### Abstract

**AIM:** To investigate the role of hepatocyte growth factor (HGF) in cholangiocarcinoma (CCA) cell invasiveness and the mechanisms underlying such cellular responses.

**METHODS:** Effects of HGF on cell invasion and motility were investigated in two human CCA cell lines, HuCCA-1 and KKU-M213, using Transwell *in vitro* assay. Levels of proteins of interest and their phosphorylated forms were determined by Western blotting. Localization of E-cadherin was analyzed by immunofluorescence staining and visualized under confocal microscope. Activities of matrix degrading enzymes were determined by zymography.

**RESULTS:** Both CCA cell lines expressed higher Met levels than the H69 immortalized cholangiocyte cell line. HGF induced invasion and motility of the cell lines and altered E-cadherin from membrane to cytoplasm localization, but did not affect the levels of secreted matrix metalloproteinase (MMP)-2, MMP-9 and

urokinase plasminogen activator, key matrix degrading enzymes involved in cell invasion. Concomitantly, HGF stimulated Akt and extracellular signal-regulated kinase (ERK)1/2 phosphorylation but with slightly different kinetic profiles in the two cell lines. Inhibition of the phosphoinositide 3-kinase (PI3K)/Akt pathway by the PI3K inhibitor, LY294002, markedly suppressed HGF-stimulated invasion of both CCA cell lines, and inhibition of the ERK pathway by U0126 suppressed HGF-induced invasion of the KKU-M213 cell line but had a moderate effect on HuCCA-1 cells.

**CONCLUSION:** These data indicate that HGF promotes CCA cell invasiveness through dys-localization of E-cadherin and induction of cell motility by distinct signaling pathways depending on cell line type.

### INTRODUCTION

Cholangiocarcinoma (CCA) is a malignant tumor of the

biliary epithelium associated with a high metastatic and mortality rate<sup>[1]</sup>. Incidence of this cancer has increased worldwide<sup>[2]</sup>, and in Thailand the highest incidence is in the northeastern region, where *Opisthorchis viverrini* infection is also prevalent<sup>[3]</sup>. Although the exact molecular mechanisms of cholangiocarcinogenesis are still under investigation, alterations in important growth factor pathways, such as hepatocyte growth factor (HGF)/Met and ErbB2, have been suggested as being involved<sup>[4]</sup>.

Overexpression and deregulation of Met, a receptor tyrosine kinase, have been reported in many types of cancers<sup>[5]</sup>. Met is activated *via* binding to its ligand, HGF, also known as scatter factor (SF), a soluble factor first identified as a growth factor for hepatocytes and a dissociation factor for epithelial cells<sup>[6]</sup>. Hitherto there have been a limited number of investigations into the role of Met in cholangiocarcinoma. Several reports have demonstrated a correlation between Met expression and CCA<sup>[7-10]</sup>. Immunohistochemical data indicate high expression of Met in well-differentiated CCA and hyperplastic bile ducts of nontumorous liver surrounding CCA, whereas Met expression is low in poorly differentiated tumor<sup>[7,8]</sup>. Met expression is increased in early developmental stages of CCA, suggesting a role in cholangiocarcinogenesis<sup>[9]</sup>. Moreover, there is a correlation between Met expression and CCA invasion through adjacent connective tissues<sup>[11]</sup>. HGF level has been shown also to correlate with CCA differentiation stages in both human and rat models<sup>[10,12]</sup>.

HGF/Met activation induces a variety of biological processes, including cell scattering, invasion, proliferation and survival<sup>[13-15]</sup>. Among the various cellular responses induced by HGF, cell invasion and metastasis have been implicated strongly in numerous cancer types. HGF has been reported to promote the main requirements of tumor invasion, namely, disruption of cell-cell adhesion complex, cell adhesion to extracellular matrix (ECM), cell motility and production of matrix degrading enzymes, such as matrix metalloproteinases (MMPs) and urokinase plasminogen activator (uPA)<sup>[15-18]</sup>. Phosphoinositide 3-kinase (PI3K) and mitogen-activated protein kinases/extracellular signal-regulated kinases (MAPKs/ERKs) are the main intracellular signaling pathways implicated in HGF-induced invasion<sup>[19,20]</sup>.

The present study focuses on the role of HGF/Met in CCA cell invasion and the mechanisms underlying cellular responses. Here, we demonstrate that Met is overexpressed in human CCA cell lines and that HGF stimulation induces CCA cell invasion, motility and E-cadherin translocation, but has no effect on MMPs or uPA activity. Use of inhibitors of MEK and PI3K indicate that HGF induces invasion in two different CCA cell lines *via* distinct signaling pathways.

## MATERIALS AND METHODS

### Cell culture

Human CCA cell lines HuCCA-1 and KKKU-M213 were kindly provided by Professor S Sirisinha (Mahidol University, Bangkok, Thailand)<sup>[21,22]</sup> and Associate Professor

B Sripa (Khon Kaen University, Khon Kaen, Thailand)<sup>[23,24]</sup>, respectively. Cholangiocyte H69 cell line was kindly provided by Professor G Alpini (Texas A&M University, TX, USA) and Professor G Gores (Mayo Clinic, MN, USA). CCA cells were grown in HAM/F12 medium (Gibco Invitrogen Co., Auckland, NZ) supplemented with 10% fetal bovine serum (FBS), 100 U/mL penicillin G sodium, 100 µg/mL streptomycin sulfate, 0.25 µg/mL amphotericin B (Invitrogen Co., Auckland, NZ) and 15 mmol/L HEPES (USB Co., OH, USA) at 37°C under a humidified 50 mL/L CO<sub>2</sub> atmosphere. H69 cells were cultured in DMEM/F12 and DMEM (1:1) (Gibco Invitrogen Co., Auckland, NZ) supplemented with hormones, epidermal growth factor and 10% FBS as previously described<sup>[25]</sup>.

### Western blotting analysis

Levels of Met, ERK1/2 and Akt and their phosphorylated forms, and E-cadherin, were determined by Western blotting. Cells ( $2 \times 10^5$ ) were cultured in 30-mm plates for two days, then incubated with 50 ng/mL recombinant NSO-produced human HGF (R&D Systems, Inc., MN, USA) in serum-free media for 15, 60 and 360 min in the presence or absence of LY294002 (Calbiochem, CA, USA) or U0126 (Tocris Bioscience, MO, USA). Cells were then lysed with 1 × SDS loading buffer (50 mmol/L Tris-HCl pH 6.8, 2% SDS, 10% glycerol and 100 mmol/L β-mercaptoethanol) and lysate proteins were separated by 8% SDS polyacrylamide gel-electrophoresis. Proteins were transferred to nitrocellulose membrane (Hybond ECL, GE healthcare, Buckinghamshire, UK), which was incubated with antibodies specific for Akt, ERK1/2 and their phospho-forms (Cell Signaling Technology, Danvers, MA) or with anti-Met, anti-E-Cadherin, anti-β-actin (Santa Cruz Biotechnology, Santa Cruz, CA) and anti-phospho-Met (Cell Signaling Technology, Danvers, MA) antibodies, followed by HRP-conjugated secondary antibodies. Signals were developed using Enhance Chemiluminescence kit (GE Healthcare, Buckinghamshire, UK) and detected with FluorChem SP (Alpha Innotech Corporation, San Leandro, CA). Band densities were quantitated using AlphaEaseFC software (Alpha Innotech Corporation, San Leandro, CA). The data were presented in the relative band density when compared to those at zero time points.

### Invasion and motility assay

HGF-induced CCA cell invasiveness was determined by Matrigel Transwell *in vitro* invasion assay as described by Albini *et al.*<sup>[26]</sup> with some modification. In brief, the upper chamber of a Transwell unit (6.5-mm diameter polycarbonate membrane with 8-µm pore size) (Corning Incorporated Life Science, Corning, NY), was coated with 30 µg of Matrigel (BD Biosciences, Bedford, MA). Cells (80% confluent) were harvested using TrypLE Express (Invitrogen, Co., Grand Island, NY) and resuspended in serum-free media in the presence or absence of 50 and 100 µmol/L LY294002 or 1 and 5 µmol/L U0126. A 200 µL aliquot of cell ( $10^5$ ) suspension was added to the upper chamber. The lower chamber was filled with 600 µL of serum-free media containing 10, 50 or

100 ng/mL human HGF as chemoattractant. BSA (0.1% in serum-free medium) was used as negative control. After 6 h of incubation at 37°C under CO<sub>2</sub> atmosphere, non-invading cells in the upper chamber were removed and cells that invaded the Matrigel and had attached to the lower surface of the Transwell membrane were fixed with 25% methanol for 30 min and stained with 0.5% crystal violet. Invaded cells were counted in 5 random fields under light microscope at 100 × magnification. The reported values represent mean ± SE of the results obtained from three independent experiments.

Motility assay was performed using the Transwell chamber in the same manner as in the invasion assay but Matrigel coating was omitted.

#### **Determination of gelatinase and urokinase plasminogen activator activities**

Gelatinase (MMP-2 and MMP-9) and uPA levels secreted into conditioned media were determined by gelatin and plasminogen gelatin zymography under non-reducing conditions. Cells (80% confluent) were incubated with serum-free media in the presence of HGF (0, 10, 50 and 100 ng/mL) for 6 h. For gelatinase activity assay, 20 × concentrated conditioned media was mixed with SDS loading buffer in the absence of sulfhydryl reducing agent and electrophoresed in 7.5% SDS-polyacrylamide gel containing 1 mg/mL gelatin. uPA zymography was performed in a similar manner except that 10 µg/mL plasminogen and 1 mg/mL gelatin were copolymerized with 10% SDS-polyacrylamide gel and conditioned media was not concentrated. Gels were washed twice with 2.5% TritonX-100 for 1 h to remove SDS, then incubated for 18 h in reaction buffer (for gelatinase: 50 mmol/L Tris-HCl pH 7.5, 10 mmol/L CaCl<sub>2</sub>, 1 µmol/L ZnCl<sub>2</sub> and 1% TritonX-100; for uPA: 100 mmol/L Tris-HCl pH 7.8, 150 mmol/L NaCl and 1% Triton X-100). Gels were stained for 2 h with 0.25% Coomassie blue and destained with 45% methanol and 10% acetic acid. Unstained bands in gelatin gel with estimated molecular weight of 65 and 85 kDa corresponded to MMP-2 and MMP-9 respectively, and that of 45 kDa in plasminogen-gelatin gel corresponded to uPA.

#### **Immunofluorescence analysis**

CCA cells (3 × 10<sup>5</sup>) were grown on sterile coverslips for two days. Then the monolayer cells were treated with 0-100 ng/mL HGF for 6 h. Cells were washed twice with PBS, fixed in solution containing 3% paraformaldehyde and 2% sucrose, permeabilized with 0.5% Triton X-100 and incubated with 10% FBS, 0.1% Triton X-100 in PBS. Cells were then incubated overnight at 4°C with mouse anti-E-cadherin monoclonal antibodies (Santa Cruz Biotechnology, Santa Cruz, CA), followed by fluorescent Alexa Fluor<sup>®</sup> 568-conjugated goat anti-mouse IgG secondary antibodies (Molecular Probes, Eugene, OR). After washing with PBS, the coverslips were mounted with 0.01% para-phenylenediamine dihydrochloride (Sigma Aldrich, Inc., St. Louis, MO) in 70% glycerol, and visualized under a confocal laser scanning microscope

(Olympus FV1000; Olympus Co. Tokyo, Japan) equipped with Olympus FV10-ASW 1.7 software.

#### **Statistical analysis**

Invasion and motility results are expressed as mean ± SE. Multiple comparisons were performed using one-way analysis of variance (ANOVA) with *P* value < 0.05 considered statistically significant.

## **RESULTS**

#### **Met expression and phosphorylation in CCA cells**

Western blotting analysis of both CCA cell lines (HuCCA-1 and KKU-M213) showed higher Met expression than in normal cholangiocytes (H69) (Figure 1A). Stimulation of cells by exogenous HGF resulted in induction of tyrosine phosphorylation at the critical autophosphorylation sites (pY1234/1235) in the catalytic domain of Met, but with a slight difference in the kinetics of Met activation between the two CCA cell lines; i.e. HGF stimulated a more rapid Met phosphorylation in HuCCA-1 cells (reaching a maximum at 15 min) than in KKU-M213 (maximum at about 15-60 min) (Figure 1B and C).

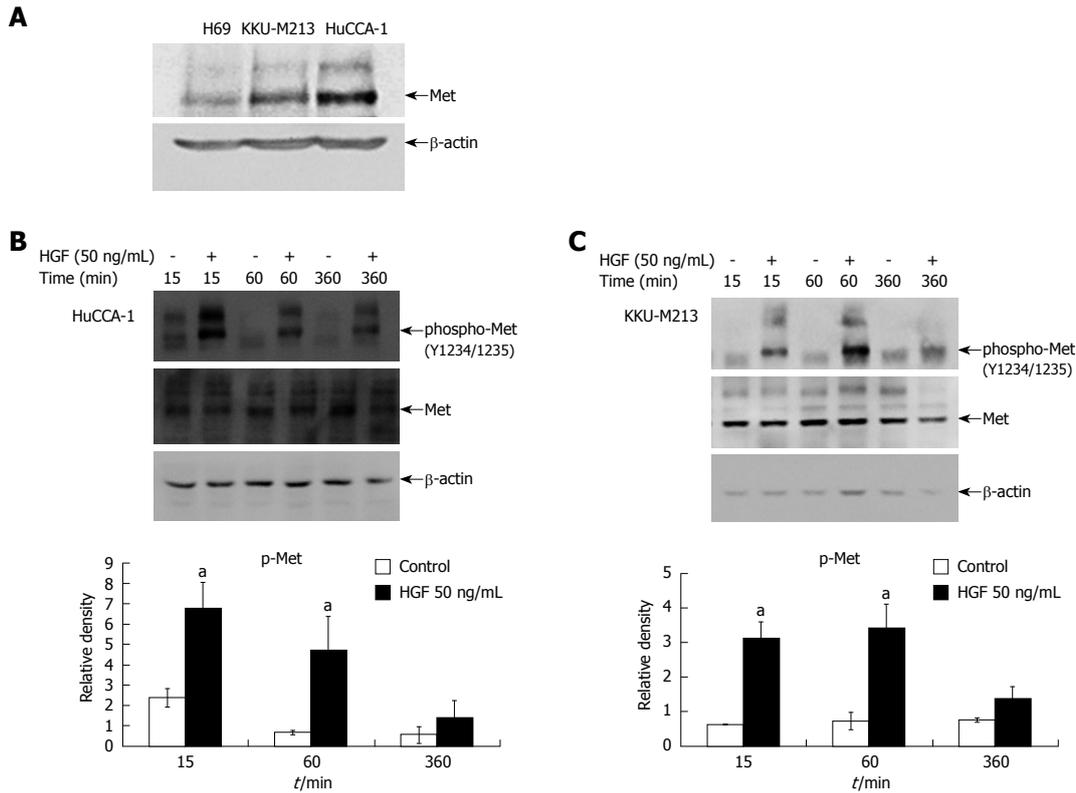

#### **Effects of HGF on CCA cell invasiveness and motility**

HGF has been reported as being able to induce invasion of several cancer cell types<sup>[27]</sup>. Here, CCA cell invasiveness and motility in response to HGF were investigated using a Transwell *in vitro* invasion/motility assay. In the absence of HGF, CCA cells showed abilities to migrate and invade, which were stimulated further by HGF in a dose-dependent manner over the concentration range of 10-100 ng/mL (Figure 2). Although basal migration and invasion abilities of HuCCA-1 were relatively low when compared to that of KKU-M213, they were dramatically stimulated by HGF to levels comparable to those of HGF-induced KKU-M213.

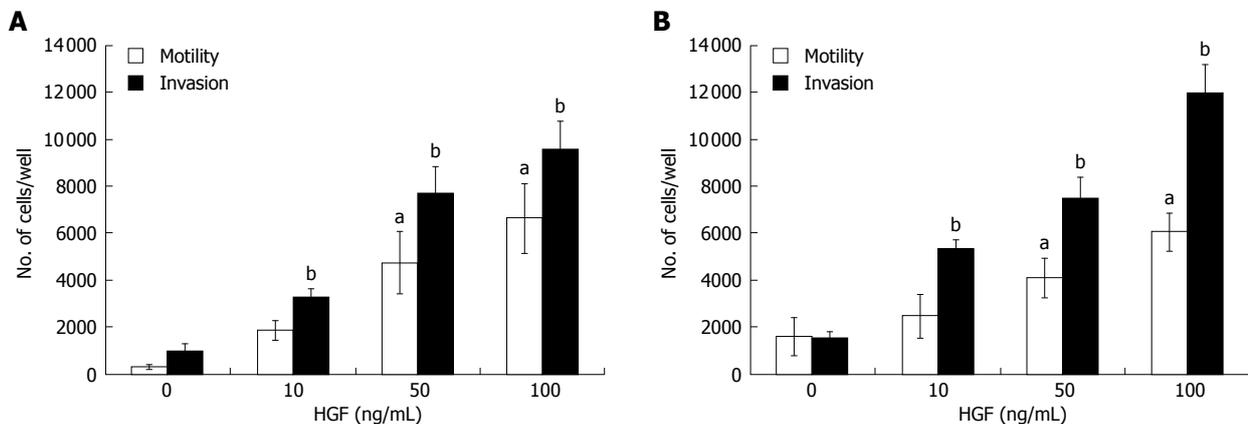

H69 cells, immortalized cholangiocytes, possessed very low invasive ability. Of 10<sup>5</sup> cells added to the upper compartment of the Transwell chamber, only 70 ± 21 cells invaded in the control and 335 ± 72 cells invaded upon HGF treatment. Although the HGF could induce H69 invasion, the level of invasion was marginal when compare to those of CCA cell lines.

#### **Effects of HGF on E-cadherin expression and localization and matrix metalloproteinase and uPA secretion**

HGF is able to induce changes in expression and localization of E-cadherin resulting in cell movement in several type of cancers<sup>[28-30]</sup>. To investigate the possibility of an involvement of E-cadherin in HGF-induced CCA cell migration, we determined the effects of HGF on E-cadherin expression by Western blotting and on localization by immunofluorescence staining. E-cadherin protein level did not change within 6 h of HGF treatment (Figure 3A). However, immunofluorescence demonstrated that HGF altered E-cadherin localization from the cell boundary to the cytoplasmic compartment

**Figure 1** Steady state level of Met expression in cholangiocarcinoma cell lines and activation by hepatocyte growth factor (HGF). Cell lysates from 80% confluent cells cultured in 10% fetal bovine serum (FBS) medium were examined for Met expression by Western blotting analysis (A). Lysates from HuCCA-1 (B) and KKKU-M213 (C) cells treated with or without 50 ng/mL HGF for various times were analyzed by Western blotting for levels of Met and phospho-Met (pY1234/1235). The graphs show band densities of phospho-Met relative to those at zero time points. Data are presented as mean  $\pm$  SE of results obtained from three independent experiments. <sup>a</sup> $P < 0.05$  vs untreated control.

**Figure 2** HGF induction of cholangiocarcinoma motility and invasiveness. *In vitro* invasion and motility assays of HuCCA-1 (A) and KKKU-M213 (B) cells were conducted in a Transwell unit coated with and without Matrigel. Cells ( $10^5$ ) in serum-free medium were plated in the upper chamber of a Transwell unit and 0-100 ng/mL HGF added to the lower chamber. After 6 h of incubation, cells invading to the lower compartment of the Transwell unit were stained and counted. The numbers of invaded/motile cells are presented as mean  $\pm$  SE of results obtained from three independent experiments. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , vs untreated control.

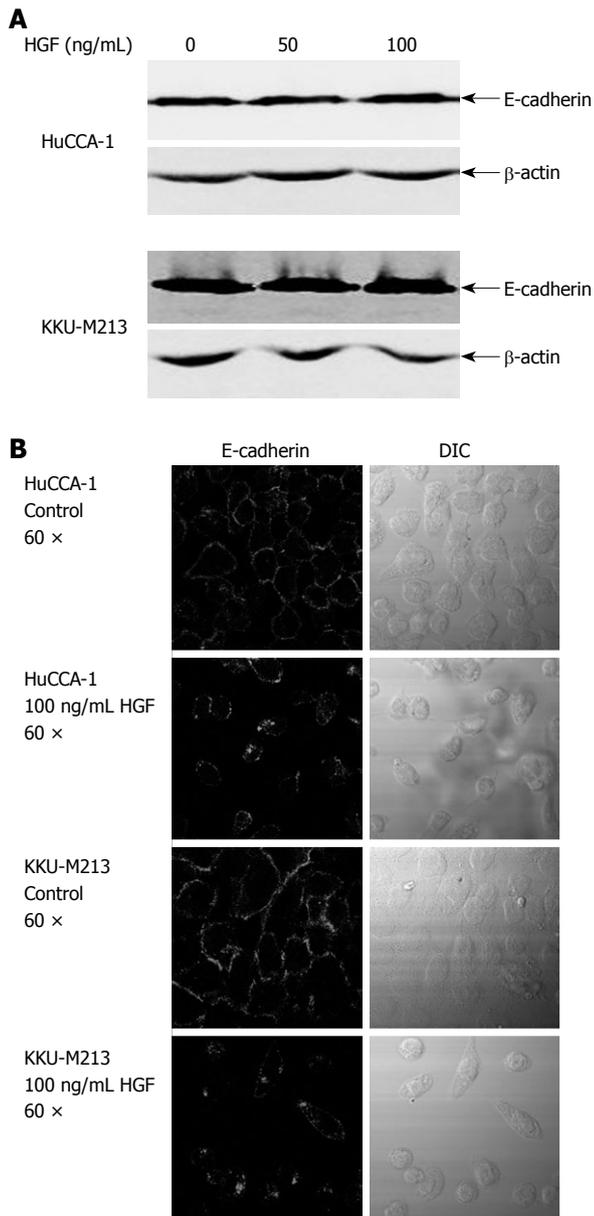

(Figure 3B and C).

The effect of HGF on secretion of matrix degrading enzymes, a major factor contributing to cell invasiveness, was investigated by gelatin zymography. Zymograms from conditioned media of HuCCA-1 cells showed a clear band indicating MMP-2 activity, while those of KKKU-M213 cells revealed both MMP-2 and MMP-9 activities (Figure 4A), demonstrating that the two CCA cell lines constitutively expressed high amounts of

MMP-2 and/or MMP-9 at basal levels. However, these enzyme activities were not increased following HGF treatment (Figure 3A). Similarly, high basal activity of uPA was found in both CCA cell lines, which was not affected by the presence of HGF (Figure 4B).

**Involvement of ERK1/2 and PI3K signaling pathways in HGF-induced CCA cell invasiveness**

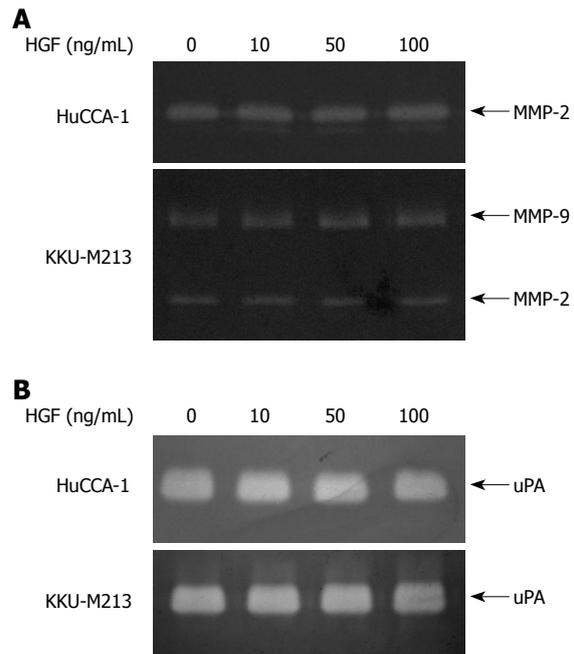

The mechanism responsible for HGF-induced inva-

**Figure 3** Effects of HGF on E-cadherin expression and localization. A: cholangiocarcinoma (CCA) cells were treated with HGF for 6 h, then cell lysate was analyzed by Western blotting with anti-E-cadherin and  $\beta$ -actin monoclonal antibodies; B: After treatment with 0 and 100 ng/mL HGF for 6 h, cells were analyzed by immunofluorescence using anti-E-cadherin antibody and visualized under confocal laser scanning microscopy (60  $\times$  objective magnification plus 2  $\times$  digital magnification).

siveness of CCA cell lines was investigated by examining the signaling pathways of ERK1/2 and PI3K. HGF (50 ng/mL) stimulated both HuCCA-1 and KKKU-M213 phosphorylation of ERK1/2 and Akt, with the latter being the major downstream effector of PI3K (Figure 5A and B). However, different time response profiles were observed between these two cell lines in HGF-induced ERK1/2 and Akt activation. In KKKU-M213 cells, HGF significantly induced activation of ERK1/2 and Akt at up to 360 min, whereas in HuCCA-1 cells, after 360 min of induction, activation decreased to nearly those of unstimulated levels.

To confirm the roles of these two signaling pathways

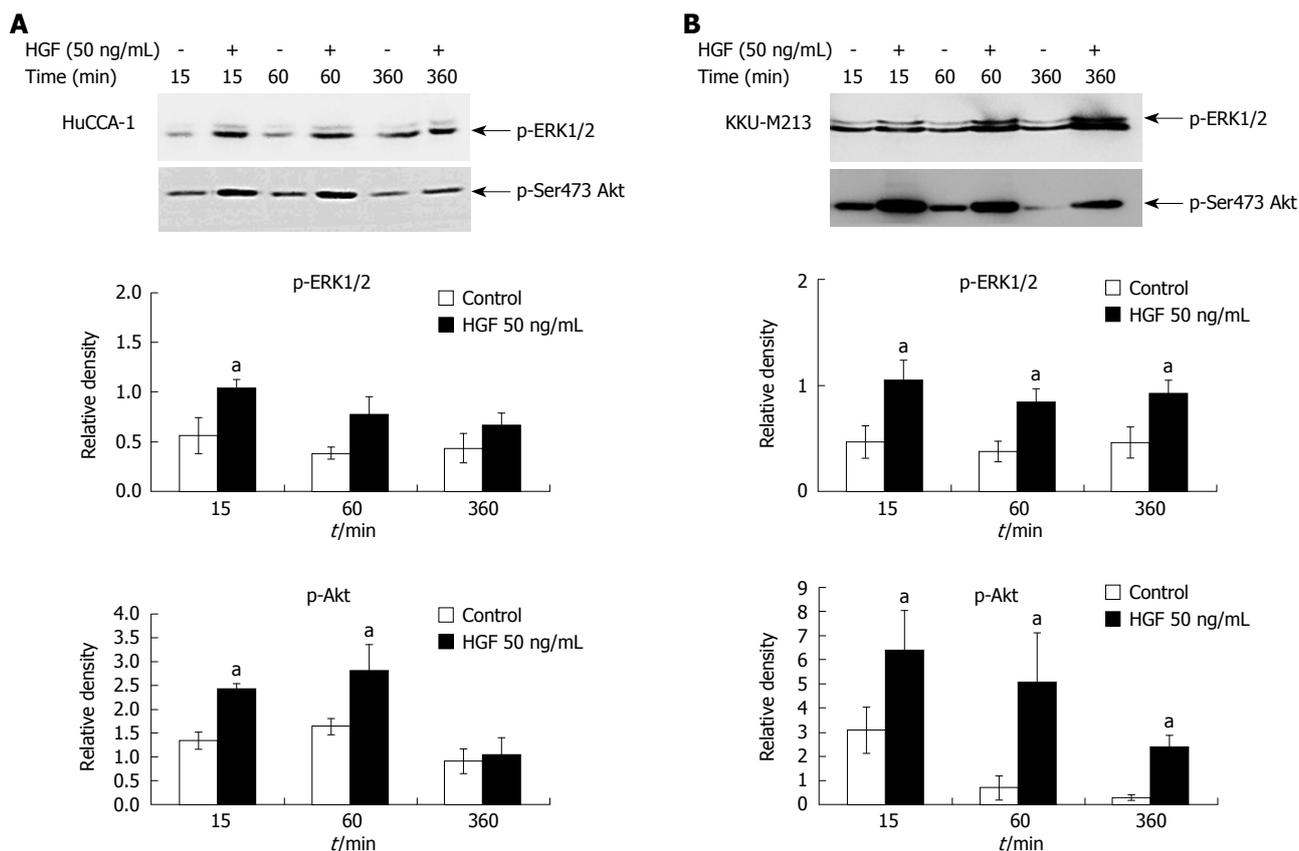

**Figure 4** Effect of HGF on levels of secreted matrix degrading enzymes from cholangiocarcinoma HuCCA-1 and KKKU-M213 cell lines. Cells were treated with various concentrations of HGF (0-100 ng/mL) in serum-free medium for 6 h. Conditioned media were then analyzed for MMP-2 (approximate 65 kDa) and MMP-9 (approximate 85 kDa) gelatinolytic activity by gelatin zymography (A) and for uPA by plasminogen-gelatin zymography (B).

in response to HGF stimulation, we tested the antagonistic effect of U0126 and LY294002; a MEK1 and a PI3K inhibitor, respectively. LY294002 (50  $\mu$ mol/L) inhibited HGF-stimulated phosphorylation of Akt in both CCA cell lines to an undetectable level (Figure 6A) and markedly inhibited HGF-induced cell invasion, but did not have any significant effect on the invasion of non HGF-stimulated cells (Figure 6B and C). U0126 (1 and 5  $\mu$ mol/L) reduced HGF-induced invasion of KKKU-M213 cells (to 29% and 18% of untreated control, respectively) (Figure 7C). However, U0126 only had a marginal inhibitory effect on HGF-induced invasion of the HuCCA-1 cell line (Figure 7B). Nevertheless, U0126 completely inhibited ERK1/2 phosphorylation of HuCCA-1 cells, whereas phospho-ERK1/2 was still detectable in KKKU-M213 cells even at the highest U0126 concentration used (Figure 7A).

## DISCUSSION

Overexpression of Met has been reported in CCA and is correlated with progression and invasion of this type of cancer<sup>[9,11]</sup>. In this study, we demonstrated that HGF induced cell invasion, motility and change in E-cadherin localization in two human CCA cell lines, HuCCA-1 and KKKU-M213, both of which overexpress Met; but without affecting secretion of the matrix degrading enzymes, MMP-2, MMP-9 and uPA. However, the signaling pathways underlying HGF-induced invasiveness of the two cell lines were different, with ERK1/2 activation being more important for HGF-induced KKKU-M213 cell invasion than for HuCCA-1 cell invasion.

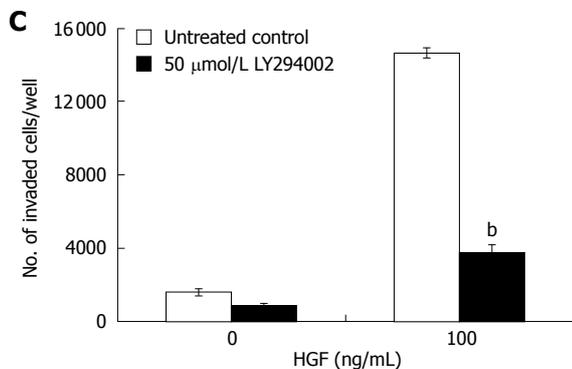

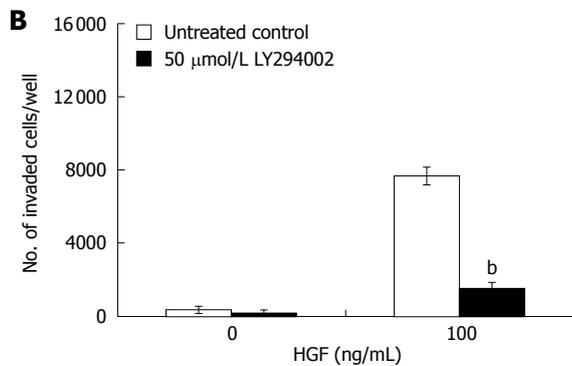

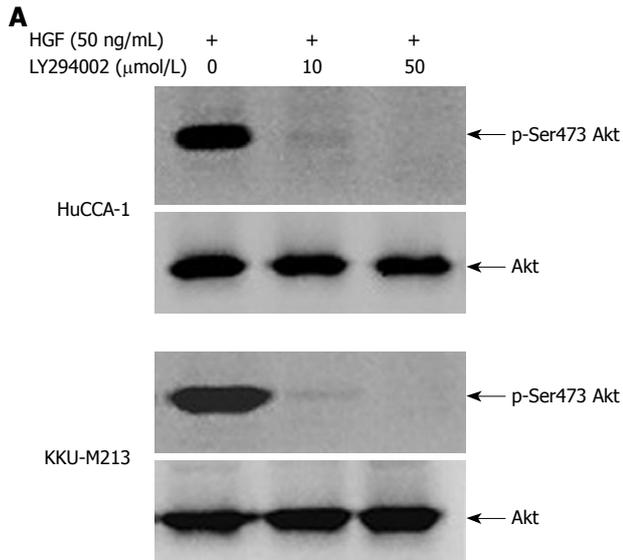

**Figure 5** HGF induction of ERK1/2 and Akt phosphorylation in cholangiocarcinoma HuCCA-1 and KKU-M213 cell lines. About 80% confluent cells were treated with 50 ng/mL HGF in serum-free medium for 15, 60, 360 min. Lysates from HuCCA-1 (A) and KKU-M213 (B) cells were assessed for total and phosphorylated forms of ERK1/2 and Akt by Western blotting assay. The graphs showed band densities of phospho-ERK1/2 and phospho-Akt relative to those at zero time points. Data are presented as mean  $\pm$  SE of results obtained from three independent experiments. <sup>a</sup> $P < 0.05$  vs untreated control.

Two major factors contributing to an increase in cancer cell invasiveness are enhancement of extracellular matrix degradation and activation of cell motility. The effects of HGF on induction of these phenomena vary with different cell types. For instance, HGF enhances cell motility but not MMP-9 or uPA activities in breast cancer MDA-MB-231 cell line<sup>[16]</sup>, while it induces both motility and matrix degrading enzyme expression in colon cancer Caco-2, prostate cancer PC-3 and DU-145 cells<sup>[31,32]</sup>. In our study, HGF induced invasion of both CCA cell lines by increasing motility but not MMP-2, MMP-9 or uPA levels. As the expression of the basal levels of these matrix degrading enzymes was already high in both CCA cell lines, this may be sufficient for providing cellular transmigration. Therefore, induction of cell motility alone by HGF, without augmenting extracellular matrix degrading enzyme levels, appears to be sufficient for cell invasiveness. Alterations of only some process(es) required for cell invasion have been reported as being able to alter cell invasiveness. For instance, inhibitors of ERK1/2<sup>[33]</sup> and myosin light chain kinase<sup>[34]</sup> suppress prostate cancer cell invasion by decreasing cell motility but not matrix degrading enzyme activity.

E-cadherin is the key mediator of cell-cell adhesion. Cell scattering induced by HGF results from disruption of E-cadherin function, either by reducing expression or changing its cellular localization<sup>[29]</sup>. In this study, we found

that HGF caused E-cadherin to move from membrane to cytoplasm but had no effect on amount. These results are consistent with previous studies in a keratinocyte cell line, in which HGF reduced E-cadherin at cell-cell boundaries without changing its protein level<sup>[35,36]</sup>. Although we did not investigate the mechanism of HGF-disrupted E-cadherin function, previous reports have implicated the involvement of Ras-RIN2-Rab5 and  $\beta$ -catenin in this process. Kimura *et al*<sup>[37]</sup> demonstrated in a cell free system that HGF activates Ras which binds and activates RIN2, a Rab5-GEF (guanine nucleotide exchange factor of Rab5), leading to Rab5 activation. This active Rab5, a small G protein regulating endocytosis, in turn promotes E-cadherin endocytosis. In addition, Shibamoto *et al*<sup>[36]</sup> showed that HGF promotes tyrosine phosphorylation of  $\beta$ -catenin and decreases E-cadherin at the cell-cell boundaries resulting in the reduction of cell-cell adhesion mediated by E-cadherin.

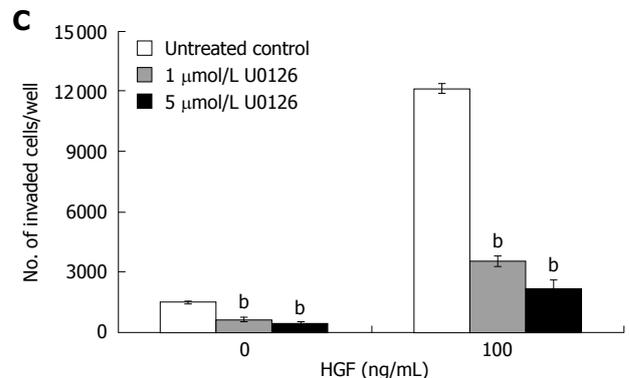

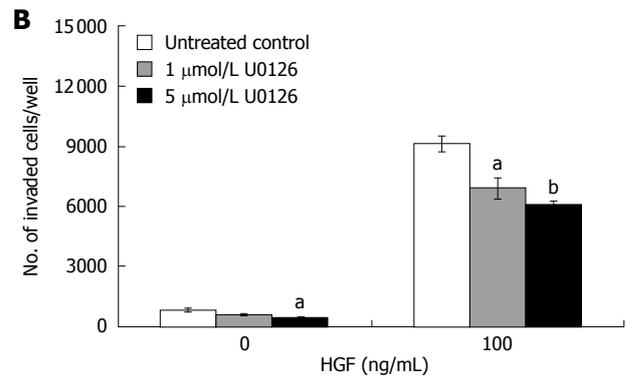

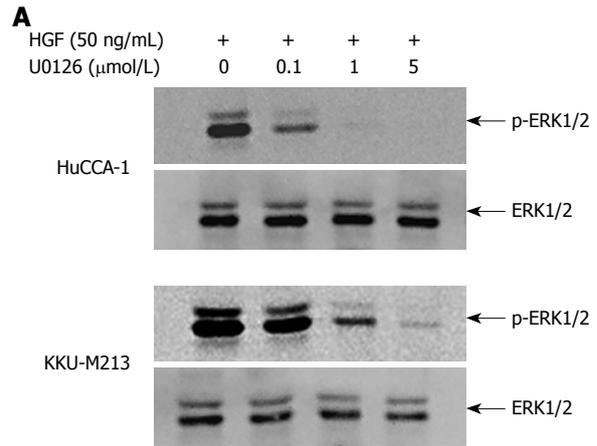

Basement membrane normally acts as a barrier for tumor cell invasion; therefore, it is generally expected that the rate of invasion at which a cell degrades this barrier should be slower than or equal to the rate of cell migration. However, with the HuCCA-1 cell line, the basal cell invasion rate (with no HGF stimulation) was higher than that of migration. This suggests that some component(s) in Matrigel may have a role in inducing HuCCA-1 cell invasion. In support of this notion,

**Figure 6** Suppression of HGF-induced cholangiocarcinoma cell invasiveness by PI3-kinase inhibitor, LY294002. HuCCA-1 and KKKU-M213 cells were treated with 50 ng/mL HGF in the absence (control) or presence of 10 and 50  $\mu\text{mol/L}$  LY294002 for 6 h, and subsequently Akt phosphorylation was determined by Western blotting (A). *In vitro* invasion of HuCCA-1 (B) and KKKU-M213 (C) cells was evaluated in the absence or presence of HGF with or without 50  $\mu\text{mol/L}$  LY294002. Numbers of invaded cells are presented as mean  $\pm$  SE of results obtained from three independent experiments. <sup>b</sup> $P < 0.01$  vs control.

Chintala *et al*<sup>[38]</sup> have shown that Matrigel and components of ECM (namely, type IV collagen and fibronectin) induce migration and invasion of many glioma cell lines.

In the KKKU-M213 cell line, HGF was better at inducing invasion than migration, and this was not related to the stimulation of secretion of matrix degrading enzymes. A possible explanation is the existence

**Figure 7** Suppression of HGF-induced cholangiocarcinoma cell invasiveness by MEK1 inhibitor, U0126. HuCCA-1 and KKKU-M213 cells were treated with 50 ng/mL HGF in the absence (control) or presence of 0.1, 1 and 5  $\mu\text{mol/L}$  U0126 for 6 h, and subsequently ERK1/2 phosphorylation was determined by Western blotting (A). *In vitro* invasion of HuCCA-1 (B) and KKKU-M213 (C) cells was evaluated in the absence or presence of HGF with or without 1 and 5  $\mu\text{mol/L}$  U0126. Numbers of invaded cells are presented as mean  $\pm$  SE of results obtained from three independent experiments. <sup>a</sup> $P < 0.05$  and <sup>b</sup> $P < 0.01$  vs control.

of a synergism between HGF and extracellular matrix component(s) in the Matrigel. A combination of HGF and Matrigel induced higher motility than HGF alone (data not shown). Cooperation between HGF and ECM component(s) to promote cell migration could occur by enhancing the function of integrins<sup>[16,39]</sup>, adhesion molecules regulating a variety of cellular properties including adhesion and migration by binding to ECM components. HGF induces cell scattering and migration by

increasing integrin  $\alpha 2$  expression in MDCK cells<sup>[39]</sup> and also promotes breast cancer MDA-MB-231 cell invasion and adhesion by inducing integrin aggregation at lamellipodia, thereby enhancing avidity of integrins to their ligands in ECM and increasing association of integrin to actin, which may participate in cell migration<sup>[16]</sup>.

A variety of signaling pathways are involved in HGF-induced cell invasiveness, including PI3K, ERK1/2 and Src<sup>[40]</sup>. In CCA, Src, FAK<sup>[41]</sup> and ERK1/2<sup>[42]</sup> are involved in HGF-induced HuCCA-1 cell invasion. Here, we showed that HGF induced Met activation concomitant with the promotion of both ERK1/2 and Akt phosphorylation in these two CCA cell lines. To reveal the involvement of ERK and PI3K pathways in HGF-induced invasion, inhibitors of specific signaling transduction pathways were used. PI3K inhibitor (LY294002) significantly inhibited both HuCCA-1 and KKKU-M213 cell invasion stimulated by HGF, while basal invasion was marginally affected. As for the ERK pathway, U0126, a specific inhibitor of MEK1, drastically reduced HGF-promoted KKKU-M213 cell invasion, while slightly reducing HGF-induced HuCCA-1 invasion, even though it inhibited ERK1/2 phosphorylation of the latter cell line to a greater extent than in the former. The insensitivity of HGF-stimulated HuCCA-1 invasion to U0126 treatment suggests a reduced dependence of this CCA cell line on the ERK signaling pathway, whereas HGF-induced KKKU-M213 invasion is dependent on both PI3K and ERK1/2 activation.

ERK1/2 activation is known to regulate a variety of cellular functions, such as proliferation, differentiation, migration, and invasion in response to diverse extracellular stimuli<sup>[43]</sup>. Duration of ERK1/2 activation is one of the factors determining a particular cellular response<sup>[39,44]</sup>. McCawley *et al.*<sup>[45]</sup> showed that EGF and HGF have the ability to induce SCC-12F keratinocyte migration. These two growth factors induce sustained ERK1/2 activation, which is associated with enhanced MMP-9 expression and SCC cell migration<sup>[45,46]</sup>. In MDCK cells, HGF induces sustained ERK1/2 activation, promoting cell scattering and migration *via* the enhancement of integrin- $\alpha 2$  expression, whereas EGF induces transient ERK1/2 activation, which has no effect on cell scattering<sup>[39]</sup>. Our data indicated that prolonged ERK1/2 activation was crucial for HGF-induced invasion of KKKU-M213 cells, but was not necessary for HuCCA-1 cells in which HGF rapidly and transiently activated ERK. Thus, sustained ERK activation provides a possible explanation for the difference in downstream signaling pathways observed in HGF-induced invasion of the two CCA cell lines. Moreover, this sustained ERK1/2 activation may be responsible for a synergism between HGF and Matrigel in KKKU-M213 cells by inducing integrin expression, as in MDCK cells<sup>[39]</sup>.

In summary, this study provides evidence for the contribution of a HGF signaling pathway to the induction of CCA cell invasion. HGF promoted invasion *via* stimulation of cell motility, but not MMP or uPA secretion. HGF regulated invasiveness of two independent CCA cell lines by different signaling pathways, with PI3K being a com-

mon pathway underlying HGF-induced invasiveness in both cell lines, whereas the importance of ERK1/2 was determined by the duration of ERK1/2 activation. However, the mechanisms regulating temporal ERK1/2 activation and possible synergism between HGF and matrix in inducing invasion remains to be elucidated. Understanding the signaling mechanism responsible for CCA invasiveness will be valuable to help identify better targets for cancer therapy, such as that associated with a common rather than a cell specific pathway.

## ACKNOWLEDGMENTS

The authors thank Professor Sirisinha S, Dr. Sripta B, Professor Gores G and Professor Alpini G for their generous gifts of cholangiocarcinoma and cholangiocyte cell lines and Professor Wilairat P for critical reading of the manuscript.

## COMMENTS

### Background

Cholangiocarcinoma (CCA) is a malignant tumor of the biliary epithelium associated with a high metastatic and mortality rate. Incidence of this cancer has increased worldwide, and the highest incidence occurs in northeast Thailand. Overexpression of Met has been reported in CCA and is correlated with progression and invasion of this type of cancer.

### Research frontiers

Hepatocyte growth factor (HGF)/Met activation induces a variety of biological processes, including cell scattering, invasion, proliferation and survival. Although several reports have demonstrated a correlation between Met expression and CCA, hitherto there have been only a limited number of detailed investigations into the role of Met in cholangiocarcinoma.

### Innovations and breakthroughs

HGF induced cell invasion and motility and altered E-cadherin localization in two human CCA cell lines overexpressing Met, without affecting the matrix degrading enzymes, matrix metalloproteinase (MMP)-2, MMP-9 and urokinase plasminogen activator (uPA). This is the first report of a difference in the signaling pathways responsible for the HGF-induced invasiveness of the two human CCA cell lines, in that extracellular signal-regulated kinase (ERK)1/2 activation is more important for HGF-induced invasion of one cell line than of the other.

### Applications

Understanding the role of HGF/Met in CCA invasiveness and the molecular mechanisms underlying this process provides valuable information to help identify targets for future treatment of CCA patients.

### Terminology

Phosphoinositide 3-kinase (PI3K) and ERK are signaling molecules downstream of many receptor tyrosine kinases including Met. These proteins have been shown to play an important role in cell invasion, a crucial factor of cancer metastasis. In this study HGF is shown to stimulate cell invasion and motility of CCA cell lines through PI3K and/or ERK pathways.

### Peer review

CCA is a common malignant tumor with a high metastatic and mortality rate. Investigation into its molecular mechanism is important for understanding the pathogenesis of CCA. This study focused on the role of HGF/Met in CCA cell invasion and the mechanisms underlying cellular responses. Although a number of papers on this field have been published, this study still adds some new information into the knowledge already documented.

### Abstract

**AIM:** To make a retrospective analysis of endoscopy findings and clinicopathologic characteristics of colonic schistosomiasis in order to further improve our understanding of the disease and decrease its misdiagnosis.

**METHODS:** Endoscopy findings and clinicopathologic characteristics of 46 intestinal schistosomiasis patients were retrospectively analyzed. All the patients underwent colonoscopy and all biopsy specimens stained with hematoxylin and eosin were observed under a light microscope.

**RESULTS:** Of the 46 colonic schistosomiasis patients, 1 was diagnosed as acute schistosomal colitis, 16 as chronic schistosomal colitis and 29 as chronic active schistosomal colitis according to their endoscopic findings and pathology. Not all patients were suspected of or diagnosed as colonic schistosomiasis. Of the 12 misdiagnosed patients, 4 were misdiagnosed as ulcerative

colitis, 1 as Crohn's disease, and 7 as ischemic colitis. The segments of rectum and sigmoid colon were involved in 29 patients (63.0%). Intact *Schistosoma* ova were deposited in colonic mucosa accompanying infiltration of eosinocytes, lymphocytes, and plasma cells in acute schistosomal colitis patients. Submucosal fibrosis was found in chronic schistosomal colitis patients. Among the 17 patients with a signal polyp, hyperplastic polyp, canalicular adenoma with a low-grade intraepithelial neoplastic change, tubulovillous adenoma with a high-grade intraepithelial neoplastic change were observed in 10, 5, and 2 patients, respectively. Eight out of the 46 patients were diagnosed as colonic carcinoma.

**CONCLUSION:** Endoscopy contributes to the diagnosis of colonic schistosomiasis although it is nonspecific. A correct diagnosis of colonic schistosomiasis can be established by endoscopy in combination with its clinicopathologic characteristics.

### INTRODUCTION

Colonic schistosomiasis is defined as a specific acute or chronic inflammatory reaction of *Schistosoma* ova that

are deposited mainly in colorectal mucosa. The majority of humans are infected with *Schistosoma japonicum*, *hematobium* and *mansoni*. *Schistosoma japonicum* and *mansoni* often lead to intestinal disease<sup>[1]</sup>. Chinese people are commonly infected with *Schistosoma japonicum*. In the 1950s, schistosomiasis was epidemic at a large scale in regions along the Yangtze River and in more than 400 counties in South China<sup>[2-4]</sup>. Because of the effective prevention and cure measures taken in China in recent years, schistosomiasis has been eliminated in most epidemic regions. However, its spread is not yet completely controlled and schistosomiasis occurs every year in a small number of people in the epidemic regions of China<sup>[3,4]</sup>. Since the number of colonic schistosomiasis patients is small, physicians know little about it, thus often misdiagnosing intestinal schistosomiasis. In the present study, we made a retrospective analysis of endoscopy findings and clinicopathologic characteristics of 46 colonic schistosomiasis patients in order to further improve our understanding of the disease and decrease its misdiagnosis.

## MATERIALS AND METHODS

From May 2005 to May 2009, 46 patients with colonic schistosomiasis were admitted to Endoscopy Center, Affiliated Gulou Hospital of Medical School of Nanjing University (Nanjing, China). Their endoscopy findings and clinicopathologic characteristics were retrospectively analyzed. The patients gave their written informed consent before colonoscopy (Olympus CF-240I or CF-H260AZI, Tokyo, Japan). When a lesion was detected at colonoscopy, tumor tissue samples were taken and fixed in 4% buffered paraformaldehyde, embedded in paraffin, and stained with hematoxylin-eosin. Two pathologists independently examined the tumor tissue sections under a light microscope (Olympus, Tokyo, Japan).

## RESULTS

### Clinical characteristics

Of the 46 colonic schistosomiasis patients (32 men and 14 women) at the age of  $65.4 \pm 10.8$  years (range 40-80 years), 31 were from the epidemic areas of schistosomiasis and 15 from the non-epidemic areas with a history of contacting water containing *Schistosoma* ova.

The time from onset of symptoms to visit of a doctor ranged 4 d to 7 years (mean 4.5 years). The common symptoms were repeated fever and hematochezia. Among the symptoms occurred in 46 patients, diarrhea was found in 31 (67.3%), bloody stool in 8 (17.3%), abdominal pain in 35 (76.1%), incomplete intestinal obstruction in 3 (4.7%), turgescence spleen in 6 (8.4%) and hepatosplenic schistosomiasis in 1 patients (1.5%), respectively.

### Endoscopy features

All the patients underwent colonoscopy with a success in 41 patients and a failure in 5 patients. The whole colon, right colon, and left colon were involved in 4 (8.7%), 4

Table 1 Location of affected colon

Location of colonic injury	<i>n</i>	Percent
Cecum	2	4.3
Whole colon	4	8.7
Ascending + transverse colon	1	2.2
Descending colon	8	17.4
Descending + transverse colon	1	2.2
Hepatic flexure of colon	1	2.2
Sigmoid colon	3	6.5
Sigmoid colon + rectum	9	19.6
Rectum	17	37.0

(8.7%), and 38 (82.6%) patients, respectively (Table 1). Among the 38 patients with their left colon involved, only descending colon, descending and transverse colon, only sigmoid colon, sigmoid colon and rectum, and only rectum were involved in 8, 1, 3, 9, and 17 patients, respectively. The lesion was mainly located in rectum and sigmoid colon of 29 patients (63.0%).

Among the 46 patients, acute submucosal colitis, chronic submucosal colitis, chronic active submucosal colitis were diagnosed in 1, 16, and 29 patients, respectively. Friable or edematous mucosa with more mucus exudates, scattered petechial hemorrhage, invisible submucosal blood vessels, erythema and granularity of mucosa with irregular ulcerations could be observed in acute submucosal colitis patients by colonoscopy. Chronic submucosal colitis was characterized by pale intestinal mucosa, confused vascular net with more flat or elevated yellow nodules, even intestine stricture, single polyp or more polyps. Acute and chronic inflammation reactions occurred simultaneously in the same or different segments of colon, and a clear dividing line emerged between the two types of inflammation in chronic active submucosal colitis patients. Acute inflammation was often observed in the right colon and chronic inflammation usually occurred in the left colon. Acute and chronic inflammation was also observed in the same segment of colon (Figure 1).

### Pathology characteristics

Intact *Schistosoma* ova were deposited in lamina propria with infiltration of eosinocytes and neutrophilic granulocytes in acute schistosomal colitis patients. *Schistosoma* ova were calcified and deposited with infiltration of lymphocytes and plasma cells in submucosa, lamina propria in chronic schistosomal colitis patients. Atrophy of intestinal mucosa epithelium, reduction of intestinal glands, submucosal hyperplasia and different degrees of fibrosis were also observed in chronic schistosomal colitis patients. Two different types of *Schistosoma* ova were found in chronic and acute schistosomal colitis patients. In addition, *Schistosoma* oviposition was associated with the clinical and histopathological changes in colonic schistosomiasis (Figure 2).

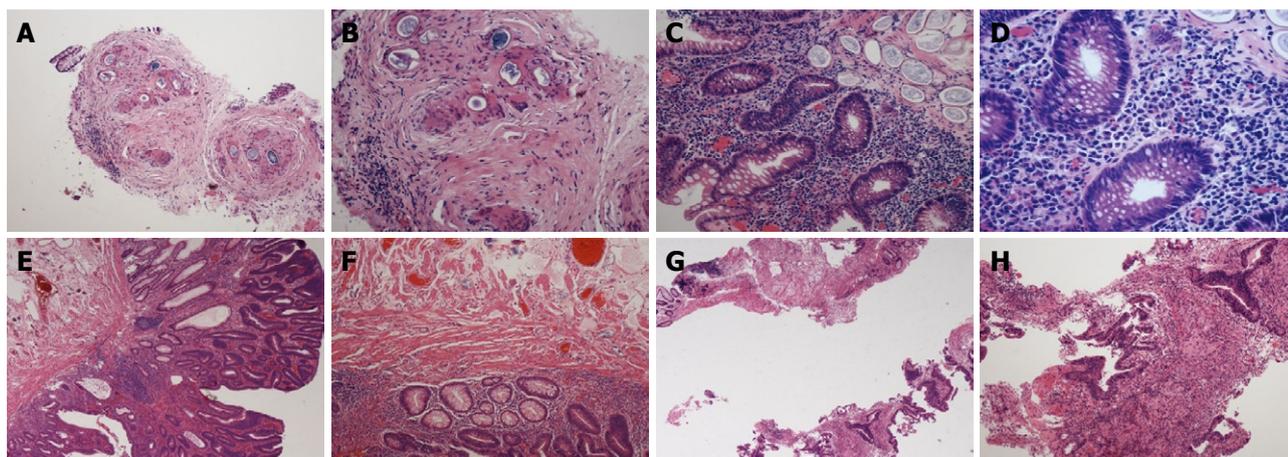

Colonoscopy showed that a single polyp in 17 out of the 46 patients. Among the 17 patients, hyperplastic polyps, canalicular adenoma with a low-grade intraepithelial neoplastic change and tubulovillous adenoma with a high-

**Figure 1** Endoscopic findings of schistosomal colonic disease. ### Therapy

High frequency electric snare of colonic polyps was performed under a colonoscope for 17 colonic schistosomiasis patients. Among these patients, colonic carcinoma was radically removed in 8 patients, schistosomiasis was treated with antischistosomiasis drug (praziquantel) in 1 patient and the other patients received symptomatic treatment.

### DISCUSSION

Schistosoma ova are mainly parasitized in the inferior mesenteric and portal vein when one is infected with them. Intestinal schistosomiasis occurs due to deposition of Schistosoma ova in submucosa producing a granulomatous reaction<sup>[5]</sup>. Mucosal edema, hemorrhage and ulceration may occur in bowel wall at its early stage, while thickened bowel wall, polyps, or enteric cavity stricture, *etc.*, can be detected at its advanced stage<sup>[6]</sup>. In our study, colonic schistosomiasis was divided into acute schistosomiasis colitis, chronic schistosomiasis colitis, and chronic active schistosomiasis colitis according to the inflammation reaction in colon. In the present study, 46 colonic schistosomiasis patients included 1 acute schistosomiasis colitis, 16 chronic schistosomiasis colitis and 29 chronic active schistosomiasis colitis patients. The difference between acute and chronic schistosomiasis colitis depends on whether Schistosoma ova are intact. A Schistosoma ovum or several Schistosoma ova are deposited in submucosa and lamina propria in acute schistosomiasis colitis patients with infiltration of eosinocytes. Schistosoma ova are calcified and deposited in submucosa and lamina propria with infiltration of lymphocytes and epithelioid cells in chronic schistosomiasis colitis patients. Fibroplasia could be observed in colonic submucosa of chronic schistosomiasis colitis patients. The deposition sites of Schistosoma ova are sigmoid colon, upper segment of rectum, descending colon, transverse colon, cecum and ascending colon. In our study, the

lesion was located in the rectum and sigmoid colon of 29 patients (63.0%) and in the colon segments of 17 patients (37.0%).

Although nonspecific, colonoscopy may provide valuable information for the diagnosis of colonic schistosomiasis. Colonoscopy can show edematous, congestive mucosa and petechial hemorrhage in acute schistosomiasis colitis patients, and confused vascular net with more close-set flat or elevated yellow nodules, polyps and intestine stricture in chronic schistosomiasis colitis patients. Acute and chronic inflammation could be observed in colon segments of chronic active schistosomiasis colitis patients. The most characteristic finding is the gray-yellow or yellowish white schistosomiasis nodules similar to those of pseudomembranous enterocolitis. In our study, colonoscopy showed schistosomiasis nodules in only 6 patients (16.2%), which may be the reason why physicians cannot make a correct diagnosis of the disease based only on colonoscopic findings. Schistosomiasis oviposition is the golden diagnostic standard for colonic schistosomiasis. Schistosoma ova are deposited in lamina propria and/or in submucosa<sup>[7]</sup> with infiltration of eosinocytes and neutrophilic granulocytes in acute schistosomiasis colitis patients. Schistosoma ova are calcified or ruptured with infiltration of lymphocytes and plasma cells in submucosa and lamina propria of chronic schistosomiasis colitis patients. Submucosal hyperblastosis and fibrosis could also be found in chronic schistosomiasis colitis patients. Two types of Schistosoma ova can be detected in chronic acute schistosomiasis colitis patients.

In our study, a definite diagnosis was not made only based on endoscopic findings. Four patients were misdiagnosed as ulcerative colitis, 1 as Crohn's disease, and 7 as ischemic colitis, indicating that physicians know little about the disease.

Colorectal cancer is one of the most common malignant gastrointestinal tumors and its occurrence has in-

creased in recent years. Its pathogenesis remains unclear, thus requiring further study. *Schistosoma japonicum* infection is considered a significant risk factor for colonic cancer in Asia although it is still controversial<sup>[5]</sup>. A total of 454 colorectal carcinoma specimens have been studied in China, showing that 289 of them are associated with *Schistosoma japonicum* infection<sup>[8]</sup>. Kaw *et al*<sup>[9]</sup> studied 1277 colonic carcinoma patients and found that schistosomiasis is often accompanied with rectal carcinoma. Mei *et al*<sup>[10]</sup> studied 352 colonic carcinoma patients and found that 14.3% of them have the complication of schistosomiasis. These colonic carcinomas are moderately-differentiated tubular and mucinous adenocarcinomas. In the present study, 8 colonic schistosomiasis patients (17.3%) had complication of colonic carcinoma, and 2 had complications of a high-grade intraepithelial neoplastic change and precancerous lesion. However, the mechanism of *Schistosoma japonicum* infection leading to carcinoma is unclear, which may be associated with chronic inflammation, ulceration and mucosa repair due to *Schistosoma ova*. Tumorigenesis may result from gene mutations in epithelial cells of glands due to the long time stimulation of mucosa by *Schistosoma ova*.

The incidence of colonic schistosomiasis has been greatly declined. However, many complications may occur if it is not early diagnosed and treated. Colonic schistosomiasis should be diagnosed based on its clinical symptoms and signs, coloscopic findings and pathologic characteristics. If *Schistosoma ova* are found in biopsy, it can be diagnosed. If *Schistosoma ova* are not observed in biopsy, the near-normal crypts with excess mucus and diffuse or focal infiltration of eosinophilic granulocytes may be highly suggestive of colonic schistosomiasis<sup>[11]</sup>.

## COMMENTS

### Background

Schistosomiasis was epidemic at a large scale in the regions along the Yangtze River and more than 400 counties in South China 50 years ago. Thanks to the effective prevention and cure measures taken in recent years, schistosomiasis has been eliminated in most epidemic regions. However, its spread is not completely controlled in several regions and schistosomiasis still occurs in a small number of people in its endemic region, which threatens their health. Since the number of patients with still suffer from schistosomiasis has greatly declined, physicians know little about it and often misdiagnose it.

### Research frontiers

Colonic schistosomiasis is seldom reported at present. In this study, the endoscopy findings and clinicopathologic characteristics of 46 colonic schistosomiasis patients were retrospectively analyzed, showing that *Schistosoma japonicum* infection may be a risk factor for colonic cancer.

### Innovations and breakthroughs

The endoscopy findings and clinicopathologic characteristics of 46 colonic schistosomiasis patients were analyzed. The disease was classified into acute schistosomal colitis, chronic schistosomal colitis, and chronic active schistosomal colitis. The results indicate that *Schistosoma japonicum* infection may be a risk factor for colonic cancer and schistosomal polyps should be removed under an endoscope.

### Applications

The endoscopy findings and clinicopathologic characteristics of colonic schistosomiasis were described, which may improve our further understanding of the disease and decrease its misdiagnosis.

### Terminology

Colonic schistosomiasis: An acute and chronic specific inflammatory reaction due to *Schistosoma ova* in colonic and rectal mucosa. Pseudomembranous enterocolitis: An infection of the colon with *Clostridium difficile*, characterized by diarrhea, fever, vomiting and abdominal pain.

### Peer review

This paper is interesting and should be published. The authors, however, need to highlight the high incidence of cancer in their populations.

### Abstract

**AIM:** To assess the feasibility of endoscopic ultrasound (EUS)-guided celiac plexus neurolysis (CPN) using a poloxamer.

**METHODS:** In this prospective evaluation, six Yorkshire pigs underwent EUS-guided CPN. Three received an injection of 10 mL of 0.25% Lidocaine plus methylene blue (group 1) and three received an injection of 10 mL of 0.25% Lidocaine plus blue colored poloxamer (PS137-25) (group 2). Necropsy was performed immediately after the animals were sacrificed. The abdominal and pelvic cavities were examined for the presence of methylene blue and the blue colored poloxamer.

**RESULTS:** EUS-guided CPN was successfully performed in all 6 pigs without immediate complication. Methylene blue was identified throughout the peritoneal and retroperitoneal cavity in group 1. The blue colored poloxamer was found in the retroperitoneal cavity immediately adjacent to the aorta, in the exact location of the celiac plexus in group 2.

**CONCLUSION:** EUS-guided CPN using a reverse phase polymer in a non-survival porcine model was technically feasible. The presence of a poloxamer gel at the site of the celiac plexus at necropsy indicates a precise delivery of the neurolytic agent.

### INTRODUCTION

Pancreatic cancer and chronic pancreatitis commonly cause pain that is difficult to control<sup>[1-3]</sup>. Opioids are frequently used in an attempt to mitigate pain, however, tolerance, nausea, constipation and other side effects develop<sup>[4,5]</sup>. Non-pharmacologic therapies are often employed to improve pain control and quality of life while reducing drug-related side effects. Celiac plexus blockade (CPB) using steroids or celiac plexus neurolysis (CPN) using alco-

hol has been utilized and considered safe. Endoscopic ultrasound (EUS)-guided CPB and CPN have demonstrated safety and efficacy through real-time imaging and anterior access to the celiac plexus from the posterior gastric wall, thereby avoiding complications related to the puncture of spinal nerves, arteries and the diaphragm.

Unfortunately, EUS-guided CPN and CPB provide limited benefit in terms of degree and duration of pain relief<sup>[3]</sup>. While benefit duration of EUS CPN diminishes after 8-12 wk, the etiology remains unknown<sup>[6,7]</sup>. One theory is that the neurolytic or blockade agent washes away from the celiac plexus injection site due to its liquid free-flowing form and does not remain in the ideal anatomical location. Thus, if a neurolytic or blockade agent could be delivered in an alternate phase (solid or gel), it could offer the potential for enhanced efficacy and safety<sup>[8]</sup>.

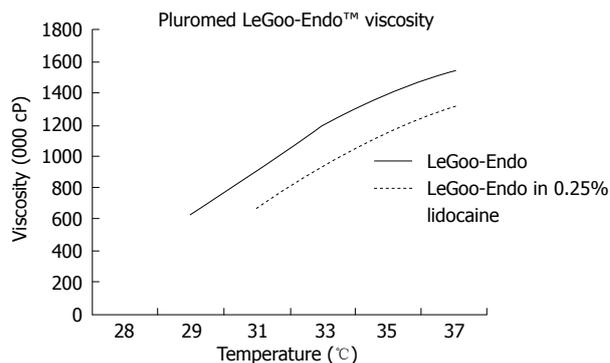

Recently, non-ionic surfactant triblock (ABA) copolymers of polyethylene oxide<sub>a</sub>-polypropylene oxide<sub>b</sub>-polyethylene oxide<sub>a</sub> (PEO<sub>a</sub>-PPO<sub>b</sub>-PEO<sub>a</sub>), also termed as poloxamers, have been widely used in industrial and medical applications<sup>[9-14]</sup>. Certain poloxamers have demonstrated rapid reverse phase thermosensitive properties at certain concentrations. Purified poloxamers PS138-25, PS107-20 and PS137-25 (Pluromed Inc., Woburn, MA, USA) are thin liquids at room temperature while at body temperature they are solid gel plugs (Figure 1). Therefore using a neurolytic or blockade agent as an additive in a purified poloxamer will potentially form a solid gel plug at the exact location of injection at the celiac plexus with enhancement of efficacy and safety. This study will assess the feasibility of EUS-guided CPN/CPB using a poloxamer in a non-survival porcine model.

## MATERIALS AND METHODS

Six Yorkshire pigs (25-30 kg) were food restricted for 24 h prior to the procedure. Intravenous (iv) Telazol (4.4 mg/kg), Atropine sulfate (0.04 mg/kg) and Xylazine (2.2 mg/kg) were used for anesthesia induction followed by inhaled Isoflurane (1% to 3%) on a semi-closed circuit for anesthesia maintenance after endotracheal intubation.

EUS-guided CPN was then performed using a linear echoendoscope (GF-UC140P, Olympus, Tokyo, Japan). Once the location of the celiac plexus was identified by its position relative to the celiac artery, a 19-gauge needle (Wilson-Cook Medical, Inc., Winston-Salem, NC, USA) was introduced under direct EUS visualization (Figure 2). The needle was flushed with 2 mL normal saline and aspiration was performed to evaluate for vessel penetration prior to additional injections.

Three pigs were randomly assigned to receive a single injection of 10 mL of Lidocaine (0.25%) plus methylene blue (group 1) and three pigs randomly received a single injection of 10 mL of Lidocaine (0.25%) plus blue colored poloxamer PS137-25 (LeGoo-endo™, Pluromed, Inc., Woburn, MA, USA) (group 2). Due to the increased viscosity of the poloxamer, a greater amount of force was required for injection. This was easily overcome with the use of a Controlled Radial Expansion (CRE) balloon dilator inflation hand pump system (Boston

**Figure 1** Temperature profile of LeGoo-Endo™ (PS137-25) that transits from liquid to gel at body temperature. The viscosity of LeGoo-Endo™ with Lidocaine is slightly higher than LeGoo-Endo™ at body temperature.

**Figure 2** Illustration of endoscopic ultrasound (EUS)-guided celiac plexus neurolysis (CPN). Figure from Arcidiacono PG, Rossi M. Celiac Plexus Neurolysis. *J Pancreas* 2004; 5: 315-321.

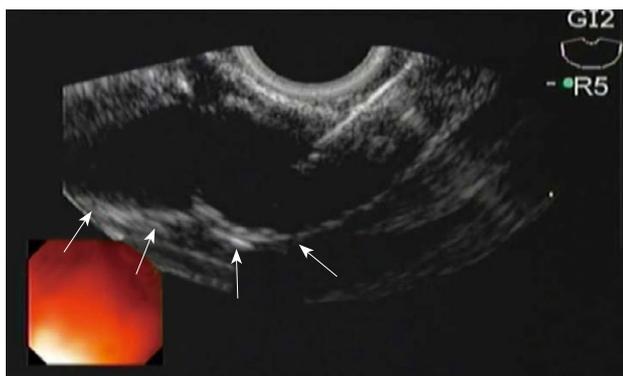

Scientific, Natick, MA, USA). During the procedure, the blood pressure, heart rate, temperature, ventilation, and oxygenation status of the pigs were continuously monitored by the professional veterinary team of the Animal Research at Children's Hospital (ARCH) (Boston, MA, USA). The investigators were not blinded to the injection group.

Using Fatal Plus (86 mg/kg), the group 1 pigs were immediately sacrificed after the procedure and the group 2 pigs were sacrificed at 60 min after the procedure. Necropsy was performed immediately upon death of the pigs and close examinations of the peritoneal and retroperitoneal cavities were made. Photographic and video records were obtained. This study was approved by the Animal Research Committee of the ARCH and complied with the National Academy of Sciences Guide for the Care and Use of Laboratory animals.

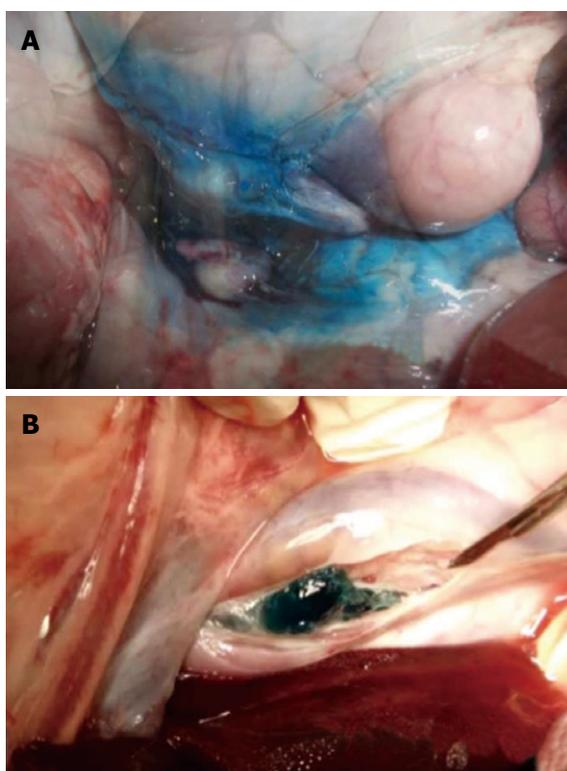

## RESULTS

All the six pigs tolerated the procedure well with no immediate complications. EUS-guided CPN was successfully performed in both groups. An echodense smudge was endosonographically visualized after injection of Lidocaine plus methylene blue and Lidocaine plus blue colored poloxamer PS 137-25 (Figure 3).

At necropsy, methylene blue was identified spread throughout the peritoneal and retroperitoneal cavities in group 1. In group 2, a blue gel plug was identified in the retroperitoneal cavity, adjacent to the aorta, in the exact

**Figure 3** EUS-guided injection of Lidocaine plus blue colored poloxamer PS 137-25. The outer margin of the hypochoic poloxamer is visualized upon injection into the celiac plexus (arrows).

location of the celiac plexus without evidence of any blue gel elsewhere in the peritoneal or retroperitoneal cavity (Figure 4).

## DISCUSSION

EUS-guided CPN and CPB are safe and effective methods for pain control in patients with pancreatic neoplasms and chronic pancreatitis<sup>[3-6,15-18]</sup>. Unfortunately, the degree and duration of therapeutic effect vary. Gress *et al.*<sup>[18]</sup> performed EUS-guided CPB in 90 patients with chronic pancreatitis and found that 55% of patients had decreased pain scores at a mean follow-up of 8 wk. This included a reduction in pain medication requirements as reported by the patients in the study. Persistent benefit was found

in 26% of patients at week 12 and in 10% at week 24. Gunaratnam *et al.*<sup>[6]</sup> performed EUS-guided CPN in 58 patients with pancreatic cancer, 78% of whom experienced a decline on a continuous 11-point visual analog pain scale 2 wk after the procedure. Only 54% experienced a decline of greater than 2 points after EUS-guided CPN and the efficacy diminished 8-12 wk after the procedure in those not receiving adjuvant therapy. Those authors also found that opioid administration increased throughout the study, however this increase was not statistically significant. Levy *et al.*<sup>[3]</sup> administered EUS-guided direct ganglia injection in 33 patients with pancreatic cancer and chronic pancreatitis, 94% and 80% of the patients reported pain relief with alcohol injection at 2-4 wk after the procedure, however long-term follow-up data was not recorded.

In a report in 1996, fluoroscopic evaluation of the abdomen was conducted in patients who underwent EUS-guided CPN. Of those examined, all were noted to have injected material spread in a periaortic distribution with dye spread anterior and lateral to the aorta with extension in both the cranial and caudal direction<sup>[16]</sup>. This study supports our findings in group 1 pigs where the injected methylene blue was identified spread throughout the peritoneal and retroperitoneal cavities.

While short-term reduction in pain has been indicated, long-term benefit with this technique is limited. This may be explained by the fact that until recently, the celiac ganglia was unable to be directly visualized, leading to a less precise delivery of therapy<sup>[3,19,20]</sup>. Other possibilities include interference with direct visualization due to the echodense smudge and potential alterations in anatomy after injecting one side of the aorta with the therapeutic agent using the double injection technique. Additionally, dispersion of the therapeutic agent away from the desired location may act to influence the efficacy and duration.

The goal of this study was to evaluate the feasibility of EUS-guided CPN using a poloxamer that would potentially remain in the desired target location. This may yield a safer and more durable therapeutic result. In group 2, where the PS137-25 was injected, a gel plug was successfully created at the intended location of the celiac ganglia. The gel maintained the therapeutic agent in the celiac plexus and potentially released the drug slowly over time, thereby optimizing long-term therapeutic results.

A limitation of this study is that it is an acute, non-survival evaluation without long-term follow-up. It is therefore unclear how the injected gel plug interacts with the porcine model over time. Additionally, the study was performed using Lidocaine instead of a steroid or alcohol as it was simpler to integrate into the PS137-25. Steroid or alcohol integration may influence the temperature phase transition point of the poloxamer, however, the formation of a gel at body temperature and liquid at room temperature would remain intact. Lastly, the quantity and rate of drug release from the gel plug was unable to be determined in this current study.

In conclusion, EUS-guided CPN using a reverse phase polymer is feasible in a non-survival porcine model. The formation of a gel plug at the exact location of the celiac ganglia

may avoid dispersion of the injected therapeutic agent and increase the duration of analgesic effect. A survival study is now necessary to determine the duration and breakdown of the gel plug within the body. This would provide useful information on potential complications related to the plugs presence and allow for assessment of the therapy from the gel plug over time. Future studies will also integrate the use of steroids and alcohols into the poloxamer.

## COMMENTS

### Background

Pancreatic cancer and chronic pancreatitis commonly cause pain that is difficult to control. Nonpharmacologic therapies are often employed to improve pain control and quality of life while reducing drug-related side effects. Endoscopic ultrasound (EUS)-guided celiac plexus blockade (CPB) using steroids or celiac plexus neurolysis (CPN) have demonstrated safety and efficacy. Unfortunately, the neurolytic or blockade agent may wash away from the celiac plexus injection site due to its liquid free-flowing form and does not remain in the ideal anatomical location. Therefore, using a neurolytic or blockade agent as an additive in a reverse thermodynamic phase poloxamer will potentially form a solid gel plug at the exact location of injection at the celiac plexus with enhancement of efficacy and safety.

### Research frontiers

Expanded research utilizing reverse phase poloxamers for additional applications in medical practice. Survival studies utilizing reverse phase poloxamers to determine the duration and breakdown of the gel plug within the body. Enhancement of the efficacy and safety of CPB and CPN.

### Innovations and breakthroughs

Recently, non-ionic surfactant triblock (ABA) copolymers of polyethylene oxide<sub>n</sub>-polypropylene oxide<sub>m</sub>-polyethylene oxide<sub>n</sub> (PEO<sub>n</sub>-PPO<sub>m</sub>-PEO<sub>n</sub>), also termed as poloxamers, have been widely used in industrial and medical applications. Certain poloxamers have demonstrated rapid reverse phase thermosensitive properties at certain concentrations. Purified poloxamers PS138-25, PS107-20 and PS137-25 (Pluromed Inc., Woburn, MA, USA) are thin liquids at room temperature while at body temperature they are solid gel plugs. Therefore, the novel use of a neurolytic or blockade agent as an additive in a purified poloxamer will potentially form a solid gel plug at the exact location of injection at the celiac plexus.

### Applications

EUS-guided CPN using a reverse phase polymer is feasible in a non-survival porcine model. The formation of a gel plug at the exact location of the celiac ganglia may avoid dispersion of the injected therapeutic agent and increase the duration of analgesic effect. A survival study is now necessary to determine the duration and breakdown of the gel plug within the body. Future studies will also integrate the use of steroids and alcohols into the poloxamer.

### Terminology

Poloxamer: A non-ionic surfactant triblock (ABA) copolymer of polyethylene oxide<sub>n</sub>-polypropylene oxide<sub>m</sub>-polyethylene oxide<sub>n</sub> (PEO<sub>n</sub>-PPO<sub>m</sub>-PEO<sub>n</sub>). Reverse phase thermosensitivity: When a material or substance is in its liquid phase at cold temperature and in its solid phase at hot temperature.

### Peer review

Dr. Thompson *et al* present an animal experience on the use of reverse phase polymer to increase the efficacy of EUS-guided celiac plexus injection for pancreatic pain control. This represent an interesting experiment outlining the possible improvement of the procedure by using a compound which facilitate the retention of the injectate at the local level (celiac plexus).

### Abstract

**AIM:** To analyze the expression of 8 putative cancer stem cell (CSC) markers within colorectal cancer tumor buds and to determine their prognostic impact in patients with this disease.

**METHODS:** Immunohistochemistry was performed on 101 colorectal cancer resections for CK22 (to identify tumor buds) as well as CD133, CD166, CD24, CD44s, CD90, EpCAM, ALDH1, and ABCG5, and their expression within tumor buds was evaluated.

**RESULTS:** CD90, CD44s, and CD133 expression in tumor buds was found in less than 5% of all cases. ALDH1, CD24, CD166 were expressed in 16.5%, 16.2%, and 34% cases, respectively, while ABCG5 and EpCAM expression was more frequent and found in 35% and 69% of cases, respectively. Of the 8 markers studied, EpCAM and ABCG5 positivity in tumor buds were significantly associated with poor prognosis ( $P = 0.023$ ,

$P = 0.038$ , respectively) in multivariable analysis with pT and pN classification [ $P = 0.048$ ; hazard ratio (HR): 2.64; 95% CI: 1.0-6.9, for EpCAM and  $P = 0.029$ ; HR: 2.22; 95% CI: 1.0-4.5, for ABCG5]. Poor survival time was particularly striking for lymph node-negative patients with ABCG5-positive buds ( $P < 0.001$ ).

**CONCLUSION:** Expression of putative stem cell markers EpCAM and ABCG5 within the tumor buds of colorectal cancer are frequently noted and are associated with poor prognosis.

ABCG5-positivity in tumor buds is an indicator of poor prognosis in node-negative colorectal cancer patients. *World J Gastroenterol* 2010; 16(6): 732-739 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i6/732.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i6.732>

### INTRODUCTION

In 1985, Gabbert and colleagues described a peculiar feature at the invasive border of differentiated colonic tumors: neoplastic glands irregularly arranged into small strands or single cells without junctional complexes and often missing even rudimentary basement membranes<sup>[1,2]</sup>.

Their observation of the tumor front of differentiated adenocarcinomas focally acquiring the phenotype of undifferentiated tumors is credited for pioneering the concept commonly referred to today as epithelial mesenchymal transition (EMT) and represented in colorectal cancer by its histological hallmark “tumor budding”.

Defined as single cells or clusters of up to 4 or 5 cells at the invasive tumor front, tumor budding can easily be spotted using pan-cytokeratin stains and is highly associated with an infiltrating tumor border configuration<sup>[5]</sup>. The adverse prognostic impact of tumor budding in colorectal cancer has consistently been reported and recognized by the American Joint Committee on Cancer/Union International Contre le Cancer (AJCC/UICC) as an additional prognostic factor to complement Tumor Node Metastases (TNM) staging<sup>[4-13]</sup>. Moreover, tumor budding is frequently linked to high-grade tumors, lymph node positivity, vascular and lymphatic invasion, as well as to both local tumor recurrence and distant metastasis<sup>[11,14-17]</sup>.

Several lines of evidence seem to suggest that tumor buds may, to some extent, represent malignant colorectal cancer stem cells (CSC) because of their potential for migration and re-differentiation locally and at sites of metastasis<sup>[18]</sup>. “Pseudopodia-like” cytoplasmic protrusions have been described in tumor buds, which seem to be in direct contact with adjacent interstitial tissue suggesting their formation during cell migration<sup>[2,19,20]</sup>. Previous studies on EMT and events occurring at the invasive tumor front implicate, in particular, Wnt pathway signaling in the process of tumor budding<sup>[21]</sup>. This is evidenced by increased  $\beta$ -catenin immunohistochemical staining in tumor buds, a concomitant loss of E-cadherin, as well as overexpression of laminin5 $\gamma$ 2 along with activation of transcriptional repressors SLUG, and ZEB1<sup>[19,22,23]</sup>. Other groups have described changes in the expression of several matrix metalloproteinases (MMP-2, MMP-7, MMP-9), and extensive staining of  $\beta$ (III)-tubulin, a major constituent of microtubules, all suggestive of invasion and migration potential of tumor buds<sup>[24-26]</sup>. Together with loss of epithelial-like properties and cell-cell adhesion, in addition to the ability to re-differentiate at distant sites, the hypothesis that tumor buds could represent putative migrating stem cells is not far-fetched.

Phenotypic characterization of colorectal CSC is still debated although putative CSC populations have been identified in several solid tumors based on functional stem cell-like properties and expression of specific markers. Recently, 4 such markers have been proposed for colorectal cancer; CD133, a glycoprotein expressed on CD34+ stem and progenitor cells in fetal liver, endothelial precursors and fetal neural stem cells; CD44s, an adhesion molecule with roles in signaling, migration, and homing, EpCAM, a homophilic Ca<sup>2+</sup>-independent cell adhesion molecule expressed on the basolateral surfaces of most epithelial cells; and CD166 or activated leukocyte cell adhesion molecule (ALCAM) known as a mesenchymal stem cell marker<sup>[27]</sup>. Other putative stem cell markers have also generated interest in other tumor types including ABCG5, a member of the ATP binding cassette family involved in

transport of sterol and other lipids, ALDH1, a member of the aldehyde dehydrogenase family of enzymes with roles in proliferation, differentiation, and survival, CD24, an adhesion molecule and ligand for P-selectin, and CD90, a mediator of thymocyte adhesion to thymic stroma<sup>[28]</sup>.

Considering the apparent stem cell-like properties of tumor buds and adverse effect of budding on clinical outcome, we hypothesized that expression of a subset of these 8 putative stem cell markers could have significant implications for prognosis in patients with positive tumor budding. Thus, the aim of this study was to determine the impact of CD166, CD44s, EpCAM, ALDH1, CD133, CD24, CD90, and ABCG5 expressed within tumor buds on prognosis in patients with colorectal cancer.

## MATERIALS AND METHODS

### Patients

Three hundred patients with pre-operatively untreated tumors who underwent tumor resection between 1987 and 1996 at the University Hospital of Basel, Switzerland were initially included in this study. These patients were randomly selected from a larger previously described cohort of 938 colorectal cancer patients with full clinicopathological information<sup>[29]</sup>. Histopathological features were re-reviewed from the corresponding hematoxylin and eosin slides by an experienced gastrointestinal pathologist (LT) and included histological subtype, pT classification, pN classification, tumor grade, and vascular invasion. Tumor border configuration and peritumoral lymphocytic inflammation were diagnosed according to Jass *et al.*<sup>[30]</sup>. Clinical data were retrieved from patient reports including age at diagnosis, tumor diameter, and tumor location. The clinical endpoint of interest was cancer-specific survival time. Censored observations included patients who died for reasons other than colorectal cancer, who were alive or who were lost to follow-up. The study design is outlined in Figure 1.

### Specimen characteristics

The paraffin-embedded colorectal cancer resection specimens for all 300 patients were retrieved from the archives of the Institute of Pathology, University Hospital of Basel as well as at the Institute of Clinical Pathology, Basel, Switzerland. The use of material for this study was approved by the local ethics committee of the University of Basel.

### Assay methods

**Immunohistochemistry for CK22 staining:** All 300 specimens were cut at 4  $\mu$ m and underwent immunostaining for CK22, a marker of epithelial cells that served to highlight areas of tumor budding, and which is routinely performed in our laboratories for diagnostic purposes. Briefly, tissues were de-waxed and re-hydrated in dH<sub>2</sub>O. Following pressure cooker-mediated antigen retrieval in 0.001 mol/L ethylenediaminetetraacetic acid pH 8.0, endogenous peroxidase activity was blocked using 0.5% H<sub>2</sub>O<sub>2</sub>. Sections were incubated with 10% normal

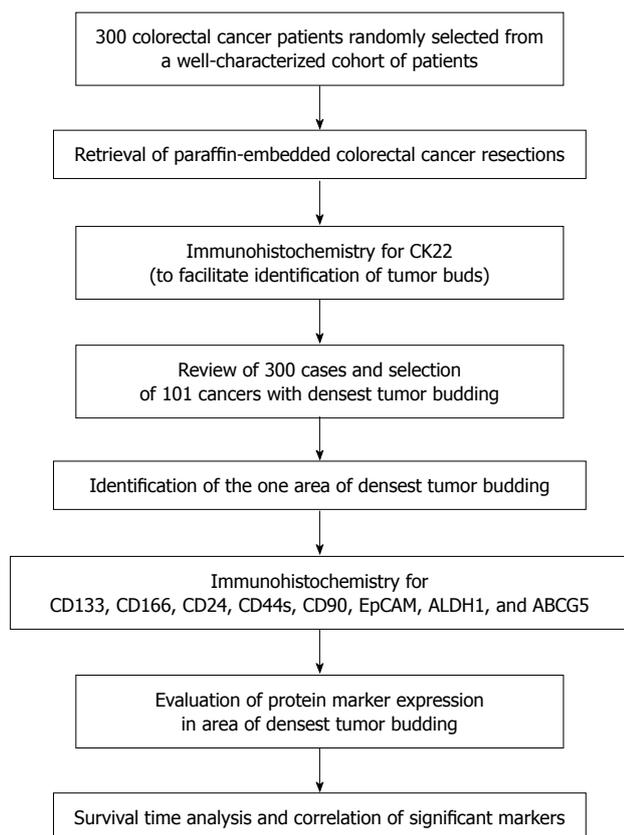

Figure 1 Study design.

goat serum for 20 min. After incubation with primary antibody (CK22 polyclonal, Genetex, Inc., 1:100), sections were incubated with horseradish peroxidase-conjugated secondary antibody (DakoCytomation) for 30 min at room temperature, immersed in amino-ethylcarbazole (DakoCytomation) for 30 min, and counterstained with hematoxylin.

**Selection of densest budding cases:** All 300 cases were evaluated using a 10 × magnification for the presence of tumor budding (AL). Since this study was designed to focus on expression of putative stem cell markers within the tumor buds themselves, cases with the densest number of budding cells were selected for the analysis (n = 101). These 101 cases were then carefully re-scored for tumor budding according to the method proposed by Ueno *et al.*<sup>11</sup>. Briefly, the tumor border was scanned at 10 × power and the area of most dense budding identified. In the center of this area, tumor buds (single cells or clusters of up to 5 cells) were counted at 20 × magnification. In order to locate this same region of dense budding on serial sections, the area was circled with a felt-tip pen. The clinico-pathological features for these 101 patients are outlined in Table 1.

**Immunohistochemistry for putative stem cell markers:** Following a similar protocol as described above, the 101 cases with densest tumor budding were immunostained for CD166 (clone 110G/07; 1:200; Novocastra), CD44s (clone DF1485; 1:50; Dako), EpCAM (clone VU-1D9; 1:200; Cell

Clinico-pathological features		Frequency n (%)
Gender (n = 101)	Female	63 (62.4)
	Male	38 (37.6)
Tumor location (n = 101)	Left-sided	64 (63.4)
	Right-sided	37 (36.6)
Histological subtype (n = 101)	Mucinous	7 (6.9)
	Non-mucinous	94 (93.1)
pT classification (n = 99)	pT1-2	16 (16.2)
	pT3-4	83 (83.8)
pN classification (n = 100)	pN0	52 (52.0)
	pN1-2	48 (48.0)
Tumor grade (n = 99)	G1-2	92 (92.9)
	G3	7 (7.1)
Vascular invasion (n = 99)	Absence	80 (80.8)
	Presence	19 (19.2)
Tumor border configuration (n = 99)	Pushing	23 (23.2)
	Infiltrating	76 (76.8)
Peritumoral lymphocytic inflammation (n = 99)	Absent	79 (79.8)
	Present	20 (20.2)
Age (n = 101)	Mean (range)	67.4 (41-89)
Tumor diameter (n = 101)	Mean (range)	54.9 (20-170)
5-year survival rate (n = 101)	% (95% CI)	69.3 (59-78)

Signaling), ALDH1 (isoform α1, clone Polyclonal; 1:500; AbCam), CD133 (clone 24139; 1:100; Cell Signaling), ABCG5 (1:200, Sigma-Aldrich), CD90 (clone 5E10, 1:100, BD Pharmingen), CD24 (clone SN3B, Neomarkers, 1:100). CD133, CD166, CD44, CD24, CD90, EpCAM, and ABCG5 were evaluated for both membrane and cytoplasmic staining; ALDH1 was exclusively evaluated in the cytoplasm of tumor buds. The number of CD166, CD44s, EpCAM, ALDH1, CD133, CD24, CD90, and ABCG5 positive tumor buds was then evaluated in the area of densest tumor budding as determined by CK22 staining.

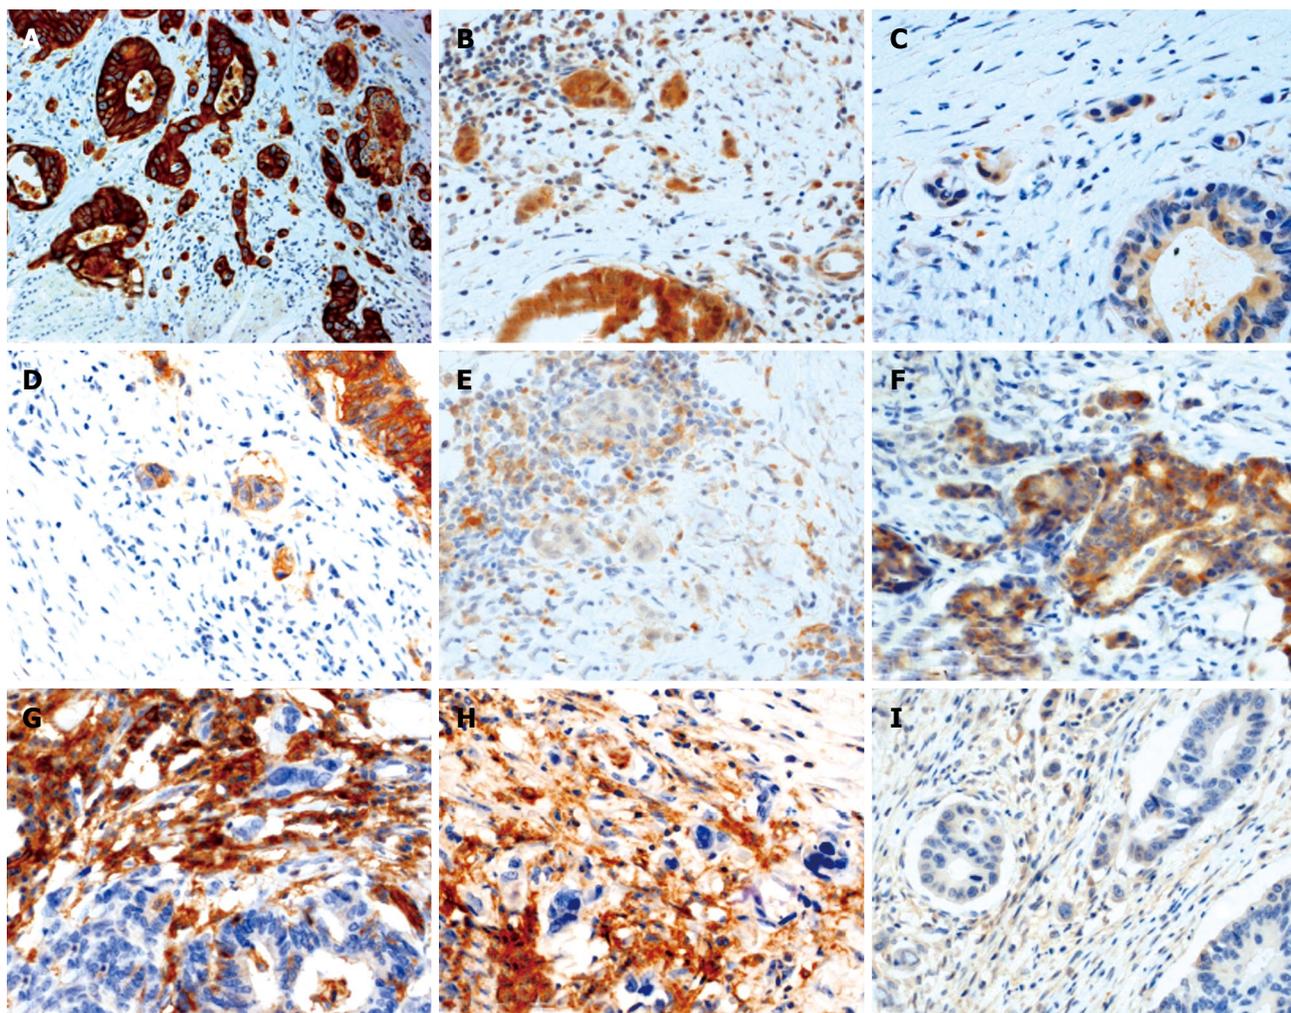

**Statistical analysis**

Univariate survival analysis was carried out using the Kaplan-Meier method and log rank test. Two multivariable Cox regression analyses were performed. First, to test the independent prognostic value of tumor budding, the effects of pT stage, pN stage, tumor grade, and vascular invasion were adjusted for. Subsequently, because of the small number of positive cases, only 2 variables could be entered into the multivariable Cox regression analysis along with positive expression of the protein in tumor buds, hence pT classification and pN classification were selected. The assumption of proportional hazards was verified prior to this analysis. Hazard ratios (HR) and 95% CI were obtained to determine the prognostic effect of positive cases adjusting for pT and pN. Kendall’s correlation coefficient (r) was obtained for correlation analysis of markers. P < 0.05 was considered statistically significant.

**RESULTS**

**Prognostic value of tumor budding**

In order to confirm the prognostic value of tumor budding in our series, cases were divided into 3 groups

**Figure 2** Immunohistochemical expression of putative cancer stem cell markers by tumor buds in colorectal cancer. A: Cytokeratin 22 staining highlighting the presence of tumor buds in low power magnification (5 ×); B-I: 40 × magnification. Positive expression of ABCG5 (B), ALDH1 (C), and EpCAM (D) in tumor buds with scattered positive staining of stromal cells, absence of staining of CD133 in tumor buds with positive staining of stromal cells (E), positive expression of CD166 in tumor buds with occasional positivity of stromal cells (F), absence of CD24 (G), CD44s (H), and CD90 staining (I) in tumor buds with positive stromal cell expression.

based on the distribution of number of tumor buds: those with < 40 buds, between 41-60 buds, and finally those with > 60 buds per 20 × field. The greater the number of tumor buds the more unfavorable was the prognosis both in univariate ( $P < 0.001$ ) and multivariable analysis with pT, pN, tumor grade, and vascular invasion (HR: 1.6, 95% CI: 1.2-2.1).

#### **Expression of putative stem cell markers within tumor buds**

CK22 staining was used to identify regions of densest tumor budding with epithelial cells exclusively immunoreactive for the protein. Staining for ABCG5, ALDH1, CD133, CD166, CD24, and CD44s could be observed in both tumor cells and inflammatory or stromal cells. EpCAM staining was predominantly limited to expression in tumor cells whereas CD90 was almost always expressed by stromal cells and only in 3 cases in the tumor itself.

Marker expression was then evaluated in the area of densest budding. Representative immunostains for all markers are shown in Figure 2. Only one case (1.03%)

was positive for CD90, while 5 (5.1%) and 6 (6.1%) cases were positive for CD44s and CD133, respectively. On the other hand, a considerably larger number of positive cases was found to express ALDH1 (16/97, 16.5%), CD24 (16/99, 16.2%) and CD166 (34/100, 34%). Finally, ABCG5 and EpCAM staining were frequent events with 39/97 (40.2%) and 69/100 (69%) positive cases, respectively (Figure 3).

#### **Prognostic differences with putative stem cell marker expression in tumor buds**

No relationship between survival time and ALDH1, CD24 and CD166 was observed. Patients with positive EpCAM or ABCG5 within tumor buds had a significantly poorer outcome in comparison to patients with no expression of these markers ( $P = 0.023$  and  $P = 0.038$ , respectively) (Figure 4). Multivariable analysis was performed for EpCAM and ABCG5 along with pT and pN classification. EpCAM maintained its significant association with a negative effect on outcome (HR: 2.64, 95% CI: 1.0-6.9,  $P = 0.048$ ), adjusted for pT and pN classification, a result

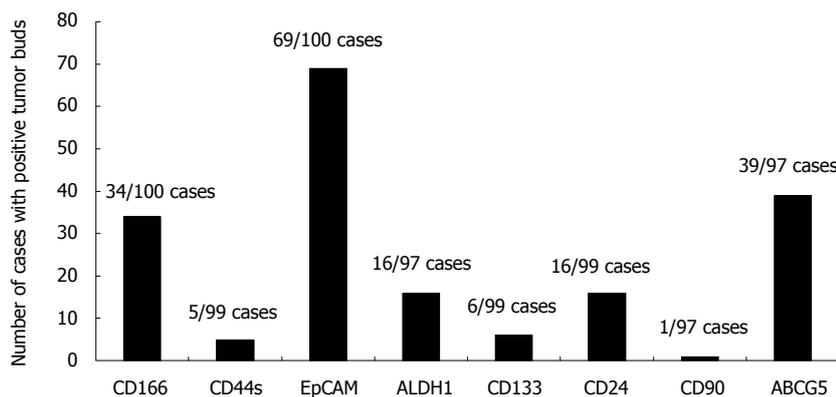

Figure 3 Histogram showing the number of cases with any degree of positive staining for the 8 putative stem cells markers.

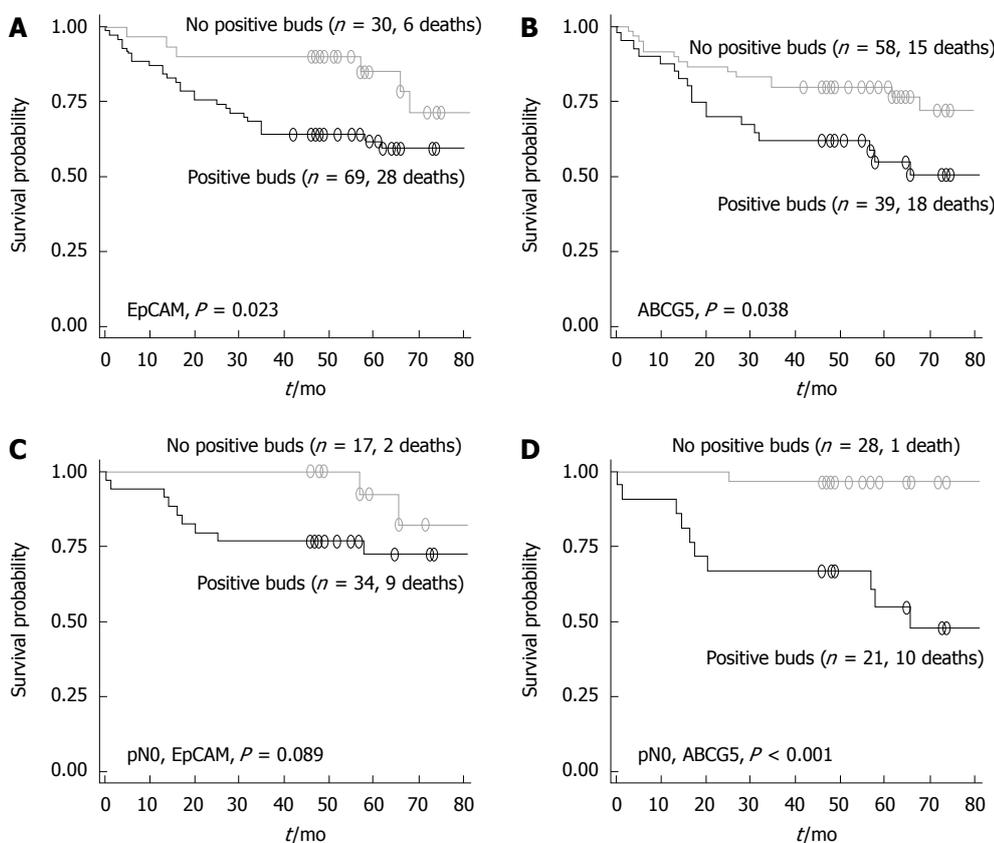

Figure 4 Kaplan-Meier survival curves illustrating the prognostic differences in patients with or without positive staining of EpCAM (A) and positive staining of ABCG5 (B) in tumor buds; differences in prognosis are further analyzed for lymph node-negative patients differing in EpCAM (C) and ABCG5 (D) expression in tumor buds.

which was also pronounced in patients with lymph node-negative disease. Similarly, positive ABCG5 expression in tumor buds was again associated with a poor patient prognosis ( $P = 0.029$ ) underlined by a relative risk of death of 2.22 (95% CI: 1.0-4.5) compared to patients lacking expression of ABCG5. ABCG5-positive patients with lymph node-negative cancers had a particularly poor outcome in comparison to their node-negative and ABCG5-negative counterparts ( $P < 0.001$ ).

**Correlation between EpCAM and ABCG5 expression**

In order to determine whether the same cases expressed

both EpCAM and ABCG5, the correlation between these markers was tested. The correlation coefficient  $r = 0.17$  and  $P = 0.08$ , indicated a positive but non-significant trend in the expression of these markers. Of the 96 patients evaluable for both EpCAM and ABCG5, 31 (32.3%) were positive and 21 (21.9%) were negative for both markers. We subsequently tested whether the combination of these markers could additionally stratify patients into prognostic subgroups. Prognosis was worse in patients positive for both EpCAM and ABCG5 ( $P = 0.013$ ) with a relative risk of death of 2.39 (95% CI: 1.2-4.7) compared to patients negative for both. In comparison to

the relative risk of death for either EpCAM or ABCG5 alone, the combination of both markers does not suggest a superior discrimination of patients into better and worse prognostic subgroups. A negative but statistically non-significant correlation between CD44s and EpCAM ( $r = -0.15$ ,  $P = 0.145$ ) and ABCG5 ( $r = -0.1$ ,  $P = 0.328$ ) was observed.

## DISCUSSION

In this study we evaluated 8 of the most promising putative cancer stem cell markers CD166, CD44s, EpCAM, ALDH1, CD133, CD24, CD90, and ABCG5 and their expression in colorectal tumor buds using 101 whole tissue sections from a well-characterized cohort of patients. Our main findings suggest that positive expression of EpCAM and ABCG5 within tumor buds is a frequent event and may confer a significant and adverse prognosis in patients with colorectal cancer, particularly in lymph node-negative patients expressing ABCG5.

Several of these putative CSC markers have previously been evaluated in tumor buds. Horst *et al.*<sup>[31]</sup> assessed CD133 in colorectal cancers using 3 different antibodies. They reported pronounced expression of CD133 in tumor glands close to the invasive margin but restricted to glandular differentiated cells and a general lack of CD133 in the tumor buds themselves. They further found that nuclear  $\beta$ -catenin expression and CD133 were not correlated and that the 2 protein markers may stain different, yet overlapping populations of tumor cells<sup>[32]</sup>. Our results of only a few CD133-positive tumor budding cases and no prognostic differences between patients with CD133-positive and -negative tumor budding are in line with these findings. Investigating rectal cancers, Gosens *et al.*<sup>[33]</sup> found strong membranous EpCAM staining in the tumor center and a progressive loss at the tumor front associated with high tumor grade, tumor budding, and a poor local and distant recurrence-free survival. This was also accompanied by a concomitant increase in cytoplasmic EpCAM staining as well as overexpression of  $\beta$ -catenin. We also observed a pronounced loss of EpCAM toward the invasive tumor front, particularly in tumors with infiltrating margins, as well as a shift in localization of EpCAM expression from membrane to cytoplasm. The findings of this study indicate that despite this loss towards the border, patients with EpCAM-positive tumor buds have a most unfavorable survival time, a result which was maintained in multivariable analysis. Although EpCAM, like CD44, is known for its cell-adhesion function, it seems to have versatile roles in signaling, cell migration, proliferation, and differentiation depending on the microenvironment<sup>[34]</sup>. In the normal epithelium, EpCAM supports adhesion, whereas in carcinoma it seems to prevent strong cell-cell adhesion, enabling cell migration and metastasis similar to E-cadherin. The intracellular localization of EpCAM and its identification by immunohistochemistry may represent differential roles of this protein in colorectal cancer

progression and partially explain why, despite loss of expression from normal at tumor center to tumor border, the positive expression in buds is linked to a poorer patient outcome.

Masaki *et al.*<sup>[35]</sup> have also described associations between membranous CD44 and CD44v6 expression and a higher degree of tumor budding. However, it is unclear from these studies whether expression was evaluated in the tumor center, then correlated with tumor budding or whether expression was evaluated in buds themselves. Our group has also previously found that loss of membranous expression of both CD44s and CD44v6 within the tumor center is highly correlated with an infiltrating tumor border configuration, a result which is in line with the findings of this study showing only rare cases expressing CD44s in tumor buds, too few in fact for adequate survival analysis.

ABCG5 is a member of the ATP-binding cassette subfamily G and plays a role in the efflux transport of cholesterol<sup>[36,37]</sup>. Its expression has been correlated with clinical melanoma progression and it is hypothesized to contribute to the refractoriness of metastatic cancer to chemotherapy<sup>[38]</sup>. Indeed, specific targeting of ABCG5 with monoclonal antibodies appears to significantly inhibit cell growth. To date, ABCG5 does not appear to have been investigated in colorectal cancer, and moreover in tumor buds. However, our findings of ABCG5 expression in a considerable number of colorectal cancer tumor buds as well as an adverse prognosis in particular in patients with lymph node-negative disease suggests that the role of ABCG5 in colorectal pathogenesis warrants further investigation.

Our results of adverse prognosis in EpCAM-positive and ABCG5-positive patients may be to some extent affected by the lack of information regarding cancer treatment. Despite this limitation, the unfavorable outcome associated with EpCAM and, particularly with ABCG5-positivity was maintained in patients with lymph node-negative colorectal cancers who, by today's treatment guidelines, are not generally considered for adjuvant chemotherapy<sup>[39]</sup>. The findings of this study regarding the prognostic value and expression of EpCAM and ABCG5 within colorectal tumor buds should be considered preliminary and require validation on independent patient cohorts.

To summarize, in contrast to CD133, CD166, CD24, CD44s, CD90, and ALDH1, the expression of putative stem cell markers EpCAM and ABCG5 within the tumor buds of colorectal tumors are frequent events indicating poor prognosis. In particular, patients with lymph node-negative disease expressing EpCAM or ABCG5 have a particularly unfavorable prognosis suggesting that the immunohistochemically analyzed EpCAM and ABCG5 in tumor buds may be useful biomarkers of poor outcome in this subgroup of patients. Further studies are necessary to address the important issue of whether EpCAM- or ABCG5-positive tumor buds indeed represent migrating colorectal CSC.

## COMMENTS

### Background

Tumor budding at the invasive tumor front of colorectal cancer is recognized as an important independent prognostic factor. Several lines of evidence seem to suggest that tumor buds may to some extent represent malignant colorectal cancer stem cells because of their potential for migration and re-differentiation locally and at sites of metastasis.

### Research frontiers

Phenotypic characterization of cancer stem cells is still debated although at least 8 putative stem cell markers have been suggested including CD166, CD44s, EpCAM, ALDH1, CD133, CD24, CD90, and ABCG5. The research hotspot is how the expression of putative cancer stem cell markers can be potentially used as prognostic biomarkers in patients with colorectal cancer.

### Innovations and breakthroughs

Considering the apparent stem cell-like properties of tumor buds and adverse effect of budding on clinical outcome, in this study the authors performed immunohistochemical staining of 8 promising putative cancer stem cell markers, namely CD166, CD44s, EpCAM, ALDH1, CD133, CD24, CD90, and ABCG5 and assessed their expression within tumor buds to determine their frequency and potential prognostic significance in patients with colorectal cancer.

### Applications

The study results suggest that, in contrast to CD133, CD166, CD24, CD44s, CD90, and ALDH1, the expression of putative cancer stem cell markers EpCAM and ABCG5 within the tumor buds of colorectal cancer are frequent events associated with poor prognosis.

### Terminology

Tumor budding: single cells or clusters of up to 4 or 5 cells at the invasive tumor front of colorectal cancer which are diagnosed at high magnification and highly associated with an infiltrating tumor growth pattern. Cancer stem cells: tumorigenic cell populations with the potential to self-renew and differentiate.

### Peer review

The study is characterized technically by an excellent application of immunohistochemistry and provides interesting evidence to aid in understanding the correlation between cancer stem cell markers in the invasive front of colorectal cancer and prognosis.

### Abstract

**AIM:** To evaluate the role and outcome of pericardiocentesis with intrapericardial cisplatin instillation for malignant pericardial effusion resulting from esophageal cancer.

**METHODS:** We retrospectively studied 7 patients who underwent pericardiocentesis with intrapericardial cisplatin instillation for malignant pericardial effusion resulting from esophageal cancer. After pericardiocentesis, we performed catheterization of the pericardial space under ultrasonogram guidance. Malignant etiology of the pericardial fluid was confirmed by cytological examination. Subsequently, cisplatin (10 mg in 20 mL normal saline) was instilled into the pericardial space.

**RESULTS:** The mean total volume of the aspirated effusion fluid was  $782 \pm 264$  mL (range, 400-1200 mL). The drainage catheter was successfully removed in all patients, and the mean duration of pericardial drainage

was  $7.7 \pm 2.7$  d (range, 5-13 d). No fluid reaccumulation was observed. Mean survival time was  $120 \pm 71$  d (range, 68-268 d).

**CONCLUSION:** Pericardiocentesis along with catheter drainage appears to be a safe and effective for pericardial malignant effusion and tamponade, and cisplatin instillation prevents recurrence.

### INTRODUCTION

The most frequent causes of spontaneous pericardial tamponade are neoplastic invasion, idiopathic or infectious pericarditis, and uremia. Pericardial effusion is a known complication of many advanced malignancies, and has a strong impact on both the quality of life and prognosis. Malignant pericardial effusion and tamponade is a rare medical-surgical emergency that impairs cardiac function and causes death. To facilitate the diagnosis, it is necessary to identify the clinical features of this condition, and

design adequate management strategies. Esophagectomy with reconstruction of the esophagus is associated with many fatal complications such as infection, anastomotic leakage, and respiratory and hemodynamic instability. The clinical syndrome of pericardial tamponade after esophagectomy has been relatively well reported. Acute distension of the stomach<sup>[1]</sup>, herniation of the omentum<sup>[2]</sup>, mediastinal bleeding<sup>[3]</sup> and even volvulus of the interposed colon<sup>[4]</sup> have been implicated as the clinical syndromes of pericardial tamponade. Moreover, the development of cardiac tamponade due to intra-pericardial fluid accumulation after esophagectomy has also been reported<sup>[5,6]</sup>.

Here, we report the outcome of intrapericardial instillation of cisplatin (CDDP) for the treatment of malignant pericardial effusion and tamponade resulting from esophageal carcinoma.

## MATERIALS AND METHODS

### Patients

We retrospectively studied 7 male patients who underwent pericardiocentesis with intrapericardial instillation of CDDP for the treatment of esophageal cancer at the Department of Surgery, Social Insurance Yokohama Central Hospital, Yokohama, Japan, between March 1997 and April 2009. Their mean age was  $67 \pm 3.4$  years (range, 61-71 years). Of the 7 patients, 5 underwent subtotal esophagectomy *via* a standard right thoracoabdominal approach along with three-field lymphadenectomy and reconstruction was performed using gastric pull-up with cervical anastomosis *via* the poststernal route, and the remaining 2 patients had undergone chemoradiotherapy previously.

### Diagnosis and definition of severity of pericardial effusion and tamponade

Echocardiography was used for the diagnosis of pericardial effusion and tamponade. When the diastolic echo-free space between the left ventricular posterior wall and the pericardium was  $< 10$  mm, the condition was classified as mild; when the space was 10-20 mm, the condition was classified as moderate; and when the space was  $> 20$  mm, the condition was classified as severe pericardial effusion<sup>[7]</sup>. Cardiac tamponade was defined according to the clinical and echocardiographic criteria<sup>[8]</sup>. The presence of the classic tamponade symptoms such as tachycardia, dyspnea, or tachypnea with clear lungs, or signs of increased systemic venous pressure, hypotension, or pulsus paradoxus, or accompanied by echocardiographic findings was accepted as cardiac tamponade<sup>[7]</sup>. We performed pericardiocentesis on the patients with cardiac tamponade and moderate to severe pericardial effusion.

### Percutaneous pericardiocentesis and cytology

Echocardiography with fluoroscopy-guided subxiphoid pericardiocentesis using an 8-French pigtail drainage catheter with multiple side holes (Aspiration Seldinger Kit/Nippon Sherwood Medical Industries LTD) was

performed under local anesthesia with mild sedation. After the catheter was placed into the pericardial space, we aspirated the fluid. Cytological examination was performed using the aspirate culture.

### Instillation of CDDP

After the cytological examination-based confirmation of the malignant etiology of the pericardial fluid and the complete drainage of the fluid, we administered 10 mg of CDDP into the pericardial space during each pericardiocentesis *via* the catheter; subsequently, the catheter was clamped. The catheter was declamped the following day, and the fluid was re-aspirated. When the volume of the re-aspirated fluid was more than 30 mL, 10 mg CDDP was re-administered. When the volume of the re-aspirated fluid was less than 30 mL, the catheter was removed.

## RESULTS

Echocardiography with fluoroscopy-guided pericardiocentesis using extended catheter drainage was performed in 7 patients with malignant cardiac tamponade resulting from esophageal cancer. Table 1 shows the patients' characteristics. Staging of esophageal cancer was performed according to guidelines of the International Union Against Cancer Classification of Malignant Tumors (UICC), and the distribution of the various stages among the patients was as follows: II B, 1/7 (14.3%); III, 3/7 (42.8%); and IV A, 3/7 (42.8%). The following clinical symptoms were observed in the patients; dyspnea was observed in all the patients (100%), and tachycardia was observed in 5 patients (71.4%).

Table 2 lists the outcomes of the patients who underwent pericardiocentesis with CDDP instillation. Total volume of the aspirated effusion fluid ranged from 400 to 1200 mL (median,  $782 \pm 264$  mL). Pericardiocentesis with CDDP instillation was required twice in 2 patients (28.6%), 3 times in 4 patients (57.1%), and 5 times was in 1 patient (14.3%), (median, 3 times). The drainage catheter was successfully removed in all the patients. The duration of pericardial drainage ranged from 5 to 13 d (median,  $7.7 \pm 2.7$  d). None of the patients showed fluid accumulation. Nausea, as a side effect of pericardiocentesis with CDDP instillation, was observed in 2 patients (28.6%); however, hematologic and renal toxicity did not develop in any of the patients. After pericardiocentesis with CDDP instillation, we performed systemic chemotherapy [5-fluorouracil (5-FU) + CDDP] in 3 patients (43%). The overall median survival time for these 7 patients was  $120 \pm 71$  d (range, 68-268 d) (Table 3).

## DISCUSSION

Cardiac tamponade can occur in any type of pericarditis case, but it is more commonly observed in neoplastic, tuberculous, and purulent pericarditis cases than in viral or idiopathic pericarditis cases. Pericardial effusion is a known complication of many advanced malignancies,

Table 1 Characteristics of the patients

Patient No.	Age	Sex	Stage of esophageal cancer	Former treatment	Symptoms
1	68	M	T2, N1, M0: Stage II B	Esophagectomy + chemotherapy	Dyspnea, tachycardia
2	69	M	T3, N1, M0: Stage III	Esophagectomy + chemotherapy	Dyspnea, tachycardia
3	64	M	T2, N1, M0: Stage III	Esophagectomy + chemotherapy	Dyspnea
4	70	M	T3, N1, M1a: Stage IVA	Esophagectomy + chemotherapy	Dyspnea, tachycardia
5	71	M	T2, N1, M1a: Stage IVA	Chemoradiotherapy	Dyspnea, tachycardia
6	65	M	T2, N1, M0: Stage II B	Esophagectomy + chemotherapy	Dyspnea, tachycardia
7	62	M	T2, N1, M1a: Stage IVA	Chemoradiotherapy	Dyspnea

Table 2 Outcomes of intrapericardial instillation of cisplatin

Patient No.	Amount of fluid (mL)	CDDP instillation (mg) × times	Duration of drainage (d)	Side effect	Reaccumulation of fluid
1	580	10 × 2	5	-	-
2	400	10 × 2	5	-	-
3	760	10 × 3	8	-	-
4	980	10 × 3	8	Nausea	-
5	1200	10 × 5	13	Nausea	-
6	685	10 × 3	8	-	-
7	870	10 × 3	8	-	-

CDDP: Cisplatin.

Table 3 Outcomes of the patients

Patient No.	Additional therapy (systemic)	Survival (d)	Cause of death
1	5-Fu + CDDP	126	Lung and pleural metastases
2	5-Fu + CDDP	268	Pleural metastases
3	5-Fu + CDDP	137	Lung and bone metastases
4	-	68	Lung and pleural metastases
5	-	61	Lung and bone metastases
6	-	104	Lung and pleural metastases
7	-	77	Pleural metastases

5-Fu: 5-fluorouracil.

and it has a strong impact on both the quality of life and prognosis. To facilitate the diagnosis of patients with malignant disease, it is necessary to identify the clinical features of cardiac tamponade and design adequate management strategies. Cardiac tamponade, observed in up to 15% of patients with cancer, can develop because of the malignant involvement of the pericardium under metastatic disease conditions, contiguous extension, or primary involvement<sup>[9]</sup>. Pericardial effusion in patients with esophageal carcinoma is most commonly associated with radiation and/or chemotherapy, and rarely with esophago-pericardial fistula<sup>[10]</sup>. All our 7 patients had advanced esophageal cancer; of them, 5 patients underwent esophagectomy and chemotherapy and the remaining 2 had undergone chemoradiotherapy previously.

The following are the typical signs of acute cardiac tamponade; a decrease in the arterial blood pressure, increase in the central venous pressure, and a small, quiet heart. The diagnosis of pericardial effusion and cardiac tamponade was confirmed using echocardiography and according to the clinical and echocardiographic criteria<sup>[8]</sup>. Because all our patients showed symptoms of dyspnea with or without tachycardia, it was necessary to confirm the diagnosis using echocardiography.

Accumulation of fluid in the pericardial space in patients is often not evident until the development of cardiac tamponade. Pericardiocentesis is generally performed as an initial treatment for symptomatic pericardial effusion and cardiac tamponade; however, re-accumulation of the fluid after pericardiocentesis is often observed. Hence, alternative procedures to pericardiocentesis, including insertion of a pleuropericardial window<sup>[11]</sup>, total or partial pericardiectomy<sup>[12]</sup>, external radiotherapy<sup>[13]</sup>, local instillation of a chemotherapeutic agent<sup>[14]</sup>, local instillation of a sclerosing agents<sup>[15]</sup>, and systemic chemotherapy<sup>[16]</sup>, are often performed. A review article that summarized the results of previous studies showed that the overall success rate of pericardiocentesis was 44.4%; indwelling pericardial catheters, 76.3%; and intrapericardial administration of sclerosing or cytotoxic agents, 81.6%, and that intrapericardial instillation was an effective treatment strategy for malignant pericardial effusion<sup>[17]</sup>.

The most serious complications of pericardiocentesis are laceration and perforation of the myocardium and the coronary vessels. Safe execution of pericardiocentesis was achieved by performing echocardiography under fluoroscopic guidance. Recent large echocardiographic series have shown that the incidence of major compli-

cations after echocardiography was 1.3%-1.6%. In fluoroscopy-guided percutaneous pericardiocentesis, cardiac perforations occurred in 0.9% cases, serious arrhythmias in 0.6%, arterial bleeding in 1.1%, pneumothorax in 0.6%, infection in 0.3%, and a major vagal reaction in 0.3%<sup>[8,18]</sup>. In our study, pericardiocentesis was performed echocardiographically under fluoroscopy guidance, and no complications developed. We believe that echocardiography with fluoroscopy-guided pericardiocentesis appears to be a safer alternative for pericardiocentesis.

The most appropriate type of pericardial drainage is subject to debate. In principle, less aggressive procedures are preferred, but at the same time, the procedures must be able to prevent recurrence of effusion accumulation. Simple needle pericardiocentesis can often resolve tamponade initially, but the probability of relapse is very high.

Recurrence, which is observed in 40%-70% of patients with large malignant pericardial effusion, may be prevented by intrapericardial instillation of sclerotic or cytotoxic agents, immunomodulators, systemic antitumor treatment, radiation therapy, percutaneous balloon pericardiectomy, or surgical methods<sup>[19,20]</sup>. Surgical drainage (or pericardiectomy, its major equivalent) is excessively required for many patients. The best option is to perform pericardiocentesis using the Seldinger technique, i.e. inserting a pigtail drainage catheter that can be retained in the pericardium until the drainage is complete<sup>[17]</sup>. If effusion recurs after the removal of the pigtail catheter, a sclerosing agent (tetracycline or bleomycin) can be instilled into the pericardial sac, or subxiphoid balloon pericardiectomy can be performed<sup>[17]</sup>.

With regard to the cytotoxic agents that can be used for intrapericardial instillation, Maisch *et al.*<sup>[20]</sup> studied the effectiveness of tetracycline, 5-FU, and CDDP in 20 patients with recurrent malignant pericardial effusion, and observed favorable outcomes (no fluid re-accumulation) only after CDDP instillation.

With regard to the side effects and complications of CDDP instillation, Maisch *et al.*<sup>[19]</sup> reported that myocardial ischemia occurred in 1 of 42 patients studied, and there were no other complications. Fiorentino *et al.*<sup>[21]</sup> reported that mild nausea occurred in all patients, but hematologic and renal toxicity and local or infectious complications did not occur in any patients in their study. In our study, 2 patients (28.6%) developed nausea. However, no significant side-effects were observed in the study of Tondini *et al.*<sup>[22]</sup> CDDP instillation did not cause hypotension and retrosternal pain, as is observed after the instillation of some other agents<sup>[19]</sup>; hence, it is thought to be a reasonable cytotoxic agent for intrapericardial administration. After the intrapericardial instillation of CDDP, 3 of the 7 patients in our study underwent systemic chemotherapy (5-FU + CDDP). The overall mean survival time after intrapericardial instillation of CDDP was reported to be  $2.8 \pm 1.3$  mo by Maisch *et al.*<sup>[19]</sup> and it was  $120 \pm 71$  d (range, 68-268 d) in our study. Maisch *et al.*<sup>[19]</sup> performed intrapericardial instillation of CDDP for patients with neoplastic pericardial effusion without esophageal cancer, but our patients had esophageal cancer. Moreover, the overall mean survival

time in our study was longer than that of the study by Maisch *et al.*<sup>[19]</sup>.

We conclude that pericardiocentesis with intrapericardial instillation of CDDP is effective for the treatment of malignant pericardial effusion resulting from esophageal cancer. In our study, the number of patients with pericardial constriction was very small for conducting statistical evaluation, but it is thought that pericardiocentesis with intrapericardial instillation of CDDP is a safe and feasible treatment in cases of medical-surgical emergency. Moreover, additional systemic chemotherapy after pericardiocentesis with intrapericardial instillation of CDDP may prolong the survival time of patient.

## COMMENTS

### Background

Pericardial effusion in patients with esophageal carcinoma is most commonly associated with radiation and/or chemotherapy, and rarely with esophago-pericardial fistula. Here, the authors report the outcome of intrapericardial instillation of cisplatin (CDDP) for the treatment of malignant pericardial effusion and tamponade resulting from esophageal carcinoma.

### Research frontiers

After the intrapericardial instillation of CDDP, 3 of the 7 patients in this study underwent systemic chemotherapy (5-fluorouracil + CDDP). The overall mean survival time after intrapericardial instillation of CDDP was  $120 \pm 71$  d (range, 68-268 d) in this study. And the overall mean survival time in this study was longer.

### Innovations and breakthroughs

The authors conclude that pericardiocentesis with intrapericardial instillation of CDDP is effective for the treatment of malignant pericardial effusion resulting from esophageal cancer.

### Applications

In this study, the number of patients with pericardial constriction was too small to conduct statistical evaluation, but it is thought that pericardiocentesis with intrapericardial instillation of CDDP is a safe and feasible treatment in cases of medical-surgical emergency. Moreover, additional systemic chemotherapy after pericardiocentesis with intrapericardial instillation of CDDP may prolong the survival time of patient.

### Peer review

This is a well written manuscript describing a series of well organized experiments. It is about malignant pericardial effusion and tamponade resulting from esophageal carcinoma. Not many cases of this disease have been reported and this is an original case series.

### Abstract

**AIM:** To characterize clinical features, surgery, outcome, and survival of malignant melanoma (MM) of the gastrointestinal (GI) tract in a surgical training center in Bangkok, Thailand.

**METHODS:** A retrospective review was performed for all patients with MM of the GI tract treated at our institution between 1997 and 2007.

**RESULTS:** Fourteen patients had GI involvement either in a metastatic form or as a primary melanoma. Thirteen patients with sufficient data were reviewed. The median age of the patients was 66 years (range: 32-87 years). Ten patients were female and three were male. Seven patients had primary melanomas of the anal canal, stomach and the sigmoid colon (5, 1 and 1 cases, respectively). Seven patients underwent curative resections: three abdominoperineal resections, two wide local excisions, one total gastrectomy and

one sigmoidectomy. Six patients had distant metastatic lesions at the time of diagnosis, which made curative resection an inappropriate choice. Patients who underwent curative resection exhibited a longer mean survival time (29.7 mo, range: 10-96 mo) than did patients in the palliative group (4.8 mo,  $P = 0.0006$ ).

**CONCLUSION:** GI MM had an unfavorable prognosis, except in patients who underwent curative resection (53.8% of cases), who had a mean survival of 29.7 mo.

### INTRODUCTION

Malignant melanoma (MM) of the gastrointestinal (GI) tract is a rare condition, especially in Eastern countries. However, its incidence is rising with unclear reason<sup>[1]</sup>. It may be either primary or metastatic. GI metastasis of MM is frequently found during autopsy (50%-60% of cases), but a small proportion of melanoma patients are

diagnosed with GI metastasis while living (2%-5% of patients)<sup>[2,3]</sup>. The most common sites of the metastasis are the stomach and small intestine. Meanwhile, primary MM can arise in any GI mucosal site, but is most common in the anorectal region and esophagus.

The prognosis of GI MM is very poor with a 5-year survival of < 10%<sup>[4]</sup>. Surgery is still the mainstay of treatment. Recent studies have reported a trend toward less radical resection because there is no significant advantage of aggressive surgery over limited surgery in terms of local disease control, recurrence, and survival time<sup>[4,5]</sup>.

In Thailand, MM is less common than in western countries and the data are limited. This study, therefore, was conducted to evaluate clinical features, surgical options, and outcome including recurrence and survival of MM of the GI tract in a surgical training center in Bangkok, Thailand.

## MATERIALS AND METHODS

A retrospective review was conducted on patients diagnosed with MM of the GI tract who were admitted to Siriraj Hospital between 1997 and 2007. Patients were identified from the hospital computer database using an ICD-10 system. Patients' charts were reviewed retrospectively for patient characteristics, presenting symptoms, physical examination findings, imaging results, operative records, presence of complications, recurrence, follow-up time, survival time, and cause of death. Diagnosis was confirmed in all patients by histological study and immunohistochemistry for S-100 protein or HMB45 monoclonal antibody. Survival time was defined as the number of months from the time of diagnosis of GI MM to the time of death or the last follow-up evaluation. The long-term follow-up data were collected by direct contact with patients or their relatives. A Kaplan-Meier method was used for statistical analysis of survival outcome. This study was approved by Siriraj ethics committee, Mahidol University (EC1 2550/307).

## RESULTS

Between 1997 and 2007, there were 14 patients diagnosed with MM of the GI tract in Siriraj Hospital. One patient was excluded from this study due to insufficient data in the medical records; thus, only 13 cases were included in this study. Ten patients were female and three were male. The median age of the patients at presentation was 66 years (range: 32-87 years). Seven patients had a primary GI MM (anorectal,  $n = 5$ ; sigmoid colon,  $n = 1$ ; and stomach,  $n = 1$ ), whereas the others (three patients, 23.1%) had metastatic MM of the GI tract. The primary melanoma sites of these three patients were ocular, thumb, and ovary. There were three patients who had advanced GI MM of unknown primary origin.

The most common presenting symptom was abdominal pain (5 patients, 38.5%), followed by intra-ab-

Table 1 Characteristic of patients with MM of the GI tract

dominal mass in four patients (30.8%). Other presenting symptoms included obstructive jaundice, small bowel obstruction, bowel habit change, and tenesmus. The anorectal region was the most common site of GI MM (7 patients, 53.8%), followed by the stomach (3 patients, 23.1%) (Table 1).

Seven patients (53.8%) underwent curative resection, which consisted of three abdominoperineal resections, two wide local excisions, one total gastrectomy, and one sigmoidectomy. There was no perioperative mortality in this study. Meanwhile, another six patients (46.2%) had distant metastatic lesions at the time of diagnosis. They therefore received only palliative surgical treatment such as colostomy, small bowel resection, and enteroenterostomy anastomosis. Patients who underwent curative resection exhibited a longer mean survival time (29.7 mo, range: 10-96 mo) than patients in the palliative group (4.8 mo, range: 4-12 mo) (Figure 1). Survival was significantly increased in patients who underwent curative resection ( $P = 0.0006$ ).

## DISCUSSION

In Thailand, MM is a rare disease. The estimated incidence rate of cutaneous melanoma in Thailand is 0.4 and 0.1 per 100000 in men and women, respectively<sup>[5]</sup>. Incidence of MM of the GI tract is exceedingly rare<sup>[6]</sup>. There have

**Figure 1** Kaplan-Meier curve demonstrating survival of patients with malignant melanoma of the gastrointestinal tract, who underwent curative resection and palliative resection.

been only a few reported cases of documented anorectal MM in Thailand<sup>[7]</sup>. MM of the GI tract can be either primary or metastatic. Primary GI melanoma must be differentiated from metastatic disease by previous history of melanoma and complete physical examination.

Patients often present with bleeding, pain or intestinal obstruction. If the patients present with GI bleeding, an endoscopy with magnification might be the procedure of choice to diagnose MM of the GI tract<sup>[8-10]</sup>. Multiple black, depressed lesions ( $1 \pm 5$  mm in diameter) with a “bull’s eye” appearance are usually viewed in the GI mucosa<sup>[9]</sup>. In the present study, approximately half of the patients presented with pain. A lower number of patients presented with gross GI bleeding and obstruction.

MM of the GI tract remains a fatal disease. Patients often present with advanced disease. In our study, almost half of the patients had metastatic disease at the time of presentation. The prognosis of GI MM is poor. The mean survival time of patients with a local or locoregional disease who underwent curative resection was only 29.7 mo. Several investigators have reported that the overall survival varies from 12 to 18 mo, with a 5-year survival of  $< 10\%$ <sup>[11]</sup>. When systemic metastasis has occurred, mean survival is only 6-8 mo<sup>[12,13]</sup>.

As a result of the poor prognosis of this disease, operative intervention has been discouraged. However, several recent studies have demonstrated better survival outcome in the patients who had complete surgical resection<sup>[14-19]</sup>. Our experiences compare favorably with those of other centers. Our study demonstrated seven patients with GI MM who underwent curative resection with a mean survival comparable to that in other centers. Several adjuvant treatment of GI MM such as chemotherapy, radiotherapy and immunotherapy have been utilized in many countries, but no such treatment was given in our center because of their unclear effectiveness. One recent randomized trial has demonstrated no survival benefit of adjuvant therapy<sup>[20]</sup>.

In conclusion, patients with GI MM had a poor prog-

nosis, especially in nonoperable cases. Surgical resection of the tumor resulted in a longer survival time. In selected patients with local or locally advanced disease, surgery should be performed where possible.

## COMMENTS

### Background

Gastrointestinal (GI) malignant melanoma (MM) is a rare malignancy. As a result of the paucity of cases, the available data about its clinical features, treatment options, and outcomes are very limited, especially in Eastern countries.

### Research frontiers

As a result of the poor prognosis of GI MM, improvement of its treatment options is an area that is in need of research. However, in order to reach that point, some basic understanding of the clinical characteristics and treatment outcomes of current surgical approaches is required. This study provides a picture of clinical experience with this rare disease from one surgical training center in Thailand.

### Innovations and breakthroughs

This study revealed that the nature of MM of the GI tract and its treatment outcomes in Thailand were similar and comparable to those from other centers.

### Applications

With a better understanding of GI MM and its poor prognosis, future research should look at how to improve the treatment outcome, through early diagnosis, selection of patients undergoing surgery, and improvement of surgical techniques.

### Peer review

This is a retrospective study on surgical management of MM of the GI tract. Patients who underwent curative resection exhibited a longer mean survival time than patients in the palliative group. Survival was significantly increased in patients who underwent curative resection.

### Abstract

**AIM:** To explore the interventional effects and mechanism of *in vitro* cultivated *Calculus Bovis* compound preparation (ICCBco) on pulmonary lesions in portal hypertensive rabbits with schistosomiasis.

**METHODS:** The experimental group included 20 portal hypertensive rabbits with schistosomiasis treated by ICCBco. The control group included 20 portal hypertensive rabbits with schistosomiasis treated by praziquantel. The morphological changes of the pulmonary tissues were observed under light and electron microscopy. The expression of fibronectin (FN) and laminin (LN) in the lung tissues was analyzed by immunohistochemistry.

**RESULTS:** Under light microscope, the alveolar exudation in the lung tissue was more frequently observed in the control group, while the alveolar space was fairly dry in the lung tissue of ICCBco group. Under electron microscope, more alveolar exudation in the lung tissue, and more

macrophages, alveolar angiotectasis and the blurred three-tier structure of alveolar-capillary barrier could be seen in the control group. In ICCBco group, fibers within the alveolar interspace slightly increased in some lung regions, and the structure of type I epithelium, basement membrane and endodermis was complete, and no obvious exudation from the alveolar space, and novascular congestion could be observed. There was a positive or strong positive expression of FN and LN in the lung tissue of the control group, while there was a negative or weak positive expression of FN and LN in ICCBco group.

**CONCLUSION:** ICCBco can effectively prevent pulmonary complications in portal hypertensive rabbits with schistosomiasis by means of improving lung microcirculation and lowering the content of extracellular matrix.

### INTRODUCTION

Portal hypertension is a vascular lesion that initially arises in liver, but is also accompanied with structural and functional changes of blood vessels in extrahepatic portal

system, systemic circulation and pulmonary circulation, which now collectively called portal hypertensive vascular lesions<sup>[1]</sup>. In clinical practice, much attention has been paid to the prevention and treatment of complications such as ascites, esophagogastric variceal bleeding; however the management of pulmonary complications is ignored which affects the prognosis of patients. Hence, drugs used for prevention and treatment of pulmonary complications seems to be very important. *In vitro* cultivated *Calculus Bovis* (ICCB)<sup>[2]</sup> developed by Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, with independent intellectual property rights, is one of the first-class national Chinese herbal medicine certificate of new drugs. ICCB is bilirubin calcium stones from *in vitro* cultivated bovine bile by simulating the formation principle and biochemical processes of gallstone *in vivo* using the modern bio-medical technology. The pharmacy, pharmacology and toxicology of the drug and phase I-IV clinical trials show that ICCB is consistent with natural bezoar in property, structure, composition, content and clinical efficacy, and no obvious toxicity and adverse effects could be observed (SFDA approval number Z20010075). *Calculus Bovis* has effects of clearing heat and toxic materials, promoting blood circulation and reducing swelling, eliminating stasis and facilitating tissue recovery, lowering vascular permeability, clearing softened blood vessels, scavenging free radicals and anti-anoxia in the principle of traditional Chinese medicine. *In vitro* cultivated *Calculus Bovis* compound preparation (ICCBco)<sup>[3-5]</sup> is mainly composed of ICCB, Chinese *Paris Rhizome*, *polygonum cuspidatum*, *appendiculate cremastra pseudobulb*, *frankincense*, and *myrrh*, with functions of clearing away heat and toxic materials, removing blood stasis, reducing swelling, eliminating blood stasis and promoting tissue regeneration. To evaluate the efficacy of ICCBco in the treatment of lung lesions in portal hypertensive rabbits with schistosomiasis as the experimental animal model, we performed a randomized, double-blind, controlled trial to observe the pathological changes and pathological mechanism of fibronectin (FN) and laminin (LN) expressions in the lung tissue of portal hypertensive rabbits with schistosomiasis.

## MATERIALS AND METHODS

### Materials

**Experimental animal:** Forty healthy adult rabbits (male, 2.5 kg in weight) provided by the Medical Experimental Animal Center of Tongji Medical College, Huazhong University of Science and Technology.

**Medicine:** ICCBco (0.25 g/granule, 60 granules/bottle), Levo-praziquantel (0.1 g/tablet, 10/box), both offered by Tongji Medical College, Huazhong University of Science and Technology.

**Reagents:** Sheep serum, rabbit anti-human FN and LN primary antibody serum (1:100) were purchased from Boster Company, Wuhan. SABC kit was obtained from Zhongshan Company, Beijing.

**Instruments:** OPTON transmission electron microscopy (TEM, Carl Zeiss EM 10 C, Oberkochen, Germany) and optical microscopy (Olympus, Japan) were used.

### Methods

**Animal model establishment:** The hair over the abdomen was shaved off, and the rabbits were infected by cercariae of *oncomelania hupensis* by the sticking and pasting method<sup>[6]</sup>. The solution containing  $200 \pm 5$  cercariae was dripped on the shaved area of each rabbit and covered by a slide for 15 min, which led to acute infection. After 40 d, ICCBco was administered to the rabbits (6 granules/d). After 60 d, levo-praziquantel was perfused to kill parasites with a dosage of 500 mg/d for two consecutive days. The pulmonary fibrosis model was established in 120 d or so, and the experimental animals were killed by necropsy procedure in 4 mo. Pulmonary samples were obtained by autopsy. The experimental animals were divided into two groups: group A (control group), treated with praziquantel ( $n = 20$ ); group B, treated with praziquantel plus ICCBco ( $n = 20$ ).

**Sample collection:** Batches of rabbits were sacrificed by injecting an overdose of anesthesia with 1% Thiopental Sodium (50 mg/kg) *via* the ear vein. A small sample of the left lung tissue about the size of 2 cm × 1 cm × 1 cm was harvested after laparotomy, routinely fixed with 10% formaldehyde solution, and embedded in paraffin wax within 12 h for pathological examination. Another sample of the left lung tissue with a size of 1 mm × 1 mm × 0.5 mm was immediately put in a vial containing 20 g/L glutaraldehyde, and then sent to the department of ultrastructural pathology for TEM examination in 1 h.

**Staining method:** Samples of lung tissue were fixed in 40 g/L neutral buffered formaldehyde solution, routinely embedded in paraffin wax, and serial sections were made at a thickness of 5 μm for hematoxylin and eosin (HE) staining and observed under optical microscopy.

Samples were fixed in 10% formaldehyde solution, and then treated with 2.5% potassium dichromate mordant prepared by 5% acetic acid for 12-18 h, and immersed in water washing for 10 min. Sections were treated with sodium thiosulfate in order to remove mercury deposition, and then fully washed with water, and stained for 2-5 min in Ehrlich's hematoxylin followed by wash in water. Differentiation was done in acid alcohol and thoroughly washed in running water until the sections turned blue, and then stained in 1% aqueous acid fuchsin solution for 5 min followed by rinsing sections in running water for 30 s or longer until color of collagen disappeared, and rinsed in distilled water. Sections were stained in Aniline Blue/Orange G for 20 min, washed in running water for 2-5 min, dehydrated, differentiated through 95% alcohols, washed in absolute alcohol and then passed into xylene for tissue transparent. At last, sections were mounted with gelatin and observed under optical microscopy.

Flesh sample of the lung tissue were cut into slices about a size of 1 cm × 1 cm × 1 cm, and placed in 25 mg/L

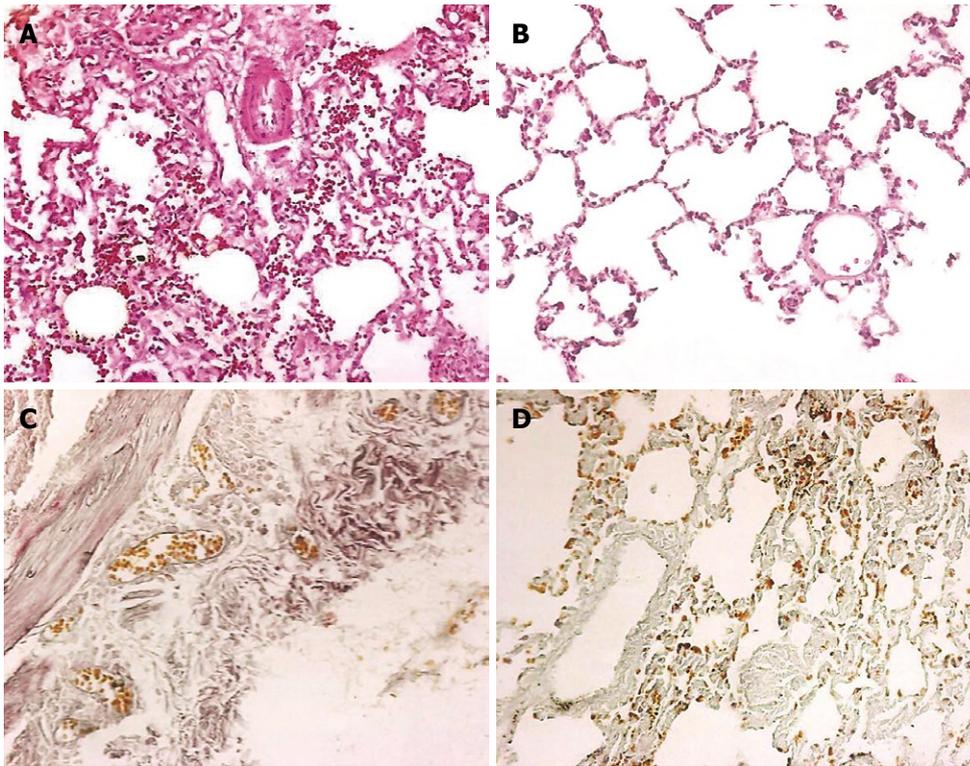

Figure 1 HE staining observation of lung tissues in control group (A) and *in vitro* cultivated *Calculus Bovis* compound preparation (ICCBco) group (B); Mallory trichrome staining in control group (C) and ICCBco group (D).

glutaraldehyde for 2 h as pre-fixation, then washed in pH 7.4 phosphate buffer solution followed by post-fixation in 10 g/L osmium acid under 4°C for 2 h. The slices were dehydrated with progressively increased concentration of alcohol and acetone, embedded in epoxy resin EPON 812. Ultrathin sections were cut and stained with double staining of uranium and lead (acetic acid-uranium-lead citrate) so as to be observed under TEM.

Sections were routinely deparaffinized, treated with 30 mL/L hydrogen peroxide, which was freshly prepared by distilled water, for 10 min at room temperature to inactivate endogenous peroxidases and rinsed three times in distilled water. Normal goat serum blocking solution was added and incubated at room temperature for 30 min in order to reduce non-specific background staining. Excessive liquid was removed without rinse. Sections were incubated in primary antibody (1:100) at 4°C overnight, then washed thrice in PBS (0.1 mol/L), and incubated in biotinylated secondary antibody for 30 min at room temperature, then rinsed thrice in PBS for 5 min. And they were incubated with SABC for 30 min at 37°C followed by rinse four times in PBS for 5 min. Sections were incubated in DAB with DAB reagent kit: One drop of reagent A and reagent B were added in 1 mL distilled water, and placed the well-mixed reagents onto the slices. The reaction was allowed to develop for 3-10 min under the control of microscopy at room temperature, and rinsed in distilled water. Sections were lightly counterstained with hematoxylin. After dehydration, transparent, and mounting process, slides were observed under microscopy. PBS was used as negative control instead of primary antibody and a known positive slice was taken as positive control. Brownish yellow granules in the cytoplasm were considered as positive FN and LN. Selected regions containing

endothelial cells under optical microscopy were input into HPIAS-1000 automatic color image analysis system and the results were shown as the average absorbance.

### Statistical analysis

All data were presented as the mean  $\pm$  SD. Statistical analysis was done using SPSS software version 11.0. Statistical differences between the two groups were analyzed using ANOVA and *t* tests. *P* values less than 0.05 were considered significant.

## RESULTS

### Morphological results

HE staining results showed that the alveolar exudation in the lung tissue was seen more frequently in group A, while the alveolar space was fairly dry in the lung tissue of group B (Figure 1A and B). Mallory trichrome staining results showed more alveolar exudation and collagen fibers in the lung tissue of group A, while fairly dry alveolar space and less collagen fibers were seen in group B (Figure 1C and D). More alveolar exudation was found in group A, and more macrophages, alveolar angioectasis and the blurred three-tier structure of alveolar-capillary barrier could also be seen under TEM observation (Figure 2A and B). In group B, fibers within the alveolar interspace slightly increased in some lung regions, and the structure of type I epithelium, basement membrane and endodermis was complete, and no obvious exudation in alveolar space and no vascular congestion were observed (Figure 2C and D).

### Immunohistochemical staining results

There was a positive or strong positive expression of FN

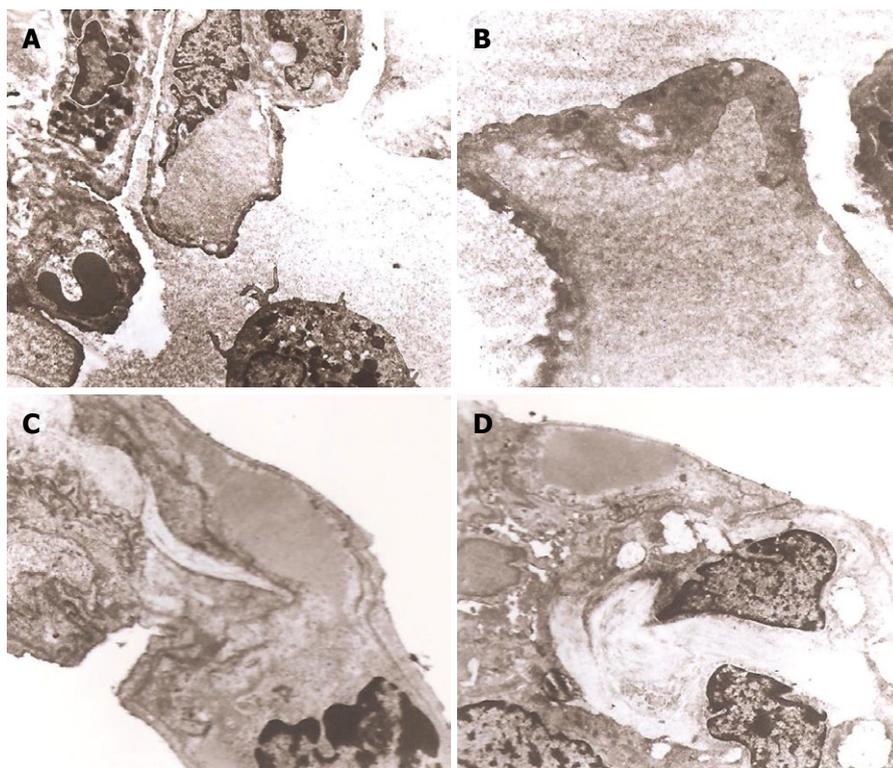

Figure 2 Observation of lung tissues in control group (A, B), and ICCBco group (C, D) under transmission electron microscope.

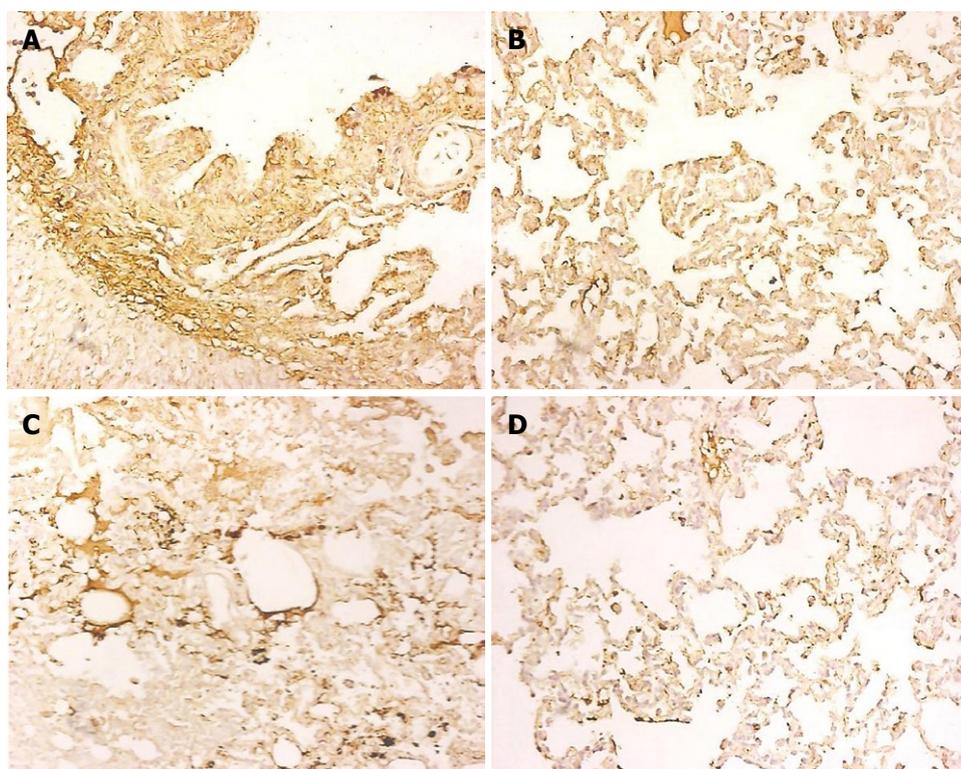

Figure 3 Expression of fibronectin (FN) and laminin (LN) of lung tissues in control group (A, C) and ICCBco group (B, D) by histochemical staining.

in the lung tissue of group A, while a negative or weak positive expression of FN in group B (Figure 3A and B). Group A showed a positive or strong positive expression of LN in the lung tissue, while group B showed a negative or weak positive expression of LN (Figure 3C and D). The integrated optical density (IOD) values are shown in Table 1.

## DISCUSSION

Rabbit model of hepatic fibrosis of schistosomiasis was consistent with the natural course and pathological development process of human liver fibrosis; previous studies have confirmed that 4 mo after rabbits were infected with schistosomiasis, the hepatic fibrosis

Table 1 IOD values in lung tissues of both groups (mean  $\pm$  SD)

Group	n	IOD value of FN	IOD value of LN
Control group	20	19.47 $\pm$ 1.21	20.23 $\pm$ 0.87
ICCBco group	20	13.15 $\pm$ 0.94	12.08 $\pm$ 1.26

A marked decrease in the expression of FN and LN in the lung tissue was seen in ICCBco group ( $P < 0.01$ ). IOD: Integrated optical density; FN: Fibronectin; LN: Laminin; ICCBco: *In vitro* cultivated *Calculus Bovis* compound preparation.

formed, indicating it is a mature model of liver fibrosis.

Schistosomiasis can not only cause liver fibrosis and portal hypertension, but also cause tissue lesions. The most dangerous lesion is pulmonary vascular lesion characterized by hypoxemia and decreased oxygen saturation. However, the exact mechanisms of hypoxemia are still controversial, and it is currently believed to be caused by the three factors together - intrapulmonary shunt, ventilation - perfusion imbalance and pulmonary diffusion dysfunction. The important fundamental cause of these pathologic changes is pulmonary vasodilation<sup>[7]</sup>. Our results showed that there was a slight increase in fibers between alveolar gap in some parts of the lung tissue, and the structure of type I epithelium, basement membrane and endodermis was complete, and there was no obvious exudation in alveolar space, and no vascular congestion in the ICCBco group, while more alveolar exudation, more macrophages, alveolar angioectasis and the blurred three-tier structure of alveolar-capillary barrier were seen in praziquantel control group. This indicates that ICCBco could make a marked improvement in pulmonary ischemia, hypoxia, pulmonary function, blood flow blockade, damage, and connective tissue hyperplasia, which would shed light on pathological basis of clinical manifestations.

Extracellular matrix (ECM) proteins can be categorized into two kinds: collagen and non-collagen protein. ECM not only provides supporting structure and attachment for tissues but also regulates cell adhesion, migration, proliferation, differentiation, and tissue trauma repair and fibrosis. FN is a glycoprotein of large molecular weight with highly active adhesion, mainly derived from macrophage. FN induces chemotactic migration of interstitial cells<sup>[8]</sup>, and promotes fibroblast division and proliferation<sup>[9]</sup>. Studies have found that FN mRNA and protein expression of alveolar macrophages and interstitial fibroblasts were markedly elevated in patients with pulmonary fibrosis<sup>[10]</sup>, FN can transmit messages into cells through adhesion molecules on the surface of fibroblast cells and plays an initial role in the lung fibrosis process. It is currently believed that FN first appears in the early pulmonary fibrosis, and after then other interstitial elements occurs. LN is a large-molecular-weight non-collagen glycoprotein existing in the transparent layer of the basement membrane, which plays an important role in the maintenance of structure and function of alveolar and capillary basement membrane. Basement membrane provides a support for the regeneration of injured epi-

thelial cells, and is the barrier for the entry of molecules and cells into the alveolar cavity<sup>[11,12]</sup>. The normal lung tissue contains very little LN. There is a significant increase of LN in pulmonary fibrosis or liver cirrhosis, which is about 10 times the level of LN in the normal lung and is consistent with collagen content in fibrosis<sup>[13]</sup>. Some scholars found that LN fluorescence in alveolar septa was enhanced in rats with early stage pulmonary fibrosis, later became thicker and deranged, presuming that LN participated in the whole process of experimental pulmonary fibrosis, and might play an important role in the development of fibrosis<sup>[14]</sup>. Previous experiments showed that abnormal accumulation of type I and III collagen, FN and LN in extracellular matrix at the early stage of schistosomiasis-induced liver fibrosis<sup>[15]</sup>. FN and LN are, therefore, better indicators for pulmonary fibrosis. In this study, we found that there was a significant decrease in the expression of FN and LN in ICCBco group compared with praziquantel control group, which suggests ICCBco could effectively inhibit the formation of pulmonary fibrosis. With functions of clearing away heat and toxic materials, removing blood stasis, reducing swelling, eliminating blood stasis and promoting tissue regeneration, it could improve pulmonary microcirculation, inhibit connective tissue proliferation, degrade extracellular matrix, reduce pulmonary damage, hence inhibiting the formation of pulmonary fibrosis.

In summary, ICCBco can effectively prevent pulmonary complications of portal hypertensive rabbits with schistosomiasis. Its function in suppressing pulmonary lesions is achieved by removing heat, toxic materials and blood stasis, reducing swelling, eliminating blood stasis and promoting tissue regeneration to block the activation of alveolar macrophages, improve pulmonary microcirculation, and reduce ECM. The successful development of ICCB and the preliminary study on portal hypertensive pulmonary lesions caused by schistosomiasis suggest that it is of great significance and prospects for further basic and clinical research, development and clinical application of new drugs and preparations to treat portal hypertensive pulmonary lesions induced by schistosomiasis.

## COMMENTS

### Background

Portal hypertension is a vascular lesion that initially arises in liver, but structural and functional changes of blood vessels in extrahepatic portal system, systemic circulation and pulmonary circulation also accompany, which now collectively called portal hypertensive vascular lesions. In clinical practice, much attention has been paid to the prevention and treatment of complications such as ascites, esophagogastric variceal bleeding; however the management of pulmonary complications is ignored which affects the prognosis of patients. Hence, drugs used for prevention and treatment of pulmonary complications seem to be very important.

### Research frontiers

*In vitro* cultivated *Calculus Bovis* compound preparation (ICCBco) is composed of ICCB, Chinese *Paris Rhizome*, *polygomon cuspidatum*, *appendiculate cremastra pseudobulb*, *frankincense*, and *myrrh*, and has the functions of clearing away heat and toxic materials, removing blood stasis, reducing swelling, eliminating blood stasis and promoting tissue regeneration, according to the principle of traditional Chinese medicine. However, the topic has not been unequivocally addressed. This study evaluated the efficacy of ICCBco in the

treatment of lung lesions in portal hypertensive rabbits with schistosomiasis as the experimental animal model.

### Innovations and breakthroughs

The present study explored the pathogenesis of portal hypertension and the prevention and treatment of its pulmonary complications (hepatopulmonary syndrome, pulmonary fibrosis, pulmonary hypertension, pulmonary venous hypertension) from a new perspective of portal hypertensive vascular disease. ICCB is a Class 1 new Chinese medicine developed by Wuhan Tongji Hospital with independent intellectual property rights, is a treasure of traditional Chinese medicine. To investigate its role in the treatment of schistosomiasis-induced pulmonary complications of portal hypertension has far-reaching significance.

### Applications

The successful development of ICCB and the preliminary study on portal hypertensive pulmonary lesions caused by schistosomiasis suggest that it is of great significance and prospects for further basic and clinical research, development and clinical application of new drugs and preparations to treat portal hypertensive pulmonary lesions induced by schistosomiasis.

### Terminology

Composed of ICCB, Chinese *Paris Rhizome*, *polygonum cuspidatum*, *appendiculate cremastra pseudobulb*, *frankincense*, and *myrrh*, ICCBco can effectively prevent pulmonary complications of portal hypertensive rabbits with schistosomiasis. ICCBco could improve pulmonary microcirculation, inhibit connective tissue proliferation, degrade extracellular matrix, reduce pulmonary damage, hence inhibiting the formation of pulmonary fibrosis.

### Peer review

This is a very interesting research but not well planned.

### Abstract

**AIM:** To investigate the prevalence and time of *Dickkopf* (*DKK*) family methylation and its clinical significance in hepatocarcinogenesis.

**METHODS:** Methylation of *DKK* family genes was quantitatively analyzed in 115 liver tissue samples, including 50 pairs of primary hepatocellular carcinoma (HCC) and matched noncancerous cirrhotic tissue samples, as well as 15 liver cirrhosis biopsy samples.

**RESULTS:** The methylation level of *DKK3* was significantly higher in HCC tissue samples than in matched noncancerous cirrhotic tissue samples ( $P < 0.0001$ ) or

in liver cirrhosis biopsy samples ( $P = 0.0139$ ). Receiver operator characteristic curve analysis confirmed that the percent of methylated reference (PMR) values of *DKK3* could effectively discriminate HCC tissue samples from noncancerous tissue samples (AUC = 0.8146) or liver cirrhosis biopsy samples (AUC = 0.7093). Kaplan-Meier survival curves revealed that the progression-free survival time of patients with a higher *DKK3* methylation level (PMR > 1%) was significantly shorter than that of those with a lower *DKK3* methylation level (PMR ≤ 1%) ( $P = 0.0255$ ). Multivariate Cox analysis indicated that methylated *DKK3* was significantly and independently related with a shorter survival time (relative risk = 2.527, 95% CI: 1.063-6.008,  $P = 0.036$ ) of HCC patients.

**CONCLUSION:** Methylation of *DKK3* is an important event in early malignant transformation and HCC progression, and therefore might be a prognostic indicator for risk assessment of HCC.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies in the world, leading to more than 500 000 deaths every year<sup>[1]</sup>. Most HCC cases (> 80%)

occur in either sub-Saharan Africa or Eastern Asia. HCC cases in China alone account for more than 40% of all cases in the world<sup>[2]</sup>. It was recently reported that the incidence of HCC is increasing worldwide<sup>[3]</sup>. Treatment of HCC is still a great challenge for clinical oncologists because most HCC patients are diagnosed at its advanced stage with distant metastasis<sup>[4]</sup>.

Dysplastic cirrhotic nodules are considered precursors of HCC because of their association with HCC occurrence. Development of HCC is closely associated with cirrhosis and 90% of the tumors are found in chronic hepatitis or cirrhotic patients<sup>[5]</sup>. One reasonable explanation for this close correlation is that necrosis and regeneration of hepatocytes due to chronic liver damage provide the stepwise accumulation of genetic and epigenetic changes necessary for hepatocarcinogenesis<sup>[2]</sup>. Therefore, elucidation of these aberrant alterations involving hepatocellular transformation at the cirrhosis stage is not only crucial to understand the molecular basis of hepatocarcinogenesis but also to provide potentially useful markers for the early diagnosis, risk assessment, treatment, and chemoprevention of HCC.

Aberrant promoter hypermethylation of tumor suppressor genes is a common event during the pathogenesis of human cancers and one of the important epigenetic mechanisms in carcinogenesis. It has been shown that methylation of multiple tumor suppressor genes in HCC may contribute to the pathogenesis of this disease<sup>[5,6]</sup>. Dickkopf (*DKK*) family is one class of the secreted Wnt antagonists and its functional loss can contribute to activation of the Wnt pathway and result in carcinogenesis through dysregulation of cell proliferation and differentiation<sup>[7]</sup>. It has been recently shown that methylation of *DKK* gene family contributes to carcinogenesis and serves as a potential biomarker for the diagnosis or prognosis of several human malignancies<sup>[8]</sup>. However, few reports are available on the epigenetic silencing of *DKK* gene and its clinical significance in HCC<sup>[9]</sup>.

In the present study, we examined the promoter hypermethylation of human *DKK* family genes in HCC and cirrhosis tissue samples by quantitative methylation-specific polymerase chain reaction (Q-MSP), and evaluated whether quantitative methylation of *DKK* genes can serve as a potentially diagnostic or prognostic biomarker for HCC.

## MATERIALS AND METHODS

### Patients and sample collection

A total of 115 liver tissue samples, including 50 pairs of primary HCC and matched noncancerous cirrhotic liver (NCL) tissue samples, as well as 15 liver cirrhotic (LC) biopsy samples, were analyzed in this study. Tumor tissue samples were collected from patients who underwent surgery in Third Central Hospital of Tianjin between December 2003 and August 2006 and stored at -80°C for further processing. Clinicopathological data were collected from patient records and pathology reports. Written informed consent was obtained from each patient and the study protocol was approved by the

Clinical Research Ethics Committee of Third Central Hospital, Tianjin.

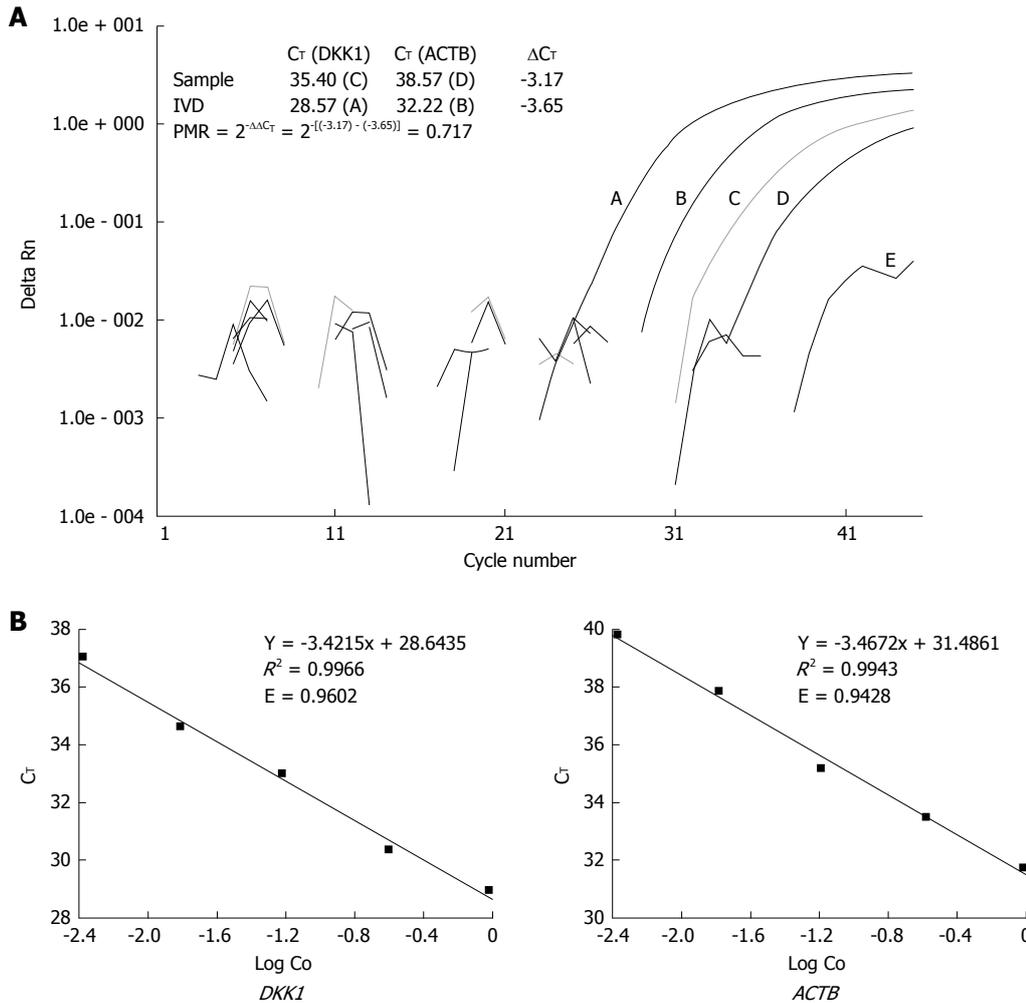

### DNA extraction and bisulfite treatment

Genomic DNA was extracted from tumor tissue samples by digesting with SDS/proteinase K in TE buffer followed by a standard phenol/chloroform extraction. The extracted DNA was subjected to bisulfite treatment as previously described<sup>[10]</sup>. Briefly, 1-2 µg genomic DNA was denatured with 0.3 mol/L NaOH at 37°C for 20 min, and incubated in 3.0 mol/L sodium bisulfite and 10 mmol/L hydroquinone at 55°C for 16 h. The DNA was desalted with a QIAquick gel extraction kit (Qiagen, Valencia, CA) and dissolved in 50 µL of 10 mmol/L TE buffer (pH 8.0). Then, 5.5 µL of 3.0 mol/L NaOH was added and incubated at 37°C for 20 min to desulfonate it. The modified DNA was neutralized with 30 µL of 10 mol/L ammonium acetate, precipitated using 2 volumes of ethanol, and resuspended in 40 µL of 1.0 mmol/L TE buffer (pH 7.6).

### Q-MSP

Fluorogenic quantitative MSP assay was carried out in the ABI Prism 7000 sequence detection system (Applied Biosystems, Foster City, CA). For each gene of the *DKK* family, a set of primers and a probe covering multiple CpG dinucleotides were designed within the putative CpG islands around the gene promoters. For the endogenous reference gene, *ACTB* ( $\beta$ -actin), the primers and probe were designed to avoid CpG dinucleotides. All primers and probes were designed according to the bisulfite-converted DNA sequences. Genes of interest were amplified in proportional to the degree of CpG methylation, while *ACTB* was amplified independently of its methylation. The sequences of primers and probes are as follows: (1) *DKK1*, 5'-GGGTTTCGCGGTATAAAGGTAGTC-3' (sense), 5'-TCCGAAAACCCCTACGATC-3' (antisense), 5'-FAM-TGGCGGTGGCGGCGTAGAGT-BHQ1-3' (Probe); (2) *DKK2*, 5'-GCGAGCGTAGCGTAAGTTCGT-3' (sense), 5'-CACTCACAATTACCCCGAAACG-3' (antisense), 5'-FAM-AGGTATCGTTGCGTTGGTAGCGATTTCG-BHQ1-3' (Probe); (3) *DKK3*, 5'-GGTATCGGCGTTGTTCGTATTTC-3' (sense), 5'-CCACCCGACTAAACCGAAT-3' (antisense), 5'-FAM-TCGCGGTTTCGTTTATCGCGTTC-BHQ1-3' (Probe); and (4) *ACTB*, 5'-TGGTGATGGA GGAGGTTTAGTAAGT-3' (sense), 5'-AACCAATAAAACCTACTCCTCCCTTAA-3' (antisense), 5'-FAM-ACCACCACCAACACACAATAACAAACACA-BHQ1-3' (Probe).

Q-MSP assay was performed in a reaction volume of 20 µL in 96-well plates, and the final reaction mixture was consisted of 1 × real-time PCR master mix (Toyobo Co., Ltd. Shanghai), 200 nmol/L probe, 400 nmol/L primers of each gene, and 2 µL bisulfite-converted DNA templates. PCR was performed at 95°C for 2 min, followed by 45 cycles at 95°C for 15 s, and at 60°C for 45 s. Reactions were done in duplicate and each plate included at least 3 controls with no template (NTC), as well as negative and positive controls on each plate. Leukocyte

**Figure 1** Quantitative methylation analysis using comparative C<sub>T</sub> method. A: Representative quantitative methylation-specific polymerase chain reaction (Q-MSP) amplification plots for *DKK1* and illustration for percent of methylated reference (PMR) calculation with comparative C<sub>T</sub> method; B: Validation experiment for comparative C<sub>T</sub> method,  $E = 10^{(1/\text{Slope})} - 1$ , where E: PCR efficiency; Slope: Slope of calibration curve. DKK: Dickkopf.

DNA collected from a healthy individual was used as a negative control. The DNA methylated *in vitro* with SssI methyltransferase (New England Biolabs Inc., Beverly, MA) was used as a positive control for all studied genes.

**PMR values**

Abbreviation PMR was used to define the percentage of fully methylated molecules at a specific locus as previously described<sup>[11]</sup>. Briefly, the PMR value was calculated by dividing the *GENE: ACTB* ratio in a sample by the *GENE: ACTB* ratio in SssI-treated leukocyte DNA (IVD) and multiplied by 100. Parallel PCR reactions were done for the genes of interest and reference. Given the high efficiency of Q-MSP amplification for both *DKK* and *ACTB* genes in this study, PMR values were detected with the comparative C<sub>T</sub> method instead of the relative standard curve method, which needs serial dilutions of bisulfite-treated universally methylated DNA to construct a relative standard curve for each gene<sup>[12]</sup>. Relation between the percentages of methylated DNA molecules and C<sub>T</sub> was described as  $PMR = 2^{-\Delta\Delta C_T} \times 100\%$  where  $\Delta\Delta C_T = \Delta C_{T(\text{Gene})} - \Delta C_{T(\text{ACTB})} = [C_{T(\text{Gene})} - C_{T(\text{ACTB})}]_{\text{Sample}} - [C_{T(\text{Gene})} - C_{T(\text{ACTB})}]_{\text{IVD}}$ .

The number of cycles at which the fluorescence signal crossed a detection threshold was determined automatically with the ABI prism 7000 detection system, and referred to as C<sub>T</sub>. Representative Q-MSP amplification plots for *DKK1* and corresponding calculation for PMR are illustrated in Figure 1A. For the ΔΔC<sub>T</sub> calculation to be valid, the efficiencies in target and reference amplification should be within 10%. PCR efficiency was calculated and compared according to the following equation recommended in technical manual of Applied Biosystems (Figure 1B).

**RNA preparation and real-time quantitative PCR**

RNA was extracted from HCC and matched NCL tissue samples using Trizol (Tiangen, Beijing) according to its manufacturer’s instructions. Total mRNA was digested with DNase I (Ambion, Austin, TX) to remove genomic DNA contamination and then subjected to reverse transcription using the reverse transcription system (Promega, Madison, WI). For the reverse-transcriptase PCR of *DDK3*, the sense primer (5'-ATCACCTGGGAGCTAGAGCCTGATG-3') and anti-sense primer (5'-ACC TCTCTGGGCAGCAGGGATCTC-3') were designed. PCR was done on the ABI Prism 7000 sequence detection

system in combination with the SYBR green teal-time PCR master mix (Toyobo Co., Ltd, Shanghai). Melting curve analyses following amplification were performed to assure the product specificity. Relative expression of *DKK3* mRNA was normalized to the housekeeping gene *GAPDH* in the same cDNA using the comparative  $C_t$  method. Primer sequences for *GAPDH* are 5'-CTCAT GACCACAGTCCATGCCATCACTG-3' (sense) and 5'-CATGAGGTCCACCACCCTGTGCTGTA-3' (anti-sense).

**Receiver operator characteristic (ROC) curve analysis**

ROC curves were plotted to assess the PMR values of *DKK* family as diagnosis biomarkers, and their discriminatory capacity was evaluated by calculating the area under the curve (AUC). Generally, a truly useless test has an AUC of 0.5, while a perfect test (one that has zero false positives and zero false negatives) has an AUC of 1.0. For each gene of *DKK* family, the PMR values in HCC tissue samples were considered patient results, while the values in matched NCL tissue samples were considered control results.

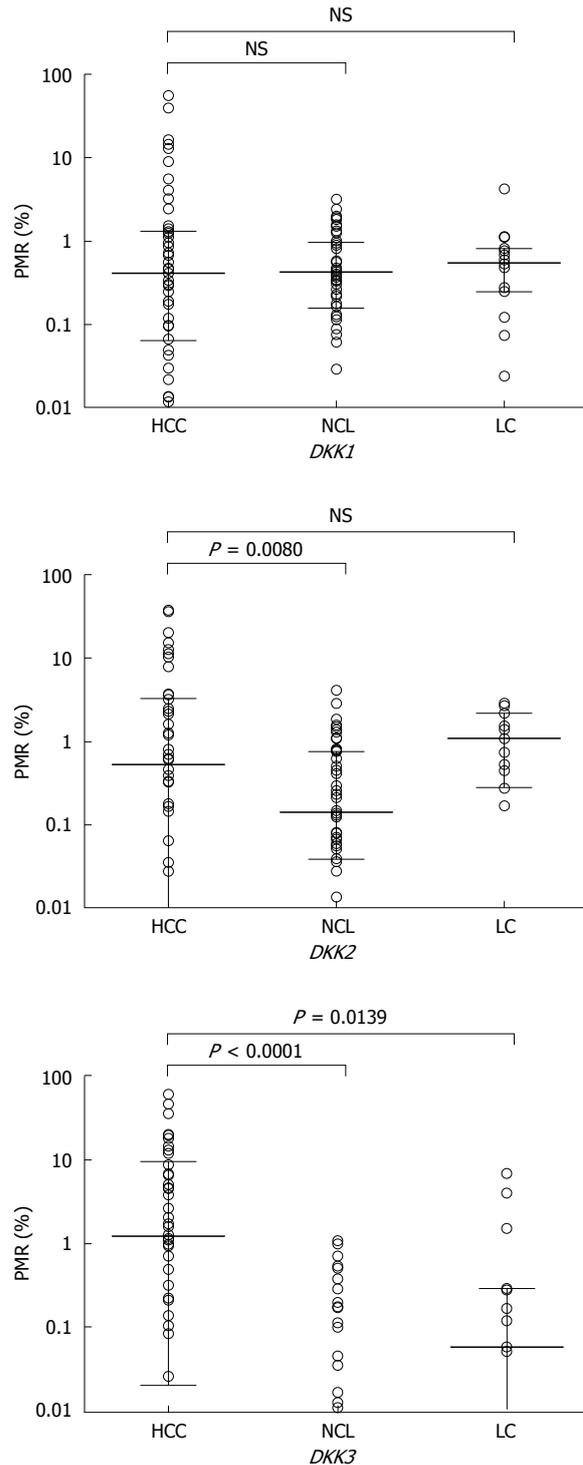

**Statistical analysis**

Relation between categorical variables was determined by Pearson  $\chi^2$  test or Fisher's exact test. Difference in median of PMR values between paired HCC and NCL tissue samples was detected by Wilcoxon matched pairs test, difference in HCC tissue and LC biopsy samples was revealed by Mann-Whitney *U* test. Variables associated with overall survival or progression-free survival rate were tested using Kaplan-Meier estimates and compared by log-rank test. Relative risk (RR) of *DKK3* methylation-related death and other clinical variables were estimated from a univariate Cox proportional hazards model. Multivariate Cox models were also constructed to estimate the RR for *DKK3* methylation with adjustments for potential confounding risk factors. All statistical tests were two-sided and  $P < 0.05$  was considered statistically significant. Statistical analyses were performed with GraphPad Prism V5.0 (GraphPad Software, San Diego, CA) and SPSS V11.0 software for Windows (SPSS Inc., Chicago, IL), respectively.

**RESULTS**

**Quantitative analysis of *DKK* gene methylation in HCC and cirrhotic liver tissue samples**

The methylation levels of *DKK* family in 3 kinds of tumor tissue sample were quantified by Q-MSP. The distribution of PMR values is illustrated in Figure 2. The methylation levels of *DKK* family in the 50 paired HCC tissue samples and NCL tissue samples were compared. Wilcoxon matched pairs test demonstrated that the methylation levels of *DKK2* and *DKK3* were significantly higher in HCC tissue samples than in corresponding NCL tissue samples ( $P = 0.0080$ ,  $P < 0.0001$ ), whereas no significant difference was found in the methylation level of *DKK1*. The difference in median PMR value was further compared between the 50

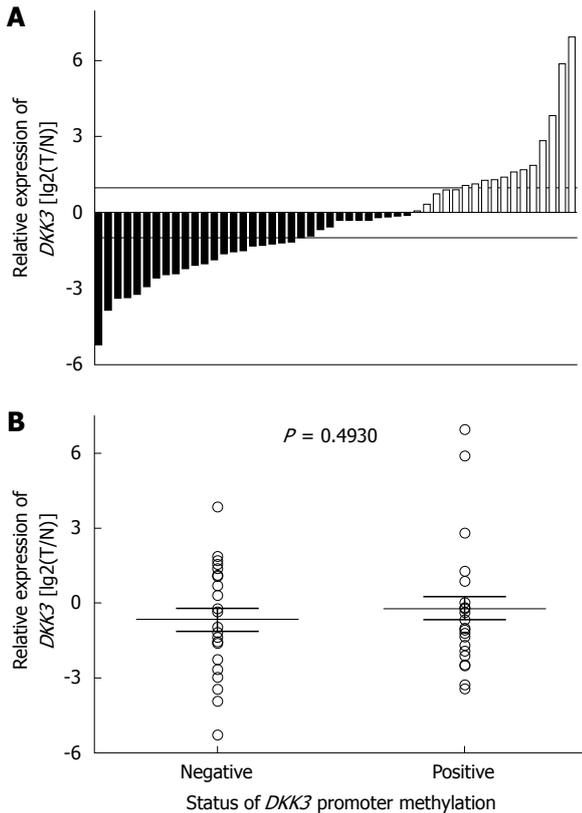

**Figure 2** Methylation levels of *DKK* family genes in hepatocellular carcinoma (HCC) and corresponding noncancerous cirrhotic liver (NCL) tissue samples and liver cirrhosis (LC) biopsy samples. Horizontal bar denotes the median PMR value, and range indicates 25%-75% quartile.

HCC and 15 LC tissue samples by Mann-Whitney test and a significant difference was only found in the median PMR value for *DKK3* gene ( $P = 0.0139$ ).

**Expression of *DKK3* mRNA in HCC tissue samples**

The expression of *DKK3* mRNA in primary HCC tissue samples was detected by real-time PCR. Fifty pairs of HCC

**Figure 3** Expression of *DKK3* mRNA in HCC (A) and NCL (B) tissue samples. Horizontal lines represent the median FC value, and range indicates 25%-75% quartile.

tissue samples and corresponding NCL tissue samples were analyzed. The expression level of *DKK3* mRNA was lower in tumor tissue samples than in its adjacent tissue samples (Figure 3A). However, the median of *DKK3* RNA expression was not statistically different between the methylated and unmethylated *DKK3* genes ( $P = 0.4930$ ) (Figure 3B).

**ROC curve analysis of PMR values in HCC and liver cirrhosis tissue samples**

To assess whether quantitative methylation assay of *DKK* family can serve as a diagnosis tool to discriminate malignant from non-malignant liver tissue samples, ROC curves were plotted with PMR values as test results. The overall discriminatory ability of the test was evaluated by calculating the AUC (Figure 4). Two ROC curves were plotted for each gene. The PMR values in HCC tissue samples and the values in two types of liver cirrhosis tissue samples (NCL and LC) were considered patient results and control results, respectively. ROC curve analysis revealed that the AUC value for the PMR of *DKK3* was relatively higher in the two kinds of tumor tissue samples (0.8146 for HCC *vs* NCL tissue samples and 0.7093 for HCC *vs* LC tissue samples, respectively).

***DKK* gene methylation and clinicopathological correlation**

To investigate the correlation between *DKK* family methy-

**Table 1** *DKK* methylation frequencies in HCC and NCL tissue samples

	Positive (PMR > 1%)	Negative (PMR ≤ 1%)	P
<i>DKK1</i>			
HCC	14	36	0.6484
NCL	12	38	
<i>DKK2</i>			
HCC	21	29	0.0076
NCL	8	42	
<i>DKK3</i>			
HCC	27	23	< 0.0001
NCL	2	48	

*DKK*: Dickkopf; HCC: Hepatocellular carcinoma; PMR: Percent of methylated reference; NCL: Noncancerous cirrhotic liver.

lation and clinicopathological variables, the continuous PMR values were converted into discrete binary data, and the patients were also divided into two subgroups. To exclude the low *DKK* methylation level in a mere minority of cells, which may have little effect on gene activity in tumor tissue samples, PMR (1%) was selected as a criterion for the methylation of *DKK*. That is, the *DKK* methylation was classified into positive (PMR > 1%) and negative (PMR ≤ 1%) groups.

The methylation patterns of *DKK* genes in paired HCC and NCL tissue samples are summarized in Table 1. Consistent with the quantitative analysis above, significantly different methylation patterns of *DKK3* were found in HCC and NCL tissue samples ( $P < 0.0001$ ). The methylation frequency of *DKK2* in HCC (64%, 32 of 50) and NCL (60%, 30 of 50) tissue samples was similar, while the methylation level of *DKK2* was higher in HCC tissue samples (42%, 21 of 50) than in NCL tissue samples (16%, 8 of 50) ( $P = 0.0076$ ). No significant difference of *DKK1* methylation was found in HCC and NCL tissue samples.

Whether methylation of *DKK* family is related with certain clinicopathological variables was further determined. Statistical analysis showed that the methylation frequency of *DKK1* or *DKK2* was not related with the clinicopathological variables (data not shown). The frequency of *DKK3* methylation was higher in multicentric HCC (Table 2).

**Overall and progression-free survival analysis**

To analyze the overall and progression-free survival rate associated with *DKK3* methylation levels, patients were divided into methylation positive and negative groups according to their PMR values. The overall survival rate was not significantly different between the two groups, while the progression-free survival rate of patients with a high *DKK3* methylation level was significantly lower than that of those with a low methylation level ( $P = 0.0255$ ) (Figure 5). Univariate Cox proportional hazards model showed that the portal vein invasion and high *DKK3* methylation level were related with an increased risk of disease progression when the tumor size was larger. Multivariate analysis model further showed that these three factors were the independently prognostic indicators for HCC (Table 3).

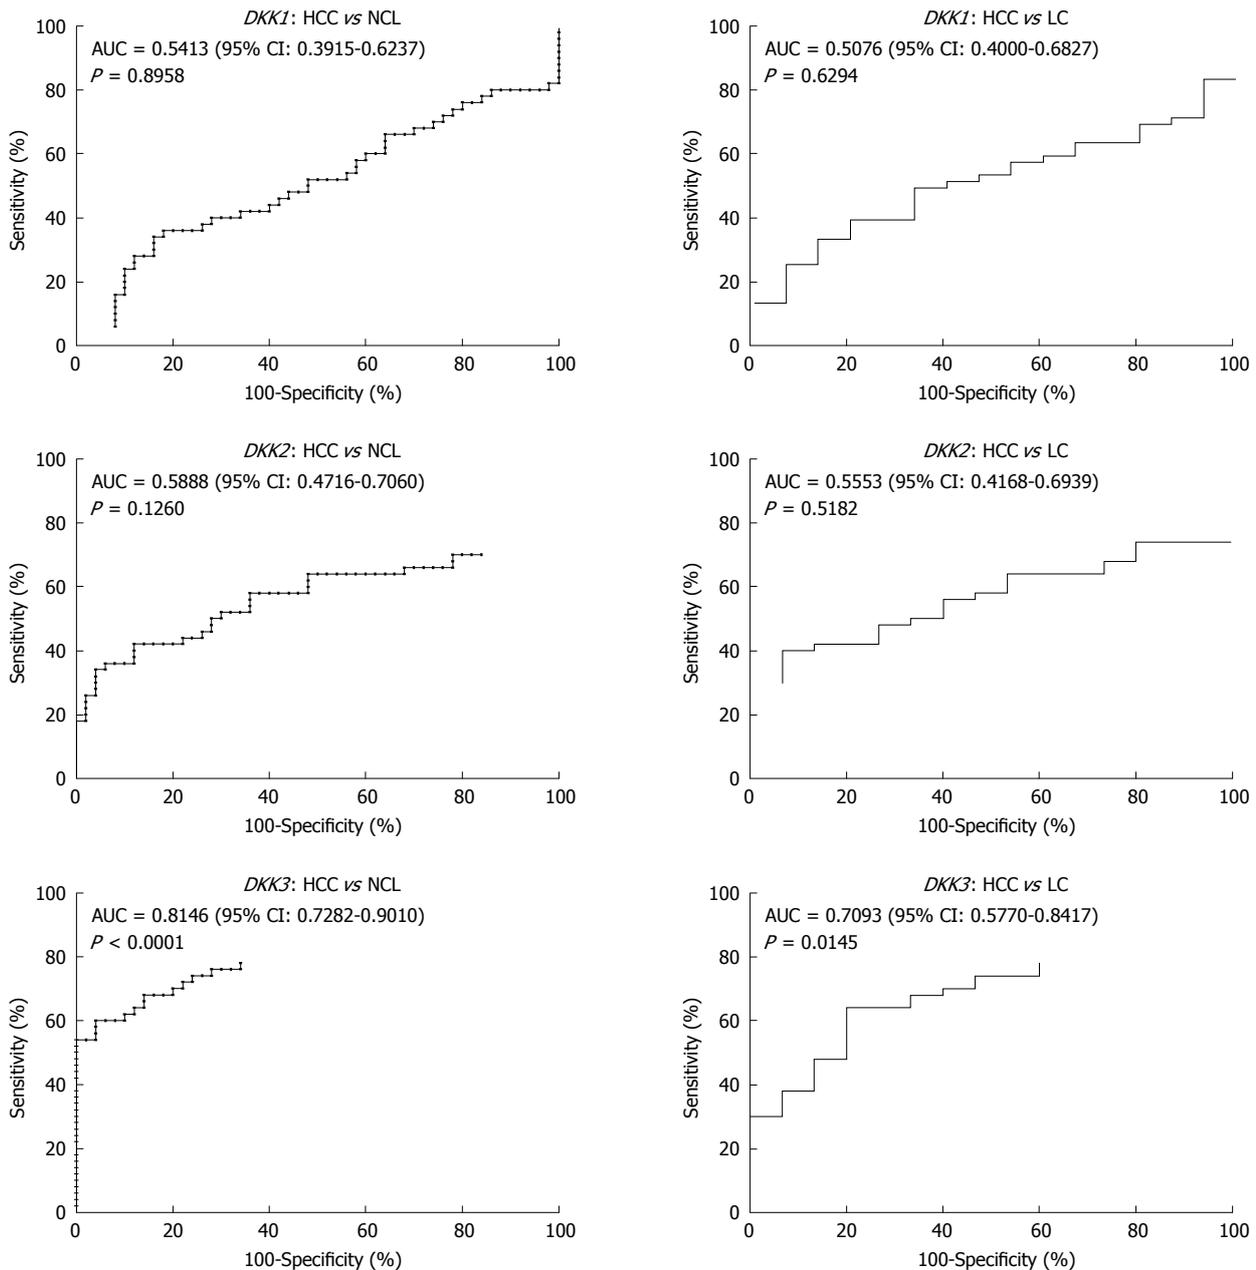

Figure 4 ROC curves for *DKK* genes used to evaluate the ability of methylation levels to distinguish tumor tissue samples from cirrhotic tissue samples.

## DISCUSSION

Development of HCC is a multistep process associated with genetic and epigenetic alterations. Methylation of multiple tumor suppressor genes is frequently observed in the development of cancer and may occur at different stages of HCC. However, not all these epigenetic alterations are directly involved in hepatocarcinogenesis. Aberrant methylation observed in HCC may be a consequence of the normal aging process, persistent viral infection, and chronic inflammation. Nishida *et al.*<sup>[13]</sup> demonstrated that methylation of tumor suppressor genes in HCC is frequent but occurs in a gene-specific and disease-specific manner. Therefore, it is important to determine the prevalence and time of promoter hypermethylation in hepatocarcinogenesis, especially at the

stage of hepatocellular transformation from a cirrhotic background. *DKK1* acts as a powerful inhibitor of the Wnt signaling pathway, and epigenetic inactivation of *DKK1* has been observed in various cancers<sup>[14-16]</sup>. In our study, a high frequency of *DKK1* methylation was also observed in liver tissue samples (Table 1), whereas quantitative methylation analysis revealed that there was no statistically different *DKK1* methylation in HCC and liver cirrhosis tissue samples, including tumor-adjacent cirrhosis and cirrhotic biopsy samples (Figure 2), suggesting that methylation of *DKK1* may be involved in early hepatocarcinogenesis but not directly contributes to neoplastic transformation from the liver cirrhotic background. Methylation of *DKK2* has been observed in some kinds of tumor, but there is little direct evidence that epigenetic inactivation of *DKK2* contributes to tumor development<sup>[14-16]</sup>. In our

study, although *DKK2* methylation occurred in tumor and corresponding cirrhosis tissue samples with a similar frequency (Table 1), the methylation level of *DKK2* was obviously higher in tumor tissue samples than in its adjacent cirrhosis tissue samples (Figure 2), indicating that methylation of *DKK2* may accumulate with the development of HCC. Interestingly, the *DKK2* methylation level was higher in cirrhotic biopsy samples than in HCC tissue samples with no statistical significance, possibly due to the aberrant methylation in fibroblasts and stromal cells of cirrhotic biopsies<sup>[17]</sup>.

In contrast to *DKK1* and *DKK2*, *DKK3* is methylated in a tumor-specific manner during hepatocarcinogenesis. In our study, *DKK3* methylation occurred more frequently in HCC tissue samples than in cirrhosis tissue samples and the *DKK3* methylation level was also dramatically higher in HCC tissue samples than in cirrhosis tissue samples, indicating that *DKK3* promoter methylation may be an important event in the hepatocellular transformation from a cirrhotic background. Hsieh *et al.*<sup>[18]</sup> found that *DKK3* expression level is lower in human hepatoma tissue samples than in noncancerous liver tissue samples. It is thus reasonable to postulate that methylation and subsequently epigenetic inactivation of *DKK3* gene may play an important role in hepatocarcinogenesis.

Although distinct methylation patterns of *DKK3* were observed in HCC tissue samples and its adjacent liver cirrhosis tissue samples, no significant difference in mRNA expression was observed between the methylated and unmethylated groups. Similar results showing a lack of clear inverse correlation between the methylation and gene expression data have also been observed<sup>[19]</sup>. HCC

**Figure 5 Overall (A) and progression-free (B) survival analysis of patients with different *DKK3* methylation levels.**

tissue is very heterogeneous and our tissue samples were not microdissected to remove contaminated normal cells. The presence of a substantial amount of normal tissue in specimens prevents an exact assessment of the gene inactivation effects of CpG island hypermethylation. Gene expression in normal stromal and epithelial cells can mask a lack of expression in a subset of cells with CpG island hypermethylation<sup>[19]</sup>. Therefore, analysis of aberrant DNA hypermethylation is advantageous over gene expression analysis in that it has a greater sensitivity in the presence of contaminated normal cells<sup>[19]</sup>.

The potential values of *DKK* gene methylation were further assessed in our study for clinical diagnosis purpose. The distinct methylation patterns of *DKK* gene (methylation frequencies or levels) in benign and malignant tissues are the prerequisite to determine a certain gene methylation as an effective molecular biomarker. Therefore, in addition to comparison of methylation frequencies in tumor and non-tumor groups, we further evaluated the discriminatory ability of quantitative methylation levels (PMR values) to distinguish HCC tissue from liver cirrhosis tissue using ROC analysis. Our results showed that the PMR values of *DKK3* could discriminate HCC from liver cirrhosis with high sensitivity and specificity (Figure 4), suggesting that *DKK3* methylation in combination with other diagnostic tools, may be a promising epigenetic biomarker for early detection of HCC.

It has been reported that aberrant *DKK3* methylation is a major event in early and late liver malignant trans-

formation and may constitute a critical target for risk assessment, treatment, and chemoprevention of HCC<sup>[20]</sup>. Therefore, another major question addressed in the present study concerns the prognostic value of *DKK3* methylation in human HCC. In the present study, progression-free survival analysis showed that patients with *DKK3* methylation tended to have relapse or metastasis shortly after resection (Figure 5). Multivariate Cox regression analysis further confirmed that *DKK3* methylation was an independent prognostic indicator (Table 3). Interestingly, the number of tumors (single or multiple) was the only clinicopathological variable associated with *DKK3* methylation in this study. HCC is prone to multicentric occurrence, and some other tumor suppressor genes are specifically methylated in multicentric HCC and can act as clonal markers<sup>[21]</sup>. Epigenetic inactivation of genes associated with multicentric occurrence may play an important role in the relapse or progression of HCC, thus patients with a high *DKK3* methylation level can represent a subset of poor prognosis after surgical resection. Our results showed that a high *DKK3* methylation level may serve as a potential prognostic factor for HCC. However, since the number of patients in the present study was relatively small, the prognostic significance of *DKK3* methylation levels needs to be further investigated in a larger cohort of patients with a longer follow-up period.

In conclusion, methylation of *DKK3* is an important event during early malignant transformation and progression of HCC, thus representing a prognostic indicator for risk assessment of HCC.

## COMMENTS

### Background

Aberrant promoter hypermethylation of tumor suppressor genes is very common in human cancers. It not only presents one of the important mechanisms in carcinogenesis, but also serves as a type of promising biomarkers for the diagnosis or prognosis of cancer patients.

### Research frontiers

Dickkopf (*DKK*) family is one class of the secreted Wnt antagonists. Its functional loss can contribute to activation of the Wnt pathway and result in carcinogenesis. Inactivation of Wnt antagonist genes and its epigenetic mechanism have been recently characterized in many cancers. However, few reports are available on the epigenetic silencing of *DKK* gene and its clinical significance in hepatocellular carcinoma (HCC).

### Innovations and breakthroughs

Using quantitative methylation-specific polymerase chain reaction (Q-MSP) technology, the authors investigated the prevalence and time of *DKK* family methylation in adequate tumor tissue and biopsy samples. The results of this study demonstrate that methylation of *DKK3* is an important event during early malignant transformation and progression of HCC, thus representing a prognostic indicator for risk assessment of HCC.

### Applications

*DKK3* methylation was identified as a specific epigenetic event involving hepatocellular transformation at cirrhosis stage, which not only provides a clue to the molecular basis of hepatocarcinogenesis, but also offers a potentially useful marker for the early diagnosis or prognosis of HCC.

### Terminology

Percent of methylated reference (PMR) is calculated by dividing the *GENE/ACTB* ratio in a sample by the *GENE/ACTB* ratio in SssI-treated DNA and multiplied by 100. The normalization performed to obtain PMR can simplify the cross-gene comparison, since the data range 0-100.

### Peer review

This is a very well-written paper trying to find anomalies in genes and their functions that may contribute to the prognostication and differential diagnosis of HCC with dysplastic nodules.

### Abstract

**AIM:** To clarify the therapeutic strategies and prognosis factors of primary clear cell carcinoma of the liver (PCCCL).

**METHODS:** The clinical pathological data of 64 patients with PCCCL treated with hepatectomy in our hospital from January 2000 to January 2006 were analyzed retrospectively. The patients were divided into two groups to make treatment analysis: curative resection only ( $n = 40$ ); and curative resection and postoperative chemotherapy with calcium folinate and tegafur ( $n = 24$ ). Meanwhile, the PCCCL patients were subdivided into two subgroups on the basis of the proportion of clear cells in the tumor for pathological analysis. There were 36 cases in subgroup A for which the proportion of clear cells was more than 70%, and 28 cases in subgroup B for which the proportion was less or equal to 70%, comparing analysis of median survival time of the counterpart groups. Univariate and multivariate analyses were performed to examine factors that affected clinical prognosis, recurrence and metastasis.

**RESULTS:** Median survival period of the curative surgery group was 38 mo, while the counterpart was 41 mo. Median survival period for group A was 41 mo,

while group B was 19 mo. The Kaplan-Meier method showed that capsule formation, preoperative liver function, hepatitis C virus infection, large vascular invasion and multiple tumor occurrences were related to disease-free survival. Cox regression analysis showed that the clear cell ratio, capsule formation, preoperative liver function and large vascular invasion were independent risk factors for overall survival.

**CONCLUSION:** Postoperative chemotherapy has no obvious effect on survival of patients with PCCCL. Clear cell ratio, capsule formation, preoperative liver function, and vascular invasion were independent risk factors for prognosis.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is a major cause of cancer mortality worldwide and is increasing in incidence; driven largely by the growing hepatitis B and hepatitis C epidemics<sup>[1,2]</sup>, which comprise approximately 75% of all HCC and liver cirrhosis (70%-80% of all cases)<sup>[3,4]</sup>. Surgical resection has long been the only curative treatment;

conventional chemotherapy and radiotherapy are ineffective for HCC<sup>[5]</sup>. Despite recent advances in diagnostic and therapeutic modalities, prognosis is usually poor, particularly in patients with coexisting liver cirrhosis. Survival rates are 3%-5% in cancer registries for the United States and developing countries. In total, 55% of cases (and deaths) are in China alone<sup>[6]</sup>. Many investigations have suggested that tumor size, number of nodules, vascular invasion, tumor encapsulation, blood transfusion, high  $\alpha$ -fetoprotein (AFP) level, and resection margin status are the main prognostic factors associated with the postoperative recurrence of HCC<sup>[7]</sup>.

Primary clear cell carcinoma of liver (PCCCL) is a particular histological type of HCC, PCCCL is not frequent and has been reported to account for 7.5%-12.5% of all liver cancer cases<sup>[8]</sup>. Microscopically, all cases of PCCCL show moderate to marked cytoplasmic accumulation of glycogen and/or macro- and microvascular intracytoplasmic fat droplets that dissolve during hematoxylin-eosin (HE) staining, which leaves behind a clear cytoplasm. Generally, the tumor cells are mainly in the mid-range degree of differentiation, and low-grade malignancy. PCCCL usually has capsule formation and is localized. Surgical resection is the most promising therapeutic method for PCCCL. The outcome for patients with PCCCL is better than for those with common type counterparts, and survival improves with an increasing proportion of clear cells<sup>[9,10]</sup>. Treatment and prognosis of PCCCL are reported rarely in the literature. Also, treatment and clinical prognostic features are not fully clarified.

## MATERIALS AND METHODS

### Subjects

The participants of this study were 64 patients [40 male, 24 female (ratio 1.67:1), aged 23-73 years, mean  $55.16 \pm 10.56$  years], who received curative hepatic resection for PCCCL at the Tianjin Medical University Cancer Hospital between January 2000 and January 2006. We used the diagnostic criteria generally accepted by pathologists in China to diagnose PCCCL as follows: (1) only when it contained > 50% clear cells; (2) exception for metastatic clear cell carcinoma from other organs; and (3) diagnosis by more than two pathologists. A total of 64 patients were eligible for this study.

### Treatment method

All 64 patients underwent surgical tumor resection. Anatomical resection included hemi-hepatectomy, segmentectomy and sub-segmentectomy, based on Child-Pugh classification. Resection margin was 1 cm beyond the tumor, and surgical margins were negative when examined by the pathologists. Clear cell ratio, large vascular invasion (large blood vessels including the portal vein, hepatic vein and/or first level branch), and lymph node metastasis were confirmed by pathology.

Patients with PCCCL who had undergone their first curative hepatic resection at the Cancer Hospital of Tianjin Medical University were eligible for postoperative

adjuvant chemotherapy if they met the following entry criteria: (1) absence of detectable residual or recurrent tumors at 1 mo after curative resection; (2) age < 70 years; (3) liver function belonging to Child A or B class; (4) absence of severe cardiac complications; and (5) general health satisfactory for toleration of the contemplated chemotherapy. The exclusion criteria were the presence of clinically confirmed extrahepatic metastasis, macroscopic evidence of tumor thrombus in the inferior vena cava or the main portal vein, other previous or synchronous malignant disorders, and postoperative dysfunction of any organ. Finally 24 patients were considered as suitable candidates for our studies.

Postoperative chemotherapy of 24 cases consisted of calcium folinate and tegafur. Calcium folinate was administered at a starting dose of 200 mg/m<sup>2</sup>, as a continuous intravenous infusion over 2 h on days 1-5. Tegafur was administered at a starting dose of 850 mg/m<sup>2</sup> given intravenously over 3 h on days 1-5. Adequate intravenous hydration and antiemetic therapy were routinely administered. Chemotherapy courses were repeated every 21 d, provided patients recovered from all toxic effects. Based on the predetermined criteria of toxicity grades, the doses of chemotherapy drugs were increased or decreased by 25%. Criteria for dose reduction included development of grade 3 non-hematological toxicity or grade 4 hematological toxicity. Complete blood, differential, and platelet counts were evaluated at least once weekly and more frequently when patients were myelosuppressed during the rest period. Serum creatinine, blood urea nitrogen, electrolyte, and magnesium levels were monitored regularly during each course.

### Survival analysis methods

The prognostic factors were examined in cumulative and disease-free survival, using the following variables: age (older or younger than 50 years); sex (male *vs* female); serum hepatitis B virus (HBV) surface antigen (HBsAg) (negative *vs* positive); serum hepatitis C virus (HCV) antibody (HCVAb) (negative *vs* positive); proportion of clear cell more than *vs* less than or equal to 70%; tumor size (greater than *vs* less than or equal to 5.0 cm); liver cirrhosis (negative *vs* positive); serum levels of AFP (greater than *vs* less than or equal to 200 ng/mL); operative procedures (anatomical *vs* non-anatomical resection); lymph node metastases (negative *vs* positive); vessel invasion (negative *vs* positive); Child-Pugh classification (Grade A *vs* Grade B or C); capsule formation (negative *vs* positive); number of nodules (solitary *vs* multiple); therapeutic strategies (curative resection *vs* curative resection and postoperative chemotherapy); TNM staging (I, II *vs* III, IV).

### Follow-up

All patients were followed up to January 2009, or up to the time of death; all patients were followed up for > 3 years. Patients were examined regularly with measurement of the serum AFP level, hepatic ultrasonography and chest radiography every month after surgical resection to check

metastasis and recurrence. Six months later, we examined serum AFP level, hepatic ultrasonography and chest radiography every 3 mo. When recurrence was suspected, further evaluations were made by abdominal, chest and brain enhanced computed tomography (CT), if necessary, by ultrasound-guided biopsy or positive electron tomography/CT examination to confirm the diagnosis. Patients who died of another disease were lost to follow-up.

**Statistical analysis**

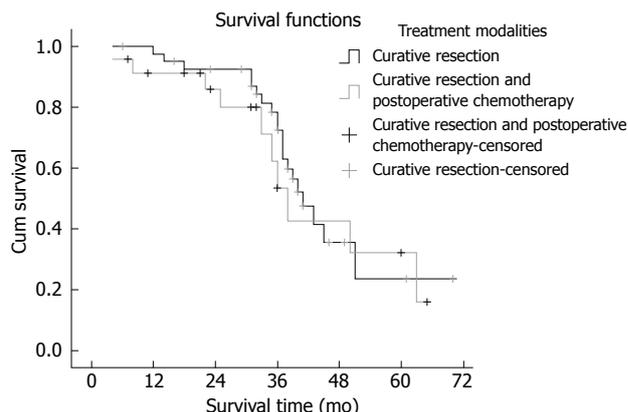

Differences in the means were assessed with the  $\chi^2$  test. The cumulative survival and the life table and Kaplan-Meier method, calculated recurrence-free survival rates and the difference between the two groups was analyzed by the log-rank test. The survival curve was described using the Kaplan-Meier method. Cox regression (proportional hazard model) was adopted for the multivariate analysis of prognostic factors. Statistical software package SPSS 13.0 (SPSS Inc., Chicago, IL, USA) was employed for all of the analyses. *P* values less than 0.05 were considered statistically significant. SPSS 13.0 was employed for all of the analyses.

**RESULTS**

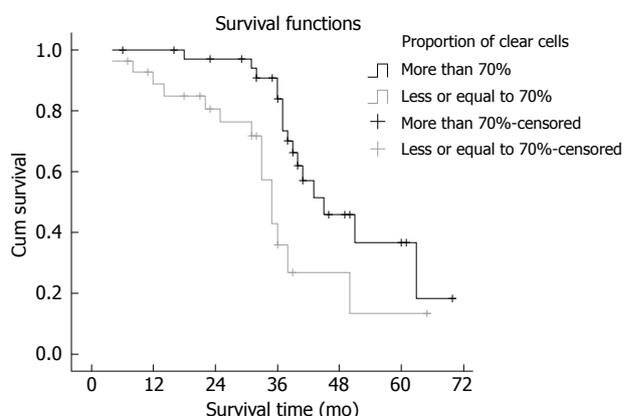

In 36 cases (56.25%), the proportion of clear cells was > 70%; 46 cases (71.88%) were positive for HBsAg, 10 cases (14%) were positive for HCVAb, and six cases (9.32%) were negative for both HBsAg and HCVAb. Fifty-six patients had liver cirrhosis (87.50%). In 50 patients, tumor diameter was > 5.0 cm (78.13%). In 26 patients, serum AFP level was > 200 ng/mL (40.63%). Forty-four patients had a solitary tumor (68.75%); 30 had large vessel invasion (46.86%); 12 had lymph node metastasis (18.75%); 24 received postoperative chemotherapy with calcium folinate and tegafur (37.50%); and 40 received curative hepatic resection without chemotherapy (62.50%). The liver function was evaluated using Child-Pugh classification. Forty patients had grade A liver function (62.50%), 21 (32.81%) had grade B, and three (4.69%) had grade C. Forty-six patients had tumor capsule formation (71.88%). Pathological stage of PCCCL was evaluated using TNM staging. Three patients had stage I, nine had stage II, 40 patients had stage III, and two had stage IV.

**Postoperative follow-up**

Seventeen patients suffered intrahepatic recurrence during follow-up; extra-hepatic metastasis occurred in 13 cases, and six patients suffered metastasis and recurrence. One patient in the curative surgical group died of perioperative complications, which resulted in a perioperative mortality of 1.56% (1/64). One patient died from traffic accidents, and two from the resection and postoperative chemotherapy group missed postoperative follow-up. After excluding the perioperative deaths and the missing patients, the postoperative cumulative and disease-free survival rates at 1, 3 and 5 years were 78.13%, 49.88% and 37.50% (mean  $\pm$  SD, 41.56  $\pm$  3.72 mo; median,

**Figure 1** Comparison of survival rates of different treatment modalities.

**Figure 2** Comparison of survival of patients with different percentage of clear cells.

39.6 mo) and 71.82%, 40.63% and 25.00% (mean  $\pm$  SD, 34.56  $\pm$  3.93 mo; median, 33.0 mo), respectively. Median survival period in the curative surgical group was 38 mo, and 41 mo in its counterpart. There was no statistical significance in the survival time between the two groups ( $\chi^2 = 0.196$ , *P* = 0.658). The survival curves are shown in Figure 1. Median survival period of the group with > 70% clear cells was 41 mo, and 29 mo in its counterpart. The proportion of clear cells had an obvious effect on the median survival period of patients ( $\chi^2 = 7.432$ , *P* = 0.006). The survival curves are shown in Figure 2. The prognosis of the patients with a higher proportion of clear cells was better than that in patients with a lower proportion of clear cells.

**Prognostic analyses**

**Univariate and multivariate analyses:** For the univariate analysis, age, sex, serum HBsAg, serum HCVAb, tumor diameter, vascular invasion, capsule formation, background of liver cirrhosis, serum AFP level, Child-Pugh classification, vascular invasion, proportion of clear cells, and lymph node metastases were included. We found that the parameters of vascular invasion, capsule formation, background of liver cirrhosis, number of nodules, proportion of clear cells, and Child-Pugh classification were statistically significant in cumulative survival (Table 1).

Vascular invasion				
Positive	30	27 (23.346-30.654)	11.755	0.001
Negative	34	41 (35.437-46.563)		
lymph node metastases				
Positive	12	31 (26.012-35.988)	0.023	0.880
Negative	52	40 (37.342-44.658)		
TNM staging				
I, II	12	43 (39.211-46.789)	16.192	0.001
III, IV	52	27 (25.371-28.629)		
Proportion of clear cells				
$\geq 70\%$	36	41 (35.535-46.465)	7.342	0.006
$< 70\%$	28	19 (16.964-21.036)		

PCCCL: Primary clear cell carcinoma of the liver.

**Table 2** Multivariate analysis of clinicopathological variables associated with the prognosis of PCCCL

Parameters	Regression coefficient	Wald value	P value	RR (95% CI)
Proportion of clear cells	1.409	6.898	0.009	4.090 (1.430-11.702)
Capsule formation	-1.364	5.172	0.023	0.256 (0.079-0.828)
Vascular invasion	1.686	9.923	0.002	5.395 (1.890-15.398)
Child-Pugh classification	1.917	4.119	0.042	6.798 (3.253-17.334)

Then, the parameters of significances were all contained in the Cox regression analysis. Using the Cox regression analysis, four clinic pathological variables were shown to have potential of predicting overall or disease-free survival of PCCCL patients, including rate of capsule formation, vascular invasion, Child-Pugh classification, and proportion of clear cells (Table 2).

**Cumulative recurrence-free survival rates and disease-free prognosis:** The life table and Kaplan-Meier method, calculated the cumulative recurrence-free survival rates and the difference between two groups were analyzed by the log-rank test. The 1-, 3- and 5-year disease-free survival rates were 71.82%, 40.63% and 25.00% (mean  $\pm$  SD, 34.56  $\pm$  3.93 mo; median, 33.0 mo). Kaplan-Meier univariate analysis

showed that the disease-free prognosis of the patients with capsule formation, better liver function, negative HCVAb, no vascular invasion, and solitary tumor were better than the patients with no capsule formation, poor liver function, positive HCVAb, vascular invasion and multiple tumors. Patients with no capsule formation, poor liver function, positive HCVAb, vascular invasion and multiple tumors were prone to metastasis and/or recurrence.

## DISCUSSION

PCCCL is a particular and relatively rare histological type of HCC. Microscopically, it is similar to the clear cell cancers (kidney, ovarian or adrenal), which makes it difficult to differentiate from the metastatic clear cell cancers of the liver. Murakata *et al*<sup>[11]</sup> have recommended hepatocyte antibody as a screening immunostain in working up a clear cell tumor in the liver when diagnostic histological criteria of HCC are absent. In this setting, it distinguishes PCCCL from other clear cell malignancies with a sensitivity of 90% and specificity of 100%. Some other studies have indicated *in situ* hybridization for albumin mRNA as a useful method to distinguish PCCCL from other clear cell tumors metastasizing to the liver<sup>[12]</sup>. In the present study, we made the diagnosis using features that point toward the diagnosis of HCC. This study integrated the patient's pathological features, biopsy, and clinical manifestations, imaging studies, endoscope bile stasis and postoperative long-term follow-up to make a clear diagnosis<sup>[4,13]</sup>. There was no misdiagnosis in our study. Some authors consider  $< 30\%$  of clear cells within the tumor as sufficient<sup>[9]</sup>, whereas others diagnose PCCCL when the tumor contains  $> 30\%$  clear cells, however, tumors with clear cells ranging from 90% to 100% are extremely rare<sup>[14]</sup>. We used the diagnostic criteria generally accepted by pathologists in China to diagnose PCCCL, that is, only when it contained  $> 50\%$  clear cells<sup>[10]</sup>. In our further studies, we formed a group according to whether the clear cell count was 70% of all cells. We found that the group with  $> 70\%$  clear cells had significantly longer survival ( $\chi^2 = 7.432$ ,  $P = 0.006$ ). This shows that the prognosis was related to the proportion of clear cells. The greater the number of clear cells, the better the prognosis.

Surgical resection is an effective way to achieve favorable outcomes and long-term survival of patients with PCCCL. Lao *et al*<sup>[15]</sup> have reported 1- and 3-year survival rates of 76.5% (13/18) and 47.1% (8/18), in all 13 surgical resection patients; the longest survival was 97 mo, and surgical resection was an effective treatment to achieve long-term survival. Compared with HCC, PCCCL has a slower development process, good differentiation, lower grade malignancy, and easier capsule formation, therefore, the tumor is more limited and prone to resection. Surgical resection is the most important means of achieving long-term survival. If there is recurrence after resection, tumor re-resection is possible, but if it cannot be removed, development is slower than for HCC. In the present study, there were 24 patients in the surgical resection and chemotherapy

group; the median survival period was 38.2 mo, and the median survival of the curative surgical resection group was 39.1 mo. The difference between these two groups was not significant ( $\chi^2 = 0.196$ ,  $P = 0.658$ ), which indicated that postoperative adjuvant chemotherapy with calcium folinate and tegafur was not sensitive to PCCCL and had no obvious effect on the survival time of patients. Other postoperative chemotherapy regimens for PCCCL were not investigated in this study. The prognosis of patients with postoperative chemotherapy requires further study.

Pecorella *et al.*<sup>[16]</sup> have reported that a 35-year-old patient who was treated with liver transplantation survived for 17 mo, which was lower than the median survival in our study. Emile *et al.*<sup>[17]</sup> have shown that prognosis was better in a large series of transplanted Caucasian patients with PCCCL than in those with other liver malignancies. In the present study, the prognosis of patients with surgical resection was better than for HCC, which may be related to better tumor differentiation, capsule formation, less vascular invasion and lymph node metastasis, and high resectability rate. The prognosis of patients with PCCCL is still controversial. Many studies have reported PCCCL has better prognosis than other HCCs<sup>[18,18]</sup>. Lai *et al.*<sup>[9]</sup> have reported that the outcome for patients with PCCCL is better than those with common-type cancers, and survival improves with an increasing proportion of clear cells. Conversely, other investigators have found that the prognosis of patients with PCCCL is similar to that of their common-type counterparts and perhaps even worse<sup>[19,20]</sup>. Yang *et al.*<sup>[14]</sup> have reported that the 3- and 5-year survival rate was 54.5% and 33.3%, respectively, which was slightly lower than the rate for non-PCCCL patients (including HCC). However, all these data failed to disclose any statistical significance, or were not statistically analyzed according to the number of cases. Our study confirmed the former results in a series of postoperative patients, and showed significantly higher 1-, 3- and 5-year survival rates in PCCCL patients. The Kaplan-Meier method showed that capsule formation, preoperative liver function, HCV infection, large vascular invasion and multiple tumor occurrences were related to disease-free survival. The prognosis of patients in the PCCCL group was related to clear cell ratio, preoperative liver function, liver cirrhosis, HCV infection, capsule formation, large vascular invasion and multiple tumor occurrences. In this study, lymph node metastasis did not significantly affect survival, which may have been related to the comparatively small number of cases in this study, therefore, we need to increase the number of sample cases for further study. Cox multivariate analysis showed that clear cell ratio, capsule formation, preoperative liver function and large vascular invasion were independent risk factors for survival. In this study, capsule formation of PCCCL was different from the clinical characteristics of HCC. Capsule formation may limit tumor growth and spread and is conducive to tumor resection and treatment. Lower malignancy and better differentiation

of clear cells may have contributed to the improved prognosis. The higher the proportion of clear cells, the better was the prognosis. Preoperative Child-Pugh classification was an independent risk factor for survival. High HCV prevalence led to poor liver function and shorter survival.

In summary, postoperative chemotherapy with calcium folinate and tegafur had no obvious effect on survival time of patients with PCCCL. Patients with a high clear cell ratio had improved prognosis. Capsule formation, poor preoperative liver function, HCV infection, large vascular invasion, and multiple tumor occurrence were risk factors for metastasis and postoperative recurrence of PCCCL. Patients with capsule formation, no large vascular invasion, high clear cell ratio, and better liver function had improved prognosis.

## ACKNOWLEDGMENTS

The authors thank Dr. Young Tang, Department of Pancreatic Oncology, Cancer Hospital of Tianjin Medical University, for help in preparing the manuscript and the statistical analysis.

## COMMENTS

### Background

Primary clear cell carcinoma of the liver (PCCCL) is a type of primary hepatocellular carcinoma (HCC), which is characterized pathologically by diffuse clear cells of the tumor, and a clear cytoplasm that does not stain with hematoxylin-eosin. At present, treatment and prognosis of PCCCL have not been reported widely in the literature. Its treatment and clinical prognostic features have not been fully clarified.

### Research frontiers

PCCCL is a particular histological type of HCC; PCCCL is not frequent and has been reported to account for 7.5%-12.5% of all liver cancer cases. Treatment and clinical prognostic features have not been fully clarified. The research hot topics are how to treat PCCCL, and its independent prognostic risk factors. Surgical resection is an effective way to achieve favorable outcomes and long-term survival of patients with PCCCL.

### Innovations and breakthroughs

Previously, there have been more case studies of PCCCL, and large sample studies have been rare. The present study found that postoperative chemotherapy with calcium folinate and tegafur had no obvious effect on patient survival. The study found that the higher the proportion of clear cells, the better the prognosis. The authors also found that the clear cell ratio, capsule formation, preoperative liver function, and vascular invasion were independent prognostic risk factors, which had not been reported previously.

### Applications

The study results suggest that postoperative chemotherapy with calcium folinate and tegafur has no obvious effect on patient survival. Surgical resection is an effective way to achieve favorable outcomes and long-term survival of patients with PCCCL.

### Terminology

Hepatectomy is a treatment approach that involves the surgical removal of part or all of the liver for therapeutic purposes. Postoperative chemotherapy is the use of certain drugs to further treat cancer after surgery according to certain symptoms and physical signs.

### Peer review

This is a good retrospective study which analyzed therapeutic strategies for patients with PCCCL, who were undergoing liver resection. The authors operated on 64 patients with this infrequent type of HCC within the past 6 years. The major oncological and surgical issues are discussed in the introduction and discussion.

### Abstract

**AIM:** To evaluate the efficacy of antiviral or corticosteroid treatment on hepatitis B virus-associated glomerulonephritis (HBV-GN).

**METHODS:** Six and five trials were used respectively to evaluate the efficacy of either antiviral or corticosteroid treatment on HBV-GN. Pediatric patients were pooled separately to assess their response to the above treatment modalities. The primary and secondary outcomes were remission of proteinuria and clearance of Hepatitis B e-antigen (HBeAg), respectively. A fixed or random effect model was established to collect the data.

**RESULTS:** The remission rate of proteinuria (RR = 1.69, 95% CI: 1.08-2.65) and the clearance rate of HBeAg (RR = 6.44, 95% CI: 3.11-13.35) were significantly higher in antiviral treatment group than in control group. The proteinuria remission was significantly associated with HBeAg clearance ( $P = 0.002$ ). However, the difference in proteinuria remission rate was not statistically significant between corticosteroid treatment group and control

group (RR = 1.45, 95% CI: 0.68-3.11). Antiviral therapy could significantly promote the HBeAg clearance in pediatric patients, but neither antiviral nor corticosteroid therapy could significantly decrease proteinuria in pediatric patients compared to controls.

**CONCLUSION:** Antiviral but not corticosteroid treatment can decrease proteinuria and promote HBeAg clearance in HBV-GN patients.

### INTRODUCTION

Hepatitis B virus-associated glomerulonephritis (HBV-GN) remains one of the most common secondary glomerular diseases in Chinese children, although its incidence seems to decrease nowadays after the popularization of HBV vaccination<sup>[1,2]</sup>. Most HBV-GN patients present with nephrotic syndrome and some show mild to moderate proteinuria with hematuria<sup>[3]</sup>. Although spontaneous remission has been reported in many pediatric patients<sup>[3]</sup>, some still develop progressive renal failure<sup>[4-6]</sup>. Therefore, it is very important to attenuate proteinuria and slow down renal disease progression in HBV-GN patients.

HBV-GN is treated with either antiviral drugs including interferon, lamivudine, and entecavir or with corticosteroids

and even immunosuppressive agents like mycophenolate mofetil, leflunomide<sup>[7,8]</sup>. It has been shown that antiviral therapy can promote the clearance of HBV and improve the coexisting renal disease<sup>[3]</sup>, but the efficacy of interferon on HBV-GN has not been confirmed<sup>[9,10]</sup>. Moreover, interferon therapy is not as successful for HBV-GN in children as for HBV-GN in adults<sup>[3]</sup>. Thus, the efficacy of antiviral therapy on HBV-GN remains to have been established, especially in pediatric patients. Corticosteroids are also used in treatment of some patients with nephrotic syndrome. However, it is argued that corticosteroid and immunosuppressive agents are unfavorable for HBV-GN since they inhibit the immune system and activate latent HBV, leading to active replication of HBV and deterioration of renal lesions<sup>[3,11]</sup>. So the efficacy of these treatment modalities on HBV-GN is still uncertain. Up to date, we are not sure if patients with HBV-GN can be treated with antiviral drugs alone and if nephrotic patients can be treated with corticosteroids.

Unfortunately, the data available in studies on HBV-GN treatment are limited and often provide inconsistent results, which can be explained by many factors like variable sample size, racial differences, disease variation as well as interference of other treatment. These inconsistencies can be solved by meta-analysis. In a meta-analysis<sup>[12]</sup> of antiviral therapy for HBV-GN published in 2006, 2 of the 6 trials included were non-controlled studies, other treatments like corticosteroids and pediatric patients were not analyzed. Thus, we performed a meta-analysis including just controlled trials to evaluate the effects of antiviral drugs and corticosteroids on HBV-GN both in adults and in children.

## MATERIALS AND METHODS

### Literature search

All eligible articles in English and Chinese published prior to November 2008 were searched from PubMed, EMBASE, Cochrane Library and CNKI. The terms, including hepatitis B virus (or hepatitis B), nephropathy, nephrotic syndrome and therapy, interferon, lamivudine, corticosteroid, prednisolone, *etc.*, were crossed. Furthermore, bibliographies of retrieved articles, proceedings of major recent meetings on nephrology and hepatology and related dissertations in English or Chinese were manually searched.

### Criteria for inclusion

Controlled clinical trials, cohort studies, and case-control studies were searched for this systematic review. The diagnosis of HBV-GN was established based on renal pathology. The primary and secondary outcomes were remission of proteinuria and clearance of Hepatitis B e-antigen (HBeAg), respectively. Only dissertations, conference papers and full-text papers published in peer-reviewed journals concerning the treatment of HBV-GN were included in the study. The decision was made based on the quality of studies rather than on their results.

### Criteria for exclusion

Publications were excluded if they were non-controlled

studies or on treatment of HBV-GN with Chinese herbal drugs. For serial reports of the same patients, only those who provided the most comprehensive information were included.

### Definition of treatment effect

The assessed outcomes included clinical and virologic responses. Clinical responses were divided into complete remission and partial remission, which were respectively defined as disappearance of proteinuria (< 0.3 g/d) and reduction in urine protein excretion. Virologic response was defined as clearance of HBeAg from serum.

### Data extraction and quality assessment

Two reviewers independently selected the studies, and extracted data and outcomes according to the inclusion criteria. In case of disagreement between the two reviewers, a third reviewer was introduced to discuss with the two reviewers and extracted the data when all the three reviewers reached a consensus.

### Statistical analysis

Meta-analysis was performed using fixed-effect or random-effect methods, depending on the absence or presence of significant heterogeneity. Statistical heterogeneity between trials was evaluated by the Cochran  $\chi^2$  test and significance was considered when  $P < 0.10$ . In the absence of statistically significant heterogeneity, the Mantel-Haenszel method in the fixed-effect model was used for meta-analysis. Otherwise, the DerSimonian and Laird method<sup>[13]</sup> in the random-effect model was selected. The relative risk (RR) with 95% confidence interval (CI) was used to assess the treatment efficacy. The combined result was an average RR and 95% CI weighted according to the standard error of the RR of the trial.  $P < 0.05$  was considered statistically significant. We used funnel plots to assess the publication bias, and tested for funnel plot asymmetry using Egger's test<sup>[14]</sup> and Begg's test<sup>[15]</sup>. All analyses were performed with STATA version 9.0 (Stata Corp, College Station, Tx) and Review Manager version 4.2 (RevMan, Cochrane Collaboration, Oxford, England).

## RESULTS

### Description of included trials in the meta-analysis

Of the 998 studies we identified in the search, 55 and 943 articles were published in English and Chinese, respectively. After a review of the titles and abstracts or full texts, 989 articles were excluded and 9 articles<sup>[16-24]</sup> (8 in English and 1 in Chinese) were included based on the pre-specified criteria. One of them was randomized controlled trial (RCT)<sup>[16]</sup>, others were cohort studies. Among the 9 articles, 5 (55.6%) were from China, corresponding to the high incidence of HBV-GN in China and the low incidence in Europe and North American. The characteristics of 9 clinical trials included are shown in Table 1, and the details of intervention methods like dose and duration of drugs, main outcomes, and follow-up time in each study are provided in Tables 2 and 3.

**Table 1** Characteristics of 9 included studies

Study	Country or region	Patients		Study design

HBV-GN: Hepatitis B virus-associated glomerulonephritis; CR: Clinical response; VR: Virologic response; UA: Unavailable; 3TC: Lamivudine; rIFN $\alpha$ : Recombinant  $\alpha$ -interferon; HBeAg: Hepatitis B e-antigen; ACEI: Angiotension converting enzyme inhibitors; ARB: Angiotensin II receptor blocker; ESRD: End-stage renal disease; t/w: Times per week.

**Therapeutic evaluation: Antiviral therapy**

The efficacy of antiviral therapy on HBV-GN was assessed using 6 trials<sup>[16-21]</sup>, including 1 RCT<sup>[16]</sup> and 5 cohort studies<sup>[17-21]</sup>. The total number of patients was 159 (72 in treatment group with 5 dropped out, 87 in control group with 3 dropped out). Among the 159 patients, 133 presented with nephrotic syndrome and 134 with membranous nephropathy. The mean follow-up time was five months to ten years, significantly different between trials.

**Clinical response in antiviral treatment group and control group:** The  $\chi^2$  test of heterogeneity was highly

significant ( $P = 0.0001$ ). Accordingly, a random-effect model was used. The remission rate of proteinuria was significantly higher in antiviral treatment group (91.0%) than in control group (56.0%) with a combined RR of 1.69 (95% CI: 1.08-2.65, Figure 1A). The result of sensitivity analysis remained unchanged even if lamivudine treatment studies were excluded (RR = 1.50, 95% CI: 0.99-2.26, Figure 1B), indicating that the result is stable.

Furthermore, three trials<sup>[16,17,21]</sup> on pediatric patients were analyzed. The  $\chi^2$  test of heterogeneity was also highly significant ( $P = 0.007$ ), so a random-effect model was selected. As shown in Figure 1C, the remission rate

Table 3 Design of 5 clinical trials on efficacy of corticosteroid therapy for HBV-GN

Author	Group	Case (n)	Intervention	Dropped-out (n)	Outcome		Follow-up
					CR	Renal insufficiency (n)	
Lai <i>et al</i> <sup>[22]</sup> , 1990	Control	7	Diuretic agents	0	2 complete remission	UA	14-37 mo
	Treatment	8	Prednisolone 60 mg/d (adult), 40 mg/m <sup>2</sup> per day (< 15 yr), for 6 mo	0	3 complete remission, 4 partial remission, 1 relapse	UA	
Ozdamar <i>et al</i> <sup>[23]</sup> , 2003	Control	4	None	0	4 complete remission	UA	5-120 mo
	Treatment	8	Prednisolone, 2 mg/kg per day	2	1 complete remission, 4 partial remission, 1 death due to sepsis	UA	
Panomsak <i>et al</i> <sup>[20]</sup> , 2006	Control	10	ACEI, fish oil, or neither	3	2 complete remission	2 ESRD	5-120 mo
	Treatment	6	Prednisolone, 2 mg/kg per day	1	3 complete remission, 2 partial remission	0	
Yang <i>et al</i> <sup>[21]</sup> , 2003	Control	14	The same supportive and symptomatic treatment as treatment group	0	9 complete remission, 2 partial remission	0	3.8 ± 2.4 yr
	Treatment	8	Prednisolone, 1.5-2 mg/kg per day, for 3 mo	0	4 complete remission, 2 partial remission	0	
Peña <i>et al</i> <sup>[24]</sup> , 2001	Control	4	Symptomatic treatment	0	4 complete remission	UA	9.95 ± 5.88 yr
	Treatment	7	Prednisone, 1.5-2 mg/kg per day, a minimum of 4 wk (1 case prednisone + CTX)	0	7 steroid-resistant during therapy, but all complete remission at the end of follow-up	UA	

CTX: Cytosan.

of proteinuria in pediatric patients was slightly higher in treatment group (86.7%) than in control group (61.1%) with a combined RR of 1.40 (95% CI: 0.80-2.47), but the difference was not statistically significant ( $P = 0.24$ ).

**Virologic response in antiviral treatment group and control group:** The  $\chi^2$  test of heterogeneity was not significant ( $P = 0.13$ ), therefore a fixed-effect model was selected. The clearance rate of HBeAg was significantly higher in antiviral treatment group (59.7%) than in control group (8.33%) with a RR of 6.44 (95% CI: 3.11-13.35, Figure 2A).

In addition, 3 trials<sup>[16,17,21]</sup> on pediatric patients were separately analyzed for virologic response. The  $\chi^2$  test of heterogeneity was significant ( $P = 0.05$ ), therefore a random-effect model was used. The clearance rate of HBeAg was significantly higher in antiviral treatment group (73.3%) than in control group (7.4%) with a RR of 10.71 (95% CI: 3.74-30.63, Figure 2B).

**Consistency analysis of clinical and virologic responses:** Kappa analysis showed that proteinuria remission was significantly related with HBeAg clearance after antiviral therapy (kappa = 0.285,  $P = 0.002$ ).

#### Effect of antiviral therapy on protection of renal function

The renal function of patients was observed in 5 of the 6 trials during the follow-up (Table 2). Renal insufficiency was found in only 3 of 47 (6.38%) patients in the antiviral treatment group and in 11 of 64 (17.2%) patients in the control group, respectively.

#### Therapeutic evaluation: Corticosteroid treatment

The efficacy of corticosteroid treatment on HBV-GN was assessed in 5 out of 9 articles<sup>[20-24]</sup>. Two of them were included in meta-analysis of antiviral therapy efficacy. Of the 23 patients in Panomsak's study<sup>[20]</sup>, 7, 6 and 10 were

treated with antiviral drugs, prednisolone and symptomatic treatment, respectively. Of the 28 patients in Yang's study<sup>[21]</sup>, 6, 8 and 14 were treated with antiviral drugs, prednisolone and symptomatic treatment, respectively. All the 5 trials were cohort studies. The clinical response at the end of follow-up is shown in Figure 3A. Of the 76 patients analyzed, 37 were in corticosteroid treatment group with 3 dropped out, 39 were in control group with 3 dropped out. Among them, 52 presented with nephrotic syndrome and 56 with membranous nephropathy. The  $\chi^2$  test of heterogeneity was highly significant ( $P = 0.001$ ), so a random-effect model was used. The combined RR was 1.45 with a 95% CI of 0.68-3.11 ( $P = 0.34$ ), indicating that there is no significant difference in proteinuria remission rate between corticosteroid treatment group and control group. However, this result should be carefully interpreted since a limited number of clinical trials can affect the conclusion of meta-analysis. Besides, it was difficult to assess the protective effect of corticosteroid treatment on renal function since only 2 of 5 clinical trials described the renal function during the followed-up.

Moreover, 3 trials<sup>[21,23,24]</sup> on pediatric patients were separately pooled to analyze the efficacy of corticosteroid treatment. The  $\chi^2$  test of heterogeneity was not significant ( $P = 0.61$ ), so a fixed-effect model was used. The combined RR was 0.91 with a 95% CI of 0.65-1.27 ( $P = 0.58$ ), indicating that the difference in the remission rate of proteinuria was also not significant between corticosteroid treatment group and control group (Figure 3B).

#### Publication bias

Publication bias may exist when no significant findings remain unpublished, thus artificially inflating the apparent magnitude of an effect. Egger and Begg tests showed that the risk of having missed trials was acceptably low, since the  $P$  values for the clinical and virologic responses to antiviral therapy and the clinical response to corticosteroid

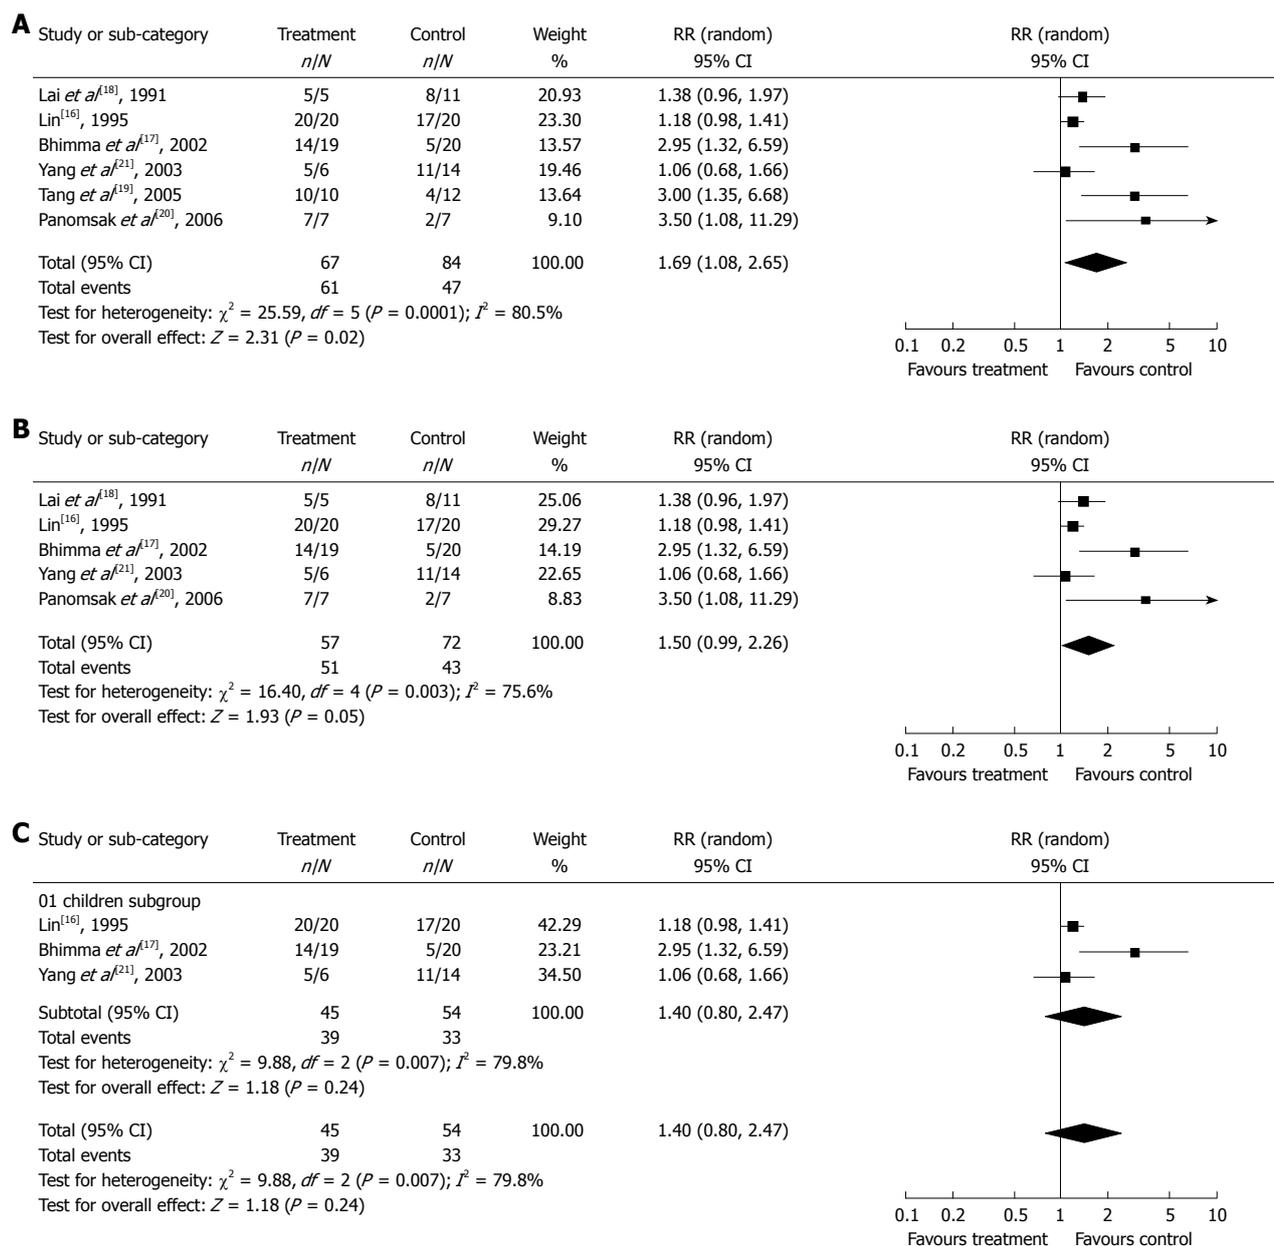

Figure 1 Proteinuria remission rate in antiviral treatment group and control group (A, B) and in pediatric patients (C).

treatment were greater than 0.05. The funnel plots of study results against precision are shown in Figure 4.

### Adverse events

Since adverse events were reported inconsistently in across studies and the relevant information in these studies was incomplete, we did not evaluate their incidence and severity of adverse events of these drugs. Some adverse events such as influenza-like illness, anemia, leucopenia, *etc.*, were reported in patients treated with IFN. Almost all patients showed good tolerance to long-term administration of lamivudine, although some patients complained of headache, dizziness, local myalgia, paresthesia, *etc.*

## DISCUSSION

Most HBV-GN patients presented with nephrotic

syndrome, many of them, especially pediatric patients showed a spontaneous remission trend, so whether the patients should be treated with antiviral drugs or with immunosuppressive agents remains to be elucidated. Antiviral therapy has been recommended in many studies for HBV-GN since it can effectively inhibit HBV replication and attenuate proteinuria<sup>[9,25-33]</sup>. Our results demonstrated that antiviral therapy could significantly improve the remission rate of proteinuria, the clearance rate of HBeAg, and renal progression. Moreover, Kappa analysis showed that proteinuria remission is significantly related with HBeAg clearance after antiviral therapy. Only 5 patients were dropped out in antiviral treatment group due to economical reasons. Almost all patients were tolerable to antiviral drugs. Our results are consistent with Fabrizi's study<sup>[12]</sup>. Since each trial used different kinds, dosages and treatment courses of antiviral drugs, the

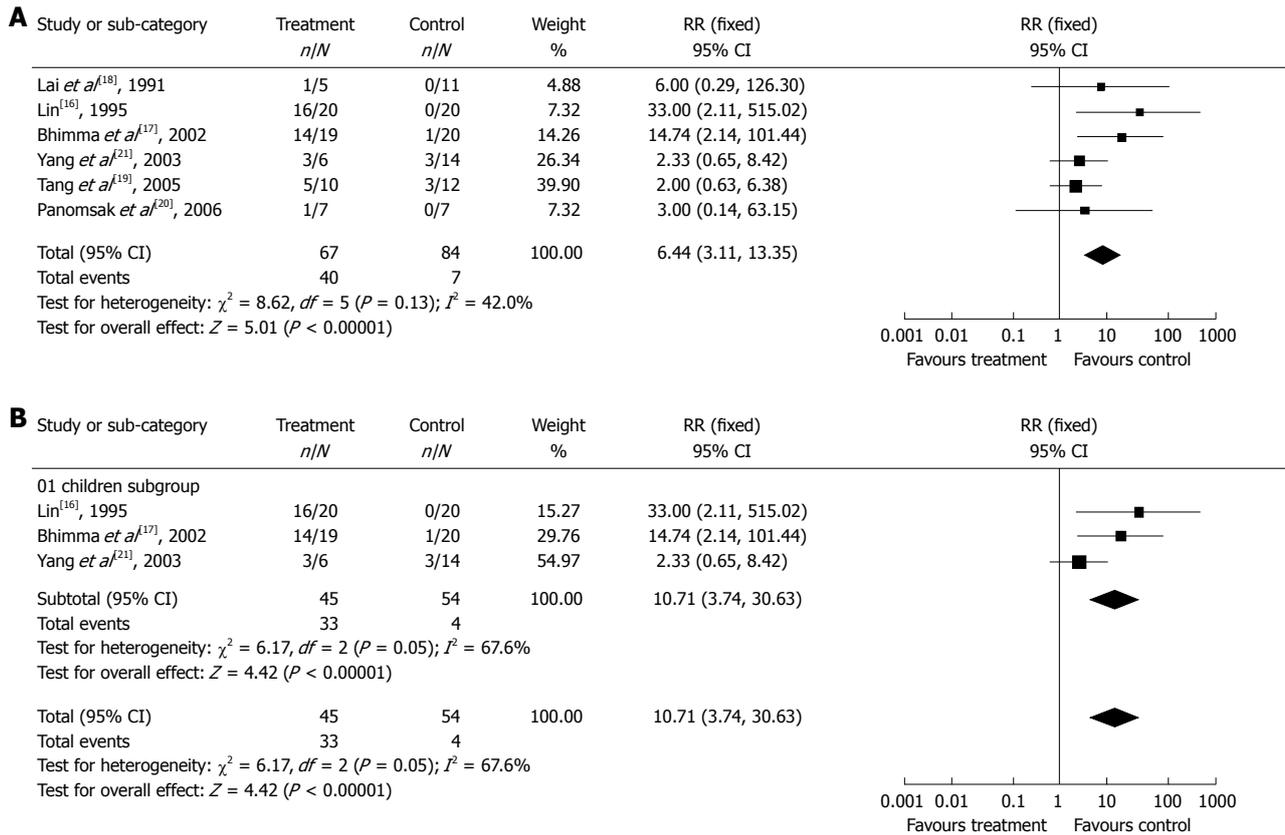

Figure 2 Clearance rate of HBsAg in antiviral treatment group and control group (A) and in pediatric patients (B).

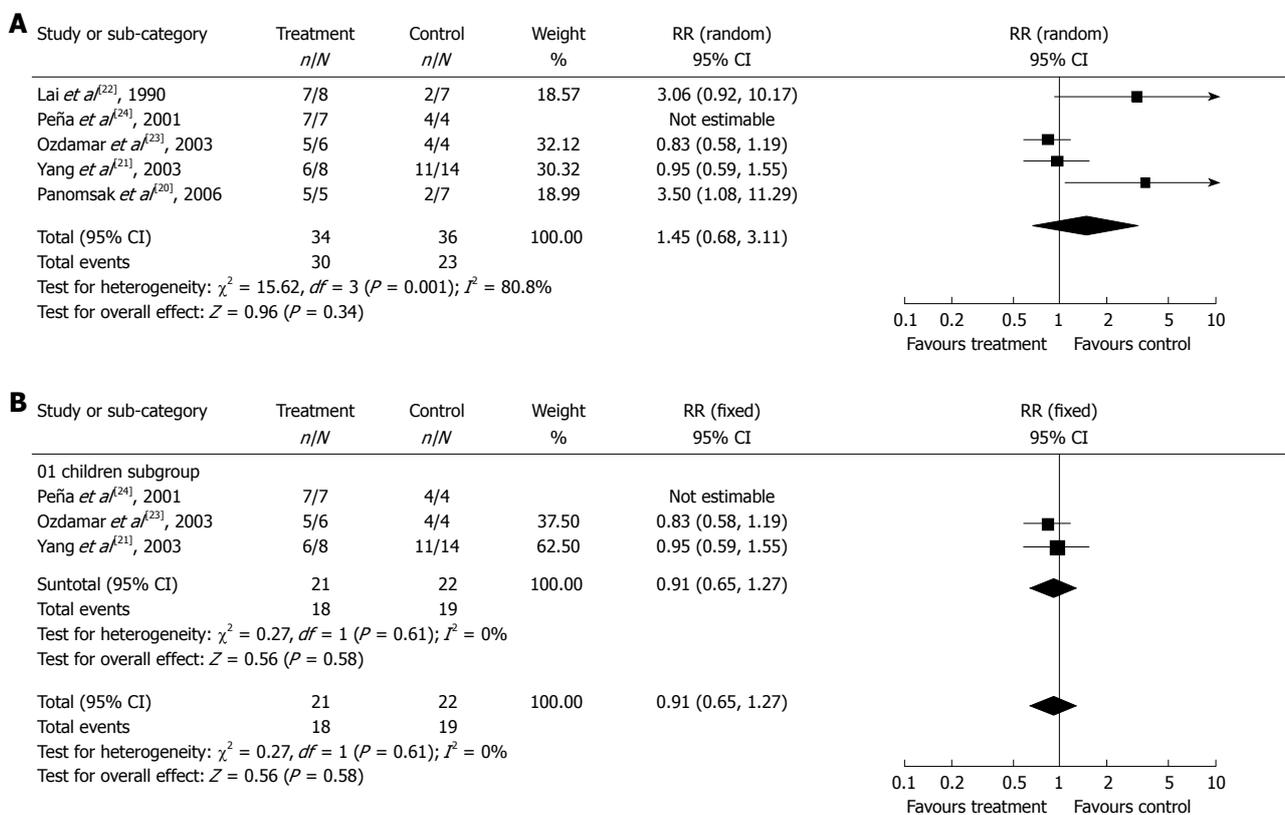

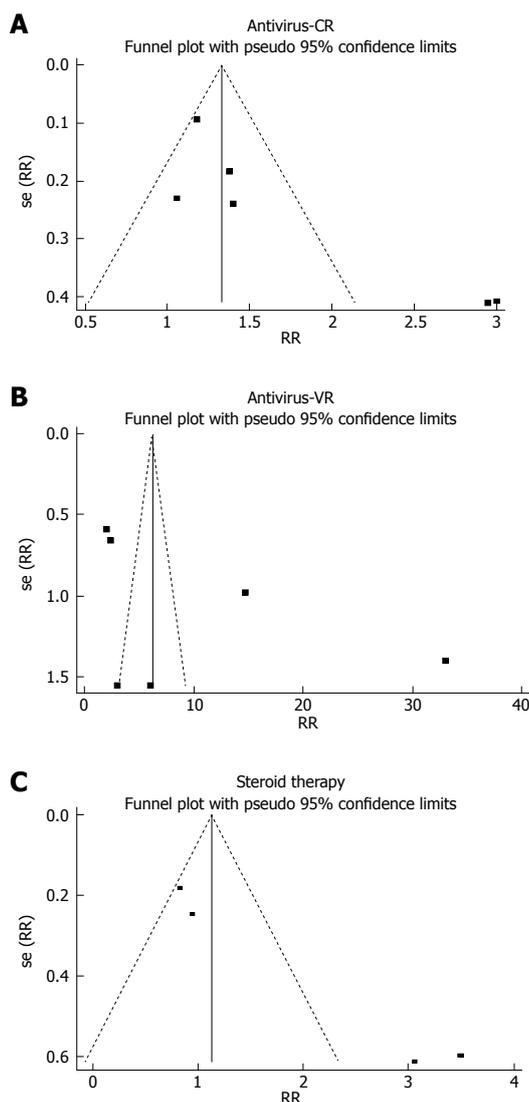

Figure 3 Proteinuria remission rate in corticosteroid treatment group and control group (A) and in pediatric patients (B).

**Figure 4** Funnel plots for 6 articles in meta-analysis of clinical response to antiviral therapy (A), 6 articles in meta-analysis of virologic response to antiviral therapy (B), and 5 articles in meta-analysis of clinical response to corticosteroid treatment (C).

meta-analysis proved the efficacy of antiviral treatment but did not necessarily mean that an exact treatment protocol should be recommended. The meta-analysis of pediatric patients showed that antiviral therapy could significantly increase the clearance rate of HBeAg, but not remarkably improve proteinuria, which is not consistent with our above findings possibly due the limited sample size. Large-scale randomized controlled trials on pediatric patients are needed to clarify if antiviral therapy can induce remission of proteinuria.

Corticosteroid is the first-line drug for idiopathic nephrotic syndrome, but it may activate potent HBV infection leading to deterioration of liver and renal lesion<sup>[22,34-36]</sup>. Our meta-analysis showed that corticosteroid treatment could not significantly improve proteinuria. The effect of corticosteroids on proteinuria remission was not better than nonspecific symptomatic treatment, but its potent risk could not be neglected. Therefore, based on the results of this meta-analysis, corticosteroid

should not be recommended for HBV-GN patients solely, especially for those with a high viral load and abnormal liver functions. Theoretically, corticosteroid in combination with antiviral drugs is certainly superior over corticosteroid alone, but no trials are available. So corticosteroid may only be used cautiously on the basis of antiviral therapy with viral load closely monitored.

As with all meta-analyses, our study had certain limitations of publication bias<sup>[37]</sup>. The number of high-quality clinical trials and enrolled patients was limited in this study. Moreover, the time of treatment was not long enough to evaluate its effects on chronic HBV-GN.

In conclusion, the efficacy and safety of antiviral therapy (including IFN and lamivudine) on HBV-GN are good. Antiviral therapy is effective on remission of proteinuria, and HBeAg clearance, delaying renal function deterioration. However, corticosteroids cannot ameliorate HBV-GN.

## COMMENTS

### Background

Hepatitis B virus-associated glomerulonephritis (HBV-GN) is one of the common secondary glomerular diseases in China. Although spontaneous remission can occur in many pediatric patients, some still develop progressive renal failure. Therefore, it is very important to attenuate proteinuria and delay renal disease progression.

### Research frontiers

So far HBV-GN has been treated like hepatitis B with antiviral drugs including interferon, lamivudine, entecavir or like primary nephrotic syndrome with corticosteroids and even immunosuppressive agents such as mycophenolate mofetil, leflunomide, etc. However, it is still uncertain up to now about the efficacy of these treatment modalities.

### Innovations and breakthroughs

The data available in previous studies on HBV-GN treatment are limited and often provide inconsistent results. So far only one meta-analysis of antiviral therapy for HBV-GN was published in 2006, but 2 of the 6 trials included were non-controlled studies. The meta-analysis including controlled studies is the first to evaluate the effects of antiviral drugs and corticosteroids on HBV-GN. Moreover, pediatric patients were separately assessed.

### Applications

The results of this study suggest that antiviral but not corticosteroid treatment can decrease proteinuria and promote Hepatitis B e-antigen clearance in HBV-associated glomerulonephritis patients. It may help doctors to optimally treat HBV-GN patients.

### Terminology

Hepatitis B virus-associated glomerulonephritis is an immune-mediated secondary glomerular disease characterized by deposits of hepatitis B viral antigens, immunoglobulins and C3 in the glomerular capillary wall and mesangium. Nephrotic syndrome, proteinuria and/or hematuria are the most common renal manifestations.

### Peer review

The present manuscript describes a meta-analysis for the evaluation of clinical and virologic responses to antiviral and corticosteroid treatment of hepatitis B-associated nephritis. Overall, the methods are appropriate and the results are believable.

### Abstract

Percutaneous radiofrequency thermal ablation (RFA) is considered an effective technique for providing local control in the majority of Hepatocellular carcinoma (HCC) patients. Although RFA is generally well tolerated, recent studies have reported complications associated with RFA. We describe a case of acute gouty arthritis in a 71-year-old man with chronic renal failure who was treated with RFA for a HCC lesion and who had hepatitis B-associated cirrhosis and mild renal insufficiency. Regular surveillance of the patient detected a 3.5 cm HCC lesion. Because the patient had declined surgery, RFA was chosen for therapy. On the third post-procedural day, the laboratory results showed increases in his uric acid and potassium levels, which were compatible with a tumor lysis syndrome. On the 6th post-procedural day, the patient complained of new right knee pain. Subsequent joint aspiration revealed monosodium urate monohydrate crystals. We made the diagnosis of acute gouty arthritis arising from tumor lysis and liver infarction caused by HCC ablation, which was aggravated by acute renal insufficiency. After adequate hydration and administration of oral colchicines, the patient's right knee pain subsided and

the uric acid serum level returned to normal. This is the first described case of acute gouty arthritis after RFA for a HCC lesion in a patient with underlying chronic renal insufficiency. To avoid hyperuricemia and an acute attack of gout after RFA therapy for HCC, early identification of patients at risk is warranted, such as those with a large tumor, rapid tumor growth, and renal insufficiency, and preventative measures should be considered.

### INTRODUCTION

Although the optimal treatment for hepatocellular carcinoma (HCC) is surgical resection, there are only a small number of patients who meet resectability criteria for HCC<sup>[1]</sup>. Percutaneous radiofrequency thermal ablation (RFA) is one of the emerging therapeutic modalities used for the minimally invasive treatment in the management of liver malignancies, particularly in patients who cannot undergo surgery<sup>[2,3]</sup>. It has been reported that the morbidity and mortality rates are low, and there are few complications associated with RFA<sup>[4,5]</sup>. Although RFA is relatively well-tolerated, severe and potentially fatal complications, such as liver failure, colon perforation and portal vein

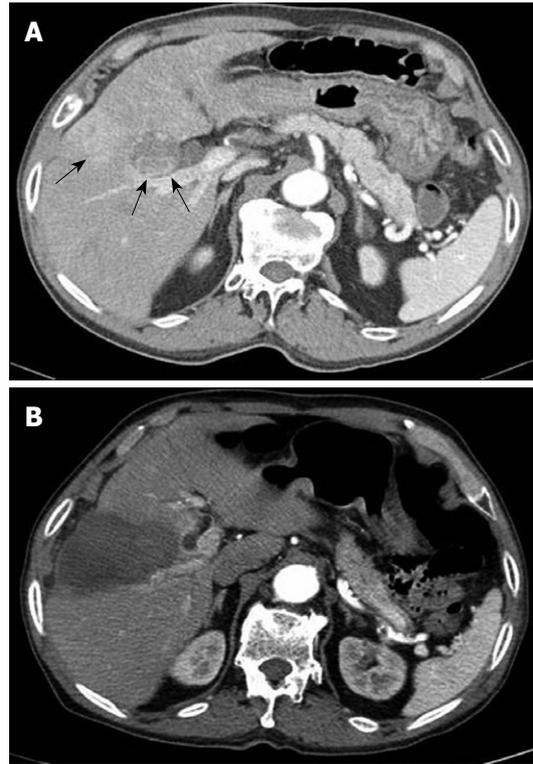

thrombosis can arise<sup>[6,7]</sup>. In addition, there are non-fatal serious complications, such as liver abscess, pleural effusion, skin burns, hypoxemia during treatment, pneumothorax, subcapsular hematoma, acute renal insufficiency, hemoperitoneum, needle tract seeding, and self-limited post-ablation syndrome<sup>[8]</sup>. However, acute gouty arthritis attacks following RFA for HCC have not been reported. We describe a case of gouty arthritis in a 71-year-old man who was treated with RFA for a large HCC in segment IV of the liver adjacent to the gallbladder bed.

## CASE REPORT

A 71-year-old male with hepatitis B virus-associated cirrhosis had undergone a previous percutaneous ethanol injection for a small HCC. Regular surveillance detected a 3.5 cm HCC lesion at segment IV of the liver adjacent to the gallbladder, posterior to the lesion where a previous percutaneous ethanol injection had been performed (Figure 1A). The baseline laboratory tests showed thrombocytopenia (platelet count,  $101 \times 10^3/\text{mm}^3$ ; normal range,  $150\text{--}440 \times 10^3/\text{mm}^3$ ), an elevated blood urea nitrogen level (44 mg/dL; normal range, 8–20 mg/dL), an increased creatinine level (1.8 mg/dL; normal range, 0.4–1.0 mg/dL), a normal uric acid level (5.5 mg/dL; normal range, 2.6–8.0 mg/dL), and a normal potassium level (3.7 mmol/L; normal range, 3.6–5.0 mmol/dL). The liver function tests revealed a borderline low albumin level (3.2 g/dL; normal range, 3.2–4.9 g/dL), a normal total bilirubin level (1.1 mg/dL; normal range, 0.3–1.2 mg/dL) and a normal prothrombin time (international normalized ratio, 0.93). The other laboratory tests, including the total calcium, phosphorus, lactate dehydrogenase (LDH), and aspartate transaminase levels, were within normal limits. Among several curative treatment options available, RFA was chosen for further therapy because the patient had declined surgery. Written informed consent was obtained from the patient before RFA.

RFA was performed under sonographic guidance using a 3.5 MHz convex probe (Sequoia, Siemens Medical Solutions). The treatment was performed under local anesthesia using 100 µg of fentanyl citrate (Myengmun) to control pain. The vital signs were monitored continuously during the procedure. Once proper positioning of the electrode in the tumor area had been confirmed by sonography, the electrodes were connected to a 500 KHz monopolar radiofrequency generator (CC-1, Valleylab) capable of producing 200 W. Four internally cooled 17-gauge electrodes (Cool-Tip, Valleylab) with 3.0 cm exposed tips delivered radiofrequency energy to the tumors. During withdrawal of the electrode, the entire electrode track was heated briefly to a temperature of 80°C by application of radiofrequency. The procedure lasted 23 min with complete ablation of the HCC without apparent complications, such as injury to the gallbladder, on the immediate follow-up computed tomography scan (Figure 1B).

The morning after the procedure, the patient complained of abdominal distension. A simple abdominal radiograph revealed no evidence of bowel perforation,

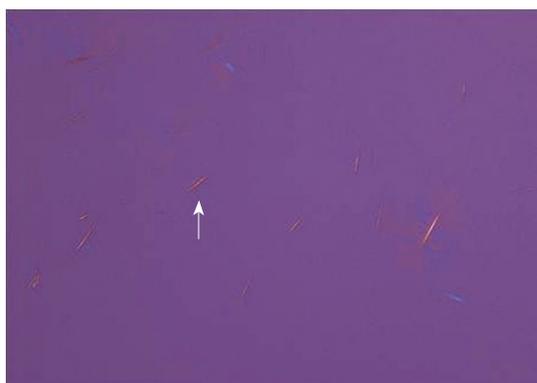

**Figure 1** Computed tomography (CT) scan of the patient. A: CT scan in an arterial phase demonstrates a 3.5 cm hepatocellular carcinoma lesion (arrows) at segment IV of the liver adjacent to the gallbladder, posterior to the lesion where a previous percutaneous ethanol injection has been performed; B: CT scan obtained after radiofrequency thermal ablation reveals complete ablation for the hepatocellular carcinoma without apparent complications such as a gallbladder injury on the immediate follow-up.

although the large intestine was distended (Figure 2). The laboratory results were normal, except an elevation of the potassium level (5.0 mmol/L) and a sustained elevated creatinine level (1.7 mg/dL). On the third post-procedural day, although the patient's symptoms had not changed, repeat laboratory results showed that his uric acid level had increased to 8.7 mg/dL, and the potassium level was maintained at 5.1 mmol/L, which were compatible with a tumor lysis syndrome. The urine output was adequate, and the acid-base gas analysis revealed no disturbances. The patient was hydrated with crystalloids and subjected to close observation. On the 6th post-procedural day, the patient complained of new right knee pain. The physical examination showed swelling and tenderness on the medial side of the right knee that was warm to touch. Joint aspiration revealed a yellow serous fluid that was confirmed, by polarizing microscopy, to be monosodium urate monohydrate crystals (Figure 3). On the same day, the laboratory data revealed that the serum uric acid and creatinine levels increased to 9.8 mg/dL and 3.2 mg/dL, respectively, which were both higher than the baseline levels before the RFA procedure. We made the diagnosis of acute gouty arthritis arising not only from tumor lysis caused by HCC ablation, but also from liver infarction adjacent to the tumor by broad ablation, which was aggravated by acute renal insufficiency in chronic renal failure. We treated the patient with an adequate intravenous

**Figure 2** A simple abdominal radiograph reveals no evidence of bowel perforation, except a distension of the large intestine.

**Figure 3** Strongly negative birefringent, needle-shaped monosodium urate crystals (arrow) in synovial fluid from a patient under compensated polarized light.

crystalloid infusion and oral colchicine (0.6 mg/d). As a result, the patient's right knee pain subsided. On the 11th post-procedural day, the uric acid level was within normal limits (7.2 mg/dL) and the levels of other electrolytes and creatinine had returned to baseline values.

## DISCUSSION

Tumor lysis syndrome has been reported for many different types of poorly differentiated lymphomas, such as high grade non-Hodgkin's lymphoma, Burkitt's lymphoma, and acute lymphocytic leukemia<sup>[9]</sup>. Because this syndrome is mostly frequently related to the cytotoxic treatment of poorly differentiated lymphomas or combination chemotherapy, it has rarely been reported for solid organ tumors, including lung, breast, and advanced gastric cancers<sup>[10-12]</sup>. However, several recent reports have demonstrated that tumor lysis syndrome may occur after various treatments of HCC, including RFA and transarterial chemoembolization (TACE)<sup>[13-15]</sup>. Shiba *et al*<sup>[14]</sup> reported a case of TACE-induced tumor lysis syndrome resulting from necrosis of a large HCC. Moreover, they suggested that factors predisposing a patient to tumor lysis include large tumor size, tumors with high sensitivity to treatment, renal insufficiency, dehydration, and hyperuricemia before treatment<sup>[14]</sup>.

Tumor lysis syndrome causes hyperuricemia, hyperkalemia, hyperphosphatemia and hypocalcemia, and may lead to acute renal failure or metabolic acidosis resulting

from deposition of uric acid in the kidney, and calcium phosphate complex in renal tubules<sup>[16]</sup>. In our patient, although metabolic acidosis did not develop, tumor lysis syndrome, including hyperuricemia, hyperkalemia, and acute renal failure did develop. Therefore, we believe that acute tumor lysis syndrome occurred in our patient as a result of tumor necrosis following RFA.

Lehner *et al*<sup>[15]</sup> reported a death caused by acute tumor lysis syndrome after ablation of a 3.2 cm HCC. They indicated that patients with pre-existing azotemia, along with elevated baseline LDH which exists in most cases of cirrhosis, and elevated uric acid level are at increased risk of tumor lysis syndrome<sup>[15]</sup>. Therefore, we suggest that the predisposing factors in our case included underlying cirrhosis with pre-existing azotemia. Moreover, because we observed that the ablated field was large compared to the target lesion, we believe hyperuricemia could be caused by liver infarction induced by ablation.

We describe, for the first time, a case of acute gouty arthritis as a possible complication following thermal ablation for HCC. A definite diagnosis of gout was made by identification of monosodium urate crystals within phagocytes in the synovial fluid using compensated polarized microscopy<sup>[17]</sup>. It is well known that numerous circumstances, such as surgery, dietary overindulgence, and ingestion of drugs affecting serum uric acid concentrations are associated with acute attacks of gouty arthritis<sup>[18]</sup>. The likely explanation for the development of acute gouty arthritis in this elderly man was the abrupt increase in the serum uric acid level from tumor cell necrosis after HCC ablation. Therefore, in this case, the acute gouty attack on the 6th post-procedural day was likely caused not only by chronic renal insufficiency, but also by hyperuricemia following tumor cell lysis and liver infarction.

After the diagnosis of acute gouty arthritis was established, the patient received colchicine immediately. Although colchicine is not a urate-lowering agent, adequate hydration and colchicine administration resulted in lowering of the serum level of uric acid to the baseline value and resolution of the patient's right knee pain 2 d after drug administration.

To date, RFA is considered an effective procedure for providing local control in HCC patients. RFA is associated with the possibility of effecting long-term, disease-free survival in selected patients compared to other local techniques, such as cryoablation and percutaneous ethanol injection<sup>[19,20]</sup>. Although RFA is a generally well-tolerated and relatively safe localized-regional therapy, complications can develop<sup>[4-8]</sup>. A recent report showed that RFA was associated with a 4% rate of major complications, a 4.8% rate of minor complications, and a negligible risk of death<sup>[4,5]</sup>. As shown in this case, acute gouty arthritis is not a life-threatening condition, but it affects the quality of life of the patient. Therefore, during therapy, patients who are at risk should be monitored closely for this possible complication. To avoid hyperuricemia and acute gouty arthritis after RFA therapy for HCC, early identification of patients at risk is warranted, such as those with a large tumor, rapid tumor growth, and renal insufficiency, and

preventative measures should be considered.

In conclusion, this is the first described case of acute gouty arthritis after RFA for a HCC lesion in a patient with underlying chronic renal insufficiency. This complication should be considered in patients at risk. Appropriate screening, management, and treatment may reduce the complications associated with RFA.

### Abstract

A female patient with anemia and hypoalbuminemia was admitted to our hospital due to an over 20-year history of recurrent dizziness, fatigue and ankle edema. She was diagnosed as multiple chronic non-specific ulcer of the small intestine characterized by non-specific histology and persistent gastrointestinal bleeding.

### INTRODUCTION

With the wide use of capsule endoscopy, small intestinal ulcer associated with chronic bleeding is commonly seen in clinical practice. However, its diagnosis and treatment are complicated. After the causes of ulcer such as Crohn's disease, Behcet's disease and tuberculosis are excluded, most cases are diagnosed as "idiopathic chronic ulcerative enteritis"<sup>[1]</sup>. Since 1960, cases of non-specific ulcer of small intestine have been reported<sup>[2-4]</sup>. Most of them were caused by non-steroidal anti-inflammatory drugs (NSAID) or potassium tablets. Matsumoto *et al*<sup>[5,6]</sup> have reported a multiple chronic non-specific ulcer of small intestine (CNSU), which is not related to NSAID. We, here, report a case of multiple chronic non-specific ulcer of the small intestine characterized by non-specific histology and persistent gastrointestinal (GI) bleeding.

### CASE REPORT

A 42-year-old female was admitted to our hospital due to an over 20-year history of recurrent dizziness, fatigue and ankle edema. Over the past 20 years, she had dizziness, fatigue and abdominal distension without any identifiable causes. At the same time, she developed ankle edema which resolved spontaneously after rest. Laboratory test at a local hospital showed that she had severe iron deficiency anemia [hemoglobin (HB) 27 g/L] and hypoalbuminemia (albumin 11 g/L). Her symptoms could always be relieved temporarily after intravenous infusion of albumin and packed red blood cells. However, over the past 4 mo, she had repeated episodes of chest tightness and palpitation after activities. She also complained of intermittent abdominal pain after meal but had no fever, nausea or vomit. Her bowel movements were normal except for occasionally mild diarrhea. She denied any decreased appetite, nausea and vomiting, hematemesis, hematochezia, melena, tenesmus and stools with mucus or pus.

She had no known history of hepatitis or chronic renal disease or smoking or alcohol, and exposure to contaminated water. She denied any use of NSAID. Her parents were healthy and her little brother was dead at the age of 10 years due to unknown cause. Her son and husband were healthy.

Physical examination demonstrated that her temperature was 36.8°C, blood pressure was 92/60 mmHg, respiration was 18/min, and heart rate was 92 bpm. The patient was alert and fully oriented but appeared pale, cold and clammy. She had no jaundice, liver palm or spider angioma, eruption or purpura on the skin. No superficial lymph nodes could be palpated. Her trachea was slightly shifted to the left with no jugular venous distention. Her right chest wall movement and tactile fremitus over the right lung base were decreased with absent breath sounds and dullness to percussion. Her heart had a grade 2/6 diastolic murmur at the apex. An abdominal bulge and positive shifting dullness were found with active bowel sound. No abdominal wall vein dilatation, tenderness or rebound tenderness were found. No mass, liver and spleen were palpable. Digital rectal examination was negative. She had moderate pitting edema of the lower extremities.

Her white blood cells were  $8.0 \times 10^{12}/L$ , HB was 59 g/L, mean cell volume was 65 fL, mean corpuscular hemoglobin was 18.1 pg, and platelets were  $445 \times 10^9/L$ . Her TB/CB was 0.15/0.07 mg/mL, A/G was 1.3/2.0, alanine aminotransferase was 25 U/L, aspartate aminotransferase was 20 U/L, reticulocytes was 2.9%, erythrocyte sedimentation rate was 28 mm/h. Bone marrow aspiration showed proliferation of erythrocyte lineage and mature red blood cells with an increased central pallor. Iron staining revealed 2% intracellular iron but no extracellular iron. No proteinuria or haematuria was detected at a urinalysis. Renal function was normal. Rheumatoid factors and full antinuclear autoantibodies were negative. Serological tests were negative for hepatitis B virus, hepatitis C virus and human immunodeficiency virus. Her serum  $K^+$  and  $Na^+$  were 3.15 mEq/L and 133 mEq/L, respectively. Abdominal ultrasonography showed the presence of moderate ascites and a right pleural effusion. Fecal occult blood test (FOBT) was positive while stool culture was negative. Both upper GI endoscopy and colonoscopy were negative. Capsule endoscopy showed multiple, sharply demarcated ulcers limited in the ileum with a circular shape. The margins of ulcers were clear and the intervening mucosa was normal. Stenosis could also be seen in the ileum.

The patient was treated with intravenous infusion of albumin and packed red blood cells as well as intramuscular injection of iron. After 4 wk of treatment, the dizziness and abdominal distension were gradually improved and lower extremity edema also receded. Hb increased temporarily to 90 g/L and abdominal ultrasound showed only a small amount of ascites and pleural effusion. However, FOBT remained positive and abdominal pain did not relieve. Oral prednisone was given for 1 wk but did not relieve the pain. A laparotomy was proposed

but she refused. She was discharged and scheduled for outpatient follow-up.

## DISCUSSION

GI bleeding-induced anemia is the most typical presenting symptom of patients suffering from CNSU and low serum protein concentration is also seen<sup>[5]</sup>. Our patient had pronounced anemia and hypoalbuminemia. Her initial manifestation was pronounced anemia followed by ascites and pleural effusions. The diagnostic criteria for CNSU were established as previously described<sup>[6]</sup>, including persistent anemia for more than 1 year, small intestinal ulcers, absence of clinical evidence suggestive of mycobacterial infection, absence of clinical evidence suggestive of Crohn's disease, and lack of any dermatologic, ophthalmologic or genital symptom suggestive of Behcet's disease. The ulcers in our patient were different from those of Crohn's disease characterized by longitudinal ulcers and cobblestone appearance. There was also no evidence of complication suggestive of Crohn's disease because no perforation and fistulisation were found although the patient had a very long course of disease. Behcet's disease could also be excluded since there was no clinical evidence showing dermatologic, ophthalmologic or genital symptom in our patient.

Capsule endoscopy confirmed the diagnosis of CNSU in our patient. Matsumoto *et al.*<sup>[5]</sup> reported that ulcers in CNSU patients are predominantly found in the ileum, which are circular or irregular in shape. The margins of ulcers are always clear and the intervening mucosa appears normal. Capsule endoscopy showed typical circular ulcers limited in the ileum of our patient, which is consistent with the reported findings<sup>[5]</sup>.

The clinical and endoscopic features of CNSU are similar to those of NSAID-induced enteropathy. Matsumoto *et al.*<sup>[6]</sup> compared the enteroscopic findings in CNSU and NSAID-induced enteropathy, and found that both are characterized by concentric stenosis and ulcers with non-specific histology while the lesions of small intestine are different in respect to their site and stage. CNSU patients have active, sharply demarcated ulcers limited in ileum while few ulcers are found in NSAID-induced enteropathy. Since our patient had no history of NSAID use, the possibility of NSAID-induced enteropathy could be excluded.

CNSU is different from another idiopathic small intestinal multiple ulcer disease described as cryptogenic multifocal ulcerous stenosing enteritis (CMUSE)<sup>[7]</sup>, which is an independent, rare and poorly understood disease characterized by non-specific small intestinal ulceration and stenosis which responds to corticosteroid therapy<sup>[7]</sup>. Perlemuter *et al.*<sup>[7]</sup> described that CMUSE syndrome is characterized by chronic diarrhea, bouts of intestinal obstruction, and ulcerative stenosis of the small intestine. A very important feature of CMUSE is that patients respond dramatically to corticosteroid therapy<sup>[7]</sup>. However, the therapeutic effect of corticosteroid in our patient was not good. Another dif-

ference is that anemia and hypoalbuminemia are not often seen in CMUSE patients. Our patient had a long history of pronounced anemia and hypoalbuminemia prior to the development of abdominal pain, suggesting that stenosis may not develop rapidly in CNSU.

Capsule endoscopy is the best diagnostic tool for obscure GI bleeding. Our patient was admitted because of her chronic GI bleeding with unknown origin. Since upper GI endoscopy and colonoscopy showed negative results, capsule endoscopy showed multiple circular ulcers. The affected site was limited in the ileum, thus providing the most important evidence for the diagnosis of our patient.

In conclusion, the pathophysiology of CNSU remains poorly understood. CNSU is a disease responsible for obscure GI bleeding arising from the small intestine. Capsule endoscopy contributes to the diagnosis of this peculiar form of small intestine disease.

### Abstract

The PillCam ESO (Given Imaging, Israel) or esophageal capsule endoscopy (ECE) is a novel technique used in the diagnostic evaluation of esophagus. Many studies have been performed to compare the accuracy of ECE against the current gold standard esophago-gastro-duodenoscopy and a meta-analysis recently published by Lu *et al* suggests that ECE may have an acceptable sensitivity and specificity in detecting esophageal varices. We would like to discuss the importance and implication of publication bias in this meta-analysis.

### TO THE EDITOR

In March 2009 issue of *World Journal of Gastroenterology*, Lu *et al*<sup>[1]</sup> published their interesting findings regarding the accuracy of esophageal capsule endoscopy (ECE) in detecting esophageal varices and its utility in screening and surveillance of esophageal varices. We would like to add that it is vital to comment on the presence or absence of any bias when reporting a meta-analysis as this will allow the readers to assess the strengths and weaknesses of the recommendation made. A recently published statement on preferred reporting items for systematic reviews and meta-analyses (PRISMA)<sup>[2]</sup>, an evolution of the original quality of reporting of meta-analyses (QUOROM) guidelines, suggests that publication bias should be assessed while reporting meta-analyses and systematic reviews. Since publication bias was not reported in the above meta-analysis, we analyzed the data for the presence or absence of publication bias.

We assessed the publication bias using funnel plot. Funnel plots were plotted using log odds ratio *vs* standard error (Figure 1A) and log odds ratio *vs* precision (Figure 1B), both showed no evidence of publication bias. We complemented the funnel plots with Eggers test<sup>[3]</sup> and rank correlation analysis<sup>[4]</sup> and both also showed no evidence of publication bias ( $P > 0.05$ ).

We hope that this information about the absence of publication bias in this meta-analysis will add more value to the conclusion reported in the above meta-analysis.

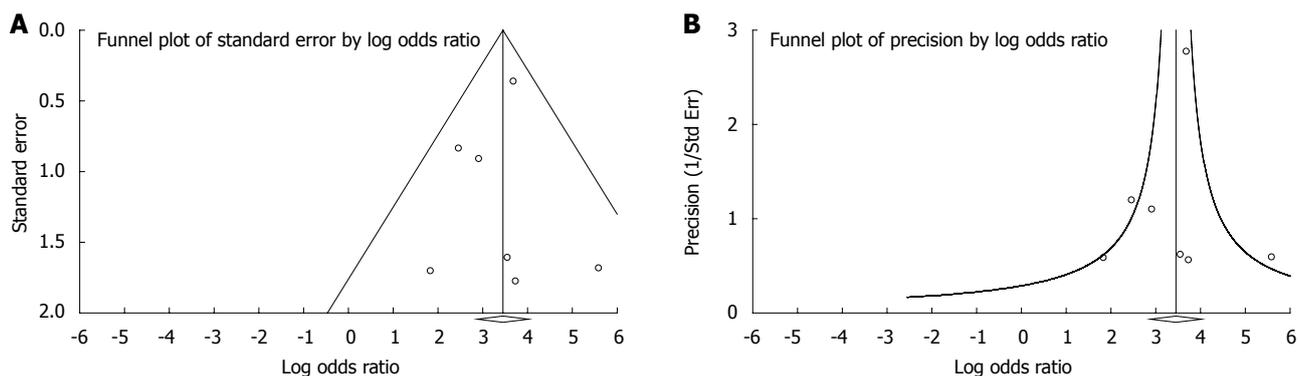

Figure 1 Funnel plot. A: Log odds ratio vs standard error; B: Log odds ratio vs precision (Precision = 1/standard error).

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systemically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### Published by

Beijing Baishideng BioMed Scientific Co., Ltd.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

## Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

ISSN 1007-9327

## Contents

Weekly Volume 16 Number 7 February 21, 2010

### EDITORIAL

- 787 Ontogeny, growth and development of the small intestine: Understanding pediatric gastroenterology  
*Drozdowski LA, Clandinin T, Thomson ABR*
- 800 Is the control of dietary cholesterol intake sufficiently effective to ameliorate nonalcoholic fatty liver disease?  
*Enjoji M, Nakamuta M*

### TOPIC HIGHLIGHT

- 804 Current indications and role of surgery in the management of sigmoid diverticulitis  
*Stocchi L*

### REVIEW

- 818 Vascular invasion in pancreatic cancer: Imaging modalities, preoperative diagnosis and surgical management  
*Buchs NC, Chilcott M, Poletti PA, Buhler LH, Morel P*
- 832 Diffusion-weighted MRI in abdominal oncology: Clinical applications  
*Sugita R, Ito K, Fujita N, Takahashi S*

### ORIGINAL ARTICLE

- 837 Analgesic effects of JCM-16021 on neonatal maternal separation-induced visceral pain in rats  
*Bian ZX, Zhang M, Han QB, Xu HX, Sung JJY*
- 846 Celecoxib inhibits *Helicobacter pylori* colonization-related factors  
*Wang J, Wang WH, Li J, Liu FX*
- 854 MicroRNA155 is induced in activated CD4<sup>+</sup> T cells of TNBS-induced colitis in mice  
*Chen DF, Gong BD, Xie Q, Ben QW, Liu J, Yuan YZ*

## BRIEF ARTICLE

- 862 Colorectal cancer prognosis twenty years later  
*Bujanda L, Sarasqueta C, Hijona E, Hijona L, Cosme A, Gil I, Elorza JL, Asensio JI, Larburu S, Enríquez-Navascués JM, Jover R, Balaguer F, Llor X, Bessa X, Andreu M, Paya A, Castells A, Gastrointestinal Oncology Group of the Spanish Gastroenterological Association*
- 868 Surgical outcome after docetaxel-based neoadjuvant chemotherapy in locally-advanced gastric cancer  
*Biffi R, Fazio N, Luca F, Chiappa A, Andreoni B, Zampino MG, Roth A, Schuller JC, Fiori G, Orsi F, Bonomo G, Crosta C, Huber O*
- 875 A novel cleansing score system for capsule endoscopy  
*Park SC, Keum B, Hyun JJ, Seo YS, Kim YS, Jeon YT, Chun HJ, Um SH, Kim CD, Ryu HS*
- 881 Etiological and clinicopathologic characteristics of intrahepatic cholangiocarcinoma in young patients  
*Zhou HB, Wang H, Zhou DX, Wang H, Wang Q, Zou SS, Hu HP*
- 886 Does *Helicobacter pylori* infection play a role in iron deficiency anemia? A meta-analysis  
*Qu XH, Huang XL, Xiong P, Zhu CY, Huang YL, Lu LG, Sun X, Rong L, Zhong L, Sun DY, Lin H, Cai MC, Chen ZW, Hu B, Wu LM, Jiang YB, Yan WL*
- 897 Betaine inhibits Toll-like receptor 4 expression in rats with ethanol-induced liver injury  
*Shi QZ, Wang LW, Zhang W, Gong ZJ*
- 904 Role of *RECK* methylation in gastric cancer and its clinical significance  
*Du YY, Dai DQ, Yang Z*

## CASE REPORT

- 909 Successful endoscopic procedures for intraductal papillary neoplasm of the bile duct: A case report  
*Tsuchida K, Yamagata M, Saifuku Y, Ichikawa D, Kanke K, Murohisa T, Tamano M, Iijima M, Nemoto Y, Shimoda W, Komori T, Fukui H, Ichikawa K, Sugaya H, Miyachi K, Fujimori T, Hiraishi H*

## LETTERS TO THE EDITOR 914

- Monocyte chemotactic protein-1* gene polymorphism and spontaneous bacterial peritonitis  
*Filik L*

**ACKNOWLEDGMENTS** I Acknowledgments to reviewers of *World Journal of Gastroenterology*

**APPENDIX** I Meetings  
I-IV Instructions to authors

**AIM AND SCOPE**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

**FLYLEAF** I-VII Editorial Board

**EDITORS FOR THIS ISSUE**

Responsible Assistant Editor: *Xiao-Fang Liu*  
Responsible Electronic Editor: *Wen-Hua Ma*  
Proofing Editor-in-Chief: *Lian-Sheng Ma*

Responsible Science Editor: *Lin Tian*  
Proofing Editorial Office Director: *Jian-Xia Cheng*

**NAME OF JOURNAL**  
*World Journal of Gastroenterology*

**LAUNCH DATE**  
October 1, 1995

**RESPONSIBLE INSTITUTION**  
Department of Science and Technology of Shanxi Province

**SPONSOR**

### Abstract

Throughout our lifetime, the intestine changes. Some alterations in its form and function may be genetically determined, and some are the result of adaptation to diet, temperature, or stress. The critical period programming of the intestine can be modified, such as from subtle differences in the types and ratios of n3:m6 fatty acids in the diet of the pregnant mother, or in the diet of the weanlings. This early forced adaptation may persist in later life, such as the unwanted increased intestinal absorption of sugars, fatty acids and cholesterol. Thus, the ontogeny, early growth and development of the intestine is important for the adult gastroenterologist to appreciate, because of the potential for these early life events to affect the responsiveness of the intestine to physiological or pathological challenges in later life.

### INTRODUCTION

The molecular mechanisms of fetal development of the intestine have been explored using transgenic and knock-out mice, with the suggestion of the importance of Wnt, bone morphogenetic protein (BMP), PTEN/PI3K and Notch signaling<sup>[1]</sup>. After midgestation, the stratified cuboidal intestinal epithelium, derived from endoderm, begins to form villi as a result of epithelial-mesenchymal interactions<sup>[2]</sup>. Wnt and Indian hedgehog signaling interact to stimulate proliferation and to act as a morphogen, in turn acting on BMP signals in the mesenchyme to influence morphogenesis during the development of the intestine<sup>[3]</sup>. The cellular differentiation along the crypt-villus axis is maintained by Wnt pathway target genes<sup>[4,5]</sup>. Unphosphorylated active PTEN in turn controls the activation of the lipid kinase PI3 kinase pathway, where the PDK1 and especially the PKB (Akt) ser1Thr kinases act as the main effector kinases of this proliferative pathway<sup>[6]</sup>.

These complex processes are integrated to produce functionally important alterations during late intrauterine and early postnatal life of intestinal morphology and function, to prepare the infant for early feeding on high-fat milk, and then weaning onto lower fat-but higher carbohydrate-containing solid foods. Understanding these ontogenic events helps to understand the early age-dependent approach to nutritional disease state.

## INTESTINAL MORPHOLOGY

At the time of birth, the human small intestine is morphologically and biochemically more mature than that of other mammals. Of interest though, since rodents are born at a more immature stage than humans, at least some of the brush border membrane (BBM) enzymatic maturation that occurs prenatally in humans only occurs after birth in rodents. This makes the rodent a useful model to better understand the process of intestinal maturation that occurs in premature infants.

The maturity of the small intestine is reflective of the length of the gestational period, with the developments of the human small intestine being largely completed in utero by the end of the first trimester<sup>[7]</sup>. Despite temporal differences in the ontogeny of the small intestine between species, the processes involved in the development of the small intestine remain similar. Thus, the human intestine goes through each of the stages that occur in rodents, so that animal studies may be used to better understand the development of the human intestine.

Development of the small intestine is comprised of three stages: (1) morphogenesis and cell proliferation, (2) cell differentiation, and (3) functional maturation<sup>[8]</sup>. Gastrulation is the process by which the primitive gut tube is formed. This consists of the endoderm, the precursor to the epithelial lining of the gastrointestinal (GI) tract, surrounded by mesenchyme. In humans, this process begins at three weeks gestation<sup>[7]</sup>.

In the embryo, the GI system is one of the first to polarize by forming an entry and exit to the systems along the anterior and posterior axis. The *hox* genes are nuclear transcription factors that activate genes that encode secretory proteins. The *hox* genes play an important role in the formation of distinct regions of the brain and skeleton<sup>[7]</sup>. Through epithelial-mesenchyme interactions, these proteins may also be involved in determining anterior-posterior patterning in the fetal gut. Similarly, Sonic hedgehog and Indian hedgehog pathways mediate epithelial-mesenchymal interactions at early stages of gut formation<sup>[2]</sup>.

Next, there is a transition into columnar epithelium, with the development of polarized enterocytes, and the formation of the BBM and basolateral membrane (BLM) of the enterocyte. The formation of nascent villi and microvilli occurs simultaneously, with cellular proliferation detectable along the villi. In humans, formation of the villus is initiated at 9-10 wk gestation, and proceeds in a cranial-caudal direction<sup>[7]</sup>. Villus and microvillus formation account for the approximate 100 000-fold increase in the intestinal surface area observed from the early first trimester period to birth<sup>[9]</sup>.

The development of intestinal crypts then follows in humans, but in rodents, crypts do not develop until after birth<sup>[10]</sup>. The human fetus and the neonatal rat have transient villus-like structures in the proximal colon with properties similar to enterocytes, including the expression of BBM enzymes and transporters<sup>[11-13]</sup>. In later life, when premalignant changes occur in the colon in the

form of development of colonic adenomatous polyps, the villous structure may recur. Interestingly, CaCO<sub>2</sub> cells derived from human colon cancer cells develop villi and villous functions, and are a good cell culture model for the assessment of, for example, intestinal absorption and metabolism.

The cells of the intestinal mucosa (the antagonists, enteroendocrine cells, Paneth and goblet cells) are compartmentalized within the crypt-villus unit. All four of the differentiated cell types of the intestinal mucosa are derived from one or more multipotent stem cells located in each intestinal crypt<sup>[14]</sup>. As cells move out of the crypt and up the villus or deeper into the crypts, "...differentiation occurs as progeny of the transit cell population migrate in vertically coherent bands..."<sup>[15]</sup>. Fibroblast growth factor receptor 3 (FGFR-3) is highly expressed in the undifferentiated crypt epithelial cells in the developing intestine, and FGFR-3 signaling through  $\beta$ -catenin/Tcf-4-dependent and independent pathways may regulate crypt epithelial stem cell expansion and crypt morphogenesis by the process of crypt bifurcation or fission<sup>[15]</sup>. Other growth factors such as Wnt(s) and FGF2 may cross talk with the  $\beta$ -catenin signaling pathway<sup>[16]</sup>.

Cellular proliferation occurs in the crypts, differentiated cells populate the villi, and the dynamic balance between proliferation and differentiation is balanced by apoptosis of the senescent cells. Hepatocyte nuclear factor 4  $\alpha$  (HNF4 $\alpha$ ) belongs to the family of nuclear receptor transcription factors found in the liver, pancreas, kidney, and intestinal tract<sup>[17,18]</sup>. HNF4 $\alpha$  may instruct "...cells to become specific to the intestinal epithelium"<sup>[19]</sup>, as well as upregulating genes during epithelial cell differentiation such as Apo A-IV, intestinal alkaline phosphatase, liver and intestinal fatty acid binding proteins<sup>[20-23]</sup>.

Bile acids regulate their own synthesis<sup>[24]</sup>. The luminal concentration of bile acids and the bile acid pool are low in the preterm and term infant, and rise as the animal ages<sup>[25,26]</sup>. These initially low values are associated with malabsorption of lipids<sup>[27]</sup>. The size of the bile acid pool increases with the activity of cholesterol 7 $\alpha$ -hydroxylase (Cyp7a1) and oxysterol 7 $\alpha$ -hydroxylase (Cyp7b1) by mechanisms that are independent of the farnesyl X receptor (FXR), and the short heterodimeric pathway (SHP)<sup>[24]</sup>.

Increased bile acid absorption by the ileal apical sodium-dependent bile acid cotransporter (ASBT) also contributes to the expansion of the bile acid pool.

In mouse models of necrotizing enterocolitis (NEC)<sup>[28]</sup>, the preinflammatory transcription factor NF- $\kappa$ B mediates this intestinal injury as the result of platelet activating factor (PAF) converting p105 into p50. The p50 further upregulates proinflammatory cytokines which lead to a systemic inflammatory response and acute bowel injury<sup>[29]</sup>.

Peroxisome proliferator-activated receptor-j (PPARj) is a nuclear receptor which associates with retinoid X receptor to "...suppress proliferation and promote differentiation of intestinal epithelial cells..." and to decrease the size of the proliferative zone of the intestinal crypts<sup>[30-32]</sup>. The thiazolidinedione drugs are PPARj ago-

nists which reduce cholera toxin mediated chloride secretion through the reduced expression of the apical CFTR channels, KCNQ1 K<sup>+</sup> channels as well as Na<sup>+</sup>-K<sup>+</sup>-2Cl<sup>-</sup> cotransporter-1 proteins in the BLM<sup>[33]</sup>.

In addition to the enterocytes, four other small intestinal mucosal cell types develop: goblet cells, enteroendocrine cells, Paneth cells, and M cells. M cells are associated with Peyer's patches, and are detected by 17 wk of gestation<sup>[34]</sup>. In the human intestine, all epithelial cell types known to occur in the adult are present by the end of the first trimester<sup>[34]</sup>. The intestinal epithelium is able to maintain the differentiation programs of each lineage, depending on the location of the cells along the crypt-villous and proximal-distal gradients<sup>[35,36]</sup>.

The regulation of GI development is complex, and involves a host of growth and transcription factors. Receptors for epidermal growth factor (EGF), transforming growth factor  $\beta$  (TGF $\beta$ ), insulin-like growth factor II (IGF-II), hepatocyte growth factor (HGF), and GLP-2 are present in fetal human intestine<sup>[37,38]</sup>. Human fetal cortisone levels in the blood increase late in gestation<sup>[39]</sup>. Corticosterone (a glucocorticoid similar to cortisol) is thought to be the main factor involved in rat small intestinal maturation<sup>[40,41]</sup>.

Studies investigating the development of human fetal small intestine xenografted to SCID mice demonstrate that the transplanted intestine normally undergoes differentiation in the absence of luminal and hormonal factors<sup>[42,43]</sup>. This finding, in conjunction with the observation that villus formation in rodents is autonomous<sup>[44]</sup>, suggests that intestinal development may be "hard-wired", i.e. is regulated largely by intrinsic factors, with extrinsic factors playing only a secondary role. Indeed, several transcription factors including *N-myc*, HNF3 $\beta$  and *Cdx-2* have been identified as potential intrinsic factors implicated in GI development. *N-myc* gene knock-out animals demonstrate defects in GI development<sup>[45]</sup>. Homologous null mutants of HNF3 $\beta$  are lethal, as many structures, including the gut tube do not develop normally<sup>[46,47]</sup>. *Cdx-2* expression is detected at the time of morphogenesis in mouse intestine, and is a known regulator of the expression of the small intestinal BBM enzymes sucrase-isomaltase (SI)<sup>[48]</sup>.

The exogenous expression of *Cdx-2* in a rat intestinal cell line induces the differentiation of goblet and absorptive cells from crypt cells. This suggests a possible role of *Cdx-2* in the ontogeny of the GI tract. Several other signaling pathways (including the Notch, Wnt/ $\beta$ -catenin and BMP pathways) are also thought to play a role in patterning the gut during development, and in regulating epithelial differentiation through epithelial-mesenchymal interactions<sup>[49,50]</sup>. What then is the importance of the extracellular matrix (ECM)?

Indeed, in addition to regulation by transcriptional factors, intestinal development may be controlled through interactions with components of the ECM. Developmental changes in E-cadherins and integrins have been described<sup>[51,52]</sup>, suggesting that the ECM

may influence the ontogeny of epithelial cells. Cultures of human fetal enterocytes demonstrate enhanced differentiation, when they are grown on components of the ECM<sup>[53]</sup>. This suggests that a permissive rather than an instructive role may be attributed to the ECM in GI development. Indeed, when major components of the ECM have been deleted, in mice, they show no changes in GI morphogenesis, indicating that these components are not essential for GI development in this model<sup>[54]</sup>.

## FUNCTIONAL DEVELOPMENT

The functional development of the BBM enzyme activity has been well characterized<sup>[55-58]</sup>.

BBM SI is first detected in the human fetus in the first trimester, but is not seen until weaning in the rat<sup>[58]</sup>. Both rat and human fetal small intestine demonstrate detectable BBM lactase-phlorizin hydrolase (LPH) activity, but LPH expression before and after birth varies depending on the species<sup>[59]</sup>. In humans, BBM enzyme activity has been correlated to morphogenesis, with the development of enzyme activity being associated with the formation of enterocytes<sup>[60]</sup>. Proximal-to-distal gradients of enzyme activity along the length of the small intestine are established early in gestation. In addition, crypt-villous gradients are evident, with LPH activity being highest at the villous tip, and SI activity maximal in the mid-villous region<sup>[61]</sup>.

### LPH

The earliest ingested nutrient in mammals is, of course, milk. The major carbohydrate in milk is disaccharide lactose. Lactose is cleaved by BBM LPH into glucose and galactose. LPH is therefore a crucial enzyme for neonates who are solely dependent on their mother's milk for nourishment.

Human LPH is first detected in the proximal small intestine at 8-9 wk of gestation, but later extends along the length of the small intestine<sup>[60]</sup>. In contrast, rat LPH is very low until 24 wk gestation, when its activity begins to increase. A rise in LPH activity in rodents occurs only late in the third trimester. In the human fetal jejunum, LPH activity correlated with the abundance of its mRNA<sup>[62]</sup>, consistent with the proposal that LPH activity is regulated transcriptionally<sup>[63-65]</sup>. Nuclear transcription factors that have been shown to interact with the LPH promoter element CE-LPH1 include CDX-2<sup>[66]</sup>, HOXC11<sup>[67]</sup>, GATA6<sup>[68]</sup>, and HNF1<sup>[67]</sup>.

Once weaning has occurred in nearly all species of mammals, both LPH activity and mRNA abundance decline<sup>[59,69,70]</sup>. Even in humans, the vast majority of the world's population experiences a decline in LPH activity sometime during childhood or adolescence. These lower values of LPH activity are 5%-10% of those values seen in early childhood<sup>[71]</sup>. In contrast, in geographical regions such as Western Europe and North America, where for thousands of years dairy cattle were raised as a continuing source of milk, LPH activity persists throughout adulthood<sup>[59,69,70]</sup>, unless an adverse process affects the small

intestine. This is known as secondary lactose deficiency (i.e. the decline in LPH activity is secondary to a disease). The decline in LPH activity in early life in characteristic locations is primary, i.e. genetically determined. Thus, if an adult with northern European ancestry presents with new onset milk intolerance, lactose deficiency is suspected, and an underlying condition such as celiac disease or inflammatory bowel disease is looked for.

In humans, the correlation between mRNA abundance and activity of LPH suggest that transcriptional and post-transcriptional mechanisms are involved in the development of hypolactasia<sup>[72]</sup>. Post-translational mechanisms may also be involved in the decline in LPH activity, through the modulation of functional protein along the villus. Glycosylation of the protein results in the 225 kDa form, however, the mature BBM LPH enzyme represents a cleavage product of this glycosylated precursor<sup>[59,73,74]</sup>. The initial cleavage occurs intracellularly in a post-Golgi compartment<sup>[75]</sup>. This yields a protein which lacks LPH activity. Once LPH is inserted in enterocyte BBM, LPH is once again cleaved, but this time by extracellular trypsin, and this yields the mature and active 145 kDa form of the LPH and it is cleaved<sup>[76]</sup>.

## SI

SI is a bifunctional enterocyte BBM disaccharidase with sucrase, isomaltase and maltase activity. Sucrase hydrolyzes sucrose into glucose and fructose. In humans, SI is first detected at 9-10 wk gestation, and gradually increases until just prior to birth, when a marked increase in SI occurs. After birth, there is a rapid decline in SI levels to values comparable to those found in early gestation. Sucrase is not normally a part of the infant's diet, so it is not clear why SI activity is so high in the human fetus.

Fetal human SI protein is in the proSI form from 15-30 wk gestation, but after 30 wk most of the protein consists of sucrase and isomaltase subunits<sup>[77]</sup>. Enterokinase activity, which activates proteases that cleave proSI, appears at 26 wk, and coincides with the appearance of the sucrase and isomaltase subunits.

SI is transiently expressed in the colon of both humans and rodents<sup>[11,13,60,78]</sup> in association with the appearance of small intestinal-like morphology. The observation that SI is expressed in colorectal cancer cells suggests that the factors that normally repress SI expression in the colon may be lost in cancer cells.

In mice, low levels of SI mRNA abundance are detectable in the small intestine<sup>[78]</sup>. However, rat studies show that there is no BBM SI activity from birth until weaning<sup>[58]</sup>. Thus, even between different types of rodents there are variations in BBM SI development. At weaning, a dramatic increase in SI activity occurs, with adult rat levels being rapidly established. Expression of SI mRNA and protein is first detected in cells located at the crypt-villous junction, suggesting that the enterocytes containing SI are programmed in crypts. As these enterocytes migrate up the villus, the entire villus ultimately becomes populated with cells expressing SI. SI expression first appears in the proximal small intestine, and then proceeds distally to the

ileum. This is a genetically programmed event that is not significantly affected by the animals' diet<sup>[70,79]</sup>. Premature SI induction can be induced by precocious stress, glucocorticosteroids, insulin, or thyroxine<sup>[70,79,80]</sup>.

There is a correlation between fetal SI activity and mRNA abundance, suggesting control at the level of either mRNA transcription or stability<sup>[81]</sup>. A number of regulatory elements (including SIF1, SIF2, and SIF3) have been identified within the promoter region of the *SI* gene, and are important for transcriptional induction. CDX-2 binds to the SIF1 element and transactivates the *SI* gene promoter<sup>[48]</sup>. CSX-2 appears to be the major regulator of SI transcription. A number of other potential transcription factors have been identified, such as HOXC11, which like CDX-2, bind to the SIF1 element of the *SI* promoter<sup>[67]</sup>. HNF1 $\alpha$  interacts with the SIF3 element and to a lesser extent SIF2, to activate SI transcription<sup>[82]</sup>. GATA zinc-finger transcription factors interact with a region of the *SI* promoter upstream of the SIF1 element.

Glycosylation of the SI protein occurs in the endoplasmic reticulum (ER) and in the Golgi apparatus, yielding a 245 kDa protein<sup>[83]</sup>. Once the protein is inserted into the BBM, the post-translational processing is by the cleavage of the molecule into two subunits which occurs *via* trypsin digestion in the intestinal lumen<sup>[83]</sup>. The SI subunits remain associated by hydrostatic bonds. Defects in post-translational processing are thought to be responsible for inherited SI deficiency in humans<sup>[84]</sup>.

## Glucose transport

The ontogeny of intestinal nutrient transport is largely dependent on the species that is studied. In all mammals, sugar transporter protein does not appear until the intestine differentiates and forms crypts, villi and microvilli. The time at which this process occurs differs between species (please see above), and may be affected by the length of the gestational period. Differentiation of the mucosa alone, however, is not solely responsible for triggering the appearance of transporters, as many of them do not appear until after birth, or even after weaning.

Much of the research on the ontogeny of intestinal transport comes from rodent studies. Rodents are considered to be altricial, meaning that they are born "premature" as compared to humans. Indeed, many of the postnatal changes in the intestine seen in rats occurs parentally in humans, making neonatal rodents an ideal model for premature infants<sup>[85]</sup>. The pig is also a useful model of ontogeny, due to the similarities between the pig and the human small intestine<sup>[86]</sup>.

The intestinal transport of nutrients, such as glucose, is first detected in the fetal small intestine of mammals, including humans<sup>[87]</sup>. Both placental nutrients<sup>[88,89]</sup> as well as the swallowing of amniotic fluid<sup>[90]</sup> contribute to fetal nutrient acquisition. In fact, the volumes of amniotic fluid which are swallowed in humans *in utero* at term are estimated to be approximately 500 mL/d<sup>[91]</sup>. Taste buds are detected early in gestation<sup>[92]</sup>, and early experiments have shown that human fetal swallowing increases trans-amniotic saccharin infusion, and decreases following the

infusion of noxious substance<sup>[93]</sup>. Injection of galactose into the amniotic fluid of fetal rabbits increases intestinal mucosal weights, as well as the uptake of glucose<sup>[94]</sup>. Thus, even fetal rabbits are able to up-regulate intestinal transport capacity in response to nutrients. The importance of fetal swallowing in the development of the GI tract is also highlighted by experiments in which fetal sheep underwent esophageal ligation to prevent amniotic fluid from reaching the small intestine<sup>[95]</sup>. A decrease in small intestinal villous height, intestinal weight and body weight resulted.

Prenatal intestinal transporters are critical for the development of the fetus, as an estimated 10%-15% of fetal protein requirements in rhesus monkeys are met through nutrients that are present in the amniotic fluid<sup>[96]</sup>. The presence of growth factors released from the GI tract may also be important, as gastric infusion of epidermal growth factor (EGF) reversed the weight loss seen following esophageal ligation<sup>[90]</sup>.

Once the epithelium lining the small intestine differentiates into columnar cells at 9-10 wk of gestation, transport BBM proteins including SGLT1 are expressed<sup>[97]</sup>. Significant levels of SGLT1 mRNA are also detected in fetal tissue, suggesting that carrier-mediated transport of glucose may be occurring<sup>[98]</sup>. Dramatic increases in the site density of SGLT1 are observed in fetal pigs between 74% of term and birth<sup>[98]</sup>. Between 17 and 30 wk gestation in humans, the duodenal-ileal gradient of glucose absorption is established<sup>[99]</sup>. In rats, glucose transport and SGLT1 protein and mRNA increase at weaning to levels higher than those seen in suckling or in adult animals<sup>[100,101]</sup>. Curiously, phloridzin does not block glucose transport by SGLT1 in suckling and mature animals to the same extent that it does in weanlings. This may suggest the presence of an age-specific alternative mechanism of glucose transport, or an age-related difference in the phloridzin binding site on SGLT1.

Kinetic analysis of glucose uptake rates in BBM vesicles from human fetal tissue suggests the presence of two transport systems. In addition to SGLT1, a low affinity, high capacity system is detected in the proximal small intestine<sup>[102,103]</sup>. This may represent GLUT2, which has been described in the BBM of adult rats exposed to high luminal sugar concentrations<sup>[104]</sup>.

Human and rat fetal small intestine also express GLUT1 (as do erythrocytes and brain tissue), which appears earlier than GLUT2, and decreases gradually during fetal life<sup>[105,106]</sup>. Although the mechanism of this developmental regulation is unknown, GLUT1 may be involved in early cell growth proliferation. Intestinal BLM GLUT2 mRNA is expressed at high levels at birth<sup>[101]</sup>, and GLUT2 transports glucose and fructose. In fact, GLUT2 mRNA is detected in fetal rats as early as day 16 following conception, even before intestinal villi are formed<sup>[106]</sup>. GLUT2 mRNA increases after weaning, and subsequently decreases to adult levels<sup>[101]</sup>. GLUT2 in the developing intestine is regulated by luminal glucose and fructose<sup>[107]</sup>. Luminal perfusion of 20 d old rat pups' intestine with fructose or glucose (100 mmol/L) increases

GLUT2 mRNA. This enhancing effect of luminal glucose or fructose was blocked by the transcription inhibitor actinomycin D, but was not affected by the protein synthesis inhibitor cycloheximide. GLUT2 mRNA was also increased in bypassed intestinal loops, suggesting that systemic factors are involved in its regulation. Interestingly, GLUT2 mRNA abundance was even higher in the bypassed loop than in the section that was perfused, suggesting a possible compensatory mechanism due to perceived starvation.

Sugar uptake increases with the gestational age of the animal, and typically peaks immediately after birth, when the intestine takes over the burden of nutrient acquisition from the placenta. Studies done on pigs using the everted sleeve method demonstrate that the maximal transport rate (Vmax) for D-glucose was highest immediately after birth, with a subsequent decrease in the value of Vmax associated with the onset of suckling<sup>[86]</sup>. In contrast, in newborn pigs the onset of suckling appears to stimulate increases in BLM GLUT2 density<sup>[108]</sup>. It is not known if GLUT2 activity protein or mRNA can be modified by sugars in the intestinal tract of humans.

At birth, all enterocytes appear to have the capability to transport nutrients. As a result, uptake occurs in enterocytes from all along the villus, rather than just from the upper third, such as occurs in older rats<sup>[109]</sup>. This may contribute to the higher rate of sugar uptake. Soon after birth, the gradient of increasing transport as one moves from the crypt to the villus is established<sup>[109]</sup>. This may be responsible for the reduced uptake capacity of the intestine observed postnatally. The "dilution" of fetal enterocytes with new immature cells that do not express transporters may be responsible for this effect. Indeed, the subsequent age-related decline in transport observed in chickens was attributed to reductions in the site density of SGLT1<sup>[110]</sup>.

Developmental changes in the intestinal transport of nutrients may also be non-specific (for example, changes in mucosal surface area, proliferation and migration of enterocytes, or changes in intestinal permeability). Indeed, the subsequent age-related decline in transport observed in chickens was attributed to reductions in the site density of SGLT1<sup>[110]</sup>.

Studies on human premature neonates have used the urinary excretion of D-xylose and 3-O-methyl-glucose as measures of passive and active carrier-mediated monosaccharide absorption of these sugars, respectively, when compared to those born before 28 wk gestation<sup>[111]</sup>. The replacement of rat fetal enterocytes along the villus requires up to 2 wk, as compared to the 24-48 h required for the replacement of adult enterocytes. Non-specific changes are responsible for ontogenic alterations in mucosal weight, surface area and transport capacity. Postnatal development of enterocytes results in increases in the surface area of microvilli and the BLM<sup>[112,113]</sup>. Reduced turnover rates result in longer lifetimes of enterocytes, resulting in slower replacement of cells.

Reductions in BBM fluidity occur in post-weaning rabbits, in association with increases in the cholesterol-

to-phospholipid ratio in the BBM<sup>[114,115]</sup>. In general, reductions in fluidity result in reductions in permeability. Human neonates show decreases in intestinal permeability within the first 30 d of life, as assessed by lactulose/mannitol urinary excretion<sup>[116]</sup>.

### Fructose transport

Although SGLT1 and GLUT2 are expressed in enterocytes both in the fetus and at birth, the expression of BBM GLUT5 is only detected in post-weaning rats<sup>[101,117-119]</sup>. This contrasts with what is seen in pigs<sup>[86]</sup> and lambs<sup>[120]</sup>. In rats, GLUT5 protein and mRNA abundance parallel fructose transport, and therefore remain low throughout the suckling phase. GLUT5 protein and mRNA also remain low throughout weaning in rats, with higher levels detected in the post-weaning phase when fructose may first appear in the rat<sup>[101,118,119]</sup>. This increase in GLUT5 mRNA and protein coincides with the rise in fructose uptake seen at this period. Although there is a temporal association between the introduction of dietary fructose and the appearance of GLUT5, the expression of the transporter is “hard wired” and occurs at this time even in the absence of dietary stimuli<sup>[121]</sup>. However, the precocious introduction of fructose into the diet of 22 d old rat pups stimulates fructose transport and GLUT5 mRNA expression<sup>[121]</sup>. Jiang *et al.*<sup>[122]</sup> showed that luminal perfusions of high concentrations (100 mmol/L) of fructose resulted in increases in GLUT5 mRNA and activity. This developmental reprogramming of fructose transport required *de novo* mRNA and protein synthesis, as both actinomycin D and cycloheximide (inhibitors of transcription and translation, respectively) abolished the effect.

In humans, the introduction of solid foods and fruit juice containing fructose at earlier stages of infancy, coupled with the increased use of fructose as a sweetener in dietary products, has resulted in increased exposure to fructose during infancy. Fructose has been implicated as the major cause of “toddler’s diarrhea”, largely because it is a late onset transporter that increases postnatally in human infants<sup>[123]</sup>. The infant intestine may not be equipped to absorb high amounts of fructose, resulting in fructose malabsorption. Fructose may then enter the colon, and the high osmolarity may cause osmotic diarrhea. Even in adults, the incidence of fructose intolerance may be increasing: in a recent study malabsorption may be over 70% in persons with persistent, unexplained, non-specific GI symptoms<sup>[124]</sup>. The dose of fructose used in this study was approximately equivalent to the amount of fructose found in two cans of pop.

### Amino acid transport

Amino acid (AA) transporters appear prenatally in the intestines of chickens, rats, rabbits, and humans, and these transporters increase dramatically in the first days after birth<sup>[125]</sup>. In rats, rabbits, and pigs, the highest rates of BBM AA and peptide uptake are seen at birth, with decreases during suckling and post-weaning<sup>[126-128]</sup>. In rats, BBM AA transporters are expressed prenatally at

the same time or shortly after SGLT1<sup>[129]</sup>. In 17-20 wk gestation human fetal small intestine, all of the AA transport systems studied (neutral, acidic, basic, and imino) were found to be functional, with a proximal-distal gradient established shortly after crypt-villus formation<sup>[130]</sup>. In human fetuses, AA transport occurs at 14 wk gestation, with glucose transport at 18 wk, and fatty acid absorption at 24 wk gestation<sup>[131]</sup>.

AA transporters, including NBAT (which transports cationic and neutral AA) and EAAC1 (which transports glutamate), are expressed in suckling rats<sup>[132]</sup>. The intestinal absorption of peptides occurs *via* PePT1, which is distributed throughout the small intestine. The distribution of these transporters in suckling rats parallels that seen in adult animals. NBAT mRNA is highest in the proximal small intestine, while EAAC1 mRNA was highest in the more distal regions. While a marked crypt-villous gradient was found for PEPT1 and NBAT, EAAC1 immunoreactivity is confined to the lower third of the villus and to the crypts. Thus, the EAAC1 transporter of glutamate is the first AA transporter with decreased expression during epithelial cell differentiation<sup>[132]</sup>.

There are developmental changes in AA and peptide transport. The ontogeny of AA transport is complicated due to the major species differences, and by the large number of AA transport systems, and the fact that some AA are essential or non-essential, depending on the age of the animal. Also protein requirements change throughout the lifespan of an animal, necessitating variations in either intake or uptake of protein or AA. For example, intestinal proline uptake per mg of tissue is maximal at birth in rats, decreases at the end of the suckling phase, and decreases further in older animals. This decline matches both the dietary protein levels and protein requirements<sup>[119]</sup>. In addition, the decline in uptake of essential AA is greater than that for non-essential AA<sup>[129]</sup>. This may be because young animals have a disproportionate need for essential AA in early life, due to their rapid growth at this age.

There are also different patterns of uptake for individual AA. For example, in cats, the basic AA transport declines more steeply than does neutral AA transport. In humans, lysine and phenylalanine transport appears later than does the transport of alanine, leucine, taurine and valine<sup>[133]</sup>. In rats, uptake declines at a similar rate with age from proline, methionine and lysine; however the decline in leucine uptake occurs twice as quickly<sup>[129]</sup>. Finally, in rats as transition occurs at weaning when the uptake of glucose, fructose, and lysine increase, this is coupled with decreases in proline and leucine uptake<sup>[119]</sup>. It is unknown why there are such complicated patterns of changes in AA uptake in early life.

### Macromolecule transport

The uptake of macromolecules across the intestinal epithelial barrier is an important route by which immunoglobulins, growth factors and antigens are absorbed. This route of entry is especially important in neonates, who rely on it to obtain important immune factors from

maternal colostrum or milk. Most species (including rats, mice, and humans) are born hypoglobulinemic, and absorb IgG from maternal milk through proximal small intestine absorption<sup>[134,135]</sup>.

The transport of macromolecules across the BBM may occur by receptor-mediated or non-specific transcytosis. The transport of macromolecules is facilitated by the presence of protease inhibitors in the maternal colostrum. Rodent studies demonstrate specific intestinal receptors that bind to the Fc portion of IgG<sup>[136]</sup>. These receptors are transcriptionally regulated, and are present in highest amounts in the duodenum<sup>[137]</sup>. In humans, IgG is transferred from the placenta to the fetus in the third trimester of pregnancy, with receptors for IgG being detected in the intestine of both the fetus and the neonate. Macromolecular movement across the BBM persists after birth, and then gradually decreases<sup>[136]</sup>. The initially high permeability of the intestine declines after birth, leading to a process commonly referred to as “gut closure”. The time at which gut closure occurs and macromolecular transport ceases varies between species, with a rapid decrease in transport observed in pigs within the first few postnatal days, and a similar decrease seen around 21 d after birth in rats and rabbits<sup>[138]</sup>. In humans, the exact time that gut closure occurs is unknown, but intrinsic features as well as growth factors, hormones and breast milk may play a role in regulating this process. The decline in permeability may also be related to changes in the thickness and viscosity of the mucus gel layer which coats the BBM. The intervillus mucus gel is increased in weaned as compared to suckling rats. This would potentially increase the effective resistance of the unstirred water layer, and thereby contribute to the decrease in the uptake of macromolecules.

In human infants, uptake of macromolecules or lactalbumin declines with advancing postconceptual and postnatal age<sup>[139]</sup>. The ability of the neonatal intestine to adapt to the presence or absence of luminal stimuli is apparent from studies demonstrating a delay in spontaneous closure of the intestine if breastfeeding is postponed beyond the first 30 h of life<sup>[140]</sup>.

### Pancreatic enzymes

The higher fecal fat losses in preterm infants compared with term infants is thought to be attributable to lower pancreatic and intestinal lipase activities. Despite the presence of lipase in breast milk and of lipases in the newborn tongue and stomach, micellar absorption of lipids appears later when pancreatic lipase and bile acid concentrations increase<sup>[141]</sup>.

The human exocrine pancreas is functionally immature at birth, with substantial development occurring after birth. Proteolytic enzymes are detected early in the human fetus (20-25 wk gestation), with each enzyme developing in a unique manner. Trypsin increases during fetal life, to reach 90% of childhood levels at term<sup>[142]</sup>. In contrast, at birth chymotrypsin and carboxypeptidase B levels are less than 60% and 25% of childhood levels, respectively. Despite the differences in the temporal de-

velopment of proteolytic enzymes, protein digestion in the preterm neonate is adequate, and may be supported by the early development of gastric pepsin and mucosal peptidases<sup>[143]</sup>.

Pancreatic amylase activity is negligible in the human fetus, and is not detectable until one month after birth<sup>[144]</sup>. Salivary amylase is detected at 20 wk gestation, and while levels are low at birth, they increase to adult levels by the third month following birth<sup>[145]</sup>. Amylase is also present in human milk, and may aid in the digestion of starch contained in weaning foods<sup>[145]</sup>. The reduced levels of amylase activity may reflect the low levels of starch in the neonatal diet. At weaning, an increase in amylase activity is detected<sup>[144]</sup>. While this may be influenced by the appearance of starch in the infant’s diet, animal studies demonstrate a persistent increase in amylase activity in rats subjected to prolonged nursing<sup>[146]</sup>. This suggests the presence of an inherent genetic program for the expression of amylase activity, not necessarily related to the starch content of the diet.

Pancreatic lipase activity in humans is detectable at 32 wk gestation. It remains low at birth, and increases 10 wk after birth<sup>[147]</sup>. Lingual and gastric lipases, however, are detected at 26 wk gestation<sup>[148]</sup>. At birth these lipases are able to hydrolyze 60%-70% of ingested fat, even in the absence of pancreatic lipase<sup>[149]</sup>. Lipase and esterase activity is present in human milk, and contributes to the increased fat absorption observed in breast-fed infants<sup>[150]</sup>. Low lipolytic activity may be the rate-limiting step in the development of efficient fat absorption<sup>[143,151,152]</sup>. Authors propose that it is the ability to take up long chain fatty acids (LCFA) from the lumen that is the rate-limiting step<sup>[153]</sup>.

The ontogeny of the intestine is “hard wired”, and occurs even in the absence of luminal and hormonal factors<sup>[41,42]</sup>. Still, a number of studies have demonstrated that variations in maternal diets, as well as weaning diets, can influence the ontogeny of the intestine<sup>[154-156]</sup>. “Critical period programming” is a phenomenon by which a biological mechanism is irreversibly turned on or off once during a lifetime in response to prevailing conditions at a critical stage<sup>[157]</sup>. This concept, which has also been referred to as “metabolic programming” or “imprinting”<sup>[158,159]</sup>, has been used to explain associations between prenatal/neonatal environment events, alterations in growth and development, and later pathophysiology<sup>[160,161]</sup>. Early exposure to a diet high in fructose during the suckling-weaning transition may contribute to modest dyslipidemia later in life<sup>[162]</sup>. Intestinal sugar uptake is also prone to critical period programming<sup>[163]</sup>.

The role of dietary lipids in the programming of intestinal nutrient transport has been studied<sup>[154-156,164,165]</sup>. Thomson *et al.*<sup>[164]</sup> demonstrated that feeding eight-week old rabbits a low cholesterol diet for two weeks reduced intestinal glucose uptake, and that this effect persisted for at least ten weeks after the animals returned to eating a normal diet. The response to diet depended on the duration of feeding, the age of the animals, and whether or not there was previous exposure to the diet. In this

study, effects on sugar transport were not explained by changes in food intake, body weight or intestinal weight. Furthermore, persistent changes were seen in the active transport of glucose, galactose, leucine and bile acids, while changes in the passive uptake of lipids were reversible.

When the ratio of polyunsaturated to saturated fatty acids in the diet of weanling rats is altered, diets enriched in saturated fatty acids increase hexose uptake, and these alterations were fast, progressive and irreversible<sup>[154]</sup>. Feeding the same diets to pregnant and lactating rats resulted in similar increases in sugar uptake in their weanling offspring<sup>[166]</sup>. Curiously, these changes were not seen in the suckling offspring, suggesting that the mechanisms responsible for adaptation may not be fully developed in these animals. Perin *et al.*<sup>[165]</sup> confirmed that the weanling intestine was capable of adaptation, by continuing to feed the offspring of pregnant dams the same diet for three weeks post-weaning. Persistent alterations in sugar uptake were seen in response to variations in dietary lipids, once again emphasizing the importance of early exposure in the programming of intestinal nutrient transport. In addition to the differences between suckling and weanling offspring, the pattern of adaptation also appeared to differ between the jejunum and ileum.

Further studies went on to characterize the effect of diets enriched with arachidonic acid, docohexanoic acid and diets with different ratios of n6 to n3 fatty acids on intestinal nutrient transport<sup>[156]</sup>. As in the previous study by Perin *et al.*<sup>[166]</sup>, these maternal diets critically influenced the ontogeny of the intestine, with many of the changes in transport being irreversible. Furthermore, responsiveness to later dietary challenges depended on early-life feeding experiences, once again emphasizing the importance of early dietary exposure to the development and later adaptability of intestinal transport of nutrients.

### Lipid and bile acid transport

Studies using human fetal jejunal explants (14-20 wk gestation) maintained in serum-free organ culture demonstrated increases in chylomicron, VLDL and HDL, paralleled by increases in triglycerides and cholesterol esters. This demonstrates the ability of the fetal intestine to absorb fat in conjunction with ontogenic increases in lipid and lipoprotein synthesis<sup>[167]</sup>. Apolipoprotein B synthesis is developmentally regulated: fetal intestine synthesizes only apoB-100 at 11 wk, but both apo-48 and apo-B100 are synthesized at 16 wk, with apoB-46 being predominant in the mature intestine.

Pinocytosis of lipid globules is important after birth. The immature rat intestine is also able to absorb fatty acids and cholesterol<sup>[168]</sup>. Triglycerides (TG) are digested by gastric and lingual lipases into fatty acids and 2-monoacylglycerols, and their uptake is higher in the immature intestine than in adults<sup>[168,169]</sup>. Fatty acid binding proteins on the BBM are present in adults<sup>[170]</sup>. Lipid uptake is thought to be passive in sucklings (Meddings and Theisen, 1989). Once taken up into the enterocytes,

lipids are resynthesized into TG, phospholipids (PL) and cholesterol esters (CE)<sup>[171]</sup>.

Bile acids include solubilizing lipids in the intestinal lumen, which facilitate their diffusion through the intestinal unstirred water layer external to the BBM. Intestinal bile acid uptake is an important step in the enterohepatic circulation of bile acids (recently reviewed in Kullak-Ublick *et al.*<sup>[172]</sup>), and this uptake is therefore important in the overall process of lipid absorption. Bile acid transporters are curiously absent during suckling when fat intake is high and when bile acid secretion and recycling would be expected to be maximal. It is speculated that the malabsorption may allow bile acids to enter the colon and affect the development of the enteric flora. It is likely that passive absorption of bile acids during the suckling period may be the mechanism by which bile acids are recirculated<sup>[172]</sup>.

Sodium-dependent bile acid transporters in the BBM or cytosol are detected in the rat at weaning<sup>[173,174]</sup>. Abrupt increases in bile acid transport at weaning occur in rat and human ileum, and are due to parallel increases in the steady state mRNA abundance and transporter number<sup>[175,176]</sup>.

## CONCLUSION

Thus, the ontogeny, early growth and development of the intestine is important for the adult gastroenterologist to appreciate, because of the potential for these early life events to affect the responsiveness of the intestine to physiological or pathological challenges in later life.

## Is the control of dietary cholesterol intake sufficiently effective to ameliorate nonalcoholic fatty liver disease?

Munechika Enjoji, Makoto Nakamuta

Munechika Enjoji, Department of Clinical Pharmacology, Faculty of Pharmaceutical Sciences, Fukuoka University, 8-19-1 Nanakuma, Jonan-ku, Fukuoka 814-0180, Japan

Makoto Nakamuta, Department of Gastroenterology and Clinical Research Center, Kyushu Medical Center, National Hospital Organization, 1-8-1 Jigyohama, Chuo-ku, Fukuoka 810-8563, Japan

Author contributions: Enjoji M drafted the editorial; both authors wrote the final version.

### Abstract

In our examination of the distribution of abdominal fat, dietary intake and biochemical data in patients with nonalcoholic fatty liver disease (NAFLD), non-obese NAFLD patients without insulin resistance presented a characteristic pattern of dietary intake. Dietary cholesterol intake was superabundant in non-obese patients compared with obese patients, although total energy and carbohydrate intake was not excessive. Namely, excess cholesterol intake appears to be one of the main factors associated with NAFLD development and liver injury. Therefore, the control of dietary cholesterol intake may lead to an improvement in NAFLD, and the NPC1L1 inhibitor ezetimibe might be a promising treatment for NAFLD. We review one pathogenic aspect of lipid metabolism dysregulation in NAFLD and survey new strategies for NAFLD treatment based on the modification of cholesterol metabolism.

Is the control of dietary cholesterol intake sufficiently effective to ameliorate nonalcoholic fatty liver disease? *World J Gastroenterol* 2010; 16(7): 800-803 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i7/800.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i7.800>

### INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD), which encompasses a broad spectrum of liver disorders ranging from simple hepatic steatosis to steatohepatitis and cirrhosis, is currently the most common cause of chronic liver disease and abnormal liver function tests in Western countries. The development of hepatic steatosis is considered to be associated with an excess intake of calories, visceral obesity and insulin resistance, which result in an increased release of free fatty acids from adipocytes and increased rates of fatty acid synthesis in the liver<sup>[1,2]</sup>. However, the mechanisms involved in the pathogenesis of NAFLD in humans have not been thoroughly investigated. Because of the associated triglyceride accumulation in hepatocytes, NAFLD has been mainly investigated as a lipogenic disorder. Indeed, fatty acid overload because of the acceleration of *de novo* synthesis and cellular uptake results in mitochondrial dysfunction, oxidative stress and impaired VLDL formation, which lead to disease progression<sup>[1,2]</sup>. These changes related to lipid metabolism were positively linked to transcriptomic and metabolomic profiles in rats with NAFLD induced by a high fat diet<sup>[3]</sup>. In addition, from our analyses of the expression profile of fatty acid metabolism-associated genes in

biopsy samples from NAFLD liver, a similar expression pattern was seen, which indicated that the expression of sterol regulatory element-binding protein-1c (SREBP-1c), a positive regulator of fatty acid synthesis, was still upregulated and the expression of AMP-activated protein kinase, a negative regulator of fatty acid synthesis, was down-regulated despite the increased uptake of free fatty acids and intracellular accumulation of fatty acids and triglycerides<sup>[4,9]</sup>. These results suggest a breakdown of the feedback regulation from the increased level of intracellular fatty acids. Recently, it has been considered that cholesterol metabolism has a significant role in the pathogenesis of NAFLD. In the examination of cholesterol metabolism-associated genes, despite cholesterol overload in hepatocytes, *de novo* synthesis of cholesterol is still activated in the NAFLD liver, meaning that cholesterol metabolism is dysregulated in NAFLD<sup>[10]</sup>. This review focuses on the intrahepatic cholesterol dysregulation in NAFLD and potential emerging therapies for NAFLD.

To understand the nature of NAFLD, a nutritional approach provided helpful information. Among NAFLD patients, a large percentage of patients have obesity with insulin resistance, however, many non-obese individuals are also included<sup>[11,12]</sup>. Considering visceral fat and insulin resistance, which are evident in obese patients, the distribution of abdominal fat, dietary intake and biochemical data were compared between obese (BMI > 25 kg/m<sup>2</sup>) and non-obese patients (BMI < 25 kg/m<sup>2</sup>) to identify potential nutritional factors that affect NAFLD<sup>[13,14]</sup>. Visceral fat and dietary intake of total energy and carbohydrates were at overtly higher levels in the obese group as a matter of course. In contrast, in non-obese patients, dietary cholesterol was significantly higher and dietary polyunsaturated fatty acids (PUFA) were significantly lower than those in obese patients. Mean concentrations of serum total cholesterol, LDL-cholesterol and triglycerides were near the upper limit of the normal range, and serum levels of adipocytokines were not in the abnormal range in either group.

Namely, superabundant dietary cholesterol and decreased dietary PUFA intake may contribute to NAFLD development without the presence of obesity or insulin resistance. These findings are supported by some animal models fed a high-cholesterol diet, which show hepatic steatosis without obesity<sup>[15-17]</sup>. However, these animals had obvious hypercholesterolemia in contrast to NAFLD patients. This might be because the dietary cholesterol levels are considerably higher (0.2%-1.25%) in animal models than in our examined NAFLD patients. Furthermore, in these patients, hypercholesterolemia might be masked by the overwork of hepatocytes, resulting in cholesterol overload in tissues. Cholesterol supply and fatty acid synthesis are associated on a stream of the liver X receptor  $\alpha$  (LXR $\alpha$ )-SREBP-1c pathway. In hepatocytes, LXR $\alpha$  is a key regulator of cholesterol and fatty acid metabolism, and its endogenous agonistic ligands are oxysterols, which are metabolites

of cholesterol. Surplus cholesterol produces increased levels of oxysterols, resulting in activation of the LXR $\alpha$ -SREBP-1c pathway and enhancement of fatty acid synthesis. Furthermore, upregulation of LXR $\alpha$  expression was more noticeable in non-obese than in obese NAFLD patients<sup>[8]</sup>. Also, in the study of PUFA, patients with NAFLD were found to have lower levels of hepatic n-3 and n-6 PUFA, and n-3 PUFA dietary intake had therapeutic effects on fatty liver in patients with NAFLD<sup>[18-20]</sup>. n-3 PUFAs, such as eicosapentaenoic acid, which function as suppressors of SREBP-1c, are considered to reduce hepatic levels of triglycerides. However, clinically, a drug containing eicosapentaenoic acid does not have a high enough efficacy in many cases to overcome NAFLD (our own data).

Until now, investigations of therapeutic interventions have largely focused on agents that modify oxidative stress and insulin sensitivity, but clearly, an effective therapy for NAFLD has not been proven. If excess cholesterol plays a key role in the onset and progression of NAFLD, the control of dietary cholesterol intake should be a beneficial treatment strategy. Niemann-Pick C1 like 1 (NPC1L1), found in the proximal jejunum and canalicular aspect of hepatocytes, is essential for the absorption/reabsorption of cholesterol from the intestines and liver. Accordingly, the NPC1L1 inhibitor ezetimibe is expected to decrease intracellular cholesterol levels and to down-regulate/inactivate the LXR $\alpha$ -SREBP-1c pathway, and may be a suitable candidate for NAFLD treatment. In animal models, knocking out NPC1L1 or treatment with a NPC1L1 inhibitor provides resistance against steatosis<sup>[21,22]</sup>. Clinically, we encountered and reported a patient with NAFLD in whom ezetimibe clearly provided an improvement against liver injury and steatosis<sup>[23]</sup>. In a clinical study, to reduce cholesterol load, ezetimibe was administered (10 mg/d, orally) to non-obese NAFLD patients ( $n = 12$ ) without any other treatments and any lifestyle modifications (unpublished data). In fact, ezetimibe was effective for liver injury because significant improvements were seen in serum aminotransferase levels, with 75% of subjects normalizing their transaminases. Six months after the treatment, alanine aminotransferase levels decreased by nearly 60% on average. However, a steatotic appearance remained as determined by liver echotexture in many of the patients (9/12) after 12 mo of treatment, indicating that a significant attenuation of fat content was not necessarily found. Of note, suppression of dietary cholesterol absorption may be a feasible option to successfully treat NAFLD, particularly in non-obese patients.

Considering the above findings, cholesterol-modifying treatments are favorable for NAFLD patients, and ezetimibe is expected to show a prompt clinical effect on laboratory findings for at least non-obese patients. Hence, the following should be examined and determined: (1) Are HMG-CoA reductase (HMGR) inhibitors (statins), which suppress *de novo* cholesterol synthesis, effective for NAFLD as well as ezetimibe? In recent reports, some

affirm but some deny the effect<sup>[24-26]</sup>. However, statins, with the exception of pravastatin, have generally shown promising results with improved serum aminotransferase levels. Combination therapy with an HMGCR inhibitor plus ezetimibe might be more effective than monotherapy, although several cases of hepatic injury as an adverse effect have been reported in patients with pre-existing chronic liver disease<sup>[27,28]</sup>; (2) Is the control of cholesterol levels also effective in obese NAFLD patients with insulin resistance? Because dietary cholesterol intake was also significantly higher in obese patients than in normal individuals<sup>[13]</sup>, ezetimibe is possibly effective for obese patients. However, in obese patients, it is difficult to remove the impact of other factors such as lifestyle modifications and other baseline agents; therefore, a study in obese patients requires circumspection; (3) Does the control of cholesterol levels improve steatosis in long-term observations? In the studies of NAFLD treatment by statins, a consistent opinion has not been drawn on the matter of the improving effect in hepatic steatosis<sup>[24,25]</sup>; (4) Further studies are required to determine whether cholesterol modifications are effective for both types of NAFLD, simple steatosis and steatohepatitis; and (5) Does the control of cholesterol levels show an additive therapeutic effect with any other treatments such as antioxidants, hepatoprotective agents or insulin sensitizers?

## CONCLUSION

According to our nutritional examinations, increased cholesterol intake may be one of the main causes of an increase in the prevalence of NAFLD. Therefore, as a potential treatment, cholesterol-lowering agents look promising. Indeed, several recent studies endorse the clinical indication of statin therapy for NAFLD. Ezetimibe has recently been viewed as an alternative to statin therapy in patients with hypercholesterolemia. Ezetimibe targets the cholesterol absorption/reabsorption step, and accordingly ezetimibe may be a suitable treatment for NAFLD. Larger trials are needed to confirm whether ezetimibe or statins are really efficacious as monotherapeutic agents and, to maximize clinical benefits while minimizing side effects, further trials may be required to investigate the best combination partners for the treatment of NAFLD.

### Abstract

Sigmoid diverticulitis is a common disease which carries both a significant morbidity and a societal economic burden. This review article analyzes the current data regarding management of sigmoid diverticulitis in its variable clinical presentations. Wide-spectrum antibiotics are the standard of care for uncomplicated diverticulitis. Recently published data indicate that sigmoid diverticulitis does not mandate surgical management after the second episode of uncomplicated disease as previously recommended. Rather, a more individualized approach, taking into account frequency, severity of the attacks and their impact on quality of life, should guide the indication for surgery. On the other hand, complicated diverticular disease still requires surgical treatment in patients with acceptable comorbidity risk and remains a life-threatening condition in the case of free peritoneal perforation. Laparoscopic surgery is increasingly accepted as the surgical approach of choice for most presentations of the disease and has also been proposed in the treatment of generalized peritonitis. There is not sufficient evidence supporting any changes in the approach to management in younger patients. Conversely, the available evidence suggests that surgery should be indicated after one attack of

uncomplicated disease in immunocompromised individuals. Uncommon clinical presentations of sigmoid diverticulitis and their possible association with inflammatory bowel disease are also discussed.

### INTRODUCTION

Sigmoid diverticulitis is a common disease of the Western World and results in a significant number of hospital admissions<sup>[1]</sup> with considerable societal costs due to loss of productivity. The prevalence of diverticula in the sigmoid increases proportionally with aging and only rarely results in the inflammation referred to as sigmoid diverticulitis. Sigmoid diverticula may cause significant bleeding which is generally unrelated to diverticular inflammation and is generally referred to as diverticular bleeding or bleeding diverticulosis. Bleeding caused by diverticula will therefore not be included in this review article. The spectrum of sigmoid diverticulitis ranges from a single episode of mild sigmoid inflammation amenable to outpatient treatment to a life-threatening generalized peritonitis caused by acute diverticular perforation which

requires urgent surgical intervention.

The aim of this review article is to analyze the clinical presentation, treatment modalities for the various forms of sigmoid diverticulitis, the indications for elective and urgent surgery and the postoperative and functional outcomes reported in the literature.

## RISK FACTORS AND PREVENTIVE STRATEGIES

There are few studies which present evidence of a causal relationship with preventable factors. The data obtained from a prospective cohort of 47228 male health professionals who were free from diverticular disease in 1986 has been fundamental in providing evidence-based outcomes. Obesity is significantly associated with an increased incidence of both diverticular bleeding and diverticulitis, which have often been considered together in the studies from this large dataset. The relative risk of diverticulitis was found to be between 1.5 and 2, depending on whether body mass index (BMI), waist circumference or waist to hip ratio were considered<sup>[2]</sup>. Correspondingly, physical activity, particularly if vigorous, is associated with decreased incidence of sigmoid diverticulitis and diverticular bleeding<sup>[3]</sup>. A diet with an increased fiber intake, particularly cellulose, is also significantly associated with a decreased risk of diverticular disease<sup>[4]</sup>. On the other hand, the presumed correlation between incidence of sigmoid diverticulitis and the consumption of nut, corn and popcorn has not been confirmed when analyzing this large prospective cohort of men<sup>[5]</sup>. With respect to the use of medications, the regular and consistent use of nonsteroidal antiinflammatory drugs and acetaminophen is associated with symptoms of severe diverticular disease, particularly bleeding<sup>[6]</sup>.

## CLINICAL PRESENTATION AND DIAGNOSIS

Sigmoid diverticulitis generally presents with abdominal pain, typically located in the left lower quadrant and associated with a variable degree of peritoneal irritation, which can range from none to generalized peritonitis. Localized peritoneal reaction with guarding and rebound tenderness may be noted. Fever and elevation of the white blood cell count can aid in the diagnosis when present. A redundant sigmoid colon may reach the right lower quadrant, and sigmoid diverticulitis under these circumstances may resemble acute appendicitis. In cases of complicated diverticulitis a stricture may lead to obstructive symptoms with nausea and vomiting as the most noticeable symptoms. On the other hand, a history of recurrent urinary tract infection, dysuria with or without urgency, pneumaturia and fecaluria can suggest a colovesical fistula. When a patient reports passing stools per vagina, insertion of a vaginal speculum can reveal a fistulous opening at the vaginal apex, thus confirming a colovaginal fistula. A previous history of hysterectomy

is a valuable clinical clue to the correct diagnosis as colovaginal and colovesical fistulas are rare in females with their uterus in place, as the uterus becomes a screen interposed between the inflamed colon and the bladder and vagina. Less commonly, sigmoid diverticulitis can involve other surrounding structures and cause coloenteric, colouterine or colocutaneous fistulas.

A full colonoscopy should be typically avoided during an episode of acute diverticulitis because of an increased risk of perforation. In select cases and experienced hands, a gentle flexible sigmoidoscopy can provide additional information and help rule out alternative diagnoses such as cancer, inflammatory bowel disease, or ischemic colitis. Computed tomography (CT) is the most commonly used imaging modality to determine the diagnosis of sigmoid diverticulitis. In this respect, CT has supplanted barium enema and gastrografin enema in the routine evaluation of the sigmoid colon<sup>[7]</sup>. It can also help establish a differential diagnosis with other conditions which might exhibit similar symptoms such as gynecologic or urinary tract disorders. Irritable bowel syndrome and diverticulitis may present with similar symptoms and physical findings. It is therefore important to confirm the diagnosis of sigmoid diverticulitis by imaging before recommending surgery.

## CLASSIFICATIONS OF SIGMOID DIVERTICULITIS AND IMPLICATIONS FOR MANAGEMENT

It is appropriate to classify sigmoid diverticulitis into different categories as the morbidity and mortality of this condition are greatly variable. Traditionally, the Hinchey classification has been used to subdivide sigmoid diverticulitis into subgroups based on the degree and extent of the abdominal and pelvic disease identified at the time of surgery and associated with perforated diverticular disease of the colon<sup>[8]</sup>. Of note, Hinchey credited Hughes for the development of an earlier, similar classification in 1963<sup>[9]</sup>. The Hinchey classification, developed before the advent of routine CT imaging, remains the most widely used classification and a few updated modifications have therefore been proposed in recent years (Table 1). In fact, the original Hinchey classification might not be the most practical classification to help in the contemporary management of at least some cases of diverticular disease. For example, the Hinchey classification separates a pericolic abscess (Hinchey 1) from a distant abscess (Hinchey 2). However, larger pericolic abscesses and similarly sized distant abscesses might carry similar morbidity and require similar management. In these cases, more important factors in the clinical management of this complication of diverticular disease might instead be the abscess size, location in the pelvis or mesocolon and also the ability to percutaneously drain the abscess regardless of its vicinity to the sigmoid, and therefore maximize the feasibility of a subsequent one-stage operation. In this respect, some proposed modifications of the Hinchey classification spe-

	Original Hinchey classification	Sher <sup>[10]</sup> , Kohler modification <sup>[11]</sup>	Wasvary modification <sup>[33]</sup>	Kaiser modification <sup>[71]</sup>
Stage I	Pericolic abscess confined by the mesentery of the colon	Pericolic abscess	I a phlegmon I b pericolic abscess	I a confined pericolic inflammation-phlegmon I b confined pericolic abscess
Stage II	Pelvic abscess resulting from a local perforation of a pericolic abscess	II A distant abscess amenable to percutaneous drainage II B complex abscess associated with/without fistula	Pelvic abscess	Pelvic, distant intrabdominal or retroperitoneal abscess
Stage III	Generalized peritonitis resulting from rupture of pericolic/pelvic abscess into the general peritoneal cavity	Generalized purulent peritonitis	Purulent peritonitis	Generalized purulent peritonitis
Stage IV	Fecal peritonitis results from the free perforation of a diverticulum	Fecal peritonitis	Fecal peritonitis	Fecal peritonitis

<sup>1</sup>This modification also includes stage 0, defined as mild clinical diverticulitis.

**Figure 1 Diverticulitis.** A: Uncomplicated sigmoid diverticulitis with colonic thickening and straining at CT (arrow), also referred to as “mild” CT diverticulitis. Two diverticula contain contrast medium without evidence of extravasation outside the sigmoid; B: “Severe” CT diverticulitis with extravasation of contrast and small amount of extraluminal air (arrow). This patient was initially managed non-operatively and eventually required surgery for recurrent disease.

Moderate diverticulitis	Severe diverticulitis
Localized sigmoid wall thickening (> 5 mm) Inflammation of pericolic fat	Same as mild diverticulitis plus one of the following: Abscess Extraluminal air Extraluminal contrast

cifically include the ability to percutaneously drain the abscess<sup>[10,11]</sup>. Furthermore, the Hinchey classification was developed based on the description of surgical findings and was not specifically designed to evaluate cases of sigmoid diverticulitis treated with antibiotics only. More recently, CT scanning has become the imaging modality of choice to diagnose sigmoid diverticulitis and has been proposed as being the imaging modality providing the most important and valuable indication as to the likelihood that medical treatment with antibiotics will fail. In this regard, Ambrosetti *et al*<sup>[12]</sup> have proposed a CT-based classification of sigmoid diverticulitis subdivided into “moderate disease” or “mild disease” in the case of localized sigmoid wall thickening (greater than 5 mm) and inflammation of the pericolic fat (Figure 1A). On the other hand, the term

“severe disease” is used instead in the case of abscess, extraluminal air or extraluminal contrast extravasation (Figure 1B and Table 2).

## UNCOMPLICATED DIVERTICULITIS

When the inflammatory process is limited to the sigmoid it is generally treated with antibiotics. If symptoms are not severe and the patient is otherwise healthy and compliant with medical treatment, wide spectrum antibiotic treatment can be administered orally on an outpatient basis and the patient followed with serial office visits. On the other hand, if the patient is systemically ill, elderly or has significant comorbidities, a hospital admission and treatment with intravenous antibiotics are warranted. Even when hospital admission is necessary, the appropriateness of an initially conservative approach with antibiotic management has been confirmed<sup>[13-17]</sup>. Most patients with uncomplicated sigmoid diverticulitis respond to medical treatment and generally experience significant decreases in their abdominal pain, temperature and white blood cell count within the first 48 h after initiation of antibiotic treatment<sup>[17,18]</sup>.

In a minority of patients non-operative treatment fails, and symptoms either persist or worsen. In these cases,

urgent or semi-urgent surgery may become necessary during the same hospital stay. Among the remaining patients who successfully recover from their first episode of sigmoid diverticulitis, only a few eventually require elective sigmoid resection for recurrent disease and even more rarely are urgent operations necessary.

Following recovery from a new onset attack of uncomplicated diverticulitis the patient should undergo colonoscopy, or alternatively a barium enema, to rule out alternative diagnoses such as ischemic colitis, inflammatory bowel disease or, most importantly, a carcinoma.

## INDICATIONS FOR ELECTIVE SURGERY

The indications for elective operation for sigmoid diverticulitis are evolving. For several years the traditional teaching has been that elective sigmoidectomy was warranted after 2 attacks of uncomplicated diverticulitis. This recommendation was based on the assumptions that after 2 attacks there was not only a very high probability of recurrent attacks of uncomplicated diverticulitis but also an increased risk of complicated diverticulitis including free perforation causing diffuse peritonitis. From this viewpoint surgery would therefore prevent the risk of complicated diverticulitis with its inherently increased morbidity and mortality. Recent studies have questioned this hypothesis<sup>[19]</sup> and suggest instead that most patients who have complicated diverticulitis experience this clinical presentation as their first manifestation of diverticular disease<sup>[20,21]</sup>. Other studies based on decision analysis models have indicated that the preferred timing of elective surgery to optimize life expectancy should be after the third<sup>[22]</sup> or fourth<sup>[23]</sup> attack of uncomplicated diverticulitis. This changed view on the indications for elective surgery has reduced the overall number of surgical procedures performed for diverticulitis. In a study of 685 390 hospital discharges for sigmoid diverticulitis, based on the Nationwide Inpatient Sample during the period 1991-2005, the ratio of hospital discharges for diverticulitis increased from 5.1 to 7.6 cases per 1000 inpatients. However, the proportion of patients who underwent surgery for uncomplicated diverticulitis declined from 17.9% to 13.7% ( $P < 0.001$ ). In spite of these shifts, the percentage of patients with free perforation from diverticular disease remained stable throughout the study period at 1.5%<sup>[24]</sup>. With the limitation of a retrospective study based on administrative data, this study with a large number of patients also confirms that a less aggressive strategy for elective surgery did not result in any worrisome increase in the rate of presentation with diffuse peritonitis from diverticular perforation. Contemporary proponents of surgery after 2 attacks argue that earlier surgery favorably impacts patient symptoms<sup>[25]</sup> and that an increased number of diverticulitis attacks proportionally increases the conversion rates at the time of elective laparoscopic sigmoidectomy<sup>[26]</sup>.

Overall, the recent data from the literature defining the natural history of uncomplicated diverticulitis has contributed to reducing the emphasis on the rule of

surgery after the second attack. As a result of this shift, the most recent version of the Practice Parameters for Diverticulitis from the American Society of Colon and Rectal Surgery states that “the number of attacks of uncomplicated diverticulitis is not necessarily an overriding factor in defining the appropriateness of surgery”<sup>[27]</sup>.

## SURGICAL TREATMENT

The tenets of surgical treatment of diverticulitis are resection of the entire sigmoid and anastomosis between a soft and pliable area of descending colon and the upper rectum. The latter is generally recognized by the confluence of the teniae, which frequently occurs at the level of the sacral promontory. Failure to completely remove the sigmoid is associated with increased recurrence rates<sup>[28,29]</sup>. Some surgeons have emphasized preservation of the inferior mesenteric artery which might minimize the risk of anastomotic leakage<sup>[30]</sup>, sexual dysfunction from intraoperative nerve injury<sup>[31]</sup>, and optimize functional results<sup>[32]</sup>. Mobilization of the splenic flexure should be left to the discretion of the operating surgeon and is generally not necessary in the case of redundant left colon. The involvement of the tissue surrounding the sigmoid colon by the inflammatory process is variable. Often it is possible to identify the ureters intraoperatively and the required pelvic dissection can be limited to the upper rectum. However, there may be cases of complicated diverticulitis in which the extent and degree of inflammatory changes warrant the use of ureteral stents and/or the creation of a colorectal anastomosis in the more distal rectum. In such cases a difficult, prolonged dissection with significant blood loss may also justify the creation of a proximal diverting stoma. With respect to the required extent of resection, it is not necessary to remove the entire colonic segment bearing diverticula, which may actually be impossible in some cases due to the extent and density of diverticula throughout the colon. However, care should be taken to prevent inclusion of any diverticula into a stapled colorectal anastomosis. These principles are generally accepted and should apply equally to open or laparoscopic surgery. On the other hand, the timing of surgery in relation to the last diverticulitis attack has been the subject of controversy. The traditional practice entails a waiting period of 4-6 wk after a diverticulitis attack before performing an elective operation. Alternatively, some surgeons have suggested that early intervention for complicated diverticular disease may avoid the prolonged hospitalization and possibly multiple hospital admissions related to the traditional stepwise approach with initial antibiotic management and delayed elective surgery<sup>[33]</sup>. It has also been suggested that early surgery might obviate the creation of a stoma with its associated possible complications<sup>[34]</sup>. In addition, there is some evidence suggesting that an earlier timing of surgery, to within 30 d from the last diverticulitis attack, is not associated with increased morbidity when compared with operations performed between 30 and 60 d, or after 60 d following the last attack<sup>[35]</sup>. However, other investigators have reported less encouraging results. In the

case of laparoscopic surgery early surgical intervention has been associated with an increased conversion rate due to inflammation<sup>[36]</sup>. More importantly, a prospective study evaluating early elective sigmoid resection, carried out after 5-8 d of initial antibiotic treatment, has shown that this approach was associated with increased morbidity when compared with operations carried out 4-6 wk after the initial hospitalization<sup>[37]</sup>. While the data regarding the outcomes of early surgery following hospitalization for sigmoid diverticulitis remains controversial, there does not seem to be sufficiently consistent evidence at the moment to justify any anticipation of elective surgery before the traditional 4-6 wk waiting period.

## INCREASED ROLE OF LAPAROSCOPIC SURGERY

While open surgery continues to be performed, especially in low volume centers and by low volume surgeons<sup>[38]</sup>, laparoscopic surgery is increasingly preferred in the elective treatment of sigmoid diverticulitis. Several single-institutional series have confirmed feasibility and safety of the laparoscopic approach<sup>[39-42]</sup>. Laparoscopic sigmoidectomy is associated with reduced recovery time and return to bowel function, reduced hospital stay, and at least in some cases decreased morbidity<sup>[43-47]</sup> and costs<sup>[45,48]</sup>. Single-institutional series by experienced surgeons have reported conversion rates of as low as 2.8% and a median hospital stay of 4 d<sup>[42]</sup>. Minimally invasive sigmoidectomy can be performed using a straight laparoscopic technique or a laparoscopic hand-assisted technique<sup>[49,50]</sup>. A single-access sigmoidectomy has also been recently described<sup>[51]</sup>. The controversy persists as to whether the hand-assisted technique allows a reduction of operative times and conversion rates while extending the benefits of laparoscopic surgery to more difficult cases.

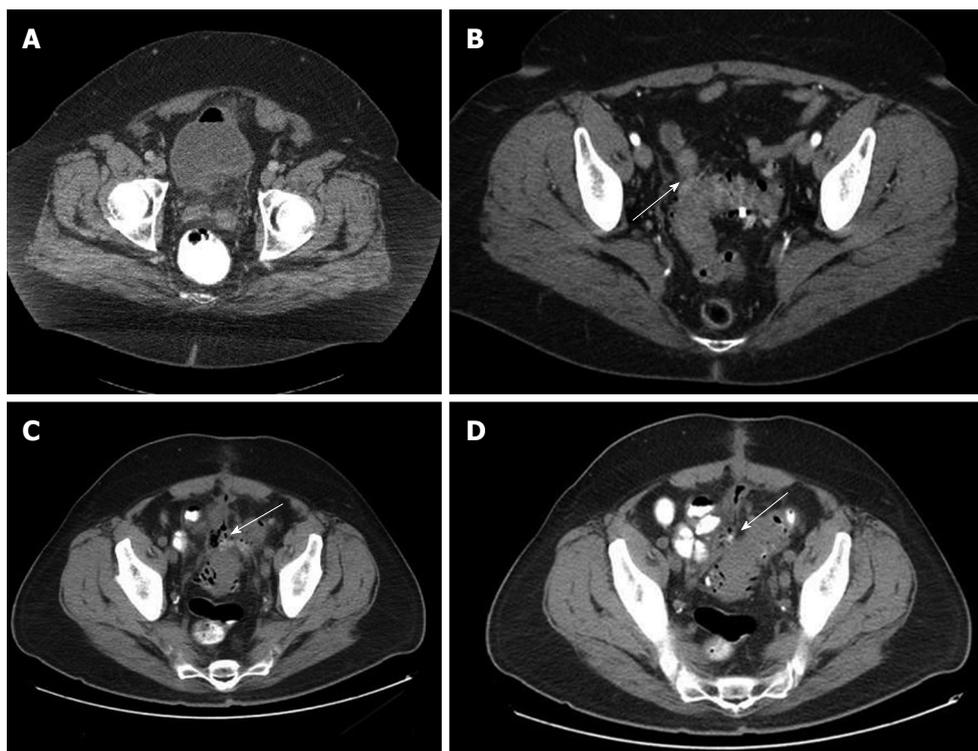

In general, the benefits of laparoscopic surgery have been confirmed by a large study based on data from the Nationwide Inpatient Sample during the years 1998-2000, which included 709 patients treated laparoscopically *vs* 17735 treated with the open technique. Laparoscopically completed patients had a mean reduction of hospital stay of almost 2 d and also reduction of postoperative morbidity when compared to their open counterparts. An important limitation of this study was that, due to the nature of the administrative database used, converted patients were not analyzed combined with the cases completed laparoscopically, which skews the results in favor of laparoscopic surgery<sup>[52]</sup>. However, a more recent study using the University Health System Consortium Database, in which converted patients were appropriately included in the laparoscopic group, confirmed a reduction in hospital stay, overall postoperative morbidity and total hospital cost in favor of laparoscopic sigmoidectomy for benign diseases<sup>[53]</sup>. In addition, there is further evidence of the benefits of laparoscopic surgery emerging from a prospective randomized trial, which has demonstrated reduction of major complications after laparoscopic surgery when

compared with open sigmoidectomy<sup>[54]</sup>. This multicenter, randomized, double-blinded study accrued 104 patients in 5 centers from 2002 to 2006. Double-blinding was carried out by covering the patient abdomen with a large dressing at the time of surgery so that patients, as well as physicians in charge of patients discharge, were unaware of the surgical technique used. Eligible patients were randomized to open *vs* laparoscopic sigmoid resection. Patients were similar with respect to gender, age, BMI, comorbidities, indications for surgery and previous surgical procedures. Conversion rate was 19% and mortality 1%. Laparoscopic surgery resulted in expected recovery benefits including significant reduction of pain based on visual analog scores and systemic analgesia requirements, decreased hospital stay and improved quality of life based on short-term SF-36 questionnaires. In addition, laparoscopic surgery resulted in significant reduction of major complications, defined as a composite inclusive of intrabdominal abscess, anastomotic leakage, pulmonary embolism and myocardial infarction. Major complications combined for a 25% rate after open surgery *vs* 10% after laparoscopic procedures<sup>[54]</sup>.

Based on the data from the last decade, it is reasonable to offer laparoscopic surgery in the surgical management of sigmoid diverticulitis and expect at least the recovery advantages reported after laparoscopic bowel resection.

## RELATIONSHIP BETWEEN SURGICAL VOLUME AND OUTCOMES

A number of studies have investigated possible differences in outcomes related to the experience of the operators. With respect to the use of laparoscopic surgery, there is evidence that the volumes of both individual surgeons and hospitals are directly proportional to the likelihood of performing laparoscopic surgery for diverticular disease. Using National Inpatient Sample Data based on over 55 000 patients, high-volume surgeons were almost 9 times more likely to perform laparoscopic surgery and high-volume hospitals were over 3 times more likely to perform laparoscopic surgery than their low-volume counterparts. These differences remained statistically significant when the data were stratified for age of the patient and timing of surgery; elective *vs* nonelective<sup>[38]</sup>. Volume/outcome studies have also been conducted within the subgroup of patients treated with laparoscopic surgery. In the multicenter, observational, German study from the Laparoscopic Colorectal Surgery Study Group of 1545 patients, the 52 participating institutions were divided into 3 groups according to the number of cases performed; greater than 100, between 30 and 100, and less than 30. While the percentage of patients with complicated diverticulitis was significantly increased in high-volume institutions (21% *vs* 8% in low-volume centers), operating times in these same institutions were shorter by approximately 30 min. Intraoperative complications, conversion rates and postoperative morbidity and mortality were numerically lowest in the high-volume centers, but these differences were not

**Figure 2** **Fistula.** A: Colovesical fistula as indicated by the presence of air in the bladder. This patient had symptoms and other CT findings consistent with sigmoid diverticulitis; B: Sigmoid diverticulitis and colovaginal fistula. This patient had undergone previous hysterectomy and complained of feculent discharge from her vagina. CT scan indicated inflamed sigmoid with adherent small bowel loop (arrow). The small bowel loop could be successfully separated from the sigmoid at the time of laparoscopic sigmoidectomy. There was no evidence of coloenteric fistula; Sigmoid diverticulitis with colocolic fistula (arrows) (C and D) (courtesy of Dr. Ravi Pokala Kiran, Department of Colorectal Surgery, Digestive Disease Institute, Cleveland Clinic, Cleveland, Ohio, USA).

statistically significant<sup>[55]</sup>. The results from this study seem to indicate that experienced surgeons in high-volume centers might be more facile at treating more complex cases with laparoscopic surgery. However, even low-volume centers can still achieve comparable postoperative outcomes and should therefore not be discouraged from performing laparoscopic surgery.

## RESULTS OF SURGERY FOR DIVERTICULITIS

Contemporary surgical treatment of diverticulitis following the principles described above is considered curative with a less than 5% recurrence rate<sup>[29,56]</sup>. A suspicion of recurrent sigmoid diverticulitis following surgical resection should be confirmed by CT scan of the abdomen and pelvis after which antibiotic treatment should be initiated, as for a case of primary uncomplicated sigmoid diverticulitis. It is important to preoperatively discuss with the patient that the risk exists that surgery might not lead to resolution of the patient's complaints. When this is the case, an anastomotic stenosis should be ruled out as a possible source of the problem which can often be successfully treated<sup>[57]</sup>. However, persistent or recurrent symptoms can be more difficult to elucidate. At least one contemporary series has reported a 25% rate of persistent symptoms after surgery<sup>[58]</sup>, which the authors felt could be only partially explained by an overlap with irritable bowel syndrome. One of the

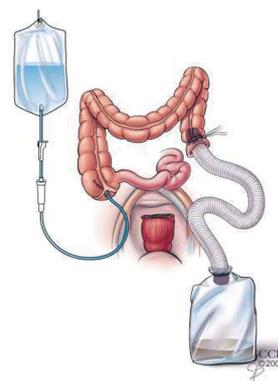

limitations of the assessment of symptoms and functional results after surgery is that sigmoid diverticulitis can cause a significant impairment of quality of life before surgery, a time at which quality of life is even more rarely assessed. The functional results of surgery should therefore be most accurately assessed when compared to the patient's preoperative status. A recent study has appropriately addressed this issue and reported a prospective evaluation of functional outcomes after laparoscopic sigmoid colectomy. A sample of 46 individuals underwent evaluation of their quality of life using the gastrointestinal quality of life indicator (GIQLI) administered before surgery and then at 3, 6, and 12 mo postoperatively. The quality of life significantly improved for the majority of the overall group, whereas it declined in only 5 patients. Urinary and sexual function were also tested using validated scores and did not change as a result of surgery<sup>[51]</sup>. When appropriately diagnosed by CT scan, sigmoid diverticulitis requiring surgery should be followed by improvement in symptoms and function in a substantial majority of cases.

## COMPLICATED DIVERTICULITIS

There are several complications which may be associated with diverticular inflammation. These include fistula (Figure 2), phlegmon, stricture, abscess and free perforation. At times the definition of complicated disease may depend on the individual clinical judgment, as uncomplicated and complicated diseases are a continuum of in-

**Figure 3 Sigmoid stricture (arrow) causing large bowel obstruction with proximal colonic dilatation.** Clinical and imaging findings at presentation did not allow ruling out sigmoid carcinoma. This patient was treated with initial Hartmann procedure and the pathology report revealed sigmoid diverticulitis. He subsequently underwent Hartmann takedown after 3 mo.

**Figure 4 On-table intraoperative colonic lavage (see explanation in text).**

creasingly severe inflammation which can cause a variable degree of stricture, intramural abscess or phlegmon. In the United States, complicated disease at presentation is more common in African-American patients and in individuals who lack medical insurance, based on an analysis from the Nationwide Inpatient Sample<sup>[59]</sup>.

In general, surgery is recommended for complicated diverticulitis after the first episode as the risk of recurrent disease without surgery is very high. However, when age or comorbidities prohibitively increase perioperative risks, it may be appropriate to approach complicated diverticulitis with medical treatment alone<sup>[60]</sup>.

Laparoscopic surgery remains feasible also for complicated diverticulitis<sup>[55,61,62]</sup> including cases with fistulas<sup>[63-66]</sup>. The morbidity after laparoscopic surgery for complicated diverticulitis might exceed that of uncomplicated disease, but this has not been uniformly proven<sup>[42]</sup>.

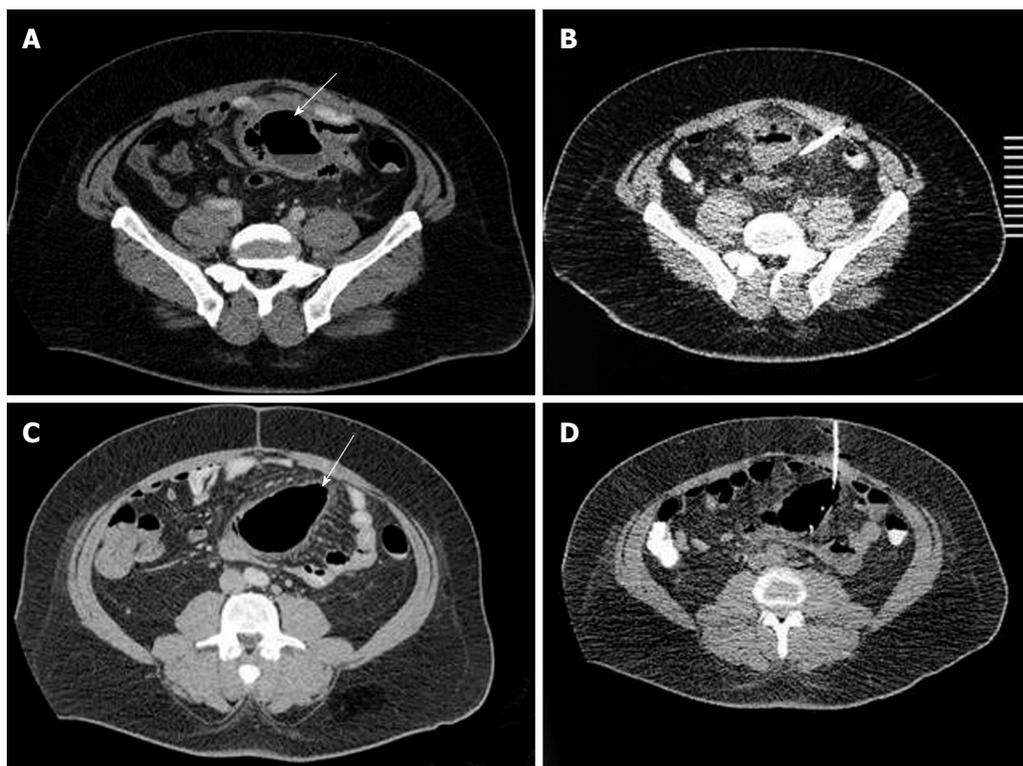

It remains controversial whether the act of conversion, which is more likely for complicated diverticular disease<sup>[67]</sup>, increases postoperative morbidity or not. It is generally accepted that when a conversion is necessary, an early conversion can minimize major complication so that it causes only minor morbidity<sup>[68]</sup> or does not result in any increased morbidity rate at all<sup>[69]</sup>.

In general, a more selective use of laparoscopic surgery for more straightforward, uncomplicated cases of diverticular disease could minimize conversion rates and therefore capitalize on the advantages derived from the laparoscopic approach. On the other hand, a more liberal use of laparoscopic surgery, including for complicated cases in patients with a previous laparotomy, is likely to result in increased conversion rates. However, this less stringent patient selection could still offer the potential benefits of laparoscopic surgery to an increasing number of individuals requiring surgery for sigmoid diverticulitis without adverse effects on long-term patient outcomes<sup>[68]</sup>.

## STRICTURE

Sigmoid diverticulitis can present in the form of a stric-

ture which may or may not be associated with typical symptoms. In the case of stricture, the indications for surgery may range from colonic obstruction requiring acute surgical intervention to the inability to rule out carcinoma as the cause of stricture (Figure 3). Sigmoid strictures can cause significant dilatation in the proximal colon, which can complicate the creation of a colorectal anastomosis after sigmoid resection. A staged procedure with sigmoidectomy and creation of a colostomy may therefore become necessary. A possible option in the surgical management of severe sigmoid stricture causing significant fecal loading is a resection with on-table colonic lavage and primary anastomosis (Figure 4). This is carried out by inserting a large Foley catheter through an appendicostomy or distal ileal enterotomy secured with a purse-string suture with the tip of the catheter placed into the cecum. This Foley catheter is connected to a bag of warm saline solution which is typically used for irrigation. A large corrugated tube, such as an anesthesia ventilator tube, is then placed in the open end of the descending colon and secured with umbilical tape or large suture to the bowel wall. The distal end of the tubing is placed into a bucket on the floor where the effluent is collected. It is frequently necessary to mobilize both the hepatic and splenic flexures and manually propel solid stools towards the distal end which can significantly increase operative times. A proximal stoma diversion in addition to a colorectal anastomosis may be a prudent adjunct to the operative procedure, with or without intraoperative colonic lavage. Alternatively, a stricture can be treated with placement of endoluminal metallic stents to correct the obstruction, reduce the discrepancy in bowel diameter and allow a subsequent one-stage surgical procedure consisting of sigmoid resection and primary colorectal anastomosis<sup>[70]</sup>. Other options in the management of large bowel obstruction related to diverticular disease are subtotal colectomy and primary ileorectal anastomosis, and, in the most difficult cases, creation of a decompressive colostomy proximal to the strictured sigmoid followed by delayed sigmoid resection. The choice among these various options depends on both the individual patient and the surgeon's level of confidence in performing each of the approaches described above.

**Figure 5** Sigmoid diverticulitis complicated by pericolic abscesses (A and C, arrows) requiring treatment by placement of two separate CT-guided percutaneous drains (B and D). This patient underwent laparoscopic sigmoidectomy with primary colorectal anastomosis and removal of both drains 6 wk after percutaneous drain placement.

## PERIDIVERTICULAR ABSCESS

There is evidence suggesting that clinical presentation of sigmoid diverticulitis as peridiverticular abscess has increased in recent years<sup>[24]</sup>. It is generally acknowledged that elective surgery should be performed after percutaneous drainage of peridiverticular abscess (Figure 5) due to the high risk of recurrent diverticulitis<sup>[13,71]</sup>. In these cases surgery is generally performed 4-6 wk after initial percutaneous drainage. Some surgeons prefer to leave the drain in place until surgery, others remove the drain if the output becomes minimal and a drain contrast study rules out an existing sigmoid fistula. An accepted exception is the use of percutaneous drainage alone to obviate the need of surgery in poor risk patients<sup>[72]</sup>.

The safety and effectiveness of percutaneous drainage in controlling the immediate symptoms of diverticular disease presenting with an abscess have been reported by several authors<sup>[14,73-77]</sup>. A number of variables have been examined as possible factors associated with the success rate of non-operative management.

Firstly, the size of the abscess seems to be an important indicator for success of non-operative management, especially when antibiotics alone are considered as first line treatment. A diameter of approximately 3-4 cm or less is more likely to be associated with successful antibiotic treatment<sup>[14,76,77]</sup>. Based on the ability of antibiotics alone to control smaller abscesses, some authors have suggested that the role of CT-guided drainage of diverticular-related abscesses should be re-evaluated and

percutaneous drainage should be utilized less often<sup>[14]</sup>. Another factor with a possible impact on management is the abscess location. In fact, there is evidence suggesting that an abscess located in the mesocolon might be more responsive to non-operative treatment than a pelvic abscess<sup>[15,71]</sup>. In this regard, in a study analyzing 73 patients initially treated with antibiotics and undergoing CT-guided drainage only in case of failure of medical treatment, 71% of patients with a pelvic abscess ultimately required surgery *vs* 51% after percutaneous drainage of a mesocolic abscess. Based on these results, the authors suggested that sigmoid colectomy should be recommended after drainage of a pelvic abscess but not necessarily after percutaneous drainage of a mesocolic abscess<sup>[74]</sup>. The success of non-operative treatment in at least some patients has prompted other investigators to question the role of routine surgery after successful drainage of pericolic abscess<sup>[20]</sup>.

It remains difficult to critically evaluate the results of the various treatment options available for abdominal and pelvic abscesses related to diverticulitis because of both variability in clinical practices and data reporting. In some institutions percutaneous drainage is the preferred approach whenever technically feasible, which generally requires an abscess diameter of at least 3 cm. On the other hand, in other institutions the initial treatment of diverticular abscesses includes antibiotics alone and only after failure of antibiotic treatment is a percutaneous drainage considered. In addition, the data regarding the effectiveness of percutaneous drainage alone without

subsequent surgery remain limited, because of both small sample sizes and short follow-up. Further studies will be necessary before the standard of care of elective surgery after initial percutaneous drainage is abandoned.

## GENERALIZED PERITONITIS FROM PERFORATED SIGMOID DIVERTICULITIS

A perforation of a sigmoid diverticulum into the free peritoneum is a life-threatening condition requiring immediate surgical intervention. The standard of care in most of these cases is a resection of the colonic segment including the perforation and creation of a proximal colostomy. Several authors refer to this operation as a Hartmann procedure, which by definition involves the resection of the sigmoid, closure of the rectal stump and creation of an end-descending colostomy, and which has also been performed laparoscopically<sup>[78,79]</sup>. Other surgeons have suggested that especially when the patient is severely septic and hemodynamically unstable the initial goal should be an expedited resection limited to the involved segment<sup>[80]</sup>, sometimes referred to as a “perforectomy”, in which at least some of the sigmoid should be left intact until the patient completes his or her recovery from the initial operation. In this case, a completion sigmoid resection would be typically performed at the time of colostomy takedown several months later so that the patient ultimately receives appropriate surgical treatment for sigmoid diverticulitis<sup>[81]</sup>. The morbidity and mortality from Hartmann procedure for free diverticular perforation remain substantial. The aggregate mortality in a total of 1051 patients reported in 54 combined studies conducted between 1966 and 2003 was almost 19% and was associated with a 24% incidence of wound infection and a 10% incidence of stoma complications<sup>[82]</sup>. In spite of advancements in intensive care, imaging and medical treatments, the mortality for this condition has remained stable over time<sup>[83]</sup>. Intestinal continuity can generally be reestablished 3-6 mo after the initial operation<sup>[84]</sup> although it has been reported that between approximately 30% and 70% of patients never have their colostomy closed<sup>[81,85-87]</sup>. In addition, a Hartmann takedown remains a difficult elective procedure<sup>[88]</sup> fraught with significant morbidity<sup>[89]</sup>.

Considering the significant morbidity and mortality associated with a Hartmann procedure and its sequelae, some authors have suggested that in select circumstances it might be possible to resect the perforated segment and primarily reestablish intestinal continuity<sup>[90,91]</sup>, which some surgeons feel can benefit from intraoperative colonic lavage as described above<sup>[92,93]</sup> (Figure 4). This view remains controversial and most surgeons would not recommend a resection and primary colorectal anastomosis for generalized peritonitis from diverticular perforation. However, in select circumstances it is possible to perform a colorectal anastomosis and proximal diverting loop ileostomy. This approach seems to be preferable to a Hartmann resection when the degree of intraoperative contamination and the

underlying patient condition allow this approach. In these cases, the use of a defunctioning stoma in addition to colorectal anastomosis might result in a good compromise between postoperative morbidity, quality of life and probability of permanent stoma<sup>[94]</sup>.

## LAPAROSCOPIC LAVAGE, A NOVEL SURGICAL APPROACH TO GENERALIZED PERITONITIS

The advent of laparoscopic surgery and the increased use of the laparoscopic approach to treat perforated peptic ulcers and appendicitis have led to the development of laparoscopic strategies for the treatment of perforated diverticulitis. In this regard, laparoscopic lavage is a recently proposed treatment option which would potentially save the patient from both a major bowel resection and the creation of a stoma. The initial experiences of laparoscopic lavage have been promising with respect to perioperative mortality and complications<sup>[95]</sup>. In addition, while most proponents of initial laparoscopic lavage have decided in favor of an elective, delayed sigmoidectomy<sup>[96-100]</sup>, a multicenter study from Ireland has reported encouraging results following a policy of lavage followed by continued observation. In fact, Myers *et al*<sup>[101]</sup> noted recurrence of sigmoid diverticulitis in 4 out of 92 treated patients, none of whom required surgery after a median follow-up of 36 mo. These data from different centers suggest that laparoscopic lavage has the potential to become, at least in select cases, the definitive treatment for perforated diverticulitis. However, the data on laparoscopic lavage for diverticular peritonitis remains limited and further investigations into this option are warranted to confirm these initial, promising results.

## YOUNGER PATIENTS: SHOULD THE INDICATIONS FOR SURGERY CHANGE?

The indication for surgery in younger patients, generally defined as those who are 50 years old or younger, has been the subject of controversy. It has been reported that younger patients more frequently require surgery for diverticulitis<sup>[102]</sup> or are prone to recurrent disease<sup>[103]</sup>. Based on the presumed association between younger age and more virulent disease, some surgeons have suggested that elective surgery should be recommended in patients younger than 50 years old after their first attack of uncomplicated diverticulitis<sup>[104,105]</sup>. However, other retrospective series have not confirmed a correlation between younger age and more severe disease<sup>[106-109]</sup>. In addition, prospective data do not support a more aggressive surgical approach for younger patients. In this regard, Guzzo and Hyman<sup>[110]</sup> examined 762 patients admitted to their institution with sigmoid diverticulitis between 1990 and 2001, including 259 individuals younger than 50. The risk of requiring surgery during the first admission was comparable between older and younger patients. In addition,

out of 196 younger patients who were treated medically at the time of their initial admission, only one (0.5%) presented with perforation during a median follow-up of 5.2 years. In another prospective study with a median follow-up of 9.5 years, 118 patients were followed after their initial attack of diverticulitis, 28 of whom were 50 years old or younger. Age and findings at initial CT scan were analyzed as possible predictive factors for risk of poor outcome during the follow-up period, defined as recurrent, persistent or complicated diverticulitis. The probability of poor outcome at 5 years was 54% in younger patients with initially severe CT diverticulitis vs 19% for older patients with mild disease, based on CT imaging. At univariate analysis, age was a predictive factor for poor outcome. However, after stratification for severity of disease, age was no longer a significant factor<sup>[111]</sup>. Based on the available contemporary data there does not seem to be sufficient justification to recommend elective surgery after one attack of sigmoid diverticulitis in younger patients and rather the disease should be treated similarly in both younger and older patients depending on its severity and inclination to recurrence.

## IMMUNOSUPPRESSED OR IMMUNOCOMPROMISED PATIENTS

Transplant recipients or patients with chronic diseases affecting the immune system are at increased risk of more aggressive and complicated diverticulitis<sup>[112-114]</sup>, including initial presentation as free peritoneal perforation<sup>[115,116]</sup>. Chronic use of steroids is also associated with increased postoperative mortality after surgery for diverticulitis<sup>[20]</sup>.

Therefore, it is generally recommended that surgery should be offered to this subset of patients after their first documented episode of diverticulitis. The studies supporting this practice are generally retrospective with small sample sizes<sup>[114]</sup>. On the other hand, there is no data presenting evidence against this practice. Therefore it seems reasonable to continue offering surgery after one episode of uncomplicated diverticulitis in immunocompromised patients. In this respect, some surgeons have emphasized that surgery should be carried out after the diverticulitis attack during the same hospital stay and a proximal diversion should be considered<sup>[117]</sup>. Other authors have even suggested that patients with one episode of uncomplicated diverticulitis who are transplant candidates should undergo prophylactic sigmoidectomy before their transplant. The evidence in favor of this practice remains scant, based on earlier studies and generally restricted to renal transplant recipients<sup>[118,119]</sup>. On the other hand, patients awaiting liver, heart and lung transplant are typically in poor health from their primary disease and generally should not be considered for prophylactic sigmoidectomy prior to their transplantation.

With respect to HIV infection and AIDS, there is no substantial data specific for sigmoid diverticulitis<sup>[120]</sup>. In general, the outcome of major abdominal surgery in

HIV-positive individuals without AIDS is not significantly different from the general population. However, when a patient develops diverticulitis in the presence of AIDS or other causes of acute immunosuppression, postoperative infections are more likely. If surgery becomes necessary in these cases, a Hartmann procedure or a primary sigmoid resection with anastomosis and proximal diversion should be therefore preferable.

## EVOLVING CONCEPTS IN DIVERTICULAR DISEASE

Sigmoid diverticulitis may have clinical manifestations which are difficult to accurately characterize. Its symptoms may overlap in some cases with the conditions collectively referred to as irritable bowel syndrome. Our understanding and therapeutic approach for this condition are evolving. From a surgical perspective it is imperative to minimize unnecessary surgery if diverticulitis cannot be documented radiologically, especially with a concurrent clinical history suggestive of irritable bowel syndrome. However, if irritable bowel syndrome can be ruled out, there seem to be a group of patients with chronic left lower quadrant abdominal pain and occasional alteration of bowel habits, but without fever or leukocytosis, who might still benefit from surgery. The condition of this subgroup of patients has been referred to as “smoldering diverticulitis”. Horgan and colleagues identified smoldering diverticulitis in 47 patients, corresponding to approximately 5% out of their denominator of 930 patients undergoing sigmoid resection for diverticulitis. A total of 88% of these patients remained pain-free after at least 12 mo of follow-up following sigmoidectomy and primary anastomosis<sup>[121]</sup>. Atypical sigmoid diverticulitis should be part of the differential diagnosis in the patient with left lower quadrant pain, as surgery is curative in the majority of these cases.

An additional, novel clinical syndrome recently proposed as a separate entity within the realm of diverticular disease is referred to as segmental colitis associated with diverticulosis (SCAD)<sup>[122-124]</sup>. This is a non-specific, localized inflammatory process associated with diverticulosis involving the sigmoid but not the rectum or the proximal colon, generally presenting in middle-aged or elderly patients with rectal bleeding, diarrhea and abdominal pain variably combined. It most commonly affects males. Histology indicates inflammation without granulomas and serology should be negative for anti-neutrophil cytoplasmic antibodies (ANCA) and anti-Saccharomyces cerevisiae antibodies (ASCA). Treatment with 5-aminosalicylate is generally effective in resolving the inflammation both symptomatically and endoscopically<sup>[122]</sup>.

The pathogenesis of SCAD and its relationship with inflammatory bowel disease remain controversial<sup>[122,125]</sup>. Regardless, SCAD is becoming increasingly accepted as a separate entity from the traditional sigmoid diverticulitis and its known complications. While anti-inflammatory agents have been effective in the management of SCAD,

their role in the more common forms of diverticular disease remain unproven.

Another area of investigation concerns the potential causal relationship between sigmoid diverticulitis and colorectal cancer, which has been suggested based on comparisons with patients having diverticulosis without diverticulitis<sup>[126]</sup>. This association has not yet been validated and will therefore require further study. At the moment, sigmoid diverticulitis is not considered a pre-cancerous or high-risk condition for the development of colorectal cancer and the recommended screening modalities do not differ from the guidelines accepted for the average-risk population.

## CONCLUSION

Sigmoid diverticulitis is a condition ranging from mild inflammation of the sigmoid to life-threatening colonic perforation. Antibiotics are generally effective in mild forms of the disease while surgery is indicated in cases of multiple recurrences or complicated disease. Based on recent data, the systematic indication for surgery after 2 attacks should be abandoned in favor of a more individualized approach. Laparoscopic surgery is gaining favor in the surgical treatment of sigmoid diverticulitis. A subset of patients with atypical presentation presents a significant challenge in management; some may benefit from surgery whereas others could benefit from anti-inflammatory agent treatment.

### Abstract

Pancreatic cancer is associated with a poor prognosis, and surgical resection remains the only chance for curative therapy. In the absence of metastatic disease, which would preclude resection, assessment of vascular invasion is an important parameter for determining resectability of pancreatic cancer. A frequent error is to misdiagnose an involved major vessel. Obviously, surgical exploration with pathological examination remains the "gold standard" in terms of evaluation of resectability, especially from the point of view of vascular involvement. However, current imaging modalities have improved and allow detection of vascular invasion with more accuracy. A venous resection in pancreatic cancer is a feasible technique and relatively reliable. Nevertheless, a survival benefit is not achieved by curative resection in patients with pancreatic cancer and vascular invasion. Although the discovery of an arterial invasion during the operation might require an aggressive management, discovery before the operation should be considered as a contraindication. Detection of vascular invasion remains one of the most important challenges in

### INTRODUCTION

The incidence of pancreatic cancer has gradually increased over the 20th century and in the early years of this century<sup>[1,2]</sup>. Cancer of the pancreas is the sixth most common cancer and fourth cause of death from cancer (22% of deaths among gastrointestinal cancers)<sup>[1-3]</sup>.

Pancreatic cancer is associated with a poor prognosis, with less than 5% of patients surviving 5 years after the diagnosis<sup>[4]</sup>. Surgical resection remains the only chance for curative therapy in these patients<sup>[5-7]</sup>. Accurate preoperative staging of pancreatic cancer is essential to avoid unnecessary surgery in those with unresectable disease and, at the same time, in order not to deny the opportunity for cure in patients with resectable disease<sup>[5,6,8]</sup>.

Only 16% of patients initially present a disease confined to the pancreas (stage I)<sup>[6,7]</sup>. Thus, of patients seen, 85%-90% have surgically unresectable tumors at the time of diagnosis<sup>[6,7,9-11]</sup>.

There is no evidence-based consensus on the optimal preoperative imaging assessment of patients with suspected pancreatic cancer<sup>[6,8,12]</sup>.

The criteria of unresectability are numerous<sup>[7,13-23]</sup>. However, in the absence of metastatic disease which precludes resection, assessment of vascular invasion is an important parameter for determining resectability for pancreatic cancer<sup>[5]</sup>. A frequent error is to misdiagnose an involved major vessel<sup>[11]</sup>. Vascular invasion is a relatively frequent discovery in pancreatic cancer; found in 21%-64% of patients, depending on the population studied<sup>[7,24]</sup>.

From the point of view of arterial vessels, a tumoral infiltration of a large trunk (celiac axis, superior mesenteric artery, or hepatic artery) must be carefully analyzed because it constitutes a contraindication to surgery<sup>[25-27]</sup>. However, isolated involvement of smaller branches such as the gastro-duodenal artery will not preclude surgical resection<sup>[25]</sup>. The superior mesenteric vessels are the most frequently involved vessels in this cancer, due to their intimate relationship with the head, the uncinate process, and body of the pancreas<sup>[25,28]</sup>.

Limited venous invasion does not represent an absolute contraindication for surgery<sup>[4,26,27,29-31]</sup>. Obviously, surgical exploration with pathological examination remains the "gold standard" in terms of evaluation of resectability, especially from the point of view of vascular involvement. However, current imaging modalities have improved and allow detection of vascular invasion with more accuracy. Detection is the key to the surgeon's preoperative planning, because the posterior and lateral surfaces of the portal and superior mesenteric vein can be evaluated only after the surgical procedure is well advanced<sup>[14]</sup>. Thus, the management of a suspicious tumoral adhesion to a vessel is one of the most important challenges in a Whipple type procedure.

In this review, the current imaging modalities for assessing vascular involvement of pancreatic cancer will be discussed. Subsequently, the management and outcome of vascular invasion in patients with pancreatic cancer will also be reviewed briefly.

## COMPUTED TOMOGRAPHY

Computer tomography (CT) gives information about localization, size and extension of tumor<sup>[8,18]</sup>, while being non-invasive<sup>[32]</sup>. A recent meta-analysis showed CT to be 91% sensitive and 85% specific for tumoral detection<sup>[33]</sup>. Phoa *et al.*<sup>[34]</sup> showed that, with regard to tumor convexity towards a vessel, Grades D (concave contour of the tumor towards vessel) or E (circumferential involvement of vessel) have a risk of invasion of 88%; and a possibility of resection of 7% for the type D and of 0% for the type E<sup>[35]</sup>. Loyer *et al.*<sup>[35]</sup> found that Grades A (fat plane separating the tumor from the vessel) and B (normal pancreatic tissue between tumor and vessel) had a resection rate of 95%, therefore these two grades are factors of better prognosis.

On the other hand, the length of tumor contact with the vessel (if it is greater than 5 mm) is a relatively good

predictive factor for vascular invasion (78% for portal vein and 81% for superior mesenteric vein)<sup>[34]</sup>.

A circumferential contact of more than 180 degrees has been shown to have a good correlation with unresectability<sup>[34,36,37]</sup>. For this criterion, Lu *et al.*<sup>[38]</sup> found a sensitivity of 84%, a specificity of 98%, a positive predictive value (PPV) of 95%, and a negative predictive value (NPV) of 93%, for unresectability. Furthermore, Phoa *et al.*<sup>[34]</sup> reported a sensitivity of 60%, and a specificity of 90%, if tumor convexity Grades D or E were combined with circumferential involvement of > 90 degrees. In addition, a strongly narrowed vessel also has an important risk of being invaded<sup>[34,36]</sup>, but prudence is essential, especially for a vein, due to the mass effect of the tumor without the presence of vascular invasion<sup>[10,39,40]</sup>. In addition, an artery may be completely invaded, with no apparent change in vessel caliber<sup>[36,39]</sup>.

Concerning the irregularity of the vascular wall, Li *et al.*<sup>[36]</sup> reported a sensitivity and a specificity of 45% and 99%, respectively, for tumor detection in arteries, and 63% and 100% in the case of veins.

Regarding the rare superior mesenteric vein teardrop sign, Hough *et al.*<sup>[41]</sup> found a sensitivity of this CT sign of 91% and a specificity of 98%; similar findings were reported in other series<sup>[36]</sup>.

Consequently, Li *et al.*<sup>[36]</sup> reported that the CT criteria for arterial invasion might be: an arterial embedment in tumor, or the combination of tumor involvement of more than one-half of the circumference of the arteries with artery wall irregularity or with artery stenosis (sensitivity of 79%, specificity of 99%). The criteria for venous invasion might be venous occlusion, tumor involvement of more than one-half of the circumference of the veins, vein wall irregularity, vein caliber stenosis, and teardrop superior mesenteric vein sign (sensitivity of 92%, specificity of 100%).

From the point of view of the detection of vascular invasion, many studies have evaluated CT (Table 1). CT has improved much these last years. Technology has developed multi-slice with 4-64 detector rows, allowed thin-sections and dual-phase, with faster time of acquisition, and numerous possibilities of image post-processing (3D reconstructions, multiplanar reconstructions)<sup>[19,29,40,42-45]</sup>.

Fourteen years ago, Yoshimi *et al.*<sup>[46]</sup> reported one of the first cases of 3D vascular reconstruction, allowing the evaluation of portal invasion with a higher accuracy than angiography alone. Currently, pancreatic section thickness of 1 mm is obtained in approximately 20 s, allowing true volume acquisition, with vascular details better than angiography<sup>[28,47,48]</sup> useful when assessing vascular invasion<sup>[44]</sup>. Furthermore, CT angiography allows anatomical study of small pancreatic vessels with a remarkable degree of accuracy<sup>[49,50]</sup>.

Moreover, dilation of the peri-pancreatic veins with no visualization of inferior branches on CT suggests tumor invasion of peri-pancreatic tissue<sup>[50]</sup>.

Several studies have highlighted the importance of

**Table 1** CT performance in the detection of vascular invasion in more than 50 patients with pancreatic cancer

CT: Computer tomography; PPV: Positive predictive value; NPV: Negative predictive value; NA: Not available.

the moment of image acquisition. With regard to the pancreas, it seems that a portal venous phase (60 s after intravenous administration of iodinated contrast medium) or that a pancreatic phase (40-70 s) provides more information than an arterial phase (18 s) or that of a hepatic phase (70 to 100 s)<sup>[19,29,51-54]</sup>. McNulty *et al*<sup>[51]</sup> reported that an arterial phase can be reserved for patients in whom CT angiography is required.

Lastly, Imbriaco *et al*<sup>[55]</sup> showed that dual-phase helical CT (arterial: 20 s, and pancreatic late: 70 s) was interesting but was comparable with single-phase helical CT (pancreatic early: 50 s).

In conclusion, CT is the assessment of choice in first intention, permitting in one non-invasive examination a TNM staging evaluation.

From the vascular point of view, many criteria exist (especially circumferential involvement of vessel of more than 180 degrees, radiological absence of a fat plane between tumor and vessel, vascular occlusion with collaterals, teardrop sign) which allow accuracy in diagnosing vascular invasion. Development of new radiological techniques (3D reconstructions, multiplanar reconstructions) has improved accuracy of assessment of vascular invasion.

## MAGNETIC RESONANCE IMAGING (MRI)

MRI with cholangiopancreatography gives much information for the evaluation of primary tumor and metastatic dissemination, improved by the use of gadolinium or mangafodipir trisodium<sup>[1,13,47,56-58]</sup>. Currently, the use of

MRI in an “all-in-one” staging method (MRI, coupled with angiography and cholangiopancreatography) is a subject under deliberation<sup>[58-60]</sup>.

MRI criteria for vascular invasion are: (1) occlusion of the vessel, with or without collaterals, (2) tumoral infiltration of peri-vascular fat tissue, (3) circumferential contact of more than 180 degrees between the tumor and the vessel, and (4) mass effect along one side of the vessel for more than 2 cm<sup>[7,56,60,61]</sup>.

As regards the detection of vascular invasion, MRI has an accuracy of approximately 94% for enhanced T1-weighted imaging<sup>[62]</sup>. Romijn *et al*<sup>[58]</sup> found in their study an accuracy of 81% with mangafodipir trisodium (definitely higher than MRI without contrast medium).

Other studies have attempted to analyze the performance of MRI in the detection of vascular invasion. They found a sensitivity of 47%-83%<sup>[24,60]</sup>, a specificity of more than 95%<sup>[7,59]</sup>, a PPV of more than 70%<sup>[7,8]</sup>, and a NPV of 23%-96%<sup>[24,60]</sup>.

Modern MRI technology makes it possible to obtain 3D reconstructions, facilitating the study of the peripancreatic vessels<sup>[61,63,64]</sup>. Some series have also demonstrated the adequate time for vascular pancreatic image acquisition: biphasic imaging at 15 and 45 s after arrival of contrast material (gadolinium) in the abdominal aorta<sup>[65]</sup>.

Accuracy of MRI for vascular visualization is quite similar to that of CT<sup>[56,66,67]</sup>. It consequently seems logical to reserve this expensive and time-consuming technology for those patients not able to benefit from CT (allergy to iodine, renal insufficiency, pregnancy) or if CT findings are inconclusive<sup>[68]</sup>.

## ANGIOGRAPHY

Currently, conventional angiography is no longer part of the diagnostic protocol in most centers<sup>[13]</sup>, because this examination does not permit the detection of the tumor itself<sup>[1]</sup>, and can easily be replaced by other less invasive methods which give more information on tumoral extension.

On the other hand, preoperative arteriography may visualize vascular abnormalities (anatomical variations, acquired stenosis), allowing a possible modification of surgical strategy (revascularisation, replacement hepatic artery, embolization of an aneurism)<sup>[17,69,70]</sup>.

With regard to vascular invasion, angiographic criteria are: (1) vascular stenosis or occlusion, with or without collaterals, (2) thrombosis of a vessel, (3) acute angle appearing in the venous wall, and (4) envelopment of the vessel within tumor<sup>[69,71-74]</sup>.

In at least 20% of cases, angiography misses the vascular invasion<sup>[10]</sup>, because it gives only information about the lumen of the vessel<sup>[72]</sup>. Angiography depends upon displacement of vessels and distortion of vascular contours unless clear vessel occlusion is present. Furthermore, the tumor may completely encase and invade the small amount of fat surrounding the vessel, and yet not cause a distortion of the contour of the vascular lumen, which is required for detection on angiography. This feature can be visualized during endoscopic ultrasonography or CT. Thus, angiography requires more extensive vascular involvement in order for it to be detected<sup>[5,74,75]</sup>.

The results reported for detection of vascular invasion by pancreatic cancer using angiography are: a sensitivity between 21%<sup>[5,8]</sup> and more than 80%<sup>[10,76]</sup>, a specificity between 50%<sup>[72]</sup> and 100%<sup>[8,69]</sup>, a PPV more than 60%<sup>[5,72]</sup>, and a NPV between 50%<sup>[72]</sup> and 83%<sup>[10]</sup>. Late angiographic times allow visualization of the portal vein, and possible invasions. In addition, it is possible to inject contrast medium directly into the portal vein by a transhepatic access, for example at the time of intravascular ultrasonography (see below).

In conclusion, studies show that angiography is paradoxically relatively poor in the detection of vascular invasion. On the other hand, it permits the visualization of arterial and venous anomalies, allowing a change in surgical strategy.

## ABDOMINAL ULTRASONOGRAPHY (US)

Abdominal US is often the first line examination for a patient presenting with jaundice and pain<sup>[13]</sup>.

From the vascular point of view, US coupled with Doppler gives a reasonably reliable measure of vascular patency and can improve accuracy in assessing vascular invasion<sup>[13,77,78]</sup>. Its sensitivity ranges between 60%<sup>[79]</sup> and more than 90%<sup>[80]</sup>; its specificity has been reported to be higher than 90%<sup>[79,80]</sup>, the PPV is higher than 90%<sup>[81]</sup>, and the NPV is higher than 75%<sup>[82,83]</sup>. Very recently, authors reported US to be 93% accurate in detecting

portal vein invasion, by using 3D vascular reconstruction technology<sup>[84]</sup>.

Color Doppler sonographic criteria for vascular invasion are: (1) absence of hyperechoic tissue between the tumor and the vessel, (2) more than 2 cm continuity between tumor and vessel, (3) circumferential contact between the tumor and the vessel, (4) circumferential narrowing of vessel lumen, and (5) vascular occlusion or thrombosis<sup>[81-83,85-87]</sup>.

In addition, perioperative US has been reported as 100% sensitive in identifying tumors, and 92% sensitive and specific in detecting portal invasion<sup>[88]</sup>. In 22% of patients with pancreatic neoplasms, US-Doppler makes it possible to modify therapeutic strategy<sup>[86]</sup>.

In conclusion, US coupled with Doppler is a relatively accurate, cheap, and non-ionizing imaging modality for initial screening of patients with suspicion of tumors of the pancreas. However, US has demonstrated weakness in recognition of deeper localizations.

With regard to the detection of vascular invasion, studies have shown that US coupled with Doppler is a reliable method. However, these series evaluated almost exclusively the portal vein and its tributaries. Recent improvement in US imaging, allowing 3D reconstruction, offers new potential for this technology in the assessment of tumoral vascular involvement.

## ENDOSCOPIC ULTRASONOGRAPHY (EUS)

EUS is a relatively new technique, providing direct ultrasonic imaging of the pancreas through the gastrointestinal lumen<sup>[2,13]</sup>. However, the probes are expensive and EUS requires a trained endoscopist<sup>[13,63]</sup>.

EUS has been shown to be accurate in diagnosing and staging pancreatic cancer<sup>[89]</sup>, with the help of fine needle aspiration (FNA), with 96.6% sensitivity, 99.0% specificity, 96.2% NPV, and 99.1% PPV<sup>[90]</sup>.

EUS criteria for vascular invasion are: (1) loss of the hyperechoic vessel wall/tumor interface, (2) direct visualization of tumor within the vessel lumen, (3) vascular encasement or occlusion, (4) non-visualization of a major vessel, in the presence of collaterals, (5) proximity of the tumor (< 3 mm) to the vessel, and (6) irregularity of the vascular wall<sup>[5,8,11,89,91-96]</sup>.

Sugiyama *et al.*<sup>[91]</sup> reported that EUS is more accurate than CT, US, and angiography for the detection of portal invasion; similar findings were shown in other series<sup>[97,98]</sup>. In addition, Brugge *et al.*<sup>[93]</sup> showed that EUS was highly sensitive in the detection of portal and splenic vein invasions.

Arterial invasion is assessed with more difficulty by EUS<sup>[92,98-100]</sup>. Globally, the sensitivity is 50%-100%<sup>[92,95,101,102]</sup>, the specificity 58%-100%<sup>[92,102]</sup>, the PPV 28%-100%<sup>[92,96]</sup>, and the NPV 18%-93%<sup>[89,94]</sup>.

Very recently, Fritscher-Ravens *et al.*<sup>[103]</sup> reported the use of 3D linear EUS in the assessment of vascular involvement with very interesting results compared with classical EUS. Linear 3D EUS enhanced the evaluation

of vascular involvement of pancreatic lesions, especially in chronic pancreatitis.

In conclusion, it is appropriate to incorporate EUS in the preoperative assessment when there is suspicion of pancreatic cancer. From the point of view of the detection of vascular invasion, EUS has shown good accuracy, especially for venous invasion.

## INTRAVASCULAR ULTRASONOGRAPHY (IVUS)

When a tumor appears to be contiguous with the portal vein or with the superior mesenteric vein, the diagnosis of vascular invasion can be difficult. Some limited reports have suggested that IVUS might allow the distinction between a simple compression by mass effect and invasion<sup>[71]</sup>.

Moreover, IVUS makes it possible to detect intra-portal thrombus, sometimes missed by CT<sup>[71]</sup>. IVUS is performed either by a transhepatic access, or by a transmesenteric catheterization (during operative time)<sup>[71,104-108]</sup>. Complications are rare<sup>[72,104-106]</sup>.

IVUS criteria for vascular invasion are: (1) obliteration of the echoic band of the portal vein by the hypoechoic tumor, (2) tumor mass blended with the venous wall, and (3) tumor protrusion into the vascular lumen<sup>[71,72,76,104-106,109]</sup>.

One of the limitations of IVUS is the lack of specificity in the case of pancreatitis<sup>[71,105]</sup>. Moreover, IVUS has a limited penetration, allowing only localised investigations. Another weakness remains the lack of spatial orientation, making the interpretation of the images difficult<sup>[72,106]</sup>.

There are few studies concerning IVUS in detection of vascular invasion in pancreatic cancer. Moreover, they report only portal and superior mesenteric vein results, not evaluating arterial invasion. The results are: sensitivity more than 95%<sup>[71,76]</sup>, specificity more than 90%<sup>[71,76]</sup>, PPV more than 90%<sup>[105]</sup>, and NPV more than 95%<sup>[105]</sup>.

Kaneko *et al.*<sup>[109]</sup>, has pioneered the use of IVUS in staging of pancreatic cancer, recently using 3D reconstructions of IVUS with a high degree of accuracy. Tezel *et al.*<sup>[110]</sup> also reported that a contact of more than 18 mm between the tumor and the portal or the superior mesenteric vein was a factor of poor prognosis. The use of IVUS allows stent placement<sup>[111]</sup>, a possibility in the palliative treatment of portal stenosis.

In conclusion, studies show that IVUS is probably superior to CT and portography for the detection of vascular invasion. However, data is available only for the portal vein and for the superior mesenteric vein. To our knowledge, there are no data concerning the utility of IVUS in detecting tumoral arterial invasion.

Because IVUS is expensive and invasive, Nakao *et al.*<sup>[105]</sup> recommend performing this examination only in cases in which the distinction between compression and invasion cannot be made by conventional imaging techniques.

## LAPAROSCOPY AND LAPAROSCOPIC ULTRASONOGRAPHY (LUS)

For almost 30 years<sup>[112]</sup>, laparoscopic examination of the

abdominal cavity has offered an excellent, although invasive, visualization of peritoneum and the liver<sup>[13,47,63,113,114]</sup>.

From the vascular point of view, incision of the gastrohepatic omentum allows a direct access to the underlying vessels<sup>[47,115]</sup>. However, it seems certain that laparoscopy alone cannot detect vascular invasion, in particular mesenteric, without help of perioperative ultrasonography<sup>[116]</sup>.

Currently, routine laparoscopy is not recommended in cases of cancer of the head of the pancreas, because it influences further surgical strategy in only 14%-19% of cases<sup>[116,117]</sup>. On the other hand, a study showed that in the case of cancer of the body or the tail of the pancreas, laparoscopy could avoid up to 50% of the operations, because of metastases not identified during staging<sup>[116]</sup>.

Obviously, laparoscopy can also be used with a palliative aim (double derivations), if the tumor is unresectable<sup>[21,117-120]</sup>. Laparoscopy has its limits: it only allows visualization of the liver surface; impossibility of analyzing the retroperitoneum and its vessels; technical problems due to adhesions<sup>[21,47,63,120,121]</sup>.

LUS was subsequently developed, and this allows detailed study of the liver, the lymphatic area, and the corresponding vessels<sup>[47,121-126]</sup>. Vascular structures can be accurately visualized by LUS in approximately 95% of patients with tumors in the head of the pancreas<sup>[126]</sup>.

LUS criteria for vascular invasion are: (1) loss of the hyperechoic vessel - tumor interface, (2) obliteration or thrombosis of a vessel, (3) a fixed stenosis, (4) vessel encasement by tumor encirclement and rigidity, and (5) presence of invading tumor within the vessel lumen<sup>[122,127-129]</sup>.

There are numerous studies evaluating resectability by LUS, but to our knowledge few have focused on vascular invasion. They have found a sensitivity of more than 50%<sup>[129]</sup>, a specificity of more than 80%<sup>[130]</sup>, a PPV of 93%<sup>[127]</sup>, and a NPV of 73%<sup>[128]</sup>.

Despite these encouraging results, several authors do not recommend systematic use of laparoscopy or LUS. They prefer to recommend this technique for doubtful cases<sup>[21,121,131-133]</sup>.

## POSITRON EMISSION TOMOGRAPHY (PET) AND POSITRON EMISSION TOMOGRAPHY COUPLED WITH COMPUTED TOMOGRAPHY

PET is a non-invasive imaging method, which gives information about cellular metabolic activity.

Currently, 18F-fluorodeoxyglucose (FDG) is injected and taken up preferentially by malignant tumors, and secondary localizations, rather than by healthy tissue<sup>[13,17,18,47,63,134-136]</sup>. The FDG is not metabolized and is trapped inside the cell<sup>[47]</sup>, allowing it to be imaged in contrast to surrounding tissue<sup>[18]</sup>.

PET is accurate in diagnosing small tumors (< 2 cm), as well as peritoneal implants and metastases<sup>[13,47,63,102,135,137-141]</sup>. In addition, PET is able to differentiate

inflammatory pathologies from tumoral ones<sup>[47,135,139,142,143]</sup>. PET differentiates malignant and benign pathologies with a sensitivity of 85%-100% and a specificity of 67%-99%; often higher than that of CT<sup>[135,141,144-146]</sup>.

In addition, false negatives exist in the case of strongly differentiated tumors, small periampullary tumors or in cases of hyperglycemia<sup>[63,135,146,147]</sup>. In the case of normoglycemic patients, PET has a sensitivity for tumoral detection of 93%-98%<sup>[135,137,146,148,149]</sup>, although in the case of hyperglycemic patients, this falls to 63%, or even less<sup>[135,137,146,149]</sup>, in parallel with the NPV which falls from 96% to 38%<sup>[146]</sup>.

Concerning lymphatic invasion, PET detection has proved poor, probably due to the proximity of regional lymph nodes to the primary tumor<sup>[102,154,135,137,150]</sup>, and the lack of anatomic detail<sup>[13,18,139]</sup>. PET alone is unable to visualize vessels and cannot assess vascular invasion<sup>[63,135,151]</sup>. Thus, the association of PET with CT (PET/CT) seems promising<sup>[139,152]</sup>.

Heinrich *et al.*<sup>[139]</sup> showed recently that PET/CT has a PPV for the differentiation between a benign and a malignant pathology of 91%, whereas its NPV is 64%. PET/CT detects a cancer of the pancreas with a sensitivity of 93%, and is more specific than CT alone (69% *vs* 21%, respectively,  $P = 0.07$ ). However, data are lacking regarding the assessment of vascular involvement. The use of multi-slice CT coupled with PET, and angio-CT protocols, might allow better visualization of the vessels.

## SURGICAL MANAGEMENT OF VASCULAR INVASION

Frequently, vascular invasion may be assessed only when the operation is already quite advanced (section of the pancreas, digestive transection)<sup>[22,27,153-156]</sup>. Palpation at the time of the Kocher maneuver (maneuver which permits exposure of structures behind duodenum and pancreatic head) is commonly performed to assess the relationship of a pancreatic head tumor to the superior mesenteric artery. However, if the tumor is large, if there is associated pancreatitis, or if the patient is undergoing reoperation, palpation is an inaccurate way to assess this critical tumor-vessel relationship prior to gastric and pancreatic transection<sup>[22]</sup>.

The management of a suspicious tumoral adhesion to a vessel is one of the most important challenges in a Whipple procedure. In such a case, the surgeon is confronted with three options: (1) leave tumor attached to the vessel, resulting in a grossly positive margin of resection; (2) try to separate the tumor from the vessel, with a considerable hemorrhagic risk; and (3) or perform a partial or segmental resection of the portion of invaded vessel with reconstruction<sup>[22]</sup>.

### Arterial invasion

If the invasion of the superior mesenteric or portal vein is not in itself a criterion of unresectability<sup>[4,154,155,157]</sup>, arterial invasion is a more controversial issue. Many authors regard

this invasion as a contraindication to surgery<sup>[27,154,158]</sup>, because of the high morbidity and mortality rates associated with arterial resection and reconstruction<sup>[159]</sup>. Furthermore, arterial invasion usually includes extensive involvement of the mesenteric neural plexus<sup>[160]</sup>, rendering radical resection oncologically unsound because of the frequent finding of positive margins<sup>[154]</sup>.

However, in many cases, the preoperative assessment cannot diagnose such an invasion. The surgeon must then adapt his surgical strategy. Fortner<sup>[161]</sup> recommended the resection of invaded arterial segment, if a reconstruction seemed possible.

From the arterial point of view, celiac or hepatic invasion, discovered during the operation, can be the object of a resection and a reconstruction, either by direct anastomosis, by interposition of a venous graft (for example reverse saphenous or internal jugular vein), or with a prosthesis<sup>[156,161-163]</sup>. An arterial graft (for example the splenic artery) can also be used<sup>[156,163]</sup>. These techniques seemed relatively reliable, with a mortality of 5%, in a recent study<sup>[164]</sup>.

Regarding the modified Appleby's operation (*en-bloc* resection of the celiac trunk with distal pancreatectomy and total gastrectomy) for advanced cancers of body and tail of the pancreas, several Japanese groups propose an extended resection of the celiac trunk, splenic artery, common hepatic artery, and/or superior mesenteric artery, resulting in 5-6 mo of average survival. Hepatic vascularization must be maintained and evaluated during the whole operation, and if necessary, compensated, in order to avoid an acute hepatic insufficiency<sup>[163,165-168]</sup>.

Recently, Gagandeep *et al.*<sup>[169]</sup> reported their experience using celiac axis resection for pancreatic cancer with a prolonged survival, and proposed the consideration of this technique for central and distal pancreatic cancer invading the celiac trunk.

Hirano *et al.*<sup>[170]</sup> reported a high R0 resectability rate (91%) with distal pancreatectomy with *en bloc* celiac axis resection.

When the superior mesenteric artery is invaded, an arterial jejunal branch is isolated. Heparin is injected there, in order to allow the clamping of the superior mesenteric artery with full safety. The artery is then reconstructed either by direct anastomosis, or by anastomosis to the aorta<sup>[161]</sup>.

In the case of an invasion of the hepatic artery, techniques of reconstruction require a venous graft (jugular, reverse saphenous, gonadic veins) or prosthesis, or an arterial graft (splenic, gastro-epiploic, gastroduodenal)<sup>[22,163,171-173]</sup>.

In some cases of cancer of the body of the pancreas, with invasion of the common hepatic artery and celiac trunk, Kondo *et al.*<sup>[174]</sup> tried to embolize the hepatic artery, obtaining a collateral pathway from the superior mesenteric artery. This allowed a distal pancreatectomy with *en bloc* resection of the celiac trunk, without hepatic ischemia.

Other authors have described more traditional techniques of resection-reconstruction, using the gastroduodenal artery<sup>[175]</sup>. Combined resection of the celiac trunk with a distal pancreatectomy has been found to improve the overall prognosis of patients with locally advanced cancer of the body and tail of the pancreas<sup>[176]</sup>.

**Venous invasion**

Contrary to arterial involvement, the invasion of the superior mesenteric vein or portal vein is not in itself a criterion of unresectability<sup>[4,154,155,157,177]</sup>.

In uncommon cases, the pancreatic tumor infiltrates the anterior surface of the inferior vena cava. It is possible to excise the invaded part, and to replace it with a synthetic prosthesis. Often, autologous tissues are preferred (jugular, saphenous veins)<sup>[22]</sup>.

When the portal vein is involved, it is legitimate to attempt a resection, especially if the vein is invaded by more than 2 cm, in order to obtain negative margins (Table 2)<sup>[4,178-180]</sup>. Portal invasion is not a predictor of aggressive tumor biology, but rather a reflection of tumor size and location<sup>[153,157,177,179]</sup>. Up to 50% of tumors thought to have vascular invasion intraoperatively have been found subsequently to have only inflammatory adhesions to the portal vein after histologic examination<sup>[157,181,182]</sup>. This finding underlines the difficulty in determining tumoral venous invasion before and during surgery, since peritumoral inflammation may simulate true tumor infiltration<sup>[178]</sup>. Very recently, Fukuda *et al.*<sup>[183]</sup> reported that the depth of portal vein invasion significantly alters survival after curative pancreatic resection combined with portal vein resection. The survival rate was similar for patients with no portal invasion and those with superficial invasion. However, a deeper portal invasion was associated with a poorer survival rate, similar to that of patients undergoing non-curative resection.

The excision is done either by a segmentary resection, or by a tangential resection<sup>[22,184,185]</sup>. The reconstruction requires an end-to-end anastomosis either by direct suture or by using an interposition venous or prosthetic graft<sup>[22,74,154,156,157,161,162,184-189]</sup>. The technical limit of portal vein resection without graft is 4 cm in the hepatic hilus and 7 cm after pancreatic resection<sup>[189]</sup>. For minimal tumor invasion into the portal vein, autologous saphenous vein patch has been described<sup>[27]</sup>. Wide resection of the portal vein may require transection of the splenic vein. To avoid segmental portal hypertension, end-to-side reanastomosis of the splenic vein to the interposition graft is recommended<sup>[184]</sup>.

If the portal clamping lasts longer than 30 min, it is recommended to clamp also the superior mesenteric artery, in order to prevent intestinal congestion<sup>[22,189]</sup>. If the portal clamping lasts longer than 60 min, it is necessary to consider a bypass between the superior mesenteric vein and femoral vein<sup>[189,190]</sup>.

Resection of the portal vein is associated with a higher morbidity rate (bleeding, infections, cardiopulmonary complications), than when this is not performed<sup>[4,185,191]</sup>.

<sup>1</sup>Included 3 arterial reconstructions. 17 patients benefited from adjunctive radiotherapy; <sup>2</sup>17% survival at 1 year if margins were positive (median survival: 6 mo) and 61.5% if margins were negative (median survival: 14 mo); <sup>3</sup>Survival at 1 year: 39.6% if the vessel was not invaded, 11.3% if the media was invaded, and 5.5% if the intima was invaded; <sup>4</sup>Median survival was 6.8 mo if the intima was invaded, 15.3 mo if the intima was spared, and 20.6 mo if there was no true vascular invasion; <sup>5</sup>5-year survival rate: 23%; <sup>6</sup>This mortality also includes arterial reconstructions (11 patients); <sup>7</sup>5-year survival rate: 12%; <sup>8</sup>3-year survival rate: 22%; <sup>9</sup>5-year survival rate: 17.9%.

In addition, Fuhrman *et al.*<sup>[154]</sup> reported an operative time, an operative blood loss, and perioperative transfusion requirements of greater magnitude in patients who required venous resection. The mortality rate is also higher after portal vein resection but this value is not always significant<sup>[4,188,192,193]</sup>. These findings are not confirmed by other series<sup>[22,27,157,181,182,185,187,191,194-201]</sup>. Numerous authors have reported a mortality rate below 5%, similar to that of standard pancreatoduodenectomy<sup>[27,154,157,164,178,181,182,185,188,194-197]</sup>.

In 62%-85% of cases, the vascular margins are found to be positive<sup>[27,31,185,192]</sup>, explaining a very poor median survival. However, recently, Siriwardana *et al.*<sup>[202]</sup> reported, in a systematic review of synchronous portal-superior mesenteric vein resection during pancreatectomy for cancer, a high rate (67.4%) of nodal involvement during the procedure. For the authors, this implied that by the time a pancreatic tumor involves the portal vein the risk of metastases is high, rendering the possibility of cure by surgery improbable<sup>[202]</sup>.

If the tumor invades the superior mesenteric vein, it is not a criterion of unresectability. Various techniques exist to allow complete resection of the tumor,

one of the most important challenges in pancreatic surgery.

**Figure 1** Proposed algorithm for the management of suspected vascular invasion in pancreatic cancer.

either by tangential excision, or by excision-reconstruction<sup>[1153,155,161,162,185,197,203,204]</sup>

In conclusion, various studies show that venous resection in pancreatic cancer is a feasible technique and relatively reliable, at least with regard to mortality, but (importantly) at the price of a higher morbidity. However, a survival benefit is not achieved by curative resection in patients with pancreatic cancer and vascular invasion<sup>[205,206]</sup>. On the other hand, the discovery of an arterial invasion during the operation might require an aggressive management, using vascular reconstruction. Furthermore, neoadjuvant treatment (combination of 5-fluorouracil/cisplatin chemoradiation) showed only limited impact on survival but appeared to be associated with improved local control<sup>[207]</sup>.

## CONCLUSION

In the absence of metastatic disease, assessment of vascular invasion is a key aspect in the evaluation of resectability for pancreatic cancer. A frequent error is to misdiagnose an involved major vessel. Obviously, surgical exploration with pathological examination remains the “gold standard” in terms of evaluation of resectability, especially from the point of view of vascular involvement. However, current imaging modalities have improved and now allow detection of vascular invasion with more accuracy. Multi-slice CT has become the best imaging modality for this purpose, and the adjunction of PET might be a means to improve results further. EUS is useful, but it remains very operator-dependant. Data are still lacking for the exact role of MRI regarding this issue (Figure 1). Detection of vascular invasion remains

### Abstract

Diffusion-weighted magnetic resonance imaging (DWI) provides image contrast that is different from that obtained by conventional magnetic resonance techniques. Although previously, DWI has been used to evaluate various diseases of the central nervous system, several technical advances have expanded the clinical applications of DWI beyond the central nervous system. As a result, many reports have been published on the use of DWI in abdominal diseases. Particularly, abdominal DWI has now being focused on evaluation of patients with abdominal cancer. DWI can be used for pretreatment tumor detection, characterization including predicting tumor response to therapy, monitoring tumor response during therapy, and follow-up study after treatment to detect possible tumor recurrence.

### INTRODUCTION

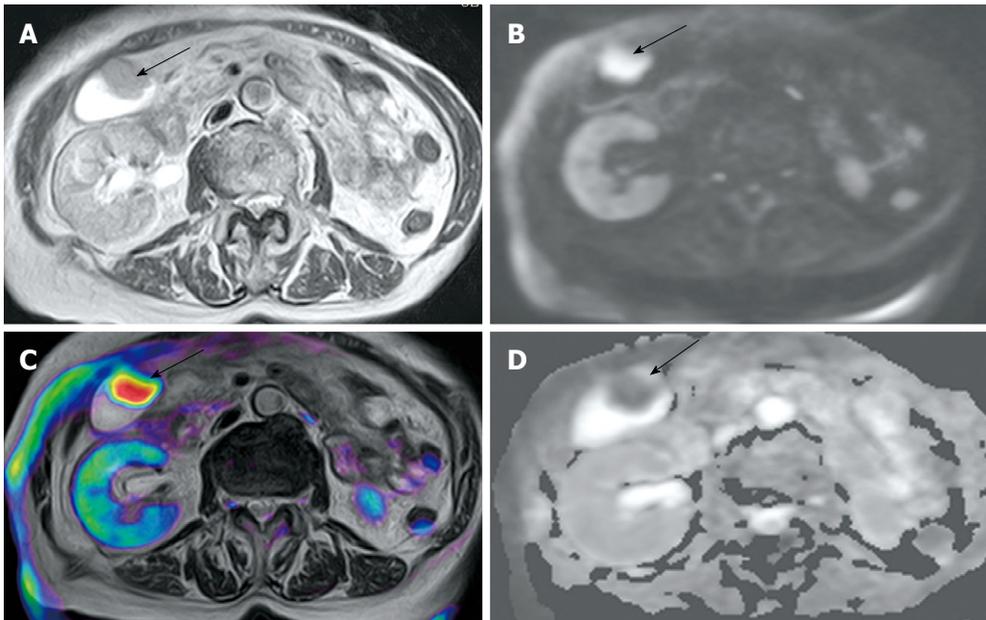

Diffusion-weighted magnetic resonance imaging (DWI) has enabled us to obtain additional information derived from the microscopic motion of water protons, which is not possible using conventional magnetic resonance imaging (MRI). Previously, DWI has been used to evaluate various diseases of the central nervous system. The most established clinical application of DWI for the central nervous system is evaluation of acute stroke<sup>[1]</sup>.

DWI has many advantages. First, it is completely noninvasive, does not require exposure to ionizing radiation or injection of contrast material, and does not cause patient discomfort. Second, because it is derived from a well-established MRI technique, DWI does not require expert technicians with sophisticated technical skills or expensive equipment, such as a cyclotron that is required for positron emission tomography. Another advantage of DWI is that it can be added easily to a routine MRI protocol because it requires only a very short prolongation of examination time<sup>[2]</sup>.

Recently, several technical advances have expanded the clinical applications of DWI beyond the central nervous system, and many studies have been published on the use of DWI in abdominal diseases. Particularly, abdominal DWI has now being focused on evaluating patients with abdominal cancer<sup>[3-9]</sup>. In this article, the application of DWI in abdominal oncology is described.

### HOW TO INTERPRET DWI

DWI can offer qualitative and quantitative information

**Figure 1 MRI of a patient with gallbladder carcinoma.** A: Axial T2-weighted MRI of a patient with gallbladder carcinoma shows a mass (arrow) protruding into the gallbladder lumen; B: Corresponding axial DW image shows high intensity (arrow); C: Corresponding color fusion image of T2-weighted image and DW image shows gallbladder carcinoma (arrow). On color fusion images, the red area corresponds to high signal intensity on DW images and blue correspond to low intensity; D: Corresponding ADC map shows low intensity (arrow).

that can be helpful for tumor assessment (Figure 1). The former assesses visual differences in signal intensity between a tumor and its surrounding normal tissue, and the latter enables calculation of values (apparent diffusion coefficient, ADC) obtained from DWI, such as a computed tomography value.

#### Qualitative assessment in DWI

Visual assessment of relative tissue signal intensity on DWI is being used for tumor detection and characterization<sup>[3]</sup>. Tumors generally tend to block diffusion more than the tissue from which they originate and show relative high signal intensity on DWI (Figure 1B); however, some normal organs, such as the spleen, adrenal gland and seminal vesicle, also show high signal intensity on DWI. Moreover, DWI has a pitfall known as “T2 shine-through”. DWI is obtained by adding a diffusion-weighting gradient (known as an MPG) to T2-weighted images, the basic sequence of conventional MRI. Thus, because DWI shows signal intensity that depends on diffusion and T2 signal intensity, a region with a high T2 signal retains the high signal on DWI, and may be mistaken for restricted diffusion. Therefore, special care must be taken with these pitfalls in diagnosing with DWI. DWI is usually interpreted by superimposing DWI and conventional morphological T2-weighted images because DWI cannot show minute morphological structures (Figure 1C).

#### Quantitative analysis in DWI

Quantitative tumor assessment is possible by calculating ADC after performing DWI with changed parameters (known as *b* values). ADC values in various malignant lesions generally tend to decrease, probably due to increased tissue cellularity or cell density, because the latter correlates with malignancy (Figure 1D). In addition to the cellular membranes, intracellular cytoskeleton, organelles, matrix fibers and soluble macromolecules contribute

to diffusion restrictions in tumors<sup>[10]</sup>; therefore, ADC values are expected to reflect histopathological tissue characteristics. ADC is calculated for each pixel of the image and is displayed as a map. By setting regions of interest within tumors on these maps, ADCs of the tumor can be measured.

## CLINICAL APPLICATIONS OF DWI IN ABDOMINAL ONCOLOGY

### Tumor detection and characterization

Tumors generally tend to show relative high signal intensity on DWI. Using qualitative assessment, Nasu *et al*<sup>[11]</sup> have shown that DWI is superior to superparamagnetic iron oxide (SPIO)-enhanced MRI in detecting liver metastases, which had been the best available examination technique. They have reported that the sensitivity and specificity of DWI was 82% and 94%, respectively. Koh *et al*<sup>[12]</sup> also have reported that the sensitivity and specificity of DWI for detecting liver metastases was 78% and 95%. Thus, qualitative assessment with DWI has superior ability for assessing liver metastasis.

In colorectal tumors, Ichikawa *et al*<sup>[7]</sup> have shown that DWI has high sensitivity and specificity for detecting tumors, and several authors have shown that DWI has high sensitivity and specificity for detecting tumors even in the pancreatico-biliary system<sup>[6,9]</sup>.

In quantitative assessment of DWI, ADC measurement has the potential to differentiate benign and malignant liver tumors. In many studies, malignancy has a lower ADC value than benignity. Taouli *et al*<sup>[13]</sup> have shown that metastatic liver tumors have the lowest ADC in malignant and benign focal lesions of the liver, and have revealed a significant difference between benign and malignant lesions. Chan *et al*<sup>[14]</sup> have shown that DWI can be used to distinguish between hepatic abscess and cystic or necrotic malignant liver tumor; ADC of abscess

cavities has a lower value than that of cystic or necrotic malignant liver tumors. Also in abdominal tumors other than in the liver, ADCs of malignant lesions have shown lower values<sup>[9,15,16]</sup>. However, most studies have reported that ADC measurement has no clear threshold to discriminate malignant and benign tumors because of substantial overlapping<sup>[9,13,15-18]</sup>.

### **Predicting and monitoring response to therapy**

Conventional criteria using morphological images have been used to evaluate antitumor therapy; however, measuring tumor size is often not adequate when tumors are treated with cytotoxic therapy and molecular targeting agents, because changes in tumor size after therapy with these drugs are not expected<sup>[14,19]</sup>; therefore, a new method for evaluating tumor response is required that can precisely reflect the clinical outcome, earlier than conventional imaging modalities.

The ability of DWI to predict therapy outcome has been shown in many clinical studies. Several authors have reported that tumors with low pretreatment ADC values show a better response to various therapies than those with high ADC<sup>[20-24]</sup>. However, studies of areas other than the abdomen have addressed that the relationship between pretreatment ADC and prognosis yield, with different results: patients suffering from a tumor with high pretreatment ADC show better long-term post-treatment prognosis than those with low ADC<sup>[25,26]</sup>.

Many researchers have reported that DWI has the potential for evaluating tumor response during treatment. The results of animal studies have proved that ADC increases can be depicted in those responding to treatment<sup>[27]</sup>. In clinical studies, researchers have reported that an early increase in the ADC value after starting therapy suggests a better treatment outcome<sup>[20,28-32]</sup>.

Monitoring response to therapy by visual assessment of DWI has been reported in brain tumors and bone metastasis, but not in the abdominal region<sup>[21,33]</sup>. Studies on bone metastasis have revealed that the treatment response after therapy could be assessed as a decrease in signal intensity<sup>[33]</sup>. Several authors have shown that tumors demonstrate an increase in ADC after treatment before a change in tumor size occurs, which heralds later diminution of the tumor size<sup>[18,22,34-36]</sup>. Chen *et al.*<sup>[34]</sup> have reported that patients with hepatocellular carcinoma show a significant rise in ADC value when they respond to treatment. Koh *et al.*<sup>[22]</sup> also have reported that patients with colorectal hepatic metastases show an increase in ADC, at least in those who show a partial response to treatment, but not in non-responders. A decrease in ADC during follow-up suggests tumor recurrence<sup>[27]</sup>.

### **FUTURE DEVELOPMENT**

Several studies have indicated that DWI may be useful for tumor staging, including lymph node and distant metastases<sup>[21,39-42]</sup>. For tumor staging, whole-body imaging is desirable. Takahara *et al.* have shown that whole-body

DWI is promising<sup>[43-45]</sup> using their method to examine the whole body by composite construction of segmented imaging. The images are processed using maximum intensity projection and 3D display<sup>[43-45]</sup>. More clinical research on this technique is needed because their study was preliminary.

The most important issue regarding DWI is non-standardization among MRI manufactures and researchers. Substantial differences in the ADC values of the same normal and diseased organs have been presented<sup>[5]</sup> by researchers using a different imaging technique; therefore, standardization of the imaging protocol is fundamental.

Currently, spatial resolution of DWI is not high enough. In order to compensate for such limited resolution, qualitative assessment might need superimposition of DWI on corresponding T2-weighted images, and quantitative assessment may require meticulous ADC measurements for small lesions. Utilization of high-field MRI may be able to solve the issue of limited spatial resolution.

### **CONCLUSION**

DWI is a promising imaging technique to evaluate abdominal tumors. This technique can be used for pretreatment tumor detection, characterization including predicting tumor response to therapy, monitoring tumor response during therapy, and follow-up study after treatment to detect possible tumor recurrence. Standardization of the imaging protocol and large clinical trials regarding the usefulness of DWI are needed.

### Abstract

**AIM:** To investigate the pharmacological effect of JCM-16021, a Chinese herbal formula, and its underlying mechanisms.

**METHODS:** JCM-16021 is composed of seven herbal plant materials. All raw materials of the formula were examined according to the quality control criteria listed in the Chinese Pharmacopoeia (2005). In a neonatal maternal separation (NMS) model, male Sprague-Dawley rats were submitted to daily maternal separation from postnatal day 2 to day 14, or no specific handling (NH). Starting from postnatal day 60, rats were administered JCM-16021 (2, 4, 8 g/kg per day) orally twice a day for 28 d. Pain threshold pressure and electromyographic activities of external oblique muscles

in response to colorectal distention recorded with a Power Lab System (AD Instruments International), were tested as pain indices. Changes in serotonin (5-HT) and 5-hydroxyindoleacetic acid (5-HIAA) concentrations in the colon of rats were analyzed; the enterochromaffin cell numbers and serotonin transporter in the colon of rats were also evaluated with an immunohistochemistry method.

**RESULTS:** NMS treatment significantly reduced pain threshold pressure ( $37.4 \pm 1.4$  mmHg), as compared to that of NH rats ( $57.7 \pm 1.9$  mmHg,  $P < 0.05$ ). After JCM-16021 treatment, the pain threshold pressure significantly increased when compared to that before treatment ( $34.2 \pm 0.9$  mmHg vs  $52.8 \pm 2.3$  mmHg in the high dose group,  $40.2 \pm 1.6$  mmHg vs  $46.5 \pm 1.3$  mmHg in the middle dose group, and  $39.3 \pm 0.7$  mmHg vs  $46.5 \pm 1.6$  mmHg in the low dose group,  $P < 0.05$ ). Also JCM-16021 significantly and dose-dependently decreased electromyographic activity to the graded colorectal distension (CRD), (the mean  $\Delta$ AUC values were:  $0.17 \pm 0.03$ ,  $0.53 \pm 0.15$ ,  $1.06 \pm 0.18$ ,  $1.22 \pm 0.24$  in the high dose group;  $0.23 \pm 0.04$ ,  $0.68 \pm 0.17$ ,  $1.27 \pm 0.26$ ,  $1.8 \pm 0.3$  in the middle dose group; and  $0.29 \pm 0.06$ ,  $0.8 \pm 0.16$ ,  $1.53 \pm 0.24$ ,  $2.1 \pm 0.21$  in the low dose group for the pressures 20, 40, 60, 80 mmHg), as compared to the NMS vehicle group. The mean  $\Delta$ AUC values were:  $0.57 \pm 0.12$ ,  $1.33 \pm 0.18$ ,  $2.57 \pm 0.37$ ,  $3.08 \pm 0.37$  for the pressures 20, 40, 60, 80 mmHg ( $P < 0.05$ ). JCM-16021 treatment significantly reduced the 5-HT concentrations (from high, middle and low dosage groups:  $60.25 \pm 5.98$  ng/100 mg,  $60.32 \pm 4.22$  ng/100 mg,  $73.31 \pm 7.65$  ng/100 mg), as compared to the NMS vehicle groups ( $93.11 \pm 9.85$  ng/100 mg,  $P < 0.05$ ); and increased the 5-HIAA concentrations (after treatment, from high, middle and low dosage groups:  $54.24 \pm 3.27$  ng/100 mg,  $50.34 \pm 1.26$  ng/100 mg,  $51.37 \pm 2.13$  ng/100 mg) when compared to that in the NMS vehicle group ( $51.75 \pm 1.98$  ng/100 mg,  $P < 0.05$ ); but did not change the enterochromaffin cell numbers in the colon of rats. In addition, NMS rats had higher SERT expression ( $n = 10$ ) than NH rats ( $n = 8$ ,

$P < 0.05$ ). JCM-16021 treatment significantly decreased SERT expression when compared to the NMS group ( $P < 0.01-0.001$ ).

**CONCLUSION:** JCM-16021 can attenuate visceral hypersensitivity, and this analgesic effect may be mediated through the serotonin signaling pathway in the colon of rats.

## INTRODUCTION

Irritable bowel syndrome (IBS) is characterized by chronic abdominal pain and altered bowel movements such as diarrhea and constipation<sup>[1,2]</sup>. Although conventional therapies (e.g. laxatives, antidepressants, antispasmodics, and bulking agents) are used to relieve the symptoms of IBS, the overall efficacy of these agents is poor<sup>[3,4]</sup>; and these agents have not been proven to be more effective than placebo in providing overall relief of symptoms in randomized, controlled clinical trials. Therefore, increasing numbers of IBS sufferers are seeking help from complementary and alternative medicines. Recently, our research group showed that JCM-16021, an herbal formula composed of seven herbs, can relieve symptoms in IBS patients<sup>[5]</sup>. In this randomized, double-blinded, and placebo-controlled trial, 84 diarrhea-predominant IBS patients received treatment (28 patients in each arm). At the end of the 8 wk treatment, 52% of participants in the JCM-16021 plus Holopon (hyoscine methobromide)-placebo group (Group A), 32% in the Holopon plus herbal-placebo group (Group B), and 42.7% in the double placebo group (Group C) experienced overall symptom improvements. Patients in Group A had the highest percentage improvement (Group A *vs* Group B *vs* Group C: 52% *vs* 32% *vs* 42.7%), but the mechanism of this effect remains unclear.

Serotonin (5-HT), an important neurotransmitter and paracrine signaling molecule, alters visceral perception and motor function by influencing the sympathetic, parasympathetic, and enteric nervous systems<sup>[6]</sup>. The majority of 5-HT is synthesized and stored in entero-

chromaffin (EC) cells in the gastrointestinal tract. Previous studies have shown that the changes in EC cells and the increased 5-HT concentrations in the human colon are associated with the generation of IBS symptoms and in other gastrointestinal functional disorders<sup>[7-10]</sup>. Furthermore, novel serotonergic agents, such as the 5-HT<sub>3</sub> antagonist alosetron and the 5-HT<sub>4</sub> agonist tegaserod, have significant impacts on IBS symptoms through their visceral analgesic properties and diverse effects on motor functions in the lower gastrointestinal tract<sup>[11]</sup>. Therefore, the 5-HT signaling pathway represents a promising target for IBS treatment.

A neonatal maternal separation (NMS)-induced visceral hyperalgesia rat model was previously established<sup>[12]</sup>. Because its characteristics mimic the symptoms of IBS patients, it is often used to study the mechanism of visceral hyperalgesia and to evaluate the pharmacological effects of potential IBS therapies<sup>[13,14]</sup>.

Considering the effects of JCM-16021 in IBS patients and the function of serotonin in visceral hyperalgesia, this study aimed to investigate the analgesic effect of JCM-16021 on NMS-induced visceral hyperalgesia in rats, and its potential underlying mechanism. We hypothesized that JCM-16021 could attenuate visceral pain through the 5-HT signaling pathway in the colon of rats. These results were previously presented as a poster at the 16th United European Gastroenterology Week in October 2008 in Vienna, Austria<sup>[15]</sup>.

## MATERIALS AND METHODS

### Herb materials

JCM-16021 is composed of seven plant materials, which are listed in Table 1. Purchasing, authentication and quality control of all seven herbs were performed based on the requirements of the Chinese Pharmacopoeia<sup>[16]</sup>. The authenticated voucher specimens (the voucher numbers are CMED-0043-02, CMED-0018-17, CMED0024-02, CMED-0044-02, CMED-0180-02, CMED-0179-02, CMED-0118-02) were stored in the Research Laboratory, Hong Kong Jockey Club Institute of Chinese Medicine, Hong Kong, China.

### Reagents

Chloral hydrate was purchased from Fluka. Hematoxylin, 5-HT, and 5-HIAA were purchased from Sigma (Sigma-Aldrich Co., St. Louis, MO, USA). Holopon (hyoscine methobromide, 99%) was purchased from GSK Hong Kong.

### Preparation and quality analysis of JCM-16021

JCM-16021 was prepared in the form of granules as follows: mixed medicinal materials weighing approximately 110 g (equal to the total amount of raw materials in one day's dosage of JCM-16021 formula for IBS patients) were macerated for 30 min, subsequently decocted for 60 min three times, and rinsed 10 times (v/w) with distilled water. The filtrates were combined and dried in a vacuum at 40°C. A water-soluble pale yellow powder, approximately 22 g,

This table presents the composition of formula and its ratio of each component in whole formula. <sup>1</sup>TLC test, + means detected, - means not detected; <sup>2</sup>Y = 4309.9x + 11.158, R<sup>2</sup> = 1, 0.155-7.75 µg; <sup>3</sup>Y = 1141.8x + 54.916, R<sup>2</sup> = 0.9999, 0.322-18.343 µg; <sup>4</sup>Y = 7822.7x + 1167.9, R<sup>2</sup> = 0.9994, 0.375-3.75 µg; <sup>5</sup>Y = 7947.5x + 1465.9, R<sup>2</sup> = 0.9982, 0.34-3.4 µg; <sup>6</sup>Y = 5782.6x - 11.063, R<sup>2</sup> = 1, 0.028-1.4 µg; <sup>7</sup>Y = 2612.4x + 1.6674, R<sup>2</sup> = 1, 0.0228-1.14 µg; ND means that the chemical marker was detected but not determined due to peak area being too small.

was obtained. To ensure the quality of the final product, all raw materials were examined according to the quality control criteria listed in the Chinese Pharmacopoeia 2005<sup>[16]</sup>. As recommended by the Chinese Pharmacopoeia 2005<sup>[16]</sup>, paeoniflorin, magnolol, honokiol, and tetrahydropalmatine were selected as the chemical markers for *Radix Paeoniae Lactiflorae*, *Cortex Magnoliae Officinalis*, and *Rhizoma Corydalis Yanhusuo*, respectively. Corilagin, a constituent of *Fructus Terminaliae Chebulae* was also selected since it is a major component of the final product. Quercitrin was used as the chemical marker of *Herba Polygoni Chinensis*. In addition, gallic acid and atractylone were qualitatively checked in *Fructus Terminaliae Chebulae* and *Rhizoma Atractylodis Macrocephalae*, respectively. Heavy metals and pesticide residues were monitored to ensure safety.

### Animals and neonatal maternal separation

Primiparous timed-pregnant Sprague-Dawley female rats were obtained from the Laboratory Animal Services Centre, The Chinese University of Hong Kong, on gestational day 13-14. Dams were housed individually in macrolon cages and maintained in rooms with temperature kept at 23 ± 2°C and an alternating 12: 12 h light-dark cycle. All of the experimental protocols were carried out with the approval of the Committee on Use of Human-Animal Subjects in Teaching and Research of the Hong Kong Baptist University and according to the Regulations of the Department of Health, Hong Kong, China.

The neonatal maternal separation (NMS) rat model was established based on a previous report<sup>[12]</sup>. Briefly, pups in the NMS group were separated from their mothers and placed into individual cages in another room 180 min daily from postnatal day 2 to day 14, whereas normally-handled

(NH) pups remained undisturbed in their home cage with the dam. All pups were weaned on postnatal day 22, and only male pups were used in the present study to avoid hormonal cycle induced variations. Male rats on postnatal day 60 were used in a series of three experiments.

### Experimental design

This experiment involved three sets of studies: The first series of experiments aimed to evaluate the pharmacological effects of JCM-16021 on visceral pain by assessing changes in pain threshold pressure before and after JCM-16021 treatment. Six groups of rats were used. Group 1 (*n* = 10) with NH rats and Group 2 (*n* = 10) with NMS rats were given distilled water as a control. Groups 3, 4 and 5 (*n* = 10, 9, 9) with NMS rats received JCM-16021 at 8, 4 and 2 g/kg per day, respectively. Group 6 received 0.3 mg/kg per day Holopon (hyoscine methobromide, 99%, GSK Hong Kong) as an active control (*n* = 8). All pain threshold pressure detection tests were conducted in the morning between 9 am and 12 pm.

The second series of experiments aimed to test the analgesic effect of JCM-16021 through assessing electromyographic (EMG) activities of the left external abdominal oblique muscles to colorectal distension (CRD) before and after treatment with JCM-16021. Grouping (*n* = 7-10) was the same as that in the first series, with surgeries performed on treatment day 23, and EMG recording conducted on treatment day 28. The pain threshold test was not performed in this set of rats.

A third series of experiments with five groups (46 rats, *n* = 8-10 each group) of rats aimed to test the effects of JCM-16021 on the concentration of 5-HT, 5-hydroxyindoleacetic acid (5-HIAA), EC cell number and expression of serotonin transporter (SERT). Group

1 with NH rats and Group 2 with NMS rats received distilled water as a control. Groups 3, 4 and 5 with NMS rats received JCM-16021 at dosages of 8, 4, and 2 g/kg per day respectively. When the treatment course finished, the rats were deeply anesthetized with an overdose of midazolam hydrochloride, and 4 cm of the colon (5-6 cm from the anus) was harvested immediately. A piece of the colon was immediately fixed in 4% neutral-buffered paraformaldehyde for immunostaining. The rest was frozen with liquid nitrogen, and stored at -80°C for later analysis of 5-HT/5-HIAA content.

### Drug administration

Starting at postnatal day 60 (body weight around 250 g), rats were daily treated orally with different dosages of JCM-16021 (8, 4 and 2 g/kg per day body weight, in 10 mL/kg distilled water), Holopon at a dosage of 0.3 mg/kg per day body weight, or vehicle (distilled water at 10 mL/kg body weight). The dosage of JCM-16021 was set according to the clinical trial and 4 g/kg per day was determined to be equivalent to the clinical dosage<sup>[5]</sup>.

### Abdominal withdrawal reflex (AWR) test

AWR tests were performed as previously described<sup>[17]</sup>. Briefly, a flexible latex balloon (medical finger glove, 4 cm long, 2.3 cm diameter flaccid) was inserted into the rat colon. Rats were allowed to adapt in a transparent box alone for 30 min after insertion of the colorectal balloon. CRD was then applied in increments of 5 mmHg, maintained for 2 s at each step to observe. The pain threshold pressure was defined as the intensity of CRD that induced a sudden and persistent abdominal muscle contraction in rats with abdomen lift off the platform. The experiments were repeated three times with at least 5 min intervals for recovery. During the test, the observers were blinded to the treatment groups of the rats.

### EMG recording test

To measure rat's visceral sensitivity, the visceral motor response (VMR) to CRD was studied by recording the EMG as previously described with modification<sup>[12,18]</sup>. Briefly, a pair of Teflon-coated stainless wires (Cooner Wire, Chatsworth, CA) was surgically implanted into the left external abdominal oblique muscles on treatment day 23 and EMG recording tests were conducted on treatment day 28. On the test day, animals were subjected to CRD. A flexible latex balloon (medical finger glove, 4 cm long, 2.3 cm diameter flaccid) tied around a urethral catheter (3 mm diameter) was lubricated with liquid paraffin oil and inserted intrarectally in its descending colon with the distal tip 1 cm from the anal verge and secured to the base of the tail under short ether anesthesia. CRD was initiated by Barostat (Distender Series II R, G&J electronics, Canada). The EMG recording signal was amplified and filtered (50-5000 Hz) by Power Lab System (AD Instruments International). Three cycles of graded CRD (20, 40, 60, and 80 mmHg; 20 s duration; 2 min inter-stimulus interval) were applied to each rat. During the five day recovery from surgery, the treatments were

continued. The overall effect of any given reagents was determined by calculating the changes of the area under the curve (AUC) of the raw EMG amplitude response after treatment, based on the formula  $\Delta\text{AUC}\% \text{ baseline} = (\text{AUC during CRD} - \text{AUC before CRD})/\text{AUC before CRD}$ .

### 5-HT and 5-HIAA content assays

5-HT and 5-HIAA concentrations in the colon were analyzed following a procedure with a slight modification<sup>[19]</sup>. Fluorescence of the handled sample was measured at an activation wavelength of 365 nm and an emission wavelength of 470 nm.

### Immunohistochemistry assay for EC cells and SERT

Immunohistochemical detection of EC cells in the colon of rats was performed using a routine streptavidin-biotin peroxidase technique employing Chr-A antibody (1:250, Santa Cruz Biotechnology, Santa Cruz, CA, USA)<sup>[20]</sup> and mouse monoclonal anti-SERT antibody (1:250, Advanced targeting system, AB-N09) as previously described<sup>[19]</sup>. The immunoreaction products were observed under a light NIKON microscope equipped with a NIKON color digital camera system. A NIKON 20 × objective was used to collect images of colon sections. The mean densities of the positive immunoreaction of serotonin transporter receptors and the positive cell numbers of Chr-A in at least 6 serial slides from the colonic sections of each rat were analyzed.

### Statistical analysis

All data are expressed as mean ± SE. The changes in visceral pain threshold pressure were analyzed by comparing the values before and after treatment for each group using a paired *t*-test, and the differences between before and after treatment in a group using a one-way analysis of variance (ANOVA). EMG activity data were analyzed by one-way ANOVA between different groups to determine whether the overall change was significant, in a similar way to the analysis of the changes of concentrations of 5-HT and 5-HIAA, EC cell numbers and SERT in rat colon. *P* < 0.05 was considered statistically significant.

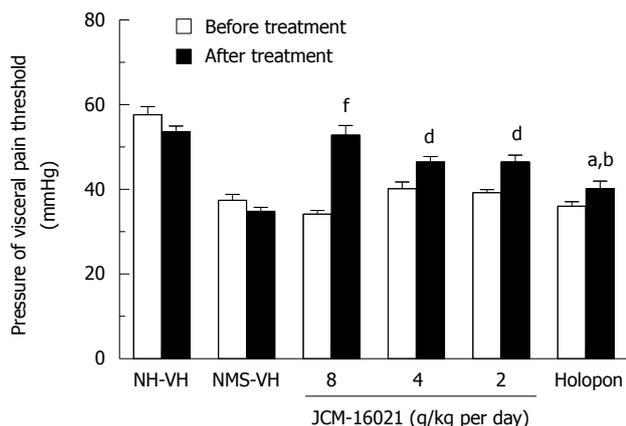

## RESULTS

### Quality control of JCM-16021

To ensure the quality of JCM-16021, eight chemical markers were qualitatively and quantitatively tracked from the raw materials to the final product, and heavy metals and pesticide residues were also examined. The results are listed in Table 1<sup>[5]</sup>.

### NMS induced visceral hyperalgesia

As shown in Figure 1, there is a significant decrease in pain threshold pressure in the NMS vehicle rats before the treatment, when comparing with that of the NH vehicle group before the treatment (*P* < 0.001). The pain threshold pressure values were  $37.4 \pm 4.4$  mmHg

**Figure 1 Pain threshold pressure assessment in different groups.** Data are presented as the mean  $\pm$  SE. Before treatment, the pain threshold of NMS groups was significantly decreased, as compared with that of the NH-VH group (<sup>a</sup> $P < 0.001$ ). After treatment, JCM-16021 and Holopon significantly increased the pain threshold pressure (<sup>f</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$ , <sup>b</sup> $P < 0.001$ ) compared with that before treatment of each group.

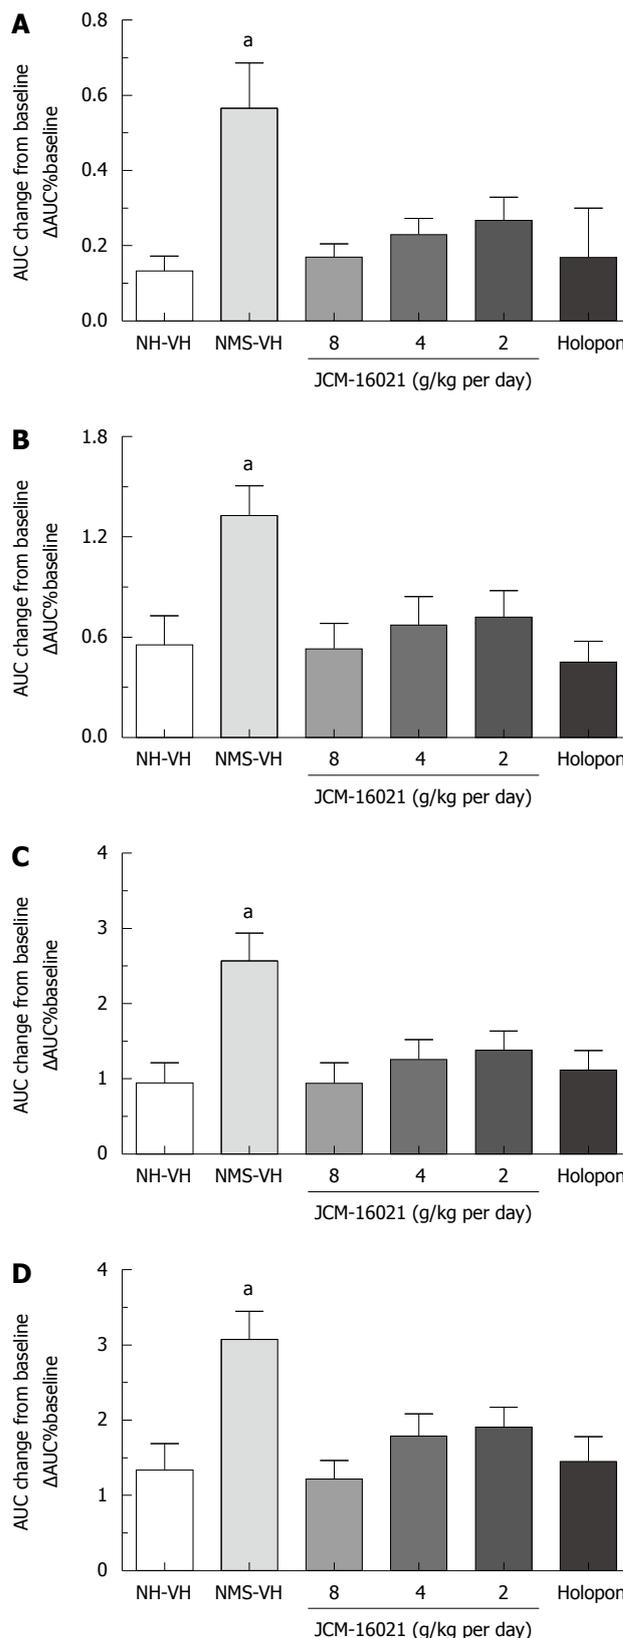

and  $57.7 \pm 5.9$  mmHg in NMS vehicle and NH vehicle groups before treatment, respectively.

In EMG tests, the visceromotor response to CRD, which was reflected as AUC changes over the baseline in the NMS vehicle group after vehicle treatment ( $0.57 \pm 0.12$ ,  $1.33 \pm 0.18$ ,  $2.57 \pm 0.37$ ,  $3.08 \pm 0.37$  under the pressures 20, 40, 60, 80 mmHg) was significantly increased compared to that of the NH vehicle group after vehicle treatment ( $0.11 \pm 0.04$ ,  $0.58 \pm 0.19$ ,  $0.96 \pm 0.3$ ,  $1.39 \pm 0.39$  under the pressures 20, 40, 60, 80 mmHg, Figure 2) ( $P < 0.05$ ). These results indicate that NMS induces allodynia (20 mmHg) and visceral hyperalgesia (40-80 mmHg) in rats.

**Analgesic effect of JCM-16021 in NMS rats**

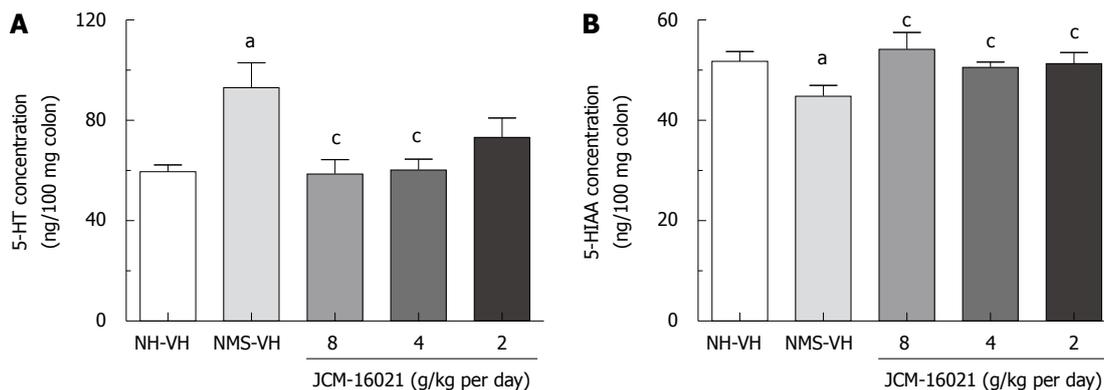

As shown in Figure 1, JCM-16021 can significantly reduce the pain threshold pressure in three dosage groups (from high dose to low dose:  $52.8 \pm 2.3$  mmHg,  $46.5 \pm 1.3$  mmHg, and  $46.5 \pm 1.6$  mmHg) comparing with that of the NMS vehicle group ( $34.8 \pm 0.9$  mmHg,  $P < 0.05$ ). After treatment the pain threshold pressure in three JCM-16021 groups also significantly decreased when compared to that before treatment (from high dose to low dose:  $52.8 \pm 2.3$  mmHg *vs*  $34.2 \pm 0.9$  mmHg,  $46.5 \pm 1.3$  mmHg *vs*  $40.2 \pm 1.6$  mmHg and  $46.5 \pm 1.6$  mmHg *vs*  $39.3 \pm 0.7$  mmHg,  $P < 0.01$ ). Holopon also had a similar analgesic effect to JCM-16021 when comparing the pain threshold pressure values either with that of NMS vehicle group or the value before the Holopon treatment.

In the EMG test, as shown in Figure 2A-D, the EMG activity to the graded CRD, which was reflected as AUC changes over the baseline, significantly and dose-dependently decreased after JCM-16021 treatment compared to that of the NMS vehicle group ( $P < 0.05$ ). The mean  $\Delta$ AUC significantly fell in the high dose group ( $0.17 \pm 0.03$ ,  $0.53 \pm 0.15$ ,  $1.06 \pm 0.18$ ,  $1.22 \pm 0.24$  for the pressures 20, 40, 60, 80 mmHg), middle dose group ( $0.23 \pm 0.04$ ,  $0.68$

**Figure 2 JCM-16021 effect on the electromyographic activity in response to graded CRD at pressures of 20 mmHg (A), 40 mmHg (B), 60 mmHg (C), 80 mmHg (D).** Data are presented as mean  $\pm$  SE ( $n = 7-10$ ). Significant difference is indicated by <sup>a</sup> $P < 0.05$  when compared with the NMS-VH group.

$\pm 0.17$ ,  $1.27 \pm 0.26$ ,  $1.8 \pm 0.3$  for the pressures 20, 40, 60, 80 mmHg), and low dose group ( $0.29 \pm 0.06$ ,  $0.8 \pm 0.16$ ,

**Figure 3** JCM-16021 effects on the concentrations of 5-HT and 5-HIAA in the colons of rats. A: JCM-16021 significantly decreased 5-HT concentration in neonatal maternal separation (NMS) rats; B: JCM-16021 significantly increased 5-HIAA concentration in NMS rats. Data are presented as mean  $\pm$  SE (ng/100 mg colon tissue,  $n = 8-10$ ). Significant difference is indicated by <sup>a</sup> $P < 0.05$  when compared with the NH control group and by <sup>c</sup> $P < 0.05$  when compared with the NMS control group.

1.53  $\pm$  0.24, 2.1  $\pm$  0.21 for the pressures 20, 40, 60, 80 mmHg), compared to that of the NMS vehicle group. The mean  $\Delta$ AUC values were: 0.57  $\pm$  0.12, 1.33  $\pm$  0.18, 2.57  $\pm$  0.37, 3.08  $\pm$  0.37 for the pressures 20, 40, 60, 80 mmHg,  $P < 0.05$ . Also Holopon significantly reduced the EMG activity compared to the NMS vehicle group ( $P < 0.05$ ).

**JCM-16021 decreases the 5-HT concentration in the colon of rats**

As shown in Figure 3A, 5-HT concentration in NMS vehicle groups ( $n = 9$ , 93.11  $\pm$  9.85 ng/100 mg) was significantly higher than that in NH vehicle groups ( $n = 8$ , 59.53  $\pm$  7.57 ng/100 mg,  $P < 0.01$ ). JCM-16021 treatment at the high and middle dosage, but not the low dosage, significantly decreased the 5-HT concentration in the colon of rats ( $P < 0.01$ ), when compared to the NMS vehicle group. After treatment with JCM-16021, the 5-HT concentrations in high, middle and low dosage groups ( $n = 9, 10, 10$ ) were 60.25  $\pm$  5.98 ng/100 mg, 60.32  $\pm$  4.22 ng/100 mg, 73.31  $\pm$  7.65 ng/100 mg, respectively. Further, although there was no significant difference in 5-HT concentration between the low dosage group and NMS vehicle group, the value was still lower than that of the NMS-VH group (93.11  $\pm$  9.85 ng/100 mg). Clearly, there is a tendency that JCM-16021 treatment could reduce the 5-HT concentration.

**JCM-16021 significantly increases the 5-HIAA concentration in the colon of rats**

NMS treatment significantly decreased 5-HIAA concentration in the colon of rats. 5-HIAA concentration in NMS vehicle groups ( $n = 9$ , 44.86  $\pm$  2.13 ng/100 mg) was significantly higher than that in NH vehicle groups ( $n = 8$ , 51.75  $\pm$  1.98 ng/100 mg,  $P < 0.05$ ). JCM-16021 treatment significantly increased the 5-HIAA concentration in the colon of rats when compared with that of the NMS control group ( $P < 0.05$ ). After treatment with JCM-16021, the 5-HIAA concentrations were 54.24  $\pm$  9.81 ng/100 mg in the high dosage group, 50.61  $\pm$  1.26 ng/100 mg in the middle dosage group, and 51.37  $\pm$  2.13 ng/100 mg in the low dosage group (Figure 3B).

**JCM-16021 does not change EC cell numbers in the colon of rats**

As shown in Figure 4, EC cell number in NMS vehicle groups ( $n = 9$ , 12.97  $\pm$  1.17) was significantly higher than that in NH vehicle groups ( $n = 8$ , 9.70  $\pm$  0.92,  $P < 0.05$ ). JCM-16021 treatment did not significantly change the EC cell number in the three dose groups.

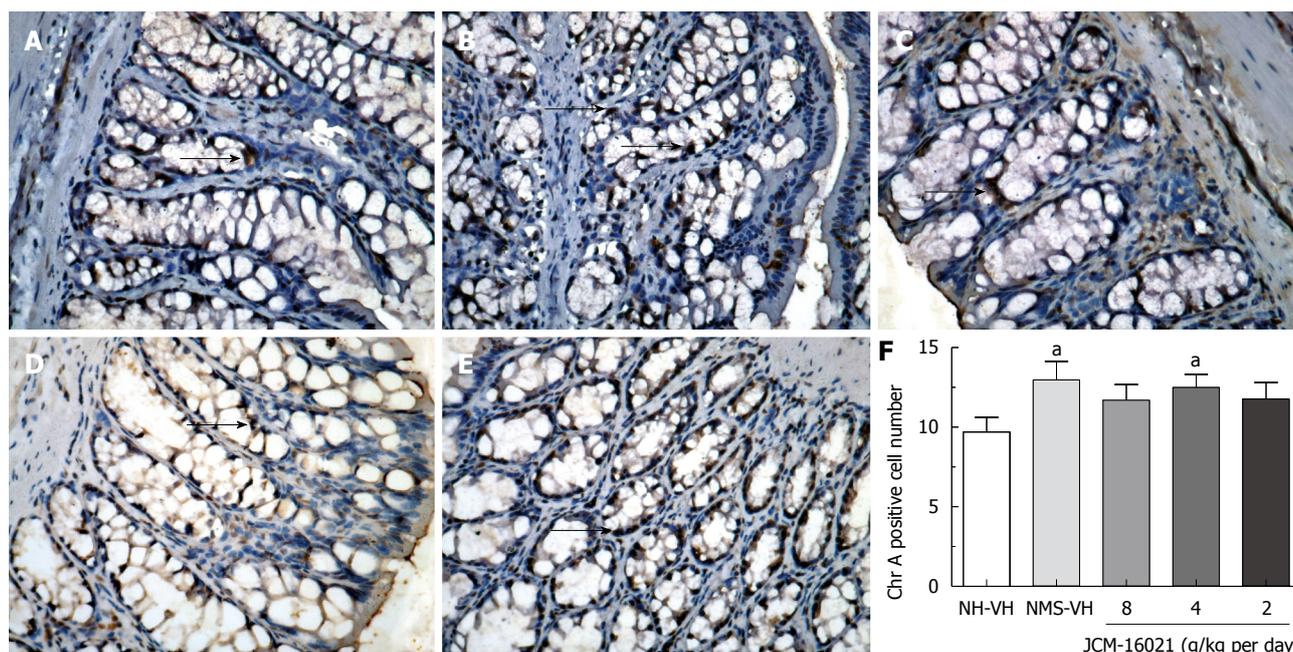

**JCM-16021 decreased SERT expression in the colon of rats**

As shown in Figure 5, NMS rats had higher SERT expression (0.61  $\pm$  0.03,  $n = 10$ ) than NH rats (0.56  $\pm$  0.05,  $n = 8$ ,  $P < 0.05$ ). JCM-16021 treatment at different dosages ( $n = 10$  in each group) significantly decreased SERT expression in the colon. The mean gray indexes among JCM-16021 groups were 0.59  $\pm$  0.03 in the high dose group, 0.54  $\pm$  0.02 in the middle dose group and 0.53  $\pm$  0.03 in the low dose group ( $P < 0.01-0.001$ ).

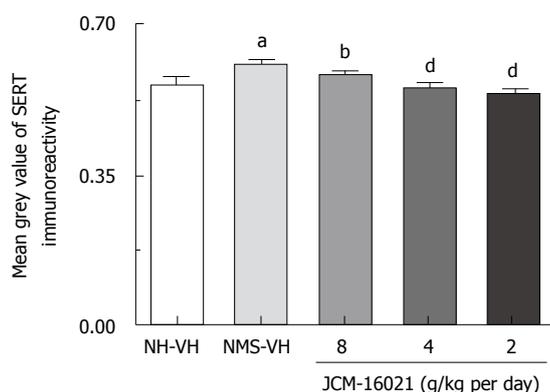

**DISCUSSION**

This study demonstrated that JCM-16021 can dose-dependently attenuate the visceromotor response to CRD in NMS rats. Moreover, it decreases 5-HT concentration and increases 5-HIAA concentration in the colon of rats. These findings indicate that JCM-16021 has an analgesic effect on visceral hyperalgesia, and this effect may be mediated through the serotonin signaling pathway in the colon of rats.

Chronic visceral hyperalgesia is an important and characteristic feature of IBS and other functional bowel disorders<sup>[21]</sup>. In order to investigate the mechanism of visceral hyperalgesia, animal models have been developed, such as the early life colon irritation model<sup>[17]</sup>, neonatal maternal separation model<sup>[12]</sup>, and adult repeated stress model in rodents<sup>[22]</sup>. The current study showed that NMS induced a lower pain threshold pressure than that seen in NH rats, and increased EMG activity in response to CRD, thus confirming that NMS induces visceral hyperalgesia in adulthood<sup>[12]</sup>. Further, our results also showed that even in 20 mmHg CRD stimulation, NMS rats still have

**Figure 4** JCM-16021 effect on enterochromaffin cell number (Chr A positive cell number) in the colons of rats. Chr A staining cells (arrows) are present in colon tissues in the normal control group (A), the NMS control group (B), the NMS with high dosage (C), the NMS with middle dosage (D), and the NMS with low dosage of JCM-16021 (E). NMS significantly increased the number of Chr A positive cells in the colons of rats, and JCM-16021 did not change the number of Chr A positive cells (F). Data are presented as mean ± SE ( $n = 8-10$ ). Significant difference is indicated by <sup>a</sup> $P < 0.05$  compared with the normal control group.

**Figure 5** SERT expression in rat colon by immunohistochemistry assay. SERT expression in the colonic tissues of NMS rats was significantly increased over that of NH rats. JCM-16021 treatment decreased SERT expression. Results are expressed as mean ± SE,  $n = 8-10$  in each group. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ , <sup>d</sup> $P < 0.001$  vs NH.

significant EMG changes compared to NH rats, thus NMS induces not only visceral hyperalgesia, but also allodynia in adulthood. Our results also showed that JCM-16021 increased the pain threshold pressure with a dose-related effect, and dose-dependently reduced the EMG activity to CRD in NMS rats. Therefore, these results indicate that JCM-16021 has an analgesic effect which can attenuate allodynia and visceral pain in NMS rats. Interestingly, the results from the AWR test showed that there is no dose-related response, but the results from the EMG test did show a dose-dependent response. The difference may originate from the objectivity of the two pain indexes; the EMG data, as a quantitative value, is more reliable than that of pain threshold pressure.

As for the mechanism of visceral hyperalgesia, it is believed that the up-regulation of visceral pain perception results, at least in part, from profound and long-lasting changes in the development of the central nervous system, including systems that regulate stress responsiveness<sup>[23,24]</sup>. With regard to the 5-HT effect in visceral hyperalgesia, previous data is not consistent. Our previous study reported that the amount of colonic 5-HT in rats with visceral hyperalgesia induced by mechanical colorectal irritation significantly increased with postnatal day<sup>[19]</sup>. Another study showed that serotonin is actively involved in pathophysiological processes of visceral hyperalgesia because serotonin concentration is significantly decreased in the spinal cord and but not in the colon; and 5-HT significantly increased in the colons of rats after CRD<sup>[13]</sup>. It is well known that 5-HT in the gastrointestinal tract is generally believed to be one of the most important mediators and regulators of bowel sensation and motility<sup>[9,25]</sup>. The current study found that 5-HT concentrations in the colons of the NMS vehicle group were significantly higher than that in the NH vehicle group supporting the concept that 5-HT is an important mediator involved in NMS-induced visceral hyperalgesia.

Our data also showed that JCM-16021 not only significantly reduces the 5-HT concentration but also significantly increases the 5-HIAA concentration. Serotonin, as an important gastrointestinal signaling molecule, is synthesized from the amino acid tryptophan *via* a short metabolic pathway consisting of two enzymes: tryptophan hydroxylase and amino acid decarboxylase. Recent studies have demonstrated that distinct changes in intestinal EC cell number and 5-HT content have significant relationships with symptoms in IBS

patients<sup>[26,27]</sup>. Therefore, the serotonin signaling pathway has been proposed as a therapeutic target to improve the symptoms of IBS<sup>[11]</sup>. Our current study found that NMS not only increases 5-HT concentration but also decreases the levels of its metabolite 5-HIAA in the colon of rats. After JCM-16021 treatment, the 5-HT concentration was decreased while 5-HIAA concentration increased. 5-HIAA is a major product of 5-HT breakdown, which is excreted in the urine. The increase in 5-HIAA indicates that more 5-HT was broken down after JCM-16021 treatment. Therefore, the data indicate that JCM-16021 affected 5-HT action and its metabolism in the colon.

It is well-known that a large proportion of 5-HT in the body is found in the gastrointestinal tract, and is primarily contained within EC cells<sup>[26]</sup>. This study found that EC cell number in NMS control rats is higher than that in NH control rats. It is possible that NMS induces hyperplasia of EC cells, thus NMS rats have higher concentrations of 5-HT in their colons compared to NH rats. Our results also showed that JCM-16021 cannot significantly change EC cell number in the colon of rats. This suggests that the hyperplasia of EC cells may be a permanent change similar to the elevated activation of the cingulate cortex and sensitization of the ascending pathway involving the spinal cord and the thalamo-cortico-amygdala pathway<sup>[24]</sup>. Therefore, EC cell number was not changed with treatment.

SERT is necessary for termination of serotonergic action in the colon. After the release by EC cells, serotonin is taken up again from the mucosa into the nerve fibers<sup>[11]</sup>. Altered SERT expression and function could contribute to the abdominal hypersensitivity and abnormal colonic motility associated with IBS and IBD<sup>[27]</sup>. A previous report showed 5-HT and mucosal SERT are both decreased in ulcerative colitis, diarrhea-predominant IBS and constipation-predominant IBS<sup>[28]</sup>. Our study showed that NMS rats with vehicle have significantly increased SERT expression in the colon with increased concentration of 5-HT, compared with NH rats with vehicle. The increase in SERT expression could be due to an adaptive response to improve disturbed gut function and ameliorate symptoms; thus increased 5-HT could be terminated quickly under different stimulations. After treatment with JCM-16021, SERT expressions were decreased along with 5-HT content. Such decreases could result in the inhibition of SERT function. It is reported that inhibition of SERT function leads to decreased transiency in the gut and lower sensitivity<sup>[27,29,30]</sup>. Our data showed that JCM-16021 reduced SERT expression in the colon of rats, indicating that JCM-16021 inhibits SERT function so as to induce lower sensitivity.

In summary, the present findings provide evidence for the analgesic effect of JCM-16021 on visceral hyperalgesia in rats. This effect may be mediated through changes in the synthesis and metabolism of 5-HT in the colons of rats.

## COMMENTS

### Background

Increasing numbers of irritable bowel syndrome (IBS) sufferers are seeking help

from complementary and alternative medicines because conventional therapies have not been proven to be more effective than placebo in providing overall relief of symptoms in randomized, controlled clinical trials. The 5-HT signaling pathway represents a promising target for IBS treatment. JCM-16021 improved the symptoms of IBS patients but the mechanism is unknown.

### Research frontiers

A neonatal maternal separation (NMS)-induced visceral hyperalgesia rat model is often used to study the mechanism of IBS and to evaluate the pharmacological effects of potential IBS therapies. This study aimed to investigate the analgesic effect of JCM-16021 on NMS-induced visceral hyperalgesia in rats, and its potential underlying mechanism.

### Innovations and breakthroughs

Recent studies have highlighted the role of serotonin (5-HT) in the generation of IBS symptoms and in other gastrointestinal functional disorders. Furthermore, novel serotonergic agents, such as the 5-HT<sub>3</sub> antagonist alosetron and the 5-HT<sub>4</sub> agonist tegaserod, have significant impacts on IBS symptoms through their visceral analgesic properties and diverse effects on motor functions in the lower gastrointestinal tract. This is the first study to report that the analgesic effect of JCM-16021, a Chinese herbal formula, on visceral hyperalgesia in rats may be mediated through changes in the synthesis and metabolism of 5-HT in the colons of rats.

### Applications

This study provides direct evidence for the analgesic effect of JCM-16021 on visceral hyperalgesia in rats. JCM-16021 might become a reliable therapy to relieve the symptoms of IBS patients.

### Peer review

This is an interesting paper showing the analgesic effect of a Chinese Medicine herb, JCM-16021 on maternal separation stress induced visceral hypersensitivity in male rats. Together with their previous data in IBS patients, this additional pre-clinical work suggests that JCM-16021 may be of therapeutic interest for IBS.

### Abstract

**AIM:** To investigate the effect of celecoxib, a selective COX-2 inhibitor, on *Helicobacter pylori* (*H. pylori*) colonization-related factors and its mechanism.

**METHODS:** After co-incubation with celecoxib, morphology of *H. pylori* strain 26695 was observed under a transmission electron microscope. Flagella motility was assessed by stab agar motility test. Adherence of *H. pylori* to AGS cells was determined by enzyme linked immunosorbent assay. Levels of mRNA expression in flagellar genes (*flaA*, *flaB*), urease genes (*ureA*, *ureB*) and adhesin genes (*babA*, *sabA*, *alpA*, *alpB*, *hpaA*, *hopZ*) were measured by real-time polymerase chain reaction.

**RESULTS:** Separation and non-integrity of bacterial cell wall, rarefaction and asymmetry of cytoplasm, and even lysis of *H. pylori* were observed in the presence of celecoxib. When *H. pylori* strains were incubated in the presence of celecoxib, their flagellar motility and

adherence to AGS cells were inhibited. The expression of *ureA*, *ureB*, *babA*, *sabA*, *alpA*, *alpB*, *hpaA*, *hopZ* was up-regulated while the expression of *flaA*, *flaB* was down-regulated in the presence of celecoxib.

**CONCLUSION:** Celecoxib inhibits flagellar motility and adherence of *H. pylori* to AGS cells, and destructs their normal structure *in vitro*.

### INTRODUCTION

About 30% of the population in developed countries and up to 90% of the population in developing countries are chronically infected with *Helicobacter pylori* (*H. pylori*)<sup>[1,2]</sup>. Non-steroidal anti-inflammatory drugs (NSAID) are the most commonly used drugs, on a world-wide scale, which are used by at least 30 million people<sup>[3]</sup>. NSAID and *H. pylori* infection are two major factors for gastric injuries. Subjects taking NSAID are often infected with *H. pylori*. However, whether these two factors exert synergistic or antagonistic actions on gastric mucosa is still controversial<sup>[4,5]</sup>. Data from a meta-analysis review have shown that the risk of peptic

ulcer is approximately 60-fold higher in *H. pylori* positive subjects taking NSAID than in *H. pylori* negative subjects not taking NSAID<sup>[6]</sup>. Since both *H. pylori* and NSAID are responsible for mucosal damage, they can increase the risk of developing uncomplicated and complicated peptic ulcer. However, data from several studies do not always confirm such an assumption<sup>[5]</sup>. A large clinical trial demonstrated that eradication of *H. pylori* delays the healing of gastric ulcers in NSAID users after treatment with omeprazole<sup>[7]</sup>, implying that *H. pylori* may protect individuals against NSAID-induced ulcer, possibly by stimulating mucosal prostaglandins and other protective factors.

Recent studies *in vitro* also suggested that aspirin and celecoxib, a selective COX-2 inhibitor, inhibit the growth of *H. pylori* and decrease the activity of urease and vacuolating cytotoxin in a dose-dependent manner<sup>[8-12]</sup>, indicating that NSAID may antagonize injuries of gastric mucosa caused by *H. pylori* infection. Colonization of *H. pylori* in gastric mucosa is a prerequisite for pathogenicity and needs to have at least 4 basic characteristics: integrate helical shape, motility of flagella, specific binding to adhesin and its receptors, and urease activity that provides an appropriate microenvironment<sup>[13]</sup>. We hypothesize that NSAID and celecoxib may influence the pathogenicity of *H. pylori* in gastric mucosa injury by altering the colonization. Therefore, the aim of the present study was to investigate the effect of celecoxib on *H. pylori* colonization-related factors and its mechanism *in vitro*.

## MATERIALS AND METHODS

### Bacterial culture

*H. pylori* 26695 strain was cultured at 37°C in a microaerobic atmosphere containing 5% O<sub>2</sub>, 85% N<sub>2</sub>, and 10% CO<sub>2</sub> for 48 h on Colombia agar medium supplemented with 8% (v/v) defibrinated goat blood containing 0.02 mmol/L celecoxib or vehicle control (1/1000 DMSO).

### Stab agar motility test

*H. pylori* strains were grown on Colombia agar medium for 48 h and then harvested into a brain heart infusion (37 g/L). After the concentration of bacteria was adjusted to 10<sup>8</sup> CFU/mL, 10 µL was inoculated into a 0.3% agar Brucella broth medium containing 8% defibrinated goat blood using a sterile picker. Five days after incubation under microaerobic condition at 37°C, the halo diameter was measured.

### Ultrastructural analysis

Forty-eight hours after exposure to 0.02 mmol/L celecoxib, *H. pylori* cells were collected and rinsed three times with 0.01 mol/L PBS, fixed in phosphate-buffer solution containing 2.5% glutaraldehyde at 4°C for 2 h. After centrifugation, pellets were embedded in 2% agar, fixed in 1% osmium tetroxide (OsO<sub>4</sub>) at 4°C, and rinsed three times with 0.01 mol/L PBS. After dehydrated

in a series of graded acetone at 4°C, specimens were embedded in Epon 812 (Emicron). The sample was cut into 90 nm-thick sections which were stained with uranyl acetate and lead citrate, and observed under a JEM1230 transmission electron microscope.

### Adhesion of *H. pylori* to AGS cells

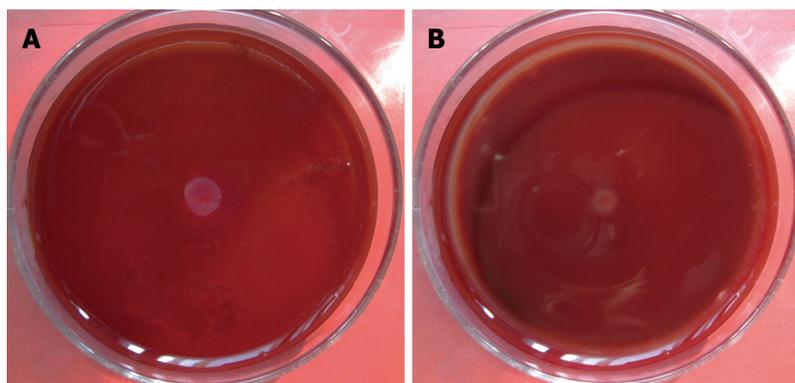

AGS cells (10<sup>4</sup>/well) were seeded in RPMI 1640 medium (Gibco) containing 10% fetal bovine serum in a 96-well plate containing 5% CO<sub>2</sub> at 37°C for 20 h. *H. pylori* (10<sup>7</sup> CFU/well) were pretreated with celecoxib at the concentrations of 0.01, 0.02 and 0.03 mmol/L. The plate was agitated at 60 r/min for 30 min at 37°C. Cultures were fixed with 1% paraformaldehyde. After washed with PBS, *H. pylori* cells were blocked with 5% bovine serum albumin (BSA) for 30 min, and incubated for 24 h with mouse monoclonal anti-*H. pylori* antibody (Santa cruz). After washed three times with PBS, goat anti-mouse IgG-HRP (Santa cruz) was added for 1 h. Binding was visualized by incubating with 100 µL TMB substrate for 30 min. Absorbance was read at 450 nm after 2 mol/L of sulphuric acid was added to terminate the reaction. Adherence of *H. pylori* to AGS cells was calculated according to the formula: [(A AGS cells with *H. pylori* - A AGS cells without *H. pylori*) / (A positive control - A negative control)] × 100. For positive control, only bacteria were added and allowed to adhere to the well. Wells containing neither AGS cells nor *H. pylori* were prepared as a negative control.

### *H. pylori* RNA isolation and reverse transcription

Forty-eight hours after pretreatment with 0.02 mmol/L celecoxib, strains of *H. pylori* were rinsed with Tris-HCl and cleared with 1 mL of TRIzol. After 200 µL of chloroform was added, the sample was vigorously shaken and centrifuged. RNA in aqueous phase was precipitated with 0.5 mL of isopropanol. The pellet was washed with ethanol and dried. The RNA was resuspended in sterile water and quantified by UV absorbance. Total RNA (4 µg) treated with RO1 RNase-free DNase (Promega) to remove DNA was used for reverse transcription reaction. In brief, 1.5 µL of random primers was added, the samples were heated to 70°C for 5 min. Then, 10 µL of 5 × RT buffer, 2.5 µL of dNTPs, and 2 µL of M-MLV were added. cDNA synthesis reaction was performed for 60 min at 37°C and then at 70°C for 10 min. Aliquots of cDNA were stored at -70°C.

### Real-time polymerase chain reaction (RT-PCR)

mRNA levels of flagellar genes (*flaA*, *flaB*), urease genes (*ureA*, *ureB*) and adhesin genes (*babA*, *sabA*, *alpA*, *alpB*, *bpaA*, *hopZ*) were measured by real-time PCR using the ABI Prism 7700 sequence detection system (Perkin-Elmer Applied Biosystems, Foster City, Calif). Specific primers and house-keeping gene 16SrRNA were designed with the aid of Primer Express 3.0 software (Applied Biosystem Perkin-Elmer) (Table 1). Real-time PCR was performed in a 25 µL reaction volume containing 2.5 µL

**Figure 1** Stab agar motility tests showing the *H. pylori* motility. A: DMSO control (1/1000); B: Celecoxib (0.02 mmol/L).

of cDNA, 12.5  $\mu$ L of SYBR green real time PCR master mix (Toyobo), 1  $\mu$ L of sense and antisense primers (5 pmol/L), and 9  $\mu$ L of DEPC water. PCR was carried out at 95°C for 10 min, followed by 40 cycles at 95°C for 15 s, at 61°C for 1 min. A further melting curve step analyzing the purity of PCR products was performed at 95°C for 15 s, at 61°C for 30 s, and at 96°C for 15 s. A standard curve was plotted using 10-fold serial dilution of each cDNA. mRNA level was expressed as the ratio of detected mRNA to 16S rRNA mRNA [detected mRNA (U/mL)/16S rRNA mRNA (U/mL)  $\times$  100 000]. PCR was carried out in quintuple using samples prepared at the same time.

### Statistical analysis

All experiments were performed at least in triplicate. Data were presented as mean  $\pm$  SD. Statistical analysis between sample and control was conducted by Student's

*t*-test using SPSS 11.0 software.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Effects of celecoxib on *H. pylori* motility

The halo diameter for the growth of *H. pylori* in the presence of celecoxib was  $5.92 \pm 1.20$  mm after 5-d incubation, which was significantly smaller than that ( $8.21 \pm 1.63$  mm) of DMSO control ( $P < 0.05$ , Figure 1), indicating that the motility of *H. pylori* is decreased in the presence of celecoxib.

### Ultrastructural effects of celecoxib on *H. pylori*

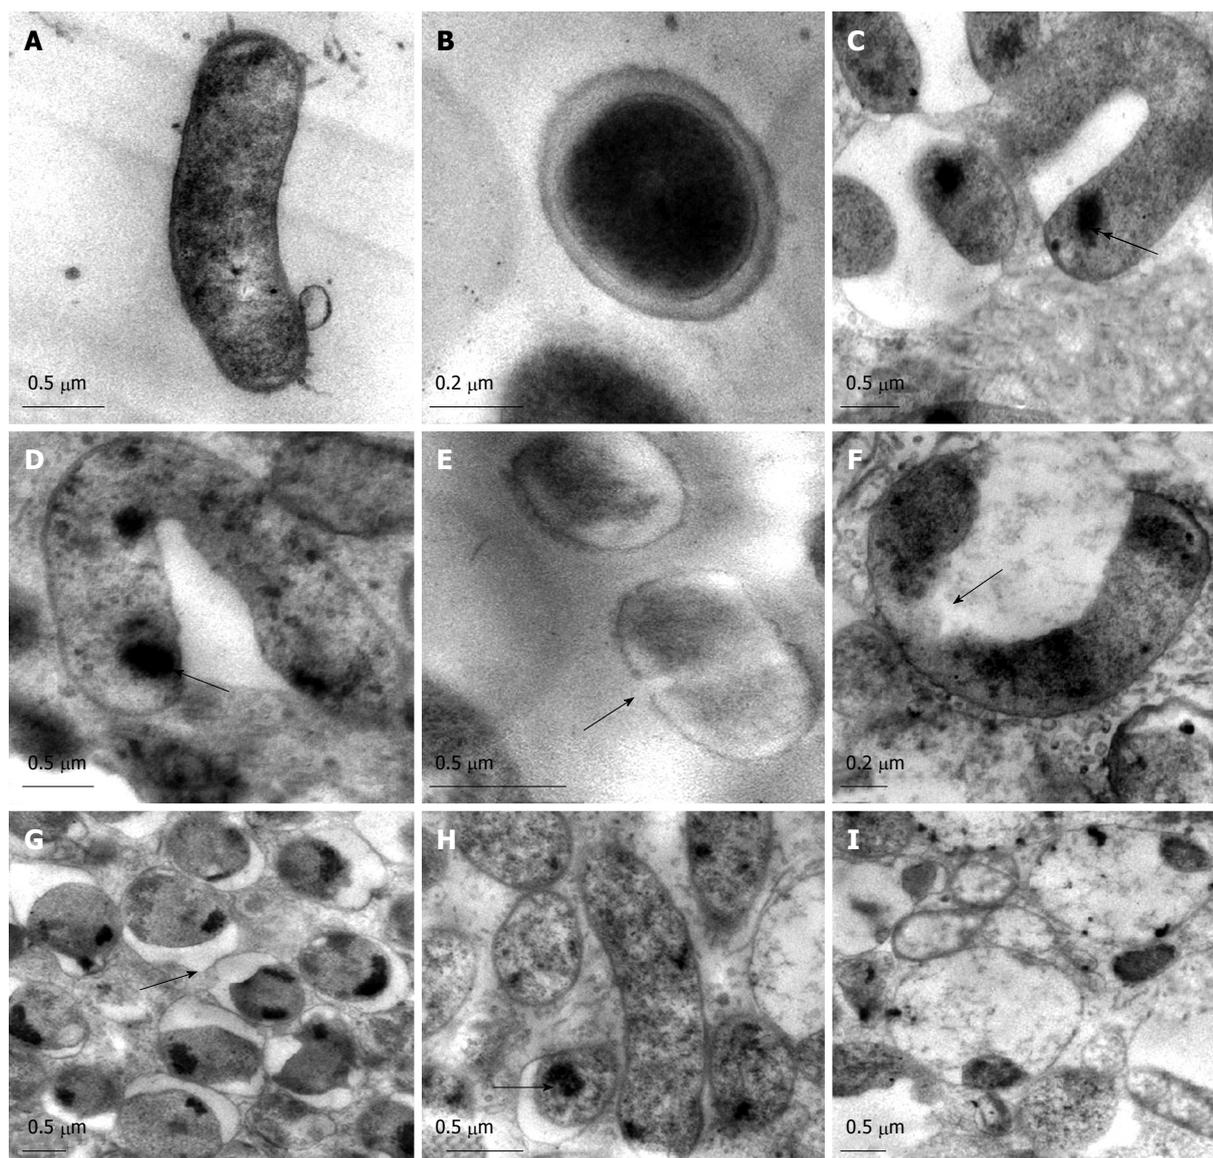

Transmission electron microscopy demonstrated that both cytoplasmic and outer membranes of *H. pylori* were intact, the cytoplasm was well-distributed and the electron density was moderate in DMSO control. When incubated with 0.02 mmol/L of celecoxib, V- and U-shaped *H. pylori* were observed. The cell wall of *H. pylori* was attenuated with abscission, or even perforation but no integrity. Separation of the outer membrane from the cytoplasmic membrane (cell wall breakaway) and even cell lysis were observed. Rarefaction and asymmetry were observed in cytoplasm of *H. pylori* and the components of *H. pylori* cells disappeared and distributed abnormally (Figure 2).

### Effects of celecoxib on *H. pylori* adherence to AGS cells

Compared to the DMSO control (1/1000), celecoxib significantly inhibited the adherence of *H. pylori* to AGS cells in a dose-dependent manner ( $P < 0.05$ ) (Figure 3).

### Effects of celecoxib on *H. pylori* flagellin, urease and adhesin gene expression

The mRNA expression levels in flagellar genes (*flaA*, *flaB*), urease genes (*ureA*, *ureB*) and adhesin genes (*babA*, *sabA*, *alpA*, *alpB*, *hpaA*, *hopZ*) were measured by real-time PCR. After treatment with 0.02 mmol/L celecoxib, the mRNA expression levels in *flaA* and *flaB* were lower than those in DMSO control ( $P < 0.05$ ). However, the mRNA expression levels were higher in urease genes (*ureA*, *ureB*) and adhesin genes (*babA*, *sabA*, *alpA*, *alpB*, *hpaA*, *hopZ*) than in DMSO control ( $P < 0.05$ ). The

**Figure 2** Transmission electron microscopy (TEM). TEM showing rod-shaped *H. pylori* (A), well-distributed cytoplasm and moderate electron density (B), U-shaped (C, arrow) and V-shaped (D, arrow) *H. pylori*, non-integrity (E, arrow) and abscission (F, arrow) of *H. pylori* cell wall, outer membrane separated from the cytoplasmic membrane (G, arrow), decreased electron density in cytoplasm (H, arrow), and cell lysis (I) after treatment with celecoxib.

mRNA expression levels in the above genes increased

or decreased 1.5-2.5 folds in the presence of celecoxib (Table 2).

## DISCUSSION

NSAID and *H. pylori* infection are the two main etiological factors for peptic ulcers. However, their role in the pathogenesis of gastric mucosal damage is still controversial<sup>[6]</sup>. It has been demonstrated that eradication of *H. pylori* can decrease the recurrence rate of peptic ulcer and its complications in chronic NSAID users<sup>[14]</sup>, while their co-existence aggravating gastric mucosal damage has not been confirmed<sup>[4,5]</sup>. It was reported that the prostaglandin synthesis level in mucosa is significantly higher in *H. pylori* positive patients than in *H. pylori* negative patients<sup>[15,16]</sup>, demonstrating that colonization of *H. pylori* reduces the inhibitory effect of NSAID

**Figure 3** Adhesion of *H. pylori* to AGS cells after treatment with celecoxib at different concentrations.

on prostaglandin synthesis. *In vitro* studies further revealed that NSAID can inhibit the growth of *H. pylori*, and decrease the activity of urease and vacuolating cytotoxin<sup>[8-12]</sup>, suggesting that NSAID may alter the pathogenicity of *H. pylori* in gastric mucosa injury when the two factors are co-existed in gastric mucosa.

*H. pylori* infection may persist for many years in the host and *H. pylori* colonization-related factors include its spiral shape, flagellar motility, urease and adhesin. Urease neutralizes the pH around *H. pylori* during exposure to the acidic lumen of stomach. The flagella and the spiral shape of *H. pylori* enable *H. pylori* strains to move and penetrate the mucin layer where they come into contact with gastric epithelial cells. Adherence of *H. pylori* to AGS cells is a crucial initial step in colonization<sup>[17,18]</sup>, as non-adhering *H. pylori* strains would be washed away during peristalsis-mediated flushing of stomach. NSAID and celecoxib do not increase the colonization of *H. pylori* in gastric mucosa<sup>[19-23]</sup>. On the contrary, the incidence of *H. pylori* infection in patients taking NSAID is low<sup>[24,25]</sup>, which may be partially explained by the fact that celecoxib can destruct the normal structure of *H. pylori*, and inhibit the motility of flagella, and the adherence of *H. pylori* to AGS cells and the activity of urease<sup>[12]</sup>, which is consistent with the findings in our study.

Adhesin, exposed on the surface of *H. pylori* cells, facilitates interaction with host cellular receptors. The particularly more important adhesins of *H. pylori* are BabA, SabA, AlpA, AlpB, HpaA, HopZ<sup>[26-30]</sup>. Their content and expression under different environmental conditions are variable. In our *in vitro* study, celecoxib inhibited the adherence of *H. pylori* to AGS cells, but increased the mRNA expression levels in *babA*, *sabA*, *alpA*, *alpB*, *hpaA*, *hopZ*. Whether the increased mRNA expression in such genes is accompanied with an increased competent protein or just a compensatory increase in mRNA expression for the inhibition of *H. pylori* growth and adherence activity remains to be further studied. On the other hand, variable expression of cell receptors in a single host and genetic variability of receptor expression in different hosts make the adherence system

very complex. Host receptor expression is up-regulated following *H. pylori* adherence<sup>[31]</sup>. In this study, the impaired adherence of *H. pylori* to AGS cells in the presence of celecoxib down-regulated the host receptor expression. In this condition, although the expression of *H. pylori* adhesins increases, the adherence of *H. pylori* to AGS cells may decrease.

Urease in *H. pylori* accounts for approximately 10% of the total bacterial protein pool<sup>[32]</sup>. Urease hydrolyzes urea and releases ammonia, which neutralizes acid, thus enabling survival and initial colonization. It has been shown that urease activity is essential for the initial bacterial colonization<sup>[33-35]</sup>. Anti-ulcer drug, ecabet, interferes with *H. pylori* colonization by inhibiting urease activity<sup>[36]</sup>. In the present study, celecoxib inhibited the urease activity in a dose-dependent manner, suggesting that it may further influence *H. pylori* colonization.

Urease is composed of two structural subunits, UreA and UreB. Urease gene clusters include *ureA*, *B*, *C*, *D*, *E*, *F*, *G*, *H*, *I*, with *ureA* and *ureB* being the structural genes. *ureC* and *ureD* are located before the structural genes. *ureI*, *ureE*, *ureF*, *urgG* and *ureH* are auxiliary genes. These genes and the structural genes are necessary for urease activity<sup>[37]</sup>. Urease is a metal enzyme possessing nickel and its activity depends on the two Ni<sup>2+</sup> inserted into its 6 active sites. The insertion process is accomplished by proteins encoded by auxiliary genes in a urease gene cluster. At present, a variety of identified proteins can regulate the activity of urease by influencing nickel ions. Besides proteins, different ion concentrations also accommodate urease activity<sup>[38]</sup>. Urease inhibitors can be generally classified into active site-directed (substrate-like) and mechanism-directed inhibitors. Since active site-directed inhibitors bridge the two paramagnetic nickel ions in the active site of urease, the octahedral nickel ions and the amino acid residues in the active site-directed inhibitors are in an orientation similar to those of the urease substrate, the mechanism-directed inhibitors are designed to interfere with the urease's catalysis mechanism leading to enzyme inactivation. In the present study, celecoxib inhibited the urease activity in *H. pylori*, but increased the mRNA expression levels in *ureA* and *ureB*. The mechanism still remains unclear. Further studies are needed to determine whether alterations occur at protein translation or modification level or some other mechanisms are involved.

The motility of *H. pylori* is considered another colonization factor. Less motile strains are less able to colonize or survive in the host than fully motile strains. It has been demonstrated that the degree of the motility of *H. pylori* strains is correlated with the degree of infectivity in gnotobiotic piglets. The most motile strains have a 100% infection rate, while the least motile strains have an infection rate of only 17%<sup>[39]</sup>. Strains without flagella or flagellar mutant strains cannot colonize the gastric mucosa, thus losing their pathogenicity. The flagella consist mainly of the flagellins, FlaA and FlaB.

Both genes coding for these flagellins are necessary for the full motility of *H. pylori*. Elimination of *flaB* yields normal-looking flagella that retain some functions and propel about 60% of the bacteria<sup>[40,41]</sup>. Elimination of *flaA* yields truncated flagella that only slightly move the bacteria. Elimination of both flagellins results in aflagellated immobile bacteria<sup>[41]</sup>. It was reported that NSAID inhibit the movement of *Proteus vulgaris*, *Proteus mirabilis*, *Providencia rettgeri*, *Providencia stuartii* and *Burkholderia cepacia* in a dose-dependent manner<sup>[42]</sup>, and prevent emergence of *Escherichia coli* flagella by inhibiting flagellin synthesis<sup>[43]</sup>. In this study, celecoxib inhibited the motility of *H. pylori* and decreased the mRNA expression in *flaA* and *flaB*.

The relation between the degree of *H. pylori* motility, cytokine response levels and the severity of disease has been extensively studied<sup>[44,45]</sup>. The *H. pylori* motility levels are correlated with IL-8 induction<sup>[44]</sup>. Kurihara<sup>[45]</sup> also found that the degree of *H. pylori* motility is low in strains isolated from remnant gastritis, which is distinct from chronic gastritis, peptic ulceration or gastric cancer, indicating that the type and phase of *H. pylori*-related diseases dictate the selective pressure for maintenance of high *H. pylori* motility levels. Further study is needed to demonstrate whether celecoxib prevents the progress of *H. pylori*-related diseases by inhibiting *H. pylori* motility.

Besides the flagella, the shape of *H. pylori* strains makes them possible to penetrate the mucin layer where they come into contact with the gastric epithelial cells. In the present study, transmission electron microscopy showed that celecoxib could impair the formation of *H. pylori*, break the bacterial outer membrane, and destruct its structure. Since the spiral shape of *H. pylori* is one of the important virulence factors, celecoxib-related morphological changes may have an impact on the progress of *H. pylori*-induced diseases.

Gastric carcinoma is the fourth most common cancer and the second leading cause of cancer-related deaths worldwide. The high mortality is largely attributed to the huge number of at-risk individuals. Chemoprevention appears to be the most promising approach in reducing the incidence and mortality of *H. pylori*-related gastric cancer. WHO defined *H. pylori* as a risk factor for gastric carcinoma and classified *H. pylori* strains as group I carcinogen in 1994<sup>[46]</sup>. The prevalence of *H. pylori* infection increases with age<sup>[47]</sup>, and 50% of NSAID users are over 60-year old. NSAID contribute to the chemoprevention of gastric cancer and prevention of lymphatic metastasis by inhibiting angiogenesis and inducing apoptosis of epithelial cells through the COX-dependent and independent pathway. It has been shown that long-term intake of NSAID and aspirin can significantly reduce the incidence of non-cardial gastric cancer in a dose-dependent manner<sup>[48]</sup>. The results of our study further suggest that celecoxib can reduce *H. pylori* colonization, thus attenuating the pathogenesis in gastric mucosa. Although regular use of aspirin can prevent gastric cancer,

it may be disadvantageous for populations with a lower risk of gastric cancer. Those with a high risk of gastric cancer can use celecoxib, a selective COX-2 inhibitor with few gastrointestinal side-effects.

## ACKNOWLEDGMENTS

The authors thank professor Jian-Zhong Zhang and You-Yong Lu for providing *H. pylori* reference strain 26695 and AGS cells (CRL-1739, ATCC), respectively.

## COMMENTS

### Background

Use of non-steroidal anti-inflammatory drugs (NSAID) and *Helicobacter pylori* (*H. pylori*) infection are the two main etiological factors for gastric injuries. Subjects taking NSAID are often co-infected with *H. pylori*, but the interaction between NSAID taking and infection with *H. pylori* remains unclear. Data from clinical and epidemiological studies are still controversial.

### Research frontiers

The relation between NSAID and *H. pylori* in the pathogenesis of gastric mucosal damage is still controversial. A number of studies have shown that it is not simply additive, synergistic or antagonistic. There may be complex interactions between them which affect the pathogenicity of each other.

### Innovations and breakthroughs

NSAID, as a harmful factor for gastric mucosal barrier, may be expected to increase the colonization of *H. pylori* in gastric mucosa. However, evidence from epidemiological studies indicates a lower prevalence of *H. pylori* infection in patients taking NSAID, which may partially be explained by the fact that celecoxib destructs the normal structure of *H. pylori*, and inhibits the flagellar motility, the adherence of *H. pylori* to AGS cells and the urease activity, as observed in this study.

### Applications

Colonization of *H. pylori* is a crucial initial step in the pathogenesis of *H. pylori* in gastric mucosa. The present study suggested that celecoxib could reduce the colonization of *H. pylori*, thus attenuating the pathogenicity in gastric mucosa.

### Terminology

SYBR green real-time polymerase chain reaction (PCR): a quantitative PCR method for determination of the copy number of PCR templates such as DNA or cDNA in a PCR reaction. SYBR green: A dye that binds to the minor groove of double stranded DNA. When SYBR green dye binds to double stranded DNA, the intensity of fluorescent emissions increases. As more double stranded amplicons are produced, SYBR green dye signals increase.

### Peer review

The study described the effect of celecoxib on *H. pylori*. The study is well-designed. The experimental data are sufficient to support its conclusion.

### Abstract

**AIM:** To investigate the expression of microRNA155 (miRNA155) in trinitrobenzene sulphonic acid (TNBS)-induced colitis and the relationship between miRNA155 and tumor necrosis factor (TNF) expressions.

**METHODS:** In TNBS colitis mice, miRNA155 and TNF mRNA expressions were measured in colons and CD4<sup>+</sup> T cells of draining lymph nodes (LNs). CD4<sup>+</sup> T cells were cultured *in vitro* with or without anti-CD3/CD28 antibody, and the expressions of miRNA155 and TNF mRNA in cells and TNF concentration in culture media were examined.

**RESULTS:** miRNA155 and TNF mRNA expressions in colons and in cells of LNs were significantly increased

in TNBS colitis compared with controls. In TNBS colitis, miRNA155 and TNF mRNA expressions in CD4<sup>+</sup> T cells of LNs and TNF concentration in CD4<sup>+</sup> T cells culture media increased compared with controls. When cultured with anti-CD3/CD28 antibody, miRNA155 and TNF mRNA expressions in CD4<sup>+</sup> T cells and TNF concentration in the CD4<sup>+</sup> T cells culture media were significantly higher than those cultured without anti-CD3/CD28 antibody. Following analysis using the Pearson's correlation coefficient, miRNA155 expression had a significant positive correlation with either TNF mRNA expression in CD4<sup>+</sup> T cells ( $r = 0.860$ ,  $P < 0.05$ ) or TNF concentration in CD4<sup>+</sup> T cells culture media ( $r = 0.892$ ,  $P < 0.05$ ).

**CONCLUSION:** miRNA155 is induced in colons and activated CD4<sup>+</sup> T cells in TNBS colitis, and the levels of miRNA155 and TNF expressions have a significant positive correlation.

### INTRODUCTION

Crohn's disease (CD) is a chronic relapsing inflammatory

disorder of the gastrointestinal tract. CD is thought to be a multifactorial, polygenic disease, however, the exact pathogenesis of CD is still unclear<sup>[1-3]</sup>. Some studies have suggested that CD is mediated by T helper type 1 (Th1) cells producing interferon- $\gamma$  (IFN- $\gamma$ ), tumor necrosis factor (TNF) and interleukin (IL)-12<sup>[4-8]</sup>. TNF, which is a proinflammatory cytokine secreted by monocytes/macrophages, T cells, B cells, NK cells and mast cells, is necessary for both the initiation and persistence of the Th1 response and contributes to intestinal inflammation in CD patients<sup>[9-11]</sup>. Today, many animal models of CD are available, and each model has reflected one aspect of human CD. Hapten-induced colitis, in which trinitrobenzene sulfonic acid (TNBS) is delivered intrarectally to rodents, displays Th1 activity of local CD4<sup>+</sup> T cells and is considered to closely resemble CD<sup>[12-14]</sup>.

MicroRNAs (miRNAs) are a group of small non-coding RNAs which posttranscriptionally regulate gene expression<sup>[15,16]</sup>. More than 700 miRNAs have been identified in mammals and are involved in a wide variety of biological processes<sup>[15,17]</sup>. They are transcribed as primary transcripts by RNA polymerase II, cleaved into a precursor miRNA by the Drosha nuclease, and exported from the nucleus by exportin 5. In the cytoplasm, the precursor miRNAs are further processed by the Dicer nuclease and are incorporated into the RNA-induced silencing complexes. The miRNAs guide the RNA-induced silencing complexes binding to the mRNAs 3'-untranslated regions (UTRs), resulting in either the mRNAs degradation or translational inhibition<sup>[18-22]</sup>.

Although the exact functions of most miRNAs have yet to be elucidated, many studies have suggested that miRNAs have been implicated in many aspects of innate and acquired immunity, such as differentiation, survival and functions of immune cells, and the intracellular signaling pathways<sup>[23-25]</sup>. miRNA155, which was reported to be involved in the production of TNF and regulation of immunity<sup>[26,27]</sup>, is processed from an exon of the noncoding RNA known as bic<sup>[27,28]</sup>. In this study, we mainly evaluated the expression of miRNA155 in TNBS colitis, and speculated on the relationship between miRNA155 and TNF expressions.

## MATERIALS AND METHODS

### Mice

Female 6- to 8-wk-old BALB/C mice weighing 18-22 g were obtained from Shanghai Experimental Animals Centre of Chinese Academy of Sciences. The mice were maintained under specific pathogen free conditions in a room at 23  $\pm$  2°C with a 12 h light-dark cycle, and had free access to food and water during the study. They were allowed to acclimate to these conditions for at least seven days before inclusion in an experiment. All procedures were approved by the Investigation and Ethics Committee of Shanghai Jiaotong University School of Medicine.

### Establishment of TNBS-induced colitis

Colitis was induced in BALB/C mice as described previously with some modification<sup>[13,29]</sup>. For sensitization, a 2 cm  $\times$  2 cm field of the abdominal skin was shaved and 150  $\mu$ L of 2.5% TNBS (Sigma Chemical Co., St. Louis, MO, USA) in 50% ethanol was applied. Five days after sensitization, mice were anesthetized slightly with an intraperitoneal injection of xylazine (10 mg/kg) and ketamine (50 mg/kg), and then intrarectally administered 100  $\mu$ L solution of 1% TNBS dissolved in 45% ethanol *via* a 3.5-French catheter equipped with a 1 mL syringe. The tip of the catheter was inserted 4 cm proximal to the anal verge. Mice were held in a vertical position for 1 min after the intrarectal injection. Control mice were given 100  $\mu$ L 45% ethanol solution without TNBS using the same technique.

### Clinical observations and histologic assessments of colitis

Daily body weight, stool consistency, and occult blood (measured by the guaiac reaction, hemoccult) were assessed. Three days after intrarectal injection, mice were killed by cervical dislocation after being anesthetized with diethyl ether and entire colons were removed from the cecum to the anus, and flushed with saline. Colon specimens located 2 cm above the anal verge were achieved. One section of the specimen was fixed overnight in 4% paraformaldehyde and embedded in paraffin, and then sections stained with hematoxylin and eosin were examined. The other sections of the colon were immediately frozen in liquid nitrogen after dissection and used for quantification of miRNA155, IL-1 $\beta$ , IL-6, TNF and IFN- $\gamma$  mRNA.

### Cell preparation

Three days after intrarectal injection, colon draining lymph nodes (LNs) were aseptically removed. Single-cell suspensions were prepared by pressing LNs through a 40  $\mu$ m cell strainer using the plunger of a 1 mL syringe. CD4<sup>+</sup> T cells were isolated from the cell suspensions with magnetic beads labeled with anti-CD4 (L3T4) monoclonal antibodies (Miltenyi Biotec Inc, Bergisch Gladbach, Germany). Cells were incubated in media (RPMI 1640 supplemented with 100 U/mL penicillin/streptomycin, 2 mmol/L L-glutamine, 50 mol/L 2-mercaptoethanol, and 10% fetal calf serum) at 8  $\times$  10<sup>4</sup> cells in 150  $\mu$ L media per well in 96-well plates for 48 h in the absence or presence of dynabeads CD3/CD28 T cells activator (Invitrogen, Carlsbad, CA, USA) at a concentration of 2  $\mu$ L/well.

### Enzyme-linked immunosorbent assay (ELISA)

After incubation for 48 h, the supernatants of the culture media were harvested and assayed for TNF concentration by ELISA using an ELISA kit (R&D Systems, Minneapolis, MN, USA).

### Quantitative real-time polymerase chain reaction (qPCR) analysis of mRNA detection

Total RNA from cells and colon samples were extracted using the TRIzol reagent (Invitrogen, Carlsbad, CA, USA). RNA concentrations were determined with a spectrophotometer (Eppendorf, Hamburg, Germany). 0.2-0.5  $\mu$ g of total RNA was reverse transcribed, and RNA expression levels were quantified by sybergreen-based qPCR using a sequence detection system (Prism 7500; Applied Biosystems Inc., Foster City, USA).  $\beta$ -actin served as the endogenous control. Gene-specific primers for the reported genes are indicated in Table 1. To evaluate the relative expression of each target gene, the comparative threshold (Ct) cycle method was used according to the manufacturer's manual. The threshold cycle (Ct) for each gene was determined as the cycle number at which the reaction crossed an arbitrarily placed threshold, and the relative amount of each mRNA to  $\beta$ -actin was described using the formula  $2^{-\Delta Ct}$  where  $\Delta Ct = (Ct_{mRNA} - Ct_{\beta-actin})$ .

### qPCR analysis of miRNA detection

Total RNA from cells and colon samples were isolated using the TRIzol reagent. Real time quantitative analyses for miRNAs were performed using stem-loop RT-PCR<sup>[30,31]</sup>. 0.2-0.5  $\mu$ g of total RNA was reverse transcribed to cDNA using a target-specific stem-loop primer indicated in Table 1. qPCR was performed on a sequence detection system (Prism 7500; Applied Biosystems Inc., Foster City, USA). In brief, cDNA in water was added to 5  $\mu$ L of the 2  $\times$  SYBR green master mix (Applied Biosystems Inc., Foster City, USA), 400 nmol/L of gene-specific primer and water to 10  $\mu$ L. The reactions were amplified at 95 $^{\circ}$ C for 10 min followed by 40 cycles at 95 $^{\circ}$ C for 15 s and 60 $^{\circ}$ C for 60 s. U6 small nuclear RNA (U6) served as the endogenous control. At the end of the qPCR, the thermal denaturation protocol was run to determine the number of products that were

present in the reaction. The relative amount of miRNA to U6 was calculated using the Ct cycle method. The relative amount of each miRNA to U6 was described using the formula  $2^{-\Delta Ct}$  where  $\Delta Ct = (Ct_{miRNA} - Ct_{U6})$ <sup>[30,31]</sup>.

### Statistical analysis

Each group contained 5-8 mice, and results were expressed as the mean  $\pm$  SD. A comparison between the two groups was made using the Student's *t*-test. The relationship between the two targets was tested with Pearson's correlation coefficient. Differences were considered significant at  $P < 0.05$ .

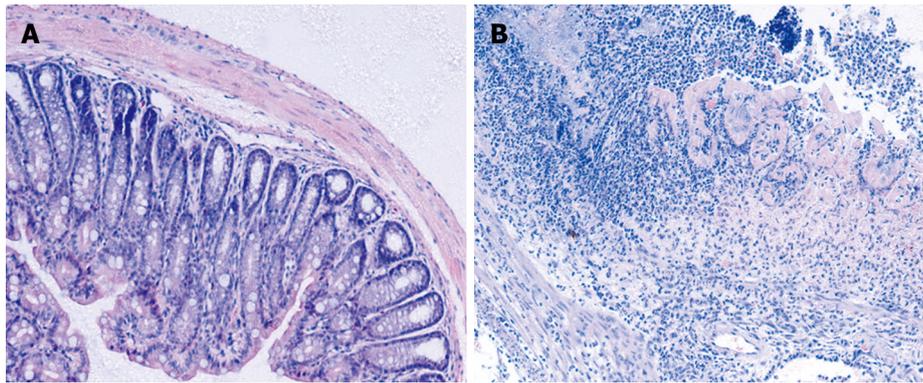

## RESULTS

### Successful establishment of experimental colitis

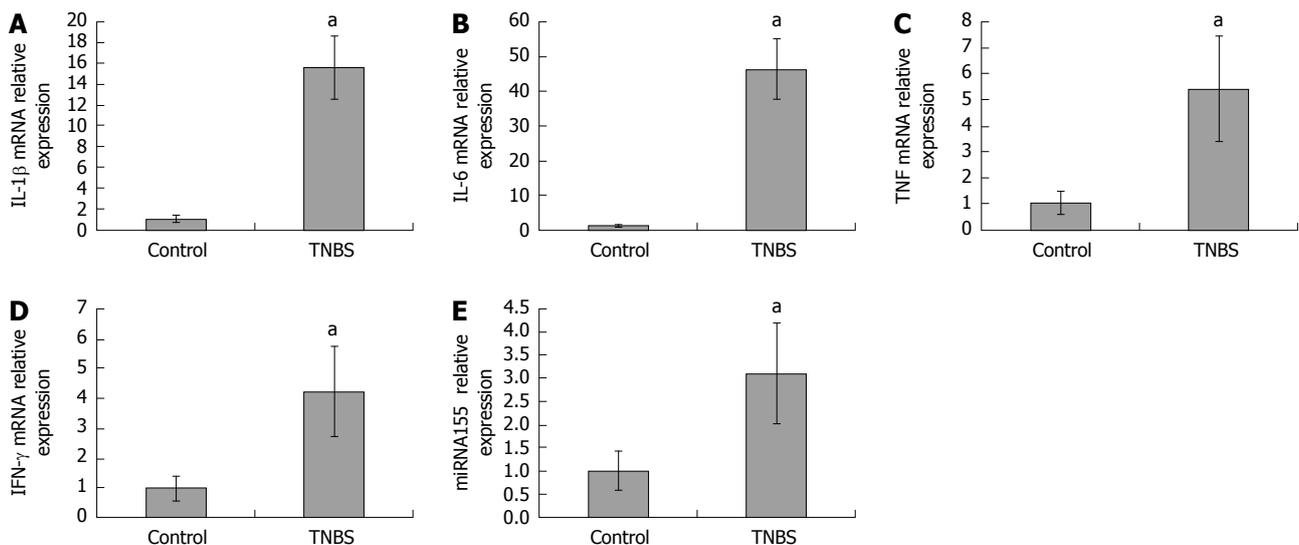

Administration of TNBS to presensitized mice resulted in a severe illness characterized by bloody diarrhea, rectal prolapse accompanied by sustained weight loss. At day 3-4, the disease reached a peak. Histologic examination of the colons showed severe depletion of mucin-producing goblet and epithelial cells, large areas of ulceration, a marked increase in the thickness of the muscular layer, and transmural inflammation involving all colon wall layers with infiltration of lymphocytes, macrophages and neutrophils extending from the mucosa into the muscular and serosal layers (Figure 1).

### Increased expressions of miRNA155, IL-1 $\beta$ , IL-6, TNF, and IFN- $\gamma$ mRNA in the colons of TNBS-induced colitis mice

To investigate miRNA155 and cytokine expressions in colons, we assessed miRNA155, IL-1 $\beta$ , IL-6, TNF and IFN- $\gamma$  mRNA in colon homogenates by qPCR. We found that miRNA155 expression in colon homogenates was significantly increased in TNBS-induced colitis, which was 3.10-fold higher than in control mice. IL-1 $\beta$ , IL-6, TNF, and IFN- $\gamma$  mRNA expressions in colon homogenates were also significantly increased in TNBS-induced colitis,

**Figure 1** Representative microphotographs of the colon sections stained with hematoxylin and eosin (original magnification,  $\times 100$ ). A: Control colon; B: Colon was obtained on day 3 after intrarectal TNBS.

**Figure 2** IL-1 $\beta$  (A), IL-6 (B), TNF (C), IFN- $\gamma$  (D) mRNA and miRNA155 (E) expressions in colon homogenates of control and TNBS colitis groups. qPCR-derived IL-1 $\beta$ , IL-6, TNF, IFN- $\gamma$ , and miRNA155 expressions in colon homogenates were significantly increased in TNBS-induced colitis. <sup>a</sup> $P < 0.05$  vs control.

and were 15.58-, 46.34-, 5.43-, and 4.23-fold higher than in control mice, respectively (Figure 2).

#### **miRNA155 and TNF mRNA expressions in the CD4<sup>+</sup> T cells of colon draining LNs and TNF concentration in CD4<sup>+</sup> T cells culture media**

As CD4<sup>+</sup> T cells play a central role in Th1 response, we evaluated the levels of miRNA155 and TNF mRNA expressions in LNs and CD4<sup>+</sup> T cells from LNs. In TNBS colitis, miRNA155 in draining LNs or CD4<sup>+</sup> T cells from LNs increased and were 3.74- and 3.07-fold higher than in controls, respectively (Figure 3). TNF mRNA in draining LNs or CD4<sup>+</sup> T cells from LNs of TNBS colitis were 3.34- and 2.06-fold higher than in controls (Figure 3). In the CD4<sup>+</sup> T cells culture media, the concentration of TNF protein increased in TNBS colitis and was 4.19-fold higher than in controls ( $128.04 \pm 38.71$  pg/mL *vs*  $30.55 \pm 8.37$  pg/mL,  $P < 0.05$ , Figure 4).

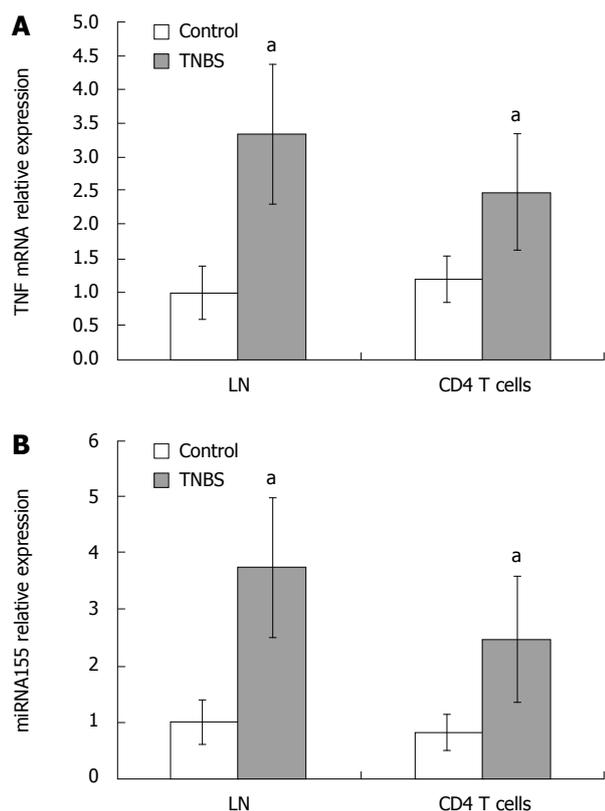

#### **Anti-CD3/CD28 antibody promoted the miRNA155 and TNF mRNA expressions in the CD4<sup>+</sup> T cells and the TNF concentration in the supernatants of CD4<sup>+</sup> T cells culture media**

To study whether the T cell receptor (TCR) and the

costimulatory receptor were involved in miRNA155 expression, and to study the relationship between miRNA155 and TNF production, we used anti-CD3/CD28 antibody to stimulate CD4<sup>+</sup> T cells. When cultured with anti-CD3/CD28 antibody, the CD4<sup>+</sup> T cells became larger and displayed an activated appearance. In control and TNBS colitis, the miRNA155 expressions in CD4<sup>+</sup> T cells cultured with anti-CD3/CD28 antibody were 4.72- and 3.61-fold higher than cells cultured without anti-CD3/CD28 antibody, and the TNF mRNA expression in CD4<sup>+</sup> T cells cultured with anti-CD3/CD28 antibody were 3.42- and 3.03-fold higher than cells cultured without anti-CD3/CD28 antibody, respectively (Figure 4). The TNF concentration in the supernatants of culture media which contained anti-CD3/CD28 antibody increased both in control and TNBS colitis mice, and were 4.28- and 6.87-fold higher than in media cultured without anti-CD3/CD28 antibody ( $135.66 \pm 32.11$  pg/mL *vs*  $30.55 \pm 8.37$  pg/mL,  $P < 0.05$ ;  $850.94 \pm 219.49$  pg/mL *vs*  $128.04 \pm 38.71$  pg/mL,  $P < 0.05$ , Figure 4).

#### **Relationship between miRNA155 and TNF gene expressions**

Since TNF plays an important role in the pathogenesis

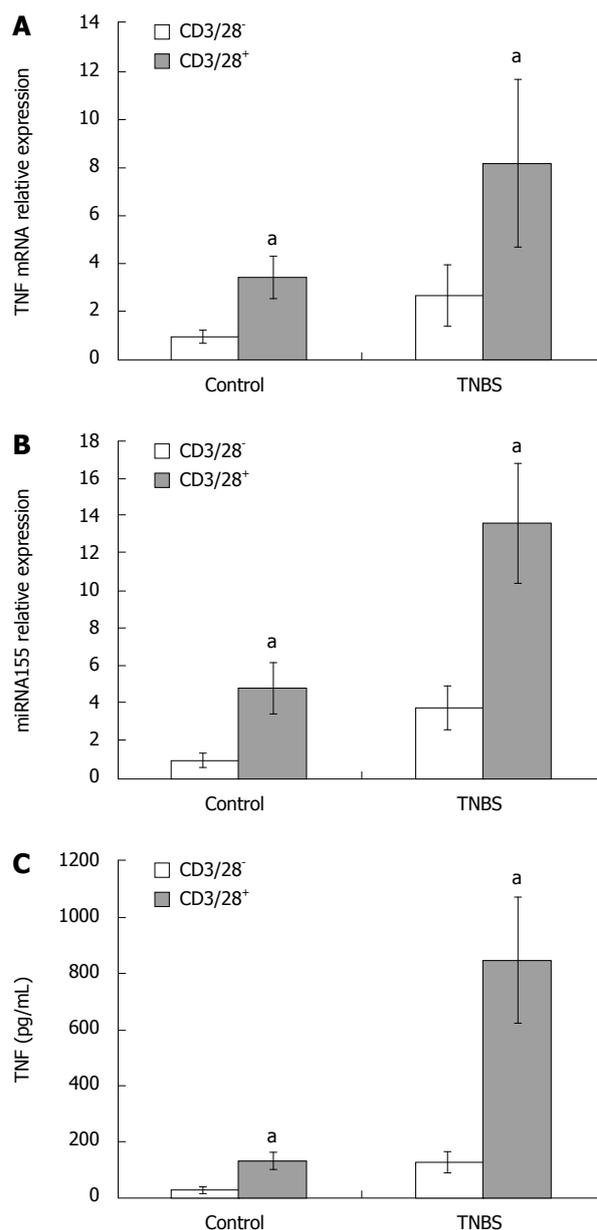

**Figure 3** TNF mRNA (A) and miRNA155 (B) expressions in LNs and CD4<sup>+</sup> T cells in control and TNBS colitis groups. TNF mRNA and miRNA155 expressions in LNs and CD4<sup>+</sup> T cells were significantly increased in TNBS-induced colitis. <sup>a</sup>*P* < 0.05 vs control.

of CD, we evaluated the potential correlation between miRNA155 and TNF gene expressions. Our data indicated that there was a significant positive correlation between miRNA155 and TNF mRNA expressions in CD4<sup>+</sup> T cells ( $r = 0.860, P < 0.05$ , Figure 5), and miRNA155 expression in CD4<sup>+</sup> T cells and TNF protein concentration in CD4<sup>+</sup> T cells culture media ( $r = 0.892, P < 0.05$ , Figure 5).

## DISCUSSION

As the exact etiology of CD is still unclear, TNBS-induced colitis was used to study many important aspects of the pathogenesis in CD. TNBS colitis is thought to resemble CD because of the mucosal inflammation mediated by excessive IFN- $\gamma$ , TNF and other proinflammatory cytokine production<sup>[12-14]</sup>. In agreement with previous results, our data also showed that TNBS colitis is a Th1 model with elevated IFN- $\gamma$  and TNF expressions in colon. In this study, we found that miRNA155 was increased in colons and in CD4<sup>+</sup> T cells of LNs in TNBS colitis and the levels of miRNA155 and TNF expressions had a significant positive correlation.

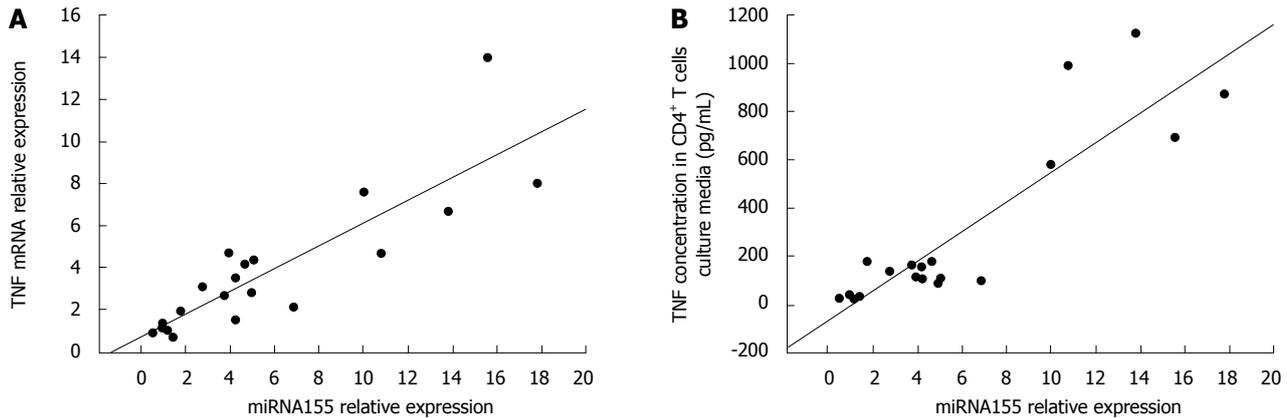

MiRNAs are a group of small noncoding RNAs which are thought to posttranscriptionally regulate gene expressions. Dysregulation of miRNAs has been associated with several autoimmune diseases<sup>[32,33]</sup>. miRNA155 is processed from an exon of the noncoding RNA. Some

**Figure 4** TNF mRNA (A) and miRNA155 (B) expressions in CD4<sup>+</sup> T cells cultured with or without anti-CD3/CD28 antibody, and the TNF protein concentration (C) in the supernatants of CD4<sup>+</sup> T cells culture media with or without anti-CD3/CD28 antibody. TNF mRNA and miRNA155 expressions in CD4<sup>+</sup> T cells cultured with anti-CD3/CD28 antibody, and the TNF concentration in the supernatants of culture media containing anti-CD3/CD28 antibody increased in comparison to those in cells or media cultured without anti-CD3/CD28 antibody. <sup>a</sup>*P* < 0.05 vs control.

studies have shown that miRNA155 is required for normal innate and acquired immunity<sup>[26,27,34,35]</sup>.

In macrophages, miRNA155 was reported to enhance the production of TNF, but may target transcripts encoding for several proteins, such as I $\kappa$ B $\epsilon$  kinase and Fas-associated death domain protein whose ultimate function results in the activation of the lipopolysaccharide (LPS)/TNF pathway<sup>[26]</sup>. Therefore, miRNA155 may exert both positive and negative effects on the activation of innate immunity. In acquired immunity, miRNA155 was reported to affect lymphoid cell development<sup>[27,34,36]</sup>. In

**Figure 5** Relationships between miRNA155 expression in CD4<sup>+</sup> T cells and TNF mRNA expression in CD4<sup>+</sup> T cells (A) or TNF concentration in CD4<sup>+</sup> T cells culture media (B). Data analyzed by Pearson's correlation coefficient.

miRNA155<sup>-/-</sup> mice, CD4<sup>+</sup> T cells are intrinsically biased toward Th2 differentiation. miRNA155 modulates the level of a transcription factor c-Maf in T cells and is likely to induce the attenuation of Th2 cell responses *in vivo*<sup>[34]</sup>. With regard to B cells, several studies have proved that B cells require miRNA155 for normal production of isotype-switched, high-affinity antibodies and for a memory response<sup>[27,36]</sup>. However, the expression of miRNA155 and its relationship with CD remains unclear. In this paper, we reported that miRNA155 expression is increased in the colon and its draining LNs in TNBS colitis. This result hints that miRNA155 may have a role in the pathogenesis of TNBS colitis. As CD4<sup>+</sup> T cells play a central role in Th1 response, we determined the level of miRNA155 expression in the CD4<sup>+</sup> T cells from LNs in TNBS colitis and found that miRNA155 was increased in CD4<sup>+</sup> T cells in TNBS colitis.

Considering TNF plays an important role in the pathogenesis of CD, we evaluated the relationship between miRNA155 and TNF expression in CD4<sup>+</sup> T cells. Our data indicated that the gene expression of miRNA155 in CD4<sup>+</sup> T cells of draining LNs in TNBS colitis has a significant positive correlation with either TNF mRNA in CD4<sup>+</sup> T cells or the concentration of TNF protein in the culture media. Some reports have shown that miRNA155 may be involved in TNF production<sup>[26,27]</sup>. Eu-miR-155 transgenic mice which specifically overexpress miRNA155 in B cells produced more TNF when challenged with LPS, and were hypersensitive to LPS/D-galactosamine-induced septic shock<sup>[26]</sup>. In addition, miRNA155<sup>-/-</sup> B cells produce less TNF when activated *in vitro* by BCR cross-linking<sup>[27]</sup>. Scientists have found that the miRNA155 effects on TNF production are at both the transcriptional and posttranscriptional level<sup>[26,27]</sup>. More TNF transcripts were observed in wild-type mice compared with miRNA155<sup>-/-</sup> mice<sup>[27]</sup>. At the posttranscriptional level, miRNA155 may target the 3'-UTR of TNF transcripts to increase the stability of transcripts and enhance translation<sup>[26]</sup>. Our results showed that the TNF protein concentration in the CD4<sup>+</sup> T cells culture media increased more than the TNF mRNA in CD4<sup>+</sup> T cells, which is in agreement with the

proposition that miRNA155 regulated TNF production at both the transcriptional and posttranscriptional levels. These findings suggested that miRNA155 may prompt the production of TNF in some types of immune cells. From our results, miRNA155 increased and had a positive relationship with TNF expression in CD4<sup>+</sup> T cells, therefore we suppose that miRNA155 may influence TNF expression in CD4<sup>+</sup> T cells and is possibly involved in the pathogenesis of TNBS colitis.

The exact mechanism of miRNA155 expression regulation in CD4<sup>+</sup> T cells remains unclear. To study the role of TCR in miRNA155 expression and the relationship between miRNA155 expression and the activation of CD4<sup>+</sup> T cells, we used anti-CD3/CD28 antibody to stimulate CD4<sup>+</sup> T cells, and found that the miRNA155 expression level was elevated in CD4<sup>+</sup> T cells when cultured with the antibody. Stimulation of the TCR/CD3 complex and costimulatory receptor CD28 in CD4<sup>+</sup> T cells by anti-CD3/CD28 antibody can lead to activation of multiple transcription factors, including NF-AT and NF- $\kappa$ B, which ultimately control transcription of cytokines and T-cell proliferation<sup>[37]</sup>. miRNA155 level was reported to have a link with the NF- $\kappa$ B pathway. NF- $\kappa$ B activity is required for the change in miRNA155 levels following TNF stimulation in macrophages, however, this relationship remains elusive<sup>[26]</sup>. The precise mechanism of the regulation of miRNA155 expression may be a new issue for future research.

In conclusion, miRNA155 expression was found to increase in colons and activated CD4<sup>+</sup> T cells in TNBS colitis. A significant positive correlation was observed between miRNA155 expression in CD4<sup>+</sup> T cells and the expression of TNF mRNA in CD4<sup>+</sup> T cells and the TNF protein concentration in CD4<sup>+</sup> T cells culture media. miRNA155 may be involved in the activation and TNF production of CD4<sup>+</sup> T cells in TNBS colitis.

## COMMENTS

### Background

MicroRNAs (miRNAs) are a group of small noncoding RNAs which post-

transcriptionally regulate gene expression. miRNA155 is reported to be involved in the production of TNF and the regulation of immunity. Tumor necrosis factor (TNF) plays an important role in the pathogenesis of Crohn's disease (CD). However, the expression of miRNA155 and its relationship with TNF production in CD remains unclear.

### Research frontiers

The exact etiology of CD is still unclear. MiRNA research may represent a new way to explore the pathogenesis of CD. The expressions and functions of most miRNAs in CD remain a mystery.

### Innovations and breakthroughs

The study found that miRNA155 is increased in colons and draining lymph nodes. In CD4<sup>+</sup> T cells which play a central role in Th1 response, miRNA155 expression is higher in TNBS colitis than in controls. As CD4<sup>+</sup> T cells were activated by anti-CD3/CD28 antibody, the miRNA155 expression was higher than that when cultured without anti-CD3/CD28 antibody. In addition, the levels of miRNA155 and TNF expressions had a significant positive correlation.

### Applications

The results of this study may enhance our understanding of the pathogenesis of CD. By investigating the exact function of miRNA155 in the pathogenesis of CD, the findings may contribute to improvements in future drug therapies.

### Terminology

MiRNA: MicroRNAs (miRNAs) are a group of small noncoding RNAs which post-transcriptionally regulate gene expressions. More than 700 miRNAs have been identified in mammals and are involved in a wide variety of biological processes. Stem-loop RT-PCR: RNA is reverse transcribed to cDNA using a gene-specific stem-loop RT primer, and then the RT products are quantified using conventional real time PCR.

### Peer review

This paper reports a set of relatively new data about the pathogenic mechanism of IBD that may be referred by those investigators working on IBD.

### Abstract

**AIM:** To evaluate changes in colorectal cancer (CRC) survival over the last 20 years.

**METHODS:** We compared two groups of consecutive CRC patients that were prospectively recruited: Group I included 1990 patients diagnosed between 1980 and 1994. Group II included 871 patients diagnosed in 2001.

**RESULTS:** The average follow up time was 21 mo (1-229) for Group I and 50 mo (1-73.4) for Group II. Overall median survival was significantly longer in Group II than in Group I (73 mo vs 25 mo,  $P < 0.001$ ) and the difference was significant for all tumor stages. Post surgical mortality was 8% for Group I and 2% for Group II ( $P < 0.001$ ). Only 17% of Group I patients received chemotherapy compared with 50% of Group II patients ( $P < 0.001$ ).

**CONCLUSION:** Survival in colorectal cancer patients has doubled over the past 20 years. This increase seems to be partly due to the generalization in the administration of chemotherapy and to the decrease of post surgical mortality.

## INTRODUCTION

Colorectal cancer (CRC) is the second most common form of cancer and the second leading cause of cancer death in both men and women in most developed countries including Spain. Mortality has increased by an annual average of 2.6% for men and 0.8% for women since 1975, without variations<sup>[1]</sup>. It is estimated that CRC caused 11 900 deaths in Spain in 2000, which represents 11% of the total deaths from cancer in men and 15% of those in women<sup>[1]</sup>.

The primary treatment for this condition is surgical resection. Despite resection of all macroscopic tumors, patients whose primary tumor has penetrated the serosa or that have regional lymph node metastases at the time of surgery have high recurrence rates. An effective adjuvant program to eradicate microscopic tumor foci is clearly needed for such high-risk patients<sup>[2]</sup>. A major advance in adjuvant treatment of CRC came with trials that explored the combination of 5-fluorouracil and levamisole or leucovorin (FL). Therapy with FL reduced the overall death rate by 33% relative to surgery alone in patients with stage III disease. During the last few years, sequential advances in chemotherapy after surgical resection (adjuvant chemotherapy) have had an irrefutable and substantial benefit<sup>[3]</sup>.

The aim of the present study was to evaluate CRC survival over the last 20 years.

## MATERIALS AND METHODS

### Study population

A total of 1990 patients diagnosed with CRC between 1980 and 1994 and 2001 were included in a prospective and consecutive manner. Patients were enrolled in two time periods: Group I included 1119 patients recruited between 1980 and 1994. Group II included 871 patients recruited during 2001. Patients were recruited as part of the EPICOLON project<sup>[4,5]</sup>. Age, sex, tumor features (location, TNM stage, differentiation) and type of chemotherapy administered, if any, was collected for all patients. Stage was defined according to the 4th Edition of the TNM classification<sup>[6]</sup>.

EPICOLON was a prospective, multicenter, nationwide study that was set up to record consecutive cases of CRC in 25 hospitals in Spain over one year. The initial aim of the study was to determine the incidence and characteristics of familial forms of CRC in Spain.

Patients went through periodical follow up in medical consultations or by telephone. Patients with familial adenomatous polyposis or inflammatory bowel disease

were excluded.

In order to evaluate survival trends, Group I was divided in three subgroups: patients diagnosed between 1980 and 1985 (343); patients diagnosed between 1986 and 1990 (392); and patients diagnosed between 1991 and 1994 (384).

Death during the first 30 d post surgery was considered postoperative mortality.

All patients provided written informed consent before enrollment in the study. The study was approved by the Institutional Review Board or Ethics Committee at each center and complied with the provisions of the Good Clinical Practice guidelines.

### Statistical analysis

Continuous variables are defined with (mean  $\pm$  SD). Discrete variables are defined by absolute and relative frequencies. The function of survival is calculated by the Kaplan Meier estimator. The accumulated probability of survival is presented at 3, 5 and 10 years of monitoring. The Log-Rank test is used to evaluate the differences in survival between the different categories of independent variables. Multivariable models are constructed using Cox regression analysis and the independent effect of each variable on mortality is estimated using Relative Risks (Hazard Ratio) and the respective confidence intervals of 95%. The SPSS v.15 program was used for analysis.

## RESULTS

### Tumor features, follow up and treatment

The average follow up time was 21 mo for Group I and 50 mo for Group II. Average follow up for deceased patients was 12 mo for Group I and 16 mo for Group II. For patients still alive, follow up was 67 mo for Group I and 60 mo for Group II.

The characteristics of the patients are described in Table 1. Both groups were similar regarding tumor stages at diagnose and tumor location. Significant differences were observed in sex and age: the average age of Group I was 66.7 years compared to 69 years in Group II; the percentage of men was 61% and 57%, respectively. Slight differences were also observed in tumor differentiation: Group I had 4% of poorly differentiated tumors and Group II 8%. The greatest differences were found in the proportion of patients that received chemotherapy: 17% in Group I and 47% in Group II.

### Mortality

The probability of survival at 3 and 5 years was approximately 20% higher in Group II than in Group I. Three year survival was 44% for Group I and 65% for Group II. Five year survival was 35% for Group I and 57% for Group II.

Overall median survival was significantly longer in Group II than in Group I (73 mo *vs* 25 mo,  $P < 0.001$ ).

**Table 1 Characteristics of the patients n (%)**

	Group I (n = 1119)	Group II (n = 871)	P value
Age mean (SD)	66.7 (12.4)	69.1 (11.5)	0.000
Sex			0.027
Males	638 (57)	531 (61)	
Females	481 (43)	340 (39)	
Tumor localization			
Distal to splenic flexure	831 (75)	644 (74)	
Proximal to splenic flexure	272 (25)	227 (26)	
TNM			0.11
I	190 (17)	122 (14)	
II	403 (36)	348 (40)	
III	302 (27)	244 (28)	
IV	224 (20)	157 (18)	
Tumor differentiation			0.000
Poor	45 (4)	70 (8)	
Well-moderate	1074 (96)	801 (92)	
Receiving chemotherapy	190 (17)	409 (46.9)	0.000

**Table 2 Mortality variation in relation to 4 independent risk factors**

	Hazard ratio (95% CI)
Stage	
II vs I	1.6 (1.2-2.1)
III vs I	3.5 (2.7-4.6)
IV vs I	13.7 (10.4-18.0)
Group	
I vs II	2.0 (1.7-2.4)
Chemotherapy	
No vs Yes	1.6 (1.3-1.9)
Grade	
I, II vs III	1.5 (1.1-1.9)

Three years after cancer diagnosis, 21% more patients were alive in Group II than in Group I.

Multivariate analysis showed 4 independent factors associated with a higher mortality risk (Table 2).

**Survival in Group I:** In Group I survival increased over the years in parallel to chemotherapy use (Figure 1). Ten percent of patients (35 patients) received chemotherapy between 1980 and 1985, 16% (63) in the period between 1986 and 1990 and 24% (92) in the period between 1991 and 1994. The median survival was 17 mo for the period between 1980 and 1985, 28 mo for the period between 1986 and 1990 and 34 mo for the period between 1991 and 1994 (Figure 1).

**Survival and stages**

Survival was greater for group II than for group I for all tumor stages (Figure 2). Postoperative mortality was 8% for Group I and 2% for Group II (Table 3). However, when patients in Group I who had died within 30 d of emergency surgery were excluded the postoperative mortality rate was equal to that in Group II. Postoperative mortality in patients operated electively in Group I was 3% (5 patients) for stage I, 2% (10 patients) for stage II, 3% (10 patients) for stage III and 4% (10 patients) for stage IV.

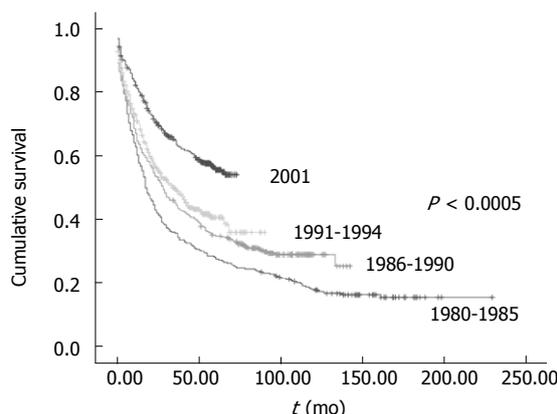

Figure 1 Kaplan-Meier analysis of overall survival in the different groups.

These data were similar to Group II. Twenty six percent more patients received chemotherapy in Group II than in Group I for stage III CRC. For the other tumor stages the percentage of patients that received chemotherapy was also greater in Group II, but to a smaller degree than stage III: 3% for stage I, 14% for stage II and 11% for stage IV.

**DISCUSSION**

The last few years have seen great advances in treatment of CRC. The survival has increased substantially. In our study survival rate almost doubled over the last 20 years, from 35% to 57% at 5 years. Determining factors in this increased survival have been the generalization of chemotherapeutic agents and surgical advances, especially pertaining to rectal cancer.

The first chemotherapeutic agent used in the treatment of CRC was fluorouracil (FL) in 1958<sup>[7]</sup>. Since then and up to the last decade, FL has been the only drug used in CRC treatment. In 1988 a meta-analysis on the effect of FL showed a 10% reduction in the risk of death and an increase of 2.3% in survival after 5 years. In a subgroup of patients the risk of death was reduced by 17% and global survival after 5 years improved up to 34%<sup>[7]</sup>. Based on the results of this and other studies, the National Cancer Institute and the American Society of Clinical Oncology recommended FL-based post surgical treatment in their annual conference in 1997. In stage III disease, FL increases overall five year survival from about 51% to 64%<sup>[8]</sup>. The use of adjuvant FL in patients with stage II disease is controversial. FL in advanced CRC prolongs median survival by approximately 5 mo (6 mo without treatment to 11 mo with FL)<sup>[9]</sup>.

The US Food and Drug Administration (FDA) has approved a host of new chemotherapeutic agents for advanced colon cancer and for relapsing disease. Since the year 2000, irinotecan was approved as a first line treatment in metastatic CRC. In 2002, oxaliplatin was approved for use along with other drugs as adjuvant treatment of relapsing CRC. Sequential exposure to various combinations of FL, irinotecan and oxaliplatin extends median overall survival by approximately 20 mo<sup>[10]</sup>. The

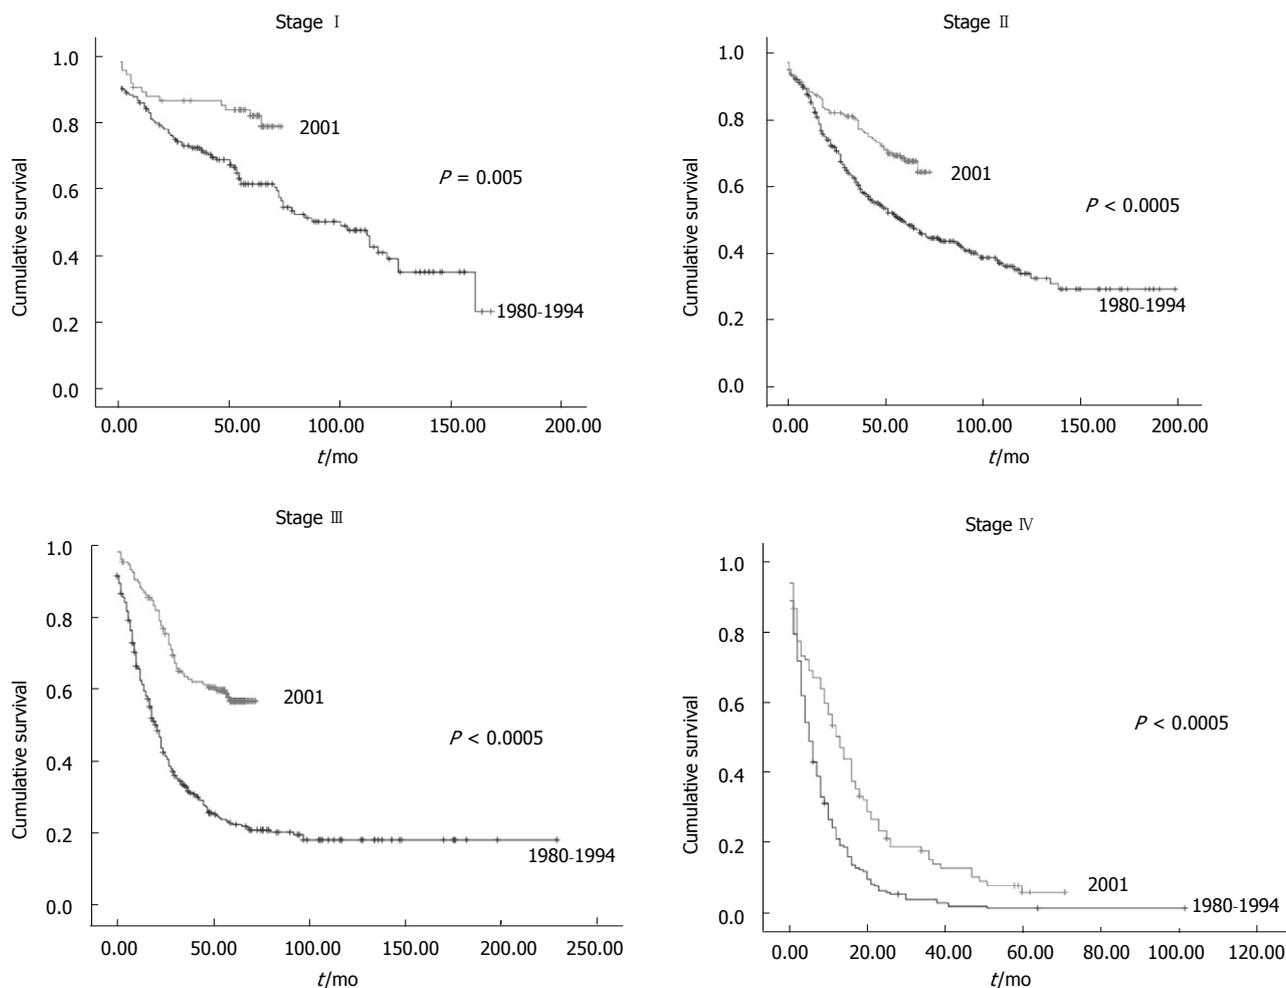

Figure 2 Kaplan-Meier analysis of overall survival and the stage of colorectal cancer according to the group of patients.

FDA approved capecitabine in 2005. Bevacizumab, a monoclonal humanized antibody united with the vascular endothelial growth factor (VEGF) was approved by the FDA for metastatic colon cancer in 2005. The availability of these new agents has resulted in a sustained increase in the use of chemotherapy for CRC patients from 17% in the period of 1980 to 1994 to 50% in 2001. This has been key to the increase of survival, fundamentally in stage III and slightly less in the other CRC stages.

The other important factor that has contributed to an increased survival has been surgical improvements, specifically in the rectal area. Surgery-related mortality has consistently decreased over the years. For example,

a Belgian study showed a decrease in surgical mortality from 20.1% between 1973 and 1979 to 7.8% between 1980 and 1986<sup>[11]</sup>. In our hospital, mortality decreased from 9.1% in 1981 to 8% in 1991<sup>[12]</sup>. In the last decade, the postoperative mortality for CRC varied between 1% and 9.9%<sup>[12-18]</sup>. Emergency surgery for CRC is associated with a high postoperative morbidity and mortality<sup>[14,18,19]</sup>. In rectal cancer, the number of abdomino-perineal resections has decreased from 26.3% in 1981 to 17.2% in 1991<sup>[12]</sup>. Between 1987 and 1992, the mortality in the Istituto di Patologia Speciale Chirurgica of the University of Bologna was 7.6% in anterior resections and 14.2% in abdomino-perineal resections<sup>[20]</sup>. Our study

also observed a significant decrease in the percentage of abdomino-perineal resections, from 30% in 1980 to 18% in 1994. The use of mechanical sutures in rectal cancer operations has allowed a higher rate of sphincter preservation after low anterior resection<sup>[21]</sup>. On the other hand, the number of anterior rectal resections has increased due to the use of mechanical sutures in the middle third of the rectum.

The availability since 1994 of self-expanding stents for obstructive colorectal cancer<sup>[22]</sup> has resulted in a dramatic decrease in the number of urgent palliative surgeries in patients with metastases and a subsequent decrease in the associated postoperative mortality in our study and others<sup>[23]</sup>.

Other factors that we have not analyzed and may also have played a significant role in the increased survival include the use of new antibiotics, improvements in the pre- and post-surgical care of patients, the improved application of radiotherapy and chemotherapy in rectal cancer, the surgical treatment of metastases and the improvement in bowel cleansing. Another limitation of our study is that the Group II cohort was not entirely similar to that of Group I, however, it was a cohort suitable for comparing with Group I (20 years earlier) and showing the differences in different variables such as survival, postoperative mortality or the application of chemotherapy-radiotherapy. In both groups of patients data were collected consecutively and protocols followed strictly.

In conclusion, we observed the survival has increased steadily over the years and is now almost double that 20 years ago. This increase has been in parallel with an increase in the administration of adjuvant chemotherapy and a decline in postoperative mortality.

## COMMENTS

### Background

Colorectal cancer (CRC) is the second leading cause of cancer mortality. In the last two decades major advances have occurred in treatment. Adjuvant chemotherapy has extended its indications and incorporated new drugs. Surgery outcomes have also significantly improved, with less emergency operations, lower postoperative mortality and a decrease in the number of abdomino-perineal resections. There are few studies geared at analyzing these factors and their influence on CRC survival looking at a 20 year time span.

### Research frontiers

Numerous clinical trials have shown that chemotherapy and surgical advances have dramatically improved the prognosis in patients with CRC. Few studies outside the mentioned clinical trials have examined the impact of these advances on clinical outcome over the past two decades.

### Innovations and breakthroughs

This study has quantified the effect of new adjuvant chemotherapy and improved surgical techniques on the prognosis of patients with CRC.

### Applications

These data show that the increased use of chemotherapy for CRC and better surgical techniques are directly linked to improved survival.

### Peer review

This article compares survival differences between two cohorts of patients operated by colorectal cancer from 1980 to 1994 and 2001. It emphasizes the

importance of the highest percentage of patients receiving chemotherapy and better postsurgical mortality in the last group doubled over the last 20 years.

mortality of a docetaxel-based chemotherapy regimen randomly administered before or after gastrectomy in patients suffering from locally-advanced resectable gastric cancer.

**METHODS:** Patients suffering from locally-advanced (T3-4 any N M0 or any T N1-3 M0) gastric carcinoma, staged with endoscopic ultrasound, bone scan, computed tomography, and laparoscopy, were assigned to receive four 21 d/cycles of TCF (docetaxel 75 mg/m<sup>2</sup> day 1, cisplatin 75 mg/m<sup>2</sup> day 1, and fluorouracil 300 mg/m<sup>2</sup> per day for days 1-14), either before (Arm A) or after (Arm B) gastrectomy. Operative morbidity, overall mortality, and severe adverse events were compared by intention-to-treat analysis.

**RESULTS:** From November 1999 to November 2005, 70 patients were treated. After preoperative TCF (Arm A), thirty-two (94%) resections were performed, 85% of which were R0. Pathological response was complete in 4 patients (11.7%), and partial in 18 (55%). No surgical mortality and 28.5% morbidity rate were observed, similar to those of immediate surgery arm ( $P = 0.86$ ). Serious chemotherapy adverse events tended to be more frequent in arm B (23% vs 11%,  $P = 0.07$ ), with a single death per arm.

**CONCLUSION:** Surgery following docetaxel-based chemotherapy was safe and with similar morbidity to immediate surgery in patients with locally-advanced resectable gastric carcinoma.

## INTRODUCTION

In spite of a declining incidence in the Western world, gastric cancer is still a major malignant disease in many populations, and the second leading cause for cancer mortality worldwide<sup>[1]</sup>. While localized disease, limited to the submucosa, can be best treated surgically, with a long-term survival of 70%-95%, the prognosis of locally-advanced tumor is poorer, due to a high unresectability rate at presentation, and a much higher relapse rate after radical surgery<sup>[2]</sup>, thus demanding further studies regarding adjuvant and neoadjuvant treatment. Docetaxel (Taxotere®; Sanofi-Aventis, Paris, France) has been approved for treatment of metastatic gastric cancer, when combined with cisplatin and infused fluorouracil (TCF regimen), showing superiority in survival, time to progression, and response rate (RR) *vs* cisplatin/fluorouracil (CF) in a randomized phase III trial<sup>[3]</sup>. A better RR for docetaxel/cisplatin (TC) *vs* epirubicin/cisplatin/protracted venous infusion fluorouracil (ECF) has been documented in a randomized phase II trial<sup>[4]</sup>. These data suggested investigational use TCF in a preoperative neoadjuvant setting. This analysis aimed to test the hypothesis that preoperative chemotherapy with TCF does not influence negatively the results of subsequent surgery, when compared to immediate surgery. Primary endpoints of this study were operative morbidity and mortality rates; secondary endpoints were surgical and pathological assessments of downstaging and assessment by the surgeon as to whether the surgery was curative or not.

## MATERIALS AND METHODS

### Patient selection and treatment

Patients with histologically-proven locally-advanced resectable gastric carcinoma (T3-4 any N M0 or any T N1-3 M0 as defined in the 1997 TNM classification) were screened for eligibility. Other inclusion criteria were: World Health Organization (WHO) performance status  $\leq 2$ ; age 18-75 years; adequate blood counts (white blood cell count  $\geq 4000/\text{mm}^3$ , platelets  $\geq 100\,000/\text{mm}^3$ ); normal renal (calculated creatinine clearance  $\geq 60$  mL/min) and liver function. Patients suffering from Siewert type I cardia location adenocarcinoma (extended mostly into the lower esophagus) were excluded. All patients underwent chest X-ray, gastric endoscopic ultrasound (EUS), spiral thoraco-abdominal computerized tomography (CT) scan, bone scintigraphy and staging laparoscopy to define

nodal status and rule out distant deposits and/or peritoneal seeding.

The trial was approved in all centers by relevant ethics committees. All patients gave written informed consent for participation in the trial.

Patients were stratified by center, tumor size, tumor location (cardia adenocarcinoma Siewert II and III *vs* tumors of the rest of the stomach) and nodal status (N+ *vs* N-). Patients received four 21-d/cycles of TCF (docetaxel 75 mg/m<sup>2</sup>, 1-h IV infusion, day 1; cisplatin 75 mg/m<sup>2</sup> 4-h IV infusion, day 1; and 5-fluorouracil (5-FU) 300 mg/m<sup>2</sup> per day continuous IV infusion, days 1 to 14), either preoperatively (Arm A) or postoperatively (Arm B). Just before starting chemotherapy all patients underwent placement of a totally implantable central venous port. In Arm A, a re-evaluation was performed after 2 cycles. If local progression had occurred, then the patient immediately underwent surgery. Otherwise two more TCF cycles were administered and surgery was performed within 3-5 wk after day 1 of the last cycle. In Arm B, surgery was scheduled to take place within 1 wk after randomization. Postoperative TCF was to be initiated 3 to 6 wk after surgery.

### Perioperative complications

Data about postoperative course and complications were reported on hospital cards by surgical teams. In addition, an epidemiology nurse was in charge of regularly collecting microbiology data with respect to nosocomial infections (surgical site, pulmonary, urinary, and/or intravascular catheter infections). Data on hospital infections were regularly submitted to the infection central committees on a 3-mo basis.

As conclusive assessments of surgical procedures remain difficult, and there is a lack of consensus on how to define complications and to stratify them by severity, we decided to apply a single classification, proposed by Dindo *et al*<sup>[5]</sup>, which is based on the evaluation of a cohort of 6336 patients and the results of a survey. In this classification, the therapy used to correct a specific complication is the cornerstone in ranking a complication. For example, life-threatening complications requiring an intermediate or intensive care management (IC/ICU) have to be differentiated from complications treated on the ward; as such complications are associated with a high mortality, stress for the patients, and substantial resource consumption. Therefore, registered complications in both groups were analyzed accordingly, with the exception of those classified as grade I (deviation from the normal postoperative course without the need for pharmacological treatment or surgical, endoscopic or radiological interventions). This grade also included wound infections treated at bedside.

### Surgery

A careful intraoperative staging of disease was first performed, in order to rule out peritoneal seeding, ovarian involvement, "drop" metastasis in the pelvis, or periaortic gross adenopathy. Attention was directed to the liver, greater omentum and root of the mesentery below the transverse colon. The stomach was always inspected and gently

**Table 1** Extent of lymphadenectomy D1 vs D2 according to the JRS GC<sup>[5,6]</sup>

	D1	D2

Middle third	1-3-4-5-6	D1+2-7-8 -9 -10 -11
Lower third	3-4-5-6	D1+1-7-8-9

JRS GC: Japanese Research Society for the Study of Gastric Cancer.

palpated to assess the location and the extent of the tumor and to exclude direct invasion of adjacent structures. Frozen sections of every suspect tissue were obtained (e.g. preaortic, infracolic nodes); intraoperative, histology-proven recognition of metastatic spread was considered an exclusion criterion. The extent of gastrectomy depended on the proximal distance of the tumor from the cardia; therefore, total gastrectomy was performed in all patients with cardia locations and in those having antral and body tumors in whom a 6-cm gross proximal margin could not be obtained. Subtotal distal gastrectomy was performed in the others (almost exclusively small-size body or antral locations). Proximal gastric resection was never carried out, as total gastrectomy with 2-3 cm extent to abdominal esophagus was chosen for all cardia locations.

Lymphadenectomy included excision of all N1 and most N2 stations (stations 7, 8, 9 and station 11), according to the classification of the Japanese Research Society for the Study of Gastric Cancer (JRS GC)<sup>[6,7]</sup> (Table 1). Hepatoduodenal ligament nodes (station 12) were also dissected, limiting the lymphadenectomy to the 12a station (left side of the hepatic artery), and leaving undissected the parts b and p of the station (right side of the ligament and just posteriorly to the portal vein, respectively). Lymph nodes of the surgical specimen were routinely dissected by experienced pathologists, using standard techniques; in some cases, depending on the pathologist's judgement, clearing fixatives were used prior to the dissection. Splenectomy was only carried out in cases of direct invasion of the spleen by the tumor, or gross appearance of metastatic nodes at station 10 (splenic hilum). Caudal pancreas was always preserved, according to the Maruyama's technique, even when splenectomy was performed, unless tumor direct involvement was clinically evident.

Surgeons were asked to document the extent of node dissection and to state whether the procedure was likely to be curative as follows: (1) Absolutely curative: absence of hepatic and/or peritoneal metastasis; serosa not involved; no infiltration within 10 mm of the proximal resection line; (2) Relatively curative: as above, but serosa involved, and/or cancer infiltrates within 10 mm of the proximal resection line, and/or nodal involvement (N stage) equals D number; and (3) Non-radical: resection line involvement; any residual disease after resection.

Reconstruction technique (Roux-en-Y, Braun or others) was entirely left to the discretion of the surgeon.

### Pathology

Pathological response to chemotherapy was centrally evaluated and classified as follows: (1) Complete

response (pCR): No residual tumor could be found after *in toto* examination of the potential tumor site. Acellular mucus or acellular necrosis in the gastric wall or in lymph nodes was not considered as residual tumor and therefore was not taken into consideration for staging (neither for T, nor for N); (2) Partial microscopic response: Microscopic residual tumor (persistence of microscopic islands of tumor cells); (3) Partial macroscopic response: Macroscopic residual tumor, but overt necrosis or calcification, or downstaging of the tumor; and (4) No response: Only minor necrosis and no downstaging of the tumor.

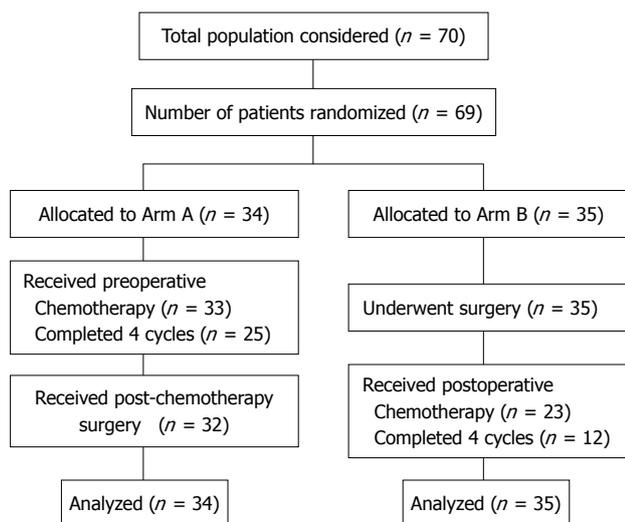

### Statistical analysis

Initially a target sample size at 240 patients was set, assuming a 3-year event-free survival rate of 20% in arm B and 35% in arm A (+ 15%). Trial was prematurely stopped at 70 randomized patients, due to insufficient accrual. Only two centers out of nine showed a good accrual rate, whereas most participating groups were not ready to be involved in such a multi-disciplinary approach. Moreover, some patients refused to participate to this kind of trial because they wanted to be operated on as soon as possible. For this reason, these study results are underpowered to detect any possibly significant differences in the experimental groups. Nevertheless, results were descriptively compared between the two arms on an intention-to-treat basis, using Mann-Whitney *U*-test and Kruskal-Wallis test to compare means and medians, respectively.  $\chi^2$  or Fisher's exact test were used to compare proportions. All tests were two-sided. A *P* value less than 0.05 was assumed significant. Intention-to-treat principle was adopted.

## RESULTS

This trial was activated in November 1999 and closed in November 2005 due to insufficient accrual. From December 1999 to August 2005 a total of 70 patients were enrolled from 9 Institutions in three countries. Eighty-five percent of included patients were from two Institutions; from Milan (IEO-European Institute of Oncology) and Geneva (University Hospitals of Geneva). One patient withdrew consent, did not receive any chemotherapy, and was excluded from the analysis. Of the remaining 69 patients, 34 were randomized to Arm A (TCF followed by surgery) and 35 to Arm B (surgery followed by TCF). One patient in Arm A did not receive any chemotherapy because he died before starting. This patient was included in the analysis, in agreement with the intention-to-treat principle. A trial profile, conforming to the Consolidated Standards of Reporting Trials (CONSORT) is shown in Figure 1. The two groups of patients were similar with respect to various characteristics (Table 2).

Table 3 shows details about surgical procedures performed and pathology reports. Thirty-two patients in Arm A (94%) underwent laparotomy: 29 (85%) had an R0 resection, and two a non-radical resection; one had no resection due to unsuspected peritoneal carcinomatosis. All 35 patients in Arm B underwent laparotomy; 32

(91%) had an R0 resection, two a non-radical resection and one no resection due to peritoneal carcinomatosis. In Arm A, pathological response was complete in 4 patients (11.7%), and partial (macro- or microscopic) in 18 (55%). The respective proportions of total *vs* subtotal gastrectomies, D ≥ 2 *vs* D1 lymph node dissections, median number of excised lymph nodes and of metastatic nodes were very similar in the two arms of the study, and all differences were not statistically significant.

Postoperative mortality and morbidity events are detailed in Table 4; they are stratified by severity, applying the classification proposed by Dindo *et al*<sup>51</sup>. In Arm A these included four septic intraabdominal complications (one anastomotic leak, two abdominal abscesses and one infected fluid peritoneal collection), one gastrojejunum anastomosis bleeding, one pneumonia requiring ICU admission, one pulmonary embolism, one urinary infection, and one fever of unknown origin. Morbidity events in Arm B included three septic intraabdominal complications (one anastomotic leak, one abdominal abscess, and one infected fluid peritoneal collection), and six extra abdominal infections (one infected mediastinal collection, three pneumonias requiring ICU admission,

<sup>a</sup>P = 0.86. ICU: Intensive care unit; MOF: Multiple organ failure.

and two central venous catheter-related blood stream infections). Three re-operations were performed, one in Arm A due to anastomotic hemorrhage, and two in Arm B, due to infected mediastinal collection and pleural empyema complicating severe pneumonia, respectively. Overall, 9 morbidity events occurred in each arm (28.5% in Arm A and 25.7% in Arm B). Two postoperative deaths occurred, in Arm B, as a consequence of multiple organ failure (MOF) complicating mediastinal infected fluid collection, in spite of re-operation. All these differences were not statistically significant (P = 0.86).

A total of 189 TCF cycles were administered; 118 in Arm A and 71 in Arm B (Table 5). In Arm A, 25 patients (74%) received all 4 cycles, two patients 3 cycles, and six patients 2 cycles. In Arm B, only 12 patients received all 4 cycles (34%), five patients 3 cycles, two patients 2 cycles, four patients 1 cycle and 12 patients received no cycle. A 64-year-old female patient who had received one cycle of preoperative TCF died after severe worsening of performance status and dyspnoea. Excluding this case, serious adverse events (SAEs) oc-

occurred more frequently in Arm B. In Arm A, 13 SAEs in 10 patients were observed (13 SAEs out of 118 cycles = 11%), 7 of them infectious (3 febrile neutropenia). In Arm B, 16 SAEs occurred in 14 patients (16 SAEs out of 71 cycles = 23%). All these differences were not statistically significant ( $P = 0.07$  and  $0.15$ , respectively).

A 58-year-old male patient in Arm B died suddenly 38 d after gastrectomy from severe arrhythmia and pulmonary infection. Table 5 details reasons for cessation of therapy in the two arms of the study.

## DISCUSSION

Prognosis of locally-advanced gastric cancer is generally poor in Western surgical and population-based series, with 5-year overall survival rates of 25% or less<sup>[8]</sup>, in spite of complete excision of the gastric and nodal components of the disease<sup>[2]</sup>. This is the consequence of a high relapse rate after radical surgery, and has prompted many studies in the last decade, aimed at improving these results by means of adjuvant and neoadjuvant treatments<sup>[9-12]</sup>. Both these approaches remain controversial and are under current investigation. A large randomized trial [Medical Research Council Adjuvant Gastric Infusional Chemotherapy (MAGIC)]<sup>[13]</sup>, demonstrated a survival benefit with the use of perioperative chemotherapy (i.e. pre- and postoperatively delivered) as compared with surgery alone. Similarly, the FFCO 9703 trial<sup>[14]</sup> showed an improvement in both disease free survival (DFS) and overall survival (OS) with the use of perioperative chemotherapy (FP regimen: 5-FU continuous infusion + cisplatin) as compared to surgery. To date, no trial has so far investigated the effects of the same chemotherapy regimen given either pre- or postoperatively.

Although our study is underpowered to detect any possible significant difference in short-term postoperative outcome, it gives some preliminary answers to questions not yet available in the medical literature that could be interesting for future studies. The first relevant information provided by the present study is the safety of surgery following a preoperative docetaxel-based chemotherapy regimen. In fact, we did not register any mortality and we had a 28.5% morbidity rate, without any significant

difference between pre- and postoperative administration of chemotherapy. Although our patient population was slightly different from that of the MAGIC and FFCO trials, since Type I Siewert adenocarcinomas of the lower third of the esophagus were excluded, results of our study compare favorably with those of the MAGIC trial, where a 45% morbidity rate and 5% mortality rate were observed. In the FFCO trial, postoperative morbidity was 21% in the surgical arm, and 28% in the perioperative chemotherapy arm, whereas surgical mortality was 5% for both groups. A possible favorable factor was that 85% of patients in our series were operated on in two high-volume institutions where D2 gastrectomy is routinely carried out as standard treatment of gastric cancer. Our results support the conclusions that D2 gastrectomy can be considered a safe treatment of gastric cancer in Western patients, at least when performed in experienced centers<sup>[15]</sup>, and that gastric cancer resection should probably be added to the growing list of procedures which are safer when performed in high-volume institutions<sup>[16,17]</sup>. This could explain why reports from single large volume institutions continue to demonstrate low operative mortality after D2 radical gastrectomy, while randomized trials show no survival benefit and severely increased surgical mortality after this procedure<sup>[18,19]</sup>.

In addition, our data indicate that chemotherapy-related SAEs tended to be more frequent in Arm B (adjuvant) than in Arm A (neoadjuvant), suggesting that lower patient tolerance to treatment is a key factor in determining higher toxicity. This could be explained by an increased risk of gastrointestinal toxicity after surgery, when patients are already deeply affected in their eating capacity by the gastrectomy. For instance, it was shown that, in a population of 23 patients followed for dietary intake and nutritional status after total gastrectomy, no patient reached recommended dietary allowances by first monthly follow up<sup>[20]</sup>.

Our trial confirms the difficulties in administering intensive adjuvant chemotherapy in gastric cancer. In the MAGIC trial, 34% of patients who completed preoperative chemotherapy and surgery did not start postoperative chemotherapy, mostly owing to early progression, patient refusal and/or surgical complication. In the weekly-PELF trial<sup>[21]</sup>, only 14% of experimental arm patients completed the scheduled adjuvant treatment without time and/or dose modifications. Even without preoperative chemotherapy, 12 patients in this series did not receive any adjuvant chemotherapy. The most frequent reasons were patient refusal and medical decision. However, even when adjuvant chemotherapy was started, only 34% of the patients received all the four cycles. In the ACT-GC Group Trial (Adjuvant Chemotherapy Trial of TS-1 for Gastric Cancer), evaluating an oral fluoropyrimidine as adjuvant agent, enrollment was stopped after 1 year as a consequence of the higher rate of overall survival in the S-1 treated group than in controls who had only surgery<sup>[22]</sup>. Nevertheless, among the 517 patients who received S-1, 71 refused to continue treatment because of adverse events, and in 72 the

decision of the investigators was to terminate treatment because of adverse events or complications (143/571, 25.04%). The dose of S-1 was reduced in 219 of the 517 treated patients (42.4%).

Laparoscopy has been reported to improve clinical staging when compared to conventional methods, identifying unexpected peritoneal or liver metastases in up to 20% of operable patients<sup>[23,24]</sup>; consequently, a significant proportion of patients can avoid unnecessary laparotomy<sup>[25]</sup>. Although in our study staging laparoscopy has been confirmed as an effective tool to demonstrate peritoneal deposits even when missed by preoperative CT scan, minimal peritoneal deposits were found and biopsied at laparotomy in 3 patients previously judged peritoneal seeding-free at laparoscopy. These false-negative results of laparoscopy occurred within the omentum and/or the lesser sac, emphasizing the limits of staging laparoscopy to demonstrate a minimal peritoneal spread in these difficult locations. Similarly, in a recent report, the sensitivity for detecting peritoneal carcinomatosis was 85% for laparoscopy<sup>[26,27]</sup>. The possible role of the preoperative PET scan in reducing the rate of false negative results of staging laparoscopy is currently under investigation, with conflicting preliminary evidence<sup>[28,29]</sup>; it seems a priori highly improbable that such small-volume disease could be detected by this imaging technique.

Finally, our data confirm the huge difficulties in performing this kind of study, which requires a high level of cooperation between different disciplines. Principal investigators analyzed the reasons for the slow accrual of patients for their neoadjuvant study with FAMTX<sup>[30]</sup> for operable gastric cancer, and observed that around half of the participating centers were not ready for such a multi-disciplinary approach, not believing in the potential efficacy of the neoadjuvant treatment. Moreover, several patients refused to participate in this kind of trial because they wanted to be operated on as soon as possible.

In conclusion, our study does not provide information on efficacy of preoperatively-delivered TCF, due to early discontinuation for slow accrual. It is also underpowered to detect any possible significant differences in short-term postoperative outcome. Nevertheless, data regarding TCF efficacy and feasibility in the preoperative setting and TCF feasibility in the adjuvant setting could be interesting for future studies. In particular, neoadjuvant TCF achieved promising results with a 12% pCR rate. This evidence prompts further studies, since patients achieving a pCR tend to have a much better outcome, as underlined in a recent phase II trial of preoperative chemo-radiation therapy for resectable gastric cancer<sup>[31]</sup>. Surgery was safe after TCF preoperative chemotherapy, while toxicity (especially gastrointestinal) made adjuvant postoperative TCF more difficult to administer fully compared to the neoadjuvant setting. These data are consistent with the results of the recent FFCD trial<sup>[14]</sup>, where postoperative chemotherapy was completed in less than 50% of the patients. This should be carefully considered when an intensive adjuvant chemotherapy regimen is planned.

## ACKNOWLEDGMENTS

We thank Sandra Thierstein, the trial coordinator at the SAKK coordinating center, for accompanying this trial. Special thanks to the following co-investigators for their efforts in accrual of patients and interpretation of data: Dr. Pace U, Dr. Cenciarelli S, Dr. Pozzi S, from the Division of Surgery, European Institute of Oncology (IEO), Milan; Dr. Mura S, Dr. Lorizzo K, Dr. Di Meglio G, Dr. Colleoni M, Lunghi L, from the Department of Medicine, IEO, Milan; Dr. Ravizza D, from the Division of Endoscopy, IEO, Milan; Dr. Scanniffio D, Dr. Boselli S, Data Management Unit, IEO, Milan; Dr. Richter M, from Biel, Switzerland; Dr. Pasetto L, from Busonera Hospital, Padua, Italy; Dr. Dittrich C, Wien, Austria; Dr. Hafner M, Triemli, Switzerland; Dr. Clemens M, Trier, Switzerland.

## COMMENTS

### Background

In spite of a declining incidence in the Western world, gastric cancer is still a major malignant disease in many populations, and the second leading cause for cancer mortality worldwide. While localized disease, limited to the submucosa, can be best treated surgically, with a long-term survival rate of 70%-95%, the prognosis of locally-advanced tumor is poorer, due to a high unresectability rate at presentation, and a much higher relapse rate after radical surgery. Docetaxel (Taxotere®; Sanofi-Aventis, Paris, France) has been approved for treatment of metastatic gastric cancer, when combined with cisplatin and infused fluorouracil (TCF regimen), showing superiority in survival, time to progression, and response rate (RR) vs cisplatin/fluorouracil (CF) in a randomized phase III trial.

### Research frontiers

The above mentioned results obtained in metastatic disease suggested the investigational use of the TCF regimen in a preoperative neoadjuvant setting. The present trial aimed to test the hypothesis that preoperative chemotherapy with TCF does not influence negatively the results of subsequent surgery, when compared to immediate surgery.

### Innovations and breakthroughs

This trial proved that surgery is safe after TCF preoperative chemotherapy, while toxicity (especially gastrointestinal) makes adjuvant postoperative TCF more difficult to administer fully compared to the neoadjuvant setting. Moreover, neoadjuvant TCF achieved promising results with a 12% pCR (pathological complete response) rate.

### Applications

Obtained data regarding TCF efficacy and feasibility in the preoperative setting and TCF feasibility in the adjuvant setting could be interesting for future studies. In fact, patients achieving a pCR tend to have a much better oncology outcome. Finally, data here presented are consistent with the results of the recent FFCD trial, where postoperative chemotherapy was completed in less than 50% of the patients. This should be carefully considered when an intensive adjuvant chemotherapy regimen is planned.

### Peer review

This is an interesting report of the efficacy of neoadjuvant chemotherapy for advanced gastric cancer.

### Abstract

**AIM:** To suggest a new cleansing score system for small bowel preparation and to evaluate its clinical efficacy.

**METHODS:** Twenty capsule endoscopy cases were reviewed and small bowel preparation was assessed with the new scoring system. For the assessment, two visual parameters were used: proportion of visualized mucosa and degree of obscuration. Representative frames from small bowel images were serially selected and scored at 5-min intervals. Intraclass correlation coefficient (ICC) was obtained to assess the reliability of the new scoring system. For efficacy evaluation and validation, scores of our new scoring system were compared with another previously reported cleansing grading system.

**RESULTS:** Concordance with the previous system, inter-observer agreement, and intra-patient agree-

ment were excellent with ICC values of 0.82, 0.80, and 0.76, respectively. The intra-observer agreements at four-week intervals were also excellent. The cut-off value of adequate image quality was found to be 2.25.

**CONCLUSION:** Our new scoring system is simple, efficient, and can be considered to be applicable in clinical practice and research.

### INTRODUCTION

Capsule endoscopy (CE) was introduced as a method for investigating the full length of the small intestine<sup>[1-3]</sup>. However, there are limitations such as impaired visualization by air bubbles, food residue, bile, and blood clots. Unfortunately, current CE does not have functions which allow suctioning of fluid or washing the small bowel mucosa during the examination. Therefore, since some of the lesions can be overlooked and missed, adequate bowel cleansing is mandatory for a successful CE<sup>[4]</sup>. There have been many studies on the necessity and methods of bowel preparation for CE<sup>[1,5-8]</sup>. Howev-

er, the benefits of bowel preparation prior to CE remain controversial and it is unclear which method is best.

One of the reasons for this controversy is that the current grading systems have not been standardized and therefore, a generally accepted grading system is not available. The presence of numerous grading systems has caused difficulties in comparing the results of studies on small bowel preparation prior to CE<sup>[4,9]</sup>. In addition, most of the previously reported grading systems are time-consuming, complicated, and difficult to apply in the clinical setting. The aim of this study is to suggest a new cleansing score system for small bowel preparation and to evaluate its clinical efficacy.

## MATERIALS AND METHODS

Twenty CE cases were reviewed according to the protocol by three examiners who had experience in interpreting more than 50 cases of CE. These examiners separately assessed small bowel cleanliness by using the grading system described below. The software program Rapid Reader 4 (Given Imaging Ltd, Yoqneam, Israel) was used to review and score the images.

### Scoring system

Two visual parameters were used in our scoring system. The first parameter was the proportion of visualized mucosa. This was scored using a 4-step scale ranging from 0 to 3: score 3, greater than 75%; score 2, 50% to 75%; score 1, 25% to 50%; score 0, less than 25% (Table 1, Figure 1). The second parameter was the degree of obscuration by bubbles, debris, and bile *etc.* This was also scored using a 4-step scale ranging from 0 to 3: score 3, less than 5%, no obscuration; score 2, mild (5% to 25%) obscuration; score 1, moderate (25% to 50%) obscuration; score 0, severe (greater than 50%) obscuration (Table 1, Figure 1). Images from the entire small bowel were serially selected at 5-min intervals (1 frame/5 min) by manual mode using the RAPID system. If the capsule got stuck or remained in the same place for more than 5 min, the frames were scored only once and not repeatedly.

Mean scores of each parameter were obtained by summing the scores of all selected images and dividing them by the number of examined frames. The representative values for each parameter were then calculated by the overall average of two mean scores.

### Efficacy evaluation

First, 20 CE cases were reviewed and frames were selected twice: once according to our scoring system and once according to one of the previously reported systems which evaluated CE images for 2 min in every 5-min period (e.g. 240 frames/5 min or 40% of the small bowel images)<sup>[6]</sup>. The images from selected frames were then graded using the aforementioned parameters. The concordance of scores between the two grading systems was analyzed.

Second, the reliability of our grading system was

Table 1 CE image scoring system

The proportion of visualized mucosa	
Score 3	≥ 75%
Score 2	50%-75%
Score 1	25%-50%
Score 0	< 25%
The degree of bubbles, debris and bile	
Score 3	< 5%, no obscuration
Score 2	5%-25%, mild obscuration
Score 1	25%-50%, moderate obscuration
Score 0	≥ 50%, severe obscuration

CE: Capsule endoscopy.

evaluated by assessing the inter-observer, intra-patient, and intra-observer agreement. For the assessment on inter-observer agreement, three examiners each scored the same selected frames separately at 5-min intervals which were then compared. For the evaluation of intra-patient agreement, each examiner reviewed the same case after choosing their own starting frame within the first 5 min of the capsule's entrance into the duodenum, from where the ensuing frames were picked up at 5-min intervals and scored accordingly. For the analysis on intra-observer agreement, the same frames from the same cases were scored once again after four weeks and scores were compared with the previous results.

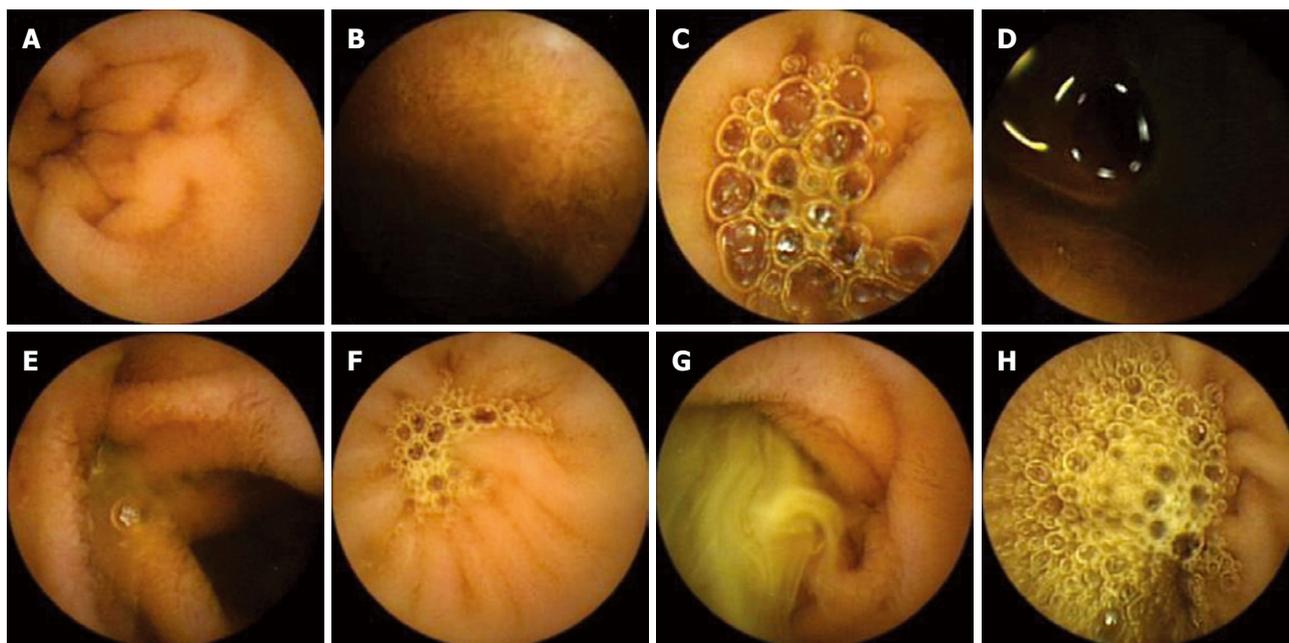

Third, in order to determine the cut-off value for adequate cleansing, our scoring system was compared with another grading system, which examined all of the images obtained from the entire small bowel. This grading system defined small bowel mucosa as "clean" if less than 25% of the mucosal surface was covered by intestinal contents or food debris, and cleanliness was graded as "adequate" if the time the mucosa appeared clean was greater than 90% of the total examination time<sup>[5]</sup>. Overall adequacy was compared with that of our scoring system and the results were analyzed using the receiver operating characteristic (ROC) curve.

### Statistical analysis

Concordance was determined by using the intraclass correlation coefficient (ICC). An ICC value less than 0.40 was considered poor, between 0.40 and 0.75 was considered fair to good, and greater than 0.75 was considered excellent<sup>[6,10,11]</sup>. The cut-off value of the cleansing scores according to our scoring system, with optimal sensitivity and specificity, was determined using the ROC curve. Area under the curve (AUC) was used for assessing the overall accuracy of our scoring system which employed the ROC curve. All statistical analyses were performed with SPSS version 12.0 (SPSS Inc, Chicago, IL, USA).

## RESULTS

Twenty cases were selected from previously diagnosed patients. Mean age of the subjects was 48.5 (21-80) years and 80% (18/20) were male. Their indications for CE

**Figure 1** Images of scores according to the proportion of the visualized mucosa (A-D) and the degree of obscuration (E-H). A: Score 3; B: Score 2; C: Score 1; D: Score 0; E: Score 3; F: Score 2; G: Score 1; H: Score 0.

**Table 2** Agreement between our scoring system A and previous scoring system B

Parameter	System	Score (median and IQR)	Inter-system ICC (95% CI)
Visualized mucosa	A	2.44 (2.20-2.62)	0.72 (0.27, 0.89)
	B	2.24 (2.11-2.48)	
Degree of obscuration	A	2.13 (1.92-2.35)	0.86 (0.53, 0.95)
	B	1.98 (1.87-2.22)	
Overall average	A	2.30 (2.09-2.50)	0.82 (0.33, 0.94)
	B	2.12 (1.97-2.36)	

A: 1 frame per 5 min; B: 2 min per 5 min. IQR: Interquartile range; ICC: Intraclass correlation coefficient.

**Table 3** Inter-observer agreement of our scoring system among three examiners

Parameter	Observer	Score (median and IQR)	Inter-observer ICC (95% CI)
Visualized mucosa	A	2.61 (2.40-2.81)	0.88 (0.47, 0.99)
	B	2.62 (2.42-2.82)	
	C	2.44 (2.20-2.62)	
Degree of obscuration	A	2.34 (2.17-2.55)	0.71 (0.39, 0.87)
	B	2.28 (2.12-2.56)	
	C	2.13 (1.92-2.35)	
Overall average	A	2.47 (2.32-2.63)	0.80 (0.35, 0.93)
	B	2.47 (2.26-2.62)	
	C	2.30 (2.09-2.50)	

were gastrointestinal bleeding (12/20, 60%), iron deficiency anemia (4/20, 20%), abdominal pain (3/20, 15%), and diarrhea (1/20, 5%). Cases were prepared with 4 L of polyethylene glycol (PEG) four hours before examination without prokinetic agent or simethicone. The concordance between our cleansing score system and a previously reported system, which selected the frames and evaluated them for 2 min in every 5-min period, was excellent with an ICC value of 0.82 [95% confidence interval (CI), 0.33-0.94, Table 2).

As for the assessment on reliability, inter-observer and intra-patient agreement were excellent with ICC values of 0.80 (95% CI: 0.35-0.93, Table 3) and 0.76 (95% CI: 0.41-0.93, Table 4), respectively. The data regarding the assessment on intra-observer agreement was available from three examiners and the results were also excellent with ICC values of 0.80, 0.82, and 0.92, respectively (Figure 2).

To assess the overall adequacy of small bowel cleansing, the ROC curve was generated to determine the cut-

off value of image quality. The cut-off value, estimated by the ROC curve at an optimal level of sensitivity and specificity, was 2.25 with 85% sensitivity and 87% specificity. The AUC of the scoring system was 0.925 (95% CI: 0.859-0.990, Figure 3).

## DISCUSSION

CE has provided a new perspective for diagnosing, treating, and monitoring small bowel diseases, such as obscure GI bleeding, Crohn's disease, celiac sprue, polyposis syndromes, and small-bowel tumors.

However, CE has several limitations, one of which is image quality. Although 12 h-fasting or PEG ingestion is used for small bowel preparation in CE, air bubbles, intestinal secretions, bile or food residue occasionally cover the small bowel mucosa and obscure the view. The capsule endoscope is not equipped with functions to allow suctioning, inflating, and washing the lumen of the small intestine. Therefore, some parts of the lumen will not be

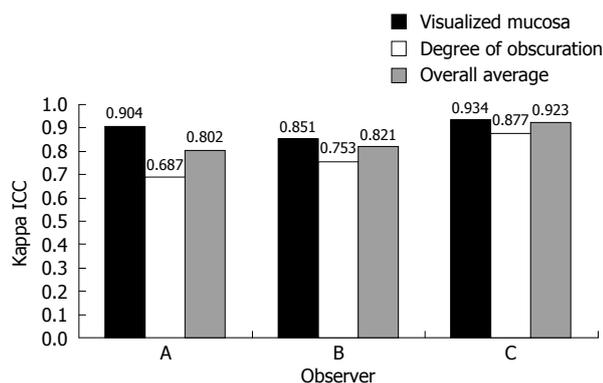

Figure 2 Intra-observer agreements between the scores at 4-wk intervals for two parameters and the overall average.

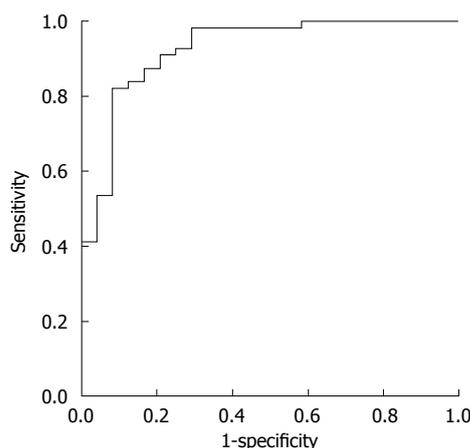

Figure 3 The area under the curve (AUC) was 0.925 (95% confidence interval, 0.859-0.990) in receiver operating characteristic (ROC) curve of image quality scores for grading small bowel cleansing.

Table 4 Intra-patient agreement of our scoring system among different starting frames

Parameter	Frame	Score (median and IQR)	Intra-patient ICC (95% CI)
Visualized mucosa	A	2.33 (1.93-2.59)	0.95 (0.81, 0.98)
	B	2.39 (1.88-2.66)	
	C	2.31 (1.90-2.44)	
Degree of obscuration	A	2.13 (1.97-2.61)	0.72 (0.39, 0.87)
	B	2.01 (1.52-2.34)	
	C	2.01 (1.57-2.20)	
Overall average	A	2.28 (2.08-2.61)	0.76 (0.41, 0.93)
	B	2.45 (1.70-2.50)	
	C	2.16 (2.09-2.50)	

visualized and examiners are unable to observe the entire small bowel mucosa thoroughly. This means that small bowel preparation plays an important role because it can improve image quality by cleansing the small bowel. There have been many studies on the preparation for CE, however, there is no standardized procedure for small bowel preparation for CE. In addition, preparation type, doses, and time of administration differ among centers.

To assess the effect of bowel preparation on the cleansing of the small bowel mucosa objectively, scoring systems for grading small bowel cleanliness have been introduced<sup>[1,5,6,12-14]</sup>. Prior studies on preparation, formulated and used their own scoring systems to grade small bowel cleanliness, thus making it difficult to compare the effect of preparation among studies<sup>[4,9]</sup>. For example, the grading system by Viazis *et al*<sup>[5]</sup> simply graded the small bowel cleanliness as “adequate” or “inadequate” and the time, during which the small bowel mucosa appeared unclean, was recorded using a timer; the concordance among the investigators was excellent (92.5%). However, thousands of frames per case had to be reviewed with this system. Therefore, grading the cleanliness is time-consuming and laborious. In the studies by Niv *et al*<sup>[1,7]</sup> the capsule images were graded according to the proportion of the small bowel transit time during which the intraluminal fluid interfered with visualization and interpretation. Although concordance on the quality of bowel preparation was excellent (kappa statistic = 0.91,  $P < 0.001$ ), this grading sys-

tem, in which the entire small bowel could be examined, is also time-consuming.

The study by Dai *et al*<sup>[13]</sup> assessed the visibility of the small bowel as a percentage of the visualized intestinal wall during 10-min video segments at 1-h intervals. In the study by Shiotani *et al*<sup>[6]</sup> individual frames were examined for 2 min of every 5-min period and scored using four visual parameters: circumference, bubbles, debris, and lightning. In recent studies, five video segments (each 5 or 10 min long) were selected from all the videos<sup>[15-17]</sup>. However, no standard guidelines for grading small bowel cleanliness are currently available. Most of the reported grading systems are time-consuming, complicated, and difficult to apply clinically. In addition, the reliability and efficacy of these grading systems have rarely been evaluated. Therefore, we designed a novel, simple, and time-sparing grading system of small bowel preparation for CE. In our scoring system, one frame was selected every 5 min (1 frame/5 min) to reduce the duration of grading small bowel cleansing. As a result, the duration of grading was greatly shortened compared with prior systems, which evaluated the entire small bowel mucosa. Our scoring system was compared with a previous method, which analyzed the frames for 2 min of every 5-min period; this method is a grading system that has recently been reported, but is time-consuming in that a substantial number of frames have to be analyzed. The concordance between this grading system and our scoring system was excellent.

Validity and reliability are two minimum qualities required for a grading system. Without reliability, even a valid scale can differ among study groups<sup>[18]</sup>. In a recent study, the quantitative index (QI) was better than the qualitative evaluation (QE) for intra-observer and inter-observer reliability<sup>[19]</sup>. To make the scoring system more reliable, we selected two parameters: the proportion of visualized mucosa and the degree of obscuration by bubbles, debris, bile, *etc.* For each parameter, small bowel cleanliness can be graded objectively by scoring the im-

ages according to the percent of the area. As a result, although the agreement on the degree of obscuration tended to be lower than that of the visualized mucosa in some cases, inter-observer, intra-patient, and intra-observer agreements were excellent. If the examiners in our study had received a calibration exercise before grading cleanliness, the concordance may have been better.

To determine whether our grading system was reasonable for assessing the adequacy of small bowel preparation, we compared our system with the grading system by Viazis *et al.*<sup>51</sup>, and the AUC of the ROC curve was 0.925. This means that our grading system had good discriminative power. From the ROC curve, we found that the cut-off value of image quality score on adequate bowel cleansing was 2.25, which was considered to have optimal sensitivity and specificity. Therefore, this value may be used as a criterion for determining the overall adequacy of small bowel preparation for CE.

In conclusion, our novel scoring system for CE was simple, objective, and efficient. It showed excellent inter-observer, intra-patient, and intra-observer agreement. In addition, a cut-off value for the adequacy of small bowel preparation was also proposed. Therefore, our scoring system may be useful in clinical practice and in studies determining the optimal small bowel cleansing method.

## COMMENTS

### Background

For successful capsule endoscopy (CE), adequate bowel cleansing is mandatory. However, the benefits of bowel preparation prior to CE remain controversial and it is unclear which method is best. One of the reasons for this controversy is that the current grading systems have not been standardized and a generally accepted grading system is not available.

### Research frontiers

Most of the reported grading systems are time-consuming, complicated, and difficult to apply clinically. In addition, the reliability and efficacy of these grading systems have rarely been evaluated. Therefore, the authors designed a novel, simple, and time-sparing grading system of small bowel preparation for CE. For assessment, two visual parameters were used: the proportion of visualized mucosa and degree of obscuration. Representative frames from small bowel images were serially selected and scored at 5-min intervals. Intraclass correlation coefficient (ICC) was obtained to assess the reliability of the new scoring system. For efficacy evaluation and validation, scores of this new scoring system were compared with those of another previously reported cleansing grading system. Concordance with the previous system, inter-observer agreement, and intra-patient agreement were excellent with ICC values of 0.82, 0.80, and 0.76, respectively. The intra-observer agreements at four-week intervals were also excellent. The cut-off value for adequate image quality was shown to be 2.25.

### Innovations and breakthroughs

In this scoring system, one frame was selected every 5 min (1 frame/5 min) to reduce the duration of grading small bowel cleansing. As a result, the duration of grading was greatly shortened compared with prior systems, which evaluated the entire small bowel mucosa. From the receiver operating characteristic (ROC) curve, the found that the cut-off value of image quality score on adequate bowel cleansing was 2.25, which was considered to have optimal sensitivity and specificity. Therefore, this value may be used as a criterion to determine the overall adequacy of small bowel preparation for capsule endoscopy.

### Applications

The new scoring system is simple, efficient, and may be useful in clinical practice and in studies to determine the optimal small bowel cleansing method.

## Terminology

ICC: A descriptive statistic that can be used when quantitative measurements are made on units that are organized into groups. It describes how strongly units in the same group resemble each other. Its major application is in the assessment of consistency or reproducibility of quantitative measurements made by different observers measuring the same quantity.

## Peer review

In this manuscript, authors have reported a novel cleansing score system for capsule endoscopy. This new scoring system is simple, and efficient. Furthermore, it showed good inter-observer, intra-patient, and intra-observer agreement.

### Abstract

**AIM:** To investigate the prevalence, risk factors, and clinicopathologic characteristics of intrahepatic cholangiocarcinoma (ICC) in young patients.

**METHODS:** A retrospective analysis was performed in ICC patients referred to the Eastern Hepatobiliary Surgery Hospital in Shanghai, China. Among 317 consecutively enrolled patients, 40 patients were aged  $\leq 40$  years (12.61%). We compared the risk factors and clinicopathologic characteristics of these patients (group I :  $n = 40$ ) with those aged  $> 40$  years (group II :  $n = 277$ ).

**RESULTS:** Group I had distinct features compared with group II, including a low frequency of hepatolithiasis ( $P = 0.000$ ); a high positive rate of serum hepatitis B surface antigen ( $P = 0.000$ ) and hepatitis B virus (HBV)-associated cirrhosis ( $P = 0.038$ ); a high frequency of  $\alpha$ -fetoprotein ( $> 400 \mu\text{g/L}$ ) ( $P = 0.011$ ); a low frequency of carbohydrate antigen 19-9 ( $> 37 \text{ U/mL}$ ) ( $P = 0.017$ ); and a high frequency of liver histological inflammation ( $P = 0.002$ ). Although there was no significant difference between the two groups in regards

to hepatic schistosomiasis, alcohol-associated cirrhosis and cirrhosis due to other causes ( $P > 0.05$ ), they only occurred in the elderly group.

**CONCLUSION:** The risk factors are significantly different between young and elderly ICC patients. HBV and HBV-associated cirrhosis are the most important risk factors for young ICC patients.

Etiological and clinicopathologic characteristics of intrahepatic cholangiocarcinoma in young patients. *World J Gastroenterol* 2010; 16(7): 881-885 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i7/881.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i7.881>

### INTRODUCTION

Intrahepatic cholangiocarcinoma (ICC) is a fatal cancer of the biliary epithelium, arising within the intrahepatic bile ducts. Globally, ICC is the most common primary hepatic malignancy after hepatocellular carcinoma (HCC). The incidence rates of ICC vary greatly among different areas of the world; this variation is related to the distribution of risk factors. Viral infection [hepatitis B virus (HBV) or hepatitis C virus (HCV)]<sup>[1]</sup>, primary sclerosing cholangitis (PSC)<sup>[2]</sup>, liver fluke infestation (particularly the endemic *Opisthorchis viverrini*)<sup>[3,4]</sup>, and hepatolithiasis are known as the risk factors for ICC<sup>[5,6]</sup>. ICC, similar to HCC, affects

predominantly those individuals aged > 40 years<sup>[7]</sup>; however, younger patients have recently been diagnosed with ICC. The risk factors and clinicopathologic features of young ICC patients have not yet been studied.

The aim of the present study was to investigate the prevalence, risk factors, and the clinicopathologic characteristics of ICC in young patients, and to compare these findings with the characteristics and risk factors associated with elderly patients with ICC.

## MATERIALS AND METHODS

We performed a retrospective analysis using medical records of the patients initially diagnosed with ICC in the Eastern Hepatobiliary Surgery Hospital of the Second Military Medical University, Shanghai, China from January 2003 to December 2006. The diagnosis of ICC was confirmed pathologically. We evaluated the age and sex distribution of the patients, and compared the risk factors and clinicopathologic characteristics of patients aged ≤ 40 years (group I) with those of patients aged > 40 years (group II).

To clarify a difference in the risk factors between the two groups, we analyzed HBV or HCV infection, liver cirrhosis, hepatolithiasis, and hepatic schistosomiasis (our previous study verified that these are the main risk factors for ICC patients from China). The presence of a seropositive HBsAg and/or anti-HCV (Abbott Laboratories, North Chicago, IL, USA) and HCV RNA (real time PCR; Abbott, IL, USA) was interpreted as an indication of chronic hepatitis infection. The diagnosis of ICC was confirmed by pathology. Liver function and serum tumor marker (carbohydrate antigen 19-9 and α-fetoprotein) concentrations were evaluated in all the patients.

To determine the pathological characteristics, the diameter of the largest tumor was measured directly in the surgical specimens from patients who had undergone hepatic resection. The WHO tumor classification was used for pathological grading of the tumor (well, moderate or poor differentiation). When histological diversity was observed in a tumor, the higher grade, according to the classification system, was taken as the overall grade. The tumor mass was estimated by computed tomography (CT), and enlarged lymph nodes were defined as lymph nodes 0.1 cm in diameter at the portal, celiac, retrocrural or retroperitoneal lymph node stations. Ultrasound, CT scan, or surgery was used to diagnose portal vein thrombosis.

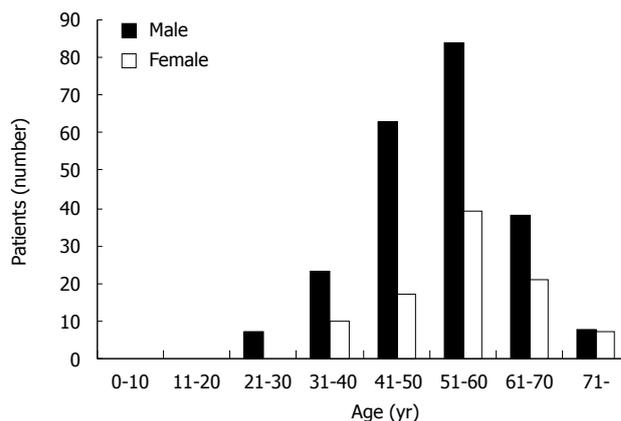

### Statistical analysis

Statistical analysis was performed using the  $\chi^2$  test to compare discrete variables, and analysis of variance (ANOVA) was made to compare continuous variables. SPSS for Windows (version 16.0) was used.  $P < 0.05$  was considered as significant difference.

## RESULTS

### Age and sex distribution

A total of 317 patients (223 men and 94 women, a male

**Figure 1** Age and sex distribution of intrahepatic cellular carcinoma (ICC) between 2003 and 2006 at the Eastern Hepatobiliary Surgery Hospital in Shanghai, China.

**Table 1** Risk factors for intrahepatic cholangiocarcinoma n (%)

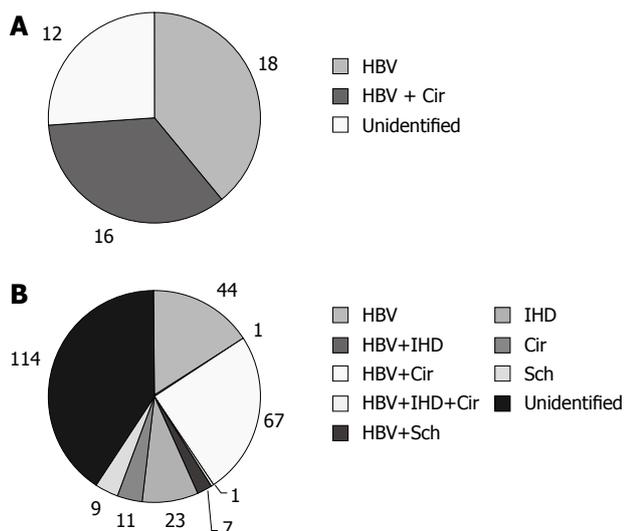

Risk factors	Group I (n = 40)	Group II (n = 277)	P value
HBV infection	34 (85.0)	120 (43.3)	0.000
HCV infection	0 (0.0)	1 (0.4)	0.703
Liver cirrhosis			0.038
Related to HBV	16 (40.0)	68 (24.5)	0.347
Related to alcohol	0 (0.0)	6 (2.2)	0.392
Other causes	0 (0.0)	5 (1.8)	
Total	16 (40.0)	79 (28.52)	
Hepatolithiasis	0 (0.0)	25 (9.0)	0.000
Liver schistosomiasis	0 (0.0)	16 (5.8)	0.119

HBV: Hepatitis B virus; HCV: Hepatitis C virus.

to female ratio, 2.37:1) initially diagnosed with ICC were enrolled in the present study. The mean age was  $53.05 \pm 10.53$  years (range 21-78). Most of ICC developed during the 4th-7th decades, with a peak at 54 years of age. Forty (12.61%) patients were aged ≤ 40 years, including 30 men and 10 women (Figure 1).

### Risk factor distribution

The risk factors for ICC are listed in Table 1. Of the 40 young ICC patients, 34 (85.0%) were seropositive for HBsAg, 16 (40.0%) had liver cirrhosis related to HBV, and none had intrahepatic-duct stones (IHD stones), liver schistosomiasis, or HCV (Figure 2A). In group II, 120 (43.3%) patients were seropositive for HBsAg, 1 (0.4%) was seropositive for anti-HCV and HCV RNA, 79 (28.5%) had liver cirrhosis, including 68 (24.5%) whose cirrhosis was related to HBV, 6 (2.2%) with liver cirrhosis related to alcohol, 5 (1.8%) with liver cirrhosis due to other causes (1 with liver cirrhosis related to HCV, 1 with nonalcoholic liver cirrhosis, and 3 with occult liver cirrhosis), 25 (9.0%) had IHD stones, and 16 (5.8%) had liver schistosomiasis (Figure 2B). It is worth mentioning that the HCV that is prevalent in Japan and some Western countries has been found to be the significant cause of ICC. In our series, only one case of ICC had HCV.

**Figure 2** Distribution of potential risk factors for ICC among young ICC patients (A) and elderly ICC patients (B). HBV = Seropositivity for HBsAg; Cir = Liver cirrhosis; IHD = Intrahepatic duct stone (Hepatolithiasis); Sch = Liver schistosomiasis.

**Clinical features**

For further comparison between the two groups, the following clinical variables were investigated: gender, total bilirubin (TBIL) (> 20 μmol/L *vs* ≤ 20 μmol/L), albumin, alanine aminotransferase (ALT) (> 42 U/L *vs* ≤ 42 U/L), aspartate aminotransferase (AST) (> 37 U/L *vs* ≤ 37 U/L), r-glutamyl-transferase (r-GT) (> 64 U/L *vs* ≤ 64 U/L), alkaline phosphatase (ALP) (> 119 U/L *vs* ≤ 119 U/L), α-fetoprotein (AFP) (> 400 μg/L *vs* ≤ 400 μg/L), and carbohydrate antigen 19-9 (CA19-9, > 37 ng/mL *vs* ≤ 37 ng/mL). AFP (> 400 μg/L) and CA19-9 (> 37 U/mL) were significantly different between group I and group II by univariate analysis (Table 2).

**Pathological characteristics**

Table 3 reveals the pathological characteristics in the two groups. There was significantly more histological inflammation (present *vs* no hepatitis) in the younger patient group (*P* = 0.002). No difference was detected between the two groups with regard to the tumor number (< 2 *vs* ≥ 2), location (right lobe, left lobe, or both lobes), tumor size (main tumor or the largest one), capsule (present *vs* absent), tumor differentiation (well, moderate or poor), portal vein invasion (invasion *vs* no invasion), microscopic satellite lesion (tiny nodule present around the main tumor *vs* no satellite), and immunohistochemical examination (cytokeratin 18 and cytokeratin 19).

**DISCUSSION**

Although several risk factors have been associated with ICC, such as viral infection (HBV and/or HCV), liver cirrhosis, IHD stones, and liver parasite infestation, the distribution characteristics of these risk factors in young and elderly ICC patients and the mechanism responsible for ICC remain unknown. Here, we not only demonstrated different etiological characteristics

**Table 2** Comparison of clinical features of ICC between the two groups *n* (%)

	Group I ( <i>n</i> = 40)	Group II ( <i>n</i> = 277)	<i>P</i> value
Gender (M/F)	30/10	193/84	0.491
ALT (> 42 U/L)	15 (60.00)	89 (32.13)	0.499

Ck: Cytokeratin.

of ICC between young and elderly patients, but also the clinicopathologic features of young patients.

Our study focused on patients with ICC who were ≤ 40 years of age, and the “young patients” were defined as those ≤ 40 years of age at diagnosis. We chose the cut-off age of 40 years based on the recommended age for starting regular HCC screening for men in Asia<sup>[8]</sup> and according to Lam *et al*<sup>[9]</sup>. The age distribution of patients with ICC in China is described by a triangular-shaped curve (Figure 1). Only 12.61% of patients were ≤ 40 years of age.

HBV or HCV infection was strongly associated

with ICC risk. Korean investigators performed a case-control study comparing 41 cases of ICC with 406 controls without cancer and found that 13.8% of cases and 3.5% of controls were anti-HCV positive and 12.5% of cases and 2.3% of controls were HBsAg positive<sup>[10]</sup>. In a Japanese hospital-based study, investigators found that 36% of 50 patients with ICC but only 3% of 205 controls (surgical patients who did not have primary liver cancer) were HCV seropositive [OR (odds ratio) = 16.87; 95% CI (confidence interval): 5.69-50.00]<sup>[11]</sup>. Through a population based cohort study including 146 394 HCV-infected and 572 293 HCV-uninfected patients, El-Serag *et al.*<sup>[12]</sup> showed a strong association of ICC with HCV infection (hazard ratio = 2.55, 95% CI: 1.31-4.95), but the association was not observed in extrahepatic cholangiocarcinoma. Our previous study also found that the incidence of HBV infection in ICC patients was significantly higher than that in non-cancer individuals (48.6% *vs* 6.6%), indicating that chronic HBV infection was independently the most important risk factor for ICC in Chinese population (OR = 9.669, 95% CI: 6.329-14.770). Our findings were consistent with that reported by Zhou *et al.*<sup>[13]</sup> recently. In our study, 85.0% of young ICC patients had chronic HBV infection, which is significantly higher than that of elderly ICC patients (43.3%). It is interesting to note that HBV infection was also the only risk factor identified in young ICC patients. It is worth mentioning that the HCV that is prevalent in Japan and some Western countries has been proven to be the significant cause of ICC. In our series, only one case of ICC had HCV.

Cirrhosis, of any cause, has also been associated with intrahepatic cholangiocarcinoma<sup>[5]</sup>. A cohort study of over 11 000 patients with cirrhosis, followed up over 6 years, showed a 10-fold risk compared with the general population<sup>[14]</sup>. A prospective controlled study from Japan reported the risk of developing cholangiocarcinoma in patients with cirrhosis related to HCV as 3.5% at 10 years, 1000 times higher than in the general population<sup>[15]</sup>. The data obtained from our previous study also showed that cirrhosis, particularly HBV-associated cirrhosis, was an important risk factor for ICC in Chinese population. In the present study, the etiological distribution of cirrhosis was significantly different between young ICC patients and elderly ICC patients. HBV-associated cirrhosis had a higher incidence in young ICC patients than in the elderly group, while alcoholic cirrhosis and cirrhosis due to other causes only occurred in elderly ICC patients.

Hepatolithiasis is rare in Western countries, but relatively common in some parts of Asia, and is associated particularly with peripheral intrahepatic cholangiocarcinoma<sup>[4]</sup>. In Taiwan, up to 70% of patients with intrahepatic cholangiocarcinoma undergoing resection reportedly have intrahepatic biliary stones, and in Japan this figure is 6%-18%<sup>[16]</sup>. Biliary stones are thought to cause bile stasis, predisposing to recurrent bacterial infections and subsequent inflammation, a potential cofactor for cholangiocarcinogenesis. In our cohort,

hepatolithiasis only occurred in elderly ICC patients. The result indicates hepatolithiasis may be not a risk factor of ICC development for young patients.

A large body of experimental and epidemiological data suggests a pathogenic association between liver parasite infection, especially *Opisthorchis viverrini* (and less definitively *Clonorchis sinensis*) and intrahepatic cholangiocarcinoma<sup>[1]</sup>. Our previous study showed that hepatic schistosomiasis had a higher incidence in ICC patients than in no-cancer individuals. The data suggests that hepatic schistosomiasis was a risk factor for ICC development (OR = 11.06, 95% CI: 3.368-36.337). Although there was no significant difference between the young ICC patients and elderly ICC patients in regards to hepatic schistosomiasis ( $P > 0.05$ ), similar to alcohol-cirrhosis and cirrhosis due to other causes, hepatic schistosomiasis also only occurred in the elderly group.

$\alpha$ -fetoprotein (AFP), a 70-kDa glycoprotein, is normally produced during fetal development by the liver and yolk sac. The protein levels drop off rapidly after birth, and by the second year of life only trace amounts are detectable in the serum. AFP is increased in the majority of patients with HCC and is useful in the diagnosis and follow-up of cases. Studies suggest that, in patients with suspected HCC clinically, AFP levels  $> 400$  ng/mL should strongly confirm the presence of HCC *via* a tissue diagnosis<sup>[17,18]</sup>. Some cancers may originate from cancer stem cells, which may form *via* the carcinogenesis of normal stem cells<sup>[19-21]</sup>. It has been suggested that hepatocytes and cholangiocytes arise from the same pool of hepatic precursor cells, also called oval cells. Carcinogenesis of such hepatic precursor cells may cause ICC<sup>[22]</sup>. Hepatic progenitor cells were also shown to strongly express AFP mRNA and produce AFP during differentiation<sup>[23]</sup>. Compared with the elderly ICC patients, young ICC patients exhibited a higher incidence of AFP  $> 400$   $\mu$ g/L (17.50% *vs* 6.14%). Our data indicated that the neoplastic transformation of oval cells may be one of the mechanisms for ICC development and that the oval cell precursor retains its ability to produce AFP in the process of malignant transformation.

In a recent prospective study, serum CA19-9 was found to be useful in diagnosing cholangiocarcinoma, in deciding whether the tumor had been radically resected and in monitoring the effect of treatment. Serum CA19-9 concentrations were significantly elevated in patients with cholangiocarcinoma compared with patients with HCC, benign biliary disease or healthy individuals. After curative resection, serum CA19-9 decreased to a preoperative level<sup>[24]</sup>. In the present study, young ICC patients exhibited a lower serum CA19-9 level, similar to HCC.

In conclusion, the risk factors for ICC are different between young and elderly patients. HBV infection and HBV-associated cirrhosis may be the main risk factors for young ICC patients. Young ICC patients share etiological and many clinicopathologic similarities with HCC patients. These results indicated that ICC in young patients and HCC have a common process of

carcinogenesis (through a similar long-term inflammatory carcinogenic process) and that both may arise from hepatic progenitor cells.

## COMMENTS

### Background

Although several risk factors have been associated with the development of Intrahepatic cholangiocarcinoma (ICC), such as hepatitis B virus (HBV), hepatitis C virus (HCV) or cirrhosis, the risk factors and clinicopathologic features of young ICC patients have not been fully studied.

### Applications

ICC in young patients and hepatocellular carcinoma (HCC) shared a common process of carcinogenesis (through a similar long-term inflammatory carcinogenic process) and that both may arise from hepatic progenitor cells. However, this presumption awaits verification by more studies.

### Peer review

The authors clearly demonstrated that the risk factors for ICC differed significantly between young patients and elderly patients in a Chinese population. They also showed that HBV infection was closely associated with the development of ICC in young patients.

association between *Helicobacter pylori* (*H. pylori*) and iron deficiency anemia (IDA).

**METHODS:** A defined search strategy was used to search Medline, Embase, the Cochrane Library, Clinical Trials, Cochrane Central Register of Controlled Trials, Premedline and Healthstar. Odds ratio (OR) was used to evaluate observational epidemiology studies, and weighted mean difference (WMD) was used to demonstrate the difference between control and intervention groups.

**RESULTS:** Fifteen observational studies and 5 RCTs were identified and used for calculation. The pooled OR for observational studies was 2.22 (95% CI: 1.52-3.24,  $P < 0.0001$ ). The WMD for hemoglobin (HB) was 4.06 g/L (95% CI: -2.57-10.69,  $P = 0.01$ ), and the WMD for serum ferritin (SF) was 9.47  $\mu\text{g/L}$  (95% CI: -0.50-19.43,  $P < 0.0001$ ). Results were heterogeneous for all comparisons.

**CONCLUSION:** This meta-analysis on observational studies suggests an association between *H. pylori* and IDA. In RCTs, eradication of *H. pylori* can improve HB and SF levels but not significantly.

### Abstract

**AIM:** To perform a meta-analysis of observational studies and randomized controlled trials (RCTs) on the

*J Gastroenterol* 2010; 16(7): 886-896 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i7/886.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i7.886>

## INTRODUCTION

Anemia, defined as a hemoglobin concentration below established cut-off levels, is a widespread public health problem with major consequences for human health as well as social and economic development<sup>[1]</sup>. The World Health Organization (WHO) estimates that about 2 billion people in the world are suffering from this disease, and that approximately 50% of all anemia cases are diagnosed as iron deficiency anemia (IDA)<sup>[2,3]</sup>. IDA affects the work capacity of patients and may contribute to mortality, thus limiting economic development. The overall death rate from IDA has been underestimated in most surveys from many developing and developed countries<sup>[4,5]</sup>. WHO suggested that researchers and clinical doctors should investigate the etiology of IDA and develop therapeutic strategies because timely treatment restores personal health and increases national productivity by 20%<sup>[6,7]</sup>.

It is known that a variety of causes such as inadequate iron intake, chronic blood loss, chronic disease, malabsorption, hemolysis, or a combination of these, can induce IDA<sup>[5,8-10]</sup>. Among possible causes, the involvement of *Helicobacter pylori* (*H. pylori*) infection remains controversial<sup>[11-13]</sup>. *H. pylori* is a highly prevalent microbial infection. Over 50% people in the world are infected by *H. pylori*. In Africa, Mexico, South America and Central America, *H. pylori* infection reaches 70%-90% of the population<sup>[14,15]</sup>. *H. pylori* has been considered as a major cause for the development of peptic ulcer disease, gastric malignancy and dyspeptic symptoms<sup>[16-19]</sup>. Recent studies have shown that *H. pylori* can also cause other extragastric diseases<sup>[20-22]</sup>. However, knowledge regarding any relation between *H. pylori* infection and IDA is limited. Moreover, studies regarding the role of *H. pylori* infection in IDA and the effectiveness of the eradication of *H. pylori* in the treatment of IDA are controversial.

This clinical research question is addressed by this meta-analysis. The aim of the study was to evaluate the association between *H. pylori* infection and IDA and examine the effect of *H. pylori* eradication on serum hemoglobin (HB) and serum ferritin (SF) levels. Observational epidemiological studies have demonstrated an association between *H. pylori* and IDA by comparing IDA risk between *H. pylori*-infected and non-infected participants. Randomized controlled trials (RCTs) have established a cause and effect relationship between *H. pylori* and IDA. In this meta-analysis, we hypothesized that there is a significant difference in IDA risk between *H. pylori*-infected and non-infected participants, and that *H. pylori* eradication therapy can significantly increase HB and SF concentration, thus alleviating IDA. We tested our

hypothesis by pooling the results of studies on *H. pylori* and IDA.

## MATERIALS AND METHODS

### Search strategy and identification of studies

We searched, without language restrictions, for all publications on *H. pylori* and IDA between January 1966, and June 2009. Searches were performed on Medline, Embase, Clinical Trials, Database of Abstracts of Reviews of Effects (DARE), Cochrane Central Register of Controlled Trials (CENTRAL), the Cochrane Database of Systematic Reviews, Premedline, Healthstar, by using the MeSH heading: “*Helicobacter pylori*”, “iron-deficiency anemia”, “anemia”, “iron” and “hemoglobin” and the non-MeSH terms “sideropenic refractory anemia” and “serum ferritin”. The reference lists of major textbooks, review articles, and of all the included articles identified by the search were then individually searched to find other potentially eligible studies. Information about unpublished and ongoing RCTs was sought from authors of the included RCTs, and experts in the field.

### Selection criteria and validity assessment

The present meta-analysis followed the Quality of Reports of Meta-Analyses of RCTs (QUOROM) guideline for RCTs and observational studies in epidemiology [Meta-analysis of Observational Studies in Epidemiology (MOOSE) and Methodological Index for Non-Randomized Studies (MINORS)] guideline in observational studies<sup>[23-25]</sup>. To avoid selection bias, selection criteria were established before searching. Two reviewers (Qu XH and Huang XL) identified articles eligible for further review by performing an initial screen of the abstracts or titles of the search results. The second screening was based on a full-text review according to the selection criteria. The observed agreement between reviewers for eligibility of articles was 96.3%, corresponding to modest agreement ( $\kappa = 0.40$ ). Discrepancies were resolved by discussion and consultation with other reviewers (Xiong P and Zhu CY).

**Observational epidemiology studies:** Observational epidemiology studies (cross-sectional, case-control, or cohort) investigating the prevalence of IDA in *H. pylori*-positive patients and negative controls were included in this meta-analysis. Duplicate publications and those studies in which patients had other underlying common IDA causes (e.g. aspirin/NSAID use, colonic carcinoma, gastric carcinoma, angiodysplasia) were excluded.

**Randomized controlled trials:** In order for an RCT to be included, its participants must have had both *H. pylori* infection and IDA/iron deficiency (ID). At least 2 authors independently assessed the methodological quality of included RCTs by Jadad scores<sup>[26]</sup>. In addition, for a study

to be eligible for inclusion, the use of therapy to eradicate *H. pylori* in intervention groups and administration of oral ferrous sulfate to both intervention and control groups were required. Discrepancies in data extraction were resolved by discussion among authors (Qu XH and Huang XL).

### Data abstraction

For observational epidemiology studies, we collected information on the year of publication, location of the study, age groups, number of cases and controls, country and region, number of IDA positive and negative patients, test method for *H. pylori*.

For RCTs, we collected information on references, year of publication, sample size, age group, treatment therapies, *H. pylori* testing methods and changes in mean  $\pm$  SD of HB and SF in both the intervention and control groups.

### Statistical analysis

For observational epidemiology studies, we recorded the prevalence of IDA in *H. pylori*-positive patients and controls for each study as an odds ratio (OR) and 95% CI and the weight of the studies. We used the heterogeneity  $\chi^2$  (Cochran Q) statistic to formally analyze heterogeneity across included studies. Meta-analysis was performed using Review Manager Version 5 (Cochrane Collaboration and Update Software) for observational studies<sup>[27]</sup>.

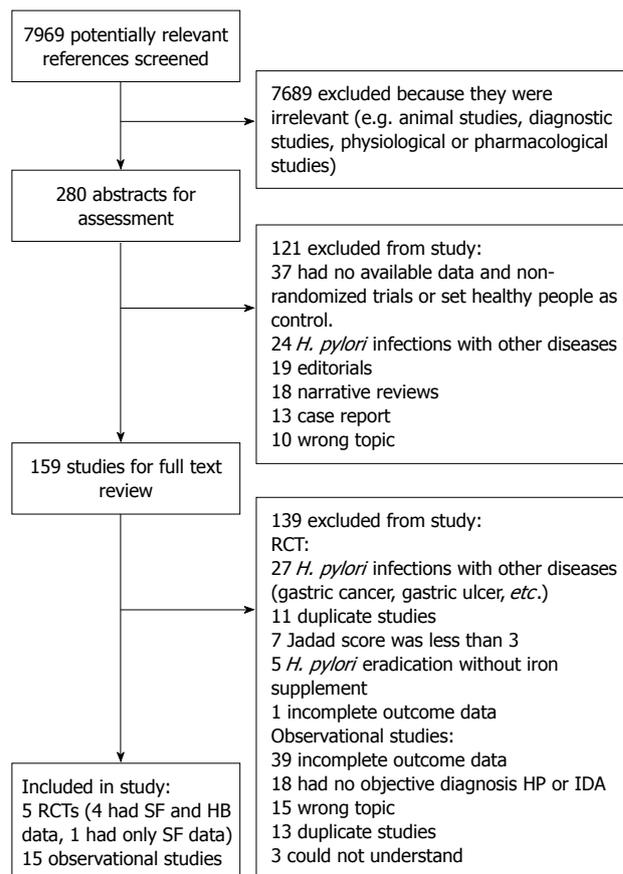

For RCTs, we collected changes in HB and SF concentration after *H. pylori* eradication and evaluated them by using weighted mean difference (WMD) with 95% CI. A  $\chi^2$  test was used to assess heterogeneity of the studies. If the studies were found to be heterogeneous, (i.e.  $\chi^2 > df$ ), we utilized the DerSimonian and Laird random-effects model<sup>[28]</sup> rather than a fixed effects model to reassess the pooled estimates. The source of heterogeneity was investigated as described below. Publication bias was performed by both Review Manager Version 5 and STATA version 10. We also performed the Duval and Tweedie nonparametric “trim and fill” procedure<sup>[29]</sup> to further assess the possible effect of publication bias in our meta-analysis.

### Subgroup analysis

Subgroup analysis was performed to assess the factors that might impact the pooled estimates and to investigate the source of heterogeneity. Sensitivity analysis was also conducted to test whether the analysis was robust by changing statistical methods, reanalyzing the data, and comparing the 2 results by the *t* test.

### Publication bias

Funnel plots and Begg’s test<sup>[30]</sup> are thought to detect the existence of publication bias of pooled ORs within observational studies. Small studies are scattered widely at the bottom of the graph, while the spread narrows for larger studies. When a funnel plot seemed to be

**Figure 1** Flow chart showing the trial flow for selection of RCTs and observational studies to be included. RCT: Randomized controlled trial; HP: *H. pylori*; IDA: Iron deficiency anemia; HB: Hemoglobin; SF: Serum ferritin.

asymmetrical, we used Duval and Tweedie’s nonparametric “trim and filled” method as a sensitivity analysis to reassess the pooled estimates<sup>[29]</sup>. This method considers the possibility of hypothetical “missing” studies that might exist and recalculates the results with the imputed missing studies.

## RESULTS

### Search results

The search strategy retrieved 7969 potentially relevant references. Of these, 7689 were not relevant, e.g. animal studies, physiological or pharmacological studies. The remaining 280 references were assessed by screening their abstracts, and we excluded any references that were editorials or narrative reviews. One hundred and fifty nine studies were subjected to a full text review and excluded according to the selection criteria as described earlier. Supplementary studies were identified that had been published only as abstracts from conference proceedings of scientific meetings. We then excluded all RCTs with a Jadad score under 3 to ensure the quality of eligible trials. Fifteen observational studies<sup>[31-45]</sup> and 5 RCTs<sup>[46-49]</sup> (4 of which<sup>[46-49]</sup> provided both HB and SF data, and one study<sup>[40]</sup> provided only SF data) meeting our criteria were included in our meta-analysis (Figure 1).

**Study characteristics and quality**

In total, 15 183 patients from 20 studies (15 observational and 5 RCTs) were included in the meta-analysis, and the characteristics of the sample are summarized in Table 1.

Of the observational studies, 4 studies with participants over 18 years old<sup>[31,35,38,39]</sup> and one study with patients aged 16-58 years old<sup>[33]</sup> were classified as adult groups. Three studies with patients aged 10-18 years old were classified as adolescent groups<sup>[32,34,36]</sup>. Two studies with patients younger than 11 years old were classified as child groups<sup>[41,49]</sup>. For the presence of *H. pylori*, 6 studies utilized serum immunoglobulin G (IgG)<sup>[31,32,34,36,37,42]</sup>, 5 utilized histological examination<sup>[33,35,38,43,44]</sup> and 3 used the urea breath test (UBT)<sup>[40,41,45]</sup>. UBT and serum IgG were utilized by Hershko *et al*<sup>[39]</sup> in their studies. Of the RCTs, 2 studies with participants aged 2-11 years old were classified as child groups<sup>[40,49]</sup> and 3 were classified as adolescent and adult groups<sup>[46-48]</sup>. All the RCTs used eradication triple therapy for *H. pylori* as intervention.

Study methodological quality is shown in Table 2 (observational studies) and Table 3 (RCTs). In observational studies, the MINORS quality score ranged from 6 to 14 points. Only 8 (53%) of the articles included employment outcomes as part of the main study aim. Five studies satisfied the criteria for inclusion. Most data were collected according to a protocol established before

the beginning of the study, and most studies have no exclusion or details about the reasons for exclusion. In RCTs, qualities of all the studies were evaluated by Jadad score. All of the studies included had a score greater than 3. Only one study fulfilled all of the evaluated quality criteria. All studies were randomized, and for 4 of them, the generation of allocation sequence was judged adequate. Only 2 studies were designed as double-blind, but placebo was offered in only one study. Three of the 5 RCTs had no exclusions, and one of the 5 RCTs gave details on the reasons for exclusion.

**Summary estimates**

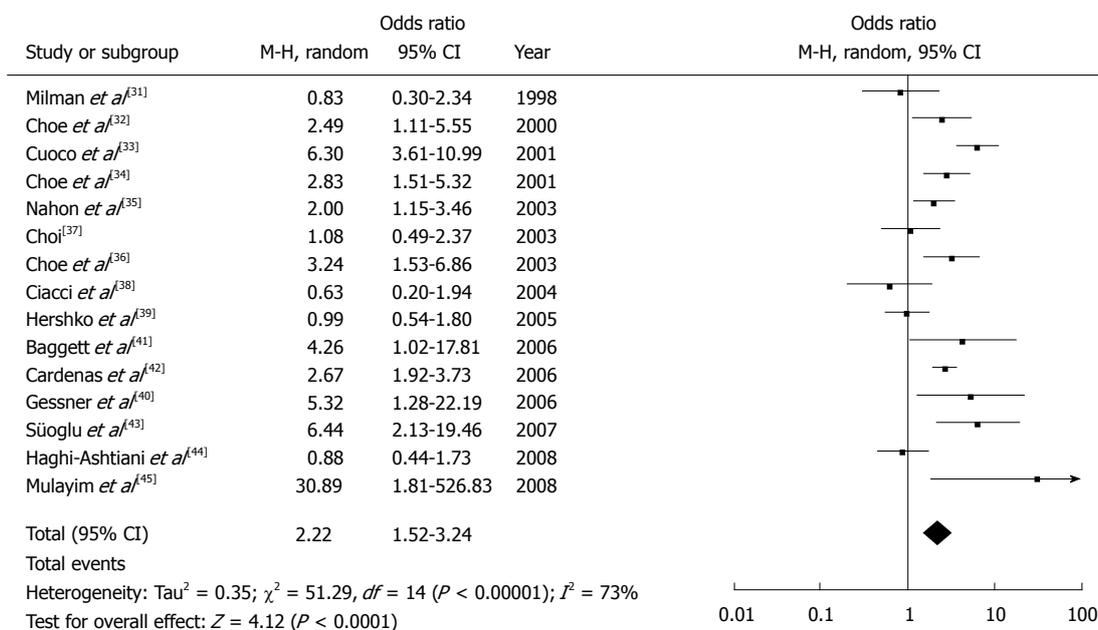

**Risk of IDA for *H. pylori*-positive versus *H. pylori*-negative patients:** We tested the heterogeneity of the 15 observational studies that provided information about prevalence OR, and the heterogeneity  $\chi^2$  statistic was 51.29 ( $P < 0.00001$ ). Therefore, the pooled estimates were evaluated under a random effects model instead of a fixed effects model. The pooled OR was 2.22 and the 95% CI was 1.52-3.24 ( $P < 0.0001$ ) suggesting that IDA is associated with *H. pylori* (Figure 2).

***H. pylori* eradication effect in IDA patients:** Four RCTs<sup>[46,48-49]</sup> reported blood parameter (HB levels and SF concentrations) differences and one RCT<sup>[40]</sup> reported

SF concentration differences between the intervention and control groups after *H. pylori* eradication therapy. We pooled summary estimates to demonstrate the treatment

effect and underlying connection between *H. pylori* and IDA. The results showed that *H. pylori* eradication therapy can improve IDA. Four RCTs compared the increase in HB levels and 5 in SF concentrations achieved with *H. pylori* eradication (plus iron) treatment and with iron administration alone in patients with IDA, and found a greater effect in the eradication group (WMD of HB: 4.06 g/L, 95% CI: -2.57-10.69,  $P = 0.01$ ; WMD of SF: 9.47  $\mu\text{g/L}$ ; 95% CI: -0.50-19.43,  $P < 0.0001$ , Figure 3).

**Subgroup analysis**

Subgroup analysis was performed to investigate the source of heterogeneity and detect the influential factors that could impact the summary estimates. The methodological

**Figure 3** The treatment effect and underlying connection between *H. pylori* and IDA. A: Weighted mean difference (WMD) forest plots of HB (g/L) involved in the meta-analysis; B: Forest plots of studies estimate changes in SF ( $\mu\text{g/L}$ ) level. IV, Random: Inverse variance heterogeneity random effects model. Horizontal lines = 95% CI. The size of the data marker corresponds to the weight of that study. The diamond represents the summary estimate. The result favors experimental groups.

and biological heterogeneity of the studies made it possible to explore the summary estimates in many different subgroups.

In observational studies, differences in the sensitivity of the *H. pylori* test methods could partly result in different pooled ORs. The 15 observational studies utilized 3 methods, enzyme-linked immunosorbent assay (ELISA) serum IgG, histological biopsy and UBT, to test for the presence of *H. pylori*. The pooled OR of ELISA serum IgG was lowest (OR = 2.16, 95% CI: 1.49-3.14,  $P = 0.10$ ) and the pooled OR of UBT was highest (OR = 5.88, 95% CI: 2.27-15.23,  $P = 0.47$ ). The pooled ORs were consistent with the sensitivity of these methods.

Subgroup analysis for different age groups revealed a significant difference between children, adolescents and adults in the association between *H. pylori* and IDA. The pooled OR of children younger than 11 years was 4.76 (95% CI: 1.73-13.08,  $P = 0.83$ ). Adolescents yielded a pooled OR of 2.85 (95% CI: 1.68-4.31,  $P = 0.89$ ), while adults had a pooled OR of 1.55 (95% CI: 0.67-3.62,  $P < 0.0001$ ).

In RCTs, factors included in the subgroup analysis were age and therapy of each study. The summary estimate from children was 0.65 g/L (95% CI: -1.52-2.82,  $P = 0.39$ ) for HB changes, significantly different from the pooled estimate of 25.03 g/L (95% CI: 9.69-40.37,  $P = 0.41$ ) from adolescent and adult groups, indicating that adult IDA patients react more strongly to *H. pylori* eradication therapy. The WMD for SF changes was 0.70  $\mu\text{g/L}$  (95% CI: -1.01-2.41,  $P = 0.45$ ) in children while the WMD was 14.79  $\mu\text{g/L}$  (95% CI: 2.53-27.05,  $P =$

0.0001) in adolescent and adult patients.

To examine the method of therapy, we separated the studies into a bismuth triple therapy group and a proton pump inhibitor (PPI) triple therapy group. Bismuth triple therapy showed an obvious advantage (WMD of SF = 11.55  $\mu\text{g/L}$ , 95% CI: 0.09- 23.01,  $P = 0.0002$ ) over PPI triple therapy (WMD of SF = 7.15  $\mu\text{g/L}$ , 95% CI: -6.45-20.75,  $P = 0.002$ ), particularly when used together with oral ferrous sulfate for *H. pylori* patients with IDA.

We analyzed the association between *H. pylori* and IDA in developed areas and less developed areas, large sample subgroups and small sample subgroups, and did not find any significant difference between those parameters. Table 4 shows the summary estimates of subgroups of both RCTs and observational studies.

### Sensitivity analysis

We chose to change the weights of every observational study involved so as to detect the stability of this meta-analysis. We then reanalyzed the data using different statistical methods. The pooled OR using a fixed effects model was 2.34 (95% CI: 1.97-2.78), which is not a significant change from the original random effects model ( $P = 0.74$ ).

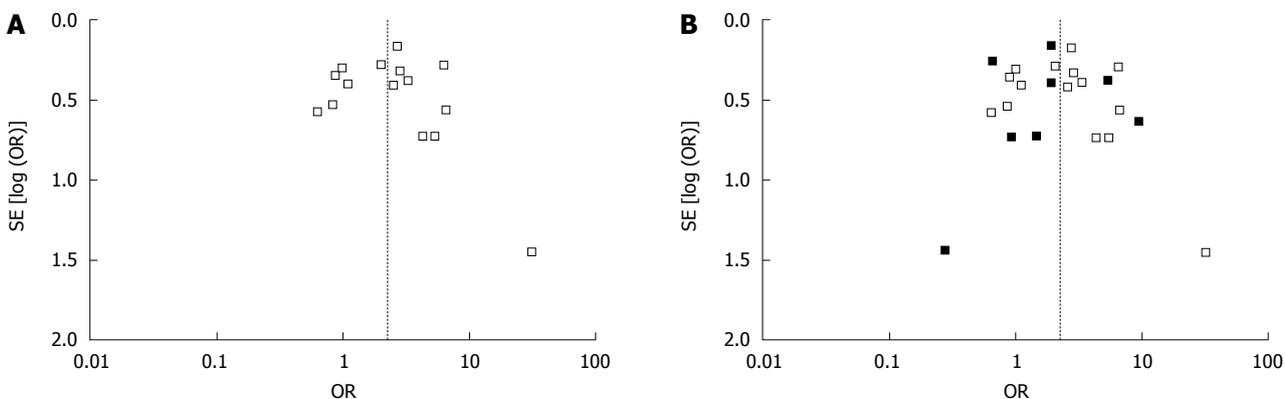

### Publication bias

Visual inspection of the Begg's funnel plot revealed asymmetry ( $P < 0.01$ ). This raises the possibility of publication bias, so we undertook a sensitivity analysis using the trim and fill method. This method conservatively imputes hypothetical negative unpublished studies

**Table 4** Summary of subgroup analyses of both observational studies and experimental studies

to mirror the positive studies that cause funnel plot asymmetry. The adjusted summary OR is based on the eventually filled funnel plot (4.32, 95% CI: 3.00-5.66,  $P < 0.001$ ), which continued to show a statistically significant association between *H. pylori* and IDA (Figure 4).

## DISCUSSION

Our results from a meta-analysis of 15 observational epidemiological studies revealed a correlation between *H. pylori* and IDA (OR, 2.22; 95% CI: 1.52-3.24,  $P < 0.0001$ ), although some studies reported only a slight association. In addition, In RCTs, eradication of *H. pylori*

can improve HB and SF levels but not significantly (WMD of HB: 4.06 g/L, 95% CI: -2.57-10.69,  $P = 0.01$ ; WMD of SF: 9.47  $\mu\text{g/L}$ , 95% CI: -0.50-19.43,  $P < 0.0001$ ).

Dufour *et al.*<sup>[50]</sup> first reported that *H. pylori* eradication had a positive effect on sideropenic refractory anemia, indicating a possible underlying association between *H. pylori* and IDA. A large population-based study from the USA reported that *H. pylori* infection was an independent risk factor for IDA in 7462 children, adolescents, and adults<sup>[42]</sup>. This research reported that *H. pylori* infection was associated with an increased risk of IDA (OR, 2.6; 95% CI: 1.5-4.6). Compared to former studies, our meta-analysis was a detailed and comprehensive investigation

procedure. It included RCTs of highly detailed power and large-scale observational epidemiology studies.

It is reported that *H. pylori* infection is observed in over 50% people in the world with peaks of 70%-90% for some countries. Moreover, IDA affects 2 billion people in the world. When 2 diseases have such a high prevalence in the population they may appear to be associated with each other. Recent studies regarding the role of *H. pylori* infection in IDA are controversial. However, whether eradication of *H. pylori* prevents IDA has been widely debated. This meta-analysis was performed to clarify this issue: whether iron deficiency could specifically be related to *H. pylori* infection. The observational studies in our meta-analysis prove the association between *H. pylori* and IDA. In fact, in the RCTs of our meta-analysis, after iron replacement, HB and SF were not different between the groups with or without *H. pylori* eradication. However, these data should be interpreted with caution because of the marked heterogeneity among studies. We carefully performed subgroup analysis, and found age and therapies had an impact on the increase in the levels of HB and SF. These results should be investigated further in the future. Larger scale RCTs should be recommended to test the results of our meta-analysis.

As with all meta-analyses, the results we obtained could be impacted by 3 factors: heterogeneity within the studies involved, bias (including selection bias<sup>[51,52]</sup> and detection bias<sup>[53,54]</sup>), and publication bias<sup>[55-57]</sup>. The generation of heterogeneity could occur by virtue of the methodological and biological heterogeneity of the studies analyzed, such as differences in diagnostic methods, the population under study, the sample size, and language of publication. Each of the subgroups described above contributed partly to the heterogeneity of the observational studies.

We assessed the included studies with caution. For observational studies, the MINORS quality score ranged from 6 to 14 points. In RCTs, quality of all the studies were evaluated by the Jadad score. All of the studies included had a score greater than 3. Our test for heterogeneity was significant, and hence we utilized a random effects model that accounted for inter-study variation. Compared with the fixed effects model, the random effects model evenly distributes weight among studies, minimizing the impact of heterogeneity<sup>[58]</sup>.

We used age as one subset determinant for the pooled estimates. A significant association between *H. pylori* and IDA was found in children younger than 11 years. The common causes of IDA, such as colonic carcinoma, gastrectomy or menstruation, were usually absent in children. Thus, *H. pylori* infection can be treated as the only indicator for refractory IDA in children, and *H. pylori* infection should be considered first in children with IDA<sup>[59-61]</sup>. The same scenario occurred in adolescents, as adolescents are particularly susceptible to ID. Because of the requirement for a large amount of iron to sustain their growth, dietary deficiency, and menstrual blood loss, girls should be more strongly affected by *H. pylori*

infection<sup>[10,34,62]</sup>. In adults, no such strong association was found. The possible explanation for this phenomenon is that *H. pylori* plays a smaller part in the etiology of IDA in adults<sup>[1,5,63]</sup>. In RCT subgroup analysis, eradication therapy for *H. pylori* did not demonstrate the same curative effect on IDA in children as in adults. This may arise from the special characteristics of children (quickly growing blood volume and large requirement)<sup>[59-61]</sup>.

Different diagnostic methods for *H. pylori* contribute to the variation of the pooled estimates because of their different sensitivities. The pooled OR value increased with the sensitivity of the diagnostic method. Therefore, UBT, which has the highest sensitivity of the 3 tests used<sup>[64-66]</sup>, obtained the highest pooled OR, while ELISA serum IgG tests yielded the lowest pooled OR. Recent guidelines have indicated that UBT is regarded as a gold standard diagnostic method and the most reliable nonendoscopic test for the existence of *H. pylori*<sup>[67]</sup>.

The way in which RCTs chose to eradicate *H. pylori* can make a difference in pooled analyses. Bismuth-based triple therapy indicated a much better response to iron intake than PPI-based triple therapy. The work done by McColl and Hutchinson may explain this phenomenon<sup>[68,69]</sup>. It was reported that PPI therapy lowers the concentration of vitamin C in gastric juice and reduces the bioavailability of ingested vitamin C thus resulting in low absorption of nonheme iron. It may also retard the clinical response to iron supplementation. Vitamin C, as an essential factor in alimentary iron absorption, not only converts ferric iron to the ferrous form, which maintains solubility at the alkaline pH of the duodenum, but also chelates with ferric chloride which is also stable at a pH > 3. PPI can also reduce the absorption of vitamin B<sub>12</sub>, a significant factor in iron absorption, probably by inhibiting intragastric proteolysis.

Publication bias was tested by Begg's test and illustrated by funnel plots. The results indicated the existence of publication bias. The funnel plot showed that there were some missing small sample studies. Therefore, meta-analysis would underestimate the association between IDA and *H. pylori*. The "trim and fill" method helped to resolve this problem by imputing the hypothetical studies symmetrically and reassessing the pooled estimates as a sensitivity analysis. The filled funnel plot showed a strong association between IDA and *H. pylori*. Possible sources of asymmetry in funnel plots were explored: variations in sample size, etc, could contribute to publication bias.

Sensitivity analysis was performed in several ways to test concordance of the results by changing the statistical methods used. The sensitivity analyses that were performed did not materially change the results, increasing the confidence that can be placed in these results when applying the conclusion in practice.

Our study has limitations. We have excluded trials that studied the relationship between *H. pylori* and iron deficiency. However, these studies have been reviewed elsewhere<sup>[70]</sup>. Furthermore, in the experimental studies,

eradication treatment without ferrous sulfate but with placebo groups were excluded because the number of studies was not adequate. This kind of design can illustrate the role that *H. pylori* plays in IDA in a better way, and we expect further investigations will take that design into consideration. Lastly, results were markedly heterogeneous for all comparisons. These data should be interpreted with caution because of the marked heterogeneity among studies.

In conclusion, our meta-analysis of 15 observational studies demonstrated an association between *H. pylori* and IDA. In addition, the meta-analysis of RCTs showed that eradication of *H. pylori* can improve HB and SF levels, though not significantly. From the analysis, we also concluded that IDA could not specifically be related to *H. pylori* infection. We do not recommend a strategy of population-based screening and treatment for *H. pylori* infection to prevent IDA. This concept should be discussed in the future. UBT is the most reliable nonendoscopic test for the existence of. Bismuth-based triple therapy has a better response to increase HB and SF levels than PPI-based triple therapy. There are no significant differences between less developed areas and developed areas in the association between *H. pylori* infection and IDA.

## COMMENTS

### Background

Both *Helicobacter pylori* (*H. pylori*) and iron deficiency anemia (IDA) have high prevalence worldwide. The relationship between these 2 remains controversial. Recent guidelines for *H. pylori* and IDA both focus on the role *H. pylori* plays in the process of IDA.

### Research frontiers

The interaction between *H. pylori* and IDA is a current 'hot topic'. *H. pylori* infection impairs iron absorption causing a considerable decrease in the concentration of gastric juice ascorbic acid (vitamin C) that is the best promoter of nonheme iron absorption. It thus causes the decline of hemoglobin in red blood cells and directly leads to anemia. The gastric colonization by *H. pylori* increases lactoferrin uptake from neutrophils and increases iron demand.

### Innovations and breakthroughs

To the best of the authors' knowledge, this is the first published meta-analysis assessing the association between *H. pylori* infection and IDA (evaluating children, adolescents and adults) and assessing the effect of *H. pylori* eradication on hemoglobin (HB) and serum ferritin (SF) levels.

### Applications

The research showed an association between *H. pylori* and IDA. Eradication of *H. pylori* can improve HB and SF levels but not significantly. The authors do not recommend a strategy of population-based screening and treatment for *H. pylori* infection to prevent IDA.

### Peer review

This is a good and interesting meta-analysis.

### Abstract

**AIM:** To test whether ethanol feeding could induce Toll-like receptor 4 (TLR4) responses, assess the hepatoprotective effect of betaine and its inhibitive effect on TLR4 in animal models of alcoholic liver injury.

**METHODS:** Forty-eight female Sprague-Dawley rats were randomly divided into four groups as control, model, low and high dose betaine groups. Except control group, all rats were fed with high fat-containing diet plus ethanol and fish oil gavages for 8 wk. Betaine was administered intragastrically after exposure of ethanol for 4 wk. The changes of liver histology were examined. The expression of TLR4 mRNA and protein was detected by RT-PCR and Western blotting, respectively. The serum aminotransferase activity [alanine transaminase (ALT), aspartate aminotransferase (AST)], serum endotoxin, and liver inflammatory factors [tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), interferon- $\gamma$  (IFN- $\gamma$ ), interleukin-18 (IL-18)] were also assayed.

**RESULTS:** Compared with control group, rats of model group developed marked liver injury, accompanied by an increase of ALT ( $159.41 \pm 7.74$  U/L vs  $59.47 \pm$

$2.34$  U/L,  $P < 0.0001$ ), AST ( $248.25 \pm 1.40$  U/L vs  $116.89 \pm 3.48$  U/L,  $P < 0.0001$ ), endotoxin ( $135.37 \pm 30.17$  ng/L vs  $44.15 \pm 7.54$  ng/L,  $P < 0.0001$ ), TNF- $\alpha$  ( $20.81 \pm 8.58$  pg/mL vs  $9.34 \pm 2.57$  pg/mL,  $P = 0.0003$ ), IFN- $\gamma$  ( $30.18 \pm 7.60$  pg/mL vs  $16.86 \pm 9.49$  pg/mL,  $P = 0.0039$ ) and IL-18 ( $40.99 \pm 8.25$  pg/mL vs  $19.73 \pm 9.31$  pg/mL,  $P = 0.0001$ ). At the same time, the expression of TLR4 mRNA and protein was markedly induced in the liver after chronic ethanol consumption ( $1.45 \pm 0.07$  vs  $0.44 \pm 0.04$ ,  $P < 0.0001$ ;  $1.83 \pm 0.13$  vs  $0.56 \pm 0.08$ ,  $P < 0.0001$ ). Compared with model group, betaine feeding resulted in significant decreases of ALT ( $64.93 \pm 6.06$  U/L vs  $159.41 \pm 7.74$  U/L,  $P < 0.0001$ ), AST ( $188.73 \pm 1.11$  U/L vs  $248.25 \pm 1.40$  U/L,  $P < 0.0001$ ), endotoxin ( $61.80 \pm 12.56$  ng/L vs  $135.37 \pm 30.17$  ng/L,  $P < 0.0001$ ), TNF- $\alpha$  ( $9.79 \pm 1.32$  pg/mL vs  $20.81 \pm 8.58$  pg/mL,  $P = 0.0003$ ), IFN- $\gamma$  ( $18.02 \pm 5.96$  pg/mL vs  $30.18 \pm 7.60$  pg/mL,  $P = 0.0008$ ) and IL-18 ( $18.23 \pm 7.01$  pg/mL vs  $40.99 \pm 8.25$  pg/mL,  $P < 0.0001$ ). Betaine also improved liver steatosis. The expression levels of TLR4 mRNA or protein in liver tissues were significantly lowered ( $0.62 \pm 0.04$  vs  $1.45 \pm 0.07$ ,  $P < 0.0001$ ; and  $0.65 \pm 0.06$  vs  $1.83 \pm 0.13$ ,  $P < 0.0001$ ). There was a statistical difference of TLR4 mRNA and protein expression between high- and low-dose betaine groups ( $0.62 \pm 0.04$  vs  $0.73 \pm 0.05$ ,  $P < 0.0001$ , and  $0.65 \pm 0.06$  vs  $0.81 \pm 0.09$ ,  $P < 0.0001$ ).

**CONCLUSION:** Betaine can prevent the alcohol-induced liver injury effectively and improve the liver function. The expression of TLR4 increases significantly in ethanol-fed rats and betaine administration can inhibit TLR4 expression.

## INTRODUCTION

Previous studies have shown that the chronic ingestion of ethanol can induce functional and structural changes in liver. Bacterial lipopolysaccharide (LPS; endotoxin), an abundant and essential component of the outer membrane of gram negative bacteria, causes liver injury in many experimental models<sup>[1,2]</sup>. Chronic alcohol administration increases gut-derived endotoxin in the portal circulation, thereby activating Kupffer cells to produce several proinflammatory cytokines such as tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) and interleukin (IL)-1<sup>[3,4]</sup>.

Toll-like receptor 4 (TLR4), a transmembrane protein with a cytoplasmic domain that bears homology to the IL-1 receptor, is expressed in monocytes and macrophages, including Kupffer cells<sup>[5]</sup>. Recently, TLR4 has been shown to mediate LPS-induced signal transduction in peripheral blood monocytes<sup>[6]</sup>. Furthermore, it has been shown that Kupffer cell activation by LPS is dependent on the presence of a functional TLR4<sup>[7]</sup>. It has been confirmed that TLR4 is involved in the mechanism of early alcohol-induced liver injury<sup>[8-11]</sup>. Ethanol administration can lead to the synthesis of TLR4 protein and its gene expression in Kupffer cells, indicating that TLR4 may play a major role in the development of alcohol-induced liver injury.

Betaine, also known as trimethyl glycine, is the only methyl donor, which can replace folate or S-adenosylmethionine in the human body<sup>[12,13]</sup>. Betaine is quaternary ammonium salt soluble alkaloids, which participates in the methionine recycling and phosphatidylcholine synthesis<sup>[14,15]</sup>. Many studies including our previous study have indicated that betaine can prevent the alcohol-induced liver injury effectively and improve the liver function<sup>[16,17]</sup>. The hepatoprotective mechanism of betaine is related to the inhibition of inflammatory factor, the decrease of lipid peroxidation, the promotion of endoplasmic reticulum stress and the prevention of apoptosis<sup>[18-21]</sup>.

In the present study, we employed the intragastric ethanol-fed rat model, which reproduces the pathological features of early alcohol-induced liver injury, to observe the changes of TLR4 expression and study the effect of betaine in alcohol-induced liver injury animal models.

## MATERIALS AND METHODS

### Chemicals and reagents

Betaine hydrochlorides (99% of purity) were kindly presented by Juhua Group Co. (Zhejiang, China). Ferrous

sulfate was obtained from Shanghai reagent chemicals Co. Ltd (Shanghai, China). Fish oil and 560 mL/L of alcohol were purchased from supermarkets. Limulus amoebocyte lysate assay kit for serum endotoxin assay was purchased from BioWhittaker Inc. (USA). Enzyme-linked immunosorbent (ELISA) kits for rat TNF- $\alpha$ , IFN- $\gamma$ , and IL-18 detection were purchased from Shanghai Senxiong Biotech industry Co. Ltd. (Shanghai, China). TRIzol reagent was purchased from Invitrogen Co. (USA). DL1000 DNA ladder marker was purchased from TaKaRa Biotech Co. Ltd. (Japan). M-MLV reverse transcriptase, deoxyribonucleotide (dNTP, 10 mmol/L), oligo (dT)<sub>15</sub> primer, Taq DNA polymerase, RNasin were purchased from Promega Biotech Co. Ltd. (USA). Polymerase chain reaction (PCR) primers for TLR4 and GAPDH were synthesized by Sai-Bai-Sheng Biocompany (Shanghai, China).

### Animal models

Forty-eight female specific pathogen free (SPF) Sprague-Dawley rats, weighing  $150 \pm 10$  g, were purchased from the Experimental Animal Center of Wuhan University. After acclimation for 1 wk, animals were randomly divided into four groups as control, model, low dose and high dose betaine groups. Each group contains 12 rats. Except rats of control group fed with ordinary diet and administrated intragastrically with physiological saline, the rats of the other three groups were fed with fat-rich diet containing common animal feeds, lard and whole milk powder (80:10:10), and were administrated intragastrically with ethanol and 0.5 mL fish oil. The initial dose of ethanol was 6 g/kg per day (solutions maximally containing 560 mL/L alcohol). Within the first week, the dose was increased progressively to a maintenance dose of 8 g/kg per day that was continued for 8 more weeks. After exposure of ethanol for 4 wk, the rats of low dose and high dose groups were administrated intragastrically with betaine 200 and 400 mg/kg per day, respectively. Animals were weighted three times per week. At the end of the experiment, animals were anaesthetized with urethane (20%, 1.0 g/kg) and sacrificed by bleeding from femoral arteries. Blood samples were collected. Immediately after exsanguination, the livers were harvested. Small portions of the livers were kept frozen at  $-70^{\circ}\text{C}$  for reverse transcriptase-polymerase chain reaction (RT-PCR), whereas other portions were separated and immersed in 10% buffered formalin solution for histological examination. All animals were given humane care in compliance with the institutional guidelines.

### Liver function assay

Blood samples were allowed to clot, and the sera were isolated by centrifugation at  $1000 \times g$  for 10 min and kept at  $-20^{\circ}\text{C}$  before determination. Serum alanine transaminase (ALT), aspartate transaminase (AST) and albumin (ALB) were determined by routine laboratory methods using a Hitachi Automatic Analyzer (Hitachi, Inc. Japan).

### Determination of serum endotoxin, TNF- $\alpha$ , IFN- $\gamma$ and IL-18

Serum levels of endotoxin, TNF- $\alpha$ , IFN- $\gamma$  and IL-18 were measured using commercial kits according to the manufacturer's protocol.

### Detection of liver TLR4 mRNA in liver tissues

Total RNA was extracted from approximately 100 mg frozen liver tissue using TRIzol reagent according to the manufacturer's protocol. The concentration of total RNA was assayed by ultraviolet spectrophotometric measurements at wavelength of 260 nm, and its purity was estimated by the ratio of  $A_{260}/A_{280}$ . The total RNA was reversely transcribed into single-stranded complementary DNA (cDNA) using the following methods: 2  $\mu$ g RNA, 0.5  $\mu$ g oligo(dT)<sub>15</sub> primer and DEPC (diethylpyrocarbonate)-treated water were added to reach a total volume of 15  $\mu$ L mixture at 70°C for 5 min, then rapidly chilled on ice. Finally, 5  $\mu$ L 5  $\times$  reaction buffer, 1.25  $\mu$ L dNTP (10 mmol/L, each), 25 units of RNasin, 200 units of M-MLV reverse transcriptase and DEPC-treated water were added to reach a total volume of 25  $\mu$ L mixture and incubated at 42°C for 60 min, then terminated by placing it on ice after deactivation at 85°C for 5 min. The cDNA was amplified by PCR. The amplification primers for rat TLR 4 were 5'-ACTCGAGCCAGAATGAGGACT-3' and 5'-ACTGCCATGTCTGAGCAATCT-3', for rat GAPDH were 5'-TCCCTCAAGATTGTTCAGCAA-3' and 5'-AGATCCACAACGGATACATT-3'. The 50  $\mu$ L PCR reaction mix contained 10 mmol/L dNTP, 2.5 mmol/L MgCl<sub>2</sub>, 20 mmol/L Tris-HCl (pH 8.4), 50 mmol/L KCl, 25 pmol/L of sense and antisense primers, and 2U of Taq DNA polymerase. Amplification was performed with 35 cycles with initial incubation at 94°C for 3 min and final extension at 72°C for 7 min, each cycle consisted of denaturation for 45 s at 94°C, annealing for 45 s at 55°C, and extension for 1 min at 72°C. The PCR products were 237 bp and 309 bp for TLR 4 and GAPDH, respectively. In all experiments, possible contamination with genomic DNA was excluded by PCR amplification in the absence of reverse transcriptase. The PCR products were electrophoresed on 2% agarose gel. Semiquantitative evaluation was performed using the Gel Doc 2000 System (BioRad Laboratories GmbH, München, Germany). GAPDH was used as a positive internal control and was positive for each specimen. Its expression was used as a correction factor for TLR 4 mRNA, thus the results were calculated as the ratio of the intensity of bands of TLR 4 cDNA per GAPDH cDNA on the gel.

### Western blotting assay of TLR4 protein in liver tissues

Liver tissue samples of 100 mg were crushed in a liquid nitrogen-cooled grinding bowl and then were lysed in cold RIPA buffer (25 mmol/L Tris-HCl pH 7.6, 150 mmol/L NaCl, 1% NP-40, 1% sodium deoxycholate, 0.1% SDS) (Pierce Biotechnology, Inc., USA), supplemented with Halt™ Protease Inhibitor Cocktail (Pierce Biotechnology, Inc., USA). Whole cell lysates were ob-

tained by subsequent centrifugation at 15000  $\times g$  for 10 min at 4°C. Protein concentrations were determined using Bradford Protein Assay Kit with bovine serum albumin (BSA) as standard (SinoBio Biotech Co., Ltd. Shanghai, China). Fifty  $\mu$ g of protein extracts were subjected to 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to a Protran® nitrocellulose membrane (Schleicher & Schuell BioScience GmbH, Whatman Group, Germany). The membrane was incubated with the rabbit anti-TLR4 polyclonal antibody (BioChain, USA) at 4°C overnight after being blocked with a 10% BSA solution. The membrane was washed with TBST buffer (20 mmol/L Tris-HCl pH 7.4, 150 mmol/L NaCl, 0.1% Tween-20) and incubated with a secondary goat anti-rabbit horseradish peroxidase (HRP)-conjugated antibody (Zhongshan Golden Bridge Biotechnology Co., Ltd., Beijing, China) for 2 h at room temperature, and finally detected by chemiluminescence using Enhanced NuGlo™ Chemiluminescent Substrate Kit (Alpha Diagnostic Intl. Inc., USA) followed by autoradiographic and densitometric analysis.  $\beta$ -actin was used as an internal control.

### Histological examinations of liver

The liver specimens were fixed in 10% formaldehyde for 12-24 h, embedded in paraffin, sliced into sections of 5  $\mu$ m thickness and stained with hematoxylin-eosin (HE). Histological assessment was performed by three pathologists independently. The severity of steatosis was scored as 0 (no hepatocytes), 1 (less than 25% of hepatocytes), 2 (26%-50%), 3 (51%-75%), and 4 (greater than 75% of hepatocytes). The severity of the inflammation was scored as 0 (none), 1 (minimal), 2 (mild), 3 (moderate) and 4 (severe) based on the degree of portal and lobular inflammation and the evidence of piecemeal and spotty necrosis. The degree of necrotic hepatocytes was also scored as 0 to 4 (none, minimal, mild, moderate, and severe, respectively) based on the evidence of piecemeal and spotty necrosis.

### Statistical analysis

All data were presented as mean  $\pm$  SE. Differences among groups were assessed using unpaired Student's *t* test and one-way ANOVA. *P* value less than 0.05 was considered to be statistically significant. Calculations were performed with the SPSS11.0 statistical software package.

## RESULTS

### General conditions of rats

During the experiment, 4 rats in the model group died because fluids were poured mistakenly into trachea when they were administrated intragastrically. The other 44 rats survived.

### Changes of weight and liver index of rats

The changes of the rat weight in models were significantly

**Table 1** Changes of weight and liver index in rats

Groups	<i>n</i>	Weight change(g)	Liver index (Liver wet weight/rats weight × 100)
Control	12	27.27 ± 1.55 <sup>b</sup>	3.65 ± 0.22 <sup>b</sup>

<sup>b</sup>*P* < 0.01 compared with model group; <sup>d</sup>*P* < 0.01 compared with low dose betaine group. TNF- $\alpha$ : tumor necrosis factor- $\alpha$ ; IL-10: Interleukin-10; IL-18: Interleukin-18; IFN- $\gamma$ : Interferon- $\gamma$ .

lower than that in controls (*P* < 0.01). Compared with the model group, there were no significant differences in betaine intervention groups (*P* > 0.05). Liver index was significantly higher in models than in controls (*P* < 0.01). Compared with the model group, liver index decreased significantly in the betaine intervention groups (*P* < 0.01), and there was no statistical difference between high dose betaine group and low dose betaine group (*P* > 0.05) (Table 1).

### Changes of liver function

The changes of the ALT and AST in models were significantly higher than in controls (*P* < 0.01). Compared with the model group, the ALT and AST levels were significantly lowered in betaine intervention groups, indicating that the betaine can greatly improve the alcohol-induced liver injury, and there was no statistical difference between high dose betaine group and low dose betaine group (*P* > 0.05). There were no significant differences in ALB and A/G between model group and betaine intervention groups (*P* > 0.05) (Table 2).

### Changes of serum endotoxin, TNF- $\alpha$ , IFN- $\gamma$ and IL-18

The levels of serum endotoxin, TNF- $\alpha$ , IFN- $\gamma$  and IL-18 were significantly higher in model group than in

control group (*P* < 0.01). Compared with model group, serum endotoxin, TNF- $\alpha$ , IFN- $\gamma$  and IL-18 significantly decreased in betaine intervention groups (*P* < 0.01). There was a statistical difference between high dose betaine group and low dose betaine group (*P* < 0.01) (Table 3).

### Expressions of TLR4 mRNA and protein in liver tissue of rats

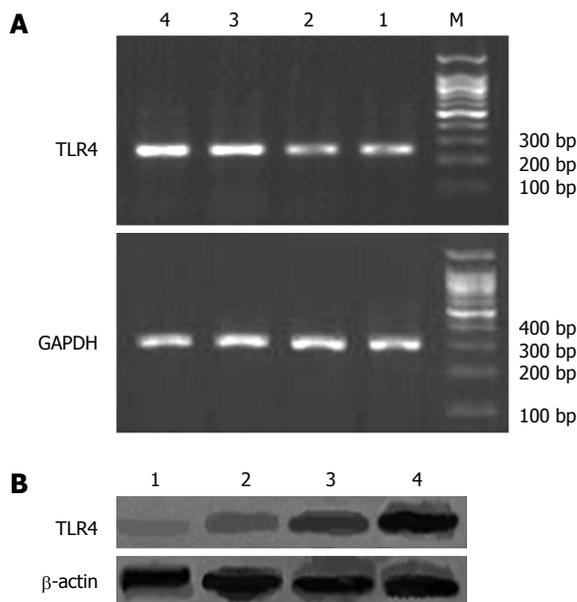

The software Quantiscan was used to analyze the absorbance of the products of TLR4 mRNA or protein quantitatively. The expression of TLR4 mRNA and protein was both significantly higher in model group than in normal (*P* < 0.01). Compared with the model group, the expression of TLR4 mRNA and protein was significantly reduced in betaine intervention groups (*P* < 0.01). There was a statistical difference of TLR4 expression between high dose betaine group and low dose betaine group (*P* < 0.01) (Table 4 and Figure 1).

### Histopathological changes of liver

The liver structure in control group was normal, and no obvious inflammation and hepatic steatosis were observed (Figure 2A). In model group, the structure of hepatic cord was deranged, and various degrees of diffuse hepatic

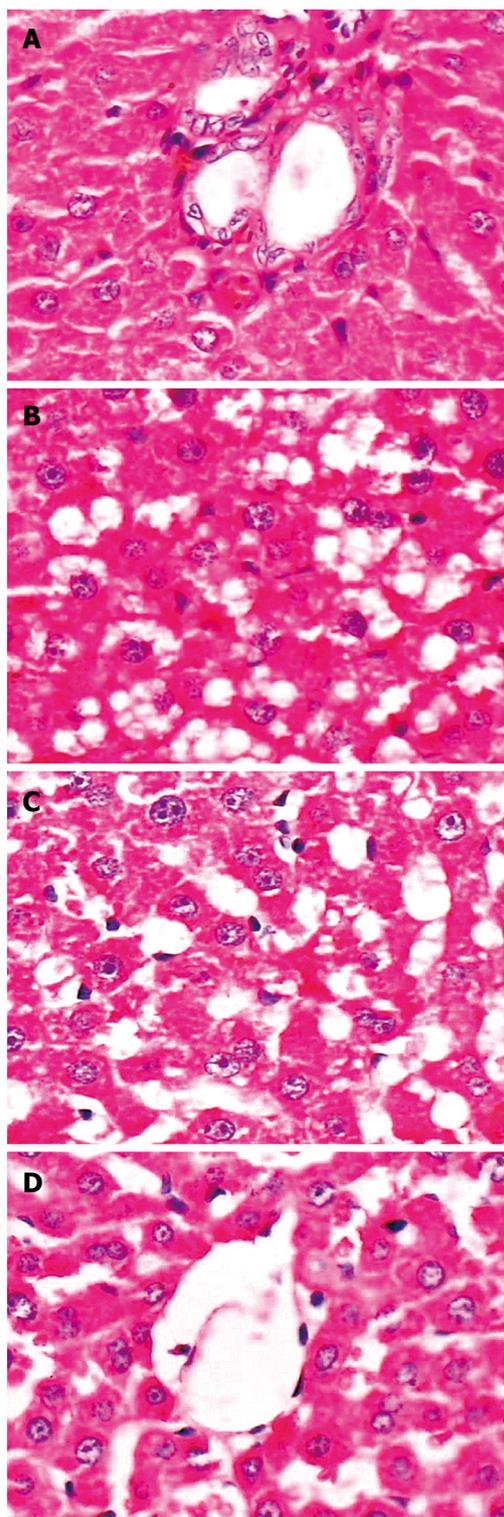

**Figure 1** Expression of TLR4 in rat liver tissues. A: RT-PCR assay of TLR4 mRNA; B: Western blotting assay of TLR4 protein. 1: Control; 2: High dose betaine group; 3: Low dose betaine group; 4: Model; M: DNA marker.

steatosis and intralobular inflammation could be found obviously (Figure 2B). Compared with model group, the degree of hepatic steatosis and inflammation was greatly reduced in betaine intervention groups. The improvement of liver histopathology in the high dose betaine group was most significant (Figure 2C and D).

## DISCUSSION

In this study, by establishing the intragastric fat-rich and ethanol diet mouse model, we found that the rats in model group had lower weight and higher liver index, obvious liver injury and hepatic steatosis, higher serum endotoxin, TNF- $\alpha$ , IFN- $\gamma$  and IL-18 levels compared with the rats in control group. Endotoxemia and oxidative stress are two key factors for the progression of alcoholic liver diseases<sup>[22]</sup>. There are solid data supporting the hypothesis that endotoxin is indeed involved in alcoholic liver injury. First, it has been shown that excessive alcohol intake increases gut permeability of normally nonabsorbed substances<sup>[23,24]</sup>. Second, intestinal gram-negative bacteria, as well as blood endotoxin levels, are increased both in alcoholic patients and in the Tsukamoto-French enteral

**Figure 2** Histopathological changes of rat liver after betaine intervention. A: In control group, liver structure was normal, without obvious inflammation and hepatic steatosis; B: In model group, the structure of hepatic cord was deranged, with various degrees of diffuse hepatic steatosis and intralobular inflammation; C: In low dose betaine group, the degree of hepatic steatosis and inflammation was greatly reduced compared with model group; D: High dose betaine group, showing more significant improvement of hepatic steatosis and inflammation than the low dose betaine group. alcohol feeding model<sup>[25,26]</sup>. Third, intestinal sterilization with antibiotics and displacement of gram-negative

bacteria with lactobacillus treatment prevents alcohol-induced liver injury<sup>[27,28]</sup>. Alcohol can increase the levels of circulating endotoxin in the portal blood. Once bound to LPS-binding protein (LBP), this complex is formed with the endotoxin receptor and CD14, activates Kupffer cells *via* TLR4<sup>[29]</sup>. Kupffer cell activation leads to the up-regulation of key cytokines, including TNF- $\alpha$ . Besides direct toxic effects on hepatocytes, TNF- $\alpha$  can indirectly damage the liver by increasing expression of intercellular adhesion molecule-1 (ICAM-1) on endothelial cells, as well as increasing the production of chemoattractant molecules from inflammatory cells<sup>[30]</sup>.

In this study, we also found that the rats in model group fed with ethanol had a significantly higher expression of TLR4 mRNA and protein than normal rats. Many studies have confirmed that TLR4 is critical for early alcoholic liver injury<sup>[8-11]</sup>. It was shown that a functional mutation in TLR4 prevents early alcohol-induced liver injury in mice. Specifically, no differences in alcohol levels or plasma endotoxin were observed between the groups fed with ethanol. Moreover, a functional mutation in the TLR4 receptor prevents all downstream events, including increased TNF- $\alpha$  expression, inflammation, and liver injury<sup>[11]</sup>. These results support the hypothesis that endotoxin and TLR4 play a major role in the development of early alcohol-induced liver injury. CD14, a glycosylphosphatidylinositol-anchored receptor for LPS, is important in mediating the effects of LPS/LPB complexes on peripheral blood monocytes<sup>[31]</sup>, and it is known that ethanol increases expression of CD14 on Kupffer cells<sup>[32]</sup>. However, CD14 lacks the ability to transduce LPS-induced cytoplasmic signals across a cell membrane, because it is not a transmembrane protein<sup>[33]</sup>. It had been suggested that LPS-induced inflammatory cell activation *via* CD14 also requires TLR4, which associates with CD14 on the cell surface, mediating LPS-induced signal transduction<sup>[34]</sup>. The finding that alcoholic liver injury is blocked in both CD14 and TLR4-deficient mice suggests that both of these receptors are necessary to initiate liver damage caused by alcohol<sup>[35]</sup>. Therefore, pharmacologic manipulation and targeting of the endotoxin-CD14/TLR4 signaling pathways could prove to be useful in alcoholic liver disease.

Previous studies have shown that betaine can prevent the alcohol-induced liver injury effectively and improve the liver function, which is related to the inhibition of inflammatory factor, the decrease of lipid peroxidation, the rivalry of endoplasmic reticulum stress and the prevention of apoptosis<sup>[16-21]</sup>. Our study indicates that in rats with alcohol-induced liver injury, betaine feeding can decrease the levels of serum ALT, AST, endotoxin, TNF- $\alpha$ , IFN- $\gamma$  and IL-18, and reduced the expressions of TLR4, and improved the degree of hepatic steatosis and inflammation in liver tissues. It is suggested that betaine can prevent the alcohol-induced liver injury effectively and improve the liver function. The hepatoprotective mechanism of betaine is probably related to the inhibition of endotoxin/TLR4 signaling pathways.

In summary, the results of this study show that the

expression of TLR4 increased significantly in ethanol-fed rats. Betaine administration can inhibit TLR4 expression, which may be one of mechanisms of alcoholic liver injury protected by betaine.

## COMMENTS

### Background

Chronic ethanol ingestion increases gut-derived endotoxin (LPS) in the portal circulation, thereby activating Kupffer cells to produce proinflammatory cytokines and induce liver injury. Toll-like receptor 4 (TLR4), *via* mediating LPS-induced signal transduction, plays a major role in the development of alcohol-induced liver injury. Blocking TLR4 signaling pathways is a therapeutic target of alcoholic liver disease. Many studies reported that betaine can prevent the alcohol-induced liver injury effectively and improve the liver function, but there are few reports about the effects of betaine on TLR4 and endotoxin in alcohol-induced liver injury.

### Research frontiers

Betaine is the only methyl donor, which can replace folate or S-adenosylmethionine to participate in methionine recycling and phosphatidylcholine synthesis in the human body. The hepatoprotective effect and mechanism of betaine is a research hotspot in the area of prevention and cure of alcoholic liver disease. Current studies show that the hepatoprotective mechanism of betaine is related to the inhibition of inflammatory factor, the decrease of lipid peroxidation, the promotion of endoplasmic reticulum stress and the prevention of apoptosis. However, whether the inhibition of TLR4 expression and reduction of endotoxin are involved in hepatoprotective effect of betaine in the alcoholic liver injury remains unclear.

### Innovations and breakthroughs

In the present study, the authors employed the intragastric ethanol-fed rat model, which reproduces the pathological features of early alcohol-induced liver injury, to observe the changes of TLR4 and endotoxin, and to study the protective effect of betaine on alcohol-induced liver injury. The authors found that the ethanol-fed rats had obvious liver injury and hepatic steatosis, higher serum endotoxin and inflammatory factor (TNF- $\alpha$ , IFN- $\gamma$  and IL-18) levels, and significantly higher TLR4 expression, whereas betaine feeding can improve the liver function, reduce the expressions of TLR4 and endotoxin levels, and improve the degree of hepatic steatosis and inflammation in liver tissues.

### Applications

The study results suggest that betaine can prevent the alcohol-induced liver injury effectively, and one of the hepatoprotective mechanisms of betaine is probably related to the inhibition of endotoxin/TLR4 signaling pathways.

### Terminology

Betaine, also known as trimethylglycine, is a chemical compound similar to folic acid and S-adenosylmethionine. These compounds function as "methyl donors" that carry methyl molecules throughout the body, thus helping in the completion of several vital chemical processes. Toll-like receptor 4 (TLR4): TLR4 is a member of the Toll-like receptors (TLRs) family which can recognize pathogen-associated molecular patterns (PAMPs) that are expressed on infectious agents, and mediate the production of cytokines necessary for the development of effective immunity, and thereby plays a fundamental role in pathogen recognition and activation of innate immunity.

### Peer review

This is a well conducted and well written study. The experiments are described in detail, the results are shown nicely and the figures are impressive. This study for the first time shows that Betaine reduces the expression of TLR4 in rats with ethanol-induced liver injury, and proposes that the hepatoprotective mechanism of betaine is secondary to inhibition of endotoxin/TLR4 signaling pathways.

### Abstract

**AIM:** To investigate the relation between *RECK* methylation and clinicopathological characteristics of gastric cancer patients and evaluate the role of *RECK* methylation in peritoneal metastasis of gastric cancer.

**METHODS:** Methylation of *RECK* gene in 40 paired samples of gastric cancer and its corresponding adjacent normal mucosa, lymph nodes and peritoneal irrigation fluid was detected by methylation-specific polymerase chain reaction.

**RESULTS:** Aberrant methylation of *RECK* gene was detected in 27.5% (11/40) of the adjacent normal mucosa samples, in 47.5% (19/40) of gastric cancer samples, in 57.1% (12/21) of the lymph node samples, and in 35% (14/40) of peritoneal irrigation fluid samples, respectively, with a significant difference between the adjacent normal mucosa and lymph node samples ( $P = 0.023$ ). Presence of *RECK* methylation in the primary tumor samples was significantly correlated with tumor invasion ( $P = 0.023$ ). The accuracy of *RECK*

methylation in peritoneal lavage fluid samples for the diagnosis of peritoneal metastasis of gastric cancer was 72.5% (26/40), with a sensitivity of 66.7% (6/9) and a specificity of 74.2% (23/31).

**CONCLUSION:** Aberrant methylation of *RECK* gene may provide useful information for the early diagnosis and treatment of peritoneal metastasis of gastric cancer.

### INTRODUCTION

Gastric cancer seriously threatens the human health worldwide. There is increasing evidence that almost all gastric cancers have epigenetic abnormalities that drive cancer development and progression in collaboration with genetic changes. Aberrant methylation in the promoter CpG island of tumor suppressor genes (*TSG*) where DNA is transcribed into RNA causes its silence. Transcription of DNA is the first major step in decoding DNA into a protein. DNA methylation can inactivate tumor suppressor genes<sup>[1]</sup>. It has been shown that aberrant methylation and diminished expression of DNA in the promoter CpG island occur in a number of tumor-related genes in gastric cancer<sup>[2]</sup>. For example, *RASSF1A*, a candidate tumor suppressor gene, is

hypermethylated in gastric cancer<sup>[3,4]</sup>, *TIMP-3*, a silenced tumor suppressor gene, encodes a protease inhibitor that may inhibit tissue invasion<sup>[5]</sup>, and *RECK*, a newly discovered metastasis suppressor gene, is silenced with aberrant CpG island hypermethylation in some common tumors<sup>[6-8]</sup>. However, the relation between methylation of *RECK* gene and gastric cancer has not been fully studied.

In this study, *RECK* gene methylation was detected in samples of primary tumor tissue and its adjacent normal mucosa, metastatic lymph nodes and peritoneal irrigation fluid by methylation-specific PCR in order to find the relation between *RECK* methylation and clinicopathological characteristics of gastric cancer and the role of *RECK* methylation in diagnosis of peritoneal metastasis of gastric cancer.

## MATERIALS AND METHODS

### Patients

Forty patients including 28 males and 12 females at the age of 34-78 years underwent resection of their gastric cancer at the First Affiliated Hospital of China Medical University from July 2008 to January 2009. All patients did not receive chemotherapy or radiotherapy before operation.

### Samples

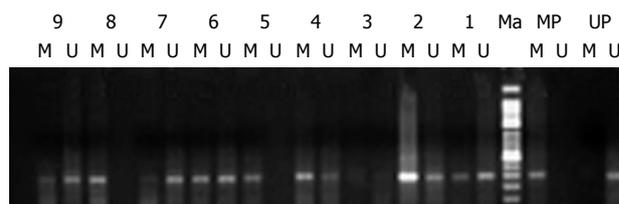

Physiological saline (50 mL) was injected into the Douglas cavity at the beginning of operation and aspirated after gentle stirring, and then peritoneal lavage fluid was collected from the cavity before operation. Half of the peritoneal lavage fluid was examined using conventional cytological methods with Papanicolaou's staining and intact cells were harvested from the other half centrifuged at 2000 r/min for 20 min as previously described<sup>[9,10]</sup> and stored in liquid nitrogen. Samples of primary tumor tissue and its paired adjacent normal mucosa and metastatic lymph nodes were taken immediately after resection of gastric cancer and stored in liquid nitrogen until use. The diagnosis of gastric cancer was made with hematoxylin and eosin (HE) staining. Paired adjacent normal mucosa samples were obtained at least 3 cm from the distal negative surgical margin to confirm the absence of malignancy. Lymph node samples were also stained with HE to confirm the occurrence of metastasis. Differentiation of tumor cells was detected and the tumor was staged following the guidelines of International Union against Cancer (UICC).

### DNA extraction and bisulfite treatment

DNA was extracted from the genome with the hydroxy-benzene-chloroform extraction method, stored at -70°C, and treated with bisulfite to convert the unmethylated cytosine to uracil.

### Methylation-specific PCR

DNA was purified using a Wizard DNA clean-up system

**Figure 1** PCR showing methylation of *RECK* in primary tumor and its paired adjacent normal mucosa and metastatic lymph node samples. M: Methylation; U: Unmethylation; Ma: 50 bp DNA ladder marker; MP: Methylation positive control; UP: Unmethylation positive control; 1-9: Sample number.

(Promega) according to its manufacturer's instructions. A 20  $\mu$ L reaction volume was consisted of 3  $\mu$ L DNA, 2  $\mu$ L 10  $\times$  PCR buffer, 0.8  $\mu$ L dNTP, 0.4  $\mu$ L primers, 0.15  $\mu$ L Tap enzyme, and 13.25  $\mu$ L double-distilled water. PCR conditions were as follows: pre-denaturation at 94°C for 10 min, followed by 40 cycles at 94°C for 30 s, at 54°C for 20 s, at 72°C for 30 s, and a final extension at 72°C for 5 min. Methyltransferase Sss I -treated DNA in peripheral blood cells from healthy people was used as a methylation positive control, untreated DNA served as an unmethylation positive control, and double-distilled water served as a negative control<sup>[4]</sup>. The sequences of primers are as follows: unmethylation primer: UF\_*RECK* (5'-GGTTAGTTTTTTTATTT-TAGTGGTTTGA-3') and UR\_*RECK* (5'-ATTC-CAAAACCTCCCAAAAACA-3'), methylation primer: MF\_*RECK* (5'-GTTAGTTTTTTT-TATTTTAGTGGTTTGA-3') and MR\_*RECK* (5'-TC-CAAAACCTCCCGAAAACGAAAACG-3')<sup>[8]</sup>. The PCR products (205 bp and 201 bp) were subjected to 2.5% agarose gel electrophoresis at 120 V for 40 min and quantified with the Fluor Chen 2.0 system.

### Statistical analysis

Statistical analysis was performed using the SPSS13.0 software package.  $\chi^2$  test and Fisher's exact test were adopted to verify the difference.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Clinicopathological characteristics of gastric cancer patients and *RECK* methylation

The methylation of *RECK* in samples of primary tumor tissue and its paired adjacent normal mucosa and metastatic lymph node was detected by methylation special-PCR (Figure 1).

Methylation of *RECK* was found in 47.5% (19/40) of primary tumor tissue samples, in 27.5% (11/40) of paired adjacent normal mucosa samples, in 57.1% (12/21) of metastatic lymph node samples, respectively. A significant relation was found between adjacent normal mucosa and metastatic lymph node samples. *RECK* methylation was related with tumor invasion ( $P = 0.023$ ) but not with other clinicopathological characteristics of gastric cancer patients such as age,

**Relation between peritoneal metastasis of gastric cancer and *RECK* methylation in peritoneal lavage fluid**

In this study, the promoter of *RECK* gene was hypermethylated in 35% (14/40) of the samples. Among the 14 samples, peritoneal metastasis of gastric cancer was observed in 9. The diagnostic accuracy of *RECK* methylation in peritoneal lavage fluid for peritoneal metastasis of gastric cancer was 72.5%, with a sensitivity of 66.7%, a specificity of 74.2%, a PPV of 47.1%, and a NPV of 95.7% (Table 2).

*RECK* methylation in peritoneal lavage fluid was found in tumors with lymph node metastasis (42.6%) and without lymph node metastasis (26.3%), although the difference between them was not statistically significant (Table 3).

**DISCUSSION**

*RECK* gene was discovered on chromosome region 9p13-p12 by Takahashi *et al*<sup>[11]</sup> in 1998. It encodes a membrane-anchored glucose protein with a relative molecular mass of 110000. *RECK* protein is an important mediator of tissue remodeling to inhibit *MMP-2*, *MMP-9* and *MT1-MMP* after transcription<sup>[12,13]</sup>. *RECK* protein limits tumor invasion and metastasis and angiogenesis through negatively regulated *MMPs*. It has been shown that several common tumors, such as colorectal, breast, and lung carcinomas, are linked to down-regulation of *RECK*<sup>[14-16]</sup>. In these tumors, *RECK* is down-regulated most likely as a result of inhibition at the *Sp1* promoter site<sup>[17]</sup>. It was reported that down-regulation of the *RECK* gene is mediated by promoter methylation which causes

**Table 2** Relation between *RECK* methylation in peritoneal lavage and peritoneal metastasis

its silence, just as other tumor suppressor genes<sup>[7,8,18]</sup>. Epigenetic alteration induced by DNA methyltransferases (DNMT) catalyzing methylation at 5 positions of cytosine ring using S-adenosylmethionine as the donor molecule for the methyl group plays an important role in tumorigenesis and progression<sup>[1]</sup>. The mechanism underlying *RECK* down-regulation appears to be multifactorial, and more studies are required to define its reasons.

In this study, *RECK* methylation was observed in samples of primary tumor tissue and its paired adjacent normal mucosa and metastatic lymph nodes from gastric cancer patients, indicating that *RECK* methylation in primary tumor tissue samples (47.5%) and in metastatic lymph node samples (57.1%) is much higher than that in paired adjacent normal mucosa samples (27.5%) ( $P = 0.023$ ) and that *RECK* methylation is correlated with tumor invasion ( $P = 0.023$ ). No significant difference was found in other factors, including age, tumor size, tumor differentiation, nodal status, Borrmann classification. However, Song *et al*<sup>[19]</sup> found that *RECK* expression is negatively related with lymph node metastasis and tumor stage in gastric cancer patients, which may be due to the small sample size, contamination of normal tissues, technical limitations<sup>[7]</sup>, and down-regulation of *RECK*. Cho *et al*<sup>[7]</sup> showed that *RECK* promoter is methylated in 44% of tumor tissue samples and down-regulation of *RECK* is significantly correlated with promoter methylation ( $P < 0.05$ ), suggesting that *RECK* methylation plays a significant role in inhibiting tumorigenesis and metastasis.

Methylation alteration occurs not only in solid cancer tissues but also in various remote samples from cancer patients. It has been recently reported that DNA methylation can act as a promising biomarker in early diagnosis and prognosis of gastric cancer<sup>[20]</sup>. In our

study, *RECK* methylation in peritoneal lavage fluid was related with peritoneal metastasis of gastric cancer. Peritoneal metastasis of gastric cancer with cytologically positive peritoneal lavage was found in 9 of 14 patients with promoter hypermethylation. *RECK* promoter hypermethylation in peritoneal lavage showed a higher sensitivity (66.7%) for the diagnosis of peritoneal dissemination of gastric cancer than cytology. The reasons why methylation alteration acts as a biomarker are as follows. First, the methylation signal can act as a marker at a low concentration. Second, the methylation pattern and underlying DNA are more stable than RNA level and molecules<sup>[10]</sup>. However, methylation alteration in peritoneal lavage has a lower specificity for the diagnosis of peritoneal dissemination of gastric cancer, which can be explained as follows. First, most cells in peritoneal lavage are mesothelial cells leading to false positive *RECK* methylation. Second, the discrepancy of methylation profile exists sometimes in peritoneal lavage and cancer tissue. In order to solve these problems, serial test, *RECK* methylation and other examinations, such as carcino-embryonic antigen in peritoneal lavage, can be used in the diagnosis of peritoneal dissemination of gastric cancer. In our study, *RECK* methylation in peritoneal lavage fluid was more frequently found in tumors with lymph node metastasis than in tumors without lymph node metastasis, suggesting that *RECK* methylation in peritoneal lavage can be considered a biomarker for predicting peritoneal metastasis of gastric cancer.

In summary, hypermethylation of *RECK* promoter is a common event in gastric cancer patients. *RECK* methylation in peritoneal lavage fluid acts as a biomarker of peritoneal metastasis of gastric cancer. Promoter hypermethylation of *RECK* gene provides a new tool for the prevention and treatment of gastric cancer. Further study is needed on the mechanism underlying *RECK* hypermethylation in gastric cancer patients.

## COMMENTS

### Background

Gastric cancer is a common tumor which seriously threatens the human health worldwide. DNA methylation in the promoter CpG island of tumor suppressor genes is one of the reasons for tumorigenesis and progression. It has been shown that DNA methylation, especially in body fluid, can act as a biomarker for predicting tumor metastasis.

### Research frontiers

*RECK* hypermethylation plays an important role in the epigenetic regulation of gene transcription. There is evidence that DNA promoter hypermethylation can cause transcription repression, contributing to tumorigenesis and progression. It has been recently shown that DNA methylation, especially in body fluid, can act as a biomarker for predicting tumorigenesis and prognosis. However, further study is needed on the mechanism underlying *RECK* hypermethylation.

### Innovations and breakthroughs

*RECK* methylation in gastric cancer and peritoneal lavage fluid was detected, showing that *RECK* methylation plays an important role in diagnosing peritoneal metastasis.

### Applications

Promoter hypermethylation of *RECK* gene provides a new tool for the prevention and treatment of gastric cancer. In addition, *RECK* methylation,

especially in peritoneal lavage fluid, can act as a biomarker for diagnosing peritoneal metastasis.

### Peer review

It is a very interested topic for the readers of *WJG*. The results of this study show that promoter hypermethylation of *RECK* gene provides a new tool for the prevention and treatment of gastric cancer and *RECK* methylation, especially in peritoneal lavage fluid, can act as a biomarker for diagnosing peritoneal metastasis, which are of great value for the diagnosis of gastric cancer.

### Abstract

Attention has recently been focused on biliary papillary tumors as the novel disease entity intraductal papillary neoplasm of the bile duct (IPNB), which consists of papillary proliferation of dysplastic biliary epithelium. As even benign papillary tumors are considered as premalignant, some investigators recommend aggressive surgical therapy for IPNB, although no guidelines are available to manage this disease. Few reports have described long-term follow-up of patients with benign IPNB without radical resection. If patients with IPNB who are treated only with endoscopic procedures are

noted, clinical profiles and alternative therapies other than resection may be recommended. We report the case of a patient who experienced repetitive cholangitis for 10 years and was finally diagnosed with IPNB. Radical resection could not be recommended because of the age of the patient, therefore, endoscopic sphincterotomy was performed. Although an endoscopic retrograde biliary drainage catheter was placed several times for repetitive cholangitis, the patient has done well during follow-up. Our case may offer insights into the natural course and management decisions for the novel disease entity of IPNB.

Successful endoscopic procedures for intraductal papillary neoplasm of the bile duct: A case report. *World J Gastroenterol* 2010; 16(7): 909-913 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i7/909.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i7.909>

### INTRODUCTION

Recently, the novel disease entity of intraductal papillary neoplasm of the bile duct (IPNB) has been proposed to include biliary papillomatosis, which comprises multiple

biliary papillomas composed of papillary proliferation of the dysplastic biliary epithelium, and papillary cholangiocarcinoma<sup>[1]</sup>. IPNB is thought to represent the biliary counterpart of pancreatic intraductal papillary mucinous neoplasm (IPMN-P) and is thus considered premalignant<sup>[1,2]</sup>. The prognosis of patients with IPNB is good when curative surgery is performed, therefore, aggressive resection is recommended as the first choice<sup>[3-5]</sup>. However, little information is available regarding the prognosis of IPNB without curative surgery, as few patients with IPNB who have been followed for several years without surgery have been reported. Here, we present a patient with IPNB who was followed for 10 years without surgical resection, and has done well during the follow-up period. This case indicates a natural course of the novel entity IPNB and alternative therapies for this disease.

## CASE REPORT

A previously healthy 76-year-old woman developed acute cholecystitis caused by gallbladder stones, and cholecystectomy was performed in 1999. Cholangioscopic examination during surgery revealed a bile duct tumor with papillary proliferation protruding into the common bile duct (Figure 1A). The tumor was followed without resection, and a biopsy specimen showed tubular adenoma packed with small glandular or papillary components.

When the patient was admitted for acute cholangitis in 2004, the papillary tumor in the bile duct appeared unchanged. The patient recovered well until she became symptomatic again in September 2007, for which an endoscopic retrograde biliary drainage (ERBD) catheter (FLEXIMA™ Biliary Stent System, Boston Scientific Co., Natick, MA, USA) was placed. In December 2007, the patient developed recurrent cholangitis because of slippage of the ERBD catheter, which was re-inserted into the bile duct. In early January 2008, the ERBD catheter slipped, and the patient was seen for abdominal pain and fever. Laboratory test results included: alkaline phosphatase, 498 U/L (normal: 104-338 U/L);  $\gamma$ -glutamyltranspeptidase, 122 U/L (normal: 18-66 U/L); aspartate aminotransferase, 58 U/L (normal: 10-37 U/L); alanine aminotransferase, 71 U/L (normal: 3-34 U/L); carbohydrate antigen 19-9, 414 U/mL (normal: 0-37 U/mL); white blood cell count, 11 400/mm<sup>3</sup> (normal: 4000-9000/mm<sup>3</sup>); and C-reactive protein, 17.3 mg/dL (normal: 0-0.3 mg/dL).

Endoscopic retrograde cholangiography (ERC) revealed extrahepatic bile duct dilatation, which was more marked than that seen in 1999, and the presence of intraductal polypoid and amorphous filling defects (Figure 1B and C). Magnetic resonance cholangiopancreatography (MRCP) showed cystic lesions connected to the intrahepatic bile duct in the left liver. Cystic lesions were enlarged compared with those in 1999 (Figure 1D and E). Abdominal computed tomography (CT) showed both intrahepatic and extrahepatic bile ducts to be dilated and the presence of a 20-mm mass in the distal common bile duct. In addition, the cystic lesion in the left liver was enlarged compared to that in 1999 (Figure 1F-I). Con-

trast-enhanced harmonic endoscopic ultrasound (CEH-EUS) with Sonazoid® (Daiichi-Sankyo, Tokyo, Japan) showed flow signals inside the whole mass, which revealed the papillary structure (Figure 2A and B). CEH-EUS for biliary diseases was approved by the ethical committee of Dokkyo Medical University, and written informed consent was obtained from the patient before the examination. Intraductal ultrasonography (IDUS) showed a 10-mm papillary mass in the middle bile duct (Figure 2C), and multilobular lesions in the distal bile duct (Figure 2D). Duodenoscopy demonstrated a 10-mm discolored mass on the ampulla of Vater. A biopsy specimen from the discolored mass showed adenoma.

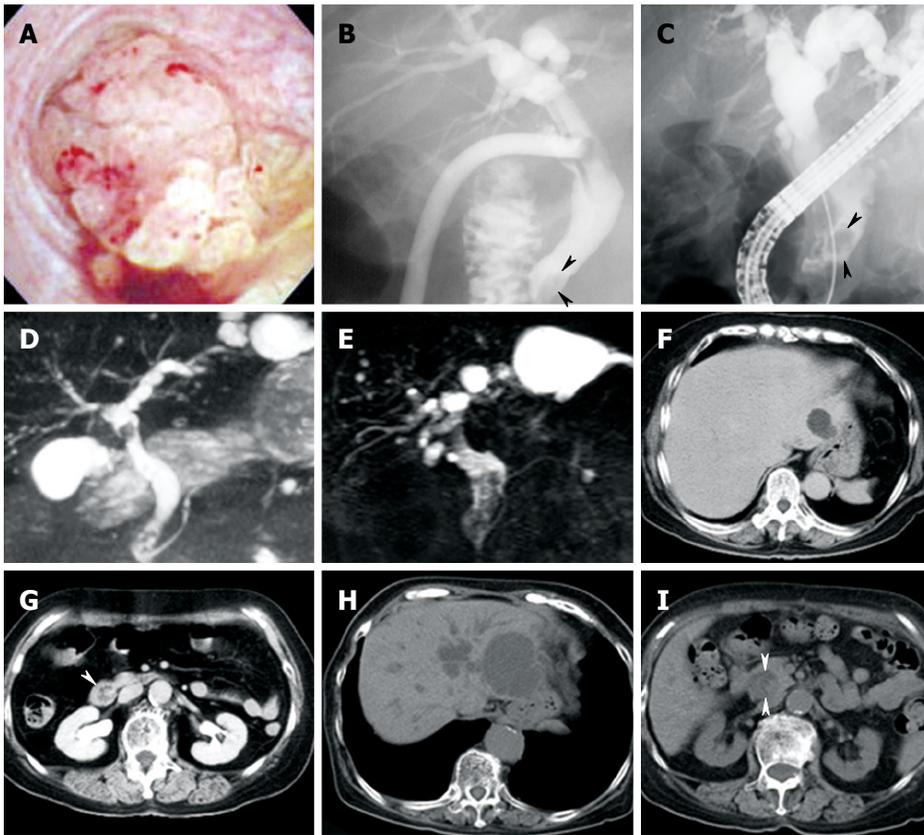

As the patient was diagnosed with cholangitis caused by obstruction of the bile duct by intraductal papillary tumor, endoscopic biliary sphincterotomy (EST) was performed (Figure 3). Radical resection was not recommended because of the age of the patient. Through the orifice of the ampulla of Vater, a soft, bead-like mass was extracted by balloon sweep and a net-type catheter.

Pathological diagnosis of the extracted mass was papillary neoplasia without invasive carcinoma (Figure 4A). Immunohistochemical analysis was performed for mucin core proteins and cytokeratins (CKs). Less than 5% of adenoma cells showed positivity for MUC1 in the apical membrane (Figure 4B). Negative results were obtained for MUC2. About 40%-50% of adenoma cells showed positivity for MUC5AC in the cytoplasm (Figure 4C). Both CK7 and CK20 were negative.

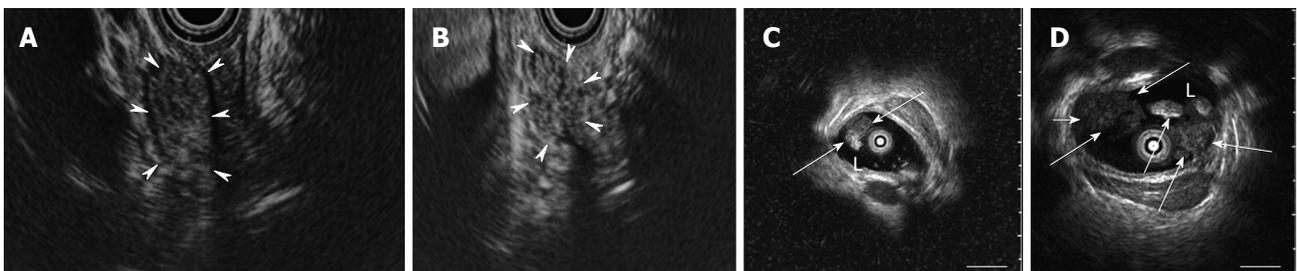

Although the patient was readmitted in May 2008 and in June 2009 with signs of cholangitis, for which no special procedures and placement of ERBD catheter were respectively performed, the patient has done well since EST.

## DISCUSSION

This case is compatible with the novel disease entity of IPNB<sup>[1]</sup>, and biliary papillomatosis can be diagnosed as discussed below. Biliary papilloma is a rare benign neoplasm that consists of papillary proliferation of atypical biliary epithelium along with delicate fibrovascular stalks<sup>[6]</sup>. Biliary papillomatosis is defined as the presence of more than three papillomas at different sites of the biliary tree. Some cholangiocarcinomas that show mainly papillary proliferation in the bile duct are designated as papillary cholangiocarcinoma. Zen *et al*<sup>[1]</sup> have proposed biliary papilloma(tosis) and papillary cholangiocarcinoma with or without mucus hypersecretion as belonging to the novel tumor entity of IPNB. In this case, cholangioscopy and tissue specimens demonstrated that the tumor originated from the biliary epithelium, and various imaging modalities revealed tumors with papillary formation. Two papillary tumors in the extrahepatic bile duct detected by IDUS, and an expanding cystic lesion in the liver contiguous with the intrahepatic bile duct suggested that at least three lesions were present at different sites of the biliary tree. To summarize, this case could be diagnosed as biliary papillomatosis, although whether malignant transformation was present is unknown.

**Figure 1** Images of cholangioscopic examination, ERC, MRCP and abdominal CT. A: Cholangioscopic examination performed in 1999. A multilobulated papillary tumor was seen protruding into the common bile duct; B: ERC performed in 1999; C: ERC performed in 2008. The extrahepatic bile duct became more dilated in 2008 than in 1999. A polypoid filling defect (arrow heads) could be detected in the distal bile duct; D: MRCP in 1999; E: MRCP in 2004. Cystic lesions connected to the intrahepatic bile ducts of the left liver became enlarged in 2004; F and G: Abdominal CT in 1999; H and I: Abdominal CT in 2004. Intra- and extrahepatic bile ducts became dilated in 2004. A mass in the distal bile duct (arrow heads) and a cystic lesion in the left liver were enlarged in 2004, compared with those in 1999.

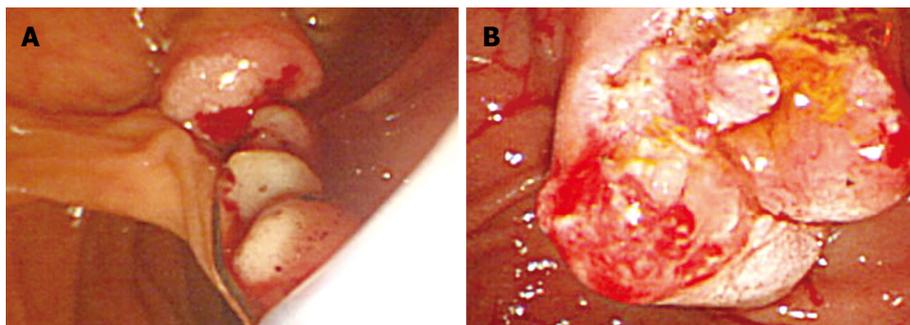

**Figure 2** Images of ultrasonographic studies. A: EUS showed a mixed echoic mass in the distal bile duct (arrow heads); B: Papillary structure of the mass could be apparently observed on CEH-EUS with Sonazoid®; C: IDUS showed a 10-mm papillary mass (arrows) in the middle bile duct; D: In the distal bile duct, multilobular and papillary lesions (arrows) were observed. L: Lumen of the bile duct.

Occasional association with mucin hypersecretion is one of the pathological similarities between IPNB and IPMN-P<sup>[11]</sup>. Zen *et al*<sup>[11]</sup> have performed immunohistochemical analysis for mucin core proteins in patients with IPNB and compared the results with patients with IPMN-P. They have proposed the typical mucin and cytokeratin expression profile of IPNB as MUC1-negative, MUC2-positive, MUC5AC-positive, CDX2-positive, CK7-positive, CK20-positive. According to Shibahara *et al*<sup>[7]</sup>, patients with MUC1-positive expression show poorer survival than those with MUC1-negative expression in papillary cholangiocarcinoma. In addition, the same group has reported that IPMN-P tends to show MUC1-negative and MUC2-positive expression, in contrast to invasive carcinoma, which shows MUC1-positive and MUC2-negative expression<sup>[8]</sup>. The mucin and cytokeratin expression profile in the present case was MUC1-positive, MUC2-negative, MUC5AC-positive, CK7-negative, CK20-negative, which

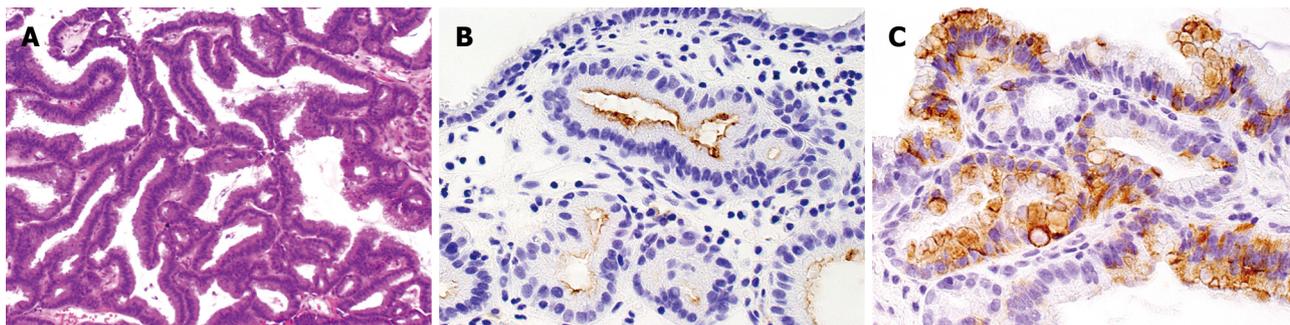

differs from the typical profile reported by Zen *et al*<sup>[11]</sup>. Reasons for this difference might have included: (1) our specimens were taken by biopsy and immunohistochemical analysis was not performed for the entire lesion; (2) even in the original paper by Zen *et al*<sup>[11]</sup>, not all cases showed the typical profile; and (3) MUC1-positivity implies that our case could have malignant potential and needs cautious observation in the future.

Surgical resection is often recommended because of the high malignancy rate, diffuse pattern of disease, and better survival after curative surgery<sup>[3-5]</sup>. Liver transplantation has been suggested as an alternative<sup>[9]</sup>, while many patients with biliary papillomatosis, which is a disease of the elderly (mean age at time of diagnosis, 63 years)<sup>[10]</sup>, would not be eligible for transplantation.

We consider that curative resection is not necessarily reasonable for every patient with IPNB for the following reasons. First, compared with the prognosis of usual

**Figure 3** EST was performed. A: A soft, bead-like mass was extracted through the orifice of the ampulla of Vater after EST; B: Image of the ampulla of Vater after extraction of the mass by balloon sweep and a net-type catheter.

**Table 1** Patients with IPNB treated by endoscopic procedures reported between 2005 and 2009

Author	Gender	Age (yr)	Follow-up after diagnosis of IPNB	Treatment	Reason surgery was not performed	Outcome
Bechmann <i>et al</i> <sup>[10]</sup>	Male	65	10 years	Whipple, right hepatectomy, PDT	Patient's age	Death without cholestasis
Park <i>et al</i> <sup>[11]</sup>	Female	78	3 wk	EST, EPBD	Unknown	Well for a short time
Brauer <i>et al</i> <sup>[12]</sup>	Male	86	1 mo	APC	Diffuse involvement of biliary system, patient's age and comorbidities	Death due to hepatic encephalopathy
Jazrawi <i>et al</i> <sup>[13]</sup>	Male	37	6 mo	Extrahepatic bile duct resection, APC	Patient's refusal	Being evaluated for liver transplantation due to disease progression
Current case	Female	86	11 years	Cholecystectomy, EST, ERBD	Patient's age	Being well irrespective of slow disease progression

EST: Endoscopic sphincterotomy; EPBD: Endoscopic papillary balloon dilatation; Whipple: Pancreaticoduodenectomy; PDT: Photodynamic therapy; APC: Argon plasma coagulation; ERBD: Endoscopic retrograde biliary drainage.

cholangiocellular carcinoma, that of biliary papillomatosis including benign and malignant cases is much better<sup>[2]</sup>. This implies that the prognosis of benign biliary papillomatosis, in particular, may be good enough to be observed without radical resection, although precise information on the clinical course of patients with biliary papillomatosis is currently unclear. Second, the Whipple procedure and hemihepatectomy are the therapies of choice depending on the location and extension of the disease. In addition, malignant change is observed in 40%-50% of cases<sup>[11]</sup>, which means that half of the cases remain benign. If radical resection were recommended for all patients, the therapy might be too invasive for the potentially large population of patients with benign disease.

A search of the English-language literature published in the past 5 years was performed using the MEDLINE

database with keywords of 'biliary papillomatosis' and 'intraductal papillary neoplasm of the bile duct'. Five patients with pathologically benign IPNB<sup>[10-13]</sup>, including the present case, have been followed up using endoscopic procedures (Table 1). Two patients had been followed for > 10 years. Among these five patients, surgery was not considered a viable option because of the age of the patient in three cases, small range of the disease in one case, and for unknown reasons in the other.

The therapy offered to these patients was EST plus additional endoscopic papillary balloon dilatation in two cases, argon plasma coagulation in two cases, and photodynamic therapy (PDT) in one case. Prognosis of these patients was unchanged with occasional cholangitis in two cases, exacerbation in one, death from another disease in one, and unknown in one. Based upon the summaries of

these patients, cases in which malignant transformation cannot be ascertained pathologically could be cautiously followed using endoscopic procedures, and using radical resection as the gold standard is unnecessary. In addition, another patient similar to our own was followed up for 10 years, and treated using endoscopic procedures for recurrent biliary papillomatosis, because there was no surgical option left. As IPNB is considered as the biliary counterpart of IPNM-P<sup>1,7</sup>, a follow-up period of over a decade for some patients with IPNB, as in our case, is not necessarily inappropriate.

To conclude, we encountered a patient with IPNB who was treated only with endoscopic procedures for 10 years, which suggests that some patients with benign IPNB could be followed conservatively without radical resection. Moreover, the present case might partly demonstrate the natural course of patients with the novel disease entity of IPNB.

### Abstract

I read with great interest the article by Gäbele *et al* published in issue 44 of *World J Gastroenterol* 2009. The results of their study indicate that -2518 *Monocyte chemotactic protein-1* (MCP-1) genotype AA is a risk factor for spontaneous bacterial peritonitis in patients with alcoholic cirrhosis. However, there are some items that need to be discussed.

### TO THE EDITOR

I read with great interest the article by Gäbele *et al*<sup>[1]</sup>

published in issue 44 of *World J Gastroenterol* 2009. The article provides important data. The results of their study indicate that the -2518 *Monocyte chemotactic protein-1* (MCP-1) genotype AA is a risk factor for spontaneous bacterial peritonitis (SBP) in patients with alcoholic cirrhosis. The authors suggested that the reduced MCP-1 ascites level may a cause for patients with SBP compared to those with G allele. However, there are some items that need to be discussed. It is debatable to get this conclusion unless ascites MCP-1 levels are measured before and after the treatment of SBP. It has been reported that the MCP-1 level in both sera and ascites is higher in SBP than in non-SBP patients, and decreases after treatment<sup>[2]</sup>. Infection other than SBP data is also missed in that article. For example, urinary tract infection and even asymptomatic bacteriuria may precede SBP. It is not easy to decide if MCP-1 polymorphism causes urinary tract infection and subsequently SBP, because MCP-1 plays a role even in asymptomatic bacteriuria<sup>[3]</sup>. Another issue of my concern is the number of SBP episodes. No data in relation with repeated SBP were provided in the article. Did the authors observe repeated SBP episodes in the patients with genotype AA over a 6-year period between 2001-2007? Did the patients respond to the antibiotic therapy well in a similar time interval?

## Meetings

### Events Calendar 2010

January 25-26  
 Tamilnadu, India  
 International Conference on Medical Negligence and Litigation in Medical Practice

January 25-29  
 Waikoloa, HI, United States  
 Selected Topics in Internal Medicine

January 26-27  
 Dubai, United Arab Emirates  
 2nd Middle East Gastroenterology Conference

January 28-30  
 Hong Kong, China  
 The 1st International Congress on Abdominal Obesity

February 11-13  
 Fort Lauderdale, FL, United States  
 21th Annual International Colorectal Disease Symposium

February 26-28  
 Carolina, United States  
 First Symposium of GI Oncology at The Caribbean

March 04-06  
 Bethesda, MD, United States  
 8th International Symposium on Targeted Anticancer Therapies

March 05-07  
 Peshawar, Pakistan  
 26th Pakistan Society of Gastroenterology & Endoscopy Meeting

March 09-12  
 Brussels, Belgium  
 30th International Symposium on Intensive Care and Emergency Medicine

March 12-14  
 Bhubaneswar, India  
 18th Annual Meeting of Indian National Association for Study of the Liver

March 23-26  
 Cairo, Egypt  
 14th Pan Arab Conference on Diabetes PACD14

March 25-28  
 Beijing, China  
 The 20th Conference of the Asian

Pacific Association for the Study of the Liver

March 27-28  
 San Diego, California, United States  
 25th Annual New Treatments in Chronic Liver Disease

April 07-09  
 Dubai, United Arab Emirates  
 The 6th Emirates Gastroenterology and Hepatology Conference, EGHC 2010

April 14-17  
 Landover, Maryland, United States  
 12th World Congress of Endoscopic Surgery

April 14-18  
 Vienna, Austria  
 The International Liver Congress™ 2010

April 28-May 01  
 Dubrovnik, Croatia  
 3rd Central European Congress of surgery and the 5th Croatian Congress of Surgery

May 01-05  
 New Orleans, LA, United States  
 Digestive Disease Week Annual Meeting

May 06-08  
 Munich, Germany  
 The Power of Programming: International Conference on Developmental Origins of Health and Disease

May 15-19  
 Minneapolis, MN, United States  
 American Society of Colon and Rectal Surgeons Annual Meeting

June 04-06  
 Chicago, IL, United States  
 American Society of Clinical Oncologists Annual Meeting

June 09-12  
 Singapore, Singapore  
 13th International Conference on Emergency Medicine

June 14  
 Kosice, Slovakia  
 Gastro-intestinal Models in the Research of Probiotics and Prebiotics-Scientific Symposium

June 16-19  
 Hong Kong, China  
 ILTS: International Liver Transplantation Society ILTS Annual International Congress

June 20-23  
 Mannheim, Germany  
 16th World Congress for Bronchoesophagology-WCBE

June 25-29  
 Orlando, FL, United States  
 70th ADA Diabetes Scientific Sessions

August 28-31  
 Boston, Massachusetts, United States  
 10th OESO World Congress on Diseases of the Oesophagus 2010

September 10-12  
 Montreal, Canada  
 International Liver Association's Fourth Annual Conference

September 11-12  
 La Jolla, CA, United States  
 New Advances in Inflammatory Bowel Disease

September 12-15  
 Boston, MA, United States  
 ICAAC: Interscience Conference on Antimicrobial Agents and Chemotherapy Annual Meeting

September 16-18  
 Prague, Czech Republic  
 Prague Hepatology Meeting 2010

September 23-26  
 Prague, Czech Republic  
 The 1st World Congress on Controversies in Gastroenterology & Liver Diseases

October 07-09  
 Belgrade, Serbia  
 The 7th Biannual International Symposium of Society of Coloproctology

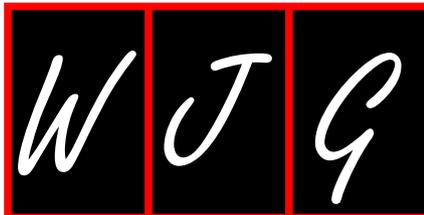

October 15-20  
 San Antonio, TX, United States  
 ACG 2010: American College of Gastroenterology Annual Scientific Meeting

October 23-27  
 Barcelona, Spain  
 18th United European Gastroenterology Week

October 29-November 02  
 Boston, Massachusetts, United States  
 The Liver Meeting® 2010--AASLD's 61st Annual Meeting

November 13-14  
 San Francisco, CA, United States  
 Case-Based Approach to the Management of Inflammatory Bowel Disease

December 02-04  
 San Francisco, CA, United States  
 The Medical Management of HIV/AIDS

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

## Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kbo I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

**ACKNOWLEDGMENTS** I Acknowledgments to reviewers of *World Journal of Gastroenterology*

**APPENDIX** I Meetings  
I-IV Instructions to authors

**AIM AND SCOPE**

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

### Abstract

Computed tomographic colonography (CTC) is a promising emerging technology for imaging of the colon. This concise review discusses the currently available data on CTC technique, test characteristics, acceptance, safety, cost-effectiveness, follow-up strategy, and extracolonic findings. In summary, CTC technique is still evolving, and further research is needed to clarify the role of automated colonic insufflation, smooth-muscle relaxants, intravenous and oral contrast, software rendering, and patient positioning. Currently, full bowel preparation is still required to achieve optimal results. The sensitivity for detecting large polyps (> 1 cm) can be as high as 85%, with specificity of up to 97%. These test characteristics are almost comparable to those of conventional colonoscopy. Patient acceptance of CTC is generally higher than that for colonoscopy, especially in patients who have never undergone either procedure. CTC is generally safe, although uncommon instances of colonic perforation have been documented. In terms of cost-effectiveness, most decision analyses have concluded that CTC would only be cost-effective if it were considerably cheaper than conventional colonoscopy. The proper follow-up strategy for small polyps or incidental extracolonic findings discovered during CTC is still under debate. At present, the exact clinical role of virtual colonoscopy still awaits determination. Even though widespread CTC screening is not available today,

in the future there may eventually be a role for this technology. Technological advances in this area will undoubtedly continue, with multi-detector row CT scanners allowing thinner collimation and higher resolution images. Stool-tagging techniques are likely to evolve and may eventually allow for low-preparation CTC. Perceptual and fatigue-related reading errors can potentially be minimized with the help of computer-aided detection software. Further research will define the exact role of this promising technology in our diagnostic armamentarium.

### INTRODUCTION

First described in 1994<sup>[1]</sup>, virtual colonoscopy, more properly termed computed tomographic colonography (CTC), uses dedicated processing software to generate 2- and 3-D reconstructions of the colon and rectum, based on data obtained by high-definition CT of the abdomen and pelvis. In recent years, there have been rapid advances in this technology, heightening its potential as a less invasive means of visualizing the colon. However, there remain numerous pitfalls to its widespread use. This article gives a succinct review of CTC technique, test characteristics, acceptance, safety and cost-effectiveness, to give an informed understanding of the potential of this promising new imaging modality.

## TECHNIQUE

CTC technique is constantly evolving, and there is still considerable variation depending on institutions. Currently, in most facilities, a full bowel preparation is required for CTC because retained stool cannot be reliably differentiated from polyps. The colon is distended with gas during the scan, as visualization is compromised in underinflated segments. The degree of insufflation may be controlled by the technician, the patient or an automated insufflation device. In most centers, room air is used for colonic distension, but carbon dioxide may be better tolerated because it diffuses through the colonic wall more quickly<sup>[2]</sup>. Smooth-muscle relaxants can theoretically reduce artifacts from colonic motility<sup>[3]</sup>, while the use of intravenous contrast may result in better differentiation of polyps from colonic fluid<sup>[4]</sup>. In addition, oral iodinated contrast can be ingested to change the attenuation of residual colonic fluid; however, studies have not demonstrated any significant improvement in accuracy<sup>[5]</sup>.

During colonography, the abdomen is scanned during one or two breath-holds that last < 2 min. Scans are performed in the craniocaudal direction, with the patient in the prone and supine positions. The incorporation of the prone position has been shown to improve distension of colonic segments and allow for displacement of fluid and stools<sup>[5]</sup>. Studies have suggested that scanning in the supine and left lateral decubitus positions improves visualization even further<sup>[6]</sup>. The best results for CTC require the use of multidetector (4-8 channels) scanners with 1.25-2.5 mm collimation, and reconstruction intervals of 1 mm. Standard helical images of the colon are processed by imaging software using one of three rendering techniques: surface rendering, volume rendering, or perspective rendering. In addition to 2-D axial, coronal and sagittal images, 3-D rendered views of the colon that simulate endoluminal views during colonoscopy can be reproduced. These allow both anterograde and retrograde “fly throughs” of the colon, with the ability to examine the proximal aspect of the haustral folds, a potential blind spot for conventional colonoscopy.

## TEST CHARACTERISTICS

Ever since publication of the initial study on the sensitivity and specificity of CTC compared to conventional colonoscopy<sup>[7]</sup>, numerous studies have reported widely disparate estimates of CTC test performance, probably due to differences in examination techniques, patient populations, reference standards, and examiner experience or skill. Many of the earlier studies used single-row scanners and showed mediocre or poor CTC sensitivity, especially for small polyps. More recent studies have used multi-detector scanners and have adopted more rigorous study designs, and some have reported favorable test performance characteristics. The results of the six largest studies to date in western populations are as follows.

In 2003, Pickhardt *et al*<sup>[8]</sup> presented a landmark study that showed that, under optimal conditions, CTC had comparable sensitivity and specificity to conventional colonoscopy. For detecting large polyps  $\geq 10$  mm in size, the sensitivity of CTC was 92%; for smaller polyps ( $\geq 6$  mm), the sensitivity was 86%. In this study, the investigators achieved excellent results by performing solid-stool tagging with oral barium and opacification of colonic fluid with iodinated contrast, post-procedure “electronic cleansing” with software that digitally removed opacified colonic fluid, and primary reading of 3-D images, with 2-D images used for problem solving. Segmental unblinding was adopted to provide an enhanced gold standard, and indeed CTC detected several lesions that were missed by conventional colonoscopy, as described by the authors in a follow-up study<sup>[9]</sup>. More recently, the multicenter ACRIN study, which featured the largest sample size to date (2531 subjects), reported a sensitivity of 90% and specificity of 86% for large polyps<sup>[10]</sup>, while another study on 1103 Italian patients achieved a sensitivity of 85% and specificity of 87% for advanced neoplasia<sup>[11]</sup>. However, three other large studies have reported less impressive results, with sensitivities of 63%, 55% and 59% for the detection of large polyps ( $\geq 10$  mm)<sup>[12-14]</sup>. Large-scale CTC screening has also been used in Asian populations, with variable degrees of success<sup>[15,16]</sup>.

Four meta-analyses have been published to summarize the available data. An earlier meta-analysis that involved 14 studies reported a pooled sensitivity of 81% for large polyps ( $\geq 10$  mm) and 43% for small polyps ( $\leq 5$  mm)<sup>[17]</sup>, while another meta-analysis of 24 studies reported a sensitivity of 93% for large polyps<sup>[18]</sup>. These two reviews did not include many of the more recent studies. A subsequent, more comprehensive meta-analysis included 33 studies (comprising a total of 6393 patients), and calculated pooled sensitivities ranging from 48% for small polyps ( $\leq 5$  mm) to 85% for large polyps ( $\geq 10$  mm). Specificity was more consistent, between 92% and 97%<sup>[19]</sup>. The most recent meta-analysis included 30 studies and used a summary receiver operating characteristic method for combining data, and reached similar conclusions<sup>[20]</sup>.

Technical factors that can limit the accuracy of CTC include poor bowel preparation, inadequate colonic distension, breath-hold artifacts and suboptimal image resolution. The sigmoid colon is often a problematic area, although diverticulosis does not appear to adversely affect the accuracy of CTC<sup>[21]</sup>. The rectum is another site with high miss rates for polyps because it is difficult to achieve adequate air insufflation there<sup>[2,22]</sup>. Studies have now confirmed that flat adenomatous lesions are common in western patients, and many of these may feature advanced neoplastic histology<sup>[23]</sup>. Such flat lesions may be difficult to recognize on CTC. Perceptual failure, when the polyp is evident on the scan but is not recognized as such by the reader, is thought to be correlated with inadequate training, limited experience and reader fatigue<sup>[24]</sup>.

## PATIENT ACCEPTANCE

At present, it is unclear if patients find CTC preferable to colonoscopy. In general, colonoscopy is perceived as being more invasive. However, colonoscopy offers the advantage of a “one-stop” diagnostic and therapeutic procedure, and its discomfort is mitigated by the use of conscious sedation in most developed countries. We recently presented data on a systematic review and meta-analysis on patient acceptance of CTC compared with conventional colonoscopy<sup>[25]</sup>; we reviewed 19 studies and found that, in general, patients preferred CTC over colonoscopy, although there was significant heterogeneity between studies (risk difference of 24%,  $P < 0.001$ ). Bowel preparation is universally perceived as the worst part of both procedures. There have been efforts to improve the accuracy of low-dose bowel preparation CTC<sup>[26-31]</sup>. If this becomes a commonly available procedure, patients will likely find CTC much more acceptable.

## SAFETY

CTC may not be as free from procedural complications as previously assumed<sup>[32]</sup>. Several cases of CTC-induced perforation have now been reported. These cases mostly have been associated with ulcerative colitis<sup>[33]</sup>, Crohn's disease<sup>[34,35]</sup> or rectosigmoid obstruction<sup>[36]</sup>, but occurrences in patients with normal colons have occurred as well<sup>[37,38]</sup>. Reviews in the United Kingdom and Israel have suggested that the rate of serious complications may be as high as 0.06%-0.08%<sup>[39,40]</sup>, which approaches the complication rates reported for conventional colonoscopy. There also have been concerns about radiation exposure. The surface radiation dose received during CTC is approximately 0.44 rem, which is roughly equivalent to that of two abdominal radiographs<sup>[41]</sup>. Although this is a relatively small dose, multiple repeated scans at regular intervals for surveillance purposes can still lead to cumulative radiation doses that may be of concern<sup>[42]</sup>. Low radiation dose protocols have been investigated<sup>[43]</sup>, but these do not appear to reduce overall radiation exposure in practice<sup>[44]</sup>.

## COST-EFFECTIVENESS

The cost-effectiveness of screening with CTC is uncertain. Several decision analysis computer simulation studies have tried to assess this question<sup>[45-48]</sup>. Sonnenberg has compared the cost-effectiveness of screening CTC and colonoscopy, and has found that to achieve cost-effectiveness similar to colonoscopy, CTC needs to have a compliance rate that is 15%-20% better than colonoscopy, or cost 54% less. Ladabaum's analysis has found that, if the sensitivities of the two tests are equal, conventional colonoscopy is more cost-effective than CTC unless CTC costs are 40% lower than those of colonoscopy<sup>[45]</sup>. The greater the prevalence of polyps in the screened population, the greater the cost advantage of conventional colonoscopy. A Canadian analysis has

concluded that CTC marginally increases mortality, with projected deaths due to missed adenomas exceeding deaths prevented by avoiding perforation<sup>[46]</sup>. The most recent study has found that CTC would only be cost-effective if its cost is  $< 43\%$  of the cost of colonoscopy<sup>[48]</sup>. However, the cost-effectiveness of CTC may be better if the analysis takes into consideration clinically useful extracolonic findings<sup>[49]</sup>. The use of computer-assisted detection may also improve cost-effectiveness<sup>[50]</sup>. Even though studies at expert centers have reported that only 7.9% of patients screened with CTC needed to be referred for colonoscopy<sup>[51]</sup>, in routine clinical practice, the referral rate may be considerably higher (perhaps as high as 15%-20%). Therefore, further studies are needed to investigate this issue, preferably using real cost data in a cohort of prospectively followed patients.

## FOLLOW-UP STRATEGIES

The proper approach to diminutive polyps ( $\leq 5$  mm in size) seen on CTC, in which the risk of cancer is extremely low<sup>[52]</sup>, is also unclear at this time. Referral of all patients with diminutive polyps for follow-up colonoscopy would dramatically increase the cost of CTC screening. The alternative approach, that is, following the polyp using repeat CTC at shorter intervals, would also be expensive and increase radiation exposure. Several decision analyses have simulated CTC screening with non-reporting of diminutive polyps and have reached conflicting conclusions regarding cost-effectiveness, outcomes and safety<sup>[53-56]</sup>. It has been estimated that up to 33% of screening patients with high-risk neoplastic lesions would be interpreted as normal if American College of Radiology guidelines on CTC reporting were followed (these guidelines recommend that polyps  $< 6$  mm be ignored)<sup>[57,58]</sup>. This is because a significant fraction (almost 7%) of relatively small polyps may harbor advanced neoplastic tissue<sup>[59]</sup>. Furthermore, some surveys have indicated that most patients and physicians favor reporting of diminutive adenomas found during CTC<sup>[60]</sup>. It is also of concern that polyp size or location reported at CTC may not be accurate, when compared with pathological assessment or colonoscopic evaluation<sup>[61,62]</sup>.

## EXTRACOLONIC FINDINGS

Extracolonic abnormalities have been found during CTC in up to 50% of patients<sup>[63-65]</sup>. Although incidental detection of previously unsuspected pathology may benefit some patients, others will be subjected to needless anxiety and testing for what will ultimately turn out to be clinically insignificant lesions or false-positive results. Some studies have suggested that this may have significant cost implications<sup>[66,67]</sup>, while others have not found this to be a problem<sup>[68,69]</sup>.

## CONCLUSION

At present, the exact clinical role of virtual colonoscopy

still awaits determination. Two types of patients for whom CTC is clearly useful are those with incomplete colonoscopy due to colonic tortuosity, and those with obstructive cancer that precludes passage of a colonoscope<sup>[70,71]</sup>, although there is some concern that patients with incomplete colonoscopies might sometimes harbor occult perforation<sup>[37]</sup>. Currently, screening CTC is not covered by Medicare or any other public or private health insurance plan. The only exception is a limited program in Wisconsin; review of data from this program has shown similar detection rates of advanced neoplasia for colonoscopic screening *vs* CTC screening<sup>[51]</sup>. Even though widespread CTC screening is not available today, in the future there may eventually be a role for this technology. As a result of its general acceptance by patients, CTC offers the possibility of increasing the overall prevalence of colon cancer screening. One approach would be to offer CTC as the primary screening modality for all patients, followed by same-day colonoscopy if lesions are found<sup>[72]</sup>; alternatively, a risk-stratified strategy using colonoscopy for high-risk patients and CTC for low-risk patients might be more resource-efficient<sup>[73]</sup>. Currently, there appears to be enough multi-detector CT scanning capability in the United States to handle large-scale screening requirements, if needed<sup>[74,75]</sup>. Of course, a prerequisite for CTC screening programs is adequate training of all radiologists; gastroenterologists can also potentially be trained to read CTC results<sup>[76]</sup>. Although decision analyses have suggested that screening CTC can result in a decrease in colonoscopy volume<sup>[77]</sup>, in practice, this has not been observed because the decrease in the number of primary screening colonoscopies is compensated for by an increase in colonoscopies for positive CTCs<sup>[78]</sup>.

Technological advances in this area will undoubtedly continue, with multi-detector row CT scanners allowing thinner collimation and higher resolution images. Stool-tagging techniques are likely to evolve and may eventually allow for low-preparation or preparationless CTC. Perceptual and fatigue-related reading errors potentially can be minimized with the help of computer-aided detection software<sup>[79,80]</sup>. Further research will define the exact role of this promising technology in our diagnostic armamentarium.

### Abstract

Colorectal cancer (CRC) is one of the most common malignancies and causes of cancer deaths throughout the world. Endoscopy has its functional and financial limitations; therefore, chemoprevention might be crucial in reducing the incidence of CRC. Although a number of studies have demonstrated the potential chemopreventive effects of folate (or folic acid), many challenges still remain. The relationship between folate intake and CRC risk is a complex association that might depend on many factors including gender, age, alcohol consumption, and smoking, all of which interfere with folate metabolism. The supplementary dose of fiber, the length of time required to observe the effects, and confounding factors exposed during the trial might also influence these findings. Therefore, more evidence from clinical studies is needed regarding the mechanisms that underlie the actions of bioactive food components in minimizing the risk of CRC.

### INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignancies and causes of cancer deaths in Europe<sup>[1]</sup> and the United States<sup>[2]</sup>. However, there has been a notable rise in the incidence of CRC in Asia over the last few decades<sup>[3]</sup>. Almost all CRCs develop from normal colonic epithelial cells with an adenomatous polyp as an intermediate step. Current efforts are directed towards detection and removal of adenomatous polyps. Therefore, endoscopy has become a part of routine clinical practice. Unfortunately, the polyp often remains indolent for years and is generally discovered only during routine screening. Even after removal, polyps can still lead to recurrence. Endoscopy has its financial limitations; therefore, chemoprevention might be crucial in reducing the incidence of CRC. In this context, chemoprevention refers to the use of chemical compounds to prevent, inhibit, or reverse carcinogenesis. The focus of chemoprevention in CRC is bioactive food components.

Bioactive food components are constituents in commonly consumed foods or dietary supplements, which result in the promotion of better health. It is clear that

bioactive food components can play an important role and influence cancer outcomes<sup>[4]</sup>, as previously demonstrated by cytochrome p450 inhibitors, inducers of cell cycle arrest and apoptosis, and inhibitors of angiogenesis<sup>[5]</sup>. Bioactive food components involved in CRC chemoprevention include folate, fiber, and short-chain fatty acids (SCFA, e.g. butyrate, which is decomposed product of fiber in large intestine), methionine, bilineurine, vitamin D, and calcium. Epigenetic changes play a very important role in the evolution from normal intestinal epithelium to colon cancer<sup>[6]</sup>. The main chemoprevention drugs for epigenetic changes are folate and butyrate<sup>[6]</sup>. This review discusses the effect of folate and fiber on CRC chemoprevention.

## FOLATE

Folate is a water-soluble B vitamin found abundantly in fresh fruits and leafy green vegetables, and provides one-carbon groups in methylation of DNA<sup>[7]</sup>, and contributes to DNA synthesis and replication as well as epigenetic regulation of gene expression<sup>[8]</sup>. Therefore, folate deficiency might impair these processes and cause chromosomal breaks, as well as deleterious alterations in gene expression. For example, folate depletion has been shown to induce the upregulation of p16<sup>INK4A</sup>, p21<sup>WAF1</sup> and p53 tumor suppressor genes, which are involved in DNA damage signaling, inhibition of cell-cycle progression through checkpoints, and apoptosis<sup>[9]</sup>. Folate deficiency also induces genomic instability and aberrant DNA methylation, which might contribute to colorectal carcinogenesis<sup>[10]</sup>. However, whether folate can prevent the occurrence of CRC should take the following into consideration:

Firstly, several epidemiologic and clinical studies have found a relationship between folate deficiency and CRC risk<sup>[7,8,11-13]</sup>. Low levels of folate in the diet or blood have been shown to be associated with a higher risk of CRC<sup>[14,15]</sup>. In contrast, high intake of dietary folate has been inversely associated with the risk of CRC<sup>[8,14]</sup>. Multiple case-control and observational cohort studies suggest a reduction of 30%-40% in CRC risk for participants with high levels of folate intake compared to those with low levels<sup>[11-13]</sup>. According to some data<sup>[16]</sup>, the risk of CRC decreases 11% for every 400 µg of total folate ingested. It has also been shown to elicit various responses that might be beneficial in reducing the risk of CRC, where these effects might be mediated through increased concentrations of colonic mucosal folate<sup>[17]</sup>.

Secondly, although a protective role against CRC has been suggested for high dietary folate intake, epidemiological evidence has not consistently shown a protective effect of high folate intake against CRC<sup>[8,18,19]</sup>. As such, high folate intake might enhance colorectal tumor recurrence and progression<sup>[20-22]</sup>. Animal studies have suggested that high-dose folic acid might promote colorectal tumorigenesis<sup>[23]</sup>, as there is a very close relationship between increases in the incidence of CRC and the remarkable increase in dietary folate intake and blood

folate levels<sup>[22]</sup>. A large, placebo-controlled multicenter trial has shown that high-dose folate might potentially increase the risk of neoplastic transformation<sup>[24]</sup> and one study has reported a significantly increased risk of CRC in subjects with high plasma folate concentrations<sup>[6]</sup>.

Thirdly, in two large prospective cohorts<sup>[25]</sup>, the Nurses' Health Study and Health Professionals Follow-Up Study, higher prediagnostic levels of plasma folate were not associated with an increased risk of CRC-specific or overall mortality. Moreover, a low folate diet induced genomic uracil misincorporation and hypomethylation in Big Blue Mice and uracil DNA glycosylase deficiency (Ung<sup>-/-</sup>) mice, which is insufficient to promote tumor development<sup>[26]</sup>. A multicenter, randomized, double-blind trial has shown that folate supplementation was found to have no effect on adenoma recurrence [relative risk (RR) = 1.07, 95% CI: 0.85-1.34]<sup>[27]</sup>.

Why did above-mentioned differences emerge? Some scholars have suggested that dietary folate supplementation protection against colonic carcinogenesis might depend on the stage of colorectal carcinogenesis, and would protect against carcinogenesis in normal colorectal tissue, but that folate might enhance pre-existing lesions<sup>[23,24,28]</sup>. Findings from several studies indicate that any relationship between folate intake and CRC risk is a complex association that might depend on many factors, including gender, age, alcohol consumption, and smoking, all of which interfere with folate metabolism (Figure 1).

### Gender

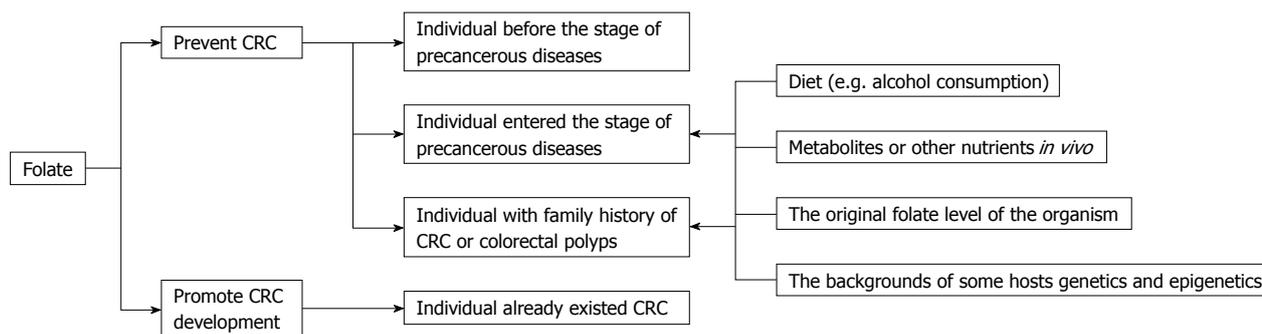

One of the earliest epidemiological papers put forth a hypothesis that men might benefit from folate more than women in colorectal neoplasia. There was a significantly reduced risk for adenomatous polyps in men, but no such association was observed for women<sup>[29]</sup>. Another study, based on the data from the National Health and Nutrition Examination Survey I (NHANES I), revealed that dietary intake of greater than 249 µg/d of folate in men was inversely associated with colon cancer, but not in women<sup>[30]</sup>. However, most investigations with regard to the relationship between colorectal neoplasia and gender revealed that men and women have the same susceptibility<sup>[31,32]</sup>.

### Age

Lower folate intake might have a more pronounced effect on aging colonic mucosa; a folate-depleted diet reduced colonic folate concentrations in older, but not younger rats<sup>[33]</sup>. Age related changes in the metabolism of folate might explain the link between age and CRC risk.

### Alcohol

Alcohol consumption was found to be a risk factor for developing CRC. There might also be an interaction between low folate levels and high alcohol consumption and CRC<sup>[34]</sup>. Folate absorption in the intestine and its availability in the body can be modified by alcohol consumption<sup>[35]</sup>.

**Figure 1** Folate supplementation protection against colorectal cancer (CRC) might depend on the stage of colorectal carcinogenesis and might be influenced by many factors.

### Folate stores

Folate stores might influence tumor responsiveness to chemotherapy. Even under conditions of high systemic folate status, transient localized folate depletion might occur<sup>[36]</sup>, especially in colonic epithelium that demonstrates rapid rates of proliferation<sup>[37]</sup>. Localized inflammation is also known to deplete folate<sup>[38]</sup>. These factors could act together to substantially reduce localized intracellular folate bioavailability.

### Metabolites

Scientists have shown that folate deficiency is significantly more frequently associated with oncogenesis when combined with hyperhomocysteinemia. Patients with folate deficiency associated with hyperhomocysteinemia had 17 times as many carcinogenic lesions as patients with normal homocysteinemia, regardless of the folate status of the disease<sup>[39]</sup>. Inflammatory bowel disease patients with folate deficiency and hyperhomocysteinemia might be associated with increased colorectal carcinogenesis<sup>[39]</sup>. A study in the general population has shown that low folate status with hyperhomocysteinemia increased the risk of recurrence of adenoma<sup>[40]</sup>.

Apart from the above-mentioned factors, distinctions between dietary folate levels and chemical drug effects, a patient's folate levels before treatment, the occurrence of folate supplementation in patients and some genetic and epigenetic discrepancies of organisms might also be causes of variances in these findings.

In summary, we think that folate deficiency makes the body inclined to generate DNA repair defects and heterotypic cells due to abnormal methylation, which develops in the early stage of abnormal cells. Folate supplementation might have preventive effects on the individual before the stage of precancerous diseases, but for those who have entered this stage (such as adenomatous polyposis), the effect is still difficult to determine. Therefore, folate should be included in the discussion of those factors that might promote CRC tumor development. On the other hand, even in high-risk groups with a family history of CRC or colorectal polyps (for example, adenomatous polyposis and Peutz-Jaegher hamartoma syndrome), folate is supplied to prevent CRC. Precancerous diseases are still influenced by a number of factors,

such as diet, metabolites or other nutrients *in vivo* (such as choline and vitamin B12), folate levels of the organism, and the predisposed backgrounds of some host's genetics and epigenetics.

### FIBER

The protective effects of bioactive food components against the development of CRC are due to not only their folate content, but also their fiber content. Fiber has been investigated as a CRC chemopreventive agent in many clinical trials. As such, it is speculated that increased dietary fiber intake can reduce the risk of CRC through a variety of mechanisms<sup>[6,41-43]</sup>. These include dilution or adsorption of fecal potential carcinogens, which potentially inhibit chemically-induced carcinogenesis; decreasing the exposure period of colonic epithelial cells to carcinogens, co-carcinogens, or promoters through reduction of contact time between intraluminal contents and the colonic mucosa; alterations in bile acid metabolism, by binding potential carcinogens like secondary bile acids; increasing the production of SCFA; and promoting a favorable colonic microflora by modifying its metabolic activities and composition.

Studies on the protective role of dietary fiber and its main end product of intestinal microbial fermentation, butyrate, against CRC remain controversial. Butyrate, an SCFA, is an important energy source for intestinal epithelial cells and plays a role in the maintenance of colonic homeostasis<sup>[44]</sup>. It induces potent effects, such as inhibition of inflammation and carcinogenesis of colonic mucosa, reinforcing various components of the colonic defense barrier, decreasing oxidative stress, as well as promotion of cancer cell growth arrest, differentiation, and apoptosis<sup>[45]</sup>.

Several studies have linked higher fiber intake to a reduced risk for CRC<sup>[46,47]</sup>. A multiethnic cohort study<sup>[48]</sup> showed that dietary fiber was inversely associated with a CRC risk after adjustment for age and ethnicity in men (RR = 0.49, 95% CI: 0.41-0.60, highest vs lowest quintile) and women (RR = 0.75, 95% CI: 0.61-0.92). After further adjustment for lifestyle and dietary factors, the inverse association remained significant in men (RR = 0.62, 95% CI: 0.48-0.79), but not in women (RR =

0.88, 95% CI: 0.67-1.14). These authors presumed that this phenomenon is related to women's hormone use. The data from the Japan Collaborative Cohort Study supported the potential protective effects of dietary fiber against CRC, mainly against colon cancer<sup>[49]</sup>. Other studies showed that high fiber and calcium intakes were more markedly associated with a lower risk of CRC in patients carrying the D1822V APC allele [odds ratio (OR): 0.50, 95% CI: 0.27-0.94 for fiber; OR: 0.51, 95% CI: 0.28-0.93 for calcium] than in those without this allele<sup>[50]</sup>.

The role of fiber in the prevention of colorectal diseases remains controversial. There is some evidence that fiber is not effective for primary prevention of CRC<sup>[51,52]</sup>. In a large prospective cohort study, total dietary fiber intake was not associated with CRC risk either<sup>[53]</sup>. Another continued follow-up study failed to show any effect of a low-fat (20% of total energy), high-fiber (18 g/1000 kcal), high-fruit and -vegetable (3.5 servings/1000 kcal) eating pattern on adenoma recurrence even after 8 years of follow-up<sup>[54]</sup>.

When analyzing the differences in the above-mentioned studies, the following aspects should be addressed: (1) Patients with different types of CRCs might be associated with the histone acetylation state of the promoters of tumor-related genes (especially apoptosis-related genes); (2) The findings are different between *in vitro* and *in vivo* experiments, possibly due to the direct administration of butyrate to *in vitro* cells compared to preventing CRC or adenoma with a high-fiber diet *in vivo*. If we use sodium butyrate interference directly in patients, we might discover different effects; (3) The timing of the different interventions will produce different results: in the early stage of DNA damage, butyrate supplementation can induce chromosomes to remain in the open stage, *via* inhibition of histone deacetyltransferase, where it is easy to repair DNA damage. Therefore, the best opportunity for butyrate prevention of CRC might be in the early stages of polyp formation, rather than during the transformation stage of adenomatoid polypus to adenocarcinoma; (4) The status of DNA mismatch repair might affect the results of butyrate prevention of CRC<sup>[55]</sup>; (5) The dose of sodium butyrate suitable for research *in vitro* and *in vivo* might be different<sup>[56]</sup>; (6) The concentration of SCFA formed in the intestinal tract is variable; (7) The complexity of dietary interactions might have an effect; and (8) The duration of the study might also influence the protective role of fiber against CRC<sup>[44]</sup>. Although the effects of increased dietary fiber intake on reducing the risk of CRC has not been unified in studies conducted to date, more studies are needed to increase knowledge in this area.

## CONCLUSION

Although treatment continues to improve, CRC remains a major cause of death throughout the world. A number of studies have demonstrated the potential chemopreventive effect of bioactive food components, but many challenges

still remain. For example, there is very little evidence from clinical studies, such that most of the available information is based on epidemiological and experimental data. The value of folate and fiber has not yet been confirmed in epidemiological and clinical studies; therefore, it cannot be accepted as standard medical practice and cannot replace endoscopic screening. Therefore, we should lubricate the timing of medication, drug dose, interaction mechanisms, and molecular regulatory network of folate and fiber to further advance the field of CRC chemoprevention research. We should then be able to identify compounds and/or molecules using high-throughput techniques, and validate them using the large number of clinical cases resources. Thus we will obtain new individual clinical application programs of CRC chemoprevention to combat this major health problem and minimize the risk of CRC. Future studies and clinical trials must be conducted in a variety of study settings and among different population groups, which will help to elucidate the role of bioactive food components in CRC.

### Abstract

Primary liver cancer is amongst the commonest tumors worldwide, particularly in parts of the developing world, and is increasing in incidence. Over the past three decades, surgical hepatic resection has evolved from a high risk, resource intensive procedure with limited application, to a safe and commonly performed operation with a range of indications. This article reviews the approach to surgical resection for malignancies such as hepatocellular cancer, metastatic liver deposits and neuroendocrine tumors. Survival data after resection is also reviewed, as well as indications for curative resection.

### INTRODUCTION

Over the past 25 years, hepatic resection has evolved from a high risk, resource intensive procedure with limited application, to a safe and commonly performed operation with broad indications. We have seen a dramatic improvement in perioperative outcome, including reductions in mortality, blood loss, transfusion rates, and hospital stay. These improved perioperative results are largely responsible for the emergence of hepatic resection as a viable and effective treatment option for selected patients with liver tumors. Continued advances in imaging technology, along with a heightened awareness of the clinical and tumor-related variables that dictate outcome, have allowed better preoperative assessment of disease extent and improved patient selection. Advances in other areas, such as minimally invasive and ablative techniques, have increased the treatment options and have had some impact on the approach to patients with liver tumors; however resection remains the most effective therapy. The current status of partial hepatectomy is not the result of any randomised trial demonstrating greater efficacy over another therapy and recurrence rates remain high. Further improvements in survival will require more effective systemic agents and as better adjuvant and neo-adjuvant therapies emerge, the results of resection are likely to improve. The indications for its application will then perhaps extend to patients currently considered to have unresectable disease.

### PRIMARY HEPATOCELLULAR CARCINOMA

Worldwide, primary hepatocellular carcinoma (HCC)

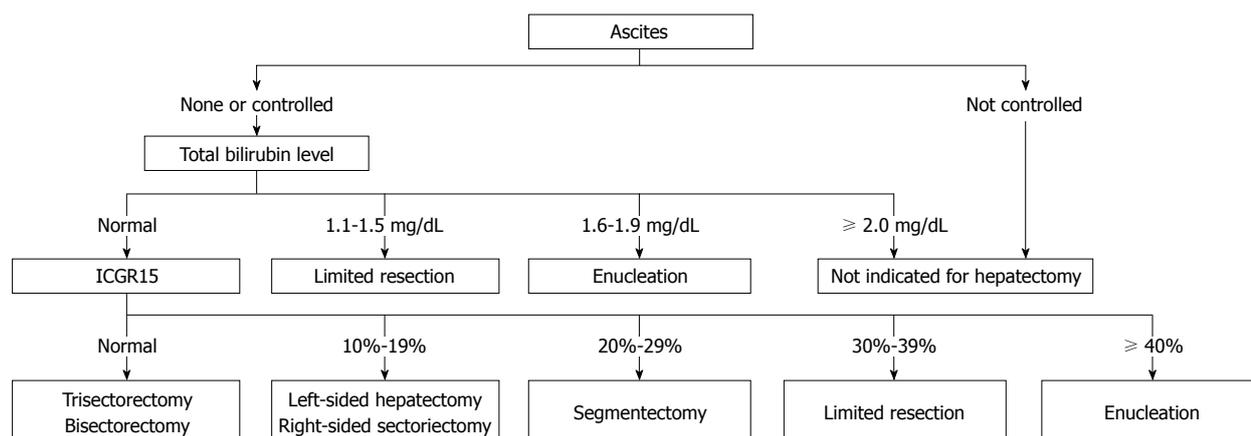

Figure 1 A decision algorithm for the selection of hepatic resection procedure<sup>[8]</sup>.

is among the most frequently encountered solid organ tumors, responsible for approximately 250 000 new cases annually. Previously considered uncommon in western countries, the incidence and mortality related to HCC is increasing, due to the increasing incidence of hepatitis C virus infection. The treatment of HCC, unlike other hepatic malignancies, is often complicated by the coexistence of chronic liver disease and cirrhosis, the presence of which frequently limit treatment options. The only curative treatments are liver resection (LR) or liver transplantation (LT). Improvements in operative technique and postoperative care now mean that a 10% mortality rate for the resection of cirrhotic livers, with up to 30% to 50% 5 years survival rates are to be expected<sup>[11]</sup>.

#### Indications and decision making for surgical resection

When HCC arises in non-cirrhotic liver, it is often diagnosed when the tumor becomes large and symptomatic. In the absence of diffuse bilobar disease, or extra-hepatic metastases, aggressive surgical management is indicated. In this situation, removal of the tumor can be considered as these patients are usually in good general condition and surgical resection tends to involve only tumor mass rather than functional hepatic parenchyma. Although their survival rates are lower than patients with small uninodular tumors, resection is safe and they can expect a 5-year survival rate of up to 39%<sup>[2,3]</sup>.

Most HCCs however occur in patients with chronic liver disease or cirrhosis. This often results in important changes in portal haemodynamics and a reduction in the functional liver parenchyma. The Child-Pugh<sup>[4]</sup> classification is the most useful tool in evaluating cirrhotic patients with impaired liver function. Other sophisticated techniques for determining hepatic reserve, for example the plasma retention rate of indocyanine green at 15 min (ICG15)<sup>[5]</sup>, preoperative portal pressure assessment<sup>[6]</sup>, and 3-dimensional-CT reconstruction of the liver, can be used in deciding whether to proceed with surgery<sup>[7]</sup>.

Resection of HCC is only considered in Child-Pugh A patients. However, Child-Pugh is only used in cirrhosis and liver damage at resection can vary widely from periportal

fibrosis to extensive fibrosis/cirrhosis. Therefore the operating surgeon must modify their technique using as many preoperative investigation results as possible before proceeding. A decision algorithm combining the presence or absence of ascites, total serum bilirubin levels and ICG retention at 15 min has been proposed by Makuuchi *et al*<sup>[8]</sup> (Figure 1). Patients with ICG15s of 20%-30% and more than 30% can only be subjected to one segmentectomy or limited resection, respectively<sup>[9]</sup>.

Other modalities like hepatic venous pressure gradient have also been proposed. Patients with a gradient below 10 mmHg are eligible for resection and those above 10 mmHg are referred for non-operative management. Factors such as tumor size, the depth and distance of the tumor from the major vessels or the presence of intra-hepatic metastases should also be taken into consideration. Patients with large tumors require careful selection. In clinical practice all patients benefit most from multidisciplinary discussion.

LR for HCC in a cirrhotic liver is contraindicated in the presence of severe liver functional impairment such as ascites, jaundice, Child-Pugh B and C, and liver atrophy. In these cases, there is an increased risk of liver decompensation or failure in the postoperative period. Other factors that preclude resection are the presence of portal vein thrombosis (reflecting extensive disease)<sup>[10]</sup>, lymph node metastases, extra-hepatic localizations and intra-hepatic diffuse disease. All these situations render any treatment palliative. The use of laparoscopic ultrasound as a preoperative assessment tool has further reduced LR rates by as much as 63%<sup>[11]</sup>. Table 1 summarizes the current indications for curative resection of HCC.

#### Results after surgical resection

The choice of treatment modality [e.g. hepatic resection, LT, or radiofrequency ablation (RFA)] can influence patient survival and this in turn is governed by the size and distribution of lesions. Improved patient selection leads to optimal survival rates for each subgroup of patients with HCC. The available literature is broadly divided into small ( $\leq 5$  cm) or 3 or less tumors ( $\leq 3$  cm)

**Table 1** Indication for curative resection of HCC

HCC: Hepatocellular carcinoma.

and large ( $\geq$  5 cm) tumors, all with differing survival rates. Large multicentre series involving Asia, Europe, USA and France<sup>[3,12,13]</sup>, have demonstrated 3-, 5- and 10-year hepatic resection survival rates of 38%-64%, 36%-41%, and 14%, respectively. Individual centres have published series of 5-year survival rates of 40%-50%<sup>[1,14-19]</sup>, and 10-year survival rates of 8%-17%<sup>[16,20,21]</sup>. Table 2 shows the survival data for patients who underwent hepatic resection for HCC from large published series. When resecting early HCC, Poon *et al.*<sup>[22]</sup> achieved a 70% 5-year survival rate and a 60% 5-year recurrence rate. Furthermore, when this cohort of patients experienced recurrence, 79% of them were eligible for salvage transplantation. It is important to note the perioperative mortality rates in hepatectomy patients range between 0.9%-6.4% and recurrence rates between 30%-55% (intra-hepatic recurrence being the most likely site)<sup>[3,13-16,20,23]</sup>.

### Disease recurrence

Microscopic vascular invasion, fibrosis and underlying cirrhosis have been consistently shown to be independent risk factors for decreased overall long-term survival in multivariate analysis<sup>[3,13-16,21,24,25]</sup>. Multiplicity and size of tumors ( $>$  5 cm) are also negative predictors of prognosis. Margin positivity is associated with local recurrence<sup>[1,26]</sup>, however the absolute width of the margin is less important<sup>[27,28]</sup>. Poon *et al.*<sup>[22]</sup> also demonstrated in their paper that recurrence is most likely disseminated by both the portal venous system for intra-hepatic metastases and multicentric carcinogenesis for multi-segmental metastases, while proportionally less recurrence occurs locally. Therefore the authors propose that the presence of venous invasion and satellite nodules, factors that are incorporated in the pathological tumor-node-metastasis staging system, are more important predictors of recurrence irrespective of the margin status<sup>[29]</sup>. A surgeon's technique and the extent of tissue dissection has been shown to indirectly influence survival, as blood transfusion perioperatively predicts poor prognosis in multivariate analysis<sup>[18,24,29]</sup>. With regards to percutaneous RFA, the preliminary results from a recent nationwide study involving 7185 patients from multiple centres in Japan showed that surgical resection was a significant negative factor for recurrence as compared with RFA, however there was no difference in the overall survival rates<sup>[30]</sup>.

### LT

LT can have the benefit of being curative and treating any underlying cirrhosis, however there are many contraindications to transplantation, as well as a worldwide shortage of suitable allografts. Comparing orthotopic LT to LR in cirrhotic patients with small ( $\leq$  3 cm) uninodular or binodular metastasis, the 3-year disease-free survival rate without recurrence is significantly better in the transplant group (83% *vs* 18%)<sup>[31]</sup>. Mazzaferro *et al.*<sup>[32]</sup> first published their results in 1996 where the 4-year survival rates post-transplant in selected patients with isolated small tumors ( $\leq$  5 cm) or two to three nodules  $\leq$  3 cm were up to 75%. Since their landmark publication, LT is universally accepted as the first line treatment for patients who fulfil the Milan criteria.

The use of LR in the presence of cirrhosis is limited because of significant morbidity, which could be related to the laparotomy itself<sup>[33]</sup>, and high recurrence rates. However, LT is also limited due to the shortage of organ donors<sup>[34]</sup> and the resultant risk of tumor progression with increased waiting times<sup>[33]</sup>. Controversy still remains over the treatment of patients with preserved liver function who could tolerate LT or resection. Therefore the use of primary resection followed by salvage transplantation (if required) for intrahepatic HCC recurrence has been proposed as an acceptable approach in such patients<sup>[34,35]</sup>. Some authors recommend the use of other neoadjuvant antitumoral procedures during the waiting time to LT, such as transarterial chemoembolization, percutaneous RFA or percutaneous ethanol injection. Whilst effective, they have the disadvantage of not being able to perform a full pathological examination of a surgical specimen, which allows assessment of prognostic factors of HCC (i.e. microvascular invasion, satellite nodules, tumor differentiation and molecular markers of recurrence), thereby further helping the transplant decision-making process<sup>[33]</sup>.

## SECONDARY TUMORS

### Colorectal liver metastases (CLM)

Stage IV colorectal carcinoma is by far the most common indication for hepatic resection in Western countries. However no single consensus exists on the indications for surgical resection. Surgery is the treatment of choice in patients with colorectal cancer, but over half of all patients develop liver metastases. It has been postulated that because haematogenous spread usually occurs in a stepwise fashion, initially to the liver, with subsequent intra-hepatic spread *via* the portal vein and further spread to the systemic circulation, surgical resection of isolated hepatic metastases from colorectal cancer may be curative. The natural history of colorectal cancer is variable, with a median survival without treatment of only 8 mo. Patients with isolated metastases have a better prognosis than those with more extensive metastatic disease<sup>[36]</sup>. However few patients with liver only metastases survive for 5 years. Around 20%-30% of these are potentially

DFS: Disease free survival; NA: Not available.

resectable and the selection criteria for surgery are constantly changing<sup>[37,38]</sup>. Chemotherapy is palliative when used alone, but can prolong survival in inoperable disease. Used in combination with surgery it may prolong time to recurrence after resection or downsize to resectability in patients previously judged inoperable<sup>[39]</sup>. With regards to percutaneous RFA, a recent systematic review by Stang *et al*<sup>[40]</sup> found that RFA of unresectable CLM is a useful adjunct to surgery and/or chemotherapy and can prolong time without toxicity and survival.

Surgical resection of hepatic metastases can be undertaken safely in the majority of patients and the median postoperative 30 d mortality is 2.8%<sup>[26]</sup>. The most common reported causes of postoperative death include hepatic failure, postoperative haemorrhage and sepsis.

The outcome of resection of colorectal liver metastasis is encouraging, with postoperative mortality in large series ranging from 0.2%-3.5%<sup>[26,41-45]</sup>. The 1-year overall survival rate is 89%-97%<sup>[26,42,46]</sup>; while the 5-year survival rate ranges between 15%-50%<sup>[26,41,45,47-49]</sup>. Five years disease free survival rates are on average 19% in radically resected patients. Some studies with longer follow-up periods report a 10-year overall survival rate of 17%-33%<sup>[14,44,45]</sup>. The rate of complication in individual studies is more variable, ranging from 3%-17%<sup>[42,45]</sup>. The recurrence rate with 5-year period of follow-up is consistent around 62%-74%<sup>[44,50]</sup>.

The factors which are predictive of poor prognosis include poor tumor differentiation<sup>[44,45,50]</sup>, increasing size and number of metastases<sup>[26,42,44,50]</sup>, Dukes' staging, presence of extra-hepatic metastasis (other than resectable pulmonary metastasis), elevated carcinoembryonic antigen (CEA) levels and positive nodal status. Fong *et al*<sup>[26]</sup> summarised the above with the Clinical Risk Score which includes 5 risk factors (size of metastasis > 5 cm, extra-hepatic metastasis, disease-free interval between primary tumor to diagnosis of metastasis, multiple metastasis

and CEA level greater than 200 ng/mL). A score of 5 is predictive of poor prognosis, whilst patients with 0-2 are more likely to have favourable outcomes. Gomez *et al*<sup>[50]</sup> also recently demonstrated in their paper that increased inflammatory markers and number of blood transfusions perioperatively are related to the early development of recurrence. Table 2 shows the survival data for patients who underwent hepatic resection for CLM from published large series.

### Neuroendocrine tumors (NET)

Cytoreductive therapy is effective in the management of metastatic NET to the liver, independent of their functioning status<sup>[51]</sup>. In functioning tumors, clinical endocrinopathies are relieved in most patients and this response usually lasts for several months. Major morbidity and mortality are not greater than the average complication rate for resection for non-neuroendocrine metastatic tumors at major centres; therefore surgical outcomes appear to justify operative intervention<sup>[51]</sup>. Patients whose primary tumor can be controlled, whose metastases outside the liver are limited, and who have a good performance status are candidates for resection. Directed anatomic and non-anatomic hepatic resections and RFA therapy can effectively reduce the amount of active disease, thereby improving hormone control and patient survival, with very low morbidity and mortality in comparison to other tumor types<sup>[51]</sup>. A full symptomatic response in up to 90% patients with a median overall survival of 48 mo adds many months of symptom-free survival to the lives of most patients. In many patients undergoing a major hepatic resection, concurrent resection of the primary tumor is also performed<sup>[51]</sup>. Resection in selected patients is not more complicated or risky than resection for other metastatic tumors. In addition, endocrinopathies do not increase anaesthetic or operative risk in selected populations. The best post-operative

results are the product of managing these patients over time, becoming familiar with their clinical syndromes and ensuring the early detection of both local recurrence and the development of resistant disease.

After complete removal of the primary tumor, LT seems to be very attractive as a means of eradicating metastatic NET. Unfortunately, there is very sparse evidence for any benefit of LT over LR. Current indications for LT include those with unresectable disease, no extrahepatic or resectable extrahepatic metastatic spread, progressive hepatic metastases, refractory symptoms to medical therapy or interventional procedures, and deposits exhibiting Ki-67 levels  $< 10\%$ <sup>[52,53]</sup>. It has also been suggested that LT should be reserved for patients with non-carcinoid (i.e. non-serotonin secreting) tumors, as the overall survival may be better than LR alone. In a recent article by Frilling *et al.*<sup>[53]</sup>, the 5-year tumor free survival was 48.3% amongst the 16 Type III (disseminated metastatic spread) patients that they transplanted. They concluded that LT for metastatic NET achieves excellent long-term palliation for highly selected patients<sup>[54]</sup>. Current methods to detect the spread of NET disease that were not readily available in the past, such as magnetic resonance imaging (MRI) and indium-111 pentetreotide (Octreoscan), may decrease the application of LT and allow for a better selection of candidates. The option of LT is still open for improvement and is dependent on organ availability and better staging of the disease.

Metastases from NET are hypervascular thus favouring the application of MRI as the single imaging method. MRI not only evaluates the location and characteristics of the lesions, but also determines their relationship with major vessels and bile ducts. Spiral CT scan has also been used extensively in the past with acceptable results. Indium-111 pentetreotide functions on the basis of somatostatin receptors present in these tumors, but its use has not been established definitely in the work-up of these patients. The best use of indium-111 pentetreotide is in the evaluation of disease beyond the primary and liver locations, for example to exclude bone metastases. Its use therefore will likely affect the preoperative work-up of candidates for operative management.

In general, surgery is appropriate for patients with metastatic NET for the following two reasons: (1) many of them still have the primary tumor in place and resection should be undertaken to avoid acute complications and (2) the addition of adjunctive ablative therapies to surgical resection accomplishes the control of  $\geq 90\%$  of the bulk of the tumor. It is important to note that even when complete resections are performed the recurrence rates for metastatic NET are extremely high (76% *vs* 91% for incomplete resection at 5 years)<sup>[55]</sup>; overall 5-year recurrence rates are up to 88%<sup>[51]</sup>. In practical terms, patients with metastatic NET are seldom cured. The best hope physicians can offer these patients is an extended survival period with minimal endocrine symptoms and decreased requirements of somatostatin analogues<sup>[51]</sup>.

### Non-neuroendocrine, non-colorectal liver metastases (NCNN)

The role of metastasectomy for colorectal and neuroendocrine liver secondaries is well established. Significant palliation and survival have been reported after aggressive surgical resection. The indication for the surgical resection of liver secondaries from NCNN tumors is less well defined. In the past, patients with metastatic liver disease were not considered curable and their life expectancy was limited. However, progress in chemotherapy has spurred the development of surgical strategies to cope with patients presenting with liver secondaries from other primary tumors. Diversity of tumor types and a wide variation in available adjuvant treatment schedules makes it difficult to draw conclusions from the published data, but LRs have been performed for metastatic spread from gastrointestinal stromal tumor, renal, lung, thyroid, parotid haemangiopericytoma, ovarian, cervical, Ampulla of Vater, pancreatic and melanoma primaries to name a few. Survival is directly related to the nature of the primary tumor. Reports to date suggest no survival advantage in resection of liver metastases from oesophageal, stomach, small intestine or pancreas. Indeed, 3 and 5 years survival rates for resected metastatic breast tumors are 53.9% and 24.6%, genitourinary tumors 50.4% and 37.8%, and leiomyosarcoma 63% and 36%, respectively<sup>[56-58]</sup>.

### CONCLUSION

Surgical resection is the mainstay of treatment for primary and secondary liver tumors. With the recent increased use of newer surgical techniques, for example laparoscopic LR using RFA for the transection of the liver parenchyma, morbidity and mortality rates from this surgery have improved. Patients with HCC meeting the local criteria for transplantation should be considered for this. Alternatively, if LT is not an easily accessible option or the patient is ineligible for transplantation, then hepatic resection and/or other antitumor treatments should be considered. The use of cytoreductive surgery in metastatic NET may successfully control symptoms and prolong survival. For patients with CLM, hepatic resection remains the best treatment option. The results for the resection of NCNN metastases are not as encouraging and are dependent on the tumor of origin.

### Abstract

Treatment decisions in autoimmune hepatitis are complicated by the diversity of its clinical presentations, uncertainties about its natural history, evolving opinions regarding treatment end points, varied nature of refractory disease, and plethora of alternative immunosuppressive agents. The goals of this article are to review the difficult treatment decisions and to provide the bases for making sound therapeutic judgments. The English literature on the treatment problems in autoimmune hepatitis were identified by Medline search up to October 2009 and 32 years of personal experience. Autoimmune hepatitis may have an acute severe presentation, mild inflammatory activity, lack autoantibodies, exhibit atypical histological changes (centrilobular zone 3 necrosis or bile duct injury), or have variant features reminiscent of another disease (overlap syndrome). Corticosteroid therapy must be instituted early, applied despite the absence of symptoms, or modified in an individualized fashion. Pursuit of normal liver tests and tissue is the ideal treatment end point, but this objective must be tempered against the risk of side effects. Relapse after treatment withdrawal requires long-term maintenance therapy, preferably with azathioprine. Treatment failure or an incomplete response warrants salvage therapy that can include conventional medications in modified dose or empirical

therapies with calcineurin inhibitors or mycophenolate mofetil. Liver transplantation supersedes empirical drug therapy in decompensated patients. Elderly and pregnant patients warrant treatment modifications. Difficult treatment decisions in autoimmune hepatitis can be simplified by recognizing its diverse manifestations and individualizing treatment, pursuing realistic goals, applying appropriate salvage regimens, and identifying problematic patients early.

### INTRODUCTION

Corticosteroid therapy is established as an effective treatment for autoimmune hepatitis<sup>[1-3]</sup>. It induces clinical, laboratory and histological remission in 80% of patients within 3 years<sup>[2,4]</sup>; the 10- and 20-year life expectancies of treated patients exceed 80%<sup>[5-7]</sup>; hepatic fibrosis is reduced or prevented in 79%<sup>[8,9]</sup>; and variceal hemorrhage, death from hepatic failure, and deteriorations warranting liver transplantation occur in less than 5%<sup>[10,11]</sup>. These successes are tempered by the development of severe treatment-related side effects in 13%<sup>[12,13]</sup>, treatment failure in 9%<sup>[14]</sup>, incomplete response in 13%<sup>[15]</sup>, and relapse after drug withdrawal in 50%-86%<sup>[2,4,16-18]</sup>. Efforts are ongoing to improve results by refining current treatment strategies<sup>[19]</sup> and by introducing different pharmacological agents, such as cyclosporine<sup>[20]</sup>, tacrolimus<sup>[21,22]</sup>, mycophenolate mofetil<sup>[23,24]</sup> and budesonide<sup>[25,26]</sup>. The benefits

from these efforts have not been fully realized, and the management algorithm is still in flux.

Treatment decisions in autoimmune hepatitis are complicated by the diversity of clinical presentations associated with the disease, uncertainties about the natural history of asymptomatic mild disease, evolving recommendations regarding treatment end points, varied nature of individuals refractory to or intolerant of the conventional therapy, and plethora of alternative immunosuppressive agents<sup>[27-30]</sup>. Diagnostic and therapeutic guidelines have been promulgated to codify the recognition and treatment of autoimmune hepatitis, but clinical judgment remains the essence of successful therapy<sup>[31,32]</sup>. Decisions to start or withdraw medication, manage a sluggish or absent response, and institute unfamiliar empirical therapy in problematic patients are difficult because they are highly individualized and not amenable to rigorous study.

In this review, the difficult treatment decisions in autoimmune hepatitis are described and the bases for making a sound judgment are provided. Treatment decisions can be guided but not codified, and every management strategy must be directed by the status of the individual patient.

## DECISION TO TREAT ACUTE SEVERE (FULMINANT) HEPATITIS WITH CORTICOSTEROIDS

Autoimmune hepatitis can have an acute severe (fulminant) presentation<sup>[33-36]</sup>, or a previously indolent chronic disease can exacerbate spontaneously and appear acute<sup>[37]</sup>. The diagnosis can be unsuspected if this propensity is not realized. Furthermore, the presence of centrilobular zone 3 necrosis on histological examination can suggest an acute viral or toxic injury<sup>[38-42]</sup>. The centrilobular zone 3 pattern can transform to the classical pattern of interface hepatitis as the disease evolves<sup>[39]</sup>, and its presence early in the disease should not delay the diagnosis or therapy.

The key to recognizing acute severe autoimmune hepatitis is to remember it in the differential diagnosis and to make the designation after viral, drug-induced, toxic and metabolic disorders have been systematically excluded<sup>[31,43]</sup>. The diagnosis may include atypical histological findings (centrilobular zone 3 necrosis) or absent classical features (autoantibodies or hypergammaglobulinemia), but it is justified by the completeness of the exclusion effort<sup>[44,45]</sup>.

Autoantibodies and hypergammaglobulinemia, especially increased serum IgG level, support the diagnosis of autoimmune hepatitis, but they are neither specific nor required for the diagnosis<sup>[31,45,46]</sup>. Seronegative patients can respond well to corticosteroid treatment, and those with severe presentations should not be denied this potential benefit because of their non-classical phenotype<sup>[47-50]</sup>. Confidence in the diagnosis can be enhanced

**Table 1** Conventional corticosteroid treatment regimens for autoimmune hepatitis<sup>[19,54,55]</sup>

Schedule	Monotherapy	Combination therapy	
	Prednisone only <sup>1</sup> (mg/d)	Prednisone <sup>1</sup> (mg/d)	Azathioprine (mg/d)
Induction period			
Week 1	60	30	50
Week 2	40	20	50
Week 3	30	15	50
Week 4	30	15	50
Maintenance period			
Fixed doses until end point	20	10	50
Conditions that favor each regimen	Cytopenia (severe) Absent thiopurine methyltransferase activity Pregnancy Malignancy (active) Short trial ( $\leq 6$ mo) Acute severe onset	Elderly/postmenopausal state Osteoporosis Brittle diabetes Obesity Acne Emotional instability/psychosis Hypertension Prolonged therapy ( $\geq 6$ mo)	

<sup>1</sup>Prednisolone can be used in place of prednisone in equivalent doses.

by applying the comprehensive scoring system developed by the International Autoimmune Hepatitis Group (IAIHG)<sup>[31]</sup>. Atypical or absent classical features can be assessed in the context of other findings that may have sufficient strength to carry the diagnosis<sup>[46]</sup>.

Corticosteroid therapy is effective in 36%-100% of patients with acute severe (fulminant) presentations<sup>[35,51,52]</sup>, and this range of response may reflect in part the timeliness of treatment<sup>[53]</sup> (Table 1). The response to corticosteroid therapy should be evident quickly<sup>[56,57]</sup>, and the failure of any laboratory test of liver inflammation to improve within 2 wk in a patient with acute severe disease is a justification for considering liver transplantation<sup>[53,56]</sup> (Table 2).

There are no clinical or laboratory features prior to therapy that reliably predict a treatment non-response<sup>[56]</sup>, but the model of end stage liver disease (MELD) can be useful in assessing risk and quantifying improvement or deterioration. MELD scores  $\geq 12$  points at presentation have a sensitivity of 97% and specificity of 68% for treatment failure in autoimmune hepatitis, and patients with such scores warrant close scrutiny<sup>[14]</sup>. Infection has been associated with protracted corticosteroid therapy in patients with acute severe (fulminant) presentations<sup>[52]</sup>, and treatment should be discontinued promptly whenever there is evidence that the disease is worsening or if there has been no improvement after 2 wk<sup>[53,56]</sup>.

## DECISION TO TREAT ASYMPTOMATIC MILD AUTOIMMUNE HEPATITIS

Autoimmune hepatitis may be asymptomatic in 25%-34% of patients<sup>[66,67]</sup>, and 25%-85% of individuals can be clas-

**Table 2** Difficult treatment decisions before starting conventional corticosteroid therapy

Problem	Response
Acute severe (fulminant) presentation	Prompt institution of conventional corticosteroid therapy with prednisone monotherapy <sup>[44,51-53]</sup> Azathioprine, 50 mg/d, can be added later if treatment is to be continued for $\geq 3$ mo <sup>[55]</sup> Liver transplantation evaluation if laboratory indices worsen at any time during treatment, especially progressive hyperbilirubinemia, or no improvement after 2 wk <sup>[56]</sup>
Asymptomatic mild or mild disease	Institute conventional corticosteroid therapy with prednisone in combination with azathioprine <sup>[58,55]</sup> Consider empirical treatment with budesonide, 3 mg <i>tid</i> , in conjunction with azathioprine, 50 mg/d, if preexistent osteopenia, diabetes, hypertension, obesity, or emotional instability <sup>[25,26]</sup>
Autoantibody-negativity	Exclude viral, drug, toxic, metabolic causes and celiac disease <sup>[31,43]</sup> Apply codified scoring criteria of IAIHG for probable or definite diagnosis <sup>[31,46]</sup> Institute conventional corticosteroid therapy with prednisone in combination with azathioprine or a higher dose of prednisone alone <sup>[19,47-50]</sup>
Overlap syndromes	Conventional corticosteroid therapy alone or in combination with azathioprine if serum alkaline phosphatase level $< 2$ times ULN <sup>[59,62]</sup> Add ursodeoxycholic acid, 13-15 mg/kg per day, to corticosteroid regimen if serum alkaline phosphatase level $\geq 2$ times ULN <sup>[60,63]</sup> Consider ursodeoxycholic acid alone, 13-15 mg/kg per day, if predominant features of PBC with minimal features of autoimmune hepatitis <sup>[64,65]</sup>

IAIHG: International Autoimmune Hepatitis Group; ULN: Upper limit of the normal.

sified as having mild disease by clinical, laboratory and histological findings<sup>[58,68,69]</sup>. Asymptomatic patients are typically men, and they have lower serum aspartate aminotransferase (AST) levels at presentation than symptomatic patients<sup>[66]</sup>. Histological features are similar between symptomatic and asymptomatic patients, including the occurrence of cirrhosis, and 26%-70% of asymptomatic patients become symptomatic during follow-up<sup>[66,67]</sup>. The asymptomatic state is meta-stable, and its presence does not exclude the existence of severe liver inflammation at presentation, especially in children, or its development later<sup>[58]</sup>.

The natural history of mild autoimmune hepatitis is unknown, and patients with mild laboratory and histological disease can have 10- and 15-year survivals that exceeds 80% without treatment<sup>[67,70]</sup>. These results are better than those in untreated patients with severe disease, in whom the early mortality is 40%-50%<sup>[1-3]</sup>, and they suggest that some patients with mild autoimmune hepatitis can do well without treatment. The difficulty is in identifying this safe population of patients. The lack of codified treatment guidelines and concerns about treatment-related side effects have resulted in highly individualized and inconsistent management strategies for these patients<sup>[30,58]</sup>.

Untreated mild autoimmune hepatitis does not have a uniformly benign prognosis. Cirrhosis develops in 49% of untreated patients within 15 years<sup>[70]</sup>; liver failure and hepatocellular carcinoma are possible<sup>[58]</sup>; asymptomatic patients frequently become symptomatic<sup>[66,67]</sup>; and 10-year mortality exceeds 10%<sup>[67]</sup>. Spontaneous resolution is possible, but untreated patients with mild autoimmune hepatitis improve less commonly (12% *vs* 63%,  $P = 0.006$ ) and more slowly than treated patients, and they have a lower 10-year survival (67% *vs* 98%,  $P = 0.01$ )<sup>[58]</sup>. The rapidity of improvement rather than the severity of inflammation may be important in preventing disease progression in mild disease, and protection can be most reliably obtained by instituting treatment<sup>[11]</sup>.

Autoimmune hepatitis is by nature a labile and aggressive disease, and phases of mild disease activity can be interspersed with phases of severe activity that can be aggressive<sup>[71,72]</sup>. In this context, the true existence of mild autoimmune hepatitis can be questioned, and treatment criteria based on perceptions of disease severity at any single time point fail to recognize this fluctuating nature. The uncertainty that mild disease remains mild indefinitely favors therapy for all such patients. The urgency rather than the need for treatment may be all that is decreased in these individuals (Table 2).

Until randomized clinical trials are performed that compare treatment against no treatment, the management strategy in patients with mild autoimmune hepatitis should lean toward conventional therapy<sup>[58]</sup> (Table 1). This option eliminates concern regarding unsuspected disease progression, and the treatment response is likely to be rapid and well-tolerated.

## DECISION TO TREAT AUTOANTIBODY-NEGATIVE AUTOIMMUNE HEPATITIS

Autoantibodies in autoimmune hepatitis are signatures of the disease, but they are not pathogenic or requisites for its occurrence<sup>[73]</sup>. They can appear and disappear during the illness<sup>[74]</sup>; they do not correlate closely with laboratory or histological indices of liver inflammation<sup>[74,75]</sup>, and they cannot be used to reliably monitor disease behavior<sup>[74,75]</sup>. Patients may have all the features of autoimmune hepatitis except the autoantibodies, and they can respond as well to corticosteroid therapy as patients with classical autoantibody-positive disease<sup>[47,50]</sup>.

Seronegative individuals may have escaped detection by testing for the conventional autoantibodies, or their serological signature may be undiscovered. These patients may express conventional autoantibodies later in the course of their disease<sup>[74]</sup>, or their diagnosis can be supported by testing for the non-classical autoantibodies, including antibodies to soluble liver antigen (anti-SLA)<sup>[76]</sup> and atypical anti-neutrophil cytoplasmic antibodies<sup>[77]</sup>. Celiac disease must also be excluded since celiac liver disease can have acute, acute severe (fulminant), and chronic presentations that may respond to gluten restriction<sup>[78-81]</sup>. IgA antibodies to tissue transglutaminase or

endomysium should be sought in all seronegative patients with active liver disease of undetermined cause<sup>[82-84]</sup> (Table 2).

Confidence in the diagnosis of autoantibody-negative autoimmune hepatitis can be strengthened by applying the comprehensive scoring system of the IAIHG<sup>[31]</sup>. Seronegative patients can frequently be categorized as having autoimmune hepatitis by this method<sup>[46]</sup>. Once the diagnosis has been made by the exclusion of other conditions that it might resemble, corticosteroid treatment should be started with regimens identical to those used in classical autoimmune hepatitis<sup>[19]</sup> (Table 1). Treatment should not be extended beyond 3 mo if there has been no improvement, and the accuracy of the original diagnosis and the legitimacy of the treatment regimen should be reassessed if the disease worsens despite compliance with the medication schedule.

## DECISION TO TREAT OVERLAP SYNDROMES

Patients with autoimmune hepatitis may have findings that suggest concurrent primary sclerosing cholangitis (PSC)<sup>[85-87]</sup>, primary biliary cirrhosis (PBC)<sup>[59,63,88,89]</sup>, or a cholestatic syndrome in the absence of PSC and PBC<sup>[90,91]</sup>. Overlap syndromes lack codified clinical or pathological definitions, and they do not have a particular etiological agent or distinctive pathogenic mechanism<sup>[92,93]</sup>. The designations are arbitrary and imprecise, and the clinical phenotypes of patients with the same overlap designation are commonly different<sup>[60,92-96]</sup>.

Twenty percent of patients with autoimmune hepatitis have antimitochondrial antibodies (AMAs)<sup>[61,97-100]</sup>; 19% have a disproportionate elevation of the serum alkaline phosphatase level<sup>[61]</sup>; 15% have increased serum levels of IgM<sup>[61]</sup>; 9% have histological features of bile duct injury<sup>[61,91,101,102]</sup>; and 8% have antibodies to the E2 subunit of the pyruvate dehydrogenase complex<sup>[103]</sup>. Any or all of these features suggest an overlap syndrome with PBC.

Similarly, 16% of patients with autoimmune hepatitis have concurrent inflammatory bowel disease<sup>[104,105]</sup>; 10% (adults) to 50% (children) have biliary changes reminiscent of PSC by magnetic resonance imaging or retrograde endoscopic cholangiography<sup>[106,107]</sup>; and 13% fail to respond to corticosteroids<sup>[14]</sup>. Any or all of these features suggest an overlap syndrome with PSC.

The overlap syndrome with PSC may be associated with intrahepatic bile duct changes (small duct PSC)<sup>[108,109]</sup> or extrahepatic bile duct changes with or without intrahepatic findings (classical PSC). Small duct PSC is probably an early stage of classical PSC as protracted follow-up demonstrates late involvement of the extrahepatic bile ducts in many patients<sup>[108,109]</sup>. The occurrence of intrahepatic biliary changes in patients with predominant features of autoimmune hepatitis could represent coincidental bile duct injury associated with the exuberant inflammatory process<sup>[90,91,102]</sup> or an overlap syndrome with small duct PSC or AMA-negative PBC<sup>[110]</sup>.

The overlap syndromes are important because they are common, occur in 18% of adults with autoimmune liver disease, and they can respond poorly to corticosteroid therapy<sup>[62]</sup>. Adults with autoimmune hepatitis, ulcerative colitis and PSC by cholangiography enter remission less frequently during corticosteroid therapy than patients with normal cholangiograms (59% *vs* 94%,  $P < 0.05$ ), and they fail treatment more commonly (41% *vs* 6%,  $P < 0.05$ )<sup>[104]</sup>. The inflammatory bowel disease is not a determinant of response since patients with ulcerative colitis and normal cholangiograms respond as well to corticosteroid therapy as counterparts without inflammatory bowel disease<sup>[104]</sup>. Cholangiography is important to make these distinctions, and it should be performed in all patients with autoimmune hepatitis and inflammatory bowel disease. Forty-two percent of these individuals will have biliary changes of PSC<sup>[104]</sup>.

The variant syndromes should be suspected when patients with autoimmune hepatitis manifest clinical, laboratory or histological features of cholestasis or respond poorly to conventional corticosteroid therapy<sup>[62]</sup>. The serum alkaline phosphatase level is useful in distinguishing classical autoimmune hepatitis from its overlap syndromes with PBC and PSC<sup>[62]</sup>. Serum alkaline phosphatase levels more than fourfold higher than the upper limit of the normal (ULN) do not occur in classical autoimmune hepatitis, and the presence of an abnormality of this degree in a patient with other features of autoimmune hepatitis compels a search for underlying PBC or PSC<sup>[61]</sup>. In children, the serum  $\gamma$  glutamyl transferase (GGT) level is a more reliable indicator of cholestasis than the serum alkaline phosphatase level. Bile duct changes are common in advanced fibrotic liver disease regardless of type, and these biliary distortions detected by magnetic resonance imaging must be distinguished from PSC<sup>[111]</sup>.

Management of the overlap syndromes is empirical and based on the predominant manifestations of the disease (Table 2). Adults with autoimmune hepatitis and features of PBC who have serum alkaline phosphatase levels less than twofold higher than ULN can be treated with corticosteroids<sup>[59,61,62]</sup>. Adults with higher serum alkaline phosphatase levels and those with florid duct lesions on histological examination are candidates for treatment with corticosteroids and ursodeoxycholic acid<sup>[63,112,113]</sup>. Ursodeoxycholic acid alone may be effective in some patients who have predominant features of PBC<sup>[64,65]</sup>.

Adults with autoimmune hepatitis and PSC are commonly given a trial of prednisone and ursodeoxycholic acid<sup>[87]</sup>, but in adults with mainly hepatitis features, corticosteroid therapy alone may be beneficial<sup>[86]</sup>. These patients typically respond less well to treatment than those with mixed features of autoimmune hepatitis and PBC<sup>[62,96]</sup>. Patients with the cholestatic syndrome in the absence of PBC and PSC can be treated with prednisone, ursodeoxycholic acid, or both depending on the serum alkaline phosphatase level<sup>[102]</sup>. Multicentered collaborative

investigations are needed to codify diagnostic criteria and establish confident treatment algorithms for these non-classical syndromes (Table 2).

The diagnosis of an overlap syndrome implies that its clinical phenotype is outside the boundaries of classical disease, but the point at which this occurs is unknown<sup>[94,113]</sup>. The features of the classical autoimmune liver diseases are not disease-specific, and they are commonly shared<sup>[62,88,114,115]</sup>. This commonality of manifestations can cluster in different densities in individual patients and suggest another disease. The overlap syndromes are probably atypical manifestations of a classical disease rather concurrent diseases or a distinctive pathological entity<sup>[92,94,113]</sup>. The diagnostic scoring systems of the IAIHG are not discriminative diagnostic indices, and they cannot be used to declare an overlap syndrome, especially because the definition of such an entity has not been codified<sup>[88,116,117]</sup>.

## DECISION TO STOP TREATMENT

Twenty-one percent of patients with autoimmune hepatitis achieve a sustained long-term remission after initial corticosteroid treatment, and 28% who relapse after drug withdrawal achieve this same result after retreatment<sup>[18]</sup>. Autoimmune hepatitis can enter a sustained inactive state after treatment<sup>[15,18,67,118]</sup>, and this possibility has justified efforts to terminate therapy in all patients despite their well-recognized high frequency of relapse<sup>[17,72]</sup>. Patients who sustain their remission after drug withdrawal have fewer laboratory abnormalities at the time of drug withdrawal than patients who relapse, and the ideal treatment end point is when normal liver tests and tissue have been achieved<sup>[15,119-123]</sup> (Table 3).

The key laboratory indices to monitor are the serum AST, alanine aminotransferase, bilirubin and  $\gamma$ -globulin levels<sup>[121]</sup>, and these tests should be normal prior to drug withdrawal. The ideal histological end points are normal liver architecture or inactive cirrhosis<sup>[15,123]</sup>. Relapse has been associated with residual plasma cell infiltration in the liver tissue despite the absence of other disruptive changes, and the plasma cells may indicate persistence of the immune response<sup>[119,123]</sup>. Plasma cell infiltration in the native liver has also been associated with recurrent autoimmune hepatitis after liver transplantation, and it may signal an active pathogenic process<sup>[134]</sup>.

Liver tissue examination immediately prior to drug withdrawal is the only confident method of confirming an ideal treatment end point, but it should not be performed for at least 3 mo after normalization of the laboratory indices. Histological improvement lags behind clinical and laboratory resolution by 3-8 mo<sup>[2]</sup>, and liver tissue examination before this interval will disclose histological features of interface hepatitis in 55% of instances<sup>[133]</sup>.

The presence of interface hepatitis on the follow-up tissue examination justifies the continuation of therapy for an additional 6 mo before reconsidering drug withdrawal. Another liver tissue examination is not neces-

**Table 3** Difficult treatment decisions during conventional corticosteroid therapy

Problem	Response
Determining treatment end point	Continue conventional therapy until normal serum AST, ALT, bilirubin and $\gamma$ -globulin levels and normal liver tissue or inactive cirrhosis (ideal end point) <sup>[119-121]</sup> Continue conventional therapy until serum AST $\leq$ 2 times ULN, bilirubin and $\gamma$ -globulin levels normal, and portal hepatitis or minimally active cirrhosis (satisfactory end point) <sup>[11,54,55]</sup> Decrease dose of culprit drug or discontinue its use if side effects emerge (drug toxicity end point) <sup>[13,55]</sup> Limit conventional corticosteroid treatment of patients aged $\geq$ 60 yr if an ideal or satisfactory end point has not been achieved $\leq$ 24 mo (incomplete response end point) <sup>[11,19,124,125]</sup>
Relapse after drug withdrawal	Institute original therapy until clinical and laboratory resolution, then increase azathioprine dose to 2 mg/kg per day as dose of prednisone is withdrawn <sup>[126,127]</sup> Continue daily azathioprine in fixed dose indefinitely <sup>[116,127]</sup> Use low dose prednisone ( $\leq$ 10 mg/d) if severe cytopenia (leukocyte counts $<$ $2.5 \times 10^9/L$ or platelet counts $<$ $50 \times 10^9/L$ ) or other azathioprine intolerances <sup>[13,55]</sup> Use low dose prednisone (2.5-5 mg/d) to supplement azathioprine maintenance if abnormal serum AST level <sup>[55,128]</sup>
Treatment failure	Prednisone, 60 mg/d, or prednisone, 30 mg/d, in combination with azathioprine, 150 mg/d, for at least 1 mo, then dose reductions by 10 mg for prednisone and 50 mg for azathioprine each month of laboratory improvement until conventional doses reached <sup>[54,55,129]</sup> Evaluate for liver transplantation if minimal criteria for listing (MELD $\geq$ 15 points) are met <sup>[130-132]</sup>
Incomplete response	Azathioprine (2 mg/kg per day) indefinitely after corticosteroid withdrawal <sup>[54,55,127]</sup> Low-dose prednisone ( $\leq$ 10 mg/d) if azathioprine intolerance <sup>[54,55,128]</sup> Adjustments to maintain serum AST level $\leq$ 3 times ULN <sup>[55,133]</sup>

MELD: Model of end stage liver disease; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase.

sary if the histological findings 6 mo earlier have shown improvement during treatment and the inflammatory changes have been mild. The frequency of relapse after full resolution of the laboratory and histological features can be reduced from 86%<sup>[17]</sup> to 60%<sup>[121]</sup>, and in some instances, as low as 20%<sup>[15]</sup>.

Full resolution of liver tests and tissue is an ideal treatment end point, but it may be achievable in only 40% of patients<sup>[121]</sup>. Relentless pursuit of an ideal end point may be hazardous because the likelihood of a full response must be balanced against the risk of treatment related side effects<sup>[12,13]</sup>. Seventy-seven percent of patients who respond will do so within 24 mo, and patients aged  $\geq$  60 years respond more quickly than adults aged  $\leq$  40 years<sup>[11]</sup>. The rapidity of response may reflect age-related differences in the vigor of the immune response (immune senescence)<sup>[135-137]</sup> or human leukocyte antigen (HLA) status<sup>[138]</sup>. Elderly patients more commonly have

**Table 4** Difficult treatment decisions after conventional corticosteroid therapy

Problem	Response
Empirical salvage drugs	Consider cyclosporine (5-6 mg/kg per day) <sup>[144-150]</sup> or tacrolimus (4 mg <i>bid</i> ) <sup>[21,22,151,152]</sup> if progressive disease on conventional treatment Consider mycophenolate mofetil (1 g <i>bid</i> ) if corticosteroid or azathioprine intolerance <sup>[23,24,153-159]</sup> Consider budesonide (3 mg <i>tid</i> ) as frontline therapy if mild disease or if azathioprine maintenance insufficient after relapse or incomplete response <sup>[25,26]</sup> Complete benefit-risk and cost analyses before use <sup>[160,161]</sup> Empirical trial must not supersede liver transplantation <sup>[55,130,131]</sup>
Liver transplantation	Consider if acute severe (fulminant) presentation unresponsive or worse within 2 wk of conventional treatment <sup>[52,53,56,57]</sup> Consider if treatment dependent $\geq 3$ yr and features of decompensation develop (ascites, encephalopathy or variceal bleeding) <sup>[130]</sup> Consider if failure to conventional therapy and MELD score $\geq 15$ points <sup>[52,131,132]</sup>
Elderly patients (aged $\geq 60$ yr)	Restrict conventional therapy to combination regimen <sup>[124]</sup> Limit initial treatment to $\leq 24$ mo <sup>[125]</sup> Institute azathioprine maintenance therapy (2 mg/kg per day) if initial response is incomplete at 24 mo <sup>[124]</sup> Consider liver transplantation if features of decompensation emerge <sup>[132]</sup>
Pregnant patients	Counsel regarding risks of prematurity and infant mortality <sup>[162-167]</sup> Institute high-risk obstetrical care <sup>[30,162]</sup> Avoid azathioprine if possible <sup>[165,168]</sup> Reduce doses of prednisone to lowest levels to stabilize if not resolve laboratory indices <sup>[169]</sup> Reestablish conventional prednisone doses prior to delivery <sup>[169]</sup> Be alert to post-partum flares <sup>[163,164,169]</sup>

HLA DRB1\*04 than young adults, and this phenotype has been associated with a quicker and better treatment response than other HLA phenotypes<sup>[138-142]</sup>. The inability to induce resolution within 24 mo of therapy portends the development of treatment-related side effects<sup>[13,143]</sup>, and it justifies a change in the end point strategy.

Improvements during the initial 24 mo of therapy may still be sufficient to consider drug withdrawal despite the absence of an ideal response. The disappearance of symptoms, improvement of the serum AST levels to less than twofold greater than ULN, normalization of the serum bilirubin and  $\gamma$ -globulin levels, and histological improvement to portal hepatitis or minimally active cirrhosis have been associated with a sustainable remission for at least 6 mo in 50% of cases, and these improvements during therapy constitute a satisfactory but not ideal end point<sup>[16,72]</sup>. A protracted interval of quiescent disease that requires no therapy is a desirable achievement, and it may be long-term despite the absence of an ideal response. Discontinuation of therapy after achieving satisfactory milestones should be consid-

ered at the 24-mo interval or at any earlier point in the course of treatment if signs of drug intolerance have emerged<sup>[54,143]</sup> (Table 3).

Failure to achieve an ideal or satisfactory response by 24 mo requires reassessment of the individual clinical situation. Ninety-four percent of patients aged  $\geq 60$  years who achieve an ideal or satisfactory end point do so within 24 mo<sup>[11]</sup>, and those elderly patients who have not done so are best treated with a long-term maintenance strategy designed to reduce or eliminate the corticosteroid dose and replace it with azathioprine<sup>[126-128]</sup> (Table 4). Similarly, patients who have shown little improvement during this interval or who are manifesting corticosteroid-related side effects should be treated with long-term azathioprine maintenance<sup>[126,127]</sup> (Table 3).

In contrast, 36% of adults aged  $\leq 40$  years achieve an ideal or satisfactory end point beyond 24 mo of therapy<sup>[11]</sup>, and their original treatment regimen can be maintained for an additional 12 mo if they are drug tolerant. Eighty-one percent of the adults aged  $\leq 40$  years who respond do so within 36 mo<sup>[11]</sup>, and those who do not are candidates for maintenance therapy with azathioprine. Most patients with autoimmune hepatitis do relapse and require long-term maintenance treatment<sup>[4,16,18]</sup>, but the patients who are able to achieve a sustained long-term remission should not be penalized by blanket assignment to continuous initial therapy<sup>[54]</sup>.

## DECISION TO TREAT AFTER RELAPSE

Relapse after drug withdrawal constitutes a recrudescence of inflammatory activity that is typified by the reappearance of interface hepatitis in the liver biopsy specimen<sup>[2]</sup>. Laboratory correlations with histological findings after drug withdrawal have indicated that an increase in the serum AST level to at least threefold higher than ULN is invariably associated with interface hepatitis, and liver tissue examination is not required to diagnose this occurrence<sup>[133]</sup>.

Reinstitution of the original treatment schedule rapidly suppresses the exacerbation, and another clinical, laboratory and histological remission can be achieved<sup>[16]</sup>. Subsequent treatment withdrawal is typically followed by another relapse, and the sequence of retreatment, drug withdrawal, and relapse can be repeated indefinitely<sup>[16]</sup>. With each exacerbation and retreatment, the frequency of achieving a sustained remission decreases (14% after three retreatments)<sup>[16]</sup>; the occurrence of drug-related side effects escalates (70% after two retreatments)<sup>[12]</sup>; and the cumulative frequencies of progression to cirrhosis (38%) and liver failure increase (20%)<sup>[170]</sup>. The optimal time to prevent these outcomes is after the first relapse, and repeated administrations of the original treatment regimen are not advised.

The preferred management of relapse is to institute long-term treatment with azathioprine after the first exacerbation<sup>[126,127]</sup> (Table 3). Clinical and laboratory resolution is achieved with conventional corticosteroid

treatment, and then the dose of prednisone is gradually withdrawn as the dose of azathioprine is increased to 2 mg/kg daily. Azathioprine is then continued indefinitely as a maintenance therapy. Eighty-seven percent of patients are able to sustain clinical and laboratory remission in this fashion over 10 years<sup>[126,127]</sup>. The most common side effect is arthralgia associated with corticosteroid withdrawal (63%). Myelosuppression and lymphopenia occur in 7% and 57% of patients, respectively, and malignancies of diverse cell types and uncertain association with therapy have developed in 8%<sup>[127]</sup>.

Prednisone in low dose can be used instead of azathioprine for long-term maintenance if there is preexistent or evolving cytopenia<sup>[128]</sup> (Table 3). The goal is to maintain the serum AST level below threefold greater than ULN on the least amount of medication. Eighty-seven percent of patients can be managed long-term on  $\leq 10$  mg/d prednisone (median dose, 7.5 mg/d)<sup>[128]</sup>. Observation intervals for up to 149 mo have indicated satisfactory outcomes that have justified continued application of the strategy. Side effects associated with the earlier conventional corticosteroid treatments improve or disappear in 85% of patients; new side effects do not develop; and survival is unaffected when compared with patients who receive standard dose corticosteroid therapy after relapse<sup>[128]</sup>. Recent studies in patients followed for as long as 43 years (median, 13.5 years) have confirmed that the low-dose prednisone strategy can be used effectively and safely in the long term<sup>[171]</sup>.

## DECISION TO TREAT THE ADVERSE RESPONSE

The unsatisfactory responses to initial corticosteroid therapy are treatment failure, incomplete response, and drug toxicity. Each adverse outcome justifies a treatment modification.

### Treatment failure

Treatment failure connotes clinical, laboratory, and histological worsening despite compliance with the original treatment schedule<sup>[129]</sup>. Nine percent of patients fail treatment<sup>[14,15,129]</sup>, and high-dose therapy with prednisone (30 mg/d) in conjunction with azathioprine (150 mg/d) or prednisone alone (60 mg/d) is the preferred initial approach to this problem<sup>[19,23,54,55]</sup> (Table 3). Doses of medication are maintained at this level for 1 mo before improvements in the laboratory tests justify an attempt at dose reduction. The dose of prednisone is reduced by 10 mg and the dose of azathioprine is reduced by 50 mg each month that the serum AST level improves, until the original conventional doses are reached<sup>[19,54,55]</sup>. Seventy percent of patients improve their clinical and laboratory findings within 2 years, but histological resolution is achieved in only 20%<sup>[129]</sup>. Most patients remain on therapy indefinitely. Manifestations of liver decompensation during high-dose therapy (encephalopathy,

ascites, or variceal hemorrhage) are indications for liver transplantation<sup>[130]</sup>.

Thirteen percent of patients have an incomplete response to conventional treatment<sup>[15,19,54,55]</sup>. The clinical, laboratory, and histological findings improve, but the improvements are insufficient to constitute an ideal or satisfactory end point. These patients are unlikely to enter remission if therapy is continued beyond 36 mo ( $< 3\%$  occurrence)<sup>[11,130]</sup>, and they are candidates for indefinite maintenance therapy with azathioprine alone<sup>[55,126,127]</sup> or low-dose prednisone<sup>[128,171]</sup> at that time (Table 3). Treatments should be adjusted to maintain the serum AST level below threefold greater than ULN if possible to reduce the likelihood of an aggressive histological lesion<sup>[133]</sup>.

### Drug toxicity

Drug toxicity compels dose reduction or premature discontinuation of the offending drug in 13% of patients<sup>[13]</sup>. Cytopenia, nausea, emotional lability, hypertension, cosmetic changes, and diabetes are typically dose-related, and these consequences can improve with dose reduction<sup>[53]</sup>. Severe reactions, including psychosis, extreme cytopenia (leukocyte counts  $< 2.5 \times 10^9/L$  or platelet counts  $< 50 \times 10^9/L$ ), and symptomatic osteopenia with or without vertebral compression, justify immediate discontinuation of the offending agent<sup>[55]</sup>. In these patients, the single tolerated drug (prednisone or azathioprine) is continued in adjusted dose to suppress inflammatory activity. Routine phenotyping or genotyping for thiopurine methyltransferase deficiency has not been predictive of azathioprine-induced toxicity at the low doses of azathioprine (50-150 mg/d) used to treat autoimmune hepatitis<sup>[172-174]</sup>. Accordingly, routine screening for this enzyme activity has not been established<sup>[13]</sup>.

## DECISION TO INSTITUTE EMPIRICAL SALVAGE THERAPY

Multiple immunosuppressive agents have emerged mainly from the transplantation arena, and they have site-specific actions of theoretical advantage in the treatment of autoimmune hepatitis<sup>[175-177]</sup>. Many such agents have been used empirically in small, single-institution, treatment trials with some success, and they have been proposed as salvage therapies<sup>[19]</sup>. None has been studied rigorously in controlled or comparative treatment trials; all must be used off-label in autoimmune hepatitis; and none has been incorporated into standard management algorithms. Target populations, dosing schedules, safety profiles and cost analyses are lacking, and the nature of the clinical situation that requires rescue is also unclear<sup>[153,160]</sup>.

The major clinical problems that warrant rescue are worsening of the liver disease despite compliance with the standard corticosteroid regimen (treatment failure) and corticosteroid or azathioprine intolerance (drug

toxicity)<sup>[153]</sup>. In the former instance, the patient must be rescued from the liver disease, and in the latter instance, the patient must be rescued from the treatment. There are conventional corticosteroid- and azathioprine-based strategies for each of these contingencies, but new pharmacological agents have a theoretical basis and burgeoning experience that support their use<sup>[19,55]</sup>.

The calcineurin inhibitor, cyclosporine, and the purine antagonist, mycophenolate mofetil, have generated the most interest (Table 4). Numerous studies have described successful salvage of patients with corticosteroid intolerance or treatment failure by administering cyclosporine<sup>[144-150]</sup>, and similar results in fewer studies have been described with tacrolimus<sup>[21,22,151,152]</sup>. In a representative study, cyclosporine improved the laboratory tests of liver inflammation, reduced the histological activity index, and was well tolerated when administered for 26 wk<sup>[20]</sup>.

Mycophenolate mofetil has induced clinical and laboratory improvements in 39%-84% of patients, and it has allowed discontinuation of corticosteroid treatment in most patients<sup>[23,24,151,154-159]</sup> (Table 4). Non-response or drug intolerance (nausea, vomiting, pancreatitis, rash, alopecia, deep venous thrombosis, and diarrhea) has been described in 34%-78% of patients treated with mycophenolate mofetil, and the potential benefits of this drug must be balanced against these deficiencies. Salvage therapy regardless of the drug is inconsistently effective, potentially toxic, interminable, and expensive<sup>[160]</sup>. Liver transplantation may offer the most reliable form of rescue, and it must be considered carefully as an alternative to empirical new drug therapy in every salvage situation<sup>[130]</sup> (Table 4).

The results of salvage therapy with cyclosporine, tacrolimus or mycophenolate mofetil can be improved by selecting the patients who are most likely to respond. The major reason for treatment failure with these agents is uncertainty about the correct target population and the proper timing, dosing and duration of treatment. Patients may advance quickly beyond drug rescue, and many patients may need a new liver rather than a new drug<sup>[53]</sup>. The ideal candidates for cyclosporine therapy are patients who have failed corticosteroid treatment or been intolerant of the conventional medications and who are still below minimal listing criteria for liver transplantation (MELD scores < 15 points)<sup>[131]</sup>. Transplantation should be considered at the first sign of liver decompensation (usually the development of ascites) during the new drug regimen<sup>[130]</sup> (Table 4).

Children with autoimmune hepatitis and cholangiographic features of sclerosing cholangitis (overlap syndrome) respond poorly to mycophenolate mofetil<sup>[24,178]</sup>, as do adult patients who are failing conventional treatment<sup>[158]</sup>. Therapy with mycophenolate mofetil should be considered mainly in adults with azathioprine intolerance<sup>[158]</sup> and children with non-response to conventional corticosteroid regimens<sup>[24]</sup>. The metabolism of mycophenolate mofetil is independent of the thiopurine methyl-

transferase pathway, and it can be considered in patients with known thiopurine methyltransferase deficiency.

Budesonide has promise as an alternative frontline therapy in treatment-naïve patients with autoimmune hepatitis<sup>[25,179,180]</sup>, but it has been variably successful as a salvage therapy in corticosteroid-treated patients with treatment failure or corticosteroid dependence<sup>[26,181]</sup>. Furthermore, it can be associated with glucocorticoid side effects, particularly in patients with cirrhosis and portosystemic shunting<sup>[161,181]</sup>. Similarly, treatment with ursodeoxycholic acid has not allowed consistent withdrawal from corticosteroid therapy or rescue from treatment failure<sup>[182]</sup>.

## DECISION TO TREAT THE ELDERLY

Twenty percent of adults with autoimmune hepatitis develop the disease after the age of 60 years<sup>[138,183,184]</sup>, and these patients have a greater degree of hepatic fibrosis at presentation than young adults aged < 40 years<sup>[185]</sup> and higher frequencies of ascites<sup>[184]</sup> and cirrhosis<sup>[138]</sup>. These findings suggest that the elderly have aggressive liver disease that is commonly indolent and unsuspected. Symptoms of fatigue and myalgia may be attributed to the aging process; concurrent immune diseases, such as rheumatoid arthritis, may mask the underlying liver disease; and liver test abnormalities may be ascribed to the medications used for other ailments. The proper diagnosis may also trigger concern about side effects associated with corticosteroid therapy and result in reluctance to treat the condition in a standard fashion<sup>[186]</sup>. These concerns are justified, but they do not mitigate the need for treatment or portend a dismal outcome.

The indications for treatment and the initial treatment regimens are the same for the elderly as for young adults<sup>[124]</sup>. The preferred schedule is prednisone in combination with azathioprine (Table 1). Elderly patients enter remission as commonly as young adults (61% *vs* 59%), and they fail treatment less often (5% *vs* 24%,  $P = 0.03$ )<sup>[138]</sup>. Relapse, sustained remission, death from liver failure or need for liver transplantation occur as commonly in the elderly as in young adults<sup>[138]</sup>, and the elderly respond more quickly to medication<sup>[11]</sup>. Patients aged  $\geq 60$  years enter remission within 6 mo more frequently than adults aged < 40 years (18% *vs* 2%,  $P = 0.02$ ), and most have achieved an ideal or satisfactory end point of therapy within 24 mo (94% *vs* 64%,  $P = 0.003$ )<sup>[11]</sup>.

The development of side effects associated with medication relates mainly to the duration of initial therapy and the cumulative durations of subsequent corticosteroid treatment<sup>[125]</sup>. Protracted corticosteroid therapy for > 24 mo and retreatment with corticosteroids after multiple relapses must be avoided to reduce the occurrence of vertebral compression and progressive osteopenia<sup>[13]</sup>. The risk of treatment-related complications in the elderly underscores the importance of limiting corticosteroid therapy to < 24 mo. Azathioprine maintenance therapy (2 mg/kg per day) should be instituted if

treatment is to be extended beyond 24 mo or be required after the first relapse<sup>[30,124]</sup> (Table 4).

A bone maintenance regimen should also be prescribed for all elderly patients undergoing initial corticosteroid treatment<sup>[13,30,124]</sup>. Regular weight-bearing exercise should be emphasized, and calcium (1-1.5 g/d), vitamin D3 (400-800 U/d), and alendronate (70 mg/wk) should be considered as adjuvant therapies. An annual bone density assessment can guide the vigor of the bone maintenance schedule. Budesonide (3 mg *tid*) can be considered as an empirical supplement to long-term azathioprine maintenance if liver inflammation is controlled inadequately<sup>[19,124]</sup>. Liver transplantation is effective in rescuing elderly patients with liver failure who have been screened for other comorbidity. The 5-year survival after liver transplantation in carefully screened elderly patients is comparable to that of young adults (80% in patients aged 60-65 years and 73% in patients aged > 65 years *vs* 78% in patients aged 18-59 years). Elderly patients also have fewer episodes of acute cellular rejection<sup>[132]</sup>.

## DECISION TO TREAT PREGNANT WOMEN

Pregnancy complicates the management of autoimmune hepatitis because of the risks that the liver disease and its treatment pose for the mother and the fetus (Table 4). Perinatal mortality is 4%<sup>[162]</sup>; serious complications develop in 9%<sup>[163]</sup>; caesarian section is required in 17%; stillbirths occur in 5%; and fetal loss is 21%<sup>[164]</sup>. These outcomes are better than those in mothers with diabetes, but they do indicate the need for high-risk obstetrical care<sup>[164]</sup>. The presence of maternal antibodies to SLA and extractable nuclear antigens (Ro/SSA) is associated with a complicated course<sup>[163]</sup>.

Azathioprine is associated with congenital malformations in pregnant mice, and it is a category D drug for pregnancy<sup>[165]</sup>. The odds ratio for having a child with congenital malformations while taking azathioprine for inflammatory bowel disease is 3.4, whereas it is negligible in similarly treated pregnant women with systemic lupus erythematosus<sup>[166]</sup>. There have been no reports of congenital malformations in the children of mothers treated with azathioprine for autoimmune hepatitis<sup>[166]</sup>, and there have been no serious consequences associated with breast feeding of these infants<sup>[167]</sup>. Nevertheless, the placenta is only a partial barrier to the metabolites of azathioprine<sup>[168]</sup>; there have been no rigorously designed studies that confirm the safety of azathioprine in pregnant women with autoimmune hepatitis<sup>[166]</sup>; and azathioprine is not an essential medication in the management of the disease<sup>[19,30]</sup>. The preferred treatment during pregnancy is with prednisone alone.

Autoimmune hepatitis can improve during pregnancy possibly because the high blood levels of estrogen promote a cytokine shift from a type 1 cytotoxic profile to an anti-inflammatory type 2 profile<sup>[187,169]</sup>. The reduced inflammatory activity may allow a reduction in the dose of prednisone or its elimination<sup>[169]</sup>. Exacerbations of

disease activity are common after delivery (12%-86%), presumably because the falling blood concentrations of estrogen facilitate a cytokine shift back to the cytotoxic type 1 profile<sup>[163,164,169]</sup>. These flares must be anticipated, and conventional dosing with prednisone should be resumed during the third trimester (Table 4).

Women with autoimmune hepatitis should not be discouraged from pregnancy, but they must be counseled about the increased frequency of prematurity and fetal loss, the normal low occurrence of congenital defects, the theoretical hazards of azathioprine during pregnancy, the possibility of an exacerbation of the liver disease after delivery, the need for high-risk obstetrical care, and the reasons for regular medical assessment during and after the pregnancy<sup>[30]</sup>.

## CONCLUSION

Current corticosteroid regimens (Table 1) are effective in the management of most patients with autoimmune hepatitis, and new pharmacological agents with powerful site-specific actions promise to strengthen the therapeutic repertoire. These treatments must be adapted and integrated to satisfy individual clinical situations. Established therapies can be improved by defining end points that permit optimal opportunity for resolution without extending beyond achievable goals and introducing undue risk of drug toxicity. The ideal treatment end point is normalization of liver tests and liver tissue, and the expected duration of initial therapy to achieve this end point is  $\leq 24$  mo (Table 2).

Autoimmune hepatitis is by nature an aggressive liver disease with fluctuating activity. Mild asymptomatic disease may be a temporary condition, and corticosteroid therapy should be considered for all patients regardless of disease activity at presentation. Other variations in the clinical phenotype, including acute severe (fulminant) presentations, absence of autoantibodies, and cholestatic features (overlap syndromes), warrant management appropriate for the predominant manifestations of the disease (Table 2).

Relapse after drug withdrawal justifies a long-term maintenance regimen with azathioprine, and azathioprine can also be used as a single-drug therapy for patients with an incomplete response to conventional schedules. Treatment adjustments are warranted in elderly patients who respond slowly and in pregnant patients in whom azathioprine avoidance is prudent and postpartum exacerbations are possible (Tables 3 and 4).

Empiric salvage therapy includes the calcineurin inhibitors (cyclosporine and tacrolimus) and mycophenolate mofetil, and they can be introduced judiciously for otherwise refractory inflammation (cyclosporine or tacrolimus) or drug intolerance (mycophenolate mofetil) (Table 4). Salvage therapy is expensive, unproven, associated with its own toxicity, inconsistently effective, and poorly guided. It should never supersede indications for liver transplantation.

Treatment decisions in autoimmune hepatitis will not be difficult if they are guided by an awareness of the phenotypic diversity of the disease, realistic therapeutic expectations, willingness to make individualized adjustments according to the clinical need, and familiarity with the alternative empirical therapies.

future structure and logistics of training needs. This is required in all subspecialties including gastroenterology, as has been done in India. It is hoped that as a consequence well-trained doctors, similar to those in India, might move to provincial hospitals in rural areas, upgrading the medical services and keeping medical power in South Africa. South Africa should become a model for Sub-Saharan Africa, as India already is for South-East Asia.

### Abstract

In South Africa, nurses and doctors are emigrating in significant numbers. Job satisfaction, safety and ensuring career progression are important in retaining doctors to make a career in Republic of South Africa (RSA). Due to budgetary constraints many hospitals have not been upgraded. Coming home after overseas training seems difficult. In RSA it takes a minimum of 13 years for a young specialist to become registered and 15 years for subspecialists. Career progression, creating more specialist trainees in public and private hospitals and shortening the period of professional training are potential solutions to the problem. India, which has a population of more than 1 billion people, is struggling with similar problems. For the past 10-15 years, private hospitals have assisted in manpower development for medical specialist and subspecialist careers. Currently their private sector trains 60% of their recognised (sub)specialties fellows. A national task force for specialist training in RSA should be instituted. It should discuss, based on the current status and projected specialist and subspecialist personnel requirements, the

### INTRODUCTION

In South Africa, the health care system faces a variety of problems. There is an overall shortage and maldistribution of medical doctors and specialists, with remote areas the least well populated. In South Africa nurses and medical doctors are the professional categories that emigrate in the most significant numbers. The impact is felt beyond the emigrating numbers of the highly developed skill base the country loses when they leave. Globally, dissatisfaction with income in developing countries is one of the major causes of doctors leaving public service, going overseas and/or joining private hospitals.

It was reported that increases in salaries of doctors in the public sector in South Africa might lead to a number of private general practitioners returning to the public service<sup>[1]</sup>. However, many doctors state that other factors such as job satisfaction, safety, working conditions, and improved career opportunities in medical specialist training are more important to stop the exodus of doctors from South Africa to wealthier and safer countries. Ensuring career progression is another factor suggested to be important in retaining academic specialists and fellows to make a career in South Africa. It is therefore imperative to understand and study which specific factors are responsible for doctors leaving the country<sup>[2-4]</sup>.

New academic hospitals such as Inkosi Albert Luthuli Central Hospital in Durban (2002), Steve Biko Academic Hospital in Pretoria (2006) and Chris Hani Baragwanath Hospital (2010) in Johannesburg have been built or are in the process of being refurbished in an attempt to equalise the provision of tertiary health care. Due to limited national and provincial budget allocations, many urban regional hospitals have not been upgraded. They, like many of the rural hospitals built in the early and mid 1900s, are in a poor state of repair. The quality of these hospitals' patient and staff accommodation is often inadequate. A so-called "capital works" programme has been implemented by the post-apartheid government to build new clinics and hospitals to improve the physical infrastructure of existing health care facilities, but it is currently short of its targets for the workforce to man these institutions once they are built.

However, public hospitals are not the only health facilities with vacancies for nursing staff and medical doctors, especially medical specialists. Private hospitals in competition with the public hospitals also face the same problems although on a smaller scale.

Medical graduates looking for specialist training in South Africa recognise a lack of opportunities and are often forced to look and sample abroad for skills development. This whets their appetite to deliver high quality specialist care. Yet on return, the lack of facilities even at the top institutes leads to frustration in not being able to utilise their newly acquired specialist skills to the benefit of their own community. Completion of training overseas also makes it difficult for doctors who have become accustomed to life in their new environment to return home once their training has been completed. This "Brain-Drain" problem has been witnessed not only in South Africa but in Sub-Saharan Africa in general<sup>[5]</sup>.

Subspecialties have been considered a luxury in the past by the Government in South Africa. Due to this point of view there is a lack of structure and funding for training in subspecialties of Internal Medicine. These bars to pursuing a subspecialist career in Republic of South Africa result in a shortage of fellows in Internal Medicine finishing their training<sup>[6,7]</sup>, and competition for posts from within a common pool allocated to all the medical subspecialties.

One solution to this problem would be to change the training for subspecialties such as cardiology, rheu-

matology, pulmonology and gastroenterology to an Internal Medicine track of 2 years instead of the full (minimum 4 years) training in Internal Medicine currently required. This would negate the need for two sets of professional exams and shorten the training period. A common trunk training system of 2-3 years is the standard in Europe and the USA<sup>[8]</sup>. In India such a common trunk is still 3 years.

---

## GASTROENTEROLOGY

The number of gastroenterologists in Europe varies between 1:5000 and 1:58000 of the population<sup>[9]</sup>. In 2007 the number of gastroenterologists per 100000 of the population was 3.9 in the USA, 3.48 in France, 2.1 in Australia, 1.41 in the UK and 1.25 in The Netherlands<sup>[9,10]</sup>. In South Africa this figure was around 0.12. Comparisons between poor and rich countries are notoriously difficult. However, South Africa is both a third and first world country and has a lot of similarities in this respect with India. The Indian model will be discussed in this article.

Unfortunately, no model has been developed and published in South Africa to calculate the required numbers of medical specialists. The Cuban South African agreement, which was signed over a decade ago, notes that South African policymakers were attracted to the Cuban emphasis on prevention and primary care<sup>[2]</sup>. This agreement neglected specialist care for the underprivileged. It seems as if the focus of the government was on training medical doctors for the most basic health care level, instead of understanding which and how many medical specialists and subspecialists are needed in post-apartheid South Africa. There is some evidence that the current basic strategy is failing as the infant mortality rate, a parameter often used to measure quality of health care, has increased since 1994. This is in contrast to Europe, but also to countries like India where great emphasis is placed on specialty and subspecialty training. For instance, additional national training numbers have been awarded to trusts in the UK to help meet the requirements of the European Working Time Directive (EWTD). In addition, expansion in the UK is planned with the recommendation that there should be 2.5 gastroenterologists per 100000 of the population<sup>[11]</sup>. In comparison, in South Africa there are less than 0.22 gastroenterologists per 100000 inhabitants. (personal communication, Karin Fenton, SAGES, Cape Town).

---

## GUT FEELING

Most internists learn during the current tubal training programmes in South Africa a "gut-feeling" within 3-4 mo, especially in "tubal gut" gastroenterology. Only sixty-two consultant gastroenterologists are available in public and private hospitals around the country, and of these only 17 consultants in gastroenterology work in Academic Hospitals. Only 6 out of the 8 academic complexes teach internists the subspecialty of gastroenterology. There is a lack of internists in general,

of internists for vacancies in training posts, and a lack of dedicated funding for these trainings posts. There is also a lack of gastroenterologists who focus on hepatology and pancreatobiliary disease. Endoscopic ultrasound, therapeutic endoscopy, transplant immunology and nutritional support have developed considerably over the past decades abroad, but not in academic South Africa. In a rather strange contrast, some private institutions in South Africa have gained considerable expertise in some of these fields with the availability of highly specialised equipment and skilled manpower. The University of the Witwatersrand Donald Gordon Medical Center has started a University driven “private” superspecialist programme involving hepatology and liver transplantation. Specialist trainees in Internal Medicine and Anaesthesiology also rotate through the ICU at this private hospital.

The smallness of the gastroenterology community in South Africa, the total sum of equipment and expertise still available in academic institutions and private practise allows a unique opportunity to join forces for developing more training positions for the projected gastroenterology needs of the country in the decades to follow.

---

## NEW SUBSPECIALTY STRUCTURE PROPOSAL

---

We would like to propose a new training programme with a common trunk of Internal Medicine for 3 years for (“sub”) specialists in cardiology, pulmonology, rheumatology and gastroenterology. Recruitment to gastroenterology will probably entail 3 years of basic medical training in Internal Medicine. A “Brain-Drain” of young doctors willing to specialise abroad should be prevented by creating training posts in private hospitals. The private hospitals should be incorporated in these programmes, like the private hospitals in countries such as India (DN Reddy: personal communication).

A new “core” curriculum should include basic upper GI endoscopy and colonoscopy and a general GI training over 3 years. Additional clinical and endoscopy training should be organised in the final year, further specialisation in GI-oncology, interventional endoscopy or hepatology should be organised if necessary<sup>[8,10]</sup>.

---

## PRIVATE HOSPITALS AT “CROSSROADS”

---

With a government that is moving towards a National Health Insurance (NHI) system in South Africa, private hospitals need to work towards the goals of strengthening the existing health services in the country. The new African National Congress leadership seems more willing to listen to new ideas aimed at improving access and affordability and might move away from the current distrust and negativism that have soured the relationship between the government and private sector. Due to the financial situation in public hospitals, medical education and training are drifting to the private hospitals. Major

strides have been made by private hospital groups in addressing the medical needs of South Africa. The private hospital groups are now collectively training more nurses than government institutions. However, medical specialist training in private has not been officially defined nor is there any government policy to regulate its introduction. South Africa is living in 2 worlds when it comes to health services: those who have and those who have not (personal communication: Netcare CEO, Richard Friedland). It would be interesting to look to countries with a similar background between those who have and have not, like India.

---

## INDIA

---

India with a population of more than 1 billion people is struggling with similar problems. The Indian government has problems in managing and investing in multi-specialty hospitals. However, banks are encouraged to finance innovations in the private sector. Medical education state secretaries realise that joint ventures will enrich India’s health system, and subsequently poor people who can not get basic services will be helped. India is the most preferred treatment destination in the region due to major factors favouring its health care system. India’s private tertiary care medical institutions, with international accreditations, are among the best in the world. They are extremely well equipped with the latest technology and have excellent training standards.

For the last 10-15 years private hospitals in India assist in training and manpower development for medical specialist, nursing and administrative staff. Private hospitals train around 60% of (sub)specialties in India. To encourage the number of junior doctors aiming for subspecialisation, the National Board of Examinations was constituted. This Board is functioning like a National University “sans Frontiers”, where students are enrolled. These students are trained in smaller well-equipped non-academic hospitals. The fact that liver transplantation is being carried out only in the best private sector hospitals and not even in one academic hospital bears ample testimony to the level of competence at these hospitals<sup>[12]</sup>. In the early 1990s, the National Board of Examinations added the subspecialties to its list. Consequently a number of junior doctors moved to smaller cities, thereby upgrading the medical services in many provincial hospitals in rural areas. Up to 5-10 years ago the common trend was that Indian doctors training abroad were reluctant to return to India. This trend is also reversing with the set up of corporate hospitals all over India, which offer state-of-the-art equipment and good salaries for medical doctors.

This initiative was followed in the whole South-East region: since October 2007 the Main Board listed Pacific Healthcare Holdings Ltd., a leading Singapore provider of integrated multidisciplinary specialist healthcare services, organised trainee programmes in South-East Asia, in close cooperation with private hospitals in India.

## COMPARISON INDIA-SOUTH AFRICA

South Africa has many similarities with India - a large multicultural, multilingual population and coexisting Public (state-run) and Private Medical Care. The public health care system faces resource constraints just as in India. As such, comparisons between medical specialist training in South Africa and India may lead to ideas for improvement, which may be easily adaptable to local conditions.

### **Medical education in South Africa**

There are eight Medical Schools in South Africa, each attached to one of the provincial universities. Students apply to the school of their choice, and may be called in for an interview depending upon their matriculation results and racial background. There is a restructuring of admission policies to redress racial inequities and train more black doctors.

The young student enters medical school and typically undergoes a 6-year undergraduate training programme. Some years ago the Department of Health in collaboration with Health Professions Council extended internship to 2 years. The argument was that newly graduated doctors lacked skills and extra supervised exposure was needed. A compulsory community service was introduced. Specialist training can be completed in 4 years. Subspecialties require a further 2 years. Cardiology and Gastroenterology introduced abroad require 3-4 years instead of 2 years training<sup>[8]</sup>. A shorter common trunk system seems the way forward if the total training period is not to be lengthened.

## PROPOSAL FOR SUBSPECIALTY TRAINING PROGRAMME IN PRIVATE HOSPITALS

Differences between training in gastroenterology in USA/Europe *vs* India and South Africa are magnified by the obvious resource gap between Third and First world countries. Private hospitals should aim to identify shortages in specialist training positions and provide flexible funding options, thereby providing incremental growth in medical specialist training capacity in the public health system. This is already common practice in Europe.

The public and private sector have to co-operate in preparing for the increased number of medical trainees seeking training positions in developing countries.

A Task Force for specialist and subspecialty training in South Africa should be instituted to meet the current and future specialist training demands, as has been done in India and Eastern-Europe<sup>[13-15]</sup>. Redefining training programmes to train specialists more efficiently would be another goal based on a common trunk system for subspecialties of Surgery and Internal Medicine.

### **Priority 2010-2015**

This "priority specialty group for South Africa" should be

identified by Task Forces for Specialist training in close cooperation with the Colleges of Medicine of South Africa. A working group for this Task Force should be instituted with the following tasks: (1) Analysing the South African medical workforce flow data, identifying the numbers entering and leaving workforces in the public and private spheres; (2) Comparing workforce numbers in South Africa with India/Middle East *vs* Europe/USA; (3) Analysing the presence of specialities in different geographical locations; (4) Defining the minimal required service access in rural areas for the basic medical specialties such as Internal Medicine, Surgery, Neurology, Gynaecology and Paediatrics; (5) Discussing the current system of 13-15 years of training for a young specialist to become registered and look for a shorter medical training period to prevent the Brain Drain; (6) Defining the minimal numbers of trainees for subspecialty training in private hospitals and providing and defining funds for training in those private hospital settings in close cooperation with Academic Hospitals; (7) Acknowledging that the medical specialist trainee workforce is complementary to public hospital service. Therefore expansion of training opportunities outside traditional academic settings in private hospitals should be defined and organized. The Medical Board of the HPCSA should expand its role to control and regulate the quality of training, not only in the Public Hospitals but in the private hospitals and prioritizing disciplines facing immediate workforce shortage or maldistribution around the country especially in remote rural areas; and (8) Development of tertiary referral centres would prevent loss of foreign exchange by keeping private patients in the country instead of leaving and spending their money abroad.

## CONCLUSION

Medical specialist training is acknowledged as an essential component of health care delivery systems. South Africa, both a developing and developed country similar to India, has a shortage of medical specialists and subspecialists. It is therefore imperative that a national solution should be developed to address the challenges of maintaining an adequate specialist workforce<sup>[6,16,17]</sup>.

We acknowledge that the academic medical complexes have been and will continue to be the cornerstone of medical training around the world. Over recent years, it has become evident that clinical training will expand from the traditional settings of public hospitals into private hospitals. India showed us the way in how to develop this, keeping junior doctors in the country and giving them access to proper specialist training. This dual pathway for obtaining (sub)specialty training in India over the last 20 years has resulted in almost double the number of specialist doctors, who are now also working inside the smaller rural hospitals in India. Additionally, the massive increase in medical student numbers underscores the need to increase the capacity to train these students in specializations to prevent further "Brain-Drain".

The complexity of medical specialist training in South Africa requires the cooperation of many stakeholders such as, government agencies, the ministries of health and education, assurance companies, academic hospital complexes, the medical board of the health professions council, CMSA, public and private hospitals, fellows registrars and junior medical doctors. A National Task Force should clarify the necessary resource investments and define accountabilities. A Task Force should co-ordinate and govern, while maintaining appropriate flexibility<sup>[18]</sup>. We hope that the Medical Societies and Associations in South Africa will consider this expansion of specialist training into settings beyond the traditional teaching hospital model.

Can future specialist training in South Africa involve both, and possibly partner, the private sector and the public teaching system? South Africa could then become a model for Sub-Saharan Africa, as India already is for the poorer Asian countries.

## ACKNOWLEDGMENTS

### Abstract

**AIM:** To compare the efficacy and safety of radical and conservative surgical interventions for liver hydatid disease.

**METHODS:** The study comprised 59 patients in two groups who had undergone radical and conservative surgical procedures for liver hydatid disease in our department between 2004 and 2009. Preoperative diagnostic tools, medical treatments, demographic and clinical characteristics, postoperative follow-up, and recurrence were compared in both groups.

**RESULTS:** This non-randomized retrospective study

included 59 patients who had undergone liver hydatid disease surgery. The radical technique was used in 18 patients (mean age:  $42.1 \pm 13.5$  years, seven male, 11 female), and the conservative technique was used in 41 patients (mean age:  $43.5 \pm 13.9$  years, 17 male, 24 female). The follow-up period ranged from 3 to 58 mo. Although operative time was significantly shorter in the conservative group ( $P < 0.001$ ), recurrence was significantly reduced in the radical group ( $P = 0.045$ ). No statistically significant differences were found in terms of hospitalization duration, cyst count and size, location, postoperative complications, scolical solution usage, or follow-up duration between the two groups.

**CONCLUSION:** The more effective method for preventing postoperative recurrence is radical surgery. Endoscopic retrograde cholangiopancreatography for bile leakage in the early postoperative period may decrease the requirement for repeat surgery.

## INTRODUCTION

Hydatid cysts are common in societies where agriculture and raising animals are common, and hydatid disease continues to be a serious public health problem in many countries, including Turkey<sup>[1-3]</sup>. Hydatid cysts can develop in any organ of the body, but are most frequently seen in the liver (60%-70%) and lungs (20%-30%)<sup>[4-6]</sup>. Infection rates are lowest in urban environments; in endemic rural areas, prevalence rates of 2%-6% or higher have been recorded<sup>[7]</sup>. In Turkey, hydatid disease is more common in Eastern and Middle Anatolia and in the Marmara and Trakya regions<sup>[3]</sup>. The first step in the prevention of hydatid disease is basic hygiene and the second step involves the approach to treatment. No consensus exists regarding the optimal treatment, although medical treatment is effective against larval *Echinococcus granulosus* (*E. granulosus*). Surgical treatment varies from complete resection to minimally invasive procedures (e.g. percutaneous aspiration)<sup>[8-12]</sup>.

In this study, we present the surgical approach to hydatid disease patients at our clinic in Diyarbakir, eastern Eastern Anatolia, and a comparison of the efficacy and safety of radical surgery and conservative surgery for liver hydatid disease.

## MATERIALS AND METHODS

A total of 59 patients who had undergone surgery for liver hydatid cysts between January 2004 and July 2009 were investigated retrospectively. All the patients in the study were operated on by two surgeons. Patients were divided into two groups according to the type of surgery. The radical surgery group ( $n = 18$ ) consisted of patients whose treatment involved pericystectomy or left lobe segmentectomy. The conservative surgery group ( $n = 41$ ) included patients who underwent conservative surgery, including partial cystectomy plus external drainage plus omentopexy, or cystectomy plus external drainage. The data analyzed included patient age, sex, occupation, residence, symptoms, diagnostic tools used, type of cyst, type of surgical procedure, and maximum diameter of the cyst, postoperative complications, preoperative and postoperative anti-helminthic treatment, recurrence, and length of follow-up.

### Clinical presentation

For 43 (72.8%) patients, abdominal pain was the initial symptom of hydatid disease. Seven of 43 patients experienced recurrence of the disease between 5 and 22 years after one or more operations elsewhere. In 14 patients, the diagnosis was made incidentally during a medical checkup. Two patients were diagnosed with a hydatid cyst preoperatively during diagnostic laparoscopy for gynecological disease.

### Preoperative diagnosis

The preoperative evaluation of the patients included liver function tests, a complete blood count, indirect

Table 1 Comparison of both groups according to Gharbi classification

Type of cyst	Gharbi classification	Radical surgery	Conservative surgery	Total
Type I	Pure fluid collection		Excluded	0
Type II	Fluid collection with a split wall	2	7	9
Type III	Fluid collection with septal	5	14	19
Type IV	Heterogenous acho pattern	4	8	12
Type V	Reflecting thick walls		Excluded	0
Type III-IV		4	7	11
Type III-IV-V		3	5	8

hemagglutination antibody (IHA), abdominal ultrasonography (USG), and abdominal computed tomography (CT). The cysts were classified according to the five categories described by Gharbi *et al*<sup>[13]</sup>. The distribution of the patients according the Gharbi classification is shown in Table 1. CT was performed in 19 patients who had more than one cyst, to obtain detailed information on the location of the cysts (Figure 1, Figure 2A and B). Magnetic resonance cholangiopancreatography was used to confirm the diagnosis in two patients who had suspicious dilatation of the common bile duct (CBD) and three patients with elevated liver function tests. Dilatation of the CBD was observed in only one patient on magnetic resonance imaging. This patient underwent a sphincterotomy *via* endoscopic retrograde cholangiopancreatography (ERCP) preoperatively.

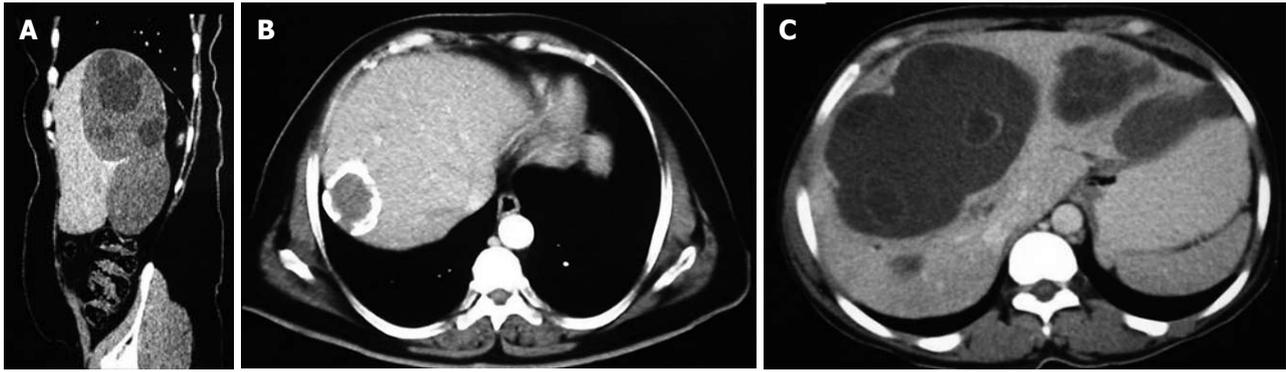

### Cyst characteristics

The size of the cysts was measured by USG and CT; the number of the cysts was counted radiologically and confirmation was made by sight during surgery.

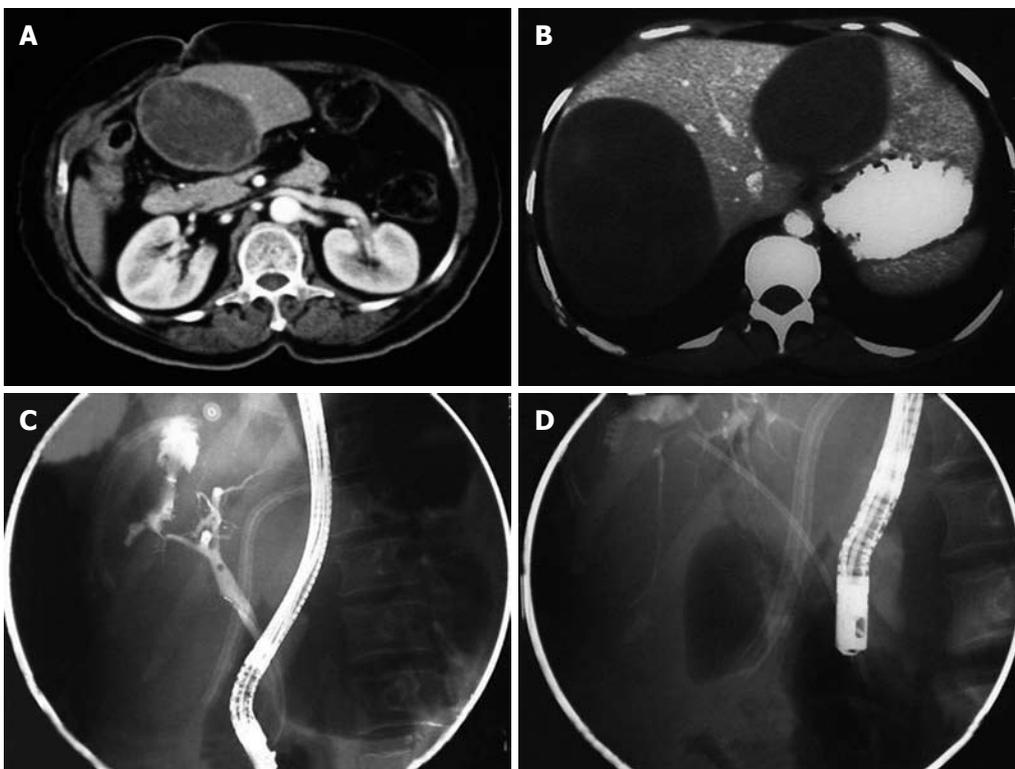

The mean  $\pm$  SD size of the cysts was  $16.28 \pm 6.97$  cm (range: 8-32 cm) in the RS group *vs*  $12.98 \pm 4.90$  cm (range: 6-26 cm) in the CS group. There was no significant difference in cyst count ( $P > 0.694$ ), cyst size ( $P > 0.088$ ) and in location ( $P > 0.650$ ) between the two groups. The other cyst characteristics are summarized in Table 2.

### Our approaches to liver hydatid cysts

As liver hydatid disease is endemic in the area where we work, a general consensus has been established for patients to be operated upon. Accordingly, the patients presenting at our clinic were categorized according to the following criteria Gharbi I : all the patients in this group were referred to other hospitals as there was the possibility of percutaneous drainage. We have recently started laparoscopy drainage techniques. This group of patients was not included in this study; (2) Gharbi II, III and IV group cases with cysts sized  $> 10$  cm were recommended for surgery; (3) Type II-IV cystic lesions in which there was compression underwent surgery regardless of size (e.g. in our cases where location was in the left lobe lateral segment and posterior to the gallbladder); (4) In

**Figure 1** Multi-detector computed tomography (CT) images in different planes following contrast injection. A: Sagittal plane multi-detector CT images showed cystic lesions in segments 6 and 7 of the right liver lobe; B: A cystic lesion with a calcified wall located in the subcapsular region in the right lobe posterior segment was seen in contrast-enhanced axial plane CT sections; C: Contrast-enhanced axial plane CT images showed widespread cysts with separate membranes in an enlarged liver.

**Figure 2** Contrast-enhanced axial CT and endoscopic retrograde cholangiopancreatography (ERCP) images of three different patients. A: A cystic lesion located in segment 3 of the left lobe was seen in contrast-enhanced axial plane CT images; B: A cystic lesion in the right lobe posterior superior and left lobe medial segment was seen in oral and intravenous contrast-enhanced axial plane CT images; C: Leakage of contrast material into the cyst cavity was observed after placing a cannula and injecting radiopaque material into the biliary tract; D: The same patient after performing a sphincterotomy and inserting a 7 Fr biliary stent.

the Gharbi V group, if the patient was symptomatic or if there was compression of the stomach, gallbladder or intestines, surgery was recommended (there were no such patients in this study). Otherwise type V cysts were kept under observation; and (5) Asymptomatic cysts < 5 cm were followed-up. If the size was seen to have increased, firstly albendazole treatment was administered. If the size continued to increase despite this, then surgery was planned.

#### **Albendazole treatment**

All patients with hydatid disease at our clinic were ad-

ministered 10 mg/kg albendazole for 14-21 d preoperatively. During this period, liver function tests were closely observed. For all patients undergoing surgery, the same treatment protocol was recommenced on postoperative day 1 and continued for 14-21 d. If patients experienced recurrence during follow-up, again 14-21 d treatment was administered preoperatively, and the postoperative treatment period was 2 mo.

#### **Surgical procedure**

In all patients, the pericystic area and operating field were covered with sponges soaked with 20% hypertonic saline

**Table 2** Comparison of surgical characteristics, follow-up time and postoperative complications among the both groups *n* (%)

Surgical features	Radical surgery	Conservative surgery	Total	<i>P</i>
Number of patients	18 (30.5)	41 (69.5)	59 (100)

NS: Not significant.

or 10% povidone-iodine (Betadine®) solution. Before injecting this solution into the cyst cavity, the cyst was punctured and as much fluid as possible was aspirated to prevent dilution of the agent. Then, 10% Betadine® or 20% hypertonic serum was instilled into the cyst cavity in a volume equal to the amount aspirated. After 15 min, the cyst fluid was aspirated again.

The surgical method was decided by collating the factors of patient age, general condition, systemic disease, American Society of Anesthesiologists (ASA) values, viral hepatitis markers, radiological images, liver function tests, blood group and the surgeon's experience.

**Radical surgery:** In the pericystectomy technique, the cyst was totally removed together with 1 cm of the liver parenchyma, without opening the cavity. In a left lobe lateral segmentectomy, to secure the vasculature of the left lobe lateral segment, the segmentectomy was performed after taking the mesentery. In both situations, one or two drains were placed in the operated area.

**Conservative surgery:** The anterior wall of the cystic lesion was removed as widely as possible. All the components of the cyst were removed from the interior. After

**Table 3** Comparison of both groups in terms of clinical and demographic characteristics *n* (%)

washing the operated area with saline or Betadine solution, one or two drains were placed. Omentopexy was not performed when cysts were located proximally but was performed when cysts were located inferior to the liver.

### Postoperative follow-up

Postoperative follow-up was carried out by physical examination, IHA, USG and CT. In order for there not to be any confusion as to whether there had been any recurrence of the disease in the future, all patients underwent IHA and abdominal CT examination at the end of the first postoperative month. Thus, we obtained baseline results for future comparison. The follow-up period was completed with IHA + USG at 6 mo, IHA + CT at 1 year, IHA + USG at 18 mo, IHA + CT at 2 years, IHA + CT at 3 years, and only USG at 4 years. During this period, any cases suspected of recurrence were examined more frequently.

### Statistical analysis

All data were collected and analyzed using SPSS version 11.5 (SPSS, Chicago, IL, USA). Comparison between two groups was done by independent sample Student's *t* test for continuous variables and  $\chi^2$  test for categorical variables. *P* < 0.05 was considered statistically significant.

## RESULTS

All demographic and clinical characteristics, operative factors, postoperative outcomes, and surgical complications of the patients in the two groups are presented in Tables 2 and 3. Group-CS comprised 41 patients, 17 male and 24 female, with a mean age of 43.5 ± 13.9 years (range: 17-67 years). Group-RS comprised 18 patients, seven male and 11 female, with a mean age of 42.1 ±

Table 4 Postoperative complications and management

Complications	Radical surgery	Conservative surgery	Management
Bilioma	0	1	Percutaneous drainage (other center)
Wound infection	0	3	Secondary healing therapy
Atelectasis	1	1	PEEP
Pneumonia	0	2	PEEP + antibiotherapy
Biliary leakage	2	3	3 cases: ERCP + sphincterotomy 1 case: ERCP + sphincterotomy + internal biliary stent 1 case: choledoc exploration + T-tube drainage

PEEP: Positive end-expiratory pressure.

13.5 years (range: 19-62 years). There was no significant difference in age ( $P > 0.703$ ), sex ( $P > 0.831$ ), residence ( $P > 0.416$ ) and occupation ( $P > 0.853$ ) between the two groups.

### Surgical characteristics

In the radical surgery group, 1-4 cysts occurred in 10, five, one and two patients, respectively. The cysts were located in the right lobe in nine patients, left lobe in five, and in both lobes in four. Fourteen patients with an exophytic cyst underwent complete pericystectomy, whereas four patients with two cysts in the left lateral segment underwent left lobe lateral segmentectomy.

In the conservative surgery group, 1-6 cysts occurred in 23, eight, four, three, two and one patients, respectively. The cysts were located in the right lobe in 23 patients, left lobe in seven, and in both lobes in 11. Partial cystectomy plus external drainage plus omentopexy was performed in 36 patients, whereas five patients had partial cystectomy plus external drainage.

In four patients, intraoperative observation revealed that the cyst cavity was connected to the biliary system. In one of these four patients, the diameter of the CBD was enlarged and exploration of the CBD and T-tube drainage were performed. In three of these four patients, the open biliary duct in the cyst was closed primarily. None of these four patients had postoperative bile leakage. Mean operation time of the radical and conservative surgery group, was  $83.25 \pm 12.0$  min and  $51.97 \pm 15.0$  min, respectively. The mean operation time was significantly longer in the radical than conservative surgery group ( $P < 0.001$ ). There was no significant difference in duration of hospitalization ( $P > 0.361$ ), and in scoloidal usage ( $P > 0.756$ ) between the two groups.

### Early postoperative complications

The postoperative complications and the approach to these complications are summarized in Table 4. There was no significant difference in postoperative complications ( $P > 0.338$ ) between the two groups. On postoper-

ative days 2-4, five patients had drainage of 250-400 mL of bile. Since the drainage did not decrease after being monitored for 3 d, ERCP was performed and four patients underwent sphincterotomy. In the case shown in Figure 2C and D, because the open biliary duct in the cystic cavity was dilated, a sphincterotomy was performed in this patient and an internal biliary stent that reached the leaking biliary duct was placed. Seven days after drainage stopped, which was 3 mo after placement, the stent was removed. One patient had 300-350 mL of bile leakage and elevated liver function tests. In addition, the CBD was dilated on CT. This patient had a previous gastrojejunostomy, therefore, ERCP was unsuccessful and repeat surgery was performed. Exploration of the CBD and T-tube drainage were performed. The drainage stopped on postoperative day 18 and the tube was removed.

One patient developed a postoperative biloma that was confirmed by CT. This patient underwent percutaneous drainage elsewhere. Local infection developed in three patients, who were treated appropriately. Four elderly patients developed atelectasis and pneumonia on the fourth postoperative day. These patients were treated with respiratory physiotherapy and antibiotic therapy.

### Follow-up and recurrence

The follow-up duration ranged from 3 to 58 mo. Seven patients developed recurrences at 8-17 mo (mean: 13.1 mo) postoperatively. Although the recurrence rate was reduced significantly in the radical surgery group ( $P < 0.045$ ), no statistically significant difference was found in terms of follow-up duration between the two groups ( $P > 0.429$ ).

The preoperative IHA values were similar in all patients who had recurrences. Cystic lesions in all seven patients were confirmed using CT. Saline solution was used as the scoloidal agent in all patients who had recurrence. No recurrence was observed in patients who underwent radical surgery. Two of the seven patients refused repeat surgery, since they were asymptomatic. In the remaining five patients, the recurrent cystic lesions were treated with a partial cystectomy and drainage.

## DISCUSSION

Hydatid liver disease is still endemic in certain regions of the world. The incidence of hydatid disease in Turkey ranges from 2/1 000 000 to 1/2000 in different studies<sup>[14-17]</sup>. The symptoms of hydatid liver disease generally differ according to the location, size, and grade of the cyst<sup>[18,19]</sup>. Overall, 75% of the patients are identified incidentally and are asymptomatic<sup>[4,19]</sup>. In our study, 23.7% of the patients were identified incidentally at routine examinations and 72.8% of the patients were identified after complaining of abdominal pain. All symptomatic and asymptomatic patients with cysts  $> 5$  cm in diameter should be considered as candidates for surgery<sup>[19]</sup>. In our study, 72.8% of the patients were symptomatic, while

27.2% were asymptomatic. In all of the patients, the cysts found were  $\geq 6$  cm.

Which treatment modality should be used for liver hydatid cysts is still a subject of controversy. Agents which are effective on *E. granulosus* larvae, such as albendazole and mebendazole are used as medical therapy. It has been reported that this treatment is administered 7-21 d preoperatively and continues for 2-3 mo postoperatively<sup>[6,18,20,21]</sup>.

As this treatment is given both pre- and postoperatively, the risk of postoperative secondary disease developing has been seen to be low. When we look at choice of surgical treatment used, conservative surgery is the most common, then radical surgery, and more recently, laparoscopy. Conservative surgery is recommended for the elderly, those with high ASA levels, deeply located cysts  $\geq 10$  cm, more than one cyst at the same time, cysts located in both lobes and in the liver posterior segment. Radical surgery can be carried out by experienced hepatobiliary surgeons on younger patients, where the cysts are located in the anterior superior liver and in the left lobe lateral segment, those with exophytic location, alveolar hydatid cyst and cysts  $\geq 5$  cm in diameter.

Although the rate of recurrence is lower with radical surgery, application is limited as the associated morbidity and mortality rates are high<sup>[6,18,22]</sup>. In the radical surgery cases in our study, four were in the left lobe lateral segment with straightforward localization and the other 14 were exophytic locations, therefore, there was no mortality or morbidity related to surgery. The laparoscopic approach is a treatment method developed in recent years using an umbrella trocar to perform partial or total cystectomy<sup>[23]</sup>.

Topcu *et al*<sup>[2]</sup> have reported cysts with biliary system involvement that were  $> 10$  cm in diameter in 22.2% of patients. In our study, the biliary system was connected to the cyst cavity in nine patients (15.2%); this was discovered intraoperatively in four patients and postoperatively in five. Six of these cysts were in the right lobe and  $> 15$  cm in size.

Most studies assert that rupture of the cyst into the biliary system is the most important complication<sup>[2]</sup>. In our study, while exploring the CBD in a patient with a dilated CBD, a daughter vesicle was found and T-tube drainage was performed. The cysts in our study were larger than those reported in the literature, although no rupture into the biliary system was observed with these large cysts.

Ezer *et al*<sup>[18]</sup> found biliary leakage in 18.3% of their patients and five of the leaks closed spontaneously within 7 d. Kayaalp *et al*<sup>[24]</sup> found biliary leakage in 26% of their patients and seven of the leaks closed within 1 wk, while biliary fistulas occurred in five patients. In our study, biliary leakage occurred in only 8.5% of the patients and a biloma developed in one (1.6%) patient.

Recurrence is one of the major problems in the management of hepatic liver disease. Recurrent disease is defined as the appearance of new active cysts after

therapy for intra- or extrahepatic disease. The failure to achieve permanent control of the primary treated cyst is considered to be the cause of local recurrence. Local recurrence occurs after surgical or radiological intervention and manifests as the reappearance of live cysts at the site of a previously treated cyst, or the appearance of new extrahepatic disease resulting from procedure-related spillage. The incidence of recurrence after liver cyst hydatid surgery is reported to range from 0% to 25% in various studies<sup>[4,18,20,25-28]</sup>. Although this rate ranges from 0% to 4.65% in patients who have had radical surgery<sup>[4,26,28]</sup>, it ranges from 4.65% to 25% in those who have had conservative surgery<sup>[4,18,20,21,27,28]</sup>. In our study, recurrence occurred in none of the patients treated with radical surgery and 11.8% of those treated with conservative surgery. Recurrence may occur many years later, however, and longer follow-up is recommended when possible.

Postoperative recurrence has been reported to have developed at different periods from 4 mo to 35 years<sup>[4,18,20,26-28]</sup>. In our study, this period was found to be a mean 13.1 mo. Our experience indicates that it is beneficial to have a longer follow-up period for cases of conservative surgery.

There are several studies which state that it is preferable to use a conservative approach when possible on patients who develop recurrence, because there are more problems associated with a second operation, such as mortality, damage to the gallbladder, and a lengthy postoperative stay. In our own study, five cases in which recurrence developed were treated with conservative surgery.

Several studies have been published on the use of different concentrations of scolicidal agents over different periods of time for the development of complications such as recurrence and postoperative cholangitis. The leading scolicidal agents that have been the subject of research are hypertonic saline (3%-30% and 5-30 min), povidone-iodine (10%), formalin, cetrimide (0.1%-0.4%), chlorhexidine (0.04%-4%), hydrogen peroxide (3%) and ethyl alcohol (95%).

Hypertonic saline solution and Betadine are the most frequently used scolicidal agents in Turkey<sup>[2,29,30]</sup>. Besim *et al*<sup>[29]</sup> have compared the effects of different scolicidal agents at different concentrations and found that the use of Betadine, 20% saline, 3% hydrogen peroxide, 95% ethyl alcohol, and 10% Savlon solutions for 15 min inactivated the protoscoleces. The infectivity was higher using concentrations of  $< 20\%$  and for  $< 5$  min. Sclerosing cholangitis has been reported with the use of 20% and 30% hypertonic saline solutions<sup>[30-32]</sup>. In our study, we used either 20% saline or 10% Betadine solution in the cystic cavity for 15 min. None of our cases developed any metabolic problem or sclerosing cholangitis.

In conclusion, the most effective method for preventing postoperative recurrences is radical surgery. This is indicated for patients meeting the indications in terms of age, medical history, location and size of the cyst, and relation of the cyst to the vasculature and biliary

tree. When  $\geq 250$  mL of biliary leakage occurs in the early postoperative period, performing sphincterotomy with ERCP or a stent within 3-5 d allows early discharge from hospital, decreases the need for repeat surgery, and reduces the costs and psychosocial problems that may occur with prolonged follow-up.

## COMMENTS

### Background

The development of hydatid disease associated with *Echinococcus granulosus* is still an important health problem. Treatment choices are medical, conservative surgery, radical surgery, laparoscopic surgery and PAIR technique. The advantages and disadvantages of these techniques have not as yet been fully clarified.

### Research frontiers

In this study, although the patients who had undergone radical surgery did not experience any recurrence of the disease during postoperative follow-up, the operating time was significantly shorter for conservative surgery.

### Peer review

The overall impression of the article is positive and it might be relevant for publication in *World Journal of Gastroenterology* as it deals with an important and relatively rare disease, which has no clear and unequivocal management guidelines.

### Abstract

**AIM:** To determine the basic demographic features of colorectal cancer (CRC) in five hospitals located in four different areas of Guangdong Province, China.

**METHODS:** A review of patient records from 1986 to 2006 from five hospitals was conducted. Patient data was obtained, including age, gender, location of lesions, staging and histological type of CRC. The Chi-square test was used to assess differences in rates and a significance level of 0.05 was used. Univariate comparisons were made *via* Fisher's exact tests.

**RESULTS:** Analysis was carried out on 8172 CRC patients, 6.1% (499/8172) of the patients were aged  $\leq$  30 years. The peak incidence was between the ages 61-70 years (27.8%). The mean age at CRC diagnosis increased from 52 years (1986-1988) to 60 years

(2004-2006) and the proportion of young CRC patients decreased from 8.0% to 5.9% over the same period. Of 8172 lesions, 4434 (54.3%) were located in rectum and 3738 (45.7%) in colon. The incidence of rectal cancer decreased significantly from 59.4% (1989-1991) to 51.8% (2004-2006) and right sided colon cancer increased from 40.6% to 48.2%. The mean age, anatomic distribution, histological type and differentiation degree were significantly different among the four geographical areas ( $P < 0.05$ ).

**CONCLUSION:** The hospitalization rate for CRC has increased in Guangdong in recent years. The characteristics of CRC from the five hospitals located in the four different areas of Guangdong Province are also different. Further studies are needed to assess more recent trend in the incidence and prevalence of CRC as well as the respective roles of genetic and environmental factors in CRC.

Colorectal cancer in Guangdong Province of China: A demographic and anatomic survey. *World J Gastroenterol* 2010; 16(8): 960-965 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i8/960.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i8.960>

### INTRODUCTION

Colorectal cancer (CRC) is one of the most common gastrointestinal tumors and ranks as the third most com-

mon cancer in the world<sup>[1]</sup>. CRC has been thought to be less common in Asian compared with Western countries<sup>[2,3]</sup>. However, recent studies from Japan, Korea and Hong Kong have shown that CRC has not only high incidence rates but also an increasing trend in the population<sup>[4-6]</sup>. Previous studies implicated that cause of CRC was more closely related to dietary habits and geography than race<sup>[7-9]</sup>. The incidence of CRC in China was lower than that in the West, but has increased in recent years<sup>[10,11]</sup> and has become a substantial cancer burden in China, particularly in the more developed provinces. Some studies have reported changes in the characteristics of colorectal cancers in China<sup>[12,13]</sup>. However, due to a lack of an effective nation-wide colorectal cancer surveillance system, there has been little information available on the relationship between colorectal cancer and geographical environment and economic status in China. The basic demographic characteristics of CRC have changed with the changing of lifestyle in Guangdong. The regional characteristics of CRC in Guangdong need to be better defined.

Guangdong Province is divided into four regions according to geographical location, which include: Triangle area, North area, West area and East area, each area is different in economic status and dietary habits. Therefore, to determine the basic demographic features of patients with CRC in different regions in Guangdong and the trends in different year group, five hospitals were selected from these four areas and 8172 patient records were reviewed. Age, gender, anatomic distribution and histological type were characterized and compared in different areas and year group. The aim of this study was to gain a broader picture of CRC in Guangdong Province and provide important information on the changing epidemiology of this disease over a period of 20 years.

## MATERIALS AND METHODS

We developed a registration form to assist in obtaining the clinical characteristics of 8172 CRC cases in the five hospitals [Nanfang Hospital and Huizhou Central People's Hospital (Pearl River Triangle area in Guangdong, highly developed region), North-Guangdong People's Hospital of Shaoguan (North area of Guangdong, a developed region), the Affiliated Hospital of Guangdong Medical College (West area of Guangdong, an under-developed area) and Meizhou People's Hospital (East area of Guangdong, an under-developed area)]. All cases in this study were identified using a series of unified Code for the following review. The data was collected retrospectively over a 20-year period from January 1986 to December 2006. Patient basic demographic data including age and gender were recorded. The location of the tumor was recorded and classified as right sided (caecum, ascending colon, hepatic flexure and transverse colon) or left sided (splenic flexure, descending colon, sigmoid colon and rectum). Staging of the tumor was graded according to Duke's classification and histological

types were also recorded. The histological type of CRC was determined by two experienced pathologists. The study protocol was approved by the Ethics Committee of Nanfang Hospital.

### Statistical analysis

According to the clinical data, we analysed the clinical characteristics of age, gender and location of tumor, and put all information to a computer. A database was established using EpiData 3.1. The  $\chi^2$  test was used to assess differences in rates, and a significance level of 0.05 was used. Univariate comparisons were made *via* Fisher's exact test.

## RESULTS

### Age and gender

The hospitalization rate for CRC in 2004-2006 was approximately 3.1-fold higher than that in 1986-1988. From 1986 to 2006, 8172 patients aged 5-91 years were investigated and the mean age was 56 years (Table 1). Of the 8172 patients, 4841 (59.2%) were male and 3331 (40.8%) were female, with a male to female ratio of 1.5:1. The highest hospitalization rate for CRC occurred in the Triangle area. Increasing age was associated with a change in the male to female ratio from 1.1:1 to 1.7:1. The overall peak incidence of age was between 61-70 years (Figure 1). Mean age of patients in 2004-2006 increased by 8 years compared with that of patients in 1986-1988 and the ratio of young CRC patients ( $\leq 30$  years) decreased from 7.2% to 5.2%.

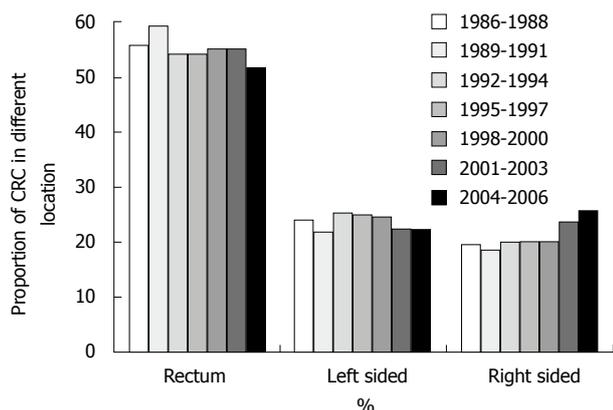

Figure 2 Year group and location of CRC.

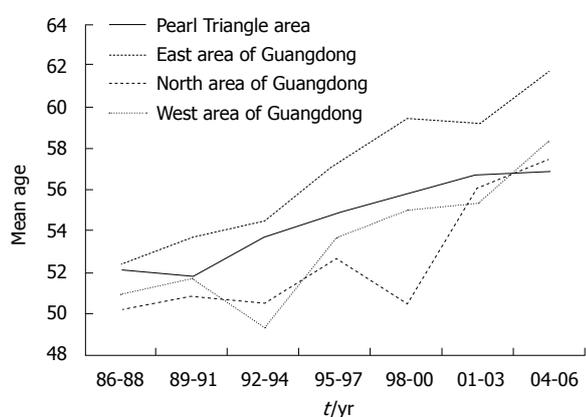

Figure 3 Mean age in different areas in different year group.

### Staging of colorectal cancer

Of 8172 lesions, 5670 lesions could be staged by Duke's staging: Duke's A stage 346 (6.1%), Duke's B stage 2829 (49.9%), Duke's C stage 1922 (33.9%), and Duke's D stage 573 (10.1%). The percentage of Duke's A stage increased from 4.5% to 7.7% and Duke's D stage decreased from 13.4% to 10.0%. The difference was significant ( $\chi^2 = 154.700, P = 0.000$ ).

### Anatomic distribution of tumors

Of 8172 lesions, 4434 (54.3%) were located in the rectum and 3738 (45.7%) in the colon, the ratio of rectum cancer to colon cancer was 1.2:1. The anatomic distribution of the tumors is shown in Table 2 and the distribution between age groups and classification as rectum cancer, right sided or left sided are shown in Table 3. The proportion of right-sided lesions increased, but the difference was not statistically significant ( $P > 0.05$ ). The proportion of CRC in the rectum decreased but that of right sided cancer increased ( $P < 0.05$ ). The relationship between distribution and year group was analyzed in Figure 2. The proportion of each distribution group has no change.

### Histological type

The CRC was classified as well, or moderately differentiated and poorly-differentiated carcinoma. Of 6638 lesions,

Age group (yr)	Rectum	Left sided	Right sided	Total
≤ 30	301 (60.3)	102 (20.4)	96 (19.3)	499 (100.0)
31-40	496 (57.0)	194 (22.3)	179 (20.6)	869 (100.0)
41-50	786 (57.8)	297 (21.8)	278 (20.4)	1361 (100.0)
51-60	1067 (54.0)	499 (25.2)	411 (20.8)	1977 (100.0)
61-70	1201 (52.9)	534 (23.5)	536 (23.6)	2271 (100.0)
> 71	583 (48.8)	304 (25.4)	308 (25.8)	1195 (100.0)
Total	4434 (54.3)	1930 (23.6)	1808 (22.1)	8172 (100.0)

Significance was determined using Chi-squared tests ( $\chi^2 = 39.223, P = 0.000$ ).

the histological type was classified as: tubular adenocarcinoma 4913 (75.6%), polypoid adenocarcinoma 578 (8.9%), mucinous adenocarcinoma 800 (12.3%), signet ring cell carcinoma 51 (0.8%), undifferentiated carcinoma 12 (0.2%), carcinoid 22 (0.3%), squamous carcinoma 21 (0.3%), adenosquamous carcinoma 9 (0.1%), and other types 95 (1.46%). In the young CRC patient group (≤ 30 years), the proportion of undifferentiated cancer was 50.1%, while only 27.0% in the group over 40 years of age. There was a significant difference in the different histological groups ( $\chi^2 = 232.823, P < 0.001$ ). In comparison of years 1986-1988 and 2004-2006, the proportion of well- and moderately differentiated tumors increased from 60.5% to 74.7%, while that of poorly-differentiated decreased from 39.5% to 25.3%. The difference was statistically significant ( $\chi^2 = 128.505, P < 0.001$ ).

### CRC patients in different areas of Guangdong

As shown in Figure 3 and Table 4, the mean age of CRC in the four geographic areas increased, of which the lowest mean age was found in North Guangdong, and the highest mean age in East Guangdong. There was no significant difference in gender distribution (data not shown). Anatomic distribution in the four different geographic areas is shown in Table 5, with rectal cancer representing the largest proportion of cases, followed by left-sided and right-sided CRC. There was a statistically significant difference in the anatomic distribution among the four geographic regions ( $P < 0.05$ ). Comparison of histological type ( $\chi^2 = 459.561, P < 0.001$ ) and degree

<sup>1</sup> $\chi^2 = 13.307, P = 0.038$ ; <sup>2</sup> $\chi^2 = 459.561, P = 0.000$ ; <sup>3</sup> $\chi^2 = 409.296, P = 0.000$ .

of differentiation ( $\chi^2 = 409.296, P < 0.001$ ) in the four areas is shown in Table 5, there were significant differences in the four geographic areas.

## DISCUSSION

China has experienced a dramatic change in economy and lifestyle over the past two decades and this has led to a substantial increase in the incidence of CRC<sup>[4,15]</sup>, especially in Guangdong Province. It is important to understand the epidemiological characteristics of CRC in Guangdong. Data from the five hospitals in four representative areas of Guangdong were selected as a representative sample of CRC characteristics in Guangdong Province.

Although the hospitalization rate was not equal to the incidence rate, the increasing hospitalization rate in our study provided some information about the characteristics of CRC in recent years. Multiple risk factors increasing the incidence of colorectal cancer include: age, dietary habit, economic status and geographic location<sup>[6]</sup>. Previous studies suggested that the epidemiology of CRC is based on three main characteristics in China<sup>[17]</sup>. First, the peak age of CRC in China was lower than that in Western Countries, and the mean age was 45 years. Second, a high proportion of rectal cancer to colon cancer (1.5:1), and finally, a higher proportion of young CRC patients (10%-19%). Our data showed that the mean age was 56 years and this trend could be found in all the four areas, which was much higher than that in the previous studies. An important attribute of this trend was the increasing proportions of the elderly patients<sup>[6,18]</sup>.

A high proportion of young CRC patients shown by previous studies has been an important characteristic of CRC in China, but it was difficult to compare data regarding age<sup>[19-21]</sup>. Compared with the elderly CRC patients, the young CRC patients had the following characteristics: a low ratio of male to female; a high proportion of rectum cancer; a high proportion of poorly differentiated carcinomas; and a low proportion of right-sided lesions. In a recent study, we defined young age as 30 years<sup>[22]</sup>, and using this definition, the proportion of young CRC patients decreased while that of elderly CRC patients ( $\geq 60$  years) increased. But the number of patients hospitalized for CRC was similar, suggesting that the decreasing number of young CRC patients was associated with the increase of elderly CRC patients.

Previous studies have shown that the proportion of female CRC patients has increased in recent years<sup>[23,24]</sup>. One possible explanation for the role of gender may be the effect of female hormones<sup>[25]</sup>. Recently there have been suggestions that hormonal replacement therapy may decrease the incidence of CRC in female<sup>[20]</sup>. However, our data is not in agreement with this trend, but the ratio of male to female increased with age. However, this requires further research.

The prevalence of cancer in the left or right colon was different based on the age, gender, as well as high- and low-incidence nations<sup>[26]</sup>. It is controversial about the anatomic distribution of tumors, particularly about the changes observed with time<sup>[27]</sup>. Previous studies showed the ratio of rectum cancer to colon cancer was 1.5:1, and a left to right-sided shift of tumors was reported in China<sup>[13]</sup>. Other studies have shown that Asians and Pacific Islanders

have a higher incidence of distal lesions in older patients ( $\geq 70$  years), compared with proximal cancers<sup>[28]</sup>. Our data clearly showed a decrease of rectal cancer and an increase of right sided lesions, but no significant difference between different age groups. Cancers of proximal and distal colon are different s because of their embryologic origin, genetic factors and biologic identity<sup>[27]</sup>. The shift of tumors could be attributed to the change of life style, environmental factors and the increase of the elderly group<sup>[29,30]</sup>. Our results also suggested that the flexible sigmoidoscopy is not the first choice for CRC screening, even though it is more cost-effective compared with screening colonoscopy. Colonoscopy may be the preferred initial screening test. Most of CRC in present study is tubular adenocarcinoma and the proportion of tubular adenocarcinoma decreased from 79.3% to 67.7% with the shift from rectum to right colon. The proportion of mucinous carcinoma and signet-ring cell carcinoma increased from 9.3% to 19.0% and similar results were reported previously by other studies. This result may be related to different genetic background and different location of tumors.

In the present study, we report the characteristics of CRC between five hospitals located in four different areas in Guangdong. The mean age of CRC in the four areas increased, the lowest mean age was seen in North Guangdong and the highest mean age in East Guangdong. There is also a significant difference in anatomic distribution, histological type and differentiation type in the four areas. The data suggests that the hospitalization rate for CRC has increased over the past 20 years in Guangdong. The characteristics of CRC are different in the five hospitals located in the four different geographic areas. Further studies are needed to assess more recent trends in the incidence and prevalence of CRC as well as the respective roles of genetic and environmental factors of CRC in China.

We thank the Affiliated Hospital of Guangdong Medical College, Meizhou People's Hospital, North-Guangdong People's Hospital of Shaoguan for their help in this work.

## COMMENTS

### Background

The incidence of colorectal cancer (CRC) in China is lower than that in the west countries, but has increased in recent years and become a substantial cancer burden in China, particularly in the more developed areas. Some studies have reported changes in the characteristics of CRC in China. However, due to a lack of an effective nation-wide surveillance system, there has been little information available on the relationship between CRC and geographical environment and economic status in China.

### Research frontiers

In the present study, the authors report a large scale of survey on the characteristics of CRC in five hospitals located in four different areas in Guangdong, China. Their data will benefit the study on prevention and treatment of CRC.

### Innovations and breakthroughs

This study has gained a broader picture of CRC in Guangdong Province and provide important information on the changing epidemiology of this disease over a period of 20 years.

## Applications

Further studies are needed to assess more recent trends in the incidence and prevalence of CRC as well as the respective roles of genetic and environmental factors of CRC in China based on the present study.

## Peer review

The authors present an analysis of colorectal cancer within 4 regions of Guangdong Province of China over a 20-year period. Their case analysis suggests an overall increase in cancer cases as well as a rising mean age at presentation. Rectal cancer was found to be more common than colon cancer though the incidence of rectal cancer appears to have decreased while right-sided colon cancers have increased.

### Abstract

**AIM:** To test if inflammation also interferes with liver stiffness (LS) assessment in alcoholic liver disease (ALD) and to provide a clinical algorithm for reliable fibrosis assessment in ALD by FibroScan® (FS).

**METHODS:** We first performed sequential LS analysis before and after normalization of serum transaminases in a learning cohort of 50 patients with ALD admitted for alcohol detoxification. LS decreased in almost all patients within a mean observation interval of 5.3 d. Six patients (12%) would have been misdiagnosed with F3

and F4 fibrosis but LS decreased below critical cut-off values of 8 and 12.5 kPa after normalization of transaminases.

**RESULTS:** Of the serum transaminases, the decrease in LS correlated best with the decrease in glutamic oxaloacetic transaminase (GOT). No significant changes in LS were observed below GOT levels of 100 U/L. After establishing the association between LS and GOT levels, we applied the rule of GOT < 100 U/L for reliable LS assessment in a second validation cohort of 101 patients with histologically confirmed ALD. By excluding those patients with GOT > 100 U/L at the time of LS assessment from this cohort, the area under the receiver operating characteristic (AUROC) for cirrhosis detection by FS improved from 0.921 to 0.945 while specificity increased from 80% to 90% at a sensitivity of 96%. A similar AUROC could be obtained for lower F3 fibrosis stage if LS measurements were restricted to patients with GOT < 50 U/L. Histological grading of inflammation did not further improve the diagnostic accuracy of LS.

**CONCLUSION:** Coexisting steatohepatitis markedly increases LS in patients with ALD independent of fibrosis stage. Postponing cirrhosis assessment by FS during alcohol withdrawal until GOT decreases to < 100 U/mL significantly improves the diagnostic accuracy.

P, Seitz HK. Increased liver stiffness in alcoholic liver disease: Differentiating fibrosis from steatohepatitis. *World J Gastroenterol* 2010; 16(8): 966-972 Available from: URL: <http://www.wjgnet.com/1007-9327/full/v16/i8/966.htm> DOI: <http://dx.doi.org/10.3748/wjg.v16.i8.966>

## INTRODUCTION

Alcoholic liver disease (ALD) is the most common cause of liver cirrhosis in the Western world. It typically presents with various histological features ranging from steatosis to steatohepatitis and fibrosis/cirrhosis. Liver biopsy is currently considered the gold standard for assessing hepatic fibrosis or cirrhosis in these patients. However, it is an invasive procedure, with rare but potentially life-threatening complications<sup>[1]</sup>. In addition, the accuracy of liver biopsy in assessing fibrosis is limited owing to sampling error and interobserver variability<sup>[2-6]</sup>.

Transient elastography (FibroScan<sup>®</sup>) is a novel rapid and noninvasive method to assess liver fibrosis *via* liver stiffness (LS)<sup>[7]</sup>. LS measurements can be routinely performed in more than 95% of patients but is limited in those with severe obesity and ascites<sup>[8]</sup>. LS has mainly been studied in patients with viral hepatitis, but also ALD, and LS was shown to be strongly associated with the degree of liver fibrosis in all of these patients<sup>[9-14]</sup>. In these studies, cut-off values have been defined that allow the diagnosis of advanced fibrosis (F3/F4). Despite some variability, cut-off values of 8.0 and 12.5 kPa are widely accepted to identify patients with F3 and F4 fibrosis, respectively. These cut-off values are used in parts of our study for comparison purposes.

Although LS closely correlates with fibrosis stage, it also increases in patients with mild<sup>[15,16]</sup> or acute hepatitis<sup>[17]</sup>, cholestasis<sup>[18]</sup> and liver congestion<sup>[19]</sup>, independent of the degree of fibrosis. High transaminase counts, cholestasis and liver congestion can even cause LS that exceeds cut-off values for F4 fibrosis (cirrhosis)<sup>[17-19]</sup>. Since steatohepatitis often coexists with all stages of fibrosis in patients with ALD it may directly interfere with reliable assessment of fibrosis in these patients. Indeed, unusually high cut-off values for liver cirrhosis (19.5 kPa<sup>[13]</sup> and 22.6 kPa<sup>[14]</sup>) have been reported recently for cirrhosis in patients with ALD compared to cut-off values of around 12-14 kPa in viral cirrhosis<sup>[12]</sup>. In these ALD studies, patients had elevated serum transaminases but the impact of alcoholic steatohepatitis (ASH) on LS was not considered.

The aim of the present sequential FibroScan (FS) study was to determine the impact of ASH on LS and to develop recommendations for non-invasive fibrosis assessment in patients with ALD. We eventually demonstrate that such selection criteria improve the diagnostic value of FS.

## MATERIALS AND METHODS

### Patients

Patients were examined after obtaining informed con-

**Table 1** Patients' characteristics of the learning cohort and validation cohort

Parameter	Learning cohort (n = 50)		Validation cohort (n = 101)	
	mean	SD	mean	SD
Male	37		73	
Female	13		28	
Age (yr)	55.8	10.8	53.2	10.6
BMI (kg/m <sup>2</sup> )	26.0	4.4	25.4	4.2
GOT (U/L)	135.2	99.9	95.0	76.0
GPT (U/L)	104.6	173.4	90.2	133.7

sent. The study was approved by the Ethical Committee of the University of Heidelberg.

**Learning cohort:** In the first part of the study, sequential analysis of LS was performed in 50 patients with ALD presenting at Salem Medical Center/University of Heidelberg from June 2007 to March 2009 for alcohol detoxification. The cohort consisted of 37 male and 13 female patients with ALD. The mean age was  $55.8 \pm 10.8$  years. Observation intervals ranged from 2-10 d (mean 5.3 d). Longer time intervals were excluded to avoid potential changes in fibrosis stage. Patients showed typical laboratory findings of ASH with glutamic oxaloacetic transaminase (GOT) higher than serum glutamic pyruvic transaminase (GPT), steatosis in abdominal ultrasound and various degrees of LS. Patients' characteristics are detailed in Table 1.

Alcohol detoxification was performed using a chlor-methiazole standard tapering protocol for 3 to 10 d. Measurements of LS were performed on the day of

admission and on the day of discharge from Salem Medical Center. Patients with additional or other liver disease and co-morbidities known to interfere with LS measurements such as liver tumors, congestive heart failure or extrahepatic cholestasis were excluded from the study.

**Validation cohort:** In the second part of our study we included 101 patients with histologically staged ALD, a full set of blood tests and FS examination at the time of liver biopsy. The cohort included 73 men and 28 women with a mean age of  $53.6 \pm 10.6$  years. More patient details are given in Table 1. Importantly, the learning cohort and validation cohort did not differ significantly with regard to clinical parameters, age or gender. Liver biopsies were staged according to the Kleiner Score F0-F4<sup>[20]</sup>. F4 fibrosis was found in 26 patients (25.7%), F3 in 19 patients (18.8%), F2 in 36 patients (36.6%), F1 in 14 patients (13.8%), and F0 in 6 patients (5.9%). Thus, 45% had significant fibrosis stage F3-4.

### LS measured by transient elastography

LS was measured by FS (Echosens, Paris, France) as described recently in detail using the M probe<sup>[7]</sup>. The tip of the probe transducer was placed on the skin between the rib bones and the level of the right lobe of the liver. The measurement depth was between 25 and 65 mm below the skin surface. Ten measurements were performed with success rates of at least 60%. The results were expressed in kilopascals. The median value was taken as the representative value. Based on previous studies<sup>[10]</sup> and a recent meta-analysis<sup>[12]</sup>, cut-off values of 8.0 and 12.5 kPa were considered to be optimal for detecting F3 and F4 fibrosis stages, respectively. LS values from 2.4 to 5.5 kPa are considered as normal<sup>[10]</sup> although no large F0 validated control groups have been studied so far. The mean interquartile range (IQR) was 16% in all measurements. FS measurements with an IQR higher than 40% were excluded. Five of the initial 106 patients (3.2%) were excluded because of invalid LS measurements or high IQR values.

### Ultrasound examination

Ultrasound examination was routinely performed in addition to FS measurements to exclude extrahepatic cholestasis, liver congestion or liver tumors after patients had fasted for at least 6 h. Liver cirrhosis was suspected when 2 of the following criteria were present: (1) nodular aspect of the liver surface; (2) portal vein diameter > 12 mm; (3) collateral circulation; and (4) hypertrophy of segment 4 (quadrate lobe)<sup>[21]</sup>.

### Histology

Liver biopsy specimens were fixed in formalin and embedded in paraffin. All biopsy specimens were analyzed independently by 2 experienced pathologists (TL, PS) blinded to the results of FS and other clinical data. Liver fibrosis and necroinflammatory activity in patients with

ALD were scored according to the recently established Kleiner score<sup>[20]</sup>. The length of each liver biopsy specimen (in millimeters) and the number of fragments were recorded. Only biopsies > 15 mm were included.

### Statistical analysis

Correlations between changes in laboratory findings (serum transaminases, cholestasis parameters), LS and histological scores were calculated using the Spearman correlation for nonparametric variables (regression coefficient  $r$ ,  $P$ ). Differences were considered significant at  $P < 0.05$ . The diagnostic performance of FS was assessed by using receiver operating characteristic (ROC) curves. A patient was assessed as positive according to whether LS was greater than a given cut-off value. The ROC curve is a plot of sensitivity *vs* 1-specificity for all possible cut-off values. The most commonly used index of accuracy is the area under the ROC curve (AUROC), with values close to 1.0 indicating high diagnostic accuracy. As can be seen in the Results section from the box plot, only fibrosis stages F3 and F4 were successfully differentiated by FS. Therefore, AUROC and cut-off values were only determined for these fibrosis stages. All statistical analyses were performed with SPSS, version 12.0.1 (SPSS, Inc., Chicago, USA).

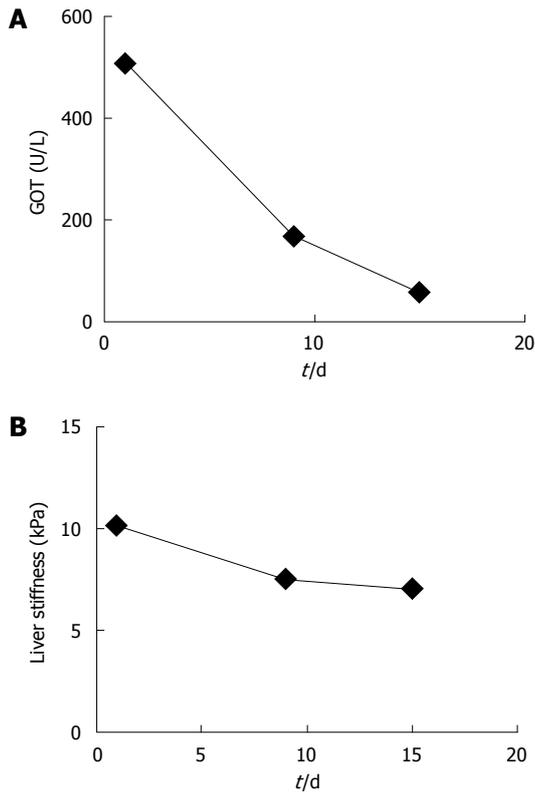

## RESULTS

### Dynamics of LS and transaminases in a single patient with acute ASH during alcohol withdrawal

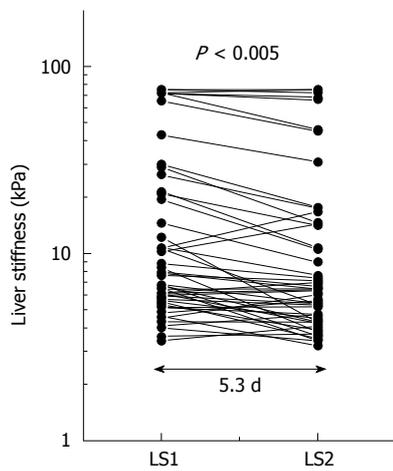

At first presentation, this female patient with chronic alcohol abuse presented with typical clinical and laboratory findings of acute and severe ASH with GOT of 511 U/L, GPT of 255 U/L and bilirubin of 3.5 mg/dL. The initial LS was 10.2 kPa which suggested advanced F3 fibrosis (Figure 1A and B). Within 9 d of alcohol detoxification, GOT decreased to 164 U/L and LS to 7.6 kPa. After another 6 d, GOT had almost normalized (55 U/L) while LS stabilized at 7.1 kPa. At the same time bilirubin had completely normalized. The patient was biopsied and histology confirmed a mild perivenular and periportal fibrosis (F2). This single case clearly demonstrated that LS increased as a result of steatohepatitis, irrespective of liver fibrosis. It also suggested that laboratory parameters such as GOT levels could be valuable bedside criteria to identify patients qualifying for reliable fibrosis assessment by FS.

### LS decreases in patients during alcohol detoxification independent of fibrosis stage

The observation above prompted us to sequentially study LS in patients with ALD undergoing alcohol detoxification under clinical surveillance (learning cohort). LS and serum transaminase activities in patients with various stages of fibrosis and steatohepatitis were obtained before and after detoxification from alcohol. Initial LS ranged from 2.5 to 75 kPa with 20 patients exceeding the cut-off value for F4 cirrhosis at 12.5 kPa.

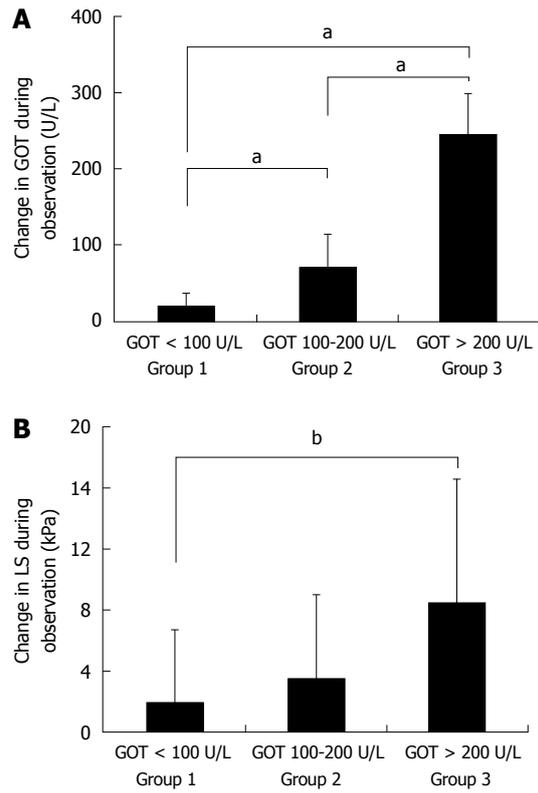

**Figure 1** Changes in liver stiffness (LS) in a single patient with severe alcoholic liver disease (ALD) during alcohol detoxification. Upon alcohol withdrawal, GOT (A) almost normalized and LS (B) decreased by more than 3 kPa. LS eventually remained stable at ca. 7 kPa corresponding well with the histologically confirmed F2 fibrosis stage.

**Figure 2** Sequential analysis of LS in 50 ALD patients following alcohol withdrawal over a mean observation period of 5.3 d. LS decreased in almost all patients during alcohol detoxification. A semilogarithmic plot was chosen to better visualize and compare changes in LS at various initial levels.

During the observation interval LS decreased significantly ( $P < 0.001$ ; mean decrease in LS, 3.5 kPa; maximum decrease, 26.3 kPa). LS decreased in 6 patients (12%) below critical cut-off values of 12.5 kPa for F4 cirrhosis ( $n = 2$ ) and 8.0 kPa for F3 fibrosis ( $n = 4$ ). Figure 2 shows the 2 sequential LS measurements depicted as a semilogarithmic plot. A decrease in LS correlated sig-

**Figure 3** Decrease in LS depends on the mean decrease in GOT levels (steatohepatitis) during alcohol withdrawal. A: Group 1 to 3 differ significantly ( $^aP < 0.05$ ) with regard to the mean decrease in GOT during alcohol withdrawal. Group 1 included patients with severe alcoholic steatohepatitis and GOT levels  $> 200$  U/L; group 2 included patients with GOT values between 100 and 200 U/L; group 3 were patients with GOT values  $< 100$  U/L. B: LS decreased by 8.4, 3.5 and 1.8 kPa, respectively, with a significant difference between groups 1 and 3 ( $^bP < 0.01$ ) (details in text).

nificantly with a decrease in GOT ( $r = 0.30$ ,  $P < 0.05$ ) and bilirubin ( $r = 0.37$ ,  $P < 0.05$ ). In 50% of patients, transaminases completely normalized during alcohol detoxification.

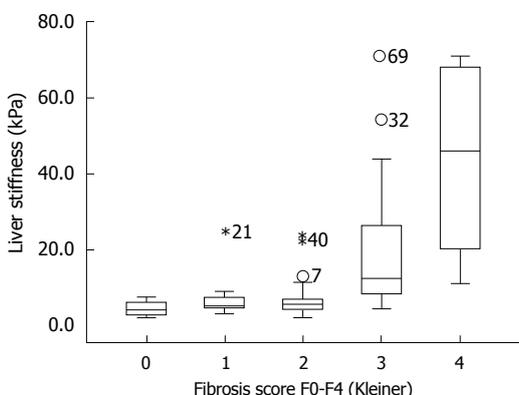

**ALD patients without significant laboratory signs of steatohepatitis (GOT  $< 100$  U/L) show stable LS**

It is known that in ALD patients GOT levels highly correlate with histological degree of ASH<sup>[22,23]</sup>. We therefore divided all 50 patients into 3 groups according to their degree of inflammation (mild, medium, severe) represented by their initial levels of GOT (not shown). Group 1 included patients with severe ASH and GOT levels  $> 200$  U/L, group 2 contained patients with GOT values between 100 and 200 U/L and group 3 patients with GOT values below 100 U/L. There was no significant difference between the 3 groups with respect to LS, observation interval, and IQR. However, as shown in Figure 3A, all groups differed significantly with regard to the mean decrease in GOT during alcohol withdrawal. Group 1 showed a mean GOT decrease of 244.8 U/L, group 2 of 70.1 U/L, and group 3 of 15.0 U/L. At the same time, LS decreased by 8.4, 3.5 and 1.8 kPa in groups 1, 2 and 3, respectively (Figure 3B) with a sig-

**Table 2** Excluding patients with elevated GOT levels indicating steatohepatitis improves the diagnostic value (AUROC, sensitivity and specificity) of FibroScan for the diagnosis of F3/F4 fibrosis

	Area under the curve (AUROC)	Std. error	Cut-off value (kPa)	Sensitivity	Specificity	Number of included patients
F4	0.921	0.03	11.5	1.00	0.77	101
F4 without GOT > 100 U/L	0.944	0.02	12.5 <sup>1</sup>	0.96 <sup>1</sup>	0.80 <sup>1</sup>	101 <sup>1</sup>
F4 without GOT > 50 U/L	0.945	0.03	10.4	0.95 <sup>1</sup>	0.90 <sup>1</sup>	86 <sup>1</sup>
F3/4	0.914	0.03	8.0	0.91	0.75	101
F3/4 without GOT > 100 U/L	0.922	0.03	8.0	0.87	0.87	80
F3/4 without GOT > 50 U/L	0.946	0.03	8.0	1.00	0.84	67

<sup>1</sup>Represent commonly used cut-off values (12.5 and 8.0 kPa) for comparison with other studies. Additional cut-off values with 100% sensitivity and different cut-off values for F4 fibrosis are specific to this study.

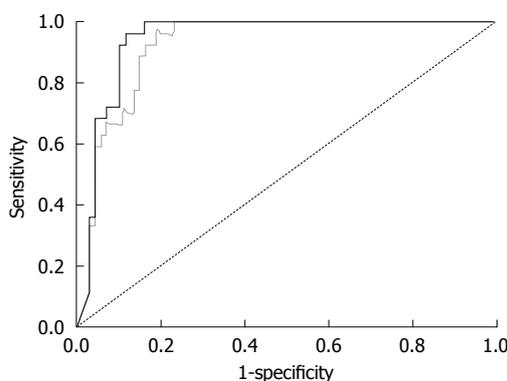

**Figure 4** Box blot showing LS as a function of fibrosis stages F0-F4. A significant increase in LS is seen from fibrosis stage F3 onwards. The length of the box represents the interquartile range within which 50% of the values were located. The line through the middle of each box represents the median. The error bars show the minimum and maximum values (range). Numbered symbols represent out-of-range patients excluded by the box plot.

nificant difference between group 1 and 3 ( $P < 0.01$ ). In group 1, 6 out of 8 patients (75%) showed a decrease in LS below critical cut-off values for F3/F4 fibrosis of 8.0 and 12.5 kPa (not shown). In contrast, only 2 patients crossed the critical cut-off value in group 2 (9%) and none in group 3.

Two patients had an increase in LS from 10.2 to 14.4 kPa and 10.7 to 16.4 kPa during alcohol detoxification therapy. Patient 35 showed an increase in GOT levels and compliance to alcohol abstinence could be questioned in this case while the reason for increased LS in the other patient remained unclear. In conclusion, LS is more likely to decrease in ALD patients with high initial GOT levels but remains stable once GOT levels are below 100 U/L.

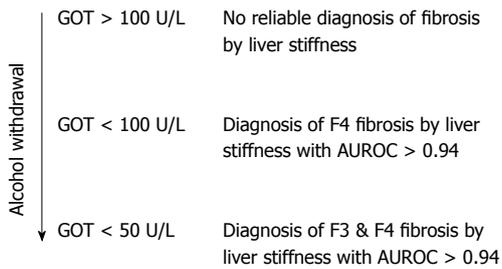

**Restriction of LS measurements to patients with GOT < 100 U/L significantly improves assessment of F4 fibrosis**

The finding that LS remained stable once GOT levels were below 100 U/L led us to the hypothesis that the diagnostic accuracy of FS will increase when ALD patients with GOT > 100 U/L are excluded. To test this hypoth-

**Figure 5** Receiver operating characteristic curves (ROC) for LS in patients with F4 fibrosis (liver cirrhosis) before (gray) and after (black) exclusion of patients with GOT > 100 U/L. The areas under the ROC (AUROC) curve are given in Table 2.

esis, we prospectively studied LS in our validation cohort of 101 consecutive patients with biopsy-staged ALD including or excluding patients with GOT > 100 U/L. The patients' characteristics are given in Table 1. Including all patients we were able to show that LS correlated highly significantly with the histological fibrosis score ( $r = 0.72, P < 0.001$ ) thus confirming recent studies<sup>[13,14]</sup>. As seen in the box plot (Figure 4), markedly elevated LS was mainly observed in advanced fibrosis (F3 and F4). Figure 5 shows the ROC curve for F4 fibrosis in the cohort of 101 patients including all patients (gray line). AUROC, which represents the diagnostic accuracy of a novel method as compared to the gold/best standard (histology) for fibrosis stage F4 was 0.921 (95% confidence interval, 0.87-0.97) (Table 2). We then identified 15 of these 101 patients (14.8%) with laboratory signs of significant ASH with an elevated GOT > 100 U/L. In 9 of these patients, there was a discrepancy between LS values of > 12.5 kPa but no histological evidence of liver cirrhosis. After exclusion of these patients with GOT > 100 U/L, AUROC for cirrhosis assessment by FS increased from 0.921 to 0.946, while specificity increased significantly from 80% to 90% at a sensitivity of 96%. Exclusion of patients with only a slight elevation of GOT (> 50 U/L)

**Figure 6 Proposed algorithm for the noninvasive assessment of fibrosis by FibroScan in patients with ALD.** GOT levels are used as criteria to exclude ongoing steatohepatitis that may falsely increase LS diagnosis independent of fibrosis stage. F4 cirrhosis can be detected by FibroScan with high accuracy if restricted to patients with GOT levels < 100 U/L. F3 fibrosis stage can be assessed with comparable accuracy if restricted to patients with GOT < 50 U/L (details in text).

or histological signs of steatohepatitis did not further improve diagnostic accuracy for F4 fibrosis in our patient cohort. In contrast, diagnostic accuracy for F3 fibrosis (cut-off value 8 kPa) further improved when excluding patients with GOT > 50 U/L (Table 2). In summary, these data demonstrated that excluding patients with laboratory signs of ASH significantly improved the diagnostic accuracy of FS in detecting fibrosis.

## DISCUSSION

LS correlates well with the histological stage of liver fibrosis in various liver diseases including patients with ALD<sup>[7-14]</sup>. However, independent of the degree of fibrosis, LS is also increased in patients with inflammatory hepatitis<sup>[15-17]</sup>, congestive heart failure<sup>[19]</sup> and cholestasis<sup>[18]</sup>. Therefore, refined clinical algorithms are required to exclude patients with increased LS as a result of such confounding factors.

We here found in a learning cohort of 50 patients with ALD that LS decreased significantly in patients with ALD following alcohol detoxification and resolution of steatohepatitis as measured by transaminases. The decrease in LS during alcohol detoxification could not be explained by changes in fibrosis stage given the short observation interval of 5.3 d. Therefore any change in LS must be attributed to other factors, most likely steatohepatitis. Of the serum transaminases, GOT showed the greatest correlation with the decrease in LS. This emphasizes the role of steatohepatitis in reversible elevation of LS. In fact, no significant changes in LS were observed in patients with GOT < 100 U/L, which fits clinical data indicating that at GOT levels < 100 U/L no relevant steatohepatitis has been demonstrated<sup>[22,23]</sup>.

After demonstrating that resolution of steatohepatitis decreased LS, we tested the hypothesis that the accuracy of cirrhosis detection can be increased by excluding patients with clinically relevant steatohepatitis. A validation cohort of 101 patients with histologically confirmed ALD was established and we compared FS accuracy in the whole cohort, and after excluding those patients with relevant clinical steatohepatitis (defined as GOT >

100 U/L). Indeed, including only ALD patients with GOT levels < 100 U/L increased the sensitivity and specificity of LS in diagnosing liver cirrhosis. We therefore suggest that GOT levels should be considered when assessing fibrosis by transient elastography in patients with ALD, and that elevated LS values at GOT > 100 U/L should be interpreted with caution because of the possibility of falsely elevated LS as a result of steatohepatitis.

This improvement in diagnostic accuracy is remarkable since any increase in AUROC above 0.9 is an important improvement given a prevalence of significant disease (F3/F4) of > 40% and an assumed 'best scenario' of liver biopsy accuracy of 90%<sup>[24]</sup>. We would also like to point out that the impact of these novel criteria clearly depends on the percentage of patients with significant ASH, which was rather low (< 15%) in our study cohort. The combined effect of both inflammation and fibrosis on LS in patients with ALD may also explain the unusually high cut-off values for F4 cirrhosis of 19.5 kPa and 22.6 kPa and a rather low AUROC of 0.87 that has recently been reported in patients with ALD<sup>[13,14]</sup>.

Although the rule of GOT < 100 U/L seems to be sufficient to eliminate any inflammation-based interference on F4 fibrosis assessment by FS, even modest signs of inflammation become relevant for lower fibrosis stages such as F3. Thus, our analysis showed that assessment of F3 fibrosis by FS was further improved if LS measurements were restricted to patients with completely normalized GOT levels. This outcome can be explained by the fact that the cut-off value for F3 fibrosis (8 kPa) can be easily reached by even mild steatohepatitis.

We conclude that, in patients with ALD, a more accurate noninvasive assessment of fibrosis stage by transient elastography can be achieved if the degree of steatohepatitis is considered. A clinical algorithm is proposed in Figure 6. It should be mentioned that other known interferences with LS assessment such as liver metastasis, mechanic cholestasis<sup>[18]</sup> or liver congestion<sup>[19]</sup> should also be excluded at the time of transient elastography. Finally, we suggest that these criteria may also be useful in improving the assessment of noninvasive fibrosis by FS in patients with other liver diseases.

## COMMENTS

### Background

Transient elastography (Fibroscan®) is a new ultrasound technology where the liver stiffness (LS) is measured via propagation velocity of an ultrasound wave. LS is low (2-6 kPa) in the soft healthy liver but dramatically increased in liver cirrhosis (up to 75 kPa). Fibroscan is now widely studied since it is a reliable, easy to perform and noninvasive bedside test to screen for liver cirrhosis. However, recent studies showed that LS is also increased under conditions other than cirrhosis namely liver congestion, cholestasis and inflammation (hepatitis). In particular, inflammation is a common confounding factor for chronic liver disease and novel algorithms are required to clearly determine whether LS is increased as a result of cirrhosis or inflammation. Dr. Sebastian Mueller and his colleagues from Heidelberg University identified in their recent study novel bedside criteria that allowed the differentiation of cirrhosis from inflammation in patients with alcoholic liver disease (ALD), the most common liver disease in developed countries.

**Research frontiers**

In a cohort of 50 patients who were hospitalized for alcohol withdrawal LS was analyzed for about a week in parallel with liver blood tests. LS decreased in all patients during alcohol withdrawal owing to reduction in liver inflammation and normalization of liver blood tests. In 6 of these 50 patients, the initial LS value had suggested liver cirrhosis but, after alcohol withdrawal, it decreased below the critical cut-off and misdiagnosis of liver cirrhosis could be avoided. Glutamic oxaloacetic transaminase (GOT) values > 100 U/L indicated inflammatory interference, while at lower counts LS was a reliable parameter for determining inflammation-independent liver fibrosis. Therefore the hypothesis was generated that measuring LS after resolution of the inflammation and at GOT levels < 100 U/L would result in more accurate assessment of LS. To test this hypothesis 100 patients with ALD underwent liver biopsy and LS determination at the same time. Comparing the stage of liver fibrosis assessed by liver biopsy with LS showed concordance in 92% of patients. When those patients with elevated liver enzyme counts > 100 U/L were excluded, transient elastography increased in accuracy for diagnosing liver cirrhosis to 94.5%.

**Innovations and breakthroughs**

The study defined novel bedside criteria based on liver transaminases that optimized noninvasive diagnosis of liver cirrhosis in patients with ALD. Active inflammation of the liver (steatohepatitis) should be excluded first by blood tests prior to the noninvasive assessment of liver fibrosis by transient elastography. If GOT levels are < 100 U/L, the LS value can identify liver fibrosis and can be used as a diagnostic tool.

**Applications**

The novel criteria should be applied to all LS measurements with ongoing steatohepatitis (increased transaminases in the blood test). Thus, a blood test is required for the correct interpretation of LS data. These novel criteria probably also hold true for other liver disease.

**Peer review**

This is an interesting paper on a highly relevant topic. The presence of steatohepatitis was evidenced by increased GOT.

### Abstract

**AIM:** To search for further immunodominant peptides of the pyruvate dehydrogenase complex E2-component (PDC-E2) recognized by antimitochondrial antibodies (AMA) in primary biliary cirrhosis (PBC).

**METHODS:** Sera from 95 patients with PBC were tested by enzyme-linked immunosorbent assay against 33 synthetic overlapping peptides (25 amino acids; aa) covering the entire length of the E2-subunit of PDC-E2. Furthermore, the inner lipoyl peptide 167-184 was used in an unlipoylated and a lipoylated form as well as coupled to ovalbumin. Sera from 11 AMA negative/ANA positive PBC patients, 63 patients with other liver disorders and 22 healthy blood donors served as controls.

**RESULTS:** Of the 95 PBC-sera, 74% reacted with the peptide 475-499 and 58% with the peptide 407-431 located within the catalytic domain of PDC-E2. Patients with other disorders or healthy controls were positive in only up to 18%. Antibodies to the unlipoylated

and lipoylated peptide 167-184 within the inner lipoyl domain were found in only 5% and 11% of the PBC sera, respectively; using ovalbumin-coupled peptides, the incidence increased up to 57% (unlipoylated form).

**CONCLUSION:** Peptides within the catalytic site of PDC-E2 rather than the previously reported lipoyl binding peptide 167-184 may represent major immunodominant epitopes recognized by AMA in PBC.

### INTRODUCTION

Antimitochondrial antibodies (AMA) are one of the most important criteria for the diagnosis of primary biliary cirrhosis (PBC), a chronic cholestatic liver disease of unknown etiology, which affects mainly middle-aged women and leads to a destruction of small bile ducts. Their target antigen named M2<sup>[1,2]</sup> is attached to the

inner mitochondrial membrane<sup>[3]</sup> and consists of five components<sup>[4]</sup>, which have been identified in the following years on molecular bases as subunits of the 2-oxo acid dehydrogenase complex of the inner mitochondrial membrane: the pyruvate dehydrogenase complex (PDC), the 2-oxoglutarate dehydrogenase complex and the branched-chain 2-oxo acid dehydrogenase complexes<sup>[5-7]</sup>. Each complex comprises multiple copies of three component enzymes termed E1 (a thiamine pyrophosphate-dependent decarboxylase), E2 (a coenzyme A-dependent decarboxylase), and E3 (a dihydrolipoyl dehydrogenase). The major M2-antigen which is recognized by nearly 90% of PBC sera is the E2 component of PDC.

The immunodominant epitope within PDC-E2 has been mapped to the region associated with the inner lipoyl domain wherein a lysine residue binds the lipoic cofactor for the enzyme with a minimum of 75 residues necessary for characteristic antibody recognition<sup>[6,8,9]</sup> suggesting that a conformational autoepitope may be primarily recognized<sup>[9]</sup>. A minor epitope is associated with the outer lipoyl domain<sup>[6,10]</sup>. Hitherto, epitope mapping with PBC sera has linked AMA-reactivity to the highly conserved amino acids surrounding the lipoyl-lysine K173, particularly linear peptides AEIETDKATIGFEVQEEG (corresponding to aa 167-184 within the human PDC-E2 but primarily labeled aa 81-100<sup>[6]</sup> according to its location within a subclone pRMIT-603 used to identify the immunodominant epitope) or LLAEIETDKATIGF (165-178)<sup>[11]</sup>. It was shown that these short peptides absorbed most reactivity with PBC sera by enzyme-linked immunosorbent assay (ELISA), albeit only at a serum dilution of 1:80000<sup>[6]</sup>. Binding of lipoic acid cofactor to K173 has been discussed to be necessary for antibody reaction<sup>[10,12]</sup>.

Until now, the large fragment of the catalytic domain of PDC-E2 (aa 331-560) has been regarded as 'immunologically silent' due to negative results in several studies<sup>[6,9,12-14]</sup>. In the present study we used peptides spanning the whole PDC-E2 enzyme, and it will be shown that sera from PBC patients recognize epitopes within the catalytic domain in an even higher incidence than those in the inner lipoyl domain.

## MATERIALS AND METHODS

### Patients

Sera from 95 patients with clinically well defined PBC were analyzed. All patients had been seen by one of the authors (Berg C), and all were AMA/anti-M2-anti-PDC-E2 positive. Detailed clinical, biochemical and histological data are given in Table 1.

Liver biopsy had been performed in 65 of the patients and was interpreted by Dr. Bianchi L, Professor, University of Basel, Switzerland. All patients had been followed for more than 5 years (range: 5-28 years). At time of first serum analysis, 65 had not yet received any therapy, 30 were already treated with ursodeoxycholic acid (at least 6 mo, doses 1000-1500 mg/d).

<sup>1</sup>Referring only to the 65 untreated patients; <sup>2</sup>Liver biopsy had been performed in 65 patients; 42 of them were untreated, and of these patients 30 were in stage I / II and 12 in stage III / IV. IFT: Immunofluorescence test; ELISA: Enzyme-linked immunosorbent assay; PBC: Primary biliary cirrhosis; PDC-E2: Pyruvate dehydrogenase complex E2-component.

Furthermore, sera from 11 patients with clinically and histologically proven PBC being AMA negative but ANA positive were investigated. Five had antibodies to nuclear dots (sp 100), three to nuclear membranes (gp 210) and two to centromeres.

The investigations have been approved by the local Ethics committee.

### Control groups

As controls we used sera from 36 patients with untreated autoimmune hepatitis, 27 patients with alcoholic liver disease, and 32 patients with collagen disorders. All patients have been seen and followed either by Berg C or Klein R. Diagnosis was based on clinical, biochemical and serological parameters.

Sera from 22 healthy blood donors (kindly provided by Dr. Wernet D, Professor, Institute for Transfusion-medicine, University of Tübingen, Germany) were used as controls, all being negative for AMA/anti-M2 as shown by immunofluorescence test (IFT), ELISA and Western blotting. All sera were stored at -20°C.

**Figure 1** Amino acid (aa) sequence of the human pyruvate dehydrogenase complex E2-component (PDC-E2). For epitope mapping 25 mer peptides with 8 overlapping amino acids were constructed (see also Table 2). Overlapping amino acids are printed in bold; amino acid sequences of the immunodominant lipoyl binding epitopes in the outer (aa 41-53) and inner lipoyl domain (aa 167-183) are underlined. \*Lipoyl binding lysine in the outer and inner lipoyl domains; \*\*Active sites within the catalytic domain (S480 and H534).

## Antigens

The M2-antigen was released from beef heart submitochondrial particles by chloroform treatment as described<sup>[2]</sup>. Commercial PDC (from porcine heart) was obtained from Sigma-Aldrich (St. Louis, USA).

Thirty-three synthetic overlapping peptides covering the entire length of PDC-E2 were obtained from Biotrend (Cologne, Germany). Peptides were 25 amino acids (aa) long with 8 overlapping aa (Figure 1).

Peptide 11 contained the immunodominant decameric epitope consisting of aa IETDKATIGF as reported by Van de Water *et al.*<sup>[6]</sup>, which had been extended to a 15 amino acid peptide by Amano *et al.*<sup>[15]</sup> (IETDKATIGFEVQEE). All peptides were high-performance liquid chromatography (HPLC)-purified (more than 90% purity). An irrelevant peptide was used as background control. The peptides were reconstituted at 5 mg/mL DMSO and stored at -20°C.

The immunodominant peptide 167-184 (AEIETDKATIGFEVQEEG) was synthesized (Biotrend, Cologne, Germany) in an unlipoylated form and a form in which lipoic acid was coupled to lysine at position 173 (167-184-LA)<sup>[12]</sup>. Purity and conjugation was proven by HPLC (elution time 984.5 m/z vs 1076.7 m/z; purity > 95%). Since these peptides may be recognized only when attached to a carrier<sup>[12]</sup>, both forms of peptides were also coupled to ovalbumin (Biotrend, Cologne, Germany). For this purpose, at the C-terminal end a cysteine had to be added (AEIETDKATIGFEVQEEGC-OVA) which had to be substituted by a lysine for coupling the LA-

conjugated [AEIETDK<sub>(alpha-lipoic)</sub>ATIGFEVQEEGK-OVA]peptide. The presence of the hydrophobic lipoic acid moiety covalently bound to the peptide was again confirmed by the significant differences in HPLC-elution profiles when peptides without or with LA were analyzed (elution time 1.067.8 m/z vs 1.163.3 m/z; purity > 93%).

## IFT

In the IFT cryostat sections from rat liver, kidney, heart, stomach and human thyroid were used to detect AMA and other autoantibodies<sup>[16]</sup>.

## ELISA

The ELISA for the detection of anti-M2/PDC-E2 antibodies was performed as described<sup>[17]</sup>.

Antibody reactivity with PDC-E2 peptides was determined using microtiter plates (Maxisorp, Nunc, Denmark) coated with 100 µL of each peptide at a concentration of 25 µg/mL in coating buffer (hydrogen bicarbonate buffer, 0.2 mol/L, pH 9.6) overnight at 4°C. After extensive washing and blocking with phosphate buffered saline (PBS) (60 mmol/L, pH 7.4) containing 1% bovine serum albumin (BSA) for 60 min they were incubated with 100 µL of patients' sera at a dilution of 1:500 for 90 min at room temperature. After washing with PBS containing 0.2% Triton X 100 and 0.5% BSA, the wells were incubated with peroxidase-conjugated monovalent anti-human IgG- and IgM-antibodies from goat (Dianova, Hamburg, Germany; dilution 1:3000) for 60 min at room temperature, washed as above, and AMA reactivity detected using orthophenyldiamine as substrate. Antibody reactivity was given as absorbance × 1000.

Optimal peptide concentrations (25 µg/mL) and serum dilutions (1:500) had been determined by serial dilutions prior to the study.

Normal ranges for antibody reactivities with all antigens/peptides were determined by analysis of 22 healthy donors. Mean value of their absorbance plus double the standard deviation was defined as cut off value.

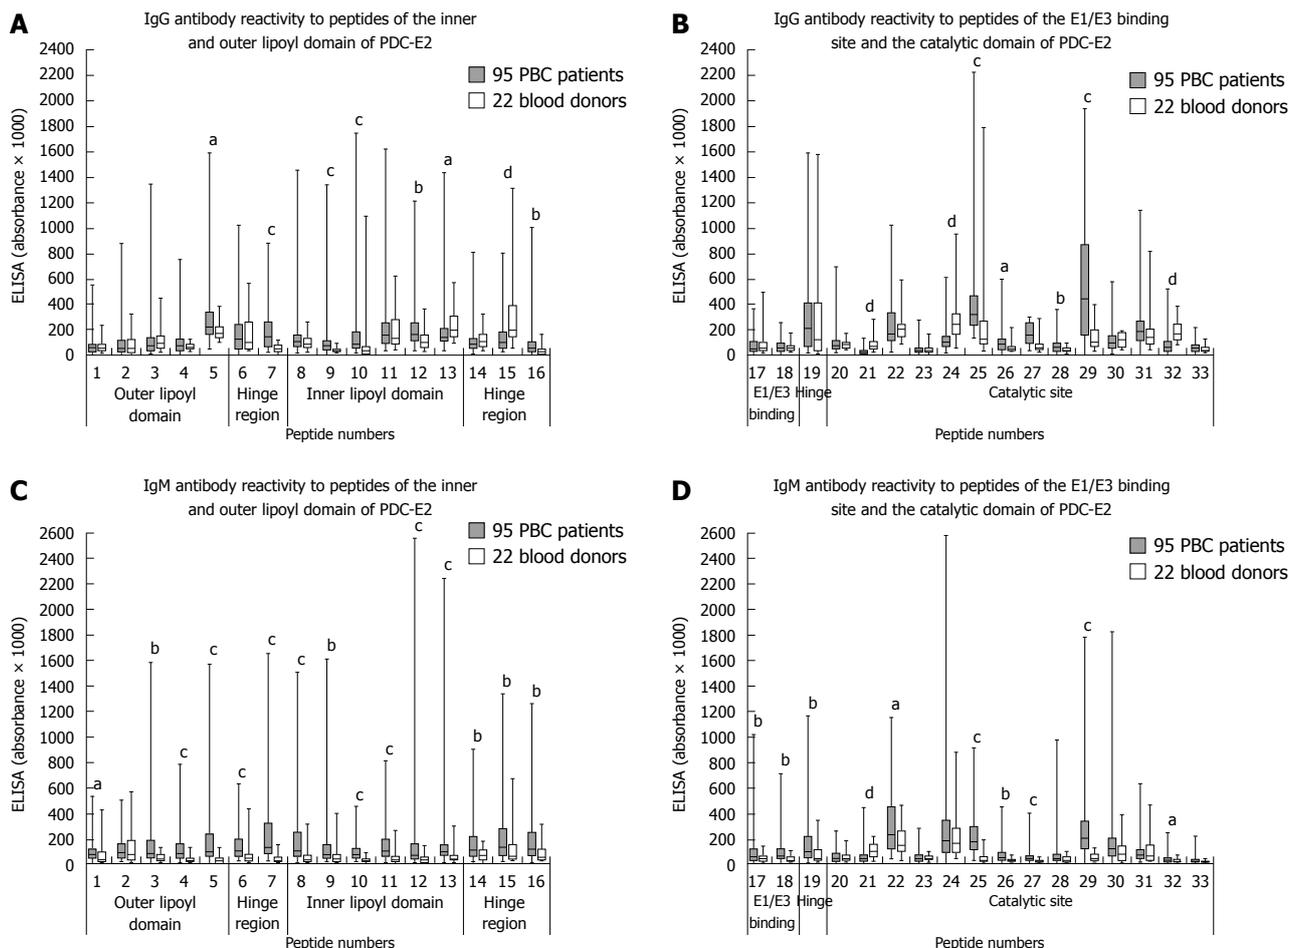

## Statistical analysis

For the comparison of antibody reactivity in different groups of patients, SPSS version 15.0 was used applying the non parametric Mann-Whitney test. For analysis of paired data the Wilcoxon signed rank test was used. Differences with  $P < 0.05$  were considered statistically significant.

## RESULTS

### High incidence of antibodies to epitopes within the catalytic site of PDC-E2 in PBC sera

Sera from 95 patients with PBC all being anti-M2/PDC-E2 positive in the ELISA using the purified M2-antigen and the commercially available PDC were tested

**Figure 2** Box plots showing the reactivity of sera from 95 primary biliary cirrhosis (PBC) patients (grey bars) and 22 blood donors (white bars) with 33 overlapping peptides spanning the whole PDC-E2 sequence. IgG antibody reactivities. A: Peptide 1-16; B: Peptide 17-33; IgM antibody reactivities. C: Peptide 1-16; D: Peptide 17-33. Solid bars extend from the 25th to 75th percentile. The line in the middle is the median. The whiskers extend down to the lowest value and up to the highest value. Significantly higher antibody reactivity with PBC sera than with sera from healthy individuals: <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01, <sup>c</sup>*P* < 0.001. Significantly lower antibody reactivity with PBC sera than with sera from healthy individuals: <sup>d</sup>*P* < 0.001. ELISA: Enzyme-linked immunosorbent assay.

against 33 peptides (25 mers) spanning the whole sequence of PDC-E2.

Surprisingly, the reactivity of the PBC sera with the peptides 3, 10 and 11 containing the immunodominant lipoyl binding epitopes in the outer (aa 41-53) and inner lipoyl domain (aa 167-183)<sup>[6,10]</sup> was rather low although significantly higher than that of healthy controls (Figure 2A and C). Only 11% had IgG-antibodies to peptide 3, 29% to peptide 10, and 12% to peptide 11; IgM-antibodies were observed in 28%, 37%, and 39%, respectively. In contrast, up to 74% of the PBC sera reacted with the two peptides 25 and 29 within the catalytic domain and the peptide 7 (aa 101-125) in the first hinge region (Tables 2 and 3), and IgG and IgM reactivity towards these three peptides was significantly higher in PBC patients than in controls (Figure 2).

The peptides 15, 21 and 24 were the only ones whose reactivity was lower with PBC sera as compared to control sera (Figure 2A, B and D).

Most PBC sera recognized several peptides in parallel. IgM-antibodies generally reacted with a higher diversity of peptides than IgG-antibodies (IgG: mean ± SD: 5.3 ± 7.7 peptides, median: 3 peptides, range: 0-30

peptides; IgM: mean ± SD: 9 ± 7.1 peptides, median: 7 peptides, range: 0-28 peptides). Two PBC sera had neither IgG- nor IgM-antibodies to any of the 33 peptides although both sera showed high antibody reactivities towards PDC and M2 in the ELISA.

Sera from patients with AMA negative/ANA positive PBC hardly reacted with any of the peptides (Tables 2 and 3).

Incidence and reactivity of antibodies to the different peptides in sera from patients with autoimmune hepatitis, alcoholic liver disease and collagen disorders resembled that in healthy controls (data not shown).

**Reactivity of PBC-sera with the inner lipoyl domain epitope aa 167-184 using different conjugates**

In view of the fact that the 25 mers peptide 10 (aa 152-176) and 11 (aa 169-193) used in the epitope mapping above did not completely respond to the published sequence 167-184 (AEIETDKATIGFEVQEEG), we also synthesized the latter peptide in an unlipoylated form and a form containing lipoic acid (LA) at aa K173 (peptide 167-184-LA) and applied both forms in the ELISA. In accordance to a previous study<sup>[12]</sup>, also with

<sup>1</sup>Twelve patients had antibodies only of the IgG-, 28 only of the IgM-, and 30 of the IgG- and IgM-type; in total, 70 (71%) reacted with peptide 7; <sup>2</sup>Four patients had antibodies only of the IgG-, 30 only of the IgM-, and 7 of the IgG- and IgM-type; in total, 41 (43%) reacted with peptide 11; <sup>3</sup>Seventeen patients had antibodies only of the IgG-, 18 only of the IgM-, and 37 of the IgG- and IgM-type; in total, 72 (76%) reacted with peptide 25; <sup>4</sup>Two had antibodies only of the IgG-, 16 only of the IgM-, and 53 of the IgG- and IgM-type; in total, 71 (75%) reacted with peptide 29. Similar data as for healthy controls were obtained with sera from patients with autoimmune hepatitis, alcoholic liver disease and collagen disorders. Peptides 3, 10, 11, 25 and 29 are previous and novel immunodominant epitopes. +: Positive; -: Negative.

these peptides reactivity of the 95 PBC sera was low (Table 4).

In order to find out whether the antibodies may recognize a conformational epitope the peptides were coupled to ovalbumin (OVA-peptide 167-184 and OVA-peptide 167-184-LA)<sup>[12]</sup>. With these conjugated peptides reactivity was stronger, but most sera showed a high reactivity already with OVA alone (Figure 3). IgG- and IgM-reactivity towards the unlipoylated OVA 167-184 was significantly higher than that towards the lipoylated form (OVA 167-184-LA), reactivity towards both forms of peptides was significantly higher than that against OVA alone.

<sup>1,2,3,4</sup>Same as Table 2. Peptides 3, 7, 10, 11, 25 and 29 are previous and novel immunodominant epitopes.

After subtracting the reactivities with OVA from that with the OVA-coupled peptides, 42 (44%) of the 95 PBC sera had IgG-antibodies to the unlipoylated (OVA 167-184) and 21 (22%) to the lipoylated peptide (OVA 167-184-LA) (Table 4). IgM antibodies were found in 57% and 31%, respectively.

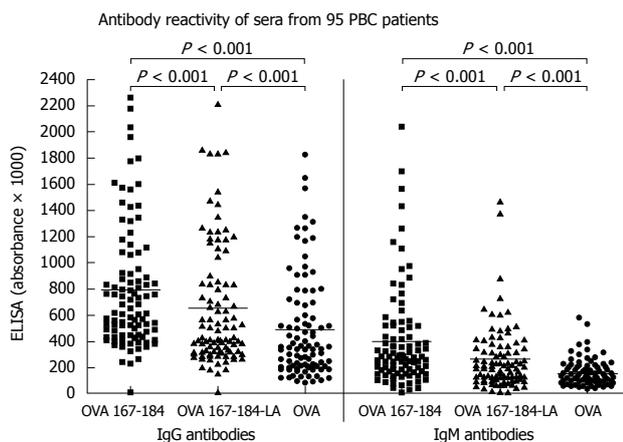

#### **Influence of UDCA-treatment on anti-peptide reactivities**

In order to see whether UDCA-treatment may influence the reactivity with distinct peptides we compared the reaction of 65 patients who were without any therapy at the time of serological analysis with that of 30 patients who received UDCA for at least 6 mo. However, no significant differences in antibody titers were observed for any of these antigens/peptides between the two groups (data not shown), and also mean number of peptides recognized by each patient did not differ [IgG: untreated group: mean  $\pm$  SD 5.7  $\pm$  6 peptides, median 4 peptides, treated group: 4.5  $\pm$  5.1 peptides, median 2 peptides ( $P = 0.11$ ); IgM: untreated group: 9.2  $\pm$  7 peptides, median

**Figure 3** IgG- and IgM-reactivity of sera from 95 PBC patients with the OVA coupled unlipoylated and lipoylated peptide 167-184 (OVA-167-184 and OVC-167-184-LA) (without subtraction of the OVA-values) and OVA alone.

7 peptides, treated group: 8.5 ± 7 peptides, median 6 peptides (*P* = 0.65)].

## DISCUSSION

The inner lipoyl domain of PDC-E2 and especially the peptide aa167-184 has been previously considered the prominent immunodominant epitope recognized by sera from PBC-patients, although there is no general consensus<sup>[6,10,11,15,18-20]</sup>. In these analyses sera from PBC patients were incubated with the peptide, and it was shown that it absorbed the anti-M2 activity, albeit only at high serum dilutions. In other studies fusion proteins were used containing the peptide and tested by ELISA against PBC sera revealing positive results. However, using this peptide in the ELISA, no significant reactivity with PBC sera was observed<sup>[5,12]</sup>. There was evidence that antigenicity could be improved after coupling the peptide to ovalbumin and/or lipoylation of K173<sup>[12]</sup>, but this is also still controversially discussed. Accordingly, the uncertainty on reactivity with the linear epitope and an absolute requirement for lipoylation of PDC-E2 for antibody reactivity strongly suggests that rather a conformational epitope within the inner lipoyl domain may

represent the immunodominant epitope as outlined by several authors<sup>[9,11]</sup>.

In the present study analyzing a large group of 95 patients with clinically, serologically and histologically defined PBC we could largely confirm these data. Thus, testing the sera by ELISA against 25 mer peptides spanning the whole sequence of PDC-E2, we found only a weak antibody reactivity to peptide 10 (aa 152-176) or peptide 11 (aa 169-193) containing the lipoyl binding K173 and a low incidence of positive results. Since these peptides derived from the peptide scan did not completely correspond to the published peptide 167-184, we also synthesized this epitope but again did not obtain significant reactions. In accordance with a previous report, antigenicity could be increased by coupling with OVA<sup>[12]</sup> while lipoylation had no additional effect. However, already antibody reactivity to OVA itself was rather high indicating that this protein is not suitable for coupling autoantigens to detect conformational autoantibodies in sera from patients with autoimmune disorders. The wide distribution of antibodies to OVA in the general population is a well known phenomenon<sup>[21]</sup>.

In contrast, we found strongly reactive linear epitopes in the first hinge region (peptide 7, aa 101-125) and in the catalytic domain of PDC-E2 - until now regarded as ‘immunologically silent’<sup>[9,14]</sup>. Thus, up to 55% of the 95 PBC sera had antibodies of the IgG- or IgM-type to peptide 7 and up to 74% to the peptides aa 407-431 (peptide 25) or aa 475-499 (peptide 29) in the catalytic domain. The specificity of this reaction was underlined by the finding that sera from patients with AMA negative PBC or other disorders did not react with these peptides. Although there have been several studies analyzing the catalytic domain they failed to detect relevant antibody reactivities<sup>[6,9,12]</sup>, but most of them used larger peptide sequences indicating that - in contrast to antibodies to the inner lipoyl domain - antibodies to the catalytic domain may be rather directed against linear and not against conformational peptides.

The reaction of PBC sera with the catalytic domain is of interest since it has been reported by several authors that anti-PDC-E2 antibodies inhibit the PDC-E2 enzyme activity, which has been attributed until now to their binding to the inner lipoyl domain<sup>[22-25]</sup>. However,

since the catalytic domain contains the active site an enzyme inhibition by interference with this region seems even more likely. Thus, the catalytic centre is formed by a long channel across the interface between the catalytic domains of two neighbored E2-subunits. The opening of the channel pointing towards the outer face of the molecule forms the lipoamide binding site, whereas the opposite entrance corresponds to the coenzyme A (CoA) binding site. In the middle of the catalytic centre there is a pair formed by H534 and Ser480 from neighboring E2-subunits (nomenclature according to human PDC) which separates these two substrate binding sites and is directly involved in the transacetylase reaction<sup>[26-32]</sup>. Our observation in the present study that highest antibody reactivity in PBC sera was obtained with peptide 29 (aa 475-499) which contains Ser480, might, therefore, also explain the inhibitory potency of PBC sera on PDC-E2-enzyme activity. The inner catalytic domain as a whole shares less than 35% sequence identity in prokaryote and human PDC. In contrast, the structures at the active sites are highly conserved in pro- and eukaryotes. The reactivity of autoantibodies with evolutionary highly conserved enzymes and their interaction with enzyme function *in vitro* is a quite frequently observed phenomenon in autoimmune disorders in general<sup>[33,34]</sup>.

The etiopathogenetic role of anti-M2/PDC-E2 antibodies for PBC is still a matter of debate. Coupling of the inner lipoyl domain with 2-octynoic acid instead of lipoic acid has been discussed to increase antigenicity of the enzyme PDC-E2, and common environmental, cosmetic and food additives containing this 2-octynoic acid have, therefore, be postulated to play a role in their induction by formation of an altered PDC-E2 in the sense of a neoantigen<sup>[15,35,36]</sup>. Our observation that anti-PDC-E2 antibodies react preferentially with the active site of the catalytic domain of PDC-E2 is strongly suggestive for a further mechanisms including molecular mimicry or defects in apoptosis<sup>[5,37,38]</sup>. Interestingly, similarity alignment (<http://www.expasy.org>) revealed that a sequence consisting of the five aa TFFTIS within peptide 29 containing the active site S480 shares an identity of 80% with a five-aa-peptide within an envelope protein of human  $\beta$ -retrovirus previously cloned from patients with PBC<sup>[39]</sup>. The relevance of this observation is, of course, still rather speculative.

Another peptide strongly recognized by PBC sera (up to 58%) was the peptide 25. However, 18% of healthy controls also reacted with this peptide indicating that probably natural autoantibodies towards this region exist. Also the fact that antibody reactivity to some peptides within the catalytic domain did not differ significantly between healthy individuals and PBC-patients (i.e. peptide 22, 30, 31) or were even lower in the PBC sera than in sera of the controls (peptides 15, 21 and 24) may point towards the existence of natural autoantibodies to several PDC-E2 epitopes as also outlined by others<sup>[5,13]</sup>. It is well known that natural autoantibodies, which play an important role in the 'first line defense' react preferentially with archaic enzymes, and this would fit with our observation. Interestingly, we

also observed antibodies to the PDC-E2 complex in sera from healthy family members of PBC-patients, but these seem to recognize other epitopes than the patients' sera (manuscript in preparation).

In general, most sera recognized several epitopes on the entire PDC-E2 molecule, and diversity of IgM antibodies was even higher than that of IgG antibodies. Using overlapping octameric peptides representing the inner lipoyl domain of PDC-E2 similar observations were made by Mackay *et al.*<sup>[5]</sup>, and they also noted that normal human sera reacted with multiple peptides, although levels of reactivity were generally lower than those observed using PBC sera<sup>[5,40]</sup>.

Two of the 95 PBC sera did not react with any of the 33 peptides although they were strongly anti-M2/PDC-E2 positive in ELISA and Western blotting again underlining the importance of conformational epitopes. Our preliminary findings that anti-M2/PDC-activity could not be significantly absorbed with any of the linear 167-184 peptides or with peptide 25 or 29 (data not shown), fit to this concept. Based upon molecular modeling of antibodies reacting with antigens, over 90% of B-cell epitopes are thought to be conformational<sup>[41,42]</sup>. Attempts to map B-cell epitopes have, therefore, met with mixed success depending largely on the system under investigation. Since there are so many different types of autoepitopes, linear, conformational, cryptic, *etc.*<sup>[43]</sup>, no universally applicable method is available that allows for the identification of all autoepitopes. Performing those analyses one has, therefore, to be aware of the techniques' advantages and disadvantages. Peptide scan as used in the present study does not allow determining conformational epitopes but it has the advantage that even cryptic epitopes can be detected. This method has been proven useful in the identification of immunodominant epitopes of several autoantigens for instance in collagen disorders<sup>[43]</sup>; and considering the concept of "epitope-spreading" it is not unlikely that the multiple immunoreactivity towards several linear and conformational epitopes in an autoimmune disease starts with cross-reactivity to a single (linear) peptide which may lead us to the initiating agent.

In conclusion, we have firmly documented that PBC sera react preferentially with peptides of the catalytic domain of PDC-E2. However, it still has to be proven whether this catalytic domain is also targeted by T-cells. Furthermore, the data again underline the importance of conformational epitopes for AMA-reactivity in PBC.

## COMMENTS

### Background

Antimitochondrial antibodies (AMA) reacting with the 2-oxo acid dehydrogenase complex of the inner mitochondrial membrane are highly specific for the serological diagnosis of primary biliary cirrhosis (PBC), a chronic cholestatic liver disorder of unknown etiology.

### Research frontiers

The M2-antigen consists of five components which have been identified as subunits of the 2-oxo acid dehydrogenase complex: the pyruvate

dehydrogenase complex (PDC), the 2-oxoglutarate dehydrogenase complex and the branched-chain 2-oxo acid dehydrogenase complexes. Each complex comprises multiple copies of three component enzymes termed E1, E2, and E3. The major M2-antigen which is recognized by nearly 90% of PBC sera is the E2 component of PDC.

### Innovations and breakthroughs

Within PDC-E2 an immunodominant epitope has been identified which is associated with the inner lipoyl domain (aa 167-184) wherein a lysine residue (K173) binds the lipoic cofactor for the enzyme. Binding of lipoic acid cofactor to K173 has been discussed to be necessary for antibody reaction. Replacement of this lipoic acid by 2-octynoic acid seemed even to enhance antibody binding. It was, therefore, speculated that xenobiotics may lead to an accumulation of 2-octynoic acid hereby preventing binding of lipoic acid to the PDC-E2 and generation of neoantigen with the consequence of generation of autoreactive B- and T-cells. The present study contradicts this concept to some extent indicating that epitopes within the catalytic site of PDC-E2 are even stronger reactive with AMA.

### Applications

The identification of immunodominant epitopes recognized by autoreactive T- or B-cells may improve our understanding with respect to their generation (for instance as consequence of cross reactivity with infectious agents or induction by neoantigens) and their possible pathogenetic role in PBC.

### Terminology

The 2-oxoacid dehydrogenase complex is a multi enzyme complex located at the inner membrane of mitochondria which catalyzes the oxidative decarboxylation of 2-oxo acids to the corresponding acyl-coenzyme A. It is not yet known why this non-organ specific protein complex becomes an autoantigen recognized by autoantibodies in a disease affecting mainly bile ducts such as PBC.

### Peer review

The authors analyse immunodominant targets of PDC-E2 in sera of about 100 patients with PBC. Interestingly, they show that the catalytic site of PDC-E2 contains several immunodominant epitopes. The group has an outstanding expertise in the field of clinical immunology. The data presented in the manuscript add to the understanding of immunological events in PBC.

### Abstract

**AIM:** To assess the appropriateness of the indication and route of administration of proton-pump-inhibitors (PPIs) and their associated cost impact.

**METHODS:** Data collection was performed prospectively during a 6-mo period on 340 patients who received omeprazole intravenously during their hospital stay in non-intensive care floors. Updated guidelines were used to assess the appropriateness of the indication and route of administration.

**RESULTS:** Complete data collection was available for 286 patients which were used to assess intravenous (IV) PPIs utilization. Around 88% of patients were receiving PPIs for claimed stress ulcer prophylaxis (SUP) indication; of which, only 17% met the guideline criteria for SUP indication, 14% met the criteria for non-steroidal-anti-inflammatory drugs-induced ulcer prophylaxis, while the remaining 69% were identified as having an unjustified indication for PPI use. The

initiation of IV PPIs was appropriate in 55% of patients. Half of these patients were candidates for switching to the oral dosage form during their hospitalization, while only 36.7% of these patients were actually switched. The inappropriate initiation of PPIs *via* the IV route was more likely to take place on the medical floor than the surgical floor (53% *vs* 36%,  $P = 0.003$ ). The cost analysis associated with the appropriateness of the indication for PPI use as well as the route of administration of PPI revealed a possible saving of up to \$17732.5 and \$14571, respectively.

**CONCLUSION:** This study highlights the over-utilization of IV PPIs in non-intensive care unit patients. Restriction of IV PPI use for justified indications and route of administration is recommended.

### INTRODUCTION

Proton-pump-inhibitors (PPIs) are the most effective agents for reducing gastric acid secretion and are commonly used in a variety of gastrointestinal (GI) related disorders<sup>[1]</sup>. The dramatic increase in PPI prescribing patterns over the past several years has raised concerns

relating to their appropriate utilization and associated cost<sup>[2,3]</sup>. Many health care centers have raised concerns related to the inappropriate use of the intravenous (IV) route of administration and unsuitable indications and to a lesser extent incorrect doses and length of therapy. Furthermore, many patients are being inappropriately discharged on PPIs which could potentially increase treatment costs, and the risk of pneumonia and *Clostridium difficile* associated disease<sup>[4]</sup>. Part of the over-utilization of IV PPIs can be explained by their safety profile and the tendency of physicians to manage ill in-patients aggressively<sup>[5]</sup>. Approved indications for IV PPIs are limited to erosive esophagitis in patients unable to tolerate oral medications and patients with pathologic hypersecretory state including Zollinger-Ellison syndrome<sup>[6]</sup>. Oral PPIs are associated with several advantages compared to the IV formulation including lower cost, reduced utilization of hospital resources, and fewer IV related complications. Guda *et al*<sup>[6]</sup> in 2004 reporting on the use of IV PPIs in two hospital settings observed that 56% of patients receiving IV PPIs had inappropriate indications and the majority of these claimed to have stress ulcer prophylaxis (SUP) indications. Prophylaxis against stress ulcer is not routinely recommended in general medicine patients<sup>[4]</sup>. Inappropriate dosing of IV PPIs has attributed to a 292% increase in the cost related to these medications and hence has resulted in an additional expenditure of \$7766 for 64 patients<sup>[7]</sup>. There is a need to assess the prescribing pattern of IV PPIs in the Middle East and Arab countries. In response to the inadequate literature available in the aforementioned region, a drug use evaluation was conducted to assess the appropriateness of the indication and route of administration of PPIs and their associated cost impact in a university hospital in Lebanon.

## MATERIALS AND METHODS

Data collection was performed prospectively from October 15, 2008 to April 15, 2009 on 340 adult patients who received a PPI after being admitted to the medical or surgical floors of a 200 beds university hospital in the Beirut area that attracts patients from all over the country. Patients were identified from the pharmacy computer system prior to and during the dispensing process. Data collection forms were filled for 340 patients, out of which 286 were determined to be complete and accurate. The form included data on patient demographics, medical problems, list of medications used, pertinent laboratory data, and criteria for PPI IV indication, dose, frequency, duration, and indication for switching to oral formulation. Assessment of the appropriateness of IV PPI use was then performed based on the American Society of Health-System Pharmacists guidelines<sup>[8]</sup> and the Eastern Association for the Surgery of Trauma for SUP<sup>[9]</sup>, non-steroidal-anti-inflammatory drugs (NSAIDs)-induced ulcer prophylaxis<sup>[10]</sup>, and criteria for IV to *po* conversion<sup>[11]</sup>.

Patients assessed for PPI indication were divided into two groups, one group of patients using the drug for treatment indication and another group using the drug

Table 1 Patient characteristics (*n* = 286)

	<i>n</i> (%)
Age, yr (median ± IQR)	64 ± 30
Weight, kg (median ± IQR)	72 ± 23
Creatinine clearance, mL/min (median ± IQR)	71.5 ± 57.6
Age ≥ 65 yr	143 (51)
Male	149 (52)
Medical floor	146 (51)
Surgical floor	140 (49)
Dose 40 mg omeprazole	272 (95)
Frequency as once daily	251 (88)
Medications	
Heparins	133 (47)
NSAIDs	74 (26)
Corticosteroids	74 (26)
Aspirin (100 mg)	42 (15)
Clopidogrel	15 (5)
Acenocoumarol	10 (4)

IQR: Interquartile range; NSAIDs: Non-steroidal-anti-inflammatory drugs.

for claimed SUP indication. The claimed SUP indication group was then sub-classified into (1) meeting criteria for SUP indication; (2) meeting criteria for NSAIDs-induced ulcer prophylaxis; and (3) unjustified prophylactic use.

Another analysis, focusing on the route of administration, divided patients into two groups, one group representing those with appropriate initial IV use and the other group representing inappropriate initial IV use.

Cost analysis was performed comparing the cost associated with appropriate initial IV PPI with that of inappropriate initial IV PPI use. The cost included 100 mL solution bag, 5 mL syringe, drug vial, IV line and related materials. Cost analysis was performed on the unnecessary duration of IV use, in cases where oral PPI was used instead of IV and inappropriate utilization. It was assumed that switching from IV to PO was done 1 d earlier in the group of appropriate IV users and prior to initial dispensing in the group of inappropriate IV users.

## Statistical analysis

Statistical analysis was performed using SPSS software. Data were entered into the computer and frequencies, percentages, means, and standard deviations were calculated. Differences in percentages were assessed using the  $\chi^2$  test, and differences in means were assessed using the student *t* test. *P*-values were assessed at the 5% level.

## RESULTS

### Patient characteristics

The study included a similar number of males and females. Half of the patients were 65 years or older, and most of them were receiving omeprazole 40 mg IV once daily. The number of patients from the medical floor and the surgical floor was equal (Table 1).

The reasons for hospital admission were various and included surgery, pain, infection, cancer treatment, dyspnea, trauma or fracture.

**Table 2 Justification of PPI indications**

	<i>n</i> (%)
Out of the total sample ( <i>n</i> = 286)	
Treatment indications	35 (12)
Claimed as using PPI for SUP indication	251 (88)
Classification of patients claimed as using PPI for SUP indication ( <i>n</i> = 251)

Duration of IV use (median ± IQR)	4.0 ± 4.0	4.0 ± 4.0	0.422

IV: Intravenous.

The most common criteria for using the IV route of administration were an order for nothing by mouth (*n* = 95, 33.2%), unable to swallow (*n* = 18, 6.3%), severe nausea and vomiting (*n* = 17, 5.9%), acute GI bleeding (*n* = 12, 4.2%), and others (*n* = 15, 5.2%) such as gastric obstruction, ileus, severe diarrhea, and malabsorption. Many patients were on antithrombotics, NSAIDs and corticosteroids during hospitalization (Table 1). Other medications included antibiotics (*n* = 205, 71.7%), analgesics (*n* = 171, 59%), metoclopramide (*n* = 98, 34.3%), antihypertensive drugs (*n* = 101, 35.3%) and insulin (*n* = 32, 11.2%).

**Justification of PPI use**

The use of IV PPIs was assessed in 286 patients. The indication for claimed SUP was used in 88% of patients, of which only 17% met the guideline criteria for SUP indication, 14% met the criteria for NSAIDs-induced ul-

**Table 4 Cost analysis for inappropriate route of administration and indication**

	Appropriate initial IV PPI use	Inappropriate initial IV PPI use
Candidate for switch	<i>n</i> = 82	<i>n</i> = 128
Cost of 40 mg IV PPI daily dose that could be avoided	\$1681	\$13120
Cost of 40 mg PPI oral daily dose (if used instead of IV)	\$184	\$1434
Cost that could be avoided with the oral use	\$1497	\$11686
Total cost that could be avoided with IV to po conversion	\$13183	
Cost that could be avoided from Unjustified prophylactic use of IV PPI ( <i>n</i> = 173)	\$17732.5	

cer prophylaxis while the majority (69%) were receiving PPI for an unjustified indication. These indications for PPI treatment were peptic ulcer (4.5%), GERD (1.4%), and stress ulcer treatment (2.4%). Stratification of the unjustified prophylactic use was correlated with age ≥ 65 years and whether or not the patient was receiving antithrombotics or corticosteroid therapy (Table 2). Antithrombotics mainly consisted of low molecular-weight heparins.

**Appropriateness of initial iv use and eligibility for oral conversion**

Only about 50% of patients who were initiated on PPIs *via* the IV route were deemed appropriate, of which half were candidates for switching to the oral form during their hospitalization. Only one third of the latter were switched to the oral form. The inappropriate initiation of PPIs *via* the IV route was more likely to take place on the medical floor compared with the surgical floor (53% *vs* 36%, *P* = 0.003).

Regardless of the type of indication, the rate of inappropriate initiation of PPIs *via* the IV route was similar to the rate of appropriate initiation (*P* = 0.556). The likelihood of switching patients to the oral form was independent of the appropriateness of initial IV use (36.7% *vs* 38.3%, *P* = 0.785) (Table 3). Most patients received a 40 mg IV dose once daily for a period of approximately 5 d.

**Cost analysis**

The cost analysis was based on the mean of 5-d of IV administration which could be avoided in the group with inappropriate IV use, and the assumption that switching could be done at least 1 d earlier in the group with appropriate IV use.

If PPIs were used for the appropriate indication and by the correct route of administration in the 286 patients assessed during the 6-mo period, at least \$17732.5 and \$13183, could have been saved, respectively (Table 4).

**DISCUSSION**

The high prescribing pattern of IV PPIs has been dem-

onstrated in this study. The majority of patients were identified as using IV PPIs for claimed SUP indication with a relatively small percentage of patients (17%) meeting the criteria for SUP, which is expected since only non-intensive care unit (ICU) patients were included in the trial. The inappropriateness of use was encountered more on the medical floor compared with the surgical floor. This highlights the need for a clinical pharmacist in that area. Among other patients claimed to be treated for SUP, 14% met the criteria for other indications such as prophylaxis of NSAIDs-induced ulcer. This left a large number of patients using PPIs for unjustified indications. Thus, to minimize over-utilization of PPIs for SUP, prescribers should specify the indication and the reason for the PPI on the medication orders, which would then facilitate medical order screening by the dispensing pharmacist. Around 36% of the patients who claimed to receive IV PPIs for SUP had no risk factors or any known justification for PPI use. It seems that age  $\geq 65$  years old was used as a criterion for PPI use; however, these patients had several medical illnesses and were on multiple drug regimens that may have increased the risk of adverse effects. A retrospective review of the medical charts of elderly patients revealed that around 30% of geriatric patients with a prescription for a PPI from a geriatric ambulatory care practice within an urban academic medical center had no documented indication<sup>[12]</sup>.

These findings highlight the role of the clinical pharmacist in the selection of appropriate candidates for switching.

The cost burden associated with inappropriate IV PPI use should be minimized. An annual projection of cost could reflect a saving of \$26 366 and \$35 465 with the appropriate route of administration and indication, respectively. It is important to note that this cost saving was underestimated since the cost of health care staff time was not included in the calculations and the delay in switching was assumed to be only 1 d. This highlighted the crucial role of a clinical pharmacist to review orders for proper indications, route of administration, and appropriate timing for switching.

The results of this study are comparable with several trials in the USA and UK that discussed the inappropriate use of IV PPIs in several institutions<sup>[7,13-15]</sup>. SUP was the most commonly encountered claimed indication for IV PPIs. A 14-mo observational study assessing the use of IV PPIs in non-ICU patients revealed that 22% of patients were receiving the drug according to their established indications. SUP was the presumed indication in 70% of patients receiving IV PPIs, of which only 13% were considered appropriate<sup>[7]</sup>. These findings were also supported by Qadeer *et al.*<sup>[16]</sup> who addressed the concern of SUP in non-ICU patients, stating that such an intervention is often unnecessary and not recommended.

With regard to the limitations of this study, the study was observational and conducted in a single academic medical center. In addition, there are no current established guidelines for the appropriate use of IV PPIs in

the hospital to evaluate their actual use. Moreover, we assumed that patients with no clear documented indication for PPI use received the drug for SUP. An additional step could have been to investigate the seniority and/or the specialty of the physicians over-prescribing IV PPIs.

As for the strengths of this study, the number of patients involved was adequate ( $n = 286$ ) over a sufficient period of time (6 mo). Non-ICU adult patients were selected because these patients may be more prone to inappropriate SUP treatment. Patients were monitored and followed during their hospital stay until discharge, PPI discontinuation or switching to oral PPI. In addition, there are limited data on the utilization pattern of an IV PPI in an institutional setting.

This study highlights the over-utilization of PPIs *via* the IV route of administration and for a claimed SUP indication in non-ICU patients, which results in increased cost to the patients, institution and payers.

Improving the prescribing patterns requires the Hospital Pharmacy and Therapeutics Committee to establish guidelines with input from gastroenterologists on the proper indications for IV PPIs, criteria for switching, dosing, and duration of therapy. Implementation of these guidelines requires multidisciplinary involvement and education of health care professionals concerning appropriate use of this class of medication. Other approaches include creating an IV order template, pharmacists reviewing orders before dispensing to patients, and automatic switching to an H<sub>2</sub> blocker if a PPI was ordered for SUP until more robust trials on PPI become available<sup>[17,18]</sup>.

## ACKNOWLEDGMENTS

We would like to thank the Pharmacy Director, Dr. Wael Abi-Ghanem, for his work in supervising the field work.

## COMMENTS

### Background

Proton pump inhibitors (PPIs) are the most effective agents for treating acid related gastrointestinal (GI) disorders. The utilization of intravenous (IV) formulations of PPIs has dramatically increased in health care institutions for inappropriate indications, route of administration and length of treatment. This is associated with an increased cost burden, increased risk of IV related infections, and utilization of hospital resources.

### Research frontiers

Utilization of IV PPIs in a hospital setting in a Middle East country was evaluated and compared to data from European and USA hospitals. The evaluation was carried out in non-intensive care units where patients do not meet the indication and/or route of administration criteria for IV PPIs, especially those receiving the drug for stress ulcer prophylaxis (SUP) where little or no evidence supports their use.

### Innovations and breakthroughs

Reports of the over-utilization of IV PPIs have been published in different international journals mainly involving European and American hospital settings. Available literature from the Middle East (especially prospective in nature) addressing this overuse pattern in non-intensive care units and emphasizing the role of a clinical and hospital pharmacist in health care systems is inadequate. In addition, a detailed cost analysis projection was performed for inappropriate indications and route of administration of PPIs.

### Applications

The study highlights the essential role of the clinical pharmacist in defining candidates for IV PPIs, especially for SUP, and fosters the role of the Pharmacy and Therapeutics Committee in implementing restriction guidelines for IV PPIs in patients who are not candidates for oral treatment or when the IV route shows better efficacy. A multifaceted approach is needed to improve the prescribing pattern which would involve education of health care professions regarding the appropriate prescribing pattern of IV PPIs.

### Terminology

Proton pump inhibitors are the most effective anti-secretory agents which inhibit the final step in gastric acid secretion and are used to treat several GI related disorders. Stress ulcers also called stress mucosal related disease is a form of hemorrhagic gastritis that occurs in patients after major stressful events such as trauma, surgery, or severe head injury.

### Peer review

The paper is well written. The observations are comparable to those made in Europe, USA, and Asia, as acknowledged by the authors in Discussion. The appropriateness of the statistics applied to analyze the data obtained may be debated, but the use of non-parametric tests is considered preferable in this type of studies.

### Abstract

**AIM:** To clarify the effects of anti-hypertensive drugs on esophageal contraction and determine their possible relationship with gastro-esophageal reflux disease.

**METHODS:** Thirteen healthy male volunteers were enrolled. Esophageal body peristaltic contractions and lower esophageal sphincter (LES) pressure were measured using high resolution manometry. All subjects were randomly examined on four separate occasions following administrations of nifedipine, losartan, and atenolol, as well as without any drug administration.

**RESULTS:** Peristaltic contractions by the esophageal body were separated into three segments by two troughs. The peak peristaltic pressures in the mid and lower segments of the esophageal body under atenolol administration were significantly higher than those without medication in a supine position. On the other hand, peristaltic pressures under nifedipine administration were lower than those observed without drug administration. Losartan did not change esophageal body peristalsis. Atenolol elevated LES pressure and slowed peristaltic wave transition, while the effects of nifedipine were the opposite.

**CONCLUSION:** Among the anti-hypertensive drugs tested, atenolol enhanced esophageal motor activity, which was in contrast to nifedipine.

### INTRODUCTION

Impaired esophageal motor functions, such as decreased

lower esophageal sphincter (LES) pressure and weak esophageal body peristalsis, are the main causes of gastroesophageal reflux disease (GERD)<sup>[1,2]</sup>. Conventional manometry has demonstrated that several different drugs impair esophageal motor function. It has also been speculated that they increase esophageal acid exposure<sup>[3]</sup>. Nifedipine, a calcium-channel blocker, was shown to reduce LES pressure, as well as the amplitude and duration of esophageal peristaltic contractions, in healthy subjects. It also increased esophageal acid exposure time<sup>[4-6]</sup>. In addition, candesartan, an angiotensin II (Ang II) receptor antagonist, was reported to reduce the amplitude of swallow-induced peristaltic contractions and LES pressure<sup>[7]</sup>. In contrast, atenolol, a catecholamine  $\beta$  receptor antagonist, was found to inhibit the relaxation of esophageal smooth muscle induced by catecholamine  $\beta$  stimulation<sup>[8]</sup>.

Recent studies using high-resolution manometry revealed that esophageal body peristalsis was composed of a chain of three contraction segments separated by two troughs<sup>[9-11]</sup>. Conventional esophageal manometry techniques are not sensitive enough to detect those three separate contraction segments<sup>[12-14]</sup>. The uppermost (first) peristaltic segment represents the skeletal muscle component of the esophageal body, while the lowest (third) segment represents the smooth muscle component. In the middle (second) segment, the muscle tissue is considered to shift from skeletal to smooth type<sup>[9-13]</sup>. Therefore, neuromuscular contraction control might be different between the three segments. In addition, the second segment was reported to be more responsive to cholinergic stimulation, whereas the third has been demonstrated to be under stronger control of non-cholinergic and non-adrenergic neurons<sup>[15-17]</sup>. Therefore, the various drugs reported to have an influence on esophageal motor function might have different effects on each of the segments of the esophageal body, though the effects of anti-hypertensive drugs on these segments have not been investigated.

The aim of this study was to clarify the effects of three different types of anti-hypertensive drugs on the three different segments of esophageal body contractions using a recently developed high-resolution manometric system.

## MATERIALS AND METHODS

### Subjects

Thirteen male volunteers were recruited for this study (mean age: 34.7 years). None of the subjects had upper gastrointestinal symptoms, a history of upper gastrointestinal surgery, or were taking medications known to influence esophageal motor function. Written informed consent was obtained from each volunteer before starting the study, which was carried out in accordance with the Declaration of Helsinki. This study was approved by the Ethics Committee of Shimane University.

### Study protocol

We evaluated esophageal motor function under sepa-

rate administrations of nifedipine, a calcium-channel blocker, atenolol, a catecholamine  $\beta$  receptor antagonist, and losartan, an angiotensin II receptor antagonist. All subjects were examined four separate times after an overnight fast, with the following administrations; (1) without medication, (2) 10 mg of nifedipine, (3) 50 mg of losartan, and (4) 50 mg of atenolol, which were performed randomly in each case. The administrations of nifedipine, losartan, and atenolol were given at 1, 4, and 4 h, respectively, before performing the esophageal motor function test, to match the maximal blood concentration of each drug with the examination period. In addition, all subjects were instructed to drink 200 mL of water at 4 h and 1 h before each esophageal motor function test.

### Esophageal manometry

We performed high-resolution manometric tests using a ManoScan 360™ (Sierra Scientific Instruments, Inc., California)<sup>[18]</sup>. The manometric catheter used with this system is 4.2 mm in diameter and has 36 intraluminal pressure transducers at 1-cm intervals, which are used to measure peristaltic pressure in the upper esophageal sphincter (UES) to LES simultaneously and continuously. Before performing esophageal pressure measurements, transducers were calibrated at 0 and 100 mmHg using externally applied pressure, according to the manufacturer's instructions. The manometric catheter was inserted in a transnasal manner using 2% lidocaine jelly (Xylocaine jelly; AstraZeneca Co., Osaka, Japan), LES pressure (LESP) was then measured in a sitting position during a 5-min resting period. Next, esophageal body peristaltic function in the sitting position was examined by swallowing 5 mL of room temperature water, which was repeated at 2-min intervals until five recordings of complete esophageal peristalsis were obtained. After finishing the tests in the sitting position, they were repeated in a supine position. The peristaltic contractions in the esophageal body were divided into three different segments (segments 1, 2, and 3 from oral to anal) separated by two troughs, as shown in Figure 1. LESP and peak intraesophageal contraction pressure in the three segments of the esophageal body were analyzed using ManoView™ analysis software (Sierra Scientific Instruments, Los Angeles, CA). Peristaltic contraction velocity between 5 and 15 cm above LES was also determined.

### Statistical analysis

Statistical analysis of paired data was performed using a Wilcoxon signed rank test. All calculations were done using the Stat View 5.0 software package (Abacus Concepts Inc., Berkeley, CA, USA) for Macintosh. Differences at  $P < 0.05$  were considered to be statistically significant.

## RESULTS

All 13 subjects completed the study protocol without any adverse events. LESP values in the supine position were significantly higher than those in the sitting position, both with and without administration of the drugs investigated in this study. Furthermore, LESP with the

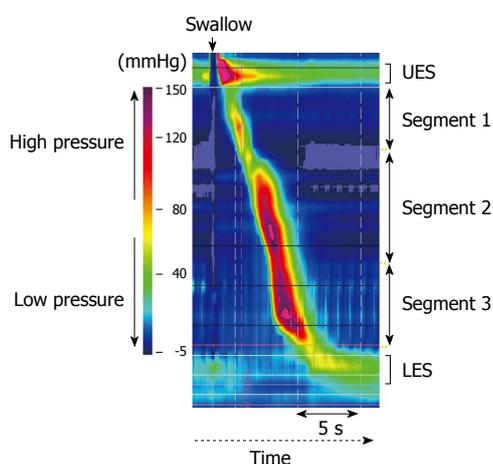

Figure 1 Peristaltic contractions in the esophageal body were divided into three different segments (segments 1, 2, and 3, from oral to anal) by two troughs. UES: Upper esophageal sphincter; LES: Lower esophageal sphincter.

administration of nifedipine tended to be lower, while that under the administration of atenolol tended to be higher, as compared to the control (Table 1).

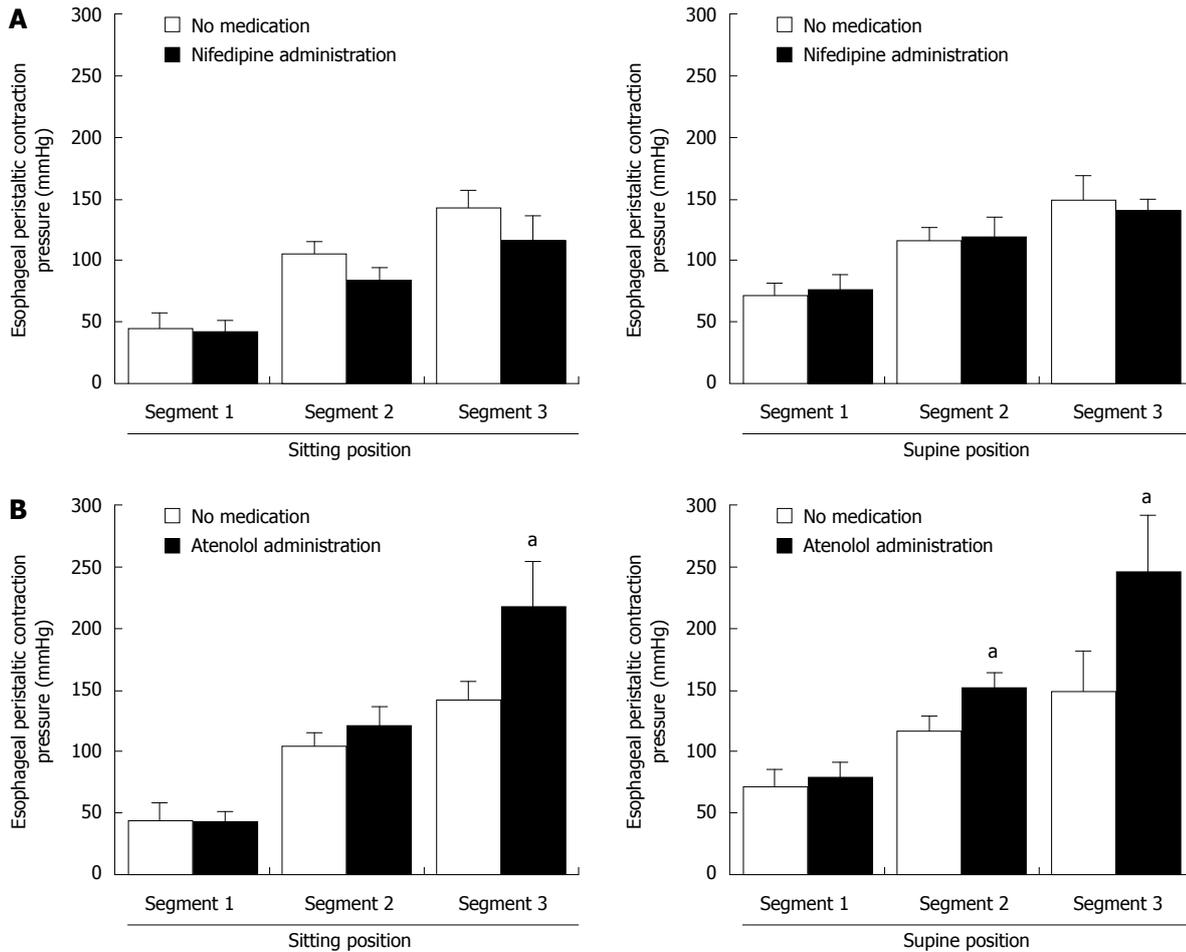

The peak peristaltic pressures in the three segments of the esophageal body in the supine position were significantly higher than those in the sitting position, and also significantly increased from segment 1 to 3 (Table 2). However, there was no difference in peak contraction pressure in segment 1 of the esophageal body with and

without administration of the drugs. In contrast, peak contraction pressure in segments 2 and 3 with nifedipine administration tended to be lower than those without medication (Table 2 and Figure 2). On the other hand, peak pressures in those segments under atenolol administration were higher than without medication (Table 2 and Figure 2). Losartan did not significantly affect peak contraction pressures in the second and third segments (Table 2).

Esophageal peristaltic velocity in the supine position tended to be lower than that in the sitting position. Furthermore, under the administration of nifedipine, it tended to be faster than that without medication. On the other hand, velocity with atenolol was significantly slower than that without medication (Table 3).

## DISCUSSION

Calcium-channel blockers, such as nifedipine, inhibit the entry of calcium into smooth muscle cells of the arterial wall, and are widely used for treatment of patients with ischemic heart disease and hypertension<sup>[5]</sup>. Orally administered nifedipine was shown not only to decrease LESP in healthy subjects and patients with achalasia, but also reduced the amplitude and duration of esophageal peristaltic contractions in healthy subjects<sup>[4,6]</sup>. Ang II is the key mediator of the rennin-angiotensin system, which maintains extracellular fluid volume and electrolyte homeostasis, and also regulates vascular tone and blood pressure<sup>[19]</sup>. The

**Figure 2** Peak esophageal peristaltic pressures in the three segments with and without administration of drugs. A: Nifedipine; B: Atenolol. <sup>a</sup>*P* < 0.05 vs no medication.

physiological functions of Ang II are mediated specifically by the Ang II type 1 (AT1) and type 2 (AT2) receptors. Losartan, an AT1 receptor antagonist, was previously reported to reduce the amplitude of swallow-induced peristaltic esophageal contractions and LESP<sup>[7]</sup>. The catecholamine  $\beta$ -adrenoceptor is currently classified into  $\beta_1$ ,  $\beta_2$ , and  $\beta_3$  subtypes, all of which are expressed in smooth muscle cells. Smooth muscle in the gastrointestinal tract is known to have the  $\beta_1$ -adrenoceptor subtype and it has been shown that smooth muscle relaxes in response to  $\beta$ -adrenoceptor stimulation. In addition, atenolol, a  $\beta_1$  blocker, was reported to inhibit the relaxation of esophageal smooth muscle induced by  $\beta_1$ <sup>[8]</sup>. These observations of the effects of nifedipine, losartan, and atenolol were obtained in studies that used conventional intraesophageal pressure monitoring systems. Those are able to determine intraesophageal pressure at some sites, but they are not sensitive enough to measure peristaltic contractions in the three different esophageal body segments<sup>[8,9]</sup>.

Peristaltic contraction in segment 3 of the esophageal body is the strongest in amplitude and the most important factor for volume clearance of acidic refluxant from the stomach<sup>[20]</sup>. Therefore, to clarify the effects of the three anti-hypertensive drugs on the development of GERD, their effects on the three different segments,

especially the lowest segment (segment 3) were investigated in the present study.

We used high-resolution manometry to measure intraesophageal pressure in 36 different sites at the same time, while contractions in each of the three esophageal segments were separately measured<sup>[14]</sup>. As reported by other investigators using conventional manometry, nifedipine tended to decrease LESP, while atenolol increased it. Similarly, nifedipine tended to decrease the amplitude of peristaltic contractions in segment 3, while atenolol significantly increased it in both the sitting and supine positions. These observations fit well with previous reports that a regular administration of calcium antagonists for treatment of hypertension is a risk factor for the future occurrence of GERD. Interestingly, atenolol significantly elevated LESP and the peristaltic amplitude in the lower esophageal body (segment 3). Such atenolol-induced alterations of esophageal motor activity may prevent the development of GERD.

An interesting finding in our study was the reciprocal relationship between contraction amplitude and peristaltic velocity of the esophageal body. Factors that induce augmentation of peristaltic amplitude, such as atenolol administration and the supine position, were found to delay peristaltic velocity<sup>[21,22]</sup>. On the other hand, factors

that caused a decrease in contraction amplitude, such as nifedipine administration and the sitting position, accelerated peristaltic contraction velocity<sup>[21,22]</sup>. Although the mechanisms by which these reciprocal phenomena occur are not clear, slowly progressing high amplitude peristalsis might be a more efficient peristaltic wave for propelling esophageal contents down to the stomach.

Another interesting finding was the lack of significant effect by losartan on esophageal motor activity, which differs from previous reports, though the reason is not clear. We used modern high-resolution measurements in the present study. Therefore, at least in healthy volunteers, we believe that the inhibiting effect of losartan on esophageal motor function is not clinically important.

In conclusion, of the anti-hypertensive drugs tested, atenolol enhanced esophageal motor activity, which was in contrast to a calcium antagonist.

## COMMENTS

### Background

Nifedipine, a calcium-channel blocker, was shown to decrease lower esophageal sphincter pressure and increase esophageal acid exposure time, while atenolol, a  $\beta_1$  blocker, was shown to inhibit relaxation of the smooth muscle of the esophagus. However, the influence of these anti-hypertensive drugs on the segment of esophageal body contraction using high-resolution manometry was not fully investigated.

### Research frontiers

Several reports have demonstrated that anti-hypertensive drugs affect the esophageal motor function and might facilitate gastroesophageal reflux. However, the details of the drug-induced impairment of esophageal motor function are not clear. This is the first published data concerning the use of high-resolution manometry to study the effects of anti-hypertensive drugs on the motor activity of the different segments of the esophageal body.

### Innovations and breakthroughs

Previous data on the effect of anti-hypertensive drugs were obtained in studies that used conventional intraesophageal pressure monitoring systems. In this study, the authors observed esophageal body contraction using high-resolution manometry with 36 intraluminal transducers. The esophageal body was divided into three segments manometrically. Nifedipine and atenolol were found to affect motor activity only in the middle and lower segments of the esophagus. Anatomical differences in the contraction of the esophageal body during the administration of anti-hypertensive drugs were clarified for the first time.

### Applications

By understanding the anatomical responses of the esophageal body motor activity to the administration of anti-hypertensive drugs, more appropriate selection of anti-hypertensive drugs for patients with gastro-esophageal reflux disease (GERD) will be facilitated.

### Terminology

Nifedipine, atenolol, and losartan are all drugs widely used for the treatment of hypertension. As both of hypertension and GERD are common diseases, the effects of anti-hypertensive drugs on the esophageal motor activity are important.

### Peer review

This is a well-designed study with limited new information about drug effects on esophageal motility. The references are well selected and the discussion is good.

### Abstract

**AIM:** To evaluate the efficacy of endoscopic examination of blood flow and edema in the remnant bowel.

**METHODS:** We retrospectively studied 15 patients who underwent massive bowel resection with enterostomy for superior mesenteric arterial occlusion (SMAO); the patients were divided into a delayed closure group (D group) and an early closure group (E group).

**RESULTS:** The mean duration from initial operation to enterostomy closure was significantly shorter in the E group ( $18.3 \pm 2.1$  d) than in the D group ( $34.3 \pm 5.9$  d) ( $P < 0.0001$ ). The duration of hospitalization after surgery was significantly shorter in the E group ( $33 \pm 2.2$  d) than in the D group ( $51 \pm 8.9$  d) ( $P < 0.0002$ ).

### INTRODUCTION

Construction of a temporary stoma is a relatively common surgical procedure. A transient stoma is known to lower the operative risk, but it should be closed at the earliest opportunity; however, in the literature, the morbidity and mortality rates after ileostomy or colostomy closure are rather high<sup>[1-8]</sup>. Several studies have compared colostomy closure and ileostomy closure, and found that a multitude of factors influence the development of complications after stoma closure, such as perioperative treatment, time of operation, and surgical technique<sup>[9-12]</sup>. Patients with superior mesenteric arterial occlusion (SMAO) often require massive bowel resection because of considerable intestinal necrosis. Massive intestinal resection often causes short-bowel syndrome and necessitates parenteral nutrition. In order to avoid

the development of this syndrome, it is important to retain as much of the remnant bowel as possible. SMAO is known to frequently occur in patients with atrial fibrillation; hence, even if the patients survive after the initial operation, the risk of disease recurrence remains considerably high. Moreover, reperfusion injury may occur in SMAO patients, thereby causing unstable hemodynamics and multiple organ failure<sup>[13,14]</sup>. Calvien *et al*<sup>[15]</sup> reported that bowel infarction recurred in 32% of patients early after the resection of the necrotic bowel. In the case of enterostomy, it is difficult to determine the timing of enterostomy closure after the initial operation. In order to assess the feasibility of early closure and its outcome, we endoscopically inspected blood flow and edema in the remnant bowel of stoma patients and defined a minimal delay as optimal for closing small bowel stomas. In this study, we evaluated the efficacy of endoscopic examination of blood flow and edema in the remnant bowel.

## MATERIALS AND METHODS

### Patients

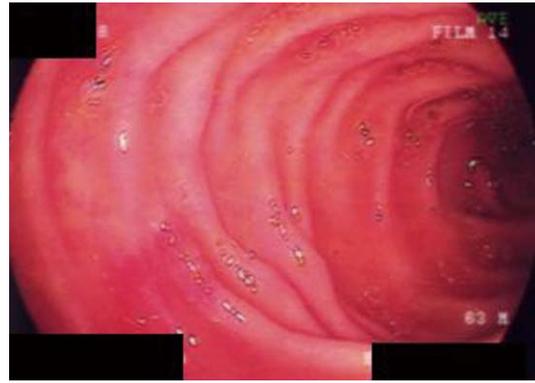

We retrospectively studied 15 patients (12 men and 3 women; age range: 57-74 years; mean age: 68 years) who had undergone massive bowel resection with enterostomy for SMAO between April 1990 and March 2009 at the Department of Surgery, Social Insurance Yokohama Central Hospital, Yokohama, Japan. The patients were divided into 2 groups according to the timing of enterostomy closure: delayed closure group (D group) and early closure group (E group). All patients gave written informed consent to this study.

### Surgical technique

The technique used for stoma closure did not differ between the E and D groups. In brief, after thorough mobilization of the bowel *via* a parastomal incision, a stoma was excised and the adhesions between the bowel and the peritoneum and omentum were cleared. Both the bowel ends were resected, and sutured manually with 2-layered end-to-end anastomosis.

### Assessment of the enterostomy closure on the basis of the clinical findings

After initial surgery, when there was an improvement in the small intestinal dilatation and sufficient bowel movement was observed, the patients were allowed to resume a normal diet. Subsequently, parenteral nutritional support was initiated for the patients in whom oral intake was not sufficient, or for those with severe diarrhea. The clinical findings were confirmed as positive when (1) oral intake was sufficient; (2) diarrhea was controlled by medications; and (3) initial disease was sufficiently controlled without recurrence. When these criteria were satisfied, enterostomy closure was performed. These patients were classified as group D.

**Figure 1** Endoscopic inspection of remnant bowel. Endoscopic examination revealed that sufficient blood flow had been retained and edema had subsided in the remnant bowel.

### Endoscopic inspection

After initial surgery, when there was an improvement in the small intestinal dilatation and sufficient bowel movement was observed, endoscopic examination was performed. We used a cholangioendoscope (Olympus CHF Type P20Q; Olympus Medical Systems Co., Tokyo, Japan) for endoscopy, and it was inserted from the opening of the enterostomy.

### Assessment of enterostomy closure on the basis of the endoscopic findings

The endoscopic findings were confirmed as positive when (1) sufficient blood flow resumed in the remnant bowel; and (2) the bowel edema subsided. Enterostomy closure was performed when these criteria were satisfied (Figure 1). However, if the criteria were not met, endoscopic examination was performed again after 3 d. These patients were classified as group E.

### Statistical analysis

Results are presented as the mean  $\pm$  SD unless otherwise stated. Univariate analysis was performed using Student's *t* test for continuous variables and Fisher's exact test and chi-square test for categorical variables. A *P* value of less than 0.05 was considered statistically significant.

## RESULTS

Delayed closure of enterostomy (D group) was performed in 8 patients and early closure of enterostomy (E group) was performed in 7 patients. Table 1 shows the patient characteristics and initial operative variables. No differences were observed in the mean age and sex ratio between the patient groups. Risk factors and initial diseases for the SMAO patients in the E group were: hypertension in 85.7%, diabetes mellitus in 57.1%, atrial fibrillation in 57.1%, and apoplexy in 14.3%; while those for the patients in the D group were: hypertension in 65.2%, diabetes mellitus in 62.5%, atrial fibrillation in 37.5%, and apoplexy in 25%. There was no significant difference between the groups with regard to the pro-

portion of patients with risk factors and initial diseases. The mean length of the resected bowel at the initial operation was 265 ± 38 cm in the E group and 239 ± 32 cm in the D group; there was no significant difference between the groups in this regard. All the patients in the E and D groups underwent jejunostomy. No deaths occurred in either of the groups. The most common initial postoperative complication observed was skin erosion, with an incidence rate of 14.3% in the E group, and 37.5% in the D group.

Table 2 shows the postoperative variables. The mean duration from initial operation to enterostomy closure was significantly shorter in the E group (18.3 ± 2.1 d) than in the D group (34.3 ± 5.9 d) (*P* < 0.0001). The postoperative complications observed were wound infection and pneumonia, with an incidence rate of 14.3% each in the E group, and 25% each in the D group. There was no significant difference between the 2 groups with regard to postoperative complications (*P* = 1). The duration of hospitalization after surgery was significantly shorter in the E group (33 ± 2.2 d) than in the D group (51 ± 8.9 d) (*P* < 0.0002).

## DISCUSSION

Under favorable local or general conditions, a transient small bowel stoma creation may be required to protect a distal anastomosis or to avoid intraperitoneal intestinal anastomosis. It is generally recommended that the temporary stoma be closed within 9-12 wk after its construction<sup>[16]</sup>. However, because some patients poorly tolerate the temporary stoma owing to extracellular dehydration, difficult pouch fitting, parenteral nutrition requirement in the cases when the stoma is very proximal, and psychological or social impact, it might be advisable to opt for early closure<sup>[17]</sup>.

On the other hand, patients with SMAO often require massive bowel resection because of considerable intestinal necrosis. Massive intestinal resection often causes short-bowel syndrome and necessitates parenter-

<sup>1</sup>Significant difference.

al nutrition. To avoid this syndrome, it is important to retain as much of the remnant bowel as possible. However, SMAO is frequently observed in patients with atrial fibrillation; hence, even if the patients survive after initial operation, the risk of disease recurrence is considered high. Moreover, reperfusion injury may occur in SMAO patients and may cause unstable hemodynamics and multiple organ failure<sup>[10,11]</sup>. Calvien *et al*<sup>[12]</sup> reported that bowel infarction recurred in 32% of the patients early after the resection of necrotic bowel. If we deem primary anastomosis as risky owing to the presence of ischemic changes along the bowel, we perform the bowel resection without anastomosis, and perform an enterostomy. However, a bowel stoma or enterostomy is also a major psychological handicap (altered body schema, odor, uncontrolled emissions, *etc.*) and causes significant physical stress (risk of severe dehydration and electrolyte imbalance). Local care in an intensive care unit needs to be prolonged sometimes, to avoid secondary skin erosions caused by the highly corrosive digestive enzymes. Parenteral nutritional support may also be required if the enterostomy is very proximal, with associated risk of infection caused by the insertion of a central venous catheter. Moreover, it is important to perform early closure of enterostomy to avoid adverse effects on the quality of life of patients. In order to assess the feasibility of early closure of enterostomy, it is necessary to adequately examine the blood flow and edema in the remnant. Thus, we directly examined the blood flow and edema in the remnant bowel of these patients by endoscopy.

Generally, endoscopic examination of the upper digestive tract is performed using esophagogastroduodenoscope, and that of the lower digestive tract (colon and rectum) is performed using colon fiberscope. However, because the opening of the jejunostomy was small in our cases, it would have been difficult to smoothly insert the esophagogastroduodenoscope or colon fiberscope into the small intestine *via* the jejunostomy. Moreover, these procedures are painful for the patients because the diameters of these endoscopes are relatively large. Hence, we used the cholangioendoscope that has a relatively smaller diameter and can be smoothly inserted into the intestine without causing any pain. A

trans-nasal esophagogastroduodenoscope with a small diameter can also be used.

In the case of enterostomy created due to SMAO, it is difficult to determine the timing of enterostomy closure after initial operation. The time chosen for enterostomy closure should be accurately determined taking the following two factors into account: the risk of anastomotic leak that usually occurs between 5 and 7 d<sup>[18]</sup> postoperatively; the development of dense adhesions due to acute inflammation that appear 2 wk after the creation of the enterostomy<sup>[19]</sup>. Moreover, the risk of bowel infarction recurrence should be carefully assessed, as high rates have been reported after necrotic bowel resection<sup>[15]</sup>. Megengaux *et al*<sup>[19]</sup> reported that small bowel stomas can be closed on the 10th d after initial surgery, without major complications. Their concept of choosing postoperative day 10 for the closure of stoma was based on the fact that this time point comes after the days when anastomotic leakages are frequently observed, i.e. postoperative days 5-7<sup>[18]</sup>, and before postoperative day 14, thereby ensuring that acute inflammation does not develop. However, because immediate anastomosis is associated with a high risk of dehiscence, Hanish *et al*<sup>[20]</sup> suggested that it is preferable to avoid this procedure in stoma patients who present with perforation associated with peritonitis or ischemia due to extensive mesenteric infarction. Because our patients required stoma creation due to SMAO, we considered that it was necessary to precisely investigate the blood flow in the remnant bowel before early closure of the stoma. In the patients of the early closure group, enterostomy closure was performed after  $18.3 \pm 2.1$  d, and no complications associated with anastomosis developed thereafter. This time is significantly shorter compared to the recommended time of 9-12 wk after the construction of enterostomy<sup>[16]</sup>.

Hospitalization in the patients of the early closure group was significantly shorter than that in the patients of the delayed closure group. The incidence rate of complications such as wound infection and pneumonia in the patients of the early closure group was 14.3%, while that of the patients of the delayed closure group was 25%. Although there was no significant difference between groups, the incidence rate of complications was lower in the early closure group than in the delayed closure group.

To the best of our knowledge, early closure of jejunostomy based on endoscopic findings *via* the stoma has never been studied in patients with SMAO. On the basis of these results, we conclude that endoscopic examination of blood flow and edema in the remnant bowel is a useful predictor to determine the time of enterostomy closure in SMAO cases.

## COMMENTS

### Background

A transient stoma is known to lower the operative risk, but it should be closed

at the earliest opportunity; however, the morbidity and mortality rates after ileostomy or colostomy closure are rather high. It is generally recommended that the temporary stoma be closed within 9-12 wk after its construction. Fifteen patients who underwent massive bowel resection with enterostomy for superior mesenteric arterial occlusion (SMAO) were divided into a delayed closure group (D group) and an early closure group (E group).

### Research frontiers

The mean duration from initial operation to enterostomy closure was significantly shorter in the E group ( $18.3 \pm 2.1$  d) than in the D group ( $34.3 \pm 5.9$  d) ( $P < 0.0001$ ). The duration of hospitalization after surgery was significantly shorter in the E group ( $33 \pm 2.2$  d) than in the D group ( $51 \pm 8.9$  d) ( $P < 0.0002$ ).

### Innovations and breakthroughs

Endoscopic examination of the blood flow and edema in the remnant bowel was found to be useful for assessing the feasibility of early closure of enterostomy in SMAO cases.

### Applications

In the authors' study, the number of patients with endoscopic examination of the blood flow and edema in the remnant bowel was very small, but they can propose that endoscopic examination of blood flow and edema in the remnant bowel is a useful predictor to determine the time of enterostomy closure in SMAO cases.

### Peer review

This manuscript is well constructed and the comparison of two methods of the preoperative evaluation clearly delivered. The conclusions were supported by the data. The topic is particularly interesting and up-to-date, because of the lack of surgical procedures to determine the timing of enterostomy closure. The work is written in good English. As a result, the work meets the standards of the *World Journal of Gastroenterology*. In conclusion the manuscript can be published.

### Abstract

**AIM:** To establish the prognosis and feasibility of *en-bloc* vascular resection of stage II pancreatic adenocarcinoma of the head and uncinate process.

**METHODS:** We retrospectively analyzed 87 patients with stage II pancreatic adenocarcinoma, who were subjected to pancreaticoduodenectomy (PD) and pylorus-preserving PD (PPPD) between 1996 and 2006 in Chang Gung Memorial Hospital, Taiwan. Twelve and 75 patients underwent PD/PPPD with and without resection of portal vein/superior mesenteric vein (PV/SMV), respectively.

**RESULTS:** The overall 1- and 3-year survival rates of patients undergoing PD/PPPD with and without vascular resection were 50.0% and 16.7%, and 44.4% and 12.2%, respectively. Morbidity and mortality rates in the PV/SMV resection vs non-resection group were 50.0% and 0.0%, and 40.0% and 2.7%, respectively. In multivariate analysis, serum bilirubin, histological

differentiation and adjuvant chemotherapy were independent prognostic factors that influenced survival.

**CONCLUSION:** In stage II adenocarcinoma of the pancreatic head and uncinate process, serum bilirubin, histological differentiation and adjuvant chemotherapy were independent prognostic factors, and *en-bloc* vascular resection is a feasible option in carefully selected patients.

### INTRODUCTION

Pancreaticoduodenectomy (PD) combined with vascular resection in locally advanced pancreatic malignancies was initially associated with high morbidity and mortality rates<sup>[1]</sup>. However, with improvement in surgical techniques and postoperative care, more aggressive *en-bloc* resection of pancreatic malignancies, along with portal vein/superior mesenteric vein (PV/SMV) is being

carried out at present, without any increase in surgical complications<sup>[2]</sup>. Unexpected tumor invasion to the lateral or posterolateral wall of the confluence of the PV/SMV is a common finding during PD for pancreatic malignancies<sup>[3]</sup>. The 5-year survival rate following PD or pylorus-preserving PD (PPPD) is 10%-15%, and the reported survival for > 5 years is less<sup>[4-6]</sup>. Mortality associated with PD has decreased dramatically to 0%-5% over the past two decades, but morbidity remains as high as 35%-60%<sup>[7-11]</sup>. Few studies are available regarding stage II pancreatic adenocarcinoma with special attention to adenocarcinoma located in the pancreatic head and uncinate process, which is more likely to invade the PV/SMV because of its close proximity to these vessels. The aim of the present study was to establish the prognostic factors and feasibility of *en-bloc* vascular resection in patients with stage II adenocarcinoma of the pancreatic head and uncinate process following PD/PPPD.

## MATERIALS AND METHODS

### Patient population

From January 1996 to December 2006, 129 consecutive patients with stage I to III adenocarcinoma of the pancreatic head and uncinate process were subjected to surgery at Chang Gung Memorial Hospital, Taipei, Taiwan. We included only stage II adenocarcinoma of the pancreatic head and uncinate process [87 patients; stage II A ( $n = 14$ ) and II B ( $n = 73$ )], as there is more possibility of vascular encasement in stage II pancreatic cancers located in the head and uncinate process. The tumors were staged according to the 6th edition of the American Joint Committee on Cancer Staging System (2002). Survival duration was calculated from the time of surgery to death or the last follow-up date (December 31, 2007), irrespective of the cause of death.

### Surgical procedure

PD and PPPD were considered as standard procedures. Resection margins from the common bile duct, pancreatic neck, retropancreatic tissue, and from the PV or SMV (in PV/SMV resection) were sent routinely for frozen sectioning, and in cases with positive resection margins, wider resection was performed until a negative resection margin was achieved. Lymph nodes around the hepaticoduodenal ligament, common hepatic artery, celiac trunk, PV, SMV and retropancreatic area were routinely dissected and removed. Reconstruction was performed by pancreaticojejunostomy. In case of PV/SMV encasement, segmental resection and reconstruction by end-to-end anastomosis ( $n = 9$ ) or a vascular graft ( $n = 3$ ; one autologous and two ePTFE grafts) were performed. Ten patients had segmental resection of the PV and two had combined PV/SMV segmental resection, and the splenic vein was anastomosed to the main portal trunk in both cases. All the patients who underwent vascular reconstruction were treated with a single dose

of heparin intraoperatively and postoperatively; heparin was not used routinely. These patients were monitored by Doppler study for vascular graft patency in the early postoperative period.

### Statistical analysis

Clinical records were compared by either Fischer's exact test or Pearson's  $\chi^2$  test, as appropriate. Age was analyzed using Student's *t* test. Patient survival rate was calculated by the methods of Kaplan-Meier and log-rank test to determine univariate significance. Factors that were deemed of potential importance on the univariate analysis ( $P < 0.05$ ) were included in the multivariate analysis. Cox's regression was used for the multivariate analysis of these factors.  $P < 0.05$  was regarded as significant. Statistical analyses were performed with SPSS for windows, version 11.5 (SPSS, Inc., Chicago, IL, USA).

## RESULTS

### Patient demographics

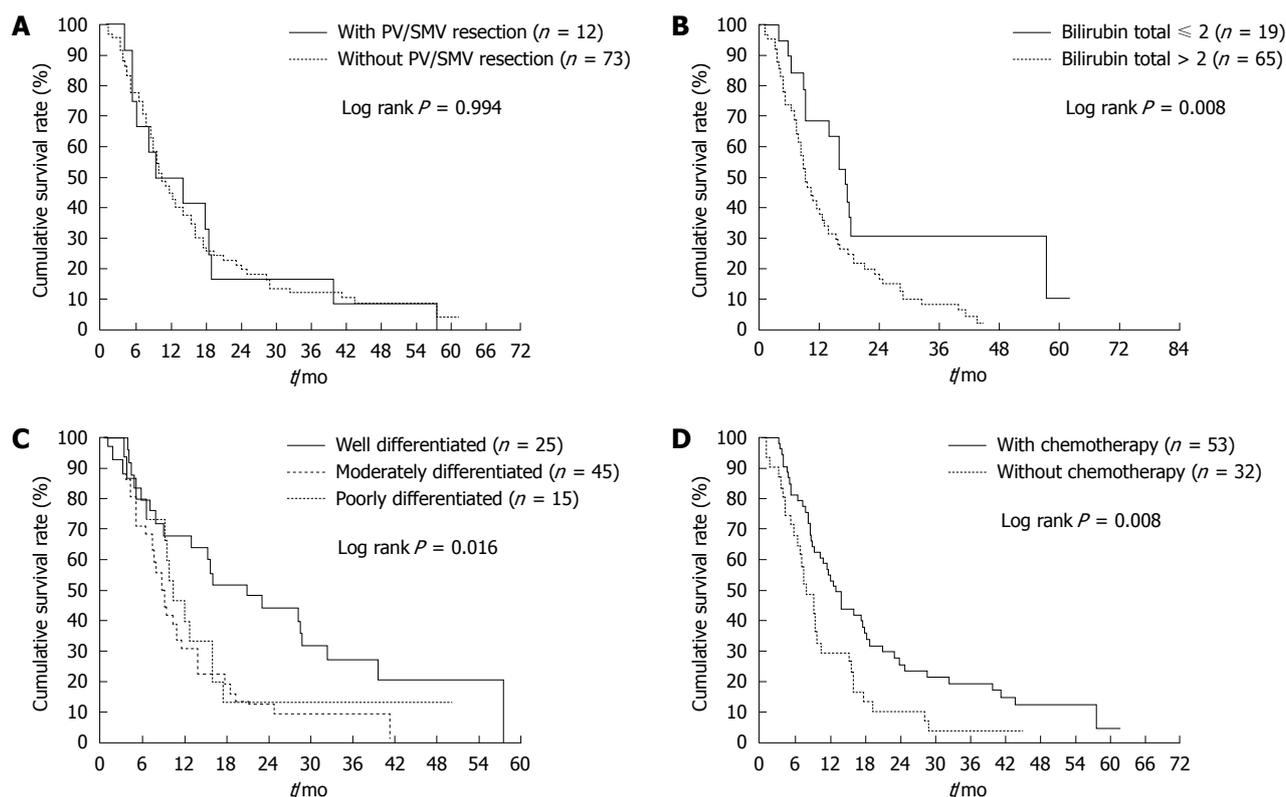

Twelve of 87 (13.8%) patients underwent PD ( $n = 8$ ) or PPPD ( $n = 4$ ) with PV/SMV resection (group I) and 75/87 (86.2%) patients underwent PD ( $n = 57$ ) or PPPD ( $n = 18$ ) without vascular resection (group II). Tumor location was in the pancreatic head ( $n = 80$ ), uncinate process ( $n = 1$ ), and in both ( $n = 6$ ).

### Patient outcome

Analysis of clinicopathological features (Table 1) revealed predominantly male patients aged > 60 years old, and common symptoms were jaundice, abdominal pain and weight loss. Most common findings were jaundice and anemia. Preoperative biliary drainage was performed (in case of total bilirubin levels > 15 mg/dL) in six (50.0%) and 44 (58.7%) patients in group I and II, respectively. Curative resection was possible in all 12 (100.0%) patients in group I and in only 48 (64.0%) in group II. Adjuvant chemotherapy (5-fluorouracil, gemcitabine and cisplatin) was given to eight (66.7%) and 41 (54.7%) patients in group I and II, respectively. Surgical mortality rate (within 1 mo) was 0.0% and 2.7% in group I and II, respectively. The two deaths in group II were due to sepsis and multiorgan failure. The overall surgical complication rate was 41.4% and the complication rate was higher in group I (50.0% *vs* 40.0%) (Table 2).

### Survival period

The median period of follow-up was 10.36 mo (range: 1.18-61.68 mo), and the last follow up date was December 31, 2007. The overall survival rate at 1 year and 3 years for stage II adenocarcinoma of the pancreatic head and uncinate process, with PV/SMV resection, was 50.0% and 16.7%, respectively in group I and 44.4% and 12.2% in group II (Figure 1A). Two patients in group I survived for > 3 years; one patient died after 4 years and the other survived for 4.5 years and is still

**Figure 1** Overall survival in stage II adenocarcinoma of pancreatic head and uncinate process after pancreaticoduodenectomy (PD)/pylorus-preserving PD (PPPD). A: With and without PV/SMV resection; B: With preoperative total bilirubin level  $\leq$  or  $>$  2 mg/dL; C: In terms of histological differentiation; D: Treated with and without adjuvant chemotherapy.

under follow-up. Univariate (Table 3) and multivariate (Table 4) analyses revealed that serum bilirubin, histological differentiation and adjuvant chemotherapy were significant prognostic factors ( $P < 0.05$ ).

The 1- and 3-year survival rate in patients with and without elevation of serum bilirubin ( $>$  or  $\leq$  2 mg/dL) was 39.1% and 8.2%, and 68.4% and 30.7%, respectively (Figure 1B). In analysis of tumor factors, that is, histological differentiation, the 1-year survival rates in well, moderately well and poorly differentiated groups were 68.0%, 31.8% and 46.7%, respectively. The 3-year survival rates in these three categories were 24.0%, 8.8% and 6.7%, respectively. Better survival was found in the well-differentiated group (Figure 1C). The 1- and 3-year survival in patients treated with or without adjuvant chemotherapy was 54.7% and 18.8%, and 29.0% and 3.2%, respectively (Figure 1D).

## DISCUSSION

In our study, the overall 1- and 3-year survival was comparable to that in the study by Fukuda *et al.*<sup>[12]</sup>, which had a survival rate of 47% and 26.8%, respectively, in group I, and 63.4% and 28.4% in group II patients. However, van Geenen *et al.*<sup>[13]</sup> have reported 55% and 6%, respectively, Ye *et al.*<sup>[14]</sup> have reported 37.7% and 5.6%, respectively, and Launois *et al.*<sup>[15]</sup> have reported 42.4% and 11.9% in group I, which is slightly less than the survival rates in our study. The 3-year survival in the

studies of Aramaki *et al.*<sup>[16]</sup> and Carrère *et al.*<sup>[17]</sup> was 21.3% and 20.0%, and 22.0% and 25.0%, in group I and II, respectively. All the above studies included all stages of pancreatic cancer, irrespective of location in the pancreas. This differs from our study, in which we focused only on stage II adenocarcinoma localized in the pancreatic head and uncinate process, where there is more probability of vascular encasement.

In our study, the mean survival time in patients undergoing curative PV/SMV resection was 16.28 mo. There was not much difference in the mortality rate in PD/PPPD with or without vascular resection, but the associated morbidity was higher in the vascular resection group. This is in contrast to earlier studies that have found that PV/SMV resection does not greatly influence morbidity and mortality in PD<sup>[12,18]</sup>. In our study, all 12 patients in group I had negative resection margins. Previous studies have reported that the resectability rate is high in PD with vascular resection<sup>[14]</sup>. PD/PPD with *en-bloc* vascular resection potentially provides an opportunity to achieve negative resection margins, and thus might be beneficial in achieving better survival rates in carefully selected patients with pancreatic adenocarcinoma<sup>[19,20]</sup>. Hence, in patients who were subjected to palliative treatment alone, based on their preoperative evaluation that showed PV/SMV encasement, some carefully selected patients, as determined by preoperative CT [length and severity (complete *vs* partial circumference) of vascular involvement], may be suitable candidates for *en-bloc* resection

behavior, and almost equal or even better survival rates can be achieved by *en-bloc* resection of PV/SMV<sup>[12,19]</sup>. Our study shows that *en-bloc* vascular resection in stage II pancreatic adenocarcinoma is a feasible option in carefully selected patients. Hence, vascular encasement should not be considered as a contraindication for surgery; risk must be balanced against the benefit by case to case evaluation.

Serum bilirubin, histological differentiation and adjuvant chemotherapy were significant prognostic factors in our series. Previous studies have focused on the significance of depth of PV invasion<sup>[18]</sup>, lymph node metastasis<sup>[21]</sup>, tumor size<sup>[22]</sup>, negative resection margin<sup>[23]</sup>, and adjuvant chemotherapy<sup>[24]</sup> in pancreatic adenocarcinoma. These preoperative and intraoperative factors

**Table 4** Multivariate analysis in stage II pancreatic adenocarcinoma of the head and uncinate process

Parameters	Hazard ratio (95% CI)	P value
Bilirubin (mg/dL)		
≤ 2/> 2	2.024 (1.613-3.774)	0.026
Differentiation		0.005
Moderately/well	2.412 (1.379-4.217)	0.002
Poorly/well	2.091 (1.034-4.225)	0.040

help in deciding the extent of resection, proper planning of adjuvant therapy, and predicting the survival outcome in these patients. In our study, preoperative biliary drainage has no statistical significance in the outcome of stage II pancreatic adenocarcinoma, similar to an earlier study<sup>[25]</sup>. Few studies have reported the potential advantages of preoperative biliary drainage, which include improved nutritional, metabolic and immune function, and the possibility of reduced postoperative morbidity and mortality<sup>[26,27]</sup>. In contrast, one study has reported that the biliary stents induce bacterial contamination and enhance the risk of cholangitis because of clogging. Biliary stenting also generates a severe inflammatory response adjacent to the wall of the bile duct, which is probably a factor that is responsible for increased risk of bile leakage and infection after biliodigestive reconstruction<sup>[28]</sup>. An experimental study has indicated that a period of 4-6 wk is necessary to recover metabolic and immune functions so that some benefit may be achieved by preoperative biliary drainage<sup>[29]</sup>.

Histological differentiation was found to be significant in our study in determining survival outcome. Patients with well-differentiated adenocarcinoma had better survival than those with moderately well and poorly differentiated adenocarcinoma. Earlier studies by Sohn *et al*<sup>[22]</sup>, Riediger *et al*<sup>[23]</sup> and Yamaguchi *et al*<sup>[30]</sup> have highlighted the significance of histological differentiation as a prognostic factor in pancreatic adenocarcinoma.

Adjuvant chemotherapy was also found to be statistically significant. In our study, patients who received adjuvant chemotherapy had better survival than those without chemotherapy. Adjuvant chemotherapy in pancreatic cancer substantially improved the disease-free survival and overall increase in survival rate, as shown by our study and an earlier one<sup>[31]</sup>. The drawback of our study is that it was a retrospective analysis. However, it still gives information about the prognostic factors and feasibility of *en-bloc* vascular resection in stage II adenocarcinoma of the pancreatic head and uncinate process.

In summary, our study concludes that serum bilirubin, histological differentiation and adjuvant chemotherapy are independent prognostic factors that influence survival in patients with stage II adenocarcinoma of the pancreatic head and uncinate process. PD/PPPD along with *en-bloc* vascular resection is a technically feasible option in carefully selected patients.

## COMMENTS

### Background

Unexpected tumor invasion to the lateral or posterolateral wall of the confluence of the portal vein/superior mesenteric vein (PV/SMV) is a common finding during pancreaticoduodenectomy for pancreatic malignancies. This study was designed to establish the prognostic factors and feasibility of *en-bloc* vascular resection in stage II adenocarcinoma of the pancreatic head and uncinate process.

### Research frontiers

With improvement in surgical techniques and postoperative care, more aggressive *en-bloc* resection of pancreatic malignancies, along with PV/SMV is being carried out at present, without any increase in surgical complications.

### Innovations and breakthroughs

Only a few studies have investigated stage II pancreatic adenocarcinoma, with special attention to adenocarcinoma in the head and uncinate process, which is more likely to invade the PV/SMV because of its close proximity to these vessels.

### Applications

*En-bloc* vascular resection is a feasible option in carefully selected patients with stage II adenocarcinoma of the pancreatic head and uncinate process. Serum bilirubin, histological differentiation and adjuvant chemotherapy are the independent prognostic factors.

### Peer review

This is a very well-focused paper that reports a single-center experience with *en-bloc* venous resection of stage II pancreatic adenocarcinoma.

### Abstract

**AIM:** To study characteristics of collateral circulation of gastric varices (GVs) with 64-row multidetector computer tomography portal venography (MDCTPV).

**METHODS:** 64-row MDCTPV with a slice thickness of 0.625 mm and a scanning field from 2 cm above the tracheal bifurcation to the lower edge of the kidney was performed in 86 patients with GVS diagnosed by endoscopy. The computed tomography protocol included unenhanced, arterial and portal vein phases. The MDCTPV was performed on an AW4.3 workstation. GV's were classified into three types according to Sarin's Classification. The afferent and efferent veins of each type of GV were observed.

**RESULTS:** The afferent venous drainage originated mostly from the left gastric vein alone (LGV) (28/86, 32.59%), or the LGV more than the posterior gastric vein/short gastric vein [LGV > posterior gastric vein/short gastric vein (PGV/SGV)] (22/86, 25.58%), as seen by MDCTPV. The most common efferent venous

drainage was *via* the azygos vein to the superior vena cava (53/86, 61.63%), or *via* the gastric/splenorenal shunt (37/86, 43.02%) or inferior phrenic vein (8/86, 9.30%) to the inferior vena cava. In patients with gastroesophageal varices type 1, the afferent venous drainage of GV mainly originated from the LGV or LGV > PGV/SGV (43/48, 89.58%), and the efferent venous drainage was mainly *via* the azygos vein to the superior vena cava (43/48, 89.58%), as well as *via* the gastric/splenorenal shunt (8/48, 16.67%) or inferior phrenic vein (3/48, 6.25%) to the inferior vena cava. In patients with gastroesophageal varices type 2, the afferent venous drainage of the GV mostly came from the PGV/SGV more than the LGV (PGV/SGV > LGV) (8/16, 50%), and the efferent venous drainage was *via* the azygos vein (10/16, 62.50%) and gastric/splenorenal shunt (9/16, 56.25%). In patients with isolated gastric varices, the main afferent venous drainage was *via* the PGV/SGV alone (16/22, 72.73%), and the efferent venous drainage was mainly *via* the gastric/splenorenal shunt (20/22, 90.91%), as well as the inferior phrenic vein (3/23) to the inferior vena cava.

**CONCLUSION:** MDCTPV can clearly display the afferent and efferent veins of all types of GV, and it could provide useful reference information for the clinical management of GV bleeding.

## INTRODUCTION

Liver cirrhosis can result in portal hypertension. Gastric fundic and/or esophageal varices are one of the severe complications. It may cause massive hemorrhage of the upper gastrointestinal tract<sup>[1]</sup>. The clinical management of gastric varices (GV) is related to their hemodynamics and locations. GV were classified into three types according to Sarin's Classification that is based on varices location by endoscopy<sup>[2]</sup>. It is essential to identify the hemodynamics of different types of GV before treatment. The conventional portal vein catheterization provides useful information regarding portal hemodynamics including GV, but it is an invasive method<sup>[3]</sup>. As an almost atraumatic method, computed tomography angiography has been adopted widely to display the portal vein system<sup>[4-7]</sup>. Multidetector computer tomography portal venography (MDCTPV) can display esophageal varices (EV), GV and related bypass circuits more specifically because of the thinner slice and better spatial resolution of the computed tomography scanner<sup>[8,9]</sup>. In our study, 86 GV patients diagnosed by endoscopy were selected and classified into three types according to Sarin's Classification<sup>[2]</sup>, and the afferent and efferent veins of different types of GV were studied by MDCTPV.

## MATERIALS AND METHODS

### Patients

Eighty-six consecutive patients with portal hypertension confirmed by endoscopy were enrolled in this study from April 2007 to December 2008, including 52 men and 34 women, aged 38-76 years (mean: 62.6 years). The etiology of portal hypertension for these 86 patients was post-hepatic cirrhosis ( $n = 45$ ), alcoholic cirrhosis ( $n = 23$ ), primary biliary cirrhosis ( $n = 7$ ), autoimmune hepatic cirrhosis ( $n = 3$ ), cryptogenic cirrhosis ( $n = 1$ ), pancreatic carcinoma ( $n = 4$ ) and chronic pancreatitis ( $n = 3$ ). There were 35 patients with a coexistent diagnosis of hepatoma. According to Child-Pugh grading, 15 cases were grade A, 50 grade B and 21 grade C.

### Examination methods

A GE 64-row MDCT scanner was applied to perform non-enhanced, arterial and portal vein phase vein enhanced scans in all patients. The scanning range was from 2 cm above the tracheal bifurcation to the lower edge of the kidney. One hundred milliliters of non-ionic contrast medium (Omnipaque 350, Nycomed Inc., Princeton, NJ, USA) was injected with a power injector at a rate of 4.0 mL/s. The arterial phase scanning started about 20-30 s after the beginning of injection, and portal phase scanning was initiated 25 s after the beginning of the arterial phase. The reconstitution thickness was set at 0.625 mm.

Fujinon EG 485 (Fujinon, Saitama, Japan) and Olympus CV240 electronic endoscope (Olympus Optical Co. Ltd., Tokyo, Japan) were used for the observation of EV and GV. The location of the varices was recorded according to endoscopic reports and imaging data.

### Image analysis

CTPV images were processed on a GE AW4.3 workstation (GE Medical Systems, Milwaukee, WI, USA). GV and collateral circulation in all cases were analyzed using maximum-intensity projection (MIP) and multi-planer reformation (MPR) techniques. All images were reviewed by three independent experienced radiologists, who were blind to the patients' clinical data. A consecutive conclusion was obtained if their diagnosis was different.

### Classification of GV

According to the varices location under endoscopy<sup>[2]</sup>, GVs were classified into three types: (1) gastroesophageal varices type 1 (GEV1): EV combined with lesser curve GV; (2) gastroesophageal varices type 2 (GEV2): EV combined with GV that extend to the greater curvature; and (3) isolated gastric varices (IGV): varices located on the body and fundus of the stomach, without EV.

Based on CTPV, the afferent venous drainage of GV could be divided into four types<sup>[10,11]</sup>: left gastric vein (LGV) alone; posterior gastric vein/short gastric vein (PGV/SGV) alone; LGV dominant (LGV > PGV/SGV; drainage from both the LGV and PGV/SGV, with the former predominating); and PGV/SGV dominant (PGV/SGV > LGV; drainage from both the LGV and PGV/SGV, with the latter predominating).

## RESULTS

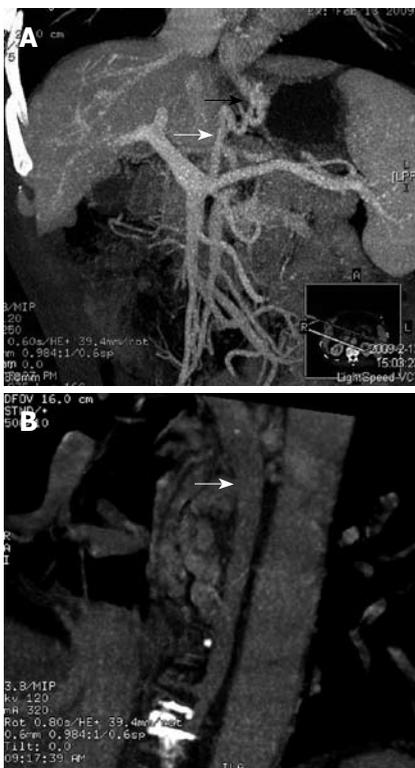

According to endoscopy, we found 48 cases of GEV1 (55.8%), 16 of GEV2 (18.6%) and 22 of IGV (25.6%) (Table 1).

MDCTPV showed that the afferent venous drainage of GV (Table 1) originated from LGV (28/86, 32.59%), PGV/SGV > LGV (22/86, 25.58%), followed by PGV/SGV (20/86, 23.26%) and PGV/SGV > LGV (16/86, 18.60%). Among the GEV1 type, the afferent vein of the GV mostly originated from the LGV (27/48, 56.25%) (Figure 1A) or LGV > PGV/SGV (16/48, 33.33%). Most cases of GEV2 type originated from PGV/SGV > LGV (8/16, 50%) (Figure 2A) or PGV/SGV (4/16, 25.00%), and then LGV > PGV/SGV (3/16, 18.75%). Most IGV cases originated from PGV/SGV (16/22, 72.73%) (Figure 3A and B) or PGV/SGV > LGV (5/22, 22.73%).

The efferent venous drainage of GV differed between patients, and several drainage veins might be observed in one patient as well (Table 1). In 53 cases, the efferent venous drainage was from the azygos vein to the superior vena cava (53/86, 61.63%); eight cases from the inferior phrenic vein to the inferior vena cava (8/86, 9.30%); and 37 cases from the gastric/splenorenal shunt to the inferior vena cava (G/S-R) (37/86, 43.02%). The main efferent venous drainage of GEV1 was *via* the azygos vein into the superior vena cava (43/48, 89.58%) (Figure 1B), whereas the efferent drainage of GEV2 was mostly *via* the azygos vein (10/16, 62.5%) to the superior vena cava, and *via* the gastric/splenorenal shunt to the inferior vena cava (9/16, 56.25%) (Figure 2B). The efferent venous drainage of IGV was mainly *via*

the gastric/splenorenal shunt to the inferior vena cava (20/22, 90.91%) (Figure 3A and B).

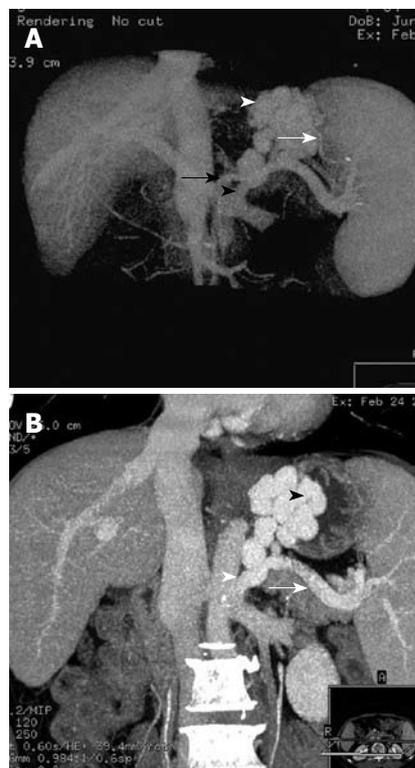

### DISCUSSION

GV are an ominous consequence of portal hypertension<sup>[9]</sup>. Sarin and Ryan have reported that GV are detected in 20% of portal hypertension patients<sup>[12,13]</sup>. Compared to endoscopic findings reported by Sarin *et al*<sup>[12]</sup>, our study with CTPV revealed that the IGV type was more common (25.6%), GEV1 was less common (55.8%) and GEV2 was similar to that report. It was probably because there were more cases of pancreas disease in our study<sup>[14]</sup>.

The afferent venous drainage of GV was mainly from

**Figure 2 Gastroesophageal varices type 2.** A: GV (arrowhead) originated from the posterior gastric vein/short gastric vein (PGV/SGV) (black arrow) and LGV (white arrow), but the former was dominant; B: GV (white arrowhead) draining to the inferior vena cava (white arrow) via the gastric/splenorenal shunt (black arrowhead).

**Figure 3 Isolated gastric varices.** A: GV (white arrowhead) originated from the PGV/SGV (white arrow) and drained to the inferior vena cava (black arrow) via the gastric/splenorenal shunt (black arrowhead); B: GV (black arrowhead) originated from the PGV/SGV and drained to the inferior vena cava via the gastric/splenorenal shunt (white arrowhead), white arrow indicates splenic vein.

three blood supplies: LGV, PGV and SGV. We showed that the afferent venous drainage of GV in GEV1 mostly originated from the LGV or LGV > PGV/SGV. In GEV2, LGV and PGV/SGV participated in the blood supply of GV. As for type IGV, the afferent venous drainage was mainly from the PGV/SGV. Our study revealed that PGV/SGV participated in the blood supply of the three types of GV, which was more than in the former study<sup>[10]</sup>. This may be because more cases of pancreatic cancer and pancreatitis were involved in this study. The latter was called left-sided portal hypertension, because the pancreas diseases involved the splenic vein, which showed PGV/SGV leading to GV, and often not accompanied by EV<sup>[15,16]</sup>.

The blood supply pattern of GV is related closely to the anatomy of the LGV, PGV and SGV. The LGV originates from the portal vein, splenic vein and portosplenic angle. The stem of the LGV gives off anterior and posterior branches above the body of stomach. The anterior branch enters the wall of the fundus and forms the varices, which are continuous with the peri-esophageal varices in the esophagogastric junction. The posterior branch, from which the paraesophageal varices are formed directly, collects blood from the lesser curvature, cardia and lower segment of the esophagus<sup>[17]</sup>. As a result, when the LGV is predominant (GEV1), the location of GV is closer to the cardia, and generally accompanied by EV. The PGV is not present in normal conditions; it only emerges when portal hypertension occurs. It originates from the splenic vein and collects blood from the greater gastric curvature. As a result, in GEV2 and IGV patients, the PGV is one of the main blood vessels. This is the same as reported by Watanabe *et al.*<sup>[3]</sup> through portal vein catheterization. In GEV1, the PGV is part of the GV blood supply. The SGV originates from the splenic vein and mainly drains blood from the fundus and greater curvature, thus contributing mainly to the fundus varices.

The para-esophageal varices may connect with the peri-esophageal varices, or join the superior vena cava *via* the azygos vein system, or *via* the inferior phrenic vein to the inferior vena cava<sup>[18]</sup>. Therefore, venous drainage of GEV1 is mostly *via* the azygos vein to the superior vena cava. EV can also exist in GEV2, but the GV blood supply seldom comes from the LGV, thus, in GEV2, only a small part of the GV drainage goes *via* the azygos vein to the superior vena cava or *via* the inferior phrenic vein to the inferior vena cava.

The gastric/splenorenal shunt is the spontaneous portosystemic shunt that runs from the branches of the PGV/SGV *via* the left adrenal vein, retroperitoneal veins and other branches of the left renal vein<sup>[8,19]</sup>. Thus it is likely to be found in GEV2 and IGV, as indicated in our study.

The CTPV view of the blood supply and drainage of GV could provide clinicians with a valuable reference for the endoscopic treatment of GV bleeding<sup>[20,21]</sup>. GV collateral vessels should be given special attention during treatment. GEV2 and IGV are supplied by multiple vessels, therefore, the simple treatment of endoscopic variceal

ligation is not ideal, and has a high rate of recurrence and postoperative hemorrhage. With regard to the gastric/splenorenal shunt that is commonly found with IGV, more attention should be paid to the dosage and injection rate of sclerosant during endoscopic sclerotherapy, so as to prevent the sclerosant from flowing into the systemic circulation *via* the shunt<sup>[22]</sup>. In some GEV1 cases, the incidence of secondary GV increases after treatment of EV<sup>[11]</sup>. On the other hand, after treatment of GV, EV are aggravated because of the special drainage pattern, which can be displayed clearly on CTPV<sup>[18]</sup>. Therefore, CTPV has its value in the follow-up after endoscopic sclerotherapy.

## COMMENTS

### Background

The collateral circulation, location, and hemodynamics of gastric varices (GV) can affect the treatment of GV bleeding.

### Research frontiers

Computed tomography angiography has been used widely to visualize the portal vein system, and it can reveal esophageal varices, GV and related bypass circuits.

### Innovations and breakthroughs

In this study, the afferent and efferent veins of different types of GV, which were classified according to their location, were revealed by the high spatial resolution imaging of multidetector computed tomography (MDCT) and the appropriate post-processing methods.

### Applications

As a noninvasive method, MDCT portal venography could provide clinicians with a valuable reference in the endoscopic and surgical treatment of GV bleeding.

### Peer review

This seems a very interesting new semiological approach to GV.

### Abstract

**AIM:** To investigate the preparation, physicochemical characterization and cytotoxicity *in vitro* of Gemcitabine-loaded poly(ethylene glycol)-block-poly(D,L-lactide) (PEG-PDLLA) nanovesicles.

**METHODS:** The nanovesicle carriers were prepared from the amphiphilic block copolymer of PEG-PDLLA by a double emulsion technique, and gemcitabine was used as the model drug. The morphology of the nanovesicles was determined by scanning and transmission electron microscopy, and the drug content, drug entrapment and drug-release curve *in vitro* were detected by UV-Vis-NIR spectrophotometry. Cytotoxicity in the human pancreatic cancer cell line SW1990 was tested by 3-(4,5-dimethyl) ethiazole (MTT) assay.

**RESULTS:** The gemcitabine-loaded nanovesicles were hollow nanospheres with a mean size of 200.6 nm, drug

loading of 4.14% and drug embedding ratio of 20.54%. The nanovesicles showed excellent controlled release that was characterized by a fast initial release during the first 72 h, followed by a slower and continuous release. The MTT assay demonstrated that gemcitabine-loaded nanovesicles exhibited dose-dependent and time-delayed cytotoxicity in the human pancreatic cancer cell line SW1990.

**CONCLUSION:** Gemcitabine-loaded PEG-PDLLA nanovesicles prepared by a double emulsion technique exhibited good performance for controlled drug release, and had similar cytotoxic activity to free gemcitabine.

### INTRODUCTION

Nanovesicles are a new type of drug carrier, which can protect incorporated drugs from *in vivo* metabolism while enhancing their therapeutic effect and reducing their toxicity. Compared with other drug delivery systems, nanovesicles are more suitable for hydrophilic drugs

because of their hollow structure and internal aqueous phase, which can burden high drug loading.

Gemcitabine has been demonstrated to display anti-tumor activity against a wide variety of cancers, including pancreatic, colon, lung, breast, bladder and ovarian cancer<sup>[1-3]</sup>. However, gemcitabine is metabolized rapidly in the blood. Thus, a major limitation of this antitumor drug is that gemcitabine has a very short plasma half-life and strong side effects when administered intravenously<sup>[4]</sup>. As a drug carrier, nanovesicles may promote the efficacy of gemcitabine and reduce its side effects.

Poly(lactic acid) (PLA) is the most widely used synthetic polymer, which is known to be biocompatible and degradable to give the natural product lactic acid<sup>[5]</sup>. However, nanoparticles based on PLA accumulate blood proteins on their surface as they circulate through the body<sup>[6,7]</sup>. This nonspecific absorption of proteins attracts attention from immune cells, with the result that nanoparticles are often removed from circulation before reaching their tumor targets. Modification with poly(ethylene glycol) (PEG) chains immobilized on the surface forms a hydrophilic palisade, which creates repulsion between the nanovesicles, and this repulsion can stop the nanovesicles from agglomerating, thus increasing their dispersion stability in aqueous media<sup>[8-10]</sup>. Furthermore, PEG is able to prevent proteins from adhering to the surface and thus avoids nanovesicles being recognized by macrophages<sup>[11,12]</sup>, which prolongs the circulation time and facilitates nanoparticle uptake by specific cancer cells for cancer therapy<sup>[13,14]</sup>.

However, there have only been a few studies on the incorporation of gemcitabine into PEG-block-poly(D,L-lactide) (PEG-PDLLA) nanovesicles. Therefore, we prepared gemcitabine-loaded nanovesicles, observed their size distribution, morphology and drug-release performance, and carried out a preliminary investigation of their cytotoxicity *in vitro*.

## MATERIALS AND METHODS

### Materials

The amphiphilic block copolymer of PEG-PDLLA was synthesized by Sun Yat-Sen University. Gemcitabine was purchased from Eli Lilly & Co (Indianapolis, IN, United States). RPMI1640 and fetal bovine serum (FBS) were purchased from Gibco (Grand Island, NY, United States).

### Cell culture

The human pancreatic cancer cell line SW1990 was obtained from the Second Affiliated Hospital of Sun Yat-Sen University. All cells were cultured as monolayers at 37°C in a 5% CO<sub>2</sub>/95% humidified atmosphere with RPMI1640 supplemented with 10% FBS, 100 U/mL penicillin, 100 µg/mL streptomycin and 2 mmol/L L-glutamine.

### Preparation of gemcitabine-loaded nanovesicles

Gemcitabine-loaded nanovesicles were prepared by a double emulsion (w/o/w) technique. The preparation was performed as follows: (1) An aqueous solution (2 mg

gemcitabine in 0.2 mL pure water) was added dropwise into an organic solution of the polymer (10 mg PEG-PDLLA in 2 mL trichloromethane), and the first emulsion (w/o) was formed by sonication; (2) The emulsion was added dropwise into an organic solution that consisted of 40 mL polyvinyl alcohol (PVA) solution at 0.5% (w/v) and the double emulsion (w/o/w) was obtained by sonication; (3) The residual trichloromethane of the double emulsion was removed completely by vacuum distillation with a rotary evaporator, and free PVA and non-incorporated gemcitabine was removed by dialysis in the pure water overnight; and (4) Nanovesicles obtained as a suspension were purified by filtration through a syringe filter (pore size 0.45 µm), and then subjected to lyophilization to yield the solid nanovesicle samples. We repeatedly prepared three groups of gemcitabine-loaded nanovesicle samples according to the above processes.

### Determination of gemcitabine incorporation efficiency

Three groups of prepared nanovesicles were redissolved in DMSO. Gemcitabine in the solution was measured by ultraviolet spectroscopy at 275 nm (Perkin-Elmer Lambda 20 UV-Vis spectrophotometer, Beijing, China), and its incorporation efficiency was evaluated by drug loading (DL) and drug embedding ratio (ER). DL (%) = mass of drug in nanovesicles × 100/mass of nanovesicles recovered. ER (%) = mass of drug in nanovesicles × 100/mass of drug used in formulation.

### Nanovesicle size and morphology

After dilution with purified water, nanovesicle size was determined by photon correlation spectroscopy (PCS) (Malvern Autosizer, United States), at a scattering angle of 90° and a temperature of 25°C. Values are reported as the mean diameter (MD). The morphology of the nanovesicles was observed by transmission electron microscopy (TEM) (JEOL-100CXII, Japan) and scanning electron microscopy (SEM) (XL-30, Holland). A drop of the nanovesicles suspension (10 µL) was placed on copper electron microscopy grids (Formvar coated) and stained with 2% (w/v) phosphotungstic acid solution. After 30 s, the sample was washed with purified water and the excess fluid was removed with a piece of filter paper. The dried sample was then examined.

### In vitro release of gemcitabine from nanovesicles

Phosphate buffer solution (PBS) at pH 7.4 and pH 5 was selected for the release medium. Nanovesicle samples (60 mg each) were resuspended in 5 mL PBS (pH 7.4 or 5) and transferred into a dialysis tubing (MW cut-off: 14000 Da). The tubing was placed in 45 mL PBS (pH 7.4 or 5). The release study was performed at 37°C in a Shanghai Yi-heng Scientific DKZ Incubator Shaker. At selected time intervals, 5 mL buffered solution outside the dialysis tubing was removed for UV-Vis analysis and replaced with 5 mL fresh buffer solution. Gemcitabine concentration was calculated based on the absorbance intensity at 268 nm. The equations were as follows:  $C_{pH 7.4} = 34.724A - 0.2971$ ,  $r^2 = 0.9999$ ;  $C_{pH 7.4} = 38.317A - 0.3289$ ,  $r^2 = 0.9999$  (C:

drug concentration; A: absorbance at 268 nm). The cumulative percentage of released gemcitabine (%) could be calculated by the equation:  $Q (\%) = (V_0 \times C_t + V \times \sum C) \times 100\% / (W \times X)$  (Q: cumulative percentage of released gemcitabine; C<sub>t</sub>: gemcitabine concentration in release medium at each time point; V<sub>0</sub>: gross removed volume of release medium; V: volume of sample; W: gross mass of nanovesicles; X: drug content of gemcitabine).

**In vitro cytotoxicity study against human SW1990 pancreatic cancer cells**

The inhibition of cell growth was evaluated by the 3-(4,5-dimethyl) ethiazole (MTT) method using triplicate assays. Gemcitabine and gemcitabine-loaded nanovesicles were diluted in RPMI1640 at  $1.0 \times 10^{-3}$  mol/L, respectively. Then, 100 μL cell solution with  $5 \times 10^4$  cells/mL was seeded in 96-well plates (Costar, Cambridge, MA, United States), and allowed to attach overnight. After 24 h incubation, gemcitabine-loaded nanovesicles with concentrations of  $10^{-7}$ ,  $10^{-6}$ ,  $10^{-5}$  and  $10^{-4}$  mol/L were added to the cell cultures. Gemcitabine added at the same concentration acted as a positive control. PBS was added as a negative control. At 24, 48, 72 and 96 h, 20 μL MTT and 200 μL RPMI culture medium were added to each well and incubated at 37°C for 4 h. Then MTT and culture medium were removed and 200 μL DMSO was added. The absorbance of the converted dye, which correlated with the number of viable cells, was determined at 490 nm. Cell viability was determined by the following equation:  $\text{Cell viability (\%)} = (\text{Abs}_{\text{test cell}} / \text{Abs}_{\text{control cells}}) \times 100\%$ . Cell inhibitory rate was determined by the following formula:  $\text{Cell inhibitory rate (\%)} = (1 - \text{Abs}_{\text{test cell}} / \text{Abs}_{\text{control cells}}) \times 100\%$ .

**Statistical analysis**

Statistical analysis was performed with SPSS for Windows version 13.0. Data were expressed as mean ± SD, and were compared using one-way ANOVA. *P* < 0.05 was considered statistically significant based on a two-tailed test.

**RESULTS**

**Nanovesicle characteristics**

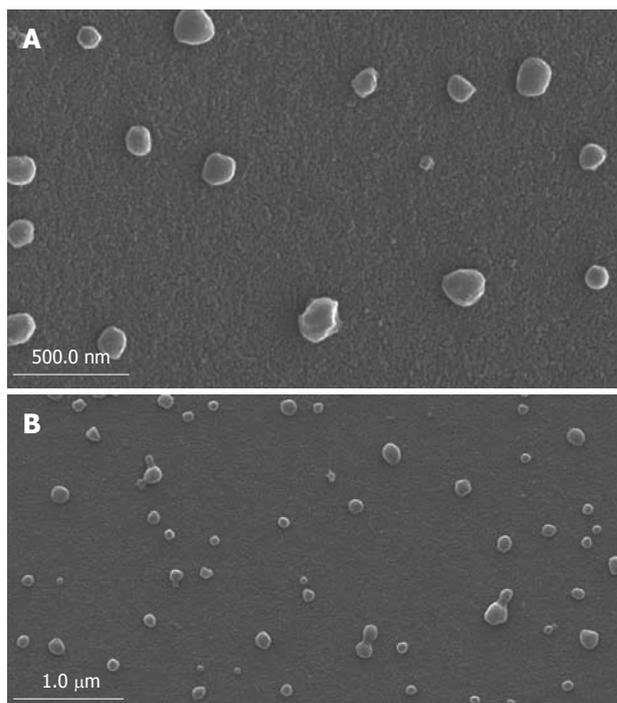

The mean diameter of prepared nanovesicles was 200.6 nm (range: 70-250 nm). As shown by SEM (Figure 1) and TEM (Figure 2), it was clear that the nanovesicles were spherical in shape, and hollow in structure, with a large central cavity in which gemcitabine was loaded.

**Vesicle loading capacity**

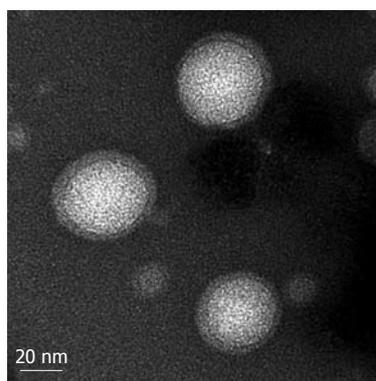

The DL and ER in three groups of gemcitabine-loaded nanovesicles are shown in Table 1. The mean value of DL was  $4.14\% \pm 0.13\%$ , and ER was  $20.54\% \pm 0.92\%$ , which indicated good duplication of the nanovesicle preparation.

**In vitro gemcitabine release study**

The *in vitro* release of gemcitabine-loaded nanovesicles

**Figure 1** Scanning electron microphotographs of poly (ethylene glycol)-block-poly (D,L-lactide) (PEG-PDLLA) nanovesicles. A: × 40 000; B: × 20 000.

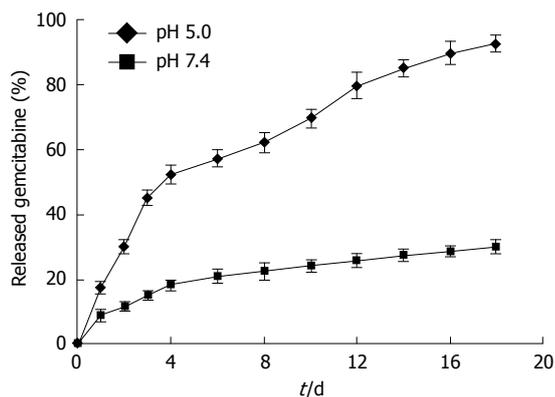

**Figure 2** Transmission electron micrographs of PEG-PDLLA nanovesicles.

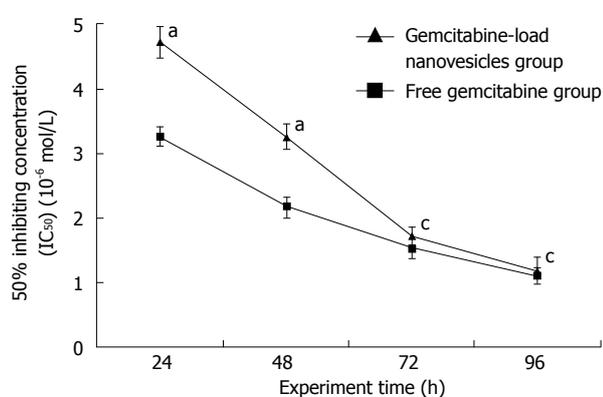

**Table 1** Drug incorporation efficiency of Gemcitabine-load nanovesicles (%)

Sample	1	2	3	mean ± SD
Drug content	4.23	3.99	4.19	4.14 ± 0.13
Drug encapsulation efficiency	21.34	19.54	20.75	20.54 ± 0.92

in two different buffered solutions (pH 7.4 and 5.0) is shown in Figure 3. A typical two-phase-release was observed in both solutions. A rapid release was observed from gemcitabine-loaded nanovesicles in the first 4 d, and a relatively slower and sustained release was observed in the following days. By comparison with the release at pH 5.0, gemcitabine-release from nanovesicles at pH 7.4 was much slower. In the first 18 d, the cumulative percentage of released gemcitabine at pH 7.4 was

**Figure 3** Release of gemcitabine from nanovesicles at pH 7.4 and 5.0. Data are presented as mean  $\pm$  SD.  $P < 0.05$  at every point of pH 5.0 vs pH 7.4.

**Figure 4**  $IC_{50}$  of gemcitabine-loaded nanovesicles and free gemcitabine in human SW1990 pancreatic cancer cells. Data are presented as mean  $\pm$  SD. <sup>a</sup> $P < 0.05$ , <sup>c</sup> $P > 0.05$  vs free gemcitabine group.

< 30%, whereas released gemcitabine at pH 5.0 was 92.70%.

### In vitro cytotoxicity study

Table 2 shows the cell inhibitory rate of gemcitabine-loaded nanovesicles and free gemcitabine at a concentration range of  $10^{-7}$  to  $10^{-4}$  mol/L. With increasing drug concentration, pancreatic cancer cells were decreased in the gemcitabine-loaded nanovesicles and free gemcitabine groups. At each drug concentration, the cell inhibitory rate in the gemcitabine-loaded nanovesicles group was lower than that in the free gemcitabine group, however, no statistically significant difference was observed (all  $P > 0.05$ ).

The  $IC_{50}$  (50% inhibiting concentration) of gemcitabine-loaded nanovesicles and free gemcitabine in human SW1990 pancreatic cancer cells at four time points is shown in Figure 4.  $IC_{50}$  gradually decreased with time in both groups. In the first 48 h,  $IC_{50}$  in the gemcitabine-loaded nanovesicles group was significantly higher than that in the free gemcitabine group ( $P < 0.05$ ). At 72 h,  $IC_{50}$  was also higher in the gemcitabine-loaded nanovesicles group than in the free gemcitabine group, but this difference was not statistically significant ( $P > 0.05$ ). Up to the end point at 96 h,  $IC_{50}$  was very similar in the two groups.

**Table 2** The inhibitory effect of Gemcitabine-loaded nanovesicles and free gemcitabine on human SW1990 pancreatic cancer cells

Drug concentration (mol/L)	Gemcitabine-loaded nanovesicles	Free gemcitabine	<i>P</i> value
	Cell inhibitory rate (%)	Cell inhibitory rate (%)	
$10^{-7}$	18.3 $\pm$ 1.6	21.7 $\pm$ 2.5	0.480
$10^{-6}$	46.2 $\pm$ 2.7	49.5 $\pm$ 4.1	0.619
$10^{-5}$	82.3 $\pm$ 5.4	78.8 $\pm$ 4.2	0.592
$10^{-4}$	93.2 $\pm$ 5.3	95.2 $\pm$ 3.7	0.552

## DISCUSSION

Gemcitabine is an anticancer nucleoside analogue that is active against various solid tumors. However, with intravenous administration, this drug is inactivated rapidly by enzymatic deamination, and it has a short biological half-life that necessitates the administration of high doses, which leads to unwanted side effects<sup>[15-17]</sup>. Therefore, as a carrier for gemcitabine delivery, nanovesicles, which are superior to other drug delivery systems for encapsulating hydrophilic drugs and can be subjected to surface modification, are used to overcome the above problems. Many advantages can be found in gemcitabine-loaded nanovesicles, including the possibility of targeting specific sites, controlled drug release, and protection of the encapsulated drug<sup>[18-24]</sup>.

Our prepared nanovesicles were spherical in shape with a hollow structure, and gemcitabine was incorporated in the core of the nanovesicles. Generally, nanovesicles < 500 nm are considered ideal for drug delivery systems, because this size allows more effective systemic circulation than smaller molecules, and they can access places in the human body that larger particles cannot reach. At the same time, nanoparticles of this size can penetrate tumors because of the leaky nature of their microvasculature. This classic effect, which is referred to as the “enhanced permeation and retention effect”, results in prolonged circulation and accumulation of a therapeutic agent within the tumor<sup>[25]</sup>. Meanwhile, the modification by PEG allows nanoparticles to escape from the vasculature through the leaky endothelial tissue that surrounds the tumor, and therefore accumulate in certain solid tumors<sup>[26,27]</sup>. As a result, nanoparticles can target the tumor through blood vessels and enhance the anticancer activity of the drug.

As shown in Figure 3, these nanoparticles have a stable release profile. The release of gemcitabine from nanovesicles exhibited a biphasic pattern that was characterized by a fast initial release during the first 72 h, followed by a slower continuous release. The fast release of gemcitabine was probably the result of rapid desorption of gemcitabine from the external layer of the nanovesicles and diffusion of the drug located near the surface, whereas the slower and continuous release may be attributed to slow trans-layer permeation kinetics and diffusion from the interior, together with erosion of the polymer. It has been shown that the aqueous medium

slowly penetrates the internal structure of the particles and causes progressive degradation of the polymer chains.

Another phenomenon was that gemcitabine release from nanovesicles at pH 5.0 was much faster than that at pH 7.4, which indicated that faster degradation of nanovesicles appeared at lower pH. This pH-dependent release is of particular interest in achieving tumor-targeted gemcitabine delivery with nanovesicles. It is expected that most of the gemcitabine encapsulated in nanovesicles will remain in the nanovesicle core for a considerable time period, when the injected nanovesicles remain in the plasma at normal physiological conditions (pH 7.4). However, faster release occurs once the nanovesicles reach the solid tumor site, where the pH value is lower than that in normal tissue<sup>[28]</sup>. In addition, particles are usually internalized inside the cells by endocytosis<sup>[22]</sup>. Therefore, further accelerated release inside the endosome/lysosome of tumor cells may occur as a result of the decreased pH values.

Moreover, in our study, gemcitabine-loaded nanovesicles were similar to free gemcitabine in terms of their cell inhibitory effect at different drug concentrations. Besides, time-delayed cytotoxicity was exhibited by gemcitabine-loaded nanovesicles in the human pancreatic cancer cell line SW1990. In the first 48 h, IC<sub>50</sub> of gemcitabine-loaded nanovesicles was significantly higher than that of free gemcitabine. However, in the following 48 h, IC<sub>50</sub> of gemcitabine-loaded nanovesicles gradually approached that of free gemcitabine. Up to the end of our experiment, IC<sub>50</sub> was very similar in the two groups. It is estimated that the cell inhibitory effect of gemcitabine-loaded nanovesicles is more obvious during the period of sustained release because of its time-dependent release and delayed nuclear uptake in human SW1990 pancreatic cancer cells, which is consistent with *in vitro* gemcitabine release studies. Therefore, our future studies will involve *in vivo* experiments and related research on gemcitabine-loaded nanovesicles.

In summary, using the double emulsion technique, small, spherical and submicron sized (< 210 nm) PEG-PDLLA nanovesicles loaded with gemcitabine were prepared which did not change the drug structure or cytotoxicity. Compared with free gemcitabine, the gemcitabine-loaded nanovesicles elicited a time-dependent improvement in cytotoxic effect that was related to delayed release. This may possibly improve the administration of gemcitabine to pancreatic cancer patients.

## ACKNOWLEDGMENTS

This study was completed partly in the Institute of Polymer Science, School of Chemistry and Chemistry Engineering, Zhongshan University. We thank Professor Xin-Tao Shuai and Hao Li for their direction in the preparation of the nanoparticles.

## COMMENTS

### Background

Gemcitabine is used widely for the treatment of pancreatic cancer. However,

because of its rapid metabolism in the blood, gemcitabine has a very short plasma half-life and strong side effects when administered intravenously. As a drug carrier, nanovesicles may promote the efficacy of gemcitabine and reduce its side effects.

### Research frontiers

Among the nanoparticle drug delivery systems, nanovesicles are recommended as drug delivery devices for anticancer agents. The double emulsion technique is suitable for the preparation of poly(ethylene glycol)-block-poly(D,L-lactide) (PEG-PDLLA) gemcitabine-loaded nanovesicles.

### Innovations and breakthroughs

On the basis of previous data, this is the first study of the preparation, physicochemical characterization and *in vitro* cytotoxicity of gemcitabine-loaded nanovesicles. The results of the present study showed that the small, spherical and submicron sized gemcitabine-loaded nanovesicles, which were prepared by a double emulsion technique, did not change the drug structure or cytotoxicity. The gemcitabine-loaded nanovesicles elicited a time-dependent improvement in cytotoxic effect that was related to delayed drug release, compared with free gemcitabine.

### Applications

Gemcitabine-loaded PEG-PDLLA nanovesicles exhibited good controlled drug release, and similar cytotoxic activity to free gemcitabine. This may provide a way of improving the administration of gemcitabine to pancreatic cancer patients.

### Terminology

The double emulsion (w/o/w) technique is a biochemical engineering method. It is performed as follows: an aqueous solution is added to an organic solution of the polymer, and the first emulsion (w/o) is formed by sonication. The emulsion is added to an organic solution, and the double emulsion (w/o/w) is obtained by sonication.

### Peer review

The authors report what is mainly a biochemical engineering study, although the carcinoma cell line utilised is gastrointestinal. The results are fairly limited but interesting, although clinical introduction of this kind of treatment is still many years away.

### Abstract

**AIM:** To evaluate the importance of sphincter of Oddi laxity (SOL) in hepatolithiasis (HL).

**METHODS:** Subjects included 98 patients diagnosed with HL between 2002 and 2007. Detailed histories were taken and the subjects were monitored until July 2008. HL patients were divided into two groups: Group I included 45 patients with SOL, and Group II included 53 patients without. Recurrence and reoperation indices of both groups were calculated and compared.

**RESULTS:** The recurrence index was 0.135 in Group I and 0.018 in Group II ( $P < 0.001$ ). The reoperation in-

### INTRODUCTION

Hepatolithiasis (HL) is prevalent in East Asia, especially in China<sup>[1-3]</sup>. While this condition results from multiple etiological factors, obstructive cholangitis is usually the main cause<sup>[2]</sup>. In our clinical practice, we have found few cases with obstruction of the common bile duct or sphincter of Oddi (SO); to the contrary, almost half of our clinical cases showed sphincter of Oddi laxity (SOL). We have also found that patients with SOL had a tendency for recurrence and always needed reoperation. The goal of this study was to determine the effect of SOL on recurrence and reoperation frequencies among patients with HL in order to recommend the most suitable therapy for this condition.

The SO is made up of the bile duct, pancreatic duct and ampulla sphincters. Regular contraction and relaxation maintain the normal pressure differences between the bile duct, pancreatic duct and the SO. The diameter of the duodenum papilla orifice is very small, no more than 2-3 mm even when the SO is completely relaxed with drugs. Normally, the SO can regulate the discharge of bile and pancreatic juice, and also prevent duodenum juice reflux. In patients with SOL, a larger diameter ( $\geq 10$  mm) of the biliary tract orifice facilitates the entry of bile juice into the duodenum without resistance, appearing as SO absence.

## MATERIALS AND METHODS

### Case selection

We considered 121 patients with HL who were admitted to the First Affiliated Hospital of the Medical College of Zhejiang University between April 2002 and March 2007. Seven cases were excluded due to histories of choledochojunostomy discovered during surgery, and ten cases were eliminated due to extensive complexity, resulting in a total of 104 selected cases. During the follow-up period of almost 6 years (until July 2008), six patients were lost. Thus, the study included 98 patients: 29 with simple intra-hepatolithiasis (IHL) and 69 with both IHL and choledocholithiasis.

Detailed histories were obtained from the patients, including age of first onset, frequency of recurrence, and previous biliary tract operation. The mean age of the patients was  $52.8 \pm 12.2$  years (range: 17-80 years), and mean age of the first onset was  $45.1 \pm 16.1$  years (range: 8-78 years) (Table 1). All patients were diagnosed by preoperative magnetic resonance cholangiopancreatography (MRCP) and B-ultrasonography (BUS), and diagnoses were confirmed in operation. The absence of residual stones was confirmed by routine choledochoscope (OL-YMPUS CHF P20, external diameter 4.9 mm) examination during operation. The following parameters were set for biliary tract operation: (1) simple cholecystectomy was removed from consideration; and (2) operation was defined as all procedures for clearing stones from the intrahepatic and extrahepatic bile ducts, including hepatectomy, endoscopic stone extraction, calculus removal from the T tube, and choledochojunostomy. Simple choledocholithotomy and T-tube drainage were performed on 35 patients, simple hepatectomy on 20 patients, choledocholithotomy and T-tube drainage with hepatectomy on 35 patients, simple choledochojunostomy on 5 patients, and choledochojunostomy with hepatectomy on 3 patients. BUS was routinely performed every 2 mo after operation, and abnormalities were confirmed with MRCP. Patients showing the symptoms related to HL were immediately examined with BUS and MRCP.

### SOL and patient groups

SOL, related to HL formation, may be primary or secondary. Patients without a history of choledochojunostomy or choledochoduodenostomy may be diagnosed with SOL according to either of the following criteria: (1) contrast media may be found in the common bile duct during duodenography; or (2) a Bake's dilator with a diameter of 10 mm is able to reach the duodenum *via* the SO without pre-dilation during surgery. Patients without a history of any sphincterotomy, including endoscopic sphincterotomy, can be defined as having primary SOL, while those with a history of sphincterotomy can be diagnosed with secondary SOL.

Table 1 Patient characteristics ( $n = 98$ )

Characteristics	
Male/female	35/63
Mean age (yr)	52.8
Mean age of first onset (yr)	45.1
Mean follow-up period (mo)	42.1
Follow-up prevalence	100%
Simple IHL/IHL with choledocholith	38/60
Recurrence rate of this operation	16.3%
Mean number of operations	1.60
Number of patients with 1 operation	67
Number of patients with 2 operations	19
Number of patients with 3 operations	7
Number of patients with 4 operations	1
Number of patients with 5 operations	1
Number of patients with 6 operations	2
Number of patients with 11 operations	1
Number of patients with simple choledocholithotomy and T-tube drainage	35
Number of patients with simple hepatectomy	20
Number of patients with choledocholithotomy, T-tube drainage and hepatectomy	35
Number of patients with simple choledochojunostomy	5
Number of patients with choledochojunostomy and hepatectomy	3
Recurrence index	0.072
Reoperation index	0.037

IHL: Intra-hepatolithiasis.

tomy or choledochoduodenostomy may be diagnosed with SOL according to either of the following criteria: (1) contrast media may be found in the common bile duct during duodenography; or (2) a Bake's dilator with a diameter of 10 mm is able to reach the duodenum *via* the SO without pre-dilation during surgery. Patients without a history of any sphincterotomy, including endoscopic sphincterotomy, can be defined as having primary SOL, while those with a history of sphincterotomy can be diagnosed with secondary SOL.

The patients were divided into two groups: HL patients with SOL (Group I) and those without (Group II). Group I included 45 patients (39 with primary SOL, 6 with secondary SOL) and Group II included 53 patients. The mean age of the patients, the mean age of the first onset, and operative procedures are presented in Table 2. Group I was divided into 2 subgroups according to the operative procedures: 6 patients who underwent choledochojunostomy (end-to-side anastomosis with common bile duct and jejunum) were placed in Group I A and 39 patients who did not undergo choledochojunostomy were placed in Group I B. The patients in Group I A had no operative histories before this hospitalization. Biliary visualization was undertaken with duodenography (hypaque meglumine 60%) in 19 (42.2%) patients of Group I and none in the patients of (0%) Group II.

### Recurrence and reoperation indices

Recurrence rate is a frequently used index in the study of lithiasis. As a traditional index, recurrence rate is al-

Table 2 Characteristics of patients in Groups I and II

	Group I	Group II
Number of patients	45	53
Male/female	18/27	17/36
Mean age (yr)	52.8	52.8
Mean age of first onset (yr)	41.9	47.8
Biliary visualization rate during duodenography	42.2%	0%
Mean follow-up period (mo)	38.4	41.9
Simple IHL/IHL with choledocholithiasis	15/30	14/39
Recurrence rate	22.2%	11.3%
Mean number of operations	2.07	1.21
Number of patients with 1 operation	22	45
Number of patients with 2 operations	12	7
Number of patients with 3 operations	7	0
Number of patients with 4 operations	1	0
Number of patients with 5 operations	0	1
Number of patients with 6 operations	2	0
Number of patients with 11 operations	1	0
Number of patients with simple choledocholithotomy and T-tube drainage	14	21
Number of patients with simple hepatectomy	7	13
Number of patients with choledocholithotomy, T-tube drainage and hepatectomy	18	17
Number of patients with simple choledochojejunostomy	4	1
Number of patients with choledochojejunostomy and hepatectomy	2	1

ways confined to consideration of a certain operation. Due to the frequent recurrence of HL, however, it is inappropriate to use only a single operation to evaluate the prognosis of this disease. To accurately describe and compare the whole history (from first onset to July 2008) of HL in each patient, we thus used the recurrence and reoperation indices concurrently. This allowed consideration of every recurrence or operation, and the intervals between two recurrences or two operations.

To determine the recurrence index, we recorded intervals (months) between each recurrence for a patient, calculated the reciprocal of each interval, and used the mean reciprocal as the recurrence index for that patient. If no recurrence occurred in the final operation, the corresponding reciprocal was designated as 0. A larger reciprocal value suggested a higher risk of recurrence. For example, the record of one patient showed that: 10 mo after the first operation, a recurrence occurred; the second recurrence occurred 5 mo after the second operation; and no recurrence occurred in the third operation. For this patient, the recurrence index is:  $(1/10 + 1/5 + 0)/3 = 0.1$ .

Like the recurrence index, there is a positive correlation between the reoperation index and the necessity of reoperation. To calculate the reoperation index, we recorded intervals (months) between every two closely succeeding operations for each patient, calculated the reciprocal of each interval, and used the mean reciprocal as the reoperation index for that patient. The reciprocal corresponding to the interval from the last operation to July 2008 was designated as 0. Thus, if the patient underwent only 1 operation, the reoperation index value was 0. For example, one patient's record shows: the second operation was performed 10 mo after the first operation;

Table 3 Comparison of Groups I and II

	Group I	Group II	P
Number of patients	45	53	-
Male/female	18/27	17/36	0.126
Mean age (yr)	52.8	52.8	0.771
Mean age of first onset (yr)	41.9	47.8	0.463
Mean follow-up period (mo)	39.9	43.9	0.145
Mean number of operations	2.07	1.21	< 0.001
Recurrence index	0.135	0.018	< 0.001
Reoperation index	0.07	0.01	< 0.001

the third and final operations were performed 5 mo after the second one. For this patient, the reoperation index is:  $(1/10 + 1/5 + 0)/3 = 0.1$ .

### Statistical analysis

All data are expressed as mean  $\pm$  SD. The *t* test was used to compare the differences of parameter mean values between groups. All *P* values were two-sided. A *P* value of < 0.05 indicated a statistically significant difference. All calculations were done using SPSS (version 11.5) software.

## RESULTS

### Patient data

The patients were monitored for a period ranging between 14 and 75 mo (median  $42.1 \pm 17.1$  mo). During this follow-up period, stones reappeared in the bile ducts of 16 of 98 patients (with a recurrence rate of 16.3%), including 2 cases of stones in the common bile duct, 4 cases in the intrahepatic bile duct, and 10 cases in both ducts. Seven of these patients received a reoperation, and the disease recurred again in 4 of them. The number of operations performed from the first onset to July 2008 are shown in Table 1; the mean number of operations was  $1.60 \pm 1.38$  (range: 1-11). The mean recurrence index was  $0.0717 \pm 0.193$  and the mean reoperation index was  $0.0373 \pm 0.127$  (Table 1).

### Comparison of Groups I and II

The patients were followed up for 16-73 mo (mean  $39.9 \pm 15.6$  mo) in Group I and for 14-75 mo (mean  $43.9 \pm 18.1$  mo) in Group II (*P* = 0.145). Recurrence was observed in 10 Group I patients (a recurrence rate of 22.2%) and 6 Group II patients (a recurrence rate of 11.3%). The mean number of operations from first onset to July 2008 was  $2.07 \pm 1.83$  (range: 1-11) in Group I, being significantly higher than that of Group II ( $1.21 \pm 0.63$ ; range: 1-5). The mean recurrence index was  $0.135 \pm 0.256$  for Group I, which was significantly higher than that of Group II ( $0.018 \pm 0.086$ ) (*P* < 0.001). The mean reoperation index was  $0.070 \pm 0.171$  for Group I, being also significantly higher than that of Group II ( $0.010 \pm 0.060$ ) (*P* < 0.001) (Tables 2 and 3).

### Comparison of Groups I A and I B

To evaluate the effect of choledochojejunostomy on the

Table 4 Comparison of Groups I A and I B

	Group I A	Group I B	P
Number of patients	6	39	-
Male/female	2/4	16/23	0.385
Mean age (yr)	58	52	0.845
Mean age of first onset (yr)	30.5	43.6	0.666
Mean follow-up period (mo)	42.5	39.5	0.905
Recurrence index	0	0.156	0.006
Reoperation index	0	0.081	0.034

SOL patients, we compared the recurrence and reoperation indices of Groups I A and I B. The follow-up period was between 18 and 61 mo (mean  $42.5 \pm 16.9$  mo) in Group I A, and between 18 and 73 mo (mean  $39.5 \pm 15.6$  mo) in Group I B ( $P = 0.905$ ). We found no recurrence among patients in Group I A (a recurrence rate of 0%), whereas recurrence occurred in 10 of 39 patients in Group I B (a recurrence rate of 25.6%). The mean recurrence indices were thus 0 for Group I A and  $0.156 \pm 0.270$  for Group I B. The mean reoperation indices were 0 for Group I A and  $0.081 \pm 0.182$  for Group I B. The differences in both the recurrence index and reoperation index values were statistically significant between groups (Table 4).

## DISCUSSION

HL is prevalent in the Asian countries of Japan, Korea and China<sup>[1-3]</sup>, and also occasionally occurs in Europe and America<sup>[4,5]</sup>. The disease is characterized by its intractable nature and frequent recurrence. Because of complications, potential carcinogenesis and even fatality<sup>[6-11]</sup>, most HL patients receive multiple operations. This study examined the role of SOL in the course of HL, and found that the frequencies of recurrence and reoperation were significantly higher in patients with SOL.

The obviously larger diameter of the papilla orifice in SOL patients indicates the injury to the SO muscle fibre and the absence of regular SO contraction. These conditions lead to duodenum juice reflux, similar to that seen in choledochoduodenostomy. During surgery on SOL patients, a Bake CBD dilator (CE-125-10-G, diameter = 10 mm) and choledochoscope (OLYMPUS CHF P20, external diameter = 4.9 mm) passed smoothly through the SO; even in some patients, a forefinger could enter the duodenum *via* the SO without any resistance, and food debris could be seen in the CBD. It results in *Escherichia coli* (*E. coli*) infection and decrease in biliary pH. *E. coli* can generate  $\beta$ -glucuronidase, which hydrolyzes direct bilirubin (water-soluble) into indirect bilirubin (water-insoluble) and may lead to the formation of stones in the biliary tract. Thus, HL tends to recur in SOL patients.

The specific causes of SOL, however, remain unknown. Congenital abnormality, mechanical injury by stones, chemical injury by bacteria, or iatrogenic injury are all possible etiological factors. Congenital maldevelopment of the smooth muscle and deficiency of some

neurotransmitter receptors can also contribute to SOL. Under inflammatory conditions where large amounts of inflammation mediators are generated over time<sup>[12]</sup>, the SO response to nitrergic neurotransmission is impaired, which may induce abnormal SO relaxation. Dilation of the common bile duct due to obstruction by stones may result in excessive dilation of the common bile duct sphincter and SOL development. In this study, absence of congenital abnormality in family histories and similarity among the mean age of the first onset ( $P > 0.05$ ) did not support congenital abnormality as a primary etiological factor of SOL.

It is not difficult to diagnose SOL. Duodenography is still considered to be a good method for describing the modality, despite its relatively low sensitivity (42.2%, Table 2). SO manometry is the best method of evaluating patients for sphincter dysfunction<sup>[13]</sup>, and it may be a feasible diagnostic method. The confidence of SO manometry, however, is suspected due to multiple factors (abdominal pressure, dynamic changes caused by the manometry, drug reactions). The invasive nature of manometry, the complexity of the operation, and the potential complication of pancreatitis restrict the use of SO manometry as a routine diagnostic method<sup>[14,15]</sup>. Due to the existence of intestinal juice reflux, simple calculus removal or hepatectomy are not sufficient for SOL patients, while choledochojejunostomy with an anti-reflux ansa intestinalis may be suitable for these patients<sup>[16]</sup>. The outcomes of six patients in Group I A showed the advantage of choledochojejunostomy, although the sample size is small. Further research on the effectiveness of this method should be conducted with a larger number of patients.

Endoscopic sphincterotomy may destroy the muscle fibres of the SO and cause iatrogenesis. The risks of cholangitis and cholangiocarcinoma have also been shown to markedly increase if the postoperative follow-up period is long enough<sup>[17]</sup>. This method should therefore be restricted to patients without SOL. Endoscopic balloon dilation is an effective alternative to endoscopic sphincterotomy<sup>[18-20]</sup>, which has been shown to result in complete recovery of sphincter function 21 d after operation<sup>[21]</sup>. An appropriate balloon size can preserve the SO and avoid undesirable effects due to an incompetent sphincter<sup>[22-26]</sup>.

SOL commonly arises in HL. HL patients with SOL tend to have a higher risk of recurrence and a larger demand for reoperation compared to those without SOL. Choledochojejunostomy with an anti-reflux ansa intestinalis may be the most promising therapy.

## COMMENTS

### Background

Hepatolithiasis (HL) is prevalent in East Asia, especially in China and obstructive cholangitis is usually considered the main cause. The authors found that almost half of the cases showed sphincter of Oddi laxity (SOL) in their clinical experience and the patients with SOL had a tendency for recurrence and always needed reoperation.

**Research frontiers**

The obstructive cholangitis is usually considered as the main cause of HL. No report has put forward the conception of SOL up to date. The phenomenon and significance of SOL is still rarely known.

**Innovations and breakthroughs**

The study has proposed the conception of SOL for the first time and considered SOL as a significant cause of occurrence or recurrence of HL. The authors of the study also put forward the recurrence and reoperation indices for the first time instead of recurrence rate, and suggested the choledochojejunostomy should be used as the surgical approach to the patients with SOL.

**Applications**

By understanding SOL, this study may represent a new strategy in the treatment of HL patients with SOL.

**Terminology**

SOL: an obviously large diameter of the papilla orifice makes the choledochoscope (OLYMPUS CHF P20, external diameter = 4.9 mm) pass smoothly through the SO. The recurrence and reoperation indices are used to accurately describe and compare the complete history of HL from the first onset to July 2008 in each patient, which allows consideration of each recurrence or operation, and the intervals between two recurrences or two operations.

**Peer review**

The study revealed that SOL is an important factor associated with a higher risk of HL recurrence and reoperation frequency in the HL patients.

### Abstract

**AIM:** To compare the influence and clearance effect of enzymatic and non-enzymatic detergents against *Escherichia coli* (*E. coli*) biofilm on the inner surface of gastroscopes.

**METHODS:** Teflon tubes were incubated in a mixture of different detergents and *E. coli* culture ( $10^6$  CFU/mL) for 72 h at 15°C, and biofilms on the inner surface of the teflon tubes were analyzed by bacterial count and scanning electron microscopy. To evaluate the clearance effect of detergents, after biofilms were formed on the inner surface of Teflon tubes by 72 h lavage with *E. coli* culture, tubes were lavaged by enzymatic and non-enzymatic detergents at a speed of 250 mL/min, then biofilms on the inner surface were analyzed by bacterial count and scanning electron microscopy.

**RESULTS:** Non-enzymatic detergent had a better inhibition function on biofilm formation than enzymatic de-

tergent as it reduced bacterial burden by 2.4 log compared with the control samples ( $P = 0.00$ ). Inhibition function of enzymatic detergent was not significantly different to that of control samples and reduced bacterial burden by 0.2 log on average ( $P > 0.05$ ). After lavaging at 250 mL/min for 3 min, no living bacteria were left in the tubes. Scanning electron microscopy observation showed biofilms became very loose by the high shear force effect.

**CONCLUSION:** Non-enzymatic detergent has a better inhibition effect on biofilm formation at room temperature. High speed pre-lavage and detergents are very important in temporal formed biofilm elimination.

### INTRODUCTION

The concept of bacterial biofilm was proposed in 1936<sup>[1]</sup>. Bacteria adhere to wet surfaces easily, then form organized colonies of cells embedded in a self-excreted matrix, which is composed principally of polysaccharide, and the polysaccharide facilitates adhesion to the surface and to each other<sup>[1,2]</sup>. In clinical medicine, many environments provide optimal conditions for the formation of bacterial biofilm, such as contact lenses, central venous catheters,

urinary catheters and so on<sup>[3]</sup>. Similarly, the presence of biofilm on the surface of gastrointestinal endoscope channels has also been confirmed in recent studies<sup>[4-6]</sup>. Bacteria residing within biofilms are up to 1000 times more resistant to chemical inactivation than bacteria in suspension<sup>[7-9]</sup>. Biofilms are not only a reservoir of pathogenic bacteria that can detach, resume their planktonic state, and contaminate the patient, but also a source of endotoxins that may enter the circulation of the patient through ruptured mucosae and cause systemic disorders<sup>[10]</sup>. It was reported that if the endoscope channels were not cleaned prior to disinfection, the decontamination of endoscopes could become a failure<sup>[11,12]</sup>. Therefore, it is important to explore a reasonable cleaning agent of gastrointestinal endoscopes to achieve a satisfactory result of anti-biofilm under the present conditions.

In this controlled study, we compared the clearout effect of enzymatic and non-enzymatic detergents against *Escherichia coli* (*E. coli*) biofilm on the inner surface of gastroscopes.

## MATERIALS AND METHODS

### Preparation of bacterial suspension

A small amount of *E. coli* ATCC 25922 (Hangzhou Tianhe Biologics Corporation, Zhejiang, China) was taken from slant medium and inoculated into sterile Muller-Hinton (M-H) broth (pH 7.4) to obtain pure bacilli. The poured plate method was used to adjust the concentration of bacteria to 10<sup>6</sup> CFU/mL.

### Bacterial biofilm formation

A high temperature sterilized Teflon tube (digestive endoscope lumen material) was cut into 15 pieces with 0.5 cm × 0.5 cm per piece, which were randomly divided into 3 groups: Group 1: enzymatic detergent group; Group 2: non-enzymatic detergent group; Group 3: blank control group. To prepare a sterile biopsy bottle for each group, 5 mL of M-H broth and 100 μL of bacterial suspension with good preparation previously were added into each group. 13 mL of rapid multi-enzyme cleaner (3M Company, Sao Paulo, Minnesota, USA), 25 μL of a non-enzymatic detergent, intercept (Minntech Corporation, Minneapolis, Minnesota, USA) with a 1:200 dilution ratio (recommended maximum dilution ratio of the products) and 20 μL sterile distilled water were added into Group 1, Group 2 and Group 3, respectively, taking care not to overlap the various pieces of material. Then each group was put into a 15°C incubator to incubate. 5 mL bacilli fluid was aspirated by sterile syringe every 24 h, adding 5 mL M-H broth; it was then soaked in 0.1 mol/L phosphate buffered saline (PBS) for 15 min through two stages after 72 h. We discarded the PBS in order to remove bacteria loosely attached to the wall, then Teflon tubes were taken from each bottle with sterile tweezers to prepare for evaluation. One sample from each group was prepared for electron microscopic evaluation, and the other 4

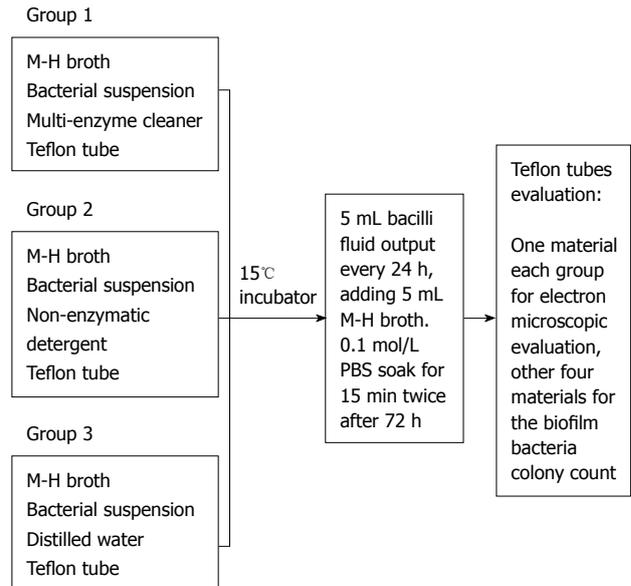

Figure 1 Bacterial biofilm formation assay.

samples were used for the biofilm bacteria colony count (Figure 1).

### Electron microscope evaluation of wall biofilm and bacterial colony counts

The teflon tubes material was transferred to a sterile Eppendorf (EP) tube, fixed with 1% osmium tetroxide for 1 h, then washed twice (each time for 15 min) in PBS buffer solutions. After washing, they were dehydrated for 15 min using alcohol and 100% acetone, replaced by amyl acetate eater, dried to CO<sub>2</sub> critical point, and sprayed gold with an ion sputtering instrument. Then they were scanned by electron microscope photographs (Stereoscan 260, Cambridge, UK). At the same time, another 12 Teflon tubes material in sterile EP tubes containing 1 mL of 0.1 mol/L PBS buffer solution were oscillated ultrasonically (38-47 kHz, 10 min) (Olympus Corporation, Tokyo, Japan), so that biofilm was stripped from the wall. We drew 100 μL PBS buffer solution from the above EP tube, then diluted the sample to 10000 times with 10 times serial dilution. 0.1 mL diluent was added into a sterile petri dish. M-H agar 20 mL cooled to 50°C was poured into the sterile petri dish, and the samples were mixed and cooled to 37°C. The petri dish was incubated for 24 h, and the growth of colonies and colony counts were examined.

### Production of biofilm-coated sample tubes

A high-temperature sterilized teflon tube with a length of 120 cm was placed in a sterilized beaker. Media contaminated with *E. coli* was run through the tube at a flow rate of 250 mL/min to mimic flow conditions (Minntech Co., Minneapolis, Minnesota, USA) during clinical endoscope procedures. The lavage lasted 4.5 h daily for 3 d, then 1/2 bacilli fluid was extracted and poured into the same amount M-H broth every 24 h.

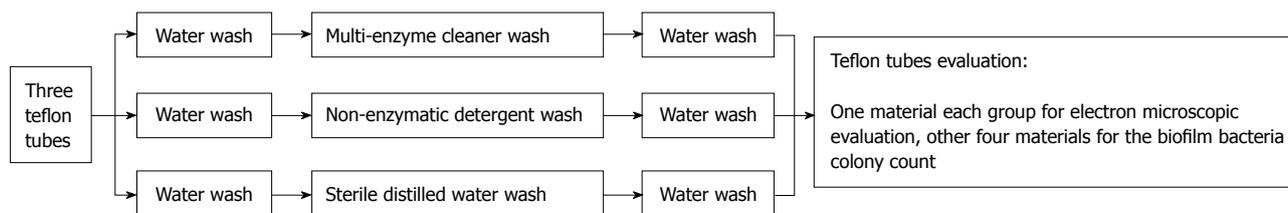

Figure 2 Cleaning steps of biofilm-coated sample tubes.

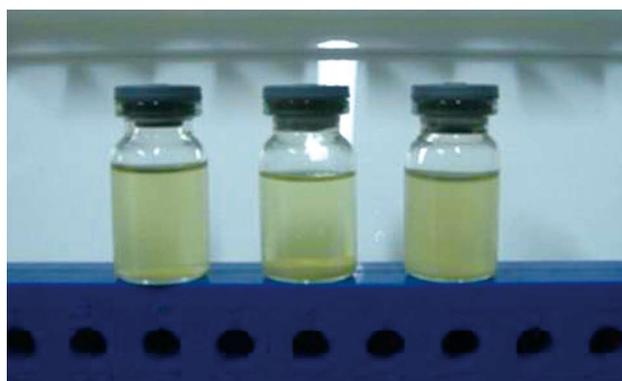

Figure 3 Mixture of detergent and bacteria cultured for 72 h. Left: The enzyme-containing washing, showing a homogeneous transparent liquid; Middle: A non-enzyme-containing detergent, showing in addition to a large amount of sediment at the bottom, the upper part was clean liquid; Right: The control group, showing bacteria bacilli and a small amount of sediment at the bottom.

### Cleaning of biofilm-coated sample tubes and biofilm evaluation

After lavage, the contaminated teflon tube was cut into 3 pieces. Next, the disconnected tubes were randomly divided into an enzyme wash group, a non-enzyme wash group, and a blank control group. According to Endoscope Disinfection Technical Operation Standards of China, after perfusion 3 sections of teflon tube were subjected to water wash (1 min), enzyme wash (3 min), and water wash again (1 min). In Group 1 enzyme wash was with multi-enzyme cleaner, in Group 2 non-enzymatic detergent was used instead of enzyme-containing detergent, and in Group 3 the enzyme wash step was replaced by sterile distilled water. After completing the above steps, tubing was cut with 5 cm spacing interception to produce 5 tubal walls of 0.5 cm × 0.5 cm, including 4 for the biofilm colony count, and 1 for scanning electron microscope observation of the concave wall biofilm (Figure 2).

### Statistical analysis

Statistical analysis was performed with SPSS 13.0 statistical package (SPSS Inc., Chicago, Illinois, USA). The mean value for different groups was compared using Student *t*-test. *P* < 0.05 was considered statistically significant.

## RESULTS

### Effects of detergent against bacterial biofilm formation on the wall

As shown in Figure 3, the bacterial suspension in the

Table 1 Wall residue biofilm colony count after bacterium and detergent suspension soaked

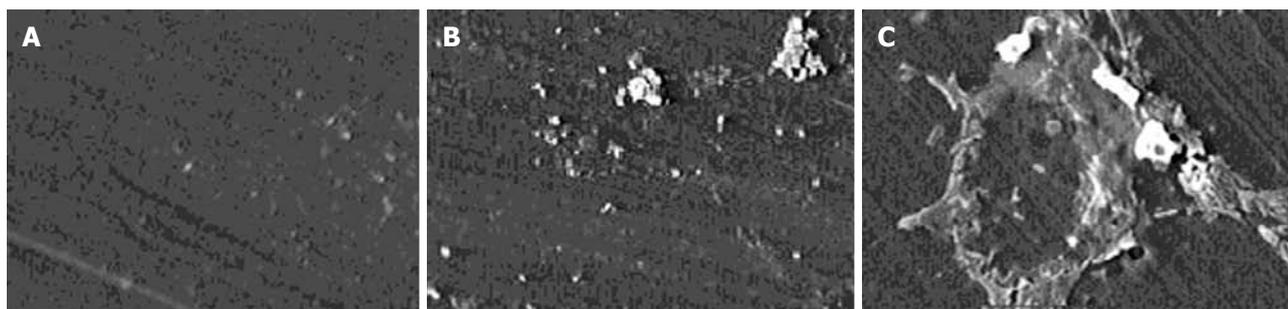

Detergents	Average actual colony count (CFU/ piece, ± SD)	Average standard colony count (lgCFU/ piece, ± SD)
Enzymatic detergent	(1.15 ± 0.86) × 10 <sup>4</sup>	3.96 ± 0.35 <sup>a</sup>
Non-enzymatic detergent	(6.85 ± 2.90) × 10	1.80 ± 0.21 <sup>b</sup>
Control	(1.69 ± 0.65) × 10 <sup>4</sup>	4.19 ± 0.22

<sup>a</sup>*P* = 0.00 vs the control group, <sup>b</sup>*P* = 0.25 vs the control group.

Figure 4 The concave wall structure after mixture of detergent and *Escherichia coli* cultured; surfaces are part of the biofilm formation.

enzymatic detergent group was limpid after culturing for 72 h, related primarily to the multi-enzyme ingredients to digest the organic components in detergent. The bacterial suspension in the non-enzymatic detergent group showed matrix components at the bottom, and the quantity was greater than the control group, which was associated with decomposed bacterial cell components and the organic components of the broth. After counting the number of bacteria in the biofilm, the non-enzymatic detergent had a better inhibition function on biofilm formation and reduced bacterial burden by 2.39 logs compared with water without any detergent (*P* < 0.05). Enzymatic detergent reduced bacterial burden by 0.23 log compared with water without any detergent, and there was no significant difference between the two groups (*P* > 0.05) (Table 1). On the surface of teflon tubes from any groups, the remaining biofilm was observed by electron microscopy (Figure 4). It was easier to find biofilm on a rough surface compared with a smooth non-porous surface, which showed that the compatibility of

**Figure 5** The concave wall structure after non-enzyme detergent (A), enzyme-containing detergent (B), and sterile distilled water (C) washing. A: No obvious biofilm residue; B: Massive biofilm structure residue; C: Relatively large biofilm attached to bacterial biomass, respectively.

detergent with the inner surface of endoscope channels was important for preventing the build-up of biofilm and removing a mature biofilm. It is generally accepted that smooth non-porous surfaces are the easiest to disinfect.

#### **Effects of detergent against bacterial biofilm removal on the wall**

After lavaging with bacterial suspension and reprocessing with different detergents, no living bacterial matter was left on the surface of teflon tubes. However, at higher magnification, scanning electron microscopy examination showed a few bacterial cells covering the internal surface of teflon tubes (Figure 5). The biofilm cells appeared as small microcolonies in the non-enzyme detergent group and blank group, but as a confluent membrane in the enzyme detergent group. The number of bacteria remaining was smaller in the non-enzyme detergent group than in the blank group.

## **DISCUSSION**

It has been reported that bacterial biofilm causes about 65% of bacterial infections in the clinic<sup>[13]</sup>. As research continues, bacterial biofilm is recognized as an ecological community composed of microbes and the irreversibly combined extracellular matrix, not simply a mixture of colonized bacteria and extracellular matrix. Biofilms have different phenotypes according to the difference in microbe growth and genetic transcription<sup>[14]</sup>. Biofilm induced biological material-related infections occurs widely in clinical departments, for instance, indwelling urinary catheter related infection, indwelling venous catheter related infection, artificial femoral head related infection. Antibiotics do not have a satisfactory effect on the infections due to the resistance of the biofilm<sup>[15]</sup>. Bacteria within biofilms are up to 1000 times more resistant to antimicrobials than the same bacteria in suspension. Endoscope related infection, as reported in articles<sup>[3,16]</sup>, also occurs in western countries with strict specifications of endoscope reprocessing procedures. Although the poor quality of disinfection of endoscopes is associated with inadequate compliance with reprocessing protocols, another explanation could be more related to the formation of biofilm on endoscope channels. We found that

an electron microscope scanning of an obsolete tube confirmed the existence of biofilm on the inner wall in a study.

In this experimental study, we adopted the endoscope lumen material (teflon) as the object of study. In the study on detergent effects on bacterial biofilm formation: biofilm colony count results showed that there was a significant difference in biofilm viable counts between non-enzyme detergent soaking teflon and the blank group ( $P < 0.05$ ), while there was no significant difference in biofilm viable counts between enzymatic detergent soaking teflon and the control group ( $P > 0.05$ ). This showed that non-enzyme detergent for biofilm formation had a better inhibitory effect than enzymatic detergent. The electron microscopy results showed that the biofilm was more easily deposited on the surface of non-flat areas, indicating detergent needs a better compatibility to the teflon tube in order to avoid producing a good place to form a biofilm because of the different affinity.

Endoscopes should be washed by water and enzymatic detergents before disinfection, otherwise the disinfectants have an inadequate effect because of the existence of blood, mucus and other organic materials<sup>[17]</sup>. Some data have revealed that a proper cleaning step could decrease the bacterial cells by 2-5 logs<sup>[18]</sup>. Our study confirmed the elimination of the number of bacteria within a biofilm by the shearing effect of high speed lavage. In the study for the effects of detergent against bacterial biofilm removal on the tube wall, lavage for 72 h to the teflon tube, then 1 min water wash, 3 min enzyme wash, and 1 min water wash again, produced a biofilm colony count of 0 in all samples of Teflon tube, but there were still differences in scanning electron microscopy; in the nearly 500-fold scan condition, a small amount of *E. coli* were found, showing small microcolonies for the non-enzyme detergent group and control group, but the number of bacteria remaining was fewer in the non-enzyme detergent group than in blank group. However, there was a confluent membrane of bacterial growth in the enzyme detergent group.

Many factors, as recognized and further researched, affect the formation or elimination of biofilms, including the characteristic of the fluid, the species of microbes,

surface of the tubes, velocity of flow, temperature and pH value<sup>[19]</sup>. The conservation of the endoscope should focus on avoiding minor injury to the inner wall of channels, which eases the formation of biofilm. It's also important to choose a green detergent with more cleansing power, but less corrosion to the tube, not only "with enzyme" or "without enzyme". According to the manual, the enzymatic detergent has maximum cleansing power at a temperature higher than room temperature. However, we observed the efficiency of detergent at a temperature of 15°C, which is a realistic temperature for use. It was reported that proteolytic enzymes in the detergent increased the risk of occupational asthma, which cannot be improved by avoidance of exposure with enzymes of detergent origin<sup>[20]</sup>.

During our short-term study, the elimination of bacterial biofilm on the inner wall of teflon tubes was studied and residual biofilm was detected by electron microscope scanning. Artificial contamination was performed using the *E. coli* bacteria only, whereas the actual contamination and the formation of biofilms is produced by miscellaneous bacteria in the clinic. Food residue, mucus, gastric acid and bile existing in the endoscope channels can decrease the shearing of the liquid and, therefore, should be completely removed to prevent the formation of biofilm. In this study, the current cleaning agents could not completely eliminate endoscopic biofilm, which should arouse our attention in the future. Therefore, a thorough cleaning of the endoscope to remove contaminants is one of many important and effective measures to prevent the formation of endoscopic biofilm. At the same time, how to effectively remove biofilm formed on the lumen is a continuing research goal. Further study on the formation and the removal of the biofilm is required and more effective detergents should be explored.

## COMMENTS

### Background

Many clinical environments provide optimal conditions for the formation of bacterial biofilm, including gastrointestinal endoscope channels. Biofilms are not only a reservoir of pathogenic bacteria, but also a source of endotoxins that may enter the circulation of the patient through ruptured mucosae and cause systemic disorders. However, if the endoscope channels are not cleaned prior to disinfection, the decontamination of endoscopes could become a failure because of biofilm formation. Therefore, it is important to explore a reasonable cleaning agent of the gastrointestinal endoscope to achieve a satisfactory result of anti-biofilm under the present conditions.

### Research frontiers

Endoscope related biofilm infections also occur in western countries with strict specifications of endoscope reprocessing procedures. Therefore, a thorough cleaning of the endoscope to remove contaminants is one of many important and effective measures to prevent the formation of endoscopic biofilm. To understand the effect of current detergents on biofilm, the authors produced a controlled study to compare the clearout effect of enzymatic and non-enzymatic detergents against *Escherichia coli* biofilm on the inner surface of gastroscopes.

### Innovations and breakthroughs

If endoscope channels are not cleaned prior to disinfection, the decontamination

of endoscopes could become a failure due to biofilms. Therefore, it is important to explore a reasonable cleaning agent of gastrointestinal endoscopes to achieve a satisfactory result of anti-biofilm under the present conditions. This study aims to draw attention to endoscopic workers to biofilms through the authors' common efforts to ensure the safety of clinical endoscopic work in the future.

### Applications

The study results suggest that the current cleaning agents cannot completely eliminate endoscopic biofilm, which should arouse our attention in the future. A thorough cleaning of the endoscope to remove contaminants is one of many important and effective measures to prevent the formation of endoscopic biofilm. How to effectively remove a biofilm that has already formed on the lumen is an ongoing research goal. Further study on the formation and the removal of biofilm is required and more effective detergents should be explored.

### Terminology

Bacterial biofilm: Bacterial biofilm is recognized as an ecological community composed of microbes irreversibly combined with the extracellular matrix, not simply a mixture of colonized bacteria and extracellular matrix.

### Peer review

The study is important as a means of exploring a reasonable cleaning agent of the gastrointestinal endoscope to achieve a satisfactory result of anti-biofilm under the present conditions. It deals with a very important topic on gastrointestinal reprocessing and it can add new information to this topic. It is also interesting and well designed.

### Abstract

**AIM:** To investigate differential points of solid-pseudopapillary neoplasm (SPN) of the pancreas and pancreatic endocrine tumor (PET).

**METHODS:** Ten cases of SPN and fourteen cases of PET were studied in this retrospective study. Clinical and pathologic features, immunostaining reactions and *β-catenin* gene mutations were analyzed.

**RESULTS:** The mean age of SPN patients was 25.6 years and these patients had no specific symptoms. The mean diameter of the tumors was 11.0 cm, 9/10 cases were cystic or a mixture of solid and cystic structures, and there was hemorrhage and necrosis on the cut surface in 8/10 (80%) cases. Characteristic pseudo-

papillary structure and discohesive appearance of the neoplastic cells were observed in all 10 (100%) cases. The results of immunostaining showed that nuclear expression of *β-catenin* and loss of E-cadherin in all the cases, was only seen in SPN. Molecular studies discovered that 9/10 (90%) cases harbored a point mutation of exon 3 in *β-catenin* gene. On the other hand, the mean age of PET patients was 43.1 years. Eight of 14 cases presented with symptoms caused by hypoglycemia, and the other 6 cases presented with symptoms similar to those of SPN. The mean size of the tumors was 2.9 cm, most of the tumors were solid, only 3/14 (21%) were a mixture of solid and cystic structures, and macroscopic hemorrhage and necrosis were much less common (3/14, 21%). Histologically, tumor cells were arranged in trabecular, acinar or solid patterns and demonstrated no pseudopapillary structure and discohesive appearance in all 14 (100%) cases. The results of immunostaining and mutation detection were completely different with SPN that membrane and cytoplasmic expression of *β-catenin* without loss of E-cadherin, as well as no mutation in *β-catenin* gene in all the cases.

**CONCLUSION:** Both macroscopic and microscopic features of SPN are quite characteristic. It is not difficult to distinguish it from PET. If necessary, immunostaining of *β-catenin* and E-cadherin is quite helpful to make the differential diagnosis.

## INTRODUCTION

Solid-pseudopapillary neoplasm (SPN) of the pancreas is a relatively rare and its histogenesis is still controversial. There are some similarities between SPN and pancreatic endocrine tumor (PET), especially the non-functioning ones, in clinical and pathological manifestations<sup>[1-3]</sup>. Both have few specific clinical symptoms and signs and lack exclusive features on ultrasonography, imaging examination and laboratory tests. Histopathologically, both may be very similar and the results of immunohistochemistry reported in the literature showed that expression profiles of the two tumors overlapped<sup>[4,5]</sup>, which sometimes results in difficulty in distinguishing the two entities. In recent years, studies have shown that the vast majority of SPN harbored a point mutation on exon 3 of  $\beta$ -catenin gene, which has not yet been discovered in other pancreas tumors. In this study we took the mutation of  $\beta$ -catenin gene as major diagnostic evidence and explored the major points of pathological differential diagnosis of SPN and non-functioning PET.

## MATERIALS AND METHODS

### Case selection

A total of 24 cases pathologically diagnosed as SPN or PET were retrieved from the files of Department of Pathology, Xiangya Hospital, Central South University, China, during the period from 1999 to 2008.

### Morphologic review

The clinical data, description of gross morphology, H&E sections and immunohistochemical staining of all the cases were reviewed and the pathological diagnoses were re-evaluated.

### Immunohistochemical study

Immunohistochemical stains were performed on formalin-fixed, paraffin-embedded 5  $\mu$ m sections from all patients. Eleven consecutive sections were prepared from each tissue block and stained for the following markers: pan cytokeratin (pan CK, DAKO), anti-trypsin (ACT, DAKO), anti-chymotrypsin (AACT, DAKO), vimentin (Vim, DAKO), synaptophysin (Syn, DAKO), chromogranin (CgA, Santa cruz), neuron-specific enolase (NSE, DAKO), insulin (Ins, Santa cruz), somatostatin (Som, Santa cruz), glucagon (Glu, Santa cruz), pancreatic polypeptide (PP, Santa cruz), E-cadherin (E-cad, Santa cruz),  $\beta$ -catenin (Santa cruz) and Ki-67 (DAKO). The sections were deparaffinized in xylene and rehydrated through

graded alcohols. Antigen retrieval was performed in 1 mmol/L of EDTA (pH 8.0) in a microwave oven at 98°C. Endogenous peroxidases were inactivated by immersing the sections in 0.3% hydrogen peroxide for 20 min. Staining was performed with the DAKO En Vision Kit (DAKO) and the sections were developed with 3,3'-diaminobenzidine tetrahydrochloride and counterstained with hematoxylin.

### DNA preparation, polymerase chain reaction (PCR) amplification

Tumor tissue was microdissected from formalin-fixed, paraffin-embedded blocks using a scalpel and placed into microcentrifuge tubes for DNA extraction. DNA extraction was performed with a FFPE DNA Isolation Kit from Omega Biotek following the manufacturers' protocol. Exon 3 of  $\beta$ -catenin was amplified by PCR. The primer sequences were as follows: sense: 5'-ATGGAACCAGACAGAAAAGC-3'; anti-sense: 5'-TCCCCACTCATAACAGGACTT-3'. PCR cycling conditions were: 2 mmol/L MgCl<sub>2</sub> and 1 U Platinum-Taq polymerase (Takara), initial denaturation 5 min 94°C, 40 denaturation cycles 30 s 94°C, 30 s annealing 52-60°C, 30 s elongation 72°C, and final elongation 7 min 72°C. Using a PCR Purification Kit (Takara), purification of the PCR product was done essentially as recommended by the manufacturer.

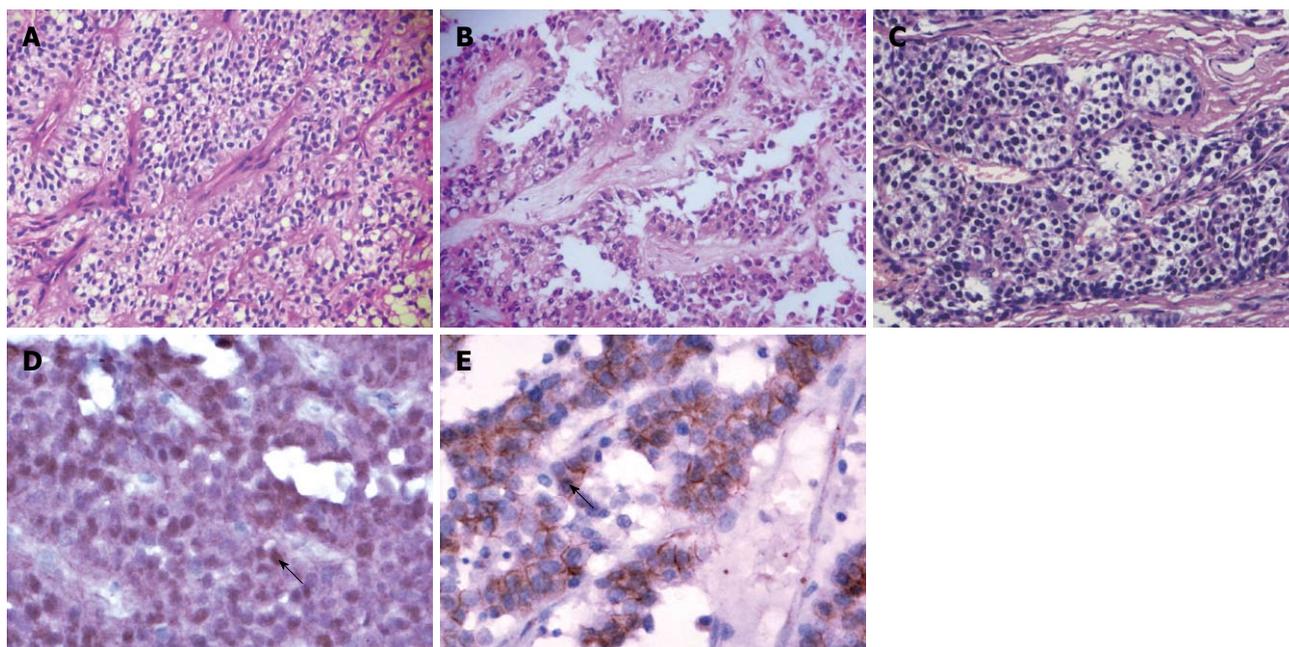

### DHPLC analysis, sequencing

DHPLC analysis was carried out on a WAVE DNA fragment analysis system (Transgenomic Inc.) equipped with a DNasep<sup>®</sup> Column. PCR products were denatured for 5 min at 95°C before being gradually reannealed by decreasing the sample temperature from 95 to 45°C over a period of 50 min to enable the formation of heteroduplexes. DHPLC analysis was carried out at a flow-rate of 0.9 mL/min and buffer B (0.1 mol/L TEAA, 25% acetonitrile), with a gradient increase of 2% per min for 4 min. Sequencing reactions were set up with 30 ng purified PCR fragment template and 10 pmol sequencing primer in 10  $\mu$ L total reaction volume following a dye terminator protocol. Sequencing primers were identical to amplification primers. Sequence alterations were verified by sequencing both DNA strands and by analyzing an independently generated PCR amplicon.

## RESULTS

Twenty-four cases, including 6 SPN and 18 PET, were re-evaluated according to clinical characteristics, gross morphology and microscopic features, results of immunohistochemistry and molecular findings. Six cases of SPN continued to have the original diagnosis, 14 cases of 18 PET were thought to be PET, the other 4 cases of PET were revised as SPN, and no other kind of tumor was found. Therefore there were 10 cases in the SPN group and 14 cases in the PET group.

There were 7 females and 3 males in the SPN group and 9 females and 5 males in the PET group. The mean

**Figure 1** Histopathological and immunohistochemical features of solid-pseudopapillary neoplasm (SPN) and pancreatic endocrine tumor (PET). A: SPN arranged in solid areas, patternless sheets of uniform epithelial cells with numerous small blood vessels (hematoxylin-eosin, original magnification  $\times 200$ ); B: SPN formed characteristic pseudopapillary changes due to the degenerative and discohesive nature of the tumor cells (hematoxylin-eosin, original magnification  $\times 200$ ); C: PET arranged in acinar-like pattern; the tumor cells are small and round with granular eosinophilic or clear cytoplasm (hematoxylin-eosin, original magnification  $\times 200$ ); D:  $\beta$ -catenin immunostaining of SPN: Nuclear translocation and accumulation of  $\beta$ -catenin protein (arrow) is seen in neoplastic epithelial cells (original magnification  $\times 200$ ); E:  $\beta$ -catenin immunostaining of PET: Membrane and cytoplasmic positive expression of  $\beta$ -catenin protein without nuclear stain (arrow) (original magnification  $\times 200$ ).

age was 25.6 years (range: 14-43 years) in the SPN group and 43.1 years (range: 16-52 years) in the PET group. Eight PET cases presented with symptoms of endocrine disorders, such as confusion, psychiatric disturbances, and even coma caused by hypoglycemia. All patients in the SPN group and 6 cases in the PET group had non-specific and similar clinical symptoms, including a dull aching pain in the abdomen (6 cases in the SPN group and 2 in the PET group); a painless abdominal mass in the epigastric region (3 in the SPN and 1 in the PET group); and non-specific abdominal symptoms for which they had been examined (1 case in the SPN group and 3 in the PET group).

Macroscopically all the SPN and PET cases were well-circumscribed single masses except for 1 PET case, which showed multiple masses. The mean diameters were 11.0 cm (range: 5-20 cm) in the SPN group and 2.9 cm (range: 1.5-5.7 cm) in the PET group. Cystic or cystic-solid areas with zones of hemorrhage and necrosis, or cystic spaces filled with necrotic debris were seen in 8/10 (80%) cases of SPN, and only 3/14 (21%) cases of PET. For both tumors there was no preferential localization within the pancreas.

On microscopy, SPN was composed of cells arranged in the form of solid sheets (Figure 1A), microcysts and pseudopapillary areas which showed characteristic pseudopapillae with the fibrovascular axis of the branch-shaped area surrounded by several layers of polygonal epithelioid cells (Figure 1B). The cells had moderate amounts of eosinophilic to vacuolated cytoplasm. The nuclei were ovoid and folded with indistinct

nucleoli and few mitoses. Regional cystic degeneration, hemorrhage, necrosis, aggregates of foamy histiocytes, cholesterol clefts were common. PET were usually arranged in three patterns: (1) trabecular or gyrus-like; (2) acinar- or duct-like (Figure 1C); and (3) solid or diffuse structure. The tumor cells were usually small and round with a granular eosinophilic or clear cytoplasm. Hemorrhage and necrosis were seen in only 3 cases, and pseudopapillary structures and cellular dyscohesive degeneration were not observed in all cases. The clinical and pathological features of SPN and PET are summarized in Table 1.

#### Immunohistochemistry

The immunohistochemical results are summarized in Table 2. Nuclear translocation and accumulation of  $\beta$ -catenin protein was seen in neoplastic cells in all SPN cases (Figure 1D). The tumor cells of PET cases showed only normal membranous and cytoplasmic  $\beta$ -catenin labeling, but were negative for nuclear accumulation (Figure 1E). The other immunostains showed an overlap, even including synaptophysin and chromogranin A, between these two tumors. Ki-67 proliferative index was less than 1% in most of the tumors in both groups.

#### DHPLC analysis

Nine of 10 SPN cases presented DHPLC heteroduplex bimodal or shoulder-type peaks on DHPLC mutation detection, which indicated mutations on exon 3 of  $\beta$ -catenin gene.

All 14 samples of PET showed a single peak on

tion that 9 cases of SPN had a point mutation of  $\beta$ -catenin gene exon 3. Mutations involving codons were as follows: 4 cases at codon 32, 2 at codon 33, 2 at codon 34 and 1 case at codon 37 (Table 3, Figure 2).

## DISCUSSION

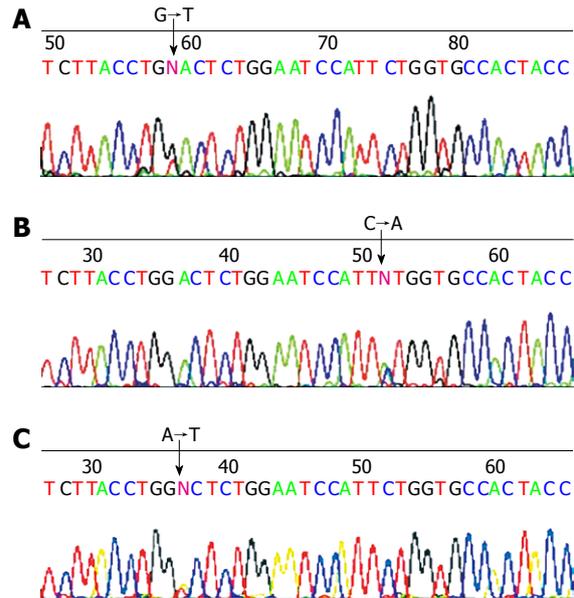

SPN of the pancreas is an uncommon tumor, constituting only about 1%-2% of exocrine pancreatic neoplasms<sup>[6]</sup>. SPN is clinically and histologically quite similar to the more common PETs, especially the non-functioning ones.

SPN predominantly occurs in adolescent girls and young women with a reported frequency of 87% to 90% (mean age of 22 to 25 years)<sup>[7]</sup>. Such a striking gender and age predilection of SPN is different from PET.

Functioning PET demonstrates specific clinical symptoms and signs which provides a suggestion for consideration of endocrine tumors. However, the clinical manifestations of SPN and non-functioning PET in our cases as mentioned in literature are not specific<sup>[8]</sup>. The patients in both groups present with unclear clinical features including abdominal discomfort, mild abdominal pain, poor appetite and nausea which are related to tumor compression on the adjacent organs, and a palpable mass in the abdomen<sup>[9,10]</sup>. Occasionally a mass may be found in the abdomen during complementary imaging studies such as ultrasound or CT scan<sup>[11,12]</sup>.

Both SPN and non-functioning PET have not been associated with specific clinical laboratory test findings including serum tumor markers<sup>[12,13]</sup>. The imaging features of both tumors present similarities in most cases, including ultrasonography, CT scanning, MRI and other imaging examinations. For both SPN and PET the best treatment is surgical resection. The routine imaging examinations are satisfactory for preoperative tumor location and understanding of the relationship between tumors and surrounding tissue. However, it is difficult for imaging studies to determine the nature of the lesions.

Both SPN and PET can occur in any part of the pancreas, though PET occurring in the pancreatic tail is more common<sup>[8]</sup>. SPN usually has much larger dimensions than PET. In contrast to the smaller mass (mean diameter 2.7 cm) of non-functioning PET, SPN is often

**Figure 2**  $\beta$ -catenin oncogene mutations in SPN. Representative DNA sequencing chromatograms demonstrate. A: A GAC→TAC mutation in codon 32 of case 5; B: A TCT→TAT mutation in codon 37 of case 2; C: A GAC→GTC mutation in codon 32 of case 9. Three samples of PET cases were randomly selected to be sequenced and the results confirmed that there was not any mutation on amplified PCR fragments of  $\beta$ -catenin gene exon 3.

much larger in size (mean of 10 cm at presentation in our study). Most of the cases in both groups are characterized with a tumor that is separated from the normal pancreas by a complete or incomplete fibrous capsule. On the cut surface, hemorrhagic and cystic areas are much more common in SPN than in PET.

Histologically, both SPN and PET could be arranged as solid areas and the size and shape of the tumor cells were relatively uniform with round or oval nuclei and vacuolated or eosinophilic large cytoplasm. It was difficult to distinguish these two kinds of tumor if only such histological pattern was used as the diagnostic basis. However, the unique morphological characteristics of SPN, large areas composing of pseudopapillary structures indicating evidence of cellular dyscohesive degeneration and cholesterol clefts, aggregation of foamy histiocytes, and characteristic microscopic features of SPN allow easy differential diagnosis from PET.

Immunohistochemical findings reported in early literature were of variation and absence of a specific profile. There was overlap of positive expression on immunostaining using such markers as  $\alpha$ 1-antitrypsin,  $\alpha$ 1-antichymotrypsin, NSE, Syn, progesterone receptor, carcinoembryonic antigen, pan CK, vimentin, CD10, CD56, and cyclin D1, so that immunohistochemistry was incapable of giving much helpful additional information for the differential diagnosis of SPN. However, more recently, the situation was changed by applications of E-cadherin and  $\beta$ -catenin which possess highly sensitivity and specificity. Literature reports<sup>[14-17]</sup> and our results showed that nuclear expression of  $\beta$ -catenin and loss of E-cadherin were seen in nearly all cases of SPN.

On the contrary, there was cytoplasmic and membrane expression of  $\beta$ -catenin and strong expression of E-cadherin in PET cases. The exclusive expression of  $\beta$ -catenin and E-cadherin in SPN can be applied to make definite differentiation from PET.

Most SPNs harbor mutations in the  $\beta$ -catenin gene and, as a result, most SPNs have an abnormal nuclear expression of  $\beta$ -catenin protein. We found 1 (case 4) in our cases without mutation in exon 3, however, it showed cystic and necrosis on macroscopy, pseudopapillary structure and discohesive appearance of the neoplastic cells on microscopy, cytoplasmic and nuclear staining for  $\beta$ -catenin, and loss of E-cadherin, which indicated alteration of  $\beta$ -catenin gene and suggested that there might exist a mutation on another exon of  $\beta$ -catenin gene.

In conclusion, SPN of the pancreas, compared with PET, is a cystic-solid or cystic tumor with a larger size mostly seen in young women, and has the morphological features of hemorrhage and necrosis on the cut surface and exclusive pseudopapillary structures on light microscopy caused by cellular dyscohesive degeneration. If one is aware of its clinical and histopathologic features, with sufficient sampling of the tumor, one usually does not confuse SPN with PET in most cases. If necessary, immunostaining of  $\beta$ -catenin and E-cadherin is quite helpful to make the differential diagnosis.

## COMMENTS

### Background

Solid-pseudopapillary neoplasm (SPN) is an uncommon pancreatic tumor with low malignant potential and unknown cell origin, constituting only about 1% of pancreatic neoplasms. Since it is rare and maybe morphologically similar to pancreatic endocrine tumor (PET), sometimes there is overlapped expression of conventional immunohistochemical markers in both tumors and a pathological misdiagnosis may take place.

### Research frontiers

In recent years, mutations of  $\beta$ -catenin, which are sufficient to induce pancreas tumorigenesis, have been found in SPN and the aberrant activation of the Wnt- $\beta$ -catenin pathway appears to be a constant feature in SPN. The mutations lead to the displacement of  $\beta$ -catenin and E-cadherin from their normal membrane location, and, as a result, SPNs have an abnormal pattern of labeling with antibodies to the  $\beta$ -catenin and E-cadherin protein which helps in differential diagnosis.

### Innovations and breakthroughs

In this study, mutations of the  $\beta$ -catenin gene were analyzed and immunostaining of  $\beta$ -catenin and E-cadherin protein were done in both SPN (10 cases) and PET (14 cases). Mutations of  $\beta$ -catenin and delocalization of  $\beta$ -catenin and E-cadherin were exclusively found in SPN.

### Applications

Characteristic morphological features and specific expressive patterns of  $\beta$ -catenin and E-cadherin make it to be easy to differentiate SPN from other pancreatic tumors

### Terminology

$\beta$ -catenin (or Beta-catenin) gene is also known as CTNNB1 gene which encodes the protein  $\beta$ -catenin.  $\beta$ -catenin is a subunit of the cadherin complex and has been implicated as an integral component in the Wnt signaling pathway.

### Peer review

This is a nice retrospective analysis of the histological features of SPN of the pancreas compared with endocrine tumors and highlights some important differences.

### INTRODUCTION

Gastric duplications are uncommon congenital anomalies<sup>[1]</sup>, which are rarely found in adults, are more common in females, and are typically diagnosed in children. They constitute 2%-7% of gastrointestinal duplications<sup>[2]</sup>. The clinical presentation is usually nonspecific, though gastric duplications can be associated with severe clinical presentations<sup>[2]</sup>. Traditionally, the majority of these duplications are cystic, non-communicating and located along the greater curvature or posterior wall; there are very few cases in the literature of gastric duplication completely communicating with the gastric lumen<sup>[3]</sup>.

We present a rare case of a communicating type gastric duplication associated with pancreas divisum in a young woman, diagnosed with a multidisciplinary approach, including computed tomography (CT), magnetic resonance imaging (MRI), endoscopy, histology and ultrasound endoscopy.

### CASE REPORT

A 48-year-old healthy female presented with epigastric pain, nausea and bloating. She was admitted to our hospital for further investigation.

Her medical history was unremarkable. Physical examination and laboratory data were normal. First, an upper gastrointestinal barium contrast study was done, which showed a double compartment stomach, with the accessory stomach starting at the esophagogastric junction and continuing along the entire greater curvature to the pylorus, where it joined the lumen of the primary stomach. Both gastric lumens were filled with barium, providing evidence of free communication of the duplication with the gastric cavity (Figure 1). The patency of the gastric duplication and primary stomach was confirmed by CT

### Abstract

We report a unique case of communicating gastric duplication associated with pancreas divisum, diagnosed with a multidisciplinary approach, including X-rays, computed tomography, magnetic resonance imaging, esophagogastroduodenoscopy, ultrasound endoscopy and histology. We believe that this approach constitutes a fuller diagnostic evaluation, resulting in better and safer surgery.

with gastrografin (Figure 2). Also, in order to rule out possible biliary and pancreatic complications, with which gastric duplications can be associated, and in view of potential surgery, MRI was performed. It showed an incomplete pancreas divisum, with no common bilio-pancreatic duct (Figure 3). To confirm the gastric nature of the wall of the double stomach, a gastroscopy with ultrasound examination was performed.

Under deep sedation, the patient was monitored continuously with electrocardiography, pulse oximetry and automatic recording of blood pressure and pulse. After introducing the scope into the esophagus, just behind the esophagogastric junction, a large cavity covered with normal mucosa was seen continuing into another cavity through a similar pylorus orifice. Beyond it, a new cavity,

continuing into the duodenum, was observed (Figure 4). During the same endoscopic examination, a 20 MHz miniprobe was inserted into the operative channel of the endoscope and it revealed, on the first cavity, the pathognomonic multilayered appearance of the wall suggestive of a digestive origin, including an echogenic inner mucosal layer and a hypoechoic muscular layer (Figure 5). Finally, multiple biopsies were taken to confirm the gastric origin of the first cavity, and the histology pattern showed the presence of gastric mucosa with moderate *Helicobacter pylori* (*H. pylori*)-related gastritis in both cavities.

Definitively attributing the patient's symptoms to this structure was difficult, but after 6 mo of omeprazole

**Figure 5** The typical gastric layer is visualized on endoscopic ultrasound.

therapy (associated with *H. pylori* eradication therapy), the patient was asymptomatic and was referred to a surgeon.

## DISCUSSION

Gastric duplications are uncommon congenital anomalies, rarely found in adults, and can involve any part of the gastrointestinal tract, from the mouth to the rectum<sup>[1]</sup>. They constitute about 4% of all alimentary tract duplications<sup>[1]</sup>. Gastric duplications share a common blood supply with the native bowel, though the stomach is the site least often affected, regardless of age. The etiology of duplication of the alimentary tract is likely multifactorial<sup>[2]</sup> (e.g. persistence of embryonic diverticula during development of the alimentary tract and recanalization and fusion of embryologic longitudinal folds). They can be cystic or tubular, are more common in females, and are, typically, diagnosed in children<sup>[2]</sup>. Gastric duplications can communicate with the gastric lumen or not. Communicating duplications usually do not require any intervention when both gastric lumens are patent, in contrast with non-communicating duplications, which require surgical treatment.

The clinical presentation is usually nonspecific; signs and symptoms of gastric duplications depend on the localization, size and whether or not there is communication with the gastric lumen. The most common symptoms are epigastric pain or discomfort, vomiting, and gastrointestinal bleeding<sup>[4]</sup>. In some cases, they can give rise to unusual complications, such as recurrent pancreatitis<sup>[5]</sup> or bile duct fistula<sup>[6]</sup>, infection, peptic ulcers developing in

the cyst, obstruction, and carcinoma arising in the cyst<sup>[7]</sup>. They can be associated with other congenital abnormalities: esophageal and duodenal diverticula, duplication cysts elsewhere in the digestive tract, annular and ectopic pancreas<sup>[8]</sup>, and spinal abnormalities<sup>[9]</sup>.

This is, to the best of our knowledge, the first report on a gastric duplication associated with a pancreas divisum. Alimentary tract duplications must be considered during evaluation of thoracic and abdominal masses, gastrointestinal hemorrhage of unclear etiology, intussusceptions and mechanical bowel obstructions.

This report presents a rare case of communicating gastric duplication associated with a pancreatic abnormality (pancreas divisum), diagnosed with a multidisciplinary approach, including not only imaging techniques (CT and MRI), but also ultrasound endoscopy and the histological pattern of the biopsy to confirm the gastric nature of both cavities, in order to refer the patient to surgery after a full evaluation.

### Abstract

Pancreatic pseudocysts, which account for 70%-90% of pancreatic cystic lesions, characteristically are non-epithelially lined cystic cavities that are contiguous with the pancreas. Pancreatic pseudocysts can be caused by acute, chronic or traumatic pancreatitis and should be differentiated from other pancreatic diseases with cystic appearances, especially cystic neoplasms. We report a unique case of a pancreatic pseudocyst filled with semisolid lipids, which appeared by endoscopic ultrasound as a solid mass, and was therefore resected.

### INTRODUCTION

Routine use of cross-sectional imaging has resulted in an increased reporting of pancreatic cystic lesions. Some of these pancreatic cystic lesions may harbor microscopic malignancy or may degenerate into malignancy, therefore, it is important to differentiate between benign (serous), malignant/premalignant, and inflammatory (pseudocysts) cystic lesions<sup>[1]</sup>. Differentiation between pseudocysts and cystic neoplasms can be attempted by many modalities. At times, the differential diagnosis can be difficult. Although a prior history of pancreatitis cannot by itself justify the diagnosis of pancreatic pseudocysts, cystic lesions that occur without a history of pancreatitis suggest a diagnosis of cystic neoplasm<sup>[2]</sup>. Thus, the decision of whether to observe or operate on the pancreatic cystic lesion is difficult.

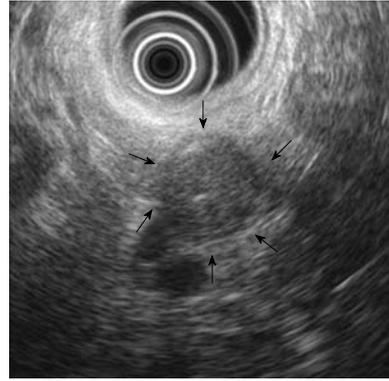

### CASE REPORT

A 51-year-old man was referred to our hospital for further evaluation of a probable gallbladder mass lesion and

**Figure 1** Image of the cystic lesion by contrast-enhanced abdominal computed tomography (arrow). There was a 17-mm well-marginated, round, low-density lesion in the body of the pancreas. The central contents of the lesion showed no enhancement in the post-contrast-enhanced image.

pancreatic cystic tumor. The patient initially visited another hospital because of fever and right upper quadrant abdominal pain. He had been treated for acute cholecystitis and showed clinical improvement. Abdominal computed tomography (CT) showed a probable gallbladder tumor and a pancreatic cystic tumor, therefore, he was referred to our hospital. At our initial evaluation, the patient was symptom free and the physical examination was normal. The patient had a history of alcohol consumption equivalent to 300 g/wk of ethanol. There was no history of pancreatitis. In laboratory analysis, white blood cell count was 5180/ $\mu$ L, hemoglobin 13.2 g/dL, and platelet count 218000/ $\mu$ L. Aspartate aminotransferase was 31 IU/L (normal 1-39 IU/L), alanine aminotransferase was 14 IU/L (normal 1-39 IU/L), total bilirubin 0.4 mg/dL (normal 0.1-1.2 mg/dL), amylase 23 IU/L (normal 20-104 IU/L), lipase 14 IU/L (normal 6-52 IU/L), carbohydrate antigen 19-9 11.3 U/mL (normal 0-37 U/mL), carcinoembryonic antigen 1.5 ng/mL (normal 0-5.0 ng/mL), total cholesterol 194 mg/dL (normal 1-240 mg/dL), and triglycerides 129 mg/dL (normal 1-250 mg/dL). A repeat abdominal CT revealed small stones in the gallbladder and mild dilatation of peripheral intrahepatic ducts without central intrahepatic and extrahepatic duct dilatation. Also, a 1.7-cm diameter, well-marginated, round, low-density lesion on the pancreatic body, compatible with a cystic lesion (Hounsfield units; pre-enhanced,  $\leq$  20 HU), was seen without post-contrast enhancement of the central portion. Rim enhancement equal to the adjacent pancreas parenchyma was seen. Pancreas parenchyma was seen with slightly atrophic changes (Figure 1). Endoscopic ultrasound (EUS) revealed a hyperechoic polypoid lesion of 14.1 mm on the fundal area of the gallbladder, with a posterior acoustic shadow. EUS also showed a 17 mm  $\times$  19 mm solid, round hypoechoic lesion on the pancreatic body. There were no other findings compatible with pancreatitis (Figure 2). EUS-guided fine needle aspiration (FNA) was not available at that time in our hospital. Endoscopic retrograde cholangiopancreatography (ERCP) was performed, which found irregular dilatations of the

**Figure 2** Image of the cystic lesion on EUS. It showed a 17-mm  $\times$  19-mm, well-circumscribed, round, homogeneous, hypoechoic solid lesion with central echogenicity (arrows).

peripheral intrahepatic ducts, without involvement of the extrahepatic and common bile ducts. Bile duct sweepings by balloon retrieval catheter showed bile sludge and *Clonorchis sinensis* (*C. sinensis*) adult organisms. Endoscopic pancreatography revealed mild displacement of the main pancreatic duct of the body due to a mass effect, but no cyst filling. After performing CT, EUS and ERCP, even though there was some disagreement about the pancreatic lesion, we thought that it was a solid neoplasm. Magnetic resonance imaging (MRI) was not performed to evaluate the pancreatic lesion further. At that time, we did not think about pseudocyst filled with semisolid lipid. The patient underwent laparoscopic cholecystectomy and body and tail pancreatectomy because of our concern that it was a solid pancreatic neoplasm. On pathological examination, the gallbladder showed xanthogranulomatous cholecystitis with *C. sinensis* infection. The pancreatic gross specimen revealed a well-encapsulated, unilocular cystic lesion filled with yellowish muddy material, which measured 17 mm in diameter (Figure 3). Microscopic findings of the resected cystic lesion were compatible with those for a pseudocyst. On hematoxylin-eosin (HE) staining, the lining of the cystic lesion consisted of fibrous and granulation tissue with no epithelial lining. Multiple extracellular fat vacuoles were shown in the cystic lesion. Findings were different from the lipocytes of a pancreatic lipoma. The surrounding pancreatic parenchyma showed mild inflammatory changes but there was no evidence of diffuse chronic pancreatitis. Sudan black B stain showed that the pseudocyst contents were lipid droplets (Figure 4A and B). No neoplasm was seen.

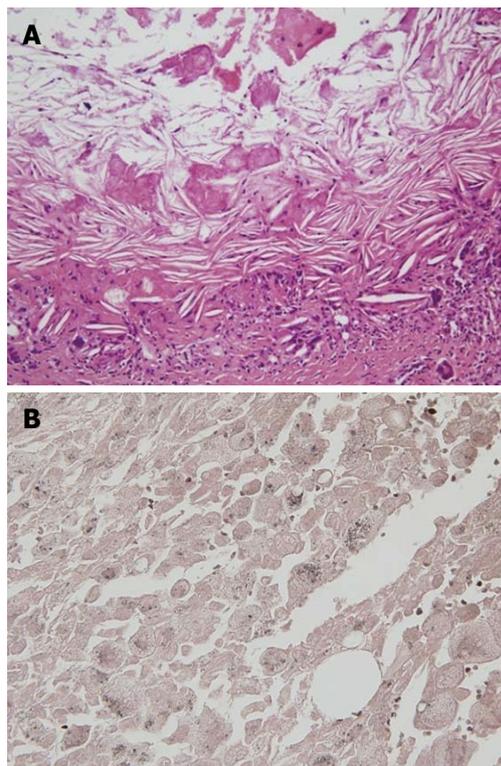

## DISCUSSION

Cystic lesions of the pancreas are being detected more often as sensitive abdominal imaging tests are being used for multiple indications. Some of these lesions are either premalignant or malignant. Therefore, it is important to differentiate between benign (serous), malignant/premalignant, and inflammatory (pseudocysts) cystic lesions<sup>[1]</sup>. The decision with respect to observation or operation is further complicated by the fact that a significant percentage of the patients with cystic lesions have pseudocysts rather than cystic neoplasms. Pancreatic pseudocysts are non-neoplastic and have been reported to account for

**Figure 3** Gross finding of the pancreatic cystic lesion. There was a 17-mm, unilocular, well-encapsulated cystic lesion filled with yellowish muddy material in the body of the pancreas.

70%-90% of pancreatic cystic diseases. The neoplastic pancreatic cystic diseases represent 10%-15% of all pancreatic cystic diseases<sup>[3]</sup>. However, more recent studies have reported that 40%-50% of patients with cysts have a history of pancreatitis. This suggests that pseudocysts only account for 40%-50% of pancreatic cystic lesions, and not 70%-90%<sup>[4,5]</sup>. They have explained that these dramatic differences were probably due to increased detection of small asymptomatic cysts in some studies, as well as differences in referral patterns<sup>[4]</sup>. Pseudocysts are cystic cavities that typically have or had connections with the pancreas, have no epithelial lining, and develop after acute or chronic pancreatitis, pancreatic trauma and surgery<sup>[6]</sup>. The diagnosis of a pancreatic pseudocyst depends on the clinical history and associated findings within the pancreas, such as gland atrophy, duct dilatation, calcification of the parenchyma, and calculi in the pancreatic duct. Although a prior history of pancreatitis cannot by itself justify the diagnosis of pancreatic pseudocysts, cystic lesions that occur without a history of pancreatitis suggest a diagnosis of cystic neoplasms<sup>[2]</sup>. Differentiation between pseudocysts and cystic neoplasms can be aided by CT, MRI, and EUS. The CT findings of a pseudocyst include a round or oval fluid collection with variably a thin or thick wall that shows evidence of contrast enhancement. Contrast-enhanced CT typically shows rim enhancement of pseudocysts<sup>[2]</sup>, which was present in our case. Most pseudocysts are unilocular and septations are infrequent<sup>[1]</sup>. The usefulness and accuracy of EUS in the differential diagnosis of pancreatic cystic diseases continues to evolve<sup>[7-14]</sup>. Koito *et al*<sup>[7]</sup> have reported the classification of the internal structures of solitary cystic lesions of the pancreas, and have compared them with pathological findings. They have concluded that the EUS findings were relatively accurate. However, Ahmad *et al*<sup>[8,9]</sup> have reported that endoscopic features alone (without FNA) cannot reliably differentiate between benign and malignant or neoplastic and non-neoplastic cystic lesions of the pancreas. Song *et al*<sup>[10]</sup> have reported that pseudocysts exhibit echogenic debris and parenchymal changes more often than do cystic tumors. In contrast, septae

**Figure 4** Microscopic finding of the pancreatic pseudocyst. A: Microscopic finding of the pancreatic pseudocyst. HE staining showed multiple lipid droplets and cholesterol clefts; B: Sudan black B stain showed positive findings for lipid droplets, stained with a dark brown color.

and mural nodules are found more frequently in cystic tumors than in pseudocysts. In our case, EUS showed a well-circumscribed, hypoechoic, round lesion with central echogenicity. These findings are more compatible with a pancreatic solid mass than a cystic lesion. The lesion was not hyperechoic as in lipoma. We did not perform FNA. If we had done so, it would probably have shown lipids and debris that were suggestive of a pseudocyst. With endoscopic pancreatography, 70% of pseudocysts have communication with the pancreatic ductal system, while serous cystadenoma, mucinous cystadenoma, and mucinous cystadenocarcinoma usually do not. Our patient presented with no evidence of pancreatitis on medical history, laboratory findings or imaging evaluations. He had documented biliary calculus disease and a history of alcohol consumption equivalent to 300 g/wk of ethanol. As a result of suspicion of a solid pancreatic neoplasm, the pancreatic body and tail and spleen were resected. The pathology revealed a well-encapsulated, unilocular, pancreatic cystic mass that measured 17 mm in diameter, which was filled with yellowish muddy material. Sudan black B stain revealed that the mass was a pseudocyst with lipid contents (lipid droplets and cholesterol clefts). This is different from a pancreatic lipoma, which would have been composed of lobules of mature adipose cells that were sharply delineated from the surrounding pancreatic tissue by a thin fibrous capsule<sup>[13]</sup>. Lipomas are benign tumors of homogeneous adipose tissue that are

histopathologically identical to subcutaneous fat. CT findings of pancreatic lipoma include homogeneous distribution of dense adipose tissue, with no central or peripheral contrast enhancement<sup>[14]</sup>.

In our case, gallbladder stones and infection with *C. sinensis* could have been the causes of pancreatitis. However, our patient did not have clinical manifestations and a history of pancreatitis. The pathophysiological process that leads to development of this lesion is uncertain. As we know, pancreatic pseudocysts are formed by the walling off of areas of peripancreatic hemorrhagic fat necrosis with fibrous tissue. As such, they usually are composed of central necrotic-hemorrhagic material rich in pancreatic enzymes, surrounded by non-epithelial-lined fibrous walls of granulation tissue. Fat necrosis is the first step in many pseudocysts. Therefore, small amounts of necrotic fat are common in pseudocysts. To the best of our knowledge, this is the first reported case of pancreatic pseudocyst densely filled with lipids. Our patient was not obese (body mass index 19.1), and the CT scan showed small/normal amounts of peripancreatic and retroperitoneal fat. Necrosis of peripancreatic fat can progress to liquefaction, with subsequent organization and encapsulation. Our patient's lesion appeared to be more than 50% intrapancreatic. Another origin of fat material in the pancreas is focal fatty replacement of the pancreas. Pancreatic lipomatosis or fatty replacement of the pancreas is the most frequent pathological finding in the adult pancreas. It is associated with a variety of diseases, including obesity, diabetes mellitus, chronic pancreatitis, hereditary pancreatitis, obstruction of the pancreatic duct by calculus or tumor, and cystic fibrosis. It is typically distributed as multiple tiny nodules throughout the pancreas; however, some investigators have found uneven fatty replacement of the pancreas, which is seen as a focal fatty mass<sup>[15,16]</sup>. This appearance may simulate a pancreatic mass such as a cystic neoplasm or other pancreatic tumor. Our patient did not have a fatty pancreas by CT, nor in the resected specimen. It is possible that our patient had focal fatty pancreas, unrecognized pancreatitis in the past, and residual organizing fatty necrosis. Unenhanced CT has a diagnostic role in comparing adjacent retroperitoneal fat with a negative attenuation value and parenchymal fat. Moreover contrast-enhanced CT may not show a negative attenuation value of this focal fatty replacement because of normal adjacent pancreatic parenchymal contrast enhancement<sup>[17,18]</sup>. MRI may be helpful for confirming the presence of this type of focal fatty replacement of the pancreas. Chemical shift MRI has the advantage that the reduction in signal intensity of focal fatty replacement on opposed-phase images differentiates focal fatty replacement of the pancreas from true pancreatic tumors, which in general do not contain lipid<sup>[17-19]</sup>. Our patient's cystic lesion would likely have shown high fat content by MRI, if it had been performed. Another possibility of the origin of fat material in the pseudocyst is that this lesion is a thrombosed splenic artery aneurysm. The position in the pan-

creas is compatible with this possibility. The cholesterol-appearing spicules in the wall also are consistent with a vascular problem. When fat is stored in organs (e.g. liver or pancreas), the vast majority is in triglyceride, and not cholesterol. However, our patients did not have a splenic artery aneurysm or any vascular disorder by CT, nor in the resected specimen.

CT showed that our patient's lesion was cystic. EUS is thought to be more accurate, therefore, the presumed solid lesion was resected. We did not attempt to make a preoperative tissue diagnosis because we assumed that all solid masses needed resection. Even though the risk appears to be quite low, percutaneous FNA biopsy of the pancreas may disseminate tumor cells intraperitoneally or along the needle path in patients who are believed to be candidates for potentially curative resection. If we had performed MRI with fat content analysis, or EUS-guided FNA, we probably would have been able to identify the lipid content of the lesion. Resection more definitely evaluated for malignancy.

In summary, we reported a unique case of a pancreatic pseudocyst filled with semisolid lipids, which appeared by EUS as a solid mass, and was therefore resected. Additional preoperative testing may have identified the true nature of the lesion. A high lipid content of pseudocysts is rare.

### Abstract

Mucormycosis is a rare but invasive opportunistic fungal infection associated with a high mortality rate, and normally occurs in immunocompromised patients. In this report, we describe an immunocompetent patient suffering from hepatic mucormycosis secondary to adrenal mucormycosis, which masquerades as hilar cholangiocarcinoma. After surgical procedure and treatment with amphotericin B and itraconazole, the patient recovered well and had a 2-year infection-free survival. To our knowledge, this special clinical manifestation of hepatic infection as well as adrenal mucormycosis has not been reported to date. Meanwhile, this is the first case of an immunocompetent patient with both adrenal and hepatic mucormycosis who has been treated successfully.

### INTRODUCTION

Mucormycosis caused by order mucorales<sup>[1,2]</sup>, a ubiquitous saprophytic mold found in soil and organic matter worldwide, is a rare but invasive opportunistic fungal infection. The disease in humans is mainly limited to people with risk factors such as neutropenia<sup>[3-6]</sup>, immune deficiencies<sup>[2-4,7,8]</sup>, malignant disease<sup>[2-8]</sup>, malnutrition<sup>[3,4]</sup>, diabetes<sup>[2-8]</sup>, trauma<sup>[2,6]</sup>, organ transplantation<sup>[2-5,7]</sup>, and iron overload<sup>[3-6]</sup>. The clinical infection due to mucorales includes rhinocerebral, pulmonary, cutaneous, gastrointestinal and disseminated diseases<sup>[3,5]</sup>. The first two are the most common diseases and all entities are associated with a high mortality rate<sup>[3]</sup>. To our knowledge, mucormycosis rarely involves liver, and hardly harms bile duct resulting in stenosis and cholestasis. This case report may present the first patient with adrenal mucormycosis in literature.

### CASE REPORT

A 36-year-old man was referred for evaluation of abdominal pain and icterus in April 2007. He was admitted to our center with a 3-mo history of abdominal pain, and 4-d icterus. He had nonsymptomatic adrenal mucormycosis characterized by mass location in the right adrenal gland area 5 mo ago. At surgical exploration in previous hospitalization, the mass was identified to be tenacious, confusing with right adrenal gland and there

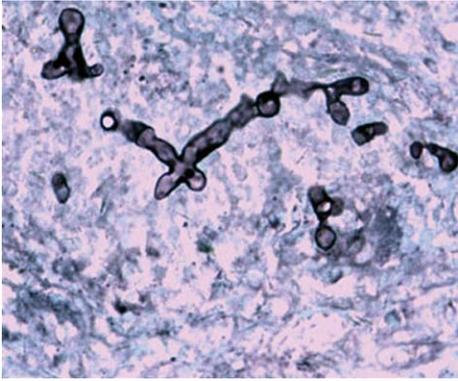

Figure 1 Adrenal mucormycosis, grocott methenamine silver stain, × 100.

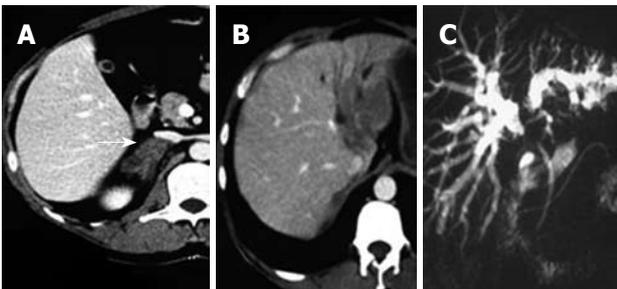

Figure 2 Imaging changes. A: Arrow shows computed tomography (CT) features of adrenal mucormycosis; B: CT features of hepatic lesion. A well circumscribed hypodense lesion in hilar and left lateral lobe, surrounding the vessels without a mass effect, should suggest an angioinvasive organism. This lesion presents necrosis of liver tissue due to fungal thrombosis; C: Magnetic resonance cholangiopancreatography demonstrates an abrupt stenosis of the primary biliary confluence with symmetric upstream dilation of the intrahepatic bile ducts.

was adhesion between mass and adjacent tissues. The patient underwent grossly total resection of the mass combined with the right adrenal gland immediately and mucormycosis infection was demonstrated histopathologically (Figure 1 and Figure 2A). Thus he was treated with itraconazole, 100 mg *bid*, for 1 mo. After his discharge, he was not followed up.

On physical examination at this second admission, his vital signs were normal and his abdomen was healthy. On investigation, his white blood cell count was 15 400/mm<sup>3</sup> with 86.2% neutrophils. Liver function test showed a bilirubin of 78.9 IU/L; direct bilirubin, 54.2 IU/L; alanine transaminase, 463 IU/L (normal range, < 55 IU/L); alkaline phosphatase, 180 IU/L (normal range, < 45 IU/L); albumin, 43 g/L (normal range, 35-55 g/L); and CA19-9, 108.6 U/mL (normal range, < 22 IU/L). Viral hepatitis screening (including tests for hepatitis A, B and C) revealed infection of hepatitis B. Chest X-ray was unremarkable. Abdominal computed tomography (CT) and magnetic resonance imaging (MRI) showed a lesion occupying the porta hepatis and partial left lateral lobe (Figure 2B); magnetic resonance cholangiopancreatography (MRCP) demonstrated an abrupt stenosis of the primary biliary confluence with symmetric upstream dilation of the intrahepatic bile ducts (Figure 2C). In light of initial evaluation, mucormycosis was suspected,

Figure 3 Cut surface of the liver mass, a yellowish-white tissue. Vessels are present in mass. Arrow shows intrahepatic bile ducts dilatation, thickening and cholestasis.

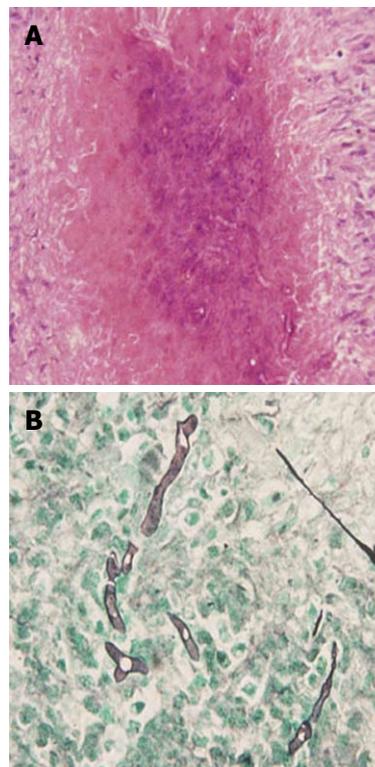

Figure 4 Pathological changes of liver tissue. Inflammatory focus containing irregularly shaped, broad, nonseptate hyphae with right angle branching typical of mucormycosis. A: Hematoxylin and eosin stain, × 40; B: Grocott methenamine silver stain, × 100.

but hilar cholangiocarcinoma (HCCA) could not be excluded.

Therefore, an exploratory laparotomy was performed, revealed that the mass was yellowish-white and tenacious, with irregular but well-defined boundary, and no obvious necrotic center was detected. The sidewall of common hepatic duct became incrassate, forming a stenosis (nearly 3 mm of inside diameter) with dilatation and thickening of the intrahepatic bile ducts (Figure 3). It was unlike a malignant tumor grossly, hence partial resection of hepatic lesion for frozen section was achieved. Given the mucorales infection on the basis of intraoperative frozen section,

we made a liver debridement to the fullest extent possible and placed a T-tube stent for 3 mo. Histopathologically, the liver was necrotic, in which extensive fungal proliferations were examined. Hematoxylin and eosin (HE), and grocott methenamine sliver (GMS) stains showed irregularly shaped broad nonseptate hyphae with the right angle branching typical of mucormycosis (Figure 4A and B). Intraoperative bile culture was performed but failed. Treatment with liposomal amphotericin B was initiated. Up to July 2007, he had received a cumulative 3 g of amphotericin B during the 3-mo hospitalization period. The patient was discharged in good general condition with an intraconazole prescription (100 mg *bid* for 4 mo). At this time, 2 years later, the patient remains alive and well. Abdominal MRI shows no evidence of the previous lesions.

## DISCUSSION

Mucormycosis is a rare fungal infection. It represents 12% of all documented filamentous mycosis observed in the participating centers during the same period (Pagano *et al.*<sup>[4]</sup>, 1993). Portals of entry for mucorales include sinuses, lungs, gastrointestinal tract and skin. In the present cohort, none of disseminated cases involves the sinuses. In contrast, they involve the lungs and/or the gastrointestinal tract<sup>[9]</sup>. Hepatic involvement is commonly presented with pulmonary or gastrointestinal infection and is considered a part of the disseminated disease<sup>[3,7]</sup>. Disseminated mucormycosis is the most severe form and is said to be uniformly fatal<sup>[8]</sup>. It is reported that the diagnosis is made ante mortem in only 12 of 185 patients<sup>[10]</sup>. The time lost before a correct diagnosis is made may be critical for survival.

Our case presented a typical hypodense mass lesion in CT findings. The hypodense hepatic lesion surrounding vessels without a mass effect (Figure 2B) suggest an angioinvasive organism causing fungal thrombosis and involvement of perivascular area subsequently. The CT findings are not pathognomonic but are valuable in narrowing the differential diagnosis<sup>[8]</sup>. Also MRI could reveal correspondences of abnormalities. MRCP demonstrated an abrupt stenosis of the primary biliary confluence with symmetric upstream dilation of the intrahepatic bile ducts, mimicking HCCA.

Differentiating mucormycosis from HCCA is important because of the differences in treatment. On imaging, obstruction at the hepatic duct confluence is generally due to HCCA. However, in up to 15% of patients, hilar obstruction could be caused by alternative diagnoses other than HCCA<sup>[11,12]</sup>. Involvement of second-order bile ducts is rare in patients with benign lesions, and was observed in only 26% of patients with HCCA-potentially helpful diagnostically in only a small proportion of cases. By contrast, vascular invasion and lobar atrophy are both common findings in patients with HCCA and significantly more common than in patients with benign lesions<sup>[11]</sup>. However, imaging ability to accurately distinguish HCCA from alternative diagnoses is limited. In addition, of the patients with benign lesions,

33% had elevated tumor markers (carcinoembryonic antigen and CA 19-9) (Jonathan Koea *et al.*<sup>[12]</sup>).

With regard to this case, culture and pathologic examinations of biopsy specimen provided the only definite diagnoses of mucormycosis. Mucorales appears in tissue as irregularly shaped, broad nonseptate hyphae with the right angle branching. The most characteristic features are perivascular and blood vessel invasions that result in arterial thrombosis and subsequent necrosis<sup>[3,9]</sup>. In our case, the sidewall of common hepatic duct became incrassate, forming a stenosis with upstream dilatation and thickening of the intrahepatic bile ducts, mimicking HCCA as the operation specimen and imaging represent. It suggested that the mucormycosis could likewise involve the bile ducts, leading to inflammation and incrassation of bile ducts. It has come to our knowledge that this characteristic has never been mentioned in the published series before.

Besides liver, there was also an adrenal gland involvement (primary infection), with no participation of the lung or other sites. As far as we know, involvement of the adrenal gland has not been described in the literature before, yet involvement of the brain, lung, kidney, stomach, colon, liver, spleen, thyroid gland, pancreas, and lymph nodes is known from autopsy<sup>[8]</sup>. However, the most initial portal of the infection remains unknown and deserves our attention.

The standard therapy for invasive mucormycosis is a combined medical-surgical approach<sup>[2,4,5,13]</sup>. High doses of amphotericin B should be used, rapidly reaching 1.0 mg/kg daily. Prolonged courses (> 6 wk) of amphotericin B are recommended, with total doses ranging between 1.5 and 3.0 g, according to the patient's underlying conditions<sup>[13]</sup>. Our patient underwent subtotal liver resection and received a cumulative 3 g of liposomal amphotericin B, and well responded to the treatment. Additionally, T-tube stent and intraconazole played an important part in the treatment.

In conclusion, this case report illustrates a new form of clinical spectrum of mucormycosis. The successful treatment can be attributed to an early accurate diagnosis, anti-fungal therapy consisting of liposomal amphotericin B and intraconazole, as well as surgical debridement. As mentioned above, a therapeutic effect of T-tube stent cannot be excluded.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board

members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on the substantial advance and its importance in the fast-developing areas; (2) Frontier: To review the most representative achievements and comment on the current research status in the important fields, and propose directions for the future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide Guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To systematically review the most representative progress and unsolved problems in the major scientific disciplines, comment on the current research status, and make suggestions on the future work; (8) Original Article: To originally report the innovative and valuable findings in gastroenterology and hepatology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce Consensus and Guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

## Instructions to authors

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://www.wjgnet.com/1007-9327/office>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/1007-9327/Instructions-toAuthprs.asp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [wjg@wjgnet.com](mailto:wjg@wjgnet.com), or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### Title page

**Title:** Title should be less than 12 words.

**Running title:** A short running title of less than 6 words should be provided.

**Authorship:** Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

**Institution:** Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

**Author contributions:** The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

**Supportive foundations:** The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

**Correspondence to:** Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. [montgomery.bissell@ucsf.edu](mailto:montgomery.bissell@ucsf.edu)

**Telephone and fax:** Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

### Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/..."; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g.  $6.92 \pm 3.86$  vs  $3.61 \pm 1.67$ ,  $P < 0.001$ ; CONCLUSION (no more than 26 words). Available from: <http://www.wjgnet.com/wjg/help/8.doc>; Writing requirements of abstract at: <http://www.wjgnet.com/1007-9327/links/Abstract.doc>.

### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

### Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the

main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A...; B...; C...; D...; E...; F...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID and DOI

Please provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at <http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed> and <http://www.crossref.org/SimpleTextQuery/>, respectively. The numbers will be used in E-version of this journal.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as  $\nu$  (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantum can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used

abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr-A*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H. pylori*, *E coli*, etc.

## RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903, Building D,

Ocean International Center,

No. 62 Dongsihuan Zhonglu,

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-5908-0039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/1007-9327/news/10.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/1007-9327/news/12.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
