during the perioperative period.

Acupuncture has been used in China for thousands of years to treat a variety of gastrointestinal problems<sup>[32]</sup>. The advantages of acupuncture are that it is a cost-effective, minimally invasive procedure with a very low incidence of side effects. Although prior studies have investigated the effects of acupuncture on gastrointestinal motility in humans<sup>[33]</sup>, few randomized clinical trials have been published. Controlled animal studies supported

by plausible physiological and laboratory evidence have, however, shown that acupuncture has positive effects on gastric and intestinal motility<sup>[34-38]</sup>. Although the exact mechanisms are not fully understood, one hypothesis is that acupuncture may help regulate the gastrointestinal tract *via* the autonomic nervous system. Several animal studies have revealed that the effect of acupuncture on gastrointestinal function is mediated through sympathetic and parasympathetic efferent pathways<sup>[39,40]</sup>.

To the best of our knowledge, only one study<sup>[41]</sup> has evaluated the efficacy of acupuncture in preventing PPOI after abdominal surgery. However, in that trial, the incidence of PPOI assessed at postoperative day 4 after ileostomy/colostomy closure was too small to show significance between the treatment and control groups. Therefore, in the current prospective, randomized study, we investigated whether acupuncture could prevent PPOI after invasive colon cancer surgery. Bowel motility was determined by time to first flatus, time to first bowel movement, and by electrogastroenterography (EGEG), a device that detects electrical signals from the abdomen. Secondary objectives were to compare postsurgical quality of life (QOL) between the treatment and control groups in terms of pain, nausea, insomnia, abdominal distension/fullness, and sense of well-being.

## MATERIALS AND METHODS

### Patient eligibility

Patients were recruited from the Fudan University Cancer Hospital between July 2004 and October 2006 and were enrolled in the trial after providing written informed consent. Regardless of sex or ethnicity, all patients 18-75 years old, who had colon cancer with a Duke A to D stage diagnosis (as long as metastatic disease did not affect bowel function) and were scheduled to undergo intraperitoneal surgery, were identified at the time of preoperative evaluation and screened for eligibility. Eligible patients had to meet the following criteria: physical status classification of category III or better according to criteria established by the American Society of Anesthesiologists<sup>[42]</sup>; planned use of epidural infusion for post-surgical pain management; no upper or lower extremity deformity or local skin infections that could interfere with accurate acupuncture point location; no active systemic infection; no chronic functional constipation as defined by Rome I criteria prior to the cancer diagnosis<sup>[43]</sup>; and no history of cerebrovascular accident or spinal cord injury. Patients were also excluded if they had chronic pain currently treated with any form of major opioid or with weak opioids at morphine equivalent doses > 30 mg/24 h; had a cardiac pacemaker; were mentally incapacitated or had a significant emotional or psychiatric disorder that precluded study participation; were pregnant; were using laxatives or other medicines known to affect bowel function, such as herbal preparations, high-dose vitamins, or iron sulfates; had known bleeding abnormalities or were on heparin

or warfarin; had any parasurgical complications needing intensive care; or were currently using acupuncture.

### Procedures

The study was designed collaboratively and conceived by faculty from Fudan University Cancer Hospital and M.D. Anderson Cancer Center, The University of Texas. An experienced statistician was involved in all stages of study development and analysis. The protocol was approved by both Institutional Review Boards. Two nurses from Fudan Cancer Hospital spent 3 mo at M.D. Anderson Cancer Center undergoing research nurse training, two physicians underwent 2 mo of faculty research training, and the acupuncturist from Fudan University Cancer Hospital spent 1 mo at M.D. Anderson Cancer Center. The acupuncturist was trained specifically in aspects of quality control and fidelity to study-related acupuncture procedures. During the course of the trial, faculty and staff from M.D. Anderson Cancer Center also visited Fudan Cancer Hospital four times to review the trial. Video conferences were conducted twice each month.

At the Fudan University Cancer Hospital, patients are generally admitted for preoperative evaluation 3-5 d prior to surgery. All patients were recruited during this time. The first 30 patients were randomized using simple randomization; however, group differences were noted for route of anesthesia administration. Therefore, from the 31st patient forward, in order to ensure group balance for anesthesia administration, patients were randomized into either treatment or control groups by a form of adaptive randomization, minimization<sup>[44]</sup>. Before a participant was assigned to a treatment group, the number of already randomized participants with similar covariate characteristics was totaled. The totals were computed based on marginal sums so that each covariate was considered separately. The treatment assignment for a participant was then based on which treatment group assignment would produce the best overall balance with respect to the covariate characteristics. The patient characteristic used for group assignment was the mode of anesthesia (iv, epidural, or iv plus epidural).

After surgery, if the patient continued to meet all eligibility criteria, she/he was randomized with equal probability into either the treatment or control group. Data were collected and recorded twice a day for 6 d or until the first bowel movement. Patients had to have a bowel movement prior to discharge; therefore, participation ended at the time of discharge for anyone leaving prior to the sixth postoperative day, regardless of whether they had received acupuncture treatment.

### Acupuncture treatment

The acupuncture treatments were performed in the patient's room by a hospital accredited physician who has over 30 years of acupuncture experience and is routinely involved in postoperative care to patients. Patients in the treatment group received acupuncture

once a day, starting on postoperative day 1, for six consecutive days or until the first bowel movement, whichever came first. After the skin was prepped with 70% alcohol, the needles were inserted and remained in place for approximately 20 min with each treatment. The treatment frequency was agreed upon by a small panel of experienced acupuncturists. Patients in the control group received standard postoperative care with no acupuncture.

During the acupuncture treatment, each patient lay in a supine position in his or her hospital bed. A tight abdominal dressing and binder was placed after surgery and not removed for 2-3 d, therefore, only points located on the extremities were selected. Electrical stimulation was applied concomitantly and continuously to two pairs of points [SJ-6 (positive) and GB-34 (negative)] bilaterally by placing lead wires on the needles connected to an electro-acupuncture stimulator (Model 980; Shanghai Medical Equipment Co. Ltd., Shanghai, China). This unit applied consistent stimulation throughout the treatment at a frequency of 2 Hz.

The acupuncture needles used (Huatuotuo, Suzhou, China) conformed to the requirements of the ISO 9002, EN46002 and CE certification, United States FDA International Good Manufacturing Practices, and the World Health Organization's standards for quality and safety. These stainless steel needles are 1.5 *cun* in length by 32-gauge diameter and are provided in individual sterile packages.

Standardized techniques for point location were used and were based on anatomical landmarks as well as proportional measurements of the patient's body. For example, finger breadth refers to the patient's middle finger, and the proportional unit of measure was the "*cun*", defined as the distance between the two medial ends of the creases of the interphalangeal joints when the patient's middle finger is flexed<sup>[45]</sup>. The following bilateral acupuncture points were selected specifically for the purpose of improving bowel motility. (1) SJ-6: located 3 *cun* proximal to the dorsal crease of the wrist, on the line connecting *Yangchi* (SJ-4) and the tip of olecranon, between the radius and ulna, on the radial side of the extensor digitorum communis muscle. The Chinese name for this point is *Zhigou*. According to the underlying theory of Traditional Chinese Medicine (TCM), this is a major point for stimulating the intestines<sup>[45]</sup> and is often paired with GB-34 to treat constipation. (2) GB-34: located in the depression anterior and inferior to the head of the fibula. The Chinese name for this point is *Yanglingquan*. This point is often paired with SJ-6 to treat constipation due to *qi* stagnation or heat<sup>[45]</sup>. (3) ST-36: on the lateral surface of the leg, 3 *cun* distal to the lower border of the patella, one finger's breadth from the tibia tuberosity between the tibia digitorum tibialis anterior muscle and the tendon of longus pedis. The Chinese name for this point is *Zusanli*. It lies just over the deep peroneal nerve and is commonly used by acupuncturists to harmonize (i.e. regulate) the gastrointestinal tract<sup>[45]</sup>. (4) ST-37: located 3 *cun* below *Zusanli* (St-36) and one finger's breadth (middle

finger) from the anterior border of the tibia. The Chinese name for this point is *Shangjuxu*. Based on TCM theory, this point also regulates the intestines<sup>[45]</sup>.

### Outcome measures

The main outcome measure of bowel motility was assessed by asking patients to record the exact date and time that they first passed flatus and the exact date and time of their first bowel movement after surgery. Time 0 was the time anesthesia ended according to the anesthetic record. The total numbers of hours between time 0 and the passage of flatus and between time 0 and the first bowel movement were then calculated. PPOI was defined as having no bowel movement for more than 96 h (4 d) after surgery.

Secondary measures included EGEG and QOL assessments. Electrical signals from the stomach and intestines associated with gastrointestinal motility were monitored *via* EGEG (Huake Electronic Technical Research Institute, Beijing, China). The surgeon placed the leads for EGEG monitoring at the time of wound closure and prior to placement of the abdominal dressing and binder. According to standard postoperative care at this hospital, the abdominal dressing and binder were not removed until postoperative day 2 or 3; therefore, assessment of bowel sounds was not performed. EGEG monitoring occurred twice per day. After attachment of the electrodes to the leads, the patient rested for 1 min, and then two consecutive 3-min recordings were obtained. Both frequency (per minute) and amplitude were measured using two channels.

Data related to postoperative QOL were obtained from the nursing and physician progress notes and the patient's self-evaluation using the Quality of Life Status (QOLS) assessment tool, which is based on the Edmonton Symptom Assessment System (ESAS)<sup>[46-48]</sup>. The QOLS used in this study was a slightly modified version of the ESAS and consisted of five items (pain, nausea, insomnia, abdominal distention, and general sense of well-being), which were rated using a 0-10 numeric rating scale.

### Statistical analysis

Our primary analysis was to determine the proportion of patients with ileus in each group at day 4 and to determine if the two groups differed in the proportions of ileus observed, using a binomial test. We powered our study to be able to estimate each proportion to within at most 16% by including 40 patients in each group. For example, if 50% of patients in one group (20 out of 40) developed ileus, the 95% confidence interval of this estimate would be 34%-66%. In addition, if we found that 40% of patients (16 out of 40) in one group developed ileus and 11% or fewer ( $\leq 4$ ) in the second group developed ileus, this difference would be considered statistically significant with 80% power and a two-sided significance level of 5%.

The time of occurrence of bowel motility indicators (i.e. first passage of flatus and first bowel movement)

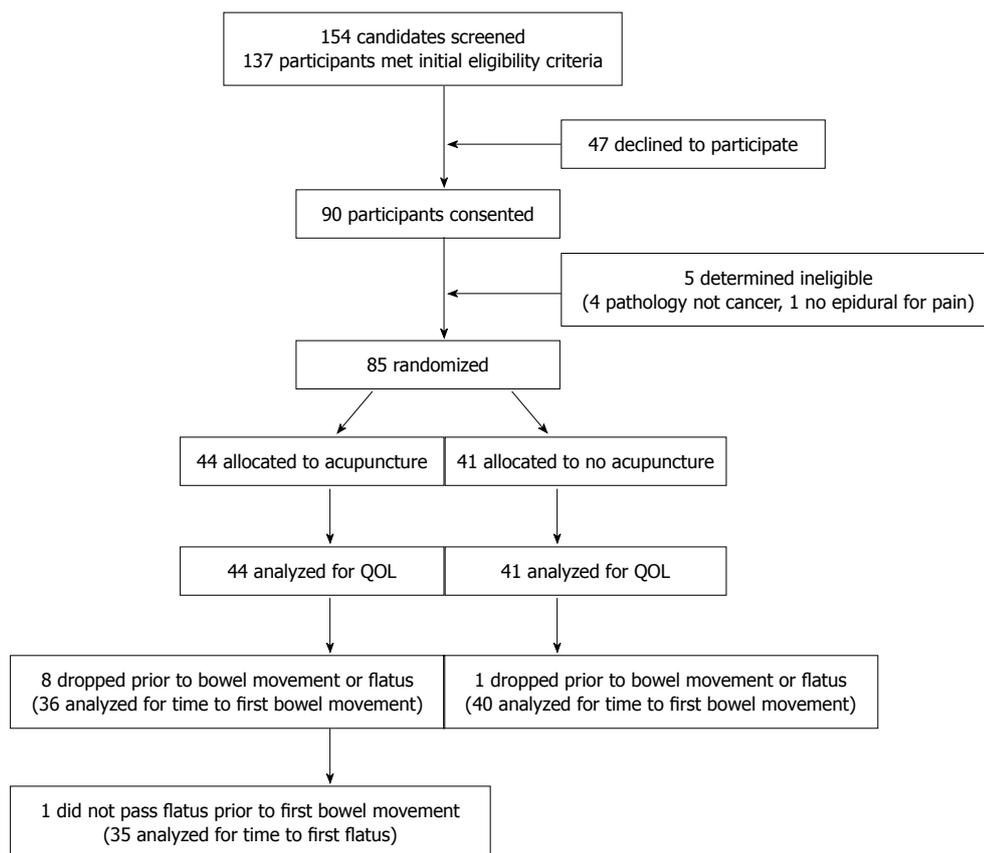

Figure 1 Flow of participants through the study.

was subtracted from the time anesthesia ended, and compared between groups using the Wilcoxon two-samples test. Unpaired *t* tests were used to compare EGEG indicators and QOL outcomes between groups.

## RESULTS

Of the 154 subjects screened, 137 met all the initial eligibility criteria. Forty-seven patients who were eligible declined to participate. Therefore, 65.7% of eligible patients (90 patients) agreed to participate. The overall mean age of the participants was 53.7 years (range, 29-73 years), and there were no group differences in mean age (acupuncture, 54.3 years; control, 53.1 years). There were 38 (45%) women and 47 (55%) men, with an even balance between groups (43% and 46% women in the acupuncture and control groups, respectively). All patients received intraperitoneal surgery, and a representative sample of the population that we wanted to assess was obtained as follows: 47 (52.2%) proctectomy, 21 (23.3%) right hemicolectomy, 11 (12.2%) sigmoidectomy, eight (8.9%) left hemicolectomy and three (3.3%) transverse colectomy. Of 90 patients, 70 (77.78%) received epidural anesthesia (37 acupuncture; 33 controls), 18 (20%) received both epidural and general anesthesia (7 acupuncture, 11 in controls), and two (2.2%) patients in the acupuncture treatment group received general anesthesia only. There were no differences between groups with regard to diagnosis,

operation methods, operation time, blood loss, and postoperative complications.

No participants were lost to follow-up. Five participants were dropped from the study after consent but prior to randomization either because a subsequent pathology report indicated that they did not have a cancer diagnosis, or because they did not receive epidural infusion for post-surgical pain management. Eighty-five patients were randomized (acupuncture = 44; no acupuncture = 41). Although some postoperative QOL data were obtained on all patients, eight in the acupuncture group and one in the no acupuncture group were dropped prior to first bowel movement or first passage of flatus, and before PPOI could be assessed on postoperative day 4, because the inconvenience of study participation (acupuncture-4 dropped on postoperative day 1, 2 on day 2, 1 on day 3, and 1 on day 4; no acupuncture-1 dropped on postoperative day 2). Figure 1 shows the flow of participants through enrollment, randomization, follow-up, and analysis.

Table 1 provides a summary of the study results. There were no significant differences between the groups in terms of bowel motility indicators, EGEG, or post-surgical QOL, thus, the null hypothesis was not rejected.

There were also no group differences when the data were analyzed on the basis of the subset of 46 patients who developed PPOI by day 4 (21 of 36 acupuncture patients *vs* 25 of 40 control patients,  $P = 0.71$ ), and

Table 1 Summary of study results

Outcome	Acupuncture			Control			P value
	n	mean ± SD	Median (range)	n	mean ± SD	Median (range)	
Hours to first flatus	35	68.26 ± 23.38	72.25 (26.75-124.63)	40	65.24 ± 17.5	64.88 (30.25-105.17)	0.36
Hours to first bowel movement	36	119.04 ± 47.97	108.67 (34.00-241.17)	40	119.38 ± 60.21	104.25 (37.00-359.00)	0.77
EGEG at morning (Freq/min)	44	9.66 ± 1.34	9.32 (7.34-12.87)	41	9.59 ± 1.63	9.65 (6.80-14.98)	0.83

General well-being <sup>1</sup>	44	4.11 ± 1.57	4 (1.67-8.00)	41	3.73 ± 1.3	3.67 (1.17-6.29)	0.34

<sup>1</sup>Based on a 0-10 numeric rating scale.

whether their PPOI had resolved by day 5 (8 of 21 acupuncture patients and 11 of 25 controls,  $P = 0.69$ ) or day 6 (13 of 21 acupuncture *vs* 16 of 25 controls,  $P = 0.88$ ). The remaining 17 patients experienced a bowel movement by day 7. There were no adverse events greater than grade I (according to the Common Terminology Criteria for Adverse Events v3.0 (CTCAE)<sup>[49]</sup>) related to the acupuncture treatment reported during the study.

## DISCUSSION

PPOI developed in 46 patients, and there was no significant difference in the number of patients with PPOI in the acupuncture group ( $n = 21$ ) *vs* the control group ( $n = 25$ ). Similarly, there were no group differences in bowel activity as assessed by EGEG or in self-reported pain, nausea, insomnia, abdominal distention, or general well-being. In this patient population, PPOI occurred in up to 50% of participants in both groups, which suggested a lack of efficacy of acupuncture to prevent PPOI. Furthermore, analyses of the subset of patients who developed PPOI on day 4 and the resolution of PPOI on days 5 or 6 also revealed no group differences. Although this was a secondary analysis based on a small number of patients, it suggested that acupuncture was not effective in treating PPOI once it developed in this population.

Several important facts, however, were learned that will help with the development of future trials. First, standard postoperative care is different in China than in the United States. At Fudan University Cancer Hospital, patients undergoing this type of surgery often do not ambulate until after postoperative day 3, and in many cases, patients may not ambulate until postoperative day 5 or 6. In addition, patients have a nasogastric tube in place for several days and, thus, progression in diet is much slower than in the United States. Finally, a tight abdominal dressing and binder is placed after surgery and not removed for 2-3 d. Each of these factors could play an important role in gastrointestinal motility postoperatively and were not analyzed separately in the current study. As this was a randomized clinical trial, however, these

factors were likely balanced between both groups. No patients in either group were given enteral or nasogastric feeding before passage of first flatus, and all patients in both groups were given similar iv fluids that included fat emulsion, amino acids, glucose and equilibrium liquids.

One limitation of the current study is that the use of epidural anesthesia in the majority of patients may have diminished the possible effects of acupuncture because of the blockade of afferent and efferent pathways, as acupuncture may act on gastrointestinal motility through neural mechanisms. Moreover, opioid use was not tracked and analyzed formally; however, through the process of randomization and based on a brief review of patient records showing consistency in pre- and postoperative medication, the authors believe this was likely to have been similar in both groups. Nevertheless, it is important to note that the acupuncture treatment in this study was designed to stimulate gastrointestinal motility. The efficacy of acupuncture for pain control is well established<sup>[50]</sup>, and future trials should explore whether or not acupuncture designed to reduce pain can also reduce the amount of opioids used, and thus lessen the occurrence of PPOI. Although acupuncture alone may not be sufficient to reduce the risk of developing postoperative ileus, adding acupuncture to a regimen that includes other preventive measures such as less opioid use, increased ambulation, and progressive diet could have a synergistic effect and help prevent this debilitating complication following abdominal surgery. Future acupuncture trials should, therefore, be designed to include evaluation of these factors, as well as different point combinations, treatment schedules, and type of needle stimulation (i.e. manual *vs* electrical).

To the best of our knowledge, only one previous randomized trial has examined the use of acupuncture to prevent PPOI<sup>[41]</sup>. That study was conducted in the United States among a population of cancer patients who underwent ileostomy/colostomy reversal, a procedure which is not commonly performed in China. Unfortunately, the incidence of PPOI in that study was too small to determine any statistically significant

differences between the groups. It is important to note that no adverse events related to acupuncture were reported during either the previous or current trial.

Providing acupuncture treatment to post-surgical patients at the bedside was found to be feasible, and the logistics of so doing were determined in the current study. Future research should evaluate the efficacy of acupuncture in a different population and for other postoperative conditions, such as anxiety, pain, nausea, vomiting, and wound healing.

In conclusion, this study confirmed findings from previous research<sup>[42]</sup> that acupuncture can be safely administered in a postoperative setting; however, it was not found to be effective in preventing PPOI in this population. Future studies examining the use of acupuncture for PPOI should include assessment of activity, diet, and postoperative pain control, as well as different point combinations, treatment schedules, and type of needle stimulation. Finally, this was a prevention study, and the efficacy of acupuncture in treating PPOI once it has developed has not been evaluated in a prospective randomized trial. Since prior animal and human data<sup>[34-38]</sup> have shown that acupuncture can regulate gastrointestinal function, further investigation is warranted.

## COMMENTS

### Background

Postoperative ileus is a common problem in patients who have major abdominal surgery. The duration is usually short, but prolonged postoperative ileus (PPOI) may lead to increased hospital stay and costs. Acupuncture is often used to treat gastrointestinal disorders in China, but it is still not known whether it is effective for preventing or treating PPOI.

### Research frontiers

Information from this study may help surgeons choose appropriate therapy for PPOI after abdominal surgery.

### Innovations and breakthroughs

This study was conducted as part of a unique collaboration between researchers in the United States and China. Only one previous randomized trial, conducted in the United States, has examined the use of acupuncture to prevent PPOI in cancer patients. Standard postoperative care is very different in the United States than in China, and some of these treatment differences could play an important role in postoperative gastrointestinal motility.

### Applications

Future studies examining the use of acupuncture to prevent or treat PPOI should include assessment of activity, diet, and postoperative medication for pain control.

### Terminology

For the purposes of this study, PPOI was defined as an inability to pass flatus or have a bowel movement by 96 h after surgery.

### Peer review

In this study, the authors investigated whether acupuncture can prevent PPOI after intraperitoneal surgery for colon cancer. Their results show that acupuncture cannot prevent PPI in this population. Subset analyses also suggest that acupuncture is not useful for treating PPOI. This was a prospective, randomized study, with novelty and innovation. It will be helpful for the surgeons to choose appropriate therapy for PPOI after abdominal surgery. Presentation and readability of the manuscript is good for publication.

### Abstract

**AIM:** To investigate whether silencing Fas-associated phosphatase 1 (FAP-1) expression enhances the efficiency of chemotherapy for colon carcinoma with oxaliplatin.

**METHODS:** Expression of FAP-1 in mRNA and protein was detected by reverse transcription polymerase chain reaction (RT-PCR) and flow cytometry. Small interfering RNA (siRNA) was designed according to the FAP-1 mRNA sequence. Cell proliferation was evaluated by methyl thiazolyl tetrazolium (MTT) assay. Anenxin V- and propidine iodine (PI) were assayed by flow cytometry for the detection of apoptosis.

**RESULTS:** The expression of FAP-1 was increased in SW480 cells after chemotherapy with oxaliplatin. Transfection of FAP-1 siRNA into SW480 cells silenced the expression of FAP-1 and consequently abolished the inhibitory function of Fas/FasL-mediated apoptosis pathway, thus increasing the efficacy of chemotherapy for colon carcinoma with oxaliplatin.

**CONCLUSION:** RNA interference combined with conventional chemotherapy is more effective against colon cancer.

## INTRODUCTION

The incidence of colon carcinoma is increasing worldwide<sup>[1]</sup>. Although great achievements have been made in surgery, chemotherapy and even some novel molecule-targeted drugs, such as bevacizumab (Avastin) used in treatment of colon carcinoma, their efficacy is still limited<sup>[2]</sup>. Since tumorigenesis is a multiple step event involving multiple genes, a single treatment modality just targets a part of the pathogenesis of colon carcinoma. The mechanism underlying the limited efficacy of the above treatment modalities still needs to be further explored in order to prolong the survival time of such patients.

Fas/FasL system is the essential pathway of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells to induce cell apoptosis<sup>[3]</sup>. Fas, an apoptotic message receptor, is belonged to the tumor necrosis factor family and expressed in many normal tissues and malignancies. Its expression pattern is mainly located in activated T lymphocytes and NK cells. By binding to Fas antibody or FasL, Fas-induced apoptotic pathway can be activated, initiating tumor cell apoptosis<sup>[4-6]</sup>. However, it has been reported that Fas receptors are highly expressed in colon carcinoma cells at both mRNA and protein levels, and FasL levels are high in blood and tissues of colon carcinoma patients<sup>[7,8]</sup>, suggesting that colon carcinoma cells can escape from the immune clearance, resist to the cytotoxic activity of host immunocytes, and are, thus, insensitive to FasR-mediated apoptosis. Although the mechanism underlying the failure of immune system to protect humans against colon malignancies remains unclear, it has been recently shown that Fas-associated phosphatase 1 (FAP-1) may play an important role in the pathogenesis of colon malignancies<sup>[9]</sup>. FAP-1, a tyrosine phosphatase, inhibits FasR-mediated apoptosis. By interacting with the cytoplasmic death domain of Fas receptors, FAP-1 acts as a negative switch in the Fas pathway<sup>[10]</sup>. Transfection of FAP-1 into Fas-sensitive cells can block FasL-induced apoptosis<sup>[11]</sup>. Fas and FAP-1 are expressed in colon cancer tissue and the expression of FAP-1 is associated with resistance against Fas-mediated apoptosis and interrupting the correspondence between FAP-1 and Fas can reverse the anti-Fas inducing apoptosis function of FAP-1<sup>[12]</sup>. Down-regulating the expression of FAP-1 by interleukin 2 can promote the sensitivity of colon cancer cells to Fas-induced apoptosis<sup>[13]</sup> and interrupting FAP-1 also increases chemosensitivity to certain kinds of cancer<sup>[14]</sup>, suggesting that FAP-1 can be used as a target for treatment of malignancies. These findings lead to a question of whether interrupting FAP-1 sensitizes chemotherapy for colon carcinoma.

It has been recently shown that RNA interference (RNAi) plays an important role in the treatment of malignancies, virus infection, and other diseases<sup>[15-19]</sup>. Small interfering RNA (siRNA) is small in size, and can easily infiltrate cell membranes and other structures. Its efficiency and specificity are higher than those of anti-sense oligonucleotide<sup>[20-23]</sup>. RNAi may be used as

a novel gene therapeutic procedure combining with chemotherapy for colon carcinoma.

In this study, the expression of FAP-1 was up-regulated after treatment with oxaliplatin. Silencing FAP-1 by siRNA effectively reversed the apoptotic resistance and increased the efficacy of chemotherapy for colon carcinoma with oxaliplatin.

## MATERIALS AND METHODS

### Colon cancer cell line and culture

Human colon adenocarcinoma cell line SW480, obtained from Chinese Type Culture Collection Committee Cell Bank (Shanghai, China), was maintained in RPMI-1640 medium (GIBCO, Grand Island, NY, USA), supplemented with 10% heat-inactivated fetal calf serum (FCS) at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub>.

### FAP-1 siRNA design

Three different sequences of FAP-1 specific siRNA, including positive control glyceraldehyde phosphate dehydrogenase (GAPDH) siRNA and negative control siRNA, were designed and synthesized by Genepharma (Shanghai, China). The sequence of each siRNA is shown in Table 1.

### siRNA transfection

siRNA was transfected with a siPORT™ NeoFX™ transfection agent (AMBION) following its manufacturer's instructions.

### Detection of FAP-1 by reverse transcription polymerase chain reaction (RT-PCR)

RNA was harvested from colon cancer cells by extracting Trizol (Invitrogen) following its manufacturer's instructions. cDNA was synthesized from 2 µg of total RNA in a 20 µL reaction system containing 0.5 µL of PrimeScript™ RTase, 4 µL of 5 × PrimeScript™ buffer, 0.5 µL of RNase inhibitor, 1 µL of Oligo dT, 2 µL of dNTP, 11 µL of RNase free H<sub>2</sub>O. The mixture was incubated for 60 min at 42°C and then for an additional 30 min at 53°C. The unhybridized RNA was digested with 10 units of RNase H at 37°C for 10 min.

PCR was performed on cDNA using the sense and anti-sense primers to amplify FAP-1 and a house keeping gene, GAPDH. All primers were designed according to the published sequences: FAP-1: (sense) 5'-AG-GTCTGCAGAGAAGCAAGAATAC-3' and (anti-sense) 5'-GAATACGAGTGTTCAGACATGG-3'; GAPDH: (sense) 5'-AACGGATTGTGGTCGTATTG-3' and (anti-sense) 5'-GGAAGATGGTGATGGGATT-3'.

The PCR conditions were as follows: denaturation at 95°C for 5 min, followed by 30 cycles at 94°C for 30 s, at 50°C for 45 s, at 72°C for 1 min, and a final extension at 72°C for 7 min for FAP-1, and denaturation at 95°C for 5 min, followed by 30 cycles at 94°C for 30 s, at 58°C for 45 s, at 72°C for 1 min, and a final extension at 72°C for 7 min for GAPDH. Primers were used at a final concentration of 0.1 µmol/L each, dNTPs at 50 µmol/L,

Table 1 siRNA sequence	
siRNA	From 5' to 3'
FAP-1 siRNA 1709	Sense: CGAAGGAAAGUAAAACAUAAATT Anti-sense: UUAUGUUUACUUUCCUUCGGT
FAP-1 siRNA 6267	Sense: CAGGUACAUUAAAGAUGAATT Anti-sense: UUCAUCUUUAAUGUACCUUGA
FAP-1 siRNA 3264	Sense: GGGAGAUCACCUUAGUGAATT Anti-sense: UUCACUAAGGUGAUCUCCCTT
GAPDH positive control	Sense: GUAUGACAACAGCCUCAAGTT Anti-sense: CUUGAGGCUGUUGUCAUACTT
Negative control	Sense: UUCUCCGAACGUGUCACGUTT Anti-sense: ACGUGACACGUUCGGAGAATT

siRNA: Small interfering RNA; FAP-1: Fas-associated phosphatase 1; GAPDH: Glyceraldehyde phosphate dehydrogenase.

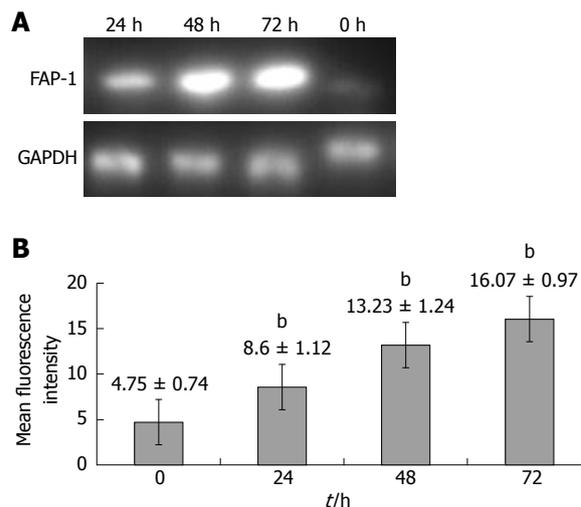

MgCl<sub>2</sub> at 1.5 mmol/L, Taq DNA polymerase at 1.0 µg per 50 µL reaction mixture. The 607 bp and 208 bp PCR products were the predicted FAP-1 and GAPDH, respectively, separated by electrophoresis on 2% agarose gel and stained with colloidal gold. The target bands were analyzed by densitometry. FAP-1 cDNA was semi-quantitated by densitometric comparison with GAPDH from the same sample.

#### Immunofluorescence analysis for FAP-1

Approximately 10<sup>6</sup> cells were incubated with 10 g/mL rabbit anti-human FAP-1 polyclone antibody (Santa Cruz) for 30 min at 4°C and washed with PBS containing 2% FCS. PE-conjugated secondary goat anti-rabbit antibody (Boster, Wuhan, China) was added to the cells for 30 min at 4°C. The cells were washed again with PBS containing 2% FCS and then the intensity of fluorescence was analyzed. Isotype-matched control antibody was used to determine the nonspecific binding. A total of 10000 cells were examined for each determination. Data were expressed as relative fluorescence intensity (RFI = mean fluorescence intensity of cells stained with anti-FAP-1 pAb/mean fluorescence intensity of cells stained with control pAb).

#### Cell proliferation assay

Cell proliferation was evaluated by methyl thiazolyl tetrazolium (MTT) assay. SW480 cells were seeded into a 96-well plate at the concentration of 3000 cells per well. Oxaliplatin (Henrui Co, LTD, Jiangsu Province, China) was administrated at a concentration of 5 µg/mL 24 h after the cells were plated. The proliferation status of SW480 cells was observed at 24, 48, 72, and 96 h, respectively, after treatment with oxaliplatin. Each group was quadruplicates and its mean OD value was used to represent the proliferation status of the group. MTT (Merck) was dissolved in RPMI 1640 and prepared at 1 mg/L for use. The medium was removed, the cells were washed three times with PBS, and 100 µL MTT solution was added into each well and incubated in dark at 37°C. Then, the MTT solution was removed and 100 µL DMSO (Sigma) was added into each well to dissolve the remaining formazan by gently shaking the plate

**Figure 1** Expression of Fas-associated phosphatase 1 (FAP-1) mRNA (A) and protein (B) after oxaliplatin administration. Oxaliplatin promotes FAP-1 expression of SW480 cells at 0, 24, 48 and 72 h after chemotherapy. <sup>b</sup>*P* < 0.01 vs 0 h group.

for 15 min. Finally, a 495 absorption value of each well was obtained with a spectrophotometer (Labsystems Dragon).

#### Detection of apoptosis by flow cytometry

Anexin V-FITC kit (Bender Medsystems) and propidium iodide (PI) were used to calculate the cells undergoing apoptosis with a flow cytometer (FacsCalibur, Becton Dickinson). Anexin V (+) PI (-) represents apoptotic cells, whereas Anexin V (+) PI (+) represents dead cells. The procedure was carried out according to the manufacturer's instructions for the Anexin V-FITC kit.

#### Statistical analysis

All experiments were performed in triplicate. The results were expressed as mean ± SE. Statistical analysis was performed by one-way analysis of variance (ANOVA) and comparisons among groups were performed by Bonferroni's multiple-comparison *t*-test. *P* < 0.05 was considered statistically significant.

## RESULTS

#### Oxaliplatin promoted FAP-1 expression in SW480 cells

To investigate whether FAP-1 is resistant to chemotherapy for colon carcinoma with oxaliplatin, RT-PCR and flow cytometry were carried out to detect the FAP-1 expression in SW480 colon carcinoma cells at 0, 24, 48 and 72 h after chemotherapy for colon carcinoma with oxaliplatin. The FAP-1 expression was increased at both mRNA (Figure 1A) and protein levels (*P* < 0.01), and reached its peak at 48 h (Figure 1B).

#### siRNA silenced FAP-1 expression

siRNA was transfected into SW480 cells with a transfection agent, siPORT (AMBION). Three sequences of FAP-1 siRNA (1709, 6267 and 3264) were designed.

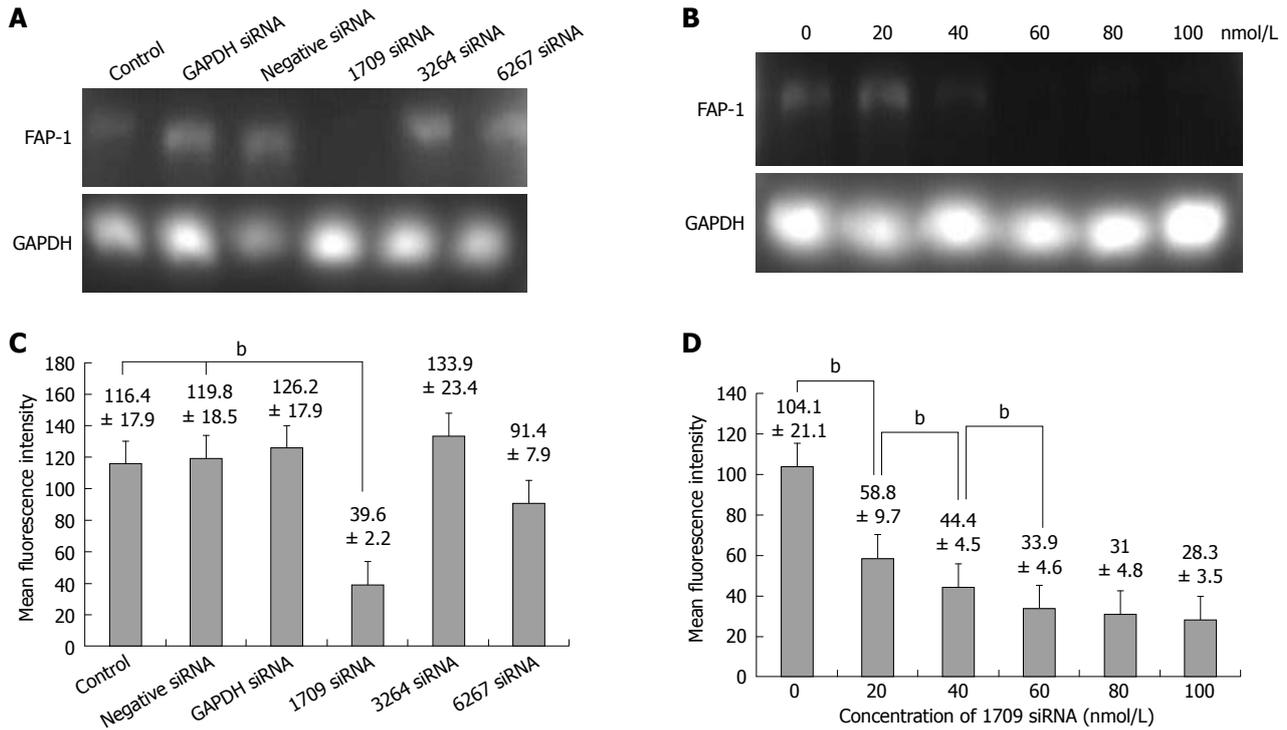

Figure 2 Small interfering RNA (siRNA) silencing FAP-1 expression in siRNA 1709 group (A and C) and at the concentration of 60 nmol/L (B and D). <sup>b</sup>*P* < 0.01 vs 0 h group.

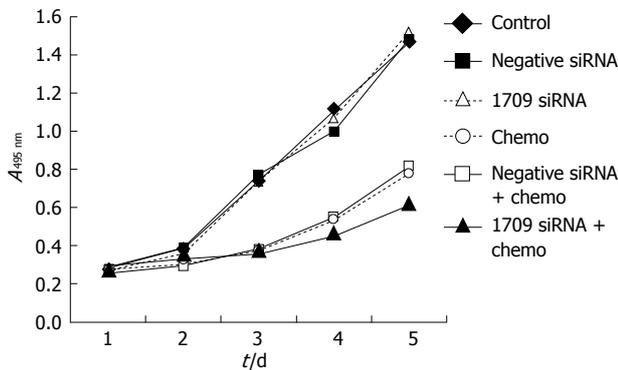

Figure 3 FAP-1 siRNA increasing the inhibitory effect of oxaliplatin on proliferation of SW480 cells.

Forty-eight hours after transfection of siRNAs into SW480 cells, the FAP-1 expression at mRNA and protein levels was detected by RT-PCR and flow cytometry. The FAP-1 protein was expressed in siRNA 1709 group (Figure 2A and C) and at the concentration of 60 nmol/L (Figure 2B and D), respectively (*P* < 0.01).

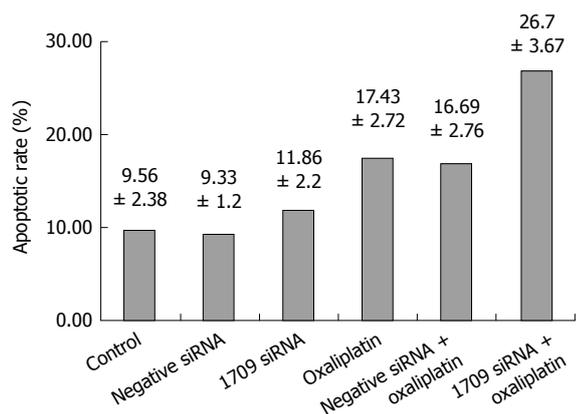

#### FAP-1 siRNA combined with oxaliplatin inhibited proliferation of SW480 cells

To investigate whether FAP-1 siRNA enhances the sensitivity of SW480 cells to oxaliplatin, cell proliferation was assayed in 6 groups including negative control group, negative siRNA group, siRNA 1709 group, oxaliplatin group, oxaliplatin+negative siRNA group, and oxaliplatin + siRNA 1709 group. Transfection was performed when

the cells were seeded. After 24 h, the culture medium was removed and washed three times with PBS and oxaliplatin dissolved in the culture medium (5 μg/mL) was added. The culture medium was replaced daily to keep the consistent concentration of oxaliplatin. Cell growth was observed daily for five days. Transfection of negative siRNA and siRNA into SW480 cells did not inhibit cell proliferation. Transfection of oxaliplatin combined with transfection of negative siRNA reduced cell proliferation. The greatest proliferation inhibition was found after treatment with oxaliplatin combined with transfection of siRNA 1709 (Figure 3).

#### FAP-1 siRNA combined with oxaliplatin increased apoptosis of SW480 cells

To investigate whether transfection of FAP-1 siRNA into SW480 cells combined with oxaliplatin increases apoptosis of colon carcinoma cells, the apoptotic rate of colon carcinoma cells was detected by flow cytometry and Anenxin V and PI immunofluorescence. Transfection was performed when the cells were seeded. After 24 h, the culture medium was removed and washed three times with PBS and oxaliplatin dissolved in culture medium at the concentration 5 μg/mL was added and the cells were harvested. The apoptotic rate of the negative control was 9.56% ± 2.38%, and similar in both siRNA transfection groups (*P* = 0.416). The apoptotic rate of oxaliplatin combined with siRNA 1709 transfection group was 26.7% ± 3.67%, which was higher than that of the oxaliplatin treatment group (*P* < 0.01, Figure 4), suggesting that oxaliplatin promotes FAP-1 expression in SW480 cells.

**Figure 4** FAP-1 siRNA enhancing the apoptosis inducing effect of oxaliplatin.

## DISCUSSION

Colon cancer represents a major public health problem, resulting in more than 1 million new cases diagnosed each year and approximately a half million deaths worldwide. Colectomy is the only procedure that may cure colon carcinoma, but the 5-year survival rate mainly depends on the stage of tumor at the time of diagnosis. The majority of patients with colon carcinoma are at an advanced stage beyond surgical treatment when they visit a doctor<sup>[1]</sup>. For patients who cannot be cured by surgery, chemotherapy is another important and complementary treatment<sup>[24]</sup>. Among the chemotherapeutic drugs, oxaliplatin is commonly used in treatment of colon carcinoma. However, its efficacy, especially in patients at advanced stage, is still limited<sup>[2]</sup>.

The main mechanism of action of oxaliplatin is mediated through the formation of DNA adducts<sup>[25-27]</sup>. When the platinum compound enters the cells, one chloride ligand is dissociated to form a reactive mono-aqua monochloro complex, which reacts rapidly with the guanines on DNA to form monoadducts. The subsequent dissociation of the second chloro ligand allows conversion of the transiently formed monoadducts to a variety of stable diadducts<sup>[28,29]</sup>. The majority are intrastrand diadducts binding to a guanine residue<sup>[30,31]</sup>. Since intrastrand adducts are the most abundant adducts and capable of blocking both DNA replication and transcription, they are considered the major cytotoxic lesions. As a final result, oxaliplatin induces primary and secondary DNA lesions leading to apoptosis of human cancer cells<sup>[32]</sup>.

It has been shown that DNA lesion repair mechanism, over-expression of copper transporters, and enhanced drug detoxification result in an increased chemo-resistance to oxaliplatin<sup>[33,34]</sup>. However, the mechanism may be more complicated. Some researchers hold that the major process leading to chemotherapy resistance is the ability of cancer cells to evade cell death signals<sup>[35]</sup>. In our study, the expression of FAP-1, a negative switch in Fas-mediated apoptosis, was elevated in SW480 colon cancer

cells after treatment with oxaliplatin. We quantified the transcription level only by densitometry rather than by RT-qPCR. The role of MMP7 (matrix metalloproteinase 7) and its cross-talk with the Fas/FasL system during the acquisition of chemo-resistance to oxaliplatin have been reported<sup>[36]</sup>. Raymond D<sup>[37]</sup> also showed that oxaliplatin can activate the Notch-1 signaling pathway in colon cancer cells and enhance its chemo-resistance to SW480 colon cancer cells, indicating that the functional disorder of the Fas apoptosis pathway mediated by FAP-1 elevation may protect SW480 cells against apoptosis and is involved in chemo-resistance effect.

In our study, since FAP-1 was elevated after treatment with oxaliplatin and might account for chemo-resistance, the FAP-1 expression was inhibited by RNA interference to make clear whether it sensitizes chemotherapy. The apoptotic rate of oxaliplatin combined with siRNA transfection was higher than that of oxaliplatin only. The greatest proliferation inhibition was found in the group of oxaliplatin combined with siRNA transfection, suggesting that the elevated FAP-1 expression is involved in the mechanism enabling SW480 cells to be insensitive to oxaliplatin treatment. Based on the fact that siRNA used to silence the expression of FAP-1 and treatment with oxaliplatin increased the apoptosis of SW480 cells and reduced their proliferation, we can develop a novel therapeutic measure to enhance the efficacy of chemotherapy. The similar phenomenon was also observed in other malignances. Etodolac, a selective cyclo-oxygenase-2, can enhance carboplatin-induced apoptosis of human tongue carcinoma cells by down-regulating FAP-1 expression<sup>[38]</sup> and sphingosine kinase isoforms can regulate oxaliplatin sensitivity to human colon cancer cells through ceramide accumulation and Akt activation<sup>[39]</sup>. Secretase inhibitors have been recently used to abrogate oxaliplatin-induced activation of the Notch-1 signaling pathway in colon cancer cells, which can enhance chemo-sensitivity<sup>[37]</sup>. In the present study, FAP-1 siRNA combined with oxaliplatin reduced the proliferation of colon carcinoma SW480 cells compared with oxaliplatin alone. No study is available so far on the Fas/FasL system and FAP-1 interacting to influence cell proliferation. We hold that the higher reduction of proliferation is due to the enhanced apoptotic rate of FAP-1 siRNA combined with oxaliplatin treatment, decreasing the number of cells.

Since the pathogenesis of colon carcinoma remains largely unclear, a variety of chemotherapies have been designed to inhibit tumor growth. So far, no single strategy can solve all the complicated problems in the treatment of colon carcinoma. Our study is an attempt to integrate gene therapy targeting FAP-1 and conventional chemotherapy for colon cancer.

In conclusion, oxaliplatin increases the expression of FAP-1. RNAi can knockdown FAP-1 and sensitize chemosensitivity, and RNA interference combined with conventional chemotherapy is more effective against colon cancer.

## COMMENTS

### Background

Colon cancer represents a major public health problem, resulting in more than one million new cases diagnosed each year and approximately a half million deaths worldwide. Chemotherapy is an important and complementary treatment modality for colon carcinoma. Among the chemotherapeutic drugs, oxaliplatin is a commonly used in treatment of colon carcinoma, but its efficacy, especially in patients at advanced stage, is still limited.

### Research frontiers

The mechanism underlying oxaliplatin chemo-resistance is complicated. DNA lesion repair mechanism, over-expression of copper transporters, and enhanced drug detoxification cannot fully explain its mechanism. In this study, Fas-associated phosphatase-1 (FAP-1) was elevated in colon carcinoma cells after oxaliplatin treatment, implicating that the functional disorder of the Fas apoptosis pathway mediated by FAP-1 elevation may protect colon carcinoma cells against apoptosis and is involved in the chemo-resistance effect. Chemotherapy can be sensitized by inhibiting FAP-1 expression with RNA interference.

### Innovations and breakthroughs

Since the pathogenesis of colon carcinoma remains largely unclear, a variety of chemotherapeutic treatment modalities available have been designed. So far, no single treatment modality can solve all the complicated problems. This study is an attempt to integrate gene therapy targeting FAP-1 and conventional chemotherapy for colon cancer.

### Applications

Oxaliplatin can increase the expression of FAP-1. RNAi can knockdown FAP-1 and sensitize chemosensitivity. This *in vitro* study showed RNA interference combined with conventional chemotherapy is more effective against colon cancer.

### Terminology

FAP-1 is a tyrosine phosphatase, which inhibits FasR-mediated apoptosis. By interacting with the cytoplasmic death domain of Fas receptors, FAP-1 acts as a negative switch in the Fas pathway. Transfection of FAP-1 into Fas-sensitive cells can block FasL-induced apoptosis.

### Peer review

This study investigated the important factors that inhibit the apoptotic effect of oxaliplatin on colorectal cancer cells, which is of significance in the treatment of colon carcinoma.

Malignant schwannoma of the pancreas involving transversal colon treated with *en-bloc* resection. *World J Gastroenterol* 2010; 16(1): 119-122 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i1/119.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i1.119>

### Abstract

Pancreatic schwannoma is a very uncommon tumor of the pancreas, with only 27 cases reported. Most pancreatic schwannomas are benign, with only four malignant tumors reported. We describe a case of giant malignant schwannoma of the pancreatic body and tail, which involved the transverse colon. The tumor was treated successfully with *en bloc* distal splenopancreatectomy and colon resection. This is believed to be the first reported radical operation for malignant schwannoma of the pancreatic body, with infiltration of the transverse colon, with excellent long-term results. The patient is alive and well 28 mo after the operation. The authors conclude that pancreatic schwannomas should be considered in the differential diagnosis of cystic neoplasms of the pancreas, although the diagnosis can only be confirmed by microscopic examination. In the case of the benign tumors, local excision is adequate, but in the case of malignant schwannoma, oncological standards must be fulfilled.

### INTRODUCTION

Mesenchymal tumors derived from Schwann cells that envelope the peripheral nerves (schwannoma/neurilemmoma) can be found throughout the body, with the most common localization in the extremities, trunk, head and neck, retroperitoneum, mediastinum and pelvis<sup>[1]</sup>. Visceral schwannomas, which arise from sympathetic and parasympathetic nerve fibers, are very rare<sup>[2]</sup>. Pancreatic schwannoma is notably uncommon, with only 27 cases reported in the English and Japanese literature to date<sup>[3-7]</sup>. Most pancreatic schwannomas are benign, with only four malignant tumors reported.

We describe a case of giant malignant schwannoma of the pancreatic body and tail, which involved the transverse colon. The tumor was treated successfully with *en bloc* distal splenopancreatectomy and colon resection.

### CASE REPORT

A 24-year-old woman was hospitalized because of unclear

abdominal symptoms, dyspepsia, weight loss and palpable tumor in the left hypochondrium. She had no anamnesis of pancreatitis or trauma, and there was no sign of von Recklinghausen's disease. The laboratory data (complete blood count, hepatic and pancreatic function tests) were within normal limits. Tumor marker levels also were within normal limits [carcinoembryonic antigen (CEA), 2.3 U/mL and carbohydrate antigen 19-9 (CA 19-9), 16.8 U/mL].

Ultrasonography of the abdomen revealed a well-demarcated, large, predominantly hyperechogenic mass, with hypoechogenic components in the body and tail of the pancreas, and compression of the posterior gastric wall. Computed tomography (CT) showed a well-circumscribed round hypodense mass (32 HU), 18 cm in diameter, which occupied the body and tail of the pancreas and displaced the splenic vein. There was suspect infiltration of the stomach and transverse colon (Figure 1).

Percutaneous needle aspiration was performed and a very small amount of the fluid was aspirated. Biochemical analysis showed normal amylase (48 U/L), CEA (1.9 ng/mL) and CA 19-9 (13 U/L) levels. Cytology revealed rare large cells with high nuclear-cytoplasmic ratios, prominent nucleoli, and cytoplasmic vacuoles, which were suggestive of malignancy. The cell block contained fragments of connective tissue and stroma with some spindle cells and hemosiderin-laden histiocytes.

We decided on operative treatment under the tentative diagnosis of a cystic neoplasm of the pancreas. Laparotomy revealed an encapsulated solid tumor in the pancreatic body and tail, which involved the transverse colon. There was no macroscopic regional lymphadenopathy. The patient underwent *en bloc* resection that consisted of hemipancreatectomy, splenectomy, omentectomy and transverse colon resection. Systematic lymphadenectomy was performed with removal of the 7, 9, 10 and 11 groups of lymph nodes, according to the Japanese Gastric Cancer Association Classification. Overall number of lymph nodes was 12, with micrometastases founded in two. The postoperative course was uneventful and the patient was discharged on postoperative day 11. No chemo or radiotherapy was added. She is free of symptoms 28 mo after surgery.

Surgical biopsies were fixed in 10% formaldehyde overnight, embedded in paraffin wax, and cut at a thickness of 4  $\mu$ m. The sections were stained with hematoxylin and eosin, Alcian blue/periodic acid-Schiff, van Gieson and immunohistochemical avidin biotin complex techniques, by using S-100 antibody for detection of schwannoma, and Ki 67 antibody to evaluate mitotic activity in tumor cells.

Microscopy showed that tumor cells infiltrated only the serosa of the transverse colon. The nuclei and cytoplasm of the spindle-shaped neoplastic cells were diffuse (Figure 2A) and strongly immunoreactive for S-100 protein (Figure 2B and C). Tumor cells showed increased proliferative activity, with numerous mitotic figures. In the hypercellular areas, we registered > 10 mitotic figures/

**Figure 1** Computed tomography (CT) of pancreatic schwannoma with involvement of the transverse colon.

high-power field. Intense nuclear staining for Ki67 (*MB1*) in the neoplastic cells was observed (Figure 2D). There was no cystic component or secondary elements of mature cartilage or bone.

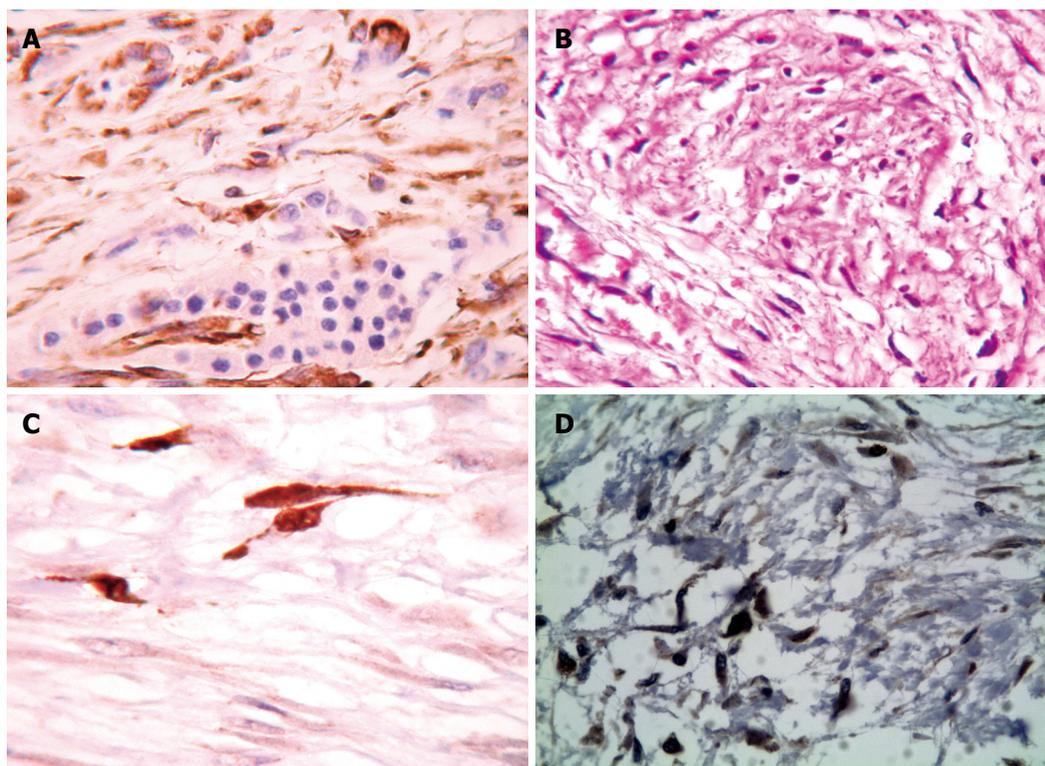

## DISCUSSION

Mesenchymal tumors derived from Schwann cells that envelope peripheral nerves (schwannoma/neurilemmoma) are uncommon. They can be found throughout the body, with the most common localization in the extremities, trunk, head and neck, retroperitoneum, mediastinum and pelvis<sup>[1]</sup>. Visceral schwannomas, which arise from sympathetic and parasympathetic nerve fibers are very rare<sup>[2]</sup>. Pancreatic schwannoma is notably uncommon, with only 27 cases reported in the English and Japanese literature to date<sup>[3-7]</sup>. The patients ranged in age from 41 to 87 years (mean 61 years), with a nearly equal sex distribution. The tumor size ranged from 1.5 to 20 cm (mean: 6.5 cm), with the pancreatic head involved in 44%, and the body and tail in 56% of cases<sup>[1]</sup>. Schwannomas usually occur as solitary lesions, but are occasionally multiple when associated with von Recklinghausen's disease<sup>[8]</sup>.

Although three cases of small solid pancreatic schwannomas have been reported<sup>[9-11]</sup>, typical presentation of schwannomas is in the form of cystic, thin-walled, and hemorrhagic masses<sup>[3]</sup>. In our case, we found a large, solid schwannoma with a well-defined capsule, along with infiltration of the transverse colon.

Typical microscopic features of schwannoma are two microscopic components: a highly ordered cellular component (Antoni A areas), and a loose myxoid component with degenerative changes (Antoni B areas)<sup>[12]</sup>. Tumor cells are invariably immunoreactive for S100 protein, vimentin and CD56, and negative for cytokeratin AE1/3, CD34, CD117 (c-kit), desmin, and smooth muscle myosin<sup>[13]</sup>.

A review of the literature has revealed only four cases of malignant schwannoma of the pancreas<sup>[2,12,14,15]</sup>. Malignant transformation of a benign schwannoma is extremely rare<sup>[8]</sup>. Also, malignant pancreatic schwannomas

**Figure 2** Microscopy of tumor cells infiltrating the serosa of the transverse colon. A: Schwannoma pattern of growth: Antoni B type. HE,  $\times 200$ ; B: Characteristic elongated cells with cytoplasmic processes in area with loose, myxoid background. Immunohistochemical ABC method,  $\times 400$ ; C: Pancreatic schwannoma with subtotal pancreatic tissue. Immunohistochemical ABC method,  $\times 400$ ; D: Intense nuclear staining for Ki67 (MIB1) in the neoplastic cells. Immunohistochemical ABC method,  $\times 400$ .

that were associated with von Recklinghausen's disease have been reported, but none of the benign pancreatic schwannomas were associated with von Recklinghausen's disease<sup>[2,15]</sup>.

Clinically, schwannoma is asymptomatic for a long time, or it is accompanied by nonspecific abdominal pain and discomfort. In the late clinical course, compression of the surrounding organs might be noticed.

To establish the diagnosis of pancreatic schwannoma, CT is the initial investigation of choice. CT findings usually show well-defined, round masses with multiple, low-attenuation, cystic necrotic areas. In tumors that are predominantly or exclusively composed of Antoni A areas (cellular component), CT shows inhomogeneous, hypodense, solid masses with contrast enhancement. When the tumor is predominantly composed of Antoni B areas (loose myxoid), CT shows homogeneous cystic masses without significant contrast enhancement<sup>[16]</sup>. On magnetic resonance imaging, schwannomas are present as masses of low signal intensity on T1-weighted images and of high signal intensity on T2-weighted images<sup>[17]</sup>.

Deep tumors tend to grow larger, therefore, they are more likely to show secondary degenerative changes such as cyst formation, calcification, hemorrhage, and hyalinization, and are known as ancient schwannomas<sup>[11]</sup>. As a result of these changes and the content of predominantly loose tissue, pancreatic schwannoma is often misdiagnosed as a pseudocyst or other cystic neoplasm of the pancreas.

Definitive preoperative diagnosis is proven using

fine-needle aspiration. However, this method correctly diagnoses only one in eight histologically proven schwannomas<sup>[18,19]</sup>. Definitive diagnosis requires histological examination and complex immunohistochemistry or ultrastructural examination<sup>[12]</sup>. For the definition of malignancy, which is often difficult in mesenchymal tumors, we use the following criteria: accentuated cell pleomorphism, high mitotic activity, rare stained necrosis, infiltration of the adjacent organs (colon), and locoregional lymph node micrometastases<sup>[2,12]</sup>.

The malignant transformation of pancreatic schwannoma is uncommon, therefore, simple enucleation of benign schwannoma is usually sufficient if the pathology is confirmed before surgery<sup>[4]</sup>.

In the case of the malignant schwannoma, oncological resection is indicated. A review of the literature has revealed one case of unresectable tumor of the pancreatic body, which was resolved by drainage<sup>[14]</sup>. In the case of pancreatic head localization, simple excision was performed in one case<sup>[2]</sup>, and radical (Whipple) operation was performed in two other cases. However, in the present literature, only short-term follow-up has been reported (maximum, 9 mo), with no data about maximum survival<sup>[12,15]</sup>.

As far as we are aware, this is the first report of radical surgery for malignant schwannoma of the pancreatic body, with infiltration of the transverse colon, with excellent long-term results. Our patient is alive and well 28 mo after the operation.

Radiotherapy has been shown to decrease tumor

growth and regression in neurogenic schwannoma, but there have been no previous reports of chemoradiation therapy<sup>[20]</sup>. However, the role of chemoradiation therapy in the management of pancreatic schwannoma has not been proven. Surgical excision with close follow-up and surveillance remain the mainstay of treatment<sup>[3]</sup>.

In conclusion, pancreatic schwannoma is very rare, but an important pathological condition. It should be considered in the differential diagnosis of cystic neoplasms of the pancreas, although the diagnosis can only be confirmed by microscopic examination. In the case of benign tumors, local excision is adequate, but in the case of malignant schwannoma, oncological standards must be fulfilled.

### Abstract

Variceal bleeding outside the esophagus and stomach is rare but important because of its difficult diagnosis and treatment. Bleeding from cholecystojejunostomy varices has been reported to be a late complication of palliative biliary surgery for chronic pancreatitis. Such ectopic variceal bleeding has never been reported after palliative surgery for pancreatic cancer, probably because of the limited lifespan of these patients. Herein, we report our successful experience using endoscopic cyanoacrylate sclerotherapy to treat bleeding from cholecystojejunostomy varices in a 57-year-old man with pancreatic head cancer. To our knowledge, this is the first case report in the literature of this rare complication.

### INTRODUCTION

Variceal bleeding outside the esophagus and stomach is rare but important because of its difficult diagnosis and treatment. These ectopic varices are usually associated with cirrhosis and, less often, may result from portal vein thrombosis, chronic pancreatitis, mesenteric venous thrombosis, or adhesion caused by prior surgery<sup>[1]</sup>. Bleeding from cholecystojejunostomy varices has been reported to be a late complication of palliative biliary surgery for chronic pancreatitis<sup>[1-4]</sup>. To our knowledge, such bleeding has never been reported after surgery for pancreatic cancer, probably because of the limited lifespan of such patients<sup>[1]</sup>. Herein, we report our successful experience using endoscopic cyanoacrylate sclerotherapy to treat bleeding from cholecystojejunostomy varices in a 57-year-old man with pancreatic head cancer.

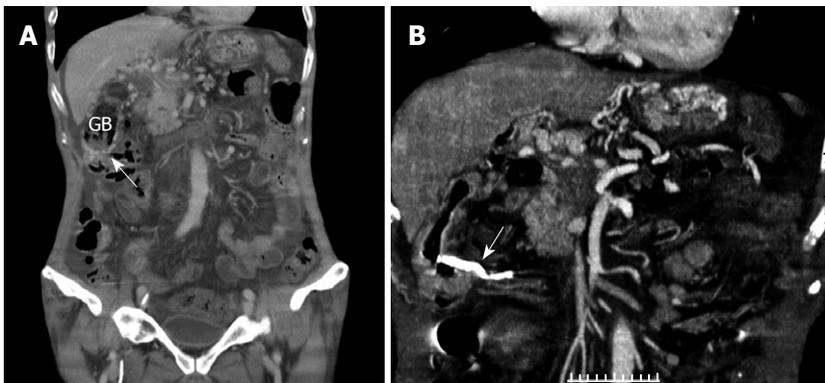

### CASE REPORT

A 57-year-old man was admitted to our hospital because of tarry stool passage. His surgical history included a Billroth-II operation for peptic ulcer 30 years ago and cholecystojejunostomy for biliary palliation due to pancreatic head cancer diagnosed 6 mo before this admission. The tumor progressed with portal vein invasion and multiple hepatic metastases during this period despite chemotherapy.

Hemoglobin count was 60 g/L on presentation and his coagulation profiles were within normal limits. An upper endoscopy disclosed no hemorrhagic lesion in

**Figure 1 Endoscopic view.** A: An anastomotic ulcer was observed in the cholecystojejunostomy; B: Anastomotic ulcer after argon plasma coagulation therapy; C: n-butyl-2-cyanoacrylate injection into the cholecystojejunostomy varices.

**Figure 2 Abdominal computed tomography.** A: Prominent vessels (arrow) formed around the gall bladder; B: Obliterated varicose vein (arrow).

the esophagus or stomach. The endoscope was then advanced to the cholecystojejunostomy area where shallow ulcers over the anastomosis were found (Figure 1A). The patient was administered intravenous proton pump inhibitor and blood component replacement therapy. The bleeding persisted and colonoscopy subsequently revealed a bleeding point above the terminal ileum. Therefore, a decision was made to perform local therapy for the anastomotic ulcer with argon plasma coagulation (Figure 1B).

The patient continued to bleed despite endoscopic therapy. abdominal computed tomography (CT) was performed, which revealed portal vein tumor invasion with collateral circulation formation. Prominent varices were found around the gall bladder and cholecystojejunostomy (Figure 2A). No tumor invasion to the bowel was noted. Retrospective review of the endoscopic images revealed that the folds were mildly engorged with mild blue color, which suggested underlying varices.

After discussion, the patient agreed to endoscopic therapy with n-butyl-2-cyanoacrylate for these varices on the 12th d of hospitalization. Endoscopic ultrasound with miniprobe was used to confirm the presence of varices beneath the anastomotic ulcer, and injection therapy with n-butyl-2-cyanoacrylate was carried out smoothly (Figure 1C). A follow-up CT revealed successful obliteration of the collateral circulation (Figure 2B). The patient died of his disease 4 mo later and had no recurrent gastrointestinal bleeding during the intervening period.

## DISCUSSION

Esophageal or gastric variceal bleeding is a common cause of severe gastrointestinal bleeding. Ectopic variceal bleeding from the duodenum<sup>[5-7]</sup>, jejunum<sup>[8]</sup>, ileum<sup>[9]</sup>, and colon<sup>[10,11]</sup> have been reported in the literature as a diagnostic and therapeutic challenge to clinicians. This ectopic variceal bleeding usually results from portal hypertension, portal vein thrombosis, mesenteric vein thrombosis, chronic pancreatitis, adhesion after surgery, or inflammatory bowel disease<sup>[1,12]</sup>. Our reported case, suffering from cholecystojejunostomy variceal bleeding, is even rarer and such bleeding has been reported to be associated only with chronic pancreatitis<sup>[1-4]</sup> in the literature. This is probably because these cancer patients have a limited lifespan, dying before such varices can develop<sup>[1]</sup>.

The diagnosis of ectopic varices is usually made after endoscopic examination: mesenteric venography<sup>[1,12]</sup>, abdominal ultrasound<sup>[13]</sup>, enteroclysis<sup>[3]</sup>, or CT<sup>[14]</sup>. In our case, the diagnosis was difficult to make during the initial endoscopic examination because the varicose vein was not prominent and was masked by an overlying anastomotic ulcer. A careful review of the CT and endoscopic images in this case suggested the presence of varices in the cholecystojejunostomy and led us to approach the case with different endoscopic measures. Consequently, we suggest that endoscopic ultrasound is mandatory, as in our case, to confirm the presence of varices prior to endoscopic therapy. Alternatively, needle aspiration or

injection of contrast may prove useful for diagnosis.

Unlike esophageal and gastric varices, the treatment options for ectopic varices have varied in the literature. Surgical resection<sup>[1]</sup> or radiological methods to decrease portal hypertension<sup>[15]</sup> have previously been reported. Both endoscopic band ligation<sup>[10]</sup> and sclerotherapy<sup>[15]</sup> have been successfully used to treat such ectopic varices. Endoscopic cyanoacrylate sclerotherapy was chosen in this patient with advanced cancer because it is minimally invasive and has previously been used to treat gastric varices endoscopically<sup>[16]</sup>. A follow-up CT demonstrated successful obliteration of the varices and thus, permanent hemostasis was achieved for our case.

In conclusion, we report a case of pancreatic cancer with bleeding from cholecystojejunal varices. The diagnosis was made by CT, endoscopy, and endoscopic ultrasound. Cyanoacrylate sclerotherapy was a successful method to achieve hemostasis in this case.

### Abstract

A 83-year-old woman was admitted to our hospital because of intermittent abdominal colicky pain and vomiting for 26 h. The pain localized over the periumbilical area with radiation along the medial side of the thigh. Computed tomography scan with three-dimensional reconstruction revealed a loop of small bowel protruding into the left obturator canal. Incarcerated obturator hernia was diagnosed and emergency laparotomy was arranged immediately. Unfortunately, her family refused surgery because of her worsening condition. On the third evening after admission, the patient developed peritonitis and sepsis. Perforation of small bowel due to the incarceration was noted during laparotomy. Bowel resection and an end-ileostomy were performed. She recovered well despite of the complication of multiple organ dysfunction syndrome. Literature is reviewed, and the pathogenesis, clinical manifestation, imaging features and treatment are discussed.

### INTRODUCTION

Obturator hernia is considered to be rare and accounts for 0.05%-0.4% of all hernias<sup>[1]</sup>. The first case of obturator hernia was published in 1724 by Arnaud De Ronsil. Throughout the centuries, obturator hernia has been considered as an uncommon but important cause of mechanical intestinal obstruction, which usually occurs in elderly, emaciated women. Although some characteristics relevant to obturator hernia have been introduced and various imaging modalities have been applied, it remains a diagnostic and therapeutic challenge for surgeons. Here we report a case with correct diagnosis but delayed operation that directly results in bowel perforation, septic shock and multiple organ dysfunction syndrome (MODS).

### CASE REPORT

A 83-year-old woman was admitted to our hospital because of intermittent abdominal colicky pain and vomiting for 26 h. The pain localized over the periumbilical area with radiation along the medial side of the thigh. The patient had had several episodes of similar syndrome during the past 13 mo, but it relieved spontaneously or by treatment with intravenous fluids and nasogastric suction. A

Figure 1 Ultrasonographic image of the left groin demonstrating a fluid-filled loop of bowel with the neck of the hernia uncertainly identified (arrow).

Figure 2 Plain abdominal film revealing multiple dilated loops of small bowel in an emaciated woman with scoliosis.

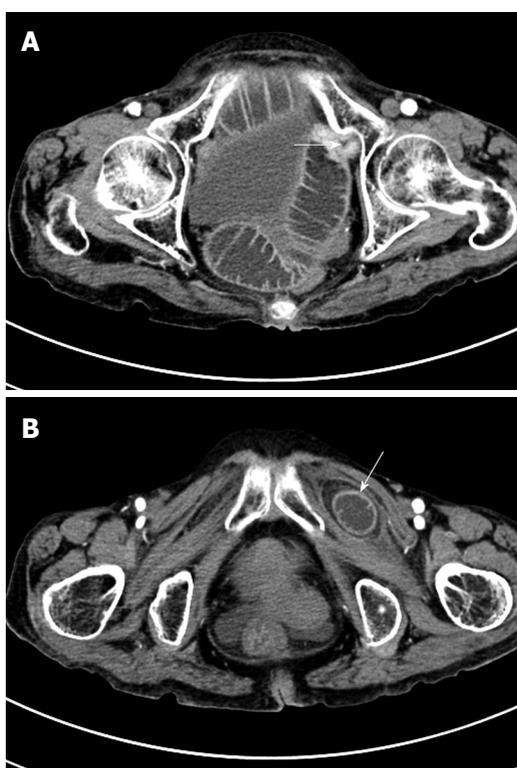

Figure 3 Abdominal axial CT image. A: Severe dilated small bowel and abrupt stenosis at the terminal ileum in the pelvic cavity (arrow); B: A low-density mass with clear border located between the pectineus and the left external obturator muscles (arrow).

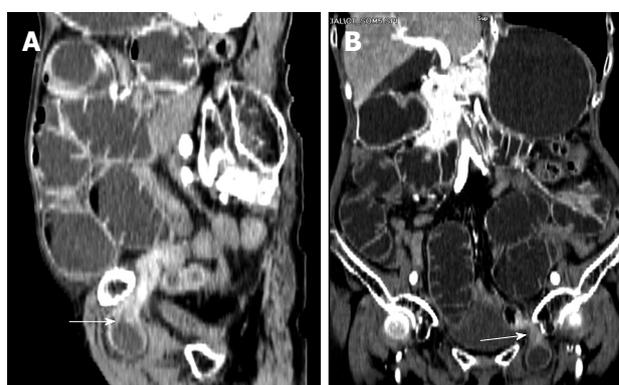

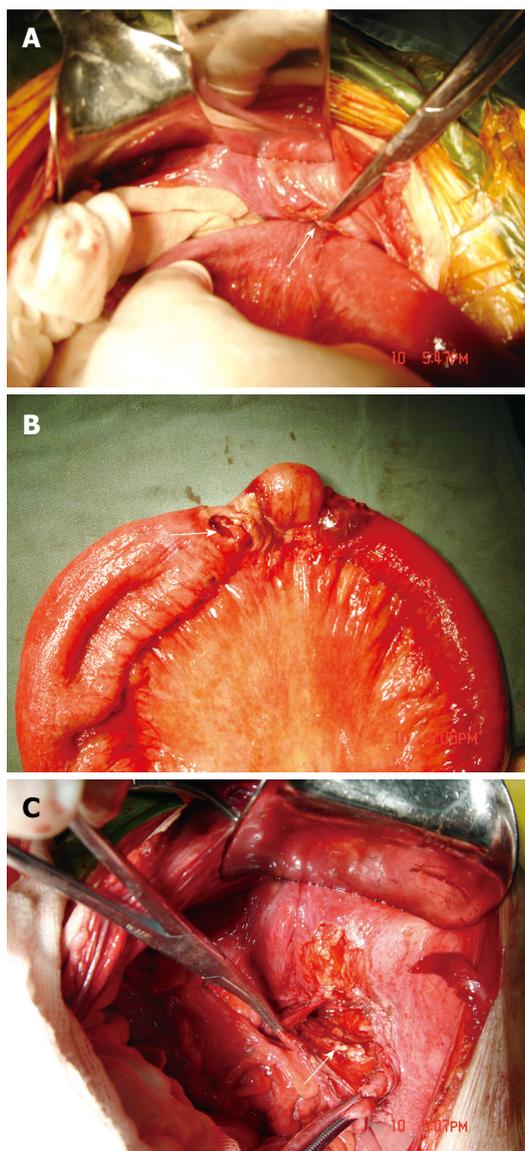

Figure 4 Three-dimensional reconstructed CT (A: Sagittal section; B: Coronal section) finding extensive dilation of the small bowel loops and a loop of small bowel protruding into the left obturator canal with the transition zone from dilated to collapsed bowel (arrows).

diagnosis of intestinal obstruction was made 7 mo prior to current admission. But the cause of disease was unclear. She had a similar attack 5 mo earlier, was suspected of having incarcerated hernia by ultrasonography. A loop of small bowel at the left groin region was noted (Figure 1). But subsequent investigations and treatment were refused after the relief of pain. She also had a history of chronic constipation, ischemic heart disease and chronic bronchitis. She had no previous abdominal surgery. On her arrival, the body temperature was 36.8°C, blood pressure was 105/75 mmHg, heart rate was 92 beats per minute. Her body mass index was 18 (body weight 39 kg, height 147 cm). Physical examination revealed an

emaciated lady with a soft but distended abdomen, visible bowel coils, mild tenderness over the lower abdomen, and hyperactive bowel sounds. No mass or rebound pain of the abdomen was noted. There was no palpable hernia in the groin. No abnormal signs were found on rectal and vaginal examinations. The Howship-Romberg sign, which characterized by pain or paresthesia in the hip with radiation down the medial thigh to the knee on the affected side, was positive. The white blood cell count was  $11.2 \times 10^9/L$  and other serum analyses were within normal limits. The initial plain abdominal radiography showed dilated loops of small bowel (Figure 2). Computed tomography (CT) scan demonstrated an abrupt stenosis at the terminal ileum in addition to the dilation of small bowel (Figure 3A). A low-density mass was also noted between the pectineus and the left external obturator muscles (Figure 3B). Three-dimensional reconstructed CT revealed a loop of small bowel protruding into the left obturator canal. The stenosis of the lumen and distended small bowel loops in the abdomen were well visualized (Figure 4). Incarcerated obturator hernia was diagnosed and emergency laparotomy was arranged immediately. Unfortunately, her family refused surgery because of her worsening condition, general weakness and the high risk involved. The patient was managed conservatively with

**Figure 5** Intraoperative photography illustrating. A: Incarcerated small bowel at left obturator foramen (arrow); B: Perforation of ileum proximal to the site of incarceration (arrow); C: A defect in the left obturator canal (arrow).

intravenous fluids and nasogastric suction. On the third evening after admission, her abdominal pain suddenly became worse and constant. Subsequently, she developed restlessness and more unbearable generalized abdominal pain. On examination, the body temperature was 37.7°C, the blood pressure was 75/55 mmHg, and the heart rate was 128 beats per minute. There were obvious signs of peritonism and bowel sounds were absent. The diagnosis of perforation of small bowel and septic shock was made. The patient underwent emergency surgery after explanation to her guardian. Laparotomy revealed a loop of the terminal ileum about 80 cm from the ileocecal valve, herniating into the left obturator canal (Figure 5A). Perforation of small bowel was noted proximal to the port of incarceration (Figure 5B). The peritoneal contamination was severe. In view of the patient's poor conditions, we resected the perforated ileal segment and performed an

end-ileostomy with closure of the distal loop. The defect at the hernia site was 1.5 cm in diameter and was closed with a few interrupted non-absorbable sutures (Figure 5C). The operating time was 75 min. Postoperatively, the patient was complicated with MODS and received subsequent treatment in intensive care unit. She recovered well and discharged 21 d after surgery. The second operation for re-established intestinal continuity was suggested 3 mo after operation. But the patient declined and now she is still uncertain about it. No recurrence of the hernia was noted during the 5 mo follow-up.

## DISCUSSION

An obturator hernia is a herniated viscera through the peritoneal defect that is bounded superiorly by the pubic ramus and inferiorly by the free edge of the obturator membrane<sup>[2]</sup>. The incidence was approximately nine times higher in women than in men due to the wider pelvis and relatively greater diameter of the obturator foramen in females<sup>[5]</sup>. Recent published series show nearly exclusive incidence in women<sup>[4-7]</sup>. It occurs most commonly in emaciated elderly women between 70 and 90 years of age. The loss of protective preperitoneal fat from aging or malnutrition makes a larger space in the obturator canal and facilitates the formation of a hernia<sup>[8,9]</sup>. Thus, it is not surprising that most of the patients are markedly underweight. The majority of obturator hernias occur on the right side probably because the sigmoid colon may cover the left obturator foramen and prevents herniation<sup>[10]</sup>. About 6% of cases are bilateral and some may be associated with other types of hernia, such as the indirect inguinal hernia, the direct inguinal hernia, or the femoral hernia<sup>[11]</sup>. It is uncertain if concomitant conditions that lead to constant and increased intra-abdominal pressure such as constipation, ascites, chronic obstructive pulmonary disease, kyphoscoliosis, or multiparity are risk factors for obturator hernia. Our case presented most of these predisposing factors, including old age, emaciation, constipation and chronic bronchitis.

There are three anatomic stages in the development of obturator hernia<sup>[8]</sup>. Stage one: preperitoneal connective tissue and fat enter the pelvic orifice of the obturator canal. Stage two begins with a peritoneal dimple through the canal and progresses to the formation of a peritoneal sac. Stage three is characterized by clinically significant symptoms produced by the entrance of an organ, usually the ileum, sometimes the omentum or part of the bladder, into the sac. Rarely, it was reported that ovary or Meckel's diverticulum can also be incarcerated<sup>[12,13]</sup>. Our case appeared obviously to be in the third stage of development at the time of admission because of the presence of intestinal obstruction.

The most common presentation of obturator hernia is mechanical small bowel obstruction caused by incarceration of the bowel into the obturator canal. The symptoms may be acute or intermittent if the hernia content reduces into the peritoneal cavity spontaneously.

In some cases, the initial symptoms are mild nausea, vomiting and anorexia, probably due to incomplete herniation or Richter's type. Obturator neuralgia is also an important complaint that extends from the inguinal crease to the anteromedial aspect of the thigh. The Howship-Romberg sign is reported to be present in nearly 50% of cases which refers to pain along the medial thigh and sometimes in the hip caused by compression of the obturator nerve by the hernia sac<sup>[10,12]</sup>. Flexion of the thigh usually relieves the pain. Extension, abduction, or medial rotation of the hip may exacerbate the pain. The clinical diagnosis is often difficult to make when this sign is absent. However, the Howship-Romberg sign was generally masked by the severe abdominal symptoms, and it was always neglected before operation. Another possible sign on presentation is the Hannington-Kiff sign<sup>[14]</sup>. It is characterized by an absent adductor reflex in the thigh, resulting from obturator nerve compression. The obturator canal is easily identified by digital vaginal examination at either 2 o'clock or 10 o'clock position. Palpation of a tender mass in the obturator region is of great value in obtaining the correct diagnosis. However, it is evident in only a few cases because the incarcerated mass is usually small and deeply situated.

Various imaging modalities have been applied to establish accurate preoperative diagnosis of this rare disease, including plain abdominal radiography, herniography, ultrasonography, CT, and gastrointestinal imaging with contrast medium. Plain radiography provides no specific findings apart from a dilated bowel loop, and can not reveal any significant information as to the cause of intestinal obstruction<sup>[15]</sup>. It is almost unuseful in diagnosing obturator hernia. Herniography can directly demonstrate the hernial sac, but has no place in the emergency diagnosis of obturator hernia and is used only in elective cases. Ultrasonography has been considered as a reliable modality with the presence of a hypoechoic tubular structure or a cystic lesion in the region of obturator canal. However, it is not easily identified due to the deep location within the pelvic musculature and smaller hernia sac<sup>[11]</sup>. In 1983, CT was first reported to be useful for detecting obturator hernia by Cubillo, and now is regarded as the standard diagnostic modality for obturator hernia with a documented accuracy of 80%<sup>[10,16]</sup>. CT images may demonstrate an air-filled or fluid-filled bowel loop in the region of the obturator foramen. In a study of a series of patients, Kammori *et al.*<sup>[10]</sup> reported that 15 of 16 patients who were confirmed to have obturator hernia were diagnosed by CT alone. With the advent of multi-slice helical CT scan and the three-dimensional reconstruction technique, the accurate images are of great help in identifying obturator hernia and understanding the relationship between obturator canal and small bowel, as was seen in our study. In our case, the history taking, clinical manifestation and Howship-Romberg sign only gave the suspicion of obturator hernia. The definitive diagnosis was made by CT images.

There is a general agreement that obturator hernia

must be treated surgically. A variety of operative approaches to obturator hernias have been described including retropubic approach, obturator approach, inguinal extraperitoneal approach, transperitoneal approach and combined approach with either a laparotomy or laparoscopy<sup>[3,17-19]</sup>. However, because of the rarity of this condition, there is no consensus on the most proper approach. In patients with an established preoperative diagnosis, an extraperitoneal approach is the best surgical procedure. However, a transperitoneal approach will be necessary in those patients with intestinal obstruction of uncertain cause. We prefer transperitoneal approach because it can obtain adequate exposure, avoid vessel damage, facilitate the reduction of the incarcerated bowel, identify and allow resection of the strangulated bowel when necessary, and easy repair of the defect as well. It should be emphasized that careful dissection of the hernia sac is essential to avoid injury of the obturator nerve or vessels, and the contralateral side must be routinely explored because of the chance of underlying hernia<sup>[18]</sup>. Recently, with the advantage of minimal invasion, laparoscopic technique has been applied in management of obturator hernia. This minimally-invasive method may provide some benefits for these high-risk patients, such as less postoperative pain, fewer complications, earlier ambulatory and shorter hospital stay<sup>[17]</sup>. However, experience with laparoscopy is largely based on isolated case report. The laparoscopic operation for obturator hernia is infeasible in an emergency and is still limited to be performed widely due to the technical problems<sup>[20]</sup>. As in other hernias, after reduction of the contents, the defect of obturator canal should be repaired. Methods of repair vary from a simple suture or using autogenous adjacent tissue like broad ligament, ovary or uterus to permanent prosthetic mesh<sup>[21,22]</sup>. But the use of mesh is not advised in the presence of peritonitis or bowel resection because of the potential risk of infection.

Early surgical intervention is essential to the appropriate treatment of obturator hernia. However, surgeons are often reluctant to operate and family members always hesitate in proceeding with clinical management because of the age, the concomitant disease and the general condition of the patient. Conservative medical treatments were attempted in hopes that the obstruction would be reduced, which undoubtedly result in delayed surgical intervention and increased the morbidity and mortality rates. In our study, the duration from onset of symptoms to surgery was 3.7 d. Here we felt deeply regret that the delayed operation led to the gut resection with ileostomy and severe complications. Fortunately, the patient recovered well.

In conclusion, obturator hernia is relatively rare and is a significant cause of intestinal obstruction, particularly in emaciated elderly women without a history of abdominal surgery. It is important that physicians consider obturator hernia in mind when making a diagnosis in patients with small bowel obstruction. For the diagnosis of obturator hernia, the intermittent attacks of intestinal obstruction,

a positive Howship-Romberg sign, a palpable tender mass in the groin area by digital vaginal examination are helpful. Abdominal CT is useful for viewing a loop of small bowel herniated into the obturator canal. The point of early surgical intervention is highlighted because it is the only hope to lower the high morbidity and mortality associated with this condition.

### Abstract

Biliary cystadenocarcinoma is a very rare malignant cystic tumor of the liver, which is often misdiagnosed due to a poor recognition of it. We report a case of a 60-year-old man with biliary cystadenocarcinoma with his real time contrast enhanced ultrasound (CEUS) characteristics compared to those of computed tomography (CT) and magnetic resonance imaging (MRI), which were correlated with the surgical and pathologic findings. Cystic wall enhancement, internal septations and intra-cystic solid portions in the arterial phase were observed on CEUS after contrast agent injection. The enhancement was washed out progressively and depicted as hypo-enhancement in the portal and late phases. CT revealed a large irregular cystic lesion in the left liver lobe with no clear septations and solid components. MRI showed an irregular cystic occupying lesion with septations.

### INTRODUCTION

Biliary cystadenocarcinoma is a very rare malignant cystic tumor of the liver. It is often misdiagnosed because of an insufficient recognition of it<sup>[1,2]</sup> and is hard to differentiate it from benign cystic lesions, such as simple cysts, hydatid cysts and its benign counterpart, cystadenoma. Although these cystic lesions of the liver are more frequently discovered because of the advances in abdominal imaging over the past several years, they are often incorrectly diagnosed, resulting in inadequate therapy<sup>[1-5]</sup>. In recent years, real time contrast-enhanced ultrasonography (CEUS) has gained substantial attention in liver imaging, and its role in differentiating benign from malignant focal liver lesions has been well established. The enhancement characteristics of common benign and malignant focal liver lesions on CEUS have been well described and analyzed, some of which are considered criteria for the differential diagnosis of focal liver lesions<sup>[6-8]</sup>. However, to

the best of our knowledge, no reports are available on the enhancement characteristics of biliary cystadenocarcinoma on real time CEUS, or on comparison between CEUS, computed tomography (CT) and magnetic resonance imaging (MRI) findings. We report a case of a 60-year-old man with a surgically proven biliary cystadenocarcinoma with its CEUS, CT, MRI and histopathologic findings compared.

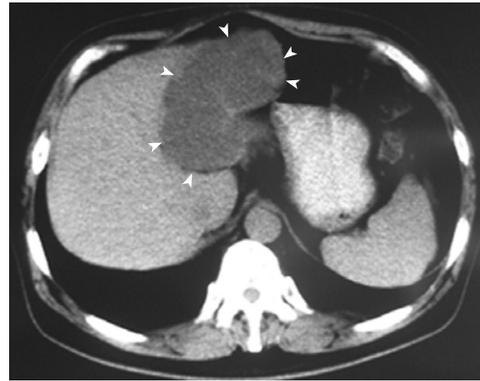

## CASE REPORT

A 60-year-old man was admitted to a local hospital due to an intermittent abdominal pain for 9 d, which was especially severe in the epigastrium. Physical examination revealed a palpable upper abdominal mass with tenderness in the epigastrium. Except for a 5-year history of diabetes mellitus, laboratory test showed normal carcinoembryonic antigen (CEA), alpha-fetoprotein (AFP), hepatitis B surface antigen (HBsAg), and anti-hepatitis B surface antigens (anti-HBs), but an elevated serum CA19-9 level of 1090 U/mL.

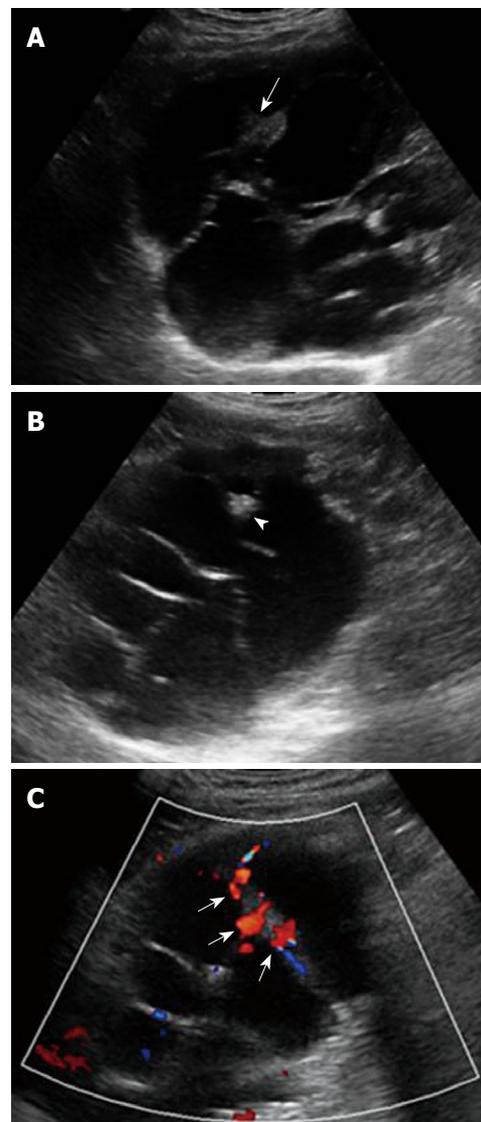

CT scan performed in the local hospital revealed a large irregular cystic lesion in the left liver lobe with no clear septations and solid components (Figure 1). After admitted to our hospital, two-dimensional ultrasonography and CEUS were performed with Philips iU22 (Philips Medical Systems, Bothell, WA) using a 1.0-5.0 MHz probe C5-1 transducer with a pure wave crystal technology to obtain B-mode and color Doppler images. The acoustic power output was adjusted to a low mechanical index of approximately 0.04 for CEUS.

B-mode ultrasonography showed a 12.5 cm × 10.6 cm × 8.2 cm anechoic cystic mass with a well-defined thick wall, mural nodules, and multiple internal septa (Figure 2A), as well as multiple thick and coarse mural and septal calcifications or stones within the septated cysts (Figure 2B). Color Doppler image demonstrated affluent blood flow in the internal septa (Figure 2C). After a conventional sonographic examination to depict the size, location, echogenicity, and internal color Doppler flow signals of the mass, pulse inversion harmonic imaging mode was initiated to examine the real-time CEUS using a sulfur hexafluoride microbubble contrast agent (SonoVue; Bracco SpA, Milan, Italy). A contrast agent (2.4 mL) was administered intravenously in a bolus fashion *via* an antecubital vein, followed by a flush of 5 mL normal saline solution. CEUS displayed hyper-enhancement of the cystic wall, internal septations and intra-cystic solid portions in the arterial phase at 18 s after contrast agent injection. The intensity reached its peak at 31 s and the enhancement was washed out progressively and depicted as hypo-enhancement in the portal and late phases (Figure 3). MRI showed an irregular cystic occupying lesion with separations (Figure 4).

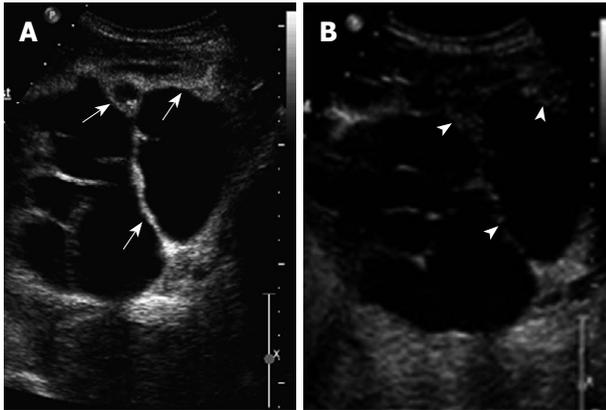

Finally, hepatic lobectomy was performed during which a large cystic mass was found with mucinous fluid present in some portions of the lesion. The mass was finally diagnosed as a biliary cystadenocarcinoma based on the pathological findings which confirmed the thick and coarse calcifications and stones on ultrasonography (Figure 5).

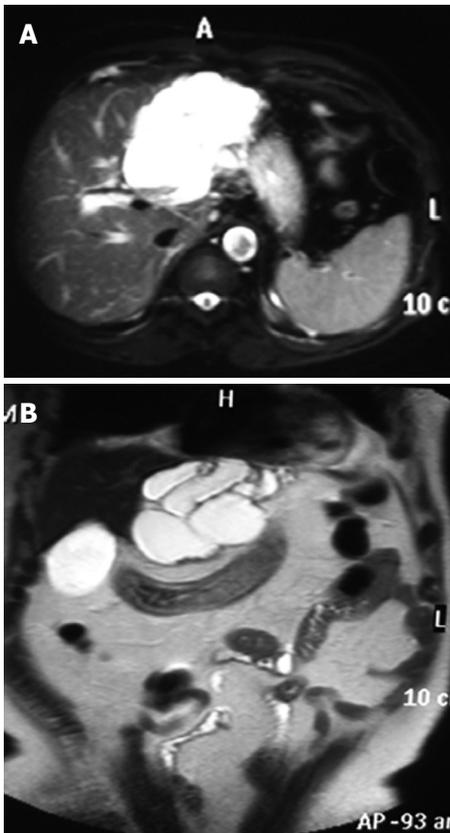

**Figure 1 Biliary cystadenocarcinoma.** Computed tomography shows a huge cystic tumor (arrowheads) in the left liver lobe, with no clear septations and solid components.

**Figure 2 Biliary cystadenocarcinoma.** A: Conventional sonography shows a multilocular cystic lesion in left lobe of the liver with nodular thickening of internal septa and mural nodules projecting into the cyst (arrow); B: Conventional sonography shows septal calcifications or stones (arrowhead); C: Color doppler flow imaging (CDFI) shows affluent vascularity in the internal septa (arrows).

## DISCUSSION

Biliary cystadenocarcinoma is a very rare malignant cystic tumor of the liver with an incidence of 0.41%<sup>[1]</sup>. Since it was first reported in 1943<sup>[9]</sup>, only a few cases of biliary cystadenocarcinoma have been reported in the literature<sup>[2,9]</sup>. Most biliary cystadenocarcinomas are primary malignant tumors originating from the intra-hepatic bile duct or from congenital intra-hepatic biliary

**Figure 5 Biliary cystadenocarcinoma.** A: Gross appearance of a cross-section of the formalin fixed specimen showing a multilocular mucinous cyst; B: Microscopically, tumor tissues showing moderately differentiated adenocarcinoma with a papillary growth pattern (HE, original magnification  $\times 100$ ).

malformation, or from benign cystadenoma<sup>[10-12]</sup>, or from very slowly growing bile ducts<sup>[2]</sup>.

Symptoms of biliary cystadenocarcinoma include abdominal pain, infection, dyspepsia, anorexia, nausea, vomiting, and occasionally, jaundice due to ductal compression. Most biliary cystadenocarcinoma patients are symptomatic with palpable upper abdominal masses<sup>[2]</sup>. Abdominal pain and a palpable upper abdominal mass were noted in our case with no jaundice. Because of insufficient knowledge about the biliary cystadenocarcinoma and its indistinctive clinical presentations, it is often misdiagnosed as a hepatic abscess, or a hydatid cyst, or a metastatic tumor with cystic degeneration, or even a simple cyst. It is most difficult to differentiate biliary cystadenocarcinoma from cystadenoma, due to their very similar clinical presentations and imaging features. Cystadenoma occurs predominately in women while 38%-44% of biliary cystadenocarcinomas occur in men<sup>[13-15]</sup>. Choi *et al*<sup>[16]</sup> reported that involvement of the left liver lobe is much more common. The majority of biliary cystadenocarcinomas are large in size, usually exceeding 10 cm in diameter, ranging 3.5-25 cm<sup>[16,17]</sup>. In our case, the lesion was found in the left liver lobe with a diameter of 12.5 cm.

Preoperative imaging studies are of key importance in differential diagnosis. The characteristic CT finding in these tumors is low-density intra-hepatic lesions with internal septa and mural nodules. Contrast enhancement can be seen along the internal septa and wall<sup>[2,3,5,17]</sup>. In our case, however, CT scan only revealed a large irregular

cystic lesion in the left liver lobe with no clear septations and solid components, while sonography showed internal septa and affluent blood signals. It was reported that CT scan fails to show any definite or probable septa while sonography reveals internal septa in the same cases. Because contrast enhanced CT was not performed for our case, CT enhancement characteristics of biliary cystadenocarcinoma could not be observed, suggesting that sonography is somewhat more sensitive than CT in detecting the septa of a cystic lesion<sup>[5,16]</sup> and is thus superior to CT in displaying the morphology of cystic hepatic lesions.

Although MRI can show small differences in tissue and provide further information concerning the nature of fluid in the cyst, and is therefore extraordinarily helpful in characterizing hepatic lesions. In our case, MRI showed an irregular cystic occupying lesion with separations. However, biliary cystadenocarcinoma could not be diagnosed in our hospital due to an insufficient recognition of it. In order to understand its enhancing characteristics and make a correct diagnosis, CEUS was performed with Philips iU22, which showed hyper-enhancement of the cystic wall with internal septations and intra-cystic solid portions in the arterial phase and reached its peak intensity in late arterial phase. However, the enhancement was washed out progressively and depicted as hypo-enhancement in the portal and late phases. An initial diagnosis of biliary adenocarcinoma was made by comparing the results in our study with published enhanced CT characteristics, which was confirmed at surgery. The hyper-enhancement in arterial phase and the hypo-enhancement in portal or late phase on CEUS in this case may indicate the malignant nature of the lesion. However, Xu *et al.*<sup>[18]</sup> have reported the hyper-enhancement of the cystic wall, internal septations, and intra-cystic solid portion in the arterial phase in 1 case with benign intrahepatic biliary cystadenoma on CEUS. The enhancement was washed out progressively and depicted as hypo-enhancement in the portal and late phases, suggesting that inadequate differences in enhancement characteristics can differentiate benign intrahepatic biliary cystadenoma from cystadenocarcinoma.

In addition to the features mentioned above, Li *et al.*<sup>[19]</sup> and Koffron *et al.*<sup>[20]</sup> have reported increased levels of CA125 and CA19-9. The CA19-9 level was also elevated in our case. Macroscopy can discover large monolocular or multilocular cystic lesions with mural nodules projecting into the cyst in most cases. Most of the cysts are filled with a great deal of clear, yellow mucous like fluid. The cystic fluid can be coffee-colored when complicated by intra-cystic hemorrhage and bile-like if the cyst communicates with intra-hepatic bile ducts<sup>[21]</sup>. Microscopy can display moderately-differentiated adenocarcinoma with a papillary growth pattern. The papillary structure is lined by monolayer columnar or pseudo-stratified epithelial cells. The tumor cells are characterized by loss of polarity, karyomegaly, and allotypic and pathologic mitotic figures. Although percutaneous liver biopsy contributes to a definite diagnosis, it is risky to induce

peritoneal implantation metastasis<sup>[22]</sup>.

Biliary cystadenocarcinoma should be suspected when CT or ultrasonography reveals an elevated mass or nodule in cystic wall or in folding. However, it is extremely difficult to differentiate cystadenoma from adenocarcinoma by imaging alone. In our case, benign hepatic cyst was considered at admission. It has been reported that tumor markers, carcinoembryonic antigen and carbohydrate antigen 19-9 are increased in serum or cystic fluid of biliary cystic tumor<sup>[23-25]</sup>. However, tumor markers cannot distinguish cystadenocarcinoma from cystadenoma or both from other cystic lesions of the liver. The increased level of serum CA125 and CA19-9 contributes to the differentiation of benign from malignant tumors and is a useful index for the prognosis of biliary cystadenocarcinoma patients<sup>[23-25]</sup>.

In conclusion, biliary cystadenocarcinoma is asymptomatic. When patients have a large cystic lesion in the liver, especially accompanying elevated serum CA125 and CA19-9 levels, a diagnosis of biliary adenocarcinoma can be established. Its definitive diagnosis is difficult to be made based on ultrasonography, CT and MRI findings. CEUS is useful in depicting the enhancing characteristics of cystic wall, internal septations and intra-cystic solid portions of biliary cystadenocarcinoma but cannot give a definite diagnosis. Further study is needed.

times a day, was compared to 2400 mg given once a day. Under ideal conditions, the predicted maximum drug in the total colon and individual colonic segments over 100 d differed by less than 3% between single and multiple doses. Despite changes in motility and defecation rates, the predicted maximum and average 5-ASA concentrations in the total colon and individual colonic segments differed by less than 10% between dosing regimens. Asymmetric distribution of 5-ASA in the colon was influenced by frequency of bowel movements and colonic transit rate. In active colitis, sigmoid 5-ASA concentration becomes negligible. Our model supports once daily administration of Asacol as standard treatment for ulcerative colitis.

A dynamic model of once-daily 5-aminosalicylic acid predicts clinical efficacy. *World J Gastroenterol* 2010; 16(1): 136-137 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i1/136.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i1.136>

### Abstract

New once daily mesalamine formulations may improve adherence to medication usage. Response to Asacol and other forms of 5-aminosalicylic acid (5-ASA) is better correlated with tissue concentrations and best predicted by concentrations of the drug within the lumen of the colon. Our group used computer simulation to predict colonic 5-ASA levels after Asacol administration. In our study, the model simulated Asacol distribution in the healthy colon, and during quiescent and active ulcerative colitis. An Asacol dosage of 800 mg, three

### TO THE EDITOR

We read with a great interest the editorial by Lakatos<sup>[1]</sup> that summarizes the available literature on the short and medium term efficacy and safety of the new once-daily mesalazine formulations. Single dose regimens may improve adherence to medication usage. However, older forms of 5-aminosalicylic acid (5-ASA) may also be administered in a single daily dosage, apparently with adequate effects<sup>[2]</sup>. Most pharmacokinetic studies on

Asacol and other forms of 5-ASA are limited to data collected from serum, urine or fecal drug concentrations. However, response is better correlated with tissue than with plasma concentrations, and is best predicted by concentrations of the drug within the lumen of the colon<sup>[3,4]</sup>. A number of factors influence the concentrations of drugs in colon, such as 5-ASA. Our group<sup>[5]</sup> created a computer model to predict 5-ASA levels in colon after Asacol administration using STELLA software (Isee Systems, Inc., Lebanon NH, USA). This model divides the intestinal system into individual compartments-upper GI tract, right colon, transverse colon, descending colon and the recto-sigmoid colon, and predicts the movement of 5-ASA from one compartment to the other. Retrospective data for drug concentrations based on serum levels have been utilized<sup>[6,7]</sup>. In addition to local transfer of the drug, each colonic compartment loses a fraction of its drug concentration due to mass movements with defecation<sup>[8]</sup>. In our study, the model was run to simulate Asacol distribution in a healthy colon, and during quiescent and active ulcerative colitis. To achieve this, simulations were performed with increasing defecation rates up to 12 bowel movements daily along with variation of upper GI and colonic motility. One hundred 24 h cycles were studied. An Asacol dosage of 800 mg, three times a day, was compared to 2400 mg given once a day. Under ideal conditions, the predicted maximum drug in the total colon and individual colonic segments over 100 d differed by less than 3% between single and multiple doses. Despite changes in motility and defecation rates, the predicted maximum and average 5-ASA concentrations in the total colon and individual colonic segments differed by less than 10% between dosing regimens. The model could also predict almost no drug within the lumen of the recto-sigmoid colon during severe disease activities<sup>[5]</sup>.

Our model supports the once daily administration of Asacol, a concept catching on with new clinical trials.

Asymmetric distribution of 5-ASA in the colon is influenced by frequency of bowel movements and the rate of colonic transit is an important factor in determining 5-ASA dosing in active ulcerative colitis.

## Meetings

### Events Calendar 2010

January 25-26  
 Tamilnadu, India  
 International Conference on Medical Negligence and Litigation in Medical Practice

January 25-29  
 Waikoloa, HI, United States  
 Selected Topics in Internal Medicine

January 26-27  
 Dubai, United Arab Emirates  
 2nd Middle East Gastroenterology Conference

January 28-30  
 Hong Kong, China  
 The 1st International Congress on Abdominal Obesity

February 11-13  
 Fort Lauderdale, FL, United States  
 21th Annual International Colorectal Disease Symposium

February 26-28  
 Carolina, United States  
 First Symposium of GI Oncology at The Caribbean

March 04-06  
 Bethesda, MD, United States  
 8th International Symposium on Targeted Anticancer Therapies

March 05-07  
 Peshawar, Pakistan  
 26th Pakistan Society of Gastroenterology & Endoscopy Meeting

March 09-12  
 Brussels, Belgium  
 30th International Symposium on Intensive Care and Emergency Medicine

March 12-14  
 Bhubaneswar, India  
 18th Annual Meeting of Indian National Association for Study of the Liver

March 23-26  
 Cairo, Egypt  
 14th Pan Arab Conference on Diabetes PACD14

March 25-28  
 Beijing, China  
 The 20th Conference of the Asian

Pacific Association for the Study of the Liver

March 27-28  
 San Diego, California, United States  
 25th Annual New Treatments in Chronic Liver Disease

April 07-09  
 Dubai, United Arab Emirates  
 The 6th Emirates Gastroenterology and Hepatology Conference, EGHC 2010

April 14-17  
 Landover, Maryland, United States  
 12th World Congress of Endoscopic Surgery

April 14-18  
 Vienna, Austria  
 The International Liver Congress™ 2010

April 28-May 01  
 Dubrovnik, Croatia  
 3rd Central European Congress of surgery and the 5th Croatian Congress of Surgery

May 01-05  
 New Orleans, LA, United States  
 Digestive Disease Week Annual Meeting

May 06-08  
 Munich, Germany  
 The Power of Programming: International Conference on Developmental Origins of Health and Disease

May 15-19  
 Minneapolis, MN, United States  
 American Society of Colon and Rectal Surgeons Annual Meeting

June 04-06  
 Chicago, IL, United States  
 American Society of Clinical Oncologists Annual Meeting

June 09-12  
 Singapore, Singapore  
 13th International Conference on Emergency Medicine

June 14  
 Kosice, Slovakia  
 Gastro-intestinal Models in the Research of Probiotics and Prebiotics-Scientific Symposium

June 16-19  
 Hong Kong, China  
 ILTS: International Liver Transplantation Society ILTS Annual International Congress

June 20-23  
 Mannheim, Germany  
 16th World Congress for Bronchoesophagology-WCBE

June 25-29  
 Orlando, FL, United States  
 70th ADA Diabetes Scientific Sessions

August 28-31  
 Boston, Massachusetts, United States  
 10th OESO World Congress on Diseases of the Oesophagus 2010

September 10-12  
 Montreal, Canada  
 International Liver Association's Fourth Annual Conference

September 11-12  
 La Jolla, CA, United States  
 New Advances in Inflammatory Bowel Disease

September 12-15  
 Boston, MA, United States  
 ICAAC: Interscience Conference on Antimicrobial Agents and Chemotherapy Annual Meeting

September 16-18  
 Prague, Czech Republic  
 Prague Hepatology Meeting 2010

September 23-26  
 Prague, Czech Republic  
 The 1st World Congress on Controversies in Gastroenterology & Liver Diseases

October 07-09  
 Belgrade, Serbia  
 The 7th Biannual International Symposium of Society of Coloproctology

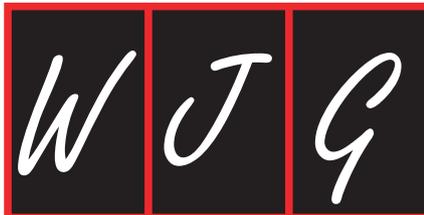

October 15-20  
 San Antonio, TX, United States  
 ACG 2010: American College of Gastroenterology Annual Scientific Meeting

October 23-27  
 Barcelona, Spain  
 18th United European Gastroenterology Week

October 29-November 02  
 Boston, Massachusetts, United States  
 The Liver Meeting® 2010--AASLD's 61st Annual Meeting

November 13-14  
 San Francisco, CA, United States  
 Case-Based Approach to the Management of Inflammatory Bowel Disease

December 02-04  
 San Francisco, CA, United States  
 The Medical Management of HIV/AIDS

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Beijing Baishideng BioMed Scientific Co., Ltd.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit

and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/InstructionstoAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the

data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039, Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/...; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, etc., and mentioned clearly

in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent** (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

**Statistical data**

Write as mean  $\pm$  SD or mean  $\pm$  SE.

**Statistical expression**

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

**Units**

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

**Abbreviations**

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

**Italics**

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

**RESUBMISSION OF THE REVISED MANUSCRIPTS**

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

**Editorial Office**

**World Journal of Gastroenterology**

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

**Language evaluation**

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

**Copyright assignment form**

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

**Responses to reviewers**

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

**Proof of financial support**

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

**Science news releases**

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

**Publication fee**

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**ACKNOWLEDGMENTS** I Acknowledgments to reviewers of *World Journal of Gastroenterology*

**APPENDIX** I Meetings  
I-IV Instructions to authors

**AIM AND SCOPE**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Abstract

*Clostridium difficile* (*C. difficile*) is now the leading cause of nosocomial diarrhea in the USA, accounting for 30% of patients with antibiotic-associated diarrhea, 70% of those with antibiotic-associated colitis, and most cases of pseudomembranous colitis. The organism has evolved over the last 8 years to become more virulent and resistant to antimicrobials (NAP1/027 strain) causing a more severe form of the disease that has increased mortality and healthcare costs. While it is generally accepted that the problem results from the overuse of antibiotics, and in particular second and third generation cephalosporins, fluoroquinolones and macrolides, recent studies suggest that acid suppression with proton pump inhibitors (PPIs) may be equally culpable. A further common, but less recognized, etiological factor is the prolonged use of elemental diets. Such diets are totally absorbed within the small intestine and therefore deprive the colonic microbiota of their source of nutrition, namely dietary fiber, fructose oligosaccharides, and resistant starch. The resultant suppression of colonic fermentation leads to suppression of the "good" bacteria, such as butyrate-producers (butyrate being essential for colonic mucosal health), and bifidobacteria and the creation of a "permissive" environment for *C. difficile* colonization and subsequent infection. Based on this analysis, the best chance of suppressing the emerging *C. difficile* epidemic is to

adopt a 3-pronged attack consisting of (1) avoidance of the use of prophylactic antibiotics, (2) the avoidance of prophylactic PPIs, and (3) the conversion of elemental diet feeding to a diet containing adequate indigestible carbohydrate after the first week of critical illness. In this review, we highlight the rising worldwide incidence of *C. difficile* associated diarrhea and the role played by non-residue diets in destabilizing the colonic microbiota.

### INTRODUCTION

In under 10 years, *Clostridium difficile* (*C. difficile*) has risen from an obscure anaerobic bacterium to a notorious "superbug" responsible for epidemics of hospital-acquired infections worldwide, attracting major media concern (e.g. "Stomach Bug Crystallizes an Antibiotic Threat", New York Times, April 13, 2009). It is now the leading cause of nosocomial diarrhea in the USA, accounting for 30% of patients with antibiotic-associated diarrhea, 70% of those with antibiotic-associated colitis, and most cases of pseudomembranous colitis<sup>[1]</sup>. Furthermore, the organism has evolved over the last 8 years to become more virulent and resistant to antimicrobials

(NAP1/027 strain) causing a severe form of the disease that prolongs hospitalization and increases mortality, creating substantial increases in health service and economic burdens<sup>[2]</sup>. USA estimates report an additional annual cost to health care of \$1.1 billion<sup>[3]</sup>. Mortality rates have increased concomitantly with these epidemic outbreaks. For example, a report from Quebec, Canada, noted that mortality from infection associated with the use of prophylactic antibiotics for surgical procedures increased from 0.7 cases per 1000 procedures in 2002 to 14.9 in 2005<sup>[4]</sup>. Subsequent studies on bacterial isolates revealed strain changes that increased the production of toxins and made the organism resistant to a wider range of broad-spectrum antibiotics<sup>[5]</sup>. Second and third generation cephalosporins, fluoroquinolones and macrolides have been shown to increase the development of virulence and adherence enhancing colonization. It is therefore understandable that the observed recent exponential increases in incidence, morbidity, mortality and associated healthcare costs are of extreme national and international concern, as they threaten our current ability to support survival in septic critically ill hospitalized patients with the latest generation of potent antibiotics.

---

## HOSPITAL CONTROL

There is no consensus on how the problem can be solved. Despite increasing resistance, the organism is still generally sensitive to both oral metronidazole and vancomycin, and yet mortality continues to increase. Thus greater effort is being directed at prevention. Of the considered 3 most powerful risk factors, age, antimicrobials and exposure to healthcare facilities, the third should be the most controllable. The mode of transmission is thought to be chiefly due to contamination from the hospital environment and from the hands of healthcare workers. Most hospitals now impose strict isolation and hygiene control to detected cases, but the ability of the organism to form spores makes it difficult to control. Although the spores are easily washed down the drain with soap and water, *C. difficile* is not killed by most routinely used hospital germicides. Only 1:10 bleach used with a 10-min contact time serves as a *C. difficile* sporicide<sup>[6]</sup> and doing this routinely is logistically impossible.

---

## PROTON PUMP INHIBITORS

However, the overuse of broad-spectrum antibiotics cannot alone explain the *C. difficile* crisis. Recent studies have suggested that the increase in incidence is better correlated with the use of gastric acid suppressing proton pump inhibitors (PPIs) than with antibiotic usage<sup>[7]</sup>. While spores are resistant to acid, the vegetative form is killed by gastric acid but has been shown to survive passage through the stomachs of patients on PPIs<sup>[8]</sup>. As the vegetative form can theoretically survive on damp surfaces for short spaces of time, it is possible that

colonic infection may be propagated from patient-to-patient through the use of equipment such as bedpans. The use of PPIs may also promote the expansion and colonization of *C. difficile* by its recognized potential to induce small bowel bacterial overgrowth with anaerobic colonic organisms<sup>[9]</sup>.

---

## ELEMENTAL DIETS

In addition, there is the commonly overlooked question of enteral feeding. While there is irrefutable evidence that conventional enteral tube feeding reduces respiratory and bloodstream infectious morbidity<sup>[10]</sup>, the technique has been associated with increased risk of *C. difficile* infection<sup>[11]</sup>. Although this is usually explained by enteral feeding providing a high-frequency portal for inoculation of *C. difficile* spores deep into the gut by healthcare workers, it could simply be explained by the fact that patients requiring enteral feeding are usually sicker, at higher risk of any complication, and more often on antibiotics. Patients receiving percutaneous endoscopic gastrostomies (PEGs) may be at even higher risk due to their higher grades of chronic illness and the conventional use of prophylactic antibiotics to prevent placement infections<sup>[12]</sup>. Enteral feeding associated *C. difficile* infections may also be related to the fact that research has focused on the importance of luminal nutrition on the upper gastrointestinal (GI) tract - and not on the colon. Critically ill patients commonly have impaired upper GI function with poor motility and ileus. Studies have shown that feeding tolerance by such patients can be remarkably good if the feed is given in a residue-free predigested, or "elemental" form, and delivered beyond the stomach into the jejunum because it is totally absorbed within the upper small intestine<sup>[13]</sup>. Unfortunately, modification of normal eating in this way has some potentially deleterious effects. Firstly, the jejunal elemental diets suppress bacteriostatic gastric and pancreobiliary secretions<sup>[14,15]</sup> and also motility. These effects together promote colonization of the small intestine with colonic microbiota, leading to small bowel bacterial overgrowth. Secondly, experimental studies have shown that elemental diets are a perfect culture medium for *C. difficile* organisms<sup>[16]</sup>. Thirdly, elemental diets contain no complex carbohydrate residues, such as fiber or "resistant" starch that escape digestion in the small intestine and enter the colon to provide a fermentable food source for the colonic microbiota.

---

## THE CRITICAL IMPORTANCE OF COLONIC NUTRITION ON THE MICROBIOTA

The absence of fiber and resistant starches not only disturbs microbial balance further, but also deprives the colonic epithelium of its chief energy source and proliferation regulator, butyrate, a short chain fatty acid that is synthesized by the microbiota during the fermentation process<sup>[17]</sup>. A further twist to the story is that it

has been shown that butyrate deficiency in the colon potentiates the growth and toxin production of *C. difficile* organisms<sup>[18]</sup>. It is reasonable to thus speculate that the prolonged use of non-residue tube feeds will enhance *C. difficile* colonization and subsequent *C. difficile* associated colitis by reducing mucosal health and therefore resistance to pathogen adherence and subsequent cytotoxic injury. It has been shown experimentally that colony adherence results in mucosal inflammation induced by the transference of cytotoxic and enterotoxic factors, disrupting the epithelial barrier<sup>[19]</sup>. Toxins A and B enter the colonic cells and kill the cells by multiple mechanisms, including catalysis of the transfer of glucose to GTPases. This may be critically important as in the absence of butyrate, colonic cell survival will be totally dependent on efficient glucose utilization. The suggestion that pre-existing mucosal injury predisposes to *C. difficile* colonization and cytotoxicity is supported by the observation that patients with chronic ulcerative colitis are at dramatically increased risk of developing severe *C. difficile* associated colitis, and that many are resistant to antimicrobial treatment, with 20% requiring total colectomy and an overall mortality rate of 50%<sup>[20]</sup>. To date, fiber supplementation of enteral feeds has not been systematically tested in the critically-ill, but it is noteworthy that Lewis *et al*<sup>[21]</sup> found that oligosaccharide supplementation (12 g/d) increased bifidobacteria counts and decreased diarrhea in patients with chronic relapsing *C. difficile* infection.

## CONCLUSION

So what can we do to reduce the incidence of *C. difficile* infection and its progression to colitis? Survival in the ICU is commonly dependent on the protracted use of broad-spectrum antibiotics, and so withholding their use is not an option. However, prophylactic antibiotics post-operatively and in conditions, such as severe pancreatitis where they are of unproven benefit, should be avoided<sup>[22]</sup>. Secondly, PPIs are grossly overprescribed in the ICU usually with the intent of preventing stress ulceration, but there is poor correlation between this and gastric acidity. One study looking at the association between *C. difficile* associated colitis and PPIs, showed that 63% of patients had no valid indication for acid suppression<sup>[23]</sup>. Not only would restriction of PPI use likely decrease the incidence of *C. difficile* associated colitis but it would also have enormous health care savings worldwide. PPIs now account for 10% of the annual prescribing costs in the UK; more judicious use would save the National Health Service at least £100 million/year<sup>[24]</sup>. Finally, the use of non-residue tube feeds should be restricted to those critically-ill patients with ileus and borderline gut function and since, in practice, ileus usually resolves and function returns with the slow progression of tube feeding over three or 4 d<sup>[13]</sup>, even in these patients a change can often be made to a fiber or “prebiotic” containing formula after the first week.

### Abstract

Portal vein thrombosis (PVT) is a relatively common complication in patients with liver cirrhosis, but might also occur in absence of an overt liver disease. Several causes, either local or systemic, might play an important role in PVT pathogenesis. Frequently, more than one risk factor could be identified; however, occasionally no single factor is discernable. Clinical examination, laboratory investigations, and imaging are helpful to provide a quick diagnosis, as prompt treatment might greatly affect a patient's outcome. In this review, we analyze the physiopathological mechanisms of PVT development, together with the hemodynamic and functional alterations related to this condition. Moreover, we describe the principal factors most frequently involved in PVT development and the recent knowledge concerning diagnostic and therapeutic procedures. Finally, we analyze the implications of PVT in the setting

### INTRODUCTION

The term portal vein thrombosis (PVT) refers to the complete or partial obstruction of blood flow in the portal vein, due to the presence of a thrombus in the vascular lumen<sup>[1]</sup>. Although in the general population PVT is considered a rare event, its prevalence among cirrhotic patients ranges between 4.4%-15%, and is responsible for about 5%-10% of overall cases of portal hypertension<sup>[2]</sup>. The first case of PVT was reported in 1868 by Balfour and Stewart, describing a patient presenting splenomegaly, ascites, and variceal dilation<sup>[3]</sup>. Several etiological causes, either of local or systemic origin, might be responsible for PVT development, although more than one factor is often identified. Furthermore, PVT clinical presentation

is different in the context of acute or chronic onset and depends on the development and the extent of a collateral circulation. Intestinal congestion and ischemia, with abdominal pain, diarrhea, rectal bleeding, abdominal distention, nausea, vomiting, anorexia, fever, lacticidosis, sepsis, and splenomegaly are common features of acute PVT. In contrast, chronic PVT can be completely asymptomatic, or characterized by splenomegaly, pancytopenia, varices, and, rarely, ascites<sup>[3]</sup>. In the presence of portal hypertension, PVT must always be investigated, especially in cirrhotic patients, even if it is considered a rare event<sup>[2]</sup>. Indeed, an early diagnosis and appropriate management of secondary portal hypertension could be, in some cases, life-saving for the patient. Furthermore, in the diagnostic iter, the identification of possible local or systemic trigger factors is of primary importance however, occasionally no single factor is discernable.

Currently, several therapeutic options are available; however, their feasibility and efficacy are still being evaluated and the risks and benefits should be carefully considered for each patient.

In this review, we discuss the features of PVT, pointing out new insights into clinical, diagnostic, and therapeutic issues, making an overview of current beliefs regarding patient outcome and, finally, reporting controversies about the correct management of PVT in the setting of liver transplantation.

## PATHOPHYSIOLOGY

As a consequence of portal vein obstruction, systemic and splanchnic hemodynamics undergo specific and important modifications<sup>[4]</sup>. On the cessation of portal blood flow, the liver loses about two thirds of its blood supply. Interestingly, this condition is usually well tolerated and patients are often asymptomatic, while an acute arterial obstruction always leads to a severe hepatic dysfunction, which is sometimes fatal. It is probably that the immediate activation of two compensatory mechanisms might supplement the loss of portal vein's contribution to liver blood flow. The first mechanism is "arterial vasodilation" of the hepatic artery, similar to that observed in portal vein clamping during liver surgery<sup>[5]</sup>. This "arterial rescue" is a kind of vascular reflex present in every organ with both an arterial and a venous circulation and is capable of preserving liver function in the acute stages of PVT. The second compensatory mechanism is "venous rescue", consisting of the rapid development of collaterals to bypass the obstruction. This vascular neo-formation begins in a few days after portal vein obstruction, and finalizes within 3 to 5 wk<sup>[6,7]</sup>. As a result, the thrombosed portal vein is replaced by a network of collateral vessels, called "cavernoma", connecting the two patent portions proximally and distally to the thrombus. Usually, the original portal vein becomes a thin, fibrotic cord, which is difficult to visualize<sup>[8,9]</sup>. At this stage, the development of a hyperkinetic circulation, characterized by low systemic vascular resistance and a high cardiac output, is common<sup>[3]</sup>.

Despite the activation of this complex system of support, the impairment of portal flow has important consequences on liver tissue. It has been demonstrated in rats, that the progressive obliteration of the portal vein stimulates apoptosis of hepatocytes in the hypoperfused lobe<sup>[10]</sup>, while increasing the mitotic activity in the normal perfused one. The latter effect is well known, and is employed therapeutically in resective liver surgery. However, this process results in a progressive loss of tissue and might be responsible for the impairment of hepatic synthetic function observed in advanced stages of portal vein obstruction<sup>[11]</sup>.

## EPIDEMIOLOGY

The concept of PVT as a rare disease is mainly based on clinical series and case reports<sup>[2]</sup>. An epidemiological study performed in southern Sweden and based on autopsies, reported the incidental finding of a PVT in about 1% of the general population<sup>[12]</sup>. Cohen *et al*<sup>[13]</sup> confirmed these data and reported that most PVT patients were cirrhotics with a primary or metastatic liver cancer. Today, thanks to the availability of more sensitive and less invasive imaging, together with the existence of curative or palliative procedures, PVT is routinely investigated and recognized without any difficulty<sup>[14-16]</sup>. Thus, PVT seems more frequent than expected: it is estimated to be responsible for 5%-10% of the overall cases of portal hypertension, which can be 40% in developing countries<sup>[3]</sup>. The incidence among cirrhotic patients is still unknown, but recent data suggest a prevalence of about 0.6%-16%<sup>[17]</sup> (the highest) among orthotopic liver transplantation (OLT) candidates<sup>[2]</sup> and of about 6.5% in patients with a hepatocellular carcinoma at the time of diagnosis<sup>[16]</sup>.

## ETIOLOGY

Several causes can be involved in the pathogenesis of PVT and, frequently, more than one coexist. A simple classification distinguishes between local (70%) and systemic (30%) risk factors (Tables 1 and 2).

Inflammatory abdominal foci (such as appendicitis, diverticulitis, inflammatory bowel diseases, pancreatitis, cholecystitis, hepatic abscesses, and cholangitis), liver cirrhosis or tumors, represent the most common local thrombotic risk factors<sup>[8,12,18]</sup>.

Malignancies, frequently of hepatic or pancreatic origin, are responsible for 21%-24% of overall cases of PVT<sup>[13,19]</sup>. Direct vascular invasion, compression by tumor mass, or a hypercoagulable state are the mechanisms involved in neoplastic PVT development; hormonal factors might also play a role in this process, especially in men<sup>[16,20,21]</sup>.

PVT is common in patients affected by liver cirrhosis, with a risk related to the severity of the disease; the prevalence ranges from 1%, at the earlier stages, to 30% in candidates for liver transplantation<sup>[8,17]</sup>. Moreover, in patients with a hepatocellular carcinoma, the incidence of PVT rises to 10%-40%<sup>[9]</sup>.

**Table 1** Most frequent local risk factors for PVT<sup>[3,8,9,17,18,64,79]</sup>

Local risk factors for PVT (70%)
Cancer
Any abdominal organ
Focal inflammatory lesions
Neonatal omphalitis, umbilical vein catheterization
Diverticulitis, appendicitis
Pancreatitis
Duodenal ulcer
Cholecystitis
Tuberculous lymphadenitis
Crohn's disease, ulcerative colitis
Cytomegalovirus hepatitis
Injury to the portal venous system
Splenectomy
Colectomy, gastrectomy
Cholecystectomy
Liver transplantation
Abdominal trauma
Surgical portosystemic shunting, TIPS
Iatrogenic (fine needle aspiration of abdominal masses <i>etc.</i> )
Cirrhosis
Preserved liver function with precipitating factors (splenectomy, surgical portosystemic shunting, TIPS dysfunction, thrombophilia)
Advanced disease in the absence of obvious precipitating factors

PVT: Portal vein thrombosis; TIPS: Transjugular intrahepatic portosystemic shunt.

**Table 2** Most frequent systemic risk factors for PVT<sup>[3,8,9,17,18,64,79]</sup>

Systemic risk factors for PVT (30%)
Inherited
Factor V Leiden mutation
Factor II (prothrombin) mutation
Protein C deficiency
Protein S deficiency
Antithrombin deficiency
Acquired
Myeloproliferative disorder
Antiphospholipid syndrome
Paroxysmal nocturnal hemoglobinuria
Oral contraceptives
Pregnancy or puerperium
Hyperhomocysteinemia
Malignancy

Other less common PVT local causes are adenopathy, systemic inflammatory response syndrome, and surgical traumas to the portal venous system, such as portosystemic shunting, splenectomy, liver transplantation, ablative therapy for HCC, and fine needle aspiration of abdominal masses<sup>[1]</sup>.

On the other hand, myeloproliferative disorders and prothrombotic conditions belong to the group of systemic risk factors, with a prevalence of about 40% and 60%, respectively (Table 3)<sup>[8,22]</sup>.

Factor V Leiden mutation is the most common thrombophilia predisposing to PVT, followed by protein C (PC) deficiency<sup>[23-26]</sup>. The role of protein S (PS) and antithrombin III (AT) deficiency in PVT etiology has not yet been confirmed, and it is difficult to evaluate

**Table 3** Prevalence of thrombotic risk factors in series of routinely investigated, consecutive adult patients with non tumorous and non cirrhotic, acute or chronic, PVT<sup>[126]</sup>

Risk factor	PVT patients (%)
Myeloproliferative disorders	30-40
Atypical	14
Classical	17
Antithrombin deficiency	0-26
Protein C deficiency	0-26
Protein S deficiency	2-30
Factor V Leiden mutation	6-32
Prothrombin mutation	14-40
TT677 methylene tetrahydrofolate reductase (MTHFR) genotype	11-50
Antiphospholipid syndrome	6-19
Hyperhomocysteinemia	12-22
Recent pregnancy	6-40
Recent oral contraceptive use	12

the influence of anticoagulation therapy on the impairment in liver function. Indeed, in cirrhotic patients it is hard to distinguish between congenital and acquired deficiencies of natural coagulants and their role in PVT pathogenesis, because if liver function is impaired, levels of coagulation inhibitors, as well as those of pro-coagulation factors, are often decreased<sup>[27]</sup>. A clinical study conducted on eleven children with PVT<sup>[28]</sup>, reported a significant improvement in PC, PS, factors II, V, and VII levels and prothrombin time after surgical correction with a Rex Shunt (mesenteric-left portal vein bypass). In contrast, a distal spleno-renal shunt or an H-type meso-caval shunt, in the same condition, did not seem to be equally effective, probably due to insufficient residual portal vein flow and the consequent impairment in liver synthetic function<sup>[29]</sup>. However, the relatively low prevalence of genetic, in respect to acquired, thrombophilic disorders, might represent a potential diagnostic matter in PVT patients, and should be considered carefully in clinical practice<sup>[30]</sup>. To overcome this problem, an accurate genetic study of the patient and, eventually, his/her family (first degree relatives) might be useful in strongly suggestive cases. Unfortunately, in practice, this policy is not applicable without difficulty. A simple method to screen the deficiency of natural anticoagulants in patients with liver disease comprises the ratio of PS or PC or AT to  $[(\text{factor II} + \text{factor X})/2]$ . If the result is less than 70%, a genetic deficiency has to be suspected and investigated<sup>[1]</sup>.

Among the other thrombophilic disorders, a prothrombin gene mutation seems to be frequent among cirrhotics with PVT<sup>[2,31-34]</sup>. However, in the general population, its role in PVT development seems less clear, as it is considered a weak prothrombotic risk factor. Moreover, a homozygous *methylene tetrahydrofolate reductase* (MTHFR) gene mutation might be associated with PVT development alone or, if heterozygote, in the presence of other cofactors<sup>[13,35-39]</sup>. Amitrano *et al.*<sup>[27]</sup> reported a strong correlation between the prothrombin A20210

mutation or the homozygous MTHFR C677-T genotype and PVT in cirrhotic patients without evidence of liver cancer.

Furthermore, the presence of anticardiolipin antibodies is quite frequent in patients with chronic liver disease; a transient positivity is often reported after infections, suggesting a relationship between microorganisms (i.e. Bacteroides species) and thrombotic events, such as PVT<sup>[40-43]</sup>. In contrast, other studies consider anticardiolipin antibodies simply as an epiphenomenon of liver damage<sup>[41,44]</sup>. Finally, the role of oral contraceptives, steroids, and pregnancy is still less clear<sup>[45-47]</sup>.

In about 22%-48% of patients, PVT is a manifestation of a myeloproliferative disease (MPD)<sup>[2,20,48]</sup>.

An intra-abdominal vascular thrombosis is often the sole presenting symptom and an overt MPD might successively develop in 51% of cases. In the Western Countries, 58% of idiopathic PVTs are associated with a latent MPD<sup>[49]</sup>. The principal diagnostic criteria are usually incompletely met in these patients, probably because of the atypical manifestation of the disease<sup>[50]</sup>. The 1849G→T point mutation in the gene encoding tyrosine-protein kinase JAK2, is a specific and easily detectable marker for MPDs, which can often be useful for a rapid diagnose in PVT patients<sup>[51-55]</sup>. Recent studies reported the presence of a JAK2 mutation in about 17%-35% of patients with PVT, but further studies are needed to confirm these data<sup>[56,57]</sup>.

Occasionally, it is not possible to recognize any overt cause of PVT; generally, the clinical course is favorable for these patients, with a low incidence of complications. However, at present, "idiopathic PVT" is less frequent, thanks to the amelioration in diagnostics and to a more scrupulous attention to patients' clinical history<sup>[12]</sup>.

In conclusion, it is reasonable to routinely investigate the most common prothrombotic disorders and exclude a local trigger, to provide a correct management of PVT and its original cause. However, the mechanism of PVT development is complex and multifactorial, and is not always attributable to a single risk factor. In the presence of sporadic local or systemic promoting events, an underlying intrinsic predisposition might be the access key to thrombosis development<sup>[1,13]</sup>.

## CLASSIFICATION

PVT onset can be acute or chronic. This is an arbitrary distinction, which is sometimes difficult to apply in clinical practice; patients who develop symptoms, such as abdominal pain, nausea, and fever, within sixty days prior to hospital admission, might have an acute PVT development<sup>[58,59]</sup>.

PVT can be classified into four categories, depending on the extension: (1) confined to the portal vein beyond the confluence of the splenic vein; (2) extended to the superior mesenteric vein, but with patent mesenteric vessels; (3) extended to the whole splanchnic venous system, but with large collaterals; or (4) with only fine collaterals<sup>[60]</sup>. This classification is useful to evaluate a

patient's operability and clinical outcome. In fact, when thrombosis is extended to both portal and mesenteric veins, the risk of bowel ischemia is considerable and mortality high, despite a lower risk of variceal bleeding<sup>[61]</sup>.

## CLINICAL PRESENTATION

PVT can occur either in childhood or in adulthood, with the same incidence<sup>[45]</sup>. Clinical presentation always depends on the onset and the extent of the thrombosis and the development of collateral circulation<sup>[62]</sup>.

### Acute PVT

Intestinal congestion and ischemia are typical manifestations of acute PVT; abdominal pain or distention, diarrhea, rectal bleeding, nausea, vomiting, anorexia, fever, lactacidosis, splenomegaly and sepsis might be variably present<sup>[63,64]</sup>. If the obstruction is not resolved quickly, intestinal perforation, peritonitis, shock, and death from multiorgan failure might occur<sup>[8]</sup>. On physical examination, the abdomen might be distended, but guarding is rare, except in case of intra-abdominal inflammation, intestinal infarction, and perforation<sup>[22]</sup>. The majority of patients exhibit splenomegaly, while ascites is rare or, eventually, present before the development of a collateral circulation. This mild, transient, ascites is due to intestinal venous congestion in the absence of the mechanisms activated in liver cirrhosis<sup>[63,64]</sup>.

### Chronic PVT

On the other hand, chronic PVT can be nearly asymptomatic, except for the presence of varices, cutaneous collaterals, or ascites<sup>[62]</sup>. Typically, patients with an advanced thrombosis do not always remember any previous trigger event or disease<sup>[22,63,64]</sup>. The majority of patients develop esophageal varices, in contrast to acute PVT; an episode of gastrointestinal bleeding is reported as the first presenting symptom in about 20%-40% of cases<sup>[9]</sup>. As this phenomenon is strictly time-dependent, it is advisable to screen all PVT patients endoscopically, at diagnosis<sup>[63]</sup>. In cirrhotics with PVT, the risk of variceal bleeding is nearly 80-120 times higher than in patients without liver disease, although the outcome seems better<sup>[65,66]</sup>.

Furthermore, hypersplenism and, consequently, pancytopenia, are commonly present in chronic PVT<sup>[1]</sup>; however, if one branch of the portal vein is preserved and the portal pressure is quite normal, they may even be absent. Ascites and encephalopathy are uncommon and only transient. They are more frequent after an episode of gastrointestinal bleeding or associated with renal failure or sepsis in older patients<sup>[8,64,67]</sup>. Abnormalities of the extrahepatic biliary tree have been reported in more than 80% of patients with chronic PVT; compression by choledochal or periportal varices or by the cavernoma, pericholedochal fibrosis, and ischemic structuring are the principal reasons<sup>[67-71]</sup>. Another finding is the "pseudocholangiocarcinoma sign"<sup>[1,11,17]</sup>, caused by the displacement, stricturing or thumbprinting of the biliary

Table 4 AASLD recommendations for diagnosis of acute and chronic PVT<sup>[126]</sup>

AASLD recommendations for diagnosis of acute PVT	AASLD recommendations for diagnosis of chronic PVT
Consider a diagnosis of acute PVT in any patient with abdominal pain of more than 24 h duration, whether or not there is also fever or ileus	Consider a diagnosis of chronic PVT in any patient with newly diagnosed portal hypertension
If acute PVT is suspected, computed tomography (CT) scan, before and after injection of vascular contrast agent, should be obtained for early confirmation of diagnosis. If CT scan is not rapidly available, obtain Doppler-sonography	Obtain Doppler-sonography, then either CT scan or MRI, before and after a vascular contrast agent, to make a diagnosis of chronic PVT
In patients with acute PVT and high fever, septic pylephlebitis should be considered, whether or not an abdominal source of infection has been identified, and blood cultures should be routinely obtained	Base the diagnosis on the absence of a visible normal portal vein and its replacement with serpiginous veins
In acute PVT, the possibility of intestinal infarction should be considered from presentation until resolution of pain. The presence of ascites, thinning of the intestinal wall, lack of mucosal enhancement of the thickened intestinal wall, or the development of multiorgan failure indicate that intestinal infarction is likely and surgical exploration should be considered	

ducts produced by contiguous neo-formed vessels; it is present in at least 80% of PVT patients at endoscopic retrograde cholangiopancreatography<sup>[67]</sup>, often mimicking a cholangiocellular cancer<sup>[72,73]</sup>. Physical examination and biochemical markers might be completely normal, but, sometimes, cholestasis, cholangitis, choledocholithiasis, cholecystitis and, at least, liver injury, might occur, configuring the so-called “portal biliopathy”<sup>[71,74]</sup>.

## DIAGNOSIS

### Imaging

The diagnosis of PVT can be quickly established by demonstrating the presence of solid material within the vasal lumen (Table 4)<sup>[22]</sup>. Nowadays, in developed countries, PVT is usually recognized at an early stage; cavernomatous transformation or the occurrence of gastrointestinal bleeding are rare. The clinical suspicion is often based on the incidental finding of hypersplenism, signs of portal hypertension or, less frequently, symptoms of portal cholangiopathy. Ultrasonography (US) is usually the investigation of choice, with a sensitivity and specificity ranging between 60% and 100%<sup>[17]</sup>; it can reveal the presence of solid, hyperechoic material into a distended portal vein or its tributaries, the presence of collateral vessels or a cavernoma (Figures 1-3)<sup>[18,22,75]</sup>. Doppler imaging can confirm the absence of flow in part or all the vasal lumen, and, if present, a cavernomatous transformation<sup>[22]</sup>. Recently, the endoscopic use of ultrasound (EUS) was demonstrated to be 81% sensitive and 93% specific in PVT diagnosis<sup>[76]</sup>, and to be capable of detecting small and non-occluding thrombi. It appears to be more accurate than US or computed tomography (CT) scans in discovering portal invasion by tumors<sup>[77,78]</sup>. However, the limit of EUS is the presence of a relatively blind area, which cannot be investigated, involving the distal superior mesenteric vein and the intrahepatic portion of the portal vein<sup>[76]</sup>.

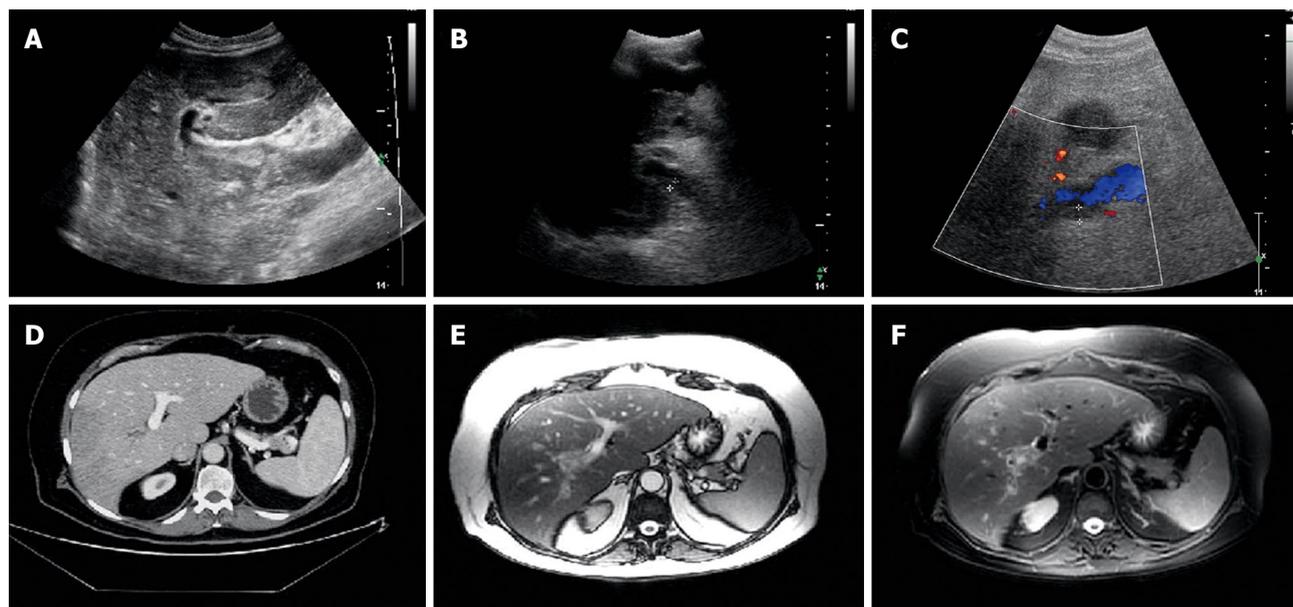

Incidentally, US is less reliable in determining the extension of the thrombus to the mesenteric circulation<sup>[79]</sup>. Instead, CT scanning and magnetic resonance imaging (MRI) can easily obtain this information, and, in addi-

tion, can estimate the impairment of the bowel and other adjacent organs (Figures 1-3). CT scanning is able to demonstrate hyperattenuating material in the portal vein lumen and the absence of enhancement after contrast injection. In addition, in hypoperfused areas, hepatic enhancement appears increased during the arterial phase and decreased during the portal phase. CT is also useful for the identification of the possible cause of the thrombosis or potential complications, such as bowel ischemia and perforation<sup>[22]</sup>. MRI might also confirm the vascular occlusion; at spin-echo MR, the clot appears isointense on T1- weighted images, or hyperintense if recent, and usually has a more intense signal on T2 images. Gradient-echo MR might help to better evaluate any confusing spin-echo MR image<sup>[80]</sup>. Furthermore, contrast-enhanced MR angiography is useful to assess flow direction in the portal venous system and its patency, to identify a cavernomatous transformation, to determine the presence of varices, and to verify the correct function of surgical shunts<sup>[81,82]</sup>. In addition, MR angiography has a high accuracy in the follow-up of the portal venous system before and after liver transplantation<sup>[82-85]</sup>. Moreover, MRI-true fast imaging with steady state precession (true FISP), might overcome the difficulty of contrast injection in cases of poor venous access and the degradation of the images by respiratory motion<sup>[86]</sup>.

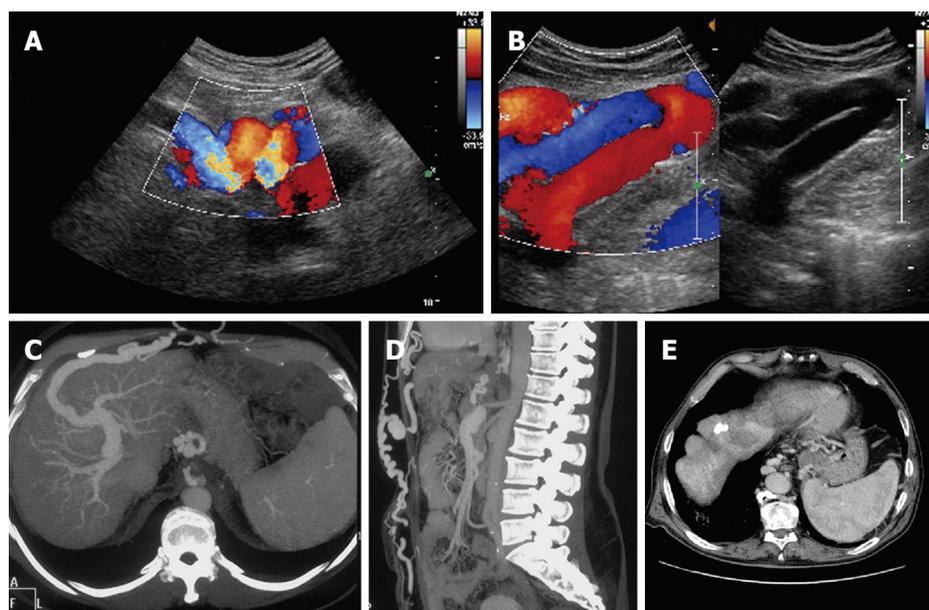

### laboratory investigations

In PVT patients, liver function is typically conserved. Laboratory investigations will be normal or quite normal, unless there is coexistence of a liver disease. However, levels of prothrombin and other coagulation factors could be moderately decreased, while D-dimer is usually increased<sup>[8,22]</sup>.

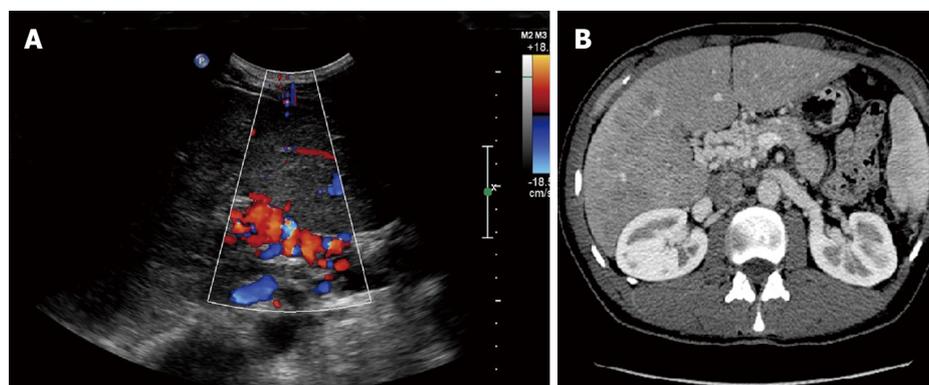

PVT is considered a milestone in the natural history of liver cirrhosis and it is related to serious complications, morbidity, and mortality, as previously discussed<sup>[87]</sup>. Thus, prevention is the first aim of PVT management in patients with an advanced liver disease. Recently, several studies tried to identify the strongest predictive factors for PVT development in these patients. In the past, male sex, previous surgery or interventional treatment for portal

hypertension, previous variceal bleeding, low platelet count, and advanced liver failure have been associated

with an increased risk of PVT development<sup>[2,31,85,88]</sup>. Interestingly, in a recent prospective study by Zocco *et al*<sup>[89]</sup>,

Table 5 Intraoperative grading of PVT extension<sup>[17]</sup>

Yerdel's grading
< 50% occlusion of the portal vein
> 50% occlusion of the portal vein (including total occlusion)
Complete thrombosis of both portal and proximal superior mesenteric vein
Complete thrombosis of portal vein and proximal and distal superior mesenteric vein

a portal flow velocity below 15 cm/s, at US-Doppler evaluation, was considered significantly predictive of PVT development, confirming the importance of Virchow's triad in the pathogenesis of vascular thrombosis.

### Original cause

As first, local causes such as cirrhosis, primary or metastatic malignancies, pylephlebitis, liver cysts, vascular abnormalities (webs or aneurysms), and pancreatitis have to be excluded. Imaging (US+Doppler, MRI or CT scan) or invasive procedures might be helpful<sup>[22]</sup>; needle biopsy of the obstructed portal vein might be specific, but also of relatively low sensitivity<sup>[90]</sup>. If no local risk factor is found, the presence of a thrombophilic disorder must be investigated. If no possible cause of the thrombosis is recognized, the PVT should be considered "idiopathic". Incidentally, a subclinical prothrombotic state has been reported in about 72% of idiopathic PVT, including an overt or occult MPD<sup>[91-93]</sup>.

### Complications

Once the diagnosis has been reached, the severity of liver and other organs' involvement should be assessed. Clinical and laboratory evaluation, as well as imaging, might be useful; the degree of the obstruction (complete or partial, limited or extensive) should be investigated. A partial thrombosis is often associated with few symptoms. Instead, a rapid and complete obstruction of the portal or mesenteric vein, without the involvement of the mesenteric venous arches, induces only intestinal congestion; the main feature is a diffuse thickening of the intestinal wall, visible even without alterations in contrast enhancement. Generally, there are no signs of other organ failures and liver function is usually preserved, probably because the increased hepatic arterial blood flow supplants portal obstruction. In addition, collateral circulation develops rapidly from pre-existing veins in the porta hepatis within 2 to 3 d after the onset of acute thrombosis, particularly in the gallbladder wall<sup>[61,94,95]</sup>. All these manifestations are completely reversible, even if a spontaneous recanalization or a cavernomatous transformation occurs. In contrast, when thrombosis spreads to mesenteric venous arches, the consequence is intestinal ischemia or infarction. Common radiological findings are the thinning of the intestinal wall and the presence of defects of enhancement after intravenous contrast injection<sup>[8]</sup>.

## PROGNOSIS

In non-cirrhotic and non-neoplastic patients, PVT has generally good outcome; exitus for gastrointestinal bleeding is uncommon<sup>[63,96,97]</sup>. Otherwise, prognosis depends on the underlying liver disease<sup>[1,12,22,79]</sup>. The overall mortality has been reported to be less than 10% in PVT chronic onset<sup>[18,98]</sup>, except for patients with malignancy or cirrhosis - about 26%<sup>[63]</sup>. Moreover, advanced age, malignancy, cirrhosis, mesenteric vein thrombosis, absence of abdominal inflammation, and serum levels of aminotransferase and albumin are associated with reduced survival<sup>[65]</sup>. Systemic risk factors, like MPD or other prothrombotic disorders, seem not to affect short-term survival<sup>[99]</sup>.

In addition, acute PVT, when recognized and treated before the occurrence of intestinal infarction, has good prognosis<sup>[61,100-103]</sup>. By contrast, in cases of bowel ischemia and multiorgan dysfunction or failure, patients in-hospital mortality rate is approximately 20%-50%<sup>[61]</sup>.

## PVT AND OLT

In the past, PVT was considered an absolute contraindication for liver transplantation. Currently, thanks to great innovations in medical care, surgical techniques, and radiological interventions, this belief has been confounded and PVT by itself can represent an indication for liver transplantation<sup>[11,64,104,105]</sup>. The first successful liver transplant in a patient with a thrombosed portal vein was reported by Shaw *et al.*<sup>[106]</sup>, in 1985. Several studies<sup>[107-111]</sup> showed that surgical thrombectomy, thromboendovenectomy with venous reconstruction, interposition of vein graft, porto-caval hemitransposition, and radiological endovascular interventions, can resolve venous obstruction in liver transplant recipients<sup>[112]</sup>. However, surgical options are various, and dependent on a correct intra-operative grading of the thrombosis (Table 5); terminal to terminal portal vein anastomosis with or without thrombectomy is the common choice in low grade PVT, while porto-caval hemitransposition is mandatory in grade 4<sup>[85,113]</sup>. Comparisons of technical difficulties, postoperative complications, survival, and mortality, in recipients with or without PVT are contrasting. Several studies reported a more complex surgical procedure, with a greater requirement of blood transfusions, an increased risk of complications (such as primary non function or dysfunction, thrombosis of the hepatic artery, relaparotomy, postoperative pancreatitis, sepsis, and renal failure), a poorer survival, and a higher mortality<sup>[113-115]</sup>. However, these data have not been confirmed and features of liver transplantation, comparing recipients with PVT and those without, are similar<sup>[74,113-116]</sup>. Interestingly, PVT patients' rates of survival at one and 5 years after OLT are equal, as if, once the peri-transplant period has been overcome, the future clinical destiny of recipients with or without a previous PVT could be overlapped. However, among patients with PVT, survival seems better in low grades of Yerdel classification; however, further studies are needed to confirm

this data. Transplantation at grade 1 PVT seems to carry results comparable to non-PVT patients<sup>[74,85,117]</sup>.

The rate of thrombosis recurrence has been estimated within 9% to 42% although some authors reported a lower incidence<sup>[74,107,108,116,118-120]</sup>. Male sex, previous treatment for PVT, Child-Pugh class C, and alcoholic liver disease might be associated with recurrence<sup>[85,114]</sup>. Furthermore, patients with an obstruction of more than half of the portal vein, extended or not to the superior mesenteric vein, seem to have increased risk of severe peri-operative complications, higher mortality, and decreased long-term survival<sup>[85,107,115]</sup>. In cirrhotics with PVT, surgical procedure may be more difficult, often complicated by rethrombosis and reintervention, but with the same morbidity and mortality of non-cirrhotic patients<sup>[113,115,121,122]</sup>.

After liver transplantation, PVT development is a rare but possible event, especially in the early postoperative period<sup>[60]</sup>. The incidence ranges between 1% and 2%<sup>[122-124]</sup>, with a preferential localization at the anastomotic site; technical complications, small diameter of the portal vein, pediatric recipient, presence of PVT pre-OLT, surgical shunting pre-OLT, or splenectomy are the principal predisposing risk factors<sup>[124]</sup>. The occlusion of the portal vein is always more scarring than the thrombosis of the hepatic artery and may be seriously threatening for both graft and patient survival<sup>[122]</sup>. Acute liver failure, bleeding from esophageal varices, and massive ascites could rapidly occur and immediate retransplantation must be quickly attempted in case of severe worsening of liver function<sup>[124]</sup>.

Thus, for all these reasons and the good results reported in literature, today PVT has no longer to be considered a contraindication but only a disadvantage and, in some cases, might present a possible indication to liver transplantation<sup>[114,116,124,125]</sup>.

## TREATMENT

Although spontaneous resolution of PVT has been reported in the literature<sup>[101,102]</sup>, a specific therapeutic management is mandatory to resolve portal vein obstruction and avoid serious complications. The goal of treatment is similar in acute and chronic PVT, and consists in correction of causal factors, prevention of thrombosis extension, and achievement of portal vein patency. However, in case of long standing thrombosis, the management of complications related to portal hypertension and portal cholangiopathy has to be concurrently considered<sup>[126]</sup>. Nowadays, anticoagulant therapy is the best way to obtain portal vein recanalization; however, there is no consensus on its application. Other modalities of treatment should be adopted only in case of partial or absent PVT resolution<sup>[12,126]</sup>. Furthermore, some conditions should be considered in the assessment of anticoagulant therapy, such as recent *vs* old thrombosis, the presence of a thrombophilic condition, or a liver disease.

### Anticoagulation in acute PVT

Although PVT might be compared to other cases of

deep vein thrombosis, there is no randomized controlled trial regarding the use of anticoagulants in acute PVT<sup>[126]</sup>. After 6 mo of therapy, a complete recanalization has been reported in about 50% of patients, with good results in the case of mesenteric vein involvement, and a low incidence of complications. In contrast, in about 10% of cases, PVT is resistant to anticoagulants<sup>[96,97,100-103]</sup>. In addition, when intestinal infarction occurs, anticoagulants administered prior to laparotomy seem to have a consistent benefit on survival<sup>[127-129]</sup>.

What is certain is that, in acute PVT onset, the sooner the treatment is given the better the outcome will be; the rate of recanalization is about 69%, if anticoagulation is instituted within the first week after diagnosis, while it falls to 25% when instituted at the second week<sup>[9,59,130]</sup>.

### Anticoagulation in chronic PVT

Opinions regarding therapeutic options in chronic PVT are more controversial and significantly variable. At present, anticoagulant treatment is administered to only 30% of patients with chronic PVT, reflecting concerns about the use of anticoagulation in the presence of gastroesophageal varices, low platelet counts, and coagulation dysfunctions<sup>[79]</sup>. However, the number of bleeding episodes in PVT patients receiving anticoagulant therapy did not increase, and in long-term follow-up studies, anticoagulants seem to be effective in preventing new thrombotic events with a low mortality<sup>[66,126]</sup>. Incidentally, a pragmatic approach, such as endoscopic eradication of varices prior to commencement of anticoagulation, should be reasonable<sup>[79]</sup>.

### Dose and duration of anticoagulants

If thrombosis is recent and there is no underlying thrombophilic condition, anticoagulation should be administered for 3-6 mo, as a complete portal vein recanalization can occasionally be delayed<sup>[79,100,101,131-133]</sup>. Recently, a panel of experts recommended the application of anticoagulant therapy only in PVT patients with a proven thrombophilic disorder or familial history of venous thrombosis<sup>[133,134]</sup>, thereby obtaining an improvement in survival and reduction in risk of gastrointestinal bleeding<sup>[135,136]</sup>.

### Anticoagulation in cirrhotic patients

The ubiquitous and long-term use of anticoagulants in cirrhotic patients with PVT should not be considered correct practice, until their safety and efficacy has been completely tested<sup>[62]</sup>. However, signs of intestinal ischemia or infarction, or an underlying prothrombotic disorder should be considered an indication for anticoagulants in cirrhotic patients, although only after an adequate prophylaxis for variceal bleeding<sup>[2,126]</sup>. In candidates for liver transplantation with a high risk PVT (obstruction of more than 50% of the portal vein), anticoagulation should be recommended, even if a scheduled prophylactic treatment has not yet been assessed<sup>[64,74,85,108,117]</sup>.

### Other treatments

Thrombolytic therapy, given either into the systemic venous circulation, the superior mesenteric artery, or the portal vein *via* a transjugular or transhepatic route, is also effective to provide recanalization in acute PVT<sup>[137-142]</sup>. However, efficacy is significantly lower and mortality increased in patients who undergo thrombolysis, if compared to conservative treatment<sup>[59,143,144]</sup>. Despite the high incidence of side effects, thrombolysis should be considered when initial anticoagulant therapy fails, even if there is no consistent evidence concerning in which conditions it should be preferred to anticoagulation<sup>[137]</sup>. Surgical thrombectomy is usually not recommended, as high morbidity and mortality have been reported; percutaneous transhepatic mechanical thrombectomy might also be effective in recent thrombosis, but vascular traumas are frequent and may stimulate rethrombosis<sup>[145]</sup>.

Other approaches, such as transjugular intrahepatic portosystemic shunt placement, should be reserved for patients developing acute PVT before or after liver transplantation, or in alternative to thrombolysis when anticoagulation fails<sup>[146,147]</sup>. It seems to be effective in resolving portal biliopathy, ascites, and portal hypertension, but it is not feasible if portal vein is not catheterizable or a cavernomatous vein cannot be dilated<sup>[148-150]</sup>.

Finally, shunt surgery (distal splenorenal shunt or Rex shunt, in children) might be applied as the last choice, and only in absence of splenic or superior mesenteric vein thrombosis<sup>[151]</sup>.

### CONCLUSION

PVT is relatively uncommon in the general population, but is more frequent among cirrhotic patients and represents a “milestone” in the natural evolution of liver disease. Local or systemic pro-thrombotic factors, alone or together, can play an important role in PVT pathogenesis, which is complex and different in each clinical context and in each patient. The consequent changes in hepatic and splanchnic hemodynamic are responsible for a mild impairment in liver function, in absence of an overt liver disease, or can precipitate a preexistent metastable clinical status in cirrhotic patients. Moreover, PVT might have indirect effects on other abdominal organs, causing intestinal ischemia and infarction, or predisposition to vascular neoformation and gastrointestinal bleeding. The identification of protean manifestations of PVT is essential to provide a prompt diagnosis, as the removal of the original trigger factor and an early therapeutic management is crucial to preserve patient health and, sometimes, life. The history of PVT has been characterized by difficulties in diagnosis and treatment, which, today, have almost been overcome. In the future, due to innovations in imaging and pharmaceuticals, clinical attention must be focused on the realization of a scheduled, preemptive, therapeutic approach to the patient, to better define the profile of toxicity and reduce side effects, especially in cirrhotic patients.

### Abstract

**AIM:** To investigate *in vitro* treatment with NVP-AEW541, a small molecule inhibitor of insulin-like growth factor-1 receptor (IGF-1R), in biliary tract cancer (BTC), since this disease is associated with a poor prognosis due to wide resistance to chemotherapeutic agents and radiotherapy.

**METHODS:** Cell growth inhibition by NVP-AEW541 was studied *in vitro* in 7 human BTC cell lines by automated cell counting. In addition, the anti-tumoral mechanism of NVP-AEW541 was studied by Western blotting, cell cycle analysis and reverse transcription-polymerase chain reaction (RT-PCR). Anti-tumoral drug effect in combination with gemcitabine, 5-fluorouracil (5-FU) and Polo-like kinase 1 inhibitor BI2536 was also studied.

**RESULTS:** *In vitro* treatment with NVP-AEW541 suppressed growth in all human BTC cell lines, however response was lower in gallbladder cancer. Treatment with

NVP-AEW541 was associated with dephosphorylation of IGF-1R and AKT. In contrast, phosphorylation of p42/p44 and Stat3 and expression of Bcl-xL were inconsistently downregulated. In addition, treated cells showed cell cycle arrest at the G1/S-checkpoint and an increase in sub-G1 peak. Moreover, IGF-1R and its ligands IGF-1 and IGF-2 were co-expressed in RT-PCR, suggesting an autocrine loop of tumor cell activation. Combined with gemcitabine, NVP-AEW541 exerted synergistic effects, particularly at low concentrations, while effects of combination with 5-FU or BI 2536 were only additive.

**CONCLUSION:** Our findings suggest that NVP-AEW541 is active against BTC *in vitro* and potentiates the efficacy of gemcitabine.

### INTRODUCTION

Insulin-like growth factor-1 receptor (IGF-1R) is a tyrosine kinase receptor with a 70% homology to the insulin receptor<sup>[1]</sup>. When activated by its ligands IGF-1, IGF-2 or insulin at supraphysiological concentrations, the IGF-1R transmits a signal to its two major substrates, insulin receptor substrate-1 (IRS-1) and Shc. The signal is subsequently transduced *via* the common signal transduction

pathway, through ras, raf and p42/44 downstream of Shc and AKT downstream of IRS-1, all the way to the nucleus<sup>[2,3]</sup>.

The IGF-1R system has emerged as an interesting target for cancer therapy, as it represents an important promoter of tumor transformation and survival of malignant cells, but is only partially involved in normal cell growth<sup>[4-6]</sup>. This is in part attributed to interactions with oncogenes. Moreover, activation of IGF-1R may contribute to tumor angiogenesis by up-regulation of vascular endothelial growth factor (VEGF) expression in certain cancer entities<sup>[7-9]</sup>. In the past, different strategies were used to inhibit IGF-1R function, among them monoclonal antibodies and anti-sense RNA directed against the receptor or recombinant IGF binding proteins, and IGF-specific antibodies reducing levels of ligands<sup>[5]</sup>. Thus, targeting the IGF-1R system with small molecule tyrosine kinase inhibitors, such as NVP-AEW541, a novel compound which is 27-fold more selective for IGF-1R than the insulin receptor at the cellular level, may be a new strategy of cancer growth inhibition<sup>[10,11]</sup>. Anti-neoplastic efficacy of NVP-AEW541 has recently been shown in experimental models of acute myeloid leukemia<sup>[12]</sup>, multiple myeloma<sup>[13]</sup>, multiple myoblastoma<sup>[14]</sup>, neuroblastoma<sup>[15,16]</sup>, medulloblastoma<sup>[17,18]</sup>, malignant rhabdoid tumors<sup>[19]</sup>, Ewing's sarcoma<sup>[20,21]</sup>, ovarian<sup>[22]</sup> and breast cancer<sup>[23-25]</sup>, mesothelioma<sup>[26]</sup>, synovial sarcoma<sup>[27,28]</sup>, head and neck squamous cell carcinoma<sup>[29]</sup>, adrenocortical tumors<sup>[30]</sup>, hepatocellular carcinoma<sup>[31,32]</sup>, neuroendocrine gastrointestinal tumors<sup>[33]</sup>, gastrointestinal stromal tumors<sup>[34]</sup>, colorectal<sup>[32,35-38]</sup>, esophageal<sup>[32]</sup>, gastric<sup>[37]</sup>, and pancreatic cancer<sup>[32,37,39]</sup>. However, little is known about the situation for biliary tract cancer (BTC), a rare tumor with a grim prognosis and limited treatment options. Two recent studies showed expression of IGF-1R and its ligands in gallbladder carcinoma (GBC)<sup>[40]</sup> and cholangiocarcinoma (CC) specimens<sup>[41]</sup>. Therefore, the objectives of the current study were to investigate IGF-1R expression in BTC cell lines and to evaluate the efficacy of *in vitro* treatment with selective IGF-1R inhibitor NVP-AEW541 alone or in combination with gemcitabine, 5-fluorouracil (5-FU) or Polo-like kinase 1 inhibitor BI 2536, which is currently being investigated in phase II studies including our hospital for the treatment of solid tumors<sup>[42]</sup>.

## MATERIALS AND METHODS

### Drugs and cells

Seven BTC cell lines; five extrahepatic CC cell lines (EGI-1, TFK-1, CC-SW-1, CC-LP-1, and SK-ChA-1)<sup>[43-47]</sup> and two GBC cell lines (Mz-ChA-1, Mz-ChA-2)<sup>[46]</sup>, were examined. All cell lines were cultured in a 37°C incubator with 5%-10% CO<sub>2</sub> in appropriate media, which were changed every 3 d. NVP-AEW541 (targeting IGF-1R) was obtained from Novartis (Basel, Switzerland), dissolved in dimethyl sulfoxide (DMSO) (as 10 mmol/L stock) and stored at -20°C according to manufacturer's

instructions. BI 2536 (targeting Plk-1) was kindly provided by Boehringer (Ingelheim, Germany). Gemcitabine and 5-FU (diluted in 0.9% NaCl) were provided by our hospital pharmacy.

### Inhibition of cell growth

Cytotoxic effects of drugs alone and in combination were determined by automated cell counting (Casy Cell Counter Model TT; Innovatis AG, Reutlingen, Germany) according to manufacturer's instructions. Briefly,  $2 \times 10^5$  cells were seeded in duplicates in T25 flasks with media containing the designated drugs or vehicle control followed by incubation for 3 or 6 d. For the 6 d experiment, medium was changed after 3 d and treatment repeated. At the end of incubation, cells were trypsinized, washed, and analyzed in triplicates by automated cell counting.

### Immunoblotting

Cell culture monolayers were washed with ice-cold PBS and lysed in flask with a buffer containing Tris-HCl (50 mmol/L, pH 7.4), NP-40 (10 g/L), NaCl (200 mmol/L), sodium-orthovanadate (200 mmol/L), 2-glycerophosphate (1 mmol/L), sodium fluoride (20 mmol/L), DTT (10 mmol/L), PMSF (200 mmol/L) and 0.2% proteinase inhibitor cocktail (Sigma-Aldrich, Munich, Germany) on ice for 30 min. The lysate was then centrifuged at 13000 r/min for 15 min and proteins in supernatant were quantified by Bradford protein assay (Bio-Rad, Munich, Germany) and stored at -80°C. Next, 50 or 60 µg of cell lysates were separated on SDS-polyacrylamide gels and electroblotted onto polyvinylidene difluoride membranes (Amersham Pharmacia Biotech, Freiburg, Germany). Membranes were then incubated in blocking solution [25 g/L dry milk or BSA in TBS-T (10 mmol/L Tris-HCl, 140 mmol/L NaCl, 1 g/L Tween-20)], followed by incubation with the primary antibody at 4°C overnight (50 g/L BSA in TBS-T). The membranes were then washed in TBS-T and incubated with horseradish peroxidase-conjugated secondary antibodies for 1 h at room temperature. Antibody detection was performed with an enhanced chemoluminescence reaction (SuperSignal West Dura or SuperSignal West Femto, Pierce, Rockford, USA). Monoclonal (mc) β-actin antibody was purchased from Sigma (Sigma-Aldrich Chemie GmbH Munich, Germany), polyclonal IGF-1Rβ antibody from Santa Cruz (Santa Cruz Biotechnology Inc., Santa Cruz, USA), mc p-IGF-1R, mc p-p42/44 (p-Erk1/2, p-MAPK), mc p42/44, mc p-AKT, mc AKT, mc p-Stat3, mc Stat3 and mc Bcl-xL antibodies were all from Cell Signaling (Cell Signaling Technology, Beverly, USA). Recombinant human IGF-1 was purchased from Biomol (Biomol, Hamburg, Germany).

### Cell cycle analysis

Cells were seeded in T-25 flasks ( $3.5 \times 10^5$ ), treated with various concentrations of NVP-AEW541 or vehicle control for 36 h, washed with PBS, trypsinized,

centrifuged, and fixed in ice-cold ethanol with phosphate-buffered saline containing 1 mmol/L EDTA. DNA was labelled with 1:100 diluted propidium iodide after digestion of RNA by RNAse A. Cells were analysed by flow cytometry with a FACSCalibur system (Becton Dickinson, San Diego, USA) and cell cycle profiles were determined using ModFitLT 2.0 for Macintosh (Verity Software House, Topsham, ME, USA). Doublets were excluded by gating for width of fluorescence signal (FL2-W). Each experiment was performed at least in triplicate.

### Reverse transcription-polymerase chain reaction (RT-PCR) for ligands IGF-1 and IGF-2

Total cell RNA was extracted using the RNeasy Mini Kit (Qiagen GmbH, Hilden, Germany) after homogenization with the QIAshredder (Qiagen) according to manufacturer's instructions. RNA was dissolved in water and quantified at 260 nm with a biophotometer (Eppendorf, Hamburg, Germany); purity was verified by optical density ( $A$ ) absorption ratio  $A_{260\text{ nm}}/A_{280\text{ nm}}$  between 1.93 and 2.06. Single step quantitative RT-PCR analysis was carried out in the LightCycler system (Roche), primers and fluorochromes were obtained from Qiagen (QuantiTect Primer Assays Hs\_IGF1\_1\_SG and Hs\_IGF2\_1\_SG and SYBR-Green RT-PCR kit) and used according to manufacturer's instructions. Products of RT-PCR were separated by gel electrophoresis to confirm correct amplification and size. RNA samples extracted from hepatocellular carcinoma tissue and from HepG2 cell line served as positive controls. Water was used to detect primer interactions and GAPDH as housekeeping gene to assure equal loading. Relative gene expression was calculated with REST software tool as used by Pfaffl and Horgan<sup>[48]</sup>.

### Caspase-3 assay

Using the caspase-3 colorimetric assay kit (Sigma, Missouri, USA) according to manufacturer's instructions, caspase-3 activity was measured. Cells were grown, treated, lysed and centrifuged, and supernatants were used. Based on the hydrolysis of the peptide substrate acetyl-Asp-Glu-Val-Asp p-nitroanilide by caspase-3, resulting pNA was measured photometrically at 405 nm after incubation at 37°C and 5% CO<sub>2</sub>. A pNA calibration curve was used to calculate results.

### Statistical analysis

Statistical calculations were performed using SPSS, version 10.0 (SPSS Inc., Chicago, USA). Numeric data were presented as mean value with SD. Inter-group comparisons were performed with the Student *t* test. *P* values less than 0.05 were considered significant.

## RESULTS

### Inhibition of cell growth

After 3 d of incubation, tested cell lines were sensitive to NVP-AEW541 (mean IC<sub>50</sub> = 0.51 ± 0.44 μmol/L) with

Table 1 Inhibition of cell growth by *in vitro* treatment with NVP-AEW541

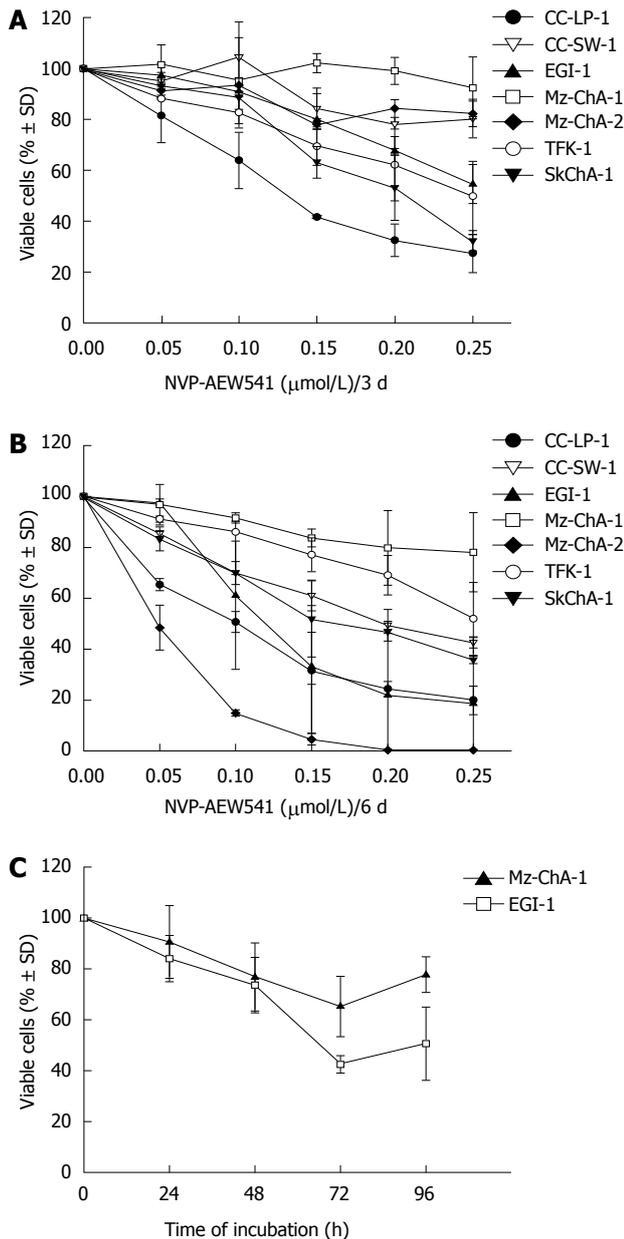

Cell line	IC <sub>50</sub> (μmol/L)	
	3 d	6 d
TFK-1	0.26	0.28
EGI-1	0.28	0.14
CC-LP-1	0.15	0.12
CC-SW-1	0.54	0.20
Sk-ChA-1	0.20	0.18
Mz-ChA-1	1.39	0.52
Mz-ChA-2	0.73	0.07

CC-LP-1 being the most sensitive and Mz-ChA-1 the least sensitive cell line (IC<sub>50</sub> values were calculated with linear regression model). Response differed markedly between the group of extrahepatic CC cell lines (mean IC<sub>50</sub> = 0.29 ± 0.15 μmol/L) and the group of the two GBC cell lines (mean IC<sub>50</sub> = 1.06 ± 0.47 μmol/L) (*P* < 0.05). Inhibition of cell growth was more pronounced if incubation time was extended to 6 d (treated twice, on days 0 and 4) with a mean IC<sub>50</sub> value of 0.22 ± 0.15 μmol/L. Although not statistically significant, there was again a difference in response for the 6 d experiment between the group of extrahepatic CC cell lines (mean IC<sub>50</sub> = 0.18 ± 0.06 μmol/L) and the group of the two GBC cell lines (mean IC<sub>50</sub> = 0.3 ± 0.32 μmol/L) (Figure 1A and B, Table 1).

Cell lines Mz-ChA-1, showing a weak, and EGI-1, showing an intermediate response to NVP-AEW541, were selected for further studies of drug mechanism, because each of these lines represented one entity of BTC (GBC and extrahepatic CC). Firstly, the *in vitro* cell growth inhibition experiment was repeated with a broader spectrum of drug doses to determine the correct 3 d IC<sub>50</sub> concentration. To verify calculated 3 d IC<sub>50</sub> concentrations and to determine the most effective length of incubation, additional experiments with drug incubation times ranging from 1 to 4 d, with 3 d IC<sub>50</sub> concentration, were carried out (Figure 1C), which showed best response after 3 d of incubation. Using data from this experiment, replication times for Mz-ChA-1 (68.16 h) and EGI-1 (30.7 h) were calculated. This difference could be one factor influencing response to NVP-AEW541. DMSO, the solvent of NVP-AEW541, had no influence on cell growth when administered alone (data not shown).

### Mechanism of drug action

IGF1-R protein was detectable in all seven cell lines by immunoblot, with expression level variation between the different cell lines (Figure 2A). However, there was no correlation between level of IGF1-R protein expression and inhibition of cell growth by NVP-AEW541. For further analysis of drug mechanism, EGI-1 and Mz-ChA-1 cells were used, representing cells with good and little response to the inhibitor, but intermediate IGF-1R protein expression, respectively. Stimulation of cell

**Figure 1** *In vitro* cell growth inhibition. A: Treatment of seven human biliary tract cancer cell lines with NVP-AEW541 for 3 d ( $n = 3$ ); B: 6 d incubation ( $n = 3$ ); C: Incubation of selected cell lines EGI-1 and Mz-ChA-1 with calculated  $IC_{50}$  for 24-96 h ( $n = 3$ ). Error bars represent SD.

lines EGI-1 and Mz-ChA-1 with recombinant human IGF-1 30 min prior to lysis resulted in phosphorylation of IGF-1R, which was not present in cells that were serum-starved for 24 h (Figure 2B, lanes 1 and 2). Twelve hours of pre-incubation with NVP-AEW541 prior to stimulation and lysis inhibited phosphorylation of IGF1-R (Figure 2B, lanes 3-5), while levels of whole IGF1-R protein remained unchanged during treatment. Assessment of phosphorylated intracellular signal transduction proteins AKT, p42/44, and Stat3, all located downstream of the IGF-1R pathway, showed variable results. Level of p-AKT was already increased in unstimulated Mz-ChA-1 cells, but not in EGI-1 cells. Treatment with NVP-AEW541 resulted in dephosphorylation in both cell lines.

Level of p-p42/44 was already increased in unstimulated EGI-1 cells, but not in Mz-ChA-1 cells. Treatment with NVP-AEW541 resulted in dephosphorylation in Mz-ChA-1 cells, but not in EGI-1 cells. This could be explained by a k-ras mutation (G12D) in the EGI-1 cell line, as already described in the COSMIC catalogue<sup>[49]</sup>, and would result in a consecutively active state of downstream target p42/44, as found by our group. Level of p-Stat-3 was already increased in both unstimulated cell lines. While dephosphorylation of Stat-3 occurred in EGI-1, phosphorylation of Stat-3 remained unchanged during treatment with NVP-AEW541 in Mz-ChA-1 cells. Furthermore, repetition with higher doses of NVP-AEW541 (up to 5 μmol/L) did not show any effect (blot not shown).

Anti-apoptotic protein Bcl-xL was significantly reduced after treatment with NVP-AEW541 in Mz-ChA-1 cells, but we could not determine any significant change of expression in EGI-1 cells after treatment. Treatment with higher doses of NVP-AEW541 did not reveal greater effects (blots not shown). Staining with β-actin antibody confirmed equal protein loading in all immunoblots.

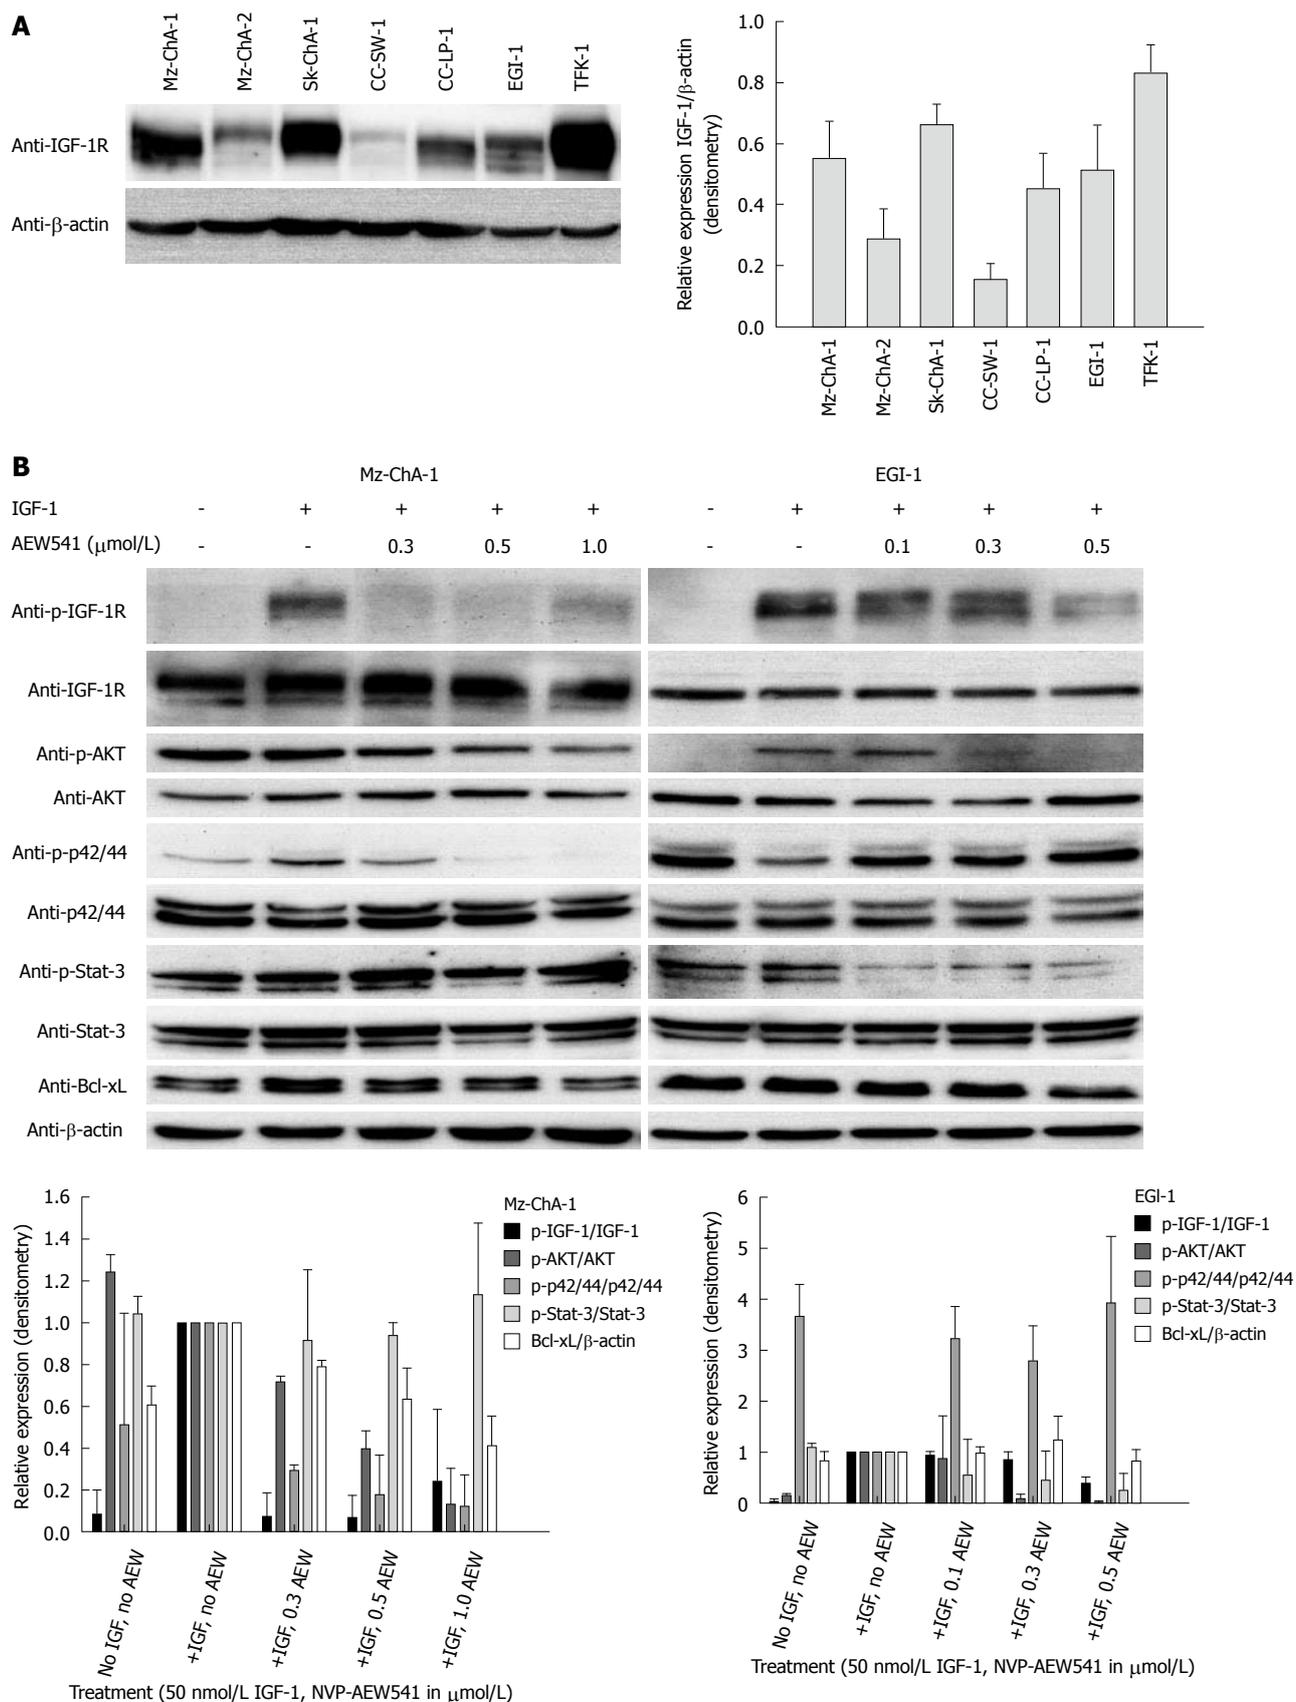

Cell cycle analysis of cell lines EGI-1 and Mz-ChA-1, treated with NVP-AEW541 for 36 h, showed an increase of G0/G1 fraction, possibly caused by G1/S-checkpoint arrest. This arrest was more pronounced when the dose was increased (Figure 3A and B). Analysis of flow cytometry sub-G1 fraction showed no significant apoptosis for NVP-AEW541 concentrations below 1 μmol/L, but marked apoptosis if NVP-AEW541 concentration was increased above 1 μmol/L (Figure 4C). Treatment with 5 μmol/L resulted in marked apoptosis, influencing cell cycle proportions. There was no significant change in caspase-3 activity induced by treatment with NVP-AEW541 (data not shown).

#### RT-PCR analysis of IGF-1R ligands IGF-1 and IGF-2

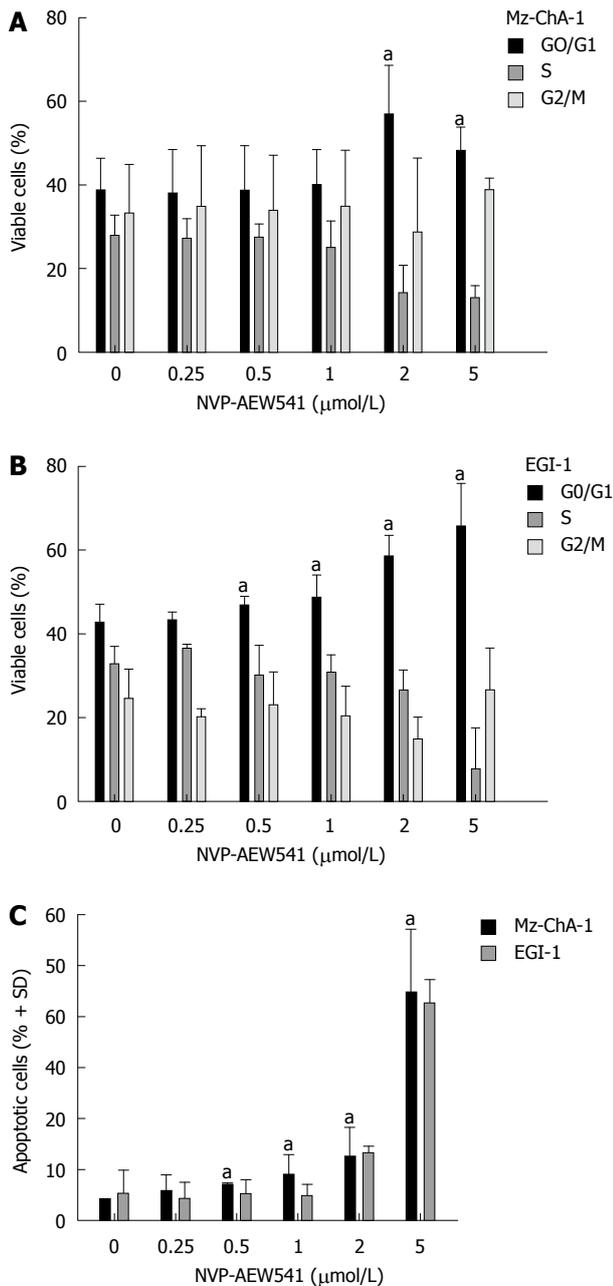

Semiquantitative RT-PCR revealed expression of ligands IGF-1 and IGF-2 in selected MzChA-1 and EGI-1 cells, suggesting an autocrine loop of IGF-1R activation. Samples of human hepatocellular carcinoma tissue served as a positive control. There was no significant change in expression levels of either IGF-1R ligand induced by treatment with  $IC_{50}$  doses of NVP-AEW541 for 3 d (Figure 4).

#### *In vitro* combination of NVP-AEW541 with gemcitabine, 5-FU or BI 2536

To evaluate efficacy of NVP-AEW541 in combination with commonly used chemotherapeutics for the treatment of BTC, further *in vitro* experiments were performed. NVP-AEW541 at  $IC_{20}$  concentration (0.8 μmol/L for Mz-ChA-1 and 0.20 μmol/L for EGI-1) was combined with increasing concentrations of gemcitabine or 5-FU over 3 d (Figure 5). Assuming that the drugs do not directly interact and using the model of effect multiplication postulated by Berenbaum<sup>[50]</sup>,

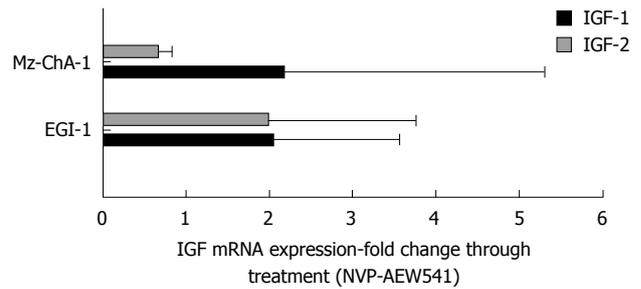

**Figure 2 Mechanism of NVP-AEW541 drug action.** A: Protein expression of IGF-1R in tested human biliary tract cancer cell lines was determined by immunoblot; B: p-IGF-1R, IGF-1R, p-AKT, AKT, p-p42/44, p42/44, p-Stat-3, Stat-3, and Bcl-xL protein levels were examined by immunoblot for selected cell lines EGI-1 and Mz-ChA-1. After 24 h of starvation, cell lines EGI-1 and Mz-ChA-1 were treated with NVP-AEW541 (12 h prior to lysis) and stimulated with ligand IGF-1 (30 min prior to lysis). β-actin served as loading control in all experiments. Densitometry was performed to analyze results which are shown relative to lane 2 as standard.

**Figure 3 Cell cycle analysis.** A: *In vitro* treatment of selected cell line EGI-1 with NVP-AEW541 for 36 h ( $n = 3$ ); B: *In vitro* treatment of selected cell line Mz-ChA-1 ( $n = 3$ ). Cells were stained with propidium iodide and analyzed by flow cytometry. ModFitLT 2.0 software was used to determine cell cycle proportions according to cellular DNA content; doublets were excluded by gating for width of fluorescence signal (FL2-W) ( $^*P < 0.05$  for G0/G1 fraction, treated cells *vs* control); C: Cells having less than single DNA content (sub-G1 fraction) were presumed to be apoptotic ( $n = 3$ ) ( $^*P < 0.05$ , treated cells *vs* control; error bars represent SD).

calculated values representing synergistic effects were compared to measured values. Even though  $IC_{50}$  doses of NVP-AEW541 for both cell lines are different, gemcitabine showed synergistic effects at low concentrations for both tested cell lines (Figure 5A and B), whereas combinations of NVP-AEW541 with 5-FU showed only additive effects (Figure 5C and D). In addition, new small-molecule Plk-1 inhibitor BI 2536 was tested

**Figure 4 Influence of NVP-AEW541 (3 d treatment with calculated  $IC_{50}$ ) on mRNA expression of IGF-1R ligands IGF-1 and IGF-2 in two of the tested cell lines.** Ratio of IGF mRNA expression in treated *vs* untreated cell lines is shown ( $n = 3$ ).

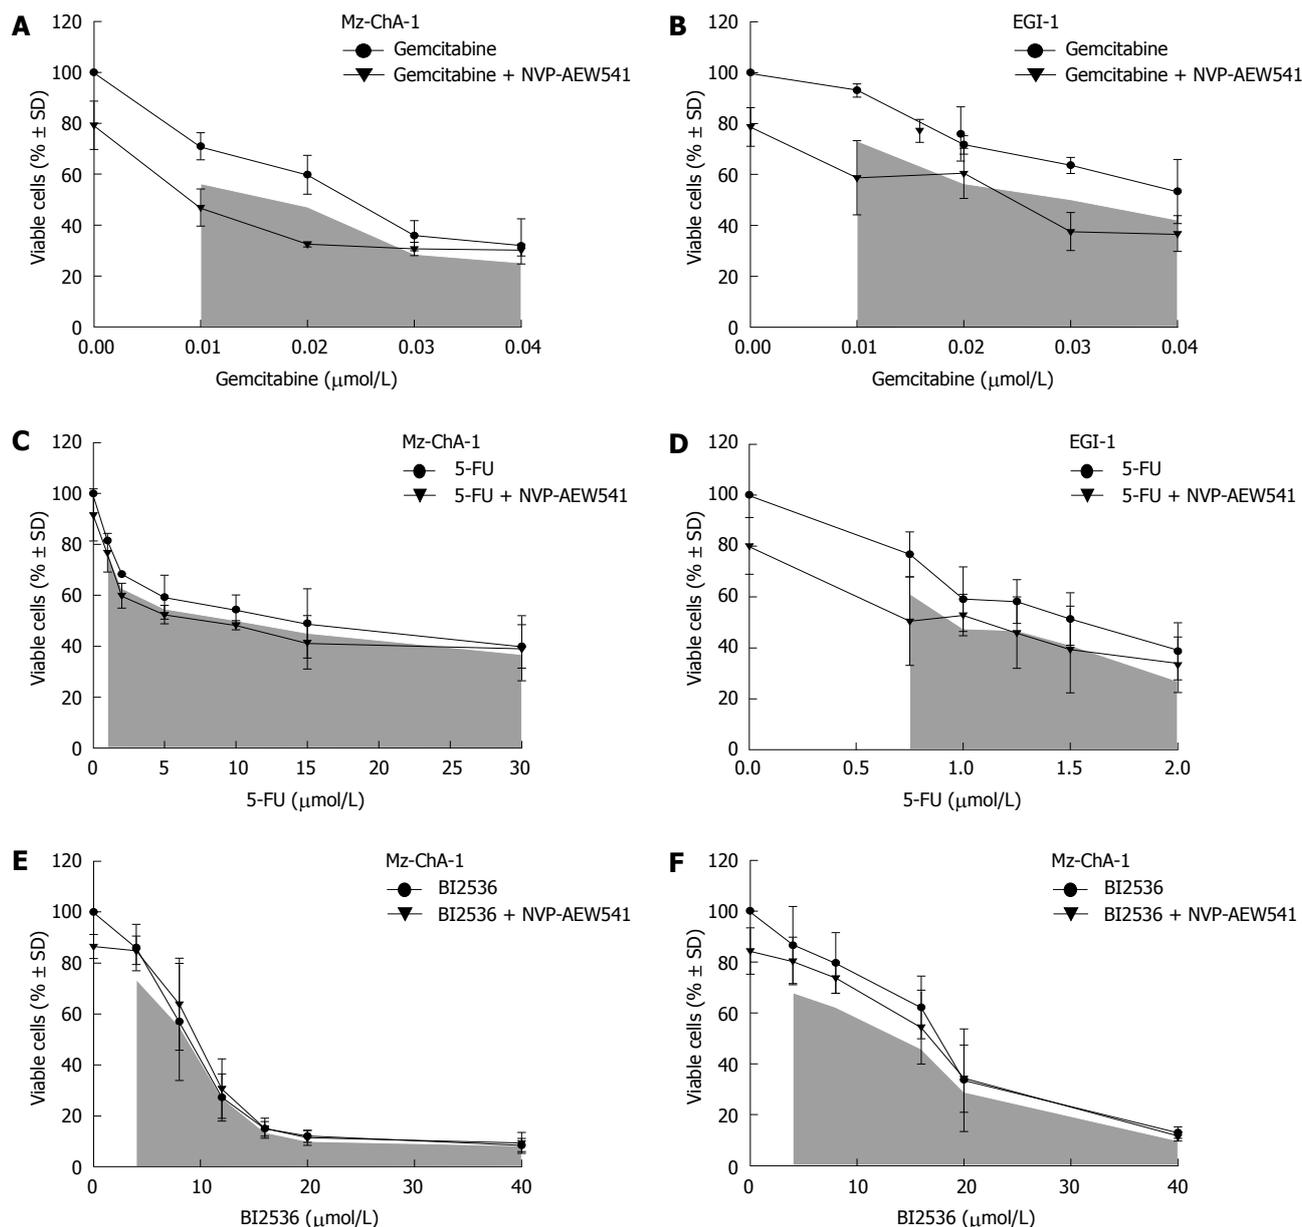

in combination with NVP-AEW541. This compound was available to us due to our participation in a phase II study for the treatment of solid tumors. Similar to the combination with 5-FU, the combination with BI 2536 resulted only in additive effects (Figure 5E and F).

## DISCUSSION

Non-resectable BTC is associated with a poor prognosis due to wide resistance to chemotherapeutic agents and radiotherapy. It is therefore essential to search for new therapeutical approaches<sup>[51]</sup>. In a recent study, analyzing tumor specimens from 57 patients with GBC, a strong immunoreactivity for IGF-1R was shown in 95%. IGF-1 and IGF-2 expression was detected in 45% and 25% of specimens, respectively<sup>[40]</sup>. Another study found IGF-1 and IGF-1R expression in all 18 examined biopsy samples of intrahepatic CC, whereas cholangiocytes of intrahepatic bile ducts of normal human liver were all negative<sup>[41]</sup>. Results of our own *in vitro* experiments support the co-expression of IGF receptor and its ligands IGF-1 and IGF-2. This co-expression, which is not a physiological state, leads to the assumption of an autocrine loop, rendering the IGF system a possible target for specific anti-cancer therapy of BTC.

Different approaches to inhibit IGF-1/-2 effects, at receptor or downstream levels, have already shown promising results in other studies. While IGF-1 neutralizing antibodies or IGF-binding proteins reduce ligand levels, strategies directed against IGF-1R employ receptor-specific antibodies which are mainly effective through degradation and downregulation of the receptor after binding, i.e. siRNAs, and small molecule tyrosine kinase inhibitors<sup>[5]</sup>. Several IGF-1R specific fully humanized monoclonal antibodies are currently already in phase II clinical trials (MK-0646 by Merck Oncology for solid tumors; AMG 479 by Amgen Oncology for Ewing's sarcoma, breast and pancreatic cancer; CP-751,871 by Pfizer Oncology for prostate cancer and NSCLC).

Our results for the small molecule tyrosine kinase inhibitor NVP-AEW541 showed a potent growth inhibition of BTC cell lines, supported by the low 3 d  $IC_{50}$

**Figure 5** *In vitro* treatment with drug combinations of NVP-AEW541 and gemcitabine, 5-fluorouracil (5-FU) or BI 2536. Selected cell lines EGI-1 and Mz-ChA-1 were incubated with increasing concentrations of gemcitabine (A, B), 5-FU (C, D) or BI 2536 (E, F) alone (black circles) and in combination with fixed IC<sub>20</sub> concentration of NVP-AEW541 (black triangles). The shaded area represents a possible drug synergism calculated according to the model of Berenbaum<sup>[50]</sup>; error bars represent SD (*n* = 3).

doses we determined. Although our results show different responses toward treatment between the groups of CC and GBC cell lines, comparable results have only been reported for acute myeloid leukemia<sup>[12]</sup>, medulloblastoma<sup>[17]</sup>, neuroblastoma<sup>[15,16]</sup>, Ewing's sarcoma<sup>[21]</sup>, fibrosarcoma cells<sup>[11]</sup>, and breast cancer cell line MCF-7<sup>[25]</sup> whereas IC<sub>50</sub> concentrations were much higher for ovarian cancer<sup>[22]</sup>, mesothelioma<sup>[26]</sup>, osteosarcoma<sup>[21]</sup>, synovial sarcoma<sup>[27]</sup>, neuroendocrine gastrointestinal tumor<sup>[33]</sup>, gastrointestinal stromal tumor<sup>[34]</sup>, pancreatic cancer<sup>[39]</sup>, hepatocellular carcinoma<sup>[31]</sup>, and colorectal cancer cells<sup>[35]</sup> (up to 50 μmol/L). However, the exact molecular mechanisms for these differences in response are still unclear. One factor might be the level of IRS-1<sup>[25]</sup>; other factors

might be mutations (e.g. of k-ras), and differences in replication time of cells.

Small molecule inhibitors act only by reducing IGF-1R activation and seem not to influence receptor expression. We were able to show the suppressive effect of NVP-AEW541 on phosphorylation of IGF-1R, while whole IGF-1R protein expression remained stable. At the same time, treatment with NVP-AEW541 did not result in significant upregulation of IGF-1 and IGF-2 levels. These results support treatment efficacy of NVP-AEW541.

Dephosphorylating effects on downstream targets p42/44 (thus reducing rate of proliferation) and AKT (thus increasing rate of apoptosis) were consistent with

previous studies (with the exception of consecutively activated p42/44 in cell line EGI-1)<sup>[11,12,15,21,26,28,34,35,39]</sup>.

The JAK/STAT (signal transducer and activator of transcription) signal cascade is another important pathway in oncogenesis in general<sup>[52]</sup>, and in the pathogenesis of CC in particular, since it has already been shown that upregulation of anti-apoptotic Mcl-1 (myeloid cell leukemia-1) by interleukin-6 depends on Stat-3 activation<sup>[53,54]</sup>. Moreover, RACK1 (receptor for activated C kinase 1) may be the adaptor for IGF-1R-mediated Stat-3 activation<sup>[55]</sup>. Moser *et al.*<sup>[39]</sup> recently reported a decrease of Stat-3 phosphorylation after blockade of IGF-1R in pancreatic cell line HPAF-II. In our own *in vitro* experiments, this effect was only seen in cell line EGI-1, but not in cell line MzChA-1.

Further results of our experiments showed that effects of NVP-AEW541 seem to be based mainly on an inhibition of cell growth, at least at low concentrations, while only high doses seem to trigger apoptosis. Although we could not detect any apoptosis by caspase-3 assay, levels of anti-apoptotic protein Bcl-xL decreased after treatment of MzChA-1 cells. In flow cytometry, the rate of apoptotic cells (sub-G1 peak) increased markedly at drug concentrations above 1  $\mu\text{mol/L}$ .

Another possible anti-cancer mechanism of NVP-AEW541, which was not examined in our experiments, might be the inhibition of angiogenesis, since it has been demonstrated that IGF-1 can induce expression of VEGF<sup>[9]</sup> and that NVP-AEW541 significantly reduces vascularization and VEGF expression in an *in vivo* mouse model for pancreatic cancer<sup>[39]</sup>. In addition, it has recently been shown that IGF-1R blockade reduces the invasiveness of gastrointestinal cancers *via* blocking production of matrilysin<sup>[37]</sup>.

Regarding the obviously different response rates of extrahepatic CC cell line EGI-1 and GBC cell line Mz-ChA-1, it is not easy to find a simple explanation. While a longer replication time and resistance to Stat-3 dephosphorylation would predict the lower response of Mz-ChA-1 cells to NVP-AEW541, it is unclear why resistance to dephosphorylation of p-p42/44 *via* k-ras mutation and resistance to Bcl-xL downregulation did not induce a lower response of EGI-1 cells to NVP-AEW541. Perhaps these factors have a different impact of contribution to resistance.

A possible side effect of NVP-AEW541 could be induction of diabetes due to the high homology of the kinase region of IGF-1R and the insulin receptor. While *in vitro* kinase assays showed a 27-fold selectivity of NVP-AEW541 towards IGF-1R<sup>[11]</sup>, a recent *in vivo* study found neither an increase of blood glucose level nor other side effects in treated animals<sup>[20]</sup>.

Since resistance against anti-cancer drugs evolves rapidly, a combination of different approaches seems necessary. The combined drugs should ideally tackle the cancer cells in different cell phases and use different modes of action. Gemcitabine and 5-FU are currently used as chemotherapy for BTC<sup>[56]</sup>. Gemcitabine is a nucleoside

analogue that is utilized instead of cytidine during DNA replication, leading to premature chain termination and subsequent apoptosis. While 5-FU is principally also a nucleoside analogue, its main effects are exerted through inhibition of thymidylate synthase and hence reduction of thymidine necessary for DNA replication. Both drugs affect cells mainly during S phase, while our flow cytometry experiments showed that treatment with NVP-AEW541 led to G1 phase arrest, leading to synergistic effects in combination with gemcitabine. In contrast, the combination with 5-FU was less effective, possibly derived from the facts that 5-FU in general seems to be less effective than gemcitabine in the treatment of BTC<sup>[56]</sup> and that 5-FU is more effective at reduced doses for extended periods of exposure<sup>[57]</sup>. Additionally, we tested the combination of NVP-AEW541 with BI 2536. Polo-like kinases are increasingly recognized as key regulators of mitosis, meiosis and cytokinesis<sup>[58]</sup> and have been implicated in the transformation of human cells<sup>[59]</sup>. BI 2536, a novel selective inhibitor of Plk-1, inhibits tumor growth *in vivo*<sup>[60]</sup>. The lack of synergistic effects of BI 2536 in combination with NVP-AEW541 may be attributed to the assumption that BI 2536 affects the M phase of the cell cycle, which occurs less frequently because of NVP-AEW541-mediated G1 arrest. Another promising combination therapy may be dual inhibition of IGF-1R and FAK (focal adhesion kinase) as has already been shown for the novel single small molecule inhibitor TAE226, which targets specifically both FAK and IGFR-1<sup>[61]</sup>. Further suggested combination partners are trastuzumab (HER-2 inhibitor) in HER-2 positive breast cancer<sup>[23]</sup>, erlotinib (EGF-R inhibitor)<sup>[38]</sup>, ICR62 (anti-EGF-R monoclonal antibody)<sup>[36]</sup>, and mammalian target of rapamycin inhibitor RAD001<sup>[13]</sup>.

In summary, our findings suggest that NVP-AEW541 is active against BTC *in vitro*. In addition, the compound potentiated the efficacy of gemcitabine. Based on this data, further preclinical and clinical evaluation of this new drug for the treatment of BTC is recommended.

## ACKNOWLEDGMENTS

The authors thank Annett Kluge and Ines Sommerer for technical assistance, Novartis Pharma for the provision of NVP-AEW541 and Boehringer-Ingelheim for the provision of BI 2536.

## COMMENTS

### Background

Carcinomas of the biliary tree are rare tumors of the gastrointestinal tract with a rising incidence worldwide for intrahepatic cholangiocarcinoma (CC) in recent years. At present, complete resection is the only potentially curative therapy, but most patients present with already advanced disease. In the palliative setting, non-resectable biliary tract cancer (BTC) is associated with a poor prognosis due to wide resistance to chemotherapeutic agents and radiotherapy.

### Research frontiers

Receptor tyrosine kinase inhibitors are currently under preclinical and clinical evaluation as new treatment options.

### Innovations and breakthroughs

After several years of preclinical research, the first clinical study data are now available for this tumor entity. Inhibitors of the epidermal growth factor receptor family, such as erlotinib, cetuximab, and lapatinib were recently investigated. Bortezomib, an inhibitor of the proteasome; imatinib mesylate, an inhibitor of c-kit; bevacizumab, an inhibitor of vascular endothelial growth factor (VEGF); and Sorafenib (BAY 43-9006), a multiple kinase inhibitor that blocks not only receptor tyrosine kinases but also serine/threonine kinases along the RAS/RAF/MEK/ERK pathway, have also been studied. Although early evidence of antitumor activity was seen, the results are still preliminary and require further investigations.

### Applications

The aim of the authors' study was to investigate the *in vitro* treatment with NVP-AEW541, a small molecule inhibitor of insulin-like growth factor-1 receptor (IGF-1R), in BTC. Their findings suggested that cell growth suppression was successful in seven human BTC cell lines. Combined with gemcitabine, NVP-AEW541 exerted synergistic effects, particularly at low concentrations, while effects of combinations with 5-fluorouracil or Polo-like kinase 1 inhibitor BI 2536 were only additive.

### Terminology

The IGF-1R system has emerged as an interesting target for cancer therapy, as it represents an important promoter of tumor transformation and survival of malignant cells, but is only partially involved in normal cell growth. This is in part attributed to interactions with oncogenes. Moreover, activation of IGF-1R may contribute to tumor angiogenesis by up-regulation of VEGF expression in certain cancer entities. In the past, different strategies were used to inhibit IGF-1R function, among them monoclonal antibodies and anti-sense RNA directed against the receptor, or recombinant IGF binding proteins and IGF-specific antibodies to reduce levels of ligands.

### Peer review

The strength of this manuscript is that it characterized a highly-resistant BTC cell line in comparison with an extrahepatic CC cell line. Also, to some extent, the mechanism leading to the resistance was examined.

### Abstract

**AIM:** To investigate whether probiotic bacteria, given perioperatively, might adhere to the colonic mucosa, reduce concentration of pathogens in stools, and modulate the local immune function.

**METHODS:** A randomized, double-blind clinical trial was carried out in 31 subjects undergoing elective colorectal resection for cancer. Patients were allocated to receive either a placebo (group A,  $n = 10$ ), or a dose of  $10^7$  of a mixture of *Bifidobacterium longum* (BB536) and *Lactobacillus johnsonii* (La1) (group B,  $n = 11$ ),

or the same mixture at a concentration of  $10^9$  (group C,  $n = 10$ ). Probiotics, or a placebo, were given orally 2 doses/d for 3 d before operation. The same treatment continued postoperatively from day two to day four. Stools were collected before treatment, during surgery (day 0) and 5 d after operation. During the operation, colonic mucosa samples were harvested to evaluate bacterial adherence and to assess the phenotype of dendritic cells (DCs) and lymphocyte subsets by surface antigen expression (flow cytometry). The presence of BB536 and La1 was evaluated by the random amplified polymorphism DNA method with specific polymerase chain reaction probes.

**RESULTS:** The three groups were balanced for baseline and surgical parameters. BB536 was never found at any time-points studied. At day 0, La1 was present in 6/10 (60%) patients in either stools or by biopsy in group C, in 3/11 (27.2%) in group B, and none in the placebo group ( $P = 0.02$ , C vs A). There was a linear correlation between dose given and number of adherent La1 ( $P = 0.01$ ). The rate of mucosal colonization by enterobacteriaceae was 30% (3/10) in C, 81.8% (9/11) in B and 70% (7/10) in A ( $P = 0.03$ , C vs B). The *Enterobacteriaceae* count in stools was 2.4 (log<sub>10</sub> scale) in C, 4.6 in B, and 4.5 in A ( $P = 0.07$ , C vs A and B). The same trend was observed for colonizing enterococci. La1 was not found at day +5. We observed greater expression of CD3, CD4, CD8, and naive and memory lymphocyte subsets in group C than in group A with a dose response trend (C > B > A). Treatment did not affect DC phenotype or activation, but after *ex vivo* stimulation with lipopolysaccharides, groups C and B had a lower proliferation rate compared to group A ( $P = 0.04$ ). Moreover, dendritic phenotypes CD83-123, CD83-HLADR, and CD83-11c (markers of activation) were significantly less expressed in patients colonized with La1 ( $P = 0.03$  vs not colonized).

**CONCLUSION:** La1, but not BB536, adheres to the colonic mucosa, and affects intestinal microbiota by

reducing the concentration of pathogens and modulates local immunity.

## INTRODUCTION

Probiotics are mono or mixed cultures of live microorganisms that might beneficially affect the host by improving the characteristics of indigenous microflora<sup>[1]</sup>. The composition and the equilibrium of microbiota are known to influence important host activities, including the local immune response and several intestinal metabolic traits<sup>[2-5]</sup>.

For therapeutic purposes, probiotics should have certain features: to be of human origin, safe for the host, and genetically stable<sup>[1,6]</sup>. Furthermore, it is important that probiotics, in order to be active, survive passage through the gastrointestinal (GI) tract irrespective of gastric acids, pancreatic enzymes, and bile acids so that they can reach the ileum and colon and colonize the intestinal mucosa and stools<sup>[6,7]</sup>.

Although the effects of probiotic administration has been intensively investigated *in vitro*, in animal models, in healthy volunteers, and in some human GI diseases (i.e. inflammatory bowel diseases, alimentary allergy, infectious diarrhea, and pouchitis)<sup>[1-6]</sup> very little is known on the possible cross-interactions among probiotic administration, changes of intestinal flora, and local immune response in surgical patients. Probiotic administration in patients undergoing GI operations has been attempted to obtain a competitive action on microbiota that contain bacteria responsible for postoperative infections. The results of randomized clinical trials (RCTs) are inconsistent with significant reduction of infection rate in upper GI surgery<sup>[8-10]</sup> and show a lack of clinical benefits in other types of operations and clinical settings<sup>[11-13]</sup>. This might be due to the substantial differences in study design, probiotic dose and strain, duration, period and combination of treatments, and particularly, the paucity of preliminary phase II studies investigating in detail

the relationship between probiotics and changes in intestinal pathophysiology.

The objectives of the study were to investigate whether peri-operative probiotic bacteria could adhere to the colonic mucosa, to assess whether this treatment could change the gut microflora by reducing potentially pathogenic bacteria, and whether the gut immune response could be modulated in a selected cohort of patients undergoing colorectal resection for cancer.

## MATERIALS AND METHODS

This was a prospective, randomized, controlled, double-blind trial of three groups in parallel. The study was carried out in two university hospitals (Department of Surgery, San Gerardo Hospital, Milano-Bicocca University, Monza, Italy and Department of Surgery, San Raffaele Hospital, Vita e Salute University, Milan, Italy).

### Patient enrolment

Eligible patients were those with histological documentation of cancer of the colon or rectum. Inclusion criteria were: both genders, age between 18 and 80 years and candidate for elective colorectal resection. The exclusion criteria were: denied written informed consent, no collection of a stool sample 4 d before the operation, unresectable tumor, neoplastic ascitis, clinically relevant pulmonary, cardiovascular, hepatic and kidney dysfunction or failure, ongoing total parenteral nutrition, immunological disorders, ongoing or recent infections (within last 30 d), pregnancy, and participation to another clinical trial. After applying these criteria, patients were allocated by an individual random number into three study arms.

Concealment assignment was by central randomization by computer. Both probiotic and placebo preparations were in foil sealed sachets that were stored in identical numbered containers. The study products and the placebo were both white powders, identical in weight, smell, and taste. Thus, the identity of the specific product was blind to participants, support staff and investigators for the entire duration of the study period.

Individually numbered treatment packs were allocated to the subjects as per the randomization schedule. Randomization was done by a program trial balance. Balancing variables were sex (male and female) and age (18-54 years and 55-80 years). All data captured by the investigator were recorded directly on the case report forms (CRF). Data entering, from CRFs into a computer database, was blinded. The blind codes were broken after all the collected data were analyzed. All data were analyzed by intention-to-treat.

The Ethical Committees of both hospitals approved the protocol.

The trial was registered at ClinicalTrial.gov of the National Institute of Health with the identifier number NCT00936572.

### Procedures and treatment

Four days before the scheduled surgery, subjects were randomly assigned to one of three groups: Placebo ( $n = 10$ ); oral treatment with low dose of probiotics every 12 h [total dose:  $2 \times 10^7$  colony forming units (CFU)/d,  $n = 11$ ]; oral treatment with high dose of probiotics ( $2 \times 10^9$  CFU/d,  $n = 10$ ). Treatments were composed of a mixture 1:1 of *Lactobacillus johnsonii* (*L. johnsonii*) (*La1*) and *Bifidobacterium longum* (*B. longum*) (*BB536*) in spray-dried form and blended with maltodextrin. The placebo was maltodextrin only. Both probiotics and placebo were mixed in 100 mL of a nutritional supplement (Clinutren 1.5, Nestle Nutrition, Milan, Italy) before drinking. All groups received treatments or placebo for three consecutive days before surgery (from day -3 to day -1 included). Treatments or placebo resumed postoperatively on day +2 until day +4 for a total of 6 d of treatment (12 doses).

Two mucosal samples were collected during surgery for probiotic adherence testing, microbiological evaluation of microbiota, and immune parameters. Stool samples were collected before treatment initiation (day -4), during surgery (day 0) and postoperatively at day +5 and analyzed as described below.

All patients received a single dose of prophylactic antibiotic (Cefoxitin, single dose, 30 min before incision).

Bowel preparation was done by an isosmotic solution (Macrogol; 3L) the evening before operation after the last preoperative dose of probiotics.

### Microbiological analysis of feces and mucosa

Weighed feces samples and mucosa (1 g) were homogenized for 1.5 min in a stomacher (PBI, Milan, Italy) before dilution in saline solution (9 g/L NaCl). Appropriate dilutions were plated using Rogosa Acetate agar (Difco) to enumerate *Lactobacillus* spp. *Bifidobacteria* isolates were enumerated using BSM media (MRS Broth, Bacto agar, Difco), 0.5 g/L of L-Cysteine Hydrochloride (Merck), while *Enterobacteriaceae* were counted on MacConkey Agar (Oxoid), enterococci on Bile Esculin Azide agar (Oxoid), and *Clostridium perfringens* (*C. perfringens*) was counted on Neomycin Nagler Agar (Eiken Chemical Co., Tokyo). Plates for *Enterobacteriaceae* and enterococci were incubated at 37°C for 24 h aerobically while *lactobacilli*, *bifidobacteria* and *C. perfringens* were incubated at 37°C for 48 h in anaerobic jars (GasPak, BBL, Coskeysville, MD, USA).

Counts of the CFU were performed for all countable plates (containing 30-300 CFU). Randomly selected CFU of *lactobacilli* and *bifidobacteria* (about 15% of colonies counted on readable plates) were isolated and cultivated in MRS broth and MRS broth with 0.5 g/L of L-Cysteine Hydrochloride, respectively to identify the *L. johnsonii* and *B. longum* species, and subsequent the identification of *La1* and *BB536* strains.

### DNA extraction

An overnight culture was collected by centrifugation at 5000 r/min for 10 min, the pellet was dissolve in 1 mL 0.9%

NaCl and transferred to a tube containing 0.5 g of glass beads (Sigma, St. Louis, Mo.). Cell lysis was performed with the Mini-Beadbeater (Biospec product) for three min at maximum speed. Subsequently, the suspension was centrifuged for five min at 10000 r/min and 1  $\mu$ L of the supernatant was used directly for polymerase chain reaction (PCR).

### Species identification

Detection of *L. johnsonii* isolates was performed with primers LJ1 (GATGATTTAGTTCTTGCACTAA) and P6 (CTACGGCTACCTTGTTACGA) using conditions described by Ventura *et al.*<sup>[14]</sup>, while *B. longum* isolates were detected with primers Blon1 (5'-TTCCAGTTGATCGCATGGTC-3') and Blon2 (5'-GGGAAGCCGTATCTCTACGA-3') with conditions described by Mullié *et al.*<sup>[15]</sup>. All amplification reactions were performed in a total volume of 25  $\mu$ L containing 200  $\mu$ mol/L of each deoxynucleoside triphosphate, 2.5 U of *Taq* (Gold), 10 pmol of each primer, and 1  $\mu$ L of the respective template DNA (which equaled about 20 ng of DNA). The PCR reactions were carried out in a Gene Amp 9700 thermal cycler (Applied Biosystem, Foster City, USA). The resulting amplicons were visualized under UV light in 1% and 1.5% (w/v) agarose (Bio-Rad Laboratories, Milan, Italy) electrophoresis gels, respectively for *L. johnsonii* and *B. longum*, followed by subsequent 0.5  $\mu$ g/mL ethidium bromide staining.

### Genetic identification of La1 and BB536 strains

Detection of *L. johnsonii La1* strains was performed using the primers NCCE722 (GCATCATGCCCTT-GAGTAGC) and NCCE723 (AATGCCCACTTTTT-GGCCTC) while the *B. longum BB536* strains detection was carried out using the primers NCC3001-A (5'-GAA-CAGGGTGTGCTGAGTGA-3') and NCC3001-B (5'-CAAGCGAGAAGATCATCGAA-3'), both of them provided by Nestec Ltd. All amplification reactions were carried out in a total volume of 25  $\mu$ L containing 200  $\mu$ mol/L of each deoxynucleoside triphosphate, 2.5 U of *Taq* (Gold), 10 pmol of each primer, and 1  $\mu$ L of the respective template DNA. The PCR reactions were carried out in a Gene Amp 9700 thermal cycler. Amplification cycle for *La1* was as follows: initial denaturation was performed at 94°C for five min, followed by 35 cycles of: 94°C for 30 s, 53°C for 30 s and 68°C for 1 min, and a final extension at 68°C for 7 min. The conditions for *BB536* were: 94°C for five min, followed by 30 cycles of: 94°C for 30 s, 60 for 30 s and 72°C for 30 s, and a final extension at 72°C for 5 min. The 540 bp *La1* PCR products were analyzed on 1.5% (w/v) agarose gels, while the 461 bp *BB536* PCR products were analyzed on 1.5% (w/v) agarose gels, both at 80 V, using a 200 bp ladder (Promega Corporation, Madison, USA) for molecular weight standards.

### Extraction and identification of dendritic cells (DCs) and lymphocytes

Colon DCs and lymphocytes were isolated from specimens

of healthy mucosa (> 10 cm from neoplasm) as previously described<sup>[16]</sup>. Briefly, after surgical excision of the colon, samples of mucosa and submucosa were separated mechanically from the muscular tunicae. Filtration through nylon mesh was used to isolate enterocytes. The enterocytes were discarded, and the remaining tissue was resuspended in medium with enzymes (liberase, DNAase, and hyaluronidase). The solution was centrifuged and the cells (containing lamina propria DCs and lymphocytes) were resuspended in HBSS before separation on a Percoll gradient. The Percoll gradient allowed separation of the lamina propria DCs from lymphocytes. Cells were washed with phosphate buffered saline and their phenotype was analysed by fluorescence activated cell sorter analysis.

DC and lymphocyte phenotypes were analyzed using antibodies to surface markers (CD11c: dendritic myeloid; CD123: dendritic plasmacytoid; CD HLA-DR: dendritic activated; CD83: dendritic mature; CD3: T cells; CD4: T helper; CD8: T suppressor; CD19: B cells; CD45RA: T naive; and CD45RO: T memory).

**Statistical analysis**

Discrete parameters, such as rate of colonization and adherence, were analyzed by a  $\chi^2$  test or Fisher's exact test. The Sidak procedure was used to correct for multiple testing.

The count of bacteria and the other continuous variables were compared and analyzed using non-parametric tests (Kruskal-Wallis and Wilcoxon tests) or using ANOVA after log10 transformed of the data.

The dose effect on *La1* colonization was tested by the Cochran-Mantel-Hanzel test for a linear trend.

We also adopted another approach on data grouping according to *La1* colonization by dividing colonized patients (*La1+*) from non-colonized (*La1-*), regardless of dose or treatment.

Categorical variables are described by frequency, while continuous variables by mean  $\pm$  SD.

**RESULTS**

A total of 49 patients were eligible for the study. Due to exclusion criteria, 31 patients were randomized, completed the study, and were analyzed on an intention-to-treat basis (Figure 1). The three groups were well balanced for baseline characteristics and surgical procedures, as shown in Table 1.

**Microbiology**

Before treatment (day -4) none of the patients was colonized by *La1* or *BB536*. The effect of treatments on microbiota is shown in Table 2.

At day 0, the group receiving the high dose had a rate of adherence of 60% (6/10) *vs* 27.2% (3/11) of the low dose groups and none in the placebo group ( $P = 0.02$  high dose *vs* placebo). Moreover, there was a significant linear positive correlation ( $P = 0.01$ ) between the number

of adherent *La1* and the dose given (data not shown). *BB536* was never found in mucosa and feces samples. We also evaluated the changes in count of enterobacteriaceae and enterococci. We observed that the group of patients receiving the high dose of probiotics had a lower count of enterobacteriaceae in stool samples than the groups treated with the low dose or placebo ( $P = 0.07$ ). The same trend was observed for the enterococci count. The percent of patients with enterobacteriaceae adherent to colonic mucosa was 30% (3/10) in the high dose group, 81.8% (9/11) in the low dose group, and 70% (7/10) in the placebo group ( $P = 0.03$  high dose *vs* low dose). Similar results were observed for enterococci adherence rate, but without reaching statistical significance among the groups ( $P = 0.372$ ).

On postoperative day five, we didnot observe

	Placebo (n = 10)	Low dose (n = 11)	High dose (n = 10)

<sup>a</sup>P = 0.004 vs unchanged/increased.

colonization/adherence in any of the three groups, for both *La1* and *BB536*.

Specific stool cultures for *Clostridium perfringens* were always negative for both mucosa and stools in all three groups.

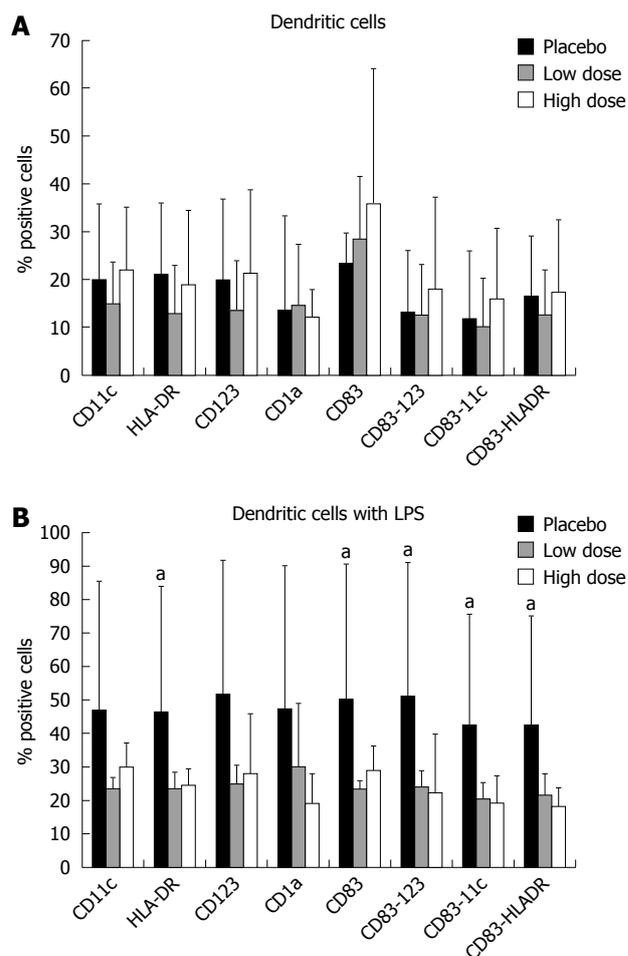

We also compared, regardless of treatment, patients who had colonization/adherence with *La1* (*La1+*) with those who did not have any *La1* adherence (*La1-*) (Table 3).

By comparing day -4 to day 0, we found that only *La1+* patients had a decrease (at least 1 log) of enterococci ( $P = 0.004$ ) and of enterobacteriaceae colonization ( $P = 0.06$ ).

### Immunology

On day 0, the *ex-vivo* analysis of intestinal DC phenotypes did not show any significant variation with respect to the type of treatment (Figure 2A). When DC were stimulated *in vitro* with lipopolysaccharide (LPS), there was a significant increase in proliferation of HLA-DR, CD83, CD83-123, CD83-11c, and CD83-HLA-DR subsets in the placebo group compared to the high dose and low dose groups. The same trend was observed for the other subsets, but without reaching a statistical difference (Figure 2B).

The Log number of dendritic subsets for CD83-123, CD83-11c, and CD83-HLADR was plotted in a linear correlation analysis with the total Log number of enteric bacteria in the stools, which includes also probiotics

**Figure 2** Percent of positive dendritic cell subsets of the three groups. A: *Ex vivo* analysis; B: *In vitro* analysis after lipopolysaccharide (LPS) stimulation. <sup>a</sup>Minimum  $P = 0.04$  vs low and high dose.

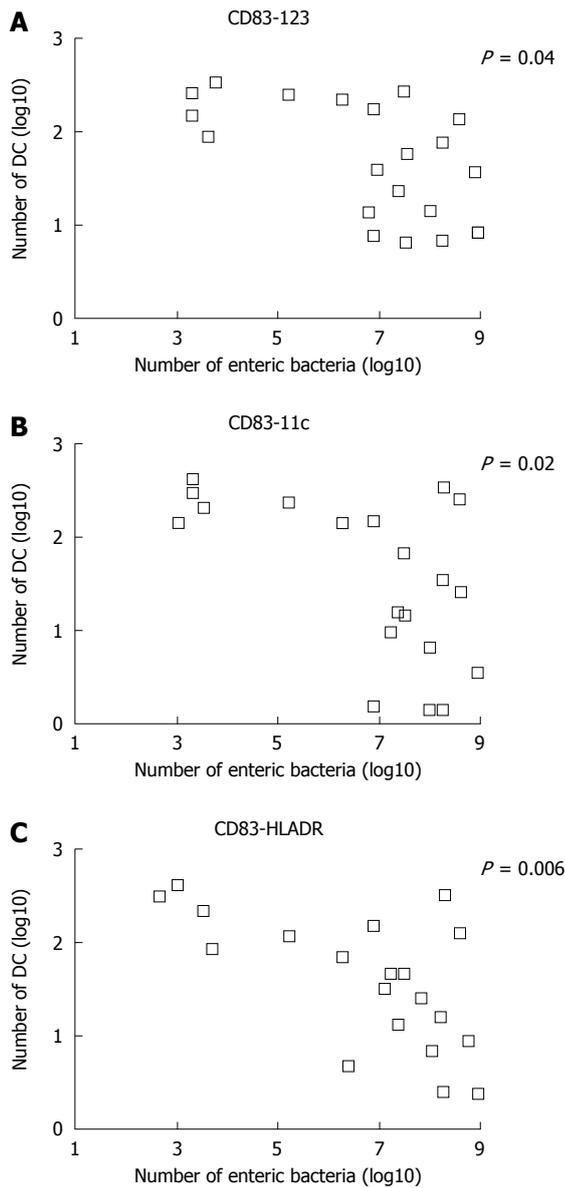

given. The analysis showed a significant inverse correlation between these two parameters (Figure 3).

By grouping patients according to colonisation (*La1+* vs *La1-*), we observed that those subjects with *La1* adherence to colonic mucosa (*La1+*) had a significant blunted proliferation of CD83-123, CD83-11c, and CD83-HLA-DR subsets compared to *La1-* (Figure 4).

The *ex-vivo* analysis of lymphocytes suggested the ability of probiotics to stimulate a non-specific proliferation of all subsets, with the exception of CD19 (B cells). The increased percent of positive cells also seemed dependent on the dose of probiotics given (Figure 5A). However, these variations did not reach statistical significance. LPS stimulation of lymphocytes did not affect T cell proliferation (Figure 5B).

## DISCUSSION

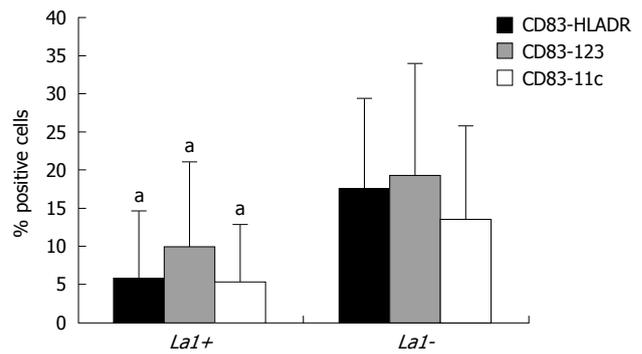

To our knowledge, this is the first clinical trial investigating the *in vivo* interaction among probiotic administration, variation of microbiota, and modulation of intestinal immune function in patients undergoing colorectal resection for cancer. This type of study might be important to better understand the potential mechanisms

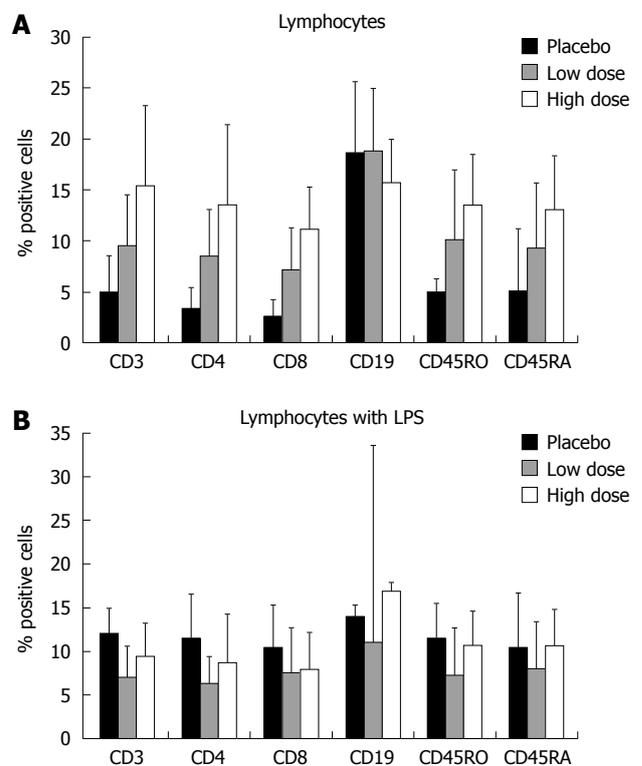

**Figure 3** Correlation between number of colonic dendritic cells (DCs) and number of bacteria in feces. A: Phenotype CD83-123; B: Phenotype CD83-11c; C: Phenotype CD83-HLADR.

of action of probiotics and subsequently to design appropriate and safe phase III trials with relevant clinical endpoints. Our data suggest that of *La1* (but not *BB536*) administered pre-operatively, is somehow able to adhere to colonic mucosa and colonize feces. This event seems to be correlated with a reduction of potentially pathogenic bacteria and modulation of the intestinal immune response. The dose given and the time of administration with respect to the operation appear to be key factors in obtaining these results.

Probiotic is a generic term that includes several species of bacteria. However, probiotic strains differ greatly in their mechanisms of action, survival during GI transit, modulation of intestinal metabolism, ability to affect the type of immune response, and competition with microbiota and pathogens<sup>[2,6]</sup>. Most of the data available are from animal or *in vitro* studies. Furthermore,

**Figure 4** Percent of positive subsets of DCs in *Lactobacillus johnsonii* (*La1*) colonized patients (*La1+*) vs non-colonized patients (*La1-*). <sup>a</sup>Minimum  $P = 0.03$  *La1+* vs *La1-*.

the same probiotic strain might have dissimilar clinical effects and efficacy in different GI illnesses, and a specific disease might not be successfully treated by different probiotics<sup>[2,6,17]</sup>.

We decided to test a mixture of two probiotics (*La1* and *BB536*) because they have been previously and repeatedly shown to have positive effects, such as safety for clinical use, non-pathogenicity, genetic stability, survival during GI transit<sup>[18]</sup>, antimicrobial properties, competitive antagonism with pathogens<sup>[19,20]</sup>, and the ability to modulate the intestinal immune system<sup>[21-24]</sup>. In particular, *BB536* has been shown, in single arm studies, to survive during intestinal passage and reach the colon intact, even though the experimental setting was different from ours<sup>[25]</sup>. These characteristics should make

these probiotics suitable for testing in a trial with patients who are candidates for colorectal resection, because infectious complications are usually sustained by the subject's own intestinal microbiota, more frequently than in other types of operation. *In vivo*, potential synergistic or antagonistic effects between these two probiotics are unknown in this kind of patients.

We believe that it is essential to have a comprehensive knowledge of the potential positive and negative interactions between defined probiotic strains and the host before designing a trial with a therapeutic strategy, such as reduction of surgical morbidity. This might avoid negative results or worse outcomes in specific clinical conditions, such as severe pancreatitis where the deleterious effect of probiotics on oxygen intestinal metabolism was not fully investigated a priori<sup>[13]</sup>.

Several RCTs tested such therapeutic strategies in surgery. They have been recently reviewed by van Santvoort *et al.*<sup>[26]</sup>. In most of these trials, synbiotics rather probiotics were used; the majority of the enrolled patients were candidates for hepato-biliary-pancreatic surgery, liver transplantation, or mixed cases. Most of the protocols were designed for exclusively postoperative treatment. Moreover, among these studies there were large variations of probiotic strain and dose, timing, duration, and route (oral *vs* enteral) of administration. Only one trial by Reddy *et al.*<sup>[27]</sup> was selective for colorectal patients. They reported a synergistic positive effect of synbiotics, neomycin, and bowel preparation on the prevalence of enterobacteriaceae colonization and bacterial translocation, but these events were not associated with a significant reduction of septic morbidity. The different trial characteristics make it quite difficult to compare them and draw any firm conclusion on efficacy.

Our trial suggest that the rate of preoperative colonic adherence and colonization by *La1* was suboptimal, reaching 60% with the higher dose tested, while *BB536* was never recovered. Several factors might explain these results: all patients underwent bowel preparation, which might affect transit time and peristalsis, thereby reducing the capability of probiotics to adhere. In fact, it has been shown that preoperative intestinal washout might cause loss of superficial mucus and epithelial cells<sup>[28]</sup>. Other factors might have been the dose ( $10^9$  not being enough), the preoperative timing of administration being too short, and the strains tested (particularly *BB536*) not being ideal in this type of patient. In any case, we did observe a reduction of pathogens and a modulation of the intestinal immune system in *La1* colonized patients. Moreover, we did not observe colonization and survival of both probiotics in the post-operative period. Our explanation is based on two hypotheses. First, the tolerance of probiotic administration in the postoperative period was quite low (less than 50%), in contrast to the tolerance of the pre-operative period (100%). This might explain why we could not recover live probiotics at day five postoperatively. Second, it might be due to the presence of postoperative ileus. This condition slows down

the GI transit time and increased residence in the lumen might have killed the probiotics.

Animal and *in vitro* data strongly suggest that probiotics possess the ability to modulate the intestinal and systemic immune response<sup>[1-5]</sup>. DCs are bone-marrow-derived "professional" antigen-presenting cells. They can acquire antigens and then interact with lymphocyte populations. The different response after DCs - T cell cross talk is influenced by several factors, including the phenotype of DC and signals received in the local environment. Specific intestinal DCs acquire, on activation, signals that might drive the development of Th1, Th2, T regulatory, or Th0 cell responses<sup>[29]</sup>. The nature of T cell polarization is largely dependent on the type of microbial products. In particular, specific strains of lactobacilli, including *La1*, can modulate DC and T-cell specific responses *via* the release of anti-inflammatory cytokines<sup>[21]</sup>. This might explain the beneficial effect of probiotic treatment of a number of inflammatory bowel diseases, such as alimentary intolerance or allergy, infectious diarrhea, and pouchitis in Crohn's disease<sup>[30-34]</sup>. Our data agree with the above findings and suggest that administration of probiotics can partially affect intestinal DC phenotype and activation. In fact, we observed an *in vivo* inverse correlation between number of enteric bacteria in feces (including probiotics administered) and number of mature and activated intestinal DCs. Thus, increases in microbiota appear to be correlated with a significant decrease of specific DC subsets. When DCs were stimulated "*ex vivo*" with LPS, only in placebo patients did we observe an enhanced ability of DCs to proliferate. Moreover, DCs isolated from patients colonized with *La1* had a significantly blunted ability to proliferate. Although speculative, there results suggest that increasing the probiotic concentration in stools might modulate the immune activity of DCs. In particular, it is possible that probiotics might avoid an excessive activation of DCs with a possible Th1 driven pro-inflammatory response in the intestinal mucosa. In fact, DCs isolated from subjects receiving probiotics were not able to respond to a second inflammatory challenge, such as LPS.

We also observed an unexpected non-specific *in vivo* proliferation of all lymphocyte subsets, with the exception of B cells, in the patients receiving probiotics. This effect also appeared to be dose dependent. We speculate that in this specific setting, lymphocytes might have been activated by immune pathways that we did not investigate, such as through monocyte or epithelial cell cross talk<sup>[35,36]</sup>.

The clinical significance and impact of these observations remain to be elucidated. However, the results suggest a role for probiotics in blunting a surgery-induced over-inflammatory response at intestinal and distant sites<sup>[37]</sup>.

In conclusion, our data suggest that *La1*, but not *BB536*, adheres to the colonic mucosa and colonizes stools, affects intestinal microbiota by reducing the con-

centration of pathogens, and modulates local immunity. Further trials are warranted to understand if, in this cohort of patients, better results might be obtained by different single probiotics or by a mixture of probiotic strains, increased dose, longer treatment period or timing of administration. The results of these future trials should be taken into consideration before designing phase III trials.

## COMMENTS

### Background

The therapeutic use of probiotic bacteria is generating great interest in several diseases, but extensive research is required to understand when their administration is really beneficial.

### Research frontiers

The administration of probiotics in patients undergoing resection for colon cancer has been tested for safety and efficacy.

### Innovations and breakthroughs

The results of the present work suggest that giving probiotics before colon surgery might reduce the number of enteric bacteria that might be responsible for postoperative infectious complications. Moreover, probiotics are able to modulate the immune response of the intestine and there is an intensive cross-talk between immune cells and bacteria.

### Applications

These data should be useful to design future clinical studies with a larger number of patients to understand if there is a correlation between metabolic, immunological and microbiological changes and reduction of surgery-related infections.

### Terminology

Probiotics: Mono or mixed cultures of live microorganisms that might beneficially affect the host by improving the characteristics of indigenous microflora.

### Peer review

This is the first clinical trial investigating *in vivo* the interaction among probiotic administration, variation of microbiota, and modulation of intestinal immune function in patients undergoing colorectal resection for cancer. Such studies might be important to better understand the potential mechanisms of action of probiotics and subsequently to design appropriate and safe trials with relevant clinical endpoints.

locus (IGR2198a\_1 rs11739135 and IGR2096a\_1 rs12521868), *CARD15* (R702W rs2066845 and L1007fs rs2066847), *ATG16L1* (rs2241880) and *IL23R* (rs1004819, rs2201841) genes were genotyped by PCR-RFLP, the G908R (rs2066844) in *CARD15* was determined by direct sequencing.

**RESULTS:** The association of *ATG16L1* T300A with CD was confirmed [ $P = 0.004$ , odds ratio (OR) = 1.69, 95% CI: 1.19-2.41], and both *IL23R* variants were found to represent significant risk for the disease ( $P = 0.008$ , OR = 2.05, 95% CI: 1.20-3.50 for rs1004819 AA;  $P < 0.001$ , OR = 2.97, 95% CI: 1.65-5.33 for rs2201841 CC). Logistic regression analysis of pairwise interaction of the inflammatory bowel disease (IBD) loci indicated that *IL23R*, *ATG16L1*, *CARD15* and *IBD5* (IGR2198a\_1) contribute independently to disease risk. We also analysed the specific combinations by pair of individual *ATG16L1*, *IL23R* rs1004819, rs2201841, IGR2198a\_1, IGR2096a\_1 and *CARD15* genotypes for disease risk influence. In almost all cases, the combined risk of susceptibility pairs was higher in patients carrying two different risk-associated gene variants together than individuals with just one polymorphism. The highest OR was found for *IL23R* rs2201841 homozygous genotype with combination of positive *CARD15* status ( $P < 0.001$ , OR = 9.15, 95% CI: 2.05-40.74).

**CONCLUSION:** The present study suggests a cumulative effect of individual IBD susceptibility loci.

### Abstract

**AIM:** To investigate the interaction of interleukin-23 receptor (*IL23R*) (rs1004819 and rs2201841), autophagy-related 16-like 1 (*ATG16L1*) (rs2241880), caspase recruitment domain-containing protein 15 (*CARD15*) genes, and *IBD5* locus in Crohn's disease (CD) patients.

**METHODS:** A total of 315 unrelated subjects with CD and 314 healthy controls were genotyped. Interactions and specific genotype combinations of a total of eight variants were tested. The variants of *IBD5*

## INTRODUCTION

Two main clinical presentations of inflammatory bowel disease (IBD) are Crohn's disease (CD) and ulcerative colitis (UC)<sup>[1]</sup>. IBD is now widely believed to originate from an uncontrolled mucosal immunity of the gastrointestinal tract<sup>[2]</sup>. Twin and family studies have reported that besides environmental factors genetic susceptibility is essential in IBD development<sup>[3]</sup>. Up to now, many novel candidate genes have been found to confer increased risk for the disease, some loci seem to be specific to CD or UC, others have been reported to confer susceptibility to IBD overall; at the moment the most replicated loci are interleukin-23 receptor (*IL23R*) and autophagy-related 16-like 1 (*ATG16L1*).

Duerr *et al*<sup>[4]</sup> identified *IL23R* gene as an IBD-associated gene in a genome-wide association study. Subsequent genome-wide association studies provided replication and confirmed the role of *IL23R* in CD<sup>[5-7]</sup>.

In a European genome-wide association study the coding variant T300A (rs2241880) within the *ATG16L1* gene was reported to be highly associated with CD, and to carry the whole disease risk exerted by this locus<sup>[8]</sup>. The association of *ATG16L1* gene and CD was replicated in numerous studies<sup>[9-12]</sup>. *IL23R* and *ATG16L1* T300A were also proved to be risk variants in the Hungarian CD population<sup>[13]</sup>.

The rising number of CD candidate genes gives us the possibility to evaluate gene-gene interactions among susceptibility genes. Playing a role in biomolecular mechanisms, these interactions, or epistases are ubiquitous features of the genetic architecture of common human diseases<sup>[14]</sup>; their existence has been proved by several studies<sup>[15-17]</sup>. Since gene-gene interactions cannot only enhance but also weaken the individual gene effects, which can explain the lack of replication of single-locus results<sup>[14,18]</sup>, complex gene-gene interactions may be considered more important than independent effects of single susceptibility genes.

Therefore our aim was to join the major susceptibility genes into a gene-gene interaction analysis in the Hungarian CD population: two *IL23R* gene risk variants, namely the intronic rs2201841 and rs1004819, the *ATG16L1* gene variant T300A, the three well-known SNPs (R702W, L1007fs and G908R) of caspase recruit-

ment domain-containing protein 15 (*CARD15*) gene and two markers located in *IBD5* (IGR2198a\_1 and IGR2096a\_1) were tested for statistical interaction.

## MATERIALS AND METHODS

### Patients

We examined 315 unrelated patients with CD (151 males, 164 females, mean age 38.65 ± 0.79 years). The CD group included mixed Caucasian patients who had typical symptoms and diagnosis. A group of 314 clinically healthy subjects (170 males, 144 females, mean age 40.8 ± 0.80 years) with no IBD or other autoimmune disease were collected for the study. The origin of DNA samples was the central Biobank governed by the University of Pecs, as part of the National Biobank Network of Hungary ([www.biobank.hu](http://www.biobank.hu)), which belongs also to the pan-European Biobanking and Biomolecular Resources Research Infrastructure preparatory phase project (<http://bbmri.eu/bbmri/>). The governance, maintenance and management principles of the Biobank had been approved by the national Scientific Research Ethics Committee, Budapest (ETT TUKEB).

During the entire investigation period the guidelines and regulations of the 1975 Helsinki Declaration and the currently operative national laws were followed; the patients gave their informed consent for use of their collected, anonymized DNA samples for research purposes.

### Genotyping

Genomic DNA was extracted from peripheral blood leukocytes with a routine salting out method. For genotyping the variants of *IBD5* locus (IGR2198a\_1 rs11739135 and IGR2096a\_1 rs12521868), *CARD15* (R702W rs2066845 and L1007fs rs2066847), *ATG16L1* (rs2241880) and *IL23R* (rs1004819, rs2201841) genes PCR-RFLP methods were applied, the primers designed and used are given in Table 1. The PCR amplifications were performed on MJ Research PTC-200 thermal cyclers (Bio-Rad, Hercules, CA, USA) using the following conditions: initial denaturation at 96°C for 2 min followed by 35 cycles of denaturation at 95°C for 30 s, annealing for 45 s at 54°C (rs1004819), 55°C (rs2241880 and rs2201841), 58°C (rs11739135, rs12521868), 60°C (rs2066847), and 62°C (rs2066845), extension at 72°C for 45 s and final extension at 72°C for 5 min. Each polymerase chain reaction contained 200 µmol/L of each dNTP, 1 U of *Taq* polymerase, 5 µL of reaction buffer (100 mmol/L Tris HCl, pH = 9.0; containing 500 mmol/L KCl, 15 mmol/L MgCl<sub>2</sub>), 0.2 µmol/L of each primer and 1 µL DNA to be amplified in a final volume of 50 µL. The amplicons were digested by allele-specific restriction endonucleases *Hin1* II (rs11739135), *Tru1* I (rs12521868), *HinP1* I (rs2066845), *Bsp1* I (rs2066847), *Lwe* I (rs2241880), *Taa* I (rs1004819) and *Hpy*F3 I (rs2201841). The amplicon contained an obligate cleavage site of the restriction enzyme for the suitable

<sup>1</sup>Mismatch bases are underlined. F: Forward; R: Reverse; *IL23R*: Interleukin-23 receptor; *ATG16L1*: Autophagy-related 16-like 1; *CARD15*: Caspase recruitment domain-containing protein 15.

visual control of the efficacy of the digestion. The restriction fragments were separated by electrophoresis on 3% agarose gels containing ethidium bromide and visualized by UV transillumination. The genotyping of G908R (rs2066844) in *CARD15* was carried out by direct sequencing by BigDye Terminator labelling with ABI 3100 automatic sequencer (Foster City, CA, USA).

### Statistical analysis

Statistical analysis was carried out using the SPSS 15.0. package for Windows (SPSS Inc., Chicago, IL, USA). The allele frequencies were compared with Pearson's  $\chi^2$  test. Haploview 4.1 was used to test linkage disequilibrium. The  $r^2$  values for *IGR2198a\_1* and *IGR2096a\_1*; and for *IL23R* rs1004189 and rs2201841 were below 0.8 ( $r^2 = 0.63$  and  $r^2 = 0.62$ , respectively). Binary logistic regression analysis was applied to observe the individual contributions of *IBD5*, *CARD15*, *ATG16L1* and *IL23R*, and to test for pairwise statistical interaction. An association was considered significant if a *P* value of < 0.05 was attained. *CARD15* status was classified as - (wild type) or + (at least one mutation in any of the three *CARD15* SNPs). The individual *CARD15* genotypes and *CARD15* status were stratified by *IBD5* genotypes; *IL23R* and *ATG16L1* genotypes were stratified by *CARD15* genotypes, *CARD15* status and *IBD5* genotypes; and *ATG16L1* genotype was stratified by *IL23R* genotypes. The odds ratios (ORs) and confidence intervals for these specific combinations of *IBD5*, *CARD15*, *ATG16L1* and *IL23R* were derived from  $\chi^2$  in 2x2 contingency tables.

## RESULTS

All analysed allele frequencies and genotype distributions were in Hardy-Weinberg equilibrium both in patients and controls; results are shown in Table 2.

Table 2 Case-control genotypes and allele frequencies of variants in *IL23R*, *ATG16L1*, *CARD15* and *IBD5* *n* (%)

	CD ( <i>n</i> = 315)	Controls ( <i>n</i> = 314)	OR (95% CI) <sup>1</sup>	<i>P</i>

<sup>1</sup>*CARD15* status is denoted - (wild type) and + (at least one mutation in any of the three SNPs). CD: Crohn's disease.

rs2201841 C, *IGR2198a\_1* C, *IGR2096a\_1* T, *CARD15* 702W, *CARD15* 1007fsinsC variants confer risk for CD; OR values ranged from 1.44 to 2.57 ( $P < 0.02$ ).

For *IL23R* rs1004189 and rs2201841, and for *ATG16L1* a highly significant increase in risk was observed in homozygous individuals ( $P = 0.008$ , OR = 2.05, 95% CI: 1.20-3.50 for rs1004189 AA;  $P < 0.001$ , OR = 2.97, 95% CI: 1.65-5.33 for rs2201841 CC;  $P = 0.004$ , OR = 1.69, 95% CI: 1.19-2.41 for *ATG16L1* GG genotype).

The *CARD15* G908R (rs2066845) did not show any association with CD.

Next, we analysed the possible statistical interactions by pairs of *ATG16L1*, *IL23R* variants, *CARD15* status and *IBD5* (*IGR2198a\_1*). No evidence of interactions between these seven markers was found. None of the  $P$  values was significant; the lowest  $P$  value was 0.25 (Table 3).

Finally, we observed the specific combinations of single markers by pairs, the combined ORs are shown in Tables 4-6. The individual *IL23R* and *ATG16L1* genotypes were stratified by *CARD15* genotypes and *CARD15* status; results are shown in Table 4. *ATG16L1* and both *IL23R* variants showed significant association with CD on the background of a wild type *CARD15* genotype. The rs2201841 CC genotype in itself was found to be a stronger CD risk factor than *CARD15*. The ORs were higher in individuals carrying one of the *CARD15* variants with either the *ATG16L1* GG genotype or *IL23R* rs1004189 variant ( $P < 0.001$ , OR = 3.33, 95% CI: 1.96-5.67 for rs1004189 A carriers; and  $P < 0.001$ , OR = 3.82, 95% CI: 1.86-7.86 for *ATG16L1* GG genotype on the background of *CARD15* + status). The *IL23R* rs2201841 CC genotype and + *CARD15* status together showed by far the highest OR ( $P < 0.001$ , OR = 9.15, 95% CI: 2.05-40.74).

The *IL23R* rs2201841 C variant in homozygous form increased the susceptibility for the disease on the *ATG16L1* nonhomozygous (i.e. wild type and heterozygous subjects together) background significantly; we could not detect a similar effect for rs1004189 A carriers. *ATG16L1* was associated with CD in the absence of *IL23R* rs2201841 CC genotype, but not in rs1004189 noncarriers. We found that bearing the *ATG16L1* GG genotype

together with one of the *IL23R* susceptibility variants enhanced the risk for CD ( $P < 0.001$ , OR = 2.51, 95% CI: 1.55-4.08 for rs1004189;  $P = 0.001$ , OR = 4.68, 95% CI: 1.72-12.78 for rs2201841 homozygous genotype).

The ORs calculated for specific combinations of *IBD5* with *IL23R* and *ATG16L1* genotypes are shown in Table 5. We detected significantly increased risk in patients carrying the *IL23R* rs2201841 CC genotype on a wild type *IBD5* background. The IGRs showed significant association with the disease on an *IL23R* rs2201841 nonhomozygous or *ATG16L1* nonhomozygous background. *ATG16L1* did not significantly influence the susceptibility of CD except in the presence of IGR variants ( $P < 0.001$ , OR = 2.38, 95% CI: 1.46-3.87 for *IGR2198a\_1* C; and  $P = 0.001$ , OR = 2.32, 95% CI: 1.42-3.79 for *IGR2096a\_1* T background). Moreover, for the combinations of IGRs and *IL23R* rs1004189 we could detect significantly elevated high ORs only in carriers of *IGR2198a\_1* C and rs1004189 A, or in patients with *IGR2096a\_1* T and rs1004189 A variants ( $P = 0.001$ , OR = 2.44, 95% CI: 1.43-4.15 for *IGR2198a\_1* C; and  $P = 0.001$ , OR = 2.41, 95% CI: 1.42-4.09 for *IGR2096a\_1* T). The IGRs and *IL23R* rs2201841 CC genotypes together resulted in higher risk than the IGRs in themselves, but this OR value was lower than the OR calculated for the rs2201841 CC genotype alone ( $P < 0.001$ , OR = 3.66, 95% CI: 1.81-7.41 for *IGR2198a\_1* C; and  $P < 0.001$ , OR = 3.71, 95% CI: 1.80-7.67 for *IGR2096a\_1* T in patients carrying *IL23R* rs2201841 homozygous genotype).

The ORs for individual *CARD15* genotypes stratified by *IBD5* *IGR2198a\_1* and *IGR2096a\_1* genotypes are summarized in Table 6. Both the *IBD5* markers significantly increased the risk of CD in the absence of *CARD15* mutations; the *CARD15* variants were confirmed to be stronger risk factors for CD than IGRs. The *IBD5* variants showed higher significant risk together with + *CARD15* status ( $P < 0.001$ , OR = 3.19, 95% CI: 1.90-5.37 for *IGR2198a\_1*; and  $P < 0.001$ , OR = 3.18, 95% CI: 1.87-5.39 for *IGR2096a\_1* on the background of *CARD15* + status).

## DISCUSSION

Since the identification of *NOD2/CARD15* as the first susceptibility gene for CD in 2001<sup>[19,20]</sup>, several additional loci have been implicated in CD and confirmed by replication, among others the *IBD5*, *IL23R* and *ATG16L1*<sup>[4-6,8,9,21,22]</sup> loci.

Recently the idea was raised that exploring gene-gene interactions might lead to a better understanding of disease cause and might help the prediction of disease risk. So far numerous studies have assessed the risk for the development of CD by combining information from the known genetic risk variants associated with the disease. Though Hampe *et al.*<sup>[8]</sup> found a modest but significant association between *ATG16L1* and *CARD15* in their pioneer study, no interaction was demonstrated between the two loci in the majority of

<sup>1</sup>*IGR2198a\_1*, *IGR2096a\_1*, *CARD15* R702W, G908R and L1007fs: OR relative to wild type genotype; *CARD15* status: OR relative to - (wild type) group. <sup>a</sup>*P* < 0.05 *vs* controls.

subsequent Caucasian studies<sup>[10,23,24]</sup>. Prescott *et al*<sup>[12]</sup> also demonstrated that *ATG16L1* increased the susceptibility for CD irrespective of *CARD15* status; at the same time they detected increased *ATG16L1* G allele frequency in *CARD15* carriers compared with noncarriers, which may indicate a weak interaction between these candidate CD susceptibility genes. Moreover, an additive effect was reported between *ATG16L1* and *CARD15*<sup>[25]</sup>. The independence of *ATG16L1* and *IBD5* variants was also confirmed in IBD<sup>[12,23]</sup>.

Besides the individual risk of *IL23R* variants several

studies examined their epistatic interaction with other IBD genes like *CARD15*<sup>[24-26]</sup>. Mostly the well-replicated *IL23R* R381Q protecting variant was implied in gene-gene interaction analyses and was reported to act independently of *CARD15*. In one study an additive effect was found between this *IL23R* variant and *CARD15* gene<sup>[25]</sup>. The epistasis of the intronic rs1004189 risk variant with *CARD15* and *IBD5* was examined in a German CD population, but no gene-gene interaction was found<sup>[26]</sup>. No evidence of epistatic interaction between *CARD15* and *IBD5* was demonstrated in an Italian IBD study either<sup>[27]</sup>.

Besides combining the most associated CD susceptibility variants by pair, multilocus analyses with three or more loci were also performed. Latiano *et al.*<sup>[24]</sup> did not find any significant interaction between *ATG16L1*, *IL23R*, *CARD15* and *IBD5* by triplets. Prescott *et al.*<sup>[12]</sup> established a combined additive risk for all high risk genotypes in *ATG16L1*, *CARD15* and *IBD5*, which was 20 fold that of the baseline risk for individuals carrying none of the risk alleles. Weersma *et al.*<sup>[28]</sup> found an association between the increase in the number of risk alleles (*ATG16L1*, *IL23R*, *CARD15*, *IBD5* and *DLG5*) and an increased risk for the development of CD.

Here we selected two risk-conferring variants of *IL23R* and *ATG16L1* T300A mutation, and studied them together with the well-replicated *CARD15* and *IBD5* loci in Hungarian CD patients. Besides confirming our previous results with respect to *IL23R* rs2201841<sup>[29]</sup>, we found a significant positive association between *IL23R* rs1004819 variant and CD observed in the Hungarian population for the first time. For *ATG16L1* rs2241880 the estimated risk derived from the 315 CD patients showed a significant 1.7-fold increase in risk for the homozygous genotype. Our data are in line with most previous reports in Hungarian and other Caucasian populations<sup>[12,13]</sup>. Our results also verify that the previously identified R702W and L1007fs alterations in *CARD15* gene act as CD susceptibility factors in the Hungarian population<sup>[30,31]</sup>. Since neither *SLC22A4* nor *SLC22A5* variants seem to confer risk for CD in the Hungarian population<sup>[32]</sup>, we tested two other disease-associated *IBD5* markers, IGR2198a\_1 (rs11739135), IGR2096a\_1 (rs12521868) for gene-gene interactions<sup>[22,33,34]</sup>.

First we observed the statistical pairwise interactions between *IL23R* (rs1004189, rs2201841), *ATG16L1* (rs2241880), *CARD15* status and IGR2198a\_1 (rs11739135). No evidence of epistatic interaction was found by logistic regression suggesting that all examined loci contribute independently to disease risk.

Next, we analysed the specific combinations of individual genotypes by pairs with respect to CD risk. We detected a significant association with CD for IGR2198a\_1 and IGR2096a\_1, respectively, on the background of wild type (-) *CARD15* status, indicating that these two *IBD5* markers and *CARD15* are independent determinants of disease risk. Also high, significant ORs were found for *ATG16L1* and *IL23R* variants (rs1004189, rs2201841), respectively, both in the presence and absence of *CARD15* mutations, suggesting that these genes also act independently on CD risk. We detected a significant association in patients bearing *IL23R* rs2201841 CC genotype and wild type *IBD5* background together, and *vice versa*. In carriers of IGR variants a significantly high risk was detected on *IL23R* rs2201841 nonhomozygous background; accordingly they may play an independent role in CD susceptibility. Similar to the results of previous studies<sup>[12,25]</sup>, *ATG16L1* increased the disease risk both in the presence and absence of *CARD15*, moreover in our study it was independent from *IL23R* rs2201841

genotype, but not from rs1004189 and *IBD5* status. For combinations of *IL23R* rs1004189 and *IBD5* markers, significant association was seen only in individuals carrying together the rs1004189 mutation and one of the two IGR variants.

In almost all specific pairwise combinations, the highest OR was found in patients with two different risk-associated gene variants, this cumulative OR was by far the highest in individuals with *IL23R* rs2201841 CC genotype and + *CARD15* status.

However, we cannot detect significant statistical interaction between the analysed *IL23R*, *ATG16L1*, *CARD15* and *IBD5* risk alleles. The results of the present study suggest that these susceptibility factors may have a possible cumulative effect in the Hungarian CD population. By combining information from the known common risk polymorphisms significant predictive value from genetic markers might be gained; accordingly further large, well-powered studies should be performed to clarify the exact nature of these possible correlations.

## COMMENTS

### Background

Up to now, strong evidence has been provided that genetic factors play a significant role in determining the susceptibility of individuals to inflammatory bowel disease (IBD), especially for Crohn's disease (CD). After the identification of the disease-associated *NOD2* [caspase recruitment domain-containing protein 15 (*CARD15*)] gene, huge genome-wide linkage-analyses and meta-analyses have reported several CD susceptibility regions like *IBD5* locus, *DLG5*, interleukin-23 receptor (*IL23R*), and autophagy-related 16-like 1 (*ATG16L1*) gene.

### Research frontiers

Besides establishing the risk of carrying single variants, numerous studies have performed gene-gene interaction analyses for the major well-replicated susceptibility genes (*CARD15*, *ATG16L1*, *IL23R* genes and *IBD5* locus). Mostly the independence of these main loci has been reported; nevertheless some studies have found an increased disease risk for carrying two or more certain risk variants together compared to non-carriers or individuals with only one susceptibility variant. In the present study two SNPs of *IL23R*, one of the *ATG16L1*, three of the *CARD15* genes and two of *IBD5* locus were genotyped and involved in interaction analysis in the Hungarian CD population.

### Innovations and breakthroughs

The present study confirms the reported association between *IL23R* rs2201841 and *ATG16L1* rs2241880 variants and CD susceptibility. The authors examined the *IL23R* rs1004189 in the Hungarian CD population for the first time, and found it significantly more frequent in patients compared to healthy controls. The analysis of statistical pairwise interactions between *IL23R*, *ATG16L1*, *CARD15* status and *IBD5* confirmed the independence of these susceptibility genes, while the specific combinations by pair showed the highest odds ratio in patients with two different risk-associated gene variants, suggesting that they may have a cumulative effect in this Hungarian CD population.

### Applications

The exploration of epistatic interactions between the major susceptibility genes and the specification of high risk genotype combinations could support the better understanding of the development of CD and could facilitate the diagnosis of high-risk patients.

**Peer review**

The authors investigated the interactions of the major IBD susceptibility alleles in a Hungarian CD cohort. This is of high clinical significance as this methodology could help the diagnosis of high-risk patients.

### Abstract

**AIM:** To elucidate the effect of antioxidants, resveratrol (RVT) and astaxanthin (AXN), on hepatitis C virus (HCV) replication.

**METHODS:** We investigated the effect of recent popular antioxidant supplements on replication of the HCV replicon system OR6. RVT is a strong antioxidant and a kind of polyphenol that inhibits replication of various viruses. AXN is also a strong antioxidant. The replication of HCV RNA was assessed by the luciferase reporter assay. An additive effect of antioxidants on antiviral effects of interferon (IFN) and ribavirin (RBV) was investigated.

**RESULTS:** This is the first report to investigate the effect of RVT and AXN on HCV replication. In contrast to other reported viruses, RVT significantly enhanced HCV RNA replication. Vitamin E also enhanced HCV RNA replication as reported previously, although AXN did not affect replication. IFN and RBV significantly reduced HCV RNA replication, but these effects were dose-dependently hampered and attenuated by the addition of RVT. AXN did not affect antiviral effects of IFN or RBV.

**CONCLUSION:** These results suggested that RVT is not suitable as an antioxidant therapy for chronic hepatitis C.

### INTRODUCTION

Chronic liver disease develops in over 70% of those infected with hepatitis C virus (HCV), and HCV is now the most common cause of liver cirrhosis and also hepatocellular carcinoma (HCC), especially in Japan. It has been said that the median time for progression to cirrhosis is 30-40 years, but other factors such as male gender, the age at infection, co-infection with hepatitis

B virus or human immunodeficiency virus (HIV), and alcohol consumption accelerate progression of this chronic disease. Oxidative stress has been postulated to be one of the deleterious factors of chronic hepatitis, and it was reported that antioxidant levels were significantly reduced in chronic hepatitis and cirrhosis<sup>[1]</sup>. Moreover, it was also found that HCV proteins themselves generate oxidative stress, and the additive effect of oxidative stress caused by the inflammatory process in hepatitis and that induced by HCV proteins may further advance the disease stage of chronic hepatitis C<sup>[2]</sup>. Therefore, it is thought that antioxidant therapy has a role in slowing disease progression to cirrhosis and subsequent HCC. In fact, there are studies suggesting a beneficial effect of antioxidant therapy for patients who did not respond to interferon (IFN) therapy, and that a combination of antiviral and antioxidant therapies may enhance the overall response rate of patients with chronic hepatitis C<sup>[3,4]</sup>.

Current recommended therapy for previously untreated and relapsed patients is a combination of pegylated interferon (Peg-IFN) and ribavirin (RBV), resulting in a sustained virological response in around 50% of genotype 1 patients with high viral load<sup>[5]</sup>. Recent studies have shown that protease and polymerase inhibitors possess a strong additive effect on antiviral therapy of Peg-IFN/RBV and seem to be promising<sup>[6]</sup>. However, these regimens are expensive and adverse effects are sometimes severe and frequent, meaning that large numbers of patients give up treatment for a variety of reasons<sup>[7]</sup>. These conditions have led patients with chronic hepatitis C to use complementary and alternative medicine (CAM) including various supplements, and a previous survey found that about 40% of patients of liver disease outpatient clinics in the US used CAM at least once during the preceding month<sup>[8]</sup>. Moreover, a large number of supplements are used by patients universally to maintain their health condition or improve quality of life even if they are cared by medical doctors and they always do not tell doctors whether they used CAM and/or supplements. The most frequent CAM or supplements taken by patients with chronic hepatitis C were antioxidants, which may be beneficial for this disease as described above.

Resveratrol (RVT) was discovered to be a strong activator of *sirtuin*, a gene for longevity<sup>[9]</sup>, and has been implicated as the most important polyphenol responsible for the beneficial effects of red wine consumption, which has been called as the “French Paradox”<sup>[10]</sup>. Polyphenols contained in red wine have shown a strong antioxidative effect on cardioprotection, anti-atherosclerosis and relaxation of vascular endothelium through nitric oxide release. *Sirtuin* is activated when a person undergoes calorie restriction, and RVT is thought to be a surrogate for calorie restriction, which induces stabilization of DNA and also increases longevity by 70%. RVT is also known to improve liver lesions such as acetaminophen-induced hepatic injury and liver fibrosis in the mouse. When RVT was administered to mice fed a high-fat diet, fatty liver induced by this high-

calorie diet was significantly improved<sup>[11]</sup>. In addition to these favorable reactions, it has been reported that RVT inhibited viral replication of several major viruses, such as cytomegalovirus (CMV), varicella-zoster, influenza A, and herpes simplex virus (HSV)<sup>[12-15]</sup>. This supplement is popular and is thought to be one of candidates for the supplemental treatment of chronic hepatitis C.

Another candidate is astaxanthin (AXN: 3,3'-dihydroxy-b, b-carotene-4,4'-dione), which also showed a strong antioxidative effect<sup>[16]</sup>. AXN is the carotenoid responsible for the pink pigmentation in the flesh of salmon, lobster, krill and other aquatic animals and plants. Recent studies have indicated that AXN is more powerful than its carotenoid cousin,  $\beta$  carotene, at neutralizing singlet oxygen<sup>[17]</sup>. This supplement is known to improve the condition of so-called metabolic syndrome<sup>[18,19]</sup>, and is therefore popular. The antiviral effect of this supplement has not been examined so far.

These reports suggested that RVT and AXN might be good candidates for an antioxidative as well as an anti-HCV agent. However, we have no information whether these antioxidants affect HCV replication or not and if they are suitable for patients with chronic hepatitis C. In this study, we tried to assess the effect of these antioxidants on HCV replication using the HCV replicon system as an *in vitro* tool<sup>[20]</sup>. This is the first report to investigate the effect of RVT and AXN on HCV replication *in vitro*.

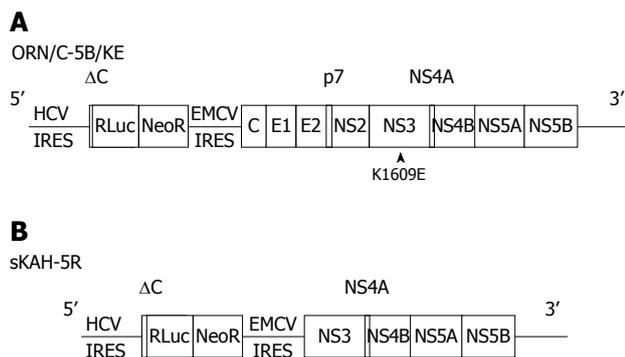

## MATERIALS AND METHODS

### Cells and virus

OR6 cells, a cell line cloned from ORN/C-5B/KE cells<sup>[21]</sup> supporting genome-length HCV RNA (strain O of genotype 1b) encoding the luciferase reporter gene, were used. This cell line was originally derived from a hepatoma cell line, HuH-7, as described elsewhere<sup>[21]</sup>. The schematic organization of the ORN/C-5B/KE gene is shown in Figure 1A. This cell line was cultured and maintained as previously reported<sup>[22]</sup>. Another cell line used was sKAH-5R<sup>[23]</sup>, which was established from a patient with acute hepatitis C, having subgenomic HCV RNA encoding the luciferase reporter gene (Figure 1B). The latter cell line was cultured under the same conditions as the OR6 cells, which includes the gene without a structural region of HCV RNA from the ORN/C-5B/KE gene.

### Chemicals

We evaluated RVT and AXN as new supplements, and vitamin E (VE) was used as a control because its effect on the HCV replicon system was already reported elsewhere<sup>[24]</sup>. RVT (3,5,4'-trihydroxystilbene), RBV (1-b-D-ribofuranosyl-1H-1,2,4-triazole-3-carboxamide), AXN (3,3'-dihydroxy-b,b-carotene-4,4'-dione), VE and IFN-2b were purchased from Sigma-Aldrich Japan (Tokyo, Japan). AXN, RVT and VE were prepared as 10-20 mg/mL stock solutions in dimethylsulfoxide (DMSO) and stored at -80°C until used. This stock solution was diluted with culture medium. The final

**Figure 1** Organization of hepatitis C virus (HCV) RNA used in the replicon systems. A: Genome-length HCV RNA generated in OR6 cells; B: Subgenomic HCV RNA used in sKAH-5R and s1B-4R cells. Structural region of HCV RNA was deficient in the replicated RNA of sKAH-5R and s1B-4R cells.

concentration of DMSO was 0.2%, which did not interfere with viral replication, the highest concentration of RVT used in this study was 100  $\mu\text{mol/L}$ , that of AXN was 50  $\mu\text{mol/L}$ , and that of VE was 15  $\mu\text{mol/L}$ . To monitor the anti-HCV effects of IFN and RBV on replication, OR6 cells ( $1.5 \times 10^4$  /well) were plated onto 24-well plates at least in triplicate for each assay and cultured for 4 h. Then the cells were treated with IFN at a final concentration of 1, 2, 4, 10, or 20 U/mL or RBV at a final concentration of 10 or 25  $\mu\text{mol/L}$  for 72 h, harvested with renilla lysis reagent (Promega, Madison, WI), and assayed for luciferase activity according to the manufacturer's protocol. The same protocol was applied for sKAH-5R cells. The additive effect of RBV, RVT and AXN on the antiviral effect of IFN (1 U) was studied and compared using luciferase activity.

#### Luciferase reporter assay

Approximately  $1$  to  $4.5 \times 10^4$  cells were plated onto 6-well plates and cultured for 24 h. Cells were treated with each agent for 72 h. The cells were then harvested with Renilla lysis reagent and subjected to the Renilla luciferase (RL) assay according to the manufacturer's protocol.

#### Cell viability

We tested the toxic effect of RBV as described elsewhere<sup>[22]</sup>. The effect of RVT (5-100  $\mu\text{mol/L}$ ) and AXN (1-50  $\mu\text{mol/L}$ ) on cell viability was investigated. To examine the cytotoxic effect of RVT and AXN on cells with replicon RNA, the cells were seeded at a density of  $2 \times 10^5$  cells per dish onto 6-well plates. After 24 h culture, the cells were treated with RVT at final concentrations of 25 and 50  $\mu\text{mol/L}$  in the absence of G418. After incubation for 72 h, the number of viable cells was counted in an improved Neubauer-type hemocytometer after trypan blue dye (Invitrogen, Carlsbad, CA) treatment.

#### Statistical analysis

The difference in relative luciferase activity was tested using the Student's *t*-test and the Mann-Whitney *U*-test as appropriate. *P*-values < 0.05 were considered statistically

significant. Every experiment was performed in triplicate and two independent experiments were done.

## RESULTS

### RVT dose-dependently enhanced HCV RNA replication but AXN inhibited replication

The effect of RVT and AXN was examined in comparison to that of VE, using the OR6 assay system, in which genomic length HCV RNA replication is represented by RL fluorescence activity.

After treatment of OR6 cells with various concentrations of RVT for 72 h, the luciferase activity was dose-dependently increased up to 20  $\mu\text{mol/L}$  (Figure 2A). The activity gradually decreased at higher concentrations, but at 100  $\mu\text{mol/L}$  it was still higher than that without RVT. Since it has been reported that the proliferation of the HCV subgenomic replicon is dependent on host-cell growth, we examined the effect of RVT on cell number and viability of OR6 cells by the trypan blue dye exclusion test. As shown in Figure 2B, RVT did not increase OR6 cells until 15  $\mu\text{mol/L}$ , and the cell viability decreased at higher concentrations than 20  $\mu\text{mol/L}$  of RVT. This decrease seen in higher concentrations paralleled the luciferase activity shown in Figure 2A, and it seemed that RVT further enhanced HCV RNA replication at concentrations higher than 20  $\mu\text{mol/L}$  when estimated by the number of viable cells. Different from the effect of RVT, AXN did not enhance luciferase activity (Figure 2C). The luciferase activity decreased at a concentration more than 10  $\mu\text{mol/L}$ , and this decrease seemed to be due to decrease in cell viability (Figure 2D).

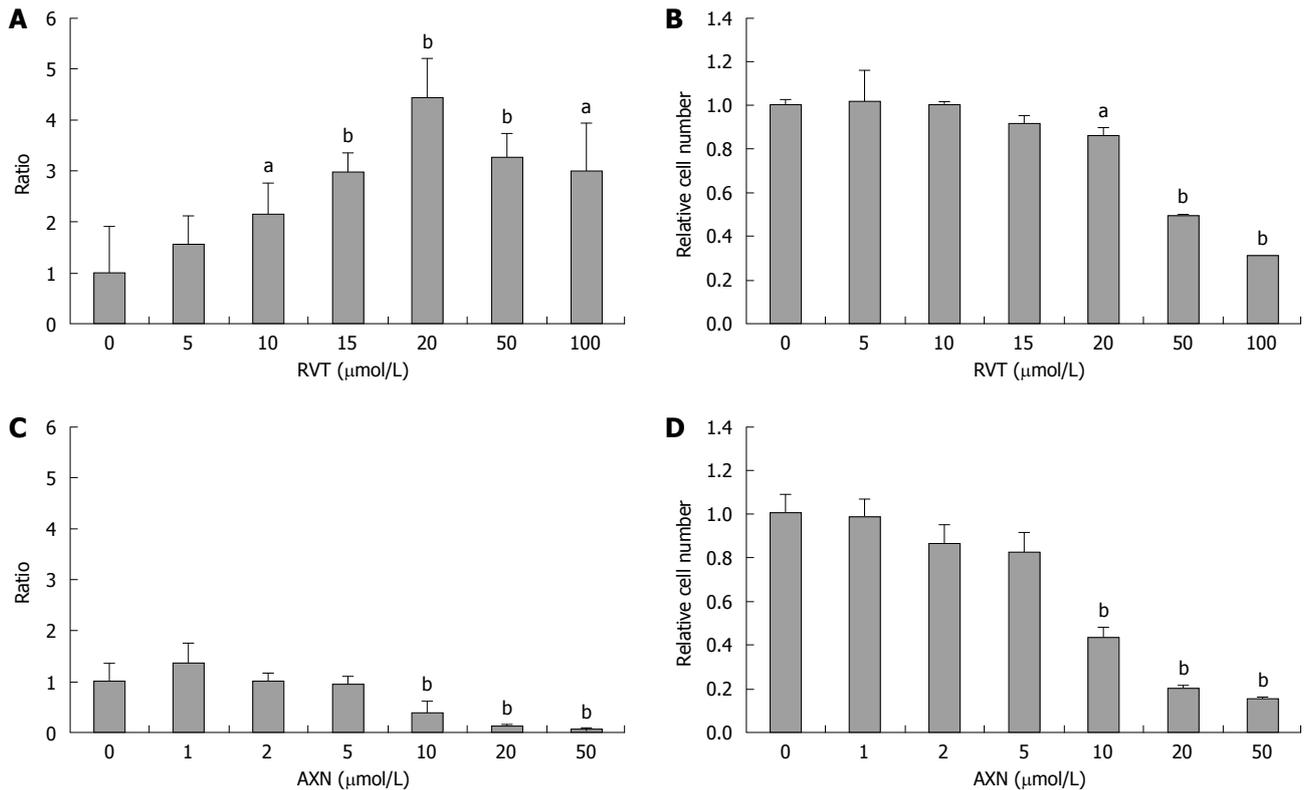

VE dose-dependently increased luciferase activity up to a concentration of 15  $\mu\text{mol/L}$  (Figure 3). This result indicated that VE also upregulates HCV RNA replication in OR6 cells. The cytotoxic effect of VE was not observed in the cell viability test. This result was compatible to the data already reported elsewhere<sup>[24]</sup>.

### Proliferative effect of RVT was also observed in the subgenomic replicon

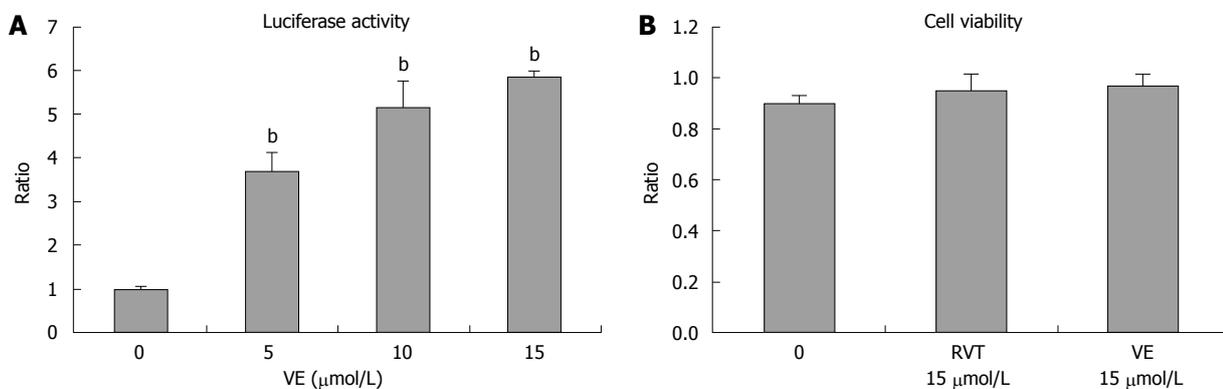

Next, we further investigated the effect of RVT on other clones of HCV RNA. We tested the effect of RVT on the subgenomic HCV RNA-replicating cell, sKAH-5R. RVT also enhanced the replication of sKAH-5R subgenomic HCV RNA at 2-10  $\mu\text{mol/L}$  (Figure 4A). This concentration is not toxic to the sKAH-5R cells, but more than 20  $\mu\text{mol/L}$  of RVT was toxic to sKAH-5R cells (Figure 4B). Thus, subgenomic replicons showed the same results observed in the full-genome length replicon.

### Anti-viral effects of IFN and RBV

The effects of IFN-2b and RBV were independently applied to these cells to demonstrate that anti-viral agents reduce HCV RNA replication in this cell line. Figure 5A shows the time course of luciferase activity after administration of IFN. Luciferase activity was

**Figure 2** Luciferase activity and cell viability of OR6 cells after addition of resveratrol (RVT) and astaxanthin (AXN) for 72 h. The indicated concentrations of RVT or AXN were added to the culture medium of OR6 cells, and after 72 h of culture, cells were harvested with Runilla lysis buffer and the lysate was subjected to the luciferase assay. Cell viability was evaluated by a trypan blue dye exclusion assay. A: Luciferase activity after addition of RVT; B: Cell viability after addition of RVT; C: Luciferase activity after addition of AXN; D: Cell viability after addition of AXN. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

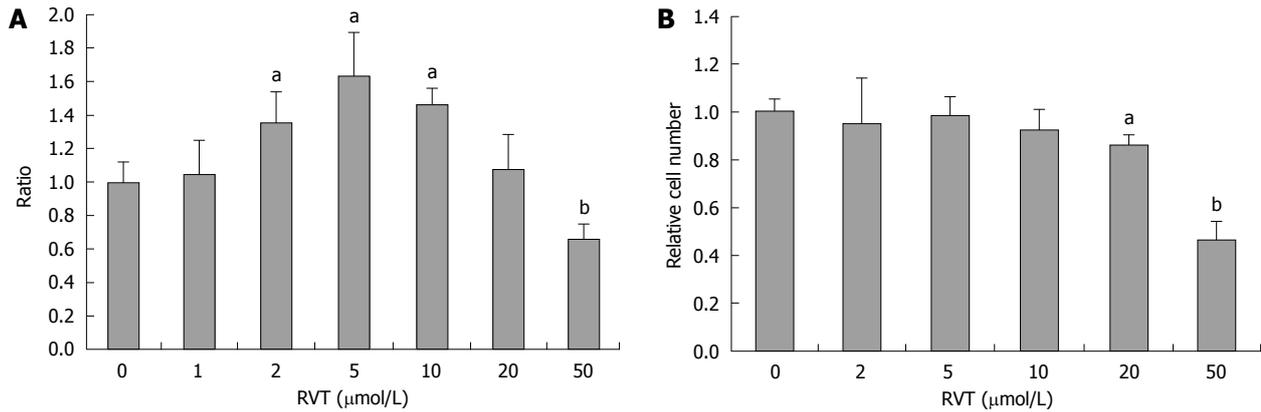

**Figure 3** The effect of vitamin E (VE) on luciferase activity and cell viability of OR6 cells (72 h). Cells were treated with the indicated concentrations of VE for 72 h. A: Luciferase activity after addition of VE; B: Cell viability after addition of RVT and VE. <sup>b</sup>*P* < 0.01.

dose-dependently inhibited by IFN. Figure 5B shows the effect of RBV at concentrations of 10 and 25 μmol/L on luciferase activity of OR6 cells 72 h after addition of RBV in comparison to that of IFN (1 U/mL). RBV also reduced luciferase activity of OR6 cells dose-dependently, but the effect was smaller than that of IFN. Anti-viral effects of IFN and RBV were thus confirmed in this cell line.

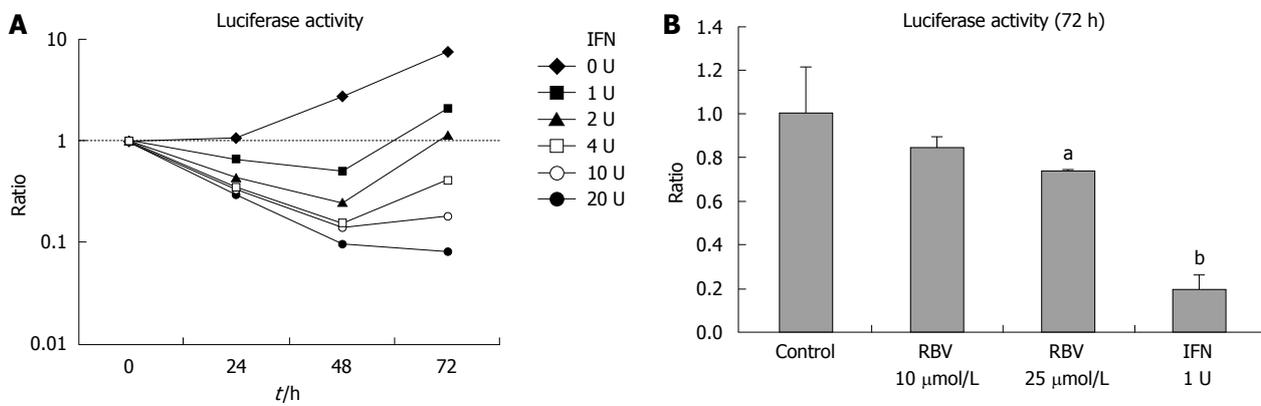

**RVT reversed anti-viral activity of IFN and RBV, but AXN did not affect it**

We then investigated whether RVT reverses the anti-viral

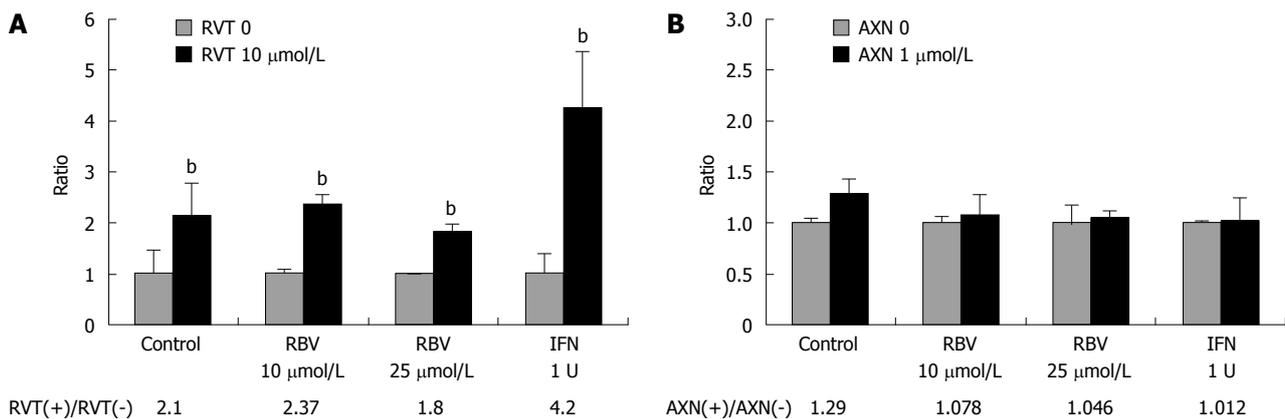

effects of RBV and IFN. Luciferase activity of OR6 cells 72 h after treatment with RBV or IFN was compared to treatment with RBV plus RVT or IFN plus RVT (Figure 6A). The effect of treatment with 10 μmol/L of RVT alone on OR6 cells showed a 2.1-fold increase of luciferase activity. The addition of RVT (10 μmol/L) to RBV- or IFN-treated cells reversed the anti-proliferative effect of RBV on HCV RNA even when the cells were treated with 25 μmol/L of RBV plus 1 U/mL of IFN, which was normally enough to reduce HCV RNA to 1/5 (Figure 5B). Ten μmol/L RVT upregulated luciferase activity in RBV- or IFN-treated OR6 cells around 2-fold

**Figure 4** The effect of resveratrol on subgenomic replicon cells, sKAH-5R. RVT was added to the cells for 72 h and luciferase activity was assayed as was indicated in Figure 2. A: Luciferase activity after addition of RVT; B: Cell viability after addition of RVT. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

**Figure 5** Sequential change of luciferase activity of OS6 cells after addition of interferon (IFN). A: IFN was added for the indicated duration and the ratio to the luciferase activity at time 0 was shown. Statistical significance (<sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01) is shown below: at 24 h 0 vs 1<sup>a</sup>, 2<sup>b</sup>, 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; at 48 h, 0 vs 1<sup>b</sup>, 2<sup>b</sup>, 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; 1 vs 2<sup>b</sup>, 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; 20 vs 2<sup>b</sup>, 4<sup>b</sup> and 10<sup>b</sup>; at 72 h, 0 vs 1<sup>b</sup>, 2<sup>b</sup>, 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; 1 vs 2<sup>a</sup>; 1 vs 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; 2 vs 4<sup>b</sup>, 10<sup>b</sup> and 20<sup>b</sup>; 4 vs 10<sup>b</sup> and 20<sup>b</sup>; 10 vs 20<sup>b</sup>; B: Luciferase activity after addition of RBV and IFN for 72 h was shown as the ratio to that without antiviral agents. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01.

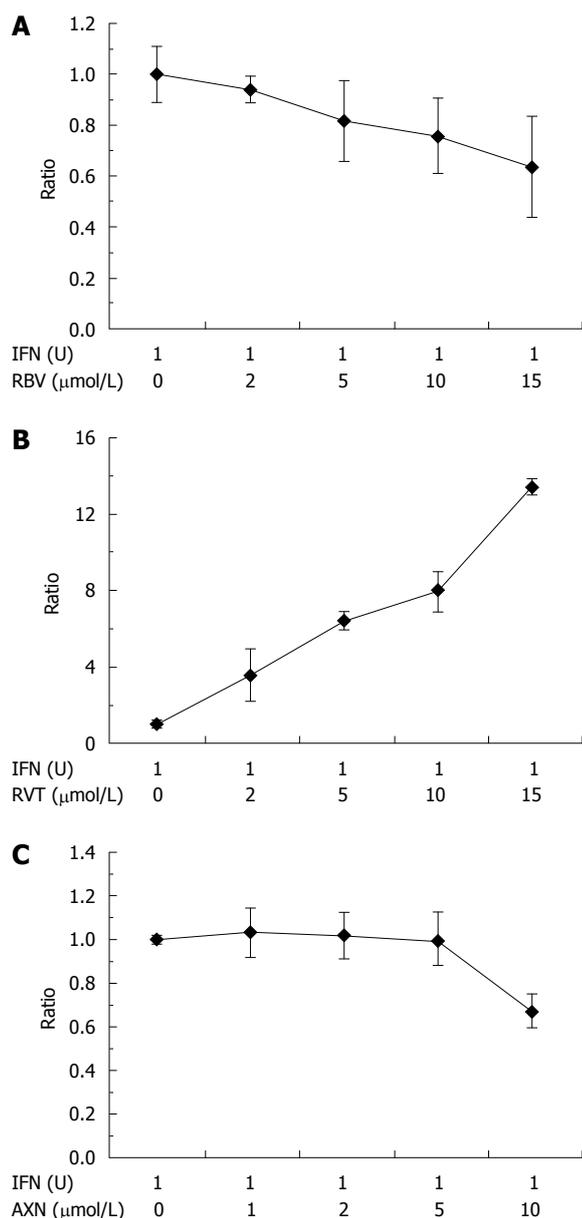

**Figure 6** The enhancing effect of RVT on replication of HCV RNA, even when treated with ribavirin (RBV) and IFN. RVT was simultaneously added to RBV or IFN. A: The ratio was calculated as the ratio of luciferase activity with RVT to that without RVT. <sup>b</sup>*P* < 0.01 vs RVT 0; B: The same procedure was applied in AXN.

and 4.2-fold, respectively (Figure 6A). On the other hand, AXN did not affect the effect of RBV and IFN (Figure 6B), indicating that AXN has no disadvantageous effect on antiviral activity of IFN and RBV.

This proliferative effect of RVT was further emphasized by comparison to the additive effects of RBV

with IFN. We compared the dose-dependent effect of RBV, RVT and AXN on the anti-proliferative effect of IFN (Figure 7). RBV (A), RVT (B) and AXN (C) were added to OS6 cells at concentrations of 0, 1, 2, 5, 10 or 15 μmol/L with 1 U/mL of IFN for 48 h. The ratio between luciferase activity of RBV-, RVT- or AXN-treated

**Figure 7** The comparative effect of RBV (A), RVT (B) and AXN (C) on the luciferase activity of IFN-treated cells. Cells were simultaneously treated with 1 U/mL of IFN and the indicated concentrations of RBV, RVT and AXN were added with IFN.

cells and that without co-treatment is shown. RBV further reduced the IFN-induced decrease in luciferase activity (Figure 7A), while RVT reversed this decrease, and further increased luciferase activity (Figure 7B). This effect was dose-dependent and it is noted that the enhanced ratio was strikingly large. On the other hand, AXN did not affect antiviral effect of IFN (Figure 7C).

## DISCUSSION

We have shown that RVT, a natural polyphenol contained in red wine and peanuts, enhanced *in vitro* replication of HCV RNA without producing significant proliferation of host cells. This is the first report demonstrating a proliferative effect of RVT on HCV. RVT inhibited

replication of HSV-1, HSV-2<sup>[25-27]</sup> human CMV<sup>[13]</sup>, Influenza A and orthomyxo virus<sup>[15]</sup>. Moreover, it was reported that RVT inhibited replication of HIV-1 synergistically with nucleoside analogues<sup>[28]</sup>. These reports suggest that RVT has a broad spectrum of anti-viral activities, and that RVT may selectively target the host, rather than the virus, as a mode of action for inhibiting viral replication. In spite of these inhibitory effects on viral replication, the mechanism of enhancing replication of HCV RNA is unclear. These results suggested that RVT is not suitable for antioxidant therapy of chronic hepatitis C. We also examined the effect of VE on replication of HCV RNA in OS6 cells, and VE enhanced its replication as effectively as RVT. On the other hand, AXN did not enhance replication of HCV RNA and had no effect on antiviral activity of IFN and RBV. These results indicated that we could recommend patients with chronic hepatitis C do not take RVT, especially when they receive antiviral therapy.

RVT is a non-flavonoid polyphenol and exerts anti-oxidative, anti-neoplastic and anti-inflammatory properties<sup>[11]</sup>. Moreover, RVT has received much attention as an agent for prolongation of lifespan by activating silent information regulator 2 proteins, or sirtuins<sup>[25]</sup>, which are implicated in influencing aging and regulating transcription, apoptosis and stress resistance<sup>[29]</sup>. These are causes for the popularity of this supplementation. Therapeutic intervention in liver injury with RVT has been suggested in various liver diseases<sup>[30]</sup>, such as alcohol-induced liver disease<sup>[31]</sup>, drug-induced liver injury<sup>[32]</sup>, ischemia-reperfusion injury<sup>[33]</sup>, and fatty liver diseases<sup>[11,34]</sup>. Furthermore, RVT has been implicated to be favorable for prevention of hepatic fibrosis<sup>[35,36]</sup>. These observations in combination with anti-viral effects indicated that RVT might be therapeutically beneficial or suitable for chronic hepatitis C. However, the direct effect of RVT on HCV RNA replication has not been studied thus far. In spite of our expectation, RVT did not inhibit replication of HCV, and on the contrary, it enhanced replication. Moreover, RVT hampered the anti-viral effect of IFN or RBV, and HCV RNA replication was enhanced even when enough concentration of IFN or RBV was administered to OR6 cells to reduce HCV replication. This condition was quite different from that observed in HIV-1 replication, in which the effect of RVT was synergistic with anti-viral effect of nucleotide analogues. Unlike RVT, AXN did not affect HCV replication and IFN-based antiviral activity, while it possesses strong antioxidant power.

An immunological response against virus-infected cells is an important pathogenic mechanism of chronic viral hepatitis. Reactive oxygen species (ROS) produced by activated macrophages and a consequent rise of lipid peroxidation cause direct activation of hepatic stellate (Ito) cells, leading to hepatic fibrosis and cirrhosis<sup>[37]</sup>. Moreover, HCV core protein directly increases ROS as well as lipid peroxidation products and antioxidant gene expression<sup>[38]</sup>. HCV infection is also associated with liver

iron accumulation<sup>[39]</sup>, which further produces ROS in the liver. These observations suggested that anti-oxidant therapy has an important role in slowing disease progression to cirrhosis in chronic hepatitis C. In consequence of this theory, the use of CAM is common in patients with chronic liver disease<sup>[8]</sup>. Liu *et al.*<sup>[40]</sup> reviewed medicinal herbs for HCV infection and concluded that some agents may have an effect on liver enzymes, but there is no firm evidence supporting efficacy of CAM. However, few studies have investigated the effect of antioxidants on HCV itself. Yano *et al.*<sup>[24]</sup> investigated the effect of ordinary nutrients on HCV RNA replication using the replicon system, and found that some antioxidants such as  $\beta$ -carotene, vitamin D<sub>2</sub> and linoleic acid inhibited replication. They also showed an effect of VE on HCV RNA replication that was the same as in our study. In our study, AXN did not affect replication of HCV RNA. Thus, there is a group of antioxidants which inhibit replication of HCV, while there is another group of antioxidants which enhance its replication. The precise mechanism of this difference has not been clarified, but the investigation of this mechanism may provide new insights into anti-viral mechanisms. Recently it has been demonstrated that anti-HCV nutrients induce activation of the MEK-ERK1/2 signaling pathway through phosphorylation of ERK1/2<sup>[41]</sup>. Study of this phenomenon may provide clues for a new therapeutic strategy in anti-viral treatment of HCV.

RVT has been shown to have a large number of regulatory biological functions, and Docherty *et al.*<sup>[25-27]</sup> extensively studied the mechanism by which RVT inhibits the replication of HSV. However, even though it has been extensively studied, the molecular mechanism of RVT's action is not clear. Our results were quite different from those of Docherty's. In our study, not all antioxidants but 2 of 3 antioxidants increased the replication of HCV suggesting that the molecular mechanism of each agent is likely variable depending on viruses when we speculate in combination with studies of Docherty *et al.*<sup>[25-27]</sup> and Yano *et al.*<sup>[24]</sup>. On the other hand, reports suggesting a correlation between HCV replication and lipid metabolism have accumulated recently. It has been demonstrated that the cellular lipid droplet is an important structure for replication or assembly of viral components of HCV, especially HCV core protein<sup>[42]</sup>. The inhibitory effect of 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors on HCV have also been reported<sup>[43]</sup>. Moreover, the success of peg-IFN plus RBV combination therapy, that resulted in the disappearance of HCV, affected lipid metabolism thereafter *in vivo*<sup>[44]</sup>. Thus, it is conceivable that HCV genomic structure as well as the intracellular lipid is indispensable for viral replication of HCV. It is thought that RVT and VE affect intracellular lipid metabolism because they are lipid-soluble antioxidants. It is also interesting that HCV itself produces ROS, and that antioxidants affect the replication of HCV.

Bechmann *et al.*<sup>[45]</sup> recently demonstrated that RVT

in response to free fatty acid administration deteriorates fibrogenic activation of human hepatic stellate cells. They showed that RVT upregulated the expression of key mRNAs associated with activated, fibrogenic stellate cells, and also demonstrated that the combined presence of free fatty acids and RVT significantly reduced the hepatic stellate cells' susceptibility to apoptosis. This report was controversial since previous reports<sup>[35,36]</sup> demonstrated favorable effects of RVT on prevention of fibrosis progression. Bechmann *et al.*<sup>[45]</sup> pointed out that the concentration of RVT was different from the previous study, and species' differences (employing rat *vs* human hepatic stellate cells) might be significant. Thus, RVT may have different therapeutic effects at various concentrations, and further investigation is needed to clarify a role of RVT in chronic liver diseases. Their result also suggested that patients with chronic hepatitis C should not take RVT as an additive nutrient, especially when they receive IFN-based antiviral therapy. Further investigations focusing on the enhancing mechanism of RVT on HCV RNA and different responses between RVT and AXN is necessary, and these approaches may develop a new strategy of anti-HCV agents.

In conclusion, we recommend patients with chronic hepatitis C who receive IFN-based antiviral therapy not to take RVT as an antioxidant supplement, although AXN may not affect anti-viral therapy.

## COMMENTS

### Background

Antiviral therapy for chronic hepatitis C has been developing, but the current standard therapy with pegylated interferon (Peg-IFN) and ribavirin combination therapy for 12 mo has achieved around 50% of patients who are infected with genotype 1 hepatitis C virus (HCV). Patients who have not attained viral clearance tend to take several supplementations for this chronic disease with an expectation for retardation of disease progression. A previous survey found that about 40% of patients of liver disease outpatient clinics in the US used complementary and alternative medicine (CAM) at least once during the preceding month. Among CAM, antioxidants have been popularly used by patients with chronic hepatitis C because it is said that oxidative stress deteriorates chronic hepatitis. However, the information about the use of supplementations for chronic hepatitis C was insufficient.

### Research frontiers

Resveratrol (RVT) was discovered to be a strong activator of *sirtuin*, a gene for longevity, and the most important polyphenol responsible for the beneficial effects of red wine, which has been called the "French Paradox". RVT showed a strong antioxidative effect on cardioprotection, anti-atherosclerosis and relaxation of vascular endothelium through nitric oxide release. This information resulted in the popularity of this supplementation for people who suffered from chronic diseases. Since RVT inhibits the replication of other viruses, it is thought that RVT also inhibits HCV replication. However they revealed RVT enhanced HCV replication.

### Innovations and breakthroughs

The investigation on HCV replication has been enabled by using the replicon system, in which HCV RNA replicates but unfortunately viral particles were not produced. Recently, the cell culture system in which HCV particles are produced was developed by Dr. Wakita T, and many new insights of HCV virology have been discovered. This study focused on the effect of taking daily supplementations on viral replication and antiviral therapy of HCV.

### Applications

The authors recommend patients with chronic hepatitis C who receive IFN-

based antiviral therapy not to take RVT as an antioxidant supplement, although astaxanthin (AXN) may not affect anti-viral therapy.

### Peer review

In this study, Nakamura *et al* tried to show the efficacy of antioxidants, RVT and AXN, on HCV replication. Since RVT inhibits the replication of other viruses, it was thought that RVT also inhibited HCV replication. However they revealed RVT enhanced HCV replication. These results are very interesting.

### Abstract

**AIM:** To investigate the role of hepatopoietin Cn (HPPCn) in apoptosis of hepatocellular carcinoma (HCC) cells and its mechanism.

**METHODS:** Two human HCC cell lines, SMMC7721 and HepG2, were used in this study. Immunostaining, Western blotting and enzyme linked immunosorbent assay were conducted to identify the expression of HPPCn and the existence of an autocrine loop of HPPCn/HPPCn receptor in SMMC7721 and HepG2. Apoptotic cells were detected using fluorescein isothiocyanate (FITC)-conjugated Annexin V and propidium iodide.

**RESULTS:** The HPPCn was highly expressed in human HCC cells and secreted into culture medium (CM). FITC-labeled recombinant human protein (rhHPPCn) could specifically bind to its receptor on HepaG2 cells. Treatment with 400 ng/mL rhHPPCn dramatically increased the viability of HCC-derived cells from 48.1% and 36.9% to 85.6% and 88.4%, respectively ( $P < 0.05$ ). HPPCn silenced by small-interfering RNA reduced the expression and secretion of HPPCn and increased the apoptosis induced by trichostatin A. Additionally, HPPCn could up-regulate the expression of myeloid cell leukemia-1 (Mcl-1) in HCC cells *via* mitogen-activated protein kinase (MAPK) and sphingosine kinase-1.

**CONCLUSION:** HPPCn is a novel hepatic growth factor that can be secreted to CM and suppresses apoptosis of HCC cells by up-regulating Mcl-1 expression.

Chang J, Liu Y, Zhang DD, Zhang DJ, Wu CT, Wang LS, Cui CP. Hepatopoietin Cn suppresses apoptosis of human hepatocellular carcinoma cells by up-regulating myeloid cell leukemia-1. *World J Gastroenterol* 2010; 16(2): 193-200 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i2/193.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i2.193>

## INTRODUCTION

Hepatocellular carcinoma (HCC) represents the fifth-most prevalent malignant disease affecting humans worldwide with an increasing incidence<sup>[1]</sup>. There is evidence that the protumorigenic growth factor signaling is dysregulated in human HCC affecting different signaling systems, such as insulin-like growth factor, hepatocyte-growth factor (HGF), transforming-growth factor  $\alpha$  (TGF- $\alpha$ )/epidermal-growth factor (EGF), and TGF- $\beta$ <sup>[2]</sup>.

Hepatopietin Cn (HPPCn) is a novel hepatic growth factor derived from a hepatocyte-stimulating substance, which was first reported by LaBrecque in 1975<sup>[3,4]</sup>. It has been shown that the HPPCn mRNA level increases in partially hepatectomized mice following liver injury<sup>[5]</sup>. Recombinant human protein (rhHPPCn) specifically stimulates cell proliferation in primary cultures of hepatocytes and HCC-derived cell lines (HepG2, SMMC7721) *in vitro* as well as liver regeneration following partial hepatectomy *in vivo*. In addition, rhHPPCn can protect hepatocytes against ethanol-induced injury<sup>[6]</sup>.

Investigations of HPPCn have been mainly restricted to its remarkable activity in stimulating liver regeneration. However, its mechanism and potential effect on HCC are unclear. In this study, HPPCn was highly expressed in cytoplasm and nuclei of human HCC cells and secreted into the culture medium (CM), and fluorescein isothiocyanate (FITC)-labeled rhHPPCn could specifically bind to its receptor on HepG2 cells, suggesting that there is an autocrine loop of HPPCn/HPPCn receptor in HCC-derived cell lines. Furthermore, exogenous rhHPPCn suppressed trichostatin A (TSA)-induced apoptosis of HCC cells and up-regulated myeloid cell leukemia-1 (Mcl-1) expression in HCC-derived cells *via* the mitogen-activated protein kinase (MAPK) or sphingosine kinase-1 (SPK1).

## MATERIALS AND METHODS

### Cell lines and cell culture

Two human HCC cell lines, SMMC7721 and HepG2, were used in this study. Cells were cultured in Roswell Park Memorial Institute (RPMI) 1640 medium (Sigma, Saint Louis, MO, USA) supplemented with 10% fetal calf serum, 2 mmol/L glutamine, 100 U/mL penicillin, and 100 mg/mL streptomycin.

### Antibodies and other reagents

Recombinant human HPPCn and anti-HPPCn sera were produced as previously described<sup>[5]</sup>. Primary antibodies, including those against Mcl-1, phos-Erk1/2 (tyr204), phos-Stat3, non-activated Erk1/2, or Stat3, were obtained from Santa Cruz Company (Santa Cruz, CA, USA). Other reagents used in this study were monoclonal anti-mouse/goat/rabbit peroxidase conjugate (Sigma, St. Louis, MO), enhanced chemiluminescence (ECL)

kit, and 3, 3', 5, 5' tetramethylbenzidine (TMB) substrate (Biozol, Eching, Germany).

### Immune staining

Liver tissue samples were fixed with 4% (w/v) freshly prepared paraformaldehyde and cut into 4  $\mu$ m-thick sections with a vibratome (Leica VT1000S; Germany). Non-specific protein binding sites were blocked using 2% bovine serum albumin in phosphate-buffered saline (PBS) for 1 h, and anti-HPPCn serum in a blocking solution was incubated overnight at 4°C in a humidified chamber. The sections were incubated with peroxidase-labeled secondary antibody, treated with 3,3'-diaminobenzidine and hydrogen peroxide, and observed under a microscope.

### Enzyme linked immunosorbent assay (ELISA)

Cells ( $2 \times 10^6$ ) were seeded in a 75 cm<sup>2</sup> tissue culture flask, cultured for 8 h, washed 3 times with a serum-free medium, and cultured for an additional 30 h in 10 mL of a serum-free medium. The supernatant liquid was used as a conditioned medium. To prepare a concentrated conditioned medium, the CM was concentrated to a final volume of 1 mL by ultra-filtration (Millipore, USA) with a 5000-MW-cut-off<sup>[7]</sup>.

In order to detect HPPCn protein in CM, 100  $\mu$ L of the harvested CM was dispensed in a 96-well ELISA plate and incubated overnight at 4°C. The ELISA plate was washed 3 times with PBS, incubated for 2 h with an anti-HPPCn antibody, washed with PBS and then with secondary antibody, incubated for 2 h followed by an additional 15 min in a TMB-substrate. Color intensity was measured with an ELISA-Reader (Dynatech Laboratories, Frankfurt, Germany).

### Western blotting

Protein samples were separated by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred to a nitrocellulose membrane. The nitrocellulose membrane was blocked with a 5% solution of non-fat milk in TBS containing 0.1% Tween 20 (TBST), incubated with primary antibody in 5% bovine serum albumin containing TBST at 4°C overnight, washed 3 times with TBST and incubated with secondary antibody in 5% milk containing TBST. After washed 5 times with TBST, the membrane was developed using the ECL method.

### Cell-binding assay

FITC-labeled rhHPPCn was prepared by incubating FITC (Sigma, St. Louis, MO) with recombinant protein (1/20, w/w) in a borate buffer (0.05 mol/L Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>, pH 9.3) at 4°C for 12 h, followed by purification through a Sephadex G-25 column, according to its manufacturer's instructions (Pharmacia Biotech, Alameda, CA)<sup>[8,9]</sup>.

For the analysis of rhHPPCn binding to HepG2, cells ( $2 \times 10^3$ - $4 \times 10^5$ ) were stained with FITC-labeled rhHPPCn in RPMI with 1% BSA for 30 min at 37°C, washed with PBS containing 1% BSA to remove unbound proteins, resuspended and analyzed by flow cytometry

using a FACScan flow cytometer (Becton Dickinson, Mountain View, CA, USA). Cells on the flow cytometer were gated by forward *vs* side scatter to eliminate dead cells.

### Apoptosis assay

Apoptotic cells were detected using FITC-conjugated Annexin V (Caltag Laboratories, Burlingame, CA, USA) and propidium iodide (PI). Cells were washed twice with cold PBS and resuspended in an Annexin V-binding buffer containing 10 mmol/L 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES), 140 mmol/L NaCl, and 5 mmol/L CaCl<sub>2</sub> at a concentration of  $1 \times 10^6$  cells/mL. The suspension (100  $\mu$ L containing  $1 \times 10^5$  cells), 5  $\mu$ L of Annexin V-FITC and 10  $\mu$ L of PI were added into a 5-mL culture tube. The tube was gently vibrated and incubated for 15 min in the dark at room temperature. After a binding buffer (400  $\mu$ L) was added into the tube, the cells were analyzed by flow cytometry.

### RNA interference

Small interfering RNA (siRNA) for human HPPCn was synthesized by Shanghai Gene Chemical Company (Shanghai, China). The sequences employed in silencing human HPPCn are sense: 5'-CGAACCUCACGCAUCUAAATT-3' and antisense: 5'-UUUAGAUGCGUGAGGUUCGGA-3'. The sequences employed for non-silencing human HPPCn are sense: 5'-UUCUCCGAACGUGUCACGUTT-3' and antisense: 5'-ACGUGACACGUUCGGAGAATT-3'. The HepG2 and SMMC7721 cells were transfected with siRNA using 1,2-dimyristyloxypropyl-3-dimethyl-hydroxy ethyl ammonium bromide-cholesterol (Invitrogen, San Diego, CA, USA) as recommended by its manufacturer.

### Sphingosine (Sph) kinase activity assay

Cells were lysed by freeze-thawing (3 times). The lysates were cleared by centrifugation at 12000 *g* for 30 min at 4°C. The protein concentration of cell lysates was measured by bicinchoninic acid assay (Pierce, Rockford, IL, USA). The SPK activity was assayed by incubating the cell lysates with Sph (Sigma, St Louis, MO, USA) and <sup>32</sup>P-ATP (10  $\mu$ Ci, 50 mmol/L) for 30 min at 37°C. The products were separated by thin-layer chromatography on silica gel G60 (Merck KGaA, Darmstadt, Germany) using 1-butanol/methanol/acetic acid/water (80:20:10:20) and observed by autoradiography<sup>[10]</sup>.

### Statistics analysis

Results were presented as mean  $\pm$  SD of three independent experiments. The data were analyzed by unpaired Student's *t* test using SPSS version 10.0 (SPSS Inc, USA). *P* < 0.05 was considered statistically significant.

## RESULTS

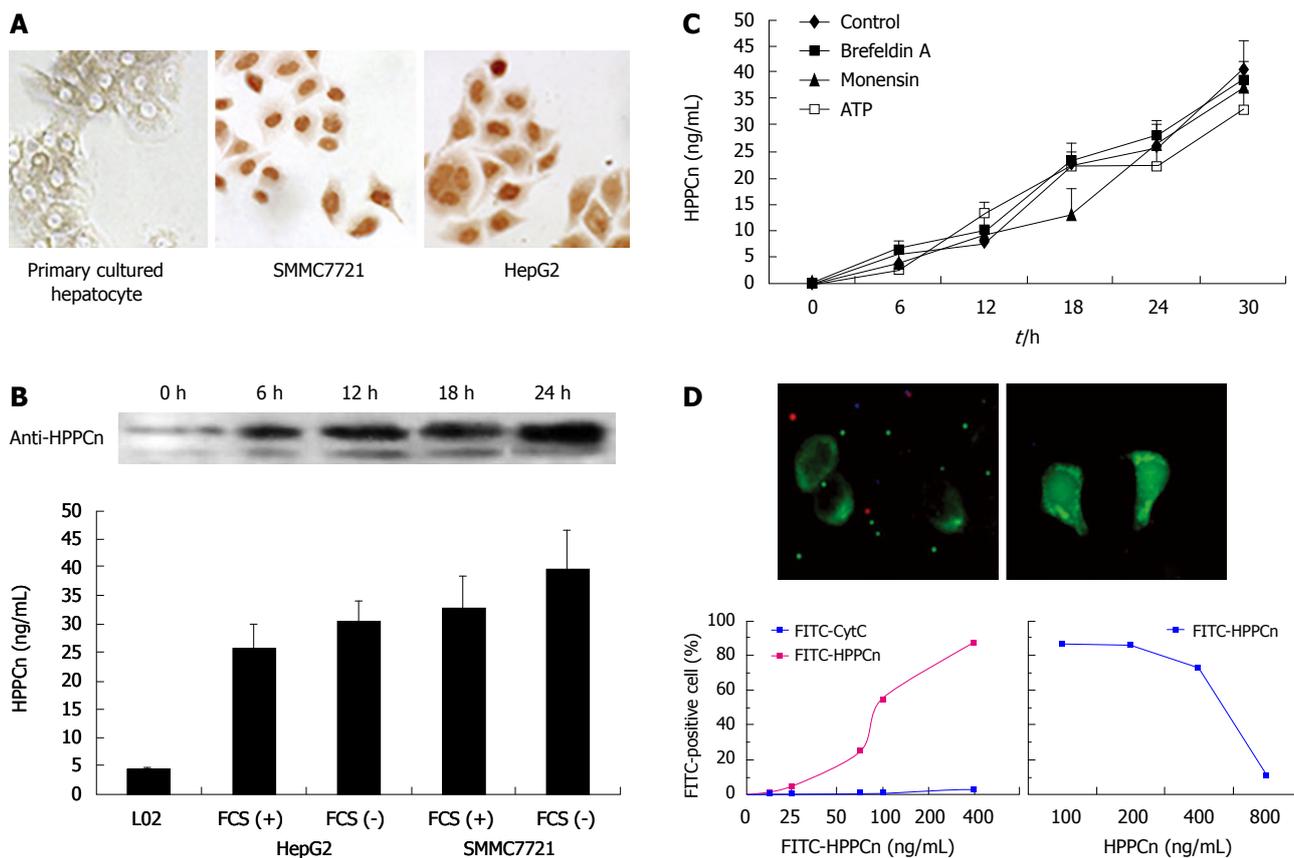

### HPPCn acted as an autocrine factor for HCC cells *in vitro*

Sequence analysis revealed that HPPCn was a nuclear factor and a member of the leucine-rich acidic nuclear

protein family. Since extracellular HPPCn can act as an autocrine factor for HCC cells *in vitro*, we studied its production, secretion, and mechanism of action. The intracellular localization of HPPCn was observed in human HCC cells with immune staining (Figure 1A). The HCC cells (HepG2 and SMMC7721) were strongly stained for HPPCn and the staining was mostly restricted to nuclei and cytoplasm. However, in primarily cultured hepatocytes, the HPPCn staining was weak and mainly restricted to cytoplasm of HCC cells. To determine whether HPPCn is secreted by HCC cells, we analyzed their CM by ELISA and Western blotting, which showed that HPPCn protein was released into CM by HepG2 and SMMC7721 (Figure 1B). The kinetics of HPPCn secretion by HCC cells is shown in Figure 1C. The HPPCn secretion, first detected at 6 h following culture, increased even at 18 and 30 h following culture, suggesting that brefeldin A and monensin, inhibitors of the endoplasmic reticulum (ER)-Golgi pathway, do not affect the HPPCn secretion<sup>[11]</sup>. The secretion of HPPCn triggered by ATP is negligible<sup>[12,13]</sup>. To eliminate the possibility of its leakage (as opposed to secretion) from HCC cells, we assessed the cellular damage with trypan blue staining, which showed that over 99% of the cells were still alive (data not shown), indicating that accumulation of HPPCn in the CM of those cells is caused by its secretion rather than by its leakage from HCC cells. To test the binding of HPPCn to HCC cells, HepG2 cells were incubated with different concentrations of FITC-labeled rhHPPCn and cytochrome C (Cyt-C) at 37°C for 1 h and analyzed by flow cytometry. Fluorescence was found in membrane of HepG2 cells incubated with FITC-labeled HPPCn (Figure 1D) but not in membrane of those incubated with Cyt-C control (results not shown). Furthermore, HCC cells binding to FITC-labeled HPPCn and the density of the bound rhHPPCn tended to reach a plateau when the concentration of FITC-labeled HPPCn was higher than 400 ng/mL (Figure 1D), indicating that the binding of HCC cells to FITC-labeled HPPCn is saturated. In addition, we assessed the reversibility of bound HPPCn with a competitive inhibition curve (Figure 1D), which showed that approximately 30% of HCC cells were bound to FITC-labeled HPPCn following incubation in the presence of 100 ng/mL of unlabeled HPPCn and approximately 10% of HCC cells were bound to FITC-labeled HPPCn when the concentration of unlabeled rhHPPCn was higher than 800 ng/mL, indicating that HCC cells can express and secrete HPPCn and HPPCn can bind to HCC cells in a specific, saturated, and reversible manner and that an autocrine loop of HPPCn/HPPCn receptor is existed in HCC cells.

### HPPCn suppressed apoptosis of HCC cells

HPPCn showed its effect on TSA-induced apoptosis of HCC cells. TSA was initially characterized by an anti-fungal drug and strongly inhibited TSA activity at nanomolar level<sup>[14]</sup>. It has been demonstrated that TSA induces apoptosis of human HCC cell lines (HepG2, Hep3B, and Huh-7) by inducing acetylation of p53 and

**Figure 1** Hepatopoietin Cn (HPPCn) acting as an autocrine factor for hepatocellular carcinoma (HCC) cells *in vitro*. A: Immunohistochemistry showing staining with anti-HPPCn antibody in primarily cultured hepatocytes and HCC cells; B: Western blotting and enzyme-linked immunosorbent assay (ELISA) showing the secretion of HPPCn into culture medium (CM) of HCC-derived cells; C: ELISA showing the kinetics of HPPCn secretion from HCC cells; D: Binding of HPPCn to HCC cells.

histones (H2A, H2B, H3, and H4)<sup>[15-18]</sup>, and inhibits HGF-induced invasion of HepG2 cells but does not affect increased phosphorylation of Erk and Akt in HGF-treated HepG2 cells<sup>[19]</sup>.

The viability of HepG2, SMMC7721 and L02 cells was 48.11%, 36.9% and 31.9%, respectively, 24 h after treatment with 300 nmol/L of TSA (Figure 2A), and increased to 85.6% and 88.4%, respectively, in HCC-derived cells after treatment with 400 ng/mL rhHPPCn ( $P < 0.02$ ). In normal hepatocytes, the protective effect of HPPCn was moderate. HPPCn silenced by small-interfering RNA reduced the expression and secretion of HPPCn (Figure 2B and C) and enhanced TSA-induced apoptosis of HCC cells (Figure 2D), indicating that exogenous HPPCn suppresses apoptosis of HCC cells while HPPCn silenced by siRNA increases the apoptosis of HCC cells.

**HPPCn induced Mcl-1 expression in HCC cells via SPK/S1P and MEK/ERK pathways**

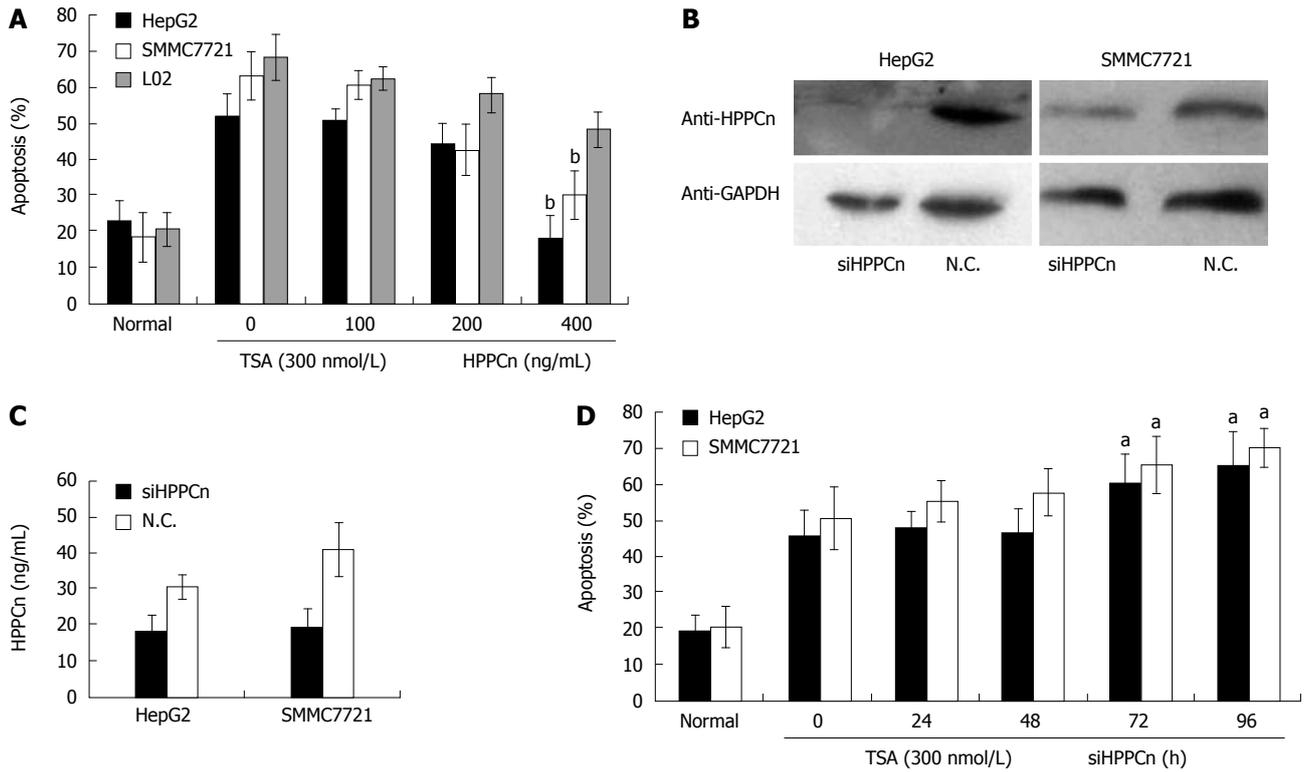

It has been recently demonstrated that Mcl-1, an anti-apoptotic member of the Bcl-2 protein family that interferes with mitochondrial activation, plays a role in the survival of HCC cells<sup>[20]</sup>. The specific up-regulation of Mcl-1 expression in HCC cells could inhibit HCC cell apoptosis induced by chemotherapeutic drugs including histone deacetylase inhibitors<sup>[21]</sup>. However,

Mcl-1 knockdown significantly augments the apoptosis sensitivity of HCC cells toward chemotherapy in combination with PI3K inhibitors<sup>[22,23]</sup>. In addition, certain growth factors (such as HGF and EGF) can induce Mcl-1 expression in HCC cells by activating the PI3K/Akt and MEK/ERK pathways<sup>[24,25]</sup>.

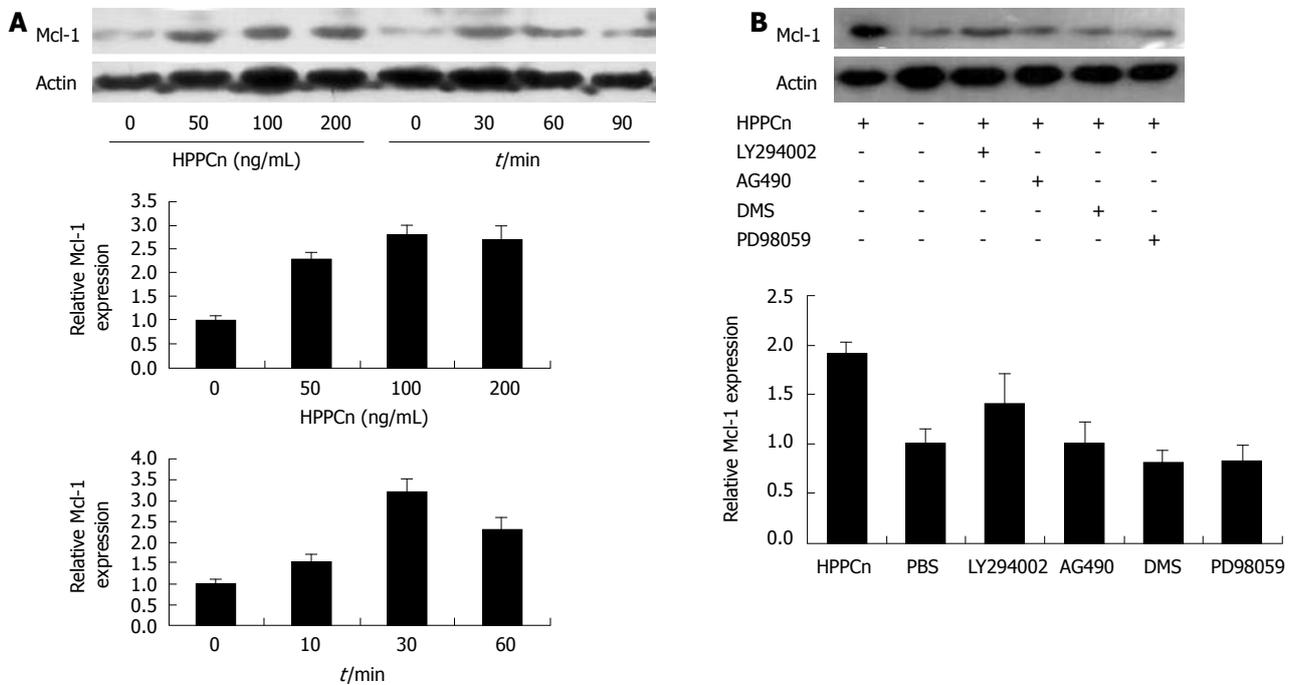

In order to test whether HPPCn influences Mcl-1 expression in HCC cells, HepG2 cells were treated with rhHPPCn at different concentrations for different periods of time. HPPCn induced Mcl-1 expression in a dose- and time-dependent manner (Figure 3A). Furthermore, treatment with rhHPPCn activated the SPK, Stat3, and ERK pathways in HepG2 cells (Figure 4). Thereafter, we determined if the blockage of these pathways can inhibit HPPCn-induced Mcl-1 expression. Cells were pre-incubated with LY294002, PD98059 AG490, or DMS for 1 h, and treated with HPPCn for an additional 3 h. Kinase inhibited by specific inhibitors abrogated the effect of HPPCn on Mcl-1 expression (Figure 3B), demonstrating that HPPCn can activate the signaling pathways involved in survival of HCC cells and up-regulate Mcl-1 expression *via* the MAPK and SPK pathways in HCC-derived cells.

**DISCUSSION**

HPPCn is a novel hepatic growth factor with a specific

proliferation stimulating activity and suppresses apoptosis of HCC cells as an autocrine factor. In this study, the

potential nuclear localization sequences and immune staining suggested that HPPCn was a nuclear factor and

**Figure 4** Effects of rhHPPCn on the activities of SPK (A), Jak-Stat3 (B), and Erk1/2 (C). HepG2 cells were treated for 30 min with the indicated concentration of rhHPPCn and 200 ng/mL rhHPPCn for the indicated periods of time. The phosphorylation of Stat3 and Erk1/2 were determined by Western blotting with antibodies against both species of Stat3 and Erk1/2. The densities of signals were determined by densitometry.

localized in nuclei of HCC cells. ELASA and Western blotting showed that the secretion of HPPCn into CM was not influenced by brefeldin A or monensin, two inhibitors of ER-Golgi pathway. Furthermore, FITC-labeled rhHPPCn binding to HCC cells was specific, saturated and reversible, suggesting that HPPCn acts as an autocrine growth factor in HCC cells *in vitro*.

It has been reported there are some autocrine loops in HCC cells, such as basic fibroblast growth factor (bFGF)/flg, TGF- $\alpha$ /erbB2<sup>[26-28]</sup>, and augments of liver regeneration (ALR)<sup>[7]</sup>. However, the action of bFGF and TGF- $\alpha$  is neither hepatocyte-specific nor liver-specific. It has been shown that ALR protects hepatocytes in Eck's fistula but not cultured hepatocytes and hepatic cell lines against atrophy<sup>[29,30]</sup>. Thus, identification of HPPCn autocrine mechanism in HCC cells might elucidate the pivotal process of hepatic carcinogenesis.

It is interesting to note that HPPCn resembles HCC-derived growth factor (HDGF) and high-mobility group box 1 protein (HMGB1). Extracellular HDGF can stimulate the proliferation of cultured hepatoma cells,

fibroblasts, smooth muscle cells, and endothelial cells. However, it has been reported that nuclear localization is a prerequisite for the mitogenic activity of intracellular HDGF<sup>[31,32]</sup>. Similarly, as a nuclear protein, HMGB1 promotes the interaction between DNA and other proteins, and regulates several families of DNA-binding proteins. It has been reported that HMGB1 relocalizes in LPS-activated monocytes from nuclei to secretory organelles, and activates endothelial cells, promotes angiogenesis, and initiates inflammation as a cytokine<sup>[13,33]</sup>. Another similarity between HPPCn, HMGB1, and HDGF is their secondary structure. Motifs within their N-terminal domains, referred to as LRR, HMG box, and HATH, are involved in protein-protein interaction. In addition, these proteins contain 2 or 3 nuclear localization sequences but lack of any signal peptide-like hydrophobic region, indicating that HPPCn is a bifunctional nuclear protein and acts as a growth factor for cells<sup>[34,35]</sup>.

HPPCn activates signaling pathways involved in survival of HCC cells and up-regulates Mcl-1 expression *via* MAPK, SPK1 in HCC cells. It has been recently

demonstrated that Mcl-1, an anti-apoptotic member of the Bcl-2 protein family which interferes with mitochondrial activation, plays a role in the survival of HCC cells. Furthermore, some growth factors, including HGF and EGF, induce Mcl-1 expression in HCC cells by activating the PI3K/Akt and MEK/ERK pathways contributing to the poor prognosis of HCC patients, suggesting that Mcl-1 is one of the important molecules involved in HPPCn action.

In conclusion, HPPCn is a novel hepatic growth factor that can be secreted to CM and suppresses apoptosis of HCC cells by up-regulating Mcl-1 expression.

## COMMENTS

### Background

There is evidence that protumorigenic growth factor signaling is dysregulated in human hepatocellular carcinoma (HCC) affecting different signaling systems such as insulin-like growth factor, hepatocyte-growth factor, transforming-growth factor  $\alpha$  (TGF- $\alpha$ )/epidermal-growth factor, and TGF- $\beta$ .

### Research frontiers

Hepatopoietin Cn (HPPCn) is a novel hepatic growth factor derived from a hepatocyte-stimulating substance (HSS). Recombinant human protein (rhHPPCn) specifically stimulates cell proliferation in primary culture of hepatocytes and HCC-derived cell lines (HepG2, SMMC7721) *in vitro* as well as liver regeneration following partial hepatectomy *in vivo*. In addition, rhHPPCn has been demonstrated to be capable of protecting hepatocytes against ethanol-induced injury.

### Innovations and breakthroughs

In this study, HPPCn was highly expressed in cytoplasm and nuclei of human HCC cells and secreted into the culture medium. Fluorescein isothiocyanate-labeled rhHPPCn could specifically bind to its receptor on HepaG2 cells, suggesting that an autocrine loop of HPPCn/HPPCn receptor is existed in HCC-derived cell lines. Exogenous rhHPPCn suppressed trichostatin A-induced apoptosis of HCC cells. Moreover, HPPCn up-regulated the expression of myeloid cell leukemia-1 (Mcl-1) in HCC-derived cells *via* the mitogen-activated protein kinase or sphingosine kinase-1.

### Applications

The mechanism of HPPCn underlying liver regeneration the authors observed in this contributes to the diagnosis and treatment of liver diseases.

### Terminology

HSS: A hepatic stimulator substance isolated from rat liver and human fetal liver can increase synthesis of hepatic DNA *in vivo* and *in vitro* as shown by 3H-TdR incorporation. However, its composition still remains unknown.

### Peer review

The manuscript written by Chang *et al* describes autocrine growth of human HCC cells inhibited by HPPCn. The study showed that HPPCn could suppress apoptosis of HCC cells by up-regulating the expression of Mcl-1 and by activating the PI3K/AKT and MEK/ERK pathways, suggesting that HPPCn plays an important role in the hepatocarcinogenesis. The data are interesting and the experiments are well organized.

### Abstract

**AIM:** To evaluate the suitability of rupintrivir against Enterovirus 71 (EV71) induced severe clinical symptoms using computational methods.

**METHODS:** The structure of EV71 3C protease was predicted by homology modeling. The binding free energies between rupintrivir and EV71 3C and human rhinovirus 3C protease were computed by molecular dynamics and molecular mechanics Poisson-Boltzmann/surface area and molecular mechanics generalized-born/surface area methods. EV71 3C fragments obtained from clinical samples collected during May to July 2008 in Shanghai were amplified by reverse-transcription and polymerase chain reaction and sequenced.

**RESULTS:** We observed that rupintrivir had favorable binding affinity with EV71 3C protease (-10.76 kcal/mol). The variability of the 3C protein sequence in isolates

### INTRODUCTION

During March to May 2008, an outbreak of hand, foot and mouth disease (HFMD) erupted in Anhui province, China. Thousands of people, mostly infants and children, were admitted into hospitals with moderate to severe symptoms, e.g. encephalitis, aseptic meningitis and pulmonary edema *etc.*, and over twenty deaths were reported by the health authorities. Laboratory investigations revealed that human enterovirus 71 (EV71) was responsible for this epidemic. Our center also

received 103 cases of HFMD (77 positive for EV71) from May to July 2008 with mild (fever, pneumonia) to severe (meningitis, encephalitis) symptoms and one patient died of viral encephalitis. Currently, treatment options for EV71 infection are limited, individual symptoms such as fever, encephalitis and meningitis are eased by supportive medication.

EV71 belongs to the picornaviridae family, which also include Poliovirus, Rhinovirus, and Coxsackie virus *etc.* It has a 7.4 kb positive-stranded RNA genome encoding one big polyprotein which was cleaved by virally encoded 2A and 3C protease in the process of protein synthesis<sup>[1]</sup>. This results in four structural proteins, VP1, VP2, VP3, VP4, and several non-structural proteins, 2A, 2B, 2C, 3A, 3B, 3C and 3D-Pol. In addition to its role in precursor polyprotein cleavage, the 3C protease is capable of cleaving host factors associated with host cell transcription and binding viral RNA as a constituent of replication complex<sup>[2-4]</sup>. The pivotal role of 3C in the viral life cycle makes it an ideal target for drug design. Indeed, there have been publications on the development of 3C peptidomimetic inhibitors against the picornaviridae family members<sup>[5-7]</sup>, including HRV (Human rhinovirus), an etiological cause of common colds<sup>[8]</sup>. Among them, rupintrivir (Figure 1), an irreversible inhibitor of HRV 3C, is by far the only 3C inhibitor that has entered clinical trials<sup>[9-12]</sup>. Matthews *et al.*<sup>[8]</sup> designed this molecule by taking advantage of covalent adduct formation (Michael reaction) with a reactive serine or cysteine at the active site of the protease such that the inhibitory potency is greatly enhanced. The Phase I and Phase II results, according to the company's press release, showed good safety and pharmacokinetics profiles. Furthermore, reduction in respiratory symptom scores and HRV titer in the upper respiratory tract of experimentally induced HRV infection was also documented.

It has been recently reported that a cell based yeast two hybrid assay system supported the idea that rupintrivir can effectively bind to EV71 3C<sup>[13]</sup>. We attempted to evaluate the affinity of rupintrivir to EV71 3C by homology modeling and atomistic molecular dynamics (MD) simulation. First, a comparative model of EV71 3C was constructed based on the crystal structure of HRV (1CQQ) and Poliovirus 3C protease (1L1N). EV71 3C-rupintrivir was then modeled according to the HRV 3C-rupintrivir complex (1CQQ) and 2 nanosecond MD simulations were performed on both complexes. We observed that rupintrivir can fit into the catalytic core of EV71 3C and is stable during MD. Binding free energy analyses using molecular mechanics Poisson-Boltzmann/surface area and molecular mechanics generalized-born/surface area methods were also performed. The estimated values suggested that rupintrivir has a decreased but still favorable affinity to EV71 3C compared with its HRV homolog. To test whether rupintrivir could fit for the majority of circulating isolates of EV71, we collected the 3C sequences of various epidemics from Genbank together with those obtained from clinical isolates in our center and analyzed the effects on drug-target interaction.

It was found that the residues which make direct contacts with rupintrivir showed minimal sequence variation in 48 divergent isolate sequences. Taken together, we suggest that rupintrivir has a significant affinity and chemical reaction rate with EV71 3C. Given that the pharmacokinetics and safety profiles of this drug have been proved, the findings of this study suggest that rupintrivir may be speedily utilized for treatment of severe EV71 infections, which will be significantly more efficient, in terms of time and resource, than development from a new chemical entity.

## MATERIALS AND METHODS

### Patients

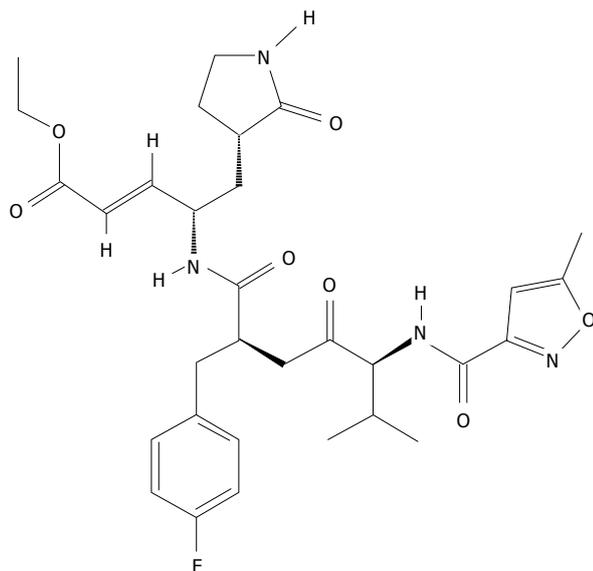

One hundred and three cases of HFMD were admitted into the Shanghai Public Health Clinical Center and tested for EV71 and Coxsackie virus 16 with reverse transcription and polymerase chain reaction during May to July 2008. Seventy seven of these patients tested positive for EV71, in whom, respiratory symptoms and neurological symptoms (meningitis, encephalitis) were documented. There was one death of a 20-mo-old child caused by severe viral encephalitis after being transferred to our hospital.

### Viral culture, sequencing and phylogenetic analysis

Throat swabs and stools were obtained from patients with HFMD in Shanghai public health clinical center. If they tested positive for EV71, samples were grown in RD cells, a human rhabdomyosarcoma cell line, in DMEM with 10% fetal bovine serum, 2 mmol/mL L-glutamine, 100 U/mL penicillin and 0.1 mg/mL streptomycin at 37°C with 5% CO<sub>2</sub>. If cytopathic effects were observed, culture supernatants were collected and RNA was extracted with TRIzol (Invitrogen) reagent and reverse transcribed with superscript II reverse transcriptase (Invitrogen). cDNA from four isolates (42T, 44T, 61T, 122F) were used as templates to amplify viral 3C sequence. The primers used were as follows, 3C forward: 5'-GATYRTHCCTGAW RCTCCCACCA, 3C reverse 5'-GGGTCTTTACTRKK CAASACWG. The 891 bp fragment covering the entire 3C sequence was amplified and TA-cloned into pGEM-T easy vector (Promega). To ensure accuracy, each cDNA was amplified and TA-cloned twice and each clone was sequenced in both directions and assembled. Nucleotide sequences of the 3C region of the four EV71 strains were submitted to Genbank and were analyzed together with the 44 strains in GenBank. The 48 strains were aligned with CLUSTALX software. Phylogenetic trees were constructed by the neighbor joining method and plotted using the program Tree-view. The robustness of the trees was then tested by bootstrap analysis with 1000 pseudo-replicates.

### Homology modeling of EV71 3C protease

The 3C reference sequence (GenBank EU703812) was from a complete genome of an EV71 isolate in Fuyang, Anhui Province, May 2008 and was reported by National

**Figure 1** Chemical structure of rupintrivir.

Polio and Measles Lab, Institute for Viral Disease Control and Prevention, China CDC. Two homologous entries in the protein data bank with over 44% and 55% identity, i.e. 1CQQ (HRV 3C-rupintrivir complex, resolution 1.85 Å) and 1L1N (poliovirus 3C, resolution 2.10 Å) were used as templates for modeling. Homology modeling was performed on a SGI Tezro workstation using the *Homology* module in the Insight II 2000 software package. The protein sequences were aligned with PSI-BLAST and were further refined by using structural alignment functionality. This alignment was used for comparative modeling implemented in the *Modeler* module which generates structures by applying spatial restraints and MD refinement<sup>[14]</sup>. Three models were generated with the optimization level set as “high” and the coordinate with the lowest probability density function value was chosen. The quality of the model was assessed by *MolProbability sever*<sup>[15]</sup> and *3D-profile*<sup>[16,17]</sup>.

The initial coordinate for the EV71 3C-rupintrivir complex was constructed in Insight II according to the 1CQQ crystal structure. Briefly, EV71 3C and 1CQQ were superimposed and the covalent bond between the Cys147 thiol group and rupintrivir C19 was broken. After removal of HRV 3C protease, EV71 3C and rupintrivir were merged and subjected to further energy minimization.

### Molecular dynamic simulations

The simulations were performed using the AMBER 9 package with AMBER99SB<sup>[18]</sup> and GAFF<sup>[19]</sup> force fields. The coordinate of rupintrivir was prepared by breaking the bond between the inhibitor and the Cys147 thiol group in 1CQQ and resuming the trans-unsaturated bond. Partial charges and missing force field parameters were generated by the Antechamber program<sup>[19]</sup> in the AMBER suite using the AM1-BCC method. The 1CQQ complex (inhibitor detached from Cys147) and the

EV71 3C-rupintrivir structure as described above were employed as the starting point for energy minimization and MD simulations. Missing hydrogen atoms were added using the Xleap program. The protonation state of the histidine residues was checked by H++ server<sup>[20]</sup>. The complexes were solvated with 8 Å of TIP3P in a truncated octahedron by *solvateOct* command in Xleap. The systems were neutralized by sodium or chlorine ions.

Because of the large VDW repulsion energy caused by the manually built coordinate, the EV71-rupintrivir complex was carefully minimized before starting MD in a four-step manner, with 200 cycles of steepest descent and 800 cycles of conjugate gradient each step and descending restraints (500, 50, 10 and 2 kcal/mol-Å<sup>2</sup>). The 1CQQ complex was minimized with similar parameters except with less restraint (50, 10, 2 and 0 kcal/mol-Å<sup>2</sup>). The particle mesh Ewald method was used to treat long-range electrostatics and a cutoff was set to 12 Å. The SHAKE procedure was utilized to fix all hydrogen atoms, the time step was set to 2.0 fs. The system was heated in 50 ps from 0 to 300 K using Langevin dynamics with a collision frequency of 2.0/ps and 2.0 kcal/mol-Å<sup>2</sup> restraint. A 500 ps equilibration was performed in a NPT ensemble followed by a 2 ns production dynamics. The coordinates were saved every 2 ps.

### Binding free energy analysis

The binding free energy was calculated using the MMPBSA<sup>[21]</sup> and MMGB-SA procedures<sup>[22,23]</sup>. The binding free energy is calculated as follows:  $\Delta G_{\text{binding}} = \Delta E_{\text{gas}} + \Delta G_{\text{sol}} - T\Delta S$ , where  $\Delta E_{\text{gas}} = \Delta E_{\text{ele}} + \Delta E_{\text{vdw}}$ . The gas phase energy, desolvation energy and entropic contributions are averaged over the snapshots generated during MD. The desolvation energy can be further separated into polar and nonpolar parts, that is,  $\Delta G_{\text{sol}} = \Delta G_{\text{PB}}/\Delta G_{\text{GB}} + \Delta G_{\text{SA}}$ . The polar solvation energy can be estimated by Poisson Boltzmann or Generalized Born method implemented in the *mm\_pbsa* script<sup>[23]</sup> in AMBER9. The nonpolar solvation energy ( $\Delta G_{\text{SA}}$ ) is computed with Molsurf. The  $\Delta G_{\text{PB}}$  was calculated with grid spacing set to 0.5 Å and ionic strength was set to 0. The  $\Delta E_{\text{gas}}$  and  $\Delta G_{\text{sol}}$  was calculated with 100 snapshots of the trajectory at time interval of 20 ps. The entropy contribution ( $T\Delta S$ ) was estimated by normal-mode analysis utilizing the *nmode* module, which computes vibrational, rotational, and translational entropies. Each snapshot was minimized 50 000 steps until the energy gradient was below 0.0001 kcal/mol Å with a distance-dependent dielectric constant of 4r (r is the distance between two atoms). Ten snapshots at each trajectory were calculated due to the computation cost of normal mode analysis.

### Energy decomposition using MM-GBSA method

Apart from the computation efficiency compared with the PBSA approach, the GBSA energies can be further decomposed on a per residue and even a backbone or side-chain basis which provides a simple means to evaluate energy contributions of each residue. All energy

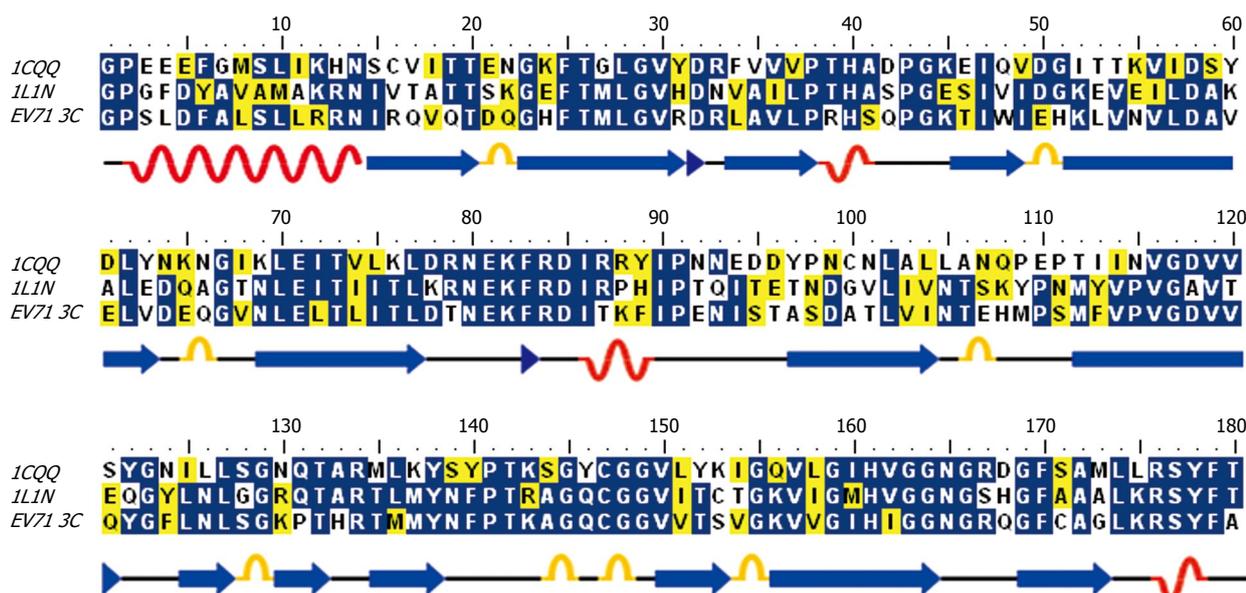

Figure 2 Sequence alignment of EV71 3C protease with HRV 3C (1CQQ) and Poliovirus 3C (1L1N). Secondary structures (α helices and β sheets) were illustrated.

components were estimated using the decomposition functionality in *mm\_pbsa* module using 100 snapshots of the trajectory at time interval of 20 ps.

### Trajectory analysis and visualization

Trajectories from MD simulation were analyzed by the *ptraj* module. Hydrogen bond formation was analyzed by the *hbond* command and atom-to-atom distance, angle and dihedral angle were measured by *distance*, *angle* and *dihedral* command, respectively. Trajectories were visualized and inspected by VMD<sup>[24]</sup>, the Chimera suite<sup>[25]</sup> was used for graphic presentations of the complexes.

## RESULTS

### Homology modeling of EV71 3C protease

Using PSI-BLAST to search similar PDB sequences, a number of homologous entries were found including 1L1N (poliovirus 3C protease, 55% identity), 2IJD (poliovirus 3CD precursor, 54% identity), 2B0F (NMR structure of HRV 3C protease, 49% identity) and 1CQQ (Type 2 HRV 3C with rupintrivir, 44% identity). 1L1N<sup>[26]</sup> and 1CQQ<sup>[8]</sup> were subsequently chosen for template of homology modeling because of higher resolution and the preferable holo coordinate (Figure 2). The predicted structures generated by *Modeler* were then evaluated by *Profile-3D*; one model was selected with a score of 85.38 (expected score 82.94) and a sound folding profile for further analysis. The stereochemical property as indicated by the Ramachandran plot was highly reasonable. 98.9% of the residues were in favored regions and 99.4% were in allowed regions. Only one residue (Asp32) was barely outside of the allowed regions (data not shown).

The structure of EV71 3C protease retained the key features of HRV and poliovirus 3C with a two β-barrels fold and a shallow groove for substrate binding between

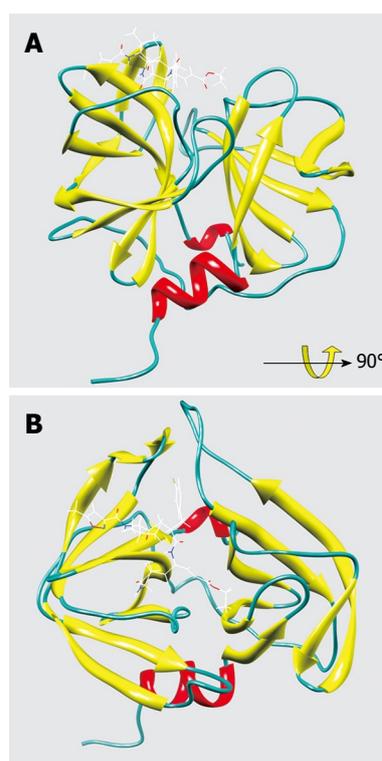

Figure 3 The overall structure of EV71 3C protease complexed with rupintrivir. A: A solid ribbon presentation of EV71 3C with rupintrivir; B: 90° rotation view of the structure.

the two domains (Figure 3). The backbone root mean square deviation (RMSD) between EV71 3C-1L1N and EV71 3C-1CQQ is 0.229 Å and 1.48 Å, respectively

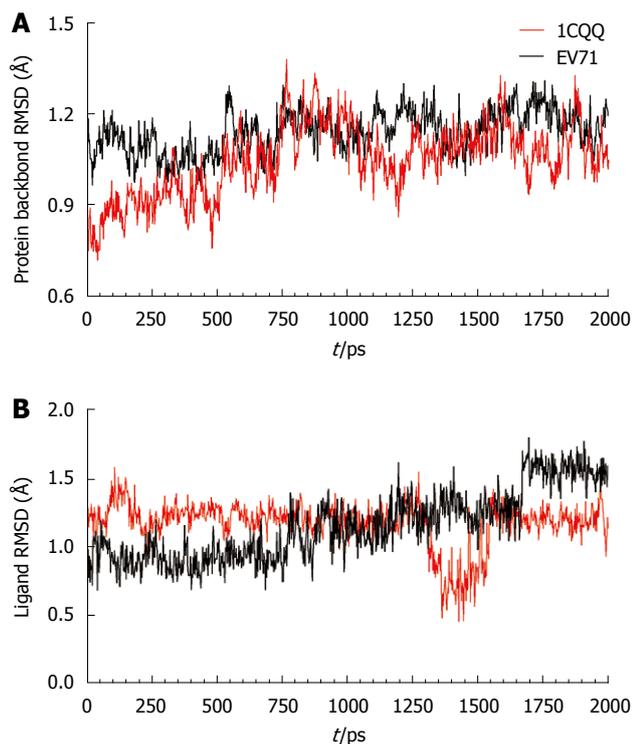

### Stability of the EV71 3C-rupintrivir complex

To further probe the stability of the EV71 3C-rupintrivir complex, we then performed MD simulations and RMSD of *C<sub>α</sub>* atoms during the production phase relative to initial coordinate was plotted (Figure 4A). Compared with 1CQQ complex (RMSD 1.04 Å), the EV71 protein backbone showed relatively higher displacement during

**Table 1** Binding free energies (kcal/mol) of Rhinovirus 3C protease and EV71 3C protease complexed with rupintrivir

production MD (1.56 Å), which was mainly caused by the five N terminal residues (G<sub>1</sub>PSLD<sub>5</sub>). Unlike its template, 1CQQ, these residues did not adopt a helical conformation and showed very high fluctuation during MD (data not shown). This was presumably caused by the less reasonable starting coordinate assigned during homology modeling. Nevertheless, these residues were not in close contact with the inhibitor and hence did not significantly influence the binding energy. Indeed, if the displacement was measured without these residues, EV71 complex showed displacement similar to that of 1CQQ and reached equilibrium and remained stable during the simulation (Figure 4A). Ligand heavy-atom RMSD plot (Figure 4B) also indicated similar displacement (average, 1CQQ:1.18 Å, EV71: 1.16 Å) but remained stable in a 2ns run (STD, standard deviation, 1CQQ: 0.16 Å, EV71: 0.25 Å).

Both 1CQQ and EV71 MD simulations retained

**Figure 5** Binding mode of AG7088 with 1CQQ (A) and EV71 3C (B). The protein surface is rendered semitransparent with associated backbone and side chain atom.

the major binding mode in the crystal structure (Figure 5). The P1 lactam group filled into the pocket formed by Thr142, His 161 *etc.*, the carboxamide oxygen and the amide nitrogen interacted with these residues *via* hydrogen bonds. The P2 4-fluoro-Phe group fitted very well in the S2 specificity pocket. The isoxazole group was buried in the S4 pocket and the vinyl group was close to and oriented well with the SG atom of Cys147.

#### Binding free energy estimate of EV71-rupintrivir complex

We then estimated the binding free energy of EV71 complex and 1CQQ complex using MM-PBSA and MM-GBSA methods. To save computational cost, the single trajectory approach was used since no significant conformational changes upon complex formation were reported. Indeed, 1L1N (no inhibitor bound) and 1CQQ (rupintrivir bound) have 0.75 Å backbone RMSD with 43.89% sequence identity, and the shapes of catalytic core are essentially the same (catalytic pocket residue backbone RMSD = 1.01 Å). As shown in Table 1, the PBSA method predicted binding free energy of -18.96 kcal/mol for 1CQQ and -10.76 for EV71 complex. However, the GBSA method gave considerably higher free energy (-27.56 kcal/mol for 1CQQ, -21.41 kcal/mol for EV71) because of lower estimation of unfavorable electrostatic solvation energy. The non-polar solvation energy gave a favorable contribution (-8.22 kcal/mol in 1CQQ and -8.11 kcal/mol in EV71) because of reduced surface area. Overall, we observed that the EV71 complex still had

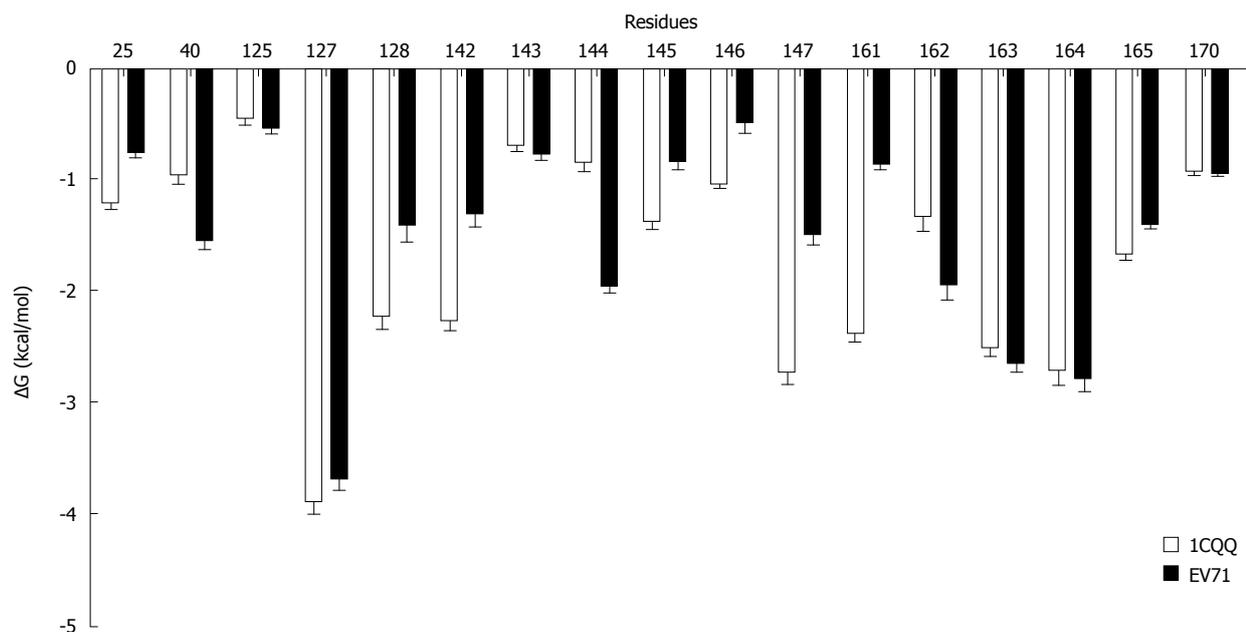

Figure 6 Energy decomposition (using MM-GBSA) of the key interaction residues in 1CQQ and EV71 3C complexes.

favorable binding energy although slightly lower than that in 1CQQ.

### Energy decomposition

To further analyze the energy contributions of individual residues, we decomposed the binding energies of 1CQQ and EV71 complex (Figure 6). It can be concluded from the plot that the decreased binding free energy was not governed by a single or two residues but a sum of cumulative effects. Indeed, residue Phe25, Ser128, Thr142, Gly145, 146Tyr/Gln, Cys147, His161 contributed less favorably in EV71 complex. Notably, all these sites, except for residue 146, have the same amino acid which suggests that the decreased energy contribution is caused by minute differences in the backbone coordinate. Nevertheless, we also observed several sites (His40, Ala144 and Ile162) that had more binding energy contributions than those in 1CQQ. Further analysis indicates that these residues all have preferred VDW and solvation energy.

### Sequence variability of EV71 3C protease and its effect on rupintrivir binding

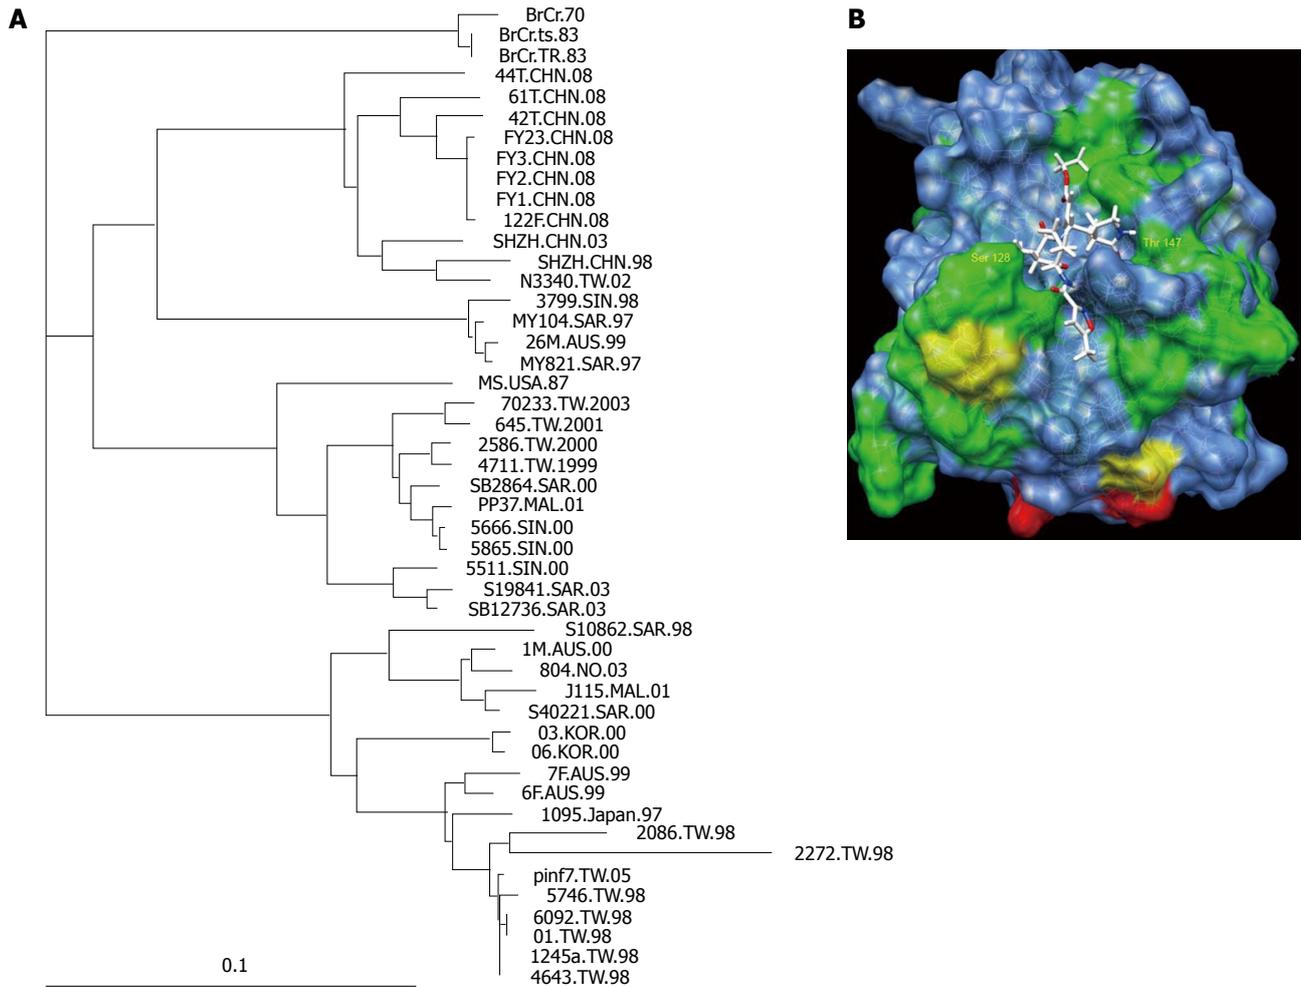

As RNA viruses typically exhibit a high mutation rate in their replication process which could facilitate drug resistance, we sought to evaluate natural sequence variations in isolates collected in various epidemics and their effect on rupintrivir binding. Four sequences of 3C isolated in our hospital were also included (Figure 7A). Phylogeny analysis indicated that very high similarity between isolates in Shanghai and in Fuyang, Anhui province and 122F has 100% identity with the EU703812 reference sequence (Figure 7A). We then further scrutinized the variability of the residues with considerable contact with rupintrivir. As shown in Figure 8, most strains exhibited high conservation on key residues (red open box) in the binding site (residue 25, 40, 125-128, 142-147, 161-165,

170). However, variations on key sites were repeatedly shown in isolate 2272.TW.98 which was obtained from a patient who died of pulmonary hemorrhage and shock in 1998, Taiwan. Further structural analysis suggests that Arg128 in 2272.TW.98 (Ser in Reference sequence) may create a steric hindrance to the 4-fluoroPhe group of rupintrivir (Figure 7B). In addition, the Pro142 in 2086.TW.98, which replaced the conserved Thr residue important for hydrogen bond formation with the lactam ring, could also drastically affect inhibitor docking. The variability observed in residue 144, 145 in 2272.TW.98 and BrCr.70 is unlikely to abolish rupintrivir's activity as the unsaturated ester group is shown to be quite flexible in simulation (data not shown). Taken together, although the catalytic core of EV71 3C is generally preserved in a wide range of isolates, potential natural drug resistance may exist which would limit the usefulness of rupintrivir.

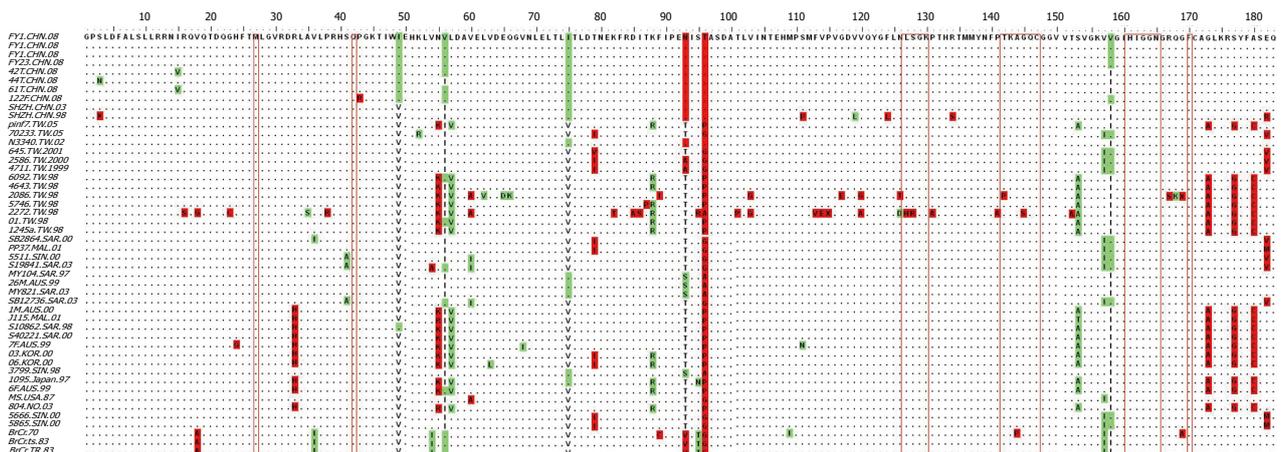

## DISCUSSION

Since the first case of EV71 infection in California in 1969, EV71 has been identified in several small-scale outbreaks in United States, Europe, Australia, Japan, Brazil and Malaysia<sup>[27-32]</sup>. EV71 infection has become a prominent public health issue since the outbreak in Taiwan, China, 1998, with 129 106 cases of HFMD and 405 cases of severe disease<sup>[33]</sup>. Notably, a recent EV71 epidemic in Anhui province during March to May 2008, PR China has also caused over 20 deaths and raised public awareness of the HFMD.

There have been some reports on anti-EV71 drug development in recent years<sup>[34-36]</sup>. Notably, Kuo *et al.*<sup>[7]</sup> designed a series of compounds against EV71 3C based on the structure of rupintrivir. Nevertheless, most of these drugs are still in the early phase and need

**Figure 7** Sequence variability of EV71 3C protease and its effect on rupintrivir binding. A: Phylogenetic tree of 48 isolates of EV71 in various outbreaks; B: A colored representation of sequence variation on the surface of 3C protease. Positions with two, three and over three different residues are labeled green, yellow and red, respectively. Residue Ser 128 and Thr 142 were labeled.

**Figure 8** Sequence alignment of 3C protease from isolates collected in various epidemics (CHN: Mainland China; TW: Taiwan, China; FY: Fuyang, Anhui Province, China; SHZN: Shenzhen, China; AUS: Australia; SAR, SIN, MAL: Malaysia; KOR: Korea; NO: Norway). Residues important for rupintrivir are labeled with red open boxes.

further optimization of pharmacokinetics and ADMET (absorption, distribution, metabolism, excretion and toxicity) profiles. EV71 vaccine research is also in an early development stage<sup>[37]</sup> and needs further human

safety tests. The scarcity of available antiviral medication renders clinical intervention of severe cases challenging.

In this report, we suggest that an available drug, rupintrivir, is an attractive candidate for treatment of

severe cases of EV71 infection. MD and MM-PBSA (GBSA) analysis suggested a decreased but still favorable interaction with EV71 3C protease compared with HRV 3C. In addition, rupintrivir had been shown to be effective against all the human HRV serotypes and several human enterovirus strains (CVB2, 5, EV6, 9) because of high conservation in the rupintrivir binding site, although EV71 was not tested<sup>[9]</sup>. Recently, using plaque reduction assay and a real-time fluorescence resonance energy transfer model, rupintrivir showed around 0.8  $\mu\text{mol/L}$  EC50 activity<sup>[38]</sup>. Of note, the EC50 in EV71 (0.8  $\mu\text{mol/L}$ <sup>[38]</sup>) and in type 2 HRV (20 nmol/L<sup>[8,9]</sup>) can be well correlated with free energy estimate in our research (-18.96 kcal/mol in HRV and -10.76 kcal/mol in EV71, MM-PBSA method). Collectively, using molecular simulation and binding free energy estimation, we suggest that rupintrivir can effectively inhibit EV71 3C protease, which is confirmed by recent *in vitro* viral culture study. Utilization of old drugs for treatment of new indications has its intrinsic superiority since all the pre-clinical research and most of clinical research can be obviated. If rupintrivir could prove its efficacy in HFMD patients, this drug could be quickly administered to EV71 patients with severe symptoms and possibly reduce the mortality rate of HFMD in infants.

## COMMENTS

### Background

The enterovirus 71 (EV71) is the major pathogen causing hand foot and mouth disease (HFMD). During March to May 2008, an epidemic of HFMD erupted in Anhui province and the surrounding area, China with significant mortality. The authors' hospital received over one hundred of these patients including several with severe complications.

### Research frontiers

To date, there have been no antiviral drugs available for EV71 infection with severe symptoms. Although, reports of compounds that can inhibit EV71 replication *in vitro* are accumulating, they still need to be tested in pharmacokinetics, ADMET (absorption, distribution, metabolism, excretion and toxicity) and other safety profiles.

### Innovations and breakthroughs

In this article, the authors modeled the EV71 3C protease, which is critical for viral replication, based on the crystal structure of rhinovirus and poliovirus 3C. They further evaluated an irreversible inhibitor of rhinovirus 3C, rupintrivir as a possible drug against EV71 by molecular dynamics and molecular mechanics Poisson-Boltzmann/surface area and molecular mechanics generalized-born/surface area methods. This is the first attempt to computationally evaluate the suitability of rupintrivir in inhibiting EV71 3C protease.

### Applications

With the *in vitro* and computational evidence supporting its anti-EV71 activity together with its safety profile in previous clinical trials, rupintrivir may be quickly administered to EV71 patients with severe symptoms and possibly reduce the mortality rate of HFMD in infants.

### Terminology

EV71 belongs to the picornaviridae family and is the major cause of HFMD. HFMD is a human syndrome caused by intestinal viruses of the picornaviridae family. The most common viruses causing HFMD are Coxsackie A virus and EV71. HFMD usually affects infants and children and mostly causes mild symptoms. However, significant mortality has been observed in Anhui province 2008 and in previous outbreaks in Taiwan in 1998.

### Peer review

The manuscript is a predictive study for the use of rupintrivir against EV71 infection, based on a computer analysis of the relationship of rupintrivir structure

and EV71 structure. Data showed the potential binding of rupintrivir on the EV71 3C protease. The study is well conducted and the analysis appears solid.

### Abstract

**AIM:** To study the protein C activation system in human liver myofibroblasts, and the effects of activated protein C (APC) on these cells.

**METHODS:** Human liver myofibroblasts were obtained by outgrowth. Expression of protease activated receptor 1 (PAR-1), endothelial protein C receptor (EPCR) and thrombomodulin (TM) was analyzed by flow cytometry. Extracellular signal-regulated kinase (ERK)1/2 activation was assessed by Western blotting using anti-phospho-ERK antibodies. Collagen synthesis was studied with real-time reverse transcription-polymerase chain reaction (RT-PCR). Activation of protein C was studied by incubating liver myofibroblasts with zymogen protein C in the presence of thrombin and detecting the generation of APC with a colorimetric assay using a peptide substrate.

**RESULTS:** Primary cultures of human liver myofibroblasts expressed EPCR on their surface, together with PAR-1 and TM. This receptor system was functional since exposure of myofibroblasts to APC induced

ERK1/2 phosphorylation in a dose- and time-dependent manner. Furthermore, APC significantly upregulated the expression of collagen mRNA, as shown by real-time RT-PCR. Collagen upregulation was controlled through the ERK pathway as it was inhibited when using the mitogen-activated protein/extracellular signal-regulated kinase kinase inhibitor PD98059. Finally, using a cell-based colorimetric assay, we showed that intact myofibroblasts converted protein C into APC in the presence of thrombin.

**CONCLUSION:** These data suggest that APC is a new modulator of liver myofibroblast activity and contributes to the pathophysiology of chronic liver diseases.

### INTRODUCTION

Liver myofibroblasts are key players in the pathogenesis of chronic liver diseases such as fibrosis and cancer. Liver fibrosis is a major health problem as it complicates every chronic liver disease, whether due to hepatitis viruses, alcohol, non-alcoholic steatohepatitis or other causes. Liver fibrosis may progress to cirrhosis, which is an important cause of morbidity. The cell types responsible for the deposition of the excess extracellular

matrix characteristic of fibrosis have been identified as being predominantly hepatic stellate cells and portal fibroblasts<sup>[1,2]</sup>. During liver injury, these cells differentiate into myofibroblasts that proliferate and synthesize fibrosis components. Besides liver fibrosis, a number of studies have shown that the stroma of hepatocellular carcinoma, the major type of primary liver cancer, is populated with myofibroblasts that play major roles in promoting, for instance, extracellular matrix deposition and tumor cell invasion<sup>[3-7]</sup>.

Recently, we and others have demonstrated that the serine proteinase thrombin, a key effector of blood coagulation, affects the phenotype of liver myofibroblasts<sup>[8-11]</sup> and behaves as a pro-fibrogenic molecule in the liver<sup>[12,13]</sup>. Experiments using either antagonists<sup>[12]</sup>, or knock-out animals<sup>[14]</sup> have shown that the pro-fibrogenic effects of thrombin are dependent largely upon signal transduction through protease activated receptor-1 (PAR-1). Upon binding to PAR-1, thrombin cleaves the N terminus of the receptor and the new N terminus behaves as a tethered ligand that activates another PAR1 molecule, which leads to intracellular signaling<sup>[15]</sup>. Besides thrombin, PAR-1 is also a receptor for several other molecules that include matrix metalloproteinase-1<sup>[16]</sup> and especially activated protein C (APC)<sup>[17]</sup>.

APC is generated from protein C (PC) by cleavage with thrombin. This requires that thrombin is bound to thrombomodulin (TM), and PC to its specific cell surface receptor, endothelial protein C receptor (EPCR). The best-known functions of APC are its anticoagulant properties through proteolytic inactivation of factors V a and VIIIa. However, cellular effects of APC have also been shown, which depend on PAR-1 signaling upon interaction with EPCR-bound APC. EPCR is deemed endothelium-specific, therefore, these effects have been studied mostly in endothelial cells where APC is credited with a cytoprotective effect. Recently, EPCR expression also has been demonstrated on a few other cell types, such as lung epithelial cells<sup>[18]</sup>, leukocytes<sup>[19]</sup>, keratinocytes<sup>[20]</sup>, and vascular smooth muscle cells<sup>[21]</sup>. Liver myofibroblasts exhibit many common features with vascular smooth muscle cells, and it is already known that they express functional PAR-1, therefore, we questioned whether they express other cell surface components of the APC system and have functional responses to APC.

## MATERIALS AND METHODS

### Materials

Human PC was purified from plasma as described previously<sup>[22]</sup>. APC was generated using the *Agkistrodon contortrix contortrix* C snake venom protease that recognizes the thrombin cleavage site in PC<sup>[23]</sup>. Monoclonal anti-EPCR antibodies (JRK 1494 and HEPER 1489) and anti-TM antibody (CTM 1009) were kindly provided by Dr. Charles Esmon. Anti-PAR-1 was from Santa Cruz Biotechnology Inc. (Santa Cruz, CA, USA; clone ATAP2), and anti-smooth muscle  $\alpha$ -actin (ASMA) from

Dako (clone 1A4). Human thrombin (1000 NIH U/mg) was from Sigma (St Louis, MO, USA; T4393).

### Cell culture

Human hepatic myofibroblasts were obtained from explants of non-tumor liver resected during partial hepatectomy, and characterized as described previously<sup>[24,25]</sup>. Specifically, the procedure, based on the selective growth advantage of myofibroblasts in the culture conditions used, allowed for a 100% pure myofibroblast population, as shown by positive staining for ASMA and vimentin, and negative staining for CD68 (a Kupffer cell marker), von Willebrand factor (an endothelial cell marker) or cytokeratin (an epithelial cell marker). Myofibroblasts were used between the 3rd and the 6th passage, and were grown in DMEM that contained 5% fetal calf serum, 5% pooled human serum and 5 ng/mL epidermal growth factor (EGF). EGF was removed from the medium at least 3 d before the experiments were conducted.

### Flow cytometry

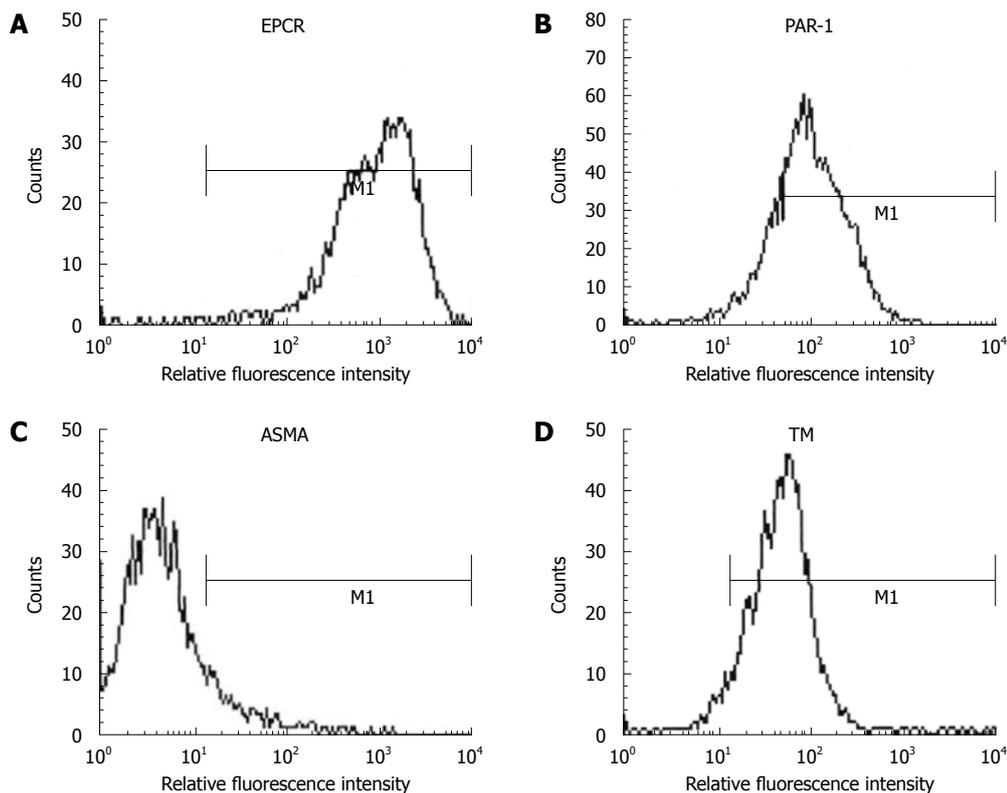

Myofibroblasts were detached from culture plates by incubation in 2 mmol/L EDTA for 15 min at 37°C and collected by centrifugation. One to two hundred thousand cells were incubated with anti-EPCR (JRK 1494, 1/1000), anti-TM (1/50), or anti-PAR-1 (1/50) antibodies. Following a wash with PBS/0.1% BSA, cells were incubated with a secondary phycoerythrin-coupled antibody (1/200) for 15 min at 4°C. After a final wash, the cells were resuspended in PBS/0.1% BSA for analysis.

### Mitogen-activated protein kinase (MAPK) phosphorylation

Extracellular signal-regulated kinase (ERK) phosphorylation was measured essentially as described previously<sup>[10]</sup>. Briefly, cells were grown to confluency and serum-starved for 2 d, and subsequently exposed to the required agonists in serum-free Waymouth medium. At the end of the incubation, cell lysates were prepared in the presence of proteases and phosphatase inhibitors as described previously<sup>[4]</sup>. Equivalent amounts of proteins were separated by SDS-PAGE, transferred to polyvinylidene difluoride membranes, and analyzed by Western blotting for MAPK phosphorylation using phospho-ERK antibody (Cell Signaling Technology, Beverly, MA, USA). The blots were washed and the appropriate peroxidase-conjugated secondary antibody was applied. Immuno-detected proteins were visualized by using an enhanced chemiluminescence assay (Amersham Biopharmacia, Orsay, France). Membranes were stripped and reblotted using antibody to total-ERK. Signals were acquired on a Macintosh computer connected to a Kodak Digital Science DC120 camera and were quantified by using NIH Imaging software.

### APC generation

APC generation from PC by human liver myofibroblasts was demonstrated with a colorimetric method using

**Figure 1** Human liver myofibroblasts express endothelial protein C receptor (EPCR) (A), protease activated receptor 1 (PAR-1) (B), anti-smooth muscle  $\alpha$ -actin (ASMA) (C) and thrombomodulin (TM) (D). Fixed unpermeabilized cells were labeled with antibodies to ASMA and thrombomodulin, and analyzed by flow cytometry. The signal obtained with a control antibody was superimposable with that of ASMA and was not shown for clarity.

**Table 1** Primer sequences used for real-time quantitative reverse transcription-polymerase chain reaction (RT-PCR)

Name	Primer sequence	Amplicon size (bp)
RLP0	F: 5'-GGCGACCTGGAAGTCCAAC-3' R: 5'-CCATCAGCACCACAGCCTTC-3'	149
Collagen $\alpha$ 1(I)	F: 5'-ATGTTACAGCTTTGTGGACCT-3' R: 5'-CAGCTGACTTCAGGGATGT-3'	92

commercial reagents (Spectrozyme aPC plasma specific chromogenic substrate; American Diagnostica, Greenwich, CT, USA). Briefly, confluent quiescent myofibroblasts were incubated for 30 min with purified PC with or without added thrombin 0.1 U/mL (1.8 nmol/L) in HBSS/0.1% BSA. Supernatants were collected and incubated with an APC chromogenic substrate. The optical density of the solution was measured at 405 nm in a Dynatech microplate reader (MTX Lab Systems, Inc., Vienna, VA, USA).

#### Reverse transcription-polymerase chain reaction (RT-PCR) for collagen I

Total RNA was extracted from liver samples using Nucleospin RNA II (Macherey Nagel, Düren, Germany). RNA was reverse transcribed using Superscript II (Promega, Charbonnières-les-Bains, France). Nucleotide sequences of primers for collagen  $\alpha$ 1(I) and for RLP0 (which

encodes the human acidic ribosomal phosphoprotein P0, used as a control) are shown in Table 1. Controls without template or reverse transcriptase were also performed.

PCR reactions were performed using a Stratagene  $\times$  4000 thermocycler (Stratagene, Amsterdam, The Netherlands) and the SYBR Green PCR Core reagents kit (Bio-Rad, Marnes-la-Coquette, France). Five microliters of diluted cDNA samples (produced from 3 ng RNA) were added to 20  $\mu$ L PCR master mix, and experiments were performed in duplicate. Data analysis was performed using Mx4000 version 4.2 (Stratagene). Gene expression results were first normalized to internal control RLP0<sup>[26]</sup>, and the relative levels of expression were quantified by calculating  $2^{-\Delta\Delta Ct}$ <sup>[27]</sup>.

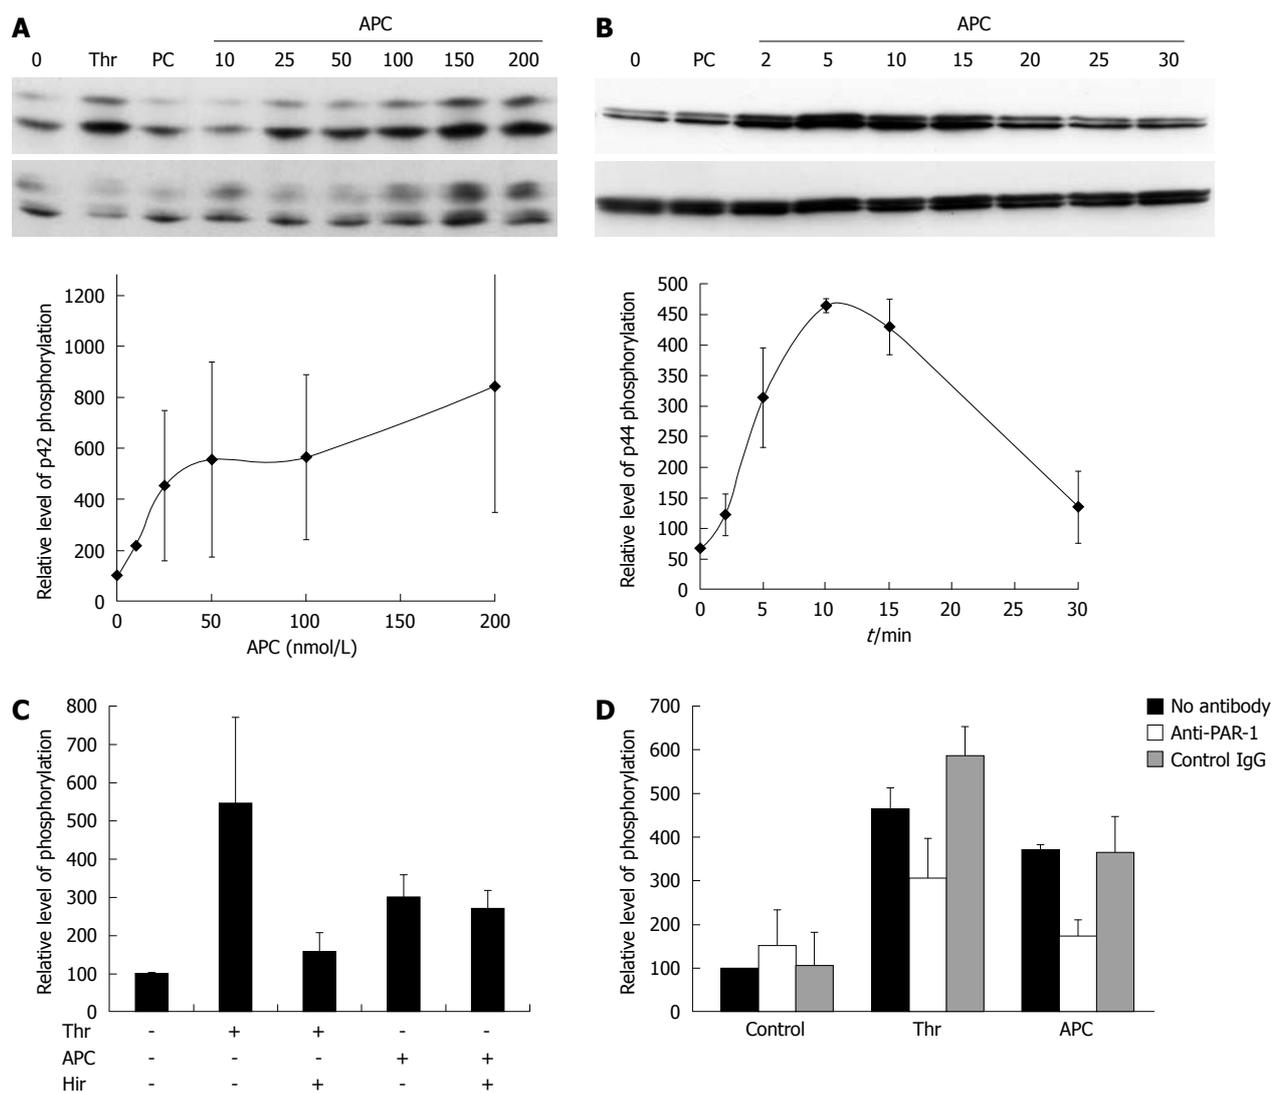

#### Statistical analysis

Differences between multiple means were analyzed by the non-parametric Kruskal-Wallis test using the StatCrunch software (<http://www.statcrunch.com>). A value of  $P < 0.05$  was considered significant.

## RESULTS

### Cultured myofibroblasts express the APC activating complex

APC signaling requires the presence of EPCR and PAR-1 at the cell surface. We thus examined the expression of these two receptors on cultured human liver

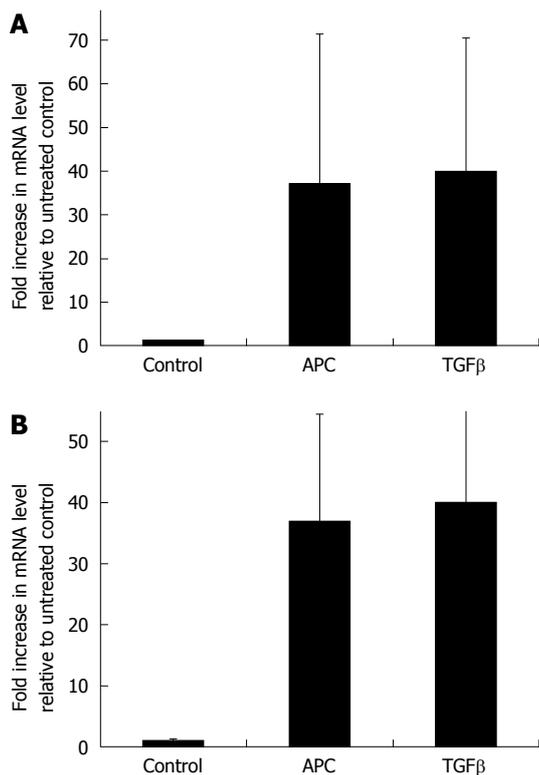

**Figure 2** Effect of activated protein C (APC) on extracellular signal-regulated kinase (ERK) phosphorylation. **A:** Dose-response of APC. Cells were exposed for 10 min to 27 nmol/L thrombin (Thr), 100 nmol/L nonactivated protein C (PC), or APC. ERK phosphorylation was assessed using Western blotting. The upper panel shows a blot labeled with an antibody to phospho-ERK, and the lower panel shows the same blot re-hybridized with an antibody to total ERK. The graph shows the quantification of p42 phosphorylation in three similar independent experiments. Results are shown as mean  $\pm$  SE. Phospho-p42 signals were normalized first to total p42 signals, and the results were expressed as a percentage of the non-stimulated control. Similar results were obtained when quantitating p44 phosphorylation; **B:** Kinetics of APC induced phosphorylation of ERK. Cells were exposed to 100 nmol/L APC. The upper panel shows a blot labeled with an antibody to phospho-ERK, and the lower panel shows the same blot re-hybridized with an antibody to total ERK. The graph shows the quantification of p44 phosphorylation in three similar independent experiments. Phospho-p44 signals were normalized first to total p44 signals, and the results were expressed as a percentage of the non-stimulated control. Similar results were obtained when quantitating p42 phosphorylation; **C:** APC effect is not due to contaminating thrombin. Cells were exposed for 10 min to 27 nmol/L Thr or 100 nmol/L APC. They were pretreated with or without hirudin. The graph shows the quantification of combined ERK1/ERK2 phosphorylation in four similar independent experiments; **D:** APC signals through PAR-1. Cells were exposed for 10 min to 27 nmol/L Thr or 100 nmol/L APC. They were preincubated with the indicated antibodies. The graph shows the quantification of combined ERK1/ERK2 phosphorylation in three similar independent experiments.

myfibroblasts, using flow cytometry on unpermeabilized cells. As shown in Figure 1, liver myfibroblasts expressed easily detectable EPCR and PAR-1. As a control to show that we detected only cell-surface-exposed molecules, we similarly labeled the cells with an antibody to ASMA, an abundant cytoplasmic protein, and found no signal (Figure 1C), although this protein could be demonstrated easily by Western blotting of cell extracts (data not shown). Thus, myfibroblasts express APC receptors on their surface. In addition, we also showed the expression of TM, the thrombin receptor required for PC cleavage (Figure 1D).

### APC induces intracellular signaling

As a readout for the effects of APC, we measured the phosphorylation of the MAPKs ERK1 and ERK2, which is a hallmark of signaling *via* PAR-1. Western blotting demonstrated a dose-dependent increase in phosphorylation of ERK1/2. The maximum level of phosphorylation obtained at a concentration of 100 nmol/L was comparable with that obtained with 27 nmol/L thrombin (1 IU/mL) (Figure 2A). Non-activated PC had no detectable effect. The effect of APC reached a maximum after 10 min of stimulation (Figure 2B). Although the preparation of APC from PC avoided the

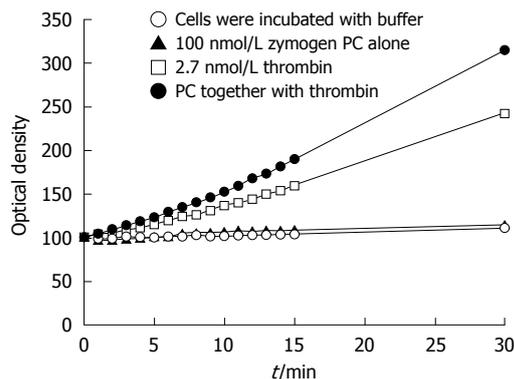

**Figure 3 APC upregulates collagen transcripts.** A: Cells were exposed for 24 h to 100 nmol/L APC or 1 ng/mL transforming growth factor- $\beta$ 1. Collagen transcripts were measured by real-time reverse transcription-polymerase chain reaction and normalized to those of the RPL0 gene. Results are expressed as fold increase over control values and are the mean  $\pm$  SE of five experiments; B: Cells were exposed for 6 h to 100 nmol/L APC, in the presence or absence of the mitogen-activated protein kinase (MAPK) inhibitor PD98059 (50  $\mu$ mol/L), before measuring collagen transcripts. Results are the mean  $\pm$  SE of three experiments.

use of thrombin, we made sure that the effects of APC were not due to trace amounts of thrombin. Thus, cells were pretreated with the specific thrombin inhibitor, hirudin, prior to APC addition. Although hirudin abolished the effects of thrombin on ERK1/2 phosphorylation, it did not alter those of APC, which indicated that they were not caused by contaminating thrombin (Figure 2C).

In order to know whether the effects of APC required PAR-1, cells were incubated with blocking antibodies to PAR-1 or control IgG before adding APC. The PAR-1 antibody blocked by 56.0%  $\pm$  8.7% the effect of APC on ERK1/2 phosphorylation, and as expected, also that of thrombin (37.6%  $\pm$  10.9%,  $P = 0.03$  in both cases) (Figure 2D).

#### APC signaling leads to increased collagen synthesis

We found that exposure of cells to APC significantly increased the amount of  $\alpha$ 1(I) collagen transcripts as compared to the control conditions. Actually, under the conditions used, the effects of 100 nmol/L APC were equivalent to those of transforming growth factor- $\beta$ , a prototypic inducer of extracellular matrix synthesis, used at a concentration of 1 ng/mL (Figure 3A). In order

**Figure 4 Human liver myofibroblasts can generate APC from PC.** Supernatants were collected and incubated with an APC chromogenic substrate. The graph shows the optical density at 405 nmol/L, which resulted from cleavage of the substrate, which was proportional to the amount of APC generated. It represents the mean of two separate experiments.

to know whether this effect of APC involved MAPK signaling, experiments were repeated with or without addition of the MAPK inhibitor PD98059. As shown in Figure 3B, treatment with PD98059 abrogated the effect of APC on  $\alpha$ 1(I) expression.

#### Myofibroblasts generate APC from PC

Human liver myofibroblasts expressed all components of the APC-generating system, therefore, we asked whether they provided a suitable surface for APC generation from PC. We thus incubated cells with the PC zymogen alone or together with thrombin. As shown in Figure 4, incubation of myofibroblasts with PC in the absence of thrombin did not lead to cleavage of the chromogenic substrate. Thrombin alone had a known nonspecific effect<sup>[28]</sup>, which was abolished by hirudin (data not shown). However, when PC and thrombin were added, the amount of peptide cleavage was considerably greater, which indicated that APC was generated.

## DISCUSSION

We show here that human liver myofibroblasts express EPCR. EPCR is functional since treatment of myofibroblasts with APC leads to enhanced ERK phosphorylation, a hallmark of PAR-1 activation<sup>[29]</sup>. We found that APC upregulated collagen mRNA levels, which suggests its role in extracellular matrix metabolism, which is one of the major functions of liver myofibroblasts. It has been shown previously that APC signaling *via* PAR-1 and EPCR leads to extracellular matrix remodeling<sup>[20]</sup>. It is thus possible that APC contributes, together with thrombin, to the liver wound-healing response.

We further showed that myofibroblasts also express TM, the thrombin receptor required for activation of PC to APC. This raised the hypothesis that myofibroblasts could provide a suitable surface for generation of APC from PC in the presence of thrombin. This was indeed proven in the cell-based assay that we ran. Thus, liver myofibroblasts, in addition to endothelial cells, are among

the rare cell types that can generate APC. APC generation by liver myofibroblasts could prove extremely important for these cells to respond to APC under physiological or pathophysiological conditions. Indeed, APC and thrombin share the same signaling receptor, PAR-1, but efficient activation by APC requires concentrations about 10000-fold higher than those of thrombin<sup>[30]</sup>. It is thus not yet entirely clear how APC, which requires thrombin for its generation, can still activate PAR-1 in the presence of thrombin. However, recent evidence suggests that APC signaling is much more efficient when APC is locally generated from PC than when provided exogenously<sup>[31]</sup>. This may be linked to the observation that receptors for PC activation and APC signaling are co-localized within lipid rafts<sup>[32]</sup>. Our finding that human liver myofibroblasts can generate APC makes it very likely that they can respond efficiently to endogenously generated APC. There is evidence that thrombin, which is required for PC activation, is generated in the fibrotic liver, as demonstrated by the presence of fibrin deposition in experimental<sup>[33]</sup> or human liver disease<sup>[34]</sup>. Therefore, our data suggest that APC can indeed contribute to the pathophysiology of chronic liver diseases through effects on liver myofibroblasts, in addition to endothelial cells.

## ACKNOWLEDGMENTS

We thank Dr. C Esmon for antibodies.

## COMMENTS

### Background

A number of recent studies have emphasized the interface between liver fibrosis and the blood hemostasis system, by showing the deleterious role of thrombin and its cellular receptors on the progression of liver fibrosis.

### Research frontiers

Activated protein C (APC) is a major inhibitor of coagulation but also has cytokine-like properties by interacting with a complex of cell surface receptors. Besides endothelial cells, few cells have been shown to express such functional receptors.

### Innovations and breakthroughs

In this study, the authors showed that human liver myofibroblasts, the major fibrogenic cell type in the liver, can bind and activate protein C (PC). Furthermore, they demonstrate that APC triggers collagen synthesis in these cells, which suggests that the local generation of APC by myofibroblasts in the liver may modulate the liver wound-healing process.

### Applications

This study gives new insight into the interplay between blood hemostasis components and liver fibrogenesis.

### Terminology

PC is a circulating protein that can be activated following binding to the endothelial protein C receptor by thrombin, itself bound to thrombomodulin. APC is a major inhibitor of blood coagulation. It can also bind to cell surface protease activated receptor-1 and induce intracellular signals, like a cytokine.

### Peer review

The manuscript is clear and the results are convincing. The data add important new details about pro-fibrogenic activity of liver myofibroblasts.

### Abstract

**AIM:** To test the hypothesis that liver cirrhosis is associated with mobilization of hematopoietic progenitor cells.

**METHODS:** Peripheral blood samples from 72 patients with liver cirrhosis of varying etiology were analyzed by flow cytometry. Identified progenitor cell subsets were immunoselected and used for functional assays *in vitro*. Plasma levels of stromal cell-derived factor-1 (SDF-1) were measured using an enzyme linked immunosorbent assay.

**RESULTS:** Progenitor cells with a CD133<sup>+</sup>/CD45<sup>+</sup>/CD14<sup>+</sup> phenotype were observed in 61% of the patients. Between 1% and 26% of the peripheral blood mononuclear cells (MNCs) displayed this phenotype. Furthermore, a distinct population of c-kit<sup>+</sup> progenitor cells (between 1% and 38 % of the MNCs) could be detected in 91% of the patients. Additionally, 18% of the patients showed a population of progenitor cells (between 1% and 68% of the MNCs) that was characterized by expression of breast cancer resistance protein-1. Further phenotypic analysis disclosed that the circulating precursors expressed CXC chemokine receptor 4, the receptor for SDF-1. In line with this finding, elevated plasma levels of SDF-1 were present in all patients and were found to correlate with the number of mobilized CD133<sup>+</sup> progenitor cells.

**CONCLUSION:** These data indicate that in humans, liver cirrhosis leads to recruitment of various populations of hematopoietic progenitor cells that display markers of intrahepatic progenitor cells.

## INTRODUCTION

Since 2000, several studies have suggested that after transplantation of bone-marrow-derived hematopoietic stem and progenitor cells, such cells have the capacity to migrate into the liver and differentiate into functional hepatocytes<sup>[1-4]</sup>. However, recent data have indicated that cell fusion, but not transdifferentiation, is the principle mechanism by which bone-marrow-derived cells acquire the features of hepatocytes<sup>[5-7]</sup>, and that the myelomonocytic progeny rather than the bone marrow stem cells are the major fusion partners of hepatocytes<sup>[8,9]</sup>.

In a previous study, we have demonstrated that partial hepatectomy (PH) in healthy human liver donors induces a significant mobilization of CD133<sup>+</sup> hematopoietic progenitor cells into the peripheral blood<sup>[10]</sup>. Besides their hematopoietic potential, these cells can differentiate into cells with a hepatocytic morphology and phenotype *in vitro*, which suggests that the mobilized progenitor cells participate in liver repair *in vivo*. The released progenitor cells display a uniform monocytic phenotype, and with respect to their hematopoietic differentiation capacity, represent myelomonocytic precursor cells. Hence, these cells might be endowed with a high fusion potential. It has been shown that a subset of peripheral blood CD14<sup>+</sup> cells can differentiate into multiple cell lineages of all three germ layers<sup>[11,12]</sup>, therefore, it is also conceivable that the CD133<sup>+</sup> progenitor cells identified in our study are the ancestor cell of this subset, with a similar differentiation plasticity.

By hypothesizing that PH-induced CD133<sup>+</sup> cells also occur in other clinical situations of liver injury, we analyzed peripheral blood samples of patients with liver cirrhosis for the presence of these precursors. As in our previous study, we used antibodies against the stem cell markers c-kit and breast cancer resistance protein-1 (Bcrp-1) to characterize further the phenotype of circulating CD133<sup>+</sup> cells. Using this approach, we found different populations of hematopoietic progenitor cells, including the CD133<sup>+</sup> population observed after PH.

## MATERIALS AND METHODS

### Materials

Phycoerythrin (PE)-conjugated anti-CD133 monoclonal antibody (MoAb; clone AC141), anti-CD133 MoAb-conjugated super paramagnetic beads, anti-c-kit MoAb-conjugated super paramagnetic beads, and anti-IgG2b secondary microbeads were purchased from Miltenyi Biotec (Bergisch Gladbach, Germany). Anti-BCRP-1 MoAb and PE-anti-Bcrp-1 were purchased from eBioscience (Vienna, Austria). PE-anti-c-kit MoAb was from DAKO Cytomation (Hamburg, Germany). Fluorescein isothiocyanate (FITC)-conjugated anti-CD34 MoAb, anti-CD45 MoAb, anti-CD14 MoAb, as well as PE- and FITC-conjugated isotype-matched mouse immunoglobulins were from BD Pharmingen (Heidelberg, Germany), and FITC-anti-CXC chemokine receptor

4 (CXCR4) MoAb from R&D Systems (Wiesbaden, Germany). The stromal cell-derived factor-1 (SDF-1) enzyme linked immunosorbent assay (ELISA) kit was purchased from R&D Systems. Fibronectin was from Gibco Life Technologies (Karlsruhe, Germany), and chamber slides were from Becton Dickinson. Methylcellulose and methylcellulose supplemented with hematopoietic growth factors were purchased from Cell Systems (St. Katharinen, Germany). Paraformaldehyde and methanol were from Sigma (Deisenhofen, Germany). Anti-multi-cytokeratin antibody (rabbit anti-human polyclonal) was from Novocastra (Newcastle, UK). Anti-rabbit immuno alkaline-phosphatase polymer (N-Histofine) and the New Fuchsin substrate (N-Histofine Substrate Kit) were purchased from Medac (Hamburg, Germany).

### Collection of peripheral blood samples

The study involved peripheral blood samples from 72 patients with liver cirrhosis of varying etiology. All patients were enrolled into University Hospital Hamburg-Eppendorf Liver Transplant Protocols and gave informed consent for their blood samples to be used for experimental purposes. The study protocol was approved by the University Hospital's Research Committee and conformed to the ethical guidelines of the 1975 Declaration of Helsinki. All samples were collected in heparinized tubes and immediately prepared for analysis.

### Flow cytometry

After lysis with hemolytic buffer (0.155 mol/L NH<sub>4</sub>Cl, 0.012 mol/L NaHCO<sub>3</sub>, 0.1 mmol/L EDTA, pH 7.2) for 5 and 2 min,  $1 \times 10^6$  cells were incubated with PE-conjugated anti-CD133 MoAb in combination with either FITC-conjugated anti-CD34 MoAb, anti-CD45 MoAb, anti-CD14 MoAb or anti-CXCR4 MoAb. Other combinations included FITC-anti-CD34 MoAb, FITC-anti-CD14 MoAb, or FITC-anti-CXCR4 with either PE-anti-Bcrp-1 or PE-anti-c-kit. Isotype-matched mouse immunoglobulins (BD Pharmingen) served as controls. All incubations were performed at 4°C in the presence of normal goat serum. Two-color flow cytometry was accomplished using a FACSCalibur flow cytometer (Becton Dickinson) and CellQuest software (Becton Dickinson). Each analysis included at least 50 000 events. By using isotype controls for PE and FITC, gates for analysis were set such that the lower left panel contained at least 98% of the total cells. The percentage of positive cells was assessed after correction for the percentage of cells that was reactive with the respective isotype control.

### Isolation of mobilized progenitor cells by magnetic cell sorting

Cells were incubated with either anti-CD133 MoAb, anti-c-kit MoAb conjugated super paramagnetic beads or with anti-Bcrp-1 MoAb and anti-IgG2b secondary microbeads, washed, and processed through a MACS magnetic

separation column (Miltenyi Biotec), as previously described<sup>[13]</sup>. An aliquot of the purified cells was analyzed by flow cytometry.

### Quantification of SDF-1 by ELISA

The plasma levels of SDF-1 were measured using a sandwich ELISA (R&D Systems) according to the manufacturer's instructions. Absorbance at 450 nm was determined by an automated ELISA reader (THERMOMax; Molecular Devices, Ismaning, Germany). Regression curve was used to convert OD units to picograms per milliliter of SDF-1. Patients' samples were run in triplicate.

### Suspension cultures

Immunoselected cells were cultured in fibronectin-coated chamber slides at a density of  $2 \times 10^6$  cells/mL in stem cell growth medium, as previously described<sup>[13]</sup>. Hepatocytic differentiation was induced as previously described<sup>[10]</sup>. Cells were incubated for up to 28 d at 37°C in 5% CO<sub>2</sub>. Additional feeding was performed on alternate days. The supernatant was then removed by gentle pipetting and replaced with fresh medium.

### Clonogenic assays for hematopoietic progenitors

Purified cells were plated at  $1 \times 10^3$  cells/mL in semisolid growth medium (methylcellulose) that was supplemented with various hematopoietic growth factors, as previously described<sup>[13]</sup>. All cultures were performed in duplicate, incubated at 37°C in 5% CO<sub>2</sub> and 95% humidity, and scored after 14 d culture, using an inverted microscope.

### Immunocytochemical analysis of CD133-derived cells

Cultured CD133-derived cells were fixed with 4% paraformaldehyde for 10 min at room temperature followed by fixation with methanol for 2 min at -20°C or with ice-cold acetone for 10 min. After blocking with 10% goat serum for 20 min, specimens were incubated with an anti-multi-cytokeratin antibody overnight at room temperature. The reactivity was detected by using an anti-rabbit immuno alkaline-phosphatase polymer in combination with the New Fuchsin substrate. Specimens were counterstained with hematoxylin. Negative controls included replacement of primary antibody with isotypes or PBS, as well as staining of peripheral blood smears. Positive controls were performed using cytopspins with freshly thawed primary human hepatocytes (own preparations from resected liver tissue).

### Statistical analysis

Distribution of data was tested with the Kolmogorov-Smirnov test. Variables are expressed as mean  $\pm$  SE. Bivariate correlations were analyzed with Spearman's rho as indicated.  $P < 0.05$  was considered significant. For all statistical analysis, SPSS version 13.0 was used.

## RESULTS

### Patients' characteristics

The characteristics of the patients studied are shown in

Table 1 Patient characteristics

	AIH	ALD	Hepatitis B	Hepatitis C	Other
<i>n</i>	11	30	9	13	9
Sex (M/F)	3/8	21/9	7/2	8/5	5/4
Age (yr, $\pm$ SE)	47.4 $\pm$ 7	52.9 $\pm$ 8	52.5 $\pm$ 5	50.5 $\pm$ 8	51.8 $\pm$ 9
Child A	6	11	7	6	4
Child B	3	17	2	6	4
Child C	2	4	0	1	1

AIH: Autoimmune hepatitis (including primary biliary sclerosis and primary sclerosing cholangitis); ALD: Alcoholic liver disease. Other includes patients with polycystic liver and with non-specified cirrhosis.

Table 2 Types and frequencies of circulating progenitor cells in patients with liver cirrhosis

Cell subset	Positive/total number of patients	% of the MNCs
CD133 <sup>+</sup>	44/72 (61.2%)	5.8 $\pm$ 4.9
c-kit <sup>+</sup>	65/72 (90.9%)	9.2 $\pm$ 3.2
Bcrp-1 <sup>+</sup>	12/72 (17.9%)	4.1 $\pm$ 3.7

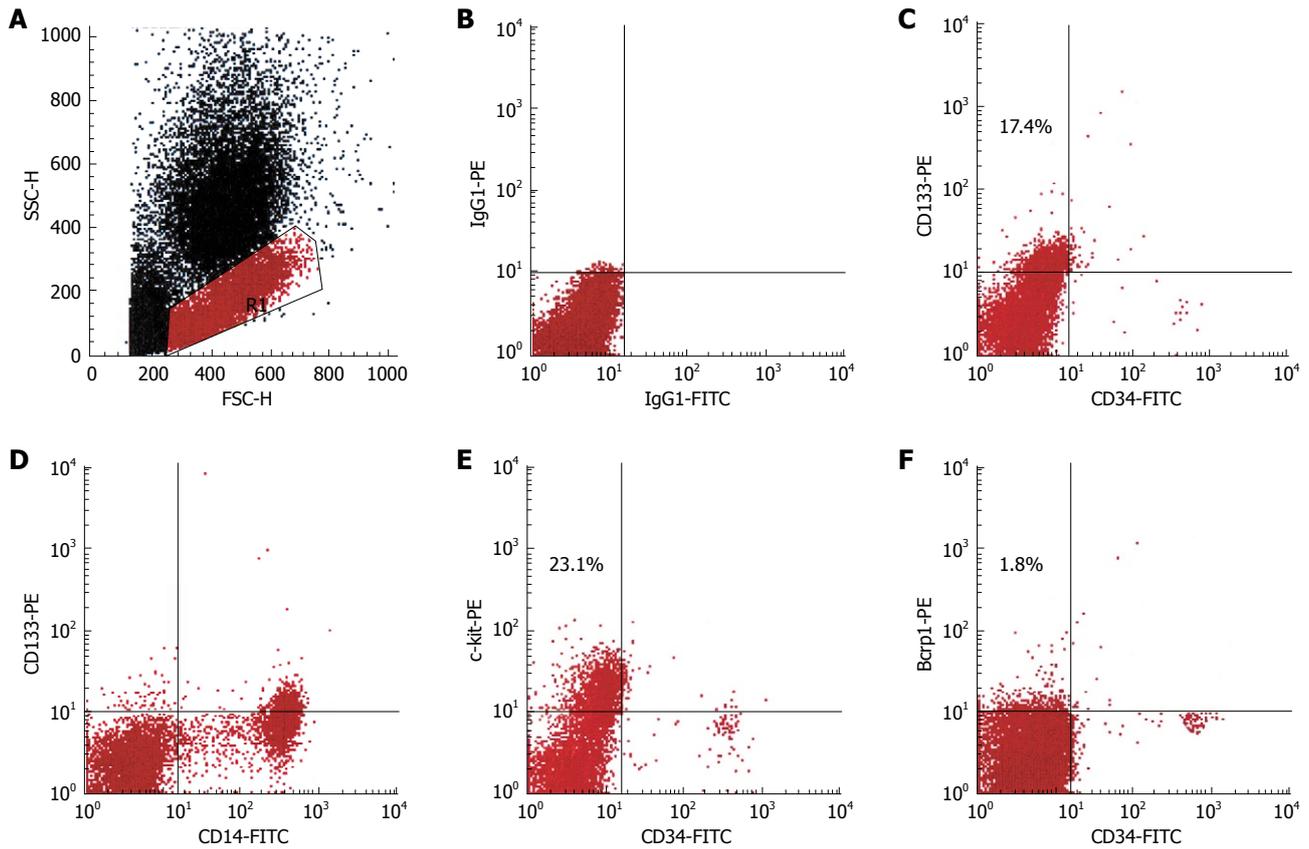

Table 1. Cirrhosis was caused by autoimmune inflammation (11 patients), alcoholic liver disease (ALD, 30 patients), hepatitis B (9 patients), hepatitis C (13 patients), or to non-specified etiology. Autoimmune-mediated cirrhosis was observed more frequently in female patients, whereas male patients were predominantly affected by ALD and viral hepatitis. The subgroups did not significantly differ in age. With respect to the Child score, advanced liver cirrhosis was most prominent in the ALD group.

### Mobilization of CD133<sup>+</sup>, c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> populations

As revealed by flow cytometry, CD133<sup>+</sup> cells were observed in 61% (44/72) of all patients (Table 2). On average, 5.8% of the peripheral blood mononuclear cells (MNCs) expressed this marker. Further phenotypical characterization showed that the vast majority of these cells coexpressed CD14 (Figure 1) and CD45 but not CD34 (data not shown), which indicated that this population was identical to PH-induced progenitor cells. Unexpectedly, a distinct population of c-kit<sup>+</sup> cells was found in > 90% of the patients studied. Between 1% and 38% of the MNCs displayed this phenotype. In 12 patients, an additional population of Bcrp-1<sup>+</sup> cells was detectable, which on average, represented 4.1% of the MNCs (Table 2). All three subsets coexpressed CD45, whereas coexpression of CD34 and/or CD14 was variable in c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> populations (data not shown).

### Lack of correlation between phenotypes and numbers of mobilized progenitor cells and clinical parameters

Analysis of peripheral blood samples from the same patient at different time points showed that progenitor cell mobilization is not a permanent phenomenon. The phenotypes and numbers of circulating progenitors varied in the same patient in an irregular timely manner. Thereby, no correlation was found with any clinical parameters,

**Figure 1** Characterization of circulating progenitor cell populations by flow cytometry. A: Forward/sideward scatter analysis; B: Isotype controls; Representative two-color flow cytometry analysis of the peripheral blood mononuclear cell (MNC) fraction, demonstrating CD133<sup>+</sup> (C and D), c-kit<sup>+</sup> (E), and Bcrp-1<sup>+</sup> (F) populations.

such as liver enzymes, bilirubin, serum albumin, leukocyte count, and platelet count or with the etiology or stage of disease (data not shown). However, numbers of circulating CD133<sup>+</sup> progenitor cells inversely correlated with patients' age (Figure 2A). In addition, there was a significant positive correlation between the numbers of CD133<sup>+</sup>/CD34<sup>+</sup> and Bcrp-1<sup>+</sup>/CD34<sup>+</sup> peripheral blood cells (Figure 2B).

**Mobilization involves the SDF-1/CXCR4 chemokine receptor system**

To investigate the molecular mechanisms that mediate progenitor cell mobilization, peripheral blood progenitor cells were analyzed for the expression of CXCR4, the receptor for SDF-1. Virtually all mobilized CD133<sup>+</sup> cells coexpressed this receptor, whereas in the c-kit<sup>+</sup> populations, on average, half of the cells stained positive for CXCR4 (Figure 3). As mentioned before, Bcrp-1<sup>+</sup> populations were only observed in a few patients. In the set of experiments in which coexpression of CXCR4 was studied, no patient showed elevated numbers of Bcrp-1<sup>+</sup> cells, therefore, the expression of CXCR4 on these cells remains to be explored. In view of the finding that the CD133<sup>+</sup> and c-kit<sup>+</sup> population were found to exhibit CXCR4, the plasma levels of SDF-1 were measured (*n* = 44). Elevated SDF-1 levels were noted in all patients studied. Statistical analysis revealed a significant positive correlation of the plasma levels with the number of mobilized CD133<sup>+</sup>/CD34<sup>+</sup> cells (Figure 2C).

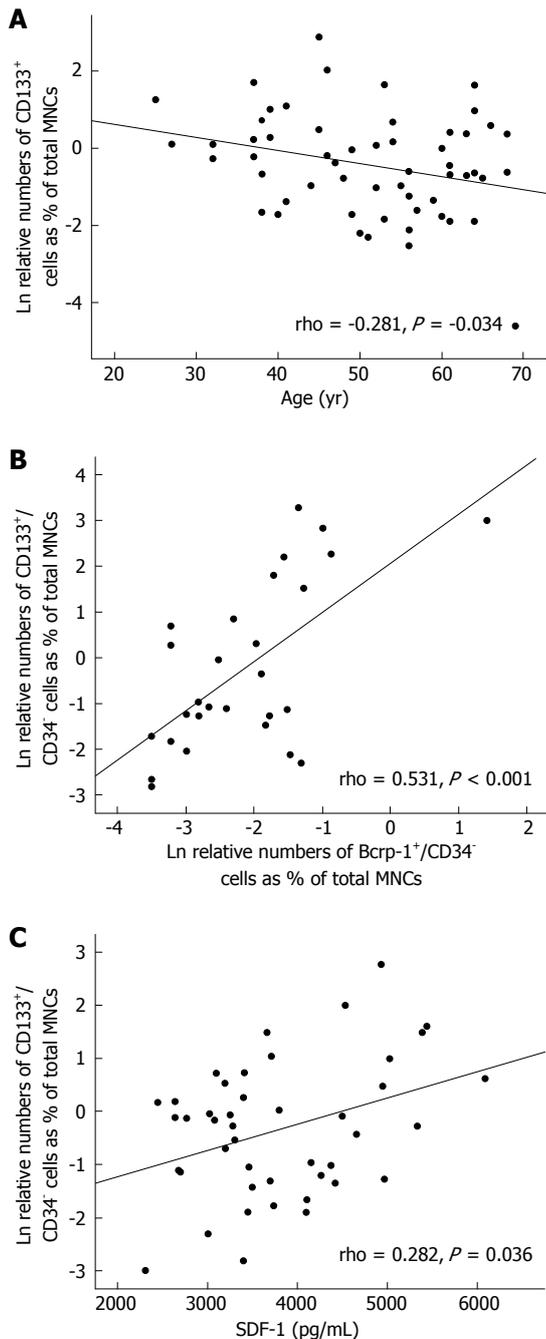

**Table 3** Clonogenic potential of circulating hematopoietic progenitor cell populations (mean ± SE)

Cells	BFU-E	CFU-E	CFU-GEMM	CFU-GM	CFU-G	CFU-M
c-kit	5 ± 2	13 ± 5	3 ± 3	19 ± 8	53 ± 11	27 ± 9
Bcrp-1	8 ± 3	9 ± 2	4 ± 1	9 ± 7	37 ± 14	13 ± 5
CD133	0	0	0	5 ± 3	46 ± 13	63 ± 15

The results of three independent experiments per populations are shown, each experiment was performed in duplicate. BFU-E: Burst-forming unit erythrocyte; CFU-E: Colony-forming unit erythrocyte; CFU-GEMM: Colony-forming unit granulocyte-erythrocyte-macrophage-megakaryocyte; CFU-GM: Colony-forming unit granulocyte-macrophage; CFU-G: Colony-forming unit granulocyte; CFU-M: Colony-forming unit macrophage.

**In vitro functional properties of the mobilized populations**

To evaluate the clonogenic potential of the cirrhosis-induced progenitor cells, each subset was enriched by immunoselection and transferred to a standard colony assay for hematopoietic stem and progenitor cells. As shown in Table 3, c-kit<sup>+</sup> populations and Bcrp-1<sup>+</sup> cells had the capacity to produce colonies of the erythroid, granulocytic, and macrophage/monocytic lineage, as well as mixed colonies. In line with our previous study, CD133<sup>+</sup> populations solely gave rise to colonies of the granulocytic and macrophage/monocytic lineage. The three progenitor cell populations were also evaluated for their potential to differentiate into the hepatocytic lineage, using culture conditions that were suitable for stimulating hepatocytic

**Figure 2 Significant correlations.** Correlation of numbers of circulating CD133<sup>+</sup> cells with patient age (A). Correlation of the numbers of circulating CD133<sup>+</sup>CD34<sup>-</sup> cells with the numbers of circulating Bcrp-1<sup>+</sup>/CD34<sup>-</sup> cells (B) and with stromal cell-derived factor-1 (SDF-1) plasma levels (C).

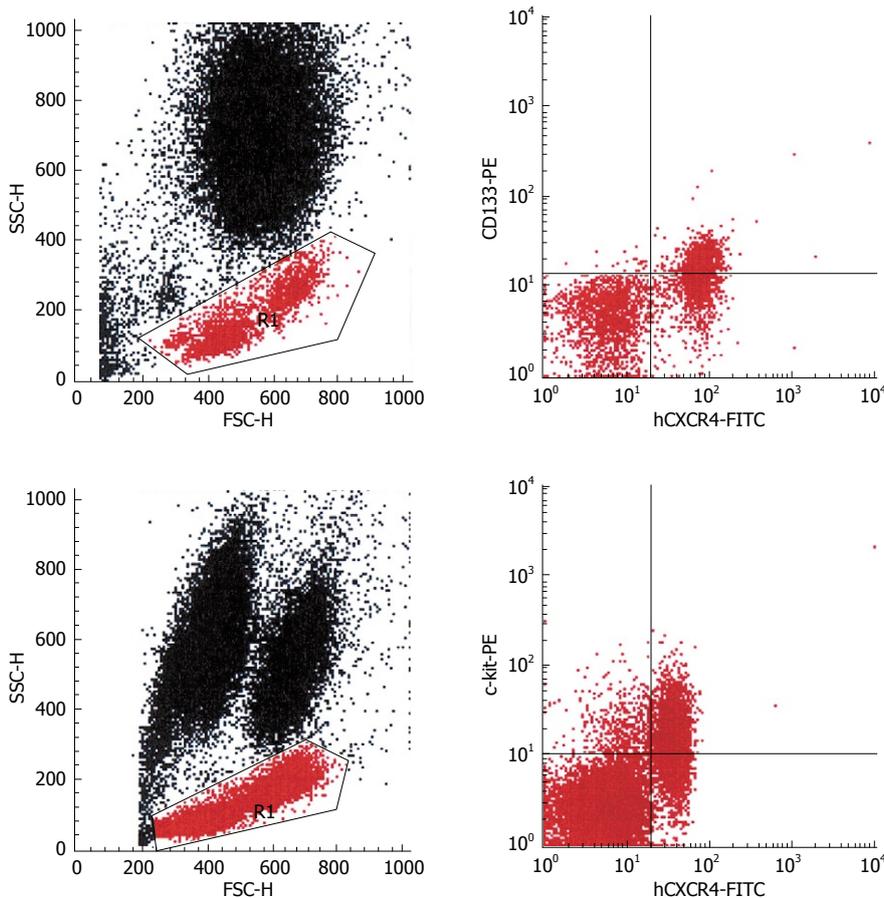

differentiation of PH-induced CD133<sup>+</sup> progenitor cells<sup>[10]</sup>. CD133<sup>+</sup> populations reproducibly generated an adherent layer of cytokeratin-expressing cells, while c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> progenitor cells did not differentiate towards the hepatocytic lineage and could only be maintained in culture for 5 d (data not shown).

## DISCUSSION

We demonstrated in this study that liver cirrhosis is associated with mobilization of CD133<sup>+</sup>, c-kit<sup>+</sup>, and

Bcrp-1<sup>+</sup> populations of hematopoietic progenitor cells. Our previous studies have shown that liver resection leads to a mobilization of a unique population of CD133<sup>+</sup> progenitor cells with a myelomonocytic phenotype and hematopoietic as well as hepatocytic differentiation potential *in vitro*. The finding that identical cells are present in the peripheral blood of patients with liver cirrhosis is highly indicative of a certain role of these cells in liver regeneration. In this context, there is increasing evidence that the intrahepatic compartment of progenitor cells, which are referred to as “oval cells” in rodents and as “ductular reactions” in humans, and which can only be observed as proliferates in diseased liver, expresses CD133<sup>[14-18]</sup>. A recent study has suggested that the human liver contains CD133<sup>+</sup> stem cells that differ from the “ductular reactions” with respect to functional properties, and the fact that the CD133<sup>+</sup> stem cells can be isolated from healthy livers<sup>[19]</sup>. The demonstration of circulating c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> progenitor cell populations in patients with liver cirrhosis might also be of functional significance, because both markers also have been shown to be expressed on human intrahepatic progenitor cells<sup>[20,21]</sup>. However, functional analyses *in vitro* have suggested that the c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> populations identified in this study are multi-lineage hematopoietic progenitor cells without hepatocytic potential, whereas the CD133<sup>+</sup> subset represents hematopoietic progenitor cells committed to the myelomonocytic lineage, which possess hepatocytic potential. Alternatively, it is possible that the c-kit<sup>+</sup> and Bcrp-1<sup>+</sup> cells require other stimuli than used to differentiate into hepatocytic cells.

Progenitor cell mobilization in patients with liver cirrhosis was found not to be a permanent phenomenon. Only a minority of patients showed all three populations at the same time point. Unexpectedly, the occurrence of mobilized progenitor cells did not correlate with any clinical parameter. This led us to the hypothesis that mobilization and recruitment, respectively, of progenitor cells in these patients is triggered by intra-organ hypoxia. It has been shown that: (1) hypoxia induces mobilization of bone-marrow-derived endothelial progenitor cells for neovascularization<sup>[22]</sup> and the production of SDF-1 in endothelial cells<sup>[23]</sup>, and (2) SDF-1 is involved in stress-induced stem cell recruitment to the liver<sup>[24,25]</sup>. Therefore, we investigated expression of the SDF-1 receptor CXCR4 on the progenitor cell populations and assayed the plasma levels of SDF-1 in these patients as a first approach to test our hypothesis. Virtually all mobilized CD133<sup>+</sup> cells coexpressed CXCR4, whereas only a portion of c-kit<sup>+</sup> cells displayed this receptor. Coexpression of CXCR4 by Bcrp-1<sup>+</sup> cells could not be evaluated because the patients included in this set of experiments did not mobilize Bcrp-1<sup>+</sup> cells. However, the number of circulating CD133<sup>+</sup> cells was found to correlate positively with SDF-1 plasma levels, which were elevated in all patients studied, and the numbers of circulating CD133<sup>+</sup>/CD34<sup>-</sup> cells correlated with the numbers of Bcrp-1<sup>+</sup>/CD34<sup>-</sup> cells, which indicated that

**Figure 3** Coexpression of CXC chemokine receptor 4 (CXCR4), the receptor for SDF-1, on circulating CD133<sup>+</sup> cells and c-kit<sup>+</sup> cells as revealed by flow cytometry.

the numbers of Bcrp1<sup>+</sup>/CD34<sup>-</sup> cells might also correlate with SDF-1 plasma levels. Hence, we hypothesize that within the Bcrp1<sup>+</sup> population, Bcrp1<sup>+</sup>/CD34<sup>-</sup> cells coexpress CXCR4. Interestingly, the numbers of c-kit<sup>+</sup>/CD34<sup>-</sup> cells did not show a correlation with SDF-1 plasma levels. This finding is in line with the observation that not all c-kit<sup>+</sup> cells coexpressed CXCR4.

There are many hints in the literature that suggest that hypoxia-inducible factor 1 $\alpha$  (HIF-1 $\alpha$ ) plays a major role in progenitor cell recruitment to injured liver tissue. Using a mouse model of soft tissue ischemia, Ceradini *et al.*<sup>[26]</sup> have shown that HIF-1 $\alpha$  regulates progenitor cell trafficking in a hypoxic-dependent manner *via* induction of SDF-1 expression in endothelial cells of the ischemic tissue. The authors have hypothesized that hypoxia is a fundamental requirement for progenitor cell trafficking and function. We do not believe that hypoxia is a prerequisite for progenitor cell recruitment in all situations of tissue injury, because numerous studies have shown that expression of HIF-1 $\alpha$  can be induced independently of hypoxia by many cytokines, growth factors and hormones<sup>[27]</sup>. Nevertheless, we believe that intrahepatic hypoxia is the initial event that triggers progenitor cell recruitment in liver injury. Hence, progenitor cell mobilization after PH could arise *via* an acute state of intrahepatic hypoxia, because large parts of the hepatic endothelium are removed. Liver cirrhosis most likely causes intermittent hypoxia each time when progressive fibrosis ligates relatively large intrahepatic blood vessels.

This would explain the intermittent occurrence of mobilized progenitor cells in these patients.

The origin of mobilized progenitor cells after PH and in patients with liver cirrhosis remains to be determined. The finding that the number of circulating CD133<sup>+</sup> cells correlated inversely with patient age suggests that at least this population is mobilized from the bone marrow, because it is known that the reserve pool of hematopoietic bone marrow stem and progenitor cells decreases with age<sup>[28]</sup>. No correlation was found between the number of c-kit<sup>+</sup> cells and age, which indicates that the c-kit<sup>+</sup> cells do not solely derive from the bone marrow. The c-kit<sup>+</sup> population might also comprise liver-derived angioblasts<sup>[19]</sup> that occur in the circulation because of hypoxia-induced proliferation of these cells in the liver. With respect to Bcrp1<sup>+</sup> cells, the number of patients that showed an increased number of these cells did not suffice to calculate the statistical significance of the correlation with age.

In summary, we have shown that liver cirrhosis is associated with an intermittent mobilization of various populations of hematopoietic progenitor cells into the circulation. One of the populations, characterized by expression of CD133, is identical to the progenitor cell population observed in peripheral blood after liver resection. Coexpression of CXCR4 on CD133<sup>+</sup> cells and c-kit<sup>+</sup> cells suggests their origin from the bone marrow. Furthermore, our data indicate an involvement of the SDF-1/CXCR4 chemokine receptor system in the mobilization process. Animal studies are needed to evaluate

the exact role of each progenitor cell population in liver regeneration.

## COMMENTS

### Background

The liver is known to possess enormous regenerative potential. Nevertheless, the cellular mechanisms that govern human liver regeneration are not understood completely. There is an increasing body of evidence to suggest that various types of stem and progenitor cells play a role in this process.

### Research frontiers

The authors have demonstrated recently that liver resection in humans leads to a significant increase in the number of circulating cells that express the hematopoietic stem cell marker CD133 and the leukocyte markers CD45 and CD14. This was the first study to indicate that CD133<sup>+</sup> progenitor cells might contribute to liver regeneration. Meanwhile, several studies have shown that the human liver contains various populations of CD133<sup>+</sup> stem and progenitor cells. In addition, these cells are believed to be involved in hepatocarcinogenesis, a process that results from chronic liver regeneration.

### Innovations and breakthroughs

The present study further supports the hypothesis that the CD133<sup>+</sup> hematopoietic precursor cells observed after liver resection contribute to liver regeneration, because circulating cells with an identical phenotype were found in a large number of patients with liver cirrhosis of varying etiology. Furthermore, this study is believed to be the first to demonstrate the presence of two additional populations of hematopoietic progenitor cells in the peripheral blood of these patients. Both populations are characterized phenotypically by the expression of stem cell markers that are also known to be expressed on human intrahepatic progenitor cells.

### Applications

Understanding the cellular mechanisms of liver regeneration is a prerequisite for the development of novel strategies for treating liver disease. Further studies are needed to define the exact role of the three identified progenitor cell populations in liver regeneration and to evaluate their therapeutic potential.

### Terminology

CD133 is an antigen that is expressed on hematopoietic stem and progenitor cells, endothelial progenitor cells, neural progenitor cells, intrahepatic stem and progenitor cells, epithelial cells and various cancer stem cells. The physiological function of this molecule is not known yet. The antigen c-kit is the receptor for the hematopoietic cytokine stem cell factor and is expressed on hematopoietic stem and progenitor cells, endothelial and intrahepatic progenitor cells, as well as on monocytes, mast cells and dermal melanocytes. Breast cancer resistance protein-1 is a membrane protein, which was initially shown to be expressed on breast cancer cells. Functionally, it belongs to the ATP-binding cassette transporters that serve as protective efflux pumps for many cells, including hematopoietic stem cells and intrahepatic progenitor cells.

### Peer review

The article is well written, with interesting results that provide sufficient experimental evidence to draw the conclusions. The figures reflect the major findings of the study, and are presented appropriately. The discussion is well organized. References are appropriate, relevant and up to date.

### Abstract

**AIM:** To assess the hepatitis B virus (HBV)-DNA and the prevalence of occult HBV infection in end-stage renal failure (ESRF) patients from Central Greece.

**METHODS:** Sera from 366 ESRF patients attending five out of six dialysis units from Central Greece were investigated for HBV-DNA by real-time polymerase chain reaction. Only serum samples with repeatedly detectable HBV-DNA were considered positive. IgG antibodies to hepatitis C virus (anti-HCV) were tested by a third generation enzyme linked immunosorbent assay (ELISA), while IgG antibodies to hepatitis E virus (anti-HEV) were tested by two commercially available ELISAs.

**RESULTS:** HBV-DNA was detected in 15/366 patients (4.1%) and HBsAg in 20/366 (5.5%). The prevalence of occult HBV infection was 0.9% (3/346 HBsAg-negative patients). Occult HBV was not associated with a specific marker of HBV infection or anti-HCV or anti-HEV reactivity. There was no significant difference in HBV-DNA titres, demographic and biochemical features, between patients with occult HBV infection and those with HBsAg-positive chronic HBV infection.

**CONCLUSION:** In central Greece, 4% of ESRF patients had detectable HBV-DNA, though in this setting, the prevalence of occult HBV seems to be very low (0.9%).

### INTRODUCTION

Infections with hepatitis B virus (HBV) and hepatitis C virus (HCV) are well-known and important causes of liver disease in end-stage renal failure (ESRF) patients on haemodialysis (HD)<sup>[1-4]</sup>. The adoption of preventive

measures and extensive infection control guidelines, along with a decreased need for transfusions after the introduction of erythropoietin, and the development of an effective HBV vaccine, have significantly contributed to the progressive reduction of HCV and HBV prevalence in HD patients<sup>[2,4]</sup>. However, the relatively low response rates to HBV vaccination in this group of patients might contribute, under some specific circumstances, to the ongoing HBV transmission in this setting.

On the other hand, three studies from different parts of Greece have reported a high prevalence of antibodies against the hepatitis E virus (HEV) -an icosahedral non-enveloped single stranded RNA virus- in ESRF patients on HD, compared to the healthy population<sup>[5-7]</sup>, suggesting that the oral-faecal route may not be the only mode of transmission in HD. However, a similar prevalence of anti-HEV antibodies in Greek patients who have undergone open-heart surgery might indicate that past infections, and not viral exposure during HD or other interventional procedures, are responsible for the acquisition of HEV<sup>[8]</sup>.

In chronic renal failure patients undergoing maintenance HD, the diagnosis of liver disease based on biochemical tests is difficult; taking into account that aminotransferase levels in HD patients are usually suppressed<sup>[9]</sup>. It has been hypothesized that reduced immune competence of chronic uremic patients is a possible cause of attenuated inflammatory reactions in the liver and consequently reduced hepatocyte destruction<sup>[2,4,9]</sup>. Therefore, the quantitative detection of HBV-DNA has been shown to be the most efficient method to evaluate viral replication in HD patients infected with HBV<sup>[2]</sup>. Besides, several studies using sensitive HBV-DNA polymerase chain reaction (PCR) assays have revealed the presence of HBV-viremia in patients who cleared HBsAg from either acute self-limited or chronic HBV infection, or even after a successful anti-HBV treatment<sup>[10]</sup>. Demonstration of this clinical entity has resulted in the introduction of the concept of "occult" HBV infection, which is characterised by undetectable serum HBsAg but detectable HBV-DNA in serum or the liver<sup>[11]</sup>. Occult HBV infection has been reported in patients with chronic HCV infection<sup>[12-15]</sup>, hepatocellular carcinoma, and cryptogenic or autoimmune liver diseases<sup>[16,17]</sup>. Data on occult HBV infection among patients on long term HD is scarce<sup>[18-23]</sup>, as most of the studies have investigated the presence of occult HBV infection in the context of chronic HCV infection<sup>[21-23]</sup>. Greece belongs to the intermediate endemicity countries with a wide variance of HBsAg seropositivity among different regions and various populations, ranging from 3%-5% and markers of previous HBV infection between 17% and 25%<sup>[24-28]</sup>. Unpublished data from our group (Gatselis, Stefanos, Koukoulis and Dalekos, data in preparation), have estimated the prevalence of HBV infection in 2006, in a representative sample of the general population of the region of Thessaly to be 4.26% (range 3.6%-5.2%, age range 18-80 years,  $n = 1174$ ).

For these reasons, we conducted a large study in Thessaly, Central Greece to: (1) determine the presence of HBV-DNA in all 366 consecutive ESRF patients with or without chronic HBV infection attending the five out of six Nephrology and Dialysis units in Thessaly region; and (2) assess the prevalence of occult HBV infection in this cohort. Additionally, the possible clinical impact of HBV-DNA positivity in these patients (either in the context of chronic or occult HBV infection) was assessed by comparing epidemiological, clinical, laboratory and HBV, HCV and HEV serological markers between HBV-DNA-positive and -negative patients.

## MATERIALS AND METHODS

Thessaly is one of the thirteen regions of Greece and covers the largest part of central Greece. The prefectures of Larissa (capital city Larissa), Magnesia (capital city Volos), Trikala (capital city Trikala) and Karditsa (capital city Karditsa) constitute the Thessaly region<sup>[25,29]</sup>. The population is approximately 800 000 people (census 2001; 7.5% of the national population and 0.22% of the EU population). All 366 ESRF patients (243 men, 123 women; mean  $\pm$  age  $60.5 \pm 14$  years and mean duration of HD  $49.2 \pm 48.2$  mo) attending five out of the six Nephrology and Dialysis units of Thessaly region in Central Greece were studied. Sixty patients were from the Nephrology and Dialysis unit of the General Hospital in the city of Larissa (unit 1), 70 from the only private dialysis centre in the city of Larissa (unit 2), 119 from the dialysis unit of the General Hospital in the city of Volos (unit 3), 56 from the dialysis unit of the General Hospital in the city of Trikala (unit 4) and 61 from the dialysis unit of the General Hospital in the city of Karditsa (unit 5). The aetiology of renal failure was as follows: diabetic nephropathy (16.7%), idiopathic glomerulonephritis (14.5%), vascular renal disease (9.3%), urinary tract obstruction (9.3%), polycystic kidney disease (7.7%), systemic diseases (3.3%), tubulointerstitial diseases (1.6%), other causes (3.3%), and unknown (34.3%). The patients' characteristics are shown in Table 1.

Serum samples were collected between May and August 2001 (before HD) and then stored at  $-80^{\circ}\text{C}$  in aliquots until tested. Serological markers of HBV infection (HBsAg, anti-HBs, anti-HBc, HBeAg, and anti-HBe) were determined using standard third generation commercially available enzyme immunoassays (Abbott GmbH, Wiesbaden-Delkenheim, Germany). The samples were investigated for the presence of HBV-DNA using a sensitive commercially available real time PCR kit (COBAS Taqman HBV Test; cut-off of detection: 6 IU/mL)<sup>[30]</sup>. The COBAS TaqMan HBV Test is an *in vitro* nucleic acid amplification test for quantitation of HBV in human serum or plasma, using the High Pure Viral Nucleic Acid kit for manual specimen preparation and the COBAS TaqMan 48 Analyzer for automated amplification and detection. The highly conserved HBV precore/core region was

Table 1 Characteristics of 366 ESRF patients (mean  $\pm$  SD)

Known history of viral hepatitis (yes/no) <sup>2</sup>	51/315
History of transfusions (yes/no)	129/247
Number of blood units	6.8 $\pm$ 4.7
Duration of erythropoietin treatment (mo)	46.2 $\pm$ 35.8

<sup>1</sup>Haemodialysis duration was calculated from the date of the first haemodialysis procedure to the date of the collection of the sera; <sup>2</sup>Proven history of viral hepatitis, either icteric or anicteric. M: Male; F: Female; ESRF: End-stage renal failure.

amplified. Every sample with detectable HBV-DNA by real time PCR was tested again in another experiment. Only serum samples with repeatedly detectable HBV-DNA were considered positive for HBV-DNA.

Anti-HCV antibody was tested by a third generation enzyme linked immunosorbent assay (ELISA) (HCV 3.0 ELISA Ortho, Raritan, NJ) according to the manufacturers' instructions. For the detection of anti-HEV IgG antibodies two commercially available ELISAs (Abbott Diagnostika, Wiesbaden-Delkenheim, Germany and Genelabs Diagnostics, Singapore Science Park, Singapore) were used. These assays included two recombinant antigens, which correspond to the structural regions of the HEV genome<sup>[7]</sup>. Both ELISAs were performed according to the manufacturers' instructions. Only repeatedly reactive samples in both assays were considered positive for the presence of anti-HEV IgG. According to the above criteria, initially reactive specimens that were non-reactive on retesting were considered negative.

Levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were determined using standard techniques. Informed consent was obtained from all patients involved in the study. The Local Ethical Committee of the Medical School, University of Thessaly, approved the study protocol.

### Statistical analysis

Results were expressed as mean  $\pm$  SD or median and range as appropriate. Data were analyzed by unpaired *t*-test,  $\chi^2$  (two by two with Yates' correction), and Fisher's exact test, where applicable. A two-sided *P* value < 0.05 was considered as statistically significant. Confidence intervals (95% CI) were determined using the formula  $P = p \pm 1.96 (pq/n)^{1/2}$  where *p* is the frequency, *q* is 1 - *p* and *n* is the number of individuals tested from each group.

## RESULTS

In total, HBV-DNA was detected in 15 of the 366 patients with ESRF (4.1%; 95% CI: 2%-6.1%). Twenty patients (5.5%) were HBsAg positive (overt HBV infection) and

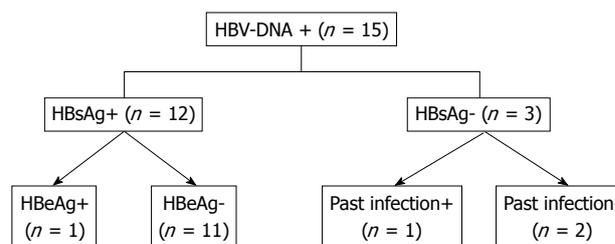

Figure 1 Flowchart of the profile of 15 hepatitis B virus (HBV)-DNA positive haemodialysis patients.

245 were anti-HBs positive (66.9%) (Table 2). Eighty-eight (24%) and 15 (4.1%) were anti-HCV and anti-HEV positive, respectively (Table 2). The prevalence of HBV-DNA seropositivity ranged from 1.4%-10% among the five Dialysis units (*P* = 0.163) (Table 2). The median HBV-DNA titre was 25 IU/mL (range: 7-10 584 IU/mL). HBV-DNA seropositivity was not associated with age, sex, history of hepatitis, history of blood transfusions, the number of blood units transfused, the dialysis type, or with the aetiology of renal failure, aminotransferase activity or anti-HEV reactivity. As expected, there was a significant association between the presence of HBV-DNA and HBsAg, anti-HBc, anti-HBe positivity (*P* < 0.05 for all, Table 3). The absence of HBV-DNA was associated with the presence of anti-HBs and anti-HCV (*P* < 0.05 for both, Table 3).

Amongst the 15 HBV-DNA positive patients, 12 had overt HBV infection (80%), including one HBeAg positive, 10 anti-HBe positive and one anti-HBe positive patient who was also anti-HBs positive. Of the three remaining HBV-DNA positive patients, one had markers of past HBV infection (anti-HBc and anti-HBs positive) and two had no serological markers of present or past HBV infection (Figure 1). Thus, the overall prevalence of occult HBV infection amongst the 346 HBsAg negative ESRF patients in the five Nephrology and Dialysis units in the Thessaly region was 0.9% (3/346; 95% CI: 0%-1.9%). Actually, the prevalence of occult HBV infection in Volos Dialysis Unit was 2.6% (3/116) compared to zero prevalence in all other Dialysis Units in the Thessaly region (*P* = 0.199). HBV-DNA titres (median titre: 19 IU/mL, range: 7-37 IU/mL) in patients with occult HBV infection were not significantly different compared to those with overt HBV infection (median: 27 IU/mL, range: 9-10 584 IU/mL, *P* = 0.391). Occult HBV infection was associated neither with age, sex, history of hepatitis, history of blood transfusions, the number of blood units transfused, biochemical parameters (AST, ALT) nor with the aetiology of renal failure (data not shown). Moreover, occult HBV-DNA detection was not associated with a specific marker of past HBV infection and anti-HCV or anti-HEV reactivity. No statistical significance was found comparing the age, HD duration, biochemical parameters, and serological markers of HCV and HEV infections or the duration of erythropoietin treatment

between patients with occult and overt HBV infection (data not shown). Serological markers of HBV, HCV and HEV infections in the 15 HBV-DNA positive patients are presented in Table 4.

## DISCUSSION

The present study demonstrated that 4.1% of Greek patients with ESRF from Central Greece had detectable HBV-DNA by real-time PCR, including 0.9% with occult HBV infection. Interestingly, 5.5% of HD patients had chronic HBV infection (overt HBV infection) but only 60% of them (thus 3.3% of total ESRF patients) were HBV-DNA positive. HBsAg prevalence in patients on maintenance HD varies among studies and geographical areas, from 0.8% to 17%, remaining very high in less developed countries<sup>[2,18,31,32]</sup>. The prevalence of anti-HBc was relatively high in our study (48%). As anti-HBc positivity indicates previous exposure to HBV infection, this finding in our HD patients in association with the 5.5%

prevalence of HBsAg might suggest contact with HBV during adulthood, though this cannot be safely ascertained if it has taken place in an HD setting. Nevertheless, a similar prevalence of markers of previous HBV infection has already been reported in our country for several high-risk groups of HBV infection, such as HD patients, alcoholics, and heroin addicts, while in refugees this prevalence can be as high as 70%<sup>[22,26,33-35]</sup>. Furthermore, with the development of sensitive PCR-based testing for HBV-DNA, studies in dialysis units have demonstrated that the prevalence of occult HBV infection ranges from 0% to 58% in published reports<sup>[18-23]</sup>. These variations could be attributed to differences in the sensitivity of the methods used for the detection of HBV-DNA, in the patients' sample investigated in each study, and in geographic variations of HBV prevalence. Though our aim was to strictly assess the prevalence of occult HBV infection in a very large cohort of HD patients, a recent publication on Greek blood donors with occult HBV infection was able to successfully perform the molecular characterization of HBV strains in less than half of occult cases, revealing several amino acids substitutions related to diagnostic escape and antiviral resistance<sup>[30]</sup>.

It should be stated herein, however, that the detection of HBV-DNA in serum samples rather underestimates the true prevalence of occult HBV infection<sup>[11]</sup>. Indeed, the most correct and precise methodological approach for the determination of the prevalence of occult HBV infection is the analysis of liver DNA extracts. This is further supported by a recent study from our group,

which assessed the prevalence of occult HBV infection in patients with autoimmune liver diseases<sup>[17]</sup>. However, the availability of liver tissues is often limited by restrictions on the performance of liver biopsies, which in the setting of HD is often very difficult and usually contraindicated.

In agreement with previous reports, we found that both groups of ESRF patients with chronic HBV infection and occult HBV infection had low levels of HBV-DNA<sup>[2,18,23]</sup>. HBV-DNA titres have been reported to remain low and stable over time, which can probably explain the low mortality rates due to liver disease in ESRF patients in developed countries<sup>[2]</sup>. The mechanisms responsible for the inhibition of HBV activity are as yet undefined in this specific group of patients. The passage of HBV-DNA from serum into the dialysate compartment during HD session, the destruction of HBV genome during HD procedure, and the interplay between HBV and the immune system could all play a role<sup>[2]</sup>. The low viral load observed in these subjects could also be attributed to multiple amino acid substitutions in the polymerase region, which might give rise to less fit viral strains, as was recently demonstrated in Greek blood donors with occult HBV infection<sup>[30]</sup>. The longer half-life of interferon in dialysis patients is another important factor, though none of the patients in our study was receiving antiviral treatment. Moreover, viral interactions can maintain HBV infection in a latent state, as in ESRF patients with chronic HCV infection and occult HBV viremia<sup>[22,23]</sup>. In these cases, a negative interference has been considered between the two viruses, leading to low HBV-DNA levels<sup>[36,37]</sup>. In our study, HBV-DNA positivity was negatively associated with HCV infection, further supporting the possibility of reciprocal replicative suppression of the two viruses. In this context, all three HD patients with occult HBV infection in our study were negative for anti-HCV and HCV-RNA by a transcription mediated amplification assay<sup>[38]</sup>. On the contrary, HBV-DNA positivity was not associated with markers of HEV infection.

The emerging evidence of the potential clinical significance of occult HBV infection is the main reason for the growing interest in this topic. Accumulating data shows that occult HBV infection might be transmitted in cases of blood transfusions, in the event of organ transplantations, and in particular, in cases of orthotopic liver transplantation as an obvious consequence of the fact that hepatocytes are the reservoir of the viral strains<sup>[11]</sup>. However, the risk of occult HBV transmission in cases of kidney transplantation seems to be low<sup>[39-41]</sup>. Nevertheless, virological and clinical reactivations of occult HBV infection have been repeatedly observed in several clinical conditions, where an immunosuppressive status evolves, including haematological or other malignancies, HIV infection, haematopoietic stem cell transplantation, and organ transplantation<sup>[11]</sup>. Therefore, the theoretical basis of HBV reactivation in HD cases with occult hepatitis B, who had undergone kidney transplantation and are under immunosuppression, is still unresolved.

In conclusion, approximately 4% of ESRF patients on HD from Central Greece have detectable HBV-DNA levels, amongst which 20% have occult HBV infection, which might indicate that the absence of HBsAg in the blood of HD patients is not sufficient to ensure lack of circulating HBV. However, in the total group of HBsAg negative HD patients, the prevalence of occult HBV infection in our region seems to be one of the lowest worldwide (0.9%). The demographic and biochemical features of HBV-DNA positive subjects, including those with occult HBV infection, do not help to distinguish these individuals from those who are HBV-DNA negative. We believe that longitudinal studies including even larger numbers of patients are needed to further clarify the clinical significance and outcome of occult HBV infection in this setting.

## ACKNOWLEDGMENTS

The authors thank all medical and nursing staff of the renal units in Central Greece for the data provided.

## COMMENTS

### Background

The prevalence and clinical significance of occult hepatitis B virus (HBV) infection in the haemodialysis (HD) setting in large series of patients with end-stage renal failure (ESRF) on HD has not been adequately addressed.

### Research frontiers

This situation might have considerable implications, either from the public health point of view (due to the risk transmission of the virus among individuals in the hemodialysis units) or from the clinical point of view, as attested by well-known cases of acute and severe exacerbations of HBV infection under some circumstances, such as transplantation and the subsequent immunosuppressive treatment.

### Innovations and breakthroughs

Occult HBV infection in HD patients ranges from 0% to 58% in published reports. Though their large study in 366 ESRF patients on HD from Central Greece revealed the presence of HBsAg in 5.5% and HBV-viremia in approximately 4%, the actual presence of occult HBV infection was identified in only 0.9% of HBsAg negative patients (one of the lowest frequencies of occult HBV infection in HD patients worldwide). These discrepancies in the frequencies of occult HBV infection in a HD setting could be ascribed to differences in the number of patients tested, the sensitivity of the methods used for the detection of HBV-DNA, the patients' specimen investigated in each study (serum or liver tissue), and geographical variations regarding in HBV prevalence.

### Applications

Based on the potential clinical significance of occult HBV infection in the HD setting, the authors believe that further multicentre longitudinal studies, including larger numbers of patients, are needed to further clarify whether occult HBV infection is a major clinical problem in this setting or not.

### Terminology

Occult HBV infection, is a clinical entity characterised by undetectable HBsAg in the serum but detectable HBV-DNA in serum or the liver. The use of sensitive HBV-DNA polymerase chain reaction assays in serum samples or, preferably, in liver tissues when available using the highly conserved HBV precore/core regions for amplification, appears to be the assay of choice for the diagnosis of this condition.

### Peer review

This study described the occult HBV infection in 366 ESRF patients on HD in Nephrology and Dialysis units of the Thessaly region in Central Greece. The authors concluded that the prevalence of occult HBV infection was 0.9%, although the HBsAg prevalence was 5.5% in this cohort. This study provides

basic epidemiological data, which is of great interest, as it includes some original and useful data for this patients setting.

### Abstract

**AIM:** To understand the demographic characteristics of patients in Southwestern Ontario, Canada with ulcerative colitis (UC) in order to predict disease severity.

**METHODS:** Records from 1996 to 2001 were examined to create a database of UC patients seen in the London Health Sciences Centre South Street Hospital Inflammatory Bowel Disease Clinic. To be included, patients' charts were required to have information of their disease presentation and a minimum of 5 years of follow-up. Charts were reviewed using standardized data collection forms. Disease severity was generated during the chart review process, and non-endoscopic Mayo Score criteria were collected into a composite.

**RESULTS:** One hundred and two consecutive patients'

data were entered into the database. Demographic analyses revealed that 51% of the patients were male, the mean age at diagnosis was 39 years, 13.7% had a first degree relative with inflammatory bowel disease (IBD), 61.8% were nonsmokers and 24.5% were ex-smokers. In 22.5% of patients the disease was limited to the rectum, in 21.6% disease was limited to the sigmoid colon, in 22.5% disease was limited to the left colon, and 32.4% of patients had pancolitis. Standard multiple regression analysis which regressed a composite of physician global assessment of disease severity, average number of bowel movements, and average amount of blood in bowel movements on year of diagnosis and age at time of diagnosis was significant,  $R^2 = 0.306$ ,  $F(7, 74) = 4.66$ ,  $P < 0.01$ . Delay from symptoms to diagnosis of UC, gender, family history of IBD, smoking status and disease severity at the time of diagnosis did not significantly predict the composite measure.

**CONCLUSION:** UC severity is associated with younger age at diagnosis and year of diagnosis in a longitudinal cohort of UC patients, and may identify prognostic UC indicators.

## INTRODUCTION

Canada has one of the highest rates of ulcerative colitis (UC) in the world, with an annual incidence of approximately 3500 cases and a prevalence of roughly 60 000<sup>[1]</sup>. Each patient with UC is faced with a chronic disease with an uncertain course, experiencing periods of relapse and remission, and often requiring long-term medical therapy. In some cases, however, the disease remains mild or becomes more severe but it is difficult to predict the ultimate course of UC without simply monitoring the patient for years.

Many therapies have been studied over the past 60 years for the treatment of UC, starting with sulfasalazine and hydrocortisone<sup>[2]</sup>, through newer 5-aminosalicylate products<sup>[3]</sup>, immunosuppressives<sup>[4,5]</sup>, and now biological therapies. A treatment pyramid has been proposed, with less potent and more tolerable agents at the bottom and more powerful agents with greater potential toxicities at the top<sup>[6]</sup>. The recent introduction of infliximab has provided another treatment option for UC patients with refractory disease, but the long-term safety and efficacy of this therapy is unknown<sup>[7]</sup>. In addition, the substantial cost of biological therapies makes using these agents as initial therapy difficult to justify given the large number of patients who respond to more inexpensive treatments.

Studies examining groups of UC patients have been published from various geographic regions over a number of decades, with many looking at cohorts of UC patients longitudinally<sup>[8-11]</sup>. Many of these studies, however, were published prior to the introduction of newer therapies and may lack applicability to current UC patients. Furthermore, few studies have looked at Canadian UC patients, and therefore the relevance of these results to our patient population is unknown. The aim of this study was to examine the UC population of Southwestern Ontario (SWO), Canada in an effort to gather information on the natural history of the disease and determine predictors of future disease severity at the time of diagnosis.

## MATERIALS AND METHODS

Patients with UC seen in the London Health Sciences Centre South Street Hospital Inflammatory Bowel Disease Clinic from 1996-2001 were identified by a search of diagnostic codes. Individual clinic charts for these patients were reviewed to determine if they met the study inclusion criteria, which included a new diagnosis of UC, details of disease presentation at diagnosis, and documentation of follow up for at least 5 years.

Patient data were collected retrospectively from clinic charts using standardized data collection forms created specifically for this study. Demographic data including age, sex, year of diagnosis, age at diagnosis, smoking status, and a family history of inflammatory bowel disease (IBD) as well as annual measurements of disease severity and course of disease were recorded.

Disease severity was measured using a modified

Table 1 Demographic data of the UC patient cohort *n* (%)

Gender (male/female)	52 (51)/50 (49)
Mean age at diagnosis (yr)	39 (range 9-85; SD = 17.9)
Family history of IBD in 1st degree relative	14 (13.7)
Non-smokers/ex-smokers	63 (61.8)/25 (24.5)

UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

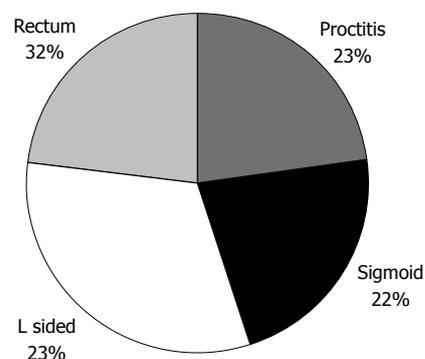

Figure 1 Extent of disease in the ulcerative colitis (UC) patient cohort.

version of the Mayo Scoring System for assessment of UC activity<sup>[12]</sup>, which excluded the endoscopic component. Values from 0 to 3 were recorded for each of: frequency of bowel movements, amount of blood in bowel movements, and physician assessment of disease severity.

Statistical analysis was carried out using SPSS 15.0 for a multiple regression analysis of demographic factors on the disease severity composite. Microsoft Excel was used for the data management and averages.

This study was approved by the Research Ethics Board at The University of Western Ontario.

## RESULTS

One hundred and two consecutive patient charts who met the inclusion criteria were reviewed. Demographic analyses demonstrated that 51% of the cohort was male, 13.7% had a family history of IBD, and 61.8% were nonsmokers (Table 1). Average delay from time of symptom onset to time of diagnosis was 1.8 years (range 0-34 years; SD = 4.5 years).

Data examining the extent of disease are shown in Figure 1. Colectomy rates were calculated at 14.7% of the cohort (15 patients), and are plotted against time in Figure 2. Figure 3 outlines the indications for colectomy, while Figure 4 displays the demographics of this group. Seven of these patients underwent an ileal pouch-anal anastomosis with the remaining 8 patients undergoing an ileostomy. Of those who underwent ileal pouch anal-anastomosis, 5 (71%) had at least 1 subsequent episode of pouchitis. In the patients who had a colectomy, 10 patients (66.6%) had pancolitis while disease extent was limited to the sigmoid colon in 4 patients (26.7%) and to the left colon in 1 patient (6.7%). The average composite severity score for this group was 3.24 across

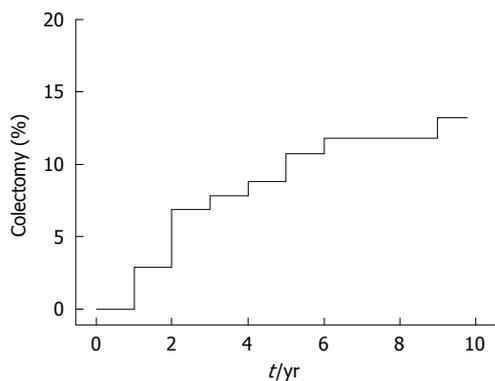

Figure 2 Kaplan Meier curve of colectomy over time.

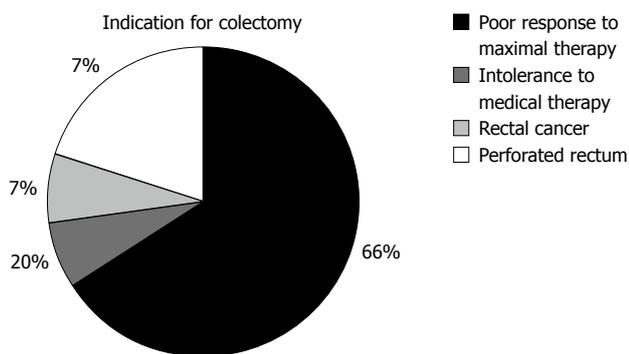

Figure 3 Indications for colectomy in 15 patients in the UC cohort.

at least 5 years of follow up (1.15 for number of bowel movements, 0.85 for blood in bowel movements, and 1.24 for physician global assessment of severity).

Three patients died during the follow up period, two from unrelated malignancies (melanoma and squamous cell lung cancer) and one from congestive heart failure.

Disease severity was determined for each patient during each year of follow up. All patients except one had complete data for at least 5 years of follow up after diagnosis, with the reviewer unable to assign severity status to one patient during 1 year of follow up. Data are listed in Figure 5 with severity divided into three groups: low (modified Mayo Score 0-2), moderate (modified Mayo Score 3-5), and high (modified Mayo Score 6-9).

The composite of disease severity was averaged across the number of years with UC, with a mean value for the cohort of 2.12 (standard deviation 1.18; minimum 0.36; maximum 6.22). When grouped into categories of severity, 77.5% (79 patients) had an average score of less than three, 21.5% (22 patients) had an average score between three and six, and 1% (1 patient) had an average score of greater than six.

Pearson product moment correlation analyses were conducted in order to evaluate the extent of interrelationship between the composite value of disease severity and demographic variables. Demographic variables included year of diagnosis, delay from symptom onset to diagnosis, gender, smoking status at time of diagnosis, family history of IBD in a first degree relative, severity

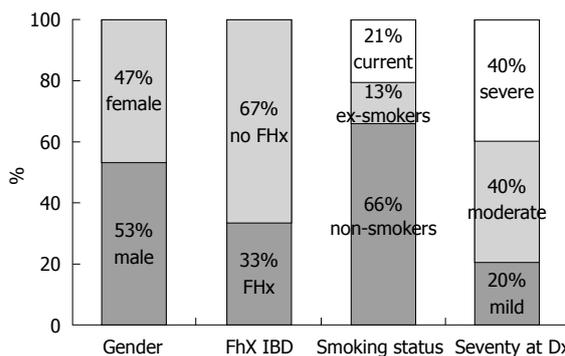

Figure 4 Demographic data on UC patients who underwent colectomy.

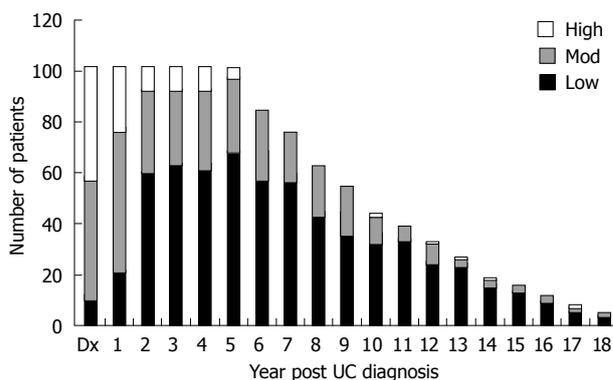

Figure 5 Ulcerative colitis disease severity at time of diagnosis and during follow up divided into 3 categories: low severity (modified Mayo Score 0-2), moderate severity (modified Mayo Score 3-5), high severity (modified Mayo Score 6-9).

at diagnosis, and age at diagnosis. Year of diagnosis was positively associated with the composite of disease severity [ $r(102) = 0.35, P < 0.01$ ], such that a more recent year of diagnosis was associated with a higher composite score. Smoking status at time of diagnosis [ $r(97) = -0.22, P < 0.05$ ] and age at diagnosis [ $r(102) = -0.32, P < 0.01$ ] were negatively associated with the composite score of disease severity, such that current smokers and younger patients had a higher composite score.

Regression analysis was performed on the composite value of disease severity on various demographic variables. Standard multiple regression analyses on year of diagnosis and age at time of diagnosis were significant,  $R^2 = 0.306, F(7, 74) = 4.66, P < 0.01$ . The correlation indicated that more severe disease was present in those diagnosed at an earlier age, and those diagnosed more recently had a worse course of disease. Delay from symptoms to diagnosis of UC, gender, family history of IBD, smoking status and disease severity at the time of diagnosis did not significantly predict the composite measure.

## DISCUSSION

UC is a chronic disease with a variable and uncertain course. Patients diagnosed with the disease have no means to predict whether their disease will be ongoing,

consist of severe relapses, or remain indolent. Previous studies have looked at the natural course of UC, however, this study has the added benefit of following a fairly large cohort of patients with UC for a minimum of 5 years. Demographics such as disease extent, gender, and presence of a family history of IBD compare favorably with the cohort from Farmer's 1992 study of over 1000 individuals from the Cleveland Clinic<sup>[8]</sup>. Previously reported colectomy rates range from 8.7% in a recent European trial<sup>[9]</sup>, to 45% in a Swedish study from 1990<sup>[11]</sup>. Our value of 15% lies well within this range, and indeed, is comparable to the Northern European portion of the aforementioned study. This allows some quality assurance that patients in the SWO IBD clinic have similar demographics and outcomes to other areas of the world.

The Mayo Scoring System<sup>[12]</sup> is a validated tool that measures disease activity in patients with UC. We applied this tool to UC patients at diagnosis and during follow-up in an effort to determine which demographic variables could predict long term disease activity. The endoscopy score was excluded from this tool as sigmoidoscopy/colonoscopy was not routinely performed on a regular basis in most patients. Thus the score was out of a maximum of 9 rather than 12. Some scales, such as the Simple Clinical Colitis Activity Index<sup>[13]</sup> and Seo *et al*<sup>[14]</sup> index do not rely on endoscopic scores, while other scores such as the Ulcerative Colitis Disease Activity Index and St. Mark's index<sup>[15]</sup> incorporate an endoscopic component into their values. In a comparison between those scores that contain endoscopy related elements against those that did not, it was found that endoscopy added little additional information to the assessment of disease activity<sup>[16]</sup>. Therefore, the use of the Mayo score without the endoscopic system is likely a valid alternative.

We found that younger age at diagnosis predicts a more severe future disease course. Previous studies have shown that patients with early onset UC are more prone to colorectal cancer<sup>[17]</sup>, however the finding that severity of future disease is predicted is not widely prevalent in the current literature. One theory that has arisen in discussion as well as at presentations is that the more severe the disease, the earlier it unmasks itself clinically. This then leads to more symptoms during the patient's follow up and a worse course clinically for the patient.

While younger age at diagnosis seems to play a significant role in predicting disease severity, so does the year of diagnosis. It is difficult to tease out the fine nuances of younger age and year of diagnosis, as these obviously affect each other. It would seem from the analysis, however, that the year independently predicts the outcome, and therefore we have to consider that as our arsenal for UC has grown, perhaps our treatment of this condition has not improved as much as we originally thought. An alternative explanation could be found in the fact that all patients in this study were seen in a rapidly growing IBD clinic in a tertiary care referral centre, and perhaps the severity of cases has been high with mild or moderate cases being managed by community practitioners.

The above variables predicted future disease severity,

however, there were a number of factors not found to be predictive. One of the most intriguing was smoking status, as multiple previous studies have found that smoking was a protective factor<sup>[18]</sup>, while non- or ex-smokers had a higher risk of relapsing disease<sup>[19]</sup>. In addition, disease severity at presentation did not correlate with the severity index over the disease course, nor did delay from diagnosis to treatment. This was unexpected, as literature by Sandborn<sup>[20]</sup> found that classifying presentations into one of four severity categories was useful for prognosticating disease. In addition, gender and family history all seemed to have a minimal role in predicting future disease.

The limitations of the study make a large sweeping commentary on our prediction of UC difficult. It is retrospective in design, and relies heavily on chart review. The number of patients in the study compares favorably with many previous reviews of UC and contains patients with similar disease extent and severity, but with just over 100 patients it is difficult to be certain of the effect in a larger group. Additionally, the geographic nature of the population may make it hard to extract information on other populations in Canada or the rest of the world.

The information provided by the demographic variables is valuable in many ways. Firstly, to the patient this may alleviate much of the sense of unknown, and allow them to cope with the diagnosis and treatment more effectively. In addition to this, however, it allows the clinician to triage which patients may progress more quickly and customize their therapy accordingly. For instance, if a younger patient presents with confirmed UC, one may be more willing to adopt a "top down" approach and start them on anti-TNF agents immediately. This may help save time, patient discomfort, and reduce the risk of outcomes such as colectomy in that severe symptoms do not have the potential to develop. Rather than navigate patients through the pyramid of UC agents, this would guide patients to the agent most suited to their specific condition.

This study provides evidence that predictors of disease severity in UC may exist in simple demographic information that is available to any clinician and may help ease the unpredictability of this condition as well as help physicians treat patients with tailored therapy. Additional studies looking prospectively at patients with UC in an effort to help predict disease severity would be most useful and easily conducted.

## COMMENTS

### Background

Ulcerative colitis (UC) is an inflammatory disease of the large intestine that

affects many Canadians. The individuals, often young and in the prime of their life, experience symptoms such as diarrhea, bleeding from the bowels, and abdominal discomfort. They can expect periods of health interrupted by worsening of their disease, with some having very serious symptoms and others having minimal to no symptoms.

### Research frontiers

The natural history of the disease has been looked at in previous studies, but predicting which patients will have severe disease and which will have mild disease has not been fully examined.

### Innovations and breakthroughs

This article describes a Canadian population of patients with UC that have been followed for at least 5 years, and looked back to see if any of their characteristics, such as age, gender, smoking status, delay to diagnosis, year of diagnosis or the manner in which they presented, predicted how they will progress in coming years. Age at diagnosis and year of diagnosis seemed to predict the disease course, with a younger age at diagnosis and a more recent year of diagnosis predicting a more severe disease pattern.

### Applications

These findings allow physicians to give patients newly diagnosed with UC an idea of what to expect in the coming years. Although not completely predictive, those patients who present with UC who are younger may expect a more severe disease course. Physicians treating these patients may be more inclined to start stronger therapies initially in these patients.

### Peer review

The original manuscript by Roth *et al* is a very interesting and a very well written manuscript. It is a retrospective study, with a good attempt to find out the predictors of severity from the demographic parameters. The paper is nicely laid out with a very good selection of references and nicely addressed limitations. A retrospective study, it is a good attempt to find out the predictors of severity from the demographic parameters.

### Abstract

**AIM:** To assess the diagnostic ability of endoscopic ultrasonography (EUS) for evaluating causes of distal biliary strictures shown on endoscopic retrograde cholangiopancreatography (ERCP) or magnetic resonance cholangiopancreatography (MRCP), even without identifiable mass on computed tomography (CT).

**METHODS:** The diagnostic ability of EUS was retrospectively analyzed and compared with that of routine cytology (RC) and tumor markers in 34 patients with distal biliary strictures detected by ERCP or MRCP at Dokkyo Medical School Hospital from December 2005 to December 2008, without any adjacent mass or eccentric thickening of the bile duct on CT that could cause biliary strictures. Findings considered as benign strictures on EUS included preservation of the normal

sonographic layers of the bile duct wall, irrespective of the presence of a mass lesion. Other strictures were considered malignant. Final diagnosis of underlying diseases was made by pathological examination in 18 cases after surgical removal of the samples, and by clinical follow-up for > 10 mo in 16 cases.

**RESULTS:** Seventeen patients (50%) were finally diagnosed with benign conditions, including 6 "normal" subjects, while 17 patients (50%) were diagnosed with malignant disease. In terms of diagnostic ability, EUS showed 94.1% sensitivity, 82.3% specificity, 84.2% positive predictive value, 93.3% negative predictive value (NPV) and 88.2% accuracy for identifying malignant and benign strictures. EUS was more sensitive than RC (94.1% vs 62.5%,  $P = 0.039$ ). NPV was also better for EUS than for RC (93.3% vs 57.5%,  $P = 0.035$ ). In addition, EUS provided significantly higher sensitivity than tumor markers using 100 U/mL as the cutoff level of carbohydrate antigen 19-9 (94.1% vs 53%,  $P = 0.017$ ). On EUS, biliary stricture that was finally diagnosed as malignant showed as a hypoechoic, irregular mass, with obstruction of the biliary duct and invasion to surrounding tissues.

**CONCLUSION:** EUS can diagnose biliary strictures caused by malignant tumors that are undetectable on CT. Earlier detection by EUS would provide more therapeutic options for patients with early-stage pancreaticobiliary cancer.

Endoscopic ultrasonography can diagnose distal biliary strictures without a mass on computed tomography. *World J Gastroenterol* 2010; 16(2): 237-244 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i2/237.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i2.237>

## INTRODUCTION

Determining the etiology of a distal biliary stricture is crucial to the provision of appropriate therapy. However, such determination can be particularly problematic in cases of biliary strictures without an identifiable mass that could cause the stricture on computed tomography (CT) or magnetic resonance imaging (MRI). Empiric resection may be necessary to differentiate benign and malignant strictures, and the decision to operate has traditionally been made on the basis of clinical history and cholangiographic appearance of the stricture<sup>[1]</sup>. However, determining the cause of a stricture on the basis of morphologic features and brush cytology is unreliable<sup>[2]</sup>.

Intraductal ultrasonography (IDUS) with wire-guided, thin-caliber, high-frequency probes is promising for the diagnosis of biliary stricture<sup>[3,4]</sup>. This technique is easily performed as an adjunct to endoscopic retrograde cholangiopancreatography (ERCP) without significant lengthening of the procedure. For the diagnosis of biliary stricture without an identifiable mass, however, data from IDUS are insufficient<sup>[4,6]</sup>. In addition, the number of patients for whom IDUS can be performed has decreased, since magnetic resonance cholangiopancreatography (MRCP) has been replacing the role of diagnostic ERCP. Moreover, if patients with an identifiable mass on CT or MRI are excluded, the proportion of benign strictures is about 30%-50%<sup>[4,5,7,8]</sup>. This relatively high percentage of benign strictures complicates the decision to perform IDUS in all patients with biliary strictures of indeterminate etiology, as IDUS sometimes causes complications such as ERCP-induced pancreatitis and cholangitis.

The utility of endoscopic ultrasonography (EUS) for diagnosing unexplained biliary strictures thus warrants urgent discussion, since EUS is now the first choice in screening for small pancreatic tumors that cannot be detected by other imaging modalities and is not associated with ERCP-related complications<sup>[9]</sup>. However, only 1 paper by Lee *et al*<sup>[1]</sup> has mentioned the utility of EUS features in patients with unexplained biliary stricture. According to Lee *et al*<sup>[1]</sup>, sonographic features of EUS, including the presence of a pancreatic mass, an irregular bile duct wall, or bile duct thickness > 3 mm, could improve the diagnosis of unexplained stricture.

The aim of this study was to assess the ability of EUS to diagnose distal biliary strictures for which cross-sectional imaging modalities such as CT and MRI could not detect a causative mass or bile duct thickness. Moreover, we report the sonographic appearance of malignant and benign strictures using EUS, as the lack of easily recognizable morphologic criteria has partly caused the limited availability of EUS for diagnosing biliary strictures of indeterminate etiology.

## MATERIALS AND METHODS

### Inclusion criteria

This retrospective analysis was performed on 34 patients who underwent EUS at Dokkyo Medical School Hospital from December 2005 to December 2008 for evaluation of strictures in the biliary tract that were detected by ERCP or MRCP and who did not have an identifiable mass lesion causing the stricture on cross-sectional CT or MRI. Patients with strictures at the proximal bile duct were excluded from this study, since EUS is already known to be less accurate for strictures of that portion<sup>[10]</sup>. All patients provided written consent for the procedure performed.

### EUS examination

EUS and ERCP were performed with the patient under conscious sedation by 1 of 2 operators (S.Y. and Y.M.). EUS was performed using a 7.5-MHz US probe (UM-200; Olympus, Tokyo, Japan) connected to a standard EUS processor (EU-30; Olympus). This probe provides radial scanning perpendicular to its axis. For the purposes of this study, EUS images were reviewed to identify extrinsic compression at the stricture site without knowledge of the final diagnosis. Evaluation points were: (1) presence of a mass that could create extrinsic compression at the site of the stricture; (2) disruption of the normal 2 or 3 sonographic layers of the bile duct wall<sup>[11]</sup>; and (3) continuation of a mass into adjacent structures, referring to previously defined criteria for evaluation of biliary strictures on IDUS<sup>[3,10,12]</sup>. Findings considered as a benign stricture on EUS included preservation of the normal sonographic layers of the bile duct wall, irrespective of the presence of a mass lesion. Other strictures were considered malignant.

Thirty patients underwent dynamic CT with a liver protocol using the method reported by Yanaga *et al*<sup>[13]</sup>. All scans were performed on a multidetector helical CT scanner (SOMATOM Sensation 64; Siemens, Tokyo, Japan). A multiphase scanning technique was used and 3-phase contrast-enhanced CT was performed during the hepatic arterial phase, portal phase and equilibrium phase. For the remaining 4 patients who could not use contrast medium due to renal dysfunction, only plain CT was performed. Images were reconstructed at an 8-mm slice thickness, and interpreted by CT radiologists who specialize in body imaging.

In 25 patients, MRCP was performed using 1.5-T

MRI (MAGNETOM Symphony; Siemens) or 3-T MRI (MAGNETOM Trio, A Tim System; Siemens). For ERCP, the procedure was performed in a standard fashion with a side-viewing therapeutic duodenoscope (Olympus JF 260V; Olympus) using standard iodinated contrast medium. Brushings of the biliary stricture were obtained during ERCP. The remainder of the ERCP procedure was then performed according to the individual needs of each patient. When a drainage tube was placed for palliative treatment in patients suffering from obstructive jaundice, bile pooled for 24 h was collected for cytopathological analysis 3 times. For routine cytology (RC), specimens obtained from brushings and bile collected from a drainage tube were reviewed by dedicated gastrointestinal cytopathologists.

As tumor markers, carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA19-9) were examined at admission, and CEA > 5.0 ng/mL or CA19-9 > 37 U/mL were considered to indicate malignancy.

### Final diagnosis and follow-up

The final diagnosis was based on definitive cytologic studies diagnostic for malignancy or surgical removal followed by pathological examination in 18 patients and clinical follow-up for > 10 mo in 16 patients. Repeat ERCP, biliary brushing and bile collection were performed as clinically indicated. Clinical follow-up included imaging with abdominal CT, EUS and MRCP. Follow-up information was also obtained from hospital medical records, by contacting primary care physicians.

### Statistical analysis

Continuous variables are expressed as median (range). Each test is expressed in proportions in terms of sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy. Analysis was performed using StatView software (Hulinks, Inc., Tokyo). Comparisons between continuous variables were performed using non-parametric tests. Comparisons between qualitative variables were performed using a  $\chi^2$  test for independence or Fisher's exact probability test. Values of  $P < 0.05$  were considered statistically significant.

## RESULTS

### Patient characteristics

Thirty-four patients (17 men, 17 women) met the inclusion criteria. The median age of the patients was 71 years (range, 23-90 years). Jaundice (total bilirubin > 2 mg/dL) was evident at presentation in 13 patients. In the 21 patients without jaundice, abnormal liver blood tests were found in 8 patients, and 6 patients complained of abdominal pain. Abnormal hepatobiliary images on transabdominal US at medical check-up were detected in 7 patients, who had neither abnormalities in blood data nor clinical symptoms. No significant difference in clinical characteristics was seen between patients with benign stricture, normal cases and those with malignant strictures (Table 1).

Table 1 Patient characteristics

Final diagnosis	Benign stricture and normal case (n = 17)	Malignant stricture (n = 17)	Statistical significance
Age (yr)	71.5 (23-90)	69.0 (56-84)	NS
Sex (male/female)	9/8	8/9	NS
Presenting symptoms			NS
Jaundice	5	8	
Elevated liver enzymes	2	6	
Abdominal pain	5	1

### Final diagnosis

There were 17 malignant strictures, 11 benign strictures and 6 normal cases. Among 8 cases of peripancreatic cancer (tumor located in the head of the pancreas), the diagnosis was confirmed as pancreatic cancer by pathological examinations using surgical specimens in 6 cases and 2 lesions were considered malignant based on clinical follow-up. Two patients who were clinically diagnosed as peripancreatic cancer died of liver failure 4 mo after EUS examination, accompanied by CA19-9 elevation. Among 7 cases of biliary cancer, the diagnosis was confirmed by pathological examination using surgical specimens in 5 cases and 2 lesions considered malignant on clinical follow-up were located in the middle duct. One patient who was clinically diagnosed with biliary cancer gradually became emaciated and died within 1 year of EUS examination. In another patient, peritoneal dissemination was found at surgery 4 mo after EUS examination. One patient was diagnosed with carcinoma of the papilla of Vater by pathological examination using surgical specimens. In another patient who was clinically diagnosed with carcinoma of the papilla of Vater, cytology taken from the orifice of the papilla was suspicious of adenocarcinoma and the duodenum finally became stenotic 2 years after EUS examination (Table 2).

The diagnosis of benign strictures was confirmed by surgery in 4 and by clinical follow-up in 7. Patients clinically diagnosed as benign did not show changes in images or clinical exacerbation. Six cases were considered normal for which strictures detected on ERCP or

**Table 3** Malignant strictures correctly judged as malignant on EUS

Final diagnosis	EUS findings	n (%)
Peripancreatic cancer (n = 8)	Mass adjacent to the stricture site in the pancreas head	8 (100)
	Disruption of the bile duct by the mass	6 (75)
	Continuation into adjacent structures	6 (75)
	Invasion of the main pancreatic duct	5 (62.5) <sup>a</sup>
	LN swelling	4 (50)
	Ascites	1 (12.5)
Biliary cancer (n = 6)	Mass adjacent to the stricture site in the pancreas head	6 (100)
	Disruption of the bile duct by the mass	5 (83.3)
	Continuation into adjacent structures	5 (83.3)
	Invasion of the main pancreatic duct	0 (0)
	LN swelling	3 (50)
Cancer of the ampulla of Vater (n = 2)	Mass mainly located on the luminal side	2 (100)
	Infiltration of the muscularis propria by the mass	2 (100)
	LN swelling	1 (50)

<sup>a</sup>*P* = 0.026 *vs* Biliary cancer. EUS: Endoscopic ultrasonography; LN: Lymph nodes.

MRCP were either not reproducible or were due to compression by Oddi's sphincter (Table 2).

These results suggest that the proportion of malignant strictures was 50% even if lesions which could cause the stricture were not detected on CT and/or MRI. When cases with normal images on EUS were excluded, the proportion of malignancy reached 58.6%.

### **EUS for recognizing causes of biliary strictures shown on ERCP or MRCP**

While EUS is now routinely performed without insertion of apparatus into the biliary tree, few reports have used EUS to evaluate biliary strictures without an identifiable mass on CT. We thus examined the diagnostic ability of EUS, and conducted comparisons with the diagnostic abilities of RC and tumor markers.

Malignancy was correctly diagnosed in 16 of 17 patients. Ultrasonographic findings in patients with malignant strictures correctly judged as malignancy on EUS are summarized in Table 3. A mass accompanied by invasion of surrounding tissues may be suggestive of malignancy. The proportion of invasion of the main pancreatic duct was significantly higher in patients with peripancreatic cancer than in patients with biliary cancer (62.5% *vs* 0%, *P* = 0.026), while no significant difference was seen in terms of diagnostic ability, biliary disruption and invasion of adjacent tissues by the tumors. In addition to the sonographic findings in the mass and the bile duct, EUS also detected enlarged lymph nodes > 10 mm in diameter in 50% of patients with malignant strictures. Ascites were observed in 1 patient with peripancreatic cancer. In 1 false-negative case with distal biliary cancer, no mass was detectable and was judged as benign. In this case, the mass may have been hidden by the acoustic shadow formed by impacted stones in the bile duct.

Correct diagnosis of benign disease was made in 14 of 17 patients. Ultrasonographic findings in patients

with benign strictures correctly judged as benign on EUS are summarized in Table 4. Smooth tapering of the bile duct, preservation of the normal layered structure of the bile duct wall and no mass adjacent to the stricture site may be suggestive of benign disease. There were 3 false-positive patients with fibrotic strictures, diagnosed as systemic lupus erythematosus in 1 patient and unknown etiology in 2. In these cases considered to have malignancy on EUS, a drainage tube was inserted into the bile duct. In 2 patients, a solid mass was found at the distal end of the duct. The duct wall was thickened, losing the layered structure. In 1 patient, the distal end of the bile duct was filled with an irregular mass that could not be distinguished from the duct wall on EUS. The irregular mass looked extended from the duct, which looked like invasion of the adjacent tissues on imaging. Fibrotic change was ascertained when surgery was performed, while masses could not be confirmed during surgery, probably because the substance that looked like masses was debris.

Six strictures identified by ERCP or MRCP were ultrasonographically considered as benign and finally diagnosed as "normal" duct. Four strictures were not reproducible during clinical follow-up. Diagnoses on EUS were calcification on the duct wall in 2 patients, cuneate deformity of the duct wall in 1 patient and normal biliary tree in 1 patient. Two were considered as strictures due to compression by Oddi's sphincter, accompanied by acute cholangitis which improved and was not recurrent.

To summarize, EUS identified lesions that could cause biliary strictures, irrespective of pathological features, in 32 of 34 patients (sensitivity 90.5%, specificity 100%, PPV 100%, NPV 86.7%, accuracy 94.1%) (Table 5). In terms of pathological features, EUS correctly identified causes in 16 of 17 malignant strictures and in 14 of 17 benign lesions. With regard to the proportion of correct diagnosis, no significant difference was seen between patients with malignant and benign lesions (94.1% *vs* 82.4%, *P* = 0.60). The diagnostic abilities of EUS were 94.1% sensitivity, 82.3% specificity, 84.2% PPV, 93.3% NPV and 88.2% accuracy (Table 6). Following RC, adequate samples were obtained in 24 patients (16 malignant, 8 benign strictures), and RC correctly identified the causes in 8 of 14 malignant strictures and in 8 of 16 benign strictures. In terms of the proportion of correct diagnosis, no significance difference was evident between patients with malignant and benign lesions (62.5% *vs* 100%, *P* = 0.066). The diagnostic abilities of RC were 62.5% sensitivity, 100% specificity, 100% PPV, 57.2% NPV, and 75% accuracy.

Tumor markers were measured in 34 patients, and correctly identified malignancy in 13 of 17 malignant strictures and correctly identified a benign disease in 12 of 17 benign strictures. In terms of the proportion of correct diagnosis, no significant difference was seen between patients with malignant and benign lesions (76.5% *vs* 70.6%, *P* > 0.999). The diagnostic abilities of tumor

Table 4 Benign strictures correctly judged as benign on EUS

Final diagnosis	Reason to diagnose as benign stricture	EUS findings
Inflammatory stricture clinically diagnosed as acute cholangitis ( <i>n</i> = 1)	No exacerbation during follow-up (> 23 mo)	Stenosis of the distal end of the bile duct The normal layered structure of the bile duct wall No mass adjacent to the stricture site
Biliary dilation ( <i>n</i> = 3)	No change for > 18 mo	The dilated bile duct gradually tapering at the ampulla of Vater ( <i>n</i> = 2) A 1-cm long narrowing portion at the distal end of the duct smoothly continuous from the dilated proximal duct ( <i>n</i> = 1)
Chronic pancreatitis including 1 autoimmune pancreatitis ( <i>n</i> = 2)	No exacerbation during follow-up (> 10 mo)	Smooth tapering of the distal end of the bile duct without a mass adjacent to the stricture site (in case of autoimmune pancreatitis) Marked calcification at the stricture site ( <i>n</i> = 1)
Anomalous arrangement of the pancreaticobiliary duct ( <i>n</i> = 1)	Confirmed by MRCP	Connection of the pancreatic duct to the biliary duct outside the papilla of Vater
Congenital choleductal cyst ( <i>n</i> = 1)	Confirmed by surgery	Cystic dilatation at the distal end of the bile duct

MRCP: Magnetic resonance cholangiopancreatography.

Accuracy	94.1

PPV: Positive predictive value; NPV: Negative predictive value.

Table 6 Diagnosis of malignant vs benign causes (%)

	Sensitivity	Specificity	PPV	NPV	Accuracy
EUS ( <i>n</i> = 34)	94.1	82.3	84.2	93.3	88.2
Brushing ( <i>n</i> = 24)	62.5 <sup>a</sup>	100	100	57.2 <sup>c</sup>	75.0
Tumor marker (CA19-9 > 37 U/mL) ( <i>n</i> = 34)	76.5	70.6	72.2	75.0	73.5
Tumor marker (CA19-9 > 100 U/mL) ( <i>n</i> = 34)	53.0 <sup>b</sup>	82.4	75.0	63.6	67.7

<sup>a</sup>*P* = 0.039 vs EUS; <sup>b</sup>*P* = 0.017 vs EUS; <sup>c</sup>*P* = 0.035 vs EUS. CA19-9: Carbohydrate antigen 19-9.

markers were 76.5% sensitivity, 70.6% specificity, 72.2% PPV, 75% NPV and 73.5% accuracy.

The diagnostic ability of CA19-9 has been reported to be improved when the cutoff level is increased to 100 U/mL<sup>[14]</sup>, for the level of CA19-9 increases in patients with cholestasis<sup>[15]</sup>. Analysis of tumor markers was thus performed using 100 U/mL as the cutoff level for CA19-9. The results were 53% sensitivity, 82.4% specificity, 75% PPV, 63.6% NPV and 67.7% accuracy. With regard to the proportion of correct diagnoses using 100 U/mL as the cutoff level of CA19-9, no significant difference was seen between patients with malignant and benign lesions (53.0% vs 82.4%, *P* = 0.14).

Diagnostic sensitivity and NPV were superior for EUS than for RC (*P* = 0.039 and 0.035, respectively). Compared with tumor markers using 100 U/mL as the cutoff level for CA19-9, EUS showed significantly higher sensitivity (*P* = 0.017).

### Ultrasonographic findings on EUS and frequency of malignancy on final diagnosis

Hypoechoic masses with irregular margins, tumor size > 10 mm and mixed echogenicity reportedly imply malignancy on IDUS<sup>[3,10,12]</sup>. Thus, (1) the presence of a mass, (2) tumor size > 10 mm, (3) the margin and internal echo of a mass; (4) disruption of the normal sonographic layers of the bile duct wall, and (5) continuation of a mass into adjacent structures were analyzed to study the relationship between EUS findings and final diagnosis (Table 7).

The proportion of patients with malignancy was significantly higher when a mass was detected (*P* = 0.0069), especially with an irregular margin (*P* = 0.025) and hypoechoic or mixed echoic pattern (*P* = 0.004), the bile duct was accompanied by disruption (*P* = 0.0013) and a case showed invasion to surrounding tissues (*P* < 0.001). There was no significant difference between malignant and benign strictures in terms of tumor size.

To summarize, the data suggest that biliary stricture can be diagnosed as malignancy on EUS when a mass is

**Figure 1** A 62-year-old man with biliary cancer. A: Magnetic resonance cholangiopancreatography (MRCP) showing 11-mm long stricture (arrow) in the distal common bile duct; B: Computed tomography (CT) showing the normal pancreas head; C: Endoscopic ultrasonography (EUS) showing an irregularly shaped mass (black arrow) accompanied by disruption of the bile duct and portal vein invasion (white arrow). CBD: Common bile duct; PV: Portal vein.

adjacent to the stricture, has an irregular margin, a hypoechoic or mixed echoic pattern, disruption of the bile duct, and invasion to surrounding tissue. A typical case is shown in Figure 1.

## DISCUSSION

Consensus has yet to be reached on the management of biliary strictures with unknown etiology. Even after excluding biliary strictures with an identifiable mass on cross-sectional imaging, our data indicate that the risk of malignant stricture is 50%, consistent with previous data<sup>[4,5,7,8]</sup>. The frequency of malignancy is not negligible, allowing surgical exploration as a pre-emptive approach. In particular, when accompanied by obstructive jaundice, the majority of biliary strictures are believed to be malignant and surgery is routinely performed<sup>[7]</sup>. However, the remaining 50% of biliary strictures are benign or are eventually diagnosed as normal when no identifiable mass is seen on CT/MRI. In addition, our data show that 38.5% of biliary strictures are benign, even if accompanied with jaundice. Since the frequency of benign strictures is quite high and these strictures can be managed by endoscopic therapies, recommending exploratory surgery in all patients may not be justifiable. To differentiate patients with a low risk of malignancy from those with a high risk of malignancy who would benefit from surgical exploration, a new diagnostic approach should be provided for the management decision.

IDUS has recently seen clinical use at the time of ERCP for patients with painless jaundice and no identifiable mass on CT/MRI<sup>[5,16]</sup>. In previous studies, IDUS has proven quite accurate in distinguishing benign and malignant strictures, with reported accuracies of 76%-90%<sup>[3,6,17]</sup>. In addition, for indeterminate biliary strictures of unknown etiology, IDUS has provided approved diagnostic ability<sup>[5,8]</sup>. According to Stravropoulos, the sensitivity and specificity of IDUS are both 83%. When IDUS is used with ERCP, IDUS increases the diagnostic accuracy of ERCP from 58% to 90%<sup>[5]</sup>. According to Domagk, IDUS provides correct preoperative diagnosis in 83% of cases<sup>[8]</sup>.

For indeterminate biliary strictures, our study shows that the diagnostic abilities of EUS were 94.1% sensitivity, 82.3% specificity, 84.2% PPV, 93.3% NPV and 88.2% accuracy, comparable to the abilities of IDUS. In addition, compared with RC and tumor markers, EUS showed significantly higher sensitivity and NPV to distinguish benign and malignant strictures. These results suggest that EUS offers high diagnostic ability for distal biliary strictures even without a mass on CT, detecting pancreaticobiliary cancers at a very early stage.

Despite a long search, the only previously published paper on the diagnostic ability of EUS for biliary strictures with unknown etiology was that by Lee *et al*<sup>[1]</sup>. Their diagnostic criteria for malignancy included the finding of a pancreatic head mass and/or irregular bile duct wall, similar to the criteria in our study. According to Lee *et al*<sup>[1]</sup>, EUS for malignancy offers 88% sensitivity, 100% specificity, 100% PPV, and 84% NPV. Compared with our results, Lee *et al*<sup>[1]</sup> achieved much higher specificity. Unlike our patients, however, almost all patients in their study had a stent in place at the time of referral for EUS, possibly making the bile duct wall thicker and/or irregular even in patients with benign stricture. Irregularity of the duct wall might thus have been diagnosed as malignant when the wall was extremely irregular, which would have made the diagnostic criteria for malignancy stricter than expected.

Patients with a final diagnosis of “normal” reaped the greatest benefits from this study, in which the definition of benign strictures was strict. In “normal” cases, EUS could exclude the possibility of malignancy, avoiding unnecessary follow-up and invasive procedures such as surgical exploration.

In our institution, patients with operable lesions judged as malignant based upon our EUS “criteria” and no known contraindication underwent surgery. Patients with lesions judged as benign on EUS and low clinical suspicion for malignancy were treated endoscopically or clinically followed at the outpatient clinic. When clinical data were suggestive of malignancy, further diagnostic procedures such as surgical exploration were performed,

irrespective of EUS results. EUS plus MRCP could replace ERCP with IDUS as the first choice to direct management decisions for indeterminate biliary strictures with no identifiable mass on cross-sectional imaging, especially in cases showing low clinical suspicion for malignancy.

Three false-positive patients showed biliary stricture caused by benign fibrosis. When these patients were referred for EUS, endoscopic biliary drainage tubes had been inserted. Biliary drainage tubes could have caused recurrent cholangitis due to tube occlusion by biliary sludge, leading to thickening of the bile duct wall. In 1 case of benign stricture caused by fibrosis, a hypoechoic mass was detected at the end of the bile duct on EUS, but was not found during surgery. This case indicates that biliary sludge should be considered as a possible diagnosis when a drainage tube is inserted<sup>[18,19]</sup>. The introduction of contrast-enhanced EUS to search for vascular images inside a mass may lead to differentiation of biliary sludge from tumor.

Our study did not perform EUS-FNA, which could have increased the diagnostic ability. According to Lee *et al.*<sup>[1]</sup>, however, EUS-FNA shows 47% sensitivity, 100% specificity, 100% PPV, and 50% NPV, suggesting that sonographic features of biliary strictures are more accurate for diagnosis than the results of EUS-FNA cytology. While some authors have reported EUS-FNA as highly diagnostic for biliary strictures<sup>[20,21]</sup>, the lesions that could explain strictures in those papers were large enough to be detected on CT/MRI, possibly increasing the diagnostic ability of cytology.

RC examination could have compensated for false-negative results in 1 patient with bile duct cancer. In this patient, we could not detect the tumor on EUS, as the tumor was behind impacted stones in the bile duct. This case supports previous reports that malignancy is frequently accompanied by biliary stones<sup>[22]</sup>, recommending cytology examination to prevent false-negative diagnosis, particularly in cases with stones in the biliary tree.

Our results indicate that tumor markers using 100 U/mL as the cutoff level for CA19-9 are less diagnostic than imaging features of biliary strictures detected on EUS, when 100 U/mL is considered as malignancy<sup>[14]</sup>. This is compatible with other studies<sup>[15,23]</sup> noting that tumor markers specific to cancers along the biliary tract are unavailable. When 37 U/mL was used as the cutoff level for CA19-9, no significant difference was seen between the diagnostic abilities of EUS and tumor markers. This is probably because the CA19-9 level increases in cases of cholestasis<sup>[15]</sup>, leading to false-positive cases.

Although preliminary, this study may be the first report to suggest criteria for EUS to classify biliary strictures as benign or malignant. Limited information is available on the criteria for EUS, partly due to the limited availability of EUS<sup>[7]</sup>, while definite criteria for IDUS to classify biliary strictures as benign or malignant have almost been established. According to Menzel, hypoechoic masses with irregular margins and inhomogeneous echo-poor areas

invading surrounding tissue on IDUS are suggestive of malignancy<sup>[10]</sup>. Tamada *et al.*<sup>[3]</sup> reported that the presence of a hypoechoic mass with irregular margins, or infiltration of surrounding tissues, size > 10 mm, and disruption of normal sonographic layers of the bile duct wall, is predictive of malignancy. These data using IDUS are compatible with our results on EUS, suggesting that the presence of a mass adjacent to the biliary stricture, particularly with irregular margins, hypo- or mixed-echoic pattern, disruption of the bile duct, and invasion to surrounding tissue imply malignancy. In our study, mass size was not correlated with the pathological diagnosis of strictures. In the study by Tamada *et al.*<sup>[3]</sup>, malignant masses may have been larger than benign masses, as lesion size was not among the inclusion criteria for subjects in that study. Since our objectives were biliary strictures for which CT could not identify a mass, the lesions should have been much smaller than those studied in other investigations. Malignant and benign lesions may thus have shown no significant difference in size in the present study.

A major limitation in this study was that dynamic CT was performed according to the routine protocol in all cases. If thinner section thickness (e.g. 1-2 mm instead of 8 mm) was used or 3-dimensional analysis instead of horizontal analysis alone was performed, the causative mass could have been detected. If the dynamic study had been adjusted to the location of each biliary stricture, more detailed information could also have been obtained<sup>[24]</sup>. However, no imaging modalities have shown detectability of small pancreatic cancer superior to EUS<sup>[9]</sup>. In extrahepatic bile duct carcinoma, particularly without thickening of biliary walls, identification of local extension or depth using CT alone is known to be difficult<sup>[25]</sup>. In the diagnosis of cancer of the papilla of Vater, depicting tumors by CT is accepted as difficult<sup>[14]</sup>. These reports indicate that detectability of lesions that can cause biliary stricture remains insufficient using CT alone.

In conclusion, sonographic appearance on EUS offers high diagnostic ability for extrahepatic biliary strictures, even if cross-sectional imaging modalities cannot depict the causative lesion. Particularly in cases of benign stricture where the final diagnosis is "normal", invasive procedures such as surgical exploration or excessive follow-up investigations may be avoided. Furthermore, earlier diagnosis of malignant strictures by EUS would provide more therapeutic options for patients with very early-stage pancreaticobiliary cancer.

## COMMENTS

### Background

There is no consensus regarding how to manage distal biliary stricture without an identifiable mass on cross-sectional imaging, since benign and malignant strictures cannot be definitely distinguished. For indeterminate biliary strictures, intraductal ultrasonography (IDUS) has recently yielded a diagnostic accuracy of around 80%-90%. However, the ability of endoscopic ultrasonography (EUS) to diagnose unexplained strictures has not been fully examined.

### Research frontiers

The authors demonstrated that EUS can diagnose biliary strictures caused by

malignant tumors that are undetectable on computed tomography scan. They also gave a summary of the sonographic features of malignant strictures, which could increase the diagnostic sensitivity of EUS.

### Innovations and breakthroughs

There is only one previously published study on the diagnostic utility of EUS for biliary strictures with an unknown etiology. In that study, however, almost all patients had a stent in place, possibly making the bile duct wall thicker and irregular even in patients with benign strictures. Since this clinical study included many patients without a stent, sonographic features between benign and malignant strictures could be compared, providing characteristic EUS images for malignancy.

### Applications

EUS plus magnetic resonance cholangiopancreatography could be a first-line, noninvasive examination for the diagnosis of distal biliary stricture, followed by IDUS/endoscopic retrograde cholangiopancreatography examinations or histological confirmation, when the latter are required, especially in cases showing low clinical suspicion for malignancy.

### Peer review

This is an interesting retrospective study of clinical relevance. In spite of some limitations, this paper adds to the core knowledge related to diagnostic challenges in patients with a bile duct stricture.

### Abstract

**AIM:** To compare the cost and accuracy of upper gastrointestinal (GI) X-ray and upper endoscopy for diagnosis of gastric cancer using data from the 2002-2004 Korean National Cancer Screening Program (NCSP).

**METHODS:** The study population included 1503646 participants in the 2002-2004 stomach cancer screening program who underwent upper GI X-ray or endoscopy. The accuracy of screening was defined as the probability of detecting gastric cancer. We calculated the probability by merging data from the NCSP and the Korea Central Cancer Registry. We estimated the direct costs of the medical examination and the tests for upper GI X-ray, upper endoscopy, and biopsy.

**RESULTS:** The probability of detecting gastric cancer

*via* upper endoscopy was 2.9-fold higher than *via* upper GI X-ray. The unit costs of screening using upper GI X-ray and upper endoscopy were \$32.67 and \$34.89, respectively. In 2008, the estimated cost of identifying one case of gastric cancer was \$53094.64 using upper GI X-ray and \$16900.43 using upper endoscopy. The cost to detect one case of gastric cancer was the same for upper GI X-ray and upper endoscopy at a cost ratio of 1:3.7.

**CONCLUSION:** Upper endoscopy is slightly more costly to perform, but the cost to detect one case of gastric cancer is lower.

### INTRODUCTION

Gastric cancer is the second most common cause of cancer death worldwide, and countries in East Asia, such as China and Japan, have a high incidence of gastric cancer. Korea has 66 cases per 100000 in men and 34 cases per 100000 in women. Although the incidence has declined in recent decades, gastric cancer remains the most frequent cancer diagnosis in Korea<sup>[1,2]</sup>. The

prevention and early detection of gastric cancer is therefore a high priority.

Many Asian countries have no national guidelines or recommendations for gastric cancer screening. In high-risk regions such as Japan and Korea, where gastric cancer is highly prevalent, screening is recommended for individuals over 40 years of age. Japan utilizes mass X-ray screening programs to detect gastric cancer in its early stages<sup>[1,3]</sup>. In recent years, mass screening with upper endoscopy has replaced upper gastrointestinal (GI) X-ray in several cities in Japan, and is considered to be a superior technique by the Japanese medical system<sup>[4,5]</sup>. Upper endoscopy is a highly effective screening method that detects early gastric cancer at a higher rate than upper GI X-ray. However, there are cost issues associated with upper endoscopic mass screening, in that it is nearly 4-fold more expensive than upper GI X-ray in the Japanese medical system<sup>[5,6]</sup>. In addition, primary screening endoscopy was proposed as a cost-effective method to screen for gastric cancer in an intermediate-risk population such as in Singapore<sup>[7]</sup>.

Despite this promising result, direct evidence about the effectiveness of upper endoscopy among individuals at average risk of gastric cancer is still not sufficient to justify its use for routine screening, and no nationwide screening program is available<sup>[2,8]</sup>. Upper endoscopy may be the most cost-effective screening program for Korea, given the relatively low cost of the technique and the high incidence of gastric cancer.

Korea has an organized population-based screening program in which people within a specified age range regularly receive a personal letter inviting them to undergo cancer screening. In 1999, Korea began screening for gastric cancer as a part of the National Cancer Screening Program (NCSP). The target population was enrolled in Medicaid and had National Health Insurance with a premium below 50%. Currently, NCSP provides screening services free of charge. The NCSP recommends biennial upper GI X-ray or upper endoscopic gastric cancer screening for men and women older than 40<sup>[9]</sup>. Although the NCSP offers either upper GI X-ray or upper endoscopy examination as an initial screening method for gastric cancer, there is a lack of agreement about the recommendation of screening method among the government, physicians, and the general population<sup>[2]</sup>.

Given the limited healthcare resources, policy-makers require estimates of the effectiveness and costs of alternative prevention programs. Ideally, policy decisions should be based on the long-term effectiveness and cost-effectiveness of gastric cancer screening<sup>[10]</sup>. However, screening for gastric cancer is not commonly practiced, and there is a paucity of data to lend support to such a program. Few data are currently available regarding the long-term effectiveness of alternative gastric cancer screening strategies. The evaluation of the effects of gastric cancer screening on prognosis is incomplete and epidemiologic data on the survival, mortality, and distribution of gastric cancer stage are still insufficient in Korea. In the present study, we examined the short-

term cost-effectiveness. The data presented here are preliminary, and we were unable to show that the screening programs examined are associated with a decrease in gastric cancer mortality.

## MATERIALS AND METHODS

### Measures of effectiveness

We estimated an intermediate outcome: the cost per case detected<sup>[10,11]</sup>. The effectiveness of screening was defined as the probability of detecting gastric cancer. We compared other accuracy indicators between upper GI X-ray and upper endoscopy, such as sensitivity and specificity. We calculated accuracy by merging data from the NCSP and the Korea Central Cancer Registry (KCCR), a nationwide hospital-based cancer registration program that covers more than 90% of the cancer cases in Korea<sup>[12]</sup>.

We used data from the NCSP collected from 2002 to 2004. In total, 1 608 810 participated in the stomach cancer screening program. Of the 1 608 810 participants, male and female subjects who were free of gastric cancers and had complete information related to gastric cancer screening results and identification number were included in this study. The data from 1 503 646 participants in the stomach cancer screening program were finally included in this analysis.

The screening results of the NCSP were reported as follows: “normal”, “benign”, “suspicious”, or “cancer”. We defined both “suspicious” and “cancer” as positive results in each screening method. Outcomes of stomach cancer incidence were based on a 1-year follow-up using the KCCR as a gold standard. We defined cancer incidence by the International Classification of Diseases, code C16 (ICD-10:C16). This research was approved by the Institutional Review Board (IRB) committee.

### Cost calculation

We used 2 models to calculate the total cost of gastric cancer screening. One model included the additional costs for diagnostic follow-up after obtaining abnormal results to consider the costs of upper endoscopy incurred after the upper GI X-ray, which was outside the scope of the NCSP. The costs for diagnostic follow-up were based on the payment system for clinics. The other model included only the direct costs of providing preventive cancer screening services (i.e. only the cost a screening program would incur).

We estimated the screening costs of the medical examination and the tests for upper GI X-ray, upper endoscopy, and biopsy. When the upper GI X-ray identified an abnormal result, the diagnosis had to be confirmed with upper endoscopy and biopsy, even if the final result was a false positive. Therefore, the patient may incur expenses in addition to the initial screening test. We performed 2 cost analyses: in model I (the standard model), we calculated the cost of diagnosis confirmation when the results of the upper GI X-ray were positive (“suspicious” or “cancer”), whereas model II represented

**Table 1** Characteristics of gastric cancer screening participants (2002-2004) *n* (%)

	Upper GI X-ray	Upper endoscopy	Total (%)
Year			
2002	290410 (75.0)	96637 (25.0)	387047 (100.0)
2003	393217 (70.9)	161736 (29.1)	554953 (100.0)
2004	383751 (68.3)	177895 (31.7)	561646 (100.0)
Total (%)	1067378 (71.0)	436268 (29.0)	1503646 (100.0)

GI: Gastrointestinal.

**Table 2** Results of gastric cancer screening (2003-2005)

	Upper GI X-ray ( <i>n</i> )			Upper endoscopy ( <i>n</i> )		
	Cancer	No cancer	Total	Cancer	No cancer	Total
Positive	892	108178	109070	1041	16105	17146
Negative	1227	957081	958308	724	418398	419122
Total	2119	1065259	1067378	1765	434503	436268

the expense to the screening program and only included the cost of the screening test.

The stomach cancer screening costs were based on the 2008 National Cancer screening payment system. Costs were expressed in US dollars (USD), based on the average exchange rate of 1121.88 won for 1 USD in 2008. We varied the cost-ratio of upper GI X-ray and upper endoscopy screening programs, to explore the change in cost-effectiveness when the cost of upper endoscopy was higher than that of upper GI X-ray, as in other countries.

## RESULTS

### Characteristics of the gastric cancer screening participants

Between January 2002 and December 2004, 1 503 646 people took part in the NCSP (Table 1). Of those, 71% were screened using upper GI X-ray and 29% were screened with upper endoscopy. Of the participants who were screened in 2002, 75.0% of the participants underwent upper GI X-ray and 25.0% underwent upper endoscopy. In 2004, 68.3% underwent upper GI X-ray and 31.7% underwent upper endoscopy.

### Gastric cancer screening test accuracy

During a 1-year follow-up period, 3884 new gastric cancer cases were reported, and the gastric cancer incidence was 258.3 per 100 000 people. Of the 1 067 378 people screened with the upper GI X-ray, 109 070 positive results were obtained: 892 were true positives and 108 178 were false positives. In contrast, of the 436 268 participants screened with upper endoscopy, 17 146 positive results led to 1041 true positives and 16 105 false positives (Table 2).

The probability of finding a true positive for gastric cancer in 1 503 646 participants was 836 per 100 000 for the upper GI X-ray screening test and 2386 per 100 000 for upper endoscopy (Table 3). Therefore, the probability

**Table 3** Estimated costs and effectiveness of gastric cancer screening programs

	Model I		Model II	
	Upper GI X-ray	Upper endoscopy	Upper GI X-ray	Upper endoscopy
Probability of gastric cancer ( <i>n</i> )	0.000836	0.002386	0.000836	0.002386
Unit cost, US\$ (a)	44.37	40.33	37.14	40.33
Cost to detect one case of gastric cancer (a/ <i>n</i> )	53094.64	16900.43	44445.78	16900.43
Reduction in cost to detect one case of gastric cancer		36194.21		27545.35

Model I: Including screening test costs and confirmation test costs, if the results of upper GI X-ray were abnormal; Model II: Including screening test costs only.

**Table 4** Unit cost in 2008 for the gastric cancer screening tests

	Units	Cost in USD
Screening cost	Medical examination	\$4.47
	Upper gastrointestinal X-ray	\$32.67
	Upper endoscopy	\$34.89
	Biopsy	\$24.54
Confirmation cost		\$70.73

Confirmation cost: the cost of endoscopic examination with biopsy when the results of the upper GI X-ray were positive ("suspicious" or "cancer").

of detecting gastric cancer with upper endoscopy was about 2.9-fold higher than with upper GI X-ray. The sensitivities of upper GI X-ray and upper endoscopy were 42.1% and 59.0%, respectively, and the specificities were 89.8% and 96.3%, respectively. The positive predictive value was 0.008 for upper GI X-ray and 0.061 for upper endoscopy, and the negative predictive values were 0.999 and 0.998, respectively.

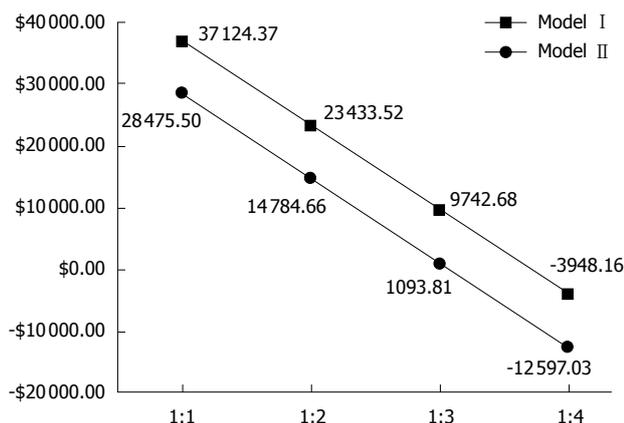

### Cost of gastric cancer screening tests

Table 4 shows the unit costs for gastric cancer screening in 2008. Screening using upper GI X-ray and upper endoscopy cost \$32.67 and \$34.89, respectively, and the cost ratio was 1:1.07.

### Cost-effectiveness of the screening tests

The cost of identifying one case of gastric cancer was estimated to be \$53 094.64 with upper GI X-ray screening and \$16 900.43 with upper endoscopy in 2008. Therefore, using upper endoscopy as the initial screening test would reduce the cost of detecting one case of gastric cancer by \$36 194.21 in model I and \$27 545.35 in model II.

Figure 1 shows the difference in cost-effectiveness according to various cost ratios for the upper GI X-ray

**Figure 1** Changes in the reduction in costs (in USD) according to the cost ratios of upper GI X-ray and upper endoscopy. Model I : Including screening test costs and confirmation test costs, if the results of the upper gastrointestinal X-ray were abnormal; Model II : Including screening test costs only.

and upper endoscopy screening programs. This was analyzed to explore the change in cost-effectiveness when the cost of upper endoscopy exceeded that of upper GI X-ray, as in other countries. At a ratio of 1:1, we can save \$37 124.37 in model I. However, when upper endoscopy screening was 4-fold more expensive than upper GI X-ray, it cost \$3948.16 more to conduct an upper endoscopy test than an upper GI X-ray. In model I, the cost to detect one case of gastric cancer was the same for upper GI X-ray and upper endoscopy at a cost ratio of 1:3.7.

## DISCUSSION

We found that the upper endoscopy screening test was more accurate and the detection rate was higher than for upper GI X-ray. A few studies have examined the accuracy of upper endoscopy in detecting cancer<sup>[1,4,5,13-16]</sup>. A study conducted in Niigata, Japan found that the detection rate of gastric cancer when using endoscopy was 2.7-4.6-fold higher than when using upper GI X-ray or photofluorography<sup>[1,5]</sup>. These investigators reported an endoscopic sensitivity of 77.8% based on a 3-year follow-up using the cancer registry system in Fukui prefecture<sup>[14]</sup>. Another study based on a follow-up survey of individual participants reported that the sensitivity of endoscopy was 84%<sup>[16]</sup>. Our findings for sensitivity and specificity were lower than those reported by others for both upper endoscopy and the upper GI X-ray.

It is difficult to directly compare the results of different studies because of differences in target populations and gastric cancer screening systems. For example, our target population was a general population and included people from across the nation. The other studies mentioned here were conducted in municipalities within a prefecture and were hospital-based. Moreover, in Japan photofluorography is the initial assessment for gastric cancer screening followed by upper GI X-ray and upper endoscopy<sup>[1,3,4,13,17]</sup>, whereas in Korea upper GI X-ray or upper endoscopy are the initial tests in organized gastric cancer screening programs.

Despite the diagnostic advantages of upper endoscopy, it is more expensive and requires more staff and technological expertise than upper GI X-ray. In financial terms, the test is not as effective if the cost is high. The cost of upper endoscopy is 3-4-fold more expensive than upper GI X-ray in Japanese gastric cancer screening programs<sup>[5,6]</sup>. However, Japanese studies showed that even when the ordinary examination fee is charged, upper endoscopy was still the most cost-effective method for detecting gastric cancer<sup>[1,5,6]</sup>. Nevertheless, it is unlikely that upper endoscopy would be feasible as a mass screening program, even in highly developed countries such as Japan, because of a lack of experienced endoscopists<sup>[1,5]</sup>.

In contrast, there are a number of skilled endoscopists in Korea, making upper endoscopy mass screening more practical. In 2008, there were more than 4000 board-certified endoscopic specialists in Korea who were members of the Korean Society of Gastrointestinal Endoscopy, and their ranks have been increasing by about 150 persons annually. Upper endoscopy mass screening for gastric cancer has a higher detection probability than upper GI X-ray, and upper endoscopy is a more cost-effective screening method in Korea, given the relatively low cost of this technique (about the same as upper GI X-ray) and the high incidence of gastric cancer<sup>[1,18]</sup>. The results of our study indicate that upper endoscopy will be a more cost-effective mass screening program than upper GI X-ray until the cost per cancer case detected becomes 3.7-fold more expensive than with upper GI X-ray.

The majority of people who undergo cancer screening receive no benefit from the procedure and may actually be exposed to additional health risks as a result of screening. These risks arise from complications that can result in hospitalization or even death, from false positive results that lead to unnecessary, invasive follow-up procedures, and from over diagnosis (i.e. the treatment of cancers that, in the absence of screening, would neither have been detected in the patient's lifetime nor caused death). Therefore, mass screening is a tradeoff between major benefits to a few and small risks to many<sup>[19]</sup>.

Calculation of the total cost of gastric cancer screening must include the costs of upper endoscopy incurred after the initial assessment, as well as those of complications that infrequently result from the procedure. The balance of cost-effectiveness includes not only financial costs, but also non-financial costs including anxiety, emotional distress, and inconvenience. We did not include these non-financial costs in our study. Upper endoscopy is an invasive, but relatively safe procedure with an extremely low complication rate (mortality, 1 in 3300-40 000)<sup>[7,13,20]</sup>. Upper endoscopy enables simultaneous biopsy for histological confirmation of malignancy. Early detection with upper endoscopy permits curative management by surgical resection and endoscopic mucosal resection<sup>[4,17]</sup>. Upper endoscopy can detect gastric cancer at an earlier stage than upper GI X-ray. However, we were unable to compare the stage distribution of gastric cancer detected by upper endoscopy or upper GI X-ray, because NCSP does not require the reporting

of detailed clinical information including the stage of gastric cancer detected by screening.

Another weakness in our study was the inability to control self-selection bias, because we did not have information about socioeconomic status such as income level, education level, or job status and risk factors. These problems should be resolved in a prospective study that we have planned for the future. In a previous study, respondents with higher income levels were more likely to have an upper endoscopy test. Under the Korean health insurance system, the cost of the upper endoscopy test is almost the same as that for the upper GI X-ray. In addition, the NCSP offers a free-of-charge endoscopy test for gastric cancer screening. Despite these programs, disparities in the use of endoscopy vary with household income, possibly suggesting that misconceptions exist about the cost of endoscopy. In addition, the higher rates of endoscopy use in those with a family history of gastric cancer might indicate that the endoscopy test was the preferred test for a high-risk population<sup>[2]</sup>.

Screening large numbers of people is a costly undertaking. Healthcare providers and policy-makers are increasingly interested in the efficient allocation of medical resources, including those used for cancer screening programs. It is essential to have a framework that compares the health benefits and resource expenditures associated with competing medical and public health interventions that will allow decision-makers to identify cost-effective interventions. A complete cost-effectiveness analysis of alternative screening strategies depends on the treatment cost and its effect in terms of life years saved (or quality-adjusted life years saved)<sup>[10,19]</sup>. Longer follow-up is required to generate the mortality results critical for decision-making. However, decisions about whether and how to screen for cancer cannot always be delayed until mortality data are available. Some degree of modeling is frequently required to translate intermediate trial outcomes to long-term outcomes, making cost-effectiveness analysis necessary<sup>[19]</sup>.

The data presented here are preliminary, and we were unable to show that the screening programs examined were associated with a decrease in gastric cancer mortality. Follow-up studies are needed to further investigate this. However, the intermediate outcomes used here indicate that, in Korea, upper endoscopy is a more cost-effective screening program than upper GI X-ray. Although the incidence and mortality of gastric cancer has decreased in Korea during the last decade, gastric cancer screening continues to be a major issue because incidence and mortality remain high.

The best test is a matter of personal preference, which should be considered when physicians make recommendations for screening. Upper endoscopy is gaining acceptance as a standard method for gastric cancer screening and the preferred gastric cancer screening method according to a population-based survey<sup>[2,21]</sup>. The providers' assessment of individuals' screening preferences, in combination with intervention strategies to promote performance of the preferred screening method, may increase compliance with gastric cancer screening recommenda-

tions<sup>[22,23]</sup>. It will be imperative to consider these results when making decisions about population-based screening strategies<sup>[24]</sup>. Evidence-based screening should be promoted in the future to prevent premature death from gastric cancer. To achieve this goal, it is necessary to determine the effectiveness of upper GI X-ray and upper endoscopy mass screening in reducing mortality.

## COMMENTS

### Background

In high-risk regions such as Japan and Korea, where gastric cancer is highly prevalent, screening is recommended for individuals over 40 years of age. However, many Asian countries have no national guidelines or recommendations for gastric cancer screening.

### Research frontiers

In recent years, mass screening with upper endoscopy has replaced upper gastrointestinal (GI) X-ray in several cities in Japan, and is considered to be a superior technique by the Japanese medical system. However, there are cost issues associated with upper endoscopic mass screening. In addition, primary screening endoscopy was proposed as a cost-effective method to screen for gastric cancer in an intermediate-risk population such as in Singapore. Despite this promising result, direct evidence about the effectiveness of upper endoscopy among individuals at average risk of gastric cancer is still not sufficient to justify its use for routine screening, and no nationwide screening program is available.

### Innovations and breakthroughs

The authors identified that upper endoscopy slightly more costly to perform, but the cost to detect one case of gastric cancer was lower. Their study showed the usefulness of endoscopy as an organized screening technique across the nation.

### Applications

Upper endoscopy mass screening is a more cost-effective screening method than upper GI X-ray in Korea, and with its relatively low cost, the high incidence of gastric cancer, and the number of skilled endoscopists, upper endoscopy mass screening is more practical for gastric cancer screening.

### Peer review

The work is an interesting study to be accepted for publication.

### Abstract

**AIM:** To determine the long-term outcomes regarding reinfection with *Helicobacter pylori* (*H. pylori*) and endoscopic changes after successful *H. pylori* eradication.

**METHODS:** From June 1994 to January 2007, 186 patients (M:F = 98:88; mean age 50.0 ± 11.4 years), in whom *H. pylori* had been successfully eradicated, were enrolled. The mean duration of follow up was 41.2 ± 24.0 mo.

**RESULTS:** *H. pylori* reinfection occurred in 58 patients (31.2%). The average annual reinfection rate was 9.1% per patient year. No recurrence of peptic ulcer was detected at the follow up endoscopy. There were no significant differences between the *H. pylori* eradication regimens for the reinfection rate and no significant differences in endoscopic findings between the *H. pylori*-recurred group and the *H. pylori*-cured group.

### INTRODUCTION

*Helicobacter pylori* (*H. pylori*) is known to cause many gastrointestinal diseases including peptic ulcers, gastric carcinoma and mucosa-associated lymphoid tissue lymphoma<sup>[1]</sup>. Successful eradication of *H. pylori* infection is important in the prevention of recurrent peptic ulcer disease and gastric cancer<sup>[2-4]</sup>. Reinfection rate of *H. pylori* infection after successful eradication is an important problem in the management of peptic ulcer disease. The reinfection rate of *H. pylori* varies considerably among different studies. Reported rates of *H. pylori* recurrence in western countries range from 0.5% to 2.5%<sup>[3,5,6]</sup>. The high prevalence of *H. pylori* infection in Korea suggests the possibility that the reinfection rate might be higher than in western countries. The high prevalence of *H. pylori* infection may possibly be associated with high

rates of reinfection after eradication because of the high risk of re-exposure to infection<sup>[7]</sup>. The aims of this study were firstly to determine the rate of *H. pylori* reinfection and secondly to determine endoscopic changes after successful eradication of *H. pylori* and after subsequent reinfection in an endemic area such as Korea.

## MATERIALS AND METHODS

Patients, who were treated for *H. pylori* infection between June 1994 and January 2007 at Ewha Womans University Mokdong Hospital, Seoul, Korea and who had a negative <sup>14</sup>C urea breath test (UBIT<sup>®</sup>, Otsuka, Japan) 1 mo after eradication, were enrolled. Informed consent was obtained from the patients and ethical approval was given by Ewha Womans University Mokdong Hospital ethical committee (approval No. 187-16). After successful eradication of *H. pylori* infection and cessation of acid-suppression therapy, patients were offered endoscopic examination routinely every year. Follow up endoscopic examination and rapid urease testing (ASAN Helicobacter Test<sup>®</sup>, Asan Pharmaceutical, Korea) were performed. The initial and follow up endoscopies were performed by one endoscopist. The presence and grading of reflux esophagitis, atrophic gastritis, and gastric intestinal metaplasia were determined according to LA classification and Kimura-Takemoto classification of atrophic pattern<sup>[8]</sup>. Atrophic gastritis and gastric intestinal metaplasia were also evaluated histologically. Three endoscopic specialists reviewed the images of the endoscopic findings to reduce the inter-observer variation. Improvements and aggravation were determined by endoscopic and histologic findings. Rapid urease test was performed on biopsy specimens from the body of the stomach at the greater curvature.

Follow up duration was defined as being the length of time from successful eradication until the final test in each patient. Reinfection was defined as being when *H. pylori* recurrence took place at least 1 year after eradication therapy. The cumulative and average annual reinfection rates were calculated. Demographics and mucosal changes were compared between recurred patients (*H. pylori*-recurred group) and those remaining successfully eradicated (*H. pylori*-cured group) using Student's *t*-test and  $\chi^2$  with significance set at  $P < 0.05$ .

## RESULTS

### Subjects

One hundred and eighty six patients (98 men and 88 women) were enrolled. Sixteen patients showed recurrence of *H. pylori* within 1 year post eradication, and these were excluded from the study. Mean age was  $50.0 \pm 11.4$  years. The reasons for the initial endoscopy were; epigastric pain (40.9%), indigestion (25.3%), bleeding (5.9%) and routine check (28.0%). At the initial endoscopy, 19 patients had gastric ulcers, 79 patients had duodenal ulcers and 8 patients had gastroduodenal

**Table 1** Recurrence of *Helicobacter pylori* (*H. pylori*) after successful eradication therapy *n* (%)

Follow up period	<i>n</i>	Recurrence
1 ≤ yr < 2	186	14 (7.5)
2 ≤ yr < 3	133	15 (11.3)
3 ≤ yr < 4	90	8 (8.9)
4 ≤ yr < 5	62	8 (12.9)
5 ≤ yr < 6	40	3 (7.5)
6 ≤ yr < 7	27	6 (22.2)
7 ≤ yr < 8	13	2 (15.4)
8 ≤ yr < 9	7	2 (28.5)
9 ≤ yr < 10	1	0 (0.0)
Total		58 (31.2)

**Table 2** Recurrence rate according to the *H. pylori* eradication regimen *n* (%)

Therapeutic regimens	<i>n</i>	Recurrence
Omeprazole + clarithromycin + amoxicillin	137	41 (30.0)
Bismuth subcitrate + ranitidine + metronidazole + amoxicillin	39	14 (35.9)
Omeprazole + bismuth subcitrate + metronidazole + tetracycline	10	3 (30.0)

ulcers. The other mucosal findings at initial examination were; 23 had reflux esophagitis (12.4%), 91 had chronic superficial gastritis (48.9%), 60 had erosive gastritis (32.3%), 21 had atrophic gastritis (11.3%) and 14 patients had gastric intestinal metaplasia (7.5%).

Post eradication follow up varied from 13 to 112 mo and mean follow up duration was  $41.2 \pm 24.0$  mo.

### Reinfection of *H. pylori* after successful eradication

Reinfection of *H. pylori* after successful eradication occurred in 58 of 186 patients (31.2%). The follow up period and the time when recurrences were found are summarized in Table 1. The annual reinfection rate was 9.1% per patient year (58/638.8 patient years).

One hundred and thirty seven patients were treated with proton pump inhibitor-based triple regimens, 41 of these patients (30.0%) had recurrence. Thirty nine patients were treated with bismuth-based quadruple regimens, 14 of these (35.9%) had recurrence. Among 10 patients who were treated with proton pump inhibitor-based quadruple regimens, 3 (30.0%) patients had recurrence. There was no significant difference among the regimens for reinfection rate (Table 2).

### Endoscopic mucosal changes and comparison between *H. pylori*-recurred group and *H. pylori*-cured group

A comparison between the *H. pylori*-cured group and recurred group is summarized in Table 3. In the recurred group, mean follow up period was 42.5 mo (range 13-104 mo) and in the cured group, mean follow up was 40.6 mo (range 13-112 mo).

At the initial endoscopy, 23 cases of reflux esophagitis, 21 cases of atrophic gastritis and 14 cases of gastric intestinal metaplasia were noted. Peptic ulcers including

scar stage were observed in 106 cases. Six cases of ulcer were in the acute or healing stage and 100 cases were in the scar stage. At the follow up endoscopy, there were no cases of recurrence or aggravation of ulcers. Newly developed or aggravated cases of reflux esophagitis at the follow up endoscopy were seen in 33 subjects and improved cases were seen in 12 subjects. Nine subjects were newly developed or aggravated and 4 subjects were improved in the atrophic gastritis group and for the gastric intestinal metaplasia group, 7 were newly developed or aggravated and 9 were improved at the follow up endoscopy. There were no significant differences in mucosal changes at the initial and follow up endoscopies between *H. pylori*-recurred group and *H. pylori*-cured group.

## DISCUSSION

Infection with *H. pylori* occurs worldwide, but the prevalence varies greatly between countries and among population groups within the same country. The overall prevalence of *H. pylori* infection is strongly correlated with socioeconomic conditions<sup>[2]</sup>. The prevalence is over 80% in many developing countries, and in Korea the prevalence of *H. pylori* infection is also high at 69.4%, as compared with 20% to 50% in industrial countries<sup>[2,5,6,9]</sup>.

The reinfection rate after eradication therapy for *H. pylori* is extremely low in developed countries such as Europe and the USA. Here, the annual reinfection rates are reported to be around 1%. In contrast to the low rates of *H. pylori* reinfection reported in western populations, high recurrence rates have been reported in such developing countries as Peru, Brazil, Chile,

Vietnam and Bangladesh, all of which are countries with a high prevalence of *H. pylori* infection<sup>[1,5-7,10-12]</sup>. The high prevalence of *H. pylori* infection may possibly be associated with high recurrence of infection after eradication because of the high risk of re-exposure to infection<sup>[7]</sup>.

In 1998, Kim *et al.*<sup>[13]</sup> reported that *H. pylori* reinfection rate in patients followed for up to 5 years was 12.8%. In our study, the patients were followed for up to 9 years and the average annual reinfection rate was 9.1% per patient year. The *H. pylori* reinfection rate was lower than the rate of the previous report but still higher than that of developed countries<sup>[14]</sup>. This high rate of reinfection could be explained by the high prevalence of *H. pylori* infection among asymptomatic Korean adults which may facilitate the transmission of *H. pylori* within families and may affect the high reinfection rates. Since the Korean economy has developed and sanitary conditions have been improved, recent reports have shown that rates of reinfection are lower than in previous reports<sup>[3,15]</sup>.

Recurrence of *H. pylori* is thought to occur *via* two distinct mechanisms, recrudescence and reinfection. Recrudescence reflects reappearance of the original strain of *H. pylori* following its temporary suppression rather than successful eradication. True reinfection occurs when, after successful eradication, a patient becomes infected with either the original strain or a new strain of *H. pylori*<sup>[16]</sup>. Many investigators have found that recurrence rates during the first 3-12 mo after cure are due to late recrudescence. Demonstrated *H. pylori* negativity for 1 year post-treatment is a reliable indicator of successful eradication without recrudescence<sup>[3,7,15,17]</sup>. Recrudescence is related to the efficacy of the regimen used. Studies showed that recurrence of *H. pylori* infection more frequently occurred in patients treated with a low-efficacy treatment regimen than in those treated with a high-efficacy regimen. It seems that low-efficacy therapy does not actually cure *H. pylori* infection in the gastric mucosa but only temporarily suppresses it and does not completely eradicate it from the host<sup>[3,5,15,17]</sup>.

In our study 16/241 patients (6.6%) showed recurrence of *H. pylori* within 1 year post-eradication and this rate was higher than in any previous reports<sup>[3]</sup>. There was no significant difference between regimens in recrudescence and, in addition, there was no significant difference between regimens in recurrence rate. Recent investigations have suggested that long-term effectiveness of antimicrobial therapy may be limited by high rates of recrudescence and reinfection, due to high levels of antibiotic resistance and pressure from high levels of infection<sup>[3,12]</sup>.

The eradication of *H. pylori* infection results in a marked reduction of ulcer relapse. Many studies have shown that peptic ulcer recurrence is usually caused by *H. pylori* reinfection<sup>[6,13]</sup>. However, in our study, no recurrence of peptic ulcer was detected at the follow up endoscopy. Probably the reason why no such recurrence was detected in our study was that the initial stages of ulcer activity, which we observed at initial endoscopy,

were mostly at scar status. Since there was no recurrence of ulcers, we should carefully consider that *H. pylori* eradication might not be necessary at the ulcer scar stage of disease.

Some reports have shown a significantly lower prevalence of *H. pylori* infection among patients with gastroesophageal reflux disease than among those without this disease, suggesting that *H. pylori* infection might protect against reflux esophagitis<sup>[18]</sup>. However, in our study, there was no difference in incidence of this disease between *H. pylori*-cured patients and *H. pylori*-recurred patients. This suggests that there is no relationship between *H. pylori* infection and reflux esophagitis.

*H. pylori* infection may have a role to play in the progression of atrophy and intestinal metaplasia. The rate of glandular atrophy and intestinal metaplasia was found to be higher in *H. pylori*-positive patients but it was very low in those without *H. pylori* infection<sup>[19-25]</sup>. There was no significant difference in atrophic mucosal change between *H. pylori*-recurred and *H. pylori*-cured groups in our study. This could suggest that *H. pylori* reinfection does not affect the progression of the atrophy. We suggest the need for a comparative study of *H. pylori*-positive patients, *H. pylori*-recurred patients, *H. pylori*-negative patients and *H. pylori*-cured patients with regard to endoscopic and histologic findings. Also, polymorphic DNA fingerprinting is needed to detect whether the reinfecting strain is the identical or a different strain.

In conclusion, the reinfection rate in Korea is 9.1%, which represents a decreasing trend, but this is still higher than in the developed countries<sup>[25]</sup>. This may be due to the high prevalence of *H. pylori* infection which may influence high rates of reinfection after eradication. The endoscopic mucosal changes, including reflux esophagitis, metaplasia or atrophy, showed no significant differences between the *H. pylori*-recurred group and *H. pylori*-cured group. There was no incidence of recurred or aggravated ulcers.

## COMMENTS

### Background

Successful eradication of *Helicobacter pylori* (*H. pylori*) is important for the prevention of recurrent peptic ulcer disease and gastric cancer. Reinfection rate of *H. pylori* infection after successful eradication is also an important problem in the management of peptic ulcer disease.

### Research frontiers

The reinfection rate after eradication therapy for *H. pylori* is extremely low in developed western countries. In contrast to this, high recurrence rates have been reported in developing countries such as Peru, Brazil, Chile, Vietnam and Bangladesh, which are countries with a high prevalence of *H. pylori* infection. The high prevalence of *H. pylori* infection may possibly be associated with high rates of reinfection after eradication because of the high risk of re-exposure to infection. In this study, the authors demonstrate the *H. pylori* reinfection rate and endoscopic changes after successful eradication in Korea.

### Innovations and breakthroughs

The high prevalence of *H. pylori* infection in Korea suggests the possibility that the reinfection rate might be higher than western countries. This study showed that the reinfection rate is 9.1% in Korea and that the endoscopic mucosal changes, including reflux esophagitis, metaplasia or atrophy, showed no significant differences between the *H. pylori*-recurred group and *H. pylori*-cured group.

### Applications

The reinfection rate in Korea is 9.1% which represents a decreasing trend but which is still higher than in the developed countries. This may be due to the high prevalence of *H. pylori* infection which may influence high rates of reinfection after eradication. *H. pylori* infection may have a role to play in the progression of atrophy and intestinal metaplasia, but there was no significant difference in atrophic mucosal changes between *H. pylori*-recurred and *H. pylori*-cured groups which suggests that *H. pylori* reinfection does not affect the progression of the atrophy.

### Terminology

Recurrence of *H. pylori* is thought to occur via two distinct mechanisms, recrudescence and reinfection. Recrudescence means reappearance of the original strain of *H. pylori* following its temporary suppression rather than successful eradication. Reinfection occurs when a patient becomes infected with either the original strain or a new strain of *H. pylori* after successful eradication. Demonstrated *H. pylori* negativity for 1 year post-treatment is a reliable indicator of successful eradication without recrudescence.

### Peer review

This manuscript describes an endoscopic cohort study of patients infected with *H. pylori* receiving eradication therapy. The authors aimed to investigate the reinfection rate after eradication therapy and the endoscopic findings after eradication, after a mean follow-up of 41 mo. They observed a reinfection rate of 9% per year, after confirmation of eradication at 1 year follow-up.

### Abstract

**AIM:** To evaluate the epidemiologic features of young age gastric cancer (GC).

**METHODS:** Retrospectively, a total of 3242 patients with GC between 18 and 45 years of age and 3000 sex- and age-matched controls were reviewed. All subjects were stratified into 3 groups based on age (A, 18-30 years; B, 31-40 years; C, 41-45 years). Epidemiologic characteristics and risk factors were investigated with reference to their age and gender.

**RESULTS:** Compared to controls, more frequent intake of high risk diet ( $P = 0.00075$ ), history of heavy smoking ( $P = 0.00087$ ), intake of heavy alcohol ( $P = 0.00091$ ), lower social economic status ( $P = 0.00083$ ), body mass index  $> 30$  ( $P = 0.00097$ ), urban residence

( $P = 0.00065$ ), and more frequent exposure to harmful occupational environments ( $P = 0.00072$ ) were observed in all age groups and both genders in young age GC. These relationships were weaker in females compared to males of the same age, and were stronger as the age of patients increased. However, in group C of young age GC patients, environmental factors played important roles in females and males with a similar body weight. In females, older age at first delivery ( $> 35$  years), lack of lactation history, nulliparity, and poor nutritional status during pregnancy were significantly associated with an increased risk of GC ( $P = 0.00034$ ). In this study, 252 patients (7.8%) had a family history of GC with high odds ratio (OR) (3.22-4.21). In particular, family history was more closely associated with GC in males (OR, 4.21 in male vs 3.46 in female) and more advanced cases ( $P = 0.00051$ ).

**CONCLUSION:** Hormonal associated factors were more commonly associated with females whereas environmental factors were more commonly associated with males in young age GC patients.

## INTRODUCTION

Although gastric cancer (GC) is considered to be a disease of the middle aged and elderly<sup>[1]</sup>, 2%-15% of patients with GC are younger than 45 years of age (defined as young age GC)<sup>[2-5]</sup>, and there has been an increase in the relative proportion of young age GC compared with older age GC<sup>[6-8]</sup> especially in young females<sup>[8]</sup>. Until now, a lot of studies about epidemiologic and clinicopathologic features of GC, including risk factors, have been conducted in the elderly. However, in young age GC, only a few studies with small-sized samples have been conducted. The results of these studies were widely variable within each study<sup>[1-8]</sup>, which may be due to bias or low statistical power. In this study, we reviewed our institution's experience of the demographic and clinicopathologic features of GC in young patients between 18 and 45 years of age (defined as young age GC) from January 1990 to April 2008. Simultaneously, a total of 3000 sex- and age-matched healthy controls living in the same period were enrolled, all of whom received endoscopy at the Department of Gastroenterology and Health Care Center for the evaluation of the risk of young age GC. This retrospective, large-scale, and population-based study with abundant epidemiologic and clinicopathologic information in a single institution may reduce the limitation and bias of small sample-sized studies like those performed previously and confirm more accurate data.

The question of whether young age GC is different from that of older patients has been raised but remains unresolved. According to epidemiologic studies of GC, a marked variation was seen in the incidence of GC according to sex and ethnics<sup>[1-8]</sup>. This fact suggests that sex hormones may modulate GC risk because the status of sex hormones is dependent on age. Therefore, sex as well as age may be considered simultaneously to precisely evaluate the epidemiologic study of GC including risk factors. Additionally, according to previous data, the demographic and clinicopathologic features of young age GC were somewhat different between patients younger and older than 30 years of age<sup>[9]</sup>. Therefore, further epidemiologic evaluation of young age GC should be done after subdivision of age into younger and older than 30 years old. Based on these assumptions, we investigated the epidemiologic characteristics and risk factors of young age GC with reference to age and sex in Korea, a country with a high rate of GC.

## MATERIALS AND METHODS

### Subjects

From January 1990 to April 2008, a total of 21 738 patients were diagnosed with GC at Severance Hospital, Seoul, Korea. Among them, 3 242 patients between 18 and 45 years of age (14.9%) were enrolled in the current study. In same period, a total of 3000 sex- and age-matched individuals who received endoscopy with or

without gastrointestinal symptoms at the Department of Gastroenterology and Health Care Center were also enrolled as healthy controls to evaluate the risk of young age GC. All subjects were stratified into 3 groups based on age (A, 18-30 years; B, 31-40 years; C, 41-45 years) at initial diagnosis.

### Epidemiologic and clinicopathologic characteristics

This study included data on each subject's age, sex, life-style (e.g. smoking or alcohol, and diet pattern), occupational environment, place of residence, body mass index (BMI), family history of GC, socioeconomic status, and combined diseases. For women, history of oral contraceptive use, pregnancy/delivery (time of first pregnancy/delivery, nutrition conditions during pregnancy, and parity status), lactation, and menstruation were also investigated. Socioeconomic conditions were stratified into 3 groups based on household income epidemiology in Korea. For evaluation of nutritional status during pregnancy, weight gain, electrolyte imbalances and the level of albumin and hemoglobin during pregnancy were investigated. The level of weight gain was estimated according to prepregnant BMI categories as recommended by the Institute of Medicine<sup>[10]</sup>.

For all subjects, hematological (total blood count), biochemical (routine chemistry), and serological [IgG for *Helicobacter pylori* (*H. pylori*)] evaluations including tumor markers [carcinoembryonic antigen,  $\alpha$ -fetoprotein ( $\alpha$ FP), and cancer antigen (CA125)] were conducted. For GC, tumor location, number of lesions, growth type (Lauren classification), histological type (World Health Organization classification), and TNM stage were analyzed at initial diagnosis, and treatment-related results including overall survival were assessed.

### Specimen histology

Tissue samples were stained with hematoxylin and eosin solution. Giemsa staining was also performed to detect *H. pylori* infection. The degree of gastritis, combined glandular atrophy with intestinal metaplasia (IM), and *H. pylori* infection were graded according to the updated Sydney classification<sup>[11]</sup>.

### Statistical analysis

The data are presented as median  $\pm$  SD. Analysis of variance with multiple comparison (Scheffe post hoc) and  $\chi^2$  analysis (Pearson) were conducted to compare data among age groups in each different gender using the Statistical Package for the Social Sciences (SPSS/PC+ 13.0, Chicago, IL, USA). Analysis of survival was performed using the Kaplan-Meier method. For comparison of laboratory findings between the cancer groups and controls, *t*-test was conducted. Epidemiologic risk factors of young age GC were evaluated by comparing them with age-matched controls in each different gender using logistic regression with odds ratios (OR) and 95% confidence intervals (CI). A *P* value of less than 0.05 was considered statistically significant.

<sup>1</sup>Survival analysis was performed using the Kaplan-Meier method; <sup>2</sup>This included node metastasis.

**RESULTS**

**Demographic and clinicopathologic features**

The demographic and clinicopathologic features of all subjects enrolled in this study are summarized in Tables 1 and 2. All subjects were Korean. The median age of cancer patients was 38 years and that of controls was 35 years. The male-to-female ratio of young age GC was 1.2:1.0 on the whole, but it was 1.0:1.6 in group A, 1.0:1.0 in group B, and 1.7:1.0 in group C, respectively, with female predominance when patients were younger.

No statistically significant distinctive laboratory findings were observed in young age GC patients compared with controls except slightly decreased hemoglobin and albumin levels in all genders and elevated αFP and CA125 levels in young women with carcinomatosis (data was not shown).

Histologically, young age GC was frequently located in the upper third or whole stomach diffusely as patients were younger (Table 2). The ratio of adenocarcinoma-to-signet ring cell carcinoma was 1.0:1.1 on the whole. However, in females, the ratio was 1.0:1.8 in group A,

1.0:1.4 in group B, and 1.1:1.0 in group C, respectively, whereas in males, it was 1.0:1.3 in group A, 1.0:1.0 in group B, and 1.6:1.0 in group C, respectively. These results may indicate that undifferentiated histology is more predominant when patients are younger ( $A > B > C$ ,  $P < 0.05$ ) in both genders. This phenomenon is notably more predominant in younger females. With regard to concomitant gastric pathology around cancer, IM was rarely observed in patients younger than 30 years of age (group A) whereas it was frequently observed in group C (Table 2,  $P < 0.05$ ). IM change was more frequently observed in males compared to females within the same age group (Table 2,  $P < 0.05$ ).

Overall, patients with stage IV cancer presented with poor prognosis. However, in resectable cancer, particularly in EGC, prognosis was not poorer compared to that of the elderly reported in previous studies (data was not shown). Females presented with more advanced features compared to males of the same age. Among 1495 female patients, 37 (2%) were diagnosed with Krukenberg tumor.

There was no significant difference in survival among age groups (Table 1,  $P > 0.05$ ) on the whole although younger patients and females presented with relatively more advanced stage and poor prognosis. Females with a history of recent pregnancy and delivery showed poorer prognosis.

### Risk factors

We evaluated the risk factors of young age GC by comparison of demographic and clinicopathologic features of young age GC with those of sex- and age-matched controls using logistic regression with OR and 95% CIs (Tables 3 and 4). The evaluations were performed after all people were stratified by age and sex with the assumption that older patients may be more frequently exposed to environmental carcinogens and exposed to them for longer than younger patients and that sex hormones may modulate the development of GC. However, we evaluated the influence of hormonal circumstances on the development of GC only in females in this study because a marked variation of sex hormones was rarely observed in young males under 45 years old whereas it was frequently observed in females of reproductive age with regular menstrual changes (Table 4).

In cancer patients, more frequent intake of beef and canned, smoked, and salted food and less frequent intakes of fresh fruit/vegetables (defined as high-risk diet), history of heavy smoking (defined as more than 20 pack-years) and history of heavy alcohol intake (defined as more than 60 g/d) were observed compared with controls in all age groups and both genders, as described previously<sup>[12]</sup> (Table 3,  $P < 0.05$ ). However, these relationships were somewhat weaker in females compared to males of the same age, and these relationships were stronger as the age of patients increased (Table 3,  $P < 0.05$ ). Lowest socioeconomic

status, BMI > 30, and urban residence increased the risk of GC in all groups and both genders (Table 3,  $P < 0.05$ ). Frequent exposure to harmful industrial and occupational environments (excessive electromagnetic waves, toxic chemicals such as asbestos, lead, sulfur granules, and toxic gases such as CO, NO, methane gas, *etc.*) was also closely associated with increased cancer risk in all age groups and both genders (Table 3,  $P < 0.05$ ). However, these associations were stronger in older patients ( $A < B < C$ ) and males.

*H. pylori* infection is considered as a very important epidemiologic risk factor of GC in both the young and the old<sup>[13,14]</sup>. However, in the current study, *H. pylori* positivity was infrequently observed in group A and B, and *H. pylori* positivity alone was not related to increased cancer risk (Table 2). Additionally, *H. pylori* positivity was not different between genders although the prevalence of young age GC was different according to gender. Only concomitant IM change combined with *H. pylori* positivity was related to increased cancer risk (Table 3,  $P < 0.05$ ). This risk factor was weighted in patient older than 40 years of age and males in whom IM change was relatively frequently observed compared to patients younger than 30 years and females in whom these changes were rarely observed (Table 3,  $P < 0.05$ ).

We also found that in females, frequent use of oral contraceptives without progesterone, older age at first delivery (> 35 years), lack of lactation history, and nulliparity were significantly associated with an increased risk of GC (Table 4,  $P < 0.05$ ). Poor nutritional status during pregnancy (defined as weight gain during pregnancy which is lower than the normal level according to prepregnant BMI categories as recommended by the Institute of Medicine<sup>[10]</sup>) was also associated with an increased risk of GC (Table 4,  $P < 0.05$ ). However, age at menarche and the state of menopause did not influence GC (Table 4,  $P > 0.05$ ). The incidence of other estrogen-associated gynecologic malignancies, such as ovarian, breast, and uterine cancers, were also evaluated and revealed no association with young age GC (Table 4,  $P > 0.05$ ).

In the current study, 252 patients (7.8%) had a family history of GC, which is similar to previous studies<sup>[15]</sup>. In particular, family history was more closely associated with GC in males and more advanced cases (Tables 3 and 4,  $P < 0.05$ ) but the reason is not known.

Overall, environment factors were significantly associated with an increase of GC in all age groups and both genders although these relationships were somewhat weaker in females compared to males of the same age, and these relationships were stronger as the age of patients increased. However, in group C, environmental factors played important roles in females and males with similar weight. In females, hormonal factors associated with reproductive factors, but not menstrual factors, were significantly associated with an increase in GC.

**Table 3** Frequency of control group and young age GC, age-adjusted OR estimates and 95% CI by demographic and clinical characteristics, Korea, 1990 to 2008 *n* (%)

<sup>1</sup>High-risk diet is defined as more frequent intake of beef and canned, smoked, and salted food and less frequent intake of fresh fruit/vegetables; <sup>2</sup>Heavy smoking is defined as more than 20 pack-years; <sup>3</sup>Heavy alcohol intake is defined as more than 60 g/d; <sup>4</sup>Socioeconomic conditions were evaluated by household income, stratified into 3 groups based on income epidemiology in Korea. This condition comes under the lowest income group; <sup>5</sup>Family history was defined as first-degree relative with GC. The 3000 normal controls included 1650 males and 1350 females. Group A, 18-30 years of age, *n* = 350; Group B, 31-40 years of age, *n* = 1500; Group C, 41-45 years of age, *n* = 1150; Whole, 18-45 years of age, *n* = 3000. The 3242 young age GC included 1747 males and 1495 females. Group A, 18-30 years of age, *n* = 371; group B, 31-40 years of age, *n* = 1584; group C, 41-45 years of age, *n* = 1287; whole, 18-45 years of age, *n* = 3242. GC: Gastric carcinoma; OR: Odds ratio; CI: Confidence interval; BMI: Body mass index.

## DISCUSSION

Although epidemiologic characteristics of young age GC were varied according to geographical regions and ethnicity, near-universal findings were commonly demonstrated in each article for epidemiologic studies of young age GC, which are as follows: (1) female dominance, (2) located in the upper area, (3) diffuse

growth types, (4) undifferentiated histology (particularly signet ring cell carcinoma), and (5) advanced stage and poor prognosis, which were different from those of the elderly<sup>[1-8]</sup> although some studies showed different results. On the whole, we also observed similar results to those described previously. However, there are several different points in our study compared with previous studies.

**Table 4** Frequency of control group and young age GC, age-adjusted OR estimates and 95% CI by hormonal and reproductive characteristics, Korea, 1990 to 2008 *n* (%)

Risk factors	GCs	Controls	OR	95% CI	P-value

Other gynecologic malignancy <sup>3</sup>	19 (1.3)	16 (1.1)	1.14	0.58-2.22	0.237

<sup>1</sup>Pregnancy was maintained for at least 5 mo; <sup>2</sup>This condition was during pregnancy; <sup>3</sup>These conditions included estrogen-associated cancers such as breast, ovarian, and uterine. GC vs control = 1495 vs 1431.

In this study, we evaluated the epidemiologic features of young age GC after subdividing young patients into 3 age groups and 2 genders under assumption that the effects of sex hormones and environmental factors may be influenced by age; hormonal activities reach a peak around 30 years of age and decline slightly with age, and exposure of environmental carcinogens may be more frequently and longer in the old based on previous studies<sup>[16-20]</sup>.

For demographic risk factors, our study supports the previous results<sup>[12]</sup>. Environmental factors such as life style, socioeconomic status, occupation, resistance, and IM change with *H. pylori* infection in gastric mucosa were statistically significantly associated with young age GC, particularly in males and older patients. Generally, environmental factors might play important roles in the initiation of cancer development. Several life style factors, such as a history of smoking or alcohol use, and diet, are common weighty risk factors<sup>[12]</sup>. Low socioeconomic conditions were particularly associated with the intestinal type of GC as those in this income bracket are more likely to be exposed to poor quality food, which may cause intestinalization of the gastric mucosa at a relatively young age. Additionally, few have access to health care services and notification of IM changes in stomach may become delayed. Over the past few decades, people have been exposed to harmful industrial occupational materials called "endocrine disruptors" as societies have undergone rapid industrialization. These endocrine disruptors are thought to be carcinogens. Therefore, the industrialized occupational environment may influence the increase of GC development at a younger age<sup>[13]</sup>. In same period, females also were exposed to similar harmful environment circumstances. However, these associations were weaker in aged-matched females. We guess the reasons that male patients might have more frequent and

prolonged exposure to environmental carcinogens than females is due to social positions<sup>[14]</sup>. Some epidemiologic data have pointed to an association between *H. pylori* infection and increased risk of young age GC<sup>[21,22]</sup>. Of course, *H. pylori* infection is a critical environmental factor of GC in old age, particularly intestinal type<sup>[16]</sup>, and IM change was combined in most *H. pylori*-associated GC. However, the prevalent histology of young age GC was diffuse-type cancer, and prevalence of IM change was rare in young age GC. In this study, the association between *H. pylori* infection and increased risk of young age GC was more common in older patients and males than in younger patients and females. Therefore, we suggest that *H. pylori*-associated risk factors may play a limited role in the development of young age GC according to age and gender.

GC incidence varies considerably according to studies<sup>[1-8]</sup>. In our series, the male-to-female ratio was 1.2:1.0 on the whole, but it was 1.0:1.6 in group A, 1.0:1.0 in group B, and 1.7:1.0 in group C, respectively, with female predominance as patients were younger (Table 2). The reason for this higher number of female patients in the younger group is not yet known. However, the role of the sex hormones, especially estrogen, has been suggested<sup>[16-20]</sup> although the results have varied among different studies. Some investigators asserted their protective effects on GC whereas others emphasized the opposite. The differences may be derived from geographical or ethnic differences, or the relatively small-sized sample number<sup>[23,24]</sup>. Our study may support the harmful role of estrogen in young age GC in females. In accordance with these results, we observed a close relationship between GC development and hormonal circumstances in young females (Table 4). Additionally, the effect of counter action of progesterone was not noted in many studies asserting the protective effects of estrogen on GC development. Our results may imply

that excessive exposure to estrogen without counter exposure to progesterone is related to an increase in the development of GC in young females.

In conclusion, our study demonstrated that the epidemiologic characteristics including risk factors of young age GC were different according to age and gender. Hormonal factors were more commonly associated with females, particularly in the younger age group, whereas environmental factors were more commonly associated with males, particularly in the older age group.

The development of GC is influenced by a combination of environmental factors and specific genetic alterations including hormonal factors and the role of genetics is considered to be greater in younger patients than older patients<sup>[25]</sup>. Thus, further investigations of the molecular genetics of young age GC are needed to support the results of our study.

## COMMENTS

### Background

Two percent to fifteen percent of patients with gastric cancer (GC) are younger than 45 years of age and there has been an increase in the relative proportion of young age GC compared with older age GC, especially in young females. The question of whether young age GC is different from that of older patients has been raised but remains unresolved. Thus, an epidemiologic study about young age GC is significantly important clinically.

### Research frontiers

The development of GC is influenced by a combination of environmental factors and specific genetic alterations including hormonal factors. The role of genetics is considered to be greater in younger patients than older patients. According to epidemiologic studies of GC, a marked variation was seen in the incidence of GC according to sex and ethnicity. Sex hormones are considered to modulate the risk of development of GC. Also, according to previous data, the demographic and clinicopathologic features of young age GC were somewhat different between patients younger and older than 30 years of age.

### Innovations and breakthroughs

Until now, only a few studies with small-sized samples have been conducted in young age GC patients. However, this retrospective, large-scale, and population-based study with abundant epidemiologic and clinicopathologic information in a single institution may reduce the limitations and bias derived from small sized sample studies like those conducted previously, and confirm more accurate data. The authors also evaluated the epidemiologic features of young age GC after subdividing young patients into 3 age groups and 2 genders under the assumption that the effects of sex hormones and environmental factors may be influenced by age; hormonal activities reach a peak around 30 years of age and decline slightly with age, and exposure to environmental carcinogens may be more frequent and longer in the old, based on previous studies.

### Applications

The authors' study demonstrated that the epidemiologic characteristics and the development risk of young age GC were affected by both environmental factors and hormonal factors, especially sex hormones, with different factors contributing a different degree of risk according to age and gender. Their study demonstrated that hormonal factors were more commonly associated with females, particularly in the younger age group, whereas environmental factors were more commonly associated with males, particularly in the older age group. This knowledge may help to clarify the exact pathophysiology of young age GC and help devise an appropriate treatment approach.

### Peer review

This paper is thought to be an excellent epidemiologic study surveying risk factors for stomach cancer in patients aged 45 or younger. It is an interesting study of significant clinical importance. However, there are some limitations to the study that require attention from the authors.

### Abstract

**AIM:** To identify prognostic factors from pretreatment variables of the initial transarterial chemoembolization (TACE) procedure in unresectable hepatocellular carcinoma (HCC).

**METHODS:** One thousand and five hundred and sixty-nine patients with unresectable HCC underwent TACE as initial treatment were retrospectively studied. Pretreatment variables of the initial TACE procedure with a *P* value less than 0.05 by univariate analysis were subjected to Cox proportional hazards model.

**RESULTS:** The median overall survival time and 1-, 5-, 10-year survival rates were 10.37 mo, 47%, 10%, and 7%, respectively. A Cox proportional hazard model showed that 8 pretreatment factors of regional lymph

nodes metastasis, Child-Pugh class, macrovascular invasion, greatest dimension,  $\alpha$ -fetoprotein (AFP), Hepatitis virus B, tumor capsule, and nodules were independent prognostic factors. Patients with multimodality therapy have better survival than those with TACE treatment only.

**CONCLUSION:** Tumor status, hepatic function reserve, AFP, and hepatitis virus B status were independent prognostic factors for unresectable HCC. Distant metastasis might not be a contraindication to TACE. Multimodality therapy might improve survival.

### INTRODUCTION

Hepatocellular carcinoma (HCC) constitutes the majority of liver cancers which is the sixth most common cancer and the third most common cause of cancer death worldwide<sup>[1]</sup>. While curative therapies include surgical resection, transplantation and percutaneous ablation<sup>[2]</sup>, these are not suitable for use in a great number of HCC patients due either to advanced stage of disease or to poor liver function at the time of diagnosis<sup>[3,4]</sup>. Transarterial chemoembolization (TACE) has become the most popular modality for

palliative treatment among these patients. Two randomized trials from Europe and Asia have confirmed better survival associated with TACE as compared with conservative treatment in selected patients<sup>[5,6]</sup>.

However, considerable controversies remain surrounding definition of suitable candidates for TACE. Many published studies attempted to delineate the survival and identify the prognostic factors related to TACE<sup>[7-14]</sup> and have shown varying patient baseline characteristics and outcomes across a wide range of geographical distribution, probably because of different inclusion criteria, epidemiological variations in hepatitis B and C infections, and local surveillance for HCC.

Globally, more than half of new HCC cases occur in China<sup>[15]</sup>. However, to the best of our knowledge, the baseline characteristics, outcomes and prognostic factors among TACE-treated HCC patients in China have not been fully described. In the present study, we conducted a 13 year retrospective analysis of patients with unresectable HCC who underwent TACE as initial treatment and to identify prognostic factors from variables prior to the initial TACE procedure. We hypothesized that findings of this study should help to select patients who would benefit most from TACE, and help to design and estimate samples for further prospective randomized studies.

## MATERIALS AND METHODS

### Ethics

This study was approved by the Ethical Committee of the Cancer Center of Sun Yat-Sen University and it followed the ethical guidelines of the 1975 Declaration of Helsinki. Written informed consent was obtained from every patient before treatment.

### Patients

From September 1991 to December 2004, 1830 patients with unresectable HCC underwent TACE at the Cancer Center of Sun Yat-sen University. All patients received routine preoperative investigations, including liver function tests,  $\alpha$ -fetoprotein (AFP), hepatitis serology, chest radiography, abdominal ultrasonography, and abdominal CT scanning with contrast-enhancement of images in the arterial and portal venous phases. AFP > 200 ng/mL (normal, < 20 ng/mL) refers to an abnormal elevation of the tumor marker. Further investigations were performed in those with suspected extrahepatic metastases. Only patients who met the following inclusion criteria were enrolled: (1) the hepatic lesion was clinicopathologically diagnosed as HCC based on the diagnostic criteria used by the European Association for the Study of the Liver<sup>[16]</sup>; (2) there was not any treatment prior to TACE; and (3) the HCC was considered to be unresectable by our leading investigator (Professor Jin-Qing Li). Unresectable disease was defined as extensive bilobar involvement of the liver by a large solitary tumor or by multiple tumors, or invasion of major blood vessels including the main portal vein, hepatic veins, inferior vena cava, and main hepatic

artery. Patients with any of the following were excluded: (1) obstructive jaundice; (2) hepatic encephalopathy; (3) Child-Pugh score > 11; and (4) poor data integrity.

Finally, 1569 patients were recruited, comprising 1423 (90.7%) males and 146 (9.3%) females with a mean age of  $49.36 \pm 11.62$  (mean  $\pm$  SD) years. Diagnosis of HCC was based on biopsy in 131 (8.3%) patients, AFP plus radiology in 1167 (74.4%), and radiology alone in 271 (17.3%), respectively.

There were 1338 (86.0%) patients who tested positive for Hepatitis virus B surface antigen (HbsAg) and 48 (3.1%) positive for hepatitis virus C antibody. The mean tumor size was  $10.53 \pm 4.09$  cm (range, 1.0-28.0 cm) and macrovascular invasion was seen in 293 (18.7%) patients. Tumor(s) with direct invasion of adjacent organs was seen in 30 (1.9%) patients. The rate of regional lymph node involvement was 3.2% ( $n = 50$ ) according to the CT-revealed threshold size (larger than 1.0 cm). In total, 269 (17.1%) patients were found with distant metastases to lung [221 (82.3%)], bone [24 (9.0%)], adrenal gland [17 (6.4%)], pelvic cavity [3 (1.1%)], kidney [2 (0.7%)], respectively. According to the TNM classification<sup>[17]</sup>, 502 (32.0%) patients were classified as Stage I, 91 (5.8%) as Stage II, 659 (42.0%) as Stage IIIa, 14 (0.9%) as Stage IIIb, 34 (2.2%) as Stage IIIc, and 269 (17.1%) as Stage IV. According to the Child-Pugh classification, 1413 (90.8%) patients were Child-Pugh class A, 144 (9.2%) were class B, and none were class C.

### Treatment procedure

All patients gave informed consent before any procedure. TACE was performed using the Seldinger technique. A selective 5 French catheter was introduced and visceral angiography was carried out to assess the arterial blood supply to the liver and to confirm patency of the portal vein. Depending on the size, location and arterial supply of the tumor, the tip of the catheter was advanced into the right or left hepatic artery, or tumor-feeding branches (as there was a need for super selective catheterization in some cases).

Hepatic artery infusion chemotherapy was performed using one drug or combinations of mitomycin C, carboplatin, and fluorouracil. After that, chemoembolization was performed using doxorubicin mixed with 5 mL of lipiodol (Lipiodol Ultra-Fluide; Andre Guerbet Laboratories, Aulnay-Sous-Bois, France). Pure lipiodol or gelatin sponge particles were then injected if the chemoembolized artery territory did not show stagnant flow. The dose of anticancer agent-lipiodol emulsion and the pieces of embolic materials used for TACE were determined based on the tumor size, extension of the lesions and tumor blood supply.

### Follow-up

After the initial TACE treatment, patients were followed up by CT scan every 1 to 2 mo to evaluate their tumor status. The survival of TACE-treated patients was calculated from the date of procedure through to the end of follow-up on March 17, 2008. All patient deaths, irrespective of causes, were deemed as the end point.

The mean length of follow-up was 16.62 mo (range, 0.07-133.27). TACE-related death was defined as death within 1 mo of the initial therapy.

New TACEs were performed every 4-10 wk until CT scans and AFP levels suggested the stabilization of the tumor, and unless the patient rejected further treatment or it was not technically feasible either because of hepatic artery occlusion or impaired liver function. The patients were started on multimodality therapy (including surgery, local ablation, radiotherapy, and systemic chemotherapy) when treatment options other than TACE were indicated.

There were 838 (53.4%) patients treated with only one session of TACE, 447 (28.5%) with two sessions, 156 (9.9%) with three sessions, and 128 (8.2%) with more than three sessions. On average, 1.79 sessions (range, 1 to 11) of TACE were given to each patient. There were 359 patients on multimodality therapy, among which 107 patients underwent exploratory laparotomy. Surgical resection was performed in 97 (6.2%), 7 underwent liver transplantation, 3 underwent lung resection, 217 (13.8%) underwent local ablation (including alcohol injection, radiofrequency, microwave), 40 (2.5%) underwent radiotherapy and 60 (3.8%) underwent systemic chemotherapy.

### Statistical analysis

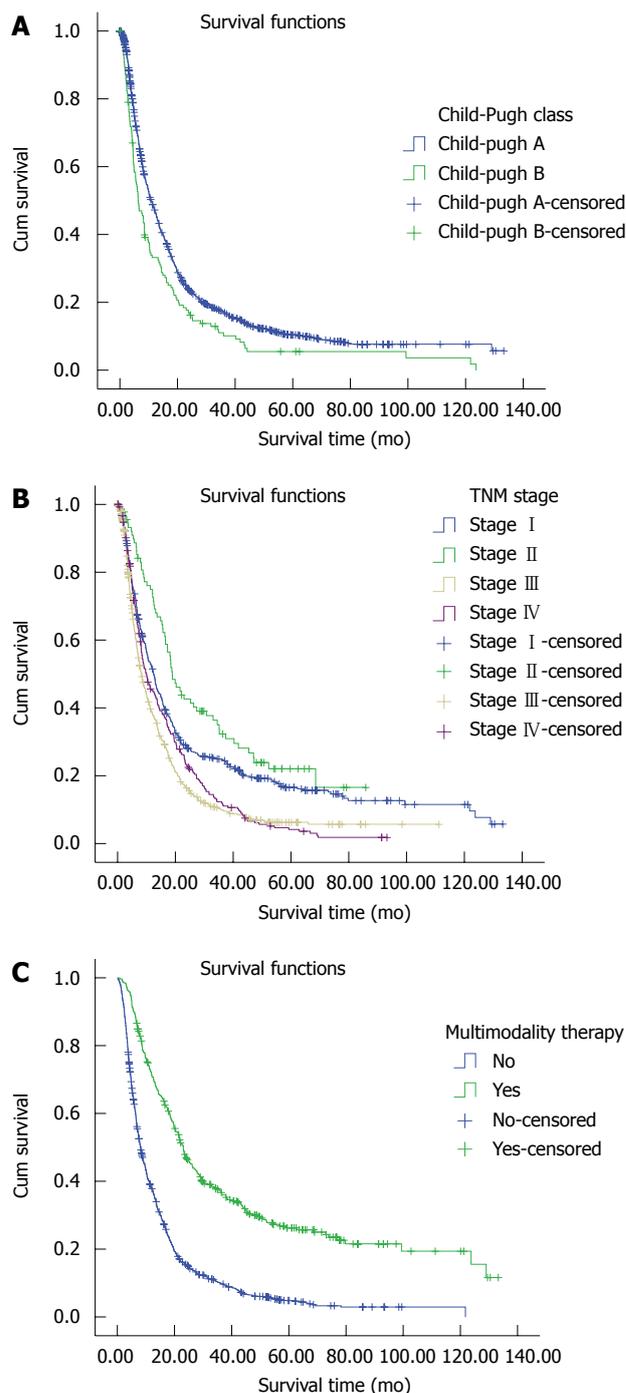

Pretreatment variables with possible prognostic significance were analyzed. Each variable was stratified into 2-4 strata. The survival rates were obtained by the Life Table method. Median survival lengths were obtained by the Kaplan-Meier method and compared by the log-rank test. Multivariate analysis was performed with the Cox proportional hazards model. All variables with a *P* value less than 0.05 by univariate analysis were subjected to multivariate analysis. All significance tests were rendered 2-tailed, and a *P* value less than 0.05 was considered statistically significant. All statistical processing was performed using the Statistical Package for Social Science V8.0 (SPSS, Inc., Chicago, IL, USA).

## RESULTS

During a 13 years follow-up, the total numbers of patient deaths, patients lost to follow-up (in our institute the follow-up is once a year; if a patient cannot be followed up after 1 year, they are considered to be lost to follow-up) and alive cases were 1301 (82.9%), 203 patients (12.9%) and 65 (4.1%), respectively. The annual distribution of deaths was 798 in year 1, 328 in year 2, 85 in year 3, 56 in year 4, 17 in year 5, 8 in year 6, 5 in year 7, 1 in year 9, and 3 in year 12, respectively. The number of patients lost to follow-up was 106 in year 1, 18 in year 2, 27 in year 3, 12 in year 4, 8 in year 5, 4 in year 6, 11 in year 7, 11 in year 8, 3 in year 9, and 1 each in years 10 through 12, respectively.

### Survival rates

Of the 1569 patients who underwent TACE as initial treatment, the overall median length of survival and 1-, 2-, 3-, 4-, 5-, 10-, and 12-year survival rates were

**Figure 1 Survival rates (Kaplan-Meier method).** A: Patients with Child-Pugh classes A and B with statistical significance (*P* = 0.000); B: Comparison among TNM stages; C: Comparison of survival rates stratified by multimodality therapy with statistical significance (*P* = 0.000).

10.37 mo, 47%, 24%, 17%, 12%, 10%, 7%, and 4%, respectively. Kaplan-Meier analysis showed a significant difference in median survival length between patients with Child-Pugh class A and those with class B (Figure 1A) but not among patients with different TNM stages. Patients with Stage II disease showed the best survival rate (Figure 1B).

multimodality therapy were 23.13 mo, 72%, 47%, 37%, 30%, 26%, 19%, and 12%, compared with 8.23 mo, 40%, 16%, 11%, 7%, 5%, 3%, and 0, respectively, among those treated with TACE alone. There was a statistical difference in survival between these two subsets of patients ( $P = 0.000$ ) (Figure 1C).

### Factors related to survival of patients

Univariate analysis revealed 9 pretreatment factors as

prognostic variables: age, hepatitis B virus (HBV), AFP, Child-Pugh class, nodules, greatest dimension, tumor capsule, macrovascular invasion, and regional lymph node metastasis (Table 1). Multivariate analysis showed the following as independent prognostic factors: regional lymph nodes metastasis, Child-Pugh class, macrovascular invasion, greatest dimension, AFP, HBV, tumor capsule, and nodules with hazard ratios ranging from 1.164 to 1.736 (Table 2).

### Complications and TACE-related mortality

Severe complications occurred in 353 (22.5%) patients after the initial TACE, including abnormal embolization in 9 patients, ascites in 235, pleural effusion in 32, acute renal failure in 4, hepatic failure in 38, jaundice in 197, upper gastrointestinal bleeding in 12, respiratory tract infection in 16, and abdominal infection in 3. Among these, there were 22 (1.4%) cases of TACE-related death with 20 caused by hepatic failure and 2 by upper gastrointestinal bleeding.

## DISCUSSION

For patients of unresectable HCC, the overall median survival was 8.7 wk<sup>[18]</sup> and 3 mo<sup>[19]</sup> in two untreated

populations. The goal of TACE as a palliative treatment is to prolong survival and to enhance quality of life. Unlike neoplasms of other organs, the survival of HCC depends not only on tumor status, but also on hepatic functional reserve, performance status, and response to treatment<sup>[14,20,21]</sup>.

In the current study, performance status was not assessed because of data unavailability. Given that all pre-TACE HCCs were unresectable in our cohort, the eligibility for other treatment modalities after initial TACE may indirectly reflect patient response to treatment. In our effort to screen for prognosis-related factors using univariate analysis of pretreatment factors indicated as significant, subsequent multivariate analysis stratified by multimodality therapy showed 8 factors as independently prognostic: regional lymph nodes metastasis, Child-Pugh class, macrovascular invasion, greatest dimension, AFP, HBV, tumor capsule, and nodules. These factors could be classified into 3 groups in nature: tumor status, hepatic function reserve, AFP and HBV. While AFP level has been shown to be an independent prognostic factor in many studies<sup>[7,10,13,14,20,22,23]</sup>, the cutoff values of AFP level varied widely. In the current study, survival rates appeared statistically different among patients with AFP being less than 20, 21-200, and greater than 200 ng/mL. As an important causal factor of HCC in the current study, HBV infection was seen in most of the patients with a prevalence (86.2%) similar to data from Hong Kong<sup>[5]</sup> (80.0%), but higher than those from Japan<sup>[7]</sup> (11.0%), Spain<sup>[6]</sup> (6.3%), and America<sup>[24]</sup> (49.0%). However, HBV status as an independent prognostic factor has seldom been reported<sup>[25]</sup>. As shown by Kaplan-Meier analysis in our study, the survival rates in HBsAg-negative and HBsAg-positive HBeAg-negative individuals did not differ from each other ( $P = 0.062$ ), but were statistically higher compared with HBeAg-positive patients ( $P = 0.000$ ). These findings suggested the potential benefits of antiviral therapy in HBeAg-positive patients. As with almost all reports related to TACE, in the current study Child-Pugh class was an independent prognostic factor. As to the tumor status, macrovascular invasion, greatest dimension, and nodules were proven by a large prospective cohort study<sup>[7]</sup>. Tumor capsule has been rarely noted as a prognostic factor<sup>[23]</sup>. Regional lymph node metastasis as independent factor was not assessed fully due to lack of data in most literature.

Surprisingly, adjacent organs invasion and distant metastasis, two of major components in TNM staging system, were not independent prognostic factors. Zhang *et al.*<sup>[26]</sup> showed that 67.5% Stage IV HCC patients died of liver failure caused by the progressive intrahepatic lesions and only 20% of those died of respiratory failure due to metastatic lesions. These results may explain why the survival rates of distant metastasis patients were not different from that of local unresectable HCC patients who underwent TACE. The progressive treatment for intrahepatic lesions may be of importance for Stage IV HCC. Our data supported the concept that the validity of the TNM stage system had only been assessed in patients who underwent resection<sup>[27]</sup>.

In the current study, tumor status and liver function were main prognostic factors. Since only 144 (9.2%) patients were Child-Pugh class B, the overall survival rates were largely determined by tumor status. Overall, the median survival length and survival rates in our study appeared somewhat dissatisfactory as compared with results from a meta-analysis<sup>[28]</sup>, which revealed survival rates of  $62\% \pm 20\%$ ,  $30\% \pm 15\%$ , and  $19\% \pm 16\%$  at 1, 3, and 5 years, along with a mean survival time of  $18 \pm 9$  mo. This may be explained by a higher percentage of patients with locally advanced lesions included in our study than in others. To the best of our knowledge, the mean greatest dimension ( $10.53 \pm 4.09$  cm) in the current study may be greater than any lesions reported before. However, the 10-year survival rate up to 7% in the whole group and 3% in TACE group supported the concept of heterogeneity of HCC in terms of survival.

In the current study, 353 (22.5%) patients developed severe complications after the initial TACE, which was mostly correlated to liver function. TACE-related death occurred in 22 (1.4%) patients, in which 20 deaths were caused by hepatic failure and 2 by upper gastrointestinal bleeding. While acute liver function impairment may arise from TACE treatment, Caturelli *et al.*<sup>[29]</sup> showed that TACE did not induce significant long term worsening of liver function in patients with class A or B cirrhosis. Hence, the relations among TACE variables, interval of TACE treatment, survival, and complications need to be further explored.

In conclusion, tumor status, hepatic function reserve, AFP, and HBV status were independent prognostic factors for unresectable HCC treated by TACE. Distant metastasis might not be a contraindication for TACE treatment. For a better survival, once the tumor status allows treatments other than TACE, multimodality therapy should be recommended.

## COMMENTS

### Background

Hepatocellular carcinoma (HCC) constitutes the majority of liver cancers, which is the sixth most common cancer and the third most common cause of cancer death worldwide. A great number of HCC patients are suitable for curative therapy due either to advanced stage of disease or to poor liver function at the time of diagnosis. Transarterial chemoembolization (TACE) has become the most popular modality for palliative treatment among these patients. However, suitable candidates for TACE are still difficult to determine.

### Research frontiers

Two randomized trials from Europe and Asia have confirmed better survival associated with TACE compared with conservative treatment in selected patients. But the survival and prognostic factors of different studies varied due to the difference in patient baseline characteristics, treatment procedure, and regimens used. Hence, it is important to identify the prognostic factors associated with different geographical distributions of HCC.

### Innovations and breakthroughs

In the current study, the pretreatment prognostic factors of regional lymph node metastasis, Child-Pugh class, macrovascular invasion, greatest dimension,  $\alpha$ -fetoprotein, Hepatitis virus B, tumor capsule, and nodules were similar to other studies. However, three important items were indicated: (1) distant metastasis might not be a contraindication to TACE; (2) antiviral therapy in HBeAg-positive patients might benefit survival; (3) multimodality therapy might improve survival.

### Applications

The finding of this study might help to select patients who would benefit most from TACE, and help to design and estimate samples for further prospective randomized studies.

### Peer review

In this manuscript, the authors retrospectively reviewed their experience with TACE in unresectable HCC. This experience is quite extensive, as it concerns 1569 patients over a 13-year period.

### Abstract

Single-incision laparoscopic surgery is a rapidly evolving field as a bridge between traditional laparoscopic surgery and natural orifice transluminal endoscopic surgery. We report one of the initial clinical experiences in Japan with this new technique. Four cases of gallbladder diseases were selected for this new technique. A single curved intra-umbilical 25-mm incision was made by pulling out the umbilicus. A 12-mm trocar was placed through an open approach, and the abdominal cavity was explored with a 10-mm semi-flexible laparoscope. Two 5-mm ports were inserted laterally from the laparoscope port. A 2-mm mini-loop retractor was inserted to retract the fundus of the gallbladder. Dissection was performed using an electric cautery hook and an Endograsper rotulator. There were two women and two men with a mean age of 50.5 years (range: 40-61 years). All procedures were completed successfully without any perioperative complications. In all cases, there was no need to extend the skin incision. Average operative time was 88.8 min. Postoperative follow-up did not reveal any umbili-

cal wound complication. Single-incision laparoscopic cholecystectomy is feasible and a promising alternative method as scarless abdominal surgery for the treatment of some patients with gallbladder disease.

### INTRODUCTION

Since the introduction of laparoscopic cholecystectomy as the gold standard procedure to remove the gallbladder, many surgeons have attempted to reduce the number and size of ports in laparoscopic cholecystectomy to decrease parietal trauma and improve cosmetic results.

These efforts are some of the fundamentals of the natural orifice transluminal endoscopic surgery (NOTES) approach<sup>[1-4]</sup>, which removes transabdominal incisions completely, but NOTES is technically challenging and current instruments need to be further improved. As a bridge between traditional laparoscopic surgery and NOTES, the recent focus has been on the development of single-incision laparoscopic surgery (SILS) to further

minimize the invasiveness of laparoscopic surgery by reducing the number of incisions.

SILS was described as early as 1992 by Pelosi *et al*<sup>51</sup> who performed a single-puncture laparoscopic appendectomy, and in 1997, by Navarra *et al*<sup>61</sup> who performed a laparoscopic cholecystectomy *via* two transumbilical trocars and three transabdominal gallbladder stay sutures. SILS can be performed using refinements of existing technology, and surgeons can perform SILS without any new instruments, specific competence, or training. SILS may offer the advantages of reducing postoperative pain, and virtually scarless surgery.

We report our initial experience with four patients who underwent single-incision laparoscopic cholecystectomy, and review the previous literature.

## CASE REPORT

Four cases of gallbladder disease were selected for this new technique from June to July 2009. Indications included chronic cholecystitis and symptomatic cholelithiasis. There were two women and two men with a mean age of 50.5 years (range: 40-61 years). One patient had previously undergone appendectomy for acute appendicitis. Body mass index was 19.4-26.6 (mean: 23.0). All procedures were completed successfully without any perioperative complications. In all cases, there was no need to extend the skin incision. Average operative time was 88.8 min. Characteristics of patients and operative data are included in Table 1. The procedures were performed by the same surgeon.

### Surgical technique

A single curved, intra-umbilical, 25-mm incision was made by pulling out the umbilicus. After exposing the fascia, a 12-mm trocar was placed through an open approach, and the abdominal cavity was explored with a 10-mm semi-flexible laparoscope (LTFVH; Olympus). Pneumoperitoneum was induced and maintained at 8 mmHg with carbon dioxide. Two 5-mm ports were inserted through the anterior sheet of the abdominal rectus muscle, each placed 1 cm laterally from the laparoscope port. The patient was put in an anti-Trendelenburg position and rotated to the left, as in standard laparoscopic cholecystectomy. A 2-mm mini-loop retractor (Mini-loop retractor II; Hakkou-shoji) was inserted through an extra incision in the right subcostal space to retract the fundus of the gallbladder (Figures 1 and 2). Dissection was performed as a normal retrograde cholecystectomy using an electric cautery hook in the left trocar and an Endograsper rotulator (Rotulator Endograsp II, 5 mm; Autosuture) in the other trocar. On the occasion when the optimal exposure of the Triangle of Calot was inadequate, we inserted the hook and the grasper for traction. The cystic artery and duct were first exposed, then separately clipped with a standard 5-mm clip applicator (Endoclip III 5-mm clip applicator; Autosuture) and excised using an endoshear rotulator (Rotulator

Endo Mini-Shears; Autosuture). The gallbladder was extracted with a standard endocatch (Endocatch Gold, 10 mm; Autosuture) through the umbilical site. Careful control of homeostasis was achieved, and a Penrose drain was placed in the cholecystectomy lodge through the 2-mm incision for the mini-loop retractor II. Finally the 25-mm trocar site was closed with an absorbable suture, and the umbilicus was restored to its physiological position.

Patients received food orally at 24 h postoperatively, and were mobilized. Drains were removed on the first postoperative day. All cases were discharged between the third and fifth postoperative day. Postoperative follow-up did not reveal any umbilical wound complications.

## DISCUSSION

Laparoscopic surgery is a well-established alternative to open surgery across disciplines. Although the magnitude of impact varies by procedure, generally the benefits of laparoscopy on postoperative pain, cosmetics, hospital stay, and convalescence are recognized widely.

Many surgeons have attempted to reduce the number

**Figure 2** Gallbladder suspension using the Mini-loop retractor II. The fundus of the gallbladder was suspended with this retractor (C and D), which was only tightened with a looped wire (A and B).

and size of ports in laparoscopic surgery to decrease parietal trauma and improve cosmetic results, and recently two innovations have been developed: NOTES, which removes transabdominal incisions completely and SILS, which completes laparoscopic procedures by trocars located at one umbilical incision.

SILS, however, is not a new concept, and was described as early as 1992 by Pelosi *et al*<sup>[5]</sup> who performed a single-puncture laparoscopic appendectomy. In recent years, SILS has been focused upon as a bridge between NOTES and traditional laparoscopic surgery, because NOTES is technically challenging and current instruments need to be further improved. SILS, on the other hand,

enables the application of a wide range of already existing instruments. The main point for reducing the number of incisions is not only the cosmetic advantage but also lowered incision risks, morbidity of bleeding, incisional hernia, and organ damage.

Table 2 provides an overview of comparative features of single-incision laparoscopic cholecystectomy<sup>[6-25]</sup>. Out of 252 reported cases, 14 (5.6%) were converted to standard laparoscopic cholecystectomy. The reasons to convert were difficult dissection in nine cases, bleeding from the cystic artery in two, choledochoscopy for common bile duct exploration in two, and failure in trocar insertion in one case. There were five complications in

252 reported cases: one subcutaneous hematoma, one hepatic injury, one bile leakage, one mesenteric injury, and one injury of the right hepatic duct. Operative times in some series have been reported to be on a par with conventional laparoscopic surgery, but a majority of the procedures are lengthy, which may only be justified in patients who have a special cosmetic interest (Table 2).

The real challenge of SILS is to avoid conflict between the operative instruments and the camera, to maintain the pneumoperitoneum and reduce operative stress. As a result of the limited space with using only a single incision, it is difficult for both the surgeon and the assistant to work in the area. For that reason, we propose that using a semi-flexible endoscopic camera system would make the procedure more comfortable. Especially, the visualization and dissection of Calot's triangle would be easier and safer. Although the use of this semi-flexible endoscopic camera system with a cable connection on the posterior and crossed-over articulating instruments enables the procedure to be performed without interference, the use of crossed-over articulating instruments requires a longer operative time for achievement of careful and precise dissection, and some adjustments in the strategy of exposure are necessary, particularly because less strength is applied to the tissue than with the standard laparoscopic technique.

Some authors have suggested percutaneous puncture of the gallbladder for drainage or introduction of suspension hooks for better visualization of Calot's triangle<sup>[7,18]</sup>. These maneuvers, however, may inadvertently increase the chances of bactobilia and lead to perforation of the gallbladder, which leads to an increased risk of bile peritonitis, particularly in the setting of acute cholecystitis. To avoid these complications, we introduced the mini-loop retractor II to achieve optimal visual exposure. The fundus of the gallbladder was suspended with this retractor, which was only tightened with a looped wire. The use of this retractor enables the surgeon to grasp the gallbladder without injury for visualizing Calot's triangle, without increasing the risk of perforation of the gallbladder.

This report documents the feasibility of single-incision laparoscopic cholecystectomy. The clinical advantages of this approach may eventually require a randomized controlled trial to compare it with conventional laparoscopic cholecystectomy. The major advantage of this method is improved cosmetics, without any visible abdominal scars. Disadvantages of SILS include the conflict between the operative instruments, and the camera and the smaller degree of instrument triangulation compared to that of conventional laparoscopic surgery. Some of these disadvantages may be overcome with the use of the semi-flexible endoscopic camera system and crossed-over articulating instruments. Despite the limitations of SILS, we were able to perform our operation in four cases. All procedures were completed successfully within a reasonable time.

In conclusion, we documented the feasibility of single-incision laparoscopic cholecystectomy. This pro-

cedure is a promising alternative method, with scarless abdominal surgery, for the treatment of some patients with gallbladder disease. Further advantages of single-incision laparoscopic cholecystectomy compared to conventional laparoscopic cholecystectomy will ultimately require a clinical trial.

### Abstract

We report the first case of single port laparoscopic right hemicolectomy for advanced colon cancer. An abdominal 3 cm length incision was made *via* the umbilicus. A small wound retractor and a surgical glove were used as a single port. All soft tissue anterior to the superior mesenteric vein was completely removed and D3 lymph node dissection was achieved. The total operative time was 180 min with minimal blood loss (< 50 mL). The size of the tumor was 5 cm × 3 cm and its tumor stage was T3N0. Sixty-nine lymph nodes were harvested and none were positive. We believe that single port surgery for colon cancer is a feasible and safe procedure with surgical results comparable to conventional laparoscopic procedures.

### INTRODUCTION

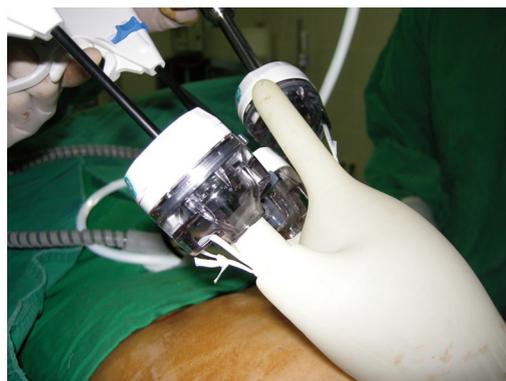

The laparoscopic approach for colorectal surgery has been shown to result in shorter hospital stays, faster return of bowel function, less pain and better cosmetic results than open surgery<sup>[1,2]</sup>. Moreover, the long term recurrence and survival results of laparoscopic surgery for advanced colon cancer are not different from those of conventional surgery<sup>[3,4]</sup>. Therefore, laparoscopic surgery has been considered the best treatment for colon cancer. Natural orifice transluminal endoscopic surgery (NOTES) has recently been developed and introduced for certain procedures in humans. However, there are many technical limitations for the use of NOTES in colon resection and anastomosis. Until now, experimental studies of NOTES for colon surgery have only been performed using animals or cadavers<sup>[5,6]</sup>. Single port laparoscopic surgery (SPLS) has advantages over NOTES in ease of instrument use and operative technique. This is the first report on SPLS performed for a right hemicolectomy in advanced colon cancer with D3 lymph node dissection.

### CASE REPORT

Our patient was a 60-year-old woman who was diagnosed with ascending colon cancer. Colonoscopy revealed an encircling mass in the ascending colon and biopsy demonstrated adenocarcinoma (Figure 1). An abdominopelvic computed tomography scan showed enhanced wall thickening in the ascending colon and no distant metastasis (Figure 2). The patient's body mass index was 25. The patient's consent about single port

**Figure 1** Encircling mass in the ascending colon visualized during colonoscopy.

**Figure 3** Operative photograph of the single port setting with multiple trocars and instruments.

**Figure 2** Abdominal CT showed enhanced wall thickening in the ascending colon.

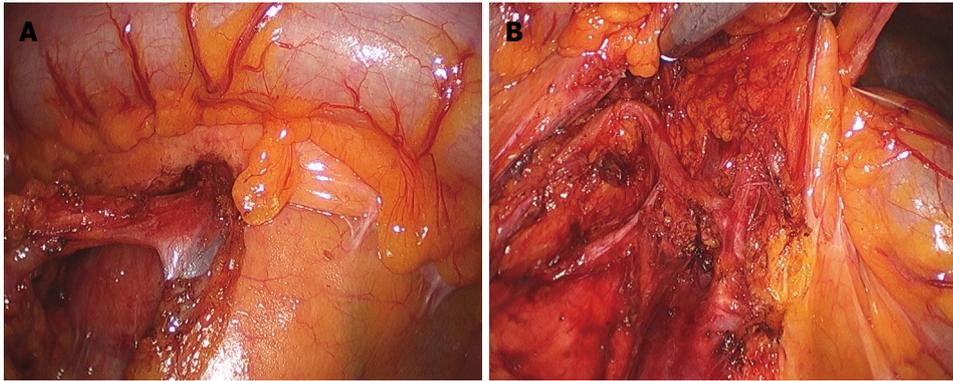

surgery was obtained. A 3 cm abdominal incision was made *via* the umbilicus using the method reported by Casciola *et al*<sup>7</sup>. A small wound retractor (ALEXIS wound retractor S, Applied Medical, Santa Margarita, CA, USA) and a surgical glove were used as a single port, as in previous reports<sup>18,9</sup> (Figure 3). The surgical technique was similar to laparoscopic right hemicolectomy and involved a medial to lateral approach using a 0 degree 10 mm scope. We used a hook type monopolar suction irrigator and 5 mm standard straight laparoscopic instrument for dissection of lymph nodes and vessels. We successfully removed all lymph nodes and connective tissue around the ileocolic vessels and midcolic vessels. The vessels were divided using Ligasure V (Covidien, Valleylab, Norwalk, CT, USA). All of the soft tissue anterior to the superior mesenteric vein was completely removed and D3 lymph node dissection was achieved (Figure 4A and B). The specimen was put into a plastic bag within the abdominal cavity and was retrieved through the umbilical port without wound extension. Extracorporeal anastomosis was performed using staplers. The total operative time was 180 min with minimal blood loss (< 50 mL). The patient's total hospital stay was 4 d and she was discharged without complications (Figure 5A). The surgical specimen was 27.5 cm in length with 10 cm surgical margins and the tumor size was 5 cm × 3 cm (Figure 5B and C). There were 69 harvested lymph

nodes and there were no positive lymph nodes. The pathologic staging of the tumor was T3N0M0.

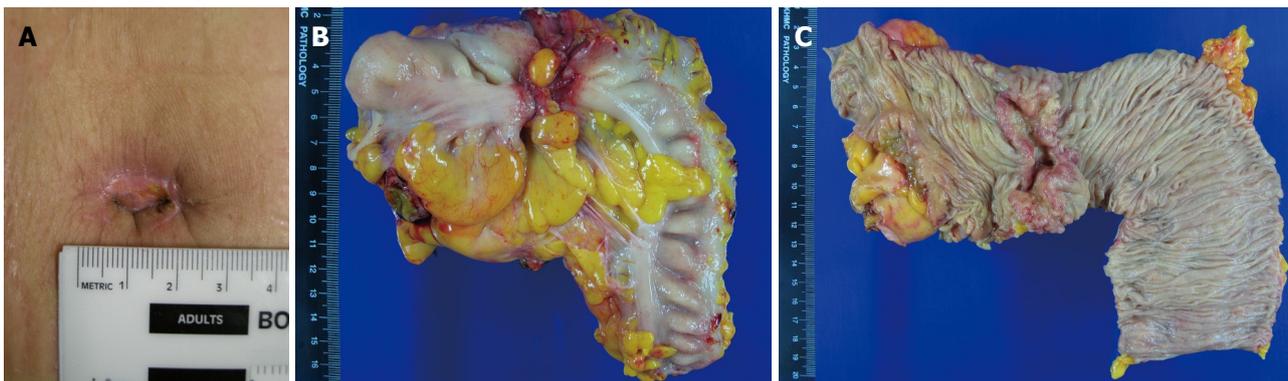

## DISCUSSION

Laparoscopic surgery for advanced colon cancer provides increased patient satisfaction with improvements in postoperative pain, cosmetic results, and recovery<sup>1-4</sup>. However, laparoscopic surgery typically requires 5-6 trocars with 5-12 mm-sized incisions for each trocar, with associated risks for trocar site bleeding, herniation of the viscera, wound infection, wound pain and unwanted cosmetic outcomes<sup>10,11</sup>. Single port surgery has been reported in nephrectomy, appendectomy, cholecystectomy, adnexal mass resection, and sacrocolpopexy<sup>12-15</sup>. Like laparoscopic surgery, SPLS was developed and, gradually, more complex and difficult procedures have been performed. Bucher *et al*<sup>16</sup> reported a successful single port access right hemicolectomy operation for a 5 cm sized polyp in the ascending colon. They respected oncologic principles for cancer surgery. The surgical specimen length was 38 cm with a 10 cm surgical margin and 33 lymph nodes were retrieved. Leroy *et al*<sup>17</sup> performed a sigmoidectomy using a single port access for a patient with diverticular disease in the sigmoid colon. In this procedure, the surgeons used a specific single port (ASC Triport, Advanced Surgical Concepts, Wicklow, Ireland), magnets and endoscopy for bowel traction. This Triport allows the passage of 1 large-caliber instrument (up to 12 mm) and 2 other instruments of smaller diameter (up to 5 mm each). The surgical specimen was 40 cm long and anastomosis was located 10 cm from the anal margin. Although these reports demonstrated the technical feasibility and safety of single port surgery, it remains a complex and intricate procedure. Single port surgery has limitations with regard to movement range, adequate traction and triangulation for dissection.

We performed single port surgery in an advanced colon cancer patient. Before the single port laparoscopic right hemicolectomy (SPLRH) procedure, we had experience with SPLS in 10 cases of appendectomy and 1 case of colectomy for colon polyps. In those patients, we used a simple single port that was made using a

**Figure 4** Single port laparoscopic right hemicolectomy with D3 node dissection around the superior mesenteric vein (A) and artery (B).

**Figure 5** Surgical wound around the umbilicus (A) and surgical specimen of the resected colon (B and C).

conventional small wound retractor and a surgical glove. We used conventional straight laparoscopic instruments. Surprisingly, SPLRH with conventional instruments was not a difficult procedure. We were able to achieve operating space with adequate forward and backward movements of the scope and instruments. Of note, balanced scope movement according to movement of the laparoscopic instruments is important. Difficulties with scissoring and interference between instruments and scopes in the near future. Limitations which make SPLS difficult to apply across cases include internal and external conflicts between instruments and difficulty achieving traction for triangulation formation. We offer the following technical tips to avoid these limitations. Low tension under the tissue to be dissected is overcome by using cut mode in electrocautery instead of coagulation mode. To avoid internal conflict between two working laparoscopic instruments, we first established a surgical field to grasp tissue which is not located too close to the area to dissect. To avoid internal conflict between the scope and dissecting instruments, we recommend drawing the scope to the level of the abdominal wound or out of the wound, if it is possible once the right surgical plane could be found in the close view. External conflicts can be categorized into interference between trocars and interference between instruments. Use of a surgical glove is helpful to overcome these conflicts because it is flexible enough to minimize the trocar conflict. Therefore, surgeons can easily avoid trocar

conflict by pushing the trocar forward slightly. SPLS for colon cancer is a challenging procedure and it is essential to develop multiport single access and instruments for single port surgery<sup>[18]</sup>. Recently many commercial ports have been developed. New port systems include the R-Port (ASC, Wicklow, Ireland)<sup>[18]</sup>, the ASC Triport<sup>[17]</sup> and the Pnavel Uni-XTM Single Site Laparoscopic System<sup>[19]</sup> (Pnavel System, Morganville, NJ, USA). New instruments have also been developed specifically to reach curved or articulating structures<sup>[20]</sup>. Camera systems have also been improved. Cadeddu *et al*<sup>[21]</sup> used a magnetically anchored camera system during appendectomy and nephrectomy. The system showed fewer instrument collisions and improved surgical space<sup>[21]</sup>.

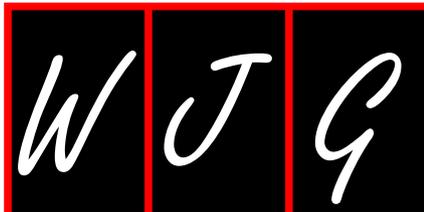

Given the evolution of single port surgery, we assume that laparoscopic surgeons will perform more technically difficult procedures including advanced cancer surgery with a single port. This is the first report of single port surgery for colon cancer. We believe that SPLS for colon cancer is an effective, minimally invasive procedure and a bridge to NOTES for colon resection.

### TO THE EDITOR

We read with great interest the article recently published in *World Journal of Gastroenterology* by Song *et al*<sup>[1]</sup>, presenting that the serum levels of soluble intercellular adhesion molecule-1, D-lactate and diamine oxidase (DAO) can be used as major monitoring indices in diagnosis and treatment of inflammatory bowel disease (IBD). However, some points on designing the study and their conclusion about the markers in diagnosis of IBD may need further considerations.

First, the study was based on the view that the intestinal permeability (IP) is increased in the active phase of IBD so that D-lactate and DAO can enter blood through the dysfunctional barrier. A high serum level of the markers, which reflects the activity of IBD, can reveal the damage to intestinal mucosa. However, several studies have identified a subset of healthy relatives who also have increased IP but no CD<sup>[2-4]</sup>. Moreover, it has been shown that IP increases in remission of IBD, especially in CD<sup>[5]</sup>.

Second, the authors stated that D-lactate could not be well metabolized as mammals have no D-lactate dehydrogenase for its decomposition. Therefore, plasma D-lactate can be used to reveal the damage to intestinal mucosa and permeability alteration in IBD. This conventional opinion is based largely on early experiments and continues to be quoted frequently. It has been reported that D-lactate is indeed metabolized<sup>[6]</sup>. The half-life of oral D-lactate (6.4 mmol/kg) is 21 min in blood of healthy humans while doubling this dosage increases its half-life to 40 min, most likely reflecting the saturation of its metabolism<sup>[7]</sup>. In addition, recent studies have identified D-lactate dehydrogenases in putative human and murine mitochondria<sup>[8,9]</sup>. These findings indicate that the plasma level of D-lactate is not a reliable marker of IBD.

### Abstract

The serological markers are increasingly used in diagnosis of inflammatory bowel disease (IBD). D-lactate and diamine oxidase are new indicators that can be used to reveal the damage to intestinal mucosa and permeability alteration in IBD. Although the two biological markers seem more sensitive, recent clinical trials and animal experiments have shown controversies about the use of them in diagnosis of IBD. Therefore, these markers should be interpreted cautiously and further prospective studies are needed to establish their clinical role in diagnosis of IBD.

Xie Q, Gan HT. Controversies about the use of serological markers in diagnosis of inflammatory bowel disease. *World J Gastroenterol* 2010; 16(2): 279-280 Available from: URL:

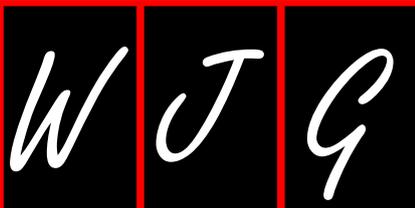

Third, DAO activity in blood, as a diagnostic marker of IBD, should be interpreted cautiously. Actually, serum DAO enzyme activity is changed by several disorders including severe burn, gut injury, diverse enteropathy and abdominal surgery, chemotherapy and kidney injury. Furthermore, gender-related differences in DAO activity with a high inter-individual variability, demonstrate that abnormal serum DAO activity in women is not always associated with a pathological status<sup>[10]</sup>.

Prerequisites for the clinical use of biomarkers in diagnosis of IBD include high sensitivity, specificity and cost-effectiveness. The rapidly expanding markers to the serologic IBD diagnostic algorithm will likely increase their sensitivity. Increased sensitivity, however, can often accompany decreased specificity, which must be carefully assessed and recognized. Further prospective clinical trials are needed to determine the role and importance of such markers in diagnosis of IBD.

## Meetings

### Events Calendar 2010

January 25-26  
 Tamilnadu, India  
 International Conference on Medical  
 Negligence and Litigation in Medical  
 Practice

January 25-29  
 Waikoloa, HI, United States  
 Selected Topics in Internal Medicine

January 26-27  
 Dubai, United Arab Emirates  
 2nd Middle East Gastroenterology  
 Conference

January 28-30  
 Hong Kong, China  
 The 1st International Congress on  
 Abdominal Obesity

February 11-13  
 Fort Lauderdale, FL, United States  
 21th Annual International Colorectal  
 Disease Symposium

February 26-28  
 Carolina, United States  
 First Symposium of GI Oncology at  
 The Caribbean

March 04-06  
 Bethesda, MD, United States  
 8th International Symposium on  
 Targeted Anticancer Therapies

March 05-07  
 Peshawar, Pakistan  
 26th Pakistan Society of  
 Gastroenterology & Endoscopy  
 Meeting

March 09-12  
 Brussels, Belgium  
 30th International Symposium on  
 Intensive Care and Emergency  
 Medicine

March 12-14  
 Bhubaneswar, India  
 18th Annual Meeting of Indian  
 National Association for Study of  
 the Liver

March 23-26  
 Cairo, Egypt  
 14th Pan Arab Conference on  
 Diabetes PACD14

March 25-28  
 Beijing, China  
 The 20th Conference of the Asian

Pacific Association for the Study of  
 the Liver

March 27-28  
 San Diego, California, United States  
 25th Annual New Treatments in  
 Chronic Liver Disease

April 07-09  
 Dubai, United Arab Emirates  
 The 6th Emirates Gastroenterology  
 and Hepatology Conference, EGH  
 2010

April 14-17  
 Landover, Maryland, United States  
 12th World Congress of Endoscopic  
 Surgery

April 14-18  
 Vienna, Austria  
 The International Liver Congress™  
 2010

April 28-May 01  
 Dubrovnik, Croatia  
 3rd Central European Congress  
 of surgery and the 5th Croatian  
 Congress of Surgery

May 01-05  
 New Orleans, LA, United States  
 Digestive Disease Week Annual  
 Meeting

 AIDS

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

## Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**AIM AND SCOPE**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Abstract

Angiogenesis is a dynamic, hypoxia-stimulated and growth factor-dependent process, and is currently referred to as the formation of new vessels from pre-existing blood vessels. Experimental and clinical studies have unequivocally reported that hepatic angiogenesis, irrespective of aetiology, occurs in conditions of chronic liver diseases (CLDs) characterized by perpetuation of cell injury and death, inflammatory response and progressive fibrogenesis. Angiogenesis and related changes in liver vascular architecture, that in turn concur to increase vascular resistance and portal hypertension and to decrease parenchymal perfusion, have been proposed to favour fibrogenic progression of the disease towards the end-point of cirrhosis. Moreover, hepatic angiogenesis has also been proposed to modulate the genesis of portal-systemic shunts and increase splanchnic blood flow, thus potentially affecting complications of cirrhosis. Hepatic angiogenesis is also crucial for the growth and progression of hepatocellular carcinoma. Recent literature has identified a number of cellular and molecular mechanisms governing the cross-talk between angiogenesis and fibrogenesis,

with a specific emphasis on the crucial role of hypoxic conditions and hepatic stellate cells, particularly when activated to the myofibroblast-like pro-fibrogenic phenotype. Experimental anti-angiogenic therapy has been proven to be effective in limiting the progression of CLDs in animal models. From a clinical point of view, anti-angiogenic therapy is currently emerging as a new pharmacologic intervention in patients with advanced fibrosis and cirrhosis.

Hypoxia, angiogenesis and liver fibrogenesis in the progression of chronic liver diseases. *World J Gastroenterol* 2010; 16(3): 281-288 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i3/281.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i3.281>

### INTRODUCTION

Angiogenesis can be envisaged as a dynamic, hypoxia-stimulated and growth factor-dependent ubiquitous process leading to the formation of new vessels from pre-existing blood vessels<sup>[1-5]</sup>, and should be distinguished from other terms that, although related to vessel formation and growth, define significantly different processes such as vasculogenesis, arteriogenesis and collateral vessel growth. Angiogenesis occurs virtually in almost all organs and tissues and is considered a critical step in either physiological conditions or in tissue repair and growth in several pathophysiological conditions<sup>[1-5]</sup>, including chronic liver diseases (CLDs)<sup>[6-8]</sup>.

Where the liver is concerned, physiological and pathological angiogenesis can occur during liver regeneration (after acute liver injury or after partial hepatectomy), in ischemic conditions, during chronic inflammatory and fibrogenic liver diseases as well as in hepatocellular carcinoma and in metastatic liver cancers<sup>[6-8]</sup>. The steps and mechanisms of hepatic angiogenesis mostly overlap with those described in other organs or tissues but a number of liver parenchyma peculiarities are likely to make the overall scenario more complex<sup>[6]</sup>. These include the existence of two different kinds of microvascular structures (portal vessels and liver sinusoids, lined by continuous or fenestrated and discontinuous endothelium, respectively), the expression of a putative liver specific angiopoietin-like peptide defined as ANGPTL3<sup>[9]</sup> and, most relevant, the unique and heterogenous phenotypic profile and functional role of hepatic stellate cells (HSCs) that, although regarded as liver specific pericytes in normal liver, also represent the most relevant pro-fibrogenic cell lineage<sup>[10-13]</sup> in CLDs. HSCs, particularly in their activated and myofibroblast-like phenotype (HSC/MFs), are indeed emerging as cells that may have an active role in modulating angiogenesis that differs from the one attributed to microcapillary pericytes<sup>[14]</sup>. The overall scenario is even more complex if one considers that in CLDs hepatic myofibroblast-like cells (MFs) constitute a heterogenous population of pro-fibrogenic cells. These highly proliferative and contractile cells may also originate from portal (myo) fibroblasts, bone marrow-derived stem cells and, as recently suggested, also from hepatocytes or cholangiocytes through a process of epithelial to mesenchymal transition<sup>[10-13]</sup>. In the following section of this editorial we will try to focus on those relevant features that link angiogenesis to liver fibrogenesis and then the progression of CLDs. The interested reader can refer to more comprehensive reviews - such as articles with more details on the basic principles and mechanisms involved in angiogenesis as well as the analysis of the role of angiogenesis in liver regeneration or hepatocellular carcinoma<sup>[10-14]</sup>.

## HEPATIC ANGIOGENESIS AND ITS RELATIONSHIPS BETWEEN CHRONIC INFLAMMATION AND FIBROGENIC PROGRESSION OF CLDs

CLDs are characterized by reiteration of liver injury due to a number of aetiological conditions, including chronic infection by viral agents [mainly hepatitis B virus (HBV) and hepatitis C virus (HCV)] as well as metabolic, toxic/drug-induced (with alcohol consumption being predominant) and autoimmune causes, resulting in persistent inflammation and progressive fibrogenesis. Chronic activation of the wound healing response is the major driving force for progressive accumulation of

extracellular matrix (ECM) components, eventually leading to liver cirrhosis and hepatic failure. Oxidative stress and redox signalling, derangement of epithelial-mesenchymal interactions or, as recently proposed, the process of epithelial to mesenchymal transition represent additional mechanisms able to sustain fibrogenesis progression towards the final end-point of cirrhosis<sup>[11,12,15-17]</sup>.

Along these lines, cirrhosis should be regarded as an advanced stage of fibrosis characterized by the formation of regenerative nodules of parenchyma, surrounded and separated by fibrotic septa, and associated with significant changes in angio-architecture. The suggestion that angiogenesis may significantly contribute to fibrogenesis and disease progression relies first on the fact that vascular remodelling, irrespective of aetiology, is a common finding in human cirrhotic livers<sup>[11,12,14,18,19]</sup>. Moreover, the formation of fibrotic septa, as well as capillarization of sinusoids, the latter due to early deposition of fibrillar ECM in the space of Disse, can result in an increased resistance to blood flow and oxygen delivery. These are the premises for hypoxia and the transcription of hypoxia-sensitive pro-angiogenic genes, usually modulated by the so-called hypoxia inducible factors (HIFs)<sup>[20-23]</sup>. In addition, it is well known that in CLDs the inflammatory response gains the role of a dynamic state relevant for the progression of fibrogenesis towards the end-point of cirrhosis<sup>[11-13,16]</sup>. Several mediators of the inflammatory response may stimulate other cells in the surrounding microenvironment to express vascular endothelial growth factor (VEGF) and other pro-angiogenic factors as well as to sustain angiogenesis<sup>[24]</sup>. Moreover, cytokines or mediators produced during CLDs such as hepatocyte growth factor (HGF), platelet-derived growth factor (PDGF) and nitric oxide (NO), can play a role in the development of angiogenesis<sup>[6,13,14]</sup>. In particular, one should consider that: (1) neo-vessels themselves can significantly contribute to perpetuation of the inflammatory response by expressing chemokines and adhesion molecules promoting the recruitment of inflammatory cells; (2) angiogenesis, early in the course of a CLD, may contribute to the transition from acute to chronic inflammation<sup>[25]</sup>.

A relevant additional point, as recently proposed<sup>[20]</sup>, is that depending on the specific pattern of fibrosis (post-necrotic or bridging fibrosis, pericellular or perisinusoidal fibrosis, biliary fibrosis or centrilobular fibrosis)<sup>[12,26]</sup>, the extent of neo-angiogenesis, in addition to favouring disease progression, may also represent a key limiting factor for fibrosis reversibility. This is potentially relevant for post-necrotic or bridging fibrosis, a pattern which is mainly seen in patients with advanced fibrosis or cirrhosis by chronic HBV or HCV infection. In this pattern of fibrosis, which is characterized by the formation of bridging septa between portal and central vein areas, angiogenesis, vascular remodelling and altered angio-architecture are particularly impressive.

## **PATHOLOGICAL ANGIOGENESIS AND PRO-ANGIOGENIC CYTOKINES HAVE BEEN DETECTED IN HUMAN CLDs**

Current evidence suggests that angiogenesis and fibrogenesis are detectable and develop in parallel in any clinical condition of CLDs that can progress towards the end-point of cirrhosis, irrespective of aetiology, as well as in the most widely used experimental animal models of CLDs<sup>[6,13,19,20]</sup>.

Where clinical data are concerned, best relationships between angiogenesis and the pattern of fibrosis (i.e. bridging fibrosis)<sup>[12,26]</sup> are usually found during chronic viral infection by either HBV or HCV. This is documented by either the abundant presence of endothelial cells (ECs) and neovessels/capillary structures found in inflamed portal tracts<sup>[6]</sup> or by the over-expression of major pro-angiogenic molecules, including VEGF and Angiopoietin 1 (Ang-1) as well as their related receptors (VEGFR type II, Tie2) and HGF<sup>[27-31]</sup>. In these clinical settings, PDGF, which is released by periportal inflammatory cells as well as by sinusoidal and perisinusoidal cells, may also play a pro-angiogenic role<sup>[32]</sup>. In addition, selected viral proteins may have a multiple pro-angiogenic role like HBV-related X protein<sup>[33]</sup>. This protein has been involved in disruption of inter-endothelial junctions by operating through a src-kinase-dependent signalling pathway, as well as in the up-regulation of inducible nitric oxide synthase (iNOS) through involvement of nuclear factor- $\kappa$ B (NF- $\kappa$ B) transcription factor<sup>[34]</sup> or even by up-regulating membrane-type matrix metalloprotease (MT-MMP) expression, and then MMP-2 activation in hepatocytes<sup>[35]</sup>.

Angiogenesis has also been detected in biopsies from patients affected by either primary biliary cirrhosis (PBC) or autoimmune hepatitis as formation of neovessels by ECs positive for CD-31 and vascular endothelial-cadherin<sup>[6]</sup>. These neo-vessels were located, particularly in PBC, mainly in portal areas in association with inflammatory infiltrate<sup>[6,36]</sup>. Once again, enhanced expression of angiogenic molecules such as VEGF, Ang-1, Ang-2, Tie-2 and endoglin has also been characterized in these PBC patients.

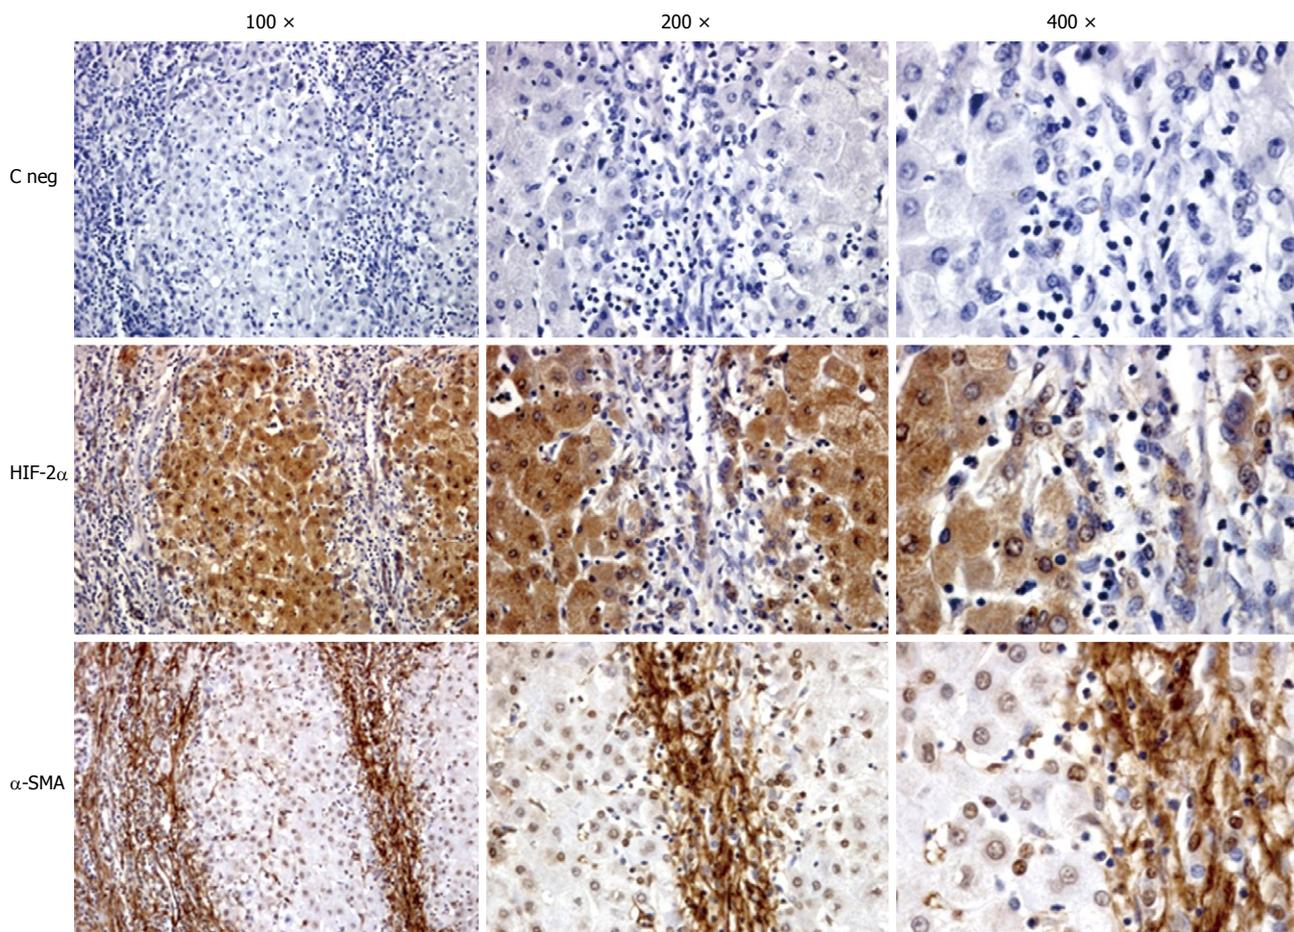

Similar data have been reported for the most widely used experimental animal models of CLDs that have been instrumental in unequivocally documenting that angiogenesis and fibrogenesis develop in parallel during progression towards cirrhosis<sup>[31,37-43]</sup>.

Both human and experimental studies have also outlined that several peptide mediators other than VEGF, Ang-1 and HGF are likely to be involved in hepatic angiogenesis associated with the fibrogenic progression process in CLDs. Unequivocal data have been provided for the pro-angiogenic action of PDGF<sup>[32]</sup> as well as for leptin, an adipocytokine that has been suggested to exert a pro-fibrogenic effect in promoting the development from non-alcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH)<sup>[40,44]</sup>. Where leptin is concerned, it has been shown that leptin can up-regulate

the expression of VEGF and Ang-1, as well as the pro-inflammatory chemokine monocyte chemoattractant protein 1 or MCP-1<sup>[44]</sup>. The role of angiogenesis in NASH development and fibrosis has been confirmed by a study performed on Zucker rats, animals that naturally develop leptin receptor mutations<sup>[40]</sup>, receiving the steatogenous choline-deficient and amino acid defined (CDA) diet.

## **THE EMERGING ROLE OF HYPOXIA IN FIBROGENIC CLDs**

Another major message coming mainly from experimental models of CLDs is that VEGF overexpression is strictly associated with hypoxic areas and is mostly limited to hepatocytes as well as to HSC/MFs<sup>[31,37-43]</sup>. This concept fits well with the rational hypothesis that hypoxia is likely to represent the major stimulus for hepatic angiogenesis. The colocalization of hypoxic areas with VEGF overexpression and/or the association between VEGF expression and progression of fibrogenesis was first described in the model of bile duct ligation (BDL)<sup>[37]</sup> and then confirmed in the diethyl-nitrosamine (DEN) model of fibrosis<sup>[38]</sup>, in the model of chronic treatment with CCl<sub>4</sub><sup>[31,39,41]</sup> and in the choline-deficient and amino acid-defined diet rat model of NAFLD evolving into NASH and significant fibrosis<sup>[40]</sup>. Of relevance, a recent study, has outlined in a mechanistic way, the strict relationships between hypoxia, angiogenesis, inflammation and fibrogenesis by using liver conditional HIF-1 $\alpha$ -deficient mice that were subjected to the BDL model of fibrosis<sup>[43]</sup>. In this study, it was clearly shown that the appearance of HIF-1 $\alpha$ -positive hypoxic areas in the liver of BDL mice can take place as early as 3 d after surgery, before the development of detectable signs of fibrosis. In particular, within hypoxic areas HIF-1 $\alpha$  was found to be activated in hepatocytes and Kupffer cells. HIF-1 $\alpha$  -/- conditional mice subjected to BDL were characterized by a very significant decrease in collagen type I and  $\alpha$ -SMA transcripts and protein levels, as well as of transcripts for PDGF-A, PDGF-B, plasminogen activator inhibitor-1 (PAI-1) and fibroblast growth factor 2 (FGF-2) as compared to wild type mice in which the typical scenario of biliary-type fibrosis and cirrhosis was associated with early and sustained up-regulation of HIF-1 $\alpha$ <sup>[43]</sup>. The authors of this study proposed that hypoxic hepatocytes, following activation of HIF-1 $\alpha$  and through the HIF-1 $\alpha$ -dependent release of these growth factors and mediators, may significantly contribute to either initial repair and revascularization of injured parenchyma as well as to fibrosis progression by targeting profibrogenic MFs. In a more recent study from the same group, this hypothesis was further investigated by exposing to hypoxia cultured hepatocytes obtained from normal mice as well as from HIF-1 $\alpha$  or HIF-1 $\beta$  deficient mice<sup>[23]</sup>. The overall scenario which emerged from the latter study indicated that hypoxic hepatocytes, through the involvement of HIF-1 $\alpha$  and HIF-2 $\alpha$ , can express and release PAI-1, VEGF and the vasoactive peptides adrenomedullin-1 (ADM-1)

**Figure 1** Immunohistochemical analysis performed on paraffin liver sections from patients with hepatitis C virus (HCV)-related liver cirrhosis (METAVIR F4). Sections (2 μm thick) were incubated with specific antibodies raised against HIF-2α or α-SMA that positively stain cells exposed to hypoxia (HIF-2α) or myofibroblast-like cells (α-SMA). Primary antibodies were labelled by using EnVision, HRP-labelled System (DAKO) antibodies and visualized by 3'-diaminobenzidine substrate. Negative controls (C neg) were obtained by replacing the respective primary antibodies by isotype and concentrations matched irrelevant antibody. Original magnification is indicated.

and ADM-2<sup>[23]</sup>. Hepatocytes exposed to hypoxia during CLD progression are then reasonably a relevant source of vasoactive mediators as well as of the master pro-angiogenic cytokine VEGF. This unavoidably underlines the relevance of the cross-talk between hypoxic hepatocytes and surrounding non-parenchymal cells like sinusoidal endothelial cells (SECs) and, as we will see later in this editorial, activated MFs. Indeed, VEGF has a well known major pro-angiogenic role by increasing vascular permeability as well as triggering endothelial cell proliferation and regulating neo-vessel lumen diameter<sup>[1-8,14,19]</sup>.

Along these lines, it is worth mentioning that in the rat model of chronic administration of CCl<sub>4</sub>, hypoxic hepatocytes have also been shown to contribute to the expression of the master profibrogenic cytokine transforming growth factor-β1 (TGF-β1)<sup>[45]</sup>. This contribution has been reported to be relevant mainly in an advanced stage of fibrosis or cirrhosis, whereas TGF-β1 is mainly produced by MFs and activated macrophages during early fibrosis and middle stage fibrogenic progression<sup>[45]</sup>.

A strict association between hypoxia and liver fibrogenesis can also be easily appreciated in the liver of human HCV cirrhotic patients by detecting HIF-2α and α-SMA

in serial sections (Figure 1). HIF-2α-positive staining in these human specimens is usually detectable in hepatocytes of pseudolobules as well as in some MFs at the interface between fibrotic septa and liver parenchyma or even within pseudolobules. Moreover, it is also evident that α-SMA-positive MFs are in close contact with HIF-2α positive hepatocytes. Along these lines, it has been suggested that hypoxia may result in VEGF- and Angiopoietin 1-dependent increased migration and chemotaxis of HSC/MFs, contributing to their recruitment towards the site of injury and alignment with both nascent and established fibrotic septa, a relevant pro-fibrogenic feature<sup>[31]</sup>.

Hypoxia has also been suggested to result in the down-regulation of HGF expression by HSCs and in the inhibition of c-met expression by hepatocytes<sup>[46]</sup>, both events being able to significantly contribute to depressed liver regeneration during chronic liver injury.

## THE ROLE OF PROFIBROGENIC CELLS IN LIVER ANGIOGENESIS

Hepatic stellate cells, due to their strategic location in the space of Disse and intimate contact with sinusoidal ECs,

have been described to behave as liver specific pericytes and then to play a role in physiological angiogenesis<sup>[10]</sup>. Recent literature data suggest that HSC/MFs in CLDs are likely to represent a hypoxia-sensitive and cyto- and chemokine-modulated cellular crossroad between necro-inflammation, pathological angiogenesis and fibrogenesis. The latter statement is strongly suggested, in addition to exhaustive literature that has characterized the pro-fibrogenic and pro-inflammatory role of these cells, by a series of studies that outlined the following major concepts: (1) HSC and HSC/MFs can behave as pro-angiogenic cells able to react to conditions of hypoxia by up-regulating transcription and synthesis of VEGF, Ang-1 and their related receptors VEGFR-2 and Tie2<sup>[51,44,47,48]</sup>; the same behaviour has also been described for human HSC/MFs in which leptin was able to trigger a ERK1/2 and PI3-K-dependent nuclear translocation of HIF-1 $\alpha$ <sup>[44]</sup>; (2) HSC/MFs also represent a cellular “target” for the action of VEGF and Angiopoietin 1; VEGF has been reported to be able to trigger HSC/MFs proliferation<sup>[59,49,50]</sup>, increase deposition of ECM components<sup>[38,39,50]</sup>, as well as increase migration and chemotaxis<sup>[51]</sup>.

This is a scenario that is likely to be relevant in the progression of a CLD, as shown recently by *in vivo* morphological data obtained in human and rat fibrotic/cirrhotic livers<sup>[51]</sup>.  $\alpha$ -SMA-positive MFs, able to express concomitantly VEGF, Ang-1 or the related receptors VEGFR-2 and Tie-2, are found at the leading edge of tiny and incomplete developing septa, but not in larger bridging septa. This distribution may reflect the existence of two different phases of the angiogenic process during CLDs: an early phase, occurring in developing septa, in which fibrogenesis and angiogenesis may be driven/modulated by HSC/MFs, and a later phase occurring in larger and more mature fibrotic septa where the chronic wound healing is less active and fibrogenic transformation more established. In such a late setting, pro-angiogenic factors are expressed only by endothelial cells, a scenario that is likely to favour stabilization of the newly formed vessels.

A very recent and elegant experimental study<sup>[51]</sup> has outlined another putative pro-angiogenic mechanism, that may have a role in vascular remodelling in cirrhosis. This mechanism is related to the action of so-called microparticles Hedgehog (Hh) ligands, which are known to be released during embryogenesis and to activate Hh signalling in endothelial cells. In this study, the authors showed that cholangiocytes and HSC/MFs can produce and then release, mainly in response to PDGF, Hh ligands in microparticles and that this event is relevant under conditions leading to experimental biliary cirrhosis (BDL model). The authors propose the following scenario: (1) in normal conditions the action of the low amount of Hh ligand released by rare immature ductular-type progenitors is counteracted by expression of Hh interacting protein (HIP) expressed by either quiescent HSC or fenestrated SEC; (2) under conditions of chronic injury, HIP expression is repressed and activation of

ductular-type progenitor cells may result in PDGF-BB up-regulation and release; this, in turn, is likely to lead HSC/MFs and ductular cells to produce Hh ligands. Hh ligands, apart from promoting proliferation and survival of both cholangiocytes and HSC/MFs, may also promote changes in SEC gene expression resulting in capillarization of sinusoids and the release of vasoactive factors such as nitric oxide, then contributing to vascular remodelling in cirrhosis<sup>[51]</sup>.

## PATHOLOGICAL ANGIOGENESIS AS A POTENTIAL THERAPEUTIC TARGET IN CLDs

The analysis of the data and concepts presented in the previous sections, concerning the proposed relationships between angiogenesis, chronic wound healing and fibrogenesis and then disease progression, unavoidably leads to the following theoretical clinical goals: (1) detection of selected pro-angiogenic molecules (i.e. in serum or plasma) may serve as a non-invasive way to monitor both disease progression as well as the response to therapy; (2) anti-angiogenic therapy may be an effective tool for blocking or slowing down fibrogenic progression of CLDs.

We are indeed far from the first goal, and at present just a single study performed on 36 chronic HCV patients (*vs* 15 healthy controls) has tried to correlate circulating levels of molecules related to angiogenesis, disease progression and efficacy of standard pegylated interferon  $\alpha$ -2b (IFN- $\alpha$ 2b) plus ribavirin therapy. VEGF, Ang-2 and soluble Tie-2 (sTie-2) were determined in the serum before and after therapy and authors reported increased levels of VEGF and Ang-2 that were significantly decreased after therapy in these patients<sup>[52]</sup>.

Where the efficacy of the angiogenic therapy is concerned, experimental data unequivocally indicate that anti-angiogenic therapy is indeed effective in preventing progressive fibrogenesis. Pioneering studies employed anti-angiogenic molecules or drugs like the semi-synthetic analogue of fumagillin TNP-470<sup>[53]</sup> or antibodies able to neutralize either VEGFR-1 (Flt-1) and/or VEGFR-2 (Flk-1)<sup>[59]</sup>, both conditions being able to significantly inhibit angiogenesis, the number of  $\alpha$ -SMA-positive cells and the development of fibrosis. The latter study also showed the *in vivo* predominance of VEGF interaction with VEGFR-2 to mediate angiogenesis during chronic liver injury. Neutralizing antibodies against VEGFR-2 were employed in other relevant studies, performed on a model of portal hypertensive rats, where VEGF expression and related angiogenesis were correlated to the development of porto-systemic collateral vessels and hyperdynamic splanchnic circulation<sup>[54,55]</sup>. These data suggest that the increase in portal blood flow, which is an important contributor to portal hypertension, depends not only on vasodilation, but also on the enlargement of the splanchnic vascular tree caused by angiogenesis.

More recently, positive results have been obtained

in the chronic CCl<sub>4</sub> rat model of CLD by employing Sunitinib, a tyrosine kinase receptor inhibitor able to target VEGF and PDGF receptors<sup>[41]</sup>. The treatment of cirrhotic animals with Sunitinib resulted in a significant decrease in hepatic vascular density, inflammatory infiltrate, abundance of  $\alpha$ -SMA-positive mesenchymal cells, ECM deposition and even portal pressure.

Positive results have been also reported in another recent study in which mice undergoing BDL or chronic CCl<sub>4</sub> treatment received an adenovirus expressing soluble Tie-2 (AdsTie-2), the receptor for Ang-1, resulting in the blocking of Ang-1 signalling and in a significant prevention of both angiogenesis and fibrosis<sup>[42]</sup>.

A final and very recent experimental study reported a beneficial effect of Sorafenib<sup>[56]</sup>, a receptor tyrosine kinase inhibitor already approved for the treatment of hepatocellular carcinoma<sup>[57,58]</sup>, one of the most common complications of liver cirrhosis. In this study, oral administration of Sorafenib in rats with portal hypertension and cirrhosis (once a day for 2 wk) resulted in the inhibition of VEGF, PDGF and Raf kinase signalling; this, in turn, resulted in an approximately 80% decrease in splanchnic neovascularization and a very significant attenuation of hyperdynamic splanchnic and systemic circulations, as well as a significant decrease in the extent of portosystemic collaterals. Of relevance, Sorafenib treatment in cirrhotic rats also led to a 25% reduction in portal pressure and to a relevant improvement in liver injury, inflammation, fibrosis and angiogenesis.

The latter study has raised, in a more compelling way, the obvious question of whether anti-angiogenic therapy has an adequate rationale to be seriously considered for therapy in patients with cirrhosis and portal hypertension. As nicely pointed out by Shah and Bruix<sup>[59]</sup>, any future clinical trial employing Sorafenib in cirrhotic patients should assess a number of critical issues, the first being the optimal dosage to be used which may be theoretically lower than the dosage used in patients with hepatocellular carcinoma (HCC). The adverse effects of Sorafenib may represent a relevant concern: it is already known that more than 40% of HCC patients are forced to interrupt treatment<sup>[57,58]</sup>, and it has been shown that a major complication of angiogenic treatments employing Bevacizumab and Sunitinib in HCC patients is variceal bleeding<sup>[60,61]</sup>. Although available data indicate that Sorafenib may be relatively safe in this complication, caution is in any case necessary because it has been authoritatively suggested that an intense anti-angiogenic effect may lead to significant damage of the vasa vasorum needed to maintain the structure of varices<sup>[59]</sup>.

Another note of caution has recently been provided by an experimental study performed in order to assess the anti-fibrotic potential of the inhibition of the vitronectin receptor integrin  $\alpha$ v $\beta$ 3, which has been shown to both promote angiogenesis by mediating migration and proliferation of SECs as well as to drive fibrogenic activation of HSCs<sup>[62]</sup>. These authors employed the specific inhibitor of integrin  $\alpha$ v $\beta$ 3, Cilengitide which was administered orally in two different animal models of liver fibrosis, BDL and chronic administration of

thioacetamide (TAA). The relevant point was that this treatment was very effective in decreasing the overall formation of neo-vessels in both portal areas of BDL and septal areas of TAA fibrotic rats. Unfortunately, despite the anti-fibrogenic *in vitro* effect exerted by Cilengitide on cultured HSC/MFs, *in vivo* treatment with this inhibitor was associated in both models with a significant increase in liver collagen deposition and up-regulation of other profibrogenic genes and of matrix metalloproteinase-13, that is an overall worsening of liver fibrosis, with no relevant effect on inflammatory response<sup>[62]</sup>.

The use of anti-angiogenic drugs and, in particular, those drugs which have already been approved for the treatment of HCC, may then represent an attractive alternative therapeutic tool to prevent or significantly slow down fibrosis progression towards cirrhosis, which also represents the main risk factor for liver cancer development, as well as the development of portal hypertension and its complications. However, a tempered final message is that angiogenesis inhibitors should be used with caution and carefully balanced in these patients, bearing in mind that angiogenesis unavoidably is a relevant event for wound healing and excessive blocking of angiogenesis may not represent the desired therapeutic objective. Clinical trials with an appropriate design and primary end-points are needed.

## CONCLUSION

Hepatic angiogenesis has been unequivocally described in CLDs, irrespective of aetiology, and in the most reliable experimental models of liver fibrosis and cirrhosis. Angiogenesis and related changes in angio-architecture have been proposed to favour fibrogenic progression of the disease towards the end-point of cirrhosis. Moreover, in CLDs these changes are believed to be involved in the increase of vascular resistance and portal hypertension as well as in the decrease of parenchymal perfusion. At the same time, hepatic angiogenesis has been proposed to modulate the genesis of portal-systemic shunts and increase splanchnic blood flow, potentially affecting complications of cirrhosis. Hypoxia and HIFs-related cellular responses are emerging as crucial in the overall scenario of CLD progression. Several cellular and molecular mechanisms have been identified which regulate the cross-talk between angiogenesis and fibrogenesis as well as between the different hepatic cell populations. In this scenario a major role is played by hypoxic hepatocytes, sinusoidal endothelial cells as well as hepatic MFs. Where MFs are concerned, whatever their origin, they are currently believed to represent a crucial cellular cross-road at the intersection between inflammation, angiogenesis and fibrogenesis. Indeed, these profibrogenic and pro-inflammatory cells also represent a cellular target for the action of pro-angiogenic cytokines as well as an effective source of VEGF and Ang-1.

Finally, experimental anti-angiogenic therapy has proven to be very effective in limiting the fibrogenic progression of animal models of CLDs. The use of

anti-angiogenic drugs, particularly of those that have already been approved for HCC therapy like Sorafenib, may then represent a rationale therapeutic option to limit the progression of human CLDs towards cirrhosis and its complications, including the development of HCC.

### Abstract

The tight junction (TJ) is a critical cellular component for maintenance of tissue integrity, cellular interactions and cell-cell communications, and physiologically functions as the "great wall" against external agents and the surrounding hostile environment. During the host-pathogen evolution, viruses somehow found the key to unlock the gate for their entry into cells and to exploit and exhaust the host cells. In the liver, an array of TJ molecules is localized along the bile canaliculi forming the blood-biliary barrier, where they play pivotal roles in paracellular permeability, bile secretion, and cell polarity. In pathology, certain hepatic TJ molecules mediate virus entry causing hepatitis infection; deregulation and functional abnormality of the TJ have also been implicated in triggering liver cancer development and metastasis. All these findings shed new insights on the understanding of hepatic TJs in the development of liver disease and provide new clues for potential intervention.

### INTRODUCTION

The liver is the core metabolic center in the mammalian body and is responsible for major physiological functions such as carbohydrate/amino acid/fatty acid metabolism, bile secretion, and detoxification. The cellular composition of the liver comprises specialized cell types - hepatocytes and nonparenchymal cells. In a normal adult liver, hepatocytes are epithelial cells and alone account for 60%-70% of the total cell mass. Hepatocytes adopt a polarized architecture, resulting in the formation of numerous cell plates in the liver. Because of the highly vascularized nature of the liver, this hepatic parenchyma is infiltrated by an extensive microcirculatory network<sup>[1,2]</sup>. In order to maintain this anatomical organization, hepatocytes are equipped basically with a vast variety of junctions, such as anchoring junctions, tight junctions (TJs), and gap junctions (GJs)<sup>[3-5]</sup>. These junctions are situated at the surface of the hepatocytes so as to mediate cell-cell contact and communication. This editorial focuses on the hepatocyte TJs - as the "cements" of the building block and the "door" for entry of hepatitis viruses. Deregulation of TJ expression and function dismantles

the architecture of the hepatic parenchyma and causes liver diseases and cancer.

## TJ IN THE LIVER: FROM STRUCTURAL ARCHITECTURE TO SIGNALING NETWORK

In the liver, TJs can be found in 2 places, associating with either hepatocytes or bile duct epithelial cells (cholangiocytes). Those associated with the former cell type are alternatively called the blood-biliary barrier (BBB). Here we review the hepatocyte-associated TJ that concentrates at the specialized location surrounding the bile canaliculi. In addition to modulating paracellular passage of small molecules and ions, this BBB functions to keep bile in the bile canaliculi and apart from the blood circulation. TJ in the liver also segregates the apical surface from the basolateral surface of the hepatocytes, thereby maintaining cell polarity<sup>[4]</sup>. Having the same TJ components as in other epithelia and endothelia, the TJ in the liver is also composed of claudins, occludin, junctional adhesion molecules (JAMs), and others such as coxsackievirus and adenovirus receptor (CAR)<sup>[6-11]</sup>.

Claudins constitute the largest TJ family; 24 claudins have been found in mammals and at least 7 of these, namely claudin-1, -2, -3, -4, -5, -7, and -10, have been studied in the liver. Most claudins are small molecules having molecular weights of approximate 22-27 kDa. They are tetra-span molecules with the amino-terminus and carboxyl-terminus in the cell cytoplasm, and they possess 2 extracellular loops and one intracellular loop. For sealing the intercellular gap, claudin needs to interact with other claudins in the adjacent cell through its extracellular loops<sup>[12,13]</sup>. Occludin is the first studied TJ integral molecule. It has similar structural features to that of claudin, being a molecule with 4 transmembrane domains and utilizes a similar binding mechanism to that of claudin. However, it differs from claudin in its large molecular weight of 65 kDa<sup>[11,14]</sup>. Another variant of occludin, occludin 1B, has been identified and it differs from occludin in having an extended amino-terminus. Both of them are found in mouse livers<sup>[15]</sup>.

JAM is a TJ molecule which has gained much attention recently. It is a single-pass membrane protein with its amino-terminus in the extracellular region and carboxyl-terminus in the cytoplasm. As the component of a barrier, a single JAM molecule needs to couple with another JAM in an adjacent cell. At least 4 members of JAM have been identified and JAM-1, JAM-2, and JAM-3 have been found in mouse livers<sup>[10,11,16]</sup>.

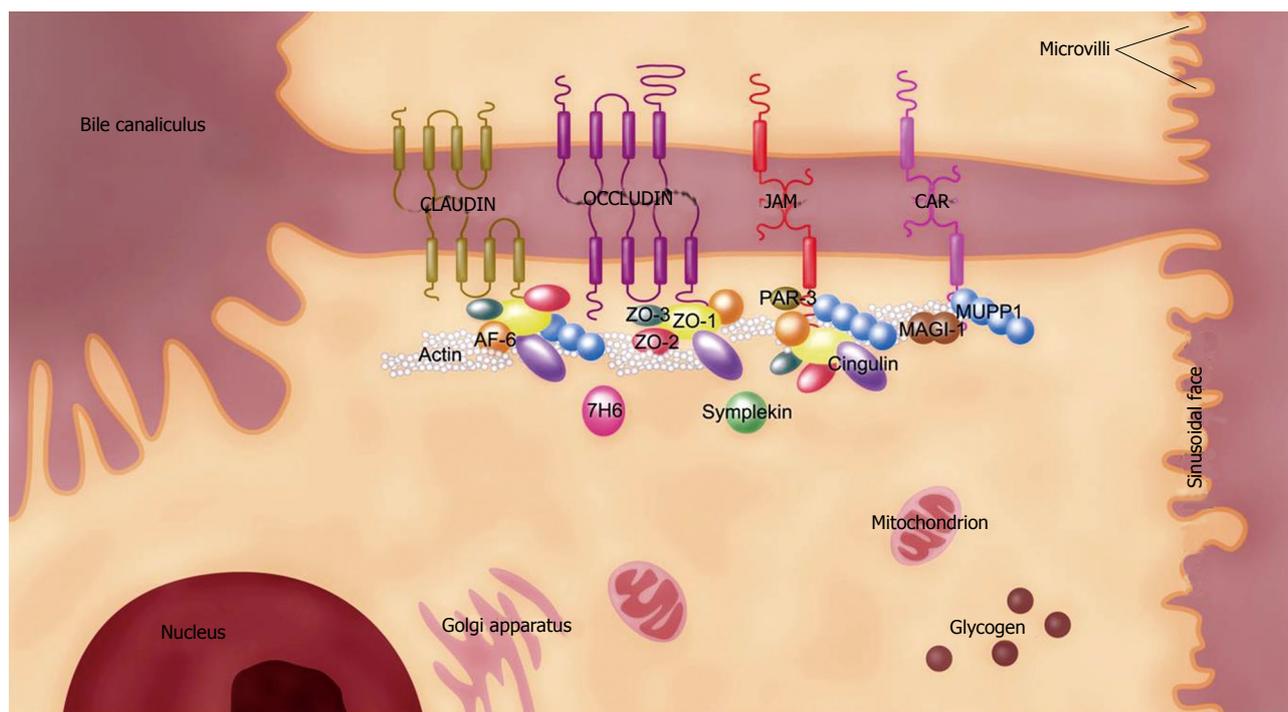

CAR was known originally as a new class of viral receptor, belonging to the immunoglobulin-like family and further studies demonstrated that CAR also had TJ functions<sup>[17]</sup>. Of the 3 isoforms of CAR (i.e. CAR-1, CAR-2, and CAR-3), only CAR-2 has been positively identified in hepatocytes and both CAR-1 and CAR-2 are associated with cholangiocytes in mouse livers<sup>[7]</sup>. As in other organs, these integral TJ proteins interact with

various scaffolding proteins to ensure structural integrity.

A plethora of adaptors and peripheral proteins are known to be present and associated with claudins, occludin, JAMs, and CARs. Adaptors such as zonula occludens-1 (ZO-1) act as a bridge linking the integral proteins to the underlying actin filament<sup>[18-20]</sup>. Cingulin, symplekin, and MAGI-1 (membrane-associated guanylate kinase inverted-1) are other peripheral proteins at TJs, and some of them have also been demonstrated in the liver<sup>[3,21-24]</sup>. By this way, a high degree of structural architecture is established at the TJ strand guarding the selective permeability barrier in the liver<sup>[25]</sup> (Figure 1).

Apart from its barrier functions, recent studies have also elucidated the other roles of the TJ as a core component in the signaling network, in particular for those junctional complexes concentrating at the BBB. Accumulating evidence suggests that the junction does not function alone on the plasma membrane, but different junctions can interact with each other either directly or indirectly. Studies performed in different systems demonstrated a disruption of one junction type could lead to loss or gain of function of another junction type, emphasizing the significance of inter-junctional crosstalk<sup>[26-28]</sup>. Epithelial cells, including hepatic cells, adopt this kind of junction-junction regulation. It is noted that enforced expression of connexin 32 into mouse hepatocytes derived from connexin 32-deficient mice results in TJ formation, accompanied by induced expression of occludin, claudin-1 and ZO-1, thereby leading to establishment of cell polarity<sup>[29]</sup>. In addition, using the same experiment setup induced the expressions of another junction protein MAGI-1 at the TJ in connexin 32 transfectants<sup>[30]</sup>. These findings unequivocally demonstrate the presence of a macrocomplex in the liver composed of at least a TJ and GJ<sup>[4]</sup>. Solid evidence from other studies also suggested the possible involvement of the TJ in manipulating other junctions such as the adherens junction (AJ). For instance, an abnormality of JAM-1 in hepatoma HepG2 cells induced the production of an AJ protein E-cadherin<sup>[31]</sup>. Our current understanding is that ZO-1 acts as the moderator in coordinating the cellular dynamics of various associated junctions and maintains the structural functionality of this multi-junctional network<sup>[32-34]</sup>.

Several cellular proteins, such as protein kinases and phosphatases, are some of the major regulators of junctions. Since most of them have numerous substrates, events of phosphorylation or dephosphorylation can modulate the status of components related to certain junctions. The p38 mitogen-activated protein kinase (MAPK) is a serine/threonine kinase that phosphorylates a handful of substrates including those associated with TJs<sup>[35]</sup>. Treatment with SB203580, a p38 MAPK inhibitor, led to strengthening of the TJ with a concomitant increase in claudin-1 in rat livers after partial hepatectomy<sup>[36]</sup>. Other events triggered by cytokines and growth factors are also involved in the regulation of TJ dynamics<sup>[37,38]</sup>. For instance, incubation of rodent hepatocytes with a multifunctional cytokine oncostatin M triggered the

**Figure 1 Molecular structure of the TJ in the mammalian liver.** The TJ in the liver is associated with hepatocytes and bile duct cells. TJ location around the bile canalicular between 2 adjacent hepatocytes is shown. For simplicity, the molecular structure depicted in this figure represents the TJ molecules found in the mammalian liver. Claudin, occludin, JAM, and CAR are 4 core units for constituting TJ by uniting a panel of peripheral proteins like ZO-1 to form multiprotein complexes. TJ molecules display differential localizations in the mammalian liver, such that some of them like human symplekin and mouse CAR-2 are associated with both hepatocytes and bile duct cells while others, such as mouse CAR-1, are only found in the latter cell type. CAR: Coxsackievirus and adenovirus receptor; JAM: Junctional adhesion molecule; MAGI-1: Membrane-associated guanylate kinase inverted-1; MUPP1: Multiple PDZ domain protein-1; PAR-3: Partitioning defective 3 homolog; TJ: Tight junction; ZO: Zonula occludens.

production of claudin-2 and subsequently strengthened the TJ barrier<sup>[39]</sup>. Further, the transforming growth factor- $\beta$  (TGF- $\beta$ ) could reduce the production of claudin-1 and weaken the barrier function in rat hepatocytes<sup>[40]</sup>.

## TJ AND LIVER-RELATED DISEASES

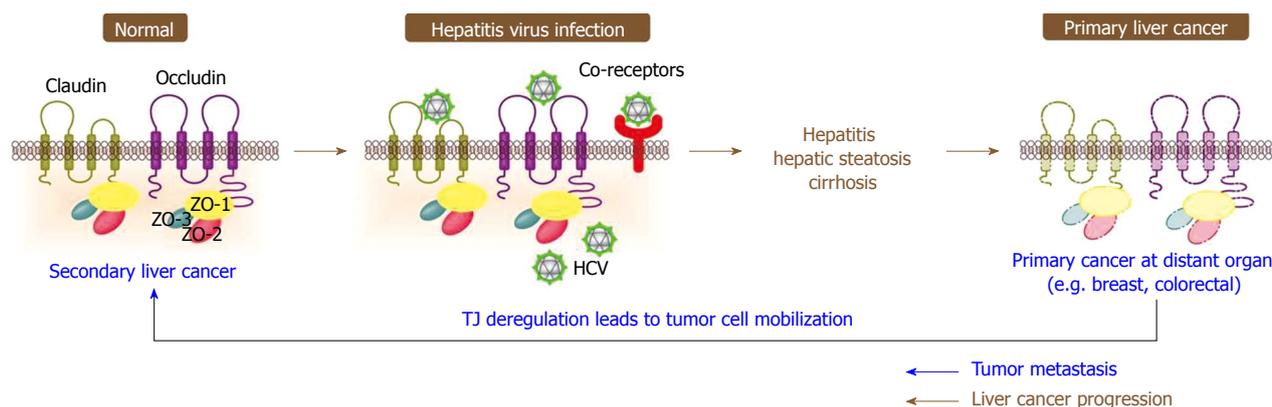

### Hepatitis

Hepatitis is an infection of the liver caused commonly by hepatitis viruses such as hepatitis B and C. At least 7 hepatitis viruses are known today and new species are being identified<sup>[41]</sup>. Hepatitis C virus (HCV) is the best studied for its ability to bind to TJ molecules on hepatocytes, and these molecules act as co-receptors for HCV entry<sup>[42]</sup>. The concept of junction proteins mediating viral entry is not restricted to the hepatitis virus, but is apparent for several other viruses including the adenovirus and coxsackievirus<sup>[43]</sup>. For the scenario of HCV infection, occludin and claudin-1 have been determined to be 2 key molecules for HCV entry<sup>[44,45]</sup>. Some reports also demonstrated other molecules including CD81 and human scavenger receptor class B member 1 (SR-BI) as co-receptors for HCV entry<sup>[46,47]</sup> and the expression levels of some of these receptors define the viral entry rate<sup>[48]</sup>. Cooperation between these receptors and TJ molecules is essential for viral entry into hepatocytes. Several studies provided further evidence indicating that the events occurred in the hepatocytes

after HCV infection. Hepatoma HuH-7 cells, having genomic replicons of HCV, could alter TJ dynamics, such that a disarrangement of TJ components was found and retention of occludin in the endoplasmic reticulum was noted<sup>[49]</sup>. Internalization of HCV is accompanied by an induced synthesis of fatty acid synthase, which is an enzyme responsible for fatty acid synthesis, and this event is associated with the production of claudin-1, but not CD81, in hepatoma HuH-7 cells<sup>[50]</sup>. This can partly explain why HCV infection frequently leads to steatosis, a fatty liver-related disease. In addition to fatty acid synthase, protein kinase A has an important role in HCV infection, since an aberration in protein kinase A function in hepatoma HuH-7 cells led to a disorganization of claudin-1 and reduced the infection susceptibility<sup>[51]</sup>. Together, these findings suggest an explicit role of TJ molecules, especially claudin-1 and occludin, in mediating HCV infection (Figure 2).

### Liver cancer

Liver cancer or hepatocellular carcinoma (HCC) is one of the most aggressive liver malignancies worldwide. The development of HCC is a complex process that is not totally established even after several decades of research. In most cases, HCC results from a pre-neoplastic inflammation of the diseased liver and is the end stage of a progressive worsening of liver conditions originating from hepatitis or cirrhotic livers, encompassing 3 phases

**Figure 2** The TJ at different stages of liver cancer progression and distant liver metastasis. During viral infection, HCV binds onto several TJ molecules (claudin-1 and occludin) and co-receptors (CD81 and SR-BI) on hepatocytes before its internalization. This event leads to hepatic steatosis and/or cirrhosis before the subsequent development of primary liver cancer that is associated with TJ deregulation. For metastatic liver cancer originating from the intrahepatic site or distant organs such as breast and colorectum, there is an initial loss of TJ molecules at the primary tumor site and a subsequent gain of these molecules in the liver with tumor cell colonization. HCV: Hepatitis C virus; SR-BI: Scavenger receptor class B member-1.

Molecules	Expression in HCC <sup>1</sup>	Clinical correlations	Ref.
CAR	Reduced	Poor tumor differentiation	[64]
Claudin-1	Reduced	Poor tumor differentiation, tumor invasion, poor survival	[63]
Claudin-10	Higher	Tumor recurrence	[67]
Occludin	Reduced	-	[9]
Symplekin	Reduced	Poor tumor differentiation	[3]
ZO-1	Reduced	-	[9]

<sup>1</sup>Relative expression of TJ molecules in HCC tissues compared to normal or adjacent non-tumor tissues. TJ: Tight junction; HCC: Hepatocellular carcinoma; CAR: Coxsackievirus and adenovirus receptor.

of development - molecular, preclinical, and clinical<sup>[52]</sup>. At the molecular level, this malignant transformation of the liver is accompanied by a stepwise change in genetic and proteomic information, which can be readily revealed using laboratory technologies including gene microarray and gel- or non-gel-based proteomics profiling, coupled with mass spectrometry<sup>[53-55]</sup>. As a result of rapid developments in molecular and profiling techniques, the gene, protein, and microRNA data related to HCC are gradually being decoded<sup>[56]</sup>. A handful of molecules, such as heat shock proteins and cadherins, and different pathways, such as Wnt and TGF- $\beta$  pathways, have been determined to be HCC-related<sup>[56-60]</sup>. The newly derived information assists the construction of the molecular network of HCC and enhances our knowledge of this cancer.

### Primary tumors in the liver

Tumor nodules originating in the liver are generally termed as primary tumors. During hepatocarcinogenesis, the liver usually undergoes several phases of transition from pre-neoplasia, dysplasia, to neoplasia<sup>[61]</sup>. Several TJ molecules are regarded as HCC biomarkers<sup>[55,62]</sup>. An endogenous expression of certain claudins is found in the normal adult liver and their expression is attenuated when HCC develops. It is noted that claudin-1 has

reduced expression in cancerous liver when compared to its healthy counterpart<sup>[63]</sup>. A general reduction in the levels of occludin, ZO-1, and CAR has been found in HCC when compared to normal liver<sup>[9,64]</sup>. Also, there is a gradual decrease in the level of 7H6 TJ-associated antigen in rats during hepatocarcinogenesis<sup>[65]</sup>. Apart from these molecules, other TJ molecules, such as JAM and cingulin, are present in hepatic cells<sup>[31,66]</sup>, but not all of these are associated with HCC. Those claudins with a high expression in normal liver have a role in liver physiology by maintaining a functional TJ barrier, whereas those claudins with elevated expression in the cancerous liver are likely to be involved in tumor formation. Sometimes these biomarkers not only indicate the advent of tumors, but can also be prognostic in nature (Table 1). A loss of claudin-1 expression in resected HCC indicates poor differentiation and high invasiveness of the tumor, and is associated with poor outcomes of patients<sup>[63]</sup>. Similarly for other TJ molecules, a reduced CAR expression in resected livers is correlated with poor differentiation of HCC<sup>[64]</sup>. However, Cheung *et al*<sup>[67]</sup> linked the high expression of claudin-10 in HCC with the high incidence of postoperative tumor recurrence in patients.

With regard to biological significance, these biomarkers usually demonstrate gain- or loss-of-function in HCC. For instance, the expression of claudin-1 is associated preferentially with the fetal cell type of human hepatoblastoma, but not the highly proliferating embryonal cell type, with expression of proliferating cell nuclear antigen (PCNA) and Ki-67, suggesting its expression is negatively correlated with rapid cell growth and division<sup>[68]</sup>. This anti-proliferative behavior of hepatic claudin-1 is further supported by a study showing a loss of claudin-1 associated with tumor aggressiveness<sup>[63]</sup>. An overexpression of claudin-10 is linked to poor outcome of HCC patients after hepatic resection. To prove the tumorigenic features of this molecule, an overexpression experiment was performed in claudin-10-deficient Hep3B hepatoma cells and an induction of tumor phenotypes was observed. In the reciprocal experiment

using RNA interference (RNAi) to silence claudin-10 in HLE hepatoma cells with a high level of claudin-10, an alleviation of tumorigenic potential accompanied by reduced cell invasion was found<sup>[69]</sup>. By these approaches, molecules can be studied for their tumorigenic properties. Besides their intrinsic tumorigenic properties being the subject of intense interest in research, TJ molecules have also been studied with regard to their associated pathways, some of which have been unfolded successfully. Borlak *et al.*<sup>[70]</sup> utilized an epidermal growth factor-induced HCC mouse model showing a positive effect of this growth factor in inducing claudin-7 in small HCCs. Also, vascular endothelial growth factor (VEGF)-treated HepG2 hepatoma cells had disruptive TJs accompanied by reduced occludin expression, suggesting VEGF as one factor triggering the spread of tumor cells into the normal liver parenchyma<sup>[71]</sup>. All these findings implicate the direct involvement of TJ molecules in the presentation of tumor phenotypes and the tumor-related signaling pathways, suggesting their interference may counteract the process of HCC. Therefore, TJ molecules may be another class of therapeutic target for HCC.

### Metastatic tumors in liver

Metastatic tumors initiated elsewhere in the body may spread to and colonize the liver. Angiogenesis is a prerequisite process for tumor metastasis, enabling the migration of tumor cells through the circulatory system of the body from one site to the other<sup>[72]</sup>. A number of factors such as growth factors and chemokines are important in triggering this event<sup>[73,74]</sup>. For tumor cells to metastasize, loss of TJ function is usually observed in cancer cells prior to this process<sup>[75]</sup>. Of the TJ molecules, claudin-7, ZO-1, and other emerging ones are associated with tumor metastasis. Thus, a decrease of claudin-7 in tumor tissues is associated with tumor metastasis in patients with breast carcinoma<sup>[76]</sup>. This finding is further validated by a separate gene microarray study, in which breast cancer metastasis to the liver is associated with a reduced expression of a panel of TJ molecules including claudin-4 and ZO-1, in addition to claudin-7<sup>[77]</sup>. For lung cancer, overexpression of claudin-1 in human lung adenocarcinoma cells reduced the metastatic potentials of tumor cells<sup>[78]</sup>. Apart from these 2 cancer types, elimination of claudin-7 is frequently observed in colorectal cancer, and is clinically related to the event of tumor cell invasion into the blood circulation and the eventual development of tumor masses in the liver<sup>[79]</sup>. In addition, malfunction of ZO-1 is observed after its phosphorylation, which also induces the migration of colorectal tumor cells into the liver<sup>[80]</sup>. Interestingly, there is a restoration of the expression of TJ molecules in tumor cells after metastasis to the liver from a distant organ. It is noted that a re-expression of ZO-1 is observed in colorectal cancer cells after metastasis to the liver when compared to those developing metastatic potential at the primary cancer site<sup>[80]</sup>. Similar re-expression of claudins such as claudin-1 and claudin-4 in liver-residing colorectal cancer cells is reported in another study examining colorectal tumor

metastasis<sup>[81]</sup>. Therefore, it is clear that loss of TJ function is a key factor triggering the induction of metastatic potential in tumor cells to other sites including the liver, while a restoration of its function is needed for tumor cells to colonize in the liver.

## CONCLUSION

In the liver, TJ is found to be associated with bile duct cells and hepatocytes. As hepatocytes are the most predominant cell type in the liver and the most studied in liver diseases, we focused our discussion on the role of hepatocyte-associated TJ molecules in hepatitis infection and liver cancer. TJs found in hepatocytes are also known as the BBB, keeping the bile in the bile canaliculi away from the blood circulation. Emerging evidence has further demonstrated the direct involvement of TJ molecules as co-receptors for HCV. On the other hand, accumulating evidence support the notion that deregulation of TJ molecules is frequently associated with increased incidence of HCC and poor prognosis of patients, signifying their putative use as biomarkers for diagnosis and prognosis of this liver malignancy. Molecules with induced expression in HCC are predicted to be tumor-inducing, while those with reduced expression are likely to be anti-tumor molecules. Proof-of-principle studies by means of RNAi or overexpression should enhance our knowledge of the roles of specific TJ molecules in liver diseases. Based on previous findings of TJ molecules as viral receptors, it is highly possible that a blocking peptide or antibody can be developed to prevent the binding of the viral particles to the TJ receptors on hepatocytes. This can open a new study area for therapeutic targeting of the TJ. Those TJ molecules with tumor-inducing properties are potential therapeutic targets for HCC. More in-depth studies should be performed to find antagonists to inhibit the functions of these molecules or to block their specific signaling pathways. With regard to advancement of HCC diagnosis, novel TJ molecules may be useful as HCC biomarkers. Further studies should be performed to investigate whether these biomarkers are eligible as supplemental criteria to diagnose HCC in patients with low levels of serum alpha-fetoprotein who constitute up to one-third of HCC cases. Therefore, study of the TJ in the liver can increase the clinical usefulness of this molecule in liver diseases.

## ACKNOWLEDGMENTS

We would like to thank Professor Ronnie Poon for his insightful comments and advice on HCC clinical medicine. We would like to acknowledge Mr. Kar-wai Leung for preparing the illustrations.

### Abstract

Collagenous sprue has traditionally been defined as a small intestinal mucosal disorder characterized by persistent diarrhea, severe malabsorption with multiple nutrient deficiencies and progressive weight loss. Pathologically, a severe to variably severe "flattened" mucosal biopsy lesion with distinctive sub-epithelial deposits in the lamina propria region is detected. Histochemical stains and ultrastructural studies have confirmed that these deposits contain collagens. Often, an initial diagnosis of celiac disease is considered but no continued response to treatment with a gluten-free diet occurs. Recent reports indicate an intimate relationship between collagenous sprue and celiac disease, sometimes with concomitant T-cell enteropathy. In addition, permanent disappearance of these deposits after resection of a localized colon cancer suggested that this disorder could actually represent a paraneoplastic morphologic marker of an occult malignancy. Studies showing either gastric or colonic involvement (or both) with this unusual collagenous inflammatory mucosal process may also reflect a far more extensive and heterogeneous process than previously appreciated.

**Key words:** Collagenous sprue; Celiac disease; Lymphoma; Paraneoplastic disease

### INTRODUCTION

In 1970, Weinstein *et al*<sup>[1]</sup> reported on a small intestinal mucosal biopsy lesion from a 51-year-old female initially thought to have celiac disease as histopathological changes included severely flattened villi. However, a long-term response to a gluten-free diet failed to develop. Subsequently, routine hematoxylin-eosin stained biopsies showed a prominent band-like deposit of sub-epithelial hyaline material in the lamina propria region of the small bowel. The deposit had the histochemical features of collagen and ultrastructural studies confirmed an electron-dense material with the typical 640 Å axial periodicity of collagen fibers. Her symptoms transiently improved with corticosteroids, but she then developed worsening diarrhea, severe malabsorption and progressive weight loss. Post-mortem examination showed very extensive pathologic changes in the proximal small intestine with sub-epithelial eosinophilic hyaline deposits of varying thickness. Short segments of normal mucosa were present in the distal small intestine. Two earlier reports by Schein<sup>[2]</sup> in 1947 and Hourihane<sup>[3]</sup> in 1963 may have reflected the same biopsy lesions (although in the latter, ileal involvement was also present).

Collagenous sprue was thought to be a "new" form of malabsorptive disorder with the specific clinical and pathological features: (1) persistent diarrhea with pan-malabsorption causing nutrient deficiencies and progressive weight loss; (2) a biopsy lesion included a unique

morphologic marker, a sub-epithelial band-like deposit with histochemical and ultrastructural features of collagen; (3) other pathologic changes of untreated celiac disease were present, but not responsive to a gluten-free diet; and (4) diffuse and patchy mucosal changes of variable severity, localized mainly in the proximal small intestine.

## OTHER CAUSES OF SEVERE “FLAT” BIOPSY LESION

Traditionally, the diagnosis of celiac disease (or gluten-sensitive enteropathy) has been established pathologically and depended on two sequential criteria: first, documentation of the typical histopathologic features of untreated disease in small bowel biopsies, and, second, a response to a gluten-free diet. Otherwise, celiac disease, even if present, cannot be diagnosed with certainty. In some cases, a “flattened” biopsy appearance may be present, but a gluten-free diet response has not been documented. This may require months to years<sup>[4]</sup>. Some investigators have loosely labeled these cases as refractory celiac disease, but this label should be reserved for those who show an initial (and documented) response to a gluten-free diet followed by later development of recurrent symptoms and biopsy changes. The most commonly reported causes for recurrent symptoms and biopsy changes include poor dietary compliance or inadvertent ingestion of a ubiquitous gluten-containing food (e.g. pill capsules, communion wafers). In these cases, removal of the offending gluten should be sufficient to resolve symptoms and biopsy changes. A second or superimposed cause (e.g. infection, folate or zinc deficiency) could also develop. In addition, another entirely separate cause for a “flat” biopsy lesion could be present<sup>[5]</sup>, as the initial true diagnosis (e.g. Crohn’s disease in duodenum without mucosal granulomas) may have been missed<sup>[6]</sup> or an associated or complicating disease (e.g. collagenous colitis, lymphoma) could have developed. In these patients, symptoms and biopsy changes may be improved with specific treatment, but not with a gluten-free diet. Finally, another “wastebasket” group with a “flat” biopsy appearance that has never been responsive to a gluten-free diet may be present, so-called sprue-like intestinal disease or unclassified sprue<sup>[7]</sup>.

## RELATIONSHIP WITH CELIAC DISEASE

Collagenous sprue has a “flat” biopsy appearance, like untreated celiac disease, but fails to show a persistent response to a gluten-free diet. In addition, collagenous sprue is characterized by the appearance of distinctive subepithelial collagen deposits. Some believed that this histopathological change might simply represent a prognostic pathologic marker for a poor outcome in celiac disease<sup>[8]</sup>. Others, however, viewed collagenous sprue as a new and previously unrecognized small bowel disorder<sup>[9]</sup>. Later reports have also described

further elements between celiac disease and collagenous sprue. Common clinical features include hyposplenism and positive endomysial antibodies that have been documented in both entities<sup>[10]</sup>. In collagenous sprue, similar complications recorded in celiac disease may also occur, including both T-cell and B-cell lymphomas<sup>[11,12]</sup>.

## NATURAL HISTORY AND LOCALIZATION

Collagen deposits may also be present in the colon (i.e. collagenous colitis) or even stomach (i.e. collagenous gastritis)<sup>[13]</sup>. An associated inflammatory process in either colonic or gastric mucosa, or both, is also present, usually with epithelial lymphocytosis. Interestingly, collagenous or lymphocytic colitis as well as collagenous or lymphocytic gastritis are all associated with biopsy-defined celiac disease<sup>[13-15]</sup>. These pathological changes also suggest that a far more extensive pathologic process may occur elsewhere in the gastrointestinal tract with collagenous sprue.

Previously published reports noted that the natural history of collagenous sprue was characterized by worsening malabsorption with an inevitably fatal outcome. In most patients, diarrhea and progressive weight loss occurred, and rarely, severe abdominal pain, sometimes with an associated vasculitis, was recorded<sup>[16]</sup>. However, more recently, independent reports with extensive biopsy studies have documented complete resolution of the lesion for prolonged periods after corticosteroid treatment<sup>[17,18]</sup> suggesting that the lesion may be reversed, at least temporarily, for extended periods, even years. Immunosuppressants have also been used in some cases.

## DISEASE HETEROGENEITY

The etiology and pathogenesis of these collagenous deposits are not known, however, different causes could be responsible. In addition to celiac disease, collagenous sprue has not only been complicated with T-cell lymphoma<sup>[12]</sup>, but associated with its co-occurrence<sup>[19]</sup>. Finally, collagen deposits in both small and large intestines were detected with an apparently coincidental, but localized, colon cancer<sup>[20]</sup>. Later, clinical and histopathological changes were resolved after the cancer was resected, suggesting that these collagen deposits could represent a paraneoplastic morphologic marker of occult malignant disease.

## FUTURE DIRECTIONS

Recent reports suggest that collagenous sprue may be more heterogeneous than previously appreciated. This has been reflected in frequently associated, but variable collagenous mucosal inflammatory changes elsewhere in the gastrointestinal tract, differential responses to treatment, particularly with steroids, and its association with other conditions, including malignant disease as a possible paraneoplastic morphologic marker.

Treatment of this condition remains an empirical exercise. Steroids and/or immunosuppressant agents have been used, but, to date, this approach has resulted in only rare success.

### INTRODUCTION

Ulcerative colitis (UC) and Crohn's disease (CD) are the two major forms of chronic relapsing inflammatory bowel disease (IBD). Apart from overlapping epidemiological, clinical, radiological, endoscopic and histological characteristics<sup>[1,2]</sup> between UC and CD, there are clear differences in the extent of inflammation in the gastrointestinal tract and in several immunological parameters<sup>[3-5]</sup> suggesting that they are distinct disease processes. The pathogenesis of IBD seems to be more complex than one single cause and probably involves an interaction between genetic predisposing factors<sup>[6-8]</sup>, exogenous and endogenous triggers<sup>[3,9-14]</sup>, and modifying factors<sup>[3,15,16]</sup>. The outcome of these interactions is a spontaneously relapsing and remitting inflammatory process in intestinal mucosa associated with recruitment and activation of lymphocytes, macrophages and other inflammatory cells<sup>[3,17-20]</sup>.

Extraintestinal and systemic manifestations occur frequently in patients with IBD<sup>[20-25]</sup>. These various disease states can be diagnosed before, concomitant with, or after the diagnosis of a specific type of IBD. Two large case studies have demonstrated that between 25% and 36% of patients with either type of idiopathic IBD will have at least one such associated disease<sup>[22-23]</sup>. Yamamoto-Furusho *et al*<sup>[8]</sup> found that extraintestinal manifestations were present in 41.5% of 848 cases with UC. More than 100 systemic complications involving almost every organ system in the body have been described<sup>[26]</sup>. The

### Abstract

Inflammatory bowel disease (IBD) has been associated with either clinical or subclinical airway and parenchymal lung involvement and interstitial lung complications. Several studies have reported that atopy has a high prevalence in IBD patients. Overlapping allergic disorders seem to be present in both the respiratory and gastrointestinal systems. The purpose of this review is to update clinicians on recent available literature and to discuss the need for a highly suspicious approach by clinicians.

**Peer reviewers:** Dr. Zoran Krivokapic, Professor, MD, FRCS, Institute for Digestive Disease, First Surgical Clinic, Clinical Center of Serbia, 6, Dr Koste Todorovica, Belgrade, 11000, Serbia; Javier Martin, MD, PhD, Department of Immunology, Institute of Parasitology and Biomedicine López-Neyra, P.T.

spectrum, the frequency and the temporal relation of the complications have led to the hypothesis that IBD is a systemic disorder<sup>[22-23,26]</sup>.

IBD is associated with a wide variety of extraintestinal lesions in many organs and over some decades the pattern has changed and the lung is regarded as one of these affected organs<sup>[21,26-31]</sup>. In recent years a few hundred cases with pulmonary involvement and IBD have been reported and in that way pulmonary involvement has been proved to be common. A growing number of studies in the literature have reported either clinical or latent pulmonary involvement in patients with IBD<sup>[29,31-34]</sup>. In this review we will focus on the extraintestinal manifestations that are associated with lungs and airways. In an attempt to classify the reported lung manifestations in patients with IBD in a more useful way, the manifestations were distinguished as follows: (1) involvement of airways; (2) pulmonary function testing abnormalities; and (3) diffuse or localized interstitial lung complications caused by either disease or treatment received. Finally, studies regarding the relationship between allergy and IBD will be discussed in detail.

## IBD AND AIRWAYS

The manifestations of IBD in airways include, chronic bronchial suppuration particularly in patients with UC<sup>[31,34-36]</sup>, bronchiectasis<sup>[32,37-40]</sup>, localized obstruction of upper airways<sup>[41]</sup>, bronchiolitis obliterans organizing pneumonia<sup>[32,42,43]</sup>, granulomatous bronchiolitis<sup>[44]</sup>, tracheobronchitis<sup>[45,46]</sup>, bronchiolitis obliterans<sup>[47]</sup>, tracheobronchial stenosis<sup>[48]</sup> and diffuse obstructive disease<sup>[34,49]</sup>. Obstructive disease was not confirmed in some studies<sup>[50]</sup>. An increased risk of both UC and CD in chronic obstructive pulmonary disease (COPD) patients has been reported in some studies, focusing attention on the association between airway diseases (AD) and IBD<sup>[51]</sup>. We have reported a small airway dysfunction, detected by density dependence methods, in patients with IBD<sup>[52]</sup>. In the study by Louis *et al*<sup>[53]</sup>, patients with IBD, free of pulmonary symptoms, independently of the presence of atopy, showed bronchial hyperresponsiveness. This interesting finding could lead to the hypothesis that local mucosal inflammation in the intestine is responsible for the mild airway inflammation and not atopy. This hypothesis is not new. Basal cell hyperplasia, membrane thickening and submucosal inflammation have been reported in patients with UC and bronchial suppuration<sup>[36]</sup>. CD may affect the oral cavity and the colon<sup>[26,54,55]</sup> while both UC<sup>[34,41]</sup> and CD<sup>[56]</sup> have been reported to involve the larynx. There are also some morphological and developmental similarities between colonic and bronchial epithelium. Both are derived from the primitive gut, whereas the lungs arise from the laryngo-tracheal bud. Both are composed of columnar epithelium with goblet cells and submucosal mucous glands. Furthermore, there is increasing evidence that an immune system specific to the gastrointestinal tract common to all mucosal surfaces exists<sup>[57]</sup>, in which lymphocytes are sensitized to antigens at one mucosal site and by circulation are localized and produce inflammation in other mucosal surfaces<sup>[53,58-61]</sup>.

## PULMONARY FUNCTION TESTING ABNORMALITIES

Previous reports concerning pulmonary function abnormalities in patients with IBD are conflicting. In some studies no differences in pulmonary function tests (PFTs) between patients with IBD and the control group were found<sup>[49,62]</sup>. In the study by Neilly *et al*<sup>[49]</sup> airway obstruction was the most common finding affecting patients with CD (45%). However, the indices of airway obstruction were not significantly different from those obtained in age-, sex- and smoking-matched controls. As discussed above, Louis *et al*<sup>[53]</sup> reported an increased bronchial responsiveness in IBD patients, while the baseline lung function tests were within the normal range. In the study by Mohamed-Hussein *et al*<sup>[63]</sup>, fifteen out of 26 patients with UC had an important impairment in PFTs. In the study by Herrlinger *et al*<sup>[64]</sup>, the impairment in PFTs was more pronounced in IBD patients with active disease than in those with inactive disease.

Pulmonary diffusion capacity (TLCO) is often impaired in IBD patients. Heatley *et al*<sup>[65]</sup> found an increased prevalence of TLCO impairment in 25% of patients with CD. Reduction of TLCO in patients with IBD has been reported in various studies<sup>[61,64,66-69]</sup>. Eade *et al*<sup>[66]</sup> and Bonniere *et al*<sup>[59]</sup> found that the reduced TLCO or other PFTs parameters were not correlated with the location and severity of IBD or with the concurrent medication mode<sup>[59,66]</sup>. We examined 132 patients, 47 (17 female, 30 male) with CD and 85 (35 female, 50 male) mean age 40 years with UC. The main finding of our study was a high prevalence of impaired TLCO in patients with CD and UC suggesting involvement of the lung parenchyma<sup>[70]</sup>. All other PFTs parameters were abnormal in a high percentage of patients, however, they did not show statistically significant differences from those in the control group. Our data suggest that the impairment of TLCO was statistically significantly higher in patients with exacerbation of disease than in remission<sup>[70]</sup>. This finding is in accordance with other studies<sup>[61,65,68-70]</sup> which reported a higher prevalence of impaired TLCO among patients with active IBD disease as compared to patients in remission. In contrast, Douglas *et al*<sup>[71]</sup> reported a reduced gas transfer factor in 16% of 44 patients with IBD but these abnormalities were not related to disease activity. The reduction in gas transfer factor indicates damage to lung parenchyma. The nature of this lung involvement remains debatable. However, some explanations will be discussed in the following section concerning the relationship between IBD and interstitial lung complications.

## INTERSTITIAL LUNG COMPLICATIONS

Interstitial lung involvement has been reported to accompany both clinical IBD entities, UC<sup>[72-78]</sup> and CD<sup>[79-83]</sup>. The interstitial lung infiltrates have been proven histologically to be either pulmonary vasculitis<sup>[76,77,84]</sup> or more often granulomatous disease<sup>[74,79,80,82,83,85,86]</sup>.

Table 1 Studies on the relationship between IBD and atopic features

Group	Protocol	Atopy history	Skin prick tests	IgE	Ref.
CD: 11 UC: 19 Normals: 16	Skin prick tests SIgE Atopy history	Allergic symptoms were more prevalent in IBD <i>vs</i> controls $P < 0.007$ (in UC $P < 0.004$ )	IBD <i>vs</i> control $P < 0.02$	No statistically significant differences	[109]
UC: 14 CD: 20 Controls: 72	IgA, IgG, IgM IgE	-	-	Increased IgG, IgM and IgE in patients <i>vs</i> controls ( $P < 0.01$ )	[114]
UC: 300 CD: 200 Controls: 254	Questionnaire	Asthma, hay fever, allergic rhinitis; UC <i>vs</i> Controls: $P < 0.02$ ; CD <i>vs</i> Controls: NS; Eczema-Any atopy-Family history; Both UC & CD <i>vs</i> controls: $P < 0.001$	-	-	[117]
UC: 39 CD: 35 Healthy: 37	Skin prick tests to various common allergens	23.1% in UC; 22.9% in CD; 21.4% in disease controls; 20% among healthy subjects	14/39 in UC and 12/35 in CD in food allergens ( $P < 0.001$ )	No differences	[119]
UC: 39 CD: 19 Normals: 20	Skin prick tests to milk proteins	Positive: 15.7% of UC and 13.3% of CD; Significant difference between patients and healthy subjects	No differences	No differences	[120]
UC: 63 CD: 59 Controls: 103	Skin prick tests to various common allergens	No difference between patients and healthy subjects	No difference between patients and healthy subjects	No difference between patients and healthy subjects	[121]
CD: 308 Normals: 930	Questionnaire	Atopic disease was more common in CD <i>vs</i> normal ( $P = 0.001$ ); Atopic eczema was twice as common in CD <i>vs</i> normal ( $P = 0.001$ )	-	-	[124]
UC: 50 Healthy: 50	Skin prick/patch tests to airborne, food, contact allergens SIgE Atopy history and family history	Allergic symptoms were more prevalent in UC and first degree relatives than in controls ( $P < 0.0001$ , $P = 0.008$ )	UC <i>vs</i> controls; Immediate type hypersensitivity $P = 0.01$ ; Delayed type hypersensitivity $P = 0.03$	IgE levels were higher in UC than in controls $P = 0.02$	[125]

IBD: Inflammatory bowel disease; CD: Crohn's disease; UC: Ulcerative colitis.

Treatment with corticosteroids<sup>[75,78]</sup> or with appropriate medication such as sulfasalazine or mesalamine for the basic gastrointestinal disease<sup>[74]</sup> appeared to be satisfactory for both diseases. Pneumonitis, in contrast, due either to sulphasalazine or mesalamine is a well-recognized adverse drug reaction in these patients<sup>[50,87-95]</sup>.

The above observations and the histological similarities between CD and sarcoidosis in particular, have led several groups to investigate the number and types of cells recovered by bronchoalveolar lavage (BAL)<sup>[58,59,96]</sup>. An increased percentage of alveolar lymphocytes was reported in the study by Wallaert *et al*<sup>[58]</sup> in patients with CD. In the same study, a correlation between BAL differential cell count and PFTs abnormalities, drug treatment or CD site and activity was not reported<sup>[58]</sup>. The same group reported an increased level of IgG and IgM in BAL recovered from patients with alveolitis but not in those with normal BAL<sup>[97]</sup>. This observation of subclinical alveolitis was confirmed in the study by Bonniere and associates in 22 patients with CD<sup>[59]</sup>. In the same study, a significant increase in superoxide anion production by alveolar macrophages related to spontaneous activation and alteration of pulmonary function was observed<sup>[59,98]</sup>. Bartholo *et al*<sup>[99]</sup> found lymphocytosis in induced sputum of patients with CD even without pulmonary symptoms. Raj *et al*<sup>[100]</sup> reported a trend for higher lymphocyte counts in the sputum of patients with CD compared with UC. Smiċjan *et al*<sup>[96]</sup> reported lymphocytosis alveolitis in patients with CD but not in patients with other inflammatory bowel

disorders including UC. In the same study, an increase in the CD4 lymphocyte subset (increased ratio of CD4/CD8) was found in patients with an active stage of CD similar to patients with sarcoidosis<sup>[96]</sup>. Yamaguchi *et al*<sup>[101]</sup> reported increased BAL lymphocytes with an elevated CD4/CD8 ratio and enhanced expression of CD2 antigen in lung T cells in 8 patients with CD. Ussov *et al*<sup>[102]</sup> found a significant increase in the pulmonary vascular granulocyte pool in patients with CD. The meaning of this subclinical alveolitis and alterations in lung parenchyma is unclear. A subclinical inflammatory alveolitis as assessed by BAL cell analysis may be present in asymptomatic patients with immunological systemic disorders and with normal chest X-ray<sup>[103]</sup>. The fact that pulmonary involvement is not as common during extrathoracic granulomatosis as CD, whereas subclinical alveolitis is frequent, suggests that the lung possibly downregulates, in some way, alveolar inflammation due to the systemic immune disorder. The alveolitis observed in IBD patients does not necessarily precede the development of pulmonary granulomatosis and fibrosis<sup>[97,103]</sup>. Increased pulmonary permeability to diethylenetriaminepenta-acetate radiolabelled with 99m-technetium (<sup>99m</sup>Tc-DTPA) related to abnormal BAL findings has also been reported in patients with CD<sup>[104]</sup>. The reduction in diffusing capacity of the lungs (DLCO) is common and early manifestations of interstitial lung diseases<sup>[64,68,97]</sup> and latent lymphocytosis alveolitis could explain, in part, the reduction in DLCO observed in patients with CD<sup>[60]</sup>.

## ATOPY AND IBD

The gastrointestinal tract comes into direct contact with a great variety of foreign substances and under certain conditions these may act as antigens causing allergic reactions<sup>[105]</sup>. On the other hand, atopic subjects are possibly susceptible to several inhalants or food allergens<sup>[106]</sup>, while clinical features of atopic disorders include many organs among them both the pulmonary and gastrointestinal systems. Hippocrates reported that milk could cause gastric upset and urticaria and was probably the first to relate general atopy with gastrointestinal allergy. Hammer *et al*<sup>[107]</sup> found an increased prevalence of all atopic features. Asthma was also documented as being highly prevalent in a large study by Bernstein *et al*<sup>[108]</sup>. Studies on the relation between IBD and atopy are listed in Table 1. Ceyhan *et al*<sup>[109]</sup> reported that allergic symptoms and skin prick test positivity were more common in IBD patients (Table 1). Fireman *et al*<sup>[110]</sup> reported a higher percentage of eosinophils in induced sputum in patients with UC. Several studies have tried to investigate the attractive hypothesis that IBD, in particular UC, may be an allergic response to food<sup>[111,112]</sup> especially in individuals susceptible to various allergens. This hypothesis is supported by certain evidence that eosinophils and eosinophil-derived mediators contribute to the histopathology and pathophysiology of IBD<sup>[19,113-116]</sup>. Most studies confirmed the observation that atopic features are more frequent in patients with IBD than in the general population<sup>[114,117-120]</sup> (Table 1). This may be an explanation for the overlapping allergic disorders in both the respiratory and gastrointestinal systems. However, the frequency of bronchial hyperresponsiveness was significantly higher in IBD patients than in normal subjects (41% *vs* 5%), even when non-atopic subjects were considered<sup>[53]</sup>. This finding is consistent with the hypothesis that another immune system common to both exists and may be responsible for the inflammation in both systems<sup>[56]</sup>. Only one study by Troncone *et al*<sup>[121]</sup> showed that there was no correlation between atopy and IBD.

Engkilde *et al*<sup>[122]</sup> found an inverse association between a contact allergy and IBD. In this study although there was a chronic contact allergic dermatitis which was considered by the authors to have a Th2 profile, contact allergy has a Th1 profile. Engkilde *et al*<sup>[122]</sup> suggested that this may be due to shared genetic factors, common environmental determinants or skewness of the immune system. Medoff *et al*<sup>[123]</sup> suggested that T cell trafficking takes place in peripheral tissue in allergic asthma. It is suggested that this trafficking may involve several interactions between innate immune cells and T cells<sup>[123]</sup>. Several explanations for this phenomenon have been given over the years, however, no definite conclusions have been reached. Hammer *et al*<sup>[107]</sup> suggested a genetic predisposition, Myrelid *et al*<sup>[124]</sup> implicated TNF mast cells and D'Arienzo *et al*<sup>[125]</sup> suggested a Th2 or Th1 helper response. The mechanisms of atopy in IBD merit further investigation.

## CONCLUSION

Three patterns of pulmonary involvement have been reported to accompany IBD: (1) airway disease including large airway stenosis, chronic bronchitis, small airway dysfunction, severe bronchial suppuration and bronchiectasis; (2) parenchymal lung involvement either as subclinical lymphocytic alveolitis or several types of pulmonary infiltrate such as granulomatous bronchiolitis and bronchiolitis obliterans; and (3) a reduction in the diffusing capacity of the lung is a well established abnormality of pulmonary function testing in some patients with IBD.

We propose that patients suffering from IBD should undergo pulmonary evaluation which should include physical examination, chest X-ray and pulmonary function testing with DLCO measurement. This pulmonary evaluation may be useful in detecting subclinical or clinical pulmonary involvement in IBD patients or as a baseline evaluation. In clinical cases with pulmonary manifestations, inhaled or systemically administered steroids appear to be an effective treatment. With regard to atopy, routine investigations should be considered, at least in patients with IBD who also present with airway dysfunction.

### Abstract

Heparan sulphate proteoglycans (HSPGs) consist of a core protein and several heparan sulphate (HS) side chains covalently linked. HS also binds a great deal of growth factors, chemokines, cytokines and enzymes to the extracellular matrix and cell surface. Heparanase can specially cleave HS side chains from HSPGs. There are a lot of conflicting reports about the role of heparanase in hepatocellular carcinoma (HCC). Heparanase is involved in hepatitis B virus infection and hepatitis C virus infection, the activation of signal pathways, metastasis and apoptosis of HCC. Heparanase is synthesized as an inactive precursor within late endosomes and lysosomes. Then heparanase undergoes proteolytic cleavage to form an active enzyme in lysosomes. Active heparanase translocates to the nucleus, cell surface or extracellular matrix. Different locations of heparanase may exert different activities on tumor progression. Furthermore, enzymatic activities and non-enzymatic activities of heparanase may play different roles during HCC development. The expression level of heparanase may also contribute to the discrepant effects of heparanase. Growth promoting as well as

growth inhibiting sequences are contained within the tumor cell surface heparan sulfate. Degrading different HSPGs by heparanase may play different roles in HCC. Systemic studies examining the processing, expression, localization and function of heparanase should shed a light on the role of heparanase in HCC.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide. Extracellular matrix (ECM) remodeling plays an important role in the development of HCC<sup>[1]</sup>.

Heparan sulphate proteoglycans (HSPGs), one of the main components of ECM, are abundant macromolecules associated with the cell surface and ECM of a wide range of cells of vertebrate and invertebrate tissues. The basic HSPG structure consists of a core protein and several heparan sulphate (HS) side chains covalently linked. Extracellular HSPGs can maintain the ECM self assembly and integrity with other macromolecules, while cell surface HSPGs may act as co-receptor for several signal pathway molecules. In fact, HS chains also bind a great deal of growth factors, chemokines, cytokines and enzymes to the ECM and cell surface. HSPGs can thus influence a

number of normal and pathological processes, among which are tissue repair, inflammation, tumor growth and metastasis, and angiogenesis<sup>[2,3]</sup>.

Recent discoveries indicated that HSPGs localized within the tumor microenvironment can be attacked by enzymes that alter proteoglycan structure resulting in dramatic effects on tumor growth and metastasis<sup>[4,5]</sup>. Heparanase, an endoglycosidase, can specially cleave HS side chains from HSPGs and release a multitude of bioactive molecules. Then, the generated HS fragments and released bioactive mediators could facilitate tumor metastasis cooperatively. In addition, heparanase also exhibits non-enzymatic activities, including cell adhesion and survival, upregulation of vascular endothelial growth factor (VEGF) and tissue factor, induction of signal transduction, and enhancement of certain HSPG shedding from the tumor cell surface<sup>[6-16]</sup>.

A large body of evidence suggest that the expression of heparanase in the tumor closely relates with the potential for tumor invasion, angiogenesis and metastasis in most tumors examined<sup>[7-10]</sup>. However, there are a lot of conflicting reports about the relationship between heparanase and HCC. It is timely to review the literature to evaluate the arguments for and against the possible roles of heparanase in HCC.

## HEPARANASE AND HEPATITIS B VIRUS (HBV) AND HEPATITIS C VIRUS (HCV) INFECTION

Cell surface heparan sulfate mediates entry and initiation of infection of HBV and HCV, the most important pathogenic factors for HCC. Proper structure and sulfation levels of heparan sulfate are prerequisite for this mediation<sup>[17-23]</sup>. Heparanase might inhibit HS-mediated HCV and HBV entry and the initiation of infection<sup>[18,21]</sup>. Degradation of cell surface heparan sulfate by pretreatment with heparanases resulted in a marked reduction of HCV envelope glycoprotein E2 binding to HepG2 cells<sup>[18]</sup>. Treatment of Namalwa B cells and human erythroleukemia K562 cells with heparinase I also reduced the cellular binding of HBV nucleocapsids<sup>[21]</sup>. However, HCV E2 bound to target cells *via* putative receptors in a noncompetitive manner. Incomplete inhibition of heparan sulfate might lead to a partial E2 blockade and evasion of the host immune response<sup>[23]</sup>. El-Assal *et al*<sup>[24]</sup> reported that heparanase expression was significantly higher in HCV-related HCC compared with that in HCV-negative patients. It is possible to assume that HCV enhances heparanase expression that may be involved in the HCV-related pathological and malignant changes.

## HEPARANASE EXPRESSION IN LIVER DISEASES

A biphasic pattern of heparanase expression is also significantly observed in rat liver following partial hepatectomy, peaking at 12 h and 96-168 h and decreasing

at 360 h post-surgery<sup>[25]</sup>. Elevated heparanase levels are noted in the early stages of thioacetamide induced rat liver fibrosis, with no further increase evident in rats exhibiting higher fibrotic grades<sup>[25]</sup>. Reduction or no significant difference in heparanase expression levels are found in liver fibrosis or cirrhosis samples resected from human patients<sup>[24,26-31]</sup>.

There are conflicting reports about the expression level of heparanase in HCC. Examining HCC patients' specimens by reverse transcriptase-polymerase chain reaction (RT-PCR) or Real-Time Quantitative RT-PCR, *in situ* hybridization, Western blotting, immunohistochemistry and tissue microarrays (TMAs), five out of the seven studies reported that heparanase was over-expressed in HCC<sup>[24,28-31]</sup>. However, two studies indicated that the expression level of heparanase was lower than that in adjacent noncancerous tissue<sup>[26,27]</sup> (Table 1).

## HEPARANASE AND HCC

### Heparanase and metastasis of HCC

Metastasis is a sequential process including breaking off from the primary tumor, traveling through the bloodstream and stopping at a distant site. Heparanase enhances HCC metastasis by degrading ECM and releasing ECM-resident growth factors and angiogenic factors. Furthermore, non-enzymatic activities of heparanase, such as promoting cell adhesion, might also play a role in HCC metastasis<sup>[6-16]</sup>.

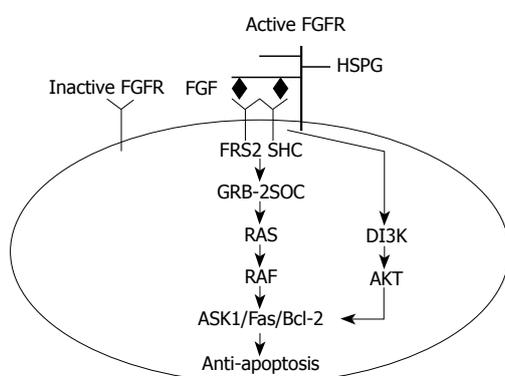

Hepatoma heparanase was first purified from a human hepatoma cell line Sk-hep-1 in 1998<sup>[32]</sup>. El-Assal *et al*<sup>[24]</sup> reported that expression of heparanase mRNA was significantly correlated with larger tumor size, potential for tumor invasion and tumor microvessel density. Many research studies also support the concept that heparanase expression closely relates with metastasis and recurrence of HCC, tumor differentiation and tumor stage<sup>[28-31]</sup>. More recently, some researchers reported that down-regulating heparanase expression either by antisense oligodeoxynucleotide or by RNA interference could significantly inhibit the invasiveness, metastasis, and angiogenesis of human HCC SMMC7721 cells both *in vitro* and *in vivo*<sup>[33]</sup>. Yang *et al*<sup>[34]</sup> reported that two polypeptide antibodies, anti-MAP1 (multiple antigenic peptides)- and anti-MAP2-antibody, can effectively inhibit the heparanase activity of HCCLM6 human hepatocellular carcinoma cells *in vitro* and influence their invasive ability. Recently, PI-88, an heparanase inhibitor, showed preliminary efficacy as an adjunct therapy for post-operative HCC<sup>[35]</sup>. Glycosaminoglycan mimetics may also compete with cellular heparan sulfate chains for the binding to CXCL12 and may affect heparanase expression, leading to inhibition of SDF-1/CXCL12-mediated migration and invasion of the Huh7 human hepatoma cells<sup>[36]</sup>.

However, Ikeguchi *et al*<sup>[26]</sup> reported that heparanase mRNA in HCC was significantly lower than that of noncancerous liver tissue and heparanase expression did not correlate with tumor differentiation, tumor stage, or patient prognosis. In another study conducted by Ikeguchi's group, the expression level of heparanase was low in HCC

Table 1 Studies examining the pro-metastatic role of heparanase in HCC

Studies	No.	Methods	Positive rate of HCC tissue	Correlation between heparanase expression and HCC progression
El-Assal <i>et al</i> <sup>[24]</sup> , 2001	55 <sup>1</sup>	RT-PCR	47%	Significant positive correlation
Ikeguchi <i>et al</i> <sup>[26]</sup> , 2002	50 <sup>2</sup>	QRT-PCR	< adjacent noncancerous tissue	No significant correlation
Ikeguchi <i>et al</i> <sup>[27]</sup> , 2003	48 <sup>2</sup>	QRT-PCR	< adjacent noncancerous tissue	Significant negative correlation
Xiao <i>et al</i> <sup>[28]</sup> , 2003	11 <sup>3</sup>	QRT-PCR, WB, ISH, IHC	> normal and cirrhosis tissue	Significant positive correlation
Chen <i>et al</i> <sup>[30]</sup> , 2004	33 <sup>2</sup>	RT-PCR	48.5%, > adjacent tissue	Significant positive correlation
Liu <i>et al</i> <sup>[31]</sup> , 2005	33 <sup>4</sup>	RT-PCR	48.5%, > paracancerous and normal tissue	Significant positive correlation
Chen <i>et al</i> <sup>[29]</sup> , 2008	120 <sup>5</sup>	IHC in TMAs	45.83%, > adjacent tumor tissue, cirrhosis, and normal liver tissue	Significant positive correlation

<sup>1</sup>55 HCC tissue samples; <sup>2</sup>Both HCC tissue samples and non-cancerous liver samples were obtained from the same patients; <sup>3</sup>16 normal liver tissue samples, 14 liver cirrhosis tissue samples and 11 HCC tissue samples; <sup>4</sup>HCC tissue samples and paracancerous tissue samples were obtained from 33 HCC patients; paracancerous tissues of 9 cases of benign liver tumor were used as normal controls; <sup>5</sup>48 cases of adjacent HCC liver, 62 cases of cirrhosis, and 23 cases of normal liver tissues. HCC: Hepatocellular carcinoma; RT-PCR: Reverse transcriptase-polymerase chain reaction; QRT-PCR: Real-time quantitative RT-PCR; WB: Western blotting; ISH: *In situ* hybridization; IHC: Immunohistochemistry; TMAs: Tissue microarrays.

**Figure 1** Heparan sulphate proteoglycan (HSPG) and fibroblast growth factor (FGF)-induced signal transduction. Basic FGF (bFGF) enhances tumor progression by protecting tumor cells from apoptosis. Cell surface HSPGs could act as a co-receptor for formation of a bFGF high-affinity receptor complex. The alteration of cell surface HSPGs resulting from heparanase might down-regulate HSPG-mediated bFGF-induced signal pathway, resulting in apoptosis of tumor cells.

and a high expression level of heparanase was associated with better disease-free 5-year survival rate<sup>[27]</sup>. Ogawa *et al*<sup>[37]</sup> established rat HCC cell lines with a high metastatic potential and found that one cell line, showing high levels of lung metastasis when injected subcutaneously in nude mice, exhibited decreased heparanase mRNA expression compared with other cell lines.

In a study of fibroblasts transfected with various oncogenes, one cell line exhibiting a metastatic phenotype was not found to have a significant increase in heparanase activities, though another one having the highest metastatic potential was shown to contain the greatest heparanase activity<sup>[38]</sup>. The hypothesis is that high heterogeneity of HCC might contribute to such discrepancy. Growth promoting as well as growth inhibiting sequences are contained within the tumor cell surface heparan sulfate<sup>[39]</sup>. Degrading different HSPGs by heparanase may play different roles in the complex process of metastasis.

### Heparanase and apoptosis of HCC

The HS side chains of HSPGs could bind a multitude

of growth factors, chemokines, cytokines and enzymes in ECM and cell surface, such as basic fibroblast growth factor (bFGF), vascular endothelial growth factor and hepatocyte growth factor. The cleaving of HSPGs by heparanase could release of HS-bound growth factors and exhibit complicated effects<sup>[7-10]</sup>. bFGF might enhance endothelial cell and tumor cell proliferation, contributing to HCC progression<sup>[40,41]</sup>. El-Assal *et al*<sup>[24]</sup> reported that bFGF and heparanase co-expressed in HCC patients' specimen and this co-expression was associated with higher tumor microvessel density than that in specimens with expression of either factor alone.

Heparanase is involved in the activation of several signal pathways including bFGF-induced signal transduction<sup>[42-47]</sup> (Figure 1). In an *in vitro* study of melanoma cells, heparanase seemed necessary for phosphorylation of extracellular signal-related kinase (ERK) or focal adhesion kinase (FAK) in response to bFGF<sup>[46]</sup>. Kato *et al*<sup>[47]</sup> reported that in postmastectomy wound fluids, syndecan-1 was converted from an inhibitor to an activator of bFGF by the degrading activities of heparanase. The release of bFGF and HS degrading fragments by heparanase might promote bFGF-receptor binding and activation<sup>[42-47]</sup>.

Heparanase expression closely related with apoptosis of several tumor cells, including HCC cells<sup>[27,48,49]</sup>. Ikeguchi *et al*<sup>[27]</sup> found a significant positive correlation between heparanase mRNA expression levels and the percentages of apoptotic hepatocytes in liver tissues. In addition to mitogenic effects, bFGF also could enhance some tumor progression by protecting tumor cells from apoptosis<sup>[50-56]</sup>. Targeting bFGF by neutralizing antibody or antisense oligonucleotides could result in apoptosis of some tumor cells<sup>[57-59]</sup>. Cell surface HSPGs could not only act as co-receptors for formation of bFGF high-affinity receptor complexes, but could also function directly as receptors for bFGF-induced signal transduction, depending on core protein or HS specific manner<sup>[60-62]</sup>. One possibility is that the alteration of cell surface HSPGs resulting from heparanase might down-regulate HSPG-mediated bFGF-induced signal pathways, resulting in apoptosis of tumor cells.

### Location of heparanase in HCC

Human heparanase is synthesized as a 65 kDa inactive precursor within late endosomes and lysosomes. Then heparanase undergoes proteolytic cleavage, yielding 8 and 50 kDa protein subunits that heterodimerize to form an active enzyme in lysosome. Active heparanase translocates to the nucleus, cell surface or ECM<sup>[6,63]</sup>. Different locations of heparanase may exert different activities. Cell surface expression and secretion of heparanase in EB mouse lymphoma cells markedly promotes tumor angiogenesis and metastasis compared with intracellular enzyme<sup>[64]</sup>. However, nucleus heparanase induces differentiation of some tumor cells, such as esophageal cancer cells, mammary cancer cells and leukemic cells. Furthermore, a nuclear location of heparanase represents a better prognosis in tumor patients than its cytoplasmic location<sup>[65-70]</sup>.

During liver regeneration, the location of heparanase exhibits a dramatic alteration from cytoplasm to cell surface in a time-dependant manner<sup>[25]</sup>. Xiao *et al.*<sup>[28]</sup> and Chen *et al.*<sup>[29]</sup> reported that high heparanase expression in HCC was localized within the cytoplasm of tumor cells and there was a significant correlation between the expression level of heparanase mRNA and tumor stage. Does the role of heparanase in HCC depend on its location?

### CONCLUSION

There are a lot of conflicting reports about the role of heparanase in HCC. Several questions are intriguing and shouldn't be ignored. (1) In a human glioma cell xenograft tumor model, moderate heparanase expression levels significantly enhanced tumor development, whereas high heparanase expression levels inhibited tumor growth<sup>[71]</sup>. Another study also showed that extensive heparanase inhibited bFGF binding in human metastatic melanoma 70W cells, while treatment of 70W cells with low heparanase concentrations enhanced bFGF binding<sup>[46]</sup>. Does the effect of heparanase depend on its expression level in HCC? (2) During the course of colon adenoma-carcinoma progression, active heparanase increases in the early stage, while latent heparanase predominantly increases in the late stage. The possibility was that enzymatic activities and non-enzymatic activities of heparanase have different roles in the early and late stages of colon cancer development<sup>[72]</sup>. Do enzymatic activities and non-enzymatic activities of heparanase play different roles during HCC development? (3) HSPGs may have promoting or inhibiting activities depending on the core protein and localization<sup>[73]</sup>. For example, Glypican-3 and syndecan-1 might act as promoter and inhibitor during the development of HCC, respectively<sup>[74,75]</sup>. Degrading different HSPGs by heparanase may play different roles in HCC; and (4) Researchers have already observed that heparan sulfates could occur in hepatic nucleus and hypothesized that alteration of heparan sulfates detected in HCC might be involved in HS-related gene expression<sup>[76-81]</sup>. For example, DNA topoisomerase I activity is modulated by heparan sulfates present in normal liver cells but is markedly reduced or absent in their transformed counterparts<sup>[80]</sup>. In-

terestingly, active heparanase also could translocate to the nucleus and degrade nuclear HS<sup>[65-70,81]</sup>. Is heparanase the criminal for the lack of biologically active HS in HCC? Do the effects of heparanase depend on its location in HCC? Systemic studies examining the processing, expression, localization and function of heparanase should shed a light on the role of heparanase in HCC.

*cagA*<sup>+</sup> and Epstein Barr virus (EBV) infections in gastric adenocarcinomas.

**METHODS:** Methylation-specific PCR (MSP) assay was performed in 89 primary gastric carcinomas (intestinal and diffuse types). Microsatellite instability (MSI) analysis was performed using the BAT26 primer set and PCR products were analyzed with the ABI PRISM 3100 Genetic Analyzer using Genescan 3.7 software (Applied Biosystems). Detection of *H. pylori* and genotyping were performed by PCR, using specific primers for *ureaseC* and *cagA* genes. The presence of EBV was assessed by *in situ* hybridization. Statistical analyses were performed using the  $\chi^2$  or Fisher's exact test.

**RESULTS:** The most frequent hypermethylated gene was *COX-2* (63.5%) followed by *DAPK* (55.7%), *CDH1* (51%), *CDKN2A* (36%) and *hMLH1* (30.3%). Intestinal and diffuse adenocarcinomas showed different methylation profiles and there was an association between methylation of *E-CDH1* and *H. pylori-cagA*<sup>+</sup> in the intestinal adenocarcinoma type. MSI was correlated with *hMLH1* methylation. There was an inverse correlation between *DAPK* hypermethylation and MSI.

**CONCLUSION:** We found a strong association between *CDH1* methylation and *H. pylori-cagA*<sup>+</sup> in intestinal-type gastric cancer, association of MSI and better prognosis and an heterogeneous *COX-2* overexpression.

### Abstract

**AIM:** To verify the methylation status of *CDH1*, *DAPK*, *COX2*, *hMLH1* and *CDKN2A* genes and to evaluate their association with *Helicobacter pylori* (*H. pylori*)-

Ferrasi AC, Pinheiro NA, Rabenhorst SHB, Caballero OL, Rodrigues MAM, Carvalho F, Souza Leite CV, Ferreira MVP, Barros MAP, Pardini MIMC. *Helicobacter pylori* and EBV in gastric carcinomas: Methylation status and microsatellite instability. *World J Gastroenterol* 2010; 16(3): 312-319 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i3/312.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i3.312>

## INTRODUCTION

Gastric cancer (GC), one of the most common cancer types, is associated with high mortality rates<sup>[1,2]</sup>. The prognosis of GC remains poor, especially when the diagnosis is undertaken at advanced stages<sup>[3]</sup>. Thus, studies to elucidate the mechanisms acting in gastric carcinogenesis and which search for possible markers to assist in both earlier diagnosis and therapeutic approaches are relevant.

Gastric adenocarcinomas can be divided into intestinal or diffuse histological types. Environmental factors appear to be related to the intestinal type, which may play a role in carcinogenesis characterized by precursor lesions of gastric mucosa, followed by intestinal metaplasia that can lead to dysplasia and GC. In contrast, in the diffuse carcinoma no precursor lesions have been identified to date<sup>[4]</sup>.

Many studies have identified the transcriptional silencing by DNA methylation as a mechanism responsible for tumor suppressor inactivation. Methylation of promoter CpG islands leads to DNA structural changes and, consequently, gene inactivation<sup>[5]</sup>. Several cancers, including gastric tumors, show methylation of multiple genes including *CDH1*, *DAPK*, *COX2*, *hMLH1* and *CDKN2A*<sup>[6,7]</sup>.

Microsatellite instability (MSI) reflects an erroneous form of DNA replication in repetitive microsatellite sequences and has been considered a hallmark of mismatch repair gene inactivation. MSI has been associated with less aggressive tumor behavior and favorable prognosis in sporadic colorectal cancer<sup>[8-10]</sup>. MSI status has been determined by means of BAT26 mononucleotide repeats because this marker is quasi-monomorphic in normal DNA and has shown high sensitivity and specificity in the identification of MSI phenotype<sup>[11]</sup>.

*Helicobacter pylori* (*H. pylori*), carcinogen class I<sup>[12]</sup>, colonizes the gastric epithelium and causes a severe inflammatory reaction that depends on factors including host genetic susceptibility, immune response, age at the time of initial infection, and environmental and virulence factors such as cytotoxin-associated gene A (*cagA*)<sup>[13-15]</sup>. The complex interactions among the different types of *H. pylori*, inflammation and genetic features of the host could promote a cascade of morphological events leading to GC<sup>[16]</sup>.

Apart from the accepted role of *H. pylori* in the pathogenesis of GC, the Epstein Barr virus (EBV) has been associated with gastric carcinoma in at least 10% of cases<sup>[17]</sup>. Countries with the highest incidences are Japan (19.3%) and Germany (18%)<sup>[17,18]</sup>. In Brazil, frequencies of EBV infec-

tion ranging between 8% and 11% have been described<sup>[19,20]</sup>.

Some studies have linked DNA hypermethylation with *H. pylori-cagA*<sup>+</sup> and EBV infection but these data are not conclusive and the studies did not examine both agents at the same time. By examining 89 primary gastric carcinomas, the present study verifies MSI frequency and the methylation status of the *CDH1*, *DAPK*, *COX2*, *hMLH1* and *CDKN2A* genes and evaluates their association with *H. pylori* (*cagA*<sup>+</sup> and *cagA*) and EBV infections and also with clinicopathological features of gastric carcinomas.

## MATERIALS AND METHODS

### Samples

Eighty-nine gastric adenocarcinomas and their corresponding adjacent normal tissue were obtained surgically from Brazilian patients at the Federal University of Ceara State, the Clinical Hospital at the UNESP Medical School in Botucatu, Sao Paulo State and the Amaral Carvalho Hospital, and immediately frozen in liquid nitrogen until micro-dissection and DNA extraction. The Research Ethics Committees of the respective institutions approved this study and each subject signed an informed consent form before tissue was obtained. Histopathological analyses determined that the tumor specimens consisted mainly (> 80%) of tumor tissues and that the adjacent tissue was free of tumor cells. The histological classification was made according to the Laurén classification system<sup>[4]</sup> and the tumors were staged according to the TNM criteria<sup>[21]</sup>. DNA was extracted using standard methods<sup>[22]</sup>.

### Bisulfite modification and methylation-specific PCR (MSP)

DNA from both tumoral and normal tissues was subjected to treatment with sodium bisulfite as described by Herman *et al.*<sup>[23]</sup>. The modified DNA was amplified with primers specific for either the methylated or unmethylated sequences of *hMLH1*, *COX2*, *DAPK*, *CDKN2A* and *CDH1* (Table 1). PCR was individually performed in 25  $\mu$ L reaction volumes, containing 1  $\times$  Platinum Taq buffer, 1.5 mmol/L MgCl<sub>2</sub>, 0.2 mmol/L of each dNTP, 0.4  $\mu$ mol/L of each primer set, 1 U of Platinum Taq DNA Polymerase (Invitrogen) and 1  $\mu$ L of treated DNA. DNA methylated *in vitro* by *Sss-I* methylase (New England Biolabs) was used as a positive control, and water and DNA from peripheral lymphocytes of healthy donors were used as negative controls. PCR products were separated on silver-staining 6% non-denaturing polyacrylamide gels<sup>[22]</sup>.

### Bisulfite sequencing analysis

To confirm reaction specificity, MSP-PCR products from each gene analyzed were cloned with TOPO TA Cloning Kit (Invitrogen) and sequenced using the ABI PRISM<sup>®</sup> BigDye Terminator v3.0 Cycle Sequencing Kit (Applied Biosystems) and ABI Prism 3100 DNA Sequencer (Applied Biosystems).

### Microsatellite instability analysis

MSI analysis was performed using the BAT26 primer set (5'-TGACTACTTTTACTTCAGCC-3', sense and 5'-AACCATTCAACATTTTAACCC-3', antisense). Sense primer was labeled with 6-FAM. PCR was performed in a final volume of 25 µL containing 1 × PCR buffer, 3.0 mmol/L MgCl<sub>2</sub>, 0.2 µmol/L dNTPs, 0.4 µmol/L of each primer, 2 U of Platinum Taq DNA Polymerase (Invitrogen) and 50 ng of DNA. The thermal conditions were 94°C/5 min followed by 40 cycles (94°C/1 min, 50°C/1 min and 72°C/1 min) and a final extension at 72°C/7 min. The dye-labeled PCR products were analyzed with ABI PRISM 3100 Genetic Analyzer using Genescan 3.7 software (Applied Biosystems). Both tumoral and normal samples were analyzed. Negative (SW480 cells) and positive (HCT116 cells) controls for MSI had been included in all the analyses. Deletions or insertions of at least 4 bp were required to satisfy the definition of instability<sup>[27]</sup>. All cases were repeated twice.

### *H. pylori* and *CagA* detection

Detection of *H. pylori* in gastric samples was performed for PCR amplification with primers specific to *H. pylori ureaseC* gene. The primer sequence used (5'-AAGCTTT-TAGGGGTGTTAGGGGTTT-3', sense and 5'-CT-TACTTTCTAACACTAACGC-3', antisense)<sup>[28]</sup> amplifies a 294 bp fragment. To detect *cagA*, the primer set 5'-ATAATGCTAAATTAGACAACCTTGAGCGA-3' (sense) and 5'-TTAGAATAATCAACAAACATAACG CCAAT-3' (antisense)<sup>[29]</sup> was utilized to amplify a 297 bp fragment. Each primer set (*ureaseC* and *cagA*) was used in an independent PCR reaction in a final volume of 25 µL containing 1 × PCR buffer [20 mmol/L Tris-HCl (pH 8.4) and 50 mmol/L KCl], 1.5 mmol/L MgCl<sub>2</sub>, 0.2 mmol/L of each dNTP, 0.4 µmol/L of each primer set, 1 U of Platinum Taq DNA Polymerase (Invitrogen) and 100 ng of DNA, under the following conditions: for *ureaseC* PCR, initial denaturation at 94°C/3 min followed by 35 cycles of denaturation at 94°C/30 s, annealing at 58°C/30 s and extension at 72°C/2 min and final extension at 72°C/5 min. The *cagA* PCR included an initial denaturation at 94°C/3 min followed by 40 cycles of denaturation at 94°C/30 s, annealing at 58°C/45 s and extension at 72°C/2 min and final extension at 72°C/5 min. Both tumoral and normal samples were analyzed. Negative and

positive controls were assayed in each run. PCR products were separated by silver-stained 6% non-denaturing polyacrylamide gel electrophoresis<sup>[22]</sup>.

### EBER1 *in situ* hybridization

The presence of EBV was assessed by RNA *in situ* hybridization reaction with a 30 bp biotinylated probe (5'-AGACACCGTCCTCACCACCCGGGACTTG TA-3') complementary to the RNA *EBER1*. EBV transcript was shown in high amounts in the nuclei of latently infected cells. Signal amplification was employed with anti-biotin antibody (clone BK, mouse, dilution 1:20; DakoCytomation<sup>®</sup>) and biotinylated anti-immunoglobulin antibody (polyclonal, rabbit, dilution 1:100; DakoCytomation<sup>®</sup>). The reaction was detected with the streptavidin-biotinperoxidase complex (DakoCytomation<sup>®</sup>) and diaminobenzidine chromogen (DakoCytomation<sup>®</sup>). The slides were counterstained with Harris's hematoxylin. A case of nasopharyngeal carcinoma was used as positive control.

### Statistical analysis

For statistical analysis the  $\chi^2$  test or Fisher's exact test was used. *P* values ≤ 0.05 were considered statistically significant.

## RESULTS

### Patients and tumor characteristics

The clinicopathological and epidemiological features of patients are shown in Table 2.

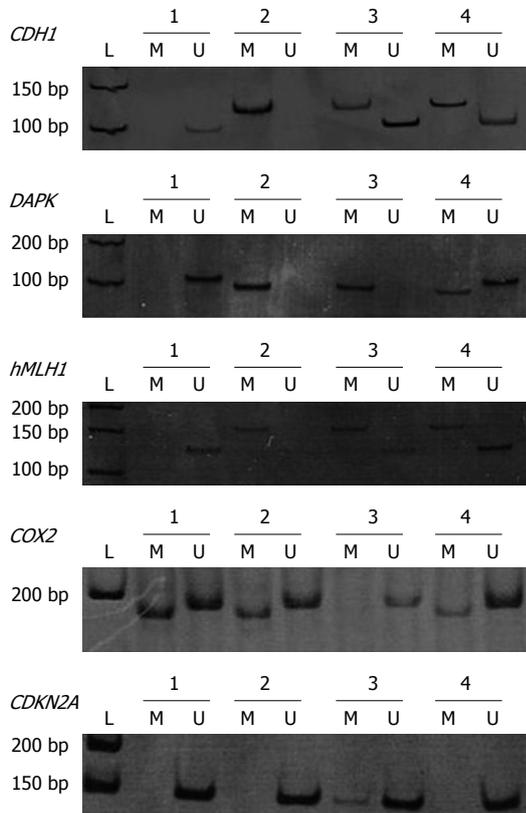

### Methylation status

Of the five genes analyzed, the *COX2* gene was the one most frequently hypermethylated (63.5%) followed by *DAPK* (55.7%), *CDH1* (51%), *CDKN2A* (36%) and *hMLH1* (30.3%). Figure 1 displays representative examples of the MSP products.

In the diffuse adenocarcinoma cases, methylation of *CDH1*, *COX2* and *CDKN2A* presented higher frequencies in early stage tumors (0- I) with a tendency to decrease along with the tumor grades (mainly *CDH1* and *COX2*). On the other hand, in the intestinal type, the methylation status of *CDH1*, *COX2*, *hMLH1* and *CDKN2A* tended to increase from the earliest stages

**Table 2** Clinicopathological and epidemiological features of patients in the four tumor stages *n* (%)

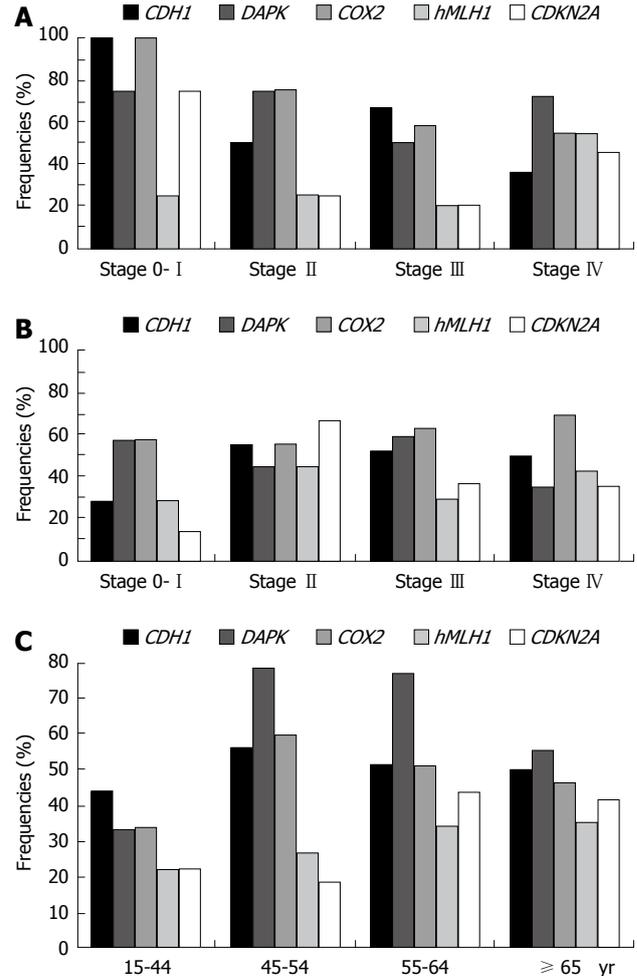

Variables	Patients	Tumor stage			
		0- I	II	III	IV

(0- I) to advanced stages (II-IV) ( $P < 0.001$ , Figure 2A and B). The methylation status tended to increase with age; the highest frequency of cases with promoter methylation was found in patients between 45 and 64 years old. Patients aged more than 50 years had a higher frequency of methylation in *CDKN2A* ( $P = 0.035$ ).

Table 3 summarizes overall results of the correlation

**Figure 2** Frequencies of methylation at *CDH1*, *DAPK*, *hMLH1*, *COX2* and *CDKN2A* genes in gastric carcinomas. A: Frequencies of methylation at *CDH1*, *DAPK*, *hMLH1*, *COX2* and *CDKN2A* distributed according to tumor stages in diffuse adenocarcinoma; B: Frequencies of methylation at *CDH1*, *DAPK*, *hMLH1*, *COX2* and *CDKN2A* distributed according to tumor stages in intestinal adenocarcinoma; C: Frequencies of methylation at *CDH1*, *DAPK*, *hMLH1*, *COX2* and *CDKN2A* distributed with regard to age groups.

between the promoter methylation frequency of each gene and relevant clinicopathological parameters.

**Microsatellite instability analysis**

MSI was observed in 17.2% of GCs. Most of the patients with MSI tumors (86.7%) had an advanced form of the disease and 66.7% of them shown lymph node metastasis. Intestinal and diffuse adenocarcinomas had similar MSI frequencies. There was a significant correlation between MSI and *hMLH1* methylation ( $P = 0.001$ ). Conversely, a significant inverse correlation was demonstrated between *DAPK* methylation and MSI ( $P = 0.012$ ).

**Detection of *H. pylori***

The presence of *H. pylori* was identified in 98% of GC patients, of whom 63.2% were *cagA*<sup>+</sup>. The frequency of *H. pylori-cagA*<sup>+</sup> infection was similar between intestinal and diffuse adenocarcinomas (64.5% vs 59.6%, respectively). In the intestinal type, *CDH1* methylation was more frequent in *H. pylori-cagA*<sup>+</sup> cases (55.8%) than in

<sup>1</sup>Statistically significant result.

*H. pylori-cagA*<sup>-</sup> cases (39.1%), a phenomenon not observed in the diffuse type. Also, *cagA*<sup>+</sup> among the intestinal cases displayed a higher frequency of *hMLH1* methylation than among diffuse *cagA*<sup>+</sup> cases (31.8% vs 15.8%, respectively). On the other hand, methylation of *DAPK* and *COX2* did not vary when the samples were grouped by histotype and *cagA* status. With regard to MSI and the presence of *cagA*, MSI was inversely correlated with the *cagA* gene (*P* = 0.012), as shown in Table 3.

**Detection of EBV**

Fifty-four tumors were analyzed for EBV, of which 5 (9.3%) specimens were EBV-positive (EBV<sup>+</sup>). According to histological classification, 4 patients presented intestinal type adenocarcinoma and one was diffuse. All EBV<sup>+</sup> cases were advanced grade (III and IV stages) and presented lymph node metastases. Two cases were EBV/*H. pylori*. The EBV<sup>+</sup> cases were found to be associated with *H. pylori*, but only one was *H. pylori-cagA*<sup>+</sup>. Although the number of EBV<sup>+</sup> cases was small, most of them displayed *DAPK*, *COX2* and *CDKN2A* methylation.

**DISCUSSION**

Our results show that methylation status tends to increase with age. This finding corroborates the fact that GC occurs at a higher frequency in older individuals<sup>[1,2]</sup>.

Moreover, previous studies showed that the age-related phenomenon of methylation of some tumor-suppressor and tumor-related genes can also be present in various non-neoplastic tissues, suggesting an association between age-related methylation and GC development<sup>[30-32]</sup>.

In this study, we demonstrate that 84.3% of GCs in our sample present methylation for about one in five of the genes analyzed. *COX2* was the gene found to be most commonly hypermethylated (63.5%) followed by *DAPK* (55.7%), *CDH1* (51%), *CDKN2A* (36%) and *hMLH1* (30.3%). An interesting observation in this study was related to the difference in methylation profiles between diffuse and intestinal adenocarcinoma types: in diffuse cases, the global methylation status, especially of *CDH1*, *COX2* and *CDKN2A*, has the highest frequency in early stage tumors (0- I) with a tendency to decrease along with tumor grades; while in the intestinal-type, the methylation status for *CDH1*, *COX2*, *hMLH1* and *CDKN2A* tended to increase from the earliest (0-I) to advanced stages (II-IV), as shown in Figure 2A and B. *CDH1* methylation was more frequent in the diffuse histotype. In fact, a vast difference was verified in stage I tumors where all diffuse-type tumors presented *CDH1* promoter methylation (100%) compared with only a small fraction (28.6%) in the intestinal-type, suggesting that *CDH1* methylation is an early event occurring in diffuse-type GCs. Since *CDH1* plays a fundamental role in maintaining cell differentiation,

polarity and normal tissue architecture<sup>[33]</sup>, the diffusely-growing and low cell cohesion characteristics of diffuse-type GC could be a function of *CDH1* down-regulation. Differences in the clinicopathological features between the intestinal and diffuse GC histological subtypes may be determined by different pathogenic processes<sup>[16,34]</sup>. The data presented in this study show that methylation in the same crucial genes could be an important pathway for the development of diffuse types. Identification of epigenetic differences between these two pathways could be of great importance in understanding gastric carcinogenesis and useful in the delineation of new therapeutic strategies.

The mechanisms that are implicated in *CDH1* promoter methylation are yet to be identified. The role of *H. pylori* in the regulation of *CDH1* expression has been described in recent studies showing that after *H. pylori* eradication, *CDH1* methylation is decreased<sup>[35,36]</sup>. In our study, we observed that in the intestinal adenocarcinoma cases, methylation in the *CDH1* promoter was more frequent in the group *H. pylori-cagA*<sup>+</sup> (55.8%) than in those with *H. pylori-cagA* (39.1%), indicating that *H. pylori-cagA*<sup>+</sup> may be involved in *CDH1* methylation in these tumors.

*DAPK* methylation has been shown to be associated with aggressive and metastatic phenotypes in some human cancers<sup>[25,37]</sup>. In the present study, we found a substantial frequency of *DAPK* methylation and observed that positive lymph node cases showed a slightly higher frequency of *DAPK* methylation than unmethylated cases (57.1% *vs* 42.9%). An important finding in this study was the inverse correlation observed between *DAPK* methylation and MSI. Although the mechanisms linking MSI to *DAPK* methylation are not known, this finding may provide a clue towards a better understanding of the association between MSI and better prognosis, since *DAPK* participates in the positive control of apoptosis.

Similar to previously reported results<sup>[38]</sup>, 36.4% of the cases displayed hypermethylated *CDKN2A*. The EBV seems to play an important role in *CDKN2A* methylation<sup>[38,39]</sup>. However, the fact that, in this study, 60% of the EBV<sup>+</sup> cases showed methylated *CDKN2A* should be interpreted cautiously because of the low number of such cases. Methylation in *CDKN2A* was more frequent in patients over 50 years of age ( $P = 0.035$ ), and was also present in some samples of non-neoplastic gastric epithelia (data not shown) suggesting a link between aging and cancer *via* an increase in methylation. However, it is noteworthy that younger patients (< 50 years) who did not present *CDKN2A* methylation still developed GC, which suggests that other factors may account for the gastric carcinogenesis in these patients. In order to better evaluate in our population the correlation between *CDKN2A* and EBV it will be necessary to increase the number of tumors analyzed for EBV.

Most of the gastric tumors in our sample (63.5%) exhibit aberrant methylation of *COX2*. The correlation between *COX2* methylation and gene downregulation has been well documented in the literature<sup>[40]</sup> although overexpression of *COX2* has also been reported in GCs and some precancerous tissues<sup>[41]</sup>. *COX2* overexpression

is associated with enhanced proliferation, angiogenesis, resistance to apoptosis and tumorigenesis<sup>[41]</sup>. Despite the apparent selective advantage given by *COX2* overexpression, the results from our research group and others<sup>[42]</sup> suggest that *COX2* overexpression may not be essential in all cases of gastric tumorigenesis. Recent studies have documented that *H. pylori*-induced inflammation is linked to *COX2* overexpression<sup>[43]</sup> and these findings led us to investigate whether *cagA* presence was related to the methylation status of *COX2*. In the present study, no significant correlation between *cagA* and *COX2* methylation status was found. Thus, *cagA* presence appears not to be the only mechanism involved in the control of *COX2* expression in *H. pylori*<sup>+</sup> gastric cells.

Methylation of promoter regions is reported to be the main cause of inactivation of *bMLH1*<sup>[44]</sup>. The present study revealed a significant relationship between *bMLH1* methylation and MSI ( $P = 0.001$ ), corroborating findings from other studies<sup>[44,45]</sup>. In fact, methylation of this mismatch repair gene has been shown to play a major role in MSI in several cancers. The data from MSI analyses found in our study (17.2%) corroborated other studies in the literature which demonstrated MSI ranging from 13% to 39%<sup>[46]</sup>. The association between MSI and clinicopathological characteristics of GC remains unknown. While some studies reported that MSI gastric tumors are associated with distal tumor location, intestinal histotype, fewer lymph node metastases and better prognosis<sup>[46,47]</sup>, others have found the absence of an association among these parameters<sup>[48]</sup>. In our data, 33.3% of MSI patients had no positive lymph nodes (N0) *vs* 18.1% for MSS (stable) patients, suggesting a tendency for a better prognosis. Previous studies detected that MSI frequency in *H. pylori*-positive groups was significantly higher than in *H. pylori*-negative ones<sup>[49-51]</sup> indicating that this agent may play an important role in genetic stability. Several studies have suggested that the virulence attributed to the *H. pylori-cagA*<sup>+</sup> strain is associated with a severe inflammatory response. It is known that in the gastric mucosa, reactive oxygen species are released as a result of *H. pylori* infection<sup>[51]</sup> and that the expression of DNA mismatch repair proteins in mismatch-competent cells might be transiently suppressed in the presence of oxidative stress<sup>[52]</sup>. In the present study, when the cases were divided into two groups (*H. pylori-cagA*<sup>+</sup> and *H. pylori-cagA*) we observed that, in contrast to our expectations, MSI was inversely correlated with *cagA* ( $P = 0.012$ ), suggesting that, apart from *cagA*, other factors may contribute to MSI occurrence. These results require further exploration with larger numbers of cases.

In conclusion, our results confirm that methylation is an early epigenetic event in the molecular pathogenesis of GC. The methylation pattern of the genes studied suggests that gastric tumorigenesis can occur through different pathways. It appears that in diffuse adenocarcinoma tumors, methylation can be an early and crucial event in enabling tumorigenesis, where methylation in *CDH1* assumes an important role and that MSI is associated with *bMLH1* methylation, although this event is infrequent. The inverse association discovered between *DAPK* methylation

and MSI provides new data for elucidating the mechanisms involved in the association of MSI and better prognosis. Analysis of a larger number of patients is necessary to confirm our findings and to ascertain the significance of the association between promoter methylation, MSI and the presence of infectious agents in gastric carcinogenesis. We observed that *H. pylori-cagA*<sup>+</sup> may be involved in the methylation process of *CDH1* in intestinal adenocarcinoma. Microsatellite instability was inversely correlated with the *cagA* gene, suggesting that other factors may contribute to MSI occurrence. *COX-2* overexpression does not occur in all GC cases.

## COMMENTS

### Background

Gastric cancer (GC) is one of the most common cancer types and it is associated with high mortality rates. The prognosis of this disease remains poor, especially when the diagnosis is undertaken at advanced stages. The most common GC is adenocarcinoma divided into two types, intestinal and diffuse, and these differ substantially in epidemiology, pathogenesis, genetic profile and prognostic features. *Helicobacter pylori* (*H. pylori*) is one of the more important etiological factors in GC. The *cagA* gene codes for one of the major *H. pylori* virulence proteins. Bacterial strains that have the *cagA* gene are associated with an ability to cause a stronger inflammatory response in the stomach and patients are at a greater risk of developing peptic ulcers or stomach cancer. The second infectious agent found to be associated with a subset of GCs is the Epstein Barr virus (EBV). DNA methylation is an epigenetic modification found in physiological events, however, when it is aberrant it can be associated with inactivation of tumor suppressor genes. Microsatellite Instability (MSI) reflects an erroneous form of DNA replication in repetitive microsatellite sequences and has been considered a hallmark of DNA mismatch repair gene inactivation and therefore consequently leads to genetic instability.

### Research frontiers

Some studies have linked DNA hypermethylation and MSI with *H. pylori-cagA*<sup>+</sup> and EBV infection but these data are not conclusive and the studies did not look at both agents at the same time. Therefore it is very important to analyze the same cases for both etiological factors and correlate them with MSI genetic and epigenetic alterations as well as with clinical and epidemiological data.

### Innovations and breakthroughs

The present study suggests that intestinal-type and diffuse-type GC show different methylation profiles in the genes analyzed and a strong association was found between methylation of *CDH1* and *H. pylori-cagA*<sup>+</sup> in the intestinal-type GC. In addition, a very significant inverse correlation was found between methylation of *DAPK* gene (*DAPK* has a pivotal role in regulation of apoptosis and survival in cells) and MSI, providing new evidence for the association of MSI and better prognosis.

### Applications

The data presented in this article represent important information about methylation profiles for intestinal-type and diffuse-type GC. Results show the association between *H. pylori-cagA*<sup>+</sup> and methylation in an important gene involved in metastasis (*CDH1*) in addition to showing the inverse association between *DAPK* methylation and MSI, providing new data for elucidating the mechanisms involved in the association of MSI and better prognosis. This will add to the available body of knowledge about gastric carcinogenesis and aid in future research into this important disease.

### Peer review

The manuscript by Ferrasi *et al* describes the methylation status and MSI frequency in the context of *H. pylori* and EBV infections in GC. This topic is of scientific and of clinical interest.

### **Abstract**

**AIM:** To evaluate how widely *Helicobacter pylori* (*H. pylori*) HopE and HopV porins are expressed among Chilean isolates and how seroprevalent they are among infected patients in Chile.

**METHODS:** *H. pylori* *hopE* and *hopV* genes derived from strain CHCTX-1 were cloned by polymerase chain reaction (PCR), sequenced and expressed in *Escherichia coli* AD494 (DE3). Gel-purified porins were used to prepare polyclonal antibodies. The presence of both genes was tested by PCR in a collection of *H. pylori* clinical isolates and their expression was detected in lysates by immunoblotting. Immune responses against HopE, HopV and other *H. pylori* antigens in sera from infected and non-infected patients were tested by Western blotting using these sera as first antibody on recombinant *H. pylori* antigens.

**RESULTS:** PCR and Western blotting assays revealed that 60 and 82 out of 130 Chilean isolates carried *hopE* and *hopV* genes, respectively, but only 16 and 9, respectively, expressed these porins. IgG serum immunoreactivity evaluation of 69 *H. pylori*-infected patients revealed that HopE and HopV were infrequently recognized (8.7% and 10.1% respectively) compared to *H. pylori* VacA (68.1%) and CagA (59.5%) antigens. Similar values were detected for IgA serum immunoreactivity against HopE (11.6%) and HopV (10.5%) although lower values for VacA (42%) and CagA (17.4%) were obtained when compared to the IgG response.

**CONCLUSION:** A scarce expression of HopE and HopV among Chilean isolates was found, in agreement with the infrequent seroconversion against these antigens when tested in infected Chilean patients.

## INTRODUCTION

*Helicobacter pylori* (*H. pylori*) are Gram-negative, micro-aerophilic, spiral-shaped bacteria isolated from human gastric biopsies in 1983<sup>[1]</sup>. In order to survive in this aggressive environment, *H. pylori* are able to neutralize their close surrounding space by production of urease, which catalyzes the conversion of urea into ammonium and CO<sub>2</sub>, raising pH close to neutral. In addition, to colonize the epithelium, this bacterium is able to bind to the epithelial cell surface, partially avoiding its removal by natural peristalsis or mucus renewal. These characteristics allow *H. pylori* to persist for decades.

*H. pylori* infection affects one half of the world population, roughly 73% in Chile<sup>[2]</sup>, with higher prevalence as age increases. After several years of chronic gastric infection, approximately 10%-15% of infected patients develop severe gastrointestinal diseases such as chronic gastritis, peptic ulcer and gastric carcinoma<sup>[3,4]</sup>. In Chile, 5% of the infected population develops gastric cancer<sup>[2]</sup> and this malignancy is the second cause of death by cancer in the country.

*H. pylori* carries various virulence factors, and some may have potential as vaccine antigens. These factors may be grouped as: (1) colonization factors, which allow bacterial residence; (2) persistence factors which enable bacteria to accomplish an effective and lasting survival; and (3) disease inducing factors which cause adverse pathological effects on the gastric mucosa<sup>[5]</sup>.

Based on a bioinformatics analysis of the *H. pylori* genome, a family of outer membrane proteins (OMPs) composed of 33 members has been identified<sup>[6]</sup>. These proteins are assembled into the outer membrane exposing, on the bacterial surface, small peptide loops which may act as epitopes to induce an immune response. This feature may be useful when selecting appropriate antigens for vaccine design. All these members contain an N-terminal signal peptide (processed by signal peptidase type I or II) that allows these proteins to cross the inner membrane on their way towards the outer membrane. The *H. pylori* OMPs form 2 families: the Hop members (21 proteins) and the Hor members (12 proteins). Hor proteins lack a characteristic N-terminal Hop motif<sup>[7]</sup>. Hop proteins have structural homology with the *Escherichia coli* (*E. coli*) outer membrane protein F (OmpF) porin<sup>[8]</sup>. Currently, 5 *H. pylori* Hop members (HopA, HopB, HopC, HopD and HopE) from strain 26695 have been characterized as porins using planar bilayer techniques<sup>[7,9]</sup> and some also behave as adhesins<sup>[10,11]</sup>. These properties make them attractive

candidates as vaccine antigens. In fact, other bacterial porins from *Salmonella*, *Pseudomonas*, *Chlamydia* and *Neisseria*, have been found to be strong immunogens<sup>[12-15]</sup>. However, in the case of *H. pylori*, it has been suggested that not all the genes encoding OMPs may be functional at a given time. Some of these genes are under a control mechanism that operates by strand slippage during DNA replication or DNA repair. DNA polymerase slippage may easily add or remove nucleotides when DNA synthesis occurs in front of a homopolymeric tract or dinucleotide repeats at the template strand (i.e. *polyG* or *polyCA* gene segments) causing mutations either at the promoter or at the coding region. This type of mutation may turn off or on some *hop* genes that may include these polynucleotide features. For instance, the *hopC* gene has been reported to carry a *polyT* tract (13 Ts in length) near the 5' end but *hopA*, *hopB* and *hopE* do not have such long *polyT* tracts either at their coding regions or 5' upstream at the promoter regions. Gene switching will produce a change in the antigenic bacterial surface, a strategy that will distract the host immune system. For this reason, whether any *H. pylori* OMP would be considered as a vaccine antigen, *omp* genes containing long homopolymeric tracts or dinucleotide repeats should be avoided.

Regarding HopV and HopW, genetic heterogeneity in orthologous members of the Hop family among *H. pylori* strains has been described<sup>[16]</sup>. These new members were defined as part of the HopA/HopE family, because of their homology at the N-terminal sequence and the presence of 7 homologous domains in the C-terminus region. Regarding functional aspects, HopV and HopW have pore sizes similar to that of the *E. coli* OmpF porin<sup>[16]</sup> and HopE has been defined as the homolog to the *E. coli* OmpF porin<sup>[17]</sup>.

Since the use of porins as antigens has been reported as successful<sup>[12-15]</sup>, we decided to evaluate members of the *H. pylori* Hop family as putative antigen candidates for vaccine development by determining how widely they are expressed among Chilean *H. pylori* isolates and how often Chilean patients develop antibodies against them. A brief bioinformatic survey indicated that some genes of the Hop family had homopolymeric tracts or dinucleotide repeats in their coding sequences and promoter regions, with potential capability to promote strand slippage which may affect stability of gene expression<sup>[18]</sup>. Considering this aspect, only porin genes having single homopolymeric tracts or dinucleotide repeats no longer than 6 bases in their coding sequences were chosen as source of putative useful antigens for a vaccine. For this reason, among several OMP genes, only *hopE* and *hopV* sequences were selected for the present study.

## MATERIALS AND METHODS

### Bacterial strains and plasmid vectors

*E. coli* DH5 $\alpha$  was used for polymerase chain reaction

Table 1 Primer sequences used for amplification and sequencing of *H. pylori* *hopE* and *hopV* genes

Name	5'→3' sequence	Restriction sites <sup>1</sup>
HopV1 <sup>2</sup>	GGGCCCATATGCTCAATTTTATGACAAAGAAGAAAAATAGAATGC	<u>Nde</u> I
HopV2 <sup>2</sup>	GGATCCCATGGTTAAAAATCCCTCAAGTAACTGATTG	<u>Bam</u> HI I
HopE1 <sup>2</sup>	GGCGCCATGGAAATTTATGAAAAAGTTTGTAGCTTTAGG	<u>Nco</u> I

<sup>1</sup>The restriction sites included in primer sequences and used for ligation to plasmid vectors are shown underlined;

<sup>2</sup>External primers used to clone porin genes; <sup>3</sup>Internal primers used for gene sequencing and also for confirmatory PCR reactions for those cases in which primers derived from 5' and 3' gene ends failed to raise PCR products; <sup>4</sup>Vector primers for 5' and 3' end gene sequencing.

(PCR) cloning, and *E. coli* BL21 (DE3), JM109 (DE3) and AD494(DE3)pLysS as host for porin expression assays. For cloning of PCR fragments plasmid pGEM-T Easy from Promega was used. For expression studies pET21a and pET21d (Novagen) were selected. *H. pylori* Chilean strain CHCTX-1 was used as DNA source for gene amplifications<sup>[19]</sup>. A collection of 130 *H. pylori* strains isolated from infected patients living in different Chilean cities was already available<sup>[20]</sup>.

### Bacterial cultures

*E. coli* cells were grown overnight in LB media at 37°C with shaking. *H. pylori* strains were grown under 50 mL/L CO<sub>2</sub> and 80% humidity in *Brucella* agar plates enriched with 5% horse blood cells and grown at 37°C for 2-3 d. *E. coli* strains were kept for short periods in LB plates at 4°C. Bacterial strains containing 14% glycerol were stored frozen for longer periods at -70°C.

### Plasmid purification, DNA manipulation and bacterial transformation

Plasmids were usually detected by the “one step” method<sup>[221]</sup>, and purified by alkaline lysis method<sup>[222]</sup>. Restriction digestions, DNA ligations and plasmid dephosphorylations were done according to standard procedures<sup>[222]</sup>. Electroporation in 0.2 cm electrode separation cuvettes was performed as previously described<sup>[233]</sup>, in a Gene Pulser™ apparatus. Electrocompetent cells were prepared according to described protocols<sup>[233]</sup> with a yield of 1 × 10<sup>9</sup> to 1 × 10<sup>10</sup> cells/mL.

### PCR assays

Primers corresponding to the 5' and 3' ends as well as the internal sequences of the *hopE* and *hopV* genes (Table 1) were designed based on *H. pylori* 26 695 GenBank sequences. As templates, chromosomal DNA from the CHCTX-1 strain<sup>[19]</sup> and from clinical isolates was prepared according to described procedures<sup>[241]</sup>. PCR reactions were carried out in a BioRad Mastercycler II thermocycler, with *Pfu* polymerase (Stratagene, CA,

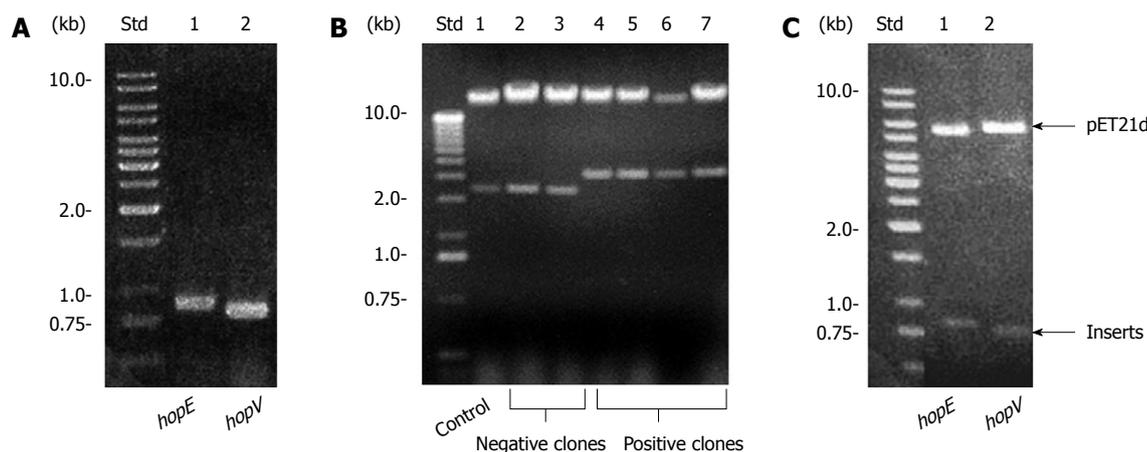

USA) or *Taq* polymerase (Promega, Madison WI, USA). Assays were done in 25 μL final volume following the manufacturer's instructions. Gene amplicons were detected by 1% agarose gel electrophoresis. Other conditions were as previously described<sup>[25]</sup>. *VacA* alleles were determined by using primers and assay conditions described by Atherton *et al*<sup>[26]</sup>.

### Polyclonal antibodies against *H. pylori* OMPs

According to standard procedures<sup>[27]</sup>, anti-HopE and anti-HopV rabbit antibodies were prepared. Proteins were obtained from *E. coli* clones expressing the *H. pylori* porins after separation by SDS-PAGE and purification from gel slices by electroelution as previously described<sup>[28]</sup>. Pathogen-free New Zealand adult female rabbits (approximately 1400 g in weight) were immunized with 250 μg of each porin dissolved in 2 mL of Tris-glycine buffer mixed (1:1) with complete Freund's adjuvant. Two animals were used for each porin inoculation and 100 μL aliquots were applied subcutaneously in the back. This was followed by 3 boosters every 15 d.

### SDS-PAGE and Western blotting

Lysates from clones expressing HopE and HopV were separated by polyacrylamide gels (12% or 15%) and run in minichambers according to Laemmli<sup>[29]</sup>. Western blotting were done as previously described<sup>[30]</sup>. As first antibody, patient serum (1:100 dilution) or rabbit anti-porin antibodies against HopE or HopV (1:1000 dilution) were used. As a second antibody for patient assays, goat anti-human IgA or anti-human IgG conjugated to peroxidase, were incubated (1:1000) overnight at 4°C. For anti-porin rabbit sera, a goat anti-rabbit peroxidase-conjugated antibody (1:1000) second antibody was used. To reduce cross reactions, rabbit antisera and human antisera were adsorbed with sonicated lysates from *E. coli* AD494(DE3)pLysS/pET21d and BL21 (DE3), respectively. Human sera immunoblotting were done with lysates expressing HopE or HopV porins and products

**Figure 1** Cloning of *H. pylori* *hopE* and *hopV* genes. A: Polymerase chain reaction (PCR) amplification of *hopE* and *hopV* genes. derived from expression of *cagA* and *vacA* gene fragments cloned from strain CHCTX-1<sup>[19]</sup>.

### Patient sera

A sera panel from 69 infected patients (63 with gastritis, 6 with ulcers) recruited from the Universidad Católica de Chile Medical Center in Santiago, with signed consent, was available. Each patient's infected condition was defined by endoscopy, positive urease rapid test and detection of hematoxylin/eosin-stained curved bacteria on gastric tissue biopsies. Also, 8 non-infected patients were included in this study. The local ethics committee approved the protocol for this study.

### Immunoprecipitation of IgG from patient sera

In order to obtain a cleaner IgA reaction in Western blotting assays using patient serum antibodies, protein G-plus-Agarose (Santa Cruz Biotechnology, catalogue #sc-2002) was utilized to first remove IgG from serum by immunoprecipitation. One hundred microliters of each serum without pre-adsorption treatment were incubated overnight with 200  $\mu$ L of protein G-plus-agarose at 4°C with mild shaking. After sedimentation for 5 min at 2500 r/min and 4°C, the supernatant of each sample was used as a source of IgG-free serum.

### DNA sequencing

DNA samples were previously purified by a commercial kit, and sequenced at our Sequencing Core Facility. T7 and internal primers for DNA sequencing are listed in Table 1.

## RESULTS

### Cloning of porin genes derived from a Chilean *H. pylori* strain as putative antigens

Selection for cloning and expression studies of the *hopE* and *hopV* genes were based on known gene

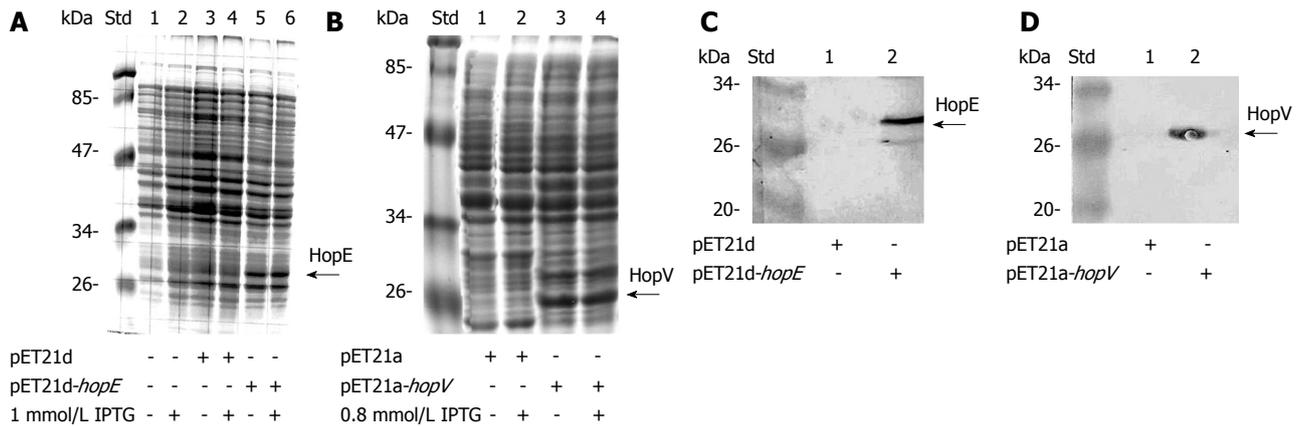

sequences from strain *H. pylori* 26695. Since our study was focused on antigens obtained from local strains, *H. pylori* CHCTX-1 strain, a clinical isolate obtained from a Chilean patient<sup>[19]</sup> was selected as the DNA source for gene cloning in this study.

Cloning of HopE and HopV porin genes, including their signal peptide regions, was done by PCR. Primers and assay conditions are described in Table 1 and Methods, respectively. Amplicons from *hopE*, and *hopV* genes were separated in a 1% agarose gel (Figure 1A), purified and treated with Taq polymerase and dATP to be ligated to pGEM-T. Recombinant plasmids were detected by insert release after *Eco*R I digestion and separation in 1% agarose gel electrophoresis. The *hopE* and *hopV* cloned inserts were subjected to *Nco* I - *Hind* III and *Nde* I - *Bam* HI double digestions and ligated to pET21d and pET21a, respectively. As expected, fragments with sizes corresponding to these genes were observed. For expression purposes, plasmids were transferred to *E. coli* AD494(DE3)pLysS cells and visualized by the "one step method"<sup>[21]</sup>. Some clones containing plasmids with the *hopE* gene are displayed in Figure 1B. Purified plasmids were used for restriction digestions and also as DNA templates for PCR gene detection. *Nco* I - *Hind* III and *Nde* I - *Bam* HI double digestions of plasmid DNA isolated from single clones were analyzed by agarose gel electrophoresis, and released inserts with sizes close to the expected ones (819 bp for *hopE* and 735 bp for *hopV*) were observed (Figure 1C).

### Expression of *H. pylori* HopE and HopV porin genes in *E. coli*

*E. coli* AD494(DE3)pLysS was able to express detectable amounts of HopE and HopV porins, as seen after SDS-PAGE and Coomassie blue staining (Figure 2A and B) and Western blotting assays (Figure 2C and D).

Expression conditions were optimized by 5 h induction with 1 mmol/L isopropyl  $\beta$ -D-thiogalactoside

**Figure 2** Expression of *H. pylori* *hopE* and *hopV* genes in *Escherichia coli* AD494(DE3)pLysS. Bacterial lysates were separated in 12%-15% PAGE-SDS gel, stained with Coomassie blue (A and B) or analyzed by Western blotting (C and D). Conditions for HopE expression are indicated below the figure (A, lanes 5 and 6; C, lane 2). Conditions for HopV expression are indicated under the figure (B, lanes 3 and 4; D, lane 2). Arrows indicate electrophoretic migration of these proteins. Lane Std: Prestained molecular weight marker in kDa (Fermentas).

(IPTG) for *hopE* and 0.8 mmol/L for *hopV* on previously saturated cultures. Protein sizes of 32 kDa for HopE and 28 kDa for HopV were observed. These porins displayed a certain amount of expression without IPTG induction, partially explained by the fact that the induction procedure was done on saturated cultures.

#### Sequence analysis of *H. pylori* *hopE* and *hopV* genes

The *hopE* (clone 1) and *hopV* (clone 13) gene sequences from the CHCTX-1 strain were obtained using external (T7 promoter and T7 terminator) as well as internal primers (Table 1) as described in Methods. Both *hopE* and *hopV* sequences were deposited at GenBank (accession numbers #EF635415 and #EF635416, respectively). As expected, these genes did not contain nonsense or frameshift mutations at their coding regions. Also, neither homopolymeric nor dinucleotide tracts longer than 6 nucleotides were found.

#### Detection of *hopE* and *hopV* genes in Chilean clinical isolates and their expression

From a collection of 240 clinical strains previously isolated<sup>[20]</sup>, we selected 130 colonies (1 to 5 isolates per patient) as representatives from 6 Chilean cities: Iquique (IQ) in the North, Valparaiso (VA) and Santiago (SA) in the central region, Los Angeles (LA) and Valdivia (VL) in the South, and Punta Arenas (PA), the Southernmost city, to evaluate the distribution of strains carrying *hopE* and *hopV* genes and their expression throughout the country.

Detection of the genes was done by standard PCR. The amplicons were almost identical in size to those expected for *hopE* and *hopV* genes from strain 26 695. Representative groups of isolates carrying *hopE* and *hopV* genes are shown in Figure 3A and B, respectively.

The *hopE* and *hopV* genes were detected in 46.9% (61 out of 130 strains) and 63.1% (82 out of 130) of the studied strains, respectively, and 40% (52 out of 130) of the strains revealed the presence of both genes simultaneously (Table 2). Among different cities,

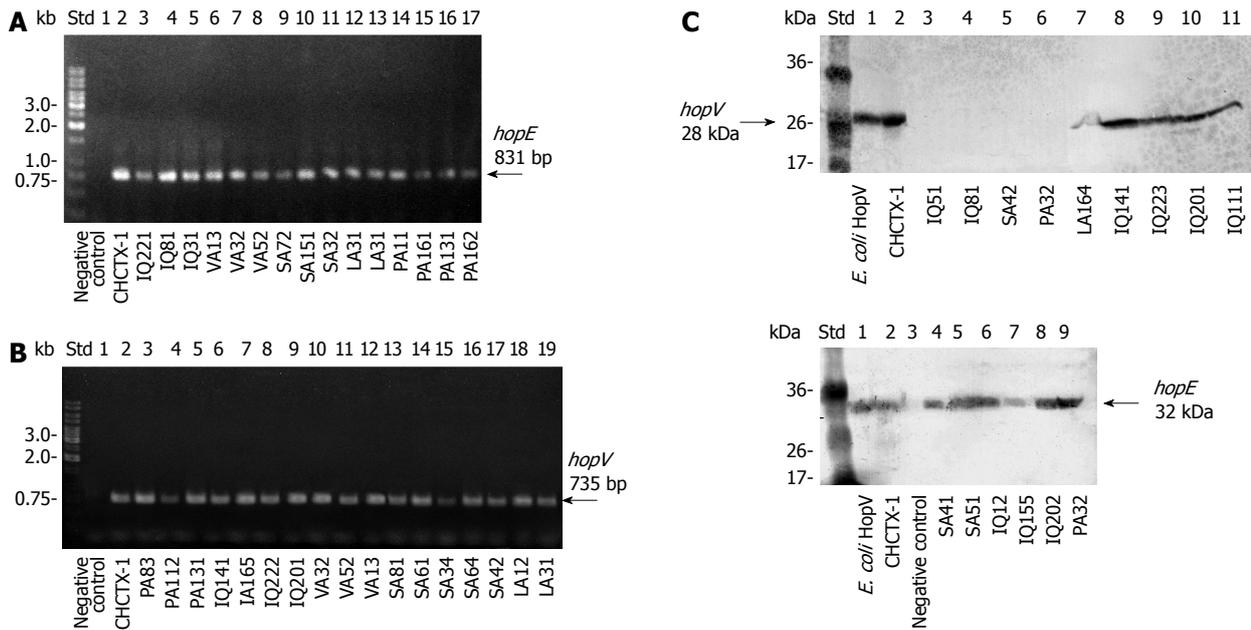

*hopE* and *hopV* gene contents varied between 30% and 69%. Curiously, *hopV* was frequently detected (69.2%) in strains from infected patients living in PA, the southernmost city. Patients from VL (mostly descendants from ancient aborigines) carried strains with a lower content (42.8%) of *hopV* gene. All PCR reactions were done at least twice using a pair of primers which bound to the gene ends. For those cases with negative amplification, additional assays using 2 primer combinations, including in each pair of primers one of the internal primers (Table 1), were performed. In most cases negative PCR reactions were confirmed and just a few strains showed positive PCR amplification only with pairs including internal primers, indicating that our initial estimation about the reduced presence of these genes in Chilean isolates was valid.

The positive results of HopE and HopV Western blotting expression assays in these isolates revealed no protein size variation, and selected results are displayed in Figure 3C.

Regarding porin expression, results showed that only 13.1% of the 130 strains expressed HopE and 6.9% expressed HopV. Altogether, 83.8% (109 out of 130 strains) did not express HopE or HopV porins either because of a lack of these genes, random inactivating gene mutations or gene silencing by the strand slippage mechanism (Table 2).

#### Recognition of HopE and HopV porins by sera from infected patients

In order to evaluate the capability of sera from Chilean *H. pylori*-infected patients to recognize recombinant *H. pylori* HopE and HopV porins, sera from 69 infected and 8 non-infected patients were tested. IgG and IgA serum antibodies against HopE and HopV antigens expressed as recombinant proteins in *E. coli* clones were tested using Western blotting assays on these bacterial lysates. VacA and CagA expressed similarly were used as immunodominant controls. The number of infected

**Figure 3** Detection of *hopE* and *hopV* genes and their expression in *H. pylori* clinical isolates from different Chilean cities. Amplicons were separated in 1% agarose gels. A: PCR detection of the *hopE* gene; B: PCR detection of the *hopV* gene. Arrows indicate migration of the respective gene fragments. Lane Std: 1 kb DNA ladder standard (Fermentas); Lane Std2: Lambda DNA/HindIII marker (Fermentas); C: Expression of HopV and HopE porins in *H. pylori* Chilean strains separated by 12% SDS-PAGE gels and detected by Western blots with respective polyclonal antibodies. Clinical isolates are indicated under the respective lanes. Std: Prestained molecular weight marker (Fermentas). The CHCTX-1 strain was included as a positive control.

**Table 2** Number of strains presenting genotypes and corresponding phenotypes indicating the presence of *hopE* (E) and *hopV* (V) genes and their expression in 130 *H. pylori* strains isolated from infected patients from 6 Chilean cities

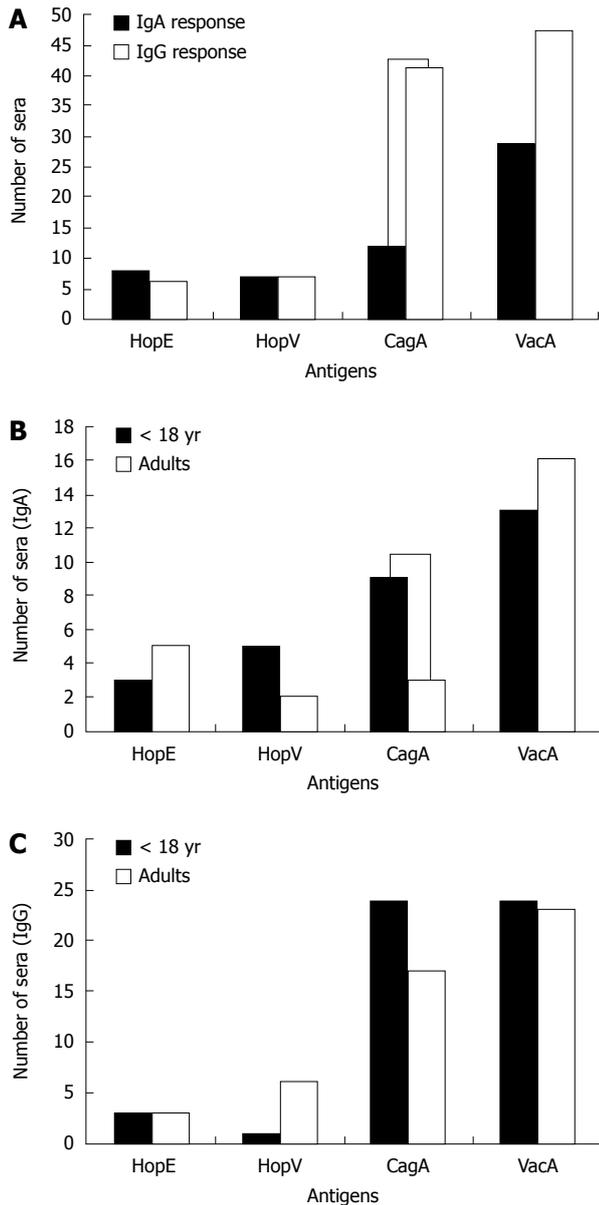

Genotypes <sup>1</sup> (E/V)	No. of strains	Phenotypes <sup>2</sup> (E/V)	No. of strains	No. of strains with different E/V phenotypes per city <sup>3</sup>					
				IQ	VA	SA	LA	VL	PA
(+/+)	52	(+/+)	5	4	-	1	-	-	-
		(+/-)	12	4	-	5	1	-	2
		(-/+)	-	-	-	-	-	-	-
		(-/-)	35	15	3	3	1	7	6
(+/-)	9	(+/-)	-	-	-	-	-	-	
		(-/-)	9	2	-	-	-	5	2
(-/+)	30	(-/+)	4	1	-	2	-	-	1
		(-/-)	26	11	-	4	-	2	9
		(-/-)	39	11	2	11	2	7	6
Totals	130	Totals	130	48	5	26	4	21	26

<sup>1</sup>Presence of *hopE* (E) and/or *hopV* (V) genes in Chilean *H. pylori* isolates determined by PCR amplifications as described in Methods using purified DNA templates from single colonies collected from 69 patients of the indicated cities. (+): gene presence; (-): no detection; <sup>2</sup>HopE and/or HopV expression assayed by Western blotting (see Methods). (+): detection; (-): no detection; <sup>3</sup>Total number of strains with the assigned phenotype per city. IQ: Iquique; VA: Valparaiso; SA: Santiago; LA: Los Angeles; VL: Valdivia; PA: Punta Arenas. The number of patients per city was IQ = 21, VA = 4, SA = 12, LA = 3, VL = 5, PA = 15. Number of strains isolated per patient ranged between 1 and 5.

patient sera able to recognize these antigens are shown in Figure 4A. It was found that, as expected, IgG human antibodies more frequently recognized VacA (68.1% or 47 out of 69) and CagA (59.4%), but rarely recognized HopE (8.7%) and HopV (10.1%) porins. A similar distribution for HopE (11.6%) and HopV (10.5%), but lower distribution values for VacA (42%) and CagA (17.4%) were found for IgA antibodies. The lower number of anti-HopE and anti-HopV reactive sera can be explained by the low proportion of *H. pylori* strains able to express these genes, being 13.1% (17/130) for

HopE and 6.9% (9/130) for HopV (Table 2). Taken together, these results strongly suggest that *H. pylori* possesses a mechanism to switch on/off these OMP genes as a strategy to evade the host immune response.

In addition, considering that the immune response in children<sup>[31,32]</sup> could be quite different from that in adults<sup>[33]</sup>, the IgA (Figure 4B) and IgG (Figure 4C) immune responses of the infected patients were plotted for 2 age groups: under 18 years of age and adults. It was noted that the number of sera with IgA and IgG responses against CagA antigen was significantly higher

**Figure 4** Frequency of recognition of 4 *H. pylori* antigens by human sera. Bars represent number of immunoreactive human sera from a panel of 69 *H. pylori*-infected patients showing IgG- and IgA-type immunoreactivity tested by Western blotting assays on *E. coli* lysates expressing separately HopE, HopV, CagA and VacA cloned antigens. A: Frequency of IgA- and IgG-type immune responses (as number of sera) which reacted with lysates containing one of these antigens; B: IgA response data taken from panel A, with patients separated by age into 2 groups: under 18 years old and adults; C: IgG response data taken from panel A, separated by age as above. As negative controls, sera from 8 non-infected patients did not display any immune response when tested with these antigens (not shown). Fisher's test was used for statistical analysis, and significance lower than 0.05 is indicated.

in patients under 18 than in adults. In contrast, IgA responses against HopE and VacA and the IgG response against HopV seemed to be more frequent in adults than in children.

## DISCUSSION

*H. pylori* colonizes the human gastric epithelium in half

of the world's population and induces strong serological and inflammatory responses in the host which persist during the entire life of the subject, rendering the host unable to eradicate infection. Knowledge of the most frequently recognized antigens in the infected population may contribute to an understanding of the bacterium survival strategy. In addition, this could also help to select appropriate antigens for vaccine design. The most extensively studied *H. pylori* virulence factors as potential vaccine antigens are urease subunits<sup>[34,35]</sup>, VacA and CagA<sup>[36]</sup>, *H. pylori* adhesin A<sup>[37]</sup> and neutrophil-activating protein<sup>[38,39]</sup>. However, results indicating reduction in colonization after oral vaccination of human subjects have been rather modest<sup>[40,41]</sup>. As new antigens are needed, and there are few studies comparing porin genes among different *H. pylori* strains, we have looked for *H. pylori* porins suitable for vaccine development. The present report provides new information, particularly about Chilean strains, regarding porin expression among clinical isolates.

Folded porins have exposed loops at the bacterial surface which may induce a strong immune response. Porins have been proposed for the design of oral vaccines to eradicate *H. pylori*<sup>[6]</sup>. This pathogen has an extensive collection of OMPs with defined pore characteristics, such as the Hop group. However, some may display a unique on/off mechanism affecting gene expression, based on DNA strand slippage during replication. The instability of expression status makes antigen selection a very important issue. Antigens that will not be permanently expressed in most of the strains should be avoided, since they will provide a limited protection.

PCR assays carried out on 130 Chilean isolates detected *hopE* and *hopV* genes in 46.9% and 63.1%, respectively. However porin expression was infrequently detected in these strains (HopE = 13.1%, HopV = 6.9%), concurring with low seroprevalence of these porins among sera of infected patients, suggesting that these genes may be under DNA strand slippage control.

Infrequent detection of expression cannot be explained by low immunoreactivity of the rabbit antisera resulting from amino acid sequence diversity among strains, since these 2 porin sequences seem to be conserved. HopE and HopV amino acid sequence identities among those from strain CHCTX-1 and the corresponding sequences from fully sequenced *H. pylori* genomes, were in the range of 98%-99% and 94%-96%, respectively.

As a complementary approach, 69 patient sera were tested by Western blotting on *E. coli* clones expressing CagA, VacA, HopE or HopV. It was revealed that HopE and HopV porins were not often recognized within the analyzed sample. Only 6 sera (8.7%) showed IgG-type immune reaction against HopE-containing lysates and 7 (10.1%) against HopV. Similar results were obtained analyzing the IgA response. These results agree with the fact that HopE and HopV porins are sporadically expressed. In contrast, CagA (its gene is present in

about 50% of the strains) and VacA (its gene is present in almost 100% of the strains) reacted with 59.4% and 68.1% of the IgG patient sera, respectively.

Regarding nucleotide sequence features, dinucleotide repeats in *hopE* and *hopV* sequences from the CHCTX-1 strain barely reached 5 nucleotides in length. However, they contained CCCCCC and TTTTTT tracts after codons 58 and 66, respectively. These findings, taken together with the low number of strains expressing these porins, and their low seroprevalence among Chilean patients, suggest that *hopE* and *hopV* may be under strand slippage gene control. Confirmation should be done by sequencing strains carrying silenced genes.

In *H. pylori*, at least 3 porin genes from the Hop family (*hopZ*, *hopP* and *hopO*) may be subjected to this on/off switching<sup>[11,42]</sup>. Another study<sup>[43]</sup> showed a similar case: 3 different *H. pylori* strains re-isolated after *Maccacrus rhesus* infection lost expression of BabA adhesin which binds Lewis b antigen. These observations support the idea that *H. pylori* can modulate expression of some OMP genes. This feature provides an adaptive mechanism to avoid induction of a strong host immune response. This is supported by the large repertoire of OMPs genes in the *H. pylori* genome. Functional redundancy of porins may explain emergence of mutations in these genes without affecting bacteria viability. It has been proposed that the role of such redundancy of outer membrane proteins is to sustain antigenic variation to support pathogen survival by evasion of the host immune response<sup>[44]</sup>. The strand slippage mechanism is not normally operating in *E. coli*, therefore, in most cases, lack of heterologous expression of *H. pylori* genes in *E. coli* should be due to mutations that previously affected the *H. pylori* genome.

In spite of the low content of homopolymeric and dinucleotide repeats found in CHCTX-1 *hopE* and *hopV* genes, some strains may have switched these genes off but, in a few cases, expression could be restored by the same mechanism. This may restrict the use of these *H. pylori* OMPs as a single source of antigens for vaccine design. However, in order to provide a wider and stronger immune response, vaccines based on a mixture of *H. pylori* antigens with the inclusion of HopE and HopV should be considered.

## ACKNOWLEDGMENTS

We thank Marco Olmos (Universidad Católica de Chile) for his careful review of the manuscript.

## COMMENTS

### Background

Few studies have been done on HopE and HopV porins from *Helicobacter pylori* (*H. pylori*). These proteins have been described as part of a large family of outer membrane proteins having similar functions, mainly as gating for influx of nutrients. Compared to other enterobacteria, such as *Escherichia coli* (*E. coli*) with only 3 major porins, *H. pylori* have shown a remarkable redundancy in this kind of outer membrane protein. The explanation for such redundancy has not

arisen. A study looking at how widely these porin genes are distributed and what proportion is actually active among clinical isolates should provide some answers.

### Research frontiers

Switching on/off in outer membrane genes in a few bacteria has been described as a mechanism to distract the immune system during infection by changing the proteins displayed on the surface. The authors found that *H. pylori* HopE and HopV porin genes seemed to be absent in some isolates, and about half of those who carried them did not express them. In addition, sera from infected patients do not frequently recognize these antigens. This feature may contribute to the ability of these bacteria to avoid the host immune response allowing their persistence in humans for an extended period of time.

### Innovations and breakthroughs

Recent reports have shown that some outer membrane protein genes from *H. pylori* could be turned on/off by random nucleotide insertions or deletions either at the promoter or within the coding region, through a mechanism called "strand slippage" during DNA replication. This is the first report proposing that this switching may also occur in the *hopE* and *hopV* genes, explaining why around 70%-90% of these genes are shut down in Chilean clinical isolates.

### Applications

Determining whether a protein is subjected to on/off switching during its expression at the bacterial surface, together with the knowledge of its immunoreactivity will be useful to select potential antigen candidates to be used in the design and development of vaccines.

### Terminology

*H. pylori* HopE and HopV proteins are part of a large family of outer membrane proteins and are located at the bacterial surface. They are defined as porins because they form a pore structure to allow the influx of small size nutrients and other compounds. They may constitute a target for the immune system. The "strand slippage" mechanism to control gene expression is a result of random errors during strand DNA replication consisting of nucleotide insertions or deletions that alter the genetic code of the protein or the functionality of elements (i.e. promoter) that control gene expression.

### Peer review

The manuscript by Lienlaf *et al* assesses the patterns of 2 porin genes in *H. pylori*. *H. pylori* remains a significant problem in developing countries around the world. Although much is now known about the pathogenesis of this bacterium and about host responses to infection, the organism remains a clinical problem. Various investigators have focused upon the establishment of a vaccine for this pathogen. An appropriate selection of a conserved and widely expressed antigen of *H. pylori* clinical isolates will assure a suitable design of a protective vaccine. This work is promising.

### Abstract

**AIM:** To investigate whether gene methylation in the peritoneal fluid (PF) predicts peritoneal recurrence in gastric cancer patients.

**METHODS:** The gene methylation of *CHFR* (checkpoint with forkhead and ring finger domains), *p16*, *RUNX3* (runt-related transcription factor 3), *E-cadherin*, *hMLH1* (mutL homolog 1), *ABCG2* (ATP-binding cassette, sub-family G, member 2) and *BNIP3* (BCL2/adenovirus E1B 19 kDa interacting protein 3) were analyzed in 80 specimens of PF by quantitative methylation-specific polymerase chain reaction (PCR). Eighty patients were divided into 3 groups; Group A ( $n = 35$ ): the depth of cancer invasion was less than the muscularis propria; Group B ( $n = 31$ ): the depth of cancer invasion was beyond the muscularis propria. Both group A and B were diagnosed as no cancer cells in peritoneal cytol-

ogy and histology; Group C ( $n = 14$ ): disseminated nodule was histologically diagnosed or cancer cells were cytologically defined in the peritoneal cavity.

**RESULTS:** The positive rates of methylation in *CHFR*, *E-cadherin* and *BNIP3* were significantly different among the 3 groups and increased in order of group A, B and C (0%, 0% and 21% in *CHFR*,  $P < 0.05$ ; 20%, 45% and 50% in *E-cadherin*,  $P < 0.05$ ; 26%, 35% and 71% in *BNIP3*,  $P < 0.05$ ). In addition, the multigene methylation rate among *CHFR*, *E-cadherin* and *BNIP3* was correlated with group A, B and C (9%, 19% and 57%,  $P < 0.001$ ). Moreover, the prognosis was analyzed in group B, excluding 3 patients who underwent a non-curative resection. Two of the 5 patients with multigene methylation showed peritoneal recurrence after surgery, while those without or with a single gene methylation did not experience recurrence ( $P < 0.05$ ).

**CONCLUSION:** This study suggested that gene methylation in the PF could detect occult neoplastic cells in the peritoneum and might be a risk factor for peritoneal metastasis.

Hiraki M, Kitajima Y, Sato S, Nakamura J, Hashiguchi K, Noshiro H, Miyazaki K. Aberrant gene methylation in the peritoneal fluid is a risk factor predicting peritoneal recurrence in gastric cancer. *World J Gastroenterol* 2010; 16(3): 330-338 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i3/330.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i3.330>

## INTRODUCTION

Peritoneal metastasis is the most frequent event in recurrent gastric cancers, and occurs in 34% of patients with recurrences, even after curative resection of the primary tumor<sup>[1,2]</sup>. In addition, peritoneal metastasis shows resistance to various chemotherapeutic drugs and causes massive ascites and intestinal obstruction. In Japan, cytological examination of peritoneal washes using Papanicolaou staining is commonly performed during surgery to detect peritoneal metastasis. However, peritoneal metastasis sometimes occurs even in cases that show a negative cytological examination. The efficacy of immunocytology<sup>[3,4]</sup>, tumor markers<sup>[5,6]</sup> and reverse transcriptase polymerase chain reaction (PCR) analysis of carcinoembryonic antigen (CEA), and cytokeratin (CK) mRNA<sup>[2,7-12]</sup> in the peritoneal washes has been examined.

Epigenetic gene silencing through DNA methylation occurs in various cancers. DNA methylation occurs in the CpG rich promoters of tumor suppressor genes, DNA repair and cell cycle checkpoint genes, resulting in suppressed gene expression<sup>[13,14]</sup>. Numerous studies have investigated gene methylation to assess the correlation with carcinogenesis and tumor progression in various cancers<sup>[15-17]</sup>. Recently, several reports have demonstrated aberrant gene methylation detected in salivary rinses<sup>[18]</sup>, pleural effusion<sup>[19]</sup>, peritoneal fluid (PF)<sup>[20,21]</sup>, lymph node<sup>[22,23]</sup>, breast ductal fluid<sup>[24]</sup>, bile<sup>[25]</sup>, pancreatic juice<sup>[26]</sup>, urine<sup>[27]</sup>, stool<sup>[28]</sup>, serum and plasma<sup>[29,29,30]</sup> from patients with various tumors and suggested the feasibility of methylation analysis in the evaluation of occult neoplastic cells or micrometastasis.

The present study investigated whether DNA methylation using PF is a possible marker for determining gastric cancer micrometastasis to the peritoneum. The DNA methylation levels of 7 genes; *CHFR* (checkpoint with forkhead and ring finger domains), *p16* (cyclin-dependent kinase inhibitor 2A), *RUNX3* (runt-related transcription factor 3), *E-cadherin*, *hMLH1* (mutL homolog 1), *ABCG2* (ATP-binding cassette, sub-family G, member 2), *BNIP3* (BCL2/adenovirus E1B 19 kDa interacting protein 3) in 80 PF specimens were analyzed by quantitative methylation-specific polymerase chain reaction (q-MSP). Furthermore, quantitative reverse transcriptase-PCR (qRT-PCR) of CEA and CK19 mRNA was examined using the same samples and the results were compared with that of q-MSP. The goal of this study was to clarify whether gene methylation in PF is feasible for determining micrometastasis to the peritoneum in gastric cancer.

## MATERIALS AND METHODS

### Ethics

The study protocol was approved by the Ethics Committee of Saga University Faculty of Medicine. Informed consent was obtained from all the patients before collection of the samples.

### Patients and sample collection

Peritoneal lavage fluid was obtained from 80 patients

who underwent surgery at the Department of Surgery, Saga University Hospital from May 2007 to August 2008. A total volume of 200 mL of normal saline was poured into Douglas's pouch and the left subphrenic space. One hundred milliliter of PF was examined by conventional cytological diagnosis with Papanicolaou staining. The remaining PF was centrifuged at 1200 g for 10 min and the pelleted cells were stored at -80°C until the extraction of genomic DNA and RNA. A gastrectomy was subsequently performed in 72 patients. A bypass operation or exploratory laparotomy was carried out in the remaining 8 patients due to either peritoneal dissemination or cytologically positive cancer cells. The histological type, depth of tumor invasion and clinical stage were determined on the basis of the criteria of the Japanese Classification of Gastric Carcinoma guidelines<sup>[31]</sup>. The 80 patients were further divided into 3 groups: Group A ( $n = 35$ ): the depth of cancer invasion was less than the muscularis propria [tumor invasion of mucosa and/or muscularis mucosa (M) or submucosa (SM), tumor involved the muscularis propria (MP)]; Group B ( $n = 31$ ): the depth of cancer invasion was beyond the muscularis propria [tumor involved the subserosa (SS), tumor penetrated the serosa (SE), tumor invasion of adjacent structures (SI)]; Group C ( $n = 14$ ): a peritoneal metastasis was histologically diagnosed [P (+)] or cancer cells were present on peritoneal cytology [CY (+)]. No peritoneal metastasis [P (-)] and benign/ indeterminate cells on peritoneal cytology [CY (-)] were confirmed at surgery in the 66 patients in group A and group B. CY (+) or P (+) was simultaneously diagnosed at surgery in 12 of 14 patients in group C. In the remaining 2 patients, cancerous ascites were collected at the recurrence. The methylation analysis was performed using specimens obtained from all 80 patients. The mRNA analysis was done using 63 samples, because high quality RNA could not be extracted in specimens from the remaining 17 cases.

### DNA extraction, sodium bisulfite modification and q-MSP

The genomic DNA was isolated from cell pellets from the abdominal fluid using an EZ1 DNA tissue kit (Qiagen, Hilden, Germany). Bisulfite modification was carried out using the EpiTet<sup>®</sup> Bisulfite Kit (Qiagen, Hilden, Germany) with 1500 ng of genomic DNA. Bisulfite-treated DNA was amplified by EpiTect<sup>®</sup> Whole Bisulfite Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. The 80 DNA samples with bisulfite modification were quantitatively analyzed for the methylation levels of 8 genes (*CHFR*, *p16*, *RUNX3*, *E-cadherin*, *hMLH1*, *ABCG2*, *BNIP3* and  $\beta$ -*actin*; an internal marker). For q-MSP, a 2  $\mu$ L aliquot was amplified by PCR using a primer set along with the Taqman probe specific for methylated sequences. A q-MSP (MethylLight) was carried out with the Light-Cycler<sup>™</sup> instrument system (Roche, Mannheim, Germany) using the Light-Cycler<sup>®</sup> TaqMan<sup>®</sup> Master (Roche, Mannheim, Germany) according to a previous report<sup>[32]</sup>. The primer sequences are shown in Table 1<sup>[33-37]</sup>. After a denaturing step at 95°C

for 10 min, PCR amplification was performed with 45 cycles of 15 s denaturing at 95°C, 5 s annealing at 60°C and a 10 s extension at 72°C. These experiments were carried out in triplicate and the mean value was then calculated. CpGenome Universally Methylated DNA (Chemicon, Temecula, CA, USA) was used as a positive control for methylation, and CpGenome Universal Unmethylated DNA (Chemicon) was used as a negative control. The quantified value of DNA methylation of a target gene was normalized by  $\beta$ -actin.

#### RNA extraction, conversion to cDNA and qRT-PCR

Total RNA was extracted from the 80 cell pellets using the ISOGEN kit (Nippon Gene, Toyama, Japan) according to the manufacturer's instructions. Samples of RNA (100 ng) were converted into cDNA and amplified using the QuantiTect® Whole Transcriptome Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. In order to quantitatively estimate the expression level of CEA and CK19 mRNA, qRT-PCR was performed on a Light-Cycler™ instrument system

(Roche, Mannheim, Germany) using LightCycler® TaqMan® Master (Roche, Mannheim, Germany) according to the manufacturer's instructions. The primer sequences are shown in Table 2. After denaturing at 95°C for 10 min, qRT-PCR amplification was performed with 45 cycles of 15 s denaturing at 95°C, 5 s annealing at 60°C and a 10 s extension at 72°C. These experiments were all carried out in triplicate and the mean value was then calculated. The quantified value of mRNA expression of a target gene was normalized by  $\beta$ -actin.

#### Comparison of gene methylation between cancer tissue and peritoneal fluid

The conventional qualitative MSP was analyzed using several cancer tissue specimens. Genomic DNA was isolated from the tissue and bisulfite treatment was carried out as described above. The methylation status in the tissue samples was determined by MSP. Amplification was performed using Takara ExTaq Hot Start Version (Takara, Shiga, Japan) according to the manufacturer's instructions. The primer se-

quences are shown in Table 1 and PCR was performed in an iCycler (Bio-Rad, Hercules, CA, USA) under the following conditions. After heating at 96°C for 3 min, 35 cycles at 96°C for 30 s, 60°C for 30 s, 72°C for 30 s and 72°C for 5 min. The PCR products were separated on 1.5% agarose gel, stained with ethidium bromide, and were then observed under ultraviolet light.

### Statistical analysis

A cut-off value for distinguishing methylation status was determined using a receiver-operator characteristic (ROC) curve, which was obtained by comparing methylation values between group A and C. The cut-off value of CEA and CK19 mRNA expression was also determined by a ROC curve as described above. Differences in the frequencies were analyzed by the  $\chi^2$  test, while also applying Fisher's exact test. A statistical analysis was carried out using the SPSS 15.0j statistical software package for Windows (SPSS Japan Inc.). A *P* value of less than 0.05 was considered to be statistically significant.

## RESULTS

The clinicopathological characteristics of the patients in this study are summarized in Table 3. The 80 patients included 28 (35.0%) females and 52 (65.0%) males with a mean age of 65.9 years (range, 39-88 years). The number of patients in group A, B and C was 35 (43.8%), 31 (38.8%) and 14 (17.5%) cases, respectively.

### DNA hypermethylation of peritoneal fluids

Initially, q-MSP of *CHFR*, *p16*, *RUNX3*, *E-cadherin*, *hMLH1*, *ABCG2* and *BNIP3* was examined in 80 PFs. Figure 1 shows the methylation level of each gene in the 3 groups. The 80 cases were then divided into 2 groups, a methylation positive and a methylation negative group as described in the Materials & Methods section. Table 4 shows that the methylation status of *CHFR*, *E-cadherin* and *BNIP3* were significantly different among the 3 groups (*P* < 0.05). In these 3 genes, the positive rate of methylation increased in order of group A, B and C. The correlation of multigene methylation among *CHFR*, *E-cadherin* and *BNIP3* in the 3 groups was further analyzed. In group A and B, 3 of 35 cases (9%) and 6 of 31 cases (19%) showed multigene methylation in 2 or more genes, respectively (Table 5). In contrast, 8 of 14 cases (57%) were methylation positive in 2 or more genes in group C. The results showed a significant relationship between methylation status of more than 2 genes and the 3 groups (*P* < 0.001).

### mRNA expression of CEA and CK19 in peritoneal fluids

The expression of CEA and CK19 mRNAs in the 63 PFs were quantitatively analyzed by qRT-PCR to detect gastric cancer cells in the peritoneal washes. Figure 2 shows the expression level of CEA and CK19 mRNAs in the 3 groups. The mRNA level was further divided into negative and positive groups and compared among the 3 groups. The results showed that CK19, but not CEA, was

significantly correlated with the 3 groups (Table 6, *P* < 0.05, *P* = 0.352). The positive rate of CK19 increased in order of group A (25%), B (46%) and C (73%).

### Comparison of gene methylation between the cancer tissue and ascites fluid

The gene methylation of *CHFR*, *E-cadherin* and *BNIP3* was examined in the primary or metastatic cancer tissue and was compared with those in the corresponding PF

**Figure 1** Methylation level of peritoneal wash specimens from gastric cancer patients measured by q-MSP according to the depth of cancer invasion and positive cancer cell findings. Left: Group A; Middle: Group B; Right: Group C.

**Figure 2** mRNA expression level of peritoneal wash specimens from gastric cancer patients measured by qRT-PCR according to the depth of cancer invasion and positive cancer cell findings. Left: Group A; Middle: Group B; Right: Group C.

in group C. Nine of 14 cases were analyzed because the tissues were not obtained in remaining 5 cases. The same methylation pattern was present in the cancer tissues and ascites in 100% of *CHFR*, 88.9% of *E-cadherin* and 77.8% of *BNIP3* (Table 7).

**Relationship between multigene methylation or mRNA expression and peritoneal recurrence**

The prognosis of patients in group A or B was followed for at least 8 mo after surgery. None of the 35 patients in group A had cancer recurrence (data not shown). The prognosis of only 28 of 31 patients in group B was followed because the remaining 3 patients were excluded from this analysis based on the results of a non-curative resection. In 28 of the patients in group B, 2 of the 5 patients with multigene methylation showed peritoneal recurrence after surgery, while patients without or with a single gene methylation did not experience recurrent cancer (Table 8). There was a significant correlation between peritoneal recurrence and multigene methylation in group B (Table 8, *P* < 0.05). Peritoneal recurrence was observed in only 1 of 10 cases that were CK19 positive, however statistical significance was not observed (Table 8, *P* = 0.943).

**DISCUSSION**

Postoperative recurrence of gastric cancer usually occurs in the peritoneum, lymph node and liver<sup>[1]</sup>. Peritoneal metastasis occurs most frequently and is highly resistant to various chemotherapies, which leads to a poor prognosis in gastric cancer patients. Peritoneal recurrence has been reported to depend on the depth of invasion, as 97.2% of recurrences occur beyond the MP. In addition, peritoneal recurrence was demonstrated in 34.9% of SS cases, 46.7% of SE cases and 60.0% of SI cases<sup>[2]</sup>.

Another study reported that 50%-60% of gastric cancer patients with serosal invasion after a curative resection eventually developed peritoneal metastasis<sup>[38]</sup>. Furthermore, the average survival after peritoneal recurrence is 4.9 mo<sup>[39]</sup>. Therefore, the detection of micrometastasis in peritoneal lavage is essential, not only to make an accurate diagnosis, but also to start chemotherapy before the metastatic nodule is grossly formed in the peritoneum. The introduction of molecular technology such as RT-PCR of cancer specific genes has addressed the detection of micrometastasis in the LN<sup>[40,41]</sup>, ascites<sup>[2,7-12,38,42,43]</sup>, bone marrow and peripheral blood<sup>[44,45]</sup> in gastric cancer. Various types of mRNA, such as CEA, CK19, and CK20 have been analyzed by RT-PCR and used as molecular markers in detecting micrometastasis in gastric cancer. Several studies have reported that the positive expression of mRNA in PF shows a significant correlation with peritoneal recurrence and survival<sup>[2,8-12,38,43]</sup>.

Recently, an analysis of cancer specific gene methylation has been utilized to detect micrometastasis in salivary rinses for head and neck cancer patients<sup>[18]</sup>, pleural effusion for lung cancer and malignant mesothelioma<sup>[19]</sup>, ductal fluid for breast cancer<sup>[24]</sup>, ascites for ovarian cancer and colorectal cancer<sup>[21,22]</sup>, bile for gallbladder cancer<sup>[25]</sup>, pancreatic juice for pancreatic cancer<sup>[26]</sup>, urine for prostate cancer<sup>[27]</sup>, stool for colorectal cancer<sup>[28]</sup> and serum<sup>[20,29,30]</sup>. However, few studies have addressed gene methylation for the detection of micrometastasis to PF in gastrointestinal cancer<sup>[21]</sup>.

The present study analyzed the promoter methylation of cancer related genes in 80 PFs. *CHFR*, *p16*, *RUNX3*, *E-cadherin*, *bMLH1*, *ABCG2* and *BNIP3* were chosen for the methylation analysis, because the frequent methylation of these 7 genes has been reported in several

malignancies including gastric cancer<sup>[15,16,21,23,25-27,33-37,46-50]</sup>. Peritoneal recurrence has been reported to depend on the depth of invasion<sup>[2]</sup>. Therefore, 80 samples from gastric cancer patients were classified into 3 groups [Group A: cancer invasion was restricted in M, SM, MP, Group B: cancer invasion deeper than MP, Group C: CY(+) or P(+)] and correlated with the gene methylation. As a result, q-MSP analysis using the 80 PFs demonstrated that the methylation status of *CHFR*, *E-cadherin* and *BNIP3* were significantly increased depending on the depth of cancer invasion. In contrast, the methylation status of the other genes was not significantly changed among the 3 groups (Table 4). These results indicate that the increasing value of the methylation of *CHFR*, *E-cadherin* and *BNIP3* from group A to group C was possibly derived from the metastatic cancer cells in the peritoneum. On the other hand, a q-MSP analysis might detect methylation from normal cells in the peritoneum at the basal level in *p16*, *RUNX3*, *bMLH1* and *ABCG2* genes. Based on these findings, *CHFR*, *E-cadherin* and *BNIP3* methylation was thus suggested to be preserved during cancer invasion, finally resulting in the occurrence of peritoneal seeding. Therefore, the methylation in more than 2 genes was compared among the 3 genes in each group. The results showed that there was a significant difference between multigene methylation and the 3 groups (Table 5). Eight of 14 patients (57%) in group C carried the multigene methylation while only 3 of 35 (9%) patients in group A exhibited multigene methylation. On the other hand, a qRT-PCR analysis examined the expression of CEA and CK19 mRNA in 63 samples (Table 6). Unexpectedly, CEA was not correlated with the classification even in group C with the highest positive rate. However, CK19 was significantly increased depending

on the depth of cancer invasion, CY and P classification. It was desirable that gene methylation should be detected in up to 100% of samples in group C with CY1 or P1. However, only 21% of gene methylation was observed in *CHFR*, 46% of *E-cadherin*, 71% of *BNIP3* and 57% of more than 2 genes were methylated in group C, indicating that gene methylation did not universally occur in all cancer cells. Thus, it is important to improve the sensitivity of multigene methylation analysis using PFs by increasing the number of genes that are specifically methylated in cancer cells. To clarify whether the methylation status of the PF originated from the cancer tissue, the methylation status of the primary or metastatic tissue in group C was compared with the methylation in the PF. The methylation status in the primary tumor was highly preserved in the PF (Table 7), thus suggesting that the methylation of the 3 genes assessed in the PF was derived from the primary tumor.

This study finally evaluated whether multigene methylation predicts peritoneal recurrence after surgery. In 21 patients in group B, peritoneal recurrence was found in 2 of 5 patients (40%) carrying multigene methylation. On the other hand, recurrence occurred in only 1 of 10 patients (10%) with positive CK19. There was a significant association between peritoneal recurrence and multigene methylation, but not CK19 (Table 8). These results suggested that multigene methylation may be a risk factor for peritoneal metastasis in the patients in group B even though the metastasis was not detected during surgery. An RT-PCR method using epithelial markers is critical in the diagnosis of micrometastasis. However, these methods only diagnose the presence of cancer cells. A methylation analysis that diagnosed micrometastasis in PFs would provide more information not only concerning the existence of cancer cells but also carcinogenesis, tumor progression and chemosensitivity, based on information on methylation status.

In conclusion, the present study investigated the methylation status in PF by both q-MSP and qRT-PCR analyses. The multigene methylation of *CHFR*, *E-cadherin* and *BNIP* in PF revealed the clinical feasibility of detecting occult neoplastic cells in the peritoneum. A methylation analysis along with a cytological examination might increase the positive detection of cancer cells in PF.

## COMMENTS

### Background

Postoperative recurrence of gastric cancer usually occurs in the peritoneum. Peritoneal recurrence is highly resistant to various chemotherapies, which leads to a poor prognosis in these patients. Therefore, the detection of micrometastasis in peritoneal lavage is essential, not only to make an accurate diagnosis, but also to start chemotherapy before the metastatic nodule is grossly formed in the peritoneum.

### Research frontiers

Epigenetic gene silencing through DNA methylation occurs in various cancers. Recently, several reports have demonstrated aberrant gene methylation detected in various samples from cancer patients and have suggested the feasibility of methylation analysis in the evaluation of occult neoplastic cells or micrometastasis. This study clarified whether gene methylation in peritoneal fluid is feasible for determining micrometastasis to the peritoneum in gastric cancer patients.

### Innovations and breakthroughs

Few studies have addressed gene methylation for the detection of micrometastasis to peritoneal fluid in gastrointestinal cancer. The authors' results indicate that gene methylation in the peritoneal fluid could detect occult neoplastic cells in the peritoneum and might be a risk factor for peritoneal metastasis.

### Applications

The development of this system may improve the accurate diagnosis of peritoneal dissemination and improve the prognosis of gastric cancer patients.

### Terminology

DNA methylation is an epigenetic modification in humans, and changes in methylation patterns play an important role in carcinogenesis, cancer progression and chemosensitivity.

### Peer review

This paper is interesting and written well.

### Abstract

**AIM:** To compare two types of classification of intestinal metaplasia (IM) of the stomach and to explore their relationship to gastric carcinoma.

**METHODS:** Forty-seven cases of gastric IM were classified into type I, type II or type III according to mucin histochemical staining and compared with a novel classification in which the specimens were classified into simple IM (SIM) or atypical IM according to polymorphism in terms of atypical changes of the metaplastic epithelium. Forty-seven IM and thirty-seven gastric carcinoma samples were stained for p53, c-erbB-2 and Ki67 proteins by Envision immunohistochemical technique.

**RESULTS:** There were no significant differences in the expression of p53 and c-erbB-2 among type I, type II, type III IM and gastric carcinomas. The positive expression rate of Ki67 was significantly higher in gastric carcinomas than in type I IM while no significant Ki67 expression differences were observed among type II,

type III IM and gastric carcinomas. The expression of p53, c-erbB-2 and Ki67 proteins in 20 SIM, 27 Atypical IM and 37 gastric carcinomas showed significant differences between SIM and gastric carcinomas while no significant differences were observed between Atypical IM and gastric carcinomas.

**CONCLUSION:** Atypical IM may better reveal the pre-cancerous nature of IM and could be a helpful indicator in the clinical follow up of patients.

### INTRODUCTION

The relationship between intestinal metaplasia (IM) and gastric carcinoma has always been controversial. Correa postulated that gastric cancer develops through a complex sequence of events from normal mucosa to superficial gastritis, chronic atrophic gastritis, IM, dysplasia, and finally to intestinal type gastric carcinoma<sup>[1]</sup>. Many investigators have given credence to the preneoplastic nature of IM<sup>[2]</sup>. Even with common occurrence and presence in gastric biopsies, not all cases of IM may develop into gastric carcinoma. A subtype of IM which

has malignant potential should be classified for clinical follow up. Generally, IM is divided into subtypes on the basis of histochemical characteristics, and IM showing sulphomucin secretion has been considered to be a lesion with precancerous nature<sup>[3-5]</sup>, but some others considered this type of IM had no special link to gastric carcinoma<sup>[2]</sup>, and Rothery<sup>[6]</sup> also found half of the cases with this IM showing sulphomucin secretion exist in benign lesions.

In our study, IM was divided into two subtypes according to the atypical changes of the metaplastic epithelium: simple IM (SIM) and atypical IM (AIM). We detected three tumor-associated proteins, p53, c-erbB-2 and Ki67, in different subtypes of IM in order to find which one is more associated with gastric carcinoma.

## MATERIALS AND METHODS

### Samples

Forty-seven formalin-fixed, paraffin-embedded samples for IM were obtained from endoscopic biopsy and thirty-seven gastric carcinoma specimens from gastrectomy at Qilu Hospital of Shandong University. Mucin histochemical staining for IM subtyping was performed.

Serial sections were cut, stained with hematoxylin-eosin and the following techniques for mucins: Alcian blue pH 2.5-periodic acid-Schiff and high iron-diamine plus Alcian blue pH 2.5 to identify neutral, sialo- and sulphomucins.

Forty-seven cases of IM were classified in accordance with the system used by Jass and Filipe<sup>[7,8]</sup>: Type I (complete): mature absorptive and goblet cells, the latter secreting sialomucins (Figure 1); Type II (incomplete): IM cells with few or absent absorptive cells; presence of columnar “intermediate” cells in various stages of differentiation, secreting neutral and acid sialomucins; goblet cells secreting sialomucins and/or occasionally sulphomucins (Figure 1); Type III (incomplete): the cell dedifferentiation is more marked than in type II; “intermediate” cells secrete predominantly sulphomucins. A variable degree of disorganized glandular architecture is often present (Figure 1).

### IM subtyping according to atypical changes

Forty-seven IM samples were classified into SIM and AIM according to atypical changes of the metaplastic epithelium.

### Immunohistochemical technique

Sections 4  $\mu$ m thick were cut, deparaffinized in xylene, and then dehydrated in descending dilutions of ethanol. For the antigen retrieval regimen, all slides were micro-waved in 10 mmol/L sodium citrate buffer (pH 6.0) at 10 min intervals for a total of 20 min. The endogenous peroxidase activity was blocked by 10 min of incubation with 3% hydrogen peroxidase (reagent A) at room temperature. After washing in PBS, the sections were incubated with monoclonal mouse anti-human antibodies p53 (MAB-0364), c-erbB-2 (CB11) and Ki67 (SP6)

**Table 1** The distribution of 47 IM samples within different subtypes of IM

	Type I	Type II	Type III	Total
SIM	11	7	2	20
AIM	6	11	10	27
Total	17	18	12	47

IM: Intestinal metaplasia; SIM: Simple intestinal metaplasia; AIM: Atypical intestinal metaplasia.

overnight at 4°C. The sections were washed with PBS and incubated with polymerase auxiliaries (reagent B) for 20 min. After washing in PBS, the sections were incubated with biotinylated secondary antibody (reagent C) for 30 min at room temperature and finally DAB was visualized. Tissues were counterstained with hematoxylin. A negative control was designed by using PBS instead of primary antibody.

### Positive criteria of immunohistochemical staining

Sections were scored by light microscopy. The percentage of positively stained cells was calculated after 100 cells were counted in more than 5 high-power ( $\times 40$ ) fields. The following definitions were made: p53 and Ki67: more than 10% positive staining in nuclei was defined as positive staining; c-erbB-2: more than 10% positive staining in cytoplasm was defined as positive staining in IM, and more than 10% positive staining in cell membrane was defined as positive staining in gastric carcinoma<sup>[9]</sup>.

### Statistical analysis

The significance of associations was determined by the  $\chi^2$  test or the Fisher's exact test,  $P$  value  $< 0.05$  was considered statistically significant.

## RESULTS

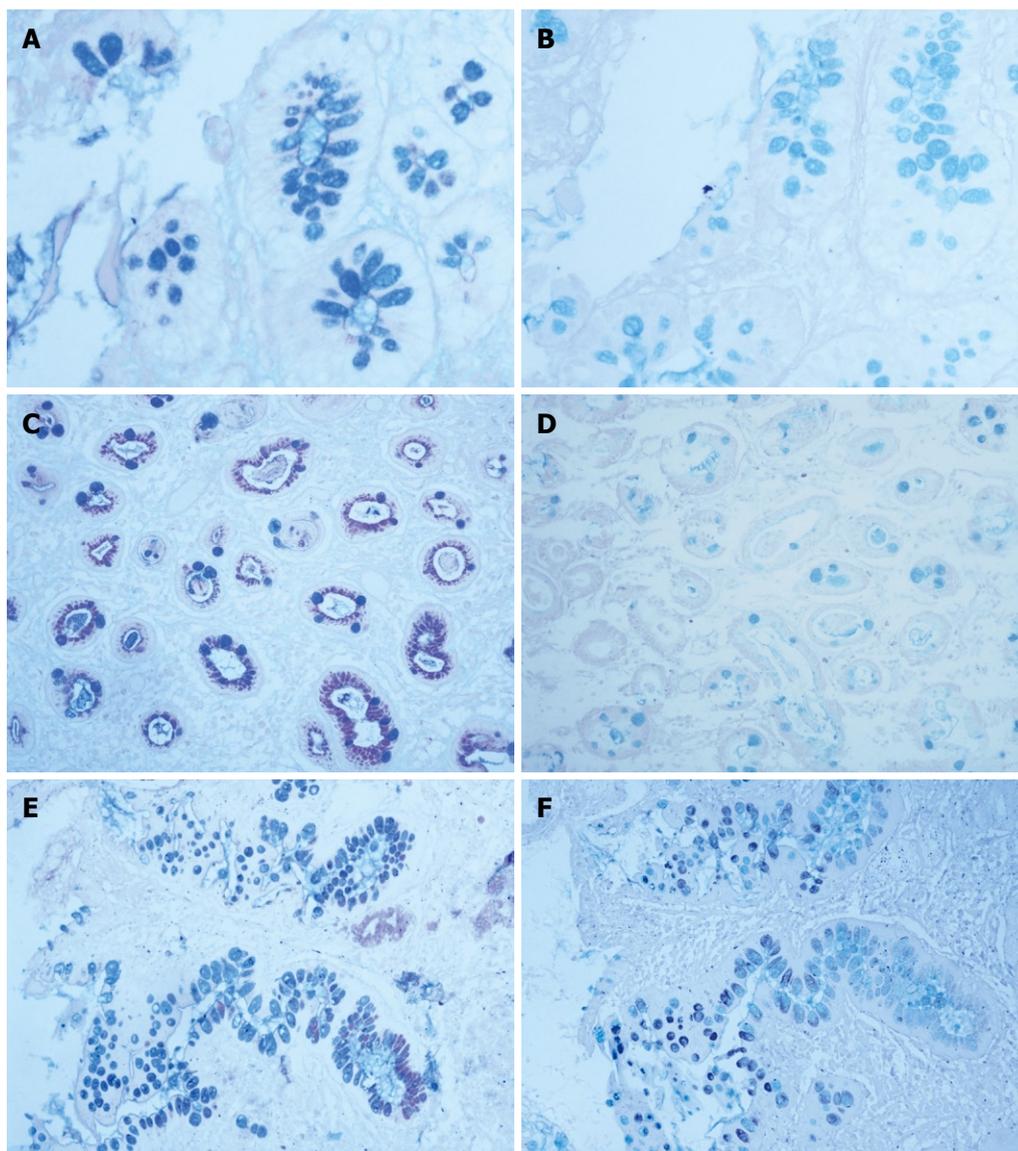

### Subtype distribution of 47 IM samples

In 47 IM samples, type I, type II and type III IM accounted for 17, 18 and 12 samples, respectively. In 20 SIM, type I, type II and type III IM accounted for 11, 7 and 2 samples, respectively. In 27 AIM, type I, type II and type III IM accounted for 6, 11 and 10 samples, respectively (Table 1).

### Expression of p53 protein

The positive expression rates of p53 in type I, type II, type III IM and gastric carcinomas were 41.18%, 27.78%, 25.00% and 54.05%, respectively. The expression of p53 in gastric carcinomas was not significantly higher than in types I, II and III ( $P > 0.05$ ).

The positive expression rates of p53 in SIM and AIM were 20.00% and 40.74%, respectively. The expression of p53 in gastric carcinomas was significantly higher than in SIM ( $P < 0.05$ ). There was no significant difference in p53 expression between AIM and gastric carcinomas ( $P > 0.05$ ) (Table 2, Figure 2).

**Figure 1** Three types of intestinal metaplasia (IM) according to histochemical stains. A: IM type I : AB-PAS AB positive (blue), PAS negative; B: IM type I : HID-AB AB positive (blue), HID negative; C: IM type II: AB-PAS AB positive (blue), PAS positive (red); D: IM type II: HID-AB AB positive (blue), HID negative; E: IM type III: AB-PAS AB positive (blue), PAS positive (red); F: IM type III: HID-AB AB positive (blue), HID positive (grey and black) (× 200).

**Table 2** The expression of p53, c-erbB-2 and Ki67 proteins in different subtypes of IM and gastric carcinoma (GC)

	Total	p53		c-erbB-2		Ki67	
		+	-	+	-	+	-
SIM	20	4 <sup>a</sup>	16	6 <sup>a</sup>	14	5 <sup>a</sup>	15
AIM	27	11	16	18	9	12	15
Type I	17	7	10	9	8	5 <sup>a</sup>	12
Type II	18	5	13	8	10	8	10
Type III	12	3	9	4	8	4	8
GC	37	20	17	22	15	28	9

<sup>a</sup>*P* < 0.05 vs GC.

**Expression of c-erbB-2 protein**

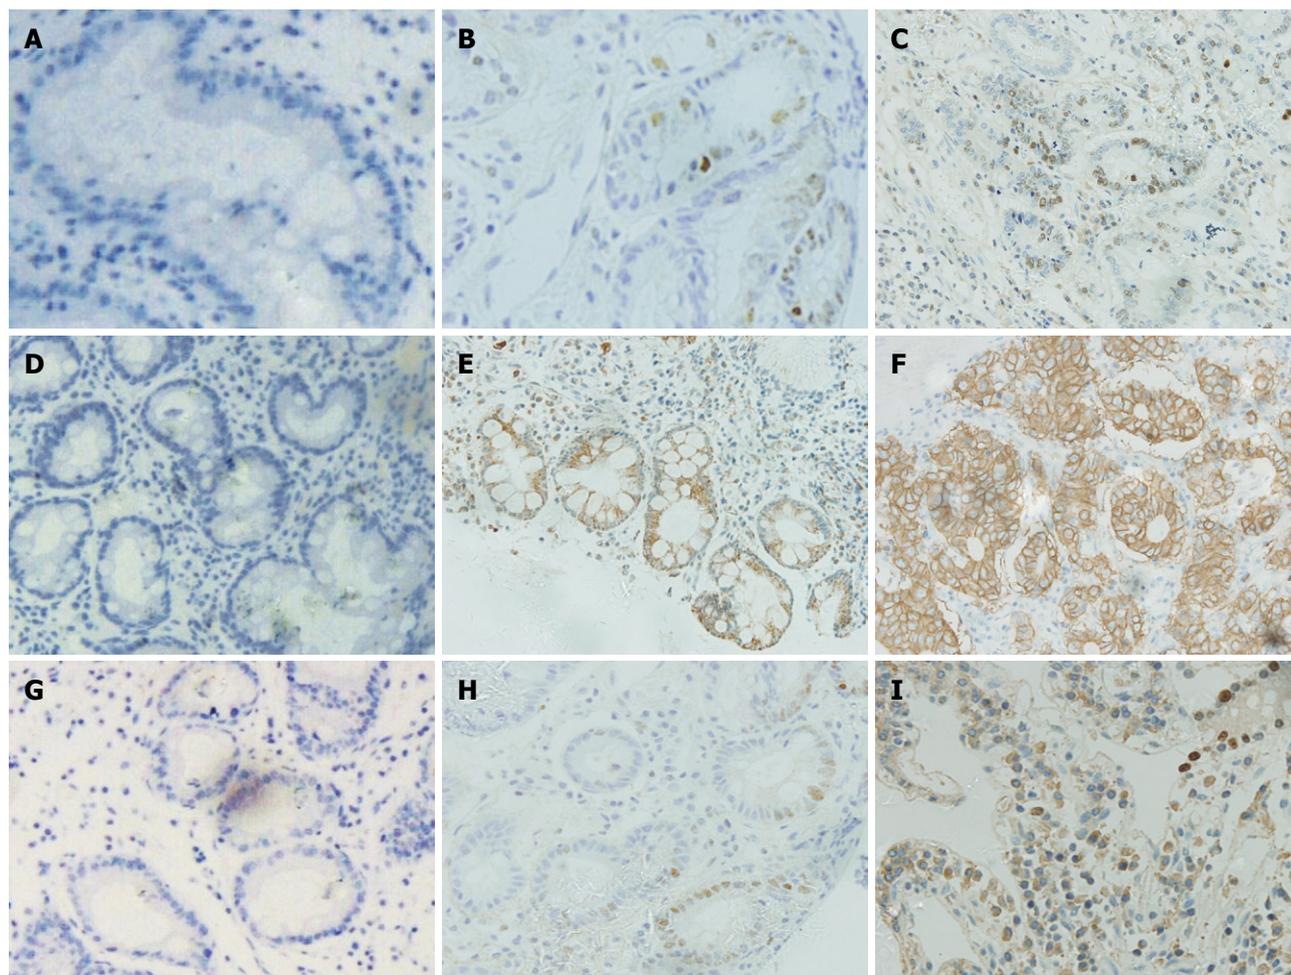

The positive expression rates of c-erbB-2 in type I, type II, type III IM and gastric carcinomas were 52.94%, 44.44%, 33.33% and 59.46%, respectively. The

expression of c-erbB-2 in gastric carcinomas was not significantly higher than in types I, II and III (*P* > 0.05).

The positive expression rates of c-erbB-2 in SIM and AIM were 30.00% and 656.67%. The expression of c-erbB-2 in gastric carcinomas was significantly higher than SIM (*P* < 0.05). There was no significant difference between expression in AIM and gastric carcinomas (*P* > 0.05) (Table 2, Figure 2).

**Expression of Ki67 protein**

The positive expression rates of Ki67 in type I, type II, type III IM and gastric carcinomas were 29.41%, 50.00%, 41.67% and 75.68%, respectively. The expression of Ki67 in gastric carcinomas was significantly higher than in type I IM (*P* < 0.05). There was no significant difference in Ki67 expression between gastric carcinomas and type II or type III.

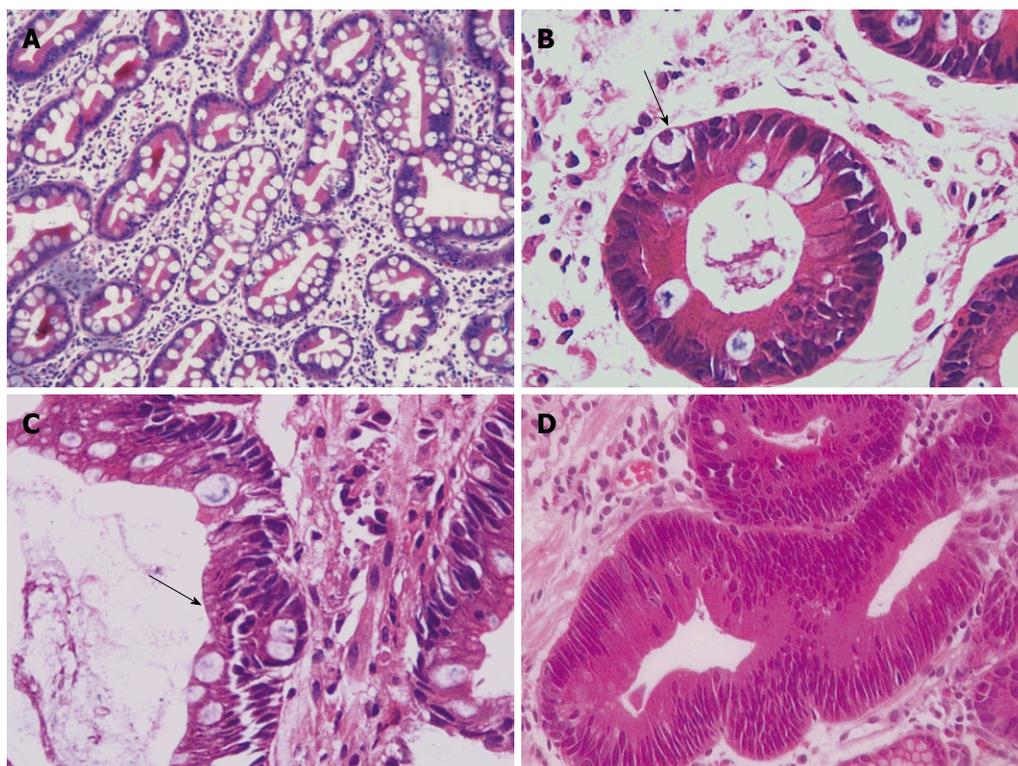

**Figure 2** Expression of p53, c-erbB-2 and Ki67 proteins in simple intestinal metaplasia (SIM), atypical intestinal metaplasia (AIM) and gastric carcinoma (GC). A: p53 negative in SIM; B: p53 positive in AIM (nuclei); C: p53 expression increased in GC (nuclei); D: c-erbB-2 negative in SIM; E: c-erbB-2 positive in AIM (cytoplasm); F: c-erbB-2 expression increased in GC (membrane); G: Ki67 negative in SIM; H: Ki67 positive in AIM (nuclei); I: Ki67 expression increased in GC (Envision method,  $\times 400$ ).

The positive expression rates of Ki67 in SIM and AIM were 25.00% and 51.85%, respectively. The expression of Ki67 in gastric carcinomas was significantly higher than in SIM ( $P < 0.05$ ) while there was no significant difference in Ki67 expression between AIM and gastric carcinomas ( $P > 0.05$ ) (Table 2, Figure 2).

## DISCUSSION

Gastric carcinoma is the fourth most common malignancy worldwide<sup>[10]</sup>, accounting for 10% of newly diagnosed cancers<sup>[11]</sup>. It is one of the most common causes of cancer mortality in China<sup>[12]</sup>. Approximately 84% of patients with gastric cancer will have advanced disease and their median survival time is only 3-4 mo if they are not treated with chemotherapy<sup>[13]</sup>. Therefore, it is necessary to diagnose at an early stage in order to improve the survival rate. Gastric carcinoma is divided into intestinal and diffuse types according to Lauren<sup>[14]</sup> and the intestinal-type of gastric carcinoma is said to have a strong association with IM<sup>[15]</sup>. Since Morson<sup>[16]</sup> pointed out in 1955 that some gastric carcinomas might arise from an area

of IM, IM has been considered to be a possible precancerous state. A large number of IM patients have been found in clinical studies, and a research group reported that the detection rate of IM was 37%<sup>[4]</sup>. Which type of IM is closely related to gastric carcinoma remains an unanswered question. Traditionally, IM is divided according to histochemical characteristics, but research concludes that sulphomucin-positive IM is of no value in surveillance for gastric cancer<sup>[17]</sup>. In view of the inconsistency of this classification, we assigned IM into the groupings of SIM (Figure 3) and IM with atypical changes as AIM (Figure 3). The predominant difference in the two types of IM is the atypical changes of the metaplastic epithelium: SIM glands are arranged neatly and the goblet cells are in normal forms, the mucosa in the foveolae is flat; while AIM glands are crowded and the goblet cells often are associated with immature differentiation, also the mucosa in the foveolae usually become deeper than in SIM. One question should be clarified regarding the difference between AIM and gastric intraepithelial neoplasia (GIN) (Figure 3): the main distinction lies in the goblet cells. There were more goblet cells (over 10%

**Figure 3** Morphological differences in three gastric lesions. A: SIM; B: AIM: reversed polarity of goblet cell (arrow); C: AIM: mitosis (arrow); D: Gastric intraepithelial neoplasia (GIN) (HE,  $\times 400$ ).

of total cells) in AIM while there were less or no goblet cells in GIN.

In our study, three tumor-associated proteins, p53, c-erbB-2 and Ki67, were selected for immunohistochemical detection. The *p53* gene is localized to chromosome arm 17p13<sup>[18]</sup>. Evidence from *in vitro* models suggests that *p53* acts as a tumor suppressor gene<sup>[19]</sup>. The evidence accumulated so far suggests that mutant *p53* may be the commonest genetic abnormality in human cancer<sup>[20]</sup>. *p53* gene mutation is known to play a considerable role in the carcinogenesis of colonic carcinoma and gastric carcinoma. Shiao *et al*<sup>[21]</sup> reported that 67% of gastric carcinomas, 58% of dysplasias and 38% of metaplastic lesions stained positively for p53. *C-erbB-2* (also called *NEU* and *HER2*) is a proto-oncogene that codes for a protein product which shows considerable homology with EGFR<sup>[22]</sup>. Several studies have reported amplification of the *c-erbB-2* gene in human neoplasms, particularly in adenocarcinomas<sup>[23]</sup>. In recent years, researchers have revealed that c-erbB-2 plays an important role in the occurrence and development of gastric carcinoma. Observations suggested that *c-erbB-2* gene rearrangement non-randomly associated with carcinomas with glandular origin derived from the gastrointestinal tract<sup>[24]</sup>. It is reported that over expression of the *c-erbB-2* gene is at a frequency of 8.2%-45% in gastric carcinoma<sup>[25-27]</sup>. Ki67 is a nuclear proliferation-associated antigen expressed in the growth and synthesis phases of the cell cycle but not in the resting phase<sup>[28]</sup>. This antigen provides information about the proportion of active cells in the cell cycle. Its expression varies

greatly during the cell cycle and is increased in many tumors<sup>[29]</sup>. Studies have revealed that the Ki67 proliferating index increases in the transformation from IM to gastric carcinoma<sup>[30]</sup>. For the reasons above, p53, c-erbB-2 and Ki67 proteins can be regarded as indicators of the pre-cancerous nature of IM in the gastric mucosa. Our results demonstrated that the expressions of p53 and c-erbB-2 in gastric carcinoma were not significantly higher than in types I, II and III IM. The expression of Ki67 in gastric carcinoma was significantly higher than in type I, but not significantly higher than in type II or type III.

It is difficult to determine which subtype of IM has a definite relationship with gastric carcinomas. In SIM and AIM classification, the expressions of all three proteins in gastric carcinomas were significantly higher than in SIM and no significant differences were observed between gastric carcinomas and AIM. Obviously, AIM may have a much more close relationship with gastric carcinoma.

We deduce that SIM may be merely a response to stimuli caused by the changing environment, while AIM may have malignant transformation and could be regarded as preneoplastic lesions. Clinical follow up of AIM patients may be helpful for the diagnosis of early gastric carcinomas. However, since details of the role of AIM in the multiple steps of carcinogenesis of gastric mucosa are still unknown, further study is necessary with regard to AIM, perhaps using more advanced methods. Furthermore, an adequate long term follow up is indispensable to assess the definite value of AIM in the screening for gastric carcinoma.

## COMMENTS

### Background

Gastric carcinoma remains a significant problem globally. The relationship between intestinal metaplasia (IM) and gastric carcinoma has always been controversial. Generally IM is divided into subtypes on the basis of histochemical characteristics; however, this classification is confusing. A new classification of IM is needed in order to follow up patients selectively.

### Research frontiers

By detecting three tumor-associated proteins, p53, c-erbB-2 and Ki67, in IM and gastric carcinoma, this study compared two types of classification in IM of the stomach and explored their relationship to gastric carcinoma.

### Innovations and breakthroughs

In the past, IM was classified according to histochemical characteristics. In this study, IM was first divided into simple IM (SIM) and atypical IM (AIM) was reported to better reveal the precancerous nature of IM and could be a helpful indicator in the surveillance of patients clinically.

### Applications

The new classification of IM could be helpful in the surveillance of patients clinically and useful for the diagnosis of early gastric carcinomas.

### Terminology

IM is defined as the appearance of intestinal epithelium in the stomach. Type I, II and III IM are subtypes of IM classified according to the histochemical characteristics of the mucin-secreting cells. SIM and AIM classification is dependent mainly on the atypical changes of the metaplastic epithelium of the stomach. p53, c-erbB-2 and Ki67 are all tumor-associated proteins that are expressed mainly in metaplastic and tumor tissues.

### Peer review

The study provides important new data about the potential risk of gastric cancer in patients with IM. However, it would be important in the future to investigate the expression of p53 and/or Her2Neu in a prospective study in patients with IM, to confirm that only patients with p53/Her2Neu expression in the IM have actually a higher risk for gastric carcinomas.

### Abstract

**AIM:** To re-evaluate the theory that colonic diverticulosis is associated with relapse of *Clostridium difficile* associated disease (CDAD) in light of data suggesting increasing rates of CDAD infection and relapse.

**METHODS:** Charts were reviewed for patients with recurrent CDAD who had also had a prior colonoscopy or flexible sigmoidoscopy. An age and gender matched control group was used to compare the prevalence of diverticulosis.

**RESULTS:** Twenty-two patients met the study criteria, and the prevalence of diverticulosis in patients with CDAD relapse was 23% compared to 32% in age and sex matched controls ( $P = 0.44$ ). A significant proportion of patients with CDAD relapse had comorbidities associated with immune suppression.

**CONCLUSION:** Diverticulosis does not appear to be associated with CDAD relapse.

### INTRODUCTION

The incidence of *Clostridium difficile* (*C. difficile*) associated disease (CDAD) has reached epidemic proportions, increasing both in terms of frequency and severity. The rates of *C. difficile* associated disease have steadily increased since the 1980s, with a marked increase in infection over the past 10 years. In one region of Canada there was a four-fold increase from 2002 to 2003 alone<sup>[1]</sup>. The cost associated with CDAD in 2008 in the U.S. has been estimated at \$32 million per day with nearly 40 000 extra hospital inpatient days due to *C. difficile* infection<sup>[2]</sup>. The increased incidence and virulence of *C. difficile* infection are felt to be caused by a new hypervirulent strain which produces significantly more toxins A and B. In addition to increasing morbidity and mortality, this hypervirulent strain has also led to an increase in relapse rates, which have been reported to be as high as 47.2%<sup>[3]</sup>, compared to historic relapse rates of approximately 20%<sup>[4]</sup>.

The exact etiology of CDAD relapse is incompletely understood, but it is probably multifactorial. Relapse of CDAD is usually caused by the original strain, although a percentage of patients are infected with a new strain<sup>[5]</sup>. One of the earliest theories for CDAD relapse was the presence of colonic diverticula, which were thought to

serve as reservoirs for *C. difficile* spores. This was largely based on an early study by Tedesco *et al*<sup>[6]</sup> which found that 18 of 22 patients (82%) with recurrent *C. difficile* infection had diverticulosis. It was theorized that *C. difficile* spores in diverticula were impervious to antibiotics and so could germinate after the completion of treatment. Tapered and pulsed antibiotic regimens for recurrent *C. difficile* infection were thus aimed at treating these dormant spores<sup>[7]</sup>. To our knowledge no paper has re-evaluated the association between diverticulosis and *C. difficile* relapse. Our study aimed to re-evaluate the association between diverticulosis and recurrent *C. difficile* infection at our medical center in light of increasing rates of CDAD infection and relapse.

## MATERIALS AND METHODS

We reviewed positive ELISA-based *C. difficile* toxin assays from 2005-2007 at our tertiary level hospital. We reviewed the charts of patients with a minimum of two positive toxin assays more than 14 d apart who also had a prior colonoscopy or flexible sigmoidoscopy at our institution. Patient charts were reviewed for the presence of diverticulosis, prior antibiotic use, comorbidities, recent hospitalizations, *C. difficile* treatment course, and number of relapses.

Relapse was defined as recurrent diarrhea with a positive toxin assay or pseudomembranous colitis after completion of treatment for *C. difficile* infection within the previous 3 mo. To be included in the study, patients must have completed full initial antibiotic therapy for a minimum of 10 d with symptomatic improvement. An age and gender matched control group was used to compare the prevalence of diverticulosis at our institution. Patients in the control group had colonoscopies performed for the purpose of colorectal cancer screening. This study was approved by our medical center's institutional review board.

## RESULTS

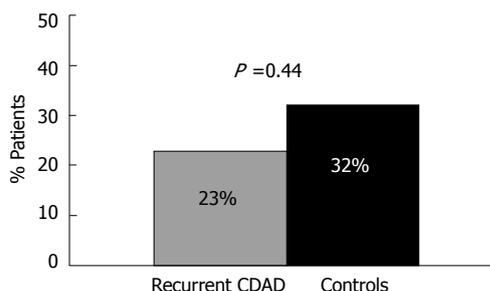

Twenty-two patients met the study criteria, with an average of 2.3 episodes of *C. difficile* infection. All patients were treated with standard metronidazole (*po* or *iv*) and/or oral vancomycin therapy. The prevalence of diverticulosis in patients with *C. difficile* relapse was 23%, with a mean patient age of 62. The prevalence of diverticulosis in the age and sex matched control group was 32% ( $P = 0.44$ , using  $\chi^2$  analysis, Figure 1). Table 1 shows the baseline characteristics of patients with recurrent *C. difficile* relapse. The inpatient mortality in this group was 18%.

## DISCUSSION

Patients with recurrent *C. difficile* infection at our institution did not have a higher prevalence of colonic diverticulosis than age and sex matched controls. The prevalence of diverticulosis in patients with relapsing *C. difficile* and controls was 23% and 32%, respectively ( $P = 0.44$ ), which is consistent with historical controls. To our knowledge this is the first paper to reevaluate

**Table 1** Baseline characteristics of patients with recurrent *Clostridium difficile* associated disease ( $n = 22$ )

Baseline characteristics	
Mean age (yr)	62 (30-90)
Female	13 (59%)
Recent hospitalizations (< 3 mo)	18 (82%)
Lymphoma/malignancy	8 (36%)
HIV/AIDS	3 (14%)
Systemic steroid use	3 (14%)
Liver cirrhosis	2 (9%)

**Figure 1** Prevalence of diverticulosis. CDAD: *Clostridium difficile* associated disease.

the association between diverticulosis and recurrent *C. difficile* infection since first described by Tedesco *et al*<sup>[6]</sup>.

We found that a high percentage of patients with recurrent *C. difficile* infection suffered from co-morbidities often associated with immune suppression. These results are not surprising since growing data suggest that host immunity plays a large role in promoting relapse<sup>[8-14]</sup>. One of the earliest studies to support this theory came from Kyne *et al*<sup>[15]</sup> where 22 patients with resolved *C. difficile* infection were compared to 22 patients with relapsing disease. Patients with relapsing *C. difficile* infection were found to have significantly lower levels of serum antibodies to toxin A. Additional independent risk factors for *C. difficile* recurrence include older age<sup>[16]</sup> and prolonged hospitalization<sup>[17]</sup>.

Patients with impaired host immunity during chemotherapy have been found to have higher rates of CDAD<sup>[8]</sup>, even without prior antibiotic use<sup>[9]</sup>. Higher rates of CDAD infection have been found in patients on nephrology, hematology, and organ transplantation wards<sup>[10]</sup>, as well as in patients with human immunodeficiency virus (HIV) infection<sup>[11]</sup>. These findings have prompted research aimed at improving host immunity in patients with CDAD relapse. Intravenous immunoglobulin (IVIg) has been used in the treatment of severe, refractory, or recurrent *C. difficile* infection<sup>[12,16]</sup>. A human monoclonal antibody against toxins A and B, MDX-1388, was shown to have efficacy in preventing relapse of *C. difficile* infection in hamsters<sup>[13]</sup>. A small study of a toxoid vaccine against *C. difficile* showed benefit in 3 patients with recurrent *C. difficile*, allowing the cessation of antibiotic treatment<sup>[14]</sup>.

Our study had several limitations. Given the small patient size our study may have been underpowered to detect a difference in the prevalence of diverticulosis.

This study was also done retrospectively and all patients originated from a single institution. Our results did not find an association between colonic diverticulosis and recurrent *C. difficile* infection at our institution, however further studies may be needed to verify these findings. The high prevalence of co-morbidities often associated with immune suppression in patients with recurrent *C. difficile*, however, is consistent with current data that suggest host immunity may play a significant role in CDAD relapse.

## COMMENTS

### Background

The incidence of *Clostridium difficile* (*C. difficile*) associated disease (CDAD) has reached epidemic proportions, increasing both in terms of frequency and severity. The exact etiology of CDAD relapse is incompletely understood, and previous research has suggested an association between CDAD relapse and colonic diverticulosis.

### Research frontiers

The increased incidence and virulence of *C. difficile* infection are felt to be caused by a new hypervirulent strain which produces significantly more toxins A and B. In addition to increasing morbidity and mortality, this hypervirulent strain has also led to an increase in relapse rates. In this study the authors did not find an association between colonic diverticulosis and CDAD relapse, but did find that a significant proportion of patients with CDAD relapse had co-morbidities associated with immune suppression.

### Innovations and breakthroughs

Recent reports have suggested that host immunity may play a role in preventing future *C. difficile* relapse. This is the first paper to re-evaluate the association between CDAD relapse and colonic diverticulosis since the emergence of a new hypervirulent strain.

### Applications

By showing a lack of association between colonic diverticulosis and CDAD relapse, this study could help guide future treatments. Previous treatments were originally aimed at treating dormant spores in diverticula with pulsed or tapering antibiotics. This study would suggest that therapy aimed at improving host immunity may be important in CDAD relapse.

### Terminology

*C. difficile* is a gram positive bacterium that may cause a colonic infection, typically after antibiotic use. This infection may become severe and may relapse, requiring multiple antibiotic treatments. Colonic diverticula are outpouchings of the colonic wall.

### Peer review

It is an interesting study that addresses a potentially important relationship between recurrence of *C. difficile* infection and diverticulosis.

### Abstract

**AIM:** To investigate the effect of transjugular intrahepatic porto-systemic shunt (TIPS) on malnutrition in portal hypertensive cirrhotic patients.

**METHODS:** Twenty-one patients with liver cirrhosis and clinical indications for TIPS insertion were investigated before and 1, 4, 12, 52 wk after TIPS. For each patient we assayed body composition parameters [dry lean mass, fat mass, total body water (TBW)], routine liver and kidney function tests, and free fatty acids (FFA). Glucose and insulin were measured for the calculation of the homeostasis model assessment insulin resistance (HOMA-IR); liver function was measured by the galactose elimination capacity (GEC); the severity of liver disease was graded by model for end-stage liver disease (MELD).

**RESULTS:** Porto-systemic gradient decreased after TIPS ( $6.0 \pm 2.1$  mmHg vs  $15.8 \pm 4.8$  mmHg,  $P < 0.001$ ). Patients were divided in two groups according to initial body mass index. After TIPS, normal weight patients had an increase in dry lean mass (from  $10.9 \pm 5.9$  kg to  $12.7 \pm 5.6$  kg,  $P = 0.031$ ) and TBW (from  $34.5 \pm 7.6$  L to  $40.2 \pm 10.8$  L,  $P = 0.007$ ), as well as insulin (from  $88.9 \pm 49.2$  pmol/L to  $164.7 \pm 107.0$  pmol/L,  $P = 0.009$ ) and HOMA-IR (from  $3.36\% \pm 2.18\%$  to  $6.18\% \pm 4.82\%$ ,  $P = 0.023$ ). In overweight patients only FFA increased significantly (from  $0.59 \pm 0.24$  mmol/L to  $0.93 \pm 0.34$  mmol/L,  $P = 0.023$ ).

**CONCLUSION:** TIPS procedure is effective in lowering portal pressure in patients with portal hypertension and improves body composition without significant changes in metabolic parameters.

## INTRODUCTION

Portal hypertension and malnutrition are two important complications of cirrhosis, both affecting prognosis and risk of death<sup>[1-3]</sup>. Portal hypertension is present in 60% of cirrhotic patients<sup>[4]</sup>; the existence of a portal-systemic shunt modifies both fasting and post-prandial metabolism, decreasing the hepatic first-pass effect of nutrients, which become more available for peripheral tissues. Also hormone levels, like insulin, share a similar defect. The lack of a significant first-pass removal by the liver makes insulin flood the systemic circulation and promotes insulin resistance, which is further aggravated by the production of inflammatory molecules [tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), lipopolysaccharide (LPS), *etc.*] which have an anti-insulin effect and contribute to systemic inflammation<sup>[5]</sup>. The final event of the above alterations is a progressive deterioration of liver function, also resulting in poor nutritional status. Malnutrition, in turn, is a risk factor for disease progression, and is associated with the development of complications<sup>[3]</sup>, with a high risk of death<sup>[6]</sup>, as well as increased morbidity and mortality after transplantation<sup>[7]</sup>.

Several studies demonstrated that transjugular intrahepatic porto-systemic shunt (TIPS) using polytetrafluoroethylene (PTFE)-covered stents are the best rescue therapy for failures of medical and endoscopic treatment of portal hypertension<sup>[8-10]</sup>.

The effects of TIPS on metabolism and body composition are not well defined. Allard *et al.*<sup>[11]</sup> and Plauth *et al.*<sup>[12]</sup> found that TIPS insertion in malnourished patients with cirrhosis and hypermetabolism resulted in improved body composition. No studies, however, have clearly defined the relation between TIPS-induced metabolic changes and changes in nutritional status, and/or the underlying mechanism. In particular, no studies addressed the potential impact of pre-TIPS overweight and obesity and associated insulin resistance on the post-TIPS nutritional status and insulin levels.

We aimed to test the effects of TIPS insertion on nutritional status and insulin levels in a group of subjects with cirrhosis and complications of portal hypertension.

## MATERIALS AND METHODS

### Subjects

Twenty-six patients with liver cirrhosis, consecutively undergoing an elective TIPS procedure were included (Table 1). Three patients did not complete the baseline examination protocol due to variceal bleeding requiring intensive care and immediate TIPS insertion. Of the remaining 23 patients (15 males and 8 females), one received an orthotopic liver transplant after TIPS, and one died during follow-up. Three patients missed one or more follow-up evaluations; therefore, only 18 patients had all the evaluations planned by protocol. The diagnosis of cirrhosis was assessed on the basis of biochemical, clinical, and ultrasonographic findings and confirmed by liver biopsy in 8 cases. Among the 21 patients who completed the follow-up, etiology was as follows: alcohol-related, 15;

**Table 1** Modification of values studied in 21 patients (mean  $\pm$  SD)

Variable	Basal Pre-TIPS	After 52 wk	P
HVPG (mmHg)	15.8 $\pm$ 4.8	6.0 $\pm$ 2.1	< 0.001

<sup>1</sup>Median (interquartile range). Values were obtained 2 wk before (Basal) and 52 wk after TIPS insertion. *P* < 0.05 is considered statically significant. TIPS: Transjugular intrahepatic porto-systemic shunt; HVPG: Hepatic venous pressure gradient; GEC: Galactose elimination capacity; MELD: Model for end-stage liver disease; HOMA: Homeostasis model assessment; IR: Insulin resistance; BMI: Body mass index; FFA: Free fatty acids; TBW: Total body water.

autoimmune, 3; primary sclerosing cholangitis, 1; HCV-related, 1; cryptogenic, 1. Abstinence from alcohol was a goal during the study, and to our knowledge all but one adhered to that policy. All patients signed a written informed consent to take part in the study in accordance with the Helsinki II Declaration. The study was approved by the Research Ethics Committee of Aarhus County.

### Experimental design

This was an observational prospective study. TIPS patients were studied approximately 2 wk before TIPS insertion, and were regularly re-evaluated at follow-up visits 1, 4, 12, and 52 wk after the procedure. All examinations were carried out after overnight fasting.

### TIPS procedure

Indications for TIPS insertion were refractory ascites (12 patients), secondary prevention of variceal bleeding (seven patients) or both (two patients). None had active variceal bleeding at the time of TIPS insertion. The TIPS procedure was carried out using covered stents according to the method described by Rössle *et al.*<sup>[13]</sup>. After insertion, a clinical and ultrasonographic control of the shunt was performed after 24 h, 4 wk, and then, at 12-wk intervals during the first year. Ascites was totally removed by paracentesis before TIPS insertion.

### Diet

Each patient had a dietetic investigation and a 7-d diary report before TIPS insertion. During the study, food intake remained unchanged both for quantity and type of nutrients.

**Body composition**

Bio-impedance analysis (Quadscan 4000, Bodystat Ltd., Isle of Man, UK) was used to estimate body composition. The predictive equations were taken from Kushner *et al*<sup>[14]</sup> and Lautz *et al*<sup>[15]</sup>. Bio-impedance analysis was chosen because, despite some limitations in patients with ascites (not present in our patients both before and after TIPS) it is a bedside tool for the determination of body composition in cirrhotic patients with/without ascites<sup>[16]</sup>. Dry lean body mass was calculated as body weight - fat mass - total body water (TBW). Dry lean mass was preferred to lean mass to reduce the possible interference of changes in TBW due to the fluctuating presence of ascites. According to Tsiaousi *et al*<sup>[17]</sup>, we considered as malnourished all patients with a body mass index (BMI) lower than 23.

**Liver function**

The galactose elimination capacity (GEC) was used to measure quantitatively metabolic liver function, from blood concentration decay curves corrected for urinary excretion, as described by Tygstrup<sup>[18]</sup>. The clinical status was assessed according to the model for end-stage liver disease score (MELD)<sup>[19]</sup>.

**Biochemical analyses**

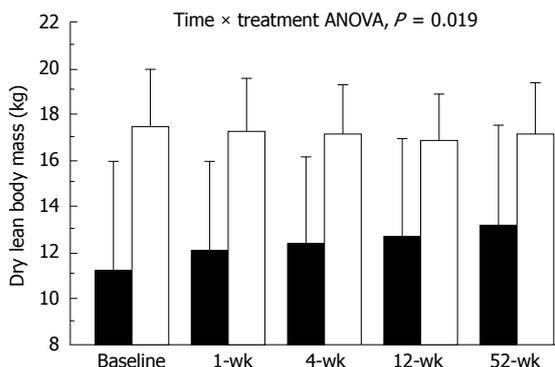

Glucose, creatinine, bilirubin and prothrombin time were routinely assayed by automatic analyzer on fresh serum/plasma samples. Free fatty acids (FFA) were determined with a colorimetric method using a commercial kit (Wako Chemicals, Neuss, Germany). Blood aliquots for insulin concentrations were stored at -80°C and measured by a two-site immunospecific insulin enzyme-linked immunosorbent assay<sup>[20]</sup>.

**Insulin secretion and sensitivity**

Basal insulin secretion and sensitivity were assessed by means of the homeostasis model assessment (HOMA)<sup>[21,22]</sup>. Secretion was estimated using the Beta index (HOMA-β), while peripheral sensitivity was measured by HOMA-IR, with the following equations: HOMA-β = 20 × fasting plasma insulin (mU/L)/[fasting plasma glucose (mmol/L) - 3.5]; HOMA-IR = fasting plasma insulin (mU/L) × fasting plasma glucose (mmol/L)/22.5 .

**Statistical analysis**

Data analysis was performed using STATA 10 statistical software (StataCorp LP, Texas, USA). Results are given as mean ± SD. Changes from baseline were explored by analysis of variance (ANOVA) for repeated measurements. Changes from baseline to end-of-observation and between groups were also tested by parametric and non-parametric paired and unpaired methods, whenever appropriate. Due to non-systematic factors, blood samples were missing from 8 examinations in 6 patients. For the statistical analyses these missing values were replaced by the mean of adjacent values. A P-value < 0.05 was considered significant in a two-tailed test.

**Figure 1** Time course of dry lean body mass in normal weight (black bars) and overweight subjects (white bars) following the TIPS procedure. The data are presented as means and standard error. Trend shows significant difference (P = 0.019).

**RESULTS**

TIPS was well tolerated by all patients, and there were no procedure-related complications. TIPS insertion produced a reduction in hepatic venous pressure gradient (P < 0.001) (Table 1). Three patients needed a stent revision during follow-up. Transient hepatic encephalopathy was observed in three patients and was reversed by diet and oral disaccharides without the need for shunt reduction.

At the end of the study period, a non-significant increase in BMI was observed in the whole population (Table 1). Patients were divided in two groups according to their BMI at enrolment [BMI ≤ 25 kg/m<sup>2</sup>, normal/underweight (NW), n = 12; BMI > 25, overweight/obesity (OW), n = 9]. A few NW cases (n = 7; 58%) showed clinical evidence of malnutrition, but only 3 had a BMI below the lower cut-off of normality (18.5 kg/m<sup>2</sup>). Analysis of variance (ANOVA) for repeated measurements did not show differences in the time trend of BMI after TIPS between the two groups. Also the non-parametric analysis of 52-wk changes failed to detect differences in BMI changes over time.

**Body composition**

Dry lean mass increased in NW patients by 14.5% (from 10.9 ± 5.9 kg to 12.7 ± 5.6 kg, P = 0.031), but did not change in OW patients; the trend was significant on ANOVA test for repeated measures (P = 0.002) (Figure 1). The increase in dry lean body mass in normal weight patients paralleled a significant increase in TBW of 14.3%, (from 34.5 ± 7.6 L to 40.2 ± 10.8 L, P = 0.007). Fat mass, both as absolute value or as percentage of body weight, did not vary significantly in the 2 groups (ANOVA, P = 0.815).

Regarding liver function, GEC did not vary over time in TIPS-treated patients; similarly MELD increased non-significantly by over 2 points during the observation period (Table 1). These changes were largely due to increased MELD values in NW patients, while no changes were observed in the OW group. Similarly, GEC remained stable in NW patients while in the OW group there was a trend toward a significant deterioration (Table 2).

**Table 2** Anthropometric, pressure and laboratory values recorded in 12 normal weight (NW: BMI  $\leq$  25 kg/m<sup>2</sup>) and in 9 overweight (OW: BMI > 25) patients with liver cirrhosis (mean  $\pm$  SD)

P < 0.05 is considered statistically significant.

### Metabolic parameters

Plasma insulin and HOMA-IR significantly increased in TIPS-treated cirrhotic patients without any change in fasting glucose (Table 1). The changes were mainly limited to normal weight patients who also had a significant increase in HOMA- $\beta$  (Table 2). However, no significant differences were demonstrated by repeated-measures ANOVA.

After TIPS insertion, changes in FFA plasma levels (Table 1) were exclusively observed in OW patients (Table 2).

No systematic changes in serum creatinine were observed (Tables 1 and 2), but patients with mild renal failure (creatinine levels  $\geq$  1.2 mg/dL, n = 7) slightly improved their values (from 1.75  $\pm$  0.37 mg/dL to 1.45  $\pm$  0.43 mg/dL, P = 0.23).

## DISCUSSION

The main finding of this study is that dry lean body mass significantly increases in NW patients with cirrhosis after TIPS insertion. Advanced cirrhosis is associated with reduced lean mass<sup>[23]</sup>; a significant protein-calorie malnutrition is present in at least 30% of patients with cirrhosis<sup>[24]</sup>. Both parameters appear to be related to the severity of the liver disease<sup>[25]</sup>. Considering that a large

fraction of our NW patients showed signs of malnutrition at baseline, TIPS appears to modify the natural history of malnutrition. This finding agrees with the results obtained by Plauth *et al*<sup>[12]</sup> and Allard *et al*<sup>[11]</sup>. Both reported an increase in dry lean mass but many questions on the metabolic mechanisms involved remain unresolved<sup>[26]</sup>. The significant increase in dry lean mass of about 1.84 kg in the year after TIPS insertion is paralleled by an increase in TBW that, in the absence of ascites and/or regional edemas, is indicative of muscle tissue formation<sup>[27]</sup>. Our results are in keeping with a very recent preliminary report by Camci *et al*<sup>[28]</sup>, on six TIPS-treated malnourished cirrhotic patients.

This beneficial effect of TIPS on lean body mass was not observed in overweight or obese subjects at baseline. The reasons for this different metabolic response are not easy to determine. NW cases were characterized by lower insulin resistance at baseline, but also lower insulin and lower insulin secretion. In these normal- or under-weight individuals, the additional metabolic and hormonal abnormalities already in the group with excess body weight do not increase the cirrhosis-related insulin resistance<sup>[29]</sup>. Muscle tissue takes up 80%-85% of glucose infused during hyperinsulinemic euglycemic clamp<sup>[30,31]</sup>. After TIPS placement, these cases were characterized by a significant increase in serum insulin, without changes in blood glucose levels, and consequently by increased HOMA-IR and HOMA- $\beta$ , and stable liver function. Under these conditions, the improved hemodynamic state, in the presence of a normal intake of nutrients, could promote insulin production and insulin action, favoring the improved nutritional state. This mechanism might not be operative in the OW group, with a much higher degree of insulin-resistance than NW cases, and where insulin did not increase further after TIPS placement. In these patients, the TIPS procedure was followed by a remarkable reduction of HOMA- $\beta$ , and the decreased insulin production could not sustain lean body mass formation.

After TIPS the plasma levels of FFA increased significantly only in the OW group. In agreement with the hypothesis of Yki-Järvinen *et al*<sup>[32,34]</sup>, the increase in FFA levels is likely to stimulate hepatic gluconeogenesis and competition with glucose in muscle metabolism. These metabolic changes could further promote insulin resistance.

Reduced portal hypertension might be an additional factor playing a role in the improved metabolic and nutritional status. Portal hypertension increases the permeability of enteric mucosa that promotes intestinal bacterial translocation and the systemic diffusion of LPS and other pro-inflammatory molecules, ultimately producing interleukin-1 $\beta$ , interleukin-6 and TNF- $\alpha$ . These molecules promote insulin-resistance and have an anti-insulin, catabolic effect, leading to protein mass wasting. Any mechanism mediated by anti-insulin molecules might play a differing effect in relation to BMI and to the levels of insulin resistance, much higher in obesity. Obesity *per se* is a chronic inflammatory state that sustains insulin-resistance<sup>[35]</sup>; in the presence of obesity the multiple factors sustaining insulin resistance could not be totally

removed by TIPS; in contrast, in subjects with poor nutritional status the less severe insulin resistance might be removed by TIPS, thus explaining improved nutritional status. Larger studies are needed to explore the potential benefits of TIPS on long-term survival of underweight patients with cirrhosis, at higher risk of morbidity and mortality according to several previous studies<sup>[36]</sup>.

Finally, the presence of insulin-resistance might be related to advanced liver disease and this condition could justify the absence of any improvement in OW patients with liver cirrhosis. We used GEC, an estimate of the functional liver mass with a prognostic value in the medium term interval<sup>[37]</sup>, and there was no overall change in GEC over time, however, in OW patients a trend towards a decrease in GEC was observed. During the study, food intake remained unchanged both for quantity and type of nutrients. Further, it is our policy that alcohol has to be withdrawn in patients before TIPS insertion, as alcohol itself increases portal hypertension and may thus be involved in both the risk of variceal bleeding and ascites formation. During follow up, alcohol abstinence is important and this policy is reflected in the high number of alcohol abstainers in the present study. We therefore suggest that changes in body composition do not reflect a change in food and/or alcohol intake but are an effect of TIPS and of the reduction in portal pressure *per se*.

Finally, the study confirmed the effectiveness of TIPS on portal hypertension with a reduction in Hepatic venous pressure gradient (HVPG) to a value of 6 mmHg, lower than the 12 mmHg threshold value of increased risk for variceal bleeding, re-bleeding and mortality<sup>[1,4]</sup>. The absence of re-bleeding episodes and the disappearance of ascites confirm this hypothesis. Furthermore, patients with functional renal failure at baseline improved their creatinine levels at follow-up. Considering that lean mass increased, this value does not reflect a worsening of malnutrition<sup>[38]</sup> but is due to a positive effect of TIPS on the hemodynamic state<sup>[39]</sup>.

In conclusion, the TIPS procedure is effective in lowering portal pressure in patients with portal hypertension and improves body composition without significant changes in metabolic parameters.

## COMMENTS

### Background

Malnutrition in portal hypertensive cirrhotic patients increases the risk and the severity of clinical complications. Transjugular intrahepatic porto-systemic shunt (TIPS) is a well established therapy for complications of portal hypertension in cirrhotic patients. However, the effect of TIPS on malnutrition is unclear.

### Research frontiers

The article provides insight into the beneficial effects of TIPS in regard to improvement in nutritional status. Malnutrition in liver diseases is an important area of research as it is an independent factor resulting in increased morbidity and mortality. Furthermore, the article addresses the effects of shunting of hormones/peptides *etc.* especially insulin, that relate to the possible mechanisms behind insulin resistance in patients with liver cirrhosis.

### Innovations and breakthroughs

Related papers have focussed on improvement in body composition without addressing the pre-TIPS nutritional status. With a simple yet comprehensive separation into normal weight and overweight subjects, the results suggest

additional nutritional benefits in the group of malnourished patients from TIPS insertion (see next section).

### Applications

TIPS treatment of the complications of portal hypertension seems to improve nutritional status in liver cirrhosis, especially in patients suffering from malnutrition. Ultimately, malnutrition may provide an additional reason/indication for TIPS insertion in patients with liver cirrhosis.

### Terminology

The TIPS procedure is a minimally invasive procedure used in patients with liver cirrhosis to reduce portal hypertension and thereby ameliorating complications of portal hypertension. Using a catheter technique *via* the right jugular vein, a stent is placed within the liver connecting the portal vein and the hepatic vein and thus reducing portal hypertension.

### Peer review

This is an interesting and novel study showing an amelioration of nutritional parameters after TIPS especially in lean cirrhotic patients. An improvement in the body composition (nutritional status) of liver cirrhosis patients after TIPS implementation has been studied previously. And this study is well conducted and long term follow up data are provided.

interleukin (IL)-1 gene cluster, IL-2, IL-4, IL-6, IL-10, IL-12, interferon  $\gamma$ , transforming growth factor  $\beta$ , and tumor necrosis factor  $\alpha$ . Variation in *KIR* genes was also explored. The results were compared with prevalence of the polymorphisms in Finnish or European populations.

**RESULTS:** All patients had pepsinogen I levels below normal (mean: 11  $\mu\text{g/L}$ , range: < 5 to 25  $\mu\text{g/L}$ ). Three patients had elevated *H. pylori* IgG antibodies, while *H. pylori* serology was negative in the rest of the patients. AIG patients carried significantly more often HLA-DRB1\*04 (58%) and DQB1\*03 (83%) than the general Finnish population did (28% and 51%, respectively;  $P = 0.045$  and  $0.034$  by the Fisher's exact test). No patient was positive for HLA-B8-DRB1\*03, a well-established autoimmune marker. Neither cytokine polymorphisms nor *KIR* gene variation showed association with AIG.

**CONCLUSION:** As explored with modern DNA-based methods, HLA-DRB1\*04 and DQB1\*03 alleles, but not HLA-B8-DRB1\*03, may predispose to AIG.

### Abstract

**AIM:** To explore whether predisposition to autoimmune gastritis (AIG) is found in human leukocyte antigen (HLA), cytokine or killer cell immunoglobulin-like receptor (*KIR*) gene variations.

**METHODS:** Twelve Finnish patients with autoimmune-type severe atrophy of the gastric corpus were included. The patients' serum was analyzed for pepsinogen I and *Helicobacter pylori* (*H. pylori*) antibodies. DNA was separated and the patients were genotyped for HLA-A, B, Cw, DRB1 and DQB1 antigens, and studied for single nucleotide polymorphisms for the following cytokines:

## INTRODUCTION

Autoimmune gastritis (AIG) is an organ-specific autoimmune disease, in which inflammation of the mucosa of the gastric corpus results in total loss of corpus-type glands, and achlorhydria. AIG patients typically have a low serum pepsinogen I (PG I) concentration, and most of them also have parietal cell antibodies (PCAs). In many, but not all patients, vitamin B12 absorption is deficient, which leads to pernicious anemia (PA)<sup>[1]</sup>.

The occurrence of AIG and PA has long been recognized to be determined strongly by genetic factors, which, however, are largely unexplored. The most important genetic association found in human AIG so far is a link with the human leukocyte antigen (HLA) region. The observed association between AIG and certain HLA antigens has, however, not been strong enough to explain the familial clustering of AIG<sup>[2]</sup>.

Polymorphisms in the genes that encode immune regulator molecules may affect the secretion or function of the corresponding proteins, and thus influence immune responses, inflammation and tissue injury. Cytokine genes have been studied widely in autoimmune diseases and associations have been found between, for instance, tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) and interleukin (IL)-10 polymorphisms and autoimmune hepatitis and pemphigus, respectively<sup>[3,4]</sup>. Also *Helicobacter-pylori* (*H. pylori*)-associated atrophic gastritis has been shown to be more frequent in patients with proinflammatory polymorphisms of genes for *IL-1* gene cluster, and TNF $\alpha$ <sup>[5]</sup>.

Killer cell immunoglobulin-like receptors (KIRs) are members of a diverse family of regulatory molecules expressed on subsets of T cells. KIRs play a role in the control of the natural killer (NK) cell immune response. The KIR receptors recognize certain HLA class I determinants and regulate NK cell activity. The number and type of *KIR* genes vary between individuals who can carry anything from seven to 12 *KIR* genes, of which, some encode activating and others inhibiting receptors<sup>[6,7]</sup>. *KIR* genes can be divided into two main haplotype groups. Group A contains only one activating and six inhibiting *KIR* genes, whereas group B haplotypes are more variable and contain several activating *KIR* genes<sup>[8]</sup>. In addition to the copy-number variation, individual *KIR* genes exhibit allelic variation. *KIR* genes have been shown to be associated with various diseases, including some autoimmune diseases<sup>[9]</sup>.

Recently, we sequenced the coding regions of genes for  $\alpha$ - and  $\beta$ -subunits of H<sup>+</sup>/K<sup>+</sup>-ATPase, which is the main autoantigen in AIG, in AIG patients, but no disease-associated polymorphisms could be found<sup>[10]</sup>. In the present study, a number of genes involved in immune activation were explored in patients with AIG, by modern molecular genetic methods. The aim of this study was to determine whether variations in the immune regulator genes, such as HLA, cytokine or KIR, are associated with the presence of AIG.

## MATERIALS AND METHODS

### Clinical information

A total of 18 patients, who had earlier undergone gastroscopy at Herttoniemi Hospital and were known to have severe atrophic corpus gastritis without any history of *H. pylori* infection, and who were under 65 years of age, were invited by letter to participate in the study. Twelve patients gave written informed consent, donated a blood sample, and completed a questionnaire about their possible vitamin B12 replacement therapy and thyroid diseases, as well as the occurrence of AIG in the family. Signs of other autoimmune diseases were looked for in the patient records. The study was approved by the Ethical Committee for Internal Medicine at Helsinki University Central Hospital.

### Blood tests

EDTA blood and serum samples were kept at -20°C until analyzed. DNA was extracted from the EDTA blood sample using a DNA purification kit (PureGene<sup>®</sup>; Centralsystems, Minneapolis, MN, USA), according to the manufacturer's instructions. Serum samples were analysed for PG I, PCAs and *H. pylori* antibodies.

For serum PG I concentrations, an immunoenzymometric assay (Gastroset PG1; Orion Diagnostica, Espoo, Finland) was used. The lower normal limit of the assay was 28  $\mu\text{g/L}$ . PCAs were determined by an enzyme immunoassay (Vareliisa Parietal Cell Antibodies; Pharmacia Diagnostics, Freiburg, Germany), which used H<sup>+</sup>/K<sup>+</sup>-ATPase as the antigen. Concentrations < 10 U/mL were normal, according to the manufacturer. For *H. pylori* antibodies, an in-house immunoassay that measured IgG antibodies was used, and titers  $\geq 700$  were considered elevated<sup>[11]</sup>.

### Immunogenetics

*HLA* genes were explored using the INNO-LiPA kit (Innogenetics, Ghent, Belgium) according to the manufacturer's instructions. The *HLA-A*, *B*, *Cw*, *DRB1* and *DQB1* genes were amplified by polymerase chain reaction (PCR), and the biotinylated PCR products were hybridized with sequence-specific oligonucleotides on membrane-based strips. Results were analyzed by the LiRAS (Innogenetics) interpretation software.

Cytokine polymorphisms in the genes of *IL-1* gene cluster, *IL-2*, *IL-4*, *IL-6*, *IL-10*, *IL-12*, interferon (IFN)- $\gamma$ , transforming growth factor (TGF)  $\beta$ , and TNF $\alpha$  were genotyped using the Cytokine Genotyping Kit (Pel-Freez Clinical Systems, Brown Deer, WI, USA). Cytokine profiles (high/intermediate/low producer) based on the polymorphisms were formed according to the published phenotypes also mentioned in the product insert of the kit. *KIR* genes (*KIR2DL1*, *KIR2DL2*, *KIR2DL3*, *KIR2DL4*, *KIR2DL5*, *KIR2DS1*, *KIR2DS2*, *KIR2DS3*, *KIR2DS4*, *KIR2DS5*, *KIR3DL1*, *KIR3DL2*, *KIR3DL3*, *KIR3DS1*, *KIR2DP1* and *KIR3DP1*) were determined using the KIR Genotyping Kit (Pel-Freez Clinical Systems), following the manufacturer's instructions. Both genotyping kits were

based on PCR amplification with sequence-specific primers that were designed to detect polymorphisms of cytokine/*KIR* genes. The PCR products were separated by gel electrophoresis, and the genotype results were interpreted on the basis of specific amplification patterns.

Prevalence of the HLA genotypes was compared with HLA frequency in the Finnish population, based on the data collected in Clinical Laboratory of Finnish Red Cross blood service. The cytokine polymorphisms and *KIR* genes were compared with the frequency of polymorphisms and *KIR* genes in populations of Finnish of European ancestry published previously<sup>[12-15]</sup>.

### Statistical analysis

Fisher's exact test was used to compare the prevalence of genotypes between patients and the populations used as controls.

## RESULTS

Demographic and clinical characteristics of the patients are summarized in Table 1. All patients had total atrophy in the gastric corpus. The mucosa of the gastric antrum was normal in eight patients, and mild chronic inflammation or sparse intestinal metaplasia was detected in four. All patients had PG I levels below normal (mean: 11 µg/L, range: < 5 to 22 µg/L), and elevated PCAs (median: 185 U/mL, range: 20-509 U/mL). Three patients (numbers 3, 10 and 11 in Tables 1 and 2) had elevated *H. pylori* IgG antibodies (titers: 730-2200), whereas *H. pylori* serology was entirely negative in the rest of the patients (titers: 50-100). All patients but one (number 2 in Tables 1 and 2) had vitamin B12 replacement therapy.

### Immunogenetics of the patients

The HLA-A, B, Cw, DRB1 and DQB1 alleles in the AIG patients are shown in Table 2. DRB1\*04 was present in seven out of 12 (58%) patients, whereas 28% of the Finnish general population carry the allele ( $P = 0.045$  by Fisher's exact test). Ten patients (83%) had DQB1\*03; its allele frequency in the Finnish population is 51% ( $P = 0.034$  by Fisher's exact test).

Only one of the 12 patients carried the DRB1\*0301-DQB1\*0201 haplotype, which is an established susceptibility factor for various autoimmune diseases<sup>[16]</sup>. It is of particular note that the only DRB1\*0301-positive patient did not have the classical A\*01-B\*08 haplotype.

The frequencies of polymorphisms in the genes of the *IL-1* gene cluster, *IL-2*, *IL-4*, *IL-6*, *IL-10*, *IL-12*, *IFN $\gamma$* , *TGF $\beta$*  and *TNF $\alpha$*  did not differ significantly from those found in Finnish (where data were available) or other European populations. The results for genotyping the *IL-1* gene cluster, *TNF $\alpha$*  and *IL-10* are shown in Table 3.

All 14 characterized *KIR* genes, *KIR2DL1*, *KIR2DL2*, *KIR2DL3*, *KIR2DL4*, *KIR2DL5*, *KIR2DS1*, *KIR2DS2*, *KIR2DS3*, *KIR2DS4*, *KIR2DS5*, *KIR3DL1*, *KIR3DL2*, *KIR3DL3* and *KIR3DS1*, were determined, as well as two *KIR* pseudogenes *KIR2DP1* and *KIR3DP1*. Ten patients

carried both A and B *KIR* haplotypes; two patients were homozygotes for A haplotype. *KIR* genotype and haplotype frequencies of the patients did not differ from those reported earlier in the Finnish population<sup>[15]</sup>.

## DISCUSSION

In Finnish AIG patients, the HLA-DRB1\*04 and DQB1\*03 alleles were more frequent than in the general population, which implies an association between certain HLA-DRB1 and DQB1 haplotypes and AIG. The well-known autoimmune markers HLA-B8, DRB1\*03 and DQB1\*02 were practically missing in the AIG patients. This suggests that the immunogenetics of AIG are different to that of many classical autoimmune diseases.

The co-localization of susceptibility foci in experimental AIG and type 1 diabetes (T1D) is the strongest known between two autoimmune diseases<sup>[2]</sup>, and the most prominent susceptibility locus for both diseases is located in the HLA region. Individuals with T1D also have PCAs more often than population controls do<sup>[17]</sup>. Over 90% of Caucasians with T1D carry the DR3 or DR4 haplotype, and the DQB1\*0302 allele is associated strongly with T1D<sup>[18]</sup>. In the present study, the DRB1\*04 allele was more frequent in AIG patients

**Table 3** IL-1, IL-10, and TNF $\alpha$  polymorphisms in 12 AIG patients, and in Finnish, Italian and Czech populations

	Genotype	AIG patients	Finnish <sup>[11]</sup> %	Italian <sup>[12]</sup> %	Czech <sup>[13]</sup> %

<sup>1</sup>The genotypes are the most proinflammatory ones.

than in the general population, but the DRB1\*03 allele was only carried by the patient with T1D. Six of our 12 patients had DQB1\*0302, the prevalence of which in the Finnish population is 13% ( $P = 0.005$  by Fischer's exact test). The AIG patient with T1D was also the only one to carry the DQB1\*02 haplotype, which is present in 91% of Finnish celiac disease patients<sup>[19]</sup>, and in 17% of the general Finnish population. Thus, Finnish AIG patients seem to share some of the haplotypes that are common in patients with T1D, but not those seen in patients with celiac disease.

In the 1970s, several studies were carried out to find a possible association between AIG or PA and HLA antigens. Increased frequency of HLA antigens A3, B7 or both has been found in AIG and PA patients<sup>[20-22]</sup>; however, these findings were not confirmed by others<sup>[23]</sup>. Subgroups of AIG patients have shown associations with different HLA antigens. Patients with a concomitant endocrine disease showed an increased frequency of the B8, B18 and BW15 antigens, and those without endocrine disease that of the B7 and B12 antigens<sup>[24]</sup>.

Of the class II HLA antigens, PA patients showed increased frequency of the DR2 and DR4 antigens and a decreased presence of the DR3 antigen, as compared to controls. PA patients with a concomitant endocrine disease showed DR3/DR4 antigens more often, and those without autoimmune endocrine disease showed DR2/DR4 and DR4/DR5 antigens, as compared to controls<sup>[25]</sup>. Possibly because of the small number of patients in the present study, no significant difference could be found between those with and without concomitant autoimmune disease.

The role of *H. pylori* in AIG and PA is still poorly understood<sup>[26]</sup>. On one hand, patients with *H. pylori* infection often develop atrophic gastritis and even autoimmune characteristics, such as PCAs<sup>[27]</sup>. On the other hand, AIG patients without any signs of *H. pylori* infection, such as the majority of patients in the present study, may be found. In studies before the *Helicobacter* era, the role of *H. pylori* in atrophic gastritis was not recognized, and patients with

*H. pylori*-associated autoimmunity may have been included; this may have made it more difficult to detect associations between AIG and, for example, HLA antigens. Our patients were relatively young with a median age of 52 years and the majority were women, which is typical for the classic AIG<sup>[1]</sup>. The three patients with positive *H. pylori* serology showed no clinical difference from the others.

In *H. pylori*-positive individuals, proinflammatory polymorphisms of the IL-1 $\beta$  gene cluster have been found to be associated with atrophic gastritis, achlorhydria<sup>[28,29]</sup>, and even gastric cancer<sup>[30]</sup>, which often is a late sequel of atrophic gastritis. Patients carrying proinflammatory IL-1 $\beta$ -511T and TNF $\alpha$ -308A, and who are homozygous for IL-1RN\*2\*2, had an OR of 5.8 for developing atrophic gastritis<sup>[31]</sup>. In addition, patients that carried three or more of the proinflammatory polymorphisms (carriage of IL-1 $\beta$ -511T+ or TNF $\alpha$ -308A; homozygosity for IL-1RN\*2\*2 or IL-10 ATA/ATA) had an OR of 26.3 for non-cardia gastric cancer<sup>[32]</sup>. However, the association between gastric cancer and IL-1 $\beta$  polymorphisms has not been seen in all studies<sup>[33]</sup>. Despite the fact that all our patients had profound atrophy in the gastric corpus at a relatively young age, the frequencies of these particular genotypes did not differ from those found in populations with European ancestry. Even though the small number of patients and the lack of controls in the present study make it impossible to detect small or modest associations, our results suggest that these polymorphisms are not crucial for the development of AIG.

In conclusion, HLA DRB1\*04 and DQB1\*03 were more frequent in AIG patients than in the general Finnish population, which suggests an association between certain HLA-DRB1 and DQB1 haplotypes and AIG. Also, the well-known autoimmune markers HLA-B8, DRB1\*03 and DQB1\*02 were practically missing in the AIG patients. However the number of patients in the present study was small, and larger studies are needed to confirm these findings.

## COMMENTS

### Background

Autoimmune gastritis (AIG) is chronic inflammation in the mucosa of the gastric body, which may lead to vitamin B12 deficiency of and pernicious anemia. The cause of this inflammation is not known, but its occurrence is known to be strongly determined by genetic factors.

### Research frontiers

In earlier studies using antigen determination for the detection of human leukocyte antigen (HLA) tissue determinants, an association was found between HLA tissue antigens and AIG. Before the present study, this association had not been studied by modern DNA-based methods.

### Innovations and breakthroughs

The study is believed to be the first to show an association between AIG and certain HLA genotypes, as explored with modern DNA-based methods.

### Applications

The study included a small number of patients. These results may in the future contribute to exploring the mechanisms of AIG and possibly other autoimmune diseases. AIG is also a risk factor for gastric cancer; thus, understanding the evolution of AIG may contribute to exploring the development of cancer.

### Peer review

This is a good pilot study that indicates the need for a much bigger, longer-term study.

### **Abstract**

**AIM:** To investigate the frequency of *NOD2*, *IL23R* and *ATG16L1* genetic variants in a case-control panel for inflammatory bowel disease (IBD) from Lithuania.

**METHODS:** One hundred and eighty unrelated IBD patients [57 Crohn's disease (CD) and 123 ulcerative colitis (UC)] and 186 healthy controls were genotyped for the following known genetic susceptibility variants: *NOD2* - Arg702Trp (rs2066844), Gly908Arg (rs2066845) and Leu1007insC (rs2066847), as well as *IL23R* - Arg381Gln (rs11209026) and *ATG16L1* - Thr300Ala (rs2241880).

**RESULTS:** The effect that carriership of at least one *NOD2* risk allele predisposes to CD was replicated in the

Lithuanian population (41.1% CD vs 16.9% controls,  $P = 2 \times 10^{-4}$ , OR = 3.48, 95% CI: 1.81-6.72). In the allelic single marker analysis, Leu1007insC was strongly associated with CD (21.4% CD vs 4.7% controls,  $P = 3.687 \times 10^{-8}$ , OR = 5.54, 95% CI: 2.85-10.75). Neither the other two *NOD2* variants, nor the known variants in *IL23R* and *ATG16L1* were found to be risk factors for CD, UC or IBD. However, our relatively small study population was underpowered to demonstrate such weak to moderate disease associations.

**CONCLUSION:** The results support a strong association between CD susceptibility and the Leu1007insC variant in *NOD2* in the Lithuanian study population.

### **INTRODUCTION**

The inflammatory bowel diseases (IBD) refer to two

clinically defined conditions, ulcerative colitis (UC) and Crohn's disease (CD) that represent major burdens of morbidity in Western countries, with prevalence rates in North America and Europe ranging from 21 to 246 per 100 000 inhabitants for UC and 8 to 214 per 100 000 inhabitants for CD<sup>[1]</sup>. Although the exact aetiology of IBD remains unclear, accumulating data suggests that IBD occurs from the combined effects of genetic predisposition and environmental factors<sup>[2]</sup>.

Linkage, candidate gene, targeted association mapping and genome-wide association studies have identified many common variants associated with IBD and have rapidly expanded our fundamental knowledge of complex disease biology. The first and most consistently replicated genetic susceptibility variants, were found in the *NOD2* gene<sup>[3-5]</sup>, attributed to the recognition of bacterial products, along with several other genetic loci coding for cytokines involved in acquired immune responses (*IL23R*<sup>[6]</sup>) and genes related to the autophagy pathway (*ATG16L1*<sup>[7]</sup>).

Given the heterogeneity in allele frequencies reported for the genetic factors involved in the pathogenesis of IBD in different European populations<sup>[8]</sup>, we aimed to perform the first genetic study of IBD in a low-incidence population<sup>[9,10]</sup> of North-Eastern Europe - Lithuania. We examined the frequencies of the previously described variants in the *NOD2*, *IL23R* and *ATG16L1* genes in a Lithuanian IBD study population.

## MATERIALS AND METHODS

### Patients

The study included 57 unrelated patients with CD, 123 with UC and 186 healthy, age- and gender-matched controls. All study participants were of Caucasian ethnicity. The recruitment of the study individuals was performed at the Department of Gastroenterology, Kaunas University of Medicine Hospital during the period from 2003 to 2006. Written informed consent from all participants and approval of the Kaunas Regional Biomedical Research Ethics Committee (Protocol No. 84/2003) was obtained. The diagnosis of either CD or UC was based on standard clinical, endoscopic, radiological and histological criteria<sup>[11]</sup>. Patients' demographic and phenotypic details are summarized in Table 1. The clinical characteristics provided in the table are given according to the Montreal classification<sup>[12]</sup>.

### Genotyping

Genomic DNA was isolated from EDTA peripheral blood using the Invisorb Blood Giga Kit from Invitex (Berlin, Germany). The three *NOD2* variants - Arg702Trp (rs2066844), Gly908Arg (rs2066845) and Leu1007insC (rs2066847), and the *IL23R* variant Arg381Gln (rs11209026) were genotyped using Applied Biosystem's (Foster City, CA, USA) allele-specific TaqMan™ or TaqMan-MGB assays (Table 2); *ATG16L1* variant Thr300Ala (rs2241880) detection was performed using a pre-designed TaqMan® single nucleotide polymorphism

**Table 1** Summary of clinical and demographic characteristics of the IBD patients *n* (%)

Characteristics	CD	UC
Gender (male/female)	27/30	68/55
Age (years ± SD)	40.5 ± 14.9	45.4 ± 16.4
Age at diagnosis (years ± SD)	31.7 ± 16.6	34.3 ± 14.7
Familial IBD	0	0
Surgery treatment	15 (26.3)	3 (2.4)
Disease extension in UC		
Proctitis	-	26 (21.1)
Left-sided colitis	-	61 (49.5)
Extended colitis	-	36 (29.3)
Disease localization in CD		
Terminal ileum, L1	17 (29.8)	-
Colon, L2	16 (28.1)	-
Ileocolon, L3	23 (40.3)	-
Upper GI, L4	1 (1.8)	-
Disease Behavior in CD		
Non-stricturing, non-penetrating, B1	41 (71.9)	-
Stricturing, B2	5 (8.8)	-
Penetrating, B3	11 (19.3)	-
Perianal disease, B4	-	-
Extraintestinal manifestations		
Joints	6 (10.5)	13 (10.6)
Cutaneous	3 (5.3)	4 (3.3)
Ocular	1 (1.8)	0
Hepatobiliary	0	2 (1.6)

IBD: Inflammatory bowel diseases; CD: Crohn's disease; UC: Ulcerative colitis.

(SNP) genotyping assay (ID C\_9095577\_20). Genotyping was performed on an automated platform using the TaqMan® (Applied Biosystems, Foster City, CA, USA) technique as previously described<sup>[13]</sup>. All genotyped markers had a call rate greater than 95% in case and healthy control samples.

### Statistical analysis

Each SNP was checked for conformance with Hardy-Weinberg equilibrium in the control group using Fisher's exact test ( $P_{HWE} > 0.01$ ). Single-marker association analyses between cases and controls were performed using  $\chi^2$  statistics or Fisher's exact genotypic test. The significance level of the tests for considering *P*-values as significant was set to  $< 0.05$ . Data were evaluated using the web interface SISA<sup>[14]</sup>. Carriership of mutated alleles in case and control populations was estimated by direct counting.

The population attributable risk percentage (PAR%) was calculated as the attributable risk percentage (AR%) multiplied by the proportion of exposed cases, where AR% was estimated from the odds ratio (OR), assuming that the exposure of the control population to the disease-associated variant reflects the true prevalence of the variant in the general population<sup>[15]</sup>.

## RESULTS

All five SNPs were successfully genotyped in our North-Eastern European IBD case-control panel comprising 57 CD and 123 UC patients from Lithuania. The distribution of genotypes within the control group was
